Foreword

The purpose of this manual is to assist the service technician when the vehicle is serviced. Major drivetrain component service information is not included in this manual, but is located in each manufacturer's service manual.

Instructions and procedures are those recommended by Freightliner Trucks or the component manufacturer.

Maintenance schedules and additional service information are included in the *Century Class Trucks Maintenance Manual*.

IMPORTANT: Descriptions and specifications in this manual were in effect at the time of printing. Freightliner Trucks reserves the right to discontinue models, and to change specifications or design at any time without notice and without incurring obligation. Descriptions and specifications contained in this publication provide no warranty, expressed or implied, and are subject to revision and editions without notice.

Refer to **www.Daimler-TrucksNorthAmerica.com** and **www.FreightlinerTrucks.com** for more information, or contact Daimler Trucks North America LLC at the address below.

Environmental Concerns and Recommendations

Whenever you see instructions in this manual to discard materials, you should attempt to reclaim and recycle them. To preserve our environment, follow appropriate environmental rules and regulations when disposing of materials.

NOTICE: Parts Replacement Considerations

Do not replace suspension, axle, or steering parts (such as springs, wheels, hubs, and steering gears) with used parts. Used parts may have been subjected to collisions or improper use and have undetected structural damage.

Descriptions of Service Publications

Daimler Trucks North America LLC distributes the following major service publications in paper and electronic (via ServicePro®) formats.

Workshop/Service Manual

Workshop/service manuals contain service and repair information for all vehicle systems and components, except for major components such as engines, transmissions, and rear axles. Each workshop/service manual section is divided into subjects that can include general information, principles of operation, removal, disassembly, assembly, installation, specifications, and troubleshooting.

Maintenance Manual

Maintenance manuals contain routine maintenance procedures and intervals for vehicle components and systems. They have information such as lubrication procedures and tables, fluid replacement procedures, fluid capacities, specifications, and procedures for adjustments and for checking the tightness of fasteners. Maintenance manuals do not contain detailed repair or service information.

Driver's/Operator's Manual

Driver's/operator's manuals contain information needed to enhance the driver's understanding of how to operate and care for the vehicle and its components. Each manual contains a chapter that covers pretrip and post-trip inspections, and daily, weekly, and monthly maintenance of vehicle components. Driver's/operator's manuals do not contain detailed repair or service information.

Service Bulletins

Service bulletins provide the latest service tips, field repairs, product improvements, and related information. Some service bulletins are updates to information in the workshop/service manual. These bulletins take precedence over workshop/service manual information, until the latter is updated; at that time, the bulletin is usually canceled. The service bulletins manual is available only to dealers. When doing service work on a vehicle system or part, check for a valid service bulletin for the latest information on the subject.

IMPORTANT: Before using a particular service bulletin, check the current service bulletin validity list to be sure the bulletin is valid.

Parts Technical Bulletins

Parts technical bulletins provide information on parts. These bulletins contain lists of parts and BOMs needed to do replacement and upgrade procedures.

Web-based repair, service, and parts documentation can be accessed using the following applications on the AccessFreightliner.com website.

ServicePro

ServicePro® provides Web-based access to the most up-to-date versions of the publications listed above. In addition, the Service Solutions feature provides diagnostic assistance with Symptoms Search, by connecting to a large knowledge base gathered from technicians and service personnel. Search results for both documents and service solutions can be narrowed by initially entering vehicle identification data.

PartsPro

PartsPro® is an electronic parts catalog system, showing the specified vehicle's build record.

EZWiring

EZWiring™ makes Freightliner, Sterling, Western Star, Thomas Built Buses, and Freightliner Custom Chassis Corporation products' wiring drawings and floating pin lists available online for viewing and printing. EZWiring can also be accessed from within PartsPro.

Descriptions of Service Publications

Warranty-related service information available on the AccessFreightliner.com website includes the following documentation.

Recall Campaigns Recall campaigns cover situations that involve service work or replacement of parts in connection with a recall notice. These campaigns pertain to matters of vehicle safety. All recall campaigns are distributed to dealers; customers receive notices that apply to their vehicles.

Field Service Campaigns Field service campaigns are concerned with non-safety-related service work or replacement of parts. All field service campaigns are distributed to dealers; customers receive notices that apply to their vehicles.

List of Abbreviations

The following is a list of definitions for abbreviations and symbols used in Freightliner publications.

A ..... amperes
AAVA ..... auxiliary air valve assembly
ABS ..... antilock braking system
ABS ..... acrylonitrile-butadiene-styrene
A/C ..... air conditioner
AC ..... alternating current
acc ..... accessories
ACM ..... aftertreatment control module
ACPU ..... air conditioning protection unit
ADLO ..... auto-disengagement lockout
AGM ..... absorbed glass mat
AGS ..... automated gear shift
AG2 ..... Aluminum Generation 2
a.m. ..... *ante meridiem* (midnight to noon)
AM ..... amplitude modulation
amp(s) ..... ampere(s)
AMT ..... automated mechanical transmission
AMU ..... air management unit
ANSI ..... American National Standards Institute
API ..... American Petroleum Institute
API ..... application programming interface
ARI ..... Air Conditioning and Refrigeration Institute
ASA ..... American Standards Association
ASF ..... American Steel Foundries
ASR ..... automatic spin regulator
assy. ..... assembly
ASTM ..... American Society for Testing and Materials
ATC ..... automatic temperature control
ATC ..... automatic traction control
ATC ..... automatic transmission control
ATD ..... aftertreatment device
ATF ..... automatic transmission fluid
ATS ..... aftertreatment system
attn ..... attention
aux. ..... auxiliary
av ..... *avoirdupois* (British weight system)
AWD ..... all-wheel drive
AWG ..... American wire gauge
AWS ..... American Welding Society
BAT ..... battery
BBC ..... bumper-to-back-of-cab
BHM ..... bulkhead module
BOC ..... back-of-cab
BOM ..... bill of material
BTDC ..... before top dead center
Btu(s) ..... British thermal unit(s)
C ..... common (terminal)
CAC ..... charge air cooler
CAN ..... controller area network
CARB ..... California Air Resources Board
CAT ..... Caterpillar
CB ..... circuit breaker
CB ..... citizens' band
CBE ..... cab behind engine
CCA ..... cold cranking amperes
CCR ..... California Code of Regulations
CD-ROM .. compact-disc/read-only memory
CDTC ..... constant discharge temperature control
CEL ..... check-engine light
CFC ..... chlorofluorocarbons (refrigerant-12)
cfm ..... cubic feet per minute
CFR ..... Code of Federal Regulations
CGI ..... clean gas induction
CGW ..... central gateway
CHM ..... chassis module
CIP ..... cold inflation pressure
CLDS ..... cab load disconnect switch
CLS ..... coolant level sensor
cm ..... centimeters
cm^3 ..... cubic centimeters
CMVSS .... Canadian Motor Vehicle Safety Standard
Co. ..... company
COE ..... cab over engine
Corp. ..... corporation
CPC ..... common powertrain controller
CPU ..... central processing unit
CRT ..... cathode ray tube
cSt ..... centistokes (unit of measurement for describing the viscosity of general liquids)
cu ft ..... cubic feet
cu in ..... cubic inches
CUM ..... Cummins
CVSA ..... Commercial Vehicle Safety Alliance
CWS ..... collision warning system
DC ..... direct current
DCA ..... diesel coolant additive
DCDL ..... driver-controlled differential lock
DDA ..... Detroit Diesel Allison (obs)
DDC ..... Detroit Diesel Corporation
DDDL ..... Detroit Diesel Diagnostic Link
DDE ..... Detroit Diesel Engines
DDEC ..... Detroit Diesel Electronic (engine) Control
DDR ..... diagnostic data reader
DDU ..... driver display unit
def ..... defrost
DEF ..... diesel exhaust fluid
DFI ..... direct fuel injection
DGPS ..... differential global positioning system
DHD ..... dealer help desk
dia. ..... diameter
DIAG ..... diagnosis
DIP ..... dual inline package (switch)
DIU ..... driver interface unit
DLA ..... datalink adaptor
DLM ..... datalink monitor
DLU ..... data logging unit
DMM ..... digital multimeter
DOC ..... diesel oxidation catalyst
DOT ..... Department of Transportation
DPF ..... diesel particulate filter
DRL ..... daytime running lights
DRM ..... dryer reservoir module
DSM ..... district service manager
DTC ..... diagnostic trouble code
DTC ..... discharge temperature control
DTNA ..... Daimler Trucks North America
DVOM ..... digital volt/ohm meter
ea. ..... each
EBS ..... electronic braking system
ECA ..... electric clutch actuator
ECAP ..... electronic control analyzer programmer
ECAS ..... electronically controlled air suspension

List of Abbreviations

ECI ..... electronically controlled injection
ECL ..... engine coolant level
ECM ..... electronic control module
ECT ..... engine coolant temperature
ECU ..... electronic control unit
EDM ..... electronic data monitor
EEPROM .. electrically erasable programmable read-only memory
EFG ..... electric fuel gauge
EFPA ..... electronic foot pedal assembly
EGR ..... exhaust gas recirculation
ELC ..... extended-life coolant
EMC ..... electromagnetic compatibility
EMI ..... electromagnetic interference
EOA ..... electric over air
EP ..... extreme pressure (describes an antiwear agent added to some lubricants)
EPA ..... Environmental Protection Agency
EPS ..... engine position sensor
ESC ..... electronic stability control
ESC ..... enhanced stability control
ESD ..... electrostatic discharge
ESS ..... engine syncro shift (transmission)
etc. ..... *et cetera* (and so forth)
ETEC ..... electronic truck engine control
EUI ..... electronic unit (fuel) injectors
EVA ..... electronic vibration analyzer
EXM ..... (chassis) expansion module
E85 ..... 85% ethanol fuel
FAS ..... Freightliner air suspension
FCCC ..... Freightliner Custom Chassis Corporation
FCU ..... forward control unit
FET ..... field effect transistor
Fig. ..... figure
fl oz ..... fluid ounces
FLA ..... post-1984 advancements Freightliner COE
FLB ..... enhanced Freightliner FLA COE
FLC ..... steel-cab Freightliner 112 Conventional
FLD ..... post-1984 advancements Freightliner 112/120 aluminum-cab Conventional
FLR ..... forward-looking radar
FM ..... frequency modulation
FMCSA .... Federal Motor Carrier Safety Administration
FMEA ..... failure mode effects analysis
FMI ..... failure mode indicator
FMSI ..... Friction Materials Standards Institute
FMVSS .... Federal Motor Vehicle Safety Standard
FRP ..... fiberglass reinforced plastic
FSA ..... field service authorization
FSM ..... fleet service manager
ft ..... feet
ft^3 ..... cubic feet
ft^3/min ..... cubic feet per minute
FTL ..... Freightliner
F.U.E.L. .... fuel usage efficiency level
g ..... grams
gal ..... gallons
GAWR ..... gross axle weight rating
GHG ..... greenhouse gas
GHG14 .... greenhouse gas and fuel efficiency regulations
GL ..... gear lubricant
GND ..... ground
gpm ..... gallons per minute
GPS ..... global positioning system
GVWR ..... gross vehicle weight rating
HBED ..... hard-braking event data
HCM ..... hybrid control module
HCOE ..... high cab over engine
HCU ..... hydraulic control unit
HD ..... heavy-duty
HDU ..... hybrid drive unit
HEPA ..... high-efficiency particulate air (filter)
HEST ..... high exhaust system temperature
HEV ..... hybrid electric vehicle
HFC ..... hydrogenated fluorocarbons (refrigerant-134a)
hp ..... horsepower
hp ..... high pressure
HRC ..... Rockwell "C" hardness
hr(s) ..... hour(s)
HSA ..... hill start aid
HSD ..... high-side driver
htr. ..... heater
HVAC ..... heating, ventilating, and air conditioning
HVLP ..... high velocity, low pressure
H/W ..... hardware
Hz ..... hertz
IAD ..... interaxle differential
ICS ..... integrated child seat
ICU ..... instrumentation control unit
i.d. ..... inside diameter
ID ..... identification
IFI ..... Industrial Fasteners Institute
IFS ..... independent front suspension
IGN ..... ignition
ILB ..... intelligent lightbar
ILO ..... *in lieu of* (in the place of)
in ..... inches
in^3 ..... cubic inches
Inc. ..... incorporated
inH_2O ..... inches of water
inHg ..... inches of mercury
I/O ..... input/output
IP ..... instrument panel
ISO ..... International Organization for Standardization
IVS ..... idle validation switch
k ..... kilo (1000)
kg ..... kilograms
km ..... kilometers
km/h ..... kilometers per hour
kPa ..... kilopascals
kW ..... kilowatts
L ..... liters
lb ..... pounds
LBCU ..... lightbar control unit
lbf·ft ..... pounds force feet
lbf·in ..... pounds force inches
LCD ..... liquid crystal display
LCOE ..... low cab over engine
LED ..... light-emitting diode
LFL ..... lower flammability limit
LH ..... left-hand
LHD ..... left-hand drive
LH DR ..... left-hand-drive
LHK ..... liters per hundred kilometers
LHS ..... low-hydrogen steel
LIN ..... Local Interconnect Network
LLC ..... limited liability company
L/min ..... liters per minute
LNG ..... liquefied natural gas
LPG ..... liquefied petroleum gas

List of Abbreviations

LPG ..... liquid propane gas
LPI ..... liquid propane injection
LPR ..... low pressure reservoir
LRR ..... low-rolling resistance
LSD ..... low-side driver
LVD ..... low-voltage disconnect
m ..... meters
max. ..... maximum
M-B ..... Mercedes-Benz
MCM ..... motor control module
MESA ..... Mining Enforcement Safety Act
mfr. ..... manufacturer
mi ..... miles
MID ..... message identifier
MIL ..... malfunction indicator lamp (light)
MIL ..... military specification
min. ..... minutes
min. ..... minimum
misc. ..... miscellaneous
mL ..... milliliters
mm ..... millimeters
mod. ..... module
mpg ..... miles per gallon
mph ..... miles per hour
MSF ..... modular switch field
MMT ..... methylcyclopentadienyl manganese tricarbonyl
MSHA ..... Mining Safety and Health Administration
MVDA ..... Motor Vehicle Dealers Association
n ..... negative (front axle wheel alignment specification)
N ..... nitrogen
N/A ..... not applicable
N·cm ..... Newton-centimeters
NC ..... normally closed (terminal or switch)
NCG ..... noncondensable gases
NHTSA ..... National Highway Traffic Safety Administration
NIOSH ..... National Institute for Occupational Safety and Health
NITE ..... no idle thermal environment
NLA ..... no longer available
NLGI ..... National Lubricating Grease Institute
N·m ..... Newton-meters
NO ..... normally open (terminal or switch)
NOAT ..... Nitrited Organic Acid Technology
NOx ..... nitrogen oxides
no. ..... number
NPT ..... national pipe thread
NPTF ..... national pipe thread fitting
NT ..... nylon tube or nylon tubing
NTSB ..... National Transportation Safety Board
OAT ..... Organic Acid Technology
OBD(s) ..... on-board diagnostic(s)
obs ..... obsolete
OC ..... open circuit
OCV ..... open circuit voltage
o.d. ..... outside diameter
O.D. ..... overdrive
OEM ..... original equipment manufacturer
OPD ..... overfill protection device
OSHA ..... Occupational Safety and Health Administration
oz ..... ounces
ozf·in ..... ounces force inches
p ..... positive (front axle wheel alignment specification)
PACE ..... programmable electronically controlled engine
PAG ..... polyalkylene glycol (oil)
parm ..... parameter
PAS ..... passenger advisory system
PC ..... personal computer
PCB ..... printed circuit board
PDC(s) ..... parts distribution center(s)
PDI ..... pre-delivery inspection
PDM ..... power distribution module
PEC ..... power electronics carrier
PEEC ..... programmable electronic engine control
PID ..... parameter identifier
PKP ..... Purple-K powder
PLC ..... power line carrier
PLD ..... *Pumpe-Linie-Düse* (pump-line-nozzle)
PNDB ..... power-net distribution box
PM ..... particulate matter
p.m. ..... *post meridiem* (noon to midnight)
p/n ..... part number
PO ..... purchase order
POE ..... polyol ester
PRD ..... pressure relief device
PRD ..... product requirements document
PSA ..... pressure-sensitive adhesive
PSG ..... pressure sensor governor
psi ..... pounds per square inch
psia ..... pounds per square inch, atmosphere
psig ..... pounds per square inch, gauge
pt ..... pints
PTCM ..... pressure time control module
PTO ..... power takeoff
PTP ..... powertrain protection
PTPDM ..... powertrain power distribution module
pvc ..... polyvinyl chloride
PWM ..... pulse width modulation
pwr ..... power
qt ..... quarts
qty. ..... quantity
R & O ..... rust inhibitors and oxidants
R–12 ..... refrigerant-12 (CFC)
R–134a ..... refrigerant-134a (HFC)
RAM ..... random access memory
RC ..... reserve capacity
recirc. ..... recirculation
Ref(s). ..... reference(s)
regen ..... regeneration
RELS ..... reduced engine load at stop
RFI ..... radio frequency interference
RH ..... right-hand
RHD ..... right-hand drive
RH DR ..... right-hand-drive
R/I ..... removal and installation
RMA ..... return material authorization
ROM ..... read-only memory
rpm ..... revolutions per minute
R/R ..... removal and replacement
RSA ..... roll-stability advisor
RSG ..... road speed governor
RSM ..... regional service manager
RTS ..... ready-to-spray
RTV ..... room temperature vulcanizing
RV ..... recreational vehicle
SA ..... source address
S-ABA ..... self-setting automatic brake adjusters

Vehicle Receipt

Prior to signing for vehicle delivery from a transporter company, the dealer is responsible for checking for transporter-related shortages or damages, and noting these discrepancies on the transporter's delivery receipt.

The dealer is also responsible for ensuring that the vehicle was built according to the Truck Sales Order/ Invoice.

Refer to Section 3 of the Daimler Trucks North America LLC *Warranty Manual* for details.

Vehicle Storage

There may be times when a vehicle is stored for long periods before customer delivery. To protect all vehicles from deterioration and weather, they must be properly maintained. Adequate protection and storage of new vehicles is the responsibility of the dealer.

Claims arising from loss and damage to improperly stored vehicles will not be reimbursed.

See Section 3 of the Daimler Trucks North America LLC *Warranty Manual* for instructions on storage of new vehicles.

Pre-Delivery Information

All pre-delivery inspections and services must be performed at an authorized Daimler Trucks North America LLC facility, assigned to fully qualified service personnel and recorded on the "New Vehicle Pre-Delivery Inspection" form.

Refer to Section 3 of the Daimler Trucks North America LLC *Warranty Manual* for details.

It is recommended the pre-delivery inspection be performed within 30 days of vehicle receipt.

Cooling System

1. Cooling system hoses must clear all moving parts by a minimum of 1/4 inch (6 mm).
2. The 1-inch (25-mm) hose from the surge tank to the engine must be free of sumps and have allowance for engine torque.
3. All hoses from the engine hard pipes must be wrapped in convoluted tubing.
4. Hoses that are protected with convoluted tubing may be secured with tie straps to clear the inner fenders.
5. Cooling system hoses should not be twisted or kinked.
6. Cooling system hoses must be routed at least six inches (152 mm) from a heat source if the heat source does not have a heat shield. If a heat shield is provided, the hose must be routed at least three inches (76 mm) from the heat source.

HVAC System

1. Cushion clamps are required to support all A/C lines. Butterfly or figure-8 clamps (two cushion clamps) may be used to prevent rubbing or chafing.
2. Heater hoses that are protected with convoluted tubing may be fastened with tie straps. If not protected with convoluted tubing, only cushion clamps or butterfly clamps may be used for heater hoses.
3. A/C lines cannot be secured to air lines, fuel lines, or electrical wires.
4. HVAC hoses should be protected from damage by routing them away from hazards of heat, wheel splash (water, gravel, ice), human traffic, and moving parts of the vehicle.
5. HVAC hoses should be routed away from sharp points and edges (such as nuts, bolts, brackets, and frame rail edges), moveable parts, and sources of abrasion, cutting, pinching, or crushing.

NOTE: If hoses are covered with convoluted tubing, they may touch any of the above.

6. Hoses that are protected with convoluted tubing may come in contact with the bends on frame rails and filters.
7. HVAC hoses must be routed at least six inches (152 mm) from a heat source if the heat source does not have a heat shield. If a heat shield is provided, the hose must be routed at least three inches (76 mm) from the heat source.
8. All HVAC hoses must be routed so that regularly serviced components, such as fuel filters, fuel/water separators, oil filters, air filters, belts, and fill and drain plugs, are readily accessible for adjustment or replacement without the need to relocate or remove the hoses.
9. All A/C hoses in the engine compartment must have convoluted tubing.
10. If cushion clamps are used over convoluted tubing at existing clamp points, no additional tie straps or tape is needed.
11. When convoluted tubing is installed on the heater hose where it routes past the splash shield on the front right-hand side of the firewall, and if it uses existing clamps, no additional tie straps or tape is needed.

Auxiliary Heater

All auxiliary heater lines are deck-mounted hard piping with rubber hose at both ends. No additional tie straps are required.

Engine Plumbing

1. On vehicles equipped with the Cummins M-11 engine and power steering, no additional tie straps or tape are needed if convoluted tubing is installed on the power steering hose where it routes under the frame rail.
2. The engine oil pressure line should not rub or chafe against the Teflon® discharge line.

Electrical Wiring

1. Wires that are bundled together should be fastened at 8- to 12-inch (203- to 305-mm) intervals. If anchor clamps are more than 12 inches (305

mm) apart, a tie strap must be used between the anchor clamps.

2. Bundles of wires that are located in an exposed area, such as under the cab or outside the frame rail, need to be fastened with heavy-duty cable ties.
3. Any wiring that will be exposed to water or heat must be covered with either loom or convoluted tubing. Loom or convoluted tubing need not butt up against Weather Pack® connectors.
4. Any wiring routed across the vehicle, on the engine crossmember, or across the rear of the engine, must be secured with a clamp or tie strap, and covered with either convoluted tubing or a loom.
5. Any wiring that may come into contact with sharp points and edges (such as nuts, bolts, brackets, and frame rail edges), moveable parts, and sources of abrasion, cutting, pinching, or crushing, must be protected by either a loom or convoluted tubing.
6. Unprotected breakouts (individual wires) of up to eight inches (203 mm) are acceptable as long as these wires are routed safely away from sharp points and edges, moveable parts, and sources of abrasion, cutting, pinching, or crushing.
7. Gray, flame-retardant convoluted tubing may be used to protect wiring in the cab or the chassis. Black nylon convoluted tubing may only be used in the chassis.
8. All wiring must be routed so that regularly serviced components, such as fuel filters, fuel/water separators, oil filters, air filters, belts, and fill and drain plugs, are readily accessible for adjustment or replacement without the need to relocate or remove any wiring.
9. In exposed locations, such as the road light harness near the headlights, loose loops of wire must be secured with tie straps.
10. All wiring should be routed a minimum of four inches (102 mm) from the exhaust. In situations where the wiring is less than four inches (102 mm) from the exhaust, a heat shield must be placed between the wiring and the exhaust.

Battery Cables

1. Battery cables must be routed along an unobstructed path from the starter to the battery box. The cables must **not** rub or chafe on brackets, tanks, air lines, or fuel lines.
2. Battery cables and electrical wiring cannot be tied or secured to fuel lines, discharge lines, or air lines.
3. Battery cables must have support brackets no more than 30 inches (762 mm) apart. Tie straps must be within six inches (152 mm) of both sides of the support brackets, and every 12 inches (305 mm) between the brackets.
4. Battery cables must have convoluted tubing from the frame bracket to the batteries, and from the frame bracket to the starter.

Fuel Lines

1. Fuel lines must not be clamped to A/C lines, battery cables, jumper cables, or any other electrical wiring.
2. Stand-off brackets or clamps may be used to prevent fuel lines from rubbing against the frame.
3. Fuel lines must be routed at least six inches (152 mm) from a heat source. If a heat shield is provided, the fuel line must be at least three inches (76 mm) from the heat source.
4. Fuel lines that are parallel may be fastened together. Fuel lines that cross or that rub on metal, plastic, or electrical parts, need to be separated with butterfly clamps.

Chassis Air Lines and Brake Hoses

1. Hoses may come in contact with each other if they are parallel, or if they are bundled together.
2. If the hoses lie on the curve or flat surface of a bracket or crossmember, they do not need convoluted tubing.
3. Brake hoses may be clamped at the top of the axle housing, and touch or lie against the axle housing in its path to the brake chamber as this assembly moves together.

4. Brake hoses must have slack between the last clamping point on the frame rail and the brake chamber to allow for full range of suspension travel.
5. Brake hoses should have butterfly clamps at breakout points.
6. Air lines and brake hoses that are bundled together should be fastened at 8- to 12-inch (203- to 305-mm) intervals. If anchor clamps are more than 12 inches (305 mm) apart, a tie strap must be used between the anchor clamps. Tie straps may be closer than 12 inches (305 mm) apart.
7. Hoses or lines that may come into contact with the sharp edge of a bracket or frame rail are to be protected by convoluted tubing.
8. Air lines and brake hoses that are parallel may be fastened together. Air lines and brake hoses that cross or that rub on metal, plastic, or electrical parts need to be separated with butterfly clamps.
9. Nylon or STX (wire braid) chassis air lines may be fastened together to prevent rubbing, as long as the lines are stationary.

VIN for Vehicles Built through April 30, 2000

IMPORTANT: See **Subject 060** for the vehicle identification numbering system for vehicles built May 1, 2000, or later.

Federal Motor Vehicle Safety Standard 115 specifies that all vehicles sold in the U.S. be assigned a 17-character Vehicle Identification Number (VIN). Using a combination of letters and numerals, the VIN defines the manufacturer, model, and major characteristics of the vehicle. See **Table 1** for the character positions of a typical Freightliner VIN, 1FUYSTEBXVPA99999.

The VIN can be found on the Vehicle Specification Decal (see the driver's manual for decal location) and stamped on the left frame rail over the front axle about 2 inches (50 mm) from the top of the web or on the top flange of the left frame rail at frame station 30.

NOTE: For Freightliner vehicles assembled and sold in Mexico, the VIN appears on a plate or label attached to the driver's door. Also, a data card placed in the glove box shows the Mexican VIN as the "CHASSIS" number. The "CABIN" number is part of the Freightliner VIN, the last six digits of which are the Freightliner serial number.

IMPORTANT: A new VIN-code structure will be used for all vehicles built after April 30, 2000. Character positions 1 through 4 and 9 through 17 are nearly the same in both versions, but positions 5 through 8 have been assigned slightly different parameters. As a result, the build date of a vehicle must be determined before the VIN can be decoded.

For all vehicles, a check digit (9th character) is determined by assignment of weighted values to the other 16 characters. These weighted values are processed through a series of equations designed to check validity of the VIN and to detect VIN alteration.

NOTE: Always specify the VIN when ordering parts.

Table 8, VIN Position 11 (Plant of Manufacture)

VIN for Vehicles Built from May 1, 2000

IMPORTANT: See **Subject 050** for the vehicle identification numbering system for vehicles built before May 1, 2000.

Federal Motor Vehicle Safety Standard 115 specifies that all vehicles sold in the U.S. be assigned a 17-character Vehicle Identification Number (VIN). Using a combination of letters and numerals, the VIN defines the manufacturer, model, and major characteristics of the vehicle. See **Table 1** for the character positions of a typical Freightliner VIN, 1FUPABAV11PA12345.

The VIN can be found on the Vehicle Specification Decal (see the driver's manual for decal location) and stamped on the left frame rail over the front axle about 2 inches (50 mm) from the top of the web or on the top flange of the left frame rail at frame station 30.

NOTE: For Freightliner vehicles assembled and sold in Mexico, the VIN appears on a plate or label attached to the driver's door. Also, a data card placed in the glove box shows the Mexican VIN as the "CHASSIS" number. The "CABIN" number is part of the Freightliner VIN, the last six digits of which are the Freightliner serial number.

IMPORTANT: A new VIN-code structure will be used for all vehicles built after April 30, 2000. As a result, the build date of a vehicle must be determined before the VIN can be decoded.

Character positions 1 through 4 and 9 through 17 are nearly the same in both versions, but positions 5 through 8 have been assigned slightly different parameters.

Another new feature is that each product line has its own model list; that is, positions 5 and 6 are will be product-specific in the new system. For example, the code AB in positions 5 and 6 for a Freightliner vehicle indicates an FLD112. Code AB in the same position for a Sterling vehicle represents an SC7000 Cargo.

For all vehicles, a check digit (9th character) is determined by assignment of weighted values to the other 16 characters. These weighted values are processed through a series of equations designed to check validity of the VIN and to detect VIN alteration.

NOTE: Always specify the VIN when ordering parts.

Threaded Fastener Types

The majority of threaded fasteners used throughout the vehicle have U.S. customary threads (diameter and pitch are measured in inches). **See Fig. 1.** However, the engine and some items attached to the cab use metric fasteners (diameter and pitch are measured in millimeters).

Most threaded fasteners used on the vehicle that are 1/2-inch diameter or larger are plain hex-type fasteners (non-flanged); *all* metric fasteners are non-flanged. Special hardened flatwashers are used under the bolt head, and between the part being attached and the hexnut, to distribute the load, and to prevent localized overstressing of the parts. The washers are cadmium- or zinc-plated, and have a hardness rating of 38 to 45 HRC.

Some fasteners smaller than 1/2-inch diameter are flanged fasteners, which have integral flanges that fit against the parts being fastened. The flanges eliminate the need for washers.

NOTE: The standard fasteners used to assemble the vehicle frame and to attach components to the vehicle frame are threaded lockbolts (Spin Hucks). These fasteners are covered in **Section 31.00.**

Fastener Grades and Classes

Fasteners with U.S. customary threads are divided into grades established by the Society of Automotive Engineers (S.A.E.) or the International Fastener Institute (I.F.I.). The fastener grades indicate the relative strength of the fastener; the higher the number (or letter), the stronger the fastener. Bolt (capscrew) grades can be identified by the number and pattern of radial lines forged on the bolt head. **See Fig. 2.** Hexnut (and locknut) grades can be identified by the number and pattern of lines and dots on various surfaces of the nut. **See Fig. 3.** Nearly all of the bolts used on the vehicle are grades 5, 8, and 8.2. Matching grades of hexnuts are always used: grade 5 or grade B hexnuts are used with grade 5 bolts; grade 8, grade C, or grade G (flanged) hexnuts are used with grade 8 or 8.2 bolts.

Fasteners with metric threads are divided into classes adopted by the American National Standards Institute (ANSI). The higher the class number, the stronger the fastener. Bolt classes can be identified by the numbers forged on the head of the bolt. **See Fig. 4.** Hexnut (and locknut) classes can be identified by the marks or numbers on various sur-

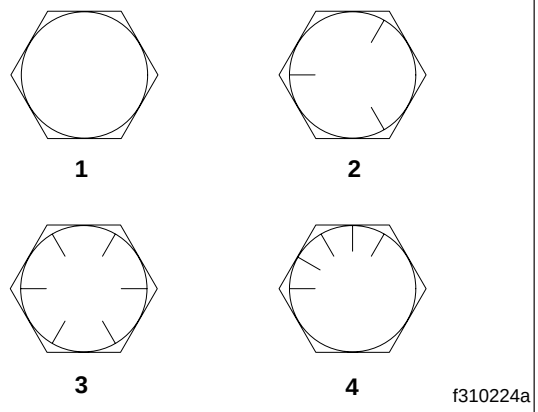
General Information



NOTE: Grade 2 bolts have no grade marking; grade 2 bolts are rarely used by Freightliner.

These grade markings are used on plain hex-type and flanged bolts (capscrews). In addition to the grade markings, the bolt head must also carry the manufacturer's trademark or identification.

faces of the nut. **See Fig. 5.** Class 8 hexnuts are always used with class 8.8 bolts; class 10 hexnuts with class 10.9 bolts.

Frame Fasteners

The standard fasteners used to assemble the vehicle frame and to attach most components to the vehicle frame are threaded lockbolts (Spin Hucks). These fasteners are covered in **Section 31.00.**

For some other components attached to the frame, grade 8 and 8.2 phosphate-and oil-coated hexhead bolts and grade C cadmium-plated and wax-coated prevailing torque locknuts are used. The prevailing torque locknuts have distorted sections of threads to provide torque retention. For attachments where clearance is minimal, low-profile hexhead bolts and grade C prevailing torque locknuts are used. **See Fig. 6.**

Tightening Fasteners

When a capscrew is tightened to its torque value in a threaded hole, or a nut is tightened to its torque value on a bolt, the shank of the capscrew or bolt is stretched slightly. This stretching (tensioning) results in a preload that reduces fatigue of the fasteners. The torque values given in the tables in **Specifications, 400** have been calculated to provide enough clamping force on the parts being fastened, and the correct tensioning of the bolt to maintain the clamping force.

Use of a torque wrench to tighten fasteners will help prevent overtensioning them. Overtensioning causes permanent stretching of the fasteners, which can result in breakage of the parts or fasteners.

When torquing a fastener, typically 80 to 90 percent of the turning force is used to overcome friction; only 10 to 20 percent is used to stretch the capscrew or bolt. About 40 to 50 percent of the turning force is needed to overcome the friction between the underside of the capscrew head or nut and the washer. Another 30 to 40 percent is needed to overcome the friction between the threads of the capscrew and the threaded hole, or the friction between the threads of the nut and bolt.

The amount of torque required to tighten a fastener is reduced when the amount of friction is reduced. If a fastener is dry (unlubricated) and plain (unplated), the amount of friction is high. If a fastener is wax-coated or oiled, or has a zinc phosphate coating or cadmium plating, the amount of friction is reduced. Each of these coatings and combinations of coatings has a different effect. Using zinc-plated hardened flatwashers under the bolt (capscrew) head and nut reduces the amount of friction. Dirt or other foreign material on the threads or clamping surfaces of the fastener or clamped part also changes the amount of friction.

Even though each different condition affects the amount of friction, a different torque value cannot be given for each different condition. To ensure they are always torqued accurately, Freightliner recommends that all fasteners be lubricated with oil (unless specifically instructed to install them dry), then torqued to the values for lubricated- and plated-thread fasteners. When locking compound or anti-seize compound is recommended for a fastener, the compound acts as a lubricant, and oil is not needed.

NOTE: Grade 2 (S.A.E.) and grade A (I.F.I.) nuts have no identification marks or notches; they are rarely used by Freightliner. Grade B (I.F.I.) nuts have three identification marks at 120 degrees, or 6 notches. Grade C (I.F.I.) nuts have three identification marks at 60 degrees, or 12 notches. Grade G (I.F.I.) flanged nuts have six identification marks as shown; each identification mark may be a dot, line, pair of dots or lines, or any other symbol at the manufacturer's option.

Fastener Replacement

When replacing fasteners, use only identical bolts, washers, and nuts; they must be the same size, strength, and finish as originally specified. See the Freightliner Service Parts Catalog for fastener specifications.

When replacing graded (or metric class) bolts and capscrews, use only fasteners that have the manufacturer's trademark or identification on the bolt head; do not use substandard bolts. Inferior, counterfeit fasteners are difficult to identify; buy your fasteners from a reputable supplier.

Fastener Selection and Installation

When using nuts with bolts, use a grade (or class) of nut that matches the bolt.

When installing non-flanged fasteners, use hardened steel flatwashers under the bolt (capscrew) head, and under the hexnut or locknut.

For bolts 4 inches (100 mm) or less in length, make sure that at least 1-1/2 threads and no more than 5/8-inch (16-mm) bolt length extends through the nut after it has been tightened. For bolts longer than 4 inches (100 mm), allow a minimum of 1-1/2 threads and a maximum of 3/4-inch (19-mm) bolt length.

Never hammer or screw bolts into place. Align the holes of the parts being attached, so that the nut and bolt surfaces are flush against the washers, and the washers are flush against the parts.

When installing fasteners in aluminum or plastic parts with threaded holes, start the fasteners by hand, to ensure straight starting and to prevent damaged threads.

Do not use lockwashers (split or toothed) next to aluminum surfaces.

When installing studs that do not have an interference fit, install them with thread locking compound, as instructed in this subject.

When installing parts that are mounted on studs, use free-spinning (non-locking) nuts and helical-spring (split) lockwashers or internal-tooth lockwashers. Do not use locknuts, because they tend to loosen the studs during removal. Do not use plain washers (flatwashers).

Do not use lockwashers and flatwashers in combination (against each other); each defeats the other's purpose.

Use stainless steel fasteners against chrome plating, unpainted aluminum, or stainless steel.

Fastener Tightening

Before installing fasteners, clean all fastener (and parts) threads, and all surfaces being clamped.

To ensure they are always torqued accurately, Freightliner recommends that *all* fasteners be lubricated with oil (unless specifically instructed to install them dry), then torqued to the values for lubricated- and plated-thread fasteners. When locking compound or antiseize compound is recommended for a fastener, the compound acts as a lubricant, and oil is not needed.

Bring parts and fasteners into contact, with no gaps between them, before using a torque wrench to tighten fasteners to their final torque values.

Tighten the nut, not the bolt head. This will give a truer torque reading by eliminating bolt body friction.

Always use a torque wrench to tighten fasteners, and use a slow, smooth, even pull on the wrench. Do not overtorque fasteners; overtightening causes permanent stretching of the fasteners, which can result in breakage of the parts or fasteners.

If specific torque values are not given for countersunk bolts, use the torque value for the corresponding size and grade of regular bolt, as given in **Specifications, 400**.

Always follow the torque sequence or torque interval when provided, to ensure that clamping forces are even, and parts and fasteners are not distorted.

Thread Locking Compound Application

When the use of thread locking compound is recommended or desired, for studs, capscrews, and bolts with a thread diameter of 1 inch (25 mm) or less, use Loctite® 271 or Perma-Lok® HM-128.

For thread diameters over 1 inch (25 mm), use Loctite 277.

General Instructions

NOTE: Follow the safety precautions given on the locking compound container.

1. Clean the male and female threads of the fasteners, removing all dirt, oil, and other foreign material. If parts are contaminated, use Stoddard solvent for cleaning; then allow the fasteners to air dry for 10 minutes. Be sure solvent is completely gone before applying adhesive.
2. Transfer a small amount of the locking compound from the container to a paper cup or small non-metal dish.
3. Using a plastic brush (a metal brush will contaminate the compound), apply a small amount of compound to the entire circumference of 3 or 4 of the male threads that will be covered by the nut after it has been tightened. Be sure enough compound is applied to fill the inside of the nut threads, with a slight excess.
4. Install and torque the nut. Readjustment of the nut position is not possible after installation is complete, without destroying the locking effect.

NOTE: To disassemble the fasteners, heat the bond line to 400°F (200°C) before removing the nut. Every time the fasteners are disassembled, replace them. If any parts are damaged by overheating, replace the parts.

Decking Devices

⚠ WARNING

The lift brackets are intended only for undecking trucks. Do not use them for vehicle towing or recovery. If used improperly, personal injury or property damage could result.

To avoid damaging vehicles during undecking, follow the instructions below for installing and removing decking devices.

Two lift brackets are required for undecking. Part A21–2611–000 is the left-hand lift bracket and part A21–2611–001 is the right-hand lift bracket. See **Fig. 1**.

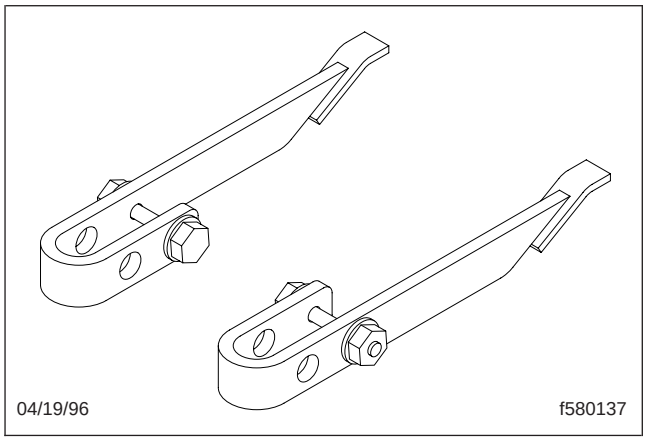

Fig. 1, Lift Brackets

Installation

1. Insert the decking device in the tow hook cutout in the front bumper and slide it to the rear until its rear extension/flange rests on top of the front springs. See **Fig. 2**.

⚠ CAUTION

When installing the lifting brackets, be sure that they do not contact or interfere with any air lines. Improper installation could result in component damage.

2. Insert the bolt through the lift bracket to secure it around the tow hook and securely tighten the nut on the bolt.

Fig. 2, Lift Bracket Attachment

3. The vehicle can now be safely hoisted for undecking. Make sure the undecking area is free of obstacles, has a vertical clearance of at least 14 feet (4.3 m) and a width of at least 12 feet (3.7 m).

Removal

1. Remove the nut and bolt securing lifting bracket to the tow hook.
2. Remove the lifting bracket from the tow hook cutout.

Engine Port Diagrams

Use the following diagrams to identify engine ports:

- For a Caterpillar 3176 Engine, see **Fig. 1**.
- For a Caterpillar 3406 Engine, see **Fig. 2**.
- For a Caterpillar C–10 or C–12 Engine, see **Fig. 3**.

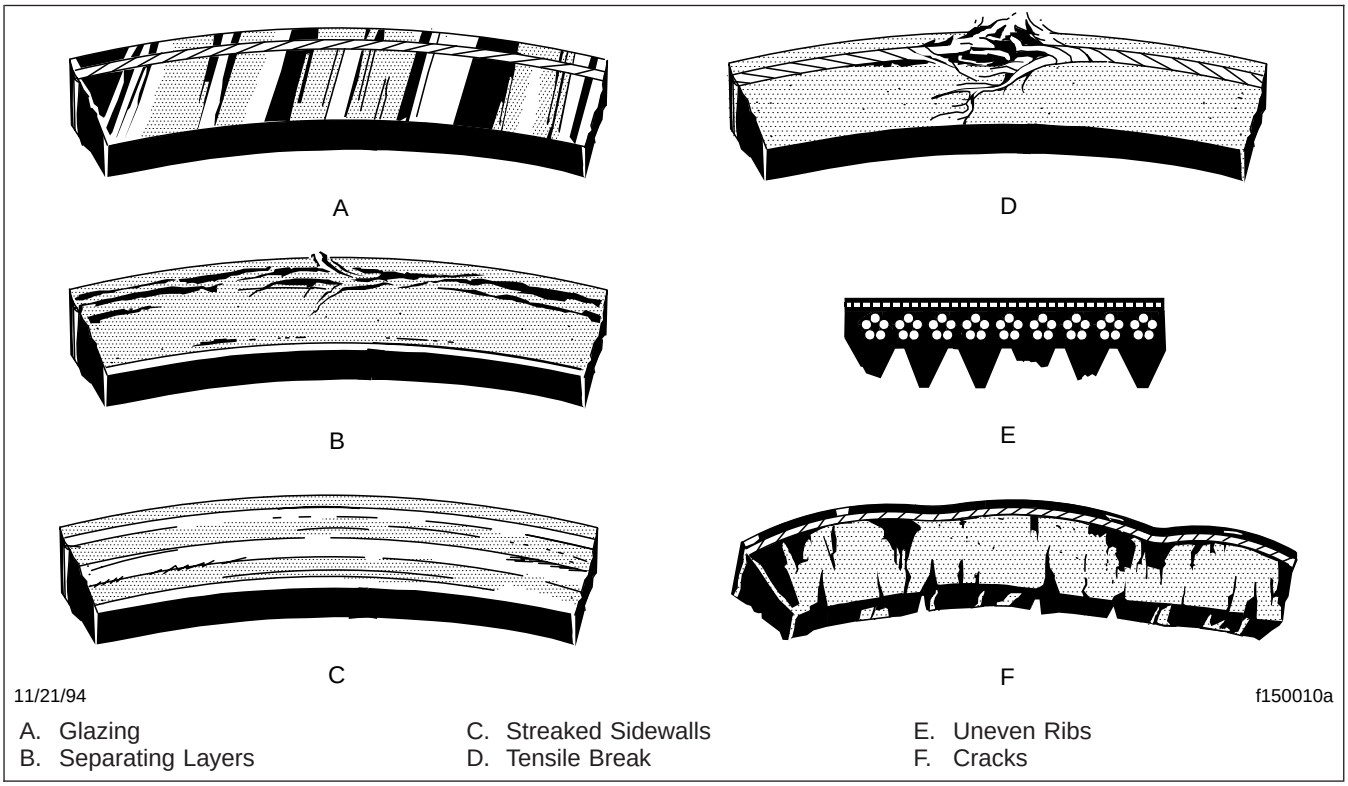
Pulley and Drive Belt Inspection, Caterpillar Engines

Inspection

1. Inspect all used drive belts (including those that are being replaced) for the following conditions (**see Fig. 1**):



A. Glazing
B. Separating Layers
C. Streaked Sidewalls
D. Tensile Break
E. Uneven Ribs
F. Cracks

Fig. 1, Drive Belt Problems

NOTE: For an installed belt, gently twist the belt about 90 degrees so you can see the sidewalls and bottom.

1.1 Inspect for glazing (shiny sidewalls). Glazing is caused by friction created when a loose belt slips in the pulleys. It can also be caused by oil or grease on the pulleys.

1.2 Inspect for separating layers. Oil, grease, or belt dressings can cause the belt to fall apart in layers. If engine parts are leaking, repair the oil leaks. Do not use belt dressings on any belt.

1.3 Check for jagged or streaked sidewalls. These are the result of a foreign object (such as sand or small gravel) in the pulley, or a rough pulley wall surface.

1.4 Check for tensile breaks (breaks in the cord body). Cuts in a belt are usually caused by large foreign objects in the pulley, or by prying or forcing the belt during installation or removal.

1.5 On poly-V belts, check for uneven ribs. Foreign objects in the pulley will erode the undercord ribs, causing the belt to lose its gripping power.

1.6 Inspect for cracks. Small, irregular cracks are usually signs of an old belt.

Replace the belt if any of the above conditions are found. Replace both belts of a set, at the same time. Matched belts must be from the same manufacturer.

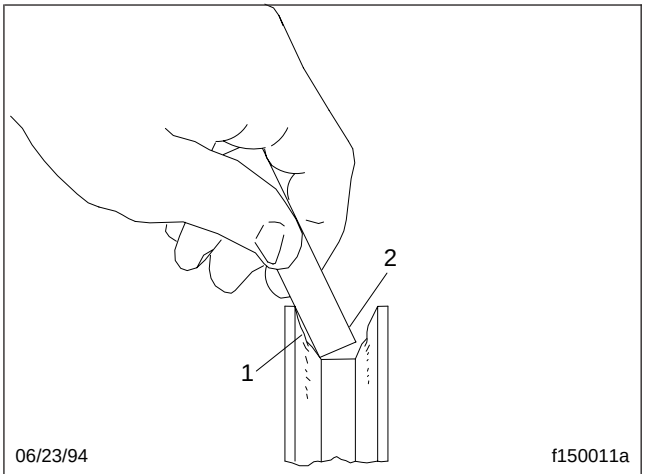
2. Check all pulley bearings for roughness. Replace the bearings if they're rough.

3. Inspect all pulleys for foreign objects, oil, or grease in the grooves. Use a nonflammable

Pulley and Drive Belt Inspection, Caterpillar Engines

cleaning solvent to remove oils. Use a wire brush to remove rust, and a file to remove burrs.

4. Inspect the pulleys for wear on the inner walls. Hold a small straightedge against the inside of the pulley walls (**Fig. 2**), or use your little finger or fingernail to find grooves in the inner walls. If there are any grooves, replace the pulley.



1. Groove in Pulley Wall
2. Small Straightedge

Fig. 2, Check for Pulley Wear

5. Check alignment of pulleys.Use a thin straightedge that is longer than the longest span between the pulleys. Place the straightedge into the V-grooves of two pulleys at a time. The straightedge should be parallel to the outer edges of the pulleys; if not, the pulleys are misaligned.

   Pulley misalignment must not be more than 1/16-inch for each foot (1.5 mm for each 30.5 cm) of distance between pulley centers.

   If there is misalignment of the pulleys, adjust the pulleys or brackets if their positions are adjustable. **See Fig. 3**. Replace bent or broken pulleys, pulley brackets, or shafts.

6. Check all drive component mounting parts for loose fasteners, cracks, or other damage. Tighten loose fasteners. Repair or replace cracked or damaged brackets.

FAN AND ALTERNATOR BELT

(See Fig. 1)

1. Remove the belt.
   - 1.1 Remove the belt from the refrigerant compressor pulley and let the belt rest on the fan hub. Refer to the refrigerant compressor belt removal procedure in this subject.
   - 1.2 Insert a 1/2-inch breaker bar in the belt tensioner and rotate the tensioner down and off the belt.
   - 1.3 Holding the belt tensioner down, remove the belt from the alternator pulley.
   - 1.4 Slowly release the belt tensioner, and remove the breaker bar.
   - 1.5 Lower the belt, and take it off the vibration damper. Raise the belt, and take it off over the fan. Remove the belt from the engine compartment.
2. Install the belt.
   - 2.1 Inspect the pulleys and used belts (even if installing new belts) as instructed in **Subject 100**.
   - 2.2 If the fan or fan hub was removed to remove the compressor belt, install the fan or fan hub with the compressor belt in the fan pulley groove. Do not attach the compressor belt to the compressor at this time.

Drive Belt Replacement, Caterpillar C-10

2.3 Loop the fan/alternator belt around the fan and align it in the rear channel of the fan pulley.

2.4 Loop the belt down and around the vibration damper pulley.

2.5 Install the refrigerant compressor belt on the compressor. Refer to the refrigerant compressor belt installation instructions in this subject.

2.6 Insert a 1/2-inch breaker bar in the belt tensioner, and rotate the tensioner down while installing the belt on the alternator pulley.

2.7 Slowly release the tensioner assembly onto the belt. The tensioner automatically tightens the belt to the correct tension.

2.8 Remove the breaker bar from the tensioner.

3. Adjust the belt tension.

3.1 The Caterpillar belt tensioner automatically adjusts the fan and alternator belt to the correct tension.

3.2 If the belt slips, repair or replace the tensioner. For instructions, refer to the Caterpillar C-10 Truck Engine Service Manual.

REFRIGERANT COMPRESSOR BELT **(See Fig. 1)**

1. Remove the belt.

1.1 Loosen the refrigerant compressor jam nut, back off the adjusting nut, and loosen the compressor mounting bolts. Move the compressor towards the fan pulley until the belt can be removed from the compressor.

1.2 Remove the compressor belt from the fan pulley. If necessary, remove the fan from the fan pulley according to the instructions in **Section 20.01**.

2. Install the belt.

2.1 Inspect the pulleys and used belts (even if installing new belts) as instructed in **Subject 100**.

2.2 Install the belt around the fan and the compressor pulleys.

If the fan was removed, install it according to the instructions in **Section 20.01**.

2.3 While keeping the belt seated in the pulley grooves, move the compressor away from the fan pulley to increase belt tension. Use your thumb to apply about 25 lb (11 kg) of force at the center of the longest belt free-span to check the tension. When belt deflection is about 1/2 to 3/4 inch (13 to 19 mm), stop, and adjust the belt tension.

3. Adjust the belt tension.

3.1 Install a belt tension gauge at the center of the belt's longest free-span.

IMPORTANT: Do not overtighten the belts; too much tension shortens belt and bearing life.

3.2 Turn the adjusting nut to adjust the tension to a reading of 100 lb (45 kg).

Tighten the jam nut 155 lbf·ft (210 N·m).

Tighten the compressor pivot bolts 70 lbf·ft (95 N·m).

Check the belt tension and adjust it if needed.

3.3 If any new belts were installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

If the compressor belt tension is not 100 lb (45 kg), adjust the tension to 100 lb (45 kg).

Belt Replacement

ALTERNATOR AND REFRIGERANT COMPRESSOR BELTS (See Fig. 1)

NOTE: Adjust the alternator and refrigerant compressor belt by moving the alternator only. Do not move the refrigerant compressor. The refrigerant compressor is mounted in a slotted bracket and must stay mounted at the bottom of the slots. Do not raise the compressor to tighten the belt.

1. Remove the belt.
   - 1.1 Back off the alternator adjusting nut, then loosen the alternator mounting fasteners enough to allow movement of the alternator.
   - 1.2 Push the loosened alternator toward the fan drive pulley until the distance between them is short enough to allow belt removal without using force.
   - 1.3 Remove the belt by slipping it off of the pulleys and working it over one fan blade at a time.
2. Install the belt.

Drive Belt Replacement, Caterpillar 3406

2.1 If the fan belt was removed, install and adjust it first. For instructions, refer to the fan belt procedure in this subject.

2.2 Inspect the pulleys and used alternator belt (even if a new belt is being installed) as instructed in **Subject 100**.

2.3 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

2.4 Install the belt on the pulleys without prying or rolling it into place.

2.5 Back off the jam nut.

2.6 While keeping the belt seated in the pulley grooves, turn the adjusting nut against the adjusting link to increase the belt tension. Use your thumb to apply about 25 lb (11 kg) of force at the center of the belt free-span to check the tension while turning the nut. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, stop, and adjust the belt tension.

3. Adjust the belt tension.

3.1 If not already done, back off the adjusting link jam nut, and loosen the alternator mounting fasteners just enough to allow movement of the alternator.

3.2 Install a belt tension gauge on the belt, at the center of the belt's longest free-span.

IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

3.3 Turn the adjusting nut to adjust the tension to a reading of 100 lb (45 kg).

3.4 Tighten the adjusting rod jam nut 95 lbf·ft (130 N·m).

3.5 Tighten the alternator mounting fasteners 70 lbf·ft (95 N·m).

3.6 Check the belt tension, and adjust it if needed.

3.7 If a new alternator belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation. If the alternator belt tension is not 100 lb (45 kg), adjust the tension to 100 lb (45 kg).

FAN BELTS **(See Fig. 1)**

1. Remove the belts.

1.1 Remove the alternator belt. For instructions, refer to the alternator belt procedure in this subject.

1.2 Loosen the fan hub mounting bolts.

1.3 Turn the fan hub adjusting bolt until there is minimal distance between the pulley centers.

1.4 Remove the fan belt by slipping it off of the pulleys and working it over one fan blade at a time. Don't roll or pry the belt off; the distance between the pulley centers must be short enough to allow belt removal without using force.

2. Install the belt.

2.1 Inspect the pulleys and used fan belt (even if a new belt is being installed) as instructed in **Subject 100**.

2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

2.3 Work the belt over the fan blades, one blade at a time. Install the belt on the pulleys without prying or rolling it into place.

2.4 While keeping the belt seated in the pulley grooves, turn the fan hub adjusting bolt to increase the belt tension. Use your thumb to apply about 25 lb (11 kg) of force at the center of the belt free-span to check the tension while turning the bolt. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, stop, and adjust the belt tension.

3. Adjust the belt tension.

3.1 If not already done, loosen the fan hub mounting bolts.

3.2 Install a belt tension gauge on the belt, at the center of the belt free-span.

IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

3.3 Turn the fan hub adjusting bolt to increase or decrease the belt tension, but do not adjust the tension to the full value with the fan hub adjusting bolt; tension can increase when the fan hub bracket bolts are tightened. Final tension must be 100 lb (45 kg).

3.4 Tighten the fan hub mounting bolts 70 lbf·ft (95 N·m).

3.5 Loosen the fan hub adjusting bolt one-half turn.

3.6 Check the belt tension, and adjust it if needed.

3.7 Install and adjust the alternator belt.

3.8 If a new belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

If the fan belt tension is not 100 lb (45 kg), adjust the tension to 100 lb (45 kg).

Engine Removal and Installation, Caterpillar 3406

Removal

1. Apply the parking brakes, chock the tires, and drain the air system.
2. Disconnect the batteries.
3. Remove the hood and the bumper. For instructions, refer to **Group 88** in this manual.
4. Disconnect the transmission from the engine. For instructions, refer to **Group 26** in this manual.
5. Remove the air cleaner housing and the brackets that hold the housing to the bulkhead. This includes removing the heat shield between the cleaner and the turbocharger. For instructions, refer to **Group 09** in this manual.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

6. Drain the radiator. For instructions, refer to **Section 20.01**.
7. Move the air conditioning components out of the way without breaking the refrigerant lines.
   - 7.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser.
   - 7.2 Free the refrigerant lines from all routing clamps and stand-off brackets between the receiver dryer and the condenser.
   - 7.3 Remove the condensers mounting fasteners, and move the condenser aside.
   - 7.4 Remove the refrigerant compressor and move the compressor aside. For instructions, refer to **Group 83** in this manual.
   - 7.5 Use tie straps to secure the refrigerant compressor and condenser out of the way.
8. Remove the air recirculation shields around the radiator and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
9. Remove the radiator and charge air cooler. For instructions, refer to **Section 20.01** in this manual. Remove the radiator mounting bracket with the radiator.
10. Disconnect or remove the remaining ducts and lines.
    - 10.1 If not already removed, remove the air duct between the turbocharger and the air cleaner.
    - 10.2 Disconnect the vent line from the engine, and move the line aside.
    - 10.3 Disconnect the two air signal lines from the air governor.
    - 10.4 Disconnect the outlet line from the air compressor.
    - 10.5 Disconnect the air line to the fan clutch solenoid, and free the line from routing clamps.
    - 10.6 Disconnect the heater supply and return hoses from the radiator outlet pipe, and free the hoses from the clamps that route them to the bulkhead.
    - 10.7 If applicable, disconnect the ether start fluid line from the engine manifold.
11. Remove the surge tank and mounting bracket from the bulkhead. For instructions, refer to **Section 20.01** in this manual.
12. Remove the windshield wiper pan. For instructions, refer to **Group 60** in this manual.
13. Label and disconnect the wiring.
14. Without draining the power steering fluid, remove the power steering fluid pump from the engine, leaving the fluid plumbing intact. For instructions, refer to **Group 46** in this manual.
15. Under the engine, disconnect or remove the remaining components.
    - 15.1 Remove the section of exhaust ducting that runs between the turbocharger and the muffler.
    - 15.2 Disconnect the fuel return lines. For instructions, refer to **Group 47** in this manual.
    - 15.3 Remove the bolts that hold the engine legs to the rear engine mounts.

Engine Removal and Installation, Caterpillar 3406

WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

16. Remove the engine from the vehicle.

    16.1 Attach the chain to the lifting eyes at the front and the rear of the engine.

    NOTE: If the engine is equipped with an exhaust brake, it may be necessary to remove the front valve cover to provide clearance for the lifting chain.

    16.2 With the two engine lifting eyes connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.

    16.3 Remove the nuts from the bolts that fasten the front engine support bracket to the underslung crossmember.

    16.4 Using the crane, lift the engine slightly and remove the upper isolator from the front engine mount.

    16.5 With the front of the engine lifted slightly, remove the front underslung crossmember. For instructions, refer to **Group 31**.

    16.6 Using the crane, lift the engine and pull it forward.

    16.7 Once the engine is clear of the vehicle, place the engine on engine stands.

Installation

WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely supported on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

1. Install the engine in the vehicle.

    1.1 Attach the chain to the lifting eyes at the front and the rear of the engine.

    1.2 With the two engine lifting eyes connected by chain to the crane, lift the engine, and position it in the engine compartment.

    1.3 Connect the engine to the rear engine mounts, and tighten the bolt that runs down through each engine leg, rubber isolators, and engine mount 213 to 269 lbf·ft (289 to 365 N·m).

    1.4 With the front of the engine lifted slightly, install the front underslung crossmember. For instructions, refer to **Group 31**.

    1.5 Assemble the lower isolator under the underslung crossmember and the front engine bracket, and secure the front engine mount with nuts and washers. Tighten the nuts 213 to 269 lbf·ft (289 to 365 N·m).

    1.6 Once the engine is securely installed in the vehicle, remove the lifting chains.

    NOTE: If the valve covers were removed, install them according to the engine manufacturer's service literature.

2. Connect and install components under the engine.

    2.1 Connect the exhaust pipe to the muffler.

    2.2 Connect the two fuel return lines. For instructions, refer to **Group 47** of this manual.

    2.3 Connect the transmission to the engine. For instructions, refer to **Group 26** in this manual.

3. Without breaking the power steering fluid lines, install the power steering pump. For instructions, refer to **Group 46** in this manual.

4. Connect the wiring. For wiring harness information, refer to **Group 54** in this manual.

5. Install the windshield wiper pan. For instructions, refer to **Group 60**.

6. Connect or install the ducts and lines.
   - 6.1 Install the V-band clamp that holds the forward end of the exhaust ducting to the rear of the turbocharger. Tighten the V-band clamp 85 lbf·in (940 N·cm).
   - 6.2 Install the air duct between the turbocharger and the air cleaner.
   - 6.3 Connect the vent line to the engine.
   - 6.4 Connect the two air signal lines to the air governor on top of the compressor.
   - 6.5 Connect the outlet line to the air compressor.
   - 6.6 Connect the air line to the fan clutch solenoid.
   - 6.7 Connect the heater supply and return hoses to the radiator outlet pipe.
   - 6.8 If applicable, connect the ether start line to the engine manifold.
7. Install the radiator, surge tank, fan shroud, and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
8. Install the air recirculation shields around the radiator and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
9. Install the air conditioning components without breaking the refrigerant lines.
   - 9.1 Install the condenser. For instructions, refer to **Group 83** of this manual.
   - 9.2 Install the refrigerant compressor. For instructions, refer to **Group 83** of this manual. For instructions on installing the compressor drive belts, refer to **Section 01.02** in this workshop manual group.
   - 9.3 Route and clamp the refrigerant lines between the compressor and the condenser.
   - 9.4 Route and clamp the refrigerant lines between the receiver-drier and the condenser.
10. Install the air cleaner housing. For instructions, refer to **Group 09** in this manual. Connect the intake air ducting to the air cleaner and the charge air cooler.
11. Install the hood and the bumper. For instructions, refer to **Group 88** in this manual.
12. Fill the radiator.
13. Connect the batteries.
14. Start the engine, and check for leaks. Repair any leaks found.
15. Test drive the vehicle.

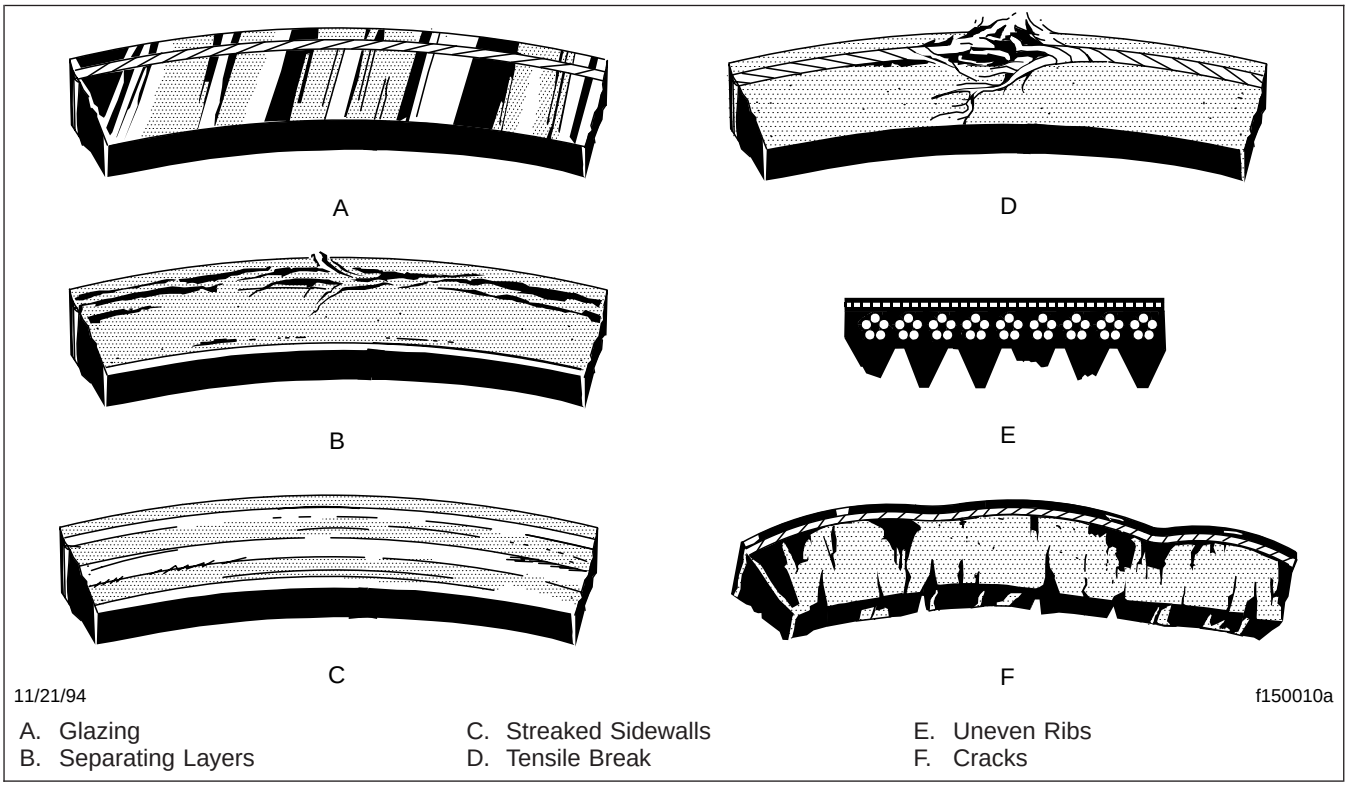
Pulley and Drive Belt Inspection, Cummins Engines

Inspection

1. Inspect all used drive belts (including those that are being replaced) for the following conditions (**see Fig. 1**):



A. Glazing
B. Separating Layers
C. Streaked Sidewalls
D. Tensile Break
E. Uneven Ribs
F. Cracks

Fig. 1, Drive Belt Problems

NOTE: For an installed belt, gently twist the belt about 90 degrees so you can see the sidewalls and bottom.

1.1 Inspect for glazing (shiny sidewalls). Glazing is caused by friction created when a loose belt slips in the pulleys. It can also be caused by oil or grease on the pulleys.

1.2 Inspect for separating layers. Oil, grease, or belt dressings can cause the belt to fall apart in layers. If engine parts are leaking, repair the oil leaks. Do not use belt dressings on any belt.

1.3 Check for jagged or streaked sidewalls. These are the result of a foreign object (such as sand or small gravel) in the pulley, or a rough pulley wall surface.

1.4 Check for tensile breaks (breaks in the cord body). Cuts in a belt are usually caused by large foreign objects in the pulley, or by prying or forcing the belt during installation or removal.

1.5 On poly-V belts, check for uneven ribs. Foreign objects in the pulley will erode the undercord ribs, causing the belt to lose its gripping power.

1.6 Inspect for cracks. Small, irregular cracks are usually signs of an old belt.

Replace the belt if any of the above conditions are found. Replace both belts of a set, at the same time. Matched belts must be from the same manufacturer.

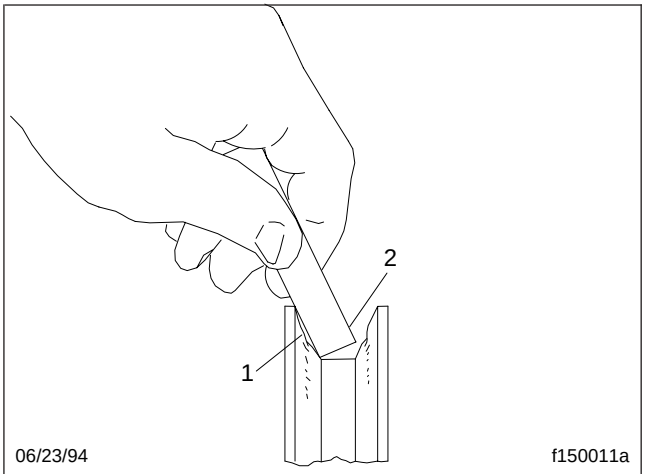
2. Check all pulley bearings for roughness. Replace the bearings if they're rough.

3. Inspect all pulleys for foreign objects, oil, or grease in the grooves. Use a nonflammable

Pulley and Drive Belt Inspection, Cummins Engines

cleaning solvent to remove oils. Use a wire brush to remove rust, and a file to remove burrs.

4. Inspect the pulleys for wear on the inner walls. Hold a small straightedge against the inside of the pulley walls (**Fig. 2**), or use your little finger or fingernail to find grooves in the inner walls. If there are any grooves, replace the pulley.



1. Groove in Pulley Wall
2. Small Straightedge

Fig. 2, Check for Pulley Wear

5. Check alignment of pulleys.Use a thin straightedge that is longer than the longest span between the pulleys. Place the straightedge into the V-grooves of two pulleys at a time. The straightedge should be parallel to the outer edges of the pulleys; if not, the pulleys are misaligned.

   Pulley misalignment must not be more than 1/16-inch for each foot (1.5 mm for each 30.5 cm) of distance between pulley centers.

   If there is misalignment of the pulleys, adjust the pulleys or brackets if their positions are adjustable. **See Fig. 3**. Replace bent or broken pulleys, pulley brackets, or shafts.

6. Check all drive component mounting parts for loose fasteners, cracks, or other damage. Tighten loose fasteners. Repair or replace cracked or damaged brackets.

12. Belt Tensioner
13. Idler Pulley

Fig. 1, Drive Belts, Cummins M11

1. Remove the belt.
   - 1.1 Loosen the alternator mounting bolt and the adjustment link locking capscrew just enough to allow movement of the alternator.
   - 1.2 Loosen the adjusting screw locknut.
   - 1.3 Turn the alternator adjusting screw, backing off the alternator toward the drive pulley far enough to allow belt removal without using force.
   - 1.4 Remove the belt, without prying or rolling it off of the pulleys.
2. Install the new belt.
   - 2.1 Inspect the pulleys and used alternator belt (even if a new belt is being installed) as instructed in **Subject 100**.
   - 2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

Drive Belt Replacement, Cummins M11

2.3 Install the belt on the pulleys without prying or rolling it into place. Be sure the ribs on the belt are seated in the grooves on each pulley.

2.4 While keeping the belt seated in the pulley grooves, turn the adjusting screw clockwise to increase the belt tension. Use your thumb to apply about 25 lbs (11 kg) of force at the center of the belt free-span to check the tension while turning the adjusting screw. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, stop.

3. Adjust the belt.

3.1 If not already done, loosen the adjusting screw locknut, and loosen the alternator mounting bolts, just enough to allow movement of the alternator.

3.2 Install a belt tension gauge at the center of the belt free-span.

3.3 Turn the adjusting screw to adjust the tension to a reading of 100 lbs (45 kg).

IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

3.4 Tighten the adjusting screw locknut 95 lbf·ft (130 N·m).

3.5 Tighten the alternator mounting fastener 70 lbf·ft (95 N·m), the adjusting block nut 35 lbf·ft (50 N·m), and the adjusting link locking capscrew 55 lbf·ft (75 N·m).

3.6 Check the belt tension, and adjust it if needed.

3.7 If a new alternator belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

3.8 If the alternator belt tension is not 100 lbs (45 kg), adjust the tension to 100 lbs (45 kg).

FAN BELT **(See Fig. 1)**

1. Remove the belt.

1.1 Loosen the locknut that secures the idler pulley to the fan bracket.

1.2 Turn the fan adjusting screw until there is minimal distance between the pulley centers.

1.3 Remove the fan belt by slipping it off of the pulleys and working it over one fan blade at a time. Don't roll or pry the belt off of the pulleys; the distance between the pulley centers must be short enough to allow belt removal without using force.

2. Install the new belt.

2.1 Inspect the pulleys and used fan belt (even if a new belt is being installed) as instructed in **Subject 100**.

2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

2.3 Work the belt over the fan blades, one blade at a time. Install the belt on the pulleys without prying or rolling it into place. Be sure the ribs on the belt are seated in the grooves on each pulley.

2.4 While keeping the belt seated in the pulley grooves, turn the idler pulley adjustment capscrew to increase the belt tension. Use your thumb to apply about 25 lbs (11 kg) of force at the center of the belt free-span to check the tension while turning the capscrew. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, stop.

3. Adjust the belt.

3.1 If not already done, loosen the locknut that secures the idler pulley to the fan bracket.

3.2 Install a belt tension gauge at the center of the belt's longest free-span.

3.3 Turn the fan adjusting screw to increase or decrease belt tension, but do not adjust the tension to the full value with the idler pulley adjustment capscrew; belt tension can increase when the idler pulley locknut is tightened. Final tension must be 100 lbs (45 kg).

IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

3.4 Tighten the idler pulley locknut 120 to 140 lbf·ft (165 to 190 N·m).

3.5 Loosen the fan adjusting screw one-half turn, to prevent breakage.

3.6 Check the belt tension, and adjust it if needed.

3.7 If a new fan belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

3.8 If the fan belt tension is not 100 lbs (45 kg), adjust the tension to 100 lbs (45 kg).

REFRIGERANT COMPRESSOR, EQUIPPED WITH A STANDARD DRIVE BELT (See Fig. 1)

1. Remove the belt.
   1.1 Back off the adjusting nut. Loosen the pivot bolts just enough to allow movement of the compressor.
   1.2 Push the loosened compressor toward the accessory drive pulley until the distance between them is short enough to allow belt removal without using force.
   1.3 Remove the belt, without prying or rolling it off of the pulleys.
2. Install the new belt.
   2.1 Inspect the pulleys and used refrigerant compressor belt (even if a new belt is being installed) as instructed in **Subject 100**.
   2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.
   2.3 Install the belt on the pulleys without prying or rolling it into place.
   2.4 Back off the jam nut.
   2.5 While keeping the belt seated in the pulley grooves, turn the adjusting nut to increase belt tension. Use your thumb to apply about 25 lbs (11 kg) of force at the center of the belt free-span to check the tension while turning the nut. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, stop.
3. Adjust the belt.
   3.1 If not already done, back off the jam nut, and loosen the mounting bolts just enough to allow movement of the compressor.
   3.2 Install a belt tension gauge at the center of the belt free-span.
   3.3 Turn the adjusting nut to adjust the tension to a reading of 100 lbs (45 kg).

   IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

   3.4 Tighten the jam nut 155 lbf·ft (210 N·m).
   3.5 Tighten the compressor mounting bolts 30 lbf·ft (40 N·m), and the adjusting link bolt 40 lbf·ft (55 N·m).
   3.6 Check the belt tension, and adjust it if needed.
   3.7 If a new refrigerant compressor belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.
   3.8 If the refrigerant compressor belt tension is not 100 lbs (45 kg), adjust the tension to 100 lbs (45 kg).

REFRIGERANT COMPRESSOR, EQUIPPED WITH A POLY-VEE SERPENTINE BELT (See Fig. 1)

1. Remove the belt.
   1.1 Insert a breaker bar in the belt tensioner and rotate the tensioner counterclockwise off the belt.
   1.2 Remove the belt from the refrigerant compressor pulley and the idler pulley.
   1.3 Slowly release the belt tensioner, then remove the breaker bar.
   1.4 Remove the belt from the lower pulley.
2. Install the belt.

Drive Belt Replacement, Cummins M11

2.1 Inspect the pulleys and used belt (even if installing a new belt) as instructed in **Subject 100**.

2.2 Loop the belt around the lower pulley and align it in the grooves of the pulley.

2.3 Insert a breaker bar in the belt tensioner, and rotate the tensioner counterclockwise.

2.4 Holding the belt tensioner up, install the belt onto the refrigerant compressor pulley and the idler pulley.

2.5 Slowly release the belt tensioner onto the belt. The tensioner automatically tightens the belt to the correct tension and maintains it.

2.6 Remove the breaker bar from the belt tensioner.

3. If the belt slips, replace the belt tensioner. For instructions, refer to the engine manufacturer's service literature.

1. Loosen the alternator adjusting link capscrew and the alternator pivot bolt.
2. Move the alternator toward the drive pulley far enough to remove the drive belt without prying or twisting it.
3. Push in on the alternator, and remove the belt.
4. Install the belt.

4.1 Inspect the pulleys and used alternator belts (even if new belts are being installed) as instructed in **Subject 100**.

4.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

4.3 Install the belts on the pulleys without prying or rolling them into place.

5. Adjust the belt tension.

5.1 Install a belt tension gauge at the center of the free-span of one of the belts.

Drive Belt Replacement, Cummins N14

IMPORTANT: Do not overtighten the belts; too much tension shortens belt life and bearing life.

5.2 Use a pry bar between the engine and the alternator to tighten the alternator belt.

Adjust the tension to a reading of 100 lbf (45 kg).

5.3 Tighten the adjusting link capscrew 50 lbf·ft (68 N·m).

5.4 Tighten the alternator pivot bolt 70 lbf·ft (95 N·m).

5.5 Check the belt tension, and adjust it if needed.

5.6 If new alternator belts were installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

If the alternator belt tension is not 100 lbf (45 kg), adjust the tension.

FAN BELTS (See Fig. 1)

1. Remove the belts.

1.1 Loosen the nuts on the bolts that secure the fan hub to the fan bracket.

1.2 Turn the fan adjusting screw until there is minimal distance between the pulley centers.

1.3 Remove both fan belts by slipping them off of the pulleys and working them over one fan blade at a time. Don't roll or pry the belts off of the pulleys; the distance between the pulley centers must be short enough to allow belt removal without using force.

2. Install the belts.

2.1 Inspect the pulleys and used fan belts (even if new belts are being installed) as instructed in **Subject 100**.

2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

2.3 Work the belts over the fan blades, one blade at a time. Install the belts on the pulleys without prying or rolling them into place.

2.4 While keeping the belts seated in the pulley grooves, turn the fan adjusting screw to increase belt tension. Use your thumb to apply about 25 lbf (11 kg) of force at the center of the belt free-span to check the tension while turning the bolt. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, adjust the belt tension.

3. Adjust the belt tension.

3.1 If not already done, loosen the nuts on the bolts that secure the fan hub to the fan hub bracket.

3.2 Install a belt tension gauge at the center of the free-span of one of the belts.

IMPORTANT: Do not overtighten the belts; too much tension shortens belt life and bearing life.

3.3 Turn the fan hub adjusting bolt to increase or decrease belt tension, but do not adjust the tension to the full value with the adjusting bolt; belt tension can increase when the fan hub bracket nuts are tightened.

Final tension must be 100 lbf (45 kg).

3.4 Tighten the fan hub bracket nuts 80 lbf·ft (110 N·m).

3.5 Loosen the fan hub adjusting bolt one-half turn to prevent breakage.

3.6 Check the belt tension, and adjust it if needed.

3.7 Install and adjust the refrigerant compressor belt, if so equipped.

3.8 If any new belts were installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

3.9 If the fan belt tension is not 100 lbf (45 kg), adjust the tension to 100 lbf (45 kg).

REFRIGERANT COMPRESSOR BELT (See Fig. 1)

1. Remove the belt.
   - 1.1 Loosen the compressor pivot bolts.
   - 1.2 Back off the refrigerant compressor adjusting nut, and lower the compressor in the compressor mounting bracket.
   - 1.3 Remove the belt without prying or rolling it off of the pulleys.
2. Install the belt.
   - 2.1 If the fan belts were removed, install and adjust them first.
   - 2.2 Inspect the pulleys and used refrigerant compressor belt (even if a new belt is being installed) as instructed in **Subject 100**.
   - 2.3 Make sure the distance between the pulleys is short enough to allow belt installation without using force.
   - 2.4 Install the belt on the pulleys without prying or rolling it into place.
   - 2.5 Rotate the compressor pulley away from the drive pulley. Use your thumb to apply about 25 lbf (11 kg) of force at the center of the belt free-span to check the tension while lifting the compressor. When belt deflection equals one belt thickness per foot (305 mm) of pulley-center distance, adjust the belt tension.
3. Adjust the belt tension.
   - 3.1 Install a belt tension gauge at the center of the longest belt free-span.

   IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

   - 3.2 Turn the adjusting nut until the belt tension is 100 lbf (45 kg).
   - 3.3 Tighten the compressor mounting capscrews 28 lbf·ft (38 N·m).
   - 3.4 Check the belt tension, and adjust it if needed.
   - 3.5 If a new refrigerant compressor belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

   If the compressor belt tension is not 100 lbf (45 kg), adjust the tension to 100 lbf (45 kg).

Removal

1. Apply the parking brakes, chock the tires, and drain the air system.
2. Disconnect the batteries.
3. Remove the hood and bumper. For instructions, refer to **Group 88** in this manual.
4. Remove the transmission. For instructions, refer to the applicable section in **Group 26** in this manual.
5. Remove the air cleaner housing and the brackets that hold the housing to the bulkhead. This includes removing the heat shield between the cleaner and the turbocharger. For instructions, refer to **Group 09** in this manual.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

6. Drain the radiator. For instructions, refer to **Section 20.01**.
7. Move the air conditioning components out of the way without breaking the refrigerant lines.
   - 7.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser.
   - 7.2 Free the refrigerant lines from all routing clamps and stand-off brackets between the receiver- drier and the condenser.
   - 7.3 Remove the condenser mounting fasteners, and move the condenser aside.
   - 7.4 Remove the refrigerant compressor and move the compressor aside.
   - 7.5 Use tie straps to secure the refrigerant compressor and condenser out of the way.
8. Remove the air recirculation shields around the radiator and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
9. Remove the radiator and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
10. Disconnect or remove the remaining ducts and lines.
    - 10.1 If not already removed, remove the air duct between the turbocharger and the air cleaner.
    - 10.2 Disconnect the vent line from the engine, and move the line aside.
    - 10.3 Disconnect the two air signal lines from the air governor on top of the compressor.
    - 10.4 Disconnect the outlet line from the air compressor.
    - 10.5 Disconnect the oil line to the gauge.
    - 10.6 Disconnect the air line to the fan clutch solenoid, and free the line from routing clamps.
    - 10.7 Disconnect the heater supply and return hoses from the radiator outlet pipe, and free the hoses from the clamps that route them to the bulkhead.
11. Disconnect the engine harness at the firewall.
12. Disconnect the power and ground connections to the starter.
13. Disconnect the harness from the rear of the engine.
14. Remove the windshield wiper pan. For instructions, refer to **Group 60**.
15. Remove the windshield wiper linkage. For instructions, refer to **Group 82** in this manual.
16. Label and disconnect the wiring.
17. Without breaking the power steering fluid lines, remove the power steering pump, and move it aside. For instructions, refer to **Group 46** in this manual.
18. Under the engine, disconnect or remove the remaining components.
    - 18.1 Remove the flex pipe section of exhaust ducting that attaches to the turbocharger.
    - 18.2 Disconnect the fuel return lines. For instructions, refer to **Group 47** in this manual.
    - 18.3 Remove the bolts that hold the engine legs to the rear engine mounts.

Engine Removal and Installation, Cummins M11

WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

19. Remove the engine from the vehicle.
    - 19.1 Attach the chain to the lifting eyes at the front and the rear of the engine.
    - 19.2 With the two engine lifting points connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.
    - 19.3 Remove the nuts from the bolts that fasten the front engine support bracket to the underslung crossmember.
    - 19.4 Using the crane, lift the engine slightly and remove the upper isolator from the front engine mount.
    - 19.5 Remove the front underslung crossmember. For instructions, refer to **Group 31**.
    - 19.6 Using the crane, lift the engine and pull it forward.
    - 19.7 Once the engine is clear of the vehicle, place the engine on engine stands.

Installation

WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely supported on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

1. Install the engine in the vehicle.
    - 1.1 Attach the chain to the lifting eyes at the front and the rear of the engine.
    - 1.2 With the two engine lifting points connected by chain to the crane, lift the engine, and position it in the engine compartment.
    - 1.3 Connect the engine to the rear engine mounts, and tighten the bolt that runs down through each engine leg, rubber isolators, and engine mount 213 to 269 lbf·ft (289 to 365 N·m).
    - 1.4 Install the front underslung crossmember. For instructions, refer to **Group 31**.
    - 1.5 Assemble the lower isolator under the underslung crossmember and the front engine bracket, and secure the front engine mount with nuts and washers. Tighten the nuts 213 to 269 lbf·ft (289 to 365 N·m).
    - 1.6 Once the engine is securely installed in the vehicle, remove the lifting chains and the special lifting bracket.
2. Connect and install components under the engine.
    - 2.1 Connect the exhaust flex pipe to the forward end of the exhaust piping.
    - 2.2 Connect the fuel return lines. For instructions, refer to **Group 47** of this manual.
3. Without breaking the power steering fluid lines, install the power steering pump. For instructions, refer to **Group 46** in this manual.
4. Connect the wiring. For wiring harness information, refer to **Group 54** in this manual.
5. Install the windshield wiper linkage. For instructions, refer to **Group 82** in this manual.
6. Install the windshield wiper pan.
7. Connect or install the ducts and lines.
    - 7.1 Install the V-band clamp that holds the forward end of the flex pipe exhaust ducting to the rear of the turbocharger. Tighten it 85 lbf·in (940 N·cm).
    - 7.2 Install the air duct between the turbocharger and the air cleaner.
    - 7.3 Connect the vent line to the engine.
    - 7.4 Connect the two air signal lines to the air governor on top of the compressor.

7.5 Connect the outlet line to the air compressor.

7.6 Connect the air line to the fan clutch solenoid.

7.7 Connect the oil line to the gauge.

7.8 Connect the heater supply and return hoses to the radiator outlet pipe.

8. Install the radiator, fan shroud, and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
9. Install the air recirculation shields around the radiator and charge air cooler. For instructions, refer to **Section 20.01** in this manual.
10. Install the air conditioning components without breaking the refrigerant lines.

    10.1 Install the condenser. For instructions, refer to **Group 83** of this manual.

    10.2 Install the refrigerant compressor. For instructions, refer to **Group 83** of this manual. For instructions on installing the compressor drive belts, refer to **Section 01.00** in this manual group.

    10.3 Route and clamp the refrigerant lines between the compressor and the condenser.

    10.4 Route and clamp the refrigerant lines between the receiver-drier and the condenser.

11. Install the air cleaner housing. For instructions, refer to **Group 09** in this manual. Connect the intake air ducting to the air cleaner and the charge air cooler.
12. Install the transmission. For instructions, refer to the applicable section in **Group 26** in this manual.
13. Install the hood and bumper. For instructions, refer to **Group 88** in this manual.
14. Fill the radiator.
15. Connect the batteries.
16. Start the engine, and check for leaks. Repair any leaks found.
17. Test drive the vehicle.

WARNING

The crane and lifting chains used to remove and install the engine must be capable of safely lifting and supporting two metric tons. Do not get under the engine until it is securely supported on engine stands or the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Disconnect the batteries.
4. Remove the bumper. For instructions, see **Section 31.03** for an aerodynamic bumper or **Section 31.12** for a non-aerodynamic bumper.
5. Remove the hood. For instructions, see **Section 88.00**.
6. Disconnect the transmission from the engine. For instructions, see **Section 26.00**.
7. Remove the air cleaner housing and the brackets that hold the housing to the bulkhead. This includes removing the heat shield between the cleaner and the turbocharger. For instructions, see **Section 09.01**.

WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

8. Drain the radiator. For instructions, see **Section 20.01**.
9. Move the air conditioning components out of the way without breaking the refrigerant lines.
   - 9.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser.
   - 9.2 Free the refrigerant lines from all routing clamps and stand-off brackets between the receiver-drier and the condenser.
   - 9.3 Remove the condenser mounting fasteners, and set the condenser aside.
   - 9.4 Remove the refrigerant compressor and set the compressor aside. For instructions, see **Section 83.00** for a Climate Control compressor or **Section 83.01** for a Sanden compressor.
   - 9.5 Use tie straps to secure the refrigerant compressor and condenser out of the way.
10. Remove the air recirculation shields around the radiator and charge air cooler. For instructions, see **Section 20.01**.
11. Remove the radiator and charge air cooler. For instructions, see **Section 20.01**. Remove the radiator mounting bracket with the radiator.
12. Remove the surge tank. For instructions, see **Section 20.01**.
13. Remove the windshield wiper pan.
14. Disconnect or remove the remaining ducts and lines.
    - 14.1 If not already removed, remove the air duct between the turbocharger and the air cleaner.
    - 14.2 Disconnect the vent line from the engine and move the line aside.
    - 14.3 Disconnect the two air signal lines from the air governor.
    - 14.4 At the air dryer, disconnect the outlet line from the air compressor.
    - 14.5 Disconnect the air line to the fan clutch solenoid, and free the line from routing clamps.
    - 14.6 Disconnect the heater supply and return hoses from the radiator outlet pipe, and free the hoses from the clamps that route them to the bulkhead.
15. Label and disconnect the wiring.
16. Disconnect the power steering fluid lines from the power steering fluid pump. Cap the lines. For instructions, see **Section 46.00** for a LuK Automotive pump, **Section 46.02** for a TRW pump or **Section 46.08** for a Vickers pump.
17. Under the engine, disconnect or remove the remaining components.

17.1 Remove the section of exhaust ducting that runs between the turbocharger and the muffler.

17.2 Disconnect the fuel return lines. For instructions, see **Section 47.00**.

17.3 Disconnect the starter motor and solenoid power cables.

17.4 Remove the bolts that hold the engine legs to the rear engine mounts.

18. Remove the engine from the vehicle.

18.1 Attach the chain to the lifting eyes at the front and the rear of the engine.

18.2 With the two engine lifting eyes connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.

18.3 Remove the nuts from the bolts that fasten the front engine support bracket to the underslung crossmember.

18.4 Using the crane, lift the engine slightly and remove the front underslung crossmember. For instructions, see **Section 31.01**.

18.5 Using the crane, lift the engine and pull it forward.

18.6 Once the engine is clear of the vehicle, place the engine on engine stands.

Installation

1. Install the engine in the vehicle.

1.1 Attach the chain to the lifting eyes at the front and the rear of the engine.

1.2 With the two engine lifting eyes connected by chain to the crane, lift the engine, and position it on the rear engine mounts.

1.3 With the front of the engine lifted slightly, install the front underslung crossmember. For instructions, see **Section 31.01**.

1.4 Connect the engine to the rear engine mounts, and tighten the bolt that runs down through each engine leg, rubber isolators, and engine mount 213 to 269 lbf·ft (289 to 365 N·m).

1.5 Assemble the lower isolator under the underslung crossmember and the front engine support bracket, and secure the front engine mount with nuts and washers. Tighten the nuts 213 to 269 lbf·ft (289 to 365 N·m).

1.6 Once the engine is securely installed in the vehicle, remove the lifting chains.

2. Connect and install components under the engine.

2.1 Connect the power cables to the starter motor and solenoid.

2.2 Connect the exhaust pipe to the muffler.

2.3 Connect the fuel return lines. For instructions, see **Section 47.00**.

2.4 Connect the transmission to the engine. For instructions, see **Section 26.00**.

3. Connect the lines to the power steering fluid pump. For instructions, see **Section 46.00** for a LuK Automotive pump, **Section 46.02** for a TRW pump or **Section 46.08** for a Vickers pump.

4. Connect the wiring. For wiring harness information, see **Section 54.12**.

5. Connect or install the ducts and lines.

5.1 Install the V-band clamp that holds the forward end of the exhaust ducting to the rear of the turbocharger. Tighten it 85 lbf·in (940 N·cm).

5.2 Install the air duct between the turbocharger and the air cleaner.

5.3 Connect the vent line to the engine.

5.4 Connect the two air signal lines to the air governor on top of the compressor.

5.5 Connect the air compressor outlet line to the air dryer.

5.6 Connect the air line to the fan clutch solenoid.

5.7 Connect the heater supply and return hoses to the radiator outlet pipe.

6. Install the radiator, fan shroud, and charge air cooler. For instructions, see **Section 20.01**.

7. Install the air recirculation shields around the radiator and charge air cooler. For instructions, see **Section 20.01**.
8. Install the air conditioning components without breaking the refrigerant lines.
   - 8.1 Install the condenser. For instructions, see **Section 83.02**.
   - 8.2 Install the refrigerant compressor. For instructions, see **Section 83.00** for a Climate Control compressor or **Section 83.01** for a Sanden compressor.
   - 8.3 Install the compressor drive belts. For instructions, see **Subject 140**.
   - 8.4 Route and clamp the refrigerant lines between the compressor and the condenser.
   - 8.5 Route and clamp the refrigerant lines between the receiver-drier and the condenser.
9. Install the surge tank. For instructions, see **Section 20.01**.
10. Install the windshield wiper pan.
11. Install the air cleaner housing. For instructions, see **Section 09.01**. Connect the intake air ducting to the air cleaner and the charge air cooler.
12. Install the hood. For instructions, see **Section 88.00**.
13. Install the bumper. For instructions, see **Section 31.03** for an aerodynamic bumper or **Section 31.12** for a non-aerodynamic bumper.
14. Fill the radiator.
15. Connect the batteries.
16. Start the engine and check for leaks. Repair any leaks found.
17. Remove the chocks from the tires.
18. Test drive the vehicle.

WARNING

The crane and lifting chains used to remove and install the engine must be capable of safely lifting and supporting two metric tons. Do not get under the engine until it is securely supported on engine stands or the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Disconnect the batteries.
4. Remove the bumper. For instructions, see **Section 31.03** for an aerodynamic bumper or **Section 31.12** for a non-aerodynamic bumper.
5. Remove the hood. For instructions, see **Section 88.00**.
6. Disconnect the transmission from the engine. For instructions, see **Section 26.00**.
7. Remove the air cleaner housing and the brackets that hold the housing to the bulkhead. This includes removing the heat shield between the cleaner and the turbocharger. For instructions, see **Section 09.01**.

WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

8. Drain the radiator. For instructions, see **Section 20.01**.
9. Move the air conditioning components out of the way without breaking the refrigerant lines.
   - 9.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser.
   - 9.2 Free the refrigerant lines from all routing clamps and stand-off brackets between the receiver-drier and the condenser.
   - 9.3 Remove the condenser mounting fasteners and set the condenser aside.
   - 9.4 Remove the refrigerant compressor with its mounting bracket and set the compressor aside. Move the heater lines and wiring harness as needed. For instructions, see **Section 83.00** for a Climate Control compressor or **Section 83.01** for a Sanden compressor.
   - 9.5 Use tie straps to secure the refrigerant compressor and condenser out of the way.
10. Remove the air recirculation shields around the radiator and charge air cooler. For instructions, see **Section 20.01**.
11. Remove the radiator and charge air cooler. For instructions, see **Section 20.01**. Remove the radiator mounting bracket with the radiator.
12. Remove the power steering fluid pump, and move the pump out of the way without breaking the lines or draining the fluid. For instructions, see **Section 46.00** for a LuK Automotive pump, **Section 46.02** for a TRW pump or **Section 46.08** for a Vickers pump.
13. Remove the surge tank. For instructions, see **Section 20.01**.
14. Remove the windshield wiper pan.
15. Remove the windshield wiper linkage. For instructions, see **Section 82.00**.
16. Disconnect or remove the remaining ducts and lines.
   - 16.1 If not already removed, remove the air duct between the turbocharger and the air cleaner.
   - 16.2 Disconnect the vent line from the engine and move the line aside.
   - 16.3 Disconnect the two air signal lines from the air governor.
   - 16.4 At the air dryer, disconnect the outlet line from the air compressor.
   - 16.5 Disconnect the air line to the fan clutch solenoid, and free the line from routing clamps.
   - 16.6 Disconnect the heater supply and return hoses from the firewall, and remove the hoses with the radiator outlet pipe.

17. Label and disconnect the wiring.
18. Remove the clutch linkage.
19. Under the engine, disconnect or remove the remaining components.
    - 19.1 Remove the section of exhaust ducting that runs between the turbocharger and the muffler.
    - 19.2 Disconnect the fuel return lines. For instructions, see **Section 47.00**.
    - 19.3 Disconnect the starter motor and solenoid power cables.
    - 19.4 Remove the bolts that hold the engine legs to the rear engine mounts.
20. Remove the engine from the vehicle.
    - 20.1 Attach the chain to the lifting eyes at the front and the rear of the engine.
    - 20.2 With the three engine lifting eyes connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.
    - 20.3 Remove the nuts from the bolts that fasten the front engine support bracket to the underslung crossmember.
    - 20.4 Using the crane, lift the engine and pull it forward.
    - 20.5 Once the engine is clear of the vehicle, place the engine on engine stands.

Installation

1. Install the engine in the vehicle.
    - 1.1 Attach the chain to the lifting eyes at the front and the rear of the engine.
    - 1.2 With the three engine lifting eyes connected by chain to the crane, lift the engine, and position it on the rear engine mounts.
    - 1.3 Connect the engine to the rear engine mounts, and tighten the bolt that runs down through each engine leg, rubber isolators, and engine mount 213 to 269 lbf·ft (289 to 365 N·m).
    - 1.4 Assemble the lower isolator under the underslung crossmember and the front engine support bracket, and secure the front engine mount with nuts and washers. Tighten the nuts 213 to 269 lbf·ft (289 to 365 N·m).
    - 1.5 Once the engine is securely installed in the vehicle, remove the lifting chains.
2. Connect and install components under the engine.
    - 2.1 Connect the power cables to the starter motor and solenoid.
    - 2.2 Connect the exhaust pipe to the muffler.
    - 2.3 Connect the fuel return lines. For instructions, see **Section 47.00**.
    - 2.4 Connect the transmission to the engine. For instructions, see **Section 26.00**.
3. Install the power steering fluid pump. For instructions, see **Section 46.00** for a LuK Automotive pump, **Section 46.02** for a TRW pump or **Section 46.08** for a Vickers pump.
4. Install the clutch linkage. For instructions, see **Section 25.03**.
5. Connect the wiring. For wiring harness information, see **Section 54.12**.
6. Connect or install the ducts and lines.
    - 6.1 Install the V-band clamp that holds the forward end of the exhaust ducting to the rear of the turbocharger. Tighten it 85 lbf·in (940 N·cm).
    - 6.2 Install the air duct between the turbocharger and the air cleaner.
    - 6.3 Connect the vent line to the engine.
    - 6.4 Connect the two air signal lines to the air governor on top of the compressor.
    - 6.5 Connect the air compressor outlet line to the air dryer.
    - 6.6 Connect the air line to the fan clutch solenoid.
    - 6.7 Install the heater supply and return hoses and the radiator outlet pipe.
7. Install the radiator, fan shroud, and charge air cooler. For instructions, see **Section 20.01**.

8. Install the air recirculation shields around the radiator and charge air cooler. For instructions, see **Section 20.01**.
9. Install the air conditioning components without breaking the refrigerant lines.
   - 9.1 Install the condenser. For instructions, see **Section 83.02**.
   - 9.2 Install the refrigerant compressor. For instructions, see **Section 83.00** for a Climate Control compressor or **Section 83.01** for a Sanden compressor.
   - 9.3 Install the compressor drive belts. For instructions, see **Subject 150**.
   - 9.4 Route and clamp the refrigerant lines between the compressor and the condenser.
   - 9.5 Route and clamp the refrigerant lines between the receiver dryer and the condenser.
10. Install the windshield wiper pan.
11. Install the wiper linkage. For instructions, see **Section 82.00**.
12. Install the surge tank. For instructions, see **Section 20.01**.
13. Install the air cleaner housing. For instructions, see **Section 09.01**. Connect the intake air ducting to the air cleaner and the charge air cooler.
14. Install the hood. For instructions, see **Section 88.00**.
15. Install the bumper. For instructions, see **Section 31.03** for an aerodynamic bumper or **Section 31.12** for a non-aerodynamic bumper.
16. Fill the radiator.
17. Connect the batteries.
18. Start the engine and check for leaks. Repair any leaks found.
19. Remove the chocks from the tires.
20. Test drive the vehicle.

Series 60 Engine Removal and Installation, Argosy COE

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.

⚠ WARNING

Before tilting the cab, read the instructions and the Danger and Warning notices in Section 60.15. Failure to follow these instructions could cause the cab to hit or crush a person, possibly resulting in serious injury or death.

2. Tilt the cab.
3. Remove the air cleaner and the air cleaner mounting bracket. See Fig. 1.

2. Air Cleaner Ducting
3. Air Cleaner
4. Mounting Bracket

Fig. 1, Air Cleaner Assembly

4. Remove the air duct between the turbocharger and the air cleaner.
5. Disconnect the batteries and remove the battery box assembly. For instructions, see Section 54.02.
6. Mark and disconnect all electrical leads, including the main wiring harness to the ECU, and the transmission wiring.
7. On vehicles with automatic transmissions, disconnect the transmission drain plug and the ATF cooler lines.

   7.1 Remove the transmission drain plug and drain the automatic transmission fluid (ATF). Install the drain plug and tighten 15 to 20 lbf·ft (20 to 27 N·m).

   7.2 Disconnect the ATF cooler lines and fittings from the transmission, and drain the remaining transmission fluid. Plug the lines and cap the fittings.
8. Disconnect the starter cables and the solenoid power cables.
9. Disconnect the alternator wiring.
10. Remove the sway bar from the cab air suspension assembly. For instructions, see Section 60.01.
11. Disconnect the wiring from the magnetic switch mounted on the overslung crossmember. For instructions, see Section 54.04.
12. Remove the bolts securing the overslung crossmember to the frame rail, and remove the crossmember.
13. Disconnect the clutch linkage from the transmission.
14. Remove the bolts attaching the shift cables to the transmission. Remove the shift cables from the shift linkage.
15. Remove the charge air cooler ducting. Cover the air intake manifold and turbocharger manifold with a cloth and clamp securely. See Fig. 2.

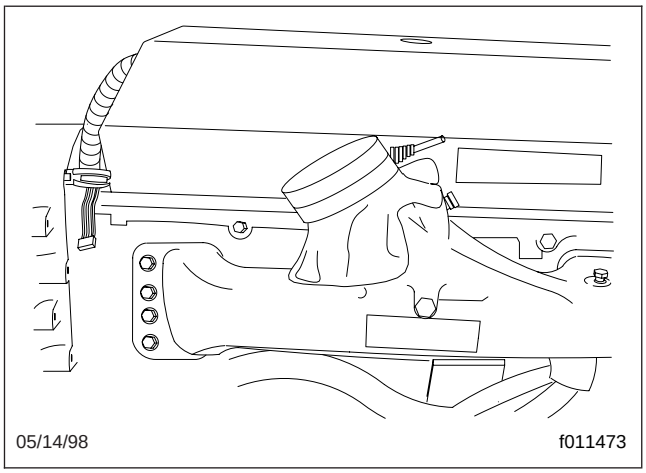

Fig. 2, Air Intake Manifold (covered)

16. Disconnect the fuel lines, and remove them from the transmission mounting clamp. Plug the lines and cap the fittings.

Series 60 Engine Removal and Installation, Argosy COE

17. Remove the section of exhaust flex pipe that runs between the turbocharger and the muffler.
18. Adjust the belt tensioner and remove the belt from the alternator and the air compressor.
19. Label and disconnect the two air signal lines from the air governor.
20. Remove the air line at the air compressor and remove the air compressor. For instructions, see **Section 13.00** for a Bendix compressor or **Section 13.02** for a Midland compressor.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

21. Drain the radiator and remove all radiator lines. Plug the lines and cap the fittings.
22. Remove the driveline from the transmission output yoke. For instructions, see **Section 26.00**. Secure the driveline to the frame rail with a chain or other suitable support.
23. Remove the engine oil dipstick and the fill tubes.
24. Remove the capscrews that hold the fan to the fan clutch, and remove the fan. Secure the fan in the shroud.
25. Label and disconnect the water heater sensor plug on the oil filter cooler. Disconnect the heater lines at the valves.
26. Move the air conditioning components out of the way without damaging the refrigerant lines.
    - 26.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser.
    - 26.2 Free the refrigerant lines from all routing clamps and stand-off brackets between the receiver-drier and the condenser.
    - 26.3 Move the refrigerant lines and harness wiring as necessary.
27. Remove the four bolts attaching the power steering pump to the front of the engine, and remove the pump.
28. Remove the bolts that secure the muffler support brace to the muffler. Pull the brace up and away from the path of the engine.
29. Remove the air service from the fan clutch.
30. Remove the brace that secures the radiator to the frame rail.

⚠ DANGER

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

31. Remove the engine from the vehicle.
    - 31.1 Attach a low-profile lifting device to an A-frame. Move the A-frame into place over the engine.

      Attach the lifting device to the front and rear lifting eyes of the engine. See **Fig. 3**.

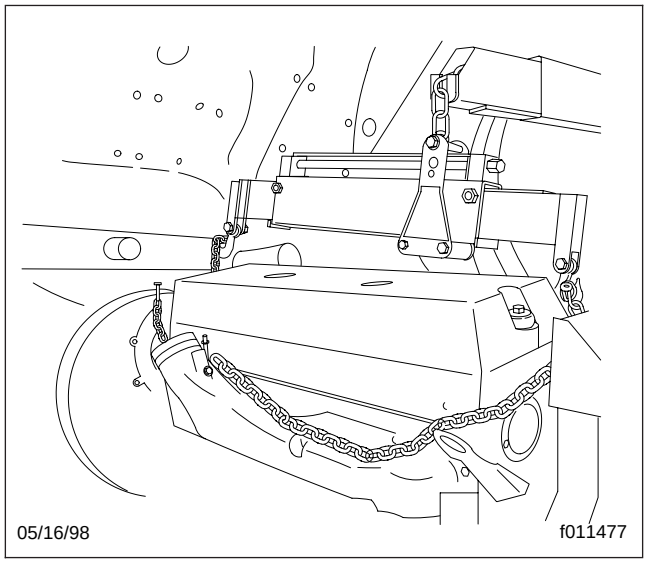

Fig. 3, Engine Lifting Device

    - 31.2 Remove the transmission support bolts, and the engine mount bolts, lower bearing washers, and locknuts. See **Fig. 4**.
    - 31.3 Remove the right transmission mount assembly.
    - 31.4 Remove the engine from the vehicle, and set the engine and transmission on an

engine stand or other suitable support. Remove the lifting device.

Installation

1. Check all of the front and rear engine support parts for damage or extreme wear. Replace the parts as needed.

   Install the isolators in the engine front crossmember. Coat the rubber mounts with soapy water, and install them in the rear engine mounts.

CAUTION

Do not lubricate the components with oil, grease, or silicone lubricants, which can soften the rubber and damage the mounts.

2. Install the right transmission mount assembly. Attach the four bolts to the frame rail and tighten them 136 lbf·ft (184 N·m).
3. Install the engine in the vehicle.

   NOTE: Make sure that all wires are clear before lowering the engine into the vehicle.

   3.1 Attach the lifting device to the engine lifting eyes. Attach the A-frame or overhead crane to the lifting device.

   3.2 Lift the engine and transmission high enough to clear the chassis. Lower the engine and transmission into position on the front and rear engine support mounts.

   3.3 Install the transmission support bolts, bearing washers, and locknuts. Tighten the bolts 280 to 380 lbf·ft (380 to 515 N·m).

   3.4 Position the isolators on the front engine support bolts. Install the bolts and tighten them 140 to 160 lbf·ft (190 to 217 N·m).

   3.5 Remove the lifting device.
4. Position the air compressor on the engine. Tighten the capscrews 20 to 25 lbf·ft (27 to 34 N·m). Replace the belt on the alternator and air compressor.
5. Connect the alternator wiring.
6. Connect the driveline to the transmission output yoke. For instructions, see **Section 26.00**.
7. On vehicles with automatic transmissions, attach the ATF cooler lines. Tighten the fittings 40 to 50 lbf·ft (54 to 68 N·m).
8. Connect the transmission and engine harness wiring, as previously marked.
9. Connect the starter cables and the solenoid power cables.

Series 60 Engine Removal and Installation, Argosy COE

10. Connect the vent line to the engine, the two air signal lines to the air governor, and the air line to the fan clutch solenoid.
11. Install the power steering pump.
12. Connect the water heater lines. Secure the valve clamp to the engine and tighten the locknuts.
13. Connect the engine oil dipstick and the fill tubes. Replace the clamps and tighten the locknuts securely.
14. Replace the section of exhaust flex pipe that runs between the turbocharger and the muffler.
15. Attach all radiator hoses and clamps to the engine. Tighten the clamps securely, but do not overtighten.
16. Position the fan on the fan clutch, and install the five capscrews. Tighten 15 lbf·ft (20 N·m).
17. Attach the charge air cooler ducting, and tighten the clamps.
18. Attach the primary and secondary fuel filters to the engine. Tighten the bolts 43 to 54 lbf·ft (58 to 73 N·m). Connect the fuel filter lines.
19. Install and securely tighten the oil filters on the oil filter cooler.
20. Position the overslung crossmember on the frame rails. Tighten the bolts 190 lbf·ft (258 N·m).
21. Connect the magnetic switch wiring. For instructions, see **Section 54.04**.
22. Position the sway bar on the cab air suspension assembly and the overslung crossmember and tighten the bolts. For instructions, see **Section 60.01**.
23. Connect the clutch linkage to the transmission.
24. Connect the shift cables to the transmission shift linkage.
25. Replace the battery box assembly on the frame rail and connect the batteries. For instructions, see **Section 54.02**.
26. Position the air cleaner mounting bracket on the overslung crossmember and tighten the bolts 40 lbf·ft (54 N·m). Position the air cleaner on the mounting bracket and tighten the bolts 40 lbf·ft (54 N·m).
27. Attach the air duct between the turbocharger and the air cleaner, and tighten the clamps.
28. Attach the support brace that runs between the muffler and the driver's side frame rail. Tighten the muffler brace bolts 50 to 60 lbf·ft (68 to 81 N·m).
29. Fill the cooling system with coolant.

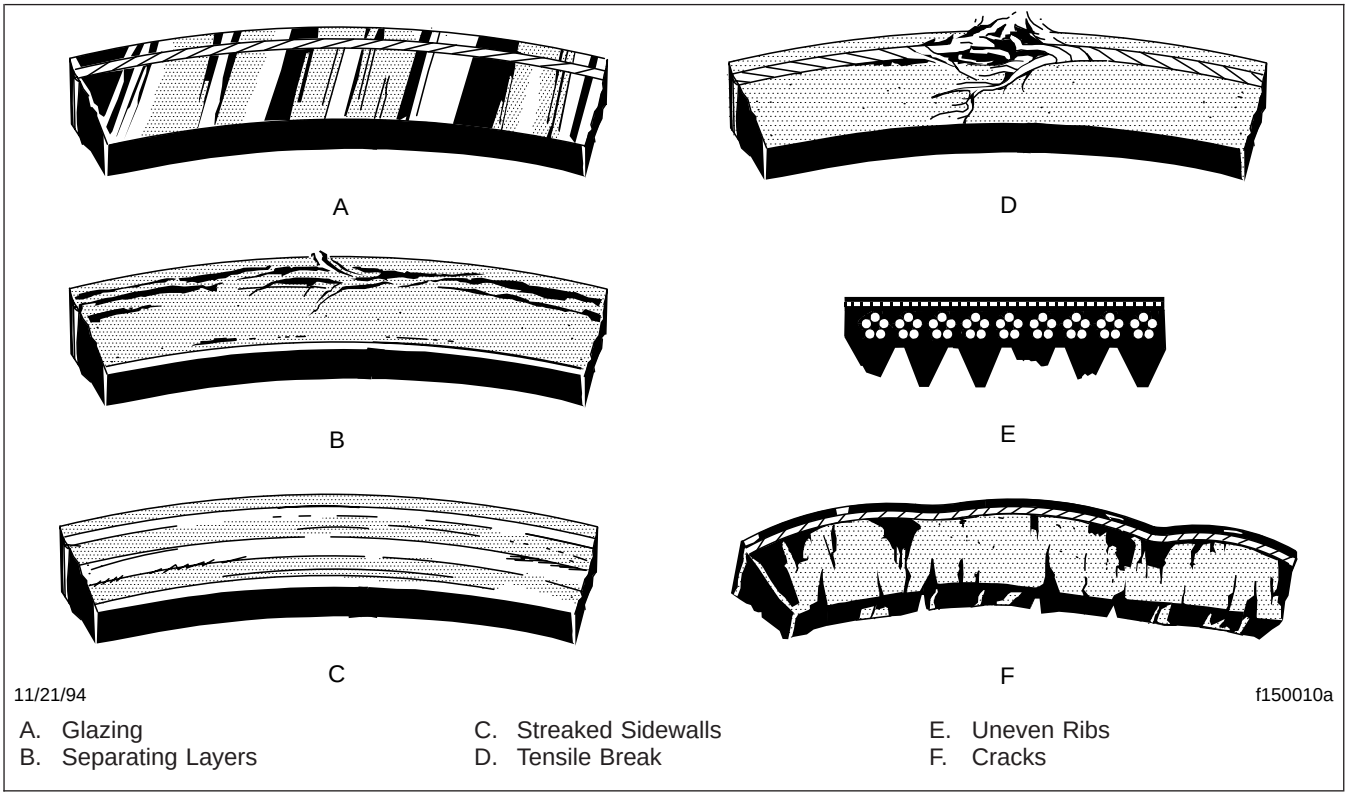
⚠ DANGER

Before returning the cab to the normal operating position, read the instructions and Danger and Warning notices in Section 60.15. Failure to follow these instructions could cause the cab to hit or crush a person, possibly resulting in serious injury or death.

30. Return the cab to the operating position.
31. Remove the chocks from the tires.

Inspection

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Inspect all used drive belts (including those that are being replaced) for the following conditions (see **Fig. 1**):



A. Glazing
B. Separating Layers
C. Streaked Sidewalls
D. Tensile Break
E. Uneven Ribs
F. Cracks

Fig. 1, Drive Belt Problems

NOTE: For an installed belt, gently twist the belt about 90 degrees so you can see the sidewalls and bottom.

2.1 Inspect for glazing (shiny sidewalls). Glazing is caused by friction created when a loose belt slips in the pulleys. It can also be caused by oil or grease on the pulleys.

2.2 Inspect for separating layers. Oil, grease, or belt dressings can cause the belt to fall apart in layers. If engine parts are leaking, repair the oil leaks. Do not use belt dressings on any belt.

2.3 Check for jagged or streaked sidewalls. These are the result of a foreign object (such as sand or small gravel) in the pulley, or a rough pulley wall surface.

2.4 Check for tensile breaks (breaks in the cord body). Cuts in a belt are usually caused by large foreign objects in the pulley, or by prying or forcing the belt during installation or removal.

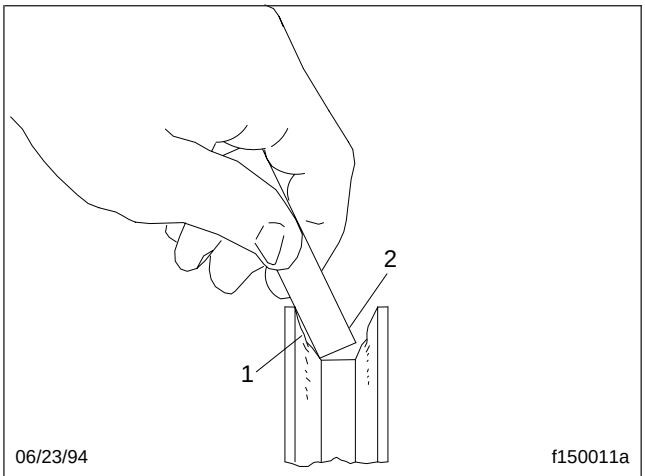
2.5 On poly-V belts, check for uneven ribs. Foreign objects in the pulley will erode the undercord ribs, causing the belt to lose its gripping power.

2.6 Inspect for cracks. Small, irregular cracks are usually signs of an old belt.

Replace the belt if any of the above conditions are found. Replace both belts of a set, at the same time. Matched belts must be from the same manufacturer.

Pulley and Drive Belt Inspection

3. Check all pulley bearings for roughness. Replace the bearings if they are rough.
4. Inspect all pulleys for foreign objects, oil, or grease in the grooves. Use a nonflammable cleaning solvent to remove oils. Use a wire brush to remove rust, and a file to remove burrs.
5. Inspect the pulleys for wear on the inner walls. Hold a small straightedge against the inside of the pulley walls, or use your little finger or fingernail to find grooves in the inner walls. If there are any grooves, replace the pulley. See **Fig. 2**.



1. Groove in Pulley Wall
2. Small Straightedge

Fig. 2, Check for Pulley Wear

6. Check alignment of pulleys.Use a thin straightedge that is longer than the longest span between the pulleys. Place the straightedge into the V-grooves of two pulleys at a time. The straightedge should be parallel to the outer edges of the pulleys. If it is not parallel, the pulleys are misaligned.

   Pulley misalignment must not be more than 1/16-inch for each foot (1.5-mm for each 30.5 cm) of distance between pulley centers.

   If there is misalignment of the pulleys, adjust the pulleys or brackets if their positions are adjustable. See **Fig. 3**. Replace bent or broken pulleys, pulley brackets, or shafts.
7. Check all drive component mounting parts for loose fasteners, cracks, or other damage.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Remove the belt.
   - 2.1 Insert a breaker bar in the belt tensioner and rotate the tensioner counterclockwise off the belt.
   - 2.2 Holding the belt tensioner up, remove the belt from the vibration damper.
   - 2.3 Slowly release the belt tensioner and remove the breaker bar.
   - 2.4 Raise the belt and take it off over the fan. Remove the belt from the engine compartment.
3. Install the belt.
   - 3.1 Inspect the pulleys and used belts (even if installing new belts) as instructed in **Subject 130**.
   - 3.2 Loop the belt around the fan and align it in the fan pulley.
   - 3.3 Insert a breaker bar in the belt tensioner and rotate the tensioner up while installing the belt around the vibration damper pulley.

3.4 Slowly release the tensioner assembly onto the belt. The tensioner automatically tightens the belt to the correct tension.

3.5 Remove the breaker bar from the tensioner.

4. Adjust the belt tension.

4.1 The Detroit Diesel belt tensioner automatically adjusts the belt to the correct tension.

4.2 If the belt slips, repair or replace the tensioner. For instructions, see the engine manufacturer's service literature.

5. Remove the chocks from the tires.

Refrigerant Compressor Belt

(See Fig. 1)

NOTE: To remove the refrigerant compressor belt, you must first remove the fan belt.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Remove the belt.

2.1 Insert a breaker bar in the belt tensioner and rotate the tensioner clockwise off the belt.

2.2 Holding the belt tensioner down, remove the belt from the refrigerant compressor.

2.3 Slowly release the belt tensioner and remove the breaker bar.

2.4 Lower the belt and take it off over the fan. Remove the belt from the engine compartment.

3. Install the belt.

3.1 Inspect the pulleys and used belts (even if installing new belts) as instructed in **Subject 130**.

3.2 Loop the refrigerant compressor belt around the fan and align it in the fan pulley.

3.3 Insert a breaker bar in the belt tensioner and rotate the tensioner clockwise while installing the belt on the refrigerant compressor pulley.

3.4 Slowly release the tensioner assembly onto the belt. The tensioner automatically tightens the belt to the correct tension.

3.5 Remove the breaker bar from the tensioner.

4. Adjust the belt tension.

4.1 The Detroit Diesel belt tensioner automatically adjusts the belt to the correct tension.

4.2 If the belt slips, repair or replace the tensioner. For instructions, see the engine manufacturer's service literature.

5. Remove the chocks from the tires.

Alternator/Water Pump Belt

(See Fig. 1)

NOTE: To remove the alternator belt, you must first remove the fan and refrigerant compressor belts.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Remove the belt.

2.1 Insert a breaker bar in the alternator belt tensioner and rotate the tensioner counterclockwise off the belt.

2.2 Holding the belt tensioner down, remove the belt from the alternator pulley.

2.3 Slowly release the belt tensioner and remove the breaker bar.

2.4 Lower the belt, and take it off the vibration damper. Raise the belt and take it off over the fan. Remove the belt from the engine compartment.

3. Install the belt.

3.1 Inspect the pulleys and used belts (even if installing new belts) as instructed in **Subject 130**.

3.2 Loop the belt around the fan and align it in the grooves of the water pump pulley.

3.3 Loop the belt down and around the vibration damper pulley.

3.4 Insert a breaker bar in the belt tensioner and rotate the tensioner down while installing the belt on the alternator pulley.

3.5 Slowly release the tensioner assembly onto the belt. The tensioner automatically tightens the belt to the correct tension.

3.6 Remove the breaker bar from the tensioner.

4. Adjust the belt tension.

4.1 The Detroit Diesel belt tensioner automatically adjusts the belt to the correct tension.

4.2 If the belt slips, repair or replace the tensioner. For instructions, see the engine manufacturer's service literature.

5. Remove the chocks from the tires.

NOTE: On a joined belt, the Krikit gauge will have a low accuracy of approximately +/– 30 percent. The Kent-Moore gauge is inherently a more accurate device. The belt tension gauge must grip the full width of the belt to get an accurate reading. If the gauge grips only one of the two V's in a Powerband belt, it will not give an accurate reading. The actual tension in the belt will likely be greater than the tension indicated by the gauge. In this case, the Kent-Moore gauge will be no more accurate than the Krikit gauge.

Belt Replacement Without an Automatic Belt Tensioner

Alternator and Refrigerant Compressor Belt

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Remove the belt. See **Fig. 1**.
   - 2.1 Back off the alternator adjusting nut.
   - 2.2 Loosen the alternator pivot bolts.
   - 2.3 Turn the alternator jam nut to rotate the alternator up and toward the engine. Turn the nut until the alternator is close enough to the engine to allow belt removal.
   - 2.4 Remove the belt by slipping it off the pulleys. Do not roll or pry the belt off the pulleys. The distance between the pulley centers must be short enough to allow belt removal without using force.
3. Install the belt.
   - 3.1 Inspect the pulleys and the belt (even if installing a new belt) as instructed in **Subject 130**.
   - 3.2 Install the belt on the pulleys without prying or rolling it into place.
   - 3.3 While keeping the belt seated in the pulley grooves, turn the adjusting nut to rotate the alternator away from the engine and to increase belt tension.

4. Adjust the belt.
   - 4.1 Install a belt tension gauge at the center of the belt's longest free-span.

   IMPORTANT: Do not overtighten the belt. Too much tension shortens belt and bearing life.

   - 4.2 Turn the adjusting nut to rotate the alternator out, away from the engine until the

belt is tensioned 100 lbf (445 N) per belt, 200 lbf (890 N) if using a joined belt.

4.3 Tighten the alternator jam nut 130 lbf·ft (176 N·m).

4.4 Tighten the alternator pivot bolts 70 lbf·ft (95 N·m).

4.5 Remove the chocks from the tires.

4.6 Operate the engine for about 30 minutes or 15 miles (24 km) and recheck the belt tension. Re-tension to a minimum of 75 lbf (334 N) per belt, 150 lbf (668 N) if using a joined belt. Check again after 8 hours of operation or 250 miles (400 km). Adjust the belt tension as needed.

Fan Belt

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Remove the belt. See **Fig. 1**.
   - 2.1 Loosen the four mounting capscrews that attach the fan hub to the engine.
   - 2.2 Loosen the fan adjusting rod to relieve tension from the belt.
   - 2.3 Remove the belt by slipping it off the pulleys and working it over one fan blade at a time. On some vehicles, it may be necessary to remove the fan. For instructions, see **Section 20.01**. Do not roll or pry the belt off the pulleys. The distance between the pulley centers must be short enough to allow belt removal without using force.
3. Install the belt.
   - 3.1 Inspect the pulleys and the belt (even if installing a new belt) as instructed in **Subject 130**.
   - 3.2 Work the belt over the fan blades, one blade at a time. Install the belt on the pulleys without rolling or prying it into place.
   - 3.3 While keeping the belt seated in the pulley grooves, turn the adjusting rod to increase belt tension.
4. Adjust the belt.
   - 4.1 Install a belt tension gauge at the center of the belt's longest free-span.

   IMPORTANT: Do not overtighten the belt. Too much tension shortens belt and bearing life.
   - 4.2 Turn the adjusting rod to increase belt tension to 100 lbf (445 N) per belt.
   - 4.3 Tighten the fan hub mounting capscrews 75 to 83 lbf·ft (100 to 112 N·m).
   - 4.4 Check the belt tension and adjust it if needed.
   - 4.5 Remove the chocks from the tires.
   - 4.6 Operate the engine for about 30 minutes or 15 miles (24 km) and recheck the belt tension. Re-tension to a minimum of 75 lbf (334 N). Check again after 8 hours of operation or 250 miles (400 km). Adjust the belt tension as needed.

Belt Replacement With an Automatic Belt Tensioner

Alternator and Refrigerant Compressor Belt

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Remove the belt. See **Fig. 2**.
   - 2.1 Insert a 1/2-inch breaker bar in the belt tensioner and rotate the tensioner away from the accessory drive belt.
   - 2.2 Holding the belt tensioner down, remove the belt from the alternator pulley.
   - 2.3 Remove the belt from the refrigerant compressor pulley and the engine pulley.
   - 2.4 Slowly release the belt tensioner and remove the breaker bar.
3. Install the belt.

General Description

Three mounts support the engine and transmission, holding a total of almost 816 kg (1800 lb). Two of the engine mounts support the rear of the engine and transmission assembly. The third supports the front of the assembly.

Each of the rear engine mounts (**Fig. 1**) is bolted to the inside of the frame rail near the flywheel housing. These mounts support legs which are bolted to the flywheel housing. The V-shaped rear engine leg sets into a V-shaped rear engine mount. See **Fig. 2** and **Fig. 3**.

The rear engine mounts for EPA07 engines are a one-piece assembly, with the elastomer isolator bonded to the metal bracket. They are designed for longer life and reduced engine vibration. The engine leg fits into a flat recess in the mount, rather than a V-shaped configuration. See **Fig. 4**.

The front engine mount is an underslung crossmember under the front of the engine. It supports a bracket (**Fig. 5** and **Fig. 6**) which is bolted to the engine at each side of the vibration damper pulley.

To isolate the engine and transmission from road shock, and to isolate the vehicle frame from engine vibration, the engine mounts are sandwiched between rubber isolator cushions (sometimes called restriction pads). Steel snubbers protect the cushions from wearing on the engine support brackets, and

Replacement

NOTE: See **Fig. 1** for this procedure.

1. Apply the parking brakes, chock the tires, and (if applicable) drain the air brake system.

⚠ WARNING

WARNING: The jack used to lift the engine must be capable of safely lifting and supporting two metric tons. Once the engine mount is disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

2. Disconnect the engine from the right rear engine mount.

   2.1 Place a jack under the rear of the engine, and raise the jack until it's braced against the engine.

   NOTE: To remove the bolt that connects the engine leg and the engine mount, you may have to disconnect and move the exhaust ducting. To do this, refer to the instructions in **Section 49.00**.

   2.2 Remove the bolt from the right rear engine mount. Save the fasteners, rubber isolator cushions, and snubbers.

   2.3 Lift the engine slightly to take its weight off the right rear engine mount. Place engine stands under the engine to keep it off the engine mount.

3. Remove the bolts which secure the mount to the frame rail. Remove the mount from the frame rail.

   If necessary, remove the four bolts which secure the right engine support bracket to the flywheel housing, and remove the bracket from the engine.

4. Place a new engine mount against the inside of the frame rail, and secure it with bolts, washers, and nuts. Tighten the nuts 120 to 152 lbf·ft (163 to 206 N·m).

5. If removed, install the engine leg on the right side of the flywheel housing. Apply thread-lock compound to the bracket mounting bolts, and tighten them to the torque values in **Table 1**.

6. Inspect the engine mount rubber isolators for wear or damage and replace them if necessary.

⚠ CAUTION

CAUTION: Do not lubricate the components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

7. Install the upper isolator in the engine mount. In order for the isolator holes to align with the holes in the engine mount, the painted side of the isolator must be towards the engine. Fasten the isolator to the mount, and tighten the capscrews 14 to 18 lbf·ft (19 to 24 N·m).

⚠ WARNING

WARNING: The jack used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

8. Secure the engine to the engine mounts.
   - 8.1 If not in place, set a jack under the rear of the engine and raise the jack until it is braced against the engine.
   - 8.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.
   - 8.3 Holding the lower isolator and snubber in place, install the bolt in the right rear engine mount, and secure it with the nut and hardened washer. Tighten the nut 213 to 269 lbf·ft (289 to 365 N·m).
9. Repeat this procedure for the other rear engine mount.
10. Remove the jack from under the engine, and remove the chocks from the tires.

⚠ WARNING

WARNING: The lifting device and chain used to lift the engine must be capable of safely lifting and supporting two metric tons. Once the engine mount is disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

2. Disconnect the engine from the front engine mount.

   2.1 Attach a chain to the front engine lifting hook(s), and position a lifting device to lift the engine. Attach the chain to the lifting device, and raise the chain to remove any slack.

   2.2 Remove the bolt(s) from the front engine mount. Save the fasteners, rubber isolator cushions, and snubber(s).

   NOTE: In order to raise the front of the engine, you may have to loosen the bolts that run through the rear engine mounts.

   2.3 Lift the engine slightly to take its weight off the front engine mount. Place engine stands under the engine to keep it off the engine mount.

3. If you're replacing the front engine support bracket, refer to the engine manufacturer's service literature.

4. Inspect the engine mount rubber isolators for wear or damage and replace them if necessary.

⚠ CAUTION

CAUTION: Do not lubricate the components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

5. Install the upper isolator(s) in the engine mount. If applicable, place the snubber(s) on the isolator(s).

⚠ WARNING

WARNING: The lifting device and chain used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

Front Engine Mount Replacement

6. Secure the engine to the front engine mount.
   - 6.1 Attach a chain to the front engine lifting hook(s). Attach the chain to a lifting device, and raise the chain to remove any slack.
   - 6.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.
   - 6.3 Holding the lower isolator in place, install the bolts in the front engine mount and secure them with the nuts and washers. Tighten the nuts 213 to 269 lbf·ft (289 to 365 N·m).

   NOTE: If you loosened the bolts that run through the rear engine mounts, tighten those bolts 213 to 269 lbf·ft (289 to 365 N·m).

   - 6.4 Remove the lifting chain from the engine lifting hooks.
7. Remove the chocks from the tires.

2. Disconnect the engine from the right rear engine mount.

   2.1 Place a jack under the rear of the engine, and raise the jack until it's braced against the engine.

   NOTE: To remove the bolt that connects the engine leg and the engine mount, you may have to disconnect and move the exhaust ducting. To do this, refer to the instructions in **Section 49.00**.

   2.2 Remove the bolt from the right rear engine mount. Save the fasteners.

   2.3 Use the jack to raise the engine slightly, and secure it with jack stands.

   2.4 Remove the two capscrews that hold the ends of the isolator to the engine mount.

   2.5 Remove the engine mount from the frame rail. For instructions, refer to **Subject 100**. Remove and discard the isolator.

3. Inspect the new engine mount rubber isolators for wear or damage and replace them if necessary.

⚠ CAUTION

CAUTION: Do not lubricate the new components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

4. Install the new isolator in the engine mount, and install the engine mount on the frame rail. In order for the isolator holes to align with the holes in the engine mount, the painted side of the isolator must be towards the engine. For instructions, refer to **Subject 100**.

⚠ WARNING

WARNING: The jack used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

5. Secure the engine to the engine mount.
   - 5.1 If not in place, set a jack under the rear of the engine and raise the jack until it is braced against the engine.
   - 5.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.
   - 5.3 Install the bolt in the right rear engine mount, and secure it with the nut and hardened washer. Tighten the nut 213 to 269 lbf·ft (289 to 365 N·m).

Once the engine mount is disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

2. Disconnect the engine from the front engine mount.

   2.1 Attach a chain to the front engine lifting hook(s), and position a lifting device to lift the engine. Attach the chain to the lifting device, and raise the chain to remove any slack.

   2.2 Remove the bolt(s) from the front engine mount. Save the fasteners, tube(s), and snubber(s). Discard the rubber isolator cushions.

   NOTE: In order to raise the front of the engine, you may have to loosen the bolts that run through the rear engine mounts.

   2.3 Lift the engine slightly to take its weight off the front engine mount. Place engine stands under the engine to keep it off the engine mount.

3. Inspect the new front engine mount rubber isolators for wear or damage and replace them if necessary.

CAUTION

CAUTION: Do not lubricate the new components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

4. Install the upper isolator(s) in the engine mount.

WARNING

WARNING: The lifting device and chain used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

5. Secure the engine to the front engine mount.

Front Engine Mount Isolator Replacement

5.1 Attach a chain to the front engine lifting hook(s). Attach the chain to a lifting device, and raise the chain to remove any slack.

5.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.

5.3 Holding the lower isolator in place, install the bolts in the front engine mount and secure them with the nuts and washers. Tighten the nuts 213 to 269 lbf·ft (289 to 365 N·m).

NOTE: If you loosened the bolts that run through the rear engine mounts, tighten those bolts 213 to 269 lbf·ft (289 to 365 N·m).

5.4 Remove the lifting chain from the engine lifting hook(s).

6. Remove the chocks from the tires.

Rear Engine Mount Replacement, EPA07 Engines

Removal

NOTE: The rear engine mounts for EPA07 engines are designed to last for the life of the vehicle, and should not normally need replacing. The isolators are bonded to the brackets and cannot be replaced separately.

If the rear engine mounts need replacing due to damage, or if you are removing and installing the engine, use this procedure.

In the past, substituting softer isolators from the MBE4000 engine was a way to sometimes remedy engine vibration problems with other engines. This will not work with the EPA07 engines, because all the engine isolators now have the same durometer hardness.

1. Shut down the engine, set the parking brake, and chock the tires.
2. Drain the air tanks.
3. Disconnect all the cables from the batteries. Cover them, using dry rags and tie straps.
4. Remove the battery mega-fuse block from the left-side frame rail, underneath the cab. The mounting nuts are inboard of the frame rail.
5. Open the hood.
6. If present, remove the two tow hooks from the right frame rail.
7. Remove the rain tray.
   - 7.1 Mark, then remove the wiper arms.
   - 7.2 Disconnect any hoses or drains from the bottom of the rain tray.
   - 7.3 Remove the fasteners that hold the rain tray to the frontwall.
   - 7.4 Remove the rain tray from the vehicle.
8. Remove the right and left quarter fenders and the inner splash shields.
9. Remove the air intake canister assembly.
10. Remove the mounting bracket for the air intake canister.
11. Remove the turbocharger heat shield.
12. Disconnect the air lines from the primary air tank, then remove the tank from the vehicle.

⚠ DANGER

Aftertreatment Device (ATD) internal temperatures can remain hot enough to cause personal injury, or ignite combustible materials, for hours after the engine has been shut down.

To avoid potentially serious burns or material damage:

- Let the ATD cool before handling it; be especially careful when opening it to expose the DPF.
- Wear appropriate protective gear.
- Be careful not to place the ATD where flammable gases or other combustible materials may come into contact with hot interior parts.

13. Make sure the aftertreatment device (ATD) is cool, then remove it from the vehicle.

⚠ CAUTION

The ATD assembly weighs from 125 to 150 pounds (57 to 68 kg) and must be protected from impact or sharp jolts. Dropping the ATD, or subjecting it to jarring impact can crack the diesel particulate filter (DPF) inside, which is built on a ceramic substrate. If that happens, the DPF is ruined and must be replaced.

A secure support is necessary to remove and install the ATD safely; the ATD lifting device (TLZ00785) is designed for the job. The ATD must be held securely to protect it from falling, or hitting hard against something else.

- 13.1 Put a transmission jack (or equivalent) under the ATD, and strap the ATD to the jack.
- 13.2 Disconnect the five sensors from the ATD.

⚠ WARNING

Wear adequate eye protection, such as safety goggles or a face shield, when working with the ATD mounting bands. The mounting bands are under spring tension, and can cause eye injury or other personal harm if they spring out of control.

- 13.3 Remove the Marmon clamps from each end of the ATD.

Rear Engine Mount Replacement, EPA07 Engines

13.4 Disconnect the ATD from the exhaust tubing, and remove it from the vehicle. Keep the ATD strapped to the jack, and make sure it is placed away from any combustible materials.

14. Remove the cab skirts from both sides of the vehicle.
15. Disconnect and remove the exhaust tubing from the turbocharger.
16. As applicable, remove the steps, air fairings, fuel tank(s), and/or the battery box.

    For instructions on removing the fuel tank(s), refer to **Group 47** in this workshop manual.

17. Remove the fasteners that hold the driveline midship-bearing bracket to the frame crossmember.
18. Using suitable straps, secure the driveline and the midship bearing to the frame crossmember. Make sure the driveshaft is supported loosely enough so that the slip joint aft of the midship bearing will be able to extend when the engine is raised.
19. Remove the overslung crossmember from the transmission housing.

    19.1 If present, remove the standoff bracket for the A/C refrigerant line from the top of the overslung crossmember. Leave the line attached to the bracket.

    19.2 Remove the fasteners that hold the overslung crossmember to the transmission housing, then remove it.

20. Disconnect both ends of the clutch linkage and remove it from the vehicle.
21. Remove the shifter and shifter boot from the transmission.
22. Raise the front of the vehicle so the tires are off the ground, and support it with safety stands. Put the safety stands behind the rear spring hangers for the front suspension.

⚠ WARNING

Never work around or under a vehicle that is supported only by a jack. Always support the vehicle with safety stands. Jacks can slip, allowing the vehicle to fall, which could result in serious injury or death.

23. From underneath the vehicle, install a suitable lifting bracket or stand, such as an engine shipping stand (for Detroit Diesel Series 60 engines) on the rear of the engine. See **Fig. 1**.

    If using the Detroit Diesel engine shipping stand, there should be two holes on each side of the engine block, just forward of the bell housing. These should match up with the holes in the engine shipping stand. When any stand or bracket is installed correctly, it should not be touching the floor, and should be wide enough and strong enough to support a jack to raise the engine.

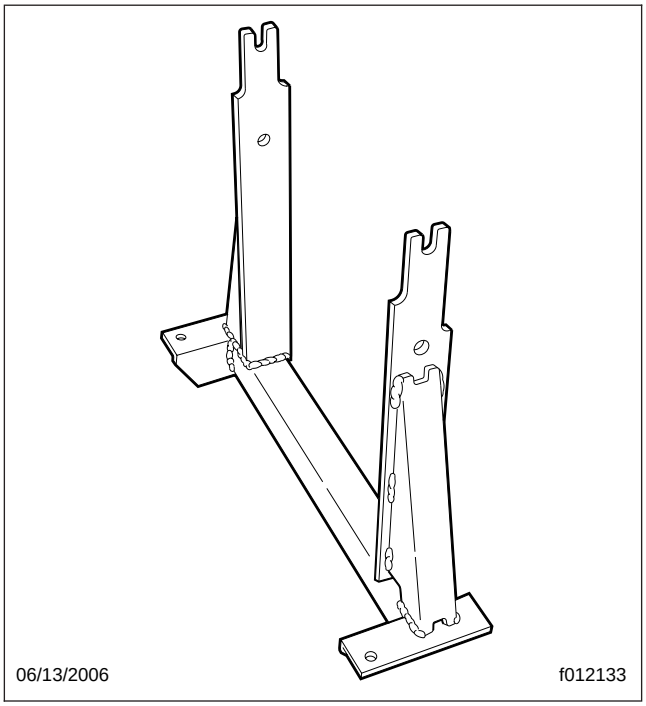

Fig. 1, Engine Shipping Stand, Detroit Diesel Series 60 Engine

24. If present, remove the starting aid bottle from the left-side frame rail.
25. On one side of the vehicle, remove the two mounting hexbolts that hold the engine leg to the frame-rail engine mount. See **Fig. 2**. If needed, repeat the procedure on the other side of the vehicle.
26. Place a jack under the engine shipping stand (or other suitable stand/bracket) attached to the rear

of the engine, and gradually raise that side of the engine until the bottom of the engine leg is above the top of the frame rail.

27. Remove the four fasteners that hold the rear engine mount to the frame rail. See **Fig. 3**.
28. Remove the rear engine mount from the vehicle.
29. If needed, remove the four bolts that hold the engine leg to the transmission housing. Remove the engine leg.

Installation

1. If applicable, install the engine leg on the bell housing. Apply Loctite® 271 (or equivalent) to the threads of the capscrews, and tighten to 320 lbf·ft (434 N·m).
2. With the engine supported, install the rear engine mount on the frame rail. Install the four 5/8–11 hexbolts with the bolt heads inboard. Tighten the hexnuts 136 lbf·ft (184 N·m).
3. If applicable, repeat the above procedure on the other side of the vehicle.
4. Lower the engine onto the rear engine mount.
5. Apply Loctite 271 to the threads of the two 3/4–10 hexbolts. Install them and the hardened washers in the holes of the engine leg and the rear engine mount and tighten to 320 lbf·ft (434 N·m).
6. Remove the fasteners that hold the engine shipping stand to the side of the transmission, and remove the stand.
7. Install the clutch linkage.
8. Install the overslung crossmember.
9. Install the shifter and shifter boot on the transmission.
10. Install the standoff bracket for the A/C refrigerant line, then attach the line to the bracket.
11. If it was removed, install the starting aid bottle to the left-side frame rail.
12. Attach the driveline midship bearing and its bracket to the frame crossmember.
13. Connect the exhaust tubing to the turbocharger.

14. Install the cab skirts to the bottom of the cab.
15. Install the ATD to the exhaust tubing. As previously marked, connect the wiring to the sensors on the ATD.
16. Install the primary air tank and connect the air lines to it.
17. In the engine compartment, install the turbocharger heat shield.
18. Install the mounting bracket for the air-intake canister.
19. Install the air-intake canister to the mounting bracket.
20. Install the right and left inner splash shields.
21. Install the right and left quarter fenders.
22. As applicable, install the steps, air fairings, fuel tank(s), and/or the battery box.

    For instructions on installing the fuel tank(s), refer to **Group 47** in this workshop manual.
23. Using the previously removed fasteners, install the rain tray on the frontwall.
24. Connect the hoses and drains to the bottom of the rain tray.
25. As previously marked, install the wiper arms.
26. If they were removed, install the two tow hooks on the side of the right frame rail.
27. Close the hood.
28. Install the battery mega-fuse block on the left-side frame rail, underneath the cab.
29. Connect the battery cables.
30. Remove the chocks.

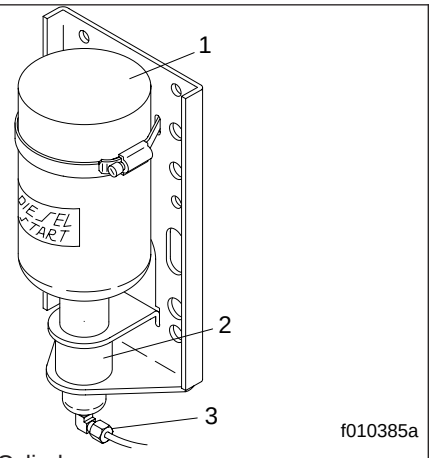
General Information

During cold weather starts, the KBi starting fluid system injects vaporized ether into the engine manifold to help ignite the diesel fuel in the cylinders. The diesel normally ignites on the compression stroke of each piston, when the compressed air within the cylinder reaches about 725°F (385°C). However, during cold weather starts, the heat of the compressed air dissipates into the surrounding engine block so the diesel may never reach the temperature it needs to ignite. Ether ignites at 360°F (182°C). Therefore, ether vapor injected with the engine intake air ignites at the lower cylinder temperature, and the burning ether ignites the diesel.

Using the starting fluid system reduces the necessary cranking time in cold weather, and it prevents excessive wear on the battery and starter.

When the engine is cold, the KBi system begins injecting ether when the starter is cranked. The system continues injecting ether vapor into the manifold for a short time to prevent stalling. The system consists of the starting fluid cylinder, the ether injection nozzle in the engine manifold, and the engine temperature sensor.

The starting fluid cylinder (**Fig. 1**) is mounted on the frame rail. It fits into the Dieselmatic® valve and Blockor® fitting which measure, hold, and release a controlled amount of fluid for each start attempt.



1. Starting Fluid Cylinder
2. Dieselmatic Valve
3. Blockor Fitting

Fig. 1, KBi Ether Start System

Ether travels through plastic tubing to the engine manifold where it sprays through the injection nozzle into the engine intake air. Inside the manifold, vaporized ether fills the cylinders and ignites.

If the weather is warm, or the engine is already warmed, the engine temperature sensor mounted in the engine water jacket prevents the KBi from injecting ether vapor. The system will inject ether only if the engine is cooler than about 40°F (4°C).

⚠ WARNING

WARNING: Service starting fluid systems only in a well-ventilated area away from sparks and open flames. The ethyl ether in these systems is flammable and toxic. Wear protective gloves and glasses, and avoid breathing ether fumes. Failure to take these precautions could result in personal injury or property damage.

3. Remove the old cylinder.
   - 3.1 Clean all dirt from the neck of the cylinder and the top of the Dieselmatic® valve before removing the cylinder.
   - 3.2 Loosen the cylinder clamp.
   - 3.3 Pry the dirt eliminator collar off the neck of the cylinder.
   - 3.4 Unscrew the cylinder from the Dieselmatic valve.

NOTE: If not replacing the cylinder immediately, place the valve cap in the valve to prevent dirt or other debris from entering the system.

4. Remove the old dirt eliminator collar from the valve assembly.
5. Replace the Dieselmatic valve gasket. Spread the new gasket with a light film of clean oil.
6. Place a new dirt eliminator collar, adhesive-side up, on the valve assembly. Peel off the collar's paper backing to expose the adhesive.
7. Install the new cylinder.
   - 7.1 Place the new cylinder into the Dieselmatic valve and hand tighten it firmly.
   - 7.2 Slide the dirt eliminator collar up so it sticks to the cylinder.
   - 7.3 Tighten the clamp around the cylinder 60 lbf·in (680 N·cm).
8. If the ambient temperature is below 40°F (4°C), test the starting fuel system.
9. Lower the hood, and remove the chocks from the tires.

Troubleshooting

Use the following procedures to check for most common problems that may prevent starting fluid delivery.

⚠ WARNING

Service starting fluid systems only in a well-ventilated area away from sparks and open flames. The ethyl ether in these systems is flammable and toxic. Wear protective gloves and glasses, and avoid breathing ether fumes. Failure to take these precautions could result in personal injury or property damage.

   - 1.2 Loosen the cylinder clamp.
   - 1.3 Pry the dirt eliminator collar off the neck of the cylinder.
   - 1.4 Unscrew the cylinder from the Dieselmatic valve.
   - 1.5 Remove the cylinder from the mounting plate. Cover the top of the valve after the cylinder is removed.
   - 1.6 Remove the old dirt eliminator collar from the valve assembly.
2. Weigh the cylinder to see if it is empty. See **Table 1** for the weight of each cylinder size.

3. Replace the Dieselmatic valve gasket. Spread the new gasket with a light film of clean oil.
4. Check that the fluid cylinder has at least 120 psi pressure at 68°F (20°C).
5. If the cylinder is good, install it; if not, replace it.
   - 5.1 Place a new dirt eliminator collar, adhesive-side up, on the valve assembly. Peel off the collar's paper backing to expose the adhesive.
   - 5.2 Place the new cylinder into the Dieselmatic valve and hand-tighten it firmly.
   - 5.3 Slide the dirt eliminator collar up so it sticks to the cylinder.
   - 5.4 Tighten the clamp around the cylinder 60 lbf·in (680 N·cm).

ELECTRICAL PROBLEMS

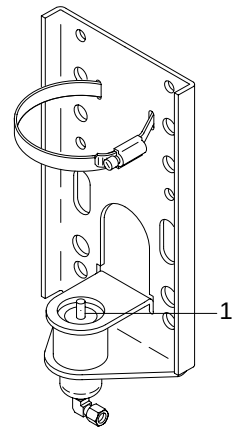
1. Check for a blown fuse, and for loose wiring connections, shorts, and broken wires.
2. Check that the black ground wire from the valve assembly is connected to the engine temperature sensor, and that the ground wire from the sensor is connected to a good ground.

3. Check that the second wire from the valve assembly is connected to the "M" terminal of the starter.

⚠ WARNING

When testing the starting fluid system, wear protective gloves and glasses, and spray the vaporized ether into a container. Failure to do so could result in personal injury.

4. Test the valve.
   - 4.1 Remove the starting fluid cylinder.
   - 4.2 If the ambient air temperature is over 40°F (4°C), remove the black ground wire from the engine temperature sensor, and ground it.
   - 4.3 Crank the starter, and look for the valve plunger (see **Fig. 2**) to move up and stay up while the starter is cranked.



06/17/94 f010384a

1. Plunger

Fig. 2, Valve Plunger

⚠ CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

5. If the plunger does not move, disconnect both valve assembly wires and momentarily touch the leads across battery terminals. If the valve plunger still does not move up, replace the valve.
6. If the valve operates correctly, check the engine temperature sensor.
   - 6.1 Connect the appropriate wire to the "M" terminal of the starter.
   - 6.2 Remove the sensor from the engine water jacket, and chill it to below freezing for at least ten minutes.
   - 6.3 Install the sensor, grounding it at a good ground.
   - 6.4 Connect the black ground wire from the valve assembly to the sensor.
   - 6.5 Crank the engine, and look for the valve plunger to move up and stay up while the starter is cranked.

⚠ CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

7. If the plunger does not move, replace the sensor.

CLOGGED ETHER NOZZLE

1. Disconnect the ether tubing from the nozzle, and cover the nozzle fitting.
2. Disconnect the black ground wire from the engine temperature sensor, and ground it.

⚠ WARNING

When testing the starting fluid system, wear protective gloves and glasses, and spray the vaporized ether into a container. Failure to do so could result in personal injury.

3. Start the engine, and look for ether to spray from the tubing.

⚠ CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

4. If no ether sprays from the tubing, disconnect the tubing at the Blockor® fitting in the base of the cylinder assembly. See **Fig. 1**.

5. Start the engine, and look for ether to spray from the Blockor fitting in the base of the cylinder assembly.

CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

6. If ether sprays from the fitting, but not from the tubing, check for kinks or blockages in the ether tubing and the nozzle. Repair or replace the tubing and nozzle, as needed.

   If no ether sprays from the fitting or tubing, check the Blockor fitting for blockages. Repair or replace the fitting, as needed.

General Information

A bypass oil filter is a remote-mounted oil filter plumbed to the engine. Not all of the engine oil runs through a bypass filter, the filter bleeds some of the oil from the engine, the rest of the oil "bypasses" the filter and stays within the engine.

Normal engine operation produces a variety of contaminants such as resins, gums, and acids. The bypass oil filter -- sometimes used with a full-flow filter (an engine-mounted filter that *all* the oil must run through) -- traps these contaminants and prevents excessive wear of engine parts. The filtered oil then returns to the engine crankcase or sump.

Freightliner uses the following models of bypass oil filters:

- Fleetguard® Model LF 750™
- Luber-finer® Model 750-CT
- Spinner II®

Fleetguard Model LF 750

(See Fig. 1)

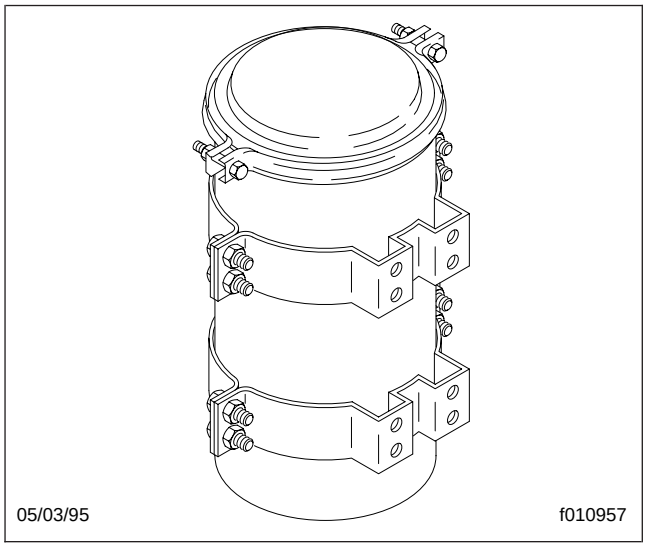

Fig. 1, Fleetguard Model LF 750 Bypass Oil Filter

Engine oil enters the Fleetguard Model LF 750 through the inlet check valve and fills the filter housing around the filter element. Oil pressure within the housing builds until oil is forced through the filter. Inside the filter, the filtered oil moves through openings in the filter hold-down assembly, and collects in the outlet tube. From the outlet tube, the oil goes back to the engine through the outlet check valve assembly.

An engine equipped with the Model LF 750 needs three gallons (11.3 liters) more oil than an engine without a bypass oil filter.

Luber-finer Model 750-CT

(See Fig. 2 and Fig. 3)

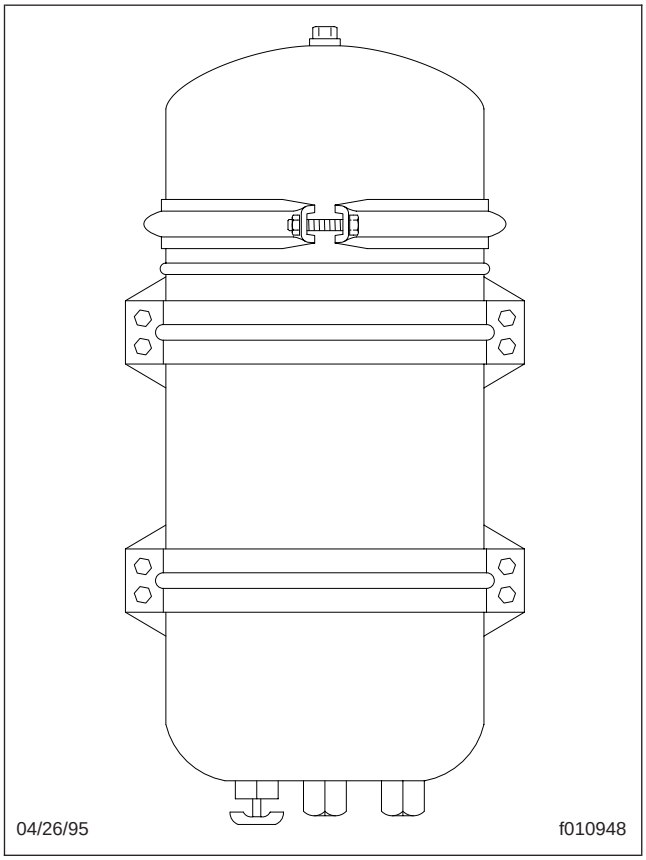

Fig. 2, Luber-finer Model 750-CT Bypass Oil Filter

To prevent thick, cold oil from clogging the filter, a thermostat within the Luber-finer model 750-CT allows engine oil to flow through the filter only after the oil has warmed to a specified temperature. The thermostat is inside the T-handle assembly that holds the filter pack in place.

Engine oil enters through the inlet check valve assembly on the bottom of the filter housing, and fills the filter housing around the filter pack (element). Inside the housing, oil pressure forces the oil through

the sides of the filter pack. Inside the filter pack, filtered oil travels through openings in the T-handle hold-down assembly, then collects in the outlet tube. From the outlet tube, filtered oil goes back to the engine through the outlet check valve assembly.

The inlet and outlet valves normally have #8 orifices.

Normal continuous operating oil pressure is about 65 psi (448 kPa). An engine equipped with the Model 750-CT needs 3 1/2 gallons (13.2 liters) more oil than an engine without a bypass oil filter. Flow rate through the filter is about one or two gallons (3.7 or 7.5 liters) per minute at normal operating pressure.

Spinner II **(See Fig. 4 and Fig. 5)**

The Spinner II uses centrifugal force to separate contaminants from the oil, and uses air pressure to force the filtered oil back to the engine.

Engine oil enters the top half of the filter housing, and travels up through a spindle in the center of a cylindrical centrifuge turbine lined with an optional paper lining. At the same time, the pressure of the oil entering the filter housing makes the centrifuge spin. The oil sprays out of the top of the spindle, and the centrifugal force of the spinning centrifuge drives the oil contaminants against the inside of the centrifuge turbine. The contaminants cake inside the centrifuge turbine, and the clean oil runs into the bottom half of the filter housing.

The clean oil collects in the bottom half of the filter housing where it lifts a float. The float opens a valve that allows brake system air to enter the housing, and the air pressure forces the cleaned oil out of the housing and back to the engine.

Normal continuous operating oil pressure is about 60 psi (413.6 kPa). An engine equipped with the Spinner II doesn't need any extra oil. Flow rate through the cleaner is about two gallons (7.5 liters) per minute at normal operating pressure.

IMPORTANT: Do the following at every scheduled engine oil change. Refer to the engine maintenance manual for the quantity of oil that must be added to the lubrication system when replacing the bypass filter.

1. Remove the oil filter element.
   - 1.1 Remove the drain plug and allow the oil to drain.
   - 1.2 Remove the clamp-ring capscrews. Remove the clamp ring and lift the cover off the filter housing.
   - 1.3 Unscrew the hold-down assembly T-handle and remove the assembly from the housing. Check the O-ring and spring for damage. Replace if needed.
   - 1.4 Remove and discard the oil filter element.
2. Clean the inside of the housing, and the hold-down assembly, with solvent.
3. Assemble the filter.
   - 3.1 Install the drain plug.
   - 3.2 Install a new filter element.
   - 3.3 Install the hold-down assembly and securely tighten the T-handle.
   - 3.4 Check the cover gasket for damage, and replace it if needed. Position the gasket on the housing.
   - 3.5 Position the cover on the housing. Install the clamp ring and capscrews. Alternately tighten the capscrews to ensure a uniform seal between the cover and gasket.
   - 3.6 Start the engine and let it idle until normal operating oil pressure is reached.

⚠ CAUTION

CAUTION: Make sure the engine oil level is correct. Operating the engine with the oil level below the low ("L") mark, or above the high mark, could result in engine damage.

   - 3.7 Add oil as needed to bring the oil level up to the high ("H") mark on the dipstick.

IMPORTANT: Do the following procedure at every scheduled engine oil change. Refer to the engine maintenance manual for the quantity of oil that must be added to the lubrication system when replacing the bypass filter.

1. Remove the old filter element.
   - 1.1 Loosen the vent plug capscrew, then open the drain cock and allow the oil to drain.
   - 1.2 Remove the clamp-ring capscrews. Remove the clamp ring and lift the cover off the filter housing.
   - 1.3 Unscrew the hold-down assembly T-handle and remove the assembly from the housing.
   - 1.4 Remove and discard the oil filter element.
2. Clean the inside of the housing, and the hold-down assembly, with solvent.
3. Assemble the filter.
   - 3.1 Close the drain cock.
   - 3.2 Install a new filter element.
   - 3.3 Check the cover gasket for damage, and replace it if needed.
   - 3.4 Install the hold-down assembly and securely tighten the T-handle.
   - 3.5 Position the cover on the housing. Install the clamp ring and capscrews. Alternately tighten the clamp capscrews to ensure a uniform seal between the cover and gasket.
   - 3.6 Add oil to the crankcase, then start the engine and let it idle until normal operating oil pressure is reached.
   - 3.7 Loosen the vent plug capscrew and bleed any trapped air from the filter housing. Tighten the vent plug capscrew as soon as oil appears at the fitting.

⚠ CAUTION

CAUTION: Make sure the engine oil level is correct. Operating the engine with the oil level below the low ("L") mark, or above the high mark, could result in engine damage.

4. Shut down the engine and add oil as needed to bring the oil level up to the high ("H") mark on the dipstick.

Fig. 1, Spinner II Bypass Oil Filter

IMPORTANT: Do the following procedure at every scheduled engine oil change. Refer to the engine maintenance manual for the quantity of oil that must be added to the lubrication system when replacing the bypass filter.

1. Clean the centrifuge bowl.

   1.1 Shut off the engine, and let the centrifuge turbine assembly come to a complete stop.

   1.2 Loosen the handle on the clamp, disengage the tee bolt and remove the cover, using a coin in the gap to separate the cover from the housing.

   1.3 Partially withdraw the centrifuge turbine assembly from the housing and allow oil to drain from the nozzles before removing the assembly completely.

   1.4 Hold the centrifuge turbine assembly in one hand and loosen the knurled nut several turns until the face of the nut projects beyond the bronze bushing face.

   1.5 Carefully separate the centrifuge bowl from the turbine base by striking the face of the nut with the palm of one hand while holding the bowl in the other. *Do not strike the nut or the bushing with or against a hard surface or you will damage them.* Finish removing the nut and then remove the bowl and baffle/screen.

   1.6 Replace the dirty centrifuge bowl with a new one, or carefully remove the cake of dirt from the bowl with a wooden spatula or other non-damaging tool. Wipe out the bowl with solvent

   NOTE: To save time cleaning the bowl, an optional die-cut Bristol paper insert is available for lining the bowl so the compressed cake of dirt can be removed quickly.

   1.7 Wash the baffle/screen and turbine base, removing and discarding the black Nitrile bowl seal.

2. Inspect and assemble the centrifuge turbine assembly.

   2.1 Inspect the top and bottom bushings of the centrifuge turbine base, and replace the turbine assembly if the bushings show severe wear.

Centrifuge Bowl Cleaning, Spinner II

2.2 Place the baffle/screen over the stem of the turbine base and seat the baffle/screen evenly over the shoulder on the base.

2.3 Install the bowl seal in the recess in the outer edge of the turbine base.

2.4 Slide a new centrifuge bowl over the stem and seat it uniformly over the bowl seal.

2.5 Install and tighten the knurled bowl nut securely, *using finger pressure only.*

3. Clean and inspect the oil filter housing.

3.1 Inspect the housing assembly, paying special attention to the journal areas of the spindle.

3.2 Clean and inspect the cover.

3.3 Remove the old cover seal, and clean the groove in the housing and the mating surface of the cover.

3.4 Replace the cover seal with a new black Nitrile seal.

4. Check the air valve control mechanism. **See Fig. 2.**

4.1 Make a hook out of stiff wire, according to the measurements in **Fig. 2**.

4.2 Insert the hook at the spot shown in **Fig. 2**, and hook the float arm.

Lifting the float should release air into the filter housing.

Lowering the float should stop the flow of air into the filter housing.

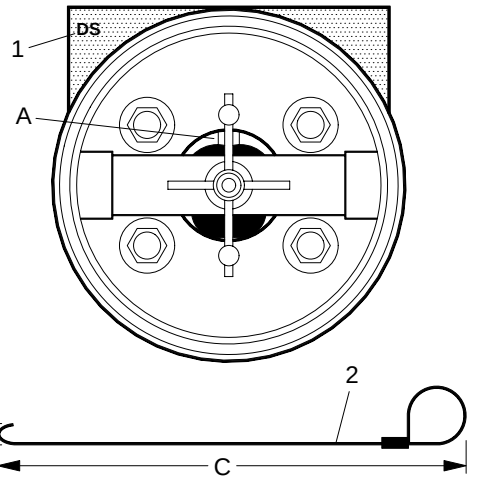
5. Install the centrifuge turbine assembly.

5.1 Install the centrifuge turbine assembly, and make sure it rotates freely.

5.2 Replace the cover, and position the clamp uniformly over the cover and housing flanges.

5.3 Tighten the clamp handle securely *by hand pressure only.*

6. With the engine running, check all the oil filter connections and joints for leaks.



NOTE: This is a view, downward into the housing assembly, with the centrifuge turbine assembly removed.

General Information

NOTE: For troubleshooting procedures, refer to **Section 01.12** in this manual.

The Jacobs engine brake model 310A (see is installed on Caterpillar 3176 engines, and slows the vehicle by converting a power-producing diesel engine into a power-consuming air compressor. The brake does this by opening the cylinder exhaust valves near the top of the normal compression stroke, releasing the compressed cylinder charge to exhaust. See **Fig. 1**.

pressing the cylinder charge is not returned during the expansion process.

Exhaust blowdown of the braking cylinder is accomplished by using the injector arm motion of that cylinder. See **Fig. 2**.

Energizing the solenoid valve permits engine lube oil to flow under pressure through the control valve to the master piston, slave piston, and accumulator.

Oil pressure makes the master piston move down, coming to rest on the corresponding injector rocker arm.

trol valve traps high pressure oil in the master/slave piston system.

Under the influence of the high pressure oil flow, the slave piston moves down, momentarily opening the exhaust valves at a pre-determined amount of slave stroke. The Power-Lash™ uncovers a passageway in the slave piston, thus allowing oil to flow back to the undersides of the control valve and accumulator piston, where it is stored for the next cycle. Prior to top dead center position, the exhaust valve is forced open, releasing the compressed cylinder air to the exhaust manifold.

Compressed air escapes into the atmosphere, completing the braking cycle.

Accumulator Removal, Inspection, and Installation

Removal (See Fig. 1)

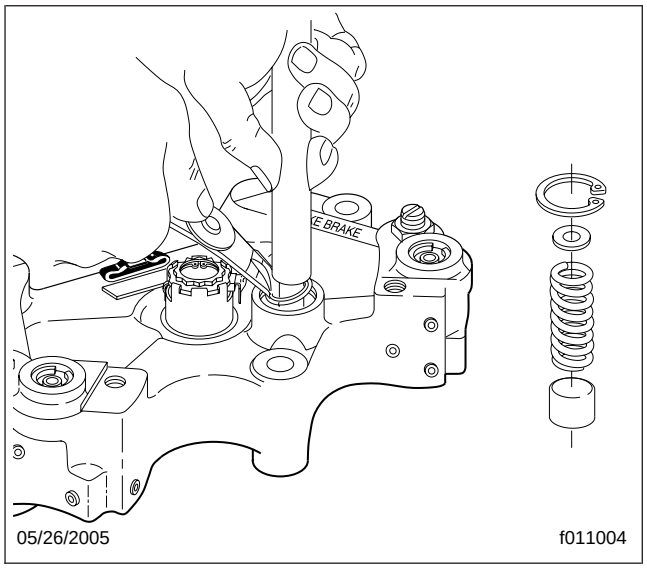

Fig. 1, Accumulator Assembly

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.

WARNING

WARNING: The accumulator spring is under strong compression. Use caution when removing the retaining ring and cover. Wear safety glasses. If the spring is accidentally discharged, personal injury may result.

2. Push down on the accumulator cover using the appropriate diameter rod and remove the retaining ring.
3. Relieve pressure on the accumulator cover; remove the cover and the spring.
4. Use a magnet to remove the piston from the accumulator bore.

Inspection

Inspect the parts for wear or damage; replace them if needed.

Installation

1. Install the piston, then the spring, the cover, and the retaining ring.
2. Install the rocker cover. For instructions, refer to **Subject 140**.

4. Control Valve

Fig. 1, Control Valve Assembly

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.

⚠ WARNING

WARNING: The control valve covers are under load from the control valve springs. Remove the control valve covers carefully to avoid personal injury. The valve covers could jump out and cause personal injury.

2. Apply pressure on the control valve cover, and remove the retaining ring using retaining ring pliers.
3. Slowly remove the cover until the spring pressure ceases, then remove the two control valve springs.
4. Using needle-nose pliers, reach into the bore and grasp the stem of the control valve. Remove the control valve.

Cleaning

1. Wash the control valves with an approved solvent. Push a wire into the hole in the base of the valve to the distance required to insure that the ball check is free. the ball should lift with light pressure on the wire. If the ball is stuck, replace the control valve. Dry the valve with compressed air and wipe clean with a paper towel.
2. Thoroughly clean the control valve bore in the housing using clean paper towels.

Installation

1. Install the control valve in the bore, then the springs, the cover, and the retaining ring.
2. Install the rocker cover. For instructions, refer to **Subject 140**.

1. Press here.

Fig. 1, Bleeding the Engine Brake

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.

⚠ WARNING

WARNING: Wear eye protection, and do not expose your face to the engine area. Take precautions to prevent oil leakage onto the engine. Whenever the engine is running with the valve covers removed, oil splashing in the engine area could cause personal injury.

NOTE: Place a rag over the control valve and the accumulator covers to reduce oil spray.

2. Start the engine, and allow it to run for a few minutes.
3. Press and release the engine brake solenoid disc several times to allow the housing to be filled with oil.
4. Watch the master piston to be sure it is moving down onto the injector rocker arm pad.
5. Watch the slave piston assembly. It should move down to contact the pin in the exhaust valve screw.
6. Check all the housings to be sure they are functioning.
7. Shut down the engine, and clean the gasket surface for the rocker cover.
8. Install the rocker cover. For instructions, refer to **Subject 140**.

Master Piston Removal, Inspection, and Installation

Removal and Cleaning (See Fig. 1)

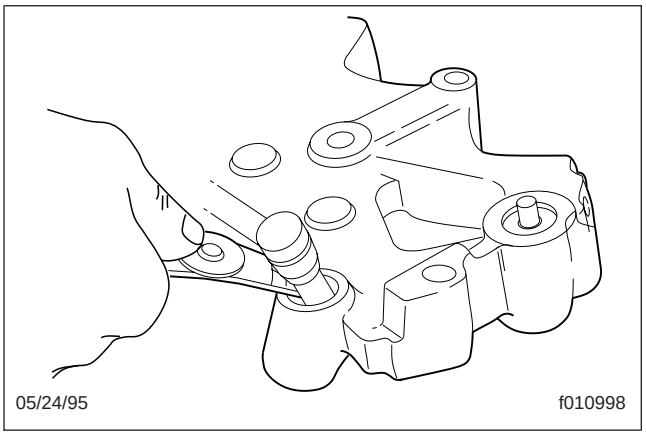

Fig. 1, Removing the Master Piston

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.
2. Press down on the master piston retaining washer to relieve the spring force. While holding the washer, use a pair of snap ring pliers to remove the retaining ring from the groove. Carefully release the retainer and remove it along with the old spring.
3. Remove the master piston from the bore. Clean the piston in a solvent, and inspect it for wear. Also inspect the piston bore for wear.

Installation

1. Install a new master piston return spring by inserting the small end into the bore. The large coil, marked with *white* paint, *should always be facing out.*
2. Place the retaining washer and snap ring over the foot of the master piston and compress them into the bore. Using snap ring pliers, replace the snap ring in the groove to retain the master piston.
3. Ensure the snap ring is properly engaged in the groove by gently grasping the master piston foot and pulling out until the master piston bottoms on the retaining washer. Release the master piston. If the assembly is correct, all parts should return to their original position.

NOTE: After the new spring is installed within the retaining washer and snap ring, it is normal to be able to see the spring in the bore around the retaining washer.

4. Repeat this procedure on the five other master pistons.
5. Install the rocker cover. For instructions, refer to **Subject 140**.

Removal (See Fig. 1)

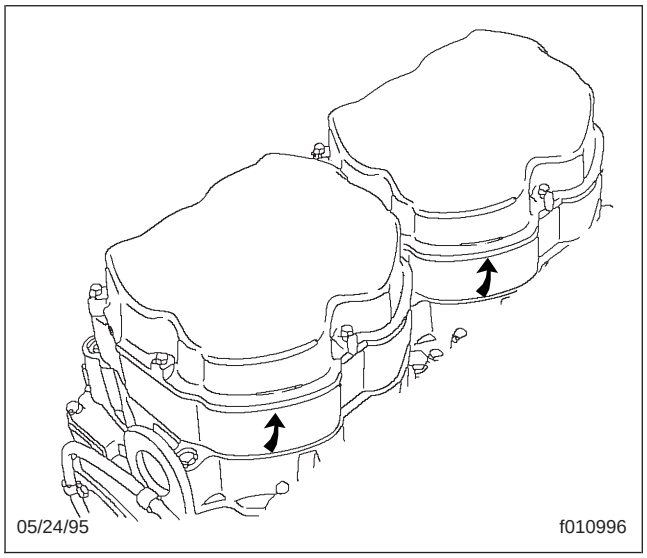

Fig. 1, Rocker Covers

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Wipe the engine brake housing area clean..
3. Remove the six bolts that hold each rocker cover, and remove the rocker covers.
4. Inspect the cover seals, and replace them if they are damaged.

Installation

⚠ CAUTION

CAUTION: Be sure to tighten all the rocker cover bolts evenly. Excessive or uneven tightening may cause the rocker cover to crack.

1. Make sure a seal is located in the groove of each cover, and install the cover on the spacer. Install the six Jacobs' bolts per cover, and tighten the bolts 5 lbf·ft (7 N·m).
2. Remove the chocks from the tires.

Slave Piston Adjusting Screw (Power-Lash™) Removal, Inspection, and Installation

Removal

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.
2. Loosen the slave piston adjusting screw locknut, and remove the adjusting screw from the housing. **See Fig. 1.**

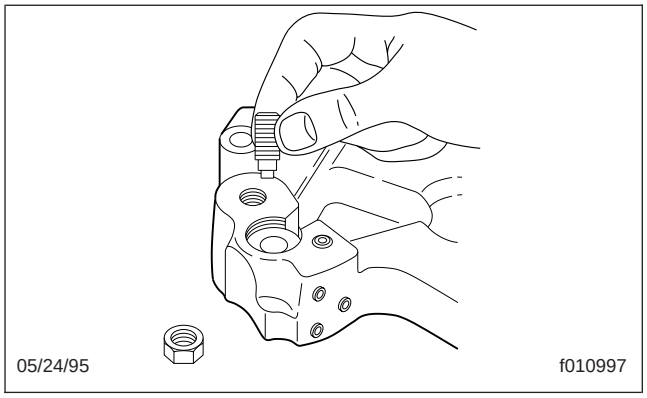

Fig. 1, Remove the Adjusting Screw

Inspection and Installation

1. Clean the adjusting screw in an approved solvent.

⚠ CAUTION

CAUTION: Do not adjust or tamper with the adjusting screw, engine damage could result.

