⚠ WARNING

Before charging the suspension system with air, make certain the air-spring locator is indexed into the upper air-spring bracket, the lock tabs are snapped into place, and that the air spring is fully seated. Failure to follow these instructions could result in premature air-spring failure, which could result in personal injury or property damage.

Thrustwasher and Rear Hanger Clamp Removal and Installation

Removal

1. Set the parking brake, and shut down the engine. Chock the tires.

IMPORTANT: Push-to-connect fittings are not serviceable. Clean dirt and debris away from the fittings to prevent foreign materials from entering the air system, or damaging the fittings. Clean the push-to-connect fittings using soapy water and a soft-bristled brush, then dry with compressed air.

2. Deflate the air springs by disconnecting the height-control-valve linkage and lowering the control arm to exhaust the air pressure. Disconnect the air lines at the air springs.

⚠ WARNING

Failure to deflate and disconnect the air system prior to raising the front of the vehicle may result in sudden failure of the air spring, resulting in personal injury or property damage.

3. Raise the vehicle and support the frame with stands.
4. Suspend the front axle, ensuring there is enough clearance to allow the rear spring mount to clear the bottom of the spring hanger.

IMPORTANT: To prevent voiding the warranty on Barksdale height-control valves, note the following:

- Do not overtighten the bolts in the Barksdale height-control valve housing. The bolts should not be loose, and should not require tightening. Only if necessary, tighten the valve housing bolts 45 lbf·in (500 N·cm). Any damage to the valve housing will void the warranty.
- Do not attempt to disassemble the Barksdale valve body or the control lever. There are no serviceable parts in the valve, and any disassembly will void the warranty.

NOTICE

When removing or loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

Special Tools

Use the kit shown in **Fig. 1** to test a Barksdale height-control valve. Test kit BKS KD2264 is available via the Direct Ship program in Paragon.

General Information

The AW5800 on-board scale converts suspension loads to an accurate on-ground weight. By comparing empty and loaded axle weights with empty and loaded suspension pressures, the scale can be calibrated to display accurate weights for any suspension load. The Air-Weigh system processes and displays weight data for each suspension to which it is connected. Complete calibration, service, parts, and troubleshooting information is available at http://www.air-weigh.com (or by telephoning 1-888-459-3444).

Components

The Air-Weigh AW5800 Truck Scale system consists of the Weight Gauge™ display, the ComLink processor, weight sensors, and an interface harness.

Weight Gauge

The Weight Gauge is used to enter weight data for calibration as well as observe the axle weights. See **Fig. 1**.

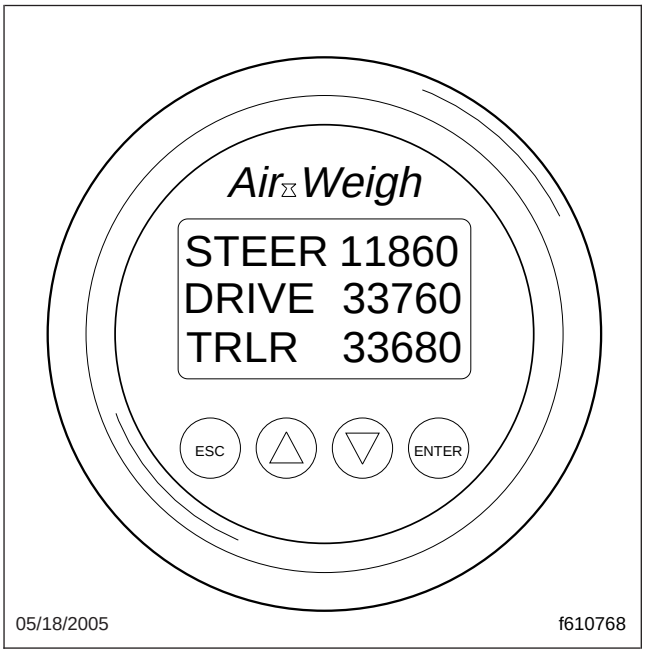

Fig. 1, Weight Gauge

The ESC and ENTER buttons are used to select menus. Up and down buttons are used for scrolling through the menus and numeric values.

The gauge fits in a standard 2-1/16 inch (52 mm) dash hole and requires at least 3 inches (75 mm) of clearance behind the dash.

ComLink Processor

The ComLink is the main computing element of the on-board scale system. It processes sensor data, stores calibration values, and acts as a transceiver. The ComLink is mounted under the dash.

Sensors and Fittings

The air pressure sensor reads pressure changes in the vehicle air suspension in relation to the change in weight being supported by the suspension. The pressure sensor is installed under the dash, is connected to the air line with a street-T fitting on one end, and has an electrical connection on the other end. It converts the input to an electrical signal to send to the ComLink.

Electrical Harnesses

A 2-ft (60-cm) long harness transmits the electrical signal to the ComLink.

The ComLink connects to the weight gauge with a 5-ft (1.5-m) electrical interface harness. The harness includes power and ground connections, gauge display data connections, and an over-weight alarm connection. The power connection includes an in-line 10 amp fuse for system protection.

General Description

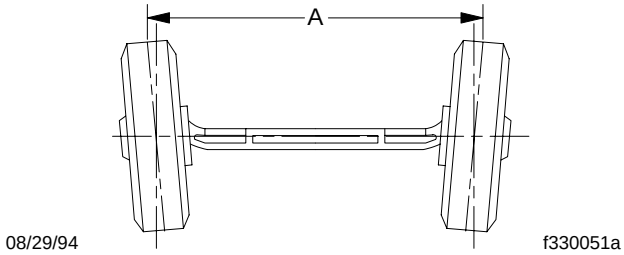
NOTE: For front axle troubleshooting procedures, refer to **Section 33.01**.

The front axle requires periodic servicing to maintain accurate wheel alignment. If the front axle is damaged enough to affect the camber angle it must be replaced. For axle removal and installation instructions, see **Subject 160**.

Correct front axle wheel alignment is needed to ensure long tire life, ease of handling, and steering stability.

Three factors are involved in wheel alignment: camber angle, caster angle, and wheel toe-in.

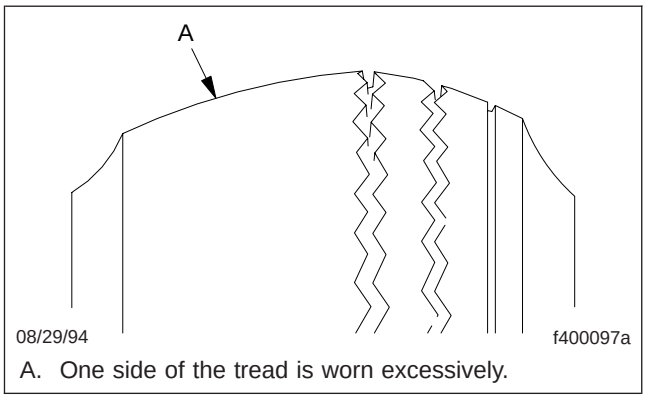
Camber angle (**Fig. 1**) is the vertical tilt of the wheel as viewed from the front of the vehicle. Camber angle is measured in degrees, and is not adjustable. Positive camber is the outward tilt of the wheel at the top. Excessive positive camber in one wheel causes the vehicle to pull in the opposite direction, rapidly wearing the outboard side of the tire tread. Negative camber is the inward tilt of the wheel at the top. Excessive negative camber in one wheel causes the vehicle to pull in the same direction that the negative-camber wheel is on, wearing the inboard side of the tire tread. If camber angles are not correct, the tires will wear smooth around the edge on one side. See **Fig. 2**.



A. Camber (Positive)

Fig. 1, Camber Angle

Caster angle (**Fig. 3**) is the tilt of the knuckle pin (or kingpin) as viewed from the side. Caster angle is measured in degrees and it is adjustable. A positive caster angle is the tilt of the top of the knuckle pin toward the rear of the vehicle. A negative caster angle is the tilt of the top of the knuckle pin toward the front of the vehicle. Caster angles are based on the design load of the vehicle. An incorrect caster angle does not cause tire wear. However, a positive caster angle that exceeds specifications could cause vehicle shimmy, road shock, and an increased steering effort. A negative caster angle that does not meet specifications could cause unstable steering. The vehicle may wander and weave, and extra steering effort may be necessary. After leaving a turn, the tendency to return to and maintain a straight-ahead position is reduced. Too much or too little caster in one wheel can cause erratic steering when the service brakes are applied to stop the vehicle.



A. One side of the tread is worn excessively.

Fig. 2, Tire Damage Due to Excessive Camber

Wheel toe-in (**Fig. 4**) is the distance in inches that the front of the wheels are closer together than the rear of the wheels, as viewed from the top. Wheel toe-in is adjustable. If it is not adjusted correctly, the vehicle could pull to one side while driving. Wheel shimmy and cupped tire treads (indentations on the road contact surface of the treads) could occur. Also, rapid or severe tire wear on the steering axle could occur, usually in a feather-edged pattern. See **Fig. 5**.

Advanced wear patterns can be seen, but less severe wear patterns are detected only by rubbing the palm of your hand flat across the tire tread.

Feather-edging more often affects the front tire on the passenger's side of the vehicle, and is usually more apparent on the outside grooves of the tire.

If any of the conditions listed above occur, the vehicle could need a front end wheel alignment, and possibly, drive axle alignment. However, in some cases these conditions are not wheel alignment related; refer to **Section 33.01** for other possible causes.

If excessive tire tread wear has resulted from incorrect wheel alignment, replace the damaged tires. For

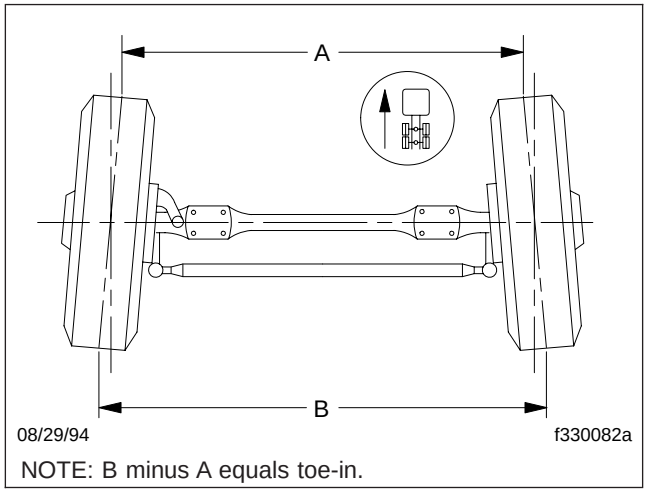
minimum tread wear specifications, refer to the wheels and tires section in the vehicle maintenance manual.



NOTE: B minus A equals toe-in.

Fig. 5, Tire Damage Due to Excessive Toe-In or Incorrect Drive Axle Alignment

Preliminary Checks

1. Steering axle wheel assemblies should be balanced, especially for vehicles that travel at sustained speeds of more than 50 mph (80 km/h). Off-balance wheel assemblies cause vibrations that result in severely shortened life for tires, and steering suspension parts.
2. Do not mix tires of different size, type, or weight. Tire wear should be even and not worn to limits exceeding government specifications. Refer to **Group 40** in this manual and the vehicle maintenance manual for more information. Replace any tire that is excessively worn.
3. Check the inflation pressure of the tires. Refer to the wheels and tires section in this manual for recommended pressures. An underinflated tire causes tread wear completely around both tire shoulders. An overinflated tire causes tread wear in the center of the tire. **See Fig. 1.**

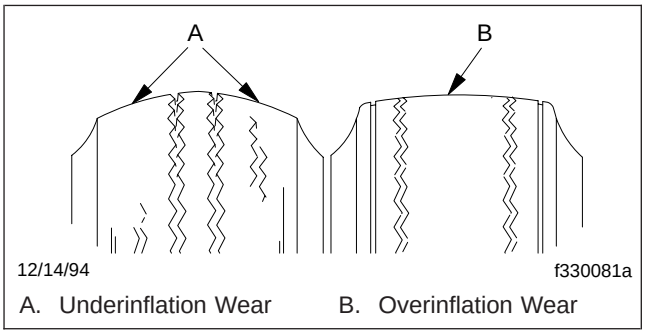

Fig. 1, Tire Damage Due to Underinflated or Overinflated Tires

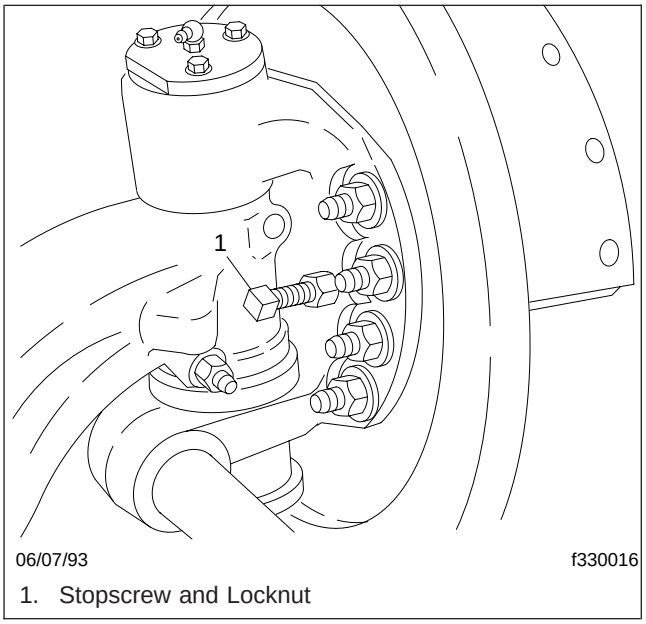
4. Check for out-of-round wheels, rims, or wheel stud holes. Replace the wheel if any of these conditions exist.
5. On each side of the vehicle, check the height of the chassis above the ground. Sagging, fatigued, or broken suspension springs create a lopsided vehicle appearance. This causes an unbalanced weight distribution. Anything that changes the ratio of weight on the springs affects the alignment angles and also the tire tread contact area. Replace damaged springs as instructed in the suspension section in this manual.
6. Inspect the front axle beam (also called the axle center) for bends or twists. If the axle beam is bent or twisted over 1/2 degree, replace it before aligning the front axle wheels.
7. Check for damaged, worn, or bent steering gear or linkage parts. Make sure the steering gear is centered. Replace damaged components, and adjust the steering gear, using the instructions in the steering section in this manual.
8. Check the steering angle, and adjust the axle steering stops, as needed. Refer to **Subject 110**.

Checking and Adjusting

Steering (or turning) angle is the degree of front wheel movement from a straight-ahead position to either an extreme right or left position. Although front wheel movement can be limited by the amount of internal travel in the steering gear, it generally depends on how much clearance there is between chassis components and the tire and wheel assemblies. All axles have adjustable stopscrew-and locknut-type axle stops (**Fig. 1**), which are located on the rear side of each front axle spindle.



1. Stopscrew and Locknut

Fig. 1, Axle Stop

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Make sure the steering gear is in the center of travel when the wheels are in a straight-ahead position. Center the gear, using the instructions in the steering section in this manual. Bottoming of the steering gear must not occur when making an extreme right or left turn.
2. If using stationary turn-plates or turntables (**Fig. 2**), drive the vehicle on the plates; the tires must be exactly straight ahead. Apply the parking brakes.

   If using portable gauges, apply the parking brakes, chock the rear tires, and raise the front of the vehicle. Place a turn-plate or turntable under each tire. With the tires exactly straight ahead, lower the vehicle so that the tires rest on the center of the gauges.

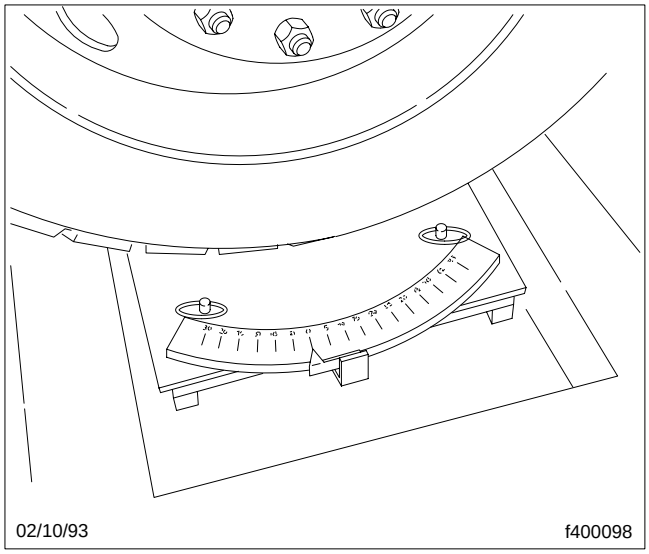


Fig. 2, Turn-Plate (Turntable), Stationary Type

3. Remove the lockpins from the gauges, and adjust the dials so that the pointers on both gauges read zero.
4. With the brakes fully applied, turn the steering wheel clockwise to the end of travel. Have someone check both sides of the vehicle for interference at the tires and wheels. There must be at least 0.50 inch (13 mm) clearance from any fixed object, and 0.75 inch (19 mm) from any moving object.

   If necessary, loosen the stopscrew locknut; adjust the stopscrew to contact the axle when the maximum turning angle of the wheels is determined.

   Tighten the locknut to the value in the torque table under **Specifications, 400**.

Steering Angle Checking and Adjusting

5. Repeat the step above with the steering wheel turned counterclockwise. Adjust the axle stop, as needed.
6. If equipped with power steering, adjust the steering gear so that pressure is released ahead of the axle stop. This will prevent possible damage to the steering or axle components. For poppet valve adjustment instructions, refer to **Group 46** in this manual.
7. Drive the vehicle off the turn-plates or turntables, or remove them from under the tires and lower the vehicle.

Measuring and Adjusting Front Axle Wheel Alignment Angles

Measuring and Adjusting

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

Precision instruments and equipment are needed for accurately measuring and adjusting wheel alignment. Refer to the operating instructions provided by the wheel alignment equipment manufacturer.

Before checking or correcting wheel alignment, make sure the vehicle is at curb weight. Curb weight is the weight of the unloaded vehicle complete with accessories and full fuel tanks.

If a road test is necessary, the route should be one that allows full left and right turns and full stops. It should also include a length of straight, level road to check the steering wheel position during straight-ahead driving.

During the road test, note any steering effort and possible roughness. Check for looseness, too much wheel play, any tendency for the vehicle to lead in one direction, and for pull during stopping.

Note the position of the steering wheel while driving on a straight, level road. When the steering gear is centered, the steering wheel spokes should be at the 4 and 8 o'clock positions, or within 10 degrees of that position. **See Fig. 1.**

If there are any problems, refer to **Section 33.01**.

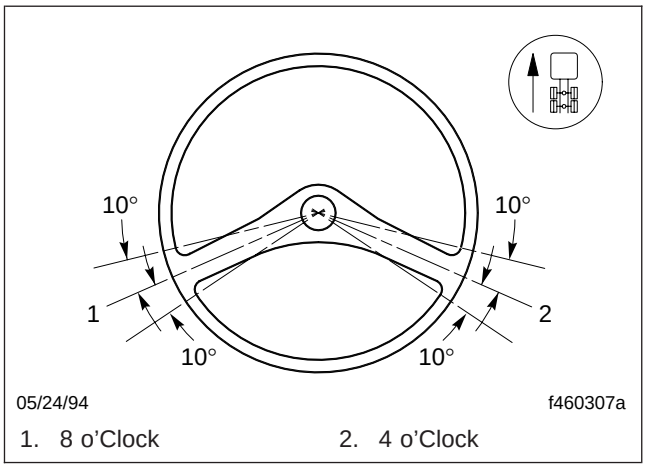

Fig. 1, Steering Wheel Position

Checking (See Fig. 1)

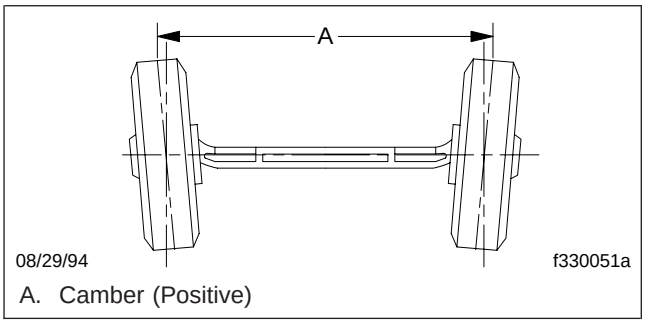

Fig. 1, Camber Angle

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Apply the parking brakes, and chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground. Place safety stands under the axle; make sure the stands will support the weight of the cab, frame, and front axle.
3. Before measuring camber, check the front wheel bearings for wear and incorrect adjustment. Try moving the wheel on the axle spindle (steering knuckle) either by grasping the front tire on the top and bottom, or by using a bar for leverage. If movement between the brake drum and the backing plate or other axle-mounted reference point is 0.05 inch (1 mm) or more, the bearings may be worn or incorrectly adjusted. Inspect the wheel bearings for damage using the instructions in **Section 33.01**. If needed, replace or adjust the bearings.
4. Remove the safety stands, and lower the vehicle to the ground.
5. Using the alignment equipment manufacturer's instructions, measure the front wheel camber.
6. Compare the camber angles with those shown in the appropriate table in **Specifications, 400**. Differences between the measurements taken in the step above and the angles in the table are caused by damaged (bent) axle components.

   Incorrect camber angles could be caused by damage in one or more of the following front axle components: the knuckle pin, the knuckle pin bushings, the axle spindle, or the axle beam. Replace twisted or otherwise damaged components. Don't try to straighten twisted or bent components; replace them with new components. If a bent or twisted front axle knuckle pin, axle spindle, or axle beam has been straightened, the axle warranty will be voided.

⚠ WARNING

WARNING: Do not attempt to straighten any twisted or bent front axle component. This could crack or weaken the component, possibly resulting in a collapsed front axle, loss of a wheel, and serious personal injury.

7. Remove the chocks from the tires.

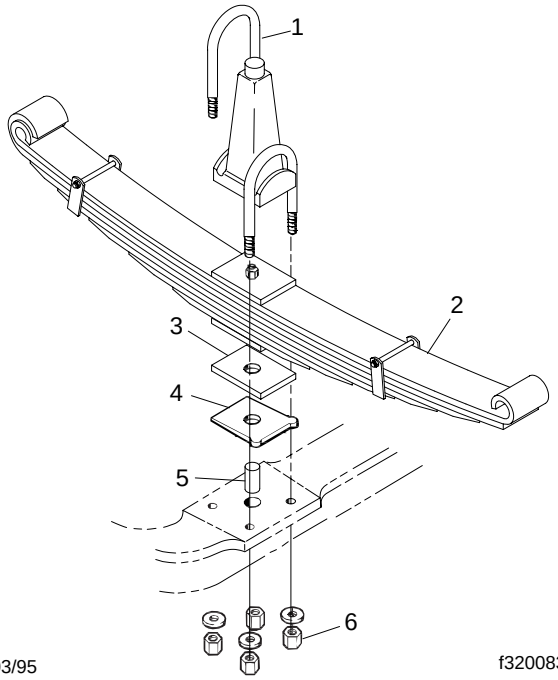
Fig. 1, Caster Angle

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

Using the alignment equipment manufacturer's operating instructions, measure the front wheel caster.

Compare the caster angles with those shown the appropriate table in **Specifications, 400**. If needed, adjust the caster angle by placing wedge-shaped shims between the axle spacer and the axle beam, as follows (**see Fig. 2**):



1. Axle Spring U-Bolt
2. Leaf Spring Assembly
3. Spacer
4. Front Caster Shim
5. Dowel Pin
6. U-Bolt High Nut

Fig. 2, Axle Spring Installation

IMPORTANT: Extreme angle shims cannot be used to correct caster angles that vary by more than 2 degrees from the values in the table. Weak or broken leaf springs, or worn shackle bushings, can cause extreme deviations to caster angles. Replace damaged parts before doing caster adjustments.

Caster Angle Checking and Adjusting

1. Apply the parking brakes, and chock the front and rear tires.
2. Back off the U-bolt nuts from the U-bolts on one side of the front axle. **See Fig. 2**.
3. Raise the spring away from the axle enough to allow removal of the front caster shim.
4. Remove the shim, and install one that will provide the correct caster angle, as specified in the table in **Specifications, 400**. Install the dowel pin and check penetration.

IMPORTANT: Place front caster shims between the axle beam and the axle spacer, or between the axle beam and the shock absorber bracket. **See Fig. 2.**

5. Lower the vehicle onto the axle.
6. Coat the threaded ends of the U-bolts with chassis lube or an antiseize compound, such as Loctite® 242. Tighten the U-bolt nuts to the value in the appropriate table in **Specifications, 400**.

   U-bolt nuts need periodic retightening. Refer to the suspension section in the vehicle maintenance manual for recommended intervals.

⚠ CAUTION

CAUTION: Failure to periodically retighten the U-bolt nuts could result in spring breakage and abnormal tire wear.

7. Using the steps above, replace the shim on the other side of the axle.
8. Remove the chocks from the tires. Do a final caster angle check.

Checking and Adjusting

(See Fig. 1)

Using the alignment equipment manufacturer's operating instructions, measure the wheel toe-in. Compare the measurement with that shown in the appropriate table in **Specifications, 400**. If corrections are needed, go to the applicable (tie rod adjustment) step below.

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Apply the parking brakes, and chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground. Place safety stands under the axle. Make sure the stands will support the weight of the cab, axle, and frame.
3. Using spray paint or a piece of chalk, mark the entire center rib of each front tire.
4. Place a scribe or pointed instrument against the marked center rib of each tire, and turn the tires. The scribes must be held firmly in place so that a single straight line is scribed all the way around each tire.
5. Place a turn-plate or turntable under each tire. Remove the safety stands from under the axle, then lower the vehicle. Remove the lockpins from the gauges; make sure the tires are exactly straight ahead.

NOTE: If turn-plates or turntables are not available, lower the vehicle. Remove the chocks from the rear tires and release the parking brakes. Move the vehicle backward and then forward about six feet (2 meters).

6. Place the trammel bar at the rear of the front tires; locate the trammel pointers at spindle height, and adjust the pointers to line up with the scribe lines. Lock in place. Make sure that the scale is set on zero.

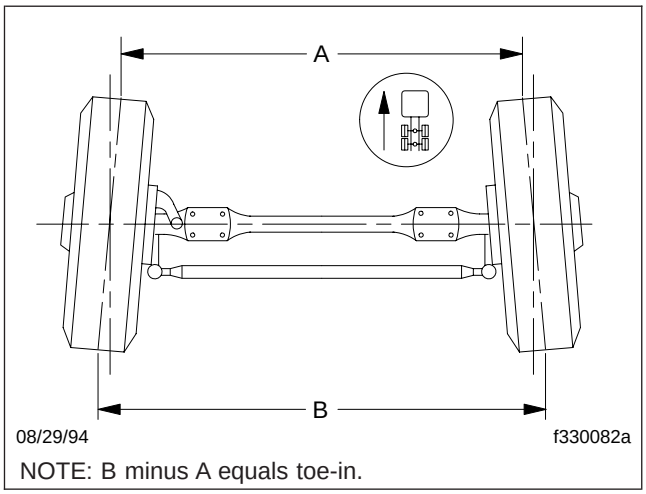


Fig. 1, Wheel Toe-In (Overhead View)

7. Place the trammel bar at the front of the tires as shown in **Fig. 2**. Adjust the scale end so that the pointers line up with the scribe lines. **See Fig. 3.**
8. Read the toe-in from the scale. Compare the toe-in with the value in the appropriate table in **Specifications, 400**. If corrections are needed, go to the next step.
9. Loosen the tie rod (cross tube) clamp nuts, and turn the tie rod as needed.

   If the vehicle is not on turn-plates or turntables, move the vehicle backward and then forward about six feet (two meters). This is important when setting the toe-in on vehicles equipped with radial tires.

   Do a final wheel toe-in check to make sure that it is correct.

   Tighten the clamp nuts to the values in the appropriate table in **Specifications, 400**.
10. If not already done, remove the chocks from the rear tires. Road test the vehicle.

Front Axle Removal and Installation

Removal

NOTE: This procedure involves removing the axle from underneath the front of the vehicle. If you cannot support the vehicle high enough for the axle to clear the bumper, then you will need to remove the bumper.

1. Park the vehicle on a level surface, set the parking brakes, then chock the rear tires.
2. Tilt the hood or cab. For cab tilt instructions, see **Group 60**.
3. Raise the vehicle, then support the frame rails with safety stands.
4. Remove the front tires.
5. If so equipped, disconnect the ABS sensors from the axle knuckles. Pull the sensors straight out.

⚠ WARNING

When draining the air system, don't look into the air jets or direct them toward another person, as dirt or sludge particles may be in the airstream. Don't disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions while working on the air brake system can cause personal injury.

6. Drain the air tanks.
7. Disconnect the air lines from the front brake chambers.
8. Remove the brake drums. See **Group 42** for instructions.
9. Remove the hubs. Refer to the applicable subject in **Section 33.01** for instructions.
10. Disconnect the steering drag link from the axle steering arm. See **Group 46** for instructions.
11. If needed, remove the front bumper. See **Group 31** for instructions.
12. Remove the U-bolts and nuts holding the axle to the leaf springs.
    - 12.1 Take the weight off the leaf springs by raising the axle.
    - 12.2 On one side of the axle, remove all the U-bolt nuts and washers, then remove the two U-bolts.
    - 12.3 Repeat the procedure on the other side of the axle.
13. Remove the axle stops from the top of the leaf springs.
14. Remove the axle spacers from the top of the axle beam.
15. Using a suitable axle jack, remove the axle by sliding it out from the front of the vehicle.
16. Remove the brake shoes, cam, and spider. See **Group 42** for instructions.

Installation

1. From the front of the vehicle, and using a suitable axle jack, roll the axle into place under the leaf springs.
2. Install the axle spacers.
3. Slowly raise the axle up to the bottom of the leaf springs, making sure the dowels on top of the axle beam line up with the holes in the axle spacers.
4. Install the axle stops onto the tops of the leaf springs.
5. Install the U-bolts.
    - 5.1 Using a suitable clamp (such as a large C-clamp) compress one of the U-bolts, then install it on one side of the axle. Do the same for the second U-bolt.
    - 5.2 Install the U-bolt nuts and washers. Tighten the nuts finger-tight.
    - 5.3 Repeat the procedure on the other side of the axle.
6. Tighten the U-bolt nuts.

    For 3/4–16 U-bolt nuts: In a diagonal pattern, tighten the U-bolt nuts successively 80 lbf·ft (108 N·m), 200 lbf·ft (270 N·m), then 300 lbf·ft (406 N·m).

    For 7/8–16 U-bolt nuts: In a diagonal pattern, tighten the U-bolt nuts successively 60 lbf·ft (81 N·m), 200 lbf·ft (270 N·m), then 460 lbf·ft (624 N·m).

Front Axle Removal and Installation

7. Install the brake spider, cam, and brake shoes. See **Group 42** for instructions.
8. If so equipped, install the ABS sensors in the axle knuckles.
9. Connect the air lines to the brake chambers.
10. Connect the drag link to the steering arm. See **Group 46** for instructions.
11. Install the tires.
12. If it was removed, install the bumper. See **Group 31** for instructions.
13. Raise the vehicle, then remove the safety stands.
14. Lower the vehicle.
15. Lower the hood or return the cab to the operating position. For cab tilt instructions, see **Group 60**.
16. Remove the chocks from the rear tires.

Specifications

IMPORTANT: When aligning the front axle, it is essential that the rear axle(s) be checked for correct alignment at the same time. Alignment of the rear axle(s) has a direct impact on how the vehicle tracks. See **Section 35.00**.

General Information

Wheel end assemblies include the wheel hub, wheel bearings, brake drum (or rotor), wheel studs, and spindle nut. See **Fig. 1**.

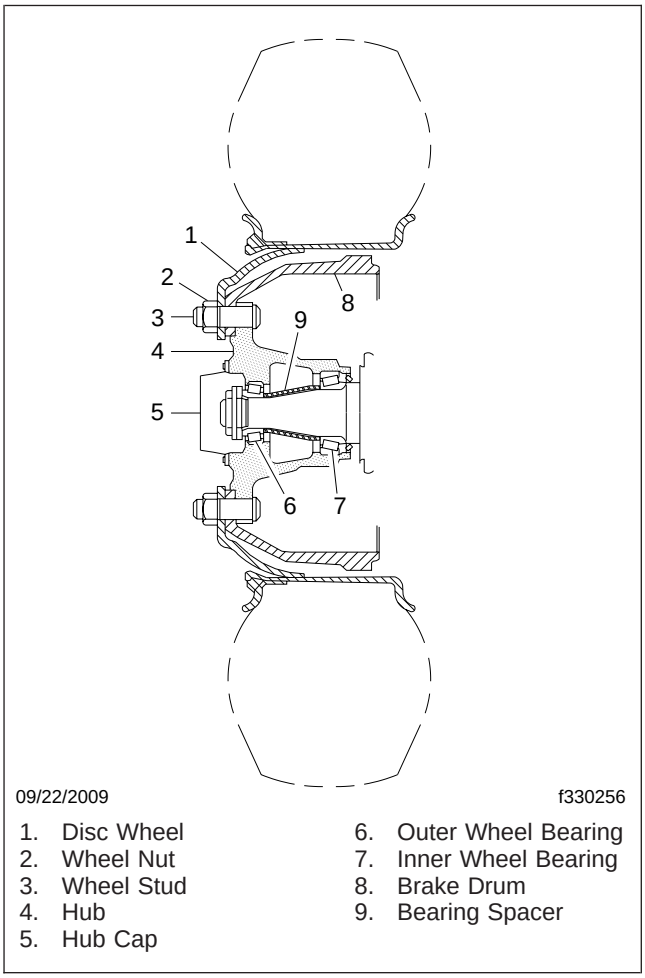

Fig. 1, Wheel End Assembly with Drum Brakes

Wheel Hub

ConMet PreSet hubs have a spacer between the inner and outer bearings that adjusts the bearings to the correct end-play and preload when the retaining nut is tightened. For more information about PreSet hubs, and removal and installation procedures, see **Subject 100**.

Tapered Wheel Bearings

Each hub has a set of inner and outer tapered wheel bearing assemblies. A typical tapered wheel bearing assembly consists of a cone, tapered rollers, a roller cage, and a separate cup that is press-fit in the hub. See **Fig. 2**. All components carry the load, with the exception of the cage, which spaces the rollers around the cone.

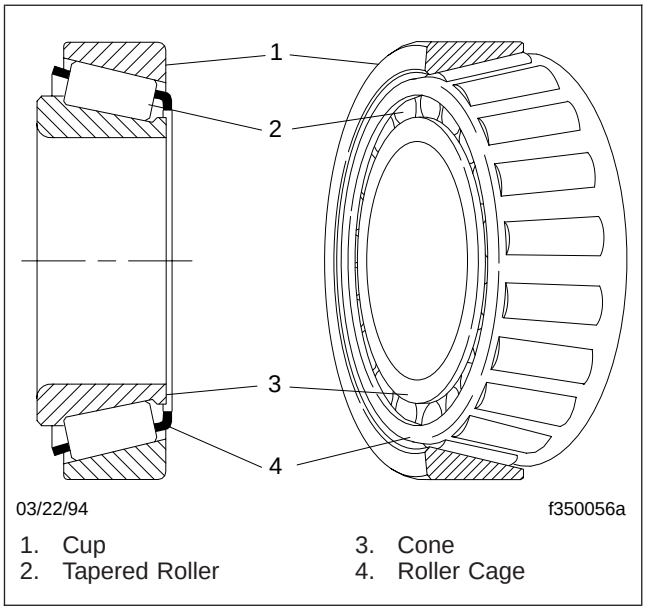

Fig. 2, Tapered Wheel Bearing Assembly

Brake Drum

The brake drum and lining work together as a mated friction pair, with the drum responsible for both heat absorption and dissipation. Lining performance and life largely depend on the condition of the drum and whether it can adequately absorb and dissipate heat generated by braking action.

Wheel Studs

A headed wheel stud (**Fig. 3**) is used on front axle disc wheel hub assemblies and has either serrations on the stud body or a flat area on the stud's head to prevent the stud from turning in the wheel hub. For replacement procedures, see **Subject 125**.

General Information

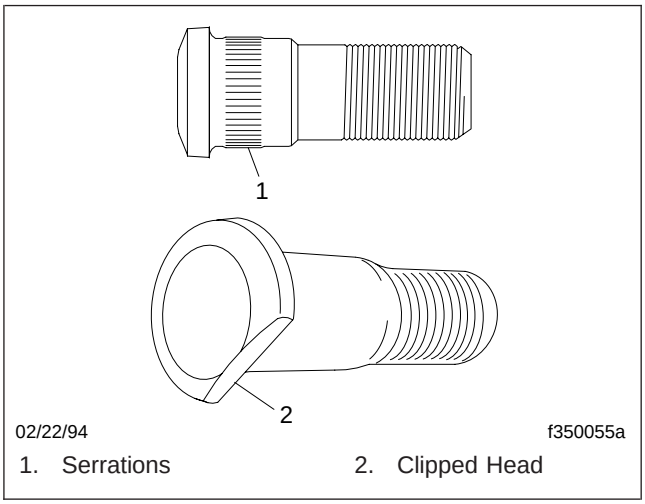

Fig. 3, Typical Wheel Studs

Meritor FF-981 Easy Steer Plus Axle

Vehicles may be equipped with the Meritor FF-981 Easy Steer Plus Axle. This axle has the hubs, bearings, and oil seals factory-installed on the axle spindles. The hubs can be removed and installed on the axle, and the studs can be replaced, but the wheel bearings and oil seal are not serviceable in the field. To install a new hub, mount it on the axle spindle, and secure it. For installation and adjustment instructions, see **Subject 140**.

General Information

ConMet PreSet® steer axle hubs are equipped with a special tubular spacer inside the hub, between the inner and outer bearings. See **Fig. 1**.

3. Bearing Spacer
4. Outer Bearing
5. Retaining Nut
6. Axle Spindle

Fig. 1, ConMet PreSet Hub, Cut-Away View

When installing a PreSet hub with the spacer and special PreSet bearings, the correct end play is set automatically and wheel bearing adjustment is unnecessary.

For vehicles equipped with ConMet PreSet hubs, it is highly recommended to **stay with the PreSet system** to optimize bearing and seal life. However, if you are replacing the bearings for a PreSet hub, and the special PreSet bearings are not available, standard wheel bearings can be used. In this case, the bearing spacer must be removed and the bearings adjusted manually. See the installation instructions for more information.

NOTE: On some axles, the hub, wheel bearings, studs, and oil seal are installed as a unitized wheel-end assembly. These wheel ends must be replaced as a unit. For Meritor unitized wheel end installation and adjustment procedures, see **Subject 140**.

Removal

For a typical wheel and axle assembly, see **Fig. 2**.

1. Chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground. Then place safety stands under the axle.
3. For drum brakes, back off the slack adjuster to release the front axle brake shoes.

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

4. Remove the wheel and tire assembly. See **Group 40** for instructions.
5. For drum brakes, remove the brake drum. For instructions, see **Subject 105**.

NOTE: Oil will spill as the hub cap and wheel hub are removed. Place a suitable container under the axle spindle to catch any spilled oil, and avoid contaminating the brake shoes with oil. Dispose of the oil properly.

6. Remove the capscrews, washers, and hub cap. Remove and discard the hub cap gasket.
7. Remove the wheel bearing locking device:
   - For an Axilok spindle nut, see **Subject 135**; then go to the next step.
   - For a Pro-Torq spindle nut, see **Subject 150**; then go to the next step.
   - If the axle is equipped with a four-piece bearing-lock system, see **Subject 130**; then go to the next step.

NOTICE

Be careful not to let the outer wheel bearing drop from the axle spindle. Dropping the bearing can warp the cage or damage the rollers, ruining the bearing. On vehicles equipped with WABCO ABS, use care when working with the hubs. To prevent damage to the tone wheel, do not drop the hub, or lay it down in a way that would damage the tone wheel.

NOTE: If working with Meritor Easy Steer Plus® hubs, remove the wheel end (hub, bearings, and oil seal) as a unit.

8. Move the hub about 1/2 inch (13 mm) to jar loose the outer wheel bearing (allow the hub-only assembly to rest on the axle spindle; be careful not to damage the axle spindle threads). Then, carefully remove the outer wheel bearing; handle the bearings with clean, dry hands. Wrap the bearings in either clean oil-proof paper or lint-free rags.

NOTICE

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

9. Remove the hub from the axle spindle. Be careful not to damage the axle spindle threads as the assembly is removed.
10. Remove the inner wheel bearing; handle the bearings with clean, dry hands. Wrap the bearings in clean, oil-proof paper or lint-free rags. If the inner wheel bearing remains in the hub after the hub is removed, place a protective cushion where it will catch the bearings, and use a hardwood drift and a light hammer to gently tap the bearing (and seal, if necessary) out of the cup.
11. Remove the oil seal from the axle spindle, if not already removed. See **Section 33.02** for additional information.

Installation

For a typical wheel and axle assembly, see **Fig. 2**.

NOTE: For Meritor unitized wheel end installation and adjustment procedures, see **Subject 140**.

1. Using cleaning solvent, remove the old oil from the axle spindle (steering knuckle) and the disassembled parts. Allow the parts to dry, or dry them with a clean, absorbent, and lint-free cloth or paper. Wrap a protective layer of friction tape on the axle spindle threads.
2. On brake drum assemblies with an aluminum hub, coat the hub and drum contact surfaces with Alumilastic® compound or an equivalent.

NOTICE

Make sure that both bearing assemblies are coated with fresh oil. Use only fresh oil on the bearing assemblies; old oil could be contaminated with dirt or water (both are corrosives) and could cause damage to both wheel bearing assemblies and the wheel hub.

3. Coat both bearing assemblies with fresh oil. Install the inner wheel bearings and oil seal. Handle the bearings with clean, dry hands. See **Section 33.02** for oil seal installation instructions.
4. Wipe a film of axle oil on the axle spindle to prevent rust from forming behind the inner wheel bearing.
5. If present, remove the temporary plastic bearing cover from the front of the hub.

NOTICE

Do not use the bearing spacer with standard wheel bearings. To do so may result in too much bearing end-play, which could damage the wheel bearings, oil seals, the axle spindle, and the hub.

6. If using PreSet bearings, ensure the tubular spacer is in the PreSet hub.

   If replacing PreSet bearings with non-PreSet bearings, remove the tubular spacer from inside the hub. Save it for future use to convert the hub back to the PreSet system.

NOTE: For Meritor unitized wheel end installation and adjustment procedures, see **Subject 140**.

NOTICE

- **On vehicles equipped with WABCO ABS, use care when installing the hubs. To prevent damage to the tone wheel, do not drop the hub or lay it down in a way that would damage the tone wheel.**
- **Do not remove the outer wheel bearing once the hub is installed on the axle. Removing the outer bearing could cause the oil seal to become misaligned, which could cause damage to the wheel bearings, the hub, and the axle spindle.**

7. Mount the hub assembly on the axle spindle.
8. Remove the friction tape, then adjust (if needed) and secure the bearings:
   - For an Axilok spindle nut, see **Subject 135**; then go to the next step.
   - For a Pro-Torq spindle nut, see **Subject 150**; then go to the next step.
   - If the axle is equipped with a four-piece bearing-lock system, see **Subject 130**; then go to the next step.
9. Place the hub cap and a new gasket in position, then install the washers and capscrews. In a star pattern, tighten the capscrews 15 lbf·ft (20 N·m).
10. If applicable, add fresh oil to the wheel hub to the level indicated on the hub cap. For recommended axle lubricants, see **Specifications, 400**.

⚠ WARNING

Failure to add oil to the wheel hub after the hub has been serviced will cause the wheel bearings to overheat and seize during vehicle operation. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury and property damage.

11. Rotate the hub to distribute the oil, then check the level at the hub cap. Add lubricant as needed.
12. For drum brakes, install the brake drum on the wheel hub. For instructions, see **Subject 105**.

Hub Assembly Removal and Installation

WARNING

If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking action, and the wheel hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

13. Install the wheel and tire assembly. See **Group 40** for instructions.
14. Adjust the front axle brakes. For instructions, see **Group 42**.
15. Remove the safety stands from under the axle and lower the vehicle.

Outboard-Mounted Drum Removal and Installation

WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

For an exploded view of a typical wheel and axle assembly, including the brake drum, see **Fig. 1**.

Removal

1. Chock the rear tires to prevent vehicle movement. Apply the parking brakes.
2. Raise the front of the vehicle until the tires clear the ground. Then place safety stands under the axle.
3. Back off the slack adjuster to release the front axle brake shoes.

WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

4. Remove the wheel and tire assembly. Refer to **Group 40** for instructions.

   To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.
5. Remove the brake drum.
6. Inspect the drum. Refer to **Subject 110** for instructions.

Installation

1. On brake drum assemblies with an aluminum hub, coat the hub and drum contact surfaces with Alumilastic® compound or an equivalent.
2. Install the brake drum on the wheel hub.

   2.1 On hub-piloted drums, position the brake drum on the top step of the pilot pad. One of the hub's pilot pads should be at the twelve o'clock (top center) position. See **Fig. 2.**

   IMPORTANT: If the drum is not positioned correctly, the pilot pad could be damaged when the wheel nuts are torqued.

   2.2 Make sure that the pilot pads securely center the drum (space between drum and hub is equal all around the hub).

   IMPORTANT: If damage to the pads prevents the drum from centering, replace the hub. If necessary to hold the drum in position, adjust the brakes before installing the wheels.
3. Install the wheel and tire assembly. To ensure that the drum does not slip off the pilot pad, follow the proper nut tightening sequence. For instructions, refer to **Group 40**.

WARNING

WARNING: If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking ability, and the hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist, could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

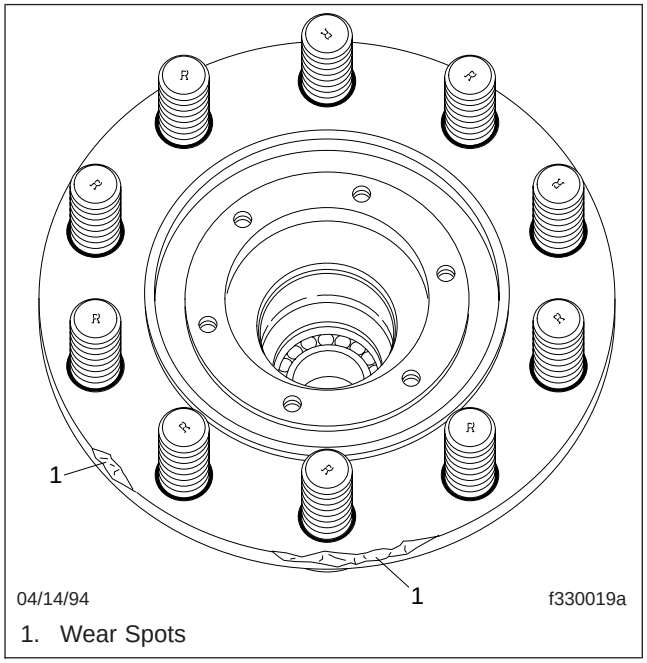
Wheel Hub Assembly Inspection

1. Inspect the wheel hub mounting flange. A loose wheel assembly will cause the flange to be worn, jagged, or warped. **See Fig. 1.** Replace the wheel hub if any of these conditions exist.

   Inspect the flange surface around the wheel studs. Improperly torqued wheel nuts will cause worn or cracked stud grooves on the hub. **See Fig. 2.** If wear spots or cracks appear anywhere on the hub, or if the hub is otherwise damaged, replace it with a new one.

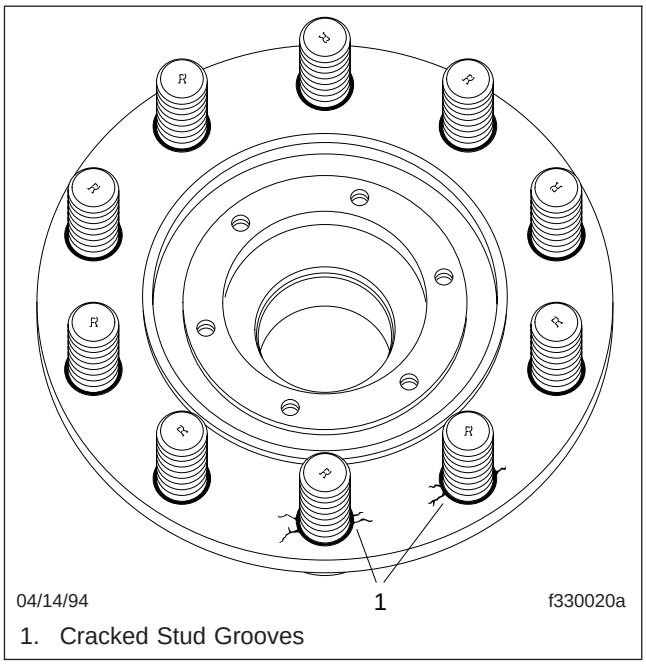


1. Wear Spots

Fig. 1, Damaged Front Axle Wheel Hub

2. Remove all the old oil from the wheel hub cavity. Inspect the inner surface of the hub for cracks, dents, wear, or other damage. Replace the wheel hub if damage exists.

3. Remove all the old grease or oil from the surfaces of the wheel bearing cups. Inspect the wheel bearing cups for cracks, wear, spalling, or flaking. **See Fig. 3.** Replace the cups if damaged in any way. Refer to **Subject 115** or **Subject 120**.



1. Cracked Stud Grooves

2. Cone

Fig. 3, Spalling (Flaking) of Wheel Bearing Assembly

4. Inspect the wheel nuts on disc wheel installations, or the rim nuts on spoke-wheel installations. Damaged nuts (**Fig. 4**), usually caused by inadequate tightening, must be replaced with new ones.

Axle Components Cleaning and Inspection

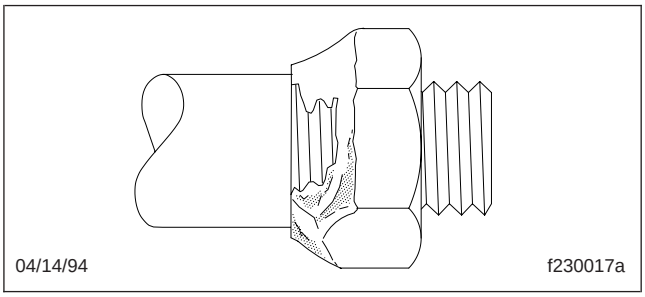

Fig. 4, Damaged Wheel Stud Nut

5. Inspect the wheel or rim studs. Replace studs that are stripped, broken, bent, or otherwise damaged. Refer to **Subject 125**.

Wheel Bearing Inspection

Wheel bearings should be very closely inspected at the time of disassembly. Optimal inspection conditions are possible only after the bearings have been thoroughly cleaned using kerosene or diesel fuel oil, and a stiff brush. Before inspecting, clean the bearings.

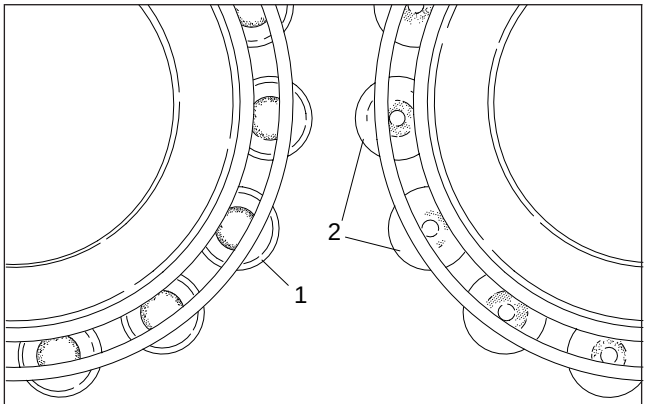
1. Remove the wheel hub and bearing cones. Refer to **Subject 100**.
2. Clean all old oil from the bearings and hub cavity with kerosene or diesel fuel and a stiff brush. Don't use gasoline or heated solvent.
3. Allow the cleaned parts to dry, or dry them with a clean absorbent cloth or paper. Clean and dry your hands and all tools used in the maintenance operation. Oil will not stick to a surface which is wet with kerosene or diesel fuel, and the kerosene or diesel fuel may dilute the lubricant.

⚠ CAUTION

CAUTION: Do not spin the bearing rollers at any time. Dirt or grit can scratch the roller surface and cause premature wear of the bearing assembly. Treat a used bearing as carefully as a new one.

4. After the bearings are cleaned, inspect the assemblies, which include the rollers, cones, cups, and cages. If any of the following conditions exist, replace the bearing assemblies:

   4.1 Large ends of rollers worn flush to the recess, or radii at the large ends of the rollers worn sharp. These are indications of advanced wear. **See Fig. 5**.



1. New Bearing
2. Worn Bearing Rollers

   4.2 Visible step wear, particularly at the small end of the roller track. Deep indentations, cracks, or breaks in the cone surfaces. **See Fig. 6.**

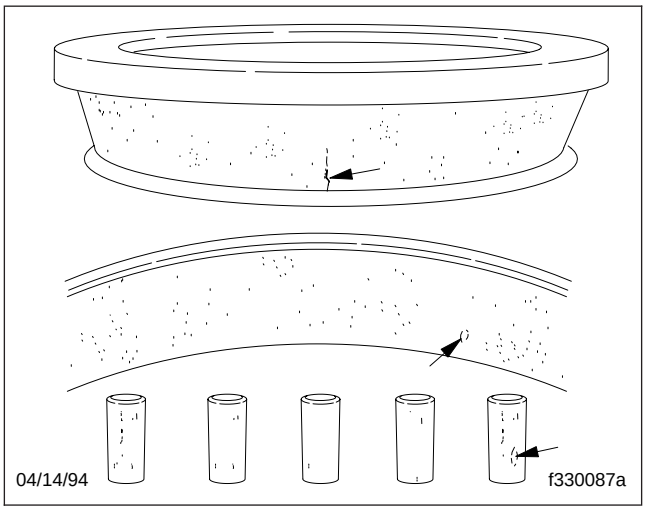

Fig. 6, Indentations, Cracks, or Breaks in Bearing Surfaces

   4.3 Bright rubbing marks on the dark phosphate surfaces of the bearing cage. **See Fig. 7.**

   4.4 Water etch on any bearing surface. Water etch appears as gray or black stains on

the steel surface, and it greatly weakens the affected area. If water etch is present, replace the bearing seals.

4.5 Etching or pitting on functioning surfaces. **See Fig. 8.**

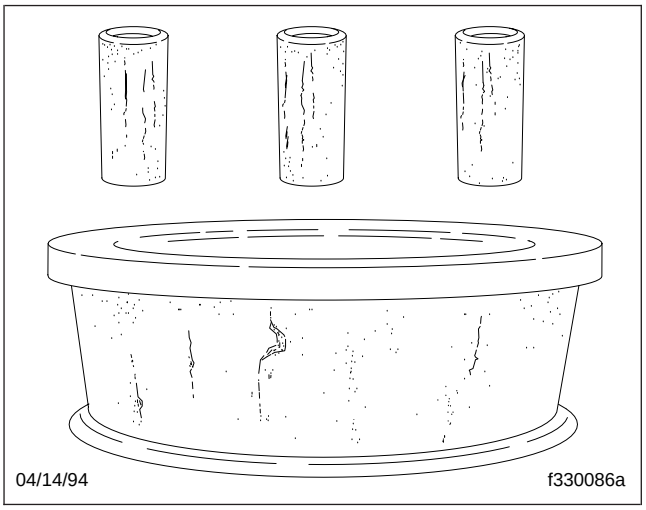

Fig. 8, Etching (Pitting) on Bearing Surfaces

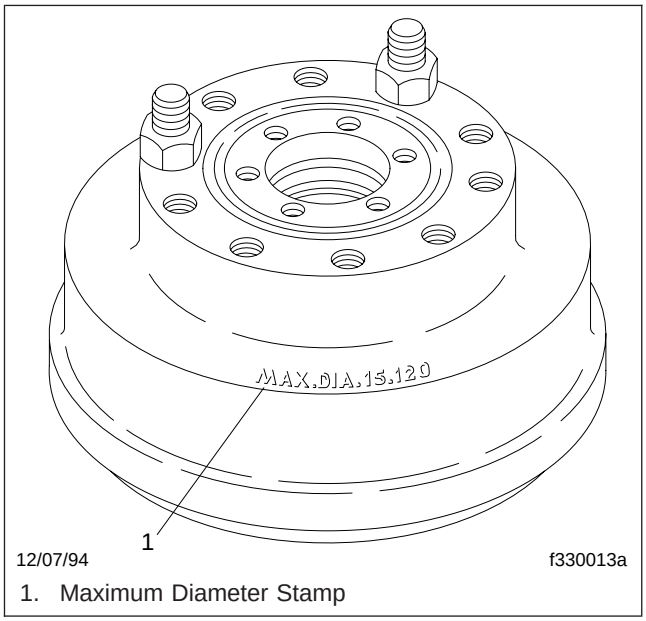
4.6 Spalling (flaking) of the bearing cup, roller, or cone surfaces. **See Fig. 3.**

After inspection, brush the bearings with fresh axle lubricant.

Brake Drum Inspection

New brake drums are purposely undersized to allow for turning (remachining), since in mounting drums on the hub, there can be some eccentricity. If a new drum is installed, the protective coating on the inner friction surface must be removed with a solvent, prior to drum installation, then rinsed with a hot water wash. Use a clean rag to remove any oily residue or metal chips from the friction surface.

If a drum must be turned or replaced, the other same-axle drum must be similarly turned or replaced to provide the same braking power on both wheels. Turned drums should not exceed the maximum allowable diameter, which is stamped on the outside surface of the drum. **See Fig. 9** for a typical location of this stamp.



1. Maximum Diameter Stamp

Fig. 9, Outboard Mounted Hub and Drum Assembly

NOTE: Drums that have been turned should then be cleaned by using fine emery cloth followed with a hot water wash. Drums that have been renewed using emery cloth should also be followed with a hot water wash.

CAUTION

CAUTION: Failure to replace drums when worn or turned to limits exceeding the maximum allowable diameter will cause drum weakness and reduced braking capacity, which can lead to distortion, higher drum temperatures, and ultimate drum breakage.

Axle Components Cleaning and Inspection

If the drums are turned or replaced, replace the brake linings. Refer to **Group 42** in this manual for instructions.

1. Inspect the inner friction surface. If a veneered (highly glossed) or glazed surface exists, renew the drum by using 80–grit emery cloth or by turning the drums.
2. Inspect for heat checking, which is a form of buckling (cracking) resulting from a temperature differential in the drum wall between a relatively cool exterior and a hot friction surface. Heat checking is normal on all drums and may not impair performance and lining life if the network of fine hairline cracks remains small. Examine heat checks of drums frequently to be certain the checks have not widened into drum weakening cracks (substantial cracks extending to the open edge of the drum). Replace the same-axle drums if substantial cracks are present, or if widening of the fine hairline cracks occurs.

NOTE: If normal heat checking as described above is present, inspect the drums at least every 12,000 miles (19 300 km) thereafter. Inspect the drums (using a flashlight from the inboard side of the wheels) every 6000 miles (9700 km). Inspect more often under adverse operating conditions.

3. Check for a contaminated inner friction surface. If fluids are present, such as oil or grease, remove the contaminants. Locate and correct the source of the contamination. If the brake drums are contaminated with fluids, the brake linings will also be affected. Since oil or grease saturated linings cannot be salvaged, they must be replaced. For brake lining replacement procedures, refer to **Group 42** in this manual.

⚠ WARNING

WARNING: If the brake drums are contaminated with fluids, replace the brake linings. Failure to replace fluid contaminated brake linings could result in a partial loss of braking capacity, which could lead to personal injury or property damage.

4. Measure the inside diameter of the drum. If the measured diameter is greater than the maximum allowable diameter, replace the same-axle drums and linings.
5. Check for a variation in gauge readings at different points on the radius of the drum's working surface. If the variation is more than 0.010 inch (0.25 mm) at any point, the drum is out-of-round to unacceptable limits. Remachine or replace the same-axle drums.
6. Inspect the outside surface of the drum. Remove any accumulation of mud, dirt, or rust; foreign matter acts as an insulator, trapping heat within the drum.
7. Check for hard, slightly raised dark-colored spots on the inner friction surface or for a bluish cast on the brake parts, both of which are caused by high temperatures. If the drums' maximum allowable diameters have not been exceeded, remachine both same-axle drums. If the spots or discoloration cannot be removed, or if remachining is not possible, replace the drums. Also replace the brake shoe return springs.

Wheel Bearing Cup Removal and Installation, Aluminum Hubs

Removal (See Fig. 1)

To insure a tight fit, wheel bearing cups are purposely larger than the wheel hub bores they occupy. To remove the bearing cups, aluminum hub bores must be temporarily expanded by heating the hub in an oven (the bearing cups will also expand, but to a considerably lesser extent). If adequate heating facilities are not available, replace the hub, wheel stud, and bearing cup assembly.

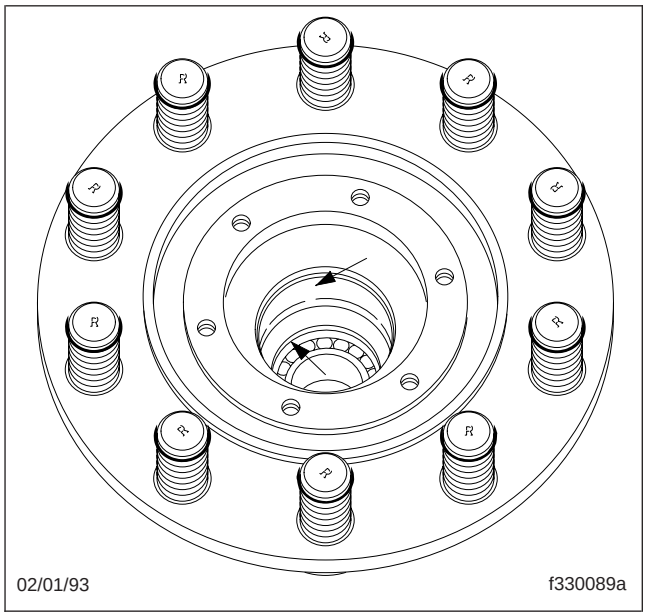


Fig. 1, Wheel Bearing Cup Locations

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Oven-heat the hub to a temperature range of 240° to 280°F (116° to 138°C). Make sure the oven thermostat is accurately set; if unsure, use an oven thermometer to check the temperature of the oven before placing the hub inside.

   If adequate heating facilities are not available, replace the hub, wheel stud, and bearing cup assembly.

⚠ WARNING

WARNING: Do not use oxyacetylene equipment or similar equipment to heat the hub. Oxyacetylene equipment or similar equipment will cause cracks in the hub which could cause loss of a wheel and loss of vehicle control, leading to personal injury or property damage.

3. Wearing heavy protective gloves, remove the hub from the oven. Place the hub on a suitable press so that the base is fully supported. Quickly press out the bearing cups.

Installation

To install the bearing cups, aluminum hubs must again be temporarily expanded using oven heating. When the hub is properly heated, the bearing cup and hub can be press-fit together, using a suitable press.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Oven-heat the hub to a temperature range of 240° to 280°F (116° to 138°C). Make sure the oven thermostat is accurately set; if unsure, use an oven thermometer to check the temperature of the oven before placing the hub inside.

⚠ WARNING

WARNING: Do not use oxyacetylene equipment or similar equipment to heat the hub. Oxyacetylene equipment or similar equipment will cause cracks in the hub which could cause loss of a wheel and loss of vehicle control, leading to personal injury or property damage.

4. Coat the replacement bearing cup hub contact surface with a film of grease.
5. Wearing heavy protective gloves, remove the hub from the oven.
6. Place the hub on a suitable press so that the base is fully supported. Quickly press-fit the bearing cup into the wheel hub until it is completely and evenly seated. Be careful not to shave the sides of the bearing cup bore as the bearing cup is seated. The accumulation of debris will prevent the cup from being seated and

Wheel Bearing Cup Removal and Installation, Aluminum Hubs

will also cause permanent damage to the wheel hub. If the sides of the bearing cup bore are damaged during installation, replace the wheel hub assembly.

7. Allow the wheel hub to cool before handling. Then, using a 0.0015–inch feeler gauge, check at several places for the seating of the bearing cup in the bearing cup bore. The gauge should not enter beneath the cup. If it does, there is probably dirt or debris preventing the cup from seating. Using the instructions above, remove the cup, then remove the foreign matter. Reinstall the cup.
8. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean, lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Wheel Bearing Cup Removal and Installation, Ferrous Hubs

Removal

Wheel bearing cups on ferrous hubs are removed and installed by driving them out and pressing them in without heating the hub.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Using a mild-steel rod through the opposite end of the hub, drive against the inner edge of the bearing cup. Alternately drive on opposite sides of the cup to avoid cocking the cup and damaging the inside of the hub.

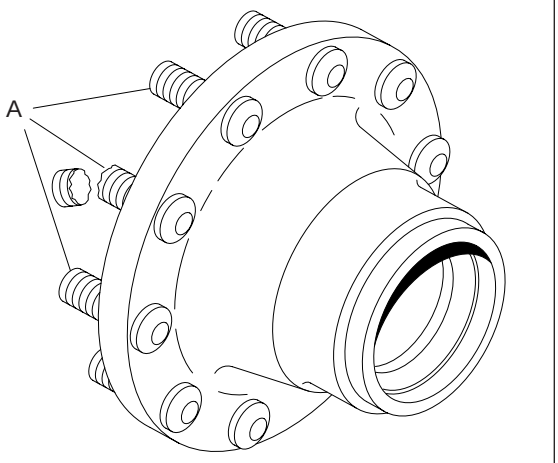
Installation

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Coat the replacement bearing cup hub contact surface with a film of grease.
4. Position the cup in the hub and press it into place, using a suitable driving tool. Cups must seat against the shoulder in the hub.
5. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Replacement

WARNING

WARNING: If a wheel stud breaks, the remaining studs are subjected to undue strain and could fail due to fatigue. When a broken stud is replaced, replace the stud on each side of it. See Fig. 1. If more than one stud is broken, replace all of the studs. Failure to replace the studs could result in the loss of a wheel or loss of vehicle control, possibly resulting in personal injury.



A. Replace

Fig. 1, Wheel Stud Replacement

1. Remove the wheel hub from the axle. For instructions, refer to **Subject 100**.
2. If a bent portion of a wheel stud will have to pass through the wheel stud bore, cut off the bent portion before removing the wheel stud.
3. Place the wheel hub on a suitable press; make sure the hub flange is supported evenly around and next to the stud being removed. With steady movement, press the damaged stud out of the hub.

CAUTION

CAUTION: Do not use a drift and hammer or concentrated heat for removing and installing the wheel studs. Constant, smooth movement of the wheel stud is necessary to ensure the least amount of metal removal from the wheel stud bore. Concentrated heat will damage the hub. If the hub is damaged during wheel stud removal or installation, replace it.

4. Apply a coating of clean axle grease to the entire shaft on headed studs.
5. With the hub on a suitable press, make sure the hub flange is supported evenly around and next to the stud being installed.
6. Position the stud in its hole. *Be sure the flat edge of the head flange on clipped studs is in line with the shoulder on the hub.*

CAUTION

CAUTION: If headed studs with serrations are being installed, position the teeth of the serrated portion in the notches carved by the original wheel studs during factory installation. If additional metal is scraped from the wheel stud bores, the locking action provided by the serrations will be greatly weakened. Loss of locking action will prevent achieving final torque of the wheel nuts during wheel installation. If final wheel nut torques during wheel installation cannot be achieved, replace the wheel hub assembly.

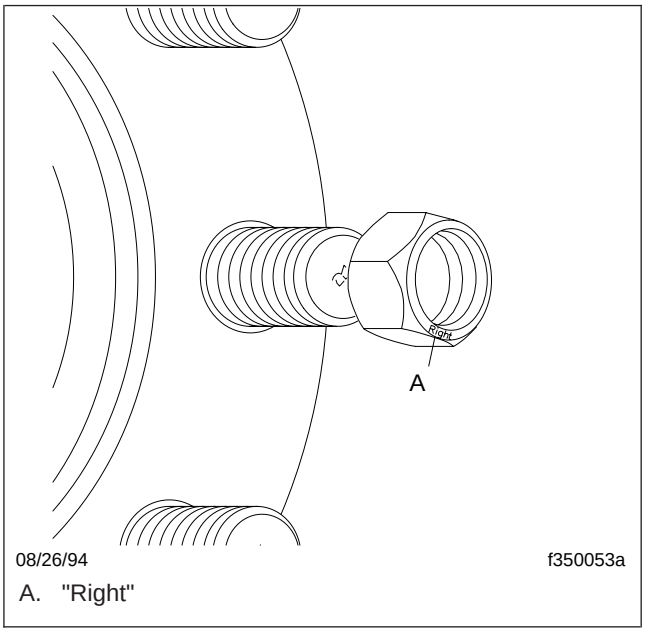
NOTE: If the left side of the vehicle is being serviced, the replacement wheel stud must be stamped with an "L" (left-hand threaded), and the nut's face must be stamped "Left" If the right side of the vehicle is being serviced, the replacement stud must be stamped with an "R" (right-hand threaded), and the nut's face must be stamped "Right" (**Fig. 2**).

7. With steady movement, press the new stud all the way into the hub.
8. Make sure the stud is fully seated and that its head (flange) is not embedded into the hub. If the head of the stud is embedded into the hub, replace the hub.

WARNING

WARNING: Don't embed the wheel stud heads in the wheel hub. Wheel studs with heads embedded in the wheel hub will weaken the wheel hub flange. Weakness in the wheel hub can result in

Wheel Stud Replacement



A. "Right"

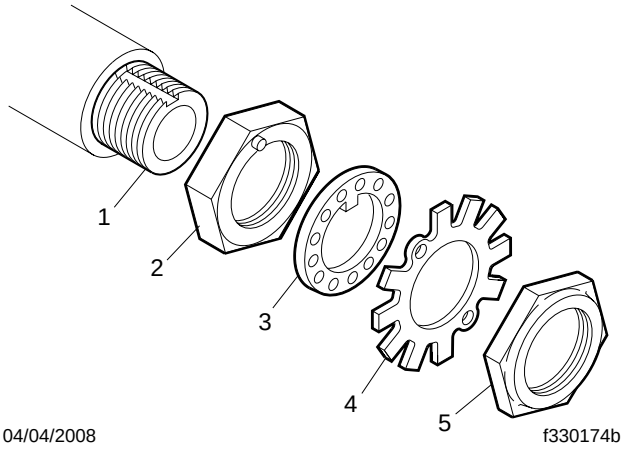
the loss of a wheel or loss of steering control, possibly resulting in personal injury.

9. Wipe off any grease on the wheel studs and wheel hub. Install wheel nuts on dry wheel studs only.
10. Install the wheel hub on the axle. For instructions, refer to **Subject 100**.

Four-Piece Wheel Bearing Lock System Removal, Installation, and Adjustment

General Information

ConMet PreSet hubs may use a four-piece wheel bearing lock system. See **Fig. 1**.



1. Axle Spindle
2. Adjusting Nut
3. Lockring
4. Bend-Type Locking Washer
5. Jam Nut

Fig. 1, Typical Four-Piece Wheel Bearing Lock Set

NOTE: For Meritor unitized wheel end installation and adjustment procedures, see **Subject 140**.

Removal

Once a four-piece wheel bearing lock set is removed, discard the bend-type locking washer, if installed. Inspect the adjusting nut, lockring, and jam nut for visible damage prior to reuse.

Installation

Instructions for installing a four-piece wheel bearing lock set for both PreSet and non-PreSet type bearings are provided in this subject. See the pertinent instructions for the type you are installing.

Using PreSet Bearings

1. Install the adjusting nut onto the axle spindle, and tighten it 300 lbf·ft (407 N·m). See **Fig. 1**.

NOTE: The gaps between holes in the lockring are spaced unevenly, so to fit the tab on the adjusting nut into one of the holes with minimal turning of the adjusting nut, gauge the distance on one side of the lockring, then the other, and choose the side that requires the adjusting nut to be advanced the least. Do not back off the nut.

2. Install the lockring (as described in the note above) and bend-type locking washer.
3. Install the jam nut, and tighten it 200 lbf·ft (271 N·m).
4. Bend the tabs on the locking washer at 6 o'clock and 12 o'clock to lock the jam nut in place. See **Fig. 2**.

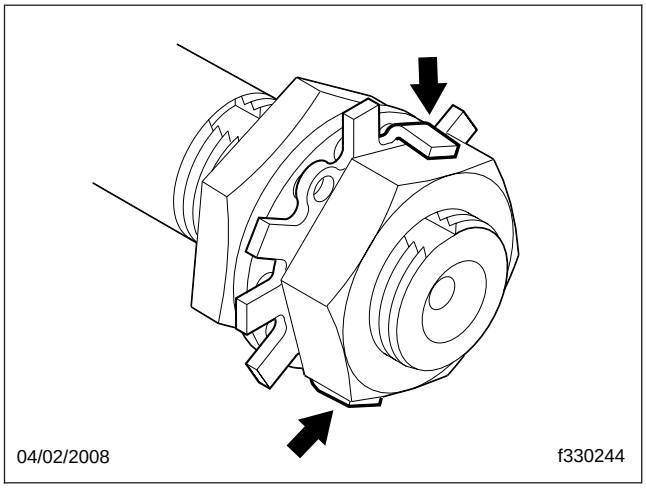


Fig. 2, Tabs Bent to Lock the Jam Nut

5. Rotate the hub in both directions. It should turn freely with no dragging or binding.

Using Non-PreSet Bearings

For ConMet PreSet hubs, when there is no bearing spacer installed and non-PreSet type bearings are being used, proper wheel bearing adjustment is critical to the performance of the bearings, wheel seals, and other related wheel end components.

1. Install the adjusting nut, as follows. See **Fig. 1**.
   - 1.1 Install the adjusting nut on the spindle, and tighten it finger-tight.
   - 1.2 While rotating the wheel hub assembly, tighten the adjusting nut 200 lbf·ft (271 N·m).

Four-Piece Wheel Bearing Lock System Removal, Installation, and Adjustment

1.3 Back off the adjusting nut one full turn.

1.4 Tighten the adjusting nut 50 lbf·ft (68 N·m) while rotating the wheel hub assembly.

1.5 Back off the adjusting nut one-quarter turn.

NOTE: The gaps between holes in the lockring are spaced unevenly, so to fit the tab on the adjusting nut into one of the holes with minimal turning of the adjusting nut, gauge the distance on one side of the lockring, then the other, and choose the side that requires the adjusting nut to be advanced the least. Do not back off the nut.

2. Install the lockring (as described in the note above) and bend-type locking washer.
3. Install the jam nut, and tighten it 200 to 300 lbf·ft (270 to 405 N·m).
4. Using a dial indicator, measure the end play as follows.

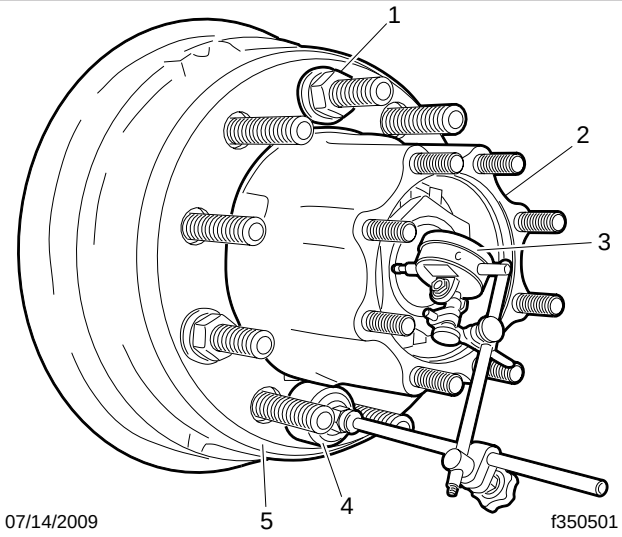
   IMPORTANT: Do not measure the wheel bearing end play with the wheel mounted on the hub; you cannot accurately measure or adjust bearing end play with the wheel mounted on the hub. Also, ensure that the brakes are not applied so that that drum and hub can move freely.

   4.1 On vehicles equipped with aluminum hubs, install an iron brake drum onto the hub to provide a ferrous surface for the magnetic base of the dial indicator. With flange nuts, secure the drum to the hub using the stud at the 12 o'clock position, followed by the studs at about the 4 o'clock and 8 o'clock positions. Ensure the nuts hold the drum securely; use washers if needed.

   4.2 Clean the spindle end; ensure it is free of debris and provides the smooth surface needed for the dial indicator to take an accurate measurement.

   4.3 Attach the magnetic base of a dial indicator to the drum (or, on vehicles equipped with iron hubs, the hub). See **Fig. 3**.

   4.4 Set the measuring end of the indicator against the spindle end as shown in **Fig. 4**. The indicator should be square with the end of the spindle.



NOTE: Assembly for rear axle shown.

5. Iron Brake Drum

Fig. 3, Dial Indicator Setup, Aluminum Hub with Iron Brake Drum

   IMPORTANT: Maintain continual pressure on the hub until you have taken both the inboard and outboard measurements. If you release the hub, an accurate measurement is not possible.

   4.5 To seat the bearings, grip the hub at the three o'clock and nine o'clock positions, and push inward while oscillating it approximately 45 degrees. Maintain pressure on the hub and note the measurement.

   NOTE: The end play measurements must be taken at the same point to prevent an uneven spindle end from skewing the results. As needed, mark the spot on the spindle where the inboard measurement was taken.

   4.6 Pull the hub and drum outward while oscillating it as before. Maintain pressure on the hub, and note the outboard extent of the end play. See **Fig. 5**.

Fig. 5, Pulling the Hub Outward to Measure End Play

4.7 Find the end play by noting the difference between the two readings.

⚠ WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use a dial indicator to measure the end play.

5. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm).** If the end play is not within this range, adjust the end play as follows.

   5.1 Remove the jam nut and locking device, and back off or tighten the inner adjusting nut.

   5.2 Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), turn the adjusting nut again.

   5.3 Measure the end play.

   If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), repeat the adjustment procedure until the correct end play is achieved.

   IMPORTANT: The correct end play **must** be achieved before completing the hub assembly installation procedure.

6. Once the end play is between 0.001 and 0.005 inch (0.03 and 0.13 mm), bend two tabs on the locking washer at 6 o'clock and 12 o'clock to lock the jam nut in place. See **Fig. 2**.

7. Rotate the hub in both directions. It should turn freely with no dragging or binding.

Axilok Spindle Nut Removal, Installation, and Adjustment

General Information

Axilok® spindle nuts are used on ConMet PreSet hubs. See **Fig. 1** and **Fig. 2**. These nuts can be damaged if they are not removed or installed correctly. Use the following guidelines when removing and installing Axilok retaining nuts.

- Use only the correct size, *six-point* socket to remove or install Axilok spindle nuts. Do not use a worn or loose-fitting socket. **Do not use a 12-point socket.**
- Do not use hammers, chisels, pliers, wrenches, or power tools to remove or install Axilok nuts.
- Do not use an Axilok nut if the locking clips are damaged or missing, or if the retainer cage tab or D-flat is damaged or missing.
- Never try to repair a damaged Axilok nut; always replace it with a new one.
- Always start an Axilok installation by hand. A good-fitting six-point socket will completely disengage the nut's locking clips, allowing it to spin freely by hand. See **Fig. 3**. Use an accurately calibrated torque wrench to tighten the nut to its final torque value.

Installation

Instructions for installing an Axilok nut for both PreSet and non-PreSet type bearings are provided in this subject. See the pertinent instructions for the type you are installing.

Using PreSet Bearings

⚠ WARNING

Follow the guidelines at the beginning of this subject when installing an Axilok nut. Axilok retaining nuts secure the hub assemblies on the axle. If the Axilok nut is not correctly installed, the hub could separate from the axle, resulting in severe personal injury or death.

1. Apply a few drops of oil through one of the holes in the Axilok retainer cage to reduce friction between the retainer cage and nut.
2. By hand, install the Axilok nut onto the axle spindle. See **Fig. 1** and **Fig. 2**.

3. Tighten the retaining nut 250 lbf·ft (339 N·m). The nut should lock in place when you remove the wrench. If it does not, advance the nut until it does. **Do not back it off**.
4. Ensure that both locking clips are present and engaged in the retainer cage. See **Fig. 3**. If the locking clips are not engaged, the nut is not locked in position and can rotate freely.

Using Non-PreSet Bearings

For ConMet PreSet hubs, when there is no bearing spacer installed and non-PreSet type bearings are being used, proper wheel bearing adjustment is critical to the performance of the bearings, wheel seals, and other related wheel end components.

⚠ WARNING

1. Apply a few drops of oil through one of the holes in the Axilok retainer cage to reduce friction between the retainer cage and nut. See **Fig. 1** and **Fig. 2**.
2. Install the Axilok nut and adjust the wheel bearings, as follows.
   - 2.1 By hand, install the Axilok nut onto the axle spindle and turn it against the bearing while spinning the hub.
   - 2.2 Tighten the nut 90 to 110 lbf·ft (122 to 149 N·m) while spinning the hub in both directions.
   - 2.3 Loosen the nut to zero torque, and spin the hub a few turns.
   - 2.4 Tighten the nut 50 lbf·ft (68 N·m) while spinning the hub in both directions. Back off the nut one-eighth to one-sixth turn.

Axilok Spindle Nut Removal, Installation, and Adjustment

2.5 Remove the wrench from the nut, and verify whether both locking clips are present and engaged in the retainer cage. See **Fig. 3**. If the locking clips are not engaged, advance the Axilok until they are.

3. Using a dial indicator, measure the end play as follows.

IMPORTANT: Do not measure the wheel bearing end play with the wheel mounted on the hub; you cannot accurately measure or adjust bearing end play with the wheel mounted on the hub. Also, ensure that the brakes are not applied so that that drum and hub can move freely.

3.1 On vehicles equipped with aluminum hubs, install an iron brake drum onto the hub to provide a ferrous surface for the magnetic base of the dial indicator. With flange nuts, secure the drum to the hub using the stud at the 12 o'clock position, followed by the studs at about the 4 o'clock and 8 o'clock positions. Ensure the nuts hold the drum securely; use washers if needed.

3.2 Clean the spindle end; ensure it is free of debris and provides the smooth surface needed for the dial indicator to take an accurate measurement.

3.3 Attach the magnetic base of a dial indicator to the drum (or, on vehicles equipped with iron hubs, the hub). See **Fig. 4**.

3.4 Set the measuring end of the indicator against the spindle end as shown in **Fig. 5**. The indicator should be square with the end of the spindle.

IMPORTANT: Maintain continual pressure on the hub until you have taken both the inboard and outboard measurements. If you release the hub, an accurate measurement is not possible.

3.5 To seat the bearings, grip the hub at the three o'clock and nine o'clock positions, and push inward while oscillating it approximately 45 degrees. Maintain pressure on the hub and note the measurement.

3.7 Find the end play by noting the difference between the two readings.

⚠ WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use a dial indicator to measure the end play.

4. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm)**. If it is not within this range, remove the Axilok nut, and repeat the tightening sequence as described earlier in this procedure. Once the end play is correct, continue with your service procedure.

Meritor Unitized Wheel-End Installation and Adjustment

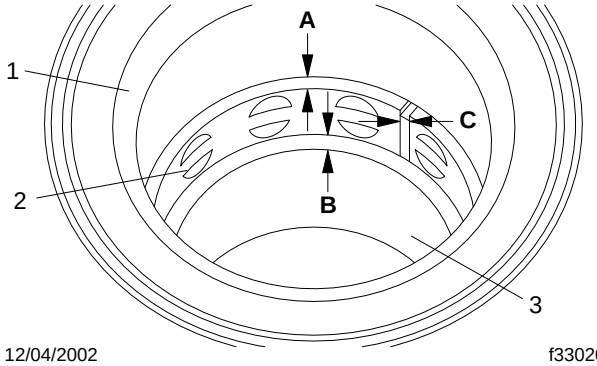
IMPORTANT: The following information is based on a Meritor technical bulletin for unitized wheel ends, and has been formatted for this Freightliner workshop manual. Contact Meritor if you wish to refer to the original technical bulletin.

Installation

WARNING

Do not service the bearings on Meritor unitized wheel ends. Disassembling the wheel end (hub) and bearings could contaminate the bearing lubricant, possibly damaging the bearings. This could result in the eventual loss of the wheel end (hub), which could cause an accident resulting in serious personal injury and property damage.

1. If not already done, clean the axle spindle and inner surfaces of the wheel bearings with a clean, lint-free cloth.
2. If installing a new wheel end (hub), inspect it as follows:
   - The inner clip ring is present and is aligned correctly between the inner and outer bearings. See **Fig. 1**.



12/04/2002 f330208

A. This gap must be equal to the "B" gap.
B. This gap must be equal to the "A" gap.
C. This gap must not exceed 1/4-inch (6 mm).

3. Outer Bearing

Fig. 1, Checking the Inner Clip Ring

   - The gaps between the inner and outer bearings and the clip ring are equal. See **Fig. 1**. If necessary, adjust by hand.
   - The bearing face is clean, with no seal coating, dirt, or rust
   - The inboard or outboard seals are undamaged and the bearings are seated correctly. See **Fig. 2** and **Fig. 3**.
   - The tone wheel teeth are all present and undamaged. See **Fig. 3**.

WARNING

Do not apply anti-seize compound to the axle spindle threads. This could result in the axle nuts losing their clamping ability, which could cause the loss of the hub and wheel assembly, which could cause an accident resulting in serious personal injury and property damage.

Meritor Unitized Wheel-End Installation and Adjustment

3. Apply anti-seize compound to the new O-ring, spindle, and inner surfaces of the wheel bearings.

   Use Meritor compound part number 2297-C-8297 or Dow Corning Molykote® D.

   If any of the compound gets on the axle spindle threads, wipe it off.

4. Install the O-ring onto the axle spindle.
5. Install the wheel end (hub) straight onto the axle spindle, being careful not to damage the spindle threads.
6. With the wheel end (hub) mounted on the axle spindle, install the inner D-ring, then the inner locknut. Tighten 600 lbf·ft (813 N·m) while rotating the wheel end (hub) at least five times.

NOTE: The inner and outer locknuts are identical, but their torque values are different.

7. Install the tabbed washer.
8. Bend one of the tabs over the flat of the inner locknut.
9. Install the outer locknut and tighten it 250 lbf·ft (339 N·m).
10. Bend an opposing tab of the tabbed washer over a flat of the outer locknut.
11. Install the brake drum. If necessary, adjust the slack adjuster. For instructions, see **Group 42** of this manual.
12. Install the wheel and tire assembly. Hand tighten the wheel nuts.
13. Raise the vehicle, remove the jackstands, then lower the vehicle.
14. Tighten the wheel nuts 500 lbf·ft (678 N·m).

NOTE: Plastic and metal hub caps are interchangeable; however, the installation procedure is different for each type.

15. If installing a metal hub cap, go to the next step.

    If installing a plastic hub cap, do the following:

    15.1 Using a wire brush, remove any grease or mud from the inner threads of the hub. Wipe the threads with a clean shop cloth.

    15.2 Apply a continuous 1/8-inch (3 mm) bead of RTV silicone sealant to the outside first thread of the hub cap. Apply the sealant around the entire circumference.

    IMPORTANT: Use only the following RTV sealants on the hub cap:

    - Meritor part number 2297-Z-7098
    - Three Bond®
    - Loctite® Ultra Grey Adhesive Sealant 18581

    15.3 Install the hub cap by hand until it is seated.

    IMPORTANT: Disregard the torque value embossed on the hub cap.

    15.4 Using a torque wrench, tighten the hub cap 75 lbf·ft (102 N·m).

    If you cannot tighten the hub cap to the correct torque value, or if it makes a popping sound while being tightened, replace it with a new one.

16. If installing a metal hub cap, do the following:

    16.1 Using a wire brush, clean the inner threads of the hub and the hub cap threads. Wipe the inner threads of the hub with a clean shop cloth.

    16.2 Apply Loctite® 17430 (Meritor part number 2297-D-7076) gasket sealant to the hub cap threads.

    16.3 Install the hub cap by hand until it is seated.

    16.4 Using a torque wrench, tighten the hub cap 350 lbf·ft (475 N·m).

    IMPORTANT: If you cannot tighten the hub cap to the correct torque value, or if it makes a popping sound while being tightened, replace it with a new one.

17. Remove the chocks from the tires.

Meritor Unitized Wheel-End End Play Checking

End Play Checking

IMPORTANT: The following information is based on a Meritor technical bulletin for unitized wheel ends, and has been formatted for this Freightliner workshop manual. Contact Meritor if you wish to refer to the original technical bulletin.

⚠ WARNING

Do not service the bearings on Meritor unitized wheel ends. Disassembling the wheel end and bearings could contaminate the bearing lubricant, possibly damaging the bearings. This could result in the eventual loss of the wheel end (hub), which could cause an accident resulting in serious personal injury and property damage.

1. Park the vehicle on a level surface, set the parking brakes, shut down the engine, and chock the rear tires.
2. Raise the vehicle until the front tires are clear of the ground. Support the vehicle with safety stands.

⚠ WARNING

Never work under a vehicle that is supported only by a jack. Jacks can slip, causing the vehicle to fall. This could result in serious injury or death.

3. Rotate the tire and wheel assembly. It should rotate smoothly and without any noise.
4. Remove the tire and wheel assembly.
5. Remove the brake drum. If needed, back off the slack adjuster.
6. Remove the hub cap.
7. Attach the magnetic base of a dial indicator to the end of the axle spindle.
8. Touch the dial indicator stem to the surface of the wheel end (hub), making sure the stem is perpendicular to the surface of the wheel end.
9. Set the dial indicator to zero.
10. Without rotating the wheel end, grasp it at the 3 and 9 o'clock positions, and push it straight in. Note the reading on the dial indicator.

    Pull the wheel end straight out. Note the reading on the dial indicator.

    The difference between the two readings is the end play.
11. If the end play is less than 0.003-inch (0.08 mm), go to the step for installing the hub cap.

    If the end play is 0.003-inch (0.08 mm) or greater, go to the next step.
12. Remove the outer locknut and tabbed washer from the axle spindle.
13. Loosen, but don't remove, the inner locknut.
14. While rotating the wheel end a minimum of five rotations, tighten the inner locknut 600 lbf·ft (813 N·m).
15. Install the tabbed washer and the outer locknut. Tighten 250 lbf·ft (339 N·m).
16. Repeat the procedure for checking the end play.
17. If the end play is greater than 0.003-inch (0.08 mm) but less than 0.006-inch (0.15 mm), the end play is correct. Go to the next step.

    If the end play is 0.006-inch (0.15 mm) or greater, replace the entire wheel end assembly. For instructions, see **Subject 140**.
18. Check the rotation of the wheel end. If it doesn't rotate smoothly and without noise, replace it. For instructions, see **Subject 140**.

    If the wheel end rotates smoothly and without noise, go to the next step.
19. Bend an opposing tab of the tabbed washer over a flat of the inner locknut. Do the same for the outer locknut. Make sure that a tab of the washer is bent over a flat of both the inner and outer locknuts.
20. Install the wheel and tire assembly. Hand tighten the wheel nuts.
21. Raise the vehicle, remove the jackstands, then lower the vehicle.
22. Tighten the wheel nuts 500 lbf·ft (678 N·m).
23. Install the hub cap.

    If installing a metal hub cap, go to the next step.

    If installing a plastic hub cap, do the following:

Meritor Unitized Wheel-End End Play Checking

23.1 Using a wire brush, remove any grease or mud from the inner threads of the hub. Wipe the threads with a clean shop cloth.

23.2 Apply a continuous 1/8-inch (3 mm) bead of RTV silicone sealant to the outside first thread of the hub cap. Apply the sealant around the entire circumference.

IMPORTANT: Use only the following RTV sealants on the hub cap:

- Meritor part number 2297-Z-7098
- Three Bond®
- Loctite® Ultra Grey Adhesive Sealant 18581

23.3 Install the hub cap by hand until it is seated.

IMPORTANT: Disregard the torque value embossed on the hub cap.

23.4 Using a torque wrench, tighten the hub cap 75 lbf·ft (102 N·m).

If you cannot tighten the hub cap to the correct torque value, or if it makes a popping sound while being tightened, replace it with a new one.

24. If installing a metal hub cap, do the following:

24.1 Using a wire brush, clean the inner threads of the hub and the hub cap threads

24.2 Apply Loctite® 17430 (Meritor part number 2297-D-7076) gasket sealant to the hub cap threads.

24.3 Install the hub cap by hand until it is seated.

24.4 Using a torque wrench, tighten the hub cap 350 lbf·ft (475 N·m).

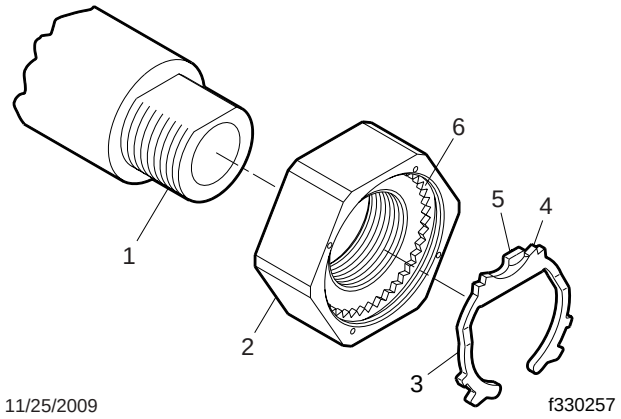
IMPORTANT: If you cannot tighten the hub cap to the correct torque value, or if it makes a popping sound while being tightened, replace it with a new one.

25. Remove the chocks from the tires.

Pro-Torq Spindle Nut Removal, Installation, and Adjustment

General Information

Pro-Torq® spindle nuts may be used on ConMet Pre-Set hubs. See **Fig. 1** and **Fig. 2**.



1. Axle Spindle
2. Pro-Torq Nut
3. Keeper Arm
4. Mating Teeth, Keeper
5. Keeper Tab
6. Mating Teeth, Nut

Fig. 1, Pro-Torq Spindle Nut and Keeper

Each time the Pro-Torq nut assembly is removed for maintenance purposes, replacing the "keeper" is recommended.

Removal

WARNING

Do not place the nut on the spindle or tighten or loosen the nut on the spindle while the keeper is locked inside the nut. Doing so may damage the spindle threads and deform the keeper, and allow the nut to unthread during operation. Failure to follow this instruction could cause the hub to separate from the axle, resulting in severe personal injury or death.

1. Insert the blade of a flathead screwdriver (or similar tool) in the slot of one of the keeper arms; see **Fig. 3**. Ensuring that the tool contacts the keeper and not the teeth of the nut, turn the tool slightly and carefully pry the arm from the undercut groove of the nut.

2. Repeat at the other arm, and remove the keeper from the nut.
3. Remove the Pro-Torq nut.

Pro-Torq Spindle Nut Removal, Installation, and Adjustment

Installation

The following procedure applies to Pro-Torq steer axle nut 448-4836. The part number is stamped on the nut.

⚠ WARNING

Do not place the nut on the spindle or tighten or loosen the nut on the spindle while the keeper is locked inside the nut. Doing so may damage the spindle threads and deform the keeper, and allow the nut to unthread during operation. Failure to follow this instruction could cause the hub to separate from the axle, resulting in severe personal injury or death.

Instructions for installing a Pro-Torq spindle nut for both PreSet and non-PreSet type bearings are provided in this subject. See the instructions pertaining to the bearing type used with the hub you are securing.

Using PreSet Bearings

1. Ensure the keeper is removed from the nut.
2. Install the Pro-Torq spindle nut, and tighten it 250 lbf·ft (339 N·m). **Do not back it off**.
3. Install the keeper.

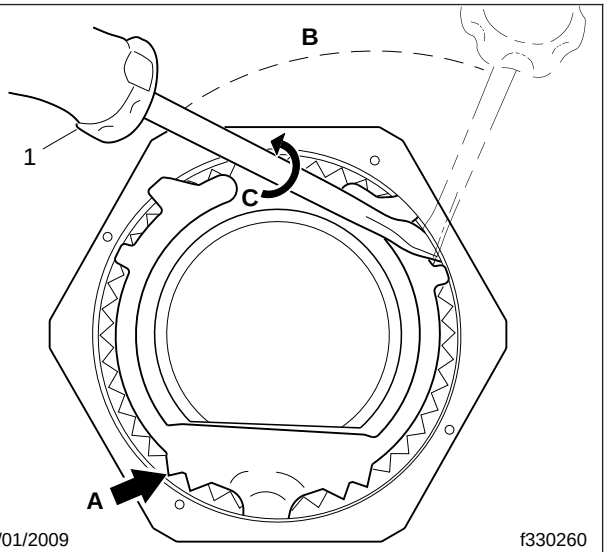
   3.1 With the correct side of the keeper facing out, insert the keeper tab in the undercut groove of the Pro-Torq nut, and engage the mating teeth.

   IMPORTANT: If the keeper cannot be engaged, advance the nut until it can be. Do not back off the nut.

   3.2 Use a flathead screwdriver to carefully compress and guide each arm past the lip and into the undercut groove of the nut as shown in **Fig. 4**. To secure the keeper it may be necessary to nudge the arms into the groove.

⚠ WARNING

Failure to secure the keeper and lock the Pro-Torq nut could cause the wheel assembly to come off the vehicle, resulting in severe personal injury or death.



A. Engage the mating teeth.
B. Compress the arm.
C. Turn the screwdriver to seat the keeper in the groove.

1. Flathead Screwdriver

Fig. 4, Installing the Keeper

4. Inspect the installation; ensure the keeper is locked in the undercut groove of the nut.

Using Non-PreSet Bearings

For ConMet PreSet hubs, when there is no bearing spacer installed and non-PreSet type bearings are being used, proper wheel bearing adjustment is critical to the performance of the bearings, wheel seals, and other related wheel end components.

1. Ensure the keeper is removed from the nut.
2. Seat the bearings.

   2.1 Using a torque wrench, tighten the nut 200 lbf·ft (270 N·m). Spin the hub at least one full rotation.

   NOTE: Torque is lost when the hub is spun.

   2.2 Tighten the nut 200 lbf·ft (270 N·m). Spin the hub at least one full rotation.

   2.3 Tighten the nut 200 lbf·ft (270 N·m), but *do not spin the hub.*

3. Loosen the nut to zero torque. *Do not spin the hub.*

Pro-Torq Spindle Nut Removal, Installation, and Adjustment

4. Adjust the bearing.

   4.1 Using a torque wrench, tighten the nut 100 lbf·ft (136 N·m). Spin the hub at least one full rotation.

   NOTE: Torque is lost when the hub is spun.

   4.2 Tighten the nut 100 lbf·ft (136 N·m). Spin the hub at least one full rotation.

   4.3 Tighten the nut 100 lbf·ft (136 N·m).

   4.4 Back off the nut one-quarter turn.

IMPORTANT: If the keeper cannot be engaged, advance the nut until it can be. Do not back off the nut.

5. Install the keeper.

   5.1 With the correct side of the keeper facing out, insert the keeper tab in the undercut groove of the Pro-Torq nut, and engage the mating teeth.

   5.2 Use a flathead screwdriver to carefully compress and guide each arm past the lip and into the undercut groove of the nut as shown in **Fig. 4**. To secure the keeper it may be necessary to nudge the arms into the groove.

⚠ WARNING

Failure to secure the keeper and lock the Pro-Torq nut could cause the wheel assembly to come off the vehicle, resulting in severe personal injury or death.

6. Inspect the installation; ensure the keeper is locked in the undercut groove of the nut.

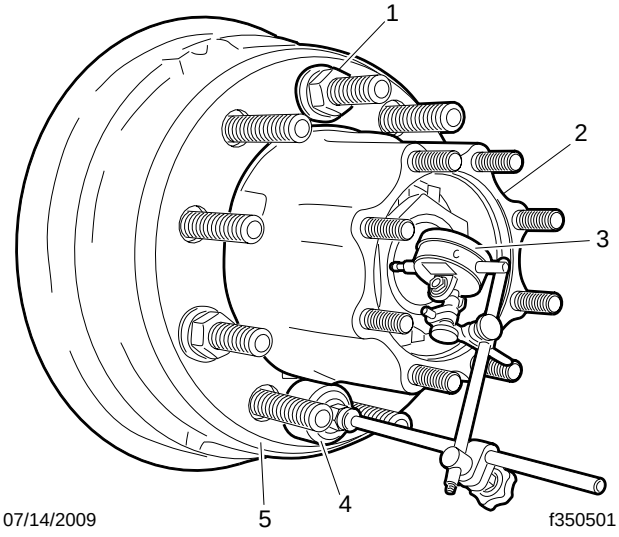
7. Using a dial indicator, measure the end play as follows.

   IMPORTANT: Do not measure the wheel bearing end play with the wheel mounted on the hub; you cannot accurately measure or adjust bearing end play with the wheel mounted on the hub. Also, ensure that the brakes are not applied so that that drum and hub can move freely.

   7.1 On vehicles equipped with aluminum hubs, install an iron brake drum onto the hub to provide a ferrous surface for the magnetic base of the dial indicator. With flange nuts, secure the drum to the hub using the stud at the 12 o'clock position, followed by the studs at about the 4 o'clock and 8 o'clock positions. Ensure the nuts hold the drum securely; use washers if needed.

   7.2 Clean the spindle end; ensure it is free of debris and provides the smooth surface needed for the dial indicator to take an accurate measurement.

   7.3 Attach the magnetic base of a dial indicator to the drum (or, on vehicles equipped with iron hubs, the hub). See **Fig. 5**.



NOTE: Assembly for rear axle shown.

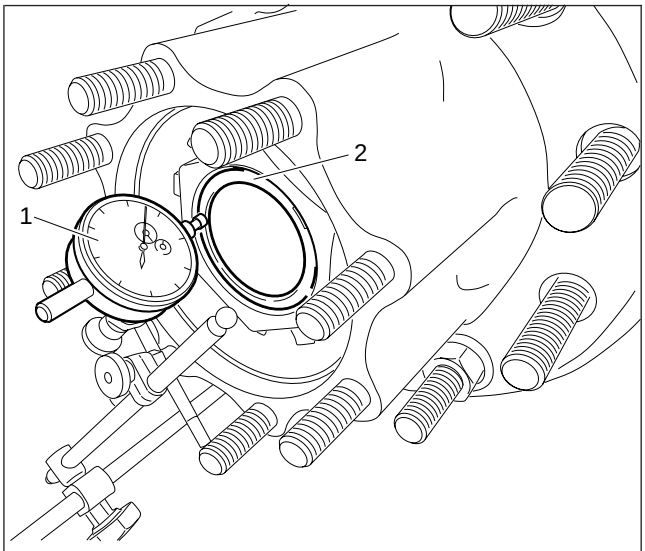
1. Flange Nut
2. Aluminum Hub
3. Dial Indicator
4. Magnetic Base
5. Iron Brake Drum

Fig. 5, Dial Indicator Setup, Aluminum Hub with Iron Brake Drum

   7.4 Set the measuring end of the indicator against the spindle end as shown in **Fig. 6**. The indicator should be square with the end of the spindle.

   IMPORTANT: Maintain continual pressure on the hub until you have taken both the inboard and outboard measurements. If you release the hub, an accurate measurement is not possible.

Pro-Torq Spindle Nut Removal, Installation, and Adjustment



The indicator should be square with the end of the spindle.

NOTE: Assembly for rear axle shown.

1. Dial Indicator
2. Spindle End

Fig. 6, Indicator Square with the Spindle

7.5 To seat the bearings, grip the hub at the three o'clock and nine o'clock positions, and push inward while oscillating it approximately 45 degrees. Maintain pressure on the hub and note the measurement.

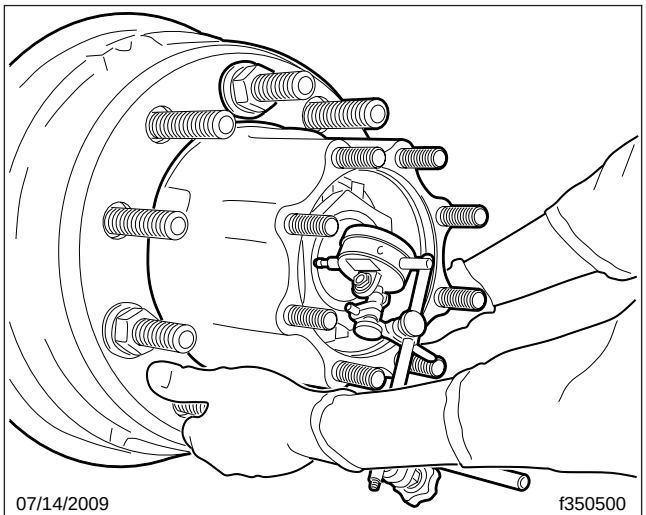
NOTE: The end play measurements must be taken at the same point to prevent an uneven spindle end from skewing the results. As needed, mark the spot on the spindle where the inboard measurement was taken.

7.6 Pull the hub and drum outward while oscillating it as before. Maintain pressure on the hub, and note the outboard extent of the end play. See **Fig. 7**.

7.7 Find the end play by noting the difference between the two readings.

⚠ WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, bearing life will diminish and the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use a dial indicator to measure the end play.



NOTE: Assembly for rear axle shown.

Fig. 7, Pulling the Hub Outward to Measure End Play

8. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm)**. If it is not within this range, remove the Pro-Torq nut, and repeat the tightening sequence as described in previous steps. Once the end play is correct, remove the iron brake drum if installed, and continue your service procedure.

If either the lateral or radial runout of the hub is beyond acceptable limits, replace the hub. For instructions, see **Subject 100** in this section.

Measurements

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

2. Remove the wheel and tire assembly. See **Group 40** for instructions.
3. For drum brakes, remove the brake drum. See **Subject 105** for instructions.
4. Clean the hub surfaces where the measurements will be taken—see **Fig. 1** and **Fig. 2**.
5. To measure lateral runout, set up a dial indicator as shown in **Fig. 1**, then turn the hub one revolution and note the highest and lowest measurements.

   For ConMet hubs, the acceptable lateral runout is 0.008 inch (0.2 mm); for other hubs, see the hub OEM for the acceptable lateral runout specification.
6. To measure radial runout, set up a dial indicator as shown in **Fig. 2**, then turn the hub one revolution and note the highest and lowest measurements.

   For ConMet hubs, the acceptable radial runout is 0.008 inch (0.2 mm); for other hubs, see the hub OEM for the acceptable radial runout specification.

One or more wheels or brake drums are out-of-balance.	Balance the wheels. Check for eccentric brake drums; correct or replace as needed.
The wheel toe-in in not correct.	Adjust the wheel toe-in.
The brakes are not adjusted evenly.	Adjust the brakes on all axles. Also, check the operation of the slack adjusters.
The front axle wheel bearings are worn or were not adjusted correctly.	Check the bearings for wear or other damage; replace them if needed.
The camber angle is not within specifications.	Check the front wheel camber angle. If not correct, find and replace the damaged axle component.

General Information

Wheel oil seals (also called "oil bath seals" or "hub seals") work as a dam to keep oil in the hub cavity so that it constantly "bathes" the wheel bearings. The seals also protect the wheel bearings by keeping dirt, dust, and water out of the hub.

The oil seal fits between the hub bore and the axle spindle (**See Fig. 1**), and the sealing element either turns with the wheel (*hub-mounted seals*) and seals against the axle spindle, or the sealing element stays stationary with the axle spindle (*spindle-mounted seals*) and seals against the turning hub.

2. Axle Spindle
3. Wheel Hub Bore

Fig. 1, Spindle-Mounted Wheel Oil Seal, Stemco Seal Shown

Until the late 1950's, truck wheel bearings were packed in grease. To retain this type of lubricant, the axle oil seal was pressed into the hub bore and turned with the wheel. Since the late 1950's, truck wheel bearings have been bathed in oil.

But oil bath lubrication created a problem.

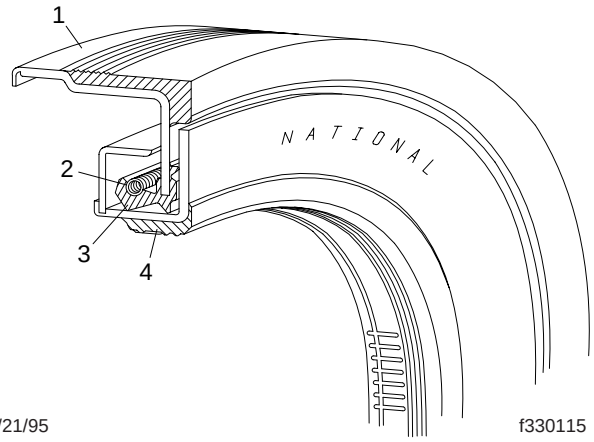
With hub-mounted seals, the turning wheel created enough centrifugal force to pull the sealing element off the axle spindle. This broke the seal, and oil escaped. To keep lube oil inside the hub cavity, the inner edge, or sealing lip, of the seal had to be strong and tight enough that the centrifugal force of the turning wheel would not pull it away from the axle spindle. However, these new, stronger, tighter seals would wear a groove into the spindle sealing surface.

To prevent damage to the spindle, wear sleeves (also called "axle rings") are pressed onto the spindle to absorb the wear from the sealing lip. Later, these wear sleeves were designed to also deflect dirt. These sleeves are called "deflector rings."

Some seal designs avoid the problem of centrifugal force by having the seal pressed onto the axle spindle. This way, centrifugal force drives the sealing element out toward the hub to create the seal.

Most wheel oil seals consist of four basic parts (**Fig. 2**):

- The outside edge (also called the outer "cup" or "case")
- The inside edge (also called the inner "cup" or "case")
- The sealing element
- The garter spring



03/21/95 f330115

1. Outside Edge
2. Garter Spring
3. Sealing Element
4. Inside Edge

Fig. 2, Wheel Oil Seal Parts, National Oil Seal, Advanced Design

The outside edge is usually metal coated with rubber or another sealing agent so that it grips the hub bore tightly enough to prevent oil escaping between the outer edge of the seal and the hub bore.

General Information

The inside edge is usually metal or rubber with a metal ring within it to prevent the sealing element from wearing a groove in the axle spindle.

The sealing element is usually molded rubber, leather, or a synthetic such as nitrile or silicone. The element is molded into lips which will seal against the axle spindle or against the outside or inside edge described above. The innermost lip, called the "primary lip," keeps the oil inside the hub cavity. The outermost lip, called the "secondary lip," keeps dirt out of the hub cavity.

The garter spring is a coiled wire spring with its ends connected to make a loop. On hub-mounted seals, the spring runs around the outside of the sealing element to press the element inwards against the sealing surface. On spindle-mounted seals, the spring runs around the inside of the sealing element to press the element outward against the sealing surface.

Freightliner uses four brands of axle oil seals:

- Chicago Rawhide (Scotseal® and Scotseal Plus®)
- Eaton (Outrunner™)
- National (5-Star Gold® and Advanced Design®)
- Stemco (Guardian® and SS4®)

Chicago Rawhide (See Fig. 3)

The Chicago Rawhide Scotseal is a unitized, one-piece design consisting of a sealing element (packing) that is assembled between metal outer and inner cups. The sealing element consists of three sealing lips; a spring-loaded primary sealing lip that is factory pre-lubed and two dirt exclusion lips. The seal is press fit into the hub bore using Scotseal service installation tools. *Do not install the Scotseal directly onto the axle spindle.*

Although you install the Scotseal into the hub bore, the seal's element grips the axle spindle tightly enough that the sealing element stays stationary with the spindle and seals against the outer cup which turns with the hub.

The Chicago Rawhide Scotseal maintains a metal-to-metal contact between the outer cup and the hub bore surface as well as a metal-to-metal contact between the sealing element inside edge and the axle spindle.

Eaton (See Fig. 4)

The Eaton Outrunner has a rubber-coated outside edge and is installed in the hub bore using Eaton installation tools.

National (See Fig. 2 and Fig. 5)

National wheel oil seals are hub-mounted, with a rubber-coated outside edge that grips inside the hub bore and also holds the sealing element. The element turns with the hub and seals against the inside edge of the seal which grips the axle spindle and acts as a wear sleeve. The shield protects the sealing element, and holds the two parts (the outside and inside edges) together.

The 5-Star Gold seal features a Teflon® lay-down sealing lip compatible with any combination of mineral and/or synthetic gear lubricants and/or greases.

Stemco (See Fig. 6 and Fig. 7)

The Stemco wheel oil seals are spindle-mounted, with a rubber-coated outside edge that grips inside the hub bore and also holds the sealing element.

Although you install the Stemco seal onto the axle spindle, the outside edge grips the hub bore tight enough that the sealing element turns with the hub and seals against the inside edge which grips the axle spindle and acts as a wear sleeve.

Seal Replacement, Chicago Rawhide

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

NOTE: This procedure applies to the Chicago Rawhide Scotseal®.

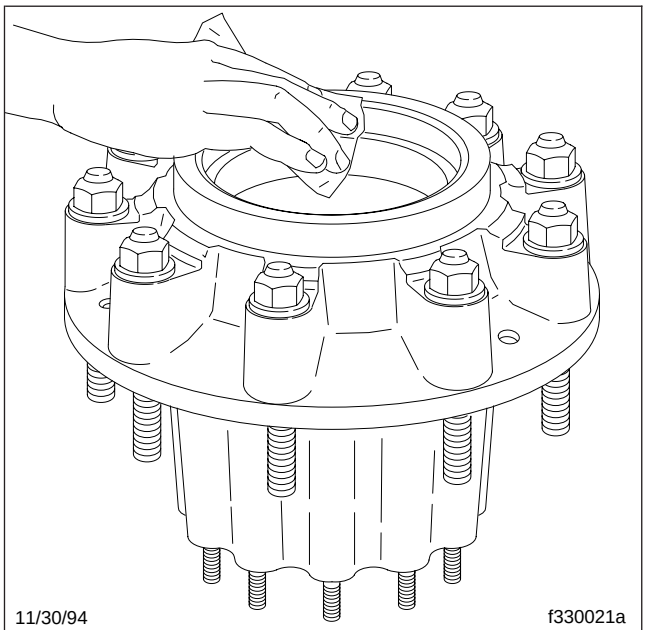
1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 33.01**.
2. Remove the inner wheel bearing assembly from the axle. Handling the bearings with clean dry hands, wrap the bearings in clean oil-proof paper or lint-free cloths. Occasionally, the inner wheel bearing cone assembly will remain in the hub after the hub is removed from the axle. In those cases, place a protective cushion to catch the bearing assembly. Using a hardwood drift and a light hammer, gently tap the bearing and seal out of the inner wheel bearing cup.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity. See **Fig. 1** and **Fig. 2**.
4. Remove all burrs from the shoulder and the seal bore with an emery cloth or a file. Clean any metal filings from the components.

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

5. Inspect the bearings and hub components for wear or damage. Replace any worn or damaged components as necessary.
6. Coat the wheel bearing cones with oil.
7. Install the inner wheel bearing cone in the inner wheel bearing cup.



NOTE: Rear hub shown.

Fig. 1, Clean the Hub

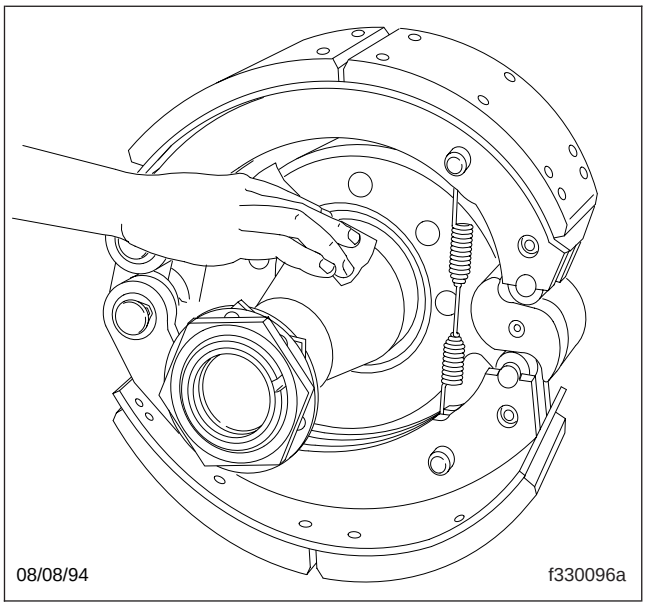


Fig. 2, Clean the Spindle

8. Seat the small outside edge of the seal in the recess of the tool adapter. See **Fig. 3**. The correct adapter is identified on the box.

Seal Replacement, Chicago Rawhide

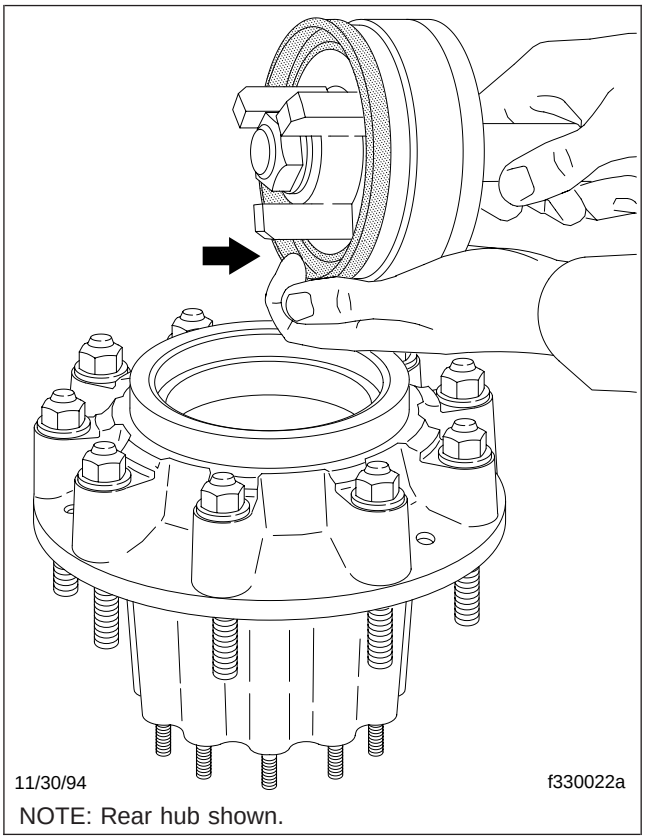

Fig. 3, Place the Seal on the Installation Tool

9. Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 4**. The plug prevents cocking of the seal in the bore.
10. Hold the tool handle firmly, and strike it until the sound of the impact changes as the seal bottoms out. See **Fig. 5**. Hold the tool firmly to avoid bounce or unseating of the seal from the adapter.
11. After the seal is bottomed in the bore, check for freedom of movement by manually moving the interior rubber part of the seal back and forth. A slight movement indicates a damage-free installation.
12. Install the wheel hub on the axle, and adjust the wheel bearings. For instructions, see **Section 33.01**.

IMPORTANT: When starting the wheel on the spindle, center the hub carefully to avoid seal damage from the leading edge of the spindle.

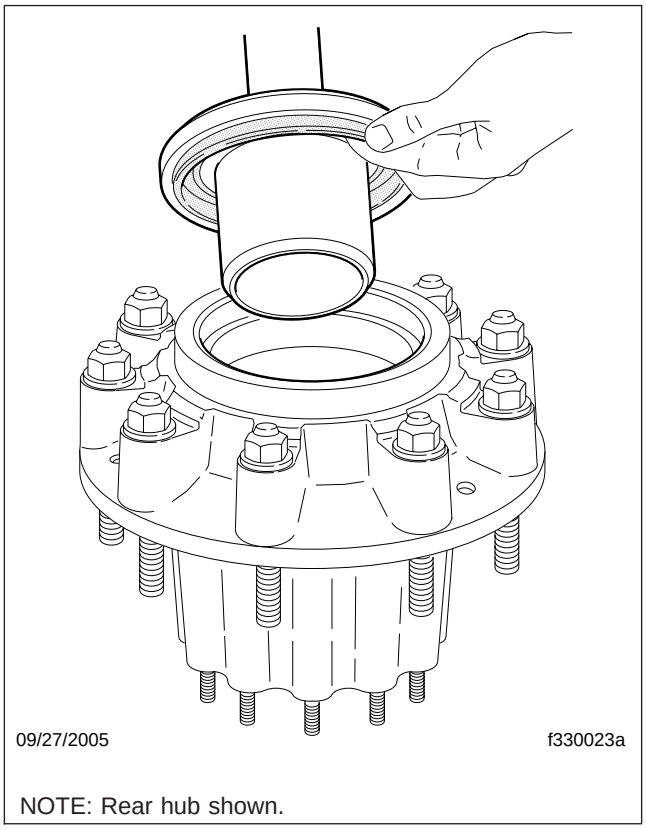

Fig. 4, Insert the Tool in the Hub Bore

13. Place the hubcap and a new gasket in position. Install the capscrews. Tighten the capscrews 15 lbf·in (20 N·m).
14. Fill the hub with oil to the level shown on the hubcap. See **Fig. 6**. Do not overfill.
15. Spin the wheel and check the oil level.
16. Adjust the brake shoe-to-drum clearance. For instructions, see **Group 42**.

Seal Replacement, Dana Spicer® Outrunner™

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

NOTE: This procedure applies to the Dana Spicer Outrunner seal.

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 33.01**.
2. Remove the inner wheel bearing assembly from the axle. Handling the bearings with clean dry hands, wrap the bearings in clean oil-proof paper or lint-free cloths. Occasionally, the inner wheel bearing cone assembly will remain in the hub after the hub is removed from the axle. In those cases, place a protective cushion to catch the bearing assembly. Using a hardwood drift and a light hammer, gently tap the bearing and seal out of the inner wheel bearing cup.

⚠ CAUTION

Never use a sharp chisel to cut through an axle ring (wear sleeve). A sharp chisel could damage the spindle or shoulder.

3. Remove the steel axle ring (wear sleeve) by striking the ring surface several times with a ball-peen hammer. See **Fig. 1**. Remove the stretched axle ring from the spindle.
4. Clean and inspect the bearings, the spindle, spindle threads, seal bore, and the hub cavity.

   IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

   4.1 Inspect the inner hub bore. Remove dirt and contaminants from all recesses and corners. Smooth any sharp edges with emery cloth, and fill in any grooves with filler. See **Fig. 2**.

   4.2 Wipe the hub area with a clean shop cloth.

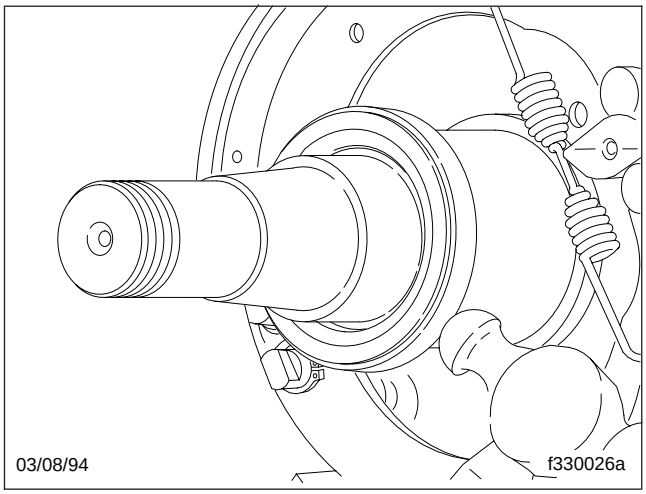

Fig. 1, Removing the Axle Ring

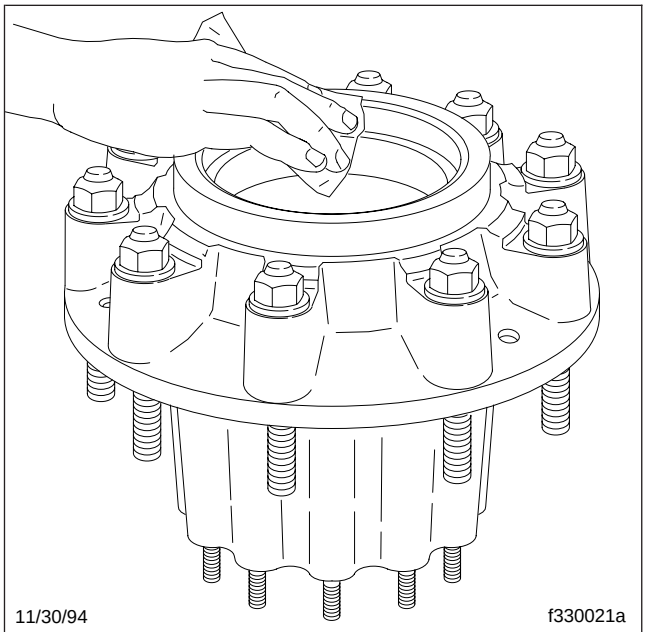

NOTE: Rear hub shown.

Fig. 2, Clean and Inspect the Hub Bore

   4.3 After removing the wear sleeve, inspect the spindle. Remove any sharp edges and burrs from the leading edges and the shoulder area. Repair deep gouges with filler and smooth with an emery cloth. See **Fig. 3**.

   4.4 Wipe the seal and shoulder area with a clean shop cloth.

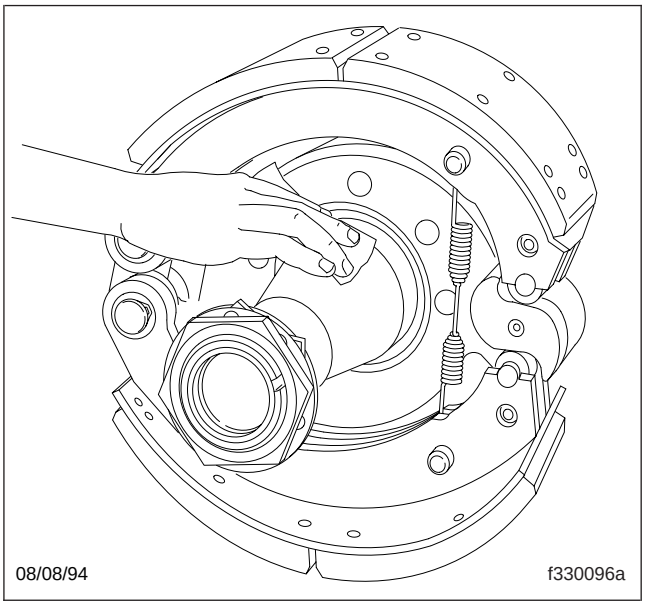

Fig. 3, Clean and Inspect the Axle Spindle

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

4.5 Inspect the bearings and hub components for wear or damage. Replace any worn or damaged components as necessary.

4.6 Coat the wheel bearing cones with oil.

5. Install the inner wheel bearing cone in the inner wheel bearing cup.

IMPORTANT: Use the Dana Spicer Outrunner installation tool *with the centering tool* when installing the seal. See **Fig. 4**.

6. Install the oil seal in the hub bore.

⚠ CAUTION

Do not use any silicone or permatex type bore sealant with this seal. The Dana Spicer Corporation recommends a light coating of bearing oil on the outer circumference of the seal.

Do not mix lubricants of different grades. Do not mix mineral and synthetic lubricants. Do not pack the bearings with grease when using an oil bath

system. Failure to follow these installation guidelines will result in less than desired performance of the Outrunner seal, and installation-related failures are not covered under warranty.

6.1 Place the Outrunner seal tool with the words "air side" facing the adapter plate of the installation tool. See **Fig. 5**. Lubricate the seal outer circumference with wheel bearing oil.

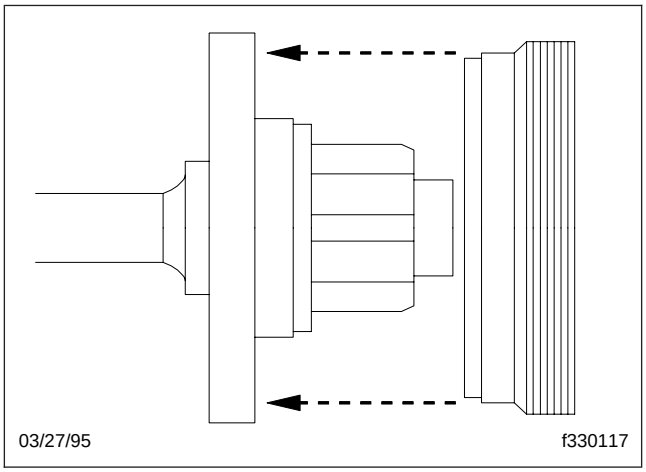

Fig. 5, Seal Placement on Tool

IMPORTANT: Install the seal in the hub bore with the hub lying flat. Do not install the seal with the hub in the vertical (upright) position.

6.2 With the hub and the wheel assembly lying flat on the floor, place the inner bearing cone in the cup.

6.3 Position the oil seal in the hub bore. Before striking the handle of the installation tool, tap the adapter plate around the outer edge to position the seal. See **Fig. 6**.

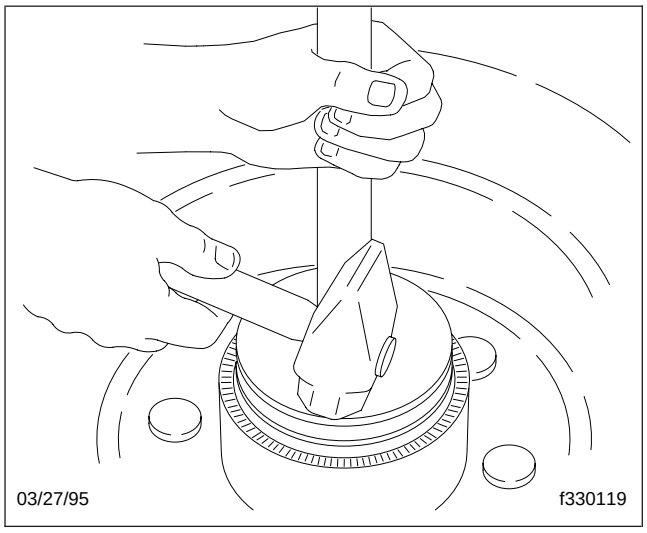

Fig. 6, Position the Seal

6.4 Hit the handle of the installation tool *gently*. See **Fig. 7**.

Because of the rubber outer circumference, the Outrunner seal is easier to install than seals with metal outer circumferences. When the adapter plate bottoms out on the hub surface, the seal is installed correctly. You will hear a metal-to-metal sound.

6.5 Check that the seal is not cocked, and that the unitized seal inner circumference and inner bearing turn freely.

6.6 Lubricate the inner circumference of the seal with a light film of clean bearing oil.

7. Install the wheel hub on the axle, and adjust the wheel bearings. For instructions, see **Section 33.01**.

IMPORTANT: When starting the wheel on the spindle, center the hub carefully to avoid seal damage from the leading edge of the spindle.

8. Place the hubcap and a new gasket in position. Install the capscrews. Tighten the capscrews 15 lbf·ft (20 N·m).

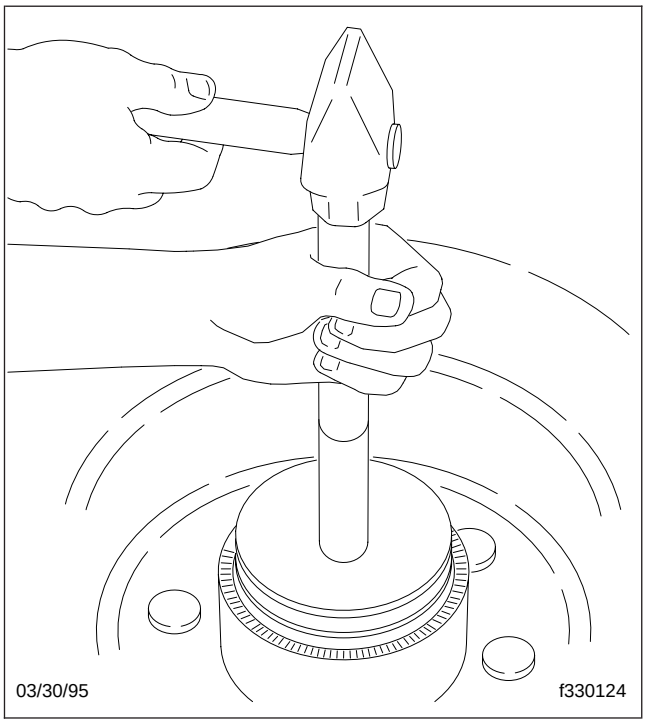

Fig. 7, Install the Seal

9. Fill the hub with oil to the level shown on the hubcap. See **Fig. 8**. Do not overfill.

2. Remove the old oil seal from the hub or spindle.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity.

⚠ CAUTION

Never use a sharp chisel to cut through an axle ring. A sharp chisel could damage the spindle or shoulder.

4. Remove the steel axle ring by striking the ring surface several times with a ball-peen hammer. See **Fig. 1**. Remove the stretched axle ring from the spindle.

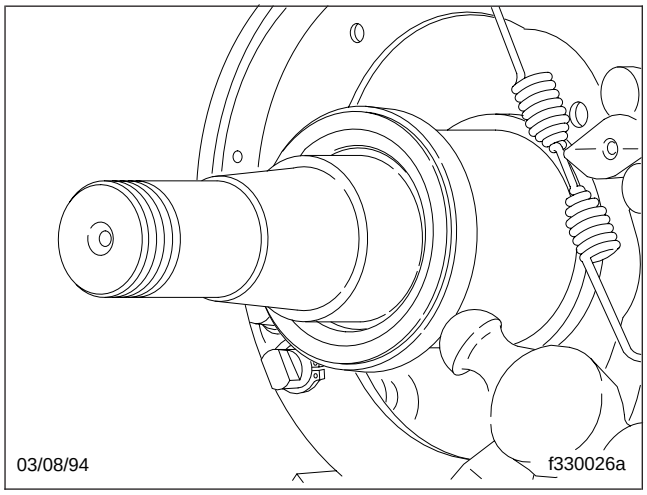

Fig. 1, Remove the Axle Ring

5. Inspect the spindle shoulder and hub bore.
   - 5.1 If necessary, use a file to remove burrs from the leading edges and shoulder area.
   - 5.2 Fill any deep scratches with a hardening compound and smooth it with an emery cloth. See **Fig. 2**.

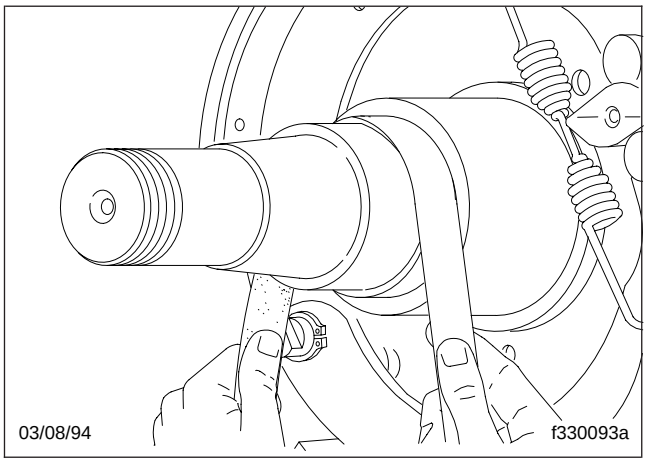

Fig. 2, Clean the Axle Spindle

   - 5.3 Use a clean cloth to remove all dirt, grit, and metal filings.
   - 5.4 Check the seal for a correct fit by placing the seal on the axle spindle, up to the first rubber rib. The correct seal will not go any farther.

   IMPORTANT: Clean the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause rapid wear of the bearing assembly.

   - 5.5 Inspect the hub bore, and remove any burrs from the leading edge with an emery cloth.

6. Select the seal installation tools designed for use with National oil bath seals. These should include a universal handle, an adapter plate, and a bearing pilot. See **Fig. 3**.

Replacement

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 33.01**.
2. Remove the old oil seal from the hub or spindle.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity.

7. Inspect the bearings and hub components for wear or damage. Replace any worn or damaged parts as necessary.

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

Fig. 4, Apply Sealant to the Spindle Shoulder

NOTE: Use a non-hardening sealant such as Permatex® Number-2 or Loctite® 515.

9. Place the oil seal on the spindle so the words "oil-bearing side" are exposed to the oil. A slight step on the inside circumference of the seal ring will allow it to be placed by hand about 1/8 inch (3 mm) onto the shoulder. See **Fig. 5**.

⚠ CAUTION

Do not install the oil seal in the hub bore. Incorrect seal installation will damage the seal and lead to possible spindle, hub, and bearing damage.

10. Position the Stemco installation tool over the spindle. See **Fig. 6**. Using a 3 to 5 lb (1 to 2 kg) hammer, drive the seal on the spindle until the tool bottoms against the shoulder. After the tool bottoms, turn it while applying several light taps with the hammer to ensure the seal ring is flush with the face of the shoulder. Wipe off all excess sealant.

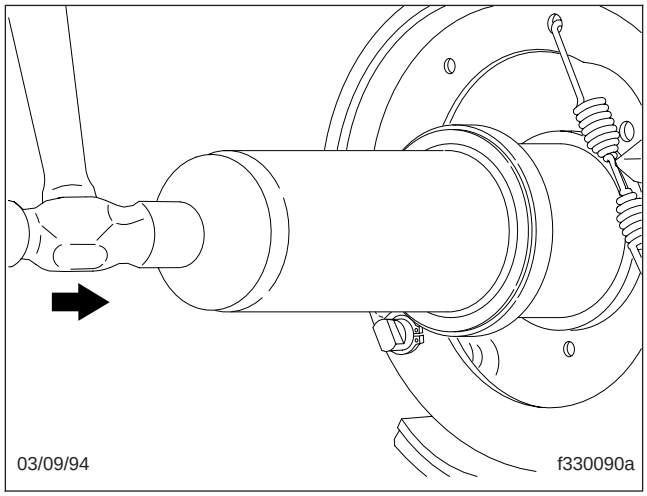

Fig. 6, Drive the Seal onto the Spindle

IMPORTANT: Use only the tool specified by Stemco for the vehicle's axle. In order for the Stemco warranty to apply, the product must be correctly installed using the correct tool made by Stemco or a tool approved by Stemco.

11. Make sure there are no gaps between the ring and shoulder. See **Fig. 7**.

12. Coat the inner wheel bearing with oil and install it on the spindle. See **Fig. 8**. No additional oil is

General Information

Detroit front axles have a unique steering knuckle design that reduces vibration and wear. Low-friction, high-strength needle bearings roll on a large-diameter kingpin, replacing the conventional bushings. They are compatible with all standard industry model brakes, hubs, and wheel bearings.

There are three basic models for the Detroit front axle: Model 2, Model 3, and Model 5. The basic model is indicated by the numbers on the axle identification tag.

The following explains a typical model number.

Typical Model Number: AF-12-3.

- *AF* = front axle
- *12* = Weight Rating (times 1000 lbs.)
- *3* = Model Number

NOTE: Detroit axles are a proprietary product, though in some applications they may be referred to as "Freightliner" or "Axle Alliance" axles or "MB components."

Removal

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the rear tires. Put the transmission in neutral.
2. At both ends of the front axle, loosen all the wheel nuts.

⚠ WARNING

Never work around or under a vehicle that is supported only by a jack. Always support the vehicle with safety stands. Jacks can slip, causing the vehicle to fall, which could result in serious injury or death.

3. Raise the front of the vehicle and support it with safety stands.
4. Drain the air system.
5. Remove the front wheel and tire assemblies. For instructions, see **Group 40**.
6. Remove the brake drums and front hubs from the axle. See **Section 33.01, Subject 100** for instructions.
7. Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
8. Remove the ABS sensors and wiring from the brake spiders (anchor plates) and secure them and their wiring out of the way.
9. Remove the brake air chambers and the slack adjusters. For instructions, see the applicable sections in **Group 42**.
10. Remove the brake spiders from the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
11. Disconnect the drag link from the axle steering arm.
12. If so equipped, disconnect the sway bar from the axle brackets.
13. Using a suitable jack, support the front axle.
14. Remove the U-bolt nuts or remove the nuts holding the axle beam to the leaf springs and the air bag brackets, as applicable.
15. Remove the U-bolts, if applicable.
16. Remove the axle from the vehicle.
17. If you are replacing the steering knuckles, put the axle on a suitable stand and secure it to prevent it from moving.

Installation

1. With the axle on a suitable jack, position it under the vehicle.
2. For a vehicle with front air suspension, raise the axle so that the holes in the axle beam line up with the bolts that hold the air bags to the leaf springs. Install the nuts and washers and tighten the nuts 220 lbf·ft (298 N·m).

   For a vehicle with a leaf-spring front suspension, install the U-bolts and nuts. For instructions on tightening U-bolt nuts, see the applicable section in **Group 32**.
3. If so equipped, connect the sway bar to the axle brackets. Tighten the sway bar fasteners 100 lbf·ft (136 N·m).
4. Connect the drag link to the steering arm. For instructions, see the applicable section in **Group 46**.
5. Install the brake spiders on the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
6. Install the brake air chambers and slack adjusters onto the axle. For instructions, see the applicable sections in **Group 42**.

10. Install the brake drums.
11. Adjust the slack adjusters. For instructions, see the applicable section in **Group 42**.
12. Install the tire and wheel assemblies. For instructions, see **Group 40**.
13. Raise the vehicle, remove the safety stands, and lower the vehicle.
14. Start the engine and build the air pressure.

Axle Removal and Installation

15. If equipped with a front air suspension, check that the suspension air bags are inflating correctly.
16. Remove the chocks from the rear tires.

Disassembly

NOTE: The following procedures can be done with the axle installed on the vehicle or with the axle removed from the vehicle.

1. If the axle has been removed, make sure it is securely mounted on a suitable stand. Go to the step for removing the tie rod from the tie-rod arm.

   If the axle is on the vehicle, park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the rear tires. Drain the air system.

2. If the axle is on the vehicle, do the following substeps to gain access to the steering knuckle.

   2.1 Remove the wheel and tire assembly from the applicable side of the vehicle.

   2.2 Remove the brake drum and hub. For instructions, see **Section 33.01, Subject 100**.

   2.3 Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.

   2.4 If so equipped, remove the ABS sensor and wiring from the brake spider (anchor plate) and secure the sensor and the wiring out of the way.

   2.5 Disconnect the air line from the brake air chamber, then remove the air chamber and the slack adjusters. For instructions, see the applicable section in **Group 42**.

   2.6 Remove the brake spider from the axle flange. For instructions, see the applicable service brake section in **Group 42**.

   2.7 Disconnect the drag link from the steering arm, if present.

   NOTE: On the driver's side of the vehicle, the steering arm connects to the steering knuckle. On the passenger's side, no steering arm is present.

