General Information

The simplest driveline consists of a transmission output-shaft end-yoke, an axle input-shaft end-yoke, and a single slip-jointed driveshaft connecting the two end-yokes. See **Fig. 1**. The driveshaft is made up of a universal joint (U-joint), a sleeve-yoke, a splined stub shaft, a driveshaft tube, a tube-yoke, and a second U-joint.

DRIVELINE CONFIGURATIONS

The specific type and number of drivelines used on each vehicle depends on its number of transmissions, its number of drive axles, and its wheelbase. See **Fig. 2**. A driveline is used between each driving and driven component. A driveline connecting a main transmission (or anauxiliary transmission) to a single drive axle or forward-rear axle of a dual-drive vehicle is always referred to as a no. 2 driveline. See **Fig. 2**, examples A, B, C,D, and E. An interaxle driveline of a dual-drive vehicle is always called a no. 3 driveline.

Fig. 1, Components of a Basic Driveline

General Information

See **Fig. 2**, examples *B*and *C*. A driveline connecting a main transmission to an auxiliary transmission is alwaysreferred to as a no. 1 driveline. See **Fig. 2**, example *C*. Business Class Trucks are not equipped with no. 1 drivelines or auxiliarytransmissions.

A long driveshaft, supported only at its ends, will sag in the middle from its own weight. When turning at high rpm, it will flex, causing an out-of-balance vibration. Therefore, vehicles having a long wheelbase use a midship bearing, mounted on a frame cross-

Fig. 2, Driveline Configurations

member, for additional support. See **Fig. 2**, example *D*. This allows the no. 2 driveline to be separated into two, shorter shafts (a coupling shaft and a no. 2 driveshaft), thus improving balance and stability.

Vehicles having an even longer wheelbase use two crossmember-mounted midship bearings, allowing the no. 2 driveline to be separated into three short shafts, joined by four U-joints. See **Fig. 2**, example *E*. The first shaft is the primary coupling shaft, the second is the intermediate coupling shaft, and the third is the no. 2 driveshaft.

Vehicles manufactured with all-wheel-drive use a transfer case to provide power to the front driveaxle. See **Fig. 3**.

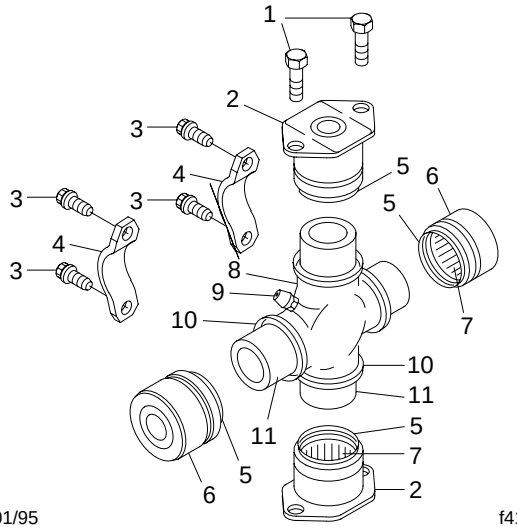
Fig. 3, All-Wheel-Drive Driveline Configuration

SLIP-JOINTS, U-JOINTS, AND YOKES

The basic function of the driveline is to send torque from the transmission to the axle in a smooth and continuous action. Because the vehicle axles are not attached directly to the frame, but are suspended by springs, theyride in an irregular, floating motion (when going over bumps or depressions), thus changing the distance between the transmission (or coupling shaft) and the rear axle, and the distance between the rear axles. The slip-joints of the no.2 and no. 3 driveshafts, by expanding and contracting, allow for length changes between drivetrain components. Couplingshafts do not require a slip-joint.

Motion of the rear axle(s) also causes changes to the relative angles between drivetrain components. U-jointsallow transfer of torque from an output shaft (or coupling shaft) to the driveshaft, and from the driveshaft to an input shaft, even though the angles between the shafts may be constantly changing.



Each U-joint consists of a cross with a close-tolerance ground cylindrical surface (trunnion) at the end of each of the four arms. Installed on each trunnion is a bearing cup lined with bearing needles. All bearing cups are sealed to retain lubricants, and to prevent entry of foreign material. See **Fig. 4**. In operation, the four bearing cups are held stationary in a pair ofyokes, while the U-joint cross pivots on its trunnions.

Full-round yokes are installed at the front of coupling shafts and at both ends of the no. 2 and no.3 driveshafts. All tube-yokes (yokes that are welded into driveshaft tubes) and all sleeve-yokes (yokes that are part of the internally splined half of slip-joints) are full-round yokes. See **Fig. 5**, Refs. 4 and 9.

An end-yoke is an internally splined yoke, held on an externally splined shaft by a locknut. As standard equipment, all end-yokes used on Business Class Trucks are half-round; full-round end-yokes are optional. End-yokes areinstalled on the transmission output shaft, on each axle input and output shaft, and behind the midship bearing of most coupling shafts. See **Fig. 5**, Refs. 2, 7, 12,and 14. A half-round flange-yoke is used with the driveline parking brake, and fastens with locknuts to the studs of a companion flange that installs on the transmission output shaft or the rear axle input shaft in the same manner as an end-yoke. See **Fig. 6**.

Spicer SPL90 (1590), 1610, 1710, 1760, and 1810 U-joints, and Rockwell 17T, 176T, and 18T U-joints are coupled to half-round end-yokes and flange-yokes by capscrews inserted through semicircular bearing straps that hold the bearing cups in place under tabs in the yoke cross-holes. See **Fig. 7**.

General Information

NOTE: Components shown are typical of all U-joints installed in Freightliner vehicles with half-round end-yokes, except Spicer SPL90 (1590) U-joints.

1. Bearing-Plate Capscrews
2. Bearing Cup (for full-round yoke)
3. Bearing-Strap Capscrew
4. Bearing Strap
5. Bearing-Cup Seal
6. Bearing Cup (for half-round yoke)
7. Bearing Needles
8. U-Joint Cross
9. Grease Fitting
10. U-Joint Cross Slinger
11. Trunnion

Fig. 4, Typical U-Joint

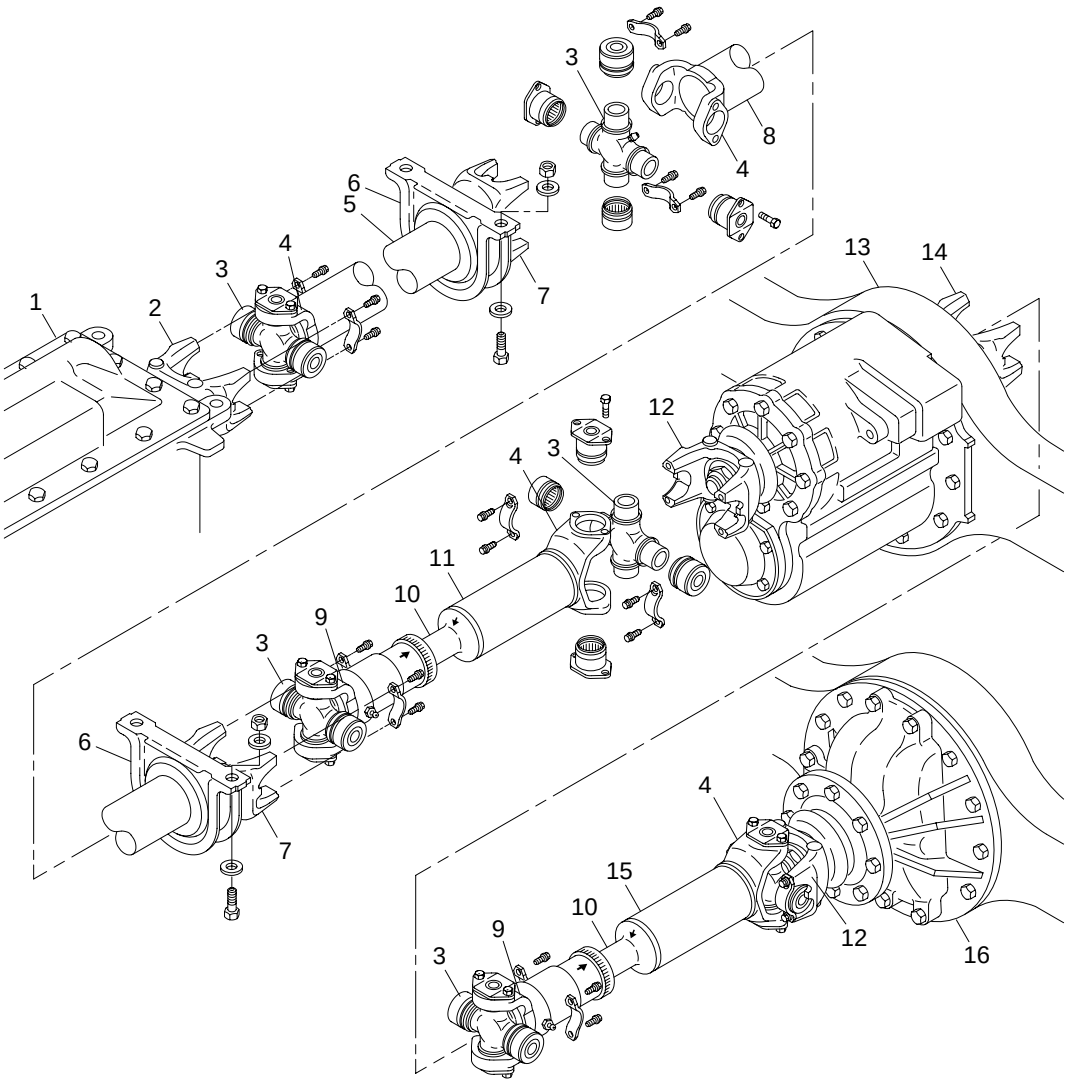
A Spicer SPL90 (1590) U-joint is installed in a full-round tube-yoke or sleeve-yoke by installing the cross and bearing cups into the yoke cross-holes, then installing a snap ring into a groove in each cross-hole. See **Fig. 8**.

Spicer 1610, 1710, 1760, and 1810 U-joints, and Rockwell 17, 176, and 18 series U-joints are installed in full-round tube-yokes, sleeve-yokes, and end-yokes, by inserting the cross through from the inside of both yoke cross-holes, then installing the bearing cups into the outsides of the yoke and over the ends of the trunnions.Capscrews, inserted through a bearing plate at the back of each cup, thread into the yoke to secure the cups. For bothSpicer and Rockwell U-joints installed from April 1, 1994, the capscrews are self-locking; for U-joints installed before April 1, 1994, non-self-locking capscrews are used with lockstraps to secure the capscrews. See **Fig. 9**.

U-JOINT ANGLES, PHASING, AND DRIVELINE BALANCE

Correct U-joint working angles, U-joint phasing, and driveline balance are vital to maintaining a quiet-running drivetrain and long life of drivetrain components (including driveline components).

The U-joint working angle is the angle formed by the intersection of the driveshaft centerline and the extended centerline of the shaft of any component (or other driveshaft) to which the U-joint connects. See **Fig. 10**. Because the double oscillating motionof a U-joint that connects angled shafts causes a fluctuating speed difference between the shafts, the effect created by the U-joint at one end of the shaft must cancel the effect created by the U-joint at the other end. This is done bymaking U-joint working angles at both ends of the driveshaft approximately equal, with the U-joints in phase. If theyoke lugs at both ends of the shaft are lying in the same plane (a plane which bisects the shaft lengthwise) theU-joints will be in phase. See **Fig. 11**.



After manufacture, each driveline yoke is statically balanced. After assembly, each driveshaft and coupling shaft is checked for out-of-roundness, straightened as necessary, then dynamically balanced.

AVOIDING DRIVELINE PROBLEMS

To ensure that U-joints turn in phase, sleeve-yokes, splined shafts, coupling shaft end-yokes, and coupling shafts, should be marked for assembly reference before disassembly. A misaligned slip-joint will seriously affect driveline balance (and U-joint phasing). Even if a slip-joint is assembled 180 degrees from its original position (which will keep the U-joints in phase), the dynamic balance of the driveshaft will be negatively affected.

A driveline can become unbalanced or greatly weakened if a driveshaft has been dented, bent, twisted, orotherwise damaged. Operating a vehicle at speeds which exceed the speed of the driveshaft's design specifications willcause an out-of-balance vibration. Any condition which allows excessive movement of a driveshaft will cause drivelineimbalance: loose end-yoke nuts, loose midship bearing mounts, loose U-joint bearing cup retaining capscrews, wornU-joint trunnions and bearings, and worn slip-joint splines.

Among the most common causes of U-joint and slip-joint damage is lack of lubrication.

U-Joint Uncoupling and Coupling With a Half-Round End-Yoke

NOTE: It is easier to check driveline parts, and to replace a U-joint or midship bearing assembly if the driveshaft is removed from the vehicle. If a driveshaft requires straightening or balancing, it must be removed, and installed on a lathe or a balance machine. Removal is required for replacement of slip-joint parts, a driveshaft tube, or a tube-yoke. To remove the driveshaft, see **Subject 120**.

Many service operations do not require driveshaft removal from the vehicle: end-yoke or companion-flange nut tightening; drive component shaft seal, end-yoke, or flange-yoke replacement; changing U-joint phasing at the slip-yoke; and transmission or axle removal (for overhaul, repair, or replacement). To perform these operations, uncouple the U-joint at the applicable end of the appropriate driveshaft.

U-Joint Uncoupling (See Fig. 1)

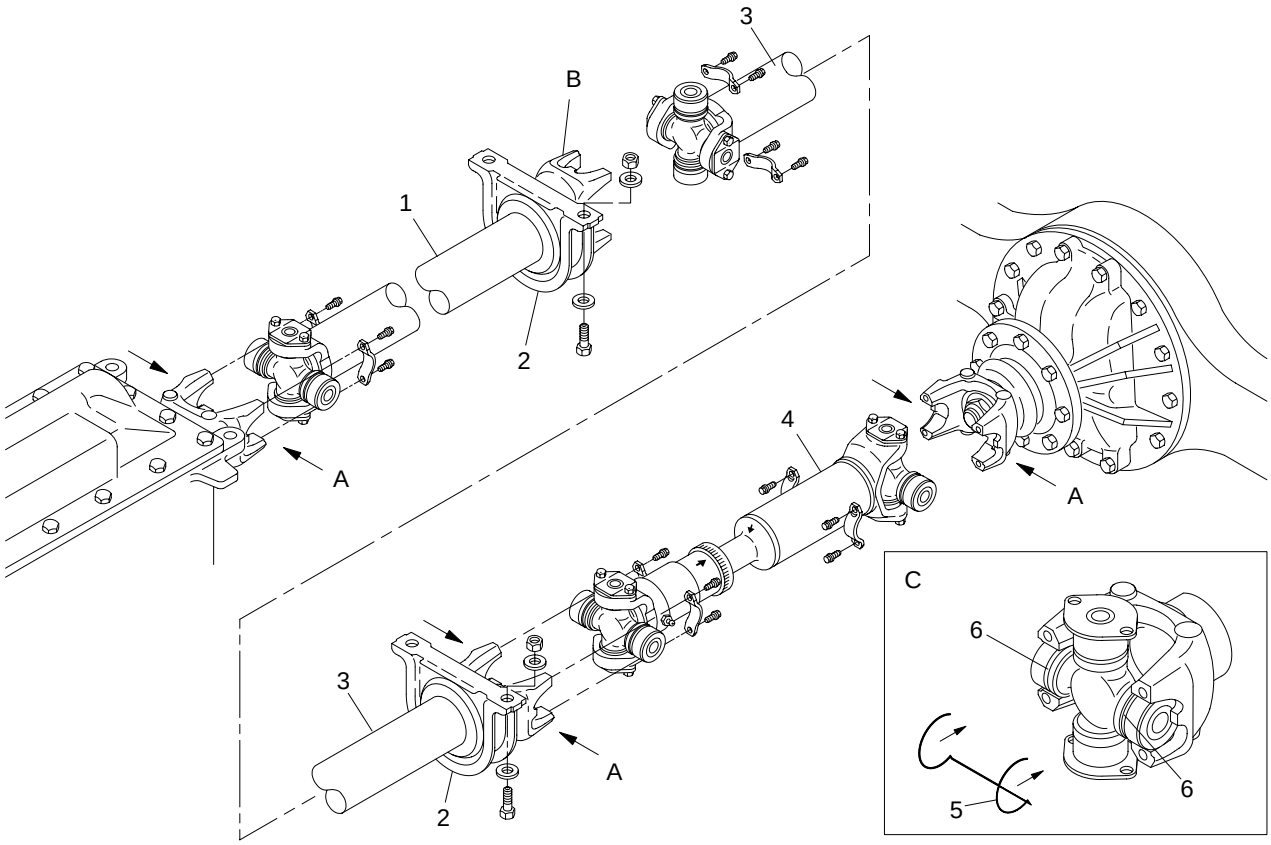
1. Apply the parking brakes, and chock the tires.
2. Turn the appropriate end-yoke (or flange-yoke) until the centerline through its cross-holes is horizontal. See **Fig. 1**, details *A* and *B*. If the half-round bearing cups do not already have a retaining wire installed, install a bearing-cup retaining wire. See **Fig. 1**, detail *C*. Or, install safety wire from the retaining-wire groove of one half-round bearing cup to the other.
3. Support the driveshaft with a nylon support strap.

   When uncoupling a coupling shaft, install two or three support straps, as needed. Remove the fasteners that attach the midship bearing(s) to its bracket(s). See **Fig. 1**.
4. Remove the capscrews that secure the bearing straps to the half-round yoke. Remove the bearing straps.
5. Compress the slip-joint to remove the U-joint from the yoke.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

U-Joint Coupling (See Fig. 1)



1. Check and clean the end-yoke.
   - 1.1 Check the torque on the end-yoke nut; see the applicable table in **Specifications 400**.
   - 1.2 Check the end-yoke (or flange-yoke) cross-holes for burrs or raised metal. Using a half-round file, remove burrs or raised metal. See **Fig. 2**.
   - 1.3 Using fine emery cloth, smooth and clean the entire surface of the yoke cross-holes and bearing straps. See **Fig. 3**.
   - 1.4 Turn the end-yoke (or flange-yoke) until its cross-holes are horizontal. See **Fig. 1**.
2. Check, clean, and lubricate the U-joint.
   - 2.1 Remove the bearing-cup retaining wire or safety wire. See **Fig. 1**, detail *C*.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

   - 2.2 Using fine emery cloth, smooth and clean the outside surfaces of both bearing cups. See **Fig. 4**.
   - 2.3 Check the U-joint trunnions and bearing cups for minute particles of dirt or grit. Clean if necessary; see **Subject 130**.
   - 2.4 Using NLGI grade 2 grease with EP additives, wipe a small amount of grease on the needles in the bearing cups.
   - 2.5 Using a light-weight oil, lubricate the lips of the bearing-cup seals. See **Fig. 5**.
   - 2.6 Install the bearing cups on the cross.
   - 2.7 Install a bearing-cup retaining wire. See **Fig. 1**, detail *C*. Or, install safety wire from the retaining-wire groove of one half-round bearing cup to the other.
3. Extend the slip-joint, while pressing the cross and bearing cups into place in the yoke cross-

U-Joint Uncoupling and Coupling With a Half-Round End-Yoke

08/11/95 f410074b

NOTE: Not all fasteners are shown.

A. End-yoke cross-hole centerline is horizontal.
B. Before uncoupling/coupling the U-joint, turn the end-yoke until its cross-hole centerline is horizontal.
C. Install a half-round bearing-cup retaining wire (or safety wire) before removing the bearing straps.

1. Primary Coupling Shaft
2. Midship Bearing
3. Intermediate Coupling Shaft
4. No. 2 Driveshaft
5. Half-Round Bearing-Cup Retaining Wire
6. Retaining-Wire Groove

Fig. 1, U-Joint Uncoupling/Coupling for Drivelines With Half-Round End-Yokes

holes. Using a rubber or plastic mallet, gently tap the bearing cups to seat them in the yoke. See **Fig. 6**.

⚠ CAUTION

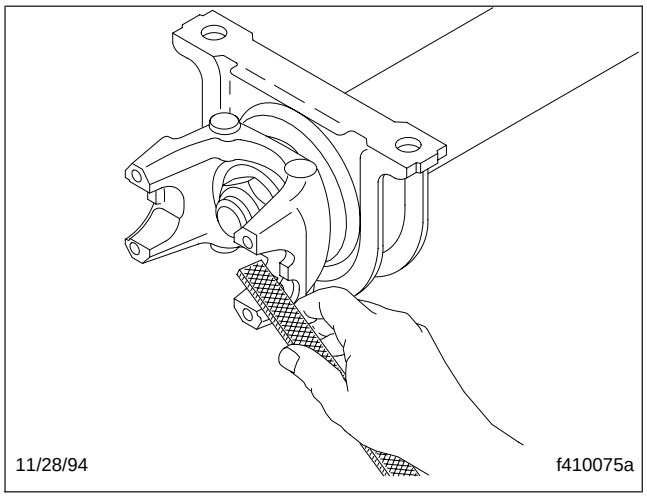
Do not use the capscrews and bearing straps to seat the bearing cups in the yoke. Seating the cross by tightening the bearing straps can deform the bearing straps, allowing the bearing cups to spin, which will cause rapid wear and serious damage to the U-joint.

4. Place the bearing straps over the cups, and install the new strap capscrews, finger-tight.

⚠ WARNING

The self-locking bearing-strap capscrews must not be reused. Replace the capscrews with new ones. Also, do not undertighten or overtighten the capscrews; use proper torque values. A loose or broken fastener at any point in the driveline weakens the driveline connection and can result in a driveshaft separating from the vehicle. Drive-

U-Joint Uncoupling and Coupling With a Half-Round End-Yoke



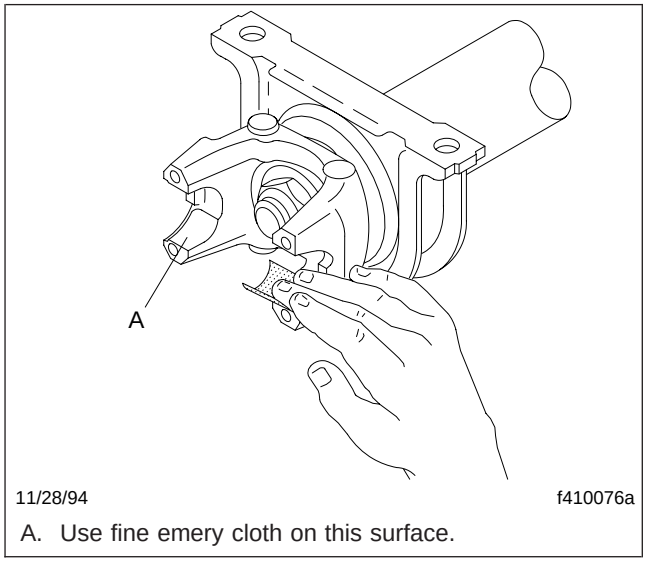


Fig. 2, Removing Burrs From a Half-Round End-Yoke Cross-Hole

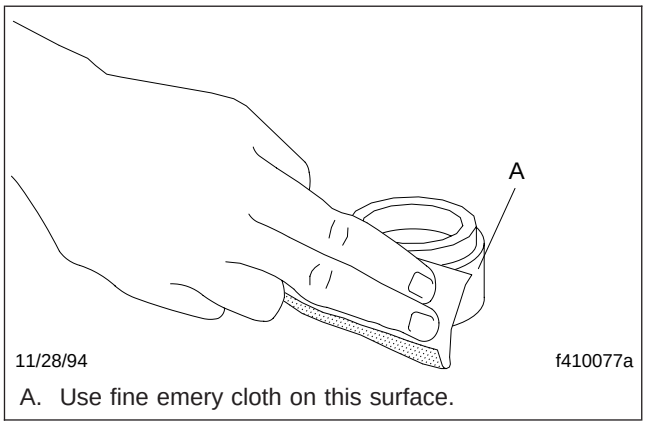
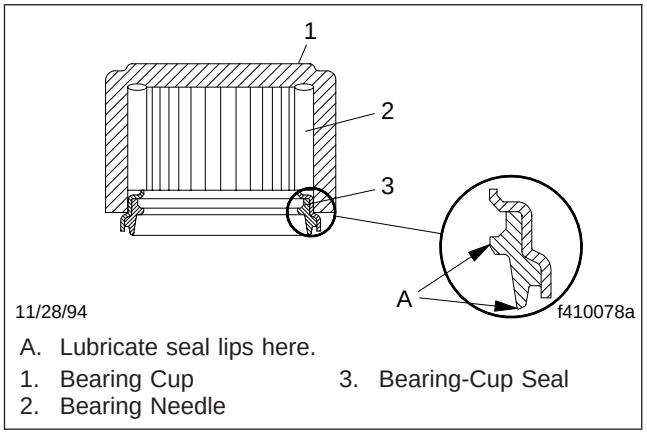


A. Use fine emery cloth on this surface.

Fig. 3, Smoothing a Half-Round End-Yoke Cross-Hole

line separation can cause loss of vehicle control that could result in serious personal injury or death.

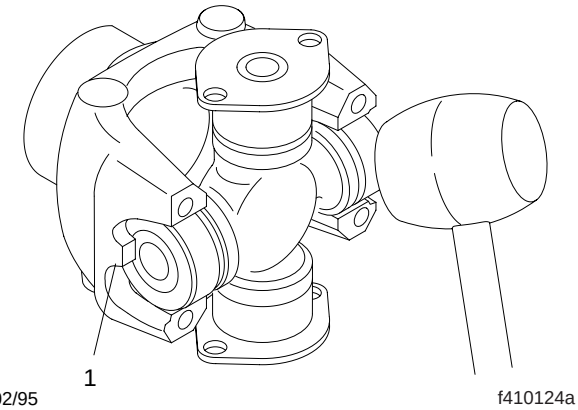


Separation of the driveline can also cause damage to the driveline, driveline components, or other areas of the vehicle.

5. Alternately tighten the bearing-strap capscrews in increments of 20 lbf·ft (27 N·m) to the applicable torque value in **Specifications, 400**.

A. Use fine emery cloth on this surface.

Fig. 4, Smoothing a Half-Round End-Yoke U-Joint Bearing Cup



A. Lubricate seal lips here.
1. Bearing Cup
2. Bearing Needle
3. Bearing-Cup Seal

Fig. 5, Sectional View of a Half-Round End-Yoke U-Joint Bearing Cup

6. If they were removed, install the fasteners that attach each midship bearing to its bracket; tighten the flanged locknuts 91 lbf·ft (123 N·m).
7. Lubricate the U-joint, following the procedure in Group 41 of the *Business Class Trucks Maintenance Manual*.
8. Remove the nylon support straps, then remove the chocks.

U-Joint Uncoupling and Coupling With a Half-Round End-Yoke

1. Retaining Tab

Fig. 6, Seating a U-Joint in a Half-Round End-Yoke

U-Joint Uncoupling and Coupling With a Full-Round End-Yoke

NOTE: It is easier to check driveline parts, and to replace a U-joint or midship bearing assembly if the driveshaft is removed from the vehicle. If a driveshaft requires straightening or balancing, it must be removed, and installed on a lathe or a balance machine. Removal is required for replacement of slip-joint parts, a driveshaft tube, or a tube-yoke. To remove the driveshaft, see **Subject 120**.

Many service operations do not require driveshaft removal from the vehicle: end-yoke or companion-flange nut tightening; drive component shaft seal, end-yoke, or flange-yoke replacement; changing U-joint phasing at the slip-yoke; and transmission or axle removal (for overhaul, repair, or replacement). To perform these operations, uncouple the U-joint at the applicable end of the appropriate driveshaft.

U-Joint Uncoupling (See Fig. 1)

1. Apply the parking brakes, and chock the tires.
2. Turn the appropriate end-yoke until the centerline through its cross-holes is vertical. See **Fig. 1**.
3. Support the driveshaft with a nylon support strap.

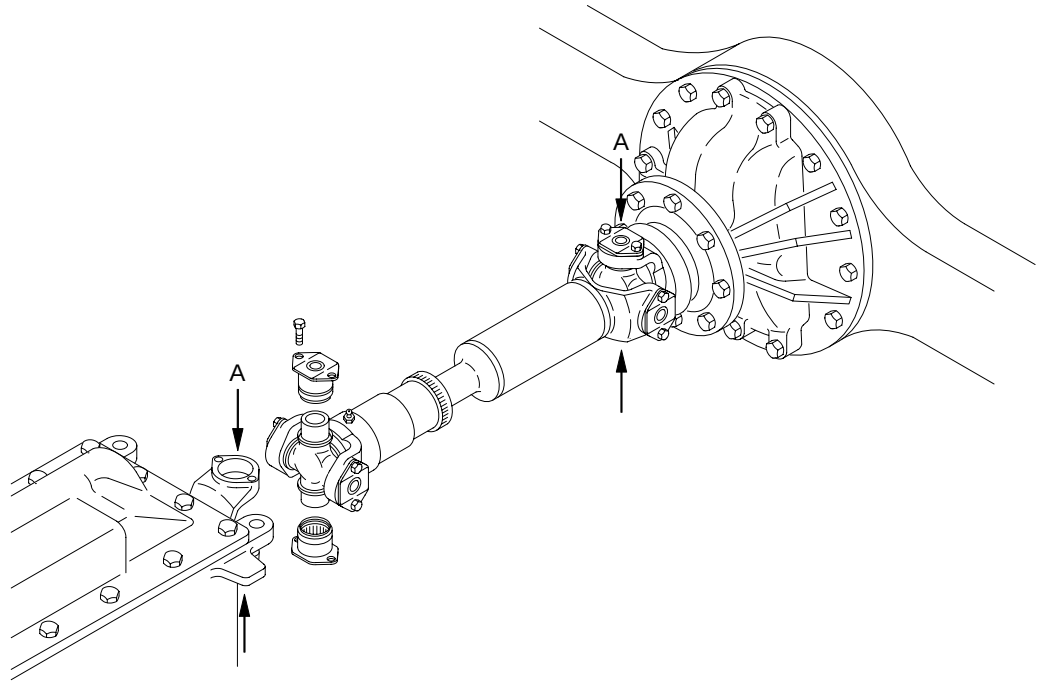
   When uncoupling a coupling shaft, install two or three support straps, as needed. Remove the fasteners that attach the midship bearing(s) to its bracket(s).
4. For a vehicle built from April 1, 1994, remove and discard all four bearing-cup-plate self-locking capscrews.

   For a vehicle built before April 1, 1994, use a pin punch to bend the tabs of the lockplates away from all four of the bearing-cup-plate capscrews. See **Fig. 2**. Remove the capscrews and lockplates.
5. Using one of the U-joint pullers listed in **Specifications 400**, remove both bearing assemblies from the end-yoke cross-holes. See **Fig. 3**.
6. Compress the slip-joint and pivot the end of the U-joint cross to remove it from the yoke. Install the bearing cups, then use tape to secure them to the U-joint cross.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

U-Joint Coupling (See Fig. 1)



1. Check and clean the end-yoke.
   - 1.1 Check the torque on the end-yoke nut; see the applicable table in **Specifications 400**.
   - 1.2 Check the end-yoke cross-holes for burrs or raised metal. Using a rat-tail or half-round file, remove burrs or raised metal. See **Fig. 4**.
   - 1.3 Using a mill file, and holding it flat against the machined surface of the yoke lug, remove any burrs or raised metal. See **Fig. 5**.
   - 1.4 Using fine emery cloth, smooth and clean the entire surface of the yoke cross-holes. See **Fig. 6**.
   - 1.5 Turn the end-yoke until the centerline through its cross-holes are vertical. See **Fig. 1**.
2. Check, clean, and lubricate the U-joint.
   - 2.1 Using fine emery cloth, smooth and clean the outside surfaces of both bearing cups. See **Fig. 7**.
   - 2.2 Check the U-joint trunnions and bearing cups for minute particles of dirt or grit. Clean if necessary; see **Subject 130**.

CAUTION

Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

   - 2.3 Using NLGI grade 2 grease with EP additives, wipe a small amount of grease on the needles in the bearing cups.
   - 2.4 Using a light-weight oil, lubricate the lips of the bearing-cup seals. See **Fig. 8**.

U-Joint Uncoupling and Coupling With a Full-Round End-Yoke

05/02/95 f410148

NOTE: Not all fasteners are shown.
A. End-yoke cross-hole centerline is vertical.

Fig. 1, U-Joint Uncoupling/Coupling of a Driveline With Full-Round End-Yokes

3. Couple the U-joint cross to the end-yoke.

   3.1 Extend the slip-joint, while pivoting the U-joint cross into place in the yoke cross-holes.

   3.2 Move one end of the cross until a trunnion projects through the cross-hole, beyond the outer machined face of the yoke lug. Using a Spicer trunnion (journal) locator (see **Specifications 400**), hold the trunnions in alignment with the cross-holes, while placing a bearing assembly over the projected trunnion, and aligning it with the cross-hole. See **Fig. 9**.

   IMPORTANT: A Spicer trunnion (journal) locator should be used, to prevent damage to the U-joint trunnions and slingers.

   3.3 By hand, press the bearing assembly flush with the face of the yoke. If the bearing assembly binds in the cross-hole, tap the *center* of the bearing plate with a rubber or rawhide mallet; do not tap the outer edges of the bearing plate. See **Fig. 10**.

   3.4 As equipped, install *new* bearing-cup-plate self-locking capscrews (**Fig. 11** for a Spicer U-joint; **Fig. 12** for a Rockwell U-joint), or the lockstrap and bearing-cup-plate (not self-locking) capscrews. Tighten the capscrews until all the parts are drawn down tight, with no gaps; do not tighten the capscrews to their final torque value.

⚠ WARNING

Self-locking bearing-cup-plate capscrews must not be reused; replace the capscrews with new ones. Also, do not undertighten or overtighten any bearing-cup-plate capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could cause serious vehicle damage, or could result in a driveshaft separating from the vehicle, possibly caus-

U-Joint Uncoupling and Coupling With a Full-Round End-Yoke

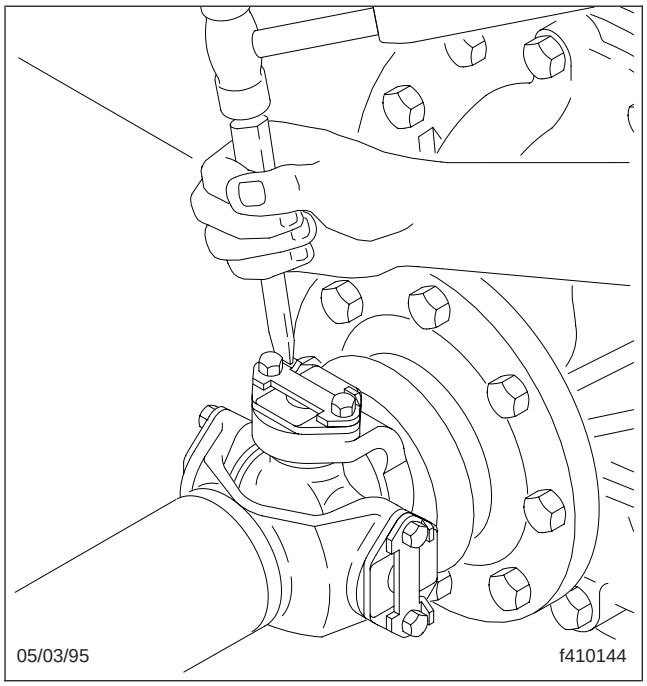


Fig. 2, Bending a Lockplate Tab Away From a U-Joint Capscrew

ing loss of vehicle control that could result in serious personal injury or death.

3.5 Move the cross until it projects beyond the machined surface of the opposite yoke lug. Repeat applicable substeps to install the opposite bearing.

3.6 Alternately tighten the bearing-cup-plate capscrews in increments of 5 lbf·ft (7 N·m), to the torque value in **Specifications 400**.

If equipped with lockplates, use a hammer and a pin punch to bend all four tabs of both lockplates upward until the tabs are firmly against a flat side of each capscrew. See **Fig. 13**.

4. If they were removed, install the fasteners that attach each midship bearing to its bracket; tighten the flanged locknuts 91 lbf·ft (123 N·m).
5. Lubricate the U-joint, following the procedure in Group 41 of the *Business Class Trucks Maintenance Manual*.
6. Remove the nylon support straps, then remove the chocks.

Fig. 12, Rockwell U-Joint Fasteners for Full-Round Yokes

U-Joint Uncoupling and Coupling With a Full-Round End-Yoke

NOTE: Sleeve-yoke shown.

Fig. 13, Bending a Lockplate Tab Against a U-Joint Capscrew

NOTE: Many service operations do not require driveshaft removal from the vehicle: end-yoke or companion-flange nut tightening; drive component shaft seal, end-yoke, or flange-yoke replacement; changing U-joint phasing at the slip-yoke; and transmission or axle removal (for overhaul, repair, or replacement). To perform these operations, uncouple the U-joint at the applicable end of the appropriate driveshaft; see **Subject 100**, for uncoupling from a *half-round* end-yoke, or see **Subject 110**, for uncoupling from a *full-round* end-yoke.

It is easier to check driveline parts, and to replace a U-joint or midship bearing assembly if the driveshaft is removed from the vehicle. If a driveshaft requires straightening or balancing, it must be removed, and installed on a lathe or balance machine. Removal is required for replacement of slip-joint parts, a driveshaft tube, or a tube-yoke.

No. 3 Driveshaft Removal

(See Fig. 1)

1. Uncouple the no. 3 driveshaft from the rearmost axle. If the no. 3 driveshaft is coupled to *half-round* end-yokes, follow the uncoupling procedure in **Subject 100**. If the no. 3 driveshaft is coupled to *full-round* end-yokes, follow the uncoupling procedure in **Subject 110**.
2. Uncouple the no. 3 driveshaft from the forward-rear axle. If the no. 3 driveshaft is coupled to half-round end-yokes, follow the uncoupling procedure in **Subject 100**. If the no. 3 driveshaft is coupled to full-round end-yokes, follow the uncoupling procedure in **Subject 110**.
3. Lift the no. 3 driveshaft out of the chassis.

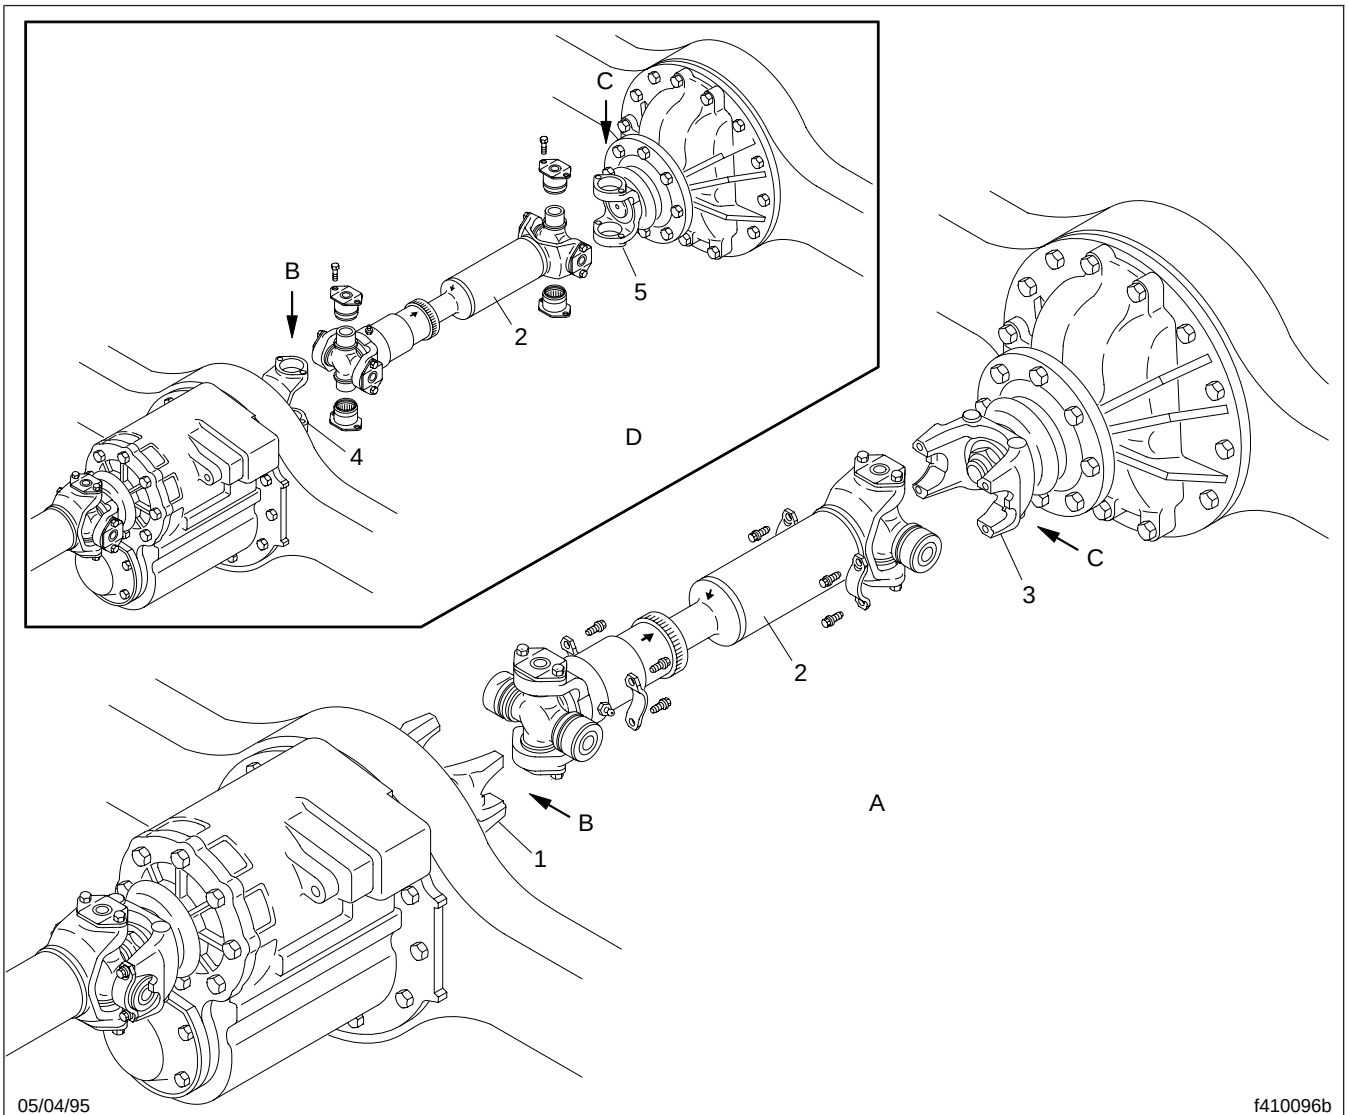
No. 2 Driveshaft Removal

(See Fig. 2)

1. Uncouple the no. 2 driveshaft from the single or forward-rear axle. If the no. 2 driveshaft is coupled to *half-round* end-yokes, follow the uncoupling procedure in **Subject 100**. If the no. 2 driveshaft is coupled to *full-round* end-yokes, follow the uncoupling procedure in **Subject 110**.
2. For a vehicle with a Spicer SPL90 (1590) *coupling shaft*, use a marking stick or paint to mark the sleeve-yoke and coupling shaft with alignment marks, as shown in **Fig. 3**. Then, pull the driveshaft sleeve-yoke off of the midship bearing splined shaft.

   For all other installations, uncouple the no. 2 driveshaft from the transmission or coupling shaft. If the no. 2 driveshaft is coupled to half-round end-yokes, follow the uncoupling procedure in **Subject 100**. If the no. 2 driveshaft is coupled to full-round end-yokes, follow the uncoupling procedure in **Subject 110**.
3. Lift the no. 2 driveshaft out of the chassis.

Intermediate Coupling Shaft Removal **(See Fig. 4)**



1. If the no. 2 driveshaft is also being removed, remove it first.

   If the no. 2 driveshaft is not being removed, use a nylon support strap to support its forward end.
2. For a vehicle with a Spicer SPL90 (1590) coupling shaft, use a marking stick or paint to mark the sleeve-yoke and coupling shaft with alignment marks, as shown in **Fig. 3**.

   For all other installations, uncouple the intermediate coupling shaft from the no. 2 driveshaft. If the intermediate coupling shaft has a *half-round* end-yoke, follow the uncoupling procedure in **Subject 100**. If the intermediate coupling shaft has a *full-round* end-yoke, follow the uncoupling procedure in **Subject 110**.
3. Uncouple the intermediate coupling shaft from the primary coupling shaft. See **Fig. 5**. If the primary coupling shaft has a half-round end-yoke, follow the uncoupling procedure in **Subject 100**. If the primary coupling shaft has a full-round end-yoke, follow the uncoupling procedure in **Subject 110**.

NOTE: If the no. 2 driveshaft was not removed from a vehicle with a Spicer SPL90 (1590) driveline, pull the midship bearing splined shaft out of the no. 2 driveshaft sleeve-yoke. See **Fig. 3**.

Driveshaft Removal and Installation

05/04/95 f410081b

A. Add alignment marks at these locations before separating the parts of the slip-joint.
1. Spicer SPL90 (1590) Coupling Shaft
2. Splined Shaft
3. Sleeve-Yoke
4. No. 2 Driveshaft

Fig. 3, Spicer SPL90 (1590) Coupling Shaft Slip-Joint

If the no. 2 driveshaft is also being removed, remove it first.

If the no. 2 driveshaft is not being removed, use a nylon support strap to support its forward end. For a vehicle with a Spicer SPL90 (1590) coupling shaft, use a marking stick or paint to mark the sleeve-yoke and coupling shaft with alignment marks, as shown in **Fig. 3**.

For a vehicle with two coupling shafts:

If the no. 2 driveshaft is also being removed, remove it first; then, remove the intermediate coupling shaft.

If the intermediate coupling shaft is also being removed (but not the no. 2 driveshaft), remove the intermediate coupling shaft first.

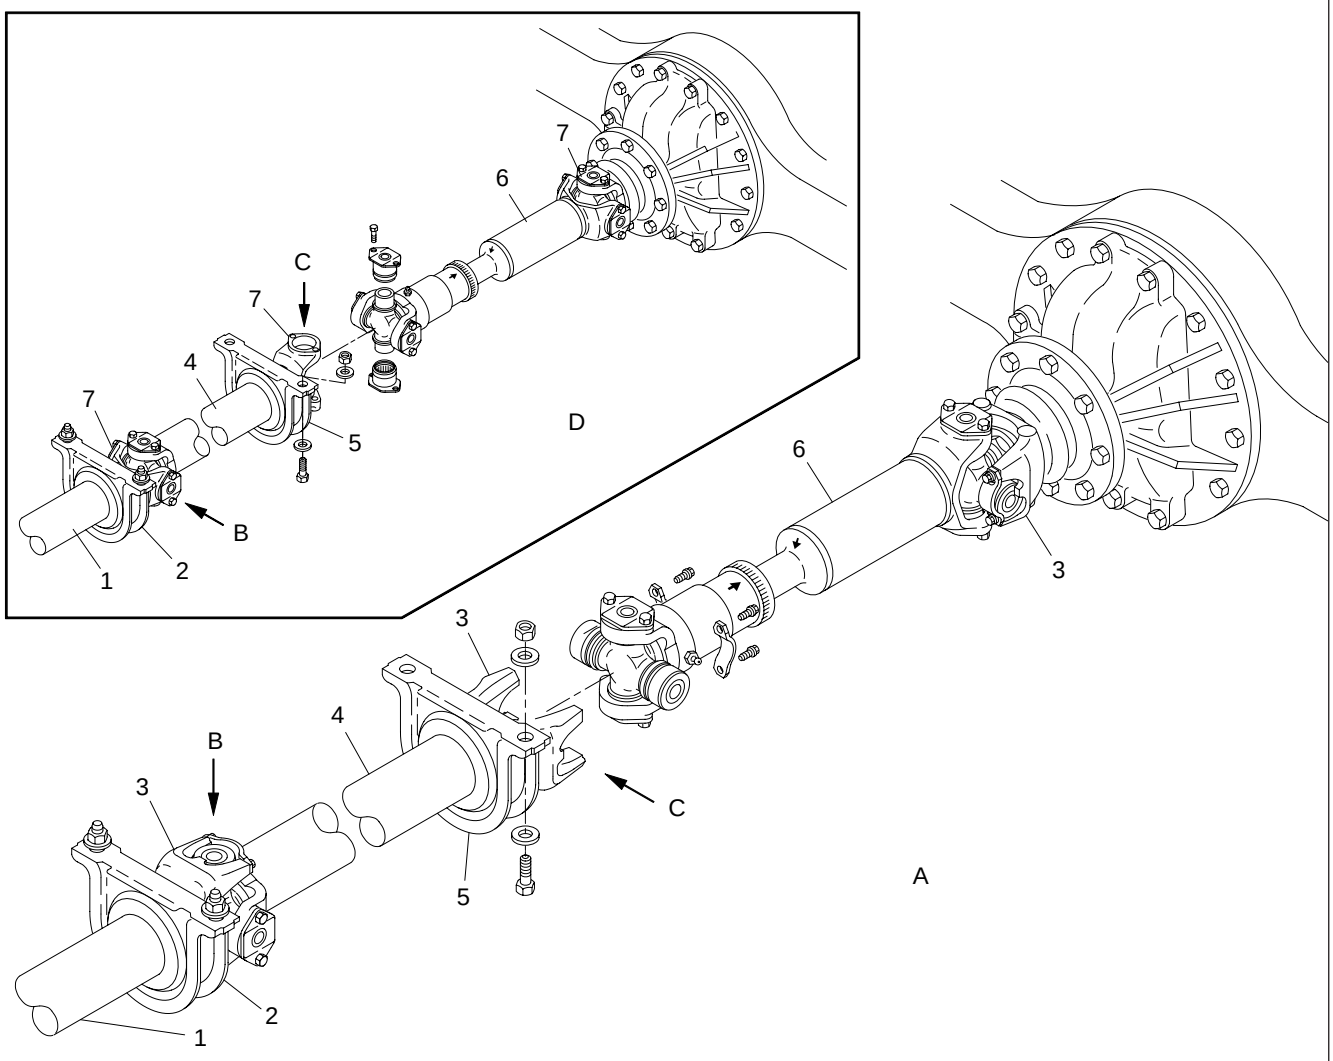
If only the primary coupling shaft is being removed, use nylon support straps to support the forward end of the no. 2 driveshaft and both ends of the intermediate coupling shaft. Then, remove the fasteners that attach the intermediate coupling shaft midship bearing to its bracket. See **Fig. 5**.

2. If not already done, uncouple the primary coupling shaft from the no. 2 driveshaft or intermediate coupling shaft. If the primary coupling shaft has a *half-round* end-yoke, follow the uncoupling procedure in **Subject 100**. If the primary coupling shaft has a *full-round* end-yoke, follow the uncoupling procedure in **Subject 110**.
3. Using two nylon support straps, support the primary coupling shaft. Then remove the fasteners that attach the primary coupling shaft midship bearing to its bracket. See **Fig. 5**.
4. Uncouple the primary coupling shaft from the transmission. If the primary coupling shaft is coupled to a half-round end-yoke, follow the uncoupling procedure in **Subject 100**. If the primary coupling shaft is coupled to a full-round end-yoke, follow the uncoupling procedure in **Subject 110**.

NOTE: If the no. 2 driveshaft was not removed from a vehicle with a Spicer SPL90 (1590) single-coupling-shaft driveline, pull the midship bearing splined shaft out of the no. 2 driveshaft sleeve-yoke. See **Fig. 3**.

5. Lift the primary coupling shaft out of the chassis.

Primary Coupling Shaft Installation (See Fig. 5)



IMPORTANT: Before installing a coupling shaft that has a fixed end-yoke (not a splined reverse-slip shaft), make sure the yokes are aligned to keep the U-joints in phase; see **Fig. 6**.

1. Place the primary coupling shaft under the vehicle and support it with nylon support straps so it can be coupled to the transmission end-yoke.

   If the no. 2 driveshaft was not removed from a vehicle with a Spicer SPL90 (1590) single-coupling-shaft driveline, align the alignment marks **(Fig. 3)** of the coupling shaft and the driveshaft sleeve-yoke, slide the sleeve-yoke over the splined reverse-slip shaft.
2. Couple the shaft to the transmission end-yoke (or flange-yoke). If the primary coupling shaft was coupled to a *half-round* end-yoke, follow the coupling procedure in **Subject 100**. If the primary coupling shaft was coupled to a *full-round* end-yoke, follow the coupling procedure in **Subject 110**.
3. *For a vehicle with one coupling shaft:*

   If the no. 2 driveshaft was also removed, install it, as instructed in this subject.

   If the no. 2 driveshaft was not removed from a vehicle equipped with other than a Spicer SPL90 (1590) driveline, couple it to the primary coupling shaft end-yoke. If the primary coupling shaft has a half-round end-yoke, follow the coupling proce-

05/04/95 f410084b

7. Full-Round End-Yoke

Fig. 5, Removal/Installation of a Primary Coupling Shaft

A. Cross-hole centerlines of both yokes must be in alignment.

Fig. 6, U-Joint Phasing of a Coupling Shaft Equipped With an End-Yoke

For a vehicle with two coupling shafts:

If the intermediate coupling shaft was also removed, install it, as instructed in this subject.

If only the primary coupling shaft was removed, couple the intermediate coupling shaft to the primary coupling shaft end-yoke. If the primary coupling shaft has a half-round end-yoke, follow the coupling procedure in **Subject 100**. If the primary coupling shaft has a full-round end-yoke, follow the coupling procedure in **Subject 110**.

Intermediate Coupling Shaft Installation (See Fig. 4)

IMPORTANT: Before installing a coupling shaft that has a fixed end-yoke (not a splined reverse-slip shaft), make sure the yokes are aligned to keep the U-joints in phase; see **Fig. 6**.

1. If the primary coupling shaft was also removed, install it first, as instructed in this subject.
2. Place the intermediate coupling shaft under the vehicle and support it with nylon support straps so it can be coupled to the primary coupling shaft end-yoke.

   If the no. 2 driveshaft was not removed from a vehicle with a Spicer SPL90 (1590) driveline, align the alignment marks (**Fig. 3**) of the coupling shaft and the driveshaft sleeve-yoke, slide the sleeve-yoke over the splined reverse-slip shaft.
3. Couple the intermediate coupling shaft to the primary coupling shaft end-yoke. If the intermediate coupling shaft was coupled to a *half-round* end-yoke, follow the coupling procedure in **Subject 100**. If the intermediate coupling shaft was coupled to a *full-round* end-yoke, follow the coupling procedure in **Subject 110**.
4. If the no. 2 driveshaft was also removed, install it, as instructed in this subject.

   If the no. 2 driveshaft was not removed from a vehicle equipped with other than a Spicer SPL90 (1590) driveline, couple it to the intermediate coupling shaft end-yoke. If the intermediate coupling shaft has a half-round end-yoke, follow the coupling procedure in **Subject 100**. If the intermediate coupling shaft has a full-round end-yoke, follow the coupling procedure in **Subject 110**.

No. 2 Driveshaft Installation

(See Fig. 2)

IMPORTANT: Before installing a no. 2 driveshaft that has a sleeve-yoke (not a splined reverse-slip shaft) at its forward end, make sure the alignment marks on the slip-joint assembly are aligned, to keep the U-joints in phase; see **Fig. 7**.

A. In Phase B. Out of Phase

Fig. 7, U-Joint Phasing

1. If a primary coupling shaft was also removed, install it first, as instructed in this subject.

Driveshaft Removal and Installation

2. If an intermediate coupling shaft was also removed, install it before installing the no. 2 driveshaft.
3. Place the no. 2 driveshaft under the vehicle with its sleeve-yoke at the forward end, and support its rear end with a nylon support strap.
4. For a vehicle with a Spicer SPL90 (1590) coupling shaft, align the alignment marks (**Fig. 3**) of the coupling shaft and the no. 2 driveshaft sleeve-yoke, then slide the sleeve-yoke over the splined reverse-slip shaft.

   For all other vehicles, couple the sleeve-yoke to the coupling shaft end-yoke or transmission output-shaft end-yoke, as applicable. If the no. 2 driveshaft was coupled to *half-round* end-yokes, follow the coupling procedure in **Subject 100**. If the no. 2 driveshaft was coupled to *full-round* end-yokes, follow the coupling procedure in **Subject 110**.
5. Couple the no. 2 driveshaft to the axle input-shaft end-yoke. If the no. 2 driveshaft was coupled to half-round end-yokes, follow the coupling procedure in **Subject 100**. If the no. 2 driveshaft was coupled to full-round end-yokes, follow the coupling procedure in **Subject 110**.

No. 3 Driveshaft Installation

(See Fig. 1)

IMPORTANT: Before installing a no. 3 driveshaft, make sure the alignment marks on the slip-joint assembly are aligned, to keep the U-joints in phase; see **Fig. 7**.

1. Place the no. 3 driveshaft under the vehicle with its sleeve-yoke at the forward end, and support its rear end with a nylon support strap.
2. Couple the sleeve-yoke to the forward-rear axle output-shaft end-yoke. If the no. 3 driveshaft was coupled to *half-round* end-yokes, follow the coupling procedure in **Subject 100**. If the no. 3 driveshaft was coupled to *full-round* end-yokes, follow the coupling procedure in **Subject 110**.
3. Couple the no. 3 driveshaft to the axle input-shaft end-yoke. If the no. 3 driveshaft was coupled to half-round end-yokes, follow the coupling procedure in **Subject 100**. If the no. 3 driveshaft was coupled to full-round end-yokes, follow the coupling procedure in **Subject 110**.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

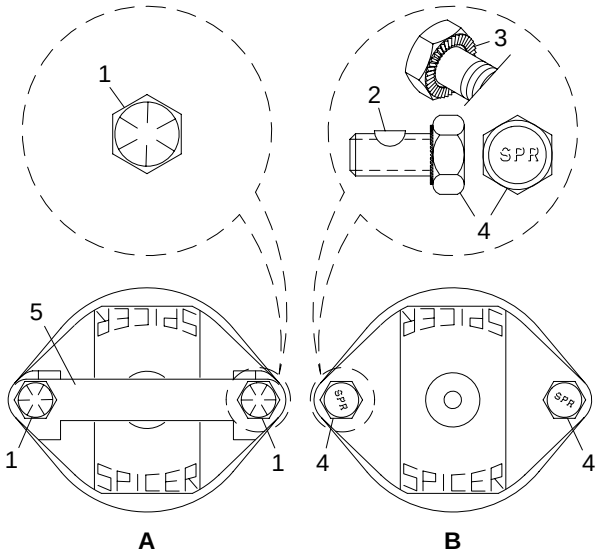
Driveline Parking Brake Flange-Yoke or Companion Flange Removal

For removal of a driveline parking brake flange-yoke or companion flange, see **Group 42**.

Spicer 1610/1710/1760/1810 U-Joint or Rockwell 17/176/18-Series U-Joint Removal

1. Remove the driveshaft from the vehicle; see **Subject 120**.
2. Place the driveshaft in V-blocks or a soft-jawed vise; do not distort the tube with excessive grip.
3. For a vehicle built from April 1, 1994, remove and discard all four bearing-plate self-locking capscrews. See **Fig. 1**, for Spicer U-joints or **Fig. 2** for Rockwell U-joints.

   For a vehicle built before April 1, 1994, use a pin punch to bend the tabs of the lockplates away from all four bearing-cup-plate capscrews. See **Fig. 3**. Remove all four capscrews and both lockplates.



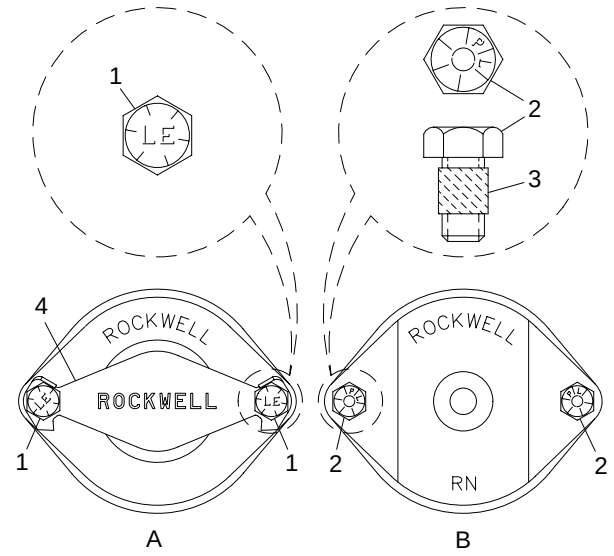
IMPORTANT: If the U-joint will be reinstalled, use care not to nick the cross trunnions or damage the slingers. See **Fig. 4**.

4. Using one of the U-joint pullers listed in **Subject 400**, remove both bearing cups from the yoke cross-holes. See **Fig. 5**. Remove the cross from the yoke.

Spicer SPL90 (1590) U-Joint Removal

1. Remove the driveshaft from the vehicle; see **Subject 110**.
2. Clamp the driveshaft in a soft-jawed vise; do not distort the tube with excessive grip.

NOTE: When removing a U-joint that connects the sleeve-yoke to the forward tube-yoke of the no. 2 driveshaft, mark the sleeve-yoke and driveshaft tube with alignment marks, clamp the driveshaft tube in the vise, and disconnect the U-joint from the tube-yoke, first. Then, clamp the sleeve-yoke in the vise, and remove the U-joint from the sleeve-yoke. See **Fig. 6**.



A. U-Joint With a Lockplate (for a vehicle built before April 1, 1994).
B. U-Joint With Self-Locking Capscrews (for a vehicle built from April 1, 1994).
1. Capscrew (not self-locking)
2. Lock Patch
3. Serrations
4. Self-Locking Capscrew
5. Lockplate

Fig. 1, Spicer U-Joint Fasteners for Full-Round Yokes

3. Remove the U-joint snap rings from the yoke.
   - 3.1 Using a hammer and a soft drift, tap the outside of the bearing cup to loosen the snap ring. See **Fig. 7**. Tap the bearing only hard enough to break the assembly away from the snap ring.
   - 3.2 Using pliers, remove the snap ring. See **Fig. 8**.
   - 3.3 Turn the shaft (or sleeve-yoke) over, then repeat this step for the opposite snap ring.
4. Press the U-joint bearing assemblies and cross out of the yoke. See **Fig. 9**.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

08/13/96 f410033b

A. U-Joint With a Lockplate (for a vehicle built before April 1, 1994).
B. U-Joint With Self-Locking Capscrews (for a vehicle built from April 1, 1994).
1. Capscrew (not self-locking)
2. Self-Locking Capscrew
3. Adhesive Band
4. Lockplate

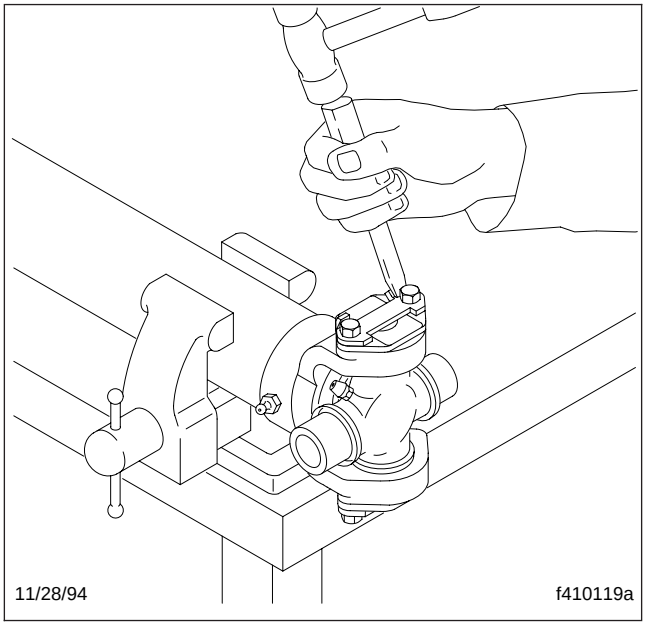


Fig. 2, Rockwell U-Joint Fasteners for Full-Round Yokes

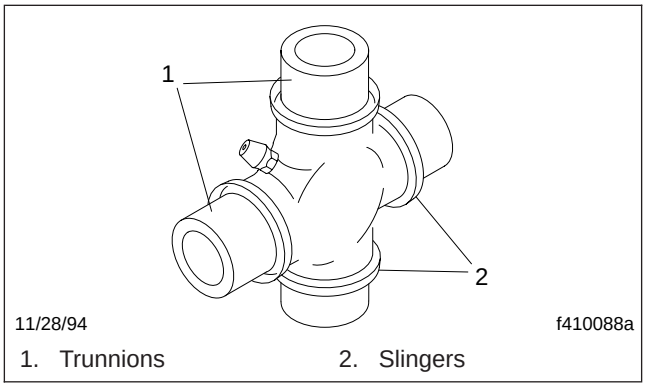
4.1 Set the yoke in an arbor press, on a piece of tube stock with an inside diameter larger than the outside diameter of the bearing cup. See **Fig. 9**.