NOTE: The part number for the screw is located at the top of the screw, next to the screwdriver slot. Refer to the manufacturer's parts manual for part number identification.

2. Inspect the slave piston adjusting screw. The plunger should protrude from the bottom of the screw, should have light spring pressure apparent when depressed, and should move freely. **See Fig. 2.** Replace the entire screw assembly if any problem is found.
3. Install the rocker cover. For instructions, refer to **Subject 140**.

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.

⚠ WARNING

The slave piston is retained by springs that are under heavy compression. Use the following tools and instructions or the springs will be discharged with enough force to cause personal injury.

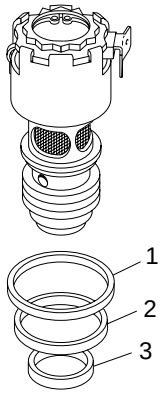
2. Remove the locknut on the slave piston adjusting screw. Back out the adjusting screw until the slave piston is fully retracted (the screw is loose).
3. Place the hole in the clamp fixture over the slave piston adjusting screw. **See Fig. 1.**
4. While holding the fixture in position, screw the holder down over the slave piston until the spring retainer is contacted.
5. Turn the handle slowly until the retainer is depressed to about 1/32 inch (1 mm), relieving pressure against the retaining ring.
6. Remove the retaining ring using retaining ring pliers. Back out the holder until the springs are loose. Remove the fixture.
7. Remove all the components, ensuring there is no binding or burrs. Clean in an approved cleaning solvent. Inspect parts and replace as needed.

Installation

1. Use the clamp fixture to install the piston and springs. Be sure the retaining ring is placed on the retainer before screwing the clamp-holder down over the slave piston.
2. Compress the slave piston springs down until the retainer is about 1/32 inch (1 mm) below the retaining ring groove. Install the retaining ring. Be sure the retaining ring is fully seated in the groove.
3. Remove the clamp fixture slowly to ensure correct seating of the retaining ring.
4. Install the rocker cover. For instructions, refer to **Subject 140**.

Solenoid Valve Removal, Cleaning, and Installation

Removal (See Fig. 1)



1. Upper Seal
2. Center Seal
3. Lower Seal

Fig. 1, Solenoid Seals

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 140**.

CAUTION

CAUTION: Do not disassemble or tamper with the solenoid valve. Engine damage could result. The solenoid valve is not field serviceable.

2. Disconnect the solenoid harness. Using a 7/8-inch socket and an extension, unscrew the solenoid valve.
3. Remove and discard the three rubber seal rings. If the lower ring stays in the bottom of the housing bore, remove it with a pick.

Cleaning and Installation

1. Wash out the solenoid valve with an approved solvent. Use a brush to clean the oil screen. When clean, dry the valve with compressed air.
2. Clean out the solenoid valve bore in the housing. Use clean paper towels. Never use rags as they may leave lint and residue which can plug the oil passageways.
3. Using new solenoid seal rings, coat them with clean lube oil. Install the upper and center seal rings on the solenoid body, and install the lower seal ring into the bottom of the solenoid bore in the housing.
4. Be sure the seals are seated properly and carefully screw the solenoid into the housing without unseating the seals. Tighten the valve 5 lbf·ft (7 N·m). Be careful not to twist the seals while installing the solenoid.
5. Install the rocker cover. For instructions, refer to **Subject 140**.

General Information

NOTE: For troubleshooting procedures, refer to **Section 01.12** in this manual.

The Jacobs engine brake model 349A is installed on Caterpillar 3406 engine, and slows the vehicle by converting a power-producing diesel engine into a power-consuming air compressor. The brake does this by opening the cylinder exhaust valves near the top of the normal compression stroke, releasing the compressed cylinder charge to exhaust. See **Fig. 1**.

The release or "blowdown" of compressed air to atmosphere prevents the return of energy to the engine piston on the expansion stroke. The effect is a net energy loss, because the work done in compressing the cylinder charge is not returned during the expansion process.

Exhaust blowdown of the braking cylinder is accomplished by using the pushrod motion of an exhaust valve of another cylinder during its normal exhaust cycle. See **Fig. 1**. Cylinder number one exhaust pushrod opens the exhaust valves of cylinder number three in this sequence.

1. Energizing the solenoid valve permits engine lube oil to flow under pressure through the control valve to the master piston and the slave piston.

General Information

2. Oil pressure makes the master piston move down, coming to rest on the corresponding exhaust rocker arm adjusting screw.
3. The exhaust rocker pushrod begins upward travel (as in a normal exhaust cycle) forcing the master piston upward and creating a high pressure oil flow to the delay piston.
4. The delay piston moves and compresses the plenum oil to high pressure. The delay piston and plenum act as a high pressure "spring" to activate the slave piston at the appropriate time.
5. The master piston moves upward, and at the appropriate time, opens the trigger valve.
6. High pressure oil flows from the delay piston through the trigger valve to the slave piston.
7. The slave piston moves down, contacts the exhaust valve bridge, and opens the exhaust valves, releasing compressed air to the exhaust manifold.
8. Compressed air escapes to atmosphere, completing a compression braking cycle.

Check Valve Removal, Inspection, and Installation

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.
2. Remove the check valve and the check valve spring.

Inspection and Installation

NOTE: The check valve assembly contains a three-piece seal. Do not attempt to remove the seal. If the seal is damaged, replace the complete check valve assembly.

1. Install the check valve spring in the bore, then install the check valve.
2. Tighten the check valve 35 lbf·ft (48 N·m).
3. Install the rocker cover. For instructions, refer to **Subject 150**.

Control Valve Removal, Cleaning, and Installation

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.

⚠ WARNING

WARNING: Use caution when removing the control valve spacer/cover. Wear safety glasses. The control valve cover is under load from the control valve spring. If the cover or spring is accidentally discharged, personal injury may result.

2. Press down on the control valve spacer/cover to relieve spring pressure. Then, use retaining ring pliers to remove the retaining ring.
3. Slowly remove the spacer/cover until the spring pressure ceases, then remove the control valve spring.
4. Use needle-nose pliers to remove the control valve.

Cleaning and Installation

NOTE: Do not use shop rags to clean the control valve. Shop rags can leave lint which can plug passageways.

1. Clean the control valve bore in the housing, using clean paper towels. Dip the new control valve in clean lube oil and place the valve into its bore.
2. Install the spring, spacer/cover, and retaining ring.
3. Install the rocker cover. For instructions, refer to **Subject 150**.

Delay Piston Removal, Cleaning, and Installation

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.

⚠ WARNING

WARNING: Remove the check valves before removing the delay piston caps. This relieves the pressure in the plenum chamber. Removing the delay piston caps with pressure in the plenum can result in personal injury.

2. Remove the check valves. For instructions, refer to **Subject 100**.
3. Slowly remove the delay piston cap.
4. Use a magnet to remove the delay piston and the delay piston spring.

Cleaning and Installation

1. Inspect the piston. If the piston is scored or damaged in any way, replace it.
2. Install the spring and the delay piston.
3. Clean the oil from the delay piston cap, and apply Loctite 271 (or equivalent) before installing the cap. Tighten the cap 65 lbf·ft (88 N·m).
4. Install the rocker cover. For instructions, refer to **Subject 150**.

Bleeding and Operation Check

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.

⚠ WARNING

WARNING: Wear eye protection, and do not expose your face to the engine area. Take precautions to prevent oil leakage onto the engine. Whenever the engine is running with the valve covers removed, oil splashing in the engine area could cause personal injury.

2. Start the engine, and allow it to run for five to ten minutes.
3. With the engine at low idle, press and release the engine brake solenoid disc several times until the master pistons move out of the housing and the engine brake begins to operate.

   Oil leaving the control valve covers should be free of air bubbles before replacing the valve covers. This permits oil to fill the brake housing passages and prepares the brake for operation.
4. Inspect the engine brake for oil or fuel leakage or component interference. Correct any problems.
5. Shut down the engine, and clean the gasket surface for the rocker cover.
6. Install the rocker cover. For instructions, refer to **Subject 150**

Master Piston Removal, Inspection, and Installation

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.
2. Remove the engine brake housing. For instructions, refer to **Subject 190**.
3. Remove the buttonhead screw and the flat spring.
4. Remove the master piston.

Inspection and Installation

1. Inspect all parts for damage and replace as needed.

   If the master piston hard-face surface is scored or damaged, the corresponding rocker arm adjusting screw, master piston assembly, flat spring, and button head screw must *all* be replaced.

NOTE: Do not change the adjustment of the master piston. Final adjustment is done on the engine.

2. Install the master piston.
3. Install a new flat spring and a new buttonhead screw.
4. Tighten the screw 60 lbf·in (680 N·cm).
5. Install the engine brake housing. For instructions, refer to **Subject 190**.
6. Install the rocker cover. For instructions, refer to **Subject 150**.

Removal

1. Apply the parking brakes, shut down the engine, chock the tires, and tilt the hood.

⚠ WARNING

WARNING: To avoid personal injury, never remove any engine brake component with the engine running.

2. Wipe the engine brake housing area clean.
3. Remove the bolts that hold each rocker cover, and remove the rocker covers.
4. Inspect the cover seals, and replace them if they are damaged.
5. If needed, remove the fasteners that hold the engine brake spacer, then remove the engine brake spacer.

Installation

1. If the engine brake spacer was removed, install it, and tighten the fasteners 10 lbf·ft (14 N·m).

⚠ CAUTION

CAUTION: Be sure to tighten all the rocker cover bolts evenly. Excessive or uneven tightening may cause the rocker cover to crack.

2. Make sure a rocker cover seal is located in the groove of each cover, and install the cover on the spacer. Install the six Jacobs bolts per cover, and tighten the bolts 10 lbf·ft (14 N·m).
3. Remove the chocks from the tires.

Slave Piston Removal, Installation, and Adjustment

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.
2. Remove the engine brake housing. For instructions, refer to **Subject 190**.

⚠ WARNING

Remove the slave piston carefully. The slave piston is retained by springs that are under heavy compression. If the following instructions are not followed and proper tools are not used, the springs could be discharged with enough force to cause personal injury.

3. Remove the jam nut from the slave piston adjusting screw (Power-Lash®).
4. Back out the adjusting screw until the slave piston is fully retracted (the screw is loose).
5. Install the slave piston removal tool, and turn the handle in to relieve the spring pressure.
6. Using retaining ring pliers, rotate the retaining ring to the slot in the housing and remove the retaining ring.
7. Turn the tool handle out to relieve the spring force, and remove the retainer, the springs, and the slave piston.

Installation and Adjustment

1. Using the slave piston removal tool, install the slave piston, springs, retainer, adjusting screw, and jam nut.
2. Rotate the slave piston retaining ring 90 degrees from the slot in the housing to ensure that it is properly seated.
3. Adjust the slave piston.
   - 3.1 With the exhaust valve on the cylinder closed, insert a Jacobs 0.018-inch feeler gage between the slave piston feet and the exhaust bridge.
   - 3.2 Turn the slave piston adjusting screw assembly in until you feel a slight drag on the feeler gage.
   - 3.3 Hold the slave piston adjusting screw in position and tighten the jam nut 25 lbf·ft (35 N·m).
   - 3.4 Continue the slave piston adjustments following the sequence in **Table 1**.

Engine Position	Slave Piston Cylinder
Cylinder 1 TDC	1, 3, 5
Cylinder 6 TDC	2, 4, 6

Solenoid Removal, Cleaning, and Installation

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.
2. Disconnect the solenoid harness.
3. Using a 7/8-inch socket and extension, remove the solenoid assembly.
4. Remove and discard the three rubber seal rings.

   If the lower seal ring stays in the bottom of the housing solenoid bore, remove it with a pick.

Cleaning and Installation

1. Wash out the solenoid assembly with an approved solvent. Use a brush to clean the oil screen. When clean, dry the valve with compressed air.

NOTE: Do not use shop rags as they may leave lint or residue which can plug passageways.

2. Use clean paper towels to clean out the solenoid valve bore in the housing.

⚠ CAUTION

CAUTION: Do not readjust or tamper with the solenoid valve, engine damage could result.

3. Install the solenoid using new seals rings.
   - 3.1 Seat the lower seal ring in the base of the solenoid valve bore.
   - 3.2 Wipe clean lube oil into and around the bore.
   - 3.3 Place the upper and center seal rings on the solenoid valve body.
   - 3.4 Make sure the seals are seated properly, and carefully screw the solenoid into the housing without unseating the seals.
   - 3.5 Tighten the valve 110 lbf·in (1240 N·cm). Be careful not to twist the seals while installing the solenoid.
4. Install the rocker cover. For instructions, refer to **Subject 150**.

Trigger Valve Removal, Inspection, and Installation

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.
2. Remove the trigger valve cap and spring.
3. Remove the trigger valve.

Inspection and Installation

1. Inspect the trigger valve parts for damage or wear, and replace them as needed.
2. Install the trigger valve, using a new cap and spring.
3. Tighten the cap 35 lbf·ft (48 N·m).
4. Install the rocker cover. For instructions, refer to **Subject 150**.

Engine Brake Housing Removal and Installation

Removal

1. Apply the parking brakes, chock the tires, shut down the engine, and tilt the hood.

⚠ WARNING

WARNING: To avoid personal injury, never remove any engine brake component with the engine running.

2. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 150**.
3. Remove the brake housing.
   - 3.1 Remove the Jacobs washers and hex-head bolts that run through the housing and support tubes and into the support bases.
   - 3.2 Remove the two flanged screws and washers at the rocker shaft location.
   - 3.3 Remove the brake housing. Repeat this step to remove the second brake housing.

Installation

1. Install the brake housing.
   - 1.1 Make sure there is an O-ring on the oil supply adapter, and place a small amount of grease on the adapter.

   IMPORTANT: The housings are marked front and rear. The front housing must be installed on the front three cylinders, and the rear housing must be installed on the rear three cylinders.

   - 1.2 Place the housing over the studs, and install the two support tubes between the housing and support bases.
   - 1.3 Install the Jacobs washers and the hex-head bolts through the housing and support tubes and into the support bases. Hand tighten the bolts.
   - 1.4 Install the two flanged screws and washers at the rocker shaft location.
   - 1.5 Tighten the flanged screws at the rocker shaft location 60 lbf·ft (82 N·m).
   - 1.6 Tighten the next head bolts at the support base locations 60 lbf·ft (82 N·m).
   - 1.7 Tighten the two flanged screws at the rocker shaft location 120 lbf·ft (163 N·m).
   - 1.8 Repeat this step to install the second brake housing.
2. Install the rocker cover. For instructions, refer to **Subject 150**
3. Remove the chocks from the tires.

General Information

NOTE: For troubleshooting procedures, refer to **Section 01.12** in this manual.

Jacobs engine brake housings are installed on the engine rocker housings. Model 404D (used on Cummins L10 engines) has two engine brake housings that operate three cylinders each. Each engine brake housing has a solenoid valve, control valve, ball check valve, master piston, and slave piston. See **Fig. 1**.

Engine brake controls consist of: two dash-mounted toggle switches, a clutch switch mounted under the dash, and the throttle switch. The switches are wired in series so that all of the switches must be closed to operate the engine brake. The engine brake is activated when one or both of the dash switches is on (up), and the clutch and throttle pedals are released. The dash switches enable the driver to operate the engine brake partially or fully.

Model 404D engine brakes can be operated at one-half or full capacity (three or six cylinders).

When activated, the engine brake converts a power-producing diesel engine to a power-absorbing air compressor. This is accomplished by motion transfer through a master-slave piston arrangement which opens the engine cylinder exhaust valves near the top of the normal compression stroke, releasing the compressed cylinder charge to exhaust. The blowdown of compressed air to atmospheric pressure prevents the return of energy to the engine piston on the expansion (power) stroke. This results in a net energy loss because the work done in compressing the cylinder charge is not returned during the expansion process. Exhaust blowdown occurs as follows (**see Fig. 2**):

1. Activating the engine brake energizes the solenoid valve, allowing engine oil to flow under pressure through the control valve to both the master piston and the slave piston.
2. Oil pressure causes the master piston to move down, coming to rest on the injector rocker lever adjusting screw.
3. The injector rocker lever adjusting screw begins upward travel (as in the normal injection cycle) forcing the master piston upward and creating a high-pressure oil flow to the slave piston. The ball check valve in the control valve holds the high-pressure oil in the master-slave piston system.
4. When the engine piston is near top dead center, the slave piston moves down under the influence of the high-pressure oil flow. This momentarily opens one of the exhaust valves, releasing compressed cylinder air to the exhaust manifold.
5. Compressed air is released to the atmosphere, completing a compression braking cycle.

Inspection

Inspect the parts for wear, then clean them in an approved cleaning solvent, or replace them if necessary.

Installation

1. Assemble the ball check valve by first inserting the ball, then the spring, and then tighten the plug. **See Fig. 3**.

⚠ CAUTION

CAUTION: Make certain the parts are installed in the order shown in Fig. 3. Improper installation may result in engine damage.

2. Install the engine brake housing using the instructions in **Subject 120**.

2. Apply pressure on the control valve cover, and remove the retaining ring, using retaining ring pliers. **See Fig. 2.**

⚠ WARNING

WARNING: The control valve covers are under load from the control valve springs. Remove them carefully to avoid personal injury.

3. Carefully remove both control valve springs and the collar. **See Fig. 3.**
4. Using needle nose pliers or your fingertips, carefully pull the control valve straight up and out of its bore. **See Fig. 4.**

Inspection

If binding occurs during removal, inspect the control valve parts for damage or wear, and replace them if necessary.

If there is no damage, clean the parts in a cleaning solvent.

⚠ WARNING

WARNING: To avoid personal injury, never remove any engine brake component with the engine running.

1. Park the vehicle, apply the parking brakes, shut down the engine, and chock the tires.
2. Disconnect the batteries.
3. Wipe clean the engine brake housing area. Remove the rocker housing cover capscrews, and remove the cover and gasket from the spacer.
4. Disconnect the solenoid electrical harness from the terminal leadout in the spacer. **See Fig. 2.**

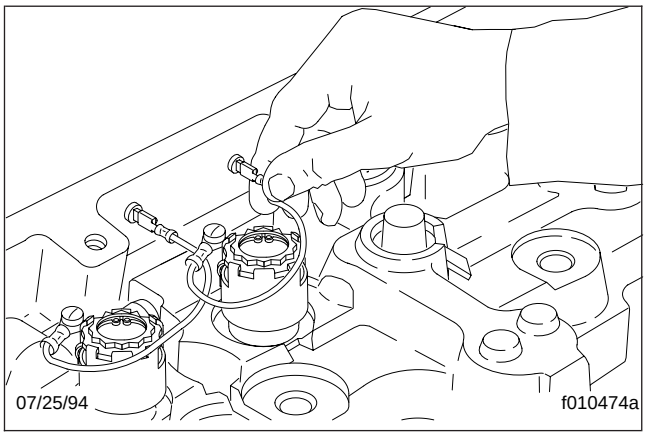

Fig. 2, Disconnect the Solenoid Harness

5. Remove the steel plates, O-ring, and gasket from the spacer. **See Fig. 3.** Disconnect the oil hose from the front brake housing, and remove it through the hole in the spacer. **See Fig. 4.**

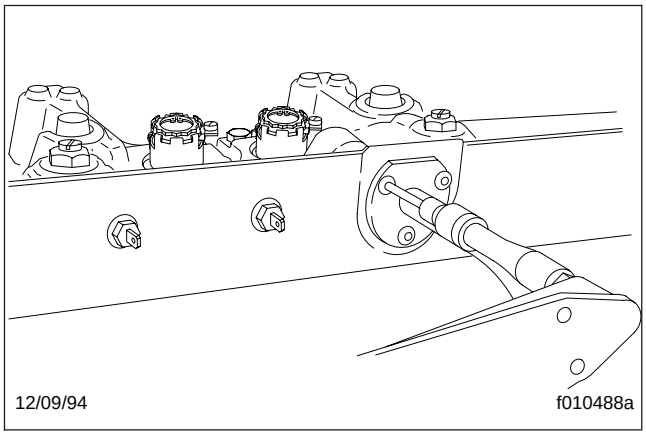

Fig. 3, Remove the Steel Plates, O-Ring, and Spacer

6. Remove the engine brake housing holddown capscrews. **See Fig. 5.**
7. Remove the engine brake housing from the rocker-shaft supports.

Installation

1. If the oil connector was previously removed from the front housing, then install the connector and O-ring into the front housing as far as it will go (**Fig. 6**).

NOTE: No washers are used with the capscrews.

5. Slide the number 5 support as far forward as possible. **See Fig. 10.**

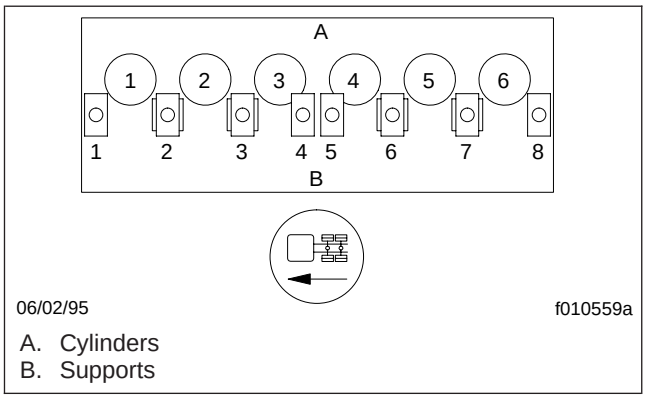

Fig. 10, Rocker-Lever Supports

6. Align the rear brake housing so that the slave pistons are over the Jacobs actuating pins in the exhaust crossheads on all three cylinders (4, 5, and 6). **See Fig. 11.** Swing each crosshead through its free side play.

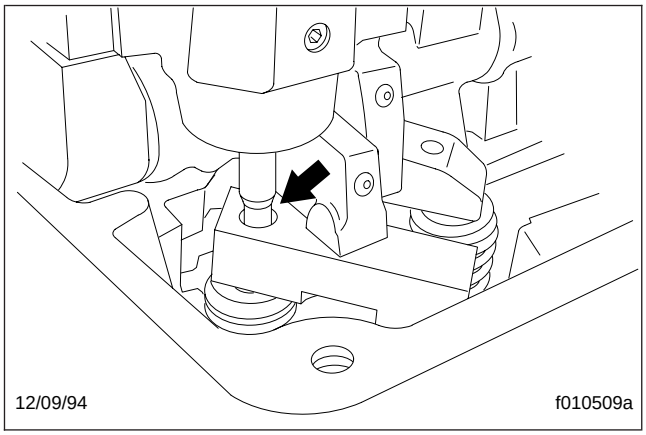

Fig. 11, Align the Brake Housing

7. All three Jacobs actuating pins should remain completely under the slave pistons. **See Fig. 12.** If necessary, tap the housing gently with a soft mallet to obtain proper alignment. Be sure the number 5 support remains in the most forward position. **See Fig. 5** for the next several steps.
8. Tighten the number 5 rocker-lever support hold-down capscrew 60 lbf·in (680 N·cm).
9. Put a 0.022-inch (0.56-mm) feeler-gauge between the number 5 support and the rocker lever on the number 4 cylinder. Set the side clearance. **See Fig. 13.**

11. Put the feeler gauge between the number 7 support and the rocker lever on the number 6 cylinder. Set the side clearance.

    With the feeler gauge in position, slide the number 8 support as far forward as possible. Tighten the capscrew 60 lbf·in (680 N·cm).

12. Check the rear brake housing slave piston-to-exhaust crosshead actuating pin alignment.

13. Slide the number 4 support as far back as possible.

14. Check the front brake housing alignment as previously outlined for the rear brake housing. After the brake housing is properly aligned, tighten the number 4 support hold-down capscrew 60 lbf·in (680 N·cm).

15. Put the feeler gauge between the number 4 support and the rocker lever on the number 3 cylinder. Set the side clearance.

    With the feeler gauge in position, slide the number 3 support as far back as possible. Tighten the capscrew 60 lbf·in (680 N·cm).

16. Put the feeler gauge between the number 3 support and the rocker lever on the number 2 cylinder. Set the side clearance.

    With the feeler gauge in position, slide the number 2 support as far back as possible. Tighten the capscrew 60 lbf·in (680 N·cm).

17. Put the feeler gauge between the number 2 support and the rocker lever on the number 1 cylinder. Set the side clearance.

    With the feeler gauge in position, slide the number 1 support as far back as possible. Tighten the capscrew 60 lbf·in (680 N·cm).

18. Check that all side clearances are within 0.020 to 0.025 inch (0.51 to 0.64 mm).

19. Check the alignment of the front brake housing slave pistons to the crosshead actuating pins.

20. Tighten the hold-down capscrews on each housing. **See Fig. 14**. First, tighten the two middle capscrews (**Fig. 15**) 45 lbf·ft (61 N·m); tighten the two outside capscrews (**Fig. 15**) the same amount. Second, using the same sequence,

tighten the capscrews 75 lbf·ft (102 N·m). Finally, tighten the middle capscrews, then the outside capscrews 95 lbf·ft (129 N·m).

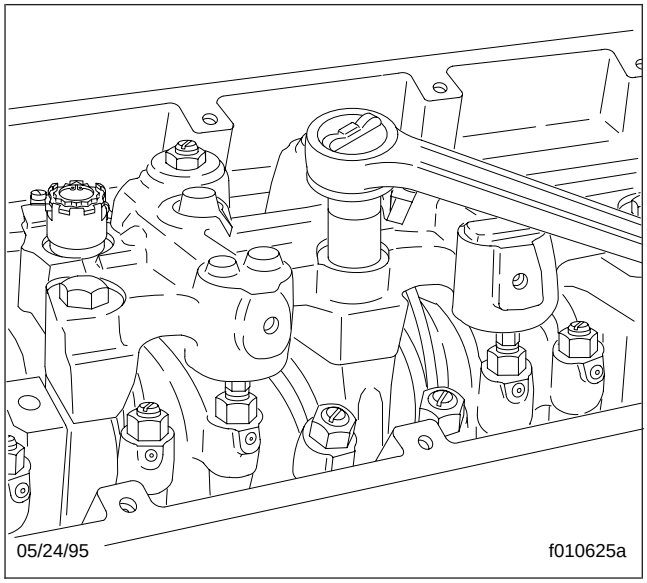

Fig. 14, Tighten the Hold-Down Capscrews

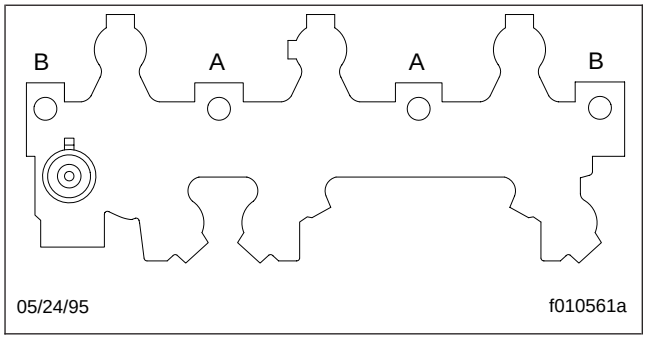

Fig. 15, Tightening Sequence

21. Adjust the injectors first, then the valves, using Cummins' L10 engine troubleshooting and repair manual. Note that the valves to be adjusted are not on the same cylinder as the injector being set. Follow the Cummins 10 Liter sequence chart. The Cummins dial indicator extension can be positioned so that the indicator extension can reach any injector. **See Fig. 16**. Use the long stem extension, Cummins PN 3376749. Make sure the extension is clear of all engine and engine brake components (moves freely).
22. If installing a new engine brake housing, or if the slave piston was removed, adjust the slave piston using the instructions in **Subject 140**. If the previously removed engine brake is being installed and the slave piston was not removed, proceed to the next step.

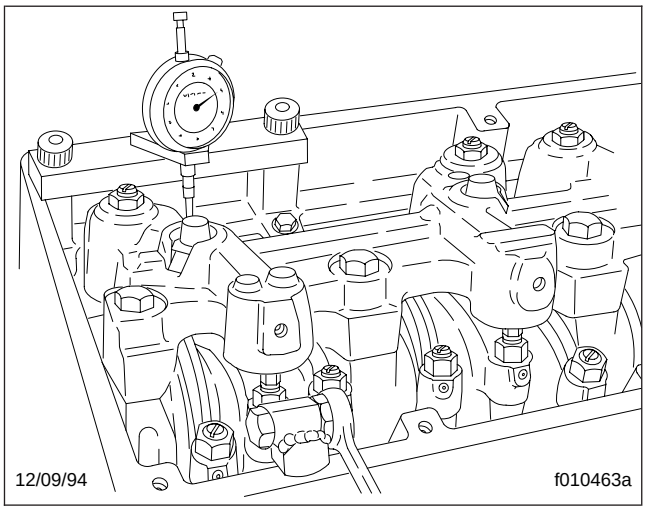

Fig. 16, Adjust the Injectors

23. Slide a new Jacobs oil-hose gasket over the male end of the Jacobs oil-hose assembly. **See Fig. 4.**
24. Insert the male end of the oil-hose assembly through the hole in the Jacobs spacer and install it in the front brake housing. **See Fig. 4.**

⚠ WARNING

WARNING: Keep the oil hose clear of all hot engine components and free from rubbing on the engine or chassis. A ruptured hose will spray hot oil and could cause heavy smoke or fire upon hitting hot engine components.

25. Slide the gasket, O-ring, and steel plates up to the spacer. Secure them in place with button-head screws. Tighten the screws 10 lbf·ft (14 N·m). Be careful to draw the plate up to the gasket evenly. **See Fig. 3.**
26. Connect the solenoid harness from each solenoid valve to the closest terminal leadout in the spacer. **See Fig. 2.**

Engine Brake Housing Removal and Installation

⚠ WARNING

WARNING: When the engine is running with the valve covers removed, there is significant oil splash in the engine brake area. Wear eye protection; do not expose your face over the engine area. Take precautions to prevent oil leakage down on the engine. Splashing oil can cause personal injury.

27. To bleed the brake units and check their operation, start the engine and allow it to run 5 to 10 minutes.

    Accelerate the engine to approximately 1800 rpm. Release the throttle, then manually depress each solenoid armature. **See Fig. 17.** This procedure should be done five or six times to permit engine oil to completely fill the brake housing passages.

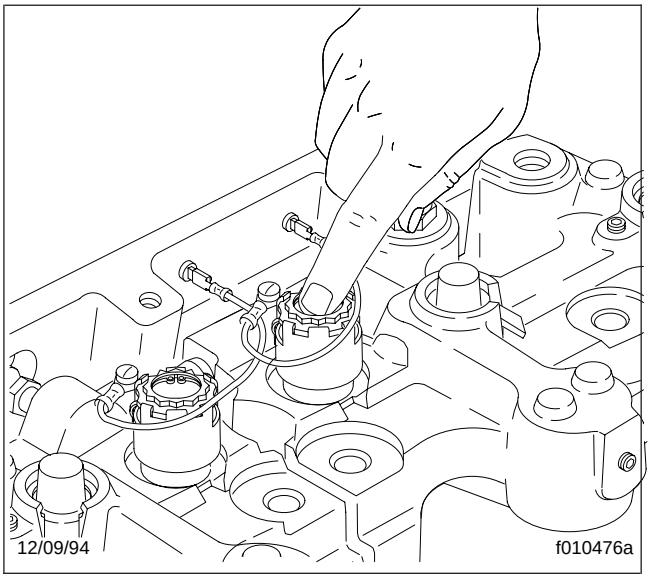

Fig. 17, Check Brake Operation

28. With the engine shut down, check the electrical system by turning the ignition switch on. With the dash switch labeled "RR CYLS" in the up position, the rear brake housing solenoid valve should activate. With the dash switch labeled "FWD CYLS" in the up position, the front brake housing solenoid valve should activate.

29. Install the rocker housing cover (**Fig. 18**).

    29.1 Remove the old cover gasket.

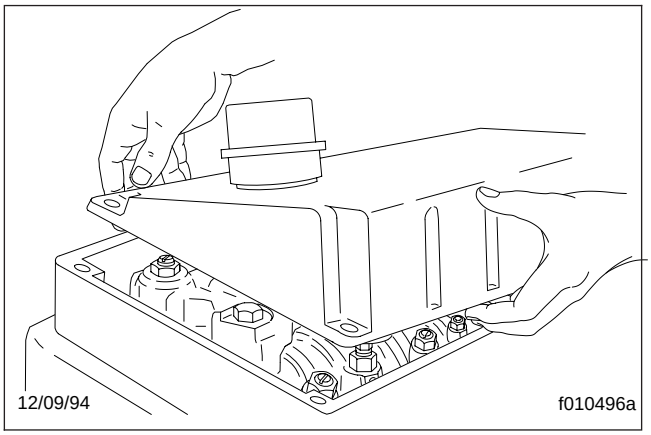

Fig. 18, Install the Rocker Housing Cover

    29.2 Apply a 1/16-inch (2 mm) bead of Cummins black RTV sealant or an equivalent, to the gasket sealing surface on the cover.

    29.3 Set the new gasket on the cover, then place the cover on the spacer.

    29.4 Install the capscrews and hold-downs.

    29.5 Using the sequence in **Fig. 19**, in 45 lbf·in (500 N·cm) increments on each pass, tighten the rocker-housing-cover capscrews 130 lbf·in (1460 N·cm).

2. Remove the screw, washer, and master piston spring from the bottom of the housing. **See Fig. 2.**
3. Remove the master piston from its bore; needle-nose pliers are usually needed to initially pull the piston up.

Inspection

If binding occurs during removal, check for burrs, or contaminants in the lube oil. If the piston is damaged, replace it. If the piston is not damaged, clean it in an approved cleaning solvent.

Installation

1. Install the piston, spring, washer, and screw. Make sure that when tightening the button head screw, the two tabs of the spring do not interfere with the sides of the center raised portion of the master piston. **See Fig. 3.**
2. Install the engine brake housing using the instructions in **Subject 120**.

⚠ WARNING

WARNING: The slave piston is retained by springs that are under heavy compression. If the following instructions are not followed and proper tools are not used, the springs could be discharged with enough force to cause personal injury. Wear safety glasses.

Use the single-valve slave-piston clamp fixture, PN 012359 to remove the slave piston.

1. Remove the engine brake housing from the vehicle using the instructions in **Subject 120**.
2. Remove the locknut on the slave piston adjusting screw. **See Fig. 2.** Back out the adjusting screw until the slave piston is fully retracted (screw is loose).
3. Place the hole in the clamp fixture over the slave piston adjusting screw. **See Fig. 3**. While holding the fixture in position, screw the holder down over the slave piston until the washer is depressed about 0.04 inch (1 mm), so that the retaining ring is loose in the groove. Remove the retaining ring. **See Fig. 4.** Back out the holder and remove the fixture.
4. Remove all slave piston components. **See Fig. 5.**

Inspection

Check for binding or burrs during removal. Clean the components in an approved cleaning solvent, or replace them if they are damaged. Make sure all components are assembled in the proper order.

Installation

1. Use the clamp fixture to install the piston and springs. Make sure the retaining ring is placed on the washer before screwing the clamp holder down over the slave piston. **See Fig. 6.**
2. Push the slave piston and springs down until the washer is about 0.04 inch (1 mm) below the retaining ring groove. Install the retaining ring. Make sure the retaining ring is fully seated in the groove. Remove the clamp fixture.

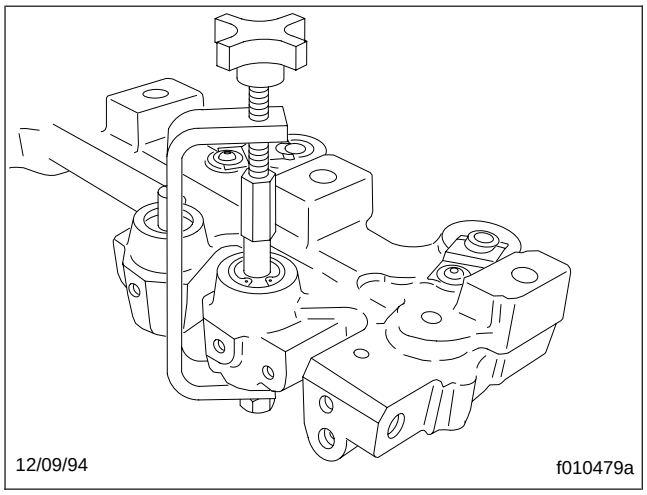

Fig. 6, Install the Piston With a Clamp

3. Remove, inspect, and install the slave piston adjusting screw using the instructions in **Subject 150**.
4. Install the engine brake housing on the vehicle using the instructions under **Subject 120**.

Adjustment

When adjusting an engine overhead, the most efficient time to adjust the slave piston lash is after setting the exhaust valves on each cylinder.

IMPORTANT: Slave piston adjustment must be made with the engine stopped and cold. The exhaust valves on the cylinder to be adjusted must be closed.

⚠ CAUTION

CAUTION: To ensure maximum engine brake efficiency, and to prevent engine damage by piston-to-valve contact, follow the instructions carefully.

Adjust the slave piston lash.

1. Insert a 0.015-inch Jacobs feeler gauge between the slave piston and the actuating pin in the crosshead. Turn the adjusting screw until you feel a light drag on the feeler gauge. **See Fig. 7.**
2. Hold the screw in position with a wrench. Using a crowfoot wrench (**Fig. 8**), tighten the locknut 22 lbf·ft (30 N·m).

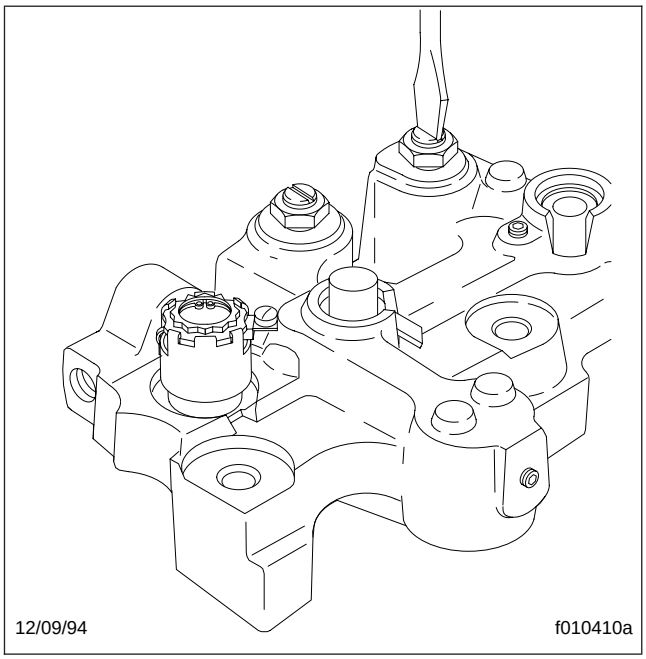

Fig. 7, Turn the Adjusting Screw

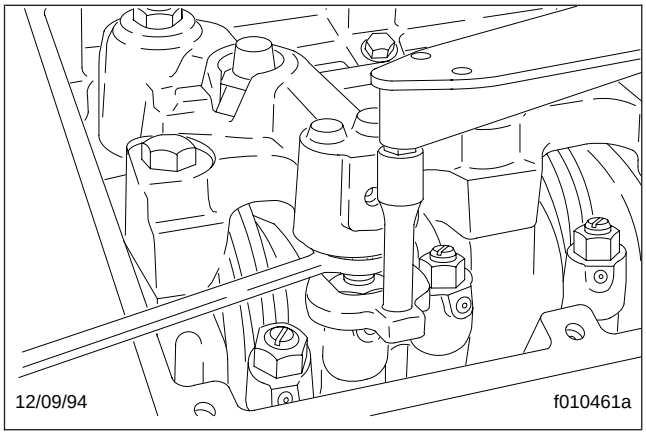

Fig. 8, Tighten the Locknut

⚠ CAUTION

CAUTION: Pay special attention to this adjustment. After the slave-piston adjusting-screw locknut is properly tightened, check the clearance with the Jacobs feeler gauge. Over-tightening Jacobs screws could cause engine damage.

3. Adjust all six slave pistons using this procedure.

2. Loosen the slave piston adjusting screw locknut, and remove the adjusting screw from the housing. **See Fig. 2.**

Inspection

1. Inspect the slave piston adjusting screw. The plunger should have light spring pressure apparent when depressed, and should move freely. **See Fig. 3.** Make sure the retaining ring is fully engaged in its groove.
2. If the screw is damaged, replace it. If the screw is not damaged, clean it in an approved cleaning solvent.

⚠ CAUTION

CAUTION: Don't attempt to adjust or tamper with the adjusting screw. This could result in engine damage.

2. Disconnect the solenoid harness from the solenoid. Using a 7/8-inch socket and extension, remove the solenoid valve. **See Fig. 2**.

Inspection

Inspect the oil filter screen and solenoid valve. **See Fig. 3 .** If the screen or solenoid valve is damaged, replace it. If it is not damaged, clean it in an approved cleaning solvent.

Installation

1. Install the solenoid using new seal rings. First, seat the lower seal ring on the bottom surface of the housing bore. Place the upper and center seal rings on the solenoid, and lubricate them with engine oil. **See Fig. 3** for seal locations. When installing the solenoid valve, make sure the seals are seated properly, then gently screw the solenoid into the housing without unseating the seals. **See Fig. 3.** Tighten the solenoid valve 60 lbf·in (680 N·cm).
2. Install the solenoid harness.

General Information

NOTE: For troubleshooting procedures, refer to **Section 01.12** in this manual.

Jacobs engine brake housings are installed on the engine rocker housings. Model 411 (used on Cummins M11 engines with CELECT) has two engine brake housings that operate three cylinders each. Each engine brake housing has a solenoid valve, control valve, ball check valve, master piston, and slave piston. See **Fig. 1**.

Engine brake controls consist of: two dash-mounted toggle switches, a clutch switch mounted under the dash, and the throttle switch. The switches are wired in series so that all of the switches must be closed to operate the engine brake. The engine brake is activated when one or both of the dash switches is on (up), and the clutch and throttle pedals are released. The dash switches enable the driver to operate the engine brake partially or fully.

Model 411 engine brakes can be operated at one-half or full capacity (three or six cylinders).

When activated, the engine brake converts a power-producing diesel engine to a power absorbing air compressor. This is accomplished by motion transfer through a master-slave piston arrangement which opens the engine cylinder exhaust valves near the top of the normal compression stroke, releasing the compressed cylinder charge to exhaust. The blow-down of compressed air to atmospheric pressure prevents the return of energy to the engine piston on the expansion (power) stroke. This results in a net energy loss because the work done in compressing the cylinder charge is not returned during the expansion process. Exhaust blowdown occurs as follows.

1. Activating the engine brake energizes the solenoid valve, allowing engine oil to flow under pressure through the control valve to both the master piston and the slave piston.
2. Oil pressure causes the master piston to move down, coming to rest on the injector rocker lever adjusting screw.
3. The injector rocker lever adjusting screw begins upward travel (as in the normal injection cycle) forcing the master piston upward and creating a high-pressure oil flow to the slave piston. The ball check valve in the control valve holds the high-pressure oil in the master-slave piston system.
4. When the engine piston is near top dead center, the slave piston moves down under the influence of the high-pressure oil flow. This momentarily opens one of the exhaust valves, releasing compressed cylinder air to the exhaust manifold.
5. Compressed air is released to the atmosphere, completing a compression braking cycle.

Removal (See Fig. 1)

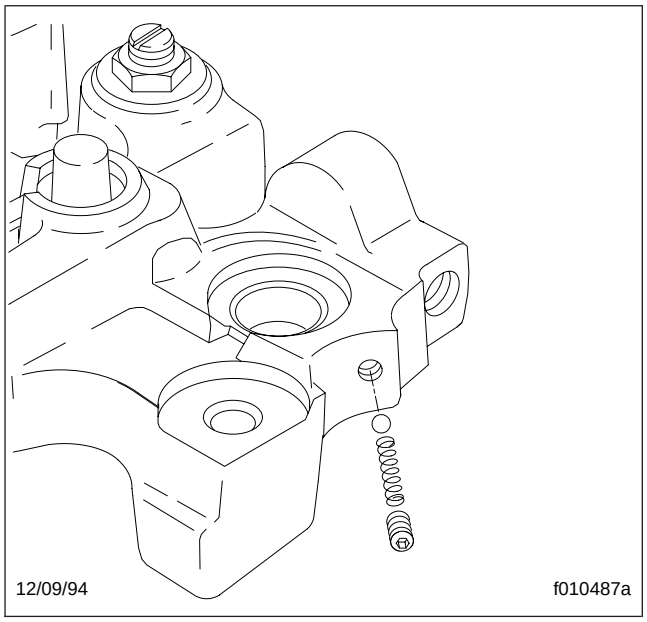

Fig. 1, Ball Check Valve, Exploded

1. Remove the engine brake housing from the vehicle. For instructions, refer to **Subject 120**.
2. Remove the hex socket pipe plug. Be careful during final turns to avoid loss of the spring and ball. Remove the spring and ball.

Installation

1. Inspect the parts for wear, then clean them in an approved cleaning solvent, or replace them if necessary.
2. Assemble the ball check valve by first inserting the ball, then the spring, and then tighten the plug 106 lbf·in (1200 N·cm).

⚠ CAUTION

CAUTION: Make certain the parts are installed in the order shown in Fig. 1. Improper installation may result in engine damage.

3. Install the engine brake housing using the instructions in **Subject 120**.

Removal

1. Wipe the engine brake housing area clean. Remove the rocker cover. For instructions, refer to **Subject 120**.

⚠ WARNING

WARNING: Control valve covers are under load from the control valve springs. Remove with care to avoid personal injury.

2. Apply pressure on the control valve cover, and remove the retaining ring, using retaining ring pliers. **See Fig. 1.**

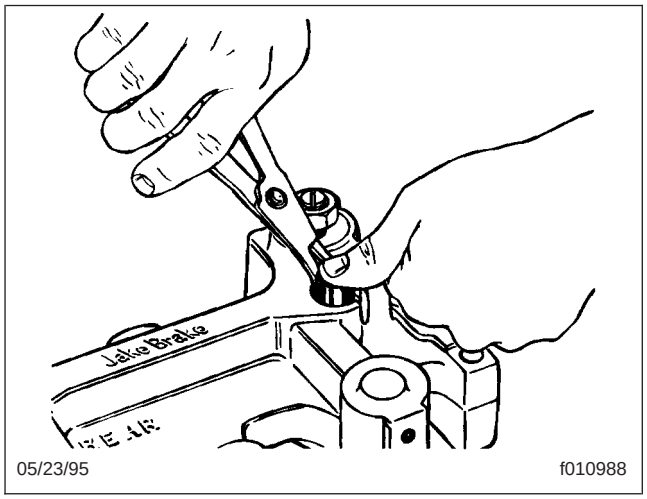

Fig. 1, Remove the Retaining Ring

3. Carefully remove the cover until the spring pressure ceases.
4. Carefully remove both control valve springs and the collar. **See Fig. 2.**
5. Using needle nose pliers or your fingertips, carefully pull the control valve straight up and out of its bore. **See Fig. 3.**
6. If binding occurs during removal, inspect the control valve parts for damage or wear, and replace them if necessary.

   If there is no damage, clean the parts in an approved cleaning solvent.

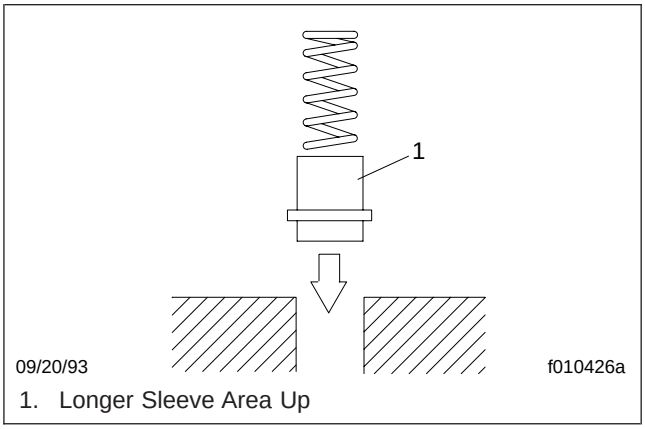
Control Valve Removal and Installation

Installation

CAUTION

CAUTION: Make sure the control valve collar is installed with the longer sleeve area up. See Fig. 4. If the collar is installed upside down, engine damage may result.

1. Install the control valve, collar, and springs. Make sure the retaining ring ears are positioned opposite the oil drain slot in the housing. **See Fig. 5.**



1. Longer Sleeve Area Up

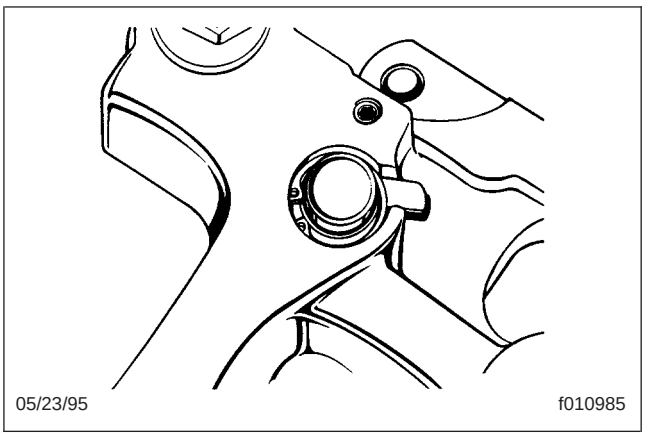

Fig. 5, Check the Retaining Ring Ears

2. Install the rocker cover. For instructions, refer to **Subject 120**.

Removal

1. Shut down the engine, and tilt the hood.

⚠ WARNING

WARNING: Never remove any engine brake component with the engine running. Hot oil spray could cause personal injury.

2. Wipe clean the engine brake housing area. Remove the rocker housing cover capscrews, and remove the cover and gasket from the spacer.
3. Disconnect the solenoid electrical harness from the terminal leadout in the spacer.
4. Remove the steel plates, O-ring, and gasket from the spacer. Disconnect the oil hose from the front brake housing, and remove it through the hole in the spacer.
5. Remove the engine brake housing hold-down capscrews.
6. Remove the engine brake housing from the rocker-shaft supports.

Installation

1. If the oil connector was previously removed from the front housing, then install the connector and O-ring into the front housing as far as it will go.
2. Back out the slave-piston adjusting screws until the slave pistons are fully retracted (screws are loose).
3. Place the rear brake housing on the rockershaft supports over cylinders 4, 5, and 6. Loosely install four Jacobs hold-down capscrews. Lubricate the threads and underside of the capscrew heads. Lubricate both ends of the oil supply tube.

NOTE: No washers are used with the capscrews.

4. Place the front brake housing on the rocker-shaft supports over cylinders 1, 2, and 3. Carefully insert the oil connector into the rear housing.
5. Install the capscrews in the sixteen locations and hand tighten them in the sequence shown in **Fig. 1**.

Then, using the same sequence, tighten the capscrews 60 lbf·ft (81 N·m).

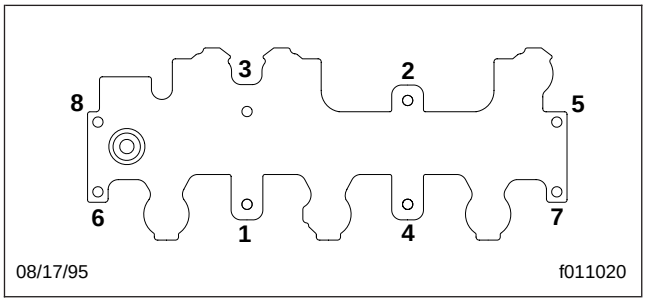

Fig. 1, Capscrew Tightening Sequence

Master Piston Removal, Inspection, and Installation

Removal and Inspection

1. Remove the brake housing from the vehicle. For instructions, refer to **Subject 120**.
2. Remove the screw, washer, and master piston spring from the bottom of the housing. **See Fig. 1.**

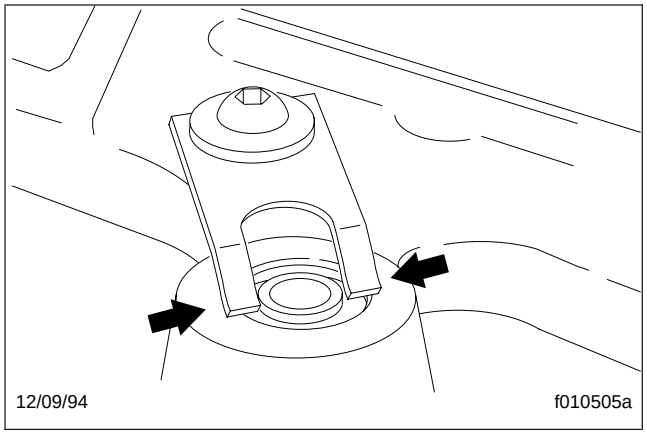

Fig. 1, Remove the Piston Spring

3. Remove the master piston from its bore; needle-nose pliers are usually needed to initially pull the piston up. **See Fig. 2.**

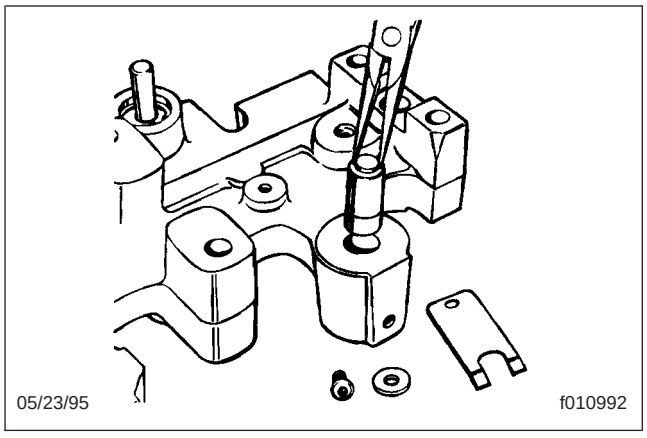

Fig. 2, Remove the Master Piston

4. If binding occurs during removal, check for burrs, or contaminants in the lube oil. If the piston is damaged, replace it. If the piston is not damaged, clean it in a cleaning solvent.

Installation

1. Install the piston, spring, washer, and screw. Make sure that when tightening the capscrew, the two tabs of the spring do not interfere with the sides of the center raised portion of the master piston. **See Fig. 1.**
2. Install the engine brake housing using the instructions in **Subject 120**.

Removal

1. Apply the parking brakes, chock the tires, shut down the engine, and tilt the hood.

⚠ WARNING

WARNING: Never remove any engine brake component with the engine running. Hot oil spray could cause personal injury.

2. Wipe the engine brake housing area clean.
3. Remove the bolts that hold each rocker cover, and remove the rocker covers.

Installation

1. Inspect the cover seals, and replace them if they are damaged.
2. Make sure a rocker cover seal is located in the groove of each cover, and install the cover on the spacer.

⚠ CAUTION

CAUTION: Be sure to tighten all the rocker cover bolts evenly. Excessive or uneven tightening may cause the rocker cover to crack.

3. Install a flatwasher, a new sleeve, and a new noise isolator on each capscrew, and install the capscrew assemblies in the cover. Tighten the bolts 130 lbf·in (1460 N·cm) in the sequence shown in **Fig. 1**.

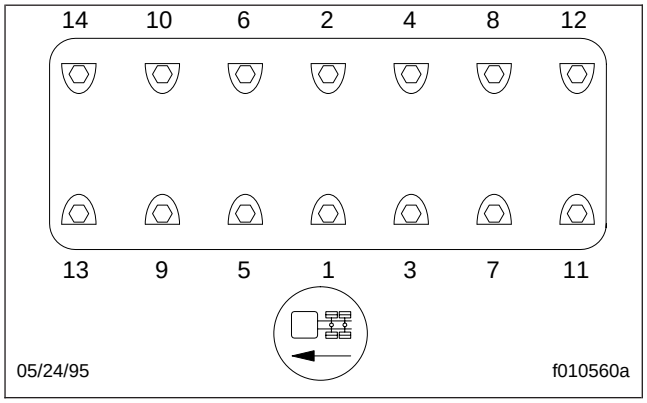

Fig. 1, Bolt Tightening Sequence

4. Remove the chocks from the tires.

Slave Piston Removal, Cleaning, and Installation

Removal

1. Remove the brake housing from the vehicle. For instructions, refer to **Subject 120**.

⚠ WARNING

WARNING: Wear safety glasses, and remove the slave piston carefully. The slave piston is retained by springs that are under heavy compression. If the following instructions are not used and the proper tools are not used, the spring could be discharged with enough force to cause personal injury.

2. Remove the locknut on the slave piston adjusting screw, and back out the adjusting screw until the slave piston is fully retracted (the screw is loose).
3. Use the slave piston clamp fixture to remove the slave piston. **See Fig. 1.** Place the hole in the clamp fixture over the slave piston adjusting screw.

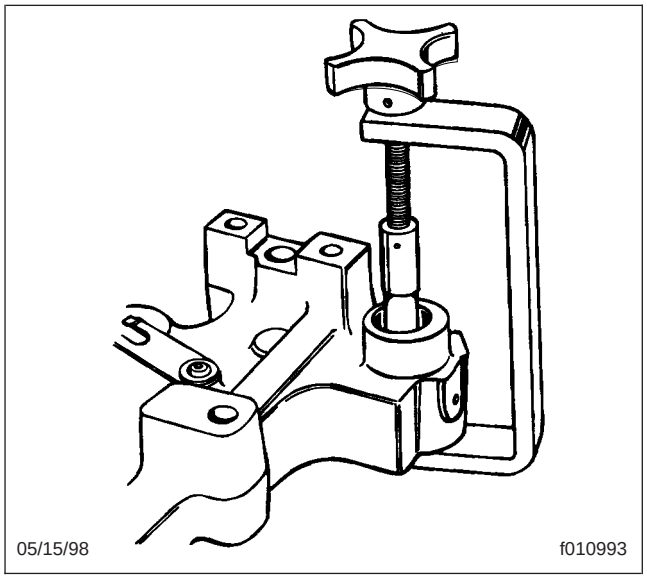

Fig. 1, Using the Clamp Fixture

4. While holding the fixture in position, screw the holder down over the slave piston stem until the retainer is contacted. Turn the handle slowly until the retainer is depressed about 1/32 inch (1 mm), relieving pressure against the retaining ring

   Using retaining ring pliers, remove the retaining ring. **See Fig. 2.**

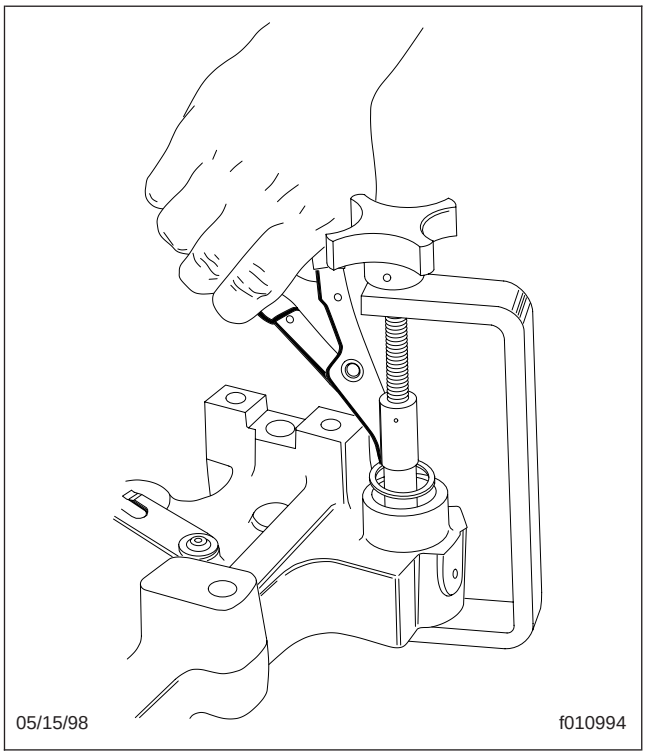

Fig. 2, Removing The Retaining Ring

5. Remove the retainer, spring, and slave piston. Check for nicks or burrs that could cause binding. **See Fig. 3.**

Cleaning

1. Clean the piston in an approved cleaning solvent.
2. Run a small wire through any holes.
3. Replace the piston if the ground surface on the outside diameter is scratched or scored.

Installation

IMPORTANT: Make sure all the components are assembled in the correct order.

1. Install the slave piston into the bore.
2. Install the springs and retainer over the slave piston foot.

Slave Piston Removal, Cleaning, and Installation

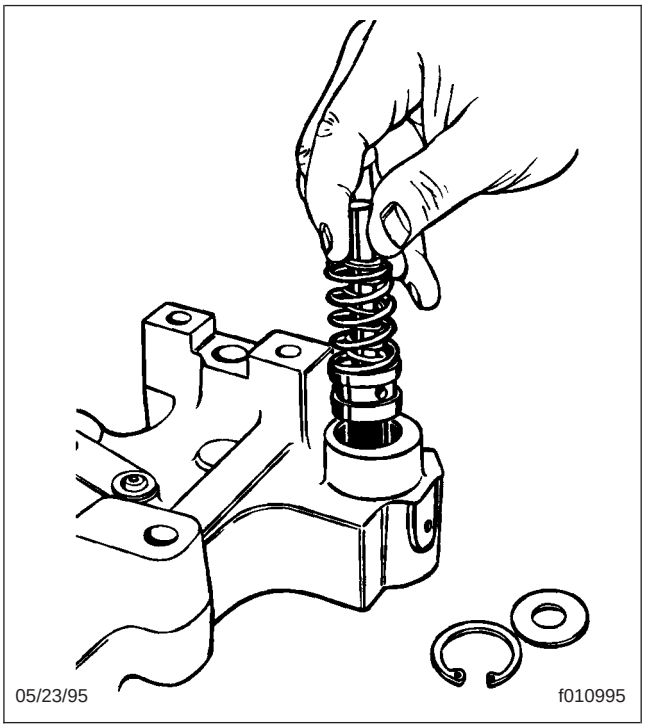

Fig. 3, Remove the Slave Piston

3. Use the clamp fixture to compress the slave piston and springs until the retainer is about 1/32 in (1 mm) below the retaining ring groove.
4. Slide the retaining ring over the threaded rod of the clamp fixture, and install the retaining ring in its groove. Make sure the retaining ring is fully engaged in the groove.

   Remove the clamping fixture slowly to ensure proper seating of the retaining ring.
5. Install the engine brake housing using the instructions in **Subject 120**.

Slave Piston Adjusting Screw Removal, Inspection, and Installation

Removal

1. Remove the rocker cover from the vehicle. For instructions, refer to **Subject 140**.
2. Remove the slave piston adjusting screw locknut, and remove the adjusting screw from the housing. **See Fig. 1.**

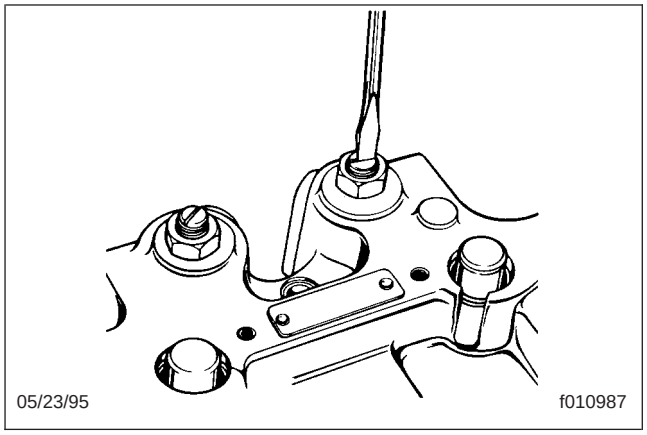

Fig. 1, Remove the Adjusting Screw

Inspection and Installation

1. Clean the adjusting screw in an approved solvent.
2. Inspect the slave piston adjusting screw. **See Fig. 2.** The plunger should protrude from the bottom of the screw, have light spring pressure apparent when depressed, and should move freely. Be sure the retaining ring is fully engaged in its groove. Replace the entire screw assembly if any defect is found.

   Using retaining ring pliers, remove the retaining ring.
3. Install the slave piston adjusting screw, and adjust the slave piston lash to 0.015 inch (0.03 mm).

NOTE: The slave piston lash must be set with the engine stopped and cold. The exhaust valves on the cylinder to be adjusted must be closed.

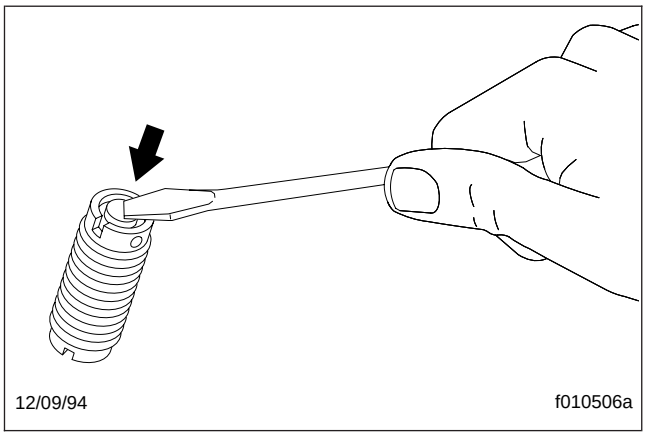

Fig. 2, Inspect the Adjusting Screw

⚠ CAUTION

CAUTION: Do not over tighten the adjusting screw locknut. Over tightening the locknut will cause poor engine brake performance.

After tightening the slave piston adjusting screw locknut, check the clearance with a Jacobs feeler gage. Readjust the piston lash if needed.

4. After the slave piston is adjusted, tighten the adjustment screw locknut 25 lbf·ft (34 N·m).
5. Install the rocker cover using the instructions in **Subject 140**.

Removal

1. Remove the rocker cover from the vehicle. For instructions, refer to **Subject 140**.
2. Disconnect the solenoid harness.
3. Using a 7/8-inch socket and extension, unscrew the solenoid valve. **See Fig. 1.**

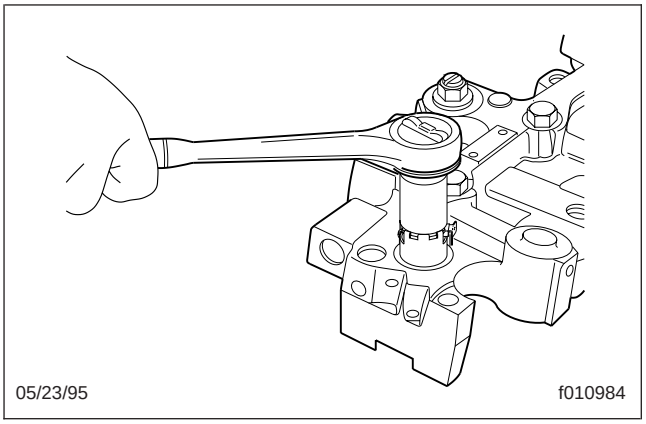

Fig. 1, Unscrew the Solenoid

CAUTION

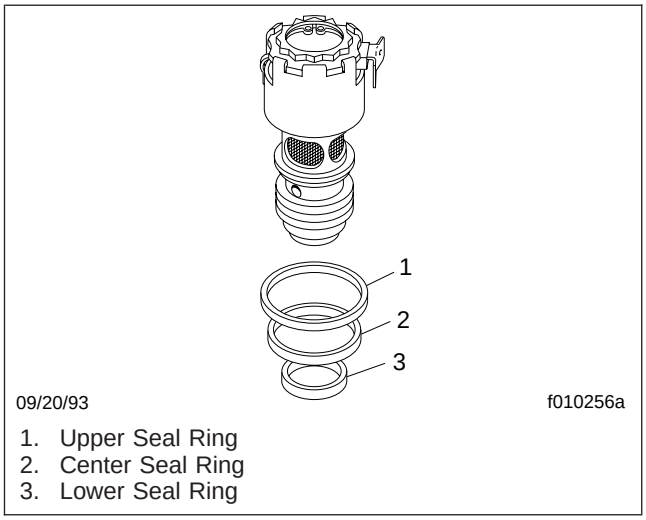
CAUTION: Do not disassemble or tamper with the solenoid valve. Engine damage could result.

4. Remove and discard the three rubber seal rings. **See Fig. 2.**

   If the lower ring stays in the bottom of the housing solenoid bore, remove it with a seal pick.

Cleaning and Installation

1. Wash out the solenoid valve with an approved cleaning solvent. Use a brush to clean the oil screen. Clean and dry the valve with compressed air. Replace the oil screen, if needed.
2. Clean out the solenoid valve bore in the housing. Use clean paper towels. Never use rags, as they may leave lint and residue which can plug the oil passageways.
3. Install the solenoid using new seal rings. Seat the lower seal ring in the base of the solenoid valve bore. Wipe clean lube oil into and around the bore, and place the upper and center seal rings on the solenoid valve body.



1. Upper Seal Ring
2. Center Seal Ring
3. Lower Seal Ring

Fig. 2, Solenoid Seal Rings

4. Be sure the seals are seated properly, and carefully screw the solenoid into the housing without unseating the seals. **See Fig. 3.** Tighten the solenoid 10 lbf·ft (7 N·m).

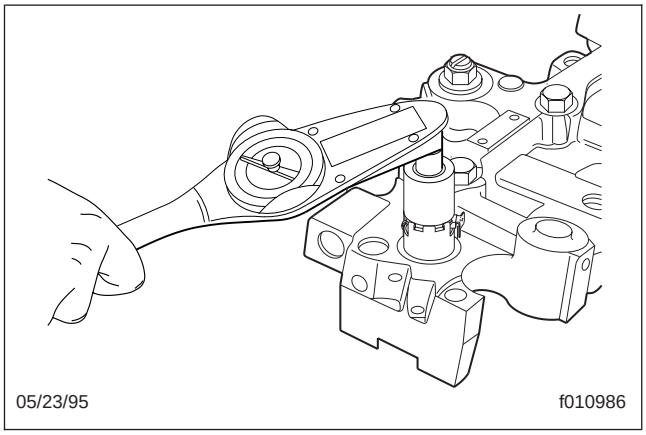


Fig. 3, Installing the Solenoid

5. Connect the solenoid wiring harness.
6. Install the rocker cover using the instructions in **Subject 140**.

General Information

NOTE: For troubleshooting procedures, refer to **Section 01.12** in this manual.

Jacobs engine brake housings are installed on the engine rocker housings. Model 750 (used on Detroit Diesel Series 50 engines) has two engine brake housings that operate two cylinders each. Each engine brake housing has a solenoid valve, control valves, ball check valves, master pistons, and slave pistons. See **Fig. 1**.

Fig. 1, Operating Schematic, Model 750 Housing Assembly

Engine brake controls consist of: dash switches and a clutch switch. The clutch switch is mounted under the dash. The engine brake is activated when the dash switches are on and the clutch and throttle pedals are released. The dash switches enable the driver to operate the engine brake partially or fully.

The Model 750 engine brake can be operated at one-half or full capacity (two or four cylinders).

When activated, the engine brake converts a power-producing diesel engine to a power-absorbing air compressor. This is accomplished by motion transfer through a master-slave piston arrangement which opens the engine cylinder exhaust valves near the top of the normal compression stroke, releasing the compressed cylinder charge to exhaust. The blow-down of compressed air to atmospheric pressure prevents the return of energy to the engine piston on the expansion (power) stroke. This results in a net energy loss because the work done in compressing the cylinder charge is not returned during the expan-

sion process. Exhaust blowdown occurs as follows (see **Fig. 1**):

1. Activating the engine brake energizes the solenoid valve, allowing engine oil to flow under pressure through the control valve to both the master piston and the slave piston.
2. Oil pressure causes the master piston to move down, coming to rest on the injector rocker arm roller.
3. The injector rocker arm begins upward travel (as in the normal injection cycle) forcing the master piston upward and creating a high-pressure oil flow to the slave piston. The ball check valve in the control valve holds the high-pressure oil in the master-slave piston system.
4. When the engine piston is near top dead center, the slave piston moves down under the influence of the high-pressure oil flow. This momentarily opens the exhaust valves, releasing compressed cylinder air to the exhaust manifold.
5. At the bottom of its stroke the slave piston separates from the plunger in the slave piston adjusting screw, allowing high-pressure oil to flow into the accumulator. This reduces the pressure in the high-pressure circuit, permitting the slave piston to retract and the exhaust valves to close in preparation for the normal exhaust valve cycle. The oil pressure reserved in the accumulator ensures that the hydraulic circuit is fully charged for the next cycle.
6. Compressed air escapes to the atmosphere completing a compression braking cycle.

Accumulator Removal, Inspection, and Installation

Removal

WARNING

WARNING: The accumulator spring is under strong compression. Be careful when removing the retaining ring and cover. Wear safety glasses. If the spring is accidentally released, personal injury could result.

1. Remove the engine brake housing from the vehicle. For instructions, refer to **Subject 120**.
2. Push down on the accumulator cover and remove the retaining ring. **See Fig. 1**.

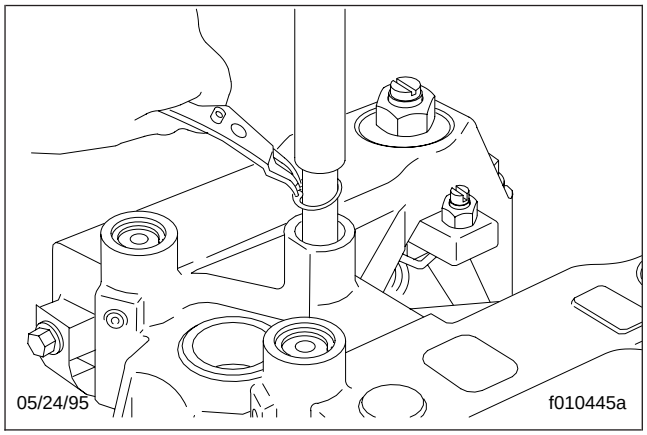

Fig. 1, Remove the Retaining Ring

3. Remove the cover and spring. **See Fig. 2**.

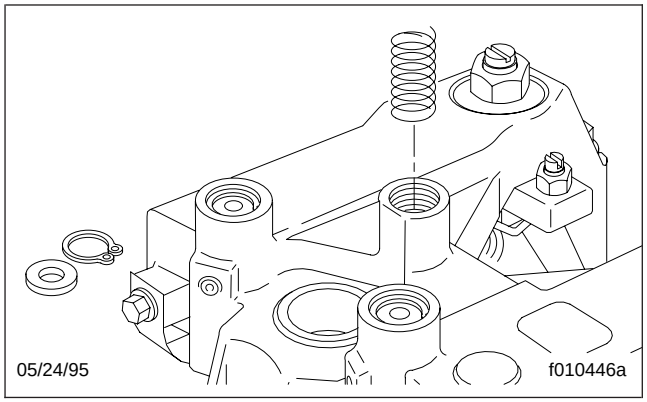

Fig. 2, Remove the Spring

4. Using a magnet, remove the piston from the accumulator bore. **See Fig. 3**.

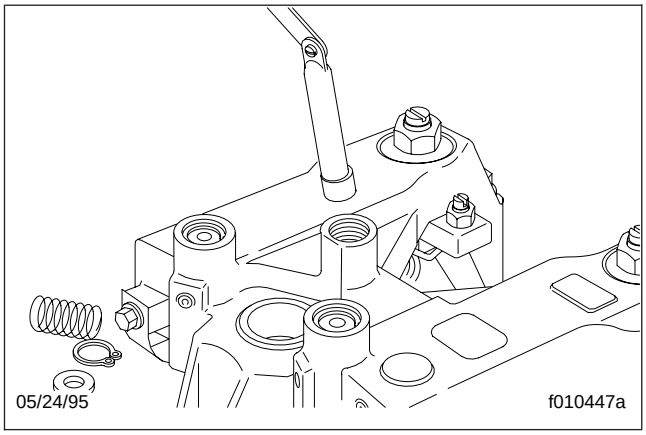

Fig. 3, Remove the Piston

Inspection

Inspect the parts for wear and damage. Replace parts as needed.

Installation

1. Install the piston, spring, cover, and retaining ring.
2. Install the engine brake housing. For instructions, refer to **Subject 120**.

Control Valve Removal, Inspection, and Installation

Removal

1. Wipe the engine brake housing area clean, and remove the rocker cover. For instructions, refer to **Subject 150**.

⚠ WARNING

WARNING: Control valve covers are under load from the control valve springs. Remove the covers with care to avoid personal injury.

2. Press down on the control valve cover to relieve spring pressure. **See Fig. 1.**

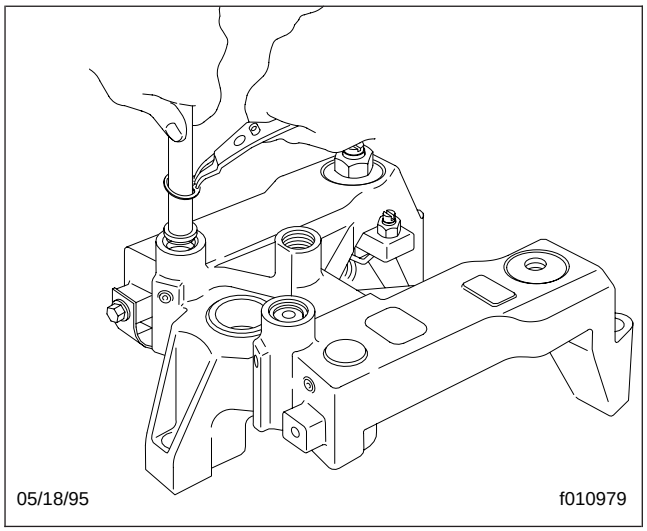

Fig. 1, Press the Control Valve Cover

3. Remove the retaining ring using retaining ring pliers.
4. Slowly remove the cover until the spring pressure is released; then, remove the two control valve springs and the collar. **See Fig. 2.**
5. Using needle nose pliers, reach into the housing bore and grasp the stem of the control valve. Remove the control valve. **See Fig. 3.**

Inspection

1. Wash the control valves with a cleaning solvent.
2. Push a wire through the hole in the base of the valve to make sure the ball check is free. The ball should lift with light pressure on the wire.

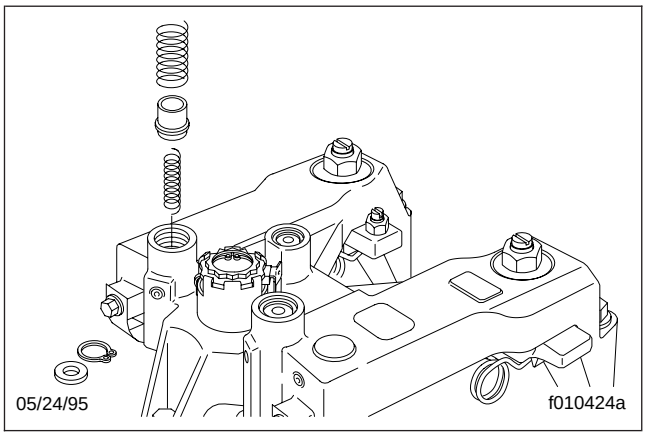

Fig. 2, Remove the Springs and the Collar

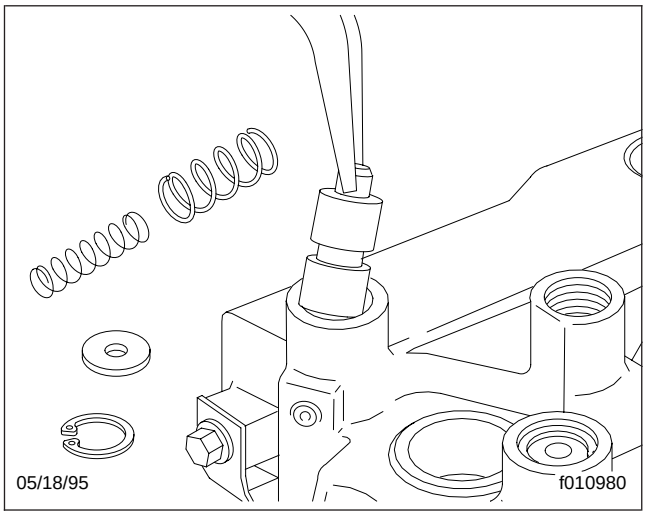

Fig. 3, Remove the Control Valve

3. Dry the valve with compressed air and wipe it clean with a paper towel.
4. Using clean paper towels, thoroughly clean the control valve bore in the housing.
5. Dip the control valves in clean lubricating oil. Holding the valve by the stem, let the valve drop into its bore. If it binds or if the ball is stuck in the valve, replace the control valve.

Installation

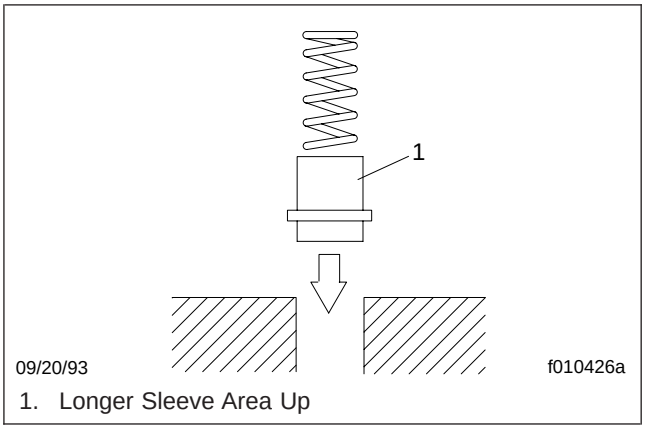
IMPORTANT: Be sure to coat all parts with clean lubricating oil before installing them.

Control Valve Removal, Inspection, and Installation

1. Install the control valve reversing the removal procedure.

NOTE: Make sure the control valve collar is installed with the longer sleeve area up. **See Fig. 4.** If the collar is installed upside down, the engine brake cylinder will not operate.

2. Make sure the retaining ring ears are rotated 90 degrees after installation.



1. Longer Sleeve Area Up

Fig. 4, Check the Valve Collar

3. Install the rocker cover. For instructions, refer to **Subject 150**.

Engine Brake Housing Removal and Installation

Removal

1. Park the vehicle, apply the parking brakes, shut down the engine, and chock the tires.
2. Disconnect the batteries.
3. Tilt the hood.

⚠ WARNING

WARNING: Never remove any engine brake component with the engine running. Hot oil spray may cause personal injury.

4. Remove the rocker cover. For instructions, refer to **Subject 150**.
5. Disconnect the wiring to the engine brake housings.
6. Remove the three bolts that hold each engine brake housing.
7. Remove the engine brake housings.

Installation

1. Place the two engine brake housings over the rocker shafts with the solenoid valves toward the camshaft side of the engine.
2. Move the housings from side to side, then position the housings in the center of the movement range.
3. Tighten the engine brake hold-down bolts.
   - 3.1 Tighten the two bolts on the camshaft side of the engine 40 lbf·ft (55 N·m).
   - 3.2 Tighten the four bolts on the exhaust side of the engine 40 lbf·ft (55 N·m).
   - 3.3 Repeat the previous two steps, but tighten the bolts 100 lbf·ft (135 N·m).
   - 3.4 Check the torque of all the hold-down bolts, and torque to 100 lbf·ft (135 N·m) if needed.
   - 3.5 Reset the engine brake lash. For instructions, refer to **Subject 160**.
   - 3.6 Connect the engine brake wiring.
   - 3.7 Connect the batteries.
   - 3.8 Install the rocker cover. For instructions, refer to **Subject 150**.

Master Piston Removal, Inspection, and Installation

Removal

1. Remove the engine brake housing from the vehicle. For instructions, refer to **Subject 120.**
2. Remove the screw, washer, and master piston spring from the housing. **See Fig. 1**.

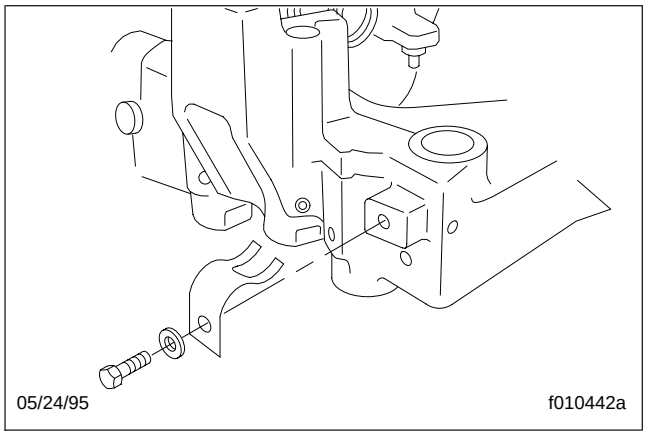


Fig. 1, Remove the Master Piston Spring

3. Using needle nose pliers if necessary, pull out the master piston. **See Fig. 2**.

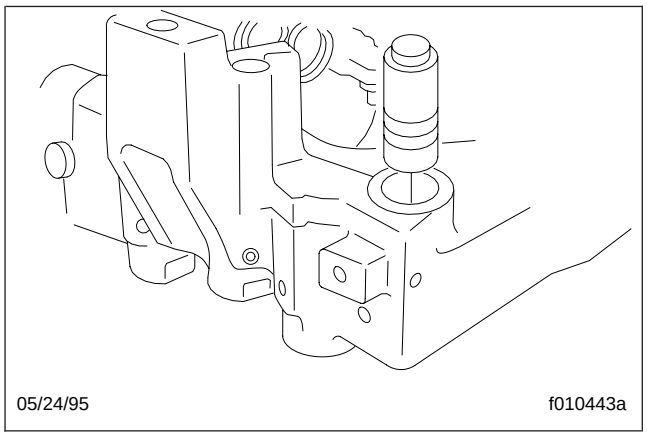

Fig. 2, Remove the Master Piston

Inspection

1. Clean the piston in a cleaning solvent.
2. Inspect the piston for excessive wear and for damage. Replace the piston if necessary.

Installation

1. Coat the piston with clean lube oil.
2. Install the master piston, spring, washer, and screw in the housing. **See Fig. 3**.

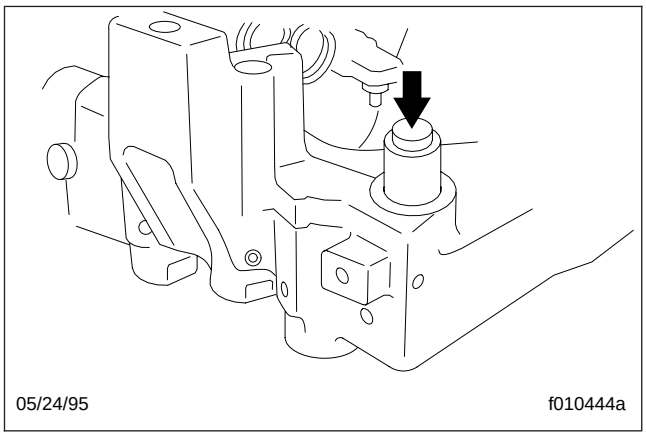

Fig. 3, Install the Master Piston

NOTE: Make sure the spring legs are centered around the master piston boss.

3. Tighten the screw 100 lbf·in (1120 N·cm).

IMPORTANT: The spring must hold the master piston completely in the housing. If not, the spring has relaxed and must be replaced.

4. Install the engine brake housing on the vehicle. For instructions, refer to **Subject 120**.

Master Piston Pin and Roller Removal, Cleaning, and Installation

Removal

The injector rocker arm contains a pin and roller for actuating the engine brake master piston. If excessive wear or damage to the roller is present, the injector rocker arm assembly must be replaced according to the following procedure.

1. Remove the engine brake housing from the vehicle. For instructions, see **Subject 120.**
2. Loosen the locknuts on the intake, exhaust, and injector adjusting screws.
3. Remove the bolts, spacers, and nuts from the rocker shafts. See **Fig. 1**.

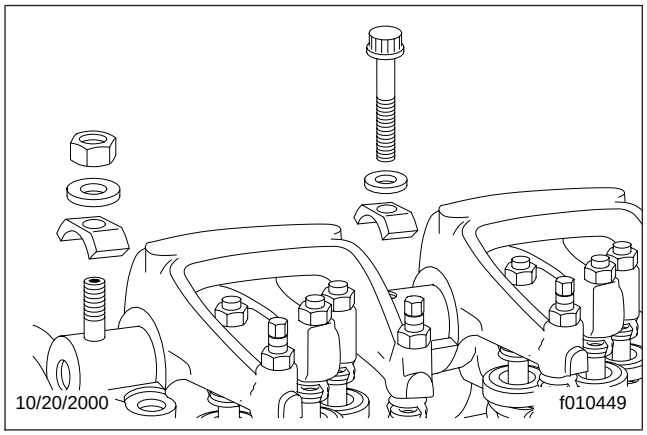

Fig. 1, Remove the Bolts from the Rocker Shaft

4. Lift off the rocker arm assembly. See **Fig. 2** .

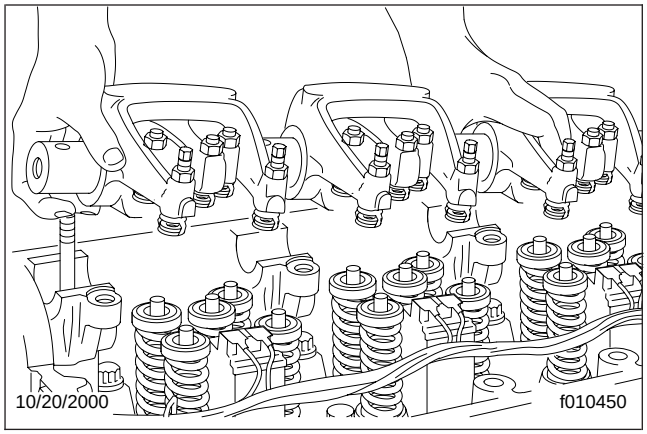

Fig. 2, Remove the Rocker Arm Assembly

5. Slide the rockers off the shaft (**Fig. 3**), marking the parts so they can be installed in the same order.

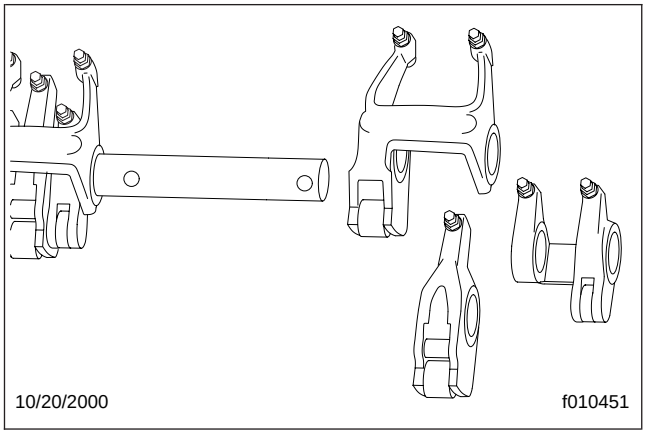

Fig. 3, Remove the Rockers

Cleaning

1. Clean the rocker arms and rocker arm shafts in a solvent.
2. Dry the components with compressed air.
3. Inspect the injector rocker arm assemblies, and replace any assembly that has a damaged roller.

Installation

1. Assemble the rockers on the shaft in the order they were removed. See **Fig. 4**.

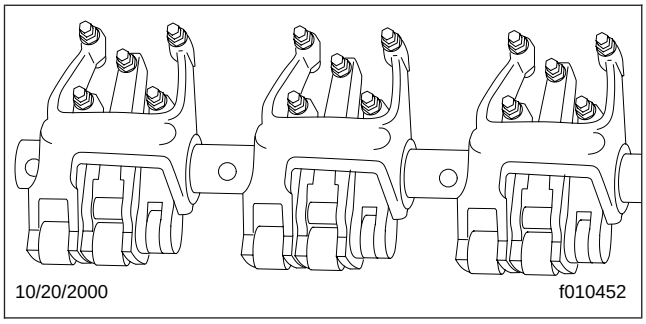

Fig. 4, Assemble the Rockers

2. Check the torque on the rocker shaft studs to be sure they were not loosened when the nuts were removed (**Fig. 5**). Tighten the studs 80 lbf·ft (110 N·m).

Master Piston Pin and Roller Removal, Cleaning, and Installation

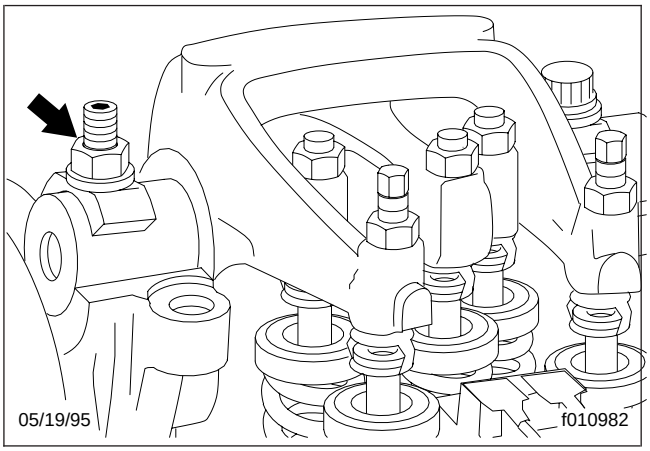

Fig. 5, Rocker Shaft Stud Nut

3. Install the rocker shaft assembly using the bolts, end spacers, and nuts. Using the sequence shown in **Fig. 6**, tighten the bolts and nuts 80 lbf·ft (110 N·m).

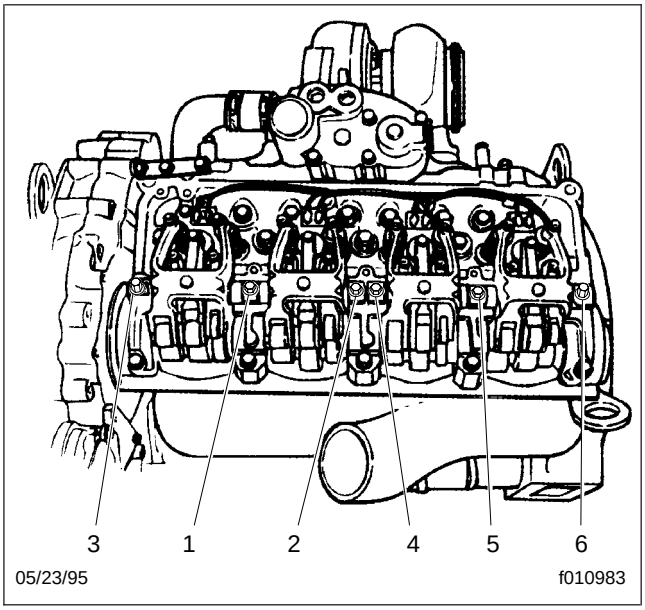

Fig. 6, Rocker Shaft Tightening Sequence

4. Install the engine brake housing on the vehicle. For instructions, see **Subject 120**.

Removal

1. Apply the parking brakes, chock the tires, shut down the engine, and tilt the hood.
2. Disconnect the batteries.

⚠ WARNING

WARNING: Never remove any engine brake component with the engine running. Hot oil spray may cause personal injury.

3. Wipe the engine brake housing area clean.
4. Remove the bolts that hold the rocker cover, and remove the rocker cover. **See Fig. 1.**

3. Install the hold-down bolt assemblies to the rocker cover base, and thread the bolts two to three threads into the cylinder head.

⚠ CAUTION

CAUTION: Use care, when tightening the rocker cover base hold-down bolts, that the injector wires do not get caught between the limiting sleeve and the cylinder head.

4. Tighten the eight rocker cover base hold-down bolts 25 lbf·ft (35 N·m) using the tightening sequence shown in **Fig. 3**. Tighten the bolts in two stages, using half-torque value first.

Rocker Cover Removal and Installation

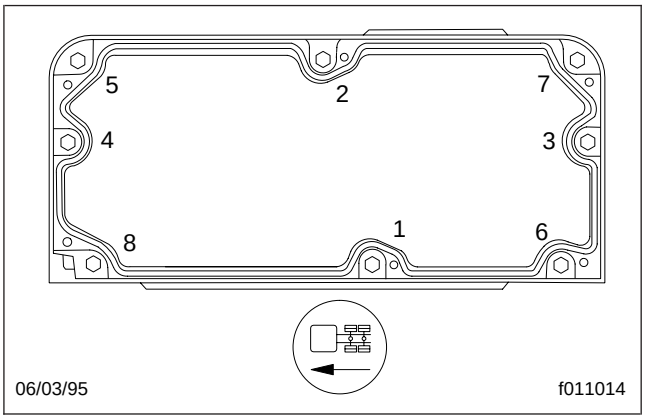

Fig. 3, Bolt Tightening Sequence

5. Be sure the groove in the top of the rocker cover base and its mating, diamond-shaped seal are clean and dry.
6. Press the diamond-shaped seal into the groove. Use care not to twist the seal. The seal has a definite shape and should be installed exactly as removed from the base.

   If the seal cannot be installed into its groove without bunching or looping, the seal is stretched and must be replaced.
7. Install the rocker cover cap to the base. Install the eight screws that attach the cap to the base and tighten the screws 20 lbf·ft (25 N·m) in two stages, using half-torque value first. Use the torque sequence shown in **Fig. 4**.

Slave Piston Adjusting Screw (Reset®) Removal, Inspection, and Installation

Removal

1. Remove the rocker cover. For instructions, refer to **Subject 150**.

⚠ CAUTION

CAUTION: Do not adjust or tamper with the adjusting screw assembly. Engine damage could result.

2. Loosen the slave piston adjusting screw locknut, and remove the adjusting screw from the housing. **See Fig. 1.**

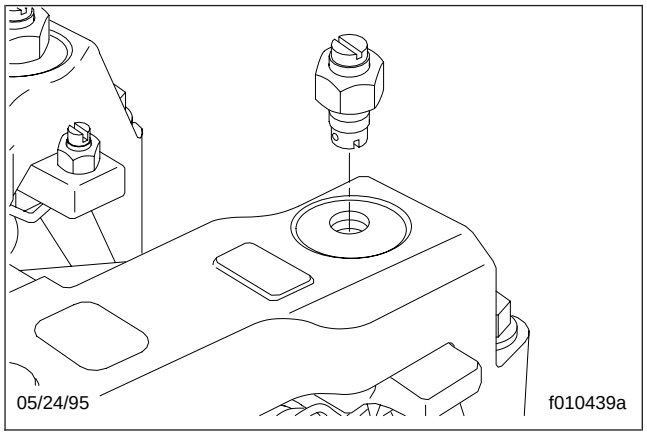

Fig. 1, Remove the Adjusting Screw

Inspection

1. Clean the adjusting screw in cleaning solvent.
2. Inspect the slave piston adjusting screw. The plunger should protrude from the bottom of the screw. There should be light spring pressure when the plunger is depressed, and the plunger should move freely. **See Fig. 2.** Be sure the retaining ring is fully engaged in its groove. If any defect is found, replace the entire screw assembly.

Installation

1. Screw the slave piston adjusting screw into the housing.
2. Tighten the locknut 25 lbf·ft (35 N·m).

Slave Piston Removal, Inspection, and Installation

Removal

1. Remove the engine brake housing from the vehicle using the instructions in **Subject 120**.
2. Remove the screw and spring that retain the slave piston assembly. **See Fig. 1.**

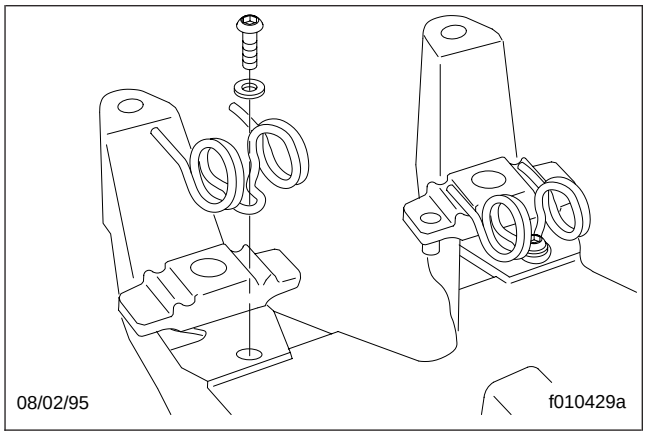

Fig. 1, Remove the Screw and Spring

3. Remove the bridge and the slave piston. **See Fig. 2.**

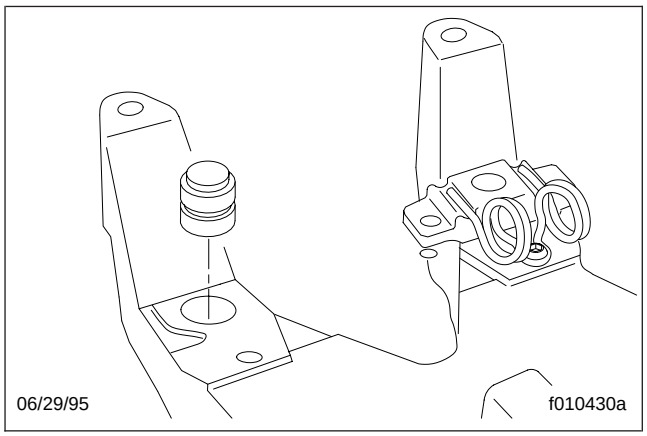

Fig. 2, Remove the Slave Piston

4. Loosen the leveling screw locknut and remove the leveling screw from the bridge. **See Fig. 3.**

Inspection

1. Inspect all components for excessive wear and for damage.

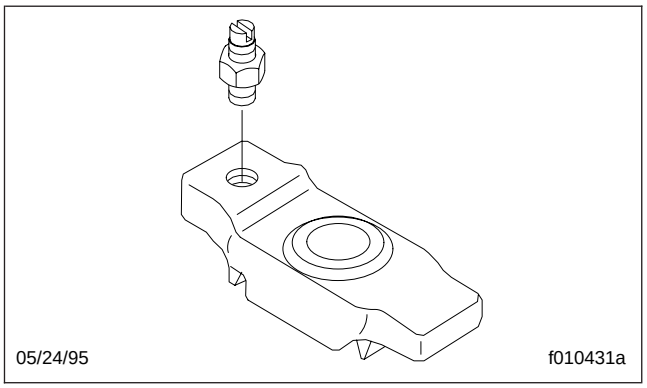

Fig. 3, Remove the Leveling Screw

2. Replace parts as needed.

Installation

1. Install the leveling screw in the bridge. **See Fig. 3.** Tighten the locknut 25 lbf·ft (35 N·m).
2. Install the slave piston and the bridge with the leveling screw toward the center of the housing. **See Fig. 4.**

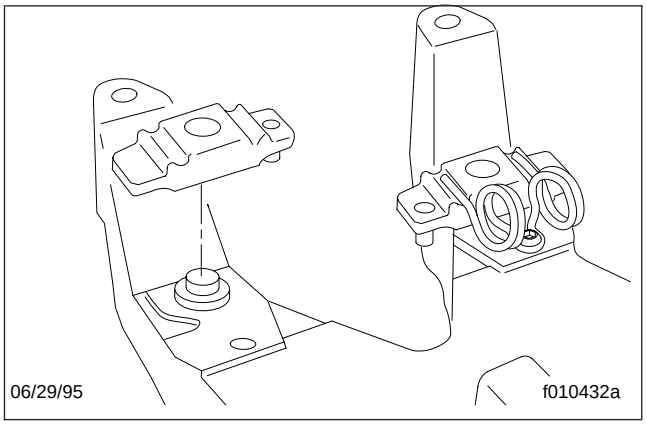

Fig. 4, Install the Slave Piston and Bridge

3. Install the slave piston assembly retaining spring with the ends over the bridge. **See Fig. 5.**
4. Install the screw over the center part of the spring. Tighten the screw 15 lbf·ft (20 N·m).
5. Install the engine brake housing on the engine using the instructions in **Subject 120**.

Removal

1. Remove the rocker cover. For instructions, refer to **Subject 150**.
2. Disconnect the solenoid harness.
3. Using a 7/8-inch socket and extension, unscrew the solenoid valve. **See Fig. 1.**

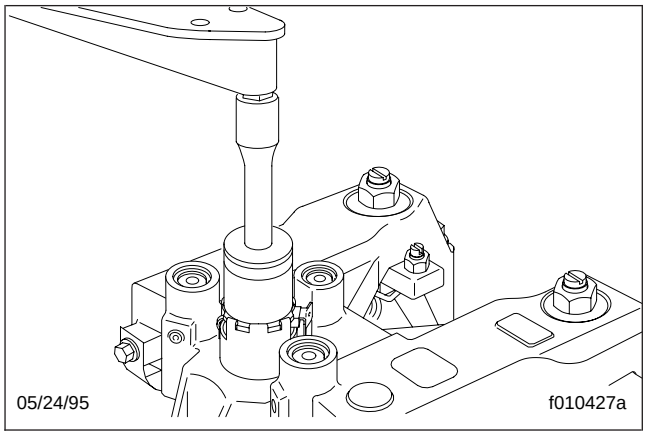

Fig. 1, Unscrew the Solenoid Valve

CAUTION

CAUTION: Do not disassemble or tamper with the solenoid valve. Engine damage could result.

4. Remove and discard the three rubber seal rings. **See Fig. 2.** If the lower ring stays in the bottom of the solenoid bore in the housing, remove it with a piece of wire.
5. Wash out the solenoid valve with a cleaning solvent. Use a brush to clean the oil screen.
6. Dry the valve with compressed air.
7. Using clean paper towels, clean out the solenoid valve bore in the housing. Do not use rags, since they can leave lint and residue, which can plug the oil passageways.

Installation

1. Coat a new set of solenoid seal rings with clean lubricating oil. Install the upper and middle seal rings on the solenoid body and the lower seal ring into the bottom of the solenoid bore in the housing. **See Fig. 3.**
2. Make sure the seals are seated properly and not twisted. Carefully screw the solenoid into the housing without unseating the seals.
3. Tighten the valve to the torque specification shown on top of the solenoid.
4. Connect the solenoid harness.
5. Install the rocker cover. For instructions, refer to **Subject 150**.

General Information

NOTE: For troubleshooting procedures, refer to **Section 01.12** in this manual.

Jacobs engine brake housings are installed on the engine rocker housings. Model 760A (used on Detroit Diesel Series 60 11.1 liter engines) and Model 765 (used on Detroit Diesel Series 60 12.7 liter engines) have three engine brake housings that operate two cylinders each. Each engine brake housing has a solenoid valve, control valves, ball check valves, master pistons, and slave pistons. See **Fig. 1**.

Engine brake controls consist of: dash switches and a clutch switch. The clutch switch is mounted under the dash. The engine brake is activated when the dash switches are on and the clutch and throttle pedals are released. The dash switches enable the driver to operate the engine brake partially or fully.

The engine brake can be operated at one-third, two-thirds, or full capacity (two, four, or six cylinders).

When activated, the engine brake converts a power-producing diesel engine to a power-absorbing air compressor. This is accomplished by motion transfer through a master-slave piston arrangement which opens the engine cylinder exhaust valves near the top of the normal compression stroke, releasing the compressed cylinder charge to exhaust. The blow-down of compressed air to atmospheric pressure prevents the return of energy to the engine piston on the expansion (power) stroke. This results in a net energy loss because the work done in compressing the cylinder charge is not returned during the expansion process. Exhaust blowdown occurs as follows (see **Fig. 2**):

1. Activating the engine brake energizes the solenoid valve, allowing engine oil to flow under pressure through the control valve to both the master piston and the slave piston.
2. Oil pressure causes the master piston to move down, coming to rest on the injector rocker arm roller.
3. The injector rocker arm begins upward travel (as in the normal injection cycle) forcing the master piston upward and creating a high-pressure oil flow to the slave piston. The ball check valve in the control valve holds the high-pressure oil in the master-slave piston system.
4. When the engine piston is near top dead center, the slave piston moves down under the influence of the high-pressure oil flow. This momentarily opens the exhaust valves, releasing compressed cylinder air to the exhaust manifold.
5. At the bottom of its stroke the slave piston separates from the valve in the slave piston reset adjusting screw, allowing high-pressure oil to flow into the accumulator. This reduces the pressure in the high-pressure circuit, permitting the slave piston to retract and the exhaust valves to close in preparation for the normal exhaust valve cycle. The oil pressure reserved in the accumulator ensures that the hydraulic circuit is fully charged for the next cycle.
6. Compressed air escapes to the atmosphere completing a compression braking cycle.

Accumulator Removal, Inspection, and Installation

Removal

⚠ WARNING

WARNING: The accumulator spring is under strong compression. Be careful when removing the retaining ring and cover. Wear safety glasses. If the spring is accidentally released, personal injury could result.

1. Remove the engine brake housing from the vehicle. For instructions, refer to **Subject 130**.
2. Push down on the accumulator cover and remove the retaining ring. **See Fig. 1**.

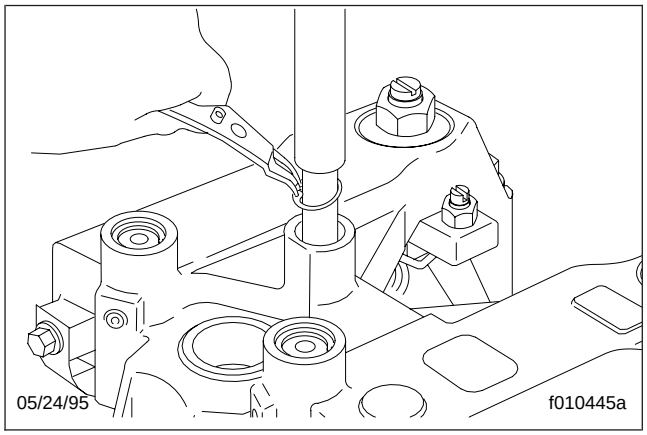

Fig. 1, Remove the Retaining Ring

3. Remove the cover and spring. **See Fig. 2**.

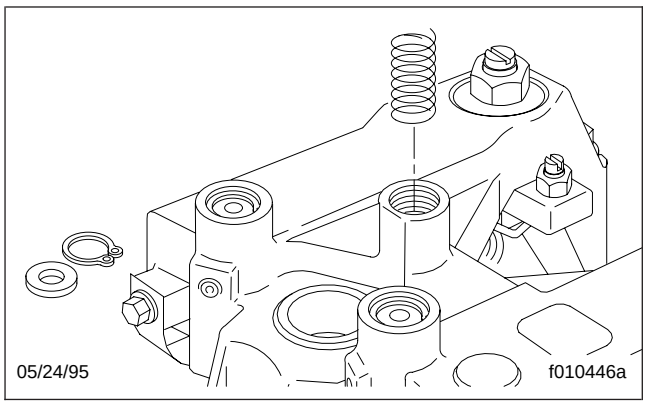

Fig. 2, Remove the Spring

4. Using a magnet, remove the piston from the accumulator bore. **See Fig. 3**.

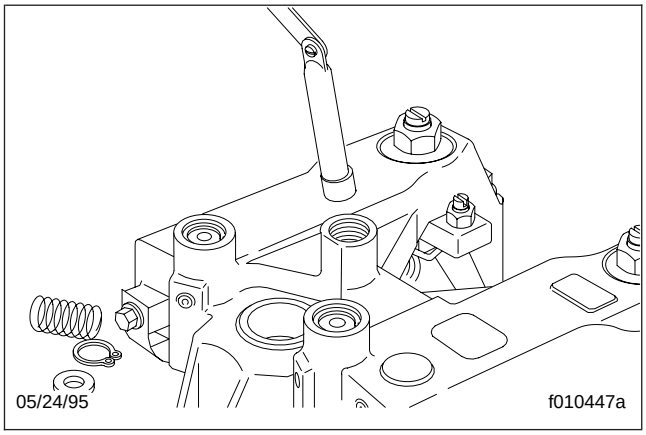

Fig. 3, Remove the Piston

Inspection

Inspect the parts for wear and damage. Replace parts as needed.

Installation

1. Install the piston, spring, cover, and retaining ring.
2. Install the engine brake housing. For instructions, refer to **Subject 130**.

Removal

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Tilt the hood.
4. Wipe the engine brake housing area clean, and remove the valve cover. For instructions, refer to the engine manufacturer's service literature.
5. Disconnect the solenoid harness.
6. Using a 7/8-inch socket and extension, unscrew the solenoid valve. **See Fig. 1.**

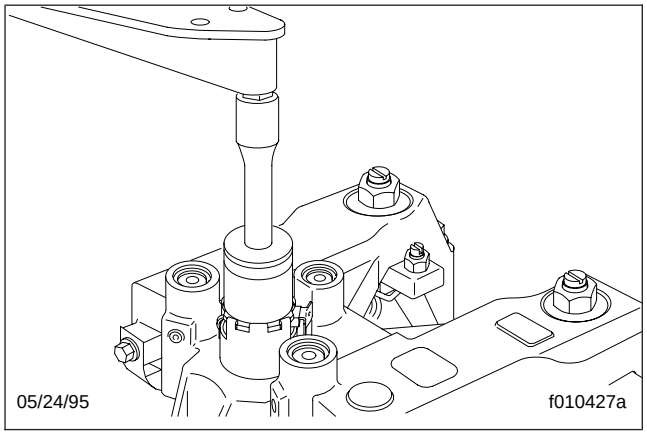

Fig. 1, Unscrew the Solenoid Valve

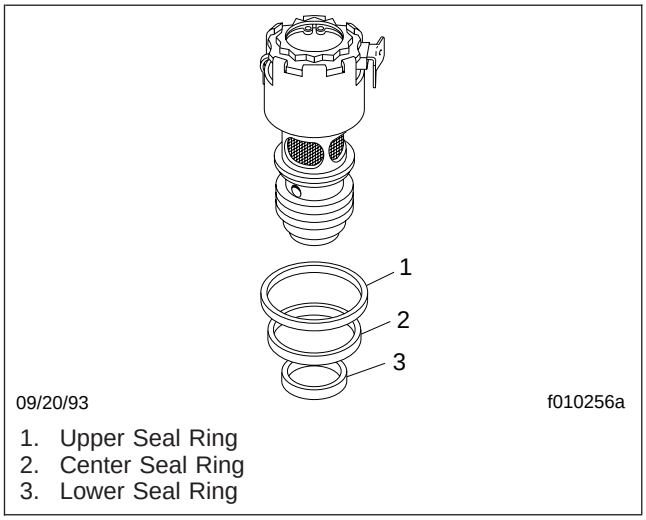
⚠ CAUTION

CAUTION: Do not disassemble or tamper with the solenoid valve. Engine damage could result.

7. Remove and discard the three rubber seal rings. **See Fig. 2.** If the lower ring stays in the bottom of the solenoid bore in the housing, remove it with a piece of wire.
8. Wash out the solenoid valve with a cleaning solvent that meets OSHA guidlines. Use a brush to clean the oil screen.
9. Dry the valve with compressed air.
10. Using clean paper towels, clean out the solenoid valve bore in the housing. Do not use rags, since they can leave lint and residue, which can plug the oil passageways.



1. Upper Seal Ring
2. Center Seal Ring
3. Lower Seal Ring

Fig. 2, Solenoid Seal Rings

Installation

1. Coat a new set of solenoid seal rings with clean lubricating oil. Install the upper and middle seal rings on the solenoid body and the lower seal ring into the bottom of the solenoid bore in the housing. **See Fig. 3.**

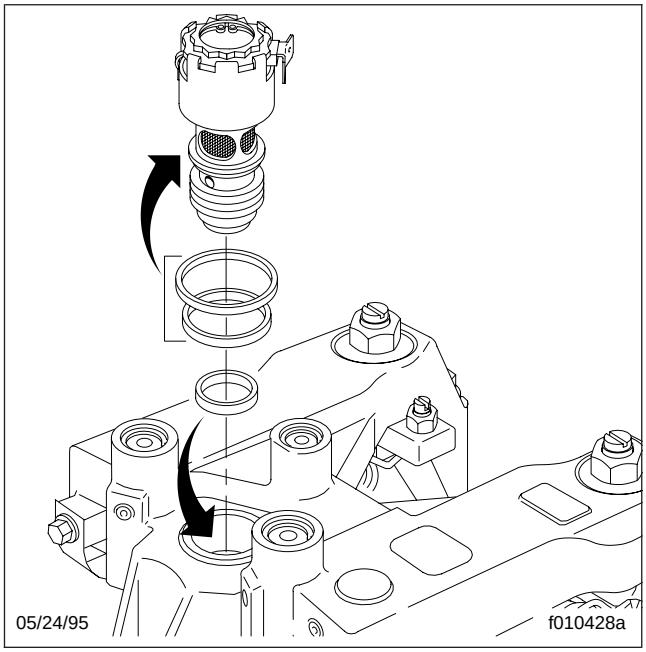


Fig. 3, Install the Seal Rings

Solenoid Valve Removal and Installation

2. Make sure the seals are seated properly and not twisted. Carefully screw the solenoid into the housing without unseating the seals.
3. Tighten the valve to the torque shown on the top of the solenoid.
4. Connect the solenoid harness.
5. Install the valve cover. For instructions, refer to the engine manufacturer's service literature.
6. Close the hood, connect the batteries, and remove the chocks from the tires.

Control Valve Removal, Inspection, and Installation

Removal

⚠ WARNING

WARNING: Never remove any engine brake component with the engine running. Hot oil spray may cause personal injury.

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Tilt the hood.
4. Wipe the engine brake housing area clean, and remove the valve cover. For instructions, refer to the engine manufacturer's service literature.
5. Press down on the control valve cover to relieve spring pressure. **See Fig. 1.**

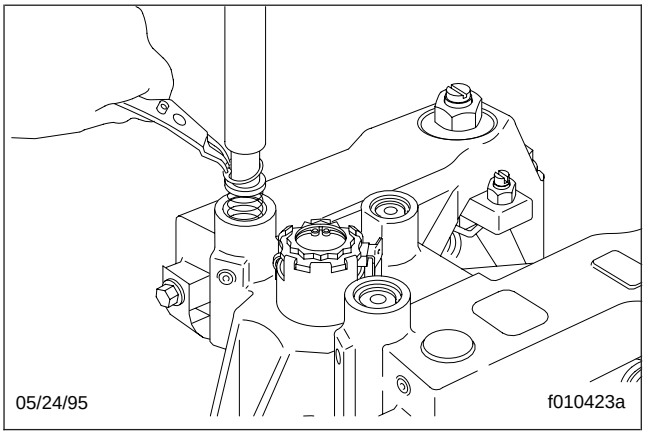

Fig. 1, Press the Control Valve Cover

6. Remove the retaining ring using retaining ring pliers.
7. Slowly remove the cover until the spring pressure is released; then, remove the two control valve springs and the collar. **See Fig. 2.**
8. Using needle nose pliers, reach into the housing bore and grasp the stem of the control valve. Remove the control valve. **See Fig. 3.**

Inspection

1. Wash the control valves with a cleaning solvent that meets OSHA guidelines.

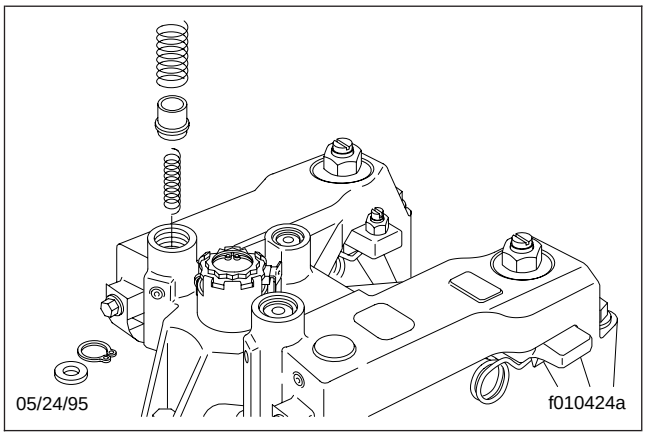

Fig. 2, Remove the Springs and the Collar

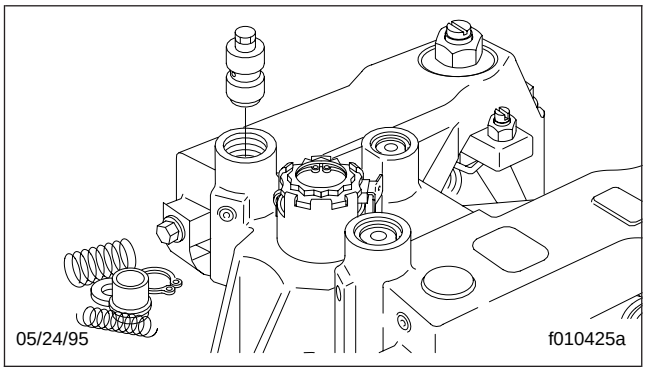

Fig. 3, Remove the Control Valve

2. Push a wire through the hole in the base of the valve to make sure the ball check is free. The ball should lift with light pressure on the wire.
3. Dry the valve with compressed air and wipe it clean with a paper towel.
4. Using clean paper towels, thoroughly clean the control valve bore in the housing.
5. Dip the control valves in clean lubricating oil. Holding the valve by the stem, let the valve drop into its bore. If it binds or if the ball is stuck in the valve, replace the control valve.

Installation

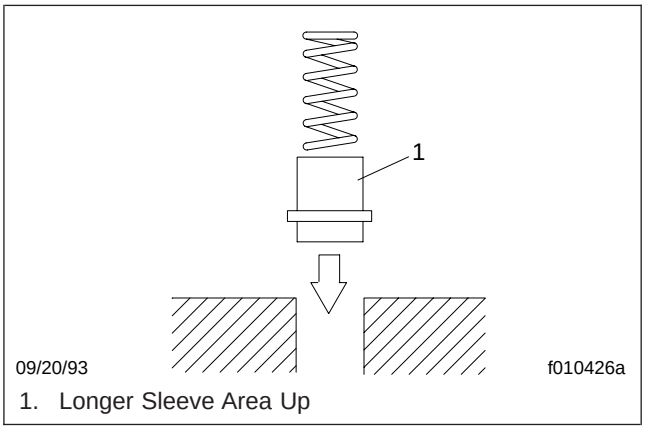
IMPORTANT: Be sure to coat all parts with clean lubricating oil before installing them.

1. Install the control valve reversing the removal procedure.

Control Valve Removal, Inspection, and Installation

NOTE: Make sure the control valve collar is installed with the longer sleeve area up. **See Fig. 4.** If the collar is installed upside down, the engine brake cylinder will not operate.

2. Make sure the retaining ring ears are rotated 90 degrees after installation.



1. Longer Sleeve Area Up

Fig. 4, Check the Valve Collar

3. Install the valve cover. For instructions, refer to the engine manufacturer's service literature.
4. Close the hood, connect the batteries, and remove the chocks from the tires.

Removal

NOTE: The engine brake has been designed to fit on the Series 60 engine with no additional valve cover spacers. On engines equipped with aluminum valve cover caps (**Fig. 1** and **Fig. 2**), it is not necessary to remove the valve cover bases to remove and install the engine brake housings.

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Disconnect the batteries.
4. Remove each valve cover and gasket.
5. Remove the engine brake housing hold-down capscrews. There is one capscrew per housing on the camshaft side of the engine. There are two capscrews per housing on the exhaust manifold side of the engine.
6. Remove the spacer bar between the exhaust side of each head and each engine brake housing mounting pad.
7. Lift each engine brake housing off the rocker shaft.

Installation

1. Place the spacer bars between the cylinder head and the engine brake mounting pads on the exhaust manifold side of the head. **See Fig. 3** and **Fig. 4.**

Engine Brake Housing Removal and Installation

2. Place each engine brake housing over the rocker shaft with the solenoid valves toward the camshaft side of the engine. Make sure the housings don't interfere with the wiring harness.
3. Apply "Never Seize" to the threads and underside of the head of the housing hold-down capscrews.
4. Install a 4-3/8 inch (110 mm) long capscrew and its washer into each engine brake housing. **See Fig. 5** and **Fig. 6**. There are three capscrews per housing.

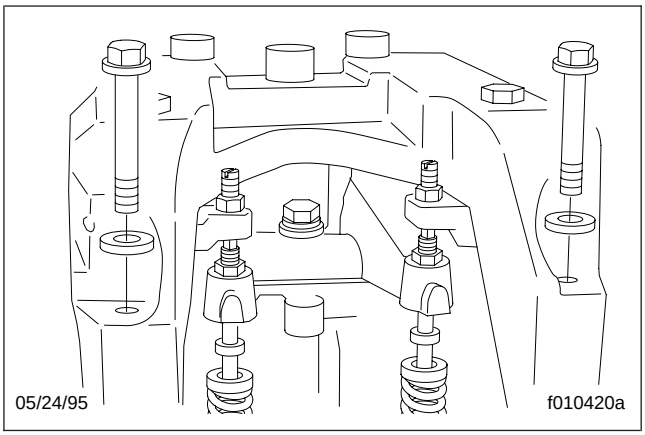

Fig. 5, Capscrews on the Exhaust Manifold Side

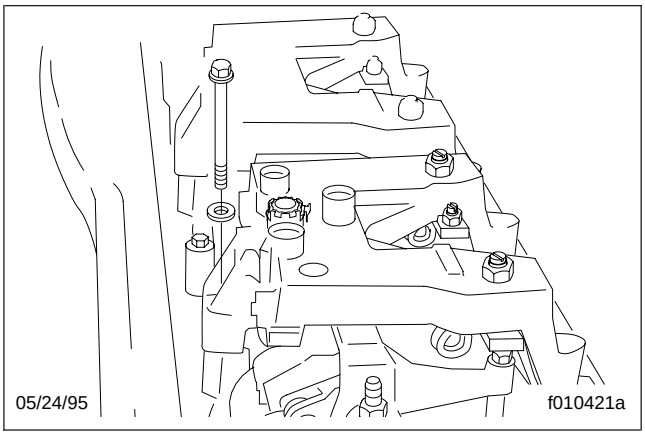

Fig. 6, Capscrew on the Camshaft Side

5. Before tightening the engine brake hold-down capscrew, move the housing from side to side, and then locate the housing in the center of the range. **See Fig. 7.**

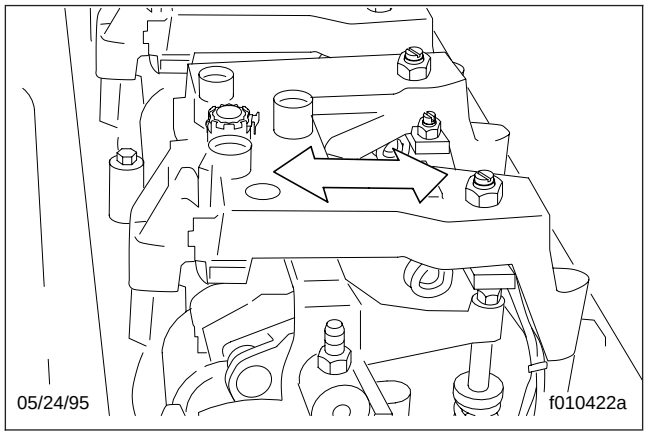

Fig. 7, Center the Housing

6. Tighten the engine brake housing hold-down capscrews.
   - 6.1 Tighten the three capscrews on the camshaft side of the engine 40 lbf·ft (55 N·m).
   - 6.2 Tighten the six capscrews on the exhaust manifold side of the engine 40 lbf·ft (55 N·m).
   - 6.3 In the same sequence, tighten all capscrews 100 lbf·ft (135 N·m).
7. Using plastic ties, secure the wiring harnesses to the spacer bars.
8. Adjust the slave piston lash. For instructions, refer to **Subject 150**.
9. Install the valve covers. For instructions, refer to the engine manufacturer's service manual.
10. Close the hood, connect the batteries, and remove the chocks from the tires.

Master Piston Removal, Inspection, and Installation

Removal

1. Remove the engine brake housing from the vehicle. For instructions, refer to **Subject 130.**
2. Remove the screw, washer, and master piston spring from the housing. **See Fig. 1**.

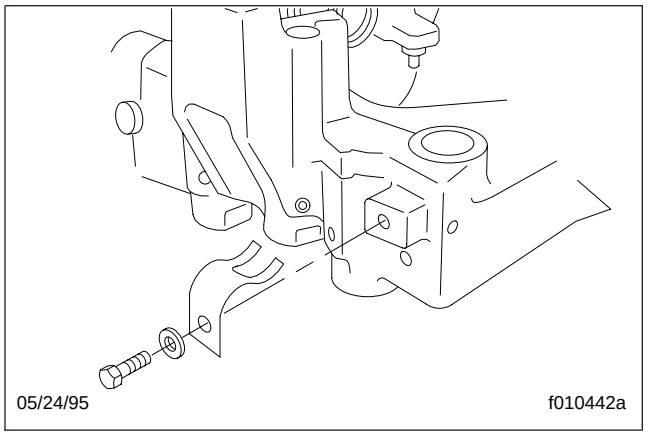

Fig. 1, Remove the Master Piston Spring

3. Using needle nose pliers if necessary, pull out the master piston. **See Fig. 2**.

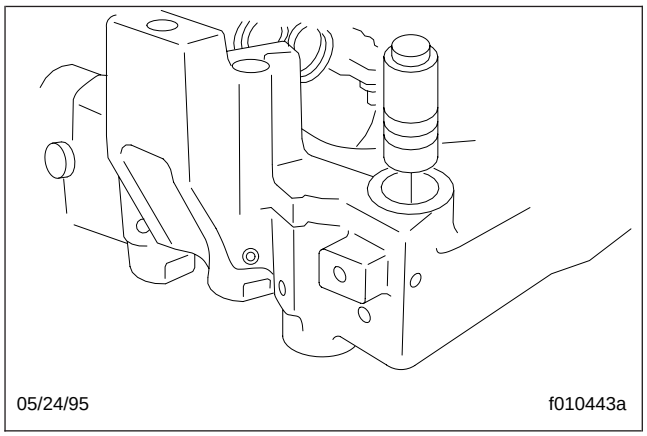

Fig. 2, Remove the Master Piston

Inspection

1. Clean the piston in a cleaning solvent.
2. Inspect the piston for excessive wear and for damage. Replace the piston if necessary.

Installation

1. Install the master piston, spring, washer, and screw in the housing. **See Fig. 3**.

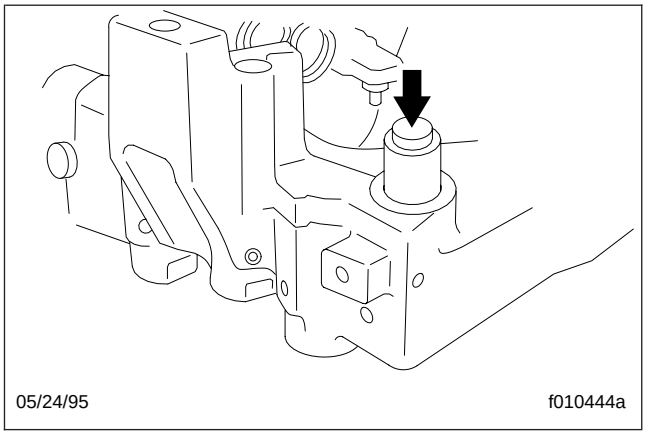

Fig. 3, Install the Master Piston

NOTE: Make sure the spring legs are centered around the master piston boss.

2. Tighten the screw 100 lbf·in (1120 N·cm).
3. Install the engine brake housing on the vehicle. For instructions, refer to **Subject 130**.
4. Reset the engine brake lash. For instructions, refer to **Subject 160**.

Slave Piston Adjusting Screw (Power-Lash®) Removal, Inspection, and Installation

Removal

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Tilt the hood.
4. Wipe the engine brake housing area clean, and remove the valve cover. For instructions, refer to the engine manufacturer's service literature.
5. Loosen the slave piston adjusting screw locknut and remove the adjusting screw from the housing. **See Fig. 1.**

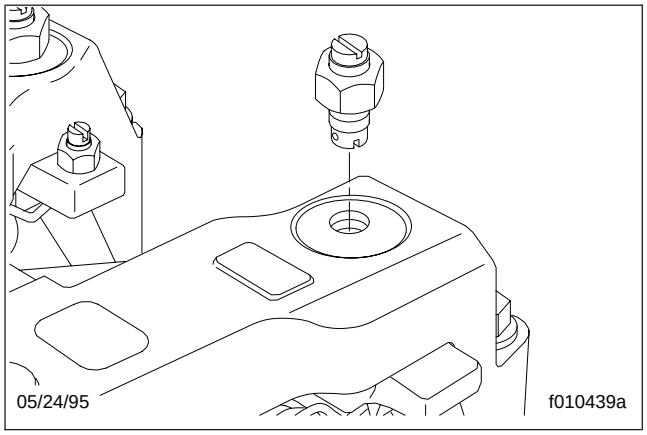

Fig. 1, Remove the Adjusting Screw

Inspection

1. Clean the adjusting screw in cleaning solvent.
2. Inspect the slave piston adjusting screw. The plunger should protrude from the bottom of the screw. There should be light spring pressure when the plunger is depressed, and the plunger should move freely. **See Fig. 2.** Be sure the retaining ring is fully engaged in its groove. If any defect is found, replace the entire screw assembly.

⚠ CAUTION

CAUTION: Do not disassemble or tamper with the slave piston adjusting screw assembly. Engine damage could result.

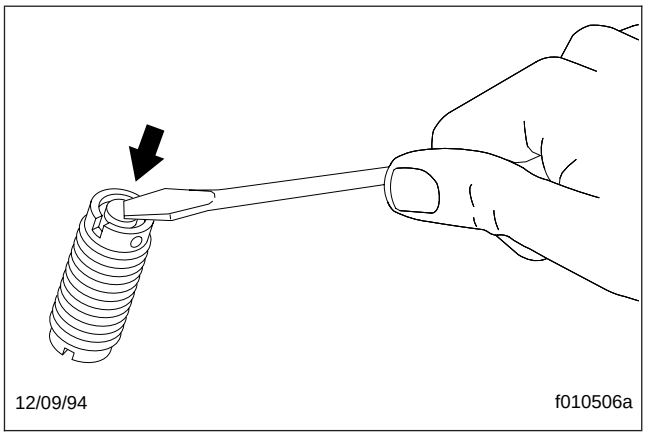

Fig. 2, Check the Plunger

Installation

1. Screw the slave piston adjusting screw into the housing.
2. Reset the engine brake lash. For instructions, refer to **Subject 160**.

Slave Piston Removal, Inspection, Installation, and Adjusting

Removal

1. Remove the engine brake housing from the vehicle using the instructions in **Subject 130**.
2. Remove the screw and spring that retain the slave piston assembly. **See Fig. 1.**

3. Remove the bridge and the slave piston. **See Fig. 2.**

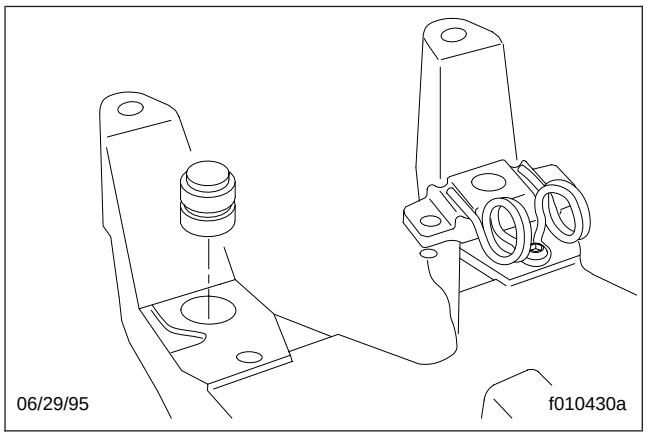

Fig. 2, Remove the Slave Piston

4. Loosen the leveling screw locknut and remove the leveling screw from the bridge. **See Fig. 3.**

Inspection

1. Inspect all components for excessive wear and for damage.
2. Replace parts as needed.

Installation

1. Install the leveling screw in the bridge. **See Fig. 3.** Tighten the locknut 25 lbf·ft (35 N·m).

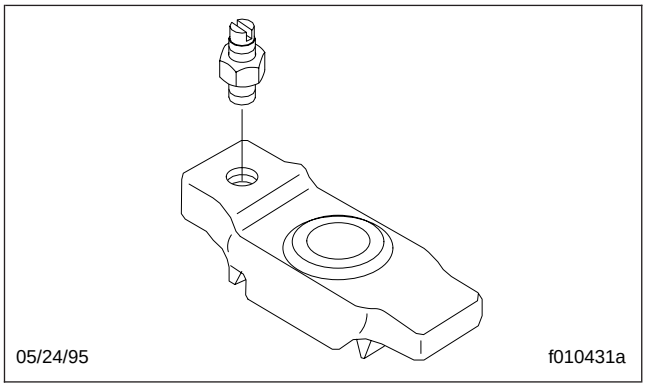

Fig. 3, Remove the Leveling Screw

2. Install the slave piston and the bridge with the leveling screw toward the center of the housing. **See Fig. 4.**

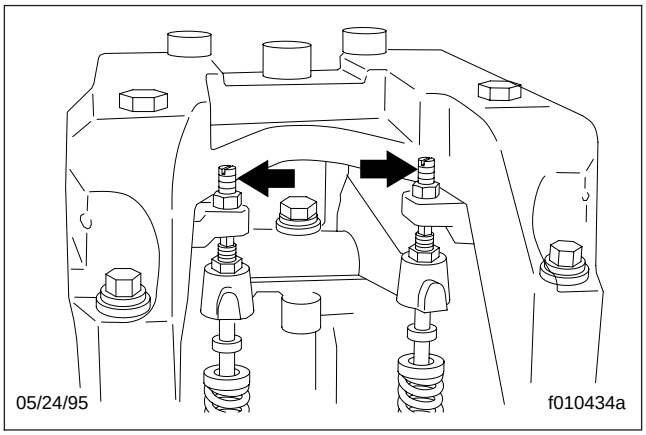

Fig. 6, Back Out the Leveling Screw

Adjusting

CAUTION

CAUTION: Follow the slave piston adjustment procedure exactly. Failure to use the correct adjustment procedure will result in poor engine brake performance and serious engine damage.

NOTE: Make the following adjustment with the engine stopped and the oil temperature 140°F (60°C) or lower. Rotate the engine until the exhaust valves on the cylinder to be adjusted are closed (rocker arm is loose).

1. Back out the *leveling screw* in the slave piston assembly until the end of the screw is beneath the surface of the bridge in the slave piston assembly. **See Fig. 6.**

NOTE: The leveling screw is the screw located in the bridge member of the slave piston assembly.

2. Place the correct feeler gauge between the solid side of the *bridge* (the side without the leveling screw) and the exhaust rocker arm adjusting screw. **See Fig. 7. See Table 1** for the correct feeler gauge.

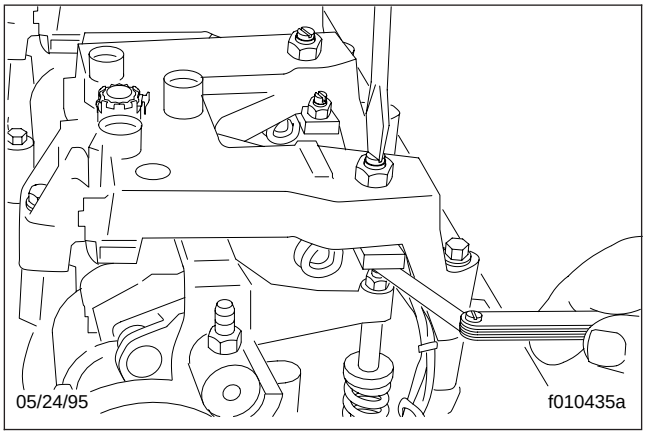

Fig. 7, Check With the Feeler Gauge

Engine Model (Displacement)	Feeler Gauge inches (mm)

IMPORTANT: The slave piston adjusting screws used in the Model 760 Engine Brake are Reset® screws. Do not disassemble these Reset screws in the field.

5. Following the same procedure, set 0.020-inch (0.5-mm) clearance between the slave piston leveling screw and the rocker arm adjusting screw. **See Fig. 10.**
6. While holding the leveling screw in this position, tighten the locknut 35 lbf·ft (47 N·m).
7. Repeat the steps above for slave pistons of the remaining cylinders. Rotate the engine to close the exhaust valves for the cylinder being adjusted.

Troubleshooting Charts

Problem—Engine Will Not Start

Possible Cause	Remedy
The solenoid valve is stuck in the "on" position.	Make sure the electrical current to the engine brake is off. If the solenoid valve stays "on" (cap down) with the current off, replace the solenoid valve.

Problem—Engine Brake Will Not Function

Possible Cause	Remedy
An electrical lead is open.	Replace any broken wires.
The clutch switch is malfunctioning.	**⚠ WARNING** **WARNING: Do not touch the electrical connections when the engine brake system is energized. Touching the connections could possibly cause electrical shock.** Use a volt/ohmmeter to make sure there is electrical current at both terminals of the switch. If voltage will not pass through the switch, replace it.
The engine oil pressure is too low.	Determine the oil pressure at the engine brakes. Refer to the **applicable section** for your engine brake. If the oil pressure is below specifications, repair the engine following the manufacturer's procedures.
The throttle switch is malfunctioning.	Check for correct operation of the throttle.

Problem—Engine Brake Engages With the Switches Off

Possible Cause	Remedy
The solenoid valve center seal ring is damaged.	Remove the solenoid. Replace all the seal rings.
The engine brake is incorrectly wired.	Check the wiring against the Jacobs wiring diagram.

Problem—Engine Brake Weak or Slow to Engage

Possible Cause	Remedy
The lubricating oil is too cold and thick.	Allow the engine to warm up before operating the Jake Brake.
The slave piston is adjusted incorrectly or is binding in its bore.	**⚠ WARNING** **WARNING: Slave piston springs are under heavy compression. Remove the slave piston carefully when disassembly is necessary. Use either an arbor press or C-clamp. Failure to follow this procedure could result in personal injury.** Adjust the slave piston.Make sure it responds smoothly to the adjusting screw— loosen the jam nut and screw the adjusting screw through its full range for full slave piston travel. Make sure the piston travels the full range without binding or sticking.

Troubleshooting

Possible Cause	Remedy
The solenoid lower seal is damaged, allowing oil to escape the housing.	Remove the solenoid valve and replace all the seal rings.
The solenoid screen is clogged, stopping the supply of oil to the engine brake.	Remov the solenoid valve; clean or replace the screen.
The master piston is not moving in its bore.	Inspect the master piston and bore for scoring or burrs. If any are present, clean the surface with a crocus cloth. If the burrs cannot be removed, replace the piston or housing. Inspect the lubricating oil for signs of contaminants. If any are present, replace the oil and filters, and correct the cause of the contamination.
The control valves are binding in the housing bores.	Remove each control valve. If the body is scored, replace the valve. Check for contaminants in the lubricating oil. Clean the housing and control valve. If it still binds, replace the housing.
The control valves are malfunctioning.	Remove each control valve. Make sure the check ball is seating in the bore and that it can be moved off the seat. Make sure there is spring pressure against the ball. Flush the valve in diesel fuel. Replace the control valve if needed.
Dash switches, clutch switch, or throttle switch has sluggish operation.	Adjust or replace the switch. Check the throttle or clutch return springs for proper operation.
The electrical insulation of the solenoid valve is breaking down.	**⚠ WARNING** **WARNING: Do not touch the electrical connections when the engine brake system is energized. Touching the connections could possibly cause electrical shock.** Make sure the solenoid valve meets electrical specifications. If not, replace the solenoid valve.
The engine brake housing plugs are leaking.	Check the plugs for signs of leaks. If leaks are found, remove the plugs, clean the threads, and install the plugs. Thread locking compound may help. Tighten the plugs 115 lbf·in (1300 N·cm).
The outer control valve spring is broken, or the engine oil pressure is extremely high.	Replace the outer control valve spring. Refer to the engine manufacturer's service manual for causes of high oil pressure.
The upper solenoid seal ring is damaged, causing oil pressure to drop below the minimum required for engine brake operation.	Remove the solenoid. Inspect the seal rings and replace them if needed.
The oil supply seals under or between the housings are damaged, causing oil pressure to drop below the minimum required for engine brake operation.	Remove the housings and replace the seals. Check for cracked or broken oil connectors. Replace the seals.
There is air in the lubricating oil, causing oil pressure to drop below the minimum required for engine brake operation.	Check for aeration of the oil. Turn the engine brake on, then off. Watch the escape oil coming from under the control valve cover. If the oil has bubbles or is foamy, air is present in the system. Aeration can be caused by an over-or underfilled crankcase, by cracks in the oil pickup tube, or by leaks in the oil suction tube or hose. Refer to the engine manufacturer's service manual for corrective measures.
The lubricating oil is being diluted by diesel fuel, causing oil pressure to drop below the minimum required for engine brake operation.	Have the lubricating oil analyzed to determine if fuel is present. Refer to the engine manufacturer's service manual for corrective measures.

Possible Cause	Remedy
The engine oil is low, causing oil pressure to drop below the minimum required for engine brake operation.	Refer to the engine manufacturer's service manual for specifications. Add oil or recalibrate the dipstick as required.
The engine rocker arm bushings are worn, causing oil pressure to drop below the minimum required for engine brake operation.	Replace the bushings. Refer to the engine manufacturer's service manual for instructions.
Oil is leaking around the cylinder heads, causing oil pressure to drop below the minimum required for engine brake operation.	Repair the cause of the leaks. Refer to the engine manufacturer's service manual for instructions.
Restrictions in the oil passage leading to the engine brake are causing oil pressure to drop below the minimum required for engine brake operation.	Inspect all the passageways; remove anything restricting the oil flow.

Problem—Engine Stalls or One or More Cylinders Continue Braking With the Dash Switches Off

Possible Cause	Remedy
The control valve inner spring is broken.	Replace the inner spring.
One or more control valves are stuck in the "on" (up) position.	Check the control valves for binding. Remove and clean or replace them if necessary. Inspect the lubrication oil for contaminants.
The solenoid valve is sticking in the "on" position.	If the solenoid valve cap remains down with no electric current being supplied, replace the solenoid valve.
The center solenoid seal ring is damaged, allowing oil to enter the engine brake with the solenoid valve closed.	Remove the solenoid and replace all the seal rings.
The solenoid valve exhaust is plugged.	Remove any restrictions at the exhaust (bottom) of the solenoid valve.
The dash switch is stuck in the "on" position.	Check for correct switch operation. Replace the switch as needed.

Problem—Engine Misses or Loses Power

Possible Cause	Remedy
The slave piston is adjusted too tight.	Adjust the slave piston. Refer to the **applicable section** for the engine brake model.

Problem— Sudden Drop in Engine Lubrication Oil Pressure

Possible Cause	Remedy
The oil inlet supply seal is missing or damaged.	Replace the seal.
The upper solenoid valve seal is missing or damaged.	Remove the solenoid and replace all the seal rings.
The external oil supply hoses or fittings are cracked and leaking.	Inspect all hoses and fittings for tightness, chafing, or cuts.

MBE4000 Engine Removal and Installation

Removal

1. Apply the parking brakes, chock the tires, and drain the air system.
2. Disconnect the battery cables at the batteries.
3. On each side of the vehicle, remove the components in the wheel well (bumper, air dam, splash shield, support arm, etc.). See **Section 31.03** for bumper and air dam removal instructions. See **Fig. 1** for splash shield removal.
   - 3.1 Remove both side fenders.
   - 3.2 Remove the splash shields.
   - 3.3 Remove the bumper and air dam assembly.
   - 3.4 Remove the bumper support arm, and outboard bumper support bracket.
4. Remove the grille. For detailed instructions, see **Section 88.00**, Subject 110.
5. Remove the hood. For detailed instructions, see **Section 88.00**, Subject 100.

Table 1, Torque Values, Engine Removal and Installation

Principles of Operation

The Environmental Protection Agency (EPA) mandated that all engines built after December 31, 2006 meet lower exhaust emissions levels:

- 1.1 grams per brake horsepower hour (g/bhp-hr) of nitrogen oxides (NOx)
- 0.01 g/bhp-hr of particulate matter (PM)

To meet the EPA07 requirements, most engine manufacturers developed an aftertreatment system (ATS). The ATS varies according to engine and vehicle configuration, but instead of a muffler, an ATS has an aftertreatment device (ATD) that outwardly resembles a muffler.

Inside the ATD on Cummins, Detroit Diesel, and Mercedes-Benz engines, the exhaust first passes over the diesel oxidation catalyst (DOC), which uses a chemical process to break down pollutants into less harmful components. The exhaust then passes through the diesel particulate filter (DPF), which traps soot particles. See **Fig. 1**.

Caterpillar ATDs have a DPF, but do not have a DOC. Instead, CAT engines burn diesel fuel at the regeneration head to superheat the exhaust and reduce it to less harmful components. CAT engines also utilize Clean Gas Induction (CGI), a process in which some of the exhaust gas downstream of the DPF is recirculated into the air intake system. See **Fig. 2**.

The DPF core in all ATDs is comprised of ceramic channels that are blocked off at alternate ends to force the exhaust through the porous walls.

As soot accumulates in the DPF, it periodically needs to be converted to its basic parts: carbon dioxide, water, and ash. The conversion takes place through an event in the ATD referred to as regeneration (regen). If the exhaust temperature is high enough, the trapped soot is reduced to ash in a process called passive regen, which occurs as the vehicle is driven normally.

Passive regen, however, cannot always keep the DPF clean, so the ATD must also periodically undergo active regen. During active regen, extra fuel is injected into the exhaust stream to superheat and reduce the soot trapped in the DPF to ash. Active regen happens only when the vehicle is moving above a certain speed, as determined by the engine manufacturer.

Both active and passive regen happen automatically, without driver input. When operating conditions do not allow for active or passive regen, the vehicle may require a driver-activated parked regen, which takes 20 to 60 minutes, depending on ambient conditions.

Over time, ash collects in the ATS and needs to be removed through cleaning at specific intervals. For ATS maintenance and repair information, see the engine manufacturer's service literature.

Service Literature Coverage

Engine service procedures in this manual are limited to components installed by Daimler Trucks North America. See the following sections for information on EPA07-compliant parts and systems installed by Daimler Trucks North America:

- **Section 01.03**, Engine Mounts
- **Section 09.02**, Charge Air Cooler
- **Section 20.01**, Radiator Assembly
- **Section 30.00**, Electronic Throttle Control
- **Section 49.01**, Aftertreatment System, EPA07
- **Section 88.00**, Hood

Complete engine coverage including engine adjustment, preventive maintenance, and engine repair are covered in each engine manufacturer's service literature:

- Caterpillar: www.cat.com
- Cummins: www.cummins.com
- Detroit Diesel: www.detroitdiesel.com
- Mercedes-Benz: www.detroitdiesel.com

Periodic inspection of the ATS is required. For instructions, see the *Century Class Trucks Maintenance Manual*.

For driver pre- and post-trip inspection information, see the *Century Class ST and Coronado Driver's Manual*.

Aftertreatment Device (ATD) A device that removes pollutants from exhaust gas after the gas leaves the combustion chamber.

Aftertreatment System (ATS) The entire exhaust system from the turbocharger to the exhaust stack or tail pipe.

Clean Gas Induction (CGI) A process whereby small amounts of exhaust gas are drawn downstream of the DPF and recirculated into the air intake system. CGI is used in CAT engines only.

Diesel Oxidation Catalyst (DOC) A flow-through device that enhances the oxidation of hydrocarbons in the ATD on Cummins, Detroit Diesel, and Mercedes-Benz engines.

Diesel Particulate Filter (DPF) A component inthe ATD that captures particulate matter from the exhaust gas, preventing discharge from the tailpipe.

Exhaust Gas Recirculation (EGR) A process whereby exhaust is recirculated into the air intake system, creating lower cylinder temperatures. EGR is

Nitrogen Oxides (NOx) Air pollutants composed of nitrogen and oxygen in various forms that contribute to the formation of smog.

Particulate Matter (PM) Soot particles formed by incomplete combustion of fuel that contribute to atmospheric pollution.

Regeneration (Regen) A process that occurs inside the ATD whereby accumulated soot is superheated and burned to ash, carbon dioxide, and water.

General Information

An average diesel truck engine needs over 10,000 gallons (38 000 liters) of clean air for each gallon (3.8 liters) of fuel burned. So that complete combustion occurs in each engine cylinder, more clean air than is needed is present in each cylinder. The air intake system routes this supply of outside air through an air cleaner, which filters out dust, dirt, abrasive particles, and other foreign material from the intake air, without restricting air flow.

From there, the air intake ducting routes this clean air to the engine. On Century Class Conventionals, the air intake ducting is made up of a one-piece rubber hose and stainless steel hose clamps. See **Fig. 1**. On Argosy COEs, there are four pieces of ducting between the air cleaner assembly and the turbocharger. See **Fig. 2**.

A lock-up (manual-reset) air restriction indicator mounts in a safety filter in the air intake ducting. See **Fig. 3**. As an option, the air restriction indicator or an air restriction (automatic-reset) gauge mounts in the dashboard. Nylon tubing connects the remote-mounted indicator or gauge to the safety filter in the ducting.

The air restriction indicator or gauge indicates when the air cleaner filter element needs to be replaced. The safety filter protects the clean-side of the air intake system in case the air restriction indicator or nylon tubing leaks or is damaged.

Air Intake Ducting Removal and Installation

Removal and Installation

WARNING

Do not operate the engine with any component of the air intake system removed. Doing so could result in engine damage, and serious personal injury can occur if the turbocharger impeller is touched when it is rotating.

CAUTION

Do not operate the vehicle with the air filter element or any air intake component removed. All air intake components and connections must be air- and water-tight. Dirt or dust entering the engine can cause internal engine damage. Most of the dirt and dust particles are silicates, which fuse into abrasive glass-like particles when exposed to engine combustion. These particles can grind piston rings, pistons, and cylinder liners.

1. Turn off the engine, apply the brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. On Century Class Conventionals, loosen the hose clamps on the air intake ducting at the air cleaner outlet and the turbocharger inlet. See **Fig. 1**, **Fig. 2**, **Fig. 3**, **Fig. 4**, **Fig. 5**, **Fig. 6** and **Fig. 7**. On Argosy COEs, loosen the hose clamps on the air intake ducting between the air cleaner outlet and the turbocharger inlet. See **Fig. 8**.
4. Remove the air intake ducting.
5. Replace any damaged parts with new identical parts.

IMPORTANT: Air intake ducting that has been enlarged, extended, or modified by bonding after original molding, are not acceptable for installation between the air cleaner and the engine.

6. Install the air intake ducting. Place the ducting over each connection so that it overlaps at least 1 inch (25 mm).
7. Tighten the hose clamp at the turbocharger 70 to 80 lbf·in (800 to 900 N·cm). Tighten the hose clamp at the air cleaner outlet 35 to 40 lbf·in (400 to 450 N·cm).

Air Cleaner Restriction Inspection

Restriction of air flow through the air cleaner element is measured at the tap in the air cleaner outlet. Check the restriction indicator at the air cleaner or in the cab if the vehicle is equipped with a dash-mounted restriction gauge.

NOTICE

Use the air intake restriction gauge rather than visual inspection to determine if servicing the air filter element is necessary. Removal of the air filter element can cause damage to the primary seal, which may allow contaminants into the engine, potentially causing engine damage.

Vehicles may be equipped with either a manual-reset restriction indicator with graduations (**Fig. 1**), or a go/no-go restriction indicator without graduations (**Fig. 2**).

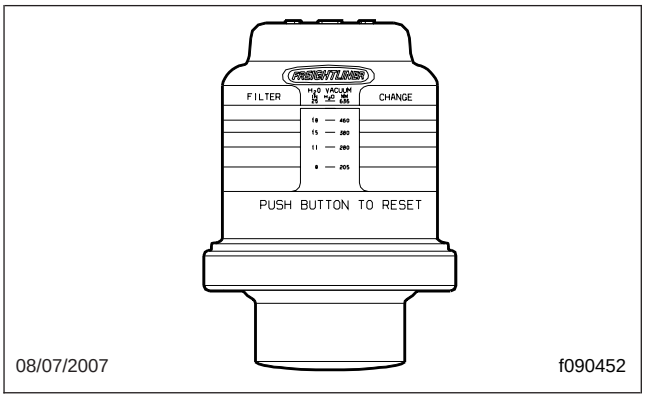

Fig. 1, Manual-Reset Air Restriction Indicator, Graduated

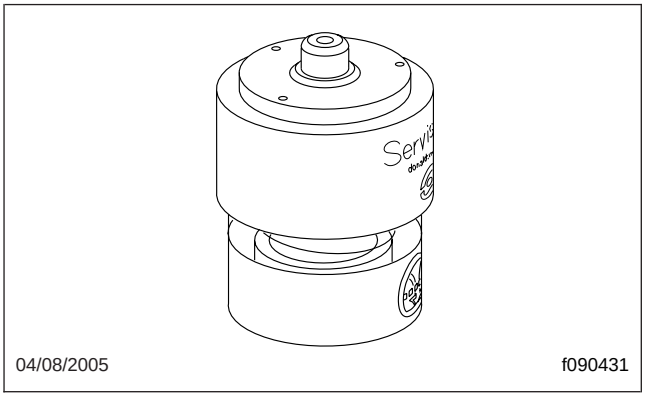

Fig. 2, Manual-Reset Air Restriction Indicator, Go/No-Go

1. For vehicles equipped with a manual-reset indicator with graduations, check the indicator with the engine off to see if air restriction equals or exceeds the value shown in **Table 1** for maximum air restriction.

   For vehicles equipped with a go/no-go restriction indicator without graduations, check the indicator with the engine off to see if the colored bar shows through the clear window.

Air Cleaner Element Maximum Restriction		
Engine	**Pre-EPA07 Engines**	**EPA07 Engines**
Caterpillar	25 inH_2O	25 inH_2O
Cummins	25 inH_2O	25 inH_2O
Detroit Diesel	20 inH_2O	22 inH_2O
Mercedes-Benz	22 inH_2O	22 inH_2O

Table 1, Air Cleaner Element Maximum Restriction at Full-Load and Rated rpm

2. If air restriction is below the maximum, no further work is necessary.

   If air restriction is at or above the maximum, push the reset button on the indicator.

3. Operate the engine to see if air restriction exceeds recommended values again. This can be done by running the vehicle on a dynamometer at **full-load and rated rpm**, or by driving the vehicle for one day in the vehicle's typical operating environment while not exceeding the rated rpm (typically 1800 rpm).

4. Check the indicator again. If air restriction continues to equal or exceed the maximum air restriction value in **Table 1** on an indicator with graduations, or if the colored bar shows through the clear window on a go/no-go indicator, replace the air cleaner element, then reset the indicator.

   For air cleaner element replacement instructions, see **Subject 110** for instructions.

Donaldson Air Cleaner Element Replacement

Element Replacement

NOTICE

All air intake components and connections must be air- and water-tight. Dirt or dust entering the engine can cause internal engine damage. Most of the dirt and dust particles are silicates, which fuse into abrasive glass-like particles when exposed to engine combustion. These particles can grind piston rings, pistons, and cylinder liners. Do not operate the engine with the air filter element or any air intake component removed.

IMPORTANT: Do not modify, or use modified air cleaners and ducting components.

If the air cleaner housing has been damaged, immediately check all ducting and connections to the air cleaner for leakage. Adjust or replace parts as necessary. If needed, replace the air cleaner assembly using the instructions in **Subject 120** or **Subject 130**.

NOTICE

Do not clean or reuse air filter elements. Cleaning and reusing the elements increases the chances of dirt entering the engine. Always replace with a new one.

1. Turn off the engine, apply the brakes, and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Remove the four capnuts or open the clips that attach the air cleaner cover to the air cleaner assembly. See **Fig. 1** and **Fig. 2**.

NOTICE

Never use impact or shock (pounding with a hammer) to release the air cleaner cover. This may distort the cover and allow the entry of dirt and contaminants into the sealed system, causing engine damage.

4. Due to high gasket-loading pressures, removing the air cleaner cover may be difficult. After removing the capnuts, gently pry around the outside of the cover to remove it from the air cleaner housing.

5. Remove the air cleaner filter element. Removal may be difficult because the inboard element-

gasket can stick to the cleaner housing. Push up and down on the outboard end of the element to release the gasket.

NOTICE

Do not leave any dirt on the inside of the air cleaner. If dirt gets inside the filter element, it may get into the engine and cause damage.

6. Check the housing and sealing surfaces for damage or dirt buildup that may cause sealing problems. Remove any dirt buildup.
7. Wipe the inside of the air cleaner housing with a clean damp cloth.
8. Inspect a new filter element for damaged gaskets and dented metal parts. If the gaskets are not smooth and flat or are damaged to the extent that dust might bypass them, discard the element.

   Place a bright light inside the new element and turn the element while looking through it from the outside. The light will reveal any hole or rupture. Holes in the element will allow dust to enter the engine. Discard the element if it is damaged.
9. Install the new filter element.

NOTICE

Do not force the air cleaner cover on the air cleaner assembly. Forcing the cover on the air cleaner assembly may indicate that the filter element is not seated correctly in the air cleaner assembly. If the cover is forced on the air cleaner assembly, dirt may get into the engine and cause damage.

10. Install the air cleaner cover. Secure the cover to the air cleaner assembly using capnuts or clips. Tighten the capnuts 95 lbf·in (1080 N·cm) evenly in a cross pattern to prevent distortion of the cover.
11. Check all connections for tightness.
12. Return the hood or cab to the operating position. For cab tilt instructions, see **Group 60**.
13. Remove the chocks from the tires.

Most of the dirt and dust particles are silicates, which fuse into abrasive glass-like particles when exposed to engine combustion. These particles can grind piston rings, pistons, and cylinder liners. Do not operate the engine with the air filter element or any air intake component removed.

IMPORTANT: Do not modify, or use modified air cleaners and ducting components.

If the air cleaner housing has been damaged, immediately check all ducting and connections to the air cleaner for leakage. Adjust or replace parts as necessary. If needed, replace the air cleaner assembly as follows:

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Examine the hood-to-cleaner-housing seal. If the seal is in serviceable condition, remove the hose clamp and seal for installation on the new air-cleaner housing. See **Fig. 1**.
3. Loosen the hose clamp that attaches the flexible duct to the air cleaner outlet port. Pull the flexible duct off the outlet port.
4. Using a socket and a long extension, remove the two sets of locknuts, washers, and spacers from the air cleaner mounting studs extending from the lower mounting bracket, above the turbocharger heat shield.
5. Remove the two sets of locknuts and washers from the air cleaner mounting studs at the upper mounting bracket.
6. Work the air cleaner housing off the four mounting studs.
7. Install the new air cleaner housing on the mounting studs.
8. Install the two sets of locknuts and washers on the air cleaner mounting studs at the upper mounting bracket.

Install the two sets of locknuts and washers on the air cleaner mounting studs at the lower mounting bracket. If a socket and long extension are used, removal of the turbocharger heat shield is not necessary.

Tighten all four locknuts 26 lbf·ft (35 N·m).

9. Remove the cover from the flexible duct. Attach the duct to the air cleaner outlet port. The hose must be installed all the way onto the port.

   Secure the connection with the hose clamp. Tighten the hose clamp 35 to 40 lbf·in (400 to 450 N·cm).

NOTICE

Do not clean or reuse air filter elements. Cleaning and reusing the elements increases the chances of dirt entering the engine. Always replace with a new one.

10. Inspect a new filter element for damaged gaskets and dented metal parts. If the gaskets are not smooth and flat or are damaged to the extent that dust might bypass them, discard the element.

Air Cleaner Piping Removal and Installation, MBE4000 Engine

NOTE: These procedures apply to vehicles with MBE4000 engines.

Removal

1. Apply the parking brakes, shut down the engine, and chock all the tires. Raise the hood.
2. Disconnect the batteries.
3. Disconnect the pipe fitting attaching the air compressor inlet hose to the air cleaner hose. Tie the air compressor inlet hose up and out of the way. See **Fig. 1**.

Installation

1. Install the air intake piping assembly, as a unit, and attach clamps to the air cleaner housing and the turbocharger.
2. Tighten all clamps 84 lbf·in (1000 N·cm). When installing all piping, make sure the component fits well down on its attachment and is firmly connected. Make sure the clamp is tight.
3. Connect the pipe fitting attaching the air compressor inlet hose to the air cleaner pipe.
4. Connect the batteries.
5. Check the air compressor inlet hose at the fitting for leaks.
6. Lower the hood and remove the chocks from the tires.

General Information

The charge air cooler (CAC) is attached to the front of the radiator, and is similar to a radiator. See **Fig. 1**. Outside ambient air passing through the CAC core cools the engine's intake air charge. The air charge leaving the turbocharger is hot compressed air, about 275 to 325°F (135 to 162°C), depending on the ambient temperature. The CAC reduces the air charge temperature to about 110°F (43°C), with a 77°F (25°C) ambient temperature, before the air charge enters the engine intake manifold. This temperature decrease lowers exhaust emissions, improves fuel economy, and increases horsepower.

Removal

1. Apply the parking brakes and chock the tires.
2. Remove the grille from the hood.
3. Tilt the hood, and support its front upper edge in a position that will allow the hood straps to be disconnected; place a support between the floor and the front of the hood, above the grille opening. Use cardboard, carpet, rags, or other padding on top of the support to protect the hood.
4. Disconnect both hood straps from the top of the radiator.
5. Loosen the constant tension hose clamps at both ends of the convoluted hoses that attach the inlet and outlet air piping to the charge air cooler (CAC) connections. Push the clamps and hoses back onto the piping, until they are not touching the CAC connections.
6. To allow extra slack in the A/C condenser hoses, remove the hose clamp that attaches the hoses near the right side of the radiator.
7. While standing in the grille opening, remove the lower sets of fasteners that attach the side air-recirculation baffle to the CAC. Remove the plastic panel retainers and fender washers that attach both of the side air-recirculation baffles to the lower air-recirculation baffle. See **Fig. 1**.
8. Place shop towels or rags on top of the right-side tire. Remove the fasteners that attach the condenser to the CAC; then, with the A/C hoses still connected, swing the condenser around, and carefully lay it on top of the padding on the right-side tire.
9. For a CAC that is mounted on a 1200-square-inch (see **Fig. 1**) or 1350-square-inch radiator, remove the two bolts and washers that attach the CAC to the right side of the radiator. While pressing the CAC rearward, remove the two nuts and washers that secure the CAC on the forward studs at the left side of the radiator. Hold it there after the fasteners have been removed, until someone else can support the left side of the CAC. Then remove the bolts.

   For a CAC that is mounted on a 1000-square-inch radiator (see **Fig. 2**), remove the two sets of fasteners that attach the CAC to the bottom of the radiator. While pressing the CAC rearward, remove the two nuts and washers, but not the bolts, that attach the CAC to the top of the radiator. Hold it there after the nuts have been removed, until someone else can support the left side of the CAC, then remove the bolts.
10. While someone else supports the left side of the CAC, pull both sides of the CAC far enough forward to clear the radiator's CAC mounting tabs or forward studs, as equipped. With the CAC held forward to clear the tabs and studs, move the CAC outboard to the right, then push the right side of the CAC back and inboard until the narrowest section of the CAC air inlet connection is tight against the radiator end tank. Work the CAC air outlet connection off the radiator's left end tank. Then move the CAC to the right until the CAC air inlet connection clears the radiator's right end tank.
11. Pass the CAC out the left side of the vehicle.
12. For a CAC that is mounted on a 1350-square-inch radiator that has aluminum CAC baffles attached to the radiator support channels, remove the six Torx® fasteners that secure the baffles to the radiator. Remove and discard the aluminum CAC baffles.
13. If a new CAC is being installed, remove both of the rubber side air-recirculation baffles from the old CAC.

Installation

1. With the hood supported at its full-open position, and one person standing inside the grille opening, pass the CAC in from the left side of the vehicle.
2. With someone supporting the left side of the CAC, move the CAC outboard to the right, then push the right side of the CAC back and inboard until the narrowest section of the CAC air inlet connection is tight against the radiator end tank. Work the CAC air outlet connection onto the radiator's left end tank.
3. Pull both sides of the CAC far enough forward to clear the radiator's CAC mounting tabs or forward studs, as equipped. Then push the CAC mounting tabs onto the 1200-square-inch or 1350-square-inch radiator's forward studs (see **Fig. 1**), or push the CAC mounting tabs between

6. Swing the A/C condenser around, and install it on the front of the CAC. Tighten all condenser and air-recirculation-baffle fasteners 96 lbf·in (1080 N·cm). Install the air-recirculation-baffle plastic panel retainers and fender washers that attach the lower air-recirculation baffle to the side air-recirculation baffles. See **Fig. 1**. Install any A/C condenser hose clamps that were removed.
7. Tilt the hood to an angle that will allow attachment of the hood straps to the top of the radiator. Attach the hood straps. Remove the hood support, then tilt the hood.
8. Pull the convoluted hoses and constant tension hose clamps forward until the hoses cover the CAC inlet and outlet connections up to the hose stops that are cast into the CAC connections.
9. Turn the constant tension hose clamps so their tightening screws are under the hoses or facing inboard. Tighten the clamp screws 45 lbf·in (500 N·cm).

IMPORTANT: Vehicles built on or after February 26, 2007, have modified constant tension clamps that adjust to changes in diameter at the hose connection. When installing a new clamp or reinstalling a modified clamp, tighten the fastener 98 lbf·in (1100 N·cm). Do not retighten the clamp unless the measured torque drops below 50 lbf·in (560 N·cm), at which time it should be tightened again 98 lbf·in (1100 N·cm).

10. Return the hood to the operating position and install the grille.

Removal

1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Open the access panel on the front of the vehicle.
3. Drain the coolant from the cooling system. For instructions, see **Group 20**.
4. Remove the lower grille panel from the cab. For instructions, see **Group 60**.
5. Tilt the cab. For instructions, see **Group 60**.
6. Loosen the constant tension hose clamps that attach the inlet and outlet hoses to the CAC. Remove the hoses from the CAC. See **Fig. 3**.
7. Remove the capscrews and washers that attach the engine oil dipstick and filler to the CAC.
8. Remove the fasteners that attach the condenser to the CAC. Swing the condenser out from the CAC without removing the refrigerant lines. Support the condenser by attaching tie straps to the condenser and to parts on the vehicle.
9. Remove the fasteners that attach the surge tank to the mounting bracket on the radiator. See

11. Remove the mounting bolts on the left-hand side of the CAC. Remove the mounting capscrews on the right-hand side of the CAC, and remove the CAC.

Installation

1. Install the CAC on the mounting brackets on the radiator. Attach the mounting bolts on the left-hand side of the CAC, and mounting capscrews on the right-hand side of the vehicle.
2. Attach the surge tank to the radiator and the CAC. Attach the short hose between the radiator and the surge tank and fasten it with a hose clamp.
3. Remove the tie straps that are supporting the condenser. Swing the condenser back on the CAC. Attach the nuts and tighten 84 lbf·in (950 N·cm).
4. Attach the engine oil dipstick and filler to the CAC. Tighten the capscrews securely.
5. Attach the inlet and outlet hoses to the CAC. Slide the constant tension hose clamps over the hoses and tighten the hose clamps 45 lbf·in (500 N·cm).
6. Attach the lower grille panel to the cab. For instructions, see **Group 60**.
7. Fill the cooling system with coolant. For coolant specifications, see **Group 20** of the *Century Class Trucks Maintenance Manual*.
8. Return the cab to the operating position. For cab tilt instructions, see **Group 60**.
9. Close the access panel.

EPA07 CAC Removal and Installation

Removal

1. Apply the parking brakes and chock the tires.
2. If the vehicle has a 37-tube charge air cooler (CAC), do the following.
   - 2.1 Remove the grille from the hood.
   - 2.2 Tilt and support the hood so that the hood straps can be be disconnected. The support system must be adjustable (while loaded with the weight of the hood) and very reliable to ensure the hood is protected from damage.
   - 2.3 Disconnect both hood straps from the top of the radiator.
3. If the vehicle has a 47-tube CAC, do the following.
   - 3.1 Disconnect any wiring that is attached to the bumper.
   - 3.2 Remove the bumper. For instructions, see **Group 31**.
   - 3.3 Remove the hood. For instructions, see **Group 88**.
   - 3.4 Remove the front closing crossmember.
4. Loosen the hose clamps at both ends of the hoses that attach the inlet and outlet air piping to the CAC, then push the clamps and hoses back onto the air piping.
5. Allow extra slack in the A/C condenser hoses by removing the hose support clamp that attaches the hoses near the right side of the radiator.
6. Place shop towels or rags on top of the right-side tire as padding for the condenser. Remove the fasteners that attach the condenser to the CAC, then, with the A/C hoses still connected, swing the condenser around, and carefully lay it on top of the padding on the right-side tire.
7. Remove the side air-recirculation baffles from the CAC.
8. Remove the bolts that hold the overflow bottle to the cooling package so that the bottle can move. The coolant does not need to be drained.
9. Loosen the two upper bolts that hold the CAC to the cooling package side rails and completely remove the two lower bolts.
10. Support the CAC, then remove the two upper bolts.
11. While someone else supports the left side of the CAC, slightly raise the right side of the CAC. See **Fig. 1**. Then, with the left side held close to the radiator, pull the right side away from the cooling package frame. See **Fig. 2**.