3. If not already done, disconnect the tie rod from the tie-rod arm.

4. Remove the tie-rod arm from the steering knuckle. See **Fig. 1**.

5. If applicable, remove the steering arm. See **Fig. 1**.

6. Remove the steering knuckle and spindle assembly from the axle beam. See **Fig. 1**.

   6.1 Remove the upper and lower snap rings that hold the cover plates in place.

   6.2 Remove the upper and lower cover plates from the steering knuckle.

   6.3 Remove and discard the O-ring from the edges of each cover plate.

   6.4 Note the orientation of the draw keys and the kingpin, then remove the draw keys and nuts that hold the kingpin in place.

   6.5 Using a brass drift, remove the kingpin by driving it downward. Make a note of where the needle bearings were installed.

   6.6 Remove the spacer(s) and shim(s) from the upper surface of the axle beam bore.

   6.7 Push down on the steering knuckle and spindle assembly to clear the lip on the thrust friction bearing and remove the assembly from the axle beam bore.

NOTE: The steering knuckle on the passenger's side (side without a steering arm) has a thrust roller bearing instead of a thrust friction bearing. Unlike the thrust friction bearing, the thrust roller bearing has no protruding lip at the top. When removing the thrust roller bearing from the axle beam bore, it is not necessary to push down on the steering knuckle.

7. Remove the grease seal from the upper steering-knuckle bore.

8. Remove the thrust friction bearing (driver's side) or the thrust roller bearing (passenger's side) from the top of the lower steering knuckle bore.

NOTE: If removing the thrust friction bearing (driver's side), note the orientation of the bearing for future reference.

9. Using a brass drift, drive out the needle bearings from the steering knuckle bores.

10. If needed, repeat the entire procedure for the other side of the axle assembly.

Assembly

IMPORTANT: If replacing the kingpin, use a complete rebuild kit with all new components.

1. Clean the steering knuckle bores and the axle beam bores. Check for damage such as grooves, scratches, and pitting.

   If any bores show significant damage, replace the component.

2. Install the grease seal — with the grooved side down (toward the road) — into the top of the upper steering knuckle bore. Carefully drive the seal down into the bore until the outer edge of the seal is flush with the bottom edge of the bore. Make sure the seal is not cocked.

3. Install new needle bearings into the bores of one of the steering knuckles. Install the same number of bearings as was removed.

NOTE: Install the needle bearings just far enough into the bores so that the cover plates can be installed.

4. Install a new thrust friction bearing (driver's side) or thrust roller bearing (passenger's side) into the top of the lower steering knuckle bore. Install the thrust friction bearing (or thrust roller bearing) with the sealed side up.

NOTE: The thrust friction bearing has a protruding lip at the top. The thrust roller bearing has no such protruding lip.

5. Partially install the steering knuckle onto the axle beam.

   5.1 Making sure the flats on the kingpin are aligned with the draw-key holes in the axle beam, put the new kingpin into the top bore of the steering knuckle. Note that the top of the new kingpin is clearly marked. Push the kingpin through the axle beam bore until the upper end of the kingpin is flush with the upper surface of the axle beam bore.

   5.2 Align the steering knuckle with the axle beam, then check the clearance between the axle beam bore and the upper steering knuckle bore. Clearance is to be a maximum of 0.003 inch (0.08 mm).

   IMPORTANT: To correctly check the clearance, the thrust friction or thrust roller bearing must be installed correctly, and upward pressure must be applied to the steering knuckle.

   5.3 If needed, install sufficient spacers to reduce the clearance to 0.002 to 0.003 inch (0.05 to 0.08 mm).

6. Install the kingpin fully into the steering knuckle bores, making sure the flats on the kingpin are still aligned with the draw-key holes in the axle beam.

7. Install new upper and lower draw keys and nuts. See **Fig. 1**.

   7.1 Install the upper draw key from the back of the axle, and the lower one from the front of the axle.

   IMPORTANT: Make sure the new draw keys are the same length as those removed. On some axle models the lower draw key is longer than the upper one.

   7.2 Tighten the draw-key nuts 30 to 55 lbf·ft (40 to 75 N·m).

8. Install new grease fittings and cover plates.

   8.1 Install the new upper cover plate (with a new O-ring) and the snap ring. Install the new grease fitting into the cover plate.

   8.2 Install the new lower cover plate (with a new O-ring) and the snap ring. Install the new grease fitting into the cover plate.

9. Install the steering arm. Apply Loctite® 277 to the threads and tighten the steering arm capscrews: if M20 capscrews are used, tighten them 425 lbf·ft (575 N·m); if M24 capscrews are used, tighten them 664 lbf·ft (900 N·m).

10. Attach the tie-rod arm to the steering knuckle. Apply Loctite® 277 to the threads and tighten the tie-rod arm capscrews: if M20 capscrews are used, tighten them 425 lbf·ft (575 N·m); if M24 capscrews are used, tighten them 664 lbf·ft (900 N·m).

11. Attach the tie-rod arm to the tie rod. Tighten the castle nut 120 to 170 lbf·ft (163 to 230 N·m) plus a maximum of one-sixth of a turn to align a slot in the castle nut with the cotter pin hole in the tie

rod stud. Insert the cotter pin and bend the tangs to secure it.

12. If removed, install the axle.
13. If removed, connect the drag link to the steering arm.
14. Install the brake spider on the axle flange. For instructions, see the applicable service brake section in **Group 42**.
15. Install the brake air chambers and slack adjusters on the axle. For instructions, see the applicable sections in **Group 42**.
16. Install the ABS sensor.
17. Install the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
18. Install the hub and adjust the wheel bearings. For instructions, see **Section 33.01**.
19. Install the brake drum.
20. Install the tire and wheel assembly. For instructions, see **Group 40**.
21. If necessary, repeat the entire procedure for the other side of the vehicle.
22. Raise the vehicle, remove the safety stands, then lower the vehicle.
23. Remove the chocks from the tires.

General Information

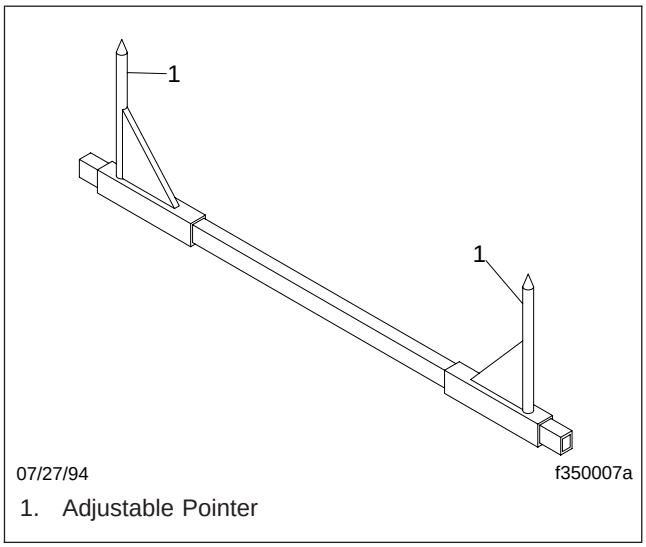
Rear axle alignment should be checked whenever rear axle or suspension components are replaced. It should also be checked when there is excessive front and rear tire wear, or hard or erratic steering.

Manufacturers of axle alignment equipment offer a variety of systems to precisely measure and correct rear axle alignment. If this type of equipment is not available, the basic tools needed for checking rear axle alignment on tandem or single axles are a straightedge (that is nonflexible and at least as long as the axle), steel tape rule, and trammel bar or center point bar.

The straightedge is used to see if a single axle, or a forward-rear axle of a tandem axle installation, is in alignment with the frame. The distance from the straightedge to the center of the wheel hub is measured on each side of the vehicle; any difference in the measurements means that the axle is out of alignment.

A center point bar (**Fig. 1**) is used to see if the forward-rear axle and rearmost axle of a tandem installation are aligned with each other (parallel). It has adjustable pointers at each end, which are inserted into the axle cap holes of each axle. By comparing the distance between the two axles on one side to the distance on the other side, it can be determined if the axles are parallel.

Instructions and a list of materials for making a center point bar are in **Subject 130**.



1. Adjustable Pointer

Fig. 1, Center Point Bar

The following preliminary checks should be completed before checking any alignment measurements.

Preliminary Checks

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. Relieve internal stresses in the suspension by driving the vehicle back and forth in a straight line.

1. Wheel assemblies should be balanced, especially for vehicles that travel at sustained speeds of more than 50 mph (80 km/h). Off-balance wheel assemblies cause vibrations that result in severely shortened life for tires and suspension parts.
2. Do not mix tires of different size, type, or weight. Tire wear should be even and not worn to limits exceeding government specifications. Refer to **Group 40** in this manual and **Group 40** in the *Century Class Trucks Maintenance Manual* for more information. Replace any tire that is excessively worn.
3. Check the inflation pressure of the tires. Refer to **Group 40** in this manual for recommended pressures. An underinflated tire causes tread wear completely around both tire shoulders. An overinflated tire causes tread wear in the center of the tire. See **Fig. 1.**

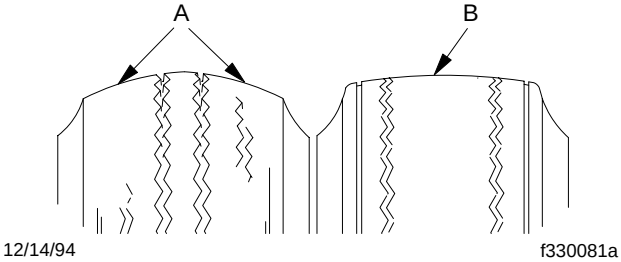


Fig. 1, Tire Damage Due to Underinflated or Overinflated Tires

4. Check for out-of-round wheels and wheel stud holes. Replace the wheel if any of these conditions exist.
5. On each side of the vehicle, check the height of the chassis above the ground; for instructions, see **Group 32** in this manual or the suspension manufacturer's service literature. Sagging, fatigued, or broken suspension springs create a lopsided vehicle appearance and an unbalanced weight distribution. Anything that changes the ratio of weight on the springs affects the alignment angles and also the tire tread contact area. Replace damaged springs as instructed in the applicable suspension section.
6. Check and, if necessary, correct frame rail alignment as instructed in **Group 31** in this manual.
7. Check and, if necessary, adjust rear axle tracking. For instructions, see **Group 32** in this manual or the suspension manufacturer's service literature.
8. Check the rear axle wheel bearings for wear and incorrect adjustment. Refer to **Section 35.01** for instructions.

Checking Using Computerized Alignment Systems

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

Follow the manufacturer's instructions for use of the alignment equipment, and use the alignment measurements given in **Fig. 1** and the applicable tables in **Specifications 400**.

Checking Using the Manual Method

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction.

1. Park the vehicle on a level surface. Relieve internal stresses in the suspension by driving the vehicle back and forth in a straight line, or by jacking the axle up and letting it down.
2. Chock the front tires and place the transmission in neutral. Release the parking brakes.

NOTICE

Do not use scribe lines for marking on frame rails. Scribe lines, which cut or scratch the metal, can develop into starting points for structural damage to the frame.

3. Select a point on the frame rail forward of the rear axle, and mark it using a pencil or soapstone. Then mark two other points, exactly 4 inches (102 mm) forward and to the rear of the original point. Make sure that all three marks are aligned and of equal distance from the outside edge of the frame rail. Using a center point or trammel bar, place one pointer on the forwardmost point, and make an arc with a pencil or soapstone on the opposite frame rail. Then place the pointer on the rearmost point and make an arc on the opposite frame rail intersecting the first arc. See **Fig. 2**. The point where the two arcs intersect and the original (or middle) point on the opposite frame rail have matching locations.
4. Line up the straightedge with the two matching points. Check that the straightedge extends out about the same distance on each side of the frame rail. Using C-clamps, clamp the straightedge to the frame; see **Fig. 3**. The straightedge must line up exactly with the points.
5. Measuring from the outside edge of each frame rail, mark the straightedge on both sides of the frame. The marks (**Fig. 3**, Ref. A) must be of equal distance from the frame and as far from the frame rail as the tires are at their farthest point from the frame.

IMPORTANT: The distance between the mark on the straightedge and the frame rail must be equal on both sides of the vehicle.

6. On each side of the vehicle, measure the distance from the mark on the straightedge to the center of the wheel hub. See **Fig. 3**.

   The difference between these measurements should be 1/4 inch (6 mm) or less. See **Fig. 1**. If the difference is more than 1/4 inch (6 mm), adjust the axle alignment. For instructions, see **Group 32** in this manual, or the suspension manufacturer's service literature.

Alignment Checking, Tandem Axle

To align a tandem axle, first, check and (if needed) align the rearmost axle; then, check and (if needed) align the forward-rear axle.

Checking Using Computerized Alignment Systems

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

Follow the manufacturer's instructions for use of the alignment equipment, and use the alignment measurements given in **Fig. 1** and the applicable tables in **Specifications 400**.

Checking Using the Manual Method

A straightedge and a center point bar are needed to manually align a tandem axle. For instructions for making a center point bar, see **Subject 130**.

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction.

1. Using the instructions in **Subject 110**, check and align the rearmost axle.
2. Using a center point bar, set the two points into the axle cap holes as shown in **Fig. 2**. Lock them in place by tightening the setscrews.
3. With the points still locked in place, move the center point bar to the other side of the vehicle, set the two points into the axle cap holes, and compare the axle spacing. If there is a difference

of 1/8 inch (3 mm) or less between the spacing on one side of the vehicle compared to the other, no further action is necessary. If the difference is more than 1/8 inch (3 mm), adjust the forward-rear axle alignment. See **Fig. 1**. For instructions, see **Group 32** in this manual, or the suspension manufacturer's service literature.

Center Point Bar Construction

Materials Required

NOTE: To obtain metric conversions (millimeters), multiply the number of inches by 25.4.

The following materials are required:

- 62" of square steel tube (1" x 1", measured outside)
- 12" of square steel tube (1-1/8" x 1-1/8", measured inside)
- 20" of 3/8" steel rod
- two 1/2" x 3" pieces of steel square-bar stock
- one 4" x 4" steel plate, 1/8" thick
- two 3/8–16 capscrews (grade 5), 2" long
- two 3/8–16 hexnuts (equivalent to grade 5)

Construction

1. Cut the 1-1/8 x 1-1/8 inch (inside measurement) square steel tube in half to obtain two pieces 6 inches long. These will be the sliding members (slides) of the center point bar.
2. Cut the 4-inch by 4-inch steel plate diagonally into two pieces (gussets). Weld one gusset to each slide, as shown in **Fig. 1**.
3. Cut the steel rod in half to obtain two 10-inch rods. Grind one end of each to form a point.
4. Weld the pointed steel rods to the slides and gussets, as shown in **Fig. 1**.
5. Drill a 1/2-inch hole in the center of each slide, on the side opposite where the pointer was welded. Drill through only one side of the tube.
6. Directly over each hole drilled in the step above, weld a 3/8–16 nut (equivalent to grade 5).
7. Weld a piece of steel stock, about 1/2-inch wide by 3-inches long, over the head of each of two 3/8–16 by 2-inch long capscrews.
8. Place a slide over each end of the 60-inch piece of steel tube, with the pointed rods to the outside. Screw the handscrews (made in the step above) into the slides until they are clamped tightly to the cross tube.

Wheel Hub

Vehicles may be equipped with ConMet PreSet® hubs. These hubs have a spacer between the inner and outer bearings that adjusts the bearings to the correct end play and preload when the retaining nut is tightened.

For more information about PreSet hubs, and hub removal and installation procedures, see **Subject 100**.

Tapered Wheel Bearings

Each hub has a set of inner and outer tapered wheel bearing assemblies. A typical tapered wheel bearing assembly consists of a cone, tapered rollers, a roller cage, and a separate cup that is press-fit in the hub. See **Fig. 2**. All components carry the load, with the exception of the cage, which spaces the rollers around the cone.

Drive Axle Spindle Assembly

The drive axle spindle assembly is made up of a drive axle flange and shaft, drive axle studs and stud nuts, a flange gasket, an axle spindle, an oil seal, and the locking assembly described above.

The surfaces of the spindle and the nut threads are machined. When these surfaces become damaged, repairs are necessary. There are standard methods for performing those repairs that preserve the proper alignment of the axle spindle assembly. Refer to the axle manufacturer for instructions.

NOTICE

The National Highway Traffic Safety Administration (NHTSA) has warned against repairs that involve cutting off a portion of a damaged spindle and welding on a replacement part. The heat of

welding can reduce the strength of spindles made with heat-treated materials and lead to spindle failure. After the cutting and welding operations, the replacement part may not be correctly aligned on the spindle. This can cause damage to the spindle nut.

Brake Drum

The brake drum and lining work together as a mated friction pair, with the drum responsible for both heat absorption and dissipation. Lining performance and life largely depend on the condition of the drum and whether it can adequately absorb and dissipate heat generated by braking action.

Wheel Studs

A headed wheel stud is used on rear axle disc wheel hub assemblies. Each of these studs has either serrations on the stud body or a flat area on the stud head to prevent the stud from turning in the wheel hub. See **Fig. 3**. Wheel studs are press-fit in the hub. For replacement procedures, see **Subject 125**.

Vehicles may use ConMet PreSet® hubs, which are equipped with a unique bearing spacer between special inner and outer bearings. See **Fig. 1.**

Fig. 1, ConMet PreSet Hub, Cut-Away View

When installing a PreSet hub with the spacer and special PreSet bearings, the correct end play is set automatically and wheel bearing adjustment is unnecessary.

For vehicles equipped with ConMet PreSet hubs, it is highly recommended to **stay with the PreSet system** to optimize bearing and seal life. However, if you are replacing the bearings for a PreSet hub, and the special PreSet bearings are not available, standard wheel bearings can be used. In this case, the bearing spacer must be removed and the bearings adjusted manually. See the installation instructions for more information.

Removal

For a typical wheel end and axle assembly, see **Fig. 2**.

1. Shut down the engine and chock the front tires. Release the parking brakes.
2. Raise the rear of the vehicle until the tires clear the ground. Then place safety stands under the axle.
3. For drum brakes, back off the slack adjuster to release the rear axle brake shoes.

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

4. Remove both wheel and tire assemblies. For instructions, see **Group 40**.
5. For drum brakes, remove the brake drum. See **Subject 105** for instructions.

NOTE: Oil will spill as the drive axle shaft (or hub cap) and the wheel hub are removed. Place a suitable container under the drive axle flange or hub cap to catch any spilled oil. Dispose of the oil properly.

6. Remove the drive axle stud nuts and washers. See **Fig. 3**.

NOTICE

When tapping the drive axle flange, avoid striking the drive axle studs. If struck, the studs may bend or break, or the stud threads can be damaged. Replace damaged studs.

7. Using a hammer and a soft drift, such as one made of brass, sharply tap the center portion of the drive axle flange. The shaft will usually spring slightly outward after the seal has broken.

NOTE: Even if the drive axle shaft doesn't spring outward, the seal may have loosened enough to allow the shaft to be pulled from the axle housing. If the seal has not broken, repeat the step above.

8. If so equipped, remove the tapered dowels and washers from the drive axle flange.

10. Remove and discard the gasket.
11. Remove the wheel bearing locking device:
    - For a Pro-Torq spindle nut, see **Subject 150**; then go to the next step.
    - For an Axilok spindle nut, see **Subject 135**; then go to the next step.

NOTICE

Be careful not to let the outer wheel bearing drop from the axle spindle. Dropping the bearing can warp the cage or damage the rollers, ruining the bearing. On vehicles equipped with WABCO ABS, use care when working with the hubs. To prevent damage to the tone wheel, do not drop the hub, or lay it down in a way that would damage the tone wheel.

12. Move the hub about 1/2 inch (13 mm) to jar loose the outer wheel bearing (allow the hub-only assembly to rest on the axle spindle; be careful not to damage the axle spindle threads).
13. Carefully remove the outer wheel bearing; handle the bearings with clean, dry hands. Wrap the bearings in either clean oil-proof paper or lint-free rags.

NOTICE

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

14. Remove the hub. Be careful not to damage the axle spindle threads as the assembly is removed.

15. Remove the inner wheel bearing. Handle the bearings with clean, dry hands, then wrap the bearings in either clean oil-proof paper or lint-free rags. If the inner wheel bearing remains in the hub after the hub is removed from the axle, place a protective cushion where it will catch the bearings, then use a hardwood drift and a light hammer to gently tap the bearing (and seal, if necessary) out of the cup.
16. Remove the oil seal from the axle spindle, if not already removed. See **Section 35.02** for oil seal removal instructions.

Installation

For a typical wheel end and axle assembly, see **Fig. 2**.

1. Using cleaning solvent, remove the old oil from the axle spindle and the disassembled parts. Allow the parts to dry, or dry them with clean, absorbent, and lint-free cloth or paper. Wrap a protective layer of friction tape on the axle spindle threads.
2. On brake drum assemblies with an aluminum hub, coat the hub-to-drum contact surfaces with Alumilastic compound or an equivalent.
3. Coat both bearing assemblies with fresh oil. Then install the inner wheel bearing and oil seal. Handle the bearings with clean, dry hands. See **Section 35.02** for oil seal installation instructions.

NOTICE

Use only fresh oil on the bearing assemblies; old oil could be contaminated with dirt or water (both are corrosives) and could cause damage to both wheel bearing assemblies and the wheel hub.

4. Wipe a film of axle oil on the axle spindle to prevent rust from forming behind the inner wheel bearing.

NOTICE

Do not use a bearing spacer with standard wheel bearings. To do so may result in too much bearing end-play, which could damage the wheel bearings, oil seals, the axle spindle, and the hub.

5. If using PreSet bearings, ensure the tubular bearing spacer is in the PreSet hub.

   If replacing PreSet bearings with non-PreSet bearings, remove the tubular bearing spacer from inside the hub. Save it for future use to convert the hub back to the PreSet system.

NOTICE

- **On vehicles equipped with WABCO ABS, use care when installing the hubs. To prevent damage to the tone wheel, do not drop the hub or lay it down in a way that would damage the tone wheel.**
- **Do not remove the outer wheel bearing once the hub is installed on the axle. Removing the outer bearing could cause the oil seal to become misaligned, which could cause damage to the wheel bearings, the hub, and the axle spindle.**

NOTE: A temporary plastic alignment sleeve may be installed in the center of a new ConMet PreSet hub. It will be pushed out when the hub is installed on the axle spindle. If it is present, remove and discard this sleeve.

6. Mount the bearings and hub on the spindle.
7. Remove the friction tape, then adjust and secure the bearings:
   - If the axle is equipped with a four-piece bearing-lock system, see **Subject 140**; then go to the next step.
   - For a Pro-Torq spindle nut, see **Subject 150**; then go to the next step.
   - For an Axilok spindle nut, see **Subject 135**; then go to the next step.
8. Install a new gasket, and the drive axle shaft or, on non-drive axles, the hub cap. The splined end of the axle shaft must seat before the drive axle flange will fit over the studs.
9. If equipped, install the dowels and washers on the drive axle studs. Install the drive axle stud nuts. Using the sequence shown in **Fig. 4**, tighten the nuts to the torque values given in the table in **Specifications, 400**.
10. For drum brakes, install the brake drum on the wheel hub. See **Subject 105** for instructions.

Hub Assembly Removal and Installation

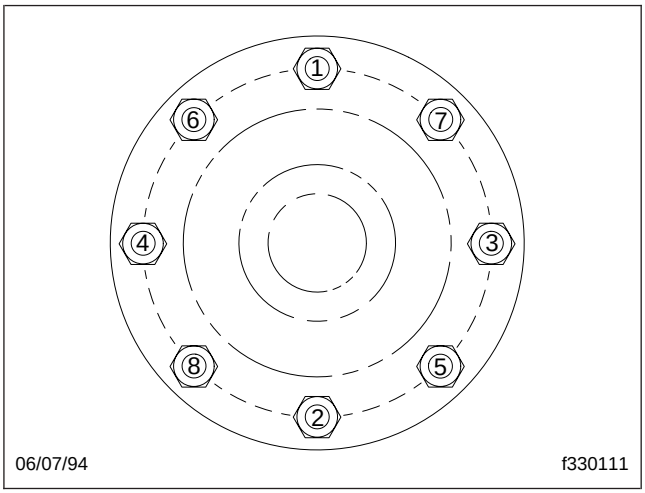

Fig. 4, Tightening Sequence, Drive Axle Stud Nuts

WARNING

If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking action, and the wheel hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

11. Install the inner and outer wheel and tire assemblies. For instructions, see **Group 40**.

WARNING

Add oil to the axle housing bowl or the wheel hub after the drive axle shaft and wheel hub have been serviced. Failure to add oil will damage the wheel bearings and cause them to seize during vehicle operation. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury.

12. For drive axles, pour the recommended drive axle lubricant through the axle housing filler hole.

    On Freightliner axles, tighten the oil filler plug 37 lbf·ft (50 N·m).

    On Meritor axles, tighten the oil filler plug 35 lbf·ft (47 N·m).

    On Dana Spicer axles, tighten the oil filler plug 40 to 60 lbf·ft (54 to 81 N·m).

13. To lubricate the wheel ends, tilt the axle to the left and right by jacking the opposite side 8 inches (20 cm). Hold the tilted position for two minutes on each side to allow oil to run into the wheel end. Return the axle to a level position, and add oil through the axle housing filler hole. About two extra pints (1 liter) of lubricant will be needed to bring the oil level even with the base of the filler hole.

NOTE: Drive axle wheel bearings are lubricated by oil drawn from the axle housing bowl section. This method ensures good exchange of heat, prevents stagnation, and minimizes the maintenance required on bearings and hub assemblies.

14. For non-drive axles, add about 1 to 1-1/2 pints (0.5 to 0.7 liter) of oil to the level shown on the hub cap. Do not overfill. Install the vent plug or threaded filler plug.
15. Turn the wheels, wait one minute, and check the lubricant level.
16. Adjust the rear axle brakes. For instructions, see **Group 42**.
17. Remove the safety stands from under the axle, then lower the vehicle.

Outboard-Mounted Drum Removal and Installation

⚠ WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

For an exploded view of a typical wheel and axle assembly, including the brake drum, see **Fig. 1**.

Removal

1. Park the vehicle, shut down the engine, apply the parking brakes and chock the front tires.
2. Raise the rear of the vehicle until the tires clear the ground. Then place safety stands under the axle.
3. Back off the slack adjuster to release the rear axle brake shoes.

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

4. Remove the wheel and tire assembly. Refer to **Group 40** for instructions.

   To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.
5. Remove the brake drum.

Installation

1. On brake drum assemblies with an aluminum hub, coat the hub and drum contact surfaces with Alumilastic® compound or an equivalent.
2. Install the brake drum on the wheel hub.

   2.1 On hub-piloted drums, position the brake drum on the top step of the pilot pad. One of the hub's pilot pads should be at the twelve o'clock (top center) position. See **Fig. 2.**

   IMPORTANT: If the drum is not positioned correctly, the pilot pad could be damaged when the wheel nuts are torqued.

   2.2 Make sure that the pilot pads securely center the drum (space between drum and hub is equal all around the hub).

   IMPORTANT: If damage to the pads prevents the drum from centering, replace the hub. If necessary to hold the drum in position, adjust the brakes before installing the wheels.
3. Install the wheel and tire assembly. To ensure that the drum does not slip off the pilot pad, follow the correct nut tightening sequence. For instructions, refer to **Group 40**.

⚠ WARNING

WARNING: If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking ability, and the hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist, could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

4. Adjust the rear axle brakes. Refer to the brake section in the vehicle maintenance manual.

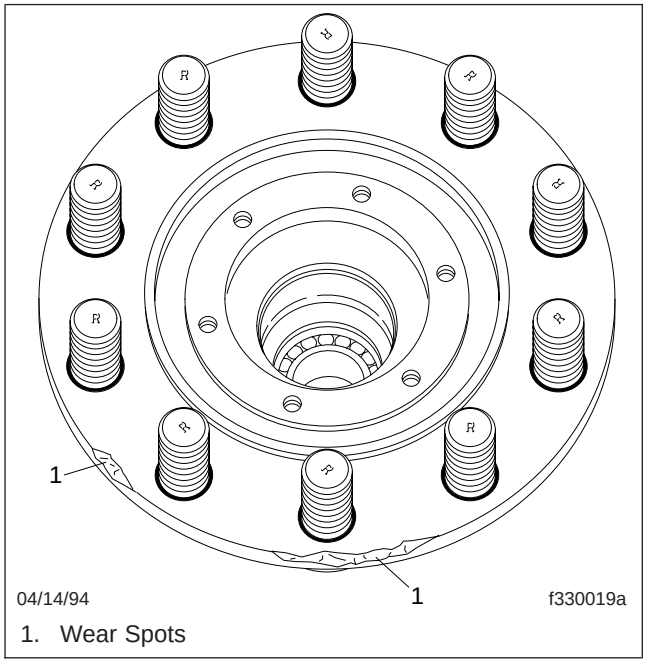
Wheel Hub Assembly Inspection

1. Inspect the wheel hub mounting flange. A loose wheel assembly will cause the flange to be worn, jagged, or warped. **See Fig. 1.** Replace the wheel hub if any of these conditions exist.

   Inspect the flange surface around the wheel studs. Improperly torqued wheel nuts will cause worn or cracked stud grooves on the hub. **See Fig. 2.** If wear spots or cracks appear anywhere on the hub, or if the hub is otherwise damaged, replace it with a new one.



1. Wear Spots

Fig. 1, Damaged Front Axle Wheel Hub

2. Remove all the old oil from the wheel hub cavity. Inspect the inner surface of the hub for cracks, dents, wear, or other damage. Replace the wheel hub if damage exists.

3. Remove all the old grease or oil from the surfaces of the wheel bearing cups. Inspect the wheel bearing cups for cracks, wear, spalling, or flaking. **See Fig. 3.** Replace the cups if damaged in any way. Refer to **Subject 115** or **Subject 120**.

4. Inspect the wheel nuts on disc wheel installations, or the rim nuts on spoke-wheel installations. Damaged nuts (**Fig. 4**), usually caused by inadequate tightening, must be replaced with new ones.

Axle Components Cleaning and Inspection

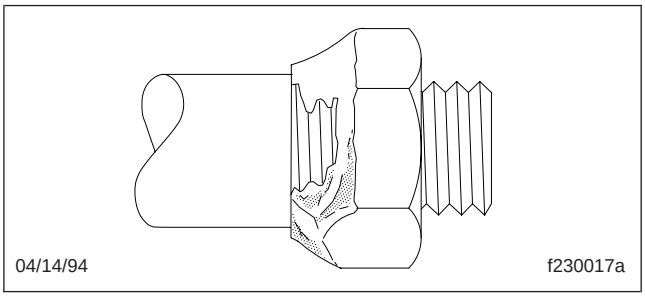

Fig. 4, Damaged Wheel Stud Nut

5. Inspect the wheel or rim studs. Replace studs that are stripped, broken, bent, or otherwise damaged. Refer to **Subject 125** or **Subject 130**.

Wheel Bearing Inspection

Wheel bearings should be very closely inspected at the time of disassembly. Optimal inspection conditions are possible only after the bearings have been thoroughly cleaned using kerosene or diesel fuel oil, and a stiff brush. Before inspecting, clean the bearings.

1. Remove the wheel hub and bearing cones. Refer to **Subject 100**.
2. Clean all old oil from the bearings and hub cavity with kerosene or diesel fuel and a stiff brush. Don't use gasoline or heated solvent.
3. Allow the cleaned parts to dry, or dry them with a clean absorbent cloth or paper. Clean and dry your hands and all tools used in the maintenance operation. Oil will not stick to a surface which is wet with kerosene or diesel fuel, and the kerosene or diesel fuel may dilute the lubricant.

⚠ CAUTION

CAUTION: Do not spin the bearing rollers at any time. Dirt or grit can scratch the roller surface and cause premature wear of the bearing assembly. Treat a used bearing as carefully as a new one.

4. After the bearings are cleaned, inspect the assemblies, which include the rollers, cones, cups, and cages. If any of the following conditions exist, replace the bearing assemblies:

   4.1 Large ends of rollers worn flush to the recess, or radii at the large ends of the rollers worn sharp. These are indications of advanced wear. **See Fig. 5**

2. Worn Bearing Rollers

the steel surface, and it greatly weakens the affected area. If water etch is present, replace the bearing seals.

4.5 Etching or pitting on functioning surfaces. **See Fig. 8.**

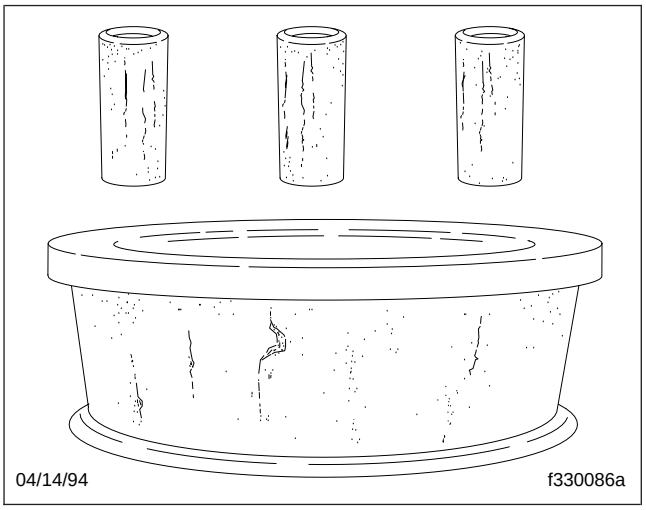

Fig. 8, Etching (Pitting) on Bearing Surfaces

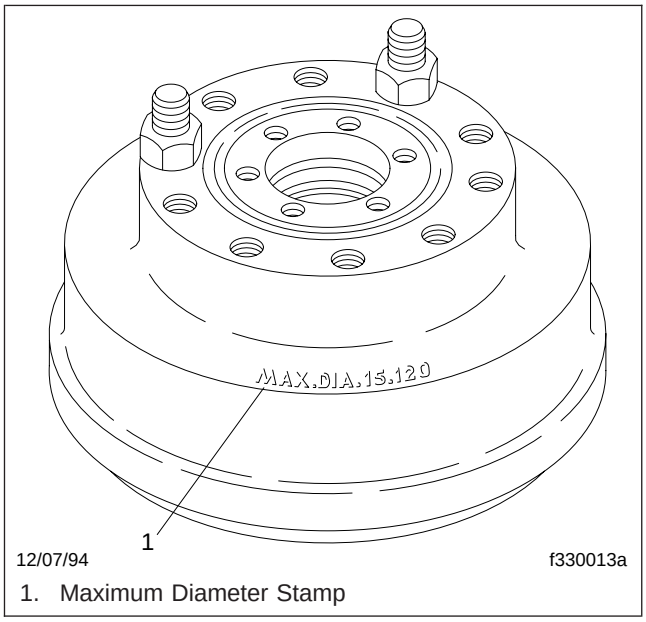
4.6 Spalling (flaking) of the bearing cup, roller, or cone surfaces. **See Fig. 3.**

After inspection, brush the bearings with fresh axle lubricant.

Brake Drum Inspection

New brake drums are purposely undersized to allow for turning (remachining), since in mounting drums on the hub, there can be some eccentricity. If a new drum is installed, the protective coating on the inner friction surface must be removed with a solvent, prior to drum installation, then rinsed with a hot water wash. Use a clean rag to remove any oily residue or metal chips from the friction surface.

If a drum must be turned or replaced, the other same-axle drum must be similarly turned or replaced to provide the same braking power on both wheels. Turned drums should not exceed the maximum allowable diameter, which is stamped on the outside surface of the drum. **See Fig. 9** for a typical location of this stamp.



1. Maximum Diameter Stamp

Fig. 9, Outboard Mounted Hub and Drum Assembly

NOTE: Drums that have been turned should then be cleaned by using fine emery cloth followed with a hot water wash. Drums that have been renewed using emery cloth should also be followed with a hot water wash.

CAUTION

CAUTION: Failure to replace drums when worn or turned to limits exceeding the maximum allowable diameter will cause drum weakness and reduced braking capacity, which can lead to distortion, higher drum temperatures, and ultimate drum breakage.

Axle Components Cleaning and Inspection

If the drums are turned or replaced, replace the brake linings. Refer to **Group 42** in this manual for instructions.

1. Inspect the inner friction surface. If a veneered (highly glossed) or glazed surface exists, renew the drum by using 80–grit emery cloth or by turning the drums.
2. Inspect for heat checking, which is a form of buckling (cracking) resulting from a temperature differential in the drum wall between a relatively cool exterior and a hot friction surface. Heat checking is normal on all drums and may not impair performance and lining life if the network of fine hairline cracks remains small. Examine heat checks of drums frequently to be certain the checks have not widened into drum weakening cracks (substantial cracks extending to the open edge of the drum). Replace the same-axle drums if substantial cracks are present, or if widening of the fine hairline cracks occurs.

NOTE: If normal heat checking as described above is present, inspect the drums at least every 12,000 miles (19 300 km) thereafter. Inspect the drums (using a flashlight from the inboard side of the wheels) every 6000 miles (9700 km). Inspect more often under adverse operating conditions.

3. Check for a contaminated inner friction surface. If fluids are present, such as oil or grease, remove the contaminants. Locate and correct the source of the contamination. If the brake drums are contaminated with fluids, the brake linings will also be affected. Since oil or grease saturated linings cannot be salvaged, they must be replaced. For brake lining replacement procedures, refer to **Group 42** in this manual.

⚠ WARNING

WARNING: If the brake drums are contaminated with fluids, replace the brake linings. Failure to replace fluid contaminated brake linings could result in a partial loss of braking capacity, which could lead to personal injury or property damage.

4. Measure the inside diameter of the drum. If the measured diameter is greater than the maximum allowable diameter, replace the same-axle drums and linings.
5. Check for a variation in gauge readings at different points on the radius of the drum's working surface. If the variation is more than 0.010 inch (0.25 mm) at any point, the drum is out-of-round to unacceptable limits. Remachine or replace the same-axle drums.
6. Inspect the outside surface of the drum. Remove any accumulation of mud, dirt, or rust; foreign matter acts as an insulator, trapping heat within the drum.
7. Check for hard, slightly raised dark-colored spots on the inner friction surface or for a bluish cast on the brake parts, both of which are caused by high temperatures. If the drums' maximum allowable diameters have not been exceeded, remachine both same-axle drums. If the spots or discoloration cannot be removed, or if remachining is not possible, replace the drums. Also replace the brake shoe return springs.

Wheel Bearing Cup Removal and Installation, Aluminum Hubs

Removal

To insure a tight fit, wheel bearing cups are purposely larger than the wheel hub bores they occupy. To remove the bearing cups, aluminum hub bores must be temporarily expanded by heating the hub in an oven (the bearing cups will also expand, but to a considerably lesser extent). If adequate heating facilities are not available, replace the hub, wheel stud, and bearing cup assembly.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Oven-heat the hub to a temperature range of 240° to 280°F (116° to 138°C). Make sure the oven thermostat is accurately set; if unsure, use an oven thermometer to check the temperature of the oven before placing the hub inside.

   If adequate heating facilities are not available, replace the hub, wheel stud, and bearing cup assembly.

⚠ WARNING

WARNING: Do not use oxyacetylene equipment or similar equipment to heat the hub. Oxyacetylene equipment or similar equipment will cause cracks in the hub which could cause loss of a wheel and loss of vehicle control, leading to personal injury or property damage.

3. Wearing heavy protective gloves, remove the hub from the oven. Place the hub on a suitable press so that the base is fully supported. Quickly press out the bearing cups.

Installation

To install the bearing cups, aluminum hubs must again be temporarily expanded using oven heating. When the hub is properly heated, the bearing cup and hub can be press-fit together, using a suitable press.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Oven-heat the hub to a temperature range of 240° to 280°F (116° to 138°C). Make sure the oven thermostat is accurately set; if unsure, use an oven thermometer to check the temperature of the oven before placing the hub inside.

⚠ WARNING

WARNING: Do not use oxyacetylene equipment or similar equipment to heat the hub. Oxyacetylene equipment or similar equipment will cause cracks in the hub which could cause loss of a wheel and loss of vehicle control, leading to personal injury or property damage.

4. Coat the replacement bearing cup hub contact surface with a film of grease.
5. Wearing heavy protective gloves, remove the hub from the oven.
6. Place the hub on a suitable press so that the base is fully supported. Quickly press-fit the bearing cup into the wheel hub until it is completely and evenly seated. Be careful not to shave the sides of the bearing cup bore as the bearing cup is seated. The accumulation of debris will prevent the cup from being seated and will also cause permanent damage to the wheel hub. If the sides of the bearing cup bore are damaged during installation, replace the wheel hub assembly.
7. Allow the wheel hub to cool before handling. Then, using a 0.0015–inch feeler gauge, check at several places for the seating of the bearing cup in the bearing cup bore. The gauge should not enter beneath the cup. If it does, there is probably dirt or debris preventing the cup from seating. Using the instructions above, remove the cup, then remove the foreign matter. Reinstall the cup.
8. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean, lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Wheel Bearing Cup Removal and Installation, Ferrous Hubs

Removal

Wheel bearing cups on ferrous hubs are removed and installed by driving them out and pressing them in without heating the hub.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Using a mild-steel rod through the opposite end of the hub, drive against the inner edge of the bearing cup. Alternately drive on opposite sides of the cup to avoid cocking the cup and damaging the inside of the hub.

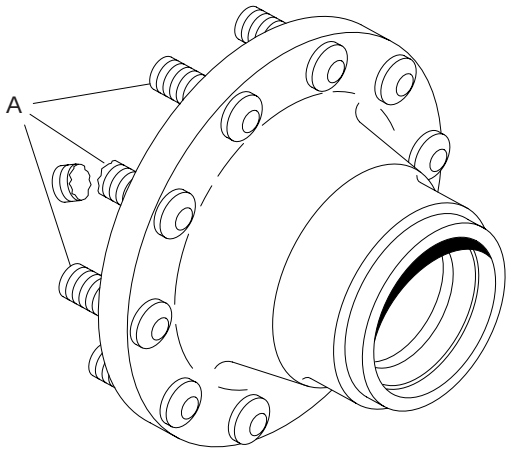
Installation

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Coat the replacement bearing cup hub contact surface with a film of grease.
4. Position the cup in the hub and press it into place, using a suitable driving tool. Cups must seat against the shoulder in the hub.
5. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Replacement

WARNING

WARNING: If a wheel stud breaks, the remaining studs are subjected to undue strain and could fail due to fatigue. When a broken stud is replaced, replace the stud on each side of it. See Fig. 1. If more than one stud is broken, replace all of the studs. Failure to replace the studs could result in the loss of a wheel or loss of vehicle control, possibly resulting in personal injury.



NOTE: Front hub shown.
A. Replace

Fig. 1, Wheel Stud Replacement

1. Remove the wheel hub from the axle. For instructions, refer to **Subject 100**.
2. If a bent portion of a wheel stud will have to pass through the wheel stud bore, cut off the bent portion before removing the wheel stud.
3. Place the wheel hub on a suitable press; make sure the hub flange is supported evenly around and next to the stud being removed. With steady movement, press the damaged stud out of the hub.

CAUTION

CAUTION: Do not use a drift and hammer or concentrated heat for removing and installing the wheel studs. Constant, smooth movement of the wheel stud is necessary to ensure the least amount of metal removal from the wheel stud bore. Concentrated heat will damage the hub. If the hub is damaged during wheel stud removal or installation, replace it.

4. Apply a coating of clean axle grease to the entire shaft on headed studs.
5. With the hub on a suitable press, make sure the hub flange is supported evenly around and next to the stud being installed.
6. Position the stud in its hole. *Be sure the flat edge of the head flange on clipped studs is in line with the shoulder on the hub.*

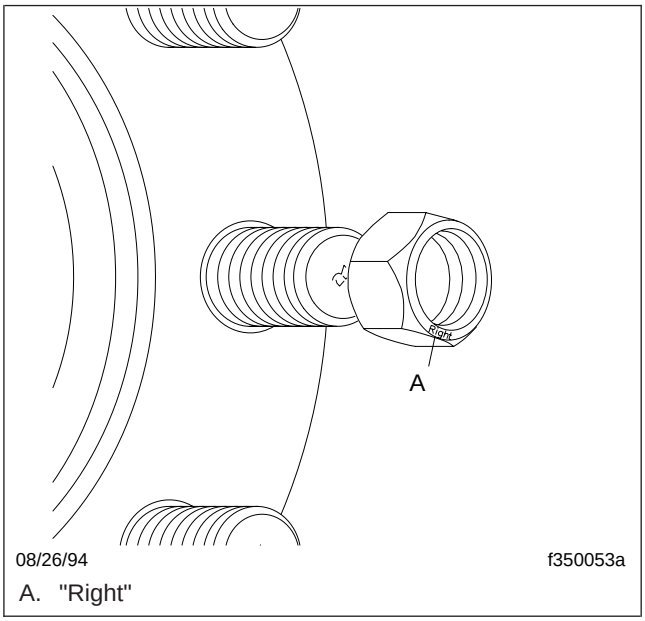
CAUTION

CAUTION: If headed studs with serrations are being installed, position the teeth of the serrated portion in the notches carved by the original wheel studs during factory installation. If additional metal is scraped from the wheel stud bores, the locking action provided by the serrations will be greatly weakened. Loss of locking action will prevent achieving final torque of the wheel nuts during wheel installation. If final wheel nut torques during wheel installation cannot be achieved, replace the wheel hub assembly.

NOTE: If the left side of the vehicle is being serviced, the replacement wheel stud must be stamped with an "L" (left-hand threaded), and the nut's face must be stamped "Left" If the right side of the vehicle is being serviced, the replacement stud must be stamped with an "R" (right-hand threaded), and the nut's face must be stamped "Right" (**Fig. 2**).

7. With steady movement, press the new stud all the way into the hub.
8. Make sure the stud is fully seated and that its head (flange) is not embedded into the hub. If the head of the stud is embedded into the hub, replace the hub.

Wheel Stud Replacement



A. "Right"

Fig. 2, Thread Stamp Location

WARNING

WARNING: Don't embed the wheel stud heads in the wheel hub. Wheel studs with heads embedded in the wheel hub will weaken the wheel hub flange. Weakness in the wheel hub can result in the loss of a wheel or loss of steering control, possibly resulting in personal injury.

9. Wipe off any grease on the wheel studs and wheel hub. Install wheel nuts on dry wheel studs only.
10. Install the wheel hub on the axle. For instructions, refer to **Subject 100**.

Replacement

1. Remove the wheel hub from the axle. For instructions, refer to **Subject 100**.
2. If enough threads remain on the damaged stud, remove it by double-nutting the stud. Turn the inner nut with a wrench in order to remove the stud. Then, proceed to the next step.

   If the drive axle stud is broken near the surface of the hub, the stud should be center-drilled using a high-speed drill, and then removed with an easy-out tool. If needed, grind off a flat surface on the damaged stud, then center-punch the surface as a starting point for drilling. Follow these recommendations:

   2.1 Determine the correct drill diameter by referring to the easy-out tool manufacturer's guidelines. At no time should it be large enough to penetrate the threads of the stud; if the stud threads in the wheel hub are damaged, replace the hub.

   2.2 Do not drill more than 1.25 inches (32 mm) into the broken stud, as measured at the stud's entrance into the wheel hub. Drilling through the bottom of the drive axle stud could damage the hub. If the wheel hub is drilled into, replace it.

   2.3 While drilling, keep the cutting surfaces of the drill well lubricated with oil, which acts as a coolant. Allow the drill and drill bit to cool frequently.
3. After the damaged stud is removed, tap out the drive axle stud hole in the wheel to rid the threads of old stud-locking compound. Use an appropriate sized tap, depending on the original drive axle stud installation size.
4. Be sure the threads of the new stud are clean and dry. Then, coat the insertion end of the drive axle stud (the coarse threads) with an anaerobic thread-lock compound.
5. Using double nuts on the fine-thread portion of the stud, install the new stud. Seat the drive axle stud using the torque values in the torque table in **Specifications, 400**.
6. Allow sufficient time for the thread-lock compound to set, as suggested by the manufacturer.
7. If the hub was removed from the axle, refer to **Subject 100** for installation instructions.

Axilok Spindle Nut Removal, Installation, and Adjustment

General Information

Axilok® spindle nuts are used on ConMet PreSet hubs. See **Fig. 1**. These nuts can be damaged if they are not removed or installed correctly. Use the following guidelines when removing and installing Axilok retaining nuts.

- Use only the correct size, *six-point* socket to remove or install Axilok spindle nuts. Do not use a worn or loose-fitting socket. **Do not use a 12-point socket.**
- Do not use hammers, chisels, pliers, wrenches, or power tools to remove or install Axilok nuts.
- Do not use an Axilok nut if the locking clips are damaged or missing, or if the retainer cage tab or D-flat is damaged or missing.
- Never try to repair a damaged Axilok nut; always replace it with a new one.
- Always start an Axilok installation by hand. A good-fitting six-point socket will completely disengage the nut's locking clips, allowing it to spin freely by hand. See **Fig. 2**. Use an accurately calibrated torque wrench to tighten the nut to its final torque value.

Installation

Instructions for installing an Axilok nut for both PreSet and non-PreSet type bearings are provided in this subject. See the pertinent instructions for the type you are installing.

Using PreSet Bearings

⚠ WARNING

Follow the guidelines at the beginning of this subject when installing an Axilok nut. Axilok retaining nuts secure the hub assemblies on the axle. If the Axilok nut is not correctly installed, the hub could separate from the axle, resulting in severe personal injury or death.

1. Apply a few drops of oil through one of the holes in the Axilok retainer cage to reduce friction between the retainer cage and nut.
2. By hand, install the Axilok nut onto the axle spindle. See **Fig. 1**.

Using Non-PreSet Bearings

For non ConMet PreSet hubs and ConMet PreSet hubs without the bearing spacer and PreSet bearings, proper wheel bearing adjustment is critical to the performance of the bearings, wheel seals, and other related wheel end components.

⚠ WARNING

Follow the guidelines at the beginning of this subject when installing an Axilok nut. Axilok retaining nuts secure the hub assemblies on the axle. If the Axilok nut is not correctly installed, the hub could separate from the axle, resulting in severe personal injury or death.

1. Apply a few drops of oil through one of the holes in the Axilok retainer cage to reduce friction between the retainer cage and nut.
2. Install the Axilok nut and adjust the wheel bearings, as follows.
   - 2.1 By hand, install the Axilok nut onto the axle spindle. Then turn it against the bearing while spinning the hub. See **Fig. 1**.
   - 2.2 Tighten the nut 90 to 110 lbf·ft (122 to 149 N·m) while spinning the hub in both directions.
   - 2.3 Loosen the nut to zero torque, and spin the hub a few turns.
   - 2.4 Tighten the nut 50 lbf·ft (68 N·m) while spinning the hub in both directions. Back off the nut one-eighth to one-sixth turn.
   - 2.5 Remove the wrench from the nut, and verify whether both locking clips are present and engaged in the retainer cage. See **Fig. 2**. If the locking clips are not engaged, advance the Axilok until they are.
3. Using a dial indicator, measure the end play as follows.

   IMPORTANT: Do not measure the wheel bearing end play with the wheel mounted on the hub; you cannot accurately measure or adjust bearing end play with the wheel mounted on the hub. Also, ensure that the brakes are not applied so that that drum and hub can move freely.

   - 3.1 On vehicles equipped with aluminum hubs, install an iron brake drum onto the hub to provide a ferrous surface for the magnetic base of the dial indicator. With flange nuts, secure the drum to the hub using the stud at the 12 o'clock position, followed by the studs at about the 4 o'clock and 8 o'clock positions. Ensure the nuts hold the drum securely; use washers if needed.
   - 3.2 Clean the spindle end; ensure it is free of debris and provides the smooth surface needed for the dial indicator to take an accurate measurement.

⚠ WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use a dial indicator to measure the end play.

4. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm)**. If it is not within this range, remove the Axilok nut, and repeat the tightening sequence as described earlier in this procedure. Once the end play is correct, continue with your service procedure.

Fig. 1, Four-Piece Wheel Bearing Lock Set

Installation

Instructions for installing a four-piece wheel bearing lock set for both PreSet and non-PreSet type bearings are provided in this subject. See the pertinent instructions for the type you are installing.

Using PreSet Bearings

1. Install the adjusting nut onto the axle spindle, and tighten it 300 lbf·ft (407 N·m). See **Fig. 1**.

NOTE: The gaps between holes in the lockring are spaced unevenly, so to fit the tab on the adjusting nut into one of the holes with minimal turning of the adjusting nut, gauge the distance on one side of the lockring, then the other, and choose the side that requires the adjusting nut to be advanced the least. **Do not back off the nut**.

2. Install the lockring (as described in the note above) and nut locking device.
3. Install the jam nut, and tighten it 200 lbf·ft (271 N·m).
4. Rotate the hub in both directions. It should turn freely with no dragging or binding.

Using Non-PreSet Bearings

For non ConMet PreSet hubs and ConMet PreSet hubs without the bearing spacer and PreSet bearings, proper wheel bearing adjustment is critical to the performance of the bearings, wheel seals, and other related wheel end components.

1. Install the adjusting nut, as follows. See **Fig. 1**.
   - 1.1 Install the adjusting nut on the spindle, and tighten it finger-tight.
   - 1.2 While rotating the wheel hub assembly, tighten the adjusting nut 200 lbf·ft (271 N·m).
   - 1.3 Back off the adjusting nut one full turn.
   - 1.4 Tighten the adjusting nut 50 lbf·ft (68 N·m) while rotating the wheel hub assembly.
   - 1.5 Back off the adjusting nut one-quarter turn.

NOTE: The gaps between holes in the lockring are spaced unevenly, so to fit the tab on the adjusting nut into one of the holes with minimal turning of the adjusting nut, gauge the distance on one side of the lockring, then the other, and choose the side that requires the adjusting nut to be turned the least.

2. Install the lockring (as described in the note above) and nut locking device.
3. Install the jam nut, and tighten it 300 to 400 lbf·ft (410 to 540 N·m).
4. Using a dial indicator, measure the end play as follows.

   IMPORTANT: Do not measure the wheel bearing end play with the wheel mounted on the hub; you cannot accurately measure or adjust bearing end play with the wheel mounted on the hub. Also, ensure that the brakes are not applied so that that drum and hub can move freely.

   - 4.1 On vehicles equipped with aluminum hubs, install an iron brake drum onto the hub to provide a ferrous surface for the magnetic base of the dial indicator. With

This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use a dial indicator to measure the end play.

5. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm).** If the end play is not within this range, adjust the end play as follows.

   5.1 Remove the jam nut and locking device, and back off or tighten the inner adjusting nut.

   5.2 Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), turn the adjusting nut again.

   5.3 Measure the end play.

   If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), repeat the adjustment procedure until the correct end play is achieved.

   IMPORTANT: The correct end play **must** be achieved before completing the hub assembly installation procedure.

6. Once the end play is between 0.001 and 0.005 inch (0.03 and 0.13 mm), rotate the hub in both directions. It should turn freely with no dragging or binding.

Each time the Pro-Torq nut assembly is removed for maintenance purposes, replacing the "keeper" is recommended.

Removal

WARNING

Do not place the nut on the spindle or tighten or loosen the nut on the spindle while the keeper is locked inside the nut. Doing so may damage the spindle threads and deform the keeper, and allow the nut to unthread during operation. Failure to follow this instruction could cause the hub to separate from the axle, resulting in severe personal injury or death.

1. Insert the blade of a flathead screwdriver (or similar tool) in the slot of one of the keeper arms; see **Fig. 3**. Ensuring that the tool contacts the keeper and not the teeth of the nut, turn the tool slightly and carefully pry the arm from the undercut groove of the nut.

Pro-Torq Spindle Nut Removal, Installation, and Adjustment

Installation

The following procedure applies to Pro-Torq drive axle nut 449-4973. The part number is stamped on the nut.

⚠ WARNING

Do not place the nut on the spindle or tighten or loosen the nut on the spindle while the keeper is locked inside the nut. Doing so may damage the spindle threads and deform the keeper, and allow the nut to unthread during operation. Failure to follow this instruction could cause the hub to separate from the axle, resulting in severe personal injury or death.

Instructions for installing a Pro-Torq spindle nut for both PreSet and non-PreSet type bearings are provided in this subject. See the instructions pertaining to the bearing type used with the hub you are securing.

Using PreSet Bearings

1. Ensure the keeper is removed from the nut.
2. Install the Pro-Torq spindle nut, and tighten it 250 lbf·ft (339 N·m). **Do not back it off**.

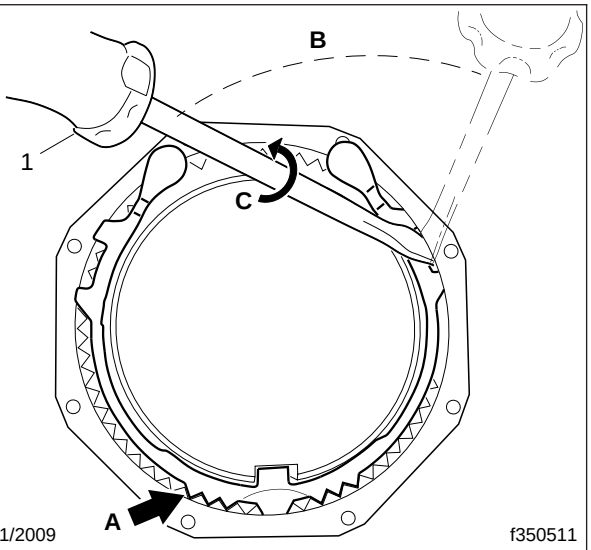
⚠ WARNING

Do not bend or manipulate the keyway tab in any way. Doing so may cause it to break off in service, which could lead to the hub separating from the axle and result in severe personal injury or death.

3. Install the keeper.
   - 3.1 With the protrusions facing outboard, insert the keeper tab in the undercut groove of the Pro-Torq nut and the keyway tab in the spindle keyway.

   IMPORTANT: If the keeper cannot be engaged, advance the nut until it can be. Do not back off the nut.

   - 3.2 Engage the mating teeth.
   - 3.3 Use a flathead screwdriver to carefully compress and guide each arm past the lip and into the undercut groove of the nut as shown in **Fig. 4**. To secure the keeper it may be necessary to nudge the arms into the groove.



A. Engage the mating teeth.
B. Compress the arm.
C. Turn the screwdriver to seat the keeper in the groove.

1. Flathead Screwdriver

Fig. 4, Installing the Keeper

⚠ WARNING

Failure to secure the keeper and lock the Pro-Torq nut could cause the wheel assembly to come off the vehicle, resulting in severe personal injury or death.

4. Inspect the installation; ensure the keeper is locked in the undercut groove and that the keyway tab does not contact the bottom of the keyway.

Using Non-PreSet Bearings

For non ConMet PreSet hubs and ConMet PreSet hubs without the bearing spacer and PreSet bearings, proper wheel bearing adjustment is critical to the performance of the bearings, wheel seals, and other related wheel end components.

1. Ensure the keeper is removed from the nut.
2. Seat the bearings.

Pro-Torq Spindle Nut Removal, Installation, and Adjustment

2.1 Using a torque wrench, tighten the nut 200 lbf·ft (270 N·m). Spin the hub at least one full rotation.

NOTE: Torque is lost when the hub is spun.

2.2 Tighten the nut 200 lbf·ft (270 N·m). Spin the hub at least one full rotation.

2.3 Tighten the nut 200 lbf·ft (270 N·m), but *do not spin the hub*.

3. Loosen the nut to zero torque. *Do not spin the hub*.
4. Adjust the bearing.

4.1 Using a torque wrench, tighten the nut 100 lbf·ft (136 N·m). Spin the hub at least one full rotation.

NOTE: Torque is lost when the hub is spun.

4.2 Tighten the nut 100 lbf·ft (136 N·m). Spin the hub at least one full rotation.

4.3 Tighten the nut 100 lbf·ft (136 N·m).

4.4 Back off the nut one-eighth turn.

WARNING

Do not bend or manipulate the keyway tab in any way. Doing so may cause it to break off in service, which could lead to the hub separating from the axle and result in severe personal injury or death.

IMPORTANT: If the keeper cannot be engaged, advance the nut until it can be. Do not back off the nut.

5. Install the keeper.

5.1 With the protrusions facing outboard, insert the keeper tab in the undercut groove of the Pro-Torq nut and the keyway tab in the spindle keyway.

5.2 Engage the mating teeth.

5.3 Use a flathead screwdriver to carefully compress and guide each arm past the lip and into the undercut groove of the nut as shown in **Fig. 4**. To secure the keeper it may be necessary to nudge the arms into the groove.

WARNING

Failure to secure the keeper and lock the Pro-Torq nut could cause the wheel assembly to come off the vehicle, resulting in severe personal injury or death.

6. Inspect the installation; ensure the keeper is locked in the undercut groove and that the keyway tab does not contact the bottom of the keyway.
7. Using a dial indicator, measure the end play as follows.

IMPORTANT: Do not measure the wheel bearing end play with the wheel mounted on the hub; you cannot accurately measure or adjust bearing end play with the wheel mounted on the hub. Also, ensure that the brakes are not applied so that that drum and hub can move freely.

7.1 On vehicles equipped with aluminum hubs, install an iron brake drum onto the hub to provide a ferrous surface for the magnetic base of the dial indicator. Ensure the nuts hold the drum securely; use washers if needed.

7.2 Clean the spindle end; ensure it is free of debris and provides the smooth surface needed for the dial indicator to take an accurate measurement.

7.3 Attach the magnetic base of a dial indicator to the drum (or, on vehicles equipped with iron hubs, the hub). See **Fig. 5**.

7.4 Set the measuring end of the indicator against the spindle end as shown in **Fig. 6**. The indicator should be square with the end of the spindle.

IMPORTANT: Maintain continual pressure on the hub until you have taken both the inboard and outboard measurements. If you release the hub, an accurate measurement is not possible.

⚠ WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, bearing life will diminish and the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use a dial indicator to measure the end play.

8. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm)**. If it is not within this range, remove the Pro-Torq nut, and repeat

the tightening sequence as described in previous steps. Once the end play is correct, remove the iron brake drum if installed, and continue your service procedure.

If either the lateral or radial runout of the hub is beyond acceptable limits, replace the hub. For instructions, see **Subject 100** in this section.

Measurements

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

2. Remove the wheel and tire assembly. See **Group 40** for instructions.
3. For drum brakes, remove the brake drum. See **Subject 105** for instructions.
4. Clean the hub surfaces where the measurements will be taken—see **Fig. 1** and **Fig. 2**.
5. To measure lateral runout, set up a dial indicator as shown in **Fig. 1**, then turn the hub one revolution and note the highest and lowest measurements.

   For ConMet hubs, the acceptable lateral runout is 0.008 inch (0.2 mm); for other hubs, see the hub OEM for the acceptable lateral runout specification.
6. To measure radial runout, set up a dial indicator as shown in **Fig. 2**, then turn the hub one revolution and note the highest and lowest

   For ConMet hubs, the acceptable radial runout is 0.008 inch (0.2 mm); for other hubs, see the hub OEM for the acceptable radial runout specification.

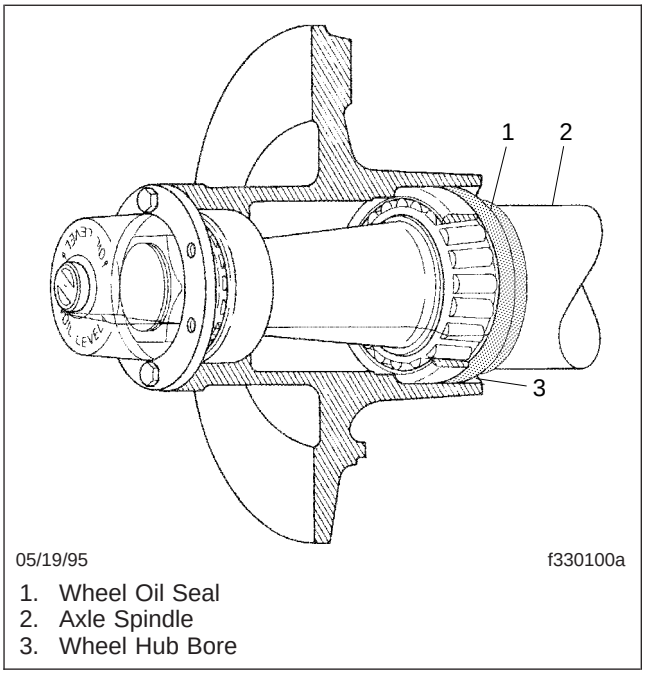
General Information

Wheel oil seals (also called "oil bath seals" or "hub seals") work as a dam to keep oil in the hub cavity so that it constantly "bathes" the wheel bearings. The seals also protect the wheel bearings by keeping dirt, dust, and water out of the hub.

The oil seal fits between the hub bore and the axle spindle (**See Fig. 1**), and the sealing element either turns with the wheel (*hub-mounted seals*) and seals against the axle spindle, or the sealing element stays stationary with the axle spindle (*spindle-mounted seals*) and seals against the turning hub.



1. Wheel Oil Seal
2. Axle Spindle
3. Wheel Hub Bore

Fig. 1, Spindle-Mounted Wheel Oil Seal, Stemco Seal Shown

Until the late 1950's, truck wheel bearings were packed in grease. To retain this type of lubricant, the axle oil seal was pressed into the hub bore and turned with the wheel. Since the late 1950's, truck wheel bearings have been bathed in oil.

But oil bath lubrication created a problem.

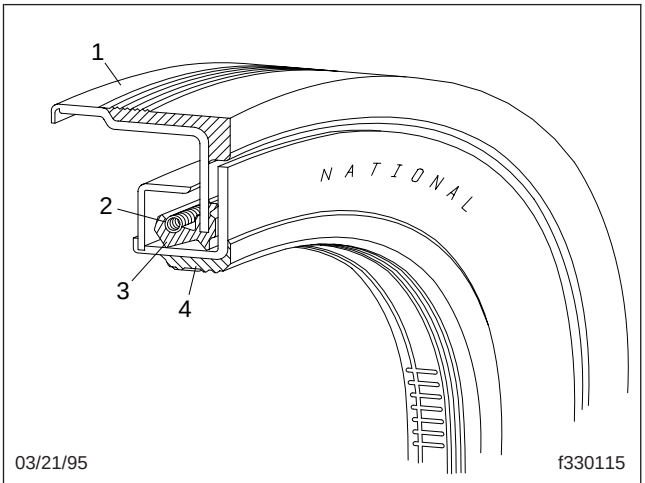
With hub-mounted seals, the turning wheel created enough centrifugal force to pull the sealing element off the axle spindle. This broke the seal, and oil escaped. To keep lube oil inside the hub cavity, the inner edge, or sealing lip, of the seal had to be strong and tight enough that the centrifugal force of the turning wheel would not pull it away from the axle spindle. However, these new, stronger, tighter seals would wear a groove into the spindle sealing surface.

To prevent damage to the spindle, wear sleeves (also called "axle rings") are pressed onto the spindle to absorb the wear from the sealing lip. Later, these wear sleeves were designed to also deflect dirt. These sleeves are called "deflector rings."

Some seal designs avoid the problem of centrifugal force by having the seal pressed onto the axle spindle. This way, centrifugal force drives the sealing element out toward the hub to create the seal.

Most wheel oil seals consist of four basic parts (**Fig. 2**):

- The outside edge (also called the outer "cup" or "case")
- The inside edge (also called the inner "cup" or "case")
- The sealing element
- The garter spring



1. Outside Edge
2. Garter Spring
3. Sealing Element
4. Inside Edge

Fig. 2, Wheel Oil Seal Parts, National Oil Seal, Advanced Design

The outside edge is usually metal coated with rubber or another sealing agent so that it grips the hub bore tight enough to prevent oil escaping between the outer edge of the seal and the hub bore.

General Information

The inside edge is usually metal or rubber with a metal ring within it to prevent the sealing element from wearing a groove in the axle spindle.

The sealing element is usually molded rubber, leather, or a synthetic such as nitrile or silicone. The element is molded into lips which will seal against the axle spindle or against the outside or inside edge described above. The innermost lip, called the "primary lip," keeps the oil inside the hub cavity. The outermost lip, called the "secondary lip," keeps dirt out of the hub cavity.

The garter spring is a coiled wire spring with its ends connected to make a loop. On hub-mounted seals, the spring runs around the outside of the sealing element to press the element inwards against the sealing surface. On spindle-mounted seals, the spring runs around the inside of the sealing element to press the element outward against the sealing surface.

Freightliner uses four brands of axle oil seals:

- Chicago Rawhide (Scotseal® and Scotseal Plus®)
- Eaton (Outrunner™)
- National (5-Star Gold® and Advanced Design®)
- Stemco (Guardian® and SS4®)

Chicago Rawhide (See Fig. 3)

The Chicago Rawhide Scotseal is a unitized, one-piece design consisting of a sealing element (packing) that is assembled between metal outer and inner cups. The sealing element consists of three sealing lips; a spring-loaded primary sealing lip that is factory pre-lubed and two dirt exclusion lips. The seal is press fit into the hub bore using Scotseal service installation tools. *Do not install the Scotseal directly onto the axle spindle.*

Although you install the Scotseal into the hub bore, the seal's element grips the axle spindle tightly enough that the sealing element stays stationary with the spindle and seals against the outer cup which turns with the hub.

The Chicago Rawhide Scotseal maintains a metal-to-metal contact between the outer cup and the hub bore surface as well as a metal-to-metal contact between the sealing element inside edge and the axle spindle.

Eaton (See Fig. 4)

The Eaton Outrunner has a rubber-coated outside edge and is installed in the hub bore using Eaton installation tools.

National (See Fig. 2 and Fig. 5)

National wheel oil seals are hub-mounted, with a rubber-coated outside edge that grips inside the hub bore and also holds the sealing element. The element turns with the hub and seals against the inside edge of the seal which grips the axle spindle and acts as a wear sleeve. The shield protects the sealing element, and holds the two parts (the outside and inside edges) together.

The 5-Star Gold seal features a Teflon® lay-down sealing lip compatible with any combination of mineral and/or synthetic gear lubricants and/or greases.

Stemco (See Fig. 6 and Fig. 7)

The Stemco wheel oil seals are spindle-mounted, with a rubber-coated outside edge that grips inside the hub bore and also holds the sealing element.

Although you install the Stemco seal onto the axle spindle, the outside edge grips the hub bore tight enough that the sealing element turns with the hub and seals against the inside edge which grips the axle spindle and acts as a wear sleeve.

Seal Replacement, Chicago Rawhide

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

NOTE: This procedure applies to the Chicago Rawhide Scotseal®.

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 35.01**.
2. Remove the inner wheel bearing assembly from the axle. Handling the bearings with clean dry hands, wrap the bearings in clean oil-proof paper or lint-free cloths. Occasionally, the inner wheel bearing cone assembly will remain in the hub after the hub is removed from the axle. In those cases, place a protective cushion to catch the bearing assembly. Using a hardwood drift and a light hammer, gently tap the bearing and seal out of the inner wheel bearing cup.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity. See **Fig. 1** and **Fig. 2**.
4. Remove all burrs from the shoulder and the seal bore with an emery cloth or a file. Clean any metal filings from the components.

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

5. Inspect the bearings and hub components for wear or damage. Replace any worn or damaged components as necessary.
6. Coat the wheel bearing cones with oil.
7. Install the inner wheel bearing cone in the inner wheel bearing cup.

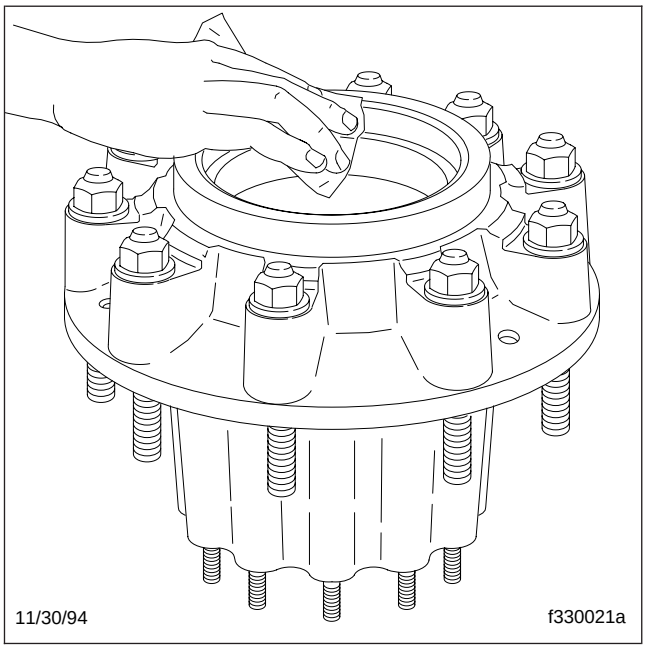

Fig. 1, Clean the Hub

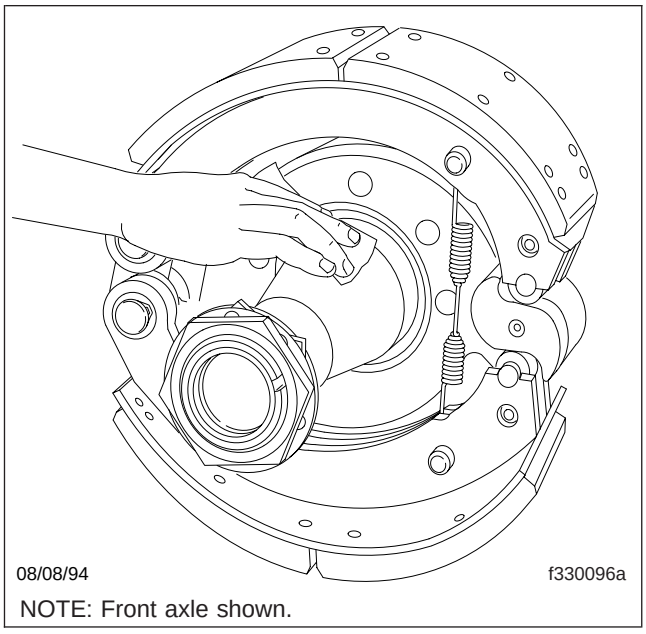

Fig. 2, Clean the Spindle

8. Seat the small outside edge of the seal in the recess of the tool adapter. See **Fig. 3**. The correct adapter is identified on the box.

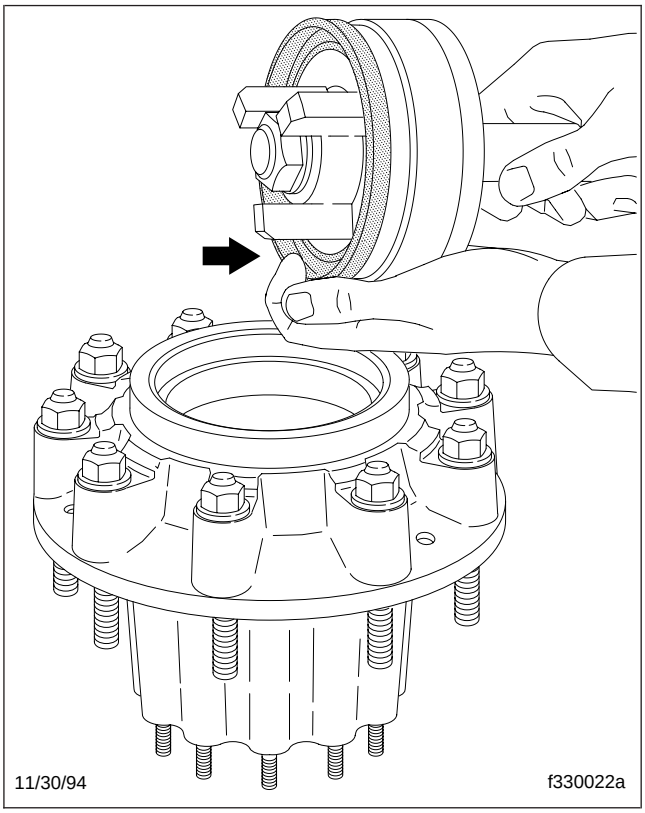

Fig. 3, Place the Seal on the Installation Tool

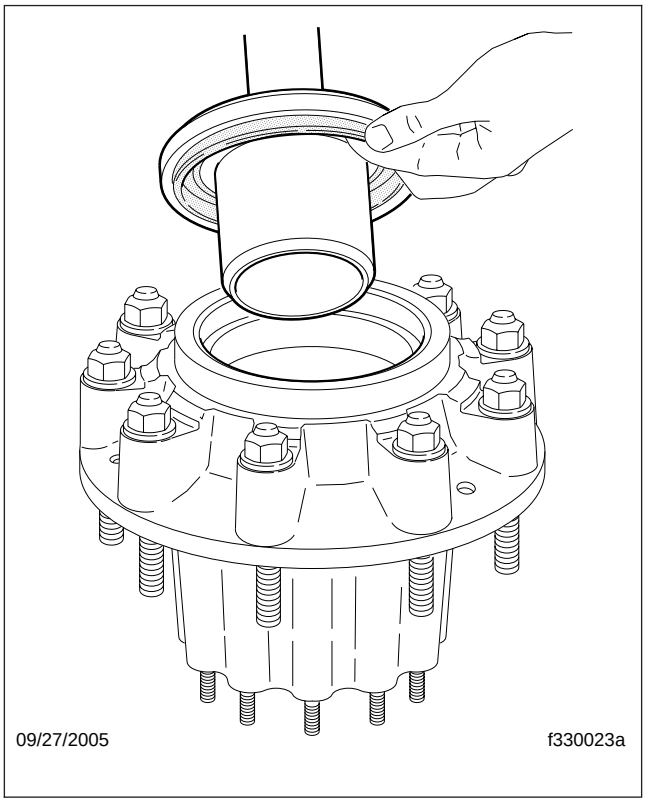

Fig. 4, Insert the Tool in the Hub Bore

9. Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 4**. The plug prevents cocking of the seal in the bore.
10. Hold the tool handle firmly, and strike it until the sound of the impact changes as the seal bottoms out. See **Fig. 5**. Hold the tool firmly to avoid bounce or unseating of the seal from the adapter.
11. After the seal is bottomed in the bore, check for freedom of movement by manually moving the interior rubber part of the seal back and forth. A slight movement indicates a damage-free installation.
12. Install the wheel, drum, and hub on the axle and adjust the wheel bearings. For instructions, see **Section 35.01**.

Seal Replacement, Dana Spicer® Outrunner™

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

NOTE: This procedure applies to the Dana Spicer Outrunner seal.

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 35.01**.
2. Remove the inner wheel bearing assembly from the axle. Handling the bearings with clean dry hands, wrap the bearings in clean oil-proof paper or lint-free cloths. Occasionally, the inner wheel bearing cone assembly will remain in the hub after the hub is removed from the axle. In those cases, place a protective cushion to catch the bearing assembly. Using a hardwood drift and a light hammer, gently tap the bearing and seal out of the inner wheel bearing cup.

⚠ CAUTION

Never use a sharp chisel to cut through an axle ring (wear sleeve). A sharp chisel could damage the spindle or shoulder.

3. Remove the steel axle ring (wear sleeve) by striking the ring surface several times with a ball-peen hammer. See **Fig. 1**. Remove the stretched axle ring from the spindle.
4. Clean and inspect the bearings, the spindle, spindle threads, seal bore, and the hub cavity.

   IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

   4.1 Inspect the inner hub bore. Remove dirt and contaminants from all recesses and corners. Smooth any sharp edges with emery cloth, and fill in any grooves with filler. See **Fig. 2**.

   4.2 Wipe the hub area with a clean shop cloth.

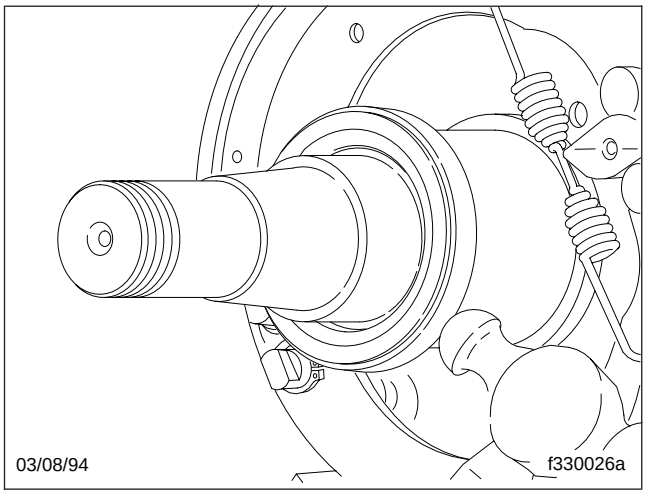

Fig. 1, Removing the Axle Ring

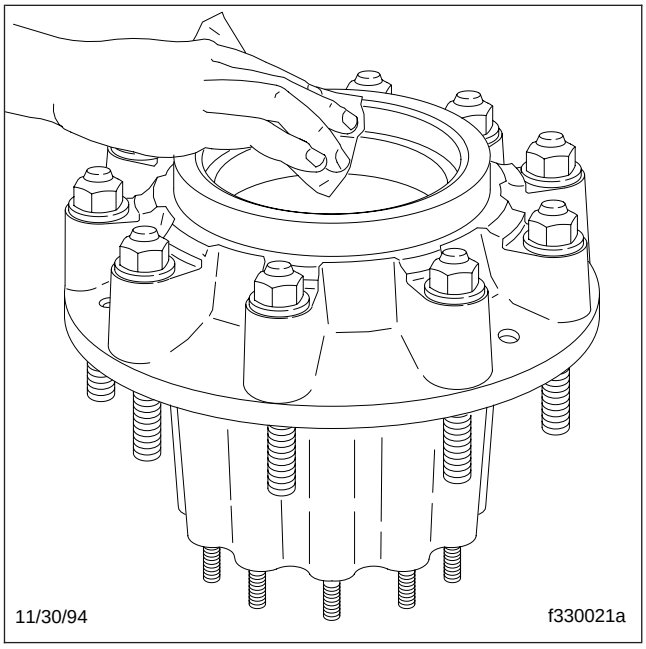

Fig. 2, Clean and Inspect the Hub Bore

   4.3 After removing the wear sleeve, inspect the spindle. Remove any sharp edges and burrs from the leading edges and the shoulder area. Repair deep gouges with filler and smooth with an emery cloth. See **Fig. 3**.

   4.4 Wipe the seal and shoulder area with a clean shop cloth.

Seal Replacement, Dana Spicer® Outrunner™

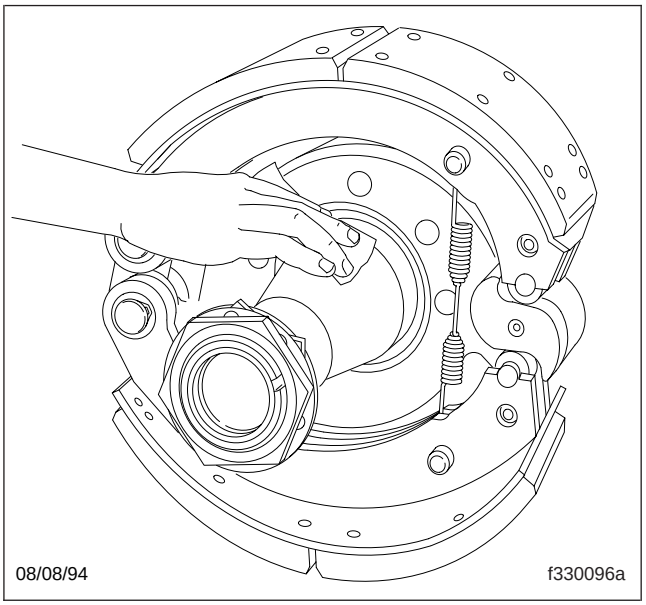

Fig. 3, Clean and Inspect the Axle Spindle

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

4.5 Inspect the bearings and hub components for wear or damage. Replace any worn or damaged components as necessary.

4.6 Coat the wheel bearing cones with oil.

5. Install the inner wheel bearing cone in the inner wheel bearing cup.

IMPORTANT: Use the Dana Spicer Outrunner installation tool *with the centering tool* when installing the seal. See **Fig. 4**.

6. Install the oil seal in the hub bore.

⚠ CAUTION

Do not use any silicone or permatex type bore sealant with this seal. The Dana Spicer Corporation recommends a light coating of bearing oil on the outer circumference of the seal.

Do not mix lubricants of different grades. Do not mix mineral and synthetic lubricants. Do not pack the bearings with grease when using an oil bath

system. Failure to follow these installation guidelines will result in less than desired performance of the Outrunner seal, and installation-related failures are not covered under warranty.

6.1 Place the Outrunner seal tool with the words "air side" facing the adapter plate of the installation tool. See **Fig. 5**. Lubricate the seal outer circumference with wheel bearing oil.

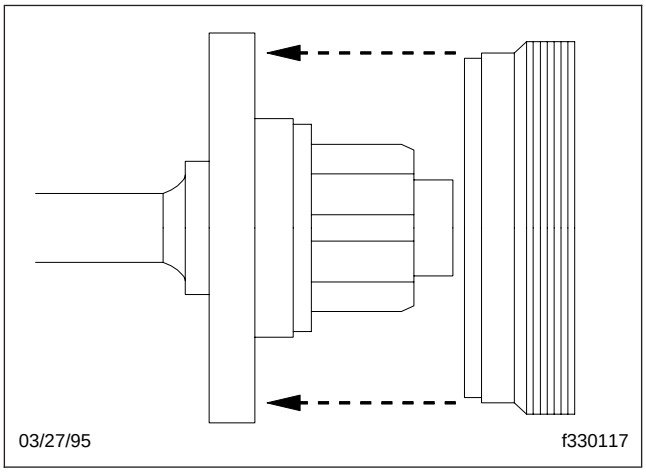

Fig. 5, Seal Placement on Tool

IMPORTANT: Install the seal in the hub bore with the hub lying flat. Do not install the seal with the hub in the vertical (upright) position.

6.2 With the hub and the wheel assembly lying flat on the floor, place the inner bearing cone in the cup.

6.3 Position the oil seal in the hub bore. Before striking the handle of the installation tool, tap the adapter plate around the outer edge to position the seal. See **Fig. 6**.

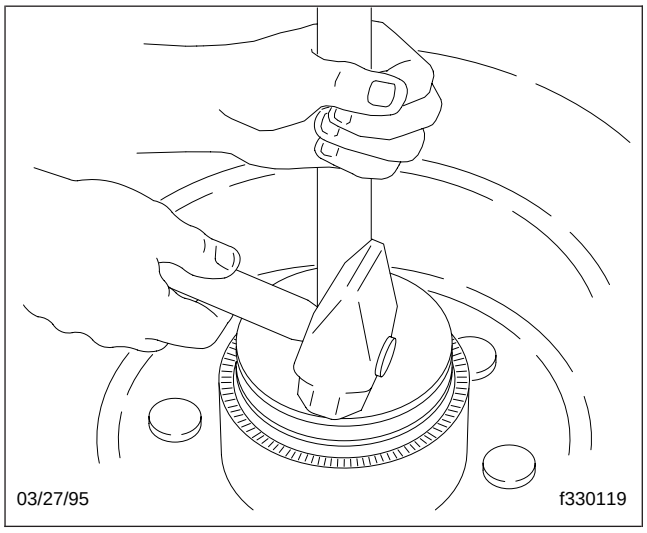

Fig. 6, Position the Seal

6.4 Hit the handle of the installation tool *gently*. See **Fig. 7**.

Because of the rubber outer circumference, the Outrunner seal is easier to install than seals with metal outer circumferences. When the adapter plate bottoms out on the hub surface, the seal is installed correctly. You will hear a metal-to-metal sound.

6.5 Check that the seal is not cocked, and that the unitized seal inner circumference and inner bearing turn freely.

6.6 Lubricate the inner circumference of the seal with a light film of clean bearing oil.

7. Install the wheel, drum, and hub on the axle and adjust the wheel bearings. For instructions, see **Section 35.01**.

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 35.01**.
2. Remove the old oil seal from the hub or spindle.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity.

⚠ CAUTION

Never use a sharp chisel to cut through an axle ring. A sharp chisel could damage the spindle or shoulder.

4. Remove the steel axle ring by striking the ring surface several times with a ball-peen hammer. See **Fig. 1**. Remove the stretched axle ring from the spindle.

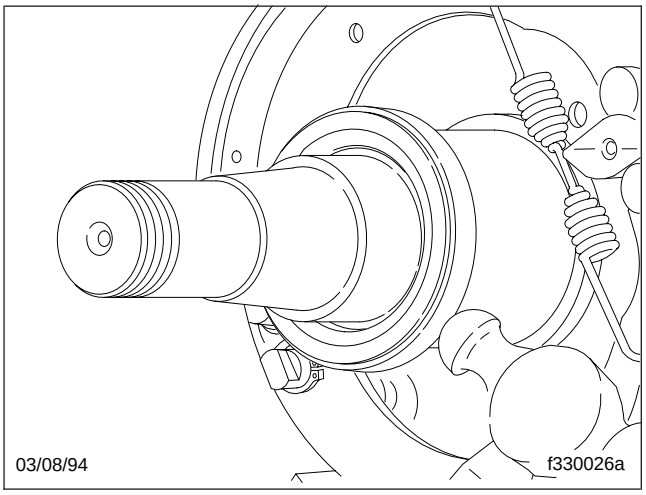

Fig. 1, Remove the Axle Ring

5. Inspect the spindle shoulder and hub bore.
   - 5.1 If necessary, use a file to remove burrs from the leading edges and shoulder area.
   - 5.2 Fill any deep scratches with a hardening compound and smooth it with an emery cloth. See **Fig. 2**.

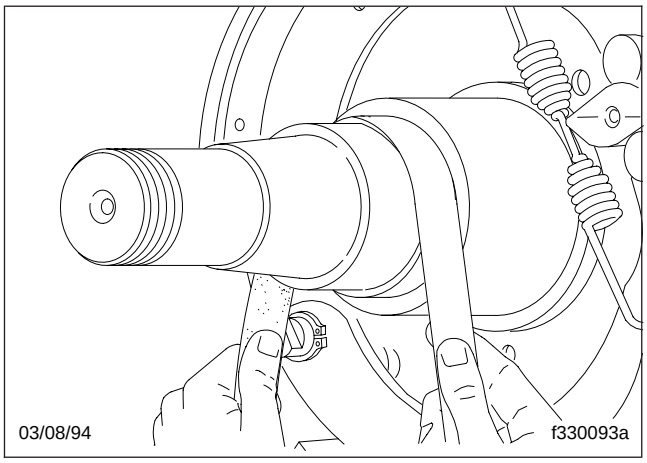

Fig. 2, Clean the Axle Spindle

   - 5.3 Use a clean cloth to remove all dirt, grit, and metal filings.
   - 5.4 Check the seal for a correct fit by placing the seal on the axle spindle, up to the first rubber rib. The correct seal will not go any farther.

   IMPORTANT: Clean the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause rapid wear of the bearing assembly.

   - 5.5 Inspect the hub bore, and remove any burrs from the leading edge with an emery cloth.

6. Select the seal installation tools designed for use with National oil bath seals. These should include a universal handle, an adapter plate, and a bearing pilot. See **Fig. 3**.

7. Install the seal in the hub.

Seal Replacement, National®

CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

7.1 Prelube the inner bearing cone with clean oil and place it in the hub. See **Fig. 4**.

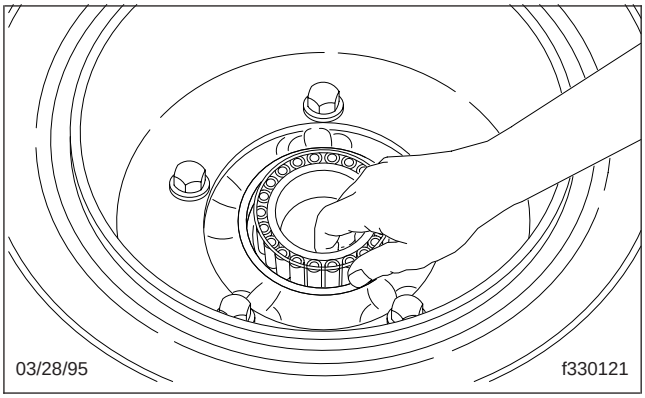

Fig. 4, Place the Bearings in the Hub

7.2 Place the oil bath seal on the installation tool with the words "air side" facing the adapter plate. Lubricate the outside edge of the seal with clean oil to ease the installation. See **Fig. 5**.

Replacement

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 35.01**.
2. Remove the old oil seal from the hub or spindle.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity.

⚠ CAUTION

Never use a sharp chisel to cut through an axle ring. A sharp chisel could damage the spindle or shoulder.

4. Remove the steel axle ring by striking the ring surface several times with a ball-peen hammer. See **Fig. 1**. Remove the stretched axle ring from the spindle.

5. Using a wire brush, remove any old sealant and corrosion from the axle spindle and shoulder. Remove any burrs with an emery cloth. See **Fig. 2**. Wipe the spindle and shoulder clean with safety solvent.

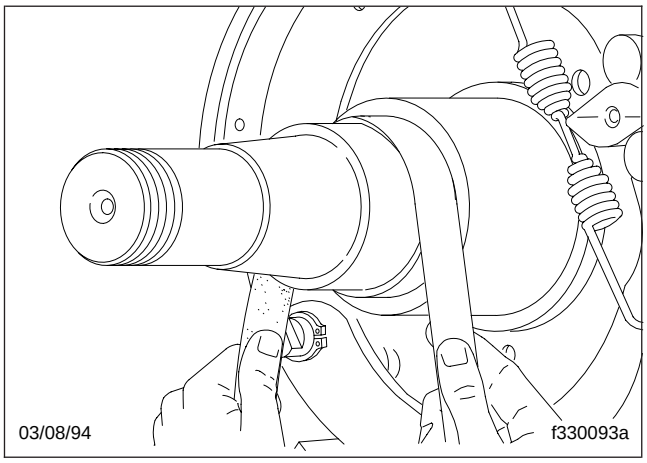

Fig. 2, Clean the Axle Spindle

6. Remove any burrs from the inside of the hub bore. See **Fig. 3**. The hub bore must be free of burrs that will scratch the outer surface of the seal and allow oil to escape from the hub. Remove any spacer rings or washers, if so equipped.

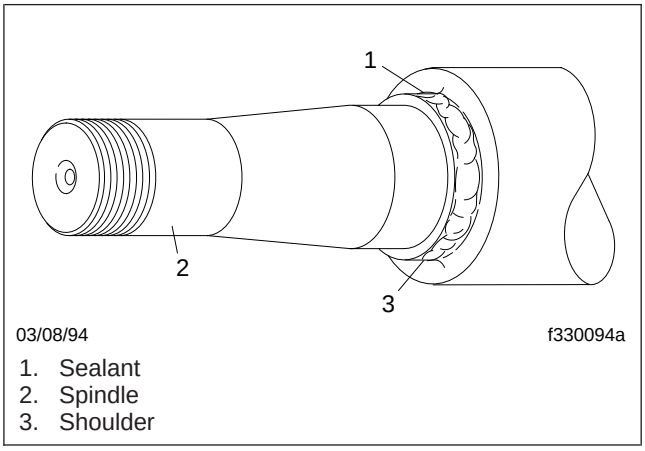
7. Inspect the bearings and hub components for wear or damage. Replace any worn or damaged parts as necessary.

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

8. If burrs were removed from the spindle shoulder, apply a thin layer of non-hardening sealant to the spindle shoulder. See **Fig. 4**.



1. Sealant
2. Spindle
3. Shoulder

Fig. 4, Apply Sealant to the Spindle Shoulder

NOTE: Use a non-hardening sealant such as Permatex® Number-2 or Loctite® 515.

9. Place the oil seal on the spindle so the words "oil-bearing side" are exposed to the oil. A slight step on the inside circumference of the seal ring will allow it to be placed by hand about 1/8 inch (3 mm) onto the shoulder. See **Fig. 5**.

⚠ CAUTION

Do not install the oil seal in the hub bore. Incorrect seal installation will damage the seal and lead to possible spindle, hub, and bearing damage.

10. Position the Stemco installation tool over the spindle. See **Fig. 6**. Using a 3 to 5 lb (1 to 2 kg) hammer, drive the seal on the spindle until the tool bottoms against the shoulder. After the tool bottoms, turn it while applying several light taps with the hammer to ensure the seal ring is flush with the face of the shoulder. Wipe off all excess sealant.

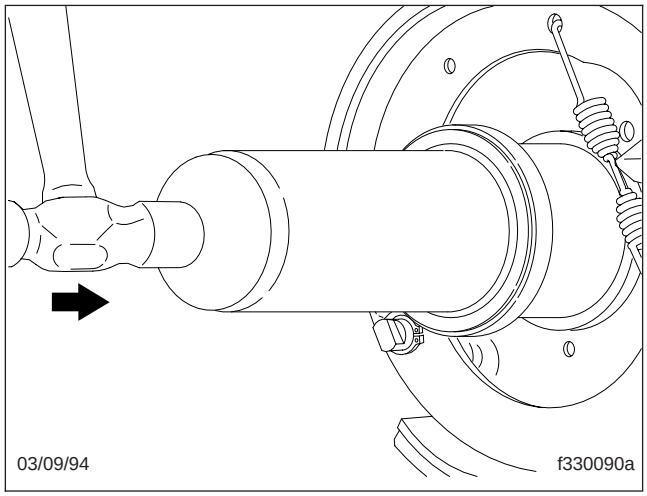

Fig. 6, Drive the Seal onto the Spindle

IMPORTANT: Use only the tool specified by Stemco for the vehicle's axle. In order for the Stemco warranty to apply, the product must be correctly installed using the correct tool made by Stemco or a tool approved by Stemco.

11. Make sure there are no gaps between the ring and shoulder. See **Fig. 7**.

12. Coat the inner wheel bearing with oil and install it on the spindle. See **Fig. 8**. No additional oil is

General Information

Detroit rear axles are compatible with industry-standard brakes, hubs, and wheel bearings.

The following explains an example of the number found on a Detroit rear axle identification tag, which is located on the carrier. See **Fig. 1**.

Typical Model Number: ART-40.0-4

- *ART* = tandem rear axle
- *40.0* = weight rating (times 1000 lb)
- *4* = basic model number

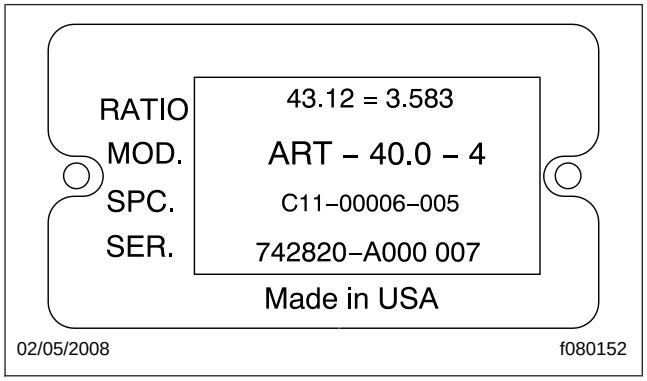

Fig. 1, Rear Axle ID Tag

Detroit rear axles may have a main differential lock, which is commonly known as the "DCDL" (Driver-Controlled Differential Lock). The DCDL is an optional feature that can lock the differential assembly to improve traction on icy road conditions. When the differential lock is engaged, the clutch collar completely locks the differential case, gearing, and axle shafts together to maximize traction of both wheels and protect against spinout. Each part of the DCDL is replaceable; see **Subject 180**.

On tandem axles there are three possible differential lock options: forward-rear carrier only, rear-rear carrier only, or both rear carriers.

NOTE: Detroit axles are a proprietary product, though in some applications they may be referred to as "Freightliner" or "Axle Alliance" axles or "MB components."

Warranty

To assist in the determination of warrantable and non-warrantable failures for these axles, warranty evaluation guides are available through WarrantyLit on **www.accessfreightliner.com**. These guides help determine whether or not pre-approval is needed for a repair. The following evaluation guides are available:

Single or Rearmost Axle Removal and Installation

Removal

For rear axle components, see **Fig. 1**.

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires. Put the transmission in neutral.
2. Using a suitable jack, raise the vehicle enough to take the weight off the axles, but not enough to raise the tires off the ground.
3. At both ends of the axle, loosen all the wheel nuts.
4. Continue to raise the vehicle evenly until there is room to fit a stand underneath the axle housing.

⚠ WARNING

Never work around or under a vehicle that is supported only by a jack. Always support the vehicle with safety stands. Jacks can slip, allowing the vehicle to fall, which could result in serious injury or death.

5. Support the vehicle with safety stands.
6. Remove the tire and wheel assemblies.
7. Drain the oil from the differential housing. Install the drain plug.
8. Disconnect the driveshaft from the differential carrier. For instructions, see **Section 41.00, Subject 120**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.

9. Release the parking brakes.
10. Cage the parking brake springs to prevent the parking brakes from engaging. For instructions, see **Group 42**.
11. If DCDL is installed on the vehicle, use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged. Turn the appropriate hubs to ensure the lock is fully engaged.
12. Drain the air system.
13. Place a basin under the axle shaft flanges to catch any oil, then remove the axle shafts. For instructions, see **Subject 120**.
14. Disconnect the DCDL air line from the carrier housing.
15. If necessary, back off the slack adjusters, then remove the brake drums.
16. Remove the hubs from the axle spindles. For instructions, see **Section 35.01, Subject 100**.
17. Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
18. If applicable, disconnect the leveling valve rod(s) from the suspension.
19. At the frame rail or crossmember, disconnect the wiring for the ABS sensors. Remove any tie straps that hold the wires to the frame rails.
20. Disconnect the air lines from the rear brake chambers.
21. Remove the brake air chambers and the slack adjusters from the axle housing. For instructions, see **Group 42**.
22. Remove the ABS sensors and wiring, and the fasteners that hold the brake spiders to the axle flanges. Remove the spiders from the axle.
23. Using a suitable jack, support the axle housing.
24. If applicable, remove the hexnuts that hold the bottom of each suspension air bag to its suspension bracket.
25. Remove the suspension components that attach the axle to the vehicle. If applicable, remove the U-bolt nuts from the U-bolts. Discard the U-bolt nuts and U-bolts.
26. Lower the axle enough to clear the suspension components.
27. Remove the axle from the vehicle.
28. If you are going to replace the differential carrier, place the axle on a secure axle stand.

Installation

1. Position the axle underneath the vehicle.
2. Install the suspension components that attach the axle to the vehicle, as follows.

   NOTE: U-bolts and U-bolt nuts cannot be reused.

   2.1 On vehicles with conventional suspensions, install the upper U-bolt brackets, new U-bolts, lower U-bolt brackets, and new U-bolt nuts.

   On vehicles with air suspensions, in addition to the U-bolts, install the hexnuts that attach the air springs to the suspension brackets. For torque values, see **Group 32**.

   On vehicles without U-bolts, install the walking beams.

   2.2 If applicable, tighten the new U-bolt nuts in a diagonal pattern. For torque values, see **Group 32**.
3. Connect the driveshaft to the differential carrier yoke. For instructions, see **Section 41.00, Subject 120**.
4. Install the brake spiders on the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
5. Install the ABS sensors and connect the wiring at the frame rail. Secure the wiring with tie straps as needed.
6. Install the brake air chambers and slack adjusters on the axle housing brackets. For instructions, see **Group 42**.
7. Connect the air lines to the brake air chambers.
8. Install the brake shoes, as removed. For instructions, see the applicable service brake section in **Group 42**.
9. Fill each hub with approved axle oil until you can see a little amount of oil trickling out of the back of the hub (use about 0.8 quart, or 0.75 liter). Install the hubs on the axle spindles, and adjust

the wheel bearings. For instructions, see the applicable subject in **Section 35.01**.

NOTE: See **Table 1** for approved axle oils.

10. If DCDL is installed on the vehicle, connect the DCDL air line, fill the air system, and use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged.
11. Using new gaskets, install the axle shafts. For instructions, see **Subject 120**.
12. Install the brake drums on the hubs.
13. Install the wheels and tires. For instructions, see **Group 40**.
14. Adjust the brakes. For instructions, see the applicable service brake section in **Group 42**.
15. Uncage the parking brake springs.
16. Using approved axle oil, fill the axle housing to the bottom of the fill hole, or until filled to capacity as shown in **Table 1**.
17. If the hubs are dry, raise one side of the vehicle about 4 inches (10 cm) to let the oil flow into the hub on the opposite side, then raise the other side in the same manner. On each side, hold the tilted position for three minutes to allow oil to run into the wheel end.

NOTICE

Make sure the hubs are filled. Driving with the hubs dry will cause bearing damage.

18. Turn the wheels, wait one minute, and check the lubricant level.
19. Raise the vehicle, remove the safety stands, then lower the vehicle.
20. If applicable, connect the suspension leveling valve(s). Start the engine, build the air pressure, and make sure the suspension air bags inflate correctly. Make sure the ride height is correct. For instructions, see **Group 32**.
21. Check the oil level in the axle housing. The level should be up to the bottom of the fill hole. Add approved axle oil, if needed.
22. Set the parking brake, then remove the chocks from the tires.

Single or Rearmost Axle Differential Carrier Removal and Installation

When the wheel lock is removed, inspect the carrier for damage and replace it if damage is found. If no damage is found, install the carrier again.

Removal

NOTE: The differential carrier can be removed either with the rear axle installed on the vehicle or with the rear axle removed from the vehicle.

Axle Installed on Vehicle

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires. Put the transmission in neutral.
2. If applicable, release the suspension air pressure.
3. Using suitable jacks, raise the vehicle evenly until there is room to fit a jack underneath the axle housing.
4. Remove the tires and wheels. For instructions, see **Group 40**.
5. Remove the oil drain plug from the bottom of the axle housing and drain the oil from the axle housing. Install the drain plug after emptying.
6. Disconnect the driveshaft from the carrier yoke. For instructions, see **Section 41.00, Subject 120**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
7. If DCDL is installed on the vehicle, use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged. Turn the appropriate hubs to ensure the lock is fully engaged.
8. Place a basin under the axle shaft flanges, then remove the axle shafts. For instructions, see **Subject 120**.
9. Do the steps under the heading, "Axle Removed from Vehicle."

Axle Removed from Vehicle

1. Using a suitable jack, support the differential carrier. Chain the differential carrier to the jack.
2. If DCDL is installed on the vehicle, ensure the lock is engaged. Turn the appropriate hubs to verify it is fully engaged.

⚠ WARNING

The differential carrier is heavy. Do not try to move it without a suitable support. To do so could result in the carrier falling, which could cause serious personal injury and component damage. Support the carrier with a suitable jack and chain it to the jack, or use a hoist if the axle has been removed from the vehicle.

3. Remove the carrier capscrews that hold the differential carrier to the axle housing. See **Fig. 1**.
4. With the differential carrier securely supported, remove it from the axle housing.

Installation

IMPORTANT: If you replace the yoke on the differential carrier, use a **new** nut when installing the new yoke.

NOTE: Use a cleaning solvent and clean rags to remove dirt. Blow dry the cleaned areas with air.

1. Remove any old sealant material from the mating surfaces of the axle housing. Clean the inside of the rear axle housing and the forward carrier mating surface.
2. Inspect the axle housing for damage. Repair or replace the axle housing as necessary.
3. Apply a thin bead of Loctite® 5900 sealant all the way around the mating surface of the axle housing, and around each bolt hole.

NOTE: Alignment dowels for installing the differential carrier can be made by sawing off the heads of two M16 x 1.5 x 100 mm bolts.

4. Install alignment dowels 180 degrees apart at the 3 o'clock and 9 o'clock positions on the axle housing flange.
5. If DCDL is installed on the vehicle, ensure it is engaged.

NOTICE

Make sure the differential carrier is centered and straight on the axle housing before you install the mounting capscrews. Attempting to install the carrier when it is not centered or straight may cause damage to the carrier.

21. Remove the chocks from the tires.

Removal

1. Chock the front tires.
2. Raise the rear of the vehicle with a suitable jack high enough to clear the axle. Support the axle with jack stands.
3. If DCDL is installed on the vehicle, use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged. Turn the appropriate wheels to ensure the lock is fully engaged.
4. Place a basin under the axle shaft flanges to catch any oil. Dispose of used oil properly.
5. If necessary, remove the tires. For procedures, see **Group 40**.

NOTE: This procedure can be done with the wheels and tires installed or with the wheels and tires removed.

6. Remove the drive axle stud nuts that attach the axle shaft to the wheel hub.
7. Tap the axle shaft flange if necessary to loosen it, then slide the axle shaft out of the axle. Remove and discard the gasket.

Installation

2. If DCDL is installed on the vehicle, ensure it is engaged.
3. Install the axle shaft, as follows. See **Fig. 1**.
   - 3.1 Carefully raise the axle with a floor jack, and support the axle with jack stands. Slide the axle shaft into the axle.
   - 3.2 Apply light pressure with the hand or knee to the axle flange.
   - 3.3 Use an adjustable wrench to center the shaft. Turn the shaft with a slight rotating motion.
4. Install the drive axle stud nuts and tighten them to the values given.
   - 1/2–20 nuts: 75 to 115 lbf·ft (102 to 156 N·m)
   - 5/8–18 nuts: 150 to 170 lbf·ft (203 to 230 N·m)

   NOTE: Use a pry bar that has a round end to help separate the carrier from the housing.

   - 9.4 When the surfaces are separated, finish removing the top two capscrews.
   - 9.5 With the carrier on the jack, slide the carrier away from the rear axle housing.

⚠ WARNING

The differential carrier is heavy. Do not try to move it without a suitable support. To do so could result in the carrier falling, which could cause serious personal injury and component damage. Support the carrier with a suitable jack and chain it to the jack, or use a hoist if the axle has been removed from the vehicle.

   - 9.6 Lift the carrier assembly onto a suitable stand.

4. Pry up the output oil seal, using a prybar or large screwdriver. Clean any old sealant from the axle housing. Do not allow dirt or grease to contaminate the seal bore or thru-shaft bearings.
5. Install the seal on the thru-shaft, as follows.

   5.1 Inspect the area around the output oil seal for damage. Use emery paper to remove scratches, nicks, or burrs on the seal bore.

Forward-Rear Axle Yoke and Seal Replacement

5.2 Assemble the output seal installer onto the threaded end of the universal handle. See **Table 1**.

5.3 Using the output seal installer assembly, press the seal into the bore until the seal surface is flush with the thru-shaft receptacle.

6. Install the output yoke on the thru-shaft. If the yoke is damaged or worn, install a new yoke.

NOTE: It is not necessary to replace the yoke when replacing the seal.

7. Coat the threads of a new M39 x 1.5 output yoke nut with Loctite® 577. Install the new washer and output yoke nut on the forward carrier output yoke. Tighten the nut 516 lbf·ft (700 N·m).
8. Connect the interaxle driveshaft. For instructions, see **Section 41.00, Subject 120**.

Main Differential Lock Disassembly and Assembly

General Information

Commonly known as DCDL (Driver-Controlled Differential Lock), a main differential lock is available on single and tandem rear axles. On tandem rear axles DCDL is available for the forward, rear, or both axles. The following procedures only apply to Model 4 rear axles with optional DCDL.

Each part of the main differential lock is replaceable. See **Fig. 1**.

Fig. 1, DCDL Components

Disassembly

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the front tires.
2. Remove the differential carrier, and place it on a work stand.

   To remove a single or rearmost axle differential carrier, see **Subject 110**.

   To remove a forward-rear differential carrier, see **Subject 140**.
3. Unlatch the retaining clip, and remove it. See **Fig. 1**.
4. Remove the clutch collar.
5. Remove the DCDL sending unit from the carrier housing.
6. Remove the three bolts that attach the air interface to the carrier housing.
7. Remove the air interface and gasket.
8. Remove the shift shaft piston from the bore in the carrier housing, and note the number of shims found on the piston. There should be at least one shim, and a maximum of three.
9. Compress the spring and pull the shift fork from the carrier housing.
10. Remove the spring from the carrier housing.

Assembly

1. Install the spring in the carrier housing, and compress it to install the shift fork in the housing. Ensure that the spring is centered in the bore.
2. Ensure the O-ring on the shift shaft piston is properly installed and lubricated. Then install the piston, being careful to properly align it in the bore. Do not force the piston into the bore.
3. Place the air interface and gasket over the air interface bore, and insert the three capscrews that attach the air interface to the carrier housing. Tighten the capscrews in a regular sequence that ensures it seats evenly. Tighten the capscrews 19 lbf·ft (25 N·m).
4. Install the clutch collar.
5. Install the retaining clip on the shift fork.

Main Differential Lock Disassembly and Assembly

6. Install the DCDL sending unit in the carrier housing, as removed.
7. Connect the DCDL air line, and engage the DCDL. Ensure the teeth of the lock fully engage the teeth of the gear inside the carrier housing.
8. The clearance between the clutch collar and ring gear must be between 0.4 and 1.4 mm. Engage the DCDL, and use a feeler gauge to measure the gap.

   If the gap between the clutch collar and ring gear measured between 0.4 and 1.4 mm, ensure the same number of shims are on the shift shaft piston (as when it was removed).

   If the gap between the clutch collar and ring gear was not between 0.4 and 1.4 mm, add or remove shims to vary the gap until it measures within the acceptable range. The acceptable maximum number of shims is three, and the minimum is one.
9. Install the differential carrier.

   For instructions on installing a single or rearmost axle differential carrier, see **Subject 110**.

   For instructions on installing a forward-rear axle differential carrier, see **Subject 140**.
10. Remove the chocks.

Adjustment

The Interaxle Differential (IAD) has an adjustment screw that can become loose or even fall out, causing an oil leak, and malfunction of the IAD. To ensure the adjustment screw is properly tightened and secured, follow the steps below. The IAD is sometimes called the power divider. See **Fig. 1**.

1. Chock the front tires.
2. Use the IAD switch in the cab to engage the lock.
3. At the forward-rear axle, rotate one of the wheels to ensure the teeth of the lock fully engage the teeth of the gear inside the carrier housing.
4. Remove the adjustment screw, and using a suitable solvent (such as brake cleaner), clean the threads of the screw and bore. Dry the surfaces completely, making sure no cleaning solvent remains.
5. Coat the threads of the adjustment screw with Loctite® 577, install it, and hand-tighten it until it hits the shaft.
6. Disengage the IAD to relieve the air pressure exerted on the adjustment screw.
7. Hand-tighten the adjustment screw one quarter turn, then tighten the locknut 30 lbf·ft (41 N·m).
8. Remove the chocks.

Repair

1. Apply the parking brakes, shut down the engine, and chock the tires.
2. Disconnect the main driveshaft from the forward carrier input yoke. For instructions, see **Section 41.00, Subject 120**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
3. Remove the yoke nut and washer from the input shaft of the forward differential carrier, then remove the yoke.
4. Remove the capscrew and the locking plate from the bearing cage on the front of the differential carrier. See **Fig. 1**.
5. Using a spanner wrench, remove the threaded ring to expose the bearing cavity. See **Fig. 2**.
6. Using a suitable solvent, such as brake cleaner, clean the surface of the bearing cavity. See **Fig. 2**. Dry the surface, making sure no cleaning solvent remains.
7. Coat the threads of the threaded ring with Loctite® 577 sealant. Apply a 1/8-inch (3-mm) diameter bead all the way around the bottom thread, then spread the sealant evenly over the threads, so that all threads are thoroughly covered with the sealant.

8. Install the threaded ring (without the new input-shaft seal) and turn it clockwise (tighten it) enough to form a uniform bead of sealant all the way around the threaded ring. See **Fig. 3**.

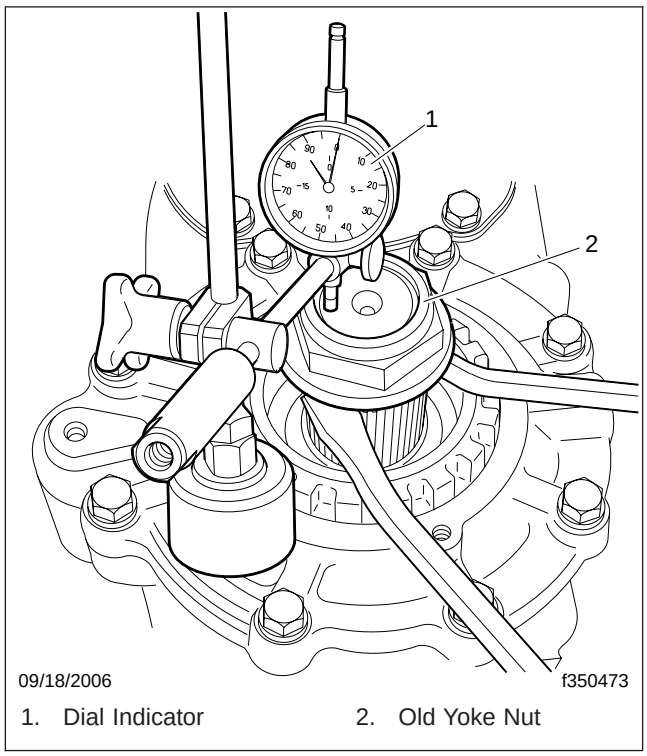
1. Threaded Ring

Fig. 3, Preliminary Installation of the New Threaded Ring

9. Install the old yoke nut on the input shaft to protect the threads, then strike the nut sharply with a brass mallet to unseat the bearing.
10. Adjust the initial bearing preload to 0.002 inch (0.05 mm), as follows:
    10.1 Install a dial indicator on the bearing cage, and using two pry bars, pry up evenly on the yoke nut (and the input shaft) to determine the bearing preload. See **Fig. 4**.



1. Dial Indicator
2. Old Yoke Nut

Fig. 4, Measuring Bearing Preload

    10.2 Tighten the threaded ring until the dial indicator reads 0.002 inch (0.05 mm).
11. Using a suitable marker or paint, mark the center of one of the teeth on the threaded ring and the surface of the bearing cage. See **Fig. 5**.

IMPORTANT: The next step is critical. Tightening the threaded ring by advancing it one tooth will set the bearing preload to 0.00 to 0.0012 inch (0.00 to 0.03 mm). If you tighten the threaded ring beyond this tolerance, you cannot back it off; you will need to remove the threaded ring and repeat the entire installation procedure.

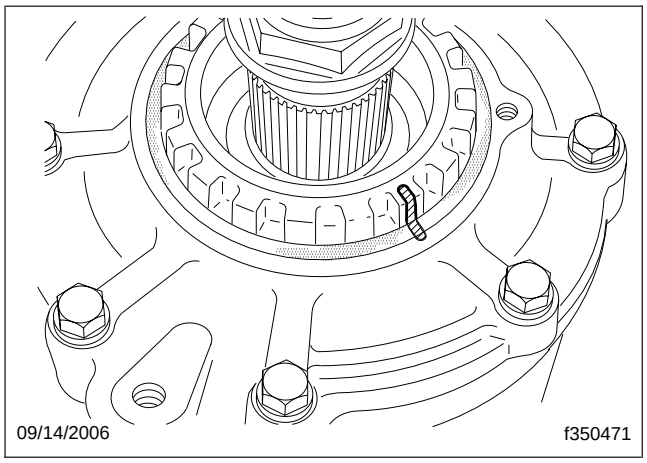


Fig. 5, Marking the Tooth and Bearing Cage

12. Very carefully advance the threaded ring one tooth while checking the paint mark. Stay close to a one-tooth advancement when making the final adjustment. Bear in mind that the new locking plate must fit into place once the correct tightness is achieved. The locking tab should fit in place either slightly before or slightly past a one-tooth advancement of the threaded ring. *You cannot back off the threaded ring once it is tightened.*

    Try fitting the new locking plate in place by turning and flipping it over as you slowly tighten the threaded ring. Tighten the threaded ring so the bearing preload is 0.00 to 0.0012 inch (0.00 to 0.03 mm). When the correct tolerance is reached, the mark on the surface of the bearing cage should line up with the center of the next tooth. See **Fig. 6**. Do not tighten the threaded ring any further.

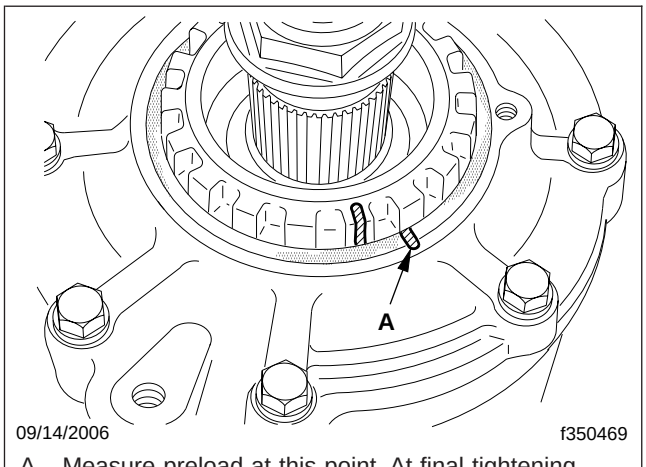
13. When the bearing preload is correct, install the new locking plate and capscrew. Tighten the capscrew 18 lbf·ft (24 N·m).

14. Install the new input-shaft seal as follows (see **Fig. 7**):

    14.1 Inspect the area around the seal for damage. Use emery paper to remove scratches, nicks, or burrs on the seal bore.

    14.2 Apply a light coating of axle oil to the seal bore.

    14.3 Coat the mating surfaces of the new seal with Loctite® 5900 sealant, or equivalent.



A. Measure preload at this point. At final tightening, this mark should be opposite the center of the next tooth, but no further.

14.4 Assemble the input shaft seal installer onto the threaded end of the universal handle. See **Fig. 7**.

Threaded Ring Repair

14.5 Using the input shaft seal installer assembly, press the seal into the bore until the seal surface is flush with the threaded ring.

15. Apply Loctite 242 to the threads of the new yoke nut, then using it and a new washer, install the existing yoke on the input shaft. Tighten the yoke nut 628 lbf·ft (850 N·m).
16. Connect the main driveshaft to the input shaft. For instructions, see **Section 41.00, Subject 120**.
17. Remove the chocks.

The following on-vehicle procedure replaces the interaxle differential (IAD) assembly and accomplishes a minor carrier rebuild by replacing the bearing races and, as needed, the shift shaft bushing. The front cover is resealed and the input shaft seal is replaced. See **Fig 1**.

Replacement

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the front tires.
2. Ensure the interaxle differential is disengaged and the system is charged with air. The rear wheels will need to turn near the end of this procedure.
3. Place a suitable strap around the driveshaft and frame to hold the driveshaft out of the way after it is disconnected.
4. Disconnect the main driveshaft from the forward carrier input yoke (for instructions, see **Section 41.00, Subject 120**), and support it with the strap.
5. Clean the carrier housing and surrounding area as needed to remove any debris that could enter the housing.
6. Drain the oil from the carrier housing.
7. Disconnect the air line connected to the bearing cage.
8. Remove the yoke nut and washer from the input shaft of the forward differential carrier, then remove the yoke.
9. Remove the capscrew and the locking plate. See **Fig 1**.
10. Using a spanner wrench, remove the threaded ring by turning it counterclockwise.
11. Remove the bearing cage capscrews from the bearing cage, and pry the bearing cage from the carrier housing. It may help to tap the bearing cage loose with a chisel; see **Fig. 2**.

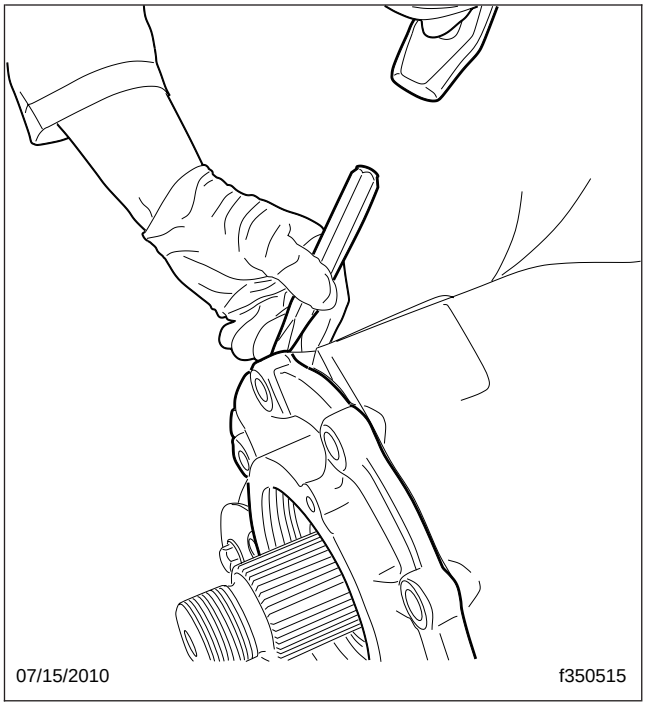

Fig. 2, Tapping the Bearing Cage Loose

12. Remove the IAD adjustment screw and locknut.

NOTICE

When unseating the shift shaft piston, multiple taps may be needed, but use moderate force only and be careful to hit the piston only (not the housing). Stop tapping it once it protrudes from the housing. The use of excessive force, or tapping it while it protrudes from the housing can damage the piston and the housing.

Interaxle Differential Replacement

13. Using a brass or plastic mallet, squarely tap the shift shaft piston to unseat it, and then remove it from the carrier housing.
14. Remove the piston spring, clutch collar, and shift fork.

NOTICE

The IAD assembly is heavy. Use appropriate support while removing and transporting it to prevent dropping and damaging it. Do not allow it to rest on the oil slinger; see Fig. 3. Resting the IAD assembly on the oil slinger could damage the oil slinger.

15. Remove the IAD assembly.

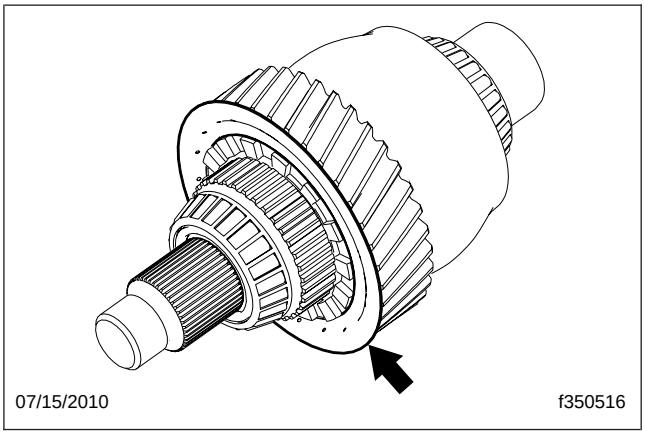

Fig. 3, Oil Slinger

16. Align the output bearing remover (see Table 1) with the notches in the rear of the carrier housing, then attach it to the housing with bearing cage capscrews, and use it to remove the output bearing race. See Fig. 4.
17. If the brass shift shaft bushing is damaged or worn, assemble the slide hammer and shift shaft bushing remover (see Table 1), and slide the hammer handle to remove the bushing. See Fig. 5.
18. Using a suitable solvent (such as brake cleaner), clean any remaining sealant from the threaded ring and mating surfaces of the carrier housing and the bearing cage. Dry the surfaces with compressed air, ensuring no cleaning solvent remains.

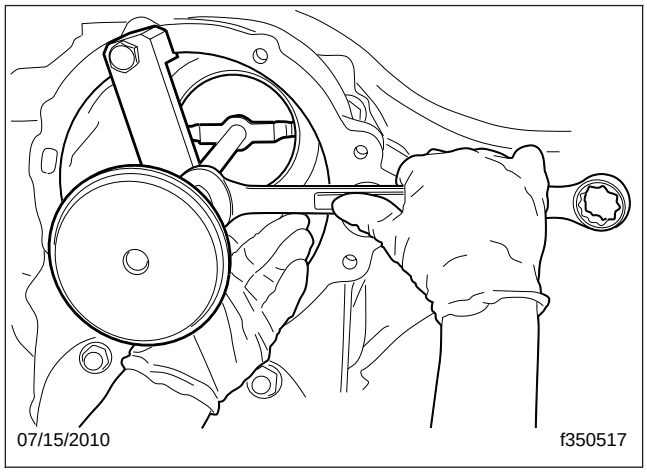

Fig. 4, Removing the Output Bearing Race

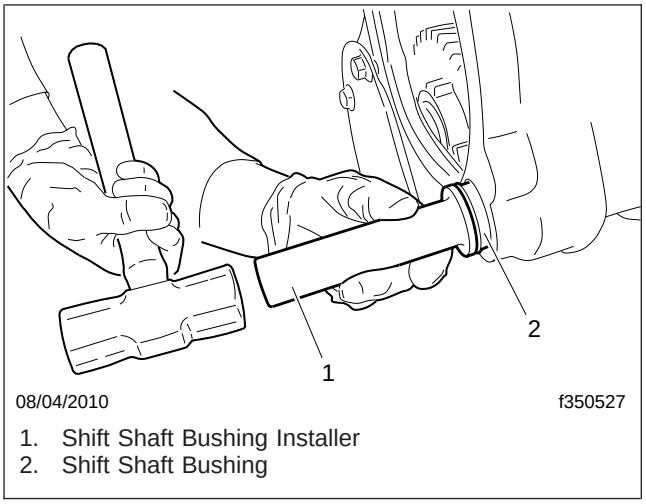
Fig. 5, Installing the Bushing Remover

19. As in the previous step, clean the groove at the piston bushing bore.
20. If the brass shift shaft bushing was removed, install a new one using a mallet and the Shift Shaft Bushing Installer. See Fig. 6.
21. A new output bearing race is included with the new IAD. Install it as follows.

    21.1 To get it started, lightly tap the race into place with a hammer handle or wood

block. The race must be square in the housing or damage will occur when it is pressed. See **Fig. 7**.

21.2 Fasten the output bearing installer to the carrier housing, and use it to press the race into the housing. As the race is installed, slight jerks can be felt and heard. See **Fig. 8**.



1. Shift Shaft Bushing Installer
2. Shift Shaft Bushing

Fig. 6, Installing the Bushing

22. Lubricate the output gear and bearing of the new IAD assembly with white grease.
23. Install the IAD assembly and output gear. Do not allow the assembly to rest on the oil slinger.
24. Install the clutch collar and shift fork.
25. Apply a thin film of white grease to the shift shaft piston, and insert it with the piston spring into the housing until about 1 inch (2.5 cm) of the piston protrudes from the bore.
26. The half-moon device (see **Table 1**) helps align the shift fork and shift shaft piston. To install it, slide it between the oil slinger and the shift fork. See **Fig. 9**.
27. Install the shift shaft piston as follows.

    27.1 The shift shaft piston installer (see **Table 1**) is designed to install the piston without damaging it or the carrier housing. Use two bearing cage capscrews to mount it to the carrier housing. See **Fig. 10**.

    27.2 Adjust the hex screw until the shift fork is snug but not bound.

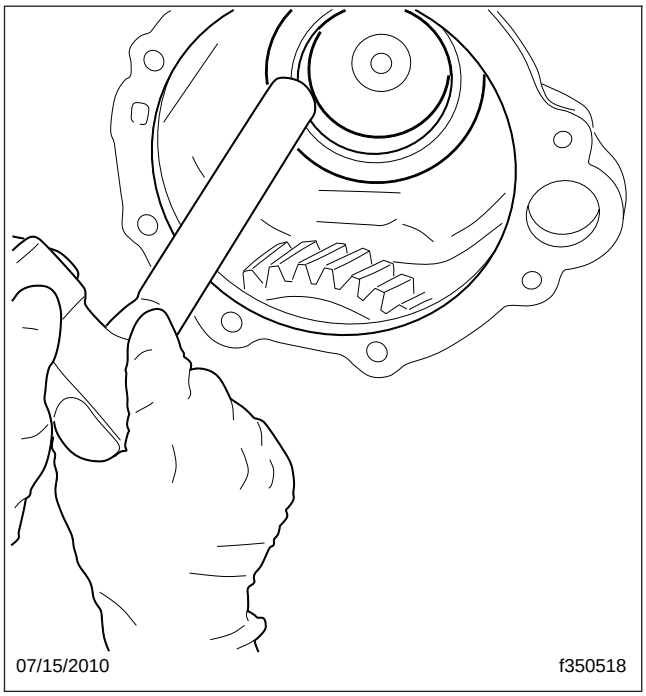


Fig. 7, Setting the Race

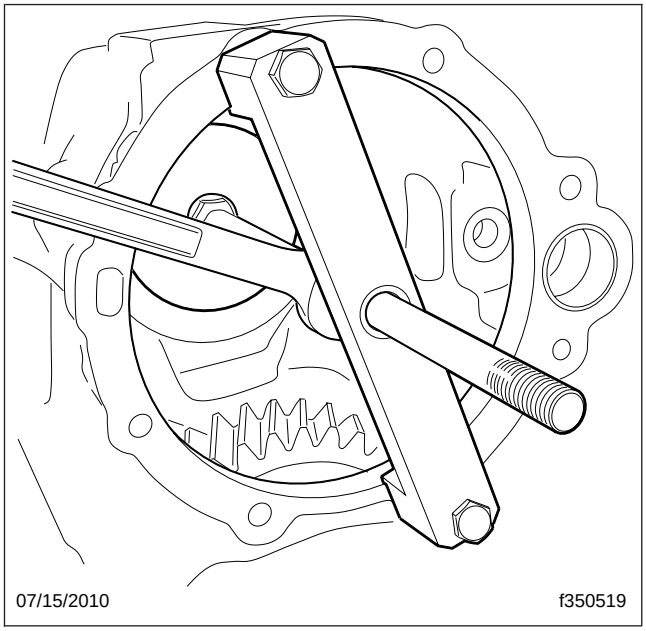

Fig. 8, Pressing a New Race into the Housing

27.3 In a single movement of moderate force, use the lever of the installer to press the piston into the bore until only about 1/8 to

Interaxle Differential Replacement

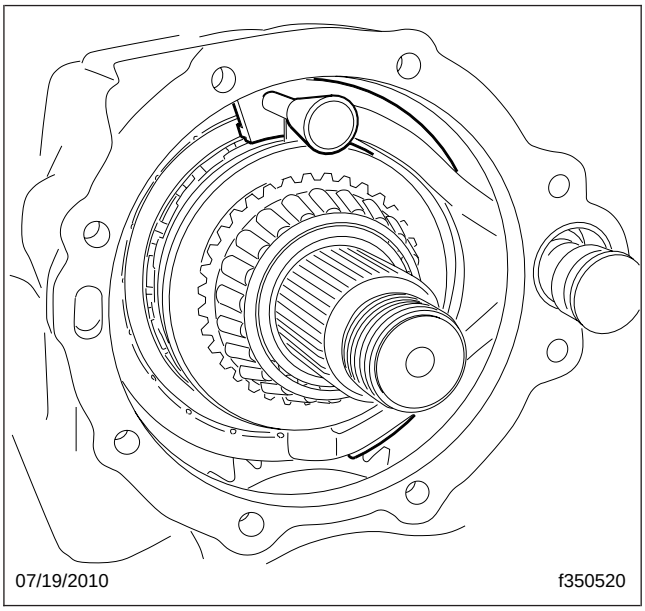

Fig. 9, The Half-Moon Device, Installed

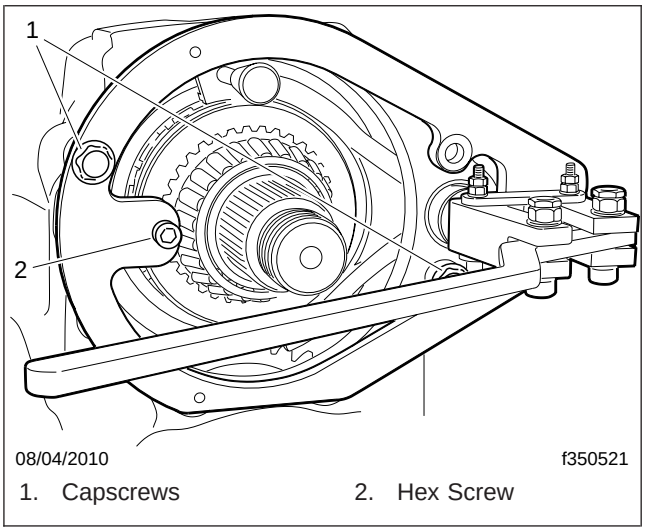

Fig. 10, Shift Shaft Piston Installer, Mounted

1/16 inch (2 to 3 mm) of the piston protrudes from the carrier housing. When the piston seats, a "click" sound may be audible. If the piston does not seat readily, adjust the hex screw, and try again.

27.4 Once the piston is seated, remove the shift shaft piston installer and the half-moon device.

28. Remove the input bearing race from the bearing cage. Place the new race into the cage so that it is more forward than in the final position. As the preload is adjusted, the race will seat to its final position.

29. Apply Loctite® 577 sealant to the threads of the threaded ring and tighten it until it is snug against the race.

IMPORTANT: Do not overapply sealant. Do not allow sealant to enter the oil return or touch the shift shaft piston.

30. Apply a small bead of Loctite 5900 to the carrier housing. See **Fig. 11**. To help ensure a good seal, spread it uniformly over the surface area.

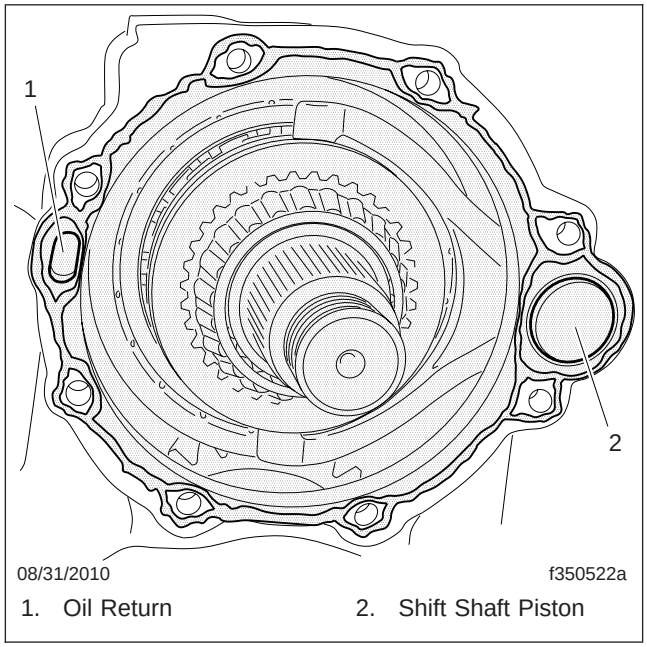

Fig. 11, Sealant Applied to Carrier Housing

31. Install the bearing cage, and using a star pattern tighten the capscrews to 103 lbf·ft (140 N·m).

32. The push-pull device (see **Table 1**) is used to set pre-load on the input bearing. Remove the two upper capscrews from the cover plate and install the device as shown in **Fig. 12**.

33. Set the correct end play as follows.

33.1 Set up a dial indicator as shown in **Fig. 13**.

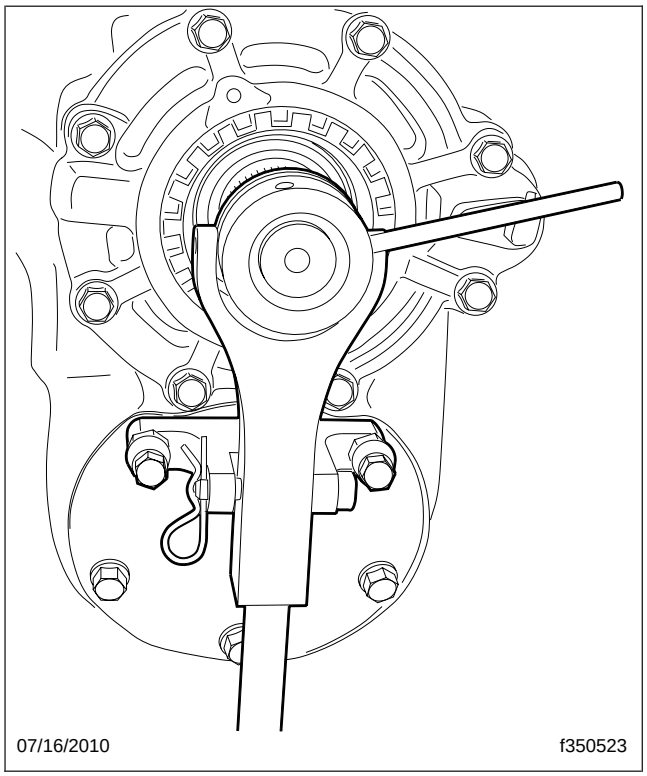

Fig. 12, Push-Pull Device, Installed

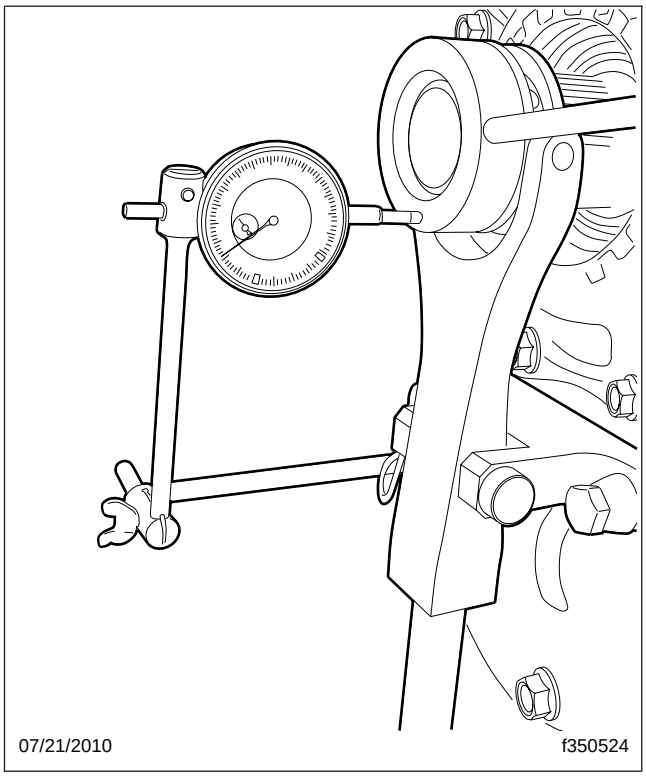

Fig. 13, Dial Indicator and Push-Pull Device

33.2 Turn the input shaft three revolutions and tighten the threaded ring until there is between 0.002 and 0.003 inch (0.05 and 0.08 mm) of end play. Turn the input shaft three more revolutions and verify the measurement.

33.3 When there is between 0.002 and 0.003 inch (0.05 and 0.08 mm) of end play, align a mark on the threaded ring with one on the bearing cage. See **Fig. 14**.

33.4 Tighten the threaded ring almost one notch.

IMPORTANT: Do not loosen the threaded ring. If the threaded ring is loosened, the bearing cage must be removed and the race re-installed.

33.5 The locking plate has six positions that can lock the threaded ring. Find the position that fits best, install it, and tighten the capscrew 18 lbf·ft (24 N·m).