4.2 Place a solid plug with an outside diameter slightly smaller than the inside diameter of the yoke cross-holes, on the upper bearing assembly. Press it through the upper cross-hole to release the lower bearing assembly.



If the bearing assembly will not pull out by hand after pressing, tap the base of the yoke lug near the bearing assembly to dislodge it.

4.3 Remove the opposite bearing assembly by turning the yoke over, and straightening the cross in the open cross-hole. Then carefully press on the end of the cross so the remaining bearing assembly moves straight out of the cross-hole.

11/28/94 f410119a

Fig. 3, Bending a Lockplate Tab Away From a U-Joint Capscrew

11/28/94 f410088a

1. Trunnions 2. Slingers

Fig. 4, U-Joint Cross

IMPORTANT: If the cross or bearing assembly is cocked, the bearing assembly will score the walls of the cross-hole and ruin the yoke.

Slip-Joint Disassembly

1. Check that the driveshaft yokes are aligned to hold the U-joints at either end in phase, as shown in **Fig. 10**. Using a marking stick or paint,

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

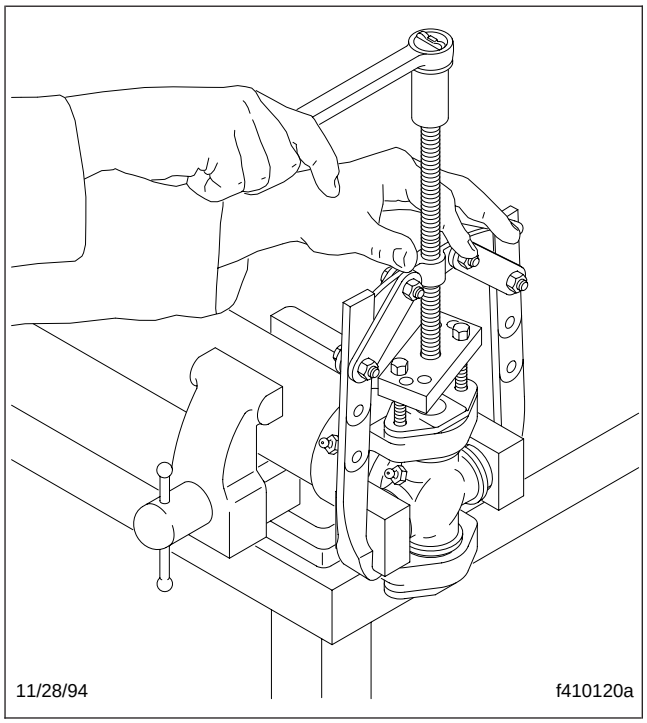


Fig. 5, Removing a Bearing Cup From a Full-Round Yoke

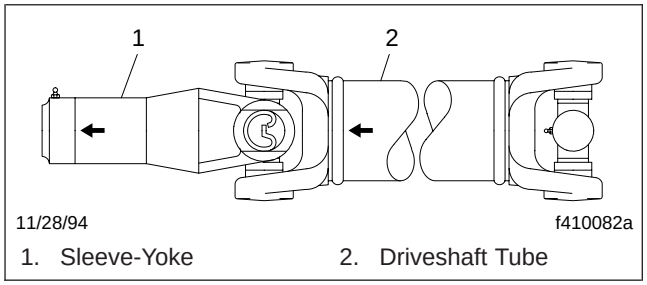

Fig. 6, Spicer SPL90 (1590) No. 2 Driveshaft (as used with a coupling shaft)

mark the sleeve-yoke and splined shaft with alignment marks, as shown in **Fig. 11**. This will ensure proper alignment of the slip-joint components when the driveshaft is assembled.

IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

2. With the driveshaft uncoupled at one end, *or* removed from the vehicle, use a strap wrench to unscrew the slip-joint dust cap from the sleeve-yoke, then pull the sleeve-yoke off of the splined shaft. Remove the dust cap, and (if so equipped) the steel washer and cork seal. See **Fig. 12**.

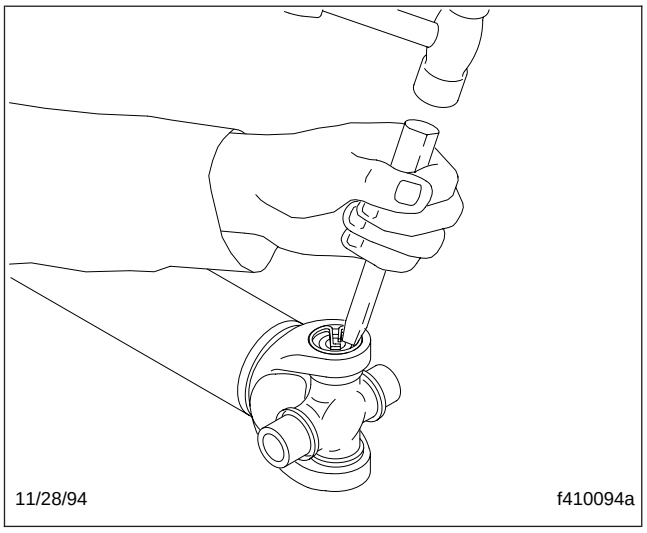

Fig. 7, Loosening a Spicer SPL90 (1590) U-Joint Snap Ring

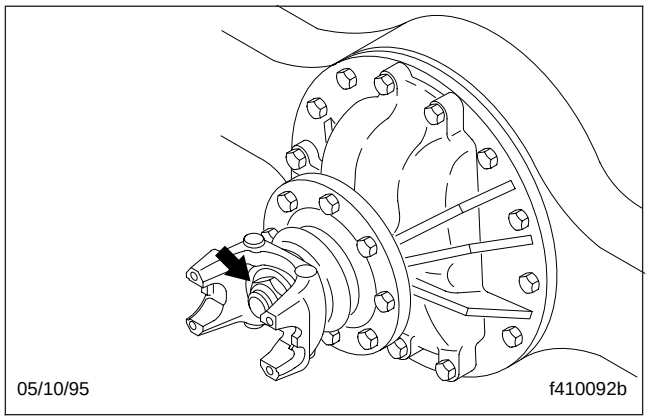
4. Dust Cap
5. Splined Stub Shaft
6. Tube
7. Tube-Yoke

Fig. 12, Slip-Joint Components

Transmission/Axle End-Yoke Removal

IMPORTANT: Before removing a transmission output-shaft end-yoke or an axle shaft end-yoke, do the steps under "End-Yoke Cleaning and Inspection."

1. Uncouple the driveshaft from the end-yoke (**Subject 100** for a half-round yoke or **Subject 110** for a full-round yoke), or remove the driveshaft from the vehicle (**Subject 120**).
2. Remove the end-yoke locknut. See **Fig. 13**.



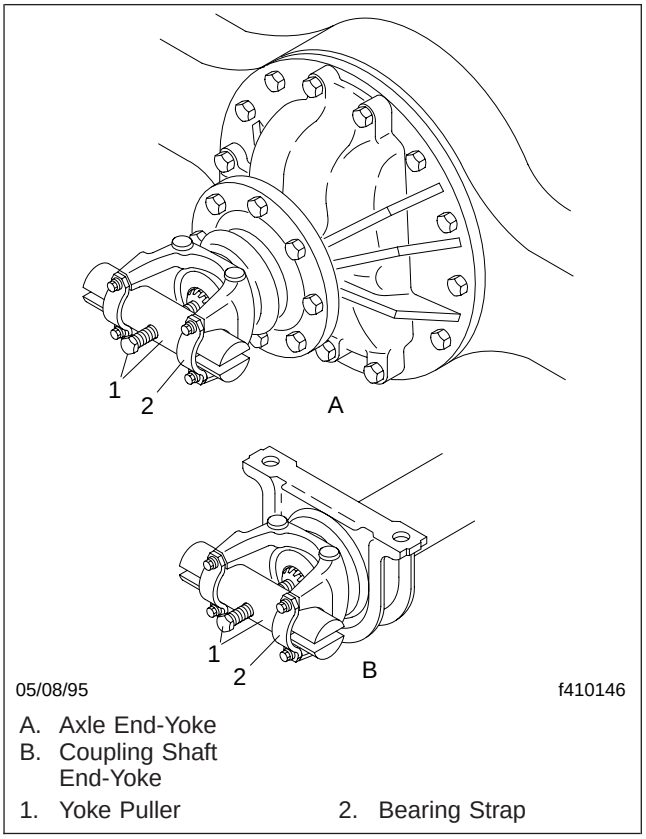


Fig. 13, Axle End-Yoke Locknut

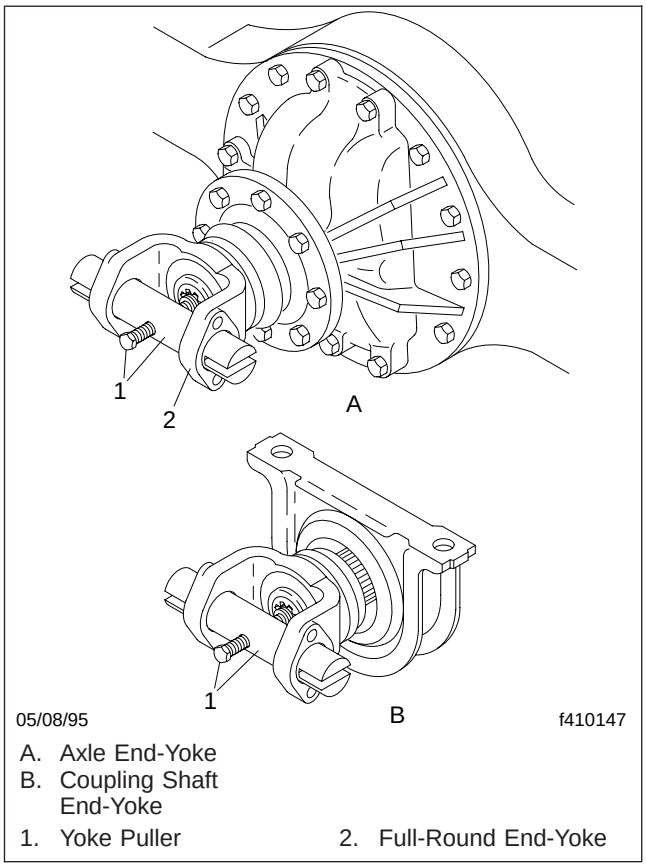
Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

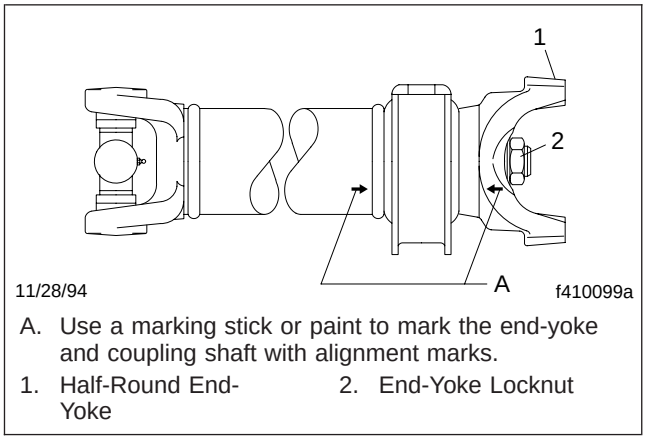
3. Using a yoke puller, remove the end-yoke. See **Fig. 14** for a half-round end-yoke, or **Fig. 15** for a full-round end-yoke.



A. Axle End-Yoke
B. Coupling Shaft End-Yoke
1. Yoke Puller
2. Bearing Strap

Fig. 14, Removing a Half-Round End-Yoke

Coupling Shaft End-Yoke and Midship Bearing Removal



1. Remove the coupling shaft from the vehicle; see **Subject 120**.
2. Clamp the coupling shaft in a soft-jawed vise; do not distort the tube with excessive grip.
3. If the coupling shaft has an end-yoke (**Fig. 16**), not a splined reverse-slip shaft, go to the next step.

   If the coupling shaft has a splined reverse-slip shaft, not an end-yoke (**Fig. 17**), use a hammer and a brass drift to remove the midship bearing and slingers. See **Fig. 18**.

A. Axle End-Yoke
B. Coupling Shaft End-Yoke
1. Yoke Puller
2. Full-Round End-Yoke

Fig. 15, Removing a Full-Round End-Yoke

A. Use a marking stick or paint to mark the end-yoke and coupling shaft with alignment marks.
1. Half-Round End-Yoke
2. End-Yoke Locknut

Fig. 16, Alignment Marks on a Coupling Shaft With an End-Yoke

4. If the coupling shaft has an end-yoke, remove the end-yoke; see **Fig. 14** for a half-round end-

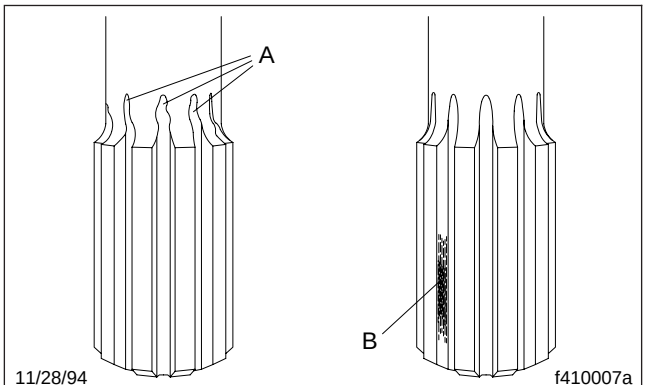
2. Slinger
3. Midship Bearing

Fig. 18, Midship Bearing and Slingers

yoke, or **Fig. 15** for a full-round end-yoke. Then, remove the midship bearing and slingers; see **Fig. 18**.

4.1 Use a marking stick or paint to mark the end-yoke and coupling shaft with alignment marks. See **Fig. 16**.

4.2 Remove the coupling shaft end-yoke locknut.



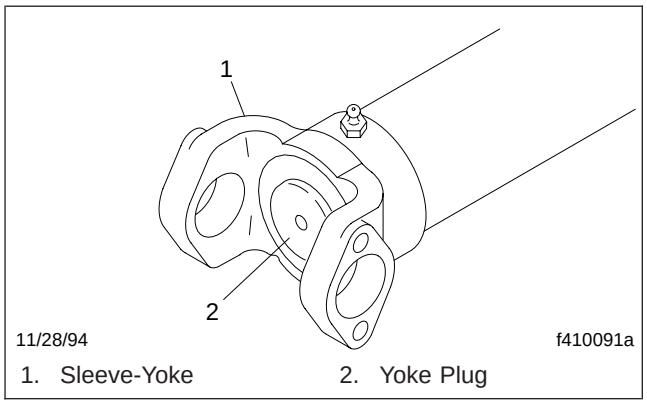
4.3 Using a yoke puller, remove the end-yoke. See **Fig. 14** for a half-round end-yoke, or **Fig. 15** for a full-round end-yoke.

4.4 Use a hammer and a brass drift to remove the midship bearing and slingers. See **Fig. 18**.

Driveshaft Tube, Slip-Joint, Sleeve-Yoke, and Tube-Yoke Cleaning and Inspection

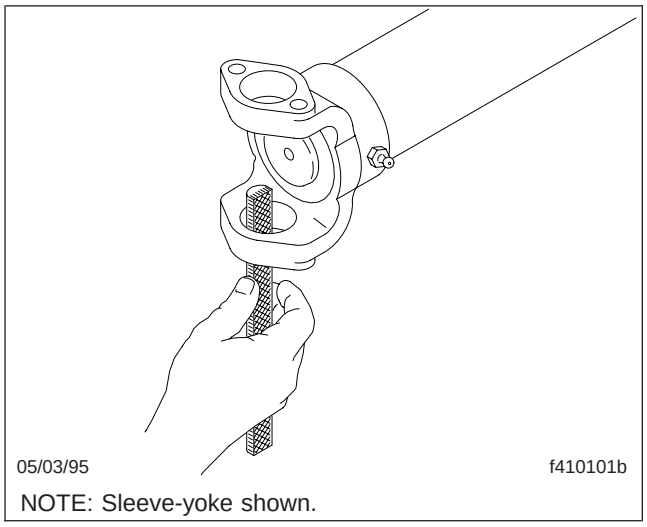
1. With the driveshaft removed, scrape or soak away any foreign material.
2. Examine the driveshaft tube for dents, bends, twists, splitting weld-seams, and signs of missing balance weights.

   Replace the driveshaft tube if damaged; see "Driveshaft Tube, Stub Shaft (Slip-Joint), or Tube-Yoke Replacement." If balance weights appear to be missing, have the driveshaft balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.
3. Clean the slip-joint (male and female) splines, then check them for twisting and galling. See **Fig. 19**. Replace both the sleeve-yoke and the splined shaft if the slip-joint is damaged; see "Slip-Joint Replacement or Assembly" and "Driveshaft Tube, Stub Shaft (Slip-Joint), or Tube-Yoke Replacement." Remove any burrs or rough spots using fine emery cloth.



A. Twisted Splines
B. Galling

Fig. 19, Damaged Slip-Joint Splines

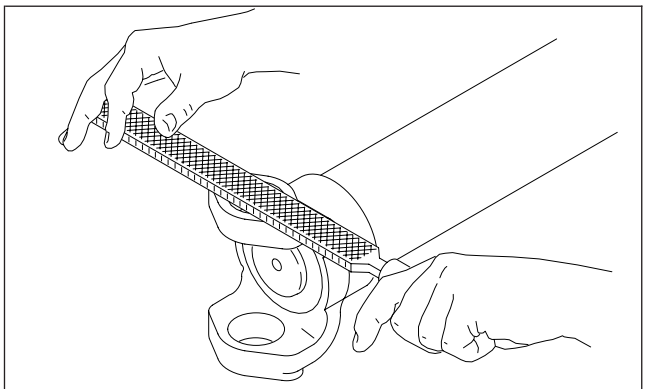


4. Check for a loose or missing sleeve-yoke plug. See **Fig. 20**. Repair or replace the plug as needed.
5. With the U-joint assemblies removed, check all driveshaft yoke cross-holes for raised metal. Using a rat-tail or half-round file, remove burrs or raised metal. See **Fig. 21**.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

1. Sleeve-Yoke 2. Yoke Plug

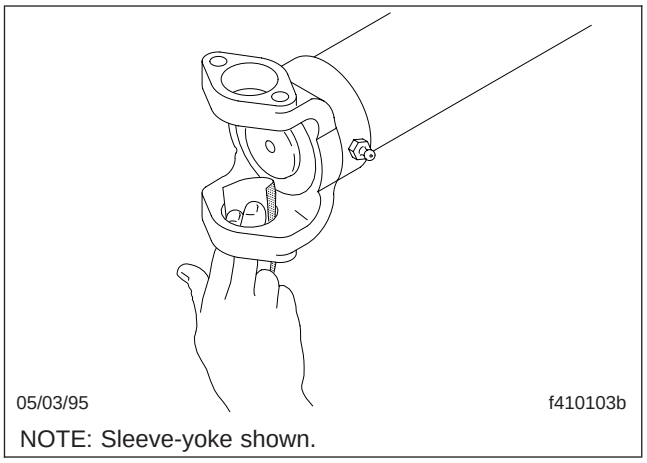
Fig. 20, Sleeve-Yoke Plug



NOTE: Sleeve-yoke shown.

Fig. 21, Removing Burrs From a Full-Round Yoke Cross-Hole

6. Using a mill file, and holding it flat against the machined surface of the driveshaft yoke lug, file each yoke lug, to remove any burrs or raised metal. See **Fig. 22**.
7. Using fine emery cloth, smooth and clean the entire surface of all driveshaft yoke cross-holes. See **Fig. 23**.



Midship Bearing Cleaning and Inspection

1. With the midship bearing removed from the coupling shaft, use clean rags or paper towels to wipe off the outside of the midship bearing, rubber cushion, and slingers.

NOTE: Sleeve-yoke shown.

Fig. 22, Removing Burrs From the Machined Surface of a Full-Round Yoke Lug

NOTE: Sleeve-yoke shown.

Fig. 23, Smoothing a Full-Round Yoke Cross-Hole

IMPORTANT: Do not immerse the midship bearing in cleaning solvent. The solvent will wash out the lubricant, requiring bearing-assembly replacement.

2. Check the midship bearing for roughness or rattles by holding the outside of the bearing while manually turning the inner bearing race. Replace the bearing assembly if there are any rough spots or rattles.
3. Check the rubber cushion for deterioration or oil-soaking, and replace the midship bearing assembly if needed.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

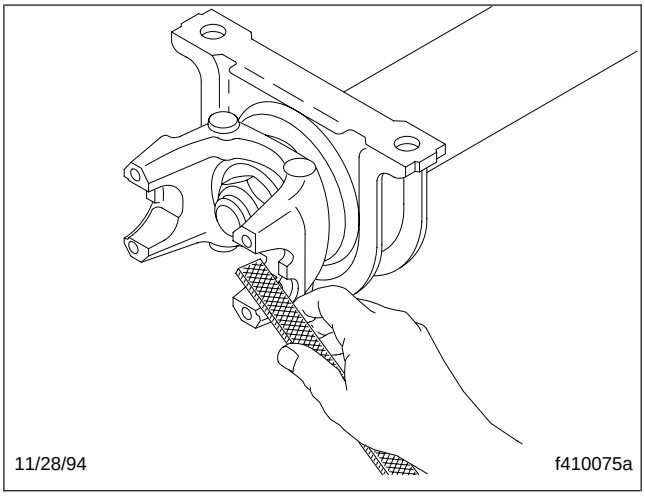
End-Yoke Cleaning and Inspection

1. With the transmission output-shaft and axle shaft end-yokes installed, check them for cracks and looseness.

   Replace cracked yokes. If the end-yoke can be moved in or out on its shaft, or can be rocked on its shaft, uncouple the driveshaft from the end-yoke. Check the drive component's shaft seal for leakage or other visible damage that may have been caused by the loose yoke. Replace the shaft seal if needed. Tighten the end-yoke nut to the torque value given in **Subject 400**. If the end-yoke is still loose after tightening the yoke nut, install a new yoke and yoke nut.

NOTE: If the end-yoke locknut is removed for any reason, install a new one.

2. With the U-joints uncoupled from the end-yokes, check all driveshaft and input/output shaft end-yoke cross-holes for raised metal. Using a rat-tail or half-round file, remove burrs or raised metal. See **Fig. 21** for full-round yokes, or **Fig. 24** for half-round yokes.



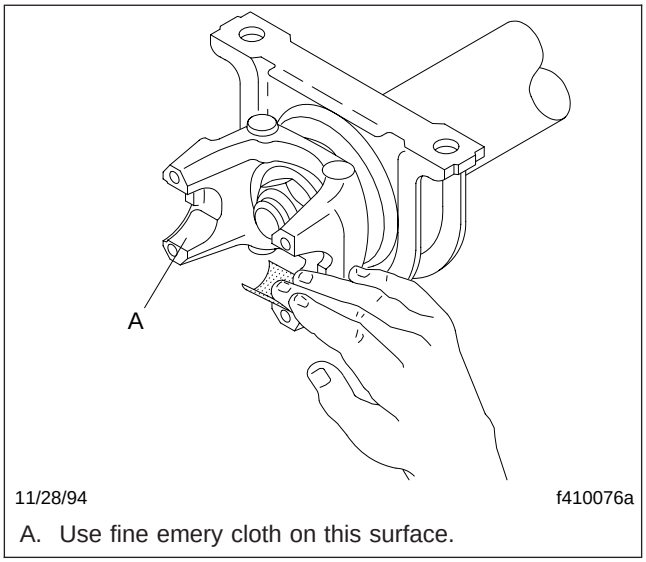


Fig. 24, Removing Burrs From a Half-Round End-Yoke Cross-Hole

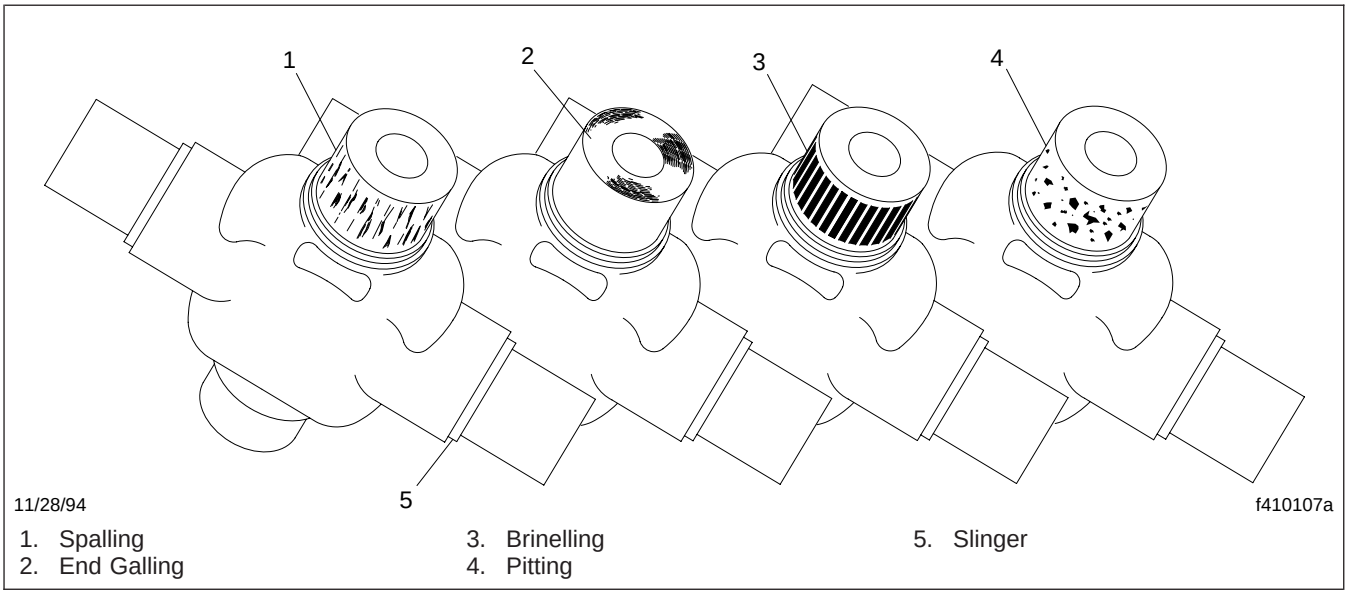
3. Using a mill file, and holding it flat against the machined surface of the *full-round* end-yoke lug, file each yoke lug, to remove any burrs or raised metal. See **Fig. 22**.

4. Smooth and clean the entire surface of all end-yoke cross-holes, using fine emery cloth. See **Fig. 23** for full-round yokes, or **Fig. 25** for half-round yokes.

A. Use fine emery cloth on this surface.

Fig. 25, Smoothing a Half-Round End-Yoke Cross-Hole



U-Joint Cleaning and Inspection

1. With the U-joints removed from the yokes, and the bearing cups removed from the crosses, inspect the U-joint cross slingers for damage, then inspect the U-joint trunnions for spalling (flaking metal), end galling (displacement of metal), brinelling (grooves caused by bearing needles), and pitting (small craters caused by corrosion). See **Fig. 26**. If damaged, replace the U-joint assembly.

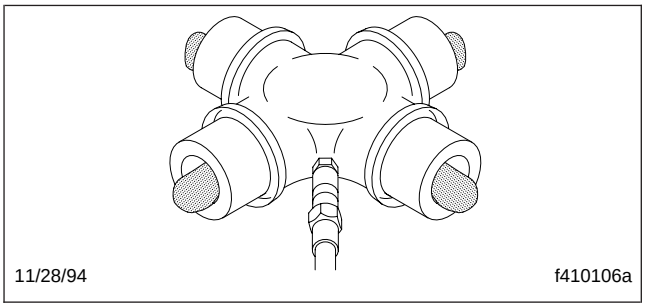
2. Using a hand-type grease gun, apply multipurpose chassis grease to the fitting on each U-joint cross until all old lubricant is forced out. See **Fig. 27**. Examine the old lubricant. If it appears rusty, gritty, or burnt, replace the U-joint assembly.

3. Soak the bearing cups in a non-flammable cleaner until particles of grease and foreign matter are loosened or dissolved. Do not disassemble the bearing cups; clean the bearing needles with a short, stiff brush, then blow them

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

1. Spalling
2. End Galling
3. Brinelling
4. Pitting
5. Slinger

Fig. 26, Damaged U-Joint Crosses



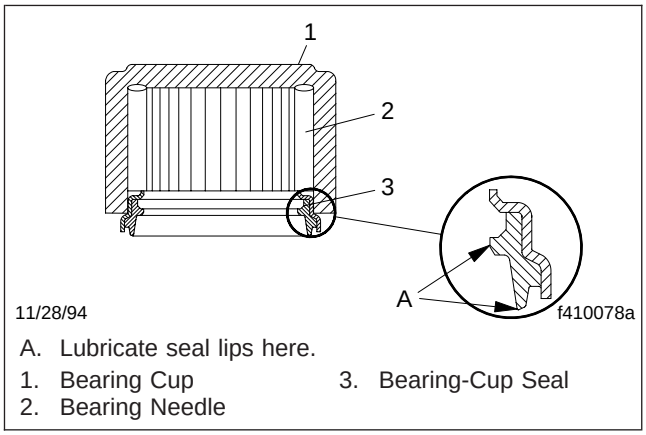


Fig. 27, Forcing Out Old Lubricant From a U-Joint Cross

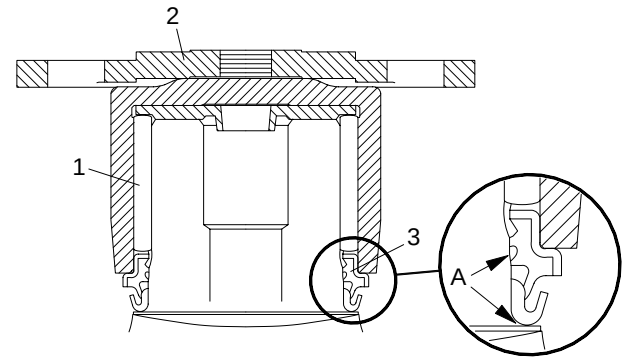
dry with compressed air. Check for minute particles of dirt or grit, and clean again if necessary.

4. Check each bearing cup for missing bearing needles. Check the bearing-cup seals for nicks. See **Fig. 28** for a half-round-yoke U-joint bearing cup, or **Fig. 29** for a full-round-yoke U-joint bearing cup. Replace the U-joint assembly if any bearing needles are missing or any seals are damaged.
5. Apply a small quantity of multipurpose chassis grease to the bearing needles in each cup, then apply a small amount of light-weight oil to the lips of the bearing-cup seals. Rotate each bearing cup on the cross to check for wear. Replace the U-joint assembly if any bearing surfaces are worn.

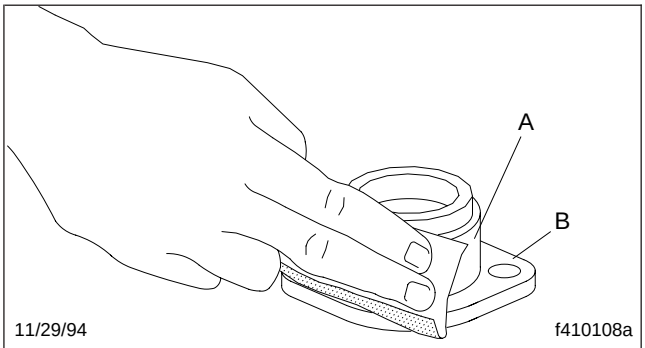


A. Lubricate seal lips here.

1. Bearing Cup
2. Bearing Needle
3. Bearing-Cup Seal

Fig. 28, Sectional View of a Half-Round End-Yoke U-Joint Bearing Cup

6. Check the underside of each bearing-cup plate for burrs or raised metal. Use a mill file to remove any burrs or raised metal. See **Fig. 30**.
7. Using fine emery cloth, smooth and clean the outside surfaces of all bearing cups. See **Fig. 30** and **Fig. 31**.



Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

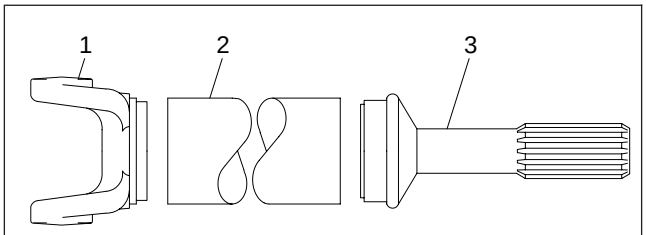
B. Use a mill file on this surface.

Fig. 30, Smoothing a Full-Round Yoke U-Joint Bearing Cup

Driveshaft Tube, Stub Shaft (Slip-Joint), and Tube-Yoke Replacement

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.



To replace a driveshaft tube, a tube-yoke, or a stub shaft (**Fig. 32**), the driveshaft must be chucked in a lathe, so the welds can be removed. Driveshaft rebuilding should be done by a machine shop that specializes in driveline repair.

11/28/94 f410077a

A. Use fine emery cloth on this surface.

Fig. 31, Smoothing a Half-Round Yoke U-Joint Bearing Cup

11/29/94 f410109a

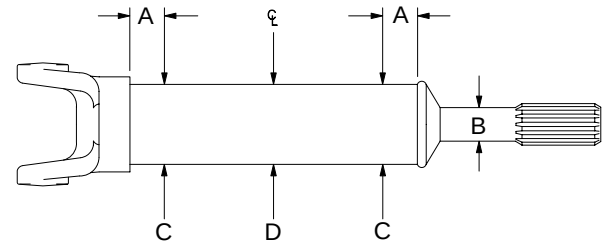
1. Tube-Yoke
2. Driveshaft Tube
3. Stub Shaft

Fig. 32, Driveshaft Tube, Stub Shaft, and Tube-Yoke

Runout limits for a new (rebuilt) driveshaft (**Fig. 33**) are:

0.005 in (0.127 mm) T.I.R. (Total Indicator Reading) on the smooth portion of the stub shaft neck;

0.010 in (0.254 mm) T.I.R. on the tube 3 in (76 mm) from the front and rear welds;



0.015 in (0.381 mm) T.I.R. at the center of the tube.

Balance the rebuilt driveshaft to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

Slip-Joint Replacement or Assembly

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

A. Measurement: 3" (76 mm)
B. Measurement: 0.015" (0.38 mm)
C. Measurement: 0.020" (0.51 mm)
D. Measurement: 0.025" (0.635 mm)

Fig. 33, Driveshaft Runout Specifications

or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

1. Place the slip-joint dust cap, and (if so equipped) steel washer and cork seal, over the splined shaft. See **Fig. 12**.
2. Coat the splines of the shaft with multipurpose chassis grease.
3. Insert the splined shaft in the sleeve-yoke, so that the alignment marks are aligned, and the U-joints at each end of the driveshaft will be in phase. See **Fig. 10** and **Fig. 11**.

IMPORTANT: If no alignment marks are visible, or new slip-joint components have been installed, align the yokes, assemble the slip-joint, then have the driveline balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

4. Using a strap wrench, tighten the slip-joint dust cap. Use only enough torque to seat the steel washer and cork seal (if so equipped) snug against the end of the sleeve-yoke; do not overtighten.

NOTE: The splines should slide freely, with only a slight drag from the slip-joint dust cap.

Midship Bearing and Coupling Shaft End-Yoke Replacement or Assembly

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

1. Place the coupling shaft in a soft-jawed vise; do not distort the tube with excessive grip.
2. Fill the entire cavity around the midship bearing with a waterproof grease, to shield the bearing from water and contaminants. Use enough grease to fill the cavities to the extreme edge of the slingers that surround the front and rear of the bearing. See **Fig. 34**.

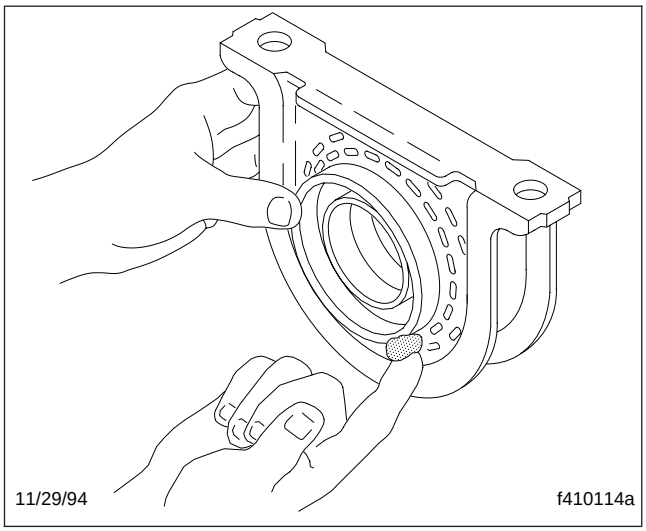


Fig. 34, Greasing a Midship Bearing

NOTE: Both Spicer and Rockwell midship bearings are permanently lubricated when manufactured; it is not necessary to pack the bearing with grease.

3. Install one of the slingers, the midship bearing, then the other slinger on the coupling shaft. Press the bearing and slingers on by hand, as far as they will go.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

4. If the coupling shaft has a splined reverse-slip shaft (not an end-yoke), coat the shaft splines with multipurpose chassis grease. See **Fig. 17**.

   If the coupling shaft has an end-yoke, install the end-yoke. See **Fig. 16**.

   4.1 Apply Loctite® 242 to the shaft threads where the end-yoke locknut will be installed.

   4.2 Align the marks added to the coupling shaft and end-yoke during removal, then place the end-yoke on the shaft so the yoke bores are aligned at both ends of the shaft. See **Fig. 16**.

   4.3 Install the end-yoke nut, and tighten it 475 to 525 lbf·ft (645 to 710 N·m). Then back the nut off slightly, and tighten it to the same torque.

Spicer 1610/1710/1760/1810 U-Joint or Rockwell 17/176/18-Series U-Joint Replacement or Installation

IMPORTANT: Parts for different series drivelines must not be intermixed. Also, components of the various makes of U-joints may not be interchangeable, and must be assembled only with compatible products. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

Worn bearing assemblies used with a new cross, or new bearing assemblies used with a worn cross will wear rapidly, making another replacement necessary in a short time. Always replace the cross and all four bearing assemblies at the same time.

If the slip-joint of a no. 2 or no. 3 driveshaft has been disassembled, assemble the slip-joint before installing the U-joints.

1. Place the assembled driveshaft in V-blocks or a soft-jawed vise; do not distort the tube with excessive grip.

2. For a no. 2 or no. 3 driveshaft, check that the slip-joint alignment marks are aligned, so that the U-joints at each end of the driveshaft will be in phase. See **Fig. 10** and **Fig. 11**.

   For a coupling shaft, check that the end-yoke and tube-yoke are aligned, so that the U-joints at each end of the coupling shaft will be in phase. See **Fig. 16**.

IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

3. Inspect and lubricate the U-joint.

   3.1 Remove the bearing cups from the cross. Inspect the bearing-cup seals for nicks or other damage. See **Fig. 28** for a half-round-yoke U-joint bearing cup, or **Fig. 29** for a full-round-yoke U-joint bearing cup.

⚠ CAUTION

CAUTION: Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

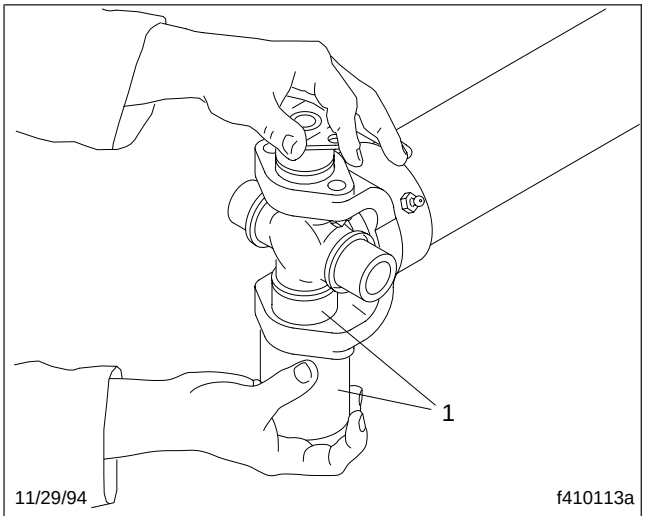
   3.2 Using a hand-type grease gun, or a high-pressure gun equipped with a low-pressure adapter, fill the lube passages in the cross with multipurpose chassis grease (lithium 12-hydroxy stearate, NLGI grade 2 with EP additives). See **Fig. 27**.

   3.3 Wipe a heavy coating of the same grease on the needles and the inside end of each bearing cup; then, using a lightweight oil, lubricate the lips of the bearing-cup seals. See **Fig. 28** for a half-round-yoke U-joint bearing cup, or **Fig. 29** for a full-round-yoke U-joint bearing cup.

4. Install the U-joint cross and bearing assemblies in the yoke.

   4.1 Position the U-joint cross in the driveshaft yoke so one grease fitting points toward the driveshaft, and aligns with the grease fitting on the sleeve-yoke (if so equipped). See **Fig. 35**.

   4.2 Move one end of the cross until a trunnion projects through the cross-hole, beyond the outer machined face of the yoke lug. Using a Spicer trunnion (journal) locator (see **Subject 400**), hold the trun-



Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

A. Install cross with grease fitting pointing toward driveshaft, and aligned with sleeve-yoke grease fitting.

Fig. 35, U-Joint Grease Fitting Positioning

nions in alignment with the cross-holes, while placing a bearing cup (plate-type) over the projected trunnion, and aligning it with the cross-hole. See **Fig. 36**.

NOTE: Sleeve-yoke shown.
1. Trunnion Locator

Fig. 36, Using a U-Joint Trunnion Locator

IMPORTANT: A Spicer trunnion (journal) locator should be used, to prevent damage to the U-joint trunnions and slingers.

4.3 By hand, press the bearing-cup-plate flush with the face of the yoke. If the bearing cup binds in the cross-hole, tap the *center* of the bearing-cup plate with a leather or rubber mallet; do not tap the outer edges of the plate. See **Fig. 37**.

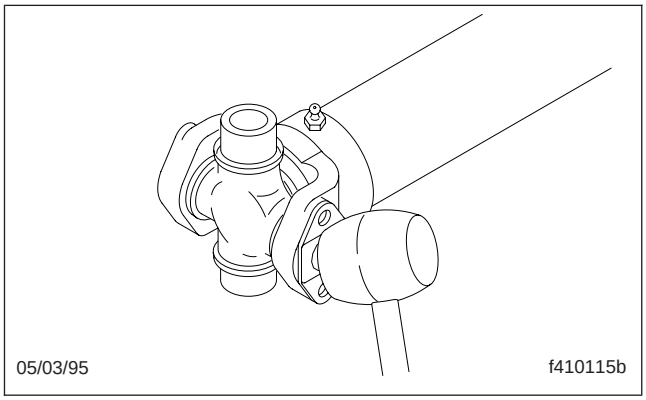


Fig. 37, Seating a U-Joint Bearing Cup In a Full-Round Yoke

4.4 As equipped, install *new* bearing-cup-plate self-locking capscrews, or the lock-plate and bearing-cup-plate (not self-locking) capscrews. See **Fig. 1** for Spicer U-joints, or **Fig. 2** for Rockwell U-joints. Tighten the capscrews until all the parts are drawn down tight, with no gaps; do not tighten the capscrews to their final torque value.

⚠ WARNING

WARNING: Self-locking bearing-cup-plate capscrews must not be reused; replace the capscrews with new ones. Also, do not undertighten or overtighten any bearing-cup-plate capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could cause serious vehicle damage, or could result in a driveshaft separating from the vehicle, possibly causing loss of vehicle control that could result in serious personal injury or death.

4.5 Move the cross until it projects beyond the machined surface of the opposite yoke lug. Using the above procedure, install the opposite bearing assembly and its fasteners.

4.6 Slightly back off all four capscrews, then alternately tighten them in increments of 5 lbf·ft (7 N·m), to the applicable torque value in **Subject 400**.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

4.7 If so equipped, bend the tabs of both lockplates upward (using a hammer and a pin punch) until they are firmly against a flat side of each capscrew. See **Fig. 38**.

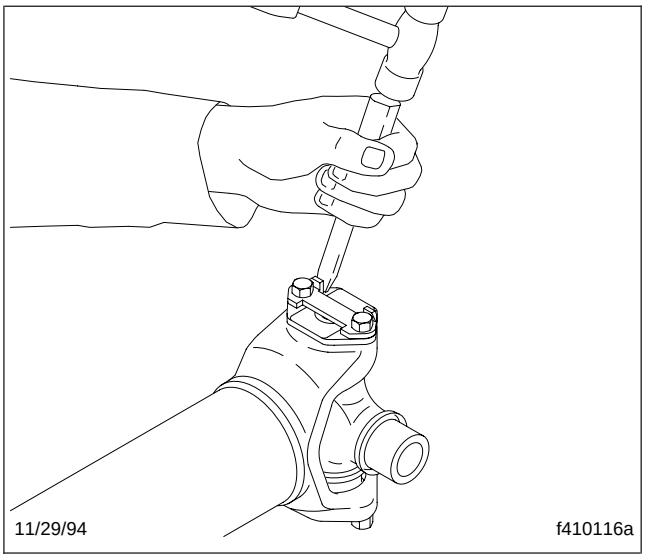

Fig. 38, Bending a Lockplate Tab Against a U-Joint Capscrew

NOTE: The U-joint should flex, and be free of excessive bind. A slight drag is the most desirable condition for new U-joints. Excessive looseness is not desirable, and may result in an unbalanced driveshaft.

Spicer SPL90 (1590) U-Joint Replacement or Installation

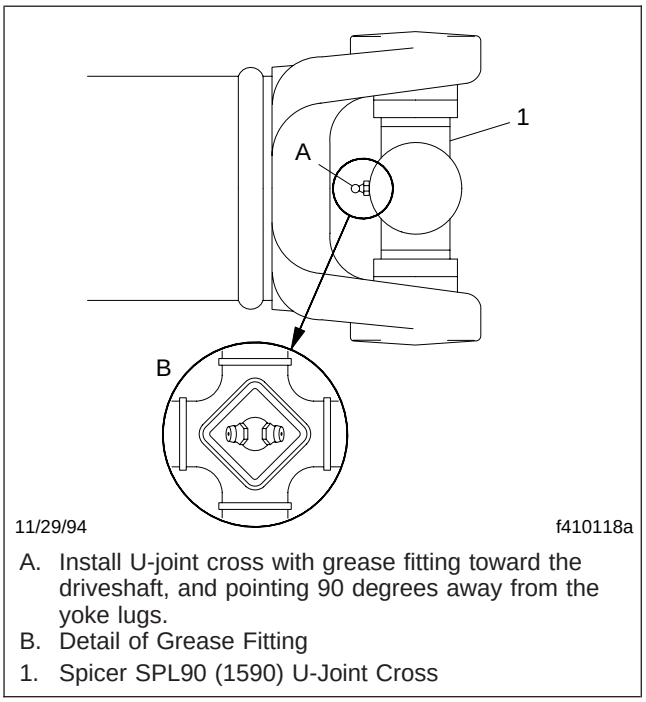
IMPORTANT: Worn bearing assemblies used with a new cross, or new bearing assemblies used with a worn cross will wear rapidly, making another replacement necessary in a short time. Always replace the cross and all four bearing assemblies at the same time.

1. Place the driveshaft in V-blocks or a soft-jawed vise; do not distort the tube with excessive grip.
2. For a no. 2 driveshaft that has a sleeve-yoke (not a splined reverse-slip shaft) at its forward end, make sure the alignment marks on the slip-joint assembly are aligned, to keep the U-joints in phase. See **Fig. 10** and **Fig. 11**.

IMPORTANT: Misaligned driveshaft yokes will cause the U-joints to be out of phase, which will cause vibration in the driveline.

NOTE: For a no. 2 driveshaft that has a splined reverse-slip shaft, install the U-joint in the sleeve-yoke first. Next, align the alignment marks that were added to the sleeve-yoke and driveshaft tube, then connect the U-joint to the forward tube-yoke of the driveshaft. See **Fig. 6**.

For a coupling shaft that has an end-yoke and a tube-yoke, check that the yokes are aligned, so that the U-joints at each end of the coupling shaft will be in phase. See **Fig. 16**.



3. Lubricate the U-joint.
   - 3.1 Using a hand-type grease gun, or a high-pressure gun equipped with a low-pressure adapter, fill the lube passages in the cross with multipurpose chassis grease (lithium 12-hydroxy stearate, NLGI grade 1 or 2 with EP additives). See **Fig. 27**.
   - 3.2 Wipe a heavy coating of the same grease on the needles of each bearing cup, and pack each bearing cup about one-quarter full of grease. See **Fig. 28**.

⚠ CAUTION

CAUTION: Do not expose the U-joint trunnions or bearing-cup needles to dirt or grit. The smallest bits of dirt or grit can cause rapid wear and serious damage to the U-joint.

4. Install the U-joint cross and bearing assemblies in the yoke.
   - 4.1 Position the U-joint cross in the yoke with its lube fitting on the inboard side (toward the driveshaft) and pointing 90 degrees away from the driveshaft yoke lugs. See **Fig. 39**.
   - 4.2 Move one end of the cross until a trunnion projects through the cross-hole, beyond the outer machined face of the yoke lug. Hold the trunnions in alignment with the cross-holes, while placing a bearing cup over the projected trunnion, and aligning it with the cross-hole. See **Fig. 40**.

Driveline Component Removal/Disassembly, Cleaning and Inspection, and Replacement or Installation/Assembly

A. Install U-joint cross with grease fitting toward the driveshaft, and pointing 90 degrees away from the yoke lugs.
B. Detail of Grease Fitting
1. Spicer SPL90 (1590) U-Joint Cross

Fig. 39, Spicer SPL90 (1590) U-Joint Grease Fitting Positioning

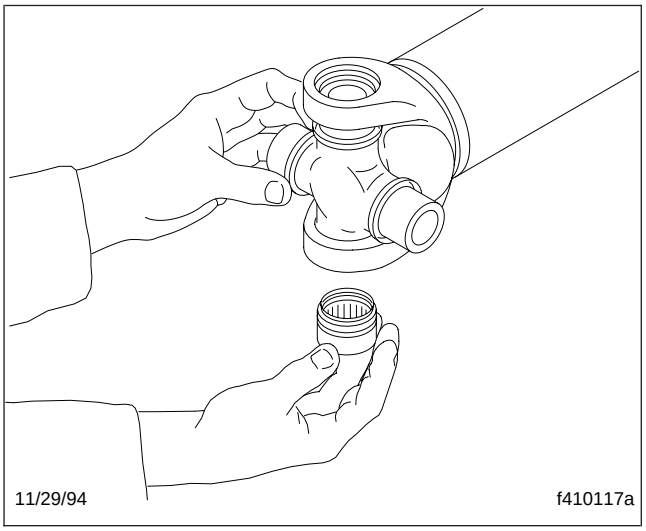


Fig. 40, Installing a Spicer SPL90 (1590) U-Joint Bearing Cup In a Full-Round Yoke

4.3 Using an arbor press, and holding the trunnion in alignment with the cross-hole, place a solid plug (with an outside diameter slightly smaller than the inside diameter of the cross-holes) on the upper bearing cup. See **Fig. 9**. Press the bearing cup into the cross-hole enough to install a snap ring.

4.4 Install the snap ring. See **Fig. 8**.

IMPORTANT: Be sure the snap ring is properly seated in its groove.

4.5 Turn the yoke over, and install the opposite bearing cup and snap ring.

If movement of the U-joint is stiff, strike the yoke ears with a soft hammer to seat the bearing needles.

Transmission/Axle End-Yoke Replacement or Installation

IMPORTANT: Parts for different series drivelines must not be intermixed. Incorrectly assembled or worn components can affect the entire driveline, resulting in too much vibration or driveline damage.

1. Apply Loctite 242 to the input- or output-shaft threads where the end-yoke locknut will be installed. See **Fig. 13**.
2. By hand, install the end-yoke on the input or output shaft as far as it will go.
3. Install a new end-yoke locknut, and tighten it to the applicable torque value in **Subject 400**.

Driveline Parking Brake Flange-Yoke or Companion Flange Replacement or Installation

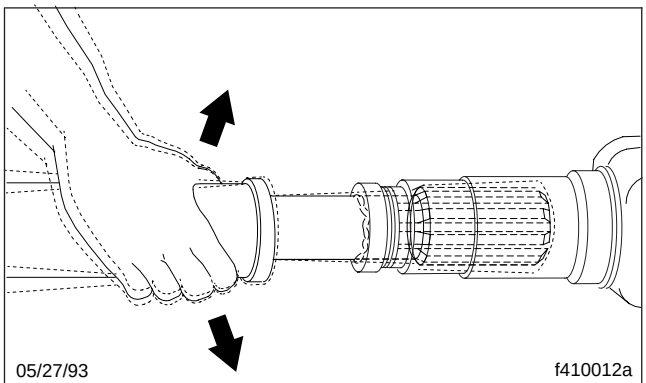
For replacement or installation of a driveline parking brake flange-yoke or companion flange, see **Group 42**.

Troubleshooting Procedure

Noise or vibration associated with the driveline can be caused by non-driveline parts. To find the cause of noise or vibration, first road test the loaded vehicle. Drive in all gears and at all speed ranges for which the vehicle was designed, including those at which problems are reported.

NOTE: Operating a vehicle at speeds that exceed its drivetrain design specifications may cause an out-of-balance vibration.

The following is a troubleshooting elimination process; checks should be made in the order listed. At each step where a problem is found, correct the problem before proceeding to the next step, then test drive the vehicle to see if other problems still exist. If no other problems exist, the elimination process may be ended at that step.



1. Check all tires for uneven wear and for out-of-roundness. Check for mismatched tires. Look for wheels and rims that are out of alignment. For instructions, see **Group 40**.
2. Check the rear suspension for loose or broken U-bolts; broken, shifted, or mismatched rear springs; or broken spring seats. If so equipped, check the air suspension for incorrect air spring height. Look for anything that could cause angular misalignment of the rear axle pinion(s). For instructions, see **Group 32**.
3. Check the frame rails and crossmembers for bends, twists, or breaks; for frame-alignment-checking and crossmember-replacement instructions, see **Group 31**.
4. Check the engine and transmission mounts; see **Group 01** (Engine) and **Group 26** (transmission). Check the coupling shaft's midship bearing mounts. Replace mountings that are deteriorated or oil-soaked; tighten loose mounting bolts. Oil-soaked or deteriorated mountings, or loose mounting bolts, can cause driveline angular misalignment.
5. Check for loose U-joint bearing-cup-plate and bearing-strap capscrews, and for loose flange-yoke locknuts. Tighten any loose fastener to the applicable torque value in **Subject 400**. Then, on U-joint bearing-cup-plates equipped with lockplates, bend a lockplate tab upward until it is firmly against a flat side of the tightened capscrew head.

CAUTION

CAUTION: Do not overtighten the bearing-cup-plate or bearing-strap capscrews, or the flange-yoke locknuts. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could result in serious vehicle damage.

6. Check all U-joint assemblies, slip-joint splines, and midship bearings for wear.
   - 6.1 Try to move each driveshaft up and down, and from side to side. If movement is greater than 0.006 in (0.15 mm) of a U-joint cross in its bearings, replace the U-joint assembly.
   - 6.2 If the midship bearing rattles or is loose on its shaft, replace it.
   - 6.3 Try to bend the sleeve-yoke and splined shaft up and down, and from side to side. See **Fig. 1**. If looseness is greater than 0.007 in (0.18 mm), replace the sleeve-yoke and splined shaft.

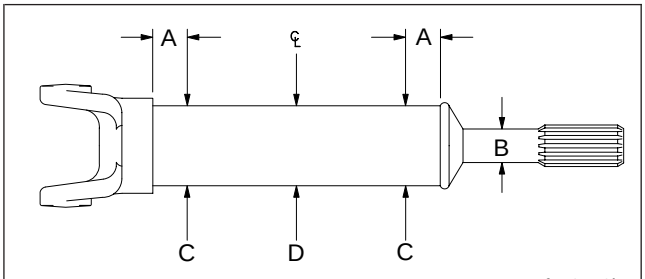
     If driveline components must be replaced, see **Subject 130**.

Try to bend the sleeve-yoke and splined shaft up and down, and from side to side.

Fig. 1, Checking for Slip-Joint Spline Wear

7. Check each driveshaft for an indication of missing balance weights. If any weights appear to be missing, have the driveshaft balanced to a maxi-

Troubleshooting



mum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

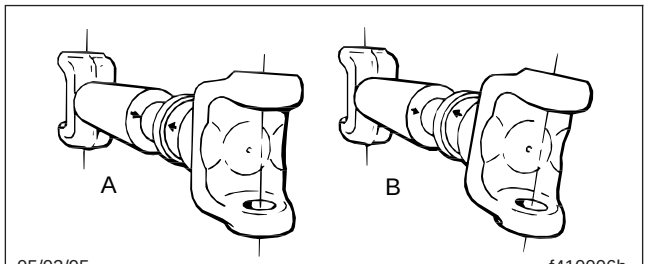
8. Check each driveshaft for dents, bends, twists, or other damage.

   If damaged, jack up the rear axle, support it on jackstands, place the transmission in neutral, and turn the driveshaft by hand to check runout.

   The driveshaft must be straight within 0.015 in (0.38 mm) on the slip-joint seal surface of the splined shaft, 0.020 in (0.51 mm) on the tube 3 in (76 mm) from the front and the rear welds, and 0.025 in (0.635 mm) at the center of the tube. See **Fig. 2**.

   If the driveshaft is not straight within specifications, replace the tube. See **Subject 130** for runout specifications for a *new* (or rebuilt) driveshaft.

06/13/96 f410110b



A. Measurement: 3" (76 mm)
B. Measurement: 0.015" (0.38 mm)
C. Measurement: 0.020" (0.51 mm)
D. Measurement: 0.025" (0.635 mm)

Fig. 2, Used Driveshaft Runout Specifications

9. Check each driveline for proper U-joint phasing. See **Fig. 3**.

   9.1 On no. 2 and no. 3 driveshafts, if the U-joints are out of phase, check the slip-joint for alignment marks. If necessary, disassemble the slip-joint, and align the marks.

   NOTE: To disassemble the slip-joint, uncouple the U-joint at one end of the driveshaft, unscrew the slip-joint seal from the sleeve-yoke, then pull the sleeve-yoke and splined shaft apart. Reverse the procedure to assemble the slip-joint.

05/02/95 f410006b

A. In Phase B. Out of Phase

Fig. 3, U-Joint Phasing

   9.2 If no alignment marks are present, disassemble the slip-joint, and reassemble it with the U-joints in one of the two in-phase positions (180 degrees apart).

   Test drive the vehicle, then assemble the slip-joint in the other in-phase position. Test drive the vehicle again.

   Determine which in-phase position provides vibration-free operation; then, assemble the slip-joint in the correct in-phase position, and mark the slip-joint with alignment marks.

   9.3 If the U-joints are out of phase on a coupling shaft, uncouple the U-joint from the coupling shaft end-yoke, then remove the end-yoke nut. Remove the end-yoke, using a yoke puller. See **Fig. 4** for a half-round end-yoke, or see **Fig. 5** for a full-round end-yoke. Align the end-yoke, then install it by hand. Install the end-yoke nut, and tighten it 475 to 525 lbf·ft (645 to 710 N·m). Slightly back off the nut, and again tighten it to the same torque. Couple the coupling shaft to the driveshaft U-joint.

10. Check the torque on all of the end-yoke nuts in the drivetrain; see the applicable torque values in **Subject 400**.

    If any yoke nut was not at its specified torque, check the yoke for wear by trying to move it up and down, and back and forth. If the yoke can be rocked on its shaft, or moved in or out on its shaft, replace the yoke and yoke nut; see **Subject 130**.

    If the yoke is not worn, tighten the yoke nut to its torque value.

1. Midship Bearing
2. Yoke Puller
3. Bearing Strap

Fig. 4, Removing a Half-Round End-Yoke From a Coupling Shaft

1. Yoke Puller
2. Full-Round Yoke
3. Midship Bearing

Fig. 5, Removing a Full-Round End-Yoke From a Coupling Shaft

11. *On single-drive vehicles:*

    Have the no. 2 driveshaft balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

    On dual-drive vehicles:

    11.1 Remove the no. 3 driveline; then, with the interaxle differential locked, test drive the vehicle.

    11.2 If vibration still exists, install the no. 3 driveline, then have the no. 2 driveshaft balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

    If *no* vibration exists, check that both rear axle gear ratios are matched. If the gear ratios do not match, replace one of the gear sets with a gear set having the correct ratio, then install the no. 3 driveline.

    11.3 Have the no. 3 driveshaft balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

    11.4 Have the no. 2 driveshaft balanced to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

12. If so equipped, balance the coupling shaft(s) to a maximum tolerance of one inch-ounce per ten pounds weight per end, at 3000 rpm.

Specifications

Description			Size	Torque: lbf·ft (N·m)

General Information

This troubleshooting guide is designed to help locate causes of problems originating in the air brake system. The corrective measures given are not intended to replace the detailed service information found in other sections of this manual or in the component manufacturer's service manuals.

Before attempting to isolate the causes of an air brake system problem, do the following:

1. Check the operation of the air compressor. Refer to the engine manufacturer's service manual.

   Check the pressure levels of the air reservoirs. Refer to the vehicle driver's manual.
2. Be sure that all relay valves are operating. For instructions, refer to the vehicle maintenance manual.
3. Check the operation of the brake chambers as instructed in the vehicle maintenance manual.
4. Examine all tubing for kinks, dents, and other damage. Replace damaged tubing.
5. Examine all hoses for cracks, drying out, overheating, and other damage. Replace damaged hoses.
6. Examine all air line fittings. Tighten loose connections; replace fittings that are damaged. For instructions, refer to the applicable section in this manual.
7. Examine leaking pipe connections for cracks or thread damage; replace as needed. If there is no damage, retighten the fitting. For instructions, refer to the applicable section in this manual.

Safety Precautions

Compression and storage of air in the air brake system is comparable to the energy in a coiled spring: when released, it may be hazardous. Because of this, certain precautions are required:

1. Chock the tires. This will prevent accidental rolling of the vehicle when air is released from the brake system.
2. Don't disconnect pressurized hoses because they will whip as air escapes from the line. Drain the air system before disconnecting the air hoses.
3. When draining the air system, do not look into the air jets or direct them toward anyone: dirt particles or sludge may be carried in the air stream.
4. As air pressure is drained and the parking/ emergency brakes apply, keep your hands away from the brake chamber push rods and parking brake chambers, which will activate automatically with the loss of pressure. This also applies to the service brake system.

⚠ WARNING

WARNING: Follow the manufacturer's procedures while working on any air device so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion. Failure to take all necessary precautions during servicing of the air brake system can result in personal injury.

Problem—Vehicle Does Not Slow Down Quickly Enough When Brakes Are Applied

Possible Cause	Remedy
The vehicle is overloaded.	Observe the recommended maximum load limits.
There is low air pressure in the brake system, about 413 kPa (60 psi) or lower.	The drain cock on the air reservoir was left open; close the drain cock.
	Check the compressor output pressure; correct as necessary.
	Check the setting of the air governor with an accurate test gauge. Adjust the air governor to the recommended specification.
The application air lines are leaking excessively.	Check the application air line, brake valve, and the service and parking brake chambers for air leaks. Repair or replace the damaged component(s).
Brake valve delivery pressure is below normal.	Lubricate the brake valve parts; overhaul the unit, if necessary.
The brake linings are worn or glazed.	Install new brake linings on the brake shoes on both sides of the axle.
The brakes need adjustment or lubrication.	Adjust or lubricate the brakes.
The automatic slack adjusters (if so equipped) are not operating.	Lubricate the automatic slack adjusters and check for binding, damaged, or inoperative slack adjuster parts. Replace damaged or inoperative parts, or eliminate the cause of the binding.
The cam has flipped over.	Replace the linings and the cam on each end of the axle. Replace the brake drums if needed.
Flat spots or dents on the roller surface were caused by skidding of the roller or incorrect handling of the rollers during installation.	Clean, then inspect the bearing rollers. Replace the rollers if damaged.
One or more of the brake drums is broken or cracked.	Replace the brake drum(s).
Wrong size brake linings were installed.	Replace the brake linings with the recommended size.
Wrong size brake chambers were installed.	Replace the brake chambers with the recommended size.
A camshaft bracket or chamber mounting bracket is bent or broken.	Replace the camshaft bracket or chamber mounting bracket.
The brake chamber mounting stud nuts or brake chamber mounting bracket is loose.	Tighten the brake chamber to its mounting bracket or the mounting bracket to the foundation brake housing.
There is a ruptured diaphragm in the service brake.	Replace the diaphragm.
The brake drums are glazed.	Turn the brake drums, if possible. If the maximum allowable diameter is exceeded, replace the drum. Do the same for both ends of the axle.