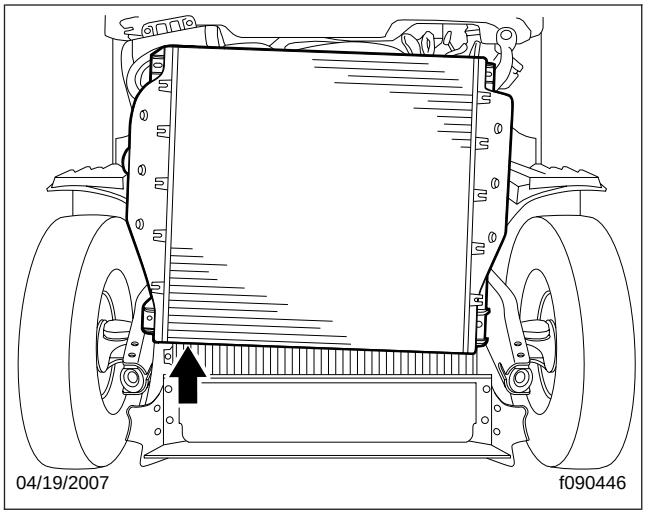

Fig. 1, 47-Tube CAC Tilted for Removal, Front View

Installation

1. With someone supporting the left side of the CAC, hook the left end tube on the cooling package, then adjust the angle of the CAC to allow the right end tube to slip past the cooling package frame.

NOTE: Installing the CAC may be more difficult than removing it, and the fit may be tight. Be sure nothing hinders the fit between the CAC and the cooling package frame.

2. Install the fasteners that attach the CAC to the radiator. Tighten all CAC mounting fasteners 28 lbf·ft (38 N·m).
3. Install the overflow bottle on the cooling package and tighten the radiator-mounting bolts and the cooling package frame-mounting bolts 18 to 24 lbf·ft (25 to 33 N·m).
4. Install the side air-recirculation baffles on the CAC, and tighten the fasteners 96 lbf·in (1080 N·cm).

EPA07 CAC Removal and Installation

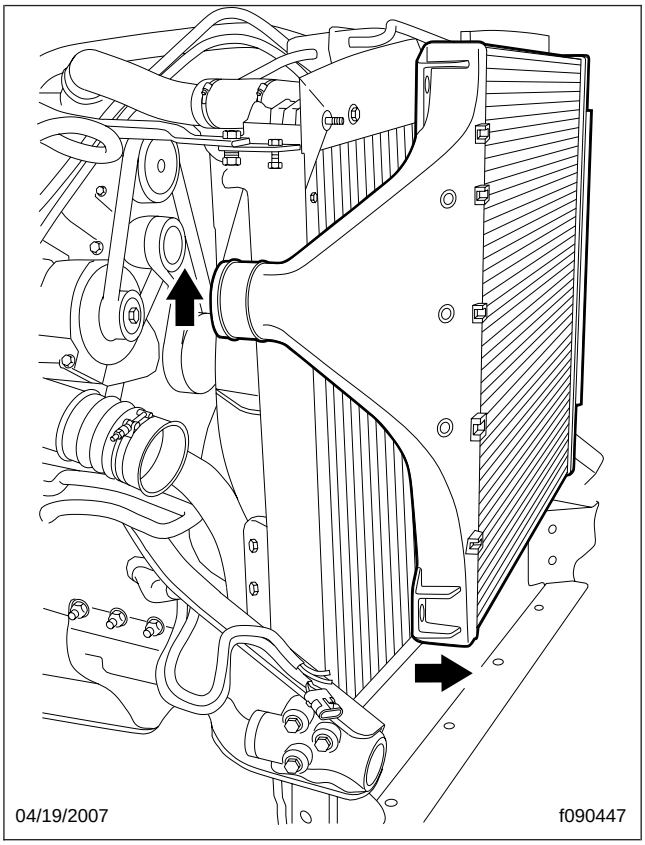

Fig. 2, 47-Tube CAC Tilted for Removal, Side View

5. Swing the A/C condenser around, and install it on the front of the CAC. Tighten all condenser fasteners 96 lbf·in (1080 N·cm). Install any A/C condenser hose support clamps that were removed.
6. Pull the convoluted hoses and constant tension hose clamps forward until the hoses cover the CAC tube ends up to the cast hose stops.
7. Turn the constant tension hose clamps so their tightening screws are under the hoses or facing inboard. Tighten the clamp screws 45 lbf·in (500 N·cm).

IMPORTANT: Vehicles built on or after February 26, 2007, have modified constant tension clamps that adjust to changes in diameter at the hose connection. When installing a new clamp or reinstalling a modified clamp, tighten the fastener 98 lbf·in (1100 N·cm). Do not retighten the clamp unless the measured torque drops below 50 lbf·in (560 N·cm), at which time it should be tightened again 98 lbf·in (1100 N·cm).

8. If the vehicle has a 37-tube CAC, do the following.
   - 8.1 Tilt the hood to an angle that allows attachment of the hood straps to the top of the radiator. Attach the hood straps and remove the hood support.
   - 8.2 Return the hood to the operating position, and install the grille.
9. If the vehicle has a 47-tube CAC, do the following.
   - 9.1 Install the front closing crossmember. All capscrews should be fitted and aligned in the tow hook receivers before any are tightened.
   - 9.2 Install the hood. For instructions, see **Group 88**.
   - 9.3 Install the bumper. For instructions, see **Group 31**.
   - 9.4 Check the hood for proper alignment.

Inspection

1. Apply the parking brakes and chock the tires.
2. Open the hood or tilt the cab. For cab tilt instructions, see **Group 60**.
3. Check the charge air cooler (CAC) convoluted hoses and the inlet and outlet piping for holes or other damage. Also check for loose or damaged constant tension hose clamps. Replace damaged parts. If hose clamps are loose, turn them so their tightening screws are under the hoses or facing inboard. Tighten the screws 45 lbf·in (500 N·cm).

IMPORTANT: Vehicles built on or after February 26, 2007, have modified constant tension clamps that adjust to changes in diameter at the hose connection. When installing a new clamp or reinstalling a modified clamp, tighten the fastener 98 lbf·in (1100 N·cm). Do not retighten the clamp unless the measured torque drops below 50 lbf·in (560 N·cm), at which time it should be tightened again 98 lbf·in (1100 N·cm).

4. Check the CAC core fins. If the fins are bent, use a small pair of needlenose pliers or a small screwdriver to straighten them.
5. Check the CAC core for clogged fins. Use compressed air or water to dislodge any material restricting airflow through the core.
6. Perform the "CAC Core Leakage Test."

CAC Core Leakage Test

Charge air coolers are designed in such a way that they may bleed an insignificant amount of air. The allowable leakage mentioned in **Table 1** represents a loss of less than 0.1 percent of charge airflow. Based on this rate, there should be no measurable loss of performance.

The CAC core leakage test should be performed using a CAC test kit, part number 5039, which can be purchased from Kent-Moore/SPX at 1–800–328–6657.

Leakage Rate Specifications		
Engine	**Pressure Drop in 15 Seconds: psi (kPa)**	**Start Pressure: psi (kPa)**
Caterpillar	5 (34)	30 (207)
Cummins	7 (48)	30 (207)
Detroit Diesel	5 (34)	25 (172)

Table 1, Leakage Rate Specifications

1. Apply the parking brakes and chock the tires.
2. Connect the test equipment to the CAC core as follows. See **Fig. 1**.
   - 2.1 Remove the inlet and outlet air piping from the convoluted hoses that attach them to the CAC air inlet and air outlet.
   - 2.2 Slip a safety ring with thumbscrew over each convoluted hose and onto the CAC air inlet and air outlet. Turn the rings so the thumbscrews are facing outboard and the safety chains are inboard. Tighten the thumbscrews securely.
   - 2.3 Install an additional constant tension hose clamp on each convoluted hose.
   - 2.4 Install the test plug without an adapter in the CAC air inlet and turn the plug so the safety chain is inboard. Tighten each constant tension hose clamp 72 lbf·in (810 N·cm).
   - 2.5 Install the test plug with adapter in the CAC air outlet and turn the plug so the safety chain is inboard. Tighten each constant tension hose clamp 72 lbf·in (810 N·cm).

⚠ WARNING

Always secure the test plugs with the safety rings. Test pressures could blow out an unsecured test plug at high speed, possibly causing eye injury or other serious personal injury.

   - 2.6 If not already installed, install a test valve/gauge assembly and air chuck in the test plug with adapter.
   - 2.7 Attach a pressurized air line to the air chuck on the pressure regulator valve.

3. Test the CAC core as follows.

⚠ WARNING

Always wear safety glasses when doing this procedure. Do not stand in front of the test plugs while the core is pressurized. A plug could suddenly release debris at high speed, possibly resulting in eye injury or other serious personal injury.

3.1 Open the test valve, then slowly open the pressure regulator valve and allow the CAC to gradually fill with air to the start pressure. See **Table 1**.

3.2 Close the test valve and watch the gauge for 15 seconds. If there is more than the specified drop in the CAC pressure in 15 seconds, replace the CAC. See **Table 1**.

IMPORTANT: Do not attempt to repair the CAC.

3.3 When testing is completed, reduce the pressure on the pressure regulator valve to bleed air from the CAC.

4. Remove the test equipment (and the additional constant tension hose clamps) from the convoluted hoses.

5. Pull the convoluted hoses and constant tension hose clamps rearward until the hoses cover

about 1-1/2 inches (38 mm) of the CAC air inlet and air outlet piping.

6. Turn the clamps so their tightening screws are under the hoses or facing inboard. Tighten the screws 45 lbf·in (500 N·cm).

IMPORTANT: Vehicles built on or after February 26, 2007, have modified constant tension clamps that adjust to changes in diameter at the hose connection. When installing a new clamp or reinstalling a modified clamp, tighten the fastener 98 lbf·in (1100 N·cm). Do not retighten the clamp unless the measured torque drops below 50 lbf·in (560 N·cm), at which time it should be tightened again 98 lbf·in (1100 N·cm).

7. Return the hood or cab to the operating position. For cab tilting instructions, see **Group 60**.

Flushing

If the charge air cooler (CAC) is suspected of being contaminated, flush the CAC.

1. Apply the parking brakes and chock the tires.
2. Remove the CAC. For instructions, see **Subject 100** for pre-EPA07 engines, or **Subject 110** for EPA07 engines.
3. Set the CAC in a horizontal position with the inlet and outlet ports facing up.

IMPORTANT: Use only naphtha or mineral spirits to clean the charge air cooler. Do not use caustic solutions such as those that are commonly used in radiator shops. Do not use steam or high-temperature cleaning operations. Caustic solutions, steam, and high-temperature cleaning operations will damage the RTV that seals the charge air cooler tubes to the headers, which may result in leaking.

4. Pour a filtered naphtha or mineral spirits solution into the CAC until it is 40 percent full.
5. Cap the inlet and outlet ports on the CAC.
6. Rock the CAC back and forth so that the solvent travels from one tank, through the tubes, to the other tank and back. Repeat this process ten times.

NOTE: Do not leave the solvent in the CAC for more than 10 minutes.

7. Remove the caps from the inlet and outlet ports.
8. Drain the CAC and properly dispose of the solvent.
9. Leave the caps off and allow the residual solvent to evaporate.
10. Install the CAC. For instructions, see **Subject 100** for pre-EPA07 engines, or **Subject 110** for EPA07 engines.

Restriction Test

After flushing the charge air cooler (CAC) because of turbocharger or engine damage, test the pressure drop across the CAC and air piping.

1. Remove the pipe plug (if equipped) from the tapped hole in the turbocharger air outlet elbow.

   Remove the pipe plug, or the nylon tube and atomizer for the ether start system (if equipped), or the air line to the turbocharger air-pressure gauge (if equipped), from the tapped hole in the left-hand rear of the intake manifold.

   Install an air pressure gauge in each tapped hole.

2. Operate the engine at rated speed and horsepower; there is no need to operate the engine at its peak torque rating. While operating the engine, read both air pressure gauges.

   Because of the turbulence of the air at the turbocharger outlet, subtract 0.3 inHg (1 kPa) from the pressure measurement taken at the turbocharger outlet, to make it a true reading.

   From that reading, subtract the reading taken at the intake manifold. This is the pressure drop of the CAC.

   If the pressure drop is more than 4 inHg (14 kPa), flush or replace the CAC as needed.

General Description

The Tu-Flo 550 and the Tu-Flo 750 are two cylinder, single-stage, reciprocating air compressors, which supply compressed air to the vehicle air system. The Tu-Flo 550 has a rated displacement of 13.2 cfm (374 L/min) of air at 1250 rpm.

The Tu-Flo 750 has a rated displacement of 16.5 cfm (468 L/min) of air at 1250 rpm. The compressor draws air from the air intake pipe, compresses the air, and delivers it to the air system supply reservoir. The compressor runs continuously but has "loaded" and "unloaded" modes, which are regulated by the air governor and the compressor loading assembly. When the governor sends an air signal to the unloader assembly, the unloader assembly holds the compressor air intake valve open so that no more compressed air is forced into the air system. As air in the system is used, its pressure drops, and at 90 psi (620 kPa), the air governor stops the signal to the compressor. Without the signal, the unloader assembly automatically closes the compressor air intake valve to force more air into the system.

On vehicles with air dryers, when the system reaches the cut-out pressure of 120 psi (825 kPa), the air governor also sends an air signal to open the sludge ejector in the air dryer.

Removal

1. Apply the parking brakes, chock the tires, and tilt the hood or cab. For cab tilting instructions, see the applicable section in **Group 60** of this manual.
2. Drain the air system.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

3. Using a cleaning solvent, remove road dirt and grease from the outside of the compressor, then dry the compressor with compressed air.
4. Drain the radiator coolant; refer to **Group 20** in this manual for instructions.
5. On Century Class conventionals, loosen the constant-torque hose clamps at both ends of the charge air cooler outlet air piping. Remove the piping to access the air compressor.
6. Marking their locations and positions, disconnect all air, coolant, and oil lines attached to the compressor. Remove tie straps as needed to move the lines out of the way.

NOTE: On vehicles with combined air dryers and air reservoir modules, the air governor is mounted on the module not the air compressor.

7. If the air governor is mounted on the compressor, remove it and the governor mounting gasket.
8. On Cummins and Detroit Diesel engines, disconnect the wire to the fuel shutoff valve (if so equipped). Remove the fuel pump and gasket; refer to the engine shop manual or rebuild manual for instructions.
9. Remove the compressor support bracket, if so equipped.

NOTE: On Argosy COE vehicles, you must remove this bracket (at the rear of the compressor) in order to remove all the fasteners holding the compressor to the drive gear flange.

10. Support the compressor, and remove the bolts that attach it to the auxiliary drive housing, accessory drive, or timing gear plate. Remove the compressor, gasket, and splined coupling.

NOTE: On Argosy COE vehicles, the compressor is mounted on an alignment stud. The stud is at the top of the compressor mounting and allows the compressor to hang in place as you're removing or installing it. The stud is threaded and a nut is installed to secure the compressor.

11. Discard all mounting gaskets.

Installation

IMPORTANT: Be sure the gasket surfaces are cleaned and not damaged.

NOTE: On Argosy COE vehicles, the compressor is mounted on an alignment stud. The stud is at the top of the compressor mounting and allows the compressor to hang in place as you're removing or installing it. The stud is threaded and a nut is installed to secure the compressor.

1. Install the splined coupling (if so equipped) and a new compressor gasket. Hold the compressor in place, and install the bolts that attach it to the auxiliary drive housing, accessory drive, or timing gear plate. Refer to the engine shop manual or rebuild manual for final torque specification.
2. Install the compressor support bracket, if so equipped.
3. On Cummins and Detroit Diesel engines, install a new gasket, install the fuel pump. Connect the wire to the fuel shutoff valve (if so equipped). Refer to the engine shop manual or rebuild manual for instructions.
4. If applicable, use a new air governor mounting gasket, install the air governor on the compressor.
5. Identify and connect all air, coolant, and oil lines to the compressor. Secure the lines as needed with tie straps.
6. On Century Class conventionals, install the charge air cooler outlet air piping. Tighten the constant-torque hose clamp screws 45 lbf·in (500 N·cm).
7. Fill the engine cooling system; refer to **Group 20** in this manual for instructions.
8. Operate the engine and check for leaks.

Air Compressor Removal and Installation

9. Remove the chocks from the tires and return the hood or cab to the operating position. For cab tilting instructions, see the applicable section in **Group 60** of this manual.

Removal

1. Chock the tires; then drain the air from all air reservoirs.

⚠ WARNING

WARNING: Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

2. Using a cleaning solvent, remove road dirt and grease from the outside of the compressor, then dry the compressor with compressed air.
3. Drain the radiator coolant; refer to **Group 20** in the vehicle workshop manual for instructions.
4. Remove the cylinder head from the crankcase. See **Fig. 1.**

   4.1 Scribe an alignment mark across the cylinder head and the crankcase, for assembly alignment.

   IMPORTANT: Do not use a marking method, such as chalk, that can be wiped off during assembling.

   4.2 Note positions of any attached components, then remove the cylinder head capscrews.

   4.3 Tap the cylinder head with a soft mallet to break the gasket seal. Remove the cylinder head.

Installation

1. Scrape off any gasket material from the cylinder head and the crankcase.

⚠ WARNING

WARNING: Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

2. Using compressed air, blow dirt particles or gasket material from all cylinder cavities.
3. Install the cylinder head on the compressor crankcase.

   3.1 Place a new cylinder head gasket on the crankcase. If the cylinder head gasket has a bead on one side, install the gasket with the bead side up.

Cylinder Head Removal and Installation

3.2 Using the previously marked alignment, position the cylinder head on the crankcase.

3.3 Position on the cylinder head any brackets, spacers, or clamps that were removed; then install the cylinder head capscrews and tighten them evenly, in a cross pattern 37 to 42 lbf·ft (50 to 57 N·m).

4. Connect the air discharge line and the water lines to the cylinder head.
5. Fill the engine cooling system; refer to **Group 20** in the vehicle workshop manual.
6. Operate the engine and make sure there are no coolant leaks.

Cylinder Head Disassembly, Cleaning and Inspection, and Assembly

Disassembly

1. Remove the compressor from the vehicle. For instructions, refer to **Subject 100.**
2. Place the compressor on a suitable work surface. Remove the cylinder head from the crankcase. For instructions, refer to **Subject 110.**
3. Remove the unloader mechanism. See **Fig. 1**.
   - 3.1 Remove the unloader plate capscrews, lockwashers, and the unloader plate. Scrape off any gasket material from the unloader plate and the cylinder head.
   - 3.2 Remove and discard the unloader pistons, O-rings, and springs.
4. Check the unloader piston bushings. If damaged or worn excessively, replace the compressor.

NOTE: Before disassembling the discharge valve mechanism, measure and record the discharge valve travel from closed to completely open. If the measurement exceeds 0.046 inch (1.17 mm), replace the compressor. If the measurement is within 0.046 inch, proceed to the next step.

5. Using a 9/16-inch Allen wrench, remove and discard the discharge valve seats, discharge valves, and discharge valve springs.
6. Remove and discard the inlet valve stops and springs, along with the inlet valves, inlet valve seats, and gaskets.

Cleaning and Inspection

1. Remove carbon deposits from the discharge cavity, rust and scale from the cooling cavities.
2. Clean carbon and dirt from the inlet and unloader passages.
3. Scrape all foreign material from the body surfaces.

Cylinder Head Disassembly, Cleaning and Inspection, and Assembly

4. Using solvent, thoroughly clean all metal parts removed from the cylinder head. Using shop air, blow the dirt particles from the cavities and passages.
5. Check that all cavities and passages are clear, including the inlet and unloader.
6. Check that all mating surfaces are clean of old gasket material. Remove any old material.
7. Inspect the cylinder head for cracks or damage.
8. With the cylinder head and head gasket secured to a flat surface or to the crankcase, apply shop air pressure to one of the coolant ports with all other ports plugged.
9. Check for leaks by applying a soap solution to the exterior of the body. If leakage is detected, replace the compressor.

Assembly

1. Install the unloader mechanism. See **Fig. 1**.
   - 1.1 With the unloader pistons being prelubricated from the manufacturer, install the new unloader springs, and the new unloader pistons. The unloader piston O-rings are pre-installed on the unloader pistons.
   - 1.2 Install the new unloader plate gasket and the unloader plate.
   - 1.3 Install the unloader plate lockwashers and capscrews. Tighten the capscrews 15 to 18 lbf·ft (20 to 25 N·m) in a cross pattern.
2. Install the inlet valve mechanism.
   - 2.1 Install the new inlet valve gaskets, new inlet valve seats, new inlet valves, and the new inlet valve springs into their bores.
   - 2.2 Install the new inlet valve stops and tighten 70 to 90 lbf·ft (95 to 122 N·m).
3. Install the new discharge valve springs, new discharge valves, and the new discharge valve seats into their bores. Tighten the seats 70 to 90 lbf·ft (95 to 122 N·m). The discharge valve travel should be 0.030 inches to 0.046 inch (0.762 mm to 1.17 mm).
4. Test for leakage at the discharge valves by applying 100 psi (690 kPa) through the cylinder head discharge port and apply soap solution to the discharge valve and seat. Leakage in the form of soap bubbles is permissible.

   If there's extreme leakage, leave the air pressure applied and with a hardwood dowel and a hammer, tap the discharge valves off of their seats several times. This will improve the seal between the discharge valve and the valve seat and should reduce leakage.

   If there's still extreme leakage, replace the discharge valve seats.

   With the air pressure still applied at the discharge port of the cylinder head, check for leakage around the discharge valve stop on top of the cylinder head. No leakage is permitted.
5. Install the compressor cylinder head. For instructions, refer to **Subject 110.**
6. Tighten the unloader plate capscrews 15 to 18 lbf·ft (20 to 25 N·m).
7. Install the compressor on the engine. For instructions, refer to **Subject 100.**

Crankcase Disassembly, Cleaning and Inspection, and Assembly

Disassembly

1. Remove the compressor from the vehicle and place it on a suitable work surface. For instructions, refer to **Subject 100**.
2. Remove the air compressor cylinder head. For instructions, refer to **Subject 110**.
3. Before disassembling the compressor, use a metal scribe to mark the parts with matching numbers or lines.

IMPORTANT: Do not use a marking method, such as chalk, that can be wiped off during assembling.

4. Remove the pistons and connecting rods. See **Fig. 1**.
   - 4.1 Remove the base plate capscrews.
   - 4.2 Tap the base plate with a soft mallet to break the gasket seal.
   - 4.3 Scrape off any gasket material from the crankcase and base plate.
   - 4.4 Remove the connecting rod bolts and connecting rod caps.
   - 4.5 Push the pistons and connecting rods out through the cylinder bore of the crankcase. Discard the pistons and connecting rod assemblies including the connecting rod caps and the connecting rod bolts.
5. Remove the crankshaft.
   - 5.1 Remove the key or keys from the crankshaft and any burrs from the crankshaft where the key or keys were removed.

   NOTE: Some compressors may have a crankshaft key at each end.

   - 5.2 Remove the end-cover capscrews, the end cover, end-cover seal, and the rear thrustwasher.
   - 5.3 If the compressor has sleeve bearings, remove and discard the sleeve bearings from the crankcase and the end cover.
   - 5.4 If the compressor has a ball-type main bearing, remove the rear snap ring (if so equipped). Press the crankshaft and ball bearing from the crankcase, then press the ball bearing from the crankshaft.
   - 5.5 Remove and discard the front and rear thrustwashers.

Cleaning and Inspection

1. Scrape off any gasket material from the top and bottom of the crankcase.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

2. Clean all parts with solvent, before inspecting them, and dry the parts with compressed air.
3. Clean all oil passages through the crankshaft, crankcase, end cover, and base plate. Inspect the passages with a wire to be sure they are clear.
4. Check the fit of the new pistons, piston rings, and connecting rods.
   - 4.1 The pistons for the Tu-Flo 750 compressor are similar to the Tu-Flo 550 and may be identified by the distance from the center of the wrist pin to the top of the piston. See **Fig. 2**.
   - 4.2 To check the ring gap, place the ring in the top of the cylinder bore and, using a piston, push the ring to mid-point of the cylinder bore and check the ring gap. The gap for compression rings must be 0.002 to 0.013 inch (0.050 to 0.330 mm).

     The gap for oil ring and expander ring must be 0.010 to 0.040 inch (0.254 to 1.016 mm). See **Fig. 3**, and **Table 1**.

Allowable End Gap	
Ring	**End Gap in inch (mm)**

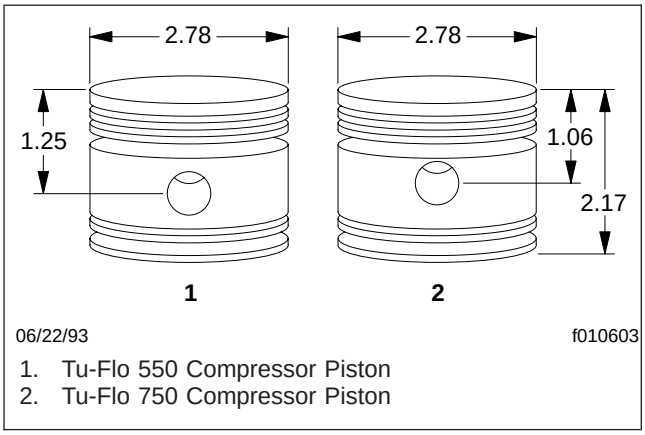
5.1 Check the crankcase surfaces for cracks and damage.



1. Tu-Flo 550 Compressor Piston
2. Tu-Flo 750 Compressor Piston

Fig. 2, Piston Comparison

5.2 On compressors where main ball bearings are used, measure the difference between the outside diameter of the ball bearing outer race and the inside diameter of the crankcase bore should be 0.0003 inch (0.008 mm) tight to 0.0023 inch (0.058 mm) loose. This is to maintain a correct fit. Replace the compressor if the fit is too loose.

5.3 Check the end cover for cracks and damage. Replace them as necessary.

5.4 Check the cylinder bore with an inside micrometer or with calipers. Cylinder bores which are scored, out-of-round, or tapered more than 0.0005 inch (0.013 mm) should be rebored and honed oversize. Oversized pistons and piston rings are available in 0.010 inch (0.254 mm), 0.020 inch (0.508 mm), and 0.030 inch (0.762 mm) oversize.

6. Inspect the crankshaft.

6.1 Check the crankshaft splines, gear teeth, tapered ends, and all machined and ground surfaces for wear, scoring, or damage. Repair the damage, or replace the crankshaft if needed.

6.2 Check the crankshaft connecting rod journals for extreme scoring, and measure them for out-of-round wear. Standard crankshaft journals are 1.1242 to 1.1250 inches (28.555 to 28.575 mm) in diameter. If the crankshaft is extremely scored or worn out-of-round, and cannot be reground, replace it.

NOTE: If the crankshaft needs to be reground or replaced, do so before proceeding to the next step. For compressors having reground crankshafts, connecting rod bearing inserts are available in 0.010 inch (0.254 mm), 0.020 inch (0.508 mm), and 0.030 inch (0.762 mm) undersize.

Assembly

1. For compressor with sleeve bearings, install the crankshaft and end cover. See **Fig. 1**.

1.1 Press the new sleeve bearings into the end cover and crankcase. Make sure the slot in the bearings line up with the oil passages in the end cover and crankcase.

If there is no oil passage present in the crankcase, press the sleeve bearing into the crankcase with the slot located 90 degrees from vertical.

1.2 Install the new front thrustwasher with the tang inserted in the slot toward the flange.

1.3 Insert the crankshaft and the rear thrustwasher with the tang toward the end cover of the compressor.

1.4 Place the end-cover seal on the boss of the end cover.

1.5 Install the end cover making sure not to pinch the end cover seal and the tang of the rear thrustwasher is inserted in the slot of the end cover. Install the capscrews and tighten the capscrews 15 to 18 lbf·ft (20 to 25 N·m) in a cross pattern.

2. If one end of the compressor uses a ball-type main bearing, install the crankshaft and end-covers.

2.1 Press the new sleeve bearings into the crankcase. Make sure the slots in the bearings line up with the oil passage in the end cover and crankcase.

If there is no oil passage present in the crankcase, press the sleeve bearing into the crankcase with the slot located 90 degrees from vertical.

2.2 Install the new front thrustwasher with the tang inserted in the slot toward the flange.

2.3 Press the ball bearing onto the correct end of the crankshaft, so that the drive end of the crankshaft will be positioned in the crankcase as marked before disassembly. Using an arbor press, carefully press the ball bearing and the crankshaft into the crankcase. Install the retainer ring if so equipped.

3. Assemble the new piston rings on the new pistons.

IMPORTANT: To properly test a compressor under operating conditions, a test rack is necessary for correct mounting, cooling, lubricating, and driving the compressor.

NOTE: Install the piston rings on the pistons starting at the center of the piston and moving outward. Rotate the piston rings in their respective grooves so that the end gap is at least 90 degrees from the previous ring's end gap.

3.1 Install the expander ring in the piston groove. The ends of the expander ring must butt and must not overlap.

3.2 Install the bottom oil ring by inserting one end below the expander ring in the ring groove, and wind the ring into position. Install the top oil ring in the same manner above the expander ring making sure the gap is staggered from the bottom oil ring and the expander ring.

3.3 Install the compression rings in the correct grooves, with the bevel or "pip" mark (if any) toward the top of the piston.

4. Assemble the new connecting rods on the new pistons.

4.1 Lubricate the wrist pins and the wrist pin bushings in the connecting rods with clean engine oil.

4.2 Position the connecting rods in the pistons and press in the wrist pins. Secure the wrist pins by installing the wrist pin buttons in the ends of the wrist pins.

5. Install the new pistons and new connecting rods.

5.1 Apply clean engine oil to both pistons, the piston rings, the wrist pins, the connecting rod caps and the new connecting rod bearings.

5.2 Turn the crankshaft so its number-one rod journal (the one nearer the drive end) is down and centered.

5.3 Using a piston ring compressor, insert the number-one connecting rod and piston through the top of the number-one cylinder bore.

NOTE: The connecting rods and connecting rod caps are matched sets, therefore the caps must not be switched or rotated end for end.

5.4 Install the connecting rod bearings on the connecting rod and connecting rod cap.

5.5 Tighten the new connecting rod bolts evenly in increments of 11 to 13 lbf·ft (15 to 17 N·m).

5.6 Turn the crankshaft so its number-two connecting rod journal is in the downward, center position.

5.7 Install the number-two connecting rod and piston in the same manner as described above.

6. Before replacing the cylinder head on the crankcase, ensure that the correct pistons have been used by turning the crankshaft one complete revolution such that each piston moves to its maximum upward stroke. At the upward stroke position, each piston should move to the top of the crankcase. If the piston does not approach the top of the crankcase, the piston is incorrect and if not replaced could result in compressor damage.

7. Install the base plate.

7.1 Position the gasket on the crankcase. Install the base plate on the crankcase as marked before disassembly.

7.2 Tighten the six capscrews 15 to 18 lbf·ft (20 to 25 N·m) in a cross pattern.

8. Install the cylinder head on the crankcase. For instructions, refer to **Subject 110**.

9. Install the compressor on the engine. For instructions, refer to **Subject 100**.

10. Operate the engine and check for leaks.

Problem—Excessive Oil Passage

Problem—Excessive Oil Passage	
Possible Cause	**Remedy**
Restricted air intake.	Check engine air filter and replace if necessary. Check compressor air inlet for kinks and excessive bends. Repair as needed.
Restricted oil return line to engine.	Check for excessive bends, kinks, and restrictions in oil return line. Return line must descend from compressor to engine crankcase. Repair as needed.
Damaged oil seal ring or loose end cover.	Inspect oil seal ring for wear or damage. Repair as needed. Check the end cover capscrew torques and tighten as necessary.
Insufficient compressor cooling (compressor runs hot).	Remove grease, grime, or dirt from the cooling fins of the compressor. Check for damaged cooling fins. Replace components found damaged. Check for correct coolant line sizes. Check the coolant flow through the compressor. Minimum allowable flow is 2.5 gallons per minute at maximum engine governed speed, and minimum allowable flow is 0.5 gallons per minute at engine idle. If low, inspect the coolant lines for rust scale, kinks, and restrictions. Repair or replace as necessary.
Compressor runs loaded an excessive amount of time.	Check air lines and connections for leakage. Repair or replace lines and connections until leakage is eliminated.
Back pressure from the engine crankcase.	Check for excessive engine crankcase pressure. Repair or replace ventilation components as necessary. NOTE: An indication of crankcase pressure is a loose or partially lifted dipstick.
Excessive engine oil pressure.	Check the engine oil pressure with a test gauge, and compare the reading to the engine specification. Do not restrict the compressor oil supply line.
Malfunctioning compressor.	Replace or repair the compressor after making certain none of the preceding conditions exist.

Problem—Noisy Compressor Operation

Problem—Noisy Compressor Operation	
Possible Cause	**Remedy**
Loose drive coupling or gear (as indicated).	Inspect the fit of the drive coupling and gear on the compressor crankshaft. Tighten or replace the components. If the crankshaft keyway is damaged, replace the compressor.
Compressor cylinder head or discharge line restrictions.	Inspect the compressor discharge port and discharge line for carbon build-up. If carbon is detected, remove the carbon and check for proper coolant flow to the compressor. Inspect the discharge line for kinks and restrictions. Replace the discharge line as necessary.
Air compressor bearing damaged or worn.	Replace the bearings.
Malfunctioning compressor.	Rebuild or replace the compressor after making certain none of the preceding conditions exist.

Troubleshooting

Problem—Excessive Build-Up and Recovery Time

Problem—Excessive Build-Up and Recovery Time	
Possible Cause	**Remedy**
Restricted air intake.	Check engine air filter and replace if necessary. Check compressor air inlet for kinks and excessive bends. Repair as needed.
Restricted discharge or compressor discharge cavity.	Inspect the compressor discharge port and line for restrictions and carbon build-up. If carbon is detected, remove the carbon. Check for proper cooling to the compressor. Inspect the discharge line for kinks and restrictions. Replace the discharge line as necessary.
Slipping drive components.	Check for faulty drive gears and coupling, and replace as necessary.
Excessive air system leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.
Unloader pistons seized.	Check the operation of the unloading mechanism. Check for corrosion and contamination of unloader pistons. Check for correct operation of the compressor air governor. If the governor is operating properly, repair or replace the unloading mechanism.
Malfunctioning compressor.	Rebuild or replace the compressor after making certain none of the preceding conditions exist.

Problem—Compressor Fails to Unload

Problem—Compressor Fails to Unload	
Possible Cause	**Remedy**
Faulty or worn unloader pistons or bores.	Inspect for worn, dirty, or corroded unloader pistons and bores. Replace as necessary.
Malfunctioning governor.	Check the setting with an accurate test gauge. Repair or replace the air governor.
Unloader air lines from governor damaged.	Inspect the air lines to and from the governor for kinks or restrictions. Repair or replace the air lines.

Table 2, Compressor Specifications

General Description

The governor **(Fig. 1),** operating in conjunction with the compressor unloading mechanism, automatically controls the air pressure in the air brake or air supply system between the desired, predetermined maximum and minimum pressures. Normal air pressure in all Freightliner vehicles is 95 to 125 psi (655 to 862 kPa). The compressor runs continuously while the engine runs, but the actual compression of air is controlled by the governor actuating the compressor unloading mechanism, which stops or starts compression when the maximum or minimum reservoir pressures are reached. The D-2 governor has a piston upon which air pressure acts to overcome the pressure setting spring, and control the inlet and exhaust valve to either admit or exhaust air to or from the compressor unloading mechanism.

D-2 governors have mounting holes, which allow for direct mounting to the compressor.

Porting consists of 3 reservoir ports (1/8-inch NPT), 3 unloader ports (1/8-inch NPT), and 1 exhaust port (1/8-inch NPT).

Fig. 1, Governor

Principles of Operation

Pressurized air enters the D-2 governor at one of its reservoir ports, and acts on the area of the piston and beneath the inlet and exhaust valve. **See Fig. 2.** As air pressure builds up, the piston moves against the resistance of the pressure-setting spring. The piston and inlet and exhaust valve move up when the reservoir air pressure reaches the cut-out setting of the governor. The exhaust stem seats on the inlet and exhaust valve, and then the inlet passage opens. Reservoir air then flows by the open inlet valve, through the passage in the piston, and out the unloader port to the compressor unloading mechanism. Air also flows around the piston, and acts upon the additional area of the piston. This added force, which results from a larger area on the piston, ensures a positive action and fully opens the inlet valve.

As the system reservoir air pressure drops to the cut-in setting of the governor, the force exerted by the air pressure on the piston will be reduced so that the pressure-setting spring will move the piston down. The inlet valve will close and the exhaust will open. With the exhaust open, the air in the unloader line will escape back through the piston, through the exhaust stem and out the exhaust port.

Tests

The following test should be performed whenever the vehicle air pressure is incorrect and the causes are unknown.

If the air governor does not function as described or if leakage is excessive, replace it with a new or remanufactured unit, or repair it using genuine Bendix parts and the instructions in this section.

1. Apply the parking brakes and chock the tires. Tilt the hood or cab. For cab tilting instructions, see **Group 60**.
2. Start the engine and build up air pressure in the air brake system.

IMPORTANT: Make sure the test gauge is registering accurately before using it to check or adjust the air governor.

3. Using a test gauge attached to the supply reservoir, check the pressure at the time the air governor cuts out. For vehicles with a dryer reservoir module (DRM), the cut-out pressure should be 125 to 135 psi (862 to 931 kPa).

   For vehicles without a dryer reservoir module, the cut-out pressure should be 120 to 130 psi (827 to 896 kPa).
4. With the engine still running, make a series of brake applications to reduce the air pressure and observe at what pressure the air governor cuts in the compressor. For vehicles with a dryer reservoir module (DRM), the minimum cut-in pressure should be 105 psi (724 kPa).

   For vehicles without a dryer reservoir module, the minimum cut-in pressure should be 100 psi (689 kPa).
5. If either the cut-out or cut-in pressures are incorrect, proceed to **Subject 130**.
6. Test the leakage on the air governor in both the cut-in and cut-out positions.

   6.1 With the compressor in the cut-in position, apply a soap solution to the air governor exhaust port. See **Fig. 1**. A slight bubble leakage is permitted. Excessive leakage indicates that the inlet valve or lower piston O-ring is worn out.

4. Reservoir Port
5. Exhaust Port

Fig. 1, Air Governor

   6.2 With the compressor in the cut-out position, apply a soap solution to the air governor exhaust port. See **Fig. 1**. A slight bubble leakage is permitted. Excessive leakage indicates that the exhaust valve seat, stem, O-ring, or upper piston O-ring is worn out.
7. Return the hood or cab to the operating position and remove the chocks from the tires. For cab tilting instructions, see **Group 60**.

Removal

NOTE: The governor may be mounted on the air compressor, on the air dryer, or remote mounted on the vehicle frame.

1. Chock the tires, and drain the air brake system. Tilt the hood or cab. For cab tilting instructions, see the applicable section in **Group 60** of this manual.
2. Disconnect the reservoir and unloader port air lines. Mark the lines for later reference. Cap the air lines tightly to keep out contaminants.
3. Remove the governor mounting capscrews and lockwashers, and remove the governor. See **Fig. 1**.

2. Gasket
3. Air Governor
4. Lockwasher
5. Capscrew

Fig. 1, Governor Mounting (mounting location may change to improve air line routing)

Installation

1. Clean the mounting pad on both the compressor and the governor block, and be sure the compressor unloading port is clear and clean.
2. Using a new governor mounting gasket, install the governor and its mounting capscrews and lockwashers. Tighten the bolts 11 to 15 lbf·ft (15 to 20 N·m).
3. Clean the connecting lines after removing the caps, and apply Loctite® 242, or equivalent sealant in small quantities, to the reservoir and unloader fittings.

CAUTION

Make sure excess sealant does not get inside the fittings. Loose material inside the plumbing may clog the governor or other components, causing damage.

4. Connect the reservoir and unloader port air lines as referenced earlier. Tighten the fittings 11 to 13 lbf·ft (15 to 18 N·m).
5. Perform the operating and leakage tests in **Subject 100**.
6. After the tests have been completed and the governor is operating properly, screw the top cover on tightly until it seals the body, preventing the entry of any foreign matter.
7. If necessary, install new filters (**Fig. 2**) in the reservoir and unloader ports. These cup-shaped filters can be installed with the head of a pencil.
8. Return the hood or cab to the operating position, and remove the chocks from the tires. For cab tilting instructions, see the applicable section in **Group 60** of this manual.

4. With a pair of retaining ring pliers, remove the spring assembly retaining ring (Ref. 16).
5. Remove the adjusting screw (Ref. 2) and spring assembly.
6. Remove the locknut (Ref. 3), then the hex-shaped upper spring seat (Ref. 15) from the adjusting screw.
7. Remove the pressure-setting spring (Ref. 14), lower spring seat (Ref. 12), spring guide (Ref. 13), and the other lower spring seat (Ref. 12) from the adjusting screw.
8. Remove the exhaust stem and its spring from the top of the piston. With the body in the inverted position, tap lightly and remove the piston.
9. Remove the inlet and exhaust valve spring (Ref. 9) and the valve (Ref. 10) from the piston.
10. Remove the two piston O-rings (Ref. 11), and with a hooked wire, remove the exhaust stem O-ring (Ref. 11).
11. Clean or remove the unloader and reservoir port filters (Ref. 7).

Cleaning and Inspecting

1. Clean all metal parts in mineral spirits.
2. Wipe all rubber parts dry, using a clean cloth.
3. Inspect the governor body for cracks or other damage. Be particularly careful that all air passages in the body, filters, exhaust stem, and piston are not obstructed.
4. Check the springs for cracks, distortion, or corrosion.
5. Replace all worn or damaged parts.

Assembly

Prior to assembly, lubricate the lower body bore, the top of the piston, the piston grooves, piston O-rings, and the spring guide and adjusting screw with Dow Corning 55-M pneumatic grease, or equivalent.

1. Install the exhaust stem O-ring (**Fig. 1**, Ref. 11) in its groove in the stem bore of the piston.
2. Install the upper and lower piston O-rings (Ref. 11).
3. Drop the inlet and exhaust valve (Ref. 10) into place at the bottom of the piston.
4. Install the inlet and exhaust valve spring (Ref. 9) with the small end against the valve. Press the

Air Governor Disassembly, Cleaning and Inspection, and Assembly

spring down until the larger coiled end snaps into the groove inside the piston.

5. Position the exhaust stem spring (Ref. 5) over the exhaust stem. Carefully press the stem into the stem bore of the piston.
6. Install the piston in the body.
7. Install one lower spring seat (Ref. 12), spring guide (Ref. 13), the other lower spring seat (Ref. 12), pressure-setting spring (Ref. 14), and the hex-shaped upper spring seat (Ref. 15) on the adjusting screw, in that order. Screw the upper spring seat (Ref. 15) down until the distance from the top of the seat to the bottom of the stem head is about 1-7/8 inches (48 mm).
8. Install the locknut (Ref. 3).
9. Before placing the adjusting screw and stem assembly in the governor body, check that the exhaust stem (Ref. 6) and its spring are in place in the piston.
10. Install the adjusting screw (Ref. 2) and spring assembly, and the retaining ring (Ref. 16).
11. Install the governor on the vehicle, using the instructions **in Subject 110.**

Adjustment

NOTE: An air governor with a dryer reservoir module (DRM) is not adjustable.

If the pressure settings of the governor are inaccurate or if they need to be changed, proceed as follows:

1. Apply the parking brakes and chock the tires. Open the hood.
2. Remove the top cover from the governor and loosen the adjusting screw locknut. See **Fig. 1.**

3. To raise the pressure settings, turn the adjusting screw counterclockwise. To lower the pressure setting, turn the adjusting screw clockwise.

NOTE: The pressure range between cut in and cut out is not adjustable.

If these adjustments do not correct the pressure settings, repair or replace the governor.

4. Tighten the adjusting screw locknut and install the top cover.
5. Return the hood to the operating position and remove the chocks from the tires.

General Information

The Midland EL–1300 and EL–1600 are two cylinder, reciprocating-type, water-cooled, and pressure lubricated air compressors. They supply compressed air to the vehicle air system. The EL–1300 has a rated displacement of 12.9 cfm (365 L/min) of air at 1250 rpm. The EL–1600 has a rated displacement of 16.1 cfm (456 L/min).

The compressor draws air from the air intake pipe, compresses the air, and delivers it to the air system supply reservoir. The compressor runs continuously while the engine is running, but has "loaded" and "unloaded" modes, which are regulated by the air governor and the compressor loading assembly. When the governor sends an air signal to the unloader assembly, the unloader assembly holds the compressor air intake valve open and no more compressed air is forced into the air system. As air in the system is used, system air pressure drops, and at 90 psi (620 kPa) the air governor stops the signal to the compressor. Without the signal, the unloader assembly automatically closes the compressor air intake valve to force more air into the system.

On vehicles with air dryers, when the system reaches the cut-out pressure of 120 psi (825 kPa), the air governor also sends an air signal to open the sludge ejector in the air dryer.

Removal

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Drain the air system.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

3. Using a cleaning solvent, remove road dirt and grease from the outside of the compressor, then dry the compressor with compressed air.
4. Drain the radiator coolant; see **Group 20** in the vehicle workshop manual for instructions.
5. Loosen the constant-torque hose clamps at both ends of the charge air cooler outlet air piping. Remove the piping to access the air compressor.
6. Marking their locations and positions, disconnect all air, coolant, and oil lines attached to the compressor. Remove tie straps as needed to move the lines out of the way.
7. Remove the air governor, and the governor mounting gasket.
8. On Cummins and Detroit Diesel engines, disconnect the wire to the fuel shutoff valve (if so equipped). Remove the fuel pump and gasket; see the engine shop manual or rebuild manual for instructions.
9. Remove the compressor support bracket, if so equipped.
10. Support the compressor, and remove the bolts that attach it to the auxiliary drive housing, accessory drive, or timing gear plate. Remove the compressor, gasket, and splined coupling, if so equipped.
11. Discard all mounting gaskets.

Installation

IMPORTANT: Be sure the gasket surfaces are cleaned and not damaged.

1. Install the splined coupling (if so equipped) and a new compressor gasket. Hold the compressor in place, and install the bolts that attach it to the auxiliary drive housing, accessory drive, or timing gear plate. See the engine shop manual or rebuild manual for final torque specification.
2. Install the compressor support bracket, if so equipped.
3. On Cummins and Detroit Diesel engines, install a new gasket, install the fuel pump. Connect the wire to the fuel shutoff valve (if so equipped). See the engine shop manual or rebuild manual for instructions.
4. With a new air governor mounting gasket, install the air governor.
5. Identify and connect all air, coolant, and oil lines to the compressor. Secure the lines as needed with tie straps.
6. Install the charge air cooler outlet air piping. Tighten the constant-torque hose clamp screws 45 lbf·in (500 N·cm).
7. Fill the engine cooling system; see **Group 20** in the vehicle workshop manual for instructions.
8. Operate the engine and check for leaks.
9. Remove the chocks from the tires and return the hood to the operating position.

Air Compressor Disassembly, Cleaning, Inspection, Assembly, and Testing

Disassembly

Be sure that required tools are available before beginning the service procedures described here. See the special tools table in **Specifications, 400**. The special tools required for the disassembly and assembly of the air compressor components are available from the Kent-Moore Tool Division, or an affiliated dealer.

1. Chock the front and rear tires.
2. Release the pressure from the air reservoirs.
3. On head-mounted governors, remove the two governor mounting bolts, then remove the governor and the gasket from the head. See **Fig. 1**

   On remote-mounted governors, disconnect both ends of the unloader tube, and remove the tube assembly.
4. Remove the two mounting bolts holding the air cleaner and the manifold to the head. Remove the air cleaner and the manifold as a unit.

NOTE: Some units are equipped with an air hose. In these applications, remove the air hose and then remove the air manifold from the head.

5. Remove the two unloader cover mounting bolts and the cylinder head bolt located through the center of the unloader cover. Remove the unloader cover and pull the unloader pin assemblies from the head.
6. Remove the five remaining head bolts. With a soft hammer, lightly tap the head assembly to loosen the head from the block. Lift the head from the block. Remove the gasket and discard.
7. Place the cylinder head on a table with the valve side up. Using an allen wrench, remove the exhaust valve seats. See **Fig. 2**. Remove the exhaust valve discs, springs and washers.
8. Using Kent-Moore socket J–25447–A, remove the intake valve cages. Remove the intake valve springs, valve discs, valve seats, and washers.
9. Remove the six cylinder block-to-crankcase mounting bolts and washers. Tap the cylinder lightly with a soft hammer to loosen the cylinder block from the crankcase. Remove the cylinder block from the crankcase leaving the pistons attached to the crankshaft. Remove the gasket and discard.
10. Remove the bottom plate on flange-mounted air compressors. Place flange- or base-mounted compressors on their side. Mark the rods and the rod caps to ensure reassembly to the original location. The rod, rod caps, and pistons must be reassembled exactly as they were removed.
11. Turn the crankshaft so that one rod and piston are at the full down stroke. Remove the two rod retaining bolts and remove the rod cap. Push the piston out of the top side of the crankcase. Repeat this step for the other piston.
12. Remove the rings from the pistons. Remove the retaining nylon buttons from the piston pins. Press the piston pin out of the piston and rod assembly.

⚠ CAUTION

Do not pry the main bearing caps off of the crankcase as damage to the caps may occur.

13. Remove the front and rear main bearing cap retaining bolts. Tap the main bearing caps loose from the crankcase. Remove the main bearing caps and gaskets from the crankcase. Remove and replace the oil seal from the front main bearing cap. If equipped, remove and replace the rear seal and spring.

NOTE: Do not remove the main bearings or the crankshaft unless replacing unsatisfactory parts.

14. On flange-mounted models, remove the drive hub with puller J–24420. Remove the flange mount.
15. On models with a rear ball bearing, place the crankcase assembly in a press supporting the rear bearing bore. Using bearing remover J–5154–B, press until the rear bearing is out of the bore.
16. On a sleeve-type rear bearing, place the crankcase assembly in a press with the front bearing bore supported. Using bearing remover J–5154–B, press until the front bearing is out of the bore.
17. With either the front or rear bearing out of the bore, remove the bearing from the crankshaft with puller J–4558–01 and J–22912–01. Use bearing remover J–5154–B and remove the opposite bearing from the bore. Using puller

Cleaning

1. Clean all parts with a cleaning solvent and dry with clean compressed air. Clean all passageways with compressed air to ensure no restrictions are present.

CAUTION

Make sure not to damage surfaces when cleaning. Surface damage could cause leakage.

2. Clean and remove all carbon build-up on the cylinder walls and head.
3. Clean the piston ring grooves and pistons.
4. Clean all gasket mating surfaces carefully.

Inspection

NOTE: See the applicable table in **Specifications, 400** for compressor specifications.

Cylinder Head Inspection

1. Check the cylinder head for cracks and damaged threads.
2. Check the valve discs for wear, cracks, pits, or grooves.
3. Check the unloader and valve springs for load at the specified height.
4. Check the exhaust valve guide diameter.
5. Measure the distance from the top of the exhaust valve seat to the valve seating surface. Measure the distance from the end of the exhaust valve stop spring seat surface.
6. Check the intake valve discs and seats.
7. Check the intake valve guide diameter.
8. Measure the distance from the top of the cage to the intake valve stop. Measure the distance from the intake valve seating surface to the valve cage contact surface. See **Fig. 3**.

10. Replace the head if the exhaust valve stop surface-to-valve spring seating surface measurement is not within specifications.
11. Check the unloader valve bore for wear, scoring, or pitting. Measure the unloader pin length.

Air Compressor Disassembly, Cleaning, Inspection, Assembly, and Testing

Piston and Piston Rod Inspection

1. Check the pistons for wear, scoring, or cracks. Ensure the piston ring groves are not cracked or broken.
2. Measure the piston diameter 90 degrees from the piston pin bore. Measure the cylinder wall bore. Ensure the piston-to-cylinder bore clearance does not exceed 0.008 inch (0.2 mm). Pistons are available in 0.02 inch (0.51 mm) oversize. If the clearance is beyond specifications, the piston must be replaced and the cylinder block must be rebored or replaced.
3. Check the piston pin fit. The pin should have a slip fit in both the piston and the rod. Maximum variation in the piston pin diameter is 0.003 inch (0.076 mm). Replace any part that does not meet specification. The rod and rod cap must be replaced as a unit.
4. Check the rod bearing inserts for scoring, pitting and wear. Ensure that the rod bearing-to-crankshaft clearance is 0.0021–0.0050 inch (0.053–0.127 mm). Replace the rod bearing inserts if they are not within specifications. Bearing inserts are available in 0.10 inch and 0.20 inch (0.25 and 0.51 mm) undersize.
5. Check the connecting rod side clearance between the rod bearing cap and the crankshaft. Clearance must not exceed 0.010 inch (0.25 mm). If not within specification, the rod and rod cap must be replaced as a unit.
6. Place new rings in the cylinder bore and measure the gap between the ring ends. Place the rings in each piston groove and measure the clearance between the ring groove and the ring. If not within specification, replace parts as necessary.

Cylinder Block, Crankcase and Crankshaft Inspection

1. Check the cylinder walls for cracks, scratches, scoring, and pitting.
2. Check the bore for out-of-round and taper. If out-of-round is more than 0.0005 inch (0.013 mm), the cylinder must be honed, rebored, or replaced. If the taper is more than 0.001 inch (0.03 mm), the cylinder must be honed, rebored, or replaced.
3. If the cylinder is within specifications, hone the cylinder walls to ensure a good crosshatch pattern.
4. Check the crankshaft and replace it if it is bent or twisted. If the crankshaft journals are worn or scored beyond repair, replace the crankshaft and the connecting rod as necessary.
5. Check the main bearing outside diameter and the crankcase bearing bore. Main bearings are not available in oversize or undersize. Check for excessive wear of the crankshaft main bearing journals. Replace the bearing or the crankcase as necessary.
6. On models with sleeve-type rear bearings, check the inside diameter of the rear bearing located in the rear cap. If the rear bearing cap assembly is not within specifications, replace it. Check the caps for cracks or excessive wear. Replace if necessary.
7. On models with a rear ball bearing, check the wear of the seal to the crankshaft. If the seal is grooved more than 0.005 inch (0.31 mm), replace it. Measure the outside diameter of the seal ring. Replace if necessary.
8. Some air compressors have bowed washers rather than oil seal springs. Check the washers for wear and replace them if worn.
9. Check the crankcase for cracks and damaged surfaces. Check the studs, if used, and replace them if they are bent or damaged.

Assembly

1. Coat the crankshaft, main bearings, rod bearings, pistons, piston rings, piston pins, and cylinder walls with new engine oil. If the crankshaft was removed, install the crankshaft and the main bearings in the crankcase.
   - 1.1 If equipped with a crankcase that has a notch in the front bearing bore, rotate the crankshaft until the front journal is aligned with the notch and install the crankshaft. If equipped with a crankcase that has no notch, install the crankshaft through the top of the crankcase.
   - 1.2 With either the front or the rear bearing out of the bore, install the bearing in the

crankshaft with puller J–4558–01 and J–22912–01. Use bearing remover J–5154–B to install the opposite bearing in the bore. Using puller J–4558–01 and J–22912–01, install the bearing in the crankshaft.

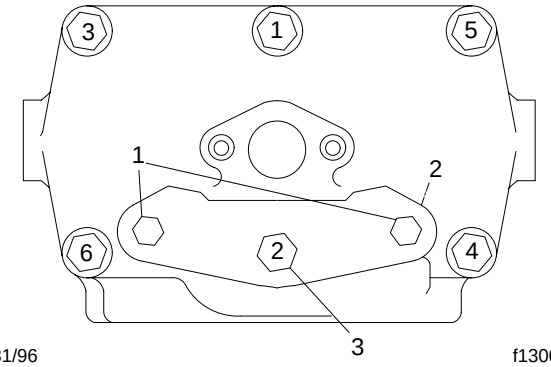
1.3 On models with a sleeve-type rear bearing, place the crankcase assembly in a press with the front bearing bore supported. Using bearing remover J–5154–B, press until the front bearing is in the bore.

1.4 On models with a rear ball bearing, place the crankcase assembly in a press supporting the rear bearing bore. Using bearing remover J–5154–B, press until the rear bearing is in the bore.

2. Replace the front main bearing cap seal. Coat the outside diameter of the seal with sealant. With the seal installed in the cap, it should be 0.00–0.005 inch (0.00–0.31 mm) below the front cap surface.
3. Replace the front cap gasket. Coat the front cap seal lip with new oil. Carefully slide the front cap over the crankshaft end. Install the mounting bolts and tighten evenly around the cap 10–14 lbf·ft (14–19 N·m).
4. On models with a sleeve-type rear main bearing cap, coat the bearing with new oil. Replace the gasket and install the rear cap on the crankshaft. Align the rear cap with the crankshaft bearing journal and the crankcase bearing bore. Install the mounting bolts and tighten evenly around the cap 10–14 lbf·ft (14–19 N·m).
5. On models with a rear main ball bearing, install the sealing ring spring or bowed washers in the cap. If bowed washers are used, make sure the outer diameter of the washer contacts the bottom of the rear cap bore. Place the sealing ring in the rear cap and lube with new oil.
6. Replace the gasket and install the rear cap on the crankshaft. Make sure the sealing ring or bowed washers are in the proper position. Install the mounting bolts and tighten them evenly around the cap 10–14 lbf·ft (14–19 N·m). After the front and rear main caps are installed, check the crankshaft to make sure it rotates freely.
7. Install a new gasket on the crankcase and place the cylinder block assembly on the gasket. Make sure the cylinder block is installed in the same position from which it was removed. Install the six mounting bolts and lockwashers. Tighten the two center bolts 8 lbf·ft (11 N·m), then tighten the four other bolts 8 lbf·ft (11 N·m). In the same sequence, tighten the bolts 27–33 lbf·ft (36–45 N·m).
8. Assemble the pistons and rods if disassembled. The piston and rod should move freely and the pin should not protrude from either side of the piston. Install the piston-pin retainer nylon buttons on both ends of the piston pin.
9. Each piston uses seven piston rings. Install two compression rings in the upper piston ring groove and two compression rings in the lower piston ring groove. Install two oil rings and one expansion ring in the middle piston ring groove. The compression rings are to be installed with the marked surface facing upward.
10. Position the piston ring gaps 120 degrees apart. Install the rod bearings on the piston rod assembly and the rod cap. Align the tab on the rod bearing with the notch in the rod and the rod cap. Install the rod and the rod cap in their original position.
11. Coat the rod bearing with new oil and remove the rod cap. Coat the cylinder walls with new oil. Compress the piston rings with a piston ring compressor and push the pistons into the cylinder until they are flush with the top of the cylinder. Rotate the crankcase assembly and install the cap on the rod with the arrows on the rod and cap aligned. Install the rod retaining bolts and tighten to specifications.
12. Repeat the above procedure for the second rod assembly.
13. Replace the gasket, install the bottom plate (if equipped), and tighten 9–13 lbf·ft (12–17 N·m). Rotate the crankshaft after assembly to ensure free movement. Some drag is allowed due to ring pressure on the cylinder walls.
14. Place the head on a table with the valve side up. Install a new washer in all four valve ports. See **Fig. 3**. Install the exhaust valve stop, spring, valve, and valve seat. Tighten the valve seat 70–90 lbf·ft (95–122 N·m). Repeat for the second exhaust valve assembly.

Air Compressor Disassembly, Cleaning, Inspection, Assembly, and Testing

15. Install the intake valve seat, valve, spring, and cage. The intake valve and valve spring must be centered so that the valve disc is not pinched between the cage and the seat during assembly. Using socket J–25447–A, tighten the intake cage 70–80 lbf·ft (95–108 N·m).
16. Place the head with the valve side down, then install the unloader spring. Replace the O-ring on the unloader pins. Apply Dow-Corning (33) lubricant to the seals forming a 0.563 inch (14.29 mm) diameter ball. Install the unloader pins in the head.
17. Place a new gasket on the unloader cover. Install the unloader cover and gasket over the unloader pins, compressing the pins into the head. Hold the cover in place and install the mounting bolts. Tighten the mounting bolts 10 lbf·in (120 N·cm).
18. Place a new head gasket on the cylinder block surface and place the head assembly on the cylinder block. Install the long head bolt in the center hole of the unloader cover. Install all head bolts and tighten in sequence 18–22 lbf·ft (24–30 N·m). See **Fig. 4**.



1. Unloader Cover Bolts
2. Unloader Cover
3. Long Head Bolt

Fig. 4, Head Bolt Tightening Sequence

CAUTION

Do not tighten the unloader cover bolts by mistake or damage will occur.

19. In sequence, tighten the head bolts 27–33 lbf·ft (37–45 N·m). See **Fig. 4**. Tighten the unloader cover bolts 8–11 lbf·ft (11–15 N·m).
20. Install the air cleaner and intake manifold assembly with a new intake gasket. Tighten the mounting bolts. Install the governor on the head with a new gasket and tighten the mounting bolts. On remote-mounted governors, install the unloader line.

Testing

1. If the compressor is belt driven and the pulley was removed or replaced, ensure that the pulley installed is the same diameter as the one removed. Attach an oil supply line with at least 10 psi (69 kPa) to the rear main bearing cap. Oil drainage must be unrestricted.
2. Attach a water supply which provides 1.5 gal/min (5.7 L/min) to the compressor. Attach a 0.625 inch (15.86 mm) inside diameter copper tube to an air tank of known capacity and to the air compressor discharge port. The air tank must have a quick-release valve to exhaust the air pressure. Attach an air line from the air tank to the reservoir port of the governor.
3. Attach the air compressor to a power source with the capability of running the air compressor at 1250 rpm. Run the compressor for five minutes at 1250 rpm, pumping against 100 psi (690 kPa). Check and adjust the governor at this time.
4. Check the air compressor for abnormal noise, oil leakage, air leakage, and overheating. Correct any problems at this time. Drain the air tank to zero pressure and close the quick-release valve.
5. Note the time required to fill the air tank to 100 psi. For the EL–1300, the time must not exceed 30 seconds per 1000 cubic inches of tank volume. For the EL–1600, the time must not exceed 24 seconds per 1000 cubic inches of tank volume. If not within specifications, see **Subject 300** for troubleshooting procedures.

Problem—Excessive Build-Up and Recovery Time

Problem—Excessive Build-Up and Recovery Time	
Possible Cause	**Remedy**
Restricted air intake.	Inspect the engine air filter and replace if necessary. Check the compressor air inlet for kinks and excessive bends. Repair if needed.
Restricted discharge or compressor discharge cavity.	Inspect the compressor discharge port and discharge line for carbon build-up. If carbon is detected, remove the carbon and check for proper coolant flow to the compressor. Inspect the discharge line for kinks and other restrictions. Repair or replace if necessary.
Loose drive coupling.	Inspect the fit of the drive coupling on the compressor crankshaft. Tighten or replace the components if necessary.
Excessive air system leakage (not including air compressor).	Inspect all the valves, air lines and connections for leakage. Repair or replace the valves and lines until the leakage is eliminated.
Malfunctioning unloading mechanism.	Check the operation of the unloading mechanism. Check for corrosion and contamination of the unloader pistons. Check for correct operation of the compressor governor. If the governor is operating properly, repair or replace the unloading mechanism.
Malfunctioning air pressure gauge.	Check the operation of the air pressure gauge. Replace if necessary.
Malfunctioning compressor.	Rebuild or replace the compressor after making certain that none of the preceding conditions exist.

Problem—Noisy Compressor Operation

Problem—Noisy Compressor Operation	
Possible Cause	**Remedy**
Loose drive coupling.	Inspect the fit of the drive coupling on the compressor crankshaft. Tighten or replace the components if necessary.
Compressor cylinder head or discharge lines.	Inspect the compressor discharge port and discharge line for carbon build-up. If carbon is detected, remove the carbon and check for proper coolant flow to the compressor. Inspect the discharge line for kinks and other restrictions. Repair or replace if necessary.
Damaged or worn bearings.	Replace the bearings.
Insufficient lubrication.	Inspect the oil lines for kinks or restrictions.
Malfunctioning compressor.	Rebuild or replace the compressor after making certain that none of the preceding conditions exist.

Problem—Compressor Fails to Unload

Problem—Compressor Fails to Unload	
Possible Cause	**Remedy**
Faulty or worn unloader pistons.	Inspect for worn, dirty, or corroded unloader pistons. Replace if necessary.
Malfunctioning governor.	Check the cut-in and cut-out pressures with an accurate test gauge. Repair or replace the governor if necessary.
Restricted unloader air lines.	Inspect the air lines to and from the governor for kinks and restrictions. Repair or replace the air lines if necessary.
Defective air pressure gauge.	Check the operation of the air pressure gauge. Replace if necessary.

Troubleshooting

Problem—Excessive Oil Passage

Problem—Excessive Oil Passage	
Possible Cause	**Remedy**
Restricted air intake.	Inspect the engine air filter and replace if necessary. Check the compressor air inlet for kinks and excessive bends. Repair if needed.
Restricted oil return line to engine.	Check for excessive bends, kinks, and restrictions in the oil return line. The return line must be routed down from the compressor to the engine crankcase. Repair if needed.
Excessive engine oil pressure.	Check the engine oil pressure with a test gauge and compare the reading to the engine specification.
Damaged oil seal ring or loose end cover.	Inspect the oil seal ring for wear or damage. Repair as needed. Check the end cover capscrew torques and tighten if necessary.
Malfunctioning compressor.	Rebuild or replace the compressor after making certain that none of the preceding conditions exist.

General Information

The Cummins 18.7 cfm compressor is used on the ISM and N14 engine. This compressor is a single cylinder engine-driven, piston-type compressor that supplies compressed air to operate air powered actuators on the vehicle. The compressor is geared directly to the engine which serves to operate the compressor and any accessory that is connected on the rear flange. The compressor will deliver air out of the exhaust port when the unloader port is at atmospheric pressure and will stop air delivery when the unloader port is pressurized to the system pressure between 100 to 125 psi (689 to 862 kPa). A governor determines the "cut-in" (start of pumping) and "cut-out" (termination of pumping) of the compressor by supplying the proper control signal to the unloader port. The governor is sensing the pressure in the air supply tank or "wet tank." If the output air pressure is inadvertently blocked or required to exceed 250 psi (1724 kPa), the compressor will stop air delivery. The air will be recycled within the compressor and no mechanical harm will be done.

Air Compressor Removal and Installation

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.

⚠ DANGER

Before tilting the cab or returning the cab to the normal operating position, read the instructions and hazard notices in Section 60.15. Failure to follow these instructions could cause the cab to fall and hit or crush a person, which will result in severe injury or death.

2. Tilt the hood or cab.
3. Drain the air reservoirs.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

4. Using a cleaning solvent, remove road dirt and grease from the outside of the air compressor, then dry the air compressor with compressed air.
5. Drain the radiator coolant below the level of the air compressor. See **Group 20** for instructions.
6. On Century Class conventionals, loosen the constant-torque hose clamps at both ends of the charge air cooler outlet air piping. Remove the piping to access the air compressor.
7. Marking their locations and positions, disconnect all air, coolant, and oil lines attached to the air compressor and governor. Remove the cushion clamps and tie straps as needed to move the lines out of the way. See **Fig. 1** and **Fig. 2**.
8. Disconnect the wire to the fuel shutoff valve (if equipped). Remove the fuel pump and gasket; refer to the engine shop manual or rebuild manual for instructions.
9. Remove the air compressor.

   9.1 Remove the air governor and mounting gasket from the compressor.

   9.2 Remove the compressor rear support bracket, if equipped.

   Note: On Argosy COE vehicles, the compressor is mounted on an alignment stud. The stud is at the top of the compressor mounting and allows the compressor to hang in place as you're removing or installing it. The stud is threaded and a nut is installed to secure the compressor.

   9.3 Support the air compressor, and remove the bolts that attach it to the auxiliary drive housing, accessory drive, or timing gear plate. Remove the compressor, gasket and splined coupling.

   9.4 Lift or lower the air compressor out of the engine compartment.

   9.5 Remove and discard the air compressor mounting gasket, and clean the mating surfaces.

Installation

IMPORTANT: Be sure the gasket surfaces are cleaned and not damaged.

1. Install the air compressor.

   Note: On Argosy COE vehicles, the compressor is mounted on an alignment stud. The stud is at the top of the compressor mounting and allows the compressor to hang in place as you're removing or installing it. The stud is threaded and a nut is installed to secure the compressor.

   1.1 Install the splined coupling (if equipped) and a new compressor gasket. Hold the compressor in place, and install the bolts that attach it to the auxiliary drive housing, accessory drive, or timing gear plate. Refer to the engine shop manual or rebuild manual for final torque specification.

   1.2 Install the compressor support bracket If equipped.

   1.3 Using a new air governor mounting gasket, install the air governor on the compressor.

2. Using a new gasket install the fuel pump on the air compressor. Connect the wire to the fuel shutoff valve (if equipped). Refer to the engine

3. Identify and connect all air, coolant, and oil lines to the compressor and governor. Secure the lines as needed with cushion clamps and tie straps.
4. On Century Class conventionals, install the charge air cooler outlet air piping. Tighten the constant-torque hose clamp screws 45 lbf·in (500 N·cm).
5. Fill the engine cooling system. See **Group 20** for instructions.
6. Operate the engine and check for leaks.
7. Remove the chocks from the rear tires.

⚠ DANGER

Before tilting the cab or returning the cab to the normal operating position, read the instructions and hazard notices in Section 60.15. Failure to follow these instructions could cause the cab to fall and hit or crush a person, which will result in severe injury or death.

Replacement

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Drain the air from all air reservoirs.
3. Remove the compressor from the vehicle. See **Subject 100** for instructions.
4. Mount the compressor on a suitable holding fixture.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

5. Using a cleaning solvent, remove road dirt and grease from the outside of the compressor, then dry the compressor with compressed air.
6. Remove the cylinder head assembly, from the crankcase.

   6.1 Scribe an alignment mark across the cylinder head and the crankcase, for assembly alignment.

   IMPORTANT: Do not use a marking method, such as chalk, that can be wiped off during assembly.

   NOTE: There is no need to remove the smaller screws.

   6.2 Note the positions of any attached components, then remove the four M8 cylinder head capscrews. Discard the capscrews. See **Fig. 1**.

   6.3 Tap the cylinder head with a soft mallet to break the gasket seal. Remove the cylinder head assembly and discard the gasket. See **Fig. 2**. Note the position of the ports with respect to the crankcase for reassembly.

   6.4 Remove the coolant and air fittings for reuse. Discard the original cylinder head.

7. Clean the crankcase.

   7.1 Rotate the crankshaft until the piston is at the top of the cylinder bore.

NOTE: Avoid the use of abrasive products similar to Scotch Brite® because of damage and abrasive grit left behind.

7.2 Remove any accumulated carbon and varnish by carefully scraping and light application of solvents. Avoid getting debris and solvents into the clearance between the piston and bore. Avoid the use of abrasive products similar to Scotch Brite because of damage and abrasive grit left behind.

Cylinder Head Replacement

WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

7.3 Using compressed air, blow dirt particles or gasket material from all cylinder cavities.

8. Inspect the top crankcase surface. It should be smooth and free of scratches to enable resealing on assembly.
9. Transfer the alignment marks from the original cylinder head to the replacement cylinder head.
10. Install the coolant and air fittings on the replacement cylinder head.
11. Install the cylinder head on the compressor crankcase.

    11.1 Position the sliding valve and the guide pins in the correct direction to enter the larger diameters in the valve body and crankcase.

    11.2 Align the marks on the cylinder head and crankcase.

    11.3 Using a new cylinder head gasket, position the gasket and head assembly on the crankcase.

    Note: You should find five cover bolts loosely holding the head assembly together.

    11.4 Install new capscrews.

CAUTION

A torque angle gauge and inch pound torque wrench must be used to perform the torque-turn capscrew tightening sequence. The tightening sequence in Table 1 must be followed to prevent damage to the cylinder head assembly.

11.5 Tighten the capscrews using the bolt tightening sequence in **Table 1**.

Troubleshooting Tables

Problem—Excessive Oil Passage

Problem—Excessive Oil Passage	
Possible Cause	**Remedy**
Restricted air intake.	Check engine air filter and replace if necessary. Check compressor air inlet for kinks and excessive bends. Repair as needed.
Restricted oil return hole in front of compressor.	Remove compressor and check the oil return hole for restrictions. Repair as needed.
Defective or worn seal in the rear bearing cap.	Replace seal.
Compressor runs loaded an excessive amount of time.	Check air lines and connections for leakage. Check for a defective governor or restricted line. Replace the governor if necessary. Repair or replace lines and connections until leakage is eliminated.
Back pressure from the engine crankcase.	Check for excessive engine crankcase pressure. Repair or replace ventilation components as necessary. NOTE: An indication of crankcase pressure is a loose or partially lifted dipstick.
Excessive engine oil pressure.	Check the engine oil pressure with a test gauge, and compare the reading to the engine specification. Do not restrict the compressor oil supply line.
Malfunctioning compressor.	Replace the compressor after making certain none of the preceding conditions exist.

Problem—Noisy Compressor Operation	
Possible Cause	**Remedy**
Loose drive coupling or gear (as indicated).	Inspect the fit of the drive coupling and gear on the compressor crankshaft. Tighten or replace the components. If the crankshaft keyway is damaged, replace the compressor.
Compressor cylinder head or discharge line restrictions.	Inspect the compressor discharge port and discharge line for carbon build-up. If carbon is detected, remove the carbon and check for proper coolant flow to the compressor. Inspect the discharge line for kinks and restrictions. Replace the discharge line as necessary.
Compressor internal engine components damaged or worn.	Replace the compressor.

Problem—Excessive Build-Up and Recovery Time

Problem—Excessive Build-Up and Recovery Time	
Possible Cause	**Remedy**
Restricted air intake.	Check engine air filter and replace if necessary. Check compressor air inlet for kinks and excessive bends. Repair as needed.

Problem—Excessive Build-Up and Recovery Time	
Possible Cause	**Remedy**
Restricted discharge or compressor discharge cavity.	Inspect the compressor discharge port and line for restrictions and carbon build-up. If carbon is detected, remove the carbon. Check for proper cooling to the compressor. Inspect the discharge line for kinks and restrictions. Replace the discharge line as necessary.
Slipping drive components.	Check for faulty drive gears and coupling, and replace as necessary.
Excessive air system leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.
Unloader piston seized.	Check the operation of the unloading mechanism. Check for corrosion and contamination of unloader pistons. Check for correct operation of the compressor air governor. If the governor is operating properly, replace the compressor.
Damaged compressor rings, valves, and gaskets.	Replace the compressor.

General Description

The function of the Bendix air compressors is to provide and maintain air under pressure to operate devices in the air brake system. See **Fig. 1** and **Fig. 2**. The Bendix BA-921 and 360cc air compressors are both single-cylinder reciprocating compressors with a rated displacement of 15.8 cubic feet per minute (cfm) at 1250 rpm. The Bendix BA-922 compressor is very similar to the BA-921 compressor, but has two cylinders and a rated displacement of 31.6 cfm at 1250 rpm.

stops or starts based on the cut-in and cut-out pressure settings of the governor.

The cylinder head assembly is made up of the cylinder head, cooling plate, and a valve plate assembly. The cylinder head contains the air and coolant ports as well as an unloader piston. The cooling plate is located between the cylinder head and valve plate assemblies, and assists in cooling the cylinder head assembly. The valve plate assembly, consisting of brazed steel plates, has several valve openings and channels for conducting air and engine coolant into and out of the cylinder head. The compressor is

The air governor operates in conjunction with the air compressor to maintain the air pressure in the air system between a maximum (cut-out) and minimum (cut-in) pressure. The air compressor turns continuously while the engine is on, but actual compression of air is controlled by the governor, which actuates the air compressor unloading mechanism. Unloading

cooled by air flowing through the engine compartment as it passes the compressor's cooling fins, and by the flow of engine coolant through the cylinder head. The vehicle's engine provides a continuous supply of oil to lubricate the compressor.

Bendix air compressors are typically equipped with a safety valve in the cylinder head safety valve port,

directly connected to the discharge port. The safety valve protects the cylinder head assembly in the event of excessively high discharge line pressure. Excessive air pressure causes the safety valve to unseat, releases air pressure, and gives an audible alert to the operator.

Replacement

1. Shut down the engine, apply the parking brakes, chock the tires, and open the hood.
2. Drain the air system.
3. Disconnect the batteries.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent eye injury could result from flying debris.

4. Using a cleaning solvent, remove road dirt and grease from the outside of the air compressor, then dry the compressor with compressed air.
5. Depending on the vehicle's engine and chassis specifications, the air compressor may be difficult to access behind the frame rail. It may be necessary to reposition or remove components above and below the frame rail that interfere with access to the compressor, such as battery cables and transmission oil cooler lines.

   Clear any wiring harnesses out of the way, removing P-clamps as necessary.
6. Remove any components attached to the air compressor, such as the fuel pump (Series 60 engines) or power steering pump (DD13/15/16 engines).
7. Drain the coolant from the radiator and cylinder block. For instructions, see **Group 20**.
8. Remove the coolant supply and return lines from the compressor. For a Bendix BA-921/922 compressor, see **Fig. 1**. For a Bendix 360cc compressor and line connections, see **Fig. 2** and **Fig. 3**.
9. Identify and disconnect all air and oil lines attached to the air compressor.
10. Remove the air governor and the air governor mounting gasket, if equipped, or remove the air governor remote line.

NOTICE

Do not allow the air compressor drive gear to make contact with the gear train during removal. Damage to the seal surface could cause oil leakage.

11. Support the air compressor and remove the mounting fasteners that attach the compressor to the engine. Remove the air compressor.
12. Discard all gaskets.

IMPORTANT: Ensure new gaskets are clean and not damaged.

13. Install a new air compressor gasket on the compressor.

NOTICE

Ensure the correct mounting capscrews are used to install the air compressor. If the wrong length is used, the cup plugs installed in the cylinder block can be pushed out into the gear train, causing damage to the gear train.

14. Using capscrews, attach the air compressor to the gear case. See **Table 1** for torque specifications.

15. If equipped with a compressor-mounted air governor, install a new gasket on the air governor and install the air governor on the compressor. If the vehicle has a remote-mounted air governor, connect the air governor remote line to the compressor.

IMPORTANT: Ensure that coolant lines connected to a Bendix 360cc compressor are equipped with an O-ring and O-ring retainer on both ends. After installing the lines, ensure that

Removal

1. Apply the parking brakes and chock the tires.
2. Drain the air tanks.
3. Open the hood. Clean the fittings and hose connections on the air compressor and power steering pump.
4. Drain the radiator coolant. For instructions, see **Group 20**.

IMPORTANT: Do not remove the power steering lines. Secure the lines and the pump so that they are out of the way.

5. Remove the two capscrews that attach the power steering pump to the air compressor and move the pump away from the compressor. See **Fig. 1**.

NOTE: Depending on vehicle configuration, it may be necessary to remove the brackets that attach the transmission cooler lines to the engine in order to obtain enough room to remove the compressor.

6. Remove and discard the O-ring located between the power steering pump and the cross plate.
7. Remove the cross plate located between the air compressor and the power steering pump.
8. Remove the three air lines from the air compressor (see **Fig. 2**), as follows.
   - 8.1 Remove the discharge air line and the elbow fitting. Check inside the discharge air line for carbon deposits and replace if necessary.
   - 8.2 Remove the unloader air line. Check the fittings for damage and replace if necessary.
   - 8.3 Loosen the hose clamp and remove the intake air line.
9. Remove all air fittings from the top of the compressor.
10. Remove the engine trim cover.
11. Remove the coolant delivery and return lines. Discard the seal rings. See **Fig. 3**.

13. Slide the drive gear away from the flywheel. Catch any oil that runs out and dispose of it properly.

Inspection

1. Install an SPX Kent-Moore locking device (J 46177) on the air compressor where the power steering pump connects to the air compressor. Tighten the capscrews until the air compressor drive is locked. This device locks the driveshaft to allow removal of the drive nut.
2. Remove the drive gear from the air compressor, as follows.
   - 2.1 Place the air compressor and locking device in a vise. Make sure the locking device is tightly secured and cannot slip out of the vise.
   - 2.2 Using an impact wrench, remove the drive nut from the drive gear.

   - 2.3 Remove the drive gear from the air compressor, using a gear puller if necessary.
   - 2.4 Discard the O-ring that seals the compressor housing to the engine block.
3. Inspect the drive gear for worn or broken teeth, spalling, and corrosion. If necessary, replace the drive gear.
4. Install a new O-ring on the air compressor housing. Install the drive gear. Tighten the drive nut 214 lbf·ft (290 N·m). See **Fig. 5**.

Installation

1. Using four capscrews, attach the air compressor to the engine. Tighten the capscrews 44 lbf·ft (60 N·m).

NOTE: Be sure to use the correct capscrew at each mounting location.

2. Install new seal rings on the coolant lines, then install the coolant lines on the air compressor. Tighten the hollow-core banjo capscrews 22 lbf·ft (30 N·m).
3. Install the engine trim cover.
4. Install the air fittings on top of the air compressor.
5. Install the three air lines on the air compressor, as follows.
   - 5.1 Install the discharge and unloader air lines. Make sure the O-rings are correctly installed on the fittings.
   - 5.2 Tighten the discharge and unloader air line fittings 60 lbf·ft (80 N·m).
   - 5.3 Install the intake air line and tighten the hose clamp.
6. Install the cross plate on the compressor output drive. Use grease to hold it in place while installing the power steering pump.
7. Install a new O-ring between the power steering pump and the cross plate.
8. Using two capscrews, attach the power steering pump to the air compressor. Tighten the capscrews 30 lbf·ft (40 N·m).
9. If the brackets that attach the transmission cooler lines to the engine were removed, install the brackets.
10. Fill the cooling system. For instructions, see **Group 20**.
11. Turn on the engine and check air line and coolant fittings for leaks. Correct any leaks as necessary.

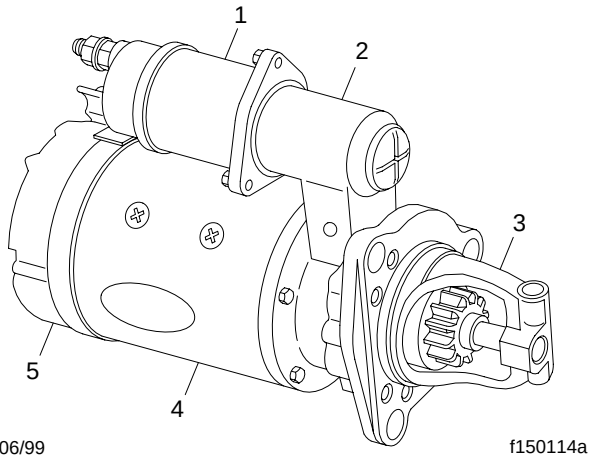
General Information and Principles of Operation

The Delco Remy starter (**see Fig. 1**) is located at the forward face of the flywheel bell housing on the left-hand side of the vehicle.

NOTE: On vehicles with the Detroit Diesel Series 55 engine, the starter is installed on the right-hand side.



1. Solenoid
2. Lever Housing
3. Nose Housing
4. Field Frame
5. End Cap

Fig. 1, 42-MT Starter Cranking Motor and Solenoid

The starter has a shift lever and solenoid plunger that are totally enclosed to protect them from exposure to dirt, icing conditions, and splash. The starter is equipped with a drive, solenoid, and brush rigging with one-piece brushes. The commutator end cap can be removed to inspect the brushes.

Lubrication is provided in the sintered bronze bushings by an oil-saturated wick. Oil can be added to each wick by removing an oil reservoir cup, which is accessible on the outside of the motor.

The solenoid engages the pinion with the ring gear and the pinion remains engaged until the solenoid circuit is interrupted. In case of a butt engagement, the pinion mechanism will rotate the pinion gear, clearing the butt engagement, engaging the ring gear, and causing the engine to crank.

Under normal operating conditions, no maintenance will be required between engine overhaul periods. At the time of engine overhaul, replace the starter with a remanufactured starter.

For the basic cranking circuit wiring, **see Fig. 2**.

Turning the ignition keyswitch to "Start" closes the magnetic switch contacts, connecting the battery to the solenoid. As a result, the plunger and the shift lever move, causing the pinion to engage the engine flywheel ring gear, closing the solenoid main contacts, and cranking the engine. When the engine starts, the pinion overruns, protecting the armature from excessive speed. When the ignition keyswitch is returned to the normal "Run" position, the pinion disengages.

To prevent overrun and damage to the drive and armature windings, release the ignition keyswitch from "Start" as soon as the engine starts. Never crank the motor longer than 30 seconds. Stop and allow the motor to cool for at least two minutes before cranking again.

The 42-MT starter is equipped with a thermal overcrank protection circuit. If overcranking should occur, a thermostat opens and stops the cranking cycle, protecting the cranking motor. After the motor cools, usually in 1 to 6 minutes, the thermostat will close and then a new start attempt can be made.

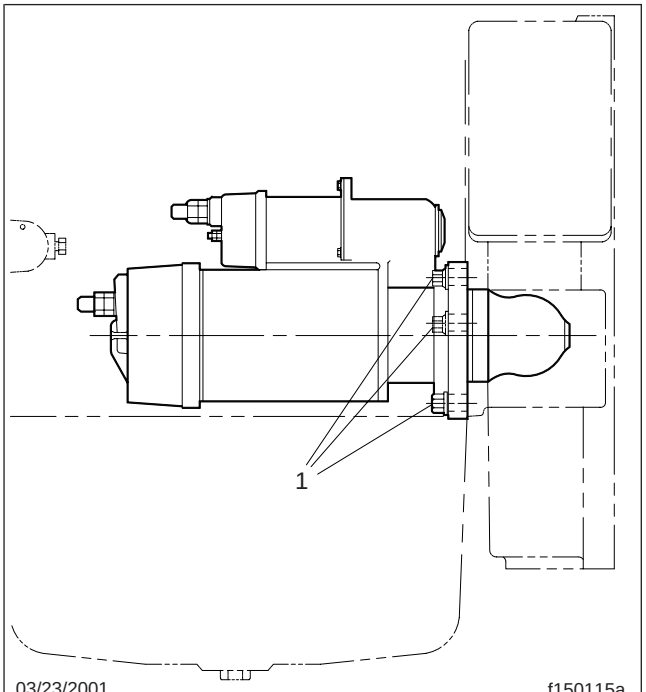
Removal

Before removing the starter from the vehicle for repair, perform the checks in **Troubleshooting 300**.

1. Turn off all electrical loads such as lights, ignition, and accessories.
2. Disconnect the batteries.
3. Tilt the hood or cab. For cab tilting instructions, refer to **Group 60** in this manual.
4. Disconnect the electrical leads attached to the starter. Mark the terminals and wires for ease of installation.

NOTE: It may be difficult to gain access to the starter mounting bolts. For ease of removal, straddle the front axle with arms extended around the leaf springs and use a long socket extender or breaker bar.

5. Remove the mounting bolts and lockwashers (**Fig. 1**) that attach the starter to the engine. Remove the starter.



1. Starter Mounting Bolts (with lockwashers)

Fig. 1, Starter Installation

Installation

1. Insert the starter nose housing through the mounting hole in the flywheel housing.
2. Install the three starter mounting bolts and lockwashers. Refer to the fastener and torque values table in **Specifications 400**.

NOTE: Torque values differ according to type of engine installed.

3. Connect the wires to the starter as previously marked. Tighten the nuts 16 to 30 lbf·in (180 to 340 N·cm).
4. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.

5. Connect the batteries.
6. Return the hood or cab to the operating position. For cab lowering instructions, refer to **Group 60** in this manual.

Ignition Keyswitch Removal and Installation

Removal

1. Disconnect the batteries.
2. Reach in underneath the keyswitch housing and remove the ignition keyswitch from the rubber grommet. It is not necessary to remove the keyswitch housing.
3. Remove the electrical connector from the rear of the keyswitch.

Installation

1. Connect the electrical connector to the ignition keyswitch.
2. Install the ignition keyswitch so that the flat side of the switch points inboard, towards the steering wheel.
3. Connect the batteries.

Problem—Starter Cranks Slowly or Not At All

Problem—Starter Cranks Slowly or Not At All	
Possible Cause	**Remedy**
The drive belt is loose.	Check the drive belt. See the drive belt subject in the appropriate engine section in **Group 01** for instructions. If necessary, tighten to the manufacturer's specifications. Start the engine and check the alternator voltage and output. See the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.
The drive belt is damaged or missing.	Check the drive pulleys for locked bearings. Repair or replace any damaged components. Replace the drive belt and start the engine. Check the alternator voltage and output. See the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.
The batteries are undercharged.	Do a load test on the batteries. See **Section 54.02** for instructions. Charge or replace batteries as needed. If the batteries were discharged, check the alternator voltage and output. See the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.
The battery cables do not deliver sufficient voltage to the starter.	Check the available cranking voltage. Go to "Available Cranking Voltage Test" for instructions.
The starter solenoid circuit is broken.	Check the starter solenoid circuit. Go to "Starter Solenoid Circuit Test" for instructions. Make repairs as needed. Start the engine to verify the repair.
The control circuit is broken.	Check the starter wiring. Go to "Starter Wiring Test" for instructions. Make repairs as needed. Start the engine to verify the repair.
The magnetic switch is broken.	Replace the magnetic switch. Go to **Section 54.04, Subject 100** for replacement instructions.
The starter ring gear or pinion gear is damaged.	Visually check the ring and pinion gears. Go to "Ring and Pinion Gear Test" for instructions.
The starter does not stay engaged.	Go to "Cold Weather Starting Test" for instructions.
The starter is damaged.	Replace the starter.
There is a mechanical problem in the engine.	See **Group 01** or the engine manufacturer's manuals.

Available Cranking Voltage Test

Battery Cable Test

1. Connect the positive lead of a carbon pile tester to the starter solenoid "B" (battery) terminal. Connect the negative lead of the carbon pile to the starter "G" (ground) terminal. See **Fig. 2**.

Troubleshooting

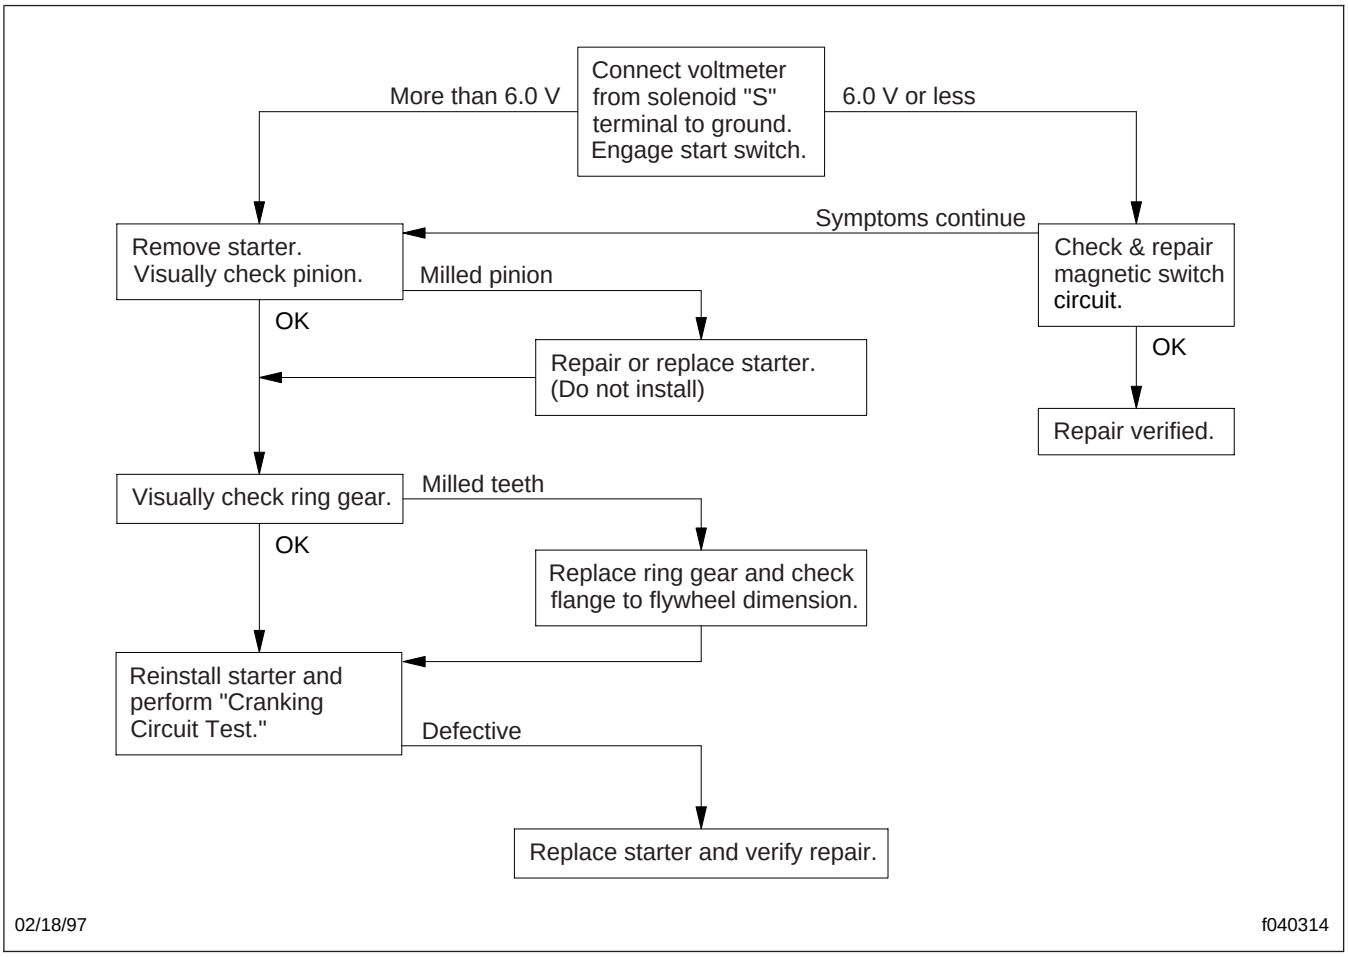

Fig. 1, Milled Pinion Symptoms

IMPORTANT: Connect the voltmeter to the starter "B" terminal, not to the carbon pile clamp.

2. Set a digital voltmeter on the low scale (2V, 3V, or 4V, depending on type of meter) and connect the positive lead to the battery positive (+) terminal. Connect the negative lead to the starter "B" terminal.
3. Turn on the carbon pile and adjust it to a 500-amp load. Read and record the voltage (V1) on the voltmeter. Turn off the carbon pile.
4. Now connect the digital voltmeter (still set on the low scale) to the battery negative (–) terminal and the starter "G" (ground) terminal.

IMPORTANT: Connect the voltmeter to the starter "G" terminal, not to the carbon pile clamp.

5. Turn on the carbon pile again and adjust it to a 500-amp load, as before. Read and record the voltage (V2) on the voltmeter. Turn off the carbon pile.

NOTE: Ignore the minus (–) sign.

6. Add the positive (V1) and the negative (V2) voltage loss readings together. If the total voltage loss is 0.500 volts or less, the battery cables are OK.

   Add the positive (V1) and the negative (V2) voltage loss readings together. If the total voltage

loss is more than 0.500 volts, repair or replace as necessary.

7. Disconnect the carbon pile and the voltmeter. Reconnect the magnetic switch to the starter "S" terminal.

Interconnecting Cable Test

1. This test requires two persons. While the first person cranks the engine, the second person uses a voltmeter to measure the voltage across the starter solenoid "B" (battery) and starter "G" (ground) terminals.
2. If the voltage is 9.0 volts or less while cranking, check the battery interconnecting cables.
   - 2.1 While cranking, measure the voltage across each battery.
   - 2.2 If the difference between any two batteries in the same battery box is more than 0.5 volt, check and replace the interconnecting cables as required.
   - 2.3 If any cable or connection feels warm to the touch, check and replace the interconnecting cables as required.
3. If the starter still does not crank, go to "Ring and Pinion Gear Test."

Starter Solenoid Circuit Test

The starter solenoid circuit includes the starter solenoid, cranking motor, magnetic switch, and ignition keyswitch. It is part of the cranking circuit. See **Fig. 3**.

If there is excessive voltage loss in the starter solenoid circuit, the starter may not engage the flywheel at all, or it may drop out too soon when battery voltage goes down. Do the following test to check for excessive voltage loss in the starter solenoid circuit.

1. Disconnect, at the solenoid, the lead from the magnetic switch to the "S" terminal on the starter solenoid.
2. Use a small clamp or 8-gauge jumper wire to connect this lead to the positive lead of a carbon pile tester. Connect the negative lead of the carbon pile to the starter "G" (ground) terminal. See **Fig. 4**.
3. Set a digital voltmeter on the high (20V) scale and connect the positive lead to the starter "B" (battery) terminal. Connect the negative lead to the magnetic switch lead to which the carbon pile is already connected.
4. Read and record (as V3) the battery voltage shown on the meter, about 12.6V.

NOTE: This step requires two persons.

5. Have one person turn the ignition keyswitch to the START position while the other person listens for the clicking sound of the magnetic switch closing. Read the voltage on the voltmeter. It should read very low voltage, less than 0.1V.

IMPORTANT: If the magnetic switch does not close, do the "Magnetic Switch Circuit Test." For instructions, see **Section 54.04**.

6. Check the starter solenoid circuit voltage loss.
   - 6.1 Turn the ignition key to the START position; then turn on the carbon pile and adjust it to a 100-amp load.

6.2 Now read and record (as V4) the voltage on the voltmeter. Turn off the carbon pile.

6.3 If the voltage drop (V4–V3) is 1.0V or less, the starter solenoid circuit is OK. Do the "Magnetic Switch Circuit Test." For instructions, see **Section 54.04**.

If the voltage drop (V4–V3) is more than 1.0V, the voltage loss is excessive. Go to "Starter Wiring Test."

Starter Wiring Test

1. Disconnect the lead from the magnetic switch to the "S" terminal on the starter solenoid (leave as in "Starter Solenoid Circuit Test").

IMPORTANT: It is difficult to gain access to the starter "S" terminal. Avoid touching the starter "B" terminal at the same time as the "S" terminal, as this can cause an electric shock.

2. Connect this lead to the positive lead of a carbon pile tester. Connect the negative lead of the carbon pile to the starter "G" (ground) terminal (leave as in "Starter Solenoid Circuit Test").

3. Set a digital voltmeter on the low scale and connect the positive lead of the voltmeter to the starter solenoid "B" (battery) terminal. Connect the negative lead of the voltmeter to the large terminal of the magnetic switch that is connected to the starter "B" terminal (circuit 15B). See **Fig. 5**. NOTE: If desired, do a continuity check on the circuit to be sure that it is connected to the correct terminal. Low resistance indicates that the connections are correct.

4. Have a second person start the engine momentarily.

IMPORTANT: If the magnetic switch does not close, do the "Magnetic Switch Circuit Test." For instructions, see **Section 54.04**.

5. Check the first wire voltage loss (V5).

   5.1 Turn the ignition key to the START position, then turn on the carbon pile and adjust it to a 100-amp load.

   5.2 Now read and record the voltage (V5) on the voltmeter. Turn off the carbon pile.

6. Now connect the positive lead of the digital voltmeter (still set on the low scale) to the magnetic switch lead which is already connected to the carbon pile (as in "Starter Solenoid Circuit Test"). Connect the negative lead of the voltmeter to the other large terminal on the magnetic switch (circuit 15C). See **Fig. 6**.

Fig. 6, Starter Wiring Test—Second Wire Voltage Loss (V6)

7. Have a second person start the engine momentarily.

8. Check the second wire voltage loss (V6).

   NOTE: Ignore the minus (–) sign.

   8.1 Turn the ignition key to the START position, then turn on the carbon pile and again adjust it to a 100-amp load.

   8.2 Now read and record the voltage (V6) on the voltmeter. Turn off the carbon pile.

   8.3 Add the two voltages (V5 and V6) together to get the total wire voltage loss. If the total wire voltage loss adds up to 0.8 volts or less, the wiring is OK. Replace the magnetic switch. For instructions, see **Section 54.04, Subject 100**.

   If the total wire voltage loss adds up to more than 0.8 volts, check the wire connections for tightness and the terminals for corrosion. Repair or replace as necessary.

9. Disconnect the carbon pile and the voltmeter. Reconnect the magnetic switch to the starter "S" terminal.

10. Check all wiring and connections and repair or replace as needed. For instructions on wire repair, see **Section 54.00**.

Magnetic Switch Circuit Test

For the "Magnetic Switch Circuit Test," see **Section 54.04**.

Ring and Pinion Gear Test

1. This test requires two persons. While the first person bars the engine over, the second person visually checks the entire flywheel ring gear and starter pinion gear visually (check all the teeth in both gears).

2. If the pinion teeth are damaged, replace the starter. If the ring gear teeth are damaged, replace the ring gear.

NOTE: For ring gear replacement procedures, see the engine manufacturer's manuals.

3. If the engine still does not crank properly after replacing the starter, look for a mechanical problem in the engine. For instructions, see **Group 01** or the engine manufacturer's manuals.

Cold Weather Voltage Test

In cold weather, the starter may fail to engage, even though it performed well at higher temperatures. Do the following test to check for cold weather voltage loss in the cranking circuit.

1. With the ignition keyswitch on, clamp a heavy battery jumper cable between the two large studs on the magnetic switch. Remove the jumper immediately to stop the engine from cranking.

2. If the engine starts with the jumper in place, do the "Starter Wiring Test." Repair/replace the wiring connections, terminals, and/or magnetic switch as necessary.

3. If the engine now starts properly, check the starter mounting bolts for tightness and do the "Alternator Wiring Test." See the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.

4. If the engine still does not start properly, go to "Available Cranking Voltage Test."

For a cranking circuit wiring diagram, **see Fig. 1**.

For a schematic of the engine starting circuit wiring harness, **see Fig. 2**.

General Description

The Leece-Neville JB series alternator is a 14-volt self-load-limiting alternator equipped with a three-step adjustable voltage regulator. See **Fig. 1**. For voltage regulator adjustment procedures, see **Subject 160**.

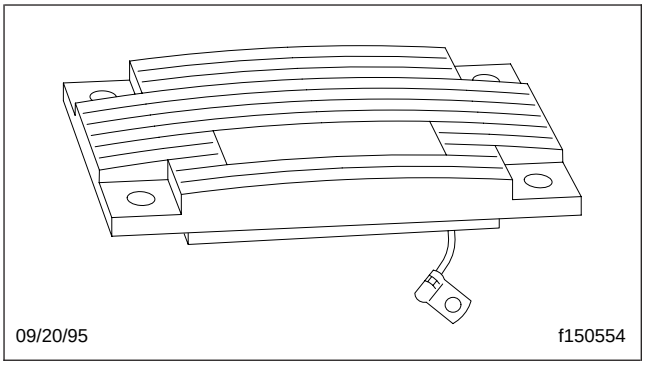

Fig. 1, Three-Step Adjustable Voltage Regulator

The optional SmartChek™ models feature a light-emitting diode (LED) that changes color to simplify troubleshooting. When the LED is green, the alternator is OK. When the LED is red, the alternator needs replacing.

Six silicon diodes mounted in heat sinks convert alternating current from the delta-wound stator into direct current. A capacitor connected between the heat sinks helps suppress transient voltage spikes, which could possibly damage the diodes.

The brushes and voltage regulator are located in a waterproof housing that may be removed for replacement or inspection. An external relay terminal is also provided for operation of a 7V battery isolator relay or other accessories that might require power from such a source.

The voltage regulator is also equipped with transient voltage protection and will withstand instantaneous opening of the charging circuit under full load conditions.

The LC models are identical to the JB models but are improved in the following ways:

- The rear rotor bearings are stronger and more durable;
- The diode post installation has been improved;
- The rectifier heat sink has a larger capacity.

The LCF models have all the same improvements as the LC models. In addition, the front bearing is secured with five bolts instead of four.

Mounting hardware and vehicle wiring require periodic inspection. See Group 15 of the *Century Class Trucks Maintenance Manual* for instructions.

Principles of Operation

Current is produced by rotating a magnet inside a stationary winding. The rotating magnet is called a rotor and the stationary winding is called a stator. See **Fig. 2**.

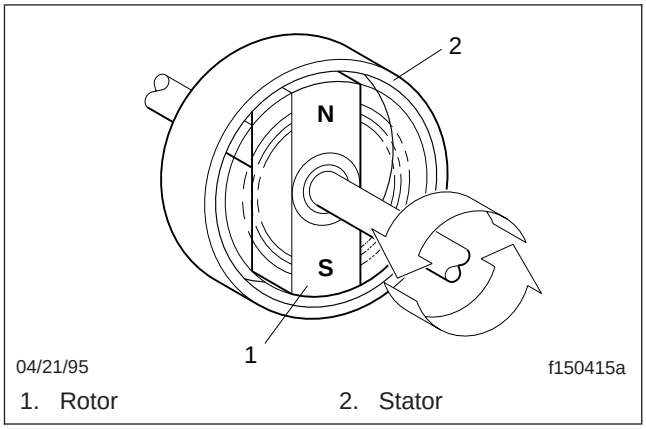

Fig. 2, Producing the Current

The rotor is electrically magnetized by a small current flowing through the brushes, riding on smooth slip rings. See **Fig. 3**. Alternating current is then produced as the magnetic poles of the rotor pass the coil windings of the stator.

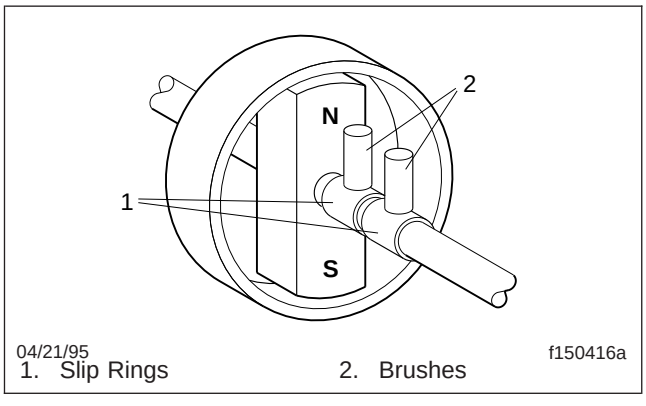

Fig. 3, Magnetizing the Rotor

General Information

These alternators have 12 magnetic poles in the rotor (see **Fig. 4**) and three separate windings in the stator (see **Fig. 5**). Since the rotor produces alternating current as it passes the coil windings of the stator, increased engine speed produces more current.

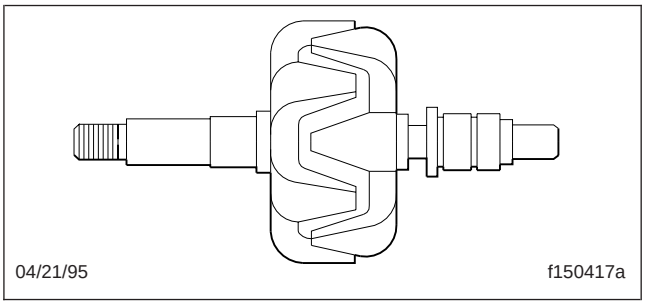

Fig. 4, Rotor

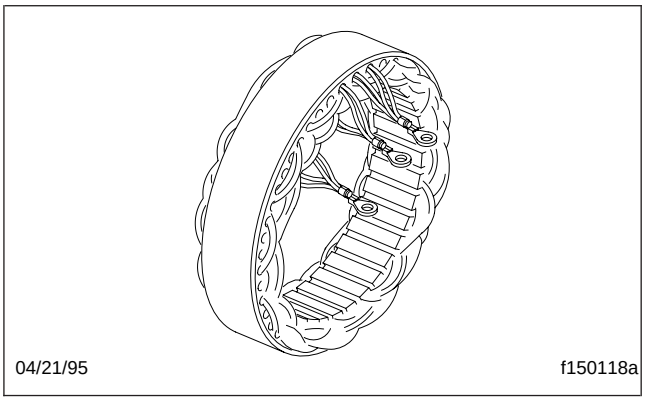

Fig. 5, Stator

Rectifier assemblies convert alternating current to direct current for storage in the batteries. Rectifiers consist of silicon diodes that work as electrical switches and permit current flow in only one direction. They are mounted in an aluminum casting, which is finned to dissipate heat. This is called a heat sink. See **Fig. 6**.

The voltage regulator (see **Fig. 1**) controls the alternator output and the state of charge of the batteries. It is used in the charging system to regulate the battery voltage to the vehicle.

The diode trio converts a small amount of alternating current from the stator into direct current which is used as a signal to turn on the regulator.

When the battery is charged, the regulator reduces the field current flow to the rotor. Reducing the field current flow, in turn, reduces the alternator output.

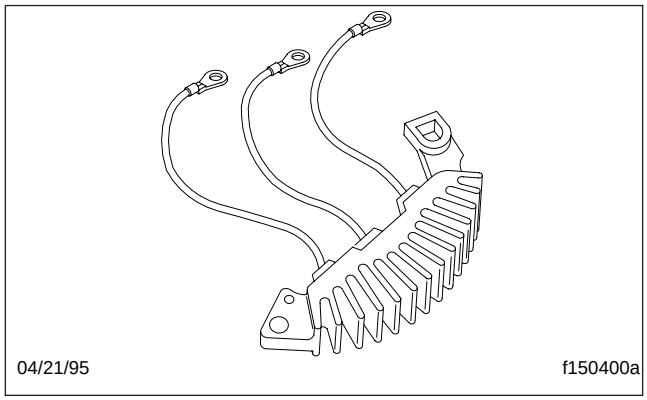

Fig. 6, Heat Sink

When the headlights or accessories place a load on the battery, the regulator increases the current flow to the rotor, and alternator output increases, to maintain voltage.

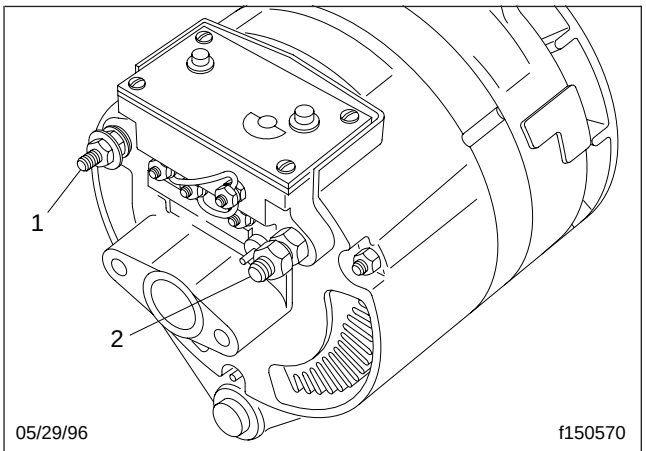
Removal

1. Disconnect the batteries.
2. Mark all electrical leads and disconnect them from the alternator. See **Fig. 1**.



1. Ground (G) Terminal
2. Output (BAT) Terminal

Fig. 1, Battery Lead Connections

3. Loosen the adjusting rod mounting capscrew (see **Fig. 2**, Ref. 8).
4. Loosen the end link mounting capscrew and the alternator mounting capscrew (see **Fig. 2**, Refs. 2 and 3). Turn the adjusting nut (Ref. 6) counterclockwise, backing the alternator toward the drive pulley far enough to remove the dual drive belts without prying or twisting the belts. Remove the drive belts from the vehicle.
5. Remove the adjusting rod jam nut (Ref. 4) and alternator mounting capscrew. Remove the alternator from the vehicle with the end link attached.
6. Inspect the drive belts. For instructions, see **Section 01.01, Subject 100**.

Installation

1. Check the torque of the alternator bracket fasteners. If necessary, tighten them 34 lbf·ft (46 N·m).
2. Install the alternator on the engine with the end link attached. Install the alternator mounting capscrew, but do not tighten it yet.

3. Install the drive belts on the pulleys. Do not pry or twist the belts. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m).
4. Tighten the adjusting nut (see **Fig. 2**, Ref. 6) until the belt is correctly tensioned. For belt tightening procedures and specifications, see **Section 01.01, Subject 110**. While holding the adjusting nut in place, install the adjusting rod jam nut and tighten it 95 lbf·ft (130 N·m).
5. Tighten the end link mounting capscrew and the alternator mounting capscrew 65 lbf·ft (88 N·m).

JB Series Alternator Removal and Installation, Cummins N14

Tighten the adjusting rod mounting capscrew 50 lbf·ft (68 N·m).

6. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).
7. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.

3. Loosen the adjusting block mounting bolt, adjusting arm mounting capscrew, and alternator mounting capscrew just enough to allow movement of the alternator. See **Fig. 2**.
4. Loosen the adjusting screw locknut. See **Fig. 2**, Ref. 4. Turn the adjusting screw (Ref. 7) counterclockwise, backing off the alternator toward the drive pulley far enough to remove the drive belt without prying or twisting the belt. Remove the belt from the vehicle.
5. Remove the adjusting block mounting bolt and the alternator mounting capscrew. Remove the alternator from the vehicle.
6. Inspect the drive belt. For instructions, see **Section 01.01, Subject 100**.

Installation

1. Check the torque of the alternator bracket fasteners. If necessary, tighten them 34 lbf·ft (46 N·m).
2. Install the alternator on the engine. Install the adjusting block mounting bolt and the alternator mounting capscrew, but do not tighten them yet.
3. Install the drive belt on the pulleys. Do not pry or twist the belt over the pulley. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m).
4. Turn the adjusting screw (see **Fig. 2**, Ref. 7) clockwise until the belt is correctly tensioned. For belt tightening specifications, see **Section 01.01, Subject 105**. Tighten the adjusting screw locknut (Ref. 4) 95 lbf·ft (130 N·m).
5. Tighten the alternator mounting capscrew (see **Fig. 2**, Ref. 3) 65 lbf·ft (88 N·m); tighten the adjusting block mounting bolt (Ref. 6) 30 lbf·ft (41 N·m); tighten the adjusting arm mounting capscrew (Ref. 8) 55 lbf·ft (75 N·m).
6. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).

Adjustment

NOTE: Before checking or adjusting the alternator voltage, check the wiring, connections, and belt tension.

1. Turn off all accessories. Run the engine at fast idle (approximately 1200 RPM) and charge the batteries.
2. Connect an accurate voltmeter across the batteries to determine the charging voltage. If the voltage is below 13.8V, or above 14.1V, adjust the voltage regulator.
3. Shut down the engine.
4. If needed, adjust the charging voltage.
   - 4.1 Remove the small black cap on the regulator cover to expose the adjustment screw.
   - 4.2 Using a small screwdriver, turn the adjusting screw until the voltage is between 13.8V and 14.1V.
     - To increase the voltage, turn the adjusting screw clockwise.
     - To decrease the voltage, turn the adjusting screw counterclockwise.
5. Run the engine at fast idle (approximately 1200 RPM) and check the voltage again to make sure it has been properly adjusted. Readjust as necessary.

NOTE: If adjustment does not bring the voltage into the proper range, replace the voltage regulator.

6. Shut down the engine.
7. Replace the plastic cap on the access hole over the adjusting screw.

Troubleshooting

Many alternators have been replaced that later investigation reveals were working properly. This may be due to incorrectly diagnosing the problem.

IMPORTANT: Before testing, make sure:

- All belts are correctly tightened;
- The wiring and terminals are clean and in good condition;
- All terminal nuts are torqued and properly protected.

To troubleshoot the SmartChek™ diagnostic alternator perform the following steps:

1. With the engine off, clean the top of the regulator using a shop cloth until you can see the SmartChek indicator.
2. Start the engine. If the SmartChek indicator glows red, replace the alternator.

   If the indicator glows green, go to the next step.
3. Turn on several vehicle accessories, such as lights and heater fans. If the green indicator changes to red, replace the alternator.

   If the indicator continues to glow green, the alternator is OK. Check the other components of the electrical system.

Delco Remy has an alternator testing tool called the Intelli-Check Alternator Analyzer. See **Fig. 1**. This tool (DR 10457848, a single tester, or DR 10457865, a four-pack of testers) is to be used as a quick check of the alternator to see if it is working correctly.

NOTE: If you do not have the Delco Intelli-Check Tester, or if the alternator rated output is above 145 amps, or if a total vehicle charging system analysis is required, see "Alternator/ Charging System Testing."

Intelli-Check Alternator Analyzer

The following information includes a pre-test procedure and operating instructions for the Delco Intelli-Check Tester, and is similar to the procedures provided by Delco with the Intelli-Check Tester.

Pre-Test Procedure (Engine Off)

1. Inspect the alternator connections to verify that all terminals are secured and tight. Verify that the sense wire is connected to the sense terminal on vehicles equipped with remote-sense alternators.
2. With the engine off, connect the red alligator clip to the output terminal of the alternator. Connect the black alligator clip to the alternator ground. An optional ground connection is to the body of the alternator. The tester LEDs will illuminate and then go off as it performs a self-test.
3. After 4 seconds the tester will activate. The following LEDs may illuminate depending on the condition of the batteries:
   - **GOOD** (green) LED indicates the battery voltage is above 12.8 and has a surface charge. The surface charge must be removed before proceeding with the alternator test. To remove the surface charge, do the following:
     A. Turn on the headlights and blower motor for 2 minutes without restarting the engine.
     B. Reset the tester by disconnecting, then reconnecting the tester alligator clips. The analyzer will again perform its self-test.
     C. Repeat the applicable steps of the Pre-Test Procedure.
   - **NO CHARGE** (red) LED indicates the battery voltage is below 12.8. This LED should illuminate for most tests. Proceed with the alternator test.
   - **LOW BATTERY VOLTAGE** (blue) LED indicates the battery voltage is below 12.35. If the batteries will start the vehicle, proceed with the alternator test. However, after completing the Intelli-Check alternator test, perform the procedures under "Alternator/Charging System Testing" to determine the condition of the rest of the charging system.

Tester Operating Instructions (Engine Running)

1. Start the engine using onboard batteries only. If the batteries will not start the engine, they must be charged for 2 hours. Start the test again after charging the batteries.
2. Verify the engine is at idle and all electrical loads are off.
3. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
   - If the **GOOD** (green) LED illuminates, proceed to the next step.
   - If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
   - If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/ Charging System Testing."
4. With the engine running, turn on all electrical loads.
5. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
6. If the **GOOD** (green) LED illuminates, the alternator is OK and the test is complete.

NOTE: If the alternator tests OK in the above tests, and the customer's complaint is reduced battery or headlight life, see "Alternator/ Charging System Testing" to completely analyze the charging system.

7. If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.

8. If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing."

Alternator/Charging System Testing

Battery Open Circuit Voltage Test, Alternator Output Voltage Test and Alternator Amperage Output Test

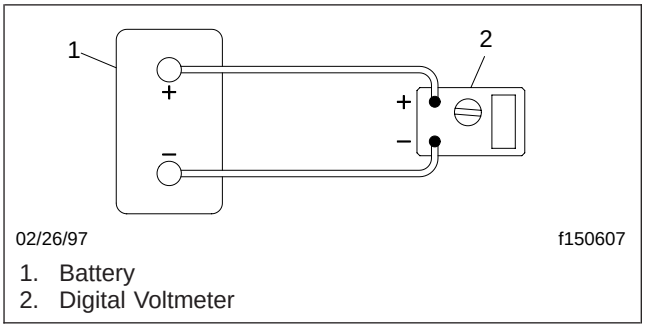
1. Use a digital volt-ohmmeter (VOM) set on the 2-20VDC (or similar) scale to test the battery open circuit voltage (OCV). With the engine shut down and the voltmeter set up as shown in **Fig. 2**, check for voltage of 12.4 volts or more.

   If the OCV is 12.4 volts or more, turn on the vehicle headlights for approximately 3 minutes.

   If the OCV is less than 12.4 volts, charge the batteries properly. For instructions, see **Group 54**.

IMPORTANT: Be sure to disconnect the batteries or remove them from the vehicle before charging.

2. Check the alternator output without a load. See **Fig. 3**.

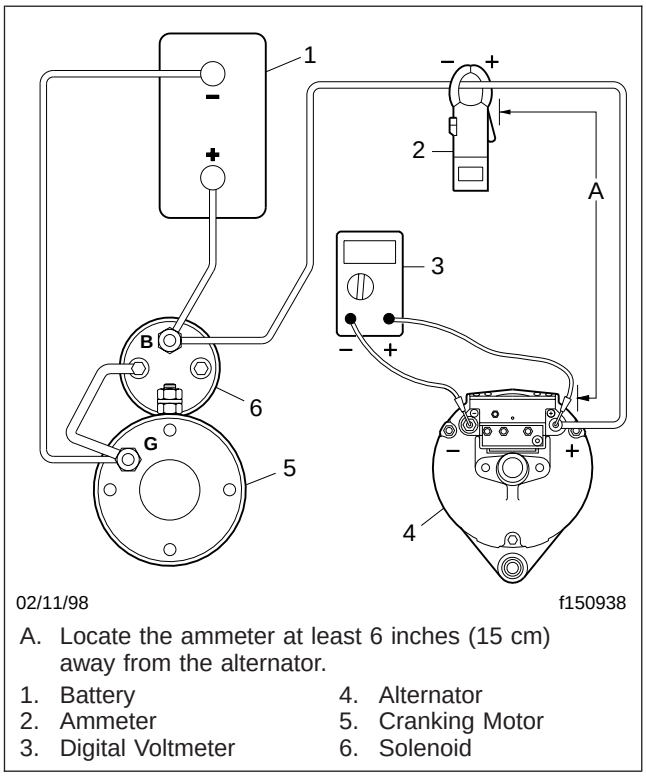


1. Battery
2. Digital Voltmeter

Fig. 2, Setup 1: Battery Open Circuit Voltage (and alternator amperage output)

2.1 Start the engine and run it at 1500 rpm for 3 to 5 minutes to stabilize the system before proceeding to the next step.

2.2 Connect the positive (+) lead of the digital voltmeter (still set on the 2-20VDC or similar scale) to the alternator (battery) terminal. Connect the negative (–) lead of the voltmeter to the alternator negative (–) ground terminal. See **Fig. 3**.



A. Locate the ammeter at least 6 inches (15 cm) away from the alternator.

1. Battery
2. Ammeter
3. Digital Voltmeter
4. Alternator
5. Cranking Motor
6. Solenoid

Fig. 3, Setup 2: Alternator Output Voltage

2.3 If the voltmeter reads from 13.8 to 14.2 volts, record this reading (V1) and go to the next step. If the alternator reads less than 13.8 volts and is adjustable, try to adjust the voltage regulator to 13.8 to 14.2 volts. If unable to obtain acceptable output, replace the alternator.

3. Check the alternator output under load. See **Fig. 3**.

   3.1 Attach a clamp-on induction ammeter around the positive (+) wire. See **Fig. 3**.

   NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

   3.2 With the engine still running at 1500 rpm, turn on the following electrical accessories to load the alternator until the ammeter reads 60 to 75 amps.

   - Both front and rear heater blowers (on HIGH)

Troubleshooting

- Headlights (high beams)
- Road lights
- Interior lights

NOTE: As an alternate method of putting load on the alternator, connect a carbon pile tester and set it to 60 to 75 amps.

3.3 Keep the voltmeter connected as in the previous step; positive (+) lead connected to the alternator positive (+) terminal; negative (–) lead connected to the alternator negative (–) terminal.

3.4 If the voltmeter reads from 13.6 to 14.2 volts, record this reading (V2) and go to the next step.

If the voltmeter reads less than 13.6 volts, replace the alternator.

4. Perform an alternator amperage output test.

4.1 Connect a carbon pile tester across the vehicle batteries as shown in **Fig. 2**.

NOTE: **Figure 2** shows a voltmeter, but the connections for the carbon pile tester are the same.

4.2 Attach a clamp-on induction ammeter around the alternator output wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

4.3 Start the engine and make sure all vehicle electrical accessories are turned off. Run it at fast speed and adjust the tester to the alternator maximum current output. Record this output value.

NOTE: Ensure that the alternator is turning at maximum available rpms and keep adjusting the tester dial until the ammeter reads its highest value.

4.4 Turn off the tester and shut down the engine.

4.5 If the output value recorded is less than 85 percent of the rated amperage output, repeat the test. If the output value recorded is still less than 85 percent of the rated amperage output, replace the alternator.

4.6 Make sure that all test instruments are removed and that the vehicle wiring is returned to its operational state.

5. To identify other problem areas within the vehicle, check the operation of the charging system. Set up the voltmeter as shown in **Fig. 2** and **Fig. 3**.

NOTE: For any load at 1500 rpm or more, battery voltage must be within 0.5 volts of the alternator voltage.

5.1 If readings at the batteries are within 0.5 volts of the readings at the alternator, the charging system is working correctly. Check other areas of the vehicle to locate the problem.

5.2 If the reading at the batteries is more than 0.5 volts lower than the reading at the alternator, do the next step.

6. Check charging system connections, cables and terminals.

6.1 Check all connections between the battery, starter and alternator for tightness and signs of corrosion. Tighten and clean as necessary.

6.2 Check all cables for breaks or partial breaks. Repair or replace as necessary.

6.3 Check each ring terminal for breakage at the point where it attaches to its wire or cable.

General Information

Delco Remy SI series alternators feature internally mounted integrated-circuit regulators and diode rectifiers, placed inside the end frame of the alternator. See **Fig. 1** for typical sectional and end views.

As vehicles are designed for higher efficiency, engine compartments are more tightly packed and operating demands are more challenging. In response to those developments and particularly the requirements of EPA07 vehicles, the 24-SI, 35-SI, 36-SI and later alternators are designed for high output in sustained temperatures up to 221°F (105°C).

The 35-SI and 36-SI are physically similar brushless alternators, but the 36-SI is designed to provide 100-amp output at low engine speeds, so that the engine does not need to run fast to power auxiliary devices and keep the batteries charged.

The 35-SI and 36-SI alternators may be used as direct replacements for earlier models, such as the 33-SI and 34-SI.

See **Fig. 2** for an end view of a typical 30-series alternator, in this case a 33-SI, cut away to show the regulator.

The 34–SI alternator is a specialized version of the 33–SI model, with two upper adjusting lugs for reduced susceptibility to vibration. All current-carrying conductors are stationary. These conductors are the field-winding stator components. The regulator and diodes are enclosed in a sealed compartment.

The rotor is the only moving part in the assembly. It is mounted on a ball bearing at the drive end, and a roller bearing at the rectifier end. For a sectional view, see **Fig. 1** for the 30–SI and **Fig. 3** for the 33–SI. Other models are similar.

All 30-series bearings are sealed so that no periodic maintenance is required.

See **Fig. 4** for terminal placement on the 30–SI, **Fig. 5** for terminal placement on the 33–SI and 34–SI, and **Fig. 6** for terminals on the 35-SI and 36-SI.

The output terminal connects to the battery's positive terminal.

The relay terminal labeled "R" is available on some alternators, to operate auxiliary equipment.

Terminal "I," where equipped, is an indicator circuit, to power an alternator warning light on the instrument panel.

2. Relay (R) Terminal
3. Indicator Light (I) Terminal
4. Remote Sense Terminal (Optional)

Fig. 6, 35-SI and 36-SI Wiring Connectors

The Remote Sense terminal (see **Fig. 6**) is available on some models such as the 35-SI and 36-SI. It connects to the batteries to monitor the state of battery charge and adjust alternator output, to keep the system at full charge.

Mounting Configuration

There are three alternator mounting configurations available to suit particular applications; see **Fig. 7**.

Most alternators have a cooling fan at the front end which sucks air through the housing from the back, exhausting out the front. The 24-SI (see **Fig. 8**) is a brush-type alternator with dual internal fans to suck cooling air in from both ends, exhausting out from the center of the casing.

Alternator Removal and Installation, Cummins N14

Removal

NOTE: Access to the alternator may be blocked by the radiator bypass tube and the heater pipe. The following information may be helpful in removing and replacing the alternator.

Draining the radiator and removing the heater pipe is quicker and easier than pulling the radiator fan. There are two tubes that cross over the top of the alternator. The smaller of the two is the heater pipe, while the larger one is the radiator bypass tube. The heater pipe is about 18 inches (46 cm) long and connects to a rubber hose on the frame rail. Disconnecting the brass fitting on the heater pipe where it enters the radiator bypass tube and pushing it to the side, allows easy access to the alternator. It is not necessary to remove the bypass tube.

Disconnect the electrical leads and the alternator bolts while the radiator is draining.

1. Disconnect the batteries.
2. Drain the radiator. For instructions, refer to **Group 20**.
3. Mark all electrical leads and disconnect them from the alternator.
4. Loosen the adjusting rod mounting capscrew (on the 33–SI, alternator, see **Fig. 1**; on the 30–SI, alternator, see **Fig. 2**).
5. Loosen the end link mounting capscrew and the alternator mounting capscrew (see **Fig. 1** or **Fig. 2**). Turn the adjusting nut counterclockwise, backing the alternator toward the drive pulley far enough to remove the dual drive belts without prying or twisting the belts. Remove the drive belts from the vehicle.
6. Disconnect the brass heater tube fitting at the radiator bypass tube and safely secure it out of the way.
7. Remove the adjusting rod jam nut and alternator mounting capscrew. Remove the alternator from the vehicle with the end link attached.
8. Inspect the drive belts. For instructions, see **Section 01.01, Subject 100**.

Installation

1. Check the torque of the alternator bracket fasteners. If necessary, tighten them 34 lbf·ft (46 N·m).
2. Install the alternator on the engine with the end link attached. Install the alternator mounting capscrew, but do not tighten it yet.
3. Install the drive belts on the pulleys. Do not pry or twist the belts. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m).
4. Tighten the adjusting nut (see **Fig. 1** or **Fig. 2**) until the belt is correctly tensioned. For belt tightening procedures and specifications, see **Section 01.01, Subject 110**. While holding the adjusting nut in place, install the adjusting rod jam nut and tighten it 95 lbf·ft (130 N·m).
5. Tighten the end link mounting capscrew and the alternator mounting capscrew 65 lbf·ft (88 N·m).

6. Connect all electrical leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).
7. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.
8. Connect the heater tube to the engine cooling inlet.
9. Service the radiator. For instructions, refer to **Group 20** in this manual.

Removal

1. Disconnect the batteries.
2. Mark all electrical leads and disconnect them from the alternator.
3. Loosen the adjusting block mounting bolt, adjusting arm mounting capscrew, and alternator mounting capscrew just enough to allow movement of the alternator. See **Fig. 1**.
4. Loosen the adjusting screw locknut. See **Fig. 1**, Ref. 4. Turn the adjusting screw (Ref. 7) counterclockwise, backing off the alternator toward the drive pulley far enough to remove the drive belt without prying or twisting the belt. Remove the drive belt from the vehicle.
5. Remove the adjusting block mounting bolt and the alternator mounting capscrew. Remove the alternator from the vehicle.
6. Inspect the drive belts. For instructions, see **Section 01.01, Subject 100**.

Installation

1. Check the torque of the alternator bracket fasteners. If necessary, tighten them 34 lbf·ft (46 N·m).
2. Install the alternator on the engine. Install the adjusting block mounting bolt and the alternator mounting capscrew, but do not tighten them yet.
3. Install the drive belt on the pulleys. Do not pry or twist the belt over the pulley. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m).
4. Turn the adjusting screw (see **Fig. 1**, Ref. 7) clockwise until the belt is correctly tensioned. For belt tightening procedures and specifications, see **Section 01.01, Subject 105**. Tighten the adjusting screw locknut (Ref. 4) 95 lbf·ft (130 N·m).
5. Tighten the alternator mounting capscrew (see **Fig. 1**, Ref. 3) 65 lbf·ft (88 N·m); tighten the adjusting block mounting bolt (Ref. 6) 30 lbf·ft (47

6. Remove the two mounting capscrews already loosened. Remove the alternator from the vehicle.
7. Inspect the drive belts. For instructions, see **Section 01.00, Subject 100**.

Installation

1. Install the alternator on the engine. Install the end link mounting capscrew and the alternator mounting capscrew, but do not tighten them yet.
2. Make sure the distance between the pulleys is short enough to allow belt installation without using force.
3. Work each belt over the fan blades, one blade at a time. Install both drive belts on the pulleys without prying or rolling them into place. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m). For belt tightening procedures and specifications, see **Section 01.00, Subject 110**.
4. After both belts have been correctly tensioned, tighten the adjusting rod jam nut 65 lbf·ft (88 N·m).
5. Tighten both the end link and alternator mounting capscrews 65 lbf·ft (88 N·m).
6. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).

NOTE: There are two drive belts to remove. Before removing the alternator belt, it is necessary to remove the refrigerant compressor belt from the fan pulley.

4. Holding the belt tensioner down, remove the drive belt from the alternator pulley. Slowly release the belt tensioner and remove the breaker bar.
5. Lower the drive belt, and take it off the vibration damper. It is not necessary to remove the belt from the vehicle.
6. Remove both alternator mounting capscrews. Remove the alternator from the vehicle.

NOTE: It is not necessary to remove the adjusting strap from the engine.

7. Inspect the drive belt. For instructions, see **Section 01.00, Subject 100**.

Installation

1. Check the torque of the adjusting strap mounting capscrew. If necessary, tighten it 65 lbf·ft (88 N·m).
2. Install the alternator on the engine. Install the alternator at the inboard edge of the slot initially. Install the top and bottom alternator mounting capscrews, but do not tighten them yet.
3. Install the drive belts on the pulleys, as removed. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m). For belt tightening procedures and specifications, see **Section 01.00, Subject 105**.
4. Verify that the edge of the tensioner arm is within the green zone on the decal. See **Fig. 2**. If within the red zone, pivot the alternator outboard until the tensioner arm enters the green zone.

NOTE: If the belt slips, repair or replace the tensioner. For instructions, see the Caterpillar C–10 & C–12 Diesel Truck Engine Service Manual.

5. When the alternator is correctly positioned, tighten both alternator mounting capscrews 65 lbf·ft (88 N·m).
6. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).
7. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.

1. Position the alternator on the engine and install the four mounting capscrews. Tighten the capscrews 43 to 54 lbf·ft (58 to 73 N·m).
2. Loop the drive belt around the pulleys.
3. Install the drive belt on the pulleys without prying or rolling it into place. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m). For belt tightening procedures and specifications, see **Section 01.02, Subject 105**.
4. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).
5. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.
6. Connect the batteries.
7. Before returning the vehicle to operation, test the alternator DC output voltage. For instructions, see "Alternator Voltage Output Test" in **Troubleshooting 300**.
8. Return the cab to the operating position. For cab lowering instructions, refer to **Group 60** in this manual.

34–SI QuadMount

1. Locate and support the alternator.
2. Install the four mounting bolts and lockwashers that attach the alternator to the engine. Tighten the capscrews 43 to 54 lbf·ft (58 to 73 N·m).
3. Connect the wires to the alternator as previously marked. Torque the nut for the battery cable 80 to 120 lbf·in (900 to 1350 N·cm). Torque the nut for the ground cable 50 to 60 lbf·in (560 to 680 N·cm).
4. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.
5. Rotate the battery switch to the ON position or re-connect the batteries.
6. Before returning the vehicle to operation, test the alternator DC output voltage. For instructions, see *Alternator Voltage Output Test* in **Troubleshooting, 300**, or use the Delco Remy Intellicheck.

Removal

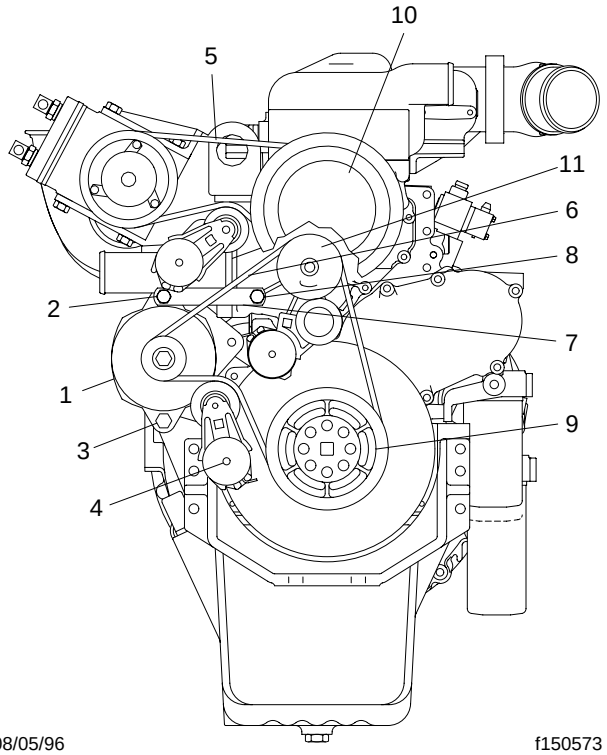
1. Disconnect the batteries.
2. Mark all electrical leads and disconnect them from the alternator.
3. Insert a breaker bar in the alternator belt tensioner (see **Fig. 1**, Ref. 4) and rotate the tensioner down and off the alternator drive belt.
4. Holding the belt tensioner down, remove the alternator belt from the alternator pulley. Slowly release the belt tensioner and remove the breaker bar.
5. Lower the drive belt, and take it off the vibration damper. It is not necessary to remove the belt from the vehicle.
6. Remove the top and bottom alternator mounting capscrews. Remove the alternator from the vehicle.
7. Inspect the drive belt. For instructions, see **Section 01.02, Subject 100**.

Installation

1. Check the torque of the adjusting strap mounting capscrew. If necessary, tighten it 65 lbf·ft (88 N·m).
2. Install the alternator on the engine. Install the two alternator mounting capscrews (top and bottom), but do not tighten them yet.
3. Install the alternator belt on the pulleys. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m). For belt tightening procedures and specifications, see **Section 01.02, Subject 110**.

NOTE: The Detroit Diesel belt tensioner automatically adjusts the alternator belt to the correct tension. If the belt slips, repair or replace the tensioner. For instructions, see the engine manufacturer's service literature.

4. Tighten both alternator mounting capscrews 65 lbf·ft (88 N·m).
5. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).



Rotate the belt tensioner down and off the belt.

Troubleshooting

Many alternators have been replaced that later investigation reveals were working properly. This may be due to incorrectly diagnosing the problem.

IMPORTANT: Before testing, make sure:

- All belts are correctly tightened;
- The wiring and terminals are clean and in good condition;
- All terminal nuts are torqued and properly protected.

Delco Remy has an alternator testing tool called the Intelli-Check Alternator Analyzer. See **Fig. 1**. This tool (DR 10457848, a single tester, or DR 10457865, a four-pack of testers) is to be used as a quick check of the alternator to see if it is working correctly.

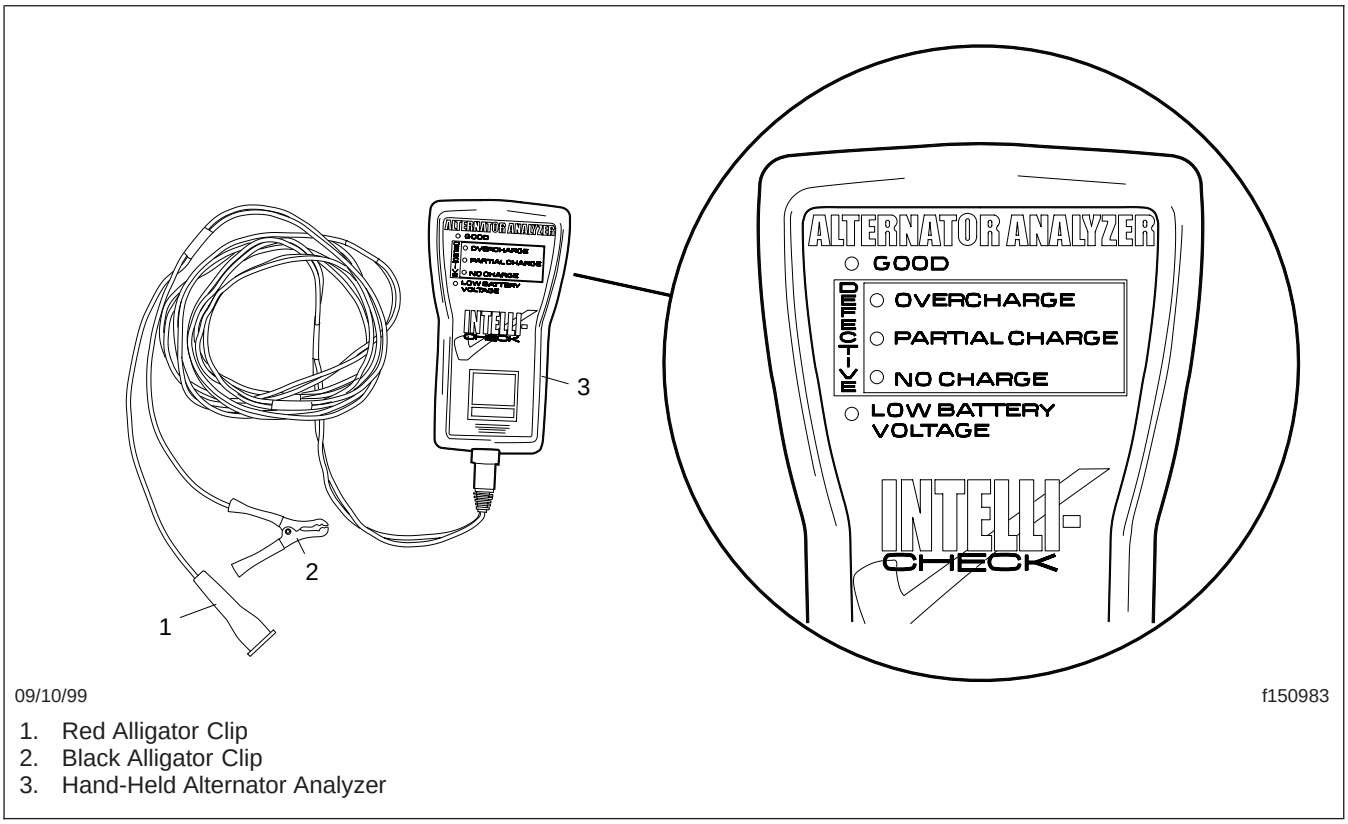
NOTE: If you do not have the Delco Intelli-Check Tester, or if the alternator rated output is above 145 amps, or if a total vehicle charging system analysis is required, see "Alternator/ Charging System Testing."

Intelli-Check Alternator Analyzer

The following information includes a pre-test procedure and operating instructions for the Delco Intelli-Check Tester, and is similar to the procedures provided by Delco with the Intelli-Check Tester.

Pre-Test Procedure (Engine Off)

1. Inspect the alternator connections to verify that all terminals are secured and tight. Verify that the sense wire is connected to the sense terminal on vehicles equipped with remote-sense alternators.
2. With the engine off, connect the red alligator clip to the output terminal of the alternator. Connect



1. Red Alligator Clip
2. Black Alligator Clip
3. Hand-Held Alternator Analyzer

Fig. 1, Delco Remy Intelli-Check Alternator Analyzer

the black alligator clip to the alternator ground. An optional ground connection is to the body of the alternator. The tester LEDs will illuminate and then go off as it performs a self-test.

3. After 4 seconds the tester will activate. The following LEDs may illuminate depending on the condition of the batteries:
    - **GOOD** (green) LED indicates the battery voltage is above 12.8 and has a surface charge. The surface charge must be removed before proceeding with the alternator test. To remove the surface charge, do the following:
        A. Turn on the headlights and blower motor for 2 minutes without restarting the engine.
        B. Reset the tester by disconnecting, then reconnecting the tester alligator clips. The analyzer will again perform its self-test.
        C. Repeat the applicable steps of the Pre-Test Procedure.
    - **NO CHARGE** (red) LED indicates the battery voltage is below 12.8. This LED should illuminate for most tests. Proceed with the alternator test.
    - **LOW BATTERY VOLTAGE** (blue) LED indicates the battery voltage is below 12.35. If the batteries will start the vehicle, proceed with the alternator test. However, after completing the Intelli-Check alternator test, perform the procedures under "Alternator/Charging System Testing" to determine the condition of the rest of the charging system.

Tester Operating Instructions (Engine Running)

1. Start the engine using onboard batteries only. If the batteries will not start the engine, they must be charged for 2 hours. Start the test again after charging the batteries.
2. Verify the engine is at idle and all electrical loads are off.
3. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
    - If the **GOOD** (green) LED illuminates, proceed to the next step.
    - If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
    - If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing."
4. With the engine running, turn on all electrical loads.
5. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
6. If the **GOOD** (green) LED illuminates, the alternator is OK and the test is complete.

NOTE: If the alternator tests OK in the above tests, and the customer's complaint is reduced battery or headlight life, see "Alternator/Charging System Testing" to completely analyze the charging system.

7. If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
8. If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing".

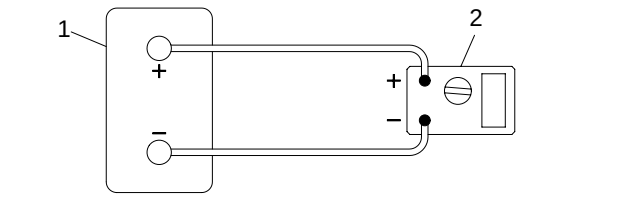
Alternator/Charging System Testing

Battery Open Circuit Voltage Test, Alternator Output Voltage Test and Alternator Amperage Output Test

1. Use a digital volt-ohmmeter (VOM) set on the 2-20VDC (or similar) scale to test the battery open circuit voltage (OCV). With the engine shut down and the voltmeter set up as shown in **Fig. 2**, check for voltage of 12.4 volts or more.

    If the OCV is 12.4 volts or more, turn on the vehicle headlights for approximately 3 minutes.

If the OCV is less than 12.4 volts, charge the batteries properly. For instructions, see **Group 54**.



1. Battery
2. Digital Voltmeter

Fig. 2, Setup 1: Battery Open Circuit Voltage (and alternator amperage output)

IMPORTANT: Be sure to disconnect the batteries or remove them from the vehicle before charging.

2. Check the alternator output without a load. See **Fig. 3**.

   2.1 Start the engine and run it at 1500 rpm for 3 to 5 minutes to stabilize the system before proceeding to the next step.

   2.2 Connect the positive (+) lead of the digital voltmeter (still set on the 2-20VDC or similar scale) to the alternator (battery) terminal. Connect the negative (–) lead of the voltmeter to the alternator negative (–) ground terminal. See **Fig. 3**.

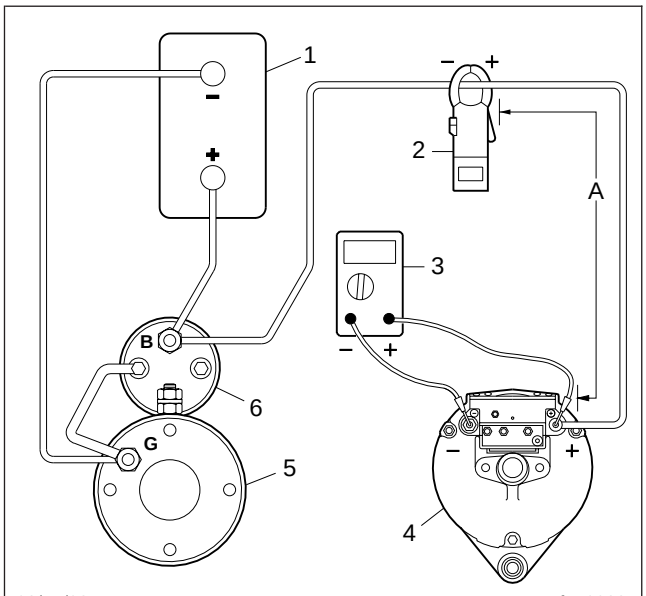
   2.3 If the voltmeter reads from 13.8 to 14.2 volts, record this reading (V1) and go to the next step. If the alternator reads less than 13.8 volts and is adjustable, try to adjust the voltage regulator to 13.8 to 14.2 volts. If unable to obtain acceptable output, replace the alternator.

3. Check the alternator output under load. See **Fig. 3**.

   3.1 Attach a clamp-on induction ammeter around the positive (+) wire. See **Fig. 3**.

   NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

   3.2 With the engine still running at 1500 rpm, turn on the following electrical accessories



A. Locate the ammeter at least 6 inches (15 cm) away from the alternator.

1. Battery
2. Ammeter
3. Digital Voltmeter
4. Alternator
5. Cranking Motor
6. Solenoid

Fig. 3, Setup 2: Alternator Output Test

to load the alternator until the ammeter reads 60 to 75 amps.

- Both front and rear heater blowers (on HIGH)
- Headlights (high beams)
- Road lights
- Interior lights

NOTE: As an alternate method of putting load on the alternator, connect a carbon pile tester and set it to 60 to 75 amps.

   3.3 Keep the voltmeter connected as in the previous step; positive (+) lead connected to the alternator positive (+) terminal; negative (–) lead connected to the alternator negative (–) terminal.

   3.4 If the voltmeter reads from 13.6 to 14.2 volts, record this reading (V2) and go to the next step.

Troubleshooting

If the voltmeter reads less than 13.6 volts, replace the alternator.

4. Perform an alternator amperage output test.

   4.1 Connect a carbon pile tester across the vehicle batteries as shown in **Fig. 2**.

   NOTE: **Figure 2** shows a voltmeter, but the connections for the carbon pile tester are the same.

   4.2 Attach a clamp-on induction ammeter around the alternator output wire. See **Fig. 3**.

   NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

   4.3 Start the engine and make sure all vehicle electrical accessories are turned off. Run it at fast speed and adjust the tester to the alternator maximum current output. Record this output value.

   NOTE: Ensure that the alternator is turning at maximum available rpms and keep adjusting the tester dial until the ammeter reads its highest value.

   4.4 Turn off the tester and shut down the engine.

   4.5 If the output value recorded is less than 85 percent of the rated amperage output, repeat the test. If the output value recorded is still less than 85 percent of the rated amperage output, replace the alternator.

   4.6 Make sure that all test instruments are removed and that the vehicle wiring is returned to its operational state.

5. To identify other problem areas within the vehicle, check the operation of the charging system. Set up the voltmeter as shown in **Fig. 2** and **Fig. 3**.

   NOTE: For any load at 1500 rpm or more, battery voltage must be within 0.5 volts of the alternator voltage.

   5.1 If readings at the batteries are within 0.5 volts of the readings at the alternator, the charging system is working correctly. Check other areas of the vehicle to locate the problem.

   5.2 If the reading at the batteries is more than 0.5 volts lower than the reading at the alternator, do the next step.

6. Check charging system connections, cables and terminals.

   6.1 Check all connections between the battery, starter and alternator for tightness and signs of corrosion. Tighten and clean as necessary.

   6.2 Check all cables for breaks or partial breaks. Repair or replace as necessary.

   6.3 Check each ring terminal for breakage at the point where it attaches to its wire or cable.

Required Equipment

See **Fig. 1** for a standard Delco Remy Tester.

NOTE: This equipment and the following tests may also be used to test Leece Neville alternators.

- Delco Remy alternators require a 2-1/2 inch V-belt pulley, p/n DR 10503932 (supplied with the Delco Remy tester).
- Leece-Neville alternators require a 3-1/2 inch V-belt pulley, p/n LN 107 22, and a 5/8-inch washer, p/n LN 120 129.

The tests in this subject require the following equipment:

- Alternator tester with the battery charged to at least 12.4 V (Delco Remy shown).
- Alternator to be tested.
- V-belt.
- Jumper lead to connect the BAT (+) alternator terminal to the remote sense terminal.
- Standard 5/8–18 hexnut, for mounting the pulley on the alternator. Use a standard hexnut, not the self-locking nut that is supplied with the alternator.

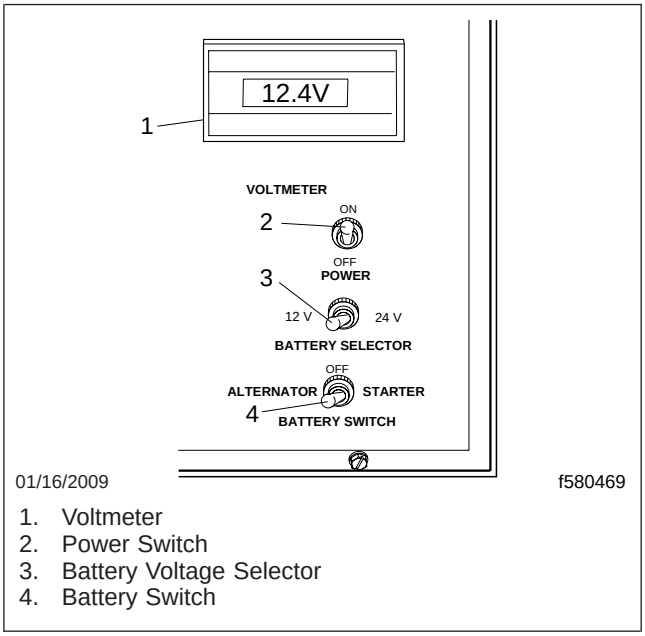
NOTICE

Repeatedly using self-locking nuts may damage the threads on the pulley shaft.

Alternator Bench Testing

Test Preparation

1. Set the battery voltage selector switch to 12V. See **Fig. 2**.



1. Voltmeter
2. Power Switch
3. Battery Voltage Selector
4. Battery Switch

Fig. 2, Alternator Tester Power Switches

2. Set the battery switch to "Alternator." See **Fig. 2**.

NOTICE

The next step supplies battery voltage to the alternator tester power and ground cables. Ensure that they are separated and insulated from each other, and that they are not touching conductive materials. Failure to observe this precaution could cause component damage.

3. Turn the tester power switch ON. See **Fig. 2**. Check the battery voltage in the voltmeter on the tester. The tester battery voltage must be at least 12.4V; if it is below 12.4V, charge or replace the tester battery as necessary. Turn the power switch OFF.
4. Mount the appropriate manufacturer's pulley on the alternator.
5. Mount the alternator on the tester.
   - 5.1 Run the belt from the largest V-groove of the bench motor drive pulley to the V-groove closest to the alternator on the alternator pulley. See **Fig. 3**. Do not use the serpentine belt groove.

2. V-Groove Closest to the Motor Pulley

Fig. 3, Belt Deflection with Alternator Mounted on Tester

   - 5.2 Move the vise to align the pulleys, so that the belt runs straight between the V-groove on the motor pulley and the V-groove closest to the alternator.
   - 5.3 Tension the V-belt with the hand wheel, so that it deflects 1/4-inch (6 mm) under hand pressure at the center of the run, then clamp the alternator in position.
6. Connect the electrical leads from the tester to the alternator. See **Fig. 4**. Take care that the tester power and ground cables are separated and insulated from each other, and that they are not touching conductive materials.
   - 6.1 Connect the red positive lead from the tester to the output terminal (BAT or +) on the alternator.

6.2 Connect the black negative lead from the tester to the output ground terminal (-) or to a mounting ear of the alternator.

7. Attach a jumper lead from the output terminal (BAT or +) to the remote sense terminal. Some testers have this jumper built-in on the positive lead, as shown in **Fig. 4**, Item 3; others may require a separate jumper as shown in **Fig. 5**.

Voltage Test

NOTICE

Ensure that the alternator tester power and ground cables are separated and insulated from each other, and that they are not touching conductive materials. Failure to do so could cause damage to the tester.

1. Turn the tester power switch ON. See **Fig. 2**, Item 2.

WARNING

The following steps involve spinning the alternator with the open V-belt; be careful that all loose objects, garments, hair, and hands are well clear of the alternator and belt, and use safety shields properly, or serious personal injury may occur.

2. Turn the motor switch (located on the lower left-hand portion of the tester) to the FORWARD position, to start the alternator free-spinning. See **Fig. 1**, Item 1.

NOTE: The voltage output limit applies only to a non-loaded alternator. The purpose of this test is to ensure that the alternator produces the proper voltage with no load (free-spin).

3. Record the alternator voltage output during free-spin. See **Fig. 2**, Item 1.
   - If the alternator output is between 13.5V and 14.7V, the alternator is functioning properly; proceed to the *Load Test*.
   - If the alternator output is not between 13.5V and 14.7V, the alternator is faulty and must be replaced.

Load Test

1. Calculate the test load for the alternator being tested. The test load is 80 percent of the alternator-output rating.

   Multiply the alternator-output rating by **0.8**, to calculate the test load.

   For example, an alternator with 100-amp output rating has an 80-amp test load (100 x 0.8 = 80).

NOTE: Contact a Delco Remy or Leece-Neville representative if you are unsure of the calculation.

2. Determine the appropriate load-control-switch setting to use for the alternator being tested. See **Fig. 1**, Item 2.

   Use the load-control-switch setting **equal to, or the next level below** the test load calculation.

   For example, on this tester the available settings are 20/40, 70/100, and 130/160 amp. The load-control-switch setting for the 100-amp alternator

would be 70 amp, because it is the available setting just below 80 amp.

NOTICE

Do not operate the alternator under load for more than 5 continuous seconds or damage to the alternator may occur.

3. Apply the appropriate load switch for 5 seconds then release.
4. Record the **difference** in voltage output between when the alternator is free-spinning, and under load.
    - For all alternators except Delco Remy 22SI, if the voltage difference between free-spin and loaded is more than 0.5V, the alternator is faulty and must be replaced. If the voltage difference between free-spin and loaded is less than 0.5V, the alternator is functioning properly.
    - For Delco Remy 22SI, if the voltage difference between free-spin and loaded is more than 1.0V, the alternator is faulty and must be replaced. If the voltage difference between free-spin and loaded is less than 1.0V, the alternator is functioning properly.
5. Turn the tester power switch OFF, then disconnect the electrical leads and jumper from the alternator.

General Description

The Delco Remy 26–SI alternator (see **Fig. 1**) is a self-rectifying, brushless unit. The integrated-circuit voltage regulator is designed for low-speed start-up. See **Fig. 2**. A special diode trio/capacitor assembly provides superior radio frequency interference (RFI) suppresion.

5. Relay (R) Terminal

Fig. 2, 26-SI Alternator Components (view from rectifier end)

The only moving part in the assembly is the rotor, which is mounted on a ball bearing at the drive end, and a roller bearing at the rectifier end. The field coil, stator windings, six rectifying diodes, and regulator circuit components are all stationary (brushless construction). See **Fig. 3**.

Standard load dump protection guards against voltage spikes caused by loose connections or interruptions in the charging line. The entire alternator is environmentally sealed to protect against dirt, road salt, and other corrosive materials.

A fan located on the drive end provides airflow for cooling. Extra-large grease reservoirs contain an adequate supply of lubricant so that no periodic maintenance is required.

Only one wire connects the alternator to the battery, along with a ground return. See **Fig. 1**. The specially designed output terminal (labeled "BAT") is connected directly to the battery. Since the vehicle's system is negative ground, the output terminal connects to the battery's positive terminal. A relay terminal (labeled "R") is available for use in some circuits to operate auxiliary equipment. The hexhead bolt on the output terminal is electrically insulated; no voltage reading can be obtained by connecting to the hexhead bolt.

Principles of Operation

As the rotor begins to turn, the permanent magnetism within induces voltage in the stator windings. The voltage across the six diodes causes current to flow, charging the battery. See **Fig. 4**.

Current from the stator flows through the three diodes to resistor R6 and the base-emitter of TR2 and TR1, to turn on these transistors.

Current also flows from the stator through the diode trio D1, D2, and D3, the field coil and transistor TR1,

returning to the stator through the other three diodes. All stator current, except through the diode trio D1, D2, and D3, flows through the six diodes connected to the stator.

Current flow through R1, R2, and R3 causes voltage to appear at the zener diode D4. When the voltage becomes high enough due to increasing alternator speed, D4 and the base-emitter of TR3 conduct current and turn on TR3. TR2 and TR1 then turn off, decreasing the field current and the system voltage. The voltage at D4 decreases; D4 and TR3 turn off; TR2 and TR1 turn back on and the system voltage increases. This cycle then repeats many times per second limiting the system voltage as determined by the setting of the potentiometer R2, and R3.

The capacitor C1 protects the diodes from high transient voltages and suppresses radio interference.

The resistor R5 prevents current leakage through TR3 at high temperatures.

The diode D5 prevents high transient voltages in the field coil when the field current is decreasing.

The resistor R7, capacitor C3, and resistor R4 all cause transistors TR2 and TR1 to turn on and off quickly.

Removal

1. Disconnect the batteries.
2. Mark all electrical leads and disconnect them from the alternator.
3. Loosen the adjusting rod mounting capscrew (see **Fig. 1**, Ref. 8).

4. Loosen the end link mounting capscrew and the alternator mounting capscrew (see **Fig. 1**, Refs. 2 and 3). Turn the adjusting nut (Ref. 6) counterclockwise, backing the alternator toward the drive pulley far enough to remove the dual drive belts without prying or twisting the belts. Remove the drive belts from the vehicle.
5. Remove the adjusting rod jam nut (Ref. 4) and alternator mounting capscrew. Remove the alternator from the vehicle with the end link attached.
6. Inspect the drive belts. For instructions, see **Section 01.01, Subject 100**.

Installation

1. Check the torque of the alternator bracket fasteners. If necessary, tighten them 34 lbf·ft (46 N·m).
2. Install the alternator on the engine with the end link attached. Install the alternator mounting capscrew, but do not tighten it yet.
3. Install the drive belts on the pulleys. Do not pry or twist the belts. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m).
4. Tighten the adjusting nut (see **Fig. 1**, Ref. 6) until the belt is correctly tensioned. For belt tightening procedures and specifications, see **Section 01.01, Subject 110**. While holding the adjusting nut in place, install the adjusting rod jam nut and tighten it 95 lbf·ft (130 N·m).
5. Tighten the end link mounting capscrew and the alternator mounting capscrew 65 lbf·ft (88 N·m). Tighten the adjusting rod mounting capscrew 50 lbf·ft (68 N·m).
6. Connect all leads to the back of the alternator as previously marked. Tighten the output terminal nut 100 lbf·in (1140 N·cm). Tighten the ground terminal nut 65 lbf·in (740 N·cm). For other terminals, tighten the nut 20 lbf·in (220 N·cm).
7. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.

NOTE: It is not necessary to remove the adjusting strap from the engine.

7. Inspect the drive belt. For instructions, see **Section 01.00, Subject 100**.

Installation

1. Check the torque of the adjusting strap mounting capscrew. If necessary, tighten it 65 lbf·ft (88 N·m).
2. Install the alternator on the engine. Install the alternator at the inboard edge of the slot initially. Install the top and bottom alternator mounting capscrews, but do not tighten them yet.
3. Install the drive belts on the pulleys, as removed. If installing a new pulley or a new alternator, tighten the pulley nut 75 lbf·ft (102 N·m). For belt tightening procedures and specifications, see **Section 01.00, Subject 105**.
4. Verify that the edge of the tensioner arm is within the green zone on the decal. See **Fig. 2**. If within the red zone, pivot the alternator outboard until the tensioner arm enters the green zone.

NOTE: If the belt slips, repair or replace the tensioner. For instructions, see the Caterpillar C–10 & C–12 Diesel Truck Engine Service Manual.

Troubleshooting

Many alternators have been replaced that later investigation reveals were working properly. This may be due to incorrectly diagnosing the problem.

IMPORTANT: Before testing, make sure:

- All belts are correctly tightened;
- The wiring and terminals are clean and in good condition;
- All terminal nuts are torqued and properly protected.

Delco Remy has an alternator testing tool called the Intelli-Check Alternator Analyzer. See **Fig. 1**. This tool (DR 10457848, a single tester, or DR 10457865, a four-pack of testers) is to be used as a quick check of the alternator to see if it is working correctly.

NOTE: If you do not have the Delco Intelli-Check Tester, or if the alternator rated output is above 145 amps, or if a total vehicle charging system analysis is required, see "Alternator/Charging System Testing."

Intelli-Check Alternator Analyzer

The following information includes a pre-test procedure and operating instructions for the Delco Intelli-Check Tester, and is similar to the procedures provided by Delco with the Intelli-Check Tester.

Pre-Test Procedure (Engine Off)

1. Inspect the alternator connections to verify that all terminals are secured and tight. Verify that the sense wire is connected to the sense terminal on vehicles equipped with remote-sense alternators.
2. With the engine off, connect the red alligator clip to the output terminal of the alternator. Connect the black alligator clip to the alternator ground. An optional ground connection is to the body of the alternator. The tester LEDs will illuminate and then go off as it performs a self-test.
3. After 4 seconds the tester will activate. The following LEDs may illuminate depending on the condition of the batteries:
    - **GOOD** (green) LED indicates the battery voltage is above 12.8 and has a surface charge. The surface charge must be removed before proceeding with the alternator test. To remove the surface charge, do the following:
        A. Turn on the headlights and blower motor for 2 minutes without restarting the engine.
        B. Reset the tester by disconnecting, then reconnecting the tester alligator clips. The analyzer will again perform its self-test.
        C. Repeat the applicable steps of the Pre-Test Procedure.
    - **NO CHARGE** (red) LED indicates the battery voltage is below 12.8. This LED should illuminate for most tests. Proceed with the alternator test.
    - **LOW BATTERY VOLTAGE** (blue) LED indicates the battery voltage is below 12.35. If the batteries will start the vehicle, proceed with the alternator test. However, after completing the Intelli-Check alternator test, perform the procedures under "Alternator/Charging System Testing" to determine the condition of the rest of the charging system.

Tester Operating Instructions (Engine Running)

1. Start the engine using onboard batteries only. If the batteries will not start the engine, they must be charged for 2 hours. Start the test again after charging the batteries.
2. Verify the engine is at idle and all electrical loads are off.
3. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
    - If the **GOOD** (green) LED illuminates, proceed to the next step.
    - If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
    - If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging sys-

tem using the instructions in "Alternator/ Charging System Testing."

4. With the engine running, turn on all electrical loads.
5. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
6. If the **GOOD** (green) LED illuminates, the alternator is OK and the test is complete.

NOTE: If the alternator tests OK in the above tests, and the customer's complaint is reduced battery or headlight life, see "Alternator/ Charging System Testing" to completely analyze the charging system.

7. If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
8. If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing".

Alternator/Charging System Testing

Battery Open Circuit Voltage Test, Alternator Output Voltage Test and Alternator Amperage Output Test

1. Use a digital volt-ohmmeter (VOM) set on the 2-20VDC (or similar) scale to test the battery open circuit voltage (OCV). With the engine shut down and the voltmeter set up as shown in **Fig. 2**, check for voltage of 12.4 volts or more.

   If the OCV is 12.4 volts or more, turn on the vehicle headlights for approximately 3 minutes.

If the OCV is less than 12.4 volts, charge the batteries properly. For instructions, see **Group 54**.

IMPORTANT: Be sure to disconnect the batteries or remove them from the vehicle before charging.

2. Check the alternator output without a load. See **Fig. 3**.

Fig. 3, Setup 2: Alternator Output Test

2.1 Start the engine and run it at 1500 rpm for 3 to 5 minutes to stabilize the system before proceeding to the next step.

2.2 Connect the positive (+) lead of the digital voltmeter (still set on the 2-20VDC or similar scale) to the alternator (battery) terminal. Connect the negative (–) lead of the voltmeter to the alternator negative (–) ground terminal. See **Fig. 3**.

2.3 If the voltmeter reads from 13.8 to 14.2 volts, record this reading (V1) and go to the next step. If the alternator reads less than 13.8 volts and is adjustable, try to adjust the voltage regulator to 13.8 to 14.2 volts. If unable to obtain acceptable output, replace the alternator.

3. Check the alternator output under load. See **Fig. 3**.

3.1 Attach a clamp-on induction ammeter around the positive (+) wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

3.2 With the engine still running at 1500 rpm, turn on the following electrical accessories to load the alternator until the ammeter reads 60 to 75 amps.

- Both front and rear heater blowers (on HIGH)
- Headlights (high beams)
- Road lights
- Interior lights

NOTE: As an alternate method of putting load on the alternator, connect a carbon pile tester and set it to 60 to 75 amps.

3.3 Keep the voltmeter connected as in the previous step; positive (+) lead connected to the alternator positive (+) terminal; negative (–) lead connected to the alternator negative (–) terminal.

3.4 If the voltmeter reads from 13.6 to 14.2 volts, record this reading (V2) and go to the next step.

If the voltmeter reads less than 13.6 volts, replace the alternator.

Troubleshooting

4. Perform an alternator amperage output test.

   4.1 Connect a carbon pile tester across the vehicle batteries as shown in **Fig. 2**.

   NOTE: **Figure 2** shows a voltmeter, but the connections for the carbon pile tester are the same.

   4.2 Attach a clamp-on induction ammeter around the alternator output wire. See **Fig. 3**.

   NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

   4.3 Start the engine and make sure all vehicle electrical accessories are turned off. Run it at fast speed and adjust the tester to the alternator maximum current output. Record this output value.

   NOTE: Ensure that the alternator is turning at maximum available rpms and keep adjusting the tester dial until the ammeter reads its highest value.

   4.4 Turn off the tester and shut down the engine.

   4.5 If the output value recorded is less than 85 percent of the rated amperage output, repeat the test. If the output value recorded is still less than 85 percent of the rated amperage output, replace the alternator.

   4.6 Make sure that all test instruments are removed and that the vehicle wiring is returned to its operational state.

5. To identify other problem areas within the vehicle, check the operation of the charging system. Set up the voltmeter as shown in **Fig. 2** and **Fig. 3**.

   NOTE: For any load at 1500 rpm or more, battery voltage must be within 0.5 volts of the alternator voltage.

   5.1 If readings at the batteries are within 0.5 volts of the readings at the alternator, the charging system is working correctly. Check other areas of the vehicle to locate the problem.

   5.2 If the reading at the batteries is more than 0.5 volts lower than the reading at the alternator, do the next step.

6. Check charging system connections, cables and terminals.

   6.1 Check all connections between the battery, starter and alternator for tightness and signs of corrosion. Tighten and clean as necessary.

   6.2 Check all cables for breaks or partial breaks. Repair or replace as necessary.

   6.3 Check each ring terminal for breakage at the point where it attaches to its wire or cable.

General Information

The Mitsubishi starter (MIB 970379FL), which weighs approximately 28 pounds (12.7 kg), uses a planetary gear reduction system. The starter attaches to the flywheel housing. In the area of the output shaft, the starter provides protection from dust, water, or oil splash for the inner starter parts. See **Fig. 1**, for a circuit diagram of the Mitsubishi isolated-ground type starter.

Fig. 1, Basic Starting Circuit (isolated-ground type)

Principles of Operation

When the start switch is closed (the switch is in the start position) current flows through the magnetic switch windings. The magnetic switch contacts close and current flows through the starter solenoid windings.

The starter clutch is thrust forward by movement of the plunger and the lever. See **Fig. 2**. Current flowing in the starter solenoid windings causes the pinion gear to slowly rotate. The pinion engages the ring gear and, when the pinion is securely engaged, the main solenoid contacts close and the starter cranks.

When the engine starts, the starter clutch prevents excessive overrun of the armature.

CAUTION

Release the start switch immediately when the engine starts, to prevent damage to the starter. Do not crank the starter for more than 30 seconds at one time or the starter may overheat. If you do crank the starter continuously for 30 seconds, wait 10 minutes to allow the starter to cool before attempting starting again.

Removal

Before removing the starter from the vehicle for repair, perform the checks in **Troubleshooting 300**.

1. Park the vehicle on a level surface. Shut down the engine, set the parking brake, and chock the tires.
2. Turn off all electrical loads such as lights, ignition, and accessories.
3. Disconnect the batteries.

⚠ DANGER

Before tilting the cab, review the cab tilting information in Section 60.15. Failure to read the warnings and to be aware of the dangers of tilting and lowering the cab could result in serious injury or death.

4. Open the hood or tilt the cab.
5. Disconnect the electrical leads attached to the starter, making note of the number of each and where they attach. Mark the terminals and wires for installation.

NOTE: It may be difficult to access the starter mounting bolts. Straddle the front axle with arms extended around the leaf springs and use a long socket extender or breaker bar.

6. Remove the three mounting bolts and lockwashers that attach the starter to the engine. Remove the starter.

Installation

1. Insert the starter nose housing through the mounting hole in the flywheel housing.
2. Install the three starter mounting bolts and lockwashers and tighten them securely.
3. Connect the wires to the starter as previously marked, making sure that all are accounted for. Make sure that all battery cables are routed so as to avoid contact with sharp edges and other chafe sites. Tighten the nuts 16 to 30 lbf·in (180 to 340 N·cm).
4. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.

5. Connect the batteries.

⚠ DANGER

Before tilting the cab, review the cab tilting information in Section 60.15. Failure to read the warnings and to be aware of the dangers of tilting and lowering the cab could result in serious injury or death.

6. Lower the hood or cab to the operating position.
7. Remove the chocks from the tires.

Battery

IMPORTANT: Before troubleshooting the starting system, ensure that the batteries are fully charged and in good condition. See **Group 54** for battery safety, testing, and charging procedures.

Wiring

Inspect the starting system wiring for damage, corrosion, and loose connections at the battery, the start switch, the magnetic switch, and at the starter solenoid. Make any necessary repairs.

Magnetic Switch

For magnetic switch test procedures, see **Section 54.04** Subject 300.

Ring Gear and Pinion

If the batteries, wiring, and magnetic switch are not faulty there may be damage to the ring gear and starter pinion teeth. This can cause the pinion to become locked by the ring gear and prevent pinion rotation and thrust motion. If you suspect this problem, remove the starter and inspect the pinion and ring gear end faces for damage or burrs. If necessary, replace the ring gear and the starter.