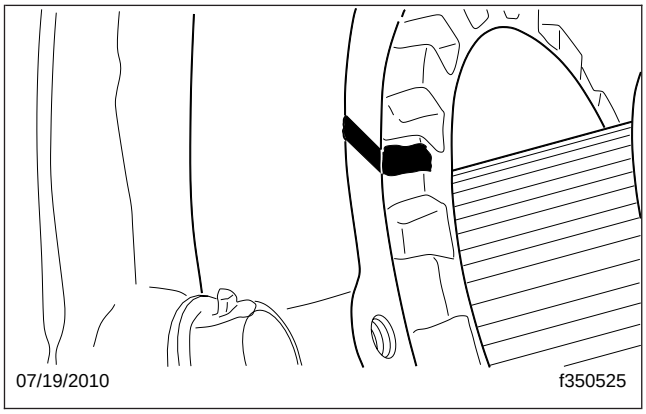

Fig. 14, Threaded Ring and Bearing Cage, Marked

33.6 Remove the push-pull device and dial indicator, and install the the two upper capscrews on the cover plate. Tighten the capscrews 63 lbf·ft (85 N·m).

34. Install a new input shaft seal and the yoke, nut, and washer; see **Subject 170** for instructions.

Interaxle Differential Replacement

35. Clean, install, and adjust the IAD adjustment screw and locknut as follows.
    - 35.1 Clean the IAD adjustment screw and locknut with a suitable solvent (such as brake cleaner). Dry the cleaned surfaces, ensuring no solvent remains.
    - 35.2 Connect an air line at the interaxle lock.
    - 35.3 Apply air, and by hand, turn the input shaft to ensure the gear cogs fully engage.
    - 35.4 Coat the threads of the adjustment screw with Loctite® 577.
    - 35.5 Install the adjustment screw, with the locknut, into the carrier housing, and handtighten the screw until it touches the engaged shift shaft piston.
    - 35.6 Disengage the IAD to relieve the air pressure exerted on the adjustment screw.
    - 35.7 Hand-tighten the adjustment screw one quarter turn, then tighten the locknut 30 lbf·ft (41 N·m).
36. Connect the main driveshaft; for instructions, see **Section 41.00, Subject 120**.
37. Using approved axle oil, fill the axle housing to the bottom of the fill hole, or until filled to capacity as shown in **Table 2**.

38. To lubricate the wheel ends, tilt the axle to the left and right by jacking the opposite side 8 inches (20 cm). Hold the tilted position for two minutes on each side to allow oil to run into the wheel end. Return the axle to a level position, and add oil through the axle housing filler hole. About two more pints (1 liter) of lubricant will be needed to bring the oil level even with the base of the filler hole.

General Information

WHEELS AND TIRES

The tires support the weight of the vehicle, and are integral parts of the transmission and braking systems. The wheels serve as load carrying members between the tires and the axle.

There are two types of wheels: spoke and disc.

Spoke wheels consist of a wheel and brake drum assembly installed on the axle **(Fig. 1),** and a tire and rim assembly that mounts on the wheel. Rim clamps and rim nuts hold the tire and rim assembly in place.

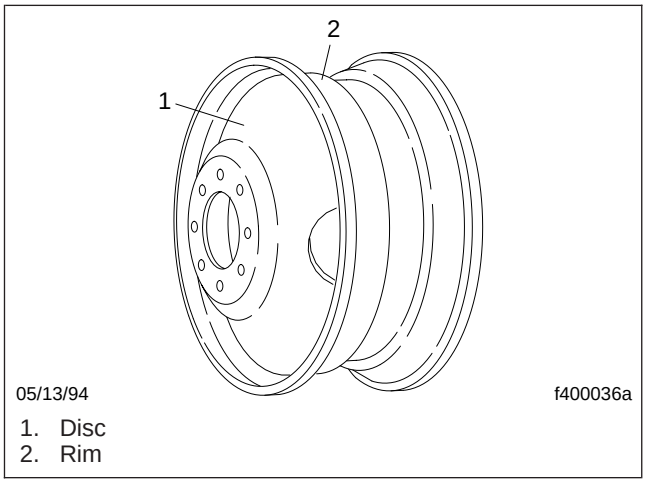
5. Continuous Side Ring
6. Split Lockring
7. Rim Clamp
8. Rim Nut

Fig. 1, Spoke Wheel and Brake Drum Assembly (Shown with Three-Piece Rim, for Tube-Type Tires)

Disc wheels consist of a rim and disc. The rim, the portion of the wheel on which the tire is mounted and supported, is welded to the disc **(Fig. 2).** After the tire is mounted on the wheel, the assembly is held in place on the hub with wheel studs and nuts.



1. Disc
2. Rim

Fig. 2, Disc wheel

Standard ten-hole dual disc wheels are held in place on the hub by self-centering inner and outer wheel nuts. Eight-hole and optional ten-hole (single and dual) disc wheels are centered by pilot pads and are held in place on the hub with cone locknuts.

Tires are constructed of either radial or bias plies:

Radial tires have ply cords that run from bead to bead, and at a right angle to the belt plies and tire tread **(Fig. 3).** The belt plies constrict the radial ply cords and give rigidity to the tread.

Bias ply tires have body ply cords that run diagonally from bead to bead **(Fig. 4).** The tires may also have narrow plies under the tread, called breakers, with cords that lie in about the same direction as the body ply cords.

Tire body plies, breakers, and belts are made of polyester, rayon, nylon, fiberglass, steel, or aramids (fibrous reinforcements). In radial ply tires, these materials are used in various combinations, including steel body/steel belt, polyester body/fiberglass belt, or nylon body/steel belt.

Wheels and tires operate either with or without tubes. Tube-type tires require a tube and flap for correct assembly on a two-or three-piece rim **(Fig. 1).** Tubeless tires require only the tire, and a one-piece drop-center wheel or rim. **See Fig. 2.**

TIRE MATCHING AND MIXING

IMPORTANT: Review and follow these requirements for matching and mixing tires, before installing any tire and wheel or rim assembly on a vehicle.

Before changing wheels and tires, consider the effect that the change may have on the Gross Vehicle Weight Rating (GVWR) of the vehicle. At the time of vehicle certification, the GVWR is calculated by adding the vehicle's Gross Axle Weight Ratings (GAWR). The GVWR and each of the GAWRs are shown on a certification label (U.S.-purchased tractors) or "Statement of Compliance" label (Canadian-purchased tractors) attached to the left rear door post. **See Fig. 5.**

Tire and rim labels (**Fig. 5** and **Fig. 6**) certify the minimum tire and rim combinations that can be installed on the vehicle for the given GAWRs. Each GAWR is determined by considering each component of the axle system, including suspension, axle, wheels, and tires. The lowest component's capacity is the value used for the system. Therefore, the tires and rims installed on the vehicle at the time of vehicle manufacture may have a higher load capacity than that certified by the tire and rim label. Tires and rims of the minimum capacity can be installed without changing the load limitations. If tires and rims are installed that have a lower load capacity than that shown on the tire and rim label, then the tires and rims determine the load limitations (the GAWRs and GVWR will be lower).

Fig. 6, Tire and Rim Labels

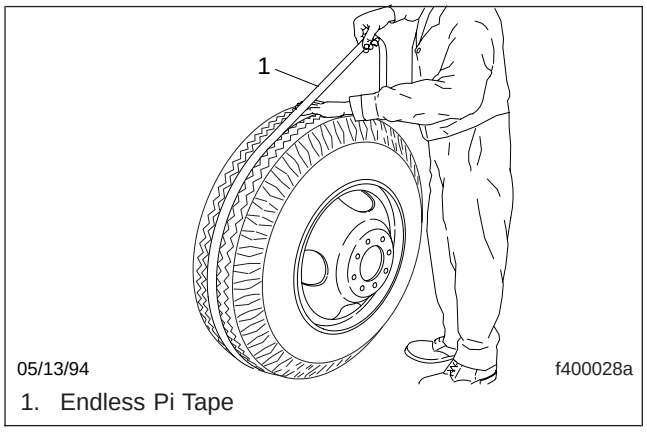
When pairing tires in a dual assembly, the tire diameters must not differ by more than 1/4 inch (6.4 mm),

or the tire circumference by more than 3/4 inch (19 mm). The total tire circumference of one driving rear axle must match, as nearly as possible, the total tire circumference of the other driving rear axle.

CAUTION

CAUTION: Mismatching dual tires overloads the larger diameter tire, causing it to overdeflect and overheat. The smaller diameter tire, lacking proper road contact, wears faster and unevenly. Tread or ply separation, tire body breaks, and blowouts can occur from mismatched duals.

With an endless pi tape **(Fig. 7)** or square **(Fig. 8),** measure the diameter of the tires 24 hours after inflation. A matching stick **(Fig. 9),** string gauge **(Fig. 10),** or tire straight edge **(Fig. 11)** can also be used to determine the difference in tire radius, which is then doubled to calculate the diameter difference.



1. Endless Pi Tape

Fig. 7, Endless Pi Tape

When pairing tires of unequal diameters (but within the above limits), mount the larger tire on the outside.

CAUTION

CAUTION: Driving a vehicle on one tire of a dual assembly dangerously exceeds the carrying capacity of the single tire and wheel. Operating in this manner can cause damage to the wheel and tire.

Inflate all tires on an axle, or on both axles of a tandem unit, to within 5 psi (35 kPa) of one another. For tire inflation specifications, refer to **Specifications, 400.**

from rubbing against one another. Rims and wheels of the same size, but of different makes and types, can have different offsets, which would affect dual spacing. If there is sidewall contact between tires, or between the inside tire and the chassis, refer to the tire manufacturer's catalog to determine the minimum dual spacing. Refer to the rim or wheel manufacturer's catalog to determine the correct offset.

Federal Motor Carrier Safety regulations require the removal of all tires with less than 4/32-inch (3 mm) remaining groove depth on a front axle, and tires with less than 2/32-inch (1.5 mm) remaining groove depth on a rear axle. However, tires with the word "Regroovable" on the sidewall, may be regrooved.

Better tire and vehicle performance is usually obtained by using tires of the same size and construction. Using tires of different construction is permitted if the following rules are observed:

- Do not mix radial and bias ply tires on the same axle.
- If both radial and bias ply tires are used, better handling is usually obtained by using the bias ply tires on the front axle.
- Use either all radial or all bias ply tires on the non-driving rear axles of a vehicle. However, all radial or all bias ply tires must be used on vehicles with tandem drive-axles.

⚠ CAUTION

CAUTION: Mixing radial and bias ply tires should be done as an emergency measure only. Some loss of steering control and premature tire wear could occur when driving under such conditions.

If installing radial tires on a vehicle formerly equipped with bias ply tires, refer to **Specifications, 400** concerning the inflation needs and load limits of the bias ply tires being removed, and of the radial ply tires being installed. Radial ply tires permit greater loads per tire, but also require higher inflation. They can also cause higher stresses on rims and wheels than bias ply tires. Contact the rim or wheel manufacturer about the compatibility of the rim or wheel with radial ply tires. Also, refer to the front axle section in this manual for information on the possible differences in toe-in setting between radial and bias ply tires.

8-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

Removal

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during removal and damage the stud threads or hub-pilot pads. Keep the wheel square to the hub during removal.

NOTE: These procedures apply to hub-piloted wheels.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock all tires that will not be serviced, to prevent vehicle movement.
2. Remove the wheels and tires from the front axle.
   - 2.1 Raise the front of the vehicle until the tires clear the floor. Place safety stands under the front axle.
   - 2.2 If the tire or wheel is damaged (or if there is suspected damage), deflate the tire being serviced by removing the valve core.
   - 2.3 Place a jack or wheel-and-tire dolly under the front wheel assembly being serviced. Turn the wheel until one hub-pilot pad is in the top-center position.
   - 2.4 Leaving the top nut until last, remove all eight two-piece flange nuts.

   IMPORTANT: On both sides of the vehicle, the two-piece flange nuts have right-hand threads.

   - 2.5 Remove the wheel. Do not let it drop on or drag across the stud threads.
3. Remove the wheels and tires from a rear axle.
   - 3.1 Raise the rear of the vehicle until the tires clear the floor. Place safety stands under the axle being serviced.
   - 3.2 If the tire or wheel is damaged (or if there is suspected damage), deflate both tires of the dual assembly being serviced by removing the valve cores.
   - 3.3 Place a jack or wheel-and-tire dolly under the dual wheel assembly being serviced. Turn the wheel until one hub pilot pad is in the top-center position.
   - 3.4 Leaving the top nut until last, remove all eight two-piece flange nuts.

   IMPORTANT: On both sides of the vehicle, the two-piece flange nuts have right-hand threads.

   - 3.5 Remove the wheel. Do not let it drop on or drag across the stud threads.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 190**. Also, follow the tire matching and mixing requirements under **Subject 050**.

1. Clean the hub and wheel mounting surfaces, and between the rims of dual wheels. Make sure the tire is correctly inflated. For instructions, see **Subject 210**.
2. Apply a few drops of light engine oil to the wheel studs and the area between the body and the flange of each two-piece flange nut. Wipe off any excess oil.

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during installation and damage the stud threads or hub-pilot pads. Keep the wheel square to the hub during installation.

IMPORTANT: Before installing the wheels, make sure the drum is positioned on the raised step of the pilot pad. One of the hub's pilot pads must be at the top location. To help keep the drum in place, it may be necessary to adjust the brakes before installing the wheels.

3. If installing a rear wheel assembly, go to the next step. Install the front wheel assembly.
   - 3.1 Locate one hub-pilot pad in the top-center position. Using a jack or wheel-and-tire dolly, position the wheel assembly on the hub. Make sure the wheel is square to the hub and that the threads or hub-pilot pads

8-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

are not damaged by contact with the wheel during installation.

3.2 Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum.

4. Install the rear wheel assembly.

4.1 Locate one hub-pilot pad in the top center position. Using a jack or wheel-and-tire dolly, position the inner wheel assembly on the hub. Make sure the wheel is square to the hub and that the threads or hub-pilot pads are not damaged by contact with the wheel during installation.

4.2 Using the same procedure, mount the outer wheel against the inner wheel. Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum. If this causes the valve stems to be in the same wheel hole, mount the outer wheel so that the outer wheel balance weight(s) are on the same side as the brake drum balance weight(s).

5. Install and hand-tighten a two-piece flange nut on the top and bottom studs.

CAUTION

The two-piece flange nuts have right-hand metric threads. Do not try to install a similar size SAE nut on a stud, or the stud and nut will be damaged.

6. Install and hand-tighten the remaining two-piece flange nuts. Tighten the two-piece flange nuts 50 to 100 lbf·ft (68 to 135 N·m) following the sequence in **Fig. 1**.

7. Check that the wheel is correctly seated against the hub and on the hub-pilot pads.

8. Following the sequence in **Fig. 1**, tighten the two-piece flange nuts 450 to 500 lbf·ft (610 to 678 N·m).

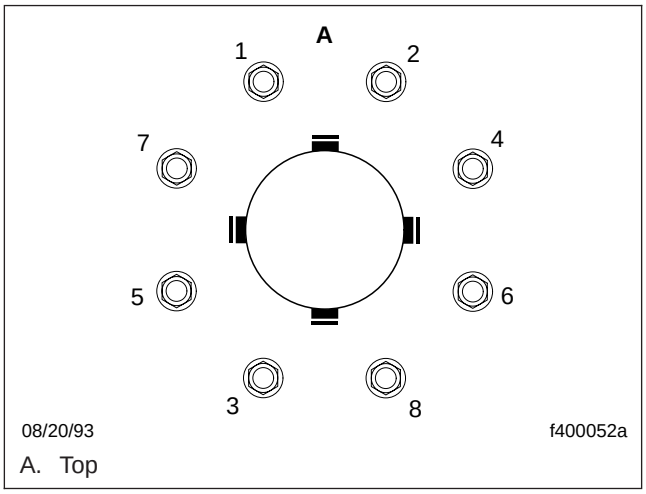

Fig. 1, 8-Stud Disc Wheel Tightening Sequence

NOTE: Nuts on double-threaded wheel studs should be tightened 390 to 450 lbf·ft (529 to 610 N·m).

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

NOTE: Replace damaged parts following the instructions in the front or rear axle section in this manual.

9. Remove the safety stands, lower the vehicle, and remove the chocks.

CAUTION

Too little wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and ex-

treme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 1.

10. After operating the vehicle for 50 to 100 miles (80 to 160 km), retighten the wheel nuts to the original specification. Follow the sequence in Fig. 1.

IMPORTANT: The two-piece flange nuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts. Tighten the two-piece flange nuts to the specified torque values 50 to 100 miles (80 to 160 km) after service work, and check the values every 50,000 miles (80 000 km) thereafter.

10-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

Removal

NOTE: These procedures apply to hub-piloted wheels.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock all tires that will not be serviced, to prevent vehicle movement.
2. If working on the front axle wheels, raise the front of the vehicle until the tires clear the floor. Place safety stands under the front axle.

   If working on the rear axle wheels, raise the rear of the vehicle until the tires clear the floor. Place safety stands under the axle being serviced.
3. If the tire or wheel is damaged or if there is suspected damage, deflate the tire (or tires, on a dual assembly) being serviced by removing the valve core.
4. Turn the wheel until one hub-pilot pad is in the top-center position.
5. Leaving the top and bottom nuts until last, remove the other eight two-piece flange nuts.

IMPORTANT: On both sides of the vehicle, the two-piece flange nuts have right-hand metric threads.

6. Place a jack or wheel-and-tire dolly under the wheel assembly being serviced. Remove the top and bottom nuts.

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during removal and damage the stud threads or hub-pilot pads. Keep the wheel square to the hub during removal.

7. Remove the wheel. Do not let it drop on or drag across the stud threads.

Installation

IMPORTANT: Before installing the wheels, it is recommended that an anti-seize compound be applied on the 360 degree wheel pilot hubs of Meritor FF-981 "Easy Steer Plus" front axles.

After time in service, a small amount of rust or corrosion may make the wheel difficult to remove because of the extended wheel-to-hub contact. Applying an anti-seize compound on the wheel pilot of the hub will ensure easy wheel removal at a later date. Compounds such as the following may be used:

- Armite Led-Plate No. 250
- Loctite Anti-Seize No. 767
- Never-Seez
- Permabond Anti-Seize No. 82-9839

Compounds are available for purchase locally.

IMPORTANT: Freightliner "Turbo" wheel assemblies require directional mounting, as shown in **Fig. 1**.

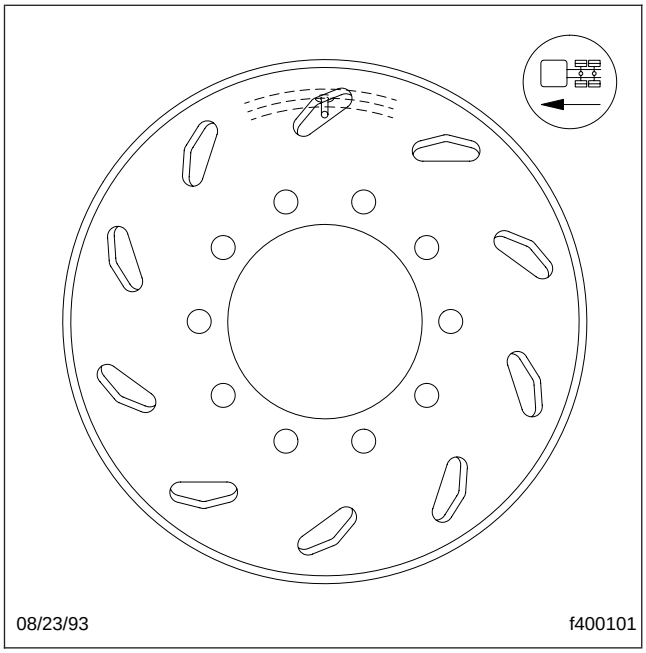

Fig. 1, Side View

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 190**. Also, follow the tire matching and mixing requirements in **Subject 050**.

1. Clean the hub and wheel mounting surfaces, and all disc faces of dual wheels. Make sure the tire is correctly inflated. For instructions, see **Subject 210**.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum.

4. Install the rear wheel assembly.
   - 4.1 Locate one hub-pilot pad in the top-center position. Using a jack or wheel-and-tire dolly, position the inner wheel assembly on the hub. Make sure the wheel is square to the hub so that the stud threads or hub-pilot pads are not damaged by contact with the wheel during installation.
   - 4.2 Using the same procedure, mount the outer wheel against the inner wheel. Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum. If this causes the valve stems to be in the same wheel hole on rear wheel assemblies, mount the outer wheel so that the outer wheel balance weight(s) is on the same side as the brake drum balance weight(s).

5. Install and hand-tighten a two-piece flange nut on the top and bottom studs.

CAUTION

The two-piece flange nuts have right-hand metric threads. Do not try to install a similar size SAE nut on a stud, or the stud and nut will be damaged.

6. Install and hand-tighten the remaining two-piece flange nuts. Tighten the nuts 50 lbf·ft (68 N·m) following the sequence in **Fig. 2**.

7. Check that the wheel is correctly seated against the hub and on the hub-pilot pads.
8. Following the sequence in **Fig. 2**, tighten the two-piece flange nuts 450 to 500 lbf·ft (610 to 678 N·m).

NOTE: Nuts on double-threaded wheel studs should be tightened 390 to 450 lbf·ft (529 to 610 N·m).

   - 3.4 Place a jack or wheel-and-tire dolly under the inner wheel assembly. Remove the inner wheel nuts, then raise and remove the inner wheel. Be careful not to damage the threads of the wheel studs as the inner wheel is pulled away.

Installation

IMPORTANT: Before installing the wheels, it is recommended that an anti-seize compound be applied on the 360 degree wheel pilot hubs of Rockwell FF–981 "Easy Steer Plus" front axles.

   2.1 Use a jack or wheel-and-tire dolly to mount the wheel assembly on the wheel studs. Be careful not to damage the threads of the wheel studs when installing the wheel assembly.

   2.2 Install a wheel nut on each wheel stud, and run them up until each nut is flush with the face or the chamfer of the wheel. Rotate the wheel a half turn to seat the parts.

   2.3 Tighten the wheel nuts 50 lbf·ft (68 N·m), following the sequence in **Fig. 2**.

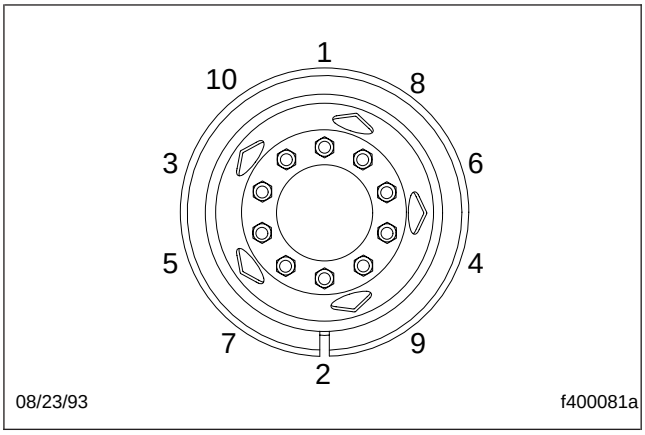

Fig. 2, 10-Stud Disc Wheel Tightening Sequence

   2.4 Using the same sequence, tighten the wheel nuts again, to the torque in the disc-type wheel fastener torque table in **Specifications, 400**.

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

3. Install a rear wheel assembly:

   3.1 Use a jack or wheel-and-tire dolly to mount the inner wheel assembly on the wheel studs. Be careful not to damage the threads of the wheel studs when installing the wheel assembly.

   IMPORTANT: Mount the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum (**Fig. 3**).

   If, on two-handhole wheels, this causes the valve stems to be in the same wheel hole, mount the outer wheel so that the outer wheel balance weight(s) are on the same side of the assembly as the brake drum balance weight(s). See **Fig. 4**.

   If, on five-handhole or aluminum wheels, the valve stems are in the same handhole, separate the valve stems by one hole. If balancing the wheels, install the wheel weights evenly and as close to 180 degrees opposite the brake drum balance weight(s) as possible. See **Fig. 5**.

   3.2 Install the inner wheel nuts on each wheel stud, and run them up until each nut is

flush with the face or the chamfer of the wheel. Rotate the wheel a half turn to seat the parts.

3.3 Tighten the inner wheel nuts 50 lbf·ft (68 N·m), following the sequence in **Fig. 2**.

CAUTION

Locknuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts to the specified torque. Not enough wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and extreme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 2.

3.6 Install the outer wheel nuts following the procedures above.

4. Remove the safety stands, lower the vehicle, and remove the chocks.

5. After operating the vehicle for 50 to 100 miles (80 to 160 km), retighten the wheel nuts to the torque in the disc-type wheel fastener torque table in **Specifications, 400**. Follow the sequence in **Fig. 2**.

Spoke Wheel, Tire and Rim Assembly; Removal and Installation

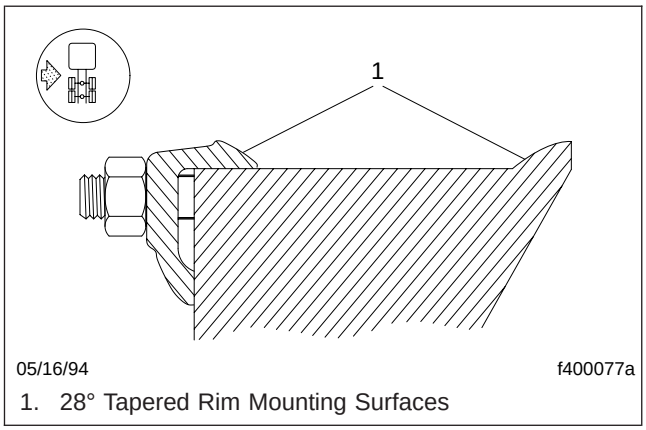
Removal

1. Chock all tires that will not be serviced, to prevent vehicle movement.
2. If removing tire and rim assemblies from a rear axle, go to the next step. Remove the tire and rim assembly from the front axle.
   - 2.1 Apply the parking brakes.
   - 2.2 Raise the front of the vehicle until the tires clear the floor. Place safety stands under the front axle.
   - 2.3 Deflate the tire being serviced by removing the valve core.
   - 2.4 Place a jack or wheel-and-tire dolly under the front tire and rim assembly being serviced. Remove the rim nuts and rim clamps, then slide the tire and rim assembly off the wheel.
3. Remove a tire and rim assembly from a rear axle.
   - 3.1 Raise the rear of the vehicle until the tires clear the floor. Place safety stands under the axle being serviced.
   - 3.2 Deflate the tire(s) being serviced by removing the valve core(s).
   - 3.3 Place a jack or wheel-and-tire dolly under the outer tire and rim assembly being serviced. Remove the rim nuts and clamps; then slide the outer tire and rim off.
   - 3.4 Remove the rim spacer. Place a jack or wheel-and-tire dolly under the inner tire and rim assembly, and slide it off.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 190**. Also, follow the tire matching and mixing requirements in **Subject 050.**

1. Clean the wheel, rim spacer, and rim mounting surfaces. The mounting surface of the wheel is the 28-degree taper on the inboard side of each spoke. **See Fig. 1.**



1. 28° Tapered Rim Mounting Surfaces

Fig. 1, Spoke Wheel Tapered Mounting Surface

2. Make sure the tire and rim assembly is inflated using the procedures in **Subject 210.**
3. If installing a rear tire and rim assembly, go to the next step. Install a front tire and rim assembly.
   - 3.1 Slide the assembly over the wheel and push it into place against the tapered mounting surface. It should fit snugly against all the tapers. Be sure that the valve stem faces out and is centered between two spokes.
   - 3.2 Install the rim clamps and nuts. Run the nuts up until the end of each wheel stud is flush with the face of its nut. Rotate the wheel a half turn to seat the parts.
   - 3.3 Tighten the rim nuts a quarter turn at a time, following the star pattern shown in **Fig. 2**. Continue until all the rim nuts are tightened to the torque in the applicable torque table in **Specifications, 400.**

⚠ CAUTION

CAUTION: Failure to tighten the nuts in the sequence shown, and to the correct torque, could cause misalignment of the tire and chording of the rim (Fig. 3). This would result in excessive vehicle vibration and permanent damage to the rim and wheel.

Fig. 2, Spoke Wheel Tightening Sequence

WARNING

WARNING: Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

NOTE: When replacing a spoke wheel, contact the wheel manufacturer for the correct torque value for the brake drum nuts attaching the spoke wheel to the brake drum.

4. Install a rear tire and rim assembly.

   4.1 Slide the inner tire and rim over the wheel hub. Push it into position against the tapered mounting surface. Make sure the valve stem faces out and is centered between two spokes.

   4.2 Slide the rim spacer over the wheel hub.

   4.3 Slide the outer tire and rim over the wheel hub. Make sure the valve stem faces inward, and is in the same position as the inner valve stem.

   4.4 Push the whole assembly in place, so that the inner rim fits snugly against the tapers all around, the spacer is seated against the inner rim, and the outer rim is seated against the spacer.

   4.5 Install the rim clamps and nuts. Run the nuts up until the end of each stud is flush with the face of its nut. Rotate the wheel a half turn to allow the parts to seat.

   4.6 Tighten the rim nuts a quarter turn at a time, following the star pattern shown in **Fig. 2.** Continue until all the rim nuts are tightened to the torque in the applicable torque table in **Specifications, 400.**

   4.7 The clamps must not bottom out until at least 80 percent of the recommended torque is reached. If the clamps do bottom out, make sure the correct clamps and rim spacers are being used. Make sure the rim edges contact the spacer edges.

CAUTION

CAUTION: Failure to tighten the nuts in the sequence shown, and to the correct torque, could cause misalignment of the tire and chording of the rim (Fig. 3). This would result in excessive vehicle vibration and permanent damage to the rim and wheel.

WARNING

WARNING: Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

Spoke Wheel, Tire and Rim Assembly; Removal and Installation

NOTE: When replacing a spoke wheel, contact the wheel manufacturer for the correct torque value for the brake drum nuts attaching the spoke wheel to the brake drum.

5. Check the wheel alignment by placing a block of wood or any other point of reference on the floor next to the tire. Rotate the tire and note any variations in the space between the tire and the block. If the variation exceeds 1/16-inch (1.5 mm) for front rims, or 1/8-inch (3 mm) for rear duals, the rim is not correctly mounted.

   To correct any misalignment, loosen the rim nuts where the largest gap occurs, and tighten the nuts on the opposite side. Recheck and correct until the variation is corrected. Make sure the rim nuts are tightened to the correct torque in the applicable torque table in **Specifications, 400.**

6. Remove the safety stands, lower the vehicle, and remove the chocks.
7. After driving the vehicle for 50 to 100 miles (80 to 160 km), retighten the rim nuts to the torque specified in the applicable torque table in **Specifications, 400.** Follow the sequence shown in **Fig. 2.**

Tire Demounting and Mounting Service Precautions

Service Precautions

⚠ WARNING

WARNING: Read the following information. Failure to follow the safety precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

IMPORTANT: Don't mount or demount tires without proper training as required in Occupational Safety and Health Administration (OSHA) Rules and Regulations 1910.177, *Servicing Multi-Piece and Single Piece Rim Wheels*. Service information containing mounting and demounting instructions are available through your rim supplier. Charts detailing service procedures are available through OSHA area offices. The address and telephone number of the nearest OSHA area office can be obtained by looking in the local telephone directory under U.S. Government, Labor Department of Occupational Safety and Health Administration.

Use the information from the above sources with the following precautions before and during the demounting and mounting of tires:

- Examine all wheel and tire parts as explained in **Subject 190** and **Subject 200**. Replace damaged, rusted, or worn parts.
- Since wheels and rims are under stress, and are dangerous if improperly assembled, be sure all parts of an assembly match in size, manufacturer, and classification within a manufacturer's line. Before assembling the wheel or rim, check the catalog issued by the wheel or rim manufacturer for the correct part numbers and sizes of approved parts. Never use a part that does not bear clear, legible, and correct numbers and manufacturer's identification, even if that part appears to fit.
- Make sure that tires are stored indoors, or outdoors under cover, to prevent water collecting inside the tire.
- Use special tools, as recommended by tire suppliers, for mounting and demounting tires. These tools must be smooth, and used with care, to avoid gouging the rim.
- Loosening tire beads may be difficult, since considerable force may be needed. The use of a machine designed for loosening tire beads is recommended.
- Handle the wheels and rims on a wooden floor or rubber mat to prevent nicking or gouging the wheel or rim.
- Do not use a duck-bill hammer, or any steel hammer on wheel or rim parts. Use rubber, leather-faced, or plastic mallets to tap parts together, if necessary.
- Lubricate the tire with an approved tire-mounting lubricant. Never use antifreeze, silicones, petroleum-based lubricants, or any flammable material (ether/starting aid).
- When lubricating a tire prior to mounting, make sure excess lubricant does not run into the tire.
- Michelin Tire Corporation recommends applying lubricant to the valley of the tire, formed by the tire and rim, before using tools to break the bead.
- Michelin also recommends applying a sufficient but sparing amount of lubricant to the entire rim face when mounting a tire on a rim, to ensure correct bead seating and ease of mounting.
- Don't reinflate a tire that has been run flat or has been run at 80 per cent or less of its recommended operating pressure. Use your spare. Before removing the low tire from the vehicle, make sure it is completely deflated. Later, have the assembly taken apart and all the parts checked for damage, including the side or lockrings.
- The air pressure contained in a tire is dangerous. When servicing a tire, stay out of any potential path or route that a rim wheel component may travel during an explosive separation.

⚠ WARNING

WARNING: Read the information in Subject 140. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

To demount or mount tubeless tires on 5 degree full drop center rims, regular or safety type, follow the same procedures used to demount or mount tubeless automobile tires.

⚠ WARNING

WARNING: Read the information in Subject 140. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

DEMOUNTING

1. Deflate the tire being serviced by removing the valve core. Check the valve stem by running a piece of wire through the stem to make sure it is not plugged.
2. Loosen both beads from the rim by driving the flat end of the tire tool between the tire bead and the rim flange. Holding the tool upright, hammer on the neck to free the tire bead from the rim **(Fig. 1).** Repeat at 8-inch (20 cm) intervals around the flanges, until both beads are free from the rim.
3. Place the wide side of the rim down. Lubricate the tire bead and the rim. Insert the curved end of two tire tools between the bead and the rim, and just to one side of the tire valve. Step on the side of the tire, opposite from the valve, to force the first bead into the rim well **(Fig. 2).** Hold one of the tools in place with your foot and pry with the second tool, forcing the bead over the rim flange. Continue to work the first bead off of the rim.

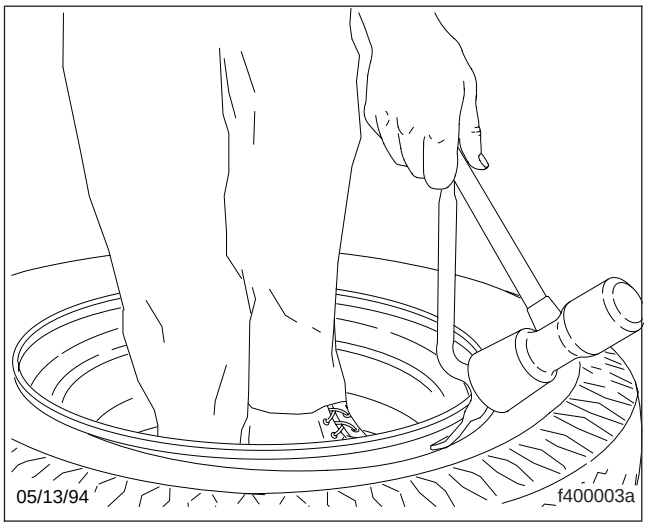

Fig. 1, Loosening the Beads

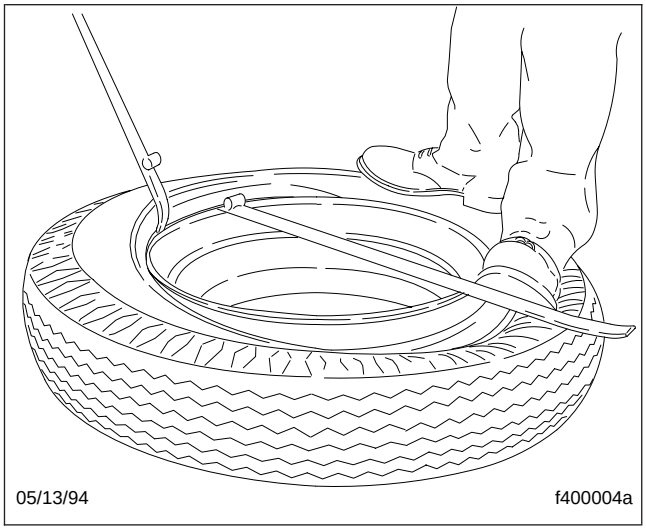

Fig. 2, Forcing Bead into the Rim Well

4. When the first bead is off the rim, and the second bead is in the rim well, stand the assembly upright with the valve stem near the top. Lubricate the second bead and rim. Insert the straight end of the tool between the tire bead and the back rim flange, hooking the tool over the second flange. Lean the tire assembly toward the tool and use a rocking or bouncing action to pry the rim out of the tire. **See Fig. 3.**

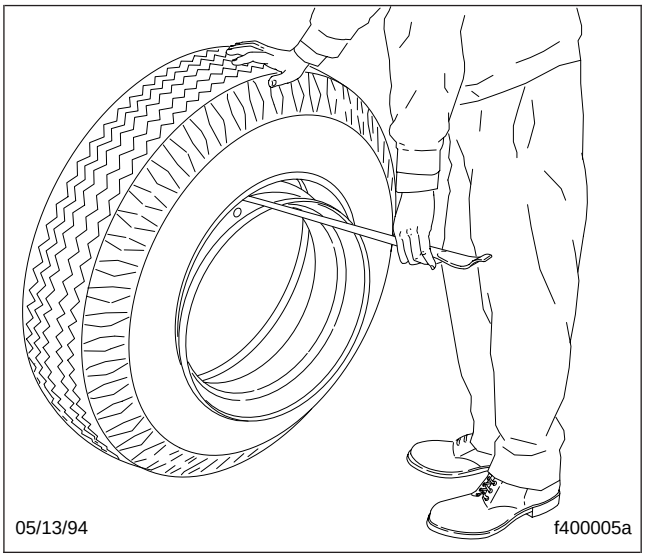

Fig. 3, Prying the Rim Out of the Tire

5. Clean and inspect all parts. Refer to **Subject 190** and **Subject 200** for procedures.

MOUNTING

1. Place the valve stem, with a rubber washer, through the valve hole from the tire side of the rim. Screw on the valve nut from the opposite side. Make sure the rubber bushing and metal collar or nut are centered and fit snugly in the valve hole **(Fig. 4).** Tighten the nut securely.

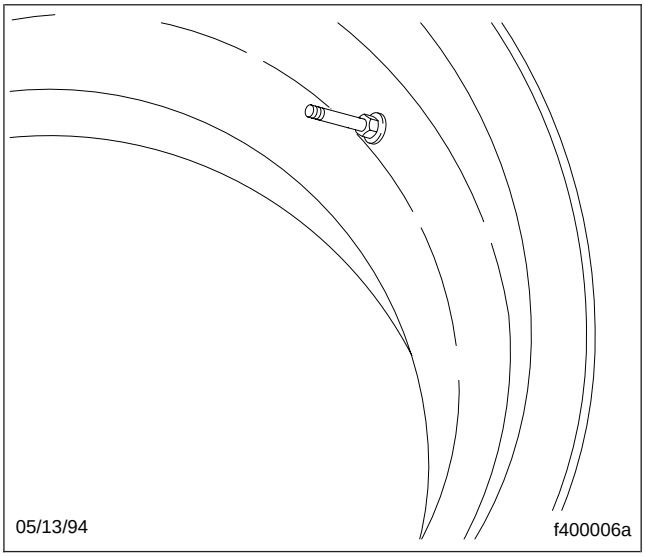

Fig. 4, Valve Stem Installation

2. Place the rim on the floor with the wide side down. Using a brush or swab, lubricate both bead seats (flanges) of the rim, and both tire beads, with an approved lubricant. Apply enough lubricant to enable correct bead seating, and to make mounting easier. Don't let excess lubricant run inside the tire.
3. Lay the tire on the rim. If there is a balance mark on the tire, line up this mark with the valve stem. Push the lower bead over the flange and into the rim well. Using the straight end of the tire tool (with the stop resting on the rim flange), take small bites to work the remaining section of the bead into the rim. **See Fig. 5.**

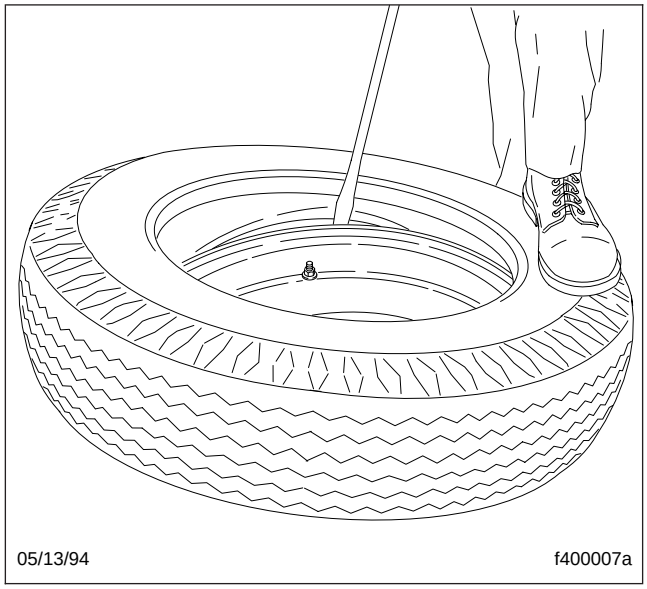

Fig. 5, Working the Lower Bead into the Rim

4. Start the upper bead over the rim flange and into the rim well by standing on the tire. If necessary, push a section of the bead into the rim well, and anchor it by attaching Vise-Grip® pliers to the rim flange (snub side toward the tire). Using the spoon end of the tire iron, with the stop toward the rim, work around the bead **(Fig. 6).** Use small bites until the bead slips over the flange and into the rim well. If necessary, insert a second tire iron and relubricate the last 8 inches (20 cm) of bead.
5. Inflate the tire. Refer to **Subject 210** for procedures.

⚠ WARNING

WARNING: Read the information in Subject 140. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

DEMOUNTING

1. Deflate the tire being serviced by removing the valve core. Check the valve stem by running a piece of wire through the stem to make sure it is not plugged.
2. Place the assembly on the floor, side ring up. Insert the hooked ends of the tire tools between the side ring and the sidewall of the tire. Pry the bead loose from the side ring using downward pressure on the tools **(Fig. 1).** Continue prying around the rim until the bead is loose.

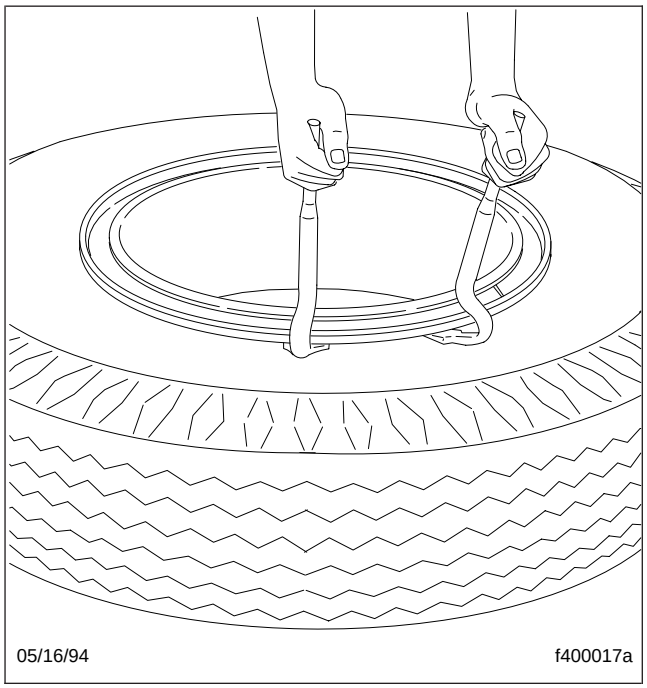

Fig. 1, Prying the Bead Loose

3. Insert the tapered end of the tool into the prying notch on the side ring **(Fig. 2).** Pry the side ring from its groove in the rim by prying around the tire until the ring is free.

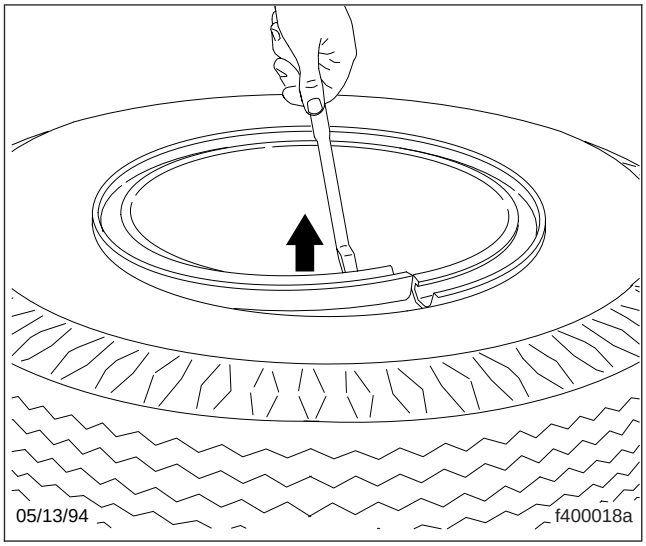

Fig. 2, Prying the Side Ring from the Groove

4. Turn the assembly over, and unseat the second tire bead from the rim. Lift the rim from the tire, and remove the tube and flap from the tire.
5. Clean and inspect all parts. Refer to **Subject 190** and **Subject 200** for procedures.

MOUNTING

1. Place the tube in the tire, then partially inflate it to round it out. Apply an approved tire lubricant to the inside and outside surfaces of both beads and to the portion of the tube that appears between the beads. Insert the flap, and lubricate the portion of the flap that faces the rim. Apply enough lubricant to enable correct bead seating, and to make mounting easier. Don't let excess lubricant run inside the tire.
2. Lay the rim flat on the floor with the valve slot up. Align the valve with the rim valve-slot. Place the tire on the rim, and insert the valve through the valve slot.
3. Place the side ring on the rim base so that the ring split is opposite the valve stem. Snap the leading end of the side ring into the rim groove

WARNING

WARNING: Read the information in Subject 140. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

DEMOUNTING

1. Deflate the tire being serviced by removing the valve core. Check the valve stem by running a piece of wire through the stem to make sure it is not plugged.
2. Loosen the tire bead from the side ring by driving the curved end of a rim tool between the side ring and the bead **(Fig. 7).** Pry the bead loose from the side ring, using downward pressure on the tool. Continue prying around the tire until the bead is loose.

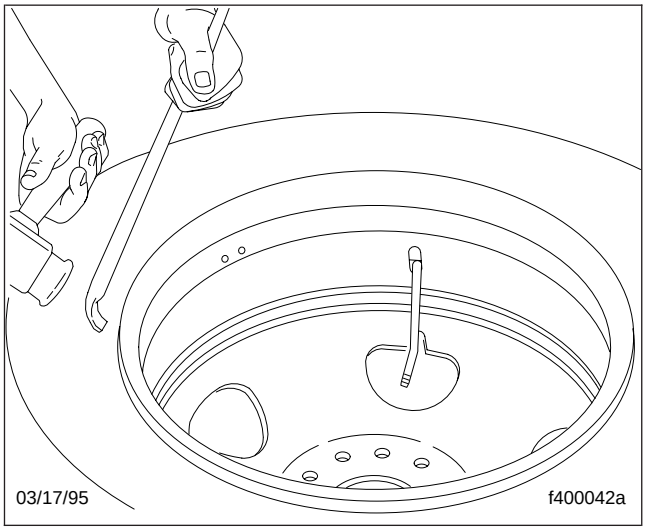

Fig. 7, Loosening the Bead

ring from the rim gutter. Continue prying the side ring away from the rim gutter until it is loose.

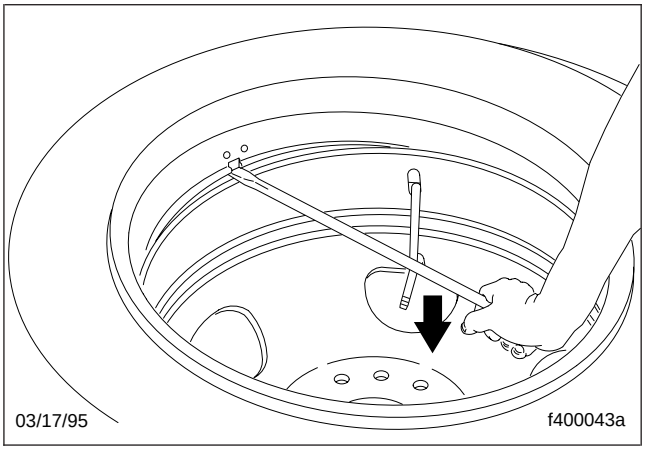

Fig. 8, Prying the Side Ring Loose

4. Turn the assembly over, and unseat the second tire bead the same way the first bead was loosened from the side ring in the step above. Stand the tire up, then remove the rim base. Remove the tube and flap from the tire.
5. Clean and inspect all parts. Refer to **Subject 190** and **Subject 200** for procedures.

MOUNTING

1. Place the tube in the tire, then partially inflate it to round it out. Apply an approved tire lubricant to the inside and outside surfaces of both beads and to the portion of the tube that appears between the beads. Insert the flap, and lubricate the portion of the flap that faces the rim. Apply enough lubricant to enable correct bead seating, and to make mounting easier. Don't let excess lubricant run inside the tire.
2. Place the disc portion of the wheel on the floor, with the rim gutter up. Position the tire, with the valve pointing in the desired direction, then insert the valve through the valve slot. Position the side ring by locating the operating notch between the two embossings, about 3 inches (8 cm) from the valve.
3. The two cutaway portions opposite each other in the inner diameter of the ring are placed so as to span the rim gutter. Opposite the valve, work half of the side ring into the gutter, as far as possible, using a mallet.
4. Insert the straight end of the rim tool into the notch. **See Fig. 9 .** Maintaining pressure with the tool, strike the side ring downward with a mallet at the point between the tool slot and the cutaway portion, forcing the side ring over the rim gutter. Remove the tool, then strike additional blows, moving toward the other cutaway portion, until the entire toe of the side ring passes over the rim gutter. Be sure the side ring has cleared the gutter of the rim base and that the side ring can be depressed by hand.

⚠ WARNING

WARNING: Read the information in Subject 140. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

1. Deflate the tire being serviced by removing the valve core. Check the valve stem by running a piece of wire through the stem to make sure it is not plugged.
2. Place the tire and wheel on the floor with the side ring up. Loosen the first bead by driving the hooked end of the rim tool between the tire and rim flange, then press downward on the bead. Do this around the rim, using two tools, as shown in **Fig. 1.**

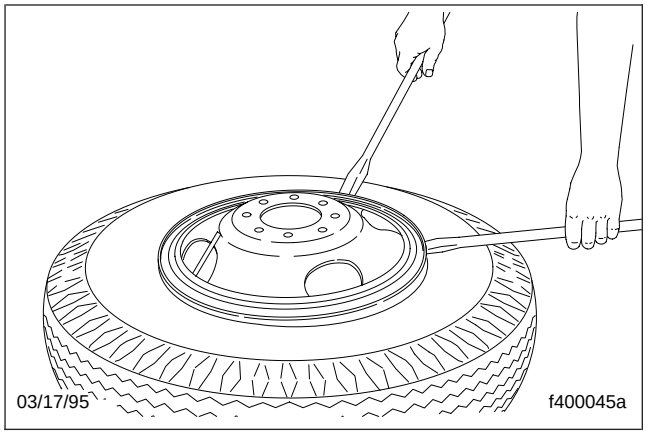

Fig. 1, Loosening the Bead

3. Insert the tool into the notch; then using foot pressure, force the side ring opposite the notch into the gutter **(Fig. 2).** Then, prying up and out on the side ring, carefully pry off the side ring. Don't bend the side ring.

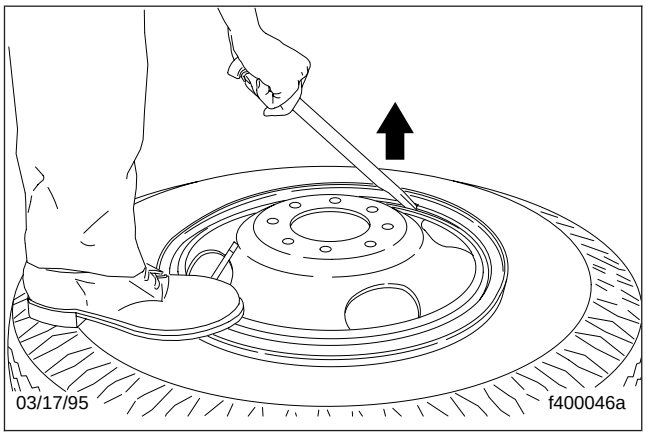

Fig. 2, Forcing the Side Ring into the Gutter

4. Force the upper tire bead into the well opposite the valve slot. With the tire tool, pry the opposite portion of the bead over the edge of the rim.
5. Turn the tire over. Using the tools, loosen the bead on the opposite bead seat. This can be done using foot pressure. Make sure one portion of the second bead is still in the rim well, then pry the opposite portion of the bead over the edge of the rim. This will free the tire from the rim **(Fig. 3).** Remove the tube and flap from the tire.

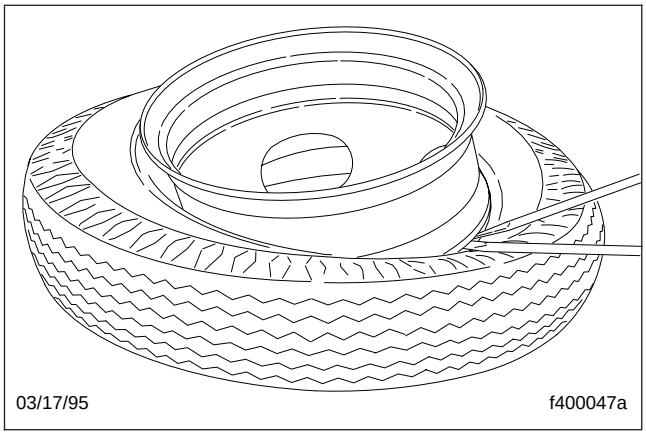

Fig. 3, Prying the Bead Over the Edge of the Rim

Demounting and Mounting Tube-Type Tires on Semi Drop-Center Wheels or Rims

6. Clean and inspect all parts. Refer to **Subject 190** and **Subject 200** for procedures.

MOUNTING

1. Place the tube in the tire and partially inflate it to round it out. Apply an approved tire lubricant to the inside and outside surfaces of both beads and to the portion of the tube that appears between the beads. Insert the flap, and lubricate the portion of the flap that faces the rim. Apply enough lubricant to enable correct bead seating, and to make mounting easier. Don't let excess lubricant run inside the tire.
2. Place the tire on the rim so that the valve lines up with the valve hole. Insert the valve through the valve hole. Using foot pressure, work the first bead into the rim well just to the side of the valve. Pry the first bead over the rim gutter with the rim tool, moving from each side of your foot, alternately, to a point just opposite your foot **(Fig. 4).** Then pry the last section over the rim gutter.

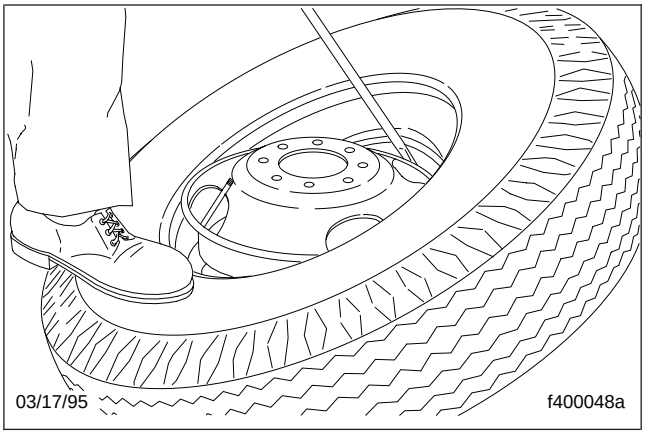

Fig. 4, Prying the Bead Over the Rim Gutter

3. To mount the second bead, start at a point opposite the valve, and using foot pressure, press the bead toe over the rim gutter and into the rim well. Mount the remainder of the bead over the rim gutter, using a thin tire tool, and following the procedure in the step above. Be careful not to pinch the tube.
4. Place half of the side ring in the rim gutter with the cutaway portions in place, as shown in **Fig. 5.** Insert the thin end of a rim tool or heavy screwdriver, then pull the side ring outward toward the centered position. Work the side ring into the gutter by striking it with a mallet.

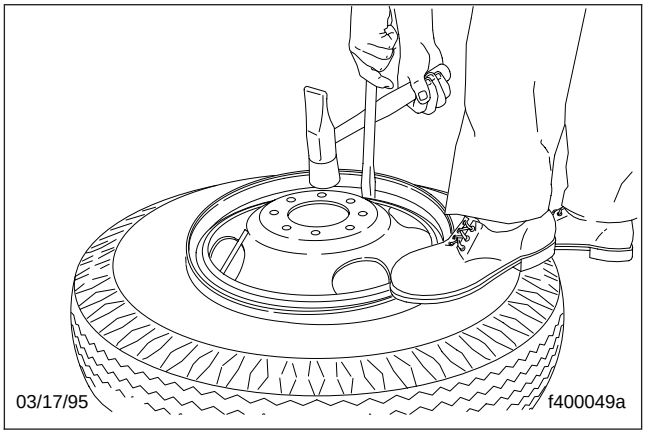

Fig. 5, Placing Half of the Side Ring in the Rim Gutter

5. Inflate the tire. Refer to **Subject 210** for procedures.

Inspection

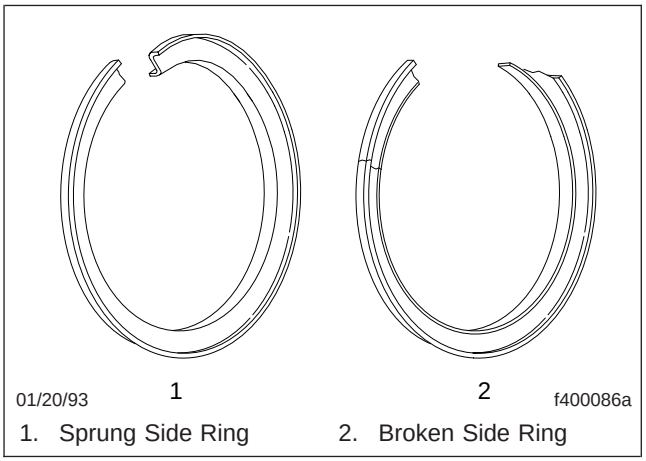
WARNING

WARNING: Inspect the tires and wheels, and correct any problems. Failure to do so could cause tire or rim damage while servicing or while in use. An incorrectly mounted tire can burst causing equipment damage and personal injury.

Examine the wheel or rim, and all parts. Remove any grease, dirt, or rust. Using a wire brush, remove any rubber from the bead seat. Use special care when cleaning the rim gutter. Rust or other foreign matter can prevent the correct fitting of side rings. Replace corroded parts. Paint the rim to prevent corrosion.

NOTE: Don't paint Alcoa aluminum disc wheels. If the wheels are corroded, contact the manufacturer for instructions.

Sprung or broken rings **(Fig. 1),** a cracked rim, wheel **(Fig. 2),** or brake drum, damaged inner or outer wheel nuts **(Fig. 3),** or an out-of-round wheel or rim, requires the replacement of the damaged part. Replace the wheel if it has out-of-round stud holes.



1. Sprung Side Ring
2. Broken Side Ring

Fig. 1, Sprung and Broke Side Rings

NOTE: Refer to the front and rear axle sections in this manual for inspection and service procedures for the hub, wheel studs, wheel, and brake drum assemblies. When replacing the spoke wheel or the brake drum, contact the wheel manufacturer for the correct torque value

for the brake drum nut that attaches the spoke wheel to the brake drum.

Inspect valve cores for cracks, bends, and air retention. Replace damaged or leaky cores.

The most critical area of a spoke wheel is the 28-degree tapered rim mounting surface **(Fig. 4).** Clean the surface and examine it for damage or excessive wear. Replace the wheel if the mounting surface is damaged or worn below the 28-degree taper.

Check the clamps, rim spacer, rim studs, and spoke-wheel nuts for damage or wear. The clamps must not be excessively worn. The end of the wedge portion must be at least 1/16-inch thick (1.5 mm). **See Fig. 5.** The rim spacer must not be bent, distorted, or crushed. Replace all damaged or broken parts.

Do not attempt to rework, weld, heat, or braze any rim or wheel parts that are cracked, broken, or damaged. Use new parts or parts that are not cracked, broken, or otherwise damaged, and that are of the same size and type.

Inspection

WARNING

WARNING: Inspect the tires and wheels, and correct any problems. Failure to do so could cause tire or rim damage while servicing or while in use. An incorrectly mounted tire can burst causing equipment damage and personal injury.

Inspect the inside and outside of the tire for out-of-roundness, loose cords, cuts, foreign objects, and other damage. Repair as needed. Contact the tire manufacturer for repair procedures.

Do not repair tires with the following problems:

- Cuts in the tread that are wire or breaker fiber deep.
- Tread worn to the wire or breaker fibers.
- Tread that is scalloped or otherwise worn unevenly.
- Visible, broken, deformed, or otherwise damaged bead wires.
- Deteriorated rubber.
- Rubber cracked to the wire or cord.
- Separations in the casing.
- Exposed cord (for example, due to weather checking or sidewall scuffing).

Inspect the tread for abnormal or excessive wear. Refer to **Troubleshooting, 300** for possible causes of abnormal wear. If the tires are wearing irregularly, they should be rotated. If the front axle tires become irregularly worn, they should be moved to the drive axle(s) or trailer axles. The front-end alignment should be checked. In a dual assembly, if one tire wears faster than its mate, the position of the two tires should be reversed. Refer to the vehicle maintenance manual for tire rotation procedures.

Government regulations require the removal of any tire with less than 2/32-inch (1.5 mm) tread remaining. Retread the tire (if possible), regroove it (only if marked "Regroovable" on the sidewall), or discard it.

Clean and inspect the tube and flap of tube-type tires. Discard tubes or flaps that are buckled or creased. Do not use an old tube in a new tire, and always mount a used flap in the same size tire and on the same size rim as the one from which it was removed. Michelin Tire Corporation recommends using only new tubes, flaps, valve cores, caps, and O-rings in a new mounting.

Tire Inflation

1. Check all parts to make sure they are correctly seated prior to inflation.

NOTE: Inflate tires in a safety cage **(Fig. 1)** or an approved portable restraining device. Always use a clip-on chuck with an inline valve and gauge. Make sure the inflation hose is long enough to permit standing to the side of the tire during inflation. Never sit on or stand in front of an assembly that is being inflated.

⚠ WARNING

WARNING: During initial tire inflation, there is the possibility of an explosion of the assembly. Observe the following safety rules to reduce the possibility of serious physical injury in the event of an explosion.

IMPORTANT: Inflate tires immediately after mounting, before the tire lubricant dries. Once the lubricant dries, bead positioning is not possible, even with increased inflation pressure.

Water in the tire can cause ply separation. During tire inflation, air tank reservoirs and lines must be dry. Use well-maintained air line moisture traps, and service them regularly.

2. After placing the tire in a safety cage, or an approved portable restraining device, inflate the tire to 10 psi (69 kPa). Check the parts for correct seating. If the seating is not correct, completely deflate the tire and correct the problem. Never attempt to seat rings or other parts by hammering on an inflated or partially inflated tire.

IMPORTANT: Due to the different flex characteristics of radial sidewalls, it may be necessary to use an inflation aid to help seat tubeless tire beads:

- Metal rings, which use a blast of compressed air to seat the beads.
- Rubber rings, which seal between the tire bead and rim, allowing the bead to move out and seat correctly. A well-lubricated, heavy-duty bicycle tube can be used to help seal between the tire bead and rim.

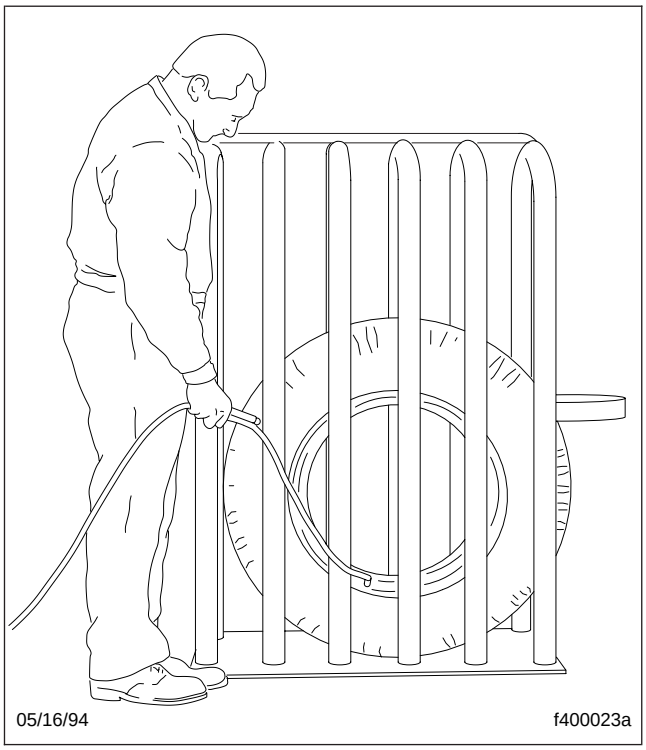

Fig. 1, Safety Cage

3. If there are no problems with the assembly at 10 psi (69 kPa), continue to inflate the tire to the recommended pressure. Refer to **Specifications, 400** for correct cold inflation pressures. Michelin Tire Corporation recommends an initial inflation pressure of 90 to 100 psi (620 to 690 kPa) to correctly seat the tire beads.

NOTE: The position of the beads, flap, and tube with 4 to 5 psi (28 to 35 kPa) pressure is shown in **Fig. 2**. The tube is fully rounded-out within the tire, but there isn't enough pressure to move the beads on wide-base rims. Depending on the tire size and rim condition, from 20 to 40 psi (140 to 275 kPa) pressure is needed to push the beads onto the bead seat. **See Fig. 3.**

4. After the initial inflation, completely deflate the tire by removing the valve core. This ensures correct bead seating, and prevents buckling or overstretching the tube in tube-type tires. Then inflate the tire to the recommended cold inflation pressure listed in **Specifications, 400**. Install valve caps and tighten them finger-tight.

⚠ CAUTION

CAUTION: Improperly inflating tube-type tires can crack or tear the edge or inside of the valve base. Once seated, the tube can stretch only in the rim area. Because resistance to stretch is greatest at the valve base, there is often enough tension to break the tube at the edge of the valve base or in the valve base.

IMPORTANT: Use tires of the same size, type, and capacity to carry the load at the recommended cold pressure. Attempting to increase the load capacity of a tire by overinflation will damage the tire assembly.

NOTE: Inflate the tires to the recommended pressure. Driving on overinflated tires will weaken the cords by reducing their ability to absorb road shocks, and will increase the danger of cuts, snags, and punctures. Overinflation will overstress and damage the rims. Driving on underinflated tires will generate excessive heat. This weakens the tire body, and reduces tire strength.

⚠ WARNING

WARNING: Inflate tires to the specified pressure. Tire underinflation or overinflation will damage wheels and tires, and could result in a blowout, causing possible personal injury and property damage.

5. Check the inflation pressure 24 hours after mounting new tires.

NOTE: When testing a vehicle on a dynamometer, severe tire damage can occur. Because the manufacturers differ in their recommendations for preventing tire damage, refer to the manufacturer's instructions for testing a vehicle on a dynamometer.

General Information

Runout is side-to-side (lateral) or up-and-down (radial) movement when the tire/wheel assembly is rotated. Runout can be measured with a dial indicator, a tire runout gauge, or another instrument capable of measuring small movements of the tire/wheel assembly.

Lateral runout, shown in **Fig. 1**, is side-to-side movement of the rotating tire/wheel assembly. This may cause a perceived "shimmy" or "wobble".

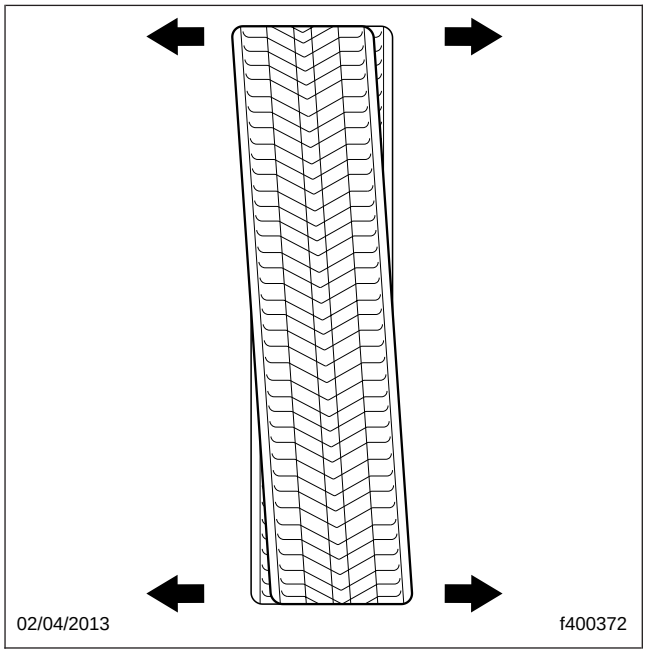

Fig. 1, Lateral Runout

Radial runout, shown in **Fig. 2**, is a changing radius of the rotating tire/wheel assembly. For a tire or wheel, its effect is to raise and lower the vehicle as it rolls along, giving the perception of a vertical "hop" or "bounce".

If a tire and wheel assembly shows visible up-and-down or side-to-side movement, it may have excessive runout. Use the inspection procedure that follows to measure runout.

Inspection

IMPORTANT: Before checking wheel runout, check the tires for proper:

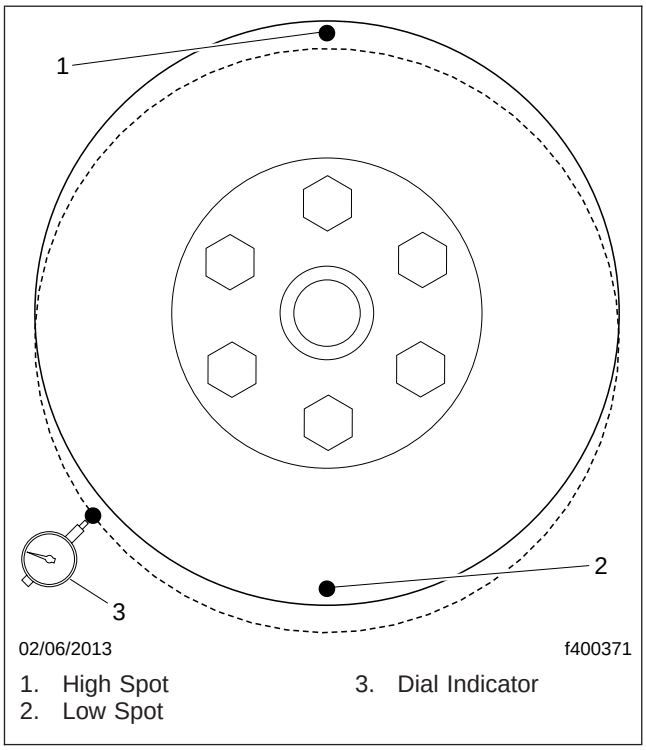

Fig. 2, Radial Runout

- inflation;
- wheel nut torque;
- bead seating on the rim.

Use a tire runout gauge, as shown in **Fig. 3**, to check lateral and radial runouts of the entire wheel end assembly.

Check radial runout on a smooth rib in the center of the tread. Check lateral runout on a smooth surface along the tire's mid-sidewall. If the wheel end assembly radial runout exceeds 0.060 inch (0.2 cm), or the lateral runout exceeds 0.150 inch (0.4 cm), the tire/wheel assembly should be removed to check the brake drum and hub runouts. Brake drum and hub runout tolerances are as follows:

- brake drum lateral runout—0.045 inch (0.11 cm)
- brake drum radial runout measured inside of the drum—0.020 inch (0.050 cm)
- hub lateral runout measured at the face of the hub—0.015 inch (0.38 cm)

Wheel and Tire Runout Measurements

- hub radial runout measured near the hub pilots—0.015 inch (0.38 cm)

If hub and brake drum runouts are within specification, then the wheel runout will need to be checked. Demount the tire from the wheel and check lateral and radial runouts for the wheel as shown in **Fig. 4**. For tire demounting instructions, see **Section 40.00**. Make certain the wheel is properly fixed in a wheel balancer or remounted on the hub. See **Table 1** for wheel runout specifications.

Troubleshooting

Problem—Excessive On-the-Road Tire Failures

Problem—Excessive On-the-Road Tire Failures	
Possible Cause	**Remedy**
Tires are not inflated to the correct pressure.	Operate the tires at the recommended inflation pressure and use the proper size tires, wheels, and rims for the load to be carried. Refer to **Specifications, 400.**
Dual tires are mismatched.	Examine all tires and match them according to the specifications in this section.
Water or foreign material is inside the casing.	Clean and dry the tires and tubes prior to mounting. Make sure excess lubricant does not flow down into the tire. Store unmounted tires indoors, or under cover, to prevent moisture from collecting inside.
Tires are contaminated with oil.	Clean the tires and inspect the engine seals, transmission seals, axle-end and drive axle seals, oil filters and oil lines for leakage. Make sure the lubricant used in mounting does not contain a petroleum derivative.
Vehicle is vibrating severely.	Follow the recommendations under "Vehicle Vibration" in this chart.
Wheel or rim components are mismatched.	Check the catalog issued by the applicable wheel or rim manufacturer for the proper part numbers and sizes of approved components. Make sure that all parts of an assembly match in size, manufacturer, and classifications within a manufacturer's line. Never use a component which does not bear clear, legible, and proper numbers and manufacturer's identification, even if it appears to fit.
Parts are corroded, worn, or otherwise damaged.	Clean or replace parts as necessary.

Tire Pressure

Do not reduce the pressure of a hot tire if it exceeds the specified pressure. In normal driving, tire temperature and inflation pressure increase. Increases of 10 to 15 psi (70 to 105 kPa) are common. Higher pressures may be signs of overloading, underinflation, excessive speed, improper tire size, or any combination of these factors, and must be checked when the tire is cool.

IMPORTANT: The load and cold inflation pressure must not exceed the rim or wheel manufacturer's recommendations, even though the tire may be approved for a higher load or inflation. Some rims and wheels are stamped with a maximum load and maximum cold inflation rating. If they are not stamped, consult the rim or wheel manufacturer for the correct tire inflation pressure for the vehicle load. If the load exceeds the maximum rim or wheel capacity, the load must be adjusted or reduced.

For further information on rims and tires (other than Michelin), and for inflation and load limits, see the "Tire and Rim Association Yearbook." Contact the Michelin Tire Corporation for further information on their tires.

General Information

The simplest driveline consists of a transmission output-shaft end-yoke, an axle input-shaft end-yoke, and a single slip-jointed driveshaft connecting the two end-yokes. See **Fig. 1**. The driveshaft is made up of a universal joint (U-joint), a sleeve-yoke, a splined stub shaft, a driveshaft tube, a tube-yoke, and a second U-joint.

Driveline Configurations

The specific type and number of drivelines used on each vehicle depends on its number of transmissions, its number of drive axles, and its wheelbase. See **Fig. 2**. A driveline is used between each driving and driven component. A driveline connecting a main transmission (or an auxiliary transmission) to a single drive axle or forward-rear axle of a dual-drive vehicle is always referred to as a No. 2 driveline. See **Fig. 2**, examples A, B, C, D, and E. An interaxle driveline of a dual-drive vehicle is always called a No. 3 drive-

line. See **Fig. 2**, examples B and C. A driveline connecting a main transmission to an auxiliary transmission is always referred to as a No. 1 driveline. See **Fig. 2**, example C.

A long driveshaft, supported only at its ends, will sag in the middle from its own weight. When turning at high rpm, it will flex, causing an out-of-balance vibration. Therefore, vehicles having a long wheelbase

use a midship bearing, mounted on a frame crossmember, for additional support. See **Fig. 2**, example D. This allows the No. 2 driveline to be separated into two, shorter shafts (a coupling shaft and a No. 2 driveshaft), thus improving balance and stability.

Vehicles having an even longer wheelbase use two crossmember-mounted midship bearings, allowing the No. 2 driveline to be separated into three short shafts, joined by four U-joints. See **Fig. 2**, example E. The first shaft is the primary coupling shaft, the second is the intermediate coupling shaft, and the third is the No. 2 driveshaft.

Slip-Joints, U-Joints, and Yokes

The basic function of the driveline is to send torque from the transmission to the axle in a smooth and continuous action. Because the vehicle axles are not attached directly to the frame, but are suspended by springs, they ride in an irregular, floating motion (when going over bumps or depressions), thus changing the distance between the transmission (or coupling shaft) and the rear axle, and the distance between the rear axles. The slip-joints of the No. 2 and No. 3 driveshafts, by expanding and contracting, allow for length changes between drivetrain components. Coupling shafts do not require a slip-joint.

Motion of the rear axle(s) also causes changes to the relative angles between drivetrain components. U-joints allow transfer of torque from an output shaft (or coupling shaft) to the driveshaft, and from the driveshaft to an input shaft, even though the angles between the shafts may be constantly changing.

Each U-joint consists of a cross with a close-tolerance ground cylindrical surface (trunnion) at the end of each of the four arms. Installed on each trunnion is a bearing cup lined with bearing needles. All bearing cups are sealed to retain lubricants, and to prevent entry of foreign material. See **Fig. 3**. In operation, the four bearing cups are held stationary in a pair of yokes, while the U-joint cross pivots on its trunnions.

Full-round yokes are installed at the front of coupling shafts and at both ends of the No. 2 and No. 3 driveshafts. All tube-yokes (yokes that are welded into driveshaft tubes) and all sleeve-yokes (yokes that are part of the internally splined half of slip-joints) are full-round yokes. See **Fig. 4**, Refs. 4 and 9.

equipment, all No. 2 driveline end-yokes are half-round, with full-round optional. And, as standard equipment, all No. 3 driveline end-yokes are full-round, with half-round optional. End-yokes are installed on the transmission output shaft, on each axle input and output shaft, and behind the midship bearing of most coupling shafts. See **Fig. 4**, Refs. 2, 7, 12, and 14.

U-Joint Angles, Phasing, and Driveline Balance

Correct U-joint working angles, U-joint phasing, and driveline balance are vital to maintaining a quiet-running drivetrain and long life of drivetrain components (including driveline components).

2. Bearing Cup (bearing-plate-type)
3. Full-Round Yoke
4. U-Joint Cross

Fig. 7, Installation of a U-Joint in a Full-Round Yoke

The U-joint working angle is the angle formed by the intersection of the driveshaft centerline and the extended centerline of the shaft of any component (or other driveshaft) to which the U-joint connects. See **Fig. 8**. Because the double oscillating motion of a U-joint that connects angled shafts causes a fluctuating speed difference between the shafts, the effect created by the U-joint at one end of the shaft must cancel the effect created by the U-joint at the other end. This is done by making U-joint working angles at both ends of the driveshaft approximately equal, with the U-joints in phase. If the yoke lugs at both ends of the shaft are lying in the same plane (a plane that bisects the shaft lengthwise) the U-joints will be in phase. See **Fig. 9**.

NOTE: Some driveshafts are designed and phased with their end yokes clocked 90 degrees from each other. This is referred to as cross phasing.

After manufacture, each driveline yoke is statically balanced. After assembly, each driveshaft and cou-

pling shaft is checked for out-of-roundness, straightened as necessary, then dynamically balanced.

Avoiding Driveline Problems

To ensure that U-joints turn in phase, sleeve-yokes, splined shafts, coupling shaft end-yokes, and coupling shafts, should be marked for assembly reference before disassembly. A misaligned slip-joint will seriously affect driveline balance (and U-joint phasing). Even if a slip-joint is assembled 180 degrees from its original position (which will keep the U-joints in phase), the dynamic balance of the driveshaft will be negatively affected.

A driveline can become unbalanced or greatly weakened if a driveshaft has been dented, bent, twisted, or otherwise damaged. Operating a vehicle at speeds that exceed the speed of the driveshaft's design specifications will cause an out-of-balance vibration. Any condition that allows excessive movement of a driveshaft will cause driveline imbalance: loose end-yoke nuts, loose midship bearing mounts, loose U-joint bearing cup retaining capscrews, worn U-joint trunnions and bearings, and worn slip-joint splines.

Among the most common causes of U-joint and slip-joint damage is lack of lubrication.

To keep a vehicle operating smoothly and economically, the driveline must be carefully checked and lubricated at regular intervals. For inspection and lubrication intervals and procedures, see **Group 41** of the *Century Class Trucks Maintenance Manual*.

U-Joint Uncoupling and Coupling With a Half-Round End-Yoke

U-Joint Uncoupling (See Fig. 1 and Fig. 2)

NOTE: It is easier to check driveline parts, and to replace a U-joint or midship bearing assembly if the driveshaft is removed from the vehicle. If a driveshaft requires straightening or balancing, it must be removed, and installed on a lathe or a balance machine. Removal is required for replacement of slip-joint parts, a driveshaft tube, or a tube-yoke. To remove the driveshaft, see **Subject 120**.

NOTE: Many service operations do not require driveshaft removal from the vehicle: end-yoke nut tightening; drive component shaft seal or end-yoke replacement; changing U-joint phasing at the slip-yoke; and transmission or axle removal (for overhaul, repair, or replacement). To perform these operations, uncouple the U-joint at the applicable end of the appropriate driveshaft.

1. Roll the vehicle forward or backward as needed to turn the rearmost end-yoke (of the driveline that is being uncoupled) until the centerline through its cross-holes is horizontal. See **Fig. 1**, Ref. A and Ref. B.
2. Apply the parking brakes, and chock the tires.
3. If the half-round bearing cups do not already have a retaining wire installed, install a bearing-cup retaining wire. See **Fig. 1**, Ref. C. Or, install safety wire from the retaining-wire groove of one half-round bearing cup to the other.
4. Support the driveshaft with a nylon support strap.

   When uncoupling a coupling shaft, install two or three support straps, as needed. Remove the fasteners that attach the midship bearing(s) to its bracket(s). See **Fig. 1** and **Fig. 2**.
5. Remove the capscrews that secure the bearing cups or straps to the half-round yoke. Remove the bearing straps, if equipped.
6. Compress the slip-joint to remove the U-joint from the yoke.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

1. Check and clean the end-yoke.
   - 1.1 Check the torque on the end-yoke nut. See **Specifications, 400**.
   - 1.2 Check the end-yoke cross-holes for burrs or raised metal. Using a half-round file, remove burrs or raised metal. See **Fig. 3.**
   - 1.3 Using fine emery cloth, smooth and clean the entire surface of the yoke cross-holes and bearing straps. See **Fig. 4.**
   - 1.4 Turn the end-yoke until its cross-holes are horizontal. See **Fig. 1** and **Fig. 2**.
2. Check, clean, and lubricate the U-joint.
   - 2.1 Remove the bearing-cup retaining wire or safety wire. See **Fig. 1**, Ref. C.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

   - 2.2 Using fine emery cloth, smooth and clean the outside surfaces of both bearing cups. See **Fig. 5.**
   - 2.3 Check the U-joint trunnions and bearing cups for minute particles of dirt or grit. Clean if necessary. See **Subject 140**.
   - 2.4 Using NLGI grade 2 grease with EP additives, wipe a small amount of grease on the needles in the bearing cups.
   - 2.5 Using a light-weight oil, lubricate the lips of the bearing-cup seals. See **Fig. 6.**

CAUTION

Do not use the capscrews and bearing straps (if equipped) to seat the bearing cups in the yoke. Seating the cross by tightening the bearing straps can deform the bearing straps, allowing the bearing cups to spin, which will cause rapid wear and serious damage to the U-joint.

⚠ WARNING

The self-locking capscrews must not be reused. Replace the capscrews with new ones. Also, do not undertighten or overtighten the capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could cause serious vehicle damage, or could result in a driveshaft separating from the vehicle. Driveline separation can cause loss of vehicle control that could result in serious personal injury or death.

Separation of the driveline can also cause damage to the driveline, driveline components, or other areas of the vehicle.

5. Alternately tighten the capscrews in increments of 20 lbf·ft (27 N·m) to the applicable torque value in **Specifications, 400**.

To perform these operations, uncouple the U-joint at the applicable end of the appropriate driveshaft.

1. Roll the vehicle forward or backward as needed to turn the end-yoke (of the driveline that is being uncoupled) until the centerline through its cross-holes is vertical. See **Fig. 1**.

   - 1.2 Check the end-yoke cross-holes for burrs or raised metal. Using a rat-tail or half-round file, remove burrs or raised metal. See **Fig. 3**.
   - 1.3 Using a mill file, and holding it flat against the machined surface of the yoke lug, remove any burrs or raised metal. See **Fig. 4**.
   - 1.4 Using fine emery cloth, smooth and clean the entire surface of the yoke cross-holes. See **Fig. 5**.
   - 1.5 Turn the end-yoke until the centerline through its cross-holes is vertical. See **Fig. 1**.
2. Check, clean, and lubricate the U-joint.
   - 2.1 Using fine emery cloth, smooth and clean the outside surfaces of both bearing cups. See **Fig. 6**.
   - 2.2 Check the U-joint trunnions and bearing cups for minute particles of dirt or grit. Clean if necessary; see **Subject 140**.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

   - 2.3 Using NLGI grade 2 grease with EP additives, wipe a small amount of grease on the needles in the bearing cups.
   - 2.4 Using a light-weight oil, lubricate the lips of the bearing-cup seals. See **Fig. 7**.
3. Couple the U-joint cross to the end-yoke.
   - 3.1 Extend the slip-joint, while pivoting the U-joint cross into place in the yoke cross-holes.
   - 3.2 Move one end of the cross until a trunnion projects through the cross-hole, beyond the outer machined face of the yoke lug.

NOTE: Not all fasteners are shown.

A. End-yoke cross-hole centerline is vertical.

Fig. 1, U-Joint Uncoupling/Coupling of a Driveline With Full-Round End-Yokes

Using a Spicer trunnion (journal) locator (see **Specifications, 400**), hold the trunnions in alignment with the cross-holes, while placing a bearing assembly over the projected trunnion, and aligning it with the cross-hole. See **Fig. 8**.

IMPORTANT: A Spicer trunnion (journal) locator should be used, to prevent damage to the U-joint trunnions and slingers.

3.3 By hand, press the bearing assembly flush with the face of the yoke. If the bearing assembly binds in the cross-hole, tap the *center* of the bearing plate with a rubber or rawhide mallet; do not tap the outer edges of the bearing plate. See **Fig. 9**.

3.4 Install *new* bearing-cup-plate self-locking capscrews (**Fig. 10**). Tighten the capscrews until all the parts are drawn down tight, with no gaps; do not tighten the capscrews to their final torque value.

⚠ WARNING

Self-locking bearing-cup-plate capscrews must not be reused; replace the capscrews with new ones. Also, do not undertighten or overtighten any bearing-cup-plate capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could cause serious vehicle damage, or could result in a driveshaft separating from the vehicle, possibly causing loss of vehicle control that could result in serious personal injury or death.

3.5 Move the cross until it projects beyond the machined surface of the opposite yoke lug. Repeat applicable substeps to install the opposite bearing.

3.6 Alternately tighten the bearing-cup-plate capscrews in increments of 5 lbf·ft (7 N·m), to the torque value in **Specifications, 400**.

Driveshaft Removal and Installation

NOTE: Many service operations do not require driveshaft removal from the vehicle: end-yoke nut tightening; drive component shaft seal or end-yoke replacement; changing U-joint phasing at the slip-yoke; and transmission or axle removal (for overhaul, repair, or replacement). To perform these operations, uncouple the U-joint at the applicable end of the appropriate driveshaft. See **Subject 100** for uncoupling from a *half-round* end-yoke, or see **Subject 110** for uncoupling from a *full-round* end-yoke.

NOTE: It is easier to check driveline parts, and to replace a U-joint or midship bearing assembly if the driveshaft is removed from the vehicle. If a driveshaft requires straightening or balancing, it must be removed, and installed on a lathe or balance machine. Removal is required for replacement of slip-joint parts, a driveshaft tube, or a tube-yoke.

No. 3 Driveshaft Removal

(See Fig. 1 and Fig. 2)

1. Uncouple the No. 3 driveshaft from the rearmost axle. If the No. 3 driveshaft is coupled to *half-round* end-yokes, follow the uncoupling procedure in **Subject 100**. If the No. 3 driveshaft is coupled to *full-round* end-yokes, follow the uncoupling procedure in **Subject 110**.
2. Uncouple the No. 3 driveshaft from the forward-rear axle. If the No. 3 driveshaft is coupled to half-round end-yokes, follow the uncoupling procedure in **Subject 100**. If the No. 3 driveshaft is coupled to full-round end-yokes, follow the uncoupling procedure in **Subject 110**.

Slip-Joint Disassembly

Except RPL Drivelines

1. Check that the driveshaft yokes are aligned to hold the U-joints at either end in phase, as shown in **Fig. 8**. Using a marking stick or paint, mark the sleeve-yoke and splined shaft with alignment marks, as shown in **Fig. 9**. This will ensure proper alignment of the slip-joint components when the driveshaft is assembled.

IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

2. With the driveshaft uncoupled at one end, *or* removed from the vehicle, use a strap wrench to unscrew the slip-joint dust cap from the sleeve-yoke, then pull the sleeve-yoke off of the splined shaft. Remove the dust cap, and (if so equipped) the steel washer and cork seal. See **Fig. 10**.

RPL Drivelines

1. Check that the driveshaft yokes are aligned to hold the U-joints at either end in phase, as shown in **Fig. 8**. Using a marking stick or paint, mark the sleeve-yoke and splined shaft with alignment marks, as shown in **Fig. 9**. This will

ensure proper alignment of the slip-joint components when the driveshaft is assembled.

IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

2. With the driveshaft uncoupled at one end, *or* removed from the vehicle, use a brass hammer and punch to tap the shroud off the slip seal. See **Fig. 11**.
3. Use a screwdriver to pry the seal out of the groove in the slip yoke, then pull the sleeve-yoke off of the splined shaft. Remove the shroud and seal.

Driveshaft Tube, Slip-Joint, Sleeve-Yoke, and Tube-Yoke Cleaning and Inspection

1. With the driveshaft removed, scrape or soak away any foreign material.
2. Examine the driveshaft tube for dents, bends, twists, splitting weld-seams, and signs of missing balance weights.

   Replace the driveshaft tube if damaged; see "Driveshaft Tube, Stub Shaft (Slip-Joint), or Tube-Yoke Replacement," in **Subject 150**. If balance weights appear to be missing, have the driveshaft balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.
3. Clean the slip-joint (male and female) splines, then check them for twisting and galling. See **Fig. 1**. Replace both the sleeve-yoke and the splined shaft if the slip-joint is damaged; see "Driveshaft Tube, Stub Shaft (Slip-Joint), or Tube-Yoke Replacement," in **Subject 150**. Remove any burrs or rough spots using fine emery cloth.

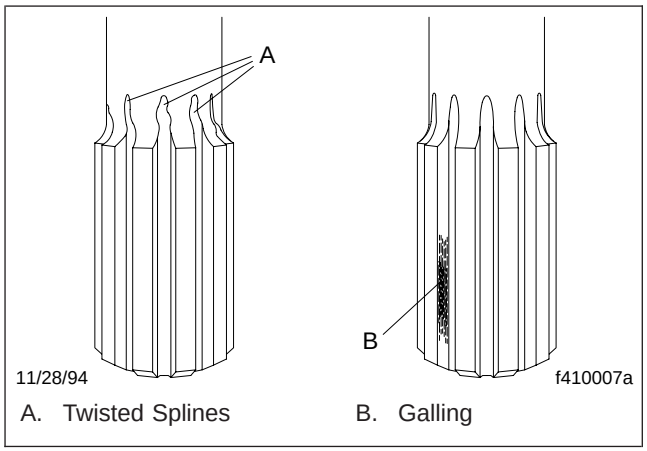

Fig. 1, Damaged Slip-Joint Splines

4. Check for a loose or missing sleeve-yoke plug. See **Fig. 2**. Repair or replace the plug as needed.
5. With the U-joint assemblies removed, check all driveshaft yoke cross-holes for raised metal. Using a rat-tail or half-round file, remove burrs or raised metal. See **Fig. 3**.

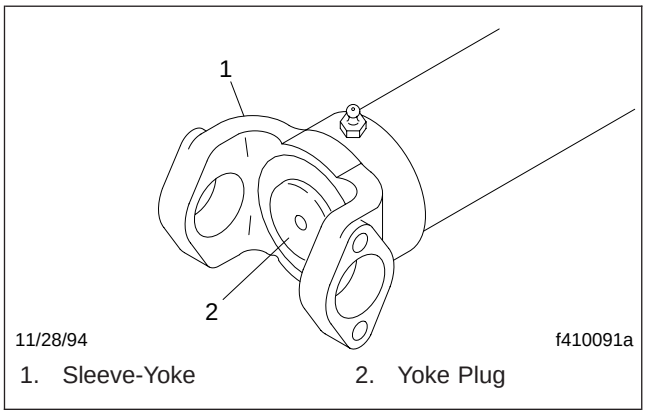

Fig. 2, Sleeve-Yoke Plug

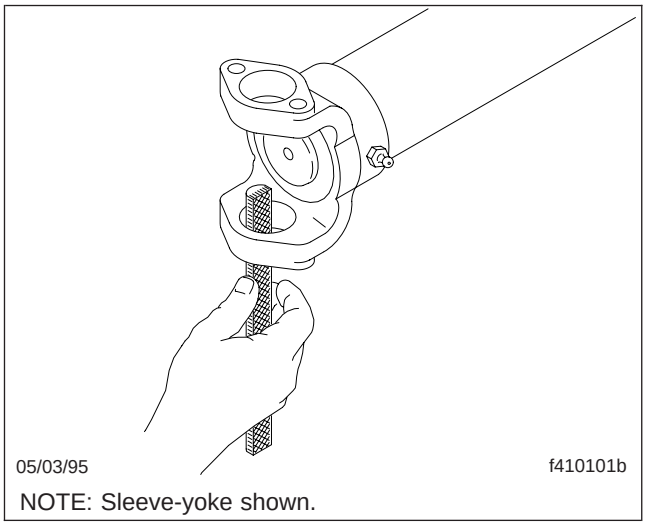

Fig. 3, Removing Burrs From a Full-Round Yoke Cross-Hole

6. Using a mill file, and holding it flat against the machined surface of the driveshaft yoke lug, file each yoke lug, to remove any burrs or raised metal. See **Fig. 4**.
7. Using fine emery cloth, smooth and clean the entire surface of all driveshaft yoke cross-holes. See **Fig. 5**.

shields, or "slingers", common to the previous design, are not required.

1. With the midship bearing removed from the coupling shaft, use clean rags or paper towels to wipe off the outside of the midship bearing, rubber cushion, and slingers.

IMPORTANT: Do not immerse the midship bearing in cleaning solvent. The solvent will wash out the lubricant, requiring bearing-assembly replacement.

2. Check the midship bearing for roughness or rattles by holding the outside of the bearing while manually turning the inner bearing race. Replace the bearing assembly if there are any rough spots or rattles.
3. Check the rubber cushion for deterioration or oil-soaking, and replace the midship bearing assembly if needed.

End-Yoke Cleaning and Inspection

1. With the transmission output-shaft and axle shaft end-yokes installed, check them for cracks and looseness.

   Replace cracked yokes. If the end-yoke can be moved in or out on its shaft, or can be rocked on its shaft, uncouple the driveshaft from the end-yoke. Check the drive component's shaft seal for leakage or other visible damage that may have been caused by the loose yoke. Replace the shaft seal if needed. Tighten the end-yoke nut to the torque value given in **Specifications, 400**. If the end-yoke is still loose after tightening the yoke nut, install a new yoke and yoke nut.

NOTE: If the end-yoke locknut is removed for any reason, install a new one.

2. With the U-joints uncoupled from the end-yokes, check all driveshaft and input/output shaft end-yoke cross-holes for raised metal. Using a rat-tail or half-round file, remove burrs or raised metal. See **Fig. 3** for full-round yokes, or see **Fig. 6** for half-round yokes.
3. Using a mill file, and holding it flat against the machined surface of the *full-round* end-yoke lug, file each yoke lug, to remove any burrs or raised metal. See **Fig. 4**.
4. Smooth and clean the entire surface of all end-yoke cross-holes, using fine emery cloth. See **Fig. 5** for full-round yokes, or see **Fig. 7** for half-round yokes.

U-Joint Cleaning and Inspection

1. With the U-joints removed from the yokes, and the bearing cups removed from the crosses, inspect the U-joint cross slingers for damage, then inspect the U-joint trunnions for spalling (flaking metal), end galling (displacement of metal),

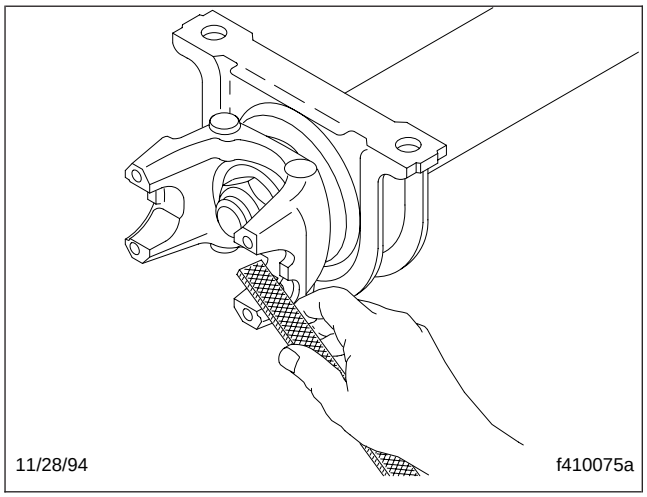

Fig. 6, Removing Burrs From a Half-Round End-Yoke Cross-Hole

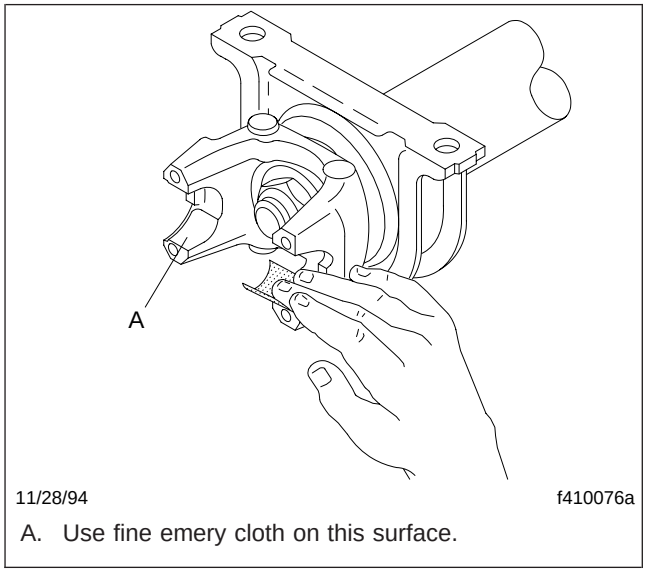

A. Use fine emery cloth on this surface.

Fig. 7, Smoothing a Half-Round End-Yoke Cross-Hole

brinelling (grooves caused by bearing needles), and pitting (small craters caused by corrosion). See **Fig. 8**. If damaged, replace the U-joint assembly.

2. Using a hand-type grease gun, apply multipurpose chassis grease to the fitting on each U-joint cross until all old lubricant is forced out. See **Fig. 9**. Examine the old lubricant. If it appears rusty, gritty, or burnt, replace the U-joint assembly.
3. Soak the bearing cups in a non-flammable cleaner until particles of grease and foreign matter are loosened or dissolved. Do not disassemble the bearing cups; clean the bearing needles with a short, stiff brush, then blow them dry with compressed air. Check for minute particles of dirt or grit, and clean again if necessary.
4. Check each bearing cup for missing bearing needles. Check the bearing-cup seals for nicks. See **Fig. 10** for a half-round-yoke U-joint bearing cup, or see **Fig. 11** for a full-round-yoke U-joint bearing cup. Replace the U-joint assembly if any bearing needles are missing or any seals are damaged.
5. Apply a small quantity of multipurpose chassis grease to the bearing needles in each cup, then apply a small amount of light-weight oil to the lips of the bearing-cup seals. Rotate each bearing cup on the cross to check for wear. Replace the U-joint assembly if any bearing surfaces are worn.
6. Check the underside of each bearing-cup plate for burrs or raised metal. Use a mill file to remove any burrs or raised metal. See **Fig. 12**.
7. Using fine emery cloth, smooth and clean the outside surfaces of all bearing cups. See **Fig. 12** and **Fig. 13**.

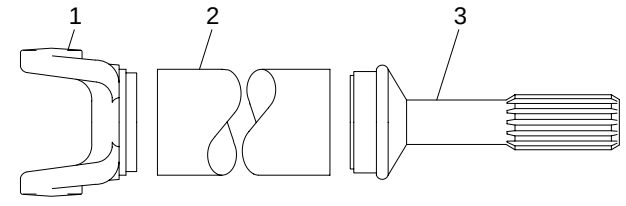
Driveshaft Tube, Stub Shaft (Slip-Joint), and Tube-Yoke Replacement

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

To replace a driveshaft tube, a tube-yoke, or a stub shaft (**Fig. 1**), the driveshaft must be chucked in a lathe, so the welds can be removed. Driveshaft rebuilding should be done by a machine shop that specializes in driveline repair.



1. Tube-Yoke
2. Driveshaft Tube
3. Stub Shaft

Fig. 1, Driveshaft Tube, Stub Shaft, and Tube-Yoke

Runout limits for a new or rebuilt driveshaft (**Fig. 2**) are:

- 0.005 inch (0.127 mm) T.I.R. (Total Indicator Runout) on the smooth portion of the stub shaft neck;
- 0.010 inch (0.254 mm) T.I.R. on the tube 3 inch (76 mm) from the front and rear welds;
- 0.015 inch (0.381 mm) T.I.R. at the center of the tube.

Balance the rebuilt driveshaft to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

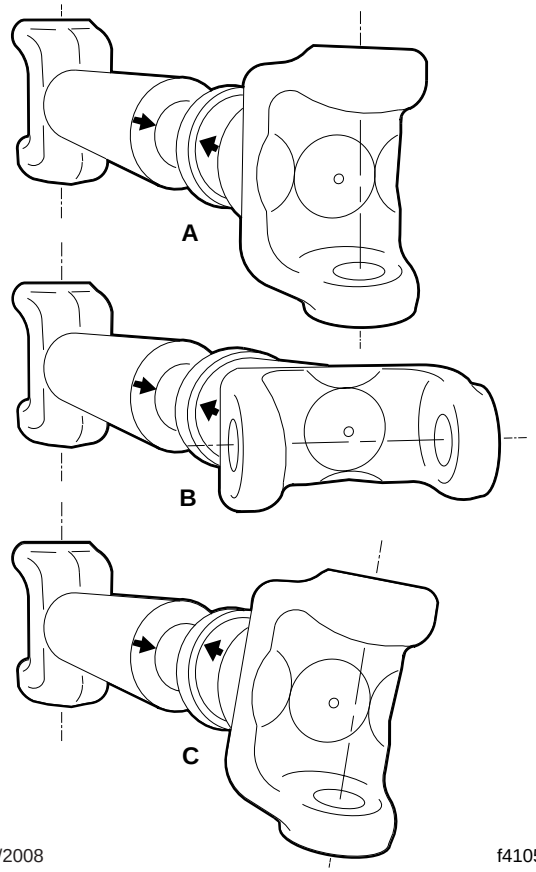
2. Coat the splines of the shaft with multipurpose chassis grease.

Driveline Component Replacement or Installation/ Assembly

NOTE: Some driveshafts are phased with the yokes set 90° apart by design. Changing the phasing will cause vibration.

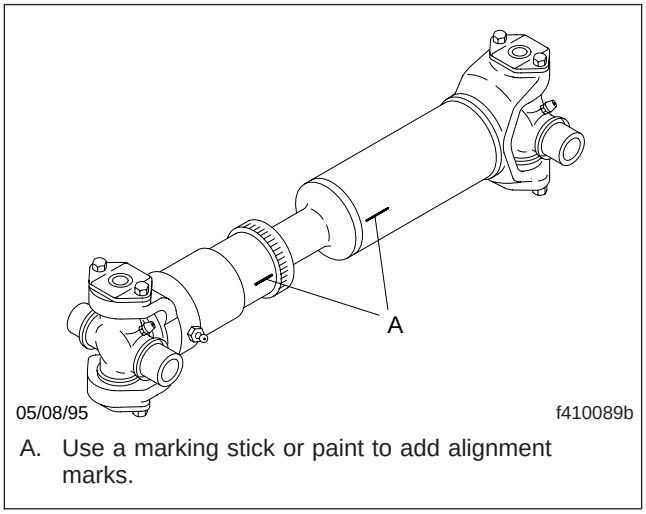
3. Insert the splined shaft in the sleeve-yoke, so that the alignment marks are aligned, and the U-joints at each end of the driveshaft will be in phase. See **Fig. 4** and **Fig. 5**.



A. In Phase (parallel phased)
B. In Phase (cross phased)
C. Out of Phase

Fig. 4, U-Joint Phasing

IMPORTANT: If no alignment marks are visible, or new slip-joint components have been installed, align the yokes, assemble the slip-joint, then have the driveline balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.



A. Use a marking stick or paint to add alignment marks.

Fig. 5, Slip-Joint Alignment Marks

4. Install the slip-joint dust cap. Use only enough torque to seat the steel washer and cork seal (if so equipped) snug against the end of the sleeve-yoke; do not overtighten.

NOTE: The splines should slide freely, with only a slight drag from the slip-joint dust cap.

RPL Drivelines

1. Remove the grease plug from the sleeve-yoke.
2. Coat the splines of the sleeve-yoke with multipurpose chassis grease.
3. Install the shroud on the splined shaft.
4. Install the seal onto the shroud.
5. Insert the splined shaft in the sleeve-yoke so that the alignment marks are aligned, and the U-joints at each end of the driveshaft will be in phase. See **Fig. 4** and **Fig. 5**.

IMPORTANT: If no alignment marks are visible, or new slip-joint components have been installed, align the yokes, assemble the slip-joint, then have the driveline balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

6. Install the seal into the shaft groove.
7. Install the shroud. Use a brass hammer to tap the shroud over the seal.
8. Install the grease plug in the sleeve-yoke.

NOTE: The splines should slide freely, with only a slight drag from the slip-joint dust cap.

Midship Bearing and Coupling Shaft End-Yoke Replacement or Assembly

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

NOTE: Vehicles manufactured after January 18, 2002, were built with a newly designed Meritor midship bearing assembly. Separate dust shields, or "slingers", common to the previous design, are not required.

1. Place the coupling shaft in a soft-jawed vise; do not distort the tube with excessive grip.
2. Fill the entire cavity around the midship bearing with a waterproof grease, to shield the bearing from water and contaminants. Use enough grease to fill the cavities to the extreme edge of the slingers that surround the front and rear of the bearing. See **Fig. 6**.

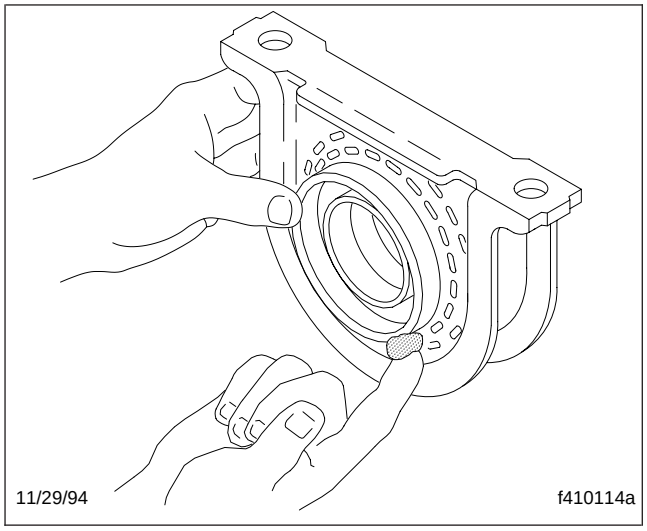


Fig. 6, Greasing a Midship Bearing

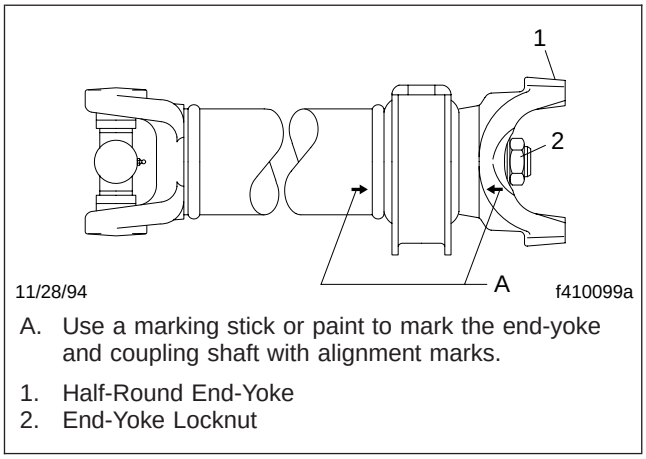
NOTE: Midship bearings are permanently lubricated when manufactured; it is not necessary to pack the bearing with grease.

3. Install one of the slingers, the midship bearing, then the other slinger on the coupling shaft. Press the bearing and slingers on by hand, as far as they will go.
4. Apply Loctite® 242 to the shaft threads where the end-yoke locknut will be installed. See **Fig. 7**.
5. Align the marks added to the coupling shaft and end-yoke during removal, then place the end-yoke on the shaft so the yoke bores are aligned at both ends of the shaft. See **Fig. 7**.



A. Use a marking stick or paint to mark the end-yoke and coupling shaft with alignment marks.

1. Half-Round End-Yoke
2. End-Yoke Locknut

Fig. 7, Alignment Marks on a Coupling Shaft With an End-Yoke

6. Install the end-yoke nut, and tighten it 475 to 525 lbf·ft (645 to 710 N·m). Then back the nut off slightly, and tighten it to the same torque.

U-Joint Replacement or Installation

IMPORTANT: Parts for different series drivelines must not be intermixed. Also, components of the various makes of U-joints may not be interchangeable, and must be assembled only with compatible products. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

Driveline Component Replacement or Installation/ Assembly

Worn bearing assemblies used with a new cross, or new bearing assemblies used with a worn cross will wear rapidly, making another replacement necessary in a short time. Always replace the cross and all four bearing assemblies at the same time.

If the slip-joint of a No. 2 or No. 3 driveshaft has been disassembled, assemble the slip-joint before installing the U-joints.

Full Round Yokes

1. Place the assembled driveshaft in V-blocks or a soft-jawed vise; do not distort the tube with excessive grip.
2. For a No. 2 or No. 3 driveshaft, check that the slip-joint alignment marks are aligned, so that the U-joints at each end of the driveshaft will be in phase. See **Fig. 4** and **Fig. 5**.

   For a coupling shaft, check that the end-yoke and tube-yoke are aligned, so that the U-joints at each end of the coupling shaft will be in phase. See **Fig. 7**.

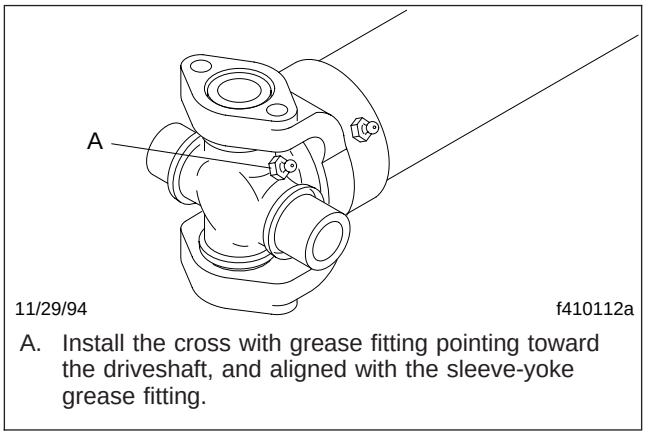
IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

3. Inspect and lubricate the U-joint; see **Subject 140**.
4. Install the U-joint cross and bearing assemblies in the yoke.

   4.1 Position the U-joint cross in the driveshaft yoke so one grease fitting points toward the driveshaft, and aligns with the grease fitting on the sleeve-yoke (if so equipped). See **Fig. 8**.

   4.2 Move one end of the cross until a trunnion projects through the cross-hole, beyond the outer machined face of the yoke lug. Using a Spicer trunnion (journal) locator (see **Specifications, 400**), hold the trunnions in alignment with the cross-holes, while placing a bearing cup (plate-type) over the projected trunnion, and aligning it with the cross-hole. See **Fig. 9**.

   IMPORTANT: A Spicer trunnion (journal) locator should be used to prevent damage to the U-joint trunnions and slingers.



A. Install the cross with grease fitting pointing toward the driveshaft, and aligned with the sleeve-yoke grease fitting.

NOTE: Sleeve-yoke shown.
1. Trunnion Locator

Fig. 9, Using a U-Joint Trunnion Locator

   4.3 By hand, press the bearing-cup-plate flush with the face of the yoke. If the bearing cup binds in the cross-hole, tap the *center* of the bearing-cup plate with a leather or rubber mallet; do not tap the outer edges of the plate. See **Fig. 10**.

   4.4 Install *new* bearing-cup-plate self-locking capscrews. See **Fig. 11**. Tighten the capscrews until all the parts are drawn down tight, with no gaps; do not tighten the capscrews to their final torque value.

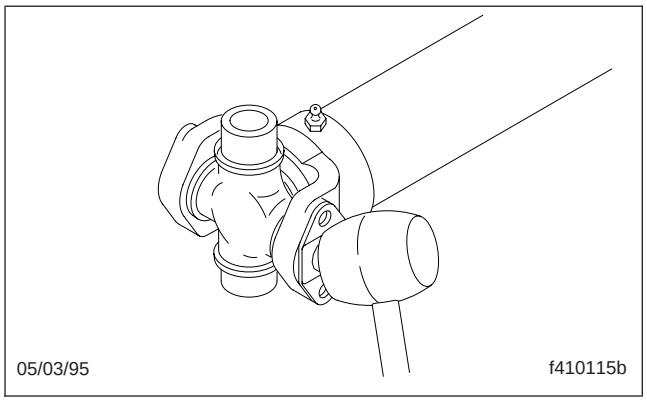

Fig. 10, Seating a U-Joint Bearing Cup In a Full-Round Yoke

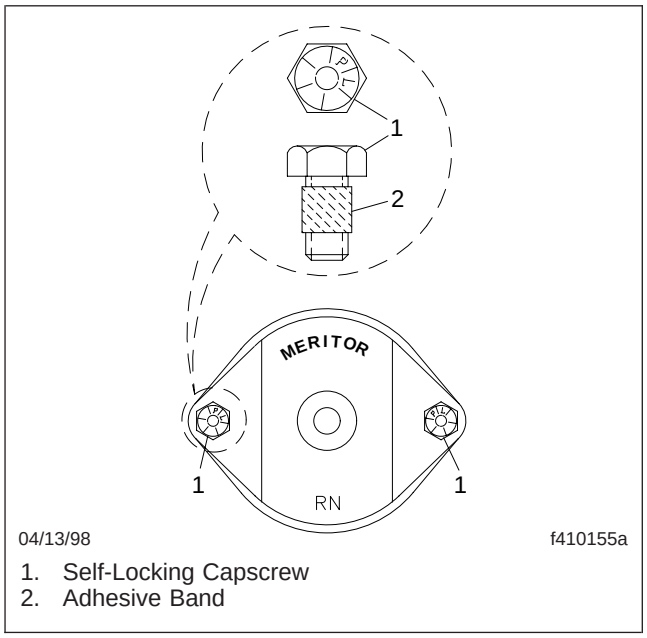

1. Self-Locking Capscrew
2. Adhesive Band

Fig. 11, Meritor U-Joint Fasteners for Full-Round Yokes

⚠ WARNING

Self-locking bearing-cup-plate capscrews must not be reused; replace the capscrews with new ones. Also, do not undertighten or overtighten any bearing-cup-plate capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could cause serious vehicle damage, or could result in a driveshaft separating from the vehicle, possibly causing loss of vehicle control that could result in serious personal injury or death.

4.5 Move the cross until it projects beyond the machined surface of the opposite yoke lug. Using the above procedure, install the opposite bearing assembly and its fasteners.

4.6 Slightly back off all four capscrews, then alternately tighten them in increments of 5 lbf·ft (7 N·m), to the applicable torque value in **Specifications, 400**.

NOTE: The U-joint should flex, and be free of excessive bind. A slight drag is the most desirable condition for new U-joints. Excessive looseness is not desirable, and may result in an unbalanced driveshaft.

RPL Series U-Joints

1. Place the assembled driveshaft in V-blocks or a soft-jawed vise; do not distort the tube with excessive grip.
2. For a No. 2 or No. 3 driveshaft, check that the slip-joint alignment marks are aligned, so that the U-joints at each end of the driveshaft will be in phase. See **Fig. 4** and **Fig. 5**.

   For a coupling shaft, check that the end-yoke and tube-yoke are aligned, so that the U-joints at each end of the coupling shaft will be in phase. See **Fig. 7**.

IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

3. Inspect the U-joint. See **Subject 140**.
4. Install the U-joint cross and bearing assemblies in the yoke.

   4.1 Position the U-joint cross in the driveshaft yoke so the grease plug hole is facing outboard. See **Fig. 12**.

   4.2 Move one end of the cross until a trunnion projects through the cross-hole, beyond the outer machined face of the yoke lug. Place a bearing cup over the projected trunnion, and align it with the cross-hole.

   4.3 Press the bearing cup into the yoke slightly past the snap ring groove. See **Fig. 13**. Check that the bearing cup is aligned with the universal joint trunnion.

Transmission/Axle End-Yoke Replacement or Installation

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

1. Apply Loctite® 242 to the input- or output-shaft threads where the end-yoke locknut will be installed. See **Fig. 18**.

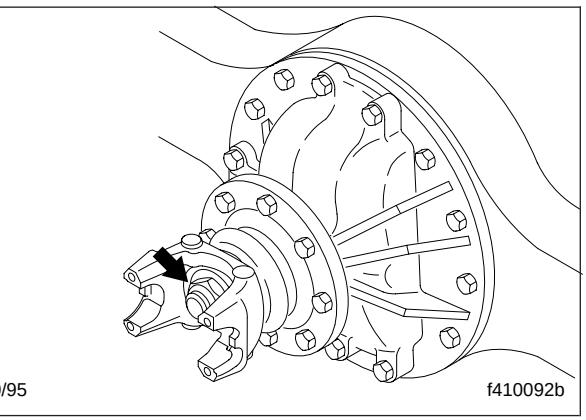

Fig. 18, Axle End-Yoke Locknut

2. By hand, install the end-yoke on the input or output shaft as far as it will go.
3. Install a new end-yoke locknut, and tighten it to the applicable torque value in **Specifications, 400**.

Troubleshooting

Noise or vibration associated with the driveline can be caused by non-driveline parts. To find the cause of noise or vibration, first road test the loaded vehicle. Drive in all gears and at all speed ranges for which the vehicle was designed, including those at which problems are reported.

NOTE: Operating a vehicle at speeds that exceed its drivetrain design specifications may cause an out-of-balance vibration.

The following is a troubleshooting elimination process; checks should be made in the order listed. At each step where a problem is found, correct the problem before proceeding to the next step, then test drive the vehicle to see if other problems still exist. If no other problems exist, the elimination process may be ended at that step.

1. Check all tires for uneven wear and for out-of-roundness. Check for mismatched tires. Look for wheels and rims that are out of alignment. For instructions, see **Group 40**.
2. Check the rear suspension for loose or broken U-bolts; broken, shifted, or mismatched rear springs; or broken spring seats. If so equipped, check the air suspension for incorrect air spring height. Look for anything that could cause angular misalignment of the rear axle pinion(s). For instructions, see **Group 32**.
3. Check the frame rails and crossmembers for bends, twists, or breaks; for frame-alignment-checking and crossmember-replacement instructions, see **Group 31**.
4. Check the engine and transmission mounts; see **Group 01** (Engine) and **Group 26** (transmission). Check the coupling shaft's midship bearing mounts. Replace mountings that are deteriorated or oil-soaked; tighten loose mounting bolts. Oil-soaked or deteriorated mountings, or loose mounting bolts, can cause driveline angular misalignment.
5. Check for loose U-joint bearing-cup-plate and bearing-strap capscrews. Tighten any loose fastener to the applicable torque value in **Specifications, 400**.

⚠ CAUTION

Do not overtighten the bearing-cup-plate or bearing-strap capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could result in serious vehicle damage.

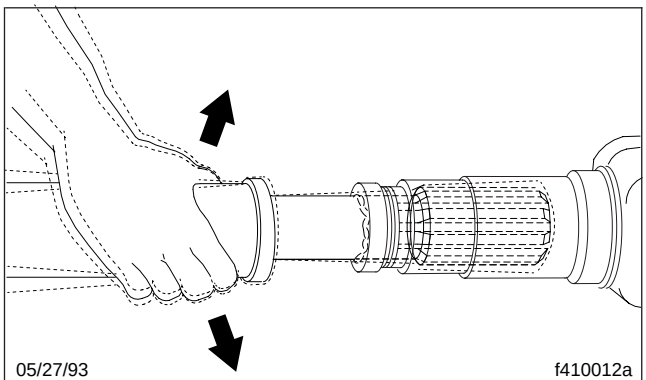
6. Check all U-joint assemblies, slip-joint splines, and midship bearings for wear.

   6.1 Try to move each driveshaft up and down, and from side to side. If movement is greater than 0.006 in (0.15 mm) of a U-joint cross in its bearings, replace the U-joint assembly.

   6.2 If the midship bearing rattles or is loose on its shaft, replace it.

   6.3 Try to bend the sleeve-yoke and splined shaft up and down, and from side to side. See **Fig. 1**. If looseness is greater than 0.007 in (0.18 mm), replace the sleeve-yoke and splined shaft.

   If driveline components must be replaced, see **Subject 150**.



Try to bend the sleeve-yoke and splined shaft up and down, and from side to side.

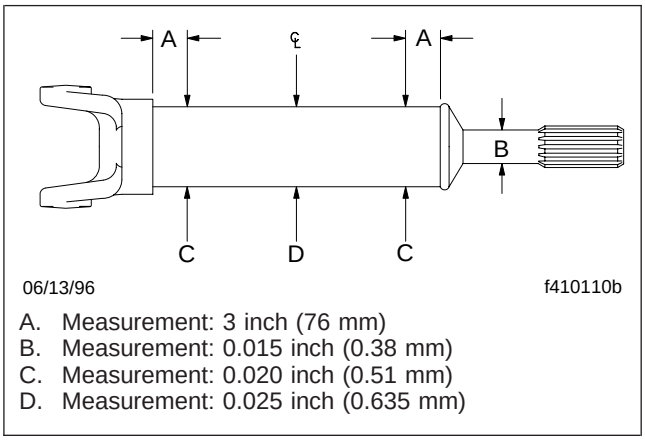
Fig. 1, Check for Slip-Joint Spline Wear

7. Check each driveshaft for an indication of missing balance weights. If any weights appear to be missing, have the driveshaft balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.
8. Check each driveshaft for dents, bends, twists, or other damage.

If damaged, jack up the rear axle, support it on jackstands, place the transmission in neutral, and turn the driveshaft by hand to check runout.

The driveshaft must be straight within 0.015 inch (0.38 mm) on the slip-joint seal surface of the splined shaft, 0.020 inch (0.51 mm) on the tube 3 inch (76 mm) from the front and the rear welds, and 0.025 inch (0.635 mm) at the center of the tube. See **Fig. 2**.

If the driveshaft is not straight within specifications, replace the tube. See **Subject 150** for runout specifications for a *new* (or rebuilt) driveshaft.



A. Measurement: 3 inch (76 mm)
B. Measurement: 0.015 inch (0.38 mm)
C. Measurement: 0.020 inch (0.51 mm)
D. Measurement: 0.025 inch (0.635 mm)

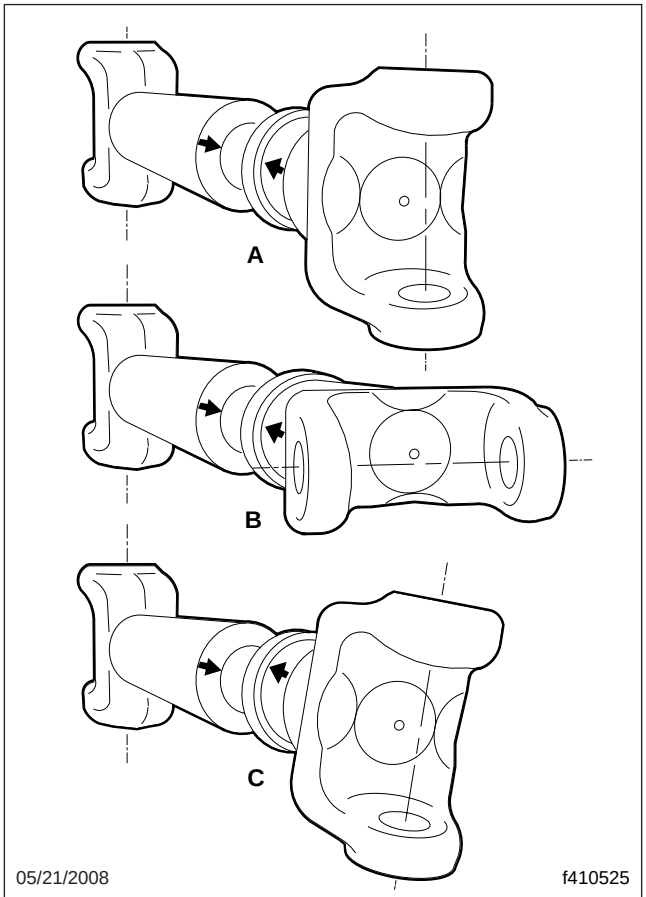
Fig. 2, Runout Specifications for a Used Driveshaft

9. Check each driveline for proper U-joint phasing. See **Fig. 3**.

9.1 On No. 2 and No. 3 driveshafts, if the U-joints are out of phase, check the slip-joint for alignment marks. If necessary, disassemble the slip-joint, and align the marks.

NOTE: To disassemble the slip-joint, uncouple the U-joint at one end of the driveshaft, unscrew the slip-joint seal from the sleeve-yoke, then pull the sleeve-yoke and splined shaft apart. Reverse the procedure to assemble the slip-joint.

9.2 If no alignment marks are present, disassemble the slip-joint, and reassemble it with the U-joints in one of the two in-phase positions (180 degrees apart).



A. In Phase (parallel phased)
B. In Phase (cross phased)
C. Out of Phase

Fig. 3, U-Joint Phasing

Test drive the vehicle, then assemble the slip-joint in the other in-phase position. Test drive the vehicle again.

Determine which in-phase position provides vibration-free operation. Assemble the slip-joint in the correct in-phase position, and mark the slip-joint with alignment marks.

9.3 If the U-joints are out of phase on a coupling shaft, uncouple the U-joint from the coupling shaft end-yoke, then remove the end-yoke nut. Remove the end-yoke, using a yoke puller. See **Fig. 4** for a half-round end-yoke, or see **Fig. 5** for a full-round end-yoke. Align the end-yoke, then

install it by hand. Install the end-yoke nut, and tighten it 475 to 525 lbf·ft (645 to 710 N·m). Slightly back off the nut, and again tighten it to the same torque. Couple the coupling shaft to the driveshaft U-joint.

1. Yoke Puller
2. Full-Round Yoke
3. Midship Bearing

Fig. 5, Remove a Full-Round End-Yoke from a Coupling Shaft

10. Check the torque on all of the end-yoke nuts in the drivetrain; see the applicable torque values in **Specifications, 400**.

    If any yoke nut was not at its specified torque, check the yoke for wear by trying to move it up and down, and back and forth. If the yoke can be rocked on its shaft, or moved in or out on its shaft, replace the yoke and yoke nut. See **Subject 150**.

    If the yoke is not worn, tighten the yoke nut to its torque value.

11. *On single-drive vehicles:*

    Have the No. 2 driveshaft balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

    On dual-drive vehicles:

    11.1 Remove the No. 3 driveline; then, with the interaxle differential locked, test drive the vehicle.

    11.2 If vibration still exists, install the No. 3 driveline, then have the No. 2 driveshaft balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

    If *no* vibration exists, check that both rear axle gear ratios are matched. If the gear ratios do not match, replace one of the gear sets with a gear set having the correct ratio, then install the No. 3 driveline.

    11.3 Have the No. 3 driveshaft balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

    11.4 Have the No. 2 driveshaft balanced to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

12. If so equipped, balance the coupling shaft(s) to a maximum tolerance of 1 inch-ounce per 10 pounds weight per end, at 3000 rpm.

Driveline Angularity

The most important consideration of driveline angularity is the U-joint working angle. A U-joint working angle is the angle formed by the intersection of the driveshaft centerline and the extended centerline of the shaft of any component to which the U-joint connects. See **Fig. 1**. Because the action of a U-joint causes a fluctuating speed difference between the shafts it connects, the effect created by the U-joint at the input-shaft end-yoke must cancel the effect created by the U-joint at the output-shaft end-yoke. This is done by making the U-joint working angles at both ends of the driveshaft approximately equal, with the U-joints in phase.

The U-joint working angles may be made approximately equal by either of two basic arrangements: a parallel arrangement (**Fig. 1**), or an intersecting arrangement (**Fig. 2**).

Driveline angularity may be adversely affected if rear suspension U-bolts are loose or broken; rear springs are broken, shifted, or mismatched; spring seats are broken; frame rails are bent, twisted, or broken; or transmission or engine mounts are loose or deteriorated.

U-Joint Phasing

The fluctuating speed difference, caused by the action of a U-joint connecting angled shafts, can be cancelled only if the U-joint at the other end of the driveshaft is in phase with that U-joint (and the U-joint working angles are approximately equal). If the yoke lugs at both ends of the driveshaft are lying in the same plane (a plane which bisects the shaft lengthwise) the U-joints will be in phase. See **Fig. 3**.

General Information

NOTE: Some dirveshafts are designed and phased with their end yokes clocked 90 degrees from each other. This is referred to as cross phasing.

B. In Phase (cross phased)
C. Out of Phase

Fig. 3, Driveline U-Joint Phasing

To ensure that the U-joints turn in phase, the sleeve-yoke and splined shaft of driveshaft slip-joints, and the coupling shaft and midship bearing end-yoke, should be marked for assembly reference before disassembly.

Driveline Balance

After manufacture, each driveline yoke is statically balanced. After assembly of the slip-joint, each driveshaft is checked for out-of-roundness, and straightened as necessary; then each shaft is dynamically balanced.

If the driveshaft slip-joint is disassembled for any reason, the sleeve-yoke and splined shaft should be marked for assembly alignment. Misaligned slip-joints will seriously affect the U-joint phasing and balance of the driveline. Even if the slip-joint is assembled 180 degrees from its original position (which will keep the U-joints in phase), the dynamic balance of the driveshaft will be negatively affected.

A driveline can become unbalanced or greatly weakened if a driveshaft has been dented, bent, twisted, or otherwise damaged. Operating a vehicle at speeds which exceed the speed of the driveshaft's design specifications will cause an out-of-balance vibration. Loose end-yoke nuts, loose midship bearing or auxiliary transmission mounts, loose bearing retainer capscrews, worn U-joint trunnions or bearings, and worn slip-joint splines can lead to excessive movement of the driveshaft and cause driveline imbalance.

Midship Bearings

A long driveshaft, supported only at its ends, will sag in the middle from its own weight. When turning at high rpm, it will flex, causing an out-of-balance vibration. Therefore, most vehicles having a long wheelbase use a midship bearing, mounted on a crossmember in the frame, for additional driveline support. See **Fig. 4**. This allows the driveshaft to be separated into two shorter shafts, thus improving balance and stability.

Angularity Standards and Drivetrain Configuration

The U-joints require a minimum working angle of 1/2 degree to ensure needle-roller movement in the U-joint bearings. Without this movement, brinelling of the trunnion bearing-contact surfaces would occur. Suspension movement causes driveshaft angles to change (and therefore, needle-roller movement) in both of the U-joints attached to driveshafts that connect to the axles. However, no angle change occurs in the U-joints attached to a driveshaft that connects the main transmission to a midship bearing or auxiliary transmission. Their working angles must be established during installation.

When a midship bearing is included in the drivetrain, it is installed so that the centerline of the coupling shaft is in horizontal (side-to-side) alignment within 1/2 degree, and within 1/2 to 1 degree of vertical alignment, with the centerline of the main transmission output shaft. See **Fig. 4**.

When an auxiliary transmission is included in the drivetrain, it is installed so that the centerline of the inter-transmission (no. 1) driveline is in exact horizontal (side-to-side) alignment (within 1/2 degree), and down 1/2 to 1 degree from vertical alignment, with the centerline of the main transmission output shaft. Further, the auxiliary transmission thru-shaft centerline must be parallel (horizontally and vertically) to the centerline of the main transmission output shaft, in order to achieve equal working angles. See **Fig. 5**.

Every U-joint has a maximum working angle, determined by the design and size of its cross assembly and yokes. Exceeding the maximum working angle can cause rapid U-joint wear, or in severe cases, destruction of the U-joint. For smooth operation and long drivetrain component life, the U-joint working angles must be kept small and approximately equal for each shaft.

The U-joint working angles may be made approximately equal by either of two basic arrangements: a parallel arrangement (**Fig. 1**) or an intersecting arrangement (**Fig. 2**). The parallel arrangement consists of installing the drivetrain components so that all of the input, output, and thru-shaft centerlines are approximately parallel. The intersecting arrangement (used only for some interaxle drivelines) consists of installing the drive components so that the rearmost

General Information

axle pinion shaft's extended centerline intersects the forward-rear axle thru-shaft's extended centerline approximately midway between the U-joints, when all of the other shafts (including the forward-rear axle thru-shaft) are approximately parallel.

All single-drive vehicles, and the forward-rear axles of dual-drive vehicles, use the parallel arrangement. Rearmost axles of dual-drive vehicles may use the parallel arrangement or the intersecting arrangement, depending on the drivetrain configuration.

The specific drivetrain configuration of each Freightliner vehicle consists of its wheelbase, number and type of axles, axle spacing, type of suspension, and number of transmissions. The specific drivetrain configuration determines the driveline arrangement and required installation angles of all the vehicle's drivetrain components.

The simplest drivetrain configuration consists of a single short driveline connecting a main transmission to a single-drive axle, in a parallel arrangement. This driveshaft is always referred to as the no. 2 driveshaft. The parallel arrangement always used on single-drive vehicles is shown in **Fig. 1**.

On dual-drive vehicles that have both axle input shafts of approximately the same height, a parallel arrangement is used. The driveshaft connecting the main (or auxiliary) transmission to the forward-rear axle is always referred to as the no. 2 driveshaft; and the interaxle driveshaft is always referred to as the no. 3 driveshaft. See **Fig. 6**, which shows a parallel arrangement when used on dual-drive vehicles.

Most dual-drive vehicles have a high thru-shaft on the forward-rear axle, and a low pinion on the rearmost axle. When the vehicle is on level ground, the interaxle (no. 3) driveshaft may create very sharp U-joint working angles with the input and output shafts when they are parallel. In normal driving, the U-joints could momentarily exceed their maximum working angle, and driveline or drivetrain damage could result. By using an intersecting arrangement at the no. 3 driveshaft, smaller U-joint working angles are created, promoting longer U-joint life and reduced driveline vibration. An intersecting arrangement used on dual-drive vehicles is shown in **Fig. 2**.

However, some axle spacings, axle models, and suspension designs allow additional axle movement or axle windup that requires additional clearances between the driveshaft and the frame or suspension components, or that creates other conditions that make the intersecting arrangement of the no. 3 driveshaft unsatisfactory. For those drivetrain configurations, it is necessary to use a modified parallel or modified-intersecting arrangement for the no. 3 driveshaft.

On drivetrain configurations that require a modified parallel arrangement, the rearmost-axle pinion shaft centerline is placed at an angle that is 2 degrees higher above horizontal than are the other input and output shafts. See **Fig. 7**.

On drivetrain configurations that require a modified-intersecting arrangement, the "proper" intersecting angle is determined, then the rearmost-axle pinion shaft centerline is placed at an angle that is 2 degrees closer to horizontal than the "proper" intersecting angle. See **Fig. 8**.

The axle pinion angles for all suspensions are factory-set for correct driveline angularity. On Freightliner spring suspensions, tapered axle planing shims at the springs maintain the correct axle pinion angle. On Hendrickson suspensions, spacers at the torque rods are used to maintain the correct axle pinion angles.

In the field, whenever axle or suspension components are changed, the axle pinion angles may also change. If this occurs, contact your district service manager for the correct axle pinion angle adjustment procedure.

Use the procedure below for the type of tool being used. The Digital Angle Analyzer is the recommended tool.

Digital Angle Analyzer

Before checking the pinion angles or engine angle, check that the engine and transmission mounts are tight and in good condition. Loose or deteriorated mounts will cause inaccurate readings.

IMPORTANT: When using a digital angle analyzer (DAA) or digital level, be sure to always take readings from the same side of the vehicle. Also, keep the same end of the DAA pointed toward the front of the truck.

Using a DAA (**Fig. 1**), measure the engine angle, driveshaft angles, and pinion angles. Read all angles to the nearest one-tenth of a degree.

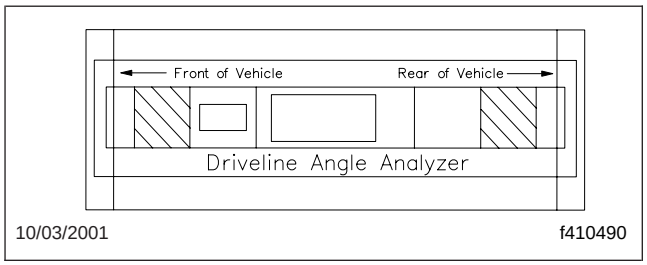

Fig. 1, Digital Angle Analyzer

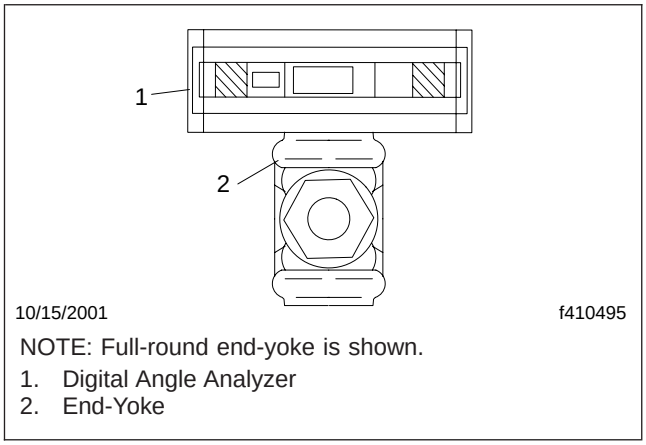
After adjustment of any driveline angle, check the angle again. Also, verify ride height if the vehicle has an air suspension.

To measure the engine angle (transmission output-shaft angle) or axle pinion angles, do the following:

1. Inflate the vehicle tires to their normal operating pressure.
2. Park the unloaded vehicle on a level surface. Do not try to level the vehicle frame by jacking the front or rear axles. If the frame cannot be leveled from front to rear, determine and record the off-level inclination of the frame, and add or subtract that value from the measured values.
3. Chock the tires and place the transmission in neutral. Release the parking brakes.
4. The transmission output-shaft, coupling-shaft, and axle input- and output-yoke angles can be measured at either the top or bottom lug of the end-yoke being checked. For a full-round end-yoke, remove the bearing cup from the yoke lug. See **Section 41.00** for full-round end-yoke bearing cup removal.
5. Turn the end-yoke until the machined surface of the yoke lug is horizontal. See **Fig. 2**.



NOTE: Full-round end-yoke is shown.

1. Digital Angle Analyzer
2. End-Yoke

Fig. 2, Horizontal Positioning of Yoke Lug Machined Surface

6. To turn the driveshaft, raise one side of the rear (single-drive) or rearmost (dual-drive) axle until the tires are off the ground. Place a safety stand under the axle. With the transmission in neutral, and the interaxle differential (if equipped) unlocked, turn the tire to move the driveshaft.
7. Calibrate the digital level by placing it on the surface where the vehicle is parked at a 90-degree angle to the frame centerline. Zero the digital level.
8. Position the DAA alongside the U-joint trunnion, on the machined surface of the end-yoke, and at a 90-degree angle to the frame centerline. See **Fig. 2**. Then turn the end-yoke until the DAA reads 0 degrees. Remove the jack stand and lower the rear axle to the ground.
9. Calibrate the digital level by placing it on the surface where the vehicle is parked parallel to the frame centerline. Zero the digital level.
10. Without changing the position of the end-yoke, turn the DAA until it is parallel to the frame centerline. See **Fig. 3**. Record the measured angle of the pinion.

Spirit Level Protractor

Before checking the pinion angles or engine angle, check that the engine and transmission mounts are tight and in good condition. Loose or deteriorated mounts will cause inaccurate readings.

Using a digital angle meter, spirit level protractor (see **Fig. 4**), or the head of a machinists's protractor, measure the engine angle, driveshaft angles, and pinion angles. Read all angles to the nearest one-tenth of a degree (6 minutes).

After adjustment of any driveline angle, check the angle again.

To measure the engine angle (transmission output-shaft angle) or axle pinion angles, do the following:

1. Inflate the vehicle tires to their normal operating pressure.
2. Park the unloaded vehicle on a level surface. Do not try to level the vehicle frame by jacking the front or rear axles. If the frame cannot be leveled from front to rear, determine and record the off-level inclination of the frame, and add or subtract that value from the measured values.

3. Chock the tires and place the transmission in neutral. Release the parking brakes.
4. The transmission output-shaft, coupling-shaft, and axle input- and output-yoke angles can be measured at either the top or bottom lug of the end-yoke being checked. For a full-round end-yoke, remove the bearing cup from the yoke lug. See **Section 41.00** for full-round end-yoke bearing cup removal.
5. Turn the end-yoke until the machined surface of the yoke lug is horizontal. See **Fig. 5**.