Problem—Service Brakes Release Too Slowly

Possible Cause	Remedy
The brake shoe anchor pins are frozen.	Inspect the anchor pins. If damaged, replace them; if not damaged, lubricate them.
Lubrication of the brake system components is inadequate.	Lubricate those components requiring periodic lubrication.
The brake foot valve push rod may be incorrectly adjusted.	Readjust the push rod and/or pedal stop bracket.

Troubleshooting

Possible Cause	Remedy
The brake foot valve is not returning to the fully released position.	Check for obstructions which might prevent the brake foot valve from returning to the fully released position. Remove any obstructions.
The exhaust port of the brake foot valve or quick-release valve is plugged.	Clear the exhaust port of obstructions.
The brake foot valve or quick-release valve is not working.	Overhaul or replace the applicable valve, as needed.
The camshaft and bushings are binding.	Clean and lubricate the camshaft bushings.
The brake shoe return spring is weak or broken.	Replace the spring.
Flat spots or dents on the roller surface were caused by skidding of the roller or incorrect handling of the rollers during installation.	Clean, then inspect the rollers. Replace the rollers if damaged.

Problem—Service Brakes Do Not Apply or Apply Too Slowly

Possible Cause	Remedy
Lubrication of the foundation brake assembly is needed.	Lubricate those components requiring periodic lubrication.
There is insufficient air pressure in the brake system.	Check all parts of the air pressure system for leaks or inoperative components.
The brake foot valve or quick-release valve is not working.	Repair or replace the brake foot valve or quick-release valve.
The camshaft bushings are binding.	Clean and lubricate the camshaft bushings.

Problem—Service Brakes Apply When the Parking Brakes Are Released With Air Pressure

Possible Cause	Remedy
The air delivery lines to the brake chamber have been reversed.	Reverse the connections of the brake chamber air lines.
There is a leaking push rod seal between the parking brake and the service brake.	Replace the push rod seal.
The braking mechanism is binding.	Lubricate the brake mechanism and make sure all parts are aligned with each other and are securely fastened.
	Check for obstructions; remove any obstructions.

Problem—Service Brakes Do Not Release

Possible Cause	Remedy
The brake shoes are incorrectly adjusted.	Adjust the brakes. Also, make sure the slack adjuster is operating correctly. If not, overhaul or replace the slack adjuster.
The brake foot valve may not be in the fully released position.	Lubricate the brake foot valve if needed. Check the adjustment of the brake foot valve push rod.
The brake foot valve is not working.	Overhaul or replace the brake foot valve.

Possible Cause	Remedy
There is a restriction in the tubing, hose, or exhaust port of the brake foot valve or quick-release valve.	Check for bends or obstructions on the exhaust side of the service brakes. Remove any obstructions; plumb the air lines so that bends are minimal.
A broken power spring may be blocking the parking brake piston movement.	Replace the power spring or replace the parking brake assembly, whichever is recommended by the parking brake manufacturer.

Problem—Service Brakes Grab or Pull

Possible Cause	Remedy
There is not enough weight on the vehicle (underloaded).	Add weight to the vehicle, reducing brake sensitivity.
Adjustment of the brakes on one axle is uneven.	Adjust the brakes.
Lubrication of the brake system components is inadequate.	Lubricate those components requiring periodic lubrication.
The brake mechanism is binding.	Lubricate the brake mechanism and make sure all parts are aligned with each other and are securely fastened.
The clevis pin or camshaft is binding at one or more wheels.	Clean and lubricate the camshaft bushings.
A brake spider is loose.	Tighten the mounting bolts or replace the brake spider.
A slack adjuster is damaged.	Replace the damaged component.
The air chamber push rods or slack adjusters are a different length.	Replace the components with the correct size and material.
The brake foot valve is not working.	Overhaul or replace the brake foot valve, as needed.
If equipped with cam brakes, there is a flat or dent on the S-head camshaft or on the cam roller(s).	Replace the damaged component(s).
Grease has saturated the brake linings or the linings are glazed.	Install a matched set of linings on both sets of brake shoes on that axle. Clean, replace, or turn both brake drums. For instructions on turning drums, refer to the brake manufacturer's service manual. Find out what is causing the saturation and repair as needed.
The brake linings are loose or broken.	Install a matched set of linings on both sets of brake shoes on that axle.
The brake linings are not a matched set. Different friction codes or different brands of brake linings are installed.	Install a new, matched set of brake linings. Clean, replace, or turn both brake drums on that axle. For instructions on turning drums, refer to the brake manufacturer's service manual.
A brake shoe is distorted or broken.	Replace the brake shoe. Install a new, matched set of linings on both sets of brake shoes on that axle.
The pilot pads are damaged, allowing the brake drum to be installed out-of-round.	Replace the wheel hub.
A brake drum is out-of-round to unacceptable limits.	Turn both the brake drums on that axle. If the maximum allowable diameter of either drum has been exceeded, replace that drum. For instructions on turning drums, refer to the brake manufacturer's service manual.
One or more brake drums is scored or broken.	Replace both of the drums on that axle.

Troubleshooting

Problem—Uneven Service Brakes

Possible Cause	Remedy
The wrong brake linings were installed, or the linings were not replaced in pairs.	Replace the brake linings with the recommended size. Install new linings on both sets of axle brake shoes.
Grease has saturated the brake linings or the linings are glazed.	Install new linings on both axle brake shoes. Clean the brake drums. Find the cause of saturation, and repair as needed.
The return spring for the brake shoe release or the service brake has broken.	Replace all broken springs.
The brake drum is out-of-round to unacceptable limits.	Turn the brake drum(s), if possible. If the maximum allowable diameter of the brake drum(s) has been exceeded, replace the drum. Also, turn or replace the other drum on the axle. For turning the drum(s), refer to the brake manufacturer's service manual.
A service brake chamber diaphragm is leaking.	Tighten the clamp ring. If leaks persist, replace the service brake diaphragm.
The wheel bearings are out of adjustment.	Adjust the wheel bearings, or replace them if damaged. For instructions, refer to the front axle group or the rear axle group of the vehicle maintenance manual.
A brake spider is damaged.	Replace the brake spider.
The brake shoes are bent or stretched.	Replace the axle brake shoes on each wheel.
Grease, oil, or dirt is on the linings.	Replace the linings on each set of axle brake shoes. Clean the brake drums. Find the cause of contamination and remedy it.

Problem—Dragging Service Brake

Possible Cause	Remedy
The service brake return spring is broken.	Replace the service brake return spring.
The service-application air is not exhausting or not exhausting fast enough, due to blockage in the control valve, the quick-release valve, or the limiting and quick-release valve.	Test the air system valves for leakage and operation.
A brake shoe retracting spring is broken.	Replace the brake shoe retracting spring.
Binding is occurring in the camshaft linkage.	Lubricate the camshaft linkage. Replace bent or broken parts.
The brake foot valve is not returning to the fully released position.	Check for obstructions which might prevent the brake foot valve from returning to the fully released position. Remove any obstructions.
The brake foot valve push rod may be incorrectly adjusted.	Readjust the push rod and/or pedal stop bracket.

Problem—Insufficient Parking Brake Application When Dash Control Valve Is Activated

Possible Cause	Remedy
The parking brake is not set for full stroke.	Adjust the brakes.
A power spring is broken.	Replace the parking brake chamber.
A power spring in a parking brake is manually caged.	Uncage the power spring, using the release bolt.

Problem—Dragging Brakes Due to Parking Brake Mechanism

Possible Cause	Remedy
The system air pressure is insufficient to fully release the parking brake.	Be sure that all air lines are clear. Check that the air governor cutout settings meet recommended specifications.
A parking brake diaphragm is ruptured or a piston seal is ineffective.	Replace the diaphragm or parking brake piston seal.
There is a broken return spring in the parking brake (double-diaphragm type brake chambers only).	Replace the parking brake chamber.

Problem— Air Pressure Will Not Rise to Normal

Possible Cause	Remedy
The air pressure gauge(s) on the dash is (are) registering inaccurately.	Check the dash gauge with an accurate test gauge. Replace the dash gauge(s) as needed.
There is excessive leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.
The compressor is not working (including excessive leakage of the compressor).	Rebuild or replace the compressor.
The air reservoir drain cock has been left open.	Close the drain cock.
The air governor cutout setting is not adjusted correctly.	Check the setting with an accurate test gauge, then adjust the air governor to the recommended specification.
There is inadequate clearance at the compressor unloading valve.	Repair or adjust the compressor at the unloading valve.
If so equipped, the compressor drive belt is slipping.	Adjust or replace the compressor drive belt.
Carbon is building up in the compressor cylinder head or discharge line.	Remove the carbon. If disassembly is not recommended by the compressor manufacturer, replace the air compressor with a factory rebuilt or a new unit.

Problem— Air Pressure Rises Above Normal

Possible Cause	Remedy
The air reservoir pressure dash gauge is inaccurate.	Check the dash gauge with an accurate test gauge. Replace the dash gauge, as needed.
The compressor air governor is out of adjustment.	Check the setting with an accurate test gauge, then adjust the air governor to the recommended specification.
The air governor is not operating.	Repair or replace the air governor.
There is too much clearance at the air compressor unloading valve.	Repair or adjust the compressor at the unloading valve.
The air compressor unloading valve is stuck closed.	
The air compressor unloading valve cavities or the unloading valve passage is blocked with carbon.	

Troubleshooting

Problem—Air Pressure Drops Quickly With the Engine Stopped and the Brakes Released

Possible Cause	Remedy
The brake foot valve is leaking.	Repair or replace the brake foot valve.
The air compressor discharge valve is leaking.	Repair or replace the discharge valve. If disassembly is not recommended by the compressor manufacturer, replace the air compressor with a factory-rebuilt or a new unit.
The air governor is leaking.	Repair or replace the air governor.
There is excessive leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.

Problem—Air Pressure Drops Quickly With the Engine Stopped and the Brakes Fully Applied

Possible Cause	Remedy
A service or parking brake chamber is leaking.	Tighten the clamp ring(s). If leaks persist, replace the service brake diaphragm or the parking brake chamber, as applicable.
The brake foot valve or quick-release valve is leaking.	Repair or replace the component(s) or assembly.
There is excessive leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.

Problem—Compressor Knocks (Continuously or Intermittently)

Possible Cause	Remedy
There is a loose drive pulley, belt, coupling, or gear (as indicated).	Tighten or replace the component. If applicable, inspect the pulley shaft for damage. Replace the shaft, if damaged.
Backlash is in the compressor drive gears on the drive coupling.	Repair or replace the compressor drive gears or drive coupling.
The air compressor bearings are damaged or worn.	Replace the bearings.
There are carbon deposits in the compressor cylinder head.	Remove the carbon deposits or replace the compressor.

Problem—Safety Valve Activates

Possible Cause	Remedy
The safety valve is out of adjustment.	Adjust the safety valve, or install a new one.
There is too much air pressure in the brake system.	Refer to the problem "Air Pressure Rises Above Normal."
The air reservoirs need to be drained more often.	Drain the air reservoirs daily.

Problem—Oil or Water in the Brake System

Possible Cause	Remedy
Excessive oil is passing through the air compressor.	Rebuild or replace the compressor.

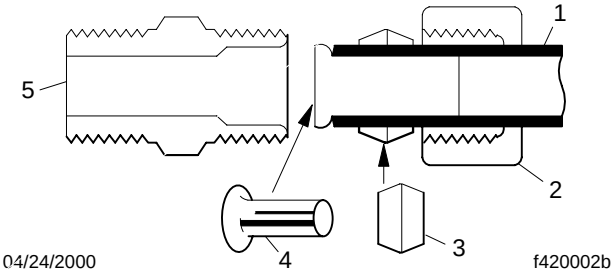
Possible Cause	Remedy
If so equipped, the air compressor air strainer is dirty.	Clean the strainer or install a new one.

WARNING

Make sure the air system has been reduced to 0 psi before attempting to remove an air line. Do not disconnect pressurized air lines as they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Replacement

CAUTION

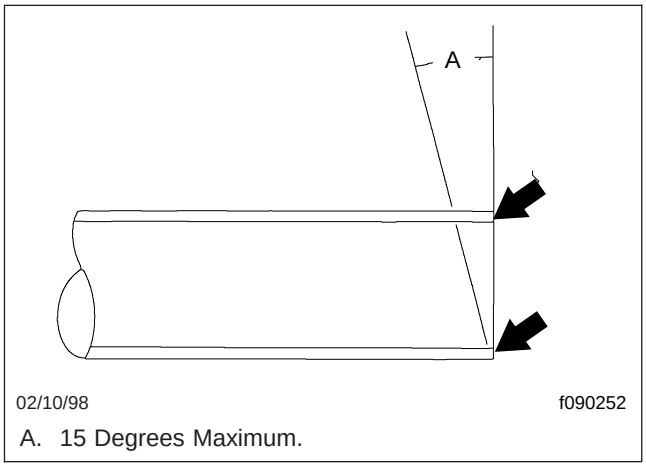


Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100.

CAUTION

If the air line is bent to a radius smaller than the specified minimum bend radius, it may kink and shut off normal airflow to the component.

NOTE: When installing a nylon or a wire braid air line, be careful not to bend it past its minimum bend radius. For minimum bend radius values, see **Specifications, 400**.

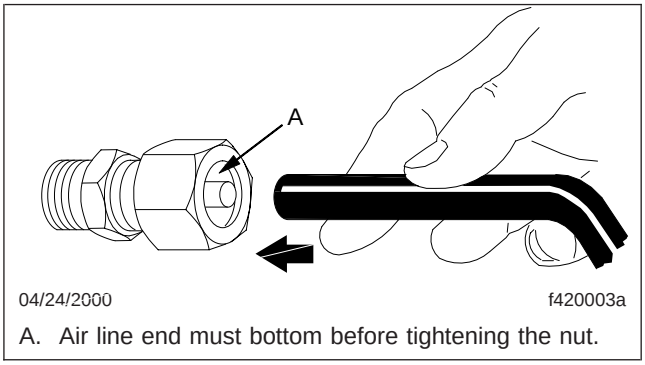


Nylon Air Lines and Compression Fittings (See Fig. 1)

1. Nylon Air Line
2. Nut
3. Sleeve
4. Stainless Steel Insert
5. Body

Fig. 1, Nylon Air Line and Compression Fitting

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line.
   - 3.1 Loosen the fitting nut.
   - 3.2 Pull the air line out of the fitting.
4. Use pliers to remove the stainless steel insert from the fitting. Discard the insert.
5. Clean all of the fitting components.
6. Place a new stainless steel insert into the fitting body. Use thumb pressure to press it into position.
7. Check the air line end for a square cut-off that does not exceed a 15-degree angle. Check that the air line is not distorted or damaged. See **Fig. 2**.



A. 15 Degrees Maximum.

Fig. 2, Check Air Line End Angle

   - 7.1 If the angle exceeds the specification, recut the air line.
   - 7.2 Use a sharp blade to prevent collapsing the air line or leaving burrs.
8. Make sure the nylon air line ends and fittings are free of grease and debris. If the air line is crimped or otherwise damaged, replace it with a new air line.
9. Install a new sleeve in the nut. Start the threads of the nut on the fitting body.
10. Insert the squared end of the air line in the fitting until it bottoms in the body of the fitting. See **Fig. 3**.

Air Lines Replacement

A. Air line end must bottom before tightening the nut.

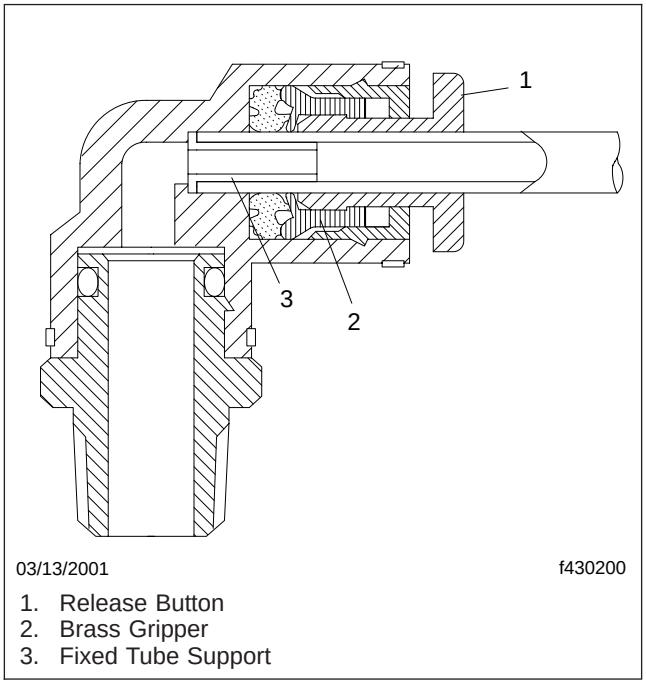


Fig. 3, Installing Nylon Air Line into Compression Fitting

11. Tighten the nut until one thread remains visible.
12. Pull back on the air line to make sure it is fully seated.
13. Pressurize the air system. Check the air system for leaks.
14. Remove the chocks from the tires.

Nylon Air Lines and KV2 One-Touch Fittings

IMPORTANT: The use of a sharp air line cutter is highly recommended. This tool will insure a clean, perpendicular cut of the air line.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Push the air line into the fitting.
4. Press and hold the release button against the body of the fitting. See **Fig. 4**.
5. Remove the air line.
6. Clean any dirt or contamination from the leading edge of the air line.
7. Lubricate the leading end of the air line with light oil, petroleum jelly or silicone lubricant.
8. Insert the end of the air line into the fitting until it bottoms.
9. Pull on the air line to verify it is properly retained.

1. Release Button
2. Brass Gripper
3. Fixed Tube Support

Fig. 4, KV2 One-Touch Fitting

10. Pressurize the air system. Check the air system for leaks.
11. Remove the chocks from the tires.

Wire Braid Air Lines

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line.
   - 3.1 Unthread the swivel fitting nut.
   - 3.2 Remove the air line assembly from the mating fitting.
4. Make sure the wire braid air line assembly is free of grease and dirt. Replace the assembly if the air line or fitting is crimped or otherwise damaged.
5. Install the air line and finger-tighten the nut.
6. Using two wrenches to prevent twisting of the air line, tighten the nut until it seats solidly. Tighten the nut one-sixth turn more.

7. Pressurize the air system. Check the air system for leaks.
8. Remove the chocks from the tires.

Safety Precautions

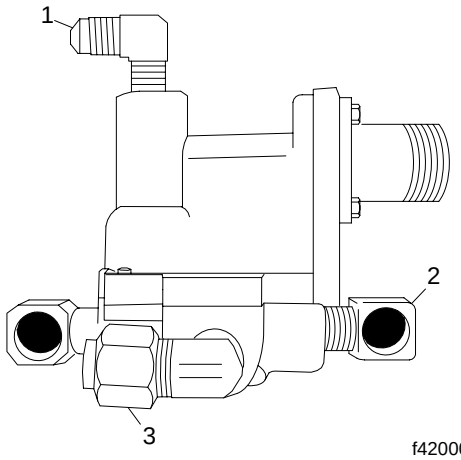
Before attempting to work on the air brake system, observe the following precautions:

- Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.
- When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.
- Air lines will whip dangerously if disconnected under pressure. Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.
- As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber pushrods and spring actuators that apply automatically with the loss of pressure. This also applies when checking the service brake system.
- Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.
- Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.
- The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.
- Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.
- To avoid injury, keep clear of the air chamber pushrod when brakes are applied or when air is exhausted from the system.

WARNING

Make sure the air system has been reduced to 0 psi before attempting to remove an air line. Do not disconnect pressurized air lines as they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Replacement



CAUTION

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100.

CAUTION

Never use diagonal pliers, a saw or dull cutting tool to cut nylon air lines. The use of such tools leaves the air line with a sharp edge, burr or out-of-round condition which can damage the seal when the air line is inserted into the fitting. This reduces the sealing ability of the fitting. The use of a sharp air line cutter is highly recommended. This tool will insure a clean, perpendicular cut of the air line.

Brass or Steel Pipe Fittings (See Fig. 1)

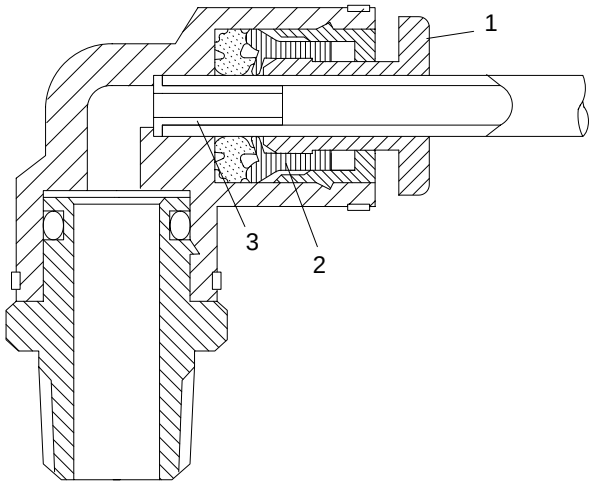
1. Wire Braid Hose Fitting
2. Brass or Steel Pipe Fitting
3. Nylon Tube Compression Fitting

Fig. 1, Screw-On Fittings

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see Subject 110.
4. Using an open-end wrench or similar tool, rotate the fitting counterclockwise until it is completely disengaged from the fitting port.
5. Make sure the fitting is free of grease, dirt, and old sealant. Apply liquid thread sealant (white) to the threads and finger-tighten securely.

NOTE: Always apply the sealant to the external thread, so that any excess will be scraped off externally rather than internally to the joint.

6. Install the fitting:
   - *For a fitting that must be positioned*, tighten one additional turn from finger-tight using a wrench. Continue to tighten the fitting clockwise until it is correctly positioned. Never turn the fitting counterclockwise to position it.
   - *For a fitting that does not require positioning*, tighten 1-1/2 additional turns from finger-tight.
7. Install the air line in the fitting. For instructions, see Subject 110.
8. Pressurize the air system. Check the air system for leaks.
9. Remove the chocks from the tires.



Brass or Steel Pipe Fittings on Plastic Components

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see Subject 110.
4. Remove the fitting.
5. Install the fitting. For tightening specifications, see the applicable table in Specifications, 400.

Fittings Replacement

6. Install the air line in the fitting. For instructions, see **Subject 110**.
7. Pressurize the air system. Check the air system for leaks.
8. Remove the chocks from the tires.

KV2 One-Touch Fittings **(See Fig. 2)**

1. Release Button
2. Brass Gripper
3. Fixed Tube Support

Fig. 2, KV2 One-Touch Fitting

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see **Subject 110**.
4. Using an open-end wrench or similar tool, rotate the fitting's hexstud end counterclockwise until it is hand-loose.
5. Continue to rotate the fitting by hand until it is completely disengaged from the fitting port.
6. Clean any dirt or thread sealant from the fitting and fitting port.
7. If required, apply liquid thread sealant (white) to the threads.
8. Insert the fitting into the port and rotate it clockwise until it is hand-tight.
9. Using an open-end wrench or similar tool, tighten the fitting to the manufacturer's recommended torque. For torque specifications, see the applicable table in **Specifications, 400**.
10. Rotate the fitting body by hand to the correct position.
11. Install the air line in the fitting. For instructions, see **Subject 110**.
12. Pressurize the air system. Check the air system for leaks.
13. Remove the chocks from the tires.

Specifications

213 Wire Braid Air Lines *			
Number	Inside Diameter Inch	Outside Diameter Inch	Minimum Bend Radius inches (mm)
4	3/16	0.49	0.75 (20)
5	1/4	0.55	1.00 (25)
6	5/16	0.62	1.25 (30)
8	13/32	0.74	1.75 (45)
10	1/2	0.83	2.25 (55)
12	5/8	0.96	2.75 (70)
16	7/8	1.21	3.50 (90)
20	1-1/8	1.49	4.50 (115)

* 213 air lines are identified by two green stripes 180 degrees apart, part numbers, and size (for example, part numbers 213-4, 213-5, and so on).

Table 1, 213 Wire Braid Air Lines

Nylon Air Lines			
Number	Inside Diameter Inch	Outside Diameter Inch	Minimum Bend Radius inches (mm)
4	0.170	1/4	1.00 (25)
6	0.251	3/8	1.50 (38)
8	0.376	1/2	2.00 (51)
10	0.441	5/8	2.50 (64)
12	0.566	3/4	3.00 (76)

Table 2, Nylon Air Lines

KV2 Stud End Torque into Metallic Ports *		
Thread, NPTF Inch	Torque †	
	lbf·in (N·cm)	lbf·ft (N·m)
1/16	62–80 (700–900)	—
1/8	62–80 (700–900)	—
1/4	106–124 (1200–1400)	—
3/8	—	16–18 (22–24)
1/2	—	21–22 (28–30)

* Aluminum, zinc, steel and brass ports.
† The component in which the KV2 One-Touch fitting is being installed may have torque values lower than those listed here. Please see the component supplier's recommended torque specifications.

Table 3, KV2 Stud End Torque into Metallic Ports

Brass or Steel Pipe Fittings on Plastic Components			
Description	Port Size Inch	Torque	
		lbf·in (N·cm)	lbf·ft (N·m)
Midland Quick Release Valve	3/8	60–90 (680–1020) *	—
	1/2	—	13–17 (18–23) *
Bendix MV-2/MV-3 Valve	1/4	—	10 (14)

* Tighten to the lower torque value. If needed, turn the fittings to allow for the proper routing of the air lines.

Table 4, Brass or Steel Pipe Fittings on Plastic Components

General Description and Principles of Operation

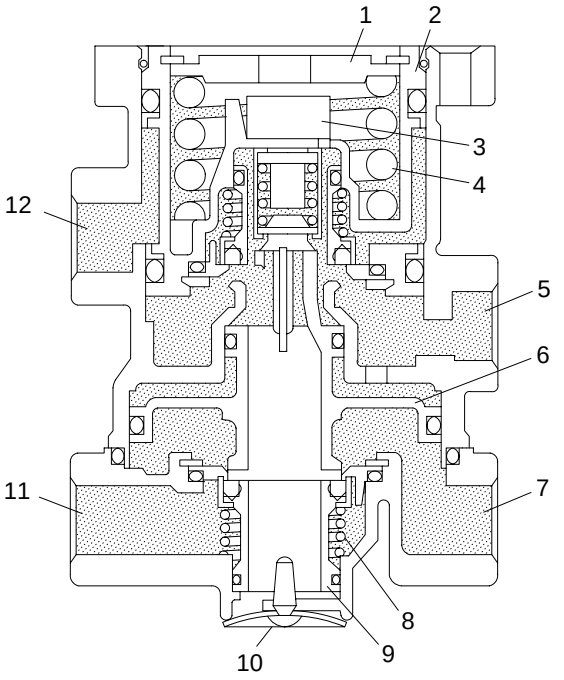
(Refer to Fig. 1)

The dual circuit brake valve (foot valve) controls the air supply and delivery of the dual circuit brake system. The brake valve is mounted on the firewall .

APPLYING

The primary circuit of the brake valve is controlled by the brake pedal and a push rod. When the brake pedal is depressed, the push rod applies pressure on the spring retainer (Ref. 1), rubber spring, and the primary (upper) piston (Ref. 2). The downward movement of the primary piston closes the upper exhaust valve, and then opens the upper inlet valve, allowing high-pressure air from port 11 (Ref. 5) to flow to low-pressure port 21 (Ref. 12).

The secondary circuit is air operated by the pressure from the primary circuit. Primary circuit pressure on top of the secondary piston (Ref. 6) first closes the lower exhaust valve, and then opens the lower inlet valve, allowing high-pressure from port 12 (Ref. 7) to flow to low-pressure port 22 (Ref. 11).



HOLDING

As air pressure builds in the primary circuit, the pressure under the primary piston will match the pressure of the rubber spring. This allows the piston to move up enough to close the upper inlet valve, and prevent the flow of air from the primary air tank into the brake valve. The exhaust port remains closed.

RELEASING

When the pedal is released, the push rod releases pressure from the spring retainer, rubber spring, and the primary (upper) piston. Air pressure builds to push the piston up, opening the upper exhaust valve and allowing air from the primary circuit to escape through the exhaust port.

In the secondary circuit, the release of primary air pressure allows air under the secondary piston, pushing the piston up and opening the lower exhaust valve (Ref. 9). All remaining air pressure is vented through the exhaust port (Ref. 10).

1. Spring Retainer
2. Primary Piston
3. Rubber Spring
4. Graduating Spring
5. Primary Supply Port (Port 11)
6. Secondary Piston
7. Secondary Supply Port (Port 12)
8. Return Spring

Operating Check

IMPORTANT: If there is a change in the way a vehicle brakes, or if low pressure warnings occur, check the operation of the brake air system. Although the brake system may continue to work, do not operate the vehicle until the braking circuits, including the pneumatic and mechanical devices, have been repaired and are operating normally. Always check the brake system for correct operation after doing brake work, and before returning the vehicle to service.

Check for the correct brake valve operation as follows:

1. Apply the parking brake, then chock the tires.
2. Connect test gauges to the primary and secondary delivery ports on the brake valve. **See Fig. 1.**

NOTE: When checking the delivery pressure of the primary and secondary circuits, use test gauges that are accurate.

3. Start the engine and build air pressure to 827 kPa (120 psi).

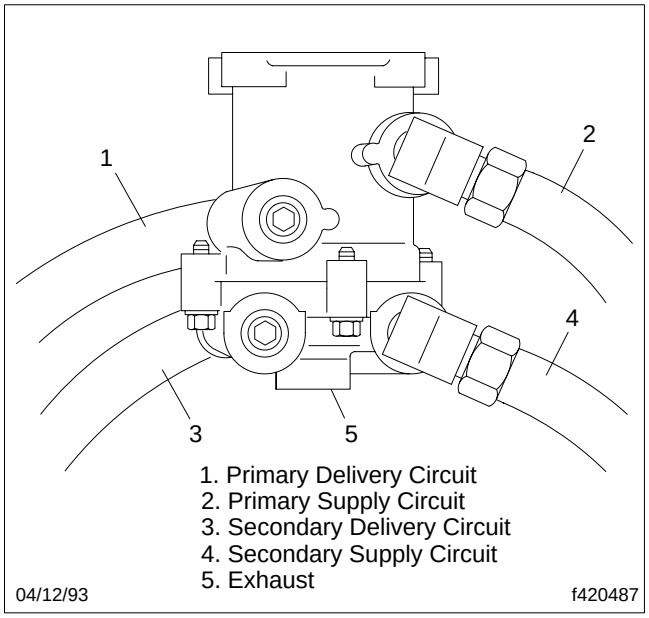

Fig. 1

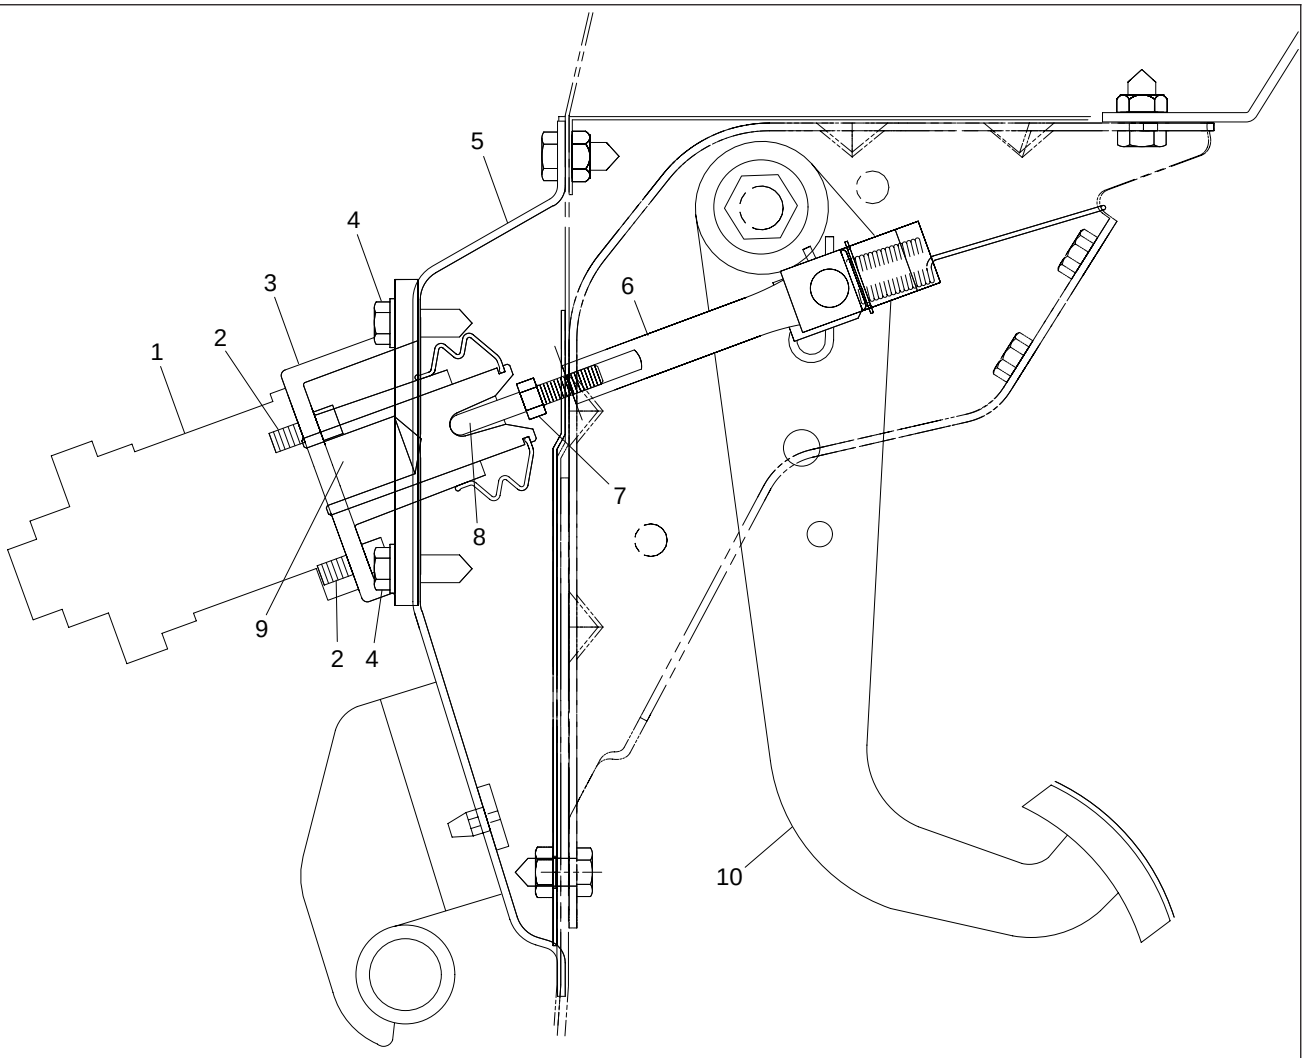
4. Depress the pedal to several different positions; check the pressure on the test gauges to ensure that it varies equally and proportionally with the movement of the brake pedal.
5. Fully depress the brake pedal, then release it. After a full application is released, the reading on the test gauges should promptly fall to zero.

NOTE: Pressure in the primary delivery circuit will be about 14 kPa (2 psi) greater than pressure in the secondary delivery circuit (if both supply reservoirs are at the same pressure). This is normal for this valve.

6. Go to "Leakage Check."



Leakage Check

1. Make and hold a pressure application of 552 kPa (80 psi).
2. Check the air line fittings for leaks: tighten or replace fittings as needed.
3. Coat the exhaust port and body of the valve with a soap solution, and check for leakage. The leakage permitted is a 2.5-cm (1-inch) bubble in 3 seconds.

   If the brake valve does not function as described above, or if leakage is excessive, replace it with a new or remanufactured unit.

   Repeat the leakage test before placing the brake valve in service.
4. Remove the chocks from the tires.

Removal (See Fig. 1 and Fig. 2)

1. Brake Valve
2. Brake Valve Mounting Fasteners
3. Mounting Adaptor
4. Capscrew and Flatwasher
5. Front Cab Mount Plate
6. Push Rod Clevis
7. Push Rod Jam Nut
8. Brake Pedal Push Rod
9. Plunger
10. Brake Pedal Assembly

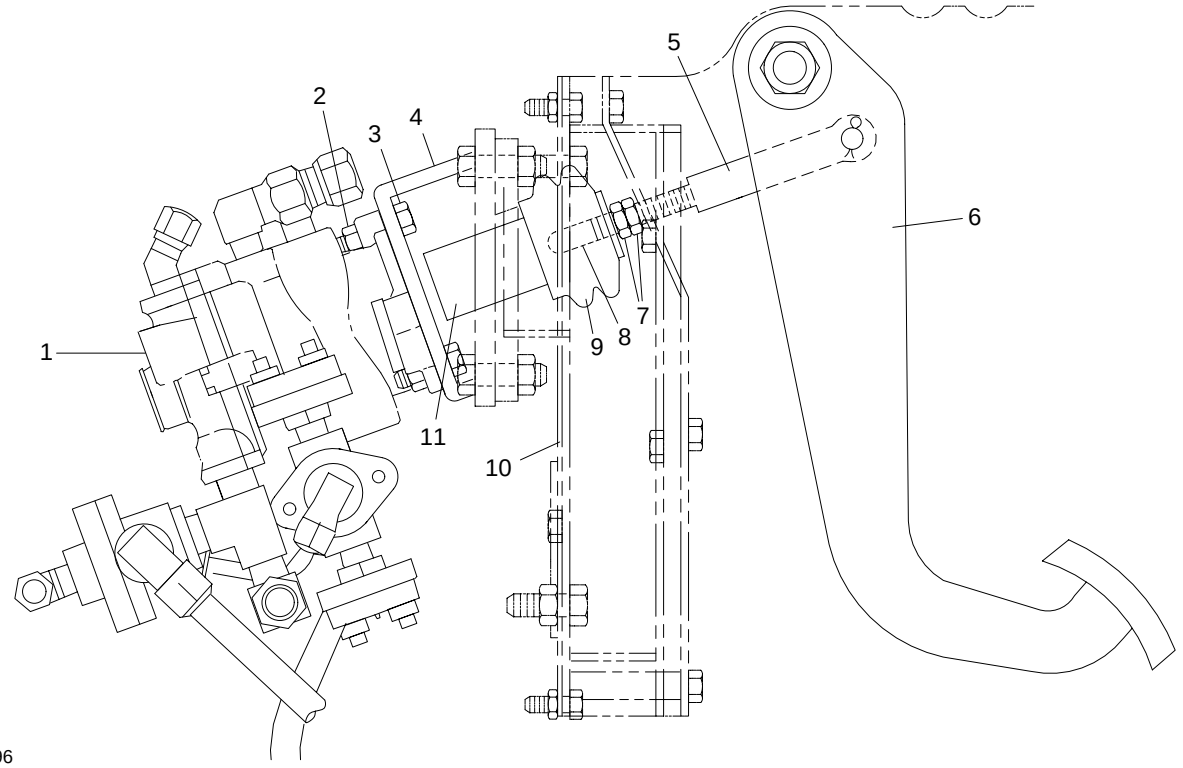


Fig. 1, Brake Valve Mounting, Left-Hand-Drive Vehicles

1. Chock the tires, then tilt the hood. For instructions, refer to the vehicle driver's manual.

⚠ WARNING

WARNING: When draining the air system, don't look into the air jets or direct them toward anyone, because dirt or sludge particles may be in

Removal and Installation

1. Brake Valve
2. 5/16–18 Hexnut
3. 5/16–18 Capscrew
4. Mounting Adaptor
5. Push Rod Clevis
6. Brake Pedal
7. Push Rod Jam Nuts
8. Brake Pedal Push Rod
9. Boot
10. Mounting Bracket Assembly
11. Plunger

Fig. 2, Brake Valve Mounting, Right-Hand-Drive Vehicles

the airstream. Don't disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can result in personal injury.

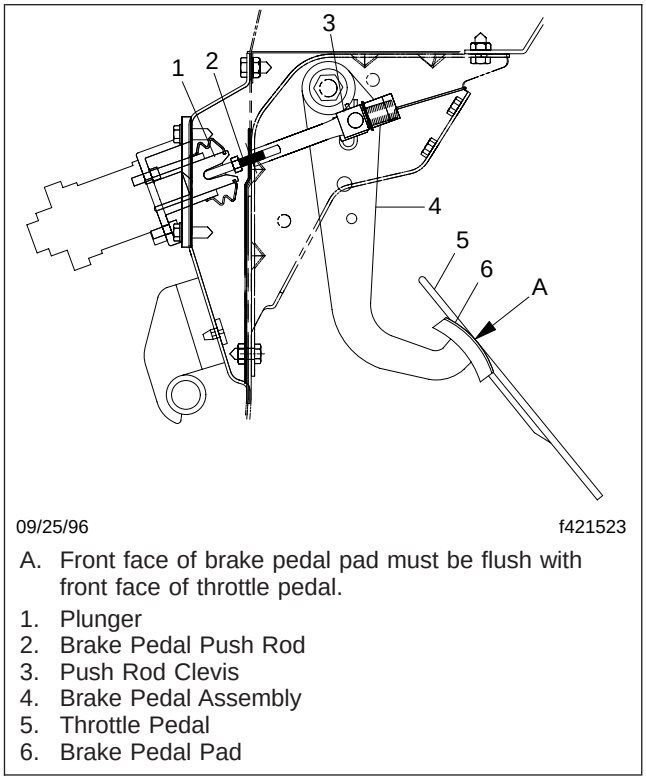
2. Drain all of the air reservoirs.
3. Mark the brake valve air supply and delivery lines for assembly reference. Carefully disconnect the air lines from the brake valve, and plug them to keep out contaminants.
4. Remove the capscrews and flatwashers that attach the brake valve and mounting adaptor to the front cab mount plate or the mounting bracket assembly.

   Remove the fasteners that attach the brake valve to the mounting adaptor.
5. Remove the plunger (and boot, if equipped) from the mounting adaptor. Wipe off the old grease from the plunger, boot, and adaptor.
6. Check the bore of the adaptor and the sliding surface of the plunger for corrosion; there should be no pitting or roughness. Check the boot (if equipped) for damage. Replace parts as needed.
7. Note the locations and positions of the elbows, then remove them from the brake valve. Clean off the dirt and old sealant from the threads of the elbows.

Installation (See Fig. 1 and Fig. 2)

⚠ WARNING

WARNING: When applying sealant, make sure that excess sealant doesn't get inside either the male or the female fittings. Loose foreign material inside the air plumbing may clog a valve, causing a loss of brake control, which could result in personal injury.



1. Apply a small quantity of Loctite® Pipe Sealant (with Teflon® 59241), or an equivalent sealant, to the male threads of each of the elbows.
2. Install the elbows in the ports of the brake valve. Tighten them finger-tight, then tighten them one additional turn with a wrench. As needed, further tighten them until they are correctly positioned.
3. Lubricate the sliding surface of the brake plunger and the adaptor bore with a silicone-based grease, Dow Corning 55 O-Ring Lubricant or Loctite V–755 O-Ring Lubricant. Install the plunger in the mounting adaptor. Make sure the plunger is positioned correctly (see **Fig. 3**). Install the boot (if equipped) on the mounting adaptor.

A. This end toward brake valve.
B. This end toward brake pedal push rod.
1. Plunger

Fig. 3, Plunger Installation

4. Attach the mounting adaptor to the brake valve. Tighten the hexnuts 15 lbf·ft (20 N·m).
5. Loosen the jam nuts on the brake pedal push rod, then turn the push rod into the clevis at least three full turns.
6. Check that the front face of the brake pedal pad is flush with the front face of the throttle pedal. See **Fig. 4**. If it isn't, adjust the brake pedal height as follows:

A. Front face of brake pedal pad must be flush with front face of throttle pedal.
1. Plunger
2. Brake Pedal Push Rod
3. Push Rod Clevis
4. Brake Pedal Assembly
5. Throttle Pedal
6. Brake Pedal Pad

Fig. 4, Brake Pedal and Valve Installation (left-hand-drive shown)

⚠ CAUTION

CAUTION: If you loosen the pedal stop bracket capscrews or remove the pedal stop bracket, don't lift the brake pedal past where the stop bracket was located. To do so could bend the push rod.

6.1 Loosen the pedal stop bracket capscrews.

6.2 Adjust the position of the pedal stop bracket, until the front face of the brake pedal pad is flush with the front face of the throttle pedal.

Removal and Installation

6.3 Tighten the pedal stop bracket capscrews 13 lbf·ft (18 N·m).

7. Install the brake valve, mounting adaptor, and new adaptor gasket (if equipped) on the outside of the front cab mount plate or mounting bracket assembly. Make sure the forward end of the brake pedal push rod enters the plunger. Install the adaptor mounting capscrews and flatwashers. Tighten the capscrews 23 lbf·ft (31 N·m).
8. Connect the air lines as previously marked. Tighten the nuts finger-tight. Using a wrench, further tighten the nuts until there is resistance, then tighten one-sixth additional turn.
9. Inside the cab, push the plunger into the mounting adaptor until increased resistance is felt. Turn the push rod into the clevis until you are certain that there is space between the end of the push rod and its seat in the plunger.
10. With the brake pedal released (in the up position), use your fingers and turn the push rod out of the clevis until it bottoms in the plunger without pushing the plunger further.

IMPORTANT: Be sure the push rod and plunger aren't "preloading" the brake valve, which could keep the brake valve from exhausting.

11. Check the pedal for free play. There should be no pedal free play and no brake valve preloading. Use a wrench to hold the push rod to keep it from turning, then tighten the double jam nuts against the clevis 15 lbf·ft (20 N·m).
12. Check and secure the air lines and electrical wires so they can't interfere with the movement of the brake pedal or push rod.
13. Lower the hood.
14. Do the operating and leakage checks. For instructions, refer to **Subject 100**.
15. Remove the chocks from the tires.
16. Test drive the vehicle in a safe area at low speed. Make several brake applications to be sure the vehicle comes to a safe stop.

Disassembly, Cleaning and Inspecting, and Assembly

Disassembly (See Fig. 1)

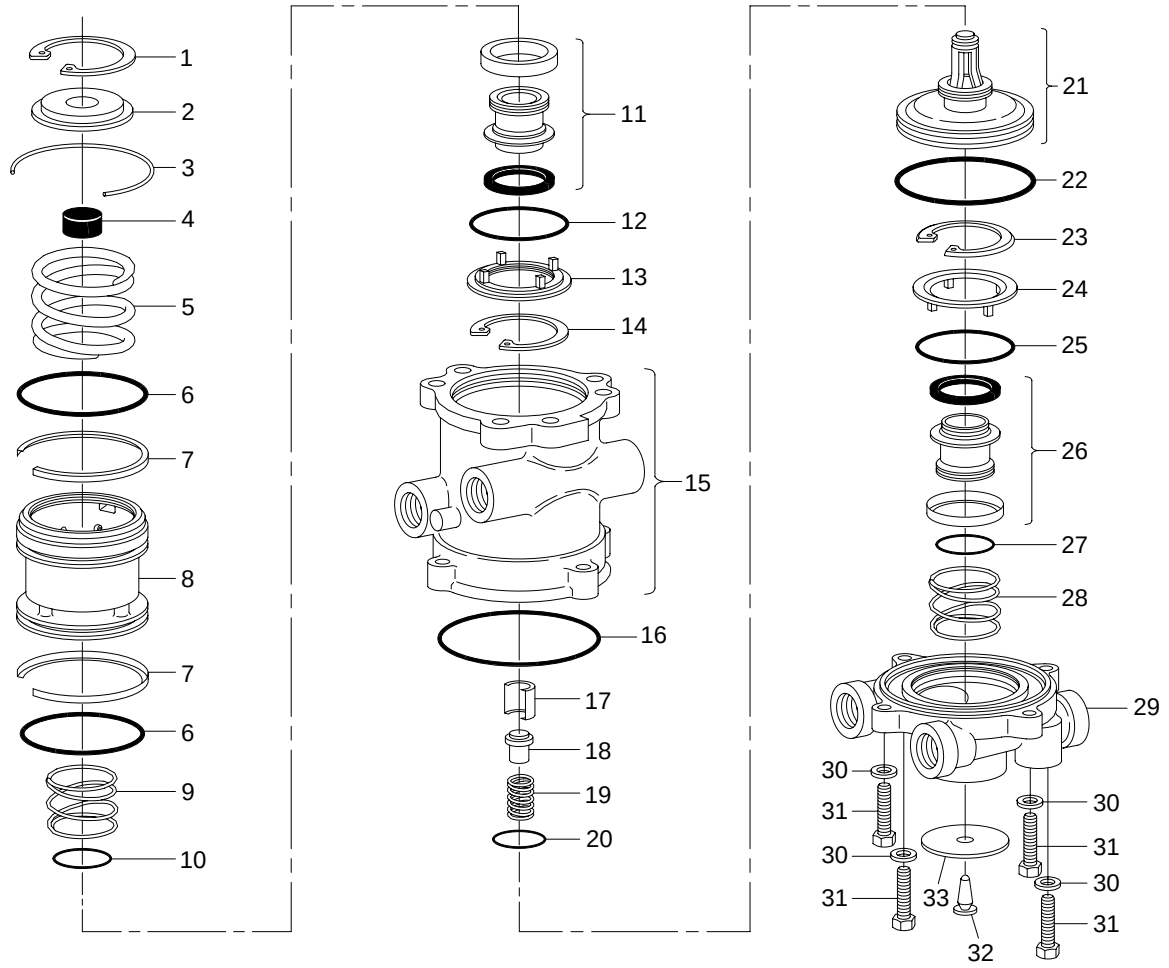
1. Remove the valve from the vehicle, following instructions in **Subject 110**.
2. Mark the upper and lower valve bodies for later assembly, then remove the four capscrews that hold them together.
3. Pull the secondary piston (Ref. 21) out of the upper valve body, then remove and discard the O-ring (Ref. 22) from it.
4. While manually depressing the valve seat (Ref. 24), remove and discard the beveled retaining ring (Ref. 23) from the lower valve body (Ref. 29).
5. Carefully release the valve seat (Ref. 24), then remove it from the lower valve body.
6. Remove and discard the O-ring (Ref. 25).
7. Remove and discard the valve assembly and its O-ring (Refs. 26 and 27) from the lower valve body.
8. Remove the valve assembly return spring (Ref. 28).
9. Remove the retainer, plunger, plunger return spring, and O-ring (Refs. 17, 18, 19, and 20) from the secondary piston.
10. Remove and discard the exhaust diaphragm retainer and the exhaust diaphragm (Refs. 32 and 33) from the lower valve body.

⚠ WARNING

WARNING: The primary piston is held down by a graduating spring, which is under tension. Be careful when removing the retaining ring and graduating spring retainer, because the spring or the piston may release suddenly, which could cause personal injury. Hold the graduating spring and the primary piston down when removing the retaining ring and spring retainer.

11. Push the primary piston (Ref. 8) into the upper body until the retaining ring (Ref. 1) is visible.
12. Being careful not to damage the piston bore, remove the retaining ring.
13. Gently tap the upper body on a padded surface to remove the primary piston. Re-move and discard the two O-rings and wear rings (Refs. 6 and 7).
14. Put the primary piston on a flat surface, then hold down the spring retainer (Ref. 2). Remove and discard the retaining ring (Ref. 1) from the piston.
15. Slowly release the spring retainer, and ease it out of the piston. Remove it and the graduating spring (Ref. 5) from the piston.
16. Remove and discard the rubber spring (Ref. 4) from inside the piston.
17. While holding down the valve seat (Ref. 13), remove and discard the beveled retaining ring (Ref. 14) from the primary piston.
18. Slowly release the valve seat, and ease it out of the piston. Remove and discard the O-ring (Ref. 10).
19. Remove and discard the valve assembly and its O-ring (Refs. 11 and 10) from the primary piston, then remove the return spring (Ref. 9).

Cleaning and Inspecting



⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Clean all the metal parts in mineral spirits, then dry them with compressed air.
2. Check all the parts. If any corrosion, wear, or damage is found, replace the part.
   - 2.1 Check the bores of both valve bodies for deep scoring.
   - 2.2 Make sure the vents on the primary piston are free of obstructions.
   - 2.3 Make sure the vent in the upper valve body is open.
   - 2.4 Check the plunger (**Fig. 2**) for wear or damage.

Disassembly, Cleaning and Inspecting, and Assembly

2.5 Check all the air line fittings, and clean any thread sealant from them.

Assembly (See Fig. 1)

IMPORTANT: Keep the work area, tools, and brake valve parts clean during assembly.

1. Using Dow Corning 55-M pneumatic grease or equivalent, lightly grease all the new O-rings, O-ring grooves, piston bores, and all sliding surfaces.
2. Put the primary piston on a flat surface, then install the rubber spring (Ref. 4) and the metal graduating spring (Ref. 5).
3. Install the graduating spring retainer (Ref. 2) on top of the graduating spring.
4. While holding down the spring retainer in the primary piston, install the retaining ring (Ref. 1). Make sure it's completely seated in its groove.
5. Install new O-rings on both valve assemblies.
6. Install the valve assembly return spring (Ref. 9) in the primary piston, then install the valve assembly (Ref. 11).
7. Install a new O-ring into its groove on the primary piston, then install the valve seat (Ref. 13) onto the valve assembly.
8. Hold down the valve seat in the piston, then install the beveled retaining ring (Ref. 14) with the flat side of the ring against the valve seat (beveled side of the ring up). Make sure the ring is seated completely.

IMPORTANT: Make sure the beveled retaining ring is installed correctly. The flat side of it must be against the valve seat, and the beveled side must be facing up. If it's not, remove the ring and install it again.

9. Install new O-rings on the primary piston.
10. Install the wear rings (Ref. 7) on the primary piston.
    - 10.1 Position a wear ring so one flange of it is in the O-ring groove, and the opposite flange faces away from the end of the piston (toward the middle of the piston).

      Repeat this step for the other wear ring.
    - 10.2 Check the wear rings; make sure they are not overlapping or covering the O-rings. If they are, remove them and install them again.
11. Being careful not to damage the piston O-rings and wear rings, install the primary piston— valve end first— in the upper valve body. Push the piston down until the piston retaining groove at the top of the bore is visible.

⚠ CAUTION

CAUTION: Don't force the piston into its bore, or you will damage its sealing surfaces. If the piston doesn't fit correctly, check the wear rings. If they were installed incorrectly, remove them and install them again.

12. Install the piston retaining ring (Ref. 3) in its groove. Make sure it's fully seated.
13. Install the plunger (Ref. 18) in the plunger return spring (Ref. 19), then install them both on the secondary piston.
14. While holding the plunger and return spring on the secondary piston, install the retainer (Ref. 17) on the piston. Make sure the retainer flanges are secure around the piston lip and the plunger groove.
15. Install new O-rings on the secondary piston.
16. Install a new exhaust diaphragm (Ref. 33) on the lower valve body, then install the diaphragm retainer.
17. Install the valve assembly return spring (Ref. 28) in the lower valve body, then install the valve assembly (Ref. 26).

Disassembly, Cleaning and Inspecting, and Assembly

18. Install the O-ring in its groove on the primary piston, then install the valve seat (Ref. 24) on the valve assembly.
19. While holding the valve seat in the lower valve body, install the beveled retaining ring with the flat side of the ring against the valve seat (beveled side of the ring up). Make sure it is seated completely.

IMPORTANT: Make sure the beveled retaining ring is installed correctly. The flat side of it must be against the valve seat, and the beveled side must be facing up. If it's not, remove the ring and install it again.

20. Being careful not to damage the O-rings, install the secondary piston in the upper valve body.
21. Install a new O-ring in the upper valve body.
22. Using the reference marks made during disassembly, install the lower valve body on the upper valve body. Tighten the capscrews 60 N·m (45 lbf·ft).
23. Install the valve on the vehicle, following instructions in **Subject 110**.

General Description and Principles of Operation

(Refer to Fig. 1 and Fig. 2)

The BP-R1 bobtail proportioning relay valve is a combination of two individual valves in a single housing. The lower portion (body) of the BP-R1 contains a standard service brake relay valve, which functions as a relay station to speed up brake application and release. The upper portion (cover) houses a brake proportioning valve, which adjusts the proportion of normal service brake application pressure to the rear brake chambers when the tractor is not towing a trailer.

Used in tractor air brake systems only, the BP-R1 is installed in place of a standard relay valve. It functions as a standard service relay during operation of a tractor-trailer combination. During bobtail tractor operation, the BP-R1 improves controllability and reduces stopping distances by limiting air pressure to the rear brake chambers, whose axle load has been greatly reduced, while retaining normal air pressure to the front brake chambers. This reduces the chance of wheel lock and instability in emergency stops.

The rear brake proportioning system is standard on all class 6 and 7 tractors. The valve is mounted on the crossmember between the rear brake chambers. See the plumbing diagram in **"Specifications, 400."**

A control line from the control port of the BP-R1 valve is connected by a tee to the inlet supply port of the tractor protection valve. This line is charged with full line pressure when a trailer is connected and its spring brakes are released; or is completely exhausted when the tractor is bobtailed and the dash valve trailer charge knob is not applied.

TRAILER SUPPLY VALVE APPLIED (TRACTOR/TRAILER MODE)

On vehicles equipped with a proportioning system, air pressure at the control port allows full service air from the foot valve to pass through the proportioning portion of the valve. This gives full braking effort to the rear axles when a trailer is connected.

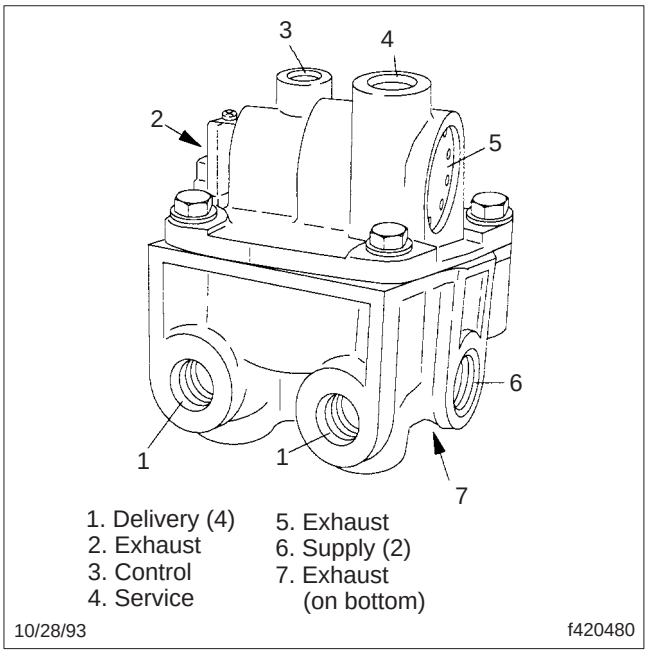

Fig. 1

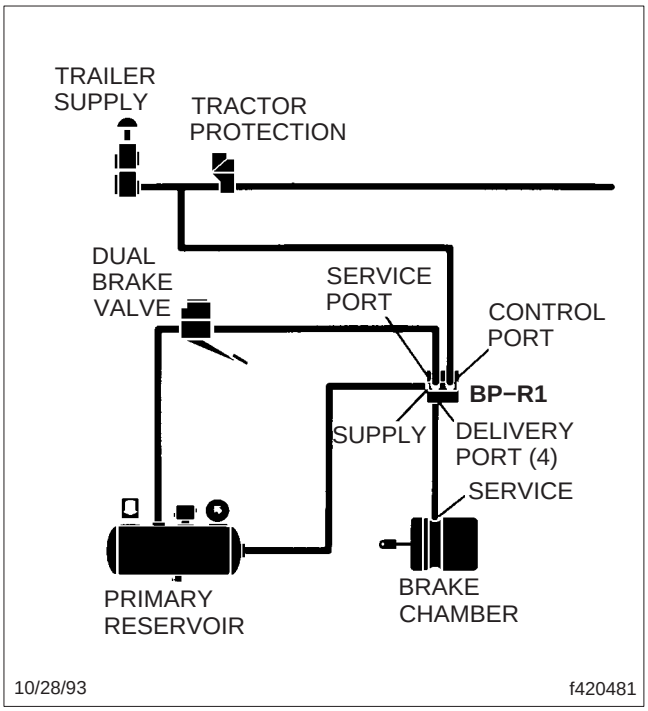

Fig. 2

General Description and Principles of Operation

TRAILER SUPPLY VALVE PULLED OUT (BOBTAIL MODE)

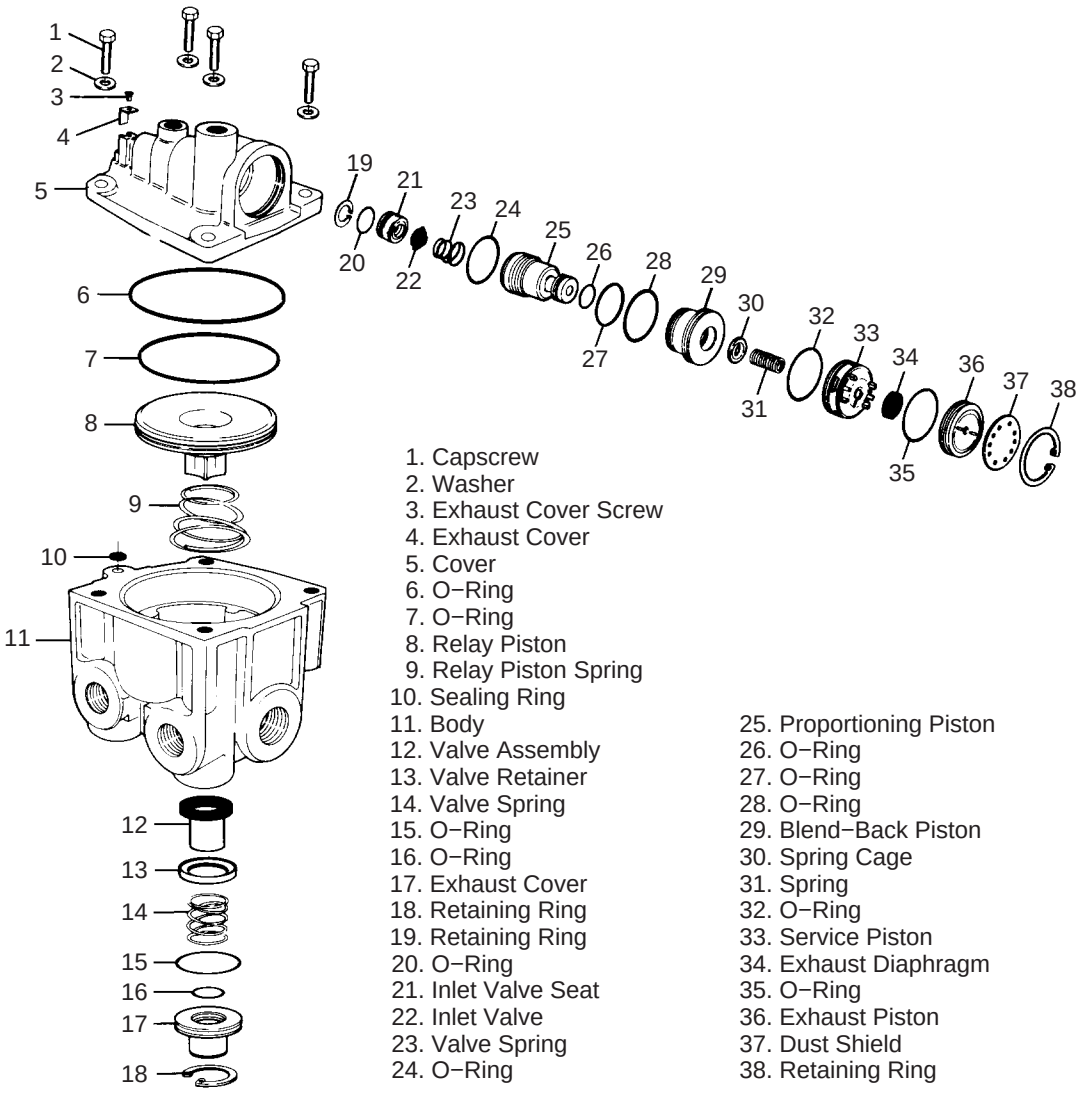
When the trailer supply valve is activated to disconnect the trailer, air in the BP-R1 control port is exhausted to atmosphere. In this mode, service application air exerts force on one side of the blend-back piston and also flows through the piston to exert force on the proportioning piston. The blend-back piston remains stationary at application pressures below 551 kPa (80 psi). Air also flows through the proportioning piston to exert force on both sides of it. Proportioning occurs due to the difference in effective area on each end of the proportioning piston. Service applications of more than 551 kPa (80 psi) cause the blend-back piston to begin to move. Above 551 kPa (80 psi) the different pressures on each side of this piston cause a "blend back" from proportioned delivery to a full one-to-one delivery.

Safety Precautions

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

When working on or around air brake systems and components, observe the following precautions.