Starter

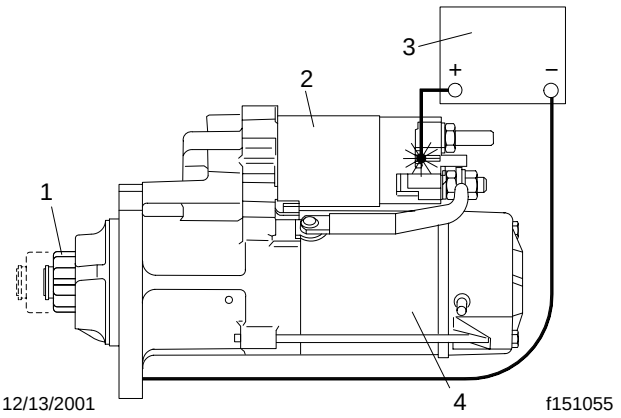
Pinion Movement/Solenoid Operation Test

Apply 8 to 12 volts between the solenoid S-terminal and ground. Watch the pinion to see if it moves forward. See **Fig. 1**.

NOTE: The starter will slowly turn at a few hundred rpms.

⚠ CAUTION

Do not apply voltage for more than 3 seconds or the solenoid may be damaged.



1. Pinion
2. Starter Solenoid
3. Battery
4. Starter Motor

Fig. 1, Testing Pinion Movement

If the pinion does not move forward, replace the starter. The pull-in winding in the solenoid may be shorted or the pinion may be blocked and will not slide. See **Fig. 2** for switch circuit diagrams for starter switch coils.

If the pinion is working properly, inspect the starter solenoid hold-in coil. Remove the M-terminal nut but keep the end of the wire in contact with the terminal. See **Fig. 3**. Apply voltage between the S-terminal and the ground (voltage applied to hold-in coil only) to cause the pinion to move forward. Immediately, remove the wire from the M-terminal and watch if the pinion remains in the forward position. If the pinion returns, you may assume that the hold-in coil is shorted. Replace the starter.

See **Specifications 400** for hold-in and pull-in coil resistance values.

Checking Output Shaft End Play

NOTE: Check the output shaft clearance before installing the starter on the engine.

1. Remove the M-terminal nut but keep the wire in contact with the terminal.
2. Apply voltage between the S-terminal and ground so that the pinion moves forward. Then, immediately remove the wire from the M-terminal.

General Information

Freightliner uses three sizes of traditional high-flow radiators in these vehicles. Century Class Conventionals use radiators that are 1000-square-inch and 1200-square-inch front areas. Argosy COEs use a 1300-square-inch radiator. All sizes are high-flow, single-pass radiators with plastic end-tanks. All are two-row radiators with 14 fins per inch. Century Class Conventional radiators are cross-flow and Argosy COE radiators are down-flow.

In high-flow cooling systems, most coolant in a warm engine is routed through the radiator. The coolant moves relatively quickly through the radiator in a single pass.

In a typical engine and radiator system, coolant flows from the radiator outlet to the water pump, from the water pump through the oil cooler, then the engine cylinder block water jacket, then the head. For typical engine coolant plumbing, see **Fig. 1**.

If the engine is cold, the engine thermostat stays closed, and water leaving the head flows back down to the water pump and the oil cooler.

If the engine is warm, the thermostat opens and coolant is forced to flow into the upper end of the driver-side radiator end tank. The coolant flows across the core, where is is cooled by ram air entering through the vehicle grille. When the coolant reaches the bottom end of the radiator passenger-side end tank, the coolant flows back out to the water pump. For the temperature that opens the thermostat on each model of engine, see **Table 1**.

The surge tank holds extra coolant, which travels down through the fill hose to the engine as needed. The low coolant level sensor in the surge tank warns the driver when coolant is running low. The surge tank is translucent polypropylene so you can see the coolant level and compare it to the maximum and minimum levels marked on the tank. See **Fig. 2**.

To prevent gas from getting trapped in the radiator or engine, vent lines run from the highest point in the radiator and engine to the surge tank. To prevent the coolant from boiling, the coolant is pressurized 11 to 12 psi.

To add coolant to Century Class Conventionals, remove the large cap on the outboard end of the tank. The standard, metal SAE cap on top of the tank is used for pressure relief and vacuum-break functions only. If too much pressure builds up in the coolant system, excess coolant will vent through the SAE cap and escape through an overflow hose.

General Information

To add coolant to Argosy COEs, remove the metal cap from the right side of the surge tank. The surge tank is mounted on top of the radiator.

When the cab heater is activated, hoses carry some of the coolant into the cab where it flows through the heater core to warm the cab air. This coolant returns to the engine/radiator cooling system.

For more information about the radiator and surge tank, see **Section 20.01**.

Troubleshooting

Possible causes of hot or cold engine coolant temperatures are listed below. For repairs, refer to other sections of this manual or to the engine and component manufacturers' service publications.

Problem—Coolant Temperature Above Normal

Problem—Coolant Temperature Above Normal	
Possible Cause	**Remedy**
Coolant leakage (see possible sources below) is causing a low coolant level. External Leakage:hoses and hose connections, radiator seams, core, draincock and cap, block core and drain plugs, water pump thermostat housing(s), overflow and surge tank, heater hoses and core, temperature sending unit(s), cylinder head(s) mating (gasket) surfaces, coolant filter, oil cooler(s) Internal Leakage: cylinder head gasket, warped head or block surfaces, cracked cylinder head or block, cylinder head capscrews loose, missing, or tightened unevenly; oil cooler, air compressor cylinder head and gasket cylinder liners, liner seals aftercooler	Perform the repairs necessary to stop leakage. Fill to the bottom of the radiator fill neck with the correct mixture of antifreeze and water.
The temperature gauge is not working.	Check the gauge circuit wires, circuit breaker, and sending unit. If the gauge circuit is okay, replace the temperature gauge. If the gauge circuit is broken, repair it and then check temperature gauge operation
The radiator fins, the aftercooler, or the air conditioner condenser fins are clogged.	Clean the outside of the core, the aftercooler, and the condenser with compressed air directed from the fan side, or with water and a mild laundry soap. Straighten bent fins.
A radiator hose is collapsed or plugged.	Replace hoses.
A fan drive belt or the water pump belt is loose.	Adjust belt tension.
The cooling fan shroud is damaged.	Repair or replace the shroud.
The radiator cap is incorrect or malfunctioning.	Make sure the correct radiator cap is installed. If the cap does not hold the correct pressure, replace it.
The on-off fan clutch is not working.	Check the solenoid valve in the fan clutch air supply line, the sending unit for the valve, and the operating air pressure to the valve. If valve operation and air pressure are okay, repair or replace the fan clutch. If the valve doesn't work or if air pressure is low, make repairs and then check fan clutch operation.
The engine oil level is incorrect.	Fill to the high (H) mark on the dipstick.
There is too much antifreeze or coolant additive in the system.	Clean and flush the cooling system. Refill the system with the correct mixture of antifreeze and water, and install the correct additive and filter, or treatment filter.

Troubleshooting

Problem—Coolant Temperature Above Normal	
Possible Cause	**Remedy**
One or both of the thermostats is incorrect or inoperative.	Make sure the correct thermostat is installed. Test the thermostat according to the engine manufacturer's instructions. Replace it if it does not operate correctly.
The water pump is not working correctly.	Repair or replace the water pump.
The radiator core is internally plugged or damaged.	To check for blockages, warm the engine to normal operating temperature. Turn off the engine, and run your hand over the finned surface of the radiator. If there is a blockage in the radiator, it should cause an obvious temperature difference from one area of the core to another. An obvious difference between inlet and outlet temperature is normal. If blockage is suspected, clean and flush the cooling system. Repair or replace a damaged core.
Air or combustion gases are entering the cooling system.	Check the cylinder head(s), head gasket(s), cylinder liners, aftercooler, air compressor cylinder head, and fan/shutter air control valve (if applicable) for leaks. Repair or replace parts, as necessary.
The aftercooler is plugged or damaged.	Repair or replace the aftercooler.
The oil cooler is plugged or damaged.	Repair or replace the oil cooler.
The engine is receiving too much fuel.	Refer to the engine manufacturer's fuel delivery system adjustment procedures
The wrong fan (replacement unit) is installed.	Install the correct fan.
The wrong radiator (replacement unit) is installed.	Install the correct radiator.
There is exhaust blockage.	Repair the exhaust system.
There is frozen coolant in the radiator.	Use the proper antifreeze-to-water ratio needed for winter temperatures.

Problem—Coolant Temperature Below Normal

Problem—Coolant Temperature Below Normal	
Possible Cause	**Remedy**
The temperature gauge is not working.	Check the gauge circuit wires, circuit breaker, and sending unit. If the gauge circuit is okay, replace the temperature gauge. If the gauge circuit is broken, repair it and then check temperature gauge operation.
The on-off fan clutch operates continuously.	Check the solenoid valve in the fan clutch air supply line, the sending unit for the valve, and the operating air pressure to the valve. If valve operation and air pressure are okay, repair or replace the fan clutch. If the valve doesn't work or if air pressure is low, make repairs and then check fan clutch operation.
One or both thermostats are incorrect or inoperative.	Make sure the correct thermostat is installed. Test the thermostat according to the engine manufacturer's instructions. Replace it if it does not operate correctly.

Single Radiator Applications

The main function of a cooling system is to keep the engine at its optimum operating temperature. This results in the most efficient use of fuel and allows the engine oil to provide a good lubricating film.

The central component of the cooling system, the radiator assembly, includes the surge tank (remote mounted on the firewall), the radiator, and the surge tank pressure relief cap. See **Fig. 1.**

The surge tank provides storage space for reserve coolant, expansion space for heated coolant, and deaeration space. See **Fig. 2.** When coolant in the radiator runs low, reserve coolant stored in the surge tank flows from the tank, through the fill hose, to the water pump. As the coolant heats and expands beyond radiator capacity, excess coolant travels back through the fill hose from the water pump to the surge tank. Any air trapped in the engine block or radiator rises to the top of the engine or radiator and escapes through the vent hoses to the surge tank.

The low coolant level sensor in the surge tank warns the driver when coolant is running low. The surge tank is translucent polypropylene so you can see the coolant level and compare it to the maximum and minimum levels marked on the tank.

These vehicles use full-flow (or high-flow) radiators. With full-flow radiators, the coolant flows into the radiator at the top of the left side tank and flows out of the radiator at the bottom of the right side tank. Most of the engine coolant is routed through the radiator, and it moves relatively quickly in a single pass.

There are two sizes of two-row radiators in use: one radiator has 1000 square inches of front area and the other has 1200 square inches. See **Fig. 3** and **Fig. 4**.

The radiators use glass-filled nylon side tanks.

The tanks and core are held in steel channels that mount on the front closing crossmember. The radiator is also secured by brace rods that run between the top of the radiator and the firewall. The fins of the radiator core are reinforced along their forward edge to resist damage from road debris and pressure washing.

Because crimping holds the nylon side tanks tanks in place, the radiators can be disassembled and assembled.

The surge tank cap limits system pressure to about 11 to 12 psi, which raises the boiling point of the coolant. If the cooling system overheats, excess coolant is released through the overflow tube.

For more general information about the radiator and surge tank, and for cooling system troubleshooting procedures, refer to **Section 20.00** in this workshop manual.

Argosy with Auxiliary Radiator (Australia Only)

General Information

The cooling system on some Argosy models operates with two radiators, the main radiator and auxiliary radiator. They work in parallel, but their fans are controlled independently. The auxiliary radiator is designed to improve the cooling capacity by sharing the work load with the main radiator. See **Fig. 5** for a system diagram.

Cooling System Operation

When the engine is started, the engine thermostat will remain closed, and the water pump will circulate the coolant through the engine block passageways. The thermostat is located where the coolant leaves the engine. When the coolant temperature rises, the thermostat begins to open and allows the coolant to start circulating through the main and auxiliary radiators. The radiators are designed to transfer heat from the hot coolant by the air drawn through the radiator fans. When the coolant temperature drops, the thermostat will close, and the coolant continues to recirculate through the engine.

Radiator Fan Control

Both the Caterpillar and Detroit Series 60 engines have different operating temperatures. The main and auxiliary radiator fans come into operation independently and at different temperature settings. **Table 1** shows the radiator fan temperature settings. The auxiliary radiator fans have been set to engage at 212°F (100°C) and disengage at 192°F (89°C) for both the Cat and Series 60 engines. For the Cat engines, the main radiator fan starts operation at 215°F (102°C) and ceases at 201°F (94°C). This means that the auxiliary radiator fans will start first and stop after the main radiator fan. Therefore, the auxiliary

radiator will help to reduce fuel consumption and noise because the engagement time of the main radiator fan is reduced. The auxiliary radiator fans have been set to engage at 212°F (100°C) and disengage at 192°F (89°C) for both the Cat and Series 60 engines. For the Cat engines, the main radiator fan starts operation at 215°F (102°C) and ceases at 201°F (94°C). This means that the auxiliary radiator fans will start first and stop after the main radiator fan. Therefore, the auxiliary radiator will help to reduce fuel consumption and noise because the engagement time of the main radiator fan is reduced.

Single Radiator Applications

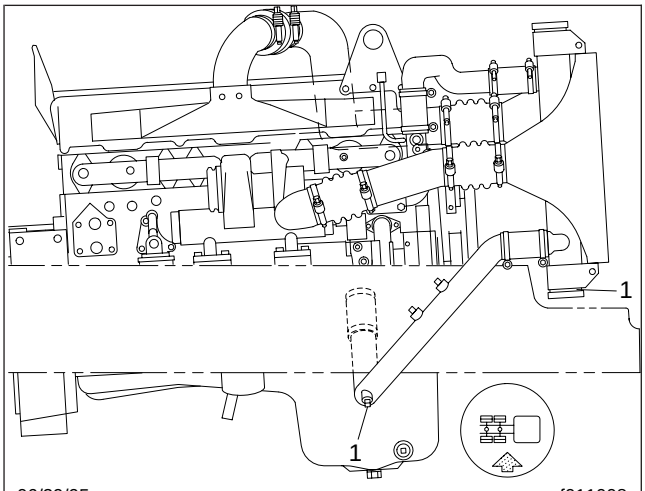
Draining

1. Park the vehicle, apply the parking brakes, and chock the tires.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.

2. Place a suitable container under the elbow of the radiator outlet pipe. The container should hold at least 15 gallons (57 liters).
3. Remove the surge tank cap.
4. Remove the plugs from the lowest points of the coolant system. This will be a plug in the radiator side tank and a plug in the elbow of the radiator outlet pipe. See **Fig. 1**.



NOTE: Cummins M11 engine shown.
1. Coolant Drain Plug

Fig. 1, Coolant Drain Plug Location

5. Allow all the coolant to drain.
6. Install the plugs in the radiator elbow and the radiator side tank.

Filling

1. Make sure the plugs are installed securely in the bottom of the radiator and the elbow of the radiator outlet pipe.
2. At the surge tank, fill the system with coolant until the level of coolant shows between the minimum and maximum coolant level lines on the surge tank. See **Fig. 2**. For approved coolant, and the coolant capacity for your engine, refer to the vehicle maintenance manual.
3. Run the engine for ten minutes, and add coolant as needed.

Argosy with Auxiliary Radiator (Australia Only)

General Information

The auxiliary radiator and associated plumbing adds complexity to the coolant system. Follow the procedure below to fill and bleed the coolant system. If this procedure is not followed there is the potential for the low coolant level sensor to shut down the engine via the engine's ECU, if that feature has been set.

Draining

1. Park the vehicle, apply the parking brakes, and chock the tires.

⚠ WARNING

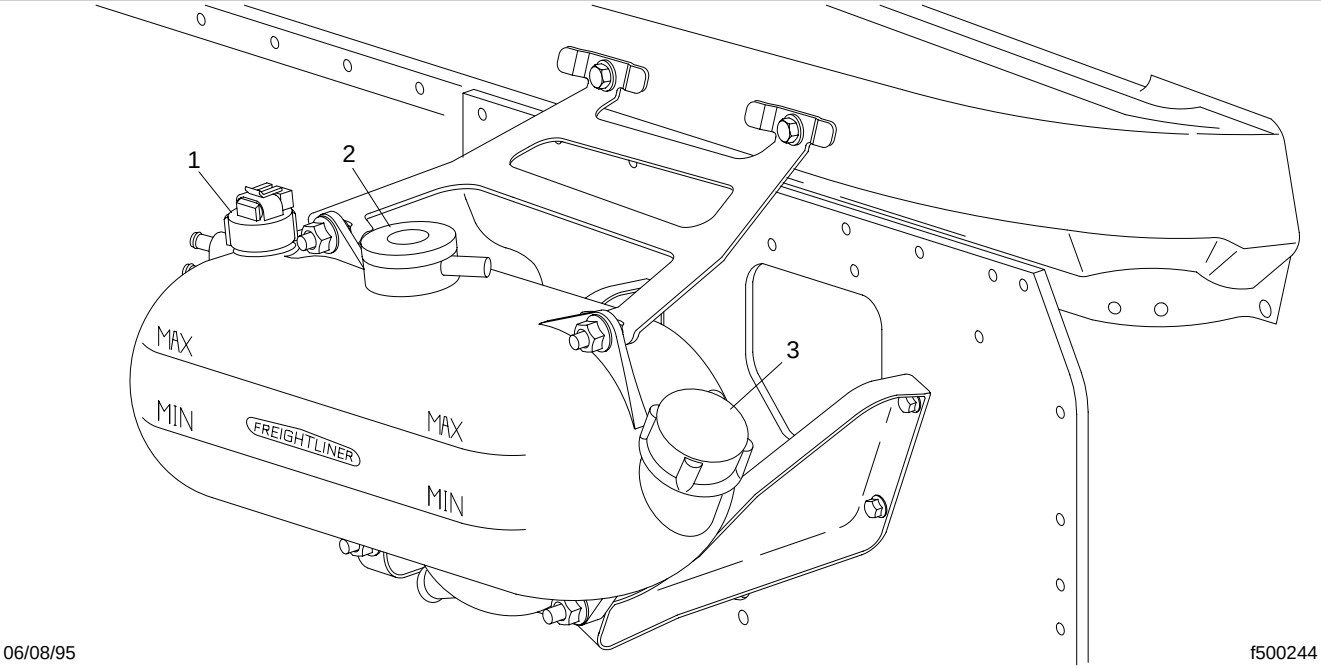
Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.

2. Place a suitable container(s) under the radiators and outlet pipe if needed. The container should hold at least 80 quarts (76 liters).
3. Remove the surge tank cap.
4. Open the bleed valve. See **Fig. 3**.

NOTE: On some engine installations there may also be a plug in the elbow of the main radiator outlet pipe that must be removed to drain the coolant system. See **Fig. 1**.

5. Remove the drain plugs in the lower tanks of both radiators.

Coolant Draining and Filling



1. Low Coolant Level Sensor
2. SAE Cap (for coolant overflow pressure relief only)
3. Fill Cap

Fig. 2, Surge Tank, Century Class Conventional

6. Allow all the coolant to drain.
7. Close the drain plugs on both radiators.

   If removed, install the plug in the elbow of the main radiator outlet pipe.
8. Close the bleed valve.

Filling and Bleeding

1. Open the remote bleed valve on the left side of the frontwall.
2. Fill the cooling system at the surge tank; continue adding coolant until a non-aerated coolant stream comes out of the remote bleed valve. This allows air to be expelled from the auxiliary system.
3. Close the remote bleed valve.
4. Continue filling until the coolant reaches the high level mark on the surge tank; replace the radiator cap.
5. Run the engine for 5 minutes to allow the system to de-aerate.
6. Check the coolant level again; add coolant to the high level mark.

Fan Removal and Installation

Removal

1. Partially remove the radiator. Do all the steps in **Subject 130** but *do not lift the radiator out of the vehicle*. Disconnect the radiator and charge air cooler, and have someone lean the components forward and hold them out of the way
2. Remove the fasteners that hold the fan to the fan clutch.
3. Remove the fan from the vehicle.

Installation

1. If not already done, disconnect the radiator according to the steps in **Subject 130** and have someone lean the components forward and hold them out of the way
2. Position the fan on the fan clutch, and tighten the fasteners 15 lbf·ft (20 N·m).
3. Install the radiator. For instructions, refer to **Subject 130** in this workshop manual section.
4. Remove the chocks from the tires.

Fig. 1, Fan Shrouds

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Remove the four screws and washers that hold the fan shroud to the radiator.
3. Remove the radiator. For instructions, refer to **Subject 130** in this workshop manual section.

   Remove the fan shroud from the vehicle.

Fan Shroud Removal and Installation

Installation (See Fig. 1)

1. Place the fan shroud on the engine, and move it back as far as possible around the fan.
2. Install the radiator. For instructions, refer to **Subject 130** in this workshop manual section.
3. Install the fan shroud on the radiator.
   - 3.1 Adjust the vertical clearance between the top of the fan blade and the fan shroud opening. It should be equal within 1/8 inch (3 mm) to the clearance between the bottom of the blade and the shroud opening.
   - 3.2 Tighten the screws 108 lbf·in (1220 N·cm).
4. Remove the chocks from the tires.

Radiator Removal and Installation

Removal

NOTE: See **Fig. 1** or **Fig. 2** for this procedure.

1. Park the vehicle, and apply the parking brakes. Chock the tires.

   For Century Class Conventionals and Coronados, remove the grille. For instructions, see **Group 88**.

   For Argosy COEs, remove the upper and lower grille. For instructions, see **Group 60**.

2. For Century Class Conventionals and Coronados, tilt the hood, and support it in the tilted position with a padded table or bench.

   For Argosy COEs, tilt the cab. For cab tilting instructions, see **Group 60**.

3. Drain the coolant. For instructions, see **Subject 100**.

4. For Century Class Conventionals and Coronados, disconnect the hood straps. For instructions, see **Group 88**.

5. If so equipped, remove the air recirculation shields along the bottom and passenger side of the radiator for Century Class Conventionals. For instructions, see **Subject 180**. For Coronados, remove all the air recirculation shields.

6. Disconnect the condensor mounts and move the condensor aside without breaking the refrigerant lines. For instructions, see **Group 83**.

7. Disconnect the hoses from the radiator.

8. Disconnect the hoses from the charge air cooler.

9. Remove the fan shroud and move it back against the engine.

   For Coronados, remove the fasteners holding the fan shroud to the radiator, but leave the shroud in place.

10. For Century Class Conventionals and Coronados, attach chains and a lifting device to the hood strap attachment bolts on the top of the radiator.

11. Disconnect the struts from the radiator.

12. For Coronado vehicles, pull the fan shroud away from the rubber seal on the metal fan ring, then remove the fan shroud from the engine compartment.

13. Remove the nuts from the radiator mounting bolts at the bottom of the radiator. (For the 1350-square-inch radiator, the nuts are at the bottom of the module support bracket underneath the charge air cooler.)

14. For Argosy COEs, mark, then disconnect all the coolant hoses from the surge tank on top of the radiator. Disconnect the low coolant sensor wiring from the rear of the surge tank.

15. For Century Class Conventionals and Coronados, use a lifting device and remove the radiator and charge air cooler from the vehicle.

    For Argosy COEs, use an assistant to help, and manually lift the radiator, the surge tank, and the charge air cooler from the vehicle.

Installation

1. For Century Class Conventionals and Coronados, use a lifting device secured to the radiator and charge air cooler with chains to lift the radiator and position it in the vehicle.

   For Argosy COEs, attach the surge tank (if removed) to the top of the radiator and the charge air cooler inlet. Tighten the fasteners 26 lbf·ft (35 N·m).

   Put the radiator, charge air cooler, and surge tank assembly in place, making sure the mounting brackets on the side of the radiator line up with the mounts on the inside of the frame rails.

2. For Century Class Conventionals and Coronados, install the nuts on the mounting bolts at the bottom of the radiator. Tighten the nuts 241 lbf·ft (327 N·m).

   For Argosy COEs, install the bolts, washers and nuts into the mounting brackets at both sides of the radiator and inside the frame rails. Tighten the nuts 136 lbf·ft (184 N·m).

3. If lifting chains were used, remove them from the radiator.

4. For Coronado vehicles, put the fan shroud in place in the engine compartment. Make sure the

   For Argosy COEs, tighten the strut fasteners 136 lbf·ft (184 N·m).

6. Install the fan shroud onto the radiator. For instructions, see **Subject 120**.

Radiator Removal and Installation

7. Connect the coolant hoses to the radiator, and connect the hose clamps. Your hose clamps can be T-bolt clamps (see **Fig. 3**), Breeze Constant-Torque clamps (see **Fig. 4**), or ABA Radial worm-drive hose clamps (see **Fig. 5**).

   When working with T-bolt type hose clamps, tighten the clamps 55 lbf·in (620 N·cm). These clamps are now standard on hoses with an inside diameter greater than 2 inches (51 mm).

   When installing the Breeze Constant-Torque hose clamps, the clamps must be tightened to the correct torque. The screw tip of the clamp should extend about 1/4 inch (6 mm) from the clamp housing, and the Belleville washer stacks should be collapsed almost flat. Use a torque wrench to install these hose clamps correctly. The correct installation torque for Breeze Constant-Torque hose clamps is as follows:

   For Breeze Constant-Torque hose clamps with a 5/16-inch tightening screw hex: 55 lbf·in (620 N·cm).

   For Breeze Constant-Torque hose clamps with a 3/8-inch tightening screw hex: 90 lbf·in (1020 N·cm).

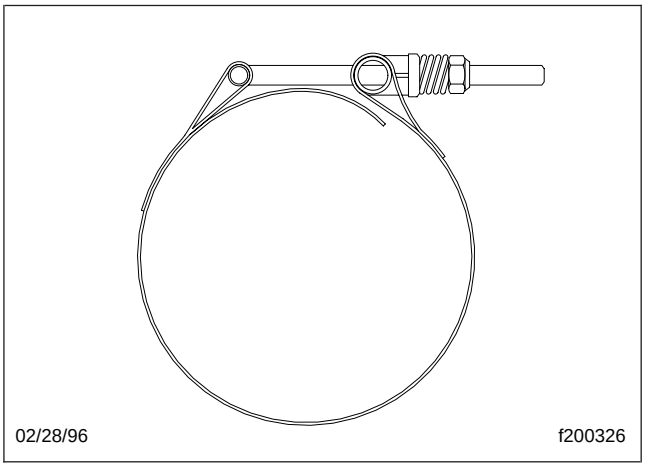

Fig. 3, T-bolt Type Hose Clamp

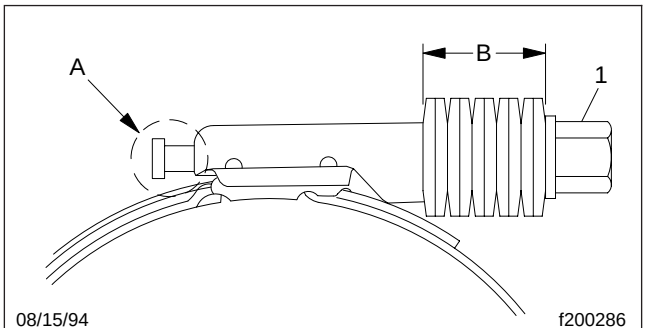
NOTE: All hose clamp adjusters lose torque after installation, due to cold-flow of the hose material from under the clamp. Breeze Constant Torque clamps typically show a 30 percent loss of torque shortly after installation; a 50 percent loss after heat-cycling, and up to 80 percent loss after time and repeated heat cycles. However, when correctly installed, Breeze Constant-Torque clamps adjust automatically, holding enough torque to keep consistent sealing pressure. During vehicle operation and shutdown, the screw tip may adjust in and out, according to temperature and pressure changes. The torque may need to be adjusted for individual applications.



A. The screw tip must extend about 1/4 inch (6 mm).
B. The Belleville washer stacks must be collapsed almost flat.
1. Tightening Screw Hex

Fig. 4, Breeze Constant-Torque Hose Clamp Installation

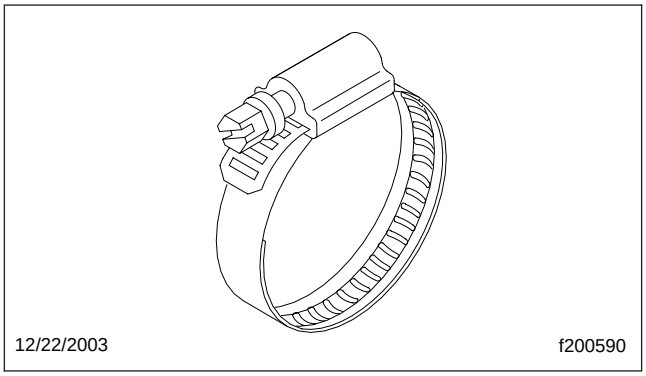


Fig. 5, ABA Radial Worm-Drive Hose Clamp (typical)

ABA Radial worm-drive hose clamps may lose 30 percent of their torque at the screw adjuster, shortly after being correctly tightened. This is due to cold-flow of the hose material, not an actual loosening of the clamp. This is the way they are designed to work, they should not be tightened further. To check the torque of an ABA clamp, it must be loosened completely, then torqued to the proper value listed in **Table 1**.

Over-tightening an ABA Radial worm-drive hose clamp can result in coolant leaks.

8. Connect the hoses to the charge air cooler. For instructions, see **Group 09**.
9. Install the condensor. For instructions, see **Group 83**.
10. Install the air recirculation shields, if so equipped. For instructions, see **Subject 180**.
11. Fill the coolant system. For instructions, see **Subject 100**.
12. For Century Class Conventionals and Coronados, install the hood straps. For instructions, see **Group 88**.
13. For Century Class Conventionals and Coronados, close the hood, then install the grille. For instructions on installing the grille, see **Group 88**.

    For Argosy COEs, return the cab to the operating position. Install the upper and lower grilles. For instructions on lowering the cab and installing the upper and lower grilles, see **Group 60**.
14. Remove the chocks from the tires.

Engine Mounted Radiator, Cooling System Pressure Testing

NOTE: If the engine-mounted radiator strut rod blocks access to the surge tank pressure cap, remove the strut as follows.

1. Unbolt the driver's side radiator strut rod from the radiator and the engine. Set the strut rod on the engine, and do not disconnect anything that might be attached to it. See **Fig. 1**.

Out of Vehicle Radiator Pressure Testing

1. Remove the radiator from the vehicle. For instructions, refer to **Subject 130**.

Radiator Pressure Testing

2. Pressure-test the radiator.

   2.1 Plug the inlet, outlet, and all other ports on the radiator assembly.

NOTICE

Don't apply a higher amount of air pressure than specified below; too much pressure will damage the radiator core.

   2.2 Remove the radiator cap, and install a pressure regulator and gauge. Using a hand pump, apply 20 psi (138 kPa) air pressure through the filler neck.

   2.3 Submerge the radiator in a tank of water and check it for leaks. Remove the radiator from the water.

   2.4 Remove the plugs and the testing gauge, and install the radiator cap. Repair the radiator, if necessary.

3. Install the radiator in the vehicle. For instructions, refer to **Subject 130**.

Surge Tank Removal and Installation, Argosy COEs

Removal

1. Park the vehicle, set the parking brakes, then chock the tires.
2. Tilt the cab. See **Group 60** for instructions.
3. Drain the coolant system enough to empty the surge tank. The surge tank is located on top of the radiator.

6. Remove the fasteners holding the surge tank to the bracket on the right side of the radiator and the charge air cooler outlet.
7. Remove the surge tank.

Installation

1. Put the surge tank in place on top of the radiator.
2. Install the 3/8–16 fasteners. Tighten them 26 lbf·ft (35 N·m).
3. Connect the coolant hoses to the surge tank, as previously marked.
4. Connect the low coolant sensor wiring.
5. Fill the coolant system through the cap on top of the surge tank.
6. Return the cab to the operating position. See **Group 60** for instructions.
7. Remove the chocks from the tires.

IMPORTANT: Disassembling and assembling radiators with nylon tanks requires the special tools listed in **Table 1**.

Disassembly (See Fig. 1)

Before disassembling the radiator, pressure flush it and check the surge tank, following the instructions in the radiator group of the vehicle maintenance manual. Clean and check the exterior of the radiator, following the instructions in the vehicle driver's manual.

1. Remove the radiator from the vehicle; for instructions, refer to **Subject 130**.

CAUTION

Use care when handling or supporting the nylon tanks. Failure to do so could damage the tanks.

2. Remove the side channels from the radiator assembly.

   2.1 Remove the eight spring clips that hold the side channel mounting pins in position. **See Fig. 2.** Insert a screwdriver blade in the open end of each clip, and pry the clip open until it clears the edge of the mounting pin. Then, slip the clip off the pin.

   2.2 Use a rubber mallet and a punch to tap out the eight mounting pins. **See Fig. 3.**

   2.3 Slip the side channels off the radiator core and tank assembly. **See Fig. 4.**

3. Leak test the radiator core and tank assembly.

   3.1 Securely plug all tank ports.

CAUTION

Don't apply a higher amount of pressure than specified below; too much pressure will damage the radiator core.

   3.2 At one tank port, install a pressure regulator and gauge. Using a hand pump, apply 20 psi (138 kPa) air pressure through the port.

   3.3 Submerge the radiator in a tank of water and check it for leaks. Mark any leaks for repair. If a leak is between the radiator core header and a tank, remove the tank and inspect the tank flange, the header sealing surface, and the sealing gasket. If the leak is in the core, but within 7.5 cm (3 inches) of the tank, remove the tank before repairing the leak. If the leak is in the tank, replace the tank.

4. Remove the tanks.

   4.1 Place the radiator core and tank assembly in the disassembly/assembly fixture, and clamp the assembly securely in place. **See Fig. 5.**

   4.2 Position the tank clamping cylinders evenly across the top of the tank. Make sure the cylinders' rubber plungers will not press against breakable fittings, such as vent tube ports.

CAUTION

Apply only enough pressure to compress the sealing gasket. Too much pressure will crack the nylon tank.

   4.3 Apply pressure evenly across the top of the tank until the tank-to-core sealing gasket is compressed enough to show a small gap between the bottom of the dimple wave lock crimp and the tank sealing flange.

CAUTION

In some places, especially around the tank ports, the wave lock crimps may have to be unlocked

4.5 Slide the hooked-end bar over the T-bar. Place the hook over the top of the wave crimp and pull the T-bar back to unlock the crimp. **See Fig. 6.**

4.6 Slide the hooked-end bar and the T-bar down the T-bar groove to the next wave crimp, and repeat the previous step until all the wave crimps are unlocked.

5. Once the wave crimps are unlocked, remove the tank.

5.1 Release the pressure from the tank, and move the clamping cylinders off the radiator core and tank assembly.

⚠ CAUTION

If needed, use a rubber mallet or the heel of your hand and tap the side of the tank to loosen it. Do not use a screwdriver against the tank sealing

Radiator Disassembly and Assembly

flange. A screwdriver blade may damage the flange and prevent a good seal after the tank is installed.

5.2 Lift the tank from the forward side, the side opposite the tank ports. Remove the nylon tank from the radiator core. **See Fig. 7.**

5.3 Remove the sealing gasket from the sealing surface of the radiator core header. **See Fig. 8.**

5.4 Clean the sealing surface of the radiator core header.

5.5 Repair any leaks marked during leak testing.

5.6 Repeat the preceding steps to remove the opposite tank.

IMPORTANT: Check the tubes of the radiator core for scale deposits. If the radiator has been pressure-flushed, and the tubes are still clogged, the radiator should be rodded or boiled out with acid by an experienced radiator shop. Otherwise, replace the core.

Assembly

1. Install the nylon tanks on the radiator core.

1.1 With the radiator securely clamped in the disassembly/assembly fixture, header sealing surface up, make sure the bottom of the radiator core and tank assembly is completely supported, and that the header sealing surface is free of any dents, tool marks, or foreign particles.

1.2 Lubricate a new sealing gasket with a soap and water solution, and position the gasket on the header sealing surface. **See Fig. 8.** To make sure the gasket is

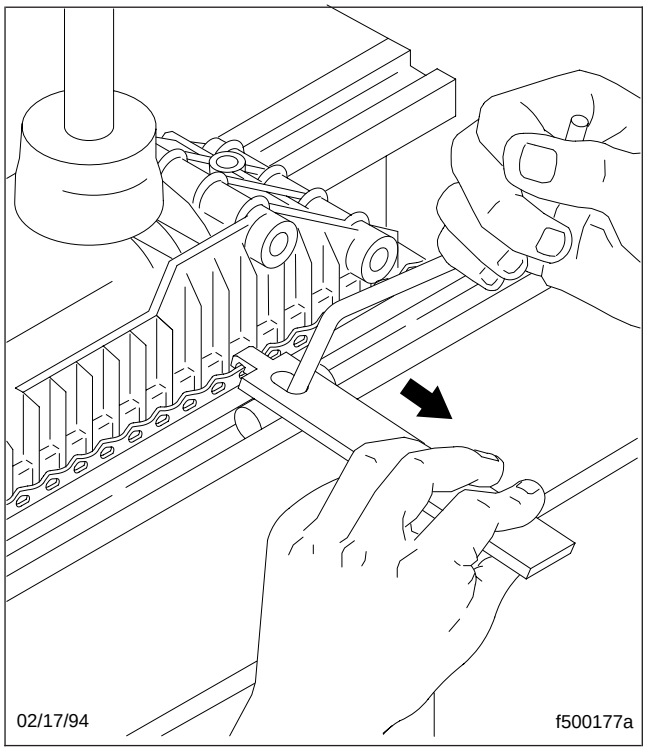

Fig. 6, Place the T-Bar

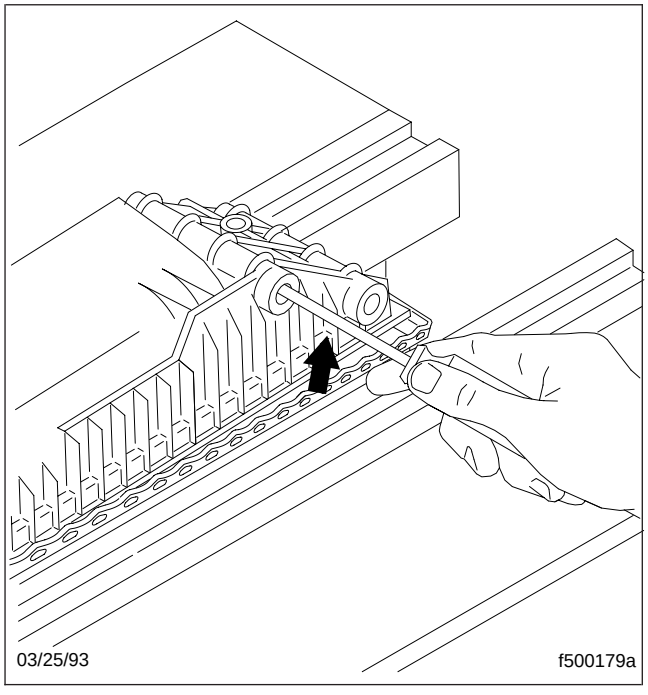

Fig. 7, Lift the Tank

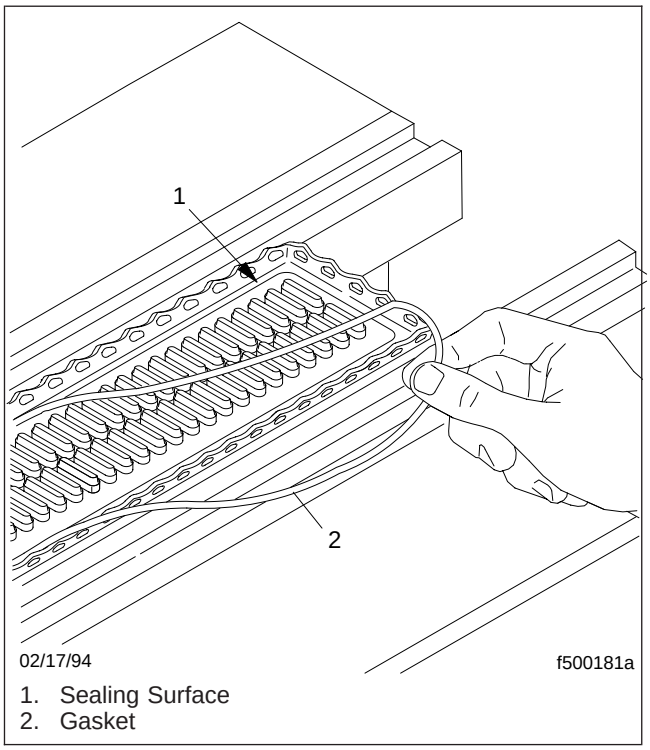

Fig. 8, Remove the Gasket

not twisted, run a finger along the gasket as it lies on the sealing surface. The mold lines of the gasket should be on the outside and inside diameters of the gasket; if you can feel a mold line cross over the top of the gasket, the gasket is twisted.

1.3 Inspect the tank sealing flange. The flange must be clean and free of defects. If the sealing flange is damaged, replace the tank.

1.4 Place the tank on the gasket, and tap the tank with a rubber mallet or the heel of your hand to seat the tank. Make sure the tank ports are facing the correct direction.

1.5 Position the tank clamping cylinders evenly across the top of the tank. Make sure the cylinders' rubber plungers will not press against breakable fittings, such as vent tube ports. **See Fig. 5.**

Radiator Disassembly and Assembly

CAUTION

Apply only enough pressure to compress the sealing gasket. Too much pressure will crack the nylon tank.

1.6 Apply pressure evenly across the top of the tank until the tank-to-core sealing gasket is compressed enough to show a small gap between the bottom of the dimple wave lock crimp and the tank sealing flange.

1.7 Place the T-bar into the T-bar groove in the disassembly/assembly fixture.

1.8 Slide the wave form bar over the T-bar, and center the bar in front of the wave crimp slot.

CAUTION

Do not push the wave crimp until it touches the side of the nylon tank, or the tank may crack.

1.9 Push the T-bar forward to crimp the header's edge until it almost touches the tank's side. **See Fig. 9.**

1.10 Slide the tools down the T-bar groove to the next wave crimp slot, and repeat the previous steps until all the wave crimps are crimped.

CAUTION

In some places, especially around the tank ports, the wave crimps may have to be crimped with a screwdriver. When using a screwdriver, use care not to crack or gouge the nylon tank.

1.11 Release the pressure from the tank, and move the clamping cylinders off the radiator core and tank assembly.

1.12 Repeat the first step in this procedure to install the opposite tank.

2. Leak test the radiator core and tank assembly. For instructions, refer to "Disassembly."

3. Install the radiator side channels.

3.1 Slide the side channels onto the radiator core and tank assembly.

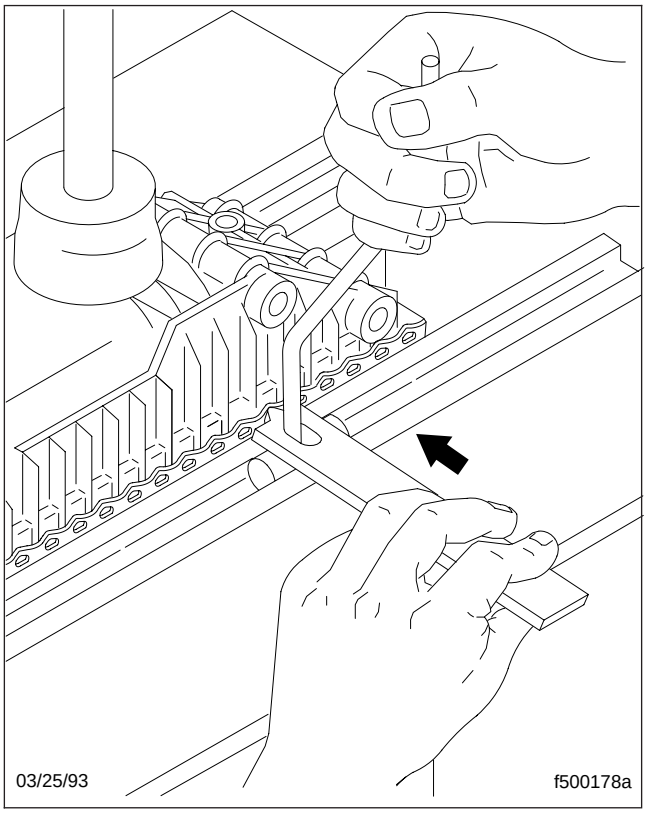

Fig. 9, Crimp the Header

3.2 Using a rubber mallet and a punch, install the eight mounting pins through the side channel holes and tank bosses. **See Fig. 10.**

3.3 Install the eight spring clips to secure the mounting pins in position. **See Fig. 11.** To install each clip, place the clip over the end of the mounting pin, and slide the clip until it engages the groove in the pin and the open end of the clips snaps over the edge of the pin. If necessary, use a clamp to compress the side channel while installing the clips.

4. Install the radiator in the vehicle. For instructions, refer to **Subject 130**.

Fan Ring Assembly Removal and Installation, Coronado

Removal

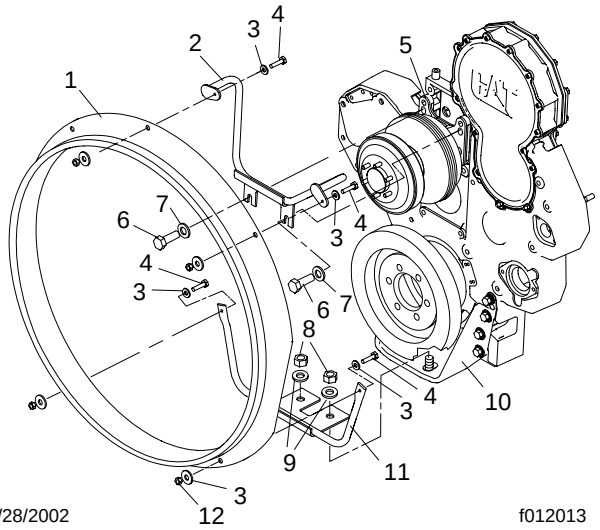
The fan ring assembly is installed on Coronado vehicles for improved fan efficiency and noise reduction. It consists of a metal ring that surrounds the fan and a rubber seal that ensures a tight fit with the fan shroud.

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires.
2. Tilt the hood.
3. Roll the rubber seal on the fan ring away from the edge of the fan shroud.
4. Remove the four fasteners holding the fan shroud in place, then move the shroud to the side or remove it from the engine compartment.
5. Remove the fasteners holding the fan ring to the upper mounting bracket. See **Fig. 1**.
6. Remove the fasteners holding the fan ring to the lower mounting bracket. See **Fig. 1**.
7. Disconnect the radiator support struts from the radiator.
8. Slide the fan ring assembly forward and over the fan, then remove it from the vehicle.

Installation

1. With the fan shroud removed or moved to the side, put the fan ring in place over the fan.
2. Loosely install the hexbolts, washers and hexnuts holding the fan ring for the upper and lower mounting brackets. See **Fig. 1**.
3. Make sure the fan ring is centered over fan by spinning the fan. The blades should not contact the ring.
4. Adjust the fan ring as needed so that it is centered. Tighten the fasteners 28 lbf·ft (38 N·m).

   Check the fan clearance again. Adjust if needed.
5. Install the fan shroud. Tighten the fasteners snugly.
6. Unroll the rubber seal on the fan ring assembly and seat it all the way around the opening in the fan shroud.



NOTE: The upper and lower mounting brackets are shown removed from the engine.

WARNING

Drain the coolant system only when engine/system is cool. Serious personal injury may result from contact with hot fluids.

2. Drain the radiator.
3. Open the hood.
4. Disconnect the hood support straps, and support the hood on a padded table.
5. Disconnect the hoses from the charge air cooler (CAC).
6. Without disconnecting the refrigerant lines, remove the A/C condenser from the front of the CAC. Cover the condenser with cardboard and secure it to the side and out of the way. Remove any stand-off brackets for the refrigerant hoses as needed.
7. Disconnect the upper and lower radiator hoses.
8. Remove the air recirculation shields from the radiator.
9. Disconnect the surge tank vent line from the top right side of the radiator.
10. Remove the fan.
11. Remove the fan shroud from the radiator (6 fasteners).
12. Disconnect the radiator struts from the top of the radiator (one on the right side; two on the left side).
13. Position a hoist over the radiator and attach lifting chains to the radiator strut studs on the top of the radiator. Use the same nuts that held the struts to the radiator.

NOTE: The studs protrude horizontally from the top of the radiator side channels.

14. Remove the 1/2–13 nuts holding the radiator mounting bracket to the isolator and front crossmember. See **Fig. 2**.

NOTE: The isolator has two integral studs. There are hexnuts at the top and bottom of each stud. The top studs fasten the isolator to the radiator mounting bracket; the bottom ones fasten it to the front crossmember.

15. Lift the radiator up and remove it from the vehicle.

Installation

1. If it was removed, install the CAC onto the front of the radiator. See **Group 09** for instructions.
2. Using a hoist, put the radiator and CAC in place over the front crossmember.
3. Making sure the studs on the mounting bracket are aligned with the holes in the isolator and the front crossmember, lower the radiator onto the crossmember.
4. Install the 1/2–13 hexnuts and washers. Tighten to 95 lbf·ft (129 N·m).
5. Remove the lifting chains, then connect the radiator support struts.

6. Install the fan shroud.
7. Install the fan.
8. Install the air recirculation shields.
9. Connect the vent line from the surge tank to the top right side of the radiator.
10. Carefully release the A/C condenser from its position and install it onto the front of the CAC. Be careful not to kink the refrigerant lines. Install any stand-off brackets that were removed.
11. Connect the upper and lower radiator hoses.
12. Connect the CAC hoses to the CAC.
13. Lift the hood slightly and, with an assistant holding it, attach the hood support straps.
14. Fill the radiator with approved coolant. See the *Century Class Maintenance Manual* for coolant capacities.
15. Start the engine and check for leaks. If any are found, tighten the applicable connections.
16. Shut down the engine.
17. Remove the chocks from the tires.

Radiator, EPA07, Removal and Installation

NOTICE

If the radiator is being replaced due to a failure of the transmission cooler, cleaning contamination from the transmission is necessary. Failure to do so can lead to a transmission failure.

Allison automatic transmissions: It is required to test the transmission fluid for contamination. The presence of water and/or any trace of ethylene glycol coolant mixtures in the transmission oil in an Allison transmission is detrimental to the internal components. Refer to the Allison service literature for more information and proper procedures, or contact an authorized Allison service facility.

Standard transmissions: The presence of water and/or ethylene glycol coolant mixtures in the lubricant in standard transmissions decreases the effectiveness of the lubricant and causes rust and wear to internal parts. If contamination is detected, refer to the transmission manufacturer's service literature for proper procedures.

Radiator Removal

1. Park the vehicle on a level surface. Shut down the engine, set the parking brake, and chock the tires.
2. Open the hood.
3. Remove the front bumper.

⚠ WARNING

During operation and for some time afterward, the contents of the cooling system are hot and highly pressurized. Opening the system when it is pressurized can allow scalding hot, pressurized coolant to erupt from the cooling system with considerable force, and can cause severe personal injury.

Be very careful when venting or opening the cooling system, and use appropriate protective gear.

4. Remove the surge tank cap.
5. Place a clean 14-gallon (53-liter) container near the radiator drain.
6. Connect a 1/2-inch hose to the drain fitting on the radiator (see **Fig. 1**) and place the other end in the container.
7. Drain the radiator into the container.

NOTE: If the oil drained from the transmission in the next step is relatively fresh and kept clean, it can be reused. If you wish to reuse the oil, be sure the drain container is clean, and be sure the drain ports on the transmission are clean before disconnecting the lines.

8. Place a container of at least 2-gallon (7.5-liter) capacity under the transmission, and drain the transmission oil into it. It will probably be easier to do this by disconnecting the oil cooler lines below the drain plug.

NOTICE

Do not attempt to turn the QLD fittings; you may destroy the fitting and severely damage the radiator.

Radiator, EPA07, Removal and Installation

IMPORTANT: The transmission oil cooler lines in some early EPA07 vehicles attach to the radiator with quick-disconnect (QLD) fittings. Removal and installation of these fittings must be done correctly, to prevent damage to the fittings and the radiator.

9. Where QLD fittings are fitted, the female ports are brazed into the radiator. They are not threaded.

   See the heading, "Gates Quick-Disconnect QLD Fittings" below, for work procedures on QLD fittings.

10. Disconnect the transmission oil cooler lines from the radiator, and let them drain into another container; see **Fig. 1**.

NOTE: The small amount of transmission oil drained at the radiator-end of the lines, after the transmission has been drained, may be contaminated with coolant as the radiator is drained. That oil should not be reused.

11. Remove the lower elbow from the radiator end tank.
12. Put a ratchet strap in position on the passenger side of the vehicle, to support the hood when the hood supports are disconnected.

    Attach one end of the ratchet strap to the underside of the hood, or the hole in the hood above the hood latch. Attach the other end to the rear hood support, on top of the inner splash shield.

13. Remove the upper radiator struts.
14. Disconnect the hood straps from the radiator. With help from another person, adjust the length of the ratchet strap so that the hood position will allow the radiator to be hoisted up, and clear of the vehicle.
15. Disconnect the charge air cooler (CAC) hoses from the CAC; see **Fig. 2** and **Fig. 3**.
16. Remove the lower elbow from the radiator end tank.
17. Disconnect the shunt line and radiator vent line, but leave the P-clamp in place on the back of the radiator module support; see **Fig. 2**.
18. Disconnect the electrical sensors on the radiator.
19. Remove the surge tank.

22. Remove the fasteners that hold the fan shrouds to the radiator.
23. Remove the upper fan shroud.
24. Remove the six hexscrews that hold the fan to the fan clutch, and remove the fan.

25. Disconnect the fasteners that hold the air-conditioner (A/C) system soft lines, to allow enough soft line flexibility so that the A/C condenser can be placed on the passenger-side tire.
26. Remove the four hexnuts that hold the A/C condenser to the radiator, and place the condenser on top of the passenger-side tire.
27. Remove the lower side recirculation baffle from the radiator. Use a screwdriver to pry the baffle off; it is held by push-on, reusable plastic rivets.
28. Attach an engine hoist to the radiator using the flanges and fasteners, where the upper radiator struts attached.
29. Remove the six hexscrews that hold the radiator to the module support.
30. Lift the radiator about 6 inches (15 cm). Remove the bottom recirculation baffle from the radiator.
31. Lift the radiator clear of the vehicle.
32. Remove the lower fan shroud from the radiator.
33. Set the radiator on a workbench, with the CAC up.
34. Remove the bolts that hold the CAC to the radiator, then remove the CAC and set it aside.
35. Use a paint pen to mark the position of the channels on the radiator.
36. Remove the fasteners that hold the channels to the radiator, and remove the channels.

Gates Quick-Disconnect QLD Fittings

As part of the changes made for EPA07 engines, the transmission oil cooler was moved into the radiator, and some early EPA07 vehicles used transmission oil cooler lines equipped with Gates Quick-Disconnect (QLD) connectors.

In July 2007, the Gates QLD connectors were superseded by JIC fittings. Only JIC-equipped radiators are available as replacements.

The Kent-Moore QLD tool (see **Fig. 4**) is the proper tool to use when disconnecting QLD connectors. One set of tools was sent to each dealer in December 2006. The tool is available from Kent-Moore in two sizes; J-48548-1 (the larger one) is used on Allison automatic transmissions, tool J-48548-2 is used for all other transmissions.

Quick-Disconnect Connectors, Removal and Installation

Removal

1. Park the vehicle on a level surface, apply the parking brake, shut down the engine, and chock the tires.

Radiator, EPA07, Removal and Installation

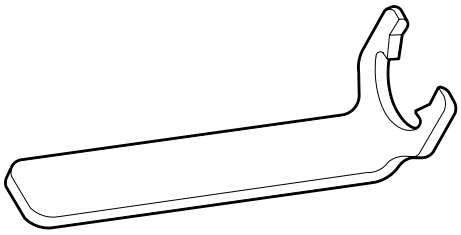

Fig. 4, Kent-Moore Tool J-48548

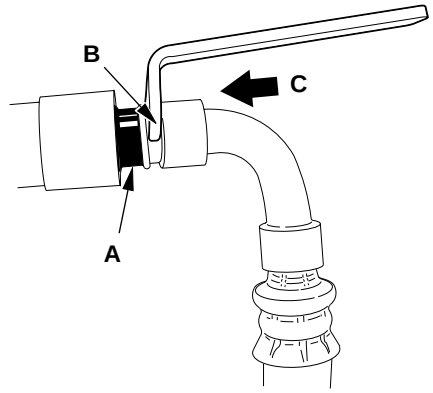
2. Thoroughly clean the area around the fitting.
3. Put the tool on the fitting as shown in **Fig. 5**.



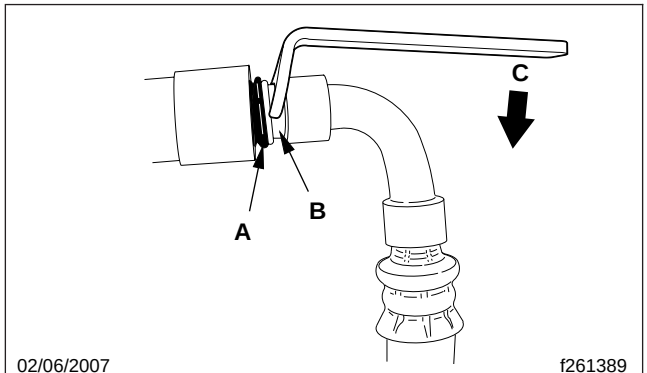
A. Dust Boot Not Compressed
B. Tool Head Inserted Perpendicular To Fitting
C. Push Male Connector Straight In, To Release

Fig. 5, QLD Fitting with Tool J-48548 in Place

4. Push the installed connector straight into the port until it stops with the rubber dust boot compressed; see **Fig. 6**.

NOTE: WD-40, or a similar substance, can be helpful if the quick-disconnect fitting is difficult to release. Clean the fitting, then spray it with the lubricant. Push and pull the fitting straight in and out, to distribute the lubricant so it eases disassembly, then use the tool to disconnect the fitting.

5. **While holding the male fitting compressed into the female port,** squeeze the flat face of the tool handle toward the male fitting, to release the snap connection; see **Fig. 5**. Use the tool so that pressure is equal on both ears where they



A. Dust Boot Compressed
B. Tool Fitted Around Metal Flange, Not Rubber Dust Boot
C. Tool Levered Straight Toward Fitting

Fig. 6, QLD Fitting Removal with Tool J-48548

push against the lower male fitting. Do not twist the tool sideways, or apply unequal pressure to either ear of the tool where it forks around the fitting. The rubber dust boot should compress, releasing the fitting so that it can separate.

6. Pull the male fitting from the radiator port. Protect the openings of the connectors when they are disconnected, to keep dirt out.

Installation

1. Apply WD-40 to the fitting, to aid assembly. Push the male connector into the port as far as possible, until the snap ring clicks into engagement.
2. Test the connection by pulling the male connector straight out, with a 10-lb (4.5-kg) force. It should hold solidly in place.
3. Remove the chocks from the tires.

Adapting QLD-Equipped Transmission Oil Cooler Lines to a JIC-Equipped Radiator

No QLD-fitted replacement radiators are available, so when a radiator must be replaced, the replacement will be JIC-equipped.

To enable using existing QLD-fitted transmission oil cooler lines with replacement JIC radiators, an adapter fitting p/n GT 7213 0003 (see **Fig. 7**) is

available. It screws into the replacement radiator and allows the existing QLD-equipped lines to connect to the JIC connectors in the radiator.

2. Install the CAC onto the radiator channels, and tighten the fasteners that hold the channels and CAC to the radiator.

2. JIC Female Fitting on Transmission Oil Cooler

B. Adapter Installed in Lower Radiator

3. QLD-to-JIC Adapter Installed

Fig. 7, QLD-to-JIC Adapter, p/n GT 7213 0003

The adapter fittings are installed only at the radiator; the original QLD connections continue to be used at the transmission.

Thread the adapters into the transmission oil cooler; tighten them 53 lbf·ft (70 N·m).

Insert the transmission oil cooler line QLD connectors into the fitting adapters, as stated above.

Test the connection by pushing the QLD fitting straight into the adapter, then pulling straight out with 10-lb (4.5-kg) force.

Radiator Installation

1. Install the channels onto the core. Leave the channel fasteners loose, so their position can be adjusted in final installation.
3. Lift the radiator with the engine hoist, and install the lower fan shroud on the radiator. Align the lower fan shroud with the alignment marks made earlier.
4. Move the radiator into position about six inches above the module support.
5. Install the bottom radiator recirculation baffle.
6. Apply sealant 48-00094-141 to the threads of the fasteners, then attach the fan. Tighten the fasteners 30 lbf·ft (40 N·m).
7. Align the marks to position the upper fan shroud on the radiator, then install the fasteners that hold it to the radiator and the lower fan shroud.

NOTE: Fan tip to fan shroud clearance should be 9/32 inch (7 mm). This is closer than on pre-EPA07 models, and clearance must be carefully checked.

Radiator, EPA07, Removal and Installation

8. Install the side recirculation baffles.
9. Install the upper fan shroud.
10. Install the radiator.
11. Install the A/C condenser, and attach the P-clamps that hold the A/C soft lines.
12. Install the surge tank.
13. Connect the radiator strut rods.
14. Connect the hood support straps, and remove the temporary support straps.
15. Connect the lower radiator elbow and transmission cooler lines. If the fittings are quick-disconnect, do the following:

    15.1 If the fitting is new, remove the plastic end cap.

    15.2 Align the male connector directly with the female port.

    15.3 Push the connector into the port as far as possible, until the snap ring clicks into engagement.

    NOTE: WD-40 or a similar substance may be used to ease assembly.

    15.4 Test the connection by pulling the male connector with a 10-lb (4.5-kg) force, straight out from the female port. It should be held solidly in place.
16. Fill the cooling system with coolant.
17. Fill the transmission with transmission oil, and check the level.
18. Install the bumper.
19. Close the hood and remove the tire chocks.
20. Test drive the vehicle.
21. Check for leaks and for correct transmission oil level.

Troubleshooting

Possible causes of hot or cold engine coolant temperatures are listed below. For repairs, refer to other sections of this manual or to the engine and component manufacturers' service publications.

Problem—Coolant Temperature Above Normal

Problem—Coolant Temperature Above Normal	
Possible Cause	**Remedy**
Coolant leakage (see possible sources below) is causing a low coolant level. External Leakage:hoses and hose connections, radiator seams, core, draincock and cap, block core and drain plugs, water pump thermostat housing(s), overflow and surge tank, heater hoses and core, temperature sending unit(s), cylinder head(s) mating (gasket) surfaces, coolant filter, oil cooler(s) Internal Leakage: cylinder head gasket, warped head or block surfaces, cracked cylinder head or block, cylinder head capscrews loose, missing, or tightened unevenly; oil cooler, air compressor cylinder head and gasket cylinder liners, liner seals aftercooler	Perform the repairs necessary to stop leakage. Fill to the bottom of the radiator fill neck with the correct mixture of antifreeze and water.
The temperature gauge is not working.	Check the gauge circuit wires, circuit breaker, and sending unit. If the gauge circuit is okay, replace the temperature gauge. If the gauge circuit is broken, repair it and then check temperature gauge operation
The radiator fins, the aftercooler, or the air conditioner condenser fins are clogged.	Clean the outside of the core, the aftercooler, and the condenser with compressed air directed from the fan side, or with water and a mild laundry soap. Straighten bent fins.
A radiator hose is collapsed or plugged.	Replace hoses.
A fan drive belt or the water pump belt is loose.	Adjust belt tension.
The cooling fan shroud is damaged.	Repair or replace the shroud.
The radiator cap is incorrect or malfunctioning.	Make sure the correct radiator cap is installed. If the cap does not hold the correct pressure, replace it.
The on-off fan clutch is not working.	Check the solenoid valve in the fan clutch air supply line, the sending unit for the valve, and the operating air pressure to the valve. If valve operation and air pressure are okay, repair or replace the fan clutch. If the valve doesn't work or if air pressure is low, make repairs and then check fan clutch operation.
The engine oil level is incorrect.	Fill to the high (H) mark on the dipstick.
There is too much antifreeze or coolant additive in the system.	Clean and flush the cooling system. Refill the system with the correct mixture of antifreeze and water, and install the correct additive and filter, or treatment filter.

Troubleshooting

Problem—Coolant Temperature Above Normal	
Possible Cause	**Remedy**
One or both of the thermostats is incorrect or inoperative.	Make sure the correct thermostat is installed. Test the thermostat according to the engine manufacturer's instructions. Replace it if it does not operate correctly.
The water pump is not working correctly.	Repair or replace the water pump.
The radiator core is internally plugged or damaged.	To check for blockages, warm the engine to normal operating temperature. Turn off the engine, and run your hand over the finned surface of the radiator. If there is a blockage in the radiator, it should cause an obvious temperature difference from one area of the core to another. An obvious difference between inlet and outlet temperature is normal. If blockage is suspected, clean and flush the cooling system. Repair or replace a damaged core.
Air or combustion gases are entering the cooling system.	Check the cylinder head(s), head gasket(s), cylinder liners, aftercooler, air compressor cylinder head, and fan/shutter air control valve (if applicable) for leaks. Repair or replace parts, as necessary.
The aftercooler is plugged or damaged.	Repair or replace the aftercooler.
The oil cooler is plugged or damaged.	Repair or replace the oil cooler.
The engine is receiving too much fuel.	Refer to the engine manufacturer's fuel delivery system adjustment procedures
The wrong fan (replacement unit) is installed.	Install the correct fan.
The wrong radiator (replacement unit) is installed.	Install the correct radiator.
There is exhaust blockage.	Repair the exhaust system.
There is frozen coolant in the radiator.	Use the proper antifreeze-to-water ratio needed for winter temperatures.

Problem—Coolant Temperature Below Normal

Problem—Coolant Temperature Below Normal	
Possible Cause	**Remedy**
The temperature gauge is not working.	Check the gauge circuit wires, circuit breaker, and sending unit. If the gauge circuit is okay, replace the temperature gauge. If the gauge circuit is broken, repair it and then check temperature gauge operation.
The on-off fan clutch operates continuously.	Check the solenoid valve in the fan clutch air supply line, the sending unit for the valve, and the operating air pressure to the valve. If valve operation and air pressure are okay, repair or replace the fan clutch. If the valve doesn't work or if air pressure is low, make repairs and then check fan clutch operation.
One or both thermostats are incorrect or inoperative.	Make sure the correct thermostat is installed. Test the thermostat according to the engine manufacturer's instructions. Replace it if it does not operate correctly.

General Information

The fan clutch engages and disengages the fan clutch hub with the engine fan. When they are engaged, the fan turns, to pull cooling air through the radiator, the charge air cooler, and the air conditioning condenser. When the fan clutch is disengaged, the engine does not turn the fan. This maintains proper cooling, and enables the air conditioning to work.

A large engine-cooling fan may require 70 to 100 engine horsepower to spin it. That reduces power available to move the vehicle, adds to engine noise, and uses more fuel. The fan clutch disengages when the fan is not needed, so the vehicle can operate as efficiently and quietly as possible.

Most Freightliner fan clutches are actuated by compressed air. A solenoid-controlled valve regulates the supply of compressed air to the fan clutch to engage and disengage the fan. Freightliner fan clutches normally disengage the fan when air is routed to them, and engage the fan when the air supply is blocked.

For the specific conditions that should trigger the engine fan, refer to your engine manufacturer's specifications.

In older vehicles, the fan clutch is controlled by an electrical circuit containing three switches. The switches are wired in parallel so that any one of them can trigger the closing of the solenoid valve, to cut air pressure to the fan clutch and cause the cooling fan to spin. See **Fig. 1**

The three switches are:

- A temperature switch, sensing the engine coolant temperature. In a normally-open temperature switch, the electrical contacts are open when the temperature is below the set point, and closed when the temperature is above the set point.
- A refrigerant pressure switch is installed in the vehicle's air conditioning system. When the air conditioner is running, the refrigerant absorbs heat from the air in the cab, through the evaporator. The heated refrigerant goes through tubing to the air conditioning condenser, which is in front of the engine radiator.

  As the refrigerant heats, the pressure rises in the air conditioner high pressure line, until the refrigerant pressure reaches the pressure switch's set point. The switch then signals the solenoid valve to engage the fan drive. The fan pulls cooling air through the air conditioner condenser coils, to cool the condenser/refrigerant and reduce refrigerant pressure.
- An optional manual override switch, located on the vehicle dashboard.

The solenoid valve is the heart of the control system, opening and closing to regulate the air flow to the fan drive. It is a 3-way valve, having two inlet/exhaust ports and one outlet port. Air pressure from the vehicle's air system feeds into one of the inlet ports (depending whether the system is normally open or normally closed) and the outlet port is connected to the fan drive. The plunger connects the solenoid outlet port to the normally-open port, on Freightliner vehicles. Turning the electric current to the solenoid valve on and off causes a plunger inside the solenoid valve to move up and down.

In the normally-open control system, when all switches are below their set points, they are open and no electrical current reaches the solenoid valve.

The solenoid valve has a 3/64-inch (1.2 mm) orifice to regulate the volume of air and ensure smooth engagement and disengagement of the fan drive.

The normally-open valve outlet port is always connected to the fan drive.

Mounting the solenoid valve in a location away from the engine minimizes the valve's exposure to excessive heat, vibration and contaminants, and prolongs the life of the solenoid valve.

Newer vehicles monitor and control all engine functions, including the fan drive, with the Electronic Control Module (ECM). An ECM consists of a digital microprocessor, random access memory (RAM), and read only memory (ROM). The ROM contains the computer's program. Programmers can change a vehicle's control systems and performance, simply by changing the ROM's programming.

NOTE: Minimum fan-on time for air conditioner engagements should be no shorter than 120 seconds, and the fan clutch should be set to engage 10°F (12°C) above the temperature at which the thermostat is fully open. Reducing the number of times the fan clutch engages and disengages extends the life of the fan clutch.

ECM-equipped vehicles have no direct connection between the sensors and the solenoid valve. Instead, information from sensors and switches feeds into the ECM, and the ECM then controls the solenoid valve. The solenoid valve controls the compressed air supply, to engage or disengage the fan clutch. See **Fig. 1**.

ECM systems are more reliable and simpler than independent hard-wired systems. The computer program sets the conditions when the fan will be engaged, and all sensors and actuators are wired to the ECM, instead of to each other. This provides more efficient and appropriate component operation.

In an ECM-controlled system, a given sensor may affect several actuators and an actuator may be affected by several sensors, depending on how the ECM is programmed.

The ECM computer monitors the data from the sensors. Then, it sends the appropriate signals to the controls and actuators based on programming logic. The ECM also sends status information to the operator's warning lights and gauges.

Sensors used in ECM systems are different from those used in non-ECM systems. In ECM systems, sensors only send digital measurements. In non-ECM systems, the sensors control switches, to open or close individual circuits.

Instead of the simple open/close type of sensor, ECM systems use thermistors and sending units to send signals to the ECM (temperature, pressure, speed, or whatever function is being sensed). For example, instead of a thermal switch opening or closing at a preset temperature, ECMs use a temperature sensor to set exact voltage, which the logic program converts into an precise temperature measurement. Instead of simply knowing if the coolant temperature is above or below the set point, for example, hotter than 190°F (88°C), the program knows the exact temperature; for example, 196.4°F (91.3°C). This makes control of the cooling system more precise and efficient.

In an ECM-controlled system, the fan drive solenoid is not wired to the sensors, as it is in an older system. Instead, it is wired to a relay controlled by the ECM. The ECM computer program compares the data from several sensors, and decides when to engage and disengage the fan drive. The program considers engine coolant temperature, air-conditioner's refrigerant pressure, intake-manifold air temperature, engine speed, and the engine brake status.

NOTE: Some vehicles have a manual override switch for the fan clutch on the dashboard.

Air conditioned vehicles not equipped with an ECM usually have two sensors to control the fan automatically:

- The coolant temperature switch (see **Fig. 3**).
- The air conditioning refrigerant pressure switch at the receiver-drier (see **Fig. 3**).

NOTE: Kysor K22RA and Horton DriveMaster® fan clutches engage and disengage differently from Horton Advantage™ fan clutches:

- Kysor K22RA and Horton DriveMaster fan clutches engage with a spring, and disengage with compressed air. When the fan clutch solenoid vents air pressure, the spring pushes the fan clutch into engagement, to spin the fan. With this system, even though the compressed air supply may be interrupted, the fan continues to turn.
- Horton Advantage fan clutches use compressed air to engage, and a spring to disengage. When the fan clutch solenoid vents air pressure, the internal spring pushes the fan clutch out of engagement.

On non-ECM vehicles with air conditioning, the fan clutch solenoid valve is also connected to a fan-cycling switch at the receiver-drier. When refrigerant pressure reaches the setting on the fan-cycling switch, the switch tells the solenoid valve to power-up the fan. See **Fig. 3**.

Horton Advantage Fan Clutch

In a cold engine start with the Horton Advantage fan clutch, the solenoid valve restricts air pressure to the fan clutch, so it does not spin the fan.

When the coolant warms to the hot end of the operating temperature range, the ECM triggers the solenoid valve. The solenoid valve then supplies compressed air to engage the fan clutch.

The vehicle compressed air supply should be clean, dry, and between 90 and 120 psi (620 and 830 kPa) for proper operation.

When the engine temperature drops to the cut-off point, the fan clutch solenoid valve vents air pressure, and the clutch disengages.

On non-ECM vehicles with air conditioning, the fan clutch solenoid valve is also controlled by a fan-cycling switch at the receiver-drier. When the refrigerant pressure reaches the setting on the fan-cycling switch, the switch triggers the solenoid valve, engage the fan clutch and spin the fan.

Horton Advantage fan clutches have System Sentry™ fuses, to protect the fan clutch bearings from overheating. See **Fig. 5**.

The Horton System Sentry fuse is a brass fitting in the piston friction disc. The fitting uses lead alloy solder to hold a brass plug. If the fan clutch slips excessively, heat from the slippage will melt the solder and release the plug. The melting System Sentry fuse releases air pressure from inside the fan clutch, disengaging the fan clutch to prevent damage to its bearings.

Replacement System Sentry plugs are included in all Horton Advantage repair kits. The replacement plugs

may be either Allen or Torx, but a Torx tool of the proper size will work to install either type of plug.

IMPORTANT: The Horton System Sentry Fuse is left-hand thread; turn it counter-clockwise to install.

IMPORTANT: If a Horton System Sentry fuse has released, determine the cause of the problem and repair it. Do not replace the fuse and put the unit back into service before fixing the cause of the problem.

If the fan clutch will not engage, check whether the fuse is melted, and check for other signs and causes of excessive fan clutch slippage.

Fan Clutch Removal and Installation, Horton Advantage

Removal

Refer to the following figures for the fan clutch installation for your engine:

- For Caterpillar 3176 engines, **see Fig. 1**.
- For Caterpillar 3406 engines, **see Fig. 2**.
- For Cummins M11 engines, **see Fig. 3**.
- For Cummins N14 engines, **see Fig. 4**.
- For Detroit Diesel Series 50 and 60 engines, **see Fig. 5** .
- For Detroit Diesel Series 55 engines, **see Fig. 6**.

WARNING

Use care when loosening the air line. The line may be pressurized, and there may be dirt or sludge in the air passages. If quickly disconnected, the line may whip or blow out debris with great force, possibly causing eye injury, or other bodily injury.

2. Disconnect the air line from the fan clutch.
3. Remove the fan shroud from the radiator, and move the shroud back against the engine. For instructions, refer to **Section 20.01** in this workshop manual.

Removal

Typical fan clutch installations are shown in the following figures. The figures do not show all possible combinations, but all installations will be similar to those shown.

- For Caterpillar 3176 engines, see **Fig. 1**.
- For Caterpillar 3406 engines, see **Fig. 2**.
- For Cummins M11 engines, see **Fig. 3**.
- For Cummins N14 engines, see **Fig. 4**.

- For Detroit Diesel Series 55 engines, see **Fig. 6**.
- For Mercedes MBE4000 engines, see **Fig. 7**.

NOTE: Protect the radiator fins from damage when working on the fan or fan clutch.

3. Tilt the top of the radiator forward for room to work. See **Section 20.01, Subj. 120**.
4. With the radiator tilted forward, remove the fan.
5. If necessary, remove the fan belts. For instructions, refer to the appropriate engine section in **Group 01**.

2. Clamp the fan clutch in a vise. See **Fig. 2**.
3. On some vehicles, the fan clutch has threaded studs on the air chamber and the fan is attached with nuts. On other vehicles, the fan is attached to the air chamber with hexbolts.

   If hexbolts were used to attach the fan, install two of the removed hexbolts in the air chamber so that a screwdriver can be used to keep the air chamber from rotating. See **Fig. 3**.

   Remove the socket-head capscrews from the air chamber.
4. If applicable, remove the two hexbolts previously installed.

⚠ WARNING

Apply air pressure slowly to the fan clutch. A sudden blast of air might blow the air chamber off the clutch, resulting in possible injury.

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Remove the fan clutch from the vehicle. For instructions, refer to **Subject 110**.

CAUTION

When caging and compressing the engagement spring of the fan clutch, depress the clutch shaft only enough to relieve the pressure on the retaining plates (about 1/16-inch, or 1.5 mm). Applying additional force after the clutch shaft bottoms in the housing can damage the housing and may ruin it.

NOTE: There are two methods of caging the engagement spring. One uses the special tools and a press. The other uses carriage bolts, washers, and wingnuts. Either method is effective.

3. Cage the engagement spring.

   If using the special support and compressor tools, place the fan clutch in a press to cage the engagement spring. See **Fig. 2**.

   If using the optional method of caging the engagement spring, do the following:

   3.1 With the access holes in the housing assembly aligned with those in the shaft assembly, install two 3-1/2-inch (89-mm) long carriage bolts and suitable washers on opposite sides of the clutch assembly.

   3.2 On the shaft assembly side, install about a 1/2-inch (13-mm) thickness of washers onto each carriage bolt.

   3.3 Install a wingnut on the end of each carriage bolt and tighten the wingnuts evenly until the engagement spring is caged.

Do not press on the cylinder during this step, or the cylinder will be damaged. Use a 5/8-inch wrench as shown in Fig. 4 on the piston rod flats.

5. If applicable, turn the clutch over in the press, and use the special compressor tool to cage the engagement spring while removing the cylinder nut and cylinder. See **Fig. 4**.

6. Inspect the fan clutch. See **Fig. 3**
   - 6.1 Inspect the two surfaces where the lining rides.
   - 6.2 Inspect the needle bearing race on the shaft.
   - 6.3 Inspect the needle bearings inside the clutch housing.
   - 6.4 Inspect the piston bearing by rotating the piston.
7. If you find cracking or scoring on any surface, or if the bearings are rough, loose, or missing, replace the fan clutch.

NOTE: If you find metal particles in the existing grease, replace the fan clutch or contact Kysor for the training needed to perform a major fan clutch rebuild. Kysor will not provide parts for a major rebuild until the technician has completed rebuild training provided by Kysor.

IMPORTANT: Do not wash the clutch parts in solvent.

Fan Clutch Minor Rebuild, Kysor K22RA

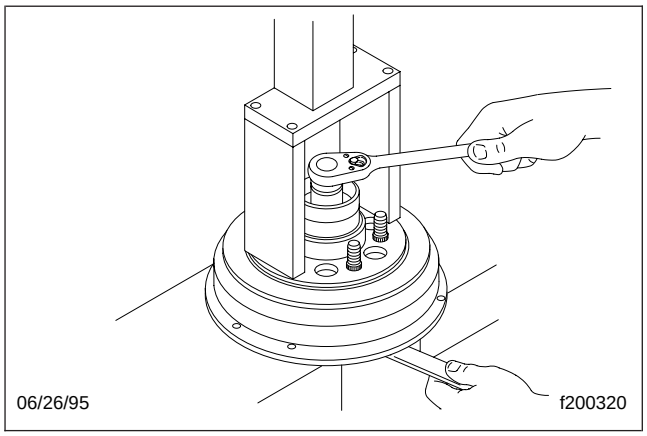

Fig. 4, Removing the Cylinder Nut and Cylinder

8. Using **Fig. 3** as a reference, lubricate the following rebuild parts with lubricant supplied with the rebuild kit (if the lubricant is unavailable, use one of the approved lubricants listed in **Specifications, 400)** :
    - The piston seal (pack the seal groove also)
    - The dust seal (pack the seal groove also)
    - The needle bearings inside the housing
    - The inside of the engagement spring
    - The outside of the piston rod assembly
    - The inside of the piston rod assembly
    - The inside of the cylinder assembly
    - Pack the lip of the grease seal

⚠ CAUTION

When caging the engagement spring, make sure the bottom edges of the housing assembly and the shaft assembly are flush and aligned all the way around. Failure to do so will cause the engagement spring pressure to affect the torque of the cylinder nut. This could result in the cylinder nut not being tight enough to effectively compress the piston seal washer, which could cause leakage and eventual fan clutch failure.

IMPORTANT: When caging the engagement spring, compress the clutch shaft only 1/16-inch (1.5 mm).

9. Assemble the fan clutch parts according to **Fig. 3**. Using either the special tools and a press, or carriage bolts, washers, and wingnuts, cage the engagement spring when installing the cylinder and lining. Be careful to depress the clutch shaft only 1/16-inch (1.5 mm).

   The piston rod seal washer is the last item to install before the cylinder goes on. See **Fig. 5**.

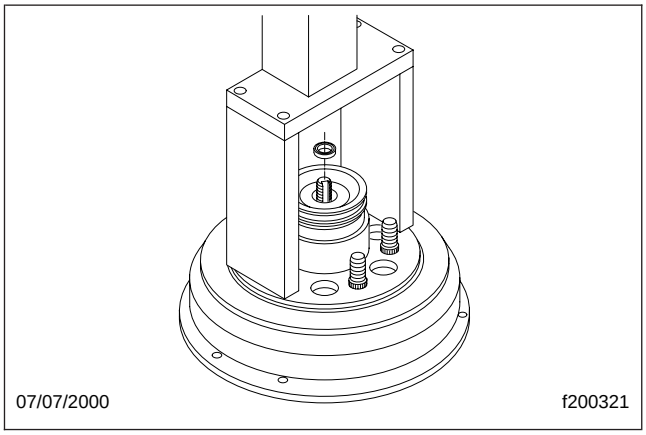

Fig. 5, Installing the Piston Rod Seal Washer

10. Tighten the cylinder nut 84 lbf·in (940 N·cm).
11. Tighten the lining screws 30 lbf·in (340 N·cm).
12. As applicable, remove the fan clutch from the press or remove the carriage bolts, washers, and wing nuts.
13. Check the front-to-rear travel of the fan clutch. For instructions, refer to Group 20 in the *Century Class Trucks Maintenance Manual*.
14. Install the fan clutch on the engine. For instructions, refer to **Subject 110**.
15. Close the hood and remove the chocks from the tires.

Relining

IMPORTANT: Premature wearing of the fan clutch lining is due to either insufficient air pressure necessary to fully disengage the clutch (allowing the clutch to remain partially engaged, thus increasing wear), or a problem in the control circuit for the fan. Before putting the fan clutch back in service, check the fan control and air supply systems and make any necessary repairs.

1. Park the vehicle on a level surface, apply the parking brake, and shut down the engine. Chock the tires.

⚠ WARNING

If the fan clutch engages during the next step, it could cause personal injury. Keep the fan clutch disengaged throughout this procedure by maintaining between 90 and 120 psi (620 and 827 kPa) of air pressure.

2. Bleed all the air from the primary and secondary tanks.
3. Disconnect the air line from the fan drive, and apply 90 to 110 psi (620 to 760 kPa) shop air pressure to the fan drive.
4. Remove the six lining plate screws, and remove the three lining plates. See **Fig. 1**.
5. Remove the old lining. If the lining sticks, use a hammer and a screwdriver to free it by tapping on the dividing cut in the lining.
6. Inspect the clutch shaft. If lining residue is present, or if the surface appears glazed over (non-metallic), temporarily release the air pressure from the clutch to allow shaft to protrude, and use a ScotchBrite to break the glaze.

NOTE: Some applications may be too tight to spread the lining and slip it over the pulley. If necessary, the lining can be cut in half with a hacksaw for installation.

7. Apply air pressure to the clutch again, and install the new lining. See **Fig. 2**.
8. Install the new lining plates. Tighten the screws 30 lbf·in (340 N·cm).
9. Remove the air pressure from the fan clutch, and allow the fan to engage.
10. Disconnect the shop air, and connect the air line to the fan drive.

Disassembly

NOTE: This procedure involves replacing only the air cartridge, System Sentry® fuse, the face seal, and the O-rings, using parts from the manufacturer's Seal Kit. If doing a major rebuild, go to **Subject 120**.

1. Remove the fan and clutch assembly from the vehicle. For instructions, refer to **Subject 100**.
2. Clamp the fan clutch in a vise. See **Fig. 1**.

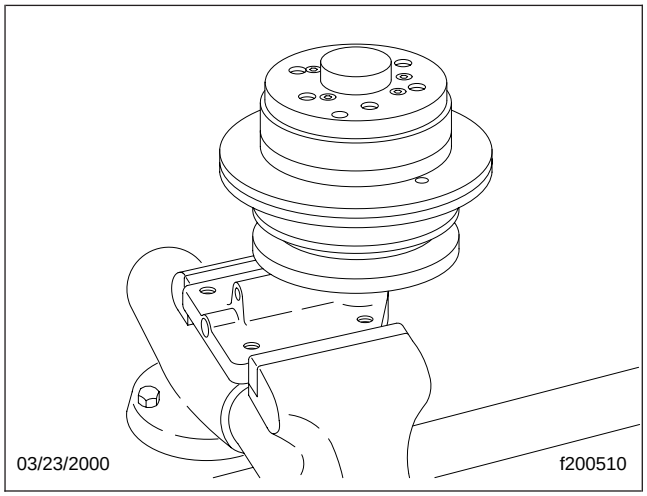

Fig. 1, Fan Clutch Placed in a Vise

3. On some vehicles, the fan clutch has threaded studs on the air chamber and the fan is attached with nuts. On other vehicles, the fan is attached with hexbolts.

   If hexbolts were used to attach the fan, install two of the removed hexbolts in the air chamber so a screwdriver can be used to keep the air chamber from rotating. See **Fig. 2**.

   Remove the socket-head capscrews from the air chamber.
4. If applicable, remove the two hexbolts previously installed.

⚠ WARNING

Apply air pressure slowly to the fan clutch. A sudden blast of air might blow the air chamber off the clutch, resulting in possible injury.

6. Remove and discard the O-rings from the air chamber and the piston friction disc. Clean the O-ring contact surfaces.
7. Remove the face seal from the air chamber. See **Fig. 3** .
8. Remove the System Sentry fuse from the piston friction disc. *Note that it is a left-hand thread.*
9. Remove the rubber umbrella valve from the air chamber.
10. Remove the adjusting nut. See **Fig. 4**.

11. Remove the retaining ring from the air cartridge assembly. See **Fig. 5**.

    Remove the cartridge assembly from the mounting bracket assembly. See **Fig. 6**.

Assembly

1. Install a new air cartridge assembly in the mounting bracket assembly. Note that the retaining ring is curved. Make sure the ring is installed with the convex surface toward the air cartridge. See **Fig. 7** .
2. Install the adjusting nut. Tighten 150 lbf·ft (203 N·m).
3. Remove any dust and debris from the air chamber.
4. Coat the new O-rings with an approved lubricant and install them. See **Fig. 8**.

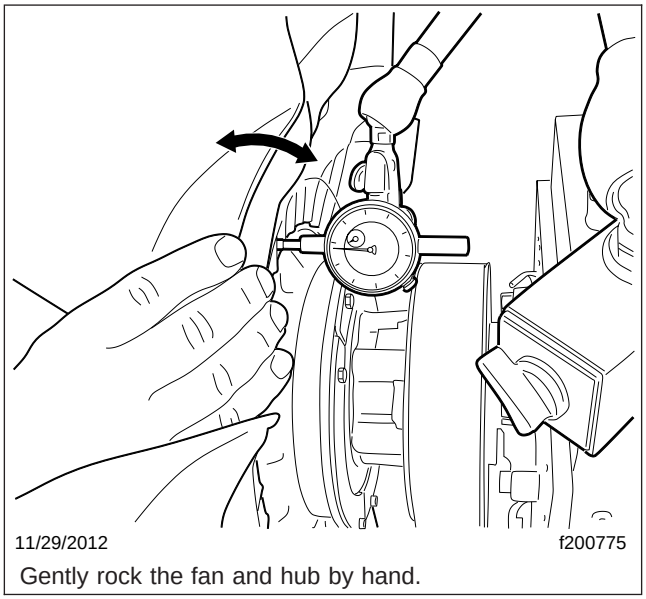
3. Drain the air from the air system.
4. Disconnect the air line to the fan clutch.
5. Disengage the clutch. Apply, and maintain, 90 to 120 psi (620 to 830 kPa) shop air to the fan clutch for the test.
6. Grasp the fan at the hub and gently rock the fan fore and aft. See **Fig. 3**.

   The total indicator reading should not exceed 0.050 in (1.27 mm).

   If reading is greater than 0.050 in (1.27 mm), replace the fan clutch. For instructions, see **Subject 100**.



Gently rock the fan and hub by hand.

General Information

An engine block heater keeps the engine coolant about 27°C (80°F) warmer than the ambient air temperature. In cold weather, the heater helps engine starting and reduces wear on the piston walls.

When starting the engine, the diesel normally ignites on the compression stroke of each piston, when the compressed air within the cylinder reaches about 385°C (725°F). However, during cold weather starts, the heat of the compressed air dissipates into the surrounding engine block so the diesel may never reach the temperature it needs to ignite. Using the engine block heater, the engine block is already warm so heat is held in the cylinder to ignite the diesel. To reduce engine wear, the block heater warms the oil film on the piston walls and reduces piston drag caused by cold oil film.

The heater consists of an element that bolts into the side of the engine water jacket. **See Fig. 1.** A cord plugs into the outside end of the element, and the cord runs to a plug below the front bumper.

To turn on the heater, connect the heater cord to a power source. The element has no thermostat. Heat dissipating from the engine block prevents coolant overheating.

Removal

See the applicable figure for the block heater installation for your engine, or one similar to it:

- For a Caterpillar 3176 engine, **see Fig. 1**.
- For a Caterpillar 3406 engine, **see Fig. 2**.
- For a Cummins L10 engine, **see Fig. 3**.
- For a Cummins N14 engine, **see Fig. 4**.
- For a Detroit Diesel Series 50 or 60 engine, **see Fig. 5**.
- For a Mercedes-Benz MBE4000 engine, **see Fig. 6**

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.

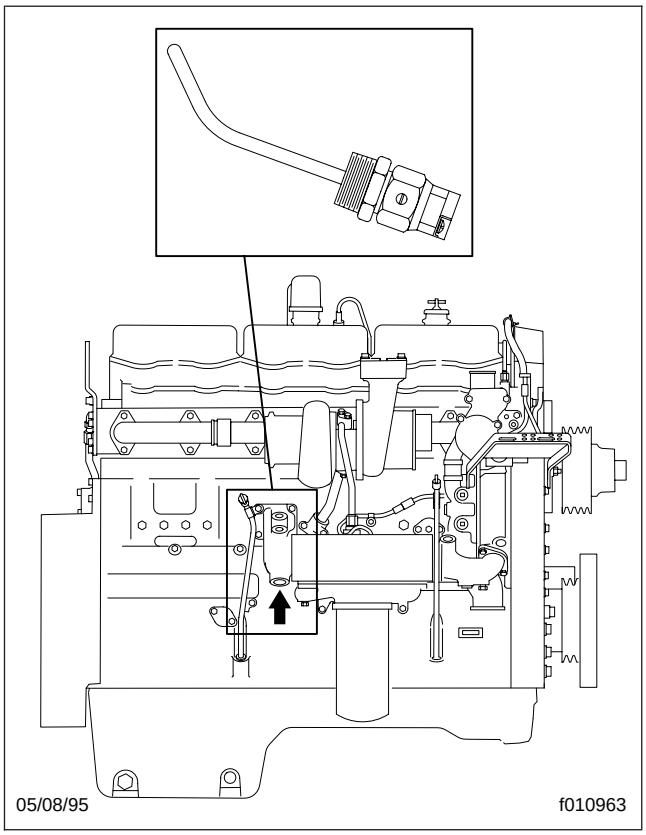

Fig. 2, Block Heater Element Installation, Caterpillar 3406

WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.

3. Drain the radiator. For instructions, refer to **Section 20.01**.
4. If applicable, unscrew the threaded cover that secures the cord to the element.
5. Pull the cord off the element.
6. Remove the element from the engine block:

   On all engines except the Cummins N14, loosen the jam nut (if applicable) and unscrew the element from the engine block.

Block Heater Element Replacement

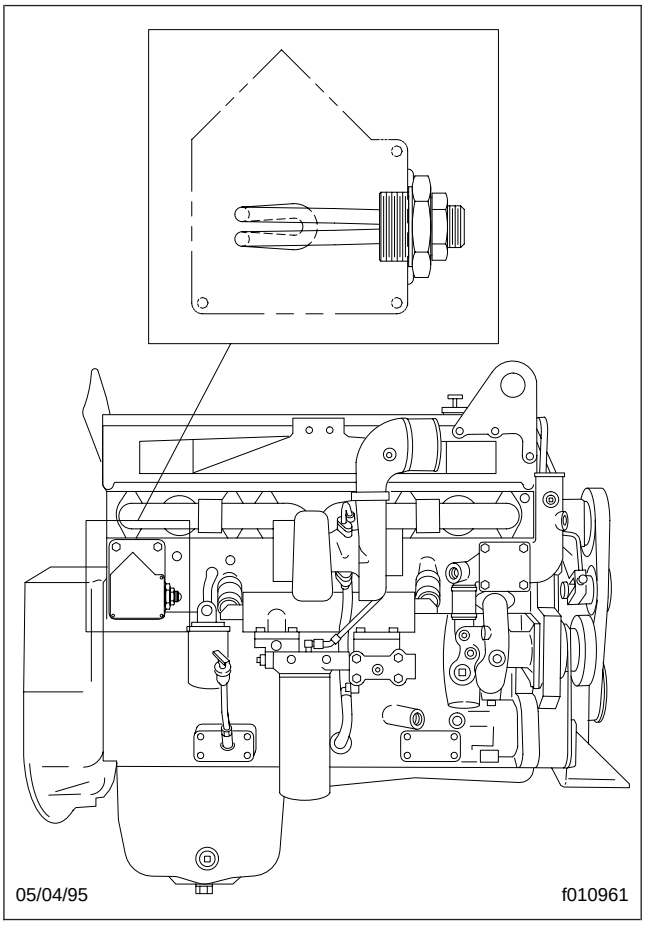

Fig. 3, Block Heater Element Installation, Cummins L10

On Cummins N14 engines, remove the six capscrews that hold the element in the side of the engine block.

Installation

1. Position the heater element in the engine block.

   On all engines except the Cummins N14, coat the threads of the element with a small amount of sealant. For the approved sealants, refer to **Specifications, 400**.

   On Cummins N14 engines, make sure the gasket is in place between the element cover plate and the engine.

2. Secure the heater element in the engine block:

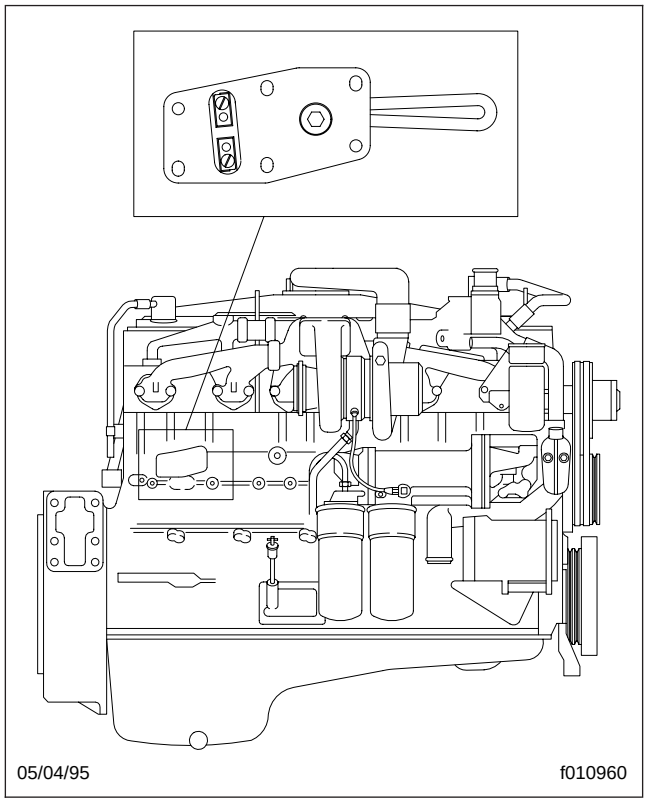

Fig. 4, Block Heater Element Installation, Cummins N14

   On all engines except the Cummins N14, screw the element into the engine block hand tight, then use a wrench to turn the element 1-1/2 turns more.

   On Caterpillar 3406 engines, tighten the jam nut 50 to 60 lbf·ft (67 to 81 N·m).

   On Cummins L10 engines, tighten the jam nut 20 to 30 lbf·ft (27 to 40 N·m).

   On Cummins N14 engines, tighten the cover plate capscrews 60 to 84 lbf·in (680 to 940 N·cm).

3. Plug the cord into the element and (if applicable) secure it by screwing the threaded cord cover in place.

4. Fill the cooling system. For instructions, refer to **Section 20.01**.

5. Start the engine and check for leaks. Repair any leaks as necessary. Run the engine for half an hour to purge any air from the coolant system.

Block Heater Element Replacement

6. To test the heater, plug a wattmeter into a power source, and connect the heater cord to the meter. A reading on the meter will indicate the heater is working.

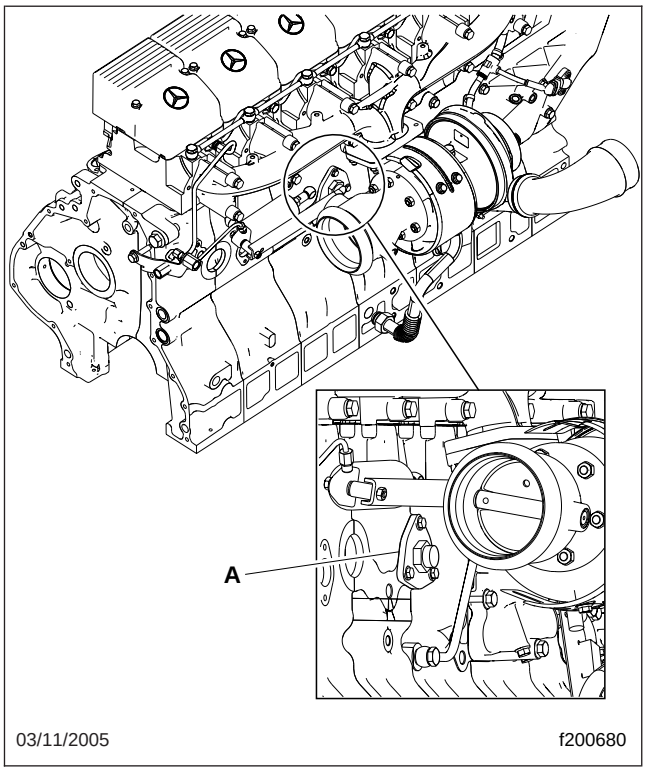

Fig. 6, Block Heater Element Installation, Mercedes-Benz MBE4000

Troubleshooting

Use the following procedures to check for the most common engine block heater problems.

WIRING PROBLEMS

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Unscrew the threaded cover that secures the cord to the element. Pull the cord off the element.
4. Using an ohmmeter, check the continuity between the two poles of the element. The resistance should be very low, typically between 9 and 10 ohms. If there is no reading, the element has burned out, and if the reading is very high, the element is about to burn out.
5. If the element is good, check the cord. Plug the cord into the element and secure it by screwing the threaded cover in place.
6. Using an ohmmeter at the receptacle, check the continuity between the two power terminals. The resistance should be low, typically between 9 and 10 ohms. If there is no reading or a very high reading, the cord is damaged. Replace the cord.
7. Check the continuity between each power terminal and the ground terminal. There should be no ohmmeter reading. If there is a reading, replace the cord.
8. Check the ohmmeter reading between the ground terminal and a good vehicle ground. The reading should be zero. If not, replace the cord.

FOULED ELEMENT

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.

3. Drain the radiator. For instructions, refer to **Section 20.01** in this manual.
4. Unscrew the threaded cover that secures the cord to the element. Pull the cord off the element.
5. Remove the element from the engine block. For instructions, refer to the **Subject 100** in this service manual section.
6. Inspect the element for residue deposits, discoloration, or damage.

   Greenish residue indicates the coolant solution contains too much antifreeze. Replace the element, and refer to the vehicle maintenance manual for the recommended antifreeze/water ratio.

   Gray or black residue indicates anti-leak coolant additives have been added to the system. Replace the element, and refer to the vehicle maintenance manual for the recommended coolant additives.

   Blue or black discoloration on the element indicates the coolant system needs more coolant. Replace the element, and fill the coolant system until coolant is visible in the surge tank sight glass.

   Holes in the element indicate the coolant solution contains too little antifreeze. The weak solution is boiling inside the engine block and causing pitting of the element and block. Replace the element, and refer to the vehicle maintenance manual for the recommended antifreeze to water concentrations.

   For element installation instructions, refer to **Subject 100** in this service manual section.

General Information

The Horton DriveMaster® fan clutch is a temperature-controlled, air-operated clutch for the engine cooling fan. It is spring engaged, and controls the engine temperature by engaging or disengaging the fan.

When the coolant temperature is below a specified range, air pressure keeps the fan disengaged to save engine power. When the coolant temperature rises above the specified range, air pressure to the fan clutch is cut off and internal spring pressure engages the fan.

Air pressure to the fan clutch is controlled by a solenoid valve; the solenoid valve is controlled by a temperature switch installed in the thermostat housing. The temperature switch is connected to the engine ECM, which controls the solenoid valve. See **Fig. 1**. When you start a cold engine, the solenoid valve allows air pressure to the fan clutch and the clutch remains disengaged. When the coolant temperature rises to the temperature switch setting, the switch provides power to the solenoid valve and the valve cuts off compressed air to engage the fan.

On vehicles with air conditioning, the fan clutch solenoid valve is connected to a fan cycling switch at the receiver-dryer. If the refrigerant pressure exceeds the setting of the fan cycling switch, the switch supplies power to the solenoid valve, which cuts off air to the fan clutch, engaging the fan.

Removal

1. Park the vehicle on a level surface, shut down the engine, set the parking brakes, and chock the tires.

⚠ WARNING

Wear safety goggles when draining the air system or disconnecting an air line because dirt and sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnected pressurized air lines, as they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

2. Drain the air tanks.
3. Tilt the hood.
4. Disconnect the left-side hose from the charge air cooler.
5. Remove the drive belts from the engine.
6. Disconnect the air line from the fan hub.
7. Remove the fan.

8.1 If equipped with a metal fan ring, remove the two top fasteners holding the upper mounting bracket for the fan ring.

8.2 Remove the fasteners holding the fan clutch mounting bracket to the front of the engine.

⚠ WARNING

The fan clutch assembly may weigh up to 55 lbs. (25 kg). Be careful when lifting it. Use a helper or a hoist, if necessary. Failure to use care when lifting the fan clutch could cause the assembly to fall, which could result in injury or component damage.

8.3 Remove the fan clutch assembly from the vehicle. If equipped with a metal fan ring, carefully push the ring forward to allow removal of the fan clutch assembly.

Installation

1. Using either a helper or a hoist, position the fan clutch assembly in place on the front of the engine, aligning the holes in the mounting bracket with those in the front of the engine.
2. Install the fasteners.

   If equipped with a metal fan ring, don't tighten the upper fan clutch fasteners completely.
3. Install the drive belts.
4. Connect the air line to the fan clutch.
5. Install the fan. Tighten the fan mounting nuts firmly.
6. Tighten the M8 fan-clutch mounting fasteners 15 lbf·ft (20 N·m).
7. Connect the left-side hose to the charge air cooler.
8. Lower the hood.
9. Remove the chocks from the tires.

Disassembly

NOTE: This procedure involves a major rebuild of the Horton DriveMaster® fan clutch, using parts from the manufacturer's Super Kit. If you are replacing just the seals or the air cartridge, see **Subject 120** for the minor rebuild procedure.

1. Remove the fan clutch assembly from the vehicle. For instructions, see **Subject 100**.
2. Put the fan clutch assembly in a vise.
3. Connect a shop air hose to the fan clutch air inlet.
4. Apply 80 to 120 psi (552 to 827 kPa) to the fan clutch to lift the fan mounting disc off the spring housing/piston assembly.

CAUTION

Use care when placing the pry bar onto the fan mounting disc. Make sure it is secure and flat on the surface. Failure to do so make cause the pry bar to slip, which could result in damage to studs or the fan mounting disc.

5. Using a pry bar, wrench, and a T55 Torx® bit, loosen the jack bolt (left-hand thread) by turning it counterclockwise. See **Fig. 2**.

7. Inspect the fan mounting disc for wear or damage.

⚠ WARNING

Do not disassemble the spring housing from the piston. The interior springs are very strong, and if released could eject the housing with considerable force, possibly resulting in serious injury. Always use the cage nut to hold the spring housing and the piston together.

8. Using a wrench and a T55 Torx bit to hold the jack bolt, install the cage nut from the kit onto the jack bolt (left-hand thread). Hand tighten it onto the spring housing.

   The cage nut will keep the spring housing and piston together as an assembly. It will also maintain pressure on the internal springs after the Torx-head screws holding the friction lining in place are removed.

9. Release the air pressure from the fan clutch.

⚠ WARNING

Release the air pressure from the fan clutch before removing the friction lining Torx-head screws. Failure to release the air pressure could result in the spring housing/piston assembly being ejected with force, which could result in personal injury.

10. Using a T27 Torx bit, remove the eight Torx-head screws holding the friction lining in place.
11. Remove the friction lining. See **Fig. 4**.
12. *Keeping the cage nut installed and tightened,* remove the spring housing/piston assembly. See **Fig. 5** .
13. Remove the air chamber seal. See **Fig. 6** .
14. Examine the inside of the air chamber for signs of moisture and/or contaminants.
15. Remove the air chamber cap retaining ring. See **Fig. 6** .
16. Using two small screwdrivers placed 180 degrees apart, gently and evenly pry the air chamber cap out of the sheave.

IMPORTANT: If the fan clutch uses spacers, be sure to install them between the bearings.

2.2 Supporting the sheave, press the new sheave bearings — and spacers, if applicable — into place. Note the position of the lip inside the sheave.

2.3 Slide the sheave onto the mounting bracket. See Fig. 8 .

2.4 Making sure that the bearing nut hex is facing up, install the bearing nut. See Fig. 12 . Tighten 130 lbf·ft (176 N·m). See Fig. 7 .

WARNING

The new spring housing/piston assembly from the kit has a cage nut installed on it. Do not remove the cage nut. This will cause the spring housing to be forcibly ejected from the piston assembly, which could result in serious injury.

14. Carefully set the new spring housing/piston assembly into position. See **Fig. 6** . Note that the new assembly has a cage nut installed on it.
15. Rotate the new spring housing/piston assembly to align the mounting holes with those of the sheave.

IMPORTANT: Handle the new friction liner by the edges to avoid contamination.

16. Set the new friction liner from the kit into place, being careful to touch only the edges.
17. Using a T27 Torx bit, install the eight Torx-head screws. See **Fig. 4** . Tighten alternately 80 lbf·in (900 N·cm).
18. Apply a minimum of 80 psi (552 kPa) of clean air to the air inlet.
19. Remove the cage nut from the spring housing/piston assembly.
20. Install the new fan mounting disc from kit.

CAUTION

Use care when placing the pry bar onto the fan mounting disc. Make sure it is secure and flat on the surface. Failure to do so make cause the pry bar to slip, which could result in damage to studs or the fan mounting disc.

21. Using a suitable wrench, a T55 Torx bit, and a pry bar, tighten the jack bolt (left-hand thread) 100 lbf·ft (136 N·m). Turn the wrench clockwise and push the pry bar counterclockwise.
22. Using shop air, actuate the fan clutch and check for correct engagement and disengagement of the fan mounting disc. If there is a problem, it must be corrected before installing the fan clutch onto the engine.
23. Check for air leaks at the bleed hole and around the spring housing/piston assembly.
24. Install the fan clutch assembly onto the engine. See **Subject 100** for instructions.

Disassembly

NOTE: This procedure involves a minor rebuild of the Horton DriveMaster® fan clutch, using parts from the manufacturer's Seal Kit. If a major rebuild of the fan clutch is needed, see **Subject 110**.

1. Remove the fan clutch assembly from the vehicle. For instructions, see **Subject 100**.
2. Put the fan clutch assembly in a vise.
3. Connect a shop air hose to the fan clutch air inlet.
4. Apply 80 to 120 psi (552 to 827 kPa) to the fan clutch to lift the fan mounting disc off the spring housing/piston assembly.

⚠ CAUTION

Use care when placing the pry bar onto the fan mounting disc. Make sure it is secure and flat on the surface. Failure to do so make cause the pry bar to slip, which could result in damage to studs or the fan mounting disc.

5. Using a pry bar, wrench, and a T55 Torx® bit, loosen the jack bolt (left-hand thread) by turning it counterclockwise. See **Fig. 1**.
6. Unscrew the fan mounting disc from the jack bolt. See **Fig. 2**.
7. Inspect the fan mounting disc for wear or damage.

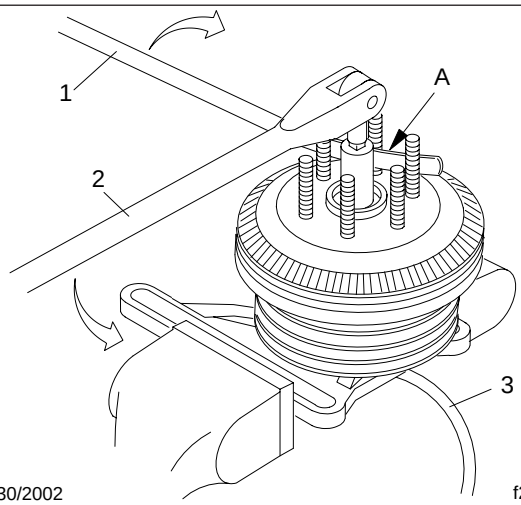
⚠ WARNING

Do not disassemble the spring housing from the piston. The interior springs are very strong, and if released could eject the housing with considerable force, possibly resulting in serious injury. Always use the cage nut to hold the spring housing and the piston together.

8. Using a wrench and T55 Torx bit to hold the jack bolt, install the cage nut from the kit onto the jack bolt (left-hand thread). Hand tighten it onto the spring housing.

   The cage nut will keep the spring housing and piston together as an assembly. It will also maintain pressure on the internal springs after the Torx-head screws holding the friction lining in place are removed.

9. Release the air pressure from the fan clutch.



A. Place the pry bar here.
1. Pry Bar (push clockwise)
2. Torx Bit and Wrench (turn counterclockwise)
3. Shop Air Hose (connected to the inlet port)

⚠ WARNING

Release the air pressure from the fan clutch before removing the friction lining Torx-head screws. Failure to release the air pressure could result in the spring housing/piston assembly being ejected with force, which could result in personal injury.

10. Using a T27 Torx bit, remove the eight Torx-head screws holding the friction lining in place.

General Description

Eaton® Fuller® clutches are pull-type clutches of a dry-disc design. They are available in 15.5-inch (394-mm) two-plate assemblies used in heavy-duty applications.

The intermediate plate separating the driven discs is carried on four lugs within the cover assembly, which is mounted on a flat flywheel. Four positive separator pins™ (roll pins) ensure an equal gap on all sides of the intermediate plate and increase the life of the clutch. Four return straps are attached to the cover assembly to retract the pressure plate when the clutch is disengaged.

Solo 15.5-Inch Clutch

Eaton Fuller Solo™ clutches are totally adjustment-free. See **Fig. 1**. As the clutch wears, its innovative wear-adjusting technology monitors clutch components and makes any necessary adjustments. The wear-adjusting technology comes from two sliding cams, which rotate to maintain the proper adjustment. Atop the upper cam, a wear indicating tab mirrors the cam's movement, letting you know when it's time to replace the clutch. See **Fig. 2**. This tab cannot be used as a mechanism for adjusting the clutch.

Heavy-duty Solo clutch discs are offered in two configurations, one standard on Century S/T and Argosy (see **Fig. 3**) and the other standard on Coronado (see **Fig. 4**):

- Seven spring dampers with four ceramic facings are standard on Century S/T and Argosy in the extended-lube (XL-100) version, and optional on the Coronado.
- Seven spring dampers with six ceramic facings and vibration control technology (VCT™plus) are standard in the extended-lube (XL-100) version on Coronado, and optional on the Century S/T and Argosy.

NOTE: An earlier version of vibration control technology (VCT™) had a disc with six spring dampers and six ceramic facings. This disc has now been replaced by VCT™plus.

Modern high-torque engines require higher performance from a clutch. The extended-lube (XL-100) clutches have a special roller yoke and a ribbed release bearing housing that reduces bearing wear and extends the service interval for lubrication.

On Century Class S/T or Argosy models, Solo clutches are only offered in the XL-100 version. On Coronado, the six-spring XL-100 version is standard,

but clutches without the extended-lube feature are offered. XL-100 clutches are not available for Severe Service applications.

On older vehicles, clutch discs with eight, nine, or ten spring dampers may be installed. These older types of vibration dampers are not adequate for modern high-horsepower engines that operate at lower peak torques.

⚠ CAUTION

If your vehicle was originally equipped with six- or seven-spring discs, do not substitute eight- or ten-spring discs. This could cause excessive torsional vibration and component damage.

Easy-Pedal 15.5-Inch Clutch

Eaton® Fuller® Easy-Pedal® clutches are easily adjustable using the Kwik-Adjust™ mechanism. See **Fig. 5**.

Easy-Pedal heavy-duty clutch discs are offered in two optional configurations on Coronado only:

- Seven spring dampers with four ceramic facings. See **Fig. 3**.
- Seven spring dampers with six ceramic facings and vibration control technology (VCT™plus). See **Fig. 4**.

NOTE: An earlier version of vibration control technology (VCT™) had a disc with six spring dampers and six ceramic facings. This disc has now been replaced by VCT™plus.

On older vehicles, clutch discs with eight, nine, or ten spring dampers may be installed. These older types of vibration dampers are not adequate for modern high-horsepower engines that operate at lower peak torques.

ten-spring discs. This could cause excessive torsional vibration and component damage.

Clutch capacity is indicated by the color code of the pressure springs in the cover assembly. See the appropriate table for Easy-Pedal clutches in **Specifications, 400**.

Principles of Operation

The primary purpose of the clutch is to transfer the power of the engine from the engine flywheel to the transmission. At the point where clutch engagement begins (clutch pedal partially released), the transmission input shaft may be stationary, as when the vehicle is not moving, or it may be rotating at a different speed than the flywheel, as in the case of upshifting or downshifting. Once the clutch is fully engaged (clutch pedal fully released), both the engine flywheel and the transmission input shaft will be rotating at the same speed.

The secondary purpose of the clutch is to damp unwanted vibrations that normally exist in the driveline system. The springs within each driven disc provide a flexible link between the friction surfaces and the disc hubs. Damped clutch discs are specifically designed to prolong the life of drivetrain components by reducing vibrations from the engine, non-uniform U-joint angles, and road dips and bumps.

When the clutch pedal is first pressed down, the first 1/2-inch to 1-inch (12.7 to 25.4 mm) of pedal movement (clutch free-pedal) causes the release yoke fingers to move into contact with the wear pads of the release bearing (release yoke free-travel). See **Fig. 6**. The release yoke pulls the release bearing away from the pressure plate inside the clutch cover. This compresses the pressure springs, allowing the driven discs to slip freely, and at a different speed from the drive discs.

Further downward movement of the clutch pedal (clutch release-pedal), causes the release bearing to move into contact with the clutch brake (release bearing travel). The pressure springs force the pressure plate toward the engine flywheel, applying friction to the driven discs. Slippage occurs between the drive and driven discs because of the difference in their speeds.

In the last 1 inch to 1-1/4 inches (25 to 33 mm) of downward pedal movement, the clutch brake and the release bearing are pressed together (clutch brake squeeze). The friction between the discs increases, and the slippage and difference in speeds decreases. When the pedal is fully released, pressure and friction are sufficient to stop the discs from slip-

General Information

B. Clutch Release-Pedal
C. Clutch Brake Squeeze

Fig. 6, Clutch Pedal Movement

ping. With no slippage, the driving and driven members turn at the same speed.

When the vehicle is stationary, the clutch brake permits shifting into first gear or reverse gear without severe gear clash. The clutch brake is between the release bearing housing and the transmission bearing cap, and is engaged by tangs to the transmission input shaft. When the pedal is fully depressed, the clutch brake is squeezed between the release bearing housing and the transmission bearing cap, stopping the rotation of the main drive gear.

The clutch brake may be a disc type or a torque-limiting type. To prevent overloads to it, the torque-limiting clutch brake is designed to slip when loads of 20 to 25 lbf·ft (27 to 34 N·m) are reached. Clutch brakes are not designed for upshifting.

NOTE: The following procedures apply only to Eaton® Fuller® Easy-Pedal® clutches. Solo™ clutches are adjustment-free.

Release yoke free-travel is the distance between the release bearing wear pads and the release yoke. At the factory, the release yoke free-travel is set to 0.105 to 0.145 inch (2.7 to 3.7 mm). This setting produces approximately two inches (51 mm) of clutch free-pedal.

IMPORTANT: When clutch free pedal is less than about 3/4 inch (19 mm), adjust the clutch internally according to the procedures in this subject. Take care to do all procedures in the proper order.

Release bearing travel is the clearance between the aft end of the release bearing housing and the forward surface of the clutch brake disc. For the clutch to release properly, the release bearing travel measurement must be between 1/2 and 9/16 inch (12.7 to 14.3 mm).

As the clutch wears, the release bearing moves towards the engine flywheel, reducing release yoke free-travel and increasing release bearing travel. If internal clutch adjustments are not made, the release yoke fingers will eventually ride against the wear pads. This could cause the following problems:

- Worn bearing wear pads and release yoke
- Damaged release bearing and housing
- Eventual clutch slippage and burn-up

Release Bearing Travel

Measurement

⚠ CAUTION

Make sure the internal adjustment is correct before making any linkage adjustments. Incorrect adjustments can cause transmission gear clash, slipping, and burning of clutch components.

1. Apply the parking brakes and chock all the tires.
2. Remove the clutch inspection cover from the bottom of the bell housing. See **Fig. 1**.
3. Slide the clutch brake (either the one-piece torque-limiting clutch brake, or the two-piece disc-type clutch brake with washer) tight against the transmission input-shaft bearing cap. See **Fig. 2**. Also, slide the release bearing as far as possible towards the transmission.

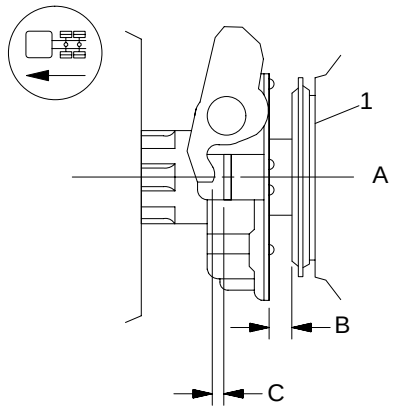
IMPORTANT: Release bearing travel tool A02–12419 is available through the PDCs. One end

of the tool has green tape on it and is 0.50 inch (12.7 mm) in diameter; the other end has blue tape on it and is 0.56 inch (14.3 mm) in diameter.

4. Measure the release bearing travel. See **Fig. 3** for the correct dimension to measure. Using both ends of the release bearing travel tool (**Fig. 4**), check this gap as follows:



03/01/94 f250172a

A. Check both dimensions: release bearing travel (B) and release yoke free-travel (C).
B. Release bearing travel: 1/2 to 9/16 inch (12.7 to 14.3 mm) between release bearing housing and clutch brake.
C. Release yoke free-travel: approximately 0.105 to 0.145 inch (2.7 to 3.7 mm) between yoke and wear pads.

4.1 Position the tool so that the legs straddle the transmission input shaft.

4.2 Insert the blue 0.56-inch (14.3-mm) end. If it fits loosely, the gap is too wide and adjustment is needed. See "Adjustment."

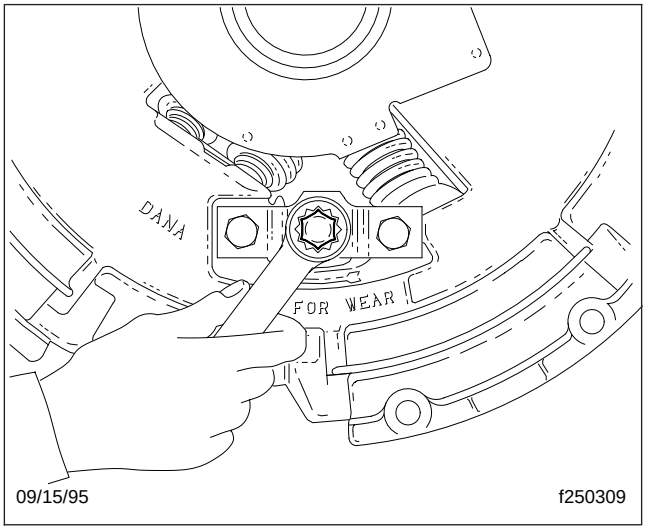
4.3 If the blue 0.56-inch (14.3-mm) end can't be inserted in the gap, then try to insert the green 0.50-inch (12.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

4.4 If the green end of the tool can't be inserted in the gap, adjustment is needed. See "Adjustment."

5. If no internal clutch adjustment is necessary, go to "Release Yoke Free-Travel."

Adjustment

To adjust Easy-Pedal clutches, use the Eaton Fuller Kwik-Adjust® mechanism (see **Fig. 5**).



09/15/95 f250309

Fig. 5, Adjustment with Kwik-Adjust

1. Turn the engine flywheel until the lockstrap is aligned with the clutch inspection-cover opening. See **Fig. 1** and **Fig. 5**.
2. Release the clutch by depressing the pedal. Block the pedal in the released position, or have someone assist you by holding the pedal down during the adjustment procedure.

NOTE: An open-end wrench is not recommended for the following step.

3. Adjust the clutch, using a 5/8-inch box-end or socket wrench on the adjustment bolt.

   3.1 Insert the 5/8-inch box-end or socket wrench through the inspection cover opening.

   3.2 To begin the adjustment, release the adjustment bolt by pressing down on the bolt head.

   NOTE: Normal wear increases the gap between the release bearing and the transmission.

   3.3 *To decrease the gap*: If clearance between the release bearing housing and the clutch brake is *more than* 9/16-inch (14.3 mm), turn the adjustment bolt clockwise (the release bearing moves toward the transmission).

   To increase the gap: If clearance between the release bearing housing and the clutch brake is *less than* 1/2-inch (12.7 mm), turn the adjustment bolt counterclockwise (the release bearing moves toward the engine).

   3.4 When the adjustment is complete, make sure the adjustment bolt is locked (pulled up flush with the mounting bolts).

NOTE: On Easy-Pedal 2000 clutches, each complete turn of the adjustment bolt represents about 1/8-inch (3.2 mm) of release bearing movement. On earlier Easy-Pedal models, each complete turn of the adjustment bolt represents about 0.02-inch (0.5 mm) of release bearing movement.

4. After adjusting, release the pedal and check the clearance between the release bearing housing and the clutch brake. When the clearance is 1/2 to 9/16 inch (12.7 to 14.3 mm), the adjustment is complete.

Release Yoke Free-Travel

IMPORTANT: Release yoke free-travel tool A02–12254 is available through the PDCs. The legs on one end of the tool have green tape on them and are 0.105 inch (2.7 mm) thick; the legs on the other end have blue tape on them and are 0.145 inch (3.7 mm) thick.

1. Measure the release yoke free-travel. See **Fig. 3** for the correct dimension to measure. Using both ends of the free-travel tool (**Fig. 6**), check the gap as follows:

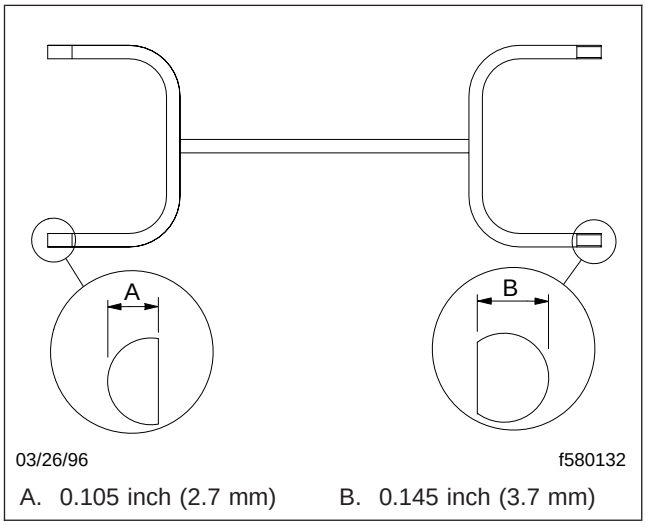


Fig. 6, Release Yoke Free-Travel Tool A02-12254

2. Position the tool so that the legs straddle the release yoke.
3. Insert the blue 0.145-inch (3.7-mm) end. If it fits loosely, the gap is too wide and linkage adjustment is needed. See the appropriate subject in **Section 25.03**.
4. If the blue 0.145-inch (3.7-mm) end can't be inserted in the gap, then try to insert the green 0.105-inch (2.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.
5. If the green end of the tool can't be inserted in the gap, linkage adjustment is needed. See the appropriate subject in **Section 25.03**.

Clutch Brake Squeeze

NOTE: This procedure requires two persons: one under the vehicle with access to the release bearing, and the other in the vehicle to depress the clutch pedal and measure the pedal travel.

Clutch Adjustments

The distance the pedal moves (from the fully depressed position) to free the feeler gauge is the clutch brake squeeze measurement.

1. Apply the parking brakes and chock all the tires.
2. Remove the clutch inspection cover from the bottom of the bell housing. See **Fig. 1**.
3. Insert a 0.010 inch (0.25 mm) feeler gauge (a business card works well if a feeler gauge is not available) between the release bearing and clutch brake.
4. Depress the clutch pedal to the end of its stroke.
5. Slowly let the pedal up. Stop when the feeler gauge can be pulled out. The pedal should be 1/2 to 1 inch (12.7 to 25.4 mm) from the end of the stroke.
6. If necessary to obtain proper clutch brake squeeze, check the linkage for worn or damaged components. Repair or replace components as necessary. Adjust the linkage according to the procedures in the appropriate subject in **Section 25.03**.

Removal

Solo™ Heavy-Duty Clutch

Use the following procedure if you need to temporarily remove and then reinstall an Eaton Fuller Solo Heavy-Duty 15.5" adjustment-free clutch. Failure to follow these steps could cause the Solo clutch to drag or not release upon installation.

IMPORTANT: Check the position of the wear indicating tab on the clutch cover. If the wear indicating tab is near the REPLACE position on the indicator, it is time to replace the clutch.

NOTICE

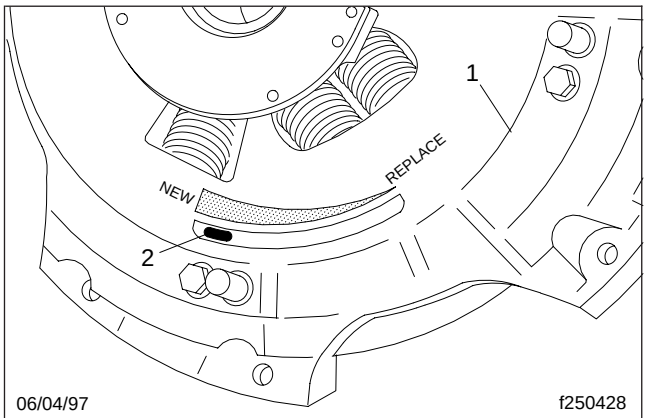
For proper installation of the Solo clutch, the wear indicating tab must be reset. Failure to reset this tab will prevent clutch release and result in possible clutch damage.

NOTE: This step requires two persons: one under the vehicle with access to the wear indicating tab, and the other in the vehicle to press the clutch pedal.

1. Reset the wear indicating tab with the clutch in the vehicle, as follows.
   - 1.1 From inside the cab, press the clutch pedal all the way down. Hold the clutch pedal down until the wear indicating tab is reset.
   - 1.2 Through the clutch inspection cover, slide the wear indicating tab to the left until it is at the NEW position on the indicator. See **Fig. 1**.
   - 1.3 From inside the cab, release the clutch pedal. Check to be sure the wear indicating tab stays at the NEW position on the indicator.

NOTE: Before pulling the transmission from the bell housing, disconnect the external clutch linkage and rotate the release yoke so the yoke will clear the release bearing when it is removed.

2. Remove the transmission. See **Section 26.00**.



With the clutch pedal down, set the tab to the NEW position on the indicator.

1. Clutch Cover
2. Wear Indicating Tab

Fig. 1, Resetting the Wear Indicating Tab

NOTICE

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

3. Remove the clutch brake from the transmission input shaft. See **Fig. 2**.

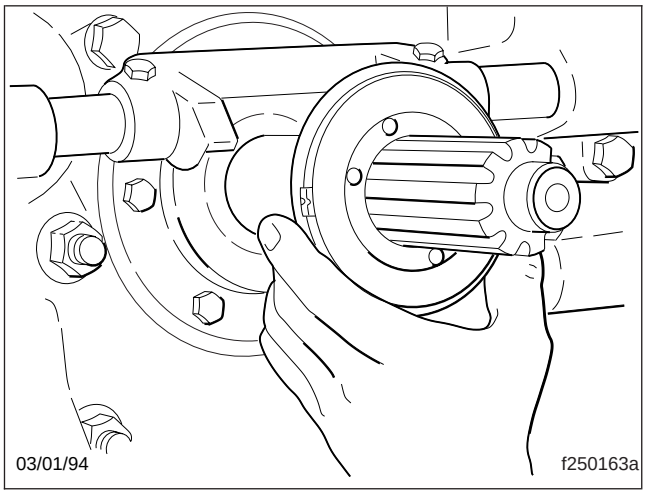


Fig. 2, Clutch Brake Removal

4. Install a spline aligning tool into the release bearing assembly, and through the driven discs. See

Clutch Removal

Fig. 3. An old transmission input shaft may be used for this purpose.

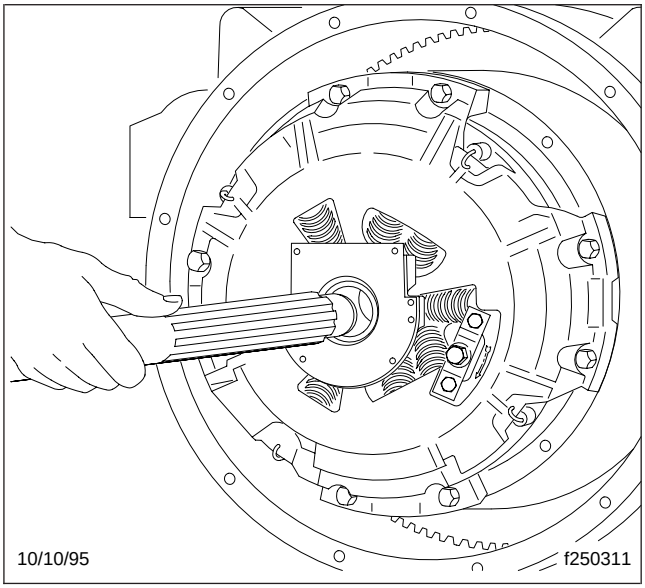

Fig. 3, Installing a Spline Aligning Tool

NOTE: Shipping bolts are installed on the clutch cover prior to installation to prevent the clutch adjustment mechanism from unloading.

5. Install four 7/16–14 x 1-3/4 shipping bolts (if available) or hexhead machine screws into the four clutch cover holes, and tighten them finger-tight plus one full turn. See **Fig. 4**.

   These bolts will cage the pressure plate, preventing the four plate spacers from moving out of position when the clutch is removed from the flywheel.

6. Progressively loosen each of the mounting capscrews in the pattern shown in **Fig. 5**. This will prevent warping or bending within the clutch, and will ease removal of the clutch mounting capscrews.

7. Remove the two top mounting capscrews from the cover assembly. Install two 7/16–14 x 5 guide studs in the open holes to help support the clutch assembly during removal. See **Fig. 6**.

NOTE: Mark the positions of the clutch components so they can be properly oriented during installation.

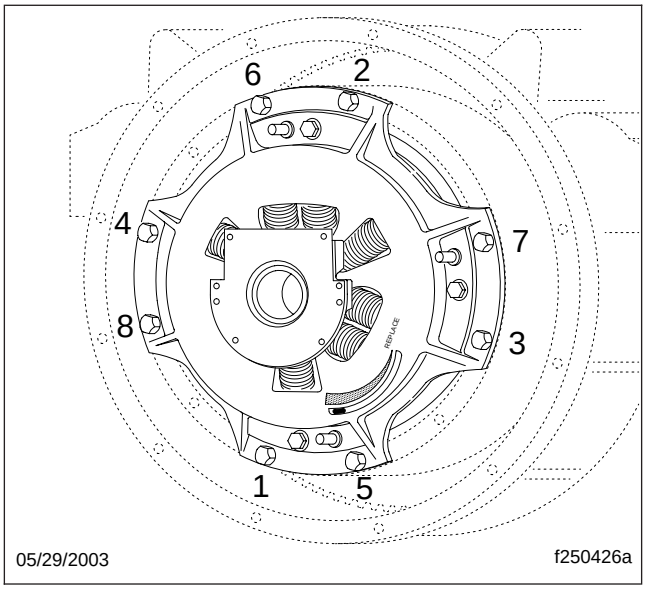

Fig. 5, Loosening Sequence

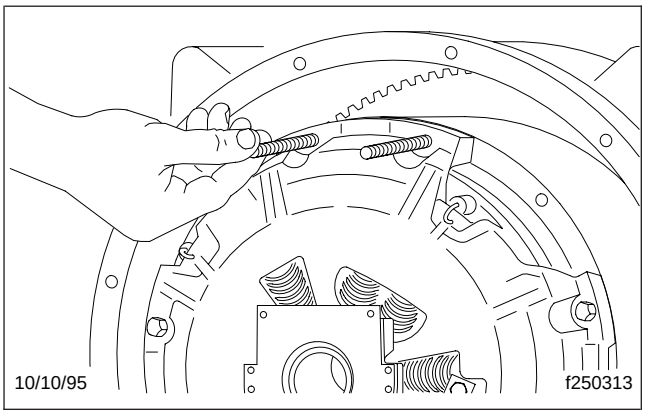

Fig. 6, Installing the Guide Studs

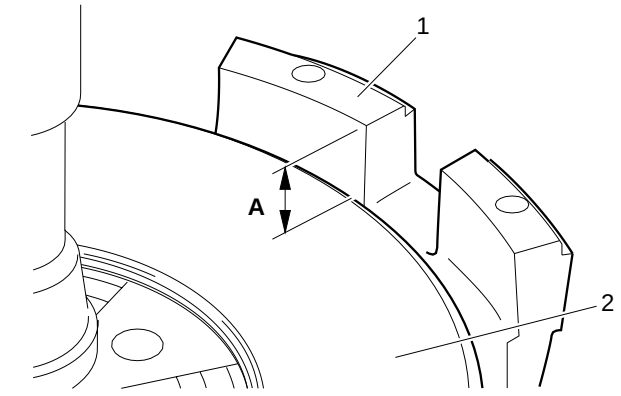
WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

8. Remove the mounting capscrews, and carefully remove the clutch assembly together with the spline aligning tool.
9. Reset the pressure plate, as follows. See **Fig. 7**.



NOTE: The pressure plate will be reset when it is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface of the clutch cover.

A. 1.75 to 1.78 inches (44.4 to 45.2 mm)

2. Pressure Plate

Fig. 7, Reset Pressure Plate

9.1 Progressively tighten the four shipping bolts in a crisscross pattern.

9.2 Measure the depth of the pressure plate. When the face of the pressure plate is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface of the clutch cover, the pressure plate is reset.

NOTE: Resetting the pressure plate will allow the clutch to release after installation.

10. Use an appropriate puller to remove the pilot bearing. Inspect the old pilot bearing for any unusual wear or damage. Discard the pilot bearing.

Easy-Pedal™ Clutch

NOTE: Before pulling the transmission from the bell housing, disconnect the external clutch linkage and rotate the release yoke so the yoke will clear the release bearing when it is removed.

1. Remove the transmission. See **Section 26.00**.

NOTICE

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

2. Remove the clutch brake from the transmission input shaft. See **Fig. 2**.
3. Install a spline aligning tool into the release bearing assembly, and through the driven discs. See **Fig. 3**. An old transmission input shaft may be used for this purpose.
4. Use a release tool and two 5/8-inch (16 mm) spacer blocks to pull the bearing back. See **Fig. 8**. The spacer blocks relieve the internal spring load in the clutch assembly, and facilitate clutch removal.
5. Remove the two top mounting bolts from the cover assembly. Install 7/16–14 x 5 guide studs in the open holes to help support the clutch assembly during removal. See **Fig. 6**.
6. Progressively loosen each of the mounting bolts in the pattern shown in **Fig. 9**. This will prevent warping or bending within the clutch, and will ease removal of the clutch mounting bolts.

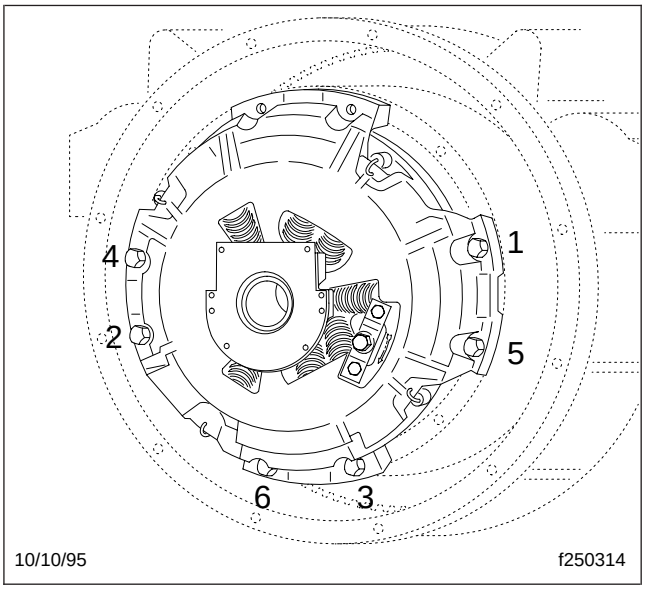

Fig. 9, Loosening Sequence, Easy-Pedal

⚠ WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

7. Remove the mounting bolts, and carefully remove the clutch assembly.

   Be careful to keep the spline aligning tool in place to retain the discs and intermediate plate. Remove the spline aligning tool, the rear driven disc, the intermediate plate, and the front driven disc.

8. Use an appropriate puller to remove the pilot bearing. Inspect the old pilot bearing. Correct the cause of any unusual wear or damage. Discard the bearing.

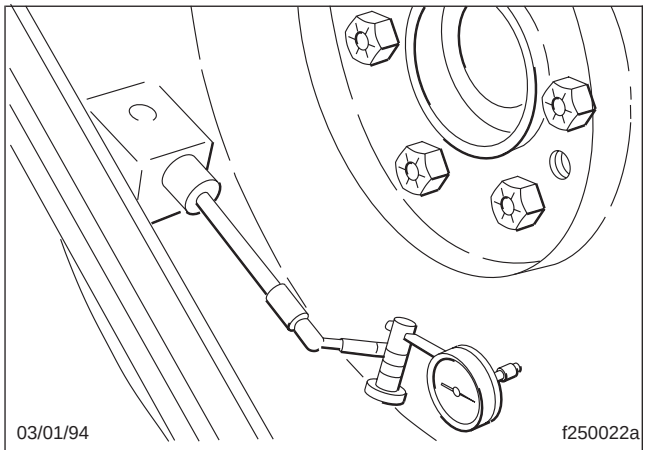
Clutch Inspection

NOTICE

Misalignment of any parts described in these procedures will cause premature wear of drivetrain components.

IMPORTANT: When taking the following readings, rotate the engine by hand; do not crank the engine with the starter. The engine may be rotated by the pulley nut at the front of the crankshaft, the flywheel mounting bolts, or the starter ring-gear on the flywheel.

1. Clean the surfaces being measured to ensure accurate measurements.
2. Measure the runout of the flywheel face (friction surface). See **Fig. 1** for the correct set-up.



Secure the dial indicator to the flywheel housing, with the gauge finger against the flywheel face, and near the outer edge.

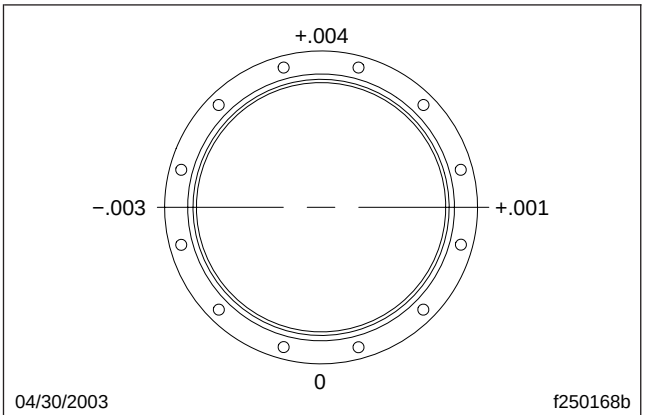
Fig. 1, Measure the Flywheel Face

2.1 Secure the dial indicator to the flywheel housing, with the gauge finger against the face of the flywheel near the outer edge.

2.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the flywheel face.

2.3 The total runout will be the difference between the highest plus and minus readings. To calculate the runout, see **Fig. 2**.

Example: The highest reading is +0.004 at 12 o'clock. The lowest reading is –0.003 at 9 o'clock. Therefore the total runout is 0.007 inch.

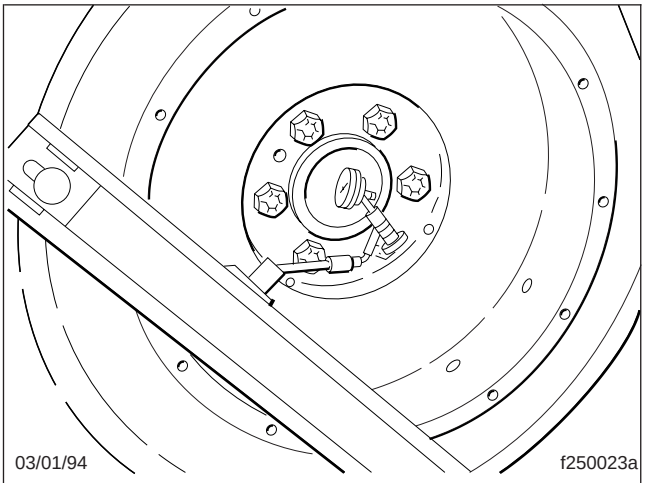


Take four readings, starting with zero at the 6 o'clock position, and going on to 9, 12, and 3 o'clock. Make sure the dial returns to zero at the original start position.

Fig. 2, Calculate the Runout

2.4 The SAE maximum total runout for the flywheel face is 0.008 inch (0.20 mm). If the readings are higher, see the engine manufacturer's manual for instructions.

3. Measure the runout of the pilot-bearing bore in the flywheel. See **Fig. 3** for the correct set-up.



Secure the dial indicator to the flywheel housing, with the gauge finger on the surface of the pilot-bearing bore.

Fig. 3, Measure the Pilot-Bearing Bore

Clutch Inspection and Pre-Installation Procedures

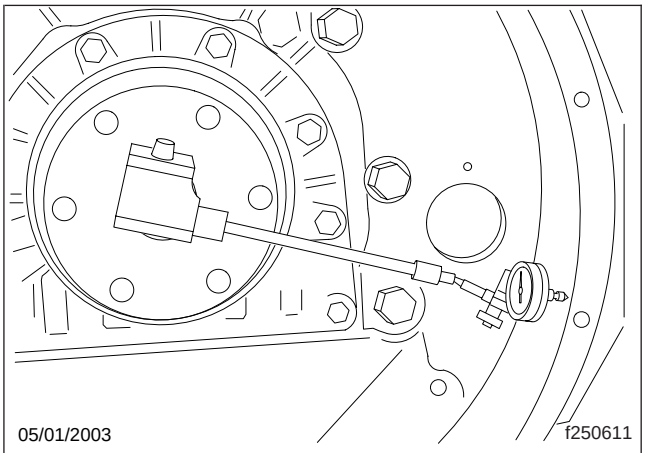
3.1 With the indicator still secured to the flywheel housing, move the gauge finger to contact the surface of the pilot-bearing bore.

3.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the bore of the pilot bearing.

3.3 Calculate the runout as before.

3.4 The SAE maximum total runout for the pilot-bearing bore is 0.005 inch (0.13 mm). If the readings are higher, see the engine manufacturer's manual for instructions.

4. Measure the runout of the flywheel housing bore. See **Fig. 4** for the correct set-up.



Secure the dial indicator to the crankshaft, with the gauge finger against the side of the flywheel housing.

Fig. 4, Measure the Flywheel Housing Bore

4.1 Secure the dial indicator to the crankshaft, with the gauge finger against the side of the flywheel housing.

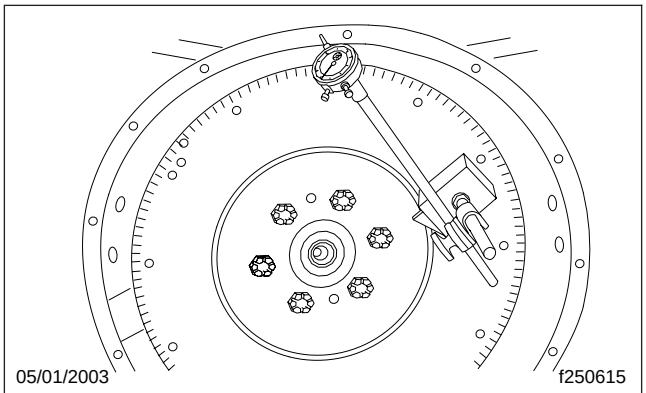
4.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the side of the flywheel housing.

4.3 Calculate the runout as before.

NOTE: Only if you have to reposition the flywheel housing is it necessary to mark the high and low runout readings in clock positions.

4.4 The SAE maximum total runout for the flywheel-housing bore is 0.008 inch (0.20 mm). If readings are higher, replace the flywheel housing. For instructions, see the engine manufacturer's manual.

5. Measure the runout of the face of the flywheel housing. See **Fig. 5** for the correct set-up.



Secure the dial indicator to the outer diameter of the flywheel, with the gauge finger against the face of the flywheel housing.

Fig. 5, Measure the Flywheel Housing Face

5.1 With the dial indicator secured to the outer diameter of the flywheel, move the gauge finger to contact the face of the flywheel housing.

5.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the face of the flywheel housing.

5.3 Calculate the runout as before.

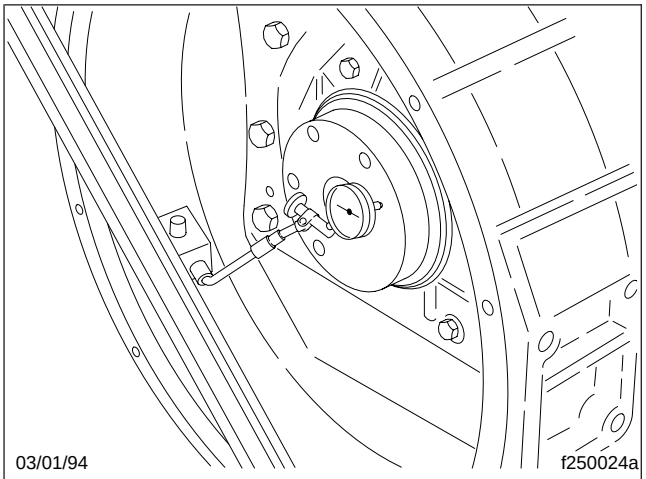
NOTE: Only if you have to reposition the flywheel housing is it necessary to mark the high and low runout readings in clock positions.

5.4 The SAE maximum total runout for the flywheel-housing face is 0.008 inch (0.20 mm). If the readings are higher, replace the housing. For instructions, see the engine manufacturer's manual.

NOTE: Use a case-bore plug and shaft set to measure the bell-housing face and pilot. Case-bore plugs are tapped into the front and rear bores of the transmission case, and have very

close tolerances. The shaft runs through the center of the plugs, and extends to the front far enough to secure a dial indicator and obtain a reading on the bell housing.

6. Measure the runout of the bell housing face and pilot.
   - 6.1 Secure the dial indicator to the case-bore shaft, with the gauge finger against the face of the bell housing.
   - 6.2 Turn the case-bore shaft through one complete revolution. With chalk or soapstone, mark the high and low points on the face of the bell housing.
   - 6.3 Calculate the runout as before.
   - 6.4 The SAE maximum total runout for the bell-housing face is 0.008 inch (0.20 mm). If the readings are higher, replace the bell housing. See the transmission manufacturer's service manual for instructions.
7. Remove the flywheel (see the engine manufacturer's manual), and measure the runout of the flywheel crankshaft face. See **Fig. 6**.



Secure the dial indicator to the flywheel housing, with the gauge finger against the crankshaft face, and near the outer edge.

Fig. 6, Measure the Crankshaft Face Runout

   - 7.1 Secure the dial indicator to the flywheel housing, with the gauge finger against the crankshaft face, and near the outer edge.
   - 7.2 Turn the crankshaft through one complete revolution. With chalk or soapstone, mark the high and low points on the face of the crankshaft.
   - 7.3 Calculate the runout as before.
   - 7.4 See the engine manufacturer's manual for maximum runout, corrective measures, and flywheel installation instructions.

Resetting (clutch out of vehicle)

NOTICE

Use this procedure if the clutch was removed without caging the pressure plate. Resetting the pressure plate allows the clutch to release after installation and prevents possible clutch damage.

1. Remove the four shipping bolts if they have been installed. See **Fig. 7**.

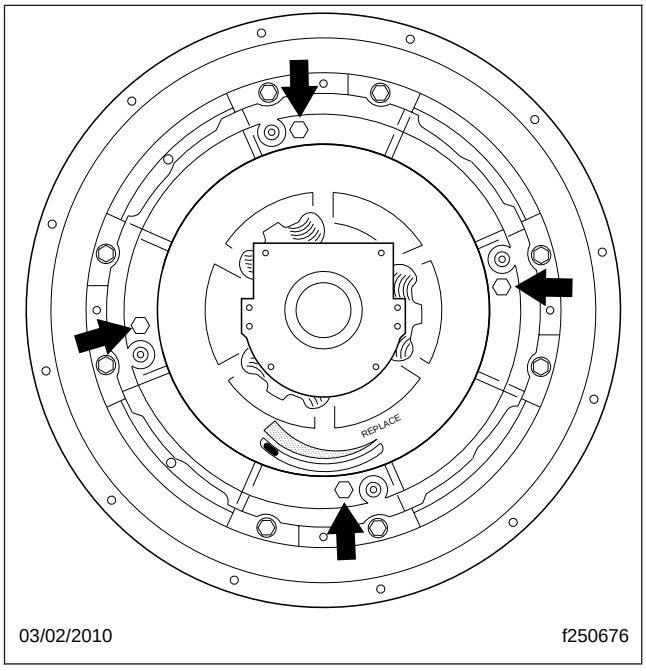


Fig. 7, Installed Shipping Bolts

2. Support the clutch cover in an arbor press with the release bearing facing down. When setting up the arbor press, allow at least 1 inch (25 mm)

clearance for both movement of the release bearing and access to install shipping bolts. See **Fig. 8**.

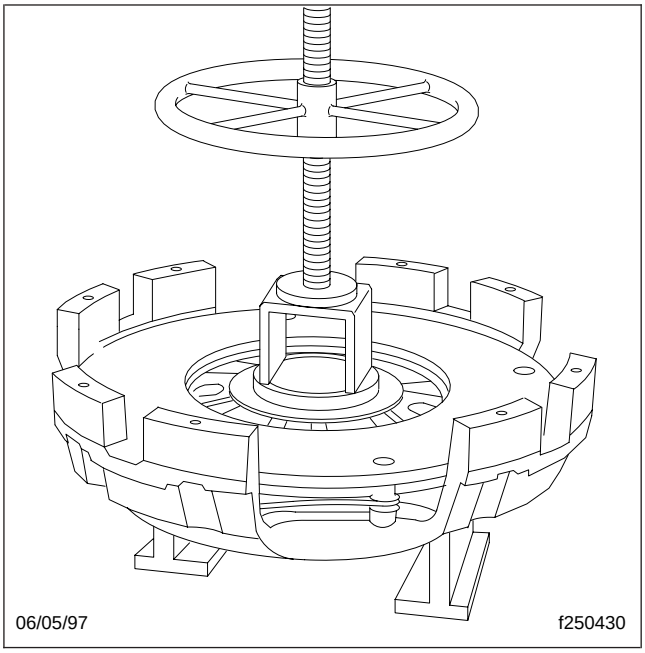

Fig. 8, Arbor Press Setup

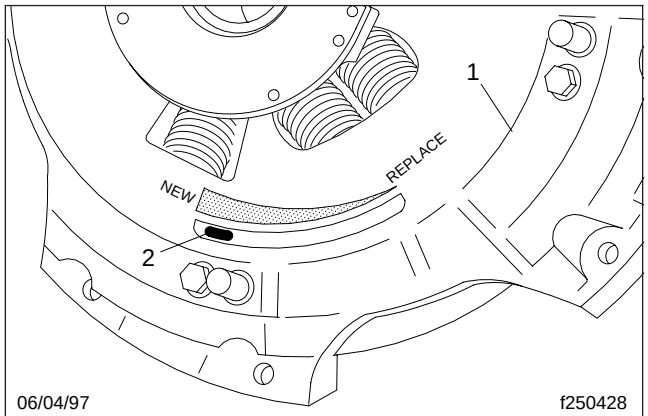
3. Center the ram and press downward on the retainer until it comes to a stop. Lock the ram in position.
4. Slide the wear indicating tab to the left until it is at the NEW position of the indicator (**Fig. 9**) and hold it in position with a magnet.

NOTE: Shipping bolts are installed on the clutch cover prior to installation to prevent the clutch adjustment mechanism from unloading.

5. Install four 7/16–14 x 1-3/4 shipping bolts (if available) or hexhead machine screws into the four clutch cover holes, and tighten them finger-tight. See **Fig. 7**.

NOTE: You may need to temporarily install slightly longer bolts to allow access of the shipping bolts.

6. Reset the pressure plate, as follows.
   - 6.1 Progressively tighten the four shipping bolts in a crisscross pattern.



1. Clutch Cover
2. Wear Indicating Tab

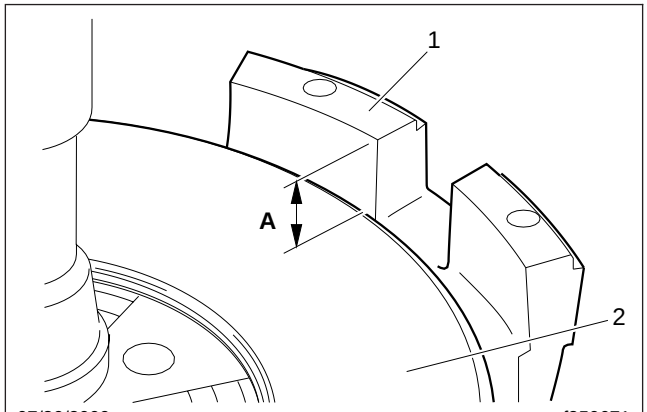
- 6.2 Measure the depth of the pressure plate. When the face of the pressure plate is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface of the clutch cover, the pressure plate is reset. See **Fig. 10**.



NOTE: The pressure plate will be reset when it is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface of the clutch cover.

Pre-Installation Procedures

Before installing a new, rebuilt, or used clutch, do the following procedures:

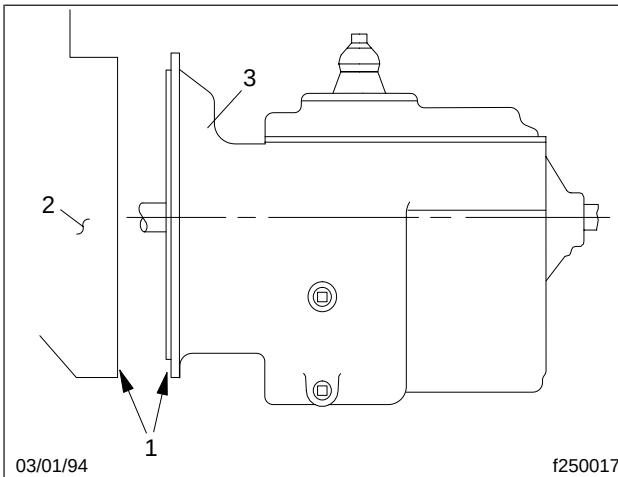
1. Install a new pilot bearing. Be sure that the pilot bearing has a press-fit in the flywheel.

NOTICE

Tap on the outer race only. Tapping on the inner race could damage the pilot bearing.

NOTE: To discourage warranty claims for drag or clutch noise, use a premium grade C3/C4 pilot bearing. Due to increased operating temperatures and longer clutch life, the standard pilot bearings and grease are no longer acceptable.

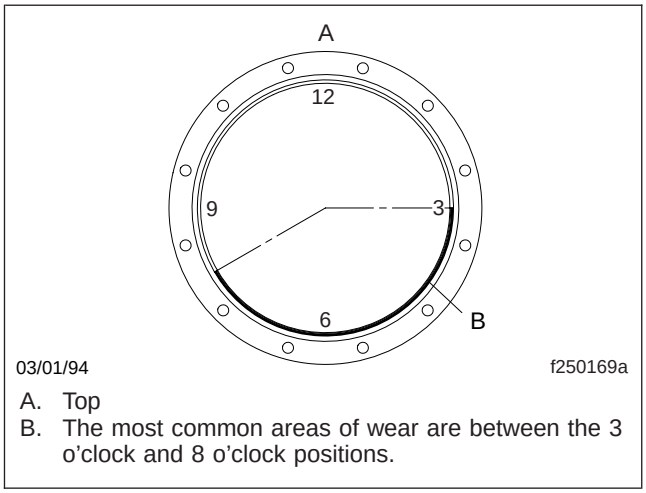
2. Check for wear on the mating surfaces of the flywheel housing and the transmission bell housing. Any noticeable wear on either part causes misalignment. If worn, replace the part. See **Fig. 11**.



1. Mating Surfaces
2. Engine Flywheel Housing
3. Transmission Bell Housing

Fig. 11, Inspect the Mating Surfaces

3. Check the flywheel for wear caused by the bell housing pilot (projecting lip of the bell housing). The correct dimension is 1/8-inch (3.2-mm). Wear is most likely to appear between the 3 o'clock and 8 o'clock positions. See **Fig. 12**.



A. Top
B. The most common areas of wear are between the 3 o'clock and 8 o'clock positions.

Fig. 12, Check for Wear

NOTE: The pilot (lip) of the bell housing can wear into the flywheel housing. This can be caused by the transmission loosening up, or by road and engine vibration after high mileage.

4. Inspect the flywheel. Replace or repair the flywheel if the wear is extreme.
   - 4.1 Visually inspect the friction surface of the flywheel for heat checks and scoring.
   - 4.2 Measure the friction surface wear with a straightedge and feeler gauge. For instructions, see the engine manufacturer's manual.
5. Inspect the input shaft, both the splined and the smooth area. See **Fig. 13**.
   - 5.1 Check the fit of the splined hubs of the driven discs by sliding them along the splines of the input shaft. The hubs must slide freely so the clutch will release cleanly. If necessary, use a hand stone to dull the sharp edges of the splines.
   - 5.2 If the input shaft splines are worn or notched, or if the hubs still do not slide freely, replace the input shaft. For instructions, see the transmission manufacturer's service manual.
   - 5.3 Inspect the smooth area of the input shaft for wear and/or rough spots. Replace the input shaft if necessary.

6. To prevent side-loading, inspect all pivot points of the clutch linkage for excessive wear and replace them if necessary. See **Fig. 13**. Pay special attention to the following points:

   6.1 Check for excessive wear at the fingers of the release yoke where they contact release bearing wear pads.

   6.2 Check the clutch cross-shaft and sleeve bushings for excessive wear. Check the sleeve bushings for walk-out.

7. To prevent clutch brake wear, check the input-shaft bearing cap and measure it as shown in **Fig. 14**.

   7.1 Visually check the bearing cap for excessive wear.

   7.2 Measure the distance between the splined end of the input shaft and the bearing cap (dimension A). If dimension A is greater than 8.71 inches (221.5 mm), replace the bearing cap.

NOTE: Torque-limiting clutch brakes are a one-piece assembly with a large and a small face. When installing a torque-limiting clutch brake on an Eaton® Fuller® or Meritor™ transmission, install the smaller face toward the transmission.

Installation

Solo™ Heavy-Duty Clutch

NOTE: Do the clutch inspection and pre-installation procedures in **Subject 120** before installing the clutch.

1. If not already installed, insert two 7/16–14 x 5 guide studs in the upper mounting holes of the flywheel. See **Fig. 1**. Rotate the flywheel to level the guide studs.

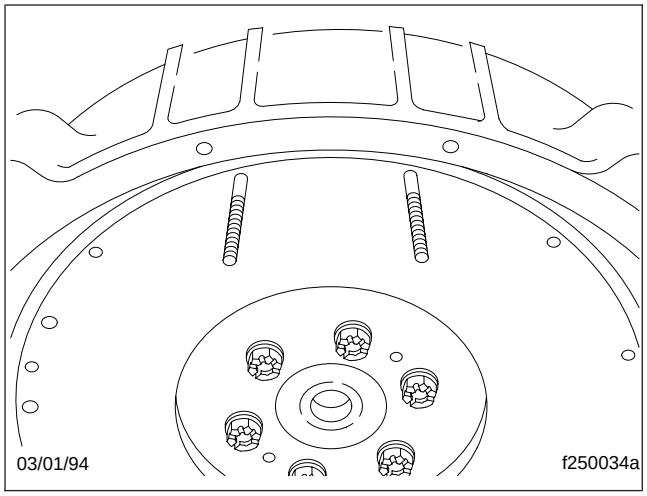

Fig. 1, Install the Guide Studs

2. If installed (on new clutches), remove the protective coating from the pressure plate and the intermediate plate.
3. Set the clutch cover upright, and insert a spline aligning tool through the release bearing sleeve. See **Fig. 2**.

NOTE: Six-spring driven discs are identical, front and rear. Either disc can be installed first on the aligning tool.

4. Install the rear driven disc and intermediate plate.
   - 4.1 Install the rear driven disc on the aligning tool, with the side stamped *INTERMEDIATE PLATE SIDE* facing away from the clutch cover. See **Fig. 3**.

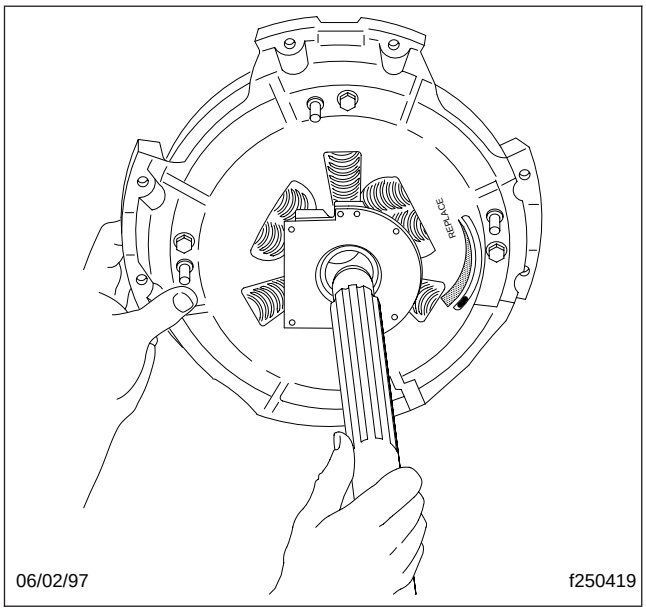

Fig. 2, Insert an Aligning Tool, Solo

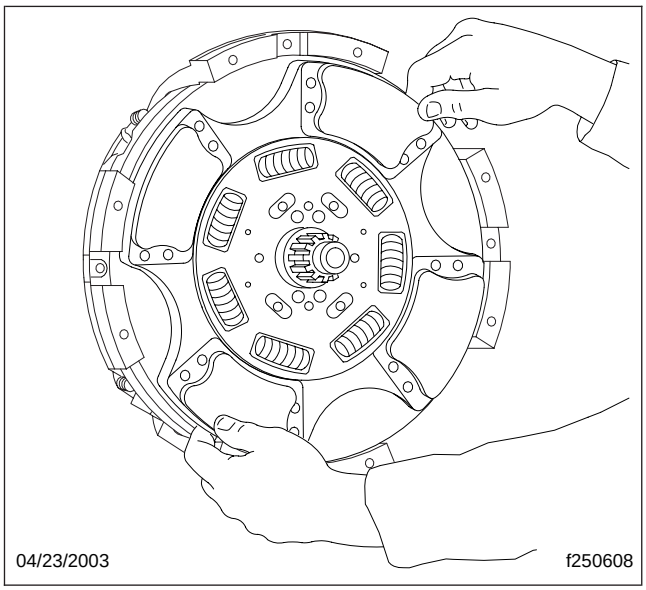

Fig. 3, Installing the Rear Driven Disc

   - 4.2 Place the intermediate plate in the clutch cover. Align the drive lugs of the plate with the notches in the cover. See **Fig. 4**.
   - 4.3 Make sure the positive separator pins™ protrude toward the flywheel side. See **Fig. 4**. The pins should be flush on the pressure-plate side.

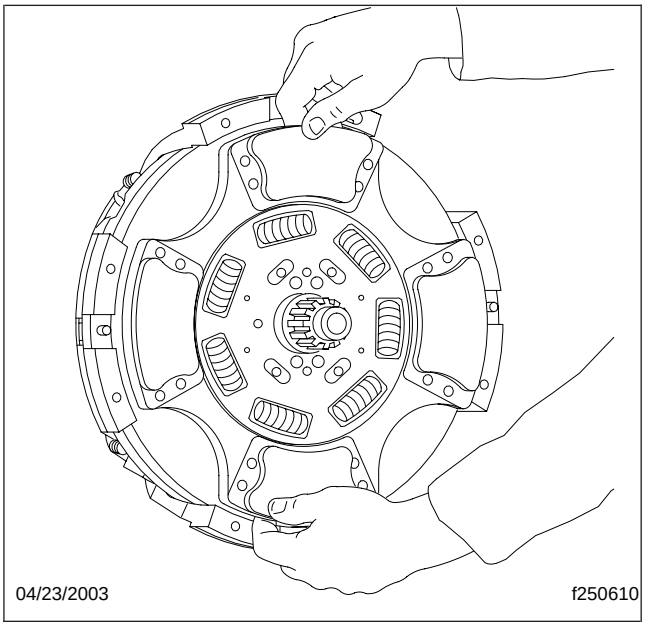

Fig. 5, Installing the Front Driven Disc

WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

6. Position the clutch over the two guide studs, and slide the assembly forward until contact is made with the flywheel surface. See **Fig. 6**.

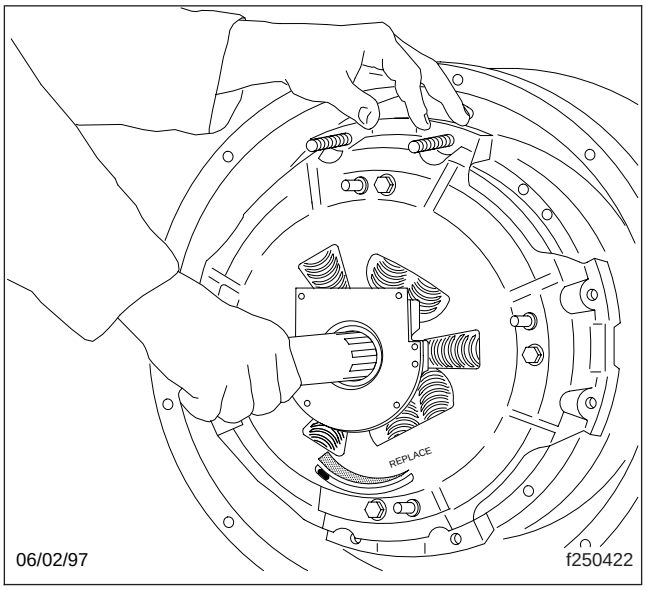

Fig. 6, Positioning the Clutch Cover, Solo

7. Install the mounting capscrews. See **Fig. 7**.
   - 7.1 Start six 7/16–14 x 2-1/4 (grade 5 or better) mounting capscrews with lockwashers, and fasten them finger-tight.
   - 7.2 Tap the aligning tool to make sure it is centered and seated in the pilot bearing.
   - 7.3 Remove the two guide studs and replace them with the two remaining 7/16–14 x 2-1/4 mounting capscrews and lockwashers.
8. Tighten the eight mounting capscrews progressively, in a crisscross pattern as shown in **Fig. 8**. The final torque is 40 to 50 lbf·ft (54 to 68 N·m).

IMPORTANT: Failure to tighten the bolts according to this procedure can have the following effects:

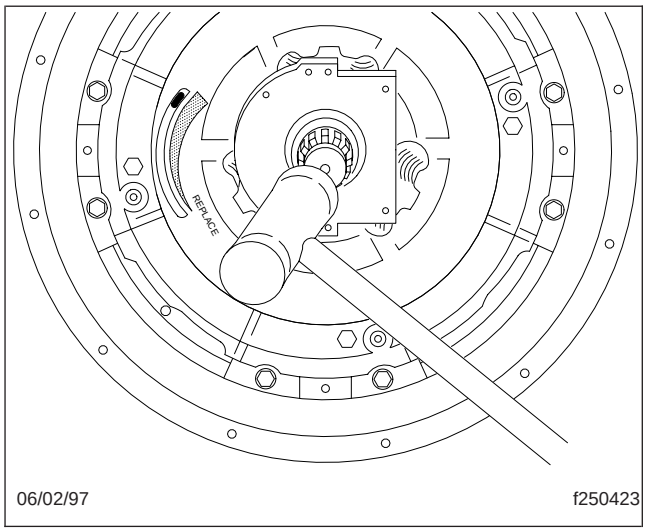

Fig. 7, Tap Aligning Tool

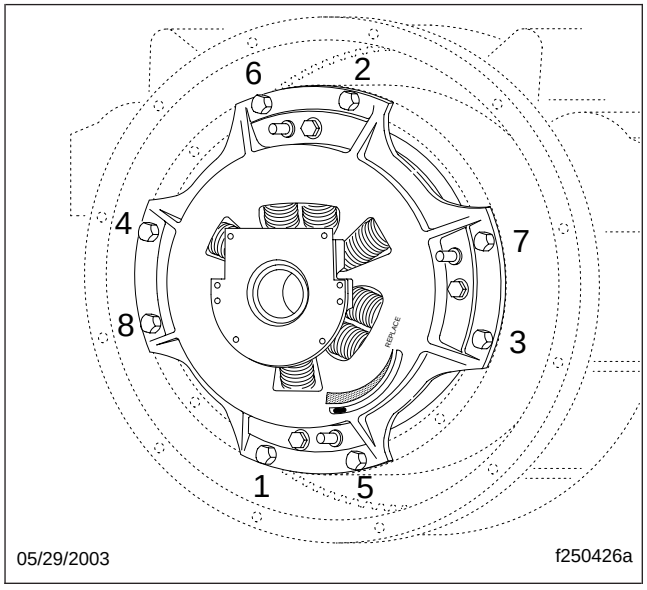

Fig. 8, Tightening Sequence, Solo

- prevent the clutch cover from centering into the pilot area of the flywheel;
- cause the clutch assembly to be out-of-balance with the flywheel;
- cause permanent damage to the clutch cover.

9. Following a crisscross pattern, remove and retain the four yellow shipping bolts from the clutch cover. See **Fig. 9**.

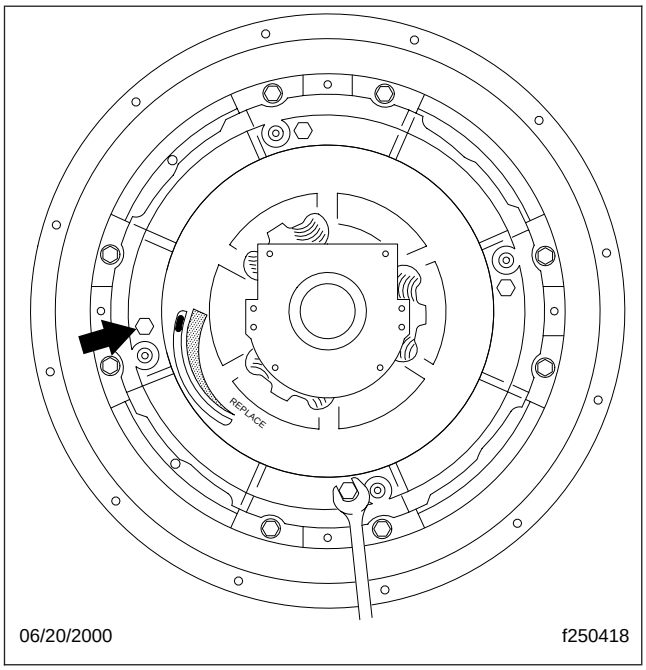

Fig. 9, Remove the Shipping Bolts

NOTE: Retain these four shipping bolts. These bolts will be needed in the future to secure the clutch assembly during removal and installation.