NOTE: To turn the driveshaft, raise one side of the rear (single-drive) or rearmost (dual-drive) axle until the tires are off the ground. Place a safety stand under the axle. With the transmission in neutral, and the interaxle differential (if equipped) unlocked, turn the tire to move the driveshaft.

6. Adjust the protractor scale to read 0 degrees. Position the protractor alongside the U-joint trunnion, on the machined surface of the end-yoke, and at a 90-degree angle to the frame centerline. See **Fig. 2**. Then turn the end-yoke until the bubble in the level vial is exactly between the two marks on the vial. Remove the jack stand and lower the rear axle to the ground.

7. Without changing the position of the end-yoke, turn the protractor until it is parallel to the frame centerline. See **Fig. 6**. Adjust the calibrated scale so the bubble is exactly between the two marks on the level vial. Record the calibrated scale reading opposite the "0" mark. Correct this value for any previously recorded off-level inclination.
8. For a full-round end-yoke, install the bearing cup. See **Section 41.00** for full-round end-yoke bearing cup installation.

Driveline Angle Checking

If a vehicle is equipped with a Freightliner spring suspension, the axle pinion angles are factory-set using alignment shims at the rear springs. These shims have notches on the thick end of the shim. Count the number of notches in the thick end of each shim to make sure that the correct shim is used. Also, make sure the thick end of the shim is positioned correctly. See the applicable table in **Specifications, 400** for shim identification and use. If the axle pinion angles on these suspensions are incorrect, contact your district service manager for the adjustment procedure.

If a vehicle is equipped with a Hendrickson suspension, spacers at the torque rods are used to maintain the correct axle pinion angles. If the measured axle pinion angles on these suspensions are not the same as the angles listed in the applicable table in **Specifications, 400**, contact your district service manager for the adjustment procedure.

NOTE: In any of the following steps, if an off-level inclination was added to or subtracted from the engine angle, the same figure must be added to or subtracted from the coupling shaft or axle pinion reading before comparing the angles.

1. Check the engine angle at the transmission output-shaft end-yoke. The engine angle must be 3 degrees ±1/2 degree. For instructions, see **Subject 100**.
2. If the driveline includes a midship bearing, place a protractor on top of the coupling shaft. Align the protractor with the shaft centerline. **See Fig. 1.** Read the scale to the nearest one-tenth of a degree (6 minutes). The centerline of the coupling shaft must be 1/2 degree out of vertical alignment with the transmission output shaft. **See Fig. 2.** Compare this reading with the measured engine angle.

   If needed, adjust the midship bearing mounting to meet the above specification. Contact your district service manager for midship bearing mount adjusting procedures.
3. On single-drive installations, measure the rear axle pinion angle at the back of the no. 2 driveline; for instructions, see **Subject 100**.

   The measured rear axle pinion angle must be equal ±1 degree to the measured engine angle. If the rear axle pinion angle does not meet the above specification, contact your district service manager.
4. On dual-drive installations, measure the forward-rear-axle pinion angle (at the rear of the no. 2 driveline); for instructions, see **Subject 100**.

   The measured forward-rear-axle pinion angle must be equal ±1 degree to the measured engine angle. If the forward-rear-axle pinion angle does not meet the above specification, contact your district service manager.

   Measure the rearmost-axle pinion angle (at the rear of the no. 3 driveline); for instructions, see **Subject 100**.

   Compare the measured angle with that shown in the applicable table in **Specifications, 400**. The measured rearmost-axle pinion angle must be equal ±1 degree to the angle shown in the table. If the measured angle is incorrect, contact your district service manager.

Table 10, Hendrickson Suspensions With 72.5-Inch Axle Spacing

General Description

The Bendix PP–DC parking brake air valve is installed on trucks with air brakes, and is used to control the rear axle parking brakes. It is a push-pull type of valve, and is mounted on the right side of the dash.

Principles of Operation

When the valve knob is pulled out, air is exhausted from the parking brake chambers, releasing the springs, and applying the parking brakes. When the knob is pushed in, air flows into the parking brake chambers from one of the reservoirs, and compresses the springs, releasing the parking brakes.

The PP–DC has a double check valve feature. If the pressure drops 20 to 30 psi (138 to 207 kPa) in either air system (primary or secondary), the valve will automatically use air pressure from the system with the higher pressure for the parking brakes. This prevents the parking brakes from applying automatically unless pressure is lost from both systems.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

Parking Brake Dash Valve Tests

IMPORTANT: To do the following tests, connect two separate 120 psi (827 kPa) air sources to the PP–DC supply ports. See **Fig. 1.** Tee an accurate test gauge into the supply lines, and provide for a means to control supply line pressure. Connect a small volume air source with a gauge to the delivery port.

Operating Test

1. Chock the tires.
2. Start the engine and build up the air pressure to the normal operating level.
3. With the valve knob pulled out, supply either supply port with 120 psi (827 kPa) of pressure. Push the valve knob in. Air pressure should rise in the delivery line and equal supply line pressure.

   Pull the valve knob out. Delivery pressure should exhaust to zero.
4. Build air pressure to each supply souce to 120 psi (827 kPa). Decrease supply pressure at the secondary service reservoir supply port at a rate of 10 psi (69 kPa) per second.

Parking Brake Dash Valve Tests

Primary supply pressure and delivery pressure should not drop below 100 psi (689 kPa). Repeat this step for decreasing primary service reservoir pressure.

5. Build air pressure to each supply souce to 120 psi (827 kPa). Then, decrease both supply pressures to below 20 to 30 psi (138 to 207 kPa). The valve knob should automatically pop out when the pressure is within that range.
6. If the valve does not work as described, repair the valve or replace it following instructions under **Subject 130.**

Leak Testing

1. Chock the tires.
2. Supply the valve with 120 psi (827 kPa) from the primary reservoir supply port.
3. With the valve knob pulled out, coat the exhaust port and the plunger stem with a soapy solution. Leakage at the either fitting should not exceed a 1-inch (2.5-cm) bubble every five seconds.There should be no leakage from the secondary reservoir supply port.
4. Supply the valve with 120 psi (827 kPa) from the secondary reservoir supply port. There should be no leakage from the primary reservoir supply port.
5. With the valve knob pushed in, coat the exhaust port and the plunger stem with a soapy solution. Leakage at the fittings should not exceed a 1-inch (2.5-cm) bubble every three seconds. If it does, replace or repair the valve, following instructions under **Subject 130.**

Parking Brake Dash Valve Removal and Installation

Removal (See Fig. 1)

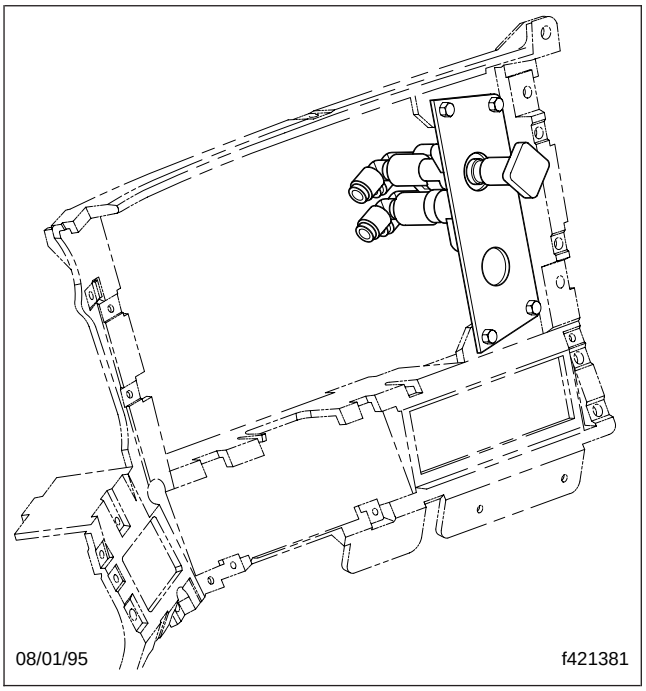

Fig. 1, Parking Brake Hand Valve Mounting (components have been removed from the auxiliary instrument panel for clarity)

⚠ WARNING

Review the precautions under Safety Precautions 100 before doing any work on the parking brake valve. Failure to do so could result in personal injury.

1. Park the vehicle on a level surface, apply the parking brakes, chock the tires, and drain the air tanks.
2. Remove the trim plate assembly from the radio and heater/air conditioner control panel.
3. Remove the screw from the right-hand trim cap. Remove the trim cap from the dash.
4. Remove the four screws that attach the auxiliary instrument panel in the dash. Pull the panel out to access the valve mounting screws.
5. Turn the valve knob counterclockwise and remove it from the valve stem.
6. Mark the air lines for later reference, then disconnect them from the valve assembly.

NOTE: The primary supply line is green; the secondary supply line is red; the exhaust line is black and 1/2 inch (13 mm) in diameter; the delivery line is black and 3/8 inch (9.6 mm) in diameter.

7. Remove the four screws that attach the valve to the auxiliary instrument panel. Remove the valve.

Installation

1. Position the valve assembly in the auxiliary instrument panel. Install the four mounting screws.
2. Connect the air lines to the applicable fittings.
   - 2.1 Tighten the fitting hand tight.
   - 2.2 Using a wrench, tighten the fitting until the connection feels firm.
   - 2.3 Tighten the fitting an additional one-sixth turn.
3. Screw the valve knob onto the valve stem.
4. Leak test the fittings, following the instructions under **Subject 110**.
5. Install the auxiliary instrument panel, right-hand trim cap, and the radio and heater/air conditioner trim plate assembly.

   For ease of installation, line up the plunger's index tabs with the spaces in the body bore.
8. Install the O-ring on the guide spool. Install the spool over the plunger and into the body. Firmly press the guide spool into position.
9. Install the screws that attach the cover to the body. Tighten the screws 35 lbf·in (400 N·cm).
10. Install the valve in the dash, then leak test it. Follow the instructions under **Subject 120** for installation and **Subject 110** for leak testing.

General Description

The dash-mounted MV-3 control module is a two-button, push-pull control valve housed in a single body, which includes a dual circuit supply valve and a check valve.

The valve body, plungers, and spools are made out of a nonmetallic, noncorrosive material. All air connections are at the back of the valve. See **Fig. 1**.

The MV-3 module has several functions: tractor protection; trailer service air control; system park; trailer park only; trailer charge with tractor spring brakes applied (tractor park only); and supply reservoir selection.

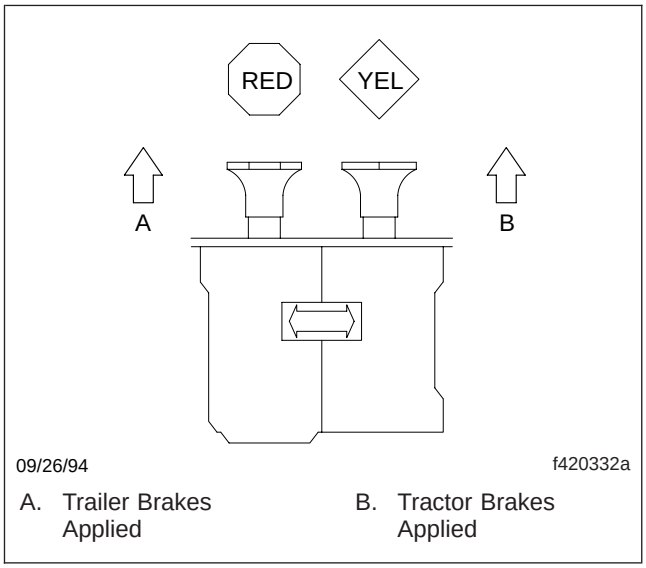
4. Delivery–Trailer Supply
5. Secondary Reservoir Supply
6. Trailer Air Supply Knob
7. Parking Brake Control Valve Knob

Fig. 1, MV-3 Parking Brake Valve

The MV-3 includes a spring-loaded, dual-circuit supply valve, which selects the primary air reservoir as the air source for both control valves, unless the pressure in the primary air reservoir falls below that of the secondary air reservoir. Then, the dual-circuit supply valve will shuttle and establish the secondary air reservoir as the air source.

The trailer air supply valve, actuated by the red knob and the yellow knob, delivers air to the trailer supply line. See **Fig. 2**. The parking brake valve, actuated by a yellow knob, controls the spring parking brakes on the tractor, and when exhausted, simultaneously causes the trailer supply valve to trip and exhaust, thus applying both the tractor and the trailer parking brakes as required by federal regulations. See **Fig. 2**. The trailer parking brakes may be independently released by pushing only the trailer air supply valve (red) knob in.



09/26/94 f420332a

A. Trailer Brakes Applied

B. Tractor Brakes Applied

Fig. 2, Trailer and Tractor Delivery Air Discharged (control knobs out)

Principles of Operation

Initial Charge

With both the primary and the secondary systems completely discharged, both knobs are out. See **Fig. 2**. When system pressure reaches 65 psi (448 kPa), the red knob (trailer air supply) may be pushed in, and should stay in, charging the trailer system and releasing the trailer parking brakes. See **Fig. 3**. The yellow knob (parking brake) may now be pushed in, which will supply air to the tractor parking brakes, releasing them.

Normal Operation Position

When both knobs are pushed in, air is supplied to the trailer and the tractor parking brakes; all parking brakes are released. See **Fig. 4**. This is the normal operating mode.

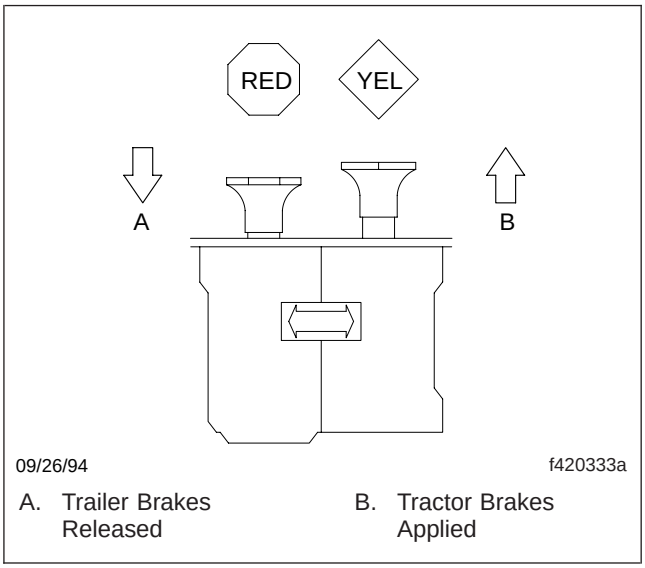


Fig. 3, Trailer Parking Brakes Released (red control knob pushed in)

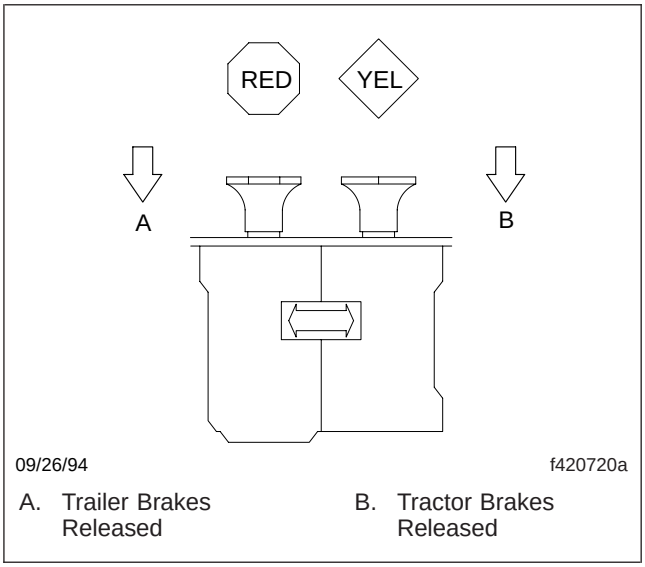

Fig. 4, Trailer and Tractor Brakes Released (both control knobs pushed in)

Actuation of Trailer Park or Emergency Brakes

To actuate the trailer parking brakes only, the red knob is pulled out, exhausting the trailer supply line. The trailer parking brakes are now applied, either by emergency air or parking brakes, depending on the type of trailer system. This mode would be used to uncouple from the trailer, and during bobtail operation. See **Fig. 5**.

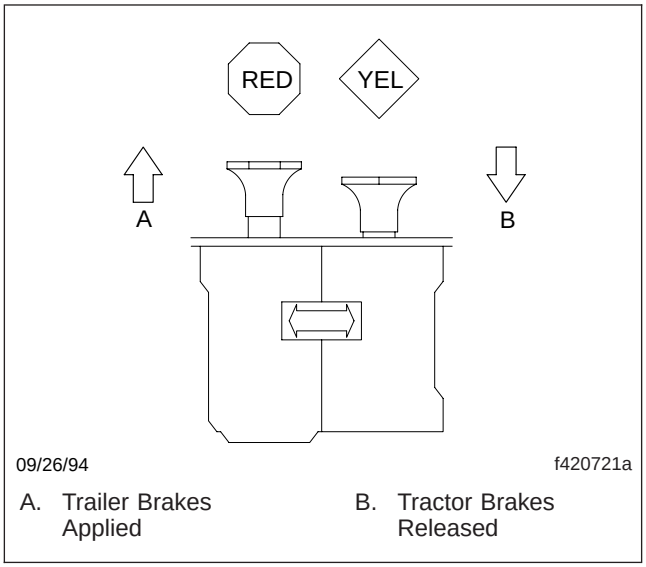

Fig. 5, Trailer Parking Brakes Applied (red control knob pulled out)

System Park

With both knobs pushed in, the parking brakes on both the tractor and the trailer may be actuated by pulling the yellow (parking brake) knob out. This exhausts the air from the tractor parking brakes and simultaneously causes the red (trailer air supply) knob to pop out, applying the trailer parking brakes (this complies with federal regulations that one control must apply all the parking brakes on the vehicle). See **Fig. 2**.

Trailer Charge

If both valves are out, parking the combination vehicle, and it is desired to recharge the trailer (leaving only the tractor parking brakes applied), the red knob may be pushed in, repressurizing the trailer supply line. This mode might also be used to park a combination vehicle with air-actuated emergency brakes on the trailer to provide demonstrated parking capability with the tractor spring brakes only. See **Fig. 3**.

Automatic Applications

If air pressure drops to 20 to 45 psi (138 to 310 kPa) in both the primary and the secondary systems, the

red knob (trailer air supply valve) will automatically pop out, applying the emergency or parking brakes on the trailer. If the red knob is held in manually and the pressure decreases to 25 to 35 psi (172 to 241 kPa), a tripper piston within the MV-3 valve will move upward, exhausting the trailer supply, and applying the trailer parking brakes. If air pressure drops in both the primary and the secondary systems, the yellow (parking brake) knob will pop out at about 20 to 40 psi (138 to 276 kPa), applying the tractor parking brakes.

A warning buzzer and light are activated when pressure in either the primary or the secondary system drops below 64 to 76 psi (441 to 524 kPa).

Tests

With the air brake system charged to 120 psi (827 kPa), check for leaks, using the following instructions. Repair or replace components as needed.

1. Apply a soap solution and check for leakage between the body and cover plate. Leakage at the exhaust port should produce less than a 1-inch (25-mm) bubble in five seconds.
2. With the trailer supply line sealed, push in the red knob. The knob must stay in. Leakage at the exhaust port must not exceed a 1-inch (25-mm) bubble in 5 seconds. See **Fig. 1**.

4. Delivery–Trailer Supply

6. Trailer Air Supply Knob
7. Parking Brake Control Valve Knob

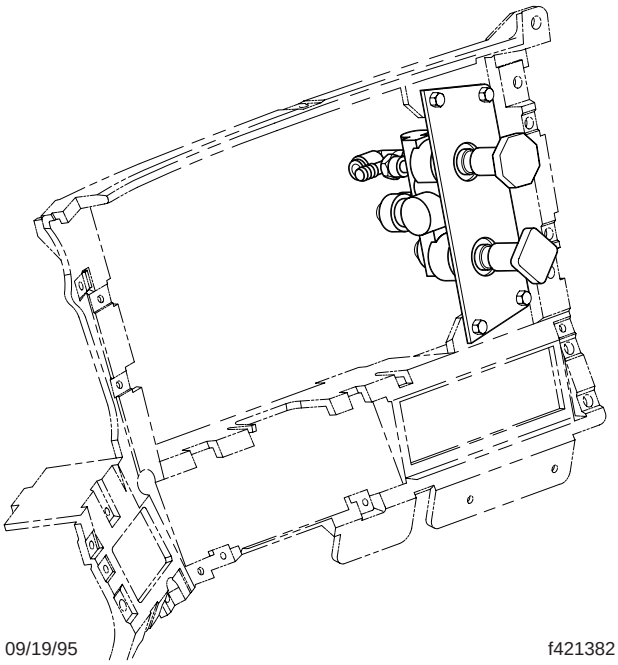
3. Slowly reduce pressure in both service reservoirs. The red knob must pop out at 20 to 35 psi (138 to 310 kPa).

NOTE: Trip-on pressure is the pressure at which the valve automatically changes position or "pops out." It is advised to use an accurate pressure gauge other than those in the truck when performing tests.

4. Hold the red knob in and continue to reduce pressure in all service reservoirs. Air must start to escape from the exhaust port when the trailer line pressure reaches 20 to 35 psi (138 to 241 kPa).
5. Release the red knob and rebuild the supply pressure to 120 psi (827 kPa). Push in the yellow knob; the yellow knob must remain in. Leakage at the exhaust port should not exceed a 1-inch (25-mm) bubble in 5 seconds.
6. Pull the red knob out. Slowly reduce pressure in all service reservoirs. There is not a federal trip pressure requirement for the yellow knob, but it will pop out at 20 to 30 psi (138 to 207 kPa).
7. Charge the system to 120 psi (827 kPa), and push both knobs in. Pull the red knob out. The yellow knob must remain in. Push the red knob in and pull the yellow knob out. The red knob must pop out at once.
8. Install a gauge to monitor tractor spring brake delivery pressure. Build 120 psi (827 kPa) pressure in the primary and secondary air reservoirs. Push in the yellow knob. Delivery pressure should equal the pressure in the primary air reservoir. Reduce the pressure in the primary air reservoir. The dual-circuit supply valve shuttle should switch to the secondary air reservoir. After the primary air reservoir pressure is reduced to zero, there should not be audible leakage at the primary air reservoir opening. Stop the leak that was created in the primary air reservoir.
9. Leaving the yellow knob in, recharge the secondary air reservoir to 120 psi (827 kPa). The delivery pressure should also read 120 psi (827 kPa). Recharge the primary air reservoir to 100 psi (690 kPa). Slowly vent the secondary air reservoir. As the secondary air reservoir pressure and the delivery line pressure descend, pressure should stabilize at about 100 psi (690 kPa).
10. Close all leakage points and charge both reservoirs to 120 psi (827 kPa). Position the red knob out and the yellow knob in. Develop a leak in the spring brake delivery line and hold the yellow knob in. See **Fig. 1**. The air reservoir pressures will go to zero. The dual-circuit supply valve shuttle should cycle during the leak-down period.
11. If the MV-3 fails to operate as described, or leakage exceeds the limits stated, replace or repair it using genuine Bendix parts.

Removal (See Fig. 1)



NOTE: Components have been removed from the auxiliary instrument panel for clarity.

Fig. 1, MV–3 Control Valve Mounting

⚠ WARNING

Wear eye protection when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Do not direct the airstreams at anyone. Do not disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

1. Park the vehicle on a level surface, apply the parking brakes, chock the tires, and drain the air tanks .
2. Remove the trim plate assembly from the radio and heater/air conditioner control panel.
3. Remove the screw from the right-hand trim cap. Remove the trim cap from the dash.
4. Unscrew the red and yellow knobs from the stems of the spools on the MV–3 valve by turning them in a counterclockwise direction. Mark these knobs in relation to the valve for later reference.
5. Remove the four screws that attach the auxiliary instrument panel in the dash. Pull the panel out to access the control module mounting screws.
6. Remove and save the four mounting screws and washers from the four corners of the cover plate.
7. With the valve and cover plate assembly pulled out slightly from the dash panel, remove the air lines from the back of the valve.
8. Pull the valve out of the dash.

Installation

1. Connect the air lines to the proper ports. The color of the air lines should match the colored collar at the valve fitting.
2. Align the valve in the dash and install the four screws and washers into the corners of the cover plate.
3. Attach the red and yellow knobs onto the threaded stems of the spools, making sure that they are oriented correctly as noted during removal.
4. Leak test the fittings, following the instructions under **Subject 100.**
5. Install the auxiliary instrument panel, right-hand trim cap, and the radio and heater/air conditioner trim plate assembly.
6. Remove the chocks.

tilting the body forward. Remove the O-ring from its groove on the piston.

3. Remove the two main spools from the body of the MV–3 valve by grasping the stem and pulling firmly. Remove the spring from the bottom of each spool cavity.
4. Pull the guide cap and guide spool over the threaded end of one of the plungers. Remove the O-ring from the guide cap and the O-ring from the guide spool. Remove the other O-rings and the exhaust seal from the plunger.
5. Repeat the previous step on the remaining spool assembly.
6. Remove the retaining ring from the cavity of the MV–3 body that contains the dual circuit supply valve.
7. Using a pair of needle nose pliers, grasp the bar in the center of the cap and dual circuit supply valve and remove the dual circuit valve assembly. Remove the three O-rings from the valve or from the cavity of the body, if some have remained there. Other than the three external O-rings, don't disassemble the piston assembly further.

NOTE: If during the removal of this assembly from the body the cap dislodges from the rest of the valve, the remaining parts can be removed using bent wire. The spring, piston and O-ring that are internal to the dual circuit valve assembly are nonserviceable.

Cleaning and Inspection

The nonmetallic components making up most of the parts of the MV–3 *should not be immersed in any solvent type cleaner.* Old lubricant should be wiped out with a clean dry cloth.

If any visible damage to the body or the spools is found, replace the complete unit.

Assembly

DUAL CIRCUIT SUPPLY VALVE

1. Lubricate all O-rings, bores, and sliding surfaces with silicone lubricant Bendix 291126, Dow Corning 55-M, or equivalent.
2. Install O-rings onto the cap and dual circuit supply valve. Then install the assembly—small diameter first—into its cavity in the body.
3. Install the retaining ring (Ref. 22) making sure it is fully seated in its groove.

SPOOLS

1. Install the O-rings and the exhaust seal onto the stem of the plunger.

⚠ CAUTION

CAUTION: The exhaust seal (Ref. 19) must be installed so that its beveled surface mates with the beveled surface of the plunger. See Fig. 2.

2. Install the O-ring onto the guide spool and the O-ring onto the guide cap. Place the guide cap on top of the guide spool, and install the entire assembly over the threaded end of the plunger; press down firmly until it snaps into place.

4. Install the piston assembly into the cavity, making sure the spring mates with the bore of the piston.

Fig. 1, Bendix AD–9 Air Dryer and Cutaway View

The AD–9 air dryer consists of the desiccant cartridge and a die-cast aluminum end cover secured to a cylindrical steel outer shell with eight capscrews and nuts. The end cover contains a check valve assembly, a safety valve, three threaded air connections and the purge valve housing assembly. The

To ease servicing, the desiccant cartridge and discharge check valve assembly are screw-in types. The purge valve housing assembly, which includes the heater and thermostat assembly, and the discharge check valve assembly, can be serviced without removing the air dryer from the vehicle. The

General Description and Principles of Operation

screw-in desiccant cartridge requires removal of the air dryer assembly from the vehicle.

The AD–9 has three female pipe thread air connections; each is identified as follows **(see Table 1):**

Port I.D.	Function/Connection
4-CON	Control Port (purge valve control and turbo cutoff)
11-SUP	Supply Port (air in)
2-DEL	Delivery Port (air out)

Table 1

There are four versions of the AD–9 air dryer:

- Standard **(see Fig. 2):**

  The standard air dryer uses a metal seat turbo cutoff valve. The function of the metal seat is to prevent turbocharger boost pressure loss through the air dryer during the purge (compressor unloaded) mode. Some low level turbo air leakage can occur in the unloaded mode.

- Discharge Line Unloader Style **(see Fig. 3):**

  The discharge line unloader style air dryer is usually used on brake systems that have compressors equipped with a discharge unloader valve, but no integral unloading mechanisms. This air dryer is designed to bypass the turbo cutoff mechanism on the dryer, allowing air from the compressor to be vented out the bottom of the air dryer when the brake system is in a non-charging mode. An air governor is used on this system and replaces the discharge line unloader valve normally installed in the compressor's discharge line. This type of air dryer can be identified by the "U" stamped on the side of the purge valve housing.

- Soft Seat Air Dryer **(see Fig. 4):**

  The soft seat style air dryer is usually used on vehicles equipped with Holset "E" and "QE" type air compressors. This air dryer eliminates the need for the Holset ECON valve (which is plumbed in the compressor discharge line).

Fig. 5, Drop-In Style Air Dryer Plumbing Diagram

The drop-in style air dryer *can only be used* on vehicles equipped with Holset "E" and "QE" type air compressors. This air dryer eliminates any external plumbing requirements (such as the ECON valve, make-up line, and make-up line check valve). All of these components are an integral part of the air dryer.

Principles of Operation

The AD–9 air dryer alternates between two operational modes or cycles during operation: the charge cycle and the purge cycle.

Charge Cycle **(See Fig. 6)**

When the compressor is loaded (compressing air), pressurized air, along with oil, oil vapor, water, and water vapor flow through the compressor discharge line to the supply port of the air dryer end cover. As air travels through the end-cover assembly, its direction of flow changes several times, reducing the temperature, causing contaminants to condense and drop to the bottom or sump of the air dryer end cover.

After exiting the end cover, air flows into the desiccant cartridge. Once in the cartridge, air first flows through an oil separator, which removes water, oil, oil vapor, and solid contaminants.

Air exits the oil separator and enters the desiccant drying bed. Air flowing through the column of desiccant becomes progressively drier as water vapor sticks to the desiccant material in a process known as adsorption. The desiccant cartridge, using the adsorption process typically removes 95 percent of the water vapor from the pressurized air.

Most of the dry air exits the desiccant cartridge through its integral single check valve to fill the purge volume between the desiccant cartridge and outer shell. Some air also exits the desiccant cartridge through the purge orifice adjacent to the check valve.

Dry air flows out of the purge volume through the single check valve assembly and out the delivery port to the first (supply) reservoir of the air system.

Fig. 6, AD–9 Charge Cycle

The air dryer remains in the charge cycle until air brake system pressure builds to the governor cutout setting.

Purge Cycle **(See Fig. 7)**

When the brake system pressure reaches the governor cutout setting, the compressor unloads (air compression stopped), and the purge cycle of the air dryer begins. When the governor unloads the compressor, it pressurizes the unloader mechanism and line connecting the governor unloader port to the AD–9 end cover control port. The purge piston moves in response to air pressure causing the purge valve to open to atmosphere and partially close off the supply of air from the compressor. This is further discussed under "Turbo Cutoff Feature."

Contaminants in the end cover sump are expelled immediately when the purge valve opens. Also, air that was flowing through the desiccant cartridge

changes direction and begins to flow toward the open purge valve. Oil and solid contaminants collected by the oil separator are removed by air flowing from the desiccant drying bed to the open purge valve.

The initial purge and desiccant cartridge decompression last only a few seconds and are signaled by an audible burst of air at the AD–9 exhaust. The actual reactivation of the desiccant drying bed begins as dry air flows from the purge volume through the desiccant cartridge purge orifice and into the desiccant drying bed. Pressurized air from the purge volume expands after passing through the purge orifice; its pressure is lowered and its volume increased. Dry air

flowing through the drying bed reactivates the desiccant material by removing the water vapor sticking to it. Generally, it takes 15 to 30 seconds for the entire purge volume of a standard AD–9 to flow through the desiccant drying bed.

The end cover single check valve assembly prevents compressed air in the brake system from returning to the air dryer during the purge cycle. After the 30 second purge cycle is complete, the air dryer is ready for the next charge cycle to begin.

The purge valve will remain open after the purge cycle is complete, and will not close until air brake system pressure is reduced and the governor signals the compressor to charge.

NOTE: The air dryer should be periodically checked for operation and tested for leaks. Refer to the brake section in the vehicle maintenance manual for intervals and procedures.

Turbocharger Cutoff Feature

(See Fig. 8)

Primarily, the turbo cutoff valve prevents loss of engine turbocharger air pressure through the AD–9 in systems where the compressor intake is connected to the engine turbocharger. The turbo cutoff valve also reduces the puffing of air out the open exhaust when a naturally aspirated, single cylinder compressor equipped with an inlet check valve is in use.

At the beginning of the purge cycle, the downward travel of the purge piston is stopped when the turbo cutoff valve (tapered portion of the purge piston) contacts its mating metal seat in the purge valve housing. With the turbo cutoff valve seated (closed position), air in the discharge line and AD–9 supply port is restricted from entering the air dryer. While the turbo cutoff *effectively* prevents loss of turbocharger boost pressure to the engine, some seepage of air may be detected under certain conditions of compressor, engine, and turbocharger operation. Even so, there will be low pressure trapped in the discharge line.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure, and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Don't disassemble a component until you have read and understood the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools, and observe all precautions pertaining to use of those tools.
5. Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.

   Make sure that when replacing tubing or hose, all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.

1. Park the vehicle on a level surface and chock the tires.
2. Completely drain all of the reservoirs.
3. Remove the air dryer.
   - 3.1 Mark and disconnect the three air lines from the end cover, and note the position of end cover ports relative to the vehicle.
   - 3.2 Unplug the vehicle wiring harness from the heater and thermostat assembly connector on the exhaust cover.

   - 3.5 Remove the air dryer from its mounting brackets.

Installation (See Fig. 1)

WARNING

WARNING: Before working on or around air brake systems and components, read the safety precautions in Subject 100. Failure to do so could result in personal injury.

1. Install the assembled air dryer on the vehicle.

Air Dryer Disassembly, Cleaning and Inspection, and Assembly

WARNING

WARNING: Before working on or around air brake systems and components, read the safety precautions in Subject 100. Failure to do so could result in personal injury.

CAUTION

CAUTION: While servicing the air dryer, don't use a clamping device (vise, C-clamp, etc.) to hold any die cast aluminum part, as damage may result. To hold the end cover, install a pipe nipple in the supply port, and clamp the nipple in a vise.

1. Remove the air dryer from the vehicle. Refer to Subject 110.
2. Remove the check valve assembly and O-ring. Remove the O-ring from the check valve assembly.
3. Remove the purge valve housing assembly.
   - 3.1 Remove the three self-tapping screws that secure the purge valve housing assembly to the end cover assembly.
   - 3.2 Pull the purge valve housing assembly out of the end cover assembly.
   - 3.3 Remove and discard the three O-rings from the exterior of the purge valve housing assembly.

   NOTE: These O-rings may lodge in and have to be removed from the end cover bores.
4. Remove the heater and thermostat assembly.
   - 4.1 Remove and discard the two screws that attach the heater and thermostat assembly to the purge valve housing.
   - 4.2 Gently rotate the electrical connector to the left until the thermostat clears the purge valve housing. Then, slide the heater element out, to the right and up. Discard the assembly.
5. Disassemble the purge valve housing assembly.
   - 5.1 If a flat non-extended exhaust cover is used, leave it intact while servicing the purge valve housing assembly.

     If an extended type exhaust cover is used for the attachment of an exhaust hose, *carefully* separate the exhaust cover from the purge valve housing. *Use a thin flat blade to pry the exhaust cover off, taking care not to damage the potting material (RTV sealant) under the cover.*
   - 5.2 Remove the bolt from the bottom of the purge valve housing assembly. Remove the diaphragm and the purge valve from the purge valve housing.
   - 5.3 Remove the purge piston, the return spring and two O-rings (one on the outside and the other in the inside of the purge piston).
6. Remove the remaining six capscrews (Ref. 24), locknuts (Ref. 7), and twelve special washers (Ref. 8) that secure the end cover to the housing (Ref. 6). Separate the end cover and desiccant cartridge (Ref. 9) from the housing (Ref. 6).
7. Remove the end-cover-to-outer-housing O-ring.
8. Don't remove the safety valve (Ref. 11) from the end cover unless it is known to be inoperative. If replacement is needed, apply thread sealant or Teflon® tape on the threads of the replacement valve and tighten 120 to 400 lbf·in (1360 to 4520 N·m). Make sure the drain hole (slot) is facing down.
9. Place a strap or chain wrench around the desiccant cartridge (Ref. 9) so that it is about 2 to 3 inches (5 to 8 cm) away from the end cover. Rotate the cartridge counterclockwise until it completely separates from the end cover.

NOTE: Torque of up to 50 lbf·ft (68 N·m) may be needed to do this disassembly.

10. Remove the desiccant cartridge O-ring from the end cover.

Cleaning and Inspection

WARNING

WARNING: Before working on or around air brake systems and components, read the safety precautions in Subject 100. Failure to do so could result in personal injury.

1. Wash all metal parts thoroughly, using a quality commercial solvent, such as mineral spirits.
2. Check for severe corrosion, pitting, and cracks on the inside and outside of all metal parts that will be reused. Superficial corrosion and pitting on the outside of the upper and lower body halves is acceptable.
3. Inspect the bores of both the end cover and the purge-valve housing for deep scuffing or gouges.
4. Make sure that all purge-valve housing and end cover passages are open and free of blockages.
5. Inspect the pipe threads in the end cover. Make sure they are clean and free of thread sealant.
6. Inspect the purge-valve housing bore and seats for excessive wear and scuffing.
7. Inspect the purge valve piston seat for excessive wear.
8. Inspect all air line fittings for corrosion. Clean all old thread sealant from the pipe threads.
9. Replace all removed O-rings with new ones that are provided in the kits.

   Replace parts that show any of the conditions described in the previous steps.

Assembly (See Fig. 1)

⚠ WARNING

WARNING: Before working on or around air brake systems and components, read the safety precautions in Subject 100. Failure to do so could result in personal injury.

1. Before assembly, coat all O-rings, O-ring grooves, and bores with a generous amount of barium-base lubricant. **See Fig. 1** during assembly unless otherwise advised.

IMPORTANT: When installing the heater and thermostat assembly, make sure that the seal ring under the electrical connector is not twisted.

2. Install the heater and thermostat assembly.
   - 2.1 Insert the heater element into the slot in the purge valve housing until the connector contacts the housing.
   - 2.2 Gently push the connector and the thermostat to the left until the thermostat clears the cavity in the housing. Then, turn the connector to the right while pushing the thermostat all the way down into the cavity.

     Make sure that the connector is seated evenly against the housing.
   - 2.3 Install the two mounting screws. Tighten the screws 10 to 20 lbf·in (113 to 226 N·cm).
3. Assemble the purge-valve housing.
   - 3.1 Install the O-ring on the purge piston. Place the return spring in the purge-valve housing. Place the O-ring in the bore of the purge piston. Insert the purge piston into the spring. Push the piston into the purge-valve housing until it bottoms.
   - 3.2 While holding the purge piston in, install the following parts: the purge valve with its rubber side first, followed by the diaphragm and the bolt. Torque the purge valve bolt 60 to 80 lbf·in (680 to 900 N·cm).
   - 3.3 Install the three O-rings in their correct locations on the purge-valve housing.
   - 3.4 If an extended type exhaust cover was removed, install it on the purge-valve housing assembly, making sure the "bubble" portion is positioned over the thermostat.
   - 3.5 Install the assembled purge-valve housing in the end cover; make sure you orient both parts so that the connector is about 10 degrees clockwise from the supply port. Also, make sure the purge-valve housing is fully seated against the end cover.
   - 3.6 Secure the purge-valve housing to the end cover using the three self-tapping screws. Start all three screws by hand, then torque them 85 to 125 lbf·in (960 to 1400 N·cm).
4. Install an O-ring on the check-valve assembly, then install the assembly in the end cover using a socket. Tighten it 200 to 250 lbf·in (2260 to 2820 N·cm).

Air Dryer Disassembly, Cleaning and Inspection, and Assembly

5. Install the desiccant cartridge in the end cover.
   - 5.1 Install the smaller desiccant cartridge O-ring in its groove in the end cover. Using a light coat of barium grease, lubricate the bottom of the desiccant cartridge in the area that will contact the O-ring and end cover.
   - 5.2 Screw the desiccant cartridge into the end cover until the cartridge contacts the O-ring. Using a strap or chain wrench positioned 2 to 3 inches (5 to 8 cm) from the bottom of the cartridge, turn the desiccant cartridge clockwise 180 to 225 degrees beyond the position where initial contact was made with the O-ring. Torque should not exceed 50 lbf·ft (68 N·m).
6. Install the housing over the desiccant cartridge.
   - 6.1 Install the large O-ring on the shoulder in the end cover. Place the housing over the desiccant cartridge and align the holes.
   - 6.2 Install the six capscrews, locknuts, and the twelve special washers, making sure they are positioned as referenced earlier. The two longer capscrews will be used to secure the air dryer to its mounting bracket.
   - 6.3 Tighten the six capscrews and nuts in a star pattern (depending on lower bracket location) 270 to 385 lbf·in (3060 to 4340 N·cm). **See Fig. 2.**

NOTE: The two remaining bolt holes in the end cover and two 3/8-inch capscrews must be the ones marked during removal to ensure correct orientation of the ports and adequate length of the capscrews.

7. Connect the electrical connector to the heater and thermostat assembly.
8. Test the air dryer for proper operation. For instructions, refer to **Subject 130.**

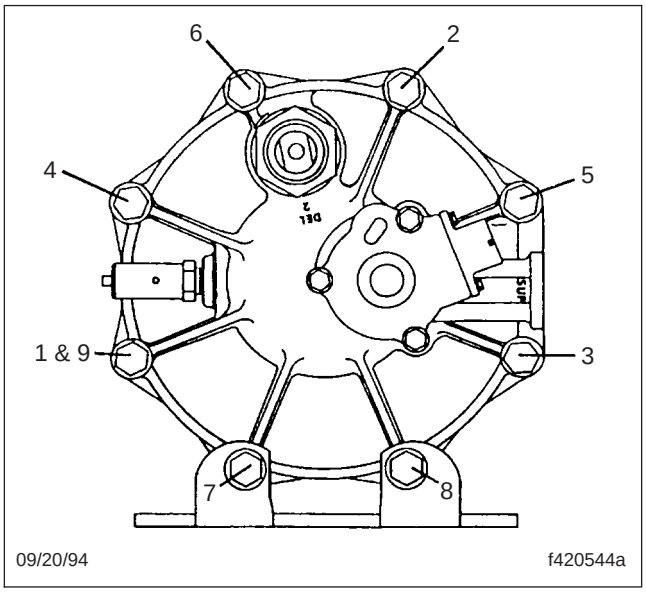

Fig. 2, End Cover to Housing Torque Pattern

Testing

During cold-weather operation, check the operation of the end cover heater and thermostat assembly.

1. With the ignition on, check for voltage to the heater and thermostat assembly. Unplug the electrical connector at the air dryer, and place the test leads on each of the pins of the male connector. If there is no voltage, look for a blown fuse, broken wires, or corrosion in the vehicle wiring harness. Check that a good ground path exists.
2. Check the thermostat and heater operation. Turn off the ignition switch and cool the end cover assembly to below 40°F (4°C). Using an ohmmeter, check the resistance between the electrical pins in the female connector. The resistance should be 1.5 to 3.0 ohms for the 12-volt heater assembly, and 6.8 to 9.0 ohms for the 24-volt heater assembly.

NOTE: Some early models of the AD–9 will have resistance readings of 1.0 to 2.5 ohms for the 12-volt heater assembly, and 4.8 to 7.2 ohms for the 24-volt heater assembly. If the resistance is higher than this, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

3. Warm the end cover assembly to over 90°F (32°C) and again check the resistance. It should exceed 1000 ohms. If it does, the thermostat and heater assembly is operating properly. If it doesn't, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

Problem—Air Dryer Is Constantly Cycling or Purging

Possible Cause	Remedy
Excessive system leakage.	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is as follows: • Single Vehicle—1 psi/min (7 kPa/min) per service reservoir • Tractor/Trailer—3 psi/min (21 kPa/min) per service reservoir
There is excessive leakage in the fittings, hoses, and tubing connected to the compressor, air dryer, and wet tank.	Using a soap solution, test for leakage at the fittings, drain valve, and safety valve in the wet tank. Repair or replace as needed.
Check valve assembly in the air dryer end cover is not working.	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at opposite end, and check for leakage. Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.
Governor is inoperative.	Test the governor for proper cut-in or cut-out pressures and excessive leakage in both positions.
Leaking purge-valve housing assembly or O-rings in the air dryer end cover.	With the supply port open to atmosphere, apply 120 psi (830 kPa) at the control port. Apply a soap solution to the supply port and exhaust port (purge valve seat area). Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. Repair or replace as needed.
Compressor unloader mechanism is leaking excessively.	Remove the air strainer or fitting from the compressor inlet cavity. With the compressor unloaded, check for unloader piston leakage. Slight leakage is allowed.
Holset "E" type compressor.	Test the air dryer system. For instructions, refer to Bendix Product Bulletin PRO-08-19 entitled "Troubleshooting the Holset "E" Compressor System with Bendix Air Dryer."
Lack of air at the governor RES port (rapid cycling of the governor).	Test the governor for proper pressure at the RES port. Pressure should not drop below cut-in pressure when the compressor begins the unloaded cycle. If the pressure does drop, check for kinks or restrictions in the line connected to the RES port. The line connected to the RES port on the governor must be the same diameter, or larger than the lines connected to the UNL ports on the governor.

Problem—Water in the Vehicle Reservoirs

Possible Cause	Remedy
Desiccant cartridge assembly contains excessive contaminants.	Replace the desiccant cartridge.
Discharge line is of improper length or material.	Discharge line must consist of at least 6 ft. (1.8m) of wire braid Teflon hose, copper tubing, or a combination of both between the discharge port of the compressor and the air dryer supply port. Discharge line lengths and inside diameter requirements are dependent on the vehicle application. Contact your local Bendix representative for further information.
Air system was charged from an outside air source that did not pass through an air dryer.	If the system must have an outside air fill provision, the outside air should pass through an air dryer. This practice should be minimized.
Air dryer is not purging.	Refer to "Problem—Air Dryer Does Not Purge or Exhaust Air."
Purge (air exhaust) is insufficient due to excessive system leakage.	Refer to "Problem—Air Dryer Is Constantly Cycling or Purging."

Troubleshooting

Possible Cause	Remedy
Air bypasses the desiccant cartridge assembly.	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed.
Purge (air exhaust) time is significantly less than the minimum allowable.	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed. Replace the desiccant cartridge assembly.
Excessive air usage—air dryer not compatible with vehicle air system.	Install an accessory bypass system. Consult your Bendix representative for additional information.

Problem—Safety Valve on Air Dryer Is Popping Off or Exhausting Air

Possible Cause	Remedy
Desiccant cartridge is plugged or saturated.	Check the compressor for excessive oil passing, or incorrect installation. Repair or replace as needed.
The check valve in the air dryer end cover is inoperative.	Test to determine if air is passing through the check valve. Repair or replace as needed.
There is a problem in the fittings, hose, or tubing between the air dryer and the wet tank.	See if air is reaching the first reservoir. Inspect for kinked tubing or hose. Check for undrilled or restricted hose or tubing fittings.
Safety valve setting is lower than the maximum system pressure.	Reduce the system pressure, or install a safety valve with a higher pressure setting.

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure

Possible Cause	Remedy
Air dryer purge valve is leaking excessively.	With the compressor loaded, apply a soap solution on the purge valve exhaust to test for excessive leakage. Repair the purge valve as needed.
The governor is inoperative.	Check the governor for proper cut-in and cut-out pressures, and excessive leakage in both positions. Repair or replace as needed.
Purge control line is connected to the reservoir or exhaust port of the governor.	Connect the purge control line to the unloader port of the governor.
Purge valve is frozen open due to an inoperative heater or thermostat, bad wiring, or a blown fuse.	Test the heater and thermostat, following instructions in this manual.
Inlet and outlet air connections are reversed—unable to build system pressure.	Reconnect the lines properly.
Discharge line is kinked or blocked.	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line. Water is collecting and freezing.	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.
System is leaking excessively.	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is as follows: • Single Vehicle—1 psi/min (7 kPa/min) per service reservoir • Tractor/Trailer—3 psi/min (21 kPa/min) per service reservoir

Possible Cause	Remedy
Purge valve stays open; supply air leaks to control side.	Replace the purge valve assembly O-rings.

Problem—Air Dryer Does Not Purge or Exhaust Air

Possible Cause	Remedy
Purge control line is broken, kinked, frozen, plugged, or disconnected.	See if air flows through the purge control line when the compressor is unloaded. The purge control line must be connected to the unloader port of the governor.
Air dryer purge valve isn't working.	See if air reaches the purge valve. If it does, repair the purge valve.
The governor is inoperative.	Check the governor for proper cut-in and cut-out pressures, and excessive leakage in both positions. Repair or replace as needed.
Inlet and outlet air connections are reversed—unable to build system pressure.	Reconnect the lines properly.
Discharge line is kinked or blocked.	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line. Water is collecting and freezing.	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.

Problem—Desiccant Is Being Expelled from the Air Dryer Purge Valve Exhaust (May Look Like Whitish Liquid, Paste, or Small Beads); or, Unsatisfactory Desiccant Life

Possible Cause	Remedy
This problem usually occurs with one or more of the previous problems.	Refer to the appropriate corrections listed previously.
Air dryer is not securely mounted; there is excessive vibration.	Vibration should be held to a minimum. Tighten the mounting fasteners.
Cloth-covered perforated plate in the air dryer desiccant cartridge is damaged, or the cartridge was rebuilt incorrectly.	Replace the plate or cartridge as needed. High operating temperatures may cause deterioration of filter cloth. Check the installation.
Compressor is passing excessive oil.	Check for proper compressor installation; if symptoms persist, replace the compressor.
Heater and thermostat, wiring, or a fuse is at fault, and isn't allowing the air dryer to purge during cold weather.	Test the heater and thermostat, following instructions in this manual.
Desiccant cartridge not attached properly to the end cover.	Check the torque and tighten if necessary. Refer to **Subject 120** for instructions.

Troubleshooting

Problem—Pinging Noise Is Excessive During Compressor Loaded Cycle

Possible Cause	Remedy
Pinging noise is due to a single cylinder compressor with high pulse cycles.	A slight pinging sound may be heard during system build-up when a single cylinder compressor is used. If this sound is deemed objectionable, it can be reduced substantially by increasing the discharge line volume. This is done by adding a 90 in ^{3} (1475 cm ^{3}) reservoir between the compressor and the air dryer.

Problem—Constant Air Seepage at the Purge Valve (Non-Charging Mode)

Possible Cause	Remedy
Air compressor inlet is pressurized by the engine turbocharger.	Some pressure leakage past the metal seat of the turbocharger cutoff feature of the AD-9 air dryer is normal, and may be heard. This slight loss of air will not affect the engine or turbocharger performance.
Check valve assembly in the air dryer end cover is not working.	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at opposite end, and check for leakage. Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.

Problem—Air Dryer Purge Piston Cycles Rapidly in the Unloaded Mode

Possible Cause	Remedy
Compressor does not "unload."	Check the governor installation: there is no air line from the governor to the compressor, or the line is restricted. Repair or replace as needed.

General Description and Principles of Operation (See Fig. 1)

The dual circuit brake valve (foot valve) controls the air supply and delivery of the dual circuit brake system. The brake valve is mounted on the firewall.

APPLYING

The primary circuit of the brake valve is controlled by the brake pedal and a plunger. When the brake pedal is depressed, the plunger applies pressure on the spring seat, rubber spring, and the primary (upper) piston. The downward movement of the primary piston closes the upper exhaust valve, and then opens the upper inlet valve, allowing high-pressure air from port 11 to flow to low-pressure port 21.

The secondary circuit is pneumatically operated by the pressure from the primary circuit. Primary circuit pressure on top of the relay piston first closes the lower exhaust valve, and then opens the lower inlet valve, allowing high-pressure from port 12 to flow to low-pressure port 22.

HOLDING

As air pressure builds in the primary circuit, the pressure under the primary piston will match the pressure of the rubber spring. This allows the piston to move up enough to close the upper inlet valve, and prevent the flow of air from the primary air tank into the brake valve. The exhaust port remains closed.

RELEASING

When the pedal is released, the push rod releases pressure from the spring seat, rubber spring, and the primary (upper) piston. Air pressure builds to push the piston up, opening the upper exhaust valve and allowing air from the primary circuit to escape through the exhaust port.

In the secondary circuit, the release of primary air pressure allows air under the relay piston, pushing the piston up and opening the lower exhaust valve. All remaining air pressure is vented through the exhaust port.

Bendix E–6 Brake Valve Operating and Leakage Checks

Operating Checks

IMPORTANT: If there is a change in the way a vehicle brakes, or if low pressure warnings occur, check the operation of the brakes' air system. Although the brake system may continue to work, do not operate the vehicle until the braking circuits, including the pneumatic and mechanical devices, have been repaired and are operating normally. Always check the brake system for proper operation after doing brake work, and before returning the vehicle to service.

Check for the proper brake valve operation as follows:

1. Apply the parking brakes, and chock the tires.
2. Connect test gauges to the primary and secondary delivery ports on the brake valve. **See Fig. 1.**

7. Primary Supply Circuit to Primary Supply Reservoir
8. Secondary Supply Circuit to Secondary Supply Reservoir

Fig. 1, Brake Valve Plumbing Circuits

NOTE: When checking the delivery pressure of the primary and secondary circuits, use test gauges that are accurate.

3. Start the engine and build air pressure to 120 psi (827 kPa).
4. Depress the pedal to several different positions; check the pressure on the test gauges to ensure that it varies equally and proportionately with the movement of the brake pedal.
5. Fully depress the brake pedal, then release it. After a full application is released, the reading on the test gauges should promptly fall to zero.

NOTE: Pressure in the primary delivery circuit will be about 2 psi (14 kPa) greater than pressure in the secondary delivery circuit (if both supply reservoirs are at the same pressure). This is normal for this valve.

6. Go to "Leakage Check."

Leakage Check

1. Make and hold a pressure application of 80 psi (552 kPa).
2. Check the air line fittings for leaks: tighten or replace fittings as needed.
3. Coat the exhaust port and body of the valve with a soap solution, and check for leakage. The leakage permitted is a one-inch bubble in 3 seconds.

   If the brake valve does not function as described above, or if leakage is excessive, replace it with a new or remanufactured unit.

   Repeat the leakage test before placing the brake valve in service.
4. Remove the chocks from the tires.

⚠ WARNING

WARNING: When draining the air system, don't look into the air jets or direct them toward another person, because dirt or sludge particles may be in the airstream. Don't disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can result in personal injury.

2. Drain all of the air reservoirs.
3. Mark the brake valve air supply and delivery lines for assembly reference. Disconnect the air lines from the brake valve, and plug them to keep out contaminants.
4. Remove the brake valve.
   - 4.1 Remove the 5/16-18 capscrews and flatwashers that attach the brake valve and mounting adaptor to the front cab mount plate.
   - 4.2 Remove the 5/16-18 locknuts and washers that attach the brake valve to the mounting adaptor.
   - 4.3 Remove the plunger from the mounting adaptor. Wipe off the old grease from the plunger and adaptor.
5. Note the locations and positions of the double check valves (if equipped), then remove them from the brake valve. Clean off the dirt and old sealant from the threads of the valves and elbows.

Installation (See Fig. 1)

⚠ WARNING

WARNING: When applying sealant, make sure that excess sealant doesn't get inside either the male or the female fittings. Loose foreign material inside the air plumbing may clog a valve, causing a loss of brake control, which could result in personal injury.

1. If equipped with a hand brake valve, apply a small quantity of Loctite® Pipe Sealant (with Teflon® 59241), or an equivalent sealant, to the male threads of each of the double check valves and the elbows.

   Install the double check valves and elbows in the ports of the brake valve. Tighten each valve finger-tight, then tighten them one additional turn with a wrench. As needed, further tighten them until they are properly positioned.

2. Lubricate the sliding surface of the brake plunger with barium grease, part number BW 246671 or Pennzoil Adhezoplex EP 2. Install the plunger in the mounting adaptor.
3. Using the 5/16–18 locknuts and washers, attach the mounting adaptor to the brake valve. Tighten the capscrews 10–13 lbf·ft (14–18 N·m).
4. Install the brake valve and mounting adaptor on the outside of the front cab mount plate. Install the adaptor mounting capscrews and flatwashers. Tighten the capscrews 10–13 lbf·ft (14–18 N·m).
5. Connect the air lines, as previously marked. Tighten the nuts finger-tight. Using a wrench, further tighten the nuts until there is resistance, then tighten one-sixth additional turn.
6. Check and secure the air lines and electrical wires so they can't interfere with the movement of the brake pedal.
7. Return the hood to the operating position. For instructions, refer to the vehicle driver's manual.
8. Perform the operating and leakage checks. For instructions, refer to **Subject 100.**
9. Remove the chocks from the tires.

Cleaning and Inspecting

Wash all metal parts in mineral spirits and dry them thoroughly with compressed air. Inspect the valve seat surfaces of the pistons and the valve housings for conditions that could cause leakage. Inspect air line fittings for corrosion, and replace corroded fittings.

Assembly (See Fig. 1)

NOTE: Keep the work area, tools, and brake valve parts clean during assembly.

1. Using Dow Corning 55-M pneumatic grease, or equivalent, lightly grease all the new O-rings, O-ring grooves, piston bores, and all sliding surfaces.

When installing these springs, use care to prevent them from flying out and possibly causing personal injury. Manually or mechanically hold down these springs when installing the locknut.

12. Push down and hold the primary and relay pistons in the upper valve body.
13. Place the stem spring (Ref. 3) over the spring seat nut (Ref. 4). Place the spring seat over the stem.

General Description

Meritor Cam-Master® brakes are air actuated, cam operated, foundation brakes. The main components in each brake assembly (wheel end) consists of:

- a camshaft-and-chamber bracket;
- a "S" head camshaft;
- a brake spider;
- two brake shoe and lining assemblies;
- a return spring;
- and, two anchor pins.

The "S" head camshaft is bushing mounted inside the camshaft-and-chamber bracket; and it transfers braking force from the slack adjuster to the brake shoe assemblies. Each brake shoe is mounted to the brake spider through an anchor pin; and it is controlled (moved) by either the outward braking force of the "S" head camshaft or the inward restoring force of the return spring. The brake spider is fastened to the axle flange and the camshaft-and-chamber bracket is mounted to the brake spider.

The steer axles are available with "Q" Plus brakes. See **Fig. 1**. Either 16-1/2 inch (419 mm) by 5 inch (127 mm) or 16-1/2 inch (419 mm) by 6 inch (152 mm) fabricated double web brake shoes are used with the "Q" Plus brakes.

The "Q" Plus brake shoes are designed with open anchor pin ends. Two retainer springs couple the brake shoes (anchor pin ends) to the anchor pins. Then, the anchor pins are coupled to the brake spider. This design makes "quick change" brake service possible.

Meritor steer axles have seven holes for attaching the spider to the axle flange. There is an eighth hole in the axle flange, which holds an ABS wheel speed sensor bushing, on both left and right sides of the steer axle. See **Fig. 2**. The seven holes used for attachment of the spider to the axle flange are 0.656 inch in diameter. The eighth hole is oversized at 0.687 inch in diameter. Depending on what side the axle flange is viewed from, the eighth hole is either in the 10 o'clock or 2 o'clock position.

The rear axles are available with either "Q" Plus or "P" Series brakes. See **Fig. 3**. 16-1/2 inch (419 mm) by 7 inch (171 mm) heavy-duty fabricated double web brake shoes are used with the "Q" Plus brakes

and 16-1/2 (419 mm) inch by 7 inch (171 mm) cast double web brake shoes are used with the "P" Series brakes.

Unlike the "Q" Plus brake shoes, the "P" Series brake shoes are designed with closed anchor pin ends. The anchor pins couple the brake shoes (the anchor pin ends) to the brake spider.

"Q" Plus LX500 and MX500 brakes are extended maintenance brakes. These brakes can be identified by an identification tag affixed to the brake shoe. An additional identification tag is affixed to the brake

camshaft-and-chamber bracket (on top of the plugged grease hole).

Principles of Operation

When the brake pedal is depressed, compressed air enters the brake chamber, causing the diaphragm to move a push rod assembly.

The push rod, which is connected to a slack adjuster, turns the slack adjuster and brake camshaft. As the camshaft turns, the S-type cam head, which is between the brake shoe rollers, forces the brake shoes against the brake drum, and braking occurs.

When the brakes are released and air is exhausted from the brake chamber, the actuator return spring (within the brake chamber) and the brake shoe return spring, return the camshaft, brake shoes, slack adjuster, and the push rod to their released positions.

General Safety Precautions

⚠ WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Asbestos and Non-Asbestos Safety

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH.

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Exposure to airborne asbestos brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by OHSA regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

Safety Precautions

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

If grinding or other machining of the brake linings is necessary, other precautions must be taken because exposure to asbestos dust is highest during such operations. In addition to the use of an approved respirator, there must be local exhaust ventilation such that worker exposure is kept as low as possible.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Asbestos-containing waste, such as dirty rags, should be sealed, labeled, and disposed of as required by EPA and OSHA regulations. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

Workers should wash before eating, drinking, or smoking, should shower after work, and should not wear work clothes home. Work clothes should be vacuumed after use and then laundered, without shaking, to prevent the release of asbestos fibers into the air.

WARNING

Before starting the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

IMPORTANT: When replacing the brake linings, use a dial indicator to measure the cam-to-bushing radial free play (the up-and-down and side-to-side free play of the camshaft) and the camshaft axial end play (the in-and-out end play of the camshaft).

Replace the bushings if the cam-to-bushing radial free play exceeds:

- for all Cam-Master brakes except Q Plus (LX500 and MX500), 0.030 inch (0.8 mm) of movement;
- for Q Plus (LX500 and MX500), 0.020 inch (0.5 mm) of movement.

Remove the snap ring from the end of the slack adjuster and add shims between the slack adjuster and the snap ring if the axial end play exceeds:

- for all Cam-Master brakes except Q Plus (LX500 and MX500), 0.060 inch (1.5 mm) of movement;
- for Q Plus (LX500 and MX500), 0.005 to 0.030 inch (0.13 to 0.80 mm) of movement.

For more instructions, see **Subject 150**.

P Series Brake Shoe Removal and Installation

Removal

1. Park the vehicle on a level surface, apply the parking brakes, and chock the tires.
2. Raise the front or rear axle, then place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.

WARNING

When work is being done on a spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

3. If the brakes have spring chambers, carefully cage and lock the springs so that the springs cannot actuate during disassembly.

NOTICE

For a Meritor automatic slack adjuster, disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

NOTE: For a Haldex or a Gunite automatic slack adjuster, there is an internal clutch that resists the manual adjusting nut from being turned in the counterclockwise direction (de-adjust direction). When turning the manual adjusting nut in the counterclockwise direction to back off the slack adjuster, a torque of approximately 30 lbf·ft (41 N·m) will need to be applied to overcome the resistance of the internal clutch.

4. For each wheel end, back off the automatic slack adjuster by turning its manual adjusting nut until the brake shoes retract and the drum will clear the linings.
5. Remove the wheels and brake drums. For instructions, see **Group 33** or **Group 35** in this manual.
6. Remove the brake shoes.

   6.1 Remove the anchor pin snap rings and washers from the anchor pins. See **Fig. 1**.

WARNING

Wear eye protection when using a drift. Do not hit steel parts with a steel hammer. To do so could cause steel pieces to break off and cause serious eye injury.

   6.2 Remove the top anchor pin with a brass drift. See **Fig. 2**.

Installation

⚠ WARNING

Wear eye protection when using a drift. Do not hit steel parts with a steel hammer. To do so could cause steel pieces to break off and cause serious eye injury.

1. If necessary and with an appropriate brass drift, install new anchor pin bushings. Align the holes in the bushings with the holes in the brake spider.
2. Install the brake shoes.

   NOTE: When lubricating the cam rollers, do not get grease on the part of the roller that touches the cam head.

   2.1 With an NLGI grade 1 or 2 multi-purpose chassis or temperature resistant grease (Meritor O-616A, O-617-A, O-617B, O-645, or O-692), lubricate the cam rollers where they touch the brake shoes. Then, attach the cam rollers to the brake shoes.

   2.2 With an NLGI grade 1 or 2 multi-purpose chassis or temperature resistant grease (Meritor O-616A, O-617-A, O-617B, O-645, or O-692), lubricate the anchor pins where they touch the brake shoes.

   2.3 Put the lower brake shoe in position on the brake spider.

⚠ WARNING

Wear eye protection when using a drift. Do not hit steel parts with a steel hammer. To do so could cause steel pieces to break off and cause serious eye injury.

   2.4 Using a brass drift, install the lower brake shoe anchor pin. If necessary, align the flat or groove on the anchor pin with the holes in the brake spider and bushing. See **Fig. 4**.

   2.5 Install the washer and snap ring on the lower brake shoe anchor pin. See **Fig. 1**.

   2.6 Install a new brake shoe return spring on the brake shoes. Then, move the upper brake shoe in position over the brake spider. See **Fig. 3**.

   2.7 Using a brass drift, install the upper brake shoe anchor pin. If necessary, align the flat or groove on the anchor pin with the holes in the brake spider and bushing. See **Fig. 2**.

   2.8 Install the washer and snap ring on the lower brake shoe anchor pin. See **Fig. 1**.

3. Install the brake drums and wheels. For instructions, see **Group 33** or **Group 35** in this manual.
4. Adjust the brakes at the slack adjusters. For instructions, see **Subject 130**.
5. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

When work is being done on a spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

6. If the brake has spring chambers, carefully release the springs.

Brake Shoe Removal and Installation

DANGER

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

7. Before you put the vehicle in service, in a safe area, check for proper brake operation.
   - 7.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.
   - 7.2 Do several low speed stops to ensure proper parts replacement and full vehicle control.
   - 7.3 Make ten 40 to 20 mph (64 to 32 km/h) snubs to seat the linings.
   - 7.4 Make ten stops from 20 mph (32 km/h) at 50 percent air pressure.
   - 7.5 Make a full-pressure stop from 20 mph (32 km/h).
   - 7.6 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than others show lack of braking effort on those wheels.

Q Plus Brake Shoe Removal and Installation

Removal

1. Park the vehicle on a level surface, apply the parking brakes, and chock the tires.
2. Raise the front or rear axle, then place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.

WARNING

When work is being done on the spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

3. If the brake has spring chambers, carefully cage and lock the springs so that the springs cannot actuate during disassembly.

NOTICE

For a Meritor automatic slack adjuster, disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

NOTE: For a Haldex or a Gunite automatic slack adjuster, there is an internal clutch that resists the manual adjusting nut from being turned in the counterclockwise direction (de-adjust direction). When turning the manual adjusting nut in the counterclockwise direction to back off the slack adjuster, a torque of approximately 30 lbf·ft (41 N·m) will need to be applied to overcome the resistance of the internal clutch.

4. For each wheel end, back off the automatic slack adjuster by turning its manual adjusting nut until the brake shoes retract and the drum will clear the linings.
5. Remove the wheels and brake drums. For instructions, see **Group 33** or **Group 35** in this manual.
6. Remove the brake shoes.
   - 6.1 Push down on the bottom brake shoe, then pull on the roller retaining clip to remove the bottom cam roller. See **Fig. 6**.
   - 6.2 Lift the top brake shoe and pull on the roller retaining clip to remove the top cam roller.
   - 6.3 Lift the bottom shoe to release tension on the brake return spring. Remove the spring. See **Fig. 7** and **Fig. 8**.
   - 6.4 Rotate the bottom shoe to release tension on the two retaining springs. Remove the springs and brake shoes. See **Fig. 9**.
7. Inspect the brake shoes and linings for wear or damage. For instructions, see **Subject 120**.

⚠ WARNING

Before starting the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Inspection

1. Remove the brake shoes using the instructions in **Subject 110**.
2. Check the linings.

   2.1 If the linings are grease-or oil-soaked, cracked, or worn to less than 1/4-inch (6.4 mm) thickness at any point, replace them.

⚠ CAUTION

Do not let the brake linings wear to the point were the rivets or bolts touch the drums. Damage to the drums will occur if the linings are allowed to wear to this point.

2.2 Replace the linings if the lining surface is closer than 1/32 inch (0.8 mm) to any rivet head.

If bolts are installed, the linings should not be allowed to wear to the point where rivets or bolts may contact the brake drums.

2.3 The lining is considered worn-out and the vehicle should not be driven if:

- Cracks on the lining surface exceed 1/16 inch (1.6 mm);
- The lining edge shows cracks or voids over 1/16 inch (1.6 mm) in width and 1-1/2 inches (38 mm) in length. See **Fig. 1**;
- Portions of the lining are missing exposing a rivet when viewed from the edge. See **Fig. 2**;
- Cracks extend across the lining face and through the lining edge, or the lining is loose on the shoe. See **Fig. 3**.

- Surface cracks extend from hole to hole or if there is scoring and contamination from road debris. See **Fig. 6**.

3. Check the brake shoes for bent or cracked webs or tables, rust, broken welds, expanded or out-of-round rivet or bolt holes, and correct alignment. Replace the shoes if any of these conditions exist.
4. Check the brake shoes for visible wear (looseness) at the anchor pin holes and the camshaft roller recesses. Replace the shoe if needed.

Pre-Adjustment Checks and General Adjustment Information

Before adjusting the brakes, check and adjust the following:

- Adjust the wheel bearings. For instructions, see **Group 33** or **Group 35** in this manual.
- Check the slack adjuster and the brake chamber for loose fasteners and tighten as necessary. For torque specifications, see **Specifications 400**. For slack adjuster installation instructions, see the appropriate section in this group.

Brakes with automatic slack adjusters should never have to be manually adjusted while in service. The only time automatic slack adjusters should be manually adjusted is during installation or after the brakes have been relined.

For cam brakes, there are two brake chamber stroke measurement specifications, applied chamber stroke and free-stroke.

The procedure for adjusting the brake chamber stroke (at the slack adjuster's manual adjusting nut) may vary between each slack adjuster manufacturer. But, there are three basic procedures in completing a manual brake chamber stroke adjustment. They consist of:

A. Adjusting the approximate brake chamber stroke from the manual adjusting nut of the slack adjuster.

B. Measuring and readjusting the free-stroke.

C. Measuring and readjusting the applied chamber stroke.

The force used to move the slack adjuster from its released position to its applied position (where the brake linings contact the brake drum) distinguishes the free-stroke from the applied chamber stroke. The free-stroke is measured using a lever to move the slack adjuster (from the released to the applied positions). The applied chamber stroke is measured using an 80 to 90 psi (550 to 620 kPa) brake application to move the slack adjuster (from the released to applied positions). The stroke (free or applied chamber) is the distance that the large clevis pin moves when the brakes are applied.

With the engine off, 100 psi (689 kPa) of air tank pressure will apply the required (80 to 90 psi [550 to 620 kPa]) brake application for measuring the applied chamber stroke. The applied chamber stroke measurement can be used for diagnostic purposes. If the applied chamber stroke is too long or too short, this may indicate excessive wear in the cam, cam bushings, return springs, or air chamber. The applied chamber stroke should always be readjusted (minimized) to within the specified limit; but it should not be reduced to the point where the free stroke is too short and the brakes drag. To check for brake drag, spin the wheel end, tap the rim lightly with a hammer, and listen for a drag noise (a sharp ringing sound).

IMPORTANT: The U.S. Department of Transportation (DOT), Federal Highway Administration has issued the applied chamber stroke specifications for cam brakes. When the applied chamber stroke is checked and readjusted, it must not be greater than the DOT specification. See **Table 1**.

Adjustment

MERITOR AUTOMATIC SLACK ADJUSTER

1. See the pre-adjustment checks and general adjustment information in this subject before adjusting the brakes.
2. Park the vehicle on a level surface, apply the parking brakes, and chock the tires.
3. Raise the front or rear axle. Then, place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
4. Fully release the brakes (the air chamber push rod must be fully retracted).

5. Check the condition of the boot on the slack adjuster. It should be held in the proper position with a retaining clip. If the boot is torn or cracked, see **Section 42.17** for slack adjuster disassembly and inspection procedures.

⚠ CAUTION

Before turning the manual adjusting nut of the slack adjuster, disengage the pull-pawl by raising it up about 1/32 inch (0.8 mm). Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

6. With a screwdriver, pry the pull-pawl up at least 1/32 inch (0.8 mm). This will disengage the pull-pawl teeth from the actuator of the slack adjuster. See **Fig. 1**. Wedge the screwdriver in place. The pull-pawl will need to be disengaged until the brake adjustment is complete.

NOTE: When the screwdriver is removed, the pull-pawl will re-engage automatically.

7. Adjust the approximate brake chamber stroke from the manual adjusting nut on the slack adjuster (**Fig. 2**).

   7.1 Turn the adjusting nut counterclockwise until the brake linings touch the brake drum.

   7.2 Then, turn the adjusting nut one-half turn in the clockwise direction.

8. Measure and readjust the free-stroke.

   8.1 Measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 3**, Ref. A. Record this measurement as dimension A.

   8.2 Using a lever, move the slack adjuster until the brake linings contact the brake drum. Then, measure the distance from the bottom of the brake chamber to the

center of the large clevis pin. See **Fig. 3**, Ref. B. Record this measurement as dimension B.

8.3 Subtract dimension A from dimension B. The difference between these dimensions is the free-stroke.

The free-stroke should be within the range specified in **Table 1**.

8.4 If the free-stroke is not within the range specified in **Table 1**, turn the adjusting nut one-eighth turn, as shown in **Fig. 2**. Then, measure the free-stroke again, and readjust until it is correct.

9. Measure and readjust the applied chamber stroke.

9.1 Build air pressure to 100 psi (689 kPa). Shut down the engine.

9.2 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 3**, Ref. B. Record this measurement as dimension C.

9.3 Subtract dimension A (measured in the previous step [**Fig. 3**, Ref. A]) from dimension C. The difference between these dimensions is the applied chamber stroke.

9.4 The applied chamber stroke must be less than the measurements specified in **Table 1**.

⚠ CAUTION

The readjusted applied chamber stroke should be as short as possible (allowable), but not so short that the free-stroke is too short and the linings drag. If the linings drag, the brakes could be damaged.

9.5 If the applied chamber stroke is incorrect, turn the adjusting nut one-eight turn, as shown in **Fig. 2**. Measure the applied chamber stroke again, and readjust until correct.

9.6 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes (see **Subject 150**). If necessary, replace the slack adjuster. For instructions, see **Section 42.17** in this group.

10. Remove the screwdriver from the pull-pawl assembly. This will engage the pull-pawl to the actuator.

11. Lower the vehicle, remove the safety stands, and remove the chocks from the tires.

Brake Adjustment

⚠ DANGER

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

12. Check for proper brake operation. For instructions, see **Subject 110**.

HALDEX AUTOMATIC SLACK ADJUSTER

1. See the pre-adjustment checks and general adjustment information in this subject before adjusting the brakes.
2. Park the vehicle on a level surface, apply the parking brakes, and chock the tires.
3. Raise the front or rear axle. Then, place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
4. Fully release the brakes (the air chamber push rod must be fully retracted).

⚠ CAUTION

If the slack adjuster is equipped with an installation indicator, the indicator must be in the slotted area as shown in Fig. 4. If the installation indicator is not within the slotted area, the control arm is installed in the wrong position. This may result in tight brakes and excessive lining wear and possible brake damage.

5. If the slack adjuster is equipped with an installation indicator, check that the installation indicator is within the slotted area. See **Fig. 4**. If the installation indicator is not within the slotted area, the control arm is not properly installed. For slack adjuster installation instructions, see **Section 42.16** in this group.
6. Check the de-adjustment torque (the internal clutch slippage) of the slack adjuster.
   - 6.1 Place a torque wrench on the 7/16-inch adjusting hexnut. See **Fig. 5**.
   - 6.2 While turning the torque wrench in a counterclockwise direction, measure how much torque is required to overcome the resistance of the internal clutch. A normal ratcheting sound will occur while the adjusting hexnut is backed off in the counterclockwise direction. The minimum allowable de-adjustment torque is 13 lbf·ft (17.6 N·m).

   If the clutch slips with a torque less than 13 lbf·ft (17.6 N·m), the slack adjuster must be replaced. For instructions see **Section 42.16** in this manual.

   - 8.3 Subtract dimension A from dimension B. The difference between these dimensions is the free-stroke. The free-stroke should be within the range specified in **Table 1**.
   - 8.4 If the free-stroke is not within the range specified in **Table 1**, turn the adjusting nut in the direction required. Then, measure the free-stroke again, and readjust until it is correct.
9. Measure and readjust the applied chamber stroke.
   - 9.1 Build air pressure to 100 psi (689 kPa). Shut down the engine.
   - 9.2 Fully apply the brakes. Then, measure the distance from the face of the brake chamber to the far side of the clevis pin hole. See **Fig. 6**, Ref. B. Record this measurement as dimension C.
   - 9.3 Subtract dimension A (measured in the previous step [**Fig. 6**, Ref. A]) from dimension C. The difference between these dimensions is the applied chamber stroke. The applied chamber stroke must be less than the measurements shown in **Table 1**.
   - 9.4 If the applied chamber stroke is not correct, turn the adjusting nut in the direction required. Then, measure the applied chamber stroke again, and readjust until it is correct.
   - 9.5 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes (see **Subject 150**). If necessary, replace the slack adjuster. For instructions, see **Section 42.16** in this group.
10. Lower the vehicle, remove the safety stands, and remove the chocks from the tires.

⚠ DANGER

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

11. Check for proper brake operation. For instructions, see **Subject 110**.

GUNITE AUTOMATIC SLACK ADJUSTER

   5.2 While turning the torque wrench in a counterclockwise direction, measure how much torque is required to overcome the resistance of the internal clutch. A normal ratcheting sound will occur while the adjusting hexnut is backed off in the counterclockwise direction. The de-adjustment torque must not be less than 15 lbf·ft (20 N·m).

   If the clutch slips with a torque less than 15 lbf·ft (20 N·m), the slack adjuster must be replaced. For instructions see **Section 42.15** in this manual.
6. Adjust the approximate brake chamber stroke from the manual adjusting nut on the slack adjuster.

   6.1 Turn the adjusting hexnut clockwise until the brake linings contact the brake drum.

   6.2 Turn the adjusting hexnut counterclockwise one-half turn. There should be about 30 lbf·ft (41 N·m) resistance, and a ratcheting sound will occur.
7. Measure and readjust the free-stroke.

8.4 If the applied chamber stroke is not correct, turn the adjusting nut in the direction required. Then, measure the free-stroke again, and readjust until it is correct.

8.5 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes (see **Subject 150**). If necessary, replace the slack adjuster. For instructions, see **Section 42.15** in this group.

9. Lower the vehicle, remove the safety stands, and remove the chocks from the tires.

⚠ DANGER

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

10. Check for proper brake operation. For instructions, see **Subject 110**.

⚠ WARNING

Before starting the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Replacement

IMPORTANT: Vehicle brake systems require the correct lining material to perform as originally designed. The type of lining material that is specified for the vehicle is based on several technical considerations and DOT braking performance regulations. To ensure fewer relines and greater compatibility with the vehicles brake system, insist on the same quality OEM friction lining material.

Always reline both wheels of a single axle and all wheels of a tandem axle at the same time. Always install the same linings and drums on both wheels of a single axle and all four wheels of a tandem axle. It is not necessary that both axles (front and rear) have the same linings and drum.

Combination linings with different friction ratings for the primary and secondary shoes are sometimes used. When combination friction lining sets are used, the lining blocks must be installed in the correct locations on the brake shoes.

NOTE: Always follow the instructions supplied with the replacement combination lining sets for correct installation. The primary linings must be installed on the primary shoe. The first shoe past the cam in the direction of the wheel rotation is the primary shoe. The primary shoe can be either at the top or the bottom position, depending on the location of the cam. If the cam is behind the axle, then the top shoe is the primary shoe. If the cam is in front of the axle, then the bottom shoe is the primary shoe. See **Fig. 1** and **Fig. 2**.

IMPORTANT: When replacing the brake linings, use a dial indicator to measure the cam-to-bushing radial free play (the up-and-down and side-to-side free play of the camshaft) and the camshaft axial end play (the in-and-out end play of the camshaft).

Replace the bushings if the cam-to-bushing radial free play exceeds:

- for all Cam-Master brakes except "Q" Plus (LX500 and MX500), 0.030 inch (0.8 mm) of movement;
- for "Q" Plus (LX500 and MX500), 0.020 inch (0.5 mm) of movement.

Brake Shoe Lining Replacement

Remove the snap ring from the end of the slack adjuster and add shims between the slack adjuster and the snap ring if the axial end play exceeds:

- for all Cam-Master brakes except "Q" Plus (LX500 and MX500), 0.060 inch (1.5 mm) of movement;
- for "Q" Plus (LX500 and MX500), 0.005 to 0.030 inch (0.13 to 0.80 mm) of movement.

For more instructions, see **Subject 150**.

2. Disassemble the lining blocks from the brake shoes.

   2.1 If the lining blocks are bolted, proceed to the next substep. Otherwise, if the lining blocks are riveted, using a suitable riveting mandrel, push out the old rivets.

CAUTION

Drilling out rivets or cutting off rivet heads with a chisel can cause the rivet hole to become out-of-round. This could damage the brake shoe.

   2.2 If the lining blocks are bolted, remove the bolts, lockwashers, and nuts.

   2.3 Separate the lining blocks from the brake shoes.

3. Check the brake shoes for rust, expanded rivet or bolt holes, broken welds and correct alignment. Replace the shoe if any of these conditions exist.

4. If necessary, clean the brake shoe with solvent and wire brush the shoe table. Then, paint the brake shoe with rust inhibitive paint.

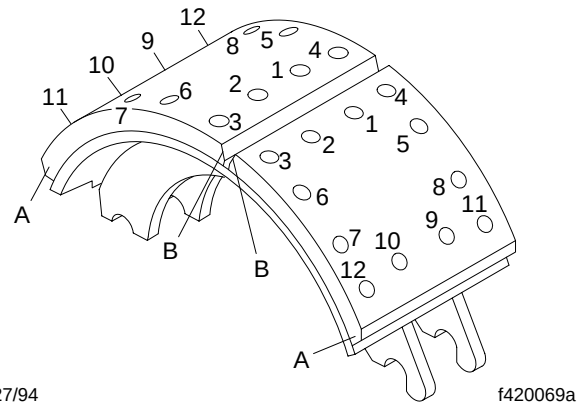
5. Assemble the lining blocks to the brake shoes.

   IMPORTANT: Use rivets that have the correct material, shank diameter, length, head size, and shape. Use tubular rivets that are 1/4-inch diameter by 9/16-inch long, SAE no. 10, made of plated steel or brass.

   5.1 If the lining blocks are bolted, proceed to the next substep. Otherwise, if the lining blocks are riveted, align the brake shoe rivet holes with the corresponding lining block holes. Using a C-clamp, clamp the lining block to the brake shoe.

   Insert the correct size rivets into all the holes and threads. Then, temporarily hold the rivets in place with masking tape.

   Fasten the rivets (from the lining block to the brake shoe) in the sequence shown in **Fig. 3**.



A. Toe
B. Heel

Fig. 3, Fastening Sequence

   5.2 If the lining blocks are bolted, align the brake shoe bolt holes with the corresponding lining block holes. Using a C-clamp, clamp the lining block to the brake shoe.

   Insert the correct size bolts, and new lockwashers into all the holes and threads. Loosely install the nuts.

   Tighten the nuts (in the sequence shown in **Fig. 3**):

   - 18 to 23 lbf·ft (24 to 31 N·m) for 3/8-inch brass bolts;
   - 80 to 100 lbf·in (900 to 1120 N·cm) for 1/4-inch brass bolts.

6. Check the lining installation by trying to insert a 0.010 inch (0.25 mm) feeler gauge between the linings and the shoe table along the edges. See **Fig. 4**, Ref. A. It should not be possible to insert the feeler gauge anywhere along the edge, except beyond the last row of rivets at each end. See **Fig. 5**, Ref. A. A larger clearance (up to 0.025 inch [0.64 mm]) may exist at the ends.

7. Circle grind the brake lining to obtain the correct lining-to-drum contact. With the cam in the full-

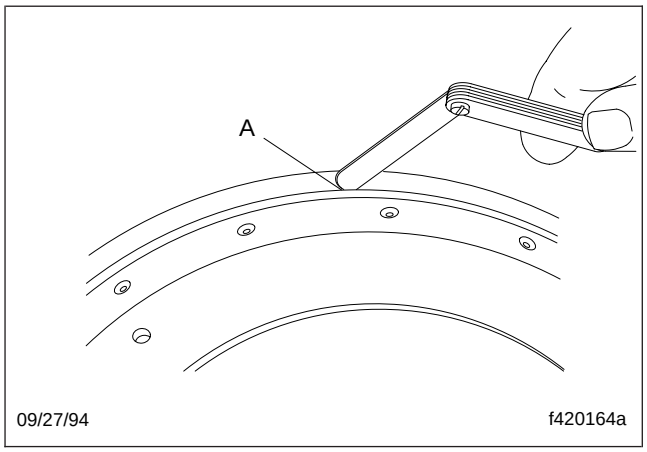


Fig. 4, Check Clearance Along Edge

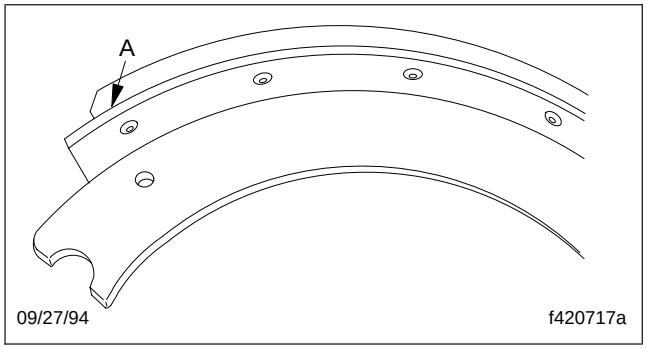

Fig. 5, Check Clearance at Ends

release position, the new brake linings must be ground 0.070 inch (1.8 mm) less than the drum diameter. The cam must be adjusted and the lining ground until there is an 80 percent lining-to-drum contact, which must be continuous and in the center of the lining.

8. Install the brake shoes, see **Subject 110** for instructions.

⚠ WARNING

Before starting the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Remove the brake shoes, see **Subject 110** for instructions.

NOTE: Meritor recommends that the brake drum not be turned or rebored (resurfaced). Turning or reboring drums can decrease the strength and heat capacity of the drum.

2. Inspect the brake drum (**Fig. 5**).
   - 2.1 Check the drum for cracks, severe heat-checking, heat spotting, scoring, pitting, distortion, and out-of-round.
   - 2.2 With, a drum caliper or other measuring device, measure the inside diameter of the drum in several locations. Replace the drum if it exceeds the maximum diameter stamped on it. Replace cracked drums. Some drums that are glazed, grooved, or

out-of-round can be repaired. For detailed instructions, see **Group 33** or **Group 35** in this manual.

3. Remove the push rod clevis pin and disconnect the slack adjuster from the push rod clevis. See **Fig. 6**.
4. Check the camshaft radial free play (**Fig. 7**).
   - 4.1 Using a dial indicator, measure the up-and-down and side-to-side free play of the camshaft.
   - 4.2 For all Cam-Master brakes except the "Q" Plus (LX500 and MX500) brakes, replace the camshaft bushings if there is more than 0.030 inch (0.8 mm) of free play. For "Q" Plus (LX500 and MX500) brakes, replace the camshaft bushings if there is more than 0.020 inch (0.5 mm) of free play.

chipped teeth and deformation. Replace as needed.

⚠ CAUTION

For a Meritor automatic slack adjuster, before turning the manual adjusting nut, disengage the pull-pawl by raising it up about 1/32 inch (0.8 mm). Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

NOTE: For a Haldex or a Gunite automatic slack adjuster, there is an internal clutch that resists the manual adjusting nut from being turned in the counterclockwise direction (de-adjust direction). When checking these slack adjusters for binding, only rotate the manual adjusting nut in the clockwise direction.

6.2 Using a wrench, turn the manual adjusting nut so that the worm gear rotates a full 360 degrees. If there is binding, or if excessive force is need to turn the slack adjuster, replace it. For instructions, see the appropriate slack adjuster section in this group.

IMPORTANT: If any slack adjuster problem is found, repair or replace the unit, depending on the manufacturer's recommendations.

7. Remove the camshaft by grasping its head and pulling the camshaft outboard from the brake spider and camshaft-and-chamber bracket. See **Fig. 8**. Then, remove the thrust washer from the camshaft.
8. Check the camshaft spline end for cracks, corrosion, or worn or deformed splines. Replace the camshaft if damaged.
9. Check the camshaft bearing journals for wear or corrosion. Replace the camshaft if it is worn or if roughness is felt in the journal area.
10. Inspect the camshaft head for brinelling, cracking, or flat spots. Replace the camshaft if a ridge can be felt between the worn area and the cam head surface.
11. From the brake spider and slack adjuster ends of the camshaft-and-chamber bracket, remove and inspect the camshaft grease seals. If a grease seal lip is nicked, cut or distorted, replace it.

⚠ WARNING

When removing bushings with a driver, wear eye protection. Do not hit steel parts with a steel hammer. To do so could cause steel pieces to break off, which could cause serious eye injury.

12. Using the correct size driver, remove the camshaft bushings from the camshaft-and-chamber bracket.
13. Check the camshaft bushings for wear. The inner surface must be smooth; if rough or abrasive, replace the bushings.
14. Remove the brake chamber stud nuts and lockwashers that attach the brake chamber to the camshaft-and-chamber bracket.

    Check the chamber for a cracked housing, bent push rod, loose clamp ring, loose air fitting, air leaks, or clogged vent holes. Repair or replace brake chamber parts as needed.
15. Remove and inspect the camshaft-and-chamber bracket. Remove and discard its gasket.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

Check the bracket for a bent, broken or cracked arm, and cracked welds. Replace the bracket if any of these conditions exist.

16. Remove the brake spider-to-axle attaching nuts, hardened washers, and bolts. Remove the brake spider from the axle flange.
17. If equipped, remove the four capscrews that attach the dust shield to the brake spider; remove the dust shield.

NOTE: For "P" Series brakes, the anchor pins have already been removed (in the brake removal).

18. Inspect the brake spider and parts for damage; replace as needed.
    - 18.1 Check the bolt holes, cam area, and anchor pin area for cracks and check for expanded anchor pin holes. Replace if damaged.
    - 18.2 Check the anchor pins. If worn or loose, replace them.
    - 18.3 Check the anchor pin bushings for wear. The inner surfaces must be smooth. If any surface is rough or abrasive, replace the part.

Cleaning

⚠ WARNING

Before starting the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

⚠ CAUTION

Do not clean ground or polished metal parts in a hot solution tank or with water, steam, or alkaline solutions. These solutions will cause parts to corrode.

For corrosion protection, do not apply brake grease or corrosion-preventive materials to the brake linings or the brake drum.

After removing the brake parts being serviced, do the following:

1. Clean the camshaft journals with an emery cloth.
2. Wire brush all parts exposed to mud, road dirt, and salt, including the exterior of the drum, brake spider, camshaft-and-chamber bracket, and dust shields (if equipped). If relining the shoes, thoroughly wire-brush the shoe tables, and paint them with a rust inhibitive coating.

⚠ CAUTION

A thick layer of oxidation and dirt on the outside of a brake drum acts as an insulator and may hinder normal heat dissipation. Make sure oxidation and dirt are removed by wire brushing, or damage to brake components could occur.

3. Using an industrial vacuum cleaner with a HEPA filter system, remove excessive dust accumulation from the brake parts.
4. Wipe the interior of the drums with a damp rag to remove lining dust.
5. Prepare the brake parts for assembly.
    - 5.1 Thoroughly, clean all the brake parts.

      For ground or polished metal parts, use a cleaning solvent to clean the parts and surfaces that are ground or polished.

      For rough metal parts, use a cleaning solvent, or a weak alkaline solution in a hot solution tank, to clean the parts. If a hot solution tank is used, leave the rough parts in the hot solution tank until they are completely cleaned and heated. Remove the rough parts from the hot solution tank and wash them with water until the alkaline solution is removed.
    - 5.2 Thoroughly dry all the brake parts with either compressed air or a clean soft cloth (or paper) rag.

⚠ WARNING

All worn or damaged brake parts must be replaced. If the brakes are assembled with worn or damaged brake parts, the brakes may not perform to their capacity and a brake failure may oc-

cur, which could cause personal injury and property damage.

5.3 Thoroughly inspect all the brake parts for wear or damage. It is very important that all the parts be carefully inspected before they are assembled. Repair or replace and worn or damaged parts.

5.4 To protect the parts from corrosion, apply a thin layer of brake grease to the parts which have been cleaned, dried, inspected, and will be assembled.

If the parts will be stored, apply a special material that prevents corrosion and rust on all surfaces. The parts should be stored in special paper (or other material) that prevents corrosion and rust.

Assembly (See Fig. 1, Fig. 2, Fig. 3, or Fig. 4)

⚠ WARNING

Before starting the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Install the dust shield, if equipped.

   Position the dust shield against the brake spider, and install the capscrews. Tighten the capscrews:

   - 5/16–18 Grade 5; 15 to 20 lbf·ft (20 to 27 N·m)
   - 3/8–16 Grade 5; 25 to 35 lbf·ft (34 to 47 N·m)
   - 3/8–16 Grade 8; 35 to 50 lbf·ft (47 to 68 N·m)

2. Install the brake spider.

   Place the brake spider on the axle flange. Using a hardened washer under the bolt head and the nut, install the mounting fasteners. Tighten the bolts (Fig. 9) in a cross pattern:

   - 7/16–20; 60 to 75 lbf·ft (81 to 102 N·m)
   - 1/2–20; 85 to 115 lbf·ft (115 to 156 N·m)
   - 9/16–18; 135 to 165 lbf·ft (176 to 224 N·m)
   - 5/8–18; 180 to 230 lbf·ft (244 to 312 N·m)

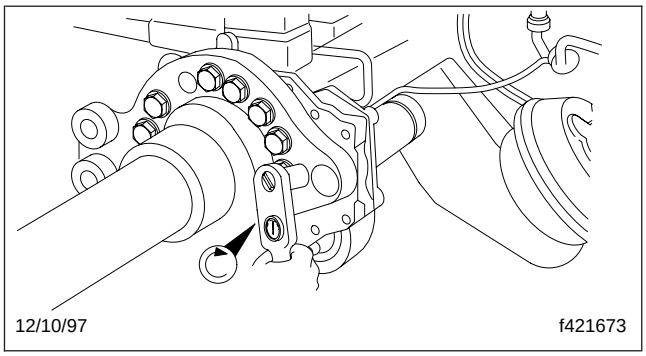

Fig. 9, Tighten the Brake Spider Bolts

3. Install the camshaft-and-chamber bracket and the brake chamber.

   3.1 Place the camshaft-and-chamber bracket and gasket against the brake spider, and install the lockwashers and capscrews. Tighten the capscrews:

   - Without hexnuts, 1/2–13 Grade 5; 65 to 85 lbf·ft (88 to 116 N·m)
   - Without hexnuts, 1/2–13 Grade 8; 70 to 100 lbf·ft (95 to 136 N·m)
   - With locknuts, 5/8–18; 130 to 165 lbf·ft (176 to 224 N·m)
   - With plain hexnuts, 5/8–18; 150 to 190 lbf·ft (203 to 258 N·m)

   3.2 Place the brake chamber on the mounting flange (camshaft-and-chamber bracket) with the chamber mounting studs through the flange holes. Install the hardened flatwashers, lockwashers, and stud nuts. Tighten the brake chamber fasteners to the torque values listed in **Specifications 400**.

   NOTE: If replacing a brake chamber, make sure that the new chamber is the same size and make as the brake chamber on the other side of the axle.

IMPORTANT: The grease seals are installed in both the brake spider and slack adjuster ends of the camshaft-and-chamber bracket, the grease seals must be installed with their lips toward the

Brake Components Disassembly and Inspection, Cleaning, and Assembly

slack adjuster end of the camshaft-and-chamber bracket tube.

NOTE: To avoid shorter lining life, Meritor recommends replacing the springs, rollers, anchor pins, and camshaft bushings when the linings are replaced. For brakes with the "Q" Plus LX500 and MX500 identification tags, if replacing the linings before the recommended service interval (3 years or 500,000 miles [800 000 km]), the camshaft bushings and the seals do not have to be replaced.

4. Using a seal driver, install the camshaft seals and the new camshaft bushings into the brake spider and slack adjuster ends of the camshaft-and-chamber bracket (**Fig. 10**). Install the seals with their lips toward the slack adjuster (**Fig. 11**).

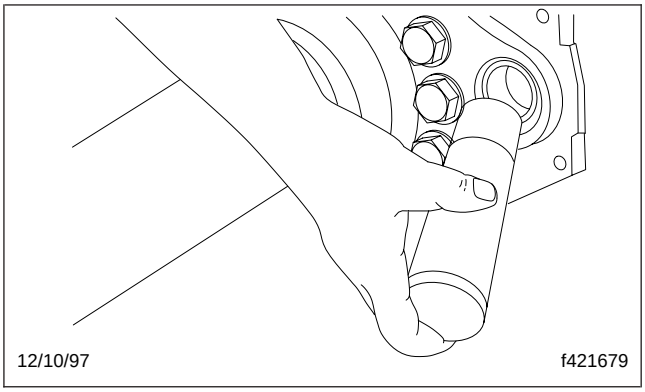

Fig. 10, Install the Seals and Bushings

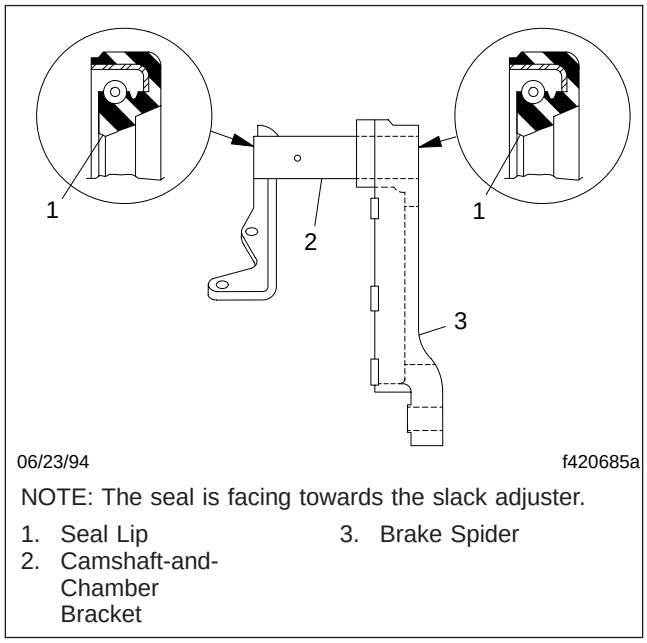
5. Install the camshaft (**Fig. 12**).
   - 5.1 Put the camhead thrust washer on the camshaft with the bent flaps toward the brake spider.
   - 5.2 Apply a thin film of grease on the inside of the camshaft bushings and journals. For the recommended grease specification, see **Specifications 400**. Don't grease the camshaft head area.
   - 5.3 Apply a thin film of rust preventive grease on the camshaft splines. For the recommended grease specification, see **Specifications 400**.
   - 5.4 Carefully slip the camshaft into the brake spider and the camshaft-and-chamber bracket tube. The camshaft should turn freely by hand.



NOTE: The seal is facing towards the slack adjuster.

1. Seal Lip
2. Camshaft-and-Chamber Bracket
3. Brake Spider

Fig. 11, Positioning the Seals

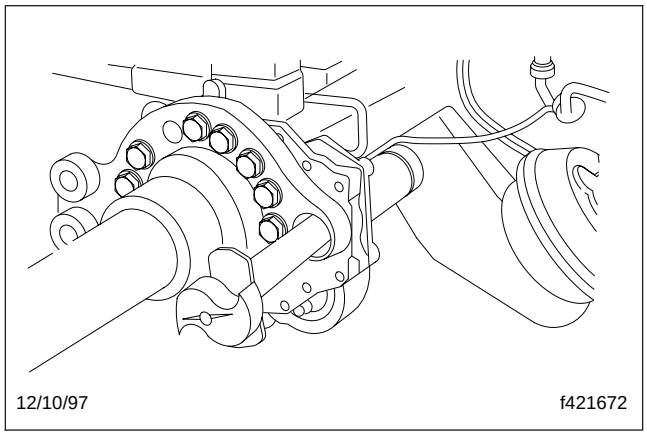


Fig. 12, Install the Camshaft

6. Install the slack adjuster.
   - 6.1 Slide the spacing washer on the camshaft. Install the slack adjuster seal with the lip facing the brake spider ("Q" Plus LX500 and MX500 only).
   - 6.2 Slide the slack adjuster on the camshaft, with the adjuster nut on the side opposite of the brake chamber.

6.3 Install the orange slack adjuster seal with the lip facing the snap ring ("Q" Plus LX500 and MX500 only), the outer washers, and snap ring.

6.4 Use a dial indicator to measure the in-and-out (axial) end-play of the camshaft. For all Cam-Master brakes, except the "Q" Plus brakes with a LX500 and MX500 identification tag, there should be no more than 0.060 inch (1.5 mm) movement. For the "Q" Plus brakes with a LX500 and MX500 identification tag, the axial end play should be within 0.005 to 0.030 inch (0.13 to 0.80 mm). See **Fig. 7**. If necessary, add the appropriate number of spacing shims to achieve the correct axial end play.

6.5 Apply anti-seize compound to the two clevis pins.

⚠ CAUTION

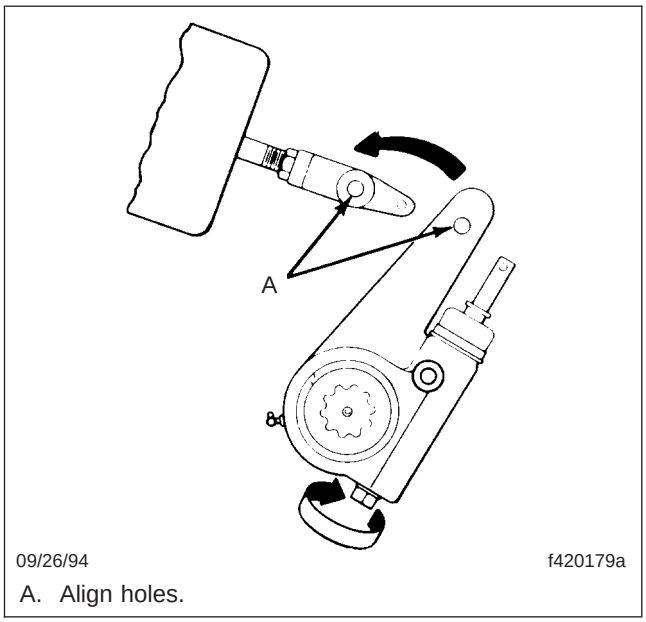
For Meritor automatic slack adjusters, before turning the manual adjusting nut, disengage the pull-pawl by raising it up about 1/32 inch (0.8 mm). Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

6.6 Using a wrench, turn the manual adjusting nut to align the large hole in the slack adjuster housing with the large hole in the clevis (**Fig. 13**). Then, insert both the clevis pins and cotter pins.

7. For the "Q" Plus brakes with the LX500 and MX500 identification tag, proceed to the next step. Otherwise, pressure lube the camshaft-and-chamber bracket bushings.

7.1 Pump multipurpose chassis grease (NLGI grade 1 or 2) into the camshaft-and-chamber bracket until it appears at the slack adjuster end of the bracket. For recommended grease specification, see **Specifications 400**.

NOTE: The use of meter-type fittings, having a maximum 40 psi (276 kPa) pressure relief at shutoff, is recommended.



A. Align holes.

Fig. 13, Attach the Slack Adjuster to the Clevis

7.2 Use care that no grease enters the drum cavity. If grease leaks out under the cam head, the camshaft grease seal is worn or damaged, or is installed backwards.

For the "Q" Plus LX500 and MX500 brakes, if the brake linings are being replaced before the service interval (every 3 years or 500,000 miles [800 000 km], whichever comes first), then the camshaft-and-chamber bracket and the slack adjuster do not need lubrication.

8. For all Cam-Master brakes, except the "Q" Plus LX500 and MX500, proceed to the next step. Otherwise, when changing the brake linings for the Q" Plus LX500 and MX500 brakes at the service interval (which is performed every 3 years or 500,000 miles [800 000 km], whichever comes first). Lubricate the camshaft-and-chamber bracket and the automatic slack adjuster.

8.1 Remove the identification tag from the camshaft-and-chamber bracket housing.

8.2 Remove the grease plugs from both the camshaft-and-chamber bracket and the automatic slack adjuster.

8.3 Install grease fittings.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

⚠ WARNING

When lubricating the camshaft-and-chamber bracket, if grease leaks out under the cam head, the camshaft grease seal is worn or damaged. See disassembly and inspection for grease seal replacement instructions. If the seal is not replaced, the brake linings could be contaminated by grease and the vehicles stopping distance could be reduced, which could result in personal injury or property damage.

8.4 Using Meritor approved NLGI grade 2 synthetic polyurea grease (EVO-LUBE TEK-615), lubricate the brake assembly through the grease fitting in the bracket (**Fig. 14**, Ref. 3) until new grease flows from the inboard seal.

Troubleshooting Tables

Problem—No Adjustment or Adjusted Stroke is Too Long

Problem—No Adjustment or Adjusted Stroke is Too Long	
Possible Cause	**Remedy**
The wrong slack adjuster is installed.	Replace the slack adjuster with the correct one.
The clevis is not installed correctly.	Check the slack adjuster installation. For instructions, see the appropriate slack adjuster section in this group.
There is excessive wear between the clevis and collar.	Check the gap between the clevis and the collar. The maximum allowable gap is 0.060 inch (1.5 mm). Replace the threaded clevis as necessary.
The jam nut at the clevis is loose.	Tighten the jam nut to specifications.
The large clevis pin bushing in the slack adjuster arm is worn.	Measure the inside diameter of the large clevis pin bushing. The inside diameter must not be larger than 0.53 inch (13.46 mm). Replace the bushing as necessary.
The return spring in the air chamber is weak or broken.	Check the air spring force. At the first movement of the push rod, the spring force must be at least 32 lbf (142.3 N). Replace the return spring or air chamber as necessary.
The spring brake is not fully retracting.	Repair or replace the spring brake.
The pull-pawl or the actuator is worn (the teeth are stripped).	Replace the pull-pawl or the actuator in the slack adjuster.
The slack adjuster has internal damage.	Inspect the slack adjuster. Repair or replace the slack adjuster as necessary. For instructions, see the appropriate slack adjuster section in this group.
There is excessive play between the slack adjuster gear and the splines of the camshaft.	Replace the camshaft and/or the slack adjuster as necessary.
Foundation brake components are worn.	Replace the components.

General Description

The Meritor automatic slack adjuster has two main functions:

- As a lever, it converts the straight-line force of the brake chamber push rod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the brake drum.
- As an automatic adjuster, it automatically maintains brake chamber push rod stroke, which controls lining-to-drum clearance during operation.

With an automatic slack adjuster, brakes adjust automatically when needed. As long as the push-rod stroke doesn't exceed the desired length, no adjustment takes place. Adjustment is made on the return stroke, as air is released and the forces in the gearset are low. The force to make an adjustment comes directly from the brake shoe return spring and the brake chamber return spring.

Principles of Operation (See Fig. 1)

The externally splined end of the worm (Ref. 21) fits the internal splines on the actuator (Ref. 16). Angled serrations on the spring-held pawl (Ref. 20) correspond with serrations on the actuator exterior. The serrations are formed to allow free upward movement of the actuator, and to lock in on the actuator serrations on a downward movement. As the brake is applied, the brake chamber push rod, connected to the end of the clevis, moves outward, forcing the slack adjuster arm to turn on the brake camshaft centerline. The actuator rod (Ref. 10) is connected to the clevis at one end, and to a small piston at the other end.

As the slack adjuster arm moves, the actuator rod is moved upward and outward, pulling the piston (Ref. 14) upward.

When lining wear becomes excessive, the brake chamber push-rod stroke goes beyond the desired length. The piston then makes contact with the retaining ring (Ref. 12) and pulls up the actuator. As the actuator moves upward and reaches a preset distance, it slides over one serration on the pawl. When the push rod moves back toward the brake chamber, the actuator is forced downward. Because the serrations in the pawl and actuator are now locked in, the actuator, following the curve of its serrations as it moves downward, turns slightly. This action causes the worm to turn, advancing the gear (Ref. 26) and the camshaft to automatically adjust the brake.

Slack Adjuster Removal and Installation

Removal

1. With the vehicle parked on a level surface, set the parking brakes, and shut down the engine. Chock the tires.

⚠ WARNING

Manually cage each parking brake chamber power spring in the release (no application) position before continuing. Loss of brake chamber air pressure will cause sudden application of the parking brakes, which could result in personal injury.

2. If the rear slack adjusters will be removed, release the parking brakes, then cage the power spring of the parking brake chamber.
3. Remove the retainer clips from the large and small clevis pins. Remove the clevis pins. See **Fig. 1**.

⚠ CAUTION

Disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

4. Using a screwdriver or an equivalent tool, pry the pawl button out about 1/32 inch (0.8 mm). See **Fig. 2**.

   Wedge the tool in place. Pull-pawls are spring-loaded; when the tool is removed, the pull-pawl will engage the teeth automatically.
5. Using a wrench, manually turn the square adjusting nut clockwise to move the slack adjuster away from the clevis. See **Fig. 3**.
6. Remove the snap ring, washer(s), and seal (if equipped) that secure the slack adjuster in place on the brake camshaft; save them for later installation.
7. Remove the slack adjuster from the camshaft.
8. Note the location and number of any remaining spacing washers on the camshaft. Remove the spacers and seal (LX500 and MX500 series only), and save them for later installation.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

1. Inspect the parts and prepare the slack adjuster for installation.
2. Check the brake camshaft splines for wear or corrosion.

IMPORTANT: The following lubricants provide corrosion protection. Do not mix them with other types of lubricants.

3. Coat the camshaft splines and the splines of the slack adjuster gear with Meritor 0-637, Meritor 0-695 (LX500 and MX500 only), Southwest SA 8249496, or an equivalent.
4. Apply the service brake several times. Make sure the return spring retracts the pushrod quickly and completely. Replace the return spring or brake chamber, if needed.
5. Slide the spacing washer(s) on the camshaft.

   On LX500 and MX500, install the slack adjuster seal with the lip facing the brake spider.
6. If reinstalling the same slack adjuster:
   - 6.1 Slide the slack adjuster on the camshaft, with the actuator rod on the side opposite the brake chamber.
   - 6.2 On LX500 and MX500, install the orange slack adjuster seal on the camshaft. The lip on the seal must face the snap ring.
   - 6.3 Install the outer washer(s) and snap ring on the camshaft.

⚠ CAUTION

Disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could

6.4 Using a screwdriver or an equivalent tool, pry the pawl button out at least 1/32 inch (0.8 mm). See **Fig. 2**. Wedge the tool in place.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting nut for positioning.

Make sure the old and new slack adjusters are the same length.

7.2 Slide the slack adjuster on the camshaft, with the actuator rod on the side opposite the brake chamber.

7.4 Install the outer washer(s) and snap ring on the camshaft.

7.5 Using a dial indicator, measure the in-and-out (axial) end play of the camshaft. If necessary, add the appropriate number of spacing washers to achieve the correct axial end play.

- For all Cam-Master brakes, except LX500 and MX500 series, there should be no more than 0.060 inch (1.52 mm) movement.
- For LX500 and MX500, the axial end play should be no more than 0.020 inch (0.51 mm).

⚠ CAUTION

Disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

7.6 Using a screwdriver or an equivalent tool, pry the pawl button out about 1/32 inch (0.8 mm). See **Fig. 2**. Wedge the tool in place.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting nut for positioning.

7.7 Using a wrench, turn the manual adjusting nut counterclockwise to align the hole in the slack adjuster housing with the large hole in the clevis. See **Fig. 4**.

Place the template over the clevis and camshaft end.

7.9 Temporarily insert the large clevis pin through the large holes in the template and the clevis.

7.10 Select the hole in the lower part of the template that matches the length of the slack adjuster. Hold the template in place on the center of the camshaft with a pencil.

7.11 Make sure the small hole in the clevis is completely visible through the 1/8-inch hole at the top of the template.

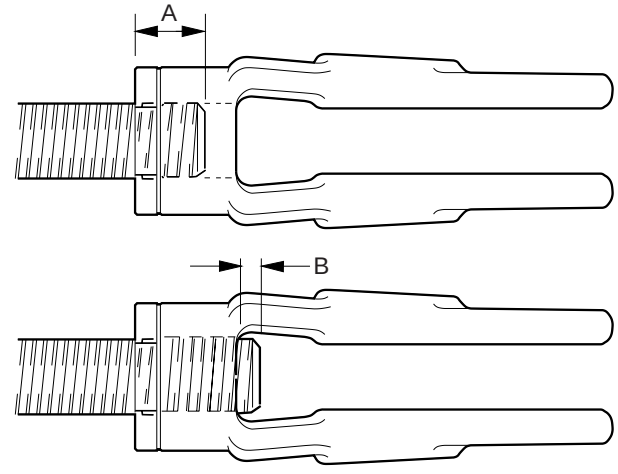
If it is not, loosen the clevis jam nut, and turn the clevis adjusting nut to adjust the position of the clevis on the pushrod until the small clevis hole is completely visible.

IMPORTANT: The pushrod must be installed in the clevis at least 1/2 inch (13 mm) and not extend beyond it more than 1/8-inch (3-mm).

7.12 Make sure there is at least 1/2 inch (13 mm) of thread engagement between the clevis and the pushrod. Also, check that the pushrod does not extend through the clevis more than 1/8-inch (3-mm). See **Fig. 7**.

If necessary, cut the pushrod, install a new pushrod, or install a new brake chamber.

7.13 Temporarily insert the small clevis pin through the template, clevis, and actuator rod to make sure the alignment is correct. Repeat the adjustment, if necessary. When the alignment is correct, remove both clevis pins and the template.



A. Minimum 1/2 inch (13 mm).
B. Maximum 1/8 inch (3 mm).

Fig. 7, Check Pushrod Engagement

8. Apply antiseize compound to the two clevis pins.
9. Insert both clevis pins with their pinheads on the inboard side of the slack adjuster. Be sure the small clevis pin is inserted through the hole in the actuator rod. Install new retaining clips to secure the clevis pins.
10. If it was loosened, tighten the clevis jam nut to the following values.
    - For 1/2–20 threads, tighten the clevis jam nut 20 to 30 lbf·ft (27 to 41 N·m).
    - For 5/8–18 threads, tighten the jam nut 25 to 50 lbf·ft (34 to 68 N·m).
11. Lube the slack adjuster through the grease fitting until the lubricant is forced out through the pawl slot or through the gear splines around the inboard snap ring.
12. Adjust the brakes. See "Brake Adjustment" below.

Brake Adjustment

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

1. If a rear axle slack adjuster was installed, manually uncage the parking brake.
2. Fully release the brakes (the air chamber pushrod must be fully retracted).

CAUTION

Before turning the manual adjusting nut on the slack adjuster, disengage the pull-pawl. Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

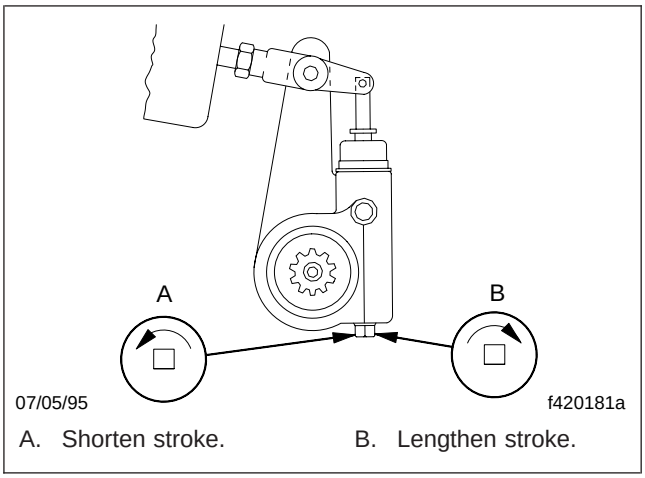
3. Using a screwdriver, pry the pull-pawl button out at least 1/32 inch (0.8 mm) to disengage the pull-pawl teeth from the slack adjuster actuator. See **Fig. 2**. Wedge the screwdriver in place. The pull-pawl will need to be disengaged until the brake adjustment is complete.

Slack Adjuster Removal and Installation

NOTE: When the screwdriver is removed, the pull-pawl will engage automatically.

4. Using the manual adjusting nut on the slack adjuster, adjust the brake chamber stroke (coarse adjustment), as follows. See **Fig. 8**.

   4.1 Turn the adjusting nut counterclockwise until the brake linings touch the brake drum.



A. Shorten stroke. B. Lengthen stroke.

Fig. 8, Adjusting the Stroke

   4.2 Then, turn the adjusting nut clockwise 1/2 turn.

5. Measure and adjust the free-stroke, as follows.

   5.1 With the brakes released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension A. See **Fig. 9**.

   5.2 Using a lever, move the slack adjuster until the brake linings contact the brake drum.

   Measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension B. See **Fig. 9**.

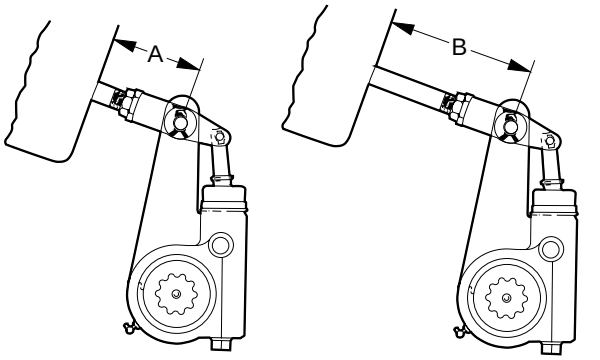
   5.3 Subtract dimension A from dimension B. The difference between these measurements is the free-stroke.

   5.4 The free-stroke for a new brake installation should be 5/8 to 3/4 inch (16 to 19 mm). For a brake that is in service, the free-stroke should be 1/2 to 5/8 inch (13 to 16 mm). If it is not, turn the adjusting nut 1/8 turn, as shown in **Fig. 8**. Then, measure the free-stroke again; readjust it until it is correct.

6. Measure and adjust the applied chamber stroke (fine adjustment), as follows.

   6.1 If system pressure is not already at 100 psi (689 kPa), start the engine and build air pressure, then shut down the engine.

   6.2 With the brakes released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension A. See **Fig. 9**.



NOTE: For either free-stroke or applied chamber stroke, subtract measurement A from B.

A. Measurement with the brakes released.
B. Measurement with the brakes applied by manual lever (free-stroke) or pressurized brake application (applied chamber stroke).

Fig. 9, Measuring the Stroke

   6.3 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 9**, Ref. B. Record this measurement as dimension B.

   6.4 Subtract dimension A from dimension B. The difference between these measurements is the true applied chamber stroke.

CAUTION

The adjusted applied chamber stroke should be as short as possible but not so short that the free-stroke is too short and the linings drag. If the linings drag, the brakes could be damaged.

6.5 The applied chamber stroke must not exceed the maximum value specified in **Table 1**.

If the applied chamber stroke is incorrect, turn the adjusting nut 1/8-turn counterclockwise to shorten the stroke, or 1/8-turn clockwise to lengthen it. See **Fig. 8**. Measure the applied stroke again and readjust it until it is correct.

6.6 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes. See **Section 42.04, Subject 150**.

7. Remove the screwdriver from the pull-pawl assembly. This will engage the pull-pawl with the actuator.

WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

8. In a safe area, check for proper brake operation before you put the vehicle in service, as follows.

8.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.

8.2 Perform six low-speed stops to ensure proper parts replacement and full vehicle control.

8.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than others show a lack of braking effort on those wheels.

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

1. Model TR-T (TR Series) Brake Chamber

Fig. 1, Brake Chamber

IMPORTANT: On MGM "TR" Series chambers, the parking/emergency brake section is factory sealed (no clamp ring) and is a *non-serviceable* unit.

General Information

MGM "TR" Series tandem cam brake chamber consists of a service brake section and a parking/emergency spring brake section. See **Fig. 2**. The service brake section is the smaller section near the clevis assembly.

In the service brake section, the flange case and non-pressure chamber contain a service return spring, piston rod assembly, and service brake diaphragm.

Fig. 2, Model TR-T (TR Series) Brake Chamber

In the parking/emergency brake section, the flange case and the head contain a return spring, a push rod assembly, a parking (spring) brake diaphragm, a piston, a power spring, and a detachable release bolt.

All MGM brake chambers are mounted to the frame using prevailing torque locknuts and hardened flatwashers.

MGM "TR" Series chambers may be equipped with an external breather tube that protects the parking brake chamber from contaminants. These chambers are called Model "TR-T" chambers. See **Fig. 2**.

Periodic maintenance of the brake chambers is required. Also, whenever the service brake chamber is disassembled (*do not attempt to disassemble the parking brake chamber*), the parts should be inspected for damage. For maintenance schedules and procedures, and for inspection of brake chamber parts, refer to the vehicle maintenance manual.

Principles of Operation

SERVICE BRAKES

As the brake pedal is depressed, compressed air enters the service brake chamber through a port. Air pressure acts upon a diaphragm, which forces the piston rod toward the non-pressure chamber, applying a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes.

Then, when the brake pedal is released, air is exhausted from the service brake chamber, and the return spring allows the diaphragm, piston rod, and slack adjuster to return to their normal positions, releasing the brakes.

PARKING/EMERGENCY BRAKES

During parking brake release, compressed air enters the parking brake chamber and acts upon the diaphragm and piston, fully compressing the power spring. When the power spring is compressed, the parking brakes are released; the service brakes can then be operated at the brake pedal.

During parking brake application, air is exhausted from the parking brake chamber. The power spring releases, forcing the piston and parking brake diaphragm toward the flange case. The resulting motion on the push rod forces the service brake diaphragm and piston rod outward, applying the brakes.

General Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc., should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Asbestos and Non-Asbestos Safety

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. Occupational Safety and Health Administration (OSHA) has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by Mining Safety and Health Administration (MSHA) or National Institute for Occupational Safety and Health (NIOSH).

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Exposure to airborne asbestos brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by OHSA regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency particulate air (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system,

Safety Precautions

remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

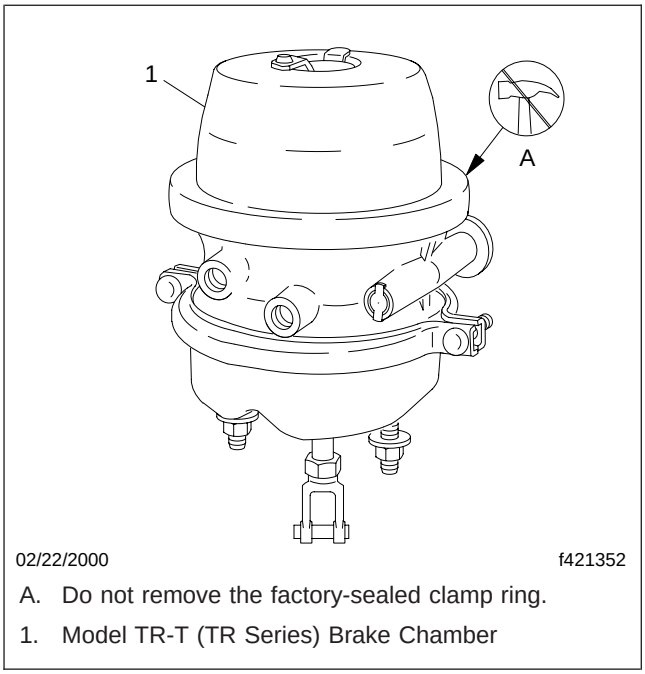
If grinding or other machining of the brake linings is necessary, other precautions must be taken because exposure to asbestos dust is highest during such operations. In addition to the use of an approved respirator, there must be local exhaust ventilation such that worker exposure is kept as low as possible.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Asbestos-containing waste, such as dirty rags, should be sealed, labeled, and disposed of as required by EPA and OSHA regulations. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

Workers should wash before eating, drinking, or smoking, should shower after work, and should not wear work clothes home. Work clothes should be vacuumed after use and then laundered, without shaking, to prevent the release of asbestos fibers into the air.

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1), for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.



A. Do not remove the factory-sealed clamp ring.

1. Model TR-T (TR Series) Brake Chamber

Fig. 1, Brake Chamber

Manual Compression (Parking Brake Release)

1. Chock the tires.
2. Remove the end cover cap from the center-hole in the head of the chamber. See **Fig. 2**.

⚠ DANGER

Do not attempt to cage the power spring if the parking brake chamber is damaged severely enough to lose its structural integrity. If the power spring were to break loose, it could result in death, severe personal injury, or property damage.

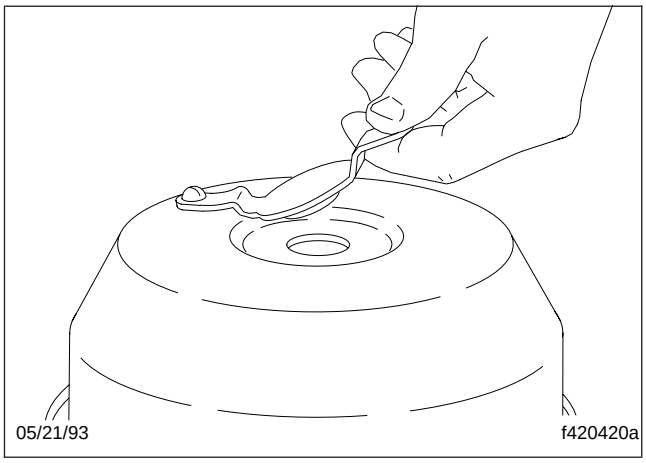


Fig. 2, Remove the End-Cover Cap

A DAMAGED PARKING BRAKE CHAMBER IS EXTREMELY DANGEROUS! Only qualified service personnel should attempt to remove and disarm a damaged chamber. Using a torch, burn off the piston rod in the space between the clevis and the base of the service chamber.

Remove the chamber carefully from its bracket, and disarm it inside a suitable container. For disarming procedures, consult the MGM service manual.

3. Manually release the parking brake (cage the power spring).

   3.1 Using a hand wrench (*don't use an impact wrench*), unscrew the release nut, and remove the nut, flatwasher, and release bolt from the storage pocket on the side of the chamber. See **Fig. 3**.

   IMPORTANT: If these parts are not stored on the chamber, they must be otherwise obtained or purchased; the parking brake cannot be manually released without them.

   3.2 Apply at least 90 psi (620 kPa) air pressure to the parking brake inlet port (set parking brake in the "release" position).

   3.3 Insert the release bolt into the center-hole in the chamber head (see **Fig. 4**). Insert the bolt until it bottoms out into the hole in the piston inside the chamber.

   IMPORTANT: If you are not absolutely sure that the formed end of the bolt has engaged

Power Spring Manual Compression and Reset

the piston correctly, repeat this step. Repeat it until you are absolutely sure.

3.4 Turn the release bolt one-quarter turn clockwise, and pull the bolt out to lock its formed end into the piston.

IMPORTANT: If the bolt doesn't lock into the piston in less than 1/2-inch (13-mm) outward movement, repeat these steps until you are sure it does lock.

3.5 Then, holding the bolt locked into the piston, install the flatwasher and release nut on the end of the release bolt, and turn down the nut against the flatwasher until it is finger-tight. See **Fig. 5**.

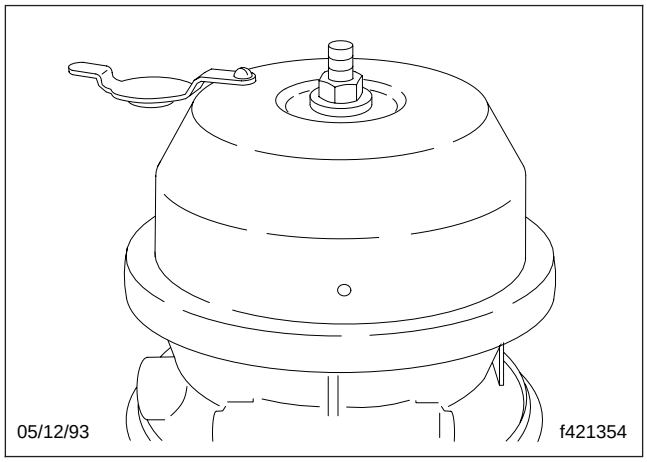

Fig. 5, Flatwasher and Release Nut Installed

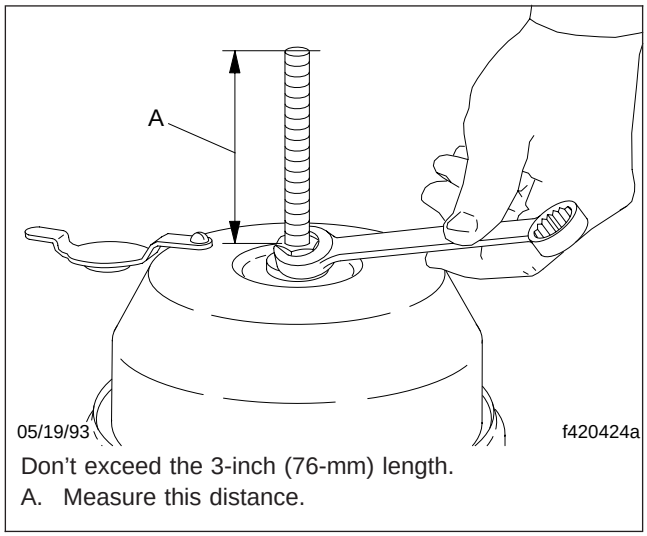
⚠ CAUTION

CAUTION: Don't exceed 50 lbf·ft (68 N·m) torque on the release nut; and don't use an impact wrench on this nut. Too much torque could distort the head of the chamber and prevent manual release of the parking brake.

3.6 Using a hand wrench (*don't use an impact wrench*), turn the release nut clockwise until the bolt extends 3 inches (76 mm) above the nut. See **Fig. 6**.



Don't exceed the 3-inch (76-mm) length.
A. Measure this distance.

Fig. 6, Turn the Release Nut

IMPORTANT: Don't exceed the 3-inch (76-mm) length.

4. Once the power spring has been caged, exhaust the compressed air from the parking brake.

Manual Reset (Parking Brake Reset)

1. Uncage the power spring.

   1.1 Apply at least 90 psi (620 kPa) air pressure to the parking brake inlet port (set parking brake in the "release" position).

⚠ CAUTION

CAUTION: Don't exceed 50 lbf·ft (68 N·m) torque on the release nut; and don't use an impact wrench on this nut. Too much torque could distort the head of the chamber and prevent manual release of the parking brake.

   1.2 With air applied to the parking brake section (the parking brake control valve is in the "release" position), use a hand wrench to turn the release nut *counterclockwise* until the bolt bottoms out in the unit.

   1.3 Remove the nut and flatwasher.

   1.4 Push the release bolt into the piston and turn the release bolt one-quarter turn counterclockwise to unlock its formed end from the piston. Remove the release bolt from the center-hole of the chamber.

2. Using a hand wrench (*don't use an impact wrench*), install the release bolt, flatwasher, and release nut in the storage pocket. MGM recommends 10 lbf·ft (14 N·m) torque on the nut against the flatwasher (see **Fig. 7**).

3. Snap the end cover cap in place over the center-hole in the chamber head. See **Fig. 8**.

⚠ CAUTION

CAUTION: If the external breather tube or end cover cap is missing or incorrectly installed, road dirt and debris can adversely affect the operation of the brake chamber. Once inside the chamber, dirt and debris cause the internal parts to deteriorate and shorten their lives. Operating the unit

without the external breather tube or end cover cap in place voids the MGM warranty.

4. Check the plastic end cover cap periodically, and replace it with a new one at once if damaged or missing. For intervals, refer to the vehicle maintenance manual.

5. Remove the chocks from the tires.

Removal

1. To make removal and installation of the parking brake section easier (without removing the service brake chamber), lock off the service chamber piston rod.

   1.1 Apply the service brakes by actuating the driver's foot brake treadle valve.

WARNING

WARNING: Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

2. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100.**

3. Mark the air lines for later reference. Then carefully disconnect them from the brake chamber.

   On chambers equipped with an external breather tube, disconnect the tube and elbow from the service brake chamber.

DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4. Remove the parking brake section from the service brake section.

   4.1 Using a hand wrench (*don't use an impact wrench*), remove the clamp nuts on the

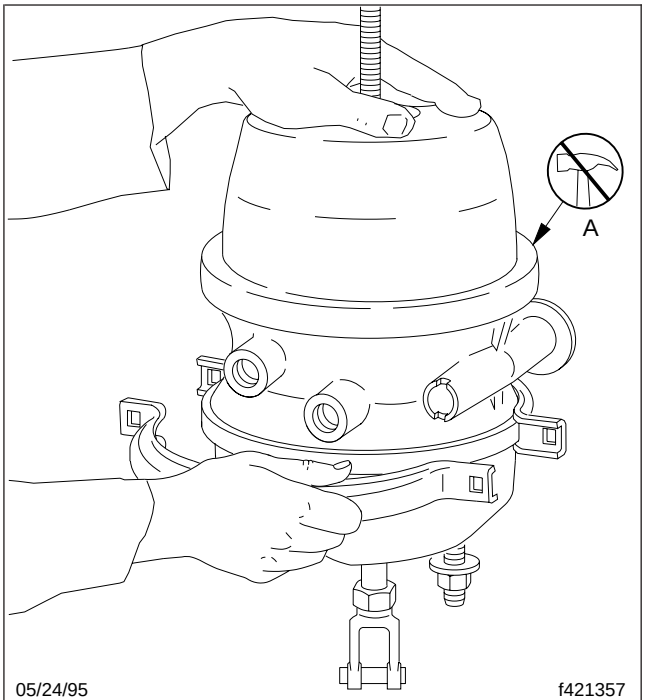
service clamp ring (*do not disassemble the parking brake section*).

4.2 While holding the parking brake section securely in place, remove the service clamp ring. Then remove the parking brake section from the service brake non-pressure chamber (see **Fig. 3**).



A. Do not remove the factory-sealed clamp ring.

5. Remove the service brake diaphragm from the bottom of the parking brake section.

Installation

IMPORTANT: At this time, take the opportunity to inspect the parking/emergency brake section, and replace it if it shows signs of damage, corrosion, or rust. Follow the detailed inspection instructions in the vehicle maintenance manual.

1. Inspect all parts in the service (non-pressure) chamber. Replace any damaged or worn parts with genuine MGM-engineered replacement parts.

2. Place the new service brake diaphragm in the bottom recess of the parking brake section (see **Fig. 4**).

3. Install the (new, if needed) parking/emergency brake section.

   3.1 If installing a new parking brake section, be sure it is the same size and make as the old one.

   3.2 Check that the release bolt is fully extended outward. For instructions, refer to **Subject 100**.

   3.3 Install the parking brake section on the service chamber so that all mating parts are aligned straight and the air lines are positioned to mate with the vehicle air supply lines.

4. Install the service brake clamp ring.

4.1 With the service brake clamp ring in place, install the clamp bolts and nuts.

4.2 Using a hand wrench (*don't use an impact wrench*), alternately tighten each clamp nut in increments of 60 to 120 lbf·in (680 to 1360 N·cm) while constantly rechecking the alignment of mating parts.

If realignment is needed, loosen the nuts again, and repeat this substep.

4.3 Firmly tap around the circumference of the service clamp ring with a rubber mallet to ensure full seating of the clamp. Tighten the nuts to a final torque of 25 to 30 lbf·ft (34 to 41 N·m).

5. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 25 lbf·ft (34 N·m).

6. Using the vehicle system air, charge the parking brake with full line pressure—at least 100 psi (690 kPa). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 25 lbf·ft (34 N·m).

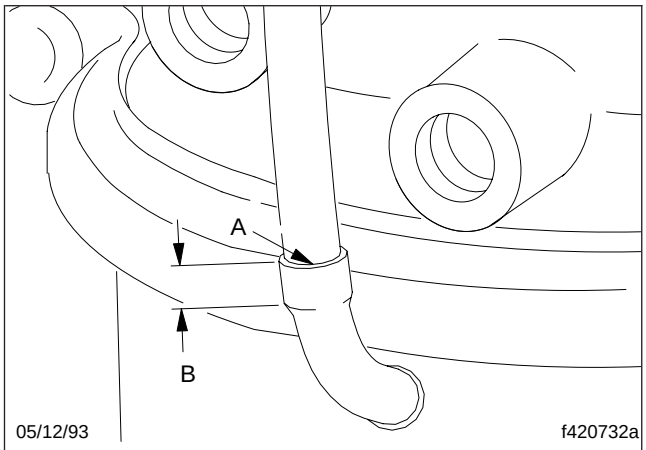
7. With the parking brake still charged with full line pressure, apply and hold the foot brake treadle valve down to charge the service brake chamber. Remove the locking-jaw pliers from the service piston rod so that the piston returns to a normal position in the chamber.

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

8. Test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, firmly tap the circumference of the clamp ring with a rubber mallet, and retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). MGM recommends 25 to 30 lbf·ft (34 to 41 N·m) torque on the clamp hexnuts.

9. On chambers equipped with an external breather tube, make sure that the open end of the tube is free of grease, dirt, and other debris. Then, apply a high-quality rubber cement to the tube and insert it into the elbow at least 1/2 inch (13 mm). See **Fig. 5**. Insert the tube into the service brake chamber.



A. Apply adhesive here.
B. Check for 1/2" (13 mm) minimum engagement.

Fig. 5, Install the External Breather Tube

10. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the end cover cap in place. For instructions, refer to **Subject 100.**

11. Adjust the brakes at the slack adjuster.

IMPORTANT: After replacing any brake chamber components, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

3. Remove the brake chamber from the vehicle.

   3.1 Remove the cotter pin(s) from the clevis pin(s), then remove the clevis pin(s) from the clevis. Disconnect the clevis from the slack adjuster.

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   3.2 Make sure the parking brake has been released manually (the power spring has been caged). For instructions, refer to **Subject 100.** Also, make sure that the service brake piston is fully retracted (in the brakes "OFF" position). Then, record both of the following dimensions in either mm or inches, measuring outward from the base of the service brake chamber **(see Fig. 3):**

Combination Service and Parking Brake Chamber Removal and Installation

X dimension: to end of threaded piston rod

Y dimension: to centerline of (large) clevis pin

IMPORTANT: If new chambers are to be attached to manual slack adjusters, the Y dimension is the most critical measurement. When installing the new assembly, its service piston rod must be cut **(see Fig. 4)** to exactly duplicate this "rod-plus-clevis" length *after* the clevis assembly is installed on the piston rod.

If new chambers are to be attached to automatic slack adjusters, the X dimension is the most critical measurement. When installing the new assembly, its service piston rod must be cut **(see Fig. 4)** to exactly duplicate the "rod only" length *before* the clevis assembly is installed on the piston rod.

3.3 From each mounting stud, remove any installed nuts and washers. Then, cautiously remove the brake chamber from the mounting bracket.

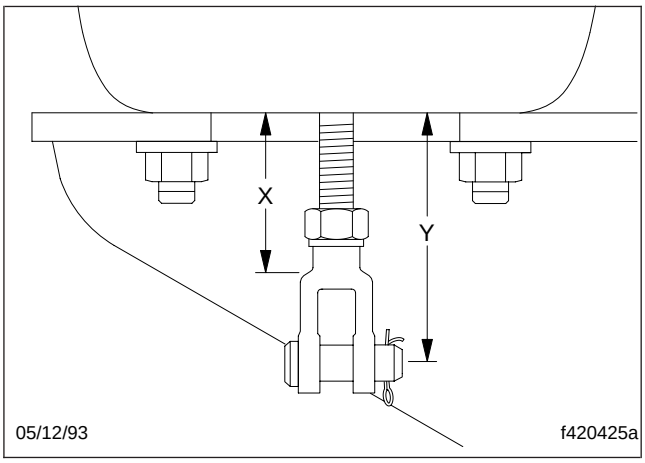

Fig. 3, Measure X and Y

Installation (See Fig. 2)

1. If installing a new brake chamber unit, do the following steps:

   1.1 First, make sure the power spring is caged (release bolt fully extended outward). If not, go to **Subject 100** and do the applicable steps.

   1.2 Make sure that the piston rod is the same length as the rod on the old unit (measure the rods when *both* chambers are caged).

   1.3 Be sure the new chamber is the same size and make as the brake chamber installed on the other side of the axle.

   1.4 Remove the prevailing torque locknut and hardened flatwasher from each of the mounting studs on the chamber.

2. Clean the face of the mounting bracket, and install the chamber on the bracket, paying close attention to positioning the chamber air inlet ports for correct alignment to the vehicle air lines.

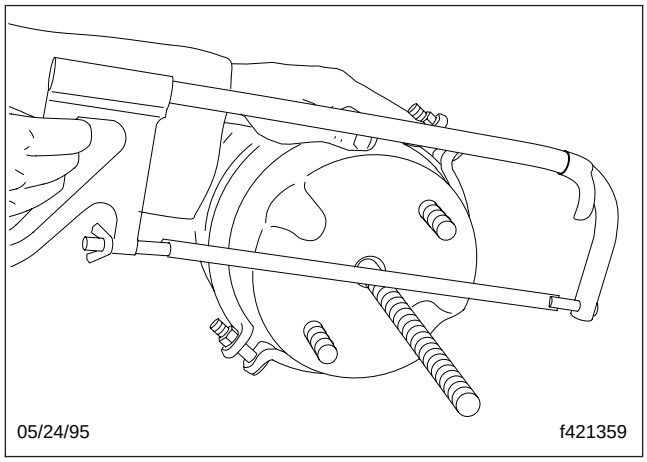

Fig. 4, Cut the Service Piston Rod

WARNING

WARNING: Tighten the mounting nuts with a hand wrench, not an impact wrench. An impact wrench could damage the mounting fasteners, reducing the force of the brakes. This could result in personal injury or property damage.

3. Install one hardened flatwasher and prevailing torque locknut on each mounting stud. Using a hand wrench (*don't use an impact wrench*), tighten the nuts 100 to 115 lbf·ft (136 to 156 N·m). Make sure the flatwasher is installed between the locknut and the mounting bracket.

Combination Service and Parking Brake Chamber Removal and Installation

On chambers equipped with an external breather tube, make sure that the tube is installed in the side of the chamber that faces away from the road surface. An improperly installed breather tube voids the MGM warranty.