1. Apply the parking brakes, chock the tires, and stop the engine when working under the vehicle. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air system pressure drops.
2. Wear safety goggles.
3. Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
4. Don't disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
5. Replacement hardware, tubing, hose, fittings, etc. should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace any components that have stripped threads or damaged parts. Don't attempt to repair parts by machining.
7. Never exceed recommended air pressure.

Operating Tests

1. Park the vehicle on a level surface and chock the tires.
2. Before testing the air brake proportioning system, do the following:
   - 2.1 Check the operation of the air compressor. Check the pressure levels of the air reservoirs.
   - 2.2 Be sure that all related valves are operating, and the system is plumbed as shown in **"Specifications, 400."**
   - 2.3 Check the operation of the brake chambers following the instructions in the brakes group of the vehicle maintenance manual.
   - 2.4 Inspect all tubing for kinks, dents, and other damage. Replace damaged tubing.
   - 2.5 Inspect all hoses for cracks, drying out, overheating, and other damage. Replace damaged hoses.
   - 2.6 Inspect all air line fittings. Tighten loose connections; replace fittings that are damaged.
3. Drain all air tanks to zero pressure.
4. Install a "tee" at the BP-R1 service port and at one of the delivery ports, then install a gauge in each.
5. Connect the tractor service and emergency gladhands to hose couplings that have been plugged; or, connect them to a trailer. Build the tractor system air pressure to governor cut-out.
6. With the dashboard trailer supply valve and system park control valve activated for tractor/trailer operation, apply, *hold,* and then release the brakes several times, varying the application pressures while watching the reaction of the gauges installed on the BP-R1. Note that a prompt application occurs and that it can be held, then promptly released.
7. Check the BP-R1 differential pressure by applying 69 kPa (10 psi) to the service port and noting the pressure registered at the delivery port. Subtract delivery port pressure from the 69 kPa (10 psi) service pressure to obtain the differential.

   NOTE: For BP-R1 valves that *don't incorporate* a relay piston spring (**Fig. 1**, Ref. 9), the measured differential should be about 28 kPa (4 psi). When a spring is in use, the differential will be higher.
8. Make and hold a full brake application of 689 kPa (100 psi) or greater, and note that full pressure is delivered to the chambers.
9. Activate the dash mounted trailer supply valve for bobtail tractor operation. Then make a *slow* brake application, increasing the pressure at the BP-R1 service port to 138 kPa (20 psi) while watching the reaction at the delivery port gauge. Note that delivery pressure rises to about 34 to 69 (5 to 10 psi) and remains constant while service pressure continues to rise to 138 kPa (20 psi). Release the application.
10. Make another brake application and *slowly* increase the pressure at the BP-R1 service port to between 414 to 483 kPa (60 and 70 psi) while observing the gauge installed at the delivery port. Note that when service port pressure rises to between 138 to 207 kPa (20 and 30 psi), delivery pressure begins to rise above the initial pressure noted above. The rise of delivery pressure should be at a proportioned rate of *about* three-to-one. At 483 kPa (70 psi) service pressure, delivered pressure should be 103 to 172 kPa (15 to 25 psi).
11. Make a full brake application, and note that both test gauges register the same pressure.
12. Remove the test gauges from the BP-R1.
13. Remove the chocks from the tires. Test drive the vehicle in a safe area at slow speed with the trailer supply valve pulled out (bobtail position). Make several brake applications to become familiar with the feel of the system before placing the vehicle back in service.

BP–R1 Brake Proportioning Valve Removal and Installation

Removal

1. Park the vehicle on a level surface, apply the parking brake, chock the tires, and drain all air tanks to zero pressure.

⚠ WARNING

WARNING: Wear safety glasses when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

2. Mark and then disconnect the air lines from the valve.
3. Remove the two bolts attaching the valve to the vehicle. Remove the valve.

Installation

1. Install the valve on the vehicle. Tighten the bolts 20 N·M (15 lbf·ft).
2. Connect the air lines to the proper ports, as marked during removal.
3. Check the proportioning valve operation **using the instructions in Subject 110**.

BP-R1 Brake Proportioning Valve Disassembly, Cleaning and Inspecting, and Assembly

Disassembly

⚠ CAUTION

CAUTION: The BP-R1, See Fig. 1, may be lightly clamped in a bench vise during disassembly, however, over-clamping will cause damage to the valve and result in leakage or malfunction.

If a vise is to be used, position the valve so that the jaws bear on the supply ports on opposing sides of the valve's body.

1. Remove all air fittings and plugs from the valve.
2. Mark the relationship of the valve cover to the body, and if the valve is equipped with a mount-

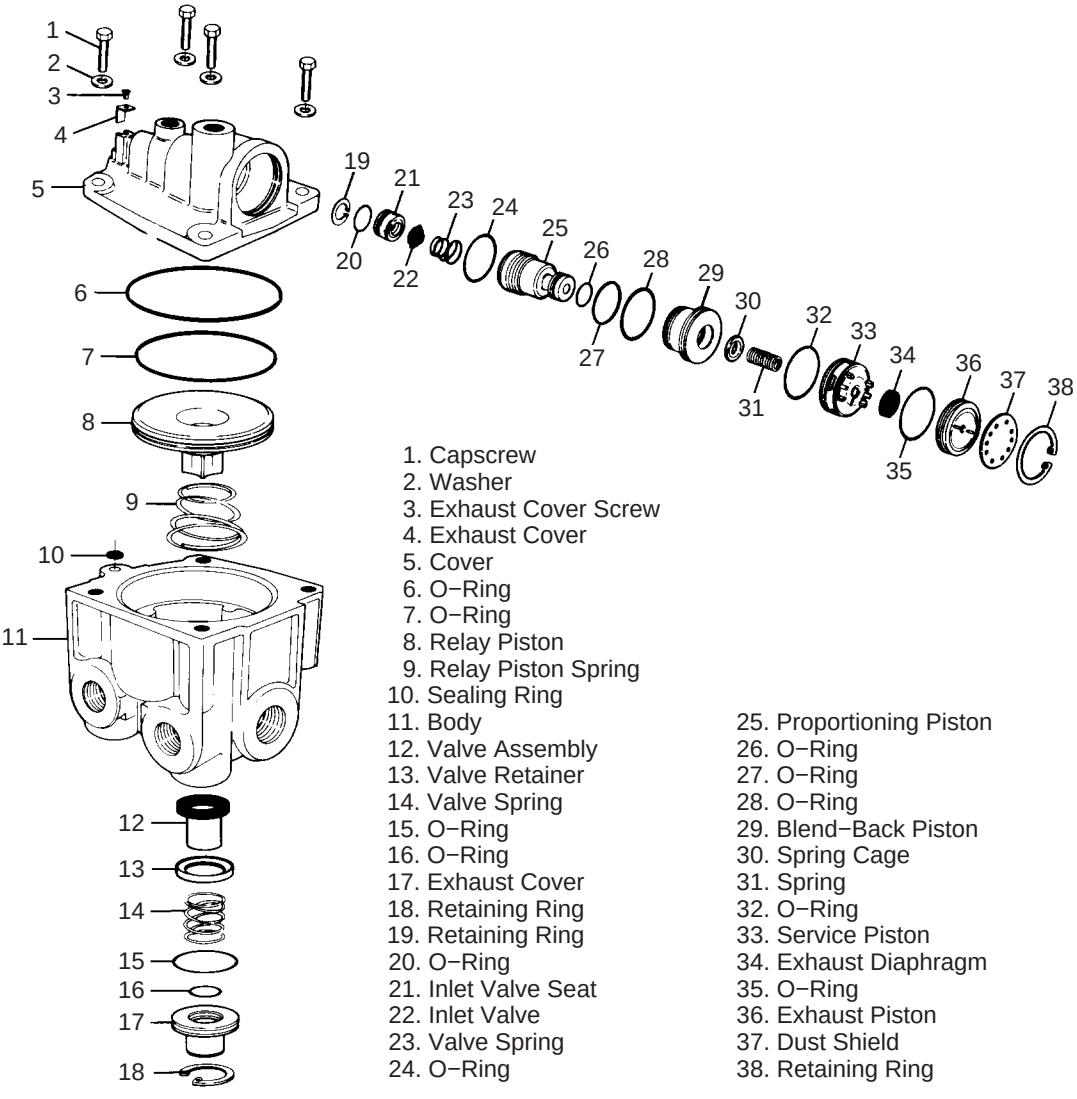

Fig. 1, BP-R1 Brake Proportioning Valve (exploded view)

BP-R1 Brake Proportioning Valve Disassembly, Cleaning and Inspecting, and Assembly

ing bracket, mark the relationship of the bracket to the cover.

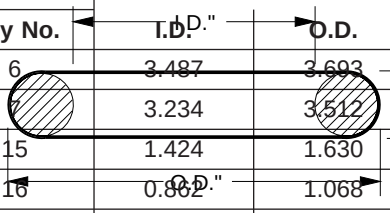
3. While holding the exhaust cover (Ref. 17), remove and discard the retaining ring (Ref. 18) that secures it to the body (Ref. 11).
4. Remove and discard the exhaust cover along with both O-rings (Refs. 15 and 16).
5. Remove and discard the valve spring (Ref. 14), valve retainer (Ref. 13), and the valve assembly (Ref. 12) from the body.
6. Remove and retain the four capscrews and washers (Refs. 1 and 2) that secure the cover (Ref. 5) to the body.
7. Separate the cover from the body, then remove and discard the sealing ring and O-ring (Refs. 10 and 6).
8. Remove and retain the relay piston (Ref. 8) and relay piston spring (Ref. 9) from the body.

NOTE: The relay piston spring is *not used in all valves* .

9. Remove and discard the O-ring (Ref. 7) from the relay piston.
10. Remove and discard the dust shield (Ref. 37) and the retaining ring (Ref. 38) from the valve cover, then remove and save the exhaust piston (Ref. 36).
11. Remove and discard the exhaust piston O-ring (Ref. 35) and the exhaust diaphragm (Ref. 34).
12. Remove and save the service piston (Ref. 33) from the valve cover, then remove and discard the service piston O-ring (Ref. 32).
13. Remove the spring (Ref. 31) and spring cage (Ref. 30) from the valve cover. Discard the spring and retain the spring cage.
14. Remove and retain the blend-back piston (Ref. 29) from the valve cover, then remove and discard both O-rings (Refs. 27 and 28).
15. Remove and save the proportioning piston (Ref. 25) from the valve cover, then remove and discard both O-rings (Refs. 26 and 24).
16. While holding the inlet valve seat (Ref. 21) in place, remove and discard the retaining ring (Ref. 19) from the proportioning piston.
17. Remove the inlet valve seat, the inlet valve (Ref. 22), and the valve spring (Ref. 23) from the proportioning piston, then remove and discard the O-ring (Ref. 20) from the valve seat. Discard the valve and spring also.
18. Remove and discard the exhaust cover screw (Ref. 3) and exhaust cover (Ref. 4).

Cleaning and Inspection

⚠ WARNING



WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using mineral spirits or an equivalent solvent, clean and thoroughly dry all metal parts. Don't damage any bores with metal tools.
2. Wash all non-metallic parts (Refs. 8, 17, 21, 25, 29, 30, 33, and 36) in a soap and water solution, making certain to rinse and dry thoroughly.
3. Inspect the interior and exterior of all metal parts that will be re-used. Check for severe corrosion, pitting, gouges and cracks. Superficial corrosion or pitting of the exterior portion of the body and cover is acceptable. Replace the entire valve if the interior of the body or cover show signs of corrosion or pitting.
4. Inspect each non-metallic part for cracks, wear or distortion. Replace the entire valve if these conditions exist.
5. Replace all rubber parts.
6. Make certain the air channel running between the top surface of the body and its supply port is clear and free of blockages.
7. Make certain all air channels and exhaust passages in the valve cover are clear and free of blockages.
8. Inspect the pipe threads in the body and valve cover. Make certain they are clean and free of thread sealant.
9. If the valve was equipped with a relay piston spring, check it for signs of corrosion, pitting, and cracks. Replace as needed.

10. Inspect all air line fittings for corrosion; replace as needed. Be sure to remove all old thread sealant before re-use.

Assembly

1. Prior to assembly, lubricate all O-rings (identify them by referring to **Table 1**), seals, and pistons, as well as body and cover bores, using the lubricant provided in the Bendix maintenance kit. Use all of the lubricant, and spread it evenly on the rubbing surfaces.

Key No.	I.D.	O.D.	W
6	3.487	3.693	0.103
7	3.234	3.512	0.139
15	1.424	1.630	0.103
16	0.862	1.068	0.103
20	0.489	0.629	0.070
24	0.739	0.879	0.070
26	0.412	0.552	0.070
27	0.737	0.943	0.103
28	1.112	1.318	0.103
32	1.176	1.316	0.070
35	1.356	1.496	0.070

Table 1, O-Ring Identification (Sectional View)

2. Install the O-ring (**Fig. 1**, Ref. 20) on the inlet valve seat (Ref. 21).
3. Install the small end of the valve spring (Ref. 23) over the rubber of the inlet valve (Ref. 22), making sure the spring coils rest on the valve's four tabs.
4. Insert the spring and valve into the valve seat, making sure the four tabs are inside the seat's bore.
5. Insert the valve, seat, and spring assembly into the proportioning piston (Ref. 25)— large end of the spring first.
6. While holding the seat in place, install the retaining ring (Ref. 19) to secure it in the piston. Make certain the retaining ring is fully seated in its groove. Make sure the valve is straight against the exhaust seat and free to move.
7. Install both the large and small diameter O-rings (Refs. 24 and 26) on the proportioning piston.
8. Install both the large and small diameter O-rings (Refs. 28 and 27) on the blend-back piston (Ref. 29), then insert the small diameter of the proportioning piston into the small diameter end of the blend-back piston.
9. Carefully insert the assembled proportioning and blend-back pistons to the edge of the bore in the cover (Ref. 5). Don't cut or pinch the O-rings.
10. With the bore of the cover facing up, install the spring cage (Ref. 30) in the blend-back piston so that its flat side rests against the blend-back piston (its depressed side out towards spring [Ref. 31]).
11. Install the O-ring (Ref. 32) on the service piston (Ref. 33), then install the spring (Ref. 31) in the cage (Ref. 30) so that its coils are in the inside diameter of the cage.
12. Install the O-ring (Ref. 35) on the exhaust piston (Ref. 36), and place the exhaust diaphragm (Ref. 34) between the six posts of the service piston.
13. Place the exhaust piston on the service piston with its six-ribbed side facing the service piston. Then install both pistons while pushing the proportioning and blend-back pistons all the way into the cover.
14. Install the dust shield (Ref. 37) in the cover.
15. While holding the dust shield in the cover, install the retaining ring (Ref. 38), making certain it is fully seated in its groove.
16. Install the exhaust cover (Ref. 4) using the screw (Ref. 3) to retain it. Torque the screw 100 to 160 N·cm (8 to 15 lbf·in).
17. Install the valve retainer (Ref. 13) on the valve assembly (Ref. 12) so that the flange of the retainer (Ref. 13) surrounds the rubber portion of the valve. Install the valve assembly in the body.
18. Install the valve spring (Ref. 14) in the body.
19. Install the large and small diameter O-rings (Refs. 15 and 16) in the exhaust cover (Ref. 17), then install the exhaust cover in the body, taking

BP-R1 Brake Proportioning Valve Disassembly, Cleaning and Inspecting, and Assembly

care not to damage the O-rings. Hold the exhaust cover in place.

20. While depressing the exhaust cover, install the retaining ring (Ref. 18) in the body. Make sure this ring is fully seated in its groove in the body.
21. If the BP-R1 was equipped with a relay piston spring (Ref. 9), install the spring in the body, large diameter first.
22. Using lubricant to hold them in place, install the large O-ring and small sealing ring (Refs. 6 and 10) on the cover.
23. Install the O-ring (Ref. 7) on the relay piston (Ref. 8), then install the piston in the body.
24. After noting the relationship marks made prior to disassembly, install the mounting bracket (not shown) on the cover, then secure the cover and mounting bracket on the body using the four capscrews and washers (Refs. 1 and 2). Torque the capscrews 1360 to 1700 N·cm (120 to 150 lbf·in).

Refer to Fig. 1 for a diagram of the Bendix air brake proportioning system.

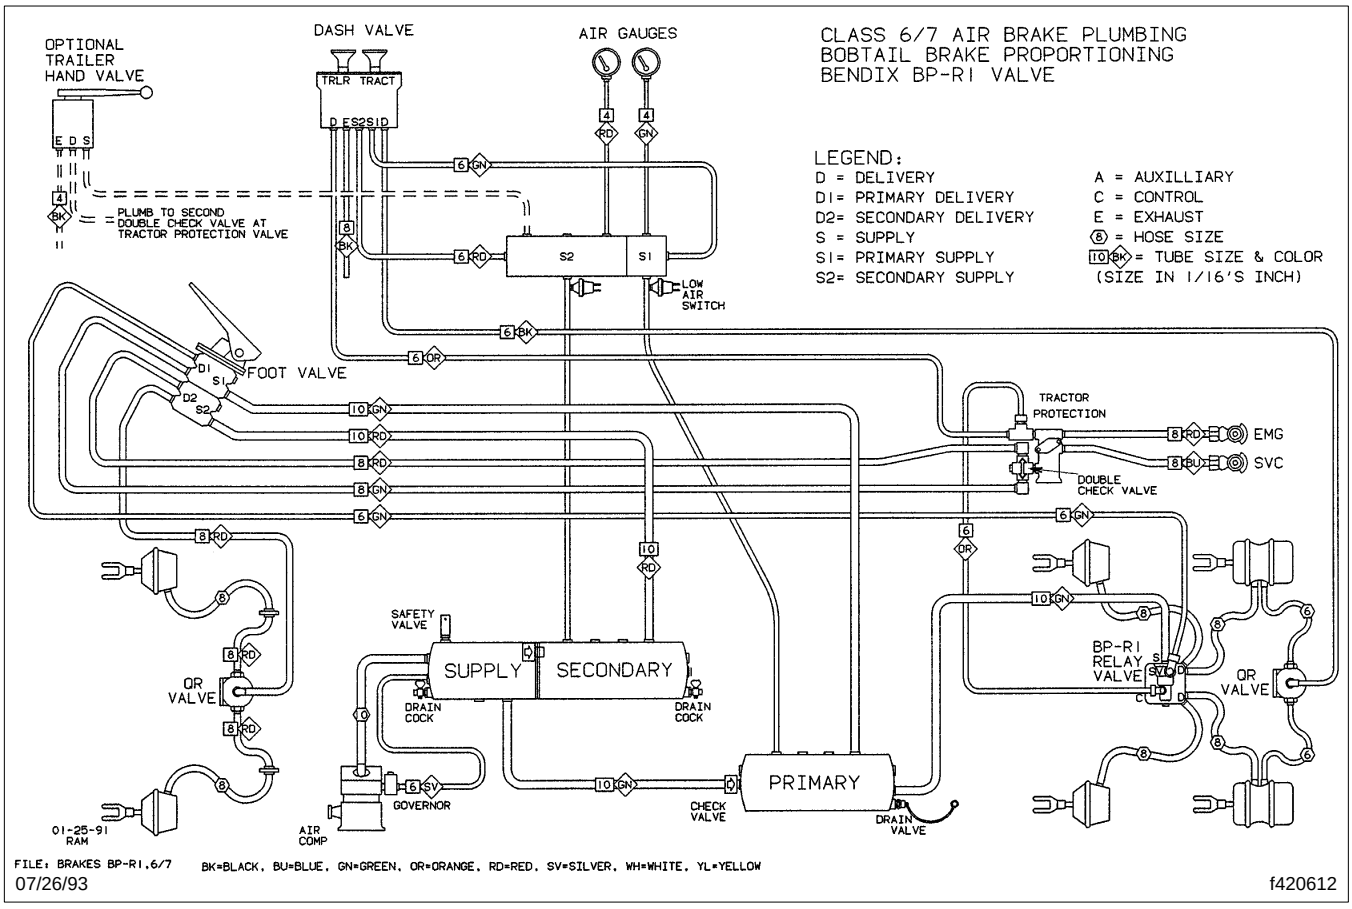


Fig. 1

General Description

The function of the Bendix AD-9 air dryer (**Fig. 1**) is to collect and remove air system contaminants in solid, liquid, and vapor form before they enter the brake system.

the heater and thermostat assembly, and the discharge check valve assembly, can be serviced without removing the air dryer from the vehicle. The screw-in desiccant cartridge requires removal of the air dryer assembly from the vehicle.

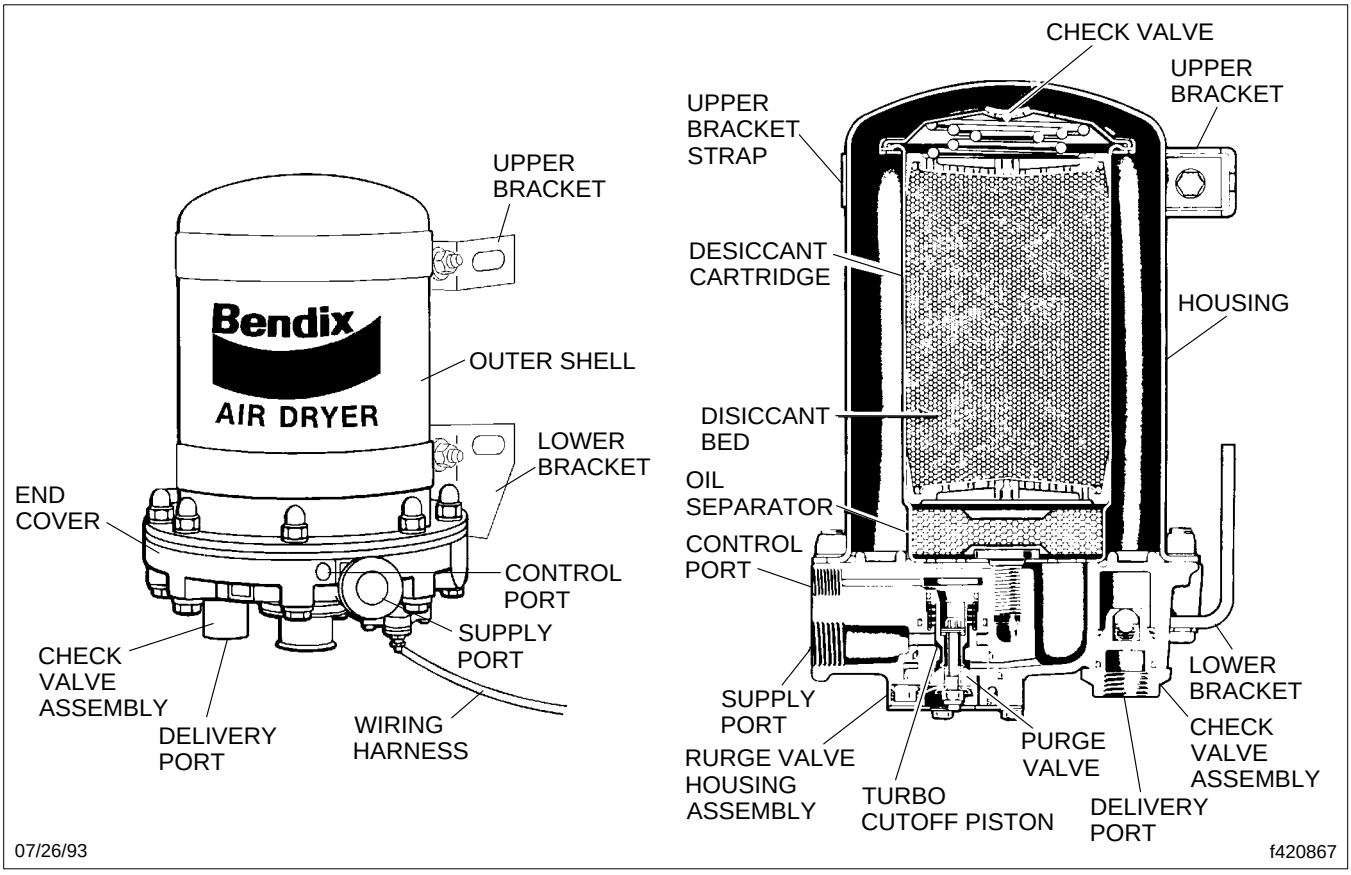

Fig. 1, Bendix AD-9 Air Dryer and Cutaway View

The AD-9 air dryer consists of the desiccant cartridge and a die-cast aluminum end cover secured to a cylindrical steel outer shell with eight capscrews and nuts. The end cover contains a check valve assembly, a safety valve, three threaded air connections and the purge valve housing assembly. The removable purge valve housing assembly features a purge valve mechanism and a turbocharger cutoff that are designed to prevent loss of engine turbo boost pressure during the purge cycle of the air dryer.

To ease servicing, the desiccant cartridge and discharge check valve assembly are screw-in types. The purge valve housing assembly, which includes

The AD-9 has three female pipe thread air connections; each is identified as follows (see **Table 1**):

Port I. D.	Function/Connection
4–CON	Control Port (purge valve control and turbo cutoff)
11–SUP	Supply Port (air in)
2–DEL	Delivery Port (air out)

Table 1, AD-9 Pipe Thread Connections

General Description and Principles of Operation

Principles of Operation

The AD-9 air dryer alternates between two operational modes or cycles during operation: the charge cycle and the purge cycle.

CHARGE CYCLE (See Fig. 2)

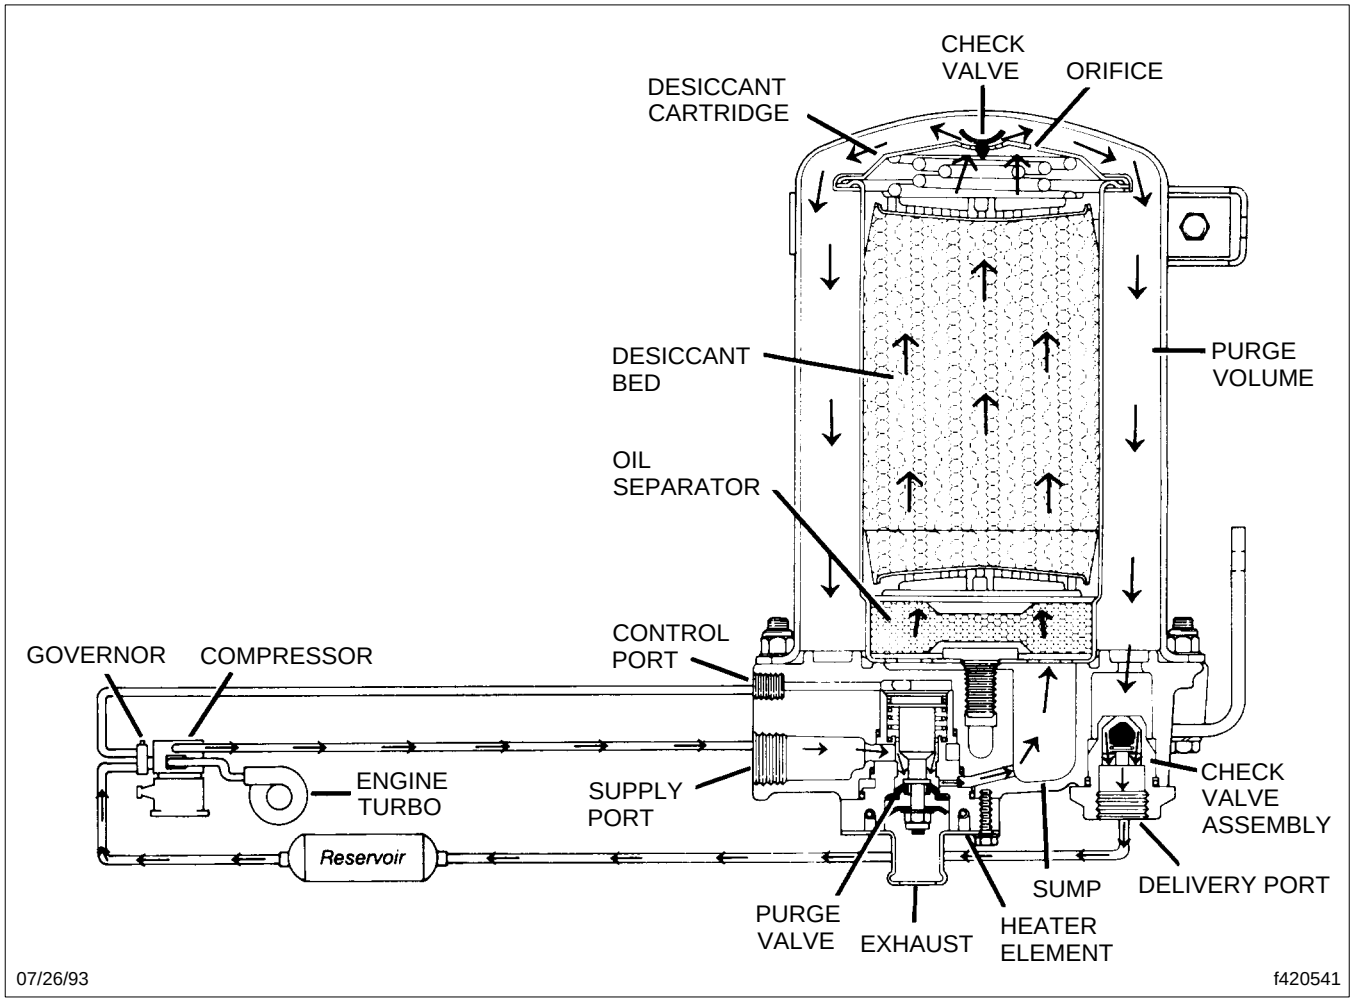

Fig. 2, AD-9 Charge Cycle

When the compressor is loaded (compressing air), pressurized air, along with oil, oil vapor, water, and water vapor flow through the compressor discharge line to the supply port of the air dryer end cover. As air travels through the end-cover assembly, its direction of flow changes several times, reducing the temperature, causing contaminants to condense and drop to the bottom or sump of the air dryer end cover.

After exiting the end cover, air flows into the desiccant cartridge. Once in the cartridge, air first flows through an oil separator, which removes water, oil, oil vapor, and solid contaminants.

Air exits the oil separator and enters the desiccant drying bed. Air flowing through the column of desiccant becomes progressively drier as water vapor sticks to the desiccant material in a process known as adsorption. The desiccant cartridge, using the adsorption process typically removes 95 percent of the water vapor from the pressurized air.

Most of the dry air exits the desiccant cartridge through its integral single check valve to fill the purge volume between the desiccant cartridge and outer shell. Some air also exits the desiccant cartridge through the purge orifice adjacent to the check valve.

Dry air flows out of the purge volume through the single check valve assembly and out the delivery port to the first (supply) reservoir of the air system.

The air dryer remains in the charge cycle until air brake system pressure builds to the governor cutout setting.

PURGE CYCLE **(See Fig. 3)**

When the brake system pressure reaches the governor cutout setting, the compressor unloads (air compression stopped), and the purge cycle of the air dryer begins. When the governor unloads the compressor, it pressurizes the unloader mechanism and line connecting the governor unloader port to the AD-9 end cover control port. The purge piston moves in response to air pressure causing the purge valve to open to atmosphere and partially close off the suppl of air from the compressor. This is further discussed under "Turbo Cutoff Feature."

Contaminants in the end cover sump are expelled immediately when the purge valve opens. Also, air that was flowing through the desiccant cartridge changes direction and begins to flow toward the open purge valve. Oil and solid contaminants collected by the oil separator are removed by air flowing from the desiccant drying bed to the open purge valve.

The initial purge and desiccant cartridge decompression last only a few seconds and are signaled by an audible burst of air at the AD-9 exhaust. The actual reactivation of the desiccant drying bed begins as dry air flows from the purge volume through the desiccant cartridge purge orifice and into the desiccant drying bed. Pressurized air from the purge volume expands after passing through the purge orifice; its pressure is lowered and its volume increased. Dry air flowing through the drying bed reactivates the desiccant material by removing the water vapor sticking to it. Generally, it takes 15 to 30 seconds for the entire purge volume of a standard AD-9 to flow through the desiccant drying bed.

The end cover single check valve assembly prevents compressed air in the brake system from returning to the air dryer during the purge cycle. After the 30 second purge cycle is complete, the air dryer is ready for the next charge cycle to begin.

The purge valve will remain open after the purge cycle is complete, and will not close until air brake system pressure is reduced and the governor signals the compressor to charge.

NOTE: The air dryer should be periodically checked for operation and tested for leaks. See Group 42 of the *Business Class Trucks Maintenance Manual* for intervals and procedures.

General Description and Principles of Operation

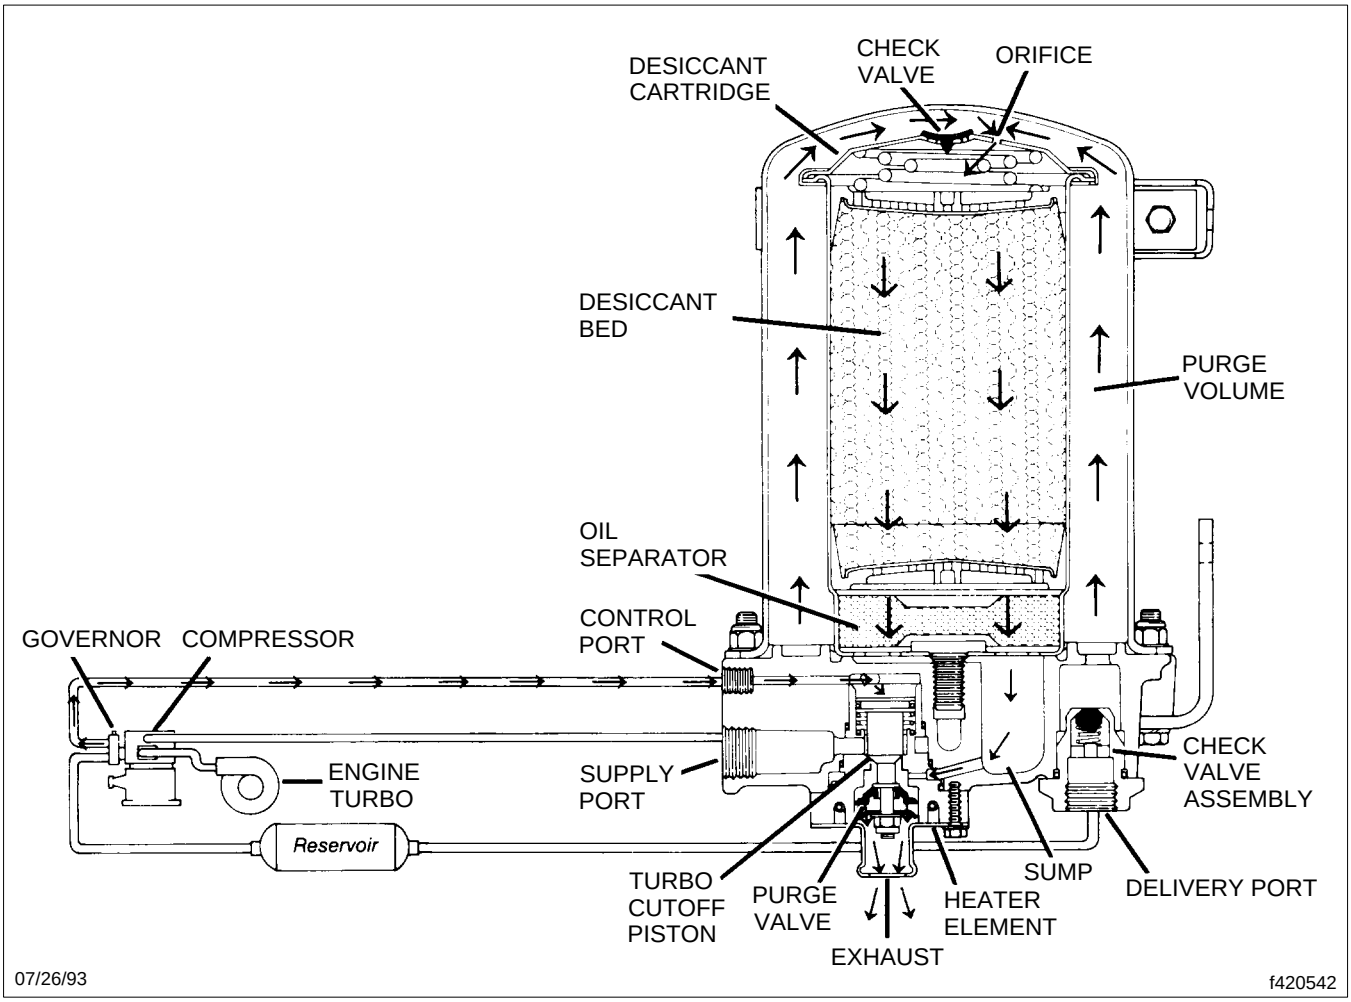

Fig. 3, AD-9 Purge Cycle

TURBO CUTOFF FEATURE (See Fig. 4)

Primarily, the turbo cutoff valve prevents loss of engine turbocharger air pressure through the AD-9 in systems where the compressor intake is connected to the engine turbocharger. The turbo cutoff valve also reduces the puffing of air out the open exhaust when a naturally aspirated, single cylinder compressor equipped with an inlet check valve is in use.

At the beginning of the purge cycle, the downward travel of the purge piston is stopped when the turbo cutoff valve (tapered portion of the purge piston) contacts its mating metal seat in the purge valve housing. With the turbo cutoff valve seated (closed position), air in the discharge line and AD-9 supply port is restricted from entering the air dryer. While the turbo cutoff *effectively* prevents loss of turbocharger boost pressure to the engine, some seepage of air may be detected under certain conditions of compressor, engine, and turbocharger operation. Even so, there will be low pressure trapped in the discharge line.

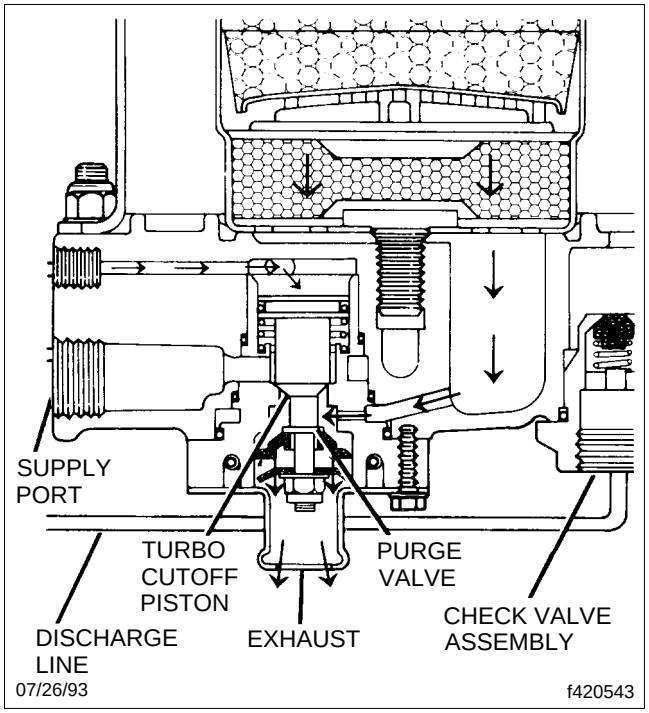

Fig. 4, AD-9 Turbo Cutoff

Safety Precautions

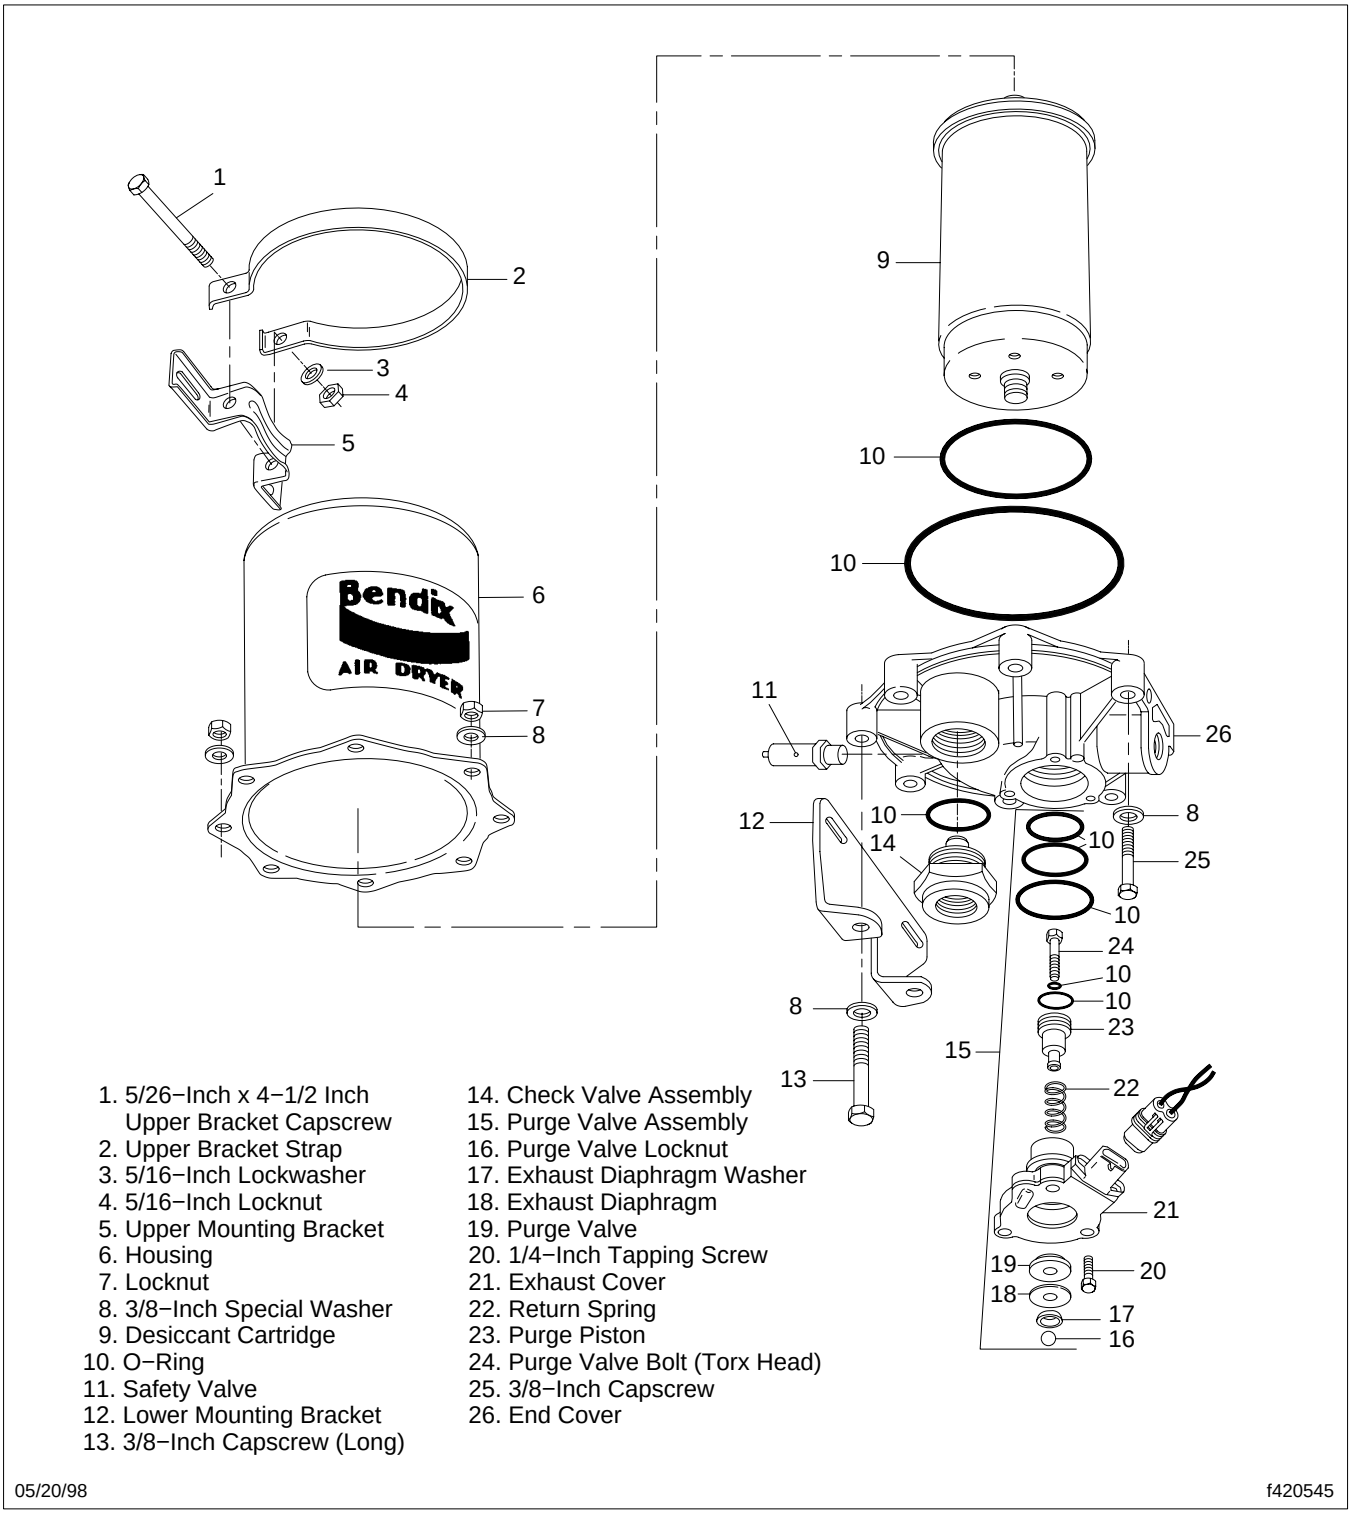
When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure, and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Don't disassemble a component until you have read and understood the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools, and observe all precautions pertaining to use of those tools.
5. Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.

   Make sure that when replacing tubing or hose, all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.

Removal

IMPORTANT: Before working on or around air brake systems and components, read **"Safety Precautions, 100."**



1. Park the vehicle on a level surface and chock the tires.
2. Drain all reservoirs to zero pressure.
3. Remove the air dryer.
   - 3.1 Identify and disconnect the three air lines from the end cover, and note the position of end cover ports relative to the vehicle.
   - 3.2 Unplug the vehicle wiring harness from the heater and thermostat assembly connector on the purge valve housing assembly.
   - 3.3 Loosen the hex bolt securing the upper mounting strap.
   - 3.4 Remove, save, and *mark* the two end cover capscrews, locknuts, and four special washers that retain the lower mounting bracket to the end cover. Also mark the two holes of the end cover. (These bolts are longer than the other six bolts.)
   - 3.5 Remove the air dryer from its mounting brackets.

Installation (Refer to Fig. 1)

IMPORTANT: Before working on or around air brake systems and components, read **"Safety Precautions, 100."**

1. Install the assembled air dryer on the vehicle.
   - 1.1 Position the air dryer up into the upper mounting bracket and strap. Align the two unused holes in the end cover with the bottom mounting bracket so that the bottom bracket supports the air dryer. The end cover should rest on the bracket.
   - 1.2 Using the remaining two capscrews (Ref. 16), four special washers (Ref. 15), and two locknuts (Ref. 17), secure the air dryer to the lower bracket. Tighten the two remaining capscrews 3060 to 4340 N·cm (270 to 385 lbf·in).
   - 1.3 Tighten the bolt and nut on the upper mounting bracket strap 900 to 1360 N·cm (80 to 120 lbf·in).
   - 1.4 As referenced earlier in "Removal", connect the three air lines to the ports on the end cover.
   - 1.5 Connect the vehicle wiring harness to the air dryer heater and thermostat assembly connector by plugging it into the air dryer connector until its lock tab snaps in place.
2. Test the air dryer following instructions in the brakes group of the vehicle maintenance manual.

Removal and Installation

1. 5/26−Inch x 4−1/2 Inch Upper Bracket Capscrew
2. Upper Bracket Strap
3. 5/16−Inch Lockwasher
4. 5/16−Inch Locknut
5. Upper Mounting Bracket
6. Housing
7. Locknut
8. 3/8−Inch Special Washer
9. Desiccant Cartridge
10. O−Ring
11. Safety Valve
12. Lower Mounting Bracket
13. 3/8−Inch Capscrew (Long)
14. Check Valve Assembly
15. Purge Valve Assembly
16. Purge Valve Locknut
17. Exhaust Diaphragm Washer
18. Exhaust Diaphragm
19. Purge Valve
20. 1/4−Inch Tapping Screw
21. Exhaust Cover
22. Return Spring
23. Purge Piston
24. Purge Valve Bolt (Torx Head)
25. 3/8−Inch Capscrew
26. End Cover

Fig. 1, AD-9 Exploded View

Disassembly, Cleaning and Inspection, and Assembly

When a major rebuild of the air dryer is undertaken, several replacement parts and maintenance kits are available that do not require full disassembly. Use the instructions provided with these parts or kits. **Refer to Fig.1** during disassembly.

Disassembly

IMPORTANT: Before working on or around air brake systems and components, read **"Safety Precautions, 100."**

CAUTION

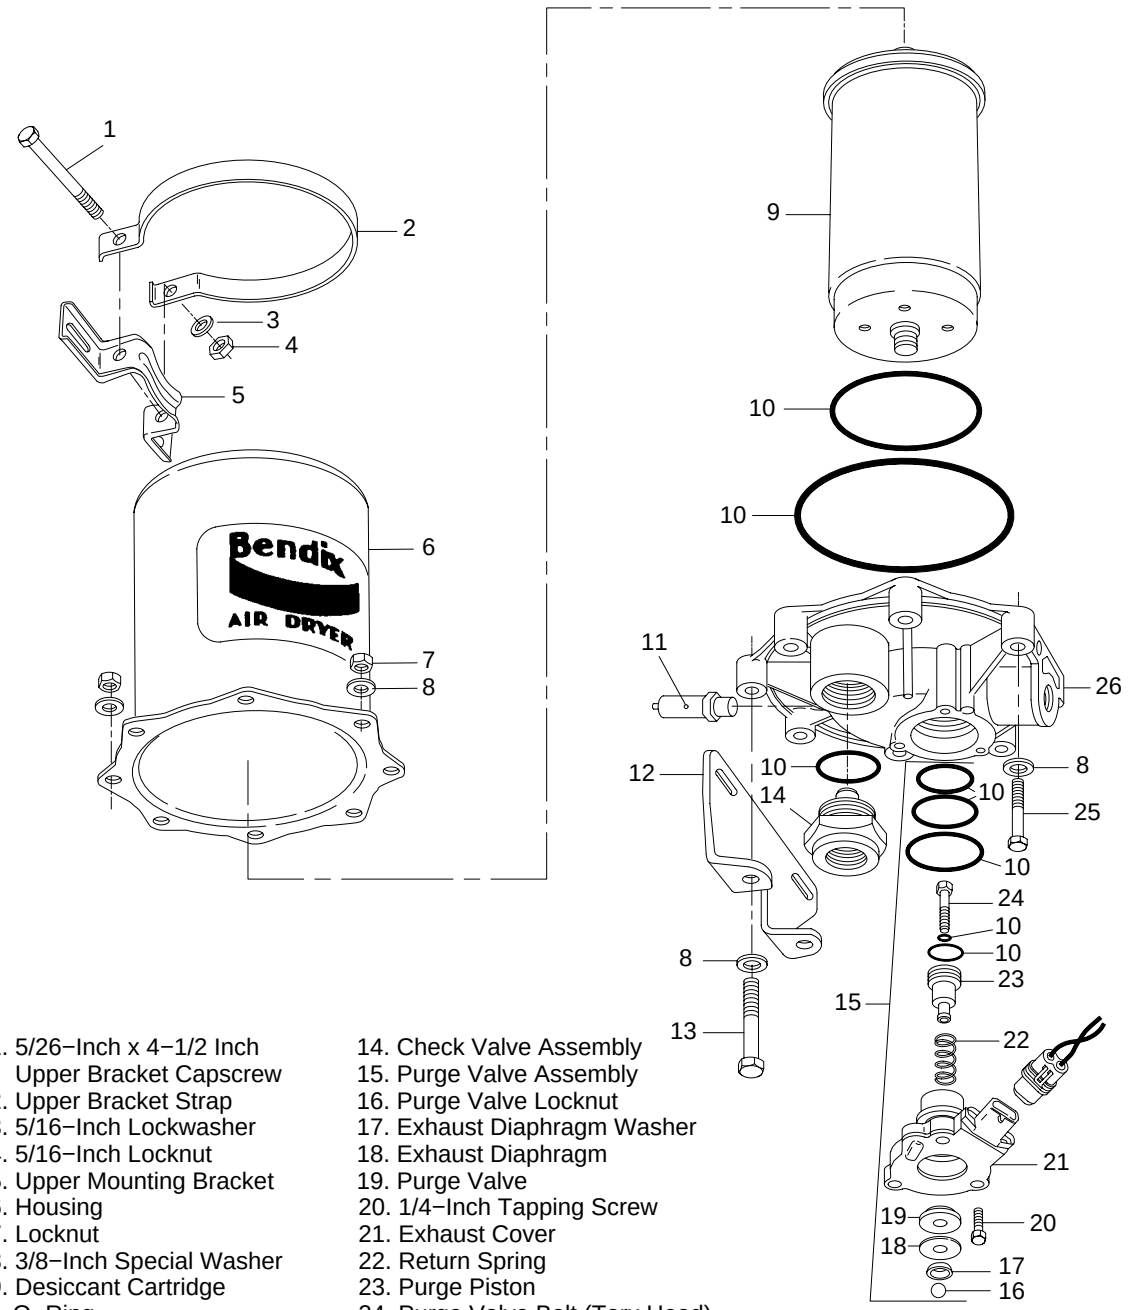
CAUTION: While servicing the air dryer, don't use a clamping device (vise, C-clamp, etc.) to hold any die cast aluminum part, as damage may result. To hold the end cover, install a pipe nipple in the supply port, and clamp the nipple in a vise.

1. Remove the air dryer from the vehicle. **Refer to "Removal and Installation, 110."**
2. Remove the check valve assembly (Ref. 13) and O-ring (Ref. 1). Remove the O-ring from the check valve assembly.
3. Remove the purge valve housing assembly.
   - 3.1 Remove the three self-tapping screws (Ref. 3) that secure the purge valve housing assembly to the end cover assembly.
   - 3.2 Pull the purge valve housing assembly out of the end cover assembly.
   - 3.3 Remove the three O-rings (Refs. 5, 6, and 7) from the exterior of the purge valve housing assembly.

   NOTE: O-rings (Refs. 5 and 6) may lodge in and have to be removed from the end cover bores.
4. Disassemble the purge valve housing assembly.
   - 4.1 If a flat non-extended exhaust cover (Ref. 28) is used, leave it intact while servicing the purge valve housing assembly.

     If an extended type exhaust cover is used for the attachment of an exhaust hose, *carefully* peel off the exhaust cover from the purge valve housing. *Use a thin flat blade to pry the exhaust cover off, taking care not to damage the potting material (RTV sealant) under the cover.*
   - 4.2 Remove the locknut (Ref. 4) from the bottom of the purge valve housing assembly. A Torx head or 12-point socket is used to hold the head of the bolt (Ref. 29). If present, remove the diaphragm washer (Ref. 30) and diaphragm (Ref. 2), and the purge valve (Ref. 10) from the purge valve housing.
   - 4.3 Remove the Torx head bolt (Ref. 29) from the opposite end, then the purge piston (Ref. 31), the return spring (Ref. 11) and two O-rings (Refs. 9 and 12) (one on the outside diameter and the other in the inside of the purge piston).

CAUTION



CAUTION: The heater and thermostat assembly is not available as a service part. Don't remove it; if the heater and thermostat are inoperative, replace the entire purge valve housing assembly, which includes these parts.

5. Remove the remaining six capscrews (Ref. 14), locknuts (Ref. 17), and twelve special washers (Ref. 15) that secure the end cover to the housing (Ref. 22). Separate the end cover and desiccant cartridge (Ref. 20) from the housing (Ref. 22).
6. Remove the end-cover-to-outer-housing O-ring (Ref. 21).
7. Don't remove the safety valve from the end cover unless it is known to be inoperative. If replacement is needed, apply thread sealant or Teflon® tape on the threads of the replacement valve and tighten 1360 to 4520 N·m (120 to 400 lbf·in). Make sure the drain hole (slot) is facing down.
8. Place a strap or chain wrench around the desiccant cartridge (Ref. 20) so that it is about 5 to 8 cm (2 to 3 inches) away from the end cover. Rotate the cartridge counterclockwise until it completely separates from the end cover.

NOTE: Torque of up to 68 N·m (50 lbf·ft) may be needed to do this disassembly.

9. Remove the desiccant cartridge O-ring (Ref. 19) from the end cover.

Disassembly, Cleaning and Inspection, and Assembly

1. 5/26−Inch x 4−1/2 Inch Upper Bracket Capscrew
2. Upper Bracket Strap
3. 5/16−Inch Lockwasher
4. 5/16−Inch Locknut
5. Upper Mounting Bracket
6. Housing
7. Locknut
8. 3/8−Inch Special Washer
9. Desiccant Cartridge
10. O−Ring
11. Safety Valve
12. Lower Mounting Bracket
13. 3/8−Inch Capscrew (Long)
14. Check Valve Assembly
15. Purge Valve Assembly
16. Purge Valve Locknut
17. Exhaust Diaphragm Washer
18. Exhaust Diaphragm
19. Purge Valve
20. 1/4−Inch Tapping Screw
21. Exhaust Cover
22. Return Spring
23. Purge Piston
24. Purge Valve Bolt (Torx Head)
25. 3/8−Inch Capscrew
26. End Cover

05/20/98 f420545

Fig. 1

Cleaning and Inspection

IMPORTANT: Before working on or around air brake systems and components, read **"Safety Precautions, 100."**

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Wash all metal parts thoroughly, using a quality commercial solvent, such as mineral spirits.
2. Check for severe corrosion, pitting, and cracks on the inside and outside of all metal parts that will be reused. Superficial corrosion and pitting on the outside of the upper and lower body halves is acceptable.
3. Inspect the bores of both the end cover and the purge-valve housing for deep scuffing or gouges.
4. Make sure that all purge-valve housing and end cover passages are open and free of blockages.
5. Inspect the pipe threads in the end cover. Make sure they are clean and free of thread sealant.
6. Inspect the purge-valve housing bore and seats for excessive wear and scuffing.
7. Inspect the purge valve piston seat for excessive wear.
8. Inspect all air line fittings for corrosion. Clean all old thread sealant from the pipe threads.
9. Replace all removed O-rings with new ones that are provided in the kits.

   Replace parts that show any of the conditions described.

Assembly (Refer to Fig.1)

IMPORTANT: Before working on or around air brake systems and components, read **"Safety Precautions, 100."**

1. Before assembly, coat all O-rings, O-ring grooves, and bores with a generous amount of barium-base lubricant. **Refer to Fig.1** during assembly unless otherwise advised.
2. Assemble the purge-valve housing.
   - 2.1 Install the O-ring (Ref. 12) on the purge piston. Place the return spring (Ref. 11) in the purge-valve housing. Place the O-ring (Ref. 9) in the bore of the purge piston. Install the Torx head bolt (Ref. 29) in the purge piston. Insert the purge piston (Ref. 31) in the inside diameter of the spring (Ref. 11). Push the piston into the purge-valve housing until it bottoms.
   - 2.2 While holding the purge piston in, install the following parts over the purge valve bolt (Ref. 29) from the opposite end of the purge-valve housing: the purge valve (Ref. 10) with its rubber side first, followed by the diaphragm (Ref. 2) (if present) and the diaphragm washer (Ref. 30) (if present) or the flatwasher, and finally the locknut (Ref. 4). Torque the purge valve locknut and bolt (Refs. 4 and 29) 680 to 900 N·cm (60 to 80 lbf·in).
   - 2.3 Install the three O-rings (Refs. 5, 6, and 7) in their correct locations on the purge-valve housing.
   - 2.4 If the exhaust cover (Ref. 28) was removed, install it on the purge-valve housing assembly, making sure the "bubble" portion is positioned over the thermostat.
   - 2.5 Install the assembled purge-valve housing in the end cover; make sure you orient both parts so that the connector is about 10 degrees clockwise from the supply port. Also, make sure the purge-valve housing is fully seated against the end cover.
   - 2.6 Secure the purge-valve housing to the end cover using the three self-tapping screws (Ref. 3). Start all three screws by hand, then torque 960 to 1400 N·cm (85 to 125 lbf·in).
3. Install the O-ring (Ref. 1) on the check-valve assembly (Ref. 13), then install the assembly in the end cover using a socket. Tighten 2260 to 2820 N·cm (200 to 250 lbf·in).
4. Install the desiccant cartridge in the end cover.

Disassembly, Cleaning and Inspection, and Assembly

4.1 Install the desiccant O-ring (Ref. 19) in its groove in the end cover. Using a light coat of barium grease, lubricate the bottom of the desiccant cartridge in the area that will contact the O-ring and end cover.

4.2 Screw the desiccant cartridge into the end cover until the cartridge contacts the O-ring. Using a strap or chain wrench positioned 5 to 8 cm (2 to 3 inches) from the bottom of the cartridge, turn the desiccant cartridge clockwise 180 to 225 degrees beyond the position where initial contact was made with the end cover O-ring. Torque should not exceed 68 N·m (50 lbf·ft).

5. Install the end cover housing over the desiccant cartridge.

5.1 Install the end cover outer housing O-ring (Ref. 21) on the shoulder in the end cover. Place the housing (Ref. 22) over the desiccant cartridge and align the holes.

5.2 Install the six capscrews (Ref. 14), locknuts (Ref. 17), and the twelve special washers (Ref. 15), making sure they are positioned as referenced earlier. The two longer capscrews (Ref. 16) will be used to secure the air dryer to its mounting bracket.

5.3 Tighten the six capscrews and nuts in a star pattern **as shown in Fig.2,** depending on lower bracket location. Tighten 3060 to 4340 N·cm (270 to 385 lbf·in).

NOTE: The two remaining bolt holes in the end cover and two 3/8-inch capscrews must be the ones marked during disassembly to ensure correct orientation of the ports and adequate length of the capscrews.

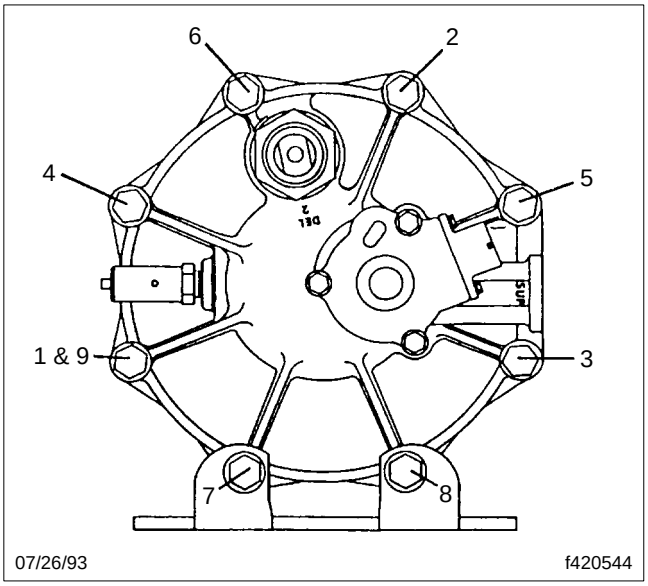


Fig. 2, End Cover to Housing Torque Pattern

Testing

During cold-weather operation, check the operation of the end cover heater and thermostat assembly.

1. With the ignition on, check for voltage to the heater and thermostat assembly. Unplug the electrical connector at the air dryer, and place the test leads on each of the pins of the male connector. If there is no voltage, look for a blown fuse, broken wires, or corrosion in the vehicle wiring harness. Check that a good ground path exists.
2. Check the thermostat and heater operation. Turn off the ignition switch and cool the end cover assembly to below 4°C (40°F). Using an ohmmeter, check the resistance between the electrical pins in the female connector. The resistance should be 1.5 to 3.0 ohms for the 12-volt heater assembly.