10. Remove the aligning tool. On maintenance-free clutches only, remove the input shaft sleeve.

NOTE: Do not be concerned if the release bearing housing touches the clutch cover.

11. Set the positive separator pins.

    11.1 Locate the pin access holes. See **Fig. 10**.

⚠ WARNING

Wear safety goggles when tapping the pins. If any of the metal parts were to chip, flying pieces of metal could possibly cause eye injury.

    11.2 Using a 1/4-inch (6-mm) diameter flat nose punch, *lightly* tap each of the four positive separator pins toward the flywheel through the access holes. This step verifies that all the four pins are flush against the flywheel. See **Fig. 11**.

NOTE: Failure to perform this step properly may cause the clutch to drag (clutch does not re-

lease). If necessary, after the transmission has been installed, the four pins can be set through the inspection opening of the transmission bell housing.

12. Using a clean cloth, remove all grease from the input shaft.
13. Shift the transmission into gear so that during assembly the transmission input shaft can be rotated into line with the clutch driven-disc hub splines.
14. Install the transmission and attach the clutch linkage.

⚠ CAUTION

Avoid springing the driven discs when the transmission is being installed. Do not excessively force the transmission into the clutch assembly or engine housing. If it doesn't enter freely, investigate the cause of the problem and then make any necessary changes. Don't let the transmission drop or hang unsupported in the driven discs. If this should occur, the rear disc will become bent or distorted, causing the clutch to drag (not release).

IMPORTANT: Be sure the release yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 12**. Align the splines by turning the transmission output shaft.

15. Lubricate the release bearing and cross-shaft bushings. For instructions and recommended lubricants, see Group 25 of the *Century Class Trucks Maintenance Manual*.

Easy-Pedal™ Clutch

NOTE: Do the clutch inspection and preinstallation procedures in **Subject 120** before installing the clutch.

1. If not already installed, insert two 7/16–14 x 5 guide studs in the upper mounting holes of the flywheel. See **Fig. 1**. Rotate the flywheel to level the guide studs.
2. If the clutch is new, remove the protective coating from the pressure plate and the intermediate plate.

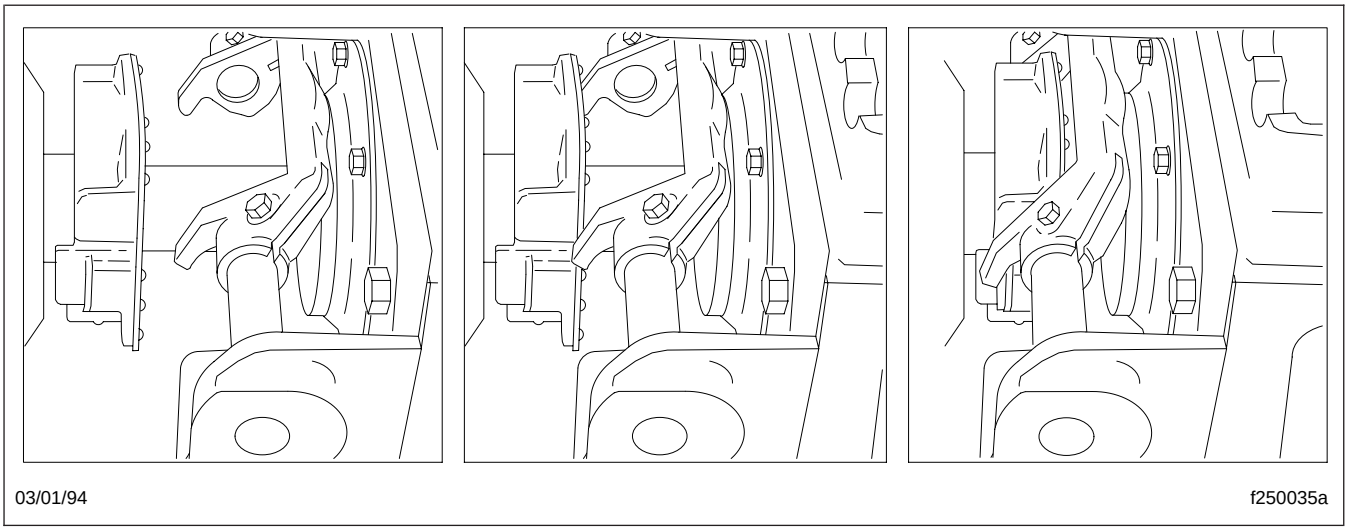

Fig. 12, Make Sure the Release Yoke Clears the Bearing

3. Set the clutch cover upright, and insert a spline aligning tool through the release bearing sleeve. See **Fig. 13**.

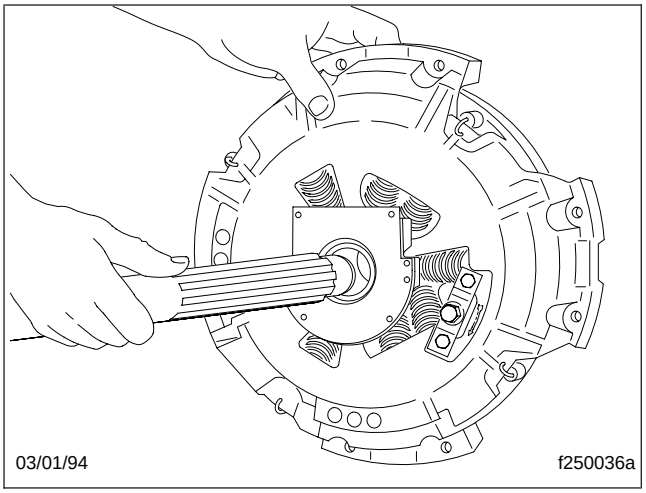

Fig. 13, Insert an Aligning Tool, Easy-Pedal

NOTE: Six-spring driven discs are identical, front and rear. Either disc can be installed first on the aligning tool.

4. Install the rear driven disc and intermediate plate.

   4.1 Install the rear driven disc on the aligning tool, with the side stamped *INTERMEDIATE PLATE SIDE* facing away from the clutch cover. See **Fig. 3**.

   NOTE: On 8-, 9-, and 10-spring discs, this side will be stamped *FLYWHEEL SIDE*.

   4.2 Place the intermediate plate in the clutch cover. Align the drive lugs of the plate with the notches in the cover. See **Fig. 4**.

   4.3 Make sure the positive separator pins™ protrude toward the flywheel side. See **Fig. 4**. The pins should be flush on the pressure-plate side.

5. Install the front driven disc on the aligning tool, with the side stamped *INTERMEDIATE PLATE SIDE* facing the intermediate plate. See **Fig. 5**.

   Be sure that both driven discs are aligned as shown in **Fig. 14**.

NOTE: On 8-, 9-, and 10-spring discs, this side is stamped *FLYWHEEL SIDE*.

⚠ WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

6. Position the clutch over the two guide studs, and slide the assembly forward until it starts in the flywheel pilot. See **Fig. 15**.

8. Tighten the eight clutch mounting bolts progressively, in the sequence shown in **Fig. 16**. The final torque is 40 to 50 lbf·ft (54 to 68 N·m).

CAUTION

If the bolts are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

Wear safety goggles when tapping the pins. If any of the metal parts were to chip, flying pieces of metal could possibly cause eye injury.

11.2 Using a 1/4-inch (6-mm) diameter flat nose punch, *lightly* tap each of the four positive separator pins toward the flywheel through the access holes. This step verifies that all the four pins are flush against the flywheel. See **Fig. 18**.

NOTE: Failure to perform this step properly may cause the clutch to drag (clutch does not release). If necessary, after the transmission has been installed, the four pins can be set through the inspection opening of the transmission bell housing.

12. Using a clean cloth, remove all grease from the input shaft.
13. Shift the transmission into gear. Rotate the transmission input shaft to line up with the clutch driven-disc hub splines during assembly.

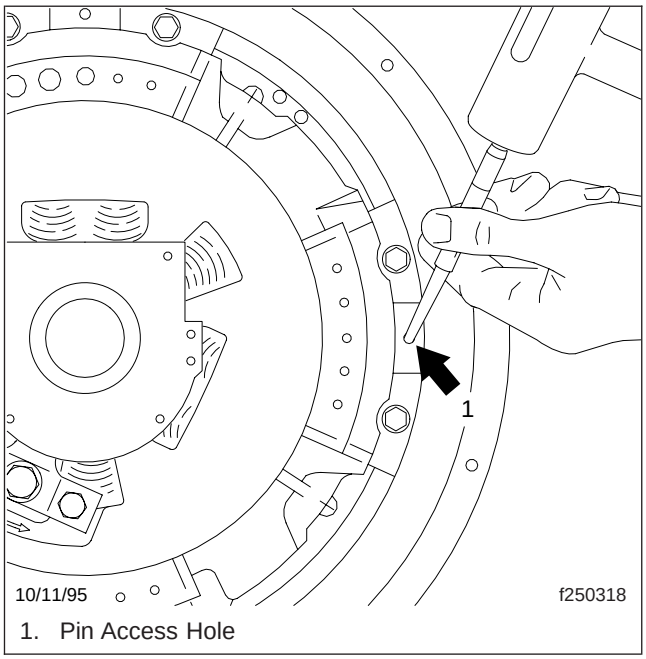

Fig. 18, Tapping the Pin, Easy-Pedal

14. Install the transmission and attach the clutch linkage.

IMPORTANT: Be sure the release yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 12**. Align the splines by turning the transmission output shaft.

⚠ CAUTION

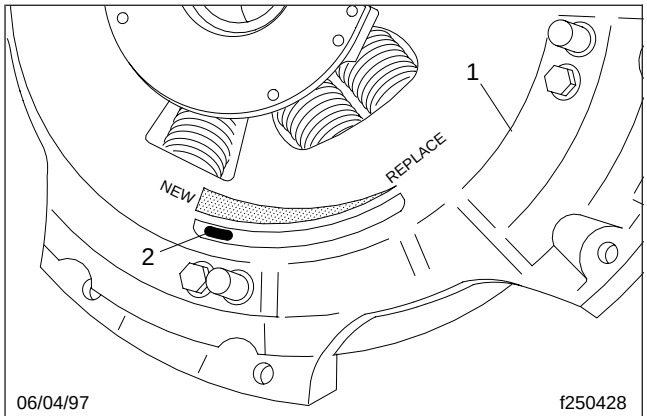
Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

15. Grease the release bearing and release shafts. For instructions and recommended lubricants, See Group 25 of the *Century Class Trucks Maintenance Manual*.
16. Adjust the clutch according to the procedures in **Subject 100**.

Resetting

NOTE: This procedure requires two persons; one under the vehicle with access to the wear indicating tab, and the other in the vehicle to operate the clutch pedal.

1. Park the vehicle on a level surface. Shut down the engine, set the parking brake, and chock the tires.
2. Inside the cab, press the clutch pedal all the way down, and hold it there until instructed to release it later in this procedure.
3. Through the clutch cover, use moderate force to slide the wear indicating tab leftward until it is at the "NEW" position on the indicator. See **Fig. 1**. If the tab does not move, follow the instructions under the heading "Releasing a Seized Cam".



With the clutch pedal down, set the tab to the "NEW" position on the indicator.
1. Clutch Cover 2. Wear Indicating Tab

Fig. 1, Resetting the Wear Indicating Tab

4. Release the clutch pedal.
5. To remove the gap between the sleeve and the pin, install four 7/16–14 x 1-3/4 bolts (shipping bolts may be used when available), and use a hand tool to tighten them until the gap is removed and the bolts are snug. See **Fig. 2**.
6. Remove the bolts.
7. Press the clutch pedal all the way down, and squeeze the clutch brake five times to reposition the bearing.

Releasing a Seized Cam

A seized cam may be caused by grease, dust, or other debris accumulated around the outer perimeter of the cam. The cam must operate freely for the clutch to work properly. The Eaton Seized Cam Adjustment Tool is designed specifically for releasing a seized cam. See **Table 1**.

1. While an assistant holds down the clutch pedal, insert the tip of the Seized Cam Adjustment Tool through the access panel and position it under the bearing. See **Fig. 3**.
2. Align the tool so that the threaded bolt extends into the slot in the cam. See **Fig. 3**.

IMPORTANT: Use the Seized Cam Adjustment Tool carefully. Do not use heavy force on it; heavy force can break the cam.

3. Using the tool, carefully try to move the cam toward the right or "Replace" position.

   If the cam moves easily, move it back to the left to verify that spring tension will pull it back to the right. If it returns to the right, then the cam has been released and you can continue with the resetting procedure. If it will not return to the right, the cam spring may be broken.

   If the cam does not move easily, continue to the next step.

IMPORTANT: Use WD-40® only. Do not substitute another penetrant for WD-40.

4. Use sideways pressure to the right and lightly pull the tool away from the engine to separate the top cam from the bottom cam. If the cam moves slightly to the right, let up on the clutch pedal. If the cam is still seized, spray WD-40 into the cam slot and three spring perches. To access all three perches, rotate the engine as needed.

   If the cam is still seized, do the following.

   4.1 Again spray WD-40 into the cam slot and all three spring perches.

   4.2 Inside the cab, release the clutch pedal, then press it all the way down. Next, with the clutch pedal pressed down, jiggle the tool in the cam slots to apply pressure in all directions.

5. Remove the tool.

Troubleshooting Tables

Problem—The Clutch Does Not Release Completely

Problem—The Clutch Does Not Release Completely	
Possible Cause	**Remedy**
The clutch pedal height is incorrect.	Adjust the clutch to obtain the following settings: • 1/2 to 9/16 inch (12.7 to 14.3 mm) release bearing travel; • 0.105 to 0.145 inch (2.7 to 3.7 mm) release yoke free-travel; and • 1/2 to 1 inch (12.7 to 25.4 mm) clutch brake squeeze.
The bushing in the release bearing sleeve assembly is damaged.	Replace the clutch cover.
The clutch cover assembly is not properly seated into the flywheel.	Re-seat the clutch cover assembly into the flywheel. Use a crisscross pattern when tightening the mounting bolts.
The intermediate plate and/or pressure plate is cracked or broken.	Replace any damaged parts.
The cross shafts protrude through the release yoke (a side-loading condition exists).	Check for protruding cross shafts. Repair or replace as necessary.
The release yoke fingers are bent or worn (a side-loading condition exists).	Install a new release yoke.
The engine housing and bell housing are misaligned (a side-loading condition exists).	Check for loose transmission mounting bolts. Tighten the transmission mounting bolts to the proper torque.
The clutch linkage is set up improperly (a side-loading condition exists).	Thoroughly examine the clutch linkage and adjust as necessary.
The driven discs are distorted or warped.	Replace any distorted or warped driven discs. If the transmission is allowed to hang unsupported during clutch installation, the driven discs may become distorted.
The driven discs are installed backwards, or the front and rear driven discs were switched with each other.	Install new driven discs. Also, check the clutch cover for any damage. Replace the clutch cover if damaged.
The input shaft spline is worn.	Replace the input shaft. Also, check the driven disc hubs for wear. Replace the driven discs if worn.
The input shaft spline is coated with grease, anti-seize compound, etc.	Clean and dry the input shaft spline before installation.
The input shaft splines are twisted.	Select a new driven disc and slide it along the full length of the splines. If the disc does not slide freely, replace the input shaft.
The input-shaft bearing cap is worn.	Replace the input-shaft bearing.
The flywheel pilot bearing fits either too tight or too loose in the flywheel and/or end of input shaft.	Check the pilot bearing for proper fit and replace it if worn.
The pilot bearing is dry or damaged.	Replace the pilot bearing.
The positive separator pins are bent, damaged or incorrectly set.	Be sure to use the proper tool when setting the positive separator pins. Also, take great care when handling the intermediate plate. For procedures, see **Subject 130**.

Troubleshooting

Problem—The Clutch Does Not Release Completely	
Possible Cause	**Remedy**
The clutch brake is damaged and/or not functioning.	Install a new clutch brake.
The driven disc faces are coated with oil or grease.	Replace the driven disc assemblies. Cleaning the old driven discs is not recommended.
There is foreign material (dirt, chaff, salt, etc.) inside the clutch cover.	Remove the foreign material and make sure the clutch inspection cover is installed.
The drive pins are cocked, causing the intermediate plate to stick on the drive lugs (Easy-Pedal only).	The drive pins must be ninety degrees square to the flywheel surface with a 0.006-inch (0.15-mm) minimum clearance between drive pins and intermediate plate slots. Repair or replace as necessary.
The pressure plate is not fully retracting (Easy-Pedal only).	Check the pressure plate return springs through the clutch inspection cover. If any are bent, stretched, or broken, replace them as necessary.
The release bearing travel is excessive and is causing the lever to contact the pressure plate (Easy-Pedal only).	Adjust the release bearing travel from 1/2 to 9/16 inch (12.7 to 14.3 mm).
The three anti-rattle springs were installed backwards (Easy-Pedal only).	Install the anti-rattle springs so the rounded sections are pointed toward the flywheel/engine.

Problem—The Clutch Rattles or Is Noisy

Problem—The Clutch Rattles or Is Noisy	
Possible Cause	**Remedy**
There is excessive flywheel runout.	Repair or replace the flywheel. For procedures, see the engine manufacturer's manual.
There is corrosion between the input shaft spline and the driven disc hubs.	Clean the mating parts between the input shaft and driven discs to ensure that the discs slide freely over the input shaft spline.
The engine idle is too fast.	Readjust engine idle to proper idling speed.
The clutch release bearing is dry or damaged.	Lubricate the clutch release bearing. If the noise persists, install a new clutch cover.
The flywheel pilot bearing is dry or damaged.	Replace the flywheel pilot bearing.
The bridge of the release yoke is hitting the clutch cover (an over-stroking condition exists).	Check for a worn, broken or missing clutch brake. Also, check the release yoke and input-shaft bearing cap for wear. Replace any worn parts.
The release yoke fingers are hitting the clutch cover.	Check if the release bearing, clutch cover, or release yoke fingers are worn or broken. Replace worn parts.
The clutch inspection cover is not installed.	Re-install the clutch inspection cover.
The sleeve bushings are worn.	Investigate for any side-loading conditions on the release bearing housing. If there is a side-loading condition, determine its cause. Also, before installing the new clutch, make sure that the side-loading condition has been corrected.
The clutch linkage is rattling excessively.	Clean, lubricate and reassemble or replace missing/worn parts.
An idle gear rattle is coming from the transmission.	Specify low-vibration driven discs. Check the engine for correct idle speed. For procedures, consult the engine manufacturer's manual.

Problem—The Clutch Rattles or Is Noisy	
Possible Cause	**Remedy**
The damper spring cover of the driven disc assembly is interfering with the flywheel.	Install the correct clutch assembly.
The rivets of the rear driven disc are interfering with the retainer assembly (Easy-Pedal only).	Adjust the clutch internally (via the adjustment bolt). For procedures, see **Subject 100**.

Problem—The Clutch Vibrates

Problem—The Clutch Vibrates	
Possible Cause	**Remedy**
The flywheel is loose.	Retighten the flywheel mounting bolts to the proper specifications.
The universal joints are worn.	Replace the worn parts.
The driveshaft is not properly phased.	Investigate and correct the phasing of the driveshaft.
The driveshaft is not balanced.	Balance and straighten the driveshaft.
The driveline angles are incorrect.	Shim the drivetrain components to equalize universal joint angles.
The flywheel is not balanced.	Balance the flywheel.
The pilot area of the clutch is not completely seated into the flywheel.	Ensure that no dirt, burrs, etc., are preventing the clutch cover from completely seating into the flywheel mounting surface.
The engine mounts are loose, damaged, or worn out.	Replace any worn or damaged parts. Retighten all bolts to proper specifications.
The engine is misfiring.	The engine is not in tune. To correct the problem, see the engine manufacturer's manual.
There is excessive flywheel runout.	Repair or replace the flywheel. For procedures, see the engine manufacturer's manual.
The rivets of the rear driven disc are interfering with the retainer assembly (Easy-Pedal only).	Adjust the clutch internally (via the adjustment bolt). For procedures, see **Subject 100**.

Problem—The Clutch Needs Frequent Adjustments

Problem—The Clutch Needs Frequent Adjustments	
Possible Cause	**Remedy**
The release yoke free-travel is insufficient.	After first adjusting the clutch for 1/2 to 9/16 inch (12.7 to 14.3 mm) release bearing travel, adjust the clutch linkage to obtain release yoke free-travel of 0.105 to 0.145 inch (2.7 to 3.7 mm).
The clutch specification is incorrect.	Check the clutch specifications in **Subject 400**. Install a new clutch with the proper specifications, if necessary.
The cross shafts and/or clutch linkage system is worn.	Investigate the entire clutch linkage system to determine if it is binding or operating sporadically and/or worn excessively.
The clutch driven discs are worn down to the rivets.	Install a new clutch. For procedures, see **Subject 130**.

Troubleshooting

Problem—The Clutch Needs Frequent Adjustments	
Possible Cause	**Remedy**
The crankshaft has excessive end play.	Repair or replace the crankshaft. Consult the engine manufacturer's manual for procedures.

Problem—The Clutch Slips

Problem—The Clutch Slips	
Possible Cause	**Remedy**
The clutch pedal has no free travel.	Readjust the clutch.
The clutch is overloaded.	Verify that the proper clutch has been specified for the particular vehicle application.
The release mechanism is binding.	Free up the release mechanism and linkage. Also, check the clutch linkage adjustment.
The driven disc faces are coated with oil or grease.	Replace the driven disc assembly.
The driver is riding the clutch pedal.	Use correct driving procedures.
The input shaft spline is worn.	Replace the input shaft.

Problem—The Clutch Grabs or Chatters

Problem—The Clutch Grabs or Chatters	
Possible Cause	**Remedy**
The clutch is worn out.	Replace the clutch and all worn components.
The linkage system is not operating freely.	Check the clutch linkage for binding or excessive wear. Replace all worn parts.
The driven disc faces are coated with oil or grease.	Replace the driven disc assembly.
The engine mounts are loose.	Retighten the engine mounts to manufacturer's specifications.
The release yoke fingers and/or the release bearing wear pads are worn excessively.	Replace all the worn parts.

General Description and Principles of Operation

Rockwell clutches **(Fig. 1)** are available in 15-1/2 inch models in Freightliner trucks. An identification plate is located on the front cover. Rockwell clutches feature the following design characteristics:

- Two-plate
- Diaphragm-spring
- Pull-type
- Dry-disc
- Eight-hole installation pattern

Mounted directly on the flywheel, the clutch cover assembly houses most of the components, including the pressure plate. A diaphragm-type spring provides the force necessary to push the pressure plate forward and engage the clutch. The center plate, which separates the driven discs, has tabs that fit into slots on the clutch cover assembly.

A splined transmission input shaft projects through the cover assembly and driven discs and rests in a pilot bearing in the center of the flywheel. The splined hubs of the driven discs mesh with the splined input shaft to transmit power from the engine to the transmission. The rest of the clutch assembly can spin freely around the input shaft when the clutch pedal is depressed.

A clutch brake stops the transmission gears from rotating when the truck is stopped and when shifting into first or reverse gears. This lets the gears engage quickly without gear clash.

The release bearing assembly transfers the movement of the clutch linkage to engage or disengage the clutch. The release bearing assembly is available with a grease fitting or as a "lubed for life" assembly. Ball bearings permit the release bearing to rotate freely. A coil spring is installed on the sleeve between the release bearing and the hub. The coil spring holds the sleeve on the retainer in a "ball joint" arrangement. This prevents vibration and allows for minor misalignment that may occur between the transmission and the engine due to tolerances between the mounting surface dimensions.

The pressure plate and cover assembly apply the force necessary to engage the clutch. The following parts are in the pressure plate and cover assembly. **See Fig. 2.**

- The *cover* is the housing for the diaphragm spring, adjusting ring, levers, retainer, and the release bearing sleeve. Three holes in the cover provide air flow to remove heat from the clutch.
- The *diaphragm spring* is a one-piece unit that produces the pressure to lock the discs between the pressure plate, the center plate, and the flywheel. The spring is located and held in the cover by the retainer.
- Six *levers* connect the cover assembly to the release bearing sleeve. The levers multiply and transfer the force of the diaphragm spring from the retainer to the pressure plate.
- The *adjusting ring*, located inside the cover and in front of the pressure plate, controls the release bearing clearance. The clearance must be adjusted periodically to compensate for clutch lining wear.
- The *pressure plate* applies the force from the diaphragm spring and locks the clutch discs between the center plate and the flywheel.

The clutch discs are splined to allow movement along the transmission input shaft. Power is transmitted from the flywheel, pressure plate, and center plate through the discs to the transmission. Dampened ceramic clutch discs absorb vibration with spring washers, friction material, and co-axial torsion springs. Ceramic disc linings **(Fig. 3),** are made from ceramic and bronze material. Rivets fasten the ceramic lining to the disc. The ceramic lining provides positive clutch engagement. The co-axial torsion springs also absorb torque shock during engagement.

The center plate increases the service life of the clutch by increasing the surface area for power transfer. The 15-1/2 inch clutch center plate is driven by tabs on the plate which fit into slots on the clutch cover.

Clutch Adjustments

NOTE: Clutch linkage adjustment is required only after repair or replacement of the clutch or clutch linkage components. Refer to the clutch linkage section in this manual for procedures.

Internal clutch adjustments should be done whenever:

- the clutch is removed or installed
- any component of the clutch linkage is serviced
- the clutch free pedal is less than 1/2 inch (13 mm).

Make sure of the following before adjusting the clutch:

- The clutch system is in good condition.
- The linkage is tight but moves freely during operation.
- There is no "false" free pedal. Keep the clutch lever from moving and depress the clutch pedal. If the pedal moves more than 1/2 inch (13 mm), "false free pedal" is in the linkage. Inspect the linkage and all pivot points for wear or damage. Repair or replace worn or damaged parts.
- The release fork moves when the clutch pedal moves.

Release-Bearing Clearance Check

1. Remove the inspection hole cover on the clutch housing.
2. Measure the distance between the end of the release bearing and the clutch brake. **See Fig. 1**. This distance must be 1/2 to 9/16 inch (12.7 to 14.3 mm).

NOTE: While checking this dimension, pull the release bearing toward the transmission, using your hand or a screwdriver.

IMPORTANT: An inspection tool A02–12419 (available through the PDCs) can be used to check the distance between the release bearing and the clutch brake. **See Fig. 2**. One end of the tool has green tape on it and is 0.50 inch (12.7 mm) in diameter; the other end has blue tape on it and is 0.56 inch (14.3 mm) in diameter.

3. If using tool A02–12419 to check the distance between the release bearing and the clutch brake, position the tool so that the legs straddle the transmission input shaft. Check the gap with both ends of the tool as follows:
   - 3.1 Insert the blue 0.56-inch (14.3-mm) end. If it fits loosely the gap is too wide and adjustment is needed. Go to the next step.
   - 3.2 If the blue 0.56-inch (14.3-mm) end can't be inserted in the gap, then try to insert the green 0.50-inch (12.7-mm) end. If the

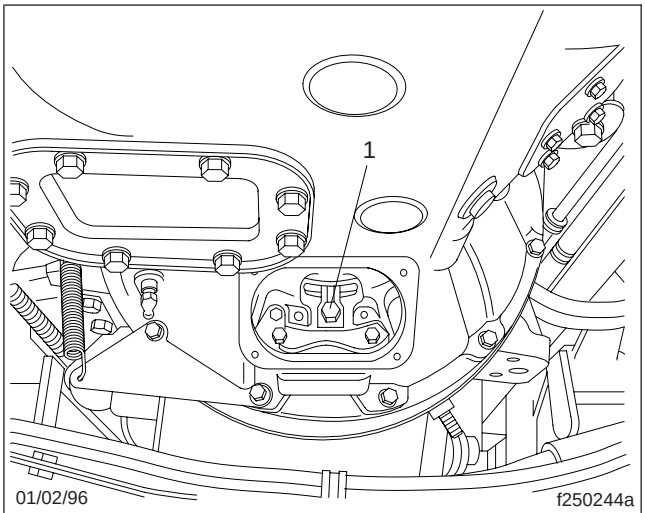
Clutch Adjustments

green end of the tool fits, snug or loose, then no adjustment is needed.

3.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Go to the next step.

4. If the release bearing clearance is not correct, adjust the clutch.

4.1 Turn the flywheel so that the lock plate is seen through the inspection cover. **See Fig. 3**.



1. Lock Plate

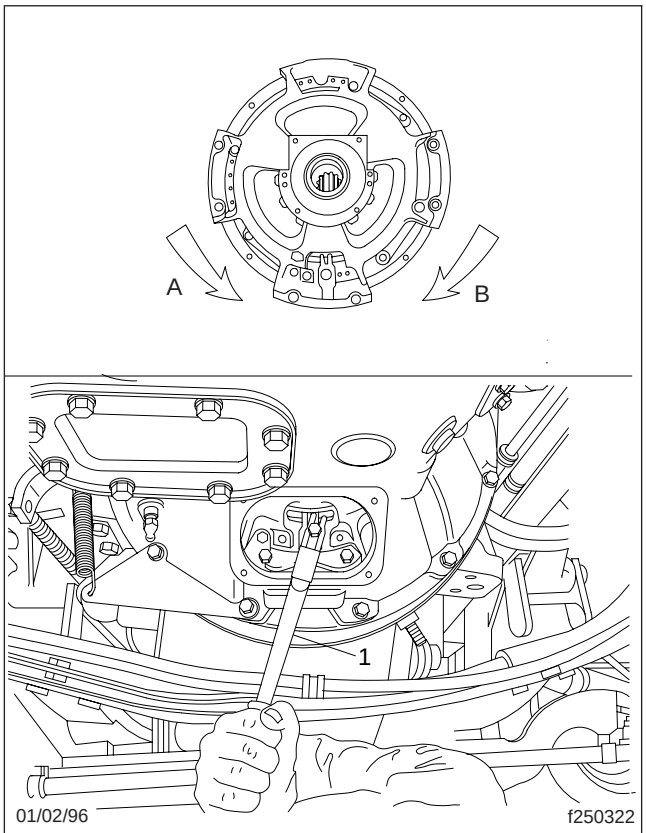
Fig. 3, Remove the Lock Plate

NOTE: Do not use the starter to move the flywheel. Turn the crankshaft with a socket wrench on the front pulley. If the front pulley is difficult to turn, use a spanner wrench on the teeth of the flywheel. See the engine manufacturer's manual for further information.

4.2 Push the clutch pedal to the bottom of its travel. Have another person hold the pedal at the bottom of its travel (or use a block of wood to hold the pedal).

4.3 Remove the capscrew and lockwasher that fasten the lock plate to the clutch cover. **See Fig. 3**.

4.4 Turn the adjusting ring to obtain the specified release bearing clearance. Using a screwdriver or an adjusting tool as a lever against the notches in the ring, move the adjusting ring. **See Fig. 4**. When the adjusting ring is moved one notch, the release bearing will move 1/32 inch (about 0.5 mm).



A. Turn the adjusting ring in this direction to move the release bearing *toward* the clutch.
B. Turn the adjusting ring in this direction to move the release bearing *away from* the clutch.

1. Adjusting Ring Tool

NOTE: The adjusting tool is available from: Kent-Moore Tools, part number J 36216; Owatonna Tools, part number 7028; or, Snap-on Tools, part number GA454.

4.5 Install the lock plate. Install the capscrew that fastens the lock plate to the clutch cover. Tighten the capscrew 25 to 30 lbf·ft (34 to 40 N·m).

4.6 Release the clutch pedal.

5. Check the clearance between the tips of the release fork and the bosses on the release bearing. The distance must be 0.105 to 0.145 inch (2.7 to 3.7 mm). **See Fig. 5**. If necessary, adjust the clutch linkage. For instructions, refer to the clutch linkage section in this group.

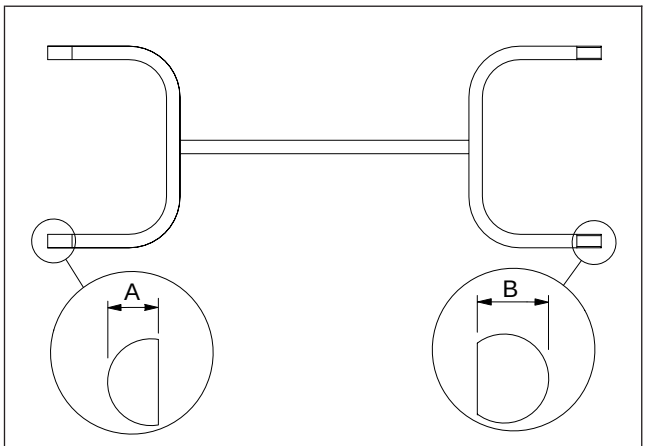
NOTE: The pedal must be released to check the release bearing clearance.

IMPORTANT: An inspection tool A02–12254 (available through the PDCs) can be used to check the distance between the bosses on the release bearing and the tips of the release fork (free travel). **See Fig. 6**.The legs on one end of the tool have green tape on them and are 0.105 inch (2.7 mm) thick; the legs on the other end have blue tape on them and are 0.145 inch (3.7 mm) thick.

6. If using tool A02–12254 to check the distance between the release bearing and the release fork, position the tool so it straddles the fork to ensure that there won't be any misalignment. Check the distance with both ends of the tool as follows:



03/26/96 f580132

A. 0.105 inch (2.7 mm)
B. 0.145 inch (3.7 mm)

Fig. 6, Inspection Tool A02-12254

6.1 Insert the blue 0.145-inch (3.7-mm) end. If it fits loosely the gap is too wide and adjustment is needed. Go to the section on clutch linkage adjustment in this group.

6.2 If the blue 0.145-inch (3.7-mm) end can't be inserted in the gap, then try to insert the green 0.105-inch (2.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

6.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Go to the section on clutch linkage adjustment in this group.

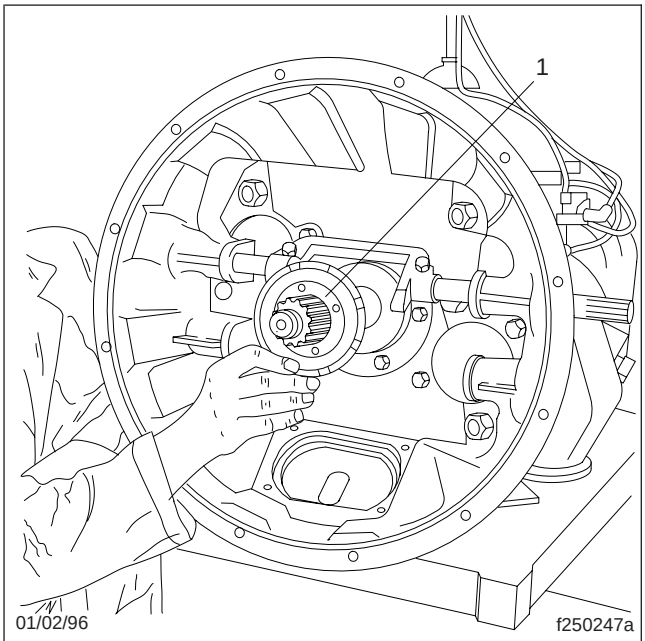
Removal

1. Remove the transmission. Follow the procedures in **Group 26** of this manual.

⚠ CAUTION

CAUTION: Do not let the rear of the transmission drop, and do not let the transmission hang unsupported by the input shaft in the pilot bearing bore in the flywheel. Taking these precautions will prevent damage to the clutch assembly and the pilot bearing.

2. Remove the clutch brake assembly from the transmission input shaft. **See Fig. 1.**

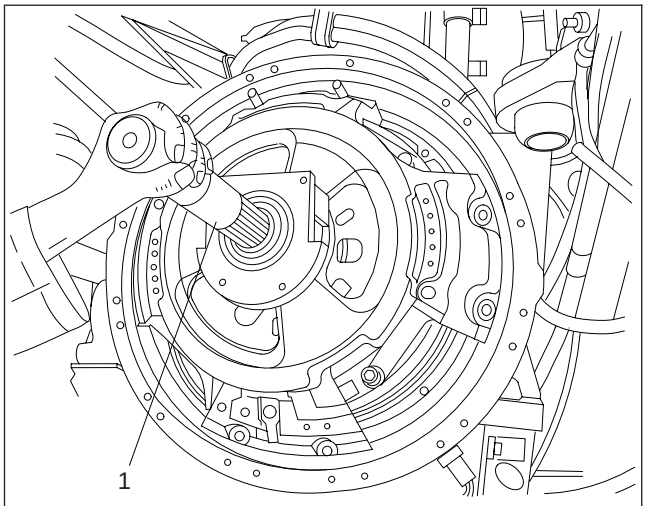


1. Clutch Brake

Fig. 1, Clutch Brake Assembly Removal

3. Install a clutch alignment tool through the clutch and into the flywheel pilot bearing to support the clutch assembly during removal. Use the correct tool so that the splines of the tool match the splines in the clutch. **See Fig. 2.**

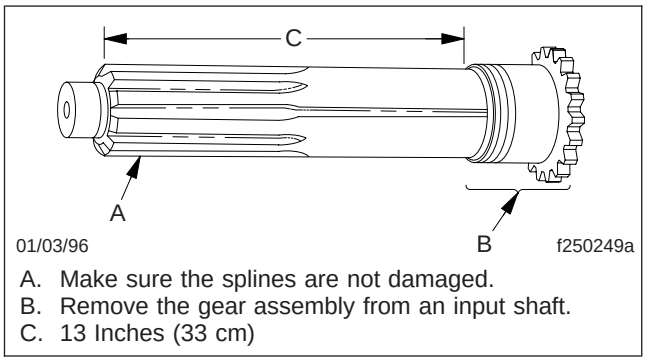
NOTE: If an alignment tool is not available, use an input shaft from a manual transmission. Remove the gear from the end of the input shaft. **See Fig. 3.**



1. Alignment Tool

Fig. 2, Clutch Alignment Tool Installation

4. Remove the top two bolts that fasten the pressure plate and cover assembly to the flywheel. Install two guide studs in the holes. **See Fig. 4.** The studs can be made by removing the head from two 7/16-inch capscrews.



A. Make sure the splines are not damaged.
B. Remove the gear assembly from an input shaft.
C. 13 Inches (33 cm)

Fig. 3, Manual Transmission Input Shaft

5. Make two wooden spacer blocks 1/2 to 5/8 inch (13 to 16 mm) thick. Insert them between the release bearing assembly and the clutch cover. The wooden spacer blocks ease removal and installation of the clutch. **See Fig. 5.**

WARNING

WARNING: The pressure plate and cover assembly is heavy and should be removed only with a lifting device. If the assembly is lifted improperly or dropped, it could cause serious personal injury.

6. Connect a lifting device to the pressure plate and cover assembly because of the weight. **See Fig. 6.**

2. 15-1/2 Inch Clutch Assembly
3. Lifting Device

Fig. 6, Connecting a Lifting Device

7. Remove the remaining bolts that fasten the pressure plate and cover assembly to the flywheel.

NOTE: When removing the clutch, the discs and the pressure plate can stay in the cover.

8. Remove the pressure plate and cover assembly over the alignment tool and off the flywheel.
9. Remove the alignment tool, the rear disc, the center plate, and the front disc. **See Fig. 7.**
10. Whenever the clutch assembly is serviced or the engine is removed, the pilot bearing in the flywheel should be removed and replaced. Use an

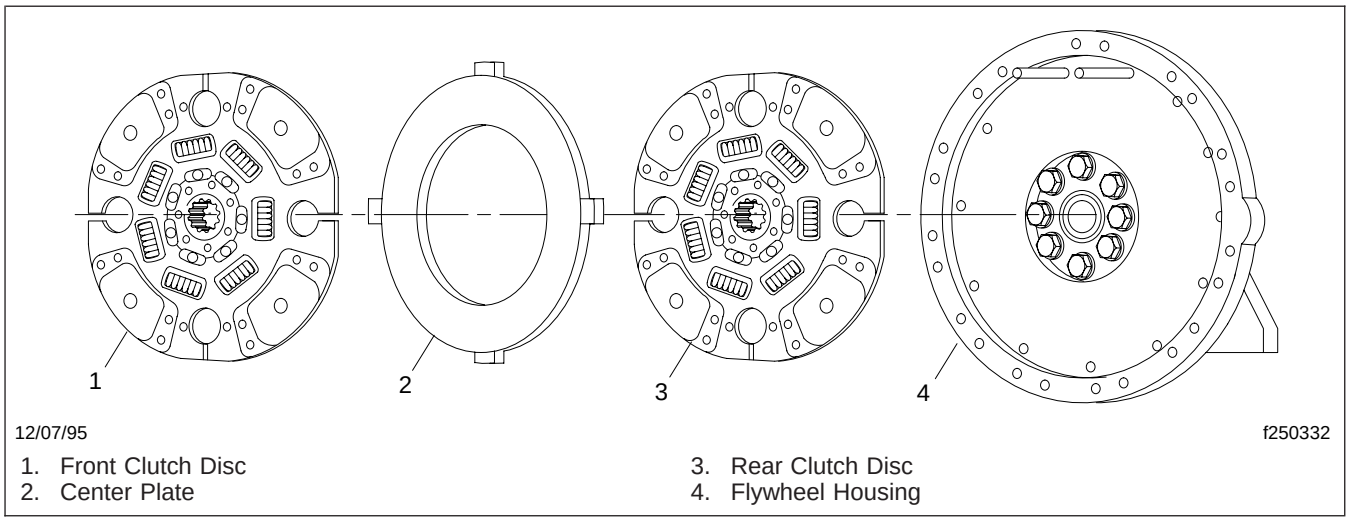

Fig. 7, Front Disc, Rear Disc, and Center Plate Removal

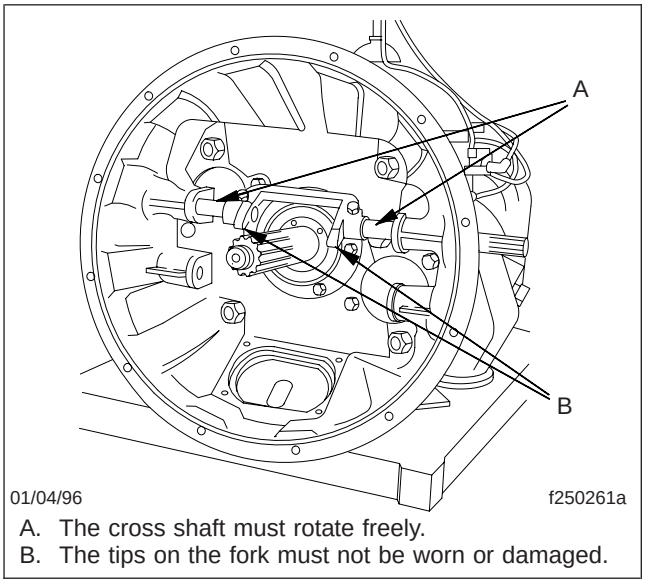
appropriate internal puller to remove the pilot bearing. Discard the pilot bearing.

Inspection

1. Remove the clutch from the vehicle. See **Subject 110** for instructions.
2. Inspect the release fork and the cross shaft. See **Fig. 1**. Make sure the release fork is straight and the tips of the fork are not worn or damaged. Replace forks that are worn or damaged.

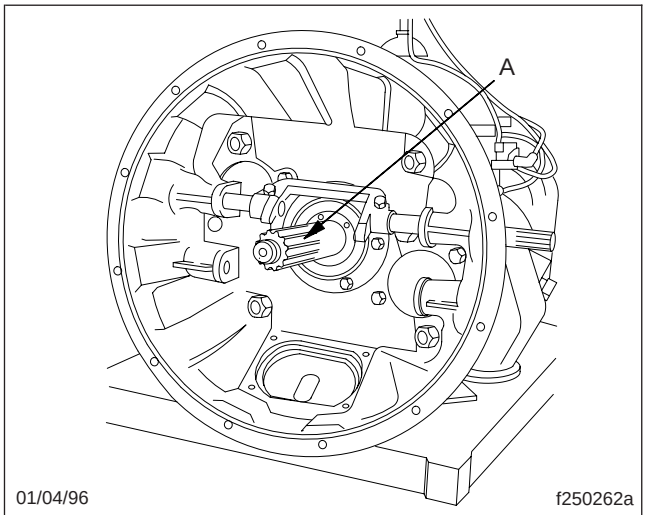
   Make sure the cross shaft rotates freely and doesn't have any side-to-side movement in the transmission housing. If used, inspect the bushings for the shaft in the housing. Replace any parts that are worn or damaged. For instructions, refer to the clutch linkage section in this group.



A. The cross shaft must rotate freely.
B. The tips on the fork must not be worn or damaged.

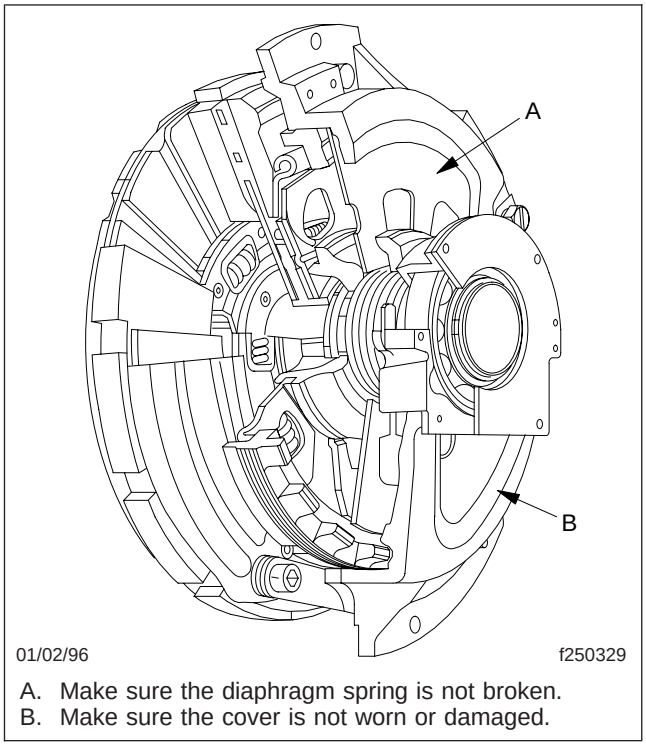
Fig. 1, Release Fork and Cross Shaft Inspection

3. Inspect the splines on the input shaft. See **Fig. 2**. Make sure the splines are not worn or damaged. Inspect the release bearing area of travel for damage. Using an emery cloth, remove small scratches from the input shaft. If the input shaft is worn or damaged, replace it. Any wear or damage on the input shaft causes the clutch to work incorrectly.
4. Remove dirt and contamination from the pressure plate and cover assembly with non-petroleum based cleaning solvents.
5. Inspect the cover for wear and damage. Make sure the diaphragm spring inside the cover is not broken. See **Fig. 3**. If the diaphragm spring is broken, the clutch cover must be disassembled to replace the spring.



A. The splines must not be worn or damaged.

Fig. 2, Input Shaft Splines Inspection



A. Make sure the diaphragm spring is not broken.
B. Make sure the cover is not worn or damaged.

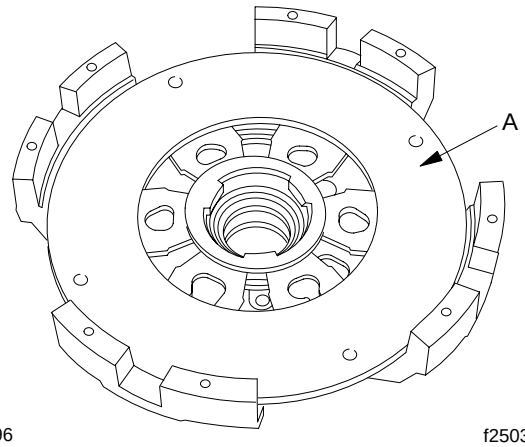
Clutch Inspection

6. Inspect the pressure plate.

   6.1 Visually check the pressure plate for wear or damage. See **Fig. 4**. If the plate is cracked, replace it. Heat marks are normal, and can usually be removed with an emery cloth. If the heat marks can't be removed, replace the pressure plate.



A. Inspect the pressure plate surface for wear, cracks, or heat damage.

Fig. 4, Pressure Plate Inspection

   6.2 Put the pressure plate and cover assembly on a bench with the plate facing up.

   6.3 Using a caliper, measure any scratches or scoring on the pressure plate. See **Fig. 5**. If the damage to the surface of the plate is more than 0.015 inch (0.38 mm), replace the pressure plate.

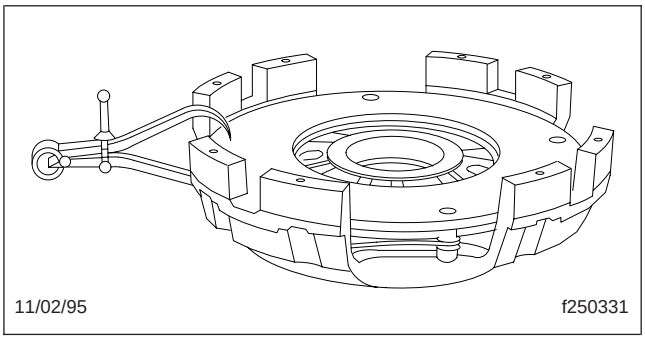


Fig. 5, Measuring Scratches or Scoring on the Pressure Plate

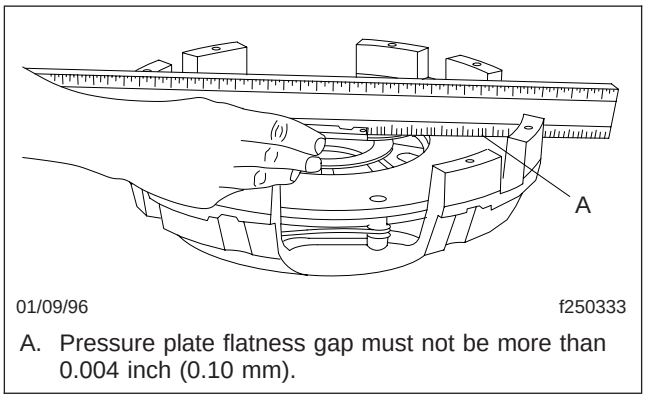
   6.4 Make sure the surface of the pressure plate is flat. Put a straightedge on the surface of the center plate, making sure it crosses the center of the plate. See **Fig. 6**. Using a feeler gauge, measure each gap that appears between the straightedge and the pressure plate. Rotate the straightedge through at least four positions. If any gap is more than 0.004 inch (0.10 mm), replace the pressure plate.



A. Pressure plate flatness gap must not be more than 0.004 inch (0.10 mm).

Fig. 6, Checking the Pressure Plate Surface

   6.5 Measure the runout of the pressure plate to make sure the surfaces are parallel to each other. Put marks on a capscrew, strap, and pressure plate location to ensure that the pressure plate is installed in the original position on the cover. Remove the capscrews that fasten the pressure plate to the strap. Put the pressure plate on a bench so that the smooth surface is up. Put the base of a dial indicator inside the center of the plate. See **Fig. 7**. Put the tip of the dial indicator on the surface of the plate. Set the dial indicator to zero. Rotate the dial indicator one complete turn around the surface of the pressure plate. If the reading on the indicator is more than 0.002 inch (0.05 mm), replace the pressure plate.

7. Inspect the clutch discs.

   7.1 Visually check for wear or damage. If any disc is worn, replace it.

   7.2 Make sure the co-axial springs are not loose in the hub. See **Fig. 8**. Springs that

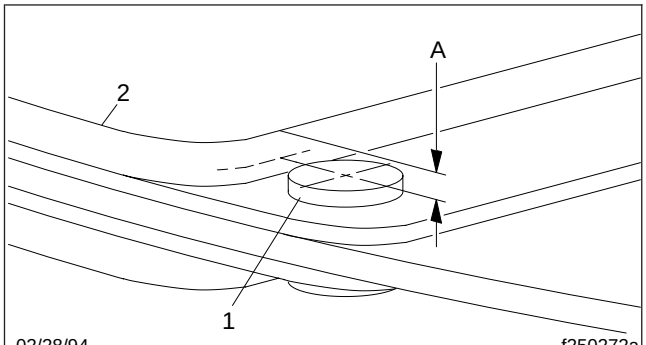
7.3 Make sure the splines in the hub are not damaged. Make sure the hub is fastened to the disc. Replace any disc that is damaged.

7.4 Using a cleaning solvent with a non-petroleum base, remove grease and oil from the discs. If the grease and oil cannot be removed, replace the disc.

7.5 Ceramic linings are fastened to the disc with rivets. Replace the disc if the lining is loose, damaged, or worn to the top of the rivets. See **Fig. 9**.



02/28/94 f250272a

A. Replace the ceramic disc if the lining is even with or below the top of the rivet.

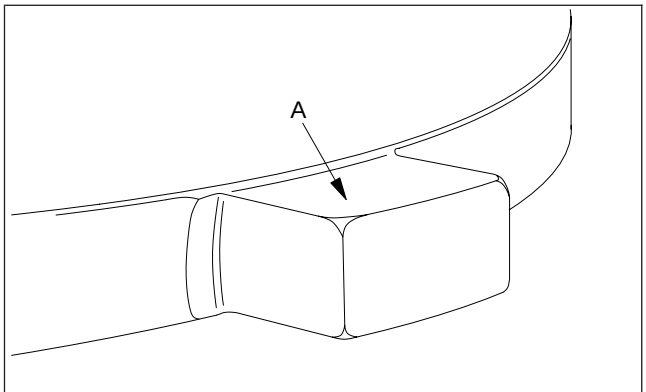
8. Inspect the center plate.

8.1 Inspect the tabs on the outer edge of the center plate. See **Fig. 10**. If the tabs are worn or damaged, replace the center plate. If not, go on to the next step and inspect the center plate.



f250275a

A. Make sure the tabs are not worn or damaged.

Clutch Inspection

8.2 Inspect the center plate for wear or damage. If the plate is cracked, replace it. Heat marks are normal, and can usually be removed with an emery cloth. If the heat marks cannot be removed, replace the center plate.

8.3 Using a micrometer or a caliper, measure the thickness of the center plate. The minimum thickness should be 0.742 inch (18.84 mm). If the center plate measures less than the minimum thickness, replace it..See **Fig. 11**.

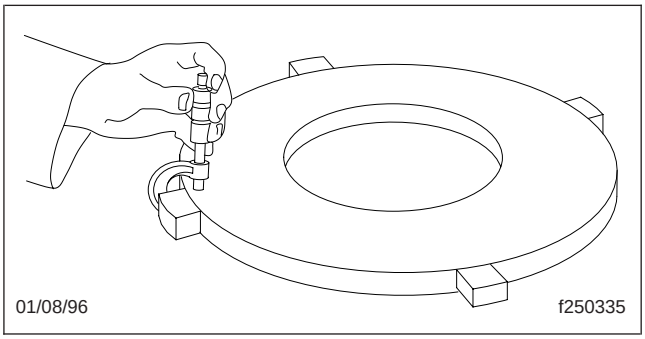

Fig. 11, Measuring Center Plate Thickness

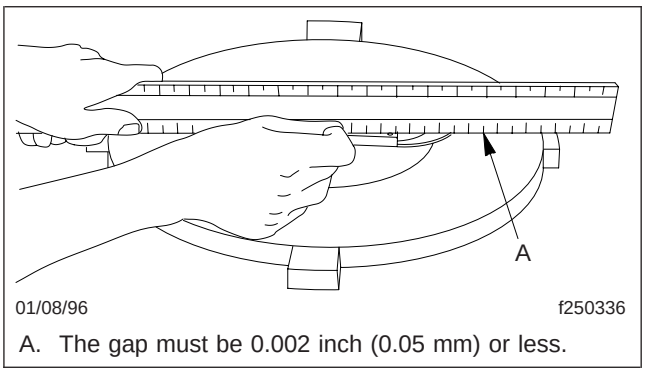
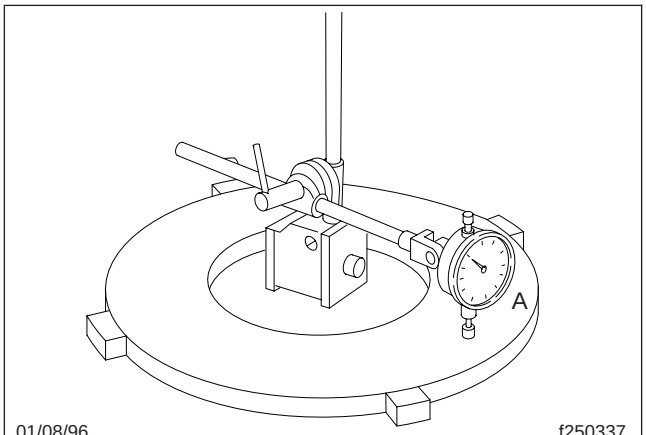
8.4 Make sure the surface of the center plate is flat. Put a straightedge on the surface of the center plate, making sure it crosses the center of the plate. See **Fig. 12**. Using a feeler gauge, measure each gap that appears between the straightedge and the pressure plate. Rotate the straightedge through at least four positions. If any gap is more than 0.002 inch (0.05 mm), grind a new surface on the center plate; if not, go on to the next step.



A. The gap must be 0.002 inch (0.05 mm) or less.

Fig. 12, Checking the Center Plate Surface

8.5 Measure the runout of the center plate to make sure the surfaces are parallel to each other. **Fig. 13**. Put the base of the dial indicator inside the center of the plate. Put the tip of the dial indicator on the surface of the plate. Set the dial indicator to zero. Rotate the dial indicator one complete turn around the surface of the center plate. If the reading on the indicator is more than 0.002 inch (0.05 mm), grind a new surface on the center plate; if not, go on to the next step.



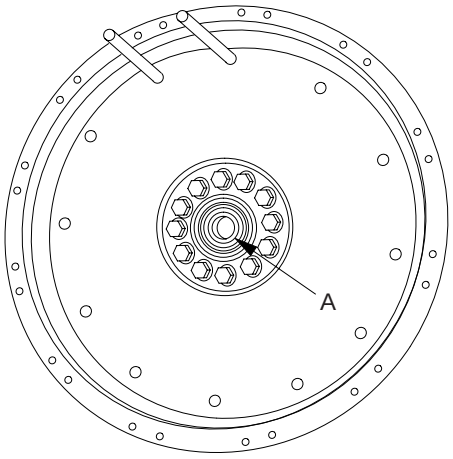
A. Runout must be 0.002 inch (0.05 mm) or less.

Fig. 13, Measuring Center Plate Runout

8.6 If either the runout or the flatness of the center plate is more than 0.002 inch (0.05 mm), grind enough material so that the plate is flat, but do not go below the minimum thickness. Refer to the table in **Specifications, 400** for center plate minimum thickness. Re-check the flatness and runout of the center plate.

9. Although the pilot bearing must be replaced whenever the clutch is removed, inspect the old pilot bearing for wear or damage. See **Fig. 14**. If worn or damaged, correct the cause.

10. Inspect the surface of the flywheel for wear or damage. If the flywheel is cracked, replace it. Heat marks are normal, and can usually be removed with an emery cloth. Some wear or damage can be removed by grinding a new surface on the flywheel. If wear or damage on the surface of the flywheel cannot be removed, replace the flywheel.



A. Make sure the pilot bearing is not worn or damaged.

Fig. 14, Inspecting the Old Pilot Bearing

Refer to the engine manufacturer's service manual for flywheel service procedures.

IMPORTANT: If the flywheel surface is reground, make sure there is still adequate thickness for the capscrews to hold the clutch to the flywheel. The threads for these capscrews are below the surface of some flywheels, requiring the use of capscrews with a shoulder. If some of the flywheel surface is removed, the capscrews may not hold. Use new capscrews that are the correct length.

11. Inspect the ring gear teeth on the outer surface of the flywheel. If the teeth are worn or damaged, replace the ring gear or the flywheel. Refer to the engine manufacturer's service manual for instructions.

    Check the tabs on the outer edge of the flywheel. Replace the flywheel if the tabs are worn or damaged.

12. The flywheel surface must be flat for correct clutch operation. Check the runout of the outer surface of the flywheel. Refer to the engine manufacturer's service manual for instructions.

NOTE: In general, maximum runout is 0.0005 inch times the flywheel diameter in inches.

13. Refer to the engine manufacturer's service manual for instructions and check the following:
    - pilot bearing bore runout
    - crankshaft end play
    - runout of the outer surface of the flywheel housing
    - runout of the inside of the flywheel housing

CAUTION

Do not clean ground or polished parts in a hot solution tank or with water, steam, or alkaline solutions. These solutions will cause the parts to corrode.

14. Clean the disassembled parts.

    14.1 Using a cleaning solvent or kerosene, clean all ground or polished parts or surfaces.

    14.2 Rough parts can be cleaned with the ground or polished parts. The rough parts can also be cleaned in hot solution tanks with a weak alkaline solution. The parts must remain in the tank until they are completely cleaned and heated.

    14.3 Dry the parts with clean paper, shop towels, or compressed air immediately after cleaning.

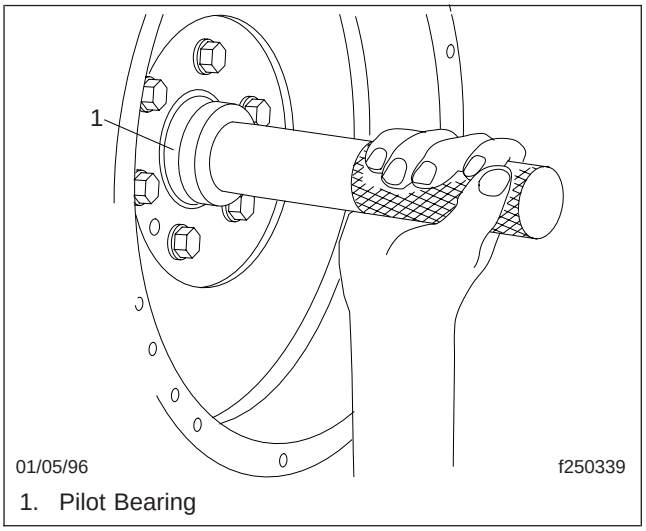
15. Apply lubricant to the cleaned and dried parts that are not damaged and are to be immediately assembled. *Do not* apply lubricant to the linings.

    If parts are to be stored, apply a special material that prevents corrosion and rust to all surfaces. *Do not* apply the material to the linings. Store the parts inside special paper or other material that prevents corrosion and rust.

Installation

NOTE: During clutch removal, spacers or wooden blocks are installed between the release bearing and the clutch cover to facilitate removal. Do not remove the spacers or wooden blocks until after the clutch is installed. The spacers or blocks make installation of the clutch easier by holding the clutch components in position.

1. Lubricate the bore in the crankshaft for the pilot bearing with the specified lubricant. Do not use too much lubricant. Excess lubricant can contaminate the discs and cause the clutch to slip.
2. Use the correct size of driver to install the pilot bearing in the crankshaft bore. **See Fig. 1.** Refer to the engine manufacturer's service manual for instructions.



1. Pilot Bearing

Fig. 1, Pilot Bearing Installation

3. Install 3/8-inch guide studs in two of the upper mounting holes for the cover and pressure plate assembly. **See Fig. 2.**

WARNING

WARNING: Tilt the front of the alignment tool up when the clutch assembly is installed. If the tool is not tilted up, components will fall off the tool, causing personal injury and component damage.

9. Using a lifting device, lift the clutch assembly onto the guide studs. **See Fig. 3.** Make sure the alignment tool is installed in the flywheel pilot bearing.
10. Install the clutch assembly against the flywheel. Remove the lifting device.
11. Install and hand-tighten the capscrews that fasten the clutch to the flywheel.
12. Remove the guide studs. Install and hand-tighten the remaining capscrews.

NOTE: When the capscrews are tightened, the wooden blocks or spacers will fall from between the release bearing and the cover.

13. Tighten the capscrews to the torque values in **Specifications, 400.**
14. Remove the alignment tool (or the input shaft used as an alignment tool).
15. If used, install the clutch brake on the transmission input shaft. Make sure the tabs on the clutch brake engage the slots on the input shaft. **See Fig. 5.**
16. Install the transmission. Follow the procedures in **Group 26** of this manual.

Troubleshooting Tables

Troubleshooting—Functional Problems

NOTE: Problem entries in the troubleshooting tables in this subject refer to functional or operational problems. Before troubleshooting the clutch, make sure that:

- the engine is operating correctly
- the engine mounts are in good condition
- the driveline angles of the engine, transmission, driveshaft, and rear axle are correct

Problem—The Clutch Does Not Disengage Completely

Problem—The Clutch Does Not Disengage Completely	
Possible Cause	**Remedy**
The clutch linkage and release bearing need adjustment.	Adjust the clutch linkage and release bearing.
The linkage is worn or damaged.	Lubricate the linkage. Make sure the linkage is not loose. If the condition persists, replace the linkage.
The release bearing is worn or damaged.	Lubricate (if applicable) the release bearing. If the condition persists, replace the release bearing.
The input shaft splines are worn or damaged.	Replace the input shaft.
The clutch housing is loose.	Tighten the fasteners to the specified torque. If necessary, replace the fasteners.
The pressure plate is worn or damaged.	Replace the pressure plate and cover assembly.
The center plate is worn or damaged.	Replace the center plate.
The center plate binds.	Inspect the tabs on the center plate and the slots in the cover. Service as needed.
Damaged clutch disc hub(s).	Replace the clutch discs.
The linings are worn beyond specification.	Replace the clutch discs.
The linings are damaged.	Replace the clutch.
Oil or grease on the linings.	Clean the linings. If the oil or grease cannot be removed, replace the clutch discs.
A clutch with incorrect lining for the vehicle application is installed.	Install a clutch with the correct type of lining.
The pilot bearing is damaged.	Replace the pilot bearing.

Problem—Clutch Pedal Hard to Operate

Problem—Clutch Pedal Hard to Operate	
Possible Cause	**Remedy**
Damaged bosses on the release bearing assembly.	Replace the bearing assembly. Make sure the clutch is adjusted correctly.
The clutch linkage is worn or damaged.	Lubricate the linkage. If the condition still exists, replace the linkage.
The pressure plate and cover assembly components are worn or damaged.	Replace the pressure plate and cover assembly.

Troubleshooting

Problem—Clutch Pedal Hard to Operate	
Possible Cause	**Remedy**
The clutch cross shaft binds.	Lubricate the cross shaft. If the condition persists, replace the cross shaft and bushings as required.

Problem—The Clutch Slips

Problem—The Clutch Slips	
Possible Cause	**Remedy**
The driver keeps his foot on the clutch pedal.	Use correct driving procedures.
The clutch linkage or release bearing needs adjustment.	Adjust the clutch linkage or release bearing.
Pressure plate and cover assembly components are worn or damaged.	Replace the pressure plate and cover assembly.
Linings are worn or damaged.	Replace the clutch discs.
Oil or grease on the linings.	Clean the linings. If the oil or grease cannot be removed, replace the clutch discs.
A clutch with incorrect lining for the vehicle application is installed.	Install a clutch with the correct type of lining.
The flywheel is worn or damaged.	Service the flywheel as needed. For instructions, refer to the engine manufacturer's service manual.

Problem—The Clutch is Noisy

Problem—The Clutch is Noisy	
Possible Cause	**Remedy**
The clutch linkage or release bearing needs adjustment.	Adjust the clutch linkage or release bearing.
The linkage is worn or damaged.	Lubricate the linkage. If the condition persists, replace the linkage.
The release bearing is worn or damaged.	Lubricate (if applicable) the release bearing. If the condition persists, replace the release bearing.
The clutch housing is worn or damaged.	Replace the clutch housing.
The clutch housing is loose.	Tighten the fasteners to the specified torque. If necessary, replace the fasteners.
The hub is damaged, or the co-axial spring(s) are broken in the clutch disc.	Replace the clutch discs.
Linings are worn below specified dimensions.	Replace the clutch discs.
Linings are damaged.	Replace the clutch discs.
Oil or grease on the linings.	Clean the linings. If the oil or grease cannot be removed, replace the clutch discs.
The pilot bearing is damaged.	Replace the pilot bearing.

Problem—The Clutch Vibrates

Problem—The Clutch Vibrates	
Possible Cause	**Remedy**
The input shaft splines are damaged.	Replace the input shaft.
The pressure plate and cover assembly are out of balance.	Remove the pressure plate and cover assembly. Check their balance and install them. If the problem persists, replace the pressure plate and cover assembly.
The splines are damaged in the clutch disc hub(s).	Replace the clutch discs.
The flywheel is loose.	Tighten the fasteners to the specified torque. If necessary, replace the fasteners. Check the flywheel mounting surface for damage. If necessary, replace the flywheel.

Troubleshooting—Component Problems

NOTE: Problem entries in the troubleshooting tables in this subject refer to damage to components.

Problem—Broken Tabs on the Clutch Brake

Problem—Broken Tabs on the Clutch Brake	
Possible Cause	**Remedy**
Vibration.	Inspect the clutch disc hubs; check the installation of the clutch. Make sure dampened discs are used.
The clutch linkage is incorrectly adjusted.	Adjust the clutch linkage. Also, check the installation of the clutch.
The driver used the clutch brake while the vehicle was moving.	Use correct driving technique.

Problem—Worn or Damaged Release Bearing Housing

Problem—Worn or Damaged Release Bearing Housing	
Possible Cause	**Remedy**
The driver keeps his foot on the pedal.	Use correct driving technique.
The clutch linkage is incorrectly adjusted.	Adjust the clutch linkage. Also, check the installation of the clutch.

Problem—Worn Bosses on the Release Bearing Housing

Problem—Worn Bosses on the Release Bearing Housing	
Possible Cause	**Remedy**
The linkage is damaged or out of adjustment.	Lubricate and adjust the linkage. Inspect the linkage for wear or damage.
The release yoke is binding.	Lubricate the release yoke shaft. If the yoke does not move freely, replace the shaft and yoke assembly.
The free pedal is out of adjustment.	Adjust the free pedal to specification.

Troubleshooting

Problem—Worn or Damaged Input Shaft Splines

Problem—Worn or Damaged Input Shaft Splines	
Possible Cause	**Remedy**
The transmission is not aligned.	Make sure the flywheel housing and the clutch housing are aligned to specification.
The transmission is not installed correctly.	Install the transmission correctly.
The clutch disc hubs are damaged.	Replace the clutch discs.
The pilot bearing is worn or damaged.	Replace the pilot bearing.
Engine vibration.	Make sure dampened discs are used.

Problem—Pressure Plate Cracked or Damaged by Heat

Problem—Pressure Plate Cracked or Damaged by Heat	
Possible Cause	**Remedy**
The driver engages the clutch while coasting.	Use correct driving techniques.
The driver uses the clutch as a brake.	Use correct driving techniques.
The clutch free pedal is not adjusted correctly.	Adjust the free pedal to specifications.
There is oil or grease on the clutch linings.	Clean the clutch discs. If the oil or grease cannot be removed, replace the clutch discs. Repair the cause of the grease or oil.
The diaphragm spring is worn or damaged.	Replace the pressure plate and the cover assembly.
The driver slips the clutch excessively during engagement.	Use correct driving techniques.

Problem—Grooves Worn in the Pressure Plate

Problem—Grooves Worn in the Pressure Plate	
Possible Cause	**Remedy**
The clutch discs are worn or damaged.	Replace the clutch discs. If damaged, replace the center plate and flywheel.

Problem—The Clutch Disc Hub is Warped

Problem—The Clutch Disc Hub is Warped	
Possible Cause	**Remedy**
The transmission was not installed correctly.	Replace the clutch discs. Install the transmission correctly.

Problem—The Hub Separates From the Clutch Disc

Problem—The Hub Separates From the Clutch Disc	
Possible Cause	**Remedy**
Excessive engine vibration.	Repair the engine.

Problem—The Hub Separates From the Clutch Disc	
Possible Cause	**Remedy**
The transmission was not installed correctly.	Install the transmission correctly.
The clutch housing is loose.	Tighten the clutch housing to the specified torque.
The driver engages the clutch while the vehicle is coasting.	Use correct driving techniques.
Shock loading.	Use correct driving techniques.

Problem—Heat Damage to the Clutch Disc

Problem—Heat Damage to the Clutch Disc	
Possible Cause	**Remedy**
The driver keeps his foot on the clutch pedal or slips the clutch.	Use correct driving techniques.
The clutch does not engage or disengage completely.	See "Troubleshooting—Functional Problems: Clutch Does Not Disengage Completely."
The free pedal is not adjusted correctly.	Adjust the free pedal.
The diaphragm spring is worn or damaged.	Replace the pressure plate and cover assembly.
There is oil or grease on the clutch linings.	Clean the clutch discs. If the oil or grease cannot be removed, replace the clutch discs. Repair the cause of the grease or oil.

Problem—The Linings Separate From the Disc

Problem—The Linings Separate From the Disc	
Possible Cause	**Remedy**

Fig. 1, Valeo Clutch

Valeo clutches installed in Freightliner heavy-duty vehicles are available in 16-inch and 17-inch models. They are single-disc, diaphragm spring, pull-type clutches. A dampened driven disc is standard. The lining is a "cerametallic" material.

Following is a description of each of the major clutch components.

- Clutch Disc—the clutch disc is the driven portion of the assembly that transmits power from the engine flywheel to the transmission input shaft. A typical disc has six paddle arms with cerametallic friction facings on the front and back sides of each arm. Power is transmitted through the friction facings to the splined hub that couples to the transmission input shaft. In the center portion of the clutch disc, between the friction facings and the splined hub, is the clutch damper unit. The damper unit is made up of several coil springs designed to absorb the torsional vibrations generated by the engine, reducing driveline noise and transmission input shaft spline wear.
- Pressure Plate—the pressure plate (**Fig. 2**) is a large cast iron disc machined on one side to press flat against the clutch disc. The pressure plate is attached to the flywheel through the clutch cover. Using spring pressure, it clamps the clutch disc to the engine flywheel allowing engine power to be transmitted to the transmission input shaft. The pressure plate casting is attached to the clutch cover by four sets of spring-steel drive straps (**Fig. 3**). These drive straps transmit engine power to the pressure plate through a flexible connection. This connection allows the pressure plate to be moved toward or away from the engine. The drive straps act as springs to pull the pressure plate casting off the disc when the diaphragm spring clamping load is disengaged. This eliminates

General Description

drag by mechanically retracting the pressure plate when the clutch pedal is depressed.

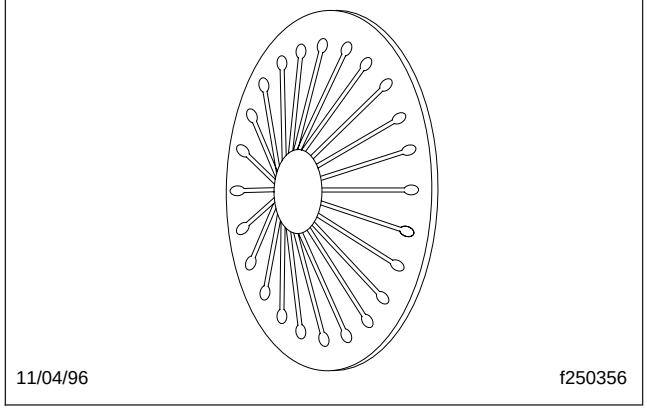
Fig. 3, Spring-Steel Drive Strap

- Diaphragm Spring—the diaphragm spring (**Fig. 4**) is a circular disc. The spring portion contains several fingers that are moved back and forth to engage and disengage the clutch. The force created by the diaphragm spring provides the load necessary to clamp the clutch disc between the pressure plate casting and flywheel. The spring is placed inside the clutch cover between the fulcrum ring and a ridge on the pressure plate. The fingers of the diaphragm are attached to the coupler.
- Fulcrum Ring—the fulcrum ring is located within the clutch cover and provides a pivot surface for the diaphragm spring.



11/04/96 f250356

Fig. 4, Diaphragm Spring

- Clutch Cover—the clutch cover (**Fig. 5**) is a lightweight steel stamping designed to provide strength and heat dissipation. It protects the vehicle from damage in case the pressure plate casting breaks. The cover completely covers the outside of the clutch and is attached to the flywheel. Four spring-steel drive straps attach the cover to the pressure plate.

- Release Bearing—the release bearing assembly is used to connect the clutch diaphragm spring to the clutch release linkage (**Fig. 6**). The assembly is attached to the diaphragm spring with a coupler and snap ring. The coupler, threaded sleeve and ball bearing inner race rotate at engine speed along with the

clutch. The release bearing outer race remains fixed inside the bearing housing which is held stationary by the release yoke.

Principles of Operation

The clutch is used to disconnect and reconnect driving (engine) and driven (transmission) members of the driveline. See **Fig. 7**. The clutch does the following:

- When engaged, the clutch allows the engine and driveline to rotate together as one solid member.
- When disengaged, the clutch disconnects the engine from the driveline allowing it to remain running while the vehicle is stopped.
- The clutch can be used to interrupt and reconnect the flow of engine power to allow the changing of transmission gears, or to engage or disengage a power takeoff unit.

The clutch pedal allows the driver to control the clutch. When the pedal is depressed, the release bearing is pulled rearward, toward the transmission. It pulls the diaphragm spring along with it, disengaging the clamp load on the driven disc. During clutch engagement, the release bearing moves toward the engine. This movement allows the diaphragm spring to clamp the clutch disc between the pressure plate and the engine flywheel, transmitting engine power to the transmission.

Clutch Adjustments

Eaton Valeo clutches require two adjustments: release bearing clearance (this distance must be 1/2 to 9/16 inch (12.7 to 14.3 mm) and clutch free-travel (this distance must be 0.105 to 0.145 inch (2.7 to 3.7 mm). See **Fig. 1**.

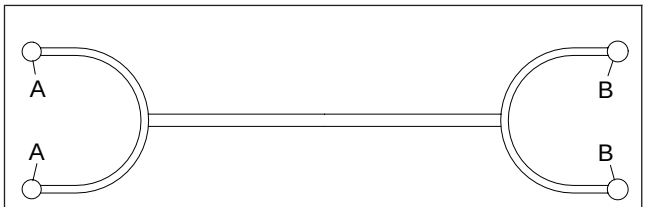
Fig. 1, Clutch Adjustment Measurements

IMPORTANT: An inspection tool A02–12419 (available through the PDCs) can be used to check the distance between the release bearing and the clutch brake. See **Fig. 2**. One end of the tool has green tape on it and is 0.50 inch (12.7 mm) in diameter; the other end has blue tape on it and is 0.56 inch (14.3 mm) in diameter.

1. If using tool A02–12419 to check the distance between the release bearing and the clutch brake, position the tool so that the legs straddle the transmission input shaft. Check the gap with both ends of the tool as follows:



03/26/96 f580133

A. 0.50 inch (12.7 mm)
B. 0.56 inch (14.3 mm)

Fig. 2, Inspection Tool A02-12419

1.1 Insert the blue 0.56-inch (14.3-mm) end. If it fits loosely the gap is too wide and adjustment is needed. Go to the next step.

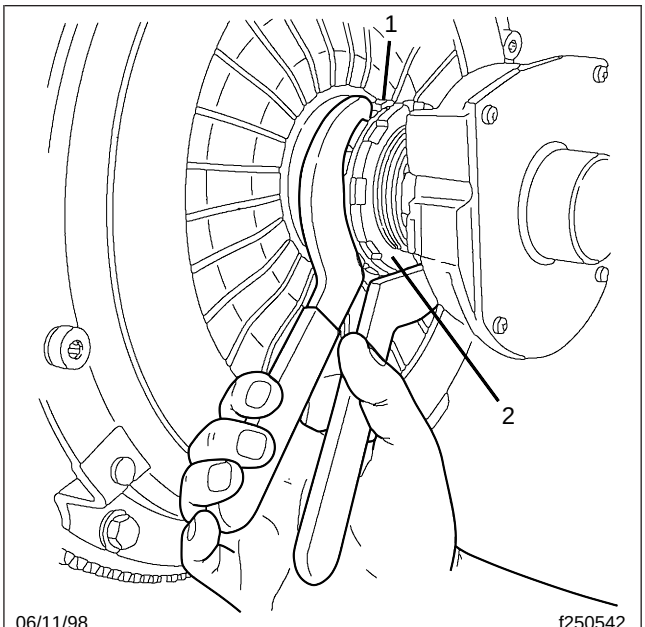
1.2 If the blue 0.56-inch (14.3-mm) end can't be inserted in the gap, then try to insert the green 0.50-inch (12.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

1.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Go to the next step.

Clutch Adjustments

2. Disconnect the external linkage to allow free movement of the release yoke.
3. Using two adjustable hook spanner wrenches (**Table 1**), loosen the release bearing locknut. Thread the locknut back toward the transmission a small distance to ensure that it will not interfere with the adjustment procedure.
4. Rotate the sleeve with the adjuster ring to the specified release bearing clearance.
5. Using the two spanner wrenches, place one on the notches of the release bearing coupler and the other on the release bearing locknut. See **Fig. 3**. Use the first wrench to prevent the coupler from rotating while using the second wrench to tighten the locknut against the coupler.

   Tighten the locknut ring against the release bearing coupler by placing the two wrenches in notches that will result in the two wrench handles slightly moving apart from one another. Then both handles can be grasped with one hand and squeezed closely together.

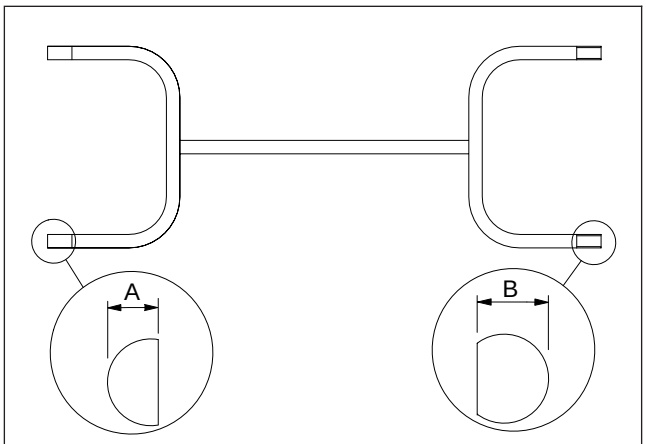


1. Coupler
2. Locknut Ring

Fig. 3, Tighten the Locknut Ring

IMPORTANT: An inspection tool A02–12254 (available through the PDCs) can be used to check the distance between the release bearing and the release fork (free travel). See **Fig. 4**. The legs on one end of the tool have green tape on them and are 0.105 inch (2.7 mm) thick; the legs on the other end have blue tape on them and are 0.145 inch (3.7 mm) thick.

6. If using tool A02–12254 to check the distance between the release bearing and the release fork, position the tool so it straddles the fork to ensure that there won't be any misalignment. Check the distance with both ends of the tool as follows:



A. 0.105 inch (2.7 mm)
B. 0.145 inch (3.7 mm)

Fig. 4, Inspection Tool A02-12254

6.1 Insert the blue 0.145-inch (3.7-mm) end. If it fits loosely the gap is too wide and adjustment is needed. Connect the external linkage, then go to the section on clutch linkage adjustment in this group.

6.2 If the blue 0.145-inch (3.7-mm) end can't be inserted in the gap, then try to insert the green 0.105-inch (2.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

6.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Connect the external linkage, then perform a clutch linkage adjustment. For instructions, see **Section 25.03**.

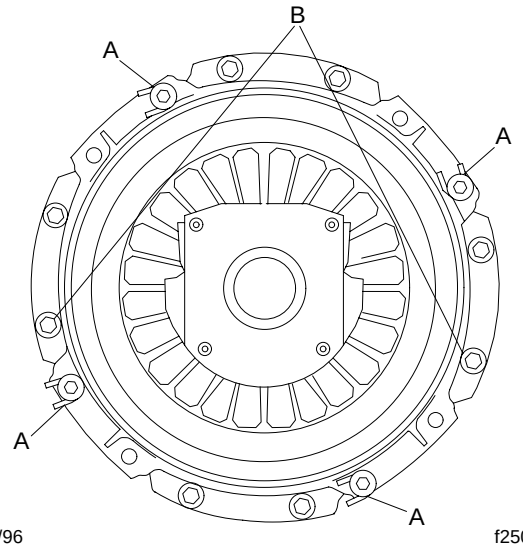
Clutch Removal

1. Remove the transmission. Follow the procedures in **Group 26** of this manual.

CAUTION

Do not let the transmission drop, and do not let the transmission hang unsupported by the input shaft in the pilot bearing. Taking these precautions will prevent damage to the clutch assembly and the pilot bearing.

2. To facilitate clutch removal and installation, Valeo clutches employ four shipping clips to hold the pressure plate toward the clutch. Install the four shipping clips. See **Fig. 1** and **Fig. 2**.



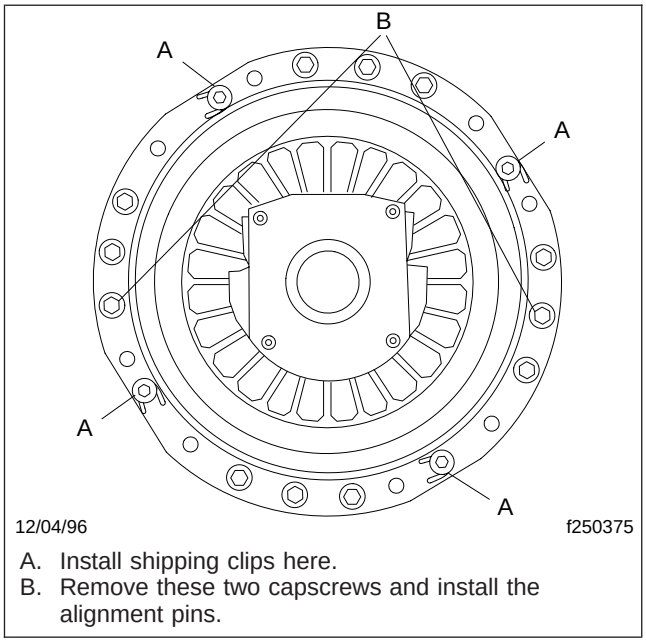
A. Install shipping clips here.
B. Remove these two capscrews and install the alignment pins.

Fig. 1, 16-Inch Clutch

3. Install a clutch alignment tool through the clutch and into the flywheel pilot bearing to support the clutch assembly during removal.

NOTE: If an alignment tool is not available, use an input shaft from a manual transmission. Remove the gear from the end of the input shaft.

4. Remove the two capscrews (that are 180 degrees apart) from the pressure plate assembly as indicated in **Fig. 1** and **Fig. 2**. Install alignment pins in the two holes. If alignment pins are not available, they may be made by removing the heads from two capscrews.



A. Install shipping clips here.
B. Remove these two capscrews and install the alignment pins.

Fig. 2, 17-Inch Clutch

5. Remove the remaining capscrews which secure the cover assembly to the flywheel.

WARNING

The cover assembly is heavy and should be removed only with a lifting device. If the assembly is lifted improperly or dropped, it could cause serious personal injury.

6. Lift the pressure plate, release bearing, and clutch assembly over the alignment tool and alignment pins.

7. Whenever the clutch assembly is serviced or the engine is removed, the pilot bearing in the flywheel should be removed and replaced. Use an appropriate internal puller and a slide hammer to remove the pilot bearing. Install the new pilot bearing with an appropriate driver.

Clutch Inspection

1. Remove the clutch from the vehicle. Refer to **Subject 110** for instructions.
2. Inspect the surface of the flywheel for wear or damage. If the flywheel is cracked, replace it. Heat marks are normal, and can usually be removed with an emery cloth. Some wear or damage can be removed by grinding a new surface on the flywheel. If wear or damage on the surface of the flywheel cannot be removed, replace the flywheel.

   Refer to the engine manufacturer's service manual for flywheel service procedures.

IMPORTANT: If the flywheel surface is reground, make sure there is still adequate thickness for the capscrews to hold the clutch to the flywheel. The threads for these capscrews are below the surface of some flywheels, requiring the use of capscrews with a shoulder. If some of the flywheel surface is removed, the capscrews may not hold. Use new capscrews that are the correct length.

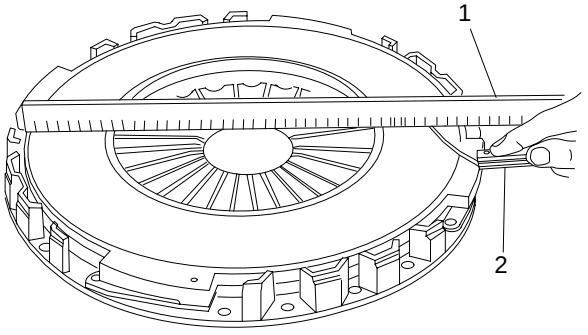
3. Inspect the ring gear teeth on the outer surface of the flywheel. If the teeth are worn or damaged, replace the ring gear or the flywheel. Refer to the engine manufacturer's service manual for instructions.

   Check the tabs on the outer edge of the flywheel. Replace the flywheel if the tabs are worn or damaged.
4. The flywheel surface must be flat for correct clutch operation. Check the runout of the outer surface of the flywheel. Refer to the engine manufacturer's service manual for instructions.
5. Refer to the engine manufacturer's service manual for instructions and check the following:
   - pilot bearing bore runout
   - crankshaft end play
   - runout of the outer surface of the flywheel housing
   - runout of the inside of the flywheel housing

⚠ CAUTION

Do not clean ground or polished parts in a hot solution tank or with water, steam, or alkaline solutions. These solutions will cause the parts to corrode.

6. Inspect the pilot bearing. Although the pilot bearing should be replaced whenever the clutch is removed, any excessive wear or damage to the pilot bearing could indicate other problems which should be remedied.
7. Check the locknut for adequate tightness against the release bearing coupler.
8. Inspect the pressure plate friction surface for wear by placing a straight edge across the width of the friction face. See **Fig. 1**. A gap in the worn area of 0.030 inch (0.75 mm) or more indicates the pressure plate and cover assembly should be replaced.



1. Straight Edge 2. Feeler Gauge

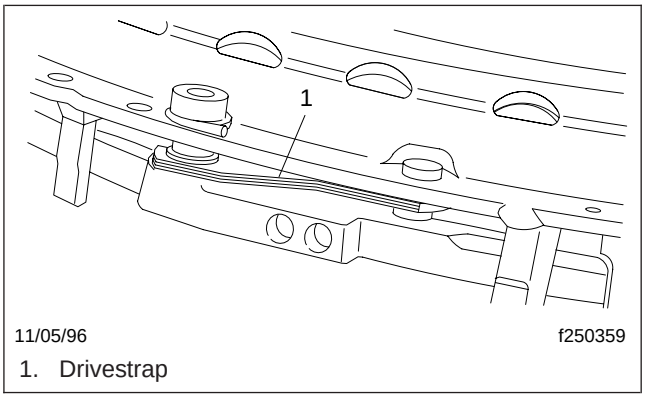
Fig. 1, Checking the Pressure Plate for Wear and Warpage

9. If reusing the pressure plate and cover assembly with a new disc, inspect the pressure plate for warpage or uneven wear by placing a straightedge across the entire diameter of the plate. If the gap at the inside wear diameter exceeds the gap at the outside wear edge by 0.008 inch (0.20 mm), there is excessive concave warpage and the pressure plate and cover assembly should be replaced. No measurable amount of convex warpage is allowed, so replacement of the assembly is required if the gap at the outside diam-

Clutch Inspection

eter exceeds the gap at the inside edge of the clutch wear area.

10. Inspect the pressure plate for heat damage such as discoloration, surface checking, or cracks. Slight discoloration or light checking is normal. Deep checking or cracks indicate that the pressure plate and cover assembly should be replaced.
11. Check the drivestrap assemblies for bends or kinks. Normal drivestrap units form a smooth, gently curving "S" shape when viewed from the edge, with all laminations fitting tightly together. See **Fig. 2**. Bent or kinked drivestraps will show an area of sharp bending next to the rivet or bolt attachments and/or noticeable gaps between laminations.



1. Drivestrap

Fig. 2, Normal Drivestrap

12. Do the following checks on the clutch disc.
    - 12.1 Inspect the friction material for signs of excessive wear or heat damage. Disc thickness should be checked with calipers or an outside micrometer. See **Fig. 3**. Minimum disc thickness is 0.295 inch (7.50 mm).
    - 12.2 Slide the clutch disc onto the transmission input shaft to look for evidence of sticking or binding splines. Clean and correct the source of interference or replace the clutch disc.
    - 12.3 Lay the clutch disc on a new pressure plate and cover assembly or flywheel to check for bent cerametallic paddle arms. Using a feeler gauge, check the gap between the friction material pads and the pressure plate and cover assembly or flywheel face. See **Fig. 4**. The gap must not exceed 0.030 inch (0.75 mm).

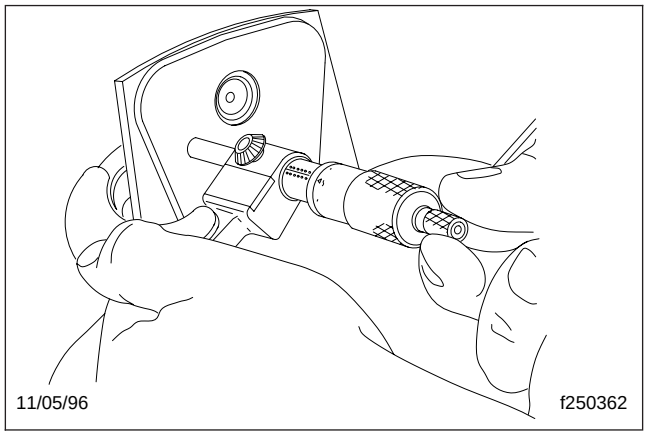


Fig. 3, Check the Clutch Disc Thickness

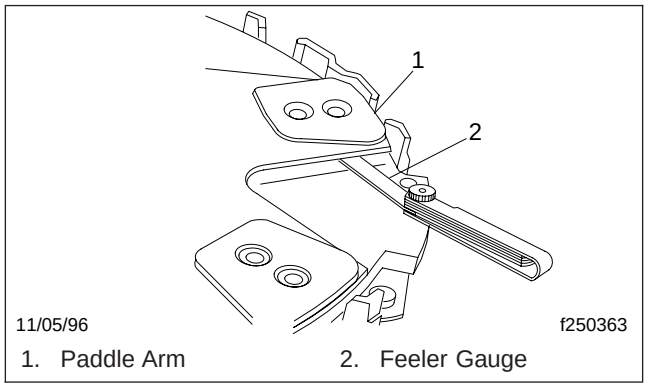
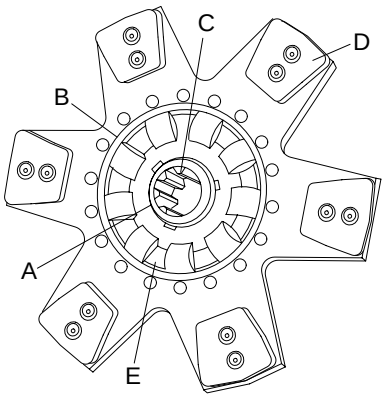


1. Paddle Arm
2. Feeler Gauge

Fig. 4, Checking for Bent Paddle Arms

    - 12.4 Examine the clutch disc for a bent hub by looking for unusually heavy and eneven friction material wear.
    - 12.5 Check for signs of driveline torsional vibration or shock loading damage like broken springs, cracked damper retainer plates, or damaged splines. See **Fig. 5**.
13. Inspect the clutch release yoke contact tips for excessive wear. Replace if needed. See **Fig. 6**.
14. Inspect the cross shafts for bushing wear, and check for end spline damage and wear. Replace as needed.
15. If a clutch brake is installed, inspect the clutch brake wear surface on the transmission. Replace the transmission front bearing cover if necessary.



A. Check the hub for damage.
B. Check the damper retaining plate.
C. Check the splines.
D. Check the paddles for unusual wear patterns.
E. Check for broken or damaged springs.

Clutch Installation

NOTE: If you are installing components which have been in operation, do the steps in **Subject 120** before installing the clutch.

1. Lubricate the bore in the crankshaft for the pilot bearing with the specified lubricant. Do not overlubricate. Excess lubricant can contaminate the disc and cause the clutch to slip.

   Using an appropriate driver, install the pilot bearing. Refer to the engine manufacturer's service manual for instructions.

2. If necessary, install the release bearing assembly on the pressure plate. See **Fig. 1** for assembly.

2.1 Stand the coupler vertically on an arbor press working surface using the rear notched end face as a base.

2.2 Place the specified size and number of shim washers on the coupler pilot.

- 16-inch clutch: 0.031 inch (0.8 mm) shim
- 17-inch clutch: 0.5 inch (0.020 mm) shim

2.3 Place two toothed Belleville washers on the coupler pilot with the teeth pointing down toward the shim washers. See **Fig. 2**.

2.4 Set the pressure plate and cover assembly on the coupler pilot end with the pressure plate side (engine side) facing up. The pressure plate and cover assembly should be positioned so that the diaphragm finger tips are resting on the solid edge of the Belleville washer.

NOTE: For ease of assembly, a shipping clip should be in place between each of the four drivestrap attaching screw heads and the pressure plate and cover assembly. If this is not the case, assemble the pressure plate and cover assembly over a disc onto a flywheel and evenly and slowly tighten each mounting screw in a crisscross pattern just enough to allow shipping clips, or an equivalent, to be installed. Then remove the pressure plate and cover assembly and continue with release bearing installation.

2.5 Place the finger contact ring on the coupler pilot with the rounded face down contacting the diaphragm spring fingers. The flat face with the counter bore at the inside diameter will face up.

2.6 Place the round wire snap ring on the exposed end of the coupler pilot. See **Fig. 3**.

2.7 Using an arbor press ram, push down on the finger contact ring at one point enough to deflect the Belleville washers and start

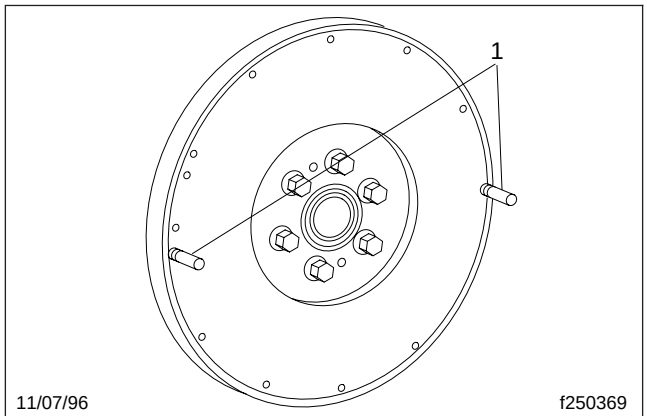
the open end of the round wire snap ring into its groove. Continue in this manner around the coupler until the snap ring is fully seated into its groove.

2.8 Thread the adjustment locknut on the release bearing barrel. Install a separating ring on the barrel.

2.9 Thread the release bearing assembly into the coupler deep enough so that it will not hit the transmission when it is installed.

3. Clean the friction surface of the pressure plate and cover assembly with a suitable brake surface cleaning solvent to remove all grease, oil, or protective film.

4. Install two alignment pins into two flywheel mounting holes that are 180 degrees apart. See **Fig. 4**.



1. Alignment Pins

Fig. 4, Install the Alignment Pins

5. With the flatter side of the clutch disc pointing towards the flywheel, insert the clutch disc alignment tool through the splines on the disc. Next, insert the pilot arbor of the alignment tool into the flywheel pilot bearing and slide the clutch disc against the flywheel. See **Fig. 5**.

⚠ WARNING

WARNING: The cover assembly is heavy and should be installed only with a lifting device. If the assembly is lifted improperly or dropped, it could cause serious personal injury.

6. Install the pressure plate and cover assembly over the alignment tool and onto the alignment pins. See **Fig. 6**. Don't allow the weight of the pressure plate assembly to hang on the release bearing and clutch disc alignment tool.

NOTE: The 17-inch pot-type clutch is centered on the flywheel with two dowel pins located 180 degrees apart on the clutch mounting flanges.

8. Start each clutch mounting capscrew and washer assembly by hand and thread them in until the capscrews contact the clutch housing cover.
9. Remove the two alignment pins, and install the remaining two capscrew and washer assemblies.

IMPORTANT: Make sure that the pressure plate and cover assembly flange fully and evenly enters the pilot lip on the flywheel rim. See **Fig. 8**.

10. Tighten the capscrews as specified below. Follow the tightening sequence in **Fig. 9** and **Fig. 10**, tighten the capscrews 40 to 55 lbf·ft (54 to 75 N·m).
11. Remove the four wire shipping clips (**Fig. 11**).

⚠ CAUTION

Do not let the transmission drop, and do not let the transmission hang unsupported by the input shaft in the pilot bearing bore in the flywheel. Taking these precautions will prevent damage to the clutch assembly and the pilot bearing. If excessive force is required to install the transmis-

Troubleshooting Tables

Troubleshooting—Functional Problems

NOTE: Problem entries in the troubleshooting tables that follow refer to functional or operational problems. Before troubleshooting the clutch, make sure that:

- the engine is operating correctly
- the engine mounts are in good condition
- the driveline angles of the engine, transmission, driveshaft, and rear axle are correct

Problem—The Clutch Does Not Disengage Completely

Problem—The Clutch Does Not Disengage Completely	
Possible Cause	**Remedy**
The clutch linkage and release bearing need adjustment.	Adjust the clutch linkage and release bearing.
The linkage is worn or damaged.	Lubricate the linkage. Make sure the linkage is not loose. If the condition persists, replace the linkage.
The release bearing is worn or damaged.	Lubricate (if applicable) the release bearing. If the condition persists, replace the release bearing.
The input shaft splines are worn or damaged.	Replace the input shaft.
The clutch housing is loose.	Tighten the fasteners to the specified torque. If necessary, replace the fasteners.
The pressure plate is worn or damaged.	Replace the clutch.
Damaged clutch disc hub.	Replace the clutch.
The clutch disc facings are worn beyond specification.	Replace the clutch.
Oil or grease on the clutch disc facings.	Clean the clutch disc facings. If the oil or grease cannot be removed, replace the clutch disc.
A clutch with incorrect clutch disc for the vehicle application is installed.	Install a clutch with the correct type of clutch disc.
The pilot bearing is damaged.	Replace the pilot bearing.
The clutch disc is bent or warped.	Replace the clutch.

Problem—Clutch Pedal Hard to Operate

Problem—Clutch Pedal Hard to Operate	
Possible Cause	**Remedy**
Damaged bosses on the release bearing assembly.	Replace the bearing assembly. Make sure the clutch is adjusted correctly.
The clutch linkage is worn or damaged.	Lubricate the linkage. If the condition still exists, replace the linkage.
The pressure plate and cover assembly components are worn or damaged.	Replace the clutch.
The clutch cross shaft binds.	Lubricate the cross shaft. If the condition persists, replace the cross shaft and bushings as required.

Troubleshooting

Problem—Clutch Pedal Hard to Operate	
Possible Cause	**Remedy**
The release bearing bushing is worn or damaged.	Replace the bearing assembly. Look for input shaft wear or damage. Make sure the clutch is adjusted correctly.
The input shaft is worn or damaged.	Replace the input shaft. Look for release bearing bushing wear or damage. Make sure the clutch is adjusted correctly.

Problem—The Clutch Slips

Problem—The Clutch Slips	
Possible Cause	**Remedy**
The driver keeps his foot on the clutch pedal.	Use correct driving procedures. Look for clutch wear or damage.
The clutch linkage or release bearing needs adjustment.	Adjust the clutch linkage or release bearing.
Pressure plate and cover assembly components are worn or damaged.	Replace the clutch.
Clutch disc facings are worn or damaged.	Replace the clutch.
Oil or grease on the clutch disc facings.	Clean the clutch disc facings. If the oil or grease cannot be removed, replace the clutch.
A clutch with incorrect clutch disc for the vehicle application is installed.	Install a clutch with the correct type of disc.
The flywheel is worn or damaged.	Service the flywheel as needed. For instructions, refer to the engine manufacturer's service manual.
The release bearing locknut is loose.	Adjust the release bearing length and tighten the locknut.

Problem—The Clutch is Noisy

Problem—The Clutch is Noisy	
Possible Cause	**Remedy**
The clutch linkage or release bearing needs adjustment.	Adjust the clutch linkage or release bearing.
The linkage is worn or damaged.	Lubricate the linkage. If the condition persists, replace the linkage.
The release bearing is worn or damaged.	Lubricate (if applicable) the release bearing. If the condition persists, replace the release bearing.
The clutch housing is worn or damaged.	Replace the clutch housing.
The clutch housing is loose.	Tighten the fasteners to the specified torque. If necessary, replace the fasteners.
Clutch brake rattle.	Replace with a different style of clutch brake.
Clutch disc facings are worn beyond specified dimensions.	Replace the clutch.
Clutch disc damper is worn or damaged.	Replace the clutch.
Clutch incorrectly installed.	Remove the clutch and install correctly.
The pilot bearing is damaged.	Replace the pilot bearing.

Problem—The Clutch is Noisy	
Possible Cause	**Remedy**
If noisy only at idle, the clutch disc may lack the idle noise damper option.	Replace with dual damper style clutch assembly.

Problem—The Clutch Vibrates

Problem—The Clutch Vibrates	
Possible Cause	**Remedy**
The input shaft splines are damaged.	Replace the input shaft.
Pilot bearing worn or damaged.	Replace the pilot bearing and input shaft if needed.
The clutch disc facings are damaged.	Replace the clutch.
The flywheel is loose.	Tighten the fasteners to the specified torque. If necessary, replace the fasteners. Check the flywheel mounting surface for damage. If necessary, replace the flywheel.
Clutch is out of balance.	Replace the clutch.
Clutch is installed incorrectly.	Remove the clutch and install correctly.
Release bearing worn or damaged.	Replace the release bearing.
Excessive driveline torsional activity (poorly phased driveshaft u-joints, incorrect driveline angles, incorrect air ride height adjustment, excessive driveshaft imbalance, incomplete ignition, etc.)	Find and correct cause of excessive driveline torsional activity.

Troubleshooting—Component Problems

NOTE: Problem entries in the troubleshooting tables that follow refer to damage to components.

Problem—Broken Tabs on the Clutch Brake

Problem—Broken Tabs on the Clutch Brake	
Possible Cause	**Remedy**
Vibration.	Inspect the clutch disc hub; check the installation of the clutch. Replace the clutch disc hub or install the clutch correctly.
The clutch linkage is incorrectly adjusted.	Adjust the clutch linkage. Also, check the installation of the clutch.
The driver used the clutch brake while the vehicle was moving.	Use correct driving technique.
The driver used the clutch to hold the vehicle on a hill when stopped.	Use correct driving technique.

Troubleshooting

Problem—Worn or Damaged Release Bearing Housing

Problem—Worn or Damaged Release Bearing Housing	
Possible Cause	**Remedy**
The driver keeps his foot on the pedal.	Use correct driving technique.
The clutch linkage is incorrectly adjusted.	Adjust the clutch linkage. Also, check the installation of the clutch; install correctly if needed.
The release bearing has been greased with incorrect thick grease or dirt contaminated grease.	Use approved lubricant and schedule lube change.

Problem—Worn Bosses on the Release Bearing Housing

Problem—Worn Bosses on the Release Bearing Housing	
Possible Cause	**Remedy**
The linkage is damaged or out of adjustment.	Lubricate and adjust the linkage. Inspect the linkage for wear or damage; replace linkage if necessary.
The release yoke is binding.	Lubricate the release yoke shaft. If the yoke does not move freely, replace the shaft and yoke assembly.
The free pedal is out of adjustment.	Adjust the free pedal to specification.

Problem—Worn or Damaged Input Shaft Splines

Problem—Worn or Damaged Input Shaft Splines	
Possible Cause	**Remedy**
The transmission is not aligned.	Make sure the flywheel housing and the clutch housing are aligned to specification.
The transmission is not installed correctly.	Install the transmission correctly.
The clutch disc hub is damaged.	Replace the clutch.
The pilot bearing is worn or damaged.	Replace the pilot bearing.
The clutch is out of adjustment.	Adjust the clutch and linkage to specifications.

Problem—Pressure Plate Cracked or Damaged by Heat

Problem—Pressure Plate Cracked or Damaged by Heat	
Possible Cause	**Remedy**
The driver engages the clutch while coasting.	Use correct driving techniques.
The driver uses the clutch as a brake.	Use correct driving techniques.
The clutch free pedal is not adjusted correctly.	Adjust the free pedal to specifications.
There is oil or grease on the clutch disc facings.	Clean the clutch disc. If the oil or grease cannot be removed, replace the clutch disc. Repair the cause of the grease or oil.
The driver slips the clutch excessively during engagement.	Use correct driving techniques.

Problem—Pressure Plate Cracked or Damaged by Heat	
Possible Cause	**Remedy**
The driver starts the truck in too high of a transmission gear.	Use correct driving techniques.

The transmission was not installed correctly.	Replace the clutch disc. Install the transmission correctly.

Problem—The Hub Separates From the Clutch Disc

Problem—The Hub Separates From the Clutch Disc	
Possible Cause	**Remedy**
Excessive engine vibration.	Repair the engine.
The transmission was not installed correctly.	Install the transmission correctly.
The clutch housing is loose.	Tighten the clutch housing to the specified torque.
The driver engages the clutch while the vehicle is coasting.	Use correct driving techniques.
Shock loading.	Use correct driving techniques.

Problem—Heat Damage to the Clutch Disc

Problem—Heat Damage to the Clutch Disc	
Possible Cause	**Remedy**
The driver keeps his foot on the clutch pedal or slips the clutch.	Use correct driving techniques.
The clutch does not engage or disengage completely.	See "Troubleshooting—Functional Problems: Clutch Does Not Disengage Completely."
The free pedal is not adjusted correctly.	Adjust the free pedal.
There is oil or grease on the clutch disc facings.	Clean the clutch disc. If the oil or grease cannot be removed, replace the clutch disc. Repair the cause of the grease or oil.
The driver does not start the vehicle in the correct gear.	Use correct driving techniques.
The driver engages the clutch while the vehicle is coasting.	Use correct driving techniques.

General Description

The clutch linkage transfers the motion of the clutch pedal to the clutch release bearing. The clutch linkage may be adjusted to maintain clutch free pedal, but only after internal clutch adjustments are made.

Clutch free pedal is required to ensure that the release bearing does not run against the fingers of the release yoke. There should not be any play or looseness in the connections and joints of the clutch linkage.

IMPORTANT: Release bearing and release fork clearance are internal clutch adjustments, and *can not be adjusted* by adjusting the clutch linkage. Refer elsewhere in this group for internal clutch adjustments, or to the clutch manufacturer's service literature.

Clutch Linkage Adjustment, Century Class Conventional

Clutch Linkage Adjustment

IMPORTANT: Observe the following points before beginning clutch linkage adjustment:

- Be sure internal clutch adjustments are correct before making adjustments to the clutch linkage. Refer to the appropriate section in this manual.
- Adjust clutch linkage only after repair or replacement of the clutch or clutch linkage components.
- Do not attempt to adjust the linkage to compensate for component wear.
- If equipped with cab air-suspension, be sure the air bags are properly inflated. If the air bags are not inflated, the clutch linkage can't be adjusted correctly. For instructions, see **Group 60** in this manual.

IMPORTANT: A special tool is used to adjust the clutch linkage. The special tool is a 3/4-inch (19-mm) spacer and may be ordered from the PDCs under part number 02–12282–000.

1. Tilt the hood.
2. Be sure the clutch pedal is all the way up, against the upper stop.
3. Remove the clutch inspection cover from the bottom of the bell housing.
4. Measure the distance between the release yoke and the release bearing. If this measurement is 0.105 to 0.145 inch (2.7 to 3.7 mm), no further work is needed. If the measurement is incorrect, do all of the remaining steps.
5. Loosen the rod-end jam nuts at the upper end of the threaded adjusting rod.
6. Disconnect the clutch rod from the lower end of the pedal shaft. See **Fig. 1**.
7. Place the special tool (part number 02–12282–000) between the clutch pedal stop bracket and the clutch pedal. See **Fig. 2**.
8. Without applying excessive force, pull the clutch rod forward until it stops (release yoke contacts the release bearing).
9. To obtain a free travel measurement of 0.105 to 0.145 inch (2.7 to 3.7 mm) between the release yoke and the release bearing, turn the clutch rod end until the center of the rod-end hole is aligned with the center of the hole in the upper clutch lever.

NOTE: Each complete turn of the rod end (or rod) equals about 1/32 inch (1 mm) movement. After lengthening the linkage, at least 3/8 inch (9.5 mm) of thread must remain engaged in each end of the rod.

10. After adjusting the length, connect the clutch rod to the pedal shaft. Install the rod end and nut. Tighten the nut 30 lbf·ft (41 N·m). See **Fig. 3**.

    Tighten both rod-end jam nuts 12 to 15 lbf·ft (16 to 20 N·m).

    Remove the special tool from the clutch pedal stop bracket.
11. Install the inspection cover on the bottom of the bell housing.

NOTE: If the clutch release shaft assembly is damaged, use the following replacement instructions.

1. Remove the transmission from the vehicle. For instructions, refer to **Group 26** in this manual.
2. Remove the capscrew and shaft key from the right (passenger side) clutch release shaft. Remove the shaft from the mounting holes on the transmission and the clutch release yoke.
3. Remove the capscrew and shaft key from the left (driver's side) clutch release shaft. Remove the shaft from the mounting holes on the transmission and the clutch release yoke.
4. Insert the right (passenger side) clutch release shaft into the mounting holes on the transmission and the clutch release yoke. Line up the release yoke with the slot in the release shaft. Install the shaft key and the capscrew. Tighten the capscrew finger-tight.

NOTE: Make sure the release shaft does not extend through the release fork.

5. Repeat the previous step and install the left (driver's side) clutch release shaft.
6. Tighten the capscrews 35 to 45 lbf·ft (47 to 61 N·m).
7. Install the transmission. For instructions, refer to **Group 26** in this manual.
8. Wipe dirt from the grease fittings. Using a pressure gun, lubricate the clutch release shaft with multipurpose chassis grease.
9. Check for binding; the clutch release shaft assembly should rotate smoothly.

Clutch Release Shaft Replacement

10. Check that the clutch engages and disengages smoothly. If needed, adjust the clutch at the linkage. For instructions, refer to **Subject 100**.

Clutch Linkage Adjustment

1. Shut down the vehicle, apply the parking brake, and chock the tires.

IMPORTANT: Observe the following points before beginning clutch linkage adjustment:

- Be sure internal clutch adjustments are correct before making adjustments to the clutch linkage. Refer to the appropriate section in this manual.
- Adjust clutch linkage only after repair or replacement of the clutch or clutch linkage components.
- Do not attempt to adjust the linkage to compensate for component wear.
- If equipped with cab air-suspension, be sure the air bags are properly inflated. If the air bags are not inflated, the clutch linkage can't be adjusted correctly. For instructions, see **Group 60** in this manual.

2. Be sure the clutch pedal is all the way up, against the upper stop.
3. Measure the distance between the release yoke and the release bearing using the clutch inspection tool (part number A02–12254). If this measurement is 0.105 to 0.145 inch (2.7 to 3.7 mm), no further work is needed. If the measurement is incorrect, do all of the remaining steps.

IMPORTANT: A special tool is used to adjust the clutch linkage. The special tool may be ordered from Kent Moore (part number J–43837).

⚠ WARNING

Before tilting the cab, read the instructions and the Danger and Warning notices in Section 60.15 of this manual. Failure to follow these instructions could cause the cab to hit or crush a person, possibly resulting in serious injury or death.

4. Tilt the cab. For instructions, see **Group 60**.

   4.1 Tilt the cab so the safety stop can be lowered onto the tilt ram.

   4.2 Lower the safety stop onto the tilt ram.

   IMPORTANT: The clutch adjustment will be inaccurate if the cab is not lowered against the safety stop.

   4.3 Return the cab until it rests against the safety stop.

5. Remove the clutch inspection cover from the bottom of the bell housing.
6. Loosen the rod-end jam nuts at the end of the threaded adjusting rod.
7. Disconnect the clutch rod from the clutch release lever. See **Fig. 1**.
8. Without applying excessive force, pull the clutch release lever toward the front of the vehicle until it stops.

NOTE: Each complete turn of the rod end (or rod) equals about 1/24 inch (0.8 mm) movement. After lengthening the linkage, at least 3/8 inch (9.5 mm) of thread must remain engaged in each end of the rod.

9. Insert the clutch adjustment tool (Kent Moore part number J–43837) short dowel into the hole in the end of the clutch release lever. If the adjustable end does not slide onto the long dowel while the tool is held in a parallel plain position with the frame rail, loosen the jam nut and adjust the rod end until it slides over the dowel. See **Fig. 2**. Tighten the jam nut.
10. After adjusting the length, connect the clutch rod to the clutch release lever. Install the rod end and nut. Tighten the nut 30 lbf·ft (41 N·m). See **Fig. 3**.

    Tighten the rod-end jam nut 12 to 15 lbf·ft (16 to 20 N·m).

⚠ DANGER

Before returning the cab to the normal operating position, read the instructions and Danger and Warning notices in Section 60.15. Failure to follow these instructions could cause the cab to hit or crush a person, possibly resulting in serious injury or death.

11. Return the cab and measure the distance between the release yoke and the release bearing using the clutch inspection tool (part number A02–12254). If this measurement is 0.105 to

Adjustment

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Raise the grille.
3. Ensure the clutch assembly is properly adjusted. Follow the manufacturer's instructions or, for Eaton Fuller Easy-Pedal clutches, see **Section 25.00 Subject 100**.
4. Measure the distance between the forward face of the cable anchor bracket and the step at the cable housing end. See **Fig. 2**. If the distance is approximately 17-mm (11/16-inch), continue to the next step. If not, adjust the clamp nuts to set the cable position.

CAUTION

The clutch return spring is loaded. When disconnecting the clevis from the lever, push up on the cable to counter the force of the spring and prevent the clevis from binding on the pin or causing an injury when the pin is removed.

5. To disconnect the clevis from the lever, push up on the cable and remove the pin.

IMPORTANT: Inspect for excessive wear on the pin and holes of the clevis and lever. Replace damaged or excessively worn components, as needed.

6. Verify the cable functions properly by moving it through the length of its free travel a few times. If

IMPORTANT: If adjustments are needed at the threaded cable end and/or cable housing clamp nuts, remember the following:

- The clutch brake must engage before the pedal reaches the lower stop.
- The clutch return spring must have tension at all lever positions.
- The threaded cable end must be securely engaged in the clevis.

8. Grip the clevis and push the cable up until it reaches the end of its free travel to verify if the holes in the clevis and clutch lever align. If aligned, continue to the next step. If not, move the clevis up or down the threads and/or adjust the cable housing clamp nuts until the holes align. See **Fig. 4**.
9. Install the clevis pin. See **Fig. 5**.
10. Remove the shim.

Clutch Linkage Torque Values	
Description	**Torque**
Clutch Linkage Jam Nuts	12–15 lbf·ft (16–20 N·m)
Clutch Rod-to-Pedal Shaft	30 lbf·ft (41 N·m)

Table 1, Clutch Linkage Torque Values

General Description

When the vehicle is stationary, a clutch brake permits shifting into first gear or reverse gear without severe gear clash.

Clutch brake engagement occurs approximately during the last 1 to 1-1/4 inches (25 to 33 mm) of downward pedal travel. The clutch brake is between the release-bearing housing (see **Fig. 1**) and the transmission bearing cap, and is engaged by tangs to the transmission input shaft. When the pedal is fully depressed, the clutch brake is squeezed between the release-bearing housing and the transmission bearing cap (see **Fig. 2**), stopping the rotation of the main drive gear.

The clutch brake may be a disc-type or a torque-limiting type. In addition, the clutch brake may be either a one-piece or two-piece design. To prevent overloads to it, the torque-limiting clutch brake is designed to slip when loads of 20 to 25 lbf·ft (27 to 34 N·m) are reached. Clutch brakes are not designed for upshifting.

One-Piece Clutch Brake Replacement

Replacement

1. Shut down the engine, set the parking brake, and chock the tires.
2. Tilt the hood.
3. Drain the air tanks.
4. Disconnect the batteries.
5. Place the transmission in gear.
6. Remove the shift tower from the top of the transmission. See **Group 26** in this manual for instructions.
7. Disconnect the driveline from the rear of the transmission. See **Group 41** in this manual for instructions.
8. Disconnect the midship bearing. See **Group 41** in this manual for instructions. Pull the driveshaft aside and position it out of the way.
9. Remove the fuel tank compression brace. See **Group 47** in this manual for instructions.
10. Disconnect the clutch rod from the clutch release lever. See **Section 25.03** in this group for instructions.
11. Disconnect the transmission wiring.
12. Disconnect the transmission air lines.
13. Remove the auxiliary air tank, if so equipped.
14. Remove the transmission oil cooler and set it aside, out of the way.

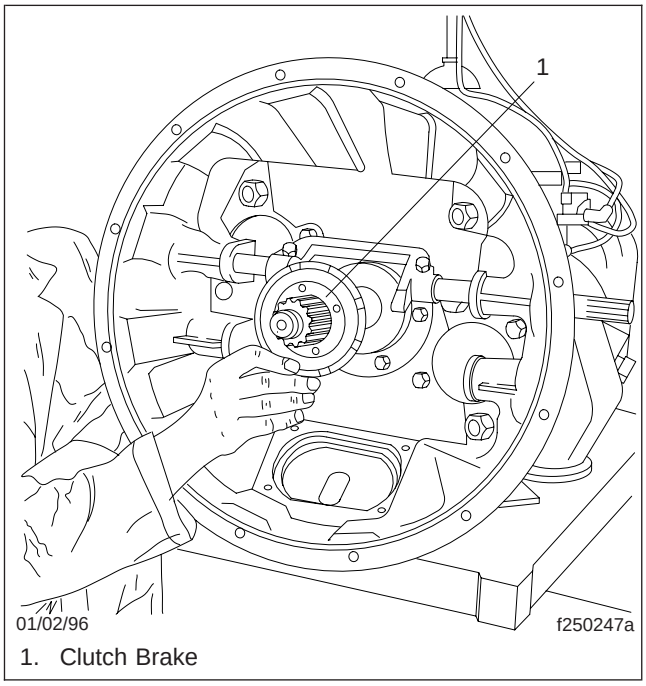
IMPORTANT: Do not disconnect the oil cooler lines.

15. Place a transmission jack in position below the transmission. Adjust the jack to support the transmission.
16. Secure the transmission to the jack.
17. Remove the flywheel housing-to-clutch housing bolts. See **Group 26** in this manual for instructions.

CAUTION

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

18. Pull the transmission back until the input shaft clears the flywheel.
19. Remove the old clutch brake from the transmission input shaft. See **Fig. 1**.



1. Clutch Brake

Fig. 1, Clutch Brake Removal

20. Align the tangs of the new clutch brake with the grooves on the input shaft and slide the clutch brake into position. See **Fig. 2**.

CAUTION

Use care to avoid springing the drive discs when the transmission is being installed. Do not force the transmission into the clutch or flywheel housing if it does not enter freely. Do not let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

21. Install the transmission. See **Group 26** in this manual for instructions.
22. Remove the transmission jack.
23. Connect the air lines and the transmission wiring.

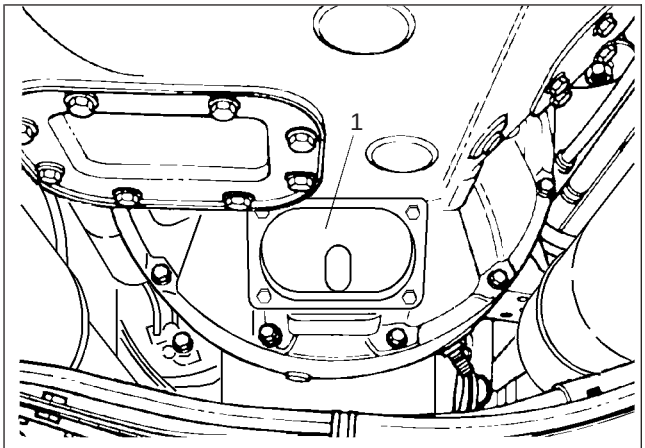
27. Install the shift tower on the top of the transmission. See **Group 26** in this manual for instructions.
28. Connect the clutch rod to the clutch release lever. See **Section 25.03** in this group for instructions.
29. Connect the driveline at the rear of the transmission. See **Group 41** in this manual for instructions.
30. Connect the midship bearing. See **Group 41** in this manual for instructions.
31. Ensure that the transmission is out of gear and adjust the clutch. See **Group 25** in this manual for instructions.
32. Connect the batteries.
33. Lower the hood and remove the chocks from the tires.
34. Test drive the vehicle and ensure that the clutch brake and clutch operate properly.

Replacement of a One-Piece Clutch Brake with a Two-Piece Clutch Brake

Replacement

1. Shut down the engine, set the parking brake, and chock the tires.
2. Tilt the hood.
3. Remove the four fasteners and the clutch inspection cover. See **Fig. 1**.



1. Inspection Cover

WARNING

Wear safety goggles when cutting off the old clutch brake. If any of the metal parts were to chip, flying pieces of metal could cause eye injury.

4. Using an air chisel, carefully cut off the old clutch brake.
5. Check the orientation and fit of the new two-piece clutch brake halves.
6. Place one half of the new two-piece clutch brake onto the input shaft and rotate it to the top side of the shaft. See **Fig. 2**.
7. Align the lower half with the upper half at the connecting points.
8. Hold both halves together and start the fasteners on both sides.
9. Align the fasteners with the grooves on the input shaft.

10. Tighten Allen-head fasteners 60 lbf·in (675 N·cm).

NOTE: Other types of two-piece clutch brakes use roll pins for fasteners.

WARNING

Wear safety goggles when driving in roll pins. If any of the metal parts were to chip, flying pieces of metal could cause eye injury.

11. If the replacement clutch brake uses roll pins, carefully drive in the roll pins equally with a punch and mallet, securing the halves to each other.
12. Install the clutch inspection cover and the four fasteners. Tighten the fasteners securely.
13. Adjust the clutch. See **Group 25** in this manual for instructions.
14. Lower the hood and remove the chocks from the tires.
15. Test drive the vehicle and ensure that the clutch brake and clutch operate properly.

NOTE: Some types of two-piece clutch brakes use roll pins for fasteners.

4. Rotate the input shaft until the Allen-head fasteners or roll pins securing the two clutch brake halves are visible.
5. If the old clutch brake uses Allen-head fasteners, remove the fasteners and remove the two brake halves from the input shaft.

⚠ WARNING

Wear safety goggles when driving out roll pins. If any of the metal parts were to chip, flying pieces of metal could cause eye injury.

6. If the old clutch brake uses roll pins, carefully drive out the pins with a punch and mallet and remove the two brake halves from the input shaft.
7. Check the orientation and fit of the new two-piece clutch brake halves.
8. Place one half of the new two-piece clutch brake onto the input shaft and rotate it to the top side of the shaft. See **Fig. 2**.

Manual Transmission Removal and Installation

Removal

1. Apply the parking brakes, chock the tires, put the transmission into high gear, and tilt the hood.
2. Disconnect the batteries.
3. Remove the air reservoirs. For instructions, see **Section 42.09**.
4. If installed, remove the transmission fluid cooler and the plug fittings in the cooler and transmission. See **Fig. 1**.

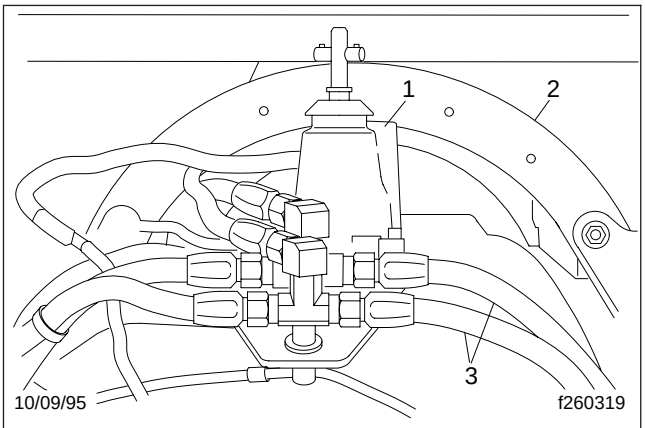
5. Disconnect the driveline from the transmission output yoke. For instructions, see **Section 41.00**.
6. Disconnect the driveline midship bearing from the midship bearing bracket, and pull the driveline off to one side, out of the way. For instructions, see **Section 41.00**.
7. Disconnect the EquiFlo bracket from the top of the transmission.
8. Remove or disconnect the shift linkage. See **Fig. 2**.



1. Shift Tower
2. Overslung Crossmember
3. Air Lines

Fig. 2, Shift Linkage Removal

8.1 Remove the shift tower boot and air lines.

8.2 Remove the shift tower from inside the cab, and cover the shift tower hole in the top of the transmission to prevent dirt from entering the transmission.

8.3 Disconnect the electrical connectors from the top of the transmission.

9. Disconnect the clutch rod from the clutch release lever. Rotate the clutch release yoke so that it will clear the clutch release bearing.
10. Disconnect all wiring at the transmission, including the speedometer sensor at the output yoke, the neutral start switch, and the back-up alarm as applicable. Mark all wires for reassembly.
11. Disconnect all air lines from the transmission, and mark those lines for reassembly. Plug all air lines, and cap all transmission air fittings.

Manual Transmission Removal and Installation

12. Position a transmission jack under the transmission, and raise its support plate against the bottom of the transmission. Adjust the support plate to the same angle as the bottom of the transmission.
13. Raise the transmission jack until it fits securely against the bottom of the transmission, then secure the transmission to the jack with a chain.
14. Remove the flywheel-housing-to-clutch-housing attachment bolts. Keep the flange of the clutch housing parallel (all the way around) to the flange of the flywheel housing, until the input shaft is clear of the clutch.

NOTICE

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent damage to the clutch discs.

15. Pull the transmission and jack straight back, until the transmission input shaft is clear of the clutch and the engine flywheel housing. Lower the transmission. See **Fig. 3**.

⚠ WARNING

After lifting the front end of the vehicle, do not get under the vehicle until it is securely supported by vehicle stands. If the vehicle is supported only by an axle jack, the vehicle can fall, resulting in personal injury or property damage.

16. Raise the front axle of the vehicle high enough that you can remove the transmission by rolling it out behind the front tire.

Installation

1. If not already done, apply the parking brakes, chock the tires, and tilt the hood.
2. If the clutch brake was removed, install the clutch brake on the transmission input shaft. See **Fig. 4.** Slide it tight against the input shaft bearing cap.

NOTE: Torque-limiting clutch brakes are a one-piece assembly with a larger and a smaller face. When installing a torque-limiting clutch brake on a Fuller® or Rockwell transmission, install the *smaller* face toward the transmission.

3. Check for wear on the fingers of the clutch release yoke, release shafts, and the release shaft bushings. Replace any worn parts as necessary.
4. Shift the transmission into gear, so that the transmission input shaft can be rotated during assembly, to line it up with the clutch driven-disc hub splines.

⚠ WARNING

After lifting the front end of the vehicle, do not get under the vehicle until it is securely supported by vehicle stands. If the vehicle is supported only by an axle jack, the vehicle can fall, resulting in personal injury or property damage.

5. If the vehicle is not already raised and supported on stands, raise the front of the vehicle high enough that you can move the transmission into position by rolling it in from behind the front tire.
6. Raise the vehicle enough to remove the vehicle stands. Remove the stands, and lower the vehicle to the ground.
7. Roll the transmission and jack into alignment behind the engine. Raise the transmission jack support plate until the flange of the clutch housing is parallel (all the way around) to the flange of the flywheel housing. Align the transmission input shaft with the hole in the release bearing sleeve. See **Fig. 5.**

NOTE: If necessary, wipe the input shaft clean with a clean, dry cloth. It is not necessary to lubricate the input shaft.

8. Push the transmission and jack straight forward, while making sure the flanges remain parallel, until the transmission input shaft begins to enter the clutch release bearing.
9. Rotate the top of the clutch release yoke rearward, and rotate the release bearing until the flat portion is at the top. Roll the transmission slowly forward. Raise or lower the transmission as required to maintain alignment.

IMPORTANT: Be sure that the release yoke clears the release bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 6**. Align the input shaft splines

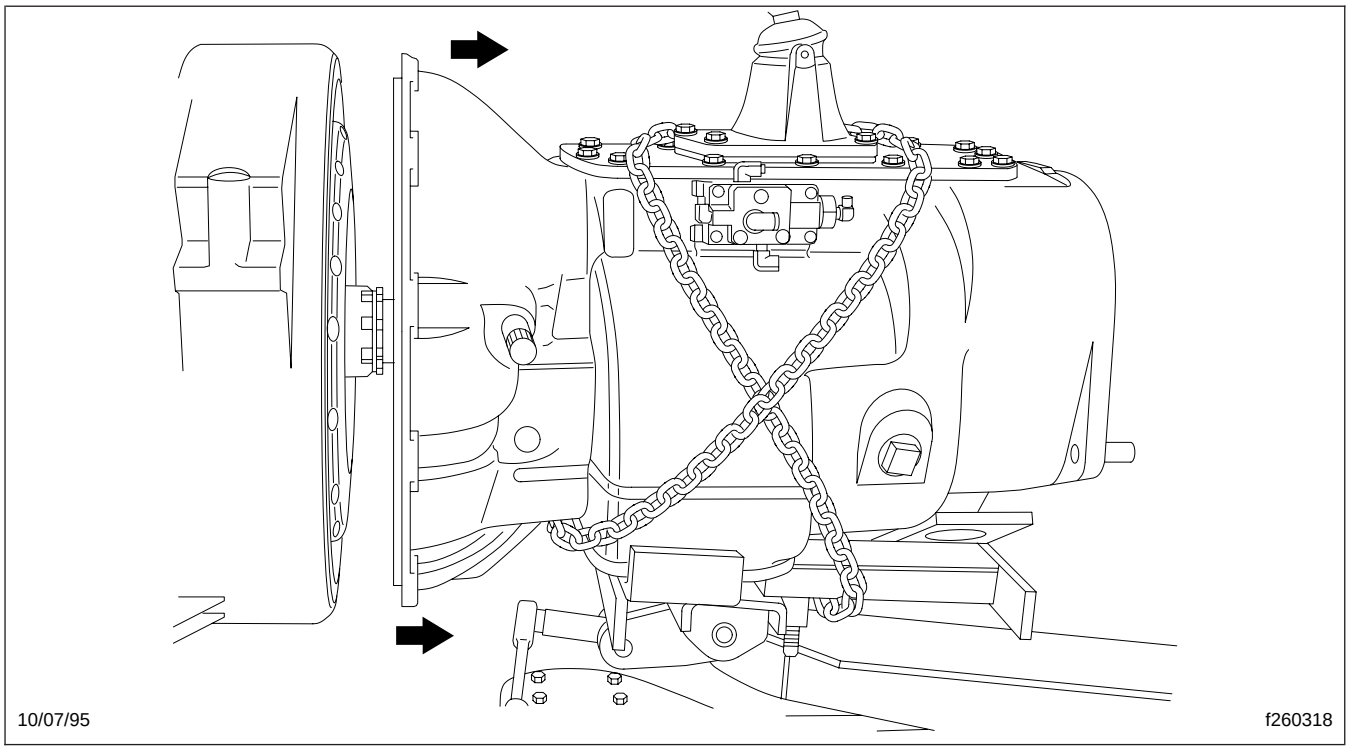


Fig. 3, Transmission Removal

with the clutch disc splines by turning the transmission output shaft.

NOTICE

Use care to avoid springing the drive discs when the transmission is being installed. Do not force the transmission into the clutch or flywheel housing if it does not enter freely. Do not let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

10. Push the transmission forward until the clutch housing pilot flange enters the flywheel housing pilot bore. Install the flywheel-housing-to-clutch-housing attachment capscrews, and using a crisscross pattern, tighten them finger-tight. Then, using the same crisscross pattern, tighten the capscrews either 43 to 53 lbf·ft (58 to 72 N·m) for Patch-Lok capscrews, or 38 to 45 lbf·ft (52 to 61 N·m) for non-locking capscrews with lockwashers.
11. Remove the chain that secures the transmission to the jack, and remove the jack from under the vehicle.
12. Install or connect the shift linkage.
    - 12.1 Install the shift tower inside the cab.
    - 12.2 Install the air lines and shift boot.
    - 12.3 Install the electrical connectors on the top of the transmission.
13. Connect the air lines and wiring to the transmission as previously marked.
14. Connect the clutch rod to the clutch release lever. For instructions, see **Section 25.00**.
15. Connect the driveline to the transmission output yoke. For instructions, see **Section 41.00**.
16. Connect the midship bearing to the midship bearing bracket. For instructions, see **Section 41.00**.
17. Connect the EquiFlo bracket to the top of the transmission. Open the fuel shut-off valves or fill the fuel tanks as applicable.

Manual Transmission Removal and Installation, Argosy COE

Removal (See Fig. 1)

1. Apply the parking brakes, chock the tires, put the transmission into high gear.

⚠ WARNING

Before tilting the cab, read the instructions and the Danger and Warning notices in Group 60 of this workshop manual. Failure to follow these instructions could cause the cab to hit or crush a person, possibly resulting in serious injury or death.

2. Tilt the cab.
3. Disconnect the batteries, and remove the battery box. See **Group 54** for instructions.
4. If installed, remove the transmission fluid cooler and the plug fittings in the cooler and transmission.
5. Disconnect the cab air suspension assembly. See **Group 60** for instructions.
6. Remove the overslung crossmember. See **Group 31** for instructions.
7. Disconnect the driveline from the transmission output yoke. For instructions, see **Group 41**.
8. Disconnect the driveline midship bearing from the midship bearing bracket, and pull the driveline off to one side, out of the way. For instructions, see **Group 41**.
9. Disconnect the EquiFlo bracket from the top of the transmission.
10. Disconnect the two shift cables from the transmission.
11. Disconnect the clutch rod from the clutch release lever. Rotate the clutch release yoke so that it will clear the clutch release bearing.
12. Disconnect all wiring at the transmission, including the speedometer sensor at the output yoke, the neutral start switch, and the back-up alarm as applicable. Mark all wires for reassembly.
13. Disconnect all air lines from the transmission, and mark those lines for reassembly. Plug all air lines, and cap all transmission air fittings.
14. Remove the rear engine mounts. See **Fig. 2**.
    - 14.1 Remove the centerbolt from the engine mount (Ref. 1).
    - 14.2 Loosen bolts on the front engine mount.
    - 14.3 Attach an overhead crane to the transmission, and lift the transmission.
    - 14.4 Position a jack stand under the engine flywheel housing.
    - 14.5 Lower the engine on the jack stand, and remove the overhead crane.
    - 14.6 Remove the four bolts from the frame rail (Ref. 11).
    - 14.7 Remove the two bolts from the rear engine mount assembly (Ref. 12).
    - 14.8 Remove the engine mount assembly.
15. Position a transmission jack under the transmission, and raise its support plate against the bottom of the transmission. Adjust the support plate to the same angle as the bottom of the transmission.
16. Raise the transmission jack until it fits securely against the bottom of the transmission, then secure the transmission to the jack with a chain.
17. Remove the flywheel-housing-to-clutch-housing attachment bolts. Keep the flange of the clutch housing parallel (all the way around) to the flange of the flywheel housing, until the input shaft is clear of the clutch.

NOTICE

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent damage to the clutch discs.

18. Pull the transmission and jack straight back, until the transmission input shaft is clear of the clutch and the engine flywheel housing. Lift the transmission up and out of the vehicle.
19. Remove the transmission from the vehicle.

Installation

1. If not already done, apply the parking brakes, chock the tires, and tilt the cab. For cab tilting instructions, see **Group 60** of this workshop manual.
2. If the clutch brake was removed, install the clutch brake on the transmission input shaft. Slide it tight against the input shaft bearing cap. See **Fig. 3**.

NOTE: Torque-limiting clutch brakes are a one-piece assembly with a larger and a smaller face. When installing a torque-limiting clutch brake on a Fuller® or Meritor transmission, install the *smaller* face toward the transmission.

3. Check for wear on the fingers of the clutch release yoke, release shafts, and the release shaft bushings. Replace any worn parts as necessary.
4. Attach the rear engine mounts.
   - 4.1 Position the rear engine mount on the engine flywheel housing. Replace the two bolts, and tighten them 68 lbf·ft (92 N·m).
   - 4.2 Attach the four bolts to the frame rail, and tighten them 136 lbf·ft (184 N·m).
5. Shift the transmission into gear, so that the transmission input shaft can be rotated during assembly, to line it up with the clutch driven-disc hub splines.
6. Lower the transmission in to the vehicle.
7. Roll the transmission and jack into alignment behind the engine. Raise the transmission jack support plate until the flange of the clutch housing is parallel (all the way around) to the flange of the flywheel housing. Align the transmission input shaft with the hole in the release bearing sleeve. See **Fig. 4**.

NOTE: If necessary, wipe the input shaft clean with a clean, dry cloth. It is not necessary to lubricate the input shaft.

8. Push the transmission and jack straight forward, while making sure the flanges remain parallel, until the transmission input shaft begins to enter the clutch release bearing.
9. Rotate the top of the clutch release yoke rearward, and rotate the release bearing until the flat portion is at the top. Roll the transmission slowly forward. Raise or lower the transmission as required to maintain alignment.

IMPORTANT: Be sure that the release yoke clears the release bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 5**. Align the input shaft splines

with the clutch disc splines by turning the transmission output shaft.

NOTICE

Use care to avoid springing the drive discs when the transmission is being installed. Do not force the transmission into the clutch or flywheel housing if it does not enter freely. Do not let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

10. Push the transmission forward until the clutch housing pilot flange enters the flywheel housing pilot bore. Install the flywheel-housing-to-clutch-housing attachment capscrews, and using a crisscross pattern, tighten them finger-tight. Then, using the same crisscross pattern, tighten the capscrews either 43 to 53 lbf·ft (58 to 72 N·m) for Patch-Lok capscrews, or 38 to 45 lbf·ft (52 to 61 N·m) for non-locking capscrews with lockwashers.
11. Replace the centerbolt in the rear engine mount, and tighten 241 lbf·ft (327 N·m).
12. Tighten the bolts on the forward engine mount, and tighten them 241 lbf·ft (327 N·m).
13. Remove the chain that secures the transmission to the jack, and remove the jack from under the vehicle.
14. Connect the two shift cables to the transmission and tighten the bolts securely.
15. Connect the air lines and wiring to the transmission as previously marked.
16. Connect the clutch rod to the clutch release lever. For instructions, see **Group 25**.

18. Connect the midship bearing to the midship bearing bracket. For instructions, see **Group 41**.
19. Connect the EquiFlo bracket to the top of the transmission. Open the fuel shut-off valves or fill the fuel tanks as applicable.
20. Install the transmission fluid cooler and all the plug fittings in the cooler and transmission.
21. Install the air reservoirs on the vehicle. For instructions, see **Group 42**.
22. Install the overslung crossmember. See **Group 31** for instructions.
23. Install the cab air suspension assembly. See **Group 60** for instructions.
24. Replace the battery box and connect the batteries. See **Group 54** for instructions.
25. Grease the clutch release bearing and the release shafts. For instructions, see Group 25 of the *Century Class Trucks Maintenance Manual*.
26. Check the clutch and clutch linkage for proper clutch pedal free-travel and clutch brake operation. For instructions, refer to the vehicle driver's manual.

    To adjust the clutch, see **Group 25**.

17. Connect the driveline to the transmission output yoke. For instructions, see **Group 41**.
27. Start the engine and run it long enough to pressurize the air system to at least 80 psi (550 kPa).

Manual Transmission Removal and Installation, Argosy COE

DANGER

Before returning the cab to the normal operating position, read the instructions and Danger and Warning notices in Group 60. Failure to follow these instructions could cause the cab to hit or crush a person, possibly resulting in serious injury or death.

28. Return the cab to the operating position.
29. Remove the chocks from the tires.

General Information

The SmartShift™ transmission shift control is an electronic transmission control device. It is required with the following automated transmissions:

- Eaton® Fuller® UltraShift™
- Eaton Fuller UltraShift™ PLUS
- Eaton Fuller AutoShift™
- ZF Meritor™ FreedomLine™
- Meritor™ SureShift™

There are three versions of the control:

- See **Fig. 1** for the UltraShift, UltraShift PLUS, and AutoShift control.
- See **Fig. 2** for the FreedomLine control.
- See **Fig. 3** for the SureShift control.

Fig. 1, SmartShift Control (with Eaton Fuller UltraShift, UltraShift PLUS, and Autoshift)

The SmartShift control replaces either the typical floor-mounted shift lever or dash-mounted pushbutton control. It mounts to the right-hand side of the steering column and is operated by the driver's right hand. SmartShift accepts driver requests for transmission functions and transmits them through hard wiring to the transmission control unit (TCU). SmartShift is a true shift-by-wire system.

Fig. 2, SmartShift Control (with ZF Meritor FreedomLine)

On SmartShift as designed for UltraShift, UltraShift PLUS, AutoShift, and FreedomLine, a two-position slide switch allows the driver to choose automatic (AUTO) or manual (MAN) mode.

NOTE: With SureShift, there is no slide switch.

In AUTO mode, gears shift automatically, without driver interaction. In MAN mode, the driver has direct control over gear shifts. Manual gear shifts are accomplished by a momentary pull or push on the control lever in the plane perpendicular to the steering wheel. See **Fig. 4**. All shifts into reverse (R) are done manually.

shift. The lever is spring-loaded and returns to mid-position when released after an upshift or downshift.

The selector switch is located at the end of the control lever. There are three different versions:

- For UltraShift, UltraShift PLUS, and AutoShift, the four-position selector switch is marked "R-N-D-L". See **Fig. 1**.
- For FreedomLine, the three-position selector switch is marked "R-N-D". See **Fig. 2**.
- For SureShift, the three-position selector switch is marked "R-N-F" (older models) or "R-N-D" (newer models). See **Fig. 3**.

For UltraShift, UltraShift PLUS, and FreedomLine, embedded in the selector switch is a small neutral lock button to prevent accidental shifts into gear from neutral. Any time you shift through N, press down on the neutral lock button to move the switch from neutral (N) to another gear. When shifting to N, it is not necessary to press the neutral lock button. For AutoShift and SureShift, all models built after November 2002 have the neutral lock button.

Replacement

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Remove the screws that secure the steering column trim panels, and separate the forward and rear panels to access the shift control. See **Fig. 1**.
3. Disconnect the electrical connector from the plug on the shift control unit. See **Fig. 2**.
4. Remove the three bolts that secure the control lever to the bracket on the column.
5. Remove the control lever.
6. Place the new lever into position and secure it using the nuts and bolts previously removed.
7. Connect the electrical connector to the control lever.
8. Using the screws previously removed, fasten the upper and lower column panels.

General Information

The following information is provided to help determine whether a problem is with the transmission or the SmartShift® Transmission Shift Control.

Resistance checks at the SmartShift connector can help determine connection problems.

DataLink Software can be used to test the SmartShift control. The tests require a ServiceLink computer connected to the vehicle. If the tests confirm the shift control is defective, this subject also includes connector resistance checks to rule out wiring issues.

Follow the procedures below for resistance checking and Freightliner SmartShift testing using DataLink Monitor and dash displays.

To determine which transmission is installed on the vehicle, check the shift pattern decal on the dash or visor.

NOTE: SmartShift controls designed for one transmission model should not be used with other models of transmission.

For Eaton Fuller UltraShift, UltraShift PLUS, and AutoShift, the four-position selector switch is marked "R-N-D-L". A slide switch is present. See **Fig. 1**.

For Meritor SureShift, the three-position selector switch is marked "R-N-F" (older models) or "R-N-D" (newer models). In addition, there is no slide switch. See **Fig. 2**.

For ZF Meritor FreedomLine, the three-position selector switch is marked "R-N-D". A slide switch is present. See **Fig. 3**.

4. Assemble the wire extension from the parts in **Table 1** to allow for easy resistance testing, as follows.
   - 4.1 Crimp the connector terminals at the end of each 3-foot (1-meter) wire.
   - 4.2 Assemble the 3-pin connector with the connector terminals and connector lock.
   - 4.3 Crimp the Metri-Pack terminals on the other end of the wires.
5. Plug the wire extension into the plug on the shift control unit. See **Fig. 6** for SmartShift terminal positions.

NOTE: Using this new wire extension prevents the need to remove the shift control.

SmartShift Control Checking Using DataLink Monitor (DLM)

1. With the wheels chocked, start the engine.
2. Connect the service computer to the engine and start ServiceLink.
3. Click on the **Transmission** icon on the left screen.
4. Click on the **Templates** tab. An overview of available templates will be shown.
5. If the vehicle is equipped with Eaton Fuller AutoShift, UltraShift, or UltraShift PLUS, click on **Eaton AutoShift**. If the vehicle is equipped with Meritor SureShift, click on **ZF Meritor SureShift**.

NOTE: The DLM template for the SureShift transmission will not work with the ZF Meritor FreedomLine transmission. For further diagnostic assistance on FreedomLine transmissions, use Meritor's TransSoft software.

6. Go directly to the appropriate heading in this subject, "SmartShift Control Testing for Eaton AutoShift" or "SmartShift Control Testing for Meritor SureShift and FreedomLine".

SmartShift Control Testing for Eaton AutoShift

The AutoShift DataLink Monitor template (see **Fig. 8**) will display the current vehicle status and will reflect change in status. Vehicle information is retrieved from the transmission ECU on the datalink. The monitor can also be used to verify readings on the instrument panel.

NOTE: To test the shift control using the datalink, the vehicle can be placed into a mode that allows the gears to be shifted without the engine running. The following step explains how to enter that mode.

1. Turn the ignition OFF, then turn the ignition back ON, but don't start the engine. The transmission controller will still be in the Engine ON mode, thereby allowing the gears to be shifted.
2. Test the operation of the shift control for Reverse (R) and Neutral (N), as follows.
   - 2.1 Select R on the selector switch. In the *Range Selected* field of the template an R should be displayed.
   - 2.2 Select N on the selector switch. In the *Range Selected* field of the template an N should be displayed.
3. Test the operation of the shift control for Drive (D), as follows.
   - 3.1 Select D on the selector switch and move the slide switch (reading "MAN/AUTO") to AUTO. In the *Range Selected* field of the template, a D should be displayed.
   - 3.2 With the selector switch still on D, toggle the slide switch from AUTO to MAN and back. Confirm that the *Range Selected* field shows a D while in AUTO and an H (High) while in MAN.

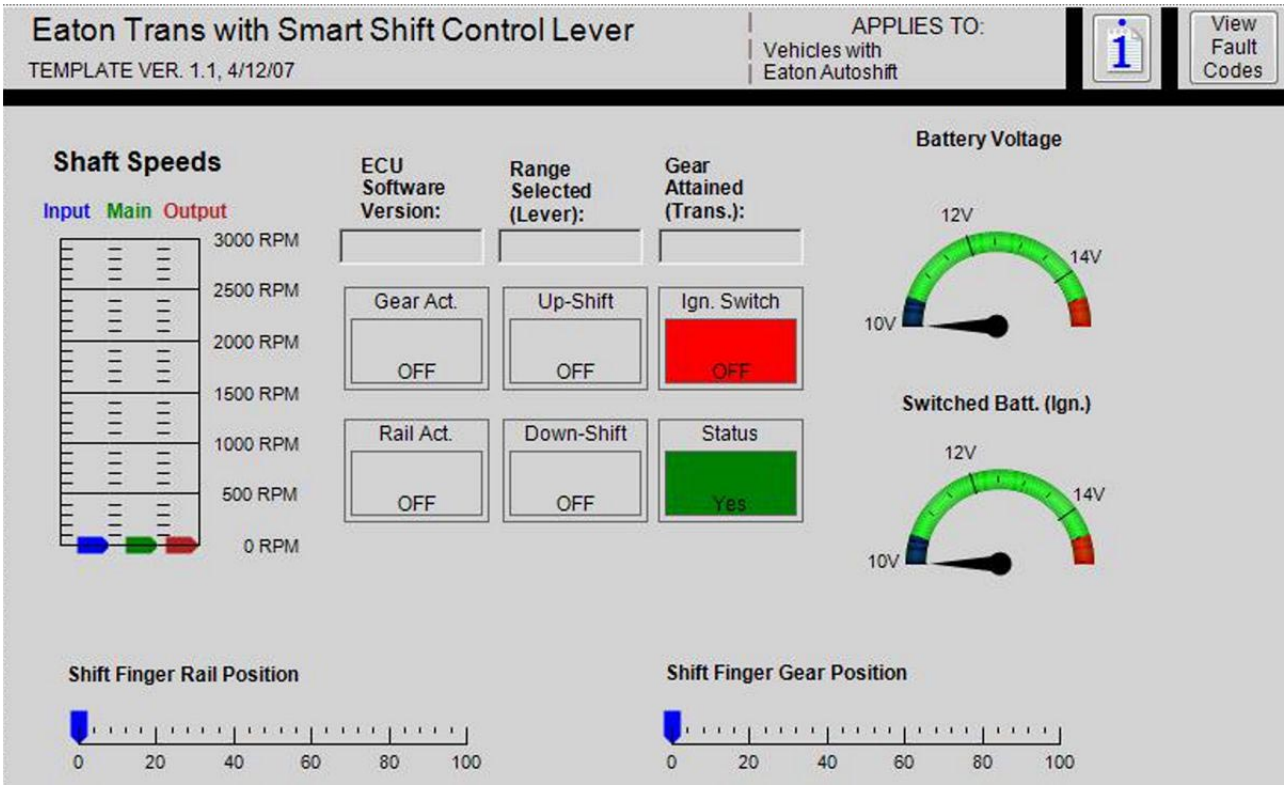

Fig. 8, DataLink Monitor Template for Eaton AutoShift

3.3 While in Manual mode, change the selector switch to L (Low) and confirm that the *Range Selected* field changes from H to L.

4. Test upshifting and downshifting, as follows.

4.1 With the selector switch on D, pull and hold the shift control lever. The *Up-Shift* field will turn green and read ON for 3 seconds.

4.2 Push and hold the shift control lever. The *Down-Shift* field will turn green and read ON for 3 seconds.

NOTE: A blinking display indicates that the transmission is attempting to shift into the gear position. A solid display shows the current gear position attained.

5. When the selector switch is in any position but N (Neutral), the *Status* field on the Monitor template will read YES.

SmartShift Control Testing for Meritor SureShift and FreedomLine

The SmartShift control test for a Meritor SureShift system can be performed by using the dash-mounted gear display. The SureShift DataLink Monitor (DLM) template can be used if further testing of the system is necessary, for example, to confirm dash display readings or gear positions. See **Fig. 9**.

NOTE: The DLM template for the SureShift transmission will not work with the FreedomLine transmission. For further diagnostic assistance on FreedomLine transmissions, use Meritor's TransSoft software.

Troubleshooting

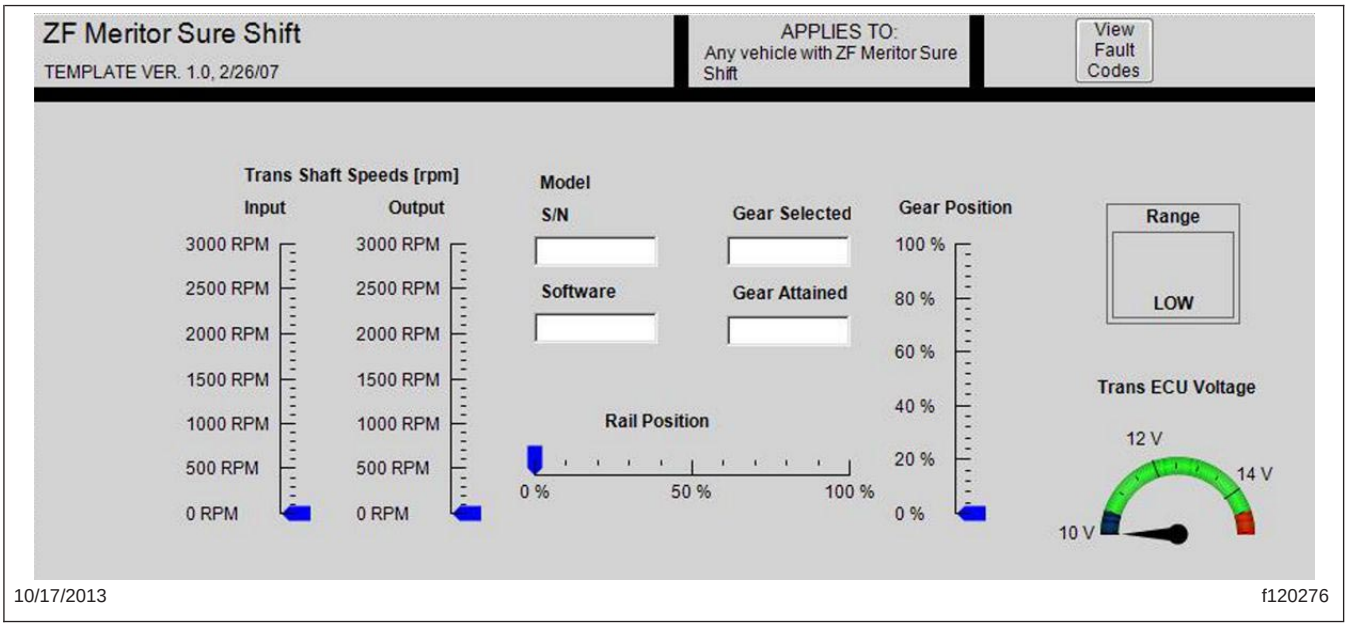

Fig. 9, DataLink Monitor Template for ZF Meritor SureShift

⚠ WARNING

For SureShift transmissions, do not depress the clutch pedal during these tests. Doing so could result in the vehicle moving, possibly causing vehicle damage or personal injury.

Make sure all tires are chocked and the parking brake is set before performing the following tests. These tests require the vehicle to be started, and precautions need to be taken to ensure the vehicle will not move.

1. Test the operation of the shift control for Reverse (R) and Neutral (N), as follows.
   - 1.1 Move the selector switch to R. Confirm that the display is changing from N to RL (Reverse Low), the default reverse gear. The display will change to CL (Clutch) after one second. Repeat this step if the reading disappeared quickly.
   - 1.2 Pull the shift control lever once to upshift to High Reverse. Confirm the display changes to RH (Reverse High).
2. Test the operation of the shift control for F or D, as follows.
   - 2.1 Move the selector switch to F (Forward) or Drive (D).
   - 2.2 Test upshifting and downshifting. Push, then pull, the shift control lever through all the gears and verify that each gear displays correctly on the dash display.

If the display or the DLM template does not confirm the SmartShift control position, the shift control should be tested. See the shift control resistance checking procedure herein.

Shift Cable Removal and Installation

Removal

1. With the vehicle parked on a level surface, apply the parking brakes and chock the tires.
2. Drain the air reservoirs.
3. Remove the two screws from the shift-knob sleeve, then slide the sleeve down; see **Fig. 1**.

2. Jam Nut, 1/2–13
3. Shift Knob
4. Torx Capscrew
5. Air Line Fittings
6. Sleeve

Fig. 1, Shift Knob Removal

4. Disconnect the three air lines from the shift knob.
   - Eaton model: Use a wrench to loosen the fittings.
   - Meritor model: Press the quick-disconnect fittings with a blunt tool such as a screwdriver.
5. Remove the two Torx® capscrews on the shift knob to release the clamping pressure on the shift column.
6. Loosen the jam nut on the shift column, using a 3/4-inch wrench. Remove the shift knob.
7. On the front of the cab, remove the lower grille panel.

⚠ CAUTION

Stand away from the front-wall access panel when opening it. The access panel can open quickly and could hit a person, possibly resulting in personal injury.

8. Raise the cab front-wall access panel; see **Chapter 3** of the *Argosy COE Driver's Manual*.

⚠ WARNING

Before tilting the cab, read the instructions and safety hazard alerts in Section 60.15 of this workshop manual. Failure to follow these instructions could cause serious personal injury or death.

9. Tilt the cab until the tunnel mount bracket is exposed on the tunnel; see **Fig. 2**.
10. Remove four 5/16–18 hexhead capscrews and washers from the corners of the tunnel mount bracket; see **Fig. 3**.
11. Pull the shift column assembly down through the tunnel.
12. Using two wrenches, remove the hexnuts that secure the ends of the cables to the tunnel mount bracket; see **Fig. 4**.
13. On the back of the tunnel mount bracket, remove the hexnuts and washers that secure the two U-bolts to the bracket. Remove the U-bolts and saddle spacers.
14. Remove the cables from the bracket.
15. Remove the hexnut and cable guide from the bracket on the front of the cab; see **Fig. 2**.
16. Disconnect the select cable from the transmission assembly, as follows.
    16.1 Using a wrench on the hexnut, remove the capscrew that secures the select cable to the rail bracket (passenger side of the transmission); see **Fig. 5**.
    16.2 Remove the hexnuts and washers on the U-bolt that secures the cable to the rail bracket (about 6 inches [150 mm] from the end of the cable). Remove the U-bolt and saddle spacer.
17. Disconnect the shift cable from the transmission assembly, as follows.
    17.1 Using two wrenches, remove the hexnut that secures the shift cable to the mount bracket (driver side of the transmission).

17.2 Remove the hexnuts and washers on the U-bolt that secures the cable to the mount bracket. Remove the U-bolt and saddle spacer.

18. Remove the cables from the brackets on the driver-side frame rail, as follows; see **Fig. 2**.

18.1 Remove the 1/2–20 hexnuts and washers that secure the frame mount and standoff brackets to the frame rail.

18.2 On the standoff bracket, remove the 5/16–18 hexnut that clamps the two parts of the cable retainer together. Remove the cables.

18.3 On the frame mount bracket, remove the 5/16–18 hexnut that clamps the two parts of the cable retainer together. Remove the cables.

19. From the front of the cab, carefully pull the cables out of the vehicle.

⚠ CAUTION

Do not adjust the rod-end jam nuts near the ends of the new cables. These nuts are factory set to the precise specification for each engine configu-

ration. Adjusting the nuts will cause the shift mechanism to malfunction. If the new cables do not fit exactly, verify that you have the correct part number for your model.

1. With the vehicle tires chocked, lay out the tunnel mount bracket and cables as shown in **Fig. 4**. Each cable has a sleeve about 4 inches (100 mm) long covering the seal at one end. The sleeved end of each cable is installed on the transmission's remote shift mechanism. The uncovered rod end is installed on the tunnel mount bracket.
2. Install the cables on the tunnel mount bracket, as follows.
   - 2.1 Insert the shift cable (shorter cable) in the bracket as shown in **Fig. 4**.
   - 2.2 Insert the cable-assembly capscrew in the arm of the bracket and secure with a 3/8–24 hexnut.
   - 2.3 Place a saddle spacer between the cable and the tunnel mount bracket, aligning the bolt holes. Insert a 5/16–24 U-bolt over the cable and through the bolt holes in the spacer and bracket; see the detail in **Fig. 5**.
   - 2.4 On the back of the bracket, install washers and hexnuts on the U-bolt.
   - 2.5 Repeat the above steps to install the select cable (longer cable) on the other side of the bracket.
3. Feed the sleeved end of the cables through the right front corner of the cab, and along the channel of the driver-side frame rail to the transmission assembly.
4. Connect the shift cable to the transmission assembly, as follows.
   - 4.1 Insert the shift cable's capscrew into the end bracket on the driver side of the remote shift mechanism; see **Fig. 5**. Install a 3/8–24 hexnut on the capscrew and tighten, using two wrenches.
   - 4.2 Place a saddle spacer under the shift-cable mount bracket and align the bolt holes. Insert a 5/16–24 U-bolt under the cable and through the bolt holes in the saddle spacer and bracket. On the top side of the bracket, install washers and hexnuts on the U-bolt. Tighten the hexnuts 16 lbf·ft (22 N·m).
5. Connect the select cable to the transmission assembly, as follows.
   - 5.1 Insert the select cable's capscrew into the end bracket on the passenger side of the remote shift mechanism. Install a 3/8–24 hexnut on the capscrew and tighten, using a single wrench.
   - 5.2 Place a saddle spacer under the select-cable rail bracket and align the bolt holes. Insert a 5/16–24 U-bolt under the cable and through the saddle spacer and bracket. On the top side of the bracket, install washers and hexnuts on the U-bolt. Tighten the hexnuts 16 lbf·ft (22 N·m).
6. On the front of the cab, insert the shift column assembly up through the opening in the tunnel.
7. Fasten the tunnel mount bracket to the tunnel with a washer and 5/16–18 hexhead capscrew in each corner of the bracket; see **Fig. 2**. Tighten the capscrews 15 lbf·ft (20 N·m).
8. Install the cable guide and hexnut on the bracket on the front of the cab.
9. Install the cables in the brackets on the driver-side frame rail, as follows.

9.1 Place both cables between the two parts of the cable retainer on the standoff bracket. Install a 5/16–18 hexhead capscrew, washer, and hexnut in the cable retainer to clamp it together.

9.2 Mount the standoff bracket on the inside of the frame rail. Insert a 1/2–20 x 1-1/4 hexhead capscrew through a washer (1/2 x 1.06 x 0.14) and the frame rail. Secure with another washer and a 1/2–20 hexnut on the outside of the frame rail.

9.3 Repeat the above steps for the frame mount bracket.

⚠ WARNING

Before returning the cab to the normal operating position, read the instructions and Danger and Warning notices in Section 60.17 of this workshop manual. Failure to follow these instructions could cause serious injury or death.

10. Return the cab to the operating position.
11. Inside the cab, place the shift knob on the shift column.
12. Tighten the jam nut on the shift column 10 to 15 lbf·ft (14 to 20 N·m), using a 3/4-inch wrench.
13. Install and tighten the two Torx capscrews on the shift knob.
14. Connect the three air lines to the shift knob. The knob is marked B (black), R (red), and G (green) to identify the connector for each of the color-coded hoses.
15. Slide the shift-knob sleeve back up into position on the shift knob. Install two screws in the lower part of the sleeve to secure it in place.

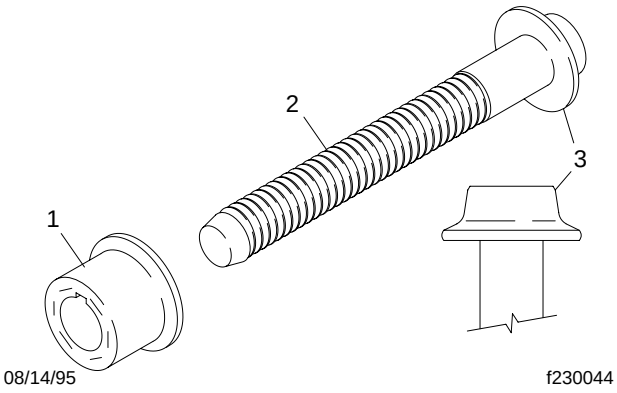
General Information

Either Huck® fasteners or grade 8 hexhead bolts and grade C prevailing torque locknuts are used for frame attachments. **See Fig. 1 and Fig. 2**. For attachments where clearance is minimal, low-profile hexhead bolts and grade C prevailing torque locknuts are used. Prevailing torque locknuts of both bolt types have distorted sections of threads to provide torque retention.



1. Spin Collar
2. Lock Pin
3. Round Head

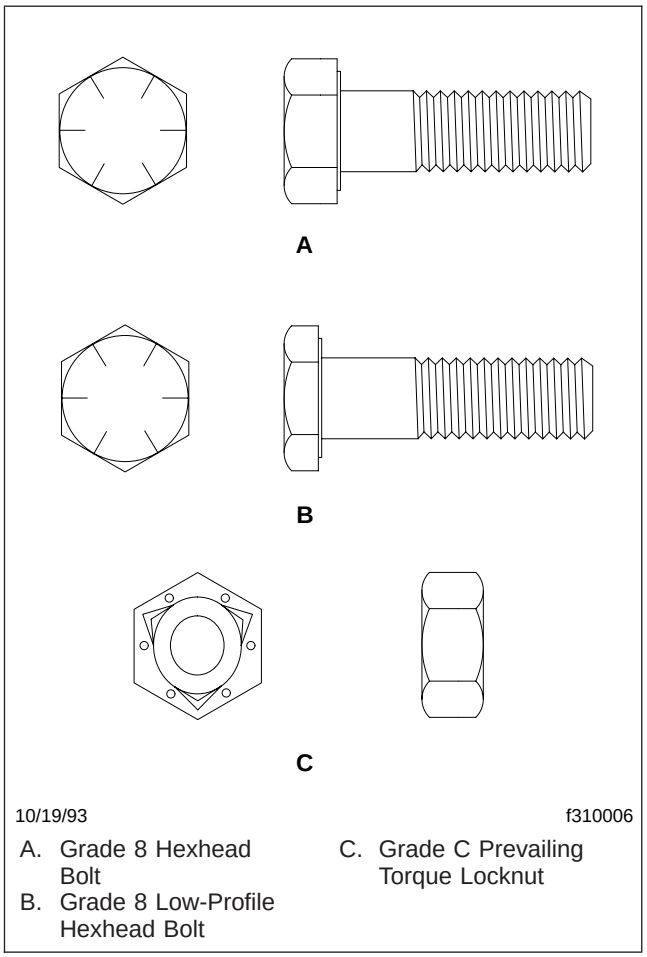
Fig. 1, Huck Fastener

When hexhead bolts and locknuts are used on an attached part, a hardened flatwasher is required to prevent the bolt head or nut from embedding in the part. In general, hardened washers are used to distribute the load, and to prevent localized overstressing of the frame rails, brackets, and other parts. They are placed directly against the part, under the nut or bolt head. These special hardened washers are used on the frame rails and for the engine rear supports, rear suspension brackets, and fifth wheel mountings. They are cadmium-or zinc-plated, and have a hardness rating of 38 to 45 HRC.

HEXHEAD BOLT REPLACEMENT

Replace hexhead bolts with identical fasteners. Refer to the Freightliner Parts Book for fastener specifications.

Apply Alumilastic® compound, or an equivalent, to all surfaces where steel and aluminum parts contact each other.



A. Grade 8 Hexhead Bolt
B. Grade 8 Low-Profile Hexhead Bolt
C. Grade C Prevailing Torque Locknut

Fig. 2, Hexhead Fasteners

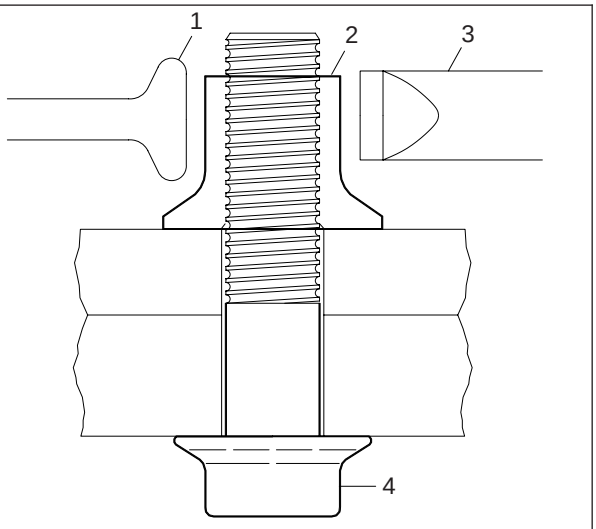
⚠ CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the frame or parts.

Never hammer or screw bolts into place. Align the holes of the frame and the part being attached to it, so that the nut and bolt surfaces are flush against the frame and the part. For bolts 4 inches (102 mm) or less in length, make sure that at least 1-1/2 threads and no more than 5/8-inch (16-mm) bolt length extend through the self-locking nut after it has been tightened. For bolts longer than four inches (102 mm), allow a minimum of 3 threads and a maximum of 3/4-inch (19-mm) bolt length.

HUCK FASTENER REMOVAL

The collar for Huck fasteners is spun on when they are installed, but it cannot be unscrewed. Use the Huck Collar Cutter to remove Huck fasteners. If the Collar Cutter isn't available, split the collar with an air chisel while supporting the opposite side of the collar with an anvil. **See Fig. 3**. Then, drive out the lock pin with a punch. Discard the fastener after removing it. Replace Huck fasteners with standard grade 8 threaded fasteners.



1. Anvil
2. Spin Collar
3. Chisel
4. Lock Pin

Fig. 3, Huck Fastener Removal

CAUTION

CAUTION: Never attempt to reuse any Huck fastener that has been removed. Reusing any Huck frame fastener can result in damage to the vehicle frame or components attached to the frame.

FRAME FASTENER TIGHTENING

CAUTION

CAUTION: Tighten standard frame fasteners periodically. Continued vehicle operation with loose fasteners could result in component, bracket, and frame damage.