4. Check mating and alignment with the vehicle air lines.

⚠ DANGER

Do not attempt to remove the factory-sealed parking brake clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4.1 Using a hand wrench (*don't use an impact wrench*), loosen the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

4.2 Reposition the air inlet ports, as needed, to mate with vehicle air supply lines.

Alternately tighten each clamp nut in increments of 60 to 120 lbf·in (680 to 1360 N·cm) while constantly rechecking the alignment of mating parts.

If realignment is needed, loosen the nuts again, and repeat this substep.

4.3 Firmly tap around the circumference of the service clamp ring with a rubber mallet to ensure full seating of the clamp. Tighten the nuts to a final torque of 25 to 30 lbf·ft (34 to 41 N·m).

5. Install the slack adjuster. Refer to the applicable slack adjuster section in this group for installation instructions.

6. Inspect the piston rod to be sure it is working free, not binding, and is square with the chamber bottom within ±3° in any direction from zero to full stroke. If there is misalignment, make corrections by loosening the locknuts and repositioning the chamber on the mounting bracket, or by shimming the slack adjuster to the right or left on the camshaft.

7. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 25 lbf·ft (34 N·m).

8. Using the vehicle system air, charge the parking brake with full line pressure, at least 100 psi (690 kPa). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 25 lbf·ft (34 N·m).

⚠ DANGER

Do not attempt to remove the factory-sealed parking brake clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

IMPORTANT: If the service brake clamp ring was loosened to reposition the air inlet ports, apply air to the parking brake, and then apply and hold the foot brake treadle valve down to charge the service brake chamber. Now test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, firmly tap the circumference of the clamp ring with a rubber mallet, and retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). MGM recommends 25 to 30 lbf·ft (34 to 41 N·m) torque on the clamp hexnuts.

9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the end cover cap in place. For instructions, refer to **Subject 100**.

10. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

IMPORTANT: After replacing any brake chamber, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack

General Description

Brake chambers convert the energy of compressed air into the mechanical force and motion needed to apply the brakes. Two chambers operate the brakes, one on each side of the axle.

Each brake chamber consists of two dished metal sections: the cover assembly and the body assembly, which are separated by a nylon-neoprene diaphragm. A metal two-segment clamp ring holds the assemblies together. **See Fig. 1.**

Fig. 1, Sectional View

In front of the diaphragm are the body, piston rod assembly, and a piston rod spring. The threaded piston rod assembly extends through the bottom of the body and connects to the clevis. **See Fig. 1.**

Different sized brake chambers are identified by numbers, which specify the effective area of the diaphragm. For example, a type 16 brake chamber has 16 square inches of effective area.

Principles of Operation

The greater the air pressure admitted to the brake chamber, the greater the force applied by the piston rod. Piston rod force is determined by multiplying the delivered air pressure by the effective diaphragm area. For example, if 60 psi (415 kPa) is admitted to a type 16 brake chamber, the force on the end of the piston rod is about 960 lb (436 kg).

When the brake pedal is depressed, air pressure from the brake valve passes through the port in the brake chamber cover to move the diaphragm and piston rod assembly forward. This compresses the spring, and applies a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes.

When the brake pedal is released, compressed air behind the diaphragm exhausts through the quick release valve. The spring then allows the piston rod assembly and diaphragm to return to their previous positions.

NOTE: For both of these tests, the air system must be pressurized to at least 80 psi (550 kPa).

Operating Test

1. Chock the tires.
2. Apply the brakes. Check that each piston rod moves out promptly, without binding.
3. Release the brakes. Check that each piston rod returns to the released position promptly, without binding.
4. Check the brake chamber stroke. It should be as short as possible without causing the brakes to drag. If needed, adjust the travel of the piston rod at the slack adjuster. For instructions, refer to the foundation brake section in this manual.

Leakage Test

1. Apply the brakes and hold them on full line pressure of at least 80 psi (550 kPa).
2. Using a soap solution, coat the clamp ring. Leakage is excessive if it produces a 1-inch (25-mm) bubble within five seconds.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

3. If the leakage is excessive, tighten the clamp ring flange nuts evenly until the leakage is reduced. For acceptable torque ranges, refer to **Specifications, 400**.
4. Using a soap solution, coat the area around the piston-rod hole. No leakage is permitted. If there is leakage, replace the diaphragm. For instructions, refer to **Subject 110**.

Brake Chamber Diaphragm Replacement

NOTE: This procedure is for service of a leaking brake chamber *diaphragm only*. If there are any other problems, refer to the applicable subjects elsewhere in this section.

Replacement

1. Chock the tires.

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Follow the manufacturer's recommendations when working on any air device so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or compressed-air propulsion.

2. Drain the air reservoirs and lines.
3. Back off the slack adjuster; for instructions, refer to the applicable slack adjuster section in this manual. Pull out the piston rod. **See Fig. 1.** Clamp the rod at the chamber body to protect it from damage.
4. Before disassembly, mark a reference line along the chamber to allow the parts to be reassembled later in their old positions. **See Fig. 2.**
5. Replace the diaphragm.
   - 5.1 Remove one clamp ring bolt and flange nut completely and loosen the other bolt and flange nut enough to remove the clamp ring.
   - 5.2 Remove the cover assembly, and replace the diaphragm.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

   - 5.3 Position the cover assembly and clamp ring (aligning the reference marks), and install the clamp ring bolt and flange nut. Tighten the flange nuts evenly to eliminate leakage. For acceptable torque ranges, refer to **Specifications, 400.**

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at other people. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in severe personal injury.

Follow the manufacturer's recommendations when working on any air device so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or compressed-air propulsion.

2. Drain the air reservoirs and lines.
3. Carefully disconnect the air line from the brake chamber.
4. Remove the brake chamber.

   4.1 Remove the cotter pin(s) from the clevis pin(s).

   NOTE: Automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   4.2 Remove the clevis pin(s) from the slack adjuster.

   4.3 From each mounting stud, remove any installed nuts and washers. Remove the brake chamber from the vehicle.

Installation (See Fig. 1)

1. Before installing a new chamber, be sure the new chamber is the same size and make as the brake chamber on the other side of the axle.
2. Install the brake chamber.

   2.1 Attach the brake chamber to the mounting bracket using a hardened flatwasher and prevailing torque locknut. Install the flatwasher between the locknut and the mounting bracket.

   2.2 Tighten the locknuts. **See Table 1** for the correct torque value.

Inspection and Cleaning

1. Clean all metal parts with cleaning solvent.
2. Inspect all parts for wear or damage; replace as needed.
   - 2.1 Check the cover and the body for dents. If any are too deep to be pounded out, replace as needed.
   - 2.2 Check the diaphragm for wear or deterioration and replace it if necessary. Midland recommends replacement of the diaphragm whenever the service brake chamber is opened for inspection.
   - 2.3 Inspect all other parts not considered serviceable. Replace if necessary.

Assembly (See Fig. 1)

1. Stand the piston rod assembly upright on a flat surface (if the chamber was removed from the vehicle).
2. Assemble the brake chamber.

Brake Chamber Disassembly, Inspection and Cleaning, and Assembly

2.1 Place the return spring on the piston rod.

2.2 Place the body on the piston rod assembly, and press the body down, working against the tension of the spring, until the body bottoms out on the flat surface. Clamp the rod at the body, making sure to protect the rod from damage. Insert the piston rod assembly through the body and clamp the rod (if the body wasn't removed from the vehicle).

2.3 Place the diaphragm in the body.

⚠ CAUTION

Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

2.4 Position the cover assembly and clamp ring (aligning the reference marks), and install the clamp ring bolt and flange nut. Tighten the flange nuts evenly to eliminate leakage. For acceptable torque ranges, see **Specifications, 400.**

3. Install the clevis locknut and clevis, and release the clamp on the piston rod.
4. If the brake chamber was removed from the vehicle, install it. For instructions, see **Subject 120**.
5. Do both of the tests found in **Subject 100.**

General Description (See Fig. 1)

Fig. 1, Location of ABS Components, Four-Channel System

The Meritor WABCO Antilock Braking System (ABS) is an electronic wheel speed monitoring and control system that works with the standard air brake system. ABS passively monitors vehicle wheel speed at all times, and controls wheel speed during emergency stops. If equipped with Automatic Traction Control, wheel spin is controlled during reduced-traction starts. In normal braking applications, the standard air brake system is in effect.

General Description and Principles of Operation

ABS includes signal-generating tone wheels and sensors located in the wheel hubs of each sensed wheel. The sensors transmit vehicle wheel speed information to an electronic control unit. According to programmed specifications, the control unit signals the appropriate solenoid control valve to increase, reduce, or maintain air pressure supply in the brake chamber. This prevents front and rear wheel lockup, and enhances steering control during emergency braking situations. If equipped with Automatic Traction Control, an additional solenoid valve is installed. During reduced-traction starts, the system automatically applies the brakes on the wheel that is spinning, left or right side, to transfer power to the opposite-side wheel. If both the left and right wheels spin, then engine power is automatically reduced.

Principles of Operation

The ABS electronic control unit (**Fig. 2**) is a digital microcomputer that serves as the information processing and command center for the antilock braking system. The control unit receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the control unit regulates the braking force applied to each wheel by sending control signals to the solenoid control valves (**Fig. 3**).

ABS MAJOR COMPONENTS

Wheel Speed Sensor

The wheel speed sensors use pulse feedback from tone wheels located in the front and rear axle wheel hubs. When the vehicle is moving, the teeth of the tone wheel cause interruptions in a magnetic field created by the sensor. The interruptions create electrical pulses that are sent by the sensor to the electronic control unit.

Electronic Control Unit (ECU)

The electronic control unit (ECU), located in a panel just behind the driver's seat, contains microcomputers to monitor the front and rear control channels. The ECU receives speed sensor pulses and interprets these signals to calculate wheel speed and a vehicle reference speed. If the calculations indicate wheel slip or lockup, the appropriate control circuit signals the solenoid control valve(s) to increase or decrease braking pressure.

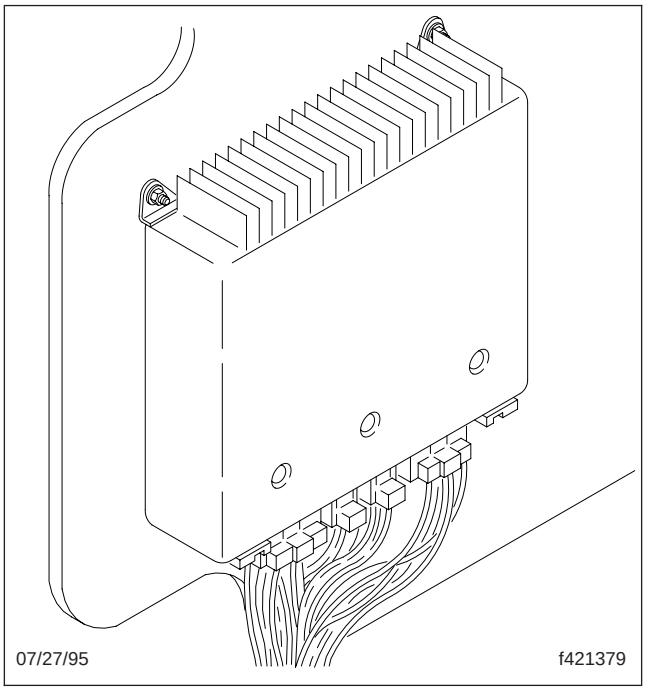

Fig. 2, Electronic Control Unit

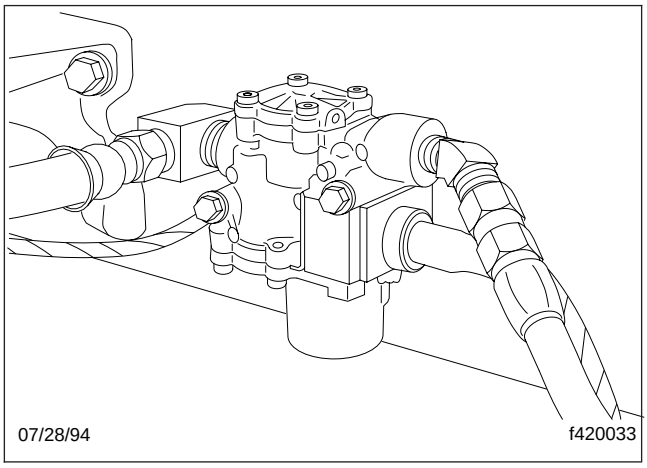

Fig. 3, Solenoid Control Valve, Front Axle Mounting shown

⚠ CAUTION

Before performing any electric welding on a vehicle, disconnect the battery power and ground cables and the electrical harness connectors at the bottom of the ABS electronic control unit (ECU). See Fig. 2. Electric currents produced

during electric welding can damage various electronic components on the vehicle.

The ECU contains another microcomputer that provides a safety circuit to constantly monitor the wheel sensors, traction control valve (if equipped), solenoid control valves, and the electrical circuitry. After the ignition switch is turned on, the tractor warning light (TRAC ABS) and the wheel spin (WHL SPIN) indicator light come on for about three seconds. See **Fig. 4**. After about three seconds, the lights go out only if all of the tractor's ABS components are working.

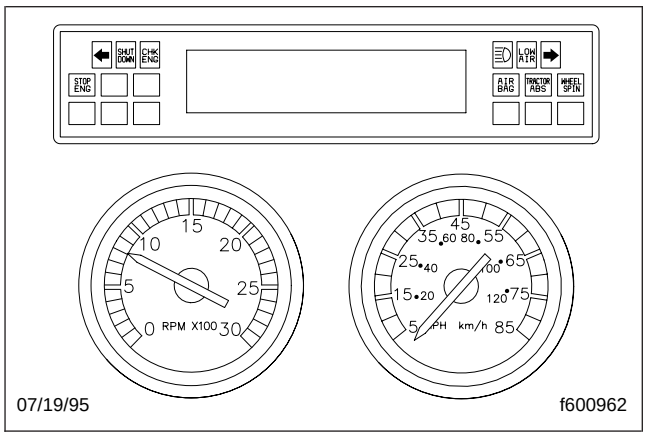

Fig. 4, ABS Dash Lights

A wheel spin (WHL SPIN) indicator light comes on if one of the drive wheels spins during acceleration. See **Fig. 4**. See the vehicle driver's manual for operating instructions.

IMPORTANT: If the TRAC ABS warning light and the WHL SPIN indicator light do not work as described above, repair the ABS/ATC system. See **Troubleshooting 300** for fault diagnosis.

If the vehicle is equipped with an electronic engine, an automatic traction control (ATC) system may be installed. On these vehicles, the ATC system automatically reduces wheel spin during reduced-traction starts.

An "ATC Function" switch (if equipped), allows the driver to select from two levels of drive axle traction-control assistance:

- NORMAL/SPIN—which reduces drive axle wheel spin on icy, wet, or sand covered roads.
- ATC—which allows a higher threshold of drive axle wheel spin to help burn through a thin layer of ice, or to help throw off accumulated mud or snow.

The ATC mode is indicated by a flashing WHL SPIN light. To engage this mode, the ATC function switch (this is a momentary switch) must be pressed once the vehicle is started. The ECU indicates the activation by a constant flashing of the WHL SPIN lamp. This mode is disengaged by again pressing the ATC function switch. See the vehicle driver's manual for complete operating instructions.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (a sensor, solenoid control valve, wiring connection, short circuit, etc.), the tractor warning light (TRAC ABS) comes on, and the control circuit where the failure occurred is switched to normal braking action. The remaining control circuit will retain the ABS effect. Even if the ABS system is completely inoperative, normal braking is maintained. An exception would be if a solenoid control valve (or combination solenoid control valve) is damaged and inoperative. As these components are an integral part of the air brake system, normal braking may be impaired or inoperative.

Solenoid Control Valve

The solenoid control valves for the front axle brakes are attached on each side of the vehicle (inboard of the forward fuel tank brackets). The combination solenoid control valves (which include a relay valve) for the rear axle brakes are attached to the either the center or forward suspension crossmember near the brake chambers. Depending on the signal received from the electronic control unit, the control valve prevents wheel lockup by reducing, maintaining, or increasing brake chamber air pressure. During normal braking applications, compressed air flows freely to the brake chamber through the control valve.

If the electronic control unit signals indicate wheel lockup, air pressure is reduced in the brake chamber. Solenoid valve 1 opens allowing compressed air to enter the inlet chamber and pilot chamber 1. See **Fig. 5**.

At the same time, solenoid valve 1 closes off the exhaust chamber preventing the escape of air from the inlet chamber to atmosphere. Compressed air in the inlet chamber is forced into pilot chamber 1, closing diaphragm valve 1; this prevents air passage to the delivery chamber. Solenoid valve 2 also opens allow-

ing air to vent from pilot chamber 2 through the exhaust port. Complete venting of all air in the delivery chamber occurs as diaphragm valve 2 opens.

As wheel speed increases, the control valve alternately increases, then maintains brake pressure until the proper wheel speed is obtained, or until wheel lockup occurs and the control cycle starts again.

During the pressure increase cycle (**Fig. 6**), both solenoid valves are closed. Compressed air entering through the inlet chamber forces diaphragm valve 1 open, allowing air to pass through the delivery chamber into the brake chamber. At the same time, pressure within the control valve keeps diaphragm valve 2 closed, preventing air from escaping through the exhaust port.

If maintaining brake air pressure (**Fig. 7**), solenoid valve 1 opens and compressed air passes from the inlet chamber into pilot chamber 1. Both of the diaphragm valves are forced closed, sealing the delivery chamber and maintaining brake air pressure.

Installation

IMPORTANT: Some ABS service hubs do not have a tone ring installed on the hub. The tone ring must be ordered separately and installed on the hub before installation of the hub onto the axle. Tone rings are made of a special material and require a specific installation procedure for proper installation.

⚠ WARNING

When installing an ABS system, special ABS hubs must be ordered. Machining of older hubs to accommodate the installation of tone rings can cause problems due to insufficient hub bore wall thickness. Machining an older hub with insufficient hub bore wall thickness could result in cracking, causing bearing damage and wheel loss. This could cause an accident resulting in personal injury and property damage.

1. Submerge the tone ring in boiling water or place it in an oven at 250°F (121°C) for approximately 15 minutes.

⚠ CAUTION

Do not attempt to heat the tone ring with a torch as this can damage the ring.

2. Using pliers, remove the tone ring from the boiling water or oven and center it on the machined area of the hub bore. See **Fig. 1**.
3. While the tone ring is still hot, make sure that it is properly centered on the machined surface. Using a rubber mallet, tap the tone ring until it bottoms out around the machined surface on the hub. See **Fig. 2**.
4. Install the hub on the axle. Position a dial indicator with a magnetic base so the dial indicator is against the tone ring teeth. See **Fig. 3**.
5. Rotate the hub and check the ring for runout. The runout should be less than 0.005 inch (0.13 mm). See **Fig. 4**.

Troubleshooting

This subject includes the following troubleshooting methods:

- Troubleshooting using the instrument panel blink codes
- Troubleshooting using the instrument control unit (ICU) fault codes

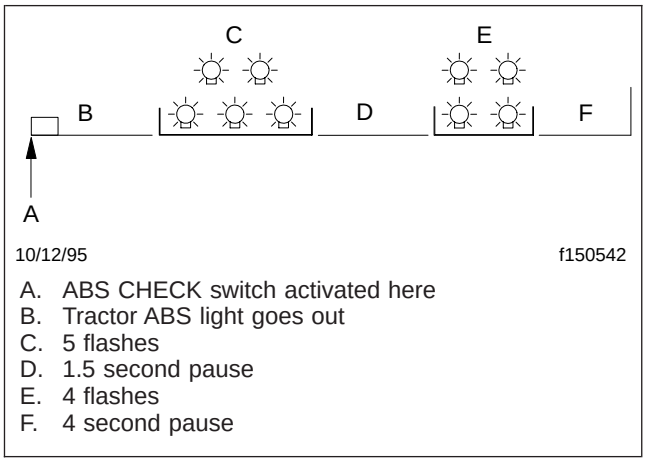
USING THE INSTRUMENTATION PANEL BLINK CODES

This system has built-in diagnostics to ensure that all components are operating properly. Under normal conditions, the tractor warning light (TRAC ABS) and wheel spin light (WHL SPIN) come on when the ignition is turned on. After about three seconds these lights should go out if all of the tractor's ABS/ATC components are working. If either light stays on, or comes back on later, a problem within the ABS/ATC system has occurred. The vehicle can continue to be driven, but the ABS system could be partially or completely inoperative. To check the type of fault code recorded, stop the vehicle and turn off the engine. Then, turn on the ignition switch, but don't start the engine. If the light is still on, there is an "active" system fault that must be repaired to ensure proper system operation. If the light is not on, a "historical or intermittent" fault (indicating a loose connector or broken wire) has been recorded in the ECU memory.

NOTE: If troubleshooting the system with the Pro-Link 9000, use the instruction booklet that is supplied with the data cartridge.

Use the ABS CHECK switch (which is located on the ECU in a panel just behind the driver's seat) and the TRAC ABS light to display system faults. With the ignition switch on, depress (for about one second) and release the switch. The TRAC ABS light should go out. After a one and one-half second pause, the TRAC ABS light will blink the first digit of the two-digit fault code. The number of blinks displaying the first digit will be a number between one and eight. After another one and one-half second pause, the second digit will be displayed. The number of blinks displaying the second digit will be a number between one and six. After a four second pause, the diagnostic code cycle continues to repeat the "active" fault code until it is repaired. If "historical" fault codes exist, the code cycle will display all recorded faults.

For example (**Fig. 1**), after the ABS CHECK switch has been depressed and released, fault code 54 is shown by five flashes, a pause of one and one-half seconds, followed by four flashes. After a four second pause, the same fault code will continue to repeat, always ending with a four second pause.



A. ABS CHECK switch activated here
B. Tractor ABS light goes out
C. 5 flashes
D. 1.5 second pause
E. 4 flashes
F. 4 second pause

Fig. 1, Fault Code 54 shown

NOTE: When there are no fault codes in the ECU memory, blink code 1-1 is displayed.

Once a fault code has been identified, use a volt/ohmmeter to check the electrical harness at the ECU's pin connectors (there is a 6-pin, 9-pin, 15-pin, and 18-pin connector at the ECU, which is located in a panel just behind the driver's seat). Connect the ohmmeter leads to the applicable pins on each connector. See **Fig. 2**, and **Table 1**, for a description of the circuit wire numbers and their location within the pin connectors.

IMPORTANT: The ignition switch must be off when connecting or disconnecting the ECU.

If the TRAC ABS or WHL SPIN lights do not operate correctly after the ignition is turned on (the lights don't come on at all or they don't go out after about three seconds), check all related circuit breakers in the electrical panel behind the driver's seat, and replace if necessary. Check the wiring to the ABS CHECK switch and the warning lamps. Refer to **Table 2**, and repair or replace the wiring as needed. Make sure that a charged 12-volt battery is available (the ABS system needs at least 11 volts to work).

ABS CHECK Switch	On the 18-pin connector, pins 10 and 18 (also, turn on the ABS CHECK switch).	0 to 2 ohms	Wiring to the switch is shorted or open; or the switch needs replacing.	Repair the wiring, or replace the switch.

Table 2, ABS CHECK Switch and Warning Lamps Wiring Checks

Refer to the applicable table in this section for fault codes, pins to be tested, and the correct volt/ohmmeter readings. Repair or replace the components and/or wiring if the readings are not correct.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals.

Refer to **Group 54** in this manual for information on special terminals and connectors, and ordering tools for them.

Refer to the wiring diagram in **Specifications, 400** when troubleshooting the ABS system. The key switch must be turned on (engine off) to activate the blink codes.

If a fault still can't be repaired, or erased from ECU memory, contact your Rockwell District Service Manager, or call Rockwell WABCO at 1-800-535-5560.

NOTE: An "active" fault code cannot be erased from ECU memory. "Historical" faults can be erased from ECU memory without being repaired. However, make sure that all "historical" fault codes are recorded because they should be repaired as soon as possible.

Historical fault codes can be erased all at once from the ECU memory. Erase historical fault codes by depressing the ABS CHECK switch for at least three seconds (but less than six seconds). After releasing the switch, the TRAC ABS light will go out in one-half second, then there will be a four second pause. After the pause, the TRAC ABS light will flash eight times (only if there are no active fault codes–if there are, you will only see the two system flashes), followed by another four second pause. Then, the TRAC ABS light will flash two times, another four second pause will follow and the same cycle of two flashes and four-second pauses will continue until the ignition switch is turned off, then back on.

IMPORTANT: Before performing any vehicle testing on a dynomometer, disable the automatic traction control (if equipped) as follows: Depress the ABS CHECK switch for at least three seconds (but less than six seconds). After releasing the switch, the TRAC ABS light will go out in one-half second, a four second pause will occur, then the TRAC ABS light will flash two times, a four second pause will follow, and the same cycle of two flashes and four-second pauses will continue until the engine is turned off, then back on. The WHL SPIN light will also be on (indicating that ATC is enabled) during this process. Make sure that all "historical" fault codes are recorded because they will be erased when performing this procedure.

USING THE INSTRUMENTATION CONTROL UNIT (ICU) FAULT CODES

The first six digits of the ICU fault code indicate the system component or area you need to troubleshooting. To find the component or area that corresponds to a fault code, see **Table 3**. After that, refer to the appropriate table for the troubleshooting procedure.

General Information

Air reservoirs serve two main purposes:

- They store compressed air used to apply the brakes and operate other air-powered devices, such as window lifts, windshield wipers, and seats.
- They provide a place where air, heated during compression, can cool and water vapor can condense into a liquid. Also, air reservoirs collect small amounts of oil passed by the compressor.

Each vehicle is equipped with three or four air reservoirs, depending on the number of rear axles. On all vehicles, each reservoir is identified as one of three types: supply, primary, and secondary.

A supply reservoir receives compressed air directly from the compressor. Also referred to as the wet tank, its functions are to collect most of the water and oil condensate from the air, and to supply air to the other reservoirs. At the outlet port of the supply reservoir (the port leading to the primary reservoir) is a safety valve, which protects the air system against excessive air pressure build-up. The supply reservoir is usually mounted on the right-hand frame rail.

Primary reservoirs are air sources for the brakes on the rear axles. One or two primary reservoirs are installed on a vehicle, depending on the number of rear axles and the air system configuration. Each primary reservoir is usually mounted behind the supply reservoir on the right-hand frame rail.

A secondary reservoir is the air source for the front axle brakes. It is usually mounted on the left-hand frame rail, and, like the primary reservoir, is equipped with an inline check valve.

The secondary reservoir supplies air to a pressure protection valve. This valve prevents complete loss of secondary air pressure if there is an air leak in any non-brake accessory.

All air reservoirs are equipped with drain valves to eject the water and oil emulsion from the tanks.

Tests

NOTE: If equipped with an automatic moisture-ejection valve, refer elsewhere in this group for leak testing.

Be sure the air system is fully charged. Using a soap solution or leak detector, check for leaks on the outside surfaces of the reservoirs and drain valves. No leakage is permitted.

If leaks exist at the drain valve, note if they occur at the joint of the valve and coupler, or through the valve body. Proceed to **Subject 110.**

If leaks occur on the surfaces of the air reservoir, replace the tank; refer to **Subject 120.**

Drain Valve Replacement and Leak Elimination

NOTE: If equipped with an automatic moisture-ejection valve, refer elsewhere in this group for instructions.

1. Apply the parking brakes, and chock the tires.
2. Drain the air system, using the instructions in the vehicle driver's manual.
3. Using two wrenches (hold the coupler in place with one of them), unscrew the drain valve from the coupler. Clean off the threads inside the coupler on the reservoir, removing all sludge and sealant build-up.

   Obtain a new drain valve if leaks occurred through the body of the valve.

   If leaks occurred at the joint of the drain valve and coupler, clean off the sludge and sealant from the threads of the valve. Check for damaged threads on the valve and inside the coupler. Replace damaged parts. If no damage exists, leakage was probably due to inadequate tightening of the drain valve in the coupler.
4. Apply Loctite®, or an equivalent sealant, to the end threads of the drain valve or coupler, as applicable, and install finger-tight. Tighten one and one-half additional turns (use two wrenches if installing the drain valve).
5. Perform a leak test after completing the installation. If leaks occur at the joint of the drain valve and coupler, tighten the valve up to one additional turn to stop the leaks.
6. Remove the chocks from the tires.

Replacement

1. Apply the parking brakes, and chock the tires.
2. Drain the air system. For instructions, refer to the vehicle driver's manual.
3. Mark all reservoir air lines, couplers, and valves for later assembly; disconnect the components. Cap the exposed ports tightly to keep out contaminants. If access is limited, remove the components after removing the reservoir from its mount.

NOTE: If the reservoir is mounted on the fuel tank bracket, loosen the bottom strap fastener first. See **Fig. 1**.

4. Remove the reservoir strap fasteners. Remove the reservoir.

4. 3/8–16 Strap Fastener

5. If access is limited, do the next step first. If not, place a new reservoir in the mount, and install the strap fasteners. On frame-mounted straps (**Fig. 2**), tighten the fasteners 20 to 25 lbf·ft (27 to 34 N·m). On fuel-tank bracket mounted straps (**Fig. 1**), tighten the fasteners 30 to 40 lbf·ft (41 to 54 N·m). Tighten the lower strap fastener 136 lbf·ft (184 N·m).

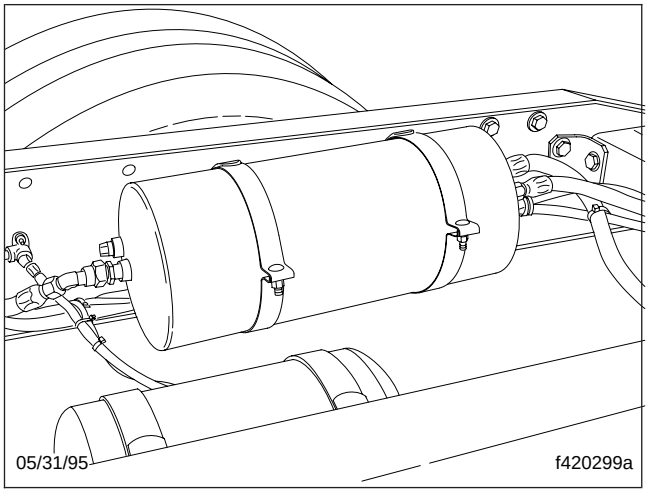

Fig. 2, Air Reservoir, Frame Rail Mounting

6. As marked earlier, connect all air lines, couplers, and valves to the new reservoir, removing the caps as each component is installed. Tighten the connections as instructed elsewhere in this group.
7. Remove the chocks from the tires.

Internal Check Valve Replacement, Two-Chamber Air Reservoir

General Information

Contamination in two-chamber, wet/secondary, reservoirs may cause the inline check valve to become clogged or stuck closed. This can result in insufficient air buildup. If insufficient air buildup is noted, replace the check valve. If the check valve can not be removed (due to corrosion), it is acceptable to install a bypass line.

There are two styles of check valves that may have been installed in the tank. An internal check valve is threaded into the internal wall that separates the wet side and secondary side of the reservoir. Or an external check valve is mounted in a port on the top surface of the reservoir.

Internal Check Valve Replacement (located in the separator wall of the reservoir)

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Drain the air reservoir.
3. Disconnect the air lines and remove the reservoir from the vehicle.
4. On the supply (wet) side of the reservoir, disconnect the pressure-protection valve, and the 90-degree elbow located on the end of the reservoir.
5. The check valve is located on the interior wall that separates the sides of the reservoir. To reach it, use a 1/4-inch drive, 1/2-inch deep-well socket with a 1/4- to 3/8-inch drive adapter, and necessary 3/8-inch extensions to reach the valve. Tape the socket and extensions, to ensure the valve will stay in the socket, and that the wrench assembly will stay together inside the tank. Insert the socket assembly through the end port of the reservoir, and remove the valve. See **Fig. 1** and **Fig. 2**.

CAUTION

Take care not to drop the check valve into the reservoir when removing or installing it. The reservoir can not be used if the check valve is lost in it. A loose check valve could scratch the teflon coating of the interior of the reservoir, causing it to corrode. If the check valve is not recoverable, replace the reservoir.

6. Install a new check valve.
7. Attach the pressure-protection valve and the 90-degree elbow.
8. Install the reservoir on the vehicle and attach the air lines.
9. Charge the air system and inspect for leaks.

Internal Check Valve Replacement

10. Remove the chocks from the tires.

Internal Check Valve Replacement (located in the side port of the reservoir)

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Drain the air reservoir.
3. Remove the check valve assembly from the top port on the reservoir. See **Fig. 3** and **Fig. 4**.

Bypass Line Installation

Check with the PDC for the appropriate bypass line kit for your vehicle.

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Drain the air reservoir.
3. On the top port on both sides of the reservoir, disconnect the existing plumbing from the tank. Install a T-fitting, and connect the existing plumbing to the top port of the T-fitting. See **Fig. 5**.
4. On the secondary (dry) side of the reservoir, on the side port of the T-fitting, install a check valve, then a 45-degree elbow.
5. On the supply (wet) side of the reservoir, on the side port of the T-fitting, install the straight brass fitting.
6. Install a 1/2-inch air line between the 45-degree elbow on the secondary (dry) side, and the brass fitting on the supply (wet) side.
7. Charge the air system and inspect for leaks.
8. Remove the chocks from the tires.

General Information

This troubleshooting guide is designed to help locate causes of problems originating in the air brake system. The corrective measures given are not intended to replace the detailed service information found in other sections of this manual or in the component manufacturer's service manuals. If the vehicle is equipped with ABS (antilock brake system), refer to the applicable section in this group for troubleshooting the ABS system.

Before attempting to isolate the causes of an air brake system problem, do the following.

1. Check the operation of the air compressor. Refer to the engine manufacturer's service manual.

   Check the pressure levels of the air reservoirs. Refer to the pretrip inspection and daily maintenance chapter in the vehicle driver's manual.
2. Be sure that all relay valves are operating. Refer to the brake section in the vehicle maintenance manual.
3. Check the operation of the brake chambers as instructed in the brake section in the vehicle maintenance manual.
4. Examine all tubing for kinks, dents, and other damage. Replace damaged tubing.
5. Examine all hoses for cracks, drying out, overheating, and other damage. Replace damaged hoses.
6. Examine all air line fittings. Tighten loose connections; replace fittings that are damaged. For instructions, refer elsewhere in this group.
7. Examine leaking pipe connections for cracks or thread damage; replace as needed. If there is no damage, retighten the fitting. For instructions, refer elsewhere in this group.

Safety Precautions

⚠ WARNING

WARNING: Follow the manufacturer's procedures while working on any air device. Some parts are subject to mechanical (spring) or pneumatic propulsion and may cause personal injury or property damage when released. Failure to take all necessary precautions during servicing of the air brake system can result in personal injury or property damage.

Compression and storage of air in the air brake system is comparable to the energy in a coiled spring: when released, it may present a hazard. Because of this, certain precautions are required.

1. Chock the tires. This will prevent accidental rolling of the vehicle when air is released from the brake system.
2. Don't disconnect pressurized hoses because they will whip as air escapes from the line. Drain the air system before disconnecting the air hoses.
3. When draining the air system, do not look into the air jets or direct them toward another person: dirt particles or sludge may be carried in the air stream.
4. As air pressure is drained and the parking/ emergency brakes apply, keep your hands away from the brake chamber push rods and parking brake chambers, which will activate automatically with the loss of pressure.

The air pressure gauge(s) on the dash is (are) registering inaccurately.	Check the dash gauge(s) with an accurate test gauge. Replace the dash gauge(s) as needed.
There is excessive leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.
The compressor is inoperative (including excessive leakage of the compressor).	Rebuild or replace the compressor.
The air reservoir drain cock has been left open.	Close the drain cock.

Fig. 1, Port Locations

The BP–R1 bobtail proportioning relay valve is a combination of two individual valves in a single housing. The lower portion (body) of the BP–R1 contains a standard service brake relay valve, which functions as a relay station to speed up brake application and release. The upper portion (cover) houses a brake proportioning valve, which adjusts the proportion of normal brake application pressure to the rear brake chambers when the tractor is not towing a trailer.

Used in tractor air brake systems only, the BP–R1 is installed in place of a standard relay valve. It functions as a standard service relay during operation of a tractor-trailer combination. During bobtail tractor operation, the BP–R1 improves controllability and reduces stopping distances by limiting air pressure to the rear brake chambers, whose axle load has been greatly reduced, while retaining normal air pressure to the front brake chambers. This reduces the chance of rear wheel lock and instability in emergency stops.

The rear brake proportioning system is standard on all tractors. The valve is mounted on the crossmember between the rear brake chambers.

A control line from the control port of the BP–R1 valve is connected to the inlet supply port of the tractor protection valve. This line is charged with full line pressure when a trailer is connected and its spring brakes are released; or is completely exhausted when the tractor is bobtailed and the dash valve trailer charge knob is not applied.

TRAILER SUPPLY VALVE APPLIED (TRACTOR/TRAILER MODE)

On vehicles equipped with a proportioning system, air pressure at the control port allows full service air from the foot valve to pass through the proportioning portion of the valve. This gives full braking effort to the rear axles when a trailer is connected.

TRAILER SUPPLY VALVE PULLED OUT (BOBTAIL MODE)

When the trailer supply valve is activated to disconnect the trailer, air in the BP–R1 control port is exhausted to atmosphere. In this mode, service application air exerts force on one side of the blend-back piston and also flows through the piston to exert force on the proportioning piston. The blend-back piston remains stationary at application pressures below 80 psi (551 kPa). Air also flows through the proportioning piston to exert force on both sides of it. Proportioning occurs due to the difference in effective area on each end of the proportioning piston. Service applications of more than 80 psi (551 kPa) cause the blend-back piston to begin to move. Above 80 psi (551 kPa) the different pressures on each side of this piston cause a "blend back" from proportioned delivery to a full one-to-one delivery.

Safety Precautions

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

When working on or around air brake systems and components, observe the following precautions.

1. Apply the parking brakes, chock the tires, and stop the engine when working under the vehicle. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air system pressure drops.
2. Wear safety goggles.
3. Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
4. Don't disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
5. Replacement hardware, tubing, hose, fittings, etc. should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace any components that have stripped threads or damaged parts. Don't attempt to repair parts by machining.
7. Never exceed recommended air pressure.

Operating Tests

1. Park the vehicle on a level surface and chock the tires.
2. Before testing the air brake proportioning system, do the following checks.
   - 2.1 Check the operation of the air compressor. Check the pressure levels of the air reservoirs.
   - 2.2 Be sure that all related valves are operating properly.
   - 2.3 Check the operation of the brake chambers following the instructions in the brake section in the vehicle maintenance manual.
   - 2.4 Inspect all tubing for kinks, dents, and other damage. Replace damaged tubing.
   - 2.5 Inspect all hoses for cracks, drying out, overheating, and other damage. Replace damaged hoses.
   - 2.6 Inspect all air line fittings. Tighten loose connections; replace fittings that are damaged.
3. Drain all air tanks to zero pressure.
4. Install a tee at the BP–R1 service port and at one of the delivery ports, then install a gauge in each.
5. Connect the tractor service and emergency gladhands to hose couplings that have been plugged; or, connect them to a trailer. Build the tractor system air pressure to governor cut-out.
6. With the dashboard trailer supply valve and system park control valve activated for tractor/trailer operation, apply, *hold*, and then release the brakes several times, varying the application pressures while watching the reaction of the gauges installed on the BP–R1. Note that a prompt application occurs and that it can be held, then promptly released.
7. Check the BP–R1 differential pressure by applying 10 psi (69 kPa) to the service port and noting the pressure registered at the delivery port. Subtract delivery port pressure from the 10 psi (69 kPa) service pressure to obtain the differential.

   NOTE: For BP–R1 valves that *don't incorporate* a relay piston spring (**Fig. 1**, Ref. 9), the measured differential should be about 4 psi (28 kPa). When a spring is in use, the differential will be higher.
8. Make and hold a full brake application of 100 psi (689 kPa) or greater, and note that full pressure is delivered to the chambers.
9. Activate the dash mounted trailer supply valve for bobtail tractor operation. Make a *slow* brake application and watch the gauges installed previously. Both gauge readings should rise until the delivery pressure is 5 to 10 psi (34 to 69 kPa). Then the service supply pressure should continue rising while delivery pressure remains constant. Hold the brake application at 20 psi (138 kPa) and check that the delivery pressure is 5 to 10 psi (34 to 69 kPa). Release the application.
10. Make another brake application and *slowly* increase the pressure at the BP–R1 service port to between 60 and 70 psi (414 to 483 kPa) while observing the gauge installed at the delivery port. Note that when service port pressure rises to between 20 and 30 psi (138 to 207 kPa), delivery pressure begins to rise above the initial pressure noted previously. The rise of delivery pressure should be at a proportioned rate of *about* three-to-one. At 70 psi (483 kPa) service pressure, delivered pressure should be 15 to 25 psi (103 to 172 kPa).
11. Make a full brake application, and note that both test gauges register the same pressure.
12. Remove the test gauges from the BP–R1.
13. Remove the chocks from the tires. Test drive the vehicle (without a trailer) in a safe area at slow speed with the trailer supply valve pulled out (bobtail position). Make several brake applications to become familiar with the feel of the system before placing the vehicle back in service.

Assembly

1. Prior to assembly, lubricate all O-rings (identify them by referring to **Table 1**), seals, and pistons, as well as body and cover bores, using the lubricant provided in the Bendix maintenance kit. Use all of the lubricant, and spread it evenly on the rubbing surfaces.

General Description

The Haldex (SAB) automatic slack adjuster, shown in **Fig. 1**, serves two main functions:

- As a lever, it converts the straight-line force of the air brake chamber pushrod to torque on the brake camshaft. Rotation of the camshaft spreads the brake shoes out against the brake drum, applying the brakes.
- As an adjuster, it maintains cam brake chamber pushrod stroke and lining-to-drum clearance automatically during normal use.

Principles of Operation

When the brakes are applied, the slack adjuster rotates and moves the shoes into contact with the drum. As the brake application continues, the rack moves upward and rotates the one-way clutch, which slips in this direction.

6. One-Way Clutch

8. Clutch Wheel

Fig. 1, Haldex Slack Adjuster

As the brake torque increases, the coil-spring load is overcome and the wormshaft is displaced axially, releasing the cone clutch.

When the brake begins its return stroke, the coil spring load returns to normal and the cone clutch is again engaged. The rack is pulled back to its original position in the notch. Any additional travel brought about by brake lining wear causes the rack to turn the locked one-way clutch and rotates the wormshaft through the locked cone clutch. The wormshaft then rotates the worm wheel and camshaft, adjusting the brakes.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc., should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Slack Adjuster Removal, Installation, and Brake Adjustment

⚠ WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

Removal

1. Park the vehicle on a level surface, set the parking brakes, and shut down the engine. Chock the front and rear tires.
2. If a rear-axle slack adjuster will be removed, release the parking brakes and cage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this group.
3. Remove the anchor bracket fasteners and the anchor bracket. See **Fig. 1**.

4. Remove the cotter pin from the clevis pin. Remove the clevis pin.
5. Remove the snap ring that secures the slack adjuster on the camshaft.

NOTICE

Do not use an impact wrench on the adjusting hexnut. To do so may damage the slack adjuster or camshaft.

6. Using a 7/16-inch box wrench, turn the adjusting hexnut counterclockwise to move the adjuster arm out of the clevis. A minimum of 13 lbf·ft (18 N·m) is required to overcome the internal clutch. You will hear a ratcheting sound.
7. Remove the slack adjuster from the camshaft.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing a new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

1. Check that the brake-chamber pushrod is fully retracted.
2. Apply antiseize compound to the camshaft splines.

IMPORTANT: When correctly installed, the brake-chamber pushrod pushes in the direction of the arrow on the slack adjuster housing.

3. Install the slack adjuster on the camshaft, with the adjusting hexnut pointing away from the brake chamber. See **Fig. 2**.
4. Using a snap ring, secure the slack adjuster on the camshaft. Use at least one inner washer and enough outer washers to allow no more than 0.060-inch (1.52-mm) movement on the shaft.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting hexnut for positioning.

5. Using a 7/16-inch box wrench, turn the adjusting hexnut clockwise until the slack adjuster hole is aligned with the pushrod clevis hole. See **Fig. 2**.

Fig. 2, Slack Adjuster Installation

6. Apply antiseize compound to the clevis pin, and insert the pin in the clevis hole. Do not install the cotter pin at this time.

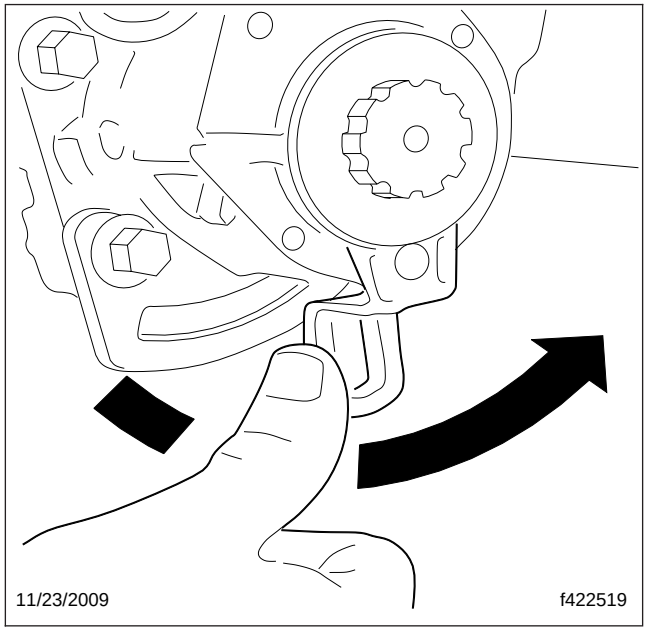
NOTICE

Never hammer the control arm. Hammering may damage the slack adjuster or camshaft splines.

7. The control arm can be placed anywhere within the range of the bracket slot for automatic adjustment to take place. However, Haldex recommends rotating all control arms towards the axle until they come to a complete stop, as shown in **Fig. 3**, and then secure the arm in that position. This will create a "common" position for all wheels.

NOTE: The anchor bracket and slack adjuster housing design will vary, depending on the axle. The anchor bracket mounting location is determined by the length of the control arm.

8. Install the control-arm anchor bracket, as follows. See **Fig. 1**.



11/23/2009 f422519

Fig. 3, Positioning the Control Arm

8.1 Tighten the anchor bracket fastener at the control arm 10 to 15 lbf·ft (14 to 20 N·m), making sure the control arm does not move from its position.

8.2 Tighten the fastener at the brake chamber mounting stud according to the brake chamber manufacturer's specifications.

9. Adjust the brakes. See "Brake Adjustment".

Brake Adjustment

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

Slack Adjuster Removal, Installation, and Brake Adjustment

1. Adjust the brake lining clearance by manually turning the adjusting hexnut clockwise until the brake lining contacts the brake drum, then back off the hexnut counterclockwise 1/2 turn. You will hear a ratcheting sound.

IMPORTANT: Incorrect installation can cause dragging brakes.

2. Make sure the brakes are still fully released. You should be able to remove the clevis pin without having the chamber clevis or slack arm move.

⚠ WARNING

Install and lock a new cotter pin in the clevis pin. Failure to do so could allow the pushrod to disengage from the slack adjuster, causing a loss of braking ability that could result in personal injury and property damage.

3. Install and lock a new cotter pin in the clevis pin.

IMPORTANT: Ensure that the air system has at least 100 psi prior to uncaging the brake chamber. This will aid in the uncaging of the parking brake since the parking brake should be fully released.

4. If a rear-axle slack adjuster was installed, manually uncage the parking brake. For instructions, refer to the applicable brake chamber section in this group.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

IMPORTANT: To check the brake adjustment, measure both the applied and free strokes.

NOTE: The location of the measurements is the same for both strokes but the applied stroke is measured with the brakes applied, while a lever is used to manually move the slack adjuster to measure the free stroke.

5. Measure the free stroke, as follows. The free stroke is the distance the slack adjuster has to travel to move the brake shoes against the drum.
   - 5.1 With the brakes released, measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement A.
   - 5.2 Using a lever, move the slack adjuster until the brake shoes contact the drum. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement B.
   - 5.3 Subtract measurement A from measurement B to determine the free stroke. For new brake installations, the free stroke should be 5/8 to 3/4 inch (16 to 19 mm). For in-service brakes, the free stroke should be 1/2 to 5/8 inch (13 to 16 mm).
6. Measure the applied stroke, as follows.
   - 6.1 With the brakes released (pushrod fully retracted), measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. See **Fig. 4**. Record the exact distance as measurement A.
   - 6.2 Apply and hold an 80 psi (552 kPa) brake application. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement B.
   - 6.3 Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 1**.
7. Apply the parking brakes.
8. Remove the chocks from the tires.
9. In a safe area, check for proper brake operation, as follows.
   - 9.1 Apply and release the brakes several times to check for correct operation of the slack adjusters.
   - 9.2 Perform six low-speed stops to ensure correct parts replacement and full vehicle control.
   - 9.3 Immediately after doing the above stops, check the drum temperatures. Any drums

Slack Adjuster Removal, Installation, and Brake Adjustment

that are significantly cooler than the others show a lack of braking effort on those wheels.

When installing a nylon tube, be careful not to bend it past its minimum bend radius. For minimum bend radius values, refer to the appropriate table in **Specifications, 400**.

CAUTION

CAUTION: If the tubing is bent to a radius smaller than the specified minimum bend radius, it may kink, and shut off normal airflow to the component.

1. Cut the end of the tubing smooth and square.
2. Make sure the nylon tubing ends and fittings are free of grease and debris. If the tubing is crimped or otherwise damaged, replace it with new tubing.
3. Install a new sleeve in the nut.
4. Insert the squared end of the tubing in the fitting, until it bottoms in the body of the fitting. See **Fig. 3**.

A. Tube end must bottom before tightening the nut.

Fig. 3, Installing Nylon Tubing

5. Tighten the nut finger-tight. Then, using two wrenches to prevent twisting of the tube, tighten the nut a minimum of 2 turns (refer to the appropriate table in **Specifications, 400**) or until one thread shows on the fitting body.

WIRE BRAID HOSES (See Fig. 1)

When installing a wire braid hose, be careful not to bend it past its minimum bend radius. For minimum bend radius values, refer to the appropriate tables in **Specifications, 400.**

CAUTION

CAUTION: If the hose is bent to a radius smaller than the specified minimum bend radius, it may kink, and shut off normal airflow to the component.

Installing Air Lines and Fittings

Make sure the wire braid hose assembly is free of grease and dirt. Replace the assembly if the hose or fitting is crimped or otherwise damaged.

Install the hose and tighten the nut finger-tight. Then, using two wrenches to prevent twisting of the hose, tighten the nut until it seats solidly. Tighten the nut one-sixth turn more.

Installing Fittings

BRASS AND STEEL PIPE FITTINGS (See Fig. 1)

For brass pipe fittings, both male and female parts, tighten as follows:

1. Make sure the fittings are free of grease, dirt, and old sealant. Apply liquid Loctite® Hydraulic Sealant (brown), or an equivalent, to the threads, then tighten securely, finger-tight.

NOTE: Always apply the sealant to the external thread, so that any excess will be scraped off externally rather than internally to the joint.

2. For fittings that must be positioned, tighten one additional turn from finger-tight using a wrench.

   Then, continue tightening until the fitting is correctly positioned.

   For fittings that do not require positioning, tighten 1-1/2 additional turns from finger-tight.

COPPER TUBE FITTINGS

For copper tube fittings, tighten the nut finger-tight. Then, using two wrenches to prevent twisting of the tube, tighten the nut the number of turns shown in the table in **Specifications, 400.**

QUICK-CONNECT FITTINGS

NOTE: If damaged, quick-connect fittings must be replaced as an assembly.

1. Push in on the fitting collar to release the air line. Pull the line out of the fitting. See **Fig. 4**.
2. Push the air line all the way into the fitting. Pull the collar away from the fitting to secure the air line. Check and make sure that the air line is seated in the fitting.

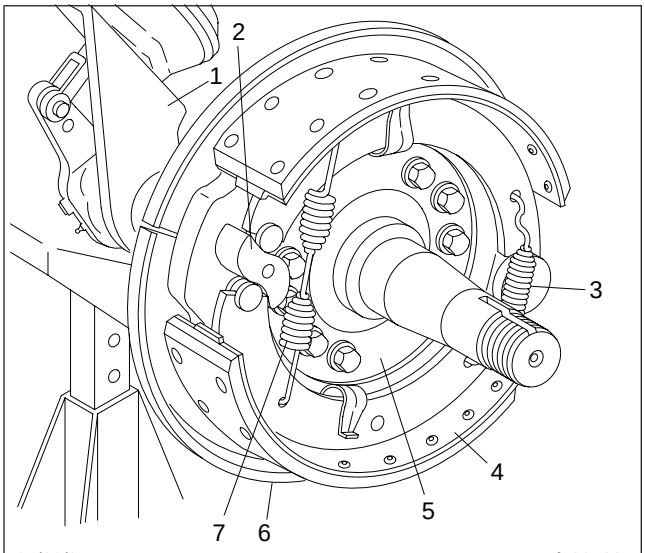
General Information

Eaton brakes **(Fig. 1)** are actuated by an S-type cam head, which is forged integrally with the camshaft and supported with nylon bushings. Cam pressure is applied through the cam rollers.



1. Air Chamber Bracket
2. Camshaft
3. Shoe Retaining Spring
4. Shoe Assembly
5. Spider
6. Dust Shield
7. Shoe Return Spring

Fig. 1, Front Axle Brake

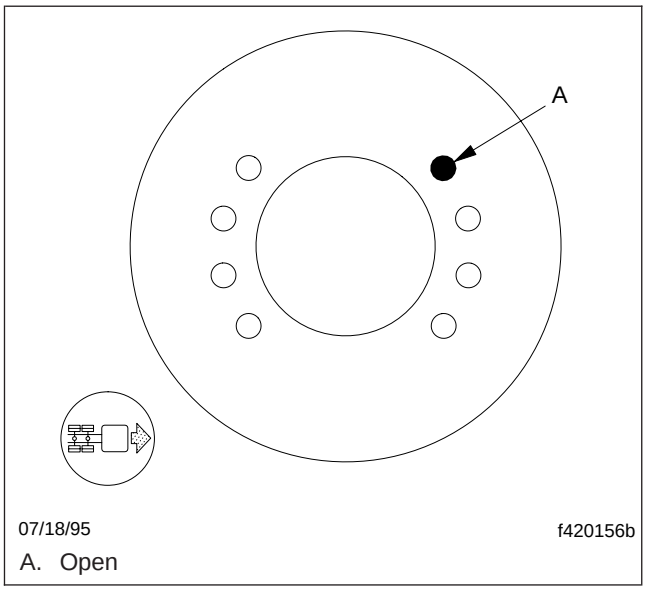
These brakes are used on both the front steer axle and rear axle.

Rockwell steer axles have seven holes for attaching the spider to the axle flange. There is an eighth hole that is left open on the brake spider, on both left and right sides of the steer axle. **See Fig. 2**, Ref. A. The seven holes used for attachment of the spider to the axle flange are 0.656 inch in diameter. The eighth hole is oversized at 0.687 inch in diameter.

Principles of Operation

When the brake pedal is depressed, compressed air enters the brake chamber, causing the diaphragm to move a push rod assembly.

The push rod, which is connected to a slack adjuster, turns the slack adjuster and brake camshaft. As the camshaft turns, the S-head, which is between the



A. Open

brake shoe rollers, forces the brake shoes against the brake drum, and braking occurs.

When the brakes are released and air is exhausted from the brake chamber, the actuator return spring (within the brake chamber) and the brake shoe return spring, return the camshaft, brake shoes, slack adjuster, and push rod to their released positions.

General Safety Precautions

⚠ WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Asbestos and Non-Asbestos Safety

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH.

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Exposure to airborne asbestos brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by OHSA regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

Safety Precautions

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

If grinding or other machining of the brake linings is necessary, other precautions must be taken because exposure to asbestos dust is highest during such operations. In addition to the use of an approved respirator, there must be local exhaust ventilation such that worker exposure is kept as low as possible.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Asbestos-containing waste, such as dirty rags, should be sealed, labeled, and disposed of as required by EPA and OSHA regulations. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

Workers should wash before eating, drinking, or smoking, should shower after work, and should not wear work clothes home. Work clothes should be vacuumed after use and then laundered, without shaking, to prevent the release of asbestos fibers into the air.

Removal

4. Install the wheels and brake drums. For instructions, refer to **Group 33** or **Group 35** in this manual.

   If working on the rear axle, manually uncage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this manual.

5. Adjust the brakes at the slack adjusters. For instructions, refer to **Subject 125**.

6. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

WARNING: Don't operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

7. In a safe area, check for proper brake operation.

   7.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.

   7.2 Do several low speed stops to ensure proper parts replacement and full vehicle control.

   7.3 Make ten 40 to 20 mph (60 to 30 km/h) snubs to seat the linings.

   7.4 Make ten stops from 20 mph (30 km/h) at 50 percent air pressure.

   7.5 Make a full-pressure stop from 20 mph (30 km/h).

   7.6 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others shows a lack of braking effort on those wheels.

Inspection

WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Remove the brake shoes. Refer to **Subject 110** for instructions.
2. Check the linings.

   On 15-inch series brakes, if the linings are grease- or oil-soaked, cracked, or worn to less than 3/16-inch (4.5-mm) thickness at any point (the lining surface should be no closer than 1/16 inch [1.5 mm] to any rivet head), replace them. **See Fig. 1.**

   On 16-1/2 inch series brakes, if the linings are grease- or oil-soaked, cracked, or worn to less than 1/4-inch (6.4-mm) thickness at any point, replace them.

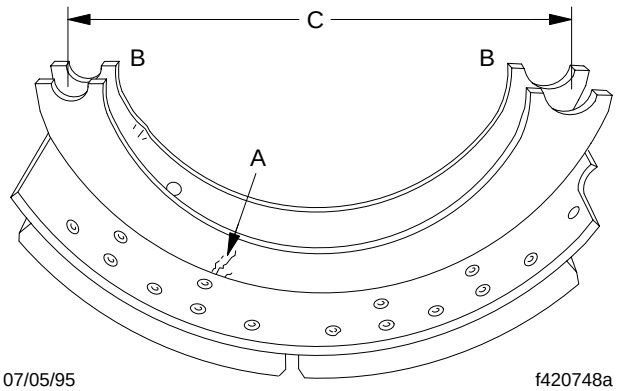
A. Check for cracks or contamination.
B. No closer than 1/16" (1.5 mm) to any rivet head.
C. 3/16" (4.5 mm) minimum thickness.

Fig. 1, Check the Brake Shoe (15-Inch Series shown)

3. Check the shoes for bent or cracked webs or tables, broken welds, loose rivets, or out-of-round rivet holes. **See Fig. 2.** Replace the shoes if any of these conditions exist.



07/05/95 f420748a

A. Check table and web for cracks or bends.
B. Check both ends for wear and elongation.
C. Measure this distance.

Fig. 2, Measuring the Shoe Span

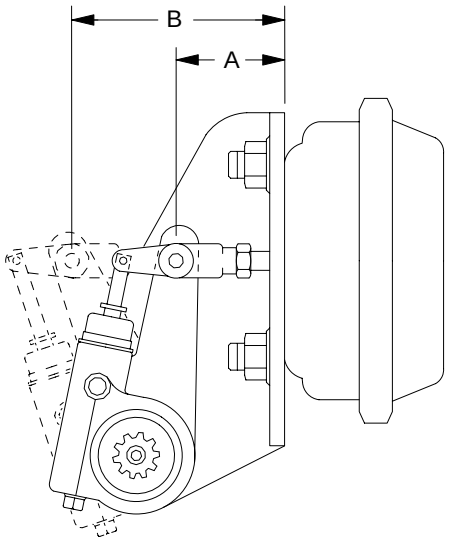
4. Check the anchor pin for looseness and camshaft roller recesses in the shoe webs for visible wear. Replace the shoe if needed.
5. Check the shoe span. Measure the distances between the centerlines of the anchor pin and camshaft roller pin recesses in the shoe web. **See Fig. 2.** On 15-inch series brakes, if the measurement is more than 11-3/4 inches (298 mm), replace the shoe. On 16-1/2 inch series brakes, if the measurement is more than 12-9/16 inches (319 mm), replace the shoe.

Adjustment

ROCKWELL AUTOMATIC SLACK ADJUSTER

1. Check the free-stroke.

   1.1 With the brakes fully released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 1**, Ref. A.



NOTE: Subtract measurement A from B.

A. Measurement With Brakes Released
B. Measurement With Brakes Applied

Fig. 1, Measuring the Initial Free-Stroke

   1.2 Use a pry bar to move the slack adjuster and apply the brakes. Again, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 1**, Ref. B.

   1.3 The difference between the two measurements is the initial free-stroke, and sets the clearance between the linings and the drum.

   1.4 The free-stroke must be 5/8 to 3/4 inch (16 to 19 mm).

   If the free-stroke is correct, go to the next step and check for correct brake chamber stroke.

   If the free-stroke is incorrect, remove the pressure relief capscrew (**Fig. 2**, Ref. 16), spring (Ref. 18), and pawl assembly (Ref. 19) from the slack adjuster housing. If equipped with a pull-pawl assembly (**Fig. 3**), carefully insert a screwdriver and raise the relief cap about 1/8 inch (3.2 mm).

⚠ CAUTION

CAUTION: Before turning the adjusting nut, remove the pressure relief capscrew, spring, and pawl assembly. If equipped with a pull-pawl assembly, raise the relief cap about 1/8 inch (3.2 mm). Failure to do so could strip the teeth on the pawl.

   1.5 Turn the adjusting nut 1/8 turn, as shown in **Fig. 4**. Measure the stroke again, and adjust until it is correct.

2. Check for correct brake chamber stroke.

   2.1 With the brakes fully released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 1**, Ref. A.

   2.2 Build air pressure to 100 psi (689 kPa). Shut down the engine. Fully apply the brakes, then measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 1**, Ref. B. The difference between the measurements is the brake chamber stroke.

   2.3 The brake chamber stroke must be less than the measurements shown in **Table 1.** If the brake chamber stroke is incorrect, remove the pressure relief capscrew (**Fig. 2**, Ref. 16), spring (Ref. 18), and pawl assembly (Ref. 19) from the slack adjuster housing. If equipped with a pull-pawl assembly (**Fig. 3**), carefully insert a screwdriver and raise the relief cap about 1/8 inch (3.2 mm).

CAUTION

CAUTION: Before turning the adjusting nut, remove the pressure relief capscrew, spring, and pawl assembly. If equipped with a pull-pawl assembly, raise the relief cap about 1/8 inch (3.2 mm). Failure to do so could strip the teeth on the pawl.

2.4 Turn the adjusting nut 1/8 turn, as shown in **Fig. 4**. Measure the stroke again, and adjust until correct.

If the stroke varies or remains greater than the specified range, check brake components. For instructions, refer to **Subject 140.** If necessary, replace the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

CAUTION

CAUTION: Don't make the adjusted chamber stroke too short. The free-stroke must not be less than 5/8 to 3/4 inch (16 to 19 mm). If the chamber stroke is too short, the linings can drag and damage the brake.

2.5 If removed, install the pawl assembly, spring, and the pressure relief capscrew. Tighten the capscrew 15 to 20 lbf·ft (20 to 27 N·m). Or, remove the screwdriver from the pull-pawl assembly (if equipped).

HALDEX AUTOMATIC SLACK ADJUSTER

1. Turn the adjusting hexnut clockwise until the brake lining meets the brake drum, then back off counterclockwise 3/4 turn. See **Fig. 5**. There will be a ratcheting sound.
2. Measure the distance from the bottom of the air chamber to the far side of the clevis-pin hole (**Fig. 6**, Ref. A). Record the exact distance as measurement A. Apply and hold an 80 psi (551 kPa) brake application. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole (**Fig. 6**, Ref. B). Record the exact distance as measurement B. Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 2.**

Replacement

WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

IMPORTANT: For the best brake performance, don't mix brake linings between axles. When relining brake shoes, both wheel ends of each axle must have the same linings. On tandem axles, all four wheel ends must also have the same linings. However, it is not necessary for the steering axle brakes to have the same linings as the rear drive axle brakes. Also, when the minimum thickness is reached for any of the brake linings on an axle, reline both brakes on that axle at the same time.

NOTE: Replace the springs each time the brakes are relined. Eaton recommends replacement of the rollers and pins at each reline.

1. Remove the brake shoes. For instructions, refer to **Subject 110.**

CAUTION

CAUTION: Drilling out rivets or cutting off rivet heads with a chisel can cause the rivet hole to become out-of-round. This could damage the brake shoe.

2. Using a suitable riveting mandrel, push out (do not drill out) the old rivets.
3. Clean the shoe table. For instructions, refer to **Subject 140.**

CAUTION

CAUTION: Make sure that the replacement lining material conforms to FMSI 1308. The FMSI number indicated is a standard for lining size and shape only. Use of an improper FMSI lining specification or friction material type may cause brake dragging, grabbing, or improper brake performance.

4. Align the brake shoe and lining rivet holes. Using a C-clamp, clamp the lining to the brake shoe.
5. Insert the correct sized rivets into all holes in the new block, and temporarily hold them in place with masking tape.

IMPORTANT: Use rivets that have the correct material, shank diameter, length, head size, and shape. Use tubular rivets that are 1/4-inch (6-mm) diameter by 1/2-inch (13-mm) long, SAE no. 10-8, made of zinc- or brass-plated steel.

6. Begin riveting at the center of each edge of the shoe and lining, and work toward each end.
7. Check for a close fit between the lining and shoe table.

   Try to insert a 0.006-inch (0.15-mm) feeler gauge between the lining and shoe table along the edges. **See Fig. 1**, Ref. A. It should not be possible to insert the gauge anywhere along the edge, except at each end beyond the last row of rivets. A larger clearance may exist in these areas.

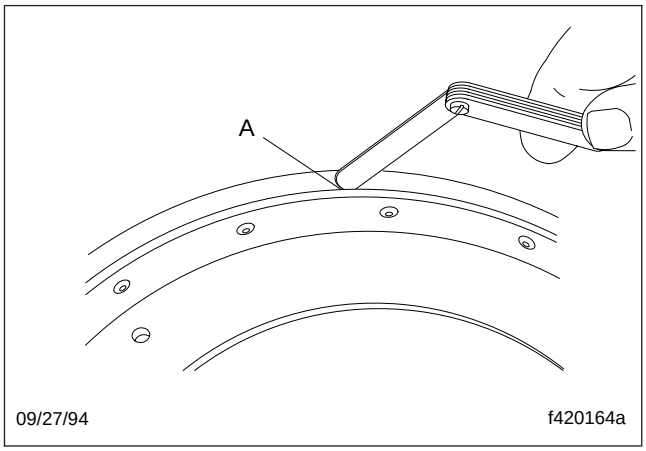

Fig. 1, Insert the Feeler Gauge between the Lining and Shoe Table

IMPORTANT: Always adjust the brakes at the slack adjusters after replacing the linings. For instructions, refer to **Subject 125.**

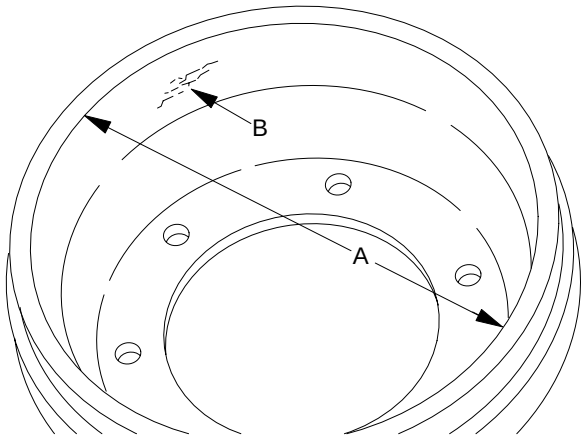
WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Check the drum for cracks, heat checks, glazing, grooving, run-out, and out-of-round. See Fig. 3.

   Measure the drum diameter. Replace the drum if it exceeds the maximum diameter stamped on it. Replace cracked drums.

   Some drums that are glazed, grooved, or out-of-round can be repaired. For detailed instructions, refer to the front or rear axle section in this manual.



A. Check for diameter and for out-of-round.
B. Check for cracks, heat checks, glazing, and grooves.

Fig. 3, Check the Drum

2. Disconnect the slack adjuster from the push rod clevis. For instructions, refer elsewhere in this group, or to the manufacturer's service information for instructions.
3. With the brake shoes removed, use a dial indicator to measure the up-and-down and side-to-side end-play of the camshaft. Replace the bushings if there is more than 0.020 inch (0.5 mm) of movement.

CAUTION

CAUTION: Don't hammer on the slack adjuster to remove it. Damage to the adjuster or camshaft spline may result.

4. Remove the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group, or to the manufacturer's service information for instructions.
5. Check the slack adjuster for damage and for binding.

   5.1 Check the slack adjuster clevis for cracks or bushing wear. Check the splines for chipped teeth and deformation. Replace as needed.

   5.2 Depress the locking sleeve, and turn the adjuster nut with a wrench at least one turn in each direction. If there is binding, or if excessive force is needed to turn the adjuster, replace it. For instructions, refer elsewhere in this group.

   IMPORTANT: If any slack adjuster problem is found, repair or replace the unit, depending on the manufacturer's recommendations.

6. Remove the camshaft by grasping its head and pulling the camshaft outboard.
7. Check the camshaft spline end for cracks, or worn or deformed splines. Replace the camshaft if damaged.
8. Check the camshaft bushing journals for wear or corrosion. Replace the camshaft if it is worn or if roughness is felt in the journal area.
9. Inspect the camshaft head for brinelling, cracking, or flat spots. Replace the camshaft if a ridge can be felt between the worn area and the cam head surface.
10. Remove the brake chamber stud nuts and lockwashers that attach the brake chamber to the camshaft support bracket. Check the chamber and parts for problems.

    Check the brake chamber for a cracked housing, bent push rod, loose clamp ring, loose air fitting, air leaks, or clogged vent holes. Repair or replace parts as needed. For instructions, refer elsewhere in this group.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

11. Remove and inspect the camshaft support bracket. Remove and discard its gasket. Check the bracket for a bent, broken, or cracked arm, and for cracked welds. Replace the bracket if any of these conditions exist.
12. Remove and inspect the old bushing and the grease seal.
    - 12.1 Check the camshaft bushing for wear. The inner surface must be smooth; if rough or abrasive, replace the bushing.
    - 12.2 Inspect the seal. Replace it if the lip is nicked, cut, or distorted.
13. On 15-inch brakes, check the stabilizing screw for bends, looseness, or damaged threads.

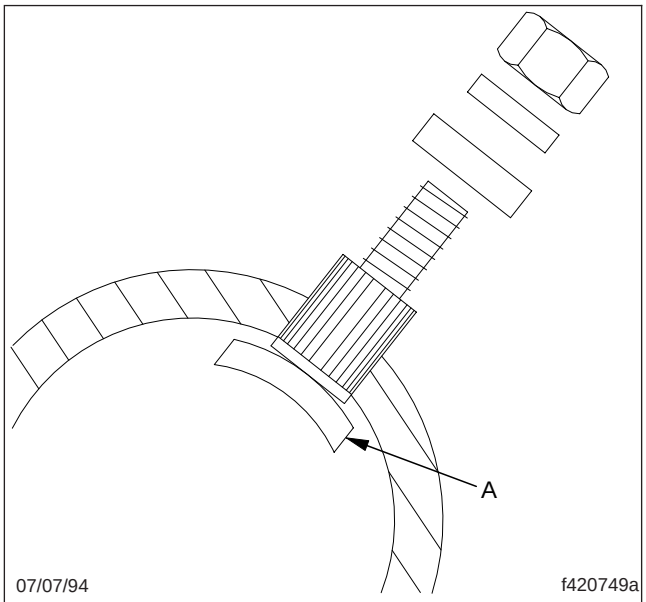
⚠ WARNING

WARNING: Wear eye protection when driving the screw into the camshaft bracket tube with a pin punch and hammer. Failure to wear eye protection could result in personal injury due to flying metal debris.

14. If necessary, replace the stabilizing screw.
    - 14.1 Remove the damaged screw by driving it into the camshaft bracket tube with a pin punch and hammer.
    - 14.2 Aligning the curvature of the screw head (**Fig. 4**) with the curvature of the bracket tube, install the new screw.
    - 14.3 Install the spacer, lockwasher, and nut. Tighten the nut 23 to 27 lbf·ft (31 to 37 N·m) to draw the screw serrations uniformly through the camshaft bracket tube wall.
    - 14.4 Remove the nut and washer before assembling the bracket on the spider.
15. Using a suitable piloted driver, install the new bushing or seal.

    On 15-inch brakes, install the new bushing to a depth of 3/8 inch (9.5 mm) from each end of the bracket tube. See **Fig. 5**.

    On 16-1/2 inch brakes, install the new bushing to a depth of 22/32 inch (17.5 mm) at the slack adjuster end of the bracket tube and to a depth of 9/32 inch (7.1 mm) at the cam head end of the bracket tube.



A. Align curvature of the head with the curvature of the of the camshaft bracket tube.

Fig. 4, Align the Screw Head

Install the grease seal flush with the end of the air chamber bracket tube.

IMPORTANT: Grease seals are installed in both the bracket and the brake spider so that the seal lip is facing toward the slack adjuster end of the bracket tube. See **Fig. 6**.

16. Remove the spider-to-axle attaching nuts, hardened washers, and bolts; remove the spider from the axle flange.
17. If equipped, remove the capscrews that attach the dust shield to the spider; remove the dust shield.
18. Inspect the spider and parts for damage; replace as needed.
    - 18.1 Check for cracks at the bolt holes, cam area, and around the anchor pin. Replace if damaged.
    - 18.2 Check the anchor pin (**Fig. 7**). If the pin is loose, or grooved more than 0.03 inch (0.8 mm) below the original surface, replace the spider assembly.
    - 18.3 Check the anchor pin and brake spider bushings for deterioration. The inner sur-

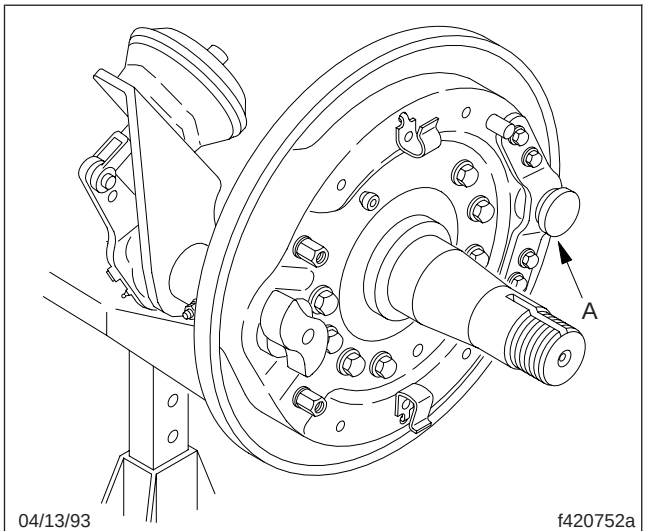
faces must be smooth. If any surface is rough or abrasive, replace the part.



A. Check for grooving and looseness.

Fig. 7, Check the Anchor Pin

18.4 On 15-inch brakes, check the anchor pin reinforcement plate attaching nuts (**Fig. 8**, Ref. A) for tightness. If needed, tighten the nuts 35 to 40 lbf·ft (47 to 54 N·m).

Check the anchor pin retaining nut (**Fig. 8**, Ref. B) for tightness. If needed, tighten the nut 475 to 525 lbf·ft (644 to 712 N·m).

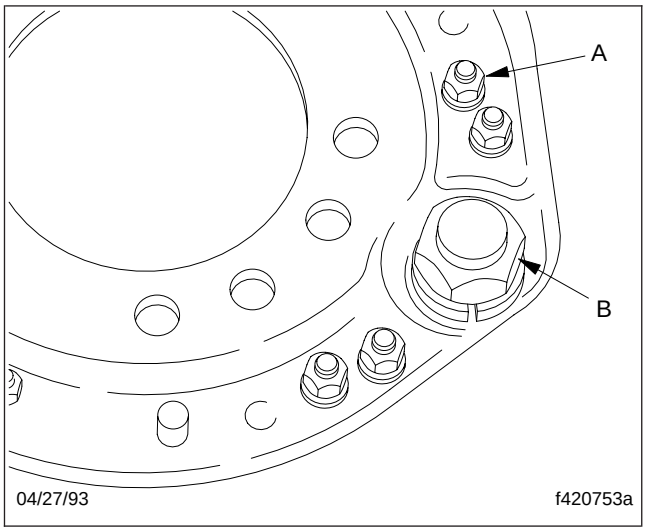


Fig. 8, Check the Anchor Pin Reinforcement Plate

IMPORTANT: If the anchor pin turns while checking the retaining nut torque, replace the

spider assembly. Eaton recommends replacement of the complete spider and pin assembly. Do not try to repair the spider assembly.

Cleaning

WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Wire brush all removed parts that have been exposed to mud, road dirt, and salt, including the exterior of the drum, spider, brake chamber bracket, and dust shields. If relining the shoes, thoroughly wire-brush the shoe tables, and paint with a rust inhibitive coating.

CAUTION

CAUTION: A thick layer of oxidation and dirt on the outside of a brake drum acts as an insulator and may hinder normal heat dissipation. Make sure oxidation and dirt are removed by wire brushing, or damage to brake parts could occur.

2. Using an industrial vacuum cleaner with a HEPA filter system, pick up excessive dust. Wipe the inside of the drums with a greaseless solvent to remove lining dust.
3. Thoroughly clean all remaining brake parts with a suitable shop solvent. Wipe dry with a clean, lint-free cloth, or use low-pressure filtered and compressed air.

Assembly (See Fig. 1 or Fig. 2)

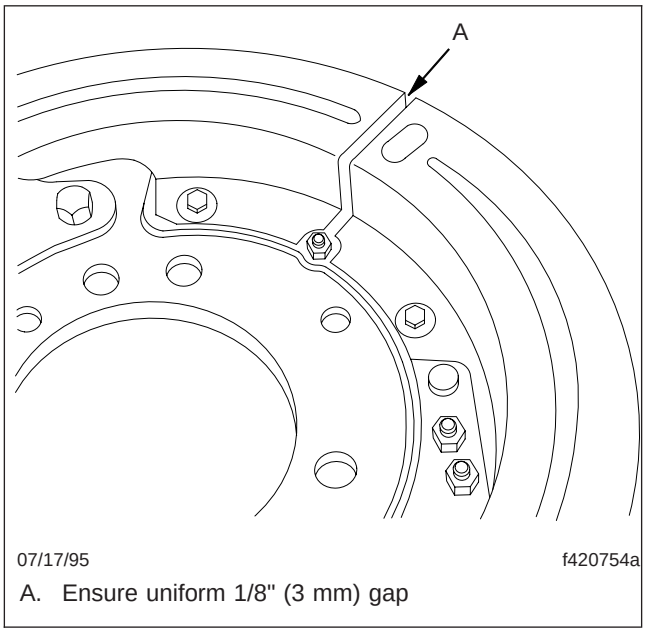
WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Install the dust shield (if equipped).

   If installing a one-piece dust shield, position it against the spider, and install the capscrews. Tighten the capscrews 11 to 16 lbf·ft (15 to 22 N·m).

   If installing a two-piece dust shield, position both halves against the spider. Tighten the attaching screws finger-tight. Reposition the dust shield halves to allow a uniform space of 1/8 inch (3 mm) along the mating edges. See Fig. 9. Tighten the screws 11 to 16 lbf·ft (15 to 22 N·m).



A. Ensure uniform 1/8" (3 mm) gap

Fig. 9, Position both halves of the Dust Shield against the Spider

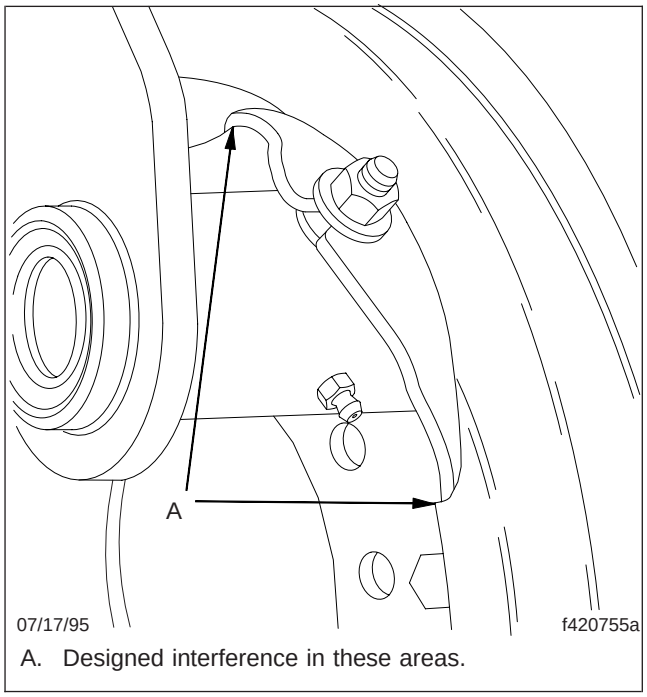
NOTE: A designed interference fit at the upper dust shield-to-brake chamber bracket area (Fig. 10) may cause the need to slightly deform the upper dust shield by hand to allow the upper half to align properly with the lower half.

2. Install the spider.

   Place the spider on the axle flange. Using a hardened washer under the bolt head and the nut, install the mounting fasteners. Tighten the bolts in a cross pattern:

   - 1/2–13; 60 to 80 lbf·ft (81 to 108 N·m)
   - 5/8–11 (flanged hexhead capscrew); 160 to 200 lbf·ft (217 to 271 N·m)

- 5/8–11 (hexhead capscrew); 130 to 160 lbf·ft (176 to 217 N·m)



A. Designed interference in these areas.

Fig. 10, Check the Fit at the Upper Dust Shield-to-Brake Chamber Bracket

3. Install the brake chamber and bracket.

   3.1 Place the brake chamber on the mounting bracket with the chamber mounting studs through the bracket holes. Install the lockwashers and stud nuts. Tighten the nuts. Refer to the brake chamber mounting torque table in **Specifications, 400.**

   3.2 Place the bracket against the spider, and install the lockwashers and barrel nuts. Tighten the nuts 55 to 65 lbf·ft (75 to 88 N·m).

   3.3 Install the washer, lockwasher, and nut on the stabilizing screw (if equipped). Tighten the nut 23 to 27 lbf·ft (31 to 37 N·m).

4. Install the camshaft and parts in the spider; install the slack adjuster.

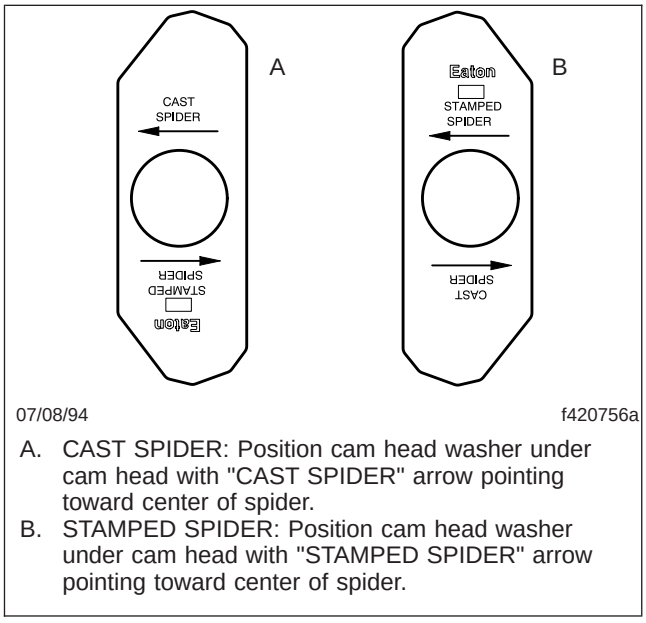
   4.1 Apply a thin film of chassis grease on the inside of the camshaft bushings and journals. Don't grease the camshaft head area.

   4.2 Apply a thin film of rust preventive grease (Rockwell 0-637, or an equivalent) on the camshaft splines.

   4.3 Carefully slip the camshaft into the spider and the mounting bracket tube.

   IMPORTANT: If equipped with Extended Service brakes, a special washer is installed between the cam head and the spider. See **Fig. 11** for installation instructions.

   4.4 Install the thick camshaft washer on the camshaft.



A. CAST SPIDER: Position cam head washer under cam head with "CAST SPIDER" arrow pointing toward center of spider.
B. STAMPED SPIDER: Position cam head washer under cam head with "STAMPED SPIDER" arrow pointing toward center of spider.

Fig. 11, Install the Special Washer

   4.5 Install the slack adjuster on the camshaft, with the adjuster nut on the side opposite of the brake chamber.

   4.6 Install the thin outer washer(s) and snap ring.

5. Use a dial indicator to measure the end play of the camshaft. There should be no more than 0.005 to 0.045 inch (0.1 to 1.1 mm) movement. Add outer washers as needed to correct.

6. Pressure lube the camshaft bracket bushings.

   Pump multipurpose chassis grease (NLGI grade 1 or 2) into the chamber bracket until it appears at the slack adjuster end of the bracket. Use

Brake Components Disassembly and Inspection, Cleaning, and Assembly

care that no grease enters the drum cavity. If grease leaks out under the cam head, the camshaft grease seal is worn or damaged, or is installed backwards.

NOTE: The use of meter-type fittings, having a maximum 40 psi (276 kPa) pressure relief at shutoff, is recommended.

7. Adjust the brakes at the slack adjusters. For instructions, refer to **Subject 125.**
8. Install the brake shoes. For instructions, refer to **Subject 110.**

General Description

A hand-operated brake valve is included in some air brake systems for tractor units pulling trailers, in addition to the standard foot brake valve and related equipment. This valve allows the driver independent control of the trailer brakes, which can be useful when checking trailer brakes, or changing adjustable fifth wheel locations.

The brake valve is mounted on the right side of the steering column. See **Fig. 1.**

2. Mounting Bracket
3. Trailer Brake Control Valve
4. Air Line Connections

Fig. 1, Trailer Brake Control Valve Installed on the Steering Column

Principles of Operation (See Fig. 2)

When the valve's control handle is moved in a clockwise direction, the cam compresses the graduating spring, which in turn forces the piston to move down. As the piston moves down, compressed air from the supply port flows to the delivery port, applying the trailer brakes through the trailer service line.

As air pressure builds in the trailer air system, the pressure under the piston will match the pressure of the compressed graduating spring. This moves the piston up enough to stop air flow through the valve, allowing air pressure in the trailer service brake system to remain constant.

When the control handle is moved counterclockwise, the cam moves up, releasing tension on the graduating spring. This allows the pressure below the piston to increase. The air pressure will then move the piston up and allow air in the service line to flow out of the exhaust port, releasing the trailer brakes.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may allow the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air—it may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released. Even when compressed air has been released at the reservoirs, residual air may still be trapped in the air lines.
3. Never exceed recommended air pressure, and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood the recommended procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to the use of those tools.

⚠ WARNING

WARNING: Don't use the hand brake valve to apply the trailer brakes for parking. It is not designed for this purpose. The air could bleed out of the trailer air tank allowing the vehicle to roll, which could cause personal injury, property damage, or damage to the vehicle.

Trailer Brake Control Valve Operating and Leakage Test

Test

1. Park the vehicle on a level surface and chock the tires.
2. Connect an accurate test gauge to the delivery port of the valve, or connect the gauge to the service hose coupling located behind the cab. When the gauge is connected to the service hose coupling, install a dummy hose coupling on the supply (emergency) hose coupling, and place the dash valve in the trailer charge position. When the valve control handle is moved to the fully applied position, the gauge should register full reservoir pressure.

NOTE: Midland valves are set to deliver full reservoir pressure. Intermediate positions should deliver proportional intermediate pressures. Upon manual release, the gauge should immediately register zero.

3. Locate the exhaust port or exhaust line and apply a soap solution.
4. With the valve in the released position, exhaust leakage should not exceed a 1-inch (2.5-cm) bubble in 5 seconds.

   With the valve fully applied, exhaust leakage should not exceed a 1-inch (2.5-cm) bubble in 5 seconds.
5. If the valve does not function properly or if leakage is excessive, replace the valve following the instructions in **Subject 120.**
6. Remove the chocks from the tires.

⚠ WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the safety precautions could result in personal injury.

Replacement

1. Chock the tires or hold the vehicle on a level surface by means other than the air brakes.
2. Drain the air system.

General Information

The DV–2 automatic reservoir drain valve **(Fig. 1)** automatically removes contaminants and water from the wet-air tank each time the brakes are applied. The drain valve is attached to a drain cock located on the bottom of either end of the wet-air tank. Since the brake application valve is protected by a check valve between the wet-and dry-air tanks, any leak or failure will not reduce the supply of air that is in the dry part of the system. If the leak is severe, it could prevent the continued resupply of air as it is used up when applying the brakes. A failed drain valve will allow moisture to build up in the wet tank which in turn could reach the dry tank, and then travel into the air brake system where it could cause brake failure. A leaking drain valve allows wet tank leakdown which in turn can cause premature wear on the air compressor during vehicle operation as the air compressor continues to run to maintain wet tank air pressure.

Principles of Operation

With no pressure in the system, the drain valve's inlet and exhaust valves are closed. **See Fig. 2.** Upon charging the system, a slight pressure opens the inlet valve which permits air and contaminants to collect in the sump. **See Fig. 3 .** The inlet valve remains open when pressure is rising in the system until the air compressor cuts off, allowing the spring action of the valve guide in the sump cavity to close the inlet valve. The inlet valve and the exhaust valve are now both closed. **See Fig. 4.** When the wet tank pressure drops approximately 2 psi (14 kPa), the air pressure in the sump cavity opens the exhaust valve and allows moisture and contaminants to be ejected from the sump cavity until pressure in the sump cavity drops sufficiently to close the exhaust valve. **See Fig. 5.**

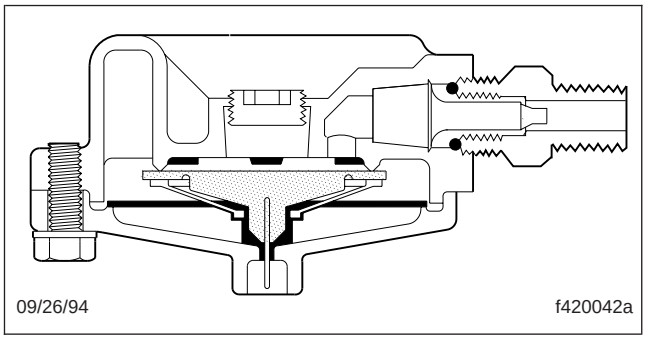

Fig. 2, No System Pressure

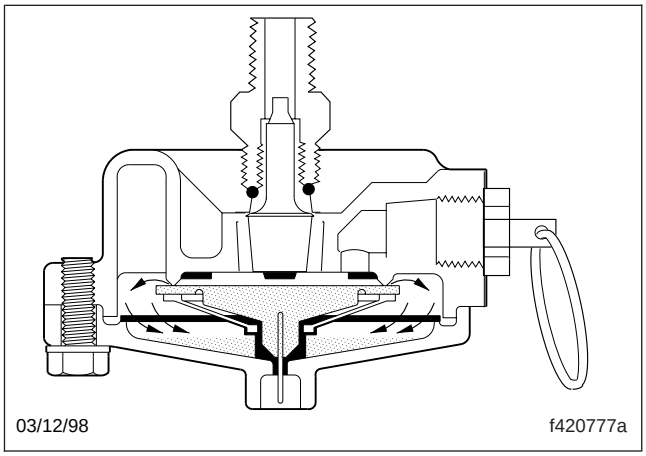

Fig. 3, Start of System Pressure Charging

The length of time the exhaust valve remains open and the amount of moisture and contaminants ejected depends upon the sump pressure and the wet tank pressure drop that occurs each time air is used from the system.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

1. Always chock the vehicle's wheels and stop the engine when working under a vehicle. Depleting vehicle air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing air pressure. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been depleted.
3. Never exceed recommended air pressure and always wear safety glasses when working with air pressure. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood the recommended procedures. Some components contain powerful springs and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

Operating Test

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

Perform the following test after repairing or replacing the DV–2 valve to ensure that the valve is functioning properly.

With the system charged, apply the brakes several times. Each time the brakes are applied, an exhaust of air should occur from the exhaust port of the drain valve. If no air comes out, push the wire stem located inside the exhaust port. If no air comes out after pushing the wire stem, there may be a plugged filter in the adapter which should be replaced.

If the drain valve does not function properly, repair or replace it following instructions in this section.

Leakage Test

Perform the following test after repairing or replacing the DV–2 valve to ensure that the valve is functioning properly.

With the system charged and pressure stabilized in the system, there should be no leaks at the drain valve exhaust port. A constant slight exhaust of air at the drain valve exhaust port could be caused by excessive leakage in the air brake system.

If the drain valve is leaking excessively, repair or replace it following instructions in this section.

Removal

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

1. Chock the tires, and drain the air system.
2. Remove the drain valve assembly from the end of the wet tank air reservoir.

Installation

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

1. Using a cleaning solvent, thoroughly flush and clean the wet tank reservoir to avoid early fouling at the drain valve. Aerate the wet tank thoroughly if solvents were used during cleaning.
2. Install the drain valve assembly on the wet tank by tightening the hexagonal nipple until the drain valve is positioned so that the valve body is parallel to the bottom of the wet tank with the exhaust port facing straight down. Make sure that the exhaust port is clear of any air, electric, or fuel lines. Make sure the drain valve is attached tight enough to prevent leakage.
3. Close the drain cocks to the wet and dry air reservoirs. Start the vehicle engine to pressurize the air system.
4. Leak test the drain valve following the instructions in **Subject 110.**

3. Remove the valve cover and sealing ring (Ref. 5).
4. Remove the valve guide (Ref. 6), and the inlet and exhaust valve (Ref. 4) from the valve body.
5. Remove the hexhead nipple (Ref. 3) from the valve body.

Cleaning and Inspection

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

⚠ WARNING

WARNING: Use eye protection when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the drain valve in an approved cleaning solvent. Dry the metal parts of the disassembled moisture ejection valve with compressed air.
2. Wipe all rubber parts clean with a clean cloth. Examine all rubber parts for wear cracks, tears, or other deterioration. If any rubber parts are worn, cracked, torn or otherwise deteriorated, replace them with new parts.
3. Examine all metal parts for wear, cracks, or other damage. If any metal parts are worn, cracked, or otherwise damaged, replace them with new parts.
4. Clean and examine the filter. If it will not clean completely, or is torn or damaged, replace it with a new filter.

⚠ CAUTION

CAUTION: Do not reassemble the drain valve with a dirty filter; to do so could result in failure of the drain valve in service.

Assembly (See Fig. 1)

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

Before assembling the drain valve, apply a light film of grease on the inlet valve seat. See Ref. 12.

⚠ CAUTION

CAUTION: Do not apply oil to the inlet and exhaust valve.

1. Install the valve sealing ring (Ref. 5) into its groove in the valve cover.
2. Install the valve guide (Ref. 6) over the inlet and exhaust valve (Ref. 4).
3. Install the valve guide, and the inlet and exhaust valve as an assembly into the valve cover. The

wire stem (Ref. 9) will project through the exhaust port (Ref. 8).

4. Install the valve body on the valve cover and install the lockwashers and capscrews. Tighten the capscrews 72 to 96 lbf·in (820 to 1080 N·cm).
5. Install the hexhead nipple onto the valve body, and tighten it 48 to 72 lbf·in (540 to 820 N·cm).
6. Install the drain valve on the wet tank following the instructions in **Subject 120.**

DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

IMPORTANT: The parking/emergency brake section is factory sealed (no clamp ring) and is a *non-serviceable* unit.

Fig. 1, Brake Chamber

General Information

Anchorlok brake chambers consist of a service brake section and a parking/emergency spring brake section. See **Fig. 1**. The service brake section is the smaller section near the clevis assembly.

In the service brake section, the service brake chamber contains a service return spring, piston rod assembly, and service brake diaphragm.

In the parking/emergency brake section, the adaptor and the parking brake chamber contain a return spring, a push rod assembly, a parking (spring) brake diaphragm, a pressure plate, a power spring, and a detachable release bolt.

All Anchorlok brake chambers are mounted to the frame using prevailing torque locknuts and hardened flatwashers.

Periodic maintenance of the brake chambers is required. Also, whenever the service brake chamber is disassembled (*do not attempt to disassemble the parking brake chamber*), the parts should be inspected for damage. For maintenance schedules and procedures, and for inspection of brake chamber parts, refer to the vehicle maintenance manual.

Principles of Operation

SERVICE BRAKES

As the brake pedal is depressed, compressed air enters the service brake chamber through a port. Air pressure acts upon a diaphragm, which forces the piston rod toward the non-pressure chamber, applying a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes. See **Fig. 2**.

1. Piston Rod Assembly
2. Service Brake Diaphragm

Then, when the brake pedal is released (see **Fig. 3**), air is exhausted from the service brake chamber, and the return spring allows the diaphragm, piston rod

assembly, and slack adjuster to return to their normal positions, releasing the brakes.

PARKING/EMERGENCY BRAKES

During parking brake release, compressed air enters the parking/emergency brake chamber below the diaphragm, forcing the diaphragm against the pressure plate to compress the power spring and release the parking/emergency brake. See **Fig. 4**. During parking brake application, a control valve in the cab exhausts air from the parking/emergency brake chamber. This allows the power spring to extend and apply the brakes. See **Fig. 5**.

Emergency brake application begins when air pressure in the service brake reservoir drops below about 80 to 85 psi (550 to 585 kPa). Maximum parking brake force is applied when air is entirely exhausted fom the parking/emergency brake chamber.

Manual Compression (Parking Brake Release)

1. Chock the tires.
2. Remove the dust plug from the center-hole in the head of the chamber. See **Fig. 2**.

⚠ DANGER

Do not attempt to cage the power spring if the parking brake chamber is damaged severely enough to lose its structural integrity. If the power spring were to break loose, it could result in death, severe personal injury, or property damage.

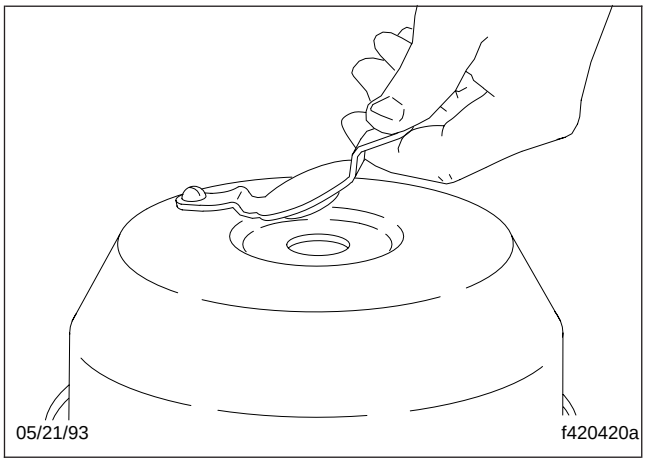

Fig. 2, Remove the Dust Plug

A DAMAGED PARKING BRAKE CHAMBER IS EXTREMELY DANGEROUS! Only qualified service personnel should attempt to remove and disarm a damaged chamber.

3. Using a torch, burn off the piston rod in the space between the clevis and the base of the service chamber. Remove the chamber carefully from its bracket, and disarm it inside a suitable container. For disarming procedures, consult the Anchorlok installation instructions.
4. Manually release the parking brake (cage the power spring).

   4.1 Using a hand wrench, (*don't use an impact wrench*), unscrew the release nut, and remove the nut, flatwasher, and release bolt from the storage pocket on the side of the chamber. See **Fig. 3**.

   IMPORTANT: If these parts are not stored on the chamber, they must be otherwise obtained or purchased; the parking brake cannot be manually released without them.

   4.2 Insert the release bolt into the center-hole in the chamber head (see **Fig. 4**). Continue to insert the bolt until it bottoms out into the hole in the pressure plate inside the chamber.

   IMPORTANT: If you are not absolutely sure that the formed end of the bolt has engaged

the pressure plate correctly, repeat this step. Repeat it until you are absolutely sure.

4.3 Turn the release bolt one-quarter turn clockwise. Pull to seat the formed end of the release bolt in the recess of the pressure plate.

4.4 Holding the release bolt locked into the pressure plate, install the flatwasher and release nut on the end of the bolt, and turn down the nut against the flatwasher until it is finger-tight. See **Fig. 5**.

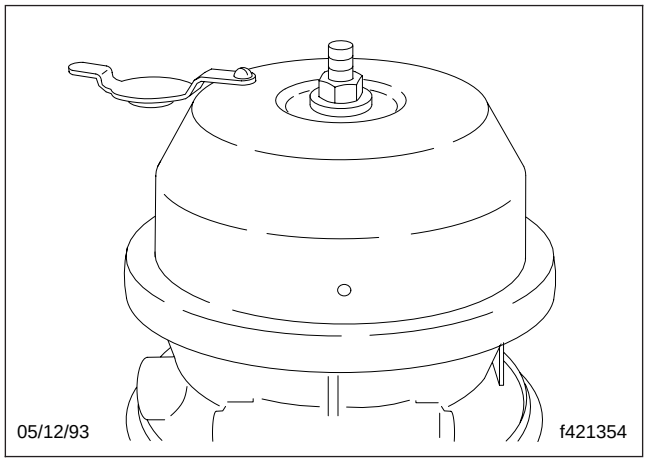

Fig. 5, Flatwasher and Release Nut Installed

⚠ DANGER

Exhaust all air pressure before tightening the release nut more than finger-tight. Tightening this nut under pressure can damage the pressure plate and result in sudden release of the power spring, causing death or severe personal injury.

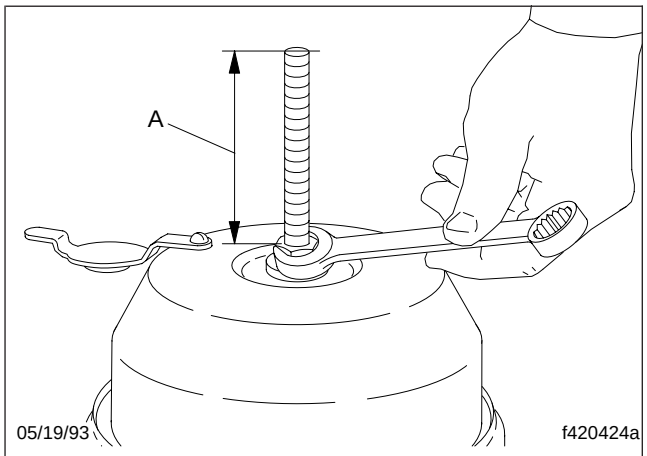
⚠ CAUTION

If equipped with S-cam, don't exceed 35 lbf·ft (47 N·m) torque on the release nut; if equipped with wedge brakes, don't exceed 20 lbf·ft (27 N·m) torque on the release nut.

4.5 Using a hand wrench (*don't use an impact wrench*), turn the release nut clockwise until the power spring is caged (see **Fig. 6**).

The bolt should extend above the nut at least 2.9 inches (74 mm) on 24-inch chambers, or 2.875 inches (73 mm) on 30-inch chambers.

IMPORTANT: Do not exceed these bolt lengths. If the bolt lengths can't be obtained without exceeding the recommended maximum torque values, replace the tandem brake chamber.



A. Measure this distance.

Fig. 6, Turn the Release Nut

Manual Reset (Parking Brake Reset)

1. Uncage the power spring.

CAUTION

Don't use an impact wrench on this nut. Too much torque could damage the pressure plate and prevent manual release of the parking brake.

1.1 With air applied to the parking brake section (the parking brake control valve is in the "release" position), use a hand wrench to turn the release nut *counterclockwise* until the power spring extends back into the parking/emergency brake chamber.

NOTE: When the power spring is fully extended, force will no longer be felt on the release nut.

1.2 Remove the nut and flatwasher.

1.3 Turn the release bolt one-quarter turn counterclockwise and unlock the bolt from the receptacle in the pressure plate. Remove the release bolt from the center-hole of the chamber.

2. Using a hand wrench, (*don't use an impact wrench*), install the release bolt, flatwasher, and release nut in the storage pocket. Tighten the nut 60 to 96 lbf·in (680 to 1080 N·cm). See **Fig. 7**.

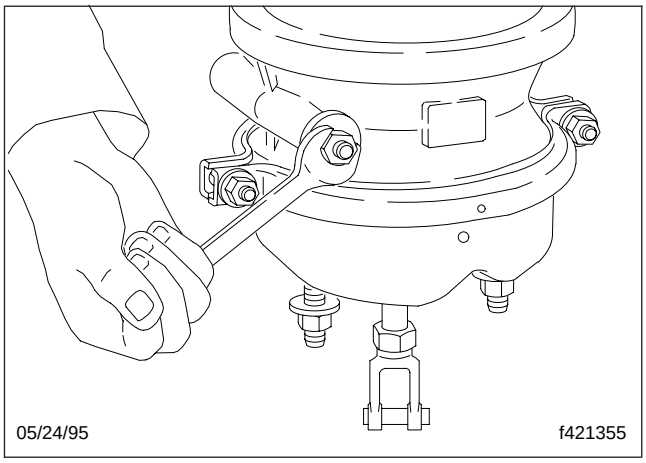


Fig. 7, Tighten the Release Nut

3. Snap the dust plug in place over the center-hole in the chamber head. See **Fig. 8**.

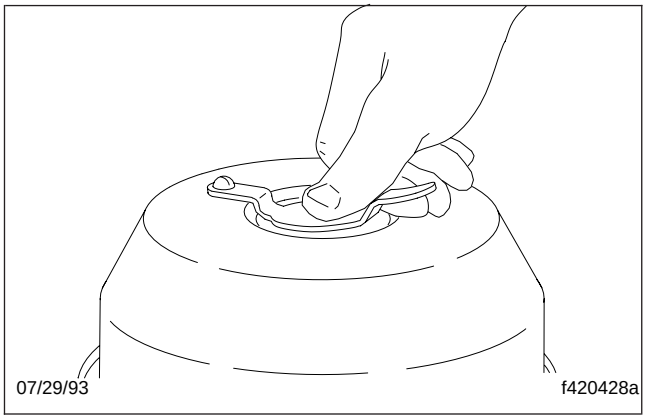

Fig. 8, Snap the Dust Plug in Place

CAUTION

If a dust plug is missing or incorrectly installed, road dirt and debris can enter the brake chamber and cause the internal parts to deteriorate.

4. Check the plastic dust plug periodically, and replace it with a new one at once if damaged or missing. For intervals, refer to the vehicle maintenance manual.

5. Remove the chocks from the tires.

DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

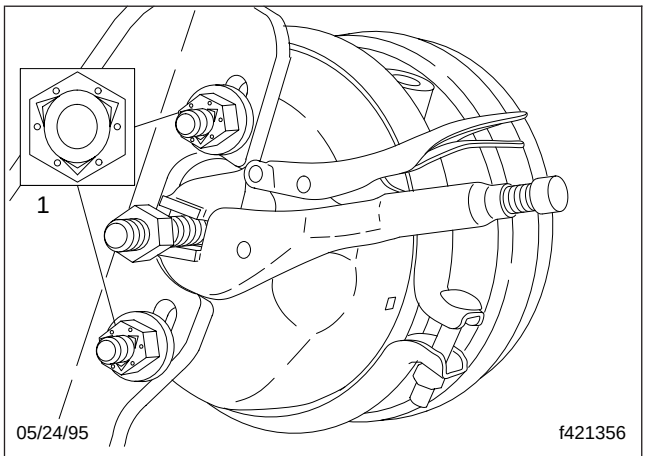
Removal

1. To make removal and installation of the parking brake section easier (without removing the service brake chamber), lock off the service chamber piston rod.

   1.1 Apply the service brakes by actuating the driver's foot brake treadle valve.

   1.2 With the brakes applied, clamp a pair of locking-jaw pliers on the piston rod to lock the rod in place when the air pressure is released (see Fig. 2).



1. Prevailing Torque Locknut

Fig. 2, Lock the Piston Rod in Place

WARNING

Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

2. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100**.
3. Mark the air lines for later reference. Then carefully disconnect them from the brake chamber.

DANGER

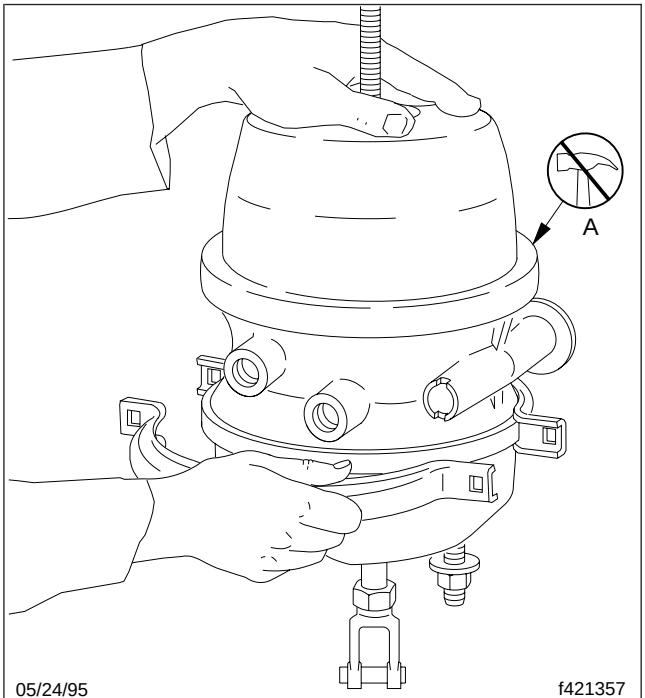
Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4. Remove the parking brake and adaptor from the service brake section.

   4.1 Using a hand wrench (*don't use an impact wrench*), remove the clamp nuts on the *service* brake clamp ring (*do not disassemble the parking brake section*).

Service Brake Diaphragm Replacement

4.2 While holding the parking brake section securely in place, remove the service clamp ring. Then remove the parking brake section from the service brake non-pressure chamber (see **Fig. 3**).



A. Do not remove the factory-sealed clamp ring.

Fig. 3, Remove the Service Clamp Ring

5. Remove the service brake diaphragm from the bottom of the parking brake section.

Installation

IMPORTANT: At this time, take the opportunity to inspect the parking/emergency brake section, and replace it if it shows signs of damage, corrosion, or rust. Follow the detailed inspection instructions in the vehicle maintenance manual.

1. Inspect all parts in the service (non-pressure) chamber. Replace any damaged or worn parts.
2. Place the new service brake diaphragm in the bottom recess of the adaptor (see **Fig. 4**).
3. Install the (new, if needed) parking/emergency brake section.

Fig. 4, Brake Chamber Parts

3.1 If installing a new parking brake section, be sure it is the same size and make as the old one.

3.2 Check that the release bolt is fully extended outward. For instructions, refer to **Subject 100.**

3.3 Install the parking brake section on the service chamber so that all mating parts are aligned straight and the air lines are positioned to mate with the vehicle air supply lines.

4. Install the service brake clamp ring.

4.1 With the service brake clamp ring in place, install the clamp bolts and nuts.

4.2 Using a hand wrench (*don't use an impact wrench*), alternately tighten each clamp nut 18 to 25 lbf·ft (24 to 34 N·m) while

constantly rechecking the alignment of mating parts.

4.3 Lightly tap around the circumference of the service clamp ring with a rubber mallet to ensure full seating of the clamp. If re-alignment is needed, loosen the nuts again, and repeat this step.

5. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 25 lbf·ft (34 N·m).
6. Using the vehicle system air, charge the parking brake with full line pressure—at least 100 psi (690 kPa). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 25 lbf·ft (34 N·m).
7. With the parking brake still charged with full line pressure, apply and hold the foot brake treadle valve down to charge the service brake chamber. Remove the locking-jaw pliers from the service piston rod so that the piston returns to a normal position in the chamber.

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

8. Test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, release all air pressure from the chamber, then retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). Anchorlok recommends 18 to 25 lbf·ft (24 to 34 N·m) torque on the clamp hexnuts.
9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the dust plug in place. For instructions, refer to **Subject 100.**
10. Adjust the brakes at the slack adjuster.

IMPORTANT: After replacing any brake chamber components, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

Replacement

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

Removal

WARNING

Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

1. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100**.
2. Mark the air lines for later reference. Then carefully disconnect them from the brake chambers.
3. Remove the brake chamber from the vehicle.

   3.1 Remove the cotter pin(s) from the clevis pin(s), then remove the clevis pin(s) from the clevis. Disconnect the clevis from the slack adjuster.

   NOTE: Automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   3.2 From each mounting stud, remove any installed nuts and washers. Then, cautiously remove the brake chamber from the mounting bracket.

Installation

1. If installing a new brake chamber unit, do the following steps:

   1.1 First, make sure the power spring is caged (release bolt fully extended outward). If not, go to **Subject 100** and do the applicable steps.

   1.2 Make sure that the piston rod is the same length as the rod on the old unit (measure the rods when *both* chambers are caged).

   1.3 Be sure the new chamber is the same size and make as the brake chamber installed on the other side of the axle.

   1.4 Remove the prevailing torque locknut and hardened flatwasher from each of the mounting studs on the chamber.
2. Clean the face of the mounting bracket, and position the chamber on the bracket. Pay close attention to positioning the chamber air inlet ports for correct alignment to the vehicle air lines.

WARNING

Tighten the mounting nuts with a hand wrench, not an impact wrench. An impact wrench could damage the mounting fasteners, reducing the

Combination Service and Parking Brake Chamber Removal and Installation

force of the brakes. This could result in personal injury or property damage.

3. Install one hardened flatwasher and prevailing torque locknut on each mounting stud. Using a hand wrench (*don't use an impact wrench*), tighten the nuts 110 to 150 lbf·ft (149 to 203 N·m). Make sure that the hardened flatwasher is installed between the locknut and the mounting bracket.
4. Check mating and alignment with the vehicle air lines.

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4.1 Using a hand wrench (*don't use an impact wrench*), loosen the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

4.2 Reposition the air inlet ports, as needed, to mate with vehicle air supply lines.

Alternately tighten each clamp nut in increments of 18 to 25 lbf·ft (24 to 34 N·m) while constantly rechecking the alignment of mating parts.

If realignment is needed, loosen the nuts again, and repeat this substep.

4.3 Lightly tap around the circumference of the service clamp ring to ensure full seating of the clamp.

5. Connect the slack adjuster. Refer to the applicable slack adjuster section in this group for installation instructions.
6. Inspect the piston rod to be sure it is working free, not binding, and is square with the chamber bottom from zero to full stroke. If there is misalignment, make corrections by loosening the locknuts and repositioning the chamber on the mounting bracket, or by shimming the slack adjuster to the right or left on the camshaft.
7. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 25 lbf·ft (34 N·m).
8. Using the vehicle system air, charge the parking brake with full line pressure, at least 100 psi (690 kPa). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 25 lbf·ft (34 N·m).

⚠ DANGER

Do not attempt to remove the factory-sealed clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

IMPORTANT: If the service brake clamp ring was loosened to reposition the air inlet ports, apply air to the parking brake, and then apply and hold the foot brake treadle valve down to charge the service brake chamber. Now test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, release all air pressure from the chamber, then retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). Anchorlok recommends 18 to 25 lbf·ft (24 to 34 N·m) torque on the clamp hexnuts.

9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the dust plug in place. For instructions, refer to **Subject 100**.
10. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

IMPORTANT: After replacing any brake chamber, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack

adjuster. For instructions, refer to the applicable slack adjuster section in this group.

General Information

The function of the QR–1 quick release valve **(Fig. 1)** is to speed up the release of air pressure from the brake chambers. If the front brake chambers are equipped with a QR–1 valve, and a foot brake application is released, the exhaust port of the quick release valve opens and the air from the front brake chambers is exhausted through the quick release valve. This accelerates the release of the front brakes.

Fig. 1, QR–1 Valve and Cross Section

When the front brake chambers are equipped with a QR–1 valve, it is located on the forward face of the crossmember just aft of the transmission. A delivery line from the foot valve is connected to the port on top of the QR–1 quick release valve; the two side ports are for brake chamber connections, and the exhaust port is located at the bottom of the valve.

Principles of Operation **(See Fig. 1)**

When the foot brake control is applied, delivery air enters the brake valve port on the QR–1 quick release valve; the diaphragm moves down, sealing the exhaust port. At the same time, air pressure forces the edges of the diaphragm down, allowing air to flow out the brake chamber ports, filling the chambers and applying the front axle brakes.

When the brake chamber air pressure (beneath the diaphragm) equals the air pressure being delivered by the foot valve (above the diaphragm), the outer edge of the diaphragm will seal against the valve body seat. The exhaust port is still sealed by the center portion of the diaphragm. When the foot brake is released, the air above the diaphragm is released back through the foot brake valve exhaust, while the air beneath the diaphragm forces the diaphragm to rise, opening the exhaust port, and allowing air in the brake chambers to exhaust.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

Operating and Leakage Tests

The following tests should also be performed after repairing or replacing the QR–1 valve to ensure that it is functioning properly.

1. With the foot brake applied (pedal pushed in) perform the following checks.

   1.1 Coat the exhaust port with a soap solution; leakage of a one-inch bubble in three seconds is allowable.

   1.2 Coat the valve body and cover with a soap solution. No leakage is permitted between the valve body and cover.

2. If the valve does not function properly, or if leakage is excessive, repair or replace it following the instructions in this section.

2. Remove the four screws holding the valve cover on the valve body.
3. If equipped, remove the spring and spring seat.
4. Remove the diaphragm.
5. Remove the cover O-ring.

Cleaning and Inspection

2. It is recommended that all rubber parts and any other part showing signs of wear or deterioration be replaced with genuine Bendix parts.

Assembly

1. If the quick release valve is not equipped with a spring, install the diaphragm into the valve body.

   If the quick release valve is equipped with a spring, position the spring in the valve body. Then, position the diaphragm over the spring seat.
2. Install the O-ring in the valve cover groove and install the valve cover. Tighten the screws 30 to 60 lbf·in (340 to 680 N·cm) evenly and securely.
3. Install the quick release valve, following the instructions **in Subject 120.**

General Information

The R–12 (**Fig. 1**) and R–14 (**Fig. 2**) relay valves are control relay stations in the air brake system to speed the application and release of the brakes. Mounted at the rear of the vehicle, they are operated by remote control and give about the same amount of air pressure to the brake chambers as they receive from the service brake foot valve or other source.

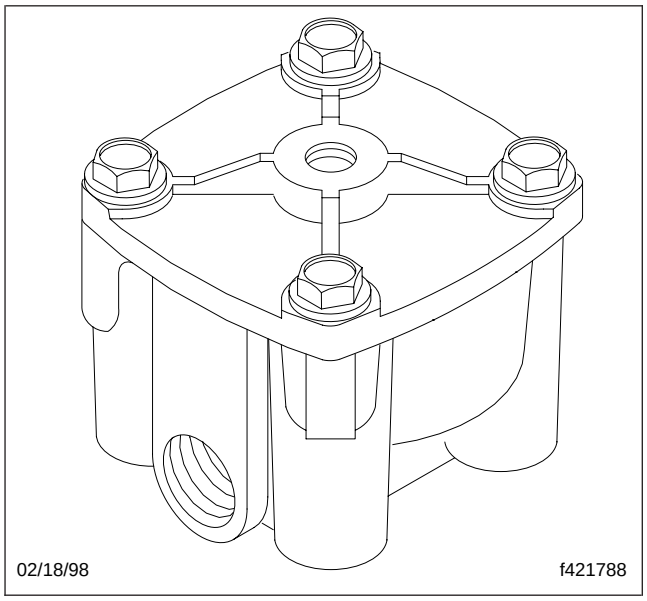

Fig. 1, R-12 Relay Valve

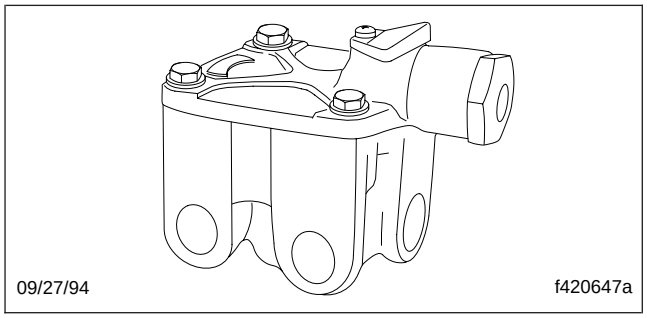

Fig. 2, R-14 Relay Valve

The valves are piston operated and have an insert-type inlet and exhaust valve that can be serviced.

Principles of Operation (See Fig. 3 and Fig. 4)

APPLICATION

Air pressure delivered to the service port enters the small cavity above the piston and moves the piston down. The exhaust seat moves down with the piston and seats on the inner or exhaust portion of the inlet/exhaust valve, sealing off the exhaust passage. At the same time, the outer or inlet portion of the inlet/exhaust valve moves off its seat, permitting supply air to flow from the reservoir, past the open inlet valve and into the brake chambers.

BALANCE

The air pressure being delivered by the open inlet valve also is effective on the bottom area of the relay piston. When air pressure beneath the piston equals the service air pressure above, the piston lifts slightly and the inlet spring returns the inlet valve to its closed position. The exhaust remains closed as the service line pressure balances the delivery pressure. As delivered air pressure is changed, the valve reacts to the change, holding the brake application at the level.

EXHAUST OR RELEASE

When air pressure is released from the service port and air pressure in the cavity above the relay piston is exhausted, air pressure beneath piston lifts the relay piston and the exhaust seat moves away from the exhaust valve, opening the exhaust passage. With the exhaust passage open, the air pressure in the brake chambers is then permitted to exhaust through the exhaust port, releasing the brakes.

ANTI-COMPOUNDING (SIMULTANEOUS SERVICE AND PARK APPLICATION), R–14 VALVE

An "anti-compound" feature allows the R–14 valve to be used as either a service or spring brake relay valve. An exhaust cover is installed that protects the 1/8-inch balance port when the R–14 anti-compound feature is not in use. See **Fig. 4**.

2. Service Port
3. Relay Piston
4. Inlet/Exhaust Assembly
5. Supply Port
6. Exhaust Port
7. Retaining Ring

Fig. 3, R-12 Relay Valve (sectional view)

In applications where the R–14 is used to control spring brake chambers, the anti-compound feature may be utilized. To utilize, the exhaust cover of the quick release portion of the R–14 is removed and a line is installed, which is connected to the delivery of the service brake valve or relay valve. With no air pressure at the service port of the R–14, the parking brakes apply. When a service brake application is made, air from the service brake valve enters the exhaust port of the quick release of the R–14 and moves the diaphragm, blocking the service port. Air then proceeds into the cavity above the relay piston, forces the piston down, closing the exhaust and opening the inlet to deliver air to the spring brake cavity.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

A. Chock the tires and stop the engine before working under the vehicle. Releasing air from the system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.

B. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.

C. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.

D. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not correctly disassembled. Use only correct tools and observe all precautions regarding use of those tools.

Operation Test

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Start the vehicle and build the brake system to cut-out pressure, about 130 psi (827 kPa).
2. Using a soap and water solution, check all air line fittings on the valve for leakage. If the fittings or air lines are leaking, replace the fittings. For instructions, see **Section 42.13**.
3. Make several service brake applications and check for prompt application and release of the brakes.
4. If brake response is slow, troubleshoot the brake system. For instructions, see **Section 42.10** in this group. If the valve is malfunctioning, repair or replace it.

Leakage Test

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Start the vehicle and build the brake system to cut-out pressure,about 130 psi (827 kPa).
2. Using a soap and water solution, check for inlet valve and O-ring leakage.
   - 2.1 Make this check with the service brakes released when the R–12 or R–14 is used to control the service brakes.
   - 2.2 Make the check with the spring brakes (parking brakes) applied when the R–14 is used to control the spring brakes.
3. While holding a full service brake application, apply a soap solution to the exhaust port. Leakage at the exhaust port should not exceed a 1-inch (2.5-cm) bubble in three seconds.

NOTE: If the anti-compound feature is in use, the line attached to the balance port must be disconnected to perform this test.

4. Coat the outside of the valve where the cover joins the body to check for O-ring leakage; no leakage is permitted.
5. If the R–14 is used to control the spring brakes, release the parking brake, apply a soap solution to the balance port. Leakage at the balance port should not exceed a 1-inch (2.5-cm) bubble in three seconds.

IMPORTANT: If the valves do not function as described in the above test, or if leakage is excessive, replace it. For instructions, see **Subject 120**.

Removal

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Chock the tires, and drain the air system.
2. Remove all air hoses from the valve. Cap the hoses and mark them for reassembly.
3. Remove the valve mounting bolts. Remove the valve.

Installation

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Attach the valve to the vehicle, using the bolts, washers, and nuts. Tighten the nuts 132 to 180 lbf·in (1500 to 2040 N·cm).
2. Remove the caps from the air lines, then depending on the type of air hose, do one of the following.

   Nylon Tubing: Connect the air line fittings to the valve ports, and tighten the nuts finger-tight. Using a wrench, tighten the nuts at least two turns, or until one thread shows on the fittings.

   Wire Braid Hoses: Connect the hose fittings to the valve ports, and hand-tighten the nuts. Using a wrench, tighten the nuts until resistance is felt. Tighten one-sixth turn more. Do not overtighten.
3. Close the air reservoir drain cocks. Start the vehicle engine to pressurize the air system.
4. Test the valve following the instructions in **Subject 110**.

Relay Valve Disassembly, Cleaning and Inspection, and Assembly

Disassembly

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

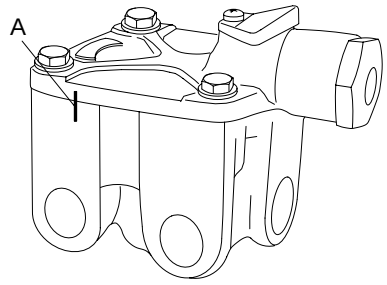
NOTE: Prior to disassembly, draw an alignment mark across the valve cover and body, for reassembly alignment. See **Fig. 1**.

2. Disassemble the valve.

   2.1 Referring to **Fig. 2**, remove the four cover capscrews and integral lockwashers.



A. Mark the valve housing for reassembly alignment.

Cleaning and Inspection

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Wash all metal parts of the valve in cleaning solvent. Dry the metal parts of the disassembled valve with compressed air.
2. Wipe all rubber parts clean with a clean cloth. Examine all rubber parts for cracks, tears, or other deterioration. If any rubber parts are worn, cracked, torn or otherwise damaged, replace them with new parts.
3. Examine all metal parts for wear, cracks, or other damage. If any metal parts are worn, cracked or otherwise damaged, replace them with new parts.
4. Check the springs for distortion and corrosion. If the springs are distorted or corroded, replace them.
5. Inspect the exhaust seat of the quick release diaphragm in the R–14 cover and make sure all internal air passages in the area are open and clean and free of nicks and scratches.

Assembly

IMPORTANT: Before working on or around air brake systems and components, refer to **Safety Precautions, 100**.

1. Lubricate the O-rings and all sliding parts with Dow Corning 55-M pneumatic grease or equivalent. Assemble the valve (**Fig. 2**).

   1.1 Install the O-ring on the relay piston.

   1.2 Install the inner and outer O-rings on the exhaust cover.

General Information

The Gunite automatic slack adjuster has two main functions:

- As a lever it converts the straight-line force of the brake chamber push rod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the drum.
- As an automatic slack adjuster, it maintains the lining-to-drum clearance needed for proper brake chamber push rod stroke.

The slack adjuster is installed between the brake chamber push rod and the brake camshaft. A clevis connects the brake chamber push rod to the top of the slack adjuster. See **Fig. 1**. The bottom of the slack adjuster is splined to the brake camshaft. The splines hold the slack adjuster internal gear to the camshaft, so the camshaft turns when the slack adjuster moves. When the brakes are applied, the brake chamber push rod moves outward forcing the slack adjuster and camshaft to rotate. This movement forces the brake shoes against the drum.

The brakes are adjusted when the slack adjuster senses an increase in the lining-to-drum clearance. The slack adjuster's internal worm shaft and ratchet shorten excessive lining-to-drum clearance. This provides maximum leverage for the brake chamber push rod. The automatic slack adjuster adjusts the brakes at the beginning of the brake application.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure.
- Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc., should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Slack Adjuster Removal and Installation

WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

IMPORTANT: This automatic slack adjuster cannot be rebuilt. If it is damaged or inoperative, replace the unit.

Each factory-installed brake chamber has a clevis welded onto the pushrod. See **Fig. 1**. On a replacement brake chamber, the clevis is threaded onto the pushrod, and has a jam nut installed. See **Fig. 2**.

Removal

1. With the vehicle parked on a level surface, chock the tires. If a rear slack adjuster is being removed, cage the parking brake power spring. For instructions, refer to the applicable brake chamber section in this group.
2. Remove the cotter pins and clevis pins.

3. Rotate the adjusting hexnut counterclockwise until the slack adjuster clears the clevis.
4. Remove the snap ring from the brake camshaft, then slide the slack adjuster off the camshaft.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

1. Coat the camshaft splines, and the splines of the slack adjuster gear with an anticorrosion grease.

Slack Adjuster Removal and Installation

2. Using the old snap ring, install the automatic slack adjuster on the brake camshaft.
3. Turn the adjusting hexnut clockwise to rotate the slack adjuster toward the brake chamber until the holes line up.
4. Install the clevis pins and cotter pins.

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

5. If the pushrod has a threaded clevis, use the gauge supplied with a new slack adjuster to check the adjustment of the clevis, as follows. See **Fig. 3**.
   - 5.1 Position the 1/2-inch hole in the gauge over the end of the 1/2-inch clevis pin.
   - 5.2 Align the applicable 1/4-inch hole in the bottom of the gauge over the center of the camshaft.
   - 5.3 Check that the 1/4-inch pin is visible in the notched area of the gauge. If the pin is not in the right location, back off the slack adjuster and readjust the pushrod length, then repeat this step.

NOTE: Make sure there is clearance between the slack adjuster and other vehicle components when the brakes are applied and the pushrod travels its maximum stroke.

6. Set the initial free-stroke, as follows.
   - 6.1 Turn the adjusting hexnut clockwise until the brake linings contact the drum.
   - 6.2 Turn the adjusting hexnut counterclockwise one-half turn. There should be about 30 lbf·ft (41 N·m) resistance, and a ratcheting sound will be heard.

A. Adjust the clevis in or out to position the 1/4-inch clevis pin within the notched area of the gauge.

1. Installation Gauge

Fig. 3, Checking the Clevis Adjustment

7. Measure the brake chamber applied stroke, as follows.
   - 7.1 With the brakes fully released, use a ruler to measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 4**.
   - 7.2 Build air pressure to at least 85 psi (586 kPa). Apply the brakes, then measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 4**. The difference between the measurements is the brake chamber stroke.
   - 7.3 The brake chamber stroke must be within the range shown in **Table 1**. If it is not, check the foundation brakes for problems such as worn cams, bushings, pins and rollers, or broken springs. Repair or replace as needed. For instructions, refer to the applicable brake section in this group. Then, repeat the two previous steps.

8. If a rear axle slack adjuster was installed, manually uncage the parking brake. Refer to the applicable brake chamber section in this group for instructions.
9. Apply the parking brakes.
10. Remove the chocks from the tires.
11. In a safe area, check for proper brake operation, as follows.
    - 11.1 Apply and release the brakes several times to check for correct operation of the slack adjusters.
    - 11.2 Perform six low-speed stops to ensure correct parts replacement and full vehicle control.
    - 11.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others show a lack of braking effort on those wheels.

Fig. 1, Brake Valve and Double Check Valve Plumbing Circuits

Freightliner vehicles use one or two shuttle type double check valves. If a vehicle is equipped with a trailer control valve it has two double check valves. Otherwise, most other vehicles will only have one. A shuttle type valve has a movable shuttle to seal off the lower pressure source. The valves are screwed into the forward side of the foot brake valve.

Double check valves are used in the air brake system to direct a flow of air into a common line from either of two sources, whichever is at the higher pressure.

Principles of Operation

As pressurized air enters either end of the double check valve inlet port, the moving shuttle responds to the greater pressure source and seals the opposite port. The air flow continues out the delivery port of the valve. The position of the shuttle will reverse if the pressure levels are reversed. Double check valves are designed so the shuttle cannot interfere with the backflow of air in the exhaust mode.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Dropping air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if they are not correctly disassembled. Use only the correct tools, and observe all precautions regarding use of those tools.

Operating and Leakage Test

1. If the vehicle is not a tractor with a trailer, go to the next step.

   If the vehicle is a tractor with a trailer, proceed as follows:

   1.1 Push in and release the foot brake pedal while checking that the brakes apply and release on both the tractor and trailer.

   1.2 Apply and release the trailer control valve while checking that only the trailer brakes apply and release.

   1.3 Apply the trailer control valve and check the exhaust port of the foot brake valve for leakage using a soap solution. A 1-inch (2.5-cm) bubble or less in five seconds is allowable. Release the valve.

   1.4 Disconnect the air line from the trailer control valve exhaust port. Push the foot brake pedal until it stops and hold it in place. Check the trailer control valve exhaust port for leakage using a soap solution. A 1-inch (2.5-cm) bubble or less in five seconds is allowable.

   1.5 Connect the air line to the trailer control valve exhaust port.

   1.6 Go to the next step.

2. If the double check valve is to be tested on the bench, connect two separately controlled air supplies to the inlet ports.

3. Connect an accurate test gauge to the double check valve outlet port or to a line from the outlet port.

4. Apply and release air to one inlet port (foot brake pedal) while checking that the test gauge registers the application and release.

5. Apply and release air to the other inlet port (trailer control valve) while checking that the gauge registers the application and release.

6. Disconnect the line from one of the double check valve inlet ports. Apply air to the opposite inlet port while checking the first port for leakage using a soap solution. A 1-inch (2.5-cm) bubble or less in five seconds is allowable. Connect the line to the inlet port. Repeat this step, checking the opposite inlet port for leaks.

7. If the double check valve does not function as described, or if the leakage is excessive, replace it. Refer to **Subject 120** for instructions.

   If the valve cannot be replaced, repair it using Bendix parts. Refer to **Subject 130** for instructions.

General Information

The QR–1C quick release valve **(Fig. 1)** is a dual function valve. Its primary function is to speed up the release of air pressure from the service brake chambers. Additionally, the valve works as an anti-compound device. The double check valve feature prevents a service and parking brake application from occuring at the same time.

Fig. 1, QR–1C Valve and Cross Section

The QR–1C valve is generally mounted near the rear axle. A balance line from the relay valve delivery port (port 2 on the WABCO combination valve) is connected to the balance port on top of the QR–1C quick release valve; the two side ports are for brake chamber connections; the supply port is connected to the delivery port of the parking brake control valve, and the exhaust port is located at the bottom of the valve.

Principles of Operation (See Fig. 1)

Parking Brakes Released

When the parking brakes are released, air from the parking brake control valve flows through the QR–1C valve. This forces the double check diaphragm and the quick release diaphragm to flex and seal the balance and exhaust ports. Air flows into the inlet ports of the parking brake chambers from the QR–1C valve delivery ports.

Parking Brakes Applied

When the parking brakes are applied, supply line air pressure to the QR–1C valve is exhausted through the parking brake control valve. As air pressure is exhausted from one side of the double check diaphragm and the quick release diaphragm, both diaphragms flex in the opposite direction to open the balance and exhaust ports. Parking brake pressure is released at the exhaust port of the QR–1C valve while a small amount of air trapped between the two diaphragms is released through a relay valve or the foot valve exhaust port.

Anti-Compounding

When a service brake application is made with the parking brakes applied, service air enters the balance port and flows through the QR–1C valve into the inlet ports of the parking brake chambers. This prevents application of the service and parking brakes at the same time. Service air passing through the QR–1C valve flexes the double check and quick release diaphragms, sealing the supply and exhaust ports. When the service brake application is released, air is exhausted from the parking brakes.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

Operating and Leakage Tests

⚠ WARNING

WARNING: Before working on or around air brake systems and components, review the safety precautions in Subject 100. Failure to do so could result in personal injury.

The following tests should also be performed after repairing or replacing the QR–1C valve to ensure that it is functioning properly.

1. Chock the tires.
2. Drain the air system.
3. Release the parking brakes.
4. Remove the air line from the valve balance port. Build system air pressure to 120 psi (827 kPa). Coat the exhaust and balance ports with a soap solution; leakage of a one-inch bubble in five seconds at either port is allowable. Install the air line at the balance port.
5. Apply the parking brakes. Step on the foot brake; the QR–1C valve should exhaust air at the exhaust port.
6. Drain the air system.
7. Remove the air line from the valve supply port. Build system air pressure to 120 psi (827 kPa). With the foot valve depressed, coat the supply port and the seam between the body and cover with a soap solution; leakage of a one-inch bubble in five seconds at the supply port is allowable. No leakage between the body and cover is permitted. Install the air line at the supply port.
8. If the valve does not function properly, or if leakage is excessive, repair or replace it following the instructions in this section.

General Information

The Allied Signal/Bendix TP–3DC is a tractor protection valve which includes an integral double check valve. The TP–3DC serves two purposes. First, as required by Federal law, the valve protects the tractor brakes in the event of trailer breakaway or a severe air system leak. Second, when used with a dash-mounted trailer supply control valve, the TP–3DC valve can be used to shut off the trailer control line before the trailer is disconnected.

The TP–3DC also includes an integral single check valve which prevents air from getting trapped in the trailer control line. Trapped air in this line could cause service/spring brake compounding and, if the trailer is parked with air applied, a trailer roll-away situation.

The TP–3DC tractor protection valve is mounted either under the left hand deck or in the frame rail channel (see **Fig. 1**).

Principles of Operation

INITIAL CHARGE **(See Fig. 3)**

Pushing in the red trailer air supply knob (Ref. 1) on the instrument panel causes air to flow into the TP–3DC valve at the tractor supply port (Ref. 2). Air flows through the valve housing, exiting via the auxiliary supply port (if used) and the trailer supply port (Ref. 4), to pressurize the trailer brake system and release the trailer parking brakes.

As air pressure builds in the trailer supply circuit, the single check valve (Ref. 5) seats, and the valve

plunger (Ref. 16) begins to move (against spring pressure) toward the guide (Ref. 8). When pressure reaches about 45 psi (310 kPa), the plunger bottoms against the guide and the inlet valve is open.

The TP–3DC valve is in the "run" mode, and ready to receive and deliver a service brake application from either the foot valve or the hand valve.

SERVICE BRAKE APPLICATION

(See Fig. 4)

When the foot pedal is pressed, air flows to the TP–3DC valve tractor control primary (Ref. 10) and secondary (Ref. 13) ports. If the trailer control valve (Ref. 14) is also used, the external double check (Ref. 12) delivers the higher pressure (trailer control

or foot valve secondary) to the TP–3DC Tractor Control secondary port.

Inside the TP–3DC valve, the higher pressure (primary or secondary) moves the diaphragm (Ref. 9) to seal off the port at the lower pressure.

With the plunger bottomed against the guide and the inlet valve open (as described earlier), the higher pressure air flows through the valve to the trailer control port (Ref. 6) and the stop lamp switch, applying the brakes and activating the stop lamps.

NOTE: While air pressure also reaches the TP–3DC single check valve, the valve stays closed because supply pressure is acting on the other side.

Fig. 5, Service Brake Release

When the foot pedal is released, air stops flowing into the TP–3DC valve at the tractor control primary (Ref. 10) or secondary (Ref. 13) port. At the same time, air in the trailer control line (Ref. 6) returns to the valve, flowing back through the open inlet valve.

The air forces the diaphragm (Ref. 9) to seat, sealing off the tractor control primary port. The air then exits the valve at the tractor control (secondary) port (Ref. 13) and flows to the foot valve or hand valve where it is exhausted.

If the red trailer air supply knob on the instrument panel is pulled out (or if a large leak develops in the trailer supply circuit), pressure in the trailer supply circuit (and the auxiliary supply circuit, if used) is vented. When pressure drops to about 20 to 30 psi (138 to 207 kPa), the pressure can no longer overcome the spring force inside the TP–3DC valve and the inlet valve closes.

With the inlet valve closed, air pressure from the brake foot or hand control valves will not reach the trailer control circuit when the brakes are applied.

Fig. 7, Anti-Compounding

If the red trailer air supply knob on the instrument panel is pulled out while the service brakes are applied, the single check valve (Ref. 5) in the TP–3DC prevents simultaneous spring and service brake application. As pressure in the trailer supply circuit drops, the spring (Ref. 7) in the TP–3DC valve forces the inlet valve closed (as described above in "Tractor Protection." Any pressure in the trailer control circuit (Ref. 6) is relieved by passing first through the single check valve and then exhausting at the trailer supply valve.

If the service brakes (hand or foot) are released and applied again, the closed inlet valve prevents air pressure from reaching the trailer control circuit.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

1. Chock the tires and stop the engine before working under the vehicle. Releasing air from the system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not correctly disassembled. Use only correct tools and observe all precautions regarding use of those tools.

Leakage Test

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

1. Chock the tires, start the engine, and run it until the air system is fully charged.
2. Shut down the engine and place the trailer air supply valve in the emergency position.
3. Disconnect the trailer control line hose coupling and apply a soap-water solution to the coupling.
4. With tractor reservoirs charged to at least 100 psi (689 kPa) make and hold a full service brake application using either the foot valve or the trailer control valve. Leakage at the hose coupling should not exceed a 1-inch (2.5-cm) bubble in five seconds.
5. Release the service brake application and place the trailer supply valve in the "run" position. Connect the trailer control valve to a test gauge.
6. Make a service brake application and note that service air pressure is present at the trailer control line hose coupling.
7. Disconnect the air line at the TP–3DC tractor control port (primary), plug the line, and apply a soap-water solution to the valve.
8. Make a service brake application and check for leakage at the open tractor control port. Leakage should not exceed a 1-inch (2.5-cm) bubble in five seconds.
9. Reconnect the air line to the tractor control port (primary) and disconnect the air line at the tractor control port (secondary). Then, plug the disconnected line and apply a soap-water solution to the valve.
10. Make and service brake application and check for leakage at the open tractor control port. Leakage should not exceed a 1-inch (2.5-cm) bubble in five seconds.

IMPORTANT: If the valve does not function as described, or if leakage is excessive, repair or replace the valve.

Removal

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.

1. Chock the tires, and open the air reservoir drain cocks to bleed the air from the system.
2. Remove the trailer hose assemblies from the TP–3DC valve. Disconnect the tractor service and supply lines. Mark the lines for later assembly reference. Cap the air lines tightly to keep out contaminants.
3. Remove the fasteners attaching the TP–3DC valve to the vehicle, and remove the valve.