NOTE: Some early models of the AD-9 will have resistance readings of 1.0 to 2.5 ohms for the 12-volt heater assembly. If the resistance is higher than this, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

3. Warm the end cover assembly to over 32°C (90°F) and again check the resistance. It should exceed 1000 ohms. If it does, the thermostat and heater assembly is operating properly. If it doesn't, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

Problem—Air Dryer Is Constantly Cycling or Purging

Possible Cause	Remedy
Excessive system leakage.	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is as follows: • Single Vehicle—7 kPa/min (1 psi/min) per service reservoir • Tractor/Trailer—21 kPa/min (3 psi/min) per service reservoir
There is excessive leakage in the fittings, hoses, and tubing connected to the compressor, air dryer, and wet tank.	Using a soap solution, test for leakage at the fittings, drain valve, and safety valve in the wet tank. Repair or replace as needed.
Check valve assembly in the air dryer end cover is not working.	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at opposite end, and check for leakage. Permissible leakage is a 2.5-cm (1-inch) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.
Governor is inoperative.	Test the governor for proper cut-in or cut-out pressures and excessive leakage in both positions.
Leaking purge-valve housing assembly or O-rings in the air dryer end cover.	With the supply port open to atmosphere, apply 830 kPa (120 psi) at the control port. Apply a soap solution to the supply port and exhaust port (purge valve seat area). Permissible leakage is a 2.5-cm (1-inch) bubble in 5 seconds. Repair or replace as needed.
Compressor unloader mechanism is leaking excessively.	Remove the air strainer or fitting from the compressor inlet cavity. With the compressor unloaded, check for unloader piston leakage. Slight leakage is allowed.
Holset "E" type compressor.	Test the air dryer system. For instructions, refer to Bendix Product Bulletin PRO-08-19 entitled "Troubleshooting the Holset "E" Compressor System with Bendix Air Dryer."
Lack of air at the governor RES port (rapid cycling of the governor).	Test the governor for proper pressure at the RES port. Pressure should not drop below cut-in pressure when the compressor begins the unloaded cycle. If the pressure does drop, check for kinks or restrictions in the line connected to the RES port. The line connected to the RES port on the governor must be the same diameter, or larger than the lines connected to the UNL ports on the governor.

Problem—Water in the Vehicle Reservoirs

Possible Cause	Remedy
Desiccant cartridge assembly contains excessive contaminants.	Replace the desiccant cartridge.
Discharge line is of improper length or material.	Discharge line must consist of at least 1.8 m (6 ft) of wire braid Teflon hose, copper tubing, or a combination of both between the discharge port of the compressor and the air dryer supply port. Discharge line lengths and inside diameter requirements are dependent on the vehicle application. Contact your local Bendix representative for further information.
Air system was charged from an outside air source that did not pass through an air dryer.	If the system must have an outside air fill provision, the outside air should pass through an air dryer. This practice should be minimized.
Air dryer is not purging.	Refer to "Problem—Air Dryer Does Not Purge or Exhaust Air."
Purge (air exhaust) is insufficient due to excessive system leakage.	Refer to "Problem—Air Dryer Is Constantly Cycling or Purging."

Troubleshooting

Possible Cause	Remedy
Air bypasses the desiccant cartridge assembly.	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed.
Purge (air exhaust) time is significantly less than the minimum allowable.	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed. Replace the desiccant cartridge assembly.
Excessive air usage—air dryer not compatible with vehicle air system.	Install an accessory bypass system. Consult your Bendix representative for additional information.

Problem—Safety Valve on Air Dryer Is Popping Off or Exhausting Air

Possible Cause	Remedy
Desiccant cartridge is plugged or saturated.	Check the compressor for excessive oil passing, or incorrect installation. Repair or replace as needed.
The check valve in the air dryer air cover is inoperative.	Test to determine if air is passing through the check valve. Repair or replace as needed.
There is a problem in the fittings, hose, or tubing between the air dryer and the wet tank.	See if air is reaching the first reservoir. Inspect for kinked tubing or hose. Check for undrilled or restricted hose or tubing fittings.
Pinging noise is due to a single cylinder compressor with high pulse cycles.	A slight pinging sound may be heard during system build-up when a single cylinder compressor is used. If this sound is deemed objectionable, it can be reduced substantially by increasing the discharge line volume. This is done by adding a 1475 cm^3 (90 in^3)reservoir between the compressor and the air dryer.
Safety valve setting is lower than the maximum system pressure.	Reduce the system pressure, or install a safety valve with a higher pressure setting.

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure

Possible Cause	Remedy
Air dryer purge valve is leaking excessively.	With the compressor loaded, apply a soap solution on the purge valve exhaust to test for excessive leakage. Repair the purge valve as needed.
The governor is inoperative.	Check the governor for proper cut-in and cut-out pressures, and excessive leakage in both positions. Repair or replace as needed.
Purge control line is connected to the reservoir or exhaust port of the governor.	Connect the purge control line to the unloader port of the governor.
Purge valve is frozen open due to an inoperative heater or thermostat, bad wiring, or a blown fuse.	Test the heater and thermostat, following instructions in this manual.
Inlet and outlet air connections are reversed—unable to build system pressure.	Reconnect the lines properly.
Discharge line is kinked or blocked.	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line. Water is collecting and freezing.	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.

Possible Cause	Remedy
System is leaking excessively.	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is as follows: • Single Vehicle—7 kPa/min (1 psi/min) per service reservoir • Tractor/Trailer—21 kPa/min (3 psi/min) per service reservoir
Purge valve stays open; supply air leaks to control side.	Replace the purge valve assembly O-rings.

Problem—Air Dryer Does Not Purge or Exhaust Air

Possible Cause	Remedy
Purge control line is broken, kinked, frozen, plugged, or disconnected.	See if air flows through the purge control line when the compressor is unloaded. The purge control line must be connected to the unloader port of the governor.
Air dryer purge valve isn't working.	See if air reaches the purge valve. If it does, repair the purge valve.
The governor is inoperative.	Check the governor for proper cut-in and cut-out pressures, and excessive leakage in both positions. Repair or replace as needed.
Inlet and outlet air connections are reversed—unable to build system pressure.	Reconnect the lines properly.
Discharge line is kinked or blocked.	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line. Water is collecting and freezing.	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.

Problem—Desiccant Is Being Expelled from the Air Dryer Purge Valve Exhaust (May Look Like Whitish Liquid, Paste, or Small Beads); or, Unsatisfactory Desiccant Life

Possible Cause	Remedy
This problem usually occurs with one or more of the previous problems.	Refer to the appropriate corrections listed previously.
Air dryer is not securely mounted; there is excessive vibration.	Vibration should be held to a minimum. Tighten the mounting fasteners.
Cloth-covered perforated plate in the air dryer desiccant cartridge is damaged, or the cartridge was rebuilt incorrectly.	Replace the plate or cartridge as needed. High operating temperatures may cause deterioration of filter cloth. Check the installation.
Compressor is passing excessive oil.	Check for proper compressor installation; if symptoms persist, replace the compressor.
Heater and thermostat, wiring, or a fuse is at fault, and isn't allowing the air dryer to purge during cold weather.	Test the heater and thermostat, following instructions in this manual.
Desiccant cartridge not attached properly to the end cover.	Check the torque and tighten if necessary. Refer to **Subject 120 for instructions.**

Troubleshooting

Problem—Pinging Noise Is Excessive During Compressor Loaded Cycle

Possible Cause	Remedy
Pinging noise is due to a single cylinder compressor with high pulse cycles.	A slight pinging sound may be heard during system build-up when a single cylinder compressor is used. If this sound is deemed objectionable, it can be reduced substantially by increasing the discharge line volume. This is done by adding a 1475 cm ^{3} (90 in ^{3}) reservoir between the compressor and the air dryer.

Problem—Constant Air Seepage at the Purge Valve (Non-Charging Mode)

Possible Cause	Remedy
Air compressor inlet is pressurized by the engine turbocharger.	Some pressure leakage past the metal seat of the turbocharger cutoff feature of the AD-9 air dryer is normal, and may be heard. This slight loss of air will not affect the engine or turbocharger performance.
Check valve assembly in the air dryer end cover is not working.	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at opposite end, and check for leakage. Permissible leakage is a 2.5-cm (1-inch) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.

Problem—Air Dryer Purge Piston Cycles Rapidly in the Unloaded Mode

Possible Cause	Remedy
Compressor does not "unload."	Check the governor installation: there is no air line from the governor to the compressor, or the line is restricted. Repair or replace as needed.

General Information

Air reservoirs serve two main purposes:

1. They store compressed air used to apply the brakes and operate other air-powered devices, such as window lifts, windshield wipers, and seats.
2. They provide a place where air, heated during compression, can cool and water vapor can condense into a liquid. Also, air reservoirs collect small amounts of oil passed by the compressor.

Each vehicle is equipped with three air reservoirs. Each reservoir is identified as one of three types: supply, primary, and secondary.

The supply reservoir (or wet tank) receives compressed air directly from the compressor. It collects most of the water and oil condensate from the air, and feeds air to the other reservoirs. At the outlet port of the supply reservoir (the port leading to the primary reservoir) is a safety valve, which protects the air system against excessive air pressure build-up.

The primary reservoir is the air source for the brakes on the rear axle. At the inlet port of the primary reservoir is an inline check valve. The check valve allows air flow in one direction only, and prevents air flow in the reverse direction in case there is a drop in upstream air pressure.

The secondary reservoir is the air source for the front axle brakes. It is equipped with an internal check valve.

The secondary reservoir supplies air to a pressure protection valve. This valve prevents complete loss of secondary air pressure if there is an air leak in any non-brake accessory.

All air reservoirs are equipped with drain valves to eject the water and oil emulsion from the tanks.

On vehicles equipped with an air dryer, the supply reservoir and the secondary reservoir are in a common tank. If there is no air dryer, the supply reservoir is a separate tank, mounted vertically in front of the secondary reservoir.

Tests

NOTE: If equipped with an automatic drain valve, refer elsewhere in this group for leak testing.

Be sure the air system is fully charged. Using a soap solution or leak detector, check for leaks on the outside surfaces of the reservoirs and drain valves. No leakage is permitted.

If leaks exist at the drain valve, note if they occur at the joint of the valve and coupler, or through the valve body. Go to **"Drain Valve Replacement and Leak Elimination, 110."**

If leaks occur on the surfaces of the air reservoir, replace the tank; refer to **"Air Reservoir Replacement, 120."**

Drain Valve Replacement and Leak Elimination

NOTE: If equipped with an automatic moisture-ejection valve, refer elsewhere in this group for instructions.

1. Apply the parking brakes, and chock the tires.
2. Drain the air system, using the instructions in the vehicle driver's manual.
3. Using two wrenches (hold the coupler in place with one of them), unscrew the drain valve from the coupler. Clean off the threads inside the coupler on the reservoir, removing all sludge and sealant build-up.

   Obtain a new drain valve if leaks occurred through the body of the valve.

   If leaks occurred at the joint of the drain valve and coupler, clean off the sludge and sealant from the threads of the valve. Check for damaged threads on the valve and inside the coupler. Replace damaged parts. If no damage exists, leakage was probably due to inadequate tightening of the drain valve in the coupler.
4. Apply Loctite®, or an equivalent sealant, to the end threads of the drain valve or coupler, as applicable, and install finger-tight. Tighten one and one-half additional turns (use two wrenches if installing the drain valve).
5. Perform a leak test after completing the installation. If leaks occur at the joint of the drain valve and coupler, tighten the valve up to one additional turn to stop the leaks.
6. Remove the chocks from the tires.

Air Reservoir Replacement

Replacement

1. Apply the parking brakes, and chock the tires.
2. Drain the air system, using instructions in the vehicle driver's manual.
3. Mark all reservoir air lines, couplers, and valves for later assembly. Carefully disconnect the parts. Cap the exposed ports tightly to keep out contaminants. If access is limited, remove the parts after removing the reservoir from its mount.
4. Remove the reservoir strap fasteners. Remove the reservoir.
5. If access is limited, do the next step first. If not, place a new reservoir in the mount, and install the strap fasteners. On two-piece straps (**Fig. 1**), tighten the nuts 20 to 25 lbf·ft (27 to 34 N·m). On one-piece straps (**Fig. 2**), tighten the nut 20 lbf·ft (27 N·m).
6. As referenced earlier, connect all air lines, couplers, and valves to the new reservoir, removing the caps as each part is installed.
7. Remove the chocks from the tires.

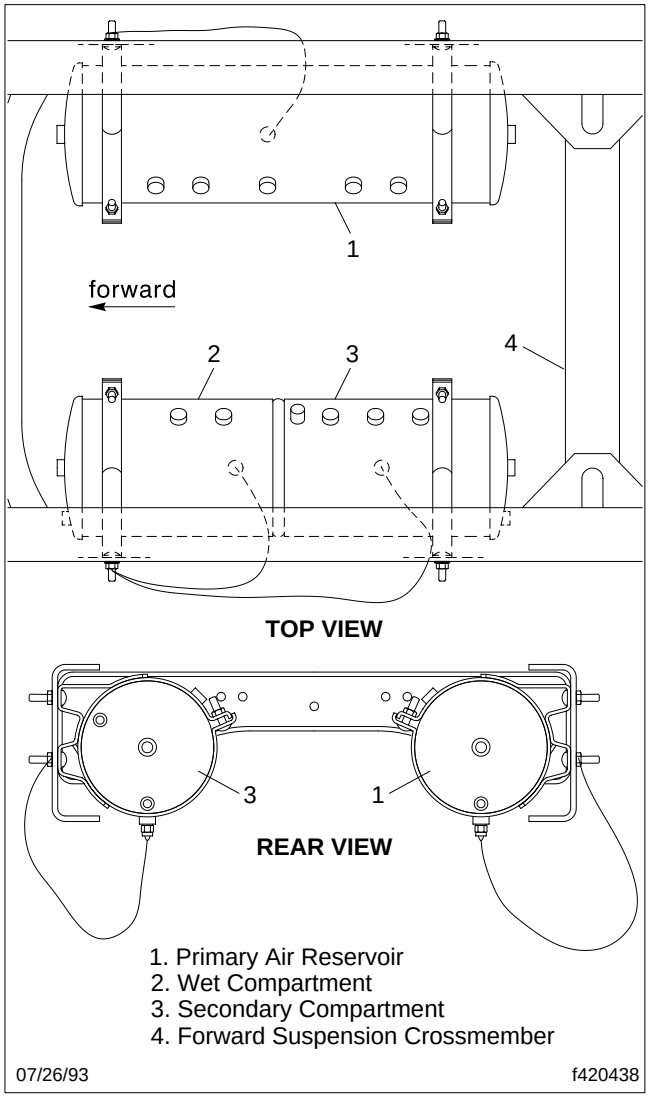

Fig. 1, Chassis Mounted Air Reservoirs (Vehicle Equipped With an Air Dryer)

Air Reservoir Replacement

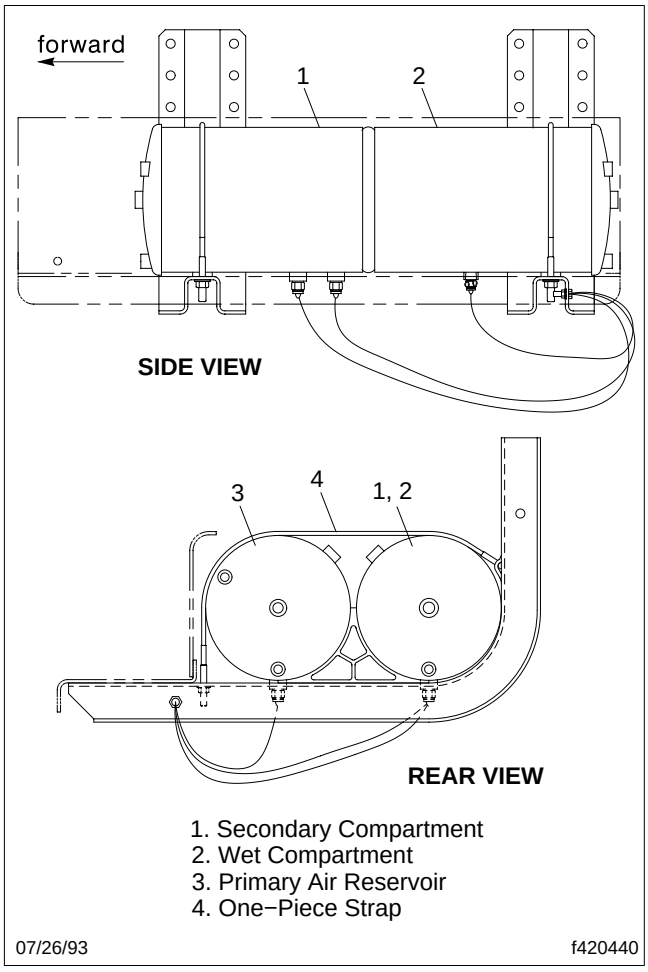

Fig. 2, Air Reservoirs Mounted on Left Step (Vehicle Equipped With an Air Dryer)

General Information

The DV-2 automatic reservoir drain valve **(Fig. 1)** automatically removes contaminants and water from the wet-air tank each time the brakes are applied. The drain valve is attached to a drain cock located on the bottom of either end of the wet-air tank. Since the brake foot valve is protected by a check valve between the wet-and dry-air tanks, any leak or sticking valve will not reduce the supply of air that is in the dry part of the system.

Principles of Operation

With no pressure in the system, the drain valve's inlet and exhaust valves are closed. **See Fig. 2.** Upon charging the system, a slight pressure opens the inlet valve which permits air and contaminants to collect in the sump. **See Fig. 3.** The inlet valve remains open when pressure is rising in the system until the air compressor cuts off, allowing the spring action of the valve guide in the sump cavity to close the inlet valve. The inlet valve and the exhaust valve are now both closed. **See Fig. 4.** When the wet tank pressure drops about 14 kPa (2 psi), the air pressure in the sump cavity opens the exhaust valve and allows moisture and contaminants to be ejected from the sump cavity until pressure in the sump cavity drops enough to close the exhaust valve. **See Fig. 5.**

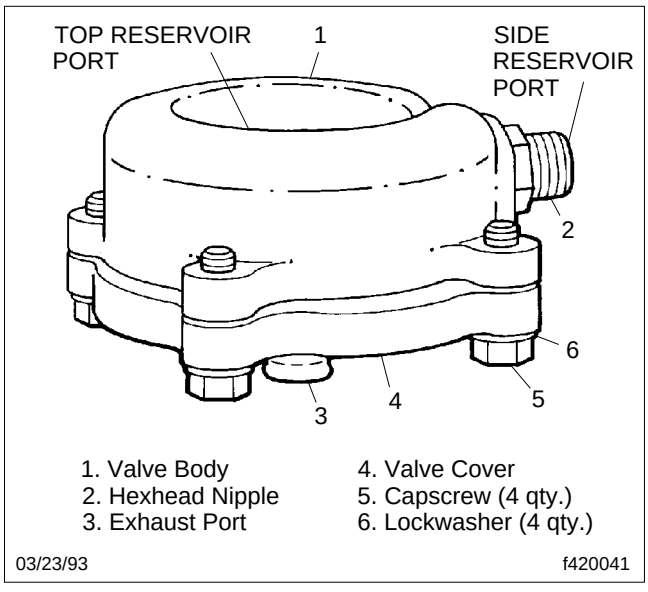

Fig. 1, DV-2 Valve

The length of time the exhaust valve remains open and the amount of moisture and contaminants ejected depends upon the sump pressure and the wet tank pressure drop that occurs each time air is used from the system.

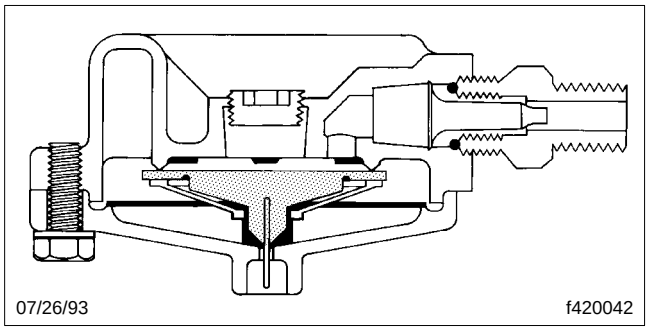

Fig. 2

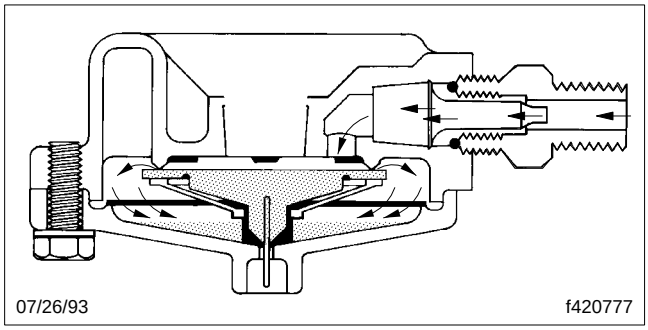

Fig. 3

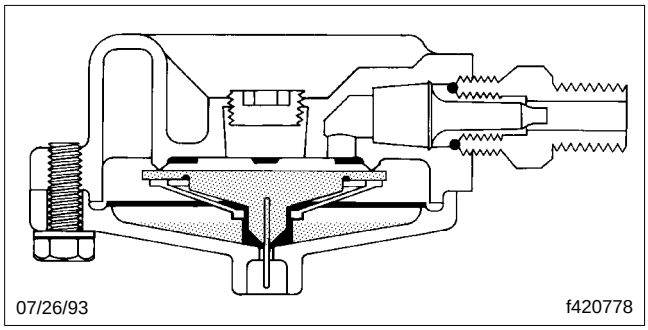

Fig. 4

General Information and Principles of Operation

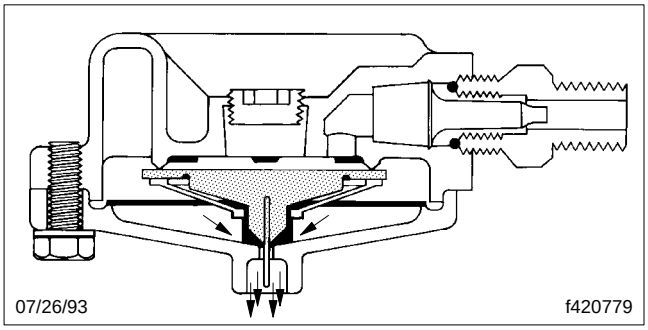

Fig. 5

Safety Precautions

When working on or around air brake systems and components, the following precautions should be observed:

1. Always chock the vehicle's wheels and stop the engine when working under a vehicle. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing air pressure. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with air pressure. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood the recommended procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use only the correct tools and observe all precautions pertaining to use of those tools.

Operating Test

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

Do the following test after repairing or replacing the DV-2 valve to ensure that the valve is functioning correctly.

With the system charged, apply the brakes several times. Each time the brakes are applied, an exhaust of air should occur from the exhaust port of the drain valve. If no air comes out, push the wire stem located inside the exhaust port. If no air comes out after pushing the wire stem, there may be a plugged filter in the adapter which should be replaced.

If the drain valve does not function correctly, repair or replace it following instructions in this section.

Leakage Test

Perform the following test after repairing or replacing the DV-2 valve to ensure that the valve is functioning correctly.

With the system charged and pressure stabilized in the system, there should be no leaks at the drain valve exhaust port. A constant slight exhaust of air at the drain valve exhaust port could be caused by excessive leakage in the air brake system.

If the drain valve is leaking excessively, repair or replace it following instructions in this section.

Removal

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Chock the tires, and drain the reservoirs.
2. Remove the drain valve assembly from the end of the wet tank reservoir.

Installation

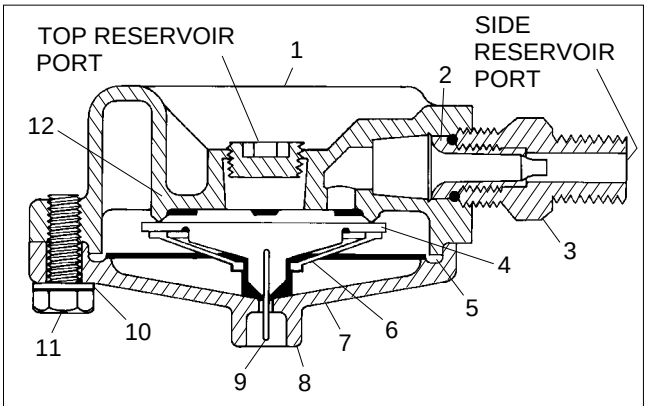
IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using an approved cleaning solvent, flush and clean the wet tank reservoir to avoid early fouling at the drain valve. Aerate the wet tank completely if solvents were used during cleaning.
2. Install the drain valve assembly on the wet tank by tightening the hexagonal nipple until the drain valve is positioned so that the valve body is parallel to the bottom of the wet tank with the exhaust port facing straight down. Make sure that the exhaust port is clear of any air, electric, or fuel lines. Make sure the drain valve is attached tight enough to prevent leakage.
3. Close the drain cocks to the wet and dry air reservoirs. Start the vehicle engine to pressurize the air system.
4. Leak test the drain valve following the instructions under **"Operating and Leakage Tests, 110."**

Disassembly, Cleaning and Inspection, and Assembly



Disassembly (Refer to Fig. 1)

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Remove the drain valve following the instructions under **"Removal and Installation, 120."**
2. Remove the four capscrews (Ref. 11) that hold the valve cover (Ref. 7) to the valve body (Ref. 1).
3. Remove the valve cover (Ref. 7) and sealing ring.
4. Remove the valve guide (Ref. 6) and the inlet and exhaust valve (Ref. 4) from the valve body.
5. Remove the hexhead nipple (Ref. 3) from the valve body.

Cleaning and Inspection

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

Fig. 1, DV-2 Valve, Cutaway View

WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

Use eye protection when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the drain valve in an approved cleaning solvent. Dry the metal parts of the disassembled moisture ejection valve with compressed air.
2. Wipe all rubber parts clean with a clean cloth. Examine all rubber parts. If any rubber parts are worn, cracked, torn or otherwise deteriorated, replace them with new parts.
3. Examine all metal parts. If any metal parts are worn, cracked, or otherwise damaged, replace them with new parts.
4. Clean and examine the filter. If it will not clean completely, or is torn or damaged, replace it with a new filter.

CAUTION

CAUTION: Do not reassemble the drain valve with a dirty filter; to do so could result in failure of the drain valve in service.

Assembly (Refer to Fig. 1)

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

Before assembling the drain valve, apply a light film of grease on the inlet valve seat. See Ref. 12.

IMPORTANT: Do not apply oil to the inlet and exhaust valve.

1. Install the valve sealing ring (Ref. 5) into its groove in the valve cover.
2. Install the valve guide (Ref. 6) over the inlet and exhaust valve (Ref. 4).
3. Install the valve guide, and the inlet and exhaust

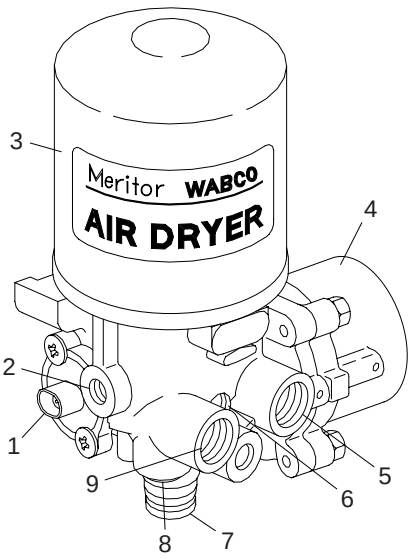
Disassembly, Cleaning and Inspection, and Assembly

valve as an assembly into the valve cover. The wire stem (Ref. 9) will project through the exhaust port (Ref. 8).

4. Install the valve body on the valve cover and install the lockwashers and capscrews. Tighten the capscrews 820 to 1080 N·cm (72 to 96 lbf·in).
5. Install the hexhead nipple onto the valve body, and tighten it 540 to 820 N·cm (48 to 72 lbf·in).
6. Install the drain valve on the wet tank following the instructions under **"Removal and Installation, 120."**

Specifications

This subject contains the following table:



•Torque Values

Description	Torque N·cm (lbf·in)
Valve Cover Capscrews	820-1080 (72-96)
Hexhead Nipple (to valve body)	540-820 (48-72)

Table 1, Torque Values

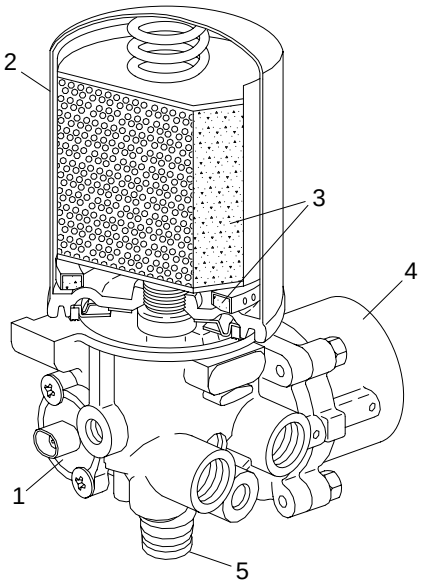
General Information

The System Saver 1000 air dryer **(Fig. 1)** is a desiccant air dryer, mounted vertically between the air compressor and the supply reservoir. The air dryer receives hot compressed air, which it cools and filters before sending it to the supply reservoir, reducing the build-up of dirt and moisture in the vehicle air system.

1. Heater/Thermostat Assembly
2. Governor Port (to air governor)
3. Desiccant Canister
4. Regeneration Valve Assembly
5. Outlet Port (to air supply reservoir)
6. Bypass Valve Assembly
7. Exhaust Port (Purge Valve Assembly)
8. Turbocharger Cutoff Valve
9. Inlet Port (from air compressor)

Fig. 1

The air dryer consists of a light weight aluminum and steel body. The desiccant cartridge is contained in a spinoff canister at the top of the air dryer.



The bottom half of the air dryer houses the following components.

- Bypass Valve–this valve allows air flow in the air dryer to go directly to the outlet port, bypassing the desiccant filter.
- Desiccant Canister–a cylindrical steel housing that contains the filter elements and the desiccant needed to filter and dry the air that passes through it.
- Heater/Thermostat Assembly–located in the air dryer base, this assembly is designed to prevent the collected moisture from freezing.
- Outlet Check Valve–this valve prevents air in the system from flowing back through the air dryer and escaping out the purge valve during the compressor unload cycle.
- Pressure-Controlled Check Valve–this valve is separate from the air dryer and is installed on the secondary air tank. The valve allows air to back flow from the secondary tank to the supply tank as long as air system pressure remains between the normal cut in and cut out range of the air governor.
- Purge Valve–this valve allows the collected moisture and contaminants to be expelled from the air dryer during the purge cycle.
- Regeneration Valve–this valve allows air from the supply and secondary tanks to bypass the outlet check valve and flow into the regeneration valve. Air then flows through an orifice where the air expands and back flushes moisture off of the desiccant. The air is then exhausted through the purge valve.
- Silencer (Muffler)–an optional component that is attached to the purge valve and used to eliminate most of the noise during the air dryer purge cycle.
- Turbocharger Cut-Off Valve–this valve closes the path between the air compressor and the air dryer purge valve to help maintain boost pressure for maximum engine horsepower during the compressor unload cycle.

Principles of Operation

Hot, compressed air enters the air dryer through the inlet port. As the hot air is forced into the desiccant cartridge, the temperature of the compressed air falls to nearly ambient. Oil and water vapor condense and initially settle into the base of the dryer. The moisture-laden air also passes through the desiccant bed, where any remaining moisture is retained by the desiccant. The clean air then passes through the air dryer outlet port to the supply reservoir. **See Fig. 2 .**

General Information and Principles of Operation

1. Heater/Thermostat Assembly
2. Desiccant Canister
3. Filter
4. Regeneration Valve Assembly
5. Exhaust Port (Purge Valve Assembly)

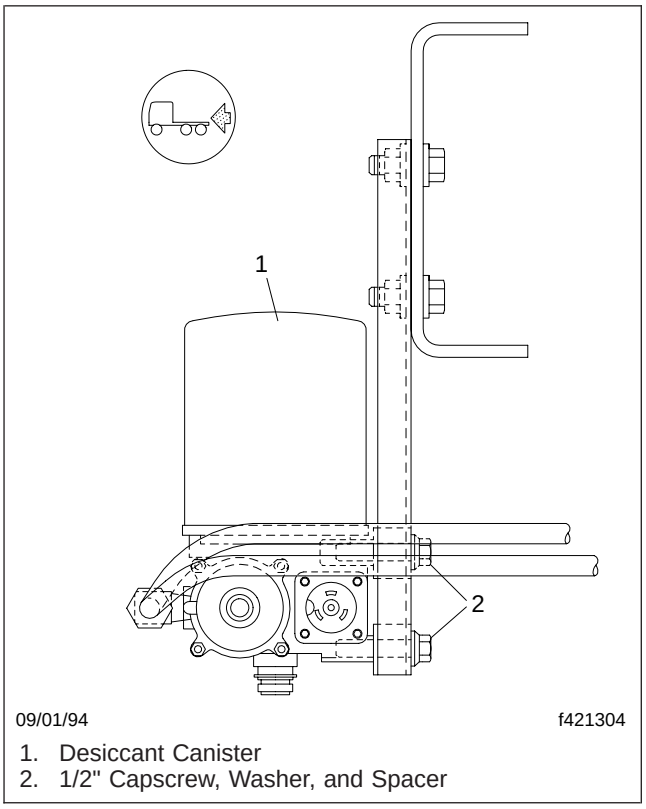
Fig. 2

When the compressor reaches 827 kPa (120 psi), the purge valve opens allowing the initial decompression of the dryer and expels the water and contaminants collected in the base of the dryer. The regeneration valve, along with the pressure-controlled check valve, allows the system air to flow back through the dryer. This back flow dries the desiccant for the next cycle.

Safety Precautions

⚠ WARNING

WARNING: When draining the air system, don't look into the air jets or direct them toward another person, as dirt or sludge particles may be in the airstream. Don't disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can cause personal injury.



When working on or around air brake systems and components, observe the following precautions.

1. Apply the parking brake, chock the tires, and stop the engine when working under the vehicle. Draining the air system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters, which may apply as air system pressure drops.
2. Wear safety goggles.
3. Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
4. Don't disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
5. Replacement hardware, tubing, hose, fittings, etc. should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace any components that have stripped threads or damaged parts. Don't attempt to repair parts by machining.
7. Never exceed recommended air pressure.

⚠ WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

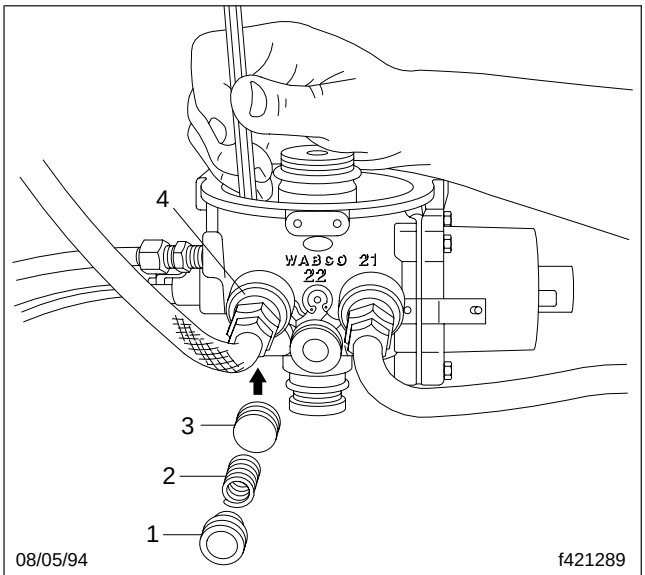
Removal (See Fig. 1)

1. Desiccant Canister
2. 1/2" Capscrew, Washer, and Spacer

Fig. 1, Air Dryer Installation (outboard rail mounting shown)

1. Drain the air system.
2. Disconnect the wiring harness from the air dryer.
3. Mark the air lines for later reference; then, disconnect them from the air dryer.
4. Remove the capscrews, washers, and spacers that attach the air dryer to the mounting bracket.
5. Remove the air dryer.

Installation (See Fig. 1)



1. Position the air dryer on the mounting bracket. Install the spacers, washers, and capscrews. Tighten them 30 to 41 N·m (22 to 30 lbf·ft).
2. Make sure the air lines are clean. Replace any line or fitting that is crimped or damaged.
3. Connect the remaining air lines to the air dryer as previously marked. Tighten the nut on each fitting finger-tight. Then, using two wrenches to prevent twisting the hose, further tighten the nut until there is firm resistance.
4. Connect the air dryer wiring harness.

Replacement

⚠ WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Remove the snap ring at the bottom of the valve assembly. The valve cover and spring may fall out of the cavity when the snap ring is removed. See Fig. 1.

1. Cover
2. Spring
3. Piston
4. Inlet Port

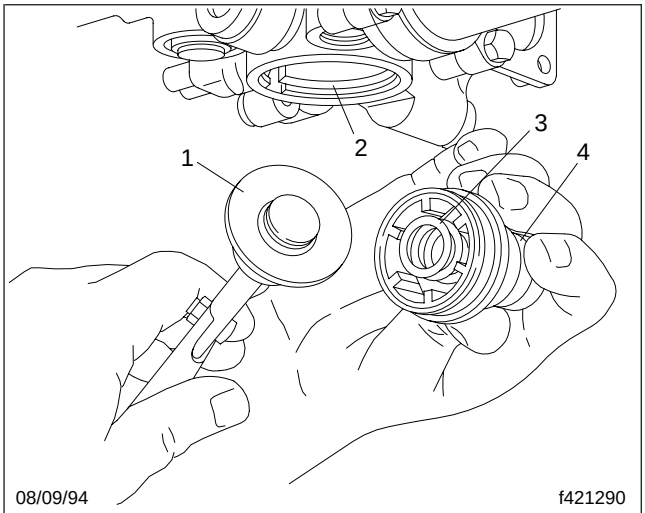


Fig. 1

3. Using a strap wrench, turn the desiccant cartridge counterclockwise and remove it.
4. Using a wooden stick, push the piston, spring, and the cover out of the valve cavity.
5. Clean the valve cavity with a commercial cleaning solvent.
6. Install new O-rings on the piston and the cover.
7. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-rings and the valve cavity.
8. Install the new piston with its hollow side facing out.

If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

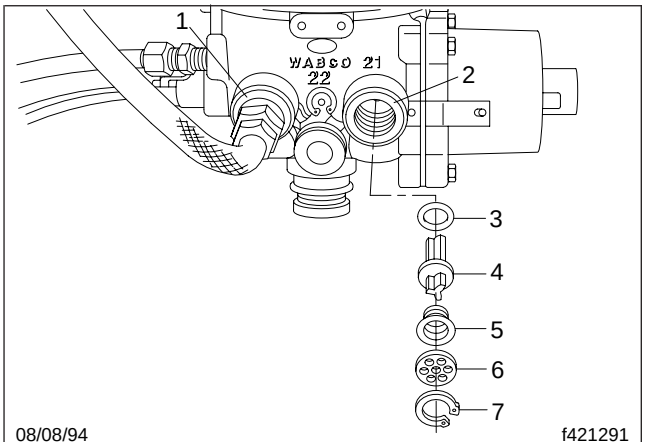
9. Install the new spring, cover, and snap ring to hold the components in place.
10. Thread the desiccant cartridge onto the dryer base (turn clockwise). When the seal contacts the base, tighten the cartridge one complete turn more. Do not over tighten.

Replacement (See Fig. 1)

1. Valve Assembly
2. Exhaust Port
3. Spring
4. Valve Head

Fig. 1

WARNING



WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Remove the snap ring, valve head, and the spring from the exhaust port.
3. Pull the valve assembly out of the exhaust port.
4. Remove the O-ring from the base of the exhaust port.
5. Clean the purge valve cavity area with a commercial cleaning solvent.
6. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the valve cavity and to all of the new O-rings. Install the O-rings in the base of the exhaust port and on the valve head.
7. Position the new valve assembly in the valve cavity.

If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

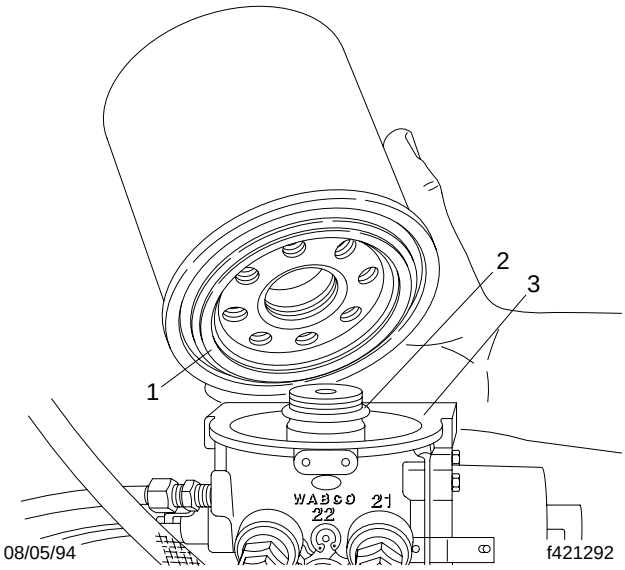
8. Install the spring in the valve head, and position them in the valve cavity.
9. Install the snap ring to secure the valve head in position.

Replacement (See Fig. 1)

1. Inlet Port
2. Outlet Port
3. O-Ring
4. Valve Body
5. Spring
6. Washer
7. Snap Ring

Fig. 1

⚠ WARNING



WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Disconnect the air line from the outlet port.
3. Remove the snap ring, washer, valve body, and the O-ring.
4. Clean the cavity area with a commercial cleaning solvent.
5. Install a new O-ring on the valve body.
6. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-ring and the valve cavity.
7. Install the new valve body. Make sure that the long end of the body is inserted first into the valve cavity.
8. Install the new spring with its small end around the "Y" shaped fins on the valve body.

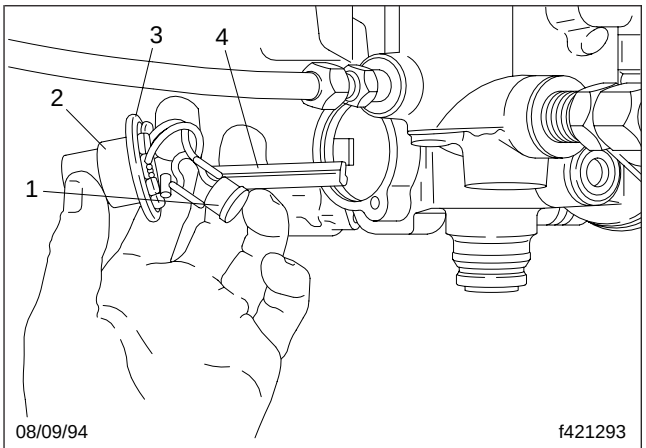
If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

9. Install a new washer and snap ring to secure the assembly in the valve cavity.
10. Connect the air line to the outlet port. Tighten the nut on the fitting finger-tight. Then, using two wrenches to prevent twisting the hose, further tighten the nut until there is firm resistance. Tighten the nut one-sixth turn more.

Replacement (See Fig. 1)

1. Seal
2. O-Ring
3. Air Dryer Base

Fig. 1



WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Using a strap wrench, turn the desiccant cartridge counterclockwise and remove it.
3. Remove and discard the O-ring.
4. Clean the top surface of the dryer base with a commercial cleaning solvent.
5. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-ring and the dryer base. Install the O-ring.
6. Thread the desiccant cartridge onto the dryer base (turn clockwise). When the seal contacts the base, tighten the cartridge one complete turn more. Do not over tighten.

If the air dryer base is damaged, preventing a tight seal, replace the air dryer.

Replacement (See Fig. 1)

1. Thermostat
2. Receptacle
3. O-Ring
4. Element

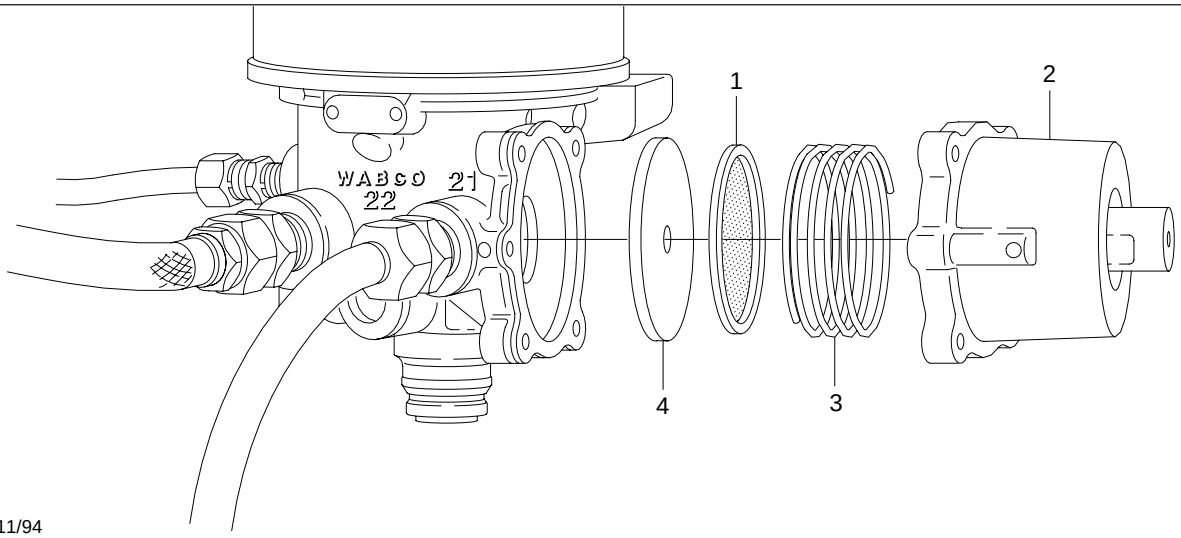


Fig. 1

⚠ WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Disconnect the wiring harness.
3. Remove the screws that attach the heater/thermostat receptacle. Remove the receptacle and the O-ring.
4. Remove the retaining screw that holds the assembly in place. Remove and discard the heater/thermostat assembly.
5. Clean the heater/thermostat assembly area with a commercial cleaning solvent.
6. Position the new heater/thermostat assembly in the cavity. Install the retaining screw.
7. Position the new receptacle and O-ring, and install the screws. Tighten the screws securely.
8. Connect the wiring harness.

Replacement (See Fig. 1)

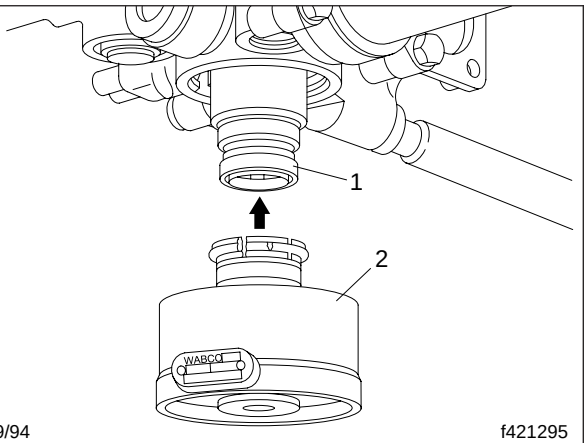
1. Retainer
2. Valve Housing Assembly
3. Spring
4. Diaphragm

Fig. 1

WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.



NOTE: When the valve housing is removed, the spring and the retainer will fall out of the housing.

2. Remove the four mounting bolts and remove the valve housing assembly.
3. Remove the rubber diaphragm.
4. Clean the groove where the diaphragm lip fits with a commercial cleaning solvent.
5. Install a new diaphragm with its lip in the groove.

If the groove is damaged, preventing a tight seal, replace the air dryer.

6. Install the new spring and retainer (with the retainer lip facing out).
7. Position the valve housing on the air dryer. Install the bolts and tighten them to 600 N·cm (53 lbf·in).

Replacement (See Fig. 1)

1. Purge Valve Head
2. Silencer

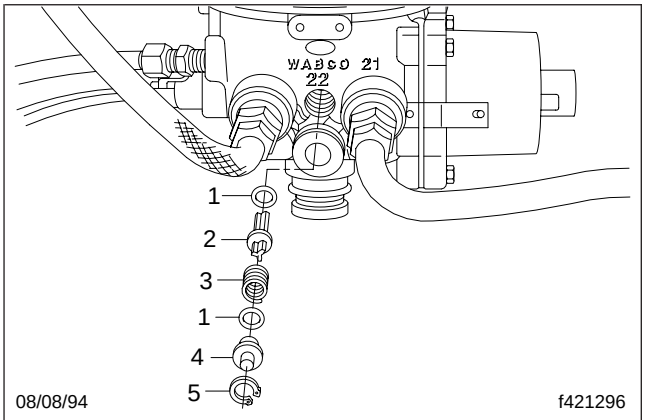


Fig. 1

WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

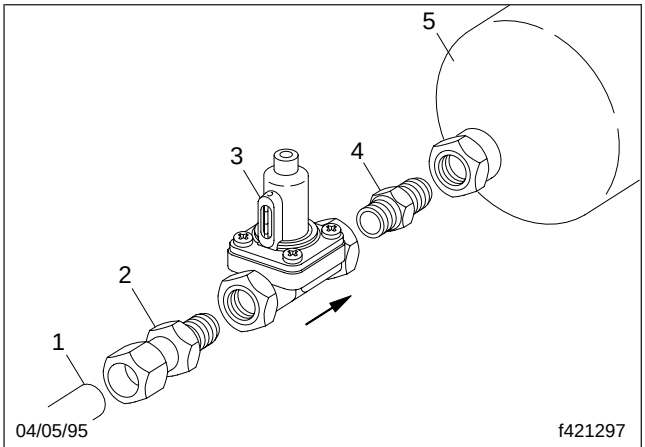
1. Using snap ring pliers, expand the snap ring and pull the silencer off of the purge valve head.
2. Push the new silencer onto the purge valve head until the silencer snaps into place.

Replacement (See Fig. 1)

1. O-Ring
2. Valve Body
3. Spring
4. Cover
5. Snap Ring

Fig. 1

⚠ WARNING



WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Remove the snap ring, cover, spring, and valve body.
3. Clean the cavity area with a commercial cleaning solvent.
4. Install new O-rings on the valve body and cover.
5. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-rings and the valve cavity.
6. Install the new valve body. Make sure that the long end of the body is inserted first into the valve cavity.
7. Install the new spring so it fits around the "Y" shaped fins on the valve body.

If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

8. Install the new cover and snap ring to secure the assembly in the valve cavity.

Replacement (See Fig. 1)

1. Air Line
2. Nylon Tube Connector
3. Pressure-Controlled Check Valve
4. Hex Nipple Pipe Fitting
5. Air Tank

Fig. 1

⚠ WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Disconnect the air line from the pressure-controlled check valve.
3. Remove the valve and the hex nipple fitting from the air tank.
4. Install the pipe fitting on the new valve.
5. Install the new valve on the air tank with the arrow on the valve pointing towards the tank.
6. Apply liquid Loctite® Hydraulic Sealant (brown), or an equivalent, to the air line threads. Connect the air line to the valve. Tighten the air line securely.

NOTE: Always apply sealant to the external threads so that any excess will be scraped off externally rather that internally to the joint.

Operating Tests

⚠ WARNING

WARNING: Before starting the procedures below, read the information in Safety Precautions 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

Air Dryer Operating Check

1. Drain the air system.
2. Start the engine and build the air pressure to as close to cutout pressure as possible (about 827 kPa [120 psi]).
3. When the compressor reaches the unload cycle, the air dryer purges, beginning regeneration of the air dryer.
4. During the purge cycle, which lasts about 10 to 15 seconds, the wet tank and secondary tank will drop about 69 kPa (10 psi). Check the secondary air gauge in the cab dash panel.
5. If the gauge needle does not show a pressure drop of about 69 kPa (10 psi), one of the following problems may exist.
   - A pressure-controlled check valve is not installed.
   - The pressure-controlled check valve is installed in the wrong air tank.
   - The pressure-controlled check valve is installed on a one-way check valve, instead of in place of a one-way check valve.
   - There is an extra check valve located somewhere between the air dryer and the secondary air tank (usually at the wet tank).
   - The secondary air gauge is not plumbed to the secondary air system.
6. If secondary air pressure drops 103 kPa (15 psi) or more during the purge cycle, and there are no other air-operated components in use, then there are air leaks or other system problems. Refer to **Troubleshooting 300** for other possible causes.

Pressure-Control Check Valve Operating Check

IMPORTANT: Install a calibrated air gauge (accurate to within 7 kPa [1 psi]) in the secondary air tank to check the control valve. Do not use the cab air gauges.

1. Start the engine and build the air pressure to as close to cutout pressure as possible (about 827 kPa [120 psi]).
2. Stop the engine after the air compressor has unloaded.
3. Drain the primary air tank(s) down to about 552 kPa (80 psi).
4. Check the calibrated air gauge. It should read 655 ± 34 kPa (95 ± 5 psi).

   If the gauge reading is less that 586 kPa (85 psi), either the pressure-control check valve is installed backwards, it is damaged, or there are air leaks in the secondary air system.

   If the gauge reading does not change, or the reading does not fall below 724 kPa (105 psi), make the checks under "Air Dryer Operating Check." If none of those problems exist, replace the control valve.

Troubleshooting Tables

Problem—Purge Cycle is too Long (more than 30 seconds)

Possible Cause	Remedy
The air dryer outlet check valve is stuck open.	Replace the check valve assembly.
The turbocharger cutoff valve is leaking.	Replace the turbocharger cutoff valve.
The regeneration valve is not working correctly.	Replace the regeneration valve.

Problem—Purge Cycle is too Short (less than 8 seconds)

Possible Cause	Remedy
The air governor is not working.	Replace the air governor.
The pressure-control check valve is not working correctly.	Replace the pressure-control check valve.
The regeneration valve is not working correctly.	Replace the regeneration valve.

Problem—System Air Pressure Drops Rapidly

Possible Cause	Remedy
Fittings are loose or damaged.	Tighten or replace loose or damaged fittings.
Air reservoir, tubing, or hoses are damaged.	Repair or replace damaged items.
The air dryer outlet check valve is stuck open.	Clean or replace the outlet check valve assembly.

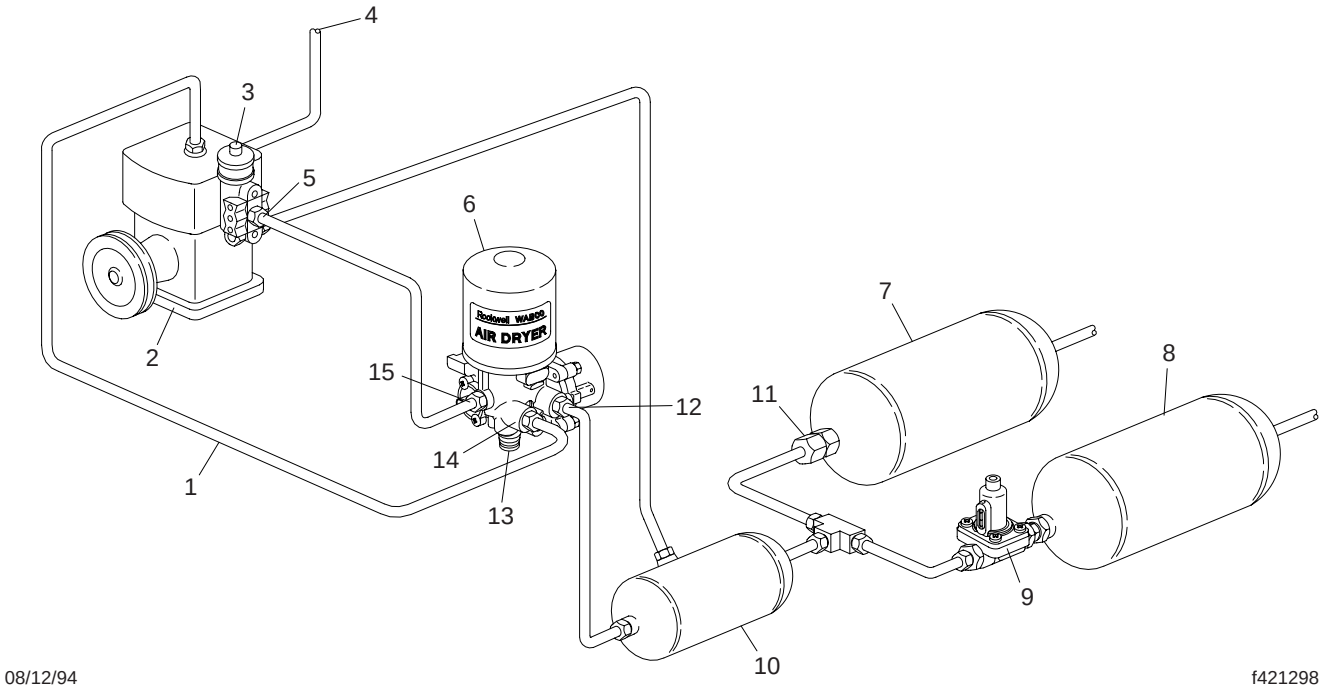
Problem—Excessive Cycling of the Air Dryer

Possible Cause	Remedy
Fittings are loose or damaged.	Tighten or replace loose or damaged fittings.
Air reservoir, tubing, or hoses are damaged.	Repair or replace damaged items.
The air dryer outlet check valve is leaking or stuck open.	Replace the outlet check valve assembly.
High air usage or demand for a particular system.	Increase air system capacity or reduce air demand.
The governor is not working properly.	Replace the air governor.
The air compressor needs to be serviced or replaced.	Rebuild or replace the air compressor.

Troubleshooting

Problem—Water and/or Oil in the Vehicle Air Reservoirs

Possible Cause	Remedy
The desiccant cartridge contains excessive contaminants.	Replace the desiccant cartridge.
Purge cycle is too short.	Refer to "Problem—Purge Cycle is too Short (less than 8 seconds)."
The bypass (relief) valve is leaking.	Replace the bypass valve.
Too much oil is pumped from the air compressor.	Rebuild or replace the air compressor.
The regeneration valve is not working correctly.	Replace the regeneration valve.
The air dryer is mounted too close to a heat source.	Locate the air dryer away from heat sources and where air can flow around it.
Discharge line is of improper length or material.	Discharge line must consist of at least 6 ft. (1.8 m) of wire braid Teflon hose, copper tubing, or a combination of both between the discharge port of the compressor and the air dryer supply port. Discharge line lengths and inside diameter requirements are dependent on the vehicle application. Contact your local Rockwell WABCO representative for further information.



Problem—The Air Compressor Runs Continuously (System Pressure Will Not Build Up)

Possible Cause	Remedy
Fittings are loose or damaged.	Tighten or replace loose or damaged fittings.
Air reservoir, tubing, or hoses are damaged.	Repair or replace damaged items.
The air compressor needs to be serviced or replaced.	Rebuild or replace the air compressor.
The purge valve is stuck open.	Replace the purge valve.
The line between the air compressor and the air dryer is blocked, leaks, or is plumbed incorrectly.	Repair or replace the line as needed.
The governor is not working properly.	Replace the air governor.
The turbocharger cutoff valve or the outlet check valve is stuck in the closed position.	Replace the turbocharger cutoff valve or the outlet check valve.
The desiccant cartridge or cartridge seal is leaking.	Tighten or replace the desiccant cartridge.
The wrong air line is connected to port 4 on the air dryer.	Correct the air line plumbing.
The air dryer outlet port is plumbed incorrectly.	Connect the outlet port line to the supply air tank.
The air dryer base is cracked.	Replace the air dryer.

Problem—The Air Dryer Does Not Unload When the Air Compressor Goes Into Standby Mode

Possible Cause	Remedy
The line between the air governor and the air dryer purge port is missing, loose, or damaged.	Install or replace the air line, or tighten the fittings.
The heater/thermostat assembly is not working.	Replace the heater/thermostat assembly or check the electrical connections.

Fig. 1, Air Dryer Plumbing Diagram

General Description

The Sloan PV-1 parking brake air valve is installed on trucks with air brakes, and is used to control the rear axle parking brakes. It is a push-pull type of valve, and is mounted on the right side of the dash. **See Fig. 1.**

Principles of Operation

When the valve knob is pulled out, air is exhausted from the rear parking brake chambers, releasing the springs, and applying the parking brakes. When the knob is pushed in, air flows into the parking brake chambers from one of the reservoirs, and compresses the springs, releasing the parking brakes.

The PV-1 has a double check valve feature. If the pressure drops in either air system (primary or secondary), the valve will automatically use air pressure from the system with the higher pressure for the parking brakes. This prevents the parking brakes from applying unless pressure is lost from both systems.

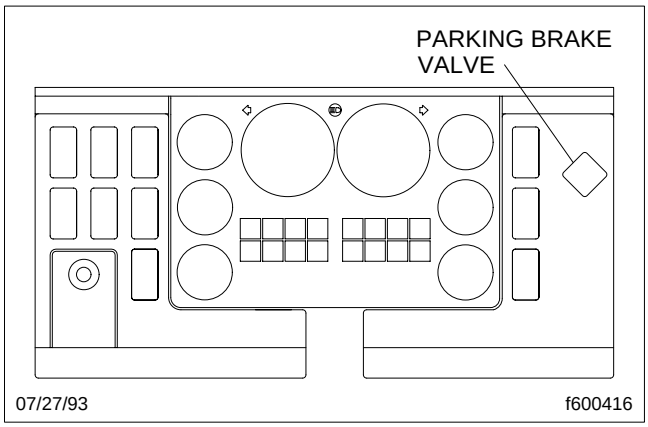

Fig. 1

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

Operating Test

1. Chock the tires.
2. Start the engine and build up the air pressure to the normal operating level.
3. Push the parking brake knob in to release the parking brakes.
4. Turn off the engine, then drain one of the air reservoirs.
5. Check if the parking brakes apply.

   If they do, the double check valve feature isn't working; replace the entire PV-1 valve assembly.

   If the parking brakes don't apply, go to the next step.
6. Start the engine again, and build up the air pressure to the normal operating level.
7. With the parking brakes still released, turn off the engine; then drain the other air reservoir.
8. Check if the parking brakes apply.

   If they do, the double check valve feature isn't working; replace the entire PV-1 valve assembly.

   If the parking brakes don't apply, the double check valve feature is working.

Leak Testing

1. Chock the tires.
2. Start the engine, and build up the air pressure to the normal operating level.
3. Coat the delivery line and exhaust line fittings on the parking valve with a soapy solution.
4. Release the parking brakes.
5. Check the leakage. Leakage at the fittings should not exceed a 2.5-cm (1-inch) bubble every three seconds. If it does, replace or rebuild the valve, following instructions under **Subject 120** or **Subject 130.**
6. Apply the parking brakes.

Removal (Refer to Fig.1)

WARNING

WARNING: Review the precautions under "Safety Precautions, 100" before doing any work on the parking brake valve. Failure to do so could result in personal injury.

1. Chock the tires.
2. Discharge the air system reservoirs.
3. Drive out the roll pin (Ref. 5), then remove the knob from the valve stem.
4. Mark the air supply, delivery, and exhaust lines for later reference, then disconnect them from the valve assembly.
5. Remove the panel mounting nut (Ref. 3), then remove the valve assembly from the dash panel.