Tighten hexhead bolts and locknuts periodically to offset the effects of "bedding in" (seating). Refer to the Maintenance Schedule and the frame section in the vehicle maintenance manual for intervals.

When tightening the fasteners, tighten the nut, not the bolt head. This will give a true torque reading by eliminating bolt body friction. For torque specifications, refer to the general information section in the vehicle maintenance manual.

NOTE: Huck fasteners do not require periodic tightening.

General Description

IMPORTANT: This workshop manual *does not cover* the procedures and calculations necessary to do frame modifications. Before doing any modification to the frame rails, consult with the Daimler Trucks North America Engineering Department.

The main body of the frame consists of two frame rails connected by a series of crossmembers. See **Fig. 1** and **Fig. 2**. The frame supports the rest of the chassis and body.

The crossmembers control axial rotation and longitudinal motion of the rails, and reduce torsional stress transmitted from one rail to the other. Crossmembers are also used for vehicle component mounting, and protecting the wires and tubing that are routed from one side of the vehicle to the other.

Follow the guidelines in this section when servicing the frame. For information on installation of specialized equipment on the frame, refer elsewhere in this section.

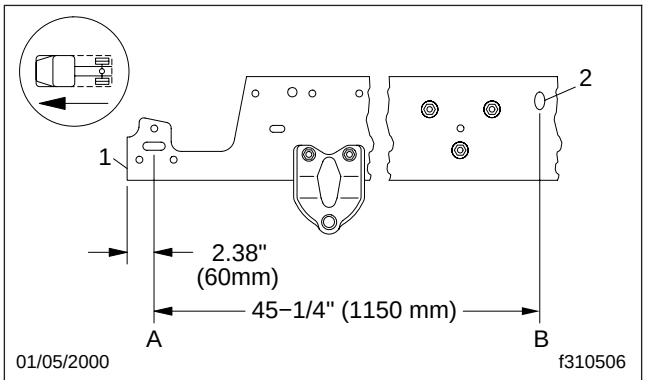
stations on the frame rails: station zero (usually written as 0.00"); and station 1150. See **Fig. 4**.

There is no identifying mark for station zero. It is located 2-3/8 inches (60 mm) to the rear of the most forward edge of the frame rail. See **Fig. 4**.



A. Station Zero (0.00)
B. Station 1150

1. Most Forward Edge of the Frame Rail
2. Station 1150 Mark

Fig. 4, Frame Rail Stations, Century Class Conventional

Station 1150 is located 45-1/4 inches (1150 mm) to the rear of station zero. Station 1150 is used when station zero is not accessible because of vehicle assembly. Station 1150 is identified by a 1/2-inch (13-

mm) high oval stamped near the top part of the frame rail web.

The vehicle's frame drilling chart lists the location of each frame rail component. For example: if a component is given a location of 2500, then that component is installed on the frame rail 98-7/16 inches (2500 mm) aft of station zero, or 53-3/16 inches (1350 mm) aft of station 1150.

Argosy COE

A frame station is a reference point on the frame rail from which the location of each component (mounted on the frame rail) is measured. There are two frame stations on the frame rails: station zero (usually written as 0.00"); and station 1300. See **Fig. 5**.

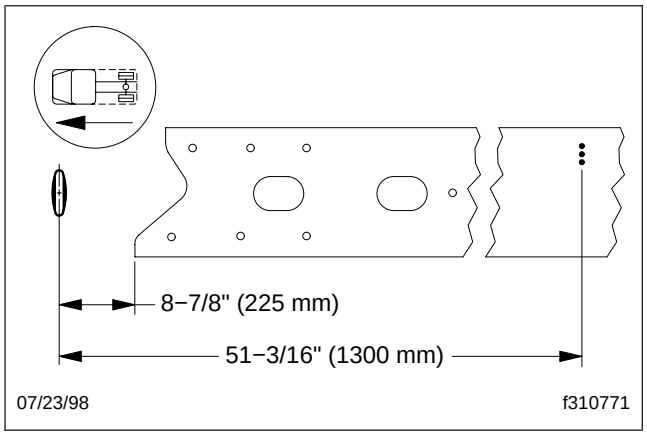


Fig. 5, Frame Rail Stations, Argosy COE

There is no identifying mark for station zero. It is located 8-7/8 inches (225 mm) forward of the most forward edge of the frame rail. See **Fig. 5**.

Station 1300 is located 51-3/16 inches (1300 mm) to the rear of station zero. Station 1300 is used when station zero is not accessible because of vehicle assembly. Station 1300 is identified by three vertical indentations near the top part of the frame rail web.

The vehicle's frame drilling chart lists the location of each frame rail component. For example: if a component is given a location of 2500, then that component is installed on the frame rail 98-7/16 inches (2500 mm) aft of station zero, or 47-1/4 inches (1200 mm) aft of station 1300.

Handling

Whenever the frame rails are lifted or moved, take care to avoid anything that may scratch, cut, or damage the exposed frame assembly. Cushion all chain hoists or cable slings with a section of heavy hose. If the frame rail is raised with a jack, place a block of wood between the jack and the frame rail.

Never heat the frame rails for straightening purposes. Such work should be done cold, as the frame rails have been heat-treated.

⚠ CAUTION

Heating the frame rail for straightening purposes will reduce the strength of the rail in localized areas, which can result in structural failure of the frame rail.

Use pencil lines or soapstone marking for any work that requires marking of the frame rail. High visibility can be obtained by first chalking the surface of the frame rail, then making the pencil marks.

Repairing Cracks, Filling Unused Holes, and Drilling Holes

Repairing Cracks

IMPORTANT: Daimler Trucks North America LLC recommends that cracked or damaged frame rails be replaced. In some cases it may be necessary to repair minor damage; before attempting any repairs, contact your regional service representative for approval.

CAUTION

Before performing any electric welding on a vehicle, read and understand the welding precautions in Subject 110. Disconnect the battery power and ground cables and any electronic control units (ECUs) installed on the vehicle. Electric currents produced during electric welding can damage various electrical components on the vehicle, such as alternator diodes and ECUs.

Freightliner vehicle components that typically use ECUs include electronic engine, electronic automatic transmission, and ABS (antilock braking system).

For any ECU with a battery power harness, disconnect its ground terminal from the chassis ground, and disconnect its power terminal from the battery positive post, or disconnect the main connection at the ECU.

1. Drill a 1/8-inch (3-mm) diameter hole at each end of the crack to prevent further spreading of the crack. See Fig. 1.

Fig. 2, Cross-Section View

NOTE: If it will not be possible to grind both sides of the frame rail, then grind the vee groove on one side to the full depth of the stock thickness. See Fig. 3.

3. Clamp a copper or aluminum bar on the opposite side of the groove. The bar will act as a "chill" strip, keeping the heat from spreading to the surrounding area of the frame rail. See Fig. 4. Deposit the weld material using the applicable welding method described in this section.
4. Grind the weld flush with the frame rail. See Fig. 5.
5. Cut a deep enough vee groove on the opposite side of the frame rail to reach the weld metal. See Fig. 6.
6. Clamp the "chill" strip on the opposite side of the groove. See Fig. 7. Weld the vee groove, as instructed above. Make full penetration of the weld.

Filling Unused Holes

1. Fill all unused holes in the frame assembly with the applicable nut, washer, and bolt combination.
2. If the diameter of a hole is less than 3/8 inch (9.5 mm), enlarge it to 3/8 inch (9.5 mm), and fill it with the applicable nut, washer, and bolt combination.
3. Tighten the fasteners to the applicable torque value. For proper frame fastening instructions, refer elsewhere in this group.

Drilling Holes

During vehicle manufacture, holes are drilled or punched in the frame rail only as specified on the vehicle frame drilling chart. If any additional holes need to be drilled, contact your regional service representative for approval.

A single exception to this rule is that holes may be drilled for tubing clips and the like through the web portion of the channel only, with the following restrictions:

- The *edge* (not the center) of the hole must be no closer than 1-11/32 inches (34 mm) from the outer face of the flange. See **Fig. 9** for the minimum distance to the flanges that holes can be placed on the web.
- Material between the centerline of the hole and the outside of the upper or lower flange must be at least 2-13/32 inches (60 mm).
- Minimum material between hole centerlines must be 2 inches (50 mm).
- All attaching fasteners must be Grade 8. Flat washers must be made with high strength steel.
- The minimum material between the rear suspension bracket and the end of the frame must be at least 2 inches (50 mm).
- Holes between the front axle centerline and the rear axle centerline cannot exceed 3/4 inches (19 mm).

Safety Precautions

CAUTION

Before performing any electric welding on a vehicle, disconnect the battery power and ground cable, and any electronic control units or similar devices installed on the vehicle. Electric currents produced during electric welding can damage various electrical components on the vehicle, which could result in malfunction of the components.

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake, and chock the front and rear tires.
2. Tilt the hood.
3. Disconnect the batteries. Attach the welding ground strap as close to the work being done as safely possible.
4. Disconnect the following ECUs and other electronic devices:

ENGINE ELECTRONIC CONTROL UNIT (ECU)

The location of the engine ECU differs with the engine manufacturer. See **Fig. 1**, **Fig. 2**, **Fig. 3**, and **Fig. 4**.

INSTRUMENT CLUSTER UNIT (ICU)

The ICU includes the driver's instrument panel, the ICU housing, and the dash message center (all installed as one unit). To disconnect the ICU, see **Section 54.03** in this manual.

DATA LOGGING UNIT (DLU)

The DLU is one of several electronic modules mounted inside a compartment on the lefthand B-pillar, behind the driver's seat. See **Fig. 5**. The data logging unit is the top unit, and is mounted above the auxiliary power distribution module. Disconnect the electrical connector from the bottom of the unit.

AIR CONDITIONING PROTECTION UNIT (ACPU)

The ACPU connector is located near the bottom of the righthand side of the firewall in the engine compartment.

ANTILOCK BRAKE SYSTEM (ABS)

The ABS ECU is mounted in the B-pillar compartment. See **Fig. 5**.

AUXILIARY POWER DISTRIBUTION MODULE (APD)

The APD module is mounted in the B-pillar compartment. See **Fig. 5**.

VORAD SYSTEM

The ECU for the VORAD system is mounted in a small compartment on the righthand B-pillar, behind the driver's seat.

DAYTIME RUNNING LIGHTS

The ECU for the Daytime Running Lights is located in a small compartment on the righthand B-pillar, behind the driver's seat.

RADIO

Disconnect the electrical connection to the radio.

ALTERNATOR

Disconnect the ground strap, as previously mentioned, and this should serve to remove any chance for damage to the alternator.

WINDOW EXPRESS MODULE

The Window Express module is located beneath the driver's step threshold plate. Remove the plate to disconnect the module connection.

VEHICLE SECURITY SYSTEM

The vehicle's security system ECU is mounted in the righthand B-pillar compartment.

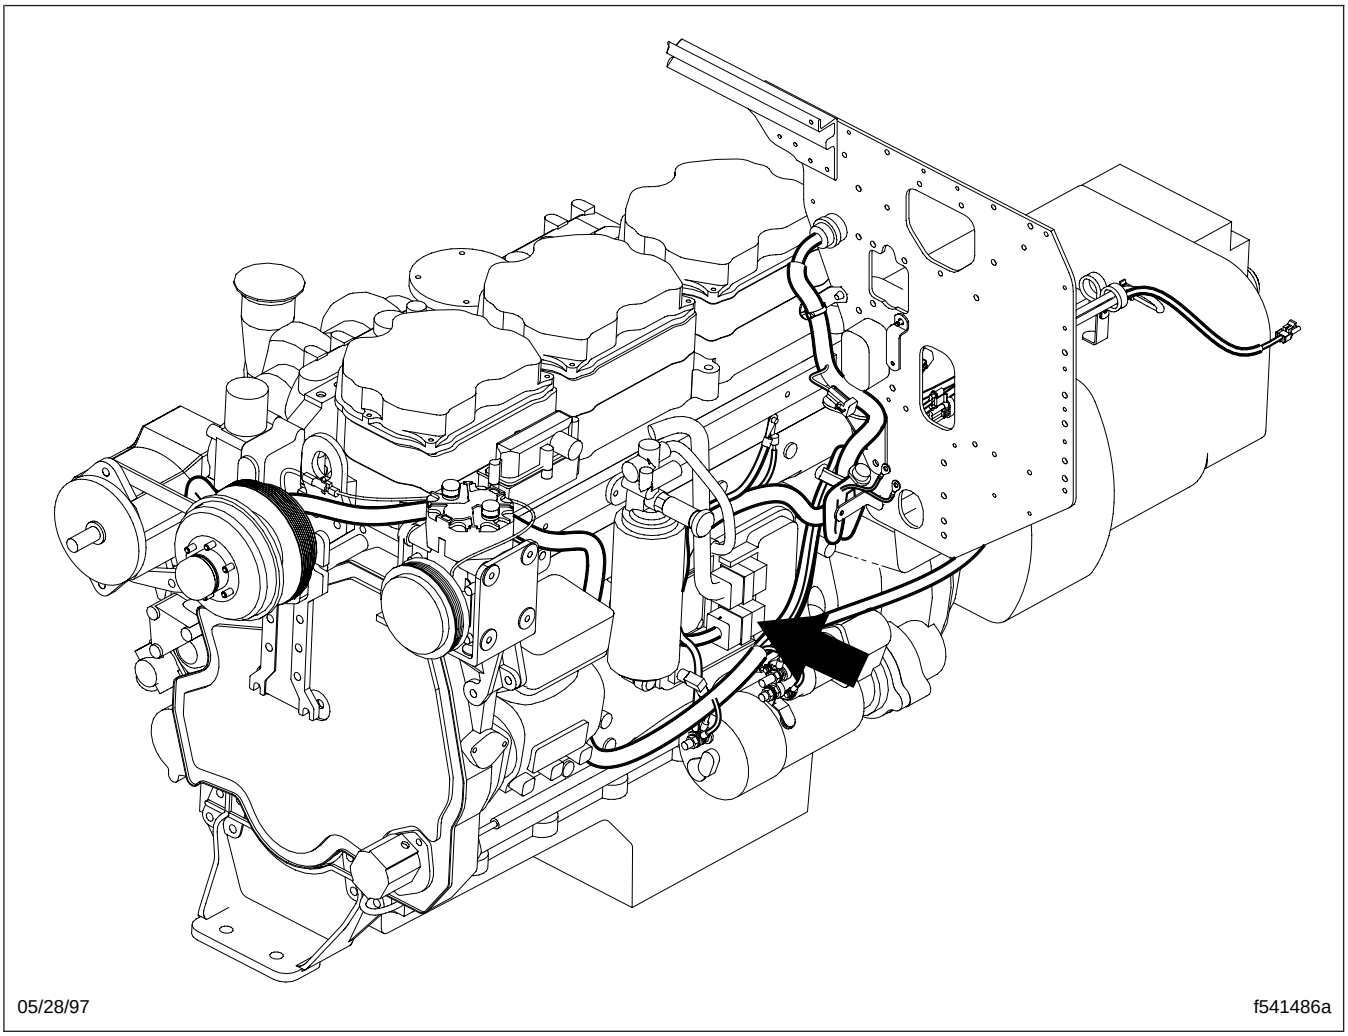

Fig. 1, Caterpillar C-10/C-12/3176 Engine ECU Location

SPACE SYSTEM

If the vehicle is so equipped, the SPACE system's ECU is disconnected by unplugging the wiring attached to the SPACE device mounted behind the operator's seat.

Welding Frame Rails

IMPORTANT: There are very few cases in which welding a heat-treated frame rail is allowable. If possible, avoid direct welding of the frame rail web. Before any welding is done, contact your regional service representative for approval.

⚠ CAUTION

Weld only as instructed in this section; all precautions and methods must be strictly followed. Failure to do so can reduce the structural strength in the welded area of the frame rail.

⚠ WARNING

Wear protective welding masks and gloves when welding. Failure to do so could result in personal injury, due to the intensity of heat, sparks, and flying debris.

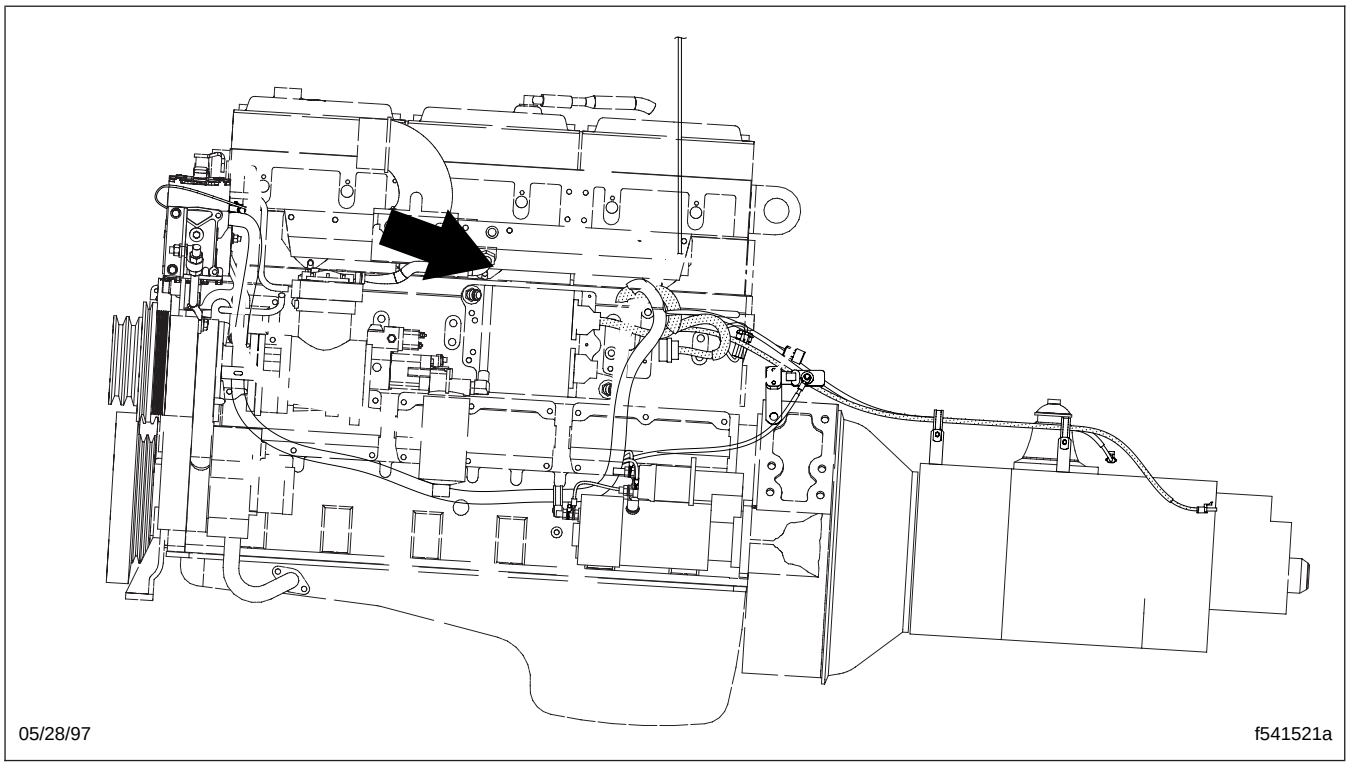

Fig. 2, Cummins N14 Engine ECU Location

1. Do not weld attachments to the frame rail. For guidelines on the attachment of equipment on the frame rails, refer elsewhere in this group.
2. Use only the applicable welding method under "Welding Methods."
3. Before welding, clean off any oil, grease, paint, scale, and other contaminants. Wipe dry with a clean cloth.
4. Do not weld in an area that allows drafts from any source such as windows, engines, or fans, as it will affect the soft flow of gas from the welding gun.
5. Do not weld into the radius of the frame rail flanges or along the edge of the flange.
6. Do not weld square with the frame side rail. Make all reinforcing welds at least 30 degrees from square. This will distribute the weld stresses over a larger area.
7. Do not notch, undercut, or leave craters during the welding process.
8. Keep as close to the weld centerline as possible.

WELDING METHODS

Gas-metal arc welding is the recommended method. If gas-metal arc welding is not available, coated-electrode arc welding can be used. For both gas-metal arc welding and coated-electrode arc welding, direct current reverse polarity is recommended, however, alternating current can be used. Use either a short arc beading technique or a narrow weave technique.

1. Review the information under "Precautions." Then, if using the gas-metal arc weld method, proceed to the next step. If using the coated-electrode arc weld method, go to the step after the next, below.
2. For the gas-metal arc welding method, use the following requirements and specifications:
   - 2.1 Use weld wire that meets American Welding Society (AWS) specification A 5.28, Class E110S.

Welding Frame Rails

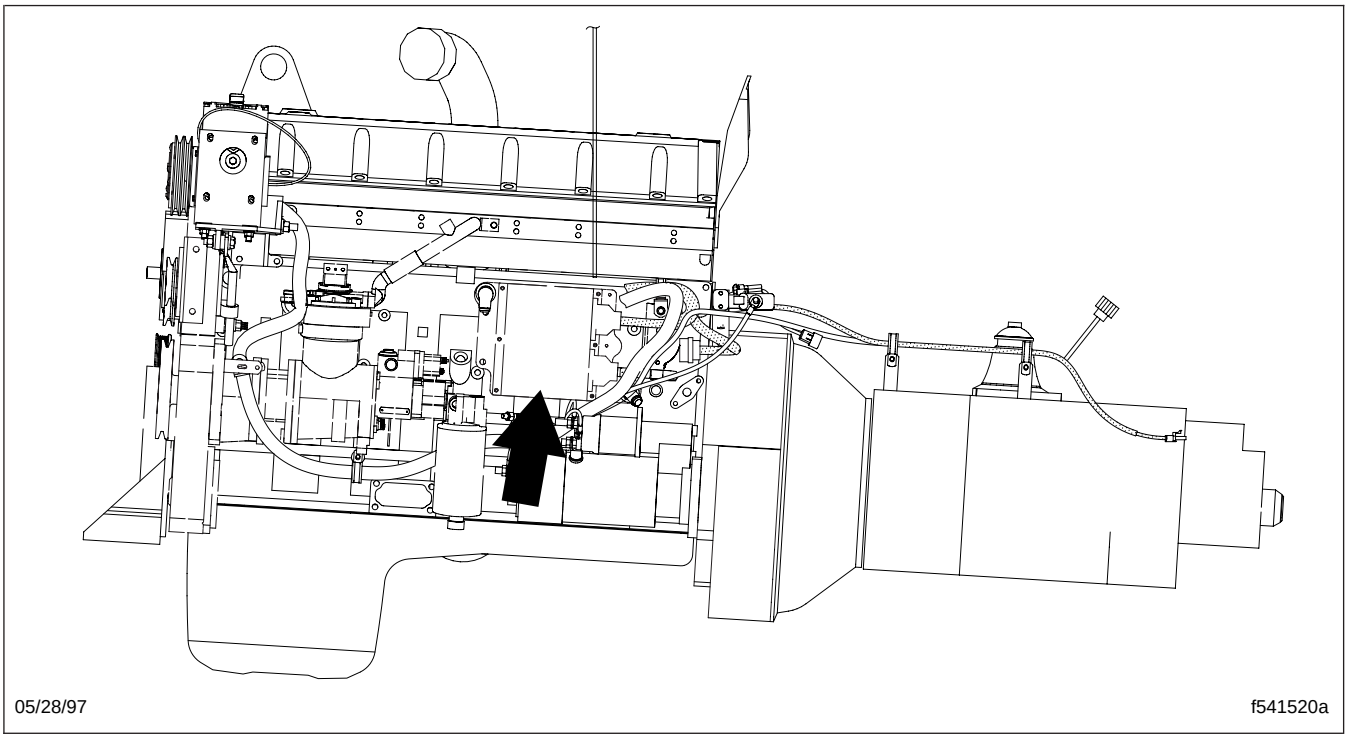

Fig. 3, Cummins M11 Engine ECU Location

2.2 Use Linde M-5 gas or an equivalent argon-oxygen mixture of 5 percent oxygen.

2.3 For machine settings, refer to the applicable table under **Specifications, 400**.

3. For the coated-electrode arc welding method, use 1/8-inch-thick AWS-E-11018 type weld rod. For amperage and voltage settings of each weld position, refer to the applicable table under **Specifications, 400**.

IMPORTANT: Always keep the weld rod free of moisture. The welding rod being used should come directly from a hermetically sealed container, or be dried at least one hour in a 700° to 800°F (371° to 427°C) oven. Immediately after removal from a sealed container or after drying, store the welding rod in an oven at 250°F (121°C). A welding rod that has been exposed to the atmosphere longer than one-half hour must be dried before use.

NOTE: On 1/4-inch-thick frame rails only, AWS-E-9018 type weld rod can be used, however, AWS-E-11018 type weld rod is recommended.

Lengthening Frame Rails

Steel frame rails can be lengthened by welding a frame rail extension onto the rear of the frame rail. The frame rail end and the extension piece are cut so that they overlap each other. Obtain approval from your regional service representative before welding and lengthening the frame rail.

CAUTION

Before performing any electric welding on a vehicle, read and understand the welding precautions in Subject 110. Disconnect the battery power and ground cables and any electronic control units (ECUs) installed on the vehicle. Electric currents produced during electric welding can damage various electrical components on the vehicle, such as alternator diodes and ECUs.

Freightliner vehicle components that typically use ECUs include electronic engine, electronic automatic transmission, and ABS (antilock braking system).

For any ECU with a battery power harness, disconnect its ground terminal from the chassis ground, and disconnect its power terminal from the battery positive post, or disconnect the main connection at the ECU.

1. Cut the frame rail end and extension to the applicable dimensions. See **Fig. 1** for truck vehicles; see **Fig. 2** for tractor vehicles. Refer only to the figure that relates to the vehicle being modified.

NOTE: If the length of the extension is to be 6 inches (152 mm) or less, then straight-cut the frame rail end and extension.

2. Grind the cut ends of the frame rail and extension to the dimensions in **Fig. 3**.
3. Align the cut ends of the extension piece with the cut ends of the frame rail so that there is a 1/16- to 1/8-inch (1.6 to 3.2 mm) gap between them. See **Fig. 3**. Using a torch, heat the cut ends to 70°F (21°C), if necessary, before welding.

NOTE: A 1/16-inch (1.6 mm) gap is recommended. The ends must not contact each other. Maintain the joint spacing by placing a short piece of clean, 1/16-inch (1.6 mm) diameter bare steel wire between the extension and frame rail. The wire sections must be short enough to be completely fused by the welding process.

4. Using one of the methods in **Subject 110**, weld the extension to the frame rail, making full penetration. See **Fig. 4**. Remove any slag between passes, and back-gouge the root of the first vee before welding the other side.

CAUTION

Residual stresses will occur in the weld if the web area is not welded first, or if the flanges contact each other when welding the web.

IMPORTANT: Weld the web area first, then the flange, working from the inside of the channel. When welding the web, make sure that the flanges do not contact each other.

5. When finished welding, sand the joint for appearance. Hold the sander so that the grind runs parallel with the length of the frame rail.

CAUTION

Do not "hollow grind" the weld. Small depressions from improper grinding of the weld will reduce the strength of the frame rail.

Frame Crossmember Removal and Installation

Removal

The placement of crossmembers affects the overall stability of the frame. If a crossmember is being eliminated, added, or relocated, contact your regional service representative for instructions and approval.

Rear-Closing Crossmember

1. Chock the tires.
2. Remove the taillights from the rear-closing crossmember. If so equipped, remove the backup alarm.
3. If the relay valve or quick-release valve is attached to the rear-closing crossmember, drain the air reservoirs, then remove the valve(s) from the crossmember.

   Remove any clamps that attach air lines or wiring to the crossmember.
4. Remove the rear mud flap brackets and fasteners.
5. Remove the fasteners that attach the crossmember to the angle brackets.
6. Remove the fasteners that attach the rearmost angle brackets to each frame rail, and remove the rearmost angle brackets. For assembly reference, note the direction that the bolts are installed.
7. Tip the top of the rear-closing crossmember to the rear and down, then slide it out the rear of the frame rails.
8. If needed, remove the forwardmost angle brackets and their fasteners. If the rear spring brackets are attached to the frame rails with the same fasteners that attach the angle brackets, before removing the fasteners, support the rear of the frame at its normal ride height, using safety stands. After removing the fasteners, remove the rear spring brackets from the springs.

Channel Crossmember

NOTE: If the vehicle is equipped with a fifth wheel, remove it if it interferes with removal of the channel crossmember. Refer to the applicable fifth wheel section in this manual for removal instructions.

1. Disconnect any suspension torque rod bracket(s) that is attached to the crossmember. Note the number and location of any spacers.
2. If the relay valve or quick-release valve is attached to the channel crossmember, drain the air reservoirs, then remove the valve(s) from the crossmember.

   Remove any clamps that attach air lines or wiring to the crossmember.
3. Remove all fasteners that attach the channel crossmember to the upper and lower gussets. Work the crossmember out of the gussets, then work it out of the top or bottom of the frame rails.
4. If removal of the gussets is needed, and if they attach to the frame with the same fasteners as the suspension brackets, chock the tires, and use safety stands to support the frame at its normal unloaded ride height. Remove the fasteners that attach the gussets and frame brackets to the frame rails. For assembly reference, note the direction that the bolts are installed. Remove the gussets and (if equipped) frame spacers.

Alligator Crossmember

1. Using the above instructions, remove the rear-closing crossmember and angle brackets, and remove the channel crossmember, gussets, and (if equipped) frame spacers.
2. If air reservoirs are mounted inside the frame rails, remove any air reservoirs that are mounted rearward of the alligator crossmember that must be replaced. Use the air reservoir removal instructions in the applicable brake section in this manual.
3. Remove the alligator crossmember that must be replaced, and any alligator crossmembers mounted rearward of it, as follows:

   3.1 Remove the fasteners that attach the crossmember lower struts to the crossmember, and to the frame rails. For assembly reference, note the direction that the bolts are installed. Remove the lower struts.

   3.2 If removing a midship bearing crossmember, support the driveline on a safety stand, then remove the fasteners that attach the midship bearing bracket to the crossmember.

Frame Crossmember Removal and Installation

3.3 If removing the rear cab-mount crossmember, support the fuel tanks, then remove the fasteners from the fuel tank brackets. Using an overhead hoist, support the rear of the cab, then remove the cab suspension bracket from the cab and the crossmember.

3.4 From the weld studs in the frame rails, remove the clamps that attach any wiring or air lines that might interfere with crossmember removal.

3.5 Unbolt the crossmember, then (if equipped) remove the frame spacer from each frame rail. For assembly reference, note the direction that the bolts are installed. Slide the crossmember out the rear of the frame rails, lifting it or lowering it as needed to clear the weld studs.

Five-Piece Welded Crossmember

NOTE: If the vehicle is equipped with a fifth wheel, and it interferes with removal of the crossmember, refer to the applicable fifth wheel section in this manual for fifth wheel removal instructions.

1. Apply the parking brakes and chock the tires on both the front and rear axles.
2. If any air brake valve is attached to the crossmember, drain the air reservoirs, then remove the valve(s) from the crossmember.

   Remove any clamps that attach air lines or wiring to the crossmember, and secure the lines or wiring away from the crossmember.
3. If rear suspension brackets are attached to the frame rails with the same fasteners that attach the crossmember, use safety stands to support the rear of the frame at its normal ride height.
4. If removing a midship bearing crossmember, support the driveline on a safety stand, then remove the fasteners that attach the midship bearing bracket to the crossmember.
5. If removing the rear cab-mount crossmember, support the fuel tanks, then remove the fasteners from the fuel tank brackets. Using an overhead hoist, support the rear of the cab, then remove the cab suspension bracket from the cab and the crossmember.
6. Take note of whether the crossmember open channel faces the front or rear of the vehicle.
7. Using a cutting torch, cut the crossmember channel in two. A slightly diagonal cut will make removal of the crossmember pieces easier.
8. Remove the fasteners that attach the crossmember halves to the frame rails, and remove the crossmember. If threaded fasteners are used, save them to use with the new crossmember. If Huckbolts are used, refer to "Frame Fasteners" in this manual for removal (and installation) information.

Overslung Crossmember, Century Class Conventional

1. Apply the parking brakes and chock the tires on both the front and rear axles.

IMPORTANT: To improve access while removing the top crossmember bolt on the left-hand side of the vehicle, have an assistant hold the clutch pedal to the floor.

2. From underneath the chassis, remove the 5/8–11 bolts and nuts that hold each side of the crossmember to the mounting brackets. See **Fig. 1**.

3. Remove the overslung crossmember by rotating it down and outward on the right-hand side of the vehicle.

Overslung Crossmember, Argosy COE

1. Apply the parking brakes and chock the tires on both the front and rear axles.
2. Tilt and support the cab as described in **Section 60.15, Subject 060**.
3. Remove the bolts, washers, and nuts that hold the air cleaner assembly and the center air line bracket to the overslung crossmember.
4. Remove the 1/2-inch bolts, washers, and nuts that hold the bracket for the cab stabilizer bar to each side of the crossmember. See **Fig. 2**. Keep the brackets and bushings on the stabilizer bar. Move the air lines and support brackets out of the way.

5. Put blocks of wood between the battery box and both frame rails to support the box when the front battery box mounting brackets are removed in the next step.
6. Support the crossmember and remove the four 5/8-inch bolts, washers, and nuts that hold the overslung crossmember to the bracket on each frame rail. See **Fig. 3**. Note that the upper two fasteners also support the front brackets for the battery box.

Front Crossmember, Argosy COE

1. Apply the parking brakes and chock the tires on both the front and rear axles.
2. Remove the four capscrews that hold the two grille brackets to the crossmember, and remove the lower grille.
3. Remove the front bumper as described in **Section 31.03, Subject 120**.
4. Using a backup wrench to prevent the nuts on the back of the crossmember from turning, remove three of the four bolts that hold the left-hand side of the front crossmember to the frame. See **Fig. 4**.
5. Loosen, but do not remove, the remaining nut and bolt on the left-hand side.
6. Using a backup wrench on the right-hand side of the crossmember to prevent the nuts from turn-

ing, remove the four bolts and nuts that hold the front crossmember to the frame.

7. Remove the loosened nut and bolt from the left-hand side.
8. Slide the crossmember horizontally to the right so that the crossmember upper flange fits into the bend in the support bracket for the right-hand side headlight panel.
9. Lower the left-hand side of the crossmember and remove the crossmember from the vehicle.

Front Closing Crossmember, Century Class S/T with Bolt-On Front Frame

1. Remove the bumper. See **Section 31.03, Subject 150**.

2. Remove the hood. See **Section 88.00, Subject 100**.
3. Remove the tow device housing from each side of the vehicle. See **Fig. 5**.
4. Remove the front closing crossmember. See **Fig. 5**.
5. Drain the air system.
6. If necessary to make room for a jack stand, remove the primary air tank.
7. Place a jack under the front axle, and lift the vehicle until a jack stand can be properly situated under each frame rail.
8. Place a jack stand under each frame rail, and lift the vehicle until the front tires clear the ground and an engine stand can be conveniently installed.
9. Remove the jack from under the front axle.
10. Install an engine stand. Remove capscrews and brackets as needed.
11. Place a jack under the engine stand, and raise the jack until it's supporting the engine.
12. Cut the tie straps that attach the wiring harnesses to the bolt-on frame brackets, and pass the harnesses through the holes in the bolt-on frame brackets. See **Fig. 5**.

IMPORTANT: When removing the fuel filter/separator from the bolt-on frame bracket, do not allow it to dangle.

13. Remove the capscrews that attach the fuel filter/separator assembly to the left bolt-on frame bracket, and secure the fuel filter/separator with tie straps to the charge air cooler tube.
14. Remove the capscrews that attach the bolt-on frame brackets to the frame rails and suspension. Remove the bolt-on frame brackets.

Installation

Alligator Crossmember

NOTE: If more than one alligator crossmember is being installed, begin with the one that belongs farthest toward the front of the vehicle.

1. Slide the crossmember into the opening at the rear of the frame rails, and work it over or under

the weld studs until it is approximately aligned with its mounting holes in the frame rails.

2. If equipped, position the correct thickness of frame spacer between each end of the crossmember and the frame rail. Install the fasteners, but do not tighten them at this time. Be sure to install each bolt in the same direction that was noted during removal.
3. If more than one alligator crossmember is being installed, repeat steps above as required for the other crossmember(s).
4. Install any clamps that were removed from the weld studs in the frame rails.
5. Install the lower struts, attaching them to the frame rails, and to the crossmember(s). Do not tighten the fasteners at this time.
6. Using the instructions below, install the channel crossmember, gussets, and (if equipped) frame spacers, then install the rear-closing crossmember and angle brackets.
7. Check the frame rail alignment and align the frame rails if needed; refer to **Subject 140.**
8. If the rear cab-mount crossmember was installed, attach the fuel tank brackets to the frame rails, if not already done. Tighten the fasteners to the torque values in **Group 00**.

   Install the cab suspension bracket on the crossmember, lower the cab, remove the overhead hoist, then attach the cab suspension bracket to the cab.
9. If the midship crossmember was installed, attach the midship bearing bracket to the crossmember. Tighten the fasteners to the applicable torque values in **Group 00**.
10. If any air reservoirs were removed, install them, using the instructions in **Group 42**.

Channel Crossmember

IMPORTANT: If an alligator crossmember is also being installed, install it first.

1. If equipped, position the correct thickness of frame spacer in each channel of the frame.

   If they were removed, install the upper and lower gussets in both sides of the frame, but do not tighten the fasteners at this time. Be sure to install each bolt in the same direction that was noted during removal.
2. Work the channel crossmember into the top or bottom of the frame, then work it into position in the gussets. Install the fasteners that attach the crossmember to the gussets, but do not tighten them at this time.
3. If it was removed from the channel crossmember, install the relay valve or quick-release valve on the crossmember. Securely tighten the fasteners.

   Install any clamps that attach air lines or wiring to the crossmember.
4. If so equipped, attach the suspension torque rod bracket(s) to the crossmember. Be sure the spacers are installed in the same location noted during removal. Tighten the bracket fasteners to the applicable torque value in **Group 00**.
5. If an alligator crossmember is also being installed, go to "Rear-Closing Crossmember," below.

   If an alligator crossmember is *not* being installed, install the fifth wheel if it was removed; refer to the fifth wheel section in this manual. Tighten the fasteners that attach the channel crossmember gussets to the frame rails, then tighten the fasteners that attach the crossmember to the gussets. Tighten the fasteners to the applicable torque values in **Group 00**.

Rear-Closing Crossmember

IMPORTANT: If an alligator crossmember(s) is also being installed, install it first.

1. If they were removed, install the forwardmost angle brackets, but do not tighten the fasteners at this time. If the rear spring brackets attach to the frame rails with the same fasteners that attach the angle brackets, install the rear spring brackets at this time. Then, remove the safety stands from under the frame rails. Be sure to install each bolt in the same direction that was noted during removal.
2. Slide the crossmember into the opening at the rear of the frame rails, then turn it upright, to position it against the angle brackets.
3. Attach the rearmost angle brackets to the frame rails, but do not tighten the fasteners at this time.

4. Install but do not tighten the fasteners that attach the crossmember to the angle brackets.
5. Install the rear mud flap brackets, and tighten the fasteners to the applicable torque value in **Group 00**.
6. If it was removed from the rear-closing crossmember, install the relay valve or quick-release valve on the crossmember. Securely tighten the fasteners.
7. Install the taillights on the rear-closing crossmember. If so equipped, install the backup alarm.

   Install any clamps that attach air lines or wiring to the crossmember.
8. If an alligator crossmember is also being installed, go to "Alligator Crossmember," above.

   If an alligator crossmember is *not* being installed, tighten the fasteners that attach the angle brackets to the frame rails, then tighten the fasteners that attach the crossmember to the angle brackets. Tighten the fasteners to the applicable torque values in **Group 00**.

Five-Piece Bolted Crossmember

NOTE: Five-piece bolted crossmember assemblies (see **Fig. 6** and **Fig. 7**) are available as service parts to replace *some* five-piece *welded* crossmembers. Always follow Parts Department information when replacing a welded crossmember with a bolted crossmember.

1. Attach one new upper gusset to the crossmember channel. Tighten the fasteners snugly, but not to their final torque value.
2. Place the crossmember channel and gusset in the frame rails with the channel opening facing the same direction as the original crossmember. Position the crossmember so its channel is resting on the lower flanges of both frame rails.
3. Slide the other upper gusset into position and attach it to the crossmember channel. Tighten the fasteners snugly, but not to their final torque value.
4. With the crossmember channel still resting on the lower flanges of both frame rails, tighten the locknuts on the button-head capscrews at the outboard end of both upper gussets 68 lbf·ft (92 N·m). See **Fig. 6**.

NOTE: The locknuts must be tightened now since, when the crossmember is in place, the frame upper flange blocks access to the capscrews. See **Fig. 7**.

5. Using a deadblow hammer, tap the crossmember into place. Align the mounting holes of the upper gussets with the holes in the frame rails. Install the fasteners, but don't tighten them.
6. Place the lower gussets in position against the crossmember channel and insert the fasteners that secure the gussets to the channel. Do not tighten the fasteners.
7. Install the fasteners that attach the gussets to the frame rails. If the welded crossmember was

secured by Huckbolts, refer to "Frame Fasteners" in this manual for installation information.

8. Tighten the fasteners that secure the gussets to the frame rails 136 lbf·ft (184 N·m). Then, tighten the fasteners that secure the gussets to the crossmember 68 lbf·ft (92 N·m).
9. If any air brake valve was removed from the old crossmember, install the valve(s) on the new crossmember and install any clamps that attach air lines or wiring to the crossmember.
10. Remove the chocks from the tires.

Overslung Crossmember, Century Class Conventional

1. Rotate the new crossmember into place from the right-hand side of the vehicle.
2. Align the holes in the crossmember with the holes in the mounting brackets. See **Fig. 1**.

IMPORTANT: To improve access, have an assistant hold the clutch pedal to the floor during the installation of the top crossmember fasteners on the left-hand side of the vehicle.

3. Install the 5/8–11 fasteners to hold the crossmember to its mounting brackets. Install the bolts so that the nuts can be tightened with a torque wrench and socket.
4. Tighten the crossmember nuts to 136 lbf·ft (184 N·m).
5. Remove the chocks from the tires.

Overslung Crossmember, Argosy COE

1. Move the crossmember into place between the battery box brackets and the mounting brackets on the frame rails. Install a 5/8–11 bolt with a washer into the bottom hole on each side of the crossmember. See **Fig. 3**. Install the washers and loosely thread the nuts on the bolts. Do not tighten any of the mounting fasteners until all the hardware is in position.
2. Install a washer on the other 5/8–11 bolt and insert them through the frame bracket, crossmember, and the lower hole in each battery box bracket. Install the washers and nuts on the bolts, but do not tighten them at this time.
3. Remove the wooden blocks from under the battery box.
4. Install the 1/2–13 bolts with washers through the bottom holes in the cab stabilizer bar brackets, through the crossmember, and through the top holes of each battery box front bracket. See **Fig. 2**. Install the washers and nuts, but do not tighten them at this time.
5. Install the 1/2–13 bolts through the air line bracket on each side of the crossmember, the top hole in the cab stabilizer bar brackets, and the crossmember. Install the washers and nuts, but do not tighten at this time.
6. Starting at the bottom bolt on each of the crossmember mounting brackets, tighten the 5/8–11 nuts 136 lbf·ft (184 N·m). Then, tighten the two 5/8–11 nuts that are directly above the bottom nuts to the same torque value.

7. Tighten the two 1/2–13 nuts on each cab stabilizer bar bracket 68 lbf·ft (92 N·m).
8. Install the air cleaner assembly and the center air line bracket and fasteners on the crossmember. Tighten the nuts to the standard torque values.
9. Lower the cab as described in **Section 60.15**, **Subject 060**. Remove the chocks from the tires.

Front Crossmember, Argosy COE

1. Make sure that the crossmember is in the proper orientation for installation so that the large oval holes are near the bottom of the crossmember. See **Fig. 4**.
2. Raise the right-hand side of the crossmember so that its upper flange fits into the bend in the right-hand headlight support bracket. Slide the crossmember into the gap between the right-hand support bracket and the frame.
3. Raise the left-hand side of the crossmember and slide it into the gap between the left-hand support bracket and the frame.
4. Separate the two 2-1/2 inch (63 mm) long bolts from the remaining six 2-1/8 inch (54 mm) mounting bolts.
5. Align the mounting holes in the crossmember with the holes in the frame. Slide washers onto the two longer mounting bolts and install the bolts through the lower hole in each of the support brackets for the headlight panels. See **Fig. 4**.
6. Install the remaining bolts, washers, and nuts in the same manner. After all eight bolt assemblies are in position, use a wrench to hold the nuts and tighten each bolt to 136 lbf·ft (184 N·m).
7. Install the front bumper as described in **Section 31.03, Subject 120**.
8. Put the lower grille in position above the front bumper. Align the holes in the two grille brackets with the holes in the crossmember and install the four capscrews and washers through the crossmember holes into the grille brackets. Tighten the capscrews to 26 lbf·ft (35 N·m).
9. Remove the chocks from the tires.

Front Closing Crossmember, Century Class S/T with Bolt-On Front Frame

1. Attach the bolt-on frame brackets to the frame rails and suspension. Hand-tighten the capscrews.

NOTE: Hand-tightening the capscrews allows for some play in the bolt-on frame brackets, which is helpful when attaching the front closing crossmember.

IMPORTANT: Each tow device housing is anchored by five capscrews — two on the top and three on the bottom. Ensure they are installed correctly and do not protrude into the tow device bore.

2. Place the tow device housing in each bolt-on frame bracket and mount the front closing crossmember.
3. Tighten the capscrews that attach the bolt-on frame brackets and front closing crossmember 136 lbf·ft (184 N·m).
4. Pass the harnesses through the holes in the bolt-on frame brackets and secure them with tie straps.
5. Remove the jacks.
6. Remove the engine stand.
7. Attach the fuel filter/separator assembly to the left bolt-on frame bracket, and tighten the capscrews 68 lbf·ft (92 N·m).
8. Install the air tank.
9. Install the hood. See **Section 88.00, Subject 100**.
10. Install the bumper. See **Section 31.03, Subject 150**.

Frame Rail Alignment

Frame rail alignment is checked by measuring the distances from two sets of points on the upper flanges of the frame rails. **See Fig. 1**. The rear set of points must be as far back as possible from the forward set of points. There must be no interference, along or between the frame rails, that would prevent measuring from any one of the four points to the other three points; the fifth wheel and deck plate (as equipped) must be removed.

There are no marks or bolt holes in the top flanges of the frame rails. Therefore, the points must be projected from the frame station marks and from the bolt holes on the frame rail webs.

IMPORTANT: Use a pencil or soapstone to make all lines, points, or other marks. Do not use any marker or tool that will scratch the surface of the frame rail. Use a machinist's square to project all points from the webs to the upper flanges, and to measure inboard from the outside face of the frame rails.

1. For each frame rail, project the exact vertical centerline of the frame station 1150 mark, from the frame web to the top flange, and mark it with a line across the top flange.

   If, because of interference, frame station 1150 cannot be used, choose and mark another matched set of points, as follows:

   1.1 Determine how far forward the upper flanges of both frame rails are clear.

   1.2 Find a matched set of bolt holes on the frame rail webs, that are aligned with, or just rearward of, the front of the clear area on the flanges. The bolt holes must be in exactly the same location in each frame rail.

   1.3 Project the exact vertical centerline of each bolt hole, and mark a line across the top flange of its respective frame rail.

2. Find the exact center of the width of each upper flange, and mark the point on each projected line. This will be the forward set of points. The forward points must be in identical locations on both frame rails.

3. As equipped, remove the fifth wheel and deck plate from the frame. Refer to the fifth wheel section in this manual for instructions.

4. Measure back along each frame rail, to find a set of bolt holes *at least* 72 inches (183 cm) rearward from the forward set of points. The bolt holes must be in exactly the same location in each frame rail.

IMPORTANT: If, because of interference, the distance must be less than 72 inches (183 cm), the distance must be the maximum that is possible.

5. Project the exact vertical centerline of each bolt hole, and mark a line across the top flange of its respective frame rail.

6. Along each line, measure and mark a point 2 inches (5 cm) inboard from the outside face of its respective frame rail. The rear points must be in identical locations on both frame rails.

7. At the forward set of points, and again at the rear set of points, measure the distance across the frame, from the outside face of each frame rail. At both locations, this distance must be 33.50 inches (851 mm). **See Fig. 1**.

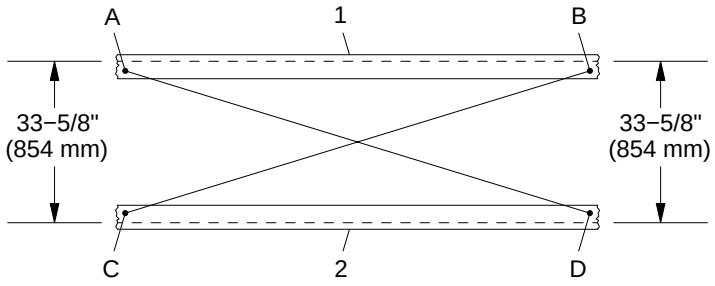
   If the distance at either location is incorrect, check the Freightliner *Parts Book* pages to determine which thickness of frame spacers, if any, belong between the crossmembers and the frame rails. Check for the correct spacers, and add or remove spacers as needed, using the procedures **in Subject 130.**

8. Measure the distance from the forward point on one frame rail to the rear point on the opposite frame rail. **See Fig. 1**. Then measure the distance from the other forward point to the rear point on its opposite frame rail. Compare the two measurements.

   If the values differ by more than 1/8 inch (3mm), proceed to the next step.

   If the measurements are within 1/8 inch (3 mm) of each other, the frame rails do not need to be aligned. If any frame fasteners are loose, tighten as described below. If no fasteners are loose, install the fifth wheel and proceed as described below.

Frame Rail Alignment



A. Right Forward Point or Bolt Hole
B. Right Rear Point or Hole
1. Right Frame Rail
C. Left Forward Point or Bolt Hole
D. Left Rear Point or Bolt Hole
2. Left Frame Rail

Fig. 1, Frame Rail Squaring

9. Loosen all of the frame fasteners just enough to allow movement of the parts when force is applied.

IMPORTANT: To align the frame rails, the frame assembly must be assembled with all of the crossmembers in place, but the attachment fasteners not tightened.

10. Using a large hammer and a large wooden block, place the block against the rear end of the frame rail that had its rear point the greater distance from its opposite rail's front point. Tap the block until the measurements are within 1/8 inch (3 mm) of each other.
11. Tighten the fasteners for the front-and rear-closing crossmembers to their applicable torque values; refer to the general information section in the vehicle maintenance manual. Again, check the frame rail alignment (described above).
12. When the measurements are within specifications, install the fifth wheel and deck plate (as equipped); refer to the fifth wheel section in this manual for instructions.
13. Tighten all of the frame fasteners, starting at the middle of the frame and working alternately toward both ends. First, tighten the fasteners that attach crossmembers to the frame. Then, tighten the fasteners that attach the upper and lower struts or gussets to the frame. Finally, tighten the fasteners that attach the lower struts or gussets to the crossmembers. Tighten all fasteners to their applicable torque values, as specified in the general information section in the vehicle maintenance manual.
14. If the frame rails needed aligning, check the axle alignment; refer to the rear axle section in this manual for instructions.

Frame Shaping

IMPORTANT: Obtain approval from your regional service representative before doing any cutting or frame shaping.

If the flange of a frame rail is cut (for relief cuts or notches), shape the edges of the flange to form a smooth ground radius of 0.06 to 0.12 inch (1.5 to 3.0 mm) over the entire length of the cut. **Figure 1** shows this dimension of the edge radius of the frame rail flanges.

NOTE: For information on relief cuts or notches, refer elsewhere in this group.

WARNING

WARNING: Wear protective eye and facial gear when grinding. Failure to wear this gear can result in personal injury due to flying metal debris from the grinding process.

Using a clean, sharp, rotary drum grinder or flapper wheel grinder, apply light pressure and grind the cut edges in the direction of the length of the frame rail, to form the radius. Do not grind across the edges. **See Fig. 2**.

CAUTION

CAUTION: Apply light pressure only. Heavy pressure can result in harmful overheating and a loss of surface temper. Grind only in the direction of the cut. See Fig. 2. Grinding across the direction of the cut can reduce the structural strength of the frame rail.

General Information

The ASF Castloc II™ and Simplex series fifth wheels are used for pulling trailers having the standard 2-inch diameter kingpin. When installed as a stationary fifth wheel (**Fig. 1**), they are bracket-mounted to the tractor frame in a position that best distributes the trailer load over the tractor axles. When used as a sliding fifth wheel (**Fig. 2**), they are mounted on the Taperloc® sliding mount (air-operated or manual release).

Fig. 2, Taperloc Slider, Manually-Operated Release

The fifth wheel lock mechanism for the trailer kingpin consists of a rotating jaw that grips the trailer kingpin, and a spring-actuated lock. The jaw rotates on a jaw pin during coupling and uncoupling operations. Kingpin release is accomplished by activating a manual lock control handle located on either the right side (curbside) or left side (roadside) of the fifth wheel. Kingpin lockup occurs when the kingpin is forced into the jaw and the operating rod handle moves to the locked position.

On air-operated sliding mounts, release or lockup of the slider saddle plate occurs when the air cylinder is activated by a two-position air-control valve in the tractor cab (**Fig. 3**). The manually-operated slider saddle plate has an operating rod that moves the operating lever to lock or unlock both sides of the saddle plate at the same time.

Fig. 3, Air Control Valve

Principles of Operation

When the tractor is moved out from under the trailer after unlocking the fifth wheel, the kingpin rotates the jaw until the jaw is in a position that allows the kingpin to disconnect. During coupling, the motion of the kingpin entering the jaw rotates the jaw into the locked position, locking the jaw around the kingpin. **See Fig. 4**.

Refer to the vehicle driver's manual for complete operating instructions.

⚠ WARNING

WARNING: Fifth wheel maintenance, adjustment, and rebuilding procedures must be done only by a qualified mechanic. Incorrect or incomplete procedures could cause the trailer to disconnect from the tractor, which could result in an accident causing death or serious injury, and property damage.

Wear safety goggles during disassembly and assembly. Parts are under spring compression, and failure to wear goggles can result in personal injury, due to parts ejecting with force.

NOTE: Although some of the parts are shaped differently, disassembly and assembly procedures are the same for ASF Castloc II and Simplex series fifth wheels.

1. Lock the fifth wheel, using a bar.
2. Steam clean the top plate. Remove it from the sliding or stationary mount by removing the clinch pins and the bracket pins. If cotter pins are present instead of clinch pins, discard them. Clinch pins may be reused. If needed, use a clamp, and compress the top plate and brackets to relieve the pressure on the bracket pins.
3. Using an overhead hoist, lift the fifth wheel off the mount and tractor frame.
4. Turn the fifth wheel upside down.

Fifth Wheel Disassembly and Assembly

NOTE: While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.

⚠ WARNING

WARNING: Do not attempt to repair or rebuild the top plate if it is cracked or if parts are damaged. The top plate or parts could malfunction. This could cause the trailer to disconnect from the tractor, which could result in an accident causing death or serious injury, and property damage.

5. Slide the jaw away from the lock, then remove the jaw from the top plate.
6. Remove the cotter pin and the lever bar pin. Discard the cotter pin. Remove the cover plate, lever bar, lock, and lock spring.
7. Remove the cotter pin holding the lock control rod to the lever bar; then remove the lock control rod and the washer. Discard the cotter pin.
8. Check the bracket shoes and bracket rubbers for wear. For instructions, refer to the vehicle maintenance manual. If needed, remove the bracket rubbers and bracket shoes as follows:

   8.1 Remove the grease fitting and drive out the bracket shoe. **See Fig. 2**.

Assembly

(See Fig. 1)

⚠ WARNING

WARNING: Fifth wheel maintenance, adjustment, and rebuilding procedures must be done only by a qualified mechanic. Incorrect or incomplete procedures could cause the trailer to disconnect from the tractor, which could result in an accident causing death or serious injury, and property damage.

Wear safety goggles during disassembly and assembly. Parts are under spring compression, and failure to wear goggles can result in personal injury, due to parts ejecting with force.

IMPORTANT: Replace any parts that show signs of wear, damage, or deterioration. Brackets, bracket shoes, bracket rubbers, and bracket pins should be replaced in pairs.

⚠ WARNING

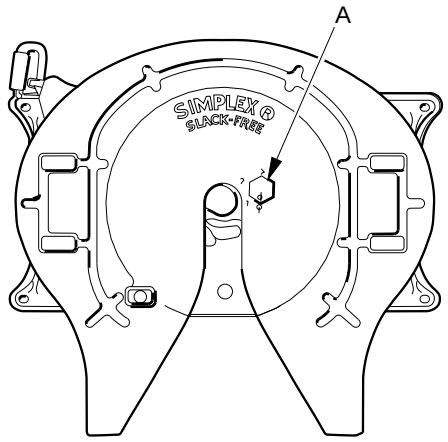
WARNING: When cleaning parts with no. 2 diesel fuel, do not smoke or use an open flame near the area. To do so could result in a possible fire.

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Apply liquid soap to the bracket rubbers, then install them, making sure the cutout on them is facing outboard.
3. Grease the bracket shoe surfaces that contact the mounting brackets. Drive the bracket shoes in place against the stop and replace the bracket shoe grease fittings.

IMPORTANT: Do not grease the bracket rubbers or pockets.

4. Apply a thin film of a multipurpose chassis grease to the cover plate, lever bar pin, lever bar, jaw, jaw pin, the lock, and the casting lock area. The casting lock area is underneath the top plate, where the lock sets.
5. Install the lock spring into the lock; then install them as a unit.
6. Install the lever bar, then the lever bar pin.

7. Install the cover plate; then install a new cotter pin in the lever bar pin.
8. Install the lock control handle onto the lever bar, using a new cotter pin and the existing washer.
9. Slide the jaw into the lock and install the jaw pin. Make sure the arrow on the jaw pin lines up with the arrow on the top plate. **See Fig. 3**. Install the clinch pin.



09/09/95 f310091a

A. Jaw pin positioned arrow-to-arrow.

Fig. 3, Jaw Pin Location

10. Using an overhead hoist, position the fifth wheel on the sliding or stationary mount brackets. Clamp the fifth wheel in place to compress the bracket rubbers. Insert the bracket pins and clinch pins.
11. Check for clearance between the jaw and kingpin as follows:

    11.1 With the jaw open, insert an ASF gauge part number 40-2-00171 (**Fig. 4**) or a new kingpin into the fifth wheel. Make sure the safety latch swings freely over the lock control handle (**Fig. 5**). This will place the fifth wheel in the coupled and locked position.

    11.2 Measure the distance between the kingpin (or gauge) and the front edge of the top plate slot. If using the gauge, make sure it is flat on the fifth wheel, and pulled as far to the rear as possible.

    11.3 Remove the gauge or kingpin.

    11.4 If the measurement was 1/8 inch (3.2 mm) or less, skip the next two steps and continue this procedure. If the measurement was more than 1/8 inch (3.2 mm), go to the next step.

12. Adjust the clearance between the jaw and kingpin as follows:

    12.1 Using a bar, move the jaw to the locked position. This will relieve the pressure on the jaw pin.

    12.2 Remove the clinch pin from the jaw pin. Lift the jaw pin just enough to clear the

indexing head. Turn the jaw pin to the next higher numbered position.

NOTE: Starting from the original position, with the arrow pointing to the rear, each turn of the jaw pin (**Fig. 6**) to one of the three positions (position numbers are indented on the casting) reduces the distance between the kingpin and jaw. **See Table 1**.

12.3 Repeat the first two substeps in the last step above.

C. Jaw
D. Lock
E. Original Position

Fig. 6, Jaw Pin Positions

12.4 If the distance is 1/8 inch (3.2 mm) or less, the clearance between the jaw and kingpin is correct. Go to the next step.

12.5 If the distance is still more than 1/8 inch (3.2 mm), remove the gauge or kingpin.

12.6 Repeat the substeps above.

IMPORTANT: Don't turn the jaw past position 3. If more than 1/8 inch (3.2 mm) clearance remains at position 3, replace the jaw, jaw pin, and lock.

13. After the final adjustment, install the clinch pin in the jaw pin.

14. Using a multipurpose chassis grease, grease the top plate and the grease fittings.

	Each Turn	Total
1	1/16" (1.6 mm)	1/16" (1.6 mm)
2	3/32" (2.4 mm)	5/32" (4.0 mm)
3	1/16" (1.6 mm)	7/32" (5.6 mm)

Table 1

IMPORTANT: The fifth wheel must be well lubricated to operate correctly. Refer to the fifth wheel section in the vehicle maintenance manual, for complete maintenance and lubrication instructions of the fifth wheel assembly.

15. Check the fifth wheel operation. For instructions, refer to the vehicle driver's manual.

⚠ WARNING

WARNING: Don't use the fifth wheel if it doesn't work correctly. The fifth wheel could malfunction, causing the trailer to disconnect from the tractor. This could result in an accident causing death or serious injury, and property damage.

Troubleshooting

Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer

Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer	
Possible Cause	**Remedy**
The trailer may be too high; the kingpin is not entering the jaws correctly	Lower the trailer landing gear until the trailer plate contacts the fifth wheel.
Bent kingpin or damaged trailer plate is interfering with the jaw movement.	Check the kingpin and trailer plate. Replace parts as needed.
The jaw pin has not been adjusted correctly.	Check the clearance between the jaw and kingpin. Adjust as needed.
The lever bar is bent.	Check the lever bar. Replace it if needed.
The lock control handle is bent.	Check the lock control handle. Replace it if needed.
The safety latch is jammed.	Check the lock control handle. Replace it if it is bent.
The cover plate is bent	Check the cover plate. Replace it if needed.
Dirt has accumulated on the moving parts.	Clean all the parts and lubricate them lightly.

Problem—Too Much Slack at the Kingpin

Problem—Too Much Slack at the Kingpin	
Possible Cause	**Remedy**
The jaw pin has not been adjusted correctly.	Check the clearance between the jaw and kingpin. Adjust as needed.
The kingpin is worn.	Check the kingpin diameter; it should not be worn more than 1/8 inch (3.2 mm). Replace if needed.

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer	
Possible Cause	**Remedy**
The operating rod is hard to pull out.	Back the tractor a little to relieve any kingpin load against the fifth wheel jaw.
There is pressure on the jaw from the kingpin.	Back the tractor into the trailer to reduce the pressure.
The jaw is adjusted too tightly.	Back the tractor inot the trailer to relieve the pressure on the jaw. Unlock the fifth wheel. Adjust the jaw as needed.
The lever bar or the lock control handle is bent.	Check both parts. Replace if needed.
The cover plate is bent.	Check the cover plate. Replace it if it is bent.

General Information

The Century Class Conventional aerodynamic bumper consists of a bumper beam, made of a vinyl ester plastic with 50% glass added, and a three-piece air dam, made of a thermo-plastic material.

The bumper beam is bolted to the rear surface of the air dam, and the entire assembly is bolted to the front of the frame rail. The air dam is painted to match the cab color. The bumper and air dam are not repairable. Replace them if they are damaged.

The Century Class S/T enhanced bumper is a three-piece aerodynamic structure. The painted steel center piece is attached to two end pieces made of impact-resistant polyolefin plastic. The end pieces are backed up with support assemblies, but there is no air dam.

The Argosy COE bumper is steel with plastic end caps. See **Fig. 1**.

Removal

1. Park the vehicle, apply the parking brakes, then chock the tires.
2. Open the hood.
3. Remove the road lights from the bumper.
4. Remove the bumper step and the air temperature sensor, if equipped.
5. From underneath the vehicle, remove the two hexbolts, washers and nuts that attach the rubber support strap to the angle bracket at the lower rear edge of the air dam. See **Fig. 1**.
6. Remove the two hexbolts, washers, and nuts attaching the bumper support strut to the Z-bracket on the end of the bumper beam.
7. Repeat the previous step on the other side of the vehicle
8. Close the hood.
9. At the front of the vehicle, remove the four nuts (the two lower then the two upper) holding the bumper and air dam assembly to the frame rail brackets. See **Fig. 1**.
10. Pull the ends of the air dam away from the splash shields.
11. Using two people, remove the bumper and air dam from the vehicle.
12. Remove the Z-brackets from the ends of the bumper beam.
13. If you are replacing the air dam, remove it from the bumper beam. See **Subject 110** for instructions.

Installation

1. If not already done, attach the air dam to the bumper beam. See **Subject 110** for instructions.
2. Confirm that the bumper sections are aligned properly by measuring the bumper assembly as shown in **Fig. 2**. Adjust the bumper sections as necessary to achieve proper alignment.
3. Install the Z-brackets to the ends of the bumper beam.
4. Put the bumper in place onto the upper and lower mounting studs. See **Fig. 1**.
5. Install the hexnuts onto the upper mounting studs. Tighten them 68 lbf·ft (92 N·m).
6. Align the top edge of the bumper air dam with the bottom edge of the hood.
   - 6.1 On one side of the vehicle, back off the jam nut on the lower mounting stud.
   - 6.2 Install the hexnut and flatwasher onto the lower mounting stud, and tighten it until the top edge of the bumper air dam is parallel with the bottom edge of the hood.
   - 6.3 Tighten the jam nut up against the rear edge of the bumper beam.
   - 6.4 Repeat the procedure for the other side of the vehicle.
7. Install the support strap to the angle bracket at the center lower rear edge of the air dam. Tighten the fasteners firmly.
8. Attach the Z-brackets to the bumper support struts. Tighten the fasteners firmly.
9. Install the bumper step and the air temperature sensor, if equipped.
10. Install the road lights in the bumper.
11. Remove the chocks from the tires.

NOTE: The air dam can be removed as a unit, or in sections. This procedure covers removal of the air dam as a unit. To remove it in sections, remove only those fasteners holding the applicable section in place, then unhook it from the adjoining air dam section.

1. Remove the bumper and air dam assembly from the vehicle. See **Subject 100** for instructions.
2. Remove the hexbolts, hexnuts, and flatwashers holding the air dam to the bumper beam. See **Fig. 1**.
3. Remove the air dam from the bumper beam.

Installation

1. Put the bumper beam inside the air dam, making sure all the holes line up.
2. Install the fasteners. Tighten them firmly. See **Fig. 1**.
3. Install the bumper and air dam assembly on the vehicle. See **Subject 100** for instructions.

NOTE: This step requires two persons.

1. With each person supporting a side of the bumper, align the opening for the tow device with the tow device housing and wrap the bumper over the torsion bar assembly.

NOTE: Ensure that there is an even gap between the bumper and hood. Each bumper mounting bracket has two holes with slots that allow for angle adjustments.

2. On each side of the front crossmember, install the three washers and capscrews that attach the bumper to the tow device housing. Tighten the capscrews 68 lbf·ft (92 N·m).
3. Connect the electronic outside air temperature sensor.
4. If the bumper is equipped with lights, connect them, then use tie wraps to secure the wiring harnesses to the frame rails.
5. Remove the chocks from the tires.

General Information

Chassis side fairing assemblies are sized to the cab or wheelbase, and ease air turbulence around the fuel tanks. They also provide access to the sleeper and back of the cab. For an example of Century Class Conventional side fairings, see **Fig. 1**.

For examples of Argosy COE side fairings, see **Fig. 2** and **Fig. 3**.

2. Intermediate Panel
3. Aft Panel

Fig. 1, Side-Fairing Panels, 48-Inch Century Class SleeperCab Shown

The side-fairing panels are made of plastic and are mounted on support rails. See **Fig. 4**. The support rails run parallel to the frame rails, and are mounted on brackets attached to the fuel tank mounting straps and the frame rail itself. On each side of the vehicle there may be one, two or three side fairing panels. The fairing panels are painted to match the color of the cab, and have perforated metal plates on each step surface to prevent slipping. Machine screws inserted through these step plates hold the fairings to the support rails underneath.

On Century Class Conventionals equipped with three fairing panels, the left aft fairing panel is latched, and swings out to allow access to the frame rail and battery box.

This subject covers both the Century Class Conventional and the Argosy COE. Refer to the procedure that applies to your vehicle.

Century Class Conventional

REMOVAL

NOTE: The following procedure covers the removal and installation of the forward, intermediate, and aft fairing panels. Not all vehicles are equipped with three fairing panels. Follow the applicable steps for the vehicle on which you are working.

When removing the side-fairing panels, it is easiest to remove the aft panel first, then the intermediate, and finally the forward panel.

1. Park the vehicle on a level surface. Apply the parking brakes; then chock the tires.
2. Remove the aft panel.
   - 2.1 Remove the Torx®-head screws and washers holding the upper and lower tread plates and the panel to the support rails. See **Fig. 1**.
   - 2.2 Remove the upper and lower tread plates from the panel.
   - 2.3 Remove the tread spacers from the upper and lower support rails.

⚠ CAUTION

Lift the panel only by the edges. Do not lift it by the oval holes that run the length of it. To do so could cause the plastic structure to break.

   - 2.4 Holding the panel by its edges, remove it from the upper and lower support rails.
3. Remove the intermediate panel using the same procedure above, except that it is necessary to lift the panel up and tilt the upper edge inward before removing it.

INSTALLATION

When installing the side fairing panels, install first the forward panel, then the intermediate panel, and finally the aft panel. This will allow you to fit them together correctly.

⚠ CAUTION

Lift the panels only by the edges. Do not lift them by the oval holes that run the length of them. To do so could cause the plastic structure to break.

1. Install the forward panel
   - 1.1 Put the forward panel in place on the upper and lower support rails.
   - 1.2 Install the tread spacers.

     IMPORTANT: Belleville washers are flat on the bottom, and convex (curved) on the top. Make sure they are installed correctly.
   - 1.3 Install the upper and lower tread plates, using the Torx-head screws and Belleville washers.
   - 1.4 Tighten the screws, but keep them loose enough to move the panel slightly.
2. Check the gap between of the upper edge of the forward panel and the lower edge of the hood. It should be 1-3/16 inches (30 mm). The edges of the panel and hood should also be parallel. See **Fig. 2**. If necessary, adjust the position of the forward panel by loosening the brackets holding the forward ends of the upper and lower support rails to the fuel tank brackets. Move the forward ends of the support rails up or down as needed.
3. Using the same procedure, install the intermediate panel.

   Make sure the plastic clips on the forward edge of the panel are underneath the rear edge of the forward panel, and that the plastic tabs on the back surface of panel hook onto the edges of the upper support rail.
4. Install the aft panel.
5. Check the vertical gaps between the panels. They should be 1/2-inch (13 mm) wide. See **Fig. 2**. Move the panels forward or backward as needed.
6. Tighten the Torx-head screws firmly.
7. Remove the chocks from the tires.

REMOVAL

1. Park the vehicle on a level surface. Apply the parking brakes; then chock the tires.
2. Remove the tread plate from each step.

⚠ CAUTION

Lift the panels only by the edges. Do not lift them by the oval holes that run the length of them. To do so could cause the plastic structure to break.

3. Remove the aft side fairing panel.
4. Remove the intermediate fairing panel.
5. Remove the forward fairing panel.
   - 5.1 Remove the four bolts inside the fairing that hold it to the rail.

5.2 Remove the panel.

6. If needed, remove the support rails by removing the bolts that attach each to the brackets.

INSTALLATION

1. If needed, install the support rails by positioning them on the brackets and installing the fasteners. Tighten the nuts 28 lbf·ft (38 N·m). See **Fig. 3**.

⚠ CAUTION

Lift the panels only by the edges. Do not lift them by the oval holes that run the length of them. To do so could cause the plastic structure to break.

2. Position the forward side fairing panel, and install the four bolts inside. Tighten them 16 lbf·ft (22 N·m).
3. Position the intermediate and aft fairing panels.
4. Install the tread plates using the machine screws, and tighten the screws 16 lbf·ft (22 N·m). See **Fig. 4**.
5. Remove the chocks from the tires.

Removal

NOTE: This procedure covers removal of forward and rear support rails. Not all vehicles are so equipped. Follow the applicable steps for the vehicle on which you are working. On vehicles equipped with rear side fairings, the left rear upper and lower support rails are latched to the forward support rails for easy removal. They can be removed from the vehicle without removing the fairing panels from them.

1. On the left side, remove the rear upper and lower support rails and panel as a unit.
   - 1.1 Unlatch and remove the deck plate between the frame rail and upper edge of the rear fairing panel.
   - 1.2 Remove the clinch pins from the two latches, then unhook the upper and lower latches. See **Fig. 1**.
   - 1.3 Swing the rear end of the panel and support rails outboard, then remove them.
2. If not already done, remove the remaining side-fairing panels from the vehicle. See **Subject 100** for instructions. Remove the left rear fairing panel from the support rails, using the same procedure.
3. Remove the remaining support rails from the left side of the vehicle. See **Fig. 1**.
   - 3.1 Remove the 3/8–16 hexbolts and aluminum spacers that hold the forward upper rail to its mounting brackets; then remove the support rail.

Support Rail Removal and Installation, Century Class Conventionals

3.2 Using the same procedure, remove the forward lower support rail from its mounting bracket.

4. Remove the support rails from the right side of the vehicle.

4.1 Remove the fasteners from one end of the flexible bracket holding the forward and rear lower support rails together. See **Fig. 1**.

4.2 Remove the 3/8–16 hexbolts and aluminum spacers that hold the forward upper rail to its mounting brackets; then remove the support rail.

4.3 Using the same procedure, remove the forward lower support rail from its mounting bracket; then remove the rear upper and lower support rails

Installation

1. On the right side of the vehicle, install the forward upper support rail. See **Fig. 1**.

1.1 Put the rail in place on the mounting brackets.

1.2 Install the aluminum spacers, then the 3/8–16 hexbolts. Tighten the hexbolts finger-tight.

1.3 Make sure the support rail is level and parallel with the frame rail. Clamp the fairing panel in place, then check it's alignment with the hood and the bottom edge of the cab. If necessary, loosen the fasteners on the upper U-bracket (see **Fig. 1**); then move the front end of the support rail (along with the fairing panel) up or down as needed. Tighten the U-bracket fasteners firmly. Tighten the 3/8–16 hexbolts 28 lbf·ft (38 N·m).

1.4 Put the rear upper support rail in place; then slide the tongue on the forward end of it into the groove in the rear end of the forward support rail.

1.5 Install the aluminum spacer, then the 3/8–16 hexbolt. Tighten the hexbolt 28 lbf·ft (38 N·m).

2. Using the same procedure, install the forward and rear lower support rails.

3. Install the flexible bracket between the forward and rear lower support rails. Tighten the fasteners firmly.

4. Using the same procedure, install and level the forward upper support rail on the left side of the vehicle. Then install and level the forward lower support rail

5. Install the upper and lower rear support rails.

5.1 If it was removed, install the latch bracket assembly (see **Fig. 1**) between the rear upper and lower support rails.

5.2 Install the latches if they removed.

5.3 Latch the support rails in place, then install the clinch pins.

6. Install the remaining side-fairing panels. See **Subject 100** for instructions.

General Information

NOTE: The Holland 3500 series XA–3501 model fifth wheel top plate has been replaced by the XA–351 model. All 3500 series fifth wheel top plates which are marked with a manufactured date after June 1, 1996 are XA–351 models.

NOTE: Service operations for the Holland 3500 series slide mounts (FW2535/FW35) are covered in **Section 31.06** in this group.

MODEL XA–3501 TOP PLATE

NOTE: The part number prefix for the stationary fifth wheel is FW3500 and the part number prefix for the sliding fifth wheel is FW2535.

Holland 3500 series XA–3501 fifth wheels are used for pulling trailers having the standard SAE kingpin. When installed as stationary fifth wheels, they are bracket-mounted to the trailer frame in a position that best distributes the trailer load over the tractor axles. When installed as sliding fifth wheels, they are mounted on the Holland 3500 series sliding mount. These fifth wheels have a capacity of 150,000 lbf (667 000 N) maximum drawbar pull and 40,000 to 50,000 lbf (178 000 to 222 000 N) maximum vertical load. The fifth wheel (**Fig. 1**) has a cast steel top plate, and is equipped with a split type "B" mechanical spring lock. This steel kingpin lock system requires a 300 lbf (1330 N) push (force) to couple, and also includes a slack adjustment and the Holland lockguard (which prevents high kingpin coupling).

The two spring-loaded lock halves separate as the kingpin enters the lock mechanism. See **Fig. 2**. The final forward motion of the kingpin forces the lock to close in a 360 degree grip around the shoulder and neck of the kingpin, and moves the yoke between the lock halves and the tapered rib members of the fifth wheel understructure. The kingpin can be released only by manually operating the kingpin lock control handle. See **Fig. 1**. An adjustment nut compensates for wear on the lock or kingpin, if necessary.

See Chapter 10 in the vehicle driver's manual for complete operating instructions.

Fig. 1, XA-3501 Fifth Wheel

MODEL XA–351 TOP PLATE

NOTE: The part number prefix for the stationary fifth wheel and the sliding fifth wheel is FW35.

The Holland 3500 series XA–351 fifth wheels are applicable for general over-the-road use. They are designed to pull trailers having a 2 inch (5 cm) SAE J700b kingpin. They have a capacity of 150,000 lbf (667 000 N) maximum drawbar pull and 55,000 lbf (244 652 N) maximum vertical load. These fifth wheels are available in three different mounting assemblies: the Kompensator®; the slide mount; and the stationary mount.

The stationary mount fifth wheels are available with four different mounting bracket styles, which include:

- a bracket with a mounting base for over-the-frame mounting;
- a bracket with a mounting angle for over-the-frame mounting;
- a bracket for angle mounting (designed to be welded to the angle) for over-the-frame mounting;
- and, a bracket for outboard angle mounting.

The mounting brackets use nylon-lined "up-shock" bushings. These fifth wheels come in a variety of heights to accommodate many applications.

The sliding fifth wheels are available with either an over-the-frame mounting bracket or an outboard

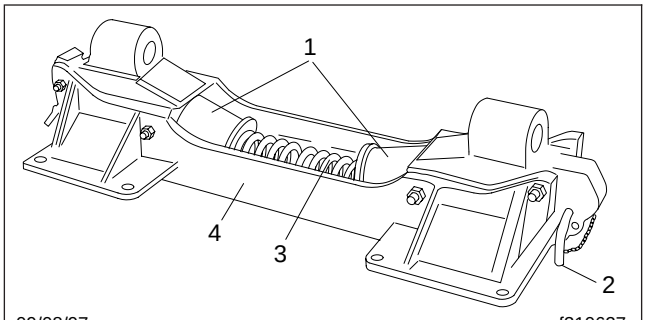
angle mounting bracket. These mounting brackets are either equipped with a manual slide release or an air slide release mechanism. These sliding mounts have a position adjustment that gives the fifth wheel top plate the ability to be released, incrementally moved (by 1.5 inch [3.8 cm] displacements) and locked in alternate positions. The position adjustment feature allows the fifth wheel position to vary combination length and tractor axle load distribution for maximum equipment utilization. The mounting brackets use nylon-lined "up-shock" bushings. The sliding fifth wheels are available in a variety of heights and slide travel lengths.

The Kompensator® fifth wheel is equipped with either a stationary or sliding mounting bracket. This fifth wheel is designed for rigid trailers that don't flex during torsional loading. It provides torsional stress relief and promotes vehicle stability with trailers that have an unusually high center of gravity (where the center of gravity is up to 44 inches [111 cm] above the top plate surface). This fifth wheels unique cradle design provides side-to-side movement to help relieve the torque and twist of the trailer. Spring cushions act as a restoring force to provide stability after absorbing the strain and pressure of the load. Additionally, it keeps the center of compensation above the fifth wheel bearing surface and centered between the frame rails. All models are available with an optional "lock-out" feature to restrict compensation for applications that do not require compensation. See **Fig. 3**.

The 3500 series top plate consists of:

- the cast steel top plate;



1. Urethane Cushions
2. Optional Lockout
3. Compression Springs
4. Kompensator® Cradle Design Mounting Bracket

Fig. 3, The Kompensator®Cradle

- the bracket pin mount;
- the release handle;
- the infinite lock adjustment nut;
- and the kingpin lock mechanism.

See **Fig. 4**.

The kingpin lock mechanism consists of:

- the infinite lock adjustment nut;
- the secondary lock;
- the release handle;
- the type "B" forged steel split lock;
- and, the yoke.

5. Release Handle

Fig. 4, XA-351 Fifth Wheel

See **Fig. 5**.

When the yoke is retracted, the two spring-loaded lock halves separate as the kingpin enters the lock mechanism. When the yoke engages, the final forward motion of the kingpin forces the lock to close in a 360 degree grip around the shoulder and neck of the kingpin. After the yoke is engaged (positioned between the lock halves and the tapered rib members of the top plate casting), the secondary lock moves behind the yoke. For fifth wheels with an automatic secondary lock, the kingpin is released by manually operating the release handle. For fifth wheels with a manual secondary lock, the fifth wheel is released by pulling the secondary release handle, then hooking the secondary release handle to the top plate casting, and finally manually operating the primary release handle. For high coupling protection, a one step rear lock is incorporated into the split lock. For increased durability of the kingpin lock mechanism, the infinite lock adjustment positions are available to compensate for wear in both the kingpin and the lock jaws.

Removal and Disassembly

(See Fig. 1)

WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

A fifth wheel rebuild kit is available for servicing the 3500 series XA–3501 fifth wheel (part number RK–63501 [left release] and RK–63500 [right release]). The kit contains all replacement parts for the fifth wheel, except the fifth wheel plate, slide mount assembly, rubber bushings, bushing pins, and roll pins.

Review the troubleshooting section before rebuilding the fifth wheel. Rebuilding may be unnecessary.

1. Steam clean the top plate. Remove it from the slide mounts (**Fig. 1**) by removing the roll pins from the bushing pins; then, remove the bushing pins from the slide mounts. Use an overhead hoist to lift the fifth wheel from the slide mount assembly and tractor frame.
2. Turn the fifth wheel upside down with the locks open.
3. While disassembling the fifth wheel, check it for cracks and for missing or damaged parts, as follows:

   3.1 Remove the lockguard, the lockguard torsion spring, the lockguard pin, and the lockguard cotter pins.

   3.2 On fifth wheels with a right-hand release, remove the secondary lock roll pin from hole F. Then, remove the right-hand secondary lock from under hole F.

   On fifth wheels with a left-hand release, remove the secondary lock roll pin from hole G. Then, remove the left-hand secondary lock with the secondary lock spring from under hole G.

   3.3 Remove the attaching release arm capscrew, capscrew washer, and roller from hole A of the release arm and yoke subassembly.

   3.4 Remove the release arm capscrew, release arm capscrew washer, and release arm roller from hole G for models with right-hand release or from hole F for models with left-hand release.

   3.5 Remove the release handle from the fifth wheel top plate. Remove the washer, release handle spring, and release handle washer from the release handle.

   3.6 Remove the yoke shaft locknut, yoke shaft washer, and rubber block from the yoke shank. Then, remove the yoke shank and the yoke shank spring from the yoke subassembly.

   3.7 Remove the yoke from the fifth wheel top plate.

   3.8 Remove the lock cotter pins, lockpins, and the lock jaws from the fifth wheel top plate.

   3.9 If the top plate is cracked, discard it. If the lockpin hole is worn, the top plate can be returned for a factory rebuild.

WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or if the lockpin does not fit tightly. The top plate could fail or the locks could malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Assembly and Installation

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

A fifth wheel rebuild kit is available for servicing the 3500 series XA–3501 fifth wheel (part numbers RK–63501 [left release] and RK–63500 [right release]). The kit contains all replacement parts for the fifth wheel, except the fifth wheel plate, slide mount assembly, rubber bushings, bushing pins, and roll pins.

Review the troubleshooting section before rebuilding the fifth wheel. Rebuilding may be unnecessary.

IMPORTANT: Use only Holland rebuilding kits. Replace all roll pins, cotter pins, springs, capscrews, nuts, and washers.

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Before installing the lock jaws (**Fig. 1**), lubricate the lockpin holes (Ref. J) with Never-Seez®.

⚠ CAUTION

Use only Never-Seez®. Other lubricants can damage the lockpin holes.

3. Place the lock jaws in the top plate with the 2-7/8 inch bore toward the face of the top plate. See **Fig. 2**.
4. Drive the lockpins (**Fig. 1**) through the top plate and lockpin holes (Ref. J) in the lock jaws until the head of the pins are flush with the top plate.
5. If the top plate is equipped with lockpin bushings, use roll pins instead of cotter pins. See **Fig. 3**.
6. Check that the lock jaws move freely.

⚠ WARNING

Use only Holland part number TF–0237 or a precision plug machined to 2.000 ± 0.005 inch (5.08 ± 0.0127 cm) to adjust the locking mechanism. Failure to do so may cause locking mechanism malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

7. Install a 2-inch (5.08 cm) diameter plug (Holland part number TF–0237) in the lock jaws. See **Fig. 4**.
8. Strike the yoke with a mallet to bend the yoke tips outward slightly. See **Fig. 5**.
9. Slide the yoke into the top plate with the threaded hole facing up, and tap the yoke into position.

⚠ WARNING

Never grind on the inside of the yoke or on the locks. This can weaken the yoke structure, possibly causing the kingpin to fit loosely. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

10. Inspect the yoke tips. The tips must be flush with the ends of the locks, or extend no more than 1/32 inch (0.8 mm) beyond. See **Fig. 6**.
    - 10.1 If the yoke tips fall short (**Fig. 7**), use a belt sander or disk grinder to grind the outside surfaces of the yoke until it fits precisely into place. See **Fig. 8**.
    - 10.2 If the yoke tips extend beyond the ends of the locks, build up the outer surfaces of the yoke using a low hydrogen E70XX welding rod. See **Fig. 9**. After welding, grind the beads smooth.
11. The outside of each yoke tip has two contact areas. Check that all four surfaces have full area contact with the top plate ribs (**Fig. 10**) after welding and grinding.
12. Continue welding, grinding, and fitting until the yoke has full contact and the yoke tips are flush with the ends of the locks.
13. Apply a coat of light grease to both the inside and outside friction surfaces of the yoke, then slide the yoke into the top plate with the threaded hole facing up.
14. Install the spring (**Fig. 1**) between the yoke and the top plate. Insert the yoke shank through the top plate and spring, then into the yoke. Make

sure that the predrilled recess in the yoke shank aligns with the threaded hole in the yoke.

15. Install the lock adjustment tag, the rubber block, a 13/16-inch i.d. steel washer, and the 3/4-inch locknut in the order stated.
16. Install the 9/16-inch i.d. washer on the release handle as shown in **Fig. 1**.
17. Pass the open end of the release handle through the guide hole (Ref. D for models with right-hand release, Ref. I for models with left-hand release) toward the outside of the top plate.
18. Inspect the release arm (cam plate) for burrs or rough edges in the cam profile (Ref. A). Remove any burrs or rough edges.

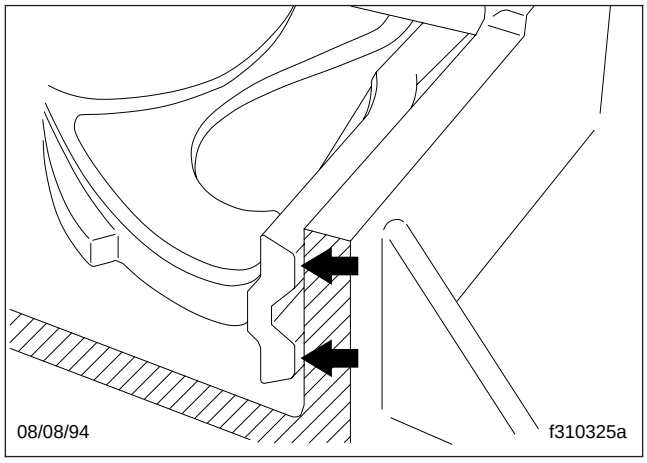

Fig. 10, Contact with Top Plate

19. Apply a light coat of grease to the cam profile and pivot holes.
20. Insert the "S" end of the release handle through the small hole in the release arm (cam plate).
21. Place the release arm (cam plate) on the top plate so that the cam profile (**Fig. 11**, Ref. A) is over the hole in the yoke and the large hole (Ref. B) is over the lug in the top plate opposite the release handle.

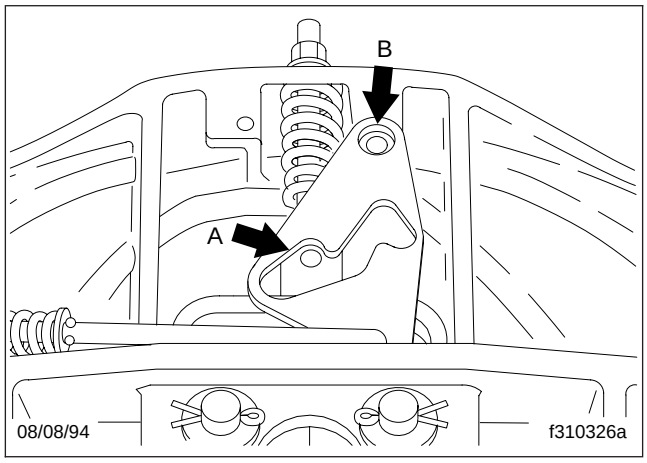

Fig. 11, Place the Release Arm

22. Slide a 9/16-inch i.d. flatwasher between the plate lug and the release arm with the rounded edge towards the cam. See **Fig. 12**.
23. Install the 1/2-inch i.d. roller (**Fig. 1**) in the large hole of the release arm.

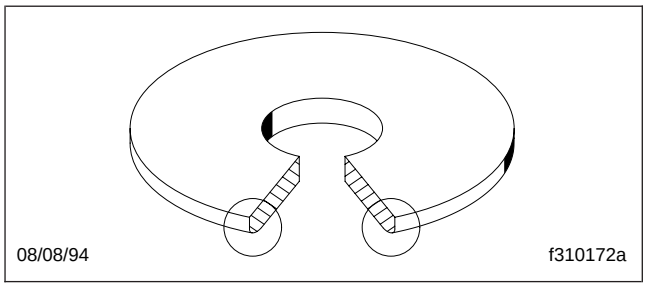

Fig. 12, Rounded Edge

24. Place a second 9/16-inch i.d. flatwasher over the release arm. Make sure the rounded edge of the washer faces the cam.
25. Install the 1/2-inch diameter capscrew through the washers, roller, and hole in the top plate lug (Ref. G for right-hand release models, Ref. F for left-hand release models).
26. Secure the capscrew with a 1/2-inch locknut. Tighten the locknut; then, check that the release arm moves freely.
27. Place a 5/8-inch i.d. washer between the yoke and the release arm. Make sure that the rounded edge of the washer faces the release arm.
28. Insert the 5/8-inch i.d. roller in the release arm opening.
29. Install the second 5/8-inch i.d. washer on top of the release arm.
30. Pass the 5/8-inch diameter capscrew through the assembly. Be certain that the bolt passes through the yoke and into the recess in the yoke shank.
31. Tighten the capscrew securely, but make sure the top washer turns freely.
32. Turn the nut on the yoke shank clockwise until the yoke just begins to move.
33. Check the plug (Holland part number TF–0237). It should fit snugly in the locks, but you should be able to turn it with some force.
34. On models with an automatic secondary lock assembly, proceed as follows:
    - 34.1 Start the roll pin into the hole in the top plate lug opposite the release arm anchor capscrew.
    - 34.2 Install the torsion spring on the secondary lock, and position them on the lug. Be sure the open end of the spring faces toward the rib of the lug. See **Fig. 13**.

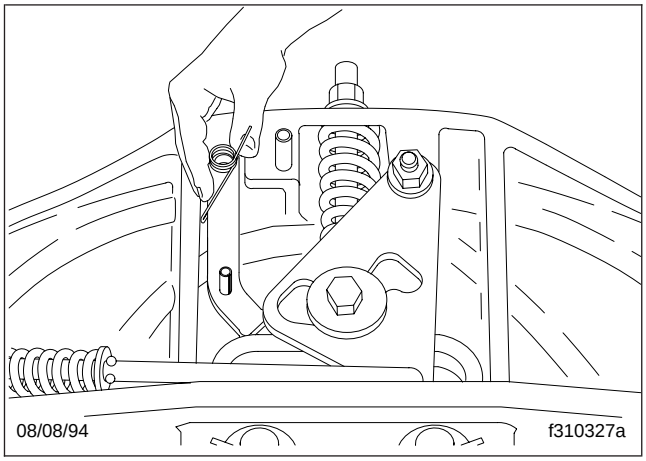

Fig. 13, Torsion Spring Installation

    - 34.3 While holding the parts in place, drive the roll pin until it is flush with the lug.
    - 34.4 Check the spring tension on the secondary lock. Check that the lock moves freely.
35. On models with a manual secondary lock assembly, proceed as follows:
    - 35.1 Pass the end of the manual secondary lock handle (**Fig. 1**) through the hole (Ref. E for right-hand release, Ref. H for left-hand release).
    - 35.2 Attach the handle to the secondary lock.
    - 35.3 Start the roll pin into the hole in the top plate lug opposite the release arm anchor capscrew.
    - 35.4 Install the torsion spring on the secondary lock, and place them in position on the lug. Be sure the open end of the spring faces toward the rib of the lug. See **Fig. 13**.
    - 35.5 While holding the parts in place, drive the roll pin until it is flush with the lug.
    - 35.6 Check the spring tension on the secondary lock. Check that the lock moves freely.
36. Pull the release handle, remove the plug, and pry open the lock jaws.

Model XA–3501 Top Plate Assembly and Installation

37. Assemble the lockguard and the torsion spring.
38. Mount the lockguard using the lockguard pin and cotter pins. See **Fig. 14**.

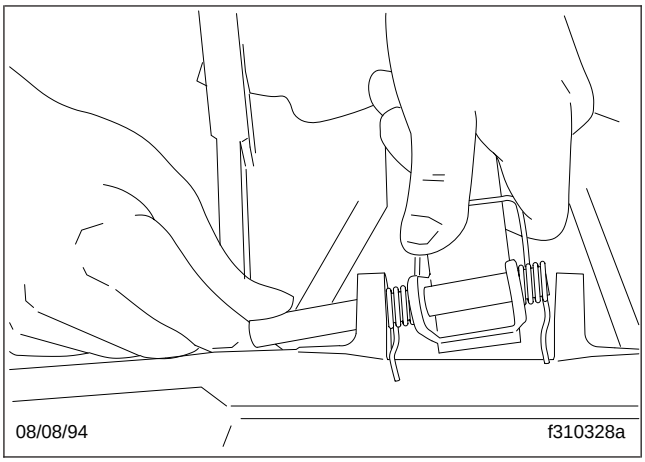

Fig. 14, Mount the Lockguard

39. Check the spring tension on the lockguard. Check that the lockguard moves freely.
40. Check the adjustment. The tip of the guard should be even with the edge of the 2-inch bore in the lock jaw. See **Fig. 15**.

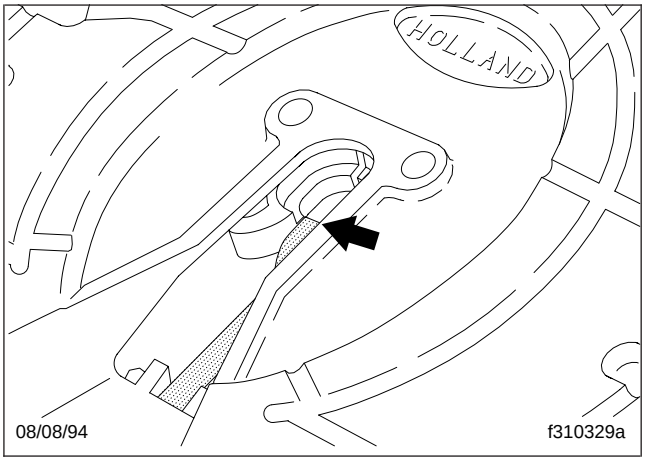

Fig. 15, Check the Guard

41. Adjust the lockguard position by supporting the end of the guard with a short piece of steel placed between the locks and the lock-guard. Tap the center of the guard to adjust it. See **Fig. 16**.

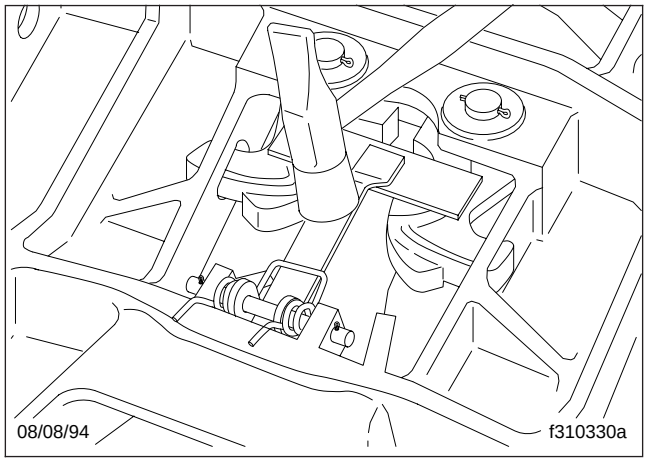

Fig. 16, Adjust the Guard

42. Using a Holland Lock Tester, close the locks. For instructions, refer to Holland Publication FW 130. Make sure that the locking mechanism functions properly. See **Fig. 17**. If the fifth wheel does not operate properly, repeat the above procedures or contact your local Holland representative for assistance.

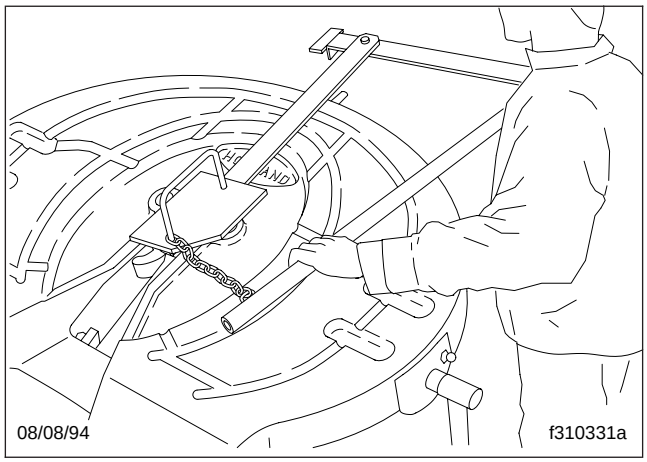

Fig. 17, Using the Lock Tester

IMPORTANT: The fifth wheel must be well lubricated to operate correctly. See Group 31 of the *Century Class Trucks Maintenance Manual*, for complete maintenance and lubrication instructions of the fifth wheel assembly.

Model XA–3501 Top Plate Assembly and Installation

⚠ WARNING

If the fifth wheel does not operate properly, do not use it. The fifth wheel could malfunction, resulting in bodily injury or property damage due to possible separation of the trailer from the tractor.

43. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Then install the roll pins.

Model XA–351 Top Plate Removal and Disassembly

WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Fifth wheel rebuild kits are available for servicing the 3500 series XA–351 fifth wheels. For the rebuild kits, the part numbers include:

- RK–351AL (left release with automatic secondary lock);
- RK–351A02L (left release with manual secondary lock);
- RK–351A (right release with automatic secondary lock);
- RK–351A02 (right release with manual secondary lock).

These fifth wheel rebuild kits contain all the replacement parts, except: the fifth wheel top plate; the bracket assembly rubber bushings; the bracket assembly bushing pins; and the bracket assembly bushing pin capscrews and locknuts.

Rebuilding the fifth wheel may be unnecessary. Review the troubleshooting section before rebuilding the fifth wheel. If the troubleshooting section does not correct the problem, then the fifth wheel may need rebuilding.

While disassembling the fifth wheel, Check it for cracks and for missing or damaged parts. Discard all used components.

Removal and Disassembly

(See Fig. 1)

1. Steam clean the top plate.
2. Remove the top plate from the bracket assembly.
   - 2.1 Loosen and remove the 1/2–20 bushing pin capscrews and locknuts from the top plate.
   - 2.2 Remove the bushing pins from the bracket assembly. See **Fig. 2**.
   - 2.3 Using an overhead hoist, lift the fifth wheel from the bracket assembly and tractor frame.
3. Disassemble the secondary lock.
   - 3.1 Turn the fifth wheel upside down with the locks open.
   - 3.2 Using a suitable driver and hammer, drive the 1/2-inch by 2-3/4 inch roll pin from the top plate and the secondary lock. See **Fig. 3**.
   - 3.3 If the fifth wheel has an automatic secondary lock, proceed to the next substep, otherwise, remove the manual secondary release handle by passing the "S" bend of the release handle through the large hole in the secondary lock and then through the guide hole. See **Fig. 4**.
   - 3.4 Remove the secondary lock.
4. Disassemble the cam plate.
   - 4.1 Loosen and remove the 5/8-inch capscrew from the threaded hole in the yoke. Remove the washers, and the roller from the cam plate. See **Fig. 5**.
   - 4.2 Loosen and remove the 1/2-inch capscrew and nut from the top plate lug. Remove the washers, and the roller from the cam plate. See **Fig. 6**.
   - 4.3 Remove the release handle by passing the "S" bend of the release handle through the large hole in the raised tab of the cam plate and through the top plate casting hole. See **Fig. 6**.
5. Disassemble the yoke.
   - 5.1 Slide the yoke shaft assembly away from the yoke, through the compression spring, and out of the top plate casting. See **Fig. 7**.
   - 5.2 Remove the compression spring and remove the yoke.
6. Disassemble the lock.
   - 6.1 Remove the cotter pins from the lockpins.
   - 6.2 Using a suitable driver and hammer, drive the lockpins out of the casting. See **Fig. 8**.

Model XA–351 Top Plate Assembly and Installation

WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Fifth wheel rebuild kits are available for servicing the 3500 series XA–351 fifth wheels. For the rebuild kits, the part numbers include:

- RK–351AL (left release with automatic secondary lock);
- RK–351A (right release with automatic secondary lock);
- RK–351A02L (left release with manual secondary lock);
- RK–351A02 (right release with manual secondary lock).

These fifth wheel rebuild kits contain all the replacement parts, except: the fifth wheel top plate; the bracket assembly rubber bushings; the bracket assembly bushing pins; and the bracket assembly bushing pin capscrews and locknuts.

Review the troubleshooting section before rebuilding the fifth wheel. Rebuilding may be unnecessary.

IMPORTANT: Use only Holland rebuilding kits. Replace all roll pins, springs, capscrews, nuts, and washers that are included in the kit. Do not reuse all parts.

WARNING

Use only genuine Holland parts and do not modify, change or add to the product. Any alterations to the fifth wheel assembly could compromise its performance. This could result in the loss of the trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Assembly and Installation

(See Fig. 1)

WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or distorted or if the lockpin does not fit tightly. The top plate could fail or the locks could malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

1. Inspect the top plate.
   - 1.1 If necessary, turn the fifth wheel upside down.
   - 1.2 Inspect the front lock surface for burrs or cracks. See **Fig. 2**. The front lock surface must be free of any burrs or cracks.
2. Install the lock.
   - 2.1 Lubricate the lockpin holes of the lock jaws with Never-Seez (provided in the kit). See **Fig. 3**.

CAUTION

Use only Never-Seez. Other lubricants can damage the lockpin holes.

   - 2.2 Align the lock jaws in the casting and position the lock jaws so that the raised edge of the kingpin guides are facing up. See **Fig. 4**.
   - 2.3 Align the holes in the lockpins so that the cotter pins can be inserted. Insert the lockpins into the casting and through the lock jaws. Using a suitable hammer, drive the lockpins into the casting until the heads are flush with the casting. See **Fig. 5**.
   - 2.4 Insert the cotter pins and spread.
   - 2.5 Check that the lock jaws move freely.

WARNING

You must use a Holland lock gauge (TF–0237) or a precision plug that is 2.000 ± 0.005 inch (5.08 ± 0.0127 cm) for proper installation of the locking

mechanism. If the proper plug is not used, the lock could malfunction or fail. This could result in the loss of the trailer connection during vehicle travel, possibly causing personal injury and property damage.

2.6 Position a 2-inch (5.08 cm) diameter "plug" into the lock jaws. See **Fig. 6**. A lock gauge, Holland part number TF–0237 is available at a Holland distributor.

3. Install the yoke.

3.1 Lubricate the surface area of the yoke tips with light grease. With the threaded hole facing up, slide the yoke into the casting and seat it around the locks. See **Fig. 7**.

3.2 Inspect the amount of yoke tip engagement. Yoke tips must extend flush with the end of the locks and no more then 1/2 inch (12.7 mm) past the locks. See **Fig. 8**. If the new yoke extends more than 1/2 inch (12.7 mm) past the locks, *do not use it.* Discard it and order part number XA–07295–THK from your nearest Holland distributor.

5.5 Check for free movement of the cam plate.

NOTE: When installing the washers, the rounded edge of the washers *must* always face the cam plate.

5.6 Align the cam plate track over the threaded hole in the yoke. Then slide a 2-5/8 inch o.d. washer between the yoke and the cam plate with the rounded side of the washer facing the cam plate. Then place the 5/8-inch roller into the cam plate track and place the second 2-5/8 inch o.d. washer over the roller with the rounded side of the washer facing the cam plate. See **Fig. 14**.

Make sure the capscrew enters the recessed hole in the yoke shaft. Then, tighten the capscrew securely. See **Fig. 14**.

5.8 Check for free movement of the cam plate.

6. Install the secondary lock.

6.1 If equipped with the automatic version, start the roll pin into the hole in the top plate opposite the cam attachment capscrew. Then, assemble and install the secondary lock and torsion spring. Make sure the flats of the torsion spring are resting against the casting. See **Fig. 15**.

With a suitable hammer, drive the roll pin through the torsion spring and secondary lock until the roll pin is flush with the casting. See **Fig. 15**.

7.1 If equipped, pull the secondary release handle and hook it on the casting. Next, pull the primary release handle to open the locks. Now, remove the 2-inch plug.

Model XA–351 Top Plate Assembly and Installation

7.2 Turn the fifth wheel right side up and close the locks using a Holland Lock tester (see Holland publication FW130 for operating instructions for the lock tester).

7.3 Verify that the locks are completely closed around the kingpin. The lock halves should be seated against each other.

7.4 Alternate tightening the adjustment nut and attempting to turn the lock tester back and forth. Continue tightening the adjustment nut until there is some resistance felt in the lock tester (as it is turned back and forth).

The fifth wheel is properly adjusted when there is resistance between locks and the lock tester, but the lock tester can still be turned by hand.

7.5 Pull the release handle and remove the lock tester.

8. Check the fifth wheel for proper operation.

8.1 Using the Holland lock tester, open and close the fifth wheel at least three times.

Each time you close the locks, verify that the locks have closed completely around the kingpin and that the adjustment nut and rubber bushing are seated snug against the casting.

8.2 Check for resistance between the locks and the lock tester one final time, and adjust as needed.

⚠ WARNING

If the fifth wheel does not operate properly, do not use it. Either disassemble it and repeat the rebuilding procedure or contact your nearest Holland representative for assistance. Never use a fifth wheel that does not operate properly. The fifth wheel could malfunction, resulting in bodily injury or property damage due to a possible separation of the trailer from the tractor.

8.3 The fifth wheel is now ready for operation.

9. Install the top plate.

9.1 Using an overhead hoist, lift and position the fifth wheel over the bracket assembly.

9.2 Install the bushing pins through the fifth wheel and into the bracket assembly. Then, install and tighten securely the 1/2–20 bushing pin capscrews and locknuts. See **Fig. 18**. Remove the overhead hoist.

Troubleshooting Chart

Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer

Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer	
Possible Cause	**Remedy**
The trailer may be too high; the kingpin is not entering the locks properly.	Lower the trailer landing gear until the bolster plate contacts the fifth wheel.
The locks are closed.	Pull the release handle and pry open the locks.
Rust or grime is interfering with the lock operation.	Spray a light lubricant or diesel fuel on all moving parts including the release handle. Operate the release mechanism several times.
The fifth wheel locks are too tight.	Check the lock adjustment. Correct as needed.
A bent release handle, bent kingpin, or damaged bolster plate is interfering with the lock movement.	Check the release handle, kingpin, and bolster plate. Replace parts as required.
The locks are damaged.	Inspect the locks and replace parts as required.
The fifth wheel needs rebuilding.	Rebuild the fifth wheel, using the parts in the appropriate rebuilding kit.

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer	
Possible Cause	**Remedy**
The secondary lock is not released.	If equipped with a manual secondary lock, pull the release handle and lock it open by resting it against the top plate. If equipped with an automatic secondary lock, inspect the lock for missing or broken parts, and repair or replace as required.
The tractor is putting pressure against the locks.	Set trailer brakes. Back the tractor into the trailer to relieve pressure and lock the tractor brakes before pulling the release handle.
There is rust or grime on the locking mechanism.	Spray a light lubricant or diesel fuel on all moving parts including the release handle. Operate the release mechanism several times.
The kingpin is bent or the bolster plate is damaged.	Check the kingpin, using a Holland TF–0110 Kingpin Gauge. Check the bolster plate, using a 48-inch (122 cm) straight edge. Repair or replace parts as required.
The fifth wheel locks are too tight.	Check the lock adjustment. Correct as needed.
The release handle will not stay out or must be held out when unlocking.	Replace the cam or release arm and the release handle spring.

General Information

NOTE: For Holland 3500 series fifth wheel service operations, see **Section 31.05** in this group.

NOTE: Prior to June 1, 1996, the Holland sliding fifth wheel mount carried a part number prefix FW2535. Since June 1,1996, the Holland sliding fifth wheel mount part number prefix has been replaced by FW35.

The Holland sliding fifth wheel mount is designed to provide maximum tractor use for different lengths and types of trailers. The FW2535/FW35 sliding fifth wheel mount is used with the Holland 3500 series fifth wheel, and is equipped with either a manually operated or an air-operated release slider.

Sliding fifth wheel assemblies are mounted on a baseplate with notched rails. See **Fig. 1**. Plungers are meshed into teeth on the baseplate to lock the fifth wheel. This assembly allows forward or rearward movement of the fifth wheel along the notched rails for optimum weight distribution over the tractor axles. The mounting baseplate is bolted to the tractor frame.

When the fifth wheel is in the desired position, it is locked in place by wedge-shaped plungers that engage in the notched rails under the sliding mount. To release the fifth wheel, the plungers are withdrawn.

The manually operated release slider contains a release lever (**Fig. 2**), which when manually pulled or released, unlocks or locks both sides of the sliding mount at the same time.

Disassembly

⚠ WARNING

Fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Incorrect or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

1. Remove the top plate.
   - 1.1 If equipped with model XA–3501 top plate, remove the roll pins (**Fig. 1**) from both the right and left side of the top plate. Then, remove the bushing pins.

     Using an overhead hoist, lift the fifth wheel off the slide mount assembly.
   - 1.2 If equipped with model XA–351 top plate, loosen and remove the 1/2–20 bushing pin capscrews and locknuts from both the left and right sides of the top plate. Then, remove the bushing pins (**Fig. 1**) from the bracket assembly.

     Using an overhead hoist, lift the fifth wheel off the slide mount assembly.

⚠ WARNING

When draining the air reservoir, do not look into the air jets, or direct them toward anyone. Dirt or sludge particles may be in the airstream, and could cause injury if ejected.

2. If the fifth wheel has a manual release sliding mount, then go to the next step. Otherwise, drain the air reservoir; then disconnect and plug the air line from the air cylinder.

⚠ WARNING

Parts are under spring compression. Wear safety goggles during disassembly and assembly, and keep fingers away from possible pinch points at the ends of springs. Failure to do so can result in bodily injury, due to parts ejecting with force.

3. Using a Holland TF–TN 2500 spring compressor (**Fig. 2**), compress one of the plunger return springs (**Fig. 3**).

4. Remove the plunger retaining pin (**Fig. 3**) from the plunger end, and either the air-release cylinder or manual release lever clevis. Then remove the plunger.

   If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), remove the plunger retaining pin from the release lever, then remove the plunger.

5. Carefully remove the spring compressor; then remove the plunger return spring, the spring compression stop, and the spring retainer (**Fig. 3**).

   Repeat the procedure for the other plunger.

6. Remove the air-release cylinder or the manual release lever.

   If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), remove the air-release cylinder or the manual release lever along with the right and left release levers (**Fig. 3**). Disconnect the release levers from the air-release cylinder or manual release lever.

⚠ WARNING

Wear protective eye and facial gear when grinding to remove the rear stops. Failure to do so could result in personal injury due to flying metal debris from the grinding.

7. If the slide mount assembly (**Fig. 3**) is damaged, dismantle it from the baseplate (Ref. 9).

   7.1 Grind down the welded area to remove the rear stops.

   7.2 Remove the slide mount assembly from the baseplate by sliding it off the rear of the tracks.

8. Remove all dirt and grease from the parts. Replace any parts that show signs of wear or damage.

NOTE: If the rubber bushings (**Fig. 1**) are damaged, or if they allow movement of more than 1/8 inch (3 mm), replace them.

Assembly

⚠ WARNING

Fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Incorrect or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

1. Using a rubber lubricant or a waterless hand cleaner, lubricate the outer surfaces of the new rubber bushings.
2. Install the rubber bushings (**Fig. 1**) into the slide mount assembly until they are flush with the outboard ends of the assembly.
3. Using a multipurpose chassis grease, lubricate the flanges on the slide mount assembly. Then slide the assembly onto the tracks of the baseplate.
4. Move the slide mount assembly to the rearmost position. Install the plungers into the outboard ends of the slide mount. Engage the plungers in the rail teeth.
5. Install the rear stops under the curled edge of the baseplate. Allow a clearance of about 1/8 inch (3 mm) from the rear stops to the slide mount (when it's in the full rear position. The stops should be about 1/4 to 1/2 inch (6 to 13 mm) from the rear edge of the baseplate). See **Fig. 4**.
6. Clamp the rear stops in place, then move the slide mount assembly forward and out of the way.
7. Weld the stops in place. The welds should be 1/4-inch (6 mm) fillet. On the forward edge, weld only the center area; not the area where the slide mount assembly contacts the stop. See **Fig. 4**.
8. Move the slide mount assembly to the rearmost position and check for clearance. Make sure the plungers seat into the rail with all teeth engaged.
9. If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), and if new release levers are being installed, attach the right and left release levers to the tie bar (**Fig. 3**). Install

3/8–16 capscrews and locknuts and tighten them firmly, but make sure the parts are not binding.

Using the 1/2–20 capscrews and locknuts, attach the air-release cylinder or the manual release lever to the ends of the release levers, tighten the nuts firmly, but make sure the parts are not binding.

10. Install the spring compression stops and the plunger return springs on the inboard ends of the plungers. Then install the spring retainers.

⚠ WARNING

Parts are under spring compression. Wear safety goggles during disassembly and assembly, and keep fingers away from possible pinch points at the ends of springs. Failure to do so can result in bodily injury, due to parts ejecting with force.

11. Using a Holland TF–TN 2500 spring compressor, compress one of the plunger return springs and its spring retainer enough to access the hole through the end of the plunger shaft.

12. If equipped with a standard fifth wheel, position the air-release cylinder or the manual release lever so that the holes in its clevis line up with the hole through the end of the plunger shaft. Install the retaining pin.

    If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), line up the holes in the clevis of one of the release levers (**Fig. 3**) with the hole in the end of the plunger shaft. Install the retaining pin.

13. Carefully remove the spring compressor.

14. Repeat the procedure on the other side of the vehicle.

15. If the fifth wheel has a manual release sliding mount, then go to the next step, otherwise connect the air lines.

    15.1 Remove the plugs from the air line.

    15.2 Connect the air line to the inlet on the air-release cylinder.

    15.3 Start the engine to build air pressure, then check the operation of the slide mechanism.

16. Adjust the plungers, following the procedure in **Subject 110**.

17. Install the top plate.

    17.1 If equipped with model XA–3501 top plate, using an overhead hoist, lift the fifth wheel onto the slide mount assembly.

    From both the right and left side of the top plate, install the bushing pins and the roll pins (**Fig. 1**).

    17.2 If equipped with model XA–351 top plate, using an overhead hoist, lift the fifth wheel onto the slide mount assembly.

    From both the right and left side of the top plate, Install the bushing pins. Then, install and tighten snugly the 1/2–20 bushing pin capscrews and locknuts (**Fig. 1**).

Adjustment

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Incorrect or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

NOTE: The locking plungers are adjusted at installation and again after one month of operation. Make additional adjustments as needed.

1. The plungers should seat in the pocket with a small amount of play when locked (engaged). See **Fig. 1**. If they wedge or bind, turn the adjusting bolt clockwise or counterclockwise as needed.

   Turning the adjusting bolt clockwise moves the plunger out of the pocket; turning it counterclockwise moves the plunger further into the pocket.

2. If the plungers don't unlock (release), check the air-release cylinder or the manual release lever for correct operation. Replace it if needed. See **Subject 100** for removal and installation instructions.

3. If the adjusted plunger binds on the bottom of the pocket, remove it; then grind the plunger top edges 1/16 inch (2 mm). See **Fig. 2**. Install the plunger. See **Subject 100** for plunger removal and installation instructions.

   Adjust the plunger, following the instructions above.

4. If the plungers are too loose, check the tension of the plunger return springs. If the springs are damaged or worn, replace them, following the instructions in **Subject 100**.

   If the plungers are still too loose, replace the plungers, following the instructions in **Subject 100**.

General Information

Fontaine H5092 series fifth wheels couple to trailers having a standard 2-inch kingpin. When installed as a stationary mount, the fifth wheel is bracket-mounted to the tractor frame in a position that best distributes the trailer load over the tractor axles. Sliding fifth wheels (**Fig. 1**), are mounted on the Fontaine HAWB or HMWS (previously called 5AWB and 5MWS) model slide mounts.

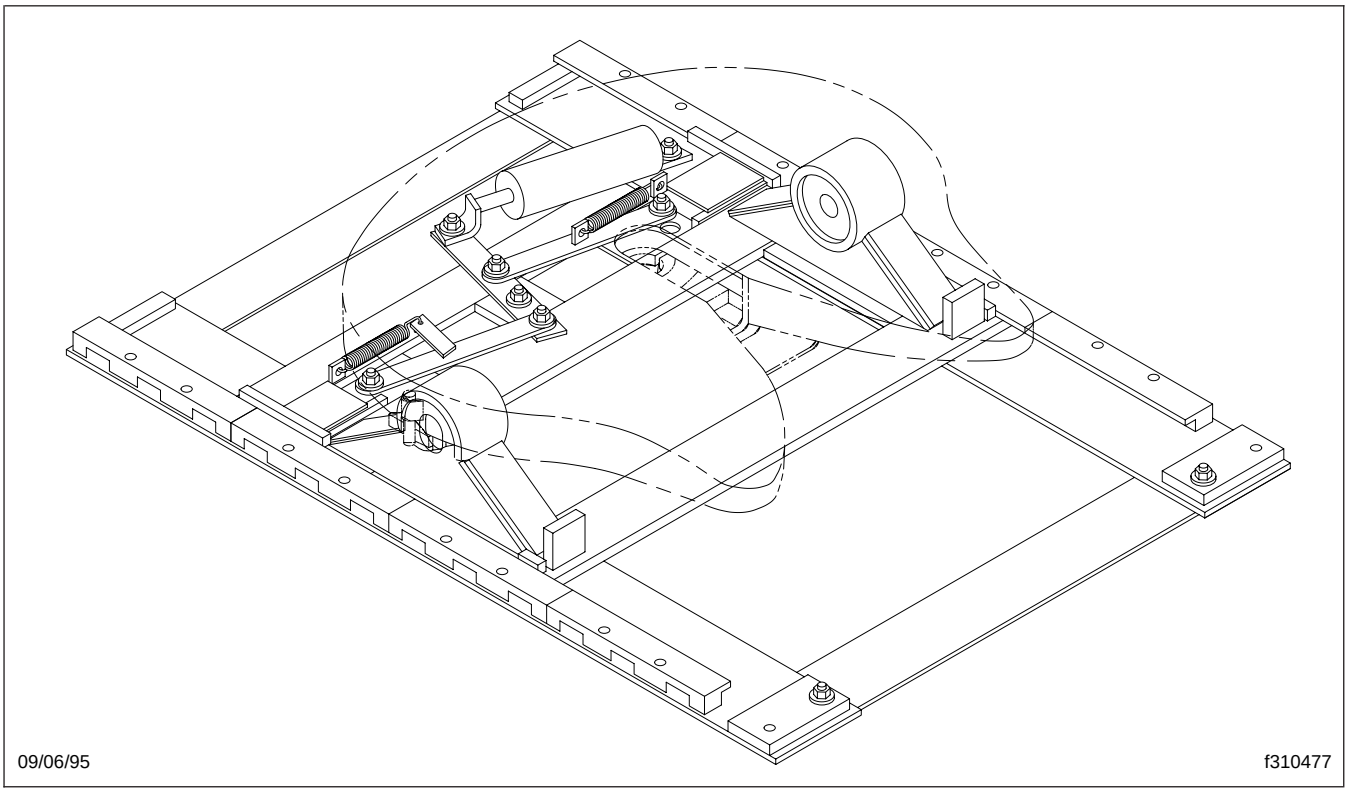

Fig. 1, Fontaine H5092 Series Air Slide Fifth Wheel

The Fontaine fifth wheel lock mechanism for the trailer kingpin consists of a spring-loaded jaw and sliding wedge. Kingpin release is accomplished by pulling a manual lock control handle located on either the right side (curbside) or left side (roadside) of the fifth wheel. Kingpin coupling occurs when the kingpin enters the throat of the fifth wheel, triggers the jaw and wedge to slide into place behind the kingpin, and moves the lock control handle into the locked position.

As the kingpin enters the lock mechanism, the jaw is moved first with the spring-loaded wedge sliding in place against the jaw. The jaw will move behind the kingpin, followed by the wedge. The wedge reinforces the jaw and automatically adjusts for slack around the kingpin. See **Fig. 2** for an illustration of the jaw and wedge in the locked position.

Placing the lock control handle in the unlocked position moves the wedge and jaw out from behind the kingpin and unlocks the fifth wheel. See **Fig. 3** for an illustration of the jaw and wedge in the unlocked position.

3. Turn the fifth wheel upside down.

NOTE: While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.

⚠ WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or if parts are damaged. The top plate or parts could malfunction. This could result in disengagement of the trailer during vehicle travel, possibly causing personal injury and property damage.

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in possible disengagement of the trailer

IMPORTANT: Replace any parts that show signs of wear, damage, or deterioration.

Fifth Wheel Assembly and Installation

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Always assemble the parts around a 2-inch kingpin or a shaft with a 2-inch diameter. Insert the jaw first and then the new wedge below it. Apply a moderate amount of grease having EP (extra pressure) additives to the sides and serrated edges of the jaw and wedge. Also apply grease to the stationary jaw in the throat of the fifth wheel. See **Fig. 2**.

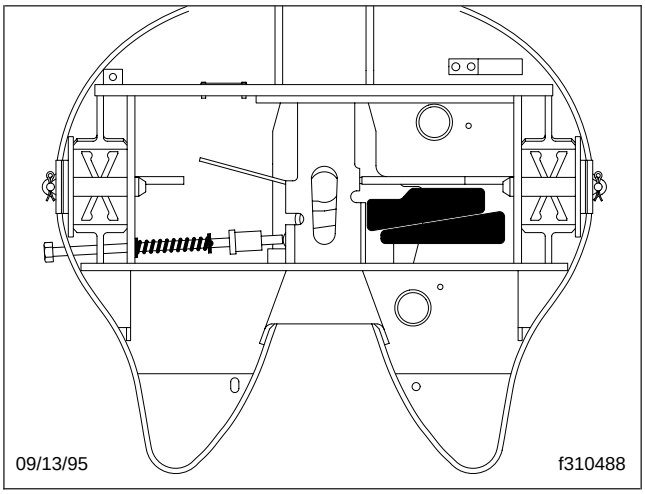

Fig. 2, Wedge and Jaw Installation

3. Insert the new wedge spring through the slot in the rear crossmember and lay the coil over the spring boss. Using a spring tool, engage the small hooked tail of the wedge spring and wind it around until it is directly over the small stud at the back of the bracket. Using a hammer, nudge the spring downward allowing it to catch on the stud. Insert a new cotter pin. See **Fig. 3**.

   Repeat these steps to replace the jaw spring.

NOTE: The jaw spring has minimal tension and can be replaced by hand.

4. Place the bumper back in position, sliding the bumper tang through the operating handle guide slot and toward the tab on the side of the fifth wheel substructure. See **Fig. 4**.
5. Apply a liberal amount of grease to the grooved middle section of the operating handle, then insert the operating handle and move it over to the side of the wheel. See **Fig. 5**.

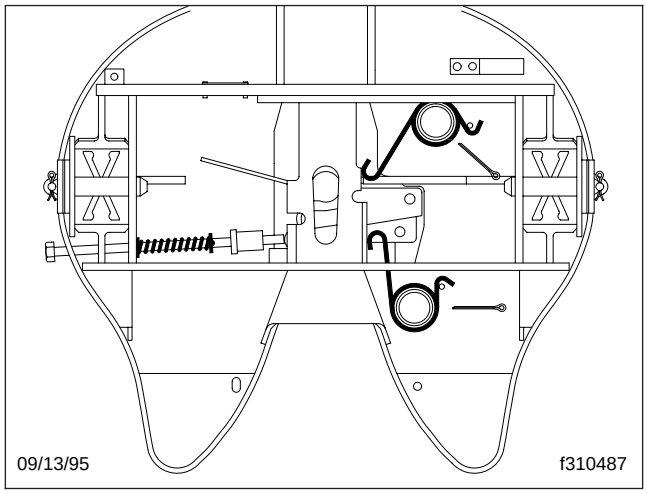

Fig. 3, Spring Installation

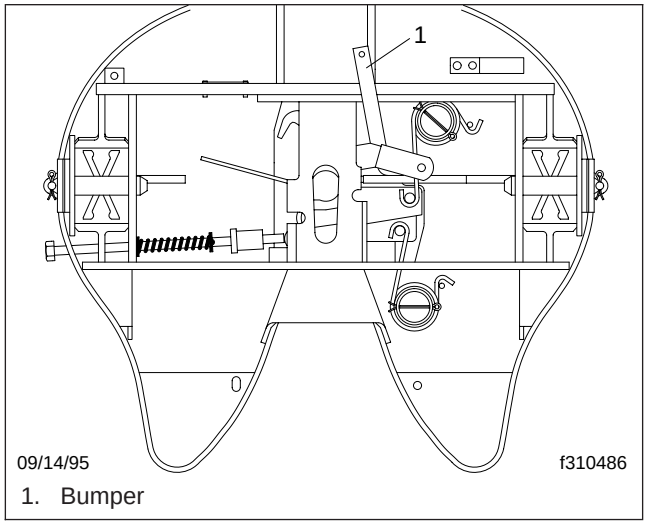

Fig. 4, Bumper Installation

6. Insert the timer over the jaw and wedge studs. the small hole on the timer fits over the jaw stud and the slotted hole fits over the wedge stud. Be certain the small bent arm of the timer is facing downward. See **Fig. 6**.
7. Slide the operating handle toward the center of the wheel to engage the handle with the studs on the jaw and wedge. Slide the top part first. This will ensure that the grooves on the operating handle are aligned with the studs. A correctly aligned operating handle should be in a vertical position once it goes over the studs. See **Fig. 7**.

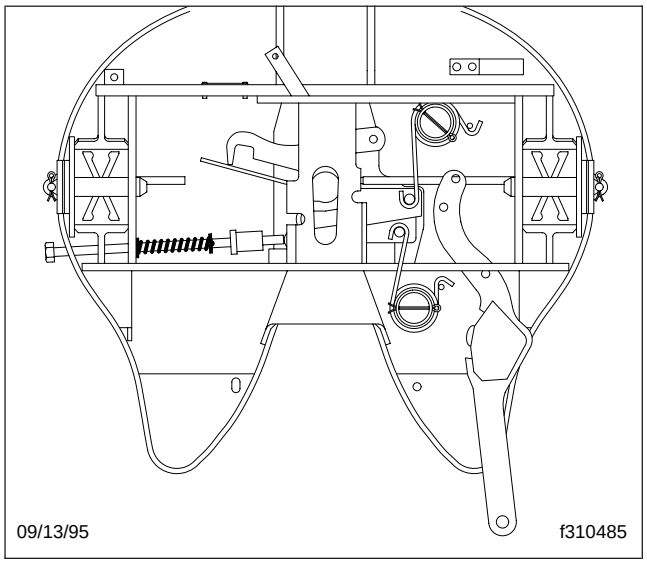

Fig. 5, Operating Handle Installation

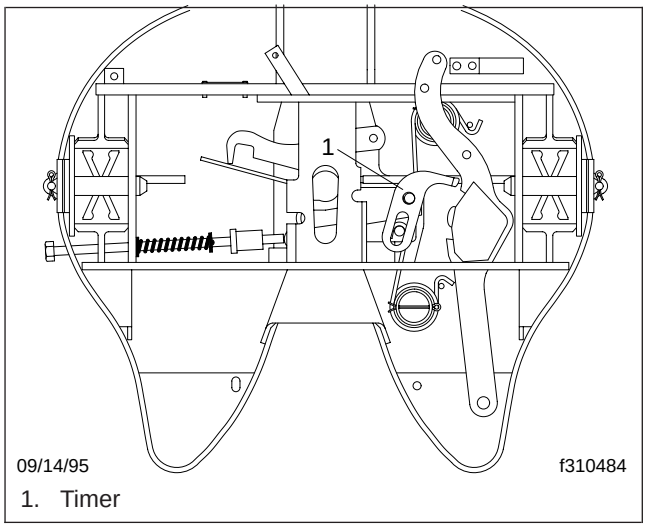

Fig. 6, Timer Installation

8. Slide the pull handle in through the safety lock and using the cotter pin and washer, fasten it in the top hole of the operating handle. See **Fig. 8**.

9. Align the bumper hole with the hole in the operating handle. Replace the bolts on the operating handle. The bolt which fastens the operating handle to the bumper must be inserted with the threads facing toward you to prevent interference with the jaw springs. The other bolt should be positioned with the threads facing downward. Each bolt has a nut, washer, and new bushings.

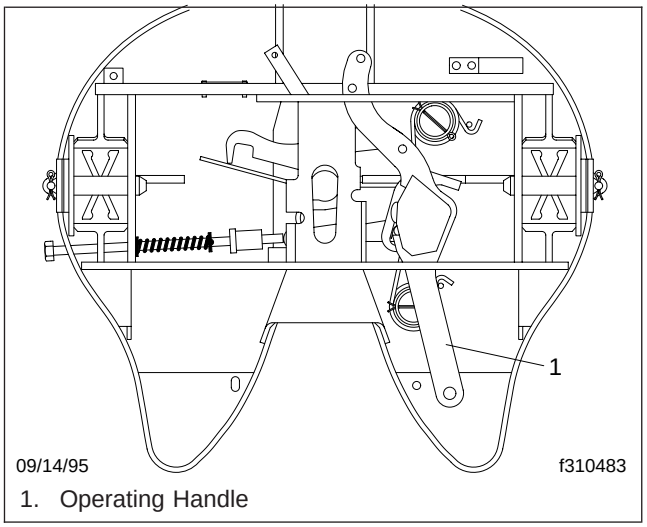

Fig. 7, Operating Handle Positioning

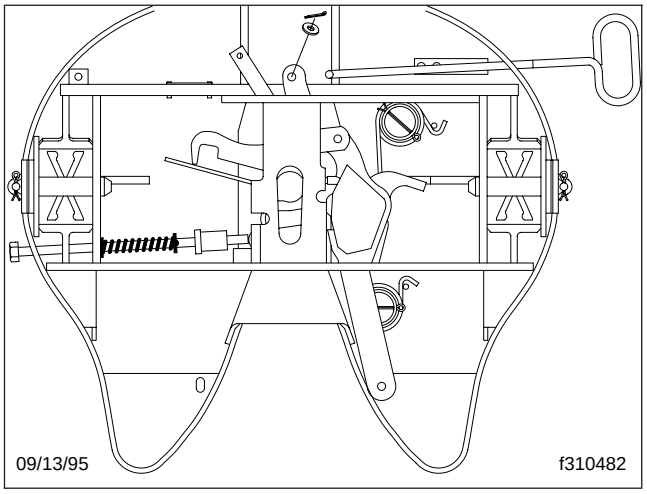

Fig. 8, Pull Handle Installation

Apply grease to the bolt parts and where there is metal to metal contact with the operating handle. See **Fig. 9**. Do not overtighten the bolts. Lubricate all pivot points.

IMPORTANT: The fifth wheel must be well lubricated to operate correctly. Refer to Group 31 of the *Century Class Maintenance Manual* for complete maintenance and lubrication instructions for the fifth wheel assembly.

10. Connect the bumper spring to its clasp. Apply grease to the bracket pockets and to the grease fittings on the side of the fifth wheel until grease

Fifth Wheel Assembly and Installation

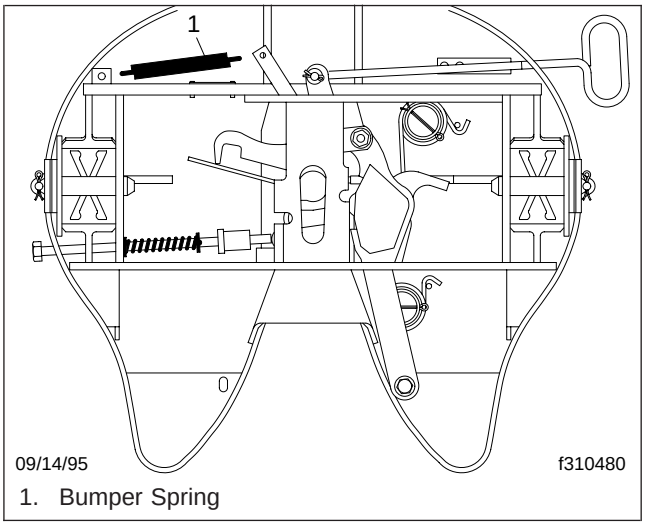
flows into the upper brackets. Also apply a liberal amount of grease to the top plate. See **Fig. 10**.



1. Bumper Spring

Fig. 10, Spring Installation

WARNING

If the fifth wheel does not operate properly, do not use it. The fifth wheel could malfunction, resulting in personal injury or property damage due to possible disengagement of the trailer from the tractor.

11. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Install the retaining pins and the 1-inch long cotter pins.

Troubleshooting Tables

Problem—Difficulty Coupling

Possible Cause	Remedy
The kingpin is too high to trip the latch	Lower the landing gear.
The trailer plate or kingpin is damaged	Check the trailer plate for flatness. Check the kingpin for squareness with the trailer plate.

Problem—Excessive Wear on the Fifth Wheel Top Plate

Possible Cause	Remedy
Damaged trailer plate	If the trailer plate is not flat, replace it.

Problem—Difficulty Uncoupling

Possible Cause	Remedy
Pressure on the locking mechanism caused by truck drifting apart from the trailer putting excess pressure on the lock	Back up the trailer and set the brakes. Strike the wedge stop rod which protrudes through the side of the fifth wheel. This spring-loaded rod will release the pressure on the locking mechanism.
Oval-shaped kingpin	Lower the landing gear.
Debris build-up in the grease	

Problem—Slack

Possible Cause	Remedy
Undersized kingpin	Replace the kingpin if worn greater than 1/8 inch (3 mm) at the 2-inch (5 cm) diameter.
Worn jaw and wedge	Jaw and wedge could have excessive wear. Replace them.

General Information

The Fontaine sliding fifth-wheel mount is designed to provide optimum axle loading for maximum tractor use with different lengths and types of trailers. The sliding fifth-wheel mount is used with the Fontaine 5092 series fifth wheel and is equipped with either an air-operated release slide (5AWB model), or a manual release slide (5MWS model).

Sliding fifth wheel assemblies are mounted on slide rails that are attached to the vehicle frame. Slots are evenly spaced along the slide rails, and retractable tapered wedges are positioned through the slots to hold the fifth wheel in the desired position. This assembly allows forward or rearward movement of the fifth wheel along the slide rails for optimum weight distribution over the tractor axles. The slide rails are bolted to the tractor frame.

When the fifth wheel is in the desired position, it is locked in place by tapered wedges that engage in the slots under the sliding mount. To release the fifth wheel, the wedges are withdrawn (manually or air-operated).

The air-operated release slide contains an air cylinder (**Fig. 1**) which locks and unlocks both sides of the sliding mount at the same time. The air cylinder is activated by a two-position air-control valve in the tractor cab.

The manual release slide assembly (**Fig. 2**) contains a slide locking control handle, located on the left side (roadside) of the fifth wheel, which locks or unlocks both sides of the sliding mount.

Refer to the vehicle driver's manual for complete operating instructions.

⚠ WARNING

WARNING: The lifting device used to remove the top plate must be able to lift 500 lbs (227 kg). The top plate weighs 254 lbs (115 kg) and if dropped could cause personal injury or property damage.

1. Remove the top plate. **See Fig. 3.**

1.1 Using a lifting device to support the top plate, remove the two cotter pins.

1.2 Remove the two lower bracket retainer pins, and discard them.

1.5 Clean and inspect all the parts. Replace parts as needed.

2. If the fifth wheel mount is equipped with a manual release (**Fig. 2**), go to the next step for disassembly instructions.

   If the fifth wheel mount is equipped with an air release cylinder (**Fig. 1**), disassemble it as follows:

2.1 Drain the air from the air cylinder, and disconnect the air line from the cylinder. Install plugs in the air line and the cylinder to prevent dirt or other matter from entering them.

2.2 Remove the locking wedge springs (**Fig. 1**, Ref. 15), the capscrews (Ref. 9), the spacers, the washers, and the locknuts. Discard the locknuts and spacers.

2.3 Remove the locking wedge release bars.

2.4 Remove the capscrew (Ref. 12), the spacer, the washer, and the locknut. Discard the locknut.

Remove the capscrew (Ref. 11), the spacers, the washers, and the locknuts. Discard the locknuts and the spacers.

2.5 Remove the locking wedges.

2.6 Remove the capscrew (Ref. 13), the spacer, the washer, and the locknut. Discard the locknut and the spacer.

2.7 Remove the air cylinder.

3. If the fifth wheel mount is equipped with a manual release (**Fig. 2**) disassemble it as follows:

3.1 Remove the three springs from the sliding mount assembly.

3.2 Remove the locknuts (**Fig. 2**, Ref. 1), the washers, the spacer bushings, and the capscrews from the tapered wedges.

3.3 Remove the locking wedges.

3.4 Remove the locknuts from the pull handle, and the locking wedge release bars.

Remove the spacer bushings, washers, and capscrews.

Remove the locking wedge release bars and the pull handle from the latching lever.

3.5 Remove the locknut, washer, spacer bushing, and capscrew from the latching lever.

Remove the latching lever.

4. If the sliding mount assembly is damaged, remove it as follows:

4.1 Remove the nuts, washers, and capscrews that secure the rear slide stops to the rear of the slide rail.

4.2 Grind down the welded area to remove the rear stops.

4.3 Remove the sliding mount assembly from the baseplate by sliding it off the rear of the tracks.

5. Remove all dirt and grease from the parts. Replace any parts that show signs of wear, damage, or deterioration.

Assembly (See Fig. 1 or Fig. 2)

WARNING

WARNING: All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in possible disengagement of the trailer from the tractor, leading to personal injury or property damage.

1. Using a multipurpose chassis lube, grease the flanges on the sliding mount. Then, slide the assembly onto the tracks of the baseplate.

2. Slide the mounting assembly to the rearmost position. Position the wedges in the rail.

Install the capscrews, washers, and nuts that secure the rear stops to the baseplate.

3. Slide the mounting assembly out of the way, then weld the stops in place. The welds should be 1/4-inch (6 mm) fillet.

4. Slide the mounting assembly to the rearmost position and check for clearance. Make sure that the wedges seat in the rail.

5. If the fifth wheel mount is equipped with a manual release (**Fig. 2**), go to the next step for assembly instructions.

If the fifth wheel mount is equipped with an air release cylinder (**Fig. 1**), assemble it as follows:

NOTE: To avoid damaging the spacers, tighten the locknuts only one turn beyond finger tight.

5.1 Install the capscrews (**Fig. 1** , Ref. 9) and spacers in the locking wedges.

5.2 Using capscrews, spacers, washers, and new locknuts, fasten the latching lever to the locking wedge release bars.

5.3 Slide the locking wedges into the slide assembly guide, and place the locking wedge bars and latching lever on the assembly. Bolt down the locking wedge release bars with new washers and locknuts.

5.4 Apply grease to the locking member and the assembly.

5.5 Install the air cylinder using new spacers and locknuts. Install the locking member spring.

6. If the fifth wheel mount is equipped with a manual release (**Fig. 2**) assemble it as follows:

NOTE: To avoid damaging the spacers, tighten the locknuts only one turn beyond finger tight.

6.1 Using a capscrew, spacer bushing, washer, and locknut, install the latching lever.

6.2 Using capscrews, spacer bushings, washers, and locknuts, attach the locking wedge release bars and pull handle to the latching lever.

6.3 Using capscrews, spacer bushings, washers, and locknuts, attach the locking wedges to the locking wedge release bars.

6.4 Install the three springs on the bracket assembly.

⚠ WARNING

WARNING: The lifting device used to remove the top late must be able to lift 500 lbs (227 kg). The top plate weighs 254 lbs (115 kg) and if dropped could cause personal injury or property damage.

7. Install the top plate on the fifth wheel mount. **See Fig. 3.**

7.1 Install new bracket bushings in the slide bracket.

7.2 Lubricate the brackets and the bearing pockets in the top plate with bearing grease.

7.3 Set the top plate on the mounting brackets, and align the bracket pin holes in the top plate with the mounting bracket holes.

7.4 Insert new lower bracket pins.

7.5 Insert new lower bracket retainer pins. Insert new cotter pins in the lower bracket retainer pins.

General Information

The Premier models 260 and 460 trailer couplings (**Fig. 1**) are air adjusted. When they are in use, an air chamber and push rod at the rear of the coupling (**see Fig. 2**) reduce any slack between the coupling and the drawbar eye of the trailer. This provides smoother towing and reduces wear on the parts.

The design and load capacity of the 260 and 460 models are the same; the only difference between the two models is the bolt-hole pattern for mounting.

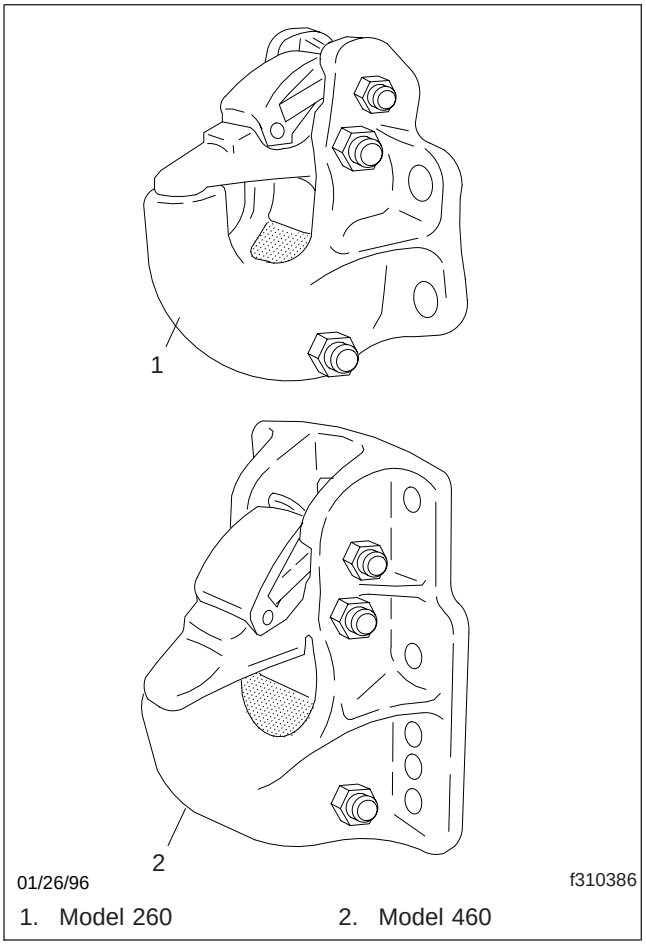

Fig. 1, Premier Trailer Couplings

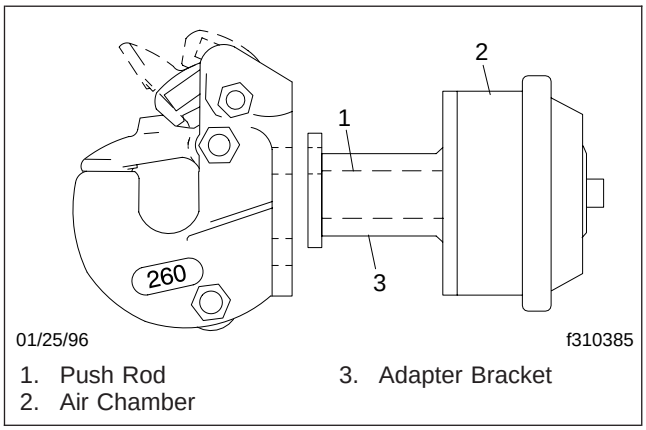

Fig. 2, Air Chamber and Push Rod

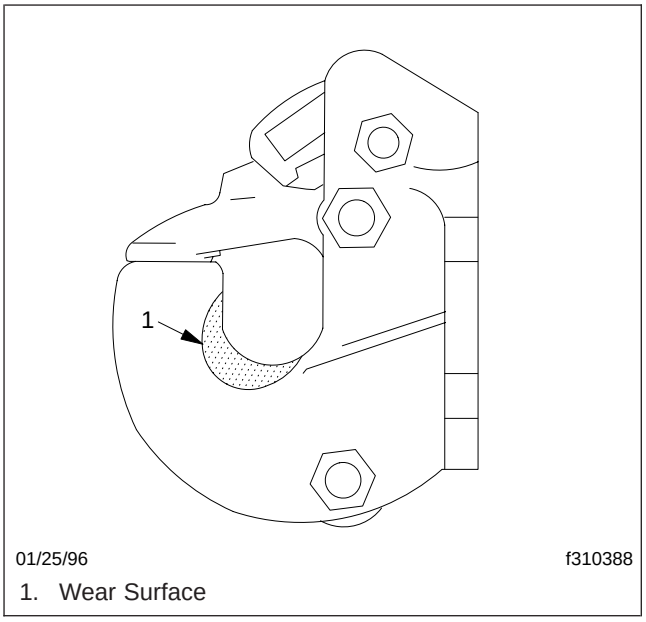
Pintle Hook Inspection

Check the pintle hook for damage or stress cracks, then check it for wear on its lower inside surface. **See Fig. 1.** Use Premier wear gauge 14014 (**see Fig. 2**) to check the percentage of wear on the pintle hook.

⚠ WARNING

WARNING: If the pintle hook is damaged, has stress cracks, or if it's worn beyond 20% of its original diameter, replace the entire coupling; don't repair it. Using a worn or damaged trailer coupling could cause the trailer to disconnect from the vehicle, which could result in an accident causing serious personal injury and property damage.

If the pintle hook is damaged, or if it's worn beyond 20% of its original diameter, replace the entire coupling; it is not repairable.



1. Wear Surface

Disassembly

CAUTION

CAUTION: If the pintle hook is damaged, has stress cracks, or if it's worn beyond 20% of its original diameter, replace the entire coupling; don't repair it.

WARNING

WARNING: When disassembling the trailer coupling, wear safety glasses. Some of the parts are under tension (such as springs), and could fly out, possibly causing eye injury.

1. Remove the coupling from the vehicle; then put it on its side, with the pawl-, latch-, and shoe-bolt nuts facing up.
2. Remove the pawl-bolt nut and pawl bolt (**see Fig. 1** and **Fig. 2**); then remove the pawl assembly from the coupling body.

4. Remove the latch nut and bolt (**see Fig. 1**); then remove the latch.
5. Remove the shoe nut and bolt.
6. From the bottom of the coupling body, compress the shoe spring, then remove the shoe from the coupling body.

Assembly

1. Check for wear on all the parts that aren't included in the new parts kit. Replace them if needed.
2. Put the coupling body on the workbench with the mounting surface down, and the bottom of the body facing you.
3. Install the shoe, then the shoe bolt and nut (**see Fig. 1**) in the bottom of the coupling body.
4. Install the shoe spring in the recess inside the coupling body.
5. Install the pawl bolt part way into the left side of the coupling body; then put the pawl spring over the end of the bolt. Make sure the tang on the spring is pointing inboard.
6. Install the pawl lock (**see Fig. 2**) in the body so the spring tang hooks onto the lip of the pawl lock. **See Fig. 3.**
7. Install new nylon bushings in the pawl, then install the compression spring and wedges in the pawl.
8. While compressing the pawl wedges, install the pawl assembly in the pawl lock and the coupling body, aligning the holes of the pawl and pawl lock with the pawl bolt.
9. Push the pawl bolt through the holes of the pawl lock and the pawl just far enough to hold them in place, then install the spacer (**see Fig. 2**) onto the end of the pawl bolt.
10. Push the pawl bolt all the way through the right side of the coupling body.

⚠ CAUTION

CAUTION: Don't overtighten the pawl-, latch-, and shoe-bolt nuts. To do so may cause the parts to bind, which could result in unnecessary wear on the latch assembly.

12. Install the nuts on the pawl bolt, latch bolt, and shoe bolt. Tighten them snugly.
13. Lubricate all the moving parts—but not the pintle hook—with a light penetrating oil. Open and close the latch several times to distribute the oil.

General Information

The Premier model 690 trailer coupling (**see Fig. 1**) is a non-air-adjusted, heavy-duty coupling. It is used for load capacities up to 90,000 lbs, and is available with either right- or left-hand operation.

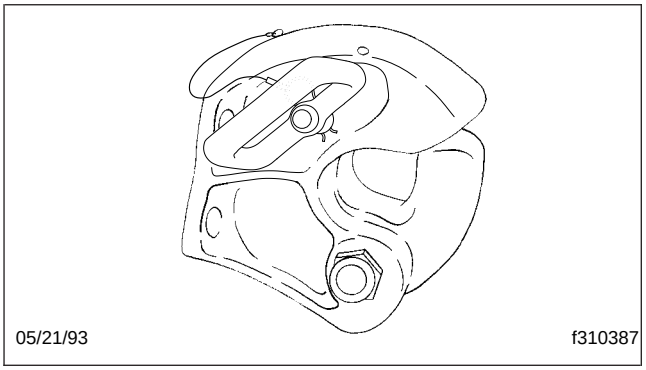

Fig. 1, Premier 690 Trailer Coupling

Pintle Hook Inspection

Check the pintle hook for damage or stress cracks, then check it for wear on its lower inside surface. **See Fig. 1.** Use Premier wear gauge 14014 (**see Fig. 2**) to check the percentage of wear on the pintle hook.

⚠ WARNING

WARNING: If the pintle hook is damaged, has stress cracks, or if it's worn beyond 20% of its original diameter, replace the entire coupling; don't repair it. Using a worn or damaged trailer coulpling could cause the trailer to disconnect from the vehicle, which could result in an accident causing serious personal injury and property damage.

6. Install the bushing over the threaded end of the handle, then install the nut.
7. Turn the handle toward yourself, then—from the bottom of the coupling body—install the small pawl spring (**see Fig. 2**) in the depression on the pawl. **See Fig. 5**. Make sure the other end of the spring fits into the depression inside the coupling body.
8. Rotate the pawl up and lock it into position by turning the handle away from you, then pushing it in.

⚠ CAUTION

CAUTION: Don't overtighten the nuts for the pintle hook and the handle. To do so may cause the parts to bind, which could result in unnecessary wear on the coupling.

9. Set the coupling body on its mounting surface, then install the new pintle hook, bolt, and nut. Tighten the nuts on the pintle hook bolt and the handle snugly.
10. Install the new locking pin assembly (**see Fig. 2**) on the top of the coupling body.
11. Lubricate all the moving parts with light penetrating oil. Don't lubricate the wear surface of the pintle hook. Open and close the pintle hook several times to distribute the oil.
12. Install the coupling on the vehicle. Tighten the mounting bolts 320 lbf·ft (434 N·m).

NOTE: Before performing the 294 bolt replacement procedure, first verify that the 690 coupling is not in need of a complete repair kit. Perform the inspection procedure in **Subject 100**.

2. If the bolt is an old style with a snap ring, remove the 295Z-87 snap ring from the end of the 294 bolt, then discard it.
3. Remove the 297 locknut and discard it.
4. Firmly gripping the 692 pintle, slide the 294 bolt out of the 690 coupling body.
5. Using a hammer or file, destroy the threaded end of the 294 bolt and discard it.
6. Thoroughly clean the 690 coupling body holes where the 294 bolt was inserted, as well as the interior surfaces of the 690 coupling body. Clean the hole and all surfaces of the 692 pintle.
7. On each side of the coupling body, measure the hole diameters where the 294 bolt was inserted. If a hole diameter exceeds 1.156 inches (29.36 mm) the coupling body is considered out-of-service and must be replaced.
8. Inspect the holes around the 691 release handle for wear. If there is a gap of 1/32-inch (0.79 mm) or greater between the 691 handle shaft and hole circumference, remove the handle assembly, then measure the hole diameters. If a hole diameter exceeds 1.30 inches (33.02 mm), the coupling is to be considered out-of-service and must be replaced.
9. Test fit the 294 bolt by inserting it from the right side through the holes of the 690 coupling body, without the 692 pintle in place. Make certain that the new 294 bolt head is flush with the outer 690 coupling body side wall.

   If the new 294 bolt head and the 690 coupling body are not flush, two possible causes are shown in **Fig. 2**.

   - Arrow A indicates a gap between the new 294 bolt head and the 690 coupling body caused by the hole in the 690 coupling body not being chamfered. This can be resolved by grinding a 45 degree chamfer, no larger than 1/16 inch (1.59 mm), around the entire circumference of the 690 coupling body hole.
   - Arrow B indicates a gap because the bolt stop is preventing the bolt from sitting flush to the coupling body. This can be corrected by grinding or filing the bolt stop until the bolt head clears it.
10. For final assembly, remove the 294 bolt and apply heavy grease to the the 692 pintle hole, the 690 coupling body holes, and the shank of the new 294 bolt (do not lubricate the threads).
11. Place the 692 pintle into the 690 coupling body, aligning the pintle hole with the body holes. From the right side, insert the new 294 bolt through the aligned holes. Clean all signs of lubrication from

General information

The Holland model PH–T–60–AL trailer coupling (see **Fig. 1**) has a rigid-type pintle hook. It is designed for trailers with a maximum gross weight of 10,000 lbs. It is mounted to the vehicle by 1/2–13 fasteners.

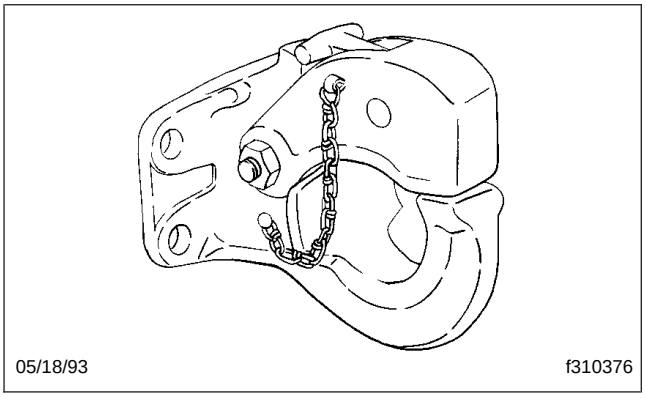

Fig. 1, Trailer Coupling

Pintle Hook Inspection

⚠ WARNING

WARNING: If the pintle hook is damaged, has stress cracks, or if it's worn beyond 1/8 inch of its original diameter, replace the entire coupling; don't repair it. Using a worn or damaged trailer coupling could cause the trailer to disconnect from the vehicle, which could result in an accident causing serious personal injury and property damage.

Check the pintle hook for damage or stress cracks, then check it for wear on its lower inside surface. **See Fig. 1**.

If the pintle hook is damaged, or if the wear surface is worn deeper than 1/8 inch (3 mm), replace the entire coupling; it is not repairable.

Assembly

1. Install a new latch and lock assembly, aligning its holes with the holes in the coupling body. See Fig. 1.

CAUTION

CAUTION: Don't overtighten the latch-bolt nut. To do so may cause the parts to bind, which result in unnecessary wear on the coupling.

2. Install the latch bolt, then the latch bolt nut. Tighten the nut snugly.
3. If replacing the cotter pin and chain, install them using a new drive pin.
4. Lubricate all the moving parts—but not the pintle hook—with a light penetrating oil. Open and close the latch several times to distribute the oil.
5. Install the coupling on the vehicle. Tighten the fasteners 68 lbf·ft (92 N·m).

Non-Aerodynamic Bumper Removal and Installation, Century Class S/T

Old-Style Bumper

Removal

1. Park the vehicle, apply the parking brakes, and chock the front tires.
2. If equipped with road lights, disconnect the wiring harness from each road light.
3. Support the bumper; then remove the upper mounting hexnut and washer, and lower capscrew and washer from each side of the bumper front. See **Fig. 1**.
4. At one end of the bumper, remove the hexnuts and washers that attach the Z-bracket to the end of the tubular support. See **Fig. 1**. Repeat the procedure on the other end of the bumper.
5. Remove the bumper and the Z-brackets from the vehicle.
6. If you are replacing the bumper, remove the Z-brackets from the bumper ends. Also remove the road lights, if so equipped.

Installation

1. If they were removed, attach the Z-brackets to the ends of the bumper, using Torx-head screws and washers. Tighten the screws firmly.
2. Put the bumper in position, aligning the upper holes in the bumper mounting brackets with the threaded studs on the hood and bumper support brackets. Align the holes in the lower part of the mounting brackets with those in the lower part of the hood and bumper support brackets. See **Fig. 1**.
3. Adjust the bumper-to-hood gap.
   - 3.1 On one side of the vehicle, install the washer and the 1/2–13 capscrew into the slotted hole on the lower part of the hood and bumper support bracket. Then install the capscrew into the lower hole on the bumper mounting bracket. See **Fig. 1**.
   - 3.2 Install the 1/2–13 hexnut and washer onto the capscrew, and tighten it finger-tight.
   - 3.3 Move the bumper up or down as needed until the upper edge of the bumper is parallel to the lower edge of the hood.
   - 3.4 Tighten the hexnut 50 lbf·ft (68 N·m).
   - 3.5 Repeat the procedure for the other side of the vehicle.
4. Install the upper mounting hexnuts and washers. Tighten them 50 lbf·ft (68 N·m).
5. On one side of the vehicle, connect the Z-bracket to the tubular support strut, using the fasteners previously removed. Tighten the fasteners 15 lbf·ft (20 N·m). Repeat the procedure on the other side of the vehicle.
6. If removed, attach the road lights to the bumper. Connect the wiring harness to each road light.
7. Remove the chocks from the front tires.

New-Style Bumper, Three-Point Hood Mounting

Removal

1. Park the vehicle, apply the parking brakes, and chock the front tires.
2. If equipped with road lights, disconnect the wiring harness from each road light.
3. Support the bumper; then remove the upper and lower mounting hexnut and washer from each side of the bumper front. See **Fig. 2** for vehicles with 1350 sq. in. radiators and **Fig. 3** for vehicles with 1200 sq. in. radiators.
4. Remove each end of the bumper from the tubular support and the splash shield. See **Fig. 4**.
   - 4.1 At one end of the bumper, remove the 1/2–13 mounting bolt and washer attaching the support arm to the outboard bumper support bracket.
   - 4.2 Remove the 5/16–18 mounting bolt, locknut, and washers attaching the splash shield to the outboard bumper support bracket.
   - 4.3 Repeat this procedure at the other end of the bumper.
5. Remove the bumper from the vehicle with the outboard bumper support bracket attached.

Installation

1. Install the two bolts that attach the rear quarter-fender to the top chassis-access step, as removed. Make the bolts finger-tight only.
2. Attach the rear quarter-fender to the tool box, as removed.
   - 2.1 Open the tool-box door and leave it up.
   - 2.2 Position the backing plate on the rear surface of the tool box and align it over the holes for the mounting screws.
   - 2.3 Install the four bolts that attach the rear quarter-fender to the tool box, as removed. Make the bolts finger-tight only.
   - 2.4 Close the tool-box door.
3. Install the bolt that attaches the rear quarter-fender to the tool-box hanger bracket, as removed.
4. Tighten all the fasteners 50 lbf·ft (68 N·m).
5. Remove the chocks from the front tires.

General Information

Frame-mounted tool/storage boxes are available on Coronado models only. Tool boxes are mounted on each side of the vehicle, front and rear, for a maximum of four tool boxes. A full-length running board extends from the front fender to the rear quarter-fender.

The upper mountings of the tool boxes are attached to the frame by means of steel hanger brackets. The lower mountings of the tool boxes are attached to the step brackets.

Tool boxes come in the following lengths:

- 23.6 inches (600 mm)
- 27.6 inches (700 mm)
- 31.5 inches (800 mm)
- 35.4 inches (900 mm)

Tool boxes come with removable covers, or with sealed doors. Each sealed-door box has a door lock and an actuator to allow the door to remain in the open position. Removable covers are standard on the front tool box, and locking doors are standard on the rear tool box.

The front tool box is normally mounted underneath the cab between the front fender and the fuel tank. See **Fig. 1**. In some installations, it can be mounted aft of the fuel tank. The front tool box requires a battery box mounted between the frame rails. If a side-mounted battery box is specified, it replaces one of the front tool boxes.

The rear tool box is mounted underneath the cab between the fuel tank and the rear quarter-fender. See **Fig. 2**. On some vehicles, the rear quarter-fender is bolted to the aft end of the tool box.

Tool Box Removal and Installation, Coronado

Front Tool Box

Removal

1. Park the vehicle and apply the parking brakes. Chock all the tires.
2. Place a floor jack underneath the tool box and raise it until it exerts light pressure on the base of the tool box.
3. Remove the lower mounting bolts, two on each side, that attach the tool box to the step brackets. See **Fig. 1**.

4. Remove the upper mounting bolts, three on each side, that attach the tool box to the tool-box hanger brackets. Allow the jack to carry the weight of the tool box.
5. Remove the front portion of the running board. See **Section 60.21** for procedures.
6. Use the floor jack to slide the tool box out of the space between the front fender and the fuel tank.

Installation

1. Using a floor jack, slide the tool box in between the hanger brackets. The upper mountings of the tool box insert inside the hanger brackets, fore and aft.

NOTE: If necessary, use a prybar and/or rubber mallet to pound the upper mountings into place.

2. Attach the 1/2–13 x 1.75 upper mounting bolts, three to each hanger bracket, as removed. If necessary, re-position the jack until the bolt holes in each tool-box mounting line up with the holes in each hanger bracket. Tighten the locknuts 68 lbf·ft (92 N·m).
3. Install the front portion of the running board, as removed. See **Section 60.21** for procedures.
4. Attach the 5/8–11 x 2 lower mounting bolts, two to each step bracket, as removed. Tighten the bolts 136 lbf·ft (184 N·m).
5. Lower the floor jack and roll it out of the way.
6. Remove the chocks from the tires.

Rear Tool Box

Removal

1. Park the vehicle, apply the parking brakes, then chock all the tires.
2. Remove the running board. See **Section 60.21** for procedures.
3. Remove the rear quarter-fender. See **Section 31.13**, Subject 100, for procedures.
4. Remove the upper mounting bolts, three on each side, that attach the tool box to the tool-box hanger brackets. See **Fig. 2**.

NOTE: Two persons are recommended for this step.

6. If you are replacing the tool box, remove the step brackets and the top chassis-access step (if installed).

Installation

1. If removed, attach the 5/8–11 x 2 lower mounting bolts, two to each step bracket, as removed. Tighten the bolts 136 lbf·ft (184 N·m).
2. If removed, install the top chassis-access step on the tool box. Tighten the screws firmly.

NOTE: Two persons are required for this step.

3. While one person holds the tool box in position, the other person attaches enough upper mounting fasteners to hold the tool box in place (two on one side, one on the other).
4. Install the remaining mounting fasteners and tighten the locknuts 68 lbf·ft (92 N·m).
5. Install the rear quarter-fender. See **Section 31.13**, Subject 100, for procedures.
6. Install the running board. See **Section 60.21** for procedures.
7. Remove the chocks from the tires.

General Information

Fontaine 6000 and 7000 series fifth wheels couple to trailers having a standard 2-inch kingpin. When installed as a stationary mount, the fifth wheel is bracket-mounted to the tractor frame in a position that best distributes the trailer load over the tractor axles. Sliding fifth wheels are mounted on the Fontaine AWB or MWS model slide mounts.

The Fontaine fifth wheel lock mechanism for the trailer kingpin consists of a spring-loaded jaw and sliding wedge. Kingpin release is accomplished by pulling a manual lock control handle located on either the right side (curbside) or left side (roadside) of the fifth wheel. Kingpin coupling occurs when the kingpin enters the throat of the fifth wheel, triggers the jaw and wedge to slide into place behind the kingpin, and moves the lock control handle into the locked position.

As the kingpin enters the lock mechanism, the jaw is moved first with the spring-loaded wedge sliding in place against the jaw. The jaw will move behind the kingpin, followed by the wedge. The wedge reinforces the jaw and automatically adjusts for slack around the kingpin. See **Fig. 1** for an illustration of the jaw and wedge in the locked position.

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could

1. Steam clean the top plate. Remove it from the sliding mount by removing the cotter pins from the retaining pins. Remove the retaining pins and bushing pins from both sides of the top plate.

Removal and Disassembly

2. Using an overhead hoist, lift the fifth wheel off the sliding mount and tractor frame.
3. Turn the fifth wheel upside down.

NOTE: While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.

4. Remove the secondary lock spring and bumper spring. See **Fig. 2**. Remove the pull handle cotter pin and washer, then slide out the pull handle.

Assembly and Installation

⚠ WARNING

Before rebuilding the fifth wheel assembly, make sure that there are no cracks in the frame crossmembers or other frame components and fifth wheel mounting components. Also check the fifth wheel bracket pin holes to ensure they are not worn oversize (pins should fit snugly). Under no circumstances should a fifth wheel be repaired or used if any component (crossmember, saddle bearing, etc.) is cracked. Operating a fifth wheel with damaged components could result in disengagement of the trailer from the tractor, leading to personal injury or property damage.

Use a Moly-based lubricant such as Mobil grease Moly 50 or equivalent when applying lubricant to the locking jaw and wedge. Lightly oil other moving parts in the fifth wheel.

See **Fig. 1** for an exploded view of a Fontaine® 6000 or 7000 No-Slack II series fifth wheel.

1. Always assemble parts around a 2-inch kingpin or a 2-inch diameter shaft. Insert the jaw first, then the wedge below it. See **Fig. 2**. Grease the jaw and wedge on the top and bottom.
2. Install the timer and the timer spring. See **Fig. 3**.
3. Install the operating handle and bolt to the pivot mount. See **Fig. 4**. Use the existing bolt, washer, hairpin cotter pin and bushing. Inspect the bushing for wear before using it and replace it if necessary. Use the new locknut that is supplied in the repair kit. Note the orientation of the bolt (**Fig. 1**).
4. Install the bumper and bolt it to the operating handle. See **Fig. 5**. Use the existing bolt and washers (inspect for wear before using and replace if necessary). Use the new locknut and bushing that is supplied in the repair kit. Note the orientation of the bolt (**Fig. 1**). After installing the bumper, check to make sure that it can pivot freely.
5. Insert the secondary lock and bolt it to the operating handle. See **Fig. 6**. Use the existing bolt and washers (inspect for wear before using and replace if necessary). Use the new locknut and bushing that is supplied in the repair kit. Note the orientation of the bolt (**Fig. 1**).
6. Install the pull handle. See **Fig. 7**. Use the existing washer and cotter pin (inspect for wear before using and replace if necessary). Attach the new secondary lock/bumper spring that is supplied in the repair kit. Open and close the fifth wheel to ensure that it works properly. The fifth wheel must be properly lubricated before opening and closing the wheel.

Use a Moly-based lubricant such as Mobil grease Moly 50 or equivalent when applying lubricant to the locking jaw and wedge. Lightly oil other moving parts in the fifth wheel.

7. Close the fifth wheel several times with a standard 2-inch kingpin tool. With the lock closed, adjust the wedge stop rod so that the end is 1/4 inch (6 mm) from the wedge. See **Fig. 8**.
8. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Install the retaining pins and the 1-inch-long cotter pins.

Troubleshooting Tables

Problem—Difficulty Coupling

Possible Cause	Remedy
The kingpin is too high to trip the latch	Lower the landing gear.
The trailer plate or kingpin is damaged	Check the trailer plate for flatness. Check the kingpin for squareness with the trailer plate.

Problem—Excessive Wear on the Fifth Wheel Top Plate

Possible Cause	Remedy
Damaged trailer plate	If the trailer plate is not flat, replace it.

Problem—Difficulty Uncoupling

Possible Cause	Remedy
Pressure on the locking mechanism caused by truck drifting apart from the trailer putting excess pressure on the lock	Back up the trailer and set the brakes. Strike the wedge stop rod which protrudes through the side of the fifth wheel. This spring-loaded rod will release the pressure on the locking mechanism.
Oval-shaped kingpin	Lower the landing gear.
Debris build-up in the grease	

Problem—Slack

Possible Cause	Remedy
Undersized kingpin	Replace the kingpin if worn greater than 1/8 inch (3 mm) at the 2-inch (5-cm) diameter.
Worn jaw and wedge	Jaw and wedge could have excessive wear. Replace them.

General Information

The leaf spring assembly absorbs and stores energy, then releases it. Front suspension leaf spring assemblies are attached to the axle with U-bolts, hardened washers, and high nuts. Individual leaves are held together by a center-bolt. The spring eyes have either a rubber, bronze, or steel bushing. The front of the spring mounts with a pin through the spring eye to a frame bracket, and the rear of the spring mounts to a pair of shackles that are suspended from a frame bracket to allow for variations in spring length when the spring flexes. The spring pins may be threaded or non-threaded type. See **Fig. 1** and **Fig. 2**.

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

Removal

See **Fig. 1** and **Fig. 2** for this procedure.

1. Apply the parking brakes and chock the rear tires. Raise the vehicle until both wheels are off the ground. Support the frame with safety stands. The axle and leaf springs can then be manipulated with a floor jack.

IMPORTANT: Make sure the frame rails on each side are an equal distance off the ground.

2. On vehicles with tapered leaf spring assemblies, unplug the road-light wires behind the front bumper. Remove the bumper mounting bolts; reference the location of the mounting bolt spacers for later assembly. Remove the bumper from the vehicle.

   On vehicles with flat leaf spring assemblies, remove the wheel and tire. For instructions, see **Group 40** in this manual.

3. Remove the shock absorber. See **Subject 120** for instructions.

4. Remove the U-bolts, axle stop/shock absorber bracket, and spring liner (if equipped) from the spring.

NOTE: if necessary, remove the mud guards to access the shackles.

5. Remove the spring from the rear shackle.

   5.1 For shackles without pinch bolts, remove the lower shackle nut, washers, and bolt.

   5.2 For shackles with pinch bolts, remove the flanged pinch bolts, washers, and nuts that secure the lower shackle spring pin.

   If the spring pin is threaded, unscrew it from the bushing.

   If the spring pin is not threaded, drive it outboard with a suitable drift and remove it. Remove the spacing washers and wear plates (used only with non-threaded pins) and keep them with the pin. Make note of their correct location for later installation.

6. Remove the spring from the front frame bracket.

   6.1 For front brackets without spring pin retainers, remove the nut, washer, and spring-eye bolt.

   6.2 For front brackets with spring pin retainers, remove the nuts, washers, and bolts that attach the spring pin retainer to the front suspension bracket.

   If the spring pin is threaded, unscrew it from the bushing.

   If the spring pin is not threaded, drive it inboard with a suitable drift to remove it. Remove the spacing washers and wear plates (used only with non-threaded pins) and keep them with the pin. Make note of their location for later installation.

7. Remove the spring assembly by lifting it up off the axle and out the front of the truck. Note the taper direction of the caster shim so that it will not be reversed during installation.

8. If the shackle pin or shackle bracket bushings are to be inspected or replaced, remove the pin.

   8.1 If the shackle pin is not threaded, drive the pin outboard using a suitable drift to remove it.

   Remove the flanged pinch bolts and flanged nuts.

   Remove the spacing washers (used only with non-threaded pins) and keep them with the pin. Make note of their correct location for later installation.

   8.2 If the shackle pin is threaded, unscrew it from the shackle pin bushing.

9. Remove the shackle bracket for inspection; replace the bushing if necessary. See the applicable steps under "Cleaning and Inspection" in this subject.

Cleaning and Inspection

1. Using a wire brush and solvent or steam cleaning equipment, wash all parts to remove dirt, grease, and scale.

⚠ WARNING

Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

2. Inspect the shackle bracket and the spring shackles for cracks, wear, or other damage. Replace damaged parts.
3. Inspect the spring for cracks and corrosion. If any leaves are cracked or broken, replace the entire spring assembly.