Installation

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.

1. Place the TP–3DC valve on the vehicle, and attach it with bolts, washers, and nuts. Tighten the nuts 11 to 15 lbf·ft (15 to 20 N·m).

NOTE: The delivery line from the trailer air supply valve is connected to the tractor emergency port of the TP–3DC valve. See **Fig. 1**. The delivery line from the brake valve (double check valve) is connected to the tractor service port of the TP–3DC valve. Trailer hose assemblies are installed in the trailer emergency and trailer service ports of the TP–3DC valve.

2. Remove the caps from the air lines, and depending on the type of air hose, use the following instructions to connect the air hoses to the TP–3DC valve:

   If equipped with nylon tube air hoses, connect the hose fittings to the valve ports, and tighten the nuts finger-tight. Then, using a wrench, tighten the nuts at least two turns, or until no threads show on the fitting.

   If equipped with wire braid hoses, connect the hose fittings to the valve ports, and hand-tighten the nuts. Using a wrench, tighten the nuts until there is resistance. Tighten one-sixth turn more. Do not overtighten.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the TP–3DC valve in cleaning solvent, then dry them using compressed air.
2. Examine the cover, body, guide, and plunger for corrosion, excessive wear, cracks, or other damage. If any of these conditions are found on a part, replace the part with a new one.
3. Check the spring for distortion and corrosion. If the spring is distorted or corroded, replace it.
4. Check the valve body bores for deep scratches or gouging

General Information

The System Saver 1200 air dryer **(Fig. 1)** is a desiccant air dryer, mounted vertically between the air compressor and the supply reservoir. The air dryer receives hot compressed air, which it cools and filters before sending it to the supply reservoir, reducing the build-up of dirt and moisture in the vehicle air system.

9. Inlet Port (from air compressor)

Fig. 1, WABCO System Saver 1200

The air dryer consists of a light weight aluminum and steel body. The desiccant cartridge is contained in a spinoff canister at the top of the air dryer.

The bottom half of the air dryer houses the following components.

- Pressure Relief Valve–this valve protects the air dryer from over pressurization. The valve is attached directly to the air dryer.
- Desiccant Canister–a cylindrical steel housing that contains the filter elements and the desiccant needed to filter and dry the air that passes through it.
- Heater/Thermostat Assembly–located in the air dryer base, this assembly is designed to prevent the collected moisture from freezing.
- Outlet Check Valve–this valve prevents air in the system from flowing back through the air dryer and escaping out the purge valve during the compressor unload cycle.
- Pressure-Controlled Check Valve–this valve is separate from the air dryer and is installed on the system air tank. The valve allows air to back flow from the system tank to the supply tank as long as air system pressure remains between the normal cut in and cut out range of the air governor.
- Purge Valve–this valve allows the collected moisture and contaminants to be expelled from the air dryer during the purge cycle.
- Regeneration Valve–this valve allows air from the supply and system tanks to bypass the outlet check valve and flow into the regeneration valve. Air then flows through an orifice where the air expands and back flushes moisture off of the desiccant. The air is then exhausted through the purge valve.
- Silencer (Muffler)–an optional component that is attached to the purge valve and used to eliminate most of the noise during the air dryer purge cycle.
- Turbocharger Cut-Off Valve–this valve closes the path between the air compressor and the air dryer purge valve to help maintain boost pressure for maximum engine horsepower during the compressor unload cycle.

Principles of Operation

Hot, compressed air enters the air dryer through the inlet port. As the hot air is forced into the desiccant cartridge, the temperature of the compressed air falls to nearly ambient. Oil and water vapor condense and initially settle into the base of the dryer. The moisture-laden air also passes through the desiccant bed, where any remaining moisture is retained by the desiccant. The clean air then passes through the air dryer outlet port to the supply reservoir. See **Fig. 2 .**

Fig. 2, Sectional View

When the compressor reaches 125 psi (862 kPa), the purge valve opens allowing the initial decompression of the dryer and expels the water and contaminants collected in the base of the dryer. The regeneration valve, along with the pressure-controlled check valve, allows the system air to flow back through the dryer. This back flow dries the desiccant for the next cycle.

Safety Precautions

⚠ WARNING

When draining the air system, do not look into the air jets or direct them toward another person, as dirt or sludge particles may be in the air-stream. Do not disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can cause personal injury.

When working on or around air brake systems and components, observe the following precautions.

1. Apply the parking brake, chock the tires, and stop the engine when working under the vehicle. Draining the air system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air system pressure drops.
2. Wear safety goggles.
3. Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
4. Don’t disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
5. Replacement hardware, tubing, hose, fittings, etc. should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace any components that have stripped threads or damaged parts. Don’t attempt to repair parts by machining.
7. Never exceed recommended air pressure.

Operating Tests

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

AIR DRYER OPERATING CHECK

1. Drain the air system.
2. Start the engine and build the air pressure to as close to cutout pressure as possible (about 125 psi [162 kPa]).
3. When the compressor reaches the unload cycle, the air dryer purges, beginning regeneration of the air dryer.
4. During the purge cycle, which lasts about 10 to 15 seconds, the wet tank and system tank sith pressure-controlled check valve will drop about 10 psi (69 kPa). Check the system air gauge in the cab dash panel.
5. If the gauge needle does not show a pressure drop of about 10 psi (69 kPa), one of the following problems may exist.
   - A pressure-controlled check valve is not installed.
   - The pressure-controlled check valve is installed in the wrong air tank.
   - The pressure-controlled check valve is installed on a one-way check valve, instead of in place of a one-way check valve.
   - There is an extra check valve located somewhere between the air dryer and the secondary air tank (usually at the wet tank).
   - The system air gauge is not plumbed to the correct air system.
6. If system air pressure drops 15 psi (103 kPa) or more during the purge cycle, and there are no other air-operated components in use, then there are air leaks or other system problems. Refer to **Troubleshooting, 300** for other possible causes.

PRESSURE-CONTROL CHECK VALVE OPERATING CHECK

IMPORTANT: Install a calibrated air gauge (accurate to within 1 psi [7 kPa]) in the system air tank with the pressure-controlled check valve to check the valve. Do not use the cab air gauges.

1. Start the engine and build the air pressure to as close to cutout pressure as possible (about 125 psi [862 kPa]).
2. Stop the engine after the air compressor has unloaded.
3. Drain the opposite system air tank(s) down to about 80 psi (552 kPa).
4. Check the calibrated air gauge. It should read 95 ± 5 psi (655 ± 34 kPa).

   If the gauge reading is less that 85 psi (586 kPa), either the pressure-control check valve is installed backwards, it is damaged, or there are air leaks in the system tank air system.

   If the gauge reading does not change, or the reading does not fall below 105 psi (724 kPa), make the checks under "Air Dryer Operating Check." If none of those problems exist, replace the control valve.

Fig. 1, Dryer Reservoir Module

The function of the dryer reservoir module (DRM) is to provide the vehicle with an integrated air dryer, secondary reservoir, purge volume, and governor.

Principles of Operation

The air dryer collects and removes air system contaminants in solid, liquid, and vapor form before they enter the brake system. It provides clean, dry air to the components of the brake system which increases the life of the system.

CHARGE CYCLE (See Fig. 2)

When the compressor is loaded, compressed air, oil, oil vapor, water, and water vapor flow through the compressor discharge line to the supply port of the air dryer body.

As air travels through the air dryer assembly, its temperature falls, causing some of the contaminants to condense and drop to the bottom of the air dryer assembly, ready to be expelled at the next purge cycle.

The air then flows into the desiccant cartridge. Once in the desiccant cartridge, air flows through an oil separator which removes oil and solid contaminants.

Air then flows into the desiccant drying bed. Air flowing through the desiccant becomes progressively dryer as water vapor adheres to the desiccant material.

Dry air exits the bottom of the desiccant cartridge and flows through the center of the base assembly. The air then flows to the delivery check valve, to the safety valve and also through an orifice plug into the purge volume reservoir. Air traveling through the delivery check valve flows to the governor and two pressure protection valves.

As pressure builds during the initial charge, the purge volume fills. When the air pressure reaches 103 psi (710 kPa), the first pressure protection valve opens, filling the primary reservoir. When the primary reservoir pressure reaches 109 psi (752 kPa) the second pressure protection valve opens and air is supplied to the secondary reservoir and accessory pressure protection valves. When air pressure in the secondary reservoir reaches 55 and 85 psi (379 to 586 kPa) respectively, the two remaining pressure protection valves open and supply air to the accessories.

NOTE: There is no external air line from the air dryer to the secondary reservoir. Air is supplied by a line passing through the purge reservoir.

The air dryer will remain in the charge cycle until the air brake system pressure builds to the governor cutout setting of approximately 130 psi (896 kPa).

PURGE CYCLE (See Fig. 3)

When air brake system pressure reaches the cutout setting of the governor, the governor unloads the compressor and the purge cycle begins. When the governor unloads the compressor, it pressurizes the compressor unloader mechanism and the dryer control port. The purge piston moves in response to air pressure, causing the purge valve to open and the turbo cutoff valve to close. When the purge valve opens, water and contaminants are expelled. Air flowing through the desiccant cartridge changes direction and begins to flow toward the open purge valve. Oil and solid contaminants collected in the oil separator are removed by air flowing from the purge volume, through the desiccant drying bed, and out through the open purge valve.

The purge cycle lasts only a few seconds and is detected by an audible burst of air at the air dryer exhaust.

Fig. 2, Air Dryer Charge Cycle

The reactivation of the desiccant drying bed begins as dry air flows from the purge volume, through the purge orifice, and into the desiccant bed. Pressurized air from the purge volume expands after passing through the purge orifice; its pressure is lowered and its volume is increased. The flow of dry air through the drying bed reactivates the desiccant material by removing the water vapor adhering to it. Approximately 30 seconds is required for the entire purge volume of a standard air dryer to flow through the desiccant dryer bed.

The delivery check valve assembly prevents air pressure in the brake system from returning to the air dryer during the purge cycle. After the purge cycle is complete, the air dryer is ready for the next charge cycle to begin.

Turbo Cutoff Feature

The primary function of the turbo cutoff valve is to prevent loss of turbocharger air pressure through the air dryer in systems where the compressor intake is connected to the engine turbocharger.

During the purge cycle, the downward travel of the purge piston is stopped when the turbo cutoff valve contacts its mating metal seat in the purge valve housing. With the turbo cutoff valve seated (closed position), air in the compressor discharge line and air dryer inlet port cannot enter the air dryer. This maintains turbocharger boost pressure to the engine.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

A. Chock the tires and stop the engine before working under the vehicle. Releasing air from the system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.

B. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.

C. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.

D. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not correctly disassembled. Use only correct tools and observe all precautions regarding use of those tools.

Replacement

Operational Tests

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Park the vehicle, shut down the engine, and chock the tires.
2. Install a pressure gauge in one of the spare governor ports labeled "RES."
3. Close all drain cocks and start the engine. Build the air system to governor cutout and shut down the engine.
4. Check all air lines and fittings leading to and from the air dryer for leakage. Note the pressure on the air gauge after the governor cutout pressure is reached, a rapid loss of pressure could indicate a leaking delivery port check valve or turbo cut-off valve.
5. To check for delivery check valve leakage, allow the system air pressure to charge and listen for the air dryer to purge. The purge should last about 30 seconds.
6. Gradually open the drain cock on the purge tank and exhaust any residual pressure.
7. Coat the drain cock with a soap solution. If leakage does not exceed a 1-inch (25.4-mm) bubble in 1 second, no further tests are needed. Remove the chocks from the tires.

   If leakage does exceed a 1-inch (25.4-mm) bubble in one second, proceed with the following step.
8. Apply the brakes a few times, bring the air pressure to a point below governor cut-in (about 95 psi [655 kPa]). The governor will then signal the end of the purge cycle, closing the turbo cut-off valve. Allow any delivery line air pressure to drain, then check again for leakage at the purge tank drain cock. If excessive leakage has stopped, the turbo cut-off valve should be checked.

NOTE: If after replacing the delivery check valve, rapid loss of system air pressure continues, the delivery check valve and turbo cut-off valve are still leaking. Check the valves.

9. Check the operation of the end cover heater and thermostat assembly during cold weather operation as follows:

   9.1 Check the electric power to the air dryer. With the ignition or engine kill switch in the ON position, check for voltage to the heater and thermostat assembly using a voltmeter or test-light. Unplug the electrical connector at the air dryer and place the test leads on each of the connections of the female connector on the vehicle power lead. If there is no voltage, look for a blown fuse, broken wires, or corrosion in the vehicle wiring harness. Check to see if a good ground path exists.

   9.2 Test the thermostat and heater operation. Turn off the ignition switch and cool the thermostat and heater assembly to below 40°F (4°C). Using an ohmmeter, check the resistance between the electrical pins in the air dryer connector half. The resistance should be 1.5 to 3.0 ohms for the 12-volt heater assembly and 6 to 9 ohms for the 24-volt heater assembly.

   Warm the thermostat and heater assembly to about 90°F (32°C) and check the resistance again. The resistance should exceed 1000 ohms. If the resistance values obtained are within the stated limits, the thermostat and heater assembly is operating properly. If the resistance values obtained are outside the stated limits, replace the heater and thermostat assembly. For instructions, see **Subject 150**.
10. Check the pressure protection valves. Observe the pressure gauges of the vehicle as system pressure builds from zero. The primary gauge should rise until it reaches approximately 109 psi (752 kPa), then level off as the second pressure protection valve opens and allow the secondary volume to build. When the secondary pressure gauge passes through approximately 55 and 85 psi (379 and 586 kPa) there should be an associated leveling off of pressure as the third and fourth pressure protection valves open. Then, both the primary and secondary gauges should reach their full pressure of about 130 psi (896 kPa)
11. Remove the chocks.

The Eaton Antilock Braking System (ABS) is an electronic wheel speed monitoring and control system that works with the standard air brake system. Its advanced electronic technology prevents wheel lockups by maintaining precise control of vehicle brake pressure. This ensures optimum vehicle stability while minimizing the stopping distance. During vehicle operation, the ABS Electronic Control Unit

(ECU) continuously monitors all the wheel speed sensors. This wheel speed data allows the ECU to: detect an impending wheel lock; maintain an optimum wheel slip; and maximize the overall braking effectiveness.

The ABS system monitors and controls the brake pressure as follows:

- Each wheel speed sensor monitors and communicates wheel rotation information (speed signal pulses) to the ECU;
- The signals from the wheel speed sensors are then received and interpreted by the ECU. The ECU constantly calculates the relationship of wheel speed, acceleration and deceleration;
- Then, based on this wheel speed information, the ECU operates the ABS pressure modulator valves to regulate the air pressure in the brake chambers;
- During normal braking, air flows freely through the modulator valves to the brake chambers;
- During an emergency braking situation, the ECU signals the pressure modulator valves to increase, reduce, or maintain air pressure supply in the brake chamber.

The ABS indicator lamp reveals the condition of the ABS system. Under normal conditions, whenever the ignition is turned on, the ABS indicator lamp lights steadily for a two-second bulb check. If there are no problems, the ABS indicator lamp goes out. If it remains on, or lights during vehicle operation, then the ABS system requires service.

NOTE: In the case of a speed sensor failure which has been corrected, the ABS indicator lamp will remain on until the speed sensor output has been verified by the ECU. In this case it is necessary to operate the vehicle above a speed of five miles per hour before the indicator light goes out.

The Automatic Traction Control (ATC) System is an option on all ABS applications. The ATC system helps improve traction on slippery or unstable driving surfaces by reducing drive wheel overspin. This system consists of two control circuits; the brake control circuit and the engine throttle control circuit. If only one drive wheel slips, the ATC brake control circuit is activated, and then braking force is applied to the slipping wheel which adds torque to the traction wheel. Brake pressure is increased until the speed of the slipping is the same as the non slipping wheel. To prevent overheating of the brakes, the ATC system automatically deactivates after being applied for an extended amount of time. Then, after allowing sufficient time to cool the brakes, the ATC system will automatically reactivate. As an added safety feature, the brake controller is deactivated at speeds above 19 mph (30 km/h). If both driving wheels slip equally, the engine controller is activated, and then the engine torque is reduced to minimize the drive wheel spin. This option requires the addition of an ATC valve and an SAE J1922 engine interface. The ECU configures itself for traction control when it detects the presence of the ATC valve.

There are three ATC modes of operation:

- During the high-speed mode (highway speed operation), the engine is throttled back to control spin out;
- During the low-speed mode (low speed operation), both the engine controls and the brake controls are used to enhance vehicle traction;
- During the mud and snow mode (optional), a dash switch allows the driver to select more engine power and wheel spin if needed.

The ATC system can not increase traction to a particular wheel, it can only utilize the available traction.

The ATC (Wheel Spin) indicator lamp reveals the condition of the ATC system. The indicator lamp lights when the ignition is switched on and remains lit until the driver applies the brake pedal. The light flashes rapidly in the ATC mode, and it flashes slowly when the "mud and snow" mode is selected.

Principles of Operation

ABS and ATC MAJOR COMPONENTS

Electronic Control Unit (ECU)

The ECU monitors and controls the ABS/ATC system. It receives and evaluates wheel speed information from four speed sensors, and if necessary, transmits control signals to the modulator valves. If the ECU detects no impending wheel lockups, the standard braking system is in effect. The ECU operates actively through the ABS release and hold modes of operation during emergency braking situations. The

ABS release and hold modes are activated by the ECU as it signals the appropriate modulator valve to reduce braking force at that halting wheel until the threat of a skid is eliminated. With automatic traction control (ATC), the ECU also sends control signals to the ATC valve and engine control interface. If a drive wheel slips, the ECU signals the ATC valve to release supply air to the brake chamber of the slipping wheel. This adds braking force to the slipping wheel, which results in the transfer of torque from the wheel with less traction to the wheel with more traction. If both drive wheels slip, the ECU signals the engine controller to reduce engine torque, which will reduce the drive wheel slip. Also, the ECU monitors the ABS/ATC system for malfunctions and stores fault codes into memory. The ECU is mounted inside the left rear compartment of the cab behind the driver's seat. It is mounted in the B-pillar. See **Fig. 2**.

Speed Sensors

Each wheel of an axle under ABS control is monitored by a speed sensor. Speed sensors for drive axles and steer axles are mounted at the wheel ends.

The Eaton ABS uses standard wheel end sensors (**Fig. 3**). The sensors generate an alternating current signal in response to the movement of the teeth on the tone wheel. Either front sensor is accessible on the inboard side of the steering knuckle. Either rear drive axle sensor is accessible by removing the wheel and drum assembly.

Modulator Valves

The ABS air modulator valves control air pressure to the individual brake assemblies. The system utilizes four modulator valves. The steer axle uses separate modulator valves (**Fig. 4**) and the drive axles incorporate two modulator valves into a combination (rear axle module) valve (**Fig. 5**).

The pressure modulator valves regulate air pressure to the brake chambers. A pressure modulator valve is located near each brake chamber or pair of brake chambers on any ABS equipped axle. Each modulator valve contains two solenoids for air control. The hold solenoid maintains air pressure; the release solenoid removes (vents) pressure from the brake chamber. The ECU signals each modulator valve to hold or release air by activating the appropriate solenoid. Each modulator valve carries a three pin terminal connection that connects with the ECU harness. See **Fig. 4**.

The combination (rear axle module) valve (**Fig. 5**) is an assembly of two pressure modulator valves and a standard relay valve. These assemblies have four

solenoids which are controlled in the same manner as the solenoids housed in the front axle pressure modulator valves. These valves are available with a crack pressure setting between 4.0 and 5.0 psi (27.5 and 34.5 kPa). The crack pressure is the ascending input pressure flow required to initiate output pressure flow. Pressure is identified on a stamped washer mounted on the relay valve.

The modulator valves have four modes of operation: the normal and ABS apply mode; the normal release mode; the ABS hold mode; and the ABS release mode.

The normal apply and ABS apply mode operates as follows (see **Fig. 6**):

- Neither solenoid is activated;
- The supply air enters the inlet port;
- Inlet air is routed through solenoid #2 which then forces the release diaphragm to block the exhaust port;
- At the same time, the hold diaphragm is vented through solenoid #1, which allows supply air to flow to the outlet;
- Supply air flows from the inlet port to the outlet port.

The normal release mode operates as follows (see **Fig. 7**):

- Neither solenoid is activated;

- The hold diaphragm is vented through solenoid #1 and there is no pressure at the inlet port;
- The release diaphragm is not pressurized and the outlet pressure forces the exhaust port open;
- Pressurized air flows from the outlet port to the inlet port and also from the outlet port to the exhaust port.

The ABS hold mode operates as follows (see **Fig. 8**):

- Solenoid #1 is activated;
- Supply air enters the inlet port;
- Inlet air routes through both the #1 and #2 solenoids;
- Both the hold and release diaphragm cavities become pressurized;
- The hold diaphragm closes off the air passage between the inlet and outlet port and the release diaphragm closes off the exhaust port;
- No air flows through the valve.

The ABS release mode operates as follows (see **Fig. 9**):

- Both solenoids are activated;
- Supply air enters the inlet port;
- Inlet air routes through solenoid #1;
- The hold diaphragm cavity becomes pressurized;
- The hold diaphragm closes off the air passage between the inlet and outlet port;
- The release diaphragm is vented through solenoid #2, which allows the outlet air pressure to force open the exhaust port;
- Pressurized air flows from the outlet port to the exhaust port.

ABS and ATC (Wheel Spin) Indicator Lamps

The amber ABS indicator lamp is located on the driver's instrument panel. The indicator lamp warns the driver of any ABS malfunctions. It is also capable of blinking diagnostic fault codes when the ECU is in the diagnostic mode.

The ATC (Wheel Spin) indicator lamp is located on the driver's instrument panel. This indicator lights when a loss of traction condition exists and the ATC system is activated.

NOTE: In some cases, vehicles without ATC are equipped with an ATC (Wheel Spin) indicator lamp. In these cases, the lamp indicates a slip condition but no control action is taken.

Diagnostic Port Connector

The diagnostic port connector is an industry standard connector, which is used to provide a connector to the J1587 diagnostic link. This connector also provides power and ground to the diagnostic test equipment.

⚠ CAUTION

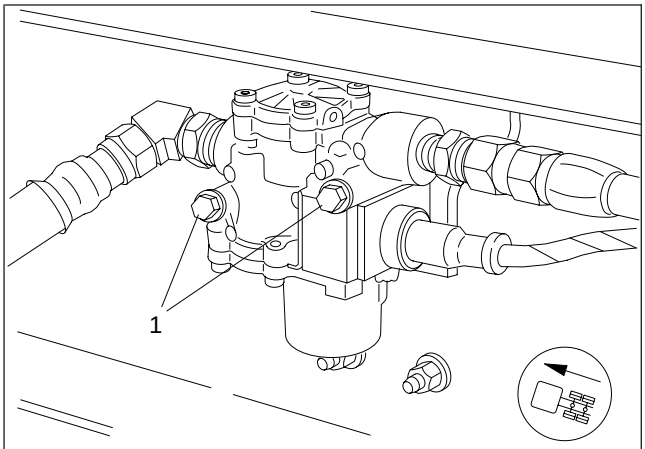
The speed sensor must slide freely in and out of the mounting sleeve bore. Operating the vehicle with seized components will damage the speed sensor and the tone wheel.

10. Lubricate the body of the speed sensor with Penzoil 707L, Valvoline LP, or Mobil HP.
11. By hand, push the speed sensor completely into the bushing (on the axle housing) until the speed sensor stops against the tone wheel.

    The speed sensor is properly installed and adjusted when it is touching the tone wheel.
12. Route the cable to the frame.
13. Connect sensor cable to harness and install fasteners to hold sensor cables in position.
14. Install the brake drum on the wheel hub. For instructions, see **Group 35** in this manual.
15. Adjust the rear axle brakes. For instructions, see **Group 42** in this manual.
16. Install the wheel and tire assembly to the rear axle and tighten the wheel nuts. For instructions, see **Group 40** in this manual.
17. Remove the safety stands, lower the vehicle, set the parking brake, and remove the chocks from the tires.

Replacement (See Fig. 1 and Fig. 2)

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Section 54.00, Subject 100** in this manual for information on special terminals and connectors, and special tools.



1. Mounting Fasteners

1. Mounting Fasteners

Fig. 2, Combination (rear axle module) Valve Mounting

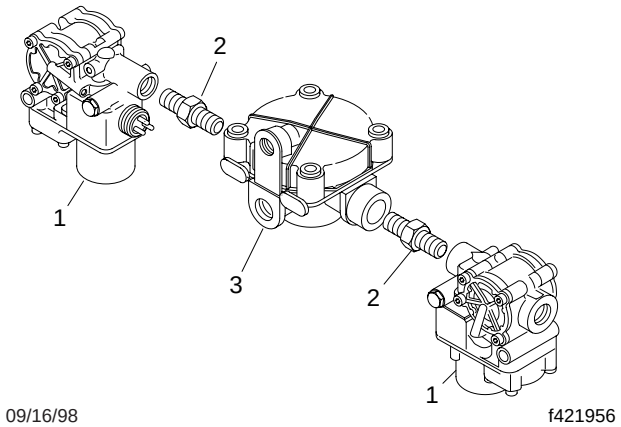
1. Turn the ignition switch to the off position.
2. Apply the parking brakes. Chock the front and rear tires to prevent vehicle movement.
3. Release the pressure from the air reservoirs.
4. Disconnect the wiring from the pressure modulator valve or the combination (rear axle module) valve.
5. Mark the air lines for ease of installation. Disconnect the air lines.
6. Remove the two mounting capscrews, washers, and nuts.
7. Remove the pressure modulator valve or combination (rear axle module) valve.

NOTE: The combination (rear axle module) valve can be disassembled, if the relay valve or one of the pressure modulator valves need replacing. For disassembly and assembly instructions, see **Subject 120**.

8. Install the pressure modulator valve or the combination valve using the above instructions in reverse order. Tighten the mounting nuts 18 lbf·ft (24 N·m).
9. Test the pressure modulator valve.
   - 9.1 Check the pressure modulator valve for leaks by applying and holding the brakes. No audible air leaks are permitted.
   - 9.2 Using a MPSI Pro-Link 9000® hand-held tester, go to component test (#4) menu screen (on the hand-held tester) and select the valve routines option. This will verify the operation and the proper location of the pressure modulator valve. For more information on the use of the hand-held tester, see **Troubleshooting, 300**.

Combination (Rear Axle Module) Valve Disassembly and Assembly

Disassembly (See Fig. 1)



1. Modulator Valve
2. Pipe Nipple
3. Relay Valve

Fig. 1, Combination (rear axle module) Valve

1. Remove the combination valve. For instructions, see **Subject 110**.
2. Carefully separate the pressure modulator valves from the relay valve.

Assembly (See Fig. 1)

1. Plug any unused ports on the replacement valve(s).

IMPORTANT: Before installing the pipe nipples into the valves, apply a small quantity of Loctite® Pipe Sealant (with Teflon® 59241), or an equivalent sealant, to the male threads of each side of the pipe nipples.

2. Using the pipe nipples, attach the ABS control valve(s) to the relay valve.
3. Install the combination valve. For instructions, see **Subject 110**.
4. Test the relay valve assembly.

   4.1 With the front and rear wheels chocked, fully charge the air system (governor cut out point). Then, release the parking brake.

   4.2 With the engine off, apply the service brake several times, then hold and check all the wheels for prompt application and release. If a sluggish response is noted at all of the wheels, inspect for a kinked or obstructed air line leading to or from the valve.

   4.3 Check for air leaks.

   Apply and hold the brakes. Coat the outside of the relay valve (where the cover joins the body and where the pressure modulator valves meet the body) with a soap solution. No air leakage is permitted.

   Increase the system air pressure to the governor cut-off. Turn the engine off. With the brakes released, coat the exhaust port of the relay valve with a soap solution. Leakage of a 1-inch (2.5-cm) bubble in five seconds is permissible.

   4.4 Depress the foot valve. Coat the exhaust port with a soap solution. Leakage of a 1-inch (2.5-cm) bubble in three seconds is permissible. Release the foot valve.

Replacement (See Fig. 1)

⚠ WARNING

Do not start and engage the transmission with one wheel raised from the floor. For vehicles equipped with ATC, if the transmission is engaged with one of the drive axles raised, all the driving torque from the transmission will go to the wheel on the floor (the drive axle not raised). This could cause the vehicle to move on its own and result in personal injury or property damage.

NOTE : Wire repairs may require the use of special tools for certain connectors and terminals. See **Section 54.00, Subject 100** in this manual for information on special terminals and connectors, and special tools.

4. Mark the air lines for ease of installation. Disconnect the air lines.
5. Remove the two mounting capscrews, washers, and nuts.
6. Remove the ATC valve.
7. Install the ATC valve using the above instructions in reverse order. Tighten the mounting nuts 18 lbf·ft (24 N·m).
8. Test the ATC valve.
   - 8.1 Check ATC valve for leaks by applying and holding the brakes. No audible air leaks are permitted.
   - 8.2 Using a MPSI Pro-Link 9000® hand-held tester, go to test (#4) menu screen (on the hand-held tester) and select the TCV option. Troubleshooting

Eaton recommends the use of a MPSI Pro-Link 9000® hand-held tester and a multimeter or digital volt-ohmmeter (DVOM) to troubleshoot the ABS system. An important part of the Eaton Antilock Brake System is the system diagnostics. The electronic control unit internally checks the systems components and, if necessary, stores retrievable diagnostic fault codes. The fault codes and the MPSI Pro-Link 9000® hand-held tester can pinpoint solutions to any system faults. The wiring schematics (in **Specifications, 400**) and the multimeter can be used to check sensor and solenoid resistance, and determine component or wiring harness faults. A test adaptor may be required to use the multimeter.

Configuration Code, Fault Codes, and Diagnostic Methods

If the ABS indicator lamp lights and stays lit, then a system malfunction (configuration conflict) has occurred. It signifies that a fault code may exist.

The configuration code defines what system components are equipped on the vehicle. It is stored and retrieved as a four digit number.

A fault code defines what type of malfunction has occurred, and it is stored and retrieved as a group of two numbers. The possible combinations of the two numbers in a fault code include:

- two 2-digit numbers;
- one 2-digit number and one 1-digit number;
- or, two one-digit numbers.

There are two ways to retrieve and display a configuration and/or fault code(s); the automatic diagnostics method, or the manual blink code diagnostics method.

AUTOMATIC DIAGNOSTICS METHOD

The automatic diagnostics method uses either an MPSI Pro-Link 9000® hand-held tester or the Freightliner ServiceLink PC platform to automatically display a fault code(s) (two numbers) on the tester display screen. For more information on using the ServiceLink computer and ServiceLink software, see Service Bulletin 00-20.

The MPSI Pro-Link 9000® hand-held tester, along with Eaton's proprietary cartridge, employs menu-driven tests for diagnosing malfunctions in the ABS system. This method can be used to: obtain short descriptions of the failures; retrieve and clear fault codes; and report the systems configuration code. Also, the tester can initiate test sequences to invoke ECU outputs and can read system parameters such as wheel speeds. A standard heavy-duty truck cartridge may be used to retrieve the fault codes, but cannot initiate test sequences. The Eaton proprietary cartridge has nine functions in its menu.

When retrieving fault codes, the hand-held tester illuminates four lines of text on its display. The first three lines of text display a short description of the failure and the last line displays the fault code. If more than one code is active, arrows appear on line 4 to indicate that you can scroll the list. If arrows do not appear, there is only one actual fault present.

NOTE: If troubleshooting the system with the Pro-Link 9000, use the instruction booklet that is supplied with the data cartridge.

Retrieving the Configuration Code, and Retrieving and Clearing Fault Codes

For a listing of possible configuration code reports, see **Table 1**. For a list of fault codes, see **Table 3**, **Table 4**, **Table 5**, **Table 6**, **Table 7**, **Table 8** and **Table 9**.

1. Assemble the MPSI Pro-Link 9000® Hand-held Tester.
2. Turn the ignition switch to the on position, but don't start the engine.
3. If the tester powers up and displays the Eaton copyright screen (the tester identifies the Eaton Generation 4 ABS ECU), then go to the next step. Otherwise, locate the cause of the tester not powering up (identifying the ECU).
   - 3.1 Check that the tester is in good working condition.
   - 3.2 Check that all the J1587 wiring and connections are complete.

3.3 If the tester is in good working condition and the J1587 circuitry is okay, then there must be an open circuit in the ECU. Replace the ECU.

4. After the Eaton copyright screen is displayed on the tester, press enter to display the menu options.
5. After the menu screen is displayed on the tester, select either #2 (fault codes) or #5 (system setup).
6. If #2 was selected, choose either actual fault codes, extended fault codes, or clear memory. If #5 was selected, then choose system configuration to display the configuration code.

NOTE: The fault codes are stored either as two 2-digit numbers, one 2-digit number and one 1-digit number, or two one-digit numbers. The configuration code is stored as a 4-digit number.

MANUAL BLINK CODE DIAGNOSTICS METHOD

The manual blink code diagnostics method uses the diagnostic switch (fastened to the ABS ECU inside the right rear compartment of the cab), the ignition switch, the brake light switch, the ABS indicator lamp, and the ATC (wheel spin) indicator lamp to report configuration codes, report and clear fault codes, and disable the ATC for dynamometer testing.

A blink code is a flash sequence displayed at the ABS indicator lamp. The diagnostic switch is used to recall the system configuration code and/or fault code input (stored in memory) through flash sequences (blink codes) at the ABS indicator lamp.

The configuration code is reported by four blink codes (a 4-digit number), which consist of four flash sequences. The configuration code is stored as a 4-digit number. See **Table 1** for a listing of possible configuration reports.

Table 1, Configuration Code Reports

The fault codes are reported by a pair of blink codes (two 2-digit numbers, one two-digit number and one 1-digit number, or two 1-digit numbers), which consist of two flash sequences. The fault code reporting process consists of: the first flash sequence; a 1.5 second pause; and finally the second flash sequence. There is a 1.5 second pause between the two flash sequences in a fault code. Also, there is a 4.5 second pause between fault codes. The flash sequence pairs continue, with 4.5 second pauses between them, until all fault codes are reported. See **Fig. 1**.

Reading the Configuration Code, Reading and Clearing Fault Codes, and Disabling the ATC for Dynamometer Testing

NOTE: When pressing the diagnostic switch for a designated amount of time (from 1 to 3 seconds), use a counting method such as one thousand one, one thousand two, etc. for the time (second) interval. This will allow more accurate configuration and/or fault code retrieval and reduce the possibility of misreading blink code information.

1. Read and record the configuration code.
   - 1.1 Turn the ignition key to the on position (engine off).
   - 1.2 Press and hold the diagnostic switch closed for at least one second but less than three seconds and then release the switch.
   - 1.3 Immediately press the diagnostic switch closed a second time (for at least one second but less than three seconds) and then release the switch.
   - 1.4 Read and record the flashing pulses at the ABS indicator lamp.
2. Read and record the fault code(s). See **Fig. 1**.
   - 2.1 Turn the ignition key to the on position (engine off).

2.2 If the vehicle is equipped with ATC, apply and release the brakes once before proceeding. This will turn off the ATC (wheel spin) indicator lamp.

2.3 Press and hold the diagnostic switch for at least one second but less than three seconds and then release the switch (remember, count one thousand one).

2.4 Read and record the flashing pulses at the ABS indicator lamp (in pairs).

2.5 Continue reading and recording the flashing pulses (in pairs) until all the fault codes are recorded.

2.6 After retrieving and recording all the fault codes, see **Table 3**, **Table 4**, **Table 5**, **Table 6**, **Table 7**, **Table 8** and **Table 9** for a list of fault codes.

3. Clear fault code(s).

3.1 With the ignition key in the off position, press and hold the diagnostic switch closed. Turn the ignition key to the on position.

3.2 Wait two seconds and then release the diagnostic switch.

3.3 If the vehicle is equipped with ATC, apply and release the brakes once before proceeding. This will turn off the ATC (wheel spin) indicator lamp.

3.4 The fault codes are now cleared.

3.5 To verify that the fault codes are cleared, repeat the step on reading fault codes.

4. Disable the ATC system for dynamometer testing.

4.1 Turn the ignition key to the on position (engine on).

4.2 Press and hold the diagnostic switch closed for at least three seconds and then release it.

4.3 The ATC (wheel spin) light turns on and the ABS light flashes 17 times, then pauses and flashes 8 times. These blink codes indicate that the ATC is disabled.

NOTE: At the next ignition cycle the ATC will be reactivated.

A. Access the active fault codes using either the blink code procedure, the MPSI Pro-Link 9000® Hand-held Tester, or the Freightliner ServiceLink computer and software.

B. Using the fault code tables, look up the code description, the possible causes of the fault condition, and the recommended procedures to repair the fault condition.

C. Perform the recommended repair procedures.

D. After the repairs are completed, clear all the codes and check for any additional codes.

See **Fig. 2** and **Table 2** for ECU harness connector information, which corresponds to the fault code tables.

2 (left front), 3 (right front), 4 (left rear), or 5 (right rear) NOTE: The first blink code of the speed sensor fault codes represents which speed sensor is at fault.	1	The sensor air gap is too large.	If necessary, clean and lubricate the sensor. Press the sensor into the mounting hole until it bottoms against the tone wheel. Clear the fault code and verify that the fault code is corrected by test driving the vehicle. The warning light will remain on until proper speed sensor outputs are detected even though the fault has been cleared. See **Subject 100** in this section for lubrication requirements.
2 (left front) NOTE: The first blink code of the speed sensor fault codes represents which speed sensor is at fault.	2	The air gap is too large or the sensor is shorted.	Using a multimeter, check the resistance in the left steer speed sensor (1) circuit. Unplug connector B at the ECU and measure the resistance between pin B-4 and pin B-5. Unplug the speed sensor cable from the connector at the wheel location and measure the resistance between the two pins. The correct resistance for the speed sensor circuit is between 950 to 1900 ohms. If the sensor resistance is out of range, replace the sensor. Clean and lubricate the sensor. Press the sensor into the mounting hole until it bottoms against the tone wheel. Clear the fault code and verify that the fault code is corrected by test driving the vehicle. The warning light will remain on until proper speed sensor outputs are detected even though the fault has been cleared. See **Subject 100** in this section for lubrication requirements.
3 (right front) NOTE: The first blink code of the speed sensor fault codes represents which speed sensor is at fault.	2	The air gap is too large or the sensor is shorted.	Using a multimeter, check the resistance in the right steer speed sensor (2) circuit. Unplug connector C at the ECU and measure the resistance between pin C-4 and pin C-5. Unplug the speed sensor cable from the connector at the wheel location and measure the resistance between the two pins. The correct resistance for the speed sensor circuit is between 950 to 1900 ohms. If the sensor resistance is out of range, replace the sensor. Clean and lubricate the sensor. Press the sensor into the mounting hole until it bottoms against the tone wheel. Clear the fault code and verify that the fault code is corrected by test driving the vehicle. Using a multimeter, check the resistance in the left rear speed sensor (3) circuit. Unplug connector D at the ECU and measure the resistance between pin D-5 and pin D-6. Unplug the speed sensor cable from the connector at the wheel location and measure the resistance between the two pins. The correct resistance for the speed sensor circuit is between 950 to 1900 ohms. If the sensor resistance is out of range, replace the sensor. Clean and lubricate the sensor. 5 (right rear) NOTE: The first blink code of the speed sensor fault codes represents which speed sensor is at fault.	2	The air gap is too large or the sensor is shorted.	Using a multimeter, check the resistance in the right rear speed sensor (4) circuit. Unplug connector D at the ECU and measure the resistance between pin D-8 and pin D-9. Unplug the speed sensor cable from the connector at the wheel location and measure the resistance between the two pins. The correct resistance for the speed sensor circuit is between 950 to 1900 ohms. If the sensor resistance is out of range, replace the sensor. Clean and lubricate the sensor. The warning light will remain on until proper speed sensor outputs are detected even though the fault has been cleared. See **Subject 100** in this section for lubrication requirements.
2 (left front), 3 (right front), 4 (left rear), or 5 (right rear) NOTE: The first blink code of the speed sensor fault codes represents which speed sensor is at fault.	3	The speed sensor signal is noisy.	Examine the tone wheel for damage. Replace the tone wheel and/or hub if necessary. Check the wheel bearing adjustment. Adjust the wheel bearing if necessary. Clear the fault code and verify that the fault code is corrected by test driving the vehicle. The warning light will remain on until proper speed sensor outputs are detected even though the fault has been cleared.

General Description (See Fig. 1)

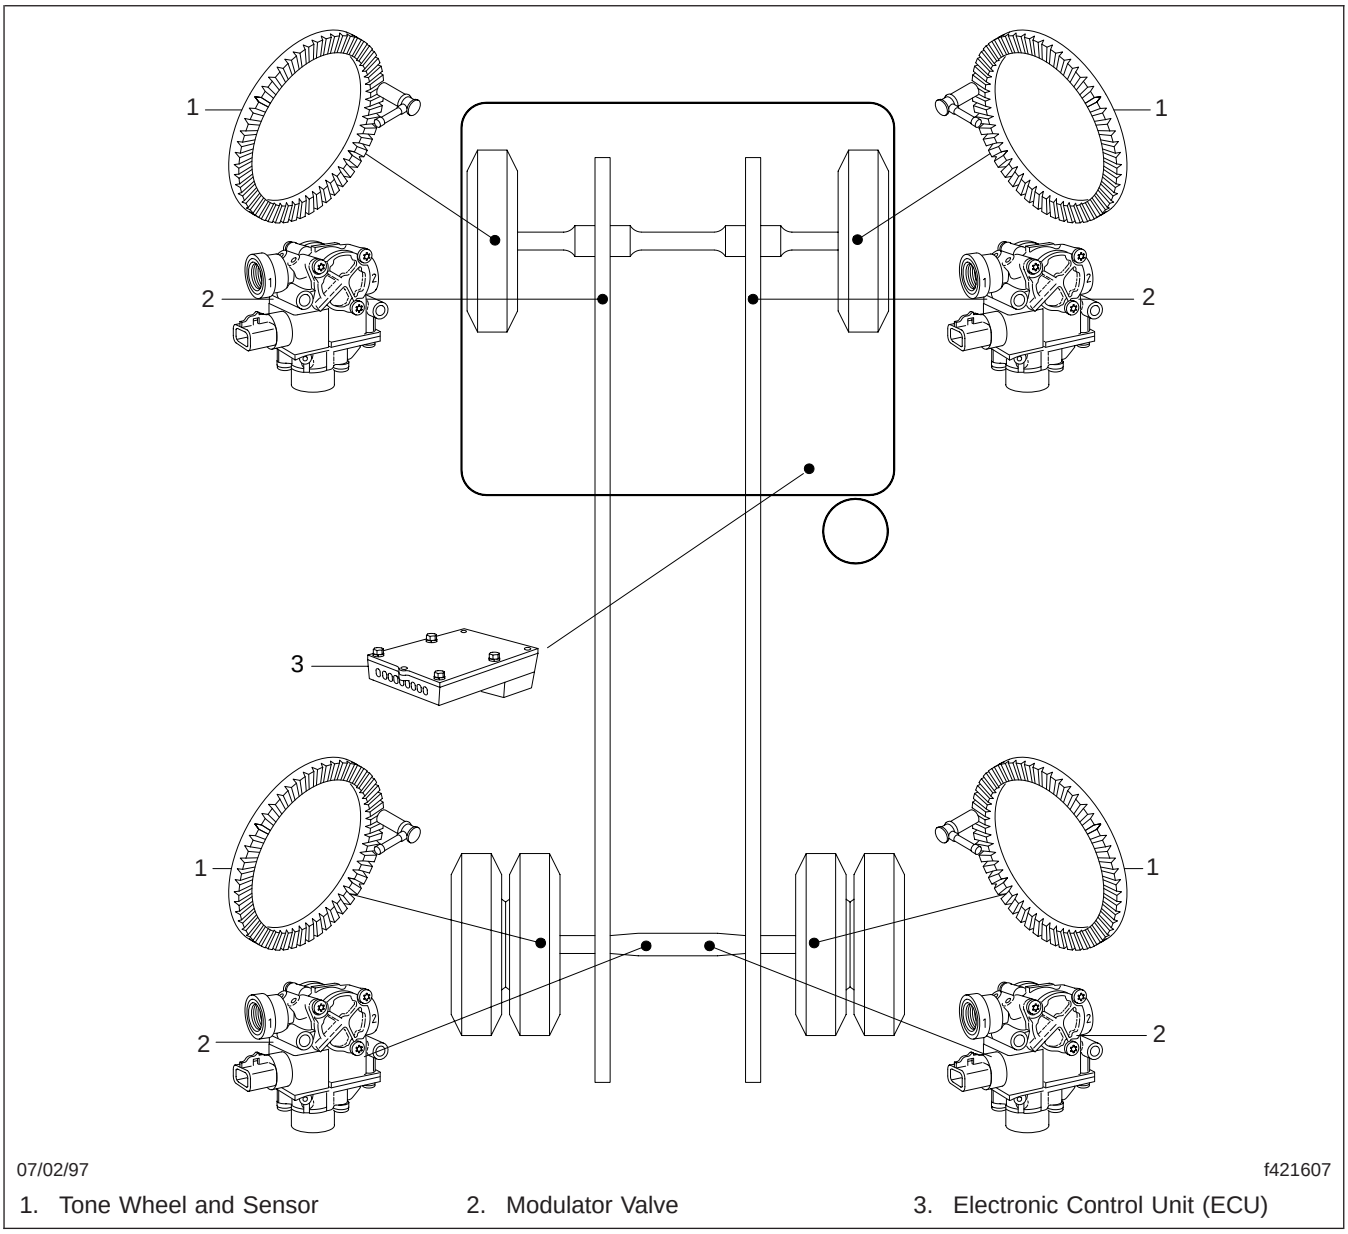

Fig. 1, Location of ABS Components, Four-Channel System

The Bendix Antilock Braking System (ABS) is an electronic wheel-speed monitoring and control system that works with the standard air brake system. ABS passively monitors vehicle wheel speed at all times, and controls wheel speed during emergency stops. In normal braking applications, the standard air brake system is in effect.

ABS includes signal-generating tone wheels and sensors located in the wheel hubs of each sensed wheel. The sensors transmit vehicle wheel speed

information to an electronic control unit. According to programmed specifications, the control unit signals the appropriate modulator valve to increase, reduce, or maintain air pressure supply in the brake chamber. This prevents front and rear wheel lockup, and enhances steering control during emergency braking situations.

Principles of Operation

The ABS electronic control unit (ECU) is a digital microcomputer that serves as the information processing and command center for the antilock braking system. See **Fig. 2**. The ECU receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the ECU regulates the braking force applied to each wheel by sending control signals to the modulator valve. See **Fig. 3**.

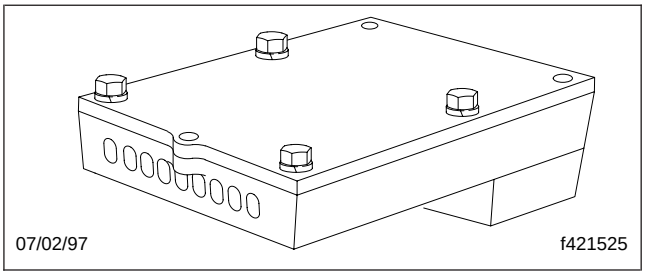

Fig. 2, ABS Electronic Control Unit (ECU)

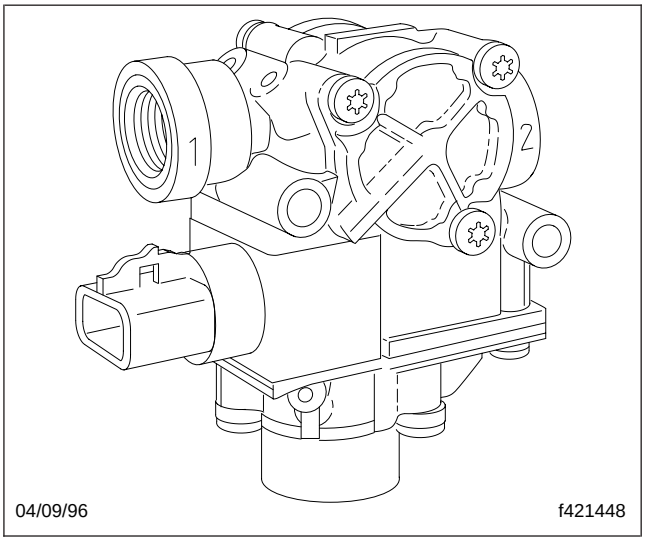

Fig. 3, Modulator Valve

ABS MAJOR COMPONENTS

Wheel Speed Sensor

The wheel speed sensors use pulse feedback from 100-tooth tone wheels located in the front and rear axle wheel hubs. When the vehicle is moving, the teeth of the tone wheel cause interruptions in a magnetic field created by the sensor. The interruptions created in the magnetic field in turn create electrical pulses that are sent by the sensor to the ECU.

Electronic Control Unit (ECU)

The ECU receives speed sensor pulses and interprets these signals to calculate wheel speed and a vehicle reference speed. If the calculations indicate wheel slip or lockup, the appropriate control circuit signals the modulator valve to increase or decrease braking pressure.

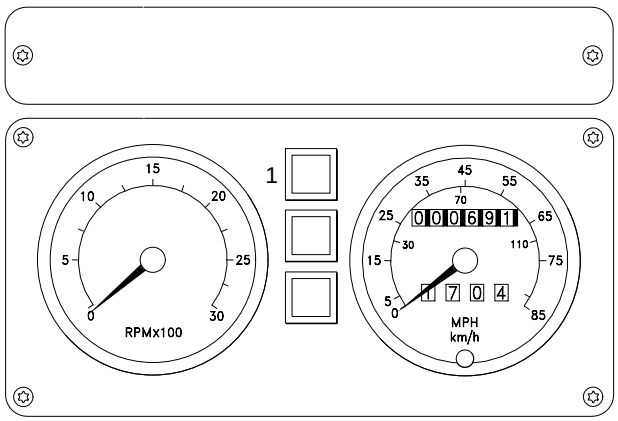
There are three versions of the ECU. The older versions (EC-15 and EC-16) are factory programmed with vehicle particulars, such as the number of speed sensors, if the traction control feature was enabled and the type of traction control (torque limiting, differential braking, or both).

The current, self-configuring ECU (EC-17) can be most easily identified while installed on the vehicle. Identification can be made by observing the reaction of the diagnostic display when the ignition is turned on and power is applied to the ECU. The current configuration of the ECU is displayed via the troubleshooting LEDs and occurs during the normal self test sequence. Only the LEDs that correspond to the sensors identified during the self-configuration will illuminate. If all antilock components are working properly, the red LEDs will turn off and the single, green, VLT LED will be illuminated. This configuration review is repeated each time the ignition is turned on.

IMPORTANT: The LED display is optional on the EC-17. The EC-17N control unit does not have an LED display and the AlliedSignal Bendix Diagnostic Communication Interface (DCI) must be used for diagnostics or reconfiguration.

On the older versions of the ECU, *all* diagnostic LEDs will illuminate and then go out if all antilock components are working properly. During normal operation, all the red LEDs will be off and the single, green, VLT LED will be illuminated. See **Troubleshooting, 300** for more information on the LED display.

The ECU contains a safety circuit to constantly monitor the wheel sensors, modulator assemblies, and the electrical circuitry. After the ignition is switched on, the tractor warning light (TRAC ABS) comes on. See **Fig. 4**. On vehicles with newer ECUs, the TRAC ABS light will go out shortly after the ignition is turned on. On vehicles with the older ECUs, the TRAC ABS light will stay lit until the vehicle reaches 7 mph (11 km/h). The TRAC ABS light will stay on if the tractor's ABS components are not working properly.



1. TRAC ABS

Fig. 4, Indicator Light

When vehicle power is supplied to the EC-17, a modulator "chuff" test is performed. When the brake pedal is depressed while the ECU is powered up, the modulator "chuff" test can be heard. This test will verify if the modulator is connected correctly and is functional. The modulators will exhaust air in the sequence of right front, left front, right rear and left rear. If they don't follow this sequence, proceed with modulator troubleshooting. See **Troubleshooting, 300**.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (a sensor, modulator valve, wiring connection, short circuit, etc.), the TRAC ABS light comes on, and the control circuit where the failure occurred is switched to normal braking action. Remaining control circuits will retain the ABS effect. Even if the ABS system is completely inoperative, normal braking is maintained. The vehicle is not disabled.

IMPORTANT: If the ABS warning lights do not work as described above, there is a possible system malfunction. If this occurs, the vehicle will continue to have normal braking ability, but without ABS. Service the ABS as soon as possible. See **Troubleshooting, 300** for fault diagnosis.

Modulator Valve

Depending on the signal received from the ECU, the modulator valve prevents wheel lockup by reducing, maintaining, or increasing brake chamber air pressure. During normal braking applications, compressed air flows freely to the brake chamber through the modulator valve.

If the ECU receives signals indicating wheel lockup during a brake application, the ECU energizes both the supply and exhaust solenoids in the modulator valve. See **Fig. 5**. Energizing the supply solenoid causes its exhaust to close and inlet to open. With the inlet of the supply solenoid open, application air is permitted to flow to the control side of the supply diaphragm. Air pressure acting on the supply diaphragm causes it to close the supply diaphragm and prevent further delivery of air to the brake chamber.

control side of the exhaust diaphragm. Air pressure, which was present on the control side of the exhaust diaphragm flows out the exhaust port of the modulator valve. With control air pressure removed from the exhaust diaphragm, brake application air forces the exhaust diaphragm to unseat which allows it to flow out the modulator exhaust port.

As wheel speed increases, the modulator valve alternately increases, then maintains brake pressure until the proper wheel speed is obtained, or until wheel lockup occurs and the control cycle starts again.

During the pressure increase cycle (**Fig. 6**), brake application air enters the supply port of the modulator valve and flows to, and through, the open exhaust solenoid, then to the exhaust diaphragm. Air pressure, along with spring force, seats the exhaust diaphragm on the exhaust passage thus preventing the escape of service air. At the same time, application air flows to the supply diaphragm and forces it away from its seat. Air flows past the open supply and out the modulator valve delivery port to the service brake chambers.

If maintaining brake air pressure (**Fig. 7**), the ECU energizes the supply solenoid and de-energizes the exhaust solenoid. This seats both diaphragms and prevents further exhaust of brake chamber air pressure and prevents the application air from flowing out of the delivery port to the brake chamber.

Using the Electronic Control Unit (ECU) Panel Lights (LEDs)

This system has built-in diagnostics to ensure that all components are operating properly. After the ignition is turned on, the tractor warning light (TRAC ABS) comes on. On vehicles with newer ECUs, the TRAC ABS light will go out shortly after the ignition is turned on. On vehicles with the older ECUs, the TRAC ABS light will stay lit until the vehicle reaches 7 mph (11 km/h). The TRAC ABS light will go out if the tractor's ABS components are working properly. See "Electronic Control Unit (ECU)" in **Subject 050** for more information. If the light stays on, or comes back on later, a problem within the ABS system has occurred. The vehicle can continue to be driven, but the ABS system could be partially or completely inoperative. However, normal braking ability is maintained. To check the type of fault code recorded, stop the vehicle and turn off the engine. Then, turn on the ignition switch, but do not start the engine. If the warning light is still on, there is a system fault that must be repaired to ensure proper system operation. Faults are displayed by the ECU panel lights. See **Fig. 1**. If the warning light is not on, an "intermittent" fault has occurred. An intermittent fault could involve a power surge, taking the system out of voltage range for a moment. In such cases, the problem basically corrects itself; the ECU memory is cleared and the system is restored to full ABS capability.

NOTE: LED lamps are not serviceable.

Following is a list of the faults displayed by the ECU panel lights (**Fig. 1**). Once a fault has been recorded, turn on the ignition switch, but do not start the engine.

- FRT (front): This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the right (RHT) or left (LFT) display light, and the modulator (MOD) or sensor (SEN) display light.
- MID (middle or forward sensed rear axle on 6S/4M systems only): This red lighted display indicates the location of a malfunctioning sensor or its wiring. This light will always come on with either the right RHT or left LFT display light, and the sensor SEN display light.

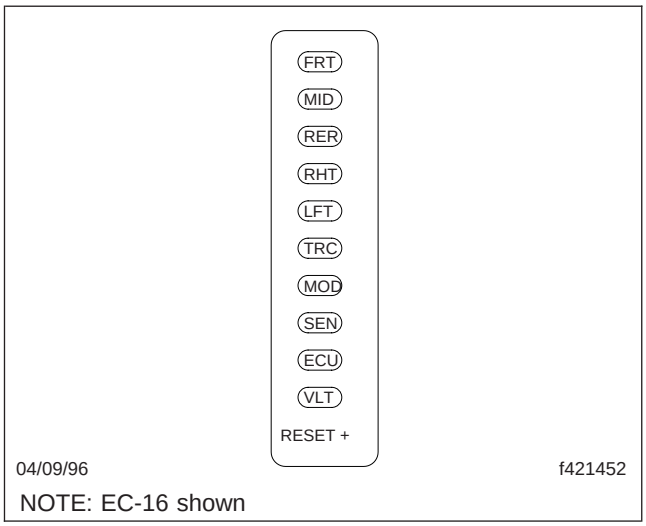

Fig. 1, ECU Panel Lights (LEDs)

- RER (rear): This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the right RHT or left LFT display light, and the modulator MOD or sensor SEN display light.
- RHT: This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the front FRT or rear RER display light, and the modulator MOD or sensor SEN display light.
- LFT: This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the front FRT or rear RER display light, and the modulator MOD or sensor SEN display light.
- TRC (traction control, if equipped): This red lighted display indicates a problem within the traction control system. This light may come on by itself, or with the modulator MOD display light (indicating a problem within the automatic traction control relay valve).
- MOD: This red lighted display indicates an open or short circuit in the solenoid(s) of one of the modulators. This light will always come on with two positioning display lights RHT or LFT plus FRT or RER. The light may also come on with the traction control TRC display light which would indicate a problem within the

automatic traction control relay valve or its wiring. Also, the red MOD light will come on if:

- – the traction enable/disable switch is in the wrong position.
- – traction engine serial communication is lost.
- – the traction solenoid is not connected or bad.

- SEN: This red lighted display indicates an open or short circuit in the sensor circuit. This light will always come on with two positioning display lights RHT or LFT plus FRT, MID, or RER.
- ECU: This red lighted display indicates that the ECU is inoperative.
- VLT (voltage): This green lighted display is always on during vehicle operation. The light indicates proper system voltage. If vehicle power is out of range (below 11 or above 17 volts), the light will flash until the power problem is corrected.
- RESET: Beneath the reset display is a magnetically sensitive switch used to clear fault codes and reset the ABS diagnostic system. This switch is also used to self-configure the ECU.

A system fault cannot be cleared from ECU memory until the fault is corrected. Once corrected, faults can be cleared one at a time from ECU memory. To clear a fault, pass a small magnet (capable of lifting a three ounce weight) over the RESET display on the ECU (**Fig. 1**). Once all of the lights on the ECU come on, remove the magnet. Holding the magnet against the RESET display for longer than 10 to 20 seconds could cause the ECU to go into a self-configuration mode.

Before troubleshooting, check all fuses in the control unit panel, and replace if necessary. Check the wiring to the warning lights. See **Table 1** and repair or replace the wiring as needed. Make sure that a charged 12-volt battery is available (the ABS system needs at least 11 volts to work).

IMPORTANT: The key switch must be on when doing the tests in **Table 1**.

Once a fault code has been identified, use a volt/ohmmeter to check the electrical harness at the ECU's 30-pin or 18-pin connector. See **Fig. 2** and **Fig. 3**. Touch the ohmmeter leads to the applicable terminals on the connector, not the ECU.

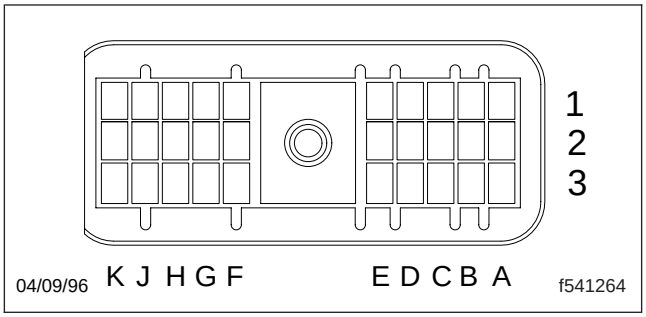

Fig. 2, 30-Pin Connector (Terminal View)

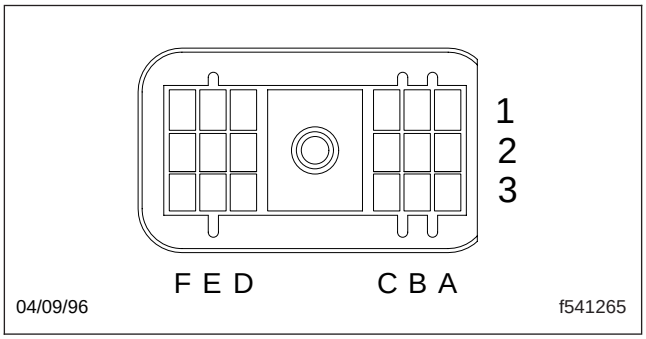

Fig. 3, 18-Pin Connector (Terminal View)

IMPORTANT: The ignition switch must be off when connecting or disconnecting the ECU.

Refer to the problem charts for a listing of all diagnostic panel displays (system faults), terminals to be tested, and the correct volt/ohmmeter readings. Repair or replace the components and/or wiring if the readings are not correct.

NOTE: If a dealer has Freightliner Service Link, fault code information can be read from Service Link. For more information, see Service Bulletin 00-20.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals.

See **Group 54** of this manual for information on special terminals and connectors, and on ordering tools for them.

See the appropriate wiring diagram in **Specifications, 400** when troubleshooting the ABS system.

General Description

The CamLaster air drum-brake is a cam-actuated, leading-trailing shoe brake with sliding shoes. The brake uses a crank/rod/slider expander mechanism (or "Z" cam) and a clearance- and force-sensing internal automatic adjuster. See **Fig. 1** and **Fig. 2**.

The camshaft rotates, moving both push rods outward, causing outward movement of the pistons with their tappets. The tappets then transfer braking force to the shoes.

An internal automatic adjuster maintains a specified lining-to-drum clearance. To compensate for lining wear, the pistons can rotate, unscrewing the tappets from the pistons and reducing the lining clearance. The tappets do not rotate since the brake shoe web engages the tappet slot. Since the adjustment occurs between the expander mechanism and the brake shoes, the expander mechanism geometry is not affected by brake lining wear.

The adjuster assembly (**Fig. 3**) consists of a bi-directional wrap-spring style clutch. The clutch transfers torque between the adjuster shaft and the adjuster bushing. The clutch will slip in one direction with a high torque load and in the other direction with a low torque load. During normal brake usage, the bias spring prevents the adjuster bushing cone seat from becoming unseated.

Principles of Operation

Brake with Correct Lining-to-Drum Clearance

When the brake is applied, the adjuster piston moves outward to take up internal gear clearance. As the brake linings contact the drum, the extra force on the tappets rapidly increases the tappet/piston thread friction torque to a level greater than the high torque level of the wrap spring. Continued motion causes

tappet/piston thread friction torque caused by the return spring is greater than the low torque of the wrap spring.

Brake with Excessive Lining-to-Drum Clearance

When the brake is applied, the adjuster piston moves outward to take up internal gear clearance. Since the wrap spring torque is greater than the tappet/piston thread torque, the adjuster piston rotates. The secondary piston also rotates since it is linked to the adjuster piston by the ring gear. Rotating the pistons unscrews the tappets and reduces the lining-to-drum clearance. When the lining contacts the drum, the tappet/piston thread friction increases rapidly and continued motion rotates the adjuster shaft as with a properly adjusted brake.

When the brake is released, the adjuster shaft rotates back to the original position, plus the incremental amount used to advance the tappets before the lining contacted the drum. Each brake application reduces the excess clearance a percentage of the existing excess clearance.

When the brake is released, the piston retracts and returns the internal gear clearance. The adjuster shaft then returns to the original position because the

General Safety Precautions

⚠ WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Asbestos and Non-Asbestos Safety

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH.

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Exposure to airborne asbestos brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by OHSA regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

Safety Precautions

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

If grinding or other machining of the brake linings is necessary, other precautions must be taken because exposure to asbestos dust is highest during such operations. In addition to the use of an approved respirator, there must be local exhaust ventilation such that worker exposure is kept as low as possible.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Asbestos-containing waste, such as dirty rags, should be sealed, labeled, and disposed of as required by EPA and OSHA regulations. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

Workers should wash before eating, drinking, or smoking, should shower after work, and should not wear work clothes home. Work clothes should be vacuumed after use and then laundered, without shaking, to prevent the release of asbestos fibers into the air.

⚠ WARNING

Before beginning the procedure below, read the safety precaution information in Subject 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Brake Shoe Removal

1. Park the vehicle on a level surface.
2. Shut down the engine, set the parking brake, and chock the tires.
3. Raise the front or the rear axle, then place safety stands under the frame or axle. Be sure that the stands will support the weight of the vehicle.

⚠ WARNING

When work is being done on a spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

4. If the brakes have spring chambers, carefully cage and lock the springs so that the springs cannot actuate during disassembly.
5. Remove the wheels. For instructions, see **Group 40** in this manual.

IMPORTANT: Do not exceed 30 lbf·ft (40 N·m) torque on the brake adjuster shaft. Do not use power tools. There may be an initial torque spike felt when disengaging the internal cone clutch. This is normal.

6. For each wheel end, rotate the brake shoe adjuster shaft counter-clockwise to increase the lining clearance of (or de-adjust) the brake shoes sufficiently for the brake drum to clear the brake linings. See **Fig. 1**.
7. Remove the brake drum. For instructions, see **Group 33** or **Group 35** in this manual.
8. Remove the brake shoes.

1. Rotate both of the tappets clockwise until they are fully seated. See **Fig. 6**.

NOTE: If necessary, release the dust boot from the spider to aid rotation.

2. Rotate both tappets counter-clockwise no more than 1/2 turn to align the slots with the shoe webs.
3. Rotate the secondary piston tappet (the tappet farthest from the adjuster shaft) counter-clockwise an additional 1/2 turn.

Shoe Pin Replacement

WARNING

Wear eye protection when using a drift to remove the old shoe pins. A piece of the pin could break off and cause serious eye injury.

NOTE: The shoe pins are made of a molded plastic material.

1. Remove both shoe pins with a brass drift. See **Fig. 7**.

WARNING

Wear eye protection when installing the new shoe pins. A piece of the pin could break off and cause serious eye injury.

2. Tap two new shoe pins into position and ensure that they are fully seated against the spider. See **Fig. 8**.

Brake Shoe Installation

1. Install the brake shoes.
   - 1.1 Place a new brake shoe in position with the web aligned with the tappet slot. See **Fig. 9**. Slide the shoe so that the shoe spring is over the shoe pin and so that the shoe web is retained in both the anchor slot and the tappet slot. Repeat for the other shoe.
   - 1.2 While holding the web of the lower shoe in position in the tappet slot, rotate the adjuster shaft clockwise until the brake spring is clear of the two spring retaining bolts. See **Fig. 2**. Remove the bolts.
   - 1.3 Rotate the adjuster shaft counterclockwise until the shoes are fully collapsed.
2. Install the brake drum. For instructions, see **Group 33** or **Group 35** in this manual.

WARNING

When work is being done on a spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

IMPORTANT: Ensure that the air chamber is installed before attempting the following steps. Also, do not exceed 30 lbf·ft (40 N·m) torque on the brake adjuster shaft and do not use power tools.

3. Rotate the adjuster shaft clockwise until the brake shoes snugly contact the brake drum. See **Fig. 1**.

NOTE: If a shoe is not centered in the drum, apply the brakes to achieve this. Then, repeat the previous step.

4. Rotate the adjuster shaft counter-clockwise 1-1/2 turns to set the initial running clearance.
5. Check the air chamber stroke and then rotate the drum and check for a dragging brake.
6. Install the wheels. For instructions, see **Group 40** in this manual.
7. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

WARNING

When work is being done on a spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

8. If the brake has spring chambers, carefully release the springs.

DANGER

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

9. Before you put the vehicle in service, in a safe area, check for proper brake operation.
   - 9.1 Apply and release the brakes several times to check for air leaks and for proper operation of the adjusters.
   - 9.2 Do several low speed stops to ensure proper parts replacement and full vehicle control.
   - 9.3 Make ten 40 to 20 mph (60 to 30 km/h) snubs to seat the linings.
   - 9.4 Make ten stops from 20 mph (30 km/h) at 50 percent air pressure.
   - 9.5 Make a full-pressure stop from 20 mph (30 km/h).
   - 9.6 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than others show a lack of braking effort on those wheels.

General Information

The Dana® Spicer® automatic slack adjuster serves two main functions:

- As a lever, it converts the straight-line force of the air brake chamber pushrod to torque on the brake camshaft. Rotation of the camshaft spreads the brake shoes out against the brake drum, applying the brakes.
- As an adjuster, it maintains cam brake chamber pushrod stroke and lining-to-drum clearance automatically during normal use.

When the brakes are applied, the slack adjuster rotates and moves the shoes into contact with the drum. The clearance notch corresponds to the normal lining-to-drum clearance. See **Fig. 1**. Different notches are available to meet the requirements of various vehicles and brake duty cycles. As the brake application continues, the rack moves upward and rotates the one-way clutch that slips in this direction.

As the brake torque increases, the coil-spring load is overcome and the wormshaft is displaced axially, releasing the cone clutch.

When the brake begins its return stroke, the coil spring load returns to normal and the cone clutch is again engaged. The rack is pulled back to its original position in the notch. Any additional travel brought about by brake lining wear causes the rack to turn the locked one-way clutch and rotates the wormshaft through the locked cone clutch. The wormshaft then rotates the worm wheel and camshaft, adjusting the brakes.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Slack Adjuster Removal and Installation

WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

Removal

1. With the vehicle parked on a level surface, apply the parking brakes, and shut down the engine. Chock the tires.
2. If a rear axle slack adjuster will be removed, release the parking brakes, then cage the power spring of the parking brake chamber. For instructions, see the appropriate brake chamber section in this group.
3. Remove the anchor bracket fasteners and the anchor bracket. See **Fig. 1**.

4. Remove the cotter pin from the clevis pin. Remove the clevis pin.
5. Remove the snap ring that secures the slack adjuster on the camshaft.

CAUTION

Do not use an impact wrench on the adjusting hexnut. To do so may damage the slack adjuster or camshaft.

6. Using a 7/16-inch box wrench, turn the adjusting hexnut counterclockwise to move the adjuster arm out of the clevis. A minimum of 13 lbf·ft (18 N·m) is required to overcome the internal clutch. You will hear a ratcheting sound.
7. Remove the slack adjuster from the camshaft.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

1. Check that the brake chamber pushrod is fully retracted.
2. Apply antiseize compound to the camshaft splines.

IMPORTANT: When correctly installed, the brake chamber pushrod pushes in the direction of the arrow on the slack adjuster housing.

3. Install the slack adjuster on the camshaft with the adjusting hexnut pointing away from the brake chamber. See **Fig. 2**.
4. Using a snap ring, secure the slack adjuster on the camshaft. Use at least one inner washer and enough outer washers to allow no more than 0.060-inch (1.52-mm) movement on the shaft.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting hexnut for positioning.

5. Using a 7/16-inch box wrench, turn the adjusting hexnut clockwise until the slack adjuster hole is aligned with the pushrod clevis hole. See **Fig. 2**.

6. Apply antiseize compound to the clevis pin and insert the pin in the clevis hole. Do not install the cotter pin at this time.

CAUTION

Never hammer the control arm. Hammering may damage the slack adjuster or camshaft splines.

7. Rotate the control arm away from the adjusting hexnut toward the brake chamber until it comes to a definite internal stop. Make sure the installation indicator is in the center of the indicator notch on the slack adjuster. See **Fig. 3**.

IMPORTANT: If the installation indicator is not aligned with the indicator notch, the brakes will be too tight.

NOTE: The anchor bracket and slack adjuster housing design will vary, depending on the axle. The anchor bracket mounting location is determined by the length of the control arm.

NOTE: The installation indicator must be aligned with the indicator notch.

8. Install the control arm anchor bracket, as follows. See **Fig. 1**.
   - 8.1 Tighten the anchor bracket fastener at the control arm 10 to 15 lbf·ft (14 to 20 N·m), making sure the control arm does not move from its position.
   - 8.2 Tighten the fastener at the brake chamber mounting stud according to the brake chamber manufacturer's specifications.
9. Adjust the brakes. See "Brake Adjustment".

Brake Adjustment

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

Slack Adjuster Removal and Installation

⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

1. Adjust the brake lining clearance by manually turning the adjusting hexnut clockwise until the brake lining contacts the brake drum, then back off the hexnut counterclockwise 1/2 turn. You will hear a ratcheting sound.

IMPORTANT: Incorrect installation can cause dragging brakes.

2. Make sure the brakes are still fully released, then check the position of the installation indicator on the control arm. It must be within the indicator notch on the slack adjuster.

   If the indicator is out of position, loosen the control arm fasteners and repeat the control-arm adjustment procedure. Then, tighten the bracket fasteners.

⚠ WARNING

Install and lock a new cotter pin in the clevis pin. Failure to do so could allow the pushrod to disengage from the slack adjuster, causing a loss of braking ability that could result in personal injury and property damage.

3. Install and lock a new cotter pin in the clevis pin.

IMPORTANT: Ensure that the air system has at least 100 psi prior to uncaging the brake chamber. This will aid in the uncaging of the parking brake since the parking brake should be fully released.

4. If a rear-axle slack adjuster was installed, manually uncage the parking brake. For instructions, refer to the applicable brake chamber section in this group.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

IMPORTANT: To check the brake adjustment, measure both the applied and free strokes.

NOTE: The location of the measurements is the same for both strokes but the applied stroke is measured with the brakes applied, while a lever is used to manually move the slack adjuster to measure the free stroke.

5. Measure the free stroke, as follows. The free stroke is the distance the slack adjuster has to travel to move the brake shoes against the drum.

   5.1 With the brakes released, measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement A.

   5.2 Using a lever, move the slack adjuster until the brake shoes contact the drum. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement B.

   5.3 Subtract measurement A from measurement B to determine the free stroke. For new brake installations, the free stroke should be 5/8 to 3/4 inch (16 to 19 mm). For in-service brakes, the free stroke should be 1/2 to 5/8 inch (13 to 16 mm). If it is not in this range, refer to **Troubleshooting 300**.

6. Measure the applied stroke, as follows.

   6.1 With the brakes released (pushrod fully retracted), measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. See **Fig. 4**. Record the exact distance as measurement A.

   6.2 Apply and hold an 80 psi (551 kPa) brake application. Measure the distance from the bottom of the brake chamber to the far

side of the clevis-pin hole. Record the exact distance as measurement B.

6.3 Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 1**.

6.4 If the stroke varies or is greater than the maximum allowed length, refer to **Troubleshooting 300**.

7. Apply the parking brakes.
8. Remove the chocks from the tires.
9. In a safe area, check for proper brake operation, as follows.

9.1 Apply and release the brakes several times to check for correct operation of the slack adjusters.

9.2 Perform six low-speed stops to ensure correct parts replacement and full vehicle control.

9.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others show a lack of braking effort on those wheels.

⚠ WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

Before performing any of the following procedures:

- Chock the wheels to prevent the vehicle from rolling.
- Ensure that the air system tank pressure is 90 to 100 psi (620 to 689 kPa).
- Check that the brake chamber push-rod is fully retracted; apply air to the release spring brake.

Refer to **Fig. 1** when making slack adjuster stroke measurements.

Applied Stroke

The applied stroke (see **Fig. 1**) of the brake should be checked per Commercial Vehicle Safety Alliance (CVSA) guidelines with full brake applicaton at 90 to 100 psi (620 to 689 kPa) reservoir pressure. The applied stroke should be at or less than the specified adjustment limits listed in **Table 1**.

Free Stroke

Free stroke is the amount of movement of the adjuster arm required to move the brake shoes against the drum. With brakes released, measure from the face of the chamber to the center of the clevis pin "A". Use a lever to move the brake adjuster until the brake shoes contact the drum. The difference between the fully retracted and drum contact measurement "B" minus "A" is the free stroke. See **Fig. 1**. The free stroke range should fall between 5/8 and 3/4 inch (16 to 20 mm).

Automatic Brake Adjuster Checking Procedures

If the brake adjuster is not maintaining the proper applied stroke, before removing the brake adjuster, check the condition of the foundation brakes. See **Table 2**, **Table 3**, and **Table 4** for procedures. If after inspecting the foundation brakes no apparent problems are found, inspect the automatic brake adjuster to determine if it is operating properly. The inspection can be performed on or off the vehicle using the following procedures.

- Chock the wheels to prevent the vehicle from rolling.
- Ensure that the air system tank pressure is 90 to 100 psi (620 to 689 kPa).
- Check that the brake chamber push-rod is fully retracted; apply air to the release spring brake.
- If air is not available, the spring brake must be manually caged back.
- Do not use air tools on the brake adjuster.

See **Table 5** for on-vehicle inspection or **Table 6** for off-vehicle inspection.

On-Vehicle Inspection		
Component	**Cause**	**Action**
Tight or dragging brakes	Control arm mispositioned	Realign the control arm and anchor bracket. See **Subject 110**.
Excessive chamber push rod travel	Improper anchor bracket connection to control arm	If anchor bracket to control arm connection is loose, worn, bent, or broken, re-secure or replace it.
	Low clutch torque	Rotate the 7/16-inch adjustment hex one full turn counterclockwise. If the torque is less than 13 lbf·ft (18 N·m), or no ratcheting sound occurs, replace the adjuster.

Table 5, On Vehicle Inspection

Troubleshooting

Off-Vehicle Inspection		
Problem	**Cause**	**Action**
Adjuster not functioning properly	Low clutch torque	Place the adjuster arm in a vise. Rotate the 7/16-inch adjustment hex counterclockwise one full turn to check de-adjustment torque. After control arm stops rotating, a minimum of 13 lbf·ft (18 N·m) will be required and a ratcheting sound should occur. If the torque is less than 13 lbf·ft (18 N·m), or no ratcheting sound occurs, replace the adjuster.
	Control arm slippage	Place the adjuster arm in a vise. Rotate the control arm counterclockwise until it rotates to an INTERNAL STOP. If the installation indicator goes past the indicator notch or does not stop rotating (arm slips freely), replace the adjuster.
	Unknown	If torque is above 13 lbf·ft (18 N·m), scribe a line on the adjustment hex. Manually pull the brake adjuster control arm clockwise then push back counterclockwise until the installation indicator stops in the indicator notch. The hex should move in a clockwise direction when the control arm of the brake adjuster is pushed back counterclockwise. If the hex does not move, replace the adjuster.
	Worn/missing control arm wear bushing, and/or anchor stud pin	Remove and replace the pin and bushings. If the adjuster has passed the above checks, re-install it on vehicle using new hardware.

Table 6, Off Vehicle Inspection

Automatic Brake Adjuster Operational Check

Functional operation of the brake adjuster can be performed on the vehicle by using the following procedure:

1. Chock the wheels to prevent the vehicle from rolling.
2. Ensure that the air system tank pressure is 90 to 100 psi (620 to 689 kPa).
3. Check that the brake chamber push-rod is fully retracted; apply air to the release spring brake.

   If air is not available, the spring brake must be manually caged back.
4. Manually de-adjust the brakes (turn adjustment hex counterclockwise one full turn) to create an excessive drum to lining clearance condition. A ratcheting sound should occur.
5. Make a full service brake application.

   On release, allow sufficient time for the brake to fully retract. During the brake release, observe rotation of the adjustment hex by attaching a wrench on the hex or scribing the hex, which will make this rotation easier to see. This rotation indicates that an excessive clearance condition has been determined by the brake adjuster, and it is making an adjustment to compensate. On each subsequent brake release, the amount of adjustment and push rod travel will be reduced until the desired clearance is achieved.
6. If rotation of the adjustment hex is not observed, refer to the foundation brake operational check and troubleshooting procedures in this subject.
7. If the foundation brake assembly checks out okay and the hex still does not turn, check the control arm and mounting bracket for possible worn, bent, or broken components.
8. If the control arm and mounting bracket function properly, replace the adjuster and hardware. See **Subject 110** for procedure.

General Description

Dana Spicer extended service (ES) brakes can be installed on both the front and rear axles. See **Table 1** for brake model identification.

The brakes are actuated by an S-type cam head that is forged integrally with the camshaft and supported with nylon bushings. Cam pressure is applied through the cam rollers. **Figure 1** shows a Dana Spicer front axle brake.

General Information

Principles of Operation

When the brake pedal is depressed, compressed air enters the brake chamber, causing the diaphragm to move a pushrod assembly.

The pushrod turns the slack adjuster and brake camshaft. As the camshaft turns, the S-head forces the brake shoes against the brake drum and braking occurs.

When the brakes are released and air is exhausted from the brake chamber, the actuator return spring (within the brake chamber) and the brake shoe return spring return the camshaft, brake shoes, slack adjuster, and pushrod to their released positions.

General Safety Precautions

⚠ WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Asbestos and Non-Asbestos Safety

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH.

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Exposure to airborne asbestos brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by OHSA regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

Safety Precautions

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

If grinding or other machining of the brake linings is necessary, other precautions must be taken because exposure to asbestos dust is highest during such operations. In addition to the use of an approved respirator, there must be local exhaust ventilation such that worker exposure is kept as low as possible.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Asbestos-containing waste, such as dirty rags, should be sealed, labeled, and disposed of as required by EPA and OSHA regulations. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

Workers should wash before eating, drinking, or smoking, should shower after work, and should not wear work clothes home. Work clothes should be vacuumed after use and then laundered, without shaking, to prevent the release of asbestos fibers into the air.

Removal

WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires on the axle that is not being repaired.
2. Raise the front or rear axle, then place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.

WARNING

When work is being done on the spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

3. If the brake has spring chambers, carefully cage and lock the springs so that the springs cannot actuate during disassembly.
4. Remove the wheels. For instructions, see Section 40.00.
5. Remove the brake drums. For instructions, see Section 33.01, Subject 100, for front axles or Section 35.01, Subject 100, for rear axles.

CAUTION

Before you back off the automatic slack adjuster, refer to the applicable slack adjuster section in this manual or to the manufacturer's service information for instructions. Failure to do so could damage the slack adjusters.

6. Back off the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

Installation

IMPORTANT: For best brake performance, do not mix Extended Service brakes with other Dana Spicer series brakes. Use the same brake series on the entire vehicle.

1. Make sure the spider, camshaft, air chamber bracket, and slack adjuster are serviceable and properly installed.

IMPORTANT: Do not lubricate the cam-head surface or the corresponding surface on the cam rollers. For efficient operation, the cam interface must remain free of oil, grease, and other contaminants.

2. Apply a thin film of NLGI grade 1, high-temperature, waterproof grease (Kendall M-621, or an equivalent) to the recesses on the end of each shoe web where the web contacts the cam roller and anchor pin.

3. To install a single-web brake shoe assembly on a 15-inch front brake:

   3.1 Place the upper brake shoe web on the anchor pin and rotate the shoe assembly downward until the web is secured in the shoe hold-down spring (clamp).

   NOTE: The shoe hold-down spring is mounted on the spider between the anchor pin and the S-cam.

   3.2 Hook one end of a new shoe retaining spring in the hole in the upper shoe web so that the coil lays across the anchor pin. See **Fig. 8**.

   3.3 Hook the lower end of the retaining spring in the hole on the lower shoe web.

   3.4 Place the lower shoe web against the anchor pin and stretch the retaining spring enough to rotate the shoe assembly into place on the spider.

   3.5 Hook one end of a new shoe return spring in the hole in the lower shoe web. Using a

4. To install a dual-web brake shoe assembly on a 15- or 16-1/2-inch rear brake:

4.1 Hook the ends of a new retainer spring in the holes on the upper and lower webs. Install a second retainer spring on the webs on the back side of the brake shoe assembly.

4.2 Place the upper and lower shoes around the anchor pin. See **Fig. 10**.

Squeeze the retainer loops and swing the retainer assembly into position (see **Fig. 13**), then snap the loops into the web holes. Make sure that both retainer loops are engaged in the web holes.

Repeat on the lower shoe.

5. Install the brake drums. For instructions, see **Section 33.01**, Subject 100, for front axles or **Section 35.01**, Subject 100, for rear axles.
6. Install the wheels. For instructions, see **Section 40.00**.
7. If working on the rear axle, manually uncage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this manual.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

Brake Shoe Removal and Installation

10. In a safe area, check for proper brake operation before you put the vehicle in service.
    - 10.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.
    - 10.2 Perform six low-speed stops to ensure proper parts replacement and full vehicle control.
    - 10.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others indicate a lack of braking effort on those wheels.

Inspection

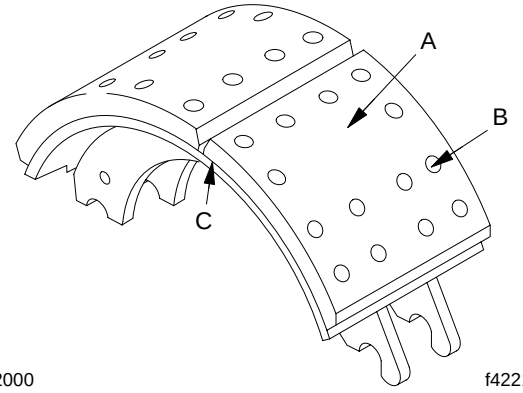
WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Remove the brake shoes. Refer to **Subject 110** for instructions.
2. Inspect the brake shoe linings.

   On front-axle brakes, if the linings are grease- or oil-soaked, cracked, or worn to less than 3/16 inch (4.5 mm) thickness at any point, replace them. See **Fig. 1**. The lining surface should be no closer than 1/16 inch (1.5 mm) to any rivet head.

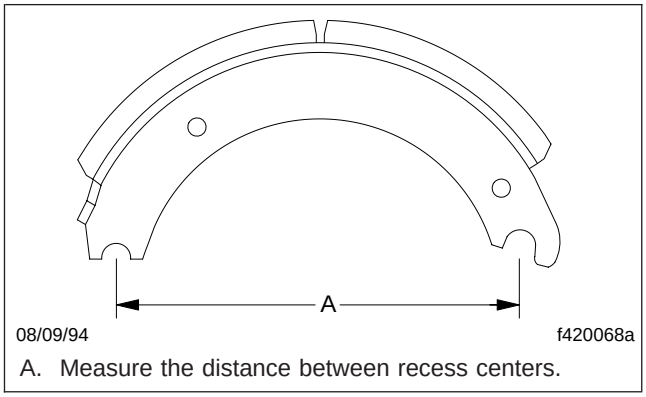
   On rear-axle brakes, if the linings are grease- or oil-soaked, cracked, or worn to less than 1/4-inch (6.4-mm) thickness at any point, replace them.



A. Check for cracks or contamination.
B. The lining surface must not be closer than 1/16 inch (1.5 mm) to any rivet head.
C. The minimum lining thickness is 3/16 inch (4.5 mm).

Fig. 1, Inspect the Brake Shoe (15-inch series shown)

3. Check the shoes for bent or cracked webs or tables, broken welds, loose rivets, or out-of-round rivet holes. Replace the shoes if any of these conditions exist.
4. Check the anchor pin for looseness and camshaft roller recesses in the shoe webs for visible wear. Replace the shoe if needed.
5. Check the shoe span. Measure the distance between the centerlines of the anchor pin and cam roller recesses in the shoe web. See **Fig. 2**.
   - On 15-inch series brakes, if the measurement is more than 11-3/4 inches (298 mm), replace the shoe.
   - On 16-1/2-inch series brakes, if the measurement is more than 12-9/16 inches (319 mm), replace the shoe.



A. Measure the distance between recess centers.

Replacement

WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

IMPORTANT: Vehicle brake systems require the correct lining material to perform as originally designed. The type of lining material that is specified for the vehicle is based on several technical considerations and Department of Transportation (DOT) braking performance regulations. To ensure fewer relines and greater compatibility with the vehicle's brake system, use the same quality of friction lining material that was installed at the factory.

Always reline both wheels of a single axle and all wheels of a tandem axle at the same time.

Always install the same linings and drums on both wheels of a single axle and all four wheels of a tandem axle. It is not necessary for the steering axle brakes to have the same linings as the rear drive axle brakes.

When the minimum thickness is reached for any of the brake linings on an axle, reline both brakes on that axle at the same time.

NOTE: Replace the springs each time the brakes are relined. Dana Spicer recommends replacement of the cam rollers at each reline.

1. Remove the brake shoes. For instructions, see **Subject 110**.

CAUTION

Drilling out rivets or cutting off rivet heads with a chisel can cause the rivet hole to become out-of-round. This could damage the brake shoe.

2. Using a suitable riveting mandrel, push out (do not drill out) the old rivets.
3. Clean the shoe table. For instructions, see **Subject 140**, "Cleaning."

CAUTION

Make sure that the replacement lining material conforms to FMSI 1308, a standard for lining size and shape only. Use of an improper FMSI lining specification or friction material type may cause brake dragging or grabbing, or improper brake performance.

4. Align the brake shoe and lining rivet holes. Using a C-clamp, clamp the lining to the brake shoe.

IMPORTANT: Use rivets that have the correct material, shank diameter, length, head size, and shape. Use tubular rivets that are:

- 1/4-inch (6-mm) diameter by 1/2-inch (13-mm) long,
- SAE no. 10-8, and
- made of zinc- or brass-plated steel.

5. Insert the correct size rivets into all the holes in the new block. Temporarily hold them in place with masking tape.
6. Secure the rivets in the correct sequence.
   - For front brake shoes with one-piece, 4-inch linings, start with the two middle holes and work toward the ends in a criss-cross pattern.
   - For rear brake shoes, follow the sequence shown in **Fig. 1**.
7. Check for a close fit between the lining and shoe table.

   Try to insert a 0.006-inch (0.15-mm) feeler gauge between the lining and shoe table along the edges. See **Fig. 2**. It should not be possible to insert the gauge anywhere along the edge, except at each end beyond the last row of rivets. A larger clearance may exist in these areas.
8. Remove the C-clamp and masking tape.

IMPORTANT: Always adjust the brakes at the slack adjusters after replacing the linings. For instructions, see **Subject 150.**

Brake Components Disassembly and Inspection, Cleaning, and Assembly

⚠ WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

Disassembly and Inspection

On front-axle brakes, the upper and lower brake shoe assemblies have single webs, one-piece brake shoe linings, and a single retaining spring. See Fig. 1.

On rear-axle brakes, the brake shoe assemblies have dual webs, two-piece brake shoe linings, and two retaining springs. Figure 2 is an exploded view of a typical rear-axle brake assembly.

1. Remove the brake shoes. For instructions, see Subject 110.
2. Inspect the drum.
   - 2.1 Check the drum for cracks. Replace any cracked drum.
   - 2.2 Using a drum caliper or other measuring device, measure the inside diameter of the drum in several places. Replace the drum if it exceeds the maximum diameter stamped on it.
   - 2.3 Check the drum for heat checks, glazing, grooving, run-out, and out-of-round. See Fig. 3. Some drums that are glazed, grooved, or out-of-round can be repaired. For detailed instructions, see Section 33.01 or Section 35.01.

IMPORTANT: Never pull the slack adjuster out of the pushrod clevis. Always turn the adjusting nut for positioning.

3. Disconnect the slack adjuster from the pushrod clevis. For detailed instructions, see the appropriate section in this manual for the automatic slack adjusters installed on the vehicle.
   - 3.1 Remove the cotter pin from the clevis pin; remove the clevis pin. See Fig. 4.

⚠ CAUTION

For a Meritor automatic slack adjuster, disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

   - 3.2 For a Meritor automatic slack adjuster, disengage the pull-pawl on the side of the adjuster. Using a screwdriver or an equivalent tool, pry the pawl button out about 1/32 inch (0.8 mm) and wedge the tool in place. See Fig. 5. Pull-pawls are spring loaded. When the tool is removed, the pull-pawl will engage the teeth automatically.

IMPORTANT: Never pull the slack adjuster out of the pushrod clevis. Always turn the adjusting nut for positioning.

   - 3.3 Using a wrench, turn the manual adjusting nut to back the slack adjuster out of the clevis.
     - On Meritor adjustors, turn the square adjusting nut clockwise.
     - On Haldex or Gunite adjusters, turn the adjusting hexnut counterclockwise. You will hear a ratcheting sound.
4. Using a dial indicator, measure the up-and-down and side-to-side end-play of the camshaft. Replace the bushings if there is more than 0.020-inch (0.5 mm) of movement.

⚠ CAUTION

Do not hammer on the slack adjuster to remove it. Damage to the adjuster or camshaft spline may result.

5. Remove the slack adjuster.
   - 5.1 From the slack adjuster side of the camshaft support bracket, remove the snap ring and any washers, spacers, and seals from the camshaft. See Fig. 1 or Fig. 2.
   - 5.2 Remove the slack adjuster from the camshaft.

binding, only rotate the manual adjusting nut in the clockwise direction.

6.2 Using a torque wrench that measures lbf·in (or N·cm), turn the manual adjusting nut clockwise so that the worm gear rotates a full 360 degrees (typically 22 turns of the wrench).

If there is binding, or if more than 25 lbf·in (280 N·cm) is needed to turn the slack adjuster, replace it. For instructions, see the applicable slack adjuster section in this group.

IMPORTANT: If any slack adjuster problem is found, repair or replace the unit, depending on the manufacturer's recommendations.

7. Check to see if a camhead thrustwasher is installed between the S-cam and the spider. If so, note the orientation for later installation. The orientation depends on the brake assembly model.

8. Remove the camshaft by grasping its head and pulling the camshaft outboard from the brake spider and camshaft support bracket.

Check the brake chamber for a cracked housing, bent pushrod, loose clamp ring, loose air fitting, air leaks, or clogged vent holes. Repair or replace parts as needed.

13. Remove and inspect the camshaft support bracket. Remove and discard the gasket. Check the bracket for a bent, broken, or cracked arm, and for cracked welds. Replace the bracket if any of these conditions exist.

⚠ WARNING

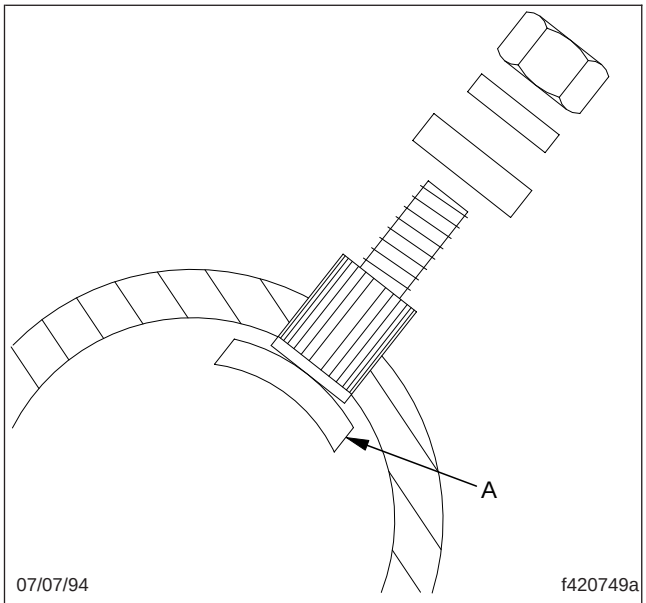
When removing bushings with a driver, wear eye protection. Do not hit steel parts with a steel hammer. To do so could cause steel pieces to break off, which could cause serious eye injury.

14. Remove and inspect the old bushing and the grease seal.
    - 14.1 Check the camshaft bushing for wear. The inner surface must be smooth; if rough or abrasive, replace the bushing.
    - 14.2 Inspect the seal. Replace it if the lip is nicked, cut, or distorted.
15. On front brakes, check the stabilizing screw for bends, looseness, or damaged threads.
16. If necessary, replace the stabilizing screw.

⚠ WARNING

Wear eye protection when driving the screw into the camshaft bracket tube with a pin punch and hammer. Failure to wear eye protection could result in personal injury due to flying metal debris.

- 16.1 Remove the damaged screw by driving it into the camshaft bracket tube with a pin punch and hammer.
- 16.2 Aligning the curvature of the screw head with the curvature of the bracket tube, install the new screw. See **Fig. 6**.



A. Align the curvature of the head with the curvature of the camshaft bracket tube.

Fig. 6, Align the Screw Head

- 16.3 Install the spacer, lockwasher, and nut. Tighten the nut 23 to 27 lbf·ft (31 to 37 N·m) to draw the screw serrations uniformly through the camshaft bracket tube wall.
- 16.4 Remove the nut and washer before assembling the bracket on the spider.

17. Using a suitable piloted driver, install the new bushing or seal.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

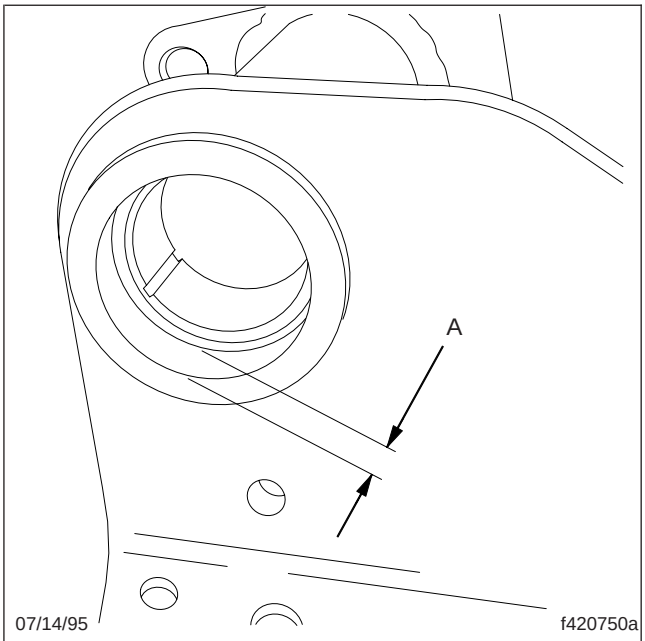
On front brakes, install the new bushing to a depth of 3/8 inch (9.5 mm) from each end of the bracket tube. See **Fig. 7**.

On rear brakes, install the new bushing to a depth of 22/32 inch (17.5 mm) at the slack adjuster end of the bracket tube and to a depth of 9/32 inch (7.1 mm) at the cam head end of the bracket tube.

Install the grease seal flush with the end of the air chamber bracket tube.

IMPORTANT: Grease seals are installed in both the bracket and the brake spider so that the seal lip is facing toward the slack-adjuster end of the bracket tube. See **Fig. 8**.

18. Remove the spider-to-axle attaching nuts, hardened washers, and bolts; remove the spider from the axle flange.

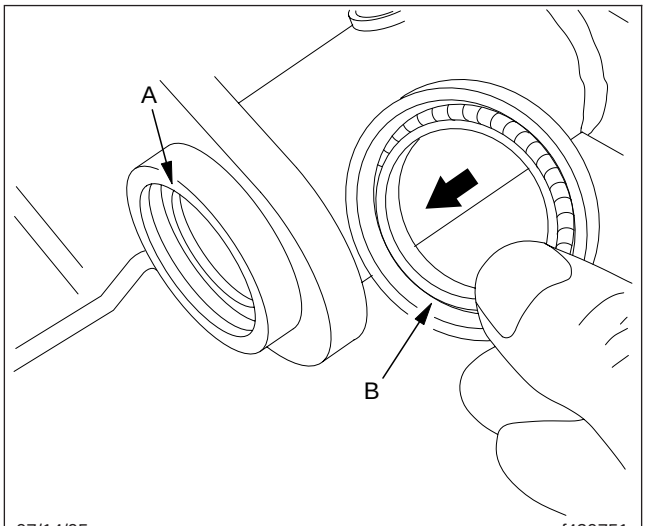


A. Recess the bushing (see text for specifications).

Fig. 7, Install the New Bushing

19. If equipped, remove the capscrews that attach the dust shield to the spider; remove the dust shield.

20. Inspect the spider and parts for damage; replace as needed.



A. Install seals flush with end of tube.
B. Lip side of both seals must face toward slack-adjuster end of the bracket.

Fig. 8, Install the Grease Seals

20.1 Check for cracks at the bolt holes, cam area, and around the anchor pin. Replace if damaged.

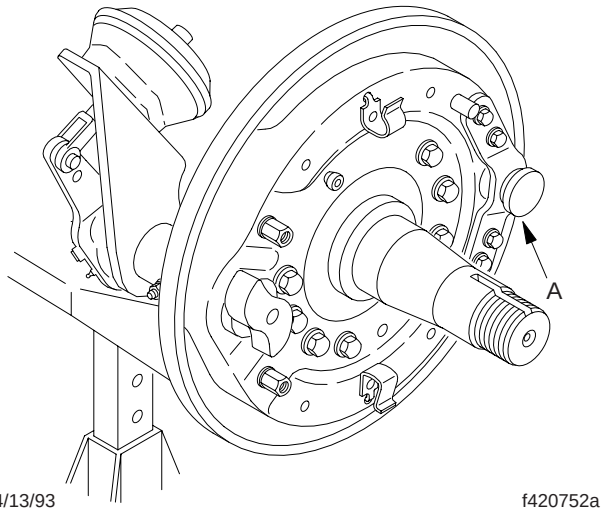
20.2 Check the anchor pin. See **Fig. 9**. If the pin is loose, or grooved more than 0.03 inch (0.8 mm) below the original surface, replace the spider assembly.

20.3 Check the anchor pin and brake spider bushings for deterioration. The inner surfaces must be smooth. If any surface is rough or abrasive, replace the part.

20.4 On front brakes, check the anchor pin reinforcement plate attaching nuts (see **Fig. 10**) for tightness. If needed, tighten the nuts 35 to 40 lbf·ft (47 to 54 N·m).

Check the anchor pin retaining nut for tightness. See **Fig. 10**. If needed, tighten the nut 475 to 525 lbf·ft (644 to 712 N·m).

IMPORTANT: If the anchor pin turns while checking the retaining nut torque, replace the spider assembly. Dana Spicer recommends replacing the complete spider and pin assembly. Do not try to repair the spider assembly.



A. Check for grooving and looseness.

Cleaning

⚠ CAUTION

Do not clean ground or polished metal parts in a hot solution tank or with water, steam, or alkaline solutions. These solutions will cause parts to corrode.

IMPORTANT: Do not apply brake grease or corrosion-preventive materials to the brake linings or the brake drum.

After removing the brake parts being serviced, do the following:

1. Clean the camshaft journals with an emery cloth.
2. Wire brush all parts that have been exposed to mud, road dirt, and salt, including the exterior of the drum, spider, brake chamber bracket, and dust shields (if equipped).

   If relining the shoes, thoroughly wire-brush the shoe tables and paint them with a rust-inhibitive coating.

⚠ CAUTION

A thick layer of oxidation and dirt on the outside of a brake drum acts as an insulator and may hinder normal heat dissipation. Make sure oxidation and dirt are removed by wire brushing, or damage to brake components could occur.

3. Using an industrial vacuum cleaner with a HEPA filter system, remove any dust accumulation from the brake parts.
4. Wipe the inside of the drums with a damp rag to remove lining dust.
5. Prepare the brake parts for assembly.

   5.1 Thoroughly clean all the brake parts.

   For ground or polished metal parts, use a cleaning solvent to clean the parts and surfaces that are ground or polished.

   For rough metal parts, use a cleaning solvent or a weak alkaline solution in a hot solution tank to clean the parts. If a hot solution tank is used, leave the rough parts in the hot solution tank until they are completely cleaned and heated. Remove the rough parts from the hot solution tank and wash them with water until the alkaline solution is removed.

   5.2 Thoroughly dry all the brake parts with a clean, lint-free cloth or paper towel, or use low-pressure filtered and compressed air.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

WARNING

All worn or damaged brake parts must be replaced. If the brakes are assembled with worn or damaged parts, they may not perform to their capacity and a brake failure could occur, which could cause personal injury and property damage.

5.3 Thoroughly inspect all the brake parts for wear or damage. It is very important that all the parts be carefully inspected before they are assembled. Repair or replace any worn or damaged parts.

5.4 For parts that will be assembled, apply a thin layer of brake grease to the parts after they have been cleaned, dried, and inspected to protect them from corrosion.

If the parts will be stored, apply a special material that prevents corrosion and rust on all surfaces. The parts should be stored in special paper (or other material) that prevents corrosion and rust.

Assembly

1. Install the dust shield (if equipped). See **Fig. 1** or **Fig. 2.**

   If installing a one-piece dust shield, place it against the spider and install the capscrews. Tighten the capscrews to the specifications in **Table 1**.

   If installing a two-piece dust shield, place both halves against the spider and tighten the attaching screws finger-tight. Reposition the dust shield halves to allow a uniform space of 1/8 inch (3 mm) along the mating edges. See **Fig. 11**. Tighten the screws to the specifications in **Table 1**.

NOTE: Because of the interference fit in the upper dust shield-to-brake chamber bracket area (see **Fig. 12**) you may need to deform the upper dust shield slightly by hand to correctly align the upper half with the lower half.

2. Install the spider.

   Place the spider on the axle flange. Using a hardened washer under the bolt head and the nut, install the mounting fasteners. Tighten the bolts to the specifications in **Table 1** in a cross pattern.

3.2 Place the bracket against the spider, and install the lockwashers and barrel nuts. Tighten the nuts to the specifications in **Table 1**.

3.3 Install the washer, lockwasher, and nut on the stabilizing screw (if equipped). Tighten the nut to the specification in **Table 1**.

4.4 Carefully slip the camshaft into the spider and the mounting bracket tube.

4.5 Install the thick camshaft washer on the camshaft.

5. Install the slack adjuster on the camshaft, with the adjuster nut on the side opposite the brake chamber.
6. Install the thin outer washer(s) and snap ring.
7. Using a dial indicator, measure the end play of the camshaft.

   7.1 With the slack adjuster centered between the brake chamber bracket and the snap ring groove, pull inboard on the slack-adjuster end of the camshaft to take up the end play.

   7.2 Set the dial indicator to zero.

   7.3 Push outboard on the slack-adjuster end of the camshaft and note the maximum reading.

   7.4 There should be 0.005 to 0.045 inch (0.1 to 1.1 mm) of movement. Add or remove outer washers as needed to adjust the end play.

⚠ WARNING

When lubricating the camshaft bracket bushings, if grease leaks out under the cam head, the camshaft grease seal is worn or damaged. If the seal is not replaced, the brake linings could be contaminated by grease and the vehicles stopping distance could be reduced, which could result in personal injury or property damage.

NOTE: Use meter-type fittings, having a maximum 40 psi (276 kPa) pressure relief at the shutoff.

8. Pressure lube the camshaft bracket bushings.

   Pump multipurpose chassis grease (NLGI grade 1 or 2) into the chamber bracket until it appears at the slack-adjuster end of the bracket. Use care that no grease enters the drum cavity.

   If grease leaks out under the cam head, the camshaft grease seal is worn or damaged, or is installed backwards. Replace the seal.

9. Adjust the brakes at the slack adjusters. For instructions, refer to **Subject 150**.
10. Install the brake shoes. For instructions, see **Subject 110**.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

Pre-Adjustment Checks and General Adjustment Information

Before adjusting the brakes, check and adjust the following:

- Adjust the wheel bearings. For instructions, see **Section 33.01** or **Section 35.01** in this manual.
- Check the slack adjuster and the brake chamber for loose fasteners and tighten as necessary. For torque specifications, see **Specifications, 400**.

  For slack adjuster installation instructions, see the appropriate section in this manual for the type of adjuster installed on the vehicle.

Brakes with automatic slack adjusters should never have to be manually adjusted while in service. The only time automatic slack adjusters should be manually adjusted is during installation or after the brakes have been relined.

For cam brakes, there are two brake chamber stroke measurement specifications: applied chamber stroke and free-stroke.

IMPORTANT: The U.S. Department of Transportation (DOT) Federal Highway Administration has issued the applied chamber stroke specifications for cam brakes. When the applied chamber stroke is checked and adjusted, it must not be greater than the DOT specification. See **Table 1**.

The specific procedure for adjusting the brake chamber stroke at the slack adjuster's manual adjusting nut may vary, depending on which slack adjuster is installed, but there are three basic steps in completing a manual brake chamber stroke adjustment:

1. Adjusting the approximate brake chamber stroke using the manual adjusting nut on the slack adjuster (coarse adjustment).
2. Measuring and adjusting the free-stroke.
3. Measuring and adjusting the applied chamber stroke (fine adjustment).

The stroke (free or applied chamber) is the distance that the large clevis pin moves when the brakes are applied. The type of force used to move the slack adjuster from its released position to its applied position (where the brake linings contact the brake drum) distinguishes the free-stroke from the applied chamber stroke.

- The free-stroke is measured using a lever to move the slack adjuster. The length of the free-stroke equals the clearance between the brake linings and the drum when the brakes are not applied.
- The applied chamber stroke is measured using an 80 to 90 psi (550 to 620 kPa) brake application to move the slack adjuster.

With the engine off, 100 psi (689 kPa) of air tank pressure will apply the required 80 to 90 psi (550 to 620 kPa) brake application for measuring the applied chamber stroke.

The applied chamber stroke measurement can be used for diagnostic purposes. A stroke that is too long or too short may indicate excessive wear in the cam, cam bushings, return springs, or air chamber.

The applied chamber stroke should always be adjusted (minimized) to within the specified limit, but it should not be reduced to the point where the free-stroke is too short and the brakes drag. To check for brake drag, spin the wheel end, tap the rim lightly with a hammer, and listen for a drag noise (a sharp ringing sound).

Adjustment

Meritor Automatic Slack Adjuster

IMPORTANT: Before adjusting the brakes, see the pre-adjustment checks and general adjustment information at the beginning of this subject.

1. Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires on the axle that is not being repaired.
2. Raise the front or rear axle and place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
3. Fully release the brakes (the air chamber pushrod must be fully retracted).

4. Check the condition of the boot on the slack adjuster. It should be held in the correct position with a retaining clip. If the boot is torn or cracked, see the slack adjuster disassembly and inspection procedures for information.

CAUTION

Before turning the manual adjusting nut on the slack adjuster, disengage the pull-pawl. Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

5. Using a screwdriver, pry the pull-pawl button out at least 1/32 inch (0.8 mm) to disengage the pull-pawl teeth from the slack adjuster actuator. See **Fig. 1**. Wedge the screwdriver in place. The pull-pawl will need to be disengaged until the brake adjustment is complete.

NOTE: When the screwdriver is removed, the pull-pawl will engage automatically.

6. Using the manual adjusting nut on the slack adjuster, adjust the brake chamber stroke (coarse adjustment). See **Fig. 2**.
   - 6.1 Turn the adjusting nut counterclockwise until the brake linings touch the brake drum.
   - 6.2 Then, turn the adjusting nut clockwise one-half turn.
7. Measure and adjust the free-stroke.

B. Measurement with the brakes applied by manual lever (free-stroke) or pressurized brake application (applied chamber stroke).

Fig. 3, Measuring the Stroke

7.4 Subtract dimension A from dimension B. The difference between these measurements is the free-stroke.

7.5 The free-stroke should be 5/8 to 3/4 inch (16 to 19 mm). If it is not, turn the adjusting nut one-eighth turn, as shown in **Fig. 2**. Then, measure the free-stroke again, and readjust it until it is correct.

8. Measure and adjust the applied chamber stroke (fine adjustment).

8.1 Start the engine and build the air pressure to 100 psi (689 kPa). Shut down the engine.

8.2 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 3**, Ref. B. Record this measurement as dimension C.

8.3 Subtract dimension A from dimension C. The difference between these measurements is the true applied chamber stroke.

8.4 The applied chamber stroke must not exceed the maximum value specified in **Table 1**.

⚠ CAUTION

The adjusted applied chamber stroke should be as short as possible but not so short that the free-stroke is too short and the linings drag. If the linings drag, the brakes could be damaged.

8.5 If the applied chamber stroke is incorrect, turn the adjusting nut one-eighth turn counterclockwise to shorten the stroke, or one-eighth turn clockwise to lengthen it. See **Fig. 2**. Measure the applied stroke again and readjust it until it is correct.

8.6 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes. See **Subject 150**. If necessary, replace the slack adjuster.

9. Remove the screwdriver from the pull-pawl assembly. This will engage the pull-pawl with the actuator.

10. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

11. Check for proper brake operation. For instructions, see **Subject 110**.

2. Raise the front or rear axle. Then, place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
3. Fully release the brakes (the air chamber pushrod must be fully retracted).

⚠ CAUTION

The installation indicator must be aligned with the indicator notch on the slack adjuster. If the indicator is not within the notched area, the control arm is installed in the wrong position. This may result in tight brakes, excessive lining wear, and possible brake damage.

4. Make sure the installation indicator is aligned with the indicator notch on the slack adjuster. See **Fig. 4**. If the indicator is not within the notched area, the control arm is not installed correctly.

8. Measure and adjust the applied chamber stroke (fine adjustment).

8.1 Start the engine and build the air pressure to 100 psi (689 kPa). Shut down the engine.

8.2 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the far side of the clevis pin hole. See **Fig. 6**, Ref. B. Record this measurement as dimension C.

8.3 Subtract dimension A from dimension C. The difference between these measurements is the applied chamber stroke.

8.4 The applied chamber stroke must not exceed the maximum value specified in **Table 1**. If the stroke is not correct, turn the adjusting nut in the required direction. Then, measure the applied chamber stroke again and readjust it until it is correct.

General Information

The System Saver Twin air dryer **(see Fig. 1)** is a desiccant air dryer, mounted vertically between the air compressor and the supply reservoir. The air dryer receives hot compressed air, which it cools and filters before sending it to the supply reservoir, reducing the build-up of dirt and moisture in the vehicle air system.

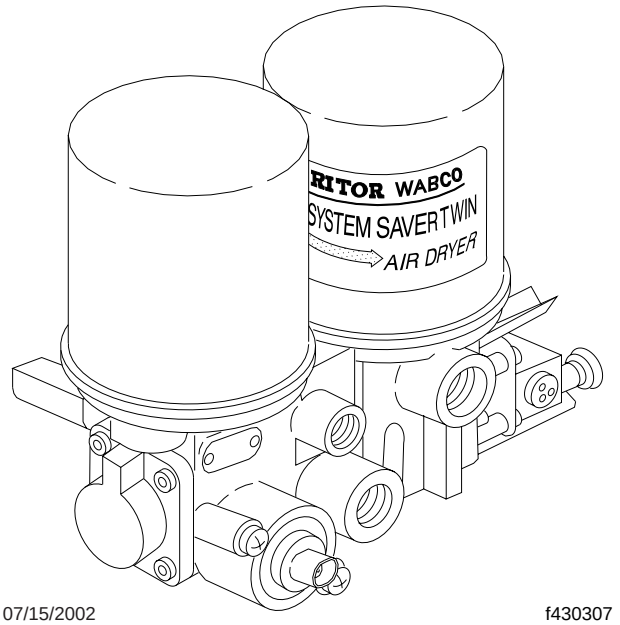

Fig. 1, WABCO System Saver Twin Air Dryer

The air dryer consists of a light weight aluminum and steel body. The desiccant cartridges are contained in two spin-off canisters that mount on the top of the air dryer.

The bottom half of the air dryer houses the following components:

- Pressure Relief Valve—this valve protects the air dryer from over-pressurization. The valve is attached to a port on the side of the air dryer. On models built before November 1996, it is installed using a street-T fitting installed at the dryer inlet port.
- Desiccant Canisters—two spin-on/spin-off cylindrical steel housings that contain the filter elements and the desiccant needed to filter and dry the air that passes through the dryer.
- Heater Assembly—located in the air dryer base, the heater keeps the water that collects in the air dryer from freezing. The assembly consists of a cylindrical resistive-type heating element and a small circular thermostat. The thermostat turns the heater on at 45°F (7°C) and turns it off at 86°F (30°C).
- Orifice and Check Valve Assembly—This valve controls the air flow for regeneration. There are three sizes: 0.8 mm for systems with compressor ratings less than 21 CFM, 1.0 mm for compressor ratings between 21 and 35 CFM, and 1.3 mm for compressor ratings greater than 35 CFM.
- Charging Valve—this valve keeps the control valves from shuttling while the system is filling and pressure is too low to ensure proper operation.
- Outlet Check Valve—this valve prevents air in the system from flowing back through the air dryer and escaping out the purge valve during the compressor unload cycle.
- Purge Valve—this valve allows collected moisture and contaminants to be expelled from the air dryer during the unloaded cycle. The purge valve remains open for the entire compressor unload cycle.

  While the compressor is running, a mild flow of air will vent to atmosphere through the purge valve. This is a normal condition.
- Solenoid and Armature Assembly—controls timing and operation of right and left piston assemblies. This determines which cartridge dries and which one regenerates.
- Piston Assemblies (Left and Right)—control air-flow direction between the cartridges. Both piston assemblies have their own covers.
- Silencer (Muffler)—this optional component is attached to the purge valve and used to eliminate most of the noise during the air dryer purge cycle.

Principles of Operation

The air dryer cartridges contain desiccant material that filters and dries compressed air. The process begins when the supply-tank pressure drops below cut-in pressure (approximately 100 psi [689 kPa]).

General Information

When this happens, the governor turns the compressor on. The compressor sends air to the supply port of the dryer, and an air drying cycle begins. See **Fig. 2**. Air flows past the piston into the right-hand cartridge where moisture and contaminants are filtered out through the desiccant material. Dry, clean air then flows to the delivery port of the dryer to the supply tank. At this point, some air is diverted to the second cartridge where it moves upward through the desiccant. This cleans and dries (regenerates) the desiccant.

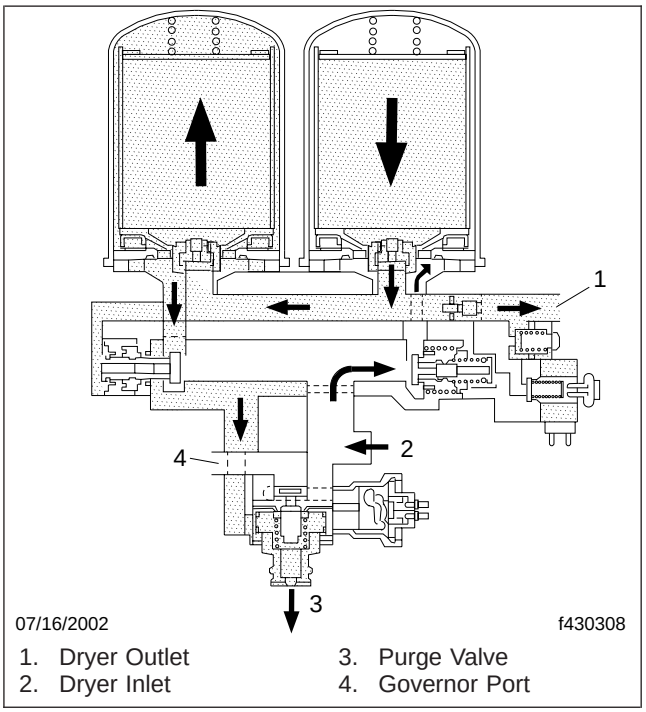

Fig. 2, Air Drying Cycle Begins, Air Enters Dryer at Supply Port

NOTE: While the compressor is running, a mild flow of air will vent to atmosphere through the purge valve.

Switching is controlled by the timer solenoid. While pressure is above 60 psi (414 kPa), the air dryer switches cartridges every 60 seconds, reversing the air flow pattern. See **Fig. 3**.

NOTE: A mild purge, or puff of air, can be heard at the purge valve at the time of the shift.

Incoming air enters the second (left) cartridge for drying and then flows to the delivery port.

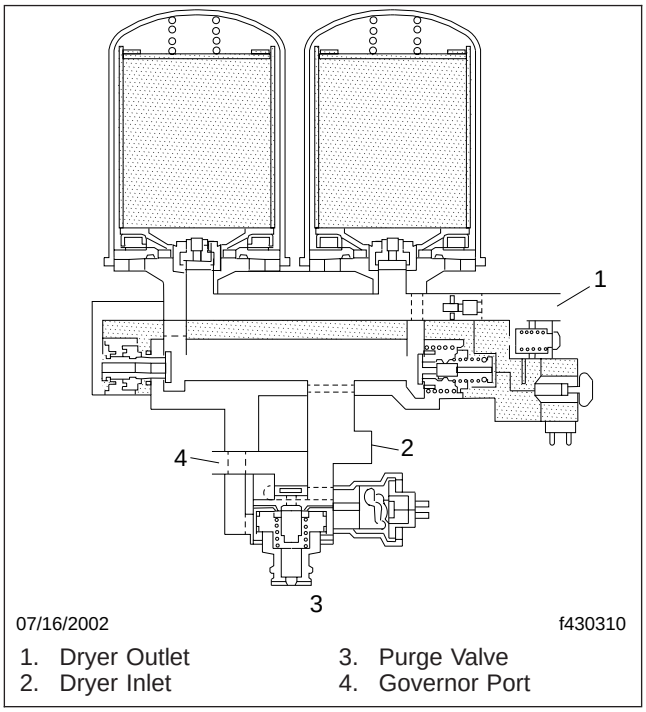

Fig. 3, At 60 psi or Greater, the Air Dryer Switches Cartridges Every 60 Seconds

See **Fig. 4**. A small amount of dried air flows into the first (right) cartridge to regenerate the desiccant. Alternating air-drying cycles continue every 60 seconds, one cartridge to the other, as long as the compressor is running.

When the supply tank reaches cutout pressure (approximately 120 psi [827 kPa]), the governor unloads the compressor and supplies air to the unloader port of the dryer, causing moisture and contaminants to pass through the purge valve and out of the dryer. See **Fig. 5**.

NOTE: A burst of air occurs when the dryer purges, then airflow from the purge valve ceases for the duration of the unloaded cycle.

Safety Precautions

⚠ WARNING

When draining the air system, do not look into the air jets or direct them toward another person, as dirt or sludge particles may be in the air-stream. Do not disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can cause personal injury.

When working on or around air brake systems and components, observe the following precautions.

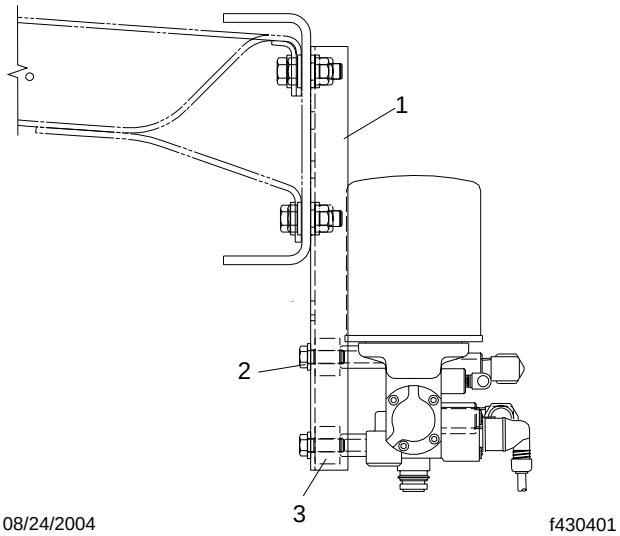
1. Apply the parking brake, chock the tires, and stop the engine when working under the vehicle. Draining the air system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air system pressure drops.
2. Wear safety goggles.
3. Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
4. Don’t disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
5. Replacement hardware, tubing, hose, fittings, etc. should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace any components that have stripped threads or damaged parts. Don’t attempt to repair parts by machining.
7. Never exceed recommended air pressure.

WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

Removal

1. Park the vehicle on a level surface, shut down the engine, and chock the tires.
2. Drain the air system.
3. Disconnect the wiring harness from the air dryer.
4. Mark the air lines for later reference, then disconnect them from the air dryer.
5. Remove the capscrews, washers, and spacers that attach the air dryer to the mounting bracket. See **Fig. 1**.



1. Air Dryer Mounting Bracket
2. 1/2-inch Capscrew and Washer
3. Spacer

Fig. 1, Air Dryer Installation (outboard rail mounting shown)

6. Remove the air dryer.

Installation

1. Position the air dryer on the mounting bracket. See **Fig. 1**. Install the spacers, washers, and capscrews. Tighten them 22 to 30 lbf·ft (30 to 41 N·m).
2. Make sure the air lines are clean. Replace any line or fitting that is crimped or damaged.
3. Connect the air lines to the air dryer as previously marked. Tighten the nut on each fitting finger-tight. Then, using two wrenches to prevent twisting the hose, further tighten the nut until there is firm resistance.
4. Connect the air dryer wiring harness.

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

See **Fig. 1** for an expanded view of the piston assemblies.

Left Piston Assembly and Piston Cover Replacement

1. Remove the left piston cover. Remove the two small O-rings from the breather holes and the two large O-rings from the grooves in the outer diameter of the cover guide. Clean the cover. Save the cover and mounting bolts for reassembly.
2. Remove the left piston and spring assembly from the piston bore. See **Fig. 2**.
3. Inspect and clean the bore area.

NOTE: Lubricate all O-rings and seals before assembling components.

4. Assemble the new piston assembly.
   - 4.1 Install the large O-ring in the groove on the head of piston guide.
   - 4.2 Install an O-ring in the first groove of the piston guide.
   - 4.3 Using snap ring pliers, install a snap ring in the snap ring groove on the shaft of the piston.
   - 4.4 Install the lip seal in the groove of the spool and insert the spool onto the piston. The lip of the seal must face away from the dryer.
   - 4.5 Install an O-ring in the groove on the piston shaft.
   - 4.6 Using snap ring pliers, install a snap ring in the snap ring groove under the spool.
   - 4.7 Install an O-ring in the groove on the piston shaft.
5. Install the two large O-rings in the grooves in the outer diameter of the cover guide. Then install the two small O-rings in the breather holes on the cover.
6. Install the spring in the left piston cover. Then insert the piston assembly into the left piston cover. The stem of the piston will face away from the dryer.
7. Install the left piston cover, with the piston assembly, into the dryer body.
8. Install the mounting bolts and tighten to 80 lbf·in (900 N·cm).

Right Piston Cover Replacement

The right piston cover houses the solenoid/armature and the charging valve assemblies. Carefully remove and save these assemblies. Clean and inspect them before reinstalling them. If you are replacing either of these assemblies, refer to the following subjects: **Subject 190**, and **Subject 200**. You must also remove the right piston assembly if you are only replacing the cover.

NOTE: Lubricate all O-rings and seals before assembling components.

1. Unscrew the power harness and disconnect it from the solenoid. Remove and save the solenoid.
2. Carefully remove the armature assembly end cap and O-ring from the solenoid. Save these for reassembly.
3. Remove the three long piston cover bolts from the armature plate. Remove the armature assembly. Carefully lift the armature plate, with the solenoid sleeve assembly, off of the dryer. Save these parts for reassembly.
4. Remove the short piston cover bolt and then the right piston cover. Remove the two small O-rings from the cover breather holes.
5. Carefully remove the charging valve nut. It is spring-loaded.
6. Remove the charging valve assembly from the cover. See **Subject 200**.

7. Carefully remove the right piston assembly from the dryer cavity.
8. Clean and lubricate the two small O-rings removed from the old cover. Install them in the breather holes in the replacement cover.
9. Install the charging valve assembly in the right piston cover.
10. Insert the piston assembly into the piston cover cavity. Do not damage the lip seal during this procedure. Use the flat side of a small, flat screwdriver to tuck the assembly into the cover.
11. Install the cover and piston assembly, charging valve down, into the dryer body.
12. Install the short mounting bolt. Finger-tighten it only at this time.

13. Install the solenoid and armature assembly. Refer to **Subject 190**, "Solenoid/Armature Assembly Replacement".
14. Connect the power harness to the solenoid. Make sure the connection is tight.
15. Test the installation.

Right Piston Assembly Replacement

NOTE: You do not have to remove the charging valve when replacing only the right piston assembly.

NOTE: Lubricate all O-rings and seals before assembling components.

1. Disconnect the power harness. Remove the solenoid and armature assembly. See **Subject 190**.
2. Remove the right piston cover. See the previous procedure.
3. Remove the right piston assembly. Clean the piston bore thoroughly.
4. If the O-rings and spool are already installed on the replacement piston, lubricate the rubber parts; then, go to step 5. If not:
   - 4.1 Install the large O-ring in the groove on the head of the piston.
   - 4.2 Use snap ring pliers to install a snap ring into the snap ring groove closest to the piston head.
   - 4.3 Insert the lubricated lip seal in the groove of the spool.
   - 4.4 Install the lubricated O-ring in the groove on the piston shaft.
   - 4.5 Install the spring over the piston shaft.
   - 4.6 Install the spool with the lip seal into the piston shaft. The lip of the seal will face **away** from the air dryer.
   - 4.7 Install the snap ring in the groove on the piston shaft to hold the spool in place.
   - 4.8 Install the O-ring into the groove on the piston shaft.
5. Insert the piston and spring assembly into the right piston cover. Remove the two small O-rings from the piston cover and install two new O-rings.
6. Install the right piston cover and piston assembly into the piston bore.
7. Install the short cover mount bolt and finger-tighten only.
8. Install the armature and solenoid assembly. See **Subject 190**.

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

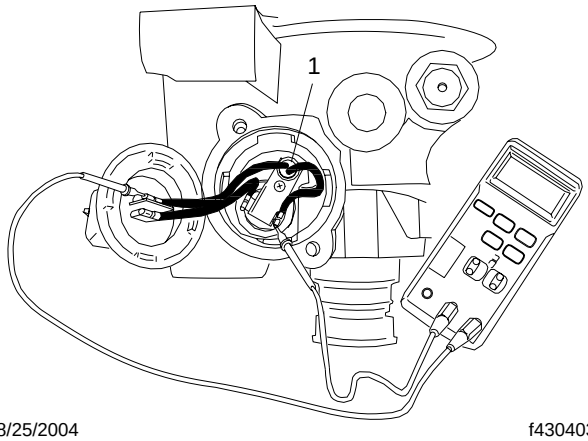
Heater Resistance

To avoid damaging the components, perform this resistance check with the heater in place. Leave the harness connected.

1. Remove the two screws that hold the connector in place and gently pull it away from the dryer housing.
2. Set your volt-ohmmeter to ohms.
3. With the wires connected and properly secured, attach one probe to the heater connector and the second probe to the lead on the thermostat. See Fig. 1.



1. Heater Element

Fig. 1, Heater Resistance Test

4. Measure the resistance. For a 12-volt system, 1.0 to 2.0 ohms resistance is acceptable. If the resistance is less than 1.0 ohm or more than 2.0 ohms, replace the heater.
5. Install the components.

Leak Test

1. Drain the air system.
2. Close the draincocks on all of the reservoirs.
3. Start the vehicle. Allow the air system pressure to build while the engine idles.
4. There will be a light airflow from the purge valve. This is normal and will continue until the air compressor unloads. After 50 to 60 seconds, and if the system pressure has built to at least 60 psi, there will be a mild purge, or exhaust of air, as the dryer switches cartridges. If there is no purge, the solenoid may be bad. Refer to "Solenoid Test" below for a quick solenoid test. When the air system reaches cutout pressure, the dryer will purge completely. After purging, the dryer will not exhaust any air until the compressor starts up again.
5. Shut down the engine.
6. Apply a soap solution to each connection that contains pressurized air. Check the connections to see if soap solution forms bubbles.
7. Repair any leaks, and repeat the leak test until all the connections are sealed.

Solenoid Test

1. Turn the ignition on. Do not start the engine.
2. Using a volt-ohmmeter, test to see that there is power to the solenoid.
3. Listen to the solenoid at the dryer. There should be a click every 50 to 60 seconds. If there is no click, the solenoid is defective or improperly installed.

Description

The Bendix SR-7™ spring brake modulating valve (see **Fig. 1** and **Fig. 2**) is used in conjunction with a dual air brake system and spring brake actuator, and performs the following functions:

- Provides a rapid application of the spring brake actuator when parking.
- Modulates the spring brake actuator application using the dual brake valve should a primary failure occur in the service brake system.
- Prevents compounding of service and spring brake forces.

The SR-7 valve has one park control, one service control, one supply, one balance, four delivery NPT ports, and an exhaust port protected by an exhaust diaphragm. The valve incorporates two mounting

CAUTION

Do not attempt to disassemble the SR-7 valve. The valve contains high spring forces that could result in personal injury if disassembly is attempted.

Operation

The operation guidelines in this subject represent the relay-valve-based SR-7. A quick-release-based valve functions similarly to the relay-valve-based version with the exception that all air delivered to the spring brakes passes through the park control port through the inline single check valve. The SR-7 quick release style can be easily identified by the pipe plug in the supply port of the valve. See **Fig. 1**. For vehicle-specific plumbing diagrams, go to **EZWiring**.

Charging the Spring Brake Actuators Below 107 psi (737 kPa)

With the air brake system charged and the parking brakes released (by pushing in the dash valve button), air enters the park control port. This opens the SR-7 valve, to supply air pressure to the spring brake chambers. As illustrated, air pressure in the chambers is below 107 psi (737 kPa) (nominal). See **Fig. 3**.

Charging the Spring Brake Actuators Above 107 psi (737 kPa)

Once the SR-7 valve delivery pressure reaches 107 psi (nominal), the inlet and exhaust are closed (valve lap position). This maintains the spring brake hold-off pressure at 107 psi (nominal). See **Fig. 4**.

Normal Service Application

During a service brake application, the valve remains in the lap position. The SR-7 valve monitors the presence of air pressure in both primary and secondary delivery circuits. See **Fig. 5**.

Fig. 3, Charging the Spring Brake Actuators Below 107 psi (737 kPa)

Parking

Actuating the park brakes (by pulling out the dash valve button) exhausts spring brake air pressure through the SR-7 valve exhaust port. See **Fig. 6**.

Service Application with Loss of Air in Primary Circuit

With the parking brakes released (dash valve button in) and the absence of air in the primary circuit delivery, a service brake application from the secondary circuit causes the pressure in the spring brakes to be exhausted proportionally to this application. This is known as spring brake modulation. A 30 psi (207 kPa) service brake application will exhaust the spring brake pressure to approximately 60 psi (414 kPa). See **Fig. 7**.

Fig. 5, Normal Service Application

Service Application with Loss of Air in Secondary Circuit

With the parking brakes released (dash valve button in) and the absence of air in the secondary circuit reservoir, the external single check valve in the supply port seals to prevent air leakage to atmosphere from the SR-7 valve. The dash valve delivery air flows through the inline single check valve and becomes SR-7 valve supply air. This air is delivered to maintain at least 107 psi (737 kPa) (nominal) in the spring brake chambers. See **Fig. 8**.

Anticompounding

The SR-7 valve provides anticompounding of the service and spring brake forces. When the park brakes are actuated (by pulling out the dash valve button), a service brake application will cause the SR-7 valve to deliver air pressure to the spring brake chambers. Thus the vehicle is held stationary using a service brake application. When the service brake application is released, the delivery pressure is exhausted from the spring brake chambers and the vehicle remains parked using the spring brake actuators. See **Fig. 9**.

Safety Precautions

Before attempting to work on the air brake system, observe the following precautions:

- Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.
- When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.
- Hoses will whip dangerously if disconnected under pressure. Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.
- As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber pushrods and spring actuators that apply automatically with the loss of pressure. This also applies when checking the service brake system.
- Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.
- Used reservoirs must not be used as replacements, in order to eliminate the possibility of component failure.
- The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured, in order to prevent valve failure.
- Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.
- To avoid injury, keep clear of the air chamber pushrod when brakes are applied or when air is exhausted from the system.

Removal

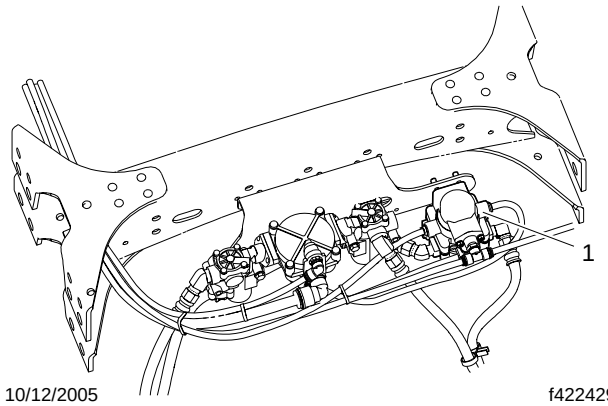
⚠ WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so could result in personal injury.

⚠ CAUTION

Do not attempt to disassemble the SR-7 valve. The valve contains high spring forces that could result in personal injury if disassembly is attempted.

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the tires.
2. Drain the air system.
3. Identify all the air lines attached to the valve, for reinstallation. See **Fig. 1** for a view of a typical installation, or access EZWiring for vehicle-specific plumbing diagrams.



1. SR-7 Valve

Fig. 1, SR-7 Spring Brake Modulating Valve Installation (typical)

4. Disconnect all the air lines from the valve.
5. Remove the two mounting nuts that secure the valve to the crossmember bracket, and remove the valve.
6. If the valve is being replaced, note the orientation of all fittings, then remove the fittings for use on the new valve.

Installation

1. If a new valve is being installed, install the fittings removed from the old valve.
2. Position the valve on the crossmember bracket and install the mounting nuts. Tighten to 15 to 18 lbf·ft (20 to 24 N·m).
3. Attach all the air lines as noted during removal.
4. Before returning the vehicle to service, perform the operating and leakage tests in **Subject 120**, *Tests*.

Operating Test

WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so could result in personal injury.

CAUTION

Do not attempt to disassemble the SR-7 valve. The valve contains high spring forces that could result in personal injury if disassembly is attempted.

1. Chock the tires.
2. Charge the air brake system to governor cut-out pressure.
3. Place the parking control valve in the PARK position. Observe that the spring brake actuators apply promptly.
4. Remove one line from a delivery port of the SR-7 valve and install a test gauge that is known to be accurate. See Fig. 1 for the port locations.
5. Place the parking control valve in the RELEASE position. Observe that the spring brake actuators fully release.
6. With the parking control valve still in the RELEASE position, note the gauge pressure reading. Correct spring brake actuator hold-off pressure is 107 psi (737 kPa) nominal.
7. Place the parking control valve in the PARK position. The gauge reading should drop to zero promptly. A lag (more than 3 seconds) in the drop of pressure would indicate faulty operation.
8. With the parking control valve still in the PARK position, gradually apply the foot brake valve and note a pressure reading increase on the gauge installed in the SR-7 valve delivery port.
9. Place the parking control valve in the RELEASE position.
10. Drain the reservoir that supplies the rear service brake circuit; apply the foot brake valve several times and note that the pressure reading on the gauge decreases each time the foot brake valve is applied (spring brake modulation). After the foot brake valve has been applied several times, the pressure reading on the gauge will drop to the point where release of the spring brake actuators will no longer occur.

NOTE: The SR-7 valve is not serviceable. If the valve does not function as described, replace it.

Leakage Test

Place the park control valve in the RELEASE position; using a soap solution, coat all ports including the exhaust port. A 1-inch (25-mm) bubble in three seconds is permitted.

NOTE: The SR-7 valve is not serviceable. If the valve does not function as described, or if leakage is excessive, replace it.

General Information

The function of the AD-IP Integral Purge Air Dryer, shown in **Fig. 1**, is to collect and remove air system contaminants in solid, liquid, and vapor form before they enter the brake system. It provides clean, dry air to the components of the brake system, which increases the life of the system and reduces maintenance costs.

Fig. 1, Bendix AD-IP Air Dryer

The AD-IP air dryer consists of a desiccant cartridge secured to a die-cast aluminum end cover with a single, central bolt. The end cover contains a check valve assembly, safety valve, heater and thermostat assembly, three pipe thread air connections, and the purge valve assembly. The removable purge valve assembly incorporates the purge valve mechanism and a turbocharger cutoff feature that is designed to prevent loss of engine turbocharger boost pressure during the purge cycle of the AD-IP air dryer. For ease of serviceability, all replaceable assemblies can be replaced without removal of the air dryer from its mounting on the vehicle.

To ease servicing, the desiccant cartridge and discharge check valve assembly are screw-in types.

The purge valve housing assembly, which includes the heater and thermostat assembly, and the discharge check valve assembly, can be serviced **without** removing the air dryer from the vehicle. The screw-in desiccant cartridge requires removal of the air dryer assembly from the vehicle.

The AD-IP has three female pipe thread air connections identified in **Table 1**.

Principles of Operation

The AD-IP air dryer alternates between two operational modes or cycles during operation: the charge cycle, shown in **Fig. 2**, and the purge cycle, shown in **Fig. 3**.

Charge Cycle

When the compressor is loaded (compressing air), compressed air, along with oil, oil vapor, water, and water vapor flows through the compressor discharge line to the supply port of the air dryer body.

As air travels through the end cover assembly, its direction of flow changes several times, reducing the temperature, causing contaminants to condense, and to drop to the bottom or sump of the air dryer end cover.

After exiting the end cover, the air flows into the desiccant cartridge. Once in the desiccant cartridge, air first flows through an oil separator located between the outer and inner shells of the cartridge. The separator removes water in liquid form as well as oil and solid contaminants.

Air, along with the remaining water vapor, is further cooled as it exits the oil separator and continues to flow upward between the outer and inner shells. Upon reaching the top of the cartridge the air reverses its direction of flow and enters the desiccant drying bed. Air flowing down through the column of desiccant becomes progressively dryer as water

vapor adheres to the desiccant material in a process known as adsorption. The desiccant cartridge, using the adsorption process, typically removes most of the water vapor from the pressurized air.

Dry air exits the bottom of the desiccant cartridge and flows through the center of the bolt used to secure the cartridge to the end cover. Air flows down the center of the desiccant cartridge bolt, through a cross-drilled passage and exits the air dryer delivery port through the delivery check valve.

Dry air flowing through the center of the desiccant cartridge bolt also flows out the cross-drilled purge orifice and into the purge volume.

The air dryer will remain in the charge cycle until the air brake system pressure builds to the governor cutout setting.

Purge Cycle

As air brake system pressure reaches the cutout setting of the governor, the governor unloads the compressor (air compressor stops compressing air) and

Fig. 3, AD-IP Purge Cycle

the purge cycle of the air dryer begins. When the governor unloads the compressor, it pressurizes the compressor unloader mechanism and the line connecting the governor unloader port to the AD-IP end cover control port. The purge piston moves in response to air pressure, causing the purge valve to open to the atmosphere and the turbo cutoff valve to close off the supply of air from the compressor (this will be further discussed under the *Turbocharger Cutoff Feature* heading). Water and contaminants in the end cover sump are expelled immediately when the purge valve opens. Also, air which was flowing through the desiccant cartridge changes direction and begins to flow toward the open purge valve. Oil and solid contaminants collected by the oil separator are removed by air flowing from the purge volume through the desiccant drying bed to the open purge valve.