Installation

1. Put the valve assembly into the dash, then install the panel mounting nut. Don't tighten the nut completely.
2. Turn the valve assembly so the air lines will reach their fittings.
3. Connect the air supply, delivery, and exhaust lines to the applicable fittings.
   - 3.1 Tighten the fitting hand tight.
   - 3.2 Using a wrench, tighten the fitting until the connection feels firm.
   - 3.3 Tighten the fitting an additional one-sixth turn.
4. Tighten the panel mounting nut firmly.
5. Put the knob onto the valve stem, making sure the label on the valve is parallel with the top of the dash, **as shown in Fig.1.** Then drive in the roll pin.
6. Leak test the fittings, following the instructions under **"Leak Testing, 110."**

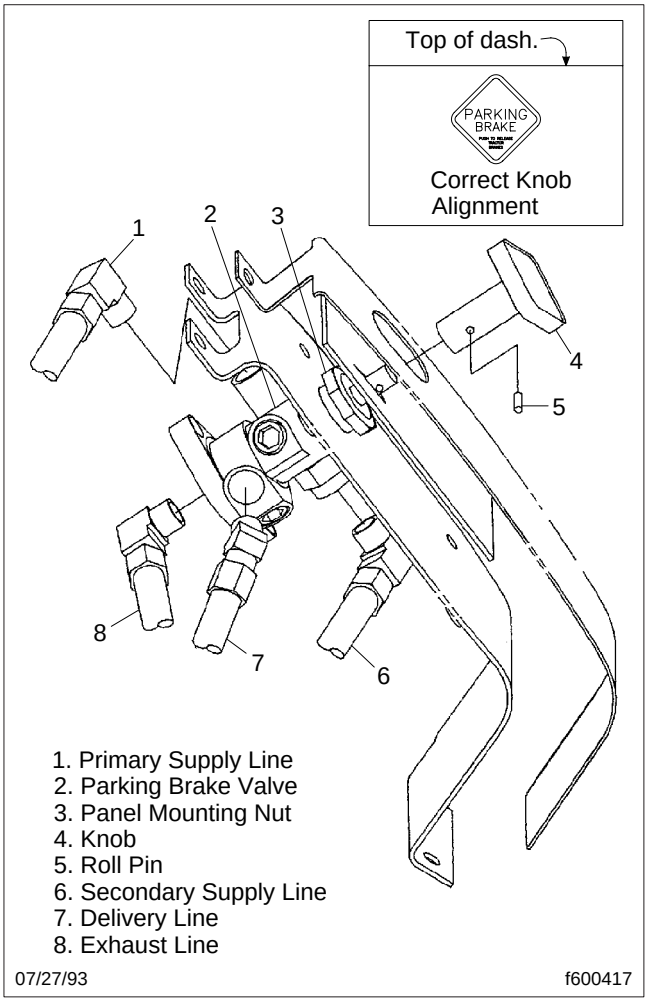

Fig. 1

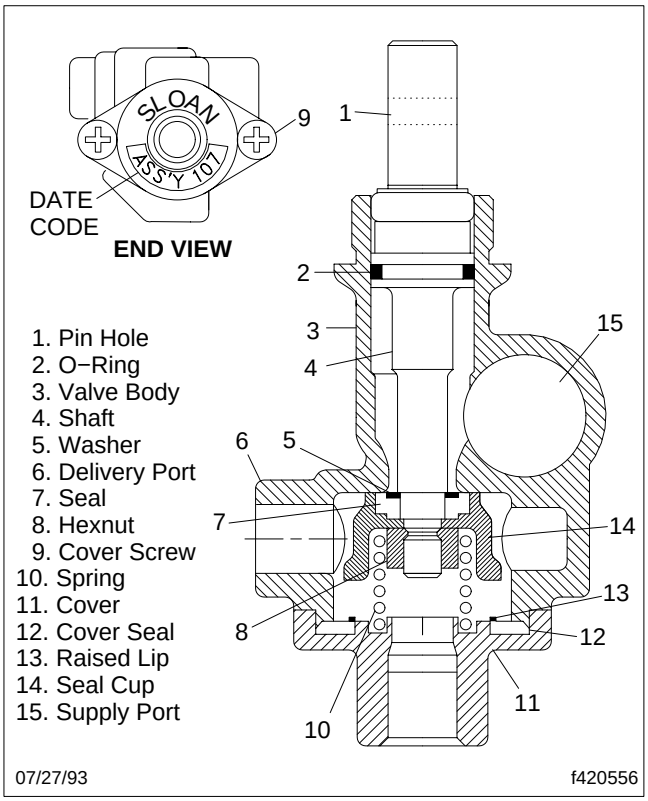
Disassembly (See Fig. 1)

1. Remove the valve assembly from the dash, following instructions in **Subject 120**.
2. Put the valve assembly in a soft-jawed or padded vise.
3. Remove the screws (Ref. 9) from the cover (Ref. 11).
4. Carefully remove the cover, cover seal (Ref. 12), and spring (Ref. 10). Discard the cover seal.
5. Insert a rod through the pin hole (Ref. 1) of the shaft to keep it from turning, then remove the hexnut (Ref. 8) from the bottom of the shaft.
6. Remove and discard the seal cup (Ref. 14), seal (Ref. 7), and the washer (Ref. 5) from the shaft.
7. Remove the shaft (Ref. 4) from the valve body.
8. Remove and discard the O-ring (Ref. 2) from the shaft.

Assembly (See Fig. 1)

1. Clean and dry all the parts.
2. Check all the parts. If any wear or damage is found, replace the entire valve assembly.
3. Lightly grease all the parts— including the new parts from the seal kit— with Dow Corning 55 silicone pneumatic grease or equivalent.
4. Install a new O-ring (Ref. 2) on the shaft (Ref. 4).
5. Install the shaft in the valve body.
6. Install a new washer (Ref. 5) on the step of the shaft.
7. Assemble a new seal (Ref. 7) into the new seal cup (Ref. 14), then install them on the step of the shaft, with the seal against the washer (Ref. 5).
8. Apply Loctite 222® or equivalent on the threads of the new hexnut (Ref. 8).
9. Install the hexnut— counter-bored side toward the seal (Ref. 7)—on the end of the shaft. Tighten the nut 460 N·cm (40 lbf·in).
10. Install a new cover seal (Ref. 12) in the cover with the raised lip (Ref. 13) on the cover seal toward the valve.
11. Grease the sealing surfaces of the seal cup (Ref. 14), and the cover seal (Ref. 12).
12. Install the spring (Ref. 10) and then the cover (Ref. 11).
13. Install the cover screws. Tighten them firmly.
14. Install the valve in the dash, then leak test it. Follow instructions in **Subject 120** and **Subject 110**.



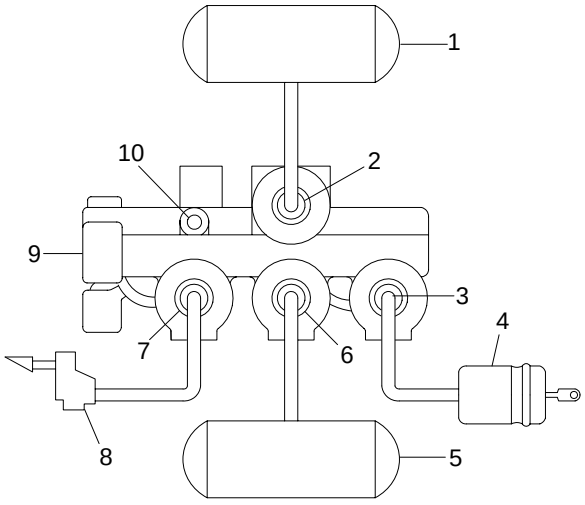


Fig. 1, Valve Assembly

General Description

The dash-mounted MV-3 control module is a two-button, push-pull control valve housed in a single body, which includes a dual circuit supply valve and a check valve.

The valve body, plungers, and spools are made out of a nonmetallic, noncorrosive material. All air connections are at the back of the valve with the exception of the optional auxiliary port, which is located in the side of the valve. **See Fig. 1.**

The MV-3 module has several uses: tractor protection control; trailer service air supply; system park; trailer park only; trailer charge with tractor spring brakes applied (tractor park only); and supply reservoir selection.

1. Primary Reservoir
2. Primary Reservoir Supply Port
3. Delivery−Tractor Port
4. Spring Brake Chamber
5. Secondary Reservoir
6. Secondary Reservoir Supply Port
7. Delivery−Trailer Port
8. Tractor Protecton Valve
9. Auxiliary Air Delivery Port
10. Exhaust Port

04/06/93 f420468

Fig. 1

The MV-3 includes a spring-loaded, dual-circuit supply valve, which selects the primary air reservoir as the air source for both control valves, unless the pressure in the primary air reservoir falls more than 207 kPa (30 psi) below that of the secondary air reservoir. Then, the dual-circuit supply valve will shuttle and establish the secondary air reservoir as the air source.

NOTE: The primary air reservoir supplies the rear tractor axle; the secondary air reservoir supplies the front axle.

The trailer air supply valve **(refer to Fig. 2),** actuated by a red knob, delivers air to the trailer supply line. The parking brake valve, actuated by a yellow knob **(Fig. 2),** controls the spring parking brakes on the tractor, and when exhausted, simultaneously causes the trailer supply valve to trip and exhaust, thus applying both the tractor and the trailer parking brakes as required by federal regulations. The trailer parking brakes may be independently released by pushing only the trailer air supply valve (red) knob in.

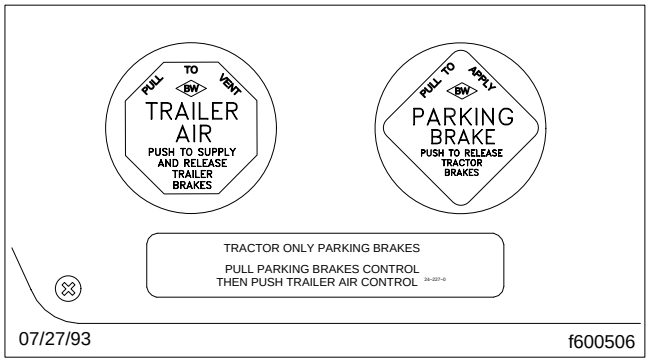

Fig. 2

Principles of Operation

INITIAL CHARGE

With both the primary and the secondary systems completely discharged, both knobs are out. **See Fig. 3.** When system pressure reaches 448 kPa (65 psi), the red knob (trailer air supply) may be pushed in, and should stay in, charging the trailer system and releasing the trailer parking brakes. **See Fig. 4.** The yellow knob (parking brake) may now be pushed in, which will supply air to the tractor parking brakes, releasing them.

NORMAL OPERATION POSITION

When both knobs are pushed in, air is supplied to the trailer and the tractor parking brakes; all parking

General Description and Principles of Operation

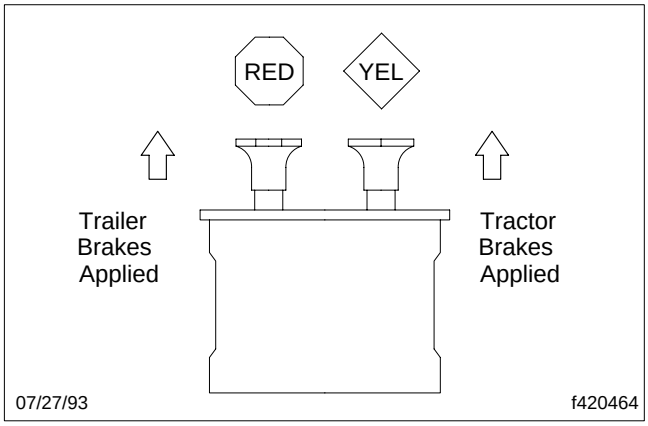

Fig. 3

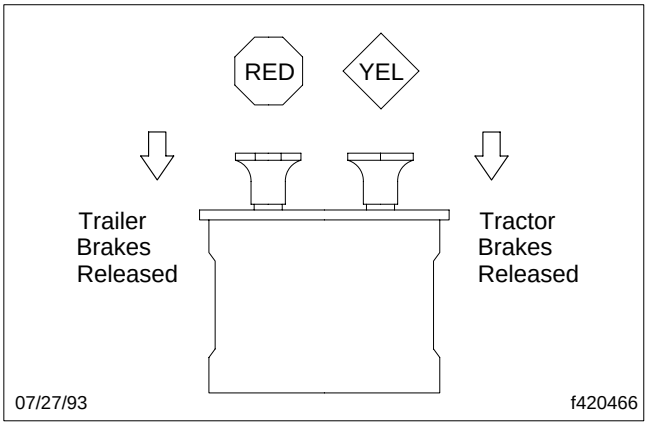

Fig. 5

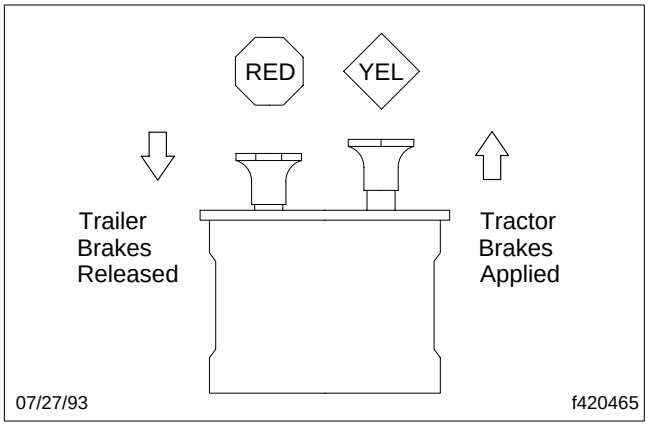

Fig. 4

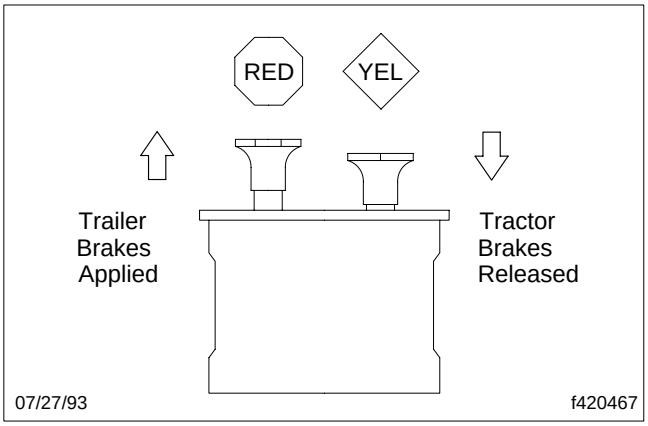

Fig. 6

brakes are released. **See Fig. 5.** This is the normal operating mode.

ACTUATION OF TRAILER PARK OR EMERGENCY BRAKES

To actuate the trailer parking brakes only, the red knob is pulled out, exhausting the trailer supply line. The trailer parking brakes are now applied, either by emergency air or parking brakes, depending on the type of trailer system. This mode would be used to uncouple from the trailer, and during bobtail operation. **See Fig. 6.**

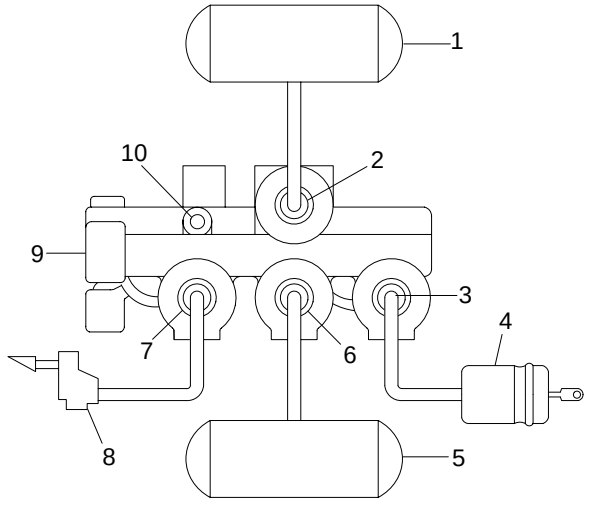
SYSTEM PARK

With both knobs in, the parking brakes on both the tractor and the trailer may be actuated by pulling the yellow (parking brake) knob out. This exhausts the air from the tractor parking brakes and simultaneously causes the red (trailer air supply) knob to pop out, applying the trailer parking brakes. (This complies with federal regulations that one control must apply all the parking brakes on the vehicle.) **See Fig. 3.**

TRAILER CHARGE

If both valves are out, parking the combination vehicle, and it is desired to recharge the trailer (leaving only the tractor parking brakes applied), the red knob may be pushed in, repressurizing the trailer supply line. This mode might also be used to park a combination vehicle with air actuated emergency brakes on the trailer to provide demonstrated parking capability with the tractor spring brakes only. **See Fig. 4.**

AUTOMATIC APPLICATION



If air pressure drops to 241 to 310 kPa (35 to 45 psi) in both the primary and the secondary systems, the red knob (trailer air supply valve) will automatically pop out, applying the emergency or parking brakes on the trailer. If the red knob is held in manually and the pressure decreases to 172 to 241 kPa (25 to 35 psi), a tripper piston within the MV-3 valve will move upward, exhausting the trailer supply, and applying the trailer parking brakes. If air pressure drops in both the primary and the secondary systems, the yellow (parking brake) knob will pop out at about 138 to 207 kPa (20 to 30 psi), applying the tractor parking brakes.

A warning buzzer and light are activated when pressure in either the primary or the secondary system drops below 441 to 524 kPa (64 to 76 psi).

Tests

With the air brake system charged to 827 kPa (120 psi), check for leaks, using the following instructions. Repair or replace components as needed.

1. Check for leakage between the body and cover plate. No leakage is permitted.
2. Push in the red knob. The knob must stay in. Leakage at the exhaust port (**Fig. 1**, Ref. 10) must not exceed a 25-mm (1-inch) bubble in 5 seconds.
3. Slowly reduce pressure in both service reservoirs. The red knob must pop out at 241 to 310 kPa (35 to 45 psi) and maintain the supply pressure. Leakage at the exhaust port must not exceed a 25-mm (1-inch) bubble in 5 seconds.

1. Primary Reservoir
2. Primary Reservoir Supply Port
3. Delivery−Tractor Port
4. Spring Brake Chamber
5. Secondary Reservoir
6. Secondary Reservoir Supply Port
7. Delivery−Trailer Port
8. Tractor Protecton Valve
9. Auxiliary Air Delivery Port
10. Exhaust Port

04/06/93 f420468

Fig. 1

4. Hold the red knob in and continue to reduce pressure in all service reservoirs. Air must start to escape from the exhaust port when the trailer line pressure reaches 138 to 241 kPa (20 to 35 psi).
5. Release the red knob and rebuild the supply pressure to 827 kPa (120 psi). Push in the yellow knob; the yellow knob must remain in. Leakage at the exhaust port should not exceed a 25-mm (1-inch) bubble in 5 seconds.
6. Pull the red knob out. Slowly reduce pressure in all service reservoirs. The yellow knob must pop out at 138 to 207 kPa (20 to 30 psi) and maintain supply pressure. Leakage at the exhaust port should not exceed a 25-mm (1-inch) bubble in 5 seconds.
7. Charge the system to 827 kPa (120 psi), and push both knobs in. Pull the red knob out. The yellow knob must remain in. Push the red knob in and pull the yellow knob out. The red knob must pop at once.
8. Install a gauge to monitor tractor spring brake delivery pressure. Build 827 kPa (120 psi) pressure in the primary and secondary air reservoirs. Push in the yellow knob. Delivery pressure should equal the pressure in the primary air reservoir. Reduce the pressure in the primary air reservoir. Delivery pressure and the primary air reservoir pressure should descend together to 621 to 724 kPa (90 to 105 psi), at which point the dual-circuit supply valve shuttle should switch to the secondary air reservoir; delivery pressure should increase to the secondary air reservoir pressure. After the primary air reservoir pressure is reduced to zero, there should not be audible leakage at the primary air reservoir opening. Stop the leak that was created in the primary air reservoir.
9. Leaving the yellow knob in, recharge the secondary air reservoir to 827 kPa (120 psi). The delivery pressure should also read 827 kPa (120 psi). Recharge the primary air reservoir to 689 kPa (100 psi). Slowly vent the secondary air reservoir. As the secondary air reservoir pressure and the delivery line pressure descend, pressure should stabilize at about 689 kPa (100 psi).
10. Close all leakage points and charge both reservoirs to 827 kPa (120 psi). Position the red knob out and the yellow knob in. Develop a leak in the spring brake delivery line (**Fig. 1**, Ref. 3) and hold the yellow knob in. The primary air reservoir

Operating Tests

pressure will go to zero; and the secondary air reservoir pressure will drop to 138 to 207 kPa (20 to 30 psi). The dual-circuit supply valve shuttle should cycle several times during the leak-down period.

Removal

1. Park the vehicle on a level surface, apply the parking brakes, chock the tires, and drain all air tanks to zero pressure.

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

2. Unscrew the red and yellow buttons from the stems of the spools on the MV-3 valve by turning in a counterclockwise direction. Mark these buttons in relation to the valve for later reference.
3. Remove the dash panel and foam gasket, and then remove the dash bracket. Save all six screws.
4. Remove and save the mounting hardware from the four corners of the cover plate.
5. Pull the valve forward, mark and then remove the air lines from the back of the valve.

Installation

1. Connect the air lines to the proper ports as marked during removal.
2. Align the valve in the dash and install the four screws into the corners of the cover plate.
3. Replace the dash bracket, gasket and dash panel with the hardware previously removed.
4. Attach the red and yellow buttons onto the threaded stems of the spools, making sure that they are oriented correctly as noted during removal.

Disassembly, Cleaning and Inspection, and Assembly

Disassembly

1. Remove the six screws (**Fig. 1**, Ref. 3) from the cover plate (Ref. 4) and carefully remove the cover plate from the valve.
2. Remove the cap (Ref. 5) and O-ring (Ref. 6) from the bore of the tripper valve. Remove the piston (Ref. 7), spring (Ref. 8), spring (Ref. 9), and check valve (Ref. 10). These parts will all fall out of the cavity of the MV-3 by tilting the body forward. Remove the O-ring (Ref. 11) from its groove on the piston.
3. Remove the two main spools from the body of the MV-3 valve by grasping the stem and pulling firmly. Remove the two springs (Ref. 21) from the bottom of each spool cavity.
4. Pull the guide cap (Ref. 12) and guide spool (Ref. 14) over the threaded end of one of the plungers (Ref. 18). Remove the O-ring (Ref. 13) from the guide cap and the O-ring (Ref. 15) from the guide spool. Remove O-rings (Refs. 16, 17, and 20) and the exhaust seal (Ref. 19) from the plunger.
5. Repeat step(s) as required on the remaining spool assembly.
6. Remove the retaining ring (Ref. 22) from the cavity of the MV-3 body that contains the dual circuit supply valve.
7. Using a pair of needle nose pliers, grasp the bar in the center of the cap (Ref. 23) and remove the dual circuit valve assembly. Remove the three O-rings (Refs. 24, 25, and 26) from the valve or from the cavity of the body, if some have remained there. Other than the three external O-rings, don't disassemble the piston assembly further.

NOTE: If during the removal of this assembly from the body the cap dislodges from the rest of the valve, the remaining parts can be removed using bent wire. The spring, piston and O-ring that are internal to the dual circuit valve assembly are non-serviceable.

Cleaning and Inspection

The nonmetallic components making up most of the parts of the MV-3 *should not be immersed in any solvent type cleaner*. Old lubricant should be wiped out with a clean dry cloth.

If any visible damage to the body or the spools is found, replace the complete unit.

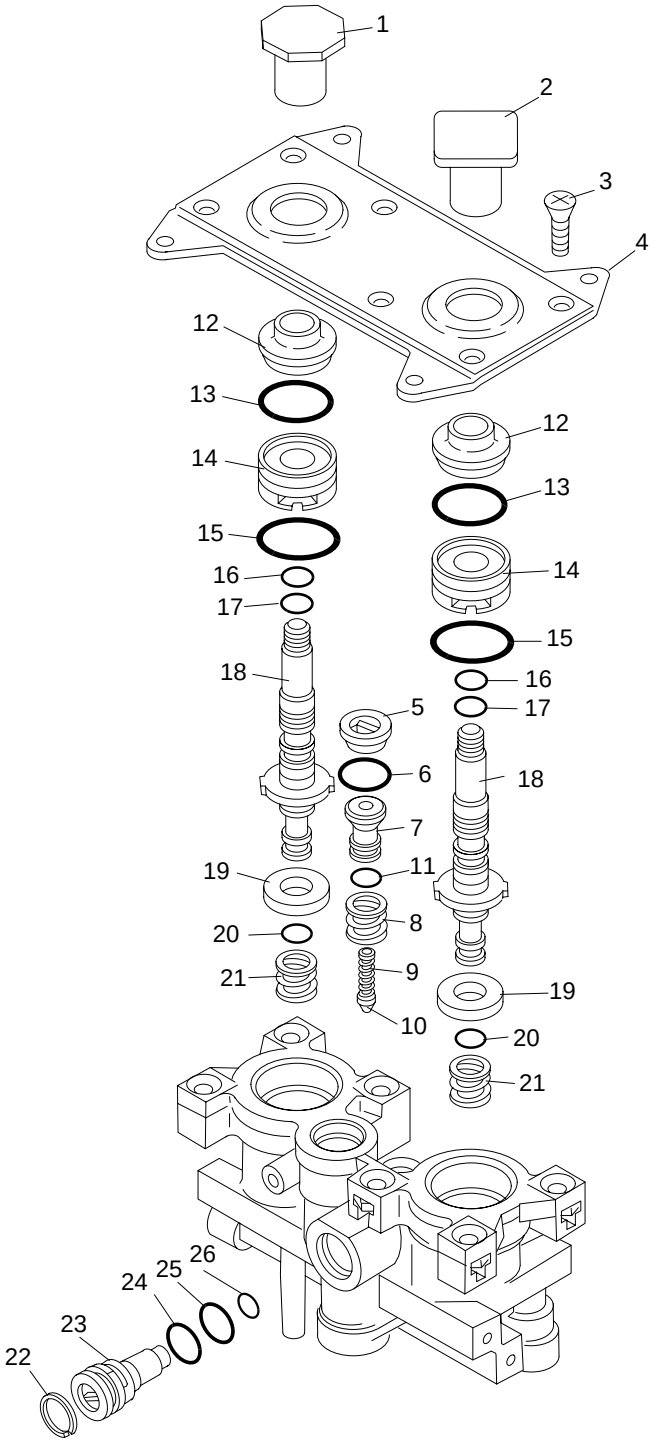
Assembly

DUAL CIRCUIT SUPPLY VALVE

1. Lubricate all O-rings, bores, and sliding surfaces with silicone lubricant Bendix 291126, Dow Corning 55-M, or equivalent.
2. Install O-rings (Refs. 24, 25, and 26) onto the dual circuit supply valve (Ref. 23). Then install the assembly— small diameter first— into its cavity in the body.
3. Install the retaining ring (Ref. 22) making sure it is fully seated in its groove.

SPOOLS

1. Install the O-rings (Refs. 16, 17, and 20) and the exhaust seal (Ref. 19) onto the stem of plungers (Ref. 18).



⚠ CAUTION

The exhaust seal (Ref. 19) must be installed so that its beveled surface mates with the beveled surface of the plunger (Fig. 2).

2. Install the O-ring (Ref. 15) onto the guide spool (Ref. 14) and the O-ring (Ref. 13) onto the guide cap (Ref. 12). Place the guide cap on top of the guide spool and install the entire assembly over the threaded end of the plunger (Ref. 18), and press down firmly until it snaps into place.
3. Install the spring (Ref. 21) over the boss in the bottom of the spool cavity in the body of the MV-3 valve. Place the spool assembly into the body, keeping the spool square to the body. Press and turn the stem until the spool is fully seated in its cavity. Note the assembly is keyed and can be installed one way only.
4. Repeat step(s) as required for the opposite spool.

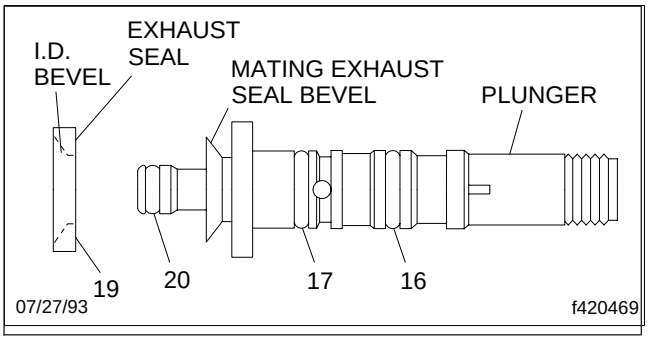

Fig. 2

SHUTTLE AND CHECK VALVE

1. Install the O-ring (Ref. 11) into its groove on the piston (Ref. 7); then install the O-ring (Ref. 6) onto the cap (Ref. 5).
2. Install the spring (Ref. 8) on the piston (Ref. 7) and the spring (Ref. 9) on the boss of the check valve (Ref. 10).
3. Install the spring and check valve into their cavity in the body of the MV-3 valve (tapered end of the valve to enter cavity first). Make sure the spring (Ref. 9) is centered in the bore.
4. Install the piston assembly into the cavity, making sure the spring (Ref. 9) mates with the bore of the piston.
5. Install the cap (Ref. 5) with O-ring (Ref. 6).
6. Attach the cover plate (Ref. 4) to the valve body using the six screws. Torque them 280 N·cm (25 lbf·in).
7. Check the operation of the valve using the instructions under **Subject 100**.

General Information

The function of the QR-1 quick release valve **(Fig. 1)** is to speed up the release of compressed air from the brake chambers. If the front brake chambers, for example, are equipped with a QR-1 valve, and the brakes are released, the exhaust port of the quick release valve opens and the air from the front brake chambers is exhausted through the quick release valve. This speeds up the release of the front brakes.

When the front brake chambers are equipped with a QR-1 valve, it is located on the rear cab mount crossmember.

When the parking brake chambers are equipped with a QR-1 valve, it is located on the rear suspension crossmember.

A delivery line from the foot valve is connected to the port on top of the QR-1 quick release valve; the two side ports are for brake chamber connections, and the exhaust port is located at the bottom of the valve.

Principles of Operation

(Refer to Fig. 1)

When the service brakes are applied, delivery air enters the brake valve port on the QR-1 quick release valve; the diaphragm moves down, sealing the exhaust port. At the same time, air pressure forces the edges of the diaphragm down, allowing air to flow out the brake chamber ports, filling the chambers and applying the front axle brakes.

When the brake chamber air pressure (beneath the diaphragm) equals the air pressure being delivered by the foot valve (above the diaphragm), the outer edge of the diaphragm will seal against the valve body seat. The exhaust port is still sealed by the center portion of the diaphragm. When the foot brake is released, the air above the diaphragm is released back through the foot brake valve exhaust, while the air beneath the diaphragm forces the diaphragm to rise, opening the exhaust port, and allowing air in the brake chambers to exhaust.

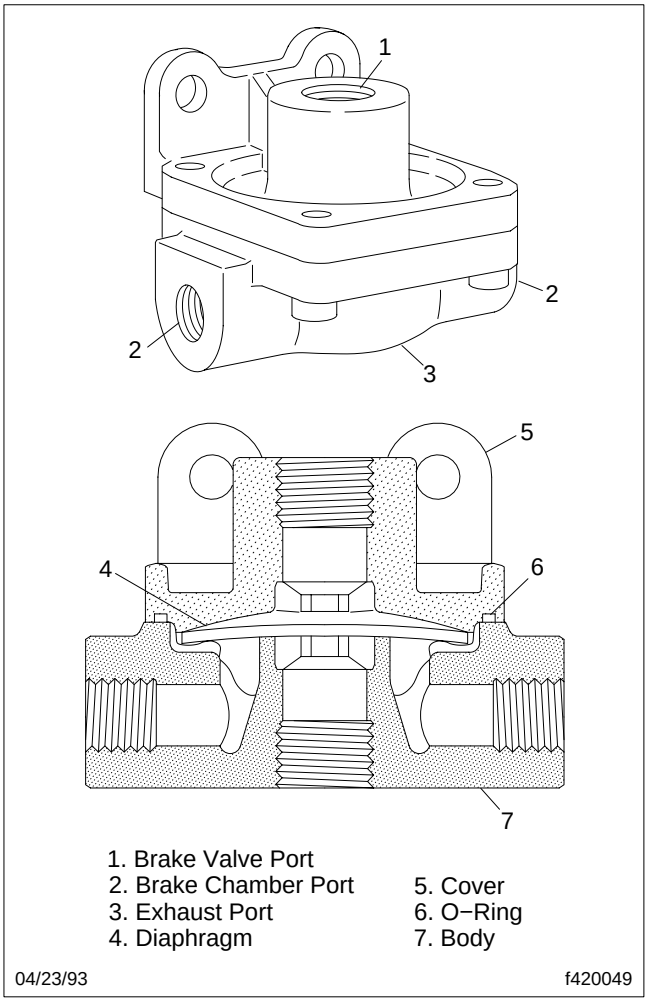

Fig. 1, QR-1 Valve and Cross Section

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

Tests

The following tests should also be done after repairing or replacing the QR-1 valve to ensure that it is functioning correctly.

1. With the brakes applied (pedal pushed in) do the following checks:

   1.1 Coat the exhaust port with a soap solution; leakage of a 2.5-cm (1-inch) bubble in three seconds is allowable.

   1.2 Coat the valve body and cover with a soap solution. No leakage is permitted between the valve body and cover.

2. If the valve does not function correctly, or if there is too much leakage, repair or replace it following the instructions in this section.

Removal

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Chock the tires or hold the vehicle by means other than air brakes.
2. Drain the air brake system by opening the reservoir drain cocks.
3. Mark and disconnect the air lines from the quick release valve.
4. Remove the mounting bolts and the valve.

Installation

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Install the quick release valve with the exhaust port facing down. Securely tighten the mounting bolts.
2. Connect the air lines to the quick release valve as previously marked.
3. Do the tests under **"Operating and Leakage Tests, 110."**

Disassembly, Cleaning and Inspection, and Assembly

Disassembly

1. Remove the quick release valve from the vehicle following the instructions under **"Removal and Installation, 120."**
2. Remove the four screws holding the valve cover on the valve body.
3. If equipped, remove the spring and spring seat.
4. Remove the diaphragm.
5. Remove the cover O-ring.

Cleaning and Inspection

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Clean all metal parts in mineral spirits. Wipe all rubber parts clean.
2. It is recommended that all rubber parts and any other part showing signs of wear or deterioration be replaced with genuine Bendix parts.

Assembly

1. If the quick release valve is not equipped with a spring, install the diaphragm into the valve body.

   If the quick release valve is equipped with a spring, position the spring in the valve body. Then, position the diaphragm over the spring seat.
2. Install the O-ring in the valve cover groove and install the valve cover. Tighten the screws 340 to 680 N·cm (30 to 60 lbf·in) evenly and securely.
3. Install the quick release valve, following the instructions under **"Removal and Installation, 120."**

General Description

The GTD 4000-2 quick release valve provides fast release of the trailer brake. It is installed on the tractor protection valve on vehicles equipped with a tractor/trailer air system, and connects to the trailer air brake line.

The valve is screwed into the service delivery port of the tractor protection valve. On some vehicles a second quick-release valve is screwed into the parking brake delivery port of the tractor protection valve. **See Fig. 1.**

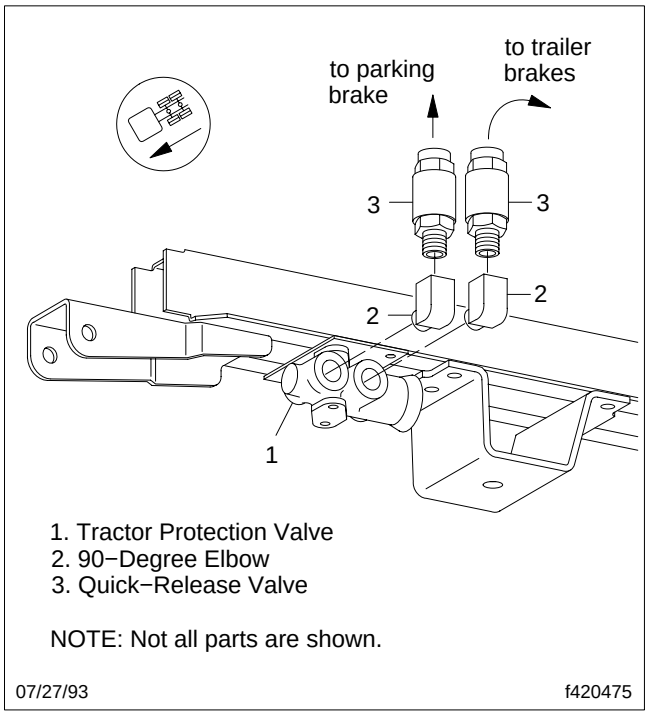

Fig. 1

Principles of Operation

(Refer to Fig. 2)

When the brakes are applied, air passes through the quick-release valve to the trailer service brakes (and to the trailer parking brake, if applicable). When the brakes are released slowly, air passes from the trailer brakes through the quick release valve, and exhausts at the foot valve.

When the brakes are released quickly, the sudden pressure drop moves the diaphragm inside the quick release valve, which prevents the air from exhausting through the foot valve. Instead, it exhausts through the quick-release valve, which releases the trailer brakes more quickly.

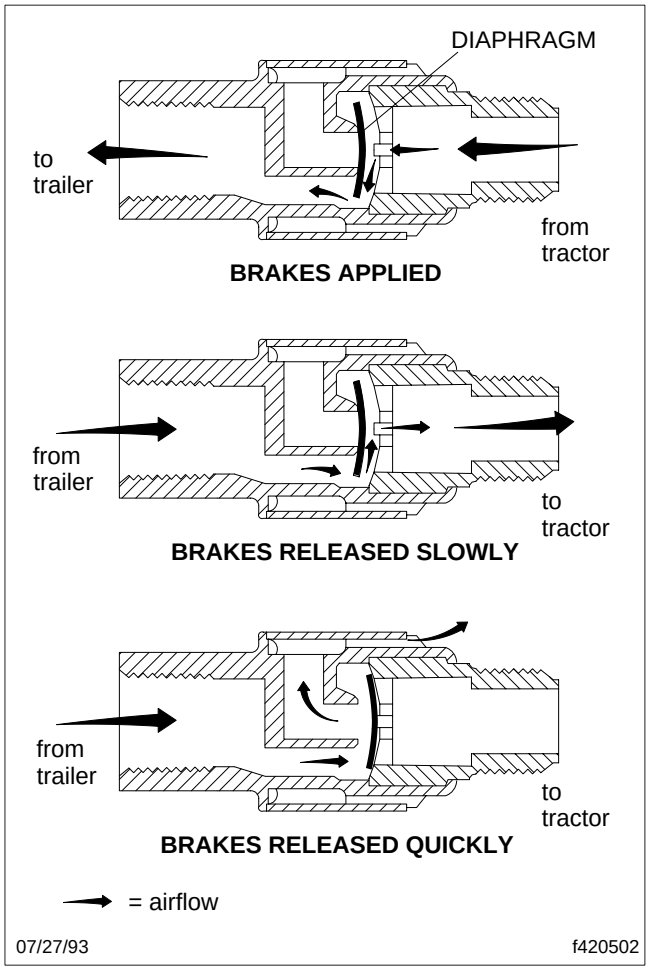

Fig. 2

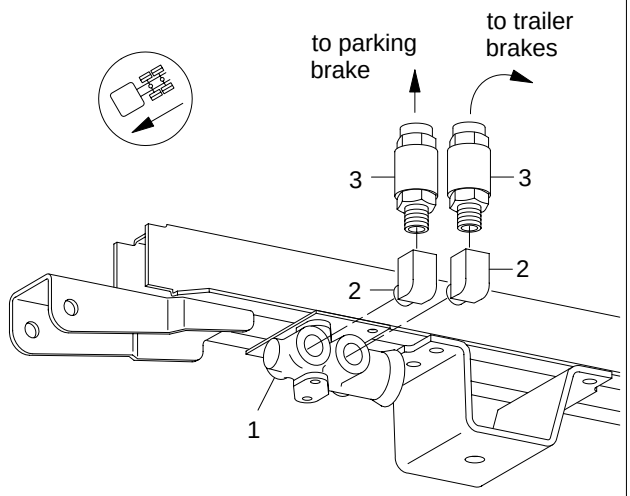
Operation Test

1. With the system pressurized and the trailer brakes connected, apply the brakes, then slowly release them. There should be no audible leakage or exhaust from the quick-release valve.
2. Apply the brakes a second time, then release them quickly. Air should exhaust through the quick-release valve.

   If the valve fails the above test, replace it.

Leakage Test



1. Pressurize the air system.
2. Coat the quick-release valve with a soapy solution. Leakage resulting in a 2.5-cm (1-inch) bubble or less every ten seconds is acceptable. If the leakage is more than above, replace the valve.

Removal

WARNING

WARNING: Wear safety goggles when draining the air system or disconnecting an air line because dirt or sludge particles could fly out at high speeds. Don't direct the air stream at other people. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

1. Drain the air from the air reservoirs.
2. Carefully disconnect the air line from the quick-release valve.
3. Unscrew the quick-release valve from the 90-degree elbow on the tractor protection valve. **See Fig. 1.**

1. Tractor Protection Valve
2. 90−Degree Elbow
3. Quick−Release Valve

NOTE: Not all parts are shown.

07/27/93 f420475

Fig. 1

Installation

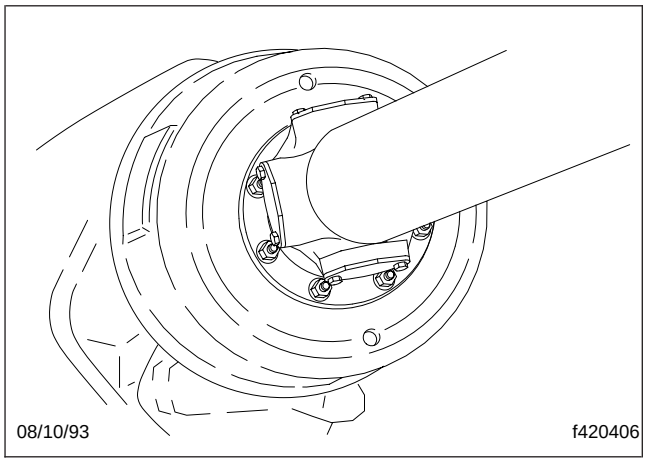
1. Screw the quick-release valve into the 90-degree elbow on the applicable delivery port of the tractor protection valve.

   Make sure the arrow stamped on the valve is pointing toward the trailer air line.
2. Connect the air line to the quick-release valve. Tighten the connection firmly.

General Description

The Bendix driveline parking brake is designed to hold the vehicle on a grade, and to stop a slow moving vehicle if the service brakes aren't working. The parking brake is manually operated, and has a mechanical linkage; it doesn't rely on hydraulic or air pressure. It is installed only on vehicles with hydraulic brakes.

The parking brake is mounted on the rear of the transmission, between it and the driveshaft. **See Fig. 1**. The main parts of the brake are the drum, brake shoes, return springs, support plate, cam, actuating lever, brake cable, and brake lever assembly. **See Fig. 2** and **Fig. 3**.



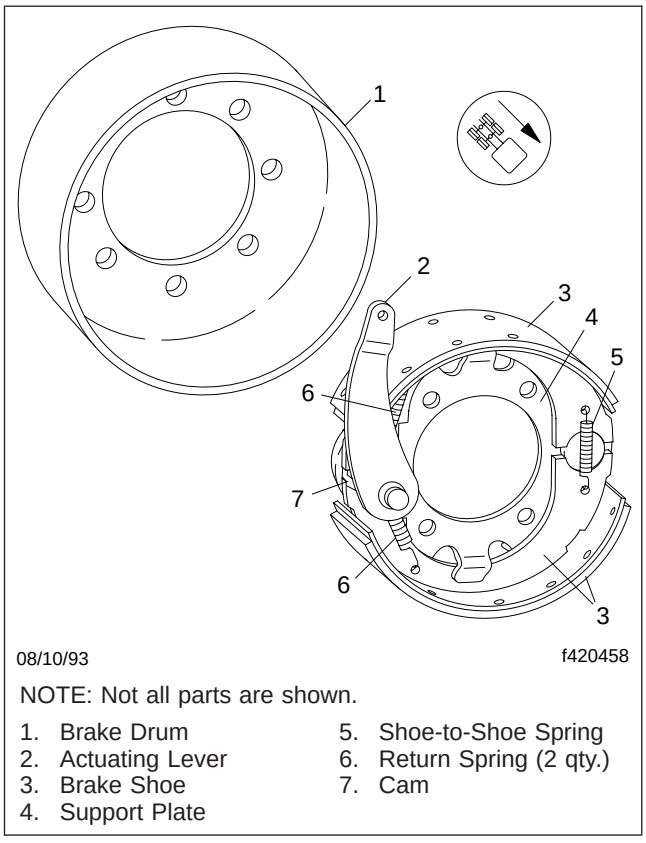


Fig. 1

The brake drum and the driveline companion flange are bolted to the transmission companion flange, which is attached to the transmission shaft. The support plate is bolted to the rear of the transmission. The brake shoes are held in place by the return springs, the shoe-to-shoe spring, and by the support plate. The brake cable runs from the actuating lever to inside the cab, where it is controlled by the parking brake lever assembly. **See Fig. 4**. A ring at the end of the parking brake lever is used to adjust the cable length to compensate for brake shoe wear.

Principles of Operation (Fig. 5)

When the brake lever is pulled up, the brake cable pulls the actuating lever, turning the cam. The cam pushes the brake shoes outward against the brake

NOTE: Not all parts are shown.

6. Return Spring (2 qty.)
7. Cam

Fig. 2, Assembled Parts

drum. Because the support plate and the shoes are mounted in a fixed position on the transmission, and the brake drum is attached to the end of the driveshaft, the driveshaft is prevented from turning. This keeps the vehicle from rolling.

When the parking brake lever is released, the tension on the cable is removed. The actuating lever and cam return to their original position, and the brake return springs and shoe-to-shoe spring pull the brake shoes away from the brake drum. The driveshaft is then free to move, and the vehicle can be moved.

General Description and Principles of Operation

Safety Precautions

Because most brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Because medical experts believe that long-term exposure to some non-asbestos fibers could also be a health hazard, also observe the following precautions if servicing non-asbestos brake linings.

Exposure to airborne brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

During brake servicing, wear an air purifying respirator with high-efficiency filters. The respirator and filter must be approved by NIOSH or MSHA, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, or can't be used, clean the brake assembly in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with an HEPA filter system, remove dust from all the brake parts. After vacuuming, remove any remaining dust using a rag soaked in water and wrung until nearly dry.

⚠ WARNING

WARNING: Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by NIOSH or MSHA. Wear a respirator at all times when disassembling the parking brake, starting with removal of the drum and continuing through assembly.

Replacement

WARNING

Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Chock the tires. Apply the parking brake to keep the brake drum in place when the driveline is disconnected.
2. Remove the driveline midship bearing carrier from the frame crossmember.
   - 2.1 Put a jackstand under the driveline at the rear of the midship bearing.
   - 2.2 Remove the bolts holding the midship bearing carrier to the bracket on the frame crossmember. See Fig. 1.

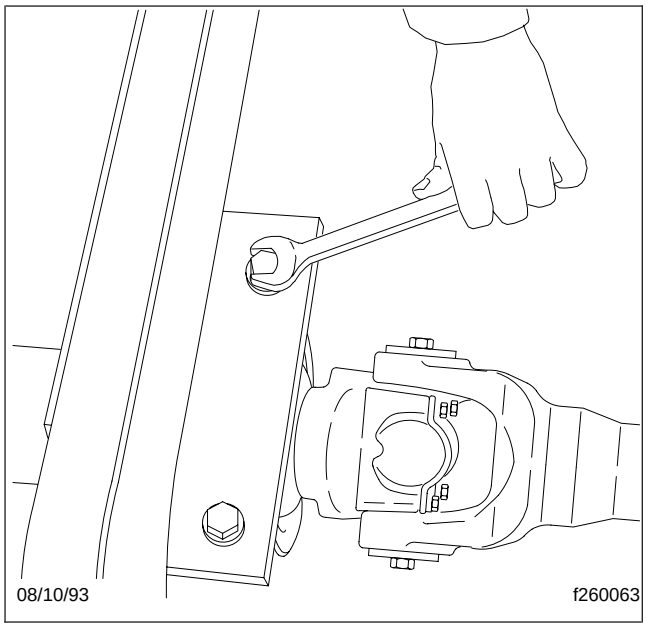

Fig. 1

   - 2.3 Lower the driveline and midship bearing carrier onto the jackstand. It should rest securely on the jackstand.
3. Disconnect the driveline companion flange from the transmission companion flange. See Fig. 2.

Slide out the driveline, and lower it to the floor. See Fig. 3.

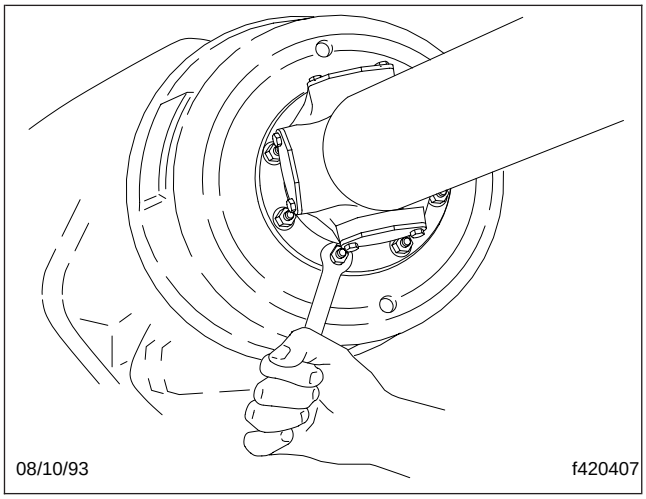

Fig. 2

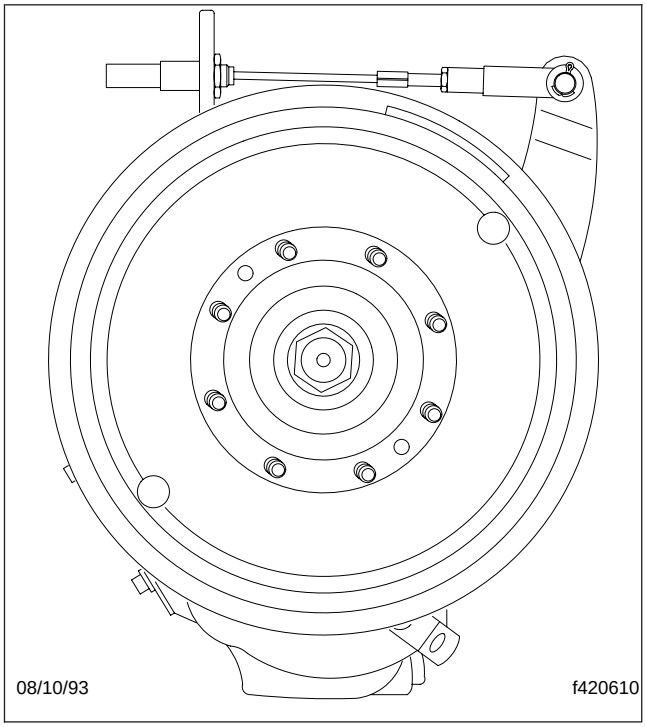

Fig. 3, Driveline Removed

4. Release the parking brake.
5. Pull the brake drum off the transmission companion flange. See Fig. 4.

Brake Shoe Replacement

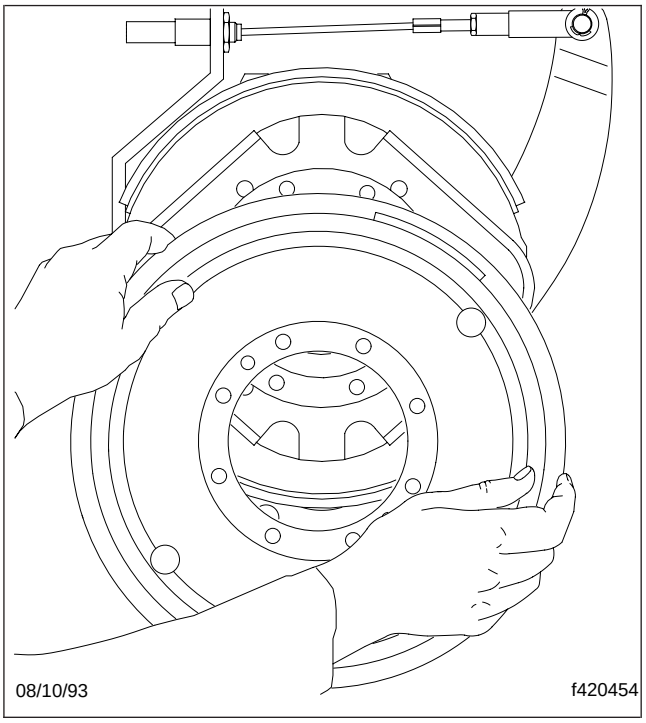

Fig. 4

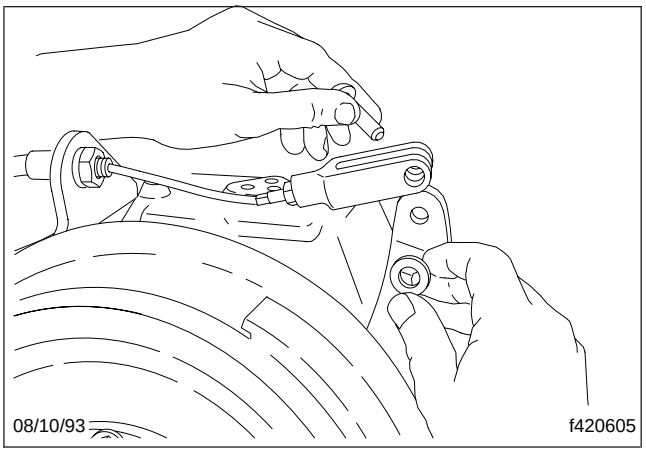
6. Disconnect the brake cable from the actuating lever. **See Fig. 5**.



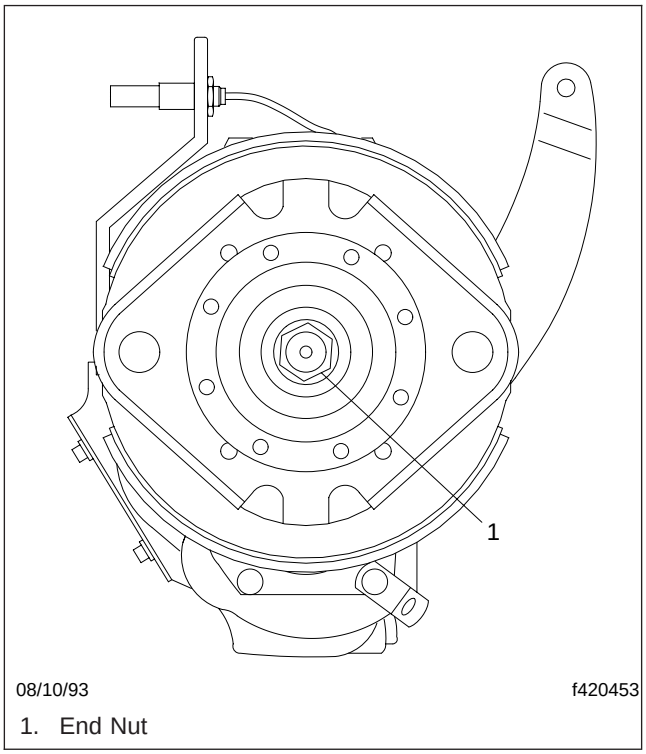


Fig. 5

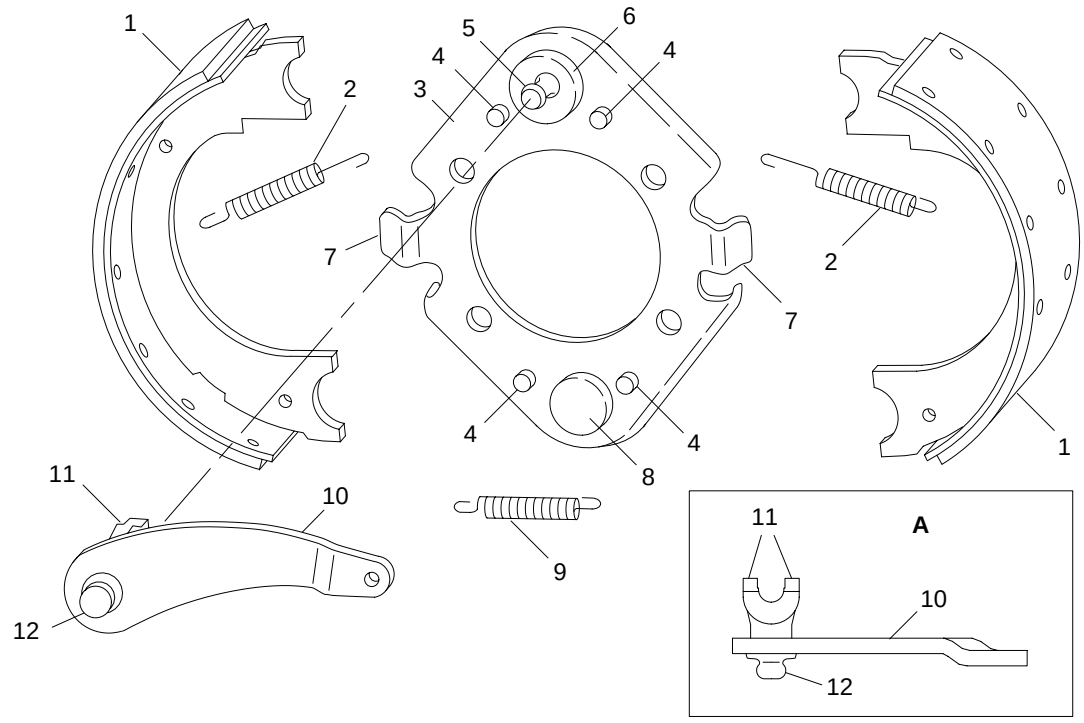
7. Remove the large end-nut from the transmission shaft. **See Fig. 6**. Remove the companion flange.
8. Remove the supporting plate and brake shoes as a unit.
9. Disassemble the brake parts. **See Fig. 7**.

1. End Nut

Fig. 6

9.1 Remove the actuating lever and cam assembly.

9.2 Remove the brake shoes from the supporting plate.



⚠ WARNING

WARNING: Brake shoe return springs are under tension, and may release unexpectedly, which could cause injury. Wear safety glasses when removing them.

9.3 Using a suitable spring removal tool, carefully remove the two brake shoe return springs.

9.4 Spread the brake shoes apart to release tension on the shoe-to-shoe spring.

9.5 Remove both brake shoes from the support plate, then remove the shoe-to-shoe spring.

A. Top view of actuating lever.

11. Cam Lugs
12. Cam Ball

Fig. 7

10. Clean all the parts. Check for damage and corrosion, and replace parts if needed. Check the support plate for cracks or bending. Replace it if needed.

CAUTION

CAUTION: Don't let any grease get on the brake drum or linings. Grease on these parts will reduce the effectiveness of the driveline parking brake. If brake linings become contaminated, replace them.

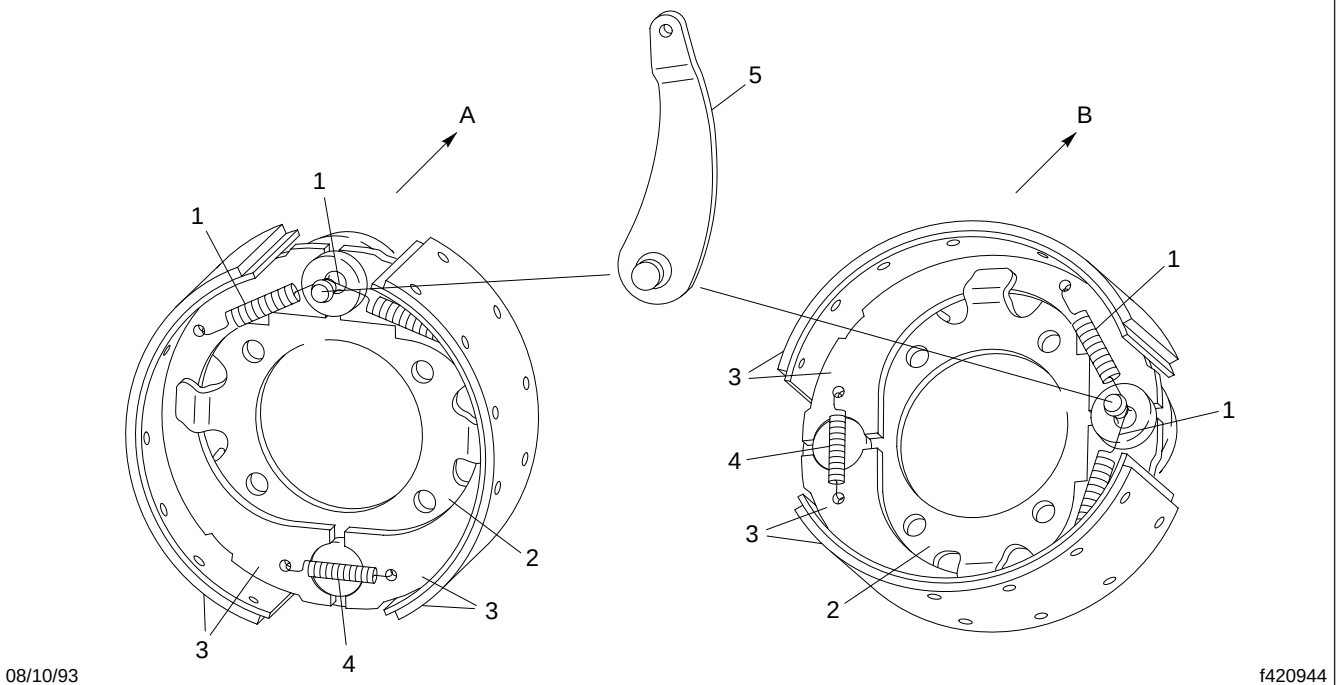
11. Using NLGI grade 2 brake grease, lightly grease the following parts (**see Fig. 7**):
    - the cam lugs and ball;
    - the mating surfaces of the brake shoe webs and the support plate lugs;
    - the support plate anchor pins;
    - the shoe bearing surfaces;
    - the ends of the brake shoe webs.
12. Install new brake shoes. **See Fig. 7** and **Fig. 8**.

    12.1 Position the brake shoes on the support plate.

    NOTE: Position the support plate so the anchor pin with the nib is at the top.

    12.2 Install a new shoe-to-shoe spring in the hole of each brake shoe.

Brake Shoe Replacement



12.3 Using a twisting motion, install the lower ends of the brake shoes over the lower anchor pin.

12.4 Put the upper ends of the brake shoes against the upper anchor pin, making sure the shoe webs are underneath the guide lugs of the support plate.

14. Install the transmission companion flange over the splines of the transmission shaft.

15. Install the large end-nut on the end of the transmission shaft. **See Fig. 6**. Tighten the nut.

- On Fuller transmissions—440 N·m (325 lbf·ft).

A. To Allison transmission.
B. To Fuller transmission.
1. Return Spring
2. Support Plate
3. Brake Shoe
4. Shoe-to-Shoe Spring
5. Actuating Lever and Cam Assembly

Fig. 8

12.5 Install two new return springs on the nib of the upper anchor pin and in the hole of each brake shoe.

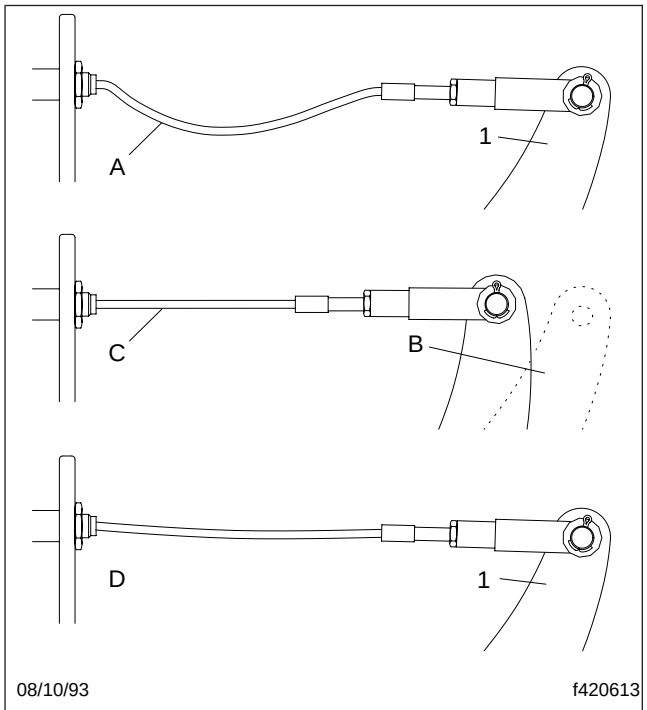
12.6 Install the actuating lever and cam assembly on the anchor pin with the nib.

13. Using the four hexbolts, nuts, and washers, position the support plate and brake shoe assembly on the transmission adapter. **See to Fig. 8**. Tighten the nuts 115 N·m (85 lbf·ft).

- On Allison transmissions—197 N·m (145 lbf·ft).

16. Install the brake drum onto the studs of the transmission companion flange.

17. Connect the driveline companion flange to the transmission companion flange.



17.1 Place the driveline companion flange so its holes fit over the studs on the transmission companion flange.

17.2 Install the eight nuts and washers on the studs. **See Fig. 2**. Tighten them 61 N·m (45 lbf·ft).

18. Connect the brake cable to the brake lever.

18.1 Check the length of the brake cable. It should be just long enough to let the clevis hole align with the hole in the brake lever, without moving the actuating lever. **See Fig. 9**.

If the brake cable is too loose or too tight, loosen the jam nut, then screw the clevis in or out until its holes line up with the hole in the actuating lever (without moving the lever). **See Fig. 10**.

A. Too loose.
B. Correct position of actuating lever.
C. Too tight.
D. Correct cable adjustment.
1. Actuating Lever

Fig. 9, Brake Cable Tightness

18.2 Tighten the jam nut firmly.

18.3 Install the clevis pin through the clevis and actuating lever holes.

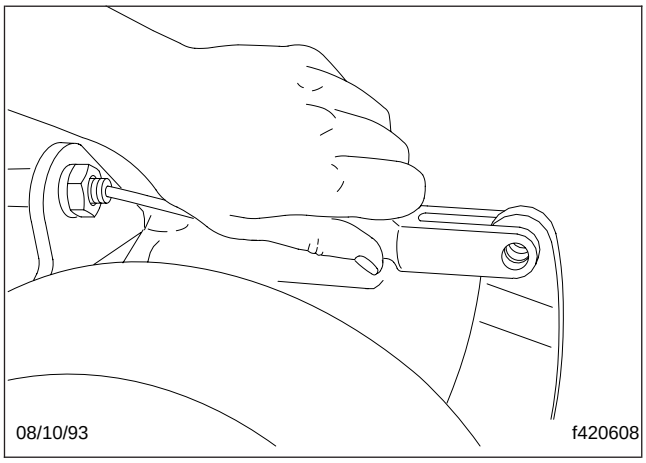


Fig. 10

18.4 Install the washer and a new cotter pin on the clevis pin.

18.5 Check the brake cable again for any slack. If it still needs adjusting, do it in the cab by turning the ring on the handle of the parking brake lever, **See Fig. 11**.