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

⚠ WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. On front spring assemblies, if cracks or breaks exist in the two top leaves, a loss of vehicle control could occur. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

4. If the protective coating is gone from some areas of the spring, paint the cleaned areas with a rust-inhibiting paint. If rusting or corrosion is severe, replace the spring.
5. Using a micrometer, check non-threaded spring pins and shackle pins for wear.

   On tapered leaf spring assemblies, replace a pin if the diameter at any point on the pin is less than 1.245 inches (31.62 mm).

   On flat leaf spring assemblies, replace a pin if the diameter at any point on the pin is less than 1.122 inches (28.50 mm).
6. Inspect threaded spring and shackle pins for cracked or broken threads. Replace any pin that has damaged threads.
7. Inspect the spring and bracket bushings. Replace the bushings if they are gouged, cracked, pitted, or otherwise damaged. For instructions, see **Subject 110**.
8. If non-threaded bushings are not damaged, inspect them for wear. Using a micrometer, check the inside diameter of each bushing. The inside diameter of any bushing should not exceed the diameter of its pin by more than 0.010 inch (0.25 mm). Replace any bushing that exceeds this limit.

Installation

See **Fig. 1** and **Fig. 2** for this procedure.

⚠ WARNING

Failure to install identical spring assemblies could affect the balance of the front suspension and cause difficult handling of the vehicle, resulting in injury or property damage.

1. Install the shackle bracket if previously removed. Tighten the mounting fastener locknuts 190 lbf·ft (260 N·m).

NOTE: All suspension bracket (frame) fasteners require periodic torquing. See **Group 32** of the *Century Class Trucks Maintenance Manual* for instructions.

2. Using multipurpose chassis grease, lubricate both spring pins, the shackle pin, and the inside surfaces of the bushings.

   Apply Alumilastic® or similar compound to all areas of the shackle that contact metal. This includes all capscrews, washers, and locknuts that contact the aluminum shackle. Do not apply the compound to the inner (bearing) surface of the bushing or on fastener threads.
3. If the shackle was disconnected from the shackle bracket, attach it to the bracket.

⚠ CAUTION

Failure to apply Alumilastic or similar compound will result in electrolytic corrosion of dissimilar metal components, and will damage the suspension system.

3.1 For shackles without pinch bolts, install the upper shackle bolt and torque to 240 lbf·ft (325 N·m).

3.2 For shackles with pinch bolts and threaded spring pins, thread the pin all the way into the bushing (with the grease fitting pointing outboard) until the spring pin grooves align with the shackle pinch-bolt bores.

Install the split ring on the inboard end of the threaded pin. Install the pinch bolts, washers, and nuts.

For aluminum shackles, torque the nuts to 45 lbf·ft (61 N·m).

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

For steel shackles, torque the nuts to 68 lbf·ft. (92 N·m).

3.3 For shackles with pinch bolts, a non-threaded spring pin, and bronze bushings, install the wear plates and spacing washers, as referenced during removal.

Insert the spring pin (with the grease fitting pointing outboard) until the spring pin grooves align with the shackle pinch-bolt bores.

Check for play between the shackle bracket and the shackle. If needed, install additional 1/32-inch spacing washers (1-1/8 inch i.d., 1-7/8-inch o.d.) so that there is less than one washer thickness of end play.

Install the pinch bolts, washers, and nuts.

For aluminum shackles, torque the nuts to 45 lbf·ft (61 N·m).

For steel shackles, torque the nuts to 68 lbf·ft. (92 N·m).

NOTE: When non-threaded shackle pins are used, make sure the correct spacing washers are inserted between the bracket ends and the shackles. Be sure the hardened wear washers are in direct contact with the shackle.

It is preferable to have an equal number of washers on each side of the bracket. If the amount of play requires an uneven number of washers, the difference between the two sides should be no more than one spacing washer.

3.4 For shackles with pinch bolts, non-threaded spring pins, and with rubber bushings, install the pin so the grease fitting end is towards the outboard side of the vehicle.

Position the grooves of the pin so that they align with the pinch bolt holes in the shackles. Install the pinch bolts, washers, and nuts.

For aluminum shackles, torque the nuts to 45 lbf·ft (61 N·m).

For steel shackles, torque the nuts to 68 lbf·ft (92 N·m).

CAUTION

Do not overtighten the shackle pinch-bolt nuts. Overtightening these nuts could distort and weaken the aluminum shackles.

4. Place the caster shim on the front axle in the position referenced earlier.
5. Install the spring assembly on the caster shim; make sure the spring center-bolt head fits into the bore in the axle.
6. Place the spring liner (if equipped) on top of the spring assembly.
7. Place the axle stop/shock absorber bracket onto the spring assembly.
8. Install the U-bolts over the spring assembly and through the holes in the axle. It may be necessary to slightly compress the sides of the U-bolts in order to get the U-bolt ends to align with the axle holes. A C-clamp attached above the U-bolt threads can be used for this purpose.
9. Attach the hardened washers and the high nuts finger-tight.
10. Attach the spring assembly to the front frame bracket.

    10.1 For front brackets without spring pin retainers, install the 3/4-10 shackle bolt and torque to 240 lbf·ft (325 N·m).

    10.2 For front brackets with spring pin retainers and threaded spring pins, thread the pin all the way into the bushing (with the grease fitting pointing outboard) until the spring pin grooves align with the bolt bores in the front suspension bracket.

    Install the split ring on the inboard end of the threaded pin.

    Install the spring pin retainers, bolts, washers, and nuts. Torque the nuts to 68 lbf·ft (92 N·m).

    10.3 For front brackets with spring pin retainers, a non-threaded spring pin, and bronze bushings, install the wear plates and spacing washers, as referenced during removal. Insert the spring pin (with the

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

grease fitting pointing outboard) until the spring pin grooves align with the bracket-bolt bores.

Check for play between the bracket and spring. If needed, install additional 1/32-inch spacing washers (1-1/8 inch i.d., 1-7/8 inch o.d.) so that there is less than one washer thickness of end play.

Install the spring pin retainers, bolts, washers, and nuts. Torque the nuts to 68 lbf·ft (92 N·m).

NOTE: When non-threaded shackle pins are used, make sure the correct spacing washers are inserted between the bracket ends and the shackles. Be sure the hardened wear washers are in direct contact with the shackle.

It is preferable to have an equal number of washers on each side of the bracket. If the amount of play requires an uneven number of washers, the difference between the two sides should be no more than one spacing washer.

10.4 For front brackets with spring pin retainers, non-threaded spring pins, and a rubber bushing, install the pin so the grease fitting end is towards the outboard side of the vehicle.

Position the grooves of the pin so that they align with the frame bracket bolt bores.

Install the spring pin retainers, bolts, washers, and nuts. Torque the nuts to 68 lbf·ft (92 N·m).

11. Attach the spring assembly to the shackle bracket.

11.1 For shackles without pinch bolts, install the lower 3/4-10 shackle bolt and torque to 240 lbf·ft (325 N·m).

11.2 For shackles with pinch bolts and a threaded spring pin, thread the pin all the way into the bushing (with the grease fitting pointing outboard) until the spring pin grooves align with the shackle pinch-bolt bores.

Install the split ring on the inboard end of the threaded pin.

Install the pinch bolts, washers, and nuts.

For aluminum shackles, torque the nuts to 45 lbf·ft (61 N·m).

For steel shackles, torque the nuts to 68 lbf·ft (92 N·m).

11.3 For shackles with pinch bolts, a non-threaded spring pin, and bronze bushings, install the wear plates and spacing washers, as referenced during removal. Insert the spring pin (with the grease fitting pointing outboard) until the spring pin grooves align with the shackle pinch-bolt bores.

Check for play between the spring and shackle. If needed, install additional 1/32-inch spacing washers (1-1/8 inch i.d., 1-7/8 inch o.d.) so that there is less than one washer thickness of end play.

Install the pinch bolts, washers, and nuts.

For aluminum shackles, torque the nuts to 45 lbf·ft (61 N·m).

For steel shackles torque the nuts to 68 lbf·ft (92 N·m).

NOTE: When non-threaded shackle pins are used, make sure the correct spacing washers are inserted between the bracket ends and the shackles. Be sure the hardened wear washers are in direct contact with the shackle.

It is preferable to have an equal number of washers on on each side of the bracket. If the amount of play requires an uneven number of washers, the difference between the two sides should be no more than one spacing washer.

11.4 For shackles with pinch bolts, a non-threaded spring pin, and a rubber bushing, install the pin so the grease fitting end is towards the outboard side of the vehicle.

Position the grooves of the pin so that they align with the pinch bolt holes in the shackles.

Install the pinch bolts, washers, and nuts.

For aluminum shackles, torque the nuts to 45 lbf·ft (61 N·m).

For steel shackles, torque the nuts to 68 lbf·ft (92 N·m).

12. Wipe all dirt from the grease fittings on the spring pins and the shackle pin. Apply multipurpose chassis grease with a pressure gun until grease appears at the opposite end of the pin.
13. Install the shock absorber. See **Subject 120** for instructions.
14. On vehicles with flat leaf spring assemblies, install the tire and wheel. For instructions, see **Group 40**.
15. Remove the jack stands from the chassis, and lower the vehicle.
16. On vehicles with tapered leaf spring assemblies, install the bumper and attach the road-light wires. Make sure the spacers are in the locations referenced earlier.

Shackle Bracket Bushing Replacement

1. With the shackle bracket removed from the vehicle, press out the worn or damaged bushing.
2. With an inside micrometer or bore gauge, check the bracket bore for damage or wear. Replace the bracket if the bushing bore is damaged or worn.
3. *If installing rubber bushings,* check the shackle bracket bolt for ease of fit in the bushing. It should have an easy slip fit without wobble between it and the bushing.

CAUTION

CAUTION:Do not press in rubber bushings by the center sleeve. To do so could damage the bushings.

4. Press the new bushing into the bracket until the bushing is centered in the bracket.
5. Check the shackle bracket bolt again for ease of fit in the bushing. It should still have an easy slip fit without wobble between it and the bushing. If binding occurs, the bushing may have been distorted during installation. Replace the bushing and check again for correct fit.
6. *If installing bronze bushings,* check the shackle pin for ease of fit in the bushing. It should have an easy slip fit without wobble between it and the bushing.
7. Press the new bushing into the bracket until the bushing is centered in the bracket. The bushing ends must be flush or inside the vertical edges of the bracket bore, and the split in the bushing must be within 1/4 inch (6 mm) of the bottom of the bracket bore.

   Check the shackle pin again for ease of fit in the bushing. It should still have an easy slip fit without wobble between it and the bushing. If binding occurs, the bushing may have been distorted during installation. Replace the bushing and check again for correct fit.
8. *If installing threaded shackle pins,* check the fit of the threaded pin in the bushing. It should screw in easily by hand without binding. Press the new bushing into the bracket until the bushing is centered in the bracket. Check the threaded pin again for ease of fit in the bushing. It should still screw in easily by hand without binding. If binding occurs, the bushing may have been distorted during installation. Replace the bushing and check again for correct fit.

Spring Bushing Replacement

1. Remove the leaf spring. See **Subject 100** for instructions
2. Press out the worn or damaged bushing.

CAUTION

CAUTION: Do not press in the bushing by the center sleeve. To do so could damage the bushing.

3. *If installing rubber bushings,* apply a coating of Perma-Bond® HM–160 or Loctite® RC–609 adhesive to the inside of the spring eye, and to the outside of the bushing. Press the new bushing into the spring eye until the bushing is flush with the edges of the spring eye.

   If installing bronze bushings, press the new bushing into the spring eye until the bushing and the spring edges are flush. The split in the bushing must be within 3/16 inch (5 mm) of the top of the spring eye.

   If installing bushings for threaded spring pins, press the new bushing into the spring eye until the bushing is flush with the edges of the spring eye.
4. Install the leaf spring. See **Subject 100** for instructions.

Shock Absorber Removal and Installation

Removal

1. Remove the hexbolt, the hardened washers, and locknut from the shock absorber and the upper mounting bracket. See **Fig. 1**.
2. Swing the shock absorber out and away from the upper mounting bracket.
3. Remove the locknut and hardened washer from the stud of the lower mounting bracket.
4. Pull straight out on the lower part of the shock absorber to remove it.

Installation

1. Apply a suitable antiseize compound to the threads of the lower mounting-bracket stud, then slide the shock absorber onto the stud.
2. Install the washer and a new locknut on the lower mounting-bracket stud and tighten the locknut just enough to hold the shock absorber in place.
3. Swing up the shock absorber and align the upper eye of the shock absorber with the holes of the upper mounting bracket.
4. Install a hardened washer and the locknut on the hexbolt. Tighten 241 lbf·ft (327 N·m).
5. Tighten the nut on the stud of the lower mount-bracket 241 lbf·ft (327 N·m).

Vehicle Lean Inspection

IMPORTANT: Chassis lean can be caused by several factors such as uneven vehicle weight distribution, mismatched springs, or improper spacer installation. The following instructions detail inspecting for and correcting chassis lean due to improper spring or spacer installation. Additional troubleshooting procedures may also be found at the Hendrickson website

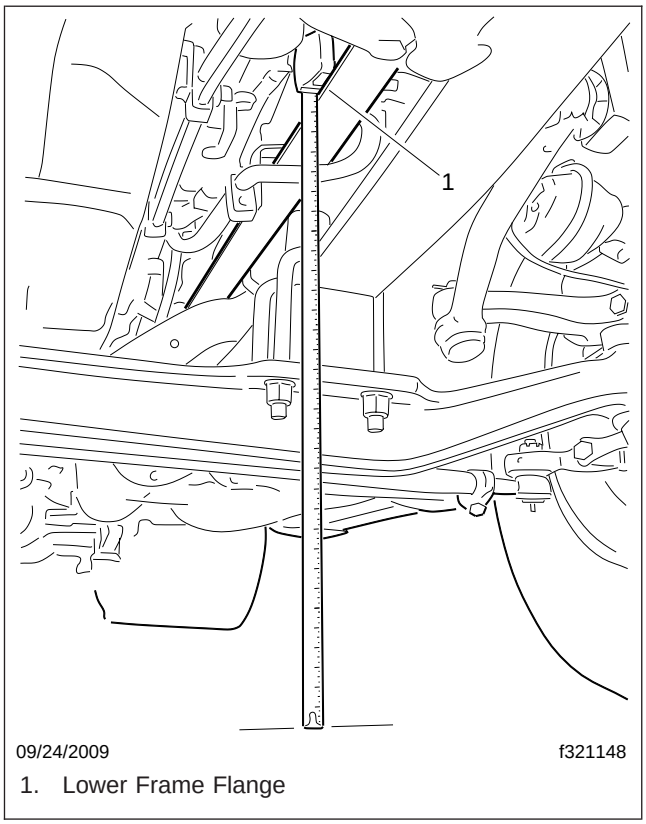
(www.hendrickson-intl.com/literature/pdfs_tech_airtek_freightliner.asp).

1. Park the vehicle on a level surface with the wheels pointing straight ahead. Set the parking brake, turn off the engine, and chock the tires. When exiting the vehicle, try not to rock the vehicle.

NOTE: The vehicle should be unloaded when performing the following inspection.

2. Check tire pressure and tire size. Pressures should be within 2 psi of each other. Tire size should be the same on each axle.
3. Check that the rear axle alignment and rear suspension ride height are within specification. Refer to the applicable sections in **Group 32** or **Group 35** in this manual.
4. Check the springs, bushings and spring mounting hardware for damage. Replace damaged components before checking for chassis lean.
5. Measure the weight of the vehicle at each wheel position. Weight imbalance will cause the vehicle to lean. If the vehicle weight differs from side to side, check the cab alignment and the fuel tank levels, and correct if necessary.
6. Measure the distance from the bottom of the lower frame flange to the ground, forward of the front axle center line. This is frame height. See **Fig. 1**.
7. If the frame height differs from side to side by 3/8 inch (9.53 mm) or more, inspect the spring part numbers, and (if present) markings on the top side of the springs with a label marking plus (+) or minus (–). Verify that both spring labels match.

   If the labels or part numbers do not match, replace one or both springs so the vehicle has matching springs. See **Fig. 2**.



1. Lower Frame Flange

Fig. 1, Measuring Frame Height

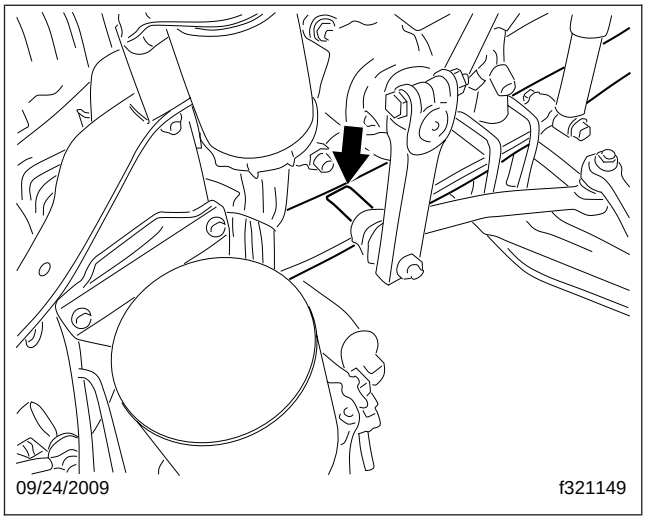


Fig. 2, Spring Label Location

8. Measure the height difference at the end of the frame rails to ground. If this measurement is greater than 3/8 inch (9.53 mm), the front axle

spacer adjustments will have minimal effect on lean and other actions are required. If the end of frame to ground measurements are less than 3/8 inch (9.53 mm) difference, correct the lean by increasing the low side front axle spacer thickness by no more than 1/2 inch (13 mm). Use a 45, 55, or 65-mm spacer in place of the existing spacer.

See **Table 1** for parts information.

9. Check the frame height again. If the difference between measurements is still equal to or greater than 3/8 inch (9.53 mm), swap springs from side to side and check the measurements again.

   If the chassis lean is still the same, the problem is with the vehicle. If the lean has changed sides, replace both springs.

10. **Figure 3** represents a checklist for weak or sagging springs.

    Use this checklist as the information may be requested when filing a warranty claim.

Troubleshooting

The following is a checklist for weak or sagging springs. This information may be requested when filing for warranty.

Conditions

☐ Is the ground level?

(If ground is not level move the truck to a level location)

☐ Is the vehicle loaded?

(Vehicle should be measured unloaded)

☐ Are the spring part numbers the same?

(Part numbers should be the same)

☐ Is there any visible damage to the spring or bushings?

(Any damage to the springs, bushings, shocks, or suspension brackets should be repaired)

Tires

☐ Are the tire pressures and sizes the same?

(Tire pressure should be within 2 psi from side to side)

☐ Do the tires have the same amount of wear?

☐ Are the tires the same size?

Measurements

☐ Measure the distance from the floor to the bottom of the frame rail on each side of the truck as close to the front axle as possible.

Passenger Side _____

Driver Side _____

(Measurements should be within 3/8” from side to side)

Weight

☐ Measure the weight of the vehicle at each forward axle position.

Passenger Side _____

Driver Side _____

(Weight should be equal from side to side. If weight is more on one side, check that the cab is centered on the frame rails, and if equipped with dual tanks, that the fuel level is equal on both sides. Due to the many options available for mounting components, the vehicle may have a weight bias to one side. If the vehicle does have a weight bias to one side, the spring can be shimmed to level the vehicle.)

General Description

There are two terms used to describe rough ride conditions: harmonic and harsh. Harmonic ride problems are those in which the once-per-revolution energy input from such things as bent or imbalanced wheels match the natural frequency of the frame flexing. This produces a fore-and-aft motion in the cab, which continues as long as the critical road speed is maintained. Harmonic ride problems can occur on smooth roads.

Harsh ride problems are those in which the suspension transfers, rather than absorbs, the momentary energy inputs produced when the tires hit bumps or holes in the road. Wavy asphalt, or a series of bumps, may cause repetition of the harsh, jarring motion in the cab, but the motion stops after the tires pass over the bumps. Harsh ride problems occur on rough roads.

This section is designed for use as an aid in locating and correcting rough ride problems. It is not intended for use as a replacement for the detailed service information located in the applicable subjects in this manual, or in the component manufacturer's service manuals.

Harmonic Ride Checks

1. Visually check the vehicle for signs of damaged or missing suspension components. Repair or replace the components using the instructions in the applicable sections in this manual.
2. Test drive the vehicle.

NOTE: When test driving the vehicle, duplicate as closely as possible the conditions under which the problem occurs. Note the area of the vehicle where the problem seems to be coming from. Pay special attention to this area during the service operations.

WARNING

WARNING: Use safety stands to securely support all of the wheel and frame weight during suspension repairs. Unsecured components may drop when the fasteners are loosened or removed, causing serious personal injury and component damage.

3. Raise the vehicle until the tires are off the ground, and all of the weight is removed from the leaf springs. Block the axle and frame with safety stands. Perform the corrections under "Harmonic Ride, Tires Off the Ground" in **Troubleshooting, 300**.
4. Remove the safety stands from under the frame and axle, then lower the vehicle. Perform the corrections under "Harmonic Ride, Tires On the Ground" in **Troubleshooting, 300**.

Harsh Ride Checks

1. Visually check the vehicle for signs of damaged or missing suspension components. Repair or replace the components using the instructions in the applicable sections in this manual.
2. Test drive the vehicle.

NOTE: When test driving the vehicle, duplicate as closely as possible the conditions under which the problem occurs. Note the area of the vehicle where the problem seems to be coming from. Pay special attention to this area during the service operations.

WARNING

WARNING: Use safety stands to securely support all of the wheel and frame weight during suspension repairs. Unsecured components may drop when the fasteners are loosened or removed, causing serious personal injury and component damage.

3. Raise the vehicle until the tires are off the ground, and all of the weight is removed from the leaf springs. Block the axle and frame with safety stands. Perform the corrections under "Harsh Ride, Tires Off the Ground" in **Troubleshooting, 300**.
4. Remove the safety stands from under the frame and axle, then lower the vehicle. Perform the corrections under "Harsh Ride, Tires On the Ground" in **Troubleshooting, 300**.
5. If the problem persists, perform the harmonic ride checks in this subject. Occasionally, ride problems associated with rough roads are harmonic ride problems masked by the road conditions.

Problem—Harmonic Ride, Tires Off the Ground

Possible Cause	Remedy
Bent, distorted, or out-of-round wheels or rims are causing a rough ride.	Inspect and repair the assemblies using the instructions in the wheels and tires section in this manual.
Bent, distorted, or out-of-round brake drums or hubs are causing a rough ride.	Replace damaged components using the instructions in the front or rear axle section in this manual.
An improperly seated tire-to-rim bead is causing an out-of-round assembly.	Inspect the tires and rims for proper bead seating. Correct the problem using the instructions in the wheels and tires section in this manual.
A tire and rim assembly on spoke wheels is improperly installed, causing an out-of-round assembly.	Remove and install the tire and rim assembly using the instructions in the wheels and tires section in this manual.
Worn or distorted rim spacers are causing an out-of-round assembly.	Replace damaged spacers using the instructions in the wheels and tires section in this manual.
The wheels, brake drums, or hub assemblies are out of balance.	Inspect the components for missing balance weights. Balance, as necessary.
Radial force variations in the tires are causing a rough ride.	Exchange the tires and wheels with a set that is known to cause no ride problems. If this corrects the problem, discard the old tires. For instructions, refer to the wheels and tires section in this manual.

Problem—Harmonic Ride, Tires On the Ground

Possible Cause	Remedy
Worn or loose cab mounts allow the cab to bounce.	With a long bar, lever the cab legs up and down. If there is looseness, replace or tighten the mounts, as necessary.
Forces from the trailer suspension are pushing on the tractor fifth wheel.	Review the ride problems that apply to the trailer suspension. Refer to the trailer manufacturer for instructions. Perform the corrections, as necessary.

Problem—Harsh Ride, Tires Off the Ground

Possible Cause	Remedy
Seized front spring shackle pins are not allowing the springs to flex.	Replace seized shackle pins. For instructions, refer to the suspension section in this manual.

Problem—Harsh Ride, Tires On the Ground

Possible Cause	Remedy
The tires are improperly inflated.	Adjust the tire pressure using the instructions in the wheels and tires section in the vehicle maintenance manual.
The frame is bottoming out against the suspension.	Check the suspension for weak or damaged springs or components. Inspect the springs for "gull-winging" when the vehicle is loaded. Replace the spring assembly, as necessary, using the instructions in the suspension section in this manual.
	Reduce the overall loaded weight on each axle to conform with the maximum spring load capacities on the vehicle specification sheet. Do not exceed the maximum spring load capacities.
	Adjust the air spring height using the instructions in the suspension section in this manual.

Troubleshooting

Possible Cause	Remedy
The vehicle normal loaded weight is markedly below the spring load capacity.	Contact the Freightliner Service Operations Regional Office for the correct application of a lower rated spring. Replace the spring assembly using the instructions in the suspension section in this manual.
When the vehicle is loaded, the front axle spring shackle angle is not within the rearward 3- to 18-degree angle.	Contact the Freightliner Service Operations Regional Office for shackle angle corrective measures. Refer to the suspension section in this manual for service instructions.
The weight on the tractor fifth wheel is causing overloading on the front axle springs.	If possible, move the fifth wheel toward the rear of the vehicle; otherwise, change the loading pattern on the trailer.
There is a loaded weight differential between the rear axles greater than 800 pounds (363 kg).	Contact the Freightliner Service Operations Regional Office for corrective measures.
Forces from the trailer suspension are pushing on the tractor fifth wheel causing a rough ride condition.	Review the ride problems that apply to the trailer suspension. Refer to the trailer manufacturer for instructions. Perform the corrections, as necessary.

General Description

The single-axle rear spring suspension (**Fig. 1**) uses a full-floating spring design. Semi-elliptical spring assemblies are attached to the axles with U-bolt assemblies. The spring ends ride in aluminum brackets that are mounted on the frame rails. Steel wear shoes are cast into each bracket. Radius rods attached to the axle seats and the forward spring brackets hold the axle in alignment.

3. Remove the fasteners that attach the radius rod to the forward spring bracket and to the axle seat.
4. Remove the radius rod and any axle alignment washers.

Installation (See Fig. 1)

IMPORTANT: At all points where steel parts contact the aluminum forward spring bracket, apply Alumilastic® compound, or an equivalent, on the mating surfaces.

CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the suspension.

1. Place the radius rod pins between the rear side of the forward spring bracket, and the front side of the axle seat.
2. Install the hexhead bolts, hardened washers, and locknuts in the axle seat and the radius rod rear pin.
3. Install any previously removed axle alignment washers between the radius rod front pin and the forward spring bracket. Install the hexhead bolts, hardened washers, and locknuts in the radius rod front pin and the forward spring bracket.
4. Tighten the radius rod locknuts to the torque value in **Specifications, 400**.
5. Check the axle alignment. For instructions, refer to the rear axle section in this manual. If necessary, adjust the rear axle alignment, using the instructions in **Subject 130**.

Replacement (See Fig. 1)

⚠ WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves.Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Chock the front tires.
2. Raise the frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Raise the rear axle until the spring no longer contacts the spring bracket wear shoes, then block the axle. Make sure the stands will securely support the weight of the axles and frame. To gain easy access to the suspension system, remove the wheel assembly; refer to the wheels and tires section in this manual for instructions.
3. Remove the U-bolt high nuts, hardened washers, U-bolt retainer, U-bolts, and upper U-bolt pad.
4. Lift the spring assembly off the axle seat, then move it to the rear, out of the forward spring bracket. Lift the front of the spring, then move it forward, out of the rear spring bracket.
5. Using chassis grease, lubricate the ends of the new spring where they contact the stationary wear shoes in the spring brackets.
6. Work the new spring assembly into the spring brackets, and place it on the axle seat. Make sure the spring center-bolt head seats in the axle seat hole.
7. Place the upper U-bolt pad on the spring assembly. Place the U-bolts over the upper U-bolt pad and the spring assembly.
8. Install the U-bolt retainer, hardened washers, and U-bolt high nuts. Tighten the high nuts until snug.
9. In a diagonal pattern, hand tighten the axle U-bolt high nuts. In the same pattern, tighten them 100 lbf·ft (136 N·m); then, 200 lbf·ft (270 N·m); then, 300 lbf·ft (407 N·m); then, torque to the final value of 420 lbf·ft (569 N·m).

⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets,and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Century Class Trucks Maintenance Manual*.

10. Install the wheel assembly, using the instructions in **Group 40**. Remove the safety stands from under the frame and axle, and lower the vehicle.
11. Check the axle alignment. For instructions, see **Group 35**. If necessary, adjust the rear axle alignment, using the instructions in **Subject 130**.

Replacement

WARNING

WARNING: Replace worn, cracked, or damaged spring brackets. Failure to do so could result in bracket breakage, possibly leading to loss of vehicle control and resulting in personal injury or property damage.

IMPORTANT: At all points where steel parts (including bolts, washers, and nuts) contact the aluminum spring brackets, apply Alumilastic® compound, or an equivalent, on the mating surfaces.

CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the suspension.

1. Chock the front tires.
2. Raise the rear of the vehicle, and block the rear axle with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will securely support the weight of the axle and frame.
3. If removing the forward spring bracket, note the number of axle alignment washers, if any, between the bracket and the radius rod front pin. Remove the fasteners that attach the radius rod to the bracket, and remove any axle alignment washers.
4. Remove the fasteners that attach the spring bracket to the frame rail, and remove the spring bracket.
5. Place the new spring bracket on the frame rail. Align the mounting holes, and install the spring bracket bolts, hardened washers, and locknuts.

NOTE: If installing the forward spring bracket, install the nuts for the top two bolts on the outboard side of the frame rail, and install the nuts for the bottom four bolts on the inboard side of the frame rail. **See Fig. 1.**

If installing the rear spring bracket, install the nuts for the top two bolts on the outboard side of the frame rail, and install the nuts for the bottom two bolts on the inboard side of the frame rail. **See Fig. 1 .**

6. Tighten the locknuts to the applicable torque value in **Specifications, 400**.

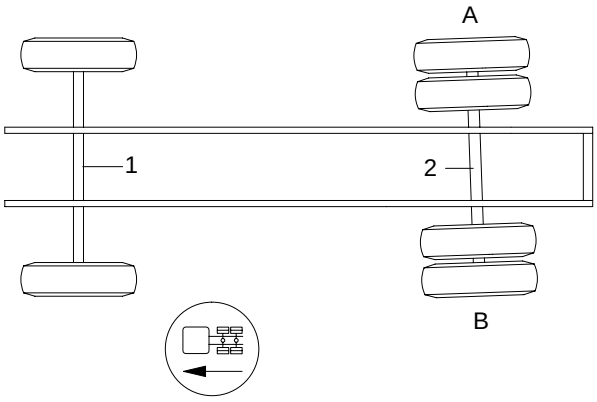
vals and instructions, refer to the suspension section in the vehicle maintenance manual.

7. If replacing the forward spring bracket, position any previously removed axle alignment washers between the bracket and the radius rod front pin. Install the bolts, hardened washers, and locknuts in the radius rod front pin and the forward spring bracket. Tighten the locknuts to the torque value in **Specifications, 400**.
8. Remove the safety stands from under the frame and axle, and lower the vehicle.
9. Check the axle alignment. For instructions, refer to the rear axle section in this manual. If necessary, adjust the rear axle alignment, using the instructions in **Subject 130**.

Rear Axle Alignment Adjustment

Adjustment

1. Using a straightedge and a tape measure, determine the amount of adjustment needed to align the axle at a right angle to the frame. For instructions, refer to the rear axle section in this manual. The difference in measurements between the sides of the vehicle is the approximate amount that the trailing end of the axle will have to be brought forward, or the leading end will have to be moved back to align it at a right angle to the frame. **See Fig. 1.**



A. Leading End
B. Trailing End
1. Front Axle
2. Rear Axle

Fig. 1, Single Axle, Shown Out of Alignment

NOTE: To adjust the axle alignment, add washers between the radius rod front pin and the forward spring bracket on the leading end, to adjust the leading end backward. Or, remove washers from the trailing end, to bring the trailing end forward. When possible, alignment washers should be removed instead of added.

2. On both sides of the axle, loosen the axle U-bolts enough to allow the springs to shift on the axle seats.
3. On the side of the vehicle that is to be adjusted, remove the fasteners that attach the radius rod to the forward spring bracket. Remove any axle alignment washers.
4. Raise the frame just enough to relieve the weight from the springs. Place safety stands under the frame. Make sure the stands will support the weight of the frame.
5. Move the loosened end of the axle forward or backward as needed, by rolling the wheels.
6. Insert the correct thickness of axle alignment washers between the radius rod front pin and the forward spring bracket.
7. Install the hexhead bolt, hardened washers, and locknut in the radius rod pin and forward spring bracket. Place an equal thickness of washers on the other end of the radius rod pin, and install the fasteners.
8. Tighten the locknuts to the applicable torque value in **Specifications, 400**.
9. Remove the safety stands, and lower the vehicle. Remove the chocks from the front tires.
10. Check the axle alignment with the straightedge and the tape measure. If alignment is within specifications, center the spring in the forward spring bracket, if needed, then tighten the axle U-bolt nuts to the torque value in **Specifications, 400**.

    If not in alignment, repeat the procedure above.

CAUTION

CAUTION: Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, refer to the suspension section in the vehicle maintenance manual.

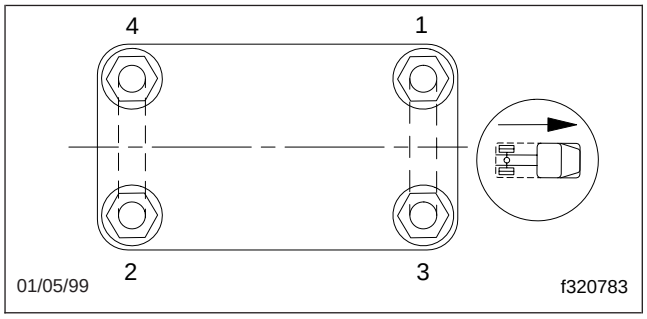

Fig. 1, Tightening Pattern for U-bolt High Nuts

General Description

The tandem-axle rear spring suspension (**See Fig. 1**) uses a six-point equalizing leaf spring design, which compensates for axle articulation, from side to side, and front to rear. Four semi-elliptical spring assemblies are attached to the axles with U-bolts. On both sides of the vehicle, the forward end of the forward spring and the rear end of the rear spring ride in aluminum brackets that are mounted on the frame rails. Steel wear shoes are cast into each bracket.

At the center, between the forward and rear springs, the springs ride on an equalizer, which pivots on a sleeve in the equalizer bracket. Equalizer travel is stopped when the top of the equalizer and equalizer bracket make contact. Each axle is held in alignment by a pair of radius rods that extend forward from the axle seats to the forward spring brackets for the forward-rear axle, and to the equalizer brackets for the rearmost axle.

2. Note the number of axle alignment washers (Ref. 4) at the forward end of each radius rod that is being removed.
3. Remove the fasteners that attach the radius rod to the forward spring bracket or equalizer bracket, and to the axle seat.
4. Remove the radius rod and any axle alignment washers.

Installation (See Fig. 1)

IMPORTANT: At all points where steel parts (including bolts, washers, and nuts) contact aluminum brackets, apply Alumilastic compound, or an equivalent, on the mating surfaces.

⚠ CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the suspension.

If installing forward and rear radius rods, install the forward radius rod before installing the rear radius rod.

1. If installing a forward radius rod, place the radius rod front pin on the front side of the forward spring bracket, and place the radius rod rear pin in front of the axle seat.

   If installing a rear radius rod, place the radius rod pins between the rear side of the equalizer bracket and the front side of the axle seat.

Radius Rod Removal and Installation

2. Install a hexhead bolt with a hardened washer through each end of the radius rod rear pin and the axle seat ears. Install the hardened washers and locknuts.
3. If installing a forward radius rod, install any previously removed axle alignment washers between the radius rod front pin and the forward spring bracket. Install the hexhead bolts, hardened washers, and locknuts.

   If installing a rear radius rod, install any previously removed axle alignment washers between the radius rod front pin and the equalizer bracket. Install the hexhead bolts, hardened washers, and locknuts.
4. Tighten the radius rod locknuts to the torque value in **Specifications, 400**.
5. After all of the radius rods are installed, check the rear axle alignment. For instructions, refer to the rear axle section in this manual. If necessary, adjust the axle alignment, using the instructions in **Subject 140**.

1. Chock the front tires.
2. Raise the rear of the vehicle, and block the axles with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will securely support the weight of the axles and frame. To allow access to the equalizer, remove the wheel assemblies on that side, using the instructions in the wheels and tires section in this manual.
3. If removing an equalizer from a vehicle with two drive axles, remove the cotter pin from the outboard end of each spring retainer pin, then remove the retainer pins.

   If removing an equalizer from a vehicle with a pusher or tag axle, remove the nuts from the flathead bolts in the wear-shoe side-restraints, on each end of the equalizer. Remove the flathead bolts and side-restraint sleeves. Remove the six capscrews and washers, and remove both wear-shoe side-restraints from the equalizer.
4. Remove the cap and tube assembly locknut, inboard bearing washer, bolt, and outboard bearing washer.
5. Insert a bar between the bottom of the equalizer and the equalizer bracket. Gently lever the weight of the equalizer off the cap and tube assembly. Insert a piece of barstock through the inboard cap and tube assembly bolt hole, and lightly tap the cap and tube assembly out of the equalizer.
6. Remove the equalizer from the equalizer bracket. Remove the wear washer(s) and equalizer bushings from the equalizer.

Inspection

1. Thoroughly clean the equalizer with steam or a hot soap solution. Inspect it for wear, cracks,or other damage. Replace the equalizer if any of these conditions are present.

⚠ CAUTION

CAUTION: Failure to replace the equalizer if it is cracked or otherwise damaged could result in progressive damage to, and eventual breakage of the equalizer. Breakage of the equalizer could cause a loss of vehicle control, resulting in personal injury or property damage.

2. Inspect the equalizer bushings, cap and tube assembly, and the equalizer bracket for wear, cracks, or other damage. If any of these conditions are present, replace the bushings or the cap and tube assembly.

Equalizer Removal, Inspection, and Installation

Installation (See Fig. 1)

1. Apply a thin film of multipurpose chassis grease to the outside of the equalizer bushings, then install the bushings in the equalizer.
2. Install the equalizer in the equalizer bracket.

NOTE: The next four steps must be completed before the Loctite begins to cure (approximately 5 to 10 minutes).

3. Apply Loctite 680 to both interior surfaces of the equalizer bracket, where the cap and tube assembly is inserted. Apply multipurpose chassis grease to the cap and tube assembly, except the last inch which connects to the equalizer bracket. Start the cap and tube assembly into the equalizer, through the equalizer bracket.
4. Push the cap and tube assembly part way through the equalizer, then place the wear washer(s) between the inboard equalizer bushing and the equalizer bracket. Push the cap and tube assembly the rest of the way into the equalizer bracket.
5. Place the outboard bearing washer on the equalizer cap and tube assembly bolt, and install the bolt in the cap and tube assembly.
6. Install the inboard bearing washer and locknut on the cap and tube assembly bolt. Tighten the locknut to the torque value in **Specifications, 400**.
7. Lubricate the equalizer assembly by applying multipurpose chassis grease at the grease fitting. Lubricate with a hand gun or pressure gun until grease is forced past the bushing seals, or if equipped with a pressure-relief grease fitting, until grease is forced out from the base of the pressure relief fitting.
8. If installing an equalizer on a vehicle with two drive axles, apply Alumilastic compound, or an equivalent, to the spring retainer pins, then install them from the inboard side. Be sure the hooked ends of the spring leaves are above the retainer pins. Install a cotter pin in the outboard end of each retainer pin, and lock it in place.

   If installing an equalizer on a vehicle with a pusher or tag axle, apply Alumilastic compound, or an equivalent, to the surfaces where the wear-shoe side-restraints contact the equalizer. Attach the side-restraints to the equalizer, offsetting them toward the inboard side of the equalizer. Tighten the equalizer wear-shoe capscrews to the torque value in **Specifications, 400**. Install the side-restraint sleeves and flathead bolts in the wear-shoe side-restraints. Be sure the hooked ends of the spring leaves are above the side-restraint sleeves. Install the nuts, and tighten them to the applicable torque value in **Specifications, 400**.

⚠ CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel contact each other, could lead to corrosion of the metals, resulting in suspension damage.

9. Install the wheel assemblies, using the instructions in the wheels and tires section in this manual. Remove the safety stands from under the frame and axle, and lower the vehicle.
10. If the radius rods have been loosened, or the equalizer bracket has been removed, check the rear axle alignment. For instructions, refer to the rear axle section in this manual. If necessary, adjust the axle alignment using the instructions in **Subject 140**.

Replacement (See Fig. 1)

⚠ WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Chock the front tires.
2. Raise the frame so that all weight is removed from the leaf springs; then block the frame with safety stands. Raise the rear axle until the spring no longer contacts the spring bracket wear shoes and the spring retainer pin (or side-restraint sleeve); then block the axle. Make sure the stands will securely support the weight of the axles and frame. To access the spring assembly, remove the wheel assembly. See **Group 40** for instructions.
3. If equipped with two drive axles, remove the cotter pin from the spring retainer pin on the end of the equalizer where the spring is being replaced. Drive the spring retainer pin out of the equalizer.

   If equipped with a pusher or tag axle, remove the nut from the flathead bolt on the end of the equalizer where the spring is being replaced. Remove the bolt and the side-restraint sleeve from the wear-shoe side-restraint.
4. Remove the U-bolt high nuts, hardened washers, U-bolt retainer, U-bolts, and upper U-bolt pad.
5. Remove the spring assembly by lifting it off the axle seat, then moving it toward the equalizer, out of the forward or rear spring bracket.
6. Using chassis grease, lubricate the new spring assembly where the ends will contact the stationary wear shoes in the spring bracket and equalizer.
7. Place the new spring assembly in the spring bracket and on the axle seat. Make sure the spring center-bolt head seats in the axle seat hole.
8. If the upper U-bolt pad is aluminum, apply Alumilastic compound, or an equivalent, to those areas of the pad that will come in contact with the U-bolts and with the upper spring leaf.

⚠ CAUTION

Failure to apply Alumilastic® compound, or an equivalent, to areas where aluminum and steel contact each other, could lead to corrosion of the metals, resulting in suspension damage.

9. Place the upper U-bolt pad on the spring assembly. Place the U-bolts over the upper U-bolt pad and the spring assembly.
10. Install the U-bolt retainer, hardened washers, and U-bolt high nuts. Tighten the high nuts until snug.
11. If installing a spring assembly on a vehicle with two drive axles, apply Alumilastic compound, or an equivalent, to the spring retainer pins, then install them from the inboard side. Be sure the hooked ends of the spring leaves are above the retainer pins. Install a cotter pin in the outboard end of each retainer pin, and lock it in place.

    If installing a spring assembly on a vehicle with a pusher or tag axle, install the side-restraint sleeves and flathead bolts in the wear-shoe side-restraints. Be sure the hooked ends of the spring leaves are above the side-restraint sleeves. Install the nuts, and tighten them to the applicable torque value in **Specifications, 400**.
12. In a diagonal pattern, hand tighten the axle U-bolt high nuts. In the same pattern, tighten them 100 lbf·ft (136 N·m); then, 200 lbf·ft (270 N·m); then, 300 lbf·ft (407 N·m); then, torque to the final value of 420 lbf·ft (569 N·m).

⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Century Class Trucks Maintenance Manual*.

Spring Bracket and Equalizer Bracket Replacement

Replacement (See Fig. 1)

WARNING

WARNING: Replace worn, cracked, or damaged spring brackets or equalizer brackets. Failure to do so could result in breakage of the bracket, possibly leading to loss of vehicle control and resulting in personal injury or property damage.

IMPORTANT: At all points where steel parts contact the aluminum spring brackets, apply Alumilastic compound, or an equivalent, on the mating surfaces.

CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the suspension.

1. Chock the front tires.
2. Raise the rear of the vehicle, and block the axles with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will securely support the weight of the axles and frame.
3. If removing the forward spring bracket or the equalizer bracket, note the number of any axle alignment washers, then remove the fasteners that attach the radius rod to the forward spring bracket or equalizer bracket. Remove any axle alignment washers.
4. If removing an equalizer bracket, remove the equalizer. For instructions, refer to **Subject 110**.
5. Remove the fasteners that attach the forward or rear spring bracket, or equalizer bracket, to the frame rail. Remove the bracket.
6. Place the new spring bracket or equalizer bracket on the frame rail. Align the mounting holes, and install the bracket bolts, hardened washers, and locknuts.

NOTE: If installing the forward spring bracket, install the nuts for the top two bolts on the outboard side of the frame rail, and install the nuts for the bottom four bolts on the inboard side of the frame rail. **See Fig. 2.**

If installing the equalizer bracket, for clearance, install all of the nuts on the inboard side of the frame rail. **See Fig. 2.**

If installing the rear spring bracket, install the nuts for the top two bolts on the outboard side of the frame rail, and install the nuts for the bottom two bolts on the inboard side of the frame rail. **See Fig. 2.**

7. Tighten the bracket mounting locknuts to the applicable torque value in **Specifications, 400.**

CAUTION

CAUTION: Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, refer to the suspension section in the vehicle maintenance manual.

8. When replacing the forward spring bracket or equalizer bracket, install any previously removed axle alignment washers between the forward radius rod front pin and the forward spring bracket, or between the rear radius rod front pin and the equalizer bracket, as applicable. **See Fig. 3** .

   Install bolts with hardened washers in the radius rod front pin, and the forward spring bracket or equalizer bracket. Install the hardened washers and locknuts, and tighten the locknuts to the torque value in **Specifications, 400**.
9. If replacing an equalizer bracket, install the equalizer. For instructions, refer to **Subject 110**.
10. Remove the safety stands from under the frame and axle, and lower the vehicle.
11. Check the rear axle alignment. For instructions, refer to the rear axle section in this manual. If necessary,adjust the axle alignment, using the instructions in **Subject 140**.

Adjustment

1. Using a straightedge and a tape measure, determine the amount of adjustment needed to align the forward-rear axle at a right angle to the frame. For instructions, refer to the rear axle section in this manual. The difference in measurements between the sides of the vehicle is the approximate amount that the trailing end of the forward-rear axle will have to be brought forward, or the leading end will have to be moved back to align it at a right angle to the frame. **See Fig. 1.**

   If the forward-rear axle alignment is within specifications, go to the step that begins "Using a center-point bar, determine...".

2. Chock the front tires. On both sides of the forward-rear axle, loosen the axle U-bolts enough to allow the springs to shift on the axle seats.

3. On the side of the vehicle that is to be adjusted, remove the fasteners that attach the forward radius rod to the forward spring bracket. Remove any axle alignment washers.

NOTE: To adjust the forward-rear axle alignment, add alignment washers between the radius rod and the forward spring bracket on the leading end, to adjust the leading end backward. Or, remove alignment washers from the trailing end, to bring the trailing end forward. When possible, alignment washers should be removed instead of added.

4. Raise the frame just enough to relieve the weight from the springs. Place safety stands under the frame. Make sure the stands will securely support the weight of the frame.

5. Move the loosened end of the axle forward or backward as needed, by rolling the wheels.

6. Between one end of the radius rod front pin and the forward spring bracket, insert the correct thickness of axle alignment washers needed to bring the forward-rear axle into alignment. Install the hexhead bolt, hardened washers, and locknut in the radius rod pin and forward spring bracket.

7. Place an equal thickness of washers on the other end of the radius rod pin, and install the fasteners.

2. Forward Rear Axle
3. Rearmost Axle

Fig. 1, Tandem Axle, Shown Out of Alignment

8. Tighten the radius rod locknuts to the torque value in **Specifications, 400**.

9. Remove the safety stands, and lower the vehicle.

10. Check the forward-rear axle alignment with the straightedge and the tape measure. If alignment is within specifications, center the spring in the forward spring bracket, if needed, then tighten the axle U-bolt nuts to the torque value in **Specifications, 400**.

    If not in alignment, repeat all of the steps above.

⚠ CAUTION

CAUTION: Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, refer to the suspension section in the vehicle maintenance manual.

11. Using a center-point bar, determine the difference between the forward-rear and the rearmost axles' center-to-center measurements on each

Rear Axle Alignment Adjustment

side of the vehicle. For instructions, refer to the rear axle section in this manual. This difference is the approximate distance that the leading end of the rearmost axle will have to be adjusted rearward, or that the trailing end will have to be adjusted forward, to align it at a right angle to the frame, and to align it parallel to the forward-rear axle. **See Fig. 1.**

12. On both sides of the rearmost axle, loosen the axle U-bolts enough to allow the springs to shift on the axle seats.
13. On the side of the vehicle that is to be adjusted, remove the fasteners that attach the rear radius rod to the equalizer bracket. Remove any axle alignment washers.
14. Raise the frame just enough to relieve the weight from the springs. Place safety stands under the frame. Make sure the stands will securely support the weight of the frame.
15. Move the loosened end of the axle forward or backward, by rolling the wheels. Move the axle just enough to provide space to allow installation of alignment washers between the equalizer bracket and the radius rod pin.
16. Between one end of the radius rod pin and the equalizer bracket, insert the additional thickness of alignment washers needed to make up for the difference in center-point bar measurements.

    For example, if one end of the axle was equipped with a 3/16-inch (4.5-mm) thickness of washers, and the difference in the center-point bar measurements is 1/4 inch (6 mm) less on that side, add an additional 1/4 inch (6 mm) of washers (for a total of 7/16 inch [10.5 mm]) to correct the alignment.

    Or, if one end of the axle was equipped with a 1/4-inch thickness of washers, and the difference in center-point bar measurements is 3/16 inch (4.5 mm) more on that side, install a 1/16-inch (1.6-mm) thickness of washers in place of the 1/4-inch (6-mm) thickness.
17. Install the bolt, hardened washers, and locknut in the equalizer bracket and the radius rod pin. Place an equal thickness of alignment washers on the other end of the radius rod pin, and install the fasteners at that end.
18. Tighten the radius rod locknuts to the torque value in **Specifications, 400**.
19. Remove the safety stands, and lower the vehicle. Remove the chocks from the front tires.
20. Using the center-point bar, check the rearmost axle alignment. If alignment is within specifications, center the spring in the rear spring bracket, if needed, then tighten the axle U-bolt nuts to the applicable torque value in **Specifications, 400**.

    If not in alignment, repeat the applicable steps above.

⚠ CAUTION

CAUTION: Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, refer to the suspension section in the vehicle maintenance manual.

General Information

The Freightliner AirLiner Suspension is a single axle or tandem axle suspension that uses a combination of air and leaf springs. The suspension is manufactured at numerous weight ratings up to 46,000 pounds (20 865 kg). The top of the air spring is bolted to a bracket on the frame rail, or through the bottom flange of the frame rail; the bottom is bolted to the rear end of the tapered leaf spring assembly or, for the 23,000-pound (10 433 kg) and 46,000-pound suspensions, to a cross bar. The axle housing is fastened to the leaf spring assembly by U-bolts. A control rod, mounted between the axle housing and the frame rail, can be used to help locate the assembly laterally.

The air springs compensate for changes in road conditions and vehicle load, maintaining vehicle height. The air springs also absorb road shock.

A height-control valve (**Fig. 1**) regulates the air flow into or out of all the air springs. As the air spring compresses or expands, changes in the clearance between the vehicle frame and the differential housing activate the height-control valve.

A pressure holding valve, located in the air line to the height-control valve, is preset to maintain a minimum pressure of 65 psi (448 kPa) in the vehicle secondary air system if a leak should occur in the air suspension system.

Ride Height Adjustment

NOTICE

Failure to adjust the suspension ride height could adversely affect driveline angles. Also, if the air springs are set too high, the driver may have difficulty (or be prevented from) backing the vehicle under a trailer. If the air springs are set too low, rapid wear of suspension parts will result.

The height-control valve make and installation may vary. Use the applicable procedure to adjust the suspension height.

- Vehicle with a Barksdale Valve
- Vehicle with a Meritor WABCO Valve Adjustable Installation
- Vehicle with a Meritor WABCO Valve Fixed Installation

The Barksdale height-control valve replaced the Meritor WABCO valve after July 25, 1997. On vehicles with tandem-axle AirLiner rear suspensions, the Barksdale vertical linkage rod is attached to the forward drive axle instead of the rearmost drive axle, and the valve is mounted on the frame rail; see **Fig. 1**.

There are two types of WABCO height-control valve installations: adjustable and fixed. On adjustable installations, the suspension height is changed by tilting the height-control valve up or down. On fixed installations, the suspension height is changed by adjusting the length of the vertical linkage rod.

Vehicle with a Barksdale Valve

IMPORTANT: Before checking the suspension height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty.

Vehicles with dual ride height control valves follow the same procedure as single valves, but with two height gauge blocks, and both height control valves adjusted simultaneously. Both linkages should be disconnected when adjusting, and both valves should be repositioned once the correct ride height has been reached on both sides.

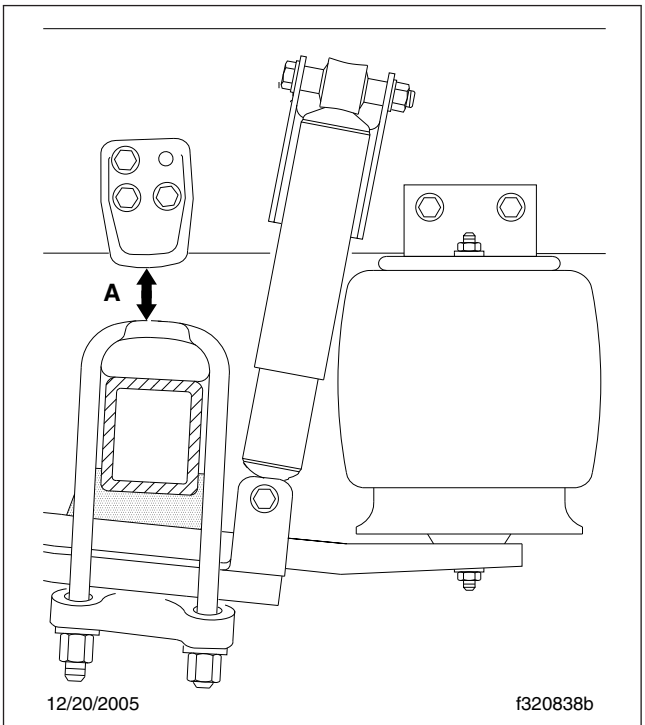
1. Park the vehicle on a level surface, using a light application of the brakes. Set the parking brake and chock the tires. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.
2. Space the tire chocks 2 inches (5 cm) ahead and behind the tire so the vehicle can roll 2 inches in either direction.
3. Release the parking brake and verify by hand that the vehicle can roll forward and aft. This should remove any load from the suspension.
4. Determine the correct ride height for the suspension:
   - Some common suspensions and ride height dimensions are shown in **Table 1**, **Table 2**, **Table 3**, **Table 4**, and **Table 5**.
   - In PartsPro, enter the VIN and Module "622" (Rear Suspension), and retrieve the Parts List. The installation drawing will be listed as a part with a D16 prefix. Use the EZ Wiring icon to view this drawing, which will specify where to measure the ride height and the target ride height distance

Suspension Ride Height Adjustment

for that suspension. This dimension is usually labelled the "E" dimension; the target ride height should be in a table on the same page of the drawing.



Measure Point	Suspension Height Measurement (A)		
	Min	Target	Max
A = Measure Here	2-3/8 inch (60 mm)	2-5/8 inch (67 mm)	2-7/8 inch (73 mm)

IMPORTANT: **Suspensions with Dual-Leaf Springs, and all Vehicles built before August 24, 2001:** Measure between the top of the U-bolt and the bottom of the axle stop (distance A).

Suspensions with Single-Leaf Springs, built after August 24, 2001: Measure between the top of the U-bolt **pad** and the bottom of the axle stop (distance B).

5. Measure the distance between either forward-most axle stop and the suspension using the dimension indicated in the drawing or figure for the suspension.
6. If the distance is within the acceptable range, no adjustment is needed. Apply the parking brakes.

   If the measurement is not within the acceptable range, go to the next step.
7. Disconnect the height-control valve linkage at the lever stud. (For dual valves, disconnect both.)

8. If there is not enough room for the block between the axle stop and the top pad, lift the valve lever to inflate the airbags enough to fit the block. (For dual valves, lift both levers.) Do not install the block yet.

9. Pin the lever in neutral position with a 5/32-inch drill bit or nylon rod to lock the lever in neutral position. See **Fig. 2**.
10. Install the height gauge block. (For dual valves, install a block on both sides.)
11. Unpin the valve lever and use it to lower the suspension until the axle stop rests on the block. (For dual valves, unpin and lower with both valves.)
12. Move the lever to neutral and pin. (For dual valves, pin both.) The vehicle should now be at the target ride height.

NOTICE

When loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

13. While holding the height-control valve mounting studs in place with an Allen wrench, loosen the nuts that attach the valve to the mounting bracket. See **Fig. 3**.

14. Adjust the position of the valve body until the

lever—still pinned in neutral position—can connect to the linkage. Attach the linkage. The linkage rod should be vertical, and the valve body should now be in the correct position for the vehicle's ride height. (For dual valves, adjust and connect both.)

If the linkage cannot reach the stud, check the surrounding components for bent or damaged parts and remedy as needed.

15. While holding the height-control valve mounting studs in place with an Allen wrench, tighten the nuts 95 lbf·in (1100 N·cm). Do not overtighten, as that could damage the valve. (For dual valves, tighten both.)
16. Disconnect the linkage from the valve lever stud. (For dual valves, disconnect both.)
17. Raise the valve lever to raise the suspension enough to remove the block, then pin the valve lever in neutral position. (For dual valves, raise and pin both valves.)

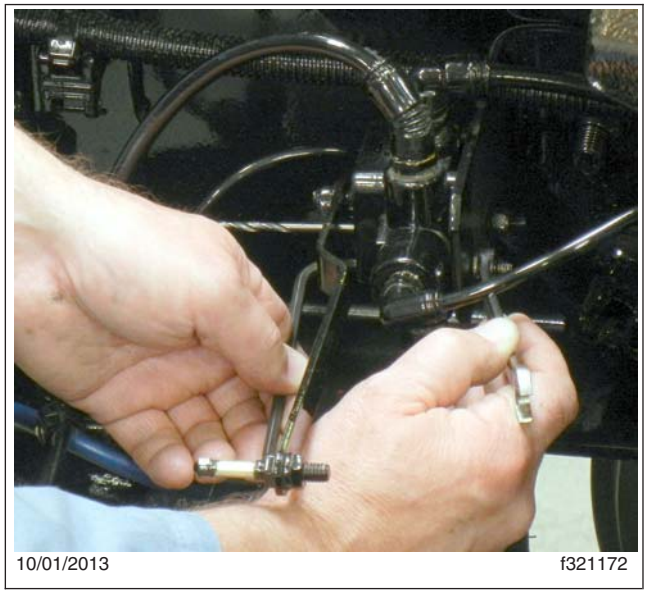

Fig. 3, Holding the height control valve mounting stud in place with an Allen wrench when loosening the nut.

18. Remove the block. (For dual valves, remove both blocks.)
19. Remove the pin or drill bit holding the height-control lever in neutral position, then connect the valve lever to the linkage. (For dual valve, unpin and connect both valve levers.)
20. Drive the vehicle unloaded for about 1/4 mile (1/2 km), then park the vehicle on a level surface using a light brake application. Chock the tires on one axle only, and put the transmission in neutral. Do not apply the parking brakes.
21. Check the ride height of the vehicle again, measuring where indicated in the drawing or figure for the suspension.

    If the distance is within the acceptable range, the ride height is correctly set. Apply the parking brakes.

    If the distance is not within the acceptable range, repeat the adjustment procedure.

IMPORTANT: Before checking the AirLiner suspension height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty.

1. Park the vehicle on a level surface, using a light application of the brakes. Do not apply the parking brakes. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.
2. Check the length of the horizontal control lever between its pivot points. See **Fig. 5**. The length should be 8 inches (203 mm). If needed, adjust the length of the horizontal control lever.
   - 2.1 Loosen the adjustment locknut on the control shaft.
   - 2.2 Move the horizontal control lever fore or aft until the length between the pivot points is 8 inches (203 mm).
   - 2.3 Tighten the adjustment locknut 62 lbf·in (700 N·cm).
3. AirLiner suspensions may have one of three types of axle seats; see **Fig. 6**.

   The three styles are:

   - a one-piece, cast axle seat, that is *not* welded to the axle housing;
   - a one-piece, cast axle seat, that *is* welded to the axle housing;
   - a two-piece, fabricated axle seat that is welded to the axle housing.

Table 5, Suspension Ride Height Measurement, Single-Leaf Spring, 10k/12k/15k Low or Extra Low Ride Height

IMPORTANT If the axle seat is a two-piece welded type, subtract 1/4 inch (6 mm) from the minimum, target, and maximum heights when adjusting the suspension height.

4. Measure the distance from the bottom of the left forwardmost axle stop to the top of the axle U-bolt; see **Table 1**, **Table 2**, **Table 3**, **Table 4**, and **Table 5** for an acceptable range of heights for each suspension.
5. If the distance is within the acceptable range, ride height is adjusted correctly. Apply the parking brakes.

   If the distance is not within the acceptable range, go to the next step.
6. Loosen the two fasteners that attach the height-control valve to the mounting bracket.
7. Rotate the height-control valve clockwise (as you are facing it from the driver's side of the vehicle). Let the air exhaust from the valve until the distance from the bottom of the left forwardmost axle stop to the top of the axle U-bolt is 2 inches (51 mm) or less.
8. Rotate the height-control valve counterclockwise, and raise the suspension height to the target height (previously noted from the appropriate table). Stop the air flow to the air bag by rotating the height-control valve clockwise.
9. Center the height-control valve.
   - 9.1 Rotate the valve very slightly clockwise and counterclockwise until you can insert a 5/32-inch (4-mm) pin or drill bit into the valve centering hole. Don't rotate the valve too much, or you will change the suspension height.
   - 9.2 Tighten the height-control valve mounting fasteners firmly.
10. Drive the vehicle unloaded for about 1/4 mile (1/2 km).

11. Check the adjusted distance between the bottom of the left forwardmost axle stop and the top of the axle U-bolt. It should be within the acceptable range for the applicable suspension previously noted.
12. If the distance is not within the acceptable range, repeat the adjustment procedure.

If the distance is within the acceptable range, ride height is adjusted correctly. Apply the parking brakes.

Vehicle With a Meritor WABCO Valve Fixed Installation

IMPORTANT: Before checking the AirLiner suspension height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty. In order to adjust the suspension height, you must change the length

Suspension Ride Height Adjustment

of the vertical linkage rod using the following procedure.

1. Park the vehicle on a level surface, using a light application of the brakes. Do not apply the parking brakes. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.
2. Check the length of the height-control valve horizontal control lever; see **Fig. 5**. See **Table 6** for the correct length.

   If the length is acceptable, go to the next step.

   If the length is not acceptable, adjust the length of the horizontal control lever as follows.

A. Measure the length of the horizontal control lever between these two points.
B. Measure the length of the vertical linkage rod between these two points.

Fig. 5, Meritor WABCO Height-Control Valve Horizontal Control Lever and Vertical Linkage Rod Measurement

   2.1 Loosen the adjustment locknut on the control shaft.

   2.2 Move the horizontal control lever fore or aft until it is the correct length.

   2.3 Tighten the adjustment locknut 62 lbf·in (700 N·cm).

3. Measure the distance from the bottom of the left forwardmost axle stop to the top of the axle U-bolt. See *Suspension Ride Height Measurement*, **Table 1**, **Table 2**, **Table 3**, **Table 4**, and **Table 5** for an acceptable range of heights for each suspension.

   If the distance is within the acceptable range, ride height is adjusted corrcetly. Apply the parking brakes.

   If the distance is not within the acceptable range, go to the next step.

4. Determine how much the suspension height needs to be adjusted so the distance matches the target height in the applicable table. Then, using **Table 7**, find the amount that the length of the vertical linkage rod needs to be changed; see **Fig. 5**.
5. Adjust the length of the vertical linkage rod as needed, adding or subtracting the amount shown in **Table 7**.

   NOTE: If the vertical linkage rod is too short, replace it with a new rod, part number 16–13485–000. The vertical linkage rod should be long enough so that at least 1/2 inch (13 mm) of it fits into both flexible end-sections of the linkage.

   5.1 Mark the existing length of the vertical linkage rod between the upper and lower flexible end-sections of the linkage; see **Fig. 5**.

   5.2 Loosen both linkage adjustment clamps.

   5.3 Slide the flexible end-sections of the linkage over the linkage rod until the rod is the correct length.

   To increase the suspension height, lengthen the vertical linkage rod; to decrease the suspension height, shorten the rod.

   5.4 Tighten the adjustment clamps.

6. Drive the vehicle unloaded for about 1/4 mile (1/2 km).

   Park the vehicle using a light brake application. Chock the tires on one axle only, and put the transmission in neutral. Don't apply the parking brakes.

7. Check the distance between the bottom of the left forwardmost axle stop and the top of the axle U-bolt.

8. If the distance is within the acceptable range, ride height is adjusted correctly. Apply the parking brakes.

   If the distance is not within the acceptable range, repeat the adjustment procedure.

Height-Control Valve Checking

It is normal to hear air escaping from the height-control valve for as much as 10 minutes after getting out of the vehicle when it is in an unladen condition. This air "leaking" is just the height-control valve exhausting air from the suspension air springs in order to return to the neutral mode.

The height-control valves used on the Century Class are Barksdale or Meritor WABCO valves. Two methods are available to check the operation of the Barksdale height-control valves. A leak in the valve may be discovered without using a test kit, but a test kit is necessary to determine if the valve has an unacceptable rate of leakage. WABCO valves can only be checked without a test kit.

Some Barksdale height-control valves have been returned for warranty because the four bolts in the valve housing were overtightened, often, enough to crack the valve housing. These bolts should not be loose, and should not normally require tightening, as there are no serviceable parts in the valve.

IMPORTANT: To prevent voiding the warranty on Barksdale height-control valves, note the following:

- Do not overtighten the bolts in the Barksdale height-control valve housing if you detect leaks in the housing. The bolts should not be loose, and should not require tightening. Only if necessary, tighten the valve housing bolts 45 lbf·in (500 N·cm). Any damage to the valve housing will void the warranty.
- Do not attempt to disassemble the Barksdale valve body or the control lever. There are no serviceable parts in the valve, and any disassembly will void the warranty.

NOTICE

When removing or loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

Checking the Height-Control Valve Without Using a Test Kit

1. Apply the parking brakes and chock the tires.
2. Run the engine to build vehicle air pressure to at least 100 psi (690 kPa).
3. Shut off the engine and wait 5 to 10 minutes for the air suspension system to equalize.

NOTE: Normal operation of the height-control valve requires a maximum of 10 minutes to settle. Any air leakage during this time is considered normal, and does not indicate a defective valve.

4. Disconnect the vertical linkage from the control lever; see **Fig. 1** or **Fig. 2**.

5. Pull the control lever up about 45 degrees for 6 to 8 seconds. If air passes through the valve, that section of the valve is working.
6. Return the control lever to the neutral position. Air should stop flowing. If so, that section of the valve is working.
7. Push the control lever down about 45 degrees for 6 to 8 seconds. If air exhausts from the valve, that section of the valve is working.
8. Return the control lever to the neutral position. If the air stops again in the neutral position, the valve is working correctly.
9. If the valve works as stated in all of the above steps, then no further checking is necessary. Connect the vertical linkage to the control lever, then tighten the linkage nut (Barksdale valves), or secure the linkage with a cotter pin (Meritor WABCO valves).

   If needed, adjust the ride height or replace the height-control valve. For adjustment of the ride height, see **Subject 110**. For replacement of the height-control valve, see **Subject 130**.

NOTE: If a leak is detected on a Barksdale height-control valve, go to "Checking the Height-Control Valve Using a Test Kit". Barksdale valves have an acceptable leak rate of 3 cubic inches (50 cc) per minute. You can determine if a leak is acceptable only by using the Barksdale test kit.

If a leak is detected at the exhaust port on a WABCO height-control valve, the valve is defective. Replace it, following the procedure in **Subject 130**.

Checking the Height-Control Valve Using a Test Kit

IMPORTANT: The procedure described below is for use on Barksdale height-control valves only.

NOTE: The Barksdale field test kit is designed to be used with the height-control valve installed on the vehicle. Refer to **Specifications 400** for information on ordering the Barksdale height-control valve test kit KD2264.

1. If not already done, park the vehicle on a level surface, apply the parking brakes, and chock the tires.
2. Run the engine to build vehicle air pressure to at least 100 psi (690 kPa).
3. Shut off the engine and wait 5 to 10 minutes for the air suspension system to equalize.

NOTE: Normal operation of the height-control valve requires a maximum of 10 minutes to settle. Any air leakage during this time is considered normal, and does not indicate a defective valve.

4. For valves without an integral dump port, go to the next step.

   For valves with an integral dump port, check the rubber exhaust flapper at the back of the valve housing for leaks; see **Fig. 3**. Use a soapy solution.

   If a leak is found, there may be contaminants blocking the piston. Cycle the height-control valve switch inside the cab for two-second bursts, four or five times, to clear away any contaminants.

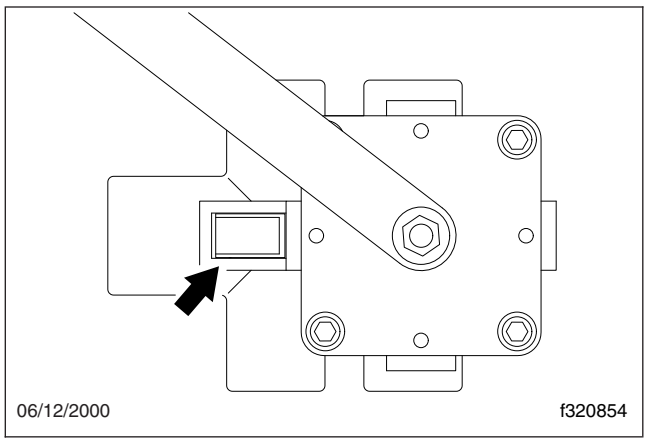

Fig. 3, Exhaust Flap Location (height-control valve with integral dump port)

5. Disconnect the vertical linkage from the horizontal control lever.
6. Rotate and hold the horizontal control lever down at about 45 degrees to exhaust air from the air springs.
7. *If equipped with an integral dump port,* turn on the quick dump switch on the dash. Leave the switch on until testing is complete.

   If not equipped with an integral dump port, disconnect the air lines from the air spring ports on the height-control valve. Leave the elbow fittings (if equipped) in place. Install a Parker plug into each air spring port (or elbow fitting); see **Fig. 4**.
8. If a flapper is present on the exhaust port of the height-control valve, remove it using needlenose pliers.
9. Clean the surface around the exhaust port, then install the test fitting into the exhaust port. The centering pin on the fitting must align with the slot on the exhaust port. Rotate the test fitting 45 degrees clockwise to lock it in place; see **Fig. 4**.

NOTE: It may be necessary to cut the tie straps that hold the chassis wiring running below the height-control valve, in order to access the exhaust port.

10. Connect one end of the air hose from the kit to the test connector on the exhaust port, and the other end to the test gauge.
11. Check the height-control valve in the fill mode, as follows.
    - 11.1 Rotate the valve control lever up 45 degrees from the horizontal to the fill position.
    - 11.2 Press the reset button on the test gauge.
    - 11.3 Observe the test gauge for 30 seconds. Refer to **Fig. 5** for the maximum allowable exhaust pressure change versus inlet pressure.

      The valve is not working correctly if the gauge pressure reading exceeds the maximum allowable within 30 seconds.

      If the gauge reads less than the maximum allowable pressure change in 30 seconds, the valve is okay.

NOTE: The test gauge will register the exhausting air. *This does not indicate a defective valve.*

12. Check the height-control valve in the exhaust mode, as follows.
    - 12.1 Rotate the valve control lever down 45 degrees from the horizontal to the exhaust position.
    - 12.2 Press the reset button on the test gauge.
    - 12.3 Observe the test gauge for 30 seconds. Refer to **Fig. 5** for the maximum allowable exhaust pressure change versus inlet pressure.

      The valve is not working correctly if the gauge pressure reading exceeds the maximum allowable within 30 seconds.

      If the gauge reads less than the maximum allowable pressure change in 30 seconds, the valve is okay.

NOTE: The test gauge will register the exhausting air. *This does not indicate a defective valve.*

13. Disconnect the test gauge and connector from the valve exhaust port.
14. If the height-control valve is defective, replace it; see **Subject 130**.
15. Install the flapper on the exhaust port by pressing it into place.
16. *For height-control valves with an integral dump port,* connect the vertical linkage to the height-control valve control lever. Turn off the quick

For height-control valves without an integral dump port, remove the two Parker plugs from the air spring ports, and connect the air lines to the air spring ports (or elbow fittings). Connect the vertical linkage to the height-control valve control lever. The ride height will automatically return to the correct position.

Replacement

NOTE: The Barksdale height-control valve replaced the Meritor WABCO valve after July 25, 1997. On vehicles with tandem-axle AirLiner rear suspensions, the Barksdale vertical linkage rod is attached to the forward drive axle instead of the rearmost drive axle, and the valve is mounted on the frame rail.

Barksdale

The Barksdale valve does not use an adjustable linkage rod. To adjust the Barksdale valve, see **Subject 110**.

1. Apply the parking brakes and chock the tires.

⚠ WARNING

Keep your hands and all objects away from the area under and around the slack adjusters and suspension components when removing the pressure from the air system. These parts will move as the air is released and can cause personal injury or damage to any objects that are between the moving parts.

2. Drain all air from the air tanks.

⚠ WARNING

Air lines under pressure can whip dangerously if disconnected. Drain all air from the air tanks before disconnecting air lines. Disconnecting pressurized air lines can cause personal injury and/or property damage.

3. Remove the nut and washer that attaches the vertical linkage to the horizontal control lever. Disconnect the vertical linkage from the control lever; see **Fig. 1**.
4. Rotate and hold the horizontal control lever down until all air is exhausted from the air springs.
5. Disconnect the air lines at the height-control valve, and mark the lines for later reference. Using tape, cover the open ends of the air lines and fittings to prevent dirt or foreign material from entering.

IMPORTANT: For quick-connect tube fittings, do not remove the tube by cutting it close to the fitting. If the remaining part of the tube cannot be pulled from the fitting, the fitting will not be reusable and the warranty on that unit will be void.

NOTICE

When removing or loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

6. While holding the height-control valve mounting studs in place with an Allen wrench, remove the nuts and washers that attach the valve to the mounting bracket. Remove the height-control valve.

Height-Control Valve Replacement

7. Position the new height-control valve on the height-control bracket. While holding the height-control valve mounting studs in place with an Allen wrench, install the nuts and washers, and tighten the nuts 95 lbf·in (1100 N·cm). Do not overtighten.
8. Remove the tape from the air lines and fittings, and connect the air lines to the height-control valve as marked earlier. Tighten nylon tube air fittings until only two threads show on the fitting. On wire-braid hose fittings, tighten the nut with a wrench until there is firm resistance, then tighten one-sixth turn more.
9. Close the drain cocks on all reservoirs.
10. Build up normal operating pressure in the air system. Check all air lines and connections for leaks. Eliminate all leaks.
11. Adjust the height-control valve; see **Subject 110**.

Meritor WABCO

1. Park the vehicle on a level surface. Apply the parking brakes and chock the tires.

⚠ WARNING

Keep your hands and all objects away from the area under and around the slack adjusters and suspension components when removing the pressure from the air system. These parts will move as the air is released and can cause personal injury or damage to any objects that are between the moving parts.

2. Drain all air from the air tanks.

⚠ WARNING

Air lines under pressure can whip dangerously if disconnected. Drain all air from the air tanks before disconnecting air lines. Disconnecting pressurized air lines can cause personal injury and/or property damage.

3. Disconnect the vertical linkage from the horizontal control lever; see **Fig. 2**.
4. Rotate and hold the horizontal control lever down until all air is exhausted from the air springs.
5. Disconnect the air lines at the height-control valve, and mark the lines for later reference. Using tape, cover the open ends of the air lines and fittings to prevent dirt or foreign material from entering.

6. Remove the height-control valve mounting bolts and nuts, then remove the height-control valve from the bracket.
7. Remove the horizontal control lever from the height-control valve.
8. Attach the new height-control valve to the bracket. Tighten the valve mounting bolt nuts 14 lbf·ft (19 N·m).
9. Remove the tape from the air lines and fittings, and connect the air lines to the height-control valve as marked earlier. Tighten nylon tube air fittings until only two threads show on the fitting. On wire-braid hose fittings, tighten the nut with a wrench until there is firm resistance, then tighten one-sixth turn more.
10. Connect the vertical linkage to the horizontal control lever. Secure the linkage with a cotter pin.
11. Connect the horizontal control lever to the height-control valve. Insert the horizontal control lever into the valve at the hole with the V-shaped mark; see **Fig. 2**. Be sure the length between pivot points is 8 inches (20.3 cm); see **Fig. 2**, Ref. A.

12. Close the drain cocks on all reservoirs.
13. Build up normal operating pressure in the air system. Check all air lines and connections for leaks. Eliminate all leaks.
14. Adjust the height-control valve; see **Subject 110**.

Shock Absorber Replacement

1. Chock the tires.
2. Remove the locknut, bolt, and spacer from the shock absorber lower mounting bracket. **See Fig. 1.**
3. Remove the nut, upper retainer, and upper bushing from the top of the shock absorber.
4. Pull the shock absorber out of the upper mounting bracket, and remove the retainer and bushing.
5. Install the replacement shock absorber, making sure the new bushings and retainers are correctly positioned. **See Fig. 1.**

⚠ WARNING

WARNING: Use only the retainers included with the replacement shock absorber. Do not use washers. They can be extruded over the nut and be ejected violently, possibly causing personal injury and property damage.

6. Tighten the shock absorber lower mounting locknut 170 lbf·ft (230 N·m).
7. Tighten the shock absorber upper mounting nut to compress the bushings to the dimension **as shown in Fig. 1**.

Air Spring Replacement

IMPORTANT: Effective March 2011, the steel bead on the inside of the air bag where it attaches to the piston, changed to a square bead to increase the pull-off force between the air bag and piston. The new air bag is stamped “BD8” and “Do Not Re-Assemble Rubber Bellow to Piston.” See **Fig. 1**. With this design change it is not possible to reseat the air bag to the piston. In the event of an air bag failure, or separation from the piston, the complete air-spring assembly must be replaced. For service it is acceptable to have a replacement air-spring assembly on one side of the vehicle, and an older style on the other side.

NOTE: The air-spring-to-frame-rail mounting bracket is not supplied with the air-spring assembly. If it needs to be replaced it must be ordered separately.

Follow these steps to replace the air-spring and piston assembly.

1. Chock the front tires. Raise the vehicle frame and support it with safety stands to remove all weight from the air springs. The leveling valve automatically releases air from the air springs when all weight is removed from the suspension.
2. Disconnect the air supply line,including the brass tee, from the air spring. Using tape, cover the ends of the air supply line and the fitting to prevent dirt or foreign material from entering.
3. Remove the locknuts and washers that connect the air spring to the upper mounting bracket, or to the frame rail flange. See **Fig. 2** and **Fig. 3.**
4. Remove the capscrews and lockwashers that connect the air spring to the rear of the leaf spring. Remove the air spring. **See Fig. 4.**

NOTE: Suspensions manufactured to a 46,000-pound (20 865 kg) or 23,000-pound (10 433 kg) weight rating have a different leaf spring, and an additional cross bar attached between the air spring and rear of the leaf spring. **See Fig. 5.**

5. Place the new air spring on the rear of the leaf spring (or the cross bar on the 23,000- and 46,000-pound suspensions), and install the washer and locknut that hold the air spring (and cross bar) in place. **See Fig. 4.** Tighten the locknut 55 lbf·ft (75 N·m).
6. *For bracket-mounted air springs:* Attach the air spring to the upper mounting bracket, using the 1/2–13 locknut on the outside of the frame rail and the 3/4–16 locknut on the inside. **See Fig. 2.** Tighten the 3/4–16 locknut 45 lbf·ft (61 N·m); tighten the 1/2–13 locknut 23 lbf·ft (31 N·m).

   For flange-mounted air springs: Attach the air spring to the frame rail flange, using the 3/4–16 locknut on the forward stud of the air spring, and the 1/2–13 locknut on the rear stud. **See Fig. 3.** Tighten the 3/4–16 locknut 45 lbf·ft (61 N·m); tighten the 1/2–13 locknut 23 lbf·ft (31 N·m).
7. Remove the tape from the ends of the air supply line, the fitting, and the brass tee. Connect the air supply line to the air spring. Tighten nylon tube air fittings until only two threads show on the fitting. On wire-braid hose fittings, tighten the nut with a wrench until there is firm resistance, then tighten one-sixth turn more.
8. Remove the safety stands, and lower the vehicle. Remove the chocks from the tires.

⚠ WARNING

WARNING: Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Chock the front tires.
2. Raise the rear of the vehicle, and support the rear axle(s) with safety stands. Raise the vehicle so that all weight is removed from the leaf springs, then securely support the frame with safety stands. Remove the wheel and tire assembly to easily access the suspension. Refer to

Leaf Spring Replacement

the wheels and tires section in this manual for instructions.

3. Remove the nut, bolt, and washers from the shock absorber lower mounting bracket. Remove the high nuts, flatwashers, and axle clamp from each U-bolt. Support the leaf spring assembly with a jack.
4. If the air spring mounts to the leaf spring, disconnect the bottom of the air spring from the leaf spring.

   If the air spring mounts to a cross bar, disconnect the cross bar from the leaf spring by removing the capscrews, nuts, and washers. See **Fig. 2.**

6. Remove the hexnut, washers, alignment shim(s), spring mounting bolt, and wear shoe clip from the spring hanger. See **Fig. 1.**

⚠ WARNING

WARNING: The leaf spring assembly is heavy. Use care when handling it to prevent injury.

7. Remove and discard the leaf spring assembly.
8. While supporting a new leaf spring assembly with a jack, position the assembly on the spring hanger. Install the bolts, wear shoe clips, washers, alignment shims, and hexnuts. Tighten the bolts just enough to hold the leaf spring assembly in place.
9. If the air spring mounts to the leaf spring, attach the air spring to the leaf spring assembly. Install the washer and locknut. Tighten the locknut 55 lbf·ft (75 N·m).

   If the air spring mounts to a cross bar, attach the cross bar to the leaf spring assembly. The longer capscrews attach in the forwardmost holes; the shorter capscrews attach in the aft holes.
10. Making sure that the U-bolt pads are in place on the top of the axle, fasten the leaf spring assembly to the axle using the U-bolts, axle clamp, washers, and high nuts making sure the U-bolt pads and axle clamps are positioned correctly.

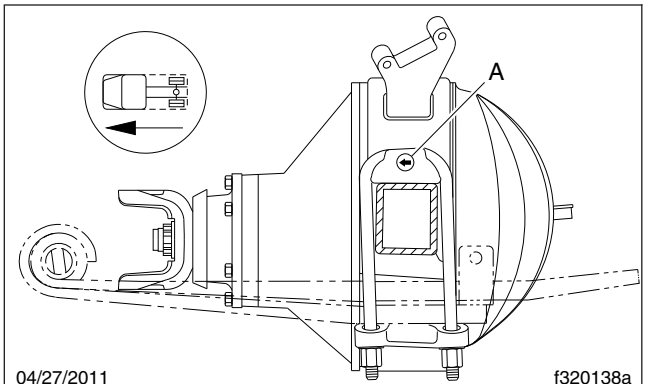
NOTE: On single-drive axles angled 5 degrees, the arrow on the U-bolt pads must point to the front of the axle housing. See **Fig. 3**. On single-drive axles angled 3 degrees, there is no arrow. Make sure that the axle bump stop on the U-bolt pad is positioned toward the vehicle centerline. See **Fig. 4 .**

With both 5- and 3-degree single-drive axle angles, the arrow on the bottom of the axle clamp (See **Fig. 1**) must point toward the rear of the vehicle.

On tandem axle suspensions, refer to **Table 1** for U-bolt pad orientation. The arrow on the bottom of the axle clamp must point toward the rear of the vehicle on the forward rear axle and toward the front of the vehicle on the rearmost axle.

11. Hand tighten the high nuts. In a diagonal pattern, tighten the axle U-bolt high nuts 60 lbf·ft (81 N·m). Then, in the same pattern, tighten them 200 lbf·ft (271 N·m); then, torque to the final value of 400 to 460 lbf·ft (542 to 624 N·m).

    For the 23,000-pound and 46,000-pound suspensions, tighten the high nuts in a diagonal pattern to a final torque value of 520 to 600 lbf·ft (705 to 813 N·m).



A. Arrow on U-Bolt Pad

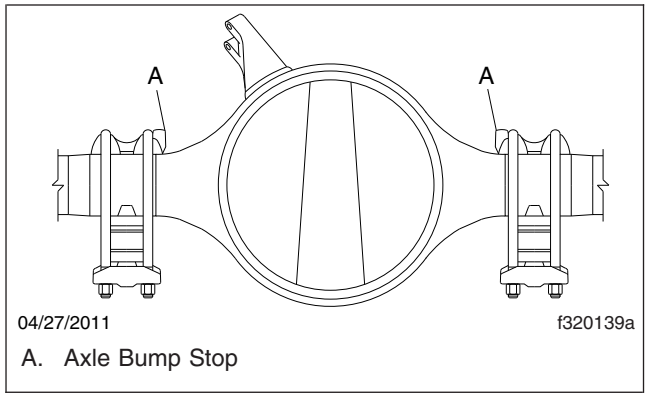
12. Install the bolt, washers, and hexnut to connect the shock absorber to its lower mounting bracket. Tighten the hexnut 170 lbf·ft (230 N·m).
13. Tighten the locknut on the bottom of the air spring 55 lbf·ft (75 N·m).

    On 23,000-pound and 46,000-pound suspensions, tighten the locknuts on the bottom of the cross bar 241 lbf·ft (327 N·m).



A. Axle Bump Stop

14. Tighten the hexnuts at the front of the leaf spring 170 lbf·ft (230 N·m).
15. Install the wheel and tire assembly. For instructions, refer to **Group 40**. Remove the safety stands, and lower the vehicle.
16. Check the rear axle alignment. For instructions, refer to the rear axle section in this manual. If necessary, adjust the rear axle alignment using the instructions in **Subject 170**.

Rear Axle Alignment Adjusting

See **Fig. 1**.

Follow the instructions in the rear axle section of this manual to see if rear axle alignment adjustment is needed. If adjustment is needed, proceed as follows:

3. When the axle is in alignment, install alignment shim(s) to take up the slack between the spring hanger and the spring pin.

IMPORTANT: Make sure the same number of shims is installed on both ends of the spring pin.

1. Loosen the spring pinch bolts so that the forward end of the leaf spring can slide fore and aft in the spring hanger.
2. Move the axle forward or backward until it is aligned within the tolerances in the rear axle alignment checking section of this manual.
4. Tighten the spring pinch bolts 170 lbf·ft (230 N·m).
5. Check the axle alignment again. If necessary, repeat the above procedure until the alignment is within tolerances.

Rear Axle Alignment

Rear Axle Tracking Adjustment

Single Axle

1. At the forward edge of the right rear tire, measure the distance from the inner side of the tire to the outer side of the right frame rail. See **Fig. 2**.

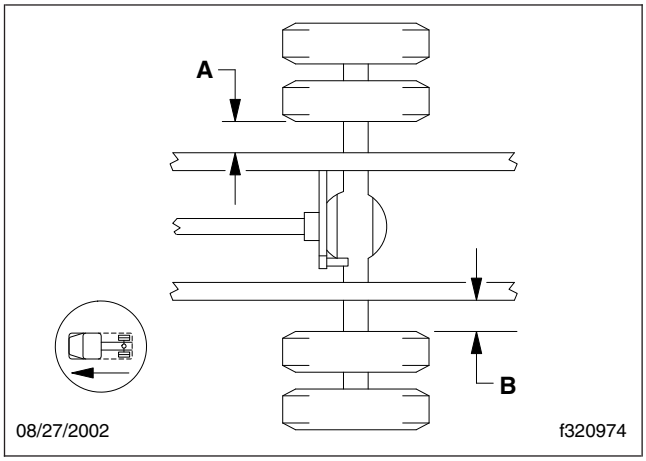

Fig. 2, Rear Axle Tracking Measurements (single axle)

2. At the rear edge of the left rear tire, measure the distance from the inner side of the tire to the outer side of the left frame rail. See **Fig. 2**.

IMPORTANT: Measurement "A" should not vary by more than 1/4-inch (6 mm) from measurement "B."

3. If measurements "A" and "B" vary by more than 1/4-inch (6 mm), loosen the fasteners holding the lateral torque rod to the frame rail. Add or remove torque-rod shims as needed.
4. For bar-pin style torque rods, tighten the fasteners 136 lbf·ft (184 N·m).

   For taper-pin style torque rods, tighten the fasteners 165 lbf·ft (224 N·m). See **Fig. 3**.

Tandem Axles

1. Check the tracking of the forward-rear axle. For instructions, see "Single Axle" in this subject. Adjust the tracking if needed.
2. At the forward-rear drive axle, measure the distance from the inner side of the right rear tire to the outer side of the right frame rail. Measure at the forward edge of the tire. See **Fig. 4**.

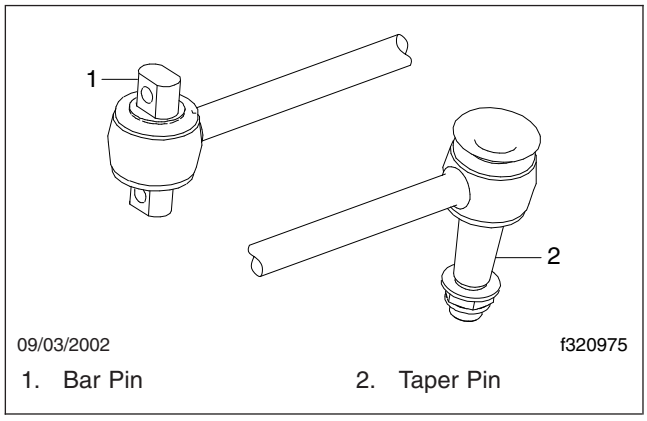

Fig. 3, Torque Rod Types

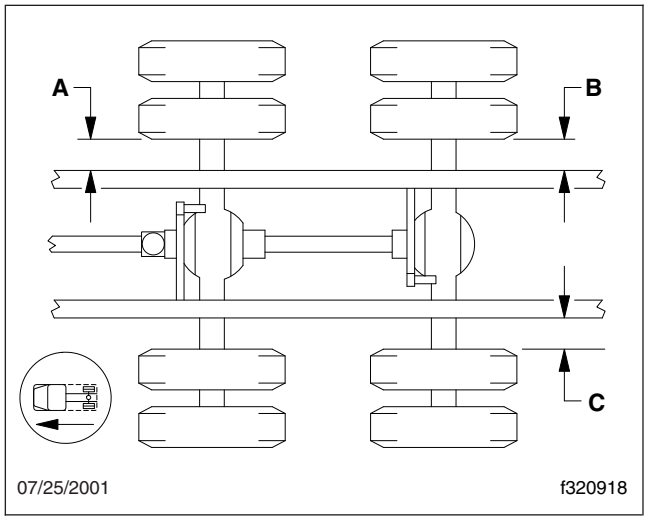

Fig. 4, Rear Axle Tracking Measurements (tandem axles)

3. At both sides of the rear-rear drive axle, measure the distance from the inner side of the rear tires to the outer side of each frame rail. Measure at the rear edge of each tire. See **Fig. 4**.

IMPORTANT: Measurements "B" and "C" should not vary by more than 1/4-inch (6 mm) from measurement "A."

4. If measurements "B" and "C" vary by more than 1/4-inch (6 mm) from measurement "A," loosen the fasteners holding the axle lateral torque rod at the rear-rear drive axle to the frame rail. Add or remove torque-rod shims as needed.

5. For bar-pin style torque rods, tighten the fasteners 136 lbf·ft (184 N·m). For taper-pin style torque rods, tighten the fasteners 165 lbf·ft (224 N·m). See **Fig. 3**.

Replacement

1. Park the vehicle. Shut down the engine, and apply the brakes.
2. Chock the tires. Raise the vehicle. Support the frame rails with jack stands.
3. Remove the fasteners holding the control rod to the frame rail bracket. Remove the shims, and set the shims aside.
4. Remove the control rod.
5. Position the new control rod so that the end with the fasteners angled up at 35 degrees is installed in the axle housing bracket. **See Fig. 1.**

NOTE: Control rods on suspensions manufactured to a 23,000-pound (10 433 kg) or 46,000-pound (20 865 kg) weight rating are larger and are attached to the axle bracket with a single bolt. Tighten the fasteners attaching the control rod frame bracket to the frame rail 160 to 170 lbf·ft (217 to 230 N·m), and the bolt connecting the control rod to the axle housing 175 to 225 lbf·ft (237 to 305 N·m). **See Fig. 2.**

Replacement

WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front tires.
2. Raise the rear of the vehicle, and support the rear axle(s) with safety stands. Raise the vehicle so that all weight is removed from the leaf springs, then securely support the frame with safety stands.
3. Remove the wheel and tire assembly to easily access the suspension. For instructions, see the information in **Group 40**.
4. Remove the leaf spring assembly. See removal information in **Subject 160**.

WARNING

The leaf spring assembly is heavy. Use care when handling it to prevent injury.

5. Remove the bushing from the leaf spring eye.

WARNING

Do not use a cutting torch to remove the outer metal of the bushing from the spring eye. Welding, torching or cutting the leaf spring assembly can damage the leaf spring material, which may result in the failure of the components and cause serious personal injury, death, or property damage.

   5.1 Using a shop press with a capacity of at least 10 tons (9 072 kg), place the spring assembly in the shop press with the spring assembly squarely supported on the press bed for safety and to avoid bending the spring assembly.

   5.2 Center the bushing tool on the outer metal of the bushing and push the bushing from the spring eye.

   5.3 Remove any burrs or material left behind by the old bushing.

6. Install the new bushing in the leaf spring eye.

   6.1 Position the bushing on the shop press.

   6.2 Apply a bonding agent, either Perma-bond HM–160 or Loctite RC–609 or 680, liberally around the outside surface of the bushing.

   6.3 Press the bushing into place.

   6.4 Allow the bonding agent to cure for 24 hours.

   NOTE: After the curing time, the bushing must resist a minimum 7,700 lb (3 490 kg) pushout force.

7. Install the leaf spring assembly. See the information in **Subject 160**.
8. Install the wheel and tire assembly. For instructions, see **Group 40**. Remove the safety stands, and lower the vehicle.
9. Check the rear axle alignment. For instructions, refer to **Group 35** in this manual. If necessary, adjust the rear axle alignment using the instructions in **Group 35**.
10. Remove the chocks from the tires.

IMPORTANT: To prevent voiding the warranty on Barksdale height-control valves, note the following:

- Do not overtighten the bolts in the Barksdale height-control valve housing. The bolts should not be loose, and should not

require tightening. Only if necessary, tighten the valve housing bolts 45 lbf·in (500 N·cm). Any damage to the valve housing will void the warranty.

- Do not attempt to disassemble the Barksdale valve body or the control lever. There are no serviceable parts in the valve, and any disassembly will void the warranty.

NOTICE

When removing or loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

General Information

The Reyco suspension has two springs at each side of the vehicle frame. See **Fig. 1.** These springs are supported and held in place by three frame-mounted brackets. The two forward brackets also serve as mounts for the axle radius rod eyes. The middle bracket is a two-piece assembly that supports one end of each tandem spring. The two pieces are fastened together in a pivoting manner, permitting movement of the individual leaf springs as they adjust to varying load and changing road contours. The distribution of the vehicle load is equalized between the axles by the leveling action of this pivoting assembly.

each spring assembly is formed into a hook which catches on a spring roller and rebound bolt to prevent excessive forward movement of the axle if a radius rod were to break.

1. Adjustable Torque Tracking Rod

Fig. 1, Reyco Suspension

Driving and braking forces are transmitted to the vehicle frame through radius rods or torque leaves. Eccentric bushings at the forward end (or eye) of each radius rod permit alignment of each axle independently of the other. A total adjustment of 7/16 inch (11 mm) can be made on each side of the vehicle.

Road shock is cushioned by rubber bushings and cushions at most points of movement. Lubrication of suspension parts is not necessary. The rear end of

Suspension Removal, Inspection, and Installation, Reyco

Removal

If the suspension system is being overhauled, remove the suspension using the following procedure:

1. Chock the front tires. Drain the vehicle air system. Disconnect all air lines leading to the rear axles, marking the lines for later assembly reference. Plug all lines and fittings to prevent dirt or foreign material from entering the lines.
2. Disconnect the driveline rear universal joint from the forward-rear axle. For instructions refer to **Group 41** of this manual.
3. Manually cage the parking brake chambers. For instructions, refer to **Group 42** of this manual.
4. Using an overhead hoist, raise the rear of the vehicle enough to relieve the weight from the suspension. Support the frame and axle with safety stands.

⚠ WARNING

WARNING: Securely support all axle and frame weight with safety stands during suspension repairs. Unsecured components may drop when fasteners are loosened or removed, causing serious personal injury and component damage.

NOTE: Do not raise the vehicle to the point where the suspension and axles hang from the vehicle.

5. On both sides of the vehicle, remove the forward rear spring bracket rebound bolt, spring roller, radius rod eye bolt, large flatwashers, and eccentric rubber bushings. **See Fig. 1.**

NOTE: The radius rod eye bushing is a two-piece unit. Insert a punch into the inside of the bushing and drive out one side of the bushing. Insert the punch from the opposite side to remove the remaining half of the bushing.

6. On both sides of the vehicle, remove the rebound bolts and the spring rollers from the equalizer arm.

NOTE: For clarity, only one of each of the rebound components is shown in **Fig. 1** even though two are used on the equalizer arm.

7. Secure all radius rods to the spring assemblies.
8. On both sides of the vehicle, remove the rear spring bracket rebound bolt, spring roller, and bushing.
9. Using the hoist, raise the frame high enough to remove the tandem assembly out from under the frame.

Inspection

1. Clean the suspension parts and inspect all parts carefully for cracks, excessive wear, or damage.
2. Inspect the rubber bushings for damage or wear.
3. Replace components as required, following the instructions in this subject.

NOTE: When repairs are made on the removed tandem suspension that involve removal and installation of the spring U-bolts or radius rods, the mounting nuts should be tightened only partially before installation. When the tandem suspension is installed, do a preliminary alignment of the axles to the frame as described below. Then tighten the rear axle U-bolt nuts to the final torque. Tighten the radius rod bolts to the final torque only after the final alignment of the axles. Refer to **Specifications, 400** for the torque settings.

Installation

1. With the frame raised on a hoist and a hydraulic floor jack under the forward rear axle differential carrier, roll the axles and suspension assembly into position under the frame; then, lower the frame.
2. On both sides of the vehicle install the rear spring bracket bushing, spring roller, and rebound bolt, washer, and nut. Tighten the nut 75 lbf·ft (102 N·m).
3. On both sides of the vehicle install the spring rollers, rebound bolts, washers, and nuts in the center spring equalizer arm. Tighten the nuts 75 lbf·ft (102 N·m).
4. On both sides of the vehicle install the forward spring bracket rebound bolt, washer, and spring roller. There is no nut on the forward spring

bracket rebound bolt. Tighten the bolt 75 lbf·ft (102 N·m).

5. Connect the driveline rear universal joint to the forward-rear axle. Refer to **Group 41** in this manual. Remove the hydraulic floor jack.
6. Lower each radius rod and align the radius rod eye with the spring bracket. Install both halves of the rubber eccentric bushing into the spring bracket from the outside with the flat of the bushing insert in the down position, or with the arrow pointing up. Install the large flatwasher onto the bolt and insert the bolt into the bushing with the arrow on the bolt head also pointing up. Install the large flatwasher and nut on the bolt. Tighten the nut, but not to its final torque.

NOTE: With all four radius rod eccentric bushings and bolts installed with the arrows pointing up, the suspension is in its base alignment to the frame.

7. Tighten the rear axle U-bolt nuts to the final torque listed in **Specifications, 400** in the sequence shown in **Fig. 2.**

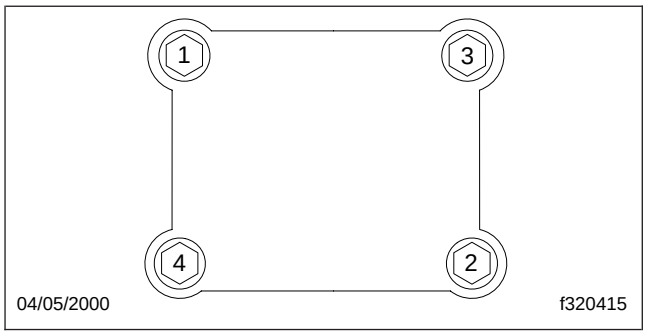

Fig. 2, U-Bolt Tightening Sequence

8. Taking care to prevent dirt and other foreign material from entering the lines or fittings, connect the air brake lines leading to the axles. Close the air system drain valve.
9. Check the axle pinion angle. For instructions, refer to **Group 41** of this manual. Adjust the angle if it is not according to specifications.
10. Check the axle alignment and adjust it if needed.
11. Make sure the radius rod eye bolt nuts are tightened to the applicable torque value in **Specifications, 400**.

Forward Rear Spring Removal

1. Park the vehicle and chock the tires.
2. Raise the vehicle and block the axles with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will support the weight of the axles and frame securely. Remove the wheel assembly to gain easy access to the suspension system.
3. Remove the U-bolts and the U-bolt anchor plate. Remove the front rebound bolt, washer, and spring roller from the front spring bracket. **See Fig. 1**.
4. Remove the rebound bolt, nut, washer, and spring roller from the front of the equalizer arm in the equalizer bracket.

NOTE: Some references in **Fig. 1** are shown at the rear of the equalizer arm. For clarity, they have been omitted at the front of the equalizer arm.

5. Slide the spring forward until it clears the equalizer arm. Lift the spring assembly at the rear to clear the equalizer arm; then, slide the spring to the rear and remove it.

Forward Rear Spring Installation

1. Locate the spring in the front spring bracket and slide it forward until the rear of the spring is in position to clear the equalizer arm.
2. Slide the spring rearward into position in the equalizer arm.
3. Install the rebound bolts, washers, spring rollers, and nuts in the front spring bracket and in the equalizer arm. There is no nut on the rebound bolt in the front spring bracket. Tighten the fasteners 75 lbf·ft (102 N·m).
4. Place the spring assembly on the axle spring seat with the center bolt head in the locating hole of the lower spring seat.
5. Place the upper U-bolt spacer pad on top of the spring. Install the U-bolts and the U-bolt anchor plate. Install the U-bolt washers and nuts. Partially tighten the nuts until preliminary adjustment of the suspension has been made; then, tighten them in sequences shown in **Fig. 2.**
6. Install the wheels. Remove all safety stands. Remove the chocks from the tires.

Rearmost Spring Removal

1. Park the vehicle and chock the tires.
2. Raise the vehicle and block the axles with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will support the weight of the axles and frame securely. Remove the wheel assembly to gain easy access to the suspension system.
3. Remove the U-bolt nuts and washers, the U-bolt anchor plate, the U-bolts, and the upper U-bolt spacer pad.
4. Remove the rear rebound bolt, nut, washer, spring roller, and bushing from the rear spring bracket.
5. Remove the rear rebound bolt, nut, washer, and spring roller from the equalizer arm in the equalizer bracket.
6. Slide the spring rearward until it clears the equalizer arm. Lift the spring assembly at the front to clear the equalizer arm and remove the spring.

Rearmost Spring Installation

1. Locate the spring in the front spring bracket and slide it to the rear until the front of the spring is in position to clear the equalizer arm.
2. Slide the spring forward into position in the equalizer arm.
3. Install the rebound bolts, washers, and spring rollers in the rear spring bracket and in the equalizer arm. Tighten the nuts 75 lbf·ft (102 N·m).
4. Place the spring assembly on the axle spring seat with the center bolt head in the locating hole of the lower spring seat.
5. Place the upper U-bolt spacer plate on top of the spring. Install the U-bolts and the U-bolt anchor plate. Install the U-bolt washers and nuts. Par-

Spring Disassembly, Inspection, and Assembly, Reyco

Disassembly, Inspection, and Assembly

1. To disassemble, use chalk or a grease pencil to make a mark down the side of the spring pile so the spring leaves can be assembled in the same relative position.
2. Anchor the spring at a point near the center bolt in a vise or arbor press. Tighten the vise or arbor press firmly.
3. Remove the bolts, nuts, and sleeve from the spring clips. Observe the spring leaves. Pay special attention to the top three leaves, since the spring easily can be assembled incorrectly even though reference marks are used.
4. Prior to inspection, wash all parts in a suitable solvent. Remove any scale, rust, or deposits from the spring leaves.
5. Inspect all the leaves for breaks and small cracks. If any are found, replace the entire spring assembly.

⚠ WARNING

WARNING: Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

6. Inspect the spring assembly for loose or broken rebound clips. Rebound clips should be tight enough to hold the spring leaves in alignment, but not tight enough to restrict the free movement of the leaves.
7. Inspect the center bolt for distortion and wear. Replace the bolt if it is not in good condition.
8. Inspect the U-bolts and spring spacer plates. Replace them if they are damaged or cracked.
9. Inspect the spring brackets at the reinforcing webs and in the corners. Do not weld or braze cracks. If the bracket is cracked, replace it.
10. For assembly, stack the spring leaves using care to position them in the proper sequence.
11. Using a long punch or other suitable tool, align the center bolt holes. Anchor the spring at a point near the center bolt hole in a vise or arbor press. Tighten the vise or arbor press firmly. Remove the alignment tool.
12. Install the center bolt and nut. Tighten the nut 70 lbf·ft (95 N·m) and peen the end of the bolt.
13. Install the bolts, nuts, and spacer sleeves to the spring clips. Tighten the nuts firmly. Peen the ends of the bolts.
14. Remove the assembly from the vise or arbor press.

Spring Bracket Removal and Installation, Reyco

Bracket Removal and Installation

1. To remove the forward spring bracket, raise the frame until all weight is off the spring, and safely block it in position.
2. Remove the rebound bolt, washer, and spring roller from the front spring bracket. **See Fig. 1.**

18. Slide the equalizer back and forth as necessary to gain access to the mounting bracket bolts.
19. Remove all the bolts, nuts, and washers that secure the equalizer bracket to the frame.
20. Remove the equalizer bracket and the spacer plate.
21. To install spring or equalizer brackets, reverse the removal procedure. Make sure the spacer plates are installed between the frame and bracket. Check the axle alignment and correct it if necessary, before tightening the radius rod eye bolt nuts to the final torque.

Radius Rod and Radius Rod Bushing Replacement, Reyco

Radius Rod Replacement

1. Raise the frame until all weight is off the spring, then safely block the frame in position.
2. Remove the locknut, washer (if so equipped), and bolt from the radius rod at the axle seat. Lower the rod. **See Fig. 1.**
3. Remove the nut and large flatwasher from the radius rod eye bolt. Using a brass drift tool, drive the eye bolt with the remaining flatwasher from the forward spring bracket or equalizer bracket.
4. Using a brass drift inside the rubber bushing, drive out one half of the bushing. Reverse the position of the drift and drive out the other half of the bushing from the opposite side of the bracket.
5. Remove the radius rod.
6. Place the eye of the new radius rod into the front spring or equalizer bracket.
7. Install both halves of the rubber eccentric bushing into the bracket from the outside with the flat of the bushing insert pointing down or the arrow pointing up.
8. Install the large flatwasher onto the radius rod eye bolt and insert the bolt into the bushing with the arrow on the bolt head pointing up.
9. Install the large flatwasher and the nut on the radius rod eye bolt. Tighten the nut, but not to its final torque.
10. Check the axle alignment and adjust it if necessary.
11. After the adjustment has been made, lower the vehicle and tighten the radius rod eye bolt nut to the applicable torque value in **Specifications, 400**.

Radius Rod Bushing Replacement

1. Raise the frame until all weight is off the spring, then safely block the frame in position.
2. Remove the radius rod as follows:
   - 2.1 Remove the locknut, washer (if so equipped), and bolt from the radius rod at the axle seat. Lower the rod. **See Fig. 1.**
   - 2.2 Remove the nut and large flatwasher from the radius rod eye bolt. Using a brass drift tool, drive the eye bolt with the remaining flat washer from the front spring or equalizer bracket.
   - 2.3 Using a brass drift inside the rubber bushing, drive out one half of the bushing. Reverse the position of the drift and drive out the other half of the bushing from the opposite side of the bracket.
   - 2.4 Remove the radius rod.
3. Press the old bushing out of the radius rod.
4. Coat the new bushing with a rubber lubricant and press it in so that the bushing is equal on both sides of the rod.
5. Install the radius rod as follows:
   - 5.1 Place the eye of the radius rod into the front spring or equalizer bracket.
   - 5.2 Install both halves of the rubber eccentric bushing into the bracket from the outside with the flat of the bushing insert pointing down or the arrow pointing up.
   - 5.3 Install the large flatwasher onto the radius rod eye bolt and insert the bolt into the bushing with the arrow on the bolt head pointing up.
   - 5.4 Install the large flatwasher and the nut on the radius rod eye bolt. Tighten the nut, but not to its final torque.
6. Check the axle alignment and adjust it if necessary.
7. After the adjustment has been made, lower the vehicle and tighten the radius rod eye bolt nut to the applicable torque value in **Specifications, 400**.

3. Remove the nut and large flatwasher from the radius rod eye bolt. Using a brass drift, drive the eye bolt with the remaining flatwasher from the equalizer bracket.
4. Secure the radius rod to the spring.
5. Remove the equalizer pivot nut, washer, and shaft.
6. Move the equalizer arm forward over the forward rear spring. Raise the frame. Slide the equalizer arm rearward through the bracket, then up and out.
7. Using a suitable press, press out the equalizer bushing.
8. Coat the new bushing with a rubber lubricant.
9. Press the bushing into the equalizer arm.
10. With the frame raised and the equalizer arm properly positioned, slide the equalizer arm into the equalizer bracket and forward over the front spring assembly.
11. Lower the frame and slide the equalizer arm over the rear spring until the center hole aligns with the hole in the equalizer bracket.
12. Apply anti-seize compound to the pivot shaft threads; then, install the pivot shaft by hand in the bracket. With steel crossmembers, install the bolt with the nut inside the frame; with aluminum crossmembers, install it with the nut outside the frame. When the shaft reaches the frame rail, back it out one-half turn. Install the lockwasher and nut. Tighten the nut 975 lbf·ft (1330 N·m).
13. Install the radius rod as follows. (**See Fig. 1**):
    - 13.1 Place the radius rod eye into the equalizer bracket. Install both halves of the rubber eccentric bushing into the bracket from the outside, with the flat of the bushing insert pointing down or the arrow pointing up.
    - 13.2 Install the large flatwasher onto the radius rod eye bolt and insert the bolt into the bushing with the arrow on the bolt head pointing up.
    - 13.3 Install the large flatwasher and the nut on the bolt. Tighten the nut, but not to its final torque.
    - 13.4 Check the axle alignment and adjust it if necessary. After the adjustment has been made, lower the vehicle and tighten the radius rod eye bolt nut to the applicable torque value shown in **Specifications, 400**.

14. Install the spring rollers and rebound bolts in the equalizer arm and tighten the nuts 45 lbf·ft (61 N·m).

Axle Alignment Checking and Adjusting, Reyco

Axle Alignment Checking

Manufacturers of axle alignment equipment offer a variety of systems to precisely measure and correct rear axle alignment. If access to this type of equipment is not available, check the axle alignment using the following procedure:

1. Position the vehicle on a level surface. Using the engine, rock the vehicle back and forth several times with the brakes applied lightly. This will release any "set" of the suspension joint.
2. Obtain a piece of bar stock, angle iron, or other suitable material about 96 in (2.5 m) long. Inspect the material for straightness. The bar should be long enough to extend past the outside edge of one outside dual tire to a similar point on the opposite dual tire.
3. Measure from the center point of the equalizer bracket to any open part of the frame in front of the wheels where the bar stock can be placed across the frame. This point must be accessible for the use of C-clamps. A point in front of the forward rear axle is recommended; however, a point behind the rearmost axle will work if none is available in front of the axle.
4. Using a square, mark a chalk line across the top of the frame rail.
5. Repeat previous steps for the opposite side of the vehicle.
6. Position the bar stock across the frame rails so that it extends an equal distance beyond the frame rail on each side. Line up the bar stock with the chalk lines and secure it with C-clamps.
7. Measure the distance from the outside edge of the secured bar stock to the center of the rearmost axle shaft.
8. Repeat previous steps on the opposite side of the vehicle. Compare the measurements taken on both sides. If they are equal or vary no more than 1/8-in (3 mm), the axle alignment is correct. If the measurements differ by more than 1/8-in (3 mm), adjust the axle alignment.
9. If the rearmost axle alignment is correct, check the forward rear axle alignment as follows:
   - 9.1 Measure the distance from the rearmost axle shaft center to the center of the forward rear axle or the bar stock.
   - 9.2 Repeat the measurement for the opposite side and compare the measurements. If they are equal or vary no more than 1/8-in (3 mm), the axle alignment is correct. If the measurements differ by more than 1/8-in (3 mm), adjust the axle alignment as described above.

Axle Alignment Adjustment (Models 101 and 101A)

1. Loosen the nut on the radius rod eye bolt three full turns.
2. Using a soft brass or lead hammer to avoid damage to the eye bolt threads, tap the end of the eye bolt and the end of the rod between the front spring bracket casting. This should loosen the components so the adjustment can be made.

NOTE: The maximum adjustment on each side of the vehicle is 7/16 inch (11 mm). In most cases, the axle alignment can be corrected by adjusting one side only; however, additional adjustment can be made from the other side of the axle if necessary.

3. Jack up the frame on the side to be corrected to remove the weight from the springs.
4. To adjust the axle forward, rotate the radius rod eye bolt forward. To adjust the axle rearward, rotate the radius rod eye bolt to the rear.
5. Lower the vehicle and check the axle alignment as described above. Repeat the adjustment as needed.
6. After the final adjustment has been made, lower the vehicle and tighten the radius rod eye bolt nut to the applicable torque value in **Specifications, 400**.

Axle Alignment Adjustment (Models 102 and 102W)

1. Jack up the frame on the side to be corrected to remove the weight from the springs.

Axle Alignment Checking and Adjusting, Reyco

2. Loosen the clamp nuts on the radius rod being adjusted.
3. Using a wrench on the radius rod flats, turn the adjustable section to move the axle forward or rearward.
4. Lower the vehicle and check the axle alignment. Repeat the adjustment as needed.
5. After the adjustment has been made, lower the vehicle and tighten the radius rod clamp nuts 190 lbf·ft (258 N·m).
6. Tighten the radius rod eye bolt nuts to the applicable torque value in **Specifications, 400**.

Problem—Spring is Noisy

Possible Cause	Remedy
The U-bolts are loose.	Tighten the U-bolts to the recommended torque
The radius rod eye bushings are worn.	Replace the radius rod eye bushings.
The shock absorbers are worn or damaged.	Replace the shock absorbers.

Problem—Spring Sags or Bottoms Out

Possible Cause	Remedy
The shock absorbers are not working properly.	Replace the shock absorbers
A spring leaf is broken.	Replace the spring leaf assembly.
The vehicle is overloaded.	Check the load capacity rating and correct if needed.

Problem—Springs Break

Possible Cause	Remedy
The U-bolts are loose.	Tighten the U-bolts to the recommended torque.
The springs are experiencing normal fatigue.	Replace the springs.
The vehicle is overloaded.	Check the load capacity rating and correct if needed.

General Description

The Hendrickson RT2 series suspension (see **Fig. 1**) uses leaf springs to lessen road shocks. The forward and rear ends of the spring assembly ride in hangers. At the forward end, the springs are attached to the hanger with pins. At the rear end, the springs have no rigid attachment to the hangers, and are free to move forward and backward to compensate for spring deflection.

The RTE2 series suspension is basically the same as the RT2 suspension. However, the RTE2 series uses a different spring assembly and a third spring hanger. This design provides a two-stage spring rate, depending on vehicle load condition. When the vehicle is unloaded, a gap exists between the top spring leaf and the no. 2 spring hanger. The weight of the vehicle is then carried through the no. 3 spring hanger, and most of the spring deflection through the top extended leaves. When the vehicle is loaded, the top extended leaf contacts the no. 2 spring hanger and the spring weight is carried through the nos. 1 and 2 spring hangers.

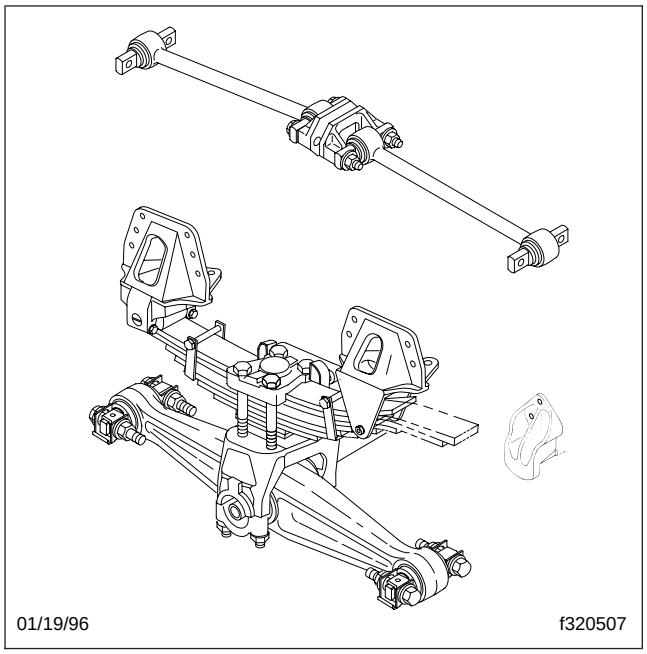

Fig. 1, RT2 and RTE2 Series Suspension

The RTE2A series suspension is similar to the RTE2 suspension, but the RTEA series uses aluminum equalizer beams instead of steel.

CAUTION

Failure to apply Alumilastic® compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the components or parts.

The axles are attached to beam hangers at the ends of the equalizer beams, allowing an articulating action between the axles to lessen road shock. Torque rods, mounted between the axles and frame rails, stabilize axle and vehicle movement caused by accelerating and braking.

All suspension fasteners require periodic tightening. For suspension inspecting, lubricating, and fastener torque checking instructions, see Group 32 of the *Century Class Trucks Maintenance Manual*.

WARNING

Periodically, torque the suspension fasteners. Failure to do so could result in damage to the frame hangers or separation of components. This could cause a loss of vehicle control, resulting in injury or property damage.

Suspension Removal and Installation, RT2 & RTE2

Removal (See Fig. 1)

1. Chock the front tires.
2. Drain the vehicle air system.
3. Disconnect all air lines leading to the rear axles, marking the lines for later assembly.

   Plug or cap all lines and fittings to prevent dirt from entering the system.
4. Disconnect the driveline rear universal joint from the forward-rear axle. Then, remove the interaxle driveline. For instructions, see **Group 41** .
5. Manually release the spring brake chambers. For instructions, see **Group 42** .

⚠ WARNING

When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

6. Remove the torque rods. For instructions, see **Subject 160** .
7. Raise the rear of the vehicle so that all weight is removed from the suspension. Then, block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

8. Remove the saddle cap nuts and washers from each side of the vehicle, and remove the saddle caps.

NOTE: If the saddle cap studs are damaged, replace them.

9. Raise the rear of the vehicle frame until there is enough clearance to roll the axles out from under the vehicle. Install safety stands under the frame, then roll the axles—with the equalizer beams attached—out from under the vehicle.

Suspension Removal and Installation, RT2 & RTE2

Installation

1. Roll the axles under the vehicle frame. Align the center bushing of each equalizer beam with the center of the saddle legs.
2. Raise the vehicle frame off the safety stands, then remove the safety stands.
3. Lower the frame, centering the saddles on the beam center bushings.
4. Lubricate the saddle cap studs with SAE 20 oil. Install the saddle caps, washers and new self-locking nuts. Do not tighten.
5. Install the torque rods. For instructions, see **Subject 160**.
6. Tighten the saddle cap locknuts 225 to 275 lbf·ft (305 to 373 N·m).

NOTE: Maintain an even gap between the saddle cap and the saddle when tightening the self-locking nuts (see **Fig. 2**).

7. Remove the safety stands from under the frame and axle, and lower the vehicle.
8. Manually reset the spring brake chambers. For instructions, see **Group 42**.
9. Connect the driveline rear universal joint to the forward-rear axle. Connect the interaxle driveline. For instructions, see **Group 41**.
10. Uncap all air lines and fittings, then connect the lines leading to the rear axles.
11. Check the axle pinion angle. For instructions, see **Group 41**.

Spring and Saddle Removal and Installation, RT2 & RTE2

Removal

1. Remove the suspension. For instructions, **refer to Subject 100**.
2. Support the spring and saddle assembly with a floor jack.
3. Remove the locknuts from the spring pin lockbolts; then remove the lockbolts and washers from the number one spring hanger.
4. Using a suitable drift, drive the spring pin through the no. 1 spring hanger and out the inboard side of the spring hanger (**see Fig. 1**).

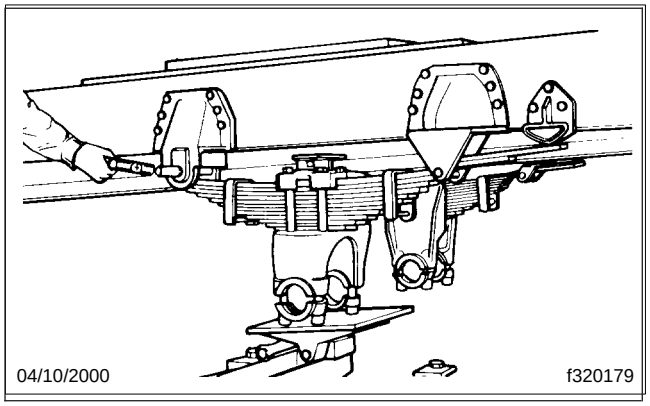

Fig. 1, Spring Hanger

5. Remove the locknut and lockwasher from the rebound spacer bolt in the no. 2 spring hanger. Remove the rebound spacer bolt and the spacer.

⚠ WARNING

WARNING: The leaf spring assembly is heavy. Use care when handling it to prevent injury.

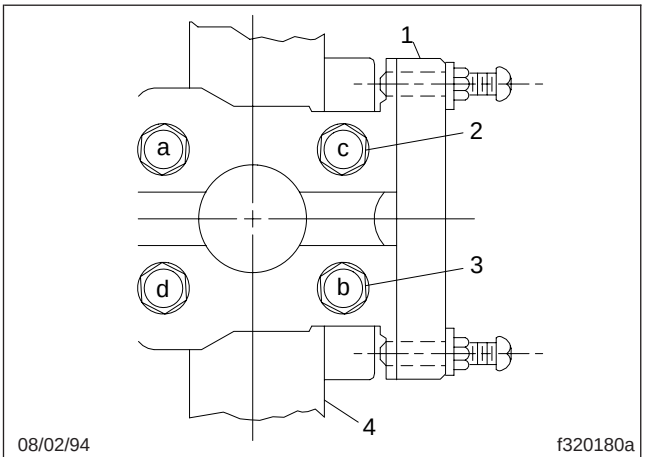
6. Lower the spring and saddle assembly from the spring hangers.
7. Loosen the spring alignment setscrews on the top pad. Remove the top pad nuts, washers, and bolts.
8. Remove the top pad from the spring assembly, then remove the spring from the saddle.

Installation

1. Seat the leaf spring assembly on the saddle.
2. Position the top pad on the spring assembly. Check that the top pad is properly seated.

NOTE: The main leaf has a cup that is forged upward at the center bolt. This cup serves as a pilot when installing the top pad, and ensures correct alignment of the spring assembly.

3. Lubricate the threads on the top pad bolts with SAE 20 oil, then install the washers and bolts through the top pad and saddle. Install new nuts and washers finger-tight. Do not tighten at this time.
4. Lubricate the threads on the spring setscrews with SAE 20 oil. Hand-tighten the spring setscrews against the leaf springs. Tighten the setscrews 100 to 150 lbf·ft (135 to 203 N·m), then tighten the setscrew locknuts until the lockwasher is locked.
5. Tighten the top pad nuts 275 to 400 lbf·ft (373 to 542 N·m). Use the tightening sequence **shown in Fig. 2**.
6. Position the spring and saddle assembly into the no. 1 and no. 2 spring hangers.



1. Top Pad
2. Top Pad Bolt
3. Hardened Washer
4. Spring

7. Coat the spring pin and the inside diameter of the spring eye bushing with multipurpose chassis grease.
8. Align the spring pin with the spring eye bushing in the forward spring hanger.

Spring and Saddle Removal and Installation, RT2 & RTE2

9. From the outboard side of the spring hanger, tap the spring pin into the bushing with a soft hammer. If necessary, adjust the spring to assist spring pin entry.
10. Place washers on the spring pin lockbolts, and insert the lockbolts through the spring hanger. If necessary, use a screwdriver to turn the spring pin until the lockbolts can slide past it.
11. Lubricate the lockbolt threads with SAE 20 oil. Install the lockwashers and locknuts. Tighten the locknuts 45 to 63 lbf·ft (61 to 85 N·m).
12. Position the rebound spacer in the no. 2 spring hanger leg, then install the rebound spacer bolt, lockwasher, and locknut. Tighten the locknut 38 to 45 lbf·ft (51 to 61 N·m).
13. Install the grease fittings in both spring eye pins. Apply multipurpose chassis grease to the grease fittings until grease appears on both sides of the spring eye bushings.
14. Install the suspension. **Refer to Subject 100** for instructions.

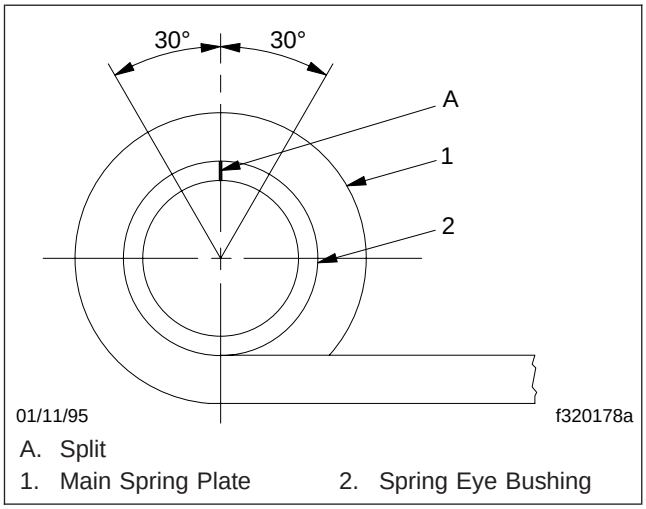
Spring Leaf, Spring Pin, and Spring Eye Bushing Replacement, RT2 & RTE2

Replacement

1. Remove the spring and saddle assembly. For instructions, **refer to Subject 110**.
2. Using a C-clamp to hold the spring leaves together, remove the center bolt and nut, and the spring alignment clips. Remove the C-clamp and separate the leaves.
3. Using a wire brush and solvent, clean all grease, dirt, and rust from the spring leaves. Inspect the spring leaves for cracks, gouges, wear, or abnormal bends. The no. 1 main and no. 2 wrapper spring leaves (the top two spring leaves) may each be replaced; if equipped with the RTE series suspension, the nos. 1, 2, and 3 spring leaves (the top three spring leaves) may each be replaced. If a spring leaf is damaged below these numbers in a pack, replace the spring assembly. Replace both spring assemblies to ensure even spring deflection.
4. Inspect the spring pin and spring eye bushing for wear or damage. If the pin diameter is less than 1.367 inch, replace it. If the inside diameter of the spring eye bushing is more than 1.395 inch, replace it.

NOTE: If necessary, press out the bushing with a hydraulic press. Install the new bushing with the split of the bushing positioned at the top (30 degrees) of the spring eye (**see Fig. 1**).

5. Position the spring leaves in order, then insert a drift through the center bolt hole to align the leaves.
6. Compress the leaves with a C-clamp, then install the spring alignment clips on the spring leaves. Install the spring alignment clip nuts and bolts. Tighten the nuts 15 lbf·ft (20 N·m).
7. Remove the drift punch. At the bottom of the spring, insert a new center bolt. Install a new center bolt nut and tighten to the value in the table under **Specifications, 400**.
8. Install the spring and saddle assembly. For instructions, refer to **Subject 110**.



A. Split
1. Main Spring Plate
2. Spring Eye Bushing

Fig. 1, Bushing Split Position

Equalizer Beam Removal and Installation, RT2 & RTE2

Removal

1. Chock the front tires.
2. Remove the saddle cap nuts and washers, then remove the saddle cap. Support the equalizer beam with safety stands.
3. Raise the rear of the vehicle until the saddle studs clear the equalizer beam. Block the axles and frame with safety stands.
4. Remove the wheels and tires. For instructions, refer to **Group 40**.
5. Remove the brake shoes, brake spider, and brake backing plate (dust shield). Refer to **Group 42** for instructions.
6. Apply a penetrating oil to all beam end connections.
7. Remove the bar pins.

NOTE: The bar pin-style beam end connection is a rubber bushing assembly consisting of a rubber insert, and outer metal tube and inner casting. It is fastened to the axle by two 1-inch (25 mm) bolts and locknuts. The bolts are positioned parallel to the vehicle's longitudinal axis making removal and installation easy.

⚠ WARNING

WARNING: Don't use a cutting torch to remove the equalizer beams from the beam hangers. The equalizer beams are heat-treated, and using a cutting torch could weaken them, causing them to break. This could result in a loss of vehicle control, possible personal injury and property damage.

8. Remove the ends of the equalizer beams from the axle beam hangers.
9. Lower the equalizer beams and the crosstube to the ground. Remove the thrustwashers and pull the beams from the crosstube.

Installation

1. Install the crosstube and thrustwashers in both equalizer beam center bushings.

   Install the bar pins, then install the crosstube and thrustwashers in both equalizer beam center bushings.
2. Position the equalizer beam assembly under the axles, then raise the assembly and place the forward ends of each beam in the forward-rear axle beam hangers. Align the beam end bushings with the beam hangers.
3. Place the rear ends of each beam in the rearmost axle beam hangers. Align the beam end bushings with the beam hangers.
4. Position the saddle caps on the saddle cap studs, then install the washers and new self-locking nuts. Tighten the nuts 225 to 275 lbf·ft (305 to 373 N·m).
5. Install the bar pin bolt locknuts, and tighten 450 to 600 lbf·ft (610 to 813 N·m).

⚠ WARNING

WARNING: Tighten the bar pin locknuts to the specified torque values. Otherwise, component wear will occur. This could result in separation of suspension components, loss of vehicle control, and possible injury or property damage.

6. Install the brake backing plate (dust shield), brake spider, and brake shoes. Refer to **Group 42** for instructions.
7. Install the wheels and tires. For instructions, refer to **Group 40**.

Equalizer Beam Rubber Center Bushing Removal and Installation, RT2 & RTE2

Removal

NOTE: If using Owatonna tools, removal of the equalizer beam is not required for removal or installation of the rubber center bushing.

1. Chock the front tires.
2. Raise the rear of the vehicle so that all weight is removed from the suspension. Block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

3. Remove the saddle cap nuts and washers from each side of the vehicle, and remove the saddle caps.
4. Raise the rear of the truck frame until the saddle studs clear the equalizer beam. Install safety stands under the frame.
5. Using a 2-1/2 inch diameter hole saw (**see Fig. 1**), cut out the end plug from the center bushing on each side of the suspension, and remove the crosstube.
6. On the inboard side of the equalizer beam, inspect the exposed edge of the bushing's outer sleeve.
7. Chisel or grind off any portion of the outer sleeve that has flared over the surface of the equalizer beam.
8. If using Owatonna tools, remove the rubber center bushings as follows (**see Fig. 2**):

    8.1 Position the hydraulic ram and slide the pulling screw through the center bushing.

    8.2 Install the center bushing removing adapter on the inboard side of the beam eye.

    IMPORTANT: Align the receiving tube so that the bushing will clear the edges of the tube when force is exerted against the beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

    8.3 Install the hexnut on the pulling screw. Full thread engagement is needed.

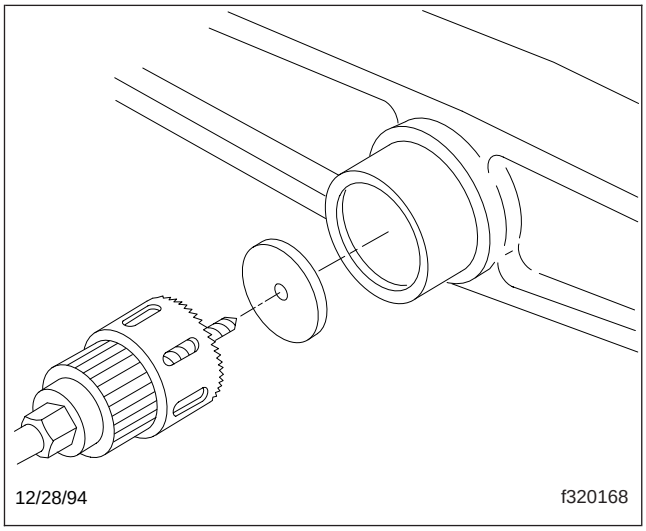


Fig. 1, Removing End Plug

2. Pulling Screw
3. Removing Adapter
4. Hexnut
5. Receiving Tube

Fig. 2, Removal of Rubber Center Bushing

    8.4 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

    8.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

Equalizer Beam Rubber Center Bushing Removal and Installation, RT2 & RTE2

8.6 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely remove the bushing.

NOTE: If the pressure gauge on the hydraulic pumping unit reads 10,000 psi (68 950 kPa) and the bushing has not broken loose, stop and check the alignment of the receiving tool and removal adapter. If both tools are aligned correctly, attach a sledging adapter on the speed nut end of the pulling screw. Maintaining hydraulic pressure, strike the sledging adapter with a heavy hammer. A loud noise followed by a sudden drop of the pressure gauge reading indicate that the bushing has broken loose.

9. If using shop-made adapters, remove the equalizer beams. For instructions, refer to **Subject 130**.

9.1 Position the equalizer beam on a 50-ton vertical hydraulic press.

9.2 Center the shop-made adapter (refer to the table under **Specifications, 400**) on the trimmed end of the equalizer beam bushing. Press the center bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.
2. Using emery cloth, clean the outer sleeves of the new equalizer beam center bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing.
3. If using Owatonna tools, install the rubber center bushings as follows (**see Fig. 3**):

3.1 Center the hydraulic ram and slide the pulling screw through the beam eye.

3.2 Position the bushing on the inboard side of the beam eye.

IMPORTANT: Center the new bushing to ensure a clean pull through the beam eye.

3.3 Fit the installing adapter over the inner sleeve and against the outer sleeve of the bushing.

3.4 Install the hexnut on the pulling screw. Full thread engagement is needed.

3.5 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

3.6 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

3.7 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely install the center bushing.

5. Pulling Screw

Fig. 3, Installing Rubber Center Bushing

NOTE: The pressure gauge on the pumping unit should read 4000 to 5500 psi (27 580 to 37 920 kPa) during installation. If the reading reaches the operating limit of 10,000 psi (68 950 kPa) and the bushing is not going into the beam, check the alignment of the bushing, tooling, and hydraulic equipment.

Installation is complete when the installing adapter is flush against the beam.

3.8 Position the crosstube in the center bushings.

3.9 Arc weld new end plugs to the tire side of each center bushing inner sleeve.

NOTE: Heat from welding the end plugs will not affect the beam or the new rubber bushings because of their distance from the point of welding.

4. Position the saddle caps on the saddle cap studs, then install the washers and new self-locking nuts. Tighten the nuts 225 to 275 lbf·ft (305 to 373 N·m).

5. If using shop-made adapters, position the equalizer beam on a 50-ton hydraulic press.

5.1 Using standard center bushings with the end plugs welded in place, position the shop-made adapter (refer to the table under **Specifications, 400**) over the inner sleeve of the bushing. Check that the adapter bottoms against the bushing outer sleeve, then press the new bushing into the beam eye.

5.2 Install the equalizer beams. For instructions, **refer to Subject 130**.

Equalizer Beam Bronze Center Bushing Removal and Installation, RT2 & RTE2

Removal

NOTE: If using Owatonna tools, you can remove or install the bronze center bushing without removing the equalizer beam.

1. Chock the front tires.
2. Raise the rear of the vehicle so that all weight is removed from the suspension. Block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

3. Remove the saddle cap nut and washers from each side of the suspension, and remove the saddle caps.
4. Raise the rear of the truck frame until the saddle studs clear the equalizer beam. Install safety stands under the frame.
5. Using a 2-1/2 inch diameter hole saw, cut out the retaining disk from the center bushing on each side of the suspension, and remove the cross-tube.

⚠ CAUTION

CAUTION: Do not use a cutting torch to burn out the retaining disk. The equalizer beams are heat treated, and the use of a cutting torch could weaken the beam.

6. If using Owatonna tools, remove the bronze center bushing as follows (**see Fig. 1**):

   6.1 Position the hydraulic ram and slide the pulling screw through the center bushing.

   6.2 Install the center bushing removing adapter on the inboard side of the beam eye.

   IMPORTANT: Align the receiving tube so that the bushing will clear the edges of the tube when force is exerted against the beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

   6.3 Install the hexnut on the pulling screw. Full thread engagement is needed.

   6.4 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

   6.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

   6.6 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely remove the center bushing.

   NOTE: If the pressure gauge on the hydraulic pumping unit reads 10,000 psi (68 950 kPa) and the bushing has not broken loose, stop and check the alignment of the receiving tool and removal adapter. If both tools are aligned correctly, attach a sledging adapter on the speed nut end of the pulling screw. Maintaining hydraulic pressure, strike the sledging adapter with a heavy hammer. A loud noise followed by a sudden drop of the pressure gauge reading indicate that the bushing has broken loose.

Equalizer Beam Bronze Center Bushing Removal and Installation, RT2 & RTE2

7. If using shop-made adapters, remove the equalizer beams. For instructions, refer to **Subject 130**.

    7.1 Position the equalizer beam on a 50-ton vertical hydraulic press.

    7.2 Center the shop-made adapter (refer to the table under **Specifications, 400**) on the center bushing. Press the bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.
2. Using emery cloth, clean the outer sleeves of the new equalizer beam center bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing, and to the inside surface of the beam eye.
3. Position the bushing on the equalizer beam eye.
4. If using Owatonna tools, install the bronze center bushings as follows (**see Fig. 2**):

    4.1 Center the hydraulic ram and slide the pulling screw through the beam eye.

    4.2 Position the bushing on the inboard side of the beam eye. Check that the grooves of the bushing are aligned with the vertical centerline of the equalizer beam (**see Fig. 3**).

    4.3 Fit the installing adapter and the removing/installing adapter against the outer sleeve of the bushing. Make sure the deep ridge on the installing adapter is positioned against the bronze bushing (**see Fig. 4**).

    4.4 Install the hexnut on the pulling screw. Full thread engagement is needed.

    4.5 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

ments are needed to completely install the center bushing.

NOTE: The pressure gauge on the pumping unit should read 4000 to 5500 psi (27 580 to 37 920 kPa) during installation. If the reading reaches the operating limit of 10,000 psi (68 950 kPa) and the bushing is not going into the beam, check the alignment of the bushing, tooling, and hydraulic equipment. Installation is complete when the installing adapter is flush against the beam.

4.8 On the inboard side of the beam, position a grease seal and installing adapter against the center bushing. Make sure the shallow end of the adapter is against the grease seal (**see Fig. 5**). Using a hammer, tap the installing adapter until it is flat against the beam. Using the same procedure, install a grease seal on the outboard side of the beam.

5. If using shop-made adapters, position the equalizer beam on a 50-ton hydraulic press.

5.1 Center the new bushing in the beam eye. Using a standard bushing driver, press the bushing in until there is equal spacing between both bushing ends and the sides of the beam eye.

5.2 Install the new grease seals (with the seal lips facing out).

NOTE: Check that the new seals are 1/6 inch (4 mm) inside the beam hub surface to ensure clearance and protection of the seals when the saddle cap is installed.

6. Apply a thin coating of multipurpose chassis grease to the inside surface of the center bushing. Slide the bushing center sleeve into the bushing.

7. Install the grease fitting into the beam hub. Rotate the center sleeve and apply multipurpose chassis grease in the grease fitting. Lubricate until clean grease appears at both ends of the grease seals.

8. Install the crosstube.

⚠ WARNING

WARNING: When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

1. On fore and aft torque rods, remove the flanged bolts and nuts from the torque rod axle brackets,

Torque Rod and Bushing Removal and Installation, RT2 & RTE2

and the crossmember mounting brackets (**see Fig. 1**). Remove the torque rods.

On transverse torque rods, remove the nuts and washers from the axle brackets, and remove the flanged bolts and nuts from the frame rail mounting brackets (**see Fig. 1**). Remove the torque rods.

NOTE: If necessary, use an impact hammer and tap the top of the axle bracket to disengage the rod stud from the axle bracket.

2. Inspect the torque rods. If bent or cracked, replace. Check the torque rod bushings. If one of the bushings is loose or damaged, replace both of the bushings.
3. Position the press plate on the hydraulic press. Check that the small counterbore of the plate hole is facing up.

NOTE: Some tapered stud torque rod bushings have a large non-removable washer on the stud that will not fit though the press plate hole. Loosen the press plate capscrews and separate the halves (**see Fig. 2**) until the washer clears the counterbore, and the torque rod sets on the press plate. Tighten the capscrews until the press plate halves are closed.

4. Position the tapered stud removal tool (using the end with the larger inside diameter) on the torque rod stud. Apply lubricating oil (**see Fig. 3**), then press the stud out of the bushing.
5. Position the bushing remover/replacer tool (using the end with the larger outside diameter) on the bushing. Install the cap, then apply lubricating oil to the torque rod bushing.
6. Press the rubber bushing out of the torque rod eye.
7. Position the straddle mount end of the torque rod into the hole of the press plate. Tighten the press plate capscrews.
8. Position the straddle mount pin remover on the straddle mount pin (**see Fig. 4**).
9. Apply lubricating oil to the straddle mount pin. Press the straddle mount pin out of the bushing.
10. Position the end of the rubber bushing remover/replacer tool (using the end that has the larger outside diameter) on the bushing. Install the cap, then apply lubricating oil to the torque rod bushing.

11. Press the rubber bushing out of the torque rod eye.

Installation

1. Remove all dirt and grease from the torque rod ends. Apply lubricant on the new bushings and in the torque rod eyes.
2. Position the press plate on the hydraulic press. Check that the small counterbore of the plate hole is facing up.
3. Position the new bushing on the tapered stud of transverse torque rods. Position the clamp and tighten it to compress the rubber (**see Fig. 5**).
4. Place the torque rod end, the bushing, and the clamp on the press plate.
5. Place the remover/replacer tool (**see Fig. 6**) and cap on top of the clamping tool and press the bushing in the torque rod end. Check that the bushing sleeve protrudes equally on each side of the torque rod end.
6. On straddle mount end assemblies, align the clamping tool on the bushing **as shown in Fig. 7**. Tighten the clamp to compress the rubber of the new straddle mount bushing.

NOTE: When tightening the clamp, make sure that the position of the bushing pin is at a right angle to the center line of the torque rod shank (**see Fig. 8**).

7. Place the torque rod end, the bushing, and the clamp on the press plate.

8. Using the larger end of the remover/ replacer tool, position the tool and cap on top of the clamp assembly.
9. Press the bushing in the torque rod end. Check that the bushing's outer sleeve protrudes equally on each side of the torque rod end.
10. Install the fore and aft torque rods as follows (**see Fig. 1**):
    - 10.1 Position a torque rod straddle mount pin in the forward-rear axle bracket. Install the flanged bolts through the axle bracket and the straddle mount pin. Install a spacer and nut on each bolt, and tighten 190 lbf·ft (260 N·m).
    - 10.2 Position a torque rod straddle mount pin in the rearmost axle bracket. Install the flanged bolts through the axle bracket and the straddle mount pin. Install a spacer and nut on each bolt, and tighten 190 lbf·ft (260 N·m).
    - 10.3 Position a torque rod spacer and straddle mount bracket on each side of the cross-member. Insert bolts through the upper and lower holes of the forward mounting bracket. Install nuts and tighten 95 lbf·ft (130 N·m).
    - 10.4 Position the straddle mount pin of the forward torque rod in the mounting bracket. Insert bolts through the forward pin, both bracket assemblies, and the straddle mount pin of the rear torque rod. Install the nuts and bearing washers. Tighten the nuts 190 lbf·ft (260 N·m).
11. Install the transverse torque rods as follows (**see Fig. 1**):
    - 11.1 Check that the tapered stud end and the tapered stud bracket hole are clean. Lubricate the tapered stud ends with SAE 20 oil.
    - 11.2 Install the tapered stud in the axle bracket. Install a washer and nut. Tighten the nut 175 to 225 lbf·ft (235 to 305 N·m).
    - 11.3 Align the straddle mount end, the mounting bracket, and the spacer against the inside frame rail.
    - 11.4 On the inboard side of the frame rail, install the bolts through the mounting assembly and the frame rail.
    - 11.5 On the outboard side of the frame rail, install a spacer over the mounting bolt studs. Install the nuts and tighten them 190 lbf·ft (260 N·m).
12. Check the axle pinion angle. For instructions, refer to **Group 41**.

General Information

The Hendrickson RS suspension (see **Fig. 1**) is a heavy-duty tandem drive that uses six rubber load cushions in place of leaf springs to lessen road shocks. Frame hangers above the four outside cushions have vertical drive pins and bushings (see **Fig. 2**) that extend down through the cushions. All driving, braking, and cornering forces are transmitted and controlled through these pins and bushings.

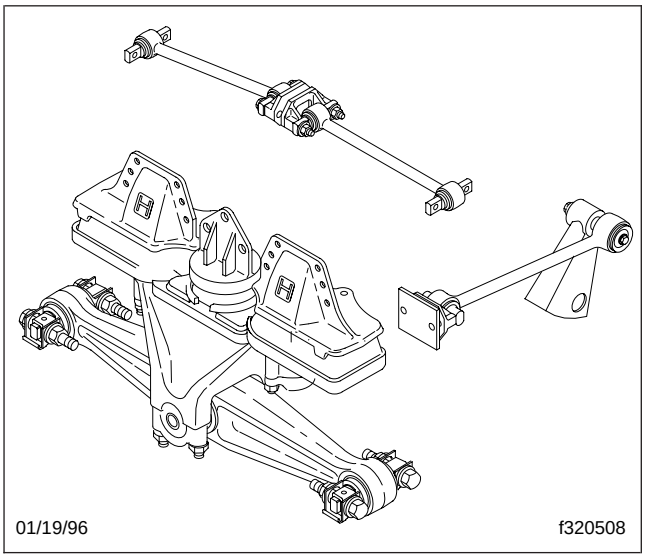

Fig. 1, Hendrickson RS Heavy-Duty Suspension

The axles are attached to beam hangers at the ends of the equalizer beams, allowing an articulating action between the axles to absorb road shock. Torque rods, mounted between the axles and frame rails, stabilize axle and vehicle movement caused by accelerating and braking.

All suspension fasteners require periodic tightening. For suspension inspecting, lubricating, and fastener torque checking instructions, refer to **Group 32** in the vehicle maintenance manual.

WARNING

WARNING: Torque suspension fasteners on a periodic schedule as suggested in the vehicle maintenance manual. Failure to to do so could result in damage to the frame hangers or separation of components. This could cause a loss of vehicle control, resulting in personal injury or property damage.

Suspension Removal and Installation, RS

1. Chock the front tires.
2. Drain the vehicle air system.
3. Disconnect all air lines leading to the rear axles, marking the lines for later assembly reference. Plug or cap all lines and fittings to prevent dirt from entering the system.
4. Disconnect the driveline rear universal joint from the forward-rear axle. Then, remove the interaxle driveline. For instructions, **refer to Group 41.**
5. Manually release the spring brake chambers. For instructions, **refer to Group 42.**
6. Remove the torque rods. For instructions, **refer to Subject 160.**

⚠ WARNING

WARNING: When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

7. Raise the rear of the vehicle so that all weight is removed from the suspension. Then, block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

8. Remove the saddle cap nuts and washers from each side of the vehicle, and remove the saddle caps.
9. Raise the rear of the vehicle frame until there is enough clearance to roll the axles out from under the vehicle. Install safety stands under the frame, then roll the axles—with the equalizer beams attached—out from under the vehicle.

Installation (See Fig. 1)

1. Roll the axles under the vehicle frame. Align the center bushing of each equalizer beam with the center of the saddle legs.
2. Raise the vehicle frame off the safety stands, then remove the safety stands.
3. Lower the frame, centering the saddles on the beam center bushings.
4. Install the saddle caps, washers and new self-locking nuts. Do not tighten.
5. Install the torque rods. For instructions, **refer to Subject 160.**
6. Tighten the saddle cap locknuts 225 to 275 lbf·ft (300 to 375 N·m).

NOTE: Maintain an even gap between the saddle cap and the saddle when tightening the self-locking nuts.

7. Remove the safety stands from under the frame and axle, and lower the vehicle.
8. Manually reset the spring brake chambers. For instructions, **refer to Group 41.**
9. Connect the driveline rear universal joint to the forward-rear axle. Connect the interaxle driveline. For instructions, **refer to Group 41** in this manual.
10. Uncap all air lines and fittings, then connect the lines leading to the rear axles.
11. Check the axle pinion angle. For instructions, **refer to Group 41.**

Saddle Removal and Installation, RS

Removal

1. Remove the suspension. For instructions, **refer to Subject 100.**
2. Support the saddle assembly with a floor jack.
3. Remove the vertical drive pin locknuts and the concave washers **(see Fig. 1).**

   On rebound control kit installations, use a 3/4–inch drive socket to remove the stop nuts. Then remove the bumper and the concave washers. **See Fig. 2 .**

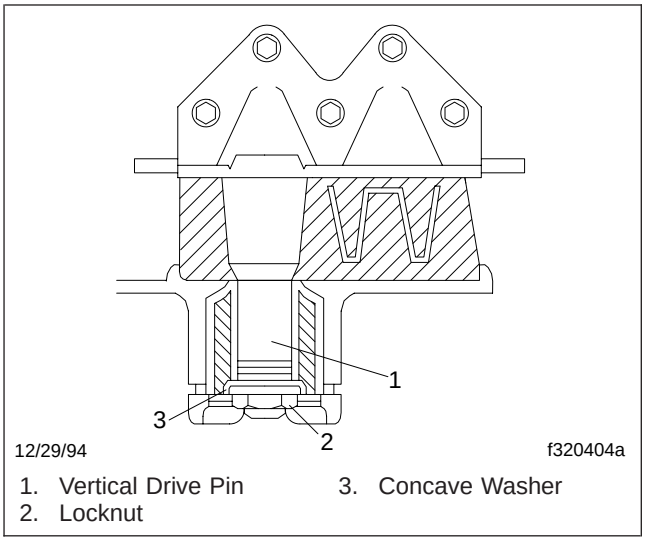

Fig. 1, Vertical Drive Pin Assembly

4. Lower the saddle and load cushions from the frame hanger and the vertical drive pins.

Installation

1. Apply Texaco Compound L, or an equivalent rust preventive lubricant, on the vertical drive pins and the vertical drive pin bushings.
2. Position the rubber load cushions on the saddle. Raise the saddle assembly, guiding the vertical drive pin bushings over the vertical drive pin.
3. Install the drive pin washers (with the concave end pointing down) over the threaded ends of the drive pins.
4. Install the vertical drive pin locknuts and tighten 175 to 225 lbf·ft (235 to 300 N·m).

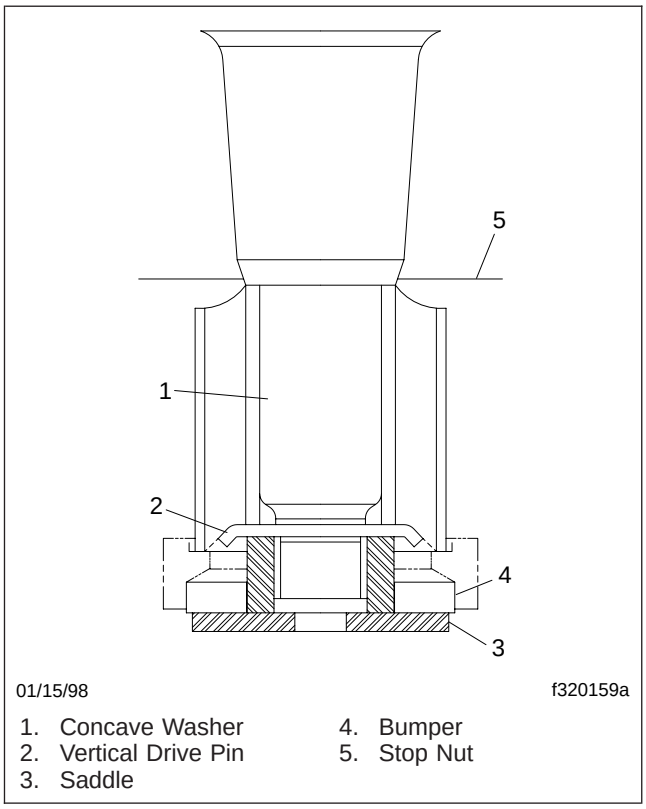

Fig. 2, Rebound Control Kit

5. On rebound control kit installations, install the stop nuts, bumpers, and the concave washers. Tighten the stop nuts 175 to 225 lbf·ft (235 to 300 N·m).
6. Install the suspension. For instructions, **refer to Subject 100.**

Load Cushion and Vertical Drive Pin Bushing Replacement

1. Remove the saddle assembly. For instructions, **refer to Subject 110.**

NOTE: If replacing only the heavy-duty load cushions, removal of the saddle assembly is not needed. These cushions can be forced out after raising the frame to open the area between the saddle and the frame hanger brackets.

2. Inspect all of the rubber load cushions for cuts or other damage. Replace a load cushion if these conditions exist.
3. Measure each load cushion. If the height of a load cushion is less than 3-11/16 inches (94 mm), replace it.
4. Remove the retainer locknuts from the drive pin bushing retainer cap, and remove the retainer cap.
5. Using a hydraulic press, press the vertical drive pin bushings out of the saddle from the top.
6. If the outer sleeve of the bushing is frozen in the saddle bore, press out the inner sleeve and rubber insert, then work the outer sleeve out of the saddle bore.

⚠ WARNING

WARNING: Do not use a cutting torch to remove the vertical drive pin bushings. Using high heat will weaken the saddle, which could cause the saddle to break. This could result in a loss of vehicle control, possible personal injury, and property damage.

7. Using emery cloth, remove small nicks or scratches from the vertical drive pin and the vertical drive pin bushing. Clean the saddle bores with a solvent.
8. Apply Texaco Compound L, or an equivalent rust preventive lubricant, on the drive pin bushings and the saddle bores.
9. Fit the bushings into the saddle bores. Position the drive pin bushing retainer cap and install the retainer cap locknuts. Tighten the locknuts 100 to 125 lbf·ft (135 to 170 N·m).
10. Install the rubber load cushions.
11. Install the saddle assembly. For instructions, **refer to Subject 110.**

Equalizer Beam Removal and Installation, RS

Removal

1. Chock the front tires.
2. Remove the saddle cap nuts and washers, then remove the saddle cap. Support the equalizer beam with safety stands.
3. Raise the rear of the vehicle until the saddle studs clear the equalizer beam. Block the axles and frame with safety stands.
4. Remove the wheels and tires. For instructions, **refer to Group 40.**
5. Apply a penetrating oil to all beam end connections.
6. Remove the bar pins.

NOTE: The bar pin-style beam end connection is a rubber bushing assembly consisting of a rubber insert and outer metal tube with inner casting. It is fastened to the axle by two 1-inch (25 mm) bolts and locknuts. The bolts are positioned parallel to the vehicle's longitudinal axis, making removal and installation easy.

⚠ WARNING

WARNING: Don't use a cutting torch to remove the equalizer beams from the beam hangers. The equalizer beams are heat-treated, and using a cutting torch could weaken them, causing them to break. This could result in a loss of vehicle control, possible personal injury and property damage.

7. Remove the ends of the equalizer beams from the axle beam hangers.
8. Lower the equalizer beams and the crosstube to the ground. Remove the thrustwashers and pull the beams from the crosstube.

Installation

1. Install the crosstube and thrustwashers in both equalizer beam center bushings.
2. Install the bar pins, then install the crosstube and thrustwashers in both equalizer beam center bushings.

Position the equalizer beam assembly under the axles, then raise the assembly and place the forward ends of each beam in the forward-rear axle beam hangers. Align the beam end bushings with the beam hangers.

3. Place the rear ends of each beam in the rearmost-axle beam hangers. Align the beam end bushings with the beam hangers.
4. Position the saddle caps on the saddle cap studs, then install the washers and new self-locking nuts. Tighten the nuts 225 to 275 lbf·ft (300 to 375 N·m).
5. Install the bar pin bolt locknuts, and tighten 450 to 600 lbf·ft (610 to 813 N·m).

⚠ WARNING

WARNING: Tighten the bar pin locknuts to the specified torque values. Otherwise, excessive component wear could result. This could result in separation of suspension components, loss of vehicle control, and possible personal injury or property damage.

6. Install the wheels and tires. For instructions, **refer to Group 40.**

Equalizer Beam Rubber Center Bushing Removal and Installation, RS

Removal

NOTE: If using Owatonna tools, removal of the equalizer beam is not required for removal or installation of the rubber center bushing.

1. Chock the front tires.
2. Raise the rear of the vehicle so that all weight is removed from the suspension. Block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

3. Remove the saddle cap nuts and washers from each side of the vehicle, and remove the saddle caps.
4. Raise the rear of the truck frame until the saddle studs clear the equalizer beam. Install safety stands under the frame.
5. Using a 2-1/2-inch diameter hole saw (**see Fig. 1**), cut out the end plug from the center bushing on each side of the suspension, and remove the crosstube.

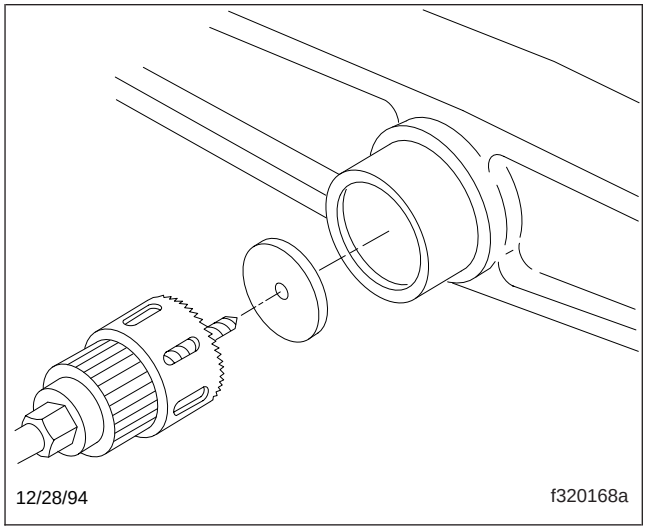

Fig. 1, End Plug Removal

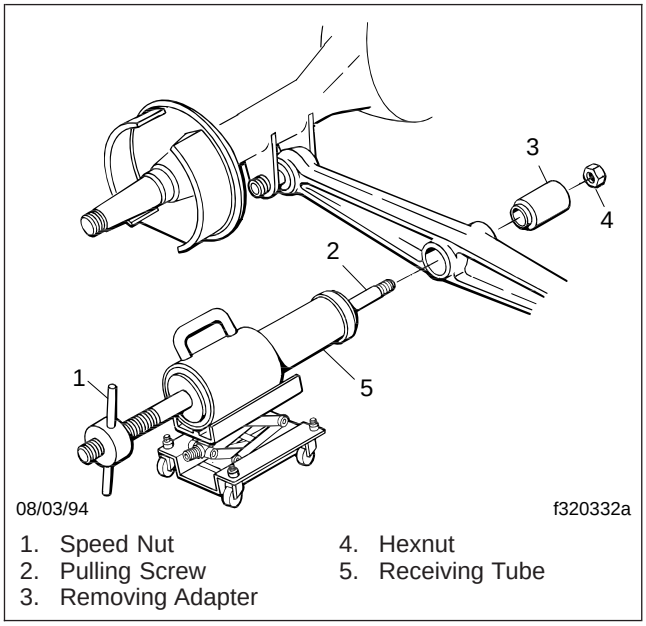
WARNING

WARNING: Don't use a cutting torch to remove the beam end bushing. Equalizer beams are heat-treated by the manufacturer. Using a cutting torch could weaken the beams, which could cause the beams to break. This could cause a loss of vehicle control, resulting in injury or property damage.

6. On the inboard side of the equalizer beam, inspect the exposed edge of the bushing's outer sleeve.
7. Chisel or grind off any portion of the outer sleeve that has flared over the surface of the equalizer beam.
8. If using Owatonna tools, remove the rubber center bushings as follows (**see Fig. 2**):



1. Speed Nut
2. Pulling Screw
3. Removing Adapter
4. Hexnut
5. Receiving Tube

beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

8.3 Install the hexnut on the pulling screw. Full thread engagement is needed.

8.4 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

8.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

8.6 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely remove the bushing.

NOTE: If the pressure gauge on the hydraulic pumping unit reads 10,000 psi (68 900 kPa) and the bushing has not broken loose, stop and check the alignment of the receiving tool and removal adapter. If both tools are aligned correctly, attach a sledging adapter on the speed nut end of the pulling screw. Maintaining hydraulic pressure, strike the sledging adapter with a heavy hammer. A loud noise followed by a sudden drop of the pressure gauge reading indicate that the bushing has broken loose.

9. If using shop-made adapters, remove the equalizer beams. For instructions, refer to **Subject 130**.

9.1 Position the equalizer beam on a 50-ton vertical hydraulic press.

9.2 Position the shop-made adapter (refer to **Specifications, 400**) on the outer metal edge of the equalizer beam bushing. Press the center bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.

2. Using emery cloth, clean the outer sleeves of the new equalizer beam center bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing.

3. If using Owatonna tools, install the rubber center bushings as follows (**see Fig. 3**):

2. Installing Adapter
3. Hexnut
4. Bushing
5. Pulling Screw

Fig. 3, Rubber Center Bushings Installation

3.1 Center the hydraulic ram and slide the pulling screw through the beam eye.

3.2 Position the bushing on the inboard side of the beam eye.

IMPORTANT: Center the new bushing to ensure a clean pull through the beam eye.

3.3 Fit the installing adapter over the inner sleeve and against the outer sleeve of the bushing.

3.4 Install the hexnut on the pulling screw. Full thread engagement is needed.

3.5 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

3.6 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

Equalizer Beam Rubber Center Bushing Removal and Installation, RS

3.7 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely install the center bushing.

NOTE: The pressure gauge on the pumping unit should read 4000 to 5500 psi (27 560 to 37 895 kPa) during installation. If the reading reaches the operating limit of 10,000 psi (68 900 kPa) and the bushing is not going into the beam, check the alignment of the bushing, tooling, and hydraulic equipment. Installation is complete when the installing adapter is flush against the beam.

3.8 Position the crosstube in the center bushings.

3.9 Arc weld new end plugs to the tire side of each center bushing inner sleeve.

NOTE: Heat from welding the end plugs will not affect the beam or the new rubber bushings because of their distance from the point of welding.

4. Position the saddle caps on the saddle cap studs, then install the washers and new self-locking nuts. Tighten the nuts 225 to 275 lbf·ft (300 to 375 N·m).

5. If using shop-made adapters, position the equalizer beam on a 50-ton hydraulic press.

5.1 Using standard center bushings with the end plugs welded in place, position the shop-made adapter (refer to **Specifications, 400**) over the inner sleeve of the bushing. Check that the adapter bottoms against the bushing outer sleeve, then press the new bushing into the beam eye.

5.2 Install the equalizer beams. For instructions, refer to **Subject 130**.

Removal

NOTE: If using Owatonna tools, you can remove or install the bronze center bushing without removing the equalizer beam.

1. Chock the front tires.
2. Raise the rear of the vehicle so that all weight is removed from the suspension. Block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

3. Remove the saddle cap nuts and washers from each side of the suspension, and remove the saddle caps.
4. Raise the rear of the truck frame until the saddle studs clear the equalizer beam. Install safety stands under the frame.
5. Using a 2-1/2-inch diameter hole saw, cut out the retaining disk from the center bushing on each side of the suspension, and remove the cross-tube.

⚠ WARNING

WARNING: Do not use a cutting torch to burn out the retaining disk. The equalizer beams are heat treated, and the use of a cutting torch could weaken the beam, causing it to break, which could result in loss of vehicle control, and possible personal injury or property damage.

6. If using Owatonna tools, remove the bronze center bushing as follows (see **Fig. 1**):

   6.1 Position the hydraulic ram and slide the pulling screw through the center bushing.

   6.2 Install the center bushing removing adapter on the inboard side of the beam eye.

   IMPORTANT: Align the receiving tube so that the bushing will clear the edges of the tube when force is exerted against the beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

   6.3 Install the hexnut on the pulling screw. Full thread engagement is needed.

   6.4 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

   6.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

sudden drop of the pressure gauge reading indicate that the bushing has broken loose.

7. If using shop-made adapters, remove the equalizer beams. For instructions, refer to **Subject 130**.

   7.1 Position the equalizer beam on a 50-ton vertical hydraulic press.

   7.2 Center the shop-made adapter (refer to **Specifications, 400**) on the center bushing. Press the bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.
2. Using emery cloth, clean the outer sleeves of the new equalizer beam center bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing, and to the inside surface of the beam eye.
3. Position the bushing on the equalizer beam eye.
4. If using Owatonna tools, install the bronze center bushings as follows (**see Fig. 2**):

   4.1 Center the hydraulic ram and slide the pulling screw through the beam eye.

   4.2 Position the bushing on the inboard side of the beam eye. Check that the grooves of the bushing are aligned with the vertical centerline of the equalizer beam (see **Fig. 3**).

   4.3 Fit the installing adapter and the removing/installing adapter against the outer sleeve of the bushing. Make sure the deep ridge on the installing adapter is positioned against the bronze bushing (see **Fig. 4**).

   4.4 Install the hexnut on the pulling screw. Full thread engagement is needed.

Using a hammer, tap the installing adapter until it is flat against the beam. Using the same procedure, install a grease seal on the outboard side of the beam.

5. If using shop-made adapters, position the equalizer beam on a 50-ton hydraulic press.

5.1 Center the new bushing in the beam eye. Using a standard bushing driver, press the bushing in until there is equal spacing be-

5.2 Install the new grease seals (with the seal lips facing out).

NOTE: Check that the new seals are 1/6 inch (4 mm) inside the beam hub surface to ensure clearance and protection of the seals when the saddle cap is installed.

6. Apply a thin coating of multipurpose chassis grease to the inside surface of the center bushing. Slide the bushing center sleeve into the bushing.

7. Install the grease fitting into the beam hub. Rotate the center sleeve and apply multipurpose chassis grease in the grease fitting. Lubricate until clean grease appears at both ends of the grease seals.

8. Install the crosstube.

Removal

IMPORTANT: To ensure that the required tools are available, see **Specifications, 400** , before beginning these procedures. Special tools are available from the Owatonna Tool Company, Owatonna, Minnesota, or an affiliated dealer.

⚠ WARNING

WARNING: When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

1. On fore and aft torque rods, remove the flanged bolts and nuts from the torque rod axle brackets, and the crossmember mounting brackets **(see Fig. 1)** . Remove the torque rods.

   On transverse torque rods, remove the nuts and washers from the axle brackets, and remove the flanged bolts and nuts from the frame rail mounting brackets **(see Fig. 1)** . Remove the torque rods.

NOTE: If necessary, use an impact hammer and tap the top of the axle bracket to disengage the rod stud from the axle bracket.

2. Inspect the torque rods. If bent or cracked, replace. Check the torque rod bushings. If one of the bushings is loose or damaged, replace both of the bushings.
3. Position the press plate on the hydraulic press. Check that the small counterbore of the plate hole is facing up.

NOTE: Some tapered stud torque rod bushings have a large non-removable washer on the stud that will not fit though the press place hole. Loosen the press plate capscrews and separate the halves **(see Fig. 2)** until the washer clears the counterbore, and the torque rod sets on the press plate. Tighten the capscrews until the press plate halves are closed.

4. Position the tapered stud removal tool (using the end with the larger inside diameter) on the torque rod stud. Apply lubricating oil **(see Fig. 3)** , then press the stud out of the bushing.
5. Position the bushing remover/replacer tool (using the end with the larger outside diameter) on the bushing. Install the cap, then apply lubricating oil to the torque rod bushing.
6. Press the rubber bushing out of the torque rod eye.
7. Position the straddle mount end of the torque rod into the hole of the press plate. Tighten the press plate capscrews.
8. Position the straddle mount pin remover on the straddle mount pin **(see Fig. 4)** .
9. Apply lubricating oil to the straddle mount pin. Press the straddle mount pin out of the bushing.
10. Position the end of the rubber bushing remover/replacer tool (using the end that has the larger outside diameter) on the bushing. Install the cap, then apply lubricating oil to the torque rod bushing.
11. Press the rubber bushing out of the torque rod eye.

Installation

1. Remove all dirt and grease from the torque rod ends. Apply lubricant on the new bushings and in the torque rod eyes.
2. Position the press plate on the hydraulic press. Check that the small counterbore of the plate hole is facing up.
3. Position the new bushing on the tapered stud of transverse torque rods. Position the clamp and tighten it to compress the rubber **(see Fig. 5)** .
4. Place the torque rod end, the bushing, and the clamp on the press plate.
5. Place the remover/replacer tool **(see Fig. 6)** and cap on top of the clamping tool and press the bushing in the torque rod end. Check that the bushing sleeve protrudes equally on each side of the torque rod end.
6. On straddle mount end assemblies, align the clamping tool on the bushing as shown in

General Description

The Hendrickson HAS suspension (see **Fig. 1**) uses air bags to support the sprung weight on vehicles with both single and tandem axles. The air bags (air springs) mount on a crossmember between the two main support beams that are fastened to the axle housing and pivot on forward-mounted hanger brackets on the frame. Torque rods, running from the hanger brackets to the axle seats, transfer vehicle motion to the frame. Lateral stability is provided by transverse torque rods from the inside of the frame rails to brackets on the axle housings. The shock absorbers help to dampen the oscillations of the air springs and control the torque reaction of the axle housings on acceleration.

height, even with varying loads. Although most vehicles with the HAS system use only one height control valve for the rear suspension, some vehicles with uneven loading may have a height control valve for each side of the vehicle. An optional suspension dump system permits the driver to temporarily lower the frame for trailer coupling or uncoupling without having to leave the cab. See **Subject 400** for a schematic of the air control system.

The suspension air control system uses air supplied from the secondary air brake system. The air supply line is connected to a secondary air manifold located behind the instrument panel. If a loss of air pressure occurs forward (upstream) of the protection valve, the air spring system will be isolated and maintain

AIR CONTROL SYSTEM

The Hendrickson HAS air suspension system allows for a smooth ride while maintaining a constant ride

the air pressure within the suspension system until repairs can be made. However, if a loss of air occurs rearward (downstream) of the protection valve, the

General Information

air in the brake system will be protected, but the air pressure in the air springs will be lost.

The vehicle ride height is maintained by a height control valve mounted on the frame and linkage that connects the valve to the suspension crossmember. (See **Fig. 2**). As the frame-to-axle housing clearance changes due to a change in the vehicle load, the linkage moves the lever on the height control valve, causing air to move in or out of the air bags. A slight delay in the operation of the height control valve prevents the system from trying to adjust the ride height for each suspension movement.

The optional air suspension dump system is used to deflate the rear suspension air springs during trailer coupling and uncoupling operations. The dump control valve is located on the dash in the cab. When the dump control valve is toggled, supply air flows through the dump control valve delivery port and pressurizes the signal line to the relay valve. The pressurization of the signal line closes the relay valve supply port while opening the ports from the air bags to the atmosphere. Air from the air bags exhausts through the relay valve until the dump control valve is released or until the frame rests on the stops inside the air bags. A pressure switch in the signal line to the relay valve senses the signal pressure and switches on an optional red status light on the dash. To allow the air springs to inflate after being dumped, the dump control valve must be first toggled downward to exhaust the pressure in the signal line.

The pilot-operated relay valve is used for rapid deflation of the air bags for trailer coupling and uncoupling. When pilot pressure from the dump control valve is applied to the relay valve, the supply air from the height control valve is stopped from flowing through the relay valve and, simultaneously, the air spring pressure is exhausted directly to the atmosphere through passages in the relay valve.