The initial purge and desiccant cartridge decompression lasts only a few seconds and is evidenced by an audible burst of air at the AD-IP exhaust.

The actual reactivation of the desiccant drying bed begins as dry air flows from the purge volume

through the purge orifice in the desiccant cartridge bolt, then through the center of the bolt and into the desiccant bed. Pressurized air from the purge volume expands after passing through the purge orifice; its pressure is lowered and its volume increased. The flow of dry air through the drying bed reactivates the desiccant material by removing the water vapor adhering to it. Generally 30 seconds are required for the entire purge volume of a standard AD-IP to flow through the desiccant drying bed.

The delivery check valve assembly prevents air pressure in the brake system from returning to the air dryer during the purge cycle. After the 30-second purge cycle is complete, the desiccant has been reactivated or dried. The air dryer is ready for the next charge cycle to begin. However, the purge valve will remain open and will not close until air brake system pressure is reduced and the governor signals the compressor to charge the system.

NOTE: The air dryer should be periodically checked for operation and tested for leaks. Refer to **Group 42** of the vehicle maintenance manual for intervals and procedures.

Turbocharger Cutoff Feature

NOTE: The air compressor is naturally aspirated; the air passes from the vehicle air filter directly to the air compressor intake.

The primary function of the turbo cutoff valve is to prevent loss of engine turbocharger air pressure through the AD-IP in systems where the compressor intake is connected to the engine turbocharger. The turbo cutoff valve also removes the "puffing" of air out of the open purge exhaust, when a naturally aspirated, single-cylinder compressor, equipped with an inlet check valve, is in use. See **Fig. 4**.

At the beginning of the purge cycle, the downward travel of the purge piston is stopped when the turbo cutoff valve (tapered portion of purge piston) contacts its mating metal seat in the purge valve housing. With the turbo cutoff valve seated (closed position), air in the compressor discharge line and AD-IP inlet port cannot enter the air dryer. In this manner, the turbo cutoff effectively maintains turbocharger boost pressure to the engine.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

- Chock the tires and shut down the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure, and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not disassemble a component until you have read and understood the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools, and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc., should be the equivalent size, type, length, and strength of the original equipment.

  Make sure that when replacing tubing or hose, all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.

WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

Removal

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Completely drain all of the reservoirs.
3. Mark and disconnect the three air lines from the end cover, and note the position of end cover ports relative to the vehicle.
4. Unplug the vehicle wiring harness from the heater and thermostat assembly connector on the purge valve assembly.
5. Remove the four bolts that secure both the upper and lower mounting brackets to the vehicle, and remove the air dryer from the vehicle. See Fig. 1.

Air Dryer Disassembly, Cleaning and Inspection, and Assembly

⚠ WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

NOTE: As a convenience when rebuilding the air dryer, several replacement parts and maintenance kits are available that do not require full disassembly. Use the instructions provided with these parts or kits.

Disassembly

NOTE: Refer to **Fig. 1** during disassembly.

NOTICE

While servicing the air dryer, do not use a clamping device (vise, C-clamp, etc.) to hold any die cast aluminum part, as damage may result. To hold the end cover, install a pipe nipple in the supply port, and clamp the nipple in a vise.

1. Remove the air dryer from the vehicle. See **Subject 110**.
2. Loosen the desiccant cartridge bolt, then separate the desiccant cartridge from the end cover. Pull the desiccant cartridge bolt out of the end cover. See **Fig. 1**.

⚠ CAUTION

Disassembly of the desiccant cartridge assembly should not be attempted! Detail parts for the cartridge are not available and the cartridge contains a 150 lb spring which can not be mechanically caged. Releasing the spring could cause serious personal injury.

3. Remove both O-rings from the desiccant cartridge bolt.
4. Remove the retaining ring that secures the purge valve assembly in the end cover.
5. Remove the 1/4-inch shoulder bolt from the bottom of the purge valve housing assembly, using a 3/8-inch socket wrench and a large blade screwdriver, inserted in the slot on top of the purge piston. Remove the exhaust diaphragm, and the purge valve from the purge valve housing.
6. Remove the O-rings from the purge valve housing.
7. Remove the purge piston and the return spring. Remove the O-ring from the purge piston.
8. Remove the retaining ring that secures the delivery check valve assembly in the end cover. Remove and separate the perforated plate, spring, check valve body, and O-ring.
9. Remove the retaining ring that secures the heater and thermostat assembly in the end cover. Gently pull the heater and thermostat out of the end cover and remove the O-ring.
10. Using a 9/16-inch wrench, remove the safety valve assembly from the end cover.

Cleaning and Inspection

1. Wash all metal parts thoroughly, using a quality commercial solvent, such as mineral spirits.

NOTE: Do not clean the desiccant cartridge.

2. Check for severe corrosion, pitting, and cracks on the inside and outside of all metal parts that will be reused. Superficial corrosion and pitting on the outside of the upper and lower body halves is acceptable.
3. Inspect the bores of both the end cover and the purge-valve housing for deep scuffing or gouges.
4. Make sure that all purge-valve housing and end cover passages are open and free of blockages.
5. Inspect the pipe threads in the end cover. Make sure they are clean and free of thread sealant.
6. Inspect the purge-valve housing bore and seats for excessive wear and scuffing.
7. Inspect the purge valve piston seat for excessive wear.
8. Make certain that the purge orifice in the cartridge bolt is open and free of obstructions.
9. Inspect all air line fittings for corrosion. Clean all old thread sealant from the pipe threads.
10. Replace all removed O-rings with new ones that are provided in the kits.

    Replace parts that show any of the conditions described in the previous steps.

Assembly

1. Before assembly, coat all O-rings, O-ring grooves, and bores with a generous amount of barium-base lubricant. See **Fig. 1** during assembly unless otherwise advised.
2. Install and center the exhaust diaphragm over the shoulder bolt, making certain that the diaphragm ID is over the bolt shoulder. Then install the purge valve on the shoulder bolt, making certain its metal support side is against the diaphragm.
3. Push the purge piston into the housing until it bottoms, and insert a large blade screwdriver in the piston's slotted head. While depressing the purge piston with the screwdriver, install the shoulder bolt with exhaust diaphragm and purge valve in the piston. Tighten the shoulder bolt 60 to 80 lbf·in (678 to 904 N·cm).
4. Install the two O-rings on the purge valve housing, placing each in its appropriate location. Install the assembled purge valve housing in the end cover while making certain the purge valve housing is fully seated against the end cover. Secure the purge valve housing in the end cover, using the retaining ring. Make certain the retaining ring is fully seated in its groove in the end cover.
5. Using a 9/16-inch wrench, install the safety valve assembly into the end cover.
6. Install the O-ring on the check valve body, and push the O-ring down, over the three guide lands until it is in the O-ring groove of the check valve body. Install the check valve spring on the check valve body so that the small coils of the spring slip over the check valve body. Install the assembled check valve body, O-ring, and spring in the end cover so that the O-ring rests on its seat in the end cover, and the spring is visible.
7. Install the O-ring on the heater and thermostat assembly. After making certain the sponge-rubber cushion is positioned between the connector body and thermostat, gently push the heater and thermostat assembly into the end cover, making certain the heating element enters the small diameter bore in the larger heater and thermostat bore in the end cover. Secure the heater and thermostat assembly in the body, using the retaining ring. Make certain the retaining ring is fully seated in its groove in the end cover.
8. Install both O-rings on the desiccant cartridge bolt, and using a twisting motion, insert the assembled desiccant cartridge bolt in the end cover.
9. Install the desiccant cartridge on the end cover, making certain the cartridge is properly seated and flush on the end cover.

NOTE: It may be necessary to rotate the cartridge slightly until the anti-rotation lugs are properly aligned and they allow the cartridge to rest flush against the end cover.

10. Tighten the desiccant cartridge bolt 50 lbf·ft (68 N·m), to secure the desiccant cartridge to the end cover.
11. Install the air dryer. For instructions, see **Subject 110**.

Testing

During cold-weather operation, check the operation of the end cover heater and thermostat assembly.

1. With the ignition on, check for voltage to the heater and thermostat assembly. Unplug the electrical connector at the air dryer, and place the test leads on each of the pins of the male connector. If there is no voltage, look for a blown fuse, broken wires, or corrosion in the vehicle wiring harness. Check that a good ground path exists.
2. Check the thermostat and heater operation. Turn off the ignition switch and cool the end cover assembly to below 40°F (4°C). Using an ohmmeter, check the resistance between the electrical pins in the female connector. The resistance should be 1.5 to 3.0 ohms for the 12-volt heater assembly, and 6.8 to 9.0 ohms for the 24-volt heater assembly.
3. Warm the end cover assembly to over 90°F (32°C) and again check the resistance. It should exceed 1000 ohms. If it does, the thermostat and heater assembly is operating properly. If it doesn't, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

Problem—Air Dryer Is Constantly Cycling or Purging

Problem—Air Dryer Is Constantly Cycling or Purging	
Possible Cause	**Remedy**
Excessive system leakage.	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is 1 psi/min (7 kPa/min) per service reservoir
There is excessive leakage in the fittings, hoses, and tubing connected to the compressor, air dryer, and wet tank.	Using a soap solution, test for leakage at the fittings, drain valve, and safety valve in the wet tank. Repair or replace as needed.
Check valve assembly in the air dryer end cover is not working.	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at opposite end, and check for leakage. Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.
Governor is inoperative.	Test the governor for proper cut-in or cut-out pressures and excessive leakage in both positions.
Leaking purge-valve housing assembly or O-rings in the air dryer end cover.	With the supply port open to atmosphere, apply 120 psi (830 kPa) at the control port. Apply a soap solution to the supply port and exhaust port (purge valve seat area). Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. Repair or replace as needed.
Compressor unloader mechanism is leaking excessively.	Remove the air strainer or fitting from the compressor inlet cavity. With the compressor unloaded, check for unloader piston leakage. Slight leakage is allowed.
Lack of air at the governor RES port (rapid cycling of the governor).	Test the governor for proper pressure at the RES port. Pressure should not drop below cut-in pressure when the compressor begins the unloaded cycle. If the pressure does drop, check for kinks or restrictions in the line connected to the RES port. The line connected to the RES port on the governor must be the same diameter, or larger than the lines connected to the UNL ports on the governor.

Problem—Water in the Vehicle Reservoirs

Problem—Water in the Vehicle Reservoirs	
Possible Cause	**Remedy**
Desiccant cartridge assembly contains excessive contaminants.	Replace the desiccant cartridge.
Discharge line is of improper length or material.	Discharge line must consist of at least 6 ft. (1.8 m) of wire braid Teflon hose, copper tubing, or a combination of both between the discharge port of the compressor and the air dryer supply port. Discharge line lengths and inside diameter requirements are dependent on the vehicle application. Contact your local Bendix representative for further information.
Air system was charged from an outside air source that did not pass through an air dryer.	If the system must have an outside air fill provision, the outside air should pass through an air dryer. This practice should be minimized.
Air dryer is not purging.	Refer to "Problem—Air Dryer Does Not Purge or Exhaust Air."
Purge (air exhaust) is insufficient due to excessive system leakage.	Refer to "Problem—Air Dryer Is Constantly Cycling or Purging."
Air bypasses the desiccant cartridge assembly.	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed.

Troubleshooting

Problem—Water in the Vehicle Reservoirs	
Possible Cause	**Remedy**
Purge (air exhaust) time is significantly less than the minimum allowable.	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed. Replace the desiccant cartridge assembly.
Excessive air usage—air dryer not compatible with vehicle air system.	Install an accessory bypass system. Consult your Bendix representative for additional information.

Problem—Safety Valve on Air Dryer Is Popping Off or Exhausting Air

Problem—Safety Valve on Air Dryer Is Popping Off or Exhausting Air	
Possible Cause	**Remedy**
Desiccant cartridge is plugged or saturated.	Check the compressor for excessive oil passing, or incorrect installation. Repair or replace as needed.
The check valve in the air dryer end cover is inoperative.	Test to determine if air is passing through the check valve. Repair or replace as needed.
There is a problem in the fittings, hose, or tubing between the air dryer and the wet tank.	See if air is reaching the first reservoir. Inspect for kinked tubing or hose. Check for undrilled or restricted hose or tubing fittings.
Safety valve setting is lower than the maximum system pressure.	Reduce the system pressure, or install a safety valve with a higher pressure setting.

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure	
Possible Cause	**Remedy**
Air dryer purge valve is leaking excessively.	With the compressor loaded, apply a soap solution on the purge valve exhaust to test for excessive leakage. Repair the purge valve as needed.
The governor is inoperative.	Check the governor for proper cut-in and cut-out pressures, and excessive leakage in both positions. Repair or replace as needed.
Purge control line is connected to the reservoir or exhaust port of the governor.	Connect the purge control line to the unloader port of the governor.
Purge valve is frozen open due to an inoperative heater or thermostat, bad wiring, or a blown fuse.	Test the heater and thermostat, following instructions in this manual.
Inlet and outlet air connections are reversed—unable to build system pressure.	Reconnect the lines properly.
Discharge line is kinked or blocked.	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line. Water is collecting and freezing.	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.
System is leaking excessively.	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is 1 psi/min (7 kPa/min) per service reservoir.
Purge valve stays open; supply air leaks to control side.	Replace the purge valve assembly O-rings.

Problem—Air Dryer Does Not Purge or Exhaust Air

Problem—Air Dryer Does Not Purge or Exhaust Air	
Possible Cause	**Remedy**
Purge control line is broken, kinked, frozen, plugged, or disconnected.	See if air flows through the purge control line when the compressor is unloaded. The purge control line must be connected to the unloader port of the governor.
Air dryer purge valve isn't working.	See if air reaches the purge valve. If it does, repair the purge valve.
The governor is inoperative.	Check the governor for proper cut-in and cut-out pressures, and excessive leakage in both positions. Repair or replace as needed.
Inlet and outlet air connections are reversed—unable to build system pressure.	Reconnect the lines properly.
Discharge line is kinked or blocked.	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line. Water is collecting and freezing.	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.

Problem—Desiccant Is Being Expelled from the Air Dryer Purge Valve Exhaust (may look like whitish liquid, paste, or small beads) or Unsatisfactory Desiccant Life	
Possible Cause	**Remedy**
This problem usually occurs with one or more of the previous problems.	Refer to the appropriate corrections listed previously.
Air dryer is not securely mounted; there is excessive vibration.	Vibration should be held to a minimum. Tighten the mounting fasteners.
Cloth-covered perforated plate in the air dryer desiccant cartridge is damaged, or the cartridge was rebuilt incorrectly.	Replace the plate or cartridge as needed. High operating temperatures may cause deterioration of filter cloth. Check the installation.
Compressor is passing excessive oil.	Check for proper compressor installation; if symptoms persist, replace the compressor.
Heater and thermostat, wiring, or a fuse is at fault, and isn't allowing the air dryer to purge during cold weather.	Test the heater and thermostat. See **Group 83** in this manual.
Desiccant cartridge not attached properly to the end cover.	Check the torque and tighten if necessary. Refer to **Subject 120** for instructions.

Troubleshooting

Problem—Pinging Noise Is Excessive During Compressor Loaded Cycle

Problem—Pinging Noise Is Excessive During Compressor Loaded Cycle	
Possible Cause	**Remedy**
Pinging noise is due to a single cylinder compressor with high pulse cycles.	A slight pinging sound may be heard during system build-up when a single cylinder compressor is used. If this sound is deemed objectionable, it can be reduced substantially by increasing the discharge line volume. This is done by adding a 90 in^3 (1475 cm^3) reservoir between the compressor and the air dryer.

Problem—Constant Air Seepage at the Purge Valve (Non-Charging Mode)

Problem—Constant Air Seepage at the Purge Valve (Non-Charging Mode)	
Possible Cause	**Remedy**
Air compressor inlet is pressurized by the engine turbocharger.	Some pressure leakage past the metal seat of the turbocharger cutoff feature of the AD-9 air dryer is normal, and may be heard. This slight loss of air will not affect the engine or turbocharger performance.
Check valve assembly in the air dryer end cover is not working.	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at opposite end, and check for leakage. Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.

Problem—Air Dryer Purge Piston Cycles Rapidly in the Unloaded Mode

Problem—Air Dryer Purge Piston Cycles Rapidly in the Unloaded Mode	
Possible Cause	**Remedy**
Compressor does not "unload."	Check the governor installation: there is no air line from the governor to the compressor, or the line is restricted. Repair or replace as needed.

General Information

The System Saver 1200 Plus air dryer, shown in **Fig. 1**, is a desiccant air dryer, mounted vertically between the air compressor and the supply reservoir. The air dryer receives hot compressed air, which it cools and filters before sending it to the supply reservoir, reducing the buildup of dirt and moisture in the vehicle air system.

Fig. 1, WABCO System Saver 1200 Plus

The air dryer consists of a light weight aluminum and steel body. The desiccant cartridge is contained in a spinoff canister at the top of the air dryer.

The bottom half of the air dryer houses the following components.

- Pressure Relief Valve—this valve protects the air dryer from over pressurization. The valve is attached directly to the air dryer.
- Desiccant Canister—a cylindrical steel housing that contains the filter elements and the desiccant needed to filter and dry the air that passes through it.
- Heater/Thermostat Assembly—located in the air dryer base, this assembly is designed to prevent the collected moisture from freezing.
- Outlet Check Valve—this valve prevents air in the system from flowing back through the air dryer and escaping out the purge valve during the compressor unload cycle.
- Purge Valve—this valve allows the collected moisture and contaminants to be expelled from the air dryer during the purge cycle.
- Silencer (Muffler)—an optional component that is attached to the purge valve and used to eliminate most of the noise during the air dryer purge cycle.
- Turbocharger Cutoff Valve—this optional valve closes the path between the air compressor and the air dryer purge valve to help maintain boost pressure for maximum engine horsepower during the compressor unload cycle. A turbocharger cutoff valve is required with air compressors that use a turbocharged air intake.

NOTE: If the air compressor is naturally aspirated, the air passes from the vehicle air filter directly to the air compressor intake and **does not** require a turbocharger cutoff valve.

Principles of Operation

Hot, compressed air enters the air dryer through the inlet port. As the hot air is forced into the desiccant cartridge, the temperature of the compressed air falls to nearly ambient. Oil and water vapor condense and initially settle into the base of the dryer. The moisture-laden air also passes through the desiccant bed, where any remaining moisture is retained by the desiccant. The clean air then passes through the air dryer outlet port to the supply reservoir.

When the compressor reaches 125 psi (862 kPa), the purge valve opens, allowing the initial decompression of the dryer, and expelling the water and contaminants collected in the base of the dryer.

Safety Precautions

⚠ WARNING

When draining the air system, do not look into the air jets or direct them toward another person, as dirt or sludge particles may be in the airstream. Do not disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can cause personal injury.

When working on or around air brake systems and components, observe the following precautions.

- Apply the parking brake, chock the tires, and stop the engine when working under the vehicle. Draining the air system may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air system pressure drops.
- Wear safety goggles.
- Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
- Do not disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
- Replacement hardware, tubing, hose, fittings, etc., should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace any components that have stripped threads or damaged parts. Do not attempt to repair parts by machining.
- Never exceed recommended air pressure.

WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

Refer to **Fig. 1** for removal and installation of the air dryer.

Removal

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so may result in personal injury.

NOTICE

The WABCO System Saver 1200 Plus air dryer can use either a standard or oil coalescing desiccant cartridge. When replacing the desiccant cartridge, it is very important to use the same type of cartridge that was originally installed on the dryer. Oil coalescing cartridges can be used in any application, but require more frequent service intervals (every 1 to 2 years instead of every 2 to 3 years for a standard cartridge). Do not replace an oil coalescing cartridge with a standard cartridge, as this may result in contamination and malfunctioning of downstream air system components.

Air Dryer Operating Tests

1. Drain the air system.
2. Start the engine and build the air pressure to as close to cutout pressure as possible (about 125 psi [862 kPa]).
3. When the compressor reaches the unload cycle, the air dryer purges, beginning regeneration of the air dryer.
4. There should be no visible pressure drop on the vehicle dash gauges during regeneration. If there is a visible pressure drop, and there are no other air-operated components in use, then there are air leaks or other system problems. Refer to **Troubleshooting 300** for other possible causes.

General Description

The LuK Automotive Hydraulics LF 73 power steering pump supplies power steering fluid for the operation of the power steering gear.

The pump is mounted on the left side of the engine, at the rear of the gear case, or the air compressor. It is powered by an adaptor gear in the engine. The main parts of the power steering pump are the housing, drive shaft, cam ring, rotor, vanes, and control valve. See **Fig. 1**.

Fig. 1, Pump Components

Principles of Operation

The drive shaft, powered by the adaptor gear in the engine gear case, turns the rotor, which is inside the cam ring. As the rotor turns, centrifugal force pushes the vanes out toward the surface of the cam ring. See **Fig. 2**. As fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port and into the system. The fluid operates the steering gear. Eventually the fluid returns to the power steering reservoir, and then back to the power steering pump.

If the system pressure gets too high, a poppet inside the control valve is forced off its seat, shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump instead of going to the outlet port. When the system pressure drops to the correct level, the poppet seats, closing off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port and then into the power steering system.

Removal

1. Shut down the engine, set the parking brakes, and chock the tires.

⚠ DANGER

Before working on an Argosy, review the cab tilting instructions in Section 60.15. Failure to read the warnings and to be aware of the dangers of tilting the cab could result in serious injury or death.

2. Open the hood or tilt the cab. For cab tilting instructions, see **Section 60.15**, Subject 060.
3. Clean all dirt from around the fittings and hose connections.
4. Put a container under the inlet port of the pump, then disconnect the fitting. Plug the hose to keep out dirt and to prevent fluid from leaking.

   Repeat this step at the pump outlet port.
5. On Cummins and Caterpillar engines, remove and discard the capscrews and washers that attach the pump to the engine accessory drive mounting flange. See **Fig. 1**. Slide the pump out of the shaft coupling or sleeve, and remove the pump from the engine.

   On Detroit Diesel Series 50 and 60 engines, remove and discard the capscrews and washers that attach the pump to the adaptor flange. See **Fig. 2**. Slide the pump out of the coupling. Remove the sprocket from the shaft if necessary. Check around the adaptor flange for oil leaks. If there are leaks, remove the adaptor flange from the engine. Remove all old gasket material.

Installation

1. Using engine oil, lightly lubricate a new gasket and the pump shaft.
2. On Cummins and Caterpillar engines, install the new gasket on the pump mounting flange, then place the pump on the engine accessory drive mounting. Turn the pump or shaft as needed to mesh the shaft with the shaft coupling or sleeve. Seat the pilot of the pump mounting flange in the accessory drive mounting, without applying unnecessary force. Install new washers and capscrews. Torque the capscrews 27 to 32 lbf·ft (37 to 43 N·m).

   On Detroit Diesel Series 50 and 60 engines, make sure that the clip is installed in the sprocket and that the coupling and sprocket are installed in the engine accessory drive. See **Fig. 2**. If the adaptor flange was removed, use engine oil to lightly lubricate a new O-ring. Install the O-ring on the flange, and install the flange on the engine. Cross tighten the capscrews 22 to 25 lbf·ft (30 to 34 N·m). Install the new gasket on the pump mounting flange, then position the pump on the adaptor flange. Turn the pump or shaft as needed to mesh the shaft with the sprocket. Seat the pump mounting flange pilot in the adaptor flange without applying unnecessary force. Install new washers and capscrews. Torque the capscrews 27 to 32 lbf·ft (37 to 43 N·m).
3. Connect the hoses to the pump inlet and outlet ports.
4. Check the fluid level of the power steering reservoir and add fluid if necessary. Start the engine and let it idle for two minutes. Do not turn the steering wheel; doing so can cause air to enter the system.

   Turn off the engine and check the fluid level in the reservoir.

5. Start the engine again. To remove air from the system, steer the vehicle from full left to full right several times.

   Add fluid as necessary to the full line on the reservoir or dipstick.

6. If the steering gear does not have a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Repeat this step, and add fluid as necessary until there are no bubbles in the reservoir.

   If the steering gear is equipped with a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Then loosen the manual bleed screw about one turn, and look for clear fluid or fluid mixed with bubbles at the threaded area of the bleed screw. Repeat this step and add fluid as necessary until only clear fluid shows. Tighten the manual bleed screw 27 to 33 lbf·in (300 to 360 N·cm). Refill the reservoir if necessary to the full line on the dipstick.

⚠ DANGER

Before lowering the cab, review the cab tilting instructions in Section 60.15. Failure to read the warnings and to be aware of the dangers of tilting the cab could result in serious injury or death.

7. Lower the hood or return the cab to the operating position. For cab lowering instructions, see **Section 60.15**, Subject 060.
8. Remove the chocks from the tires.
9. Test drive the vehicle and make sure that the steering pump and the steering system operate properly.

Replacement

⚠ WARNING

Wear safety goggles or glasses when disassembling the power steering pump. Some of the parts are held in place by springs or snap rings, which can release with considerable force, possibly causing injury.

NOTE: The shaft seal kit contains a replacement seal for LF and VT series pumps. The seal for the LF-series pump is smaller.

1. Remove the power steering pump from the engine. For instructions, see **Subject 100**.
2. Carefully remove the end plug, and the spring behind it, from the power steering pump. See **Fig. 1**. Then slide the control valve out of the pump housing. Be careful not to scratch the control valve.
3. Remove and discard the O-ring from the plug.

⚠ CAUTION

Be careful when working on the pump housing; it is aluminum, and can be easily damaged. When putting it in a vise, pad the vise jaws. Tighten the vise just enough to hold the pump.

4. Put the pump housing in a padded vise, then remove the capscrews that hold the housing and the flange assembly together.
5. Remove and discard the combination O-ring/backup rings from the pump housing.
6. Remove the pressure plate, guide pins, cam ring, rotor, vanes, and wear plate as a unit and set it aside.
7. Remove and discard the small and large O-rings from the flange assembly.
8. Remove the snap ring holding the shaft seal in place. Discard the snap ring.
9. Put the flange assembly in a vise with the inner end of the shaft pointing up. Carefully tap out the driveshaft.
10. Remove and discard the shaft seal.
11. Using a solvent compatible with the power steering fluid, clean all the components. Then use filtered compressed air to dry the components.
12. Coat all the components with clean power steering fluid. See the Approved Power Steering Fluids table in **Specifications 400**.
13. Place the spacer over the outer (drive) end of the shaft with the cupped side of the spacer facing the inner end of the shaft.
14. Using power steering fluid, lubricate the new shaft seal. Carefully place the seal over the outer (drive) end of the shaft, up against the spacer. The lettered side of the seal should be visible.

NOTE: To correctly install the driveshaft seal, it is necessary to make a suitable driver from tubular stock. See **Fig. 2** for the applicable dimensions.

15. Using a suitable driver, install the shaft seal into the bore in the flange assembly. Make sure the spring side of the seal faces the flange. See **Fig. 3**. Seat the seal firmly against the shoulder in the bore.
16. Install the small snap ring in the groove on the driveshaft with the sharp edge facing toward the bushing.
17. Put the flange assembly in a padded vise with the drive end of the shaft pointing up. Install a new large O-ring in the flange assembly.
18. Install a new small O-ring in the flange assembly.
19. Install the pressure plate, guide pins, cam ring, rotor, vanes, and wear plate as a unit. Make sure that the two guide pins are seated in the flange assembly.
20. Using power steering fluid, lubricate the new combination O-ring/backup rings. Install the rings in the pump housing with the black side facing the housing, and the white, plastic side exposed.
21. Line up the mounting holes, and install the pump housing over the flange assembly.
22. Install the capscrews and washers in the pump housing. Tighten them in a cross pattern 29 to 37 lbf·ft (40 to 50 N·m).
23. Install the control valve in the pump housing.

⚠ CAUTION

Make sure you install the control valve correctly in its bore. If it is installed backwards, the power steering pump will not work and will quickly overheat, which could cause severe damage to the pump.

23.1 Lubricate the control valve with power steering fluid. See the Approved Power Steering Fluids table in **Specifications 400**. Then install the control valve, with the hexagonal end up, into the pump housing bore. See **Fig. 4**.

23.2 Install the spring over the hexagonal end of the control valve.

23.3 Install a new O-ring on the end plug, then install the end plug. Tighten it 33 to 40 lbf·ft (45 to 55 N·m).

General Description

NOTE: Procedures in this section have been slightly modified from the original component manufacturer's service manual. See the manufacturer's service literature (**trucksteering.trw-.com**) for additional information.

TRW TAS power steering gears are integral hydraulic power steering gears that contain a manual steering mechanism, a hydraulic control valve, and a hydraulic power cylinder.

The pressure required for the steering gear to overcome resistance at the steered wheels is provided by the power steering pump. The rotary control valve directs the flow of hydraulic fluid to the appropriate cylinder cavity in the steering gear (and in the auxiliary cylinder in a dual steering gear system) at the proper flow rate and pressure. As the steering wheel is turned faster or slower, more or less fluid is required by the gear.

Principles of Operation

When the driver turns the steering wheel, that force travels from the steering wheel to the steering gear input shaft. A torsion bar, pinned at one end to the input shaft and at the other end to the worm shaft, turns with the input shaft and exerts a rotational force on the worm shaft. In response to the force exerted by the torsion bar, the worm shaft moves the rack piston forward or backward in the gear housing by means of a series of recirculating balls in the spiral channels of the worm shaft. As the rack piston slides back and forth, it turns the sector shaft. The sector shaft swings the pitman arm, which pulls or pushes the drag link. The drag link moves the axle steering arm, steering the vehicle.

The rack piston's axial movement is resisted by its engagement to the sector shaft, which is linked to the steered wheels. Because of this resistance, the torsion bar activates the control valve, which directs pressurized fluid to the upper or lower cylinder cavity (depending on the direction of turn). The pressurized fluid assists in moving the rack piston up or down in the cylinder bore.

Most TAS steering gears are equipped with two poppet (unloading) valves, one at each end of the rack piston. As the front wheels reach the axle stop—the farthest the wheels can turn in either direction—one poppet or the other, depending on the direction of the turn, will trip to prevent steering system damage. The tripped poppet reduces pressure in the gear, heat generated by the power steering pump, and outside forces acting on the steering linkage.

Some TAS steering gears are also supplied with an internal pressure relief valve (PRV). The PRV limits maximum supply pressure to protect the power steering gear, but it does not reduce pressure as the steered wheels approach the axle stops.

See **Fig. 1** for an exploded diagram of a TRW TAS power steering gear.

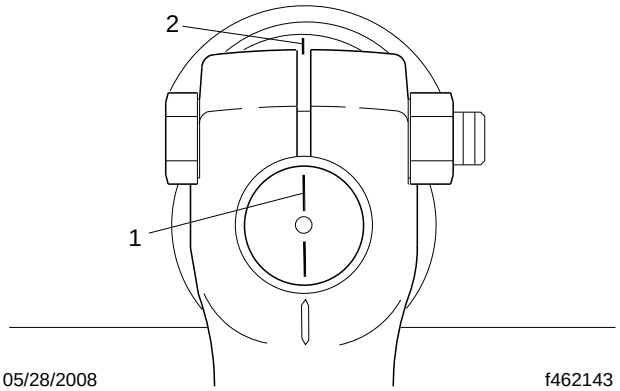
Sector Shaft Adjustment

NOTE: If the steering gear is installed on the frame rail, sector shaft adjustment can only be completed if the adjusting screw jam nut (located on the side cover) is accessible.

1. Apply the parking brakes and chock the rear tires.
2. With the engine on, turn the steering wheel until the timing mark on the sector shaft lines up with the timing mark on the housing. The sector shaft is now at its center of travel. See **Fig. 1**. Shut down the engine.



1. Housing Timing Mark
2. Sector Shaft Alignment Mark

Fig. 1, Timing Mark Placement

3. Remove the cotter pin and castle nut that attach the drag link to the pitman arm. Disconnect the drag link from the pitman arm.

IMPORTANT: To avoid resetting the poppets, do not turn the input shaft more than 1-1/2 turns from the center-of-travel position while the drag link is disconnected.

4. From the center-of-travel position, grasp the pitman arm at the lower end of the arm and gently try to move the arm back and forth. See **Fig. 2**. If the pitman arm is loose or lash (free play) is detected, the sector shaft is out of adjustment.
5. Loosen the adjusting screw jam nut.
6. If no lash was detected in step 4, use a screwdriver to turn the sector shaft adjusting screw

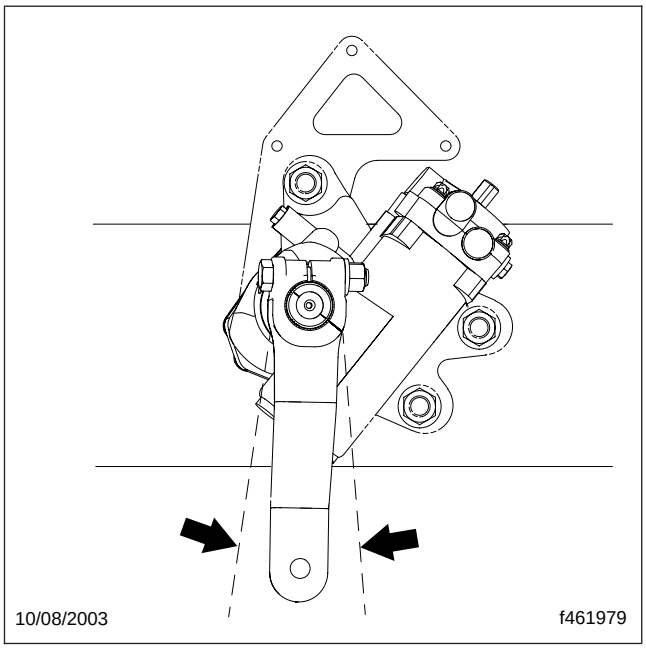


Fig. 2, Lash Check

counterclockwise until you feel lash at the sector shaft. See **Fig. 3**.

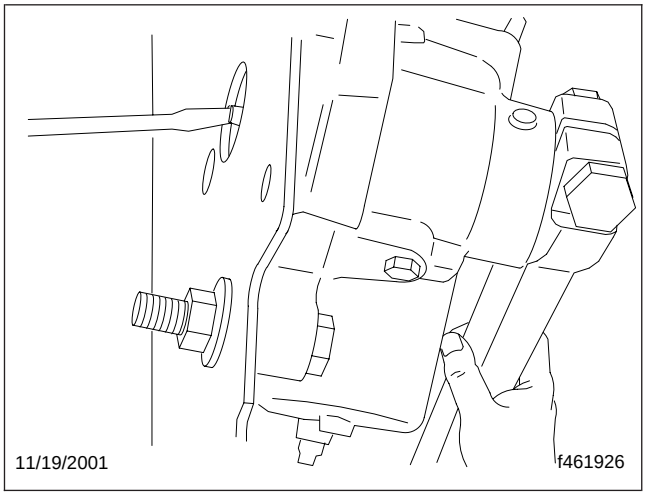

Fig. 3, Adjusting the Sector Shaft

IMPORTANT: Do not use more than 10 lbf·ft (14 N·m) of force when tightening the adjusting screw.

7. Slowly turn the adjusting screw clockwise until no lash is felt at the pitman arm. From this position, turn the adjusting screw clockwise 1/8 to 3/16 of

a turn more. Hold the adjusting screw in place and tighten the jam nut 43 lbf·ft (58 N·m).

8. Turn the steering wheel 1/4 of a turn to each side of center and recheck the pitman arm for lash. If lash is detected, adjust the sector shaft again.
9. Using a castle nut, attach the drag link to the pitman arm. Tighten the castle nut using the appropriate torque value.
    - 3/4–16: 90 to 170 lbf·ft (122 to 230 N·m)
    - 7/8–14: 160 to 300 lbf·ft (217 to 407 N·m)

WARNING

Failure to install and lock a new cotter pin in the ball stud and nut could result in disengagement of the parts and loss of steering control, which could result in personal injury or property damage.

10. Continue to tighten the castle nut until a slot on the nut aligns with the hole in the ball stud. Do **not** reverse the tightening direction of the nut when locating the cotter pin hole. Install a new cotter pin in the ball stud and nut, then lock the cotter pin in place.

NOTICE

Do not use a power grease gun to add grease to the sector shaft bearing. Doing so could damage the high-pressure seal and contaminate the hydraulic fluid.

11. Using only a hand-operated grease gun, add grease to the sector shaft bearing through the grease fitting in the housing until grease begins to extrude past the dirt and water seal.

Resetting the Poppet Valves

IMPORTANT: The axle stops must be set so that there are at least 1-3/4 steering wheel turns from a straight-ahead position to both a full-left and a full-right turn; otherwise the poppet valves will not work.

1. Verify that the axle stops are adjusted properly. See **Group 33** for instructions.
2. Start the engine and allow the vehicle to idle for 5 to 10 minutes to warm the hydraulic fluid.
3. Shut down the engine, apply the parking brakes, and chock the rear tires.
4. Hold the poppet screw with a wrench and turn the sealing nut back toward the wrench until the nut is flush with the base of the hex area of the poppet screw.
5. Make sure that the engine is off and the wheels are in the straight-ahead position.

NOTICE

Make sure the drive end of the adjusting screw is not below the face of the nut. If the drive end of the adjusting screw is below the face of the nut, the poppet seat flange will break when the upper poppet is prepared for setting.

6. Using a 7/32-inch Allen wrench, turn the adjusting screw and nut assembly (without turning the nut on the screw) into the housing until the nut is firmly against the housing. Tighten the nut against the housing. See **Fig. 4**.

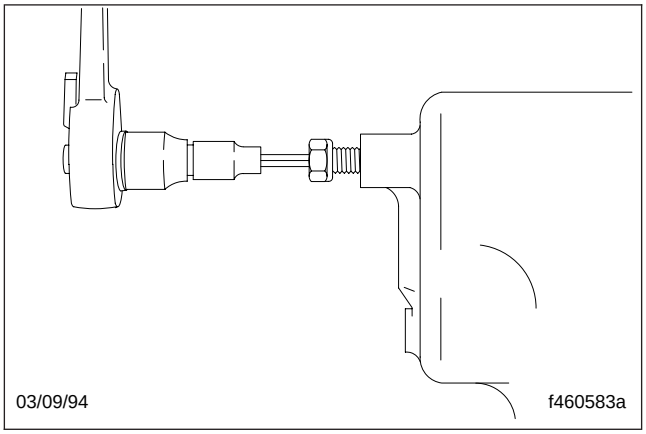

Fig. 4, Adjusting Screw and Nut Assembly

WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

7. Fill the power steering reservoir nearly full with automatic transmission fluid. Do not turn the steering wheel.
8. Place a jack under the center of the front axle and jack up the front of the vehicle so the steer axle tires are off the ground.
9. Push the upper poppet out to prepare it for setting.
   - 9.1 Start the engine and let it idle.
   - 9.2 Note which sector shaft timing mark is nearest the housing piston bore.

NOTICE

Do not hold the steering wheel at full turn for more than 10 seconds at a time. The heat buildup at pump relief pressure may damage components.

   - 9.3 Turn the steering wheel in the direction that makes this timing mark move toward the adjusting screw just installed. Turn the wheel in this direction until axle stop contact is made.
   - 9.4 Pull hard on the steering wheel. Put up to 40 lbf (178 N) pull on a 20-inch diameter steering wheel.
10. Set the upper poppet.
   - 10.1 Turn the steering wheel in the opposite direction (the timing mark will move away from the adjusting screw) until the other axle stop is contacted.
   - 10.2 Pull hard on the steering wheel. Put up to 40 lbf (178 N) pull on a 20-inch diameter steering wheel.
   - 10.3 Release the steering wheel and shut off the engine.
11. Loosen the sealing nut and back out the adjusting screw until the adjusting screw is 1 inch (2.5 cm) past the nut. See **Fig. 5**. Tighten the nut against the housing.
12. Set the lower poppet.
   - 12.1 Start the engine and let it idle.

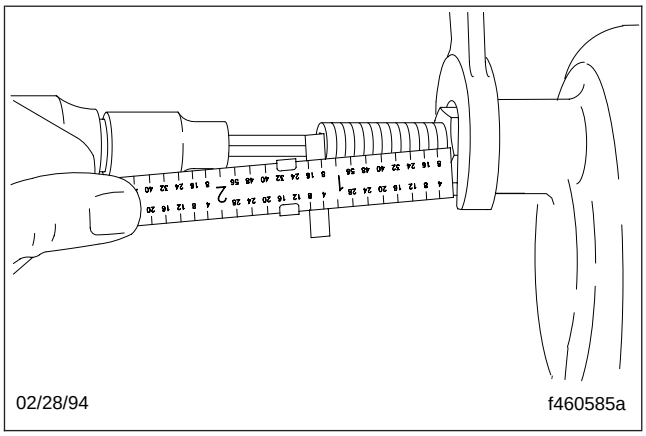

Fig. 5, Adjusting Screw Position

   - 12.2 Turn the steering wheel in the original direction (the timing mark will move toward the adjusting screw) until axle stop contact is made.
   - 12.3 Hold the steering wheel in this position with up to 40 lbf (178 N) pull on a 20-inch diameter steering wheel for 10 seconds, then release. Repeat this hold-and-release process as many times as necessary while completing the next step.
13. Position the adjusting screw.
   - 13.1 With the steering wheel held tightly at full turn, loosen the nut and hold it in place with a wrench.

IMPORTANT: Do not attempt to turn the adjusting screw in any farther. Pause the turning-in process each time the driver releases the steering wheel. Continue turning only while the steering wheel is held at full turn.

   - 13.2 Using an Allen wrench and finger pressure only, turn the adjusting screw clockwise until the Allen wrench stops.

⚠ WARNING

If the adjusting screw protrudes more than 1-1/16 inches (27 mm) from the sealing nut, the screw could fall out of the steering gear, resulting in loss of power steering. This could cause an accident resulting in personal injury or property damage.

Steering Gear Adjustments

13.3 Back off the adjusting screw 3-1/4 turns and tighten the nut 35 lbf·ft (47 N·m).

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

14. The poppets have now been completely reset. Check the power steering reservoir. If needed, add fluid.
15. Lower the vehicle.

NOTE: This subject covers both the Century Class Conventional and the Argosy COE vehicles.

Removal

1. Verify correct axle stop adjustment. Ensuring correct axle stop adjustment now will eliminate the need to reset the steering gear poppet valves after the gear is installed. For instructions, refer to **Group 33**.
2. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping where the work is to be done.
3. Shut down the engine, apply the parking brakes, and chock the tires.
4. Clean all fittings and hose connections on the steering gear until they are free of dirt.
5. Drain the fluid from the power steering system. Disconnect all hydraulic lines from the gear, marking the lines for later reference. Seal the lines and the fittings to keep out dirt.
6. Disconnect the pitman arm from the steering gear sector shaft.
   - 6.1 Remove and discard the pinch bolt, washer, and nut from the pitman arm.
   - 6.2 Remove the pitman arm using a suitable puller, then swing the pitman arm and drag link out of the way.
7. Disconnect the steering driveline from the steering gear input shaft.
   - 7.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

NOTICE

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

   - 7.2 Remove the lower end yoke from the input shaft.

WARNING

The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

NOTE: 1/4-inch spacers are used between the frame rail casting and a TAS85 steering gear on Argosy COE vehicles. These spacers are not used on the TAS65.

8. Remove the mounting fasteners that attach the steering gear to the frame rail and frame rail extension. Remove the spacers and the steering gear.

Installation

1. Install the steering gear and fasteners as shown in **Fig. 1** or **Fig. 2**. Tighten the fasteners 388 lbf·ft (526 N·m).

1. Housing Timing Mark
2. Sector Shaft Alignment Mark

Fig. 3, Timing Mark Placement

3. Connect the steering driveline to the steering gear input shaft.

3.1 Clean the steering gear input shaft and the inside of the driveline yoke.

3.2 Apply a thin film of grease to the yoke spline.

3.3 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut to the following specifications:

- 7/16–20 pinch bolt: 55 to 65 lbf·ft (75 to 88 N·m)
- M10 x 1.25 pinch bolt: 30 to 35 lbf·ft (41 to 47 N·m)

3.4 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate the fasteners have been properly tightened.

⚠ WARNING

Never leave a chisel wedged in the pitman arm slot. When using a chisel to spread the slot in the pitman arm, maintain a firm grip on the chisel at all times. Otherwise the chisel may fly loose, which could cause an injury.

NOTE: The pitman arm may not fit over the splines on the sector shaft without spreading the slot in the arm. Use a ball-peen hammer to drive a chisel into the slot. Hold the chisel in place. Install the pitman arm on the sector shaft. Remove the chisel from the slot.

4. Install the pitman arm.

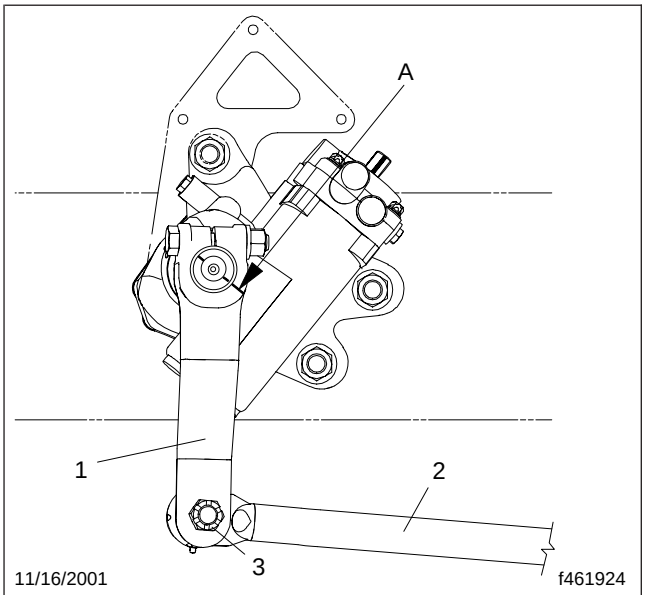
4.1 Position the pitman arm on the steering gear, aligning the timing mark as shown in **Fig. 4**.

4.2 Using a new pinch bolt, nut, and washer (if applicable), attach the pitman arm to the steering gear sector shaft.

Tighten the nut 230 lbf·ft (312 N·m).

4.3 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate the fasteners have been properly tightened.

5. If they were removed, attach the hydraulic line fittings to the steering gear. Tighten the fittings 38 lbf·ft (52 N·m). Tighten the pressure line fitting jam nut 41 lbf·ft (56 N·m).



A. The timing mark on the pitman arm must line up with the timing mark on the sector shaft.

1. Pitman Arm
2. Drag Link
3. Castle Nut

6. Remove the plugs from the hydraulic lines. Connect the lines to the steering gear as previously marked. Tighten the nut on each fitting finger tight. Then, use a wrench to tighten the nut until there is firm resistance. Tighten 1/6 of a turn more.
7. Connect the batteries.
8. Fill and bleed the steering system.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

8.1 Fill the power steering reservoir nearly full with automatic transmission fluid. Do not turn the steering wheel.

8.2 Start the engine and let it idle for ten seconds, then shut it off. Check and fill the reservoir. Repeat this step at least three times, checking the fluid level in the reservoir each time.

IMPORTANT: Do not let the fluid level drop significantly or allow the reservoir to empty. Doing so may introduce air into the system.

8.3 Start the engine and let it idle for two minutes. Do not turn the steering wheel. Shut off the engine and check the fluid level in the reservoir. If needed, add more fluid.

8.4 Start the engine again. Steer the vehicle from full left to full right several times. Check and, if necessary, refill the reservoir.

Automatic bleed systems should now be free of trapped air. Skip to the last step in this procedure.

If the vehicle has a manual bleed system (**Fig. 5**), proceed to the next step.

IMPORTANT: Do not turn the steering wheel while the bleed screw is loosened.

8.5 With the wheels in the straight-ahead position, loosen the manual bleed screw two to three turns. Allow air and aerated fluid to bleed out until only clear fluid is seen. Close the bleed screw and add fluid to the reservoir if needed.

Repeat this step until all air is out of the system.

Tighten the bleed screw 45 lbf·in (509 N·cm).

9. Close the hood and perform the post-service checks in **Subject 130**.

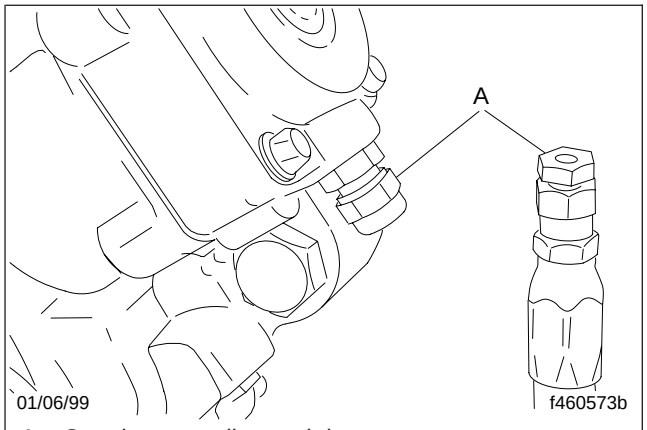
NOTE: The power steering pump is used in this procedure to force out the input shaft seal. To use this procedure, the power steering pump should have a minimum of 1500 psi (10 342 kPa) available.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Disconnect the return line from the steering gear and plug the line. See **Fig. 1**. Cap the return port of the gear with a high-pressure fitting.



A. Cap the return line and the return port.

NOTICE

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

3. Disconnect the steering driveline from the steering gear input shaft.

   3.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

   IMPORTANT: Do not turn the steering gear input shaft when removing the lower end yoke.

   3.2 Remove the lower end yoke from the input shaft. Push the driveline shaft into the driveline tube as you remove the lower end yoke.

4. Remove the dirt and water seal from the steering gear. Save this seal to determine the correct size of the new seal.
5. Using a clean cloth, remove all grease from around the input shaft.
6. Using a screwdriver inserted into the notch formed in the end of the retaining ring, remove the retaining ring. See **Fig. 2**. Be careful not to scratch the bore with the screwdriver.

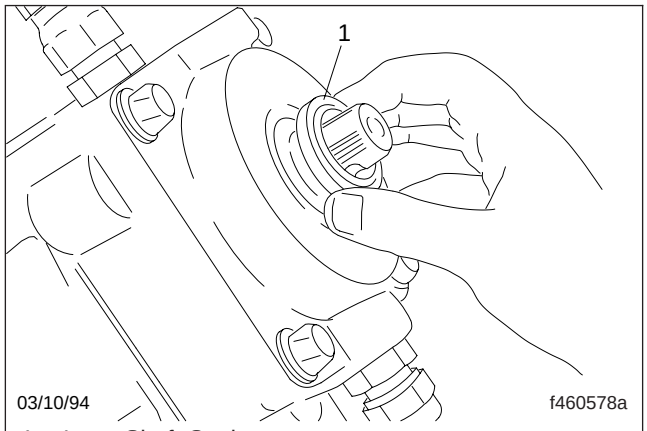
WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

9. If needed, fill the power steering reservoir with automatic transmission fluid.
10. With the vehicle in neutral, momentarily turn the starter. If the engine starts, quickly turn it off. This should force out the input shaft seal.
11. Remove the shop towel, pinch bolt, and input yoke. Remove the input shaft seal. See **Fig. 5**.
12. Inspect the seal area of the valve housing for seal fragments. Remove any seal fragments.
13. Check the seal for heat damage. If the seal is stiff and brittle, and not pliable like the new seal, it is probably heat damaged. Determine and fix the cause of any excessive heat in the vehicle. Discard the old seal.



1. Input Shaft Seal

Fig. 5, Input Shaft Seal Removal

WARNING

Do not use a socket to install the input shaft seal. You will not be able to control the seal installation depth with a socket and this could lead to leaks. Leaks could result in loss of steering assist and spillage on the roadway, which could result in personal injury or property damage.

14. Install a new input shaft seal.
    - 14.1 Using Exxon Polyrex® EP2 grease (045422), lubricate the inside diameter of the new input shaft seal and install it on the input shaft.
    - 14.2 Using a hammer and seal driver (J37073), tap the driver until the shoulder of the driver is square against the valve housing. See **Fig. 6**. Remove any seal material that may have sheared off in the seal bore or retaining ring groove.
15. Install a new retaining ring in the groove.
16. Using Exxon Polyrex EP2 grease, pack the end of the valve housing bore and around the input shaft with clean grease.
17. Install a new dirt and water seal.
    - 17.1 Choose the correct size dirt and water seal by comparing the replacement seals to the old seal.
    - 17.2 Apply Exxon Polyrex EP2 grease to the new dirt and water seal and install it on the input shaft. See **Fig. 7**. Seat it in the

groove behind the serrations and against the valve housing.

Wipe any excess grease from the valve housing bore and input shaft once the seal has been installed.

18. Connect the steering driveline to the steering gear input shaft.

    18.1 Clean the input shaft and the inside of the driveline yoke.

    18.2 Apply a thin film of grease to the yoke splines.

    18.3 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).

    18.4 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate the fasteners have been properly tightened.

19. Connect the return line to the steering gear return port.

20. Fill and bleed the steering system.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

    20.1 Fill the power steering reservoir nearly full with automatic transmission fluid. Do not turn the steering wheel.

    20.2 Start the engine and let it idle for ten seconds, then shut it off. Check and fill the reservoir. Repeat this step at least three times, checking the fluid level in the reservoir each time.

IMPORTANT: Do not let the fluid level drop significantly or allow the reservoir to empty. Doing so may introduce air into the system.

    20.3 Start the engine and let it idle for two minutes. Do not turn the steering wheel. Shut off the engine and check the fluid level in the reservoir. If needed, add more fluid.

    20.4 Start the engine again. Steer the vehicle from full left to full right several times. Check and, if necessary, refill the reservoir.

    Automatic bleed systems should now be free from trapped air.

    If the vehicle has a manual bleed system (**Fig. 8**), proceed to the next step.

IMPORTANT: Do not turn the steering wheel while the bleed screw is loosened.

Input Shaft Seal Replacement

20.5 With the wheels in the straight-ahead position, loosen the manual bleed screw two to three turns. Allow air and aerated fluid to bleed out until only clear fluid is seen. Close the bleed screw and add fluid to the reservoir if needed.

Repeat this step until all air is out of the system.

Tighten the bleed screw 45 lbf·in (509 N·cm).

Post-Service Checks

After power steering components have been worked on and before the vehicle is placed into service, the following items must be checked.

⚠ WARNING

Failure to check the following items could result in damage to the power steering system. This could cause loss of steering assist and spillage on the roadway, which could cause personal injury or property damage.

1. Operate the engine at low idle while turning the steering wheel through several full-left and full-right turns. With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level (signs that air is trapped in the system).

   If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as necessary. Bleed the air from the system.
2. With the engine turned off and warm, check the power steering reservoir fluid level. If needed, add power steering fluid.
3. At full-left and full-right wheel cuts, be sure the axle stops (on the rear-side of the spindle) are set so there is at least 1/2-inch (13-mm) clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be 3/4 of an inch (19 mm). If clearance is less than this, reset the axle stops.
4. Check that the poppets are set correctly. If necessary, adjust them. For instructions, see **Subject 100**.
5. If there are still problems with the power steering system, perform the troubleshooting procedures in **Section 46.15**. Otherwise, go to the next step.
6. Test drive the vehicle and check the steering wheel spoke position. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be pointing within ±10 degrees of the 9 o'clock and 3 o'clock positions on a four-spoke steering wheel. If not, remove the steering wheel and install it in the correct position. See **Fig. 1**.

Post-Service Checks

After power steering components have been worked on, and before the vehicle is placed into service, the following items must be checked.

⚠ WARNING

Failure to check the following items could result in damage to the power steering system. This could cause a loss of hydraulic assist, which could cause personal injury or property damage.

1. Place a thermometer in the power steering reservoir, then warm the hydraulic system to normal operating temperature of 125 to 135°F (51 to 57°C), by operating the engine at low idle, while turning the steering wheel through several full left and right turns. With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop, while checking the power steering reservoir for frothing or a change in the fluid level (a sign that air is trapped in the system). If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as necessary. Bleed the air from the system.
2. With the engine turned off and warm, check the power steering reservoir fluid level, using the instructions in the steering section in the vehicle maintenance manual.
3. At full-left and full-right wheel cuts, be sure the axle stops (on the rear-side of the spindle) are set so there is at least 1/2-inch (13-mm) clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be 3/4 inch (19 mm). If clearance is less than the above, reset the axle stops.
4. Check that the poppet plungers are set correctly. If needed, adjust them. For instructions refer to **Subject 100**.
5. If there are still problems with the power steering system, go to **Section 46.15, Subject 300**, and perform the troubleshooting procedures; otherwise, go to the next step.
6. Test drive the vehicle or take a ride with the driver. Check the steering wheel spoke position. If during straight-ahead driving on a level road, the steering wheel spokes are not within ±10 degrees of the 9 o'clock and 3 o'clock positions, remove the steering wheel and reposition it.

General Description

The TRW PS Series power steering pump supplies power steering fluid for the operation of the power steering gear. The main components of the power steering pump are the housing, input shaft, cam ring, rotor, vanes, control valve, and cover assembly.

Principles of Operation

The input shaft, powered by the adaptor gear in the engine gear case or by the crankshaft pulley, turns the rotor, which is inside the cam ring. As the rotor turns, centrifugal force pushes the vanes out toward the surface of the cam ring. As fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port and into the system. The fluid operates the steering gear. Eventually the fluid returns to the power steering reservoir, and then back to the power steering pump.

If the system pressure gets too high, a relief valve inside the control valve is forced off its seat, shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump instead of going to the outlet port. When the system pressure drops to the correct level, the relief valve seats, closing off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port and then into the power steering system.

Steering Pump Removal and Installation

Removal

1. Turn off the engine, apply the parking brakes, chock the tires, and tilt the hood or cab. For cab tilt instructions, see **Group 60**.
2. Clean all dirt from around the fittings and hose connections.
3. Put a drain pan under the pump, then disconnect the hoses from the fittings on the pump. Plug the hoses and cap the fittings to keep out dirt and to prevent fluid from leaking.
4. Remove the power steering pump.
   - 4.1 Remove the capscrews and washers that attach the pump to the engine accessory drive mounting flange.
   - 4.2 Pull the pump straight out from the engine. Keep it level to avoid spilling fluid.
5. Turn the pump upside down over the drain pan and let the fluid drain out.
6. Remove and discard the gasket from the pump mounting flange.

Installation

1. Using engine oil, lightly lubricate a new gasket and the pump shaft.
2. Install the power steering pump.
   - 2.1 Install a new gasket on the pump mounting flange, then place the pump on the engine accessory drive mounting.
   - 2.2 Install the washers and capscrews, and torque them 27 to 32 lbf·ft (37 to 43 N·m).
3. Connect the inlet hose, from the power steering reservoir, to the inlet port. Torque the fitting 26 lbf·ft (35 N·m).
4. Connect the outlet hose, from the power steering gear, to the outlet port.
5. Bleed the power steering system.
   - 5.1 Check the fluid level in the power steering reservoir and if needed, fill it to the correct level.
   - 5.2 Start the engine and let it idle for several minutes.
   - 5.3 Turn the wheels to a full-left and full-right turn. Repeat about three times.
   - 5.4 Check the fluid level in the power steering reservoir. Add fluid as necessary to the full line on the reservoir or dipstick.
   - 5.5 Shut down the engine.
6. Lower the hood or cab. For cab tilt instructions, see **Group 60**.
7. Remove the chocks from the tires.

Steering Pump Disassembly, Inspection, and Assembly

CAUTION

Be careful when working on the pump housing; it is aluminum, and can be easily damaged. When putting the pump in a vise, pad the vise jaws and clamp only the cover. Tighten the vise just enough to hold the pump.

Disassembly

WARNING

Wear safety goggles or glasses when disassembling the power steering pump. Some of the parts are held in place by springs or snap rings, which can release with considerable force, possibly causing injury.

NOTE: Prepare for fluid drainage before disassembling the pump.

1. Remove the power steering pump from the engine. For instructions, see **Subject 100**.
2. Carefully remove the end plug and the spring behind it from the pump housing. See **Fig. 1**.
3. Remove and discard the O-ring from the end plug.

IMPORTANT: TRW does not recommend disassembly of the control valve spool assembly.

4. Remove the control valve spool assembly by hand, or by pushing it with a small rod. Do not push on the small screen in the relief valve seat assembly.
5. Using a solvent-proof marker, make a mark across the housing and the cover. See **Fig. 2**. Remove the capscrews and washers that hold the housing and the cover together. Using a twisting motion, separate the housing from the cover.
6. Remove the spring.
7. Using a solvent-proof marker, draw a line across the top plate and the bottom plate. See **Fig. 3**.
8. Holding the cam ring in place, remove the top plate. Remove and discard the O-ring and backup O-ring.
9. Holding the bottom plate in place, remove the cam ring. Note and record whether the dots near the locating pin holes on the cam ring are up or down. See **Fig. 4**.
10. Look for wear on the outside edge of the vanes. Note and record the direction of the wear for assembly. Carefully remove the rotor and vanes, as the vanes will slip from their slots in the rotor.
11. Remove the locating pins. Make marks on the outside of the cover (not on the sealing surface) to note from which holes the locating pins were removed.
12. Remove the bottom plate.
13. Turn the cover over and remove the large retaining ring.
14. Press out the input shaft and ball bearing assembly.
15. Remove the spacer from the cover.
16. Using care not to damage the bore, remove the shaft seal.

Inspection

1. Using a solvent compatible with the power steering fluid, clean all the components. Using filtered compressed air, dry all the components.

NOTE: Replace any components that are damaged or worn.

2. Inspect the housing for cracks, stripped threads, a damaged valve bore, and damaged sealing areas. See **Fig. 5**.
3. Inspect the cover for nicks in the O-ring seal grooves. Make sure that the seal drain hole is open, and that the seal bore is free of nicks and other damage. See **Fig. 6**.

   Make sure that the surface on which the bottom plate rests is flat and free of nicks and other damage.
4. Check that the needles roll freely in the needle bearing. If needed, replace the needle bearing as follows.

   4.1 Place the cover in a press with the flange side down. Using an 11/16-inch socket, press the needle bearing out of the cover.

9.2 Applying pressure to the engine drive end of the input shaft, press the input shaft from the ball bearing.

9.3 Press the new input shaft (from the small splined end) into the ball bearing until the shaft bottoms out on the retaining ring.

9.4 Install the retaining ring on the input shaft with the sheared edge pointing away from the bearing. Make sure that the retaining ring is properly seated.

IMPORTANT: TRW does not recommend disassembly of the control valve spool assembly.

10. Check the control valve spool assembly for wear or chipping. If needed, back flush with air and solvent. Check the assembly for nicks or burrs.

Assembly

CAUTION

Make sure that the press is clean and free of debris. Debris could damage the face of the cover, which will affect pump operation.

1. Coat the outside surface of the shaft seal with a petroleum-based chassis grease. With the lettered side facing toward the needle bearing, press the seal into the cover. The installed seal should be flush with, or just below, the sealing surface on the cover.
2. Grease the inside surface of the shaft seal using a petroleum-based chassis grease.
3. Install the spacer. Make sure that it lies flat.

CAUTION

Do not allow the splines to contact the shaft seal. The splines could damage the shaft seal.

4. Insert the input shaft (small splined end first) into the cover. Do not allow the splines to contact the shaft seal. Insert the shaft into the seal by hand until the ball bearing contacts the cover.

Using a 7/8-inch socket, press the shaft and bearing into the cover.

CAUTION

When placing the cover in a padded vise, do not use excessive clamping force. This could damage the cover.

5. Place the cover in a padded vise and install the large retaining ring with the sheared edge out.

   Turn the cover assembly over.

6. Install the new large and small O-rings in the cover. Make sure that they are seated properly.

7. Using the marks made during disassembly as a guide, install the locating pins.

IMPORTANT: In one of the four cutouts in the cover there is a bar. When installed, the bottom plate must cover this bar.

8. Install the bottom plate with the pockets facing up. See **Fig. 8**. Make sure that the marks made during disassembly are aligned.

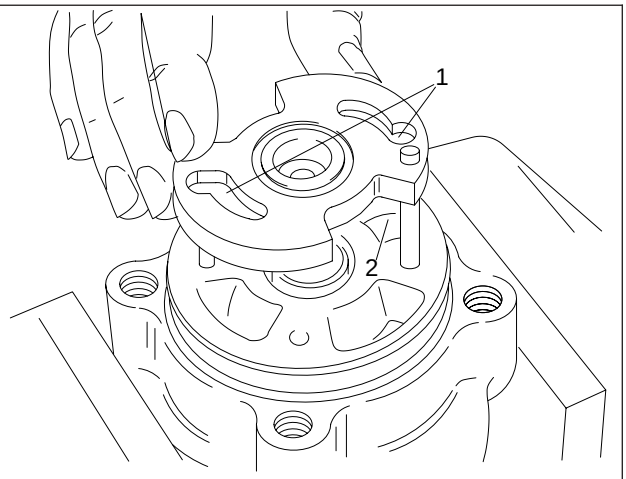

Fig. 8, Installing the Bottom Plate

9. Install the cam ring with the dots facing up or down as noted during disassembly. Make sure that the cam ring is flush with the bottom plate's large outside diameter, and that the marks made during disassembly are aligned.

10. Install the rotor and vanes. Make sure that the squared edge on each vane points toward the center of the rotor.

11. Install the top plate with the pin holes down. Make sure that the locating pins are engaged in the pin holes, not the pockets.

    Make sure that the top plate is flush with the cam, and that the marks made during disassembly are aligned.

NOTE: The backup O-ring will fit tighter on the top plate after loosely wrapping (no twisting) it around two fingers, then allowing it to unwrap.

12. Install the backup O-ring on the top plate. Seat the O-ring at the bottom of the groove.

13. Install a new O-ring (without allowing it to roll) on the top plate. Seat the O-ring at the top of the groove.

14. Grease both the O-ring and the backup O-ring.

CAUTION

The housing may have sharp edges. Use care to not cut your finger when applying grease to the housing.

15. Grease the sealing areas of the housing. See **Fig. 9**.

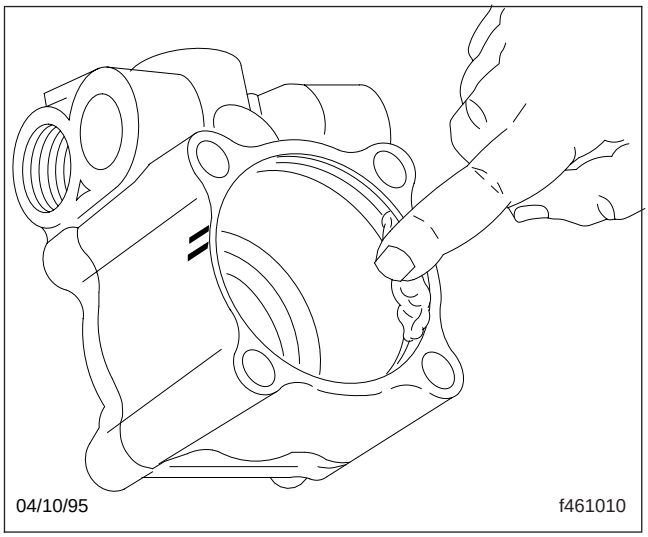

Fig. 9, Grease the Sealing Areas

16. Place the spring on the top plate.

Steering Pump Disassembly, Inspection, and Assembly

17. Place the housing over the cover assembly. Make sure that the marks made during disassembly are aligned.

CAUTION

Evenly thread the capscrews into the cover. If not evenly threaded into the cover, damage could occur to the seals, top plate, or housing.

18. Install the capscrews and washers. Evenly thread the capscrews into the cover. Alternately tighten the capscrews 30 lbf·ft (41 N·m).
19. Screw the relief valve seat assembly into the control valve spool assembly. Tighten the assembly 87 lbf·in (982 N·cm).

NOTE: Placing the spool assembly in a collet will assist the tightening procedure.

20. Insert the valve spool assembly (screen end last) into the housing. Make sure that the spool slides freely in the housing.
21. Install the spring in the housing.
22. Install a new O-ring on the end plug.
23. Lightly grease the O-ring and the end plug threads. Install the end plug and tighten 30 lbf·ft (41 N·m).
24. If the Woodruff key was removed during the input shaft replacement, install it on the new input shaft.
25. Turn the pump by hand and make sure that it turns freely.
26. Install the power steering pump on the engine. For instructions, see **Subject 100**.

General Description

A fixed-length drag link assembly (**Fig. 1**) connects the steering gear pitman arm to the axle steering arm. The ball stud and socket assemblies at each end of the drag link prevent binding when the relative angles of the pitman arm and steering arm change, which happens when the vehicle is steered or the front axle moves up or down.

Both ball-stud sockets of a fixed-length drag link assembly are an integral part of the drag link; they cannot be moved to change its length. See **Fig. 1.** The ball studs and sockets are a dual-seat design.

Drag Link Removal and Installation

Removal

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service work will be done. *Do not move the tires from the straight-ahead position during removal or at any time while the drag link is removed.*
2. Apply the parking brakes and chock the rear tires.
3. Tilt the hood or cab. For cab tilting instructions, see **Group 60** in this manual.
4. At both ends of the drag link, remove the cotter pins and castle nuts from the ball studs. See **Fig. 1**.
5. Using a ball stud removal tool, remove the ball studs from the pitman arm and the axle steering arm.
6. Check the ball stud cover for damage. If needed, replace the cover using the instructions in **Subject 120**.

Installation

1. Insert the axle-end ball stud up through the bottom of the axle steering arm, then install the castle nut, finger-tight.
2. Turn the steering wheel as needed to align the hole in the lower end of the pitman arm with the forward ball stud. Insert the ball stud in the pitman arm from the inboard side. Install the castle nut. See **Fig. 1**.
3. Tighten both of the castle nuts:
   - 3/4–16; 90 to 170 lbf·ft (122 to 230 N·m)
   - 7/8–14; 160 to 300 lbf·ft (217 to 407 N·m)

   If needed, continue tightening each nut until a slot on the nut aligns with the hole in the ball stud. *Do not back off the nut to align it with the cotter pin hole.*
4. Install and lock a new cotter pin in each of the ball studs and nuts.

⚠ WARNING

Install and lock new cotter pins in the ball studs and nuts. Failure to do so could result in disengagement of the components, causing loss of steering control, which could result in personal injury and property damage.

5. Check the vehicle maintenance manual to determine if lubrication of the drag link is required. If so, follow the instructions in the maintenance manual.
6. Check the axle stop settings, and adjust them if needed. For instructions, refer to **Group 33** in this manual.
7. Check the settings of the steering gear poppet valves (TRW) or relief valve plungers (Sheppard). Adjust them if needed. For instructions on checking and adjusting, refer to the applicable steering gear section elsewhere in this group.
8. With the front tires straight ahead, and no load on the vehicle, the steering wheel spokes should be within ±10 degrees of center as shown in **Fig. 2**. If not, remove the steering wheel and install it in the correct position.
9. Return the hood or cab to the operating position. For cab lowering instructions, see **Group 60** in this manual.

Testing

WARNING

WARNING: All steering mechanisms are essential to the safe operation of the vehicle. Follow the instructions in this subject exactly. Failure to do so may result in loss of steering, which could cause personal injury or property damage.

Have someone gently turn the steering wheel back and forth; check for looseness between the ball stud end, and both the pitman arm and steering arm. Also check for looseness of the ball stud nut.

If the ball stud *end* is loose, replace the drag link. If the ball stud *nut* is loose, replace the nut and cotter key. Tighten the ball stud nut as follows (see **Table 1**):

Size	Torque lbf·ft (N·m)
3/4–16	90–170 (122–230)
7/8–14	160–300 (217–407)

Table 1, Torque Values

Grasp the drag link near the pitman arm end, push and pull laterally to check for axial looseness in the ball stud end. If there is looseness, replace the drag link. For instructions, refer to **Subject 100.** If there is 1/8-inch (3-mm) looseness or more, do not drive the vehicle until the drag link is replaced.

Grasp the drag link near the steering arm end. Push and pull vertically to check for axial looseness in the ball stud end. If there is looseness, replace the drag link. For instructions, refer to **Subject 100.** If there is 1/8-inch (3-mm) looseness or more, do not drive the vehicle until the drag link is replaced.

Grease the drag link until the old grease is purged.

Replacement

1. Remove the drag link assembly, see **Fig. 1**. For instructions, refer to **Subject 100.**

CAUTION

CAUTION: Use care when removing the ball stud cover with a screwdriver. Damage to the sealing surface of the socket forging could occur.

2. Using a screwdriver, press or tap on the flanged portion of the cover and remove it from the ball stud socket assembly.
3. Using a clean rag, wipe off all grease and dirt from around the ball stud and socket throat.
4. Grease the socket throat and ball stud with a multipurpose chassis grease NLGI Grade 2 (8% 12-hydroxy lithium stearate grease) or NLGI Grade 1 (6% 12-hydroxy lithium stearate grease); Grade 2 is preferred. Using the same grease, fill the new ball stud cover three-quarters full.
5. Position the socket assembly in a large vise, or on a press so that the ball stud is perpendicular to the socket stem.

CAUTION

CAUTION: Do not use a screwdriver, chisel, or punch (or any other sharp-pointed tool) to install the ball stud cover. Using these types of tools could cut and damage the cover.

IMPORTANT: To install the stud cover, use a section of tubing that has an inside diameter as close as possible to the outside diameter of the stud cover. Also, make sure that the inside edge of the tube is chamfered (angled) to avoid cutting the rubber stud cover.

6. Using a section of tubing, press on the new stud cover. The cover is in place when the flanged portion of the cover is seated on the machined section (sealing face) of the socket forging.

CAUTION

CAUTION: Do not apply excessive pressure when pressing on the seal. Too much pressure during installation could deform the cover and result in incorrect sealing.

7. Install the drag link. For instructions, refer to **Subject 100.**

General Description

There are two types of steering drivelines available depending on your vehicle:

On Century Class conventionals, a single steering driveline connects the steering column to the steering gear by means of a telescoping shaft with integral yokes, an upper and a lower end yoke, and a pair of universal joints. See **Fig. 1**.

On Argosy COEs, there are two drivelines. The upper driveline connects to the base of the steering column. The lower driveline connects to the steering gear input shaft. The two drivelines connect to each other just below the cab floor where a bearing (the deck bearing) helps secure them.

Each driveline shaft consists of a tubular upper section, splined on the outside, which mates with an internally splined lower section. The telescoping shaft eases installation and removal of the steering column, steering driveline, and steering gear. It also compensates for changes in distance between the steering column and steering gear, which occur when the relative positions of the frame rails and cab change during vehicle operation, or when a COE cab is tilted.

The upper end yoke is internally serrated to match the external serrations at the end of the steering column shaft; the lower end yoke is internally serrated to match the external serrations on the steering gear input shaft. Each end yoke is secured to its respective shaft by a pinch bolt that engages a notch in the shaft.

The universal joint at each end of each steering driveline allows the transfer of steering motion from the steering column shaft, to the steering driveline, and to the steering gear input shaft, even though the driveline is at an angle to both of the other shafts. Each universal joint cross rides in four needle bearing cups, two carried in the end yoke, and two carried in the steering driveline's integral yoke. The needle bearing cups are held in place in each yoke by snap rings.

Steering Driveline Removal and Installation

Removal

NOTE: It is not necessary to loosen the steering wheel and column assembly to do this procedure.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations will be done.
2. Apply the parking brakes and chock the tires. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Remove the upper boot bushing. See **Fig. 1**.
4. From inside the cab, disconnect the upper end yoke.
   - 4.1 Detach the lower portion of the steering column cover and remove it.
   - 4.2 Remove and discard the pinch bolt and nut from the upper end yoke. Do not reuse the nut or the bolt.

CAUTION

Be careful when disconnecting the steering driveline from the steering column. Excessive force could damage the steering gear input valve attached to the opposite end of the steering shaft.

   - 4.3 Remove the upper end yoke from the steering column shaft.
5. Disconnect the lower end yoke.
   - 5.1 Remove and discard the pinch bolt and nut from the lower end yoke. See **Fig. 2**. Do not reuse the nut or the bolt.
   - 5.2 Remove the yoke from the steering gear input shaft. Do not turn the steering gear input shaft when removing the lower end yoke.

CAUTION

Do not use a torch to break the threads loose when removing the lower end yoke. Heat will damage the seals in the power steering gear.

6. Pull the steering driveline forward through the upper boot and out of the engine compartment. Be careful not to dislodge the upper boot from its seat in the frontwall.

Installation

IMPORTANT: When installing the replacement steering driveline, be sure to connect the inner tube (male) to the steering gear and connect the outer tube (female) to the steering column. See **Fig. 1**.

1. Insert the upper end of the new steering driveline through the upper boot and partially into the cab.

CAUTION

Do not pull the driveline apart. The male and female halves are preoriented so that the pinch bolt slots on each end of the shaft line up with each other. Assembling the driveline with the U-joints incorrectly oriented could cause binding at the U-joints.

2. Install the lower end yoke on the steering gear input shaft. Before installing the new nut, make sure the new 7/16–20 pinch bolt is centered in the steering gear input shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new 7/16–20 nut, and tighten it 55 to 65 lbf·ft (75 to 88 N·m).
3. Apply torque seal, OGP F900WHITE, to the exposed pinch bolt thread and to the nut. See **Fig. 3**.
4. Before attaching the upper end yoke to the steering column, be sure the front tires are straight ahead and the steering gear is centered.
5. Slide the upper end yoke onto the steering column shaft, then install a new 7/16–20 pinch bolt. Before installing the nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new 7/16–20 nut, and tighten it 55 to 65 lbf·ft (75 to 88 N·m).
6. Apply torque seal, OGP F900WHITE, to the exposed bolt threads and to the nut.
7. Inside the cab, install the steering column cover.
8. Install the upper boot bushing.

   If not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

10. Return the hood or cab to the operating position. For cab tilt instructions, see **Group 60**.

11. Leave the parking brakes applied and the chocks at the rear tires.

operation, possibly causing personal injury and property damage.

12. Start the vehicle and turn the steering wheel from side to side to check for hard steering or binding. If there is difficulty, check the assembly and installation of the driveline parts. If the cause is not the driveline, refer to the applicable steering gear section in this group.
13. Remove the chocks from the tires.

Replacement

1. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the place where service operation is to be done. Shut down the engine, apply the parking brakes, chock the tires, and open the hood.
2. Disconnect the lower end yoke.
   - 2.1 Remove the pinch bolt nut and the pinch bolt from the lower end yoke. Discard the nut and the bolt.

NOTICE

If the arrow on the driveline inner tube is not aligned with the arrow on the outer tube, the U-joints will not be correctly oriented. Assembling the driveline with the U-joints incorrectly oriented could cause binding at the U-joints.

9. Use clamps to attach the steering driveline boot to the outer and inner tubes.
10. Stroke the driveline several times to ensure that the boot is firmly in place, and that the driveline slides freely.
11. Place the spacer and a new lower boot on the steering driveline. Use a clamp to attach the upper end of the boot to the driveline.
12. Before attaching the lower end yoke to the steering gear input shaft, be sure the front tires are straight ahead, the steering gear is centered, the arrows on the driveline inner tube and the outer tube are aligned, and the driveline slides freely.
13. Install the lower end yoke on the steering gear input shaft. Before installing the pinch bolt nut, make sure the pinch bolt is centered in the steering gear input shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new pinch bolt and a new pinch bolt nut. Tighten the nut 45 to 55 lbf·ft (61 to 75 N·m).

General Description

NOTE: Procedures in this section have been slightly modified from the original component manufacturer's service manual. See the manufacturer's service literature (**www.rhsheppard.com/home.htm**) for additional information.

The Sheppard M100 integral power steering gear provides full-time hydraulic steering. This gear is installed as an option on vehicles with a front axle capacity of up to 14,000 pounds (6350 kg).

Principles of Operation

When the driver turns the steering wheel, the force is transmitted to the steering gear input shaft via the steering driveline. The input shaft is connected to a torsion bar within the steering gear. As the input shaft turns, the twisting force on the torsion bar turns the rotary valve, which causes the fluid pressure to build up at one end of the piston. The fluid pressure buildup forces the piston to move inside the bore of the gear housing. The rack teeth on the piston mesh with the teeth on the sector shaft so that the sector shaft rotates when the piston moves. As the sector shaft turns, it moves the pitman arm. The pitman arm connects to the steering linkage, which turns the wheels. See **Fig. 1**.

Removal

1. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance stopping at the place where the work is to be done. Apply the vehicle parking brakes and chock the tires.

NOTICE

Do not turn the steering wheel or the steering shaft more than a half turn (except for alignment purposes) during the removal and installation procedures. Doing so may damage the clockspring in a vehicle equipped with an air bag.

2. Clean all outside dirt from around the fittings and hose connections.
3. Drain the power steering system. Disconnect all hydraulic lines from the gear, marking the lines for later reference during installation. Seal the lines and the fittings to keep dirt out.
4. Disconnect the pitman arm from the steering gear. See **Fig. 1**. For instructions, see **Subject 160**.
5. Disconnect the steering driveline from the steering gear input shaft.

    5.1 Remove and discard the pinch bolt and nut from the lower end of the steering driveline yoke.

NOTICE

Do not pound the U-joint or input shaft coupling on or off the input shaft. Internal damage to the steering gear can result.

    5.2 Remove the steering driveline yoke from the steering gear input shaft.

⚠ WARNING

The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

6. Remove the fasteners that attach the steering gear to the frame rail.

Installation

1. Align the holes in the steering gear housing with the holes in the frame rail. Place a washer over each bolt and install the three bolts. Install a washer and nut on the end of each bolt and tighten the nuts 388 lbf·ft (526 N·m).
2. Install the pitman arm on the steering gear. For instructions, see **Subject 160**.
3. Connect the steering driveline to the steering gear input shaft.

    3.1 Clean the steering gear input shaft and the inside of the steering driveline yoke.

    3.2 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut to one of the following torque specs:

    - 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
    - 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

    3.3 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut.
4. Connect the hydraulic lines to the gear as marked earlier or as shown in the plumbing diagram in **Specifications 400**. Tighten the nut on each fitting finger tight. Then with a wrench, tighten the nut until there is firm resistance. Tighten the nut 1/6-turn more.
5. Position the steering wheel so that it is within ±10 degrees of center as shown in **Fig. 2**.

NOTICE

Do not turn the steering wheel at this time. Doing so can cause air to enter the system, possibly causing an unexpected loss of power steering assist.

6. Connect the pitman arm to the steering gear. For instructions, see **Subject 160**.
7. Adjust the automatic relief plunger. For instructions, see **Subject 130**.
8. Complete the post-service checks as instructed in **Subject 170**.

Replacement

1. Shut down the engine, apply the parking brakes, and chock the tires.

IMPORTANT: Do not remove the steering gear for this procedure.

2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.

NOTICE

Do not turn the input shaft during repairs. Damage to the steering gear will result.

3. Remove the pinch bolt on the lower end yoke of the steering shaft.

NOTICE

Do not pound the U-joint or input shaft coupling on or off the input shaft. Internal damage to the steering gear can result.

4. Remove the lower yoke from the steering gear input shaft. If necessary, secure the shaft so it will not interfere with your work.

IMPORTANT: Do not pull the slip shaft out of the steering shaft. Installation of the slip shaft requires rephasing.

5. Place a drain pan under the power steering gear. Draining the system is not necessary, but some fluid will be lost.
6. Remove the rubber boot from the input shaft.
7. Remove the capscrews that attach the bearing cap cover to the bearing cap and remove the bearing cap cover.

IMPORTANT: The thrust washer will stick to the bearing cap cover. Install the thrust washer on the bearing cap before proceeding.

8. Place the bearing cap cover on a clean work surface. Pry the salt seal out of the bearing cap cover and discard the seal. See **Fig. 1**.
9. Press the oil seal out of the bearing cap cover cover using a suitable size socket or seal driver. Use of an arbor press is recommended. See **Fig. 2**. Discard the oil seal.

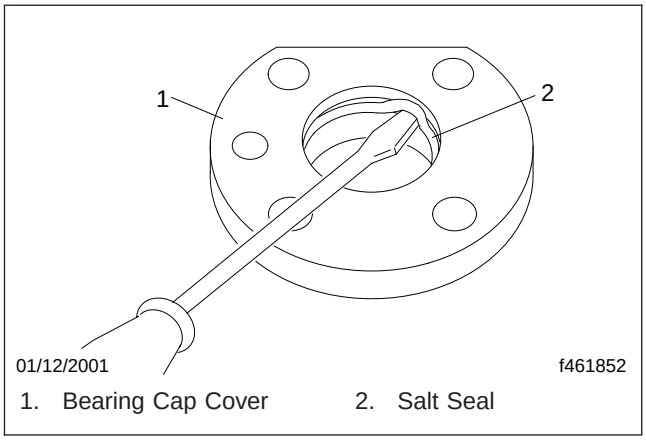

Fig. 1, Salt Seal Removal

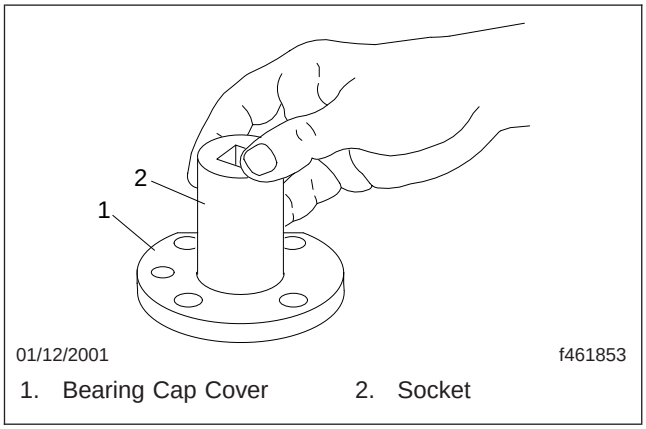

Fig. 2, Oil Seal Removal

10. Remove the O-ring from the bearing cap cover. Discard the O-ring.
11. Clean the bearing cap cover with a suitable solvent.
12. Place the bearing cap cover face down on a clean work surface. With the garter spring visible inside the oil seal, install the oil seal in the bearing cap cover using a suitable size driver and an arbor press. Coat the outside diameter of the oil seal with clean chassis lube. The garter spring will be visible when the oil seal is properly installed.
13. Install a new O-ring in the bearing cap cover. Make sure the oil seal is properly installed before proceeding.

Input Shaft Seal Replacement

14. With the lip of the salt seal facing out, press a new salt seal into the bearing cap cover until it is flush with the face of the cover. See **Fig. 3**.

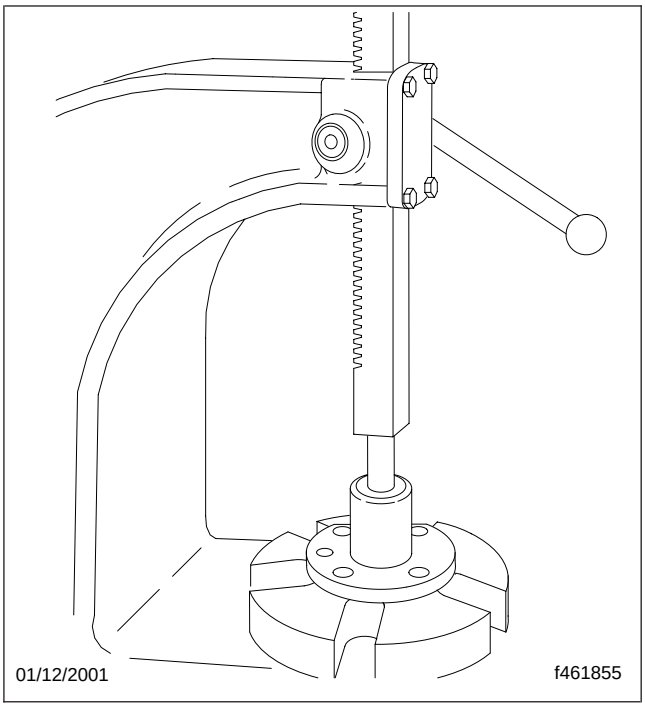

Fig. 3, Salt Seal Installation

15. Tape the input shaft splines before installing the bearing cap cover, to prevent seal damage.
16. Using capscrews, attach the bearing cap cover to the bearing cap and torque the capscrews 53 to 64 lbf·ft (72 to 87 N·m).

NOTE: Two rubber boots are included in the replacement kit. Choose the rubber boot that will provide the tightest fit on the input shaft.

17. Install the rubber boot on the input shaft. Make sure the boot is below the spline and contacts the bearing cap cover when installed.
18. Remove the tape from the input shaft splines.
19. Connect the steering driveline to the steering gear input shaft, as follows.

    19.1 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut to one of the following torque specs.

    - 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
    - 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

    19.2 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

20. If needed, fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
21. Start the engine and check for leaks.
22. Remove the drain pan and return the hood or cab to the operating position. For cab tilt instructions, see **Group 60**.

Replacement

1. Shut down the engine, apply the parking brakes, and chock the tires.

NOTE: Removal of the power steering gear is not necessary to perform this procedure. Partial disassembly of the steering gear is required to replace the sector shaft seals. Be sure to time the sector shaft after replacement.

2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.

NOTICE

Do not turn the steering wheel or the steering shaft during this procedure. Turning either the steering wheel or steering shaft will result in steering gear damage.

3. Disconnect the pitman arm from the steering gear. For instructions, see **Subject 160**.
4. Remove and discard the rubber boot on the sector shaft.
5. If the snap ring cover is equipped with a protective cap, pry the cap out of the bore.

IMPORTANT: When working with snap ring covers, you will need to remove the factory installed silicone protectant from the snap ring and carefully clean the cover area before disassembly.

6. Remove the snap ring on the sector shaft cover.
7. Clean the shaft before removing the sector shaft cover.

NOTE: A slide hammer may be used to remove the sector shaft. It may also be necessary to start the engine to force the sector shaft cover out of the housing.

8. Remove the sector shaft cover and sector shaft from the housing. Separate the cover from the sector shaft. Discard the sector shaft.

NOTE: It may be necessary to remove the dust cover from the frame side of the sector shaft. Use a gasket scraper or screwdriver to remove the frame side dust cover.

9. Pry the excluder seal from the sector shaft cover. Using a seal pick, remove the oil seal from the sector shaft cover and the steering gear housing. Remove the O-ring from the cover. Discard all seals.

NOTE: Lightly coat the new seals with clean motor oil to facilitate installation of the sector shaft.

IMPORTANT: The sector shaft oil seal has a lip. Do not press on the lip of the oil seal when installing. Press only on the body of the seal. It will be necessary to bend the oil seal when installing. Once the seal is installed, you may have to work the seal into place with your fingers or a blunt seal pick to properly seat the seal.

10. Install a new oil seal in the steering gear housing and the sector shaft cover. When properly fitted, the oil seal will ride between the bearing and the cover. The black lip of the seal must face the inside of the steering gear and the blue side must face the outside of the steering gear.
11. Install a new sector shaft in the housing. Make sure that the timing mark on the sector shaft is placed between the two timing marks on the piston rack. See **Fig. 1**. It may be necessary to tap on the sector shaft to properly seat it into the housing.

when installing. Snap ring covers must be flush or below the snap ring groove to be properly installed.

⚠ WARNING

When installing a snap-ring-style cover, the cover must be flush or below the groove in the housing. Improper installation could result in separation of the cover, possibly resulting in personal injury.

13. Apply a coat of clean chassis lube in the lip of the excluder seal. With the lip of the excluder seal facing out and using an appropriate size seal driver, install the excluder seal in the cover. See **Fig. 2**. Apply a bead of grease over the excluder seal and slide the rubber boot over the sector shaft.

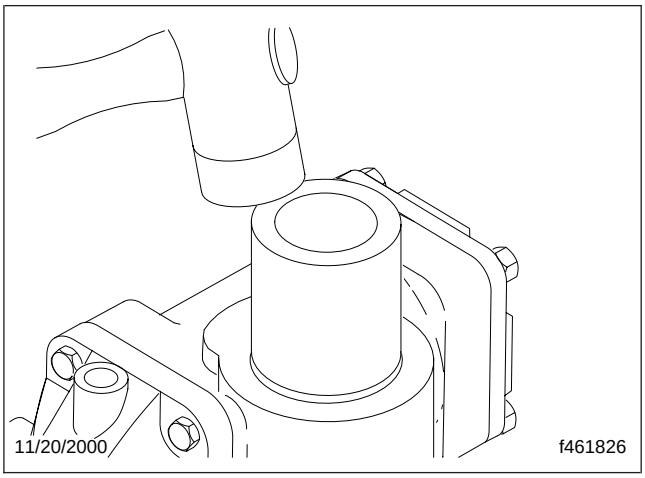

Fig. 2, Installing the Excluder Seal

14. Install the pitman arm. For instructions, see **Subject 160**.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

15. If needed, fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
16. Return the hood or cab to the operating position. For cab tilt instructions, see **Group 60**.

Adjustment

The only circumstances in which the automatic relief plungers require adjusting are when the tire size is changed, the wheel cut is reduced, or a replacement steering gear is installed. Do not adjust the automatic relief plungers under any other circumstances.

1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the housing. See **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps on the plunger bosses.

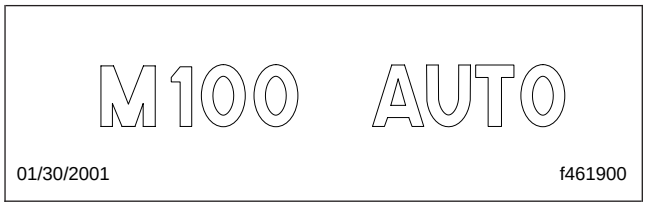

Fig. 1, Automatic Relief Plunger Identifier

4. Remove the plastic caps from both plunger bosses.

NOTICE

Make sure there are no sharp edges on the punch that could damage the bore. Take care when using the punch to ensure that the relief plunger bore is not damaged. If the relief plunger bore is damaged, a leak may occur.

5. Using a 1/4-inch punch and ball peen hammer, carefully drive the relief plunger in until it bottoms in the bore. Repeat this procedure for the other relief plunger.
6. Replace the plastic caps.
7. Set the automatic relief plungers. For instructions, see **Subject 140**.

Setting the Automatic Relief Plunger

The only circumstances in which the automatic relief plungers need to be set are when the tire size is changed, the wheel cut is extended, or a replacement steering gear is installed. Do not set the automatic relief plungers under any other circumstances.

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the housing. See **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps on the plunger bosses.

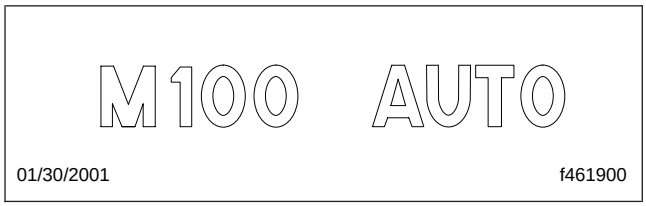

Fig. 1, Automatic Relief Plunger Identifier

4. Using a jack, raise the vehicle until the front wheels are off the ground.

NOTE: Check that the axle stops are set correctly before setting the relief plungers.

5. Start the engine and turn the tires to a full-lock position in both directions. With the tires off the ground, the automatic relief plungers will be set to the correct position when the spindle contacts the axle stop.

NOTE: As the tires reach the end of travel, you will feel the piston contact the relief plunger. Continue turning the tires until the spindle reaches the axle stop bolt.

6. Return the tires to the straight-ahead position.
7. Lower the vehicle until the tires contact the ground. Remove the jack
8. Shut off the engine.
9. Return the hood or cab to the operating position. For cab tilt instructions, see **Group 60**.

There is a relief plunger in the cylinder head and one in the bearing cap. Follow the appropriate set of procedures for the relief plunger you are repairing.

Cylinder Head Automatic Relief Plunger Repair

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the housing. See **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps on the plunger bosses.

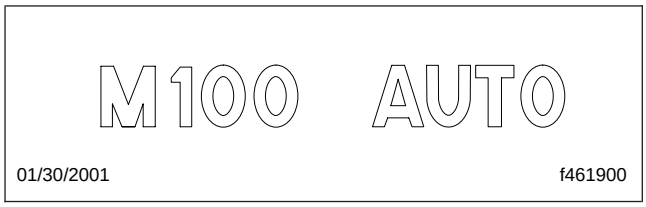

Fig. 1, Automatic Relief Plunger Identifier

4. Place a drain pan under the steering gear.
5. Mark the cylinder head and the steering gear housing for later reference during installation. Remove the capscrews that attach the cylinder head to the housing. Remove the cylinder head.

NOTICE

When driving the relief plunger assembly, do not allow the 1/4-inch punch to contact the bore, and do not hit the plunger with excessive force. Failure to follow these directions could result in damage to the steering gear or relief plunger assembly.

6. Place the cylinder head in a vise and remove the plastic cap from the plunger boss.
7. Using a 1/4-inch punch and hammer, carefully drive the relief plunger assembly in until it bottoms in the bore. The spring pin, flange, and plunger body should be accessible for repair at this point.

NOTICE

Do not allow the screwdriver bit to slip off the plunger body. Damage to the bore could result.

NOTE: The relief plunger flange is held in place with patch lock and the threads are staked at the factory. It will require approximately 15 to 20 lbf·in (150 to 205 N·cm) to remove the flange.

8. Carefully insert a screwdriver bit into the plunger bore to hold the slotted head of the relief plunger body in place. Using an open-end wrench to hold the flange in place, carefully turn the flange to remove the flange from the plunger body. See **Fig. 2**. Discard the flange.

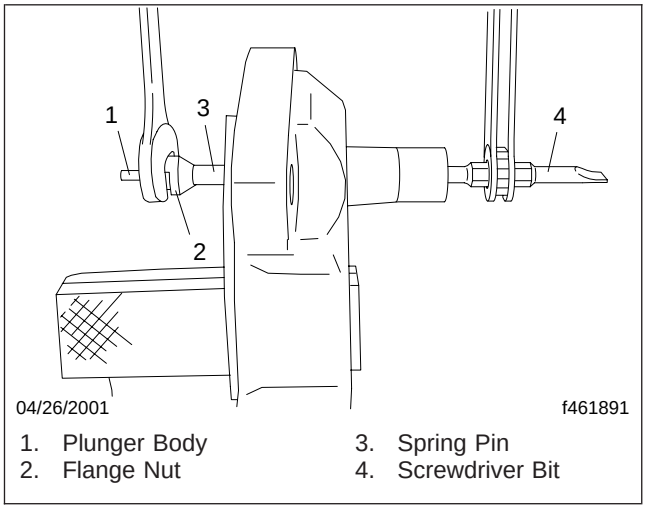

Fig. 2, Flange Removal

9. Remove the plunger body from the spring pin and discard the plunger body. It may be necessary to tap the plunger body to remove it from the spring pin. Use of a 1/8-inch pin punch is recommended.

IMPORTANT: Check the plunger bore for nicks or gouges before installing the plunger assembly. Be careful not to introduce dirt or contaminants in the plunger bore when reassembling.

NOTE: The plunger body has patch lock on the threads. It will require approximately 15 to 20 lbf·in (150 to 205 N·cm) to overcome the patch lock.

10. Coat the O-ring on the new plunger assembly with a light coat of grease. Install the plunger body through the spring pin. See **Fig. 3**.

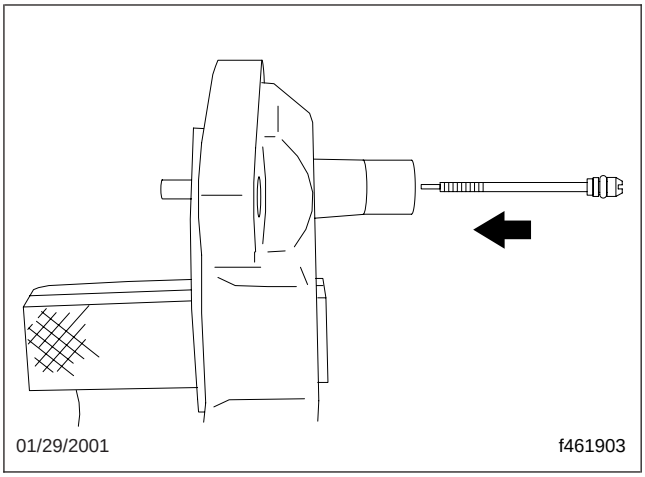

Fig. 3, Plunger Body Installation

WARNING

The flange must contact the spring pin. If it does not, a leak or steering gear damage may result. This could cause steering failure, possibly resulting in personal injury or property damage.

11. Use a screwdriver bit and ratchet to hold the plunger body in place. Using an open-end wrench, install the flange on the plunger body until the flange contacts the spring pin.

WARNING

Use extreme caution when staking the threads of the plunger body. Hitting the threads too hard could bend the plunger, which could cause steering failure, possibly resulting in personal injury or property damage.

12. With the flange against the spring pin, use a center punch to stake the threads of the plunger body. See **Fig. 4**. Be careful not to bend the plunger when staking the threads.
13. Align the marks on the cylinder head with the marks on the steering gear housing and install the cylinder head on the housing using the cylinder head capscrews. Tighten the capscrews 114 to 124 lbf·ft (154 to 168 N·m).
14. Install the plastic cap on the plunger boss.

WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

15. If needed, fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
16. Start the engine. Check the fluid level in the power steering reservoir and add more fluid if necessary. Check for leaks.
17. Set the automatic relief plunger. For instructions, see **Subject 140**.
18. Remove the drain pan and return the hood or cab to the operating position. For cab tilt instructions, see **Group 60**.

Bearing Cap Automatic Relief Plunger Repair

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the housing. See **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps on the plunger boss.
4. Place a drain pan under the steering gear.
5. Mark the bearing cap and steering gear housing for reassembly.
6. Disconnect the steering driveline from the steering gear input shaft. For instructions, see **Subject 100**.
7. Remove the plastic cap from the plunger boss.

NOTICE

When driving the relief plunger assembly, do not allow the 1/4-inch punch to contact the bore, and do not hit the plunger with excessive force. Failure to follow these directions could result in damage to the steering gear or relief plunger assembly.

8. Using a 1/4-inch punch and hammer, carefully drive the relief plunger assembly in until it bottoms in the bore.
9. Remove the four capscrews that attach the bearing cap to the steering gear housing.

NOTICE

Do not force the input shaft when turning it out of the housing. The shaft could bind and steering damage could result.

10. Separate the bearing cap assembly from the housing by turning the input shaft out of the housing. Turn the shaft until it stops.

NOTICE

Do not allow the screwdriver bit to slip off the plunger body. Damage to the bore could result.

NOTE: The relief plunger flange is held in place with patch lock and the threads are staked at the factory. It will require approximately 15 to 20 lbf·in (150 to 205 N·cm) to remove the flange.

11. Carefully insert a screwdriver bit into the plunger bore to hold the slotted head of the relief plunger body in place. Using an open-end wrench to hold the flange in place, carefully turn the flange to remove the flange from the plunger body. See **Fig. 5**. Discard the flange.

Pitman Arm Removal and Installation

Removal

NOTE: This procedure is for removing the pitman arm from the steering gear. If replacement of the pitman is required, the pitman arm must also be removed from the drag link.

NOTE: The pitman arm is easiest to remove while the steering gear is installed on the vehicle.

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.

⚠ DANGER

Do not use a hammer or apply heat to the pitman arm to remove it. Doing so could damage the sector shaft, the pitman arm, or the seals, and possibly lead to loss of vehicle control resulting in death or serious personal injury.

IMPORTANT: The pitman arm has alignment tabs, while the retainer has restraining tabs. Do not bend the aligning tabs out of the pitman arm.

3. Using a punch, bend the retaining tabs out of the pitman arm retainer.
4. Lubricate the face of the retainer with clean chassis lube.

IMPORTANT: Failure to lubricate the face of the retainer will cause difficulty in removing the pitman arm.

5. Slide the pitman arm puller over the pitman arm. Align the hole in the puller with the Allen socket in the retainer.
6. Insert the Allen drive socket through the puller and into the retainer socket. Use an impact wrench to back off the retainer. The retainer will act as a jack screw to disconnect the pitman arm from the steering gear.

Installation

⚠ WARNING

If the pitman arm is not installed to the proper specifications, it could come loose, causing an accident that could result in death or severe personal injury.

1. Align the timing marks on the pitman arm with the timing marks on the sector shaft and install the pitman arm on the sector shaft. The timing marks will appear like those in **Fig. 1** or **Fig. 2**.

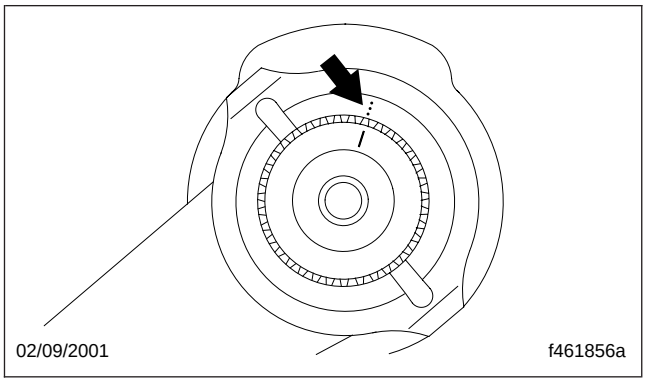

Fig. 1, Timing Mark Alignment

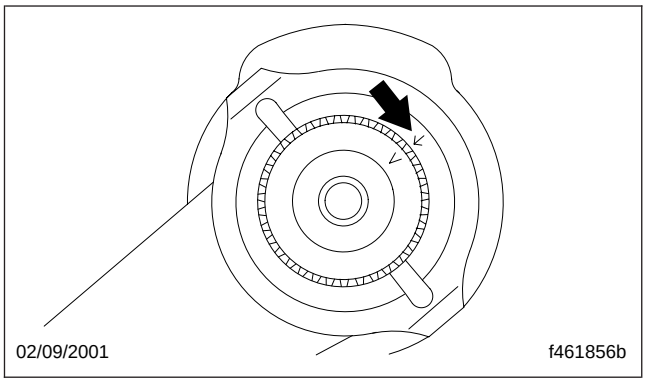

Fig. 2, Timing Mark Alignment

2. Install the pitman arm retainer on the sector shaft. Be sure to align the tabs in the notches of the pitman arm. Coat the threads of the retainer with antiseize compound. A coating of antiseize should be applied to both sides of the friction washer if a new retainer is being used.
3. Tighten the retainer 350 lbf·ft (475 N·m).

Pitman Arm Removal and Installation

WARNING

Do not back off the torque value to align the tabs. If the pitman arm is not installed to the proper specifications, it could come loose, causing an accident that could result in death or severe personal injury.

4. Continue tightening the retainer past the specified value until two of the notches in the retainer align with the tabs of the washer.

WARNING

Once the retainer is tightened to specifications and locked in place, do not retighten the retainer. Constant tightening of the retainer may cause the pitman arm to come loose, causing an accident that could result in death or severe personal injury.

5. Using a punch and hammer, bend the retaining tabs of the washer in to the notches on the retainer. See **Fig. 3**. Apply torque seal, OGP F900WHITE, to the tabs.

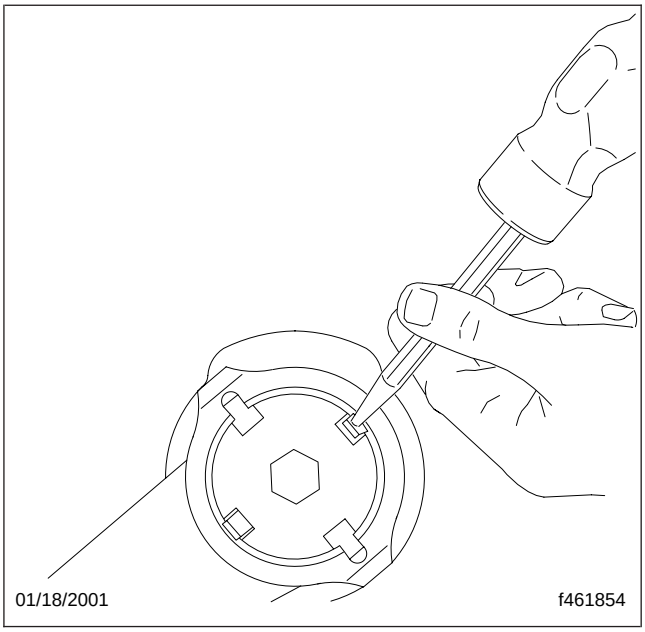

Fig. 3, Bending the Restraining Tabs

6. Reset the automatic relief plungers. For instructions, see **Subject 140**.

7. Lower the hood or tilt the cab. For cab tilt instructions, see **Group 60**.

Post-Service Checks

After power steering components have been worked on and before the vehicle is placed into service, the following items must be checked.

⚠ WARNING

Failure to check the following items could result in damage to the power steering system. This could cause a loss of hydraulic assist, which could cause personal injury or property damage.

1. Operate the engine at low idle while turning the steering wheel through several full-left and full-right turns. With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level (signs that air is trapped in the system).

   If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as necessary. Bleed the air from the system.
2. With the engine turned off and warm, check the power steering reservoir fluid level. The power steering fluid level should be between the MIN COLD mark and the middle mark just above it. If needed, add fluid that meets Dexron III or TES-389 specifications.
3. At full-left and full-right wheel cuts, be sure the axle stops on the rear side of the spindle are set so there is at least 1/2-inch (13-mm) of clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be at least 3/4-inch (19-mm). If clearance is less, reset the axle stops.
4. Check that the relief plungers are set correctly. If needed, adjust them. For instructions on adjusting the automatic relief plungers, see **Subject 130**.
5. If there are still problems with the power steering system, go to **Section 46.15** and perform the troubleshooting procedures. Otherwise, go to the next step.
6. Test drive the vehicle or take a ride with the driver. Check the steering wheel spoke position.

   If during straight-ahead driving on a level road, the steering wheel spokes are not centered as shown in **Fig. 1**, remove the steering wheel and reposition it.

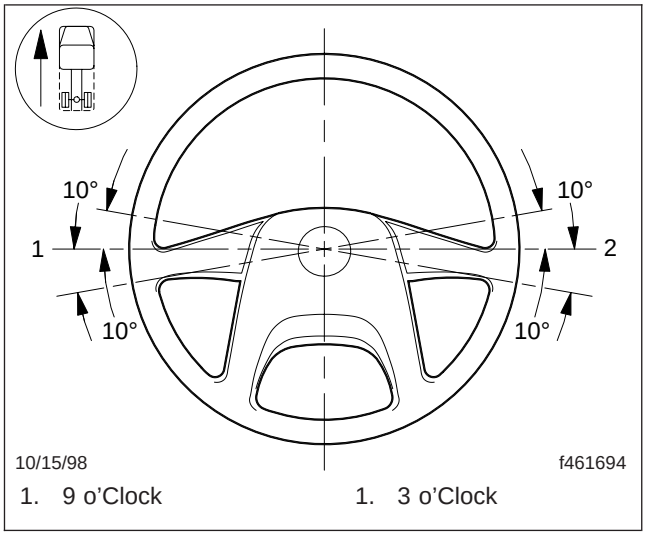

Fig. 1, Steering Wheel Centered

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

Sheppard M100 power steering gears use ATF fluid that meets Dexron III or TES-389 specifications.

NOTE: Remove the steering wheel only if the steering wheel or steering column is being replaced. If the wheel or column is being removed to allow servicing of the dash, remove the steering wheel and column as an assembly. For instructions, refer to **Subject 110**.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance stopping at the spot where service operations will be performed.

   Apply the parking brakes and chock the tires.

2. Using a small screwdriver, pry under the outermost ring of the steering wheel horn button cover. Lift the horn button cover from the steering wheel hub, then disconnect the wire terminals at the horn button. See **Fig. 1**.

IMPORTANT: The steering wheel has an alignment mark within the hub. After removing the wheel nut, mark the column shaft at the wheel alignment mark to ensure proper installation of the wheel.

3. Without turning the steering wheel, remove the wheel nut (**Fig. 1**). Using a steering wheel puller, remove the steering wheel from the shaft.

IMPORTANT: Be careful when you are removing the steering wheel, or you could damage the horn wires. A steel block measuring 1-5/8 x 5/8 x 1/4 inch (41 x 16 x 6.4 mm) can be used with the puller to protect the wires during steering wheel removal.

Removal of Steering Wheel With an Air Bag

IMPORTANT: To determine which type of supplemental protection system is installed in the vehicle, look at the module under the driver's seat. The air bag/SPACE system and the air bag only system installed prior to May 12, 2000 have a SPACE module. If the vehicle has a SPACE system, gas cylinders are also located under the driver's seat. See **Fig. 2**. The air bag only system that became available on May 12, 2000 has an air bag sensor module located under the driver's seat. See **Fig. 3**.

NOTE: Remove the steering wheel only if the steering wheel or steering column is being replaced. If the wheel or column is being removed to allow servicing of the dash, remove the steering wheel and column as an assembly. For instructions, refer to **Subject 110**.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance stopping at the spot where service operations will be performed.

   Apply the parking brakes and chock the tires.

CAUTION

Do not turn the steering wheel or the steering shaft at any time during this procedure. Doing so may damage the clockspring.

2. Disconnect the batteries by removing the negative terminal first, then the positive terminal.

Steering Wheel Removal and Installation

WARNING

Wait two minutes after disconnecting the batteries to allow the internal components to discharge. Failure to allow the components to discharge could cause the air bag to deploy, resulting in severe bodily injury or death.

Consider undeployed air bags to be dangerous and capable of deploying at any time. Follow the safety guidelines and handling instructions in Section 46.09, Subject 110. Failure to observe safety and handling information could cause the unintentional deployment of the air bag, which could result in severe injury or death.

3. Disconnect the air bag circuit from the air bag sensor module or the SPACE module.
   - 3.1 On vehicles with an air bag/SPACE system, disconnect the DSS connector at the back of the SPACE module. See **Fig. 2**.
   - 3.2 On vehicles with an air bag only system installed from May 12, 2000, disconnect the AS2 connector under the B pillar cover. See **Fig. 3**.
4. Pull the lower steering column cover off of the dash.
5. Remove the fastener cover plugs from the steering column cover.
6. Remove the T25 Torx®-head fasteners and the steering column cover. See **Fig. 4**.
7. Remove the T30 Torx-head fasteners underneath the steering wheel. See **Fig. 5**.
8. Carefully lift the air bag module from the steering wheel and disconnect the air bag connector (and the horn switch connector if equipped) from the air bag. See **Fig. 6**.
9. Remove the air bag module.
10. Without turning the steering wheel, remove the wheel nut (**Fig. 6**). Using a steering wheel puller, remove the wheel from the shaft.
11. Tape the upper and lower portions of the clockspring (**Fig. 7**) together to prevent the clockspring from turning.
12. Inspect the clockspring and clockspring connector. Replace the clockspring if there is any melting or damage. For clockspring replacement instructions, see **Section 46.09**, Subject 120.

Installation of Steering Wheel Without an Air Bag

NOTE: Before installing the steering wheel, make sure the front tires are pointed straight ahead, and the steering gear is centered.

1. With the marks on the column and steering wheel aligned, place the steering wheel on the steering column. Make sure that the steering wheel is within ±10 degrees of center as shown in **Fig. 8**.

   Insert the horn ground wires (from the center of the steering column shaft) through the center of the wheel nut. Install the wheel nut and tighten 55 to 65 lbf·ft (75 to 88 N·m).
2. Connect the ground wire terminals to the horn button. With the steering wheel in the straight-ahead position, push the horn button cover into place on the steering wheel hub.
3. Remove the chocks from the tires.

Installation of Steering Wheel With an Air Bag

NOTE: Before installing the steering wheel, make sure the front tires are pointed straight ahead and the steering gear is centered.

1. Pull the air bag connector from the steering column through the cutout above the center hole on the steering wheel. See **Fig. 7**.
2. Remove the tape from the clockspring.
3. Align the tab on the clockspring with the cutout below the center hole on the steering wheel, and place the steering wheel on the steering column. See **Fig. 7**. Make sure that the steering wheel is within ±10 degrees of center as shown in **Fig. 8**. Install the wheel nut and tighten 55 to 65 lbf·ft (75 to 88 N·m).

Removal

NOTE: If the steering wheel is not being replaced, see **Subject 100** for steering wheel removal and installation instructions.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance stopping at the spot where service operations will be performed.

   Apply the parking brakes and chock the tires.

⚠ CAUTION

Do not turn the steering wheel or the steering shaft at any time during this procedure. Doing so may damage the clockspring.

2. Depress the column adjustment knob and tilt the column until it is as far away from the dash as possible.
3. If the steering wheel is equipped with an air bag, disconnect the batteries and wait two minutes before proceeding.

⚠ WARNING

Wait two minutes after disconnecting the batteries to allow the internal components to discharge. Failure to allow the components to discharge could cause the air bag to deploy, resulting in severe bodily injury or death.

Undeployed air bags can be dangerous and are capable of deploying at any time. Follow the safety guidelines and handling instructions in Section 46.09, Subject 110. Failure to observe safety and handling information could cause the unintentional deployment of the air bag, which could result in severe injury or death.

The air bag/SPACE system and the air bag only system installed prior to May 12, 2000 have a SPACE module. If the vehicle has a SPACE system, gas cylinders are also located under the driver's seat. See **Fig. 1**. The air bag only system that became available on May 12, 2000 has an air bag sensor module located under the driver's seat. See **Fig. 2**.

4. If the steering wheel is equipped with an air bag, deactivate the air bag by disconnecting the DSS connector on air bag/SPACE systems installed prior to May 12, 2000, or by disconnecting the AS2 connector on air bag only systems installed from May 12, 2000. See **Fig. 1** and **Fig. 2**.
5. Using a T25 Torx®-driver, remove the lower steering column cover seal. See **Fig. 3**.

   Remove the steering column cover panels from the front and back of the column.
6. Remove and discard the pinch bolt and nut from the upper end yoke.
7. Remove the two screws that attach the trailer brake control valve mounting bracket to the steering column. Remove the control valve (and the horn ground wire) from the steering column.
8. Remove the two screws that attach the turn-signal switch mounting bracket. Remove the turn-signal switch assembly from the steering column. Disconnect the wiring connector from the turn-signal switch.
9. Disconnect the air line that is attached to the foot-operated release valve.
10. Remove the upper end yoke from the steering column shaft.
11. Remove the nuts and washers that attach the steering column to the mounting bracket.

    Remove the steering column assembly from the vehicle. See **Fig. 4**.

Installation

1. Position the steering column on the steering column mounting bracket. See **Fig. 4**. Tighten the nuts 26 lbf·ft (35 N·m).
2. Connect the air line to the foot-operated release valve.
3. Clean the end of the column shaft with a clean dry cloth.
4. Slide the upper end yoke onto the column shaft, then install a new pinch bolt. Before installing the nut, make sure the pinch bolt is centered in the

- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

5. Apply torque seal, OGP F900WHITE, to the exposed bolt threads and to the nut.
6. Place the turn-signal switch assembly on the steering column. If the turn signal assembly is on the left side of the steering column, align the switch so that it is pointed directly to the left. If the turn signal assembly is on the right side of the steering column, align the turn-signal switch so that it is pointed directly to the right. Install and firmly tighten the mounting screws. 7. Position the trailer brake control valve mounting bracket on the steering column. Insert the horn ground wire through the bracket. Install and firmly tighten the mounting screws.
8. Install the lower steering column cover seal. Position the steering column cover panels on the front and back of the column. Both panels have fittings that should snap into the column. Install two fasteners and attach the two panels together. See **Fig. 3**.
9. If the steering wheel is equipped with an air bag, reactivate the air bag by connecting the DSS connector on air bag/SPACE systems built prior to May 12, 2000, or by connecting the AS2 connector on air bag only systems built from May 12, 2000.

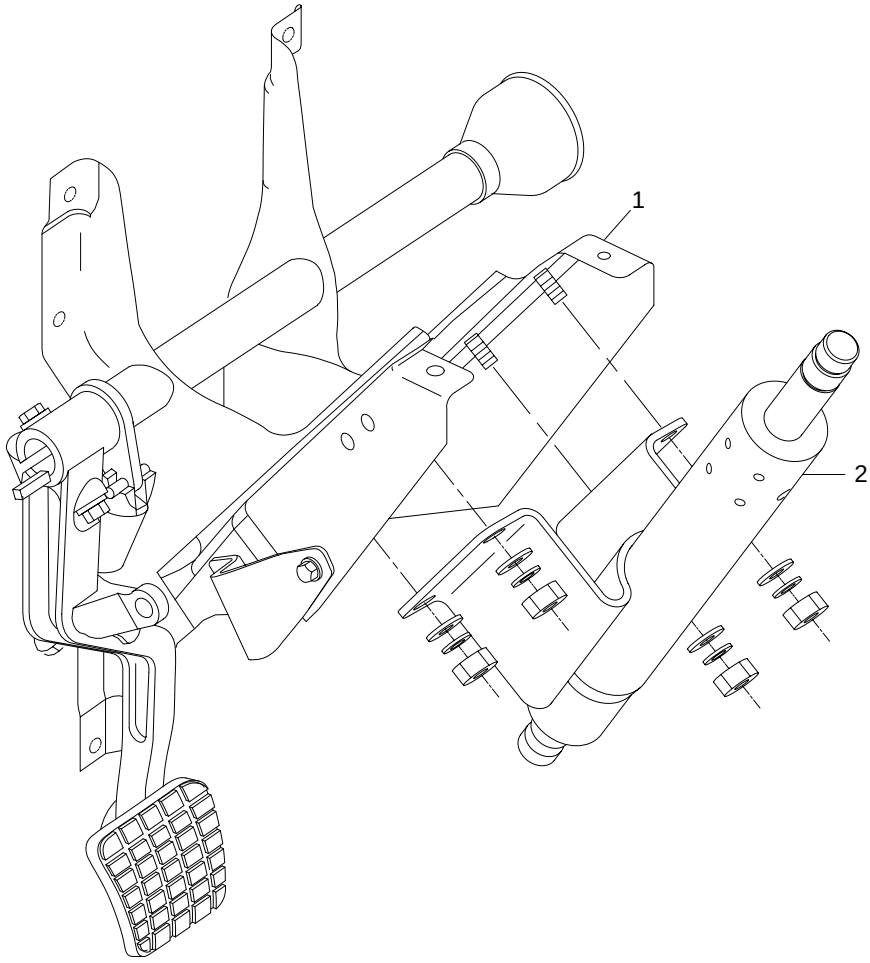
General Information



1. Steering Column Bracket Assembly
2. Fixed Steering Column

Fig. 1, Steering Column Assembly Installation

The steering wheel is cushion-rimmed, with a button for the electric horn mounted in the center of the wheel hub.

A turn signal switch attaches to the steering column just below the steering wheel. See **Fig. 1**. If the vehicle is equipped with a trailer brake control valve, it is attached to the right side of the steering column on left-hand-drive (LH DR) vehicles, and on the left side of the steering column on right-hand-drive (RH DR) vehicles.

Major parts of the steering column assembly are a jacket (tube), bearing assemblies (staked in place in the top and bottom of the jacket), a steering column shaft, and wiring and contact assemblies for the electric horn. At the upper end of the steering column shaft are threads to accept a wheel nut, and straight external serrations to match the internal serrations of the steering wheel hub. The lower end has straight external serrations to match the internal serrations of the steering driveline upper end-yoke. The steering column assembly is attached to the dash steering

column bracket with four fasteners that are hidden by the steering column cover. A lower steering column cover extends from the under-dash cover to the floor. The steering column assembly is not repairable; if any steering column parts are damaged or badly worn, the steering column assembly must be replaced.

Removal of Steering Wheel

NOTE: Remove the steering wheel only if the steering wheel or steering column is being replaced. If the wheel or column is being removed to allow servicing of the dash, remove the steering wheel and column as an assembly. For instructions, refer to **Subject 110**.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance stopping at the spot where service operations will be performed. Do not turn the steering wheel at any time during this procedure.

   Apply the parking brakes and chock the tires.

2. Using a small screwdriver, pry under the outermost ring of the steering wheel horn button cover. Lift the horn button cover from the steering wheel hub, then disconnect the wire terminals at the horn button. See **Fig. 1**.

Fig. 1, Steering Wheel Removal

IMPORTANT: The steering wheel has an alignment mark within the hub. After removing the wheel nut, mark the column shaft at the wheel alignment mark to ensure proper installation of the wheel.

3. Without turning the steering wheel, remove the wheel nut (**Fig. 1**). Using a steering wheel puller, remove the steering wheel from the shaft.

IMPORTANT: Be careful when you are removing the steering wheel, or you could damage the horn wires. A steel block measuring 1-5/8 x 5/8 x 1/4 inch (41 x 16 x 6.4 mm) can be used with the puller to protect the wires during steering wheel removal.

Installation of Steering Wheel

NOTE: Before installing the steering wheel, make sure the front tires are pointed straight ahead and the steering gear is centered.

1. With the marks on the column and steering wheel aligned, place the steering wheel on the steering column. Make sure that the steering wheel is within ±10 degrees of center as shown in **Fig. 2**.

   Insert the horn ground wires (from the center of the steering column shaft) through the center of the wheel nut. Install the wheel nut and tighten 55 to 65 lbf·ft (75 to 88 N·m).

Steering Column Assembly Removal and Installation

Removal

1. Park the vehicle on a level surface. Make sure the front tires are pointing forward. Apply the parking brakes. Shut down the engine. Chock the tires.

IMPORTANT: Once the vehicle is parked, do not turn the steering wheel at any time during the following procedures.

2. Disconnect the batteries.
3. Remove the lower steering column cover seal. See **Fig. 1**.

4. Remove the steering column cover panels from the front and back of the column.
5. Remove and discard the pinch bolt and nut from the upper end yoke.
6. Remove the two screws that attach the trailer brake control valve mounting bracket to the steering column. Remove the control valve (and the horn ground wire) from the steering column.
7. Remove the two screws that attach the turn signal switch mounting bracket. Remove the turn signal switch mounting assembly from the steering column. Disconnect the wiring connector from the turn signal switch.
8. Remove the upper end yoke from the steering column shaft.
9. Remove the nuts and washers that attach the steering column to the mounting bracket.
10. Remove the steering column assembly from the vehicle. See **Fig. 2**.

Installation

1. Position the steering column on the steering column mounting bracket. See **Fig. 2**. Tighten the nuts 26 lbf·ft (35 N·m).
2. Wipe the end of the column shaft with a clean, dry cloth.
3. Slide the upper end yoke on the column shaft. Install a new pinch bolt. Before installing the nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new nut. Tighten the nut to one of the following torque specs:
   - 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
   - 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut
4. Apply torque seal, OGP F900WHITE, to the exposed pinch bolt threads and to the nut.
5. Place the turn signal switch mounting assembly on the steering column. On left-hand-drive (LH DR) vehicles, align the switch so that it is pointed directly to the left, toward the driver's door. On right-hand-drive (RH DR) vehicles, align the switch so that it is pointed directly to the right, toward the driver's door. Install and firmly tighten the mounting screws. Connect the turn signal harness connector.
6. Insert the horn ground wire through the bracket. Position the trailer brake control valve mounting bracket on the steering column. Install and firmly tighten the mounting screws.
7. Install the lower steering column cover seal.
8. Position the steering column cover panels on the front and back of the column. Both panels have

9. Check the position of the steering wheel when the front tires are pointing forward. The steering wheel should be within ±10 degrees of center as shown in **Fig. 3**.

   If necessary, remove the steering wheel and reposition it. See **Subject 100** for instructions.

10. Connect the batteries.

General Information

The Vickers V20F power steering pump, used with Caterpillar C10/C12 engines, supplies the hydraulic fluid needed to operate the power steering system.

The primary parts of the pump include a ported body, a cover, and a pumping cartridge. Fluid from the power steering reservoir enters the pumping cartridge through the inlet port in the body. A rotor inside the pumping cartridge is driven by the driveshaft and the engine accessory drive. When the rotor turns, vanes move along the surface of a cam ring. Hydraulic fluid is circulated under pressure and forced between the vanes creating sealed chambers that carry and discharge the fluid through a pressure plate to the outlet port in the pump cover.

The integral flow control and relief valve limits the fluid flow and the system pressure to preset values. Fluid that is not used to operate the system is recirculated to the power steering reservoir.

Removal

1. Clean all dirt from around the fittings and hose connections.
2. Disconnect the hydraulic pressure line, between the power steering gear and the power steering pump, from the elbow fitting on the pump. Plug the line and cap the fitting. If the pump is being replaced, remove the elbow and plug the port in the pump. See **Fig. 1**.

3. At the power steering pump, disconnect the reservoir supply line from the pump. Drain the power steering fluid from the line. Plug the supply line and cap the fitting on the pump. If the pump is being replaced, remove the elbow and plug the port in the pump.
4. Remove the capscrews that attach the pump to the engine accessory drive mounting flange. See **Fig. 2**. Slide the pump out of the sleeve, and remove the pump from the engine.

Installation

1. Using engine oil, lightly lubricate a new gasket and the pump shaft.
2. Install the gasket on the pump mounting flange, then place the pump on the engine accessory drive mounting. See **Fig. 2**. Turn the pump or shaft as needed to mesh the shaft with the sleeve. Seat the pilot of the pump mounting flange in the accessory drive mounting without applying unnecessary force. Install the lockwashers and capscrews, and tighten the capscrews 27 to 32 lbf·ft (37 to 43 N·m).
3. Connect the hydraulic pressure and pump supply lines.
   - 3.1 Connect the pressure line to the elbow fitting at the power steering pump pressure line port. If a new pump is installed, first install the elbow fitting.
   - 3.2 Connect the supply line to the elbow fitting at the power steering pump supply line port. If a new pump is installed, first install the elbow fitting.
   - 3.3 Tighten the elbow fitting nuts finger tight. Use a wrench to tighten the nuts until

there is resistance; then tighten them one-sixth turn more.

4. Check the fluid level of the power steering reservoir and add fluid if necessary. Start the engine and let it idle for two minutes. Do not turn the steering wheel. Doing so can cause air to enter the system.

   Turn off the engine and check the fluid level in the reservoir.

5. Start the engine again. To remove air from the system, steer the vehicle from full left to full right several times. Adjust the steering gear poppet or pressure relief valves. For instructions, see **Group 46**.

   Add fluid, as necessary, to the full line on the reservoir dipstick.

6. If the steering gear does not have a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Repeat this step, and add fluid as necessary until there are no bubbles in the reservoir.

   If the steering gear is equipped with a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Then loosen the manual bleed screw about one turn and look for clear fluid or fluid mixed with bubbles at the threaded area of the bleed screw. Repeat this step and add fluid, as necessary, until only clear fluid discharges. Tighten the manual bleed screw 27 to 33 lbf·in (305 to 373 N·cm). Fill the reservoir, if necessary, to the full line on the reservoir dipstick.

Steering Pump Disassembly, Inspection, and Assembly

Disassembly

1. Remove the power steering pump. For instructions, see **Subject 100**.
2. Clamp the pump body in a vise with the cover facing up.

CAUTION

Do not use excessive pressure to clamp the pump body. Applying excessive pressure could damage the pump body.

3. Remove the capscrews from the cover, and remove the cover and O-ring. See **Fig. 1**.
4. Remove the relief valve plugs from the pump cover.
5. Insert a suitable tool through the snap-ring end of the cover and carefully push out the relief valve and spring.

CAUTION

Do not disassemble the relief valve. Valve specifications are set by the manufacturer. The valve may not work properly if disassembled, and damage to the pump could occur.

6. Remove the pressure plate and spring.
7. Note the position of the cam ring, then remove the guide pins and cam ring.
8. Remove the vanes from the rotor, then remove the rotor from the shaft.
9. Turn the pump body over. If applicable, remove the shaft key and the snap ring that holds the bearing in place.
10. Using a soft hammer, tap on the splined end of the shaft to remove the shaft from the pump body.
11. Remove the snap ring from the shaft.
12. Support the bearing inner race on a press, and press the shaft out of the bearing.
13. Using a suitable hooked tool, pull the shaft seal out of the pump body.

Inspection

1. Clean all parts in an approved cleaning solvent.
2. Check the body, pressure plate, cam ring, and rotor for scoring or wear. Replace parts if necessary.
3. Check the vanes for burrs. Check the rotor slots for wear. Replace parts if necessary.
4. Check the bearings for wear and looseness. Applying pressure, turn the bearings and check for pitted or cracked bearing races. Replace the bearings if necessary.
5. Check the oil seal sealing surface on the shaft for wear. If wear marks on the shaft cannot be removed by light polishing, replace the shaft.
6. Check that the relief valve moves easily within the cover bore. If the cover bore is worn or pitted, replace the cover.
7. Check the relief valve for burrs. Remove burrs by polishing, but take care not to round off the corners of the valve ends.

Assembly

1. Coat all parts with hydraulic fluid. If using a new assembly part, remove any burrs from the sharp edges of the part.
2. Insert the small end of the relief valve in the bore of the pump cover. On one side of the cover, install the spring and relief valve plug. Install the snap ring and the other relief valve plug on the opposite side.
3. Support the bearing inner race and press the shaft through the bearing. Install the small snap ring on the shaft.
4. Lubricate the sealing lip of the shaft seal with chassis grease. Check that the shaft seal garter spring is facing toward the cover end of the pump. See **Fig. 2**. Press the seal in place.
5. Slide the driveshaft into the pump body until the bearing is seated. If necessary, use a soft hammer and lightly tap the end of the shaft.
6. Install new O-rings in the pump body and cover.
7. Insert the cam ring guide pins in the pump body. Make sure that the arrow on the perimeter of the

General Information

NOTE: This section covers the air bag only system installed from May 12, 2000. Troubleshooting, wiring diagrams, and deactivating/reactivating procedures for this system are covered in **Section 91.05**.

One of the following three types of supplemental restraint systems may be installed in a Century Class vehicle:

- air bag only system, installed prior to May 12, 2000; see **Section 91.05**
- air bag only system, installed from May 12, 2000; covered in this section
- air bag/SPACE system; see **Section 91.05**

To determine which type of supplemental restraint system is installed in the vehicle, look at the module under the driver's seat. The air bag/SPACE system and the air bag only system installed prior to May 12, 2000 have a SPACE module. If the vehicle has a SPACE system, gas cylinders are also located under the driver's seat. See **Fig. 1**. The air bag only system that became available on May 12, 2000 has an air bag sensor module located under the driver's seat. See **Fig. 2**.

The air bag only system, when used with seat belts, provides additional protection to the driver in severe frontal collisions. The air bag is located in the steering wheel hub.

⚠ WARNING

Damaged seat belts or seat belts that were worn in an accident must be replaced and their anchoring points must be checked. Failure to do so may result in personal injury or death.

The operational readiness of the air bag only system is indicated by a supplemental restraint system (SRS) indicator on the dash. The SRS indicator comes on when starting the engine and then goes off. The indicator will remain on if there is a problem with the system. The vehicle should be serviced if the indicator does not come on or if it remains on.

⚠ WARNING

The air bag system is designed to activate only in severe frontal collisions. Only in these situations will they provide supplemental protection. The driver and the passenger should always wear seat belts. For maximum protection in the event of a collision or rollover, the driver's back must be against the seat back in a normal seated position and the driver's head must be upright. The seat belts must be fastened and properly positioned on the body. Because the air bag inflates with considerable speed and force, it is important that the driver maintain a proper seat position to stay a safe distance from the inflating air bag.

Do not place objects on the steering wheel or between you and the steering wheel. Keep your hands on the sides and lower portion of the steering wheel. Any objects may cause harm during an accident.

Failure to follow these instructions may result in death or personal injury.

⚠ WARNING

Before performing any work on the air bag system, review all service literature and comply with all warnings and precautions in this subject and in Subject 100. Unintentional or improper air bag deployment can result in injury or death.

Damaged or deployed air bag systems should be inspected for leaking propellant chemicals before any attempt is made to remove, replace, or handle the components. If a leak is found, contact

LifeGuard Technologies (1-866-765-5835) for handling instructions.

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Disconnect the batteries and wait two minutes before proceeding.

⚠ WARNING

Wait two minutes after disconnecting the batteries to allow the internal components to discharge. Failure to allow the components to discharge could cause the air bag to deploy, resulting in severe bodily injury or death.

3. Disconnect the AS2 connector under the B pillar cover. See **Fig. 2**.
4. Remove the fastener cover plugs from the steering wheel lower column cover. See **Fig. 3**.

14. Connect the AS2 connector.
15. Make sure nobody is in the cab, then connect the batteries.
16. While standing outside the cab and away from the front of the air bag, turn the ignition on. The SRS indicator should come on for several seconds and then go out. If the SRS indicator goes out and there are no active fault codes, the system is functioning properly.

    Follow the appropriate procedure in **Section 91.05, Troubleshooting 300**, if:

    - There are active fault codes;
    - The SRS indicator remains on;
    - The SRS indicator does not come on for several seconds before going out.

Safety Guidelines for the Air Bag System

⚠ WARNING

The components and chemicals used in the air bag system are hazardous. The system contains components that use combustible chemicals; care must be taken when replacing or handling system components. Damaged or deployed air bag systems should be inspected for leaking propellant chemicals before any attempt is made to remove, replace, or handle the components. If a leak is found, contact LifeGuard Technologies (1-866-765-5835) for handling instructions.

The surface of the deployed air bag may contain small amounts of sodium hydroxide (which is a by-product of the gas generant combustion) and metallic sodium. Sodium hydroxide may be irritating to the skin and eyes. Always wear rubber gloves and safety glasses when handling a deployed air bag. Immediately wash your hands and exposed skin areas with water and a mild soap. Flush your eyes immediately if exposed to sodium hydroxide.

Consider undeployed air bags to be dangerous and capable of deploying at any time. Before performing any work on these systems, review all service literature and comply with the following warnings and precautions. Unintentional or improper deployment of the air bag system can result in injury or death.

- **Carry undeployed air bags with the bag and the trim cover pointed away from your body.**
- **Place undeployed air bags face up on a surface in an enclosed area.**
- **Do not place objects near or on top of an undeployed air bag.**
- **Store undeployed and undamaged air bag modules in a cool, dry, enclosed area.**
- **Keep all liquids, acids, halogens, heavy metals, and heavy salts away from the air bag system. Do not allow system chemicals to contact other liquids, combustibles, and flammable materials. Doing so could cause chemical burns or personal injury.**
- **Do not attempt to disassemble the air bag inflator unit or breach the integrity of the sealed metallic inflator case.**
- **Do not cut, drill, braze, solder, weld, probe, or strike any part of the air bag system.**
- **Do not expose the air bag module to electricity. Never probe a circuit on the air bag side of a connector unless the harness or air bag is disconnected between the test point and the air bag.**
- **Do not attempt to adapt, reuse, or install an air bag system in any vehicle other than the specific vehicle for which it is designed.**
- **Do not cut wires or tamper with the connector between the vehicle wiring harness and the air bag module unless the troubleshooting diagnostics specifically direct you to do so. Cutting or removing the connector from the system will disable the safety shunt and could cause unintentional deployment.**
- **Allow deployed air bag systems to cool after deployment.**
- **Air bag systems should be deployed in an open area or outdoors to prevent accidental fires.**
- **Wear rubber gloves and safety glasses when handling a deployed air bag.**
- **Store, transport, dispose of, and recycle air bag system components in accordance with all applicable federal, state, and local regulations.**
- **When reactivating the system for the first time after repairs have been made, stand outside of the cab and away from the front of the air bag while turning on the ignition. Check that the SRS indicator comes on for a few seconds and then goes out. Make sure there are no active fault codes.**
- **Keep all heavy objects in the cab secured.**

Clockspring Replacement

NOTE: The following clockspring replacement procedure is for the air bag only system that became available May 12, 2000. For information on the air bag only system installed prior to May 12, 2000, see **Section 91.05**.

IMPORTANT: To determine which type of supplemental protection system is installed in the vehicle, look at the module under the driver's seat. The air bag/SPACE system and the air bag only system installed prior to May 12, 2000 have a SPACE module. If the vehicle has a SPACE system, gas cylinders are also located under the driver's seat. CAUTION

Do not turn the steering wheel or the steering shaft at any time during this procedure. Doing so may damage the clockspring.

1. Park the vehicle on a level surface with the wheels straight ahead. Shut down the engine and set the parking brakes. Chock the rear tires.
2. Disconnect the batteries and wait two minutes before proceeding.

WARNING

Wait two minutes after disconnecting the batteries to allow the internal components to discharge. Failure to allow the components to discharge could cause the air bag to deploy, resulting in severe bodily injury or death.

3. Disconnect the AS2 connector. See **Fig. 2**.

5. Remove the steering wheel. For instructions, see **Section 46.06, Subject 100**.
6. Tape the upper and lower portions of the clockspring together to prevent it from turning.
7. Disconnect the connector located under the clockspring mounting plate on top of the steering column.
8. Loosen the screws that attach the clockspring to the clockspring bracket. It is not necessary to remove the screws in order to remove the clockspring.
9. Remove the clockspring.
10. If the steering column shaft has been allowed to rotate independently of the front wheels since the clockspring replacement procedure began, re-center the clockspring.

    10.1 While holding the lower portion of the clockspring stationary, rotate the upper portion counterclockwise until resistance is felt. Stop rotation as soon as some resistance is felt or the clockspring may become damaged.

    10.2 While holding the lower portion of the clockspring stationary, rotate the upper portion clockwise four full turns.

    10.3 Turn the upper portion of the clockspring clockwise until the the mounting holes in the upper portion of the clockspring are aligned with the screws in the lower portion of the clockspring. Tape the upper and lower portions together until the steering wheel is installed.
11. Using screws, attach the clockspring to the clockspring bracket.
12. Reconnect the connector from the clockspring to the air bag wiring harness. If the clockspring is taped together, remove the tape.
13. Install the steering wheel. For instructions, see **Section 46.06, Subject 100**.
14. Install the air bag. For instructions, see **Subject 100**.
15. Reconnect the AS2 connector. See **Fig. 2**.
16. Make sure nobody is in the cab, then connect the batteries.
17. While standing outside the cab and away from the front of the air bag, turn the ignition on. The SRS indicator should come on for several seconds and then go out. If the SRS indicator goes out and there are no active fault codes, the system is functioning properly.

    Follow the appropriate procedure in **Section 91.05, Troubleshooting 300**, if:

    - There are active fault codes;
    - The SRS indicator remains on;
    - The SRS indicator does not come on for several seconds before going out.

Air Bag Disposal Procedure

⚠ WARNING

Air bags are designed to work in specific vehicle makes and models. Air bag modules and components can not be adapted, reused, or installed in any vehicle other than the vehicle they are designed and manufactured for. Any attempt to adapt, reuse, or install an air bag module or component in any other vehicle can result in death or severe injury to vehicle occupants in the event of an accident.