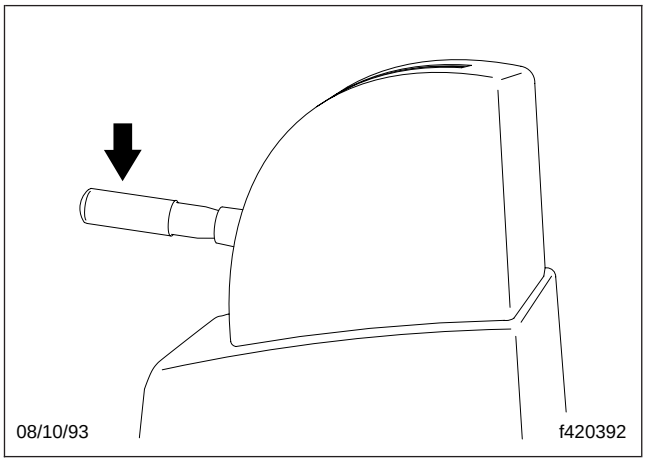

Fig. 11

19. Attach the driveline midship bearing carrier to the bracket on the frame crossmember. Tighten the fasteners 123 N·m (91 lbf·ft).

Parking Brake Cable Replacement

Replacement

1. Chock the front and rear tires.
2. Release the parking brake.
3. At the driveline end, disconnect the brake cable from the actuating lever. **See Fig. 1**.

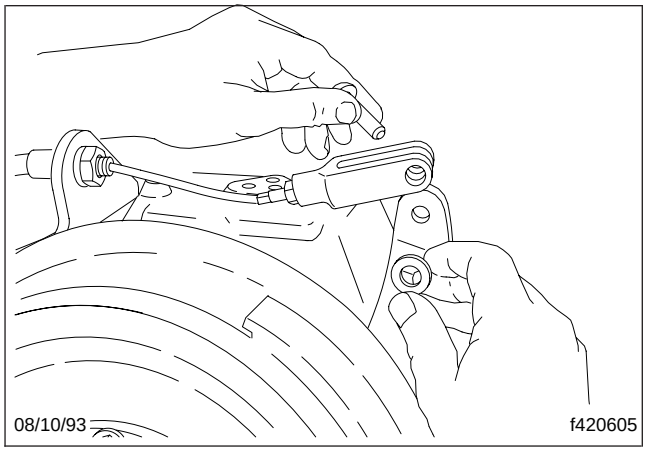

Fig. 1

4. Unscrew the clevis from the cable (**see Fig. 2**); put the clevis aside.

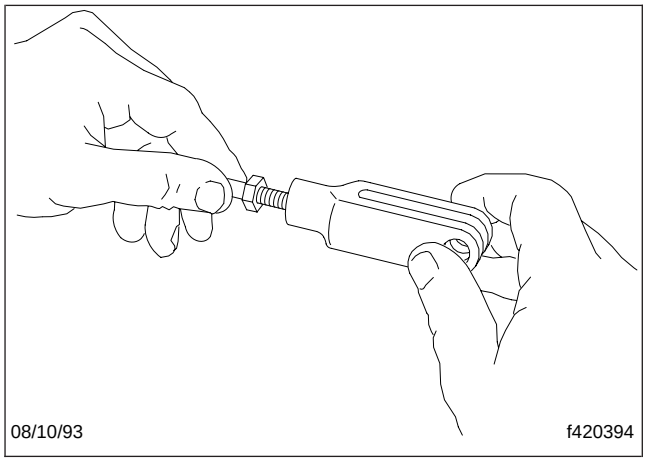

Fig. 2

5. Remove and save the small jam nut from the threaded end of the cable that was installed in the clevis.
6. Remove the brake cable jam nut and lock washer from the cable bracket on top of the transmission. **See Fig. 3**.

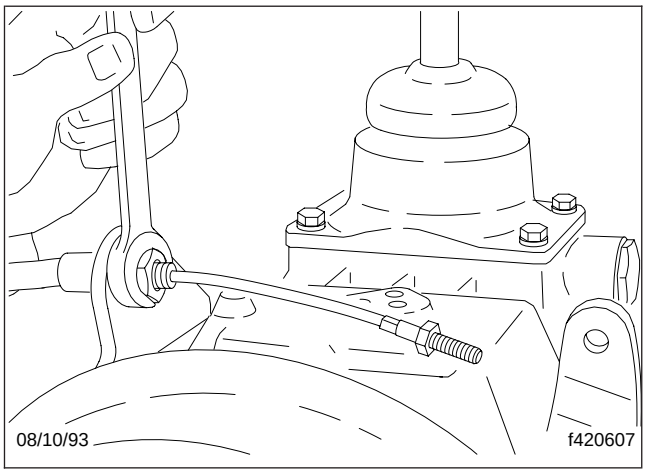

Fig. 3, Fuller Transmission Installation Shown

7. Push the brake cable end through the "D" hole in the bracket. **See Fig. 4**.

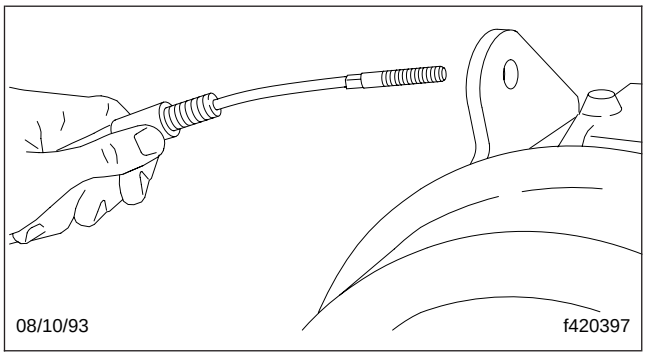

Fig. 4

8. In the cab, remove the plastic boot covering the brake lever assembly.
9. Remove the nut from the double cable clamp on the side of the transmission (**see Fig. 5**), then remove the brake cable from its half of the clamp.
10. Disconnect the parking brake cable from the parking brake lever. **See Fig. 6**.
11. Remove the parking lever assembly from the cab deck.
    - 11.1 Disconnect the electrical wire from the right side of the parking brake lever assembly. **See Fig. 7**.

Parking Brake Cable Replacement

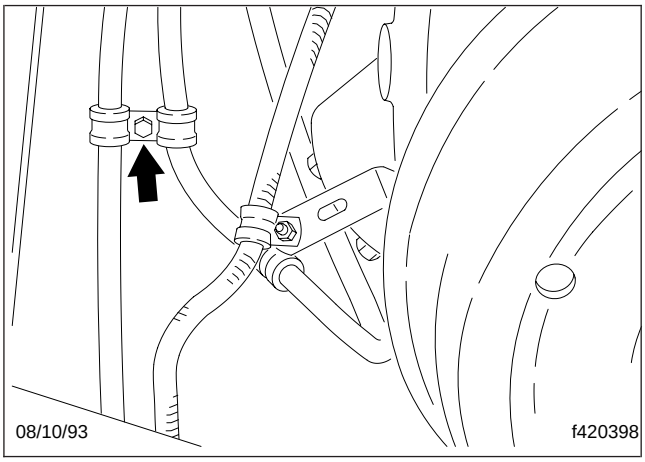

Fig. 5

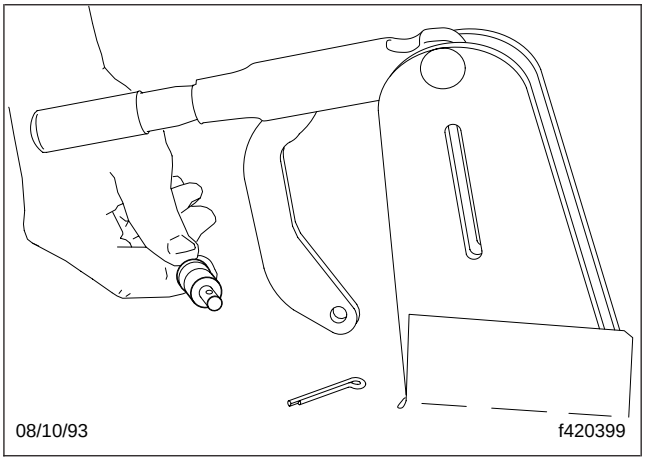

Fig. 6

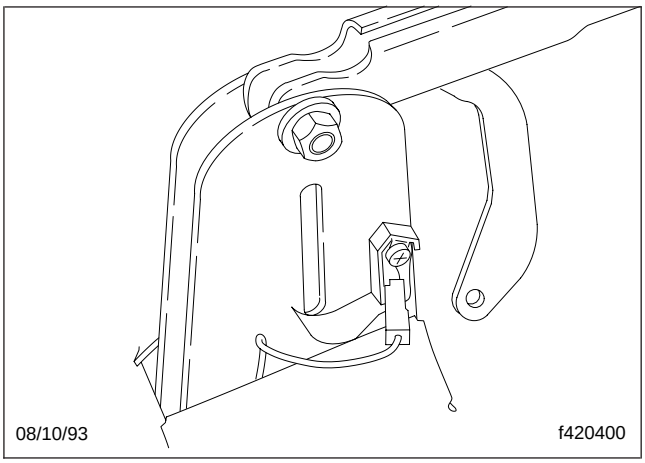

Fig. 7

11.2 Remove the four mounting bolts and washers that hold the lever assembly to the cab floor. **See Fig. 8**.

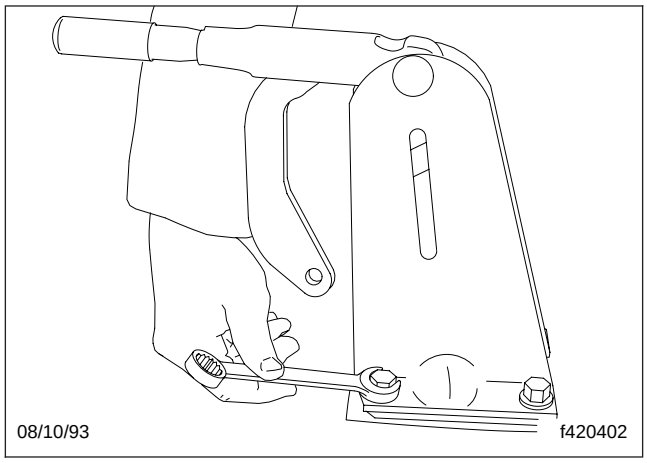

Fig. 8

11.3 Lift the lever assembly off the floor, and set it aside.

12. Remove the jam nut and lockwasher from the threaded end of the cable sheath coming through the hole in the cab deck. **See Fig. 9**.

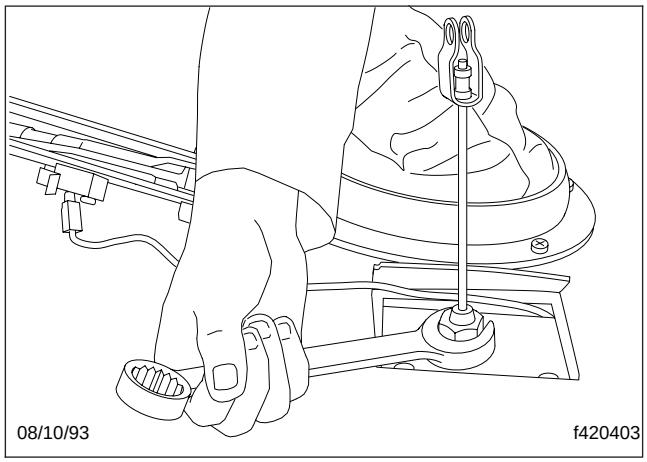

Fig. 9

13. Remove the baseplate by sliding the parking brake cable through the slot in the baseplate. **See Fig. 10**.

14. Pull the entire length of the parking brake cable up through the hole in the cab deck.

Parking Brake Cable Replacement

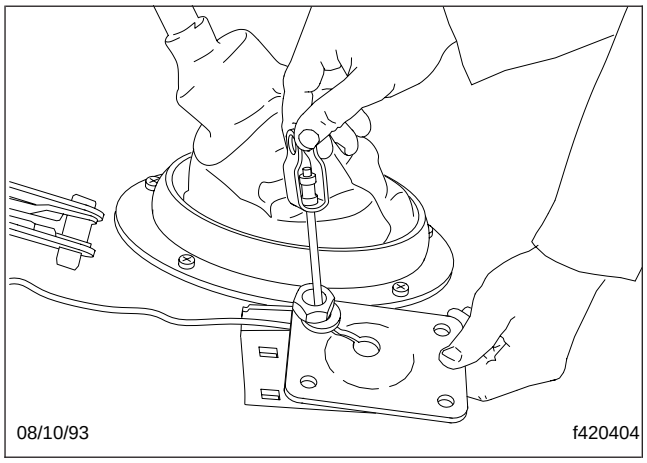

Fig. 10

15. Check the parking brake lever assembly for wear and damage. Replace it if needed.
16. Put the clevis end of the new parking brake cable assembly in the slot of the baseplate, so that the jam nut and washer are on top of the base plate. **See Fig. 10**.
17. Install the lockwasher and jam nut on the cable sheath. Tighten the nut firmly. **See Fig. 9**.
18. Install the free end of the parking brake cable through the hole in the deck. Pull about a foot of the cable up through the sheath.
19. Connect the new cable to the parking brake lever assembly.
    - 19.1 Install the bushing on the clevis pin. **See Fig. 6**.
    - 19.2 Put the clevis end of the cable up through the middle of the parking brake lever assembly.
    - 19.3 Put the curved brake lever arm (**Fig. 6**) into the middle of the brake lever assembly, and into the clevis.
    - 19.4 Line up the slots in the brake lever assembly, the hole in the curved arm, and the holes in the clevis.
    - 19.5 Install the clevis pin (with the bushing on it) from the side of the lever assembly with the electric wire connector (**Fig. 7**).
    - 19.6 Install the washer and cotter pin on the clevis pin.
20. Install the parking brake lever assembly on the cab deck.
    - 20.1 Put the baseplate on the deck, lining up the holes in the plate with those in the deck.
    - 20.2 Put the lever assembly in place so that its holes and those of the baseplate and the deck all line up.
    - 20.3 Install the four mounting bolts and washers. Tighten the fasteners firmly.
21. Connect the electrical wire to the passenger's side of the parking brake lever assembly. **See Fig. 7**.
22. Underneath the cab, route the parking brake cable through the double cable clamp on the side of the transmission (**Fig. 5**), and then up to the cable bracket on the top of the transmission.
23. Put the cable through the "D" hole in the bracket, then install the lockwasher and jam nut on the threaded end of the cable sheath. Don't tighten the nut all the way. **See Fig. 3**.
24. Connect the parking brake cable to the parking brake actuating lever.
    - 24.1 Screw the threaded end of the cable into the clevis far enough so the clevis holes will line up with the hole in the actuating lever. There should be no slack in the cable. **See Fig. 11**.

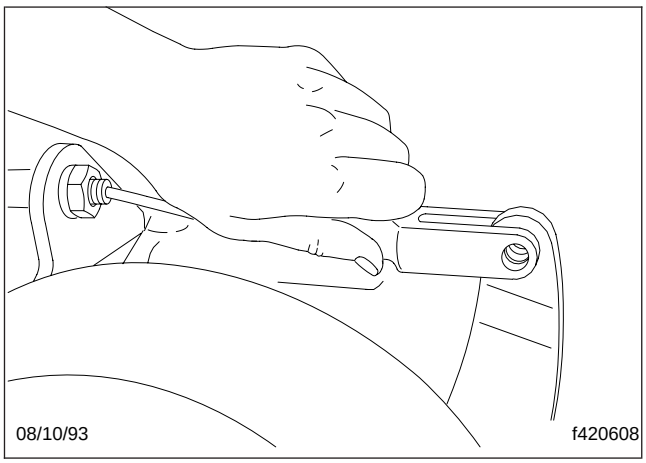

Fig. 11

- 24.2 Install the clevis pin in the holes of the clevis and that of the actuating lever.

Parking Brake Cable Replacement

24.3 Tighten the jam nut 900 N·cm (80 lbf·in).

24.4 Install the washer and a new cotter pin.

25. If a final cable adjustment is needed, make it in the cab, by turning the ring on the parking brake lever. **See Fig. 12**.

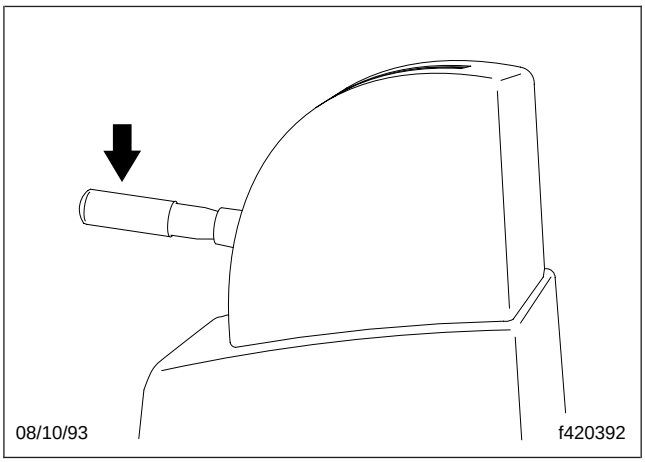

Fig. 12

Parking Brake Cable Adjustment

⚠ WARNING

Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

There are two methods of parking brake actuation available for Business Class trucks. Most vehicles have a hand-lever-actuated parking brake with the lever mounted on the cab floor. Some vehicles have an air-actuated system which is operated by a valve on the dash that controls a brake chamber mounted on the frame rail near the parking brake. When actuated, it applies the parking brake via a cable. Determine which method of actuation is used on the vehicle to be serviced, then follow the appropriate procedure below.

Prior to adjusting the parking brake cable, inspect the following components for damage, loose or missing parts, or leaks (in the case of air actuated system):

- Parking brake hand lever
- Brake chamber and plumbing (air-actuated system only)
- Cable
- Cable housing
- All mounting brackets and hardware

Make any necessary repairs before making adjustments to the brake cable.

Hand-Lever-Actuated Parking Brake Cable Adjustment

Prior to making adjustments to the hand-lever-actuated parking brake cable, ensure that the actuation system is in good working order.

1. Park the vehicle on a level surface, shut down the engine, and chock the tires.
2. Release the parking brake if it is applied.
3. Back off any excessive adjustment at the lever handle before making adjustments at the cable clevis. Leave enough for final cable adjustment, in either direction, as needed.
4. Remove the cotter pin and clevis pin from the clevis at the brake actuation lever. See **Fig. 1**.

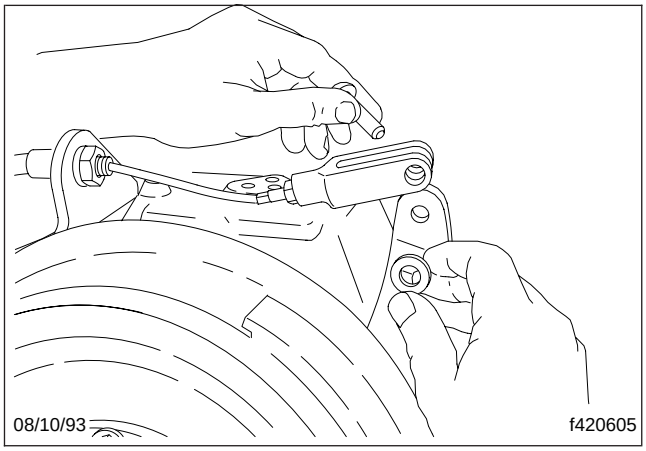

Fig. 1, Remove the Cotter Pin and Clevis Pin

5. Pull the brake actuation lever to the fully released position, then move it slightly back to take up the freeplay, and hold it there.
6. If adjustment is required, loosen the jam nut on the cable and adjust the clevis so that the pin hole in the clevis aligns with the hole in the lever.
7. Install the clevis pin and a new cotter pin.
8. Tighten the clevis jam nut to 80 lbf·in (900 N·cm).
9. If a final cable adjustment is needed, make it in the cab, by turning the ring on the parking brake lever.

   When properly adjusted, the cable should have a very slight looseness to it. See **Fig. 2**.
10. Set the parking brake and remove the chocks.
11. Test the parking brake before returning the vehicle to service.

Air-Actuated Parking Brake Cable Adjustment

Prior to making adjustments to the air-actuated parking brake cable, insure that the actuation system is in good working order.

1. Park the vehicle on a level surface and chock the tires.

Parking Brake Cable Adjustment

A. Too Loose
B. Correct Position of Actuating Lever
C. Too Tight
D. Correct Cable Adjustment
1. Actuating Lever

Fig. 2, Parking Brake Cable Installation (typical)

2. Make sure the air system is fully charged, then shut down the engine.
3. Release the parking brake if it is applied.
4. Remove the cotter pin and clevis pin from the clevis at the brake lever. See **Fig. 1**.
5. Pull the brake lever until shoe-to-drum contact is made.
6. If adjustment is required, loosen the jam nut on the cable and adjust the clevis so that the pin hole in the clevis aligns with the hole in the lever.
7. Install the clevis pin and a new cotter pin.
8. Tighten the clevis jam nut to 80 lbf·in (900 N·cm).

   When properly adjusted, the cable should have a very slight looseness to it. See **Fig. 2**.
9. Set the parking brake and remove the chocks.
10. Test the parking brake before returning the vehicle to service.

Troubleshooting

This subject contains the following troubleshooting tables:

- The Parking Brake Won't Hold the Vehicle on a Grade
- The Parking Brake Won't Release
- The Parking Brake Makes Noises While the Vehicle Is Moving

Problem—The Parking Brake Won't Hold the Vehicle on a Grade

Possible Cause	Remedy
The brake shoe linings are worn down.	Replace the brake shoes.
The brake drum is cracked.	Replace the drum.
The brake drum lining is worn down, or heavily scored.	Replace the drum.
The brake cable is binding.	Repair or replace the cable.
There is too much slack in the brake cable.	Adjust the brake cable.
The brake shoe linings have grease on them.	Replace the brake shoes, then clean the inside of the drum.

Problem—The Parking Brake Won't Release

Possible Cause	Remedy
The brake cable is too tight.	Adjust the brake cable.
The brake shoe return springs are missing, detached, or broken.	Check the return springs. Install them or replace them as needed.
The contact points between the brake shoe webs and the actuator strut are corroded or dirty.	Check the area, and clean and lubricate as needed.
The parking brake lever in the cab is binding.	Check the parking brake lever assembly for damage or corrosion. Repair or replace as needed.

Problem—The Parking Brake Makes Noises While the Vehicle Is Moving

Possible Cause	Remedy
The parking brake drum is loose.	Check the brake drum mounting bolts. Tighten as needed.
The brake shoes or backing plate is loose.	Check the brake shoes, return springs, and backing plate mounting bolts. Tighten, repair, or replace, as needed.
There is dirt inside the brake drum.	Remove the brake drum and clean it. Also clean the other brake parts.

Specifications

Description	Torque	
	N·m (lbf·ft)	N·cm (lbf·in)
Transmission End-Nut		
Fuller	440 (325)	—
Allison	197 (145)	
Support Plate Mounting Bolts	115 (85)	—

Midship Bearing Carrier Mounting Bolts	123 (91)	—
Cable Bracket Jam Nut (on top of transmission)	—	900 (80)

Table 1, Fastener Torques

General Information

The single check valve **(Fig. 1 and Fig. 2)** is installed in an air line to allow air flow in one direction and prevent air flow in the reverse direction. The check valve is installed in the upstream ends of the primary and secondary brake system air reservoirs to protect brake system air pressure in case the compressor, air pressure regulator or other air delivery component malfunctions.

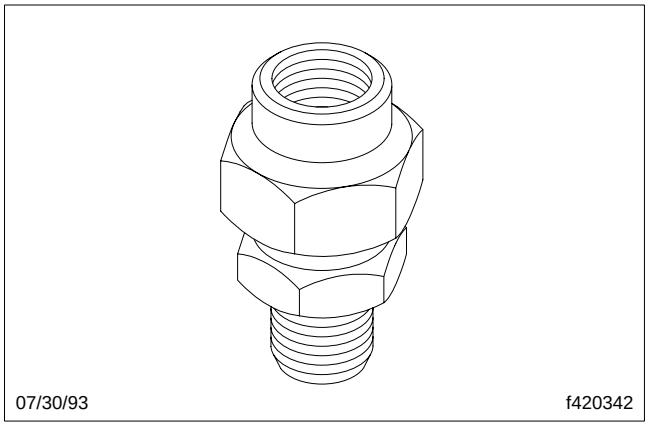

Fig. 1, Single Check Valve, Bendix

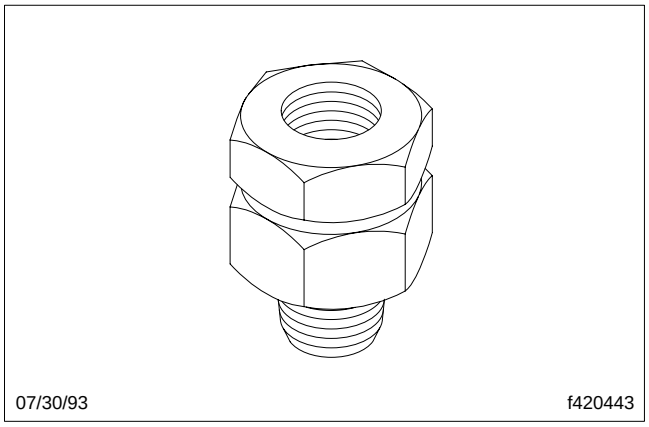

Fig. 2, Single Check Valve, Midland

Principles of Operation

When air in the system moves in the normal direction— from the compressor to the air reservoir— the check valve disk (**Fig. 3**, Ref. 4) compresses the spring (Ref. 2) and allows air to pass. When there is a drop in air pressure on the supply side of the valve, the spring pushes the check valve disk against the valve seat (Ref. 5) and prevents air from leaving the brake system.

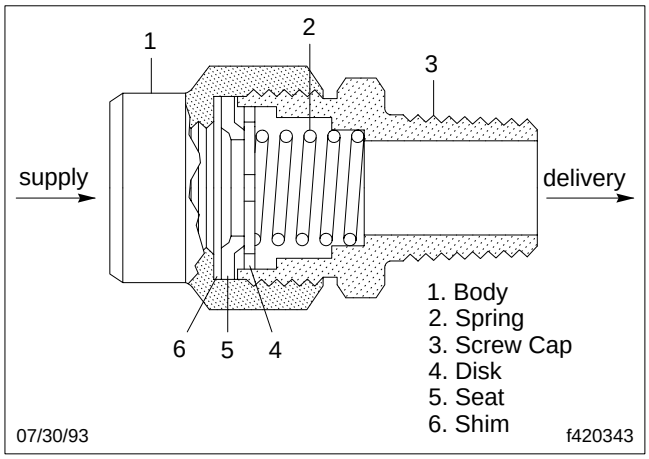

Fig. 3, Cross-Section (Bendix shown)

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the wheels and stop the engine before working under the vehicle. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not correctly disassembled. Use only the correct tools and observe all precautions regarding use of those tools.

Leakage Test

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

After repairing or replacing the single check valve, do the following test:

With the brake air system fully pressurized, drain the air from the supply reservoir (wet tank), and remove the air line from the supply side of the check valve. Coat the open end of the check valve with soap suds. A 2.5-cm (1-inch) or smaller bubble in five seconds is acceptable.

If the check valve is leaking too much, repair or replace it.

IMPORTANT: The Midland check valve is not serviceable. If it leaks or doesn't work, replace it.

Removal

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Chock the tires, then drain the air reservoirs.
2. Remove the supply line from the check valve.
3. Remove the check valve from the air reservoir.

Installation

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Screw the check valve into the supply end of the air reservoir. To ensure the valve is not reversed, the arrow marked on the valve body must point in the direction of air flow.
2. Leak test the check valve following the instructions under **"Leakage Test, 110."**
3. Connect the supply line to the open end of the check valve.

Disassembly, Cleaning and Inspection, and Assembly (Bendix only)

Disassembly

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Remove the check valve following the instructions under **"Removal and Installation, 120."**
2. Remove the screw cap from the body. **See Fig. 1.**
3. Remove the shim, seat, disk, and spring.

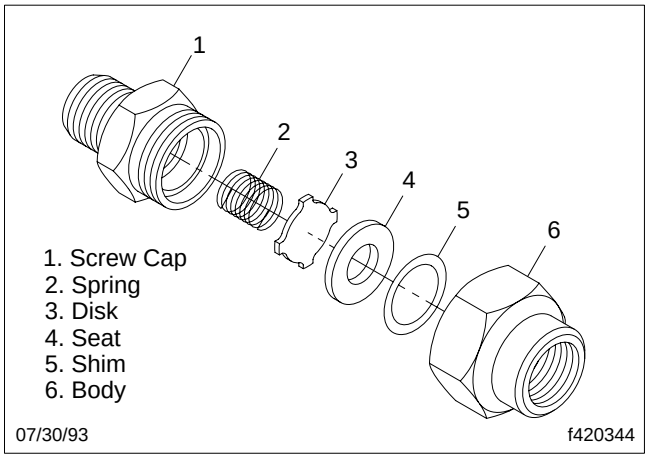

Fig. 1

Cleaning and Inspection

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

⚠ WARNING

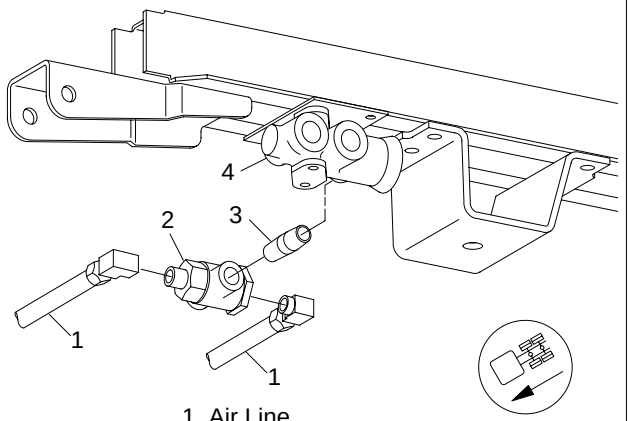
WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

Use eye protection when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all parts of the check valve in cleaning solvent. Dry the parts of the disassembled check valve with compressed air.
2. Inspect the disk for signs of wear or deterioration.
3. Check the spring for cracks, corrosion, or damage.
4. Inspect the body and screw cap for cracks or damage. Replace all worn or damaged parts with new parts.

Assembly

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**



1. Position the shim, seat, disk, and spring in the body.
2. Screw the screw cap into the body over the other parts. Tighten it securely.
3. Install the check valve following the instructions under **"Removal and Installation, 120."**

General Information

The double check valve is used in the air brake system to direct a flow of air into a common line from either of two sources, whichever is at the higher pressure. The double check valve is used only on tractors. It allows the air circuit with the higher pressure to operate the trailer service brakes. Tractors equipped with a trailer control valve have two double check valves installed; otherwise, just one is installed. The valve(s) is installed on the service port of the tractor protection valve, at the back of the cab. **See Fig. 1.**

Principles of Operation

The double check valve has movable shuttles that seal off the lower pressure air source. As pressurized air enters either end of the double check valve inlet port, the moving shuttle responds to the greater pressure source and seals the opposite port. The air flow travels out the delivery port of the valve. The position of the shuttle will reverse if the pressure levels are reversed. The double check valve is designed so the shuttle cannot interfere with the backflow of air in the exhaust mode.

1. Air Line
2. Double Check Valve
3. Nipple
4. Tractor Protection Valve

NOTE: Not all parts are shown.

Fig. 1

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if they are not correctly disassembled. Use only the correct tools, and observe all precautions regarding use of those tools.

Operating and Leakage Test

1. If the vehicle is not a tractor with a trailer, go to the step for testing the check valve on the bench.

   If the vehicle is a tractor with a trailer, proceed as follows:

   1.1 Depress the foot brake pedal and release it while checking that the brakes apply and release on both the tractor and trailer.

   1.2 Apply and release the trailer control valve while checking that only the trailer brakes apply and release.

   1.3 Apply the trailer control valve and check the exhaust port of the foot brake valve for leakage using a soap solution. A 2.5-cm (1-inch) bubble or less in five seconds is allowable. Release the valve.

   1.4 Disconnect the air line from the trailer control valve exhaust port. Depress the foot brake pedal until it stops and hold it in place. Check the trailer control valve exhaust port for leakage using a soap solution. A 2.5-cm (1-inch) bubble or less in five seconds is allowable.

   1.5 Connect the air line to the trailer control valve exhaust port.

2. If the double check valve is to be tested on the bench, connect two separately controlled air supplies to the inlet ports.
3. Connect an accurate test gauge to the double check valve outlet port or to a line from the outlet port.
4. Apply and release air to one inlet port (foot brake pedal) while checking that the test gauge registers the application and release.
5. Apply and release air to the other inlet port (trailer control valve) while checking that the gauge registers the application and release.
6. Disconnect the line from one of the double check valve inlet ports. Apply air to the opposite inlet port while checking the first port for leakage using a soap solution. A 2.5-cm (1-inch) bubble or less in five seconds is allowable. Connect the line to the inlet port. Repeat this step, checking the opposite inlet port for leaks.
7. If the double check valve does not function as described, or if the leakage is excessive, replace it. Refer to **"Removal and Installation, 120"** for instructions.

   The Bendix valve can be also repaired, using Bendix parts. Refer to **"Disassembly, Cleaning and Inspection, and Assembly (Bendix only), 130"** for instructions.

   The Midland valve is not serviceable.

Removal

1. Air Line
2. Double Check Valve
3. Nipple
4. Tractor Protection Valve

NOTE: Not all parts are shown.

09/29/94 f420503

Fig. 1

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

1. Drain the air from the air reservoirs.
2. For later reference, mark the air lines to the double check valve(s). Then carefully disconnect them **(see Fig. 1.)**.
3. Unscrew the double check valve(s) from the tractor protection valve. **See Fig. 1.**

Installation

1. Screw the double check valve(s) into the tractor service port of the tractor protection valve.
2. Connect the air lines to the double check valve as marked. Tighten the air lines firmly.

Disassembly, Cleaning and Inspection, and Assembly (Bendix only)

Disassembly (Refer to Fig. 1)

1. Remove the valve from the vehicle. Refer to **"Removal and Installation, 120"** for instructions.
2. Remove the end cap from the valve.
3. Remove the O-ring.
4. Remove the shuttle valve and shuttle guide.

Cleaning and Inspection

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Clean all metal parts in a cleaning solvent.
2. Inspect all metal parts for signs of cracks, wear, or deterioration. Replace all parts not considered serviceable.
3. Replace all rubber parts.

Assembly

1. Install the shuttle valve and shuttle guide in the valve body.
2. Coat the O-ring with BW 650M silicone lubricant (BW 291126). It is not necessary to lubricate the shuttle valve.
3. Install the O-ring.
4. Install the end cap on the valve body.
5. Install the valve on the vehicle. Refer to **"Removal and Installation, 120"** for instructions.
6. Test the valve. Refer to **"Operating and Leakage Test, 110"** for instructions.

Disassembly, Cleaning and Inspection, and Assembly (Bendix only)

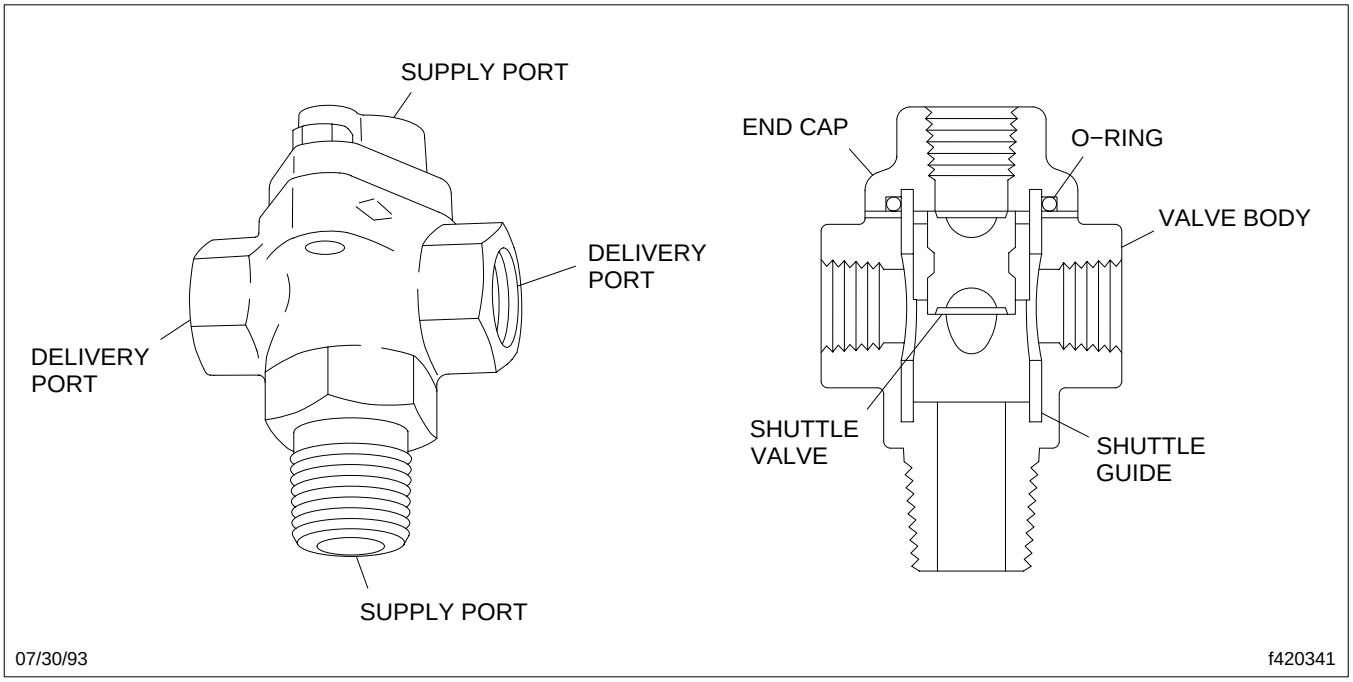

Fig. 1, Double Check Valve, Bendix

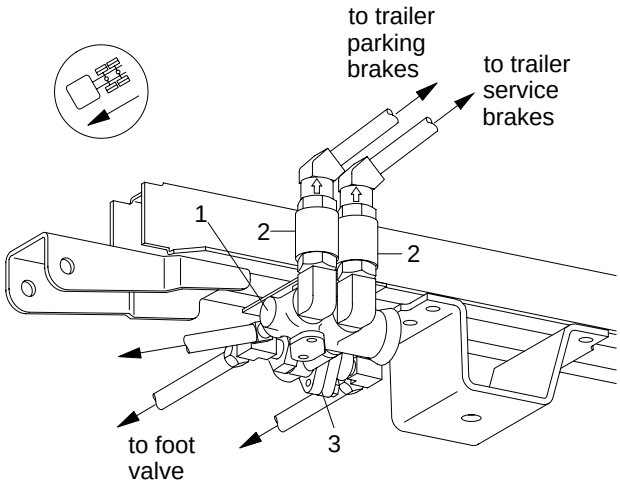


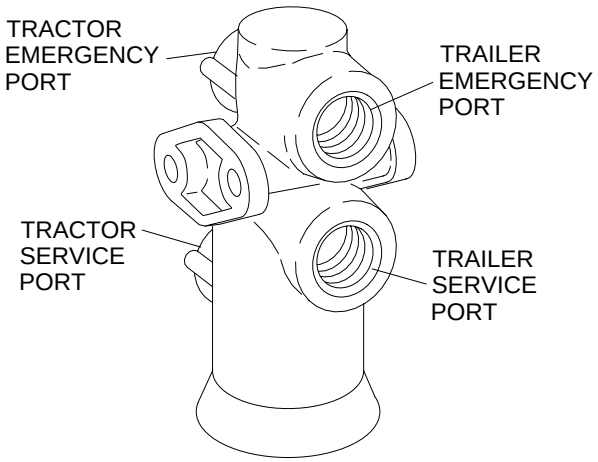
General Information

The Bendix TP-3 tractor protection valve is mounted on the back of the cab. **See Fig. 1.** Air hoses from the foot valve are connected to a double check valve on the tractor service port, and an air hose from the dash valve is connected to the tractor emergency port. **See Fig. 1 and Fig. 2.** One or two quick-release valves are installed between the trailer hoses and the trailer ports on the TP-3. **See Fig. 1.**

Principles of Operation

When the trailer air supply valve is open, air flows through the TP-3 valve emergency ports **(see Fig. 2)** to the trailer air brake system, and releases the trailer parking brakes. The air within the TP-3 valve exerts pressure on a plunger, which unseats an inlet valve, and opens the service ports. **See Fig. 3.** This allows service application of the trailer air brakes.

At least 310 kPa (45 psi) pressure on the plunger is required to open the inlet valve. Whenever the air supply is shut off (at the trailer air supply valve), or the pressure drops below the min-imum 310 kPa (45 psi), the plunger rises, seating the inlet valve and closing the service ports to protect the tractor brake system pressure.



1. TP−3 Valve
2. Quick Release Valve
3. Double Check Valve

NOTE: Not all parts are shown.

General Information and Principles of Operation

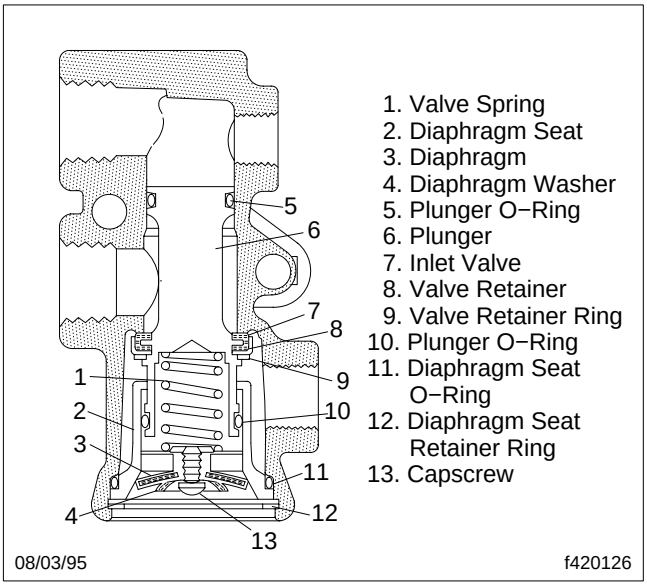

Fig. 3

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under the vehicle. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not correctly disassembled. Use only correct tools and observe all precautions regarding use of those tools.

Test

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Chock the tires. Place the trailer air supply valve in the emergency position, and disconnect the trailer air lines from the trailer supply and service couplings. Apply a soap-water solution to the couplings.
2. With tractor reservoirs charged to at least 689 kPa (100 psi) make and hold a full service brake application. Leakage at either tractor hose coupling should not exceed a 2.5-cm (1-inch) bubble in five seconds.
3. Connect the trailer supply line hose coupling, and place the trailer supply valve in the "run" position. Leakage at the service coupling should not exceed a 2.5-cm (1-inch) bubble in five seconds.
4. Connect the service brake coupling, and make and hold a full service brake application. Leakage at the diaphragm end of the TP-3 valve should not exceed a 2.5-cm (1-inch) bubble in three seconds.

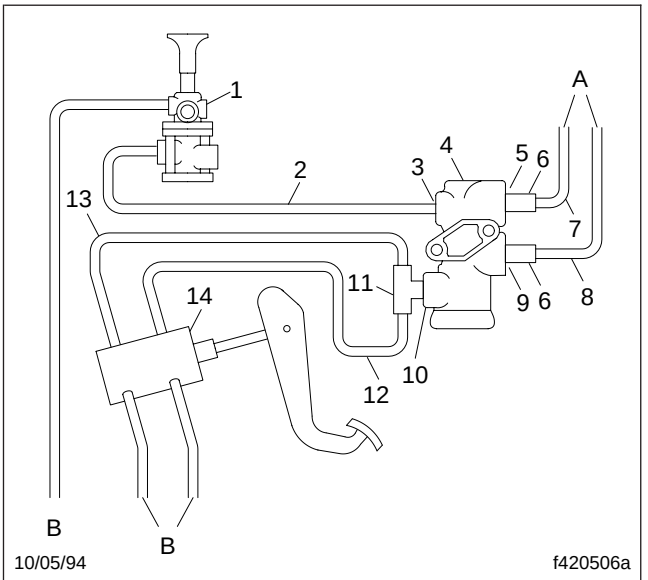
IMPORTANT: If leakage is excessive, replace the valve.

5. Remove the chocks.

Removal

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Chock the tires, and drain the air reservoirs.
2. Remove the trailer hose assemblies from the TP-3 valve. Mark the tractor service and supply lines for later assembly reference, and carefully disconnect them. Cap the air lines tightly to keep out contaminants.
3. Remove the fasteners attaching the TP-3 valve to the vehicle, then remove the valve.



Installation

1. Place the TP-3 valve on the vehicle, and attach it with bolts, washers, and nuts. Tighten the nuts 11 to 15 lbf·ft (15 to 20 N·m).
2. Remove the caps from the air lines, then connect them to the TP-3, the double check valve, and the quick-release valve(s) as shown in **Fig. 1**, and as previously marked.

   NOTE: The trailer emergency line (Ref. 7) may not be connected to a quick-release valve; it may connect directly to the port on the TP-3 valve.

   2.1 Connect the hose fittings to their applicable ports or valves, and tighten them finger-tight.

   2.2 Using a wrench, tighten the nuts at least two turns, or until no threads show on the fitting.
3. Close the drain cocks to the air reservoirs. Start the engine to pressurize the air system.
4. Leak test the TP-3 valve following the instructions under **"Leakage Test, 110."**

A. To trailer hose connections.
B. From air reservoirs.

Disassembly, Cleaning and Inspection, and Assembly

Disassembly

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Remove the valve from the vehicle. For instructions, refer to **"Removal and Installation, 120."**
2. Holding the diaphragm seat in the body, remove the diaphragm seat retainer ring. **Refer to Fig. 1**, Refs. 2 and 12.
3. Allow the valve spring to expand until the valve diaphragm seat assembly, valve spring, and plunger assembly can be removed.
4. Remove the diaphragm seat O-ring (Ref. 11) from the valve housing.
5. Remove the capscrew (Ref. 13) and diaphragm washer (Ref. 4) from the diaphragm seat assembly.
6. Remove the valve retainer ring (Ref. 9), valve retainer (Ref. 8), inlet valve (Ref. 7), and O-rings (Refs. 5 and 10) from the plunger.

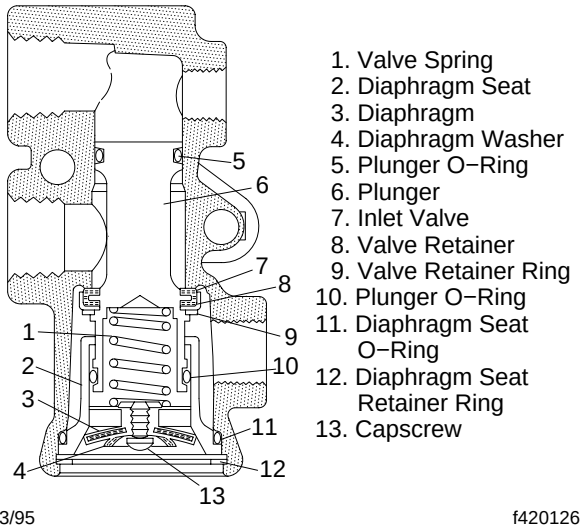

Fig. 1

Cleaning and Inspection

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the TP-3 valve in cleaning solvent. Dry the metal parts of the disassembled valve with compressed air.
2. Wipe all rubber parts clean with a clean cloth. Examine all rubber parts. If any rubber parts are worn, cracked, torn or otherwise damaged, replace them with new parts.
3. Examine all metal parts. If any metal parts are worn, cracked or otherwise damaged, replace them with new parts.
4. Check the spring. If the spring is distorted or corroded, replace it.

Assembly

IMPORTANT: Before working on or around air brake systems and components, review **"Safety Precautions, 100."**

1. Lubricate the O-rings and all sliding parts with Dow Corning 55-M pneumatic grease or equivalent.
2. Install the inlet valve (**Fig. 1**, Ref. 7) on the plunger.
3. Install the valve retainer (Ref. 8) over the inlet valve.
4. Install the valve retainer ring (Ref. 9) beneath the inlet valve retainer.
5. Install both plunger O-rings (Refs. 5 and 10) in the proper grooves.

Disassembly, Cleaning and Inspection, and Assembly

6. Place the plunger and valve assembly in the valve body.
7. Install the capscrew (Ref. 13), diaphragm washer (concave side down, Ref. 4), and diaphragm (Ref. 3) into the diaphragm seat (Ref. 2).
8. Place the inlet valve spring (Ref. 1) into the plunger.
9. Install the diaphragm seat O-ring (Ref. 11) in the body.
10. Install the diaphragm seat assembly over the spring and plunger assembly, and force them into the valve body.
11. Install the diaphragm seat retainer ring, making sure the retainer ring snaps fully into the groove.
12. Install the TP-3 valve on the vehicle following the instructions under **"Removal and Installation, 120."**

General Description

The Rockwell driveline parking brake is designed to hold the vehicle on a grade, and to stop a slow moving vehicle if the service brakes aren't working. The parking brake is manually operated, and has a mechanical linkage; it doesn't rely on hydraulic or air pressure. It is installed only on vehicles with hydraulic brakes.

The parking brake is mounted either on the rear of the transmission (**Fig. 1**), between it and the driveshaft, or on the rear drive axle (**Fig. 2**). The main parts of the brake are the drum, brake shoes, return springs, backing plate, cam, actuator strut, actuating lever, brake cable, and brake lever assembly. **See Fig. 3.**

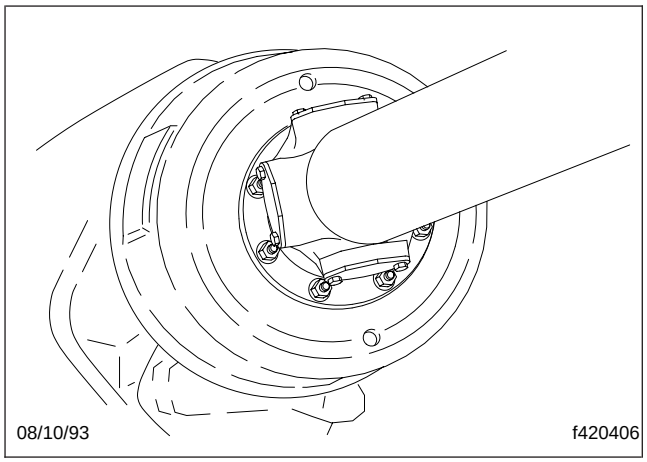

Fig. 1

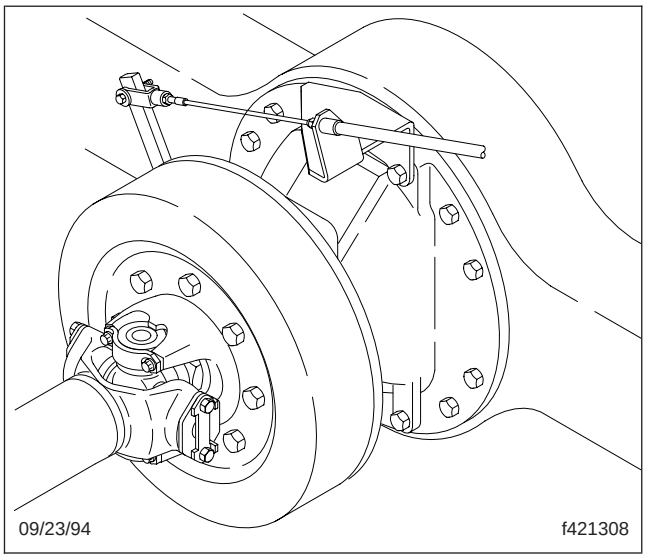
The brake drum is bolted onto the driveline companion flange, and the backing plate is bolted to the rear of the transmission, or on the rear axle. The brake shoes are held in place by the return springs. The brake cable runs from the actuating lever to inside the cab, where it is controlled by the parking brake lever assembly. **See Fig. 4**. A ring at the end of the parking brake lever is used to adjust the cable length to compensate for brake shoe wear.

Principles of Operation (Fig. 5)

When the brake lever is pulled up, the brake cable pulls the actuating lever, turning the cam. The cam fits into an oblong hole in the actuator strut, and rotates the strut slightly. This pushes the brake shoes



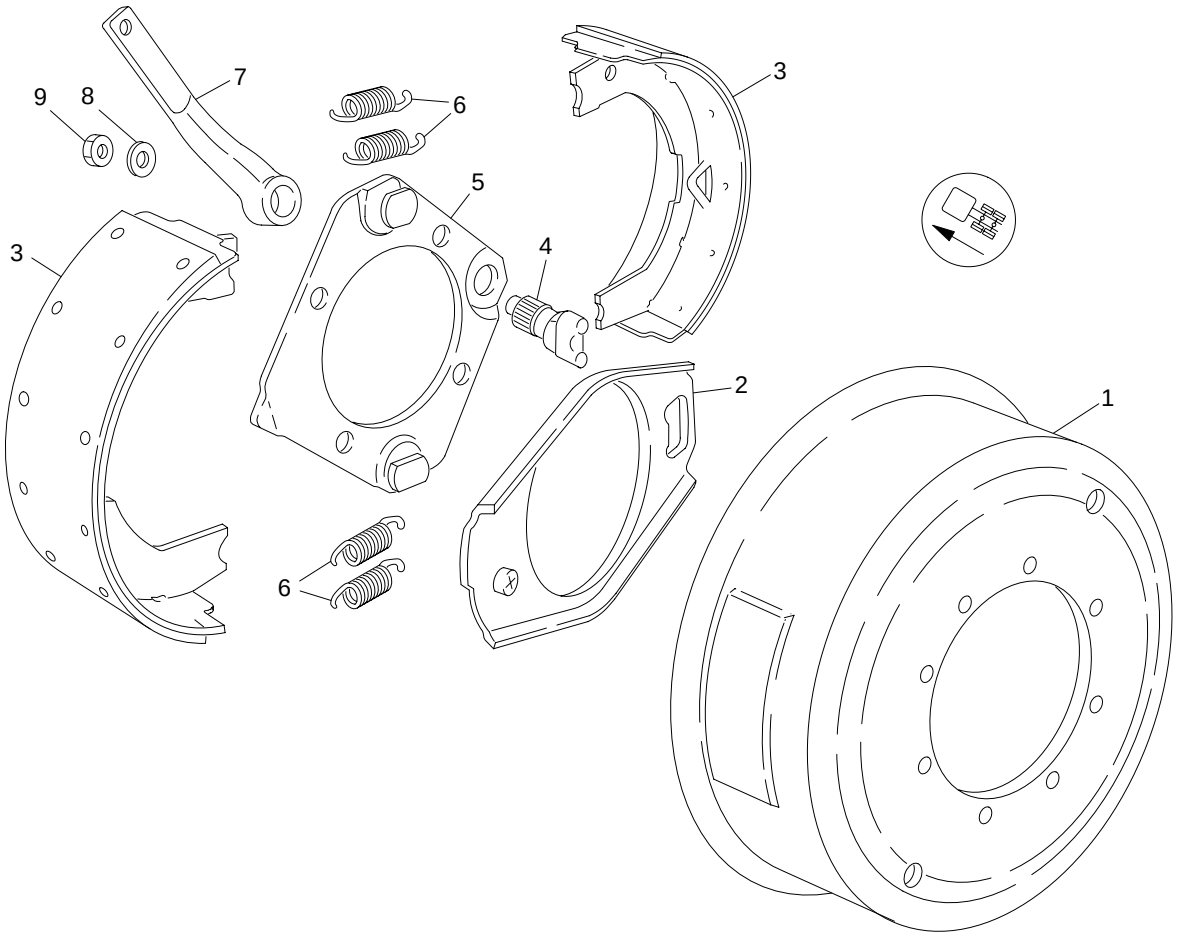


Fig. 2

outward against the brake drum. Because the backing plate and brake shoes are mounted in a fixed position on either the transmission or rear axle, and the drum is attached to the end of the driveshaft, the driveshaft is prevented from turning. This keeps the vehicle from rolling.

When the parking brake lever is released, the tension on the cable is removed. The actuating lever, cam, and actuator strut all return to their original positions, and the brake return springs pull the brake shoes away from the brake drum. The driveshaft is then free to move, and the vehicle can be moved.

Safety Precautions

Because most brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Because medical experts believe that long-term exposure to some non-asbestos fibers could also be a health hazard, also observe the following precautions if servicing non-asbestos brake linings.

Exposure to airborne brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

During brake servicing, wear an air purifying respirator with high-efficiency filters. The respirator and filter must be approved by NIOSH or MSHA, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, or can't be used, clean the brake assembly in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with an HEPA filter system, remove dust from all the brake parts. After vacuuming, remove any remaining dust using a rag soaked in water and wrung until nearly dry.

⚠ WARNING

WARNING: Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the parking brake, starting with removal of the brake drum and continuing through assembly.

Removal

WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Chock the tires. Apply the parking brake to keep the brake drum in place when the driveline is disconnected.
2. Remove the driveline midship bearing carrier from the frame crossmember.
   - 2.1 Put a jackstand under the driveline at the rear of the midship bearing.
   - 2.2 Remove the bolts holding the midship bearing carrier to the bracket on the frame crossmember. **See Fig. 1.**

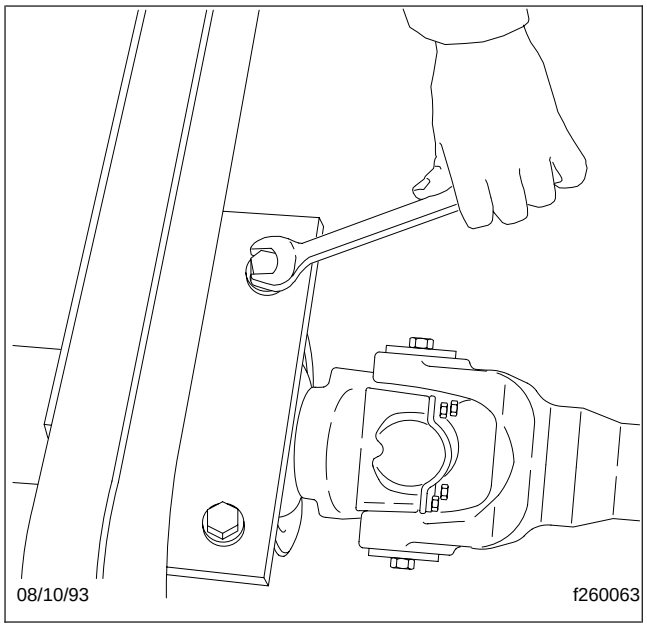

Fig. 1

   - 2.3 Lower the driveline and midship bearing carrier onto the jackstand. It should rest securely on the jackstand.
3. Disconnect the driveline companion flange from either the transmission or rear axle companion flange. **See Fig. 2.**

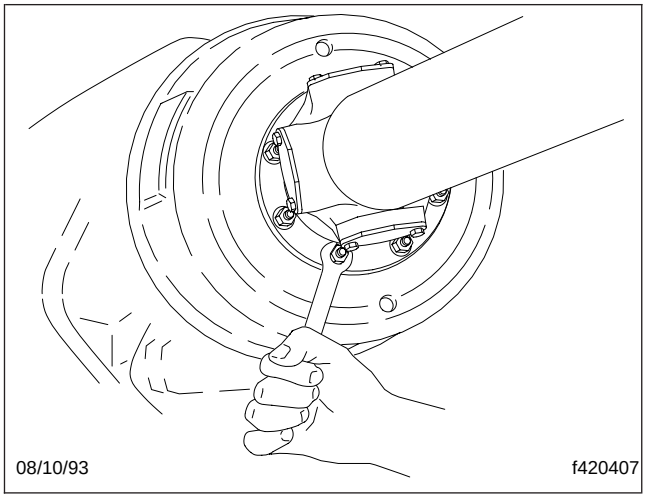

Fig. 2

4. Slide out the driveline, and lower it to the floor. **See Fig. 3.**

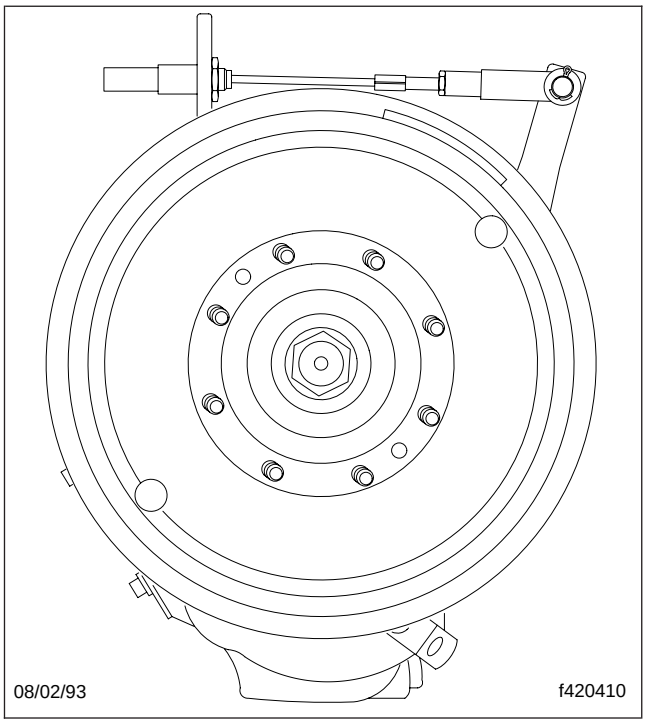

Fig. 3, Driveline Removed (transmision-mounted parking brake shown)

Removal and Installation

5. Release the parking brake.
6. Disconnect the brake cable from the actuating lever. **See Fig. 4.**

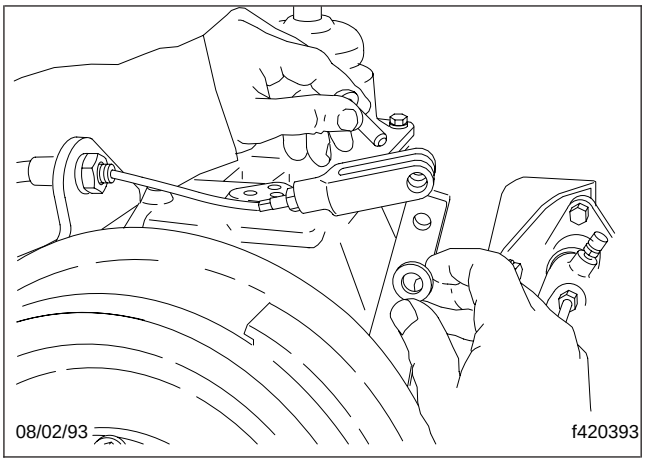

Fig. 4, (Transmision-mounted parking brake shown)

7. Pull the brake drum off either the transmission or rear axle companion flange. **See Fig. 5 .**

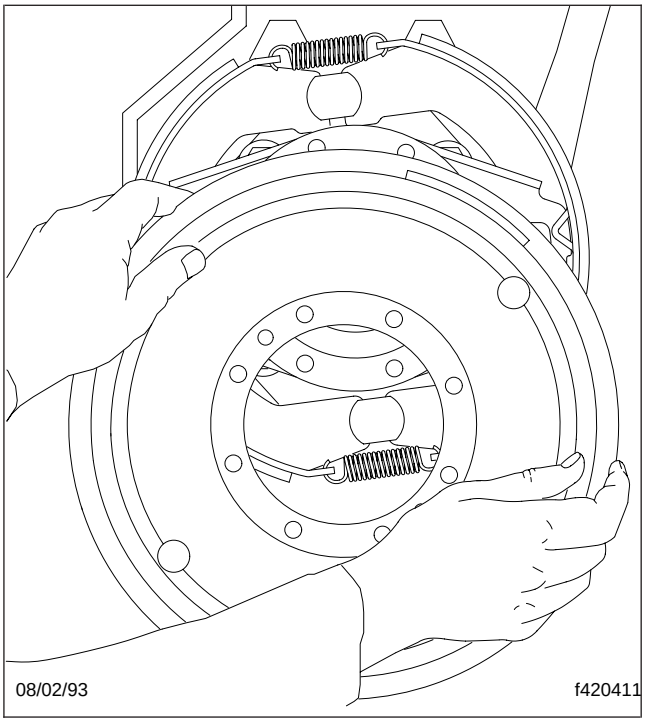

Fig. 5

8. Remove the brake shoes.
   - 8.1 Carefully remove the lower brake shoe return springs. **See Fig. 6.**

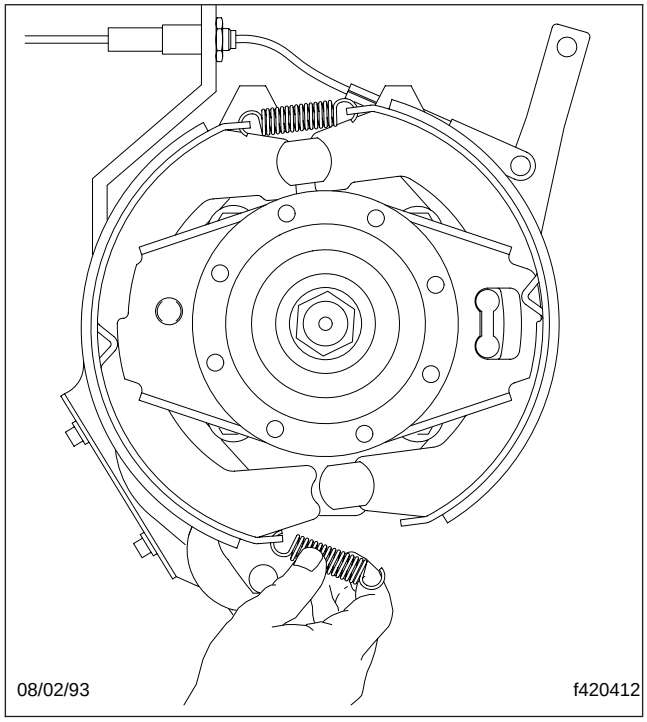

Fig. 6

   - 8.2 Pull the bottom of one brake shoe out, releasing the pressure on the upper return springs. **See Fig. 7**. Then remove the upper return springs.
   - 8.3 Remove both brake shoes.
9. Remove the actuator strut.
   - 9.1 Remove the large end-nut from either the transmission or rear axle shaft. **See Fig. 8.**
   - 9.2 Remove the companion flange that holds the actuator strut in place. **See Fig. 9.**
   - 9.3 Remove the actuator strut. **See Fig. 10.**
10. Remove the four hexbolts, washers, and nuts holding the backing plate to the square adapter on the end of the transmission (or rear axle), then remove the backing plate. **See Fig. 11** and **Fig. 12.**
11. If replacing the actuating lever or cam, remove them from the backing plate.