REAR SUSPENSION COMPONENTS

The axle housing, the lower shock mounts and the lower air bag mounts are all solidly attached to the HAS main support arms. See **Fig. 3** and **Fig. 4**. The main support arm hanger brackets, the upper shock mounts and the upper air bag mounts are all solidly mounted to the frame rails. The torque rods, with flexible bushings in each end, connect the hangers to the axle seats. When the vehicle travels over a

bump, the axle housing suddenly rises and compresses the air bags. The pressure in the air bags increases immediately, which absorbs most of the energy of the upward-moving axle housing without transferring that movement to the frame. The shock absorbers then help absorb the release of that higher pressure by slowing the downward movement of the axle housing after the bump.

The front of each main support arm is allowed to pivot and slide on replaceable slipper pads in the hanger brackets. A torque rod is attached to each hanger bracket and to each axle seat bracket by rubber bushings with internal pins, installed in the torque rods at specified angles. Shims are used for adjustment at the front of each torque rod to make sure that the wheels run parallel to the frame rails.

The torque rods control the forward and aft movement of the unsprung pieces during suspension travel. The flexible rubber bushings in the torque rods allow vertical movement of the axle housing while limiting its forward and aft movement. The driveline angles are kept within the specified limits by the torque rods' control of the rotational forces on the axle housings during acceleration and deceleration. The torque rods transfer the forward motion of the axle housing to the frame rails on acceleration and pull back on the frame during braking.

The transverse rods, also with rubber bushings in each end, connect the brackets on the axle housings to the brackets on the frame rails. The transverse rods keep a constant lateral relationship of the frame to the axle housing, while still allowing vertical movement of the axle housings.

The Hendrickson HAS suspension is available in varying capacities and for limited off-highway use. The heavy-duty or off-highway suspensions have thicker main support arms, heavier crossmembers and torque rods, and heavy-duty air bags and shock absorbers. There are two HAS ride height specifications (measured from the bottom of the frame rail to the bottom of the main support arm at the axle seat) depending on which suspension is used. The HAS suspensions are available for single or tandem axle vehicles and can be ordered with or without the suspension dump feature.

REAR SUSPENSION SERVICE NOTES

⚠ WARNING

A main support member that has been subjected to heat, nicks or gouges can fail, causing loss of vehicle control and possible personal injury or property damage.

⚠ CAUTION

Do not use an arc welder on the suspension parts or use a cutting torch to remove any fasteners. The use of heat on suspension components will adversely affect the strength of these parts. Never reinstall used suspension fasteners. Always use the same part number or an exact equivalent part number when replacing any suspension fastener. All fasteners must be tightened

to their specified torque and the U-bolts must be tightened in stages as described in Specifications 400.

Check the axle alignment after replacing components that affect alignment, such as a main support beam, a torque rod or a hanger.

NOTE: During installation, apply Pipe Sealant with Teflon D8AZ–19554–A or equivalent meeting specification WSK–M2G350–A2 or ESR–M18P7–A to the air fitting threads.

NOTE: When replacing the torque rod bushings, lubricate the new bushings with a vegetable-based oil only. Make sure the new bushings are centered in the torque rod bores.

NOTE: A shim pack of three 0.11 inch (2.8 mm) thick spacers are used to adjust axle lateral tracking offset. Install the spacers as required to adjust tracking.

Main Support Member Removal and Installation

Removal

NOTE: Operation of the HAS suspension will result in wear between the main support member and the spring hanger slipper pad. In normal use, these components will function satisfactorily even though they show some wear. Premature wear may occur, however, and requires the replacement of one or both parts. A main support member should be replaced if it has 3/8 inch (9.5 mm) or more wear at the hanger cam contact area.

1. Stop the vehicle on a level surface, shut down the engine and apply the park brakes. Chock the front and rear tires.
2. Support the axle housing with a jack stand under the pinion nose to prevent the axle housing from rotating when the U-bolts are removed.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the frame about 3 inches (75 mm). Support the frame at that position with jack stands.
4. Remove the locknuts, washers and bolts that connect the cross channel and shock absorber brackets to both main support members. See **Fig. 2**. Remove the lower shock mount fasteners on the HAS–40LH models.
5. Use a floor jack to raise the cross channel about 3 inches (75 mm). Support the cross channel assembly with jack stands.
6. Remove the locknut, washers and bolt from the rebound roller assembly at the front hanger. See **Fig. 3**. Remove the rebound roller and spacer.
7. Remove the U-bolt high nuts and washers, then remove the bottom cap, U-bolts and the top pad and Delrin liner.

8. Slide the main support member out of the hanger and remove the main support assembly from the vehicle.
9. Inspect the main support member for wear. Replace the main support member if worn more than 3/8 inch (9.5 mm) at the hanger end where it contacts the slipper pad or if it has cracks, nicks or signs of the application of heat from a torch or welder.
10. Inspect the slipper pad for wear. Replace the slipper pad if worn. Remove the four bolts and washers that hold the slipper pad to the hanger. If rivets were installed instead of bolts to hold the slipper pad, use a grinder to remove the rivet heads.

⚠ WARNING

Always use new fasteners when installing suspension components. Reuse of fasteners can lead to component damage and loss of vehicle control, possibly resulting in personal injury or property damage.

1. Install the slipper pad, bolts and washers into the hanger. Tighten the bolts 25 lbf·ft (34 N·m). Install new rivets if so equipped.
2. Slide the main support member into the hanger assembly.
3. Position the main support member on the axle seat, or on the spacer plate if the vehicle is so equipped, with the main support member center dowel sliding into the hole in the axle seat or spacer plate.

4. The Delrin liner must be positioned on the top of the main support member. Install the U-bolt top pad on the Delrin liner. Install the U-bolts over the top pad and liner and around the main support member, the spacer (if so equipped), the axle seat assembly, the axle housing, and the bottom cap. Install the washers and high nuts and tighten with your fingers, but do not fully tighten the U-bolt high nuts at this time.
5. Lower the floor jack under the cross channel until the cross channel is against the main support members. Install the shock absorber bracket (if so equipped) and bolts into the cross channel and main support members. See **Fig. 2**. Install the washers and tighten the locknuts 280 lbf·ft (380 N·m). On the HAS–40LH models, install the

lower shock absorber mount bolts, washers and nuts. Tighten the shock absorber nut 60 lbf·ft (82 N·m).

6. Install the rebound roller into the hanger. Install the bolt, washer and locknut. Tighten the locknut 60 lbf·ft (82 N·m).
7. Center the main support member between the hanger legs. Move the lever for the height control valve up to lift the frame from its jack stands. Remove the jack stands from the frame.
8. Tighten the U-bolt locknuts in stages as described in **Specifications 400**. Rap the top of the U-bolts with a hammer and then retighten the high nuts 500 lbf·ft (680 N·m).

IMPORTANT: Do not exceed the specified torque on the U-bolt high nuts. Retighten the U-bolt high nuts after 1000 miles (1600 km).

9. Move the lever for the height control valve down to lower the frame until the upper ball joint stud in the vertical linkage exactly aligns with the hole in the lever when the lever is in the horizontal position. Install the height control valve ball joint stud, washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
10. Remove the jack stand from under the nose of the axle housing.
11. Check and adjust the ride height as described in **Subject 180**.
12. Check the alignment after new main support members are installed.

Axle Seat Removal and Installation

Removal

1. Stop the vehicle on a level surface, shut down the engine and apply the park brakes. Chock the front and rear tires.
2. Support the axle housing with a jack stand under the pinion nose to prevent the axle housing from rotating when the U-bolts are removed.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.
4. Remove the nuts, washers and bolts that hold the torque rod to the hanger legs.
5. Remove the nuts and washers that hold the torque rod to the axle seat. Remove the torque rod.
6. Remove the high nuts from the U-bolts and remove the bottom cap and top pad and Delrin liner.
7. Use a floor jack to raise the cross channel and main support member just enough to remove the axle seat.
8. Remove the axle seat. See **Fig. 2**.
9. If the axle seat studs need replacement, remove them with a hammer and brass drift.

⚠ WARNING

Always use new fasteners when installing suspension components. Reuse of fasteners can lead to component damage and loss of vehicle control, possibly resulting in personal injury or property damage.

1. Install the new studs with a stud driver. Insert the stud in the hole of the axle seat and tap into position with a hammer and brass drift.
2. Lift the main support member with a floor jack and install the axle seat on the top of the axle housing. Install the spacer (if so equipped) above the axle seat.
3. Position the main support member on the axle seat, or on the spacer plate if the vehicle is so equipped, with the main support member center dowel sliding into the hole in the axle seat or spacer plate.
4. The Delrin liner must be positioned on the top of the main support member. Install the U-bolt top pad on the Delrin liner. Install the U-bolts over the top pad and liner and around the main support member, the spacer (if so equipped), the axle seat assembly, the axle housing, and the bottom cap. and tighten with your fingers, but do not fully tighten the U-bolt high nuts at this time.

5. Install the torque rod on the axle seat so that the holes in the bushing pin align with the axle seat studs. Install the washers and nuts, but do not tighten at this time.
6. Install the front end of the torque rod onto the hanger legs and install any shims that were removed. Install the bolts through the hanger legs, shims, and the front bushing pin.
7. Tighten the nuts on the front of the torque rod 175 lbf·ft (237 N·m).
8. Tighten the nuts for the torque rod pin at the axle seat 175 lbf·ft (237 N·m).
9. Move the lever for the height control valve up to lift the frame from its jack stands, Remove the jack stands from the frame.
10. Tighten the U-bolt locknuts in stages as described in **Specifications 400**. Rap the top of the U-bolts with a hammer and then retighten the high nuts 500 lbf·ft (680 N·m).

IMPORTANT: Do not exceed the specified torque on the U-bolt high nuts. Retighten the U-bolt high nuts after 1000 miles (1600 km).

11. Move the lever for the height control valve down to lower the frame until the upper ball joint stud in the vertical linkage exactly aligns with the hole in the lever when the lever is in the horizontal position. Install the height control valve ball joint stud, washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
12. Remove the jack stand from under the nose of the axle housing.
13. Check and adjust the ride height as described in **Subject 180**.
14. Check the alignment after new axle seats are installed.

Replacement (See Fig. 1)

Use the following procedure to replace the torque rod bushing.

1. Chock the front tires, and the tires of the drive axles.
2. Remove the bushing pin locknuts and washers at the axle end of the torque rod. See **Fig. 1**.

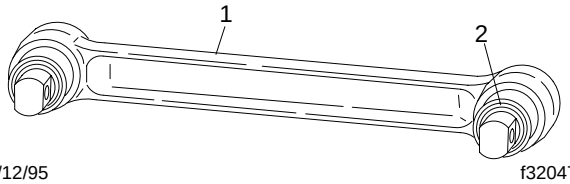
3. Loosen the rebound bolt locknut in the hanger.
4. Remove the bushing pin locknuts, bolts and washers, and any alignment shims at the hanger end of the torque rod. Note the number of shims, as the same thickness shim pack must be reinstalled to avoid affecting the vehicle's alignment.
5. Push out the old bushings. Use a vertical shop press with a capacity of at least 10 tons. A 5-inch (127 mm) piece of 2-inch by 1/4-inch (50-mm by 6-mm) wall, steel-tubing receiving tool is required. The bushings are not cartridge-type bushings and do not have a metal outer sleeve.
6. Support the torque rod end on the receiving tool with the end tube of the torque rod centered on the tool.

⚠ WARNING

Do not use heat or a cutting torch to remove the bushings from the torque rod. The use of heat will weaken the torque rod, which could cause the rod to break. This could result in a loss of vehicle control, personal injury, or property damage.

7. Push directly on the bushing pin until the bushing is pushed out of the torque rod end tube.
8. Clean and inspect the torque rod ends. Remove any nicks with emery cloth.
9. Lubricate the torque rod ends and the new rubber bushings with a vegetable-based oil. Do not use a petroleum-based or soap-based lubricant.
10. Press in the new bushings while supporting the torque rod end on the receiving tool with the end tube of the torque rod centered on the receiving tool. The bushings must be installed with the mounting flats on the bar pin positioned 90 degrees to the shank of the torque rod. See **Fig. 2**.



1. Torque Rod
2. Bushing Bar Pin

Fig. 2, Positioning the Bar Pin Mounting Flats

11. Press directly on the bar pin of the bushings, which must be centered within the torque rod end tubes. When pressing in the new bushings, overshoot the final position by approximately 3/16 inch (5 mm).
12. Press the bushing again from the opposite side to center the bushing within the torque rod end.

Torque Rod Bushing Replacement

13. Position the torque rod into the axle seat and attach it with the washers and locknuts. Handtighten the locknuts.
14. Position the torque rod onto the forward face of the hanger legs. Assemble the bolts, washers and locknuts, and any alignment shims. Tighten locknut 175 lbf·ft (237 N·m). See **Fig. 1**.
15. Tighten locknuts at the axle end of the torque rods 175 lbf·ft (237 N·m).
16. Tighten rebound bolt locknut 60 lbf·ft (81 N·m).

Height Control Valve Removal and Installation

Removal

1. Chock the front tires.
2. Drain the vehicle's air system.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Remove the height control valve vertical rod from the valve lever by removing the nut and lock washer. Push down on the lever of the height control valve to exhaust the air from the rear suspension air bags.
4. Remove the air lines attached to the height control valve. See **Fig. 1**.

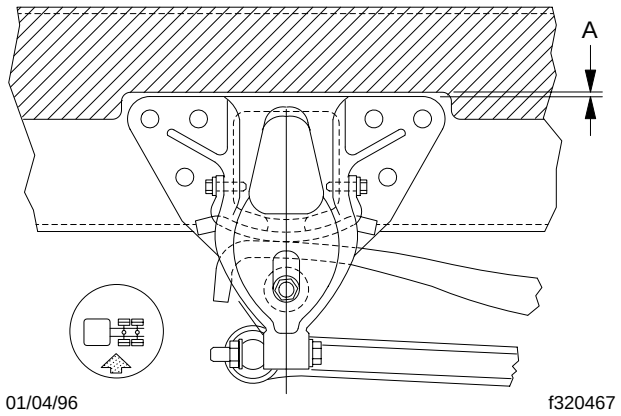
5. Remove the locknuts, washers, and bolts that attach the height control valve to the frame.
6. Remove the brass air fittings from the height control valve.

Installation

1. Install the brass air fittings into the height control valve ports.
2. Install the bolts, washers, and locknuts that attach the valve to the frame rail.
3. Attach the air lines to the height control valve.
4. Attach the height control valve vertical linkage rod to the height control valve lever, and install the lock washer and nut. See **Fig. 1**.
5. Return air to the system.
6. Adjust the height control valve for proper ride height as described in **Subject 180**.

Information

The HAS front hangers must have at least 1/4-inch (6 mm) clearance between the top of the hanger and the bottom of the fifth wheel mounting bracket on the sides of the frame rails. In some cases, the fifth wheel mounting bracket may have to be cut out to provide the correct clearance. See **Fig. 1** for an example of a fifth wheel mounting bracket that has been modified.



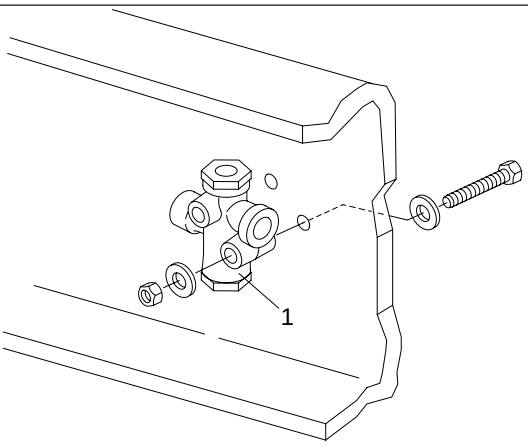
A. Clearance: 1/4 inch (6 mm)

Fig. 1, Fifth Wheel Mounting Angle Clearance

Quick Release Valve Replacement

Replacement (See Fig. 1)

1. Chock the front tires.
2. Drain the vehicle's air system.
3. Disconnect the air lines from the quick release valve. Identify the air line at the top of the valve.
4. Remove the quick release valve from the frame or cross member.
5. Remove the brass air fittings from the valve.
6. Attach the brass air fittings to the replacement quick release valve.
7. Attach the valve to the frame or cross member.



1. Quick Release Valve

8. Connect the air lines to the valve, making sure to attach the identified line to the top of the valve.
9. Build up pressure in the air system.
10. Remove the chocks from the front tires.

Slipper Pad Removal and Installation

Removal

NOTE: Operation of the HAS suspension will result in wear between the main support member and the hanger slipper pad. In normal use, these components will function satisfactorily even though the components indicate some wear.

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage from the lever of the height control valve and lift the lever to raise the rear of the frame about 3 inches (75 mm). See **Fig. 1**.
3. Support the frame with jack stands.
4. Apply an upward force on the cross channel with a jack or, on single axles, by pushing down on the height control lever to lift the cross channel. This will cause the tips of the main support members to drop away from the slipper pad. See **Fig. 2**.

IMPORTANT: Do not nick or gouge the cross channel.

5. Remove the fasteners and the slipper pad. In some instances, the screws may have to be drilled out. See **Fig. 3**.
6. In some instances, remove the rebound roller to gain enough clearance to remove the slipper pad. Loosen the rebound bolt locknut, remove the washer, the bolt, and the rebound roller assembly.
7. For rivets, remove the four 1/4-inch (6-mm) rivets by grinding away the rivet heads. With a drift pin, punch the rivets through the holes and remove the slipper pad.

Installation

1. Position the slipper pad and retainer plate on the frame hanger.
2. Tighten the hexhead self-tapping screws 25 lbf·ft (34 N·m).
3. Or, install the rivets using a rivet gun.
4. Raise the frame off the jack stands by pulling up on the height control valve lever. Remove the jack stands.
5. Push down on the height control valve lever to lower the frame until the upper ball stud on the vertical linkage rod exactly aligns with the hole in the lever when the lever is horizontal.
6. Install the ball stud into the hole in the lever and install the washer and nut. Tighten the nut 10 lbf·ft (14 N·m).
7. Remove the chocks from the tires.

Removal

1. Stop the vehicle on a level surface and shutdown the engine. Chock the front and rear tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.

5. Raise the cross channel by pushing down on the height control lever to compress the air springs just enough to clear the studs on the bottom of the air springs. Remove the cross channel.

Installation

1. Position the cross channel so that the holes in the cross channel are aligned under the studs of the air springs. Install the washers and nuts. Tighten the nuts on the air spring studs 25 lbf·ft (34 N·m).

Cross Channel Removal and Installation

2. Lower the cross channel assembly onto the main support members by pushing down on the height control valve lever.
3. Install the bolts, washers and locknuts that connect the cross channel to the main support member and lower shock absorber mounts. Tighten the locknuts 290 lbf·ft (393 N·m).
4. Raise the frame by lifting the height control valve lever and remove the jack stands.
5. Attach the ball joint stud of the vertical linkage rod to the height control valve link, and tighten the locknut on the ball joint stud 10 lbf·ft (14 N·m).
6. Remove the chocks from the tires.

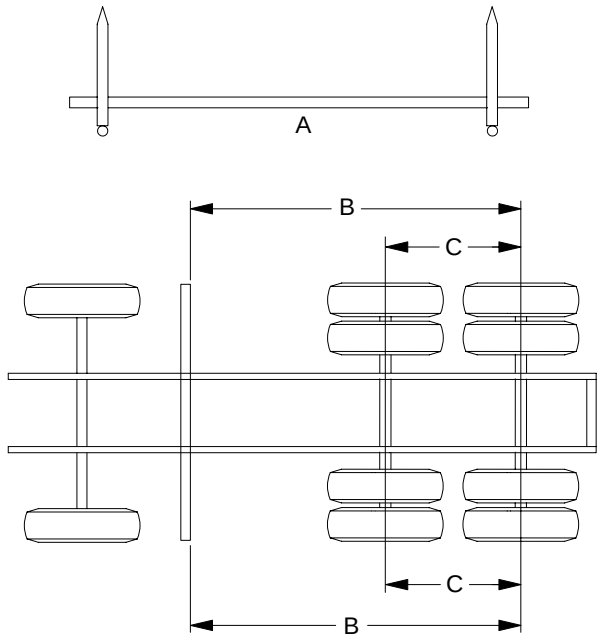
Checking and Adjustment

Use the following procedure after all repairs to the suspension:

1. Park vehicle on a level surface. Free and center all suspension joints by slowly moving the vehicle back and forth several times without applying the brakes.
2. Chock the front tires and the tires of drive axles.
3. C-clamp a nine-foot (2.74-m) piece of straight bar stock or angle iron across the frame. Select a location as far forward of the forward drive axle as possible where components will not interfere. The lower frame flange may be preferred on some vehicles, otherwise use the upper frame flange.
4. Align the straight bar stock or angle iron on the frame using a carpenter's square.
5. Check the rear drive axle first. See **Fig. 1** . Use a trammel bar or its equivalent to measure from the straight edge to the center line of the rear axle on both sides of the vehicle. If both sides measure within 3/16 inch (5 mm) of being the same, the alignment of the rear drive axle is acceptable. If the sides differ by more than 3/16-inch (5 mm), first loosen the rebound locknut, and then adjust the rear drive axle by loosening up the torque rod bar pin locknuts on the hangers. Add or remove drop-in shims as needed.

NOTE: The torque rod bar pin must be mounted to the forward face of the hanger legs. No more than four shims may be used (for a maximum thickness of 1/4 inch (6 mm).

6. Snug the torque rod bar pin locknuts but do not torque to specification.
7. With the rear drive axle properly aligned, the front drive axle alignment can be checked by measuring forward from the center of the axle shafts on the rear drive axle using a trammel bar. If the forward drive axle spacing measurements differ by more than 1/8 inch (3 mm), add or subtract shims at the forward hangers.
8. Following the adjustment of both axles, move the vehicle back and forth several times prior to removing the straight edge from the frame. Recheck the alignment.



A. Trammel Bar
B. Each side must be within 3/16 inch (5 mm) of each other.
C. Distances between axles must be within 1/8 inch (3 mm) of each other.

9. Tighten the torque rod bar pin locknuts 180 lbf·ft (244 N·m).
10. Remove the chocks from the tires.

Replacement

1. Chock the front tires.
2. Support the frame with jack stands.
3. Drain the vehicle's air system.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

4. Remove the upper ball joint nut and stud from the lever on the height control valve. See **Fig. 1**. Move the height control valve lever down to exhaust all the air from the air bags.

15. Connect the ball stud on the vertical linkage rod to the lever for the height control valve. Install the washer and tighten the nut 10 lbf·ft (14 N·m).
16. Remove the jack stands.
17. Build up pressure in the air system and check the ride height as described in **Subject 180**.
18. Remove the chocks from the tires.

Air Spring Frame Hanger Removal and Installation

Removal

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.

3. Drain the air from the vehicle's air system then lower the lever on the height control valve to exhaust the air from the air springs.
4. Disconnect the air lines from the air spring fittings.
5. Remove the brass air fittings from the air spring.
6. Remove the locknuts and washers that attach the air springs studs to the upper bracket on the frame rail. See **Fig. 2**.
7. Remove the nuts, washers and bolts that hold the upper air spring bracket to the frame rail. Remove the air spring bracket.

Installation

1. Position the air spring upper bracket on the frame rails. Install the bolts through the frame rail and upper bracket and install the washers, and locknuts. Tighten the locknuts 340 lbf·ft (461 N·m).
2. Attach the air spring to the air spring frame bracket. Tighten the outboard locknut 25 lbf·ft (34 N·m).

5. Build up pressure in the air system and raise the height control lever to lift the frame off the jack stands. Remove the jack stands and lower the vehicle.
6. Align the ball joint stud in the vertical linkage rod with the hole in the height control lever. Install the ball joint stud, the washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
7. Remove the chocks from the tires.

Shock Absorber Bracket Removal and Installation

Removal

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Remove the locknut and washer and disconnect the ball joint stud on the top of the vertical linkage rod from the height control valve lever. See **Fig. 1**.

3. Lift the height control lever to raise the rear of the frame enough to remove the load from the suspension.

   NOTE: The front of the main support member will move downward as the load is removed. Support the frame in this position with jack stands.

4. Remove the shock absorber. Refer to **Subject 170**.

5. Remove nuts, washers and bolts from the shock absorber frame hanger bracket. See **Fig. 2**. Remove the top shock absorber bracket from the frame.

Fig. 2, Shock Absorber Mounts (typical)

6. Remove the nuts, washers and bolts that attach the cross channel and lower shock absorber bracket to the rear of the main support member.

7. Remove the lower bracket by sliding the bracket to the rear.

Installation

1. Install the bolts and washers that attach the frame hanger bracket from the inboard side of the frame. Install the brackets, washers and locknuts. Tighten the nuts 340 lbf·ft (461 N·m).

2. Position the lower bracket between the cross channel and the main support member.

Shock Absorber Bracket Removal and Installation

3. Install the bolts and washers from the top of the cross channel, through the shock bracket and main support member. Install the washers and locknuts and tighten the locknuts attaching the cross channel to the main support member 290 lbf·ft (393 N·m).
4. Install the shock absorber. Install the washers at both sides of each shock bushing for a total of four washers per shock absorber.
5. Tighten shock absorber locknuts 60 lbf·ft (81 N·m).
6. Lift the lever of the height control valve to raise the rear of the frame off the jack stands. Remove the jack stands and lower the frame by pushing down on the height control valve lever.
7. Align the ball joint stud in the vertical linkage rod with the hole in the height control valve lever. Install the washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
8. Remove the chocks from the tires.

Transverse Rod Removal and Installation

Removal (See Fig. 1)

NOTE: This procedure is for replacement of a transverse rod with a tapered stud at the axle connection and a straddle mount pin at the frame bracket end. Some installations have straddle mounts at both ends of the transverse rod.

1. Chock the front and rear tires.
2. Remove the nuts and washers from the bolts that fasten the pin in the transverse rod bushing to the frame bracket. Disconnect the transverse rod where it is attached to the frame bracket bracket.
3. Remove the nut from the tapered stud in the tube bracket on the axle housing. Hit the top of the axle bracket tube hard with a large hammer to momentarily distort the tube and loosen the tapered stud. Remove the stud and transverse rod from the bracket on the axle housing.

1. Clear the tapered hole in the axle bracket of all foreign matter.
2. Insert the tapered stud and torque rod bushing into the bracket.
3. Attach the washer and locknut to the stud. Tighten 200 lbf·ft (271 N·m).
4. After tightening, hit the top of the axle bracket tube with a hammer to seat the tapered stud. Retighten.
5. Position the straddle mount end of the transverse rod at the frame bracket, and tighten 200 lbf·ft (271 N·m).
6. Remove the chocks from the tires.

General Information

NOTE: This subject applies only to Hendrickson series HAS 190/210/230/40LH/400/402/460 suspensions.

Adjust the vehicle ride height with the unloaded vehicle on a level surface. The frame slope, driveline angles, and axle mounting alignment should be checked after the ride height has been changed.

⚠ CAUTION

Failure to adjust the vehicle ride height could adversely affect driveline angles. Also, if the air springs are set too high, the driver may have difficulty (or be prevented from) backing the vehicle under a trailer. If the air springs are set too low, rapid wear of driveline parts will result.

Ride Height Adjustment

The vehicle ride height for Hendrickson HAS air suspension systems is changed by adjusting the length of the vertical linkage at the ride height control valve. Use the following procedure to adjust the ride height of the frame rails.

IMPORTANT: Before checking the ride height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty when checking the ride height.

1. Stop the vehicle on a level surface, using a light application of the brakes. Slowly move the vehicle forward and back several times without using the brakes to center the suspension joints. Do not apply the parking brakes.
2. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.

   NOTE: Allow several minutes for the air pressure to equalize in the system before checking the ride height.
3. Mark the location of the front and rear tires on the floor so that the vehicle can be checked in the same location after a test drive. Chock the front tires.

IMPORTANT: Any difference in height between the two sides of the vehicle must be corrected using spacers between the main support arm and the rear axle housing before setting the vehicle ride height. See the appropriate section in Group 32 in the vehicle's service manual for the alignment procedure.

4. Measure the distance from the bottom of the frame rail to the bottom of the main support arm at the rear axle U-bolts. See **Fig. 1**. The correct measurement for Hendrickson HAS suspension systems is 4-1/4±1/8 inches (108±3 mm) for vehicles with a specified ride height of 8-1/2 inches (215 mm) or greater. For vehicles with less than an 8-1/2-inch (215 mm) ride height, the distance between the bottom of the frame rail and the bottom of the main support arm must be 2-3/8 inches (60 mm).

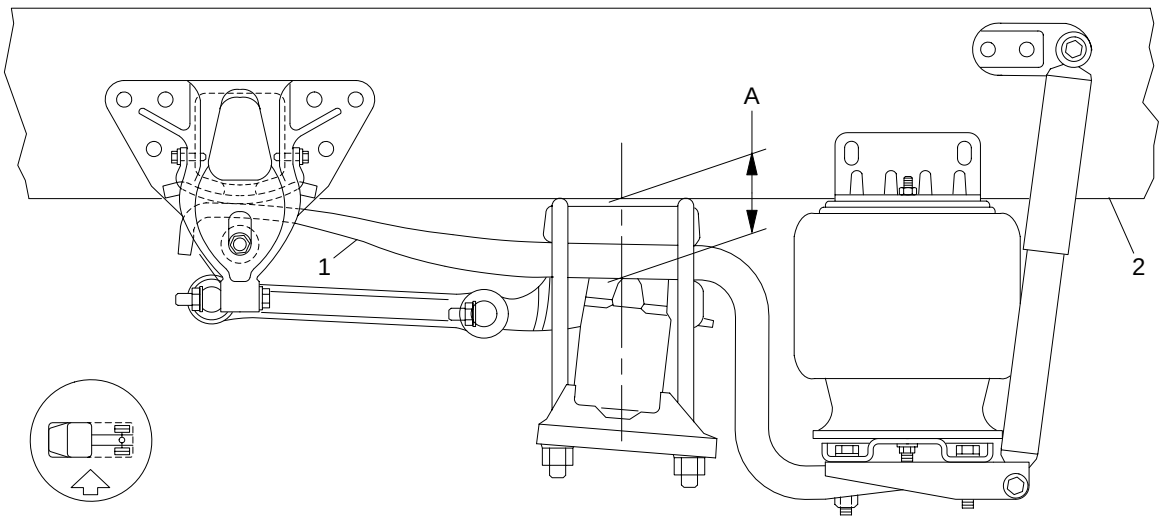
   If the measurement is the same as the specification at each support arm, the ride height is correctly adjusted. If the distance measured is not the same at each rear axle mount on the vehicle, correct this alignment problem before attempting to adjust the ride height.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

5. Remove the nut and lockwasher from the ball joint stud at the end of the lever on the ride height control valve. See **Fig. 2**. Separate the vertical rod assembly from the lever, being careful to avoid moving the lever while disconnecting the ball joint.
6. Push the lever down to lower the frame by removing the air in the suspension air bags.
7. Slowly pull the lever up to raise the frame until the ride height measurement is exactly correct for the specified ride height.
8. Make sure that the centering hole in the lever near its pivot aligns with the centering hole in the height control valve body. Check the height control valve to make sure that no air flows through

Ride Height Adjustment



A. Measure ride height here.

the ride height control valve when the lever is in the centered position.

9. Loosen the jam nuts a few turns at the top and bottom ball joints on the vertical rod that attaches to the height control lever. Note that one of the ball joints and jam nuts has left-hand threads. Hold the top ball joint with your hand and turn the vertical rod with a wrench until the top ball joint stud exactly aligns with the hole in the end of the lever when the lever is centered horizontally on the control valve.
10. Install the ball joint stud in the lever and install the lockwasher and nut on the stud. Tighten the nut on the stud to 125 lbf·inch (11 N·cm).
11. Tighten the jam nut on each ball joint without changing the length of the vertical rod.
12. Apply the parking brakes; then remove the chocks from the tires. Drive the vehicle unloaded for about 1/4 mile (1/2 km); then stop the vehicle in the exact location (as previously marked) of the original measurement.
13. Park the vehicle using only a light brake application. Chock the tires on one axle only and put the transmission in neutral. Do not apply the parking brakes.
14. Check the adjusted distance between the bottom of the frame and the bottom of the main support arm at the U-bolts. See **Fig. 2**.
15. If the distance is still not correct, loosen the ball joint jam nuts on the vertical rod and turn the rod to adjust the ride height. Lengthen the vertical rod to raise the frame or shorten the rod to lower the frame to the correct ride height. Drive the vehicle and again check the ride height.
16. Apply the parking brakes; then remove the chocks from the tires.

Problem—All Air Bags Are Deflated

Problem—All Air Bags Are Deflated	
Possible Cause	**Remedy**
The vehicle air system pressure is too low.	Run the engine until the air gauge indicates 100 psi (690 kPa).
Air is leaking from the vehicle air system.	Listen for air leakage at the air fittings, tanks, and brake componenets. Repair or replace fittings as needed.
The linkage for the height control valve is disconnected or maladjusted.	Connect the linkage and adjust as described in **Subject 180**.
The suspension dump valve is activated.	Toggle the dump control valve to the normal position.
The relay valve is stuck open.	Check and repair the relay valve.
The air bags have a leak.	Listen for leaks at the air bags, tubes, and fittings.
The height control valve is not operating correctly.	Disconnect the linkage and raise and lower the lever to check the operation of the height control valve. Make sure that no air flows through the valve when the lever is in the center position. Replace the valve if it is bad.
There is a obstruction in the lines to the height control valve.	Check the air pressure at the height control valve supply port. Remove any obstruction or restriction to air flow to the valve.
The pressure protection valve is not allowing air to flow to the height control valve.	Check the operation of the pressure protection valve between the secondary air tank and the height control valve. Replace the valve if it is not operating correctly.

Problem—One Side of the Vehicle Is Higher Than the Other

Problem—One Side of the Vehicle Is Higher Than the Other	
Possible Cause	**Remedy**
The axle seat spacer thickness is not the same on each side.	Adjust the spacers so that the frame is level before adjusting the ride height.
The load on the vehicle is not distributed evenly.	Change the position of the load to ensure equal weight on each side.
There is an obstruction to air flow to the air bags on one side of the vehicle.	Disconnect the fittings and test the flow to the air bags on the lower side of the vehicle.
The height control valve or relay valve has an internal restriction.	Check for the same pressure at the ports on each side of the valve. Replace the valve if the pressure is not the same.
The air bags or fittings have a leak.	Listen for leaks at the air bags, tubes, and fittings. Tighten the fittings, if loose, or replace any bad parts.

Problem—The Ride Height Is Not Constant

Problem—The Ride Height Is Not Constant	
Possible Cause	**Remedy**
Air is leaking from the air bags or lines.	Listen or use soap bubbles to find air leaks. Tighten or replace leaking fittings or air bags.
The height control valve is not working correctly.	Make sure that no air is exhausted from the height control valve when the lever is in the horizontal position and that the air bags inflate when the lever is raised. The bags must deflate when the lever is pushed down. There must be a slight delay between the lever movement and the valve operation. Check for fluid leaks from the height control valve. Replace the valve if damaged.

General Description

The Hendrickson HAS suspension (see **Fig. 1**) uses air bags to support the sprung weight on vehicles with both single and tandem axles. The air bags (air springs) mount on a crossmember between the two main support beams that are fastened to the axle housing and pivot on forward-mounted hanger brackets on the frame. Torque rods, running from the hanger brackets to the axle seats, transfer vehicle motion to the frame. Lateral stability is provided by transverse torque rods from the inside of the frame rails to brackets on the axle housings. The shock absorbers help to dampen the oscillations of the air springs and control the torque reaction of the axle housings on acceleration.

height, even with varying loads. Although most vehicles with the HAS system use only one height control valve for the rear suspension, some vehicles with uneven loading may have a height control valve for each side of the vehicle. An optional suspension dump system permits the driver to temporarily lower the frame for trailer coupling or uncoupling without having to leave the cab. See **Subject 400** for a schematic of the air control system.

The suspension air control system uses air supplied from the secondary air brake system. The air supply line is connected to a secondary air manifold located behind the instrument panel. If a loss of air pressure occurs forward (upstream) of the protection valve, the air spring system will be isolated and maintain

AIR CONTROL SYSTEM

The Hendrickson HAS air suspension system allows for a smooth ride while maintaining a constant ride

the air pressure within the suspension system until repairs can be made. However, if a loss of air occurs rearward (downstream) of the protection valve, the

General Information

air in the brake system will be protected, but the air pressure in the air springs will be lost.

The vehicle ride height is maintained by a height control valve mounted on the frame and linkage that connects the valve to the suspension crossmember. (See **Fig. 2**). As the frame-to-axle housing clearance changes due to a change in the vehicle load, the linkage moves the lever on the height control valve, causing air to move in or out of the air bags. A slight delay in the operation of the height control valve prevents the system from trying to adjust the ride height for each suspension movement.

The optional air suspension dump system is used to deflate the rear suspension air springs during trailer coupling and uncoupling operations. The dump control valve is located on the dash in the cab. When the dump control valve is toggled, supply air flows through the dump control valve delivery port and pressurizes the signal line to the relay valve. The pressurization of the signal line closes the relay valve supply port while opening the ports from the air bags to the atmosphere. Air from the air bags exhausts through the relay valve until the dump control valve is released or until the frame rests on the stops inside the air bags. A pressure switch in the signal line to the relay valve senses the signal pressure and switches on an optional red status light on the dash. To allow the air springs to inflate after being dumped, the dump control valve must be first toggled downward to exhaust the pressure in the signal line.

The pilot-operated relay valve is used for rapid deflation of the air bags for trailer coupling and uncoupling. When pilot pressure from the dump control valve is applied to the relay valve, the supply air from the height control valve is stopped from flowing through the relay valve and, simultaneously, the air spring pressure is exhausted directly to the atmosphere through passages in the relay valve.

REAR SUSPENSION COMPONENTS

The axle housing, the lower shock mounts and the lower air bag mounts are all solidly attached to the HAS main support arms. See **Fig. 3** and **Fig. 4**. The main support arm hanger brackets, the upper shock mounts and the upper air bag mounts are all solidly mounted to the frame rails. The torque rods, with flexible bushings in each end, connect the hangers to the axle seats. When the vehicle travels over a

bump, the axle housing suddenly rises and compresses the air bags. The pressure in the air bags increases immediately, which absorbs most of the energy of the upward-moving axle housing without transferring that movement to the frame. The shock absorbers then help absorb the release of that higher pressure by slowing the downward movement of the axle housing after the bump.

The front of each main support arm is allowed to pivot and slide on replaceable slipper pads in the hanger brackets. A torque rod is attached to each hanger bracket and to each axle seat bracket by rubber bushings with internal pins, installed in the torque rods at specified angles. Shims are used for adjustment at the front of each torque rod to make sure that the wheels run parallel to the frame rails.

The torque rods control the forward and aft movement of the unsprung pieces during suspension travel. The flexible rubber bushings in the torque rods allow vertical movement of the axle housing while limiting its forward and aft movement. The driveline angles are kept within the specified limits by the torque rods' control of the rotational forces on the axle housings during acceleration and deceleration. The torque rods transfer the forward motion of the axle housing to the frame rails on acceleration and pull back on the frame during braking.

The transverse rods, also with rubber bushings in each end, connect the brackets on the axle housings to the brackets on the frame rails. The transverse rods keep a constant lateral relationship of the frame to the axle housing, while still allowing vertical movement of the axle housings.

The Hendrickson HAS suspension is available in varying capacities and for limited off-highway use. The heavy-duty or off-highway suspensions have thicker main support arms, heavier crossmembers and torque rods, and heavy-duty air bags and shock absorbers. There are two HAS ride height specifications (measured from the bottom of the frame rail to the bottom of the main support arm at the axle seat) depending on which suspension is used. The HAS suspensions are available for single or tandem axle vehicles and can be ordered with or without the suspension dump feature.

REAR SUSPENSION SERVICE NOTES

⚠ WARNING

A main support member that has been subjected to heat, nicks or gouges can fail, causing loss of vehicle control and possible personal injury or property damage.

⚠ CAUTION

Do not use an arc welder on the suspension parts or use a cutting torch to remove any fasteners. The use of heat on suspension components will adversely affect the strength of these parts. Never reinstall used suspension fasteners. Always use the same part number or an exact equivalent part number when replacing any suspension fastener. All fasteners must be tightened

to their specified torque and the U-bolts must be tightened in stages as described in Specifications 400.

Check the axle alignment after replacing components that affect alignment, such as a main support beam, a torque rod or a hanger.

NOTE: During installation, apply Pipe Sealant with Teflon D8AZ–19554–A or equivalent meeting specification WSK–M2G350–A2 or ESR–M18P7–A to the air fitting threads.

NOTE: When replacing the torque rod bushings, lubricate the new bushings with a vegetable-based oil only. Make sure the new bushings are centered in the torque rod bores.

NOTE: A shim pack of three 0.11 inch (2.8 mm) thick spacers are used to adjust axle lateral tracking offset. Install the spacers as required to adjust tracking.

Main Support Member Removal and Installation

Removal

NOTE: Operation of the HAS suspension will result in wear between the main support member and the spring hanger slipper pad. In normal use, these components will function satisfactorily even though they show some wear. Premature wear may occur, however, and requires the replacement of one or both parts. A main support member should be replaced if it has 3/8 inch (9.5 mm) or more wear at the hanger cam contact area.

1. Stop the vehicle on a level surface, shut down the engine and apply the park brakes. Chock the front and rear tires.
2. Support the axle housing with a jack stand under the pinion nose to prevent the axle housing from rotating when the U-bolts are removed.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the frame about 3 inches (75 mm). Support the frame at that position with jack stands.
4. Remove the locknuts, washers and bolts that connect the cross channel and shock absorber brackets to both main support members. See **Fig. 2**. Remove the lower shock mount fasteners on the HAS–40LH models.
5. Use a floor jack to raise the cross channel about 3 inches (75 mm). Support the cross channel assembly with jack stands.
6. Remove the locknut, washers and bolt from the rebound roller assembly at the front hanger. See **Fig. 3**. Remove the rebound roller and spacer.
7. Remove the U-bolt high nuts and washers, then remove the bottom cap, U-bolts and the top pad and Delrin liner.

10. Inspect the slipper pad for wear. Replace the slipper pad if worn. Remove the four bolts and washers that hold the slipper pad to the hanger. If rivets were installed instead of bolts to hold the slipper pad, use a grinder to remove the rivet heads.

⚠ WARNING

Always use new fasteners when installing suspension components. Reuse of fasteners can lead to component damage and loss of vehicle control, possibly resulting in personal injury or property damage.

1. Install the slipper pad, bolts and washers into the hanger. Tighten the bolts 25 lbf·ft (34 N·m). Install new rivets if so equipped.
2. Slide the main support member into the hanger assembly.
3. Position the main support member on the axle seat, or on the spacer plate if the vehicle is so equipped, with the main support member center dowel sliding into the hole in the axle seat or spacer plate.

Install the U-bolts over the top pad and liner and around the main support member, the spacer (if so equipped), the axle seat assembly, the axle housing, and the bottom cap. Install the washers and high nuts and tighten with your fingers, but do not fully tighten the U-bolt high nuts at this time.
5. Lower the floor jack under the cross channel until the cross channel is against the main support members. Install the shock absorber bracket (if so equipped) and bolts into the cross channel and main support members. See **Fig. 2**. Install the washers and tighten the locknuts 280 lbf·ft (380 N·m). On the HAS–40LH models, install the

lower shock absorber mount bolts, washers and nuts. Tighten the shock absorber nut 60 lbf·ft (82 N·m).

6. Install the rebound roller into the hanger. Install the bolt, washer and locknut. Tighten the locknut 60 lbf·ft (82 N·m).
7. Center the main support member between the hanger legs. Move the lever for the height control valve up to lift the frame from its jack stands. Remove the jack stands from the frame.
8. Tighten the U-bolt locknuts in stages as described in **Specifications 400**. Rap the top of the U-bolts with a hammer and then retighten the high nuts 500 lbf·ft (680 N·m).

IMPORTANT: Do not exceed the specified torque on the U-bolt high nuts. Retighten the U-bolt high nuts after 1000 miles (1600 km).

9. Move the lever for the height control valve down to lower the frame until the upper ball joint stud in the vertical linkage exactly aligns with the hole in the lever when the lever is in the horizontal position. Install the height control valve ball joint stud, washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
10. Remove the jack stand from under the nose of the axle housing.
11. Check and adjust the ride height as described in **Subject 180**.
12. Check the alignment after new main support members are installed.

Axle Seat Removal and Installation

Removal

1. Stop the vehicle on a level surface, shut down the engine and apply the park brakes. Chock the front and rear tires.
2. Support the axle housing with a jack stand under the pinion nose to prevent the axle housing from rotating when the U-bolts are removed.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.
4. Remove the nuts, washers and bolts that hold the torque rod to the hanger legs.
5. Remove the nuts and washers that hold the torque rod to the axle seat. Remove the torque rod.
6. Remove the high nuts from the U-bolts and remove the bottom cap and top pad and Delrin liner.
7. Use a floor jack to raise the cross channel and main support member just enough to remove the axle seat.
8. Remove the axle seat. See **Fig. 2**.
9. If the axle seat studs need replacement, remove them with a hammer and brass drift.

Installation

⚠ WARNING

Always use new fasteners when installing suspension components. Reuse of fasteners can lead to component damage and loss of vehicle control, possibly resulting in personal injury or property damage.

1. Install the new studs with a stud driver. Insert the stud in the hole of the axle seat and tap into position with a hammer and brass drift.
2. Lift the main support member with a floor jack and install the axle seat on the top of the axle housing. Install the spacer (if so equipped) above the axle seat.
3. Position the main support member on the axle seat, or on the spacer plate if the vehicle is so equipped, with the main support member center dowel sliding into the hole in the axle seat or spacer plate.
4. The Delrin liner must be positioned on the top of the main support member. Install the U-bolt top pad on the Delrin liner. Install the U-bolts over the top pad and liner and around the main support member, the spacer (if so equipped), the axle seat assembly, the axle housing, and the bottom cap. Install the washers and high nuts

and tighten with your fingers, but do not fully tighten the U-bolt high nuts at this time.

5. Install the torque rod on the axle seat so that the holes in the bushing pin align with the axle seat studs. Install the washers and nuts, but do not tighten at this time.
6. Install the front end of the torque rod onto the hanger legs and install any shims that were removed. Install the bolts through the hanger legs, shims, and the front bushing pin.
7. Tighten the nuts on the front of the torque rod 175 lbf·ft (237 N·m).
8. Tighten the nuts for the torque rod pin at the axle seat 175 lbf·ft (237 N·m).
9. Move the lever for the height control valve up to lift the frame from its jack stands, Remove the jack stands from the frame.
10. Tighten the U-bolt locknuts in stages as described in **Specifications 400**. Rap the top of the U-bolts with a hammer and then retighten the high nuts 500 lbf·ft (680 N·m).

IMPORTANT: Do not exceed the specified torque on the U-bolt high nuts. Retighten the U-bolt high nuts after 1000 miles (1600 km).

11. Move the lever for the height control valve down to lower the frame until the upper ball joint stud in the vertical linkage exactly aligns with the hole in the lever when the lever is in the horizontal position. Install the height control valve ball joint stud, washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
12. Remove the jack stand from under the nose of the axle housing.
13. Check and adjust the ride height as described in **Subject 180**.
14. Check the alignment after new axle seats are installed.

Replacement (See Fig. 1)

Use the following procedure to replace the torque rod bushing.

1. Chock the front tires, and the tires of the drive axles.
2. Remove the bushing pin locknuts and washers at the axle end of the torque rod. See **Fig. 1**.

3. Loosen the rebound bolt locknut in the hanger.
4. Remove the bushing pin locknuts, bolts and washers, and any alignment shims at the hanger end of the torque rod. Note the number of shims, as the same thickness shim pack must be reinstalled to avoid affecting the vehicle's alignment.
5. Push out the old bushings. Use a vertical shop press with a capacity of at least 10 tons. A 5-inch (127 mm) piece of 2-inch by 1/4-inch (50-mm by 6-mm) wall, steel-tubing receiving tool is required. The bushings are not cartridge-type bushings and do not have a metal outer sleeve.
6. Support the torque rod end on the receiving tool with the end tube of the torque rod centered on the tool.

⚠ WARNING

Do not use heat or a cutting torch to remove the bushings from the torque rod. The use of heat will weaken the torque rod, which could cause the rod to break. This could result in a loss of vehicle control, personal injury, or property damage.

7. Push directly on the bushing pin until the bushing is pushed out of the torque rod end tube.
8. Clean and inspect the torque rod ends. Remove any nicks with emery cloth.
9. Lubricate the torque rod ends and the new rubber bushings with a vegetable-based oil. Do not use a petroleum-based or soap-based lubricant.
10. Press in the new bushings while supporting the torque rod end on the receiving tool with the end tube of the torque rod centered on the receiving tool. The bushings must be installed with the mounting flats on the bar pin positioned 90 degrees to the shank of the torque rod. See **Fig. 2**.

11. Press directly on the bar pin of the bushings, which must be centered within the torque rod end tubes. When pressing in the new bushings, overshoot the final position by approximately 3/16 inch (5 mm).
12. Press the bushing again from the opposite side to center the bushing within the torque rod end.

Torque Rod Bushing Replacement

13. Position the torque rod into the axle seat and attach it with the washers and locknuts. Handtighten the locknuts.
14. Position the torque rod onto the forward face of the hanger legs. Assemble the bolts, washers and locknuts, and any alignment shims. Tighten locknut 175 lbf·ft (237 N·m). See **Fig. 1**.
15. Tighten locknuts at the axle end of the torque rods 175 lbf·ft (237 N·m).
16. Tighten rebound bolt locknut 60 lbf·ft (81 N·m).

Height Control Valve Removal and Installation

Removal

1. Chock the front tires.
2. Drain the vehicle's air system.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Remove the height control valve vertical rod from the valve lever by removing the nut and lock washer. Push down on the lever of the height control valve to exhaust the air from the rear suspension air bags.
4. Remove the air lines attached to the height control valve. See **Fig. 1**.

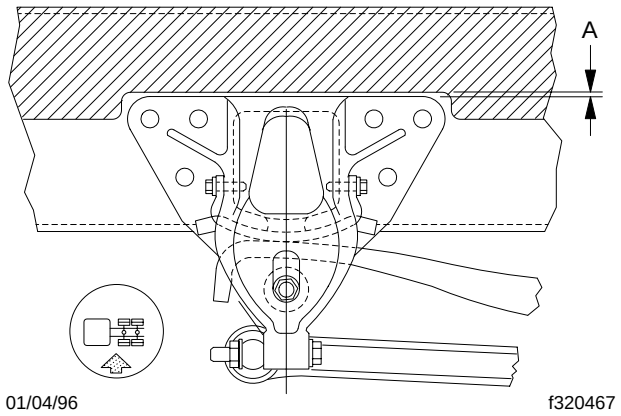
5. Remove the locknuts, washers, and bolts that attach the height control valve to the frame.
6. Remove the brass air fittings from the height control valve.

Installation

1. Install the brass air fittings into the height control valve ports.
2. Install the bolts, washers, and locknuts that attach the valve to the frame rail.
3. Attach the air lines to the height control valve.
4. Attach the height control valve vertical linkage rod to the height control valve lever, and install the lock washer and nut. See **Fig. 1**.
5. Return air to the system.
6. Adjust the height control valve for proper ride height as described in **Subject 180**.

Information

The HAS front hangers must have at least 1/4-inch (6 mm) clearance between the top of the hanger and the bottom of the fifth wheel mounting bracket on the sides of the frame rails. In some cases, the fifth wheel mounting bracket may have to be cut out to provide the correct clearance. See **Fig. 1** for an example of a fifth wheel mounting bracket that has been modified.



A. Clearance: 1/4 inch (6 mm)

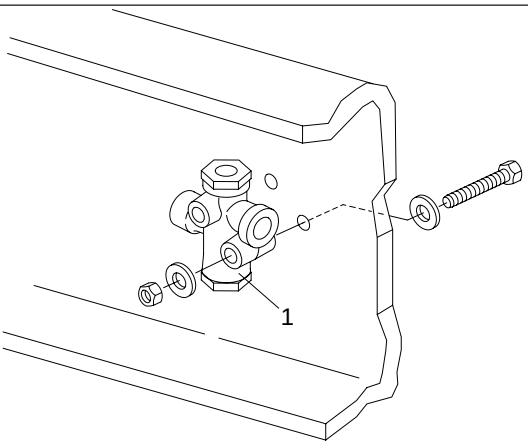
Quick Release Valve Replacement

Replacement (See Fig. 1)

1. Chock the front tires.
2. Drain the vehicle's air system.
3. Disconnect the air lines from the quick release valve. Identify the air line at the top of the valve.
4. Remove the quick release valve from the frame or cross member.
5. Remove the brass air fittings from the valve.
6. Attach the brass air fittings to the replacement quick release valve.
7. Attach the valve to the frame or cross member.



1. Quick Release Valve

8. Connect the air lines to the valve, making sure to attach the identified line to the top of the valve.
9. Build up pressure in the air system.
10. Remove the chocks from the front tires.

Slipper Pad Removal and Installation

Removal

NOTE: Operation of the HAS suspension will result in wear between the main support member and the hanger slipper pad. In normal use, these components will function satisfactorily even though the components indicate some wear.

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage from the lever of the height control valve and lift the lever to raise the rear of the frame about 3 inches (75 mm). See **Fig. 1**.
3. Support the frame with jack stands.
4. Apply an upward force on the cross channel with a jack or, on single axles, by pushing down on the height control lever to lift the cross channel. This will cause the tips of the main support members to drop away from the slipper pad. See **Fig. 2**.

IMPORTANT: Do not nick or gouge the cross channel.

5. Remove the fasteners and the slipper pad. In some instances, the screws may have to be drilled out. See **Fig. 3**.
6. In some instances, remove the rebound roller to gain enough clearance to remove the slipper pad. Loosen the rebound bolt locknut, remove the washer, the bolt, and the rebound roller assembly.
7. For rivets, remove the four 1/4-inch (6-mm) rivets by grinding away the rivet heads. With a drift pin, punch the rivets through the holes and remove the slipper pad.

Installation

1. Position the slipper pad and retainer plate on the frame hanger.
2. Tighten the hexhead self-tapping screws 25 lbf·ft (34 N·m).
3. Or, install the rivets using a rivet gun.
4. Raise the frame off the jack stands by pulling up on the height control valve lever. Remove the jack stands.
5. Push down on the height control valve lever to lower the frame until the upper ball stud on the vertical linkage rod exactly aligns with the hole in the lever when the lever is horizontal.
6. Install the ball stud into the hole in the lever and install the washer and nut. Tighten the nut 10 lbf·ft (14 N·m).
7. Remove the chocks from the tires.

Removal

1. Stop the vehicle on a level surface and shutdown the engine. Chock the front and rear tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.

5. Raise the cross channel by pushing down on the height control lever to compress the air springs just enough to clear the studs on the bottom of the air springs. Remove the cross channel.

Installation

1. Position the cross channel so that the holes in the cross channel are aligned under the studs of the air springs. Install the washers and nuts. Tighten the nuts on the air spring studs 25 lbf·ft (34 N·m).

Cross Channel Removal and Installation

2. Lower the cross channel assembly onto the main support members by pushing down on the height control valve lever.
3. Install the bolts, washers and locknuts that connect the cross channel to the main support member and lower shock absorber mounts. Tighten the locknuts 290 lbf·ft (393 N·m).
4. Raise the frame by lifting the height control valve lever and remove the jack stands.
5. Attach the ball joint stud of the vertical linkage rod to the height control valve link, and tighten the locknut on the ball joint stud 10 lbf·ft (14 N·m).
6. Remove the chocks from the tires.

Checking and Adjustment

Use the following procedure after all repairs to the suspension:

1. Park vehicle on a level surface. Free and center all suspension joints by slowly moving the vehicle back and forth several times without applying the brakes.
2. Chock the front tires and the tires of drive axles.
3. C-clamp a nine-foot (2.74-m) piece of straight bar stock or angle iron across the frame. Select a location as far forward of the forward drive axle as possible where components will not interfere. The lower frame flange may be preferred on some vehicles, otherwise use the upper frame flange.
4. Align the straight bar stock or angle iron on the frame using a carpenter's square.
5. Check the rear drive axle first. See **Fig. 1** . Use a trammel bar or its equivalent to measure from the straight edge to the center line of the rear axle on both sides of the vehicle. If both sides measure within 3/16 inch (5 mm) of being the same, the alignment of the rear drive axle is acceptable. If the sides differ by more than 3/16-inch (5 mm), first loosen the rebound locknut, and then adjust the rear drive axle by loosening up the torque rod bar pin locknuts on the hangers. Add or remove drop-in shims as needed.

NOTE: The torque rod bar pin must be mounted to the forward face of the hanger legs. No more than four shims may be used (for a maximum thickness of 1/4 inch (6 mm).

6. Snug the torque rod bar pin locknuts but do not torque to specification.
7. With the rear drive axle properly aligned, the front drive axle alignment can be checked by measuring forward from the center of the axle shafts on the rear drive axle using a trammel bar. If the forward drive axle spacing measurements differ by more than 1/8 inch (3 mm), add or subtract shims at the forward hangers.
8. Following the adjustment of both axles, move the vehicle back and forth several times prior to removing the straight edge from the frame. Recheck the alignment.

B. Each side must be within 3/16 inch (5 mm) of each other.
C. Distances between axles must be within 1/8 inch (3 mm) of each other.

2. Support the frame with jack stands.
3. Drain the vehicle's air system.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

Air Spring Frame Hanger Removal and Installation

Removal

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.

5. Remove the brass air fittings from the air spring.
6. Remove the locknuts and washers that attach the air springs studs to the upper bracket on the frame rail. See **Fig. 2**.
7. Remove the nuts, washers and bolts that hold the upper air spring bracket to the frame rail. Remove the air spring bracket.

Installation

1. Position the air spring upper bracket on the frame rails. Install the bolts through the frame rail and upper bracket and install the washers, and locknuts. Tighten the locknuts 340 lbf·ft (461 N·m).
2. Attach the air spring to the air spring frame bracket. Tighten the outboard locknut 25 lbf·ft (34 N·m).

5. Build up pressure in the air system and raise the height control lever to lift the frame off the jack stands. Remove the jack stands and lower the vehicle.
6. Align the ball joint stud in the vertical linkage rod with the hole in the height control lever. Install the ball joint stud, the washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
7. Remove the chocks from the tires.

Shock Absorber Bracket Removal and Installation

Removal

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

6. Remove the nuts, washers and bolts that attach the cross channel and lower shock absorber bracket to the rear of the main support member.

7. Remove the lower bracket by sliding the bracket to the rear.

Installation

1. Install the bolts and washers that attach the frame hanger bracket from the inboard side of the frame. Install the brackets, washers and locknuts. Tighten the nuts 340 lbf·ft (461 N·m).

2. Position the lower bracket between the cross channel and the main support member.

Shock Absorber Bracket Removal and Installation

3. Install the bolts and washers from the top of the cross channel, through the shock bracket and main support member. Install the washers and locknuts and tighten the locknuts attaching the cross channel to the main support member 290 lbf·ft (393 N·m).
4. Install the shock absorber. Install the washers at both sides of each shock bushing for a total of four washers per shock absorber.
5. Tighten shock absorber locknuts 60 lbf·ft (81 N·m).
6. Lift the lever of the height control valve to raise the rear of the frame off the jack stands. Remove the jack stands and lower the frame by pushing down on the height control valve lever.
7. Align the ball joint stud in the vertical linkage rod with the hole in the height control valve lever. Install the washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
8. Remove the chocks from the tires.

Transverse Rod Removal and Installation

Removal (See Fig. 1)

NOTE: This procedure is for replacement of a transverse rod with a tapered stud at the axle connection and a straddle mount pin at the frame bracket end. Some installations have straddle mounts at both ends of the transverse rod.

1. Chock the front and rear tires.
2. Remove the nuts and washers from the bolts that fasten the pin in the transverse rod bushing to the frame bracket. Disconnect the transverse rod where it is attached to the frame bracket bracket.
3. Remove the nut from the tapered stud in the tube bracket on the axle housing. Hit the top of the axle bracket tube hard with a large hammer to momentarily distort the tube and loosen the tapered stud. Remove the stud and transverse rod from the bracket on the axle housing.

Installation

1. Clear the tapered hole in the axle bracket of all foreign matter.
2. Insert the tapered stud and torque rod bushing into the bracket.
3. Attach the washer and locknut to the stud. Tighten 200 lbf·ft (271 N·m).
4. After tightening, hit the top of the axle bracket tube with a hammer to seat the tapered stud. Retighten.
5. Position the straddle mount end of the transverse rod at the frame bracket, and tighten 200 lbf·ft (271 N·m).
6. Remove the chocks from the tires.

Replacement

NOTE: Shock absorbers are 1 3/8 inches (35 mm) in diameter with a compressed length of 18 1/3 inches (466 mm) and an extended length of 30 inches (762 mm).

1. Chock the front tires.
2. Remove the nut, washer and bolts that attach the shock absorber to the frame hanger bracket. See **Fig. 1**.

3. Remove the fasteners that attach the shock absorber to the lower bracket.
4. Remove the shock absorber.
5. Install the new shock absorber with the rod and shield tube at the top. Install the bolts, washers and nuts in the lower bracket and the frame hanger bracket. Install washers at both sides of each shock bushing, that is four washers per shock absorber.
6. Tighten the fasteners 60 lbf·ft (81 N·m).

General Information

NOTE: This subject applies only to Hendrickson series HAS 190/210/230/40LH/400/402/460 suspensions.

Adjust the vehicle ride height with the unloaded vehicle on a level surface. The frame slope, driveline angles, and axle mounting alignment should be checked after the ride height has been changed.

⚠ CAUTION

Failure to adjust the vehicle ride height could adversely affect driveline angles. Also, if the air springs are set too high, the driver may have difficulty (or be prevented from) backing the vehicle under a trailer. If the air springs are set too low, rapid wear of driveline parts will result.

Ride Height Adjustment

The vehicle ride height for Hendrickson HAS air suspension systems is changed by adjusting the length of the vertical linkage at the ride height control valve. Use the following procedure to adjust the ride height of the frame rails.

IMPORTANT: Before checking the ride height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty when checking the ride height.

1. Stop the vehicle on a level surface, using a light application of the brakes. Slowly move the vehicle forward and back several times without using the brakes to center the suspension joints. Do not apply the parking brakes.
2. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.

   NOTE: Allow several minutes for the air pressure to equalize in the system before checking the ride height.
3. Mark the location of the front and rear tires on the floor so that the vehicle can be checked in the same location after a test drive. Chock the front tires.

IMPORTANT: Any difference in height between the two sides of the vehicle must be corrected using spacers between the main support arm and the rear axle housing before setting the vehicle ride height. See the appropriate section in Group 32 in the vehicle's service manual for the alignment procedure.

4. Measure the distance from the bottom of the frame rail to the bottom of the main support arm at the rear axle U-bolts. See **Fig. 1**. The correct measurement for Hendrickson HAS suspension systems is 4-1/4±1/8 inches (108±3 mm) for vehicles with a specified ride height of 8-1/2 inches (215 mm) or greater. For vehicles with less than an 8-1/2-inch (215 mm) ride height, the distance between the bottom of the frame rail and the bottom of the main support arm must be 2-3/8 inches (60 mm).

   If the measurement is the same as the specification at each support arm, the ride height is correctly adjusted. If the distance measured is not the same at each rear axle mount on the vehicle, correct this alignment problem before attempting to adjust the ride height.

⚠ WARNING

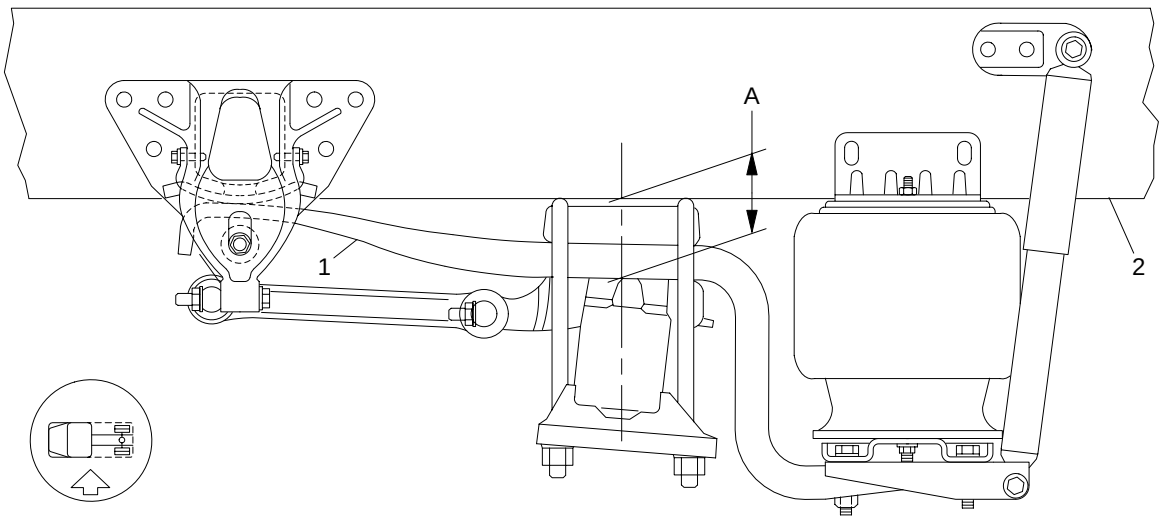
The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

5. Remove the nut and lockwasher from the ball joint stud at the end of the lever on the ride height control valve. See **Fig. 2**. Separate the vertical rod assembly from the lever, being careful to avoid moving the lever while disconnecting the ball joint.
6. Push the lever down to lower the frame by removing the air in the suspension air bags.
7. Slowly pull the lever up to raise the frame until the ride height measurement is exactly correct for the specified ride height.
8. Make sure that the centering hole in the lever near its pivot aligns with the centering hole in the height control valve body. Check the height control valve to make sure that no air flows through

Ride Height Adjustment



A. Measure ride height here.
1. Bottom of Main Support Arm
2. Bottom of Frame Rail

Fig. 1, Measuring the Ride Height

the ride height control valve when the lever is in the centered position.

9. Loosen the jam nuts a few turns at the top and bottom ball joints on the vertical rod that attaches to the height control lever. Note that one of the ball joints and jam nuts has left-hand threads. Hold the top ball joint with your hand and turn the vertical rod with a wrench until the top ball joint stud exactly aligns with the hole in the end of the lever when the lever is centered horizontally on the control valve.
10. Install the ball joint stud in the lever and install the lockwasher and nut on the stud. Tighten the nut on the stud to 125 lbf·inch (11 N·cm).
11. Tighten the jam nut on each ball joint without changing the length of the vertical rod.
12. Apply the parking brakes; then remove the chocks from the tires. Drive the vehicle unloaded for about 1/4 mile (1/2 km); then stop the vehicle in the exact location (as previously marked) of the original measurement.
13. Park the vehicle using only a light brake application. Chock the tires on one axle only and put the transmission in neutral. Do not apply the parking brakes.
14. Check the adjusted distance between the bottom of the frame and the bottom of the main support arm at the U-bolts. See **Fig. 2**.
15. If the distance is still not correct, loosen the ball joint jam nuts on the vertical rod and turn the rod to adjust the ride height. Lengthen the vertical rod to raise the frame or shorten the rod to lower the frame to the correct ride height. Drive the vehicle and again check the ride height.
16. Apply the parking brakes; then remove the chocks from the tires.

Problem—All Air Bags Are Deflated

Problem—All Air Bags Are Deflated	
Possible Cause	**Remedy**
The vehicle air system pressure is too low.	Run the engine until the air gauge indicates 100 psi (690 kPa).
Air is leaking from the vehicle air system.	Listen for air leakage at the air fittings, tanks, and brake componenets. Repair or replace fittings as needed.
The linkage for the height control valve is disconnected or maladjusted.	Connect the linkage and adjust as described in **Subject 180**.
The suspension dump valve is activated.	Toggle the dump control valve to the normal position.
The relay valve is stuck open.	Check and repair the relay valve.
The air bags have a leak.	Listen for leaks at the air bags, tubes, and fittings.
The height control valve is not operating correctly.	Disconnect the linkage and raise and lower the lever to check the operation of the height control valve. Make sure that no air flows through the valve when the lever is in the center position. Replace the valve if it is bad.
There is a obstruction in the lines to the height control valve.	Check the air pressure at the height control valve supply port. Remove any obstruction or restriction to air flow to the valve.
The pressure protection valve is not allowing air to flow to the height control valve.	Check the operation of the pressure protection valve between the secondary air tank and the height control valve. Replace the valve if it is not operating correctly.

Problem—One Side of the Vehicle Is Higher Than the Other

Problem—One Side of the Vehicle Is Higher Than the Other	
Possible Cause	**Remedy**
The axle seat spacer thickness is not the same on each side.	Adjust the spacers so that the frame is level before adjusting the ride height.
The load on the vehicle is not distributed evenly.	Change the position of the load to ensure equal weight on each side.
There is an obstruction to air flow to the air bags on one side of the vehicle.	Disconnect the fittings and test the flow to the air bags on the lower side of the vehicle.
The height control valve or relay valve has an internal restriction.	Check for the same pressure at the ports on each side of the valve. Replace the valve if the pressure is not the same.
The air bags or fittings have a leak.	Listen for leaks at the air bags, tubes, and fittings. Tighten the fittings, if loose, or replace any bad parts.

Problem—The Ride Height Is Not Constant

Problem—The Ride Height Is Not Constant	
Possible Cause	**Remedy**
Air is leaking from the air bags or lines.	Listen or use soap bubbles to find air leaks. Tighten or replace leaking fittings or air bags.
The height control valve is not working correctly.	Make sure that no air is exhausted from the height control valve when the lever is in the horizontal position and that the air bags inflate when the lever is raised. The bags must deflate when the lever is pushed down. There must be a slight delay between the lever movement and the valve operation. Check for fluid leaks from the height control valve. Replace the valve if damaged.

Troubleshooting

Problem—The Ride Height Is Not Constant	
Possible Cause	**Remedy**
There is an obstruction to air flow to the air bags.	Disconnect the fittings and test the flow to the air bags.
The height control valve has a restriction at the exhaust port.	Check for air exhausting from the valve when the height control lever is pushed down.
The height control linkage is loose.	Make sure that all the jam nuts are tight and that the ball sockets are not worn.

Problem—The Ride Height Measurement Is Not Correct

Problem—The Ride Height Measurement Is Not Correct	
Possible Cause	**Remedy**
The vehicle is loaded.	The ride height of a loaded vehicle will be slightly lower than that of an unloaded vehicle. Adjust the ride only when the vehicle is unloaded.
The ride height adjustment is not correct.	Adjust the ride height as described in **Subject 180**.
Air is leaking from the air bags or lines.	Listen or use soap bubbles to find air leaks. Tighten or replace leaking fittings or air bags.

Problem—The Air Springs Have Cuts

Problem—The Air Springs Have Cuts	
Possible Cause	**Remedy**
The ride height is adjusted too high.	Adjust the ride height so that the air bags are not continually overinflated.
The tires are too wide and are rubbing the air bags.	Install the correct tires.
A shock absorber or mount is broken.	Replace any broken components.

Problem—The Vehicle Does Not Track Straight

Problem—The Vehicle Does Not Track Straight	
Possible Cause	**Remedy**
The axle alignment is not correct.	Adjust the alignment with shims at the front of the torque rods.
The bushings in the torque rods are worn.	Replace the worn bushings.

Problem—The Vehicle Does Not Track Straight	
Possible Cause	**Remedy**
The bushings in the transverse rods are worn.	Replace the worn bushings.
A shock absorber or mount is broken.	Replace any broken components.
The U-bolt high nuts are loose.	Periodically tighten the nuts as described in **Specifications 400**.
The suspension fasteners are loose or damaged.	Tighten or replace the fasteners.

Problem—The Vehicle Vibrates When Driven

Problem—The Vehicle Vibrates When Driven	
Possible Cause	**Remedy**
The ride height is not correct.	Adjust the ride height as described in **Subject 180**.
The axle housing rotational alignment is not correct.	Adjust the rotational alignment of the axle housing with wedge-shaped shims at the axle seats. The driveline U-joint angles must be with 1% of each other.
The shock absorbers are worn or disconnected.	Replace the shock absorbers, if worn, or tighten the mounting fasteners.
The bushings in the torque rods are worn.	Replace the worn bushings.
The U-bolt high nuts are loose.	Periodically tighten the nuts as described in **Specifications 400**.
The suspension fasteners are loose or damaged.	Tighten or replace the fasteners.
The frame is not level from front to rear.	Check and adjust the ride height at the front suspension and each rear axle. The frame should not slope more than 1/2 inch (13 mm). Correct the ride height if not at specifications.

General Information

The AirLiner Plus suspension is used on vehicles with pusher or tag axles to improve traction performance.

The system maintains an accurate leveling of frame height through the use of the Rockwell WABCO ECAS (Electronically Controlled Air Suspension) system with sensors and an electronic control unit. A height sensor mounted between the frame and the drive axle housing provides the ECAS control unit with frame height information. Other sensors provide additional information, which the control unit uses to quickly lower or raise the frame height as necessary. The operation occurs while the vehicle is in motion or while parked.

The vehicle must be equipped with a rear axle air suspenion, and requires ABS with Automatic Traction Control to trigger the optional load transfer function automatically.

AirLiner Plus components include:

- A cab-mounted electronic control unit that uses information about the vehicle's rear frame height to adjust the air pressure of the air spring bags;
- A frame rail-mounted solenoid valve that adjusts the air pressure;
- An axle- and frame-mounted height sensor that provides the control unit with frame-height information;
- A brake light switch that informs the control unit when the brakes are applied;
- A dash-mounted warning light that indicates a system fault;
- A load transfer light that displays automatic load transfer status;
- A three-position dash switch that allows automatic load transfer, driver-activated load transfer, or no load transfer.
- An optional hand-held remote control unit that is used to alter the chassis height for loading and unloading.

System Operation

Indicator Lights

ECAS FAIL: Lights for approximately two seconds when the ignition key is turned on, then the light goes out and remains out during vehicle operation. If the ECAS FAIL light does not go out after two seconds, or if it comes on during vehicle operation, there is a failure in the ECAS system.

LOAD X-FER: Lights for approximately two seconds when the igition key is turned on, then the light goes out. Lights whenever there is a manual or an automatic load transfer.

Frame Height Control

ECAS will maintain the vehicle frame to a pre-set height within a 3/16-inch (5 mm) range. The optional remote control unit allows frame height adjustment within operating limits if the vehicle is parked or moving less than 7 mph.

Load Transfer Activation

If the load weight is transferred from the tag axle to the drive axle, it will remain shifted for 20 seconds and is then slowly transferred back to a normal condition. The complete load cycle takes approximately 45 seconds.

Slippage of the driving wheels (usually when starting out on a slick surface) will activate the automatic load transfer. The load transfer will activate after the Automatic Traction Control activates.

Pressing the MOM ON (momentary on) side of the LOAD X-FER dash switch will activate the load transfer system. Manual activation works, however, only at vehicle speeds less than 30 mph.

Load Transfer Termination

The load transfer cycle will immediately terminate if the service brakes are applied when the vehicle speed is more than 30 mph, when the STOP button on the remote control (if equipped) is pressed, or when the vehicle speed exceeds 75 mph.

The STOP button on the remote control will terminate the load transfer at any speed.

ECU Removal and Installation

Removal

1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. Remove the lower cover at the base of the left B-pillar.
4. Disconnect the electrical connections at the base of the B-pillar.
5. Remove the grab handle.
6. Remove the shoulder harness adjustable D-loop mechanism mounted to the B-pillar.
7. Detach the plastic channel that attaches the upholstery to the door frame. This will provide slack in the upholstery to allow access to the ECU mounted inside the B-pillar.
8. Remove the fasteners that attach the B-pillar upholstery to the cab wall.
9. Reach inside the B-pillar and remove the fasteners that attach the ECU.
10. Disconnect the electrical connections on the unit, and remove the ECU from the B-pillar.

Installation

1. Install the ECU inside the B-pillar. Connect the electrical connections.
2. Install the B-pillar upholstery.
3. Attach the plastic channel around the door frame and upholstery.
4. Install the shoulder harness adjustable D-loop mechanism.
5. Install the grab handle.
6. Connect the electrical connections at the base of the B-pillar.
7. Install the lower panel at the base of the B-pillar.
8. Remove the chocks from the tires.

Replacement

1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. Drain air from the suspension system.
4. At the ECAS solenoid valve (see **Fig. 1**), which is mounted to the frame rail, disconnect the electrical connector.

7. Remove the two bolts attaching the solenoid valve to the valve bracket.
8. Remove the valve from the bracket.
9. Attach the new valve to the bracket. Install the bolts.
10. Connect the air lines to the valve as marked earlier.
11. Connect the electrical connector to the valve.
12. Remove chocks from tires.

Replacement

1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. At the ECAS height sensor (see **Fig. 1**), which is mounted between the frame rail and the drive axle housing, disconnect the electrical plug on the back of the sensor.

12. Remove the chocks from the tires.

Troubleshooting Information

1. Indicator Lights:
    - ECAS FAIL lights up if there is a failure in the ECAS system.
    - Load XFER lights up whenever there is a manual or automatic load transfer.
2. Frame Height Control: ECAS will maintain the vehicle frame height to a preset value within 3/16-inch (4.7 mm) by adjusting the pressure in the rear suspension air bags. With the remote-control unit, the operator can adjust the frame height within the operating limits if the vehicle is parked or traveling less than 7 mph (15 km/h).
3. Load Transfer Activation: The weight is transferred from the tag axle to the drive axle by adjusting the pressure in the air bags. The load is shifted for 20 seconds, then is slowly equalized back to the normal condition. The complete load transfer cycle takes approximately 45 seconds. The load transfer occurs under the following conditions.
    - Automatic activation: The drive wheels slipping (usually when staring out on a slick surface) will activate the load transfer. If the vehicle is equipped with Automatic Traction Control, the load transfer will activate just after the ATC.
    - Manual activation: Pressing the MOM ON (Momentary On) side of the ECAS XFER dash switch will activate the load transfer. Manual activation works only at vehicle speeds less than 30 mph (50 km/h).
4. Load Transfer Termination: The load transfer cycle will terminate under the following conditions.
    - Applying the service brakes with a vehicle speed of more than 30 mph (50 km/h).
    - Vehicle speed exceeds 75 mph (120 km/h).
    - Pressing the STOP button on the remote control or disconnecting the remote control. This will terminate the load transfer at any speed.

Troubleshooting Tables

Before performing any diagnostics, make sure there are no ABS faults. Because of the interaction of the ABS and the ECAS systems, a fault in one system may cause a malfunction in the other system.

The following types of failures cause the "ECAS FAIL" indicator light to remain on:

- Grounded "ECAS FAIL" light wire;
- No power at ECAS electronic control unit (ECU) pin 1;
- Electrical fault in ECAS height sensor;
- Electrical fault in ECAS valve;
- Failure of J1587 data bus;
- Internal ECU fault;
- Faulty calibration of ECAS height control;
- Frame height cannot be adjusted within five minutes after ignition or within 30 seconds during normal service.

See **Table 1** for troubleshooting problems when the "ECAS FAIL" light remains on. This would include problems where the wrong action occurs, such as the air bags inflating rather than deflating, or the drive axle air bags deflating rather than the tag axle air bags. The causes may be crossed electrical wiring or air supply plumbing.

See **Table 2** for frame height problems.

See **Table 3** for incorrect ECAS functionality.

See **Table 4** for indicator lamp problems.

See **Table 5** for manual load transfer problems.

NOTE: All lamps are activated by the ECU for approximately two seconds after the ignition is switched on. The ignition must be switched off for at least 6.4 seconds before restarting to determine lamp condition.

General Description

The Neway Air Ride Suspension is a single axle (Model AD-123; see **Fig. 1**) or tandem axle (Model AD-246; see **Fig. 2**) suspension that uses air springs. The top of each air spring is bolted to a frame-rail bracket, and the bottom of each spring is attached to a suspension crossmember. The suspension crossmember is attached to the rear ends of two equalizing beams which carry the axle. The forward ends of the equalizing beams are journaled to brackets bolted on the frame rail.

Both models of the suspension allow for vertical travel. The maximum loading capacity of the single axle model is 22,500 pounds (10 000 kg); and the maximum loading capacity for the tandem axle model is 44,000 pounds (20 000 kg).

The Neway suspension maintains a stable, level ride by adjusting the air spring height according to vehicle load and road conditions. A height control valve mounted inside the frame rail is linked to the suspension crossmembers and monitors ride height in relation to the crossmember. See **Fig. 3**. If the load is riding too high, the suspension crossmember pulls the valve's control lever down, and the valve lowers the load by venting air from the springs. See **Fig. 4**. If the load rides too low, the suspension crossmember pushes the valve's control lever up, and the valve raises the load by delivering air to the springs. The air springs and the shocks mounted between the axle and the frame rails absorb road shock.

The design of the height control valve allows a several second delay between delivering air to and venting air from the air springs. This prevents the valve from reacting to abrupt axle movements caused by the condition of the road surface.

A torque rod (**Fig. 3**) connects each axle housing to a frame crossmember to prevent torque-induced rotation of the axle. A similar control rod (**Fig. 3**) connects each axle housing to a frame rail to prevent the axle from moving laterally.

If the air springs lose pressure, a solid rubber bumper inside the spring will support the vehicle until it can be repaired. Do not drive the vehicle over 30 mph (50 km/h) with the air springs deflated, and drive it only as far as the nearest service facility. To deflate the air springs, disconnect the control lever arm from the linkage rod, and press the valve's control lever down to simulate overinflated air springs. The valve will vent the air from the springs.

Adjustment

1. Park the unloaded or evenly loaded vehicle on a level surface. Run the engine until the air brake system is fully charged. Chock the tires.
2. Remove the bolt that secures the height control valve linkage to the control lever of each valve. **See Fig. 1.** Disconnect the linkages from the control levers.
3. Exhaust all air from the air springs by pushing the control levers down to the vertical position.
4. Connect one of the control levers to its respective linkage, and allow the air spring(s) controlled by the lever to fill until the valve shuts off.
5. Measure the distance from the underside of the frame rail to the centerline of the axle nearest the inflated spring. This dimension should be 10 inches (25 cm). Adjust the height control valve by loosening the adjustment locknut (**see Fig. 1**) and moving the control lever slightly, relative to the nylon block. When the 10-inch (25-cm) height dimension is achieved, retighten the adjustment locknut.

7. Airflow from Air Reservoir

Fig. 1, Height Control Valve

6. Disconnect the control lever from the linkage, and press it down to deflate the air springs about halfway. Reconnect the linkage to inflate the air springs, then check the height dimension. Repeat the step above and this step until the height dimension measures 10 inches (25 cm).
7. When the height control valve is adjusted, disconnect the control lever from the height control valve linkage, and push it down to the vertical position to fully deflate the air spring.
8. Repeat the previous four steps on the other height control valve(s).
9. Connect all linkage assemblies to the control levers. All height dimensions should now be equal. If they aren't, check for loose mounting bolt nuts on the height control valves. Tighten any loose nuts or capscrews. Repeat the adjustment procedures until all height dimensions are 10 inches (25 cm).

Replacement (See Fig. 1)

1. Chock the front tires to prevent vehicle movement. Open the stopcocks on the air tanks to drain the air system.
2. Raise the rear of the vehicle to remove all weight from the rear axles, and place safety stands to secure the vehicle in its raised position. When raised, the height control valves will vent all air from the air springs.
3. Taking care to prevent foreign substances from entering the line or fitting, disconnect the air supply line from the air spring.
4. Remove the locknut (see **Fig. 1**), hexnut, and washers that secure the air spring to the air spring upper mounting plate.
5. Remove the capscrews and lockwashers that connect the air spring to the air spring lower mounting plate on the transverse beam. Remove the air spring.
6. Position the new air spring on the air spring lower mounting plate, then install the capscrews and lockwashers to secure the air spring to the lower mounting plate. Tighten the capscrews to the torque under **Specifications, 400.**
7. Install the locknut, hexnut, and washers previously removed, to connect the air spring to the air spring upper mounting plate. Tighten the nuts to the torque under **Specifications, 400**.
8. Connect the air supply line to the air spring.
9. Remove the safety stands from under the vehicle, then lower the vehicle.
10. There must be 10 inches (25 cm) between the bottom of the frame rail and the centerline of the axle. Adjust the height control valve adjustment; for instructions, refer to **Subject 100**.

Replacement (See Fig. 1)

1. Remove the locknuts from the shock absorber upper and lower mounting brackets.
2. If the shock absorber is fully extended, chock the vehicle wheels and jack up the axle to relieve tension from the shock. Remove the shock absorber. If the inner metal sleeve is rusted to the mounting pin, use a small, sharp chisel to force the sleeve from the pin.
3. Install the new shock absorber on the mounting pins and secure it with the locknuts and washers previously removed. Tighten the locknuts to the torque under **Specifications, 400**.

Equalizing Beam Removal and Installation

Removal (See Fig. 1)

1. Chock the front tires.
2. Raise the rear of the vehicle to remove all weight from the rear suspension, and place safety stands to secure the vehicle in its raised position.
3. Remove the rear wheels and tires for access to the suspension. Block the axle securely to prevent it from dropping away from the vehicle as the equalizing beam is removed.
4. With the weight removed from the suspension, the air springs should be fully deflated. If they aren't, disconnect the height control valve linkage from the height control valve control lever. Push the lever down to the vertical position to deflate the air springs.
5. Remove the capscrews and lockwashers that secure the air springs to the air spring lower mounting plates on both ends of the transverse beam. See **Fig. 1**.
6. Remove the cotter pins, locknuts, flatwashers, and retainer washers from the studs in the ends of the equalizing beams. Tap the transverse beam back from the ends of the equalizing beams.

NOTE: In some cases, the transverse beam bushings will stick, making it difficult to remove the transverse beam from the equalizing beams. Use a Porta-Power, or equivalent tool, between the axle housing and the transverse beam at a point as near to the end of the transverse beam as possible to remove the beam.

7. Remove the locknut and washer from the outboard end of the rod bolt. Support the equalizing beam on a floor jack, then extract the equalizing beam center bushing bolt from the beam hanger bracket.
8. Use a drift to tap the adaptor bushings from the beam hanger bracket. Lower the equalizing beam to the floor.
9. Remove the locknut from the inboard end of the bolt. Note the positions of the spacer washers at either side of the equalizing beam so they can be reassembled in their original positions. Use a drift to drive the rod bolt out of the frame bracket. Remove the equalizing beam from the vehicle.

Installation

1. Make sure the adaptor bushings are installed in the frame bracket.
2. Position the equalizing beam with its front bushing centered in the frame bracket. Push the rod bolt into the frame bracket while inserting the spacer washers into their original positions between the equalizing beam and the frame bracket.

NOTE: Refer to **Subject 190** for placement of the spacer washers if their positions were not recorded during removal of the equalizer beam.

3. Lubricate the threads of the rod bolt with SAE-20 oil, then install the locknut. Tighten the locknut to the torque under **Specifications 400**.
4. Raise the equalizing beam so the center bushing is centered in the beam hanger bracket. Insert the beam hanger adaptor bushings through the beam hanger bracket and into the equalizing beam center bushing.
5. With a flatwasher under the head,insert the rod bolt through the beam hanger adaptor bushings with the threaded end on the outboard side of the suspension.
6. Lubricate the center bushing bolt threads with SAE-20 oil, then install the flatwasher and locknut on the bolt. Tighten the locknut to the torque under **Specifications 400**.
7. Lubricate the transverse beam bushings with rubber lubricant, soap and water solution, or a waterless hand cleaner. Install the inner halves of the bushings with their thicker ends toward the front of the vehicle.
8. Install the transverse beam on the equalizing beams, with the air spring lower mounting plates tilted toward the rear of the vehicle. Install the outer halves of the transverse beam bushings on the equalizer beam journals.
9. Apply SAE-20 oil to the threads on the studs at the rear of the equalizing beams. Install the retainer washers, flatwashers and locknuts on the studs. Tighten the locknuts to the low end of the torque ranges under **Specifications 400**. Install the cotter pins and lock them in place. Tighten the locknuts further if it's necessary in order to install the cotter pins.

Replacement (See Fig. 1)

1. Remove the equalizing beam. Refer to **Subject 130**.

⚠ WARNING

Do not use a torch to cut the bushing sleeve out of the equalizing beam. To do so could weaken the casting, possibly resulting in loss of vehicle control and personal injury.

2. Using a hydraulic press, apply 2000 to 3000 pounds (metric) pressure to remove the equalizing beam front and center bushings. See **Fig. 1**.
3. Using a wire brush and solvent, clean out the equalizing beam bushing receptacles. Inspect the entire beam for cracks or bends. Replace any damaged equalizing beam with a new one.
4. Lubricate the replacement bushings and the bushing receptacles with a non-mineral lubricant. If standard rubber lubricant is not available, use a soap and water solution or a waterless hand cleaner.
5. Press the replacement bushings into the bushing receptacles with a hydraulic press. Press the bushings slightly past center, then turn the equalizing beam over and press the bushings back to a centered position.
6. Install the equalizing beam. Refer to **Subject 130**.

Control Rod Removal, Inspection, and Installation

Removal

1. Apply the parking brakes.
2. Remove the locknuts and flatwashers (**see Fig. 1**) from the bolts that secure the control rod frame bracket to the frame rail. To ease reassembly, note the order of the axle alignment shims between the control rod frame bracket and the backing plate.
3. Remove the control rod frame bracket bolts. Swing the control rod clear, and remove the axle alignment shims and the bracket.
4. Remove the locknut and flatwasher from the ball stud on the inboard end of the control rod. Rap the ball stud eye on the control rod axle bracket with a hammer to loosen the ball stud. If this fails to break it loose, use a tie-rod separator tool to remove the ball stud from the control rod axle bracket. Remove the control rod.
5. Remove the seals from both ends of the control rod. Clean the seals and rod to remove all dirt and grease.

Inspection

Inspect the seals for dryness, cracks, or other signs of deterioration and wear. Replace damaged seals with new ones. Visually inspect the control rod for cracks or bends. Work the ball joint and control rod pin to check for looseness in the bushings. If the control rod is bent, cracked, or otherwise damaged, or if there is any slack in either of the bushings, replace the control rod with a new one.

Installation

1. Lubricate all control rod and fastener threads with SAE-20 oil, and install the seals (**see Fig. 1**) removed from the rod ends.
2. Insert the control rod ball stud through the control rod axle bracket, then install the flatwasher and locknut on the stud. Tighten the locknut to the torque under **Specifications, 400**, then rap the control rod axle mount with a hammer. Tighten the locknut again to the torque under **Specifications, 400**.

3. Position the control rod frame bracket and the axle alignment shims against the backing plate on the inside of the frame rail. Move the control rod into position on the control rod frame bracket.
4. Install flatwashers on the control rod frame bracket bolts, then install the bolts through the frame rail, the shims, the control rod frame bracket, and the control rod. Install the flatwashers and locknuts on the bolts, and tighten the locknuts to the torque under **Specifications, 400**.
5. Check the alignment of the axle. Refer to **Subject 180** for instructions.

Torque Rod Removal, Inspection, and Installation

Removal

1. Apply the parking brakes.

⚠ WARNING

WARNING: When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

2. Remove the locknuts and the flatwashers (**see Fig. 1**) from the bolts that secure the torque rod crossmember bracket to the vehicle frame crossmember. For ease of installation, note the order of the axle plane shims between the torque rod crossmember bracket and the frame crossmember.

3. Remove the torque rod crossmember bracket bolts. Swing the torque rod clear of the torque rod crossmember bracket, and remove the axle plane shims together with the torque rod crossmember bracket.
4. Remove the locknuts and flatwashers from the bolts that secure the torque rod to the torque rod axle bracket . Remove the bolts. Remove the torque rod from the vehicle.

Inspection

Inspect the torque rod for bends or cracks. Work the torque rod pins to check for looseness in the polyurethane bushings. If the torque rod is bent, cracked, or otherwise damaged, replace it with a new one. If either of the polyurethane bushings is loose, replace the bushing with a new one. For instructions, refer to **Subject 170**.

Installation

1. Lubricate all torque rod and fastener threads with SAE-20 oil.
2. Position the torque rod against the torque rod axle bracket (**see Fig. 1**). Slip a flatwasher over each of the two bolts, then insert the bolts through the torque rod axle bracket and the torque rod.
3. Install the flatwashers and locknuts on the torque rod axle bracket bolts. Tighten the locknuts to the torque under **Specifications, 400**.
4. Position the torque rod crossmember bracket and the axle plane shims against the frame crossmember, and move the torque rod into place on the torque rod crossmember bracket.
5. Install flatwashers on the bolts, and install the bolts through the frame crossmember, the shims, the torque rod crossmember bracket, and the torque rod. Install flatwashers and locknuts on the bolts, and tighten the locknuts to the torque under **Specifications, 400**.

Replacement

NOTE: In order to replace the torque rod polyurethane bushings, you need special installation tool kit P-097-009. This tool kit can be purchased from Freightliner, or it can be machined, using the dimensions given in **Specifications, 400.**

1. Remove the snap ring and washer from each side of the bushing to be removed. **See Fig. 1.** Note that the torque rod eye has a smaller shoulder on one side than on the other, and the larger shoulder has a rounded edge around the inside of the eye. The polyurethane bushing must be pressed in and out through the larger side.

2. Using the plunger from the special tool kit on a hydraulic press, press the old bushing out of the torque rod eye. Clean all dirt, grease, or foreign matter from the torque rod.
3. Coat the replacement bushing with a non-mineral lubricant, such as rubber lubricant or waterless hand cleaner. Position the bushing in the larger end of the insertion sleeve from the tool kit, then fit the beveled (smaller) end of the sleeve into the larger side of the torque rod eye.
4. Center the torque rod eye on the tool base, and insert the plunger tool into the polyurethane bushing. **See Fig. 2.** Press the bushing into the torque rod eye.

4. Torque Rod
5. Base

Fig. 2, Torque Rod Bushing Installation

5. Install the snap ring and flatwasher on one end of the torque rod pin, with the sharp edges of the washer and the snap ring facing the outward end of the pin. **See Fig. 1.**
6. Press the torque rod pin into the torque rod bushing from the same side as the bushing was pressed into the torque rod eye. Make sure the snap ring seats. Do not lubricate the torque rod pin.
7. Turn the torque rod over and install a flatwasher, with the sharp edge facing away from the bushing; then install the other snap ring onto the outer shoulder of the pin, with the sharp edge facing outward.

Torque Rod Bushing Replacement

8. Place a pressing sleeve over the end of the torque rod pin, then seat the snap ring. **See Fig. 1.**
9. After assembly, press the torque rod pin slightly to center it in the torque rod eye.

   There should be no slack on either side of the polyurethane bushing, and the bushing should be compressed by about half the thickness of the snap ring. If necessary, install a second washer under one of the snap rings to compress the bushing.

Lateral Alignment (See Fig. 1)

1. Park the vehicle on a level surface; then position the front tires straight ahead and chock them. Release the parking brakes, and place the transmission in neutral.
2. Raise the rear of the vehicle until the tires clear the ground, then place safety stands under the rear of the vehicle to hold it in this position.
3. Check the wheel bearing adjustment. Refer to the rear axle section in this manual for instructions. Adjust or replace the wheel bearings as needed.
4. Measure the lateral runout of the rear wheels. If the runout on any wheel exceeds 0.18 inch (4.6 mm), replace the wheel before proceeding with the axle alignment check.
5. Remove the safety stands and lower the rear of the vehicle. Relieve any internal stresses in the suspension by jacking the axles up and letting them down; or, remove the tire chocks, then move the vehicle back and forth (with the interaxle differential disengaged).
6. On either rear axle, measure the distance between the left frame rail and the nearest point on the inside wheel rim. See **Fig. 2**, Dimension A.
7. On the same axle, measure the distance between the right frame rail and the nearest point on the inside wheel rim (**Fig. 2**, Dimension B).
8. Compare Dimension A with Dimension B. If they're within 1/8 inch (3.25 mm) of being equal, alignment is not necessary. However, if they're different by more than 1/8 inch (3.25 mm), adjust the lateral alignment.

   8.1 Loosen the locknuts on the bolts that secure the lateral rod mount to the frame rail.

   8.2 Add or remove one axle alignment shim for each 1/8 inch (3.25 mm) difference between Dimensions A and B. Adding shims will decrease the measurement on the side of the vehicle to which the lateral rod is attached, and removing shims will increase the measurement.

   8.3 After installing the shims, lubricate the threads on the lateral rod mount bolts with engine oil; tighten the locknuts to the torque under **Specifications 400**.
9. On tandem axle installations, do the previous three steps on the other axle.
10. On suspensions equipped with an axle alignment feature (alignment bushings welded to slotted frame brackets), proceed to **Subject 190**.

    On suspensions not equipped with an axle alignment feature, no further checking is required. Apply the parking brakes; then remove the chocks from the tires.

Parallel Alignment

1. Check and, if needed, adjust the lateral alignment of the rear axle(s) before checking parallel alignment. **Refer to Subject 180** for instructions.
2. Check the axles for parallel alignment. Refer to the rear axle section in this manual for instructions.
3. Adjust the rear axle, if necessary.
   - 3.1 Using jack stands, support the vehicle frame at normal ride height. Disconnect both height control valve linkages from their respective control levers. **See Fig. 1.** Then exhaust all air from all air springs by pushing the valve control levers down.
   - 3.2 Remove the equalizing beam pivot connection locknut and bolt, and both spacer washers. **See Fig. 2.** Lower the equalizing beam from the frame bracket.
   - 3.3 Cut the welds off of the alignment bushings on both sides of the frame bracket. Remove the alignment bushings; then grind any remaining weld material off of the frame bracket and alignment bushings.
   - 3.4 Position the alignment bushings in the frame bracket; then raise the equalizing beam until the front eye is aligned with the frame bracket. Install the spacer washers and pivot connection bolt and locknut. Position the spacer washers. **See Fig. 2**. Suspension installations which have a 1/4-inch (6-mm) frame-rail spacer between the forward frame-rail bracket and the frame rail will require one spacer washer on each side of the equalizing beam. Installations without a frame-rail spacer require two spacer washers on the inboard side of the equalizing beam.
   - 3.5 Move the axle forward or backward by rolling the wheels on that side of the vehicle (only that side), until the correct axle alignment is obtained.
   - 3.6 With the axle aligned and the vehicle frame supported at normal ride height, torque the equalizing beam front bushing locknut to the torque under **Specifications, 400**.
   - 3.7 Weld both of the alignment bushings to the frame bracket, using AWS spec E7018 welding rod or Linde 3/32 FC 72 wire weld, or an equivalent. Weld (1/4-inch fillet) each bushing with three, 3/4-inch (19-mm) long welds. **See Fig. 2.**
4. Connect the linkages to their respective control levers.
5. Apply the parking brakes; then remove the jack stands from the frame and the chocks from the tires.

Troubleshooting

Problem—Air Springs Are Flat

Problem—Air Springs Are Flat	
Possible Cause	**Remedy**
Low air pressure in the vehicle brake system.	Check the air pressure gauge on the instrument panel. If the air pressure is low, run the engine until a minimum pressure of 70 psi (483 kPa) is shown on the gauge.
Air leaking from the suspension air system or the air brake system.	Listen for leakage due to loose fittings or damaged air lines, air springs, brake actuators or control valves. Tighten loose fittings or replace work or damaged air lines with new ones.

Problem—Air Spring(s) Flat on One Side of the Vehicle

Problem—Air Spring(s) Flat on One Side of the Vehicle	
Possible Cause	**Remedy**
Air leakage between the pressure holding valve and the air spring(s).	Listen for leakage due to loose fittings or damaged air lines. Tighten loose fittings or replace damaged lines with new ones.
Air spring leaking.	Inspect the air spring for leaks caused by damage, wear, or deterioration. If any air spring is leaking, install a new one.
Bent, broken, or disconnected height control valve linkage.	Inspect the linkage for damaged or loose parts. Reconnect loose linkage parts or replace damaged parts with new ones.
Height control valve out of adjustment.	Disconnect the height control valve linkage from the height control valve control lever. Move the lever upward. If the air spring then inflates, adjust the height control valve.
Inoperative height control valve.	If movement of the control lever in the previous step fails to inflate the air spring, the height control valve is damaged. Replace the valve.

Problem—Tractor Leans Due to Unequal Inflation of the Air Springs

Problem—Tractor Leans Due to Unequal Inflation of the Air Springs	
Possible Cause	**Remedy**
Damaged height control valve linkage.	Inspect the height control valves and linkages for damage. Repair or replace damaged parts.
Loose or missing height control valve bolts or adjustment locknut.	Inspect for damage to the height control valve mounting bolts or adjustment locknut. Replace any missing bolts or nuts, then adjust the height control valve.
Height control valve out of adjustment.	Adjust the height control valve.

Problem—Air Springs Deflate Rapidly When the Vehicle Is Parked

Problem—Air Springs Deflate Rapidly When the Vehicle Is Parked	
Possible Cause	**Remedy**
Air leakage from the suspension air system.	Listen for leakage due to loose fittings or damaged air lines, air springs, or height control valves. Tighten loose fittings and replace worn or damaged parts with new ones.

Troubleshooting

Problem—Tractor Rides Too High or Too Low

Problem—Tractor Rides Too High or Too Low	
Possible Cause	**Remedy**
Height control valve out of adjustment.	Disconnect the height control valve linkage from the height control valve control lever. Move the lever upward. If the air spring then inflates, adjust the height control valve.

Problem—Air Spring Blown Out

Problem—Air Spring Blown Out	
Possible Cause	**Remedy**
Air spring cut or punctured.	Locate large leaks by listening for escaping air, and locate small leaks by applying a soap and water solution to the suspected air spring and watching for bubbles. Temporarily repair punctures or cuts less than 1/8-inch (3-mm) long by applying hot patches on both sides of the hole. If the cut is more than 1/8-inch (3-mm) long, install a new air spring.
Tires, rims, or chains rubbing the air spring.	Check the clearance between the air spring and the tire. If the tire, rim, or chains contact the inflated air spring, change to narrower tires and rims to provide clearance for tires with chains.
Air brake actuator rubbing against the air spring.	Relocate the brake actuator with factory approved parts to provide adequate clearance.

Problem—Air Spring Deflated Due to Fatigue

Problem—Air Spring Deflated Due to Fatigue	
Possible Cause	**Remedy**
Driving the vehicle too long or too fast with the air springs deflated.	If the vehicle must be driven with the air springs deflated, maintain a speed of less than 30 mph (48 km/h), and drive only as far as the nearest repair facility.
Continual or repeated overextension of the air springs.	Inspect for broken or loose shock absorbers or shock absorber mounting brackets. Reconnect loose parts and replace any damaged parts. Check the adjustment on the height control valve.

Problem—Air Spring Doesn't Fully Deflate When All Weight Is Removed from the Suspension

Problem—Air Spring Doesn't Fully Deflate When All Weight Is Removed from the Suspension	
Possible Cause	**Remedy**
Restricted air line between the height control valve and the air spring.	Disconnect the height control valve linkage, and push the control lever down. If the air spring remains inflated, check for a pinched or blocked line. Clean out any plugged line and replace any damaged line.

General Description

The Chalmers 800 Series Rear Suspension is a walking beam-type tandem axle suspension that uses hollow rubber springs instead of leaf springs or air bags. Each hollow rubber spring is mounted between a frame-rail plate and the center (front-to-rear) of the steel walking beam. A sawhorse bracket assembly is attached to the frame and provides mounting points for the lower torque rods that tie the axles to the frame. The upper torque rods are fastened to brackets that bolt to the frame side rails and to tower assemblies that are welded to the top of the differential housings. **See Fig. 1.**

The 800 Series Rear Suspension allows a high degree of both parallel and diagonal articulation, while maintaining wheel load equalization to within 3 percent.

The Chalmers suspension design separates the rear suspension's responsibility for supporting/cushioning the load from that of locating/guiding the axles. The suspension is very light, relative to its load carrying capacity, but requires very little maintenance. In fact, there are no lubrication fittings since grease and oil are never needed.

The 800 Series Rear Suspension is available in three different maximum load capacities: 40,000 lb. (18 000 kg), 46,000 lb. (21 000 kg), and 50,000 lb. (23 000 kg). The 40,000 lb. version is easily distinguished from the other two versions since the upper torque rods do not cross over one another on the 40,000 lb. version.

The 800 Series is also available in three different axle spacings: 54-inch, 60-inch, and 72-inch axle-to-axle. The axle-to-axle spacing dimension is often included as part of the suspension name, e.g. "Chalmers 854 Rear Suspension" or "Chalmers 860 Suspension."

Shock absorbers are optional on all versions of the suspension, and available in two styles: beam-mounted and axle housing-mounted.

Other variations depend on whether the suspension is installed on a truck (high-mount) or a tractor (low-mount) and whether high center-of-gravity or low center-of-gravity is desired.

The rear suspension may be precision-aligned by adjusting the length of the lower torque rods. These rods have both left- and right-hand threads cut on the same tube so rotating the tube changes the effective length of the tube.

Restrictor Can Removal, Inspection, and Installation

1. If necessary, power wash the spring restrictor can area to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Raise the rear of the vehicle just enough to remove all weight from the rear axles, and place safety stands under the frame to support the vehicle in its raised position.
4. Remove the two bolts and nuts that secure the walking beam spring plate (**see Fig. 1**, Ref. 17) to the walking beam assembly. Discard the fasteners.

NOTE: On 54-inch spread suspensions, it may be necessary to remove either the front or rear tires to allow spring assembly removal.

5. Pull the lower spring plate, rubber spring, and restrictor can as one assembly outward, off the beam assembly. **See Fig. 1**, Refs. 1, 17, 18.
6. Separate the restrictor can, spring, and spring plate.

Inspection

1. Carefully inspect the restrictor can for cracks or severe corrosion. Pay special attention to the top surface of the can and the can rim. **See Fig. 2 .**

NOTE: It is recommended that both restrictor cans be replaced at the same time to ensure evenness of ride and handling characteristics.

2. Replace a cracked or severely corroded restrictor can.

Installation

1. Using a stiff wire brush or gasket scraper, clean rust and road dirt from the spring plate. Also, make sure that the center vent holes in the plate and in the walking beam are free of rust and debris. **See Fig. 3.**

IMPORTANT: Never use any mineral based oils, greases, jellies, or solvent soaps to aid in the assembly of rubber suspension parts. Use only lubricants specifically designed for use with rubber compounds.

3. Position the rubber spring on the spring plate so it is upside down, relative to its original orientation. Make sure that the spring vent hole is centered on the spring plate tube. Place the new restrictor can over the spring; make sure the can is centered on the spring.
4. Slide, as one assembly, the spring plate, spring, and restrictor cap, into position on the walking beam.
5. Install and tighten the spring plate fasteners 35 lbf·ft (47 N·m).
6. Check the gap between the spring and the restrictor can to make sure it is even, all the way around the can. Rotate the spring and/or can as necessary to make the gap even.
7. Remove the safety stands from under the vehicle, then lower the vehicle.
8. Remove the chocks from the tires.

   - 3.2 On axle-mounted shocks, remove the upper and lower locknuts and hardened washers. **See Fig. 2**, Refs. 4 and 5. Discard the fasteners.
4. Remove and discard the shock absorber.
5. On axle-mounted shock absorber installations, the compression sleeve (**see Fig. 2**, Ref. 3) may be rusted to the shock mounting pin and remain on the pin when the shock is removed. If this occurs, drive the sleeve off of the pin using a small, sharp chisel.
6. On axle-mounted shock absorber installations, clean the shock mounting pin threads using a stiff wire brush or, if necessary, a thread-chaser die.

   Lubricate the threads with a small amount of engine oil.

Walking Beam Removal, Inspection, and Installation

1. If necessary, power wash the walking beams and axle housing ends to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Relieve all drive axle brake or wind-up loads by placing the transmission in neutral and releasing the spring or driveline brakes.
4. Raise the rear of the vehicle to remove all weight from the rear axles, and place safety stands under the frame to secure the vehicle in its raised position.
5. If equipped, disconnect beam-mounted shock absorbers from the walking beam being replaced. Refer to **Subject 120**, if necessary.
6. Remove the two bolts and nuts that secure the walking beam spring plate (**see Fig. 1**, Ref. 17) to the walking beam assembly. Discard the fasteners.

NOTE: On 54-inch spread suspensions, it may be necessary to remove the front or rear tires to allow spring assembly removal.

7. Pull the lower spring plate, rubber spring, and restrictor can as one assembly outward, off the beam assembly. **See Fig. 1**, Refs. 1, 17, 18.

NOTE: Tag or otherwise mark each torque rod to ensure that it can be re-installed in the same position and orientation.

8. Disconnect the rearmost axle's upper torque rods from the rear axle tower and the lower torque rods from the rear axle housing brackets. **See Fig. 1**, Refs. 4, 8, 11, 13.
9. Roll the rear axle rearward just enough to disengage the axle saddles (Ref. 16) from the walking beam ends.
10. Lift up the free end of the walking beam and slide the beam rearward to disengage it from the front axle saddle; remove the walking beam.

Inspection

1. Inspect the beam ends carefully, looking for cracks. Cracks along weld lines may be repairable, while cracks in or across the beam flanges require walking beam replacement. **See Fig. 2.**

NOTE: Take flange thickness measurements at least 1/2" (12 mm) from the flange edges. Measurements taken at the flange edges are not an accurate indication of beam wear and may lead to unnecessary beam repair/replacement.

2. Check for excessive wear on the beam flanges, where they contact the axle housing saddle brackets.

   If flange wear is significant, use a micrometer or vernier calipers to take measurements at both

Installation

1. Position the new or repaired walking beam over the rearmost rear axle, with the front end of the beam tilted downward.
2. Slide the beam forward and downward so the front end of the beam enters the axle housing saddle bracket. **See Fig. 4.** Let the middle of the beam rest on the sawhorse bracket beam stop.

NOTE: On 54-inch spread suspensions, it may be necessary to install the spring assembly before the rearmost axle is rolled into place.

4. Connect the rearmost axle's upper and lower torque rods to the axle housing brackets. Install and tighten the torque rod bushing through-bolts 135 lbf·ft (183 N·m).
5. Slide, as one assembly, the spring plate, rubber spring, and restrictor cap, into position on the walking beam.
6. Install and tighten the spring plate fasteners 35 lbf·ft (47 N·m).
7. If so equipped, connect the beam-mounted shock absorbers to the beam brackets and tighten the fasteners 170 lbf·ft (230 N·m).
8. Remove the safety stands from under the vehicle, then lower the vehicle.
9. Remove the chocks from the tires.

Repair

NOTE: This subject addresses only instances where excessive beam flange wear occurs, but cracks in the web or flange are not present.

Cracked webs and/or flanges require walking beam replacement.

Walking beams with excessive flange wear, however, can be repaired by welding a Chalmers Wear Plate over the worn areas as described below.

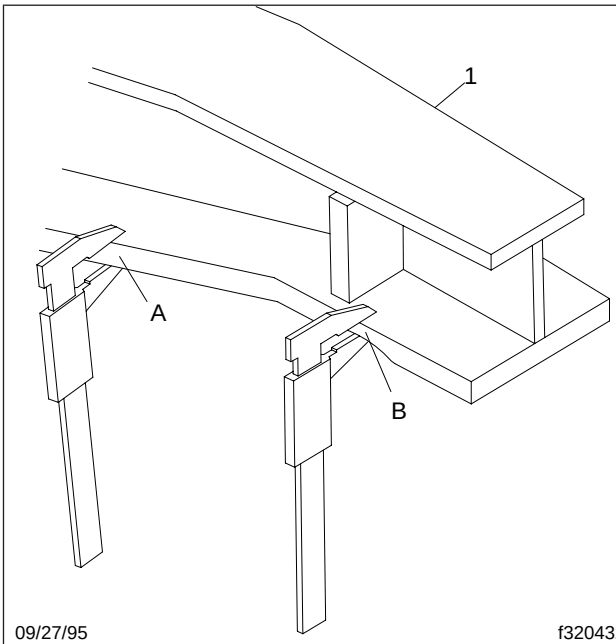
1. Remove the walking beam assembly. Refer to **Subject 130** for information.

NOTE: Take flange thickness measurements at least 1/2" (12 mm) from the flange edges. Measurements taken at the flange edges are not an accurate indication of beam wear and may lead to unnecessary beam repair/replacement.

2. Confirm that flange wear is severe enough to warrant repairs. Use a micrometer or vernier calipers to take flange thickness measurements at both unworn and worn areas. The maximum allowable difference between unworn and worn areas is 0.062" (1.5 mm). **See Fig. 1.**
3. If repair is required, clean the worn area of the beam thoroughly. Make sure that any oil or grease is removed, as well as rust or road dirt accumulation. If necessary, slight grinding of the beam is allowed to smooth raised areas.
4. Clamp Chalmers Wear Plate #700313 to the bottom flange of the beam. Make sure the plate is centered and has good surface-to-surface contact with the beam. Slight grinding is allowable to obtain good plate-to-beam contact.
5. Tack weld the plate to the beam, welding on the sides of the plate only.

⚠ CAUTION

CAUTION: Weld at the sides of the wear plate and beam only. Never weld at the ends of the wear plate. Welding the ends of the wear plate does not allow the wear plate to properly slightly expand nor contract, an action which, if the ends are welded, can cause cracks in the welds.



A. Flange thickness measurement taken at unworn area for reference.
B. Flange thickness measurement taken at wear area to assess beam condition.

6. Remove the clamps and weld the plate to the beam, again, welding on the sides of the plate only. **See Fig. 2.**
7. Prime and paint the repaired area.
8. Install the repaired walking beam assembly. Refer to **Subject 130** for information.

Torque Rod Removal and Installation

The torque rods hold the rear axles in place, maintaining both axle alignment and pinion nose angle. When servicing the torque rods, it is good practice to remove and install them one at a time to avoid the possibility of mixing them up and affecting the alignment or pinion nose angle.

Several different styles of torque rods and bushing spigots exist. On the 40,000-pound version of the 800 Series suspension, the torque rods have tubular steel bodies and the upper rods do not cross over one another. On the 46,000- and 50,000-pound versions, the lower torque rods have tubular steel bodies, but the upper torque rods are made of "I-beam" shaped ductile iron. These upper torque rods do cross over one another. See **Fig. 1** and **Fig. 2**.

1. If necessary, power wash the rear suspension to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Relieve all drive axle brake or wind-up loads by placing the transmission in neutral and releasing the spring or driveline brakes.
4. Raise the rear of the vehicle to remove all weight from the rear axles, and place safety stands under the frame to secure the vehicle in its raised position.
5. Working on one torque rod at a time, remove the torque rod bolts and spigot caps. Discard th

bolts. Set the spigot caps aside for cleaning and inspection.

Remove the torque rods by prying between the torque rod eye and the spigot base or frame bracket.

NOTE: At the axle housing towers, pry off the tower cap to access the torque rod fasteners.

Torque Rod Removal and Installation

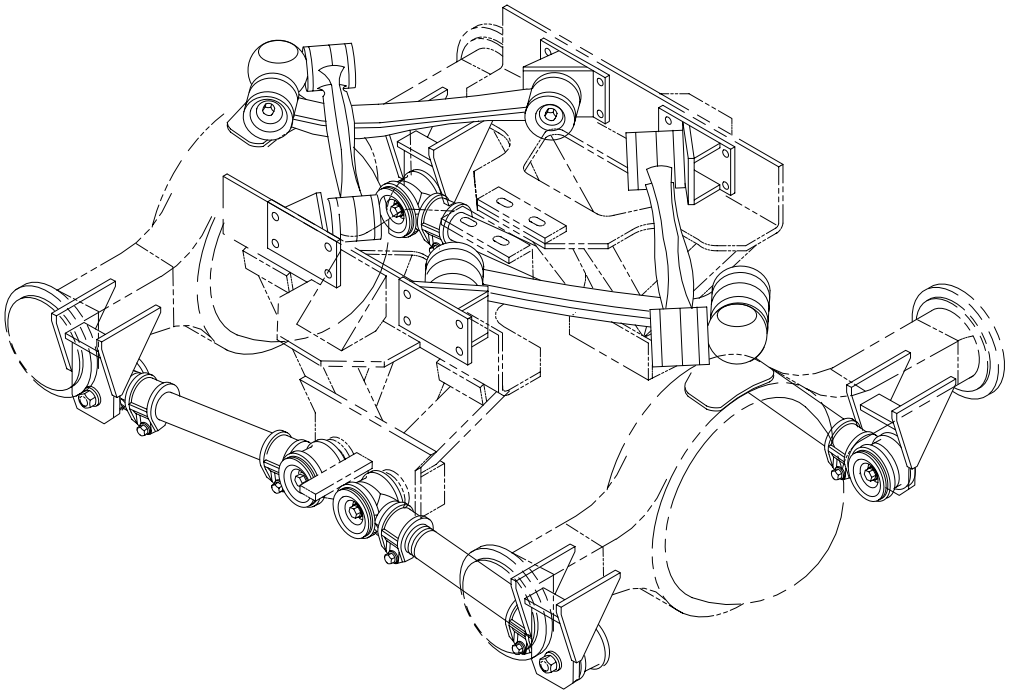

Fig. 2, Torque Rod Arrangement, 46,000- and 50,000-Pound Capacity Suspensions

6. Replace worn or damaged bushings following the instructions in **Subject 160**.
7. Inspect the spigots for damage, severe corrosion, or extensive wear. Replace damaged or severely corroded spigots. To determine whether or not a spigot is worn enough to warrant replacement, see **Fig. 3** and **Table 1**.

   The smaller of the two measurements should be used as the spigot diameter.

Installation

1. Check the torque rod bushings to make sure they are properly installed. They must be centered within the torque rod eye. **See Fig. 4.**

IMPORTANT: Never use any mineral-based oils, greases, jellies, or solvent soaps to aid in the assembly of rubber suspension parts. Use only lubricants specifically designed for use with rubber compounds.

2. Lubricate the outside of the spigots and the inside of the rubber bushings with a generous

amount of rubber lubricant such as Rimslip® or equivalent.

3. Push the torque rod into position on its spigots. After the torque rod is partially installed, use a heavy soft-faced mallet to drive the torque rod into position until the bushing contacts the spigot bottom face.

NOTE: For easier installation, alternate mallet blows between ends of the torque rod to drive it onto the spigots evenly.

4. Install the spigot caps.
5. Install and tighten the torque rod bushing through-bolts 135 lbf·ft (183 N·m).
6. Remove the safety stands from under the vehicle, then lower the vehicle. Remove the chocks.

Torque Rod Bushing Inspection and Replacement

Inspection

1. If necessary, power wash the upper and lower torque rods to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Relieve all drive axle brake or wind-up loads by placing the transmission in neutral and releasing the spring or driveline brakes.
4. Using your hands only, attempt to move the torque rod ends, checking for free play. Some movement as the bushings "give" is normal, but only free play is cause for bushing replacement.

NOTE: Never use a lever or pry bar to check for torque rod bushing free play. To do so may result in unnecessary bushing replacement.

5. If free play is detected, replace the bushing as described below.

Replacement

1. Remove the torque rod containing the worn out bushing. Refer to **Subject 150**, if necessary.

NOTE: Remove only one torque rod at a time to avoid mixing-up torque rod positions.

2. Place the torque rod on the floor or a workbench with a bushing open end facing upward. Push the tip of a large screwdriver down between the torque rod eye and the bushing and pry out the bushing. Discard removed bushings.
3. Use a wire brush and/or scraper to clean the torque rod eyes, removing all rust, scale, and rubber accumulations.
4. Inspect the torque rod eyes looking for cracks, distortion, or severe corrosion. Replace torque rods with damaged bushing eyes.

IMPORTANT: Never use any mineral based oils, greases, jellies, or solvent soaps to aid in the assembly of rubber suspension parts. Use only lubricants specifically designed for use with rubber compounds.

5. Lubricate both the inside of the torque rod eye and the outside of the new bushing with a generous amount of rubber lubricant, such as Rimslip® or equivalent.
6. Place the torque rod on a solid level floor with an open end of the eye facing upward. Position a lubricated bushing on the eye, making sure that the tapered shoulder of the bushing is centered on the eye. **See Fig. 1.**

7. Using a heavy, soft-faced mallet, strike the bushing squarely to drive it into the torque rod eye. Then, flip the torque rod over 180 degrees and tap on the torque rod shaft with the mallet while the bushing rests on the floor.

NOTE: If available, a small press may be used instead of a mallet for bushing installation.

8. The bushing is completely installed when it is centered within the torque rod eye. **See Fig. 2.**
9. Install the re-bushed torque rod. Refer to **Subject 150**, if necessary.

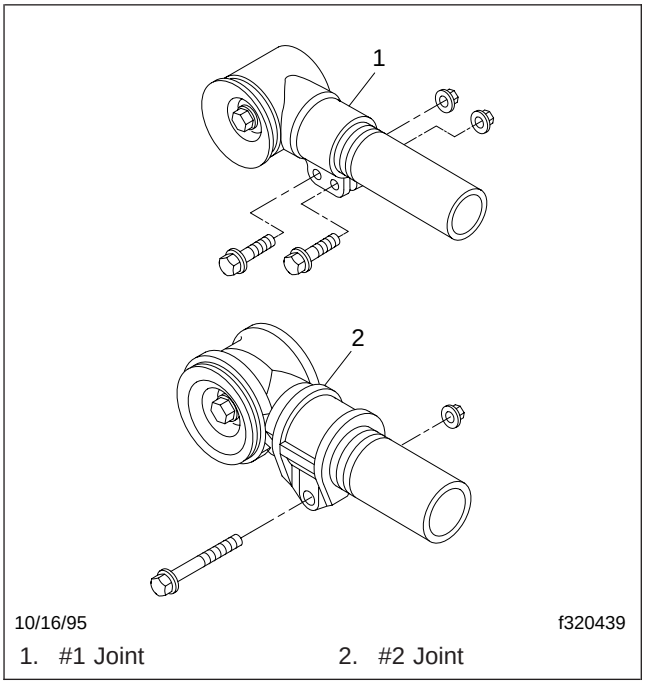
On the Chalmers 800 Series Rear Suspension, the lower torque rods provide the only means for adjusting rear axle alignment. The upper torque rods play no part in the axle alignment process.

The lower torque rod bodies consist of steel tubes, with fine threads cut into the ends of the tube. Left-hand threads are cut into one end of the tube, right-hand threads into the other end. Therefore, by simply twisting the tube body while restraining the ends, the effective length of the tube is changed.

One type of torque rod end is used. A #1 size, two 1/2-inch clamp bolt secured the rod end to the tube. On the #2 size, a single 5/8-inch bolt is used. See **Fig. 1.**



1. #1 Joint
2. #2 Joint

Fig. 1, Adjustable Torque Rod Ends

Adjustment

1. Ensure that the torque rod bushings are in a fully relaxed, neutral state by slowly moving the vehicle back and forth a few times. Apply the service brakes, *not the parking brakes*.
2. Chock the front tires to prevent vehicle movement.
3. Relieve drive axle brake or wind-up loads by placing the transmission in neutral and releasing the brakes.
4. Using a straightedge and a tape measure, determine the amount of adjustment needed to align the forward-rear axle at right angles to the frame. For instructions, see **Group 35**. The difference in measurements between the sides of the vehicle is the approximate amount that the trailing end of the forward-rear axle will have to be brought forward, or the leading end will have to be moved back to align it at a right angle to the frame. See **Fig. 2.**

   If the forward-rear axle alignment is within specifications, go to the step that begins "Using a center-point bar, determine...".

5. On the side of the vehicle that is to be adjusted forward or rearward, loosen the torque rod end pinch bolts at both ends of the torque rod.

NOTE: If the pinch bolts are badly corroded or otherwise damaged, remove and discard them. Install new Chalmers fasteners.

6. Attach a pipe wrench to the tube body (chain type preferred) and rotate the tube to shorten or

Rear Axle Alignment Adjustment

lengthen the torque rod. Continue to rotate the tube until the forward-rear axle is square to the frame.

NOTE: If the torque rod tube is difficult to rotate, apply penetrating oil to the tube threads. If this does not help, remove the pinch bolts and drive wedges between the eye lugs to relieve the clamping effect.

7. When the forward-rear axle is square with the frame, tighten the pinch bolts.
   - 7.1 Tighten 1/2-inch UNC bolts on #1 joints 65 lbf·ft (88 N·m).
   - 7.2 Tighten 5/8-inch UNC bolts on #2 joints 135 lbf·ft (183 N·m).
8. Using a center-point bar, determine the difference between the forward-rear and the rearmost axles' center-to-center measurements on each side of the vehicle. For instructions, see **Group 35**. This difference is the approximate distance that the leading end of the rearmost axle will have to be adjusted rearward, or that the trailing end will have to be adjusted forward, to align it at a right angle to the frame, and to align it parallel to the forward-rear axle. See **Fig. 2**.
9. On the side of the vehicle that is to be adjusted forward or rearward, loosen the torque rod end pinch bolts at both ends of the torque rod.

NOTE: If the pinch bolts are badly corroded or otherwise damaged, remove and discard them. Install new Chalmers fasteners.

10. Attach a pipe wrench to the tube body (chain type preferred) and rotate the tube to shorten or lengthen the torque rod. Continue to rotate the tube until the rearmost axle is square to the frame.

NOTE: If the torque rod tube is difficult to rotate, apply penetrating oil to the tube threads. If this does not help, remove the pinch bolts and drive wedges between the eye lugs to relieve the clamping effect.

11. When the rearmost axle is square with the frame, tighten the pinch bolts.
    - 11.1 Tighten 1/2-inch UNC bolts on #1 joints 65 lbf·ft (88 N·m).
    - 11.2 Tighten 5/8-inch UNC bolts on #2 joints 135 lbf·ft (183 N·m).
12. Remove the safety stands, and lower the vehicle. Remove the chocks from the front tires.
13. Using the center-point bar, check the rearmost axle alignment. If alignment is not within specifications, repeat the applicable steps above.

⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the suspension.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Century Class Trucks Maintenance Manual*.

General Description

The TufTrac Suspension (**Fig. 1**) is heavy-duty "six rod" tandem-axle suspension option for trucks built for severe on/off highway work. The TufTrac design allows a truck to maneuver over bumps, ridges and washboard roads that typically generate high rates of axle articulation, without bottoming out the suspension or losing traction.

The TufTrac suspension is available in three weight ratings – 40,000-, 46,000- and 52,000-pound (18 144-, 20 865-, 23 586-kilogram) capacities. The 40,000-pound (18 144-kilogram) capacity suspension uses two taper leaf springs and has an axle spacing of 54 inches. The 46,000-pound (20 865-kilogram) capacity suspension has three leaf springs (shown in this section), while the 52,000-pound (23 586-kilogram) suspension features four leaf springs. Both the 46,000-pound (20 865-kilogram) and the 52,000-pound (23 586-kilogram) suspensions have a standard axle spacing of 56 inches.

Principles of Operation

Six functional links in the TufTrac suspension maintain the positions of the axles. Side-to-side axle movement is controlled by two v-rods from the frame to the axles at the top of the suspension. Four bar links from the frame to the axles at the bottom control the forces of driving and braking as well as fore-and-aft road shocks. Vertical loads are carried by the rubber-isolated parabolic taper leaf spring packs.

Replacement

1. Park the vehicle on a level surface, shut down the engine and apply the parking brakes. Chock the tires.
2. Remove the lower shock mounting nut and washer. See **Fig. 1**.
3. Remove the upper shock mounting nut and washer.
4. Remove the upper and lower mounting bolts and remove the shock absorber.
5. Position the new shock absorber in place and install the mounting bolts.
6. Loosely fasten the bolts with the nuts and washers removed from the old shock absorber.
7. Torque each mounting nut 241 lbf·ft (327 N·m).
8. Remove the chocks from the tires.

   2.1 Remove the nut and bolt securing the rebound stop to the mounting bracket.

   2.2 Slide the rebound stop from the mounting bracket.

3. Remove the upper two fasteners on the center bearing.
4. Jack up the vehicle under the rear axle.
5. Support the rear frame rails with jack stands, then lower the jack. This will clear the center bearing from the top of the mounting bracket. See **Fig. 2**.
6. Remove the lower center bearing bolts attached to the spring assembly casting. Discard the bolts.
7. Remove the center bearing. See **Fig. 3**.
8. Position the new center bearing in the mounting bracket.
9. Install the upper mounting bolts and tighten 68 lbf·ft (92 N·m).
10. With the jack, raise the rear axle until bottom of the center bearing meets the mounting bracket on the leaf springs.

IMPORTANT: Be sure to use new bolts with loctite (p/n 23–12576–125) when attaching the center bearing to the leaf spring casting.

11. Install new lower mounting bracket bolts (p/n 23–12576–125). Tighten the bolts 155 lbf·ft (210 N·m).

Spring Assembly Removal, Assembly and Installation

IMPORTANT: The spring pack assembly is not available as an assembled unit in the aftermarket. If the spring pack assembly is to be replaced with a new assembly, the springs, center bearing seat and retainer bracket must be assembled before installation on the vehicle.

Removal

1. Park the vehicle on a level surface. Shut down the engine and apply the parking brakes. Chock the tires.
2. Remove the tip pad bolts above each axle on the axle clamp. There are four bolts on each pad. See **Fig. 1**.

3. Remove the center bearing. See **Subject 110**.
4. With the vehicle still raised, remove the wheels on both rear axles on the side the spring assembly will be replaced. For instructions, see **Group 40**.

⚠ WARNING

Do not attempt to remove the spring assembly by hand. The assembly is very heavy and attempting to lift it could result in bodily injury.

5. Using a lift (i.e. engine hoist), remove the leaf spring assembly from the vehicle. See **Fig. 2**.

Assembly

IMPORTANT: Leaf springs in a spring pack assembly cannot be replaced individually. The entire spring pack assembly must be replaced.

1. Support both sides of the new spring pack assembly on jack stands. Make sure all the leaf springs are interlocking with the studs and dimples at the centers of the leaf springs.
2. If the assembly contains a spacer, place it on the center of the top leaf spring. Make sure the dimple in the spacer is aligned with the stud in the center of the top leaf spring.
3. Place the center bearing seat on the top of the spacer or leaf spring, as applicable. Make sure the dimple in the middle of the center bearing seat aligns with the stud in the middle of the leaf spring or the spacer.
4. Install the two 3/4-inch U-bolts over the center bearing seat. Make sure the U-bolts rest in the grooves of the center bearing seat.
5. At the bottom of the spring pack, install the U-bolt retainer bracket over the threaded ends of the U-bolts.
6. Holding the retainer bracket in place, install a hardened washer and hexnut over the threaded end of each U-bolt.
7. Tighten the U-bolts in a diagonal sequence as follows:
   - Stage 1: 60 lbf·ft (81 N·m)
   - Stage 2: 200 lbf·ft (271 N·m)
   - Stage 3: 300 lbf·ft (407 N·m)

Installation

⚠ WARNING

Do not attempt to install the spring assembly by hand. The assembly is very heavy and attempting to lift it could result in bodily injury.

1. Place the new spring assembly on the vehicle.
   - 1.1 Attach the new assembly to the lift.
   - 1.2 Using the lift (hoist), lift the assembly into place on the axle clamps.
2. Install the center bearing. For instructions, see **Subject 110**.
3. Install the tip pad and bolts on each axle clamp. Tighten the bolts 37 lbf·ft (50 N·m). See **Fig. 1**.
4. If not already installed, install the rebound stop and mounting bolt. Tighten the nut 68 lbf·ft (92 N·m).
5. Install the wheels. For instructions, see **Group 40**.
6. Return the vehicle to its normal operating position.
7. Remove the chocks from the tires.

2. Raise the rear axle and support the frame rails with jack stands.
3. Lower the jack under the axle. See **Fig. 2**.
4. Remove the bolts holding both rods between the rear axles, below the rebound stop. See **Fig. 3**.
5. Remove the nut and bolt from the axle clamp.
6. Remove the control rod from the vehicle.

IMPORTANT: When installing the rods make sure the labels on the rods are facing upward. Forward axle rods are marked "FDA" and rear axle rods "RDA."

7. Fasten the new control rod to the axle clamp. Tighten the nut 136 lbf·ft (184 N·m).
8. Fasten the other end of the rod to the bracket below the rebound stop. Tighten the nut 136 lbf·ft (184 N·m).
9. Return the vehicle to the normal operating position.

V-Rod Replacement

1. Park the vehicle on a level surface, shut down the engine, and apply the parking brakes. Chock the tires.
2. Raise the rear axle and support the frame rails with jack stands.
3. Lower the jack under the axle. See **Fig. 2**.

6.2 Install the bolts and spacers and loosely tighten all connections.

6.3 After all fasteners and spacers are installed, torque as follows:

- Tighten the bolts at the frame bracket 136 lbf·ft (184 N·m).
- Tighten the bolts at the axle bracket 427 lbf·ft (579 N·m).

7. Return the vehicle to normal operating position.
8. Remove the chocks from the tires.

Axle Clamp and Retainer Replacement

Replacement

1. With the vehicle parked on a level surface, shut down the engine, and chock the tires.

NOTE: All of the following steps should be performed on the left side of the vehicle, first; then the right side of the vehicle.

2. Remove the two upper spring-tip pads and bolts from the suspension spring. See **Fig. 1**.
3. Disconnect the shock absorbers from the lower axle retainer on the suspension spring.
4. Disconnect the two lower torque-control rods from the lower axle retainers.
5. Remove and discard the U-bolt nuts and washers.
6. Remove the brake cam tube-support bracket.
7. Remove and discard the lower axle retainers.
8. Remove and discard the axle U-bolts from both rear axles.
9. Jack up the center of the suspension spring (at the center bearing, between the tandem) and support with jack stands at the frame. See **Fig. 2**. Make sure that all weight has been relieved from the axle clamp group and that there is sufficient clearance to remove the upper axle clamp.
10. Remove the lower spring-tip pads from both rear axles.
11. Remove and discard the upper axle clamps from both rear axles.
12. On both rear axles, install new upper axle clamps. Locate the dowel pin through the hole in the bottom of each axle clamp to confirm proper alignment.

NOTE: Confirm that you are installing the correct upper axle clamps before continuing. You can visually identify the new upper axle clamp because the step has been removed from the area directly above the U-bolt saddles. See **Fig. 3**.

Axle Clamp and Retainer Replacement

13. Install the lower spring-tip pads into the front and rear axle clamps.
14. Jack up the left-side suspension spring, remove the jack stands, and lower the spring. While the spring is being lowered, ensure that it is seated correctly onto the lower spring-tip pads.
15. Install new lower axle retainers onto both rear axles.
16. Install the brake cam tube-support bracket onto the rear axle.
17. Install new U-bolts as follows.

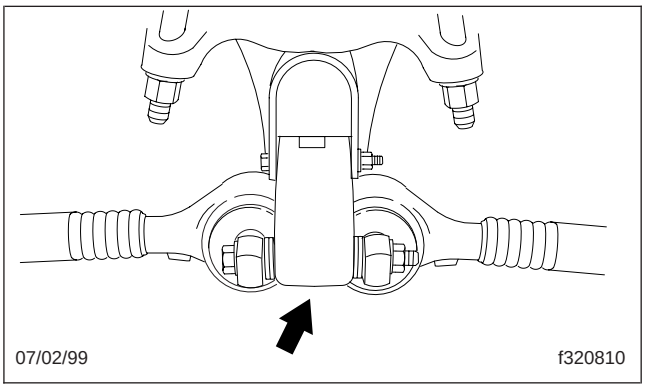

Fig. 2, Vehicle Jacking Point

IMPORTANT: Install two new washers for each U-bolt nut.

17.1 Install each U-bolt over the U-bolt saddle in the upper axle clamp and through the holes in the lower axle retainer.

17.2 Install the washers and finger-tighten the nuts in the order shown in **Fig. 4**.

Make sure all brackets are snug against the axle housing before proceeding.

IMPORTANT: U-bolt nuts must be tightened in the order shown in **Fig. 4**.

17.3 Tighten the nuts 60 lbf·ft (81 N·m), then 200 lbf·ft (271 N·m), in two separate rotations, following the order shown in **Fig. 4**.

18. Attach the lower torque-control rods to the lower axle retainers, then tighten 136 lbf·ft (184 N·m).
19. Install the shock absorbers as follows.

19.1 Install the lower shock mounting bolts.

19.2 Install the lower shock absorber mounting washers and nuts, then hand-tighten the nuts.

19.3 Tighten the nuts to 241 lbf·ft (327 N·m).

Adjustments

Rear axle positioning and alignment on a vehicle equipped with the TufTrac suspension is determined by the length of the lower control rods and the V-rods. See **Fig. 1**. The length of the control rods and V-rods can be controlled by the addition or removal of shims at the mounting points of the control rods and/or V-rods. The addition of shim(s) between the control rod or V-rod and its mounting will effectively lengthen the rod moving the axle relative to the frame. Conversely, the removal of shim(s) will shorten the length of the rod, moving the axle in the opposite direction.

The lower control rods use a horse-shoe style of shim (**Fig. 2**) while the V-rods use hardened washers for shims.

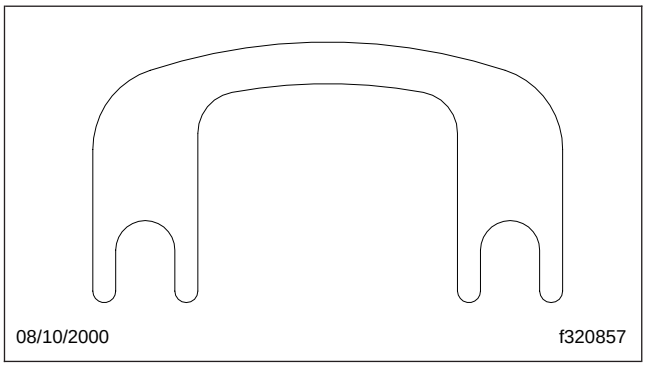

Fig. 2, Lower Control Rod Shim

Control rod shimming is performed at the center bracket. See **Fig. 3**. The purpose of this shim adjustment is to provide axle alignment and planing adjustment (angle of the axle from vertical in the side view).

Alignment Adjustments

NOTE: Alignment refers to the squareness of the axles to each other and the frame rails viewed from the top of the vehicle.

Add or remove shims at the center bracket to achieve proper alignment. See **Fig. 3**. To minimize the effect on planing angles, if possible, add or remove shims from both sides of the vehicle.

When one 3mm thick shim is added and one removed (from the opposite side) the axle position is affected as follows:

- Angle of the axle in the plan view: 0.33 degrees
- Fore-aft movement of the wheel at the outside (assuming 97.6 in. (2480 mm) wheel to wheel distance): 0.283 in. (7.2 mm)

Planing Adjustments

NOTE: planing refers to the angle of the axle from vertical in the side view.

Add or remove shims at the center bracket to change the planing angle. See **Fig. 3**. Unless alignment is required, an equal number of shims should be used left and right for a given axle; example, when adding one shim to the left forward rod add one shim to right forward rod. A shim 0.12 inch thick changes the planing angle 0.3 degrees.

V-Rods

Axle Tracking Adjustments

The tracking adjustment of the forward and rear axles is done by adding and/or removing hardened washers between the V-rod bar pin and the frame-mounted bracket. See **Fig. 4**.

General Information

The Front Airliner Suspension (also referred to as the Hendrickson AIRTEK suspension) is comprised of a front air suspension, and a welded steering axle (Hendrickson STEERTEK), that work together to form an integrated torsion system. See **Fig. 1**. See **Group 33** for Hendrickson STEERTEK front axle information.

Axle Clamp Group

The clamp group provides four-sided clamping pressure. The clamp group consists of the following:

- top axle wrap
- bottom axle wrap
- top axle wrap liner
- bottom axle wrap liner
- top pad
- 3/4-inch bolts, washers, nylon locknuts

Air Springs

The air springs are engineered to support 50 percent of the vertical load while providing very low spring rate. The "push-to-connect" air supply design also provides fast and easy installation and removal.

Leaf Spring Assembly

The leaf springs share loads equally with the air springs. Front and rear bushings are greaseless, and only require periodic inspections.

Shock Absorbers

The shock absorbers are tuned specifically for the AIRTEK system.

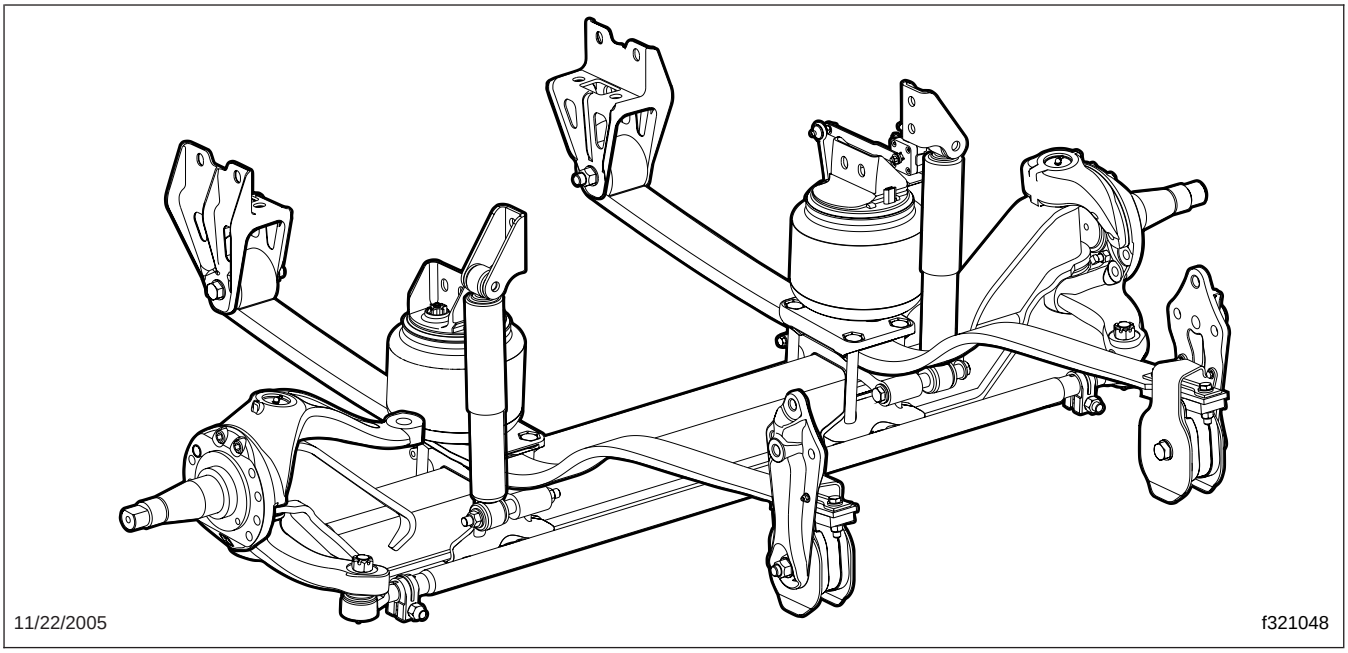

Fig. 1, Front AirLiner (Hendrickson AIRTEK) Suspension

Ride Height Adjustment

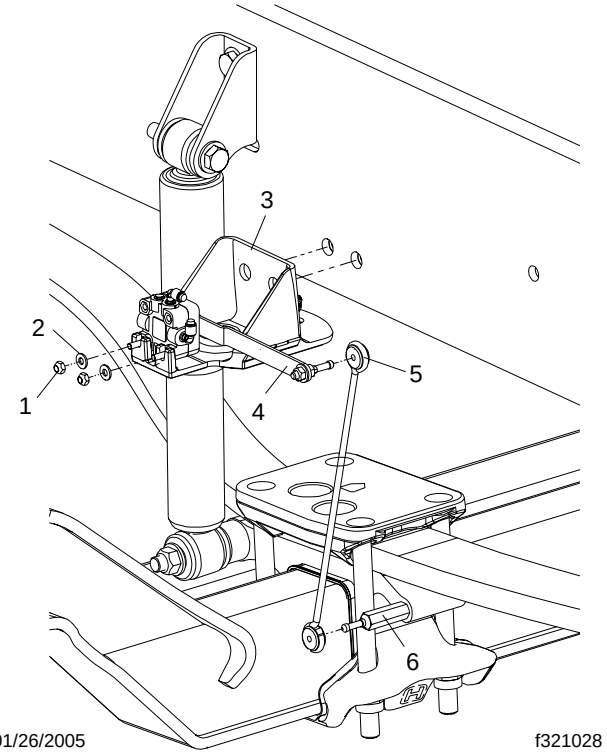
NOTE: As of August 2007, the Front AirLiner Suspension is equipped with dual height-control valves, one on each side of the vehicle. For vehicles with dual valves, inspect and adjust the ride height on both sides of the vehicle.

1. Use a work bay with a level floor. Drive the vehicle slowly, straight ahead. Try to slacken or loosen the suspension as the vehicle is positioned. End with all the wheels positioned straight ahead. Try to roll to a stop without the brakes being used.
2. Shut down the engine, then chock the tires. Do not set the parking brakes.
3. To ensure that the vehicle is level, check the tire pressure. The air pressure in both front tires should match.
4. Disconnect the vertical linkage from the stud on the horizontal control lever, and exhaust the suspension air by lowering the lever; see **Fig. 1**. If equipped with dual height-control valves, repeat for the other side of the vehicle.

NOTE: It is very important that the height-control valve be cycled completely before and after any ride height adjustments. This cycling of the height-control valve will help to make the adjustment as accurate as possible.

5. Attach the linkage to the stud on the horizontal control lever, and allow the suspension system to fill with air. If equipped with dual height-control valves, repeat for the other side of the vehicle. Wait until the airflow to the front air springs has stopped.
6. Measure the suspension ride height of the front axle. If equipped with dual height-control valves, measure the ride height on both sides of the vehicle.

   Using a Hendrickson AIRTEK height gauge, literature no. 45745-159, hold the gauge vertically and place it so the upper notch feature is between the height-control-valve mounting bolts, and sits flush against the bottom of the air-spring bracket; see **Fig. 2**. The piston-flange edge should contact the lower region marked "ACCEPTABLE."



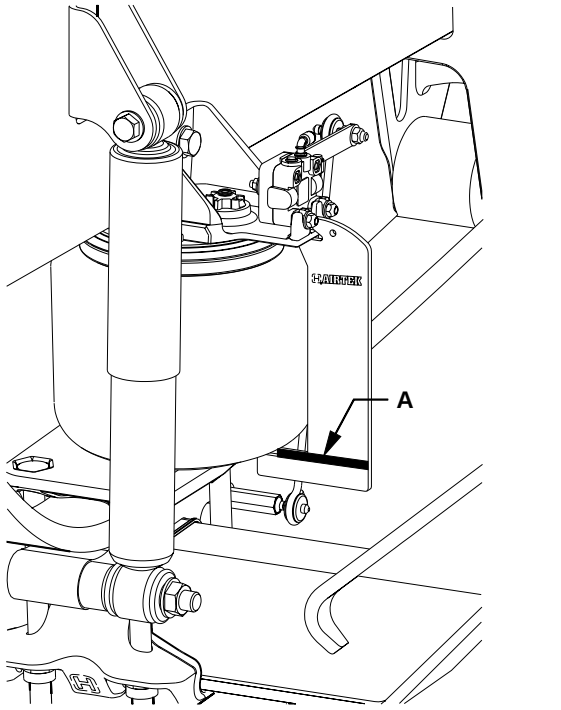
1. 1/4-Inch Locknut
2. 1/4-Inch Washer
3. Air Spring Hanger
4. Horizontal Control Lever
5. Vertical Linkage
6. Link Mount

Fig. 1, Height-Control Valve Linkage

   If the flange edge contacts at the "BELOW SPEC" region, the ride height is set too low. If the flange contacts at the "ABOVE SPEC" region, the ride height is set too high.

   If a gauge is not available, measure the vertical distance from the bottom of the upper air-spring bracket to the bottom of the air-spring piston flange. This distance should be between 7-3/4 and 8 inches (197 and 203 mm).
7. If the suspension ride height is not within specification, disconnect the vertical linkage from the horizontal control lever, fill and exhaust the suspension system, then fill the system until the suspension is at the proper ride height.
8. Move the control lever to the neutral position, then hold it in position by inserting a 5/32-inch

Ride Height Adjustment



A. Acceptable Range

Fig. 2, Using the Ride Height Gauge

(4-mm) pin or drill bit into the holes in the control lever and valve body.

NOTICE

When loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

9. While holding the height-control valve mounting studs in place with an Allen wrench, loosen the valve mounting just enough to allow movement of the height-control valve.
10. Adjust the height-control valve by rotating the valve body until the rubber grommet at the upper end of the vertical linkage lines up with the stud on the horizontal control lever.
11. Make sure the height-control valve stays in position. If necessary, hold the height-control valve mounting studs in place with an Allen wrench, and tighten the nuts slightly. Do not tighten the locknuts to the specified torque until after the proper ride height is verified.
12. Remove the pin or drill bit from the holes in the control lever and valve body.
13. Detach the linkage from the stud on the horizontal control lever, and exhaust the suspension system air, then attach the linkage to the stud on the horizontal control lever, and fill the suspension system with air. Wait until the airflow to the front air springs has stopped.
14. Measure the suspension ride height again. If necessary, repeat 6 through 14.
15. Once the proper ride height is attained, tighten the valve mounting locknuts 95 lbf·in (1100 N·cm), while holding the height-control valve mounting studs in place with an Allen wrench. Do not overtighten.

Height-Control Valve Test

It is normal to hear air escaping from the height-control valve for as much as 10 minutes after getting out of the vehicle when it is in an unladen condition. This air "leaking" is just the height-control valve exhausting air from the suspension air springs in order to return to the neutral mode.

The height-control valves used on the Century Class are Barksdale valves. Two methods are available to check the operation of the Barksdale height-control valves. A leak in the valve may be discovered without using a test kit, but a test kit is necessary to determine if the valve has an unacceptable rate of leakage.

Some Barksdale height-control valves have been returned for warranty because the four bolts in the valve housing were overtightened, often, enough to crack the valve housing. These bolts should not be loose, and should not normally require tightening, as there are no serviceable parts in the valve.

IMPORTANT: To prevent voiding the warranty on Barksdale height-control valves, note the following:

- Do not overtighten the bolts in the Barksdale height-control valve housing if you detect leaks in the housing. The bolts should not be loose, and should not require tightening. Only if necessary, tighten the valve housing bolts 45 lbf·in (500 N·cm). Any damage to the valve housing will void the warranty.
- Do not attempt to disassemble the Barksdale valve body or the control lever. There are no serviceable parts in the valve, and any disassembly will void the warranty.

NOTICE

When removing or loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

Checking the Height-Control Valve Without Using a Test Kit

1. Apply the parking brakes and chock the tires.
2. Run the engine to build vehicle air pressure to at least 100 psi (690 kPa).
3. Shut off the engine and wait 5 to 10 minutes for the air suspension system to equalize.

NOTE: Normal operation of the height-control valve requires a maximum of 10 minutes to settle. Any air leakage during this time is considered normal, and does not indicate a defective valve.

4. Disconnect the vertical linkage from the control lever; see **Fig. 1**.
5. Pull the control lever up about 45 degrees for 6 to 8 seconds. If air passes through the valve, that section of the valve is working.
6. Return the control lever to the neutral position. Air should stop flowing. If so, that section of the valve is working.
7. Push the control lever down about 45 degrees for 6 to 8 seconds. If air exhausts from the valve, that section of the valve is working.
8. Return the control lever to the neutral position. If the air stops again in the neutral position, the valve is working correctly.
9. If the valve works as stated in all of the above steps, then no further checking is necessary. Connect the vertical linkage to the control lever, then tighten the linkage nut.

   If needed, adjust the ride height or replace the height-control valve. For adjustment of the ride height, see **Subject 100**. For replacement of the height-control valve, see "Height-Control Valve Replacement" below.

NOTE: If a leak is detected on a Barksdale height-control valve, go to "Checking a Barksdale Height-Control Valve Using a Test Kit". Barksdale valves have an acceptable leak rate of 3 cubic inches (50 cc) per minute. You can

determine if a leak is acceptable only by using the Barksdale test kit.

Checking the Height-Control Valve Using a Test Kit

IMPORTANT: The procedure described below is for use on Barksdale height-control valves only.

NOTE: The Barksdale field test kit is designed to be used with the height-control valve installed on the vehicle. Refer to **Specifications 400** for information on ordering the Barksdale height-control valve test kit KD2264.

1. If not already done, park the vehicle on a level surface, apply the parking brakes, and chock the tires.
2. Run the engine to build vehicle air pressure to at least 100 psi (690 kPa).
3. Shut off the engine and wait 5 to 10 minutes for the air suspension system to equalize.

NOTE: Normal operation of the height-control valve requires a maximum of 10 minutes to settle. Any air leakage during this time is considered normal, and does not indicate a defective valve.

4. For valves without an integral dump port, go to the next step.

   For valves with an integral dump port, check the rubber exhaust flapper at the back of the valve housing for leaks; see **Fig. 2**. Use a soapy solution.

   If a leak is found, there may be contaminants blocking the piston. Cycle the height-control valve switch inside the cab for two-second bursts, four or five times, to clear away any contaminants.

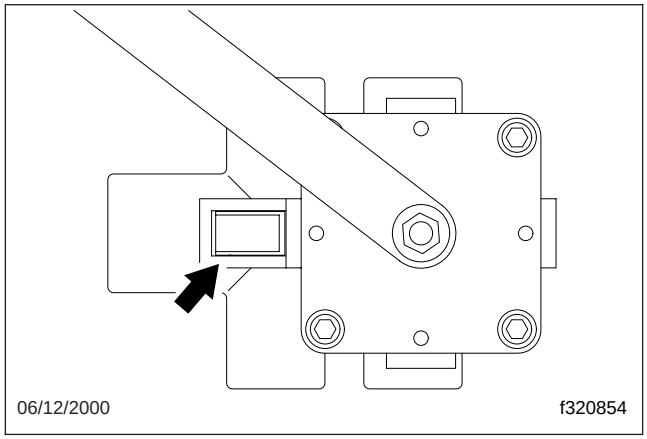

Fig. 2, Exhaust Flap Location (height-control valve with integral dump port)

5. Disconnect the vertical linkage from the horizontal control lever.
6. Rotate and hold the horizontal control lever down at about 45 degrees to exhaust air from the air springs.
7. *If equipped with an integral dump port,* turn on the quick dump switch on the dash. Leave the switch on until testing is complete.

If not equipped with an integral dump port, disconnect the air lines from the air spring ports on the height-control valve. Leave the elbow fittings (if equipped) in place. Install a Parker plug into each air spring port (or elbow fitting); see **Fig. 3**.

8. If a flapper is present on the exhaust port of the height-control valve, remove it using needlenose pliers.
9. Clean the surface around the exhaust port, then install the test fitting into the exhaust port. The centering pin on the fitting must align with the slot on the exhaust port. Rotate the test fitting 45 degrees clockwise to lock it in place; see **Fig. 3**.

NOTE: It may be necessary to cut the tie straps that hold the chassis wiring running below the height-control valve, in order to access the exhaust port.

10. Connect one end of the air hose from the kit to the test connector on the exhaust port, and the other end to the test gauge.
11. Check the height-control valve in the fill mode, as follows.

    11.1 Rotate the valve control lever up 45 degrees from the horizontal to the fill position.

    11.2 Press the reset button on the test gauge.

    11.3 Observe the test gauge for 30 seconds. Refer to **Fig. 4** for the maximum allowable exhaust pressure change versus inlet pressure.

    The valve is not working correctly if the gauge pressure reading exceeds the maximum allowable within 30 seconds.

    If the gauge reads less than the maximum allowable pressure change in 30 seconds, the valve is okay.

NOTE: The test gauge will register the exhausting air. *This does not indicate a defective valve.*

12. Check the height-control valve in the exhaust mode, as follows.

    12.1 Rotate the valve control lever down 45 degrees from the horizontal to the exhaust position.

    12.2 Press the reset button on the test gauge.

    12.3 Observe the test gauge for 30 seconds. Refer to **Fig. 4** for the maximum allowable exhaust pressure change versus inlet pressure.

    The valve is not working correctly if the gauge pressure reading exceeds the maximum allowable within 30 seconds.

    If the gauge reads less than the maximum allowable pressure change in 30 seconds, the valve is okay.

NOTE: The test gauge will register the exhausting air. *This does not indicate a defective valve.*

13. Disconnect the test gauge and connector from the valve exhaust port.
14. If the height-control valve is defective, replace it; see "Height-Control Valve Replacement" below.
15. Install the flapper on the exhaust port by pressing it into place.
16. *For height-control valves with an integral dump port,* connect the vertical linkage to the height-control valve control lever. Turn off the quick dump switch on the dash. The ride height will automatically return to the correct position.

    For height-control valves without an integral dump port, remove the two Parker plugs from the air spring ports, and connect the air lines to the air spring ports (or elbow fittings). Connect the vertical linkage to the height-control valve control lever. The ride height will automatically return to the correct position.

Height-Control Valve Replacement

1. Apply the parking brakes and chock the tires.

⚠ WARNING

Keep your hands and all objects away from the area under and around the slack adjusters and suspension components when removing the pressure from the air system. These parts will move as the air is released and can cause personal injury or damage to any objects that are between the moving parts.

2. Drain the air from the secondary air tank.

⚠ WARNING

Air lines can whip dangerously if disconnected under pressure. Drain all air from the secondary air tank before disconnecting air lines. Disconnecting pressurized air lines can cause personal injury and/or property damage.

3. Disconnect the vertical linkage, then lower the control lever to exhaust the air.
4. Remove the air lines from the height-control valve; see **Fig. 5**. Push in on the air line to release the tension, then push down on the collar and pull out the air line.

NOTICE

When removing or loosening a Barksdale height-control valve from a mounting bracket, always hold the valve-side mounting studs in place with an Allen wrench while loosening or tightening the nuts that attach the valve to the bracket. Because the mounting studs are threaded into the valve body, loosening the nuts without holding the studs can tighten the studs, which can crush the valve body and damage the valve. Conversely, tightening the nuts without holding the studs can back the studs out, causing a separation of the two halves of the valve body, and possibly a leak.

5. While holding the height-control valve mounting studs in place with an Allen wrench, remove the

nuts and washers that attach the valve to the air-spring hanger bracket. Remove the height-control valve.

6. Position the new height-control valve on the hanger bracket, parallel to the flange. While holding the height-control mounting studs in place with an Allen wrench, install the nuts and washers. Do not tighten the locknuts to the specified torque until after the proper ride height is attained.

IMPORTANT: When replacing or installing nylon air lines on quick-connect fittings, it is critical that the end of the air line is cut square. An improper cut can cause the air line to seat improperly in the quick-connect fitting, allowing air leakage.

7. Install the air lines on the height-control valve.
8. Attach the vertical linkage to the horizontal control lever and the linkage mount.
9. Adjust the height-control valve to the proper specifications; see **Subject 100**.
10. While holding the height-control mounting studs in place with an Allen wrench, tighten the height-control valve mounting locknuts 95 lbf·in (1100 N·cm). Do not overtighten.

Removal

CAUTION

Anytime the front axle on an AIRTEK suspension is suspended, it is mandatory that the shock absorbers remain connected. The shock absorbers are the rebound travel stops for the springs. Failure to do so could cause the air springs to exceed their maximum length, causing the air springs to separate from the piston, or reverse arch the steel leaf springs. This could result in premature steel leaf spring failure.

1. Set the parking brake, and shut down the engine. Chock the tires.

NOTE: It is not necessary to replace the shock absorbers in pairs if only one shock absorber requires replacement.

2. Remove the shock absorber lower mounting bolt, spacer, washers, and locknut.
3. Remove the shock absorber upper mounting bolt, washers, and locknut, then remove the shock absorber.
4. Inspect the shock absorber mounting brackets and hardware for damage or wear. Replace as necessary.

Installation

1. Place the shock absorber into the upper mounting bracket.
2. Install the shock absorber upper mounting bolt, washers, and locknut.
3. Apply a thin coating of antiseize compound to the shank of the shock absorber lower mounting bolt, the mating surfaces of the axle wrap and spacer, and the inside bore of the aluminum axle wrap. This is necessary to help prevent the bolt from seizing to the aluminum axle wrap. See **Fig. 1**.
4. Install the lower bolt from the inboard side of the axle wrap to the outboard side, then install the spacer, washers, and locknut.
5. Tighten both of the shock absorber mounting locknuts 225 to 255 lbf·ft (305 to 345 N·m).

Removal

1. Set the parking brake, and shut down the engine. Chock the tires.
2. Deflate the air springs by disconnecting the height-control-valve linkage and lowering the control arm to exhaust the air pressure. Disconnect the air lines at the air springs.

⚠ WARNING

Failure to deflate and disconnect the air system prior to raising the front of the vehicle may result in sudden failure of the air spring, resulting in personal injury or property damage.

3. Raise the vehicle and support the frame with stands.
4. Separate the air spring from the upper air-spring bracket by applying downward pressure on the air spring, pushing outward on the lock tabs outside the bracket, and inward on the inlet lock tabs to dislodge the air spring from the upper air-spring bracket. See **Fig. 1**. See **Fig. 2** for lock tab locations.

6. Pull the air spring out from between the upper bracket and the top pad casting.

Installation

⚠ CAUTION

If the air spring will be re-installed, inspect the lock tabs for damage or cracks prior to installation. Damaged lock tabs may allow the air spring to become dislodged during operation, resulting in loss of vehicle control.

Air Spring Removal and Installation

1. Insert the air spring into the top-pad casting. Make sure the lock tabs click in place.
2. Compress the air spring and slide it into position. Using the locating nodule, index the air spring position to the upper air-spring bracket.
3. Pull the air spring up into the upper air-spring bracket until the air spring snaps into place. Verify that all four lock tabs are engaged. See **Fig. 2**.

NOTE: When replacing or installing nylon air line tubing into quick-connect fittings, it is critical that the end of the air line is cut square. An improper cut can cause the air line to seat improperly in the quick-connect fitting, allowing air leakage.

4. Install the air lines on the air spring.
5. Inflate the air springs and check for leaks.
6. Lower the frame.
7. Charge the suspension system with air.

⚠ WARNING

Before charging the suspension system with air, make certain the air-spring locator is indexed into the upper air-spring bracket, the lock tabs are snapped into place, and that the air spring is fully seated. Failure to follow these instructions could result in premature air-spring failure, which could result in personal injury or property damage.

8. Check the ride height and adjust it if necessary. See **Subject 100** for instructions.
9. Remove the chocks.

Spring-Eye Bushing Replacement, and Spring-Eye Retorque

The spring-eye bushing for the front AirLiner suspension is designed for the life of the spring. If a premature failure occurs, careful consideration must be given to the contributing factor that made the bushing fail. This must be corrected in order to prevent the new bushing from failing in the same manner. It is recommended that in the event of a high-mileage bushing failure that the front leaf spring be replaced.

Spring-Eye Bushing Replacement

Remove the front spring, following the procedure in **Subject 150**. Once the leaf spring is removed from the chassis, it will be necessary to use:

- A hydraulic press with an operating capacity of a minimum of 10,000 lb (4500 kg).
- A receiving tool.
- A removal and installation driver.

⚠ WARNING

Do not use heat or a cutting torch to remove the bushing from the steel spring. The use of heat can adversely affect the strength of the spring. A component damaged in this manner can result in a loss of vehicle control, and possible personal injury or property damage.

1. Support the spring, and center the spring-end hub on the receiving tool. The leaf spring must be level to distribute the vertical-pushing load equally on the bushing.
2. Place the center of the bushing driver on the spring-eye bushing. See **Fig. 1**.
3. Pushing directly on the driver, press out the spring-eye bushing until it clears the spring-eye bore.
4. Inspect the spring eye for any cracks or burrs. If cracks are present, install a new leaf spring.
5. Remove any nicks or burrs with an emery cloth or a rotary sander.
6. Lubricate the inner diameter of the spring bore, and the new rubber bushing, with a vegetable-based oil (cooking oil). Do not use petroleum- or soap-based lubricant. They can cause an adverse reaction with the spring-eye material.

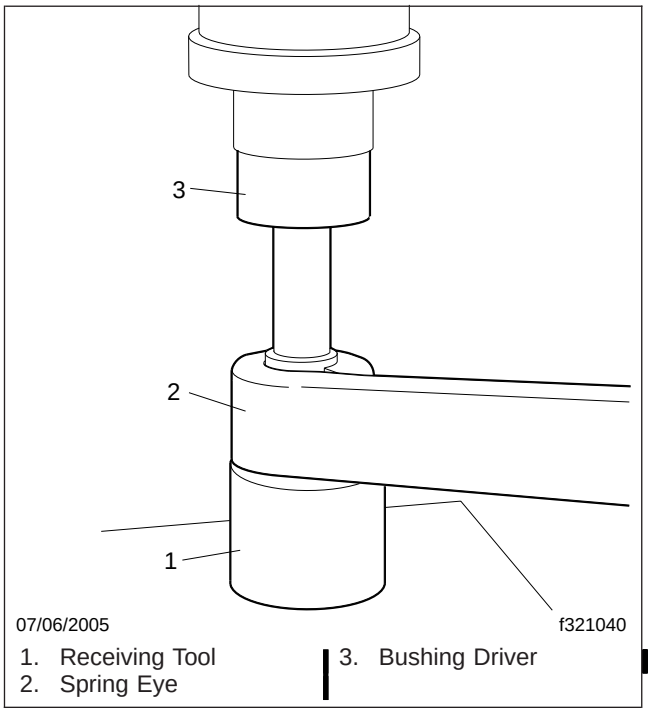

Fig. 1, Removing the Spring-Eye Bushing

7. Cut a strip of 3M Scotch® 890T black-fiber tape (duct tape or equivalent) 1-inch (25-mm) wide by 6-inches (150-mm) long.
8. Feed the tape into the spring eye, with the adhesive side facing the gap in the eye, to cover the sharp edge. Center the tape equally around each end.
9. Support the spring, and center it on the receiving tool.
10. Center the new bushing on the spring-eye bore, and line up the hydraulic press.
11. Press the bushing into the spring-eye bore, overshooting the desired final position by approximately 3/16 inch (5 mm). Press the bushing again from the opposite side, to center it in the spring-eye bore.
12. Once the bushing is installed, follow the instructions for the front leaf-spring installation in **Subject 150**.

Spring-Eye Bushing Replacement, and Spring-Eye Retorque

Spring-Eye Retorque

NOTE: This procedure is also necessary when replacing the front or rear hanger brackets, or the steel leaf spring.

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the tires.
2. Deflate the air springs by disconnecting the height-control-valve linkage and lowering the control arm to exhaust the air pressure.

⚠ WARNING

Failure to deflate and disconnect the air system prior to raising the front of the vehicle may result in sudden failure of the air spring, resulting in personal injury or property damage.

IMPORTANT: Push-to-connect fittings are not serviceable. Clean dirt and debris away from the fittings to prevent foreign materials from entering the air system, or damaging the fittings. Clean the push-to-connect fittings using soapy water and a soft-bristled brush, then dry with compressed air.

3. Disconnect the air lines at the air springs.
4. Raise the vehicle and support the frame with stands.

⚠ WARNING

The shock absorbers must remain connected when the front axle is suspended. The shock absorbers are the rebound travel stops for the springs. Disconnecting the shock absorbers could cause the air springs to exceed their maximum length, causing the air springs to separate from the piston, or reverse arch the steel leaf springs, which may result in premature steel leaf spring failure.

5. Lower the front axle. Allow at least 3 inches (76 mm) of wheel clearance to the ground. The shock absorbers must be connected. DO NOT reverse arch the springs.
6. Loosen all four front and rear spring-eye bolts. See **Fig. 2**. The suspension may drop down slightly.

IMPORTANT: DO NOT remove the spring-eye bolts. The tires must not contact the ground.

7. Allow the suspension to settle.
8. Tighten the 3/4-inch locknuts on the front and rear spring-eye bolts 285 to 305 lbf·ft (385 to 415 N·m).
9. Raise the front axle and remove the frame stands.
10. Lower the vehicle.
11. Check the air springs to verify that they are seated properly, and install the air lines into the air springs.
12. Connect the height-control valve and charge the air system.
13. Affix a long straightedge to the bottom of the frame rails, in front of the air springs.
14. With the vehicle on a level surface, measure the distance from the top of the straightedge to the ground on both sides of the vehicle. Record the measurements.
15. Determine the difference from one side to the other. Remove the straightedge.
16. Perform a road test and repeat the previous three steps.
17. If the the difference in measurements is more than 3/8 inch (9.5 mm), contact Hendrickson Tech Services.

Leaf Spring Removal and Installation

Removal

NOTE: When replacing both steel springs, use springs with the same camber designation. The camber designation of the new spring is located at the front of the top leaf and will be defined with a (+), (0), or a (–).

1. Park the vehicle on a level surface and shut down the engine. Chock the tires.
2. Deflate the air springs by disconnecting the height-control-valve linkage and lowering the control arm to exhaust the air pressure.
3. Position a floor jack with a 4-inch lifting plate, below the axle, and raise the vehicle.
4. Remove the tires.
5. Position frame stands behind the rear spring mounts. It may be necessary to remove peripheral components for installation of the frame stands.
6. Lower the jack, allowing the axle to hang, but do not remove the jack from the axle.
7. Loosen both front spring-eye bolts, but do not remove the bolts.
8. Remove both rear spring-eye centerbolts.
9. Remove both lower shock absorber mounting bolts.

NOTE: To ease removal of the spring-eye bolts it may be necessary to raise or lower the axle.

10. Disconnect both air springs from the top pads of the clamp groups.
11. On the spring that is not being replaced, loosen the clamp group nylon locknuts.

⚠ WARNING

Do not use a cutting torch to remove clamp group bolts or attaching fasteners. The use of heat on suspension components can decrease the strength of these parts. A component damaged in this manner can result in a loss of vehicle control and possible personal injury or property damage.

12. Remove the 3/4-inch clamp group bolts, nuts, washers, top pad, galvanized liner, and the bottom axle wrap, from the spring that is going to be removed. See **Fig. 1**.
13. Lower the jack, allowing the suspension to pivot down and out of the rear hanger clamps.
14. Remove the front spring-eye bolt from the spring that is being removed, then remove the spring assembly.
15. Remove the thrustwashers from the rear spring-mount assembly. See **Fig. 1**.
16. Remove the 1/2-inch bolts, then remove the rear spring-mount assembly.
17. Inspect the thrustwashers, rear spring-mount bushing, rear-hanger clamp, top axle wrap, and the front and rear spring hangers. Replace them if worn, cracked, or damaged.

Installation

1. Lubricate the front spring-eye bushing and the front hanger with a vegetable-based oil (cooking oil). **DO NOT** use petroleum- or soap-based lubricants; they can cause an adverse reaction with the spring-eye-bushing material.
2. Install the spring over the axle, and into the front spring hanger.
3. Install the 5 1/2-inch long front spring-eye bolt, washers, and nut, but do not tighten.
4. Using the dowel pin located on the top axle wrap, engage the spring to the axle. It may be necessary to loosen the other clamp group to allow the axle to pivot when installing the spring on the dowel pin.
5. Install the top pad on top of the spring.
6. Install a new bottom axle wrap liner in the bottom axle wrap.
7. Install the bottom axle wrap.
8. Install new clamp group bolts, washers, and new nylon locknuts.
9. Snug the clamp group, but DO NOT torque at this time.
10. Raise the axle and the rear spring assemblies into the rear spring hangers.
11. Install the 5-inch long centerbolts in the rear hangers. The bolt must be installed from the in-

Leaf Spring Removal and Installation

19. Raise the frame and remove the frame stands.
20. Lower the vehicle.
21. Inflate the air springs, then follow the instructions for ride height adjustment in **Subject 100**.

⚠ WARNING

Before charging the suspension system with air, make certain the air-spring locator is indexed into the upper air-spring bracket, the lock tabs are snapped into place, and that the air spring is fully seated. Failure to follow these instructions could result in premature air-spring failure, which could result in personal injury or property damage.

22. Remove the chocks from the tires.

Front Spring Hanger Replacement

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the tires.

6. Remove the frame fasteners, then remove the spring hanger.
7. Inspect the mounting surfaces on the frame for cracks or fretting.
8. Inspect the spring-eye bushing for damage or excessive wear. If damaged or worn excessively, replace the bushing. See **Subject 140** for replacement instructions.
9. Install the new hanger, flush with the bottom of the frame. Left or right hanger designation is stamped on the outboard surface of the hanger. See **Fig. 1**.
10. Install the 3/4 x 5-1/2 spring-eye bolt. Tighten the locknut 285 to 305 lbf·ft (385 to 415 N·m).

NOTE: A bottle jack may be required to raise the axle slightly to facilitate installation of the front spring-eye bolt.

11. Raise the vehicle and remove the jack stands or frame support, then lower the vehicle.
12. Inflate the air springs, then follow the instructions for ride height adjustment in **Subject 100**.

⚠ WARNING

Before charging the suspension system with air, make certain the air-spring locator is indexed into the upper air-spring bracket, the lock tabs are snapped into place, and that the air spring is fully seated. Failure to follow these instructions could result in premature air-spring failure, which could result in personal injury or property damage.