IMPORTANT: The storage, transportation, disposal, or recycling of air bag modules or components must be performed in accordance with all applicable federal, state, and local regulations including, but not limited to, those governing building and fire codes, environmental protection, occupational health and safety, and transportation.

NOTE: If a vehicle is going to be scrapped and the air bag or SPACE system has not been deployed, contact your District Service Manager for instructions on how to proceed.

1. Remove the inflator from a deployed air bag module. Send the inflator to a recycler for reclamation of the steel and aluminum components.
2. Separate the air bag from the recyclable steel and aluminum components.
3. The plastic materials may be recycled or disposed of in common trash.

Replacement

NOTE: Before replacing the air bag sensor due to a lighted SRS warning lamp, make sure that all historic (inactive) fault codes are cleared. The SRS warning lamp will stay on even after the repairs indicated by the fault codes are corrected. After correcting the faults, use Service-Link to clear all historic (inactive) codes. The SRS lamp should now be off, unless an uncorrected fault exists.

⚠ WARNING

Consider undeployed air bags to be dangerous and capable of deploying at any time. Before performing any work on the air bag system, review all service literature and comply with the warnings and precautions in Subject 110 and in this subject. Unintentional or improper air bag deployment can result in injury or death.

Damaged or deployed air bag systems should be inspected for leaking propellant chemicals before any attempt is made to remove, replace, or handle the components. If a leak is found, contact LifeGuard Technologies (1-866-765-5835) for handling instructions.

- **Do not attempt to service or to dissassemble the air bag sensor module. The sensor module cannot be serviced.**
- **Do not cut, drill, braze, solder, weld, strike, or probe any part of the air bag sensor module.**
- **Keep all liquids, acids, halogens, heavy metals, and heavy salts away from the air bag sensor module.**
- **Do not attempt to adapt, reuse, or install an air bag sensor module in any vehicle other than the specific vehicle for which it is designed.**
- **Do not cut wires or tamper with the connectors between the vehicle wiring harness and the air bag sensor module. Cutting or removing the electrical connectors could cause unintentional deployment of the air bags.**
- **Do not expose the air bag sensor module to electricity. Never probe a circuit.**

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.

⚠ WARNING

Before removing the mounting capscrews from the sensor module, be sure to disconnect the batteries and disconnect the wiring from the sensor module. Failure to follow these precautions may result in the air bag being unintentionally deployed, which could cause severe bodily injury or death.

2. Disconnect the batteries and wait two minutes before proceeding.

⚠ WARNING

Wait two minutes after disconnecting the batteries to allow the internal components to discharge. Failure to allow the components to discharge could cause the air bag to deploy, resulting in severe bodily injury or death.

3. Raise the seat to its maximum position. If the seat is equipped with a seat shroud, lift the shroud to access the air bag sensor module.
4. Remove the plastic retainers that attach the sensor module cover to the sensor module and remove the cover. See **Fig. 1** or **Fig. 2**.
5. Disconnect the wiring from the sensor module at the AS2 connector under the B pillar cover.
6. Remove the sensor module.
   - On vehicles with an EzyRider seat, remove the capscrews that attach the sensor module to the cab floor. See **Fig. 1**.
   - On vehicles with a nonproprietary seat, remove the capscrews that attach both the sensor module and the seat to the cab floor. The front mounting capscrews for the seat may need to be loosened to remove the sensor module. See **Fig. 2**.

⚠ WARNING

Do not substitute the air bag sensor mounting fasteners. Use the fasteners provided with the sensor to ensure adequate engagement.

7. Install the new sensor module.

⚠ WARNING

Before attaching the wiring to the sensor module and before connecting the batteries, be sure to attach and tighten the mounting capscrews to the sensor module. Failure to follow these precautions may result in the air bag being unintentionally deployed, which could cause personal injury or property damage.

8. Attach the wiring to the sensor module.
9. Using two plastic retainers, attach the sensor module cover to the sensor module.
10. Lower the seat. If the seat is equipped with a seat shroud, lower the shroud around the base of the seat.

General Information

The LuK Automotive Hydraulics LF 80 power steering pump supplies power steering fluid for the operation of the power steering gear.

The LF 80 power steering pump, used only on the MBE4000 engine with air brakes, is mounted on the air compressor. See **Fig. 1**. The power steering pump is driven by the air compressor through the cross plate.

3. Hydraulic Line

5. Power Steering Pump

Fig. 1, Power Steering Pump Mounting

The main parts of the power steering pump are the housing, driveshaft, cam ring, rotor, vanes, and control valve.

Principles of Operation

The power steering pump driveshaft is driven by the air compressor, which is powered by an adaptor gear connected to the engine crankshaft.

As the pump driveshaft turns the pump rotor, centrifugal force throws the vanes out against the surface of the cam ring. When fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port and into the system.

The fluid enters the steering gear, providing the gear with enough fluid to steer the vehicle. Eventually the fluid returns to the power steering reservoir and then back to the power steering pump. See **Fig. 2**.

2. Cam Ring Contour
3. Rotor
4. Vane
5. High Pressure Area
6. Driveshaft

Fig. 2, Power Steering Pump, Section View

If the system pressure gets too high, a poppet inside the control valve is forced off its seat, shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump, instead of going to the outlet port.

When the system pressure drops to the correct level, the poppet seats and closes off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port, and then into the power steering system.

Replacement

1. Turn off the engine, apply the parking brakes, chock the tires, and open the hood.
2. Clean the dirt from around the inlet and outlet ports and from the hydraulic fittings.
3. Drain the power steering fluid and remove the hydraulic lines. See **Fig. 1**.

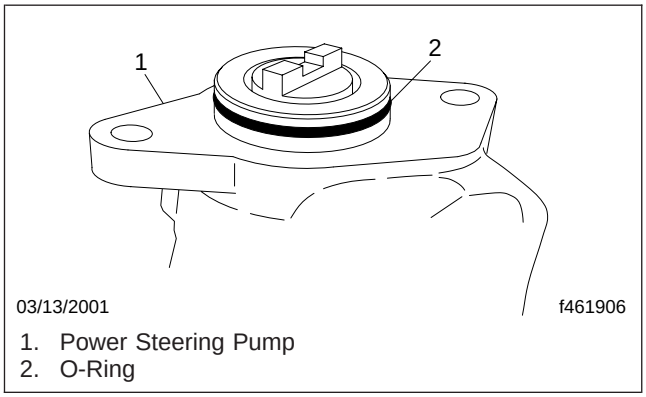
3.5 Drain the fluid into the container.

3.6 Plug the lines to keep out dirt.

4. Remove the capscrews that attach the power steering pump to the air compressor. Remove the steering pump from the air compressor.
5. Remove the cross plate and inspect it for excessive wear. Replace it if necessary. Discard the O-ring.
6. Lubricate the new O-ring with a light coating of power steering fluid, and install it in the pilot diameter of the power steering pump. See **Fig. 2**.



1. Power Steering Pump
2. O-Ring

Fig. 2, O-Ring Installation

IMPORTANT: Some power steering gears use automatic transmission fluid. Others use heavy-duty engine oil. Do not mix power steering fluids. Lubricate parts with the same fluid used in the power steering system.

7. Install the cross plate. Use grease to hold it in place while installing the pump.

IMPORTANT: Before installing a new steering pump, make sure the cross plate aligns with the air compressor shaft.

8. Using capscrews, attach the power steering pump to the air compressor. Tighten the capscrews 27 to 32 lbf·ft (37 to 43 N·m).
9. Lubricate the O-rings with a light coating of power steering fluid, and install them in the fittings of the two hydraulic lines.

IMPORTANT: Lubricate parts with the same fluid used in the power steering system.

10. Connect the inlet line, O-ring, and fitting to the steering pump inlet port. Tighten the fitting 26 lbf·ft (35 N·m).

Steering Pump Replacement

11. Connect the outlet line, O-ring, and fitting to the steering pump outlet port. Tighten the fitting 22 lbf·ft (30 N·m).
12. Add fluid to the power steering reservoir, using an approved type from the approved power steering fluids table in **Specifications 400**.
    - 12.1 Start the engine and let it idle for two minutes. Do not turn the steering wheel during this time, since this can cause air to enter the system.
    - 12.2 Turn off the engine and check the fluid level in the reservoir.
13. Bleed the air from the power steering system. See **Section 46.01**, Subject 110, for TRW steering gears and **Section 46.05**, Subject 100, for Sheppard steering gears.
14. Close the hood and remove the chocks from the tires.

General Information

The ZF steering driveline is a ball-splined telescopic shaft that consists of a cardan shaft with internal splines and a special-pattern shaft with external splines. Two rows of ball bearings run in these splines and form a positive rotating link that does not transmit noise. This design ensures freedom from radial play but light-action axial displacement with an effective stroke of ±1.18 inches (±30 mm). The ball-splined telescopic shaft has a low rate of wear and needs no maintenance.

Steering Driveline Removal and Installation

Removal

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations will be done.
2. Shut down the engine, apply the parking brakes, chock the tires, and open the hood.
3. Remove the driver's knee bolster below the steering column. See **Fig. 1**.
   - 3.1 Pull out on the bottom of the bolster.
   - 3.2 Push up on the bolster and pull it off.

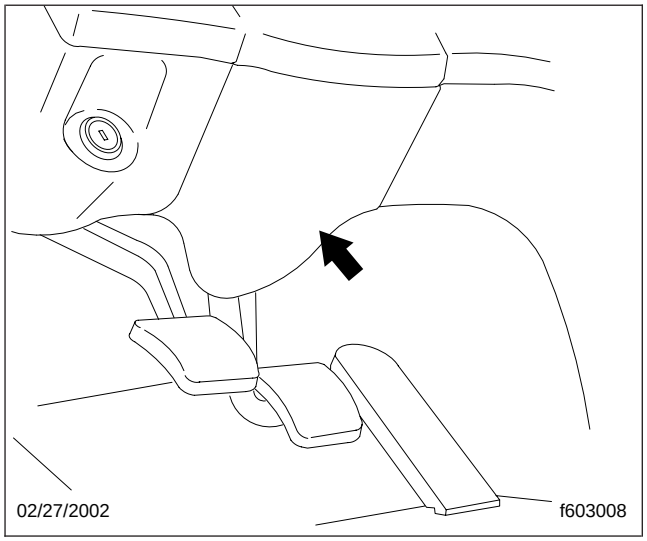

Fig. 1, Driver's Knee Bolster

4. Make a timing mark on the upper end yoke and the lower spline of the steering column. See **Fig. 2**.
5. Remove and discard the pinch bolt and nut from the lower end of the steering driveline.
6. Remove and discard the pinch bolt and nut from the upper end of the steering driveline.
7. Remove the steering driveline.
8. If the steering driveline is being replaced, remove the steering boot bushing from the steering driveline. See **Fig. 3**.

1. If the steering driveline is being replaced, install the steering boot bushing on the upper end of the new driveline.
2. Insert the upper end of the steering driveline through the steering boot and partially into the cab.
3. Align the timing mark on the upper end yoke with the timing mark on the lower spline on the steering column. Using a new M10 x 1.25 pinch bolt and nut, attach the upper end yoke to the steering column. Torque the bolt 30 to 35 lbf·ft (41 to 47 N·m).
4. Using a new M10 x 1.25 pinch bolt and nut, attach the steering driveline to the steering gear input shaft. Torque the bolt 30 to 35 lbf·ft (41 to 47 N·m).

General Information

The TRW adjustable steering column can be tilted or telescoped by pressing down on the foot pedal at the base of the column and moving the wheel to the desired position. The locking mechanism uses spring force to keep the column stationary.

The column is attached to the frontwall by both a mounting bracket behind the bulk of the column assembly, and mounting studs that connect to the frontwall bearing plate where the column shaft passes through the frontwall. The end of this shaft connects to the steering driveline (I-shaft) in the engine compartment. See **Fig. 1**.

In steering wheels without an air bag, the slip ring that attaches to the column, and connects to the horn button, is not a true clockspring, and has unlimited rotation. In steering wheels with an air bag, this ring is a clockspring with limited rotation, so care must be taken to secure the two halves of the clockspring while the steering wheel or I-shaft is removed for service.

A turn signal switch attaches to the steering column just below the steering wheel. If the vehicle is equipped with a trailer brake control valve, or SmartShift control, it is attached to the right side of the steering column. The steering column assembly is not repairable; if any steering column parts are damaged or badly worn, the steering column assembly must be replaced.

Steering wheels have different removal and installation procedures if they include an air bag: in wheels without an air bag, the horn button must be removed to access the wheel nut; in wheels with an air bag, the air bag must be deactivated, and the wheel cover module must be removed, to access the wheel nut.

Steering Wheel, No Air Bag

Removal

1. With the vehicle parked on a level surface, shut down the engine, set the parking brake, and chock the tires.
2. Remove the horn button by prying it out around the edges.
3. Disconnect the horn connectors.

IMPORTANT: The steering wheel does not have threaded wheel-puller holes. The tapered fit between the steering wheel and the column is designed to be released by hand.

4. Loosen the nut that holds the steering wheel on the steering column, but leave it on the shaft until the wheel has been released from the tapered fit.
5. Remove the wheel from the tapered fit by striking it from below, at the rim/spoke intersections, with both hands.
6. Remove the steering wheel nut and the wheel.

Installation

NOTE: Before installing the steering wheel, make sure the front tires are pointed straight ahead, and the steering gear is centered.

1. Thread the horn wires through the hole above the center of the steering wheel, and set the steering wheel on the steering column; see **Fig. 1**.
2. Make sure that the steering wheel is within ±10 degrees of center as shown in **Fig. 2**.
3. Install a new steering wheel nut and tighten it 33 to 41 lbf·ft (45 to 55 N·m).
4. Connect the horn connectors to the horn button and install the horn button.

⚠ WARNING

Wait two minutes after disconnecting the batteries to allow the internal components to discharge. Failure to allow the components to discharge could cause the air bag to deploy, resulting in severe bodily injury or death.

Undeployed air bags can be dangerous and are capable of deploying at any time. Follow the safety guidelines and handling instructions in Section 46.09, Subject 110. Failure to observe safety and handling information could cause unintentional deployment of the air bag, which could result in severe injury or death.

3. Remove the fasteners on the dash-facing side of the steering wheel that hold the steering wheel cover module in place.
4. Remove the steering wheel cover module.
5. Disconnect the steering wheel switch and air bag connectors from the steering wheel cover module, and disconnect the horn wires from the microswitch leads. See **Fig. 3**.

IMPORTANT: The steering wheel does not have threaded wheel-puller holes. The tapered fit between the steering wheel and the column is designed to be released by hand.

6. Loosen the nut that holds the steering wheel on the steering column, but leave it on the shaft until the wheel has been released from the tapered fit.
7. Remove the wheel from the tapered fit by striking it from below, at the rim/spoke intersections, with both hands.
8. Remove the steering wheel nut and the wheel.
9. Secure the clockspring with tape to prevent it from turning while the steering wheel is gone.

Installation

NOTE: Before installing the steering wheel, make sure the front tires are pointed straight ahead, and the steering gear is centered.

1. Remove the tape that keeps the clockspring from turning.

General Description

NOTE: Procedures in this section have been slightly modified from the original component manufacturer's service manual. See the manufacturer's service literature (**www.trucksteering.trw.com**) for additional information.

The TRW THP and PCF power steering gears are integral hydraulic power steering gears that contain a manual steering mechanism, a hydraulic control valve, and a hydraulic power cylinder.

The pressure required for the steering gear to overcome resistance at the steered wheels is provided by the power steering pump. The rotary control valve directs the flow of hydraulic fluid to the appropriate cylinder cavity in the steering gear (and in the auxiliary cylinder in a dual steering gear system) at the proper flow rate and pressure. As the steering wheel is turned faster or slower, more or less fluid is required by the gear.

Principles of Operation

When the driver turns the steering wheel, that force travels from the steering wheel to the steering gear input shaft. A torsion bar, pinned at one end to the input shaft and at the other end to the worm shaft, turns with the input shaft and exerts a rotational force on the worm shaft. In response to the force exerted by the torsion bar, the worm shaft moves the rack piston forward or backward in the gear housing by means of a series of recirculating balls in the spiral channels of the worm shaft. As the rack piston slides back and forth, it turns the sector shaft. The sector shaft swings the pitman arm, which pulls or pushes the drag link. The drag link moves the axle steering arm, steering the vehicle.

The rack piston's axial movement is resisted by its engagement to the sector shaft, which is linked to the steered wheels. Because of this resistance, the torsion bar activates the control valve, which directs pressurized fluid to the upper or lower cylinder cavity (depending on the direction of turn). The pressurized fluid assists in moving the rack piston up or down in the cylinder bore.

Most THP and PCF steering gears are equipped with two poppet (unloading) valves, one at each end of the rack piston. As the front wheels reach the axle stop—the farthest the wheels can turn in either direction—one poppet or the other, depending on the direction of the turn, will trip to prevent steering system damage. The tripped poppet reduces pressure in the gear, heat generated by the power steering pump, and outside forces acting on the steering linkage.

Some THP and PCF steering gears are also supplied with an internal pressure relief valve (PRV). The PRV limits maximum supply pressure to protect the power steering gear, but it does not reduce pressure as the steered wheels approach the axle stops.

See **Fig. 1** for an exploded view of the steering gear.

Removal

1. Verify that the axle stops are adjusted correctly. Ensuring correct axle stop adjustment will eliminate the possibility of resetting steering gear poppet valves after the gear is installed. See **Group 33** for instructions.
2. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping where the work is to be done.
3. Shut down the engine, apply the parking brakes, and chock the tires.
4. Disconnect the batteries and open the hood.
5. Clean all fittings and hose connections on the steering gear until they are free of dirt.
6. Drain the fluid from the power steering system. Disconnect the hydraulic lines from the steering gear, marking the lines for later reference. Plug the lines and the fittings to keep out dirt.
7. Remove the pitman arm.
   - 7.1 Remove and discard the pinch bolt, nut, and washer (if applicable) that attach the pitman arm to the steering gear sector shaft.
   - 7.2 Using a two-jaw puller, remove the pitman arm from the steering gear sector shaft. See **Fig. 1**.
8. Disconnect the steering driveline from the steering gear input shaft.
   - 8.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

NOTICE

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

   - 8.2 Remove the end yoke from the input shaft.

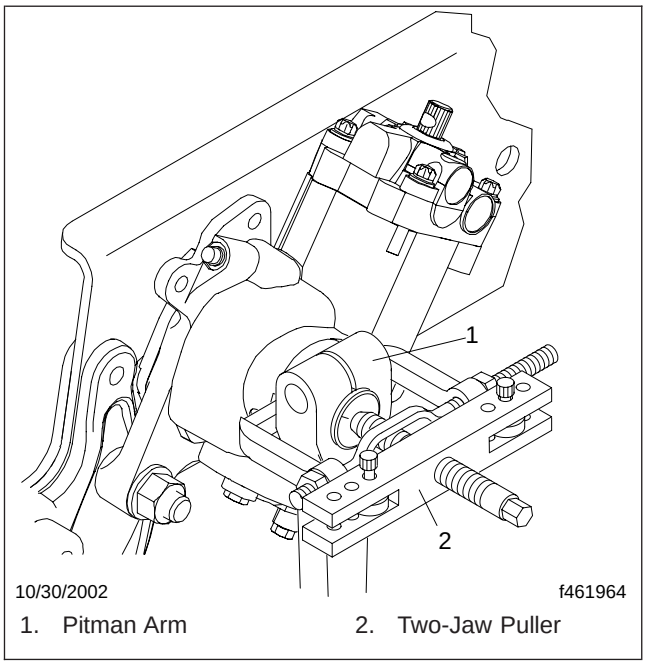

Fig. 1, Pitman Arm Removal

WARNING

The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

9. Remove the fasteners that secure the steering gear to the frame rail. Remove the steering gear.

Installation

1. Mount the steering gear on the frame rail and install the mounting fasteners. Tighten the fasteners 342 to 434 lbf·ft (464 to 588 N·m).
2. Center the steering gear so that the timing mark on the sector shaft is aligned with the timing mark on the steering gear. Keep the steering gear centered as the installation continues.
3. Connect the steering driveline to the steering gear input shaft.
   - 3.1 Align the hole in the steering driveline lower end yoke with the indentation on the input shaft.

Steering Gear Removal and Installation

3.2 Using a new pinch bolt and nut, attach the driveline lower end yoke to the input shaft. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).

3.3 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate the fasteners have been properly tightened.

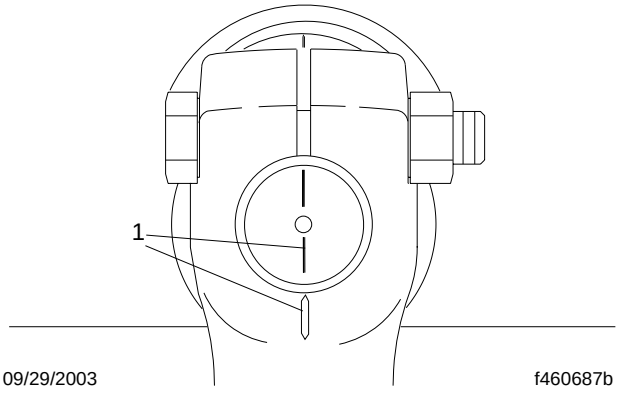
⚠ WARNING

Never leave a chisel wedged in the pitman arm slot. When using a chisel to spread the slot in the pitman arm, wear safety glasses and maintain a firm grip on the chisel at all times. Otherwise, the chisel may fly loose, which could cause an injury.

NOTE: The pitman arm may not fit over the splines on the sector shaft without spreading the slot in the arm. To wedge the slot open, drive a chisel into the slot using a ball-peen hammer. Hold the chisel in place and install the pitman arm on the sector shaft. Remove the chisel from the slot.

4. Install the pitman arm.

4.1 Make sure that the timing mark on the pitman arm is aligned with the timing mark on the sector shaft. See **Fig. 2**.



1. Timing Marks Aligned

Fig. 2, Typical Pitman Arm and Timing Marks

4.2 Using a new pinch bolt, nut, and washer (if applicable), attach the pitman arm to the steering gear sector shaft.

4.3 Tighten the nut 230 lbf·ft (312 N·m).

4.4 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate the fasteners have been properly tightened.

5. If the hydraulic line fittings were removed, attach them to the steering gear. Tighten the fittings 37 lbf·ft (50 N·m). Tighten the jam nut on the pressure line fitting to a maximum 41 lbf·ft (56 N·m).

6. Remove the plugs from the hydraulic lines. Connect the hydraulic lines to the steering gear. Tighten the nut on each fitting finger tight, then use a wrench to tighten the nut until there is firm resistance. Tighten one-sixth turn more.

7. Connect the batteries.

8. Fill and bleed the steering system. For instructions, refer to **Subject 110**.

9. Close the hood and perform the post-service checks in **Subject 150**.

Filling and Air Bleeding the System

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

1. Fill the power steering reservoir nearly full with automatic transmission fluid. Do not turn the steering wheel.
2. Start the engine and let it idle for ten seconds, then shut it off. Check and fill the reservoir. Repeat this step at least three times, checking the fluid level in the reservoir each time.

IMPORTANT: Do not let the fluid level drop significantly or allow the reservoir to empty. Doing so may introduce air into the system.

3. Start the engine and let it idle for two minutes. Do not turn the steering wheel. Shut off the engine and check the fluid level in the reservoir. If needed, add more fluid.
4. Start the engine again. Turn the steering wheel from full-left to full-right several times. If needed, add more fluid to the reservoir.

   Automatic bleed systems should now be free of trapped air.

   If the vehicle has a manual bleed system (**Fig. 1**), proceed to the next step.

IMPORTANT: Do not turn the steering wheel while the bleed screw is loosened.

5. With the wheels in the straight-ahead position, loosen the manual bleed screw two to three turns. Allow air and aerated fluid to bleed out until only clear fluid is seen. Close the bleed screw and add fluid to the reservoir if needed.

   Repeat this step until all air is out of the system.
6. Tighten the bleed screw 45 lbf·in (509 N·cm).

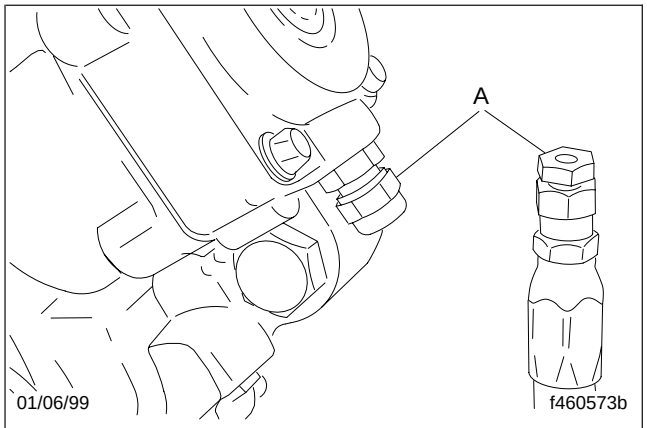
Replacement

NOTE: The power steering pump is used in this procedure to force out the input shaft seal. To use this procedure, the power steering pump should have a minimum of 1500 psi (10 342 kPa) available.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Disconnect the return line from the steering gear and plug the line. See **Fig. 1**. Cap the return port of the steering gear with a high pressure fitting.



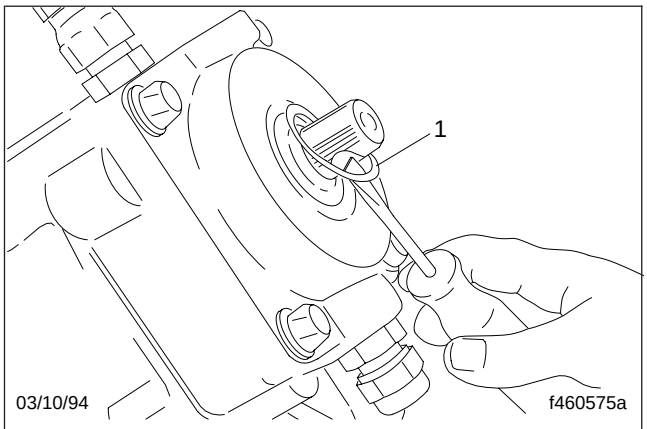
A. Cap the return line and the return port.

Fig. 1, Disconnected Return Line

NOTICE

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

3. Disconnect the steering driveline from the steering gear input shaft.
4. Remove the dirt and water seal from the steering gear. Save this seal to determine the correct size of the new seal.
5. Using a clean cloth, remove all grease from around the input shaft.
6. Using a screwdriver inserted into the notch formed in the end of the retaining ring, remove the retaining ring. See **Fig. 2**. Be careful not to scratch the bore with the screwdriver.



1. Retaining Ring

7. Using a pinch bolt and nut, attach the steering driveline to the input shaft but do not tighten the nut. See **Fig. 3**.

8. Tie or wrap a shop towel around the input shaft and place a drain pan under the steering gear to catch the oil. See **Fig. 4**.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and

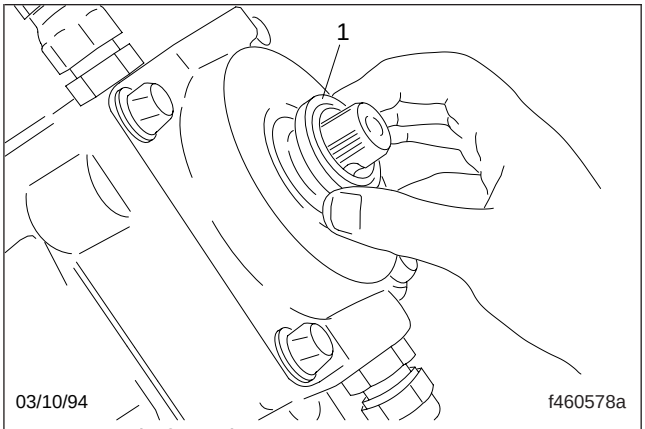
spillage on the roadway, which could cause personal injury or property damage.

9. If needed, fill the power steering reservoir with automatic transmission fluid.
10. With the vehicle in neutral, momentarily turn the starter. If the engine starts, quickly turn it off. This should force out the input shaft seal.
11. Remove the shop towel, pinch bolt, and input yoke. Remove the input shaft seal. See **Fig. 5**.



1. Input Shaft Seal

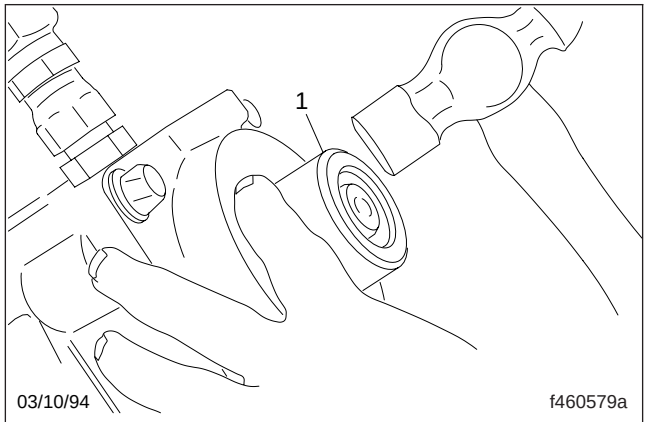
Fig. 5, Input Shaft Seal Removal

12. Inspect the seal area of the valve housing for seal fragments. Remove all seal fragments.
13. Check the input shaft seal for heat damage. If the seal is stiff and brittle, it is probably heat damaged. Determine and fix the cause of excessive heat in the vehicle.

WARNING

Do not use a socket to install the input shaft seal. You will not be able to control the seal installation depth with a socket and this could lead to leaks. Leaks could result in loss of steering assist and spillage on the roadway, which could result in personal injury or property damage.

14. Install a new input shaft seal.
    - 14.1 Using Exxon Polyrex® EP2 grease (045422), lubricate the inside diameter of the new input shaft seal and install it on the input shaft.
    - 14.2 Using a hammer and seal driver (J37073), tap the driver until the shoulder of the driver is square against the valve housing. See **Fig. 6**. Remove any seal material that may have sheared off in the seal bore or retaining ring groove.



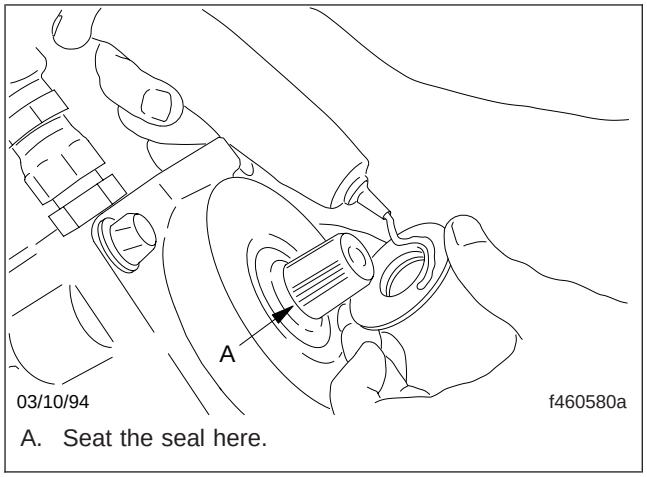
1. Seal Installer Tool

Fig. 6, Seal Installer Tool Position

15. Install a new retaining ring in the groove.
16. Using Exxon Polyrex EP2 grease (045422), pack the end of the valve housing bore.
17. Install a new dirt and water seal.
    - 17.1 Choose the correct size dirt and water seal by comparing the replacement seals to the old seal.

17.2 Apply Exxon Polyrex EP2 grease to the new dirt and water seal and install it on the input shaft. See **Fig. 7**. Seat it in the groove behind the serrations and against the valve housing.

Wipe any excess grease from the valve housing bore and input shaft once the seal has been installed.



A. Seat the seal here.

Fig. 7, Dirt and Water Seal Installation

18. Using a new pinch bolt and nut, attach the steering driveline to the input shaft. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).
19. Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate the fasteners have been properly tightened.
20. Connect the return line to the steering gear return port.
21. Bleed the air from the system. For instructions, see **Subject 110**.

Adjustment

NOTE: If the steering gear is installed on the frame rail, sector shaft adjustment can only be completed if the adjusting screw jam nut (located on the side cover) is accessible.

1. Apply the parking brakes and chock the rear tires.
2. With the engine on, turn the steering wheel until the timing mark on the sector shaft lines up with the timing mark on the housing. The sector shaft is now at its center of travel. Shut down the engine.
3. Remove the cotter pin and castle nut that attach the drag link to the pitman arm. Remove the drag link from the pitman arm.

IMPORTANT: To avoid resetting the poppets, do not turn the input shaft more than 1-1/2 turns from the center-of-travel position while the drag link is disconnected.

4. From the center-of-travel position, grasp the pitman arm at the lower end of the arm and gently try to move the arm back and forth. If the pitman arm is loose or lash (free play) is detected, the sector shaft is out of adjustment.
5. Loosen the adjusting screw jam nut.
6. If no lash was detected in step 4, use a screwdriver to turn the sector shaft adjusting screw counterclockwise until you feel lash at the sector shaft. See **Fig. 1**.

IMPORTANT: Do not use more than 10 lbf·ft (14 N·m) of force when tightening the adjusting screw.

7. Slowly turn the shaft adjusting screw clockwise until you feel no lash at the sector shaft. From this position, turn the screw clockwise 1/8 to 3/16 of a turn more. Hold the adjusting screw in place and tighten the jam nut 43 lbf·ft (58 N·m).
8. Turn the steering wheel 1/4 of a turn each side of center then back to center and check the pitman arm for lash. There should be no lash. If lash is detected, loosen the jam nut and repeat the previous step as well as this step.
9. Using a castle nut, attach the drag link to the pitman arm. Tighten the castle nut using the appropriate torque value:

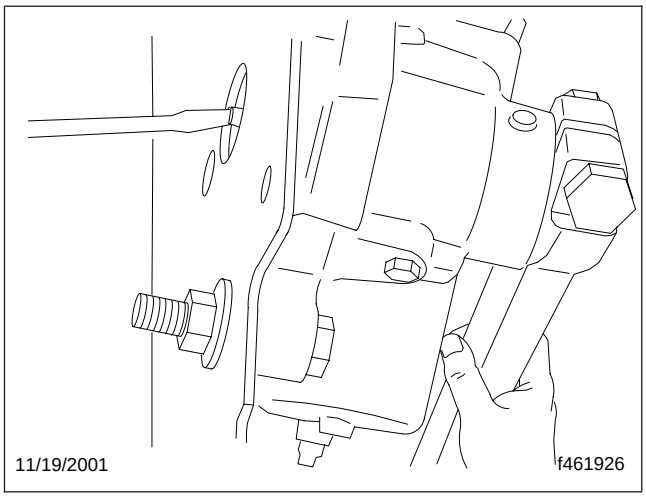


Fig. 1, Adjusting the Sector Shaft

- 3/4–16: 90 to 170 lbf·ft (122 to 230 N·m)
- 7/8–14: 160 to 300 lbf·ft (217 to 407 N·m)

⚠ WARNING

Failure to install and lock a new cotter pin in the ball stud and nut could result in disengagement of the parts and loss of steering control, which could result in personal injury or property damage.

10. Continue to tighten the castle nut until a slot on the nut aligns with the hole in the ball stud. Do **not** reverse the tightening direction of the nut when locating the cotter pin hole. Install a new cotter pin in the ball stud and nut, then lock the cotter pin in place.

NOTICE

Do not use a power grease gun to add grease to the sector shaft bearing. Doing so could damage the high-pressure seal and contaminate the hydraulic fluid.

11. Using only a hand-operated grease gun, add grease to the sector shaft bearing through the grease fitting in the housing until grease begins to extrude past the dirt and water seal.

Resetting the Poppet Valves

1. Check that the axle stops are adjusted properly. See **Group 33** for instructions.
2. Start the engine and allow the vehicle to idle for 5 to 10 minutes to warm the hydraulic fluid.
3. Shut down the engine, apply the parking brakes, and chock the rear tires.
4. Hold the poppet screw with a wrench and turn the sealing nut back toward the wrench until the nut is flush with the base of the hex area of the poppet screw.
5. Make sure that the engine is off and the wheels are in the straight-ahead position.

NOTICE

Make sure the drive end of the adjusting screw is not below the face of the nut. If the drive end of the adjusting screw is below the face of the nut, the poppet seat flange will break when the upper poppet is prepared for setting.

6. Using a 7/32-inch Allen wrench, turn the adjusting screw and nut assembly (without turning the nut on the screw) into the housing until the nut is firmly against the housing. Tighten the nut against the housing. See **Fig. 1**.

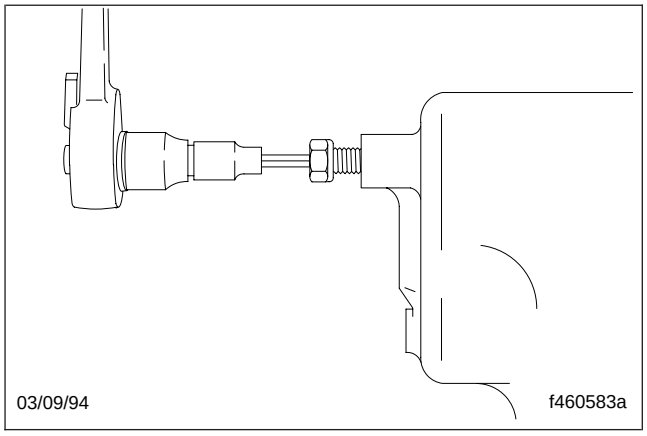

Fig. 1, Adjusting Screw and Nut Assembly

7. Place a jack under the center of the front axle and jack up the front of the vehicle so the steer axle tires are off the ground.
8. Push the upper poppet out to prepare it for setting.
   - 8.1 Start the engine and let it idle.
   - 8.2 Note which sector shaft timing mark is nearest the housing piston bore.

NOTICE

Do not hold the steering wheel at full turn for more than 10 seconds at a time. The heat buildup at pump relief pressure may damage components.

   - 8.3 Turn the steering wheel in the direction that makes this timing mark move toward the adjusting screw just installed. Turn the wheel in this direction until axle stop contact is made.
   - 8.4 Pull hard on the steering wheel. Put up to 30 lbf (133 N) pull on a 20-inch diameter steering wheel.
9. Set the upper poppet.
   - 9.1 Turn the steering wheel in the opposite direction (the timing mark will move away from the adjusting screw) until the other axle stop is contacted.
   - 9.2 Pull hard on the steering wheel. Put up to 30 lbf (133 N) pull on a 20-inch diameter steering wheel.
   - 9.3 Release the steering wheel and shut off the engine.
10. Loosen the sealing nut and back out the adjusting screw until the adjusting screw is one inch (2.5 cm) past the nut. See **Fig. 2**. Tighten the nut against the housing.
11. Set the lower poppet.
   - 11.1 Start the engine and let it idle.
   - 11.2 Turn the steering wheel in the original direction (the timing mark will move toward the adjusting screw) until axle stop contact is made.
   - 11.3 Hold the steering wheel in this position with up to 30 lbf (133 N) pull on a 20-inch diameter steering wheel for 10 seconds, then release. Repeat this hold-and-release process as many times as necessary while completing the next step.
12. Position the adjusting screw.

Poppet Adjustment on a Single Gear

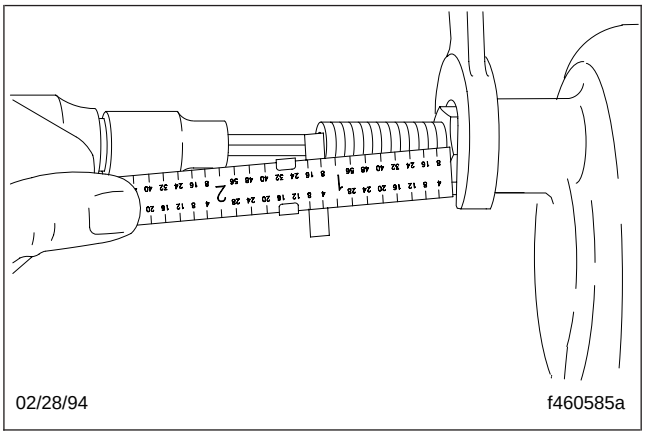

Fig. 2, Adjusting Screw Position

12.1 With the steering wheel held tightly at full turn, loosen the nut and hold it in place with a wrench.

12.2 Using an Allen wrench and finger pressure only, turn the adjusting screw clockwise until the Allen wrench stops. Do not attempt to turn the adjusting screw in any farther. Pause the turning-in process each time the driver releases the steering wheel. Continue turning only while the steering wheel is held at full turn.

12.3 Back off the adjusting screw 3-1/4 turns and tighten the nut 35 lbf·ft (47 N·m).

⚠ WARNING

If the adjusting screw protrudes more than 1-1/16 inches (27 mm) from the sealing nut, the screw could fall out of the steering gear, resulting in loss of power steering. This could cause an accident resulting in personal injury or property damage.

IMPORTANT: Once the poppet adjusting screw and sealing nut are in place, and the poppet valves have been manually adjusted, the adjustment procedure must be repeated if steering travel is either increased or decreased in the future.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

13. The poppets have now been completely reset. Check the power steering reservoir. The power steering fluid level should be between the MIN COLD mark and the middle mark just above it. If needed, add fluid.

14. Lower the vehicle.

Post-Service Checks

After power steering components have been worked on and before the vehicle is placed into service, the following items must be checked.

⚠ WARNING

Failure to check the following items could result in damage to the power steering system. This could cause loss of steering assist and spillage on the roadway, which could cause personal injury or property damage.

1. Operate the engine at idle while turning the steering wheel through several full-left and full-right turns. With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level (signs that air is trapped in the system).

   If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as necessary. Bleed the air from the system. Refer to **Subject 110** for instructions.

2. With the engine turned off and warm, check the power steering reservoir fluid level. If needed, add power steering fluid.

3. At full-left and full-right turns, be sure the axle stops on the rear side of the spindle are set so there is at least 1/2 inch (13 mm) of clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be at least 3/4 inch (19 mm). If clearance is less than the above, reset the axle stops.

4. Check that the poppets are set correctly. If needed, adjust them. For instructions, refer to **Subject 140**.

5. Test drive the vehicle. Check the steering wheel spoke position. If, during straight-ahead driving on a level road, the steering wheel spokes are not within ±10 degrees of the 9 o'clock and 3 o'clock positions, remove the steering wheel and reposition it. See **Fig. 1**.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

THP and PCF power steering gears use automatic transmission fluid that meets Dexron II, Dexron III, Mercon, or ATF +4™ specifications.

Exxon Polyrex® EP2 Grease (045422) is approved for use on steering gear components.

General Information

A *Checklist for Troubleshooting Power Steering Problems*, form STI-492, has been developed to accompany the procedures below. Form STI-492 can be downloaded or printed **here** after logging into **www.AccessFreightliner.com**.

Each step and substep in these troubleshooting procedures corresponds to a step or substep on form STI-492. Use **Table 1** to determine which steps should be completed, based on the customer's complaint. It is very important that the information provided by the driver is communicated accurately to prevent wasting of diagnostic time. For example, if complaints include "Pulling to one side" and "Noisy steering," steps 1, 3, 4, 5, and 6 will be the tests for the most likely failure modes.

Start with the lowest test number and work up to the highest. For example, when completing steps 1, 3, and 6 to determine the cause of a vehicle pulling to one side, start with step 1 and finish with step 6.

Troubleshooting Steps

NOTE: Some of these inspections and procedures can be found in the Pretrip and Post-Trip Inspections and Maintenance chapter in the vehicle driver's/operator's manual.

Steps 1 through 4 may have been performed by the customer. Verify the vehicle service history with the customer to prevent redundant testing.

All measurements and readings must be recorded on STI-492.

Refer to the applicable section in this manual to repair or replace steering system components.

1. Check the tire pressure and load.

   1.1 Check the tires for damage.

   1.2 Check that the front tires are inflated to the correct pressure, and the tire pressure is equal on both sides. Correct the pressure if needed.

   Low pressure causes increased steering effort due to friction with the road surface. Unequal tire pressure causes unequal friction between the tire and the road. This can cause pulling to one side.

Steering Complaint and Troubleshooting Steps Checklist

* If there is consistent pull to one side, a braking issue could feel like a steering assist problem. Refer to **Group 42** in this manual to ensure the brake system is functioning properly.

Table 1, Steering Complaint and Troubleshooting Steps Checklist

Troubleshooting Procedures

1.3 Check that the rear tires are inflated to the correct pressure, and the tire pressure is equal on both sides. Correct the pressure if needed.

1.4 Check that the tire sizes are correctly matched, and whether duplex or oversized tires (that were not originally specified for the vehicle) have been installed.

Extra tire width causes increased steering effort due to extra friction with the road surface. If the axle stops were turned out to reduce wheel cut due to a change in tires, the power steering gear poppets may need to be adjusted.

1.5 Communicate with the driver or operator to determine whether the vehicle is operated at or over the rated load.

Increased load causes greater steering effort. Make sure the vehicle is being operated within rated capacities.

2. Check fifth wheel lubrication and condition.

A dry fifth wheel plate makes it difficult to change direction. Check the plate surface for burrs, gouges, and irregularities.

3. Check vehicle alignment and wheel bearing adjustment.

3.1 Check the vehicle service history for the last known alignment, and inspect tire wear for indications that an alignment needs to be completed.

3.2 Check front axle caster and camber measurements.

3.3 Ensure wheel bearings and rear axle are in good condition, and that toe is set correctly.

3.4 Ensure the rear axle is properly aligned.

4. Check for loose and binding components. Check whether any steering components need maintenance or adjustment.

4.1 Check for proper lubrication of the drag link, tie rods, and knuckle pins. Apply lubrication as needed.

4.2 Check the COE steering column, if equipped. Chock the rearmost tires. With the engine shut down, turn the steering wheel and check for looseness or binding. Make sure all components are free to move, but are not excessively loose.

4.3 Check the steering driveline U-joints for looseness or binding. Lubricate them if needed.

4.4 Check the sector shaft adjustment.

- With the vehicle on the ground, the engine idling, and the front tires pointed straight ahead, turn the steering wheel until slight motion is observed at the front wheels.
- Align a reference mark on the steering wheel to a rule, then, with the engine running, slowly turn the steering wheel in the opposite direction until motion is again detected at the wheels.
- Measure the lash (free play) at the rim of the steering wheel.

Excessive lash exists if steering wheel movement exceeds 2-1/2 inches (64 mm) with a 20-inch (508-mm) steering wheel, or 2-1/4 inches (57 mm) with an 18-inch (457-mm) steering wheel.

4.5 Check that the front wheels self-return without binding.

- With the engine off, chock the rearmost tires and place the front tires on radius plates (turntables).
- Disconnect the drag link from the steering arm.
- By hand, pull one tire to the axle stop and release. The tire should self-return to almost straight ahead.
- Repeat with the opposite tire.

If a tire does not return to near straight ahead, check for binding or lack of lubrication in the steering axle kingpin bushings or tie rod linkage.

- Connect the drag link and tighten the castle nut, then install a new cotter pin.

4.6 Inspect all suspension fasteners and components for wear or looseness.

5. Check the steering system for leaks and restrictions, and test the system back pressure.

5.1 Inspect hoses, fittings, and seals for damage or leaks.

- With the engine idling, inspect for kinked or collapsed hoses. Repair or replace any collapsed or kinked hoses. If collapsed hoses are found, ensure the steering system is filled with the correct automatic transmission fluid.
- Inspect fittings for leaks. Repair leaking fittings; replace parts as needed.
- Inspect all external seals. Replace leaking seals.

  Inspect the seal bores and sealing surfaces for scrapes or burrs. Make sure the seals are installed correctly using the recommended tools.
- If you replaced the steering gear input shaft seal and found it to be excessively hard, test the system operating temperature in step 6.

5.2 Inspect the steering gear for external leakage.

- Clean the area around the input shaft and inspect the input shaft for signs of leakage after operating the vehicle under normal conditions through steering maneuvers.
- Inspect the sector shaft for signs of leakage. A well greased or heavily used steering gear may weep oil from the grease seal, but a confirmed leak will be evidenced by fluid collecting while the vehicle is being operated under normal conditions.
- Inspect the vent plug in the trunnion housing for signs of leakage. Any fluid in or around the rubber vent plug indicates leakage from an internal steering gear seal.

NOTICE

Do not turn the steering wheel or allow system pressure to exceed the rating of the gauge during the following test. Damage to the gauge could occur.

5.3 Check total steering system back pressure.

- Install a low pressure gauge—300 psi (2068 kPa) maximum—between the steering pump and the steering gear.
- Check for correct fluid level. If necessary, add fluid. If bubbles or foam appear in the reservoir, check hose fittings for looseness or leaks.
- With the engine idling, read the total system back pressure on the pressure gauge.
- If the total system back pressure is greater than 100 psi (689 kPa), or 140 psi (965 kPa) for a vehicle with hydraulic brakes, replace the steering fluid filter and re-test the system. If the system back pressure is still excessive, go to the next substep.

  If the total system back pressure is less than 100 psi (689 kPa), or 140 psi (965 kPa) for a vehicle with hydraulic brakes, restriction is not a problem—go to step 6.

5.4 Leave the low pressure gauge in place and check individual steering system components for excessive restriction. See **Fig. 1** for a plumbing diagram.

- Bypass the steering gear by disconnecting the steering gear input and output lines from the gear and coupling them together. See **Fig. 2** for an example.

  If the drop in system pressure from the value found in substep 5.3 is greater than 55 psi (379 kPa), the steering gear has excessive restriction. If the drop in pressure is less than 55 psi (379 kPa), reconnect the

gear input and output lines to the gear and continue with this substep.

- If the vehicle is equipped with hydraulic brakes, bypass the brake booster by disconnecting the booster input and output lines and coupling them together.

  If the drop in system pressure from the value found in substep 5.3 is greater than 40 psi (276 kPa), the brake booster has excessive restriction. If the drop in pressure is less than 40 psi (276 kPa), reconnect the booster input and output lines and continue with this substep.

- Test each hydraulic line in the power steering system individually by bypassing them one at a time, as was done with the steering gear and brake booster, if equipped.

  If the drop in system pressure from the value found in substep 5.3 is greater than 12 psi (83 kPa) for any one line, replace the line and test total system back pressure again.

6. Check steering pump performance. Power steering fluid temperature should be approximately 180°F (82°C) to best replicate fluid temperatures under normal driving conditions.

   If the system fails the tests in the following substeps, replace the pressure relief valve (PRV) and complete the tests in the substeps below again. If the system fails again, replace the pump.

NOTICE

Do not leave the load valve closed for longer than five seconds during the following test. Doing so could damage the power steering system.

6.1 Check for erratic pump response.

- Slowly close the load valve and watch the pressure and flow readings as the valve closes, then open the valve immediately.
- If the pressure rises rapidly or appears uncontrolled, open the load valve immediately.
- If the response was erratic, replace the PRV or pump, as required. If the response was smooth and controlled, go to the next substep.

6.2 Check the pump relief pressure.

- Slowly close the load valve. When the valve is completely closed, read the pressure gauge, then open the valve.
- If the pump relief pressure does not exceed the relief pressure in **Table 2** or **Table 3**, refer to the pump manufacturer's service literature to verify the exact relief pressure for the pump.
- If the pump relief pressure does not exceed the relief pressure in **Table 2**, **Table 3**, or the pump manufacturer's specifications, replace the PRV or pump, as required.
- If the pump relief pressure exceeds the relief pressure in **Table 2** or **Table 3**, it is acceptable. Go to the next substep.

6.3 Test the pump relief valve reaction at idle.

- Run the engine at idle and note the flow rate with the load valve open.

- Close the load valve until the pump relief pressure is reached. Smoothly and quickly open the load valve and note the flow rate. Repeat this action three times. The flow rate should return to the flow rate first noted with the load valve open.
- If the flow rate does not return smoothly and quickly, the pump relief valve is not working correctly. Replace the replace the PRV or pump, as required.
- If the flow rate returns smoothly and quickly, the pump relief valve is acceptable. Go to the next substep.

6.4 Test the pump relief valve reaction at 1500 rpm.

- Run the engine at 1500 rpm and note the flow rate with the load valve open.
- Close the load valve until the pump relief pressure is reached. Smoothly and quickly open the load valve and note the flow rate. Repeat this ac-

tion three times. The flow rate should return to the flow rate first noted with the load valve open.

- If the flow rate does not return smoothly and quickly, replace the PRV or pump, as required.
- If the flow rate returns smoothly and quickly, the pump relief valve is acceptable. Go to the next substep.

6.5 Test the flow of the pump at idle with a load applied.

For vehicles with low-pressure steering gears, run the engine at idle and slowly close the load valve until the pressure gauge reads 1000 psi (6900 kPa). Read the flow rate on the gauge, then set the pressure to 1800 psi (12 400 kPa). Read the flow gauge, then open the load valve. Compare the values to those in **Table 2**.

For vehicles with high-pressure steering gears, use 1000 psi (6900 kPa) and 2300 psi (15 860 kPa) as the test load pressures. See **Table 3** for minimum flow rate.

6.6 Test the maximum flow of the pump with no load applied.

- Run the engine at 1500 rpm, make sure the load valve is completely open, and read the flow gauge.
- If the flow rate is below the minimum indicated in **Table 2** or **Table 3**, replace the PRV or pump, as required.
- If the flow rate is above 5.5 gpm (20.8 L/min) on a vehicle with a single steering gear, or 7.7 gpm (28.8 L/min) on a vehicle with an assist cylinder installed, replace the pump.

7. Test the steering gear internal leakage.

Select TRW integral steering gears and all ThyssenKrupp rack and pinion steering gears are equipped with an internal PRV that significantly limits maximum supply pressure to protect the steering gear. These gears, unlike gears on vehicles fitted with hydraulic brake boosters, cannot be tested for internal leakage by plugging the internal PRV in the gear. The pump output must be limited to prevent excessive pressure from damaging the gear, and the internal PRV passage must be blocked to direct oil flow through the gear.

Use PartsPro® for the specific VIN to determine if the steering gear is equipped with an internal PRV, which will be listed as a serviceable part under module 536.

If a TRW steering gear has an internal PRV but no hydraulic brake booster, see the following heading, **Internal Leakage Test Setup, TRW Steering Gears With an Internal PRV**, for instructions on setting up the necessary test components before proceeding with the following substeps.

ThyssenKrupp rack and pinion steering gears are also equipped with an internal PRV, but cannot be tested for internal leakage.

IMPORTANT: Make sure the fluid temperature is approximately 180°F (82°C) and the vehicle is stationary with the front wheels pointing forward.

7.1 Run the engine at idle with the load valve open.

⚠ WARNING

Keep fingers clear of the stop bolt and spacer block during the following test. Make sure that the spacer block contacts the axle stop squarely. Contact that is not square could break the stop bolts or eject the spacer block, which could cause serious personal injury.

7.2 Place an unhardened steel spacer, 1-inch (25-mm) thick, between the axle and the stop bolt on one side of the axle.

The spacer should have an extension or handle long enough to keep fingers clear of the axle stop area. A brazing rod or welding rod works well for this purpose.

NOTICE

While running the following test, do not hold the steering wheel in the full-turn position for more than five seconds. Doing so could damage the pump.

Troubleshooting Procedures

7.3 Have someone turn the steering wheel, applying enough force to completely close the rotary valve.

Complete closure of the rotary valve requires approximately 20 lbf (27 N) pull on the steering wheel, and will be indicated by a pressure reading nearly equal to the system relief pressure (tested in substep 6.2).

7.4 Hold the steering wheel in the full-turn position. Note the steering gear internal leakage on the PSSA.

7.5 Repeat the previous substeps for the opposite turn.

The maximum permissible internal leakage for a single gear is 1.0 gpm (3.8 L/min). If leakage is greater in either turning direction, replace the steering gear components as needed.

For systems with two or more steering gears and/or linear cylinders, the total acceptable internal leakage is 1.0 gpm (3.8 L/min) for each steering gear/ram in the system. Maximum internal leakage on a dual-gear system is 2.0 gpm (7.6 L/min). If the leakage is more than 2.0 gpm (7.6 L/min) on a dual-gear system, isolate the auxiliary cylinder from the system using the substeps that follow.

7.6 Disconnect the auxiliary cylinder hydraulic lines at the main gear auxiliary ports.

7.7 Plug the main steering gear ports with suitable steel or high-pressure plugs or caps.

7.8 Repeat the internal leakage test.

If the internal leakage is less than 1 gpm (3.8 L/min), repair or replace the auxiliary gear or linear cylinder. If the internal leakage is greater than 1 gpm (3.8 L/min), repair or replace the main gear.

8. Check the steering gear poppet relief valve and stop bolt adjustment.

NOTE: Poppets limit the steering assist when the front wheels approach the stop bolts. Improper adjustment can apply excessive force to the steering linkage, or cause loss of assist, as the steering wheel approaches either full-left or full-right turn.

8.1 Check the steering system for stop bolt adjustment.

Make sure the stop bolt settings limit the steering travel so there is ½-inch (13-mm) clearance from all stationary components, and 3/4-inch (19-mm) clearance from all moving components.

8.2 Make sure the pitman arm is situated on the steering gear sector shaft correctly. Check that the pitman arm and sector shaft timing marks are aligned.

NOTICE

If power steering pump relief pressure is reached while the steering wheel is at full lock, release the steering wheel from this position. Do not allow the pump relief pressure to be maintained for longer than five seconds or damage to the pump may result.

8.3 Check the poppet relief pressure.

- Install the PSSA between the steering pump and the steering gear. See the following heading, **Power Steering System Analyzer Setup**, for instructions on PSSA installation.
- Run the engine at idle with the load valve open. Turn the steering wheel to either full-lock position. Note the pressure gauge reading, then repeat for the opposite turn.
- The pressure should drop slightly before the stop bolts are contacted. If the pressure increases (from contact with the stop bolts), the poppets must be manually reset.

  If the pressure is relieved and assist is lost when the wheel is too far from the axle stop bolts, refer to the applicable section in this manual for gear-specific information.
- After poppet replacement or adjustment, test again for correct poppet relief function and record the new pressure.

8.4 Check for normal hissing sound at full turn.

NOTE: Noise from the power steering system does not necessarily mean there is a problem. Some noises are normal and are the result of proper operation.

See **Table 4** for possible causes and remedies for common noises associated with the power steering system and power steering pump.

8.5 Check for abnormal power steering noise.

Listen for a hissing sound at less than full turn. If a hissing sound is heard, check the steering gear poppet and the axle stop adjustment.

NOTICE

If the temperature exceeds 250°F (121°C), damage to hoses, seals, and other components may result if the vehicle continues to operate at excessive steering system temperatures. If this temperature is exceeded, stop the test and record the last noted temperature on STI-492.

9. Test the system operating temperature.

- Run the engine at governed speed.
- Observe the power steering fluid temperature until it stabilizes.
- Record the power steering fluid temperature in 10-minute intervals until 40 minutes have passed.
- If the temperature does not exceed 250°F (121°C) during the test, excessive heat due to system components is probably not the cause of the complaint. The system may still experience overheating due to driving and load conditions.

  If the temperature exceeds 250°F (121°C), excessive steering system back pressure or excessive pump flow may be the cause of the high temperature problem. If system back pressure or restriction values found in substeps 5.3 and 5.4 above were close to the maximum allowable, complete step 5 again. If steering pump flow and relief pressures found in step 6 above were close to the maximum allowable, complete step 6 again.
- If excessive heat continues to be a problem, a cooler may need to be added to the system.

Power Steering System Noise	
Noise	**Remedy**
Growling or other abnormal steering noise	Check the fluid level. Check for air bubbles and foam. Check for hose and fitting leaks. If there is air in the fluid, check for inlet tube and hose leaks. Correct all leaks.
A change from the usual pump sound	Check the steering fluid reservoir for air bubbles and foam. If there is air in the fluid, check for inlet tube and hose leaks. Correct all leaks.
Clicking noise during a turn	Check for loose steering components. Tighten any loose steering components. Check the front suspension for insufficient spring pin shims. Add front spring pin shims if needed.
Hissing when the steering wheel is at or near full turn	This is normal; no action is needed.
Steering Pump intake line is plugged	Drain the system. Clear the intake line if needed. Fill the system.
Air leak at the pump or reservoir connections, fittings, or shaft seal	Check all the connections by pouring power steering fluid over them, and listening for a reduction in sound. Tighten all connections as needed.
Pump input shaft is misaligned	Replace the pump.

Troubleshooting Procedures

Power Steering System Analyzer Setup

The hydraulic power steering system is tested with a Power Steering System Analyzer (PSSA), and with the hydraulic fluid at operating temperature. The PSSA and adaptor kit are available from SPX Kent-Moore.

A PSSA is a combination of a flow meter, a shutoff valve, and a high-pressure gauge. See **Fig. 3**. The PSSA will allow you to measure flow and pressure, and provide a load on the pump in the hydraulic lines of the steering system.

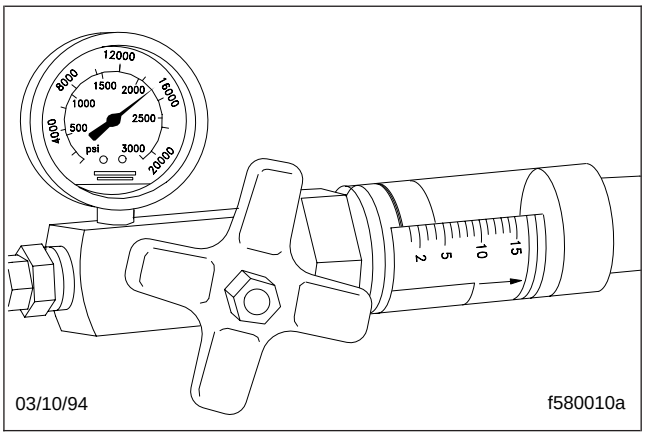

Fig. 3, Power Steering System Analyzer

1. Install a PSSA between the pump high-pressure line and the steering gear.
2. Fill and bleed the steering system as needed.

NOTICE

Do not leave the load valve fully closed for longer than five seconds. Doing so could damage the power steering system.

3. Run the engine at idle.
4. Partially close the load valve on the PSSA until the pressure gauge reads 1000 psi (6895 kPa).
5. Open the valve when the fluid temperature reaches about 180°F (82°C).

Internal Leakage Test Setup, TRW Steering Gears With an Internal PRV

Select TRW steering gears are equipped with an internal PRV that limits maximum supply pressure to protect the steering gear. These gears cannot be tested for internal leakage using the standard procedure. The pump output must be limited to prevent excessive pressure from damaging the gear, and the internal PRV passage must be blocked to direct oil flow through the gear.

Use PartsPro® to determine if a specific TRW steering gear is equipped with an internal PRV, which will be listed as a serviceable part under module 536.

If your TRW steering gear has an internal PRV, complete the following steps to set up the necessary internal leakage test components. See **Table 5** for a list of required leakage test components. The plumbing fittings and hose part numbers are recommended, but may be replaced with identical parts from other suppliers, if necessary.

The ThyssenKrupp rack and pinion steering gear is also equipped with an internal PRV, but cannot currently be tested for internal leakage.

IMPORTANT: The front wheels must be raised or on turnplates during this procedure.

1. Turn the engine off. Remove the relief valve cap, O-ring, and relief valve from the steering gear. See **Fig. 4**.
2. Install the relief valve plug, J-37130, in the internal PRV hole. Install the relief valve cap and O-ring over the plug.
3. Assemble the relief valve cartridge body, relief valve, and tee fittings as shown in **Fig. 4**.
4. Install the PSSA and other test components as shown in **Fig. 4**.
5. Open the external relief valve (**Fig. 4**, Item 15) on the relief valve cartridge. Ensure the PSSA shutoff valve is fully open.
6. Raise the front wheels off the ground and turn the steering wheel to the right and left full-lock positions five times to bleed air from the system.
7. Start the engine and bleed the remaining air out of the system by continuing to turn the wheel from side to side.

NOTICE

Do not leave the PSSA shutoff valve fully closed for longer than five seconds. Doing so could damage the power steering system.

8. With the engine on, close the shutoff valve on the PSSA.
9. Set the system relief pressure by closing the external relief valve (**Fig. 4**, Item 15) until the gauge on the PSSA reaches 2,000 psi (13 790 kPa), then fully open the shutoff valve on the PSSA.
10. Continue with the steering gear internal leakage test (step 9 of the **Troubleshooting Steps** heading above).

Principles of Operation

The rack and pinion steering system is mounted to the front axle with two brackets, and connected by outer tie rods to the tie rod arms that pivot the wheels. See **Fig. 1**. When the steering wheel is turned, the intermediate steering shaft turns the input shaft, rotating the torsion bar and pinion gear within the rack housing. When the torsion bar twists, power steering fluid provides power assist, via a rack-mounted piston, to the pinion gear, moving the rack. The rack, with a tie rod at each end, then moves the tie rod arms.

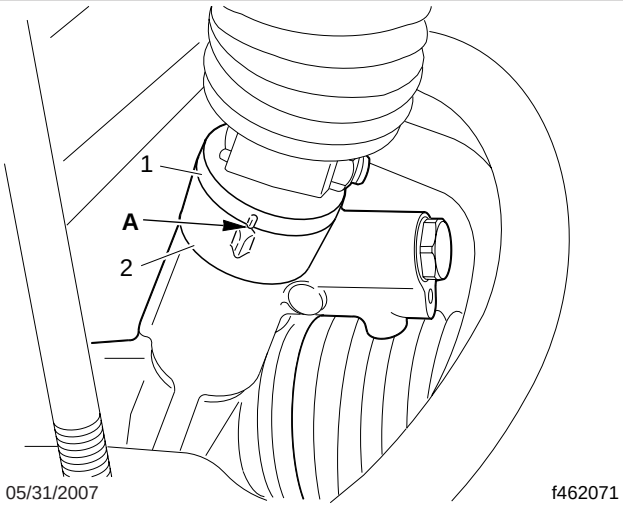
Alignment

Rack and pinion steering gears require a different alignment procedure from integral (recirculating ball) steering gears, and can only be aligned using a calibrated, computerized, multiwheel alignment tool, operated by a certified service technician.

1. Complete the setup needed for the computerized alignment tool (identical to the setup for integral steering gears).
2. With the wheels on turnplates, center the rack travel by aligning the timing pointers on the input shaft seal cover and the input shaft housing. (**Fig. 1**).



A. Align the pointers.

1. Input Shaft Seal Cover
2. Input Shaft Housing

Fig. 1, Rack and Pinion Pointer Alignment

3. Whenever the computerized alignment program requires that the steering wheel be pointed straight ahead, the steering rack on-center pointers should be aligned.

NOTE: Do not clock the steering wheel; it is clocked at the end of the procedure.

4. Adjust each tie rod length to obtain the specified toe-in dimension, as follows.

   4.1 Loosen the driver-side tie rod jam nut, see **Fig. 2**. If necessary, hold the inner tie rod in place with a backup wrench on the inner tie rod flat (**Fig. 2**, Item 3).

   4.2 With the gear on-center, place a wrench on the driver-side inner tie rod flat and align the left tire by rotating the inner tie rod.

   Total left side toe-in should be between 0 and 0.085 degrees.

   4.3 Tighten the tie rod jam nut 285 to 305 lbf·ft (386 to 413 N·m).

   4.4 Loosen the passenger-side tie rod clamp nut, see **Fig. 2**.

   4.5 With the gear on-center, place a wrench on the passenger-side inner tie rod flat and align the right tire by rotating the inner tie rod.

   Total right side toe-in should be between 0 and 0.085 degrees.

   4.6 Tighten the tie rod clamp nut 30 to 36 lbf·ft (41 to 48 N·m).

IMPORTANT: Total toe-in for both sides should be as close to 0 degrees as possible, and no greater than 0.17 degrees.

NOTICE

Maximum wheel cut should not exceed 46 degrees. Excessive wheel cut may damage the inner tie rod.

5. Turn the wheels as far right and left as possible to check for interference between the wheels/tires and other components. There must be at least 1/2 inch (13 mm) clearance from any fixed object, and 3/4 inch (19 mm) from any moving object.

IMPORTANT: The spline/pinch bolt connections between the steering gear and the last U-joint in the column fit in only one position, so reclocking the splined connections after alignment is not possible.

6. Make sure that the steering wheel is within 10 degrees of center as shown in **Fig. 3**. If not, remove and center the wheel, as follows.

   6.1 *If the vehicle has an airbag, deactivate and remove the airbag module according*

to the instructions in **Section 46.07**. If the vehicle does not have an airbag, remove the horn button by prying it out around the edge.

6.2 Loosen the nut that holds the steering wheel on the steering column, but leave it on the shaft until the wheel has been released from the tapered fit.

6.3 Remove the wheel from the tapered fit by striking it upward from below, at the rim/spoke intersections, with both hands.

6.4 Remove and discard the steering wheel nut, and install and center the steering wheel.

6.5 Install a new steering wheel nut and tighten it 33 to 41 lbf·ft (45 to 55 N·m).

6.6 *If the vehicle has an airbag, install and reactivate the airbag according to the instructions in* **Section 46.07**. If the vehicle does not have an airbag, install the horn button.

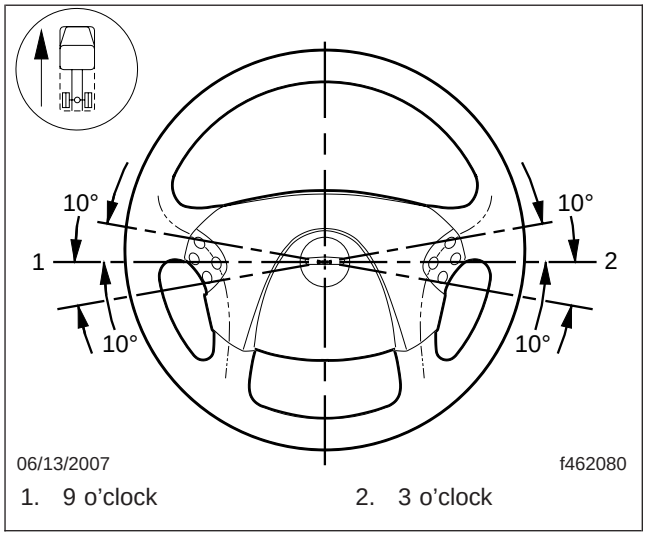

Fig. 3, Steering Wheel Centered

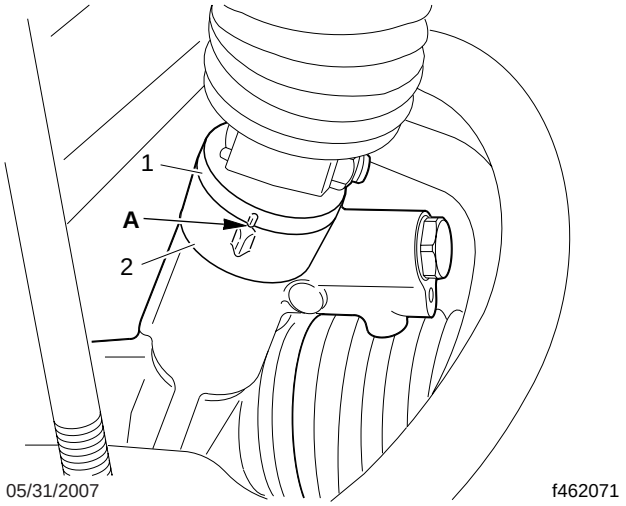
Removal

1. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where the work is to be done.
2. Turn off the engine, apply the parking brakes, chock the tires, and open the hood.
3. Clean all fittings and hose connections on the steering gear until they are free of dirt.
4. While holding the power steering fluid line fittings in place with a backup wrench, disconnect the fluid lines from the steering gear. Plug the lines and the fittings to keep out dirt and prevent fluid leakage.
5. Remove and discard the cotter pins and castellated nuts from the outer tie rods.

   Disconnect the outer tie rods from the tie rod arms.
6. Disconnect the end yoke of the steering I-shaft from the rack and pinion input shaft. Discard the pinch bolt and nut.
7. Remove and discard the steering gear mounting bolts and nuts that connect the rack and pinion to the axle steering gear brackets, then remove the gear.

Installation

1. Install the steering gear on the axle steering gear brackets, using new mounting bolts and nuts. Tighten the fasteners 202 to 256 lbf·ft (274 to 347 N·m).
2. Attach the outer tie rods of the rack and pinion gear to the tie rod arms, using new castellated nuts. Tighten the castellated nuts 240 lbf·ft (325 N·m). Continue to tighten until the the next castellated nut slot aligns with the hole in the ball stud and insert the new cotter pin.
3. Center the rack travel and align the timing pointers on the input shaft seal cover and the input shaft housing. See **Fig. 1**.
4. Using a new pinch bolt and nut, attach the steering I-shaft to the steering gear input shaft. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).



A. Align the pointers.

1. Input Shaft Seal Cover
2. Input Shaft Housing

Fig. 1, Rack and Pinion Pointer Alignment

5. Apply torque seal, OGP F900WHITE, to the exposed pinch bolt threads and nut.
6. If needed, install power steering fluid line fittings (**Fig. 2**, Item 5) on the steering gear and tighten 30 to 35 lbf·ft (41 to 47 N·m).
7. Connect the power steering fluid lines to the fittings, ensuring that the hoses do not touch the axle or each other. While holding the fittings in place with a backup wrench, tighten the pressure hose 43 to 47 lbf·ft (58 to 64 N·m) and the return hose 55 to 61 lbf·ft (75 to 83 N·m).

NOTICE

Do not loosen or tighten the hard transfer line tube fittings. Tightening the tube fittings can cause the O-ring seal to leak.

8. Fill and bleed the power steering system.

8.4 Start the engine and turn the steering wheel fully left and right several times to bleed the remaining air from the system.

8.5 If the steering system needs additional bleeding, repeat the previous substep after the fluid in the reservoir has had time to release any air.

8.6 Remove the jack stands and lower the vehicle.

9. Set the toe-in using the instructions in **Subject 100**.

Replacement

1. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where the work is to be done.
2. Turn off the engine, apply the parking brakes, chock the tires, and open the hood.
3. Clean all fittings and connections until they are free of dirt and debris.
4. While holding the fittings in place with a backup wrench, disconnect the power steering fluid lines from the steering gear. Plug the lines and the fittings to keep out dirt and prevent fluid leakage.
5. Remove and discard the pinch bolt and nut from the I-shaft end yoke, and disconnect the end yoke from the input shaft.
6. Clean the valve and input shaft seal cover until they are free of dirt and debris.
7. Work the input shaft seal cover off with a screwdriver.
8. Remove the dust cover.
9. Remove the retaining ring with retaining ring pliers.
10. Clean the area thoroughly to prevent any contaminants from entering the gear after the seal is removed.
11. Wrap the input shaft and seal area with a clean cloth to prevent fluid spray when removing the seal, then remove the input shaft seal by blowing compressed air into the outlet port. See **Fig. 1**.
12. Install the protective cap on the input shaft.
13. Apply grease, Renolit JP1619N (Mercedes-Benz DBL 6804.70), on the input shaft seal lip, then install the new seal on the input shaft.
14. Position the depth tool over the input shaft and press the seal into the housing by lightly tapping on the tool with a rubber mallet until the tool hits the upper edge of the housing. Check the position of the seal after each tap to make sure it stays level. The seal is correctly installed when it is fully under the retaining ring groove.
15. Install the retaining ring with retaining ring pliers. The ring must be seated fully in the retaining ring groove.

17. Install the dust cover, making sure the outer lip of the cover curves upward. Wipe away any excess grease.
18. Remove the protective cap from the input shaft.
19. Install the input shaft seal cover on the input shaft.
20. Using a new pinch bolt and nut, attach the steering I-shaft to the steering gear input shaft. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).
21. Apply torque seal, OGP F900WHITE, to the exposed pinch bolt threads and nut.
22. Check the power steering fluid line fittings for a torque value of 30 to 35 lbf·ft (41 to 47 N·m). Tighten them if needed.
23. Connect the power steering fluid lines to the fittings, ensuring that the hoses do not touch the axle or each other. While holding the fittings in place with a backup wrench, tighten the pressure hose 43 to 47 lbf·ft (58 to 64 N·m) and the return hose 55 to 61 lbf·ft (75 to 83 N·m).

NOTICE

Do not loosen or tighten the hard transfer line tube fittings (Fig. 1, Item 2). Tightening the tube fittings can cause the O-ring seal to leak.

24. Fill and bleed the power steering system.
    - 24.1 Raise the front wheels off the ground and support the vehicle with jack stands.
    - 24.2 Fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.

General Information

NOTE: Procedures in this section have been slightly modified from the original component manufacturer's service manual. See the manufacturer's service literature (**www.rhsheppard.com/home.htm**) for additional information.

The Sheppard HD94 integral power steering gear (see **Fig. 1**) is a full-time hydraulic steering unit that uses pressurized hydraulic fluid to help the driver turn the front wheels. The HD94 is designed for vehicles with a front axle capacity between 10,000 and 14,600 pounds (4545 and 6635 kg). The Sheppard HD94 gear can steer a vehicle within this front axle weight rating through a turn at low speed and engine idle.

The pressure required for the steering gear to steer the vehicle is created by the power steering pump to overcome resistance at the steered wheels. The maximum operating pressure for the Sheppard HD94 steering gear is 2683 psi (18 499 kPa). As the steering wheel is turned faster or slower, more or less fluid is required by the gear.

Principles of Operation

When the engine is running, a constant low-pressure flow of hydraulic fluid through the steering gear allows for instant response as the steering wheel is turned. The constant flow also helps to absorb road shock and eliminate steering wheel kick.

When the driver turns the steering wheel, the force is transmitted to the steering gear input shaft via the steering driveline. The input shaft is connected to a torsion bar within the steering gear. As the input shaft turns, the twisting force on the torsion bar turns the rotary valve, which causes the fluid pressure to build up at one end of the piston. The fluid pressure buildup forces the piston to move inside the bore of the gear housing. The rack teeth on the piston mesh with the teeth on the sector shaft so that the sector shaft rotates when the piston moves. As the sector shaft turns, it moves the pitman arm. The pitman arm connects to the steering linkage, which turns the wheels.

The Sheppard HD94 steering gear is equipped with two automatic relief plungers, one located in the cylinder head and one in the bearing cap cover near the input shaft. The plungers reduce system temperature and excessive stress on the mechanical components of the steering system by preventing the system from reaching full pump pressure when the axle stops contact the axle.

Removal

1. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the place where the work is to be done. Shut down the engine, apply the parking brakes, and chock the tires.

NOTICE

Do not turn the steering wheel or the steering shaft more than a half turn (except for alignment purposes) during the removal and installation procedures. Doing so may damage the clockspring in a vehicle equipped with an air bag.

2. Clean all outside dirt from around the fittings and hose connections.
3. Drain the power steering system. Disconnect all hydraulic lines from the gear, marking the lines for later reference during installation. Seal the lines and the fittings to keep dirt out.
4. Disconnect the pitman arm from the steering gear. For instructions, see **Subject 110**.
5. Disconnect the steering driveline from the steering gear input shaft, as follows.

   5.1 Remove and discard the pinch bolt and nut from the lower end yoke of the steering driveline yoke.

NOTICE

Do not pound the U-joint or input shaft coupling on or off the input shaft. Internal damage to the steering gear can result.

   5.2 Remove the steering driveline yoke from the steering gear input shaft.

WARNING

The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

6. Remove the fasteners that attach the steering gear to the frame rail. Remove the steering gear and place it on a clean surface.

Installation

1. Align the holes in the steering gear housing with the holes in the frame rail. See **Fig. 1**. Place a washer over each bolt and install the three bolts. Install a washer and nut on the end of each bolt and tighten the nuts 388 lbf·ft (526 N·m).

2. Install the pitman arm on the steering gear. For instructions, see **Subject 110**.
3. Position the steering wheel so that it is within ±10 degrees of center as shown in **Fig. 2**.
4. Connect the steering driveline to the steering gear input shaft, as follows.

   4.1 Clean the steering gear input shaft and the inside of the steering driveline yoke.

NOTICE

Do not turn the steering wheel at this time. Doing so can cause air to enter the system, possibly causing an unexpected loss of power steering assist.

   4.2 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut to one of the following torque specs.

4.3 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate that the nut has been properly tightened.

5. Connect the hydraulic lines to the gear as marked earlier. Tighten the nut on each fitting finger-tight. Then with a wrench, tighten the nut until there is firm resistance. Tighten the nut one-sixth turn more.

   Apply torque seal, OGP F900WHITE, to the exposed bolt threads and the nut to indicate that the nut has been properly tightened.

6. Fill and bleed the system. For instructions, see **Subject 150**.
7. Adjust the automatic relief plungers. For instructions, see **Subject 130**.

Removal

NOTE: This procedure is for removing the pitman arm from the steering gear. If replacement of the pitman arm is required, the pitman arm must also be removed from the drag link.

NOTE: The pitman arm is easiest to remove while the steering gear is installed on the vehicle.

1. Shut down the engine, apply the parking brakes, and chock the tires.

⚠ DANGER

Do not use a hammer or apply heat to the pitman arm to remove it. Doing so could damage the sector shaft, the pitman arm, or the seals, and possibly lead to loss of vehicle control resulting in death or serious personal injury.

IMPORTANT: The pitman arm has alignment tabs, while the retainer has restraining tabs. Do not bend the alignment tabs out of the pitman arm.

2. Using a punch, bend the restraining tabs out of the retainer.
3. Using an Allen drive socket and an impact wrench, remove the retainer. If the retainer is undamaged, it may be reused. Otherwise, replace the retainer.
4. Lubricate the end of the sector shaft with clean chassis lube. Failure to lubricate the face of the retainer will cause difficulty in removing the pitman arm.
5. Slide the pitman arm puller over the pitman arm. Align the hole in the puller with the sector shaft and washer.
6. Insert the Allen drive socket through the puller and into the retainer socket. Use an impact wrench to back off the retainer. The retainer will act as a jack screw to disconnect the pitman arm from the steering gear.

Installation

⚠ WARNING

If the pitman arm is not installed to the proper specifications, it could come loose, causing an accident that could result in death or severe personal injury.

1. Align the timing marks on the pitman arm with the timing marks on the sector shaft. See **Fig. 1**. Install the pitman arm on the sector shaft.

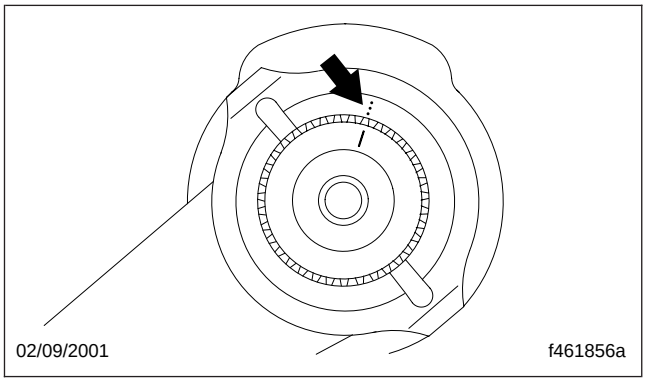

Fig. 1, Timing Mark Alignment

2. Install the pitman arm retainer on the sector shaft. Be sure to align the restraining tabs of the retainer with the notches of the pitman arm. Coat the retainer threads with anti-seize compound. If using a new retainer, apply a coat of anti-seize to both sides of the friction washer.
3. Tighten the retainer 350 lbf·ft (475 N·m).

⚠ WARNING

Do not back off the torque value to align the tabs. If the pitman arm is not installed to the proper specifications, it could come loose, causing an accident that could result in death or severe personal injury.

4. Continue tightening the retainer past the specified value until two of the notches in the retainer align with the tabs of the washer.

Pitman Arm Removal and Installation

WARNING

Once the retainer is tightened to specifications and locked in place, do not retighten the retainer. Constant tightening of the retainer may cause the pitman arm to come loose, causing an accident that could result in death or severe personal injury.

5. Using a punch and hammer, bend the restraining tabs of the washer into the notches on the retainer. See **Fig. 2**. Apply torque seal, OGP F900WHITE, to the tabs.

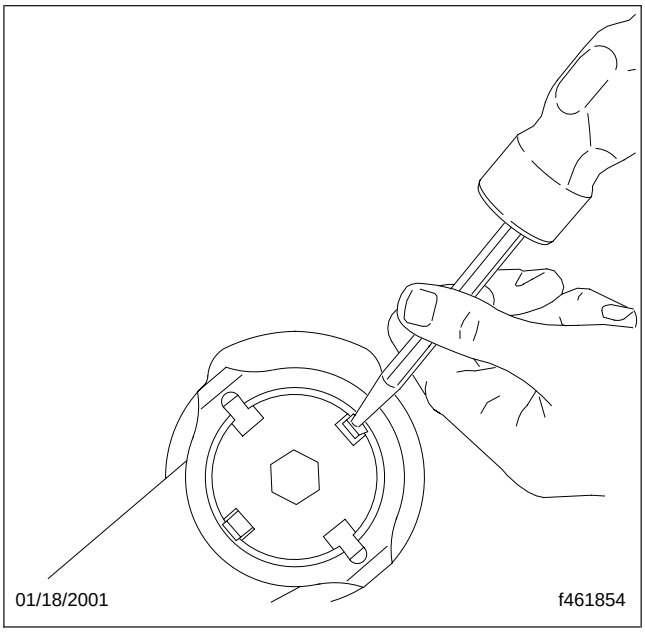

Fig. 2, Bending the Restraining Tabs

6. Reset the automatic relief plungers. For instructions, see **Subject 130**.

Input Shaft Seal Replacement

1. Shut down the engine, apply the parking brakes, and chock the tires.

IMPORTANT: Do not remove the steering gear for this procedure.

2. Disconnect the steering driveline from the steering gear input shaft.

   2.1 Remove and discard the pinch bolt and nut from the lower end yoke of the steering driveline yoke.

NOTICE

Do not pound the U-joint or input shaft coupling on or off the input shaft. Internal damage to the steering gear can result.

   2.2 Remove the steering driveline yoke from the steering gear input shaft. If necessary, secure the steering shaft so it will not interfere with your work.

NOTICE

Do not turn the input shaft during repairs. Damage to the steering gear will result.

3. Place a drain pan under the power steering gear. Draining the system is not necessary, but some fluid will be lost.
4. Remove the rubber boot from the input shaft.
5. Clean all outside dirt from around the input shaft.
6. Remove the four capscrews that attach the bearing cap cover to the bearing cap, and remove the bearing cap cover.

IMPORTANT: The thrustwasher may stick to the bearing cap cover. If it does, reinstall the thrustwasher on the bearing cap before proceeding.

7. Place the bearing cap cover on a clean work surface. Pry the salt seal out of the bearing cap cover, and discard the seal. See **Fig. 1**.
8. Tap the input (high pressure) seal out of the bearing cap cover using a suitable size socket or seal driver, and discard the seal; see **Fig. 2**.
9. Remove the O-ring from the bearing cap cover, and discard the O-ring.

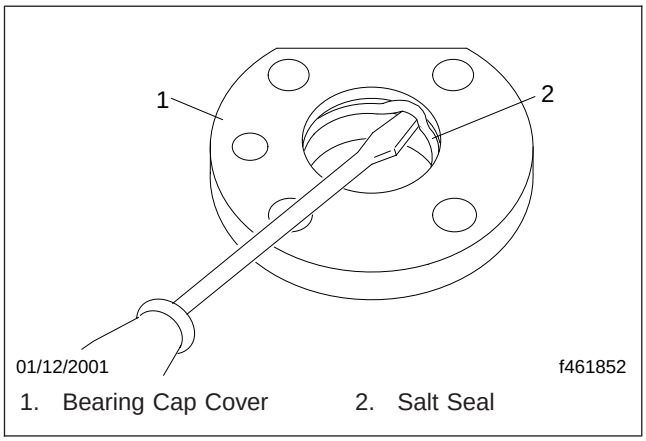

Fig. 1, Salt Seal Removal

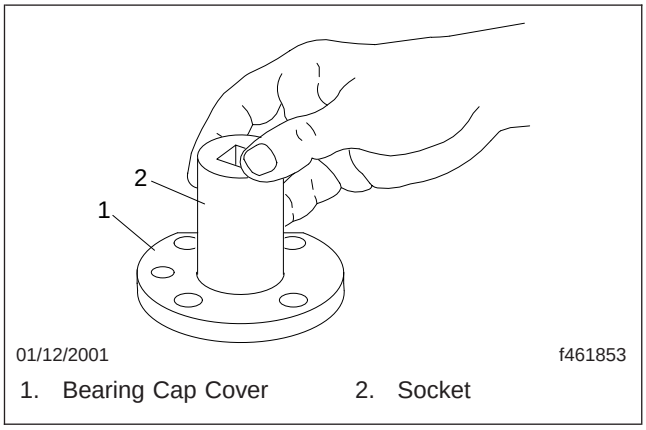

Fig. 2, Input Seal Removal

10. Clean the bearing cap cover with a suitable solvent.
11. Place the bearing cap cover face down on a clean work surface. Using a suitable size driver and an arbor press, tap the new input seal into the bearing cap cover with the gold spring facing the bottom of the cover. Coat the outside diameter of the input seal with clean chassis lube.
12. With the lip facing out, press a new salt seal into the bearing cap cover until it is flush with the face of the cover. See **Fig. 3**. Make sure the seal lip, or silver spring, is facing the top of the cover.
13. Install a new O-ring onto the outside of the cover. Tap the cover washer, if equipped, into the cover.
14. Fill the area between the seals with clean chassis grease. Lubricate the O-ring and seal lips

Seal Replacement

with grease. If the cover has a grease fitting, remove it and fill the hole with silicone sealant.

15. Tape the input shaft splines before installing the bearing cap cover, to prevent seal damage.
16. Using four capscrews, attach the bearing cap cover to the bearing cap, making sure not to roll the lip of the input seal. Align the hole in the bearing cap cover with the relief plunger hole in the bearing cap, and tighten the capscrews 53 to 64 lbf·ft (72 to 87 N·m).

NOTE: Two rubber boots are included in the replacement kit. Choose the boot that will provide the tightest fit on the input shaft.

17. Install a rubber boot over the input shaft. Make sure the boot is below the splines and contacts the bearing cap cover when installed.
18. Remove the tape from the input shaft splines.
19. Slide the steering driveline lower end yoke onto the input shaft and install a new M10 x 1.25 pinch bolt and nut. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

20. If needed, fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
21. Start the engine and check for leaks.

Sector Shaft Seal Replacement

1. Shut down the engine, apply the parking brakes, and chock the tires.

NOTE: Removal of the power steering gear is not necessary to perform this procedure. Partial disassembly of the steering gear is required to replace the sector shaft seals. Mark the sector shaft timing if a new sector shaft is being installed.

2. Disconnect the pitman arm from the steering gear. For instructions, see **Subject 110**.

NOTICE

Do not turn the steering wheel or the steering shaft during this procedure. Turning either the steering wheel or steering shaft will result in steering gear damage.

3. Start the engine and allow the pressure in the steering system to push the sector shaft cover out of the housing. Shut down the engine when the cover exits the housing.
4. Remove and discard the rubber V-boot on the sector shaft.
5. If the snap ring cover is equipped with a protective cap, pry the cap out of the bore with a screwdriver. Do not damage the housing.

IMPORTANT: When working with snap ring covers, remove the factory-installed silicone protectant from the snap ring and carefully clean the cover area before disassembly.

6. Remove the adhesive plastic dust cover, if equipped, from the back of the housing. Clean any paint or corrosion from the housing so that the cover slides freely out of the housing.
7. Remove the snap ring from the housing.

NOTE: A slide hammer may be used to remove the sector shaft.

8. Remove the sector shaft cover and sector shaft from the housing. Separate the cover from the sector shaft.
9. Using a seal pick, pry the excluder seal from the sector shaft cover. Remove the two-piece L-seal from the housing, if equipped, or remove the O-ring from the sector shaft cover. Discard all seals.

IMPORTANT: The sector shaft oil seals are two-piece seals. It is necessary to bend the seals to install them. Once a seal is installed, work it into place with your fingers or a blunt seal pick until it is properly seated. Push only on the body of the seal and not on the seal lip. Damage to the seal lip will cause an oil leak. The seals should look perfectly round when installed.

10. Install one new oil seal into the steering gear housing, and one new oil seal into the sector shaft cover. When properly fitted, the black lip of the seals will face the inside of the gear.

    Lubricate the seals with clean chassis lube.

11. Install the two-piece L-seal as follows.

    11.1 Insert the black pressure seal into the housing with the L-side facing out.

    11.2 Insert the backup ring into the L-side of the pressure seal. When assembled correctly, the back-up ring will be on the side of the pressure seal facing out.

    11.3 Apply a coat of clean chassis lube to the L-seal.

12. Apply a coat of clean chassis lube to the lip of the excluder seal, if equipped, and install the excluder seal over the sector shaft splines and into the seal groove of the cover. See **Fig. 4**.
13. Install the sector shaft in the housing. Make sure that the timing mark on the sector shaft is placed between the two timing marks on the piston. See **Fig. 5**. It may be necessary to tap on the sector shaft to properly seat it into the housing.

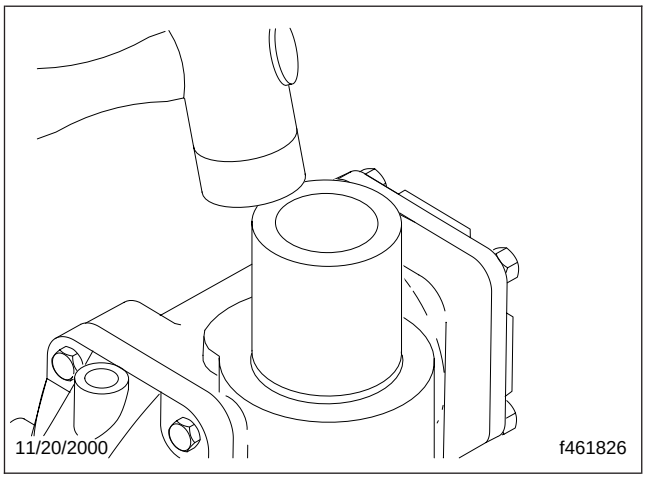

Fig. 4, Excluder Seal Installation

Fig. 5, Timing Mark Alignment

14. Install the sector shaft cover over the sector shaft. When properly installed, the sector shaft cover should be flush with or below the snap ring groove in the housing.

⚠ CAUTION

When installing a snap-ring-style cover, the cover must be flush or below the groove in the hous-

ing. Improper installation could result in separation of the cover, possibly resulting in personal injury.

15. Install the snap ring, or install the cover retaining bolts or retaining clips.

    Tighten retaining bolts 72 to 87 lbf·ft (98 to 118 N·m). Tighten retaining clips 31 to 38 lbf·ft (42 to 52 N·m).

16. Install the snap ring protective cover into the housing, over the snap ring, by lightly tapping on the outside diameter of the cover until it seats in the bore.

17. Pack the rubber V-boot with clean chassis lube, and slide the V-boot over the sector shaft splines until the lip contacts the sector shaft cover. If installing a boot with one lip larger than the other, ensure that the larger lip is facing the pitman arm. Clean all excess grease from the sector shaft splines.

18. Clean the housing with solvent, apply a small bead of RTV silicone on the edge of the frame-side dust cover disk, and apply the disk over the sector shaft bore.

19. Install the pitman arm. For instructions, see **Subject 110**.

20. Fill and bleed the system. For instructions, see **Subject 150**.

Automatic Relief Plunger Adjustment and Setting

Relief plungers prevent the power steering pump from operating at maximum relief pressure at the end of steering travel. When properly adjusted, the relief plungers reduce system temperature and excessive stress on the mechanical components of the steering system by preventing the system from reaching full pump pressure when the axle stops contact the axles. A relief plunger is located in each end of the steering gear. One plunger is located in a small hole in the bearing cap cover next to the input shaft, while the other is located near the cylinder head.

NOTICE

Failure to set or adjust the automatic relief plungers could result in damage to the steering system. Relief plungers must be set or adjusted whenever a steering gear is replaced.

Adjusting Automatic Relief Plungers

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the side of the housing. See **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps over the plunger bosses.

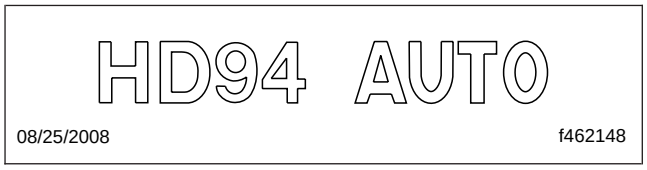

Fig. 1, Automatic Relief Plunger Identifier

3. Remove the plastic caps from both plunger bosses.

NOTICE

Make sure there are no sharp edges on the punch that could damage the bore. Take care when using the punch to ensure that the relief plunger bore is not damaged. If the relief plunger bore is damaged, a leak may occur.

4. Using a 1/4-inch punch and ball-peen hammer, carefully drive the relief plunger in until it bottoms in the bore. Repeat this procedure for the other relief plunger.
5. Install the plastic caps on the plunger bosses.
6. Set the automatic relief plungers using the procedure in "Setting Automatic Relief Plungers."

Setting Automatic Relief Plungers

NOTE: Check that the axle stops are set correctly before setting the relief plungers.

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the side of the housing. See **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps over the plunger bosses.
3. Using a jack, raise the vehicle until the front wheels are off the ground.
4. Start the engine and let it idle. Ensure the axle stops are set for maximum wheel cut with a minimum of 1 inch (25 mm) clearance between the tire and any part of the chassis.
5. Turn the wheels from side to side until the axle stops contact the axle. This allows the piston in the steering gear to contact the automatic plunger assemblies and push them back to their set positions. The axle stops must make contact with the axle.

NOTE: As the tires reach the end of travel, you will feel the piston contact the relief plunger. Continue turning the tires until the spindle reaches the axle stop bolt.

6. Return the tires to the straight-ahead position and lower the vehicle until the tires contact the ground.
7. Turn the steering wheel to a full-lock position in both directions, checking for chassis flexion when the axle stops contact the axle. If the chassis flexes, adjust the automatic relief plungers using the procedure in "Adjusting Automatic Relief Plungers."

Under normal use, automatic relief plungers do not need regular maintenance. The automatic relief plunger is serviceable only as a kit and is only required if a leak is present. See **Specifications 400** for part numbers. Follow the appropriate procedure for the relief plunger in need of repair.

Cylinder Head Automatic Relief Plunger Repair

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the housing; see **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps on the plunger bosses.

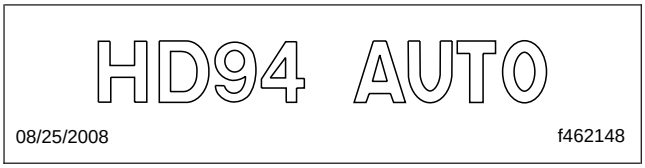

Fig. 1, Automatic Relief Plunger Identifier

3. Place a drain pan under the steering gear.
4. Remove the plunger cartridge from the cylinder head.
5. Remove the plastic plug from the plunger boss.

NOTICE

When driving the relief plunger assembly, do not allow the 1/4-inch punch to contact the bore, and do not hit the plunger with excessive force. Failure to follow these directions could result in damage to the steering gear or relief plunger assembly.

6. Place the cartridge in a vise. Using a 1/4-inch punch and hammer, carefully drive the relief plunger assembly in until it bottoms in the bore. The spring pin, flange, and plunger body should now be accessible for repair.

NOTICE

Do not allow the screwdriver bit to slip off the plunger body. Damage to the bore could result.

NOTE: The relief plunger flange is held in place with patch lock, and the threads are staked at the factory. It will require approximately 15 to 20 lbf·in (170 to 225 N·cm) to remove the flange.

7. Carefully insert a screwdriver bit (mounted in a ratchet) into the plunger bore to hold the slotted head of the relief plunger body in place. Using an open-end wrench to hold the flange across the flat sides, carefully turn the flange to remove it from the plunger body; see **Fig. 2**. Discard the flange.

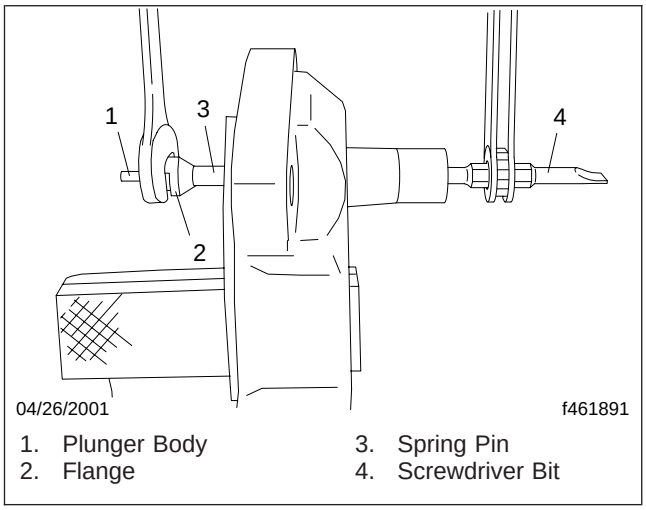

Fig. 2, Flange Removal

8. Remove the plunger body from the spring pin and discard the plunger body. It may be necessary to tap the plunger body to remove it from the spring pin. Use of a 1/8-inch pin punch is recommended.

IMPORTANT: Check the plunger bore for nicks or gouges before installing the plunger assembly. Be careful not to introduce dirt or contaminants in the plunger bore when reassembling.

9. Cover the O-ring on the new plunger assembly with a light coat of grease. Install the plunger body through the spring pin; see **Fig. 3**.

⚠ WARNING

The flange must contact the spring pin. If it does not, a leak or steering gear damage may result. This could cause steering failure, possibly resulting in personal injury or property damage.

Automatic Relief Plunger Repair

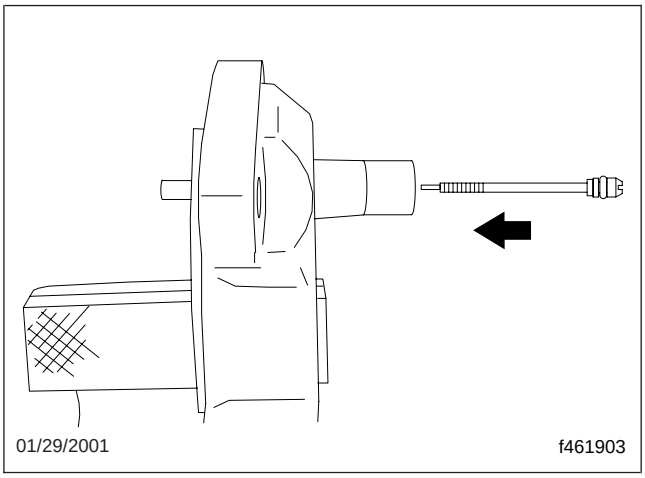

Fig. 3, Plunger Body Installation

10. Use a screwdriver bit and ratchet to hold the plunger body in place. Using an open-end wrench, install the flange on the plunger body until the flange contacts the spring pin.
11. Install the plunger cartridge in the cylinder head. Tighten the capscrews 30 to 50 lbf·ft (41 to 68 N·m).
12. Install the plastic plug on the plunger boss.

WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

13. If needed, fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
14. Start the engine and check for leaks.
15. Set the automatic relief plungers. For instructions, see **Subject 130**.

Bearing Cap Automatic Relief Plunger Repair

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Verify that the steering gear has automatic relief plungers. Steering gears with automatic relief plungers will have the word AUTO cast into the housing; see **Fig. 1**. Steering gears with automatic relief plungers also have plastic caps on the plunger boss.
3. Place a drain pan under the steering gear.
4. Mark the bearing cap and steering gear housing for reassembly.
5. Disconnect the steering driveline from the steering gear input shaft. For instructions, see **Subject 100**.
6. Remove the plastic plug from the plunger boss.

NOTICE

When driving the relief plunger assembly, do not allow the 1/4-inch punch to contact the bore, and do not hit the plunger with excessive force. Failure to follow these directions could result in damage to the steering gear or relief plunger assembly.

7. Using a 1/4-inch punch and hammer, carefully drive the relief plunger assembly in until it bottoms in the bore.
8. Remove the four capscrews that attach the bearing cap to the steering gear housing.

NOTICE

Do not force the input shaft when turning it out of the housing. The shaft could bind and steering damage could result.

9. Separate the bearing cap assembly from the housing by turning the input shaft out of the housing. Turn the shaft until it stops.

NOTICE

Do not allow the screwdriver bit to slip off the plunger body. Damage to the bore could result.

10. Carefully insert a screwdriver bit (mounted in a ratchet) into the plunger bore to hold the slotted head of the relief plunger body in place. Using an open-end wrench to hold the flange across the flat sides, carefully turn the flange to remove it from the plunger body; see **Fig. 4**. Discard the flange.

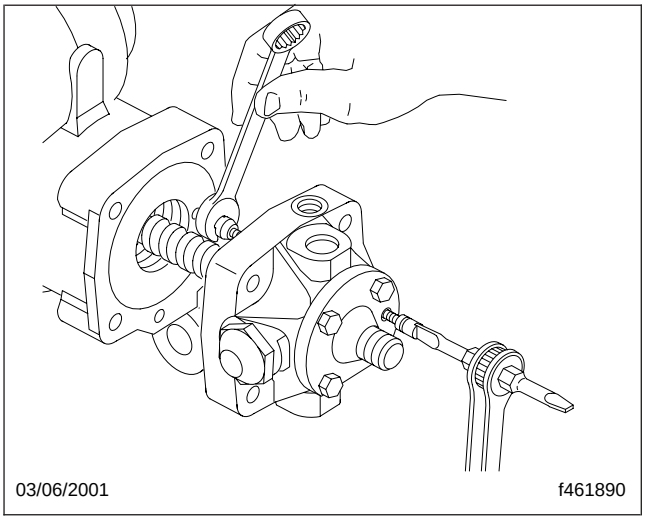

Fig. 4, Flange Removal

NOTE: The automatic relief plunger flange is held in place with patch lock, and the threads are staked at the factory. It will require approximately 15 to 20 lbf·in (170 to 225 N·cm) to remove the flange.

11. Remove the plunger body from the spring pin and discard it. It may be necessary to tap the plunger body to remove it from the spring pin. Use of a 1/8-inch pin punch is recommended.

IMPORTANT: Check the plunger bore for nicks or gouges before installing the plunger assembly. Be careful not to introduce dirt or contaminants into the plunger bore when reassembling.

12. Cover the O-ring on the new plunger assembly with a light coat of grease. Install the plunger body through the spring pin; see **Fig. 5**.

⚠ WARNING

The flange must contact the spring pin. If it does not, a leak or steering gear damage may result. This could cause steering failure, possibly resulting in personal injury or property damage.

13. Use a screwdriver bit and ratchet to hold the plunger body in place. Using an open-end wrench, install the flange on the plunger body until the flange contacts the spring pin.
14. Align the marks on the bearing cap with the marks on the steering gear housing, and install the bearing cap on the housing using the bearing cap capscrews. Tighten the capscrews 114 to 140 lbf·ft (154 to 190 N·m).
15. Install the plastic cap on the plunger boss.
16. Connect the steering driveline to the steering input shaft. For instructions, see **Subject 100**.

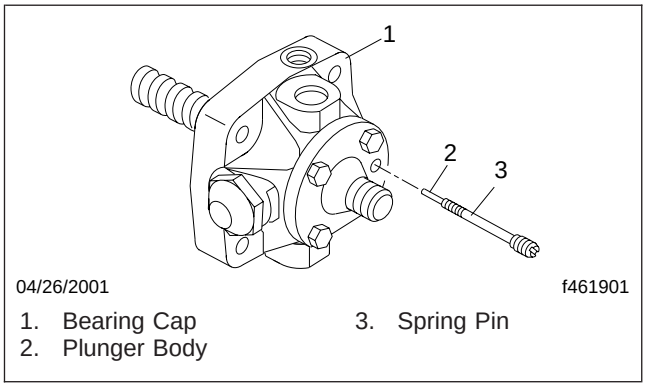

Fig. 5, Plunger Body Installation

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

17. If needed, fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
18. Start the engine and check for leaks.
19. Set the automatic relief plungers. For instructions, see **Subject 130**.

Most single steering gears can be bled simply by turning the steering wheel all the way from one axle stop to the other. Some gears, however, require bleeding through a bleeder screw.

Typical Steering Gear

1. Shut down the engine and apply the parking brakes.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

2. Fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
3. With the weight of the vehicle on the ground, start the engine and allow it idle.
4. Turn the wheels to full left. Hold the wheel in pressure for about five seconds once you reach an axle lock.
5. Turn the wheels to full right. Hold the wheel in pressure for about five seconds once you reach an axle lock.
6. Repeat steps 4 and 5 three more times.

Steering Gear Equipped With a Bleeder Plug

NOTE: This procedure requires two technicians.

1. Shut down the engine, apply the parking brakes, and chock the tires.

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

2. Fill the power steering reservoir with automatic transmission fluid that meets Dexron III or TES-389 specifications.
3. Find the bleeder plug on the sector shaft bore above the pitman arm.
4. Find and remove the tape covering the 1/8-inch Allen bleeder screw in the center of the head.
5. Start the engine and allow it to idle.
6. Turn the wheels to full left. Using a 1/8-inch Allen wrench, open the bleeder screw about four turns.

IMPORTANT: Do not remove the bleeder screw from the bleeder plug. A check ball behind the screw may be lost.

7. With the bleeder screw open, turn the wheels to full right. At the full right turn position, close the bleeder screw.

IMPORTANT: When the bleeder screw is open, turn the steering wheel to the right only. Turning the steering wheel to the left with the bleeder screw open will introduce additional air into the system.

8. Turn the steering wheel back to full left and repeat the two steps above, until no aeration is found in the bled oil.
9. Check the fluid level in the power steering reservoir and fill if necessary.

Specifications

⚠ WARNING

Fill the power steering system with only approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. Leaks could result in loss of power steering assist and spillage on the roadway, which could cause personal injury or property damage.

Sheppard HD94 power steering gears use ATF fluid that meets Dexron III or TES-389 specifications.

General Description and Principles of Operation

The fuel system delivers fuel to the engine. It consists of the engine fuel system components, the fuel tanks and tank mounting components, and the fuel lines and shut-off valves.

The engine fuel system components include fuel filters, injectors, fuel transfer pumps, and a fuel governor. For service and maintenance procedures, refer to the applicable engine manufacturer's service and maintenance manuals.

The fuel tanks, which provide a clean storage area for fuel, are held in place by metal straps and brackets that transfer the load to the vehicle frame. A cab access step assembly or an air fairing attaches to the fuel tank straps and brackets.

Flexible, reinforced wire-braid hoses (fuel lines) bring fuel from the tank to the engine, and return surplus fuel from the engine to the tank.

The EquiFlo® Inboard Fuel System is standard on all single-tank vehicles and recommended for all dual-tank systems. This system consists of inboard-routed fuel lines, with the suction and return lines installed in a common opening of the fuel tank(s); a new quarter-turn, non-vented fuel cap, and shut-off valves (when so equipped) located on top of the transmission. The fuel tank vent and line are located on the top of the tank. See **Fig. 1.**

The fuel lines are routed inboard of the frame rails and upward to a point on the transmission, where the shut-off valves (if so equipped) are located.

Fuel is drawn equally from and returned to each tank, so that their levels stay equal. The suction and return fuel lines, although entering the fuel tank via the same opening, are designed to direct the fuel flow to the bottom of the tank. See **Fig. 1.** This ensures thorough mixing of the fuel before it is drawn up by the suction line, so that vapor can disperse, and (electronic engines only) warm fuel is not recirculated.

Replacement

If there is any damage to the fuel tank, replace it.

IMPORTANT: Fuel tanks are subject to U.S. Federal Motor Carrier Safety Regulations setting standards for strength, leakage and venting. These standards are achieved through the use of specific materials and construction methods.*These standards also apply to replacement fuel tanks.*

⚠ WARNING

Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

1. Remove the chassis fairings. For instructions, refer to **Section 60.05**.

IMPORTANT: On dual tank installations, close the fuel shutoff valve(s) before draining the tank.

2. Drain the fuel from the tank.
   - 2.1 Remove the drain plug from the fuel tank that is to be replaced.
   - 2.2 Drain the fuel into a suitable container of sufficient volume to hold the amount of fuel in the tank.
   - 2.3 If the fuel is to be re-used, store it in a clean container, and keep it free from contaminants.
3. Disconnect the fuel suction line and return line from the tank, and cap the lines.
4. Remove and clean all of the pipe plugs, and save them for installation on the new tank.
5. Before removing the fuel tank bands, measure the distance from the forward edge of the fuel tank to the edge of the fuel tank band. See **Fig. 1**.
6. To prevent the fuel tank from rolling during and after removal, nail several 2 x 4 or 4 x 4 wooden blocks to the top of a pallet, then place the pallet on the forks of a fork lift. See **Fig. 2**.

   Move the fork lift and pallet into place to support the fuel tank as the tank bands are being removed.

Fuel Tank Replacement

Drop the tank bands and isolators. Leave the tensioner lug inside the band.

8. Remove the fuel tank from the fuel tank bracket.
9. After removing the tank, inspect the tank bands, isolators, and brackets for damage. Replace worn or damaged parts with new parts. Refer to **Subject 120** for bracket replacement procedures; refer to **Subject 110** for band replacement procedures.
10. Using the fork lift and pallet, place the fuel tank in its approximate installed position. Make sure the fuel filler neck is rotated 25±5 degrees outboard of vertical. See **Fig. 2**.

    Install the forward tank band and band isolator loosely.

    10.1 Holding the tank on the forklift, attach the band and isolator to the eye bolt.

    10.2 Install a hardened flatwasher and the inner 5/8–11 hexnut, but do not tighten it yet.
11. Move the new tank fore or aft until the distance between the forward edge of the tank and the tank band is equal to the distance measured in **Fig. 1**.

NOTE: On vehicles equipped with side fairings, the fuel tank filler neck does not have to be centered in the fill door opening of the side fairing. The centerline of the fuel tank cap is to be within 1 inch (25 mm) of either side of the centerline of the fill door opening. See **Fig. 4**. Don't move the fuel tanks to center the fuel tank filler neck in the fill door opening.

12. Install the other tank band around the tank; then insert the isolators under the brackets so that the relief in each isolator aligns with the tank longitudinal weld seam. See **Fig. 3**.

⚠ CAUTION

Fuel tanks can be damaged by direct isolator pressure on the tank weld seam, and by overtightening the fuel tank bands. Be sure the weld seam aligns with reliefs in the isolators, and that the bands are tightened to specification.

13. Tighten the inner hexnuts alternately in stages until each is tightened 30 to 35 lbf·ft (41 to 47 N·m). When both hexnuts have been tightened, install a jam nut on each hexnut. Hold each hexnut with a 15/16-inch wrench while tightening its jam nut 30 lbf·ft (41 N·m).
14. Make certain the fuel lines are clean, then install them on their fittings on the fuel tank.

    Coat the pipe plug threads with Loctite® 592, or an equivalent. Install pipe plugs in any remaining open threaded holes.
15. Install the chassis fairings. For instructions, refer to **Section 60.05**.
16. Fill the fuel tank with clean fuel. Prime the engine fuel pump; for instructions, refer to the engine manufacturer's operation and maintenance manual.

Replacement

1. Remove the chassis fairings. For instructions, refer to **Section 60.05**.
2. Support the fuel tank, using a floor jack or fork lift, and padding to protect the tank.
3. Remove the nuts and washer from the tank band eye bolt at the outboard end of the tank bracket, see **Fig. 1**.
4. Drop the tank band. Inspect both the band and bracket isolators for wear or damage, and replace if needed.
5. Remove the band.
   - 5.1 Remove the small clevis pin from the bottom end of the fuel tank bracket, freeing the band.
   - 5.2 Remove the band from the fuel tank.
6. Install the band.
   - 6.1 Position the small end of the new band in place on the bottom edge of the fuel tank bracket.
   - 6.2 Install the small clevis pin and two hardened flatwashers onto the fuel tank bracket and band, and fasten it in place, using a cotter pin.
7. Apply Alumilastic® compound or equivalent to the bracket where it contacts the band.

⚠ CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the components or parts.

8. Position the new tank band, with band isolator, around the tank; then insert the bracket isolator under the bracket so that a relief in the isolator aligns with the tank longitudinal weld seam. **See Fig. 1.**

⚠ CAUTION

CAUTION: Fuel tanks can be damaged by direct isolator pressure on the tank weld seam, and by over-tightening the fuel tank bands. Be sure the weld seam aligns with reliefs in the isolators and that the bands are tightened to specification.

9. Attach the upper end of the band and tighten the band nuts.
   - 9.1 Position the large end of the band, with tensioner lug in place, on the end of the eye bolt.
   - 9.2 Install a hardened flatwasher and the inner hexnut. Tighten the inner hexnut 30 to 35 lbf·ft (41 to 47 N·m).
   - 9.3 Install a jam nut on the hexnut. Hold the hexnut with a 15/16-inch wrench while tightening its jam nut 30 lbf·ft (41 N·m).
10. Repeat this procedure to replace the other band. When both bands have been replaced, check both inner hexnuts and both jam nuts for tightness.

CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the components or parts.

   3.2 Position the new tank bracket against the frame rail. From inside the frame rail, install the 5/8–11 grade 8 bolts and washers. On the other side of the frame rail, Install hardened washers and hexnuts. The 4-inch capscrews go in the top holes; the 2-1/4 inch capscrews in the bottom holes. Tighten the hexnuts 160 lbf·ft (217 N·m).

   3.3 Install the fuel tank band; refer to **Subject 110**.

Flushing

In the event of a catastrophic failure of the high-pressure fuel pump, it is necessary to clean the fuel tanks and all other system components between the tanks and the engine. For information about cleaning the engine components after a failure, refer to the engine manufacturer's service literature.

IMPORTANT: Always follow EPA and local regulations when disposing of contaminated fuel.

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Drain all of the fuel from the tank(s) into a suitable container. Dispose of the contaminated fuel in an appropriate manner.
3. Remove the tank(s) from the vehicle. For instructions, refer to **Subject 100**.
4. Thoroughly steam clean the inside of the tank until all water leaving the drain hole looks clean.
5. Install the drain plug and cap any other open outlets.
6. Put two gallons of diesel fuel in the tank, and install the cap. Slosh the diesel around in the tank making sure it reaches all interior surfaces. This should collect most of any remaining contaminants in the tank.
7. Drain this fuel from the tank into a suitable container. Dispose of the contaminated fuel in an appropriate manner.
8. If equipped, remove the fuel/water separator(s) from the system. For instructions, refer to **Group 47**.
9. Remove and discard the filter element. Then thoroughly clean the unit.
10. Install a new filter element.
11. Remove all of the fuel lines from the system and replace them with new lines.
12. Install the fuel/water separator. For instructions, refer to **Group 47**.
13. Install the fuel tank(s) on the vehicle. For instructions, refer to **Subject 100**.

General Description

The Con Met fuel/water separator (see **Fig. 1**) removes water and solid contaminants from diesel fuel. Installed on the left frame rail between the fuel tank and the fuel transfer pump, the separator has no moving parts and contains no filters.

It is available in a basic model, or with a sight bowl, and/or a heater activated by a mechanical thermostat. All fuel and coolant line fittings are 1/2-inch NPT.

Principles of Operation

Diesel fuel enters at the top of the separator (see **Fig. 2**) and flows down through a specially-designed baffle, causing the water in the fuel to coalesce in large droplets which then accumulate in the bottom of the unit and can be drained by opening a valve.

The heater, if installed (see **Fig. 3**), routes engine coolant through a tube to heat the fuel as it trickles down through the baffle. If a sight bowl is also installed, a heater rod warms the water in the sight bowl.

Fuel passing through the thermostat activates a valve that controls coolant flow and regulates fuel

2.4 When the unit is completely drained, close the drain valve.

2.5 If opened, close the vacuum breaker valve.

⚠ WARNING

WARNING: Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

3. If a heater is installed, drain the coolant. Refer to **Section 20.01** for instructions.
4. Disconnect the 1/2-inch NPT fuel line fittings to the intake and exhaust lines on the separator body.

   If a heater is installed, disconnect the 1/2-inch NPT coolant line fittings to the heater body. Also, disconnect the 1/2-inch NPT fuel line and coolant line fittings to the thermostat.

NOTE: If installed, remove the thermostat. For instructions, refer to **Subject 110**.

5. Remove the mounting capscrews, lockwashers and hexnuts that secure the mounting bands to the mounting bracket. See **Fig. 2.** Remove the fuel/water separator from the vehicle.
6. If installed, remove the sight bowl and clean it. See **Fig. 3.**

   6.1 Unscrew the sight bowl from the separator body.

   6.2 Wipe the sight bowl clean using a soft cloth.

   6.3 Inspect the gasket for damage and install a new one if necessary. Lubricate the gasket with a thin film of engine oil and install it on the sight bowl.

   6.4 Lubricate the threads on the sight bowl with a thin film of engine oil.

   6.5 Hand tighten the sight bowl until the gasket has fully contacted the separator body, and then tighten 1/4 to 1/3 turn more.

General Description

The fuel/water separator is mounted on the frame rail, between the fuel tank and the fuel pump. Fuel drawn to the engine travels through the fuel/water separator, which removes water and solid contaminants. The fuel/water separator includes a spin-on filter element and a sight bowl. See **Fig. 1**. The fuel/water separator may also be equipped with the following optional components:

- Ignition-controlled heater to melt ice and wax in the fuel
- Water sensor probe to alert the operator to drain the sight bowl
- Manual priming pump to easily prime the fuel/water separator

Principles of Operation

Diesel fuel enters at the top of the separator and flows down past the heater element, if equipped, to the top of the filter element. As the fuel flows down the sides of the element, the heavier contaminants fall directly to the collection bowl. The filter element itself contains a resin that repels water and forces it to bead and fall to the collection bowl.

Filtered fuel is drawn out through the top of the separator, and the water and solid contaminants remain in the collection bowl. As water collects, it completes the circuit between the two prongs of the water sensor probe, if equipped, and a warning light on the dash alerts the operator to drain the bowl.

The heater is operated by turning on the ignition switch for 5 minutes before starting the engine.

General Description

The Arctic Fox fuel heater Model C406 (see **Fig. 1**) is installed in the fuel tank facing the fuel filler neck. It comes in two different lengths to accomodate 23- and 27-inch cylindrical tanks.

Fig. 1, Arctic Fox Fuel Heater

Twelve 1/4-inch capscrews bolt the heater to the tank, attaching to a mounting flange that is an integral part of the heater head. A heating coil, consisting of a coolant tube in the form of a closed loop, extends down into the tank.

To prevent overheating, the unit is equipped with a temperature probe that monitors fuel temperature. It is connected to a bypass thermostat that controls an automatic coolant shut-off valve.

Principles of Operation

Hot engine coolant is routed through the heating coil, warming the fuel as it passes. A bypass thermostat shuts off the coolant flow when the fuel in the tank reaches a temperature of approximately 80°F (27°C).

The hot coolant is then directed through a bypass circuit within the thermostat head, which sends it straight back to the engine. For this reason, the head of the fuel heater stays hot even when the heating circuit has been bypassed.

Arctic Fox Fuel Heater Replacement

Replacement

IMPORTANT: When installed in the fuel tank, the clearance between the bottom of the fuel heater and the inside of the tank wall must be at least 1 inch (25 mm) and no more than 2 inches (51 mm).

1. Apply the parking brakes, shut down the engine, and chock the tires.

⚠ WARNING

2. Drain the coolant. Refer to **Section 20.01** for instructions.
3. Mark the coolant fittings and lines. Disconnect the coolant lines from the fittings on the fuel heater.

⚠ WARNING

Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

4. Remove the twelve 1/4-inch capscrews attaching the fuel heater mounting flange to the fuel tank. See **Fig. 1.**

     NOTE: Be sure the heads of the capscrews are snug to the top of the mounting flange.
   - 6.4 Now tighten each capscrew 78 to 95 lbf·in (880 to 1080 N·cm).
7. Using the sequence shown in **Fig. 2**, recheck each capscrew for 78 to 95 lbf·in (880 to 1080 N·cm).

Troubleshooting

Problem—The Heat Exchanger Is Not Cooling the Fuel

Problem—The Heat Exchanger Is Not Cooling the Fuel	
Possible Cause	**Remedy**
The cooling fins are dirty.	Wearing eye protection, clean the heat exchanger fins carefully. If necessary, use water flowing at low pressure to remove debris lodged in the fins. **⚠ CAUTION** **Do not direct a high-pressure stream of water at the fuel cooler. This will damage the fins.**
The cooling fins are bent.	Using a 12 fin/inch fin comb, straighten any bent fins.
The heat exchanger is clogged with contaminated fuel.	Using a compatible fuel system fluid, flush out the heat exchanger in both directions (through both fittings).
There are hairline cracks in the heat exchanger.	Replace the fuel cooler.
The heat exchanger's fuel tubing is dented badly enough to restrict fuel flow past the heat exchanger.	Replace the fuel cooler.

Problem—The Fuel Cooler Is Leaking

Problem—The Fuel Cooler Is Leaking	
Possible Cause	**Remedy**
The fuel line connections are loose.	Tighten the connections until the leaks disappear. Do not tighten more than 15 lbf·ft (20 N·m) and use a back-up wrench on the heat exchanger fitting. Start the engine and make sure there are no more leaks.
The sealant on the fittings is not adequate.	Remove the fittings, clean off any dried or cracked sealant, and apply Loctite® 271 (or equivalent) to all fitting threads.
The fitting(s) are cracked or stripped.	Replace the fitting(s).

Fuel/water separators are mounted between the fuel tank and the fuel pump. Fuel drawn to the engine travels through the fuel/water separator, which removes water and impurities. See **Fig. 1** for an example of a Fuel Pro 382, or **Fig. 2** for an example of a Fuel Pro 482.

At the fuel/water separator inlet port, a check valve prevents the fuel from draining back to the fuel tank. Large pieces of dirt and water separate from the fuel in the lower housing, and collect in the bottom to be drained out when the drain valve is opened. From the lower housing, the fuel level rises into the clear cover, which contains the replaceable filter. In the clear cover, the fuel passes through the filter element into the center of the filter, and to the outlet port.

When the filter is new, the fuel is able to pass through the lower part of the filter element. As the element's lower portion clogs, the fuel level rises in order to pass through the filter. This process continues until the filter element is clogged all the way to the top.

For efficiency, the filter should be changed only when the fuel level has reached the top of the filter element. There is no significant restriction to fuel flow until the element is completely clogged.

DAVCO fuel/water separators come in a number of different configurations. There may be an electric heating element installed in the lower housing or there may be fluid heating in the lower housing. If there is fluid heat, the warming fluid may be fuel returning from the engine or engine coolant. **Fig. 3** shows the patterns that fuel and heating fluids follow in fluid-heated units. Configurations may vary between fuel/water separator models.

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

Most service procedures are done with the fuel/water separator in place, but some procedures, such as pressure testing, require that the fuel/water separator be removed from the vehicle.

Removal

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve (**Fig. 1**, Item 1) has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Unplug the electric heating element, if equipped, or disconnect the heating fluid lines.
5. Disconnect the fuel outlet line.
6. Disconnect the fuel inlet line. If the inlet line is difficult to reach, loosen the connection, then fully disconnect it after the fuel/water separator is removed from the frame rail.
7. Remove the fuel/water separator mounting fasteners and remove the fuel/water separator from the frame rail. If the fuel inlet line was not completely disconnected in the previous step, disconnect it.

Removal and Installation

Installation

IMPORTANT: All fittings, including the locking collars, must be very clean as they are installed. A piece of grit or a damaged surface on a sealing face or in threads can cause air leaks.

Use teflon pipe thread sealant to ensure that the tapered thread fuel line fittings will not leak. Do not use sealer on compression fittings and do not seal the fittings with tape, which will eventually leak.

1. If the inlet fuel line is inaccessible when the fuel/water separator is mounted on the vehicle, loosely connect the inlet fuel line before mounting the fuel/water separator on the frame rail.

   To minimize restrictions, keep fuel line routing as smooth as possible, with no low-hanging loops that could trap water. If the fuel line is being made to length on the job, be sure that the inner liner of the hose is not cut by the fitting. Be certain the interior of all fuel lines is clean and free of debris before connecting them, and confirm that all fittings are clean.
2. Mount the fuel/water separator on the frame rail and install the mounting fasteners.

NOTICE

The lower housings on DAVCO fuel/water separators are made of aluminum. To avoid damaging threads, be careful not to overtighten fasteners or fittings on the fuel/water separator.

3. If the fuel inlet line was loosely connected previously, tighten it. If it was not connected, connect and tighten it.
4. Connect the fuel outlet line.
5. Install the electric heating element, if equipped, and connect the wiring harness, or connect the fluid heater lines. It does not matter which direction the heating fluid flows through the housing; the lines can be reversed.
6. Prime the system
   - 6.1 Ensure that the drain valve is closed.
   - 6.2 Remove the vent cap from the cover, and fill the housing to the top with clean diesel fuel.
   - 6.3 Install and hand-tighten the vent cap.
   - 6.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 6.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.
   - 6.6 Check for leaks and shut down the engine.

The following equipment is recommended to test DAVCO pre-heaters and thermoswitches:

- A precision low-resistance ohmmeter capable of measuring 0.1 ohm or less
- A clamp-on DC current-flow meter
- A means of chilling a thermoswitch, such as ice, dry ice, or compressed carbon dioxide
- A flameless source of heat, such as an infrared heat lamp

2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Disconnect the heating fluid lines from the bottom plate. These will be either engine coolant lines or return fuel lines. Plug engine coolant lines after removing them from the bottom plate of the housing.

5. Remove the bottom plate and lower housing O-ring.
6. While looking into the fluid port of the bottom plate (**Fig. 4**), flow cold water over the thermovalve for 30 seconds, then run hot water over the thermovalve to determine whether the thermovalve spool is opening and closing.

   When the fuel entering the fuel/water separator is cold, the thermovalve moves up, allowing warming fluid to enter the heater loop in the heat exchanger. When the fuel is warm, the thermovalve moves down, causing the warming fluid to bypass the heater loop and return directly to the tank. See **Fig. 5**.

Identifying Bubble Types

Vapor Bubbles

Vapor bubbles are harmless and are present in all diesel fuel systems. Vapor bubbles are often mistaken for air bubbles, but *do not affect engine performance.*

Vapor bubbles (see **Fig. 1**) may be visible in a diagnostic sight tube installed between the fuel/water separator and the fuel pump. They consist of harmless fuel vapor and trapped air, may vary from champagne-size to 1/4-inch (6-mm) diameter, and may increase in volume or size as the engine rpm increases. The lower pressure inside a fuel/water separator filter, caused by the suction of the fuel pump pulling fuel through the fuel/water separator, creates vapor bubbles. These vapor bubbles are normal and harmless to engine operation. In the fuel pump, the fuel is pressurized and the vapor bubbles dissolve. Vapor bubbles do not appear on the fuel return side of the system.

There is no troubleshooting or repair procedure required for vapor bubbles. Vapor bubbles do not cause performance issues and will not be present downstream of the fuel pump.

3. Fuel Outlet Line, Vapor Bubbles Visible
4. Fuel/Water Separator, Vapor Bubbles Visible *Inside* Filter, *No* Bubbles Visible in Clear Cover
5. Fuel Return Line (no bubbles)

Fig. 1, Harmless Vapor Bubbles

Air and Gas Bubbles

Air or gas bubbles indicate harmful leaks, and can cause hard starting and impaired engine performance. All diesel fuel holds some trapped air, caused by the natural splashing that occurs in the fuel tank. But excessive air bubbles, severe enough to degrade engine performance, indicate an air leak on the suction side of the fuel system, from the fuel tank into the fuel pump.

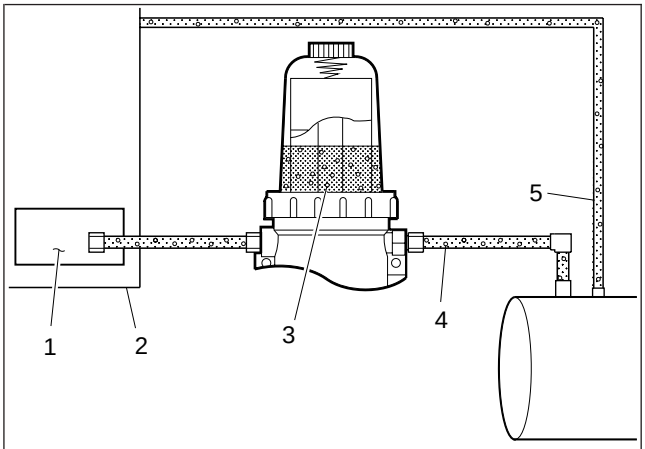
Air bubbles visible in the clear cover of a DAVCO fuel/water separator may indicate an air leak in the fuel system upstream of the bubbles, or in the fuel/water separator; see **Fig. 2**. If there are no bubbles visible in the clear cover but the engine runs rough, there may be an air leak at or between the fuel/water separator outlet port and the fuel pump inlet. These bubbles will be visible in a diagnostic sight tube installed between the fuel pump and the fuel/water separator, and in a diagnostic sight tube installed in the fuel return hose.

Exhaust gas bubbles may also be visible in the clear filter cover. They are the result of leaking fuel injector seals, which can allow combustion gases to enter the fuel system, pass through the fuel return line into the fuel tank, and be drawn into the fuel/water separator. They may be visible in a diagnostic sight tube installed in the fuel return line. To test for combustion gas in the fuel, disconnect the return line at the tank, submerge the end in a bucket of fuel, run the engine, and watch for bubbles. As they pop, these bubbles may smell like exhaust fumes.

In extreme cases, these combustion gas bubbles cause enough aeration in the fuel tank to create visible bubbles in the clear cover of the fuel/water separator and impair engine performance. See the engine manufacturer's documentation for diagnosis and repair of injector seal leakage.

Use the following procedures to determine which bubbles are present in the fuel system, and whether repair is necessary.

Troubleshooting



1. Fuel Pump
2. Engine
3. Fuel/Water Separator, Bubbles Visible in Clear Cover
4. Fuel Inlet Line, Bubbles Visible
5. Fuel Return Line, Bubbles Visible

Fig. 2, Air Bubbles Indicating a Leak

Initial Diagnostic Procedure

1. Apply the parking brake, chock the tires, and turn on the engine.
2. Check for air bubbles in the fuel/water separator clear cover.
3. If no bubbles are visible in the clear cover, but the engine continues to run rough, lopes, or has loss of power, there may be an air leak between the fuel/water separator outlet and the fuel pump inlet.

   If so, bubbles should be visible in a diagnostic sight tube installed at the fuel pump inlet. Air bubbles may also be visible in a diagnostic sight tube installed in the fuel return line to the fuel tank.
4. Replace fuel lines and tighten fittings as needed.
5. If the fuel level has risen to the top of the filter, replace the filter.

NOTE: A DAVCO fuel/water separator, properly assembled with the rubber grommet in the bottom of the fuel filter, does not restrict fuel flow until the fuel level has risen to the top of the filter.

Testing Procedures

Air Leak in the Fuel System

Air leaks are sometimes caused by:

- loose fittings;
- a faulty inlet check valve;
- faulty O-rings;
- leakage elsewhere in the fuel system;
- or dirt on threads and sealing surfaces.

Air leaks originating between the fuel tank and the fuel/water separator cause air bubbles visible in the clear cover, as shown in **Fig. 2**.

If there are symptoms of sucking air and there are no bubbles in the clear cover, look for the air leak at:

- the outlet fitting;
- the fuel pump inlet connection;
- the fuel hose connections;
- or at the vent cap O-ring.

1. Shut down the engine, apply the parking brake, and chock the tires.

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

2. Remove the fuel hose from the fuel pump inlet port.
3. Install a jumper hose from the inlet port into the fuel tank through the fill cap, or into a container of fuel.
4. Start the engine and look for bubbles in the clear filter cover. If the air bubbles are eliminated, the

air source (and the leak) is at either the fuel tank fittings, or the hose connections.

If air bubbles persist after the tank fittings and hose connections are secured, the leak may be in the fuel/water separator.

5. If the leak is suspected to be in the fuel/water separator, disconnect all fuel connections, coat the threads with teflon pipe thread sealant, and reconnect the fuel connections and tighten them securely.

Air Pressure Testing

⚠ WARNING

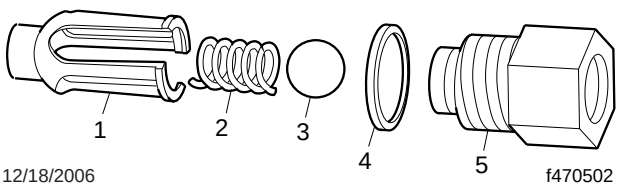
Wear goggles and skin protection when pressure-testing a fuel/water separator, and be careful not to perform this test near a source of possible ignition, such as an open flame. Never exceed the maximum pressure stipulated for the test, and do not perform this test if the clear cover appears to be damaged.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Remove the fuel/water separator from the chassis. For instructions, see **Subject 100**.
5. Plug the fuel outlet port. Do not remove the filter, filter cover, collar, vent cap, drain valve, or check valve. Do not remove the electric heating element (if equipped), and do not plug the fluid heat ports (if equipped).
6. Apply 15 psi (207 kPa) air pressure at the fuel inlet. Immerse the unit in a tank of water and look for air bubbles.
7. If a leak is found, repair the fuel/water separator as needed.
8. Install the fuel/water separator onto the chassis frame rail. For instructions, see **Subject 100**.
9. Prime the system
   - 9.1 Ensure that the drain valve is closed.
   - 9.2 Remove the vent cap from the cover, and fill the housing to the top with clean diesel fuel.
   - 9.3 Install and hand-tighten the vent cap.
   - 9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.
10. If no bubbles appear, the air leak is not in the fuel/water separator.

Check Valve Operation Test

When air is introduced into the fuel system, (e.g. when draining fluid or when replacing the fuel filter), the check valve (**Fig. 3**) works to keep the fuel system primed from the fuel tank to the fuel/water separator.



1. Plastic Spring Retainer
2. Retaining Spring
3. Check Ball
4. Seal (Diesel Pro® units only)
5. Check Valve Body

Fig. 3, Check Valve Assembly

To test for proper check valve operation, remove the fuel inlet line, then open the vent cap. Fuel should not flow out of the check valve, although a slight seepage of fuel is normal. If fuel drains back out of the check valve, complete the following procedure.

1. Shut down the engine, apply the parking brake, and chock the tires.

Troubleshooting

WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.

3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Place a shop towel under the fuel inlet fitting. Hold the check valve body in place with an open-end wrench and, using a flare-nut wrench, carefully remove the fuel inlet fitting. Drain any residual fuel into the container.
5. Remove the check valve assembly from the fuel/water separator housing, see **Fig. 3**.
6. Clean and inspect the check valve body. If the valve body is damaged, or if the ball seat is not smooth, replace the valve. For instructions, see **Subject 120**.
7. If the valve body and ball seat are not damaged, clean the threads on the check valve body, fuel inlet fitting, and the water separator housing.
8. Apply a teflon pipe thread sealant to the check valve body threads. Install the check valve body in the fuel/water separator housing. Do not use tape to seal the fuel fittings; it may eventually leak.

   Tighten the check valve body 44 to 60 lbf·ft (60 to 81 N·m) on a Fuel Pro 382, or 45 lbf·ft (61 N·m) on a Fuel Pro 482.

9. Prime the system
   - 9.1 Ensure that the drain valve is closed.
   - 9.2 Remove the vent cap from the clear cover, and fill the housing to the top with clean diesel fuel.
   - 9.3 Install and hand-tighten the vent cap O-ring and vent cap.
   - 9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.
   - 9.6 Check for leaks and shut down the engine.

Other Conditions Visible Inside the Cover

The clear filter covers fitted to DAVCO fuel/water separators provide the opportunity to monitor several aspects of fuel condition and engine status, as described in **Table 1**.

Conditions Visible Inside DAVCO Clear Filter Covers

If You See:	What to Do:	Comments:
Amber-colored fuel below the top of the filter element	Nothing, the filter is doing its job	Do not change the filter.
Amber-colored fuel with dark patches in places on the filter element	Dark patches indicate bacteria or algae may be present. Use Fleetguard Monitor Kit CC2650 to test for microbiological activity.	It may be necessary to use a microbicide, and suggest vehicle operator carry extra filters.

Conditions Visible Inside DAVCO Clear Filter Covers		
If You See:	**What to Do:**	**Comments:**
Extremely dark or cloudy fuel with thick black film or sludge collecting on the filter element	Black film or sludge on the filter media indicates the presence of asphaltenes. It may be necessary to use an asphaltene conditioner.	Do not assume this is oil from the engine. Monitor the vehicle for oil consumption. Refer to engine manufacturer's service literature for more information.
Bubbles inside the clear cover	Check for air leaks anywhere in the fuel system. Any leak in any fitting will cause bubbles to appear in the clear cover.	This problem will lead to power complaints; it must be remedied.
No bubbles in the cover, but the engine is running rough	Check for air leaks between the fuel/water separtor outlet port and the fuel pump inlet. Check and tighten all fuel fittings in the area of the leak.	—
Coolant in the fluid drained from the fuel/water separator	Check for leaks in the engine, where fuel and coolant are near each other. The most common problem place is the injector cup.	Do not allow the equipment to be operated until the problem is found and repaired.

General Information

The exhaust system routes hot exhaust gas away from the cab, and reduces engine exhaust noise. Vehicles can have either a horizontally mounted or a vertically mounted exhaust system. Vehicles are available either with or without a vertical exhaust stack.

System components include the engine outlet exhaust pipe, muffler, muffler mounting components, saddle clamps, wide-band exhaust clamps, flex pipe, exhaust stack, and exhaust system heat shields.

A vehicle can have single or dual mufflers.

The muffler can be mounted horizontally (**Fig. 1**) where it is supported by brackets which are bolted to inside of the frame rails.

a bracket bolted to the corner of the cab. This installation uses isolators between the muffler and the cab.

Or, the muffler can be cab *and* frame-rail mounted (**Fig. 6**) where it is supported by a frame rail bracket and a bracket bolted to the back of the cab. This installation uses isolators between the muffler and the cab, and between the muffler and the frame rail bracket.

On Argosy COEs, the muffler is always frame-mounted. See **Fig. 3**.

On the Coronado, the muffler is mounted under the cab, between the frame rails. See **Fig. 7**.

Most exhaust installations consist of an engine exhaust pipe, sometimes called the turbo pipe, mounted to the rear of the turbocharger and secured

The muffler can be mounted outboard (**Fig. 2**, **Fig. 3**, or **Fig. 4**) where it is supported by uprights which are bolted to the outside of the frame rails.

On Century Class Conventionals, the muffler can be mounted on the cab (**Fig. 5**) where it is supported by

with a V-clamp. From there, flex pipe and exhaust piping route the exhaust to the muffler. A bracket attached to the frame rail or the cab uses a clamp to hold and support the engine exhaust piping as it runs to the muffler. Band clamps connect all piping joints between the turbocharger and the muffler, and hold the exhaust piping to the muffler.