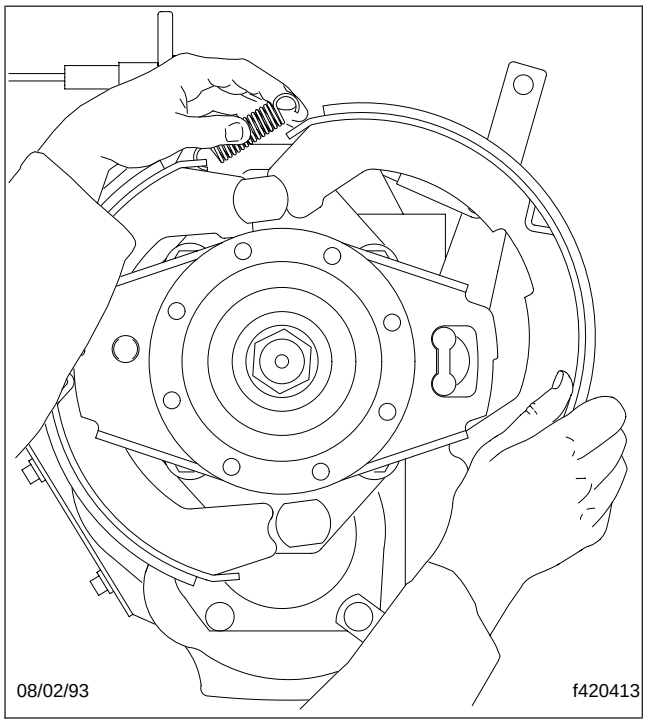

Fig. 7

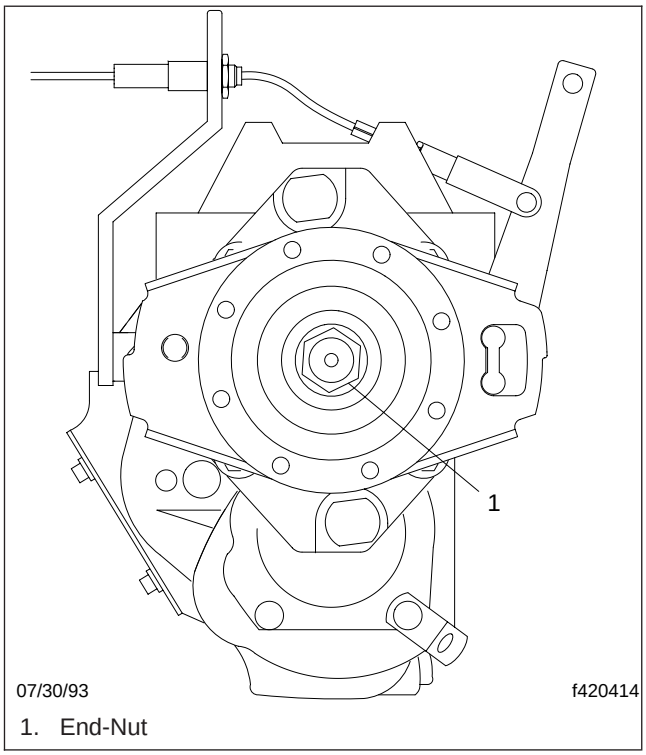
11.1 Mark the splines of the lever and cam for later reference.

11.2 Put the backing plate in a padded vise, then remove the nut and washer holding the lever and the cam together. Remove them from the backing plate. **See Fig. 13** and **Fig. 14.**



Installation

1. Clean all the parts. Check for damage and corrosion, and replace parts if needed. Check the backing plate for cracks or bending. Replace it if needed.

CAUTION

CAUTION: Don't let any grease get on the brake drum or linings. Grease on these parts will reduce the effectiveness of the driveline parking brake. If brake linings become contaminated, replace them.

2. Using NLGI grade 2 brake grease, lubricate the following parts (**see Fig. 15**):

1. End-Nut

Fig. 8

- cam head face and journals;
- the mating surfaces of the brake shoe webs and the actuator strut;
- at both sides of the cam hole in the backing plate.

3. If the cam and actuating lever were removed, install them on the backing plate.

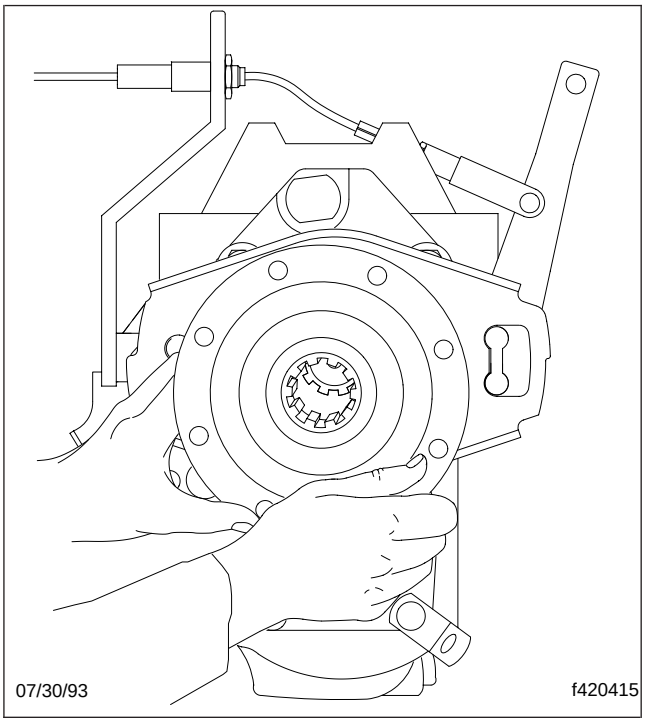
3.1 Put the cam through the hole in the backing plate. **See Fig. 14.**

3.2 Using the reference marks made during removal, align the splines of the actuating lever with those of the cam, then install the lever on the cam.

3.3 Install the nut and washer on the cam. **See Fig. 13**. Tighten the nut until there is 0.025 to 0.25 mm (0.001 to 0.010 inch) clearance between the actuating lever and the backing plate.

4. Using the four hexbolts, nuts, and washers, install the backing plate on the transmission or rear axle. **See Fig. 11**. Tighten the nuts.

Removal and Installation



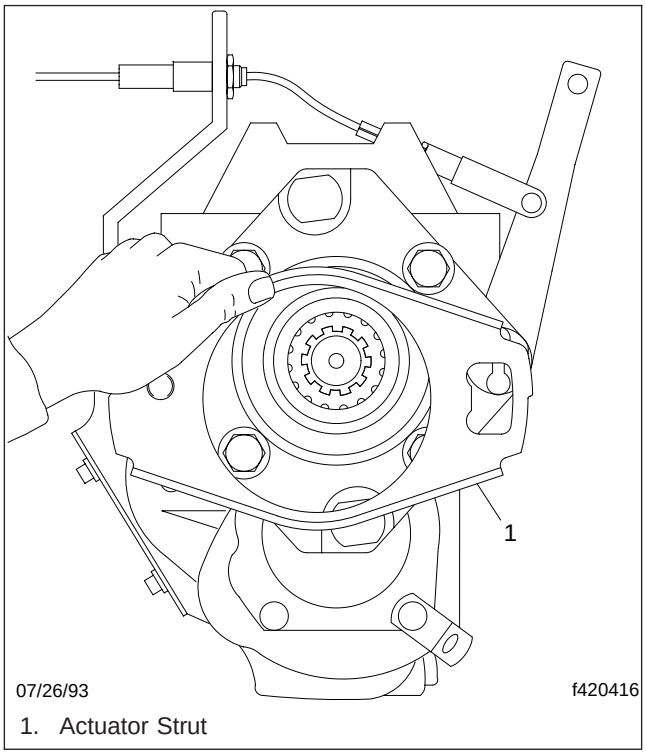


Fig. 9

- If mounted on Fuller transmissions—230 to 251 N·m (170 to 185 lbf·ft)
- If mounted on Allison transmissions—203 to 224 N·m (150 to 165 lbf·ft)
- If mounted on the rear axle—203 to 224 N·m (150 to 165 lbf·ft)

5. Install the brake shoes on the backing plate so that the web ends are up against the bosses on the backing plate.
6. Install four new brake return springs.
7. Install the actuator strut on the backing plate.
   - 7.1 Put the actuator strut on the backing plate so its pressure points are against those of the brake shoe webs, and so the slot in the actuator strut will go over the cam.
   - 7.2 Install the companion flange over the splines of the transmission shaft (or rear axle shaft). **See Fig. 9.**
   - 7.3 Install the large end-nut on the end of the transmission or rear axle shaft. **See Fig. 8** . Tighten the nut.

1. Actuator Strut

Fig. 10

- If mounted on Fuller transmissions—440 N·m (325 lbf·ft)
- If mounted on Allison transmissions—950 N·m (700 lbf·ft)
- If mounted on the rear axle—1000–1250 N·m (740–920 lbf·ft)

8. Install the brake drum onto the studs of the transmission (or rear axle) companion flange. **See Fig. 5.**
9. Connect the driveline companion flange to the transmission (or rear axle) companion flange.
   - 9.1 Place the driveline companion flange so its holes fit over the studs on the transmission (or rear axle) companion flange.
   - 9.2 Install the eight nuts and washers on the studs. **See Fig. 3**. Tighten them 61 N·m (45 lbf·ft).
10. Connect the brake cable to the brake lever.
    - 10.1 Check the length of the brake cable. It should be just long enough to let the cle-

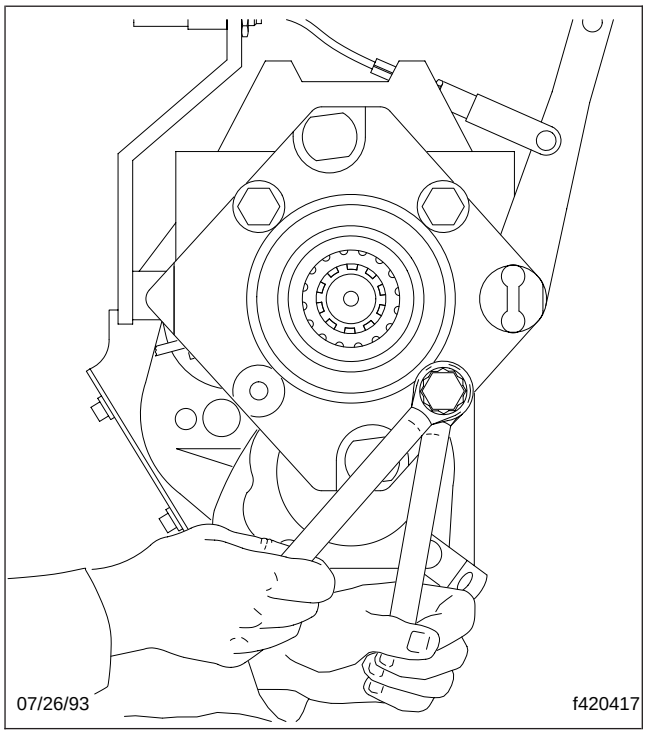

Fig. 11

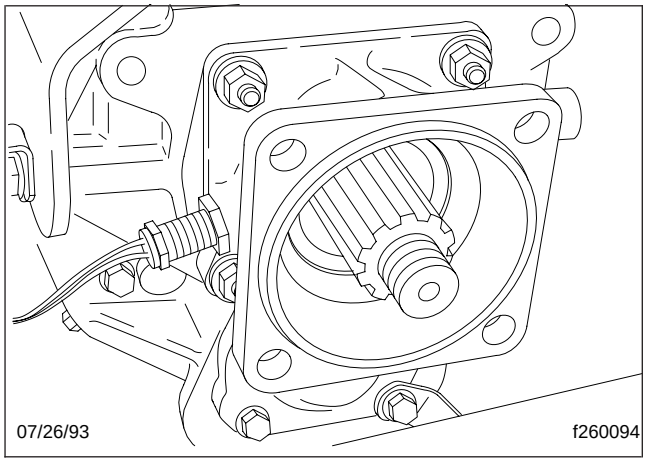

Fig. 12, Backing Plate Removed

vis hole align with the hole in the actuating lever, without moving the actuating lever. **See Fig. 16.**

If the brake cable is too loose or too tight, screw the clevis in or out until the its holes line up with the hole in the actuating lever (without moving the lever). **See Fig. 17.**

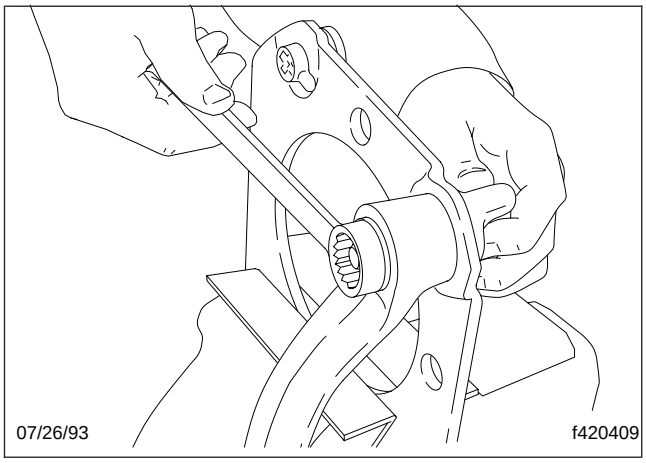

Fig. 13

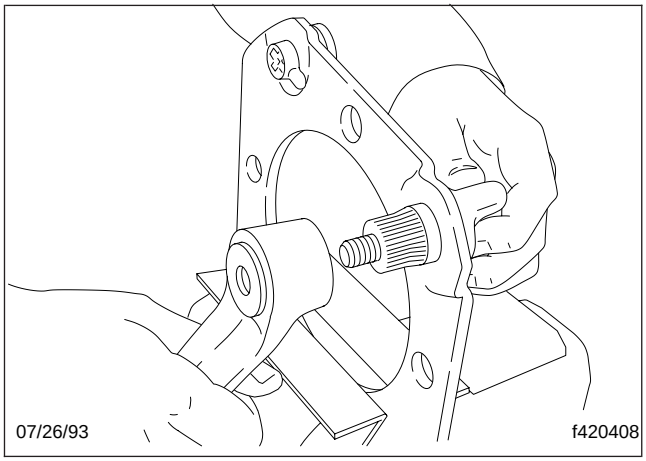

Fig. 14

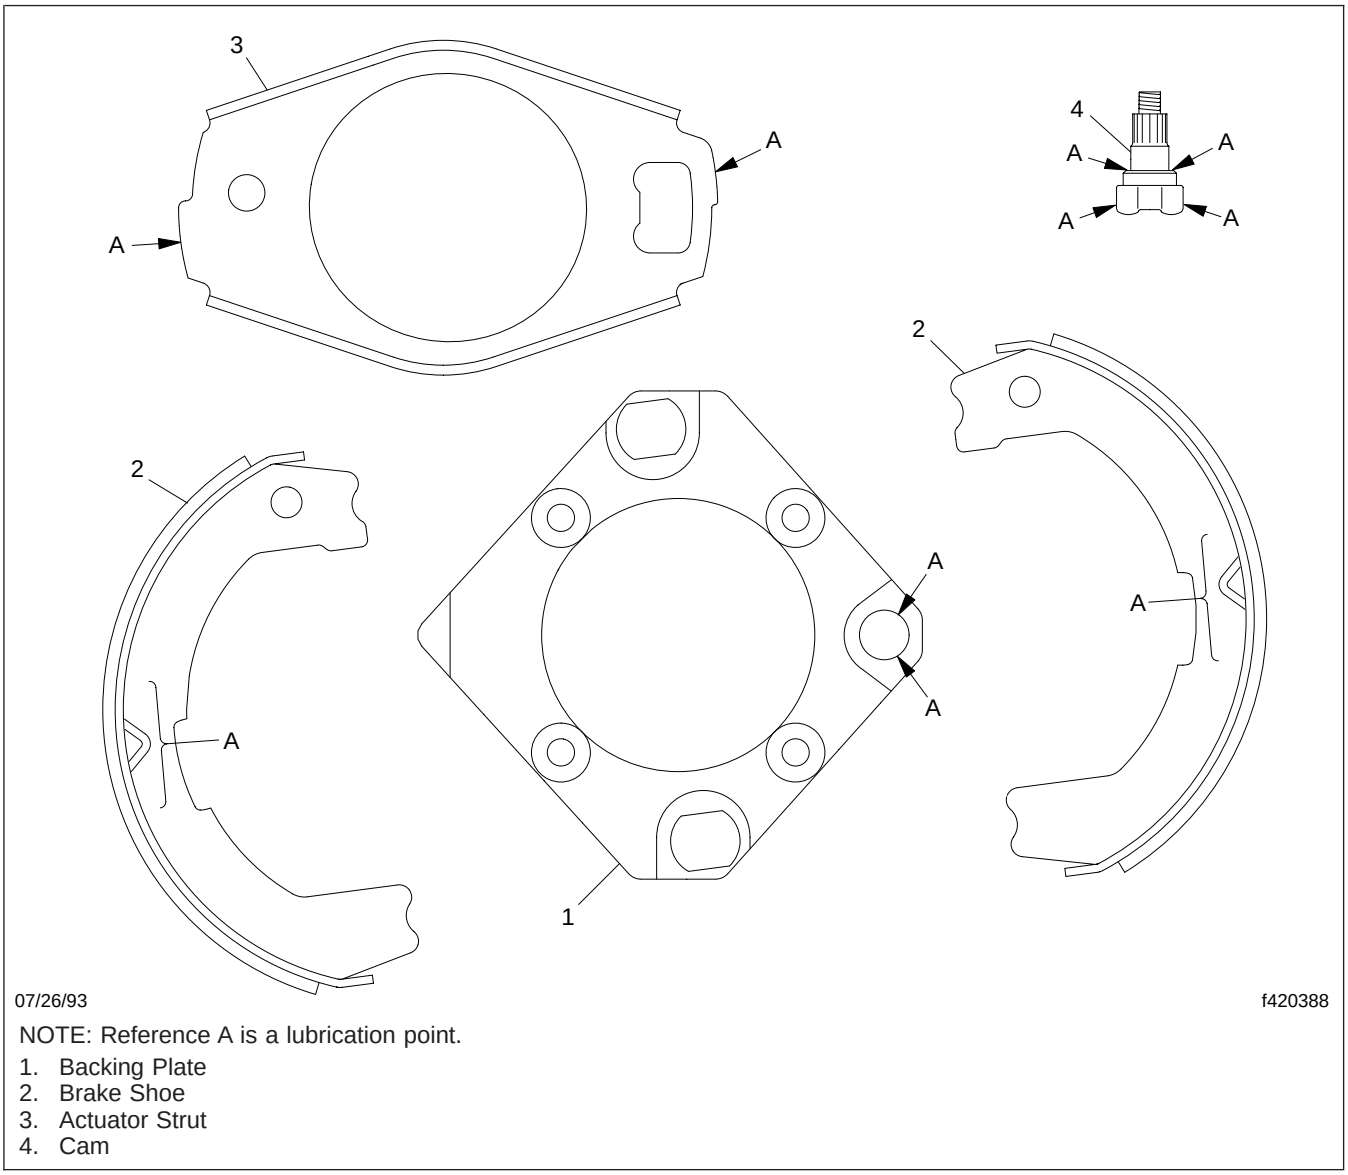
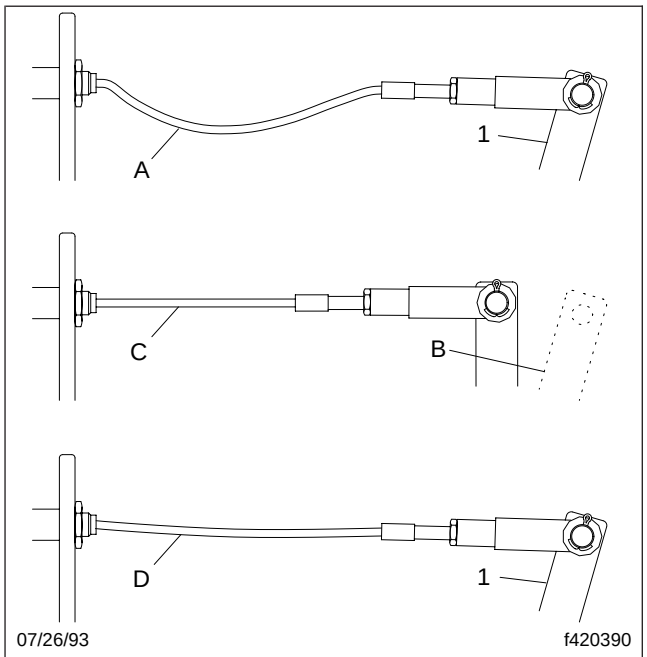


10.2 Install the clevis pin through the clevis and actuating lever holes.

10.3 Install the washer and a new cotter pin on the clevis pin.

10.4 Check the brake cable again for any slack. If it still needs adjusting, do it in the cab by turning the ring on the handle of the parking brake lever. **See Fig. 18.**

11. Attach the driveline midship bearing carrier to the bracket on the frame crossmember. Tighten the fasteners 123 N·m (91 lbf·ft).



Removal and Installation

Replacement

⚠ WARNING

Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Chock the tires. Apply the parking brake to keep the brake drum in place when the driveline is disconnected.
2. Remove the brake drum. For instructions, refer to **Subject 110.**
3. Check the inside of the brake drum for cracking, scoring, or other damage. If needed, resurface or replace the drum. If the inside diameter of the drum is more than 307 mm (12.09 inches), replace the drum.
4. Remove the old brake shoes.

   4.1 Carefully remove the lower brake shoe return springs. **See Fig. 1.**

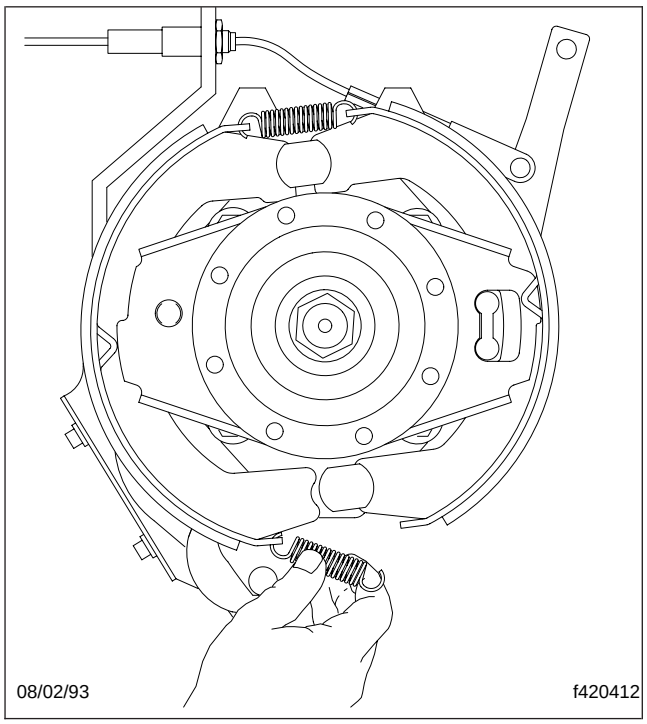

Fig. 1

   4.2 Pull the bottom of one brake shoe out, releasing the pressure on the upper return springs, then remove the upper return springs. **See Fig. 2.**

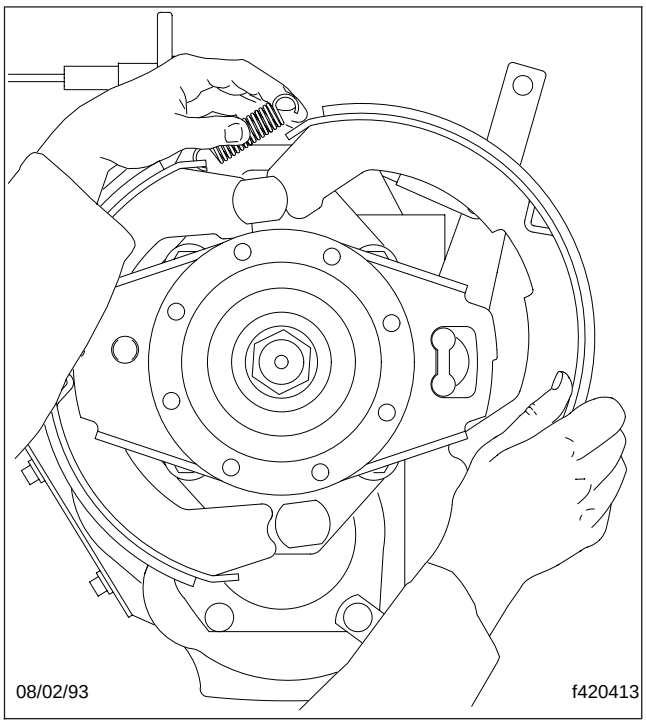

Fig. 2

   4.3 Remove both brake shoes.

⚠ CAUTION

CAUTION: Don't let any grease get on the brake drum or linings. Grease on these parts will reduce the effectiveness of the driveline parking brake. If brake linings become contaminated, replace them.

5. Using NLGI grade 2 brake grease, lubricate the following parts (**see Fig. 3**):
   - cam head face and journals;
   - the mating surfaces of the brake shoe webs and the actuator strut;
   - at both sides of the cam hole in the backing plate.
6. Install new brake shoes.

Brake Shoe Replacement

NOTE: Reference A is a lubrication point.

1. Backing Plate
2. Brake Shoe
3. Actuator Strut
4. Cam

Fig. 3

6.1 Install the brake shoes on the backing plate so that the web ends are up against the bosses on the backing plate.

6.2 Install four new brake return springs.

7. Install the brake drum and connect the driveline. For instructions, refer to **Subject 110.**

8. Adjust the brake cable by turning the ring on the end of the parking brake lever in the cab.

Replacement

1. Chock the front and rear tires.
2. Release the parking brake.
3. At the driveline end, disconnect the brake cable from the actuating lever. **See Fig. 1 .**

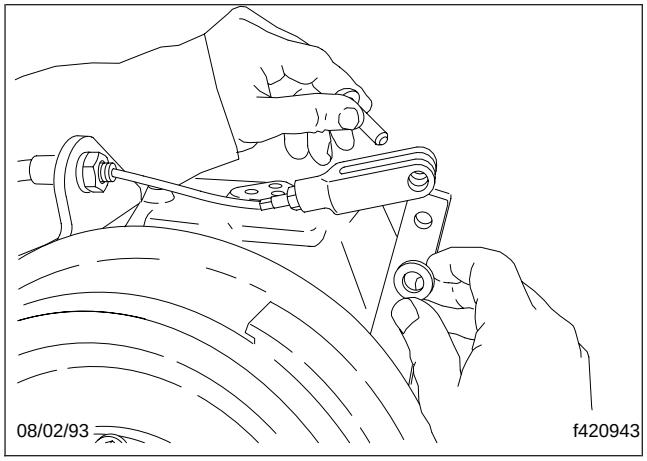

Fig. 1

4. Unscrew the clevis from the cable (**see Fig. 2**); put the clevis aside.

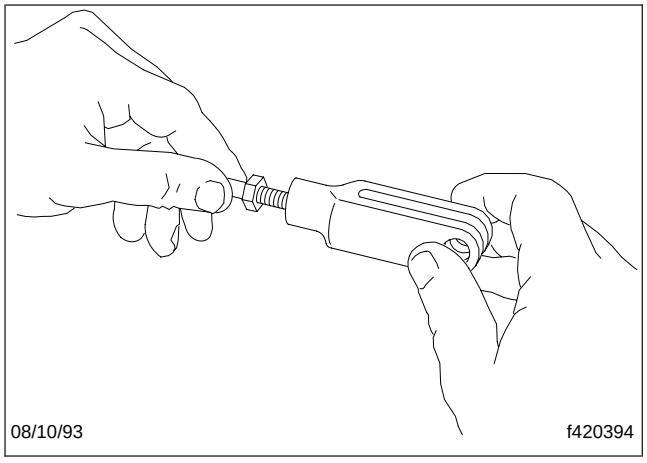

Fig. 2

5. Remove and save the small jam nut from the threaded end of the cable that was installed in the clevis.
6. Remove the brake cable jam nut and lock washer from the cable bracket on top of the transmission. **See Fig. 3.**

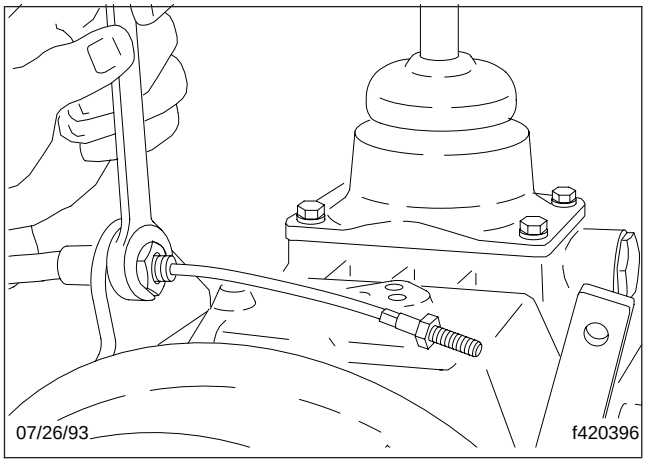

Fig. 3, Fuller Transmission Installation Shown

7. Push the brake cable end through the "D" hole in the bracket. **See Fig. 4.**

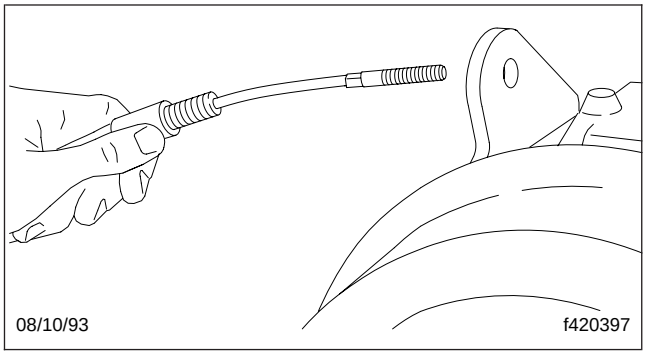

Fig. 4

8. In the cab, remove the plastic boot covering the brake lever assembly.
9. Remove the nut from the double cable clamp on the side of the transmission (**see Fig. 5**), then remove the brake cable from its half of the clamp.
10. Disconnect the parking brake cable from the parking brake lever. **See Fig. 6.**
11. Remove the parking lever assembly from the cab deck.

Parking Brake Cable Replacement

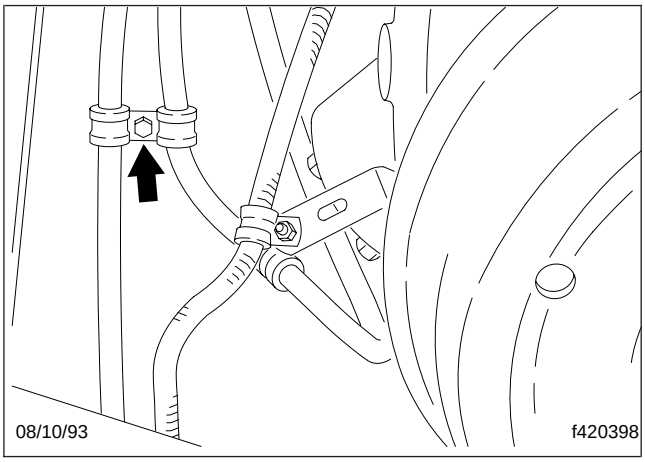

Fig. 5

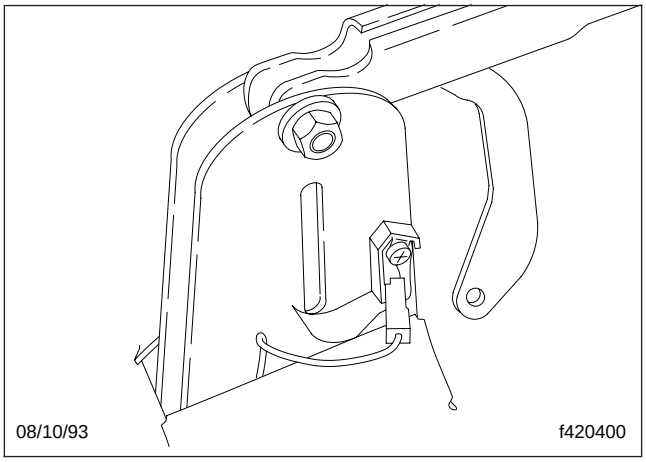

Fig. 7

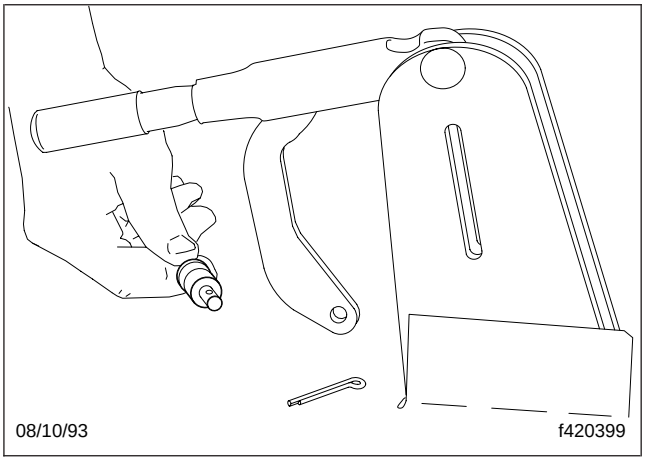

Fig. 6

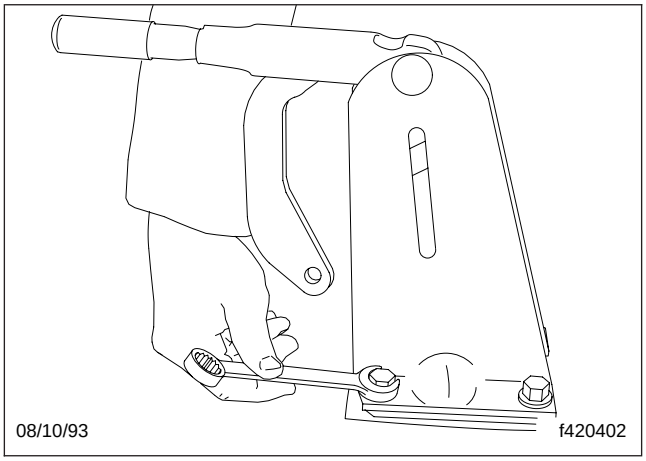

Fig. 8

11.1 Disconnect the electrical wire from the right side of the parking brake lever assembly. **See Fig. 7.**

11.2 Remove the four mounting bolts and washers that hold the lever assembly to the cab floor. **See Fig. 8.**

11.3 Lift the lever assembly off the floor, and set it aside.

12. Remove the jam nut and lockwasher from the threaded end of the cable sheath coming through the hole in the cab deck. **See Fig. 9.**

13. Remove the baseplate by sliding the parking brake cable through the slot in the baseplate. **See Fig. 10.**

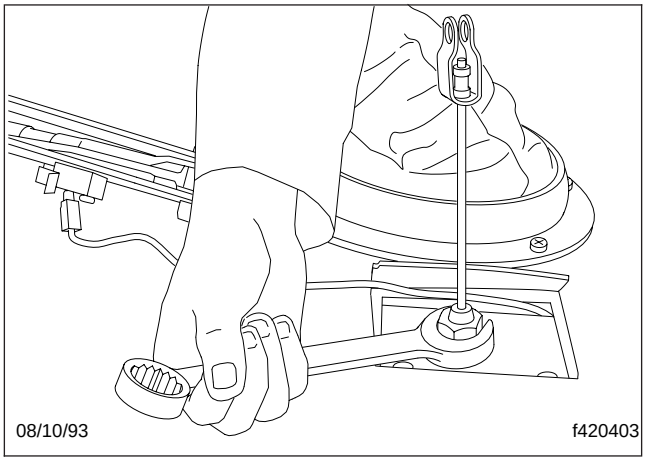

Fig. 9

Parking Brake Cable Replacement

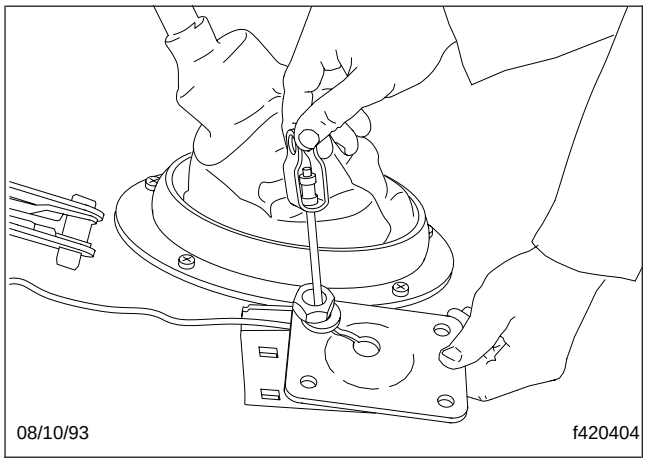

Fig. 10

14. Pull the entire length of the parking brake cable up through the hole in the cab deck.
15. Check the parking brake lever assembly for wear and damage. Replace it if needed.
16. Put the clevis end of the new parking brake cable assembly in the slot of the baseplate, so that the jam nut and washer are on top of the base plate. **See Fig. 10.**
17. Install the lockwasher and jam nut on the cable sheath. Tighten the nut firmly. **See Fig. 9 .**
18. Install the free end of the parking brake cable through the hole in the deck. Pull about a foot of the cable up through the sheath.
19. Connect the new cable to the parking brake lever assembly.
    - 19.1 Install the bushing on the clevis pin. **See Fig. 6.**
    - 19.2 Put the clevis end of the cable up through the middle of the parking brake lever assembly.
    - 19.3 Put the curved brake lever arm (**Fig. 6**) into the middle of the brake lever assembly, and into the clevis.
    - 19.4 Line up the slots in the brake lever assembly, the hole in the curved arm, and the holes in the clevis.
    - 19.5 Install the clevis pin (with the bushing on it) from the side of the lever assembly with the electric wire connector (**Fig. 7**).
    - 19.6 Install the washer and cotter pin on the clevis pin.
20. Install the parking brake lever assembly on the cab deck.
    - 20.1 Put the baseplate on the deck, lining up the holes in the plate with those in the deck.
    - 20.2 Put the lever assembly in place so that its holes and those of the baseplate and the deck all line up.
    - 20.3 Install the four mounting bolts and washers. Tighten the fasteners firmly.
21. Connect the electrical wire to the passenger's side of the parking brake lever assembly. **See Fig. 7.**
22. Underneath the cab, route the parking brake cable through the double cable clamp on the side of the transmission (**Fig. 5**), and then up to the cable bracket on the top of the transmission (or rear axle).
23. Put the cable through the "D" hole in the bracket, then install the lockwasher and jam nut on the threaded end of the cable sheath. Don't tighten the nut all the way. **See Fig. 3.**
24. Connect the parking brake cable to the parking brake actuating lever.
    - 24.1 Screw the threaded end of the cable into the clevis far enough so the clevis holes will line up with the hole in the actuating lever. There should be no slack in the cable. **See Fig. 11.**
    - 24.2 Install the clevis pin in the holes of the clevis and that of the actuator lever.
    - 24.3 Tighten the jam nut (installed previously) 900 N·cm (80 lbf·in).
    - 24.4 Install the washer and a new cotter pin.
25. If a final cable adjustment is needed, make it in the cab, by turning the ring on the parking brake lever. **See Fig. 12.**

Parking Brake Cable Replacement

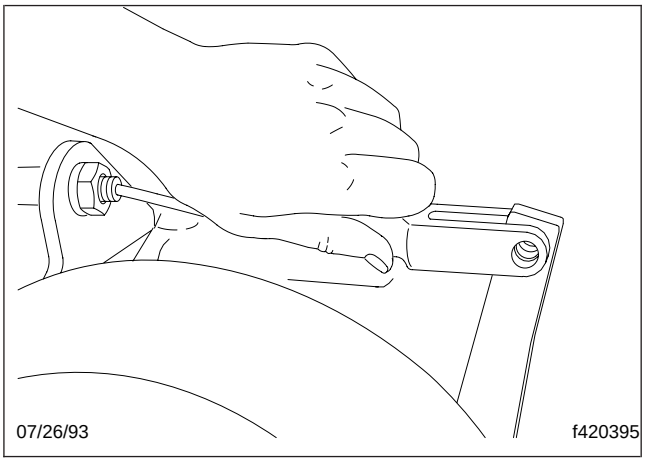

Fig. 11

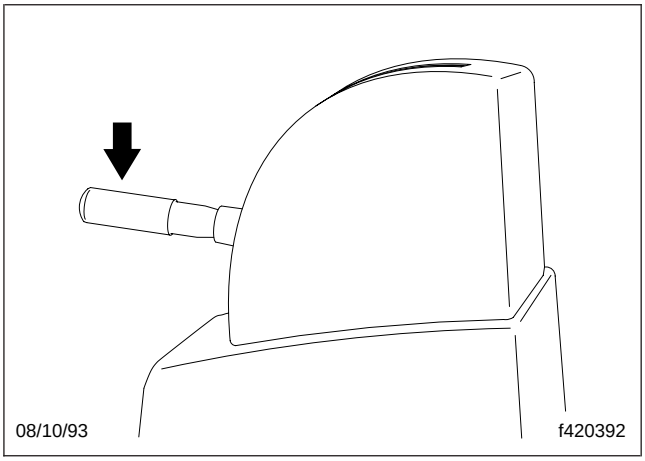

Fig. 12

Park Brake Cable Adjustment

⚠ WARNING

Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

There are two methods of parking brake actuation available for Business Class trucks. Most vehicles have a hand-lever-actuated parking brake with the lever mounted on the cab floor. Some vehicles have an air-actuated system which is operated by a valve on the dash that controls a brake chamber mounted on the frame rail near the parking brake. When actuated, it applies the parking brake via a cable. Determine which method of actuation is used on the vehicle to be serviced, then follow the appropriate procedure below.

Prior to adjusting the parking brake cable, inspect the following components for damage, loose or missing parts, or leaks (in the case of air actuated system):

- Parking brake hand lever
- Brake chamber and plumbing (air-actuated system only)
- Cable
- Cable housing
- All mounting brackets and hardware

Make any necessary repairs before making adjustments to the brake cable.

Hand-Lever-Actuated Parking Brake Cable Adjustment

Prior to making adjustments to the hand-lever-actuated parking brake cable, ensure that the actuation system is in good working order.

1. Park the vehicle on a level surface, shut down the engine, and chock the tires.
2. Release the parking brake if it is applied.
3. Back off any excessive adjustment at the lever handle before making adjustments at the cable clevis. Leave enough for final cable adjustment, in either direction, as needed.
4. Remove the cotter pin and clevis pin from the clevis at the brake actuation lever. See **Fig. 1**.

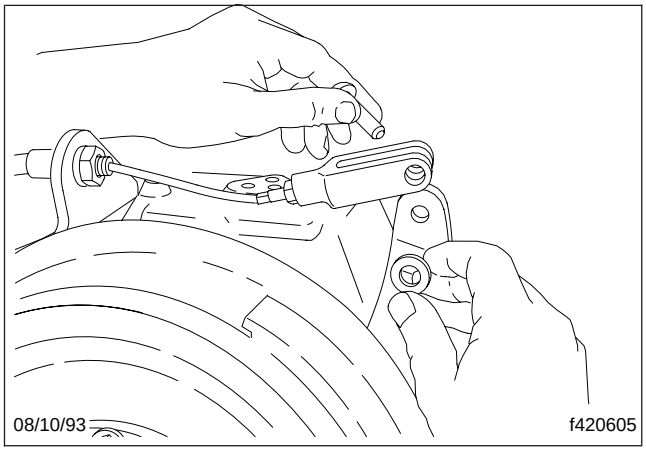

Fig. 1, Remove the Cotter Pin and Clevis Pin

5. Pull the brake actuation lever to the fully released position, then move it slightly back to take up the freeplay, and hold it there.
6. If adjustment is required, loosen the jam nut on the cable and adjust the clevis so that the pin hole in the clevis aligns with the hole in the lever.
7. Install the clevis pin and a new cotter pin.
8. Tighten the clevis jam nut to 80 lbf·in (900 N·cm).
9. If a final cable adjustment is needed, make it in the cab, by turning the ring on the parking brake lever.

   When properly adjusted, the cable should have a very slight looseness to it. See **Fig. 2**.
10. Set the parking brake and remove the chocks.
11. Test the parking brake before returning the vehicle to service.

Air-Actuated Parking Brake Cable Adjustment

Prior to making adjustments to the air-actuated parking brake cable, insure that the actuation system is in good working order.

1. Park the vehicle on a level surface and chock the tires.

Park Brake Cable Adjustment

A. Too Loose
B. Correct Position of Actuating Lever
C. Too Tight
D. Correct Cable Adjustment
1. Actuating Lever

Fig. 2, Parking Brake Cable Installation (typical)

2. Make sure the air system is fully charged, then shut down the engine.
3. Release the parking brake if it is applied.
4. Remove the cotter pin and clevis pin from the clevis at the brake lever. See **Fig. 1**.
5. Pull the brake lever until shoe-to-drum contact is made.
6. If adjustment is required, loosen the jam nut on the cable and adjust the clevis so that the pin hole in the clevis aligns with the hole in the lever.
7. Install the clevis pin and a new cotter pin.
8. Tighten the clevis jam nut to 80 lbf·in (900 N·cm).

   When properly adjusted, the cable should have a very slight looseness to it. See **Fig. 2**.
9. Set the parking brake and remove the chocks.
10. Test the parking brake before returning the vehicle to service.

Troubleshooting

This subject contains the following troubleshooting tables:

- The Parking Brake Won't Hold the Vehicle on a Grade
- The Parking Brake Won't Release
- The Parking Brake Makes Noises While the Vehicle Is Moving

Problem—The Parking Brake Won't Hold the Vehicle on a Grade

Possible Cause	Remedy
The brake shoe linings are worn down.	Replace the brake shoes.
The brake drum is cracked.	Replace the drum.
The brake drum lining is worn down, or heavily scored.	Replace the drum.
The brake cable is binding.	Repair or replace the cable.
There is too much slack in the brake cable.	Adjust the brake cable.
The brake shoe linings have grease on them.	Replace the brake shoes, then clean the inside of the drum.

Problem—The Parking Brake Won't Release

Possible Cause	Remedy
The brake cable is too tight.	Adjust the brake cable.
The brake shoe return springs are missing, detached, or broken.	Check the return springs. Install them or replace them as needed.
The contact points between the brake shoe webs and the actuator strut are corroded or dirty.	Check the area, and clean and lubricate as needed.
The parking brake lever in the cab is binding.	Check the parking brake lever assembly for damage or corrosion. Repair or replace as needed.

Problem—The Parking Brake Makes Noises While the Vehicle Is Moving

Possible Cause	Remedy
The parking brake drum is loose.	Check the brake drum mounting bolts. Tighten as needed.
The brake shoes or backing plate is loose.	Check the brake shoes, return springs, and backing plate mounting bolts. Tighten, repair, or replace, as needed.
There is dirt inside the brake drum.	Remove the brake drum and clean it. Also clean other brake parts.

Table 1, Fastener Torques

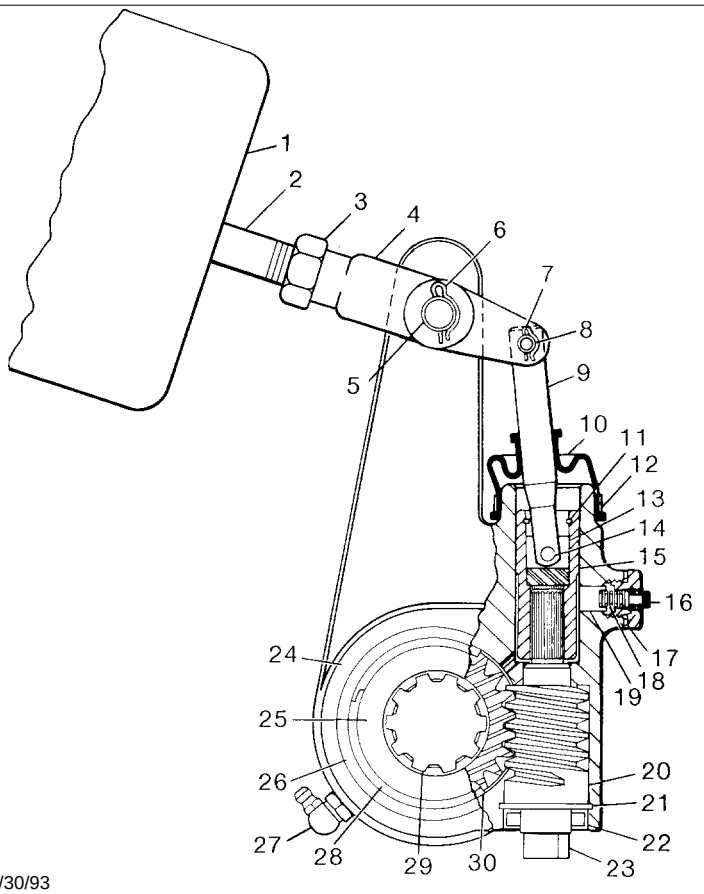
General Description

The Rockwell automatic slack adjuster has two main functions:

- As a lever, it converts the straight-line force of the brake chamber push rod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the brake drum.
- As an automatic adjuster, it automatically maintains brake chamber push-rod stroke, which controls lining-to-drum clearance during operation.

With an automatic slack adjuster, brakes are adjusted only when needed. As long as the push-rod stroke doesn't exceed the desired length, no adjustment takes place. Adjustment is made on the return stroke, as air is released and the forces in the gearset are low. The force to make an adjustment comes directly from the brake shoe return spring and the brake chamber return spring.

Principles of Operation



(Refer to Fig. 1)

The externally splined end of the worm (Ref. 20) fits the internal splines on the actuator (Ref. 15). Angled serrations on the spring-held pawl (Ref. 19) correspond with serrations on the actuator exterior. The serrations are formed to allow free upward movement of the actuator, and to lock in on the actuator serrations on a downward movement.

As the brake is applied, the brake chamber push rod, connected to the end of the clevis, moves outward, forcing the slack adjuster arm to turn on the brake camshaft centerline. The actuator rod (Ref. 9) is connected to the clevis at one end, and to a small piston at the other end. As the slack adjuster arm moves, the actuator rod is moved upward and outward, pulling the piston (Ref. 13) upward.

When lining wear becomes excessive, the brake chamber push-rod stroke goes beyond the desired length. The piston then makes contact with the retaining ring (Ref. 11) and pulls up the actuator. As the actuator moves upward and reaches a preset distance, it slides over one serration on the pawl. When the push rod moves back toward the brake chamber, the actuator is forced downward. Because the serrations in the pawl and actuator are now locked in, the actuator, following the curve of its serrations as it moves downward, turns slightly. This action causes the worm to turn, advancing the gear (Ref. 25) and the camshaft to automatically adjust the brake.

Removal

1. Park the vehicle on a level surface, and chock the tires. If the rear slack adjusters will be removed, release the parking brakes, then cage the power spring of the parking brake chamber.

⚠ WARNING

WARNING: Loss of brake chamber air pressure will cause sudden application of the parking brakes, which could result in personal injury. Manually cage each parking brake chamber power spring in the release (no application) position before continuing.

2. Mark or measure the position of the clevis on the brake chamber push rod. **See Fig. 1.**

A. Mark or measure this distance.
1. Brake Chamber

3. Clevis
4. Slack Adjuster

Fig. 1, Mark or Measure the Clevis Position

3. Remove the cotter pins from the clevis pins. Remove the clevis pins.

4. Remove the pressure relief capscrew, spring, and pawl assembly from the slack adjuster housing. **See Fig. 2**, Refs. 17, 19, and 20. If equipped with a pull-pawl assembly **(Fig. 3),** carefully insert a screwdriver and raise the relief cap about 1/8 inch (3.2 mm).

⚠ CAUTION

CAUTION: Before turning the adjusting nut, remove the pressure relief capscrew, spring, and pawl assembly. If equipped with a pull-pawl assembly, raise the relief cap about 1/8 inch (3.2 mm). Failure to do so could strip the teeth on the pawl.

5. Using a wrench, turn the manual adjusting nut, and move the slack adjuster away from the clevis. **See Fig. 4.**

6. Remove the snap ring and washers that attach the slack adjuster to the brake camshaft and save them for later installation.

7. Remove the slack adjuster from the camshaft.

8. Note the location and number of any remaining spacing washers on the camshaft, and then remove them. Save them for later installation.

9. If replacing the clevis, loosen the clevis jam nut. Remove the clevis and jam nut from the brake chamber push rod.

Installation

1. Inspect parts, and then prepare the slack adjuster for installation.

   1.1 Check the brake camshaft splines for wear or corrosion.

   1.2 Coat the camshaft splines and the splines of the slack adjuster gear with Rockwell lubricant 0-637, Southwest SA 8249496, or an equivalent.

   IMPORTANT: These lubricants provide corrosion protection. Do not mix these lubricants with other types.

   1.3 Apply the service brake and parking brake several times. Make sure the return spring retracts the push rod quickly and completely. Replace the return spring or brake chamber if needed.

2. If previously removed, install the clevis and jam nut.

   Check that the clevis is in the same position on the brake chamber push rod as marked or mea-

sured during removal. Do not tighten the jam nut against the clevis.

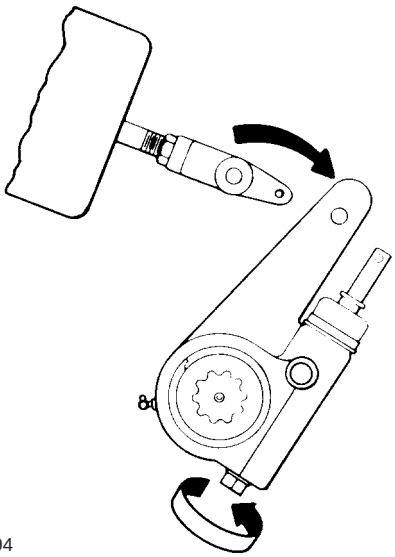
NOTE: Use a clevis with a 1/2-20 UNF thread if equipped with type 9, 12, or 16 brake chambers. Use a clevis with a 5/8-18 UNF thread size if equipped with type 20, 24, 30, or 36 brake chambers.

3. Install the slack adjuster.

   3.1 If installing a new slack adjuster, use an installation template **(Fig. 5)** and measure the new slack adjuster to make sure it is the same length as the slack adjuster that was removed. Refer to the appropriate table in **Specifications 400** for the

A. Insert screwdriver here.

Fig. 3, Pull-Pawl Assembly (sectional view)



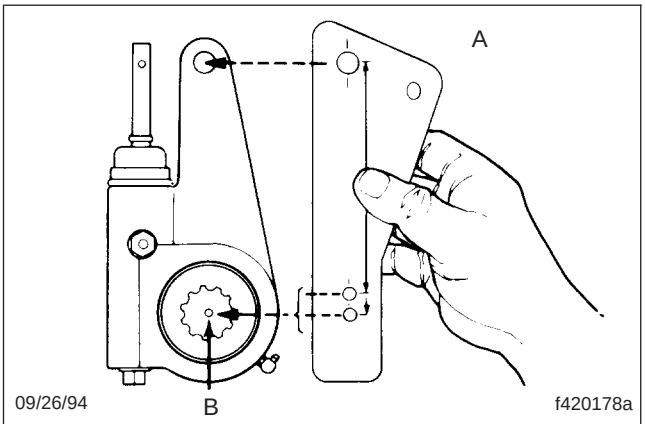


Fig. 4, Move the Slack Adjuster Away from the Clevis

length of slack adjusters that should be used with various sizes of brake chambers.

NOTE: Depending on the type of brakes used (disc or drum) on a tractor or trailer, several types of installation templates are used. They can be made using the measurements provided in **Fig. 6.** Or, they can be ordered from:

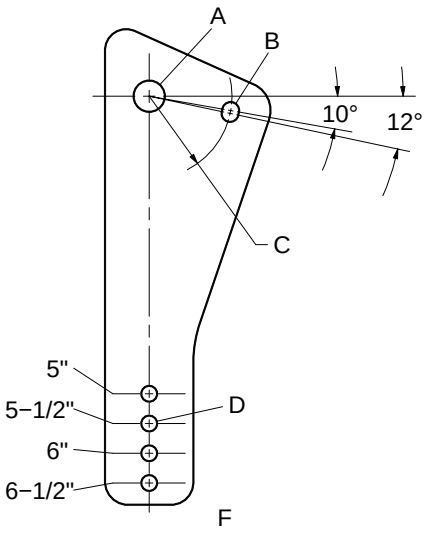
A. Measure slack adjuster arm length.
B. Camshaft Center

Fig. 5, Measure the New Slack Adjuster

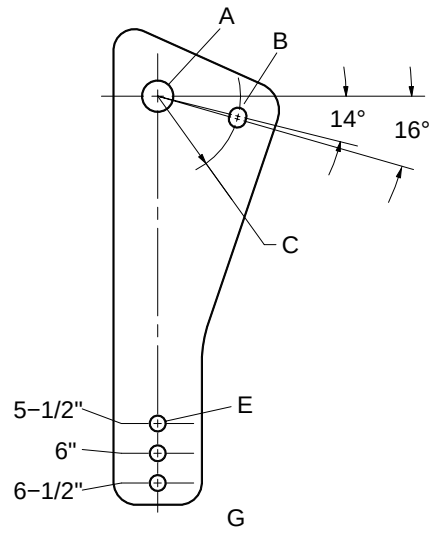
Attn: Literature Distribution Rockwell International 2135 W. Maple Road Troy, Michigan 48084

3.2 Position the slack adjuster on the camshaft.

3.3 Install the spacing washers and the snap ring that attach the slack adjuster to the camshaft. Add enough washers to limit the camshaft end play to 0.060 inch (1.5 mm). Check the end play using the instructions in the applicable brake chamber section in this manual.



3.4 If installing a new slack adjuster, remove the pressure relief capscrew, spring, and pawl assembly from the slack adjuster housing. If equipped with a pull-pawl assembly **(Fig. 3),** carefully insert a screwdriver and raise the relief cap about 1/8 inch (3.2 mm).



⚠ CAUTION

CAUTION: Before turning the adjusting nut, remove the pressure relief capscrew, spring, and pawl assembly. If equipped with a pull-pawl assembly, raise the relief cap about 1/8 inch (3.2 mm). Failure to do so could strip the teeth on the pawl.

3.5 Using a wrench, turn the manual adjusting nut to align the hole in the slack ad-

Removal and Installation

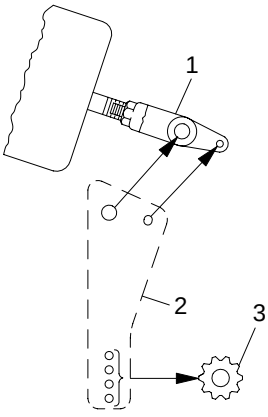
juster housing with the large hole in the clevis. **See Fig. 7.** Insert the large clevis pin.



09/26/94 f420179a

A. Align holes.

Fig. 7, Aligning the Holes

3.6 With the brakes fully released, place the applicable installation template over the clevis and camshaft end. **See Fig. 8.**

09/27/94 f420897a

1. Clevis 2. Template 3. Camshaft End

Fig. 8, Position the Installation Template

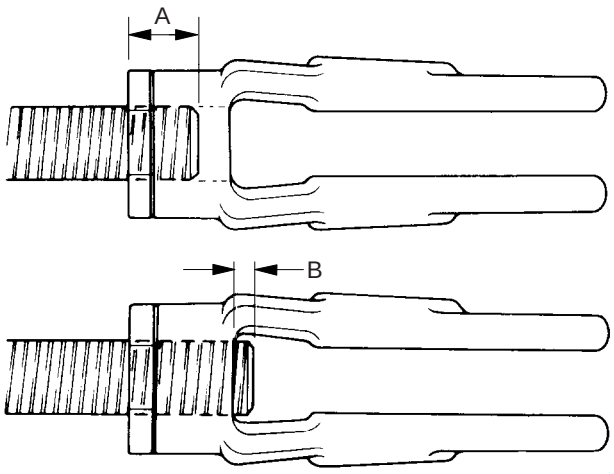
3.7 Temporarily insert the large clevis pin through the large holes in the template and the clevis.

3.8 Select the hole in the template that matches the length of the slack adjuster. Hold the template in place on the center of the camshaft with a pencil.

3.9 Look through the small hole in the template and see if the small hole in the clevis is completely visible. If the hole in the clevis is not completely visible, adjust the position of the clevis on the push rod until the small clevis hole is completely visible. Temporarily place the small clevis pin through the template and clevis to make sure the alignment is correct. Remove both pins and the template. Insert both clevis pins with the pin head on the inboard side of the slack adjuster. Be sure the small clevis pin is inserted through the hole in the actuator rod. Install and lock new cotter pins to secure the clevis pins.

IMPORTANT: Make sure that there is at least 1/2 inch (13 mm) of thread engagement between the clevis and the push rod. Also, check that the push rod doesn't extend through the clevis more than 1/8 inch (3.2 mm). **See Fig. 9.** If needed, either cut the push rod, install a new push rod, or install a new brake chamber.

3.10 For 1/2-20 UNF threads, tighten the clevis jam nut 20 to 30 lbf·ft (27 to 41 N·m). For 5/8-18 UNF threads, tighten the jam nut 25 to 50 lbf·ft (34 to 68 N·m).



4. Set the free-stroke.

4.1 Turn the manual adjusting nut counterclockwise until the brake linings contact the brake drum.

4.2 Set the approximate clearance between the linings and the drum: turn the adjusting nut clockwise one-half turn.

4.3 With the brakes fully released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 10**, Ref. B.

4.4 Use a pry bar to move the slack adjuster, and apply the brakes. Again, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 10** , Ref. A.

A. Minimum 1/2" (13 mm)
B. Maximum 1/8" (3.2 mm)

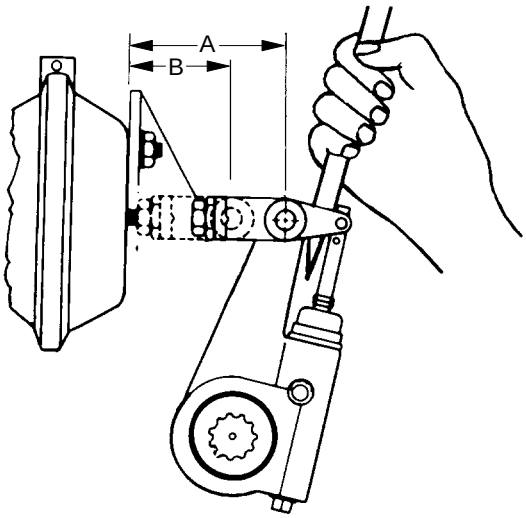
Fig. 9, Check Thread Engagement

The difference between the two measurements is the initial free-stroke, and sets the clearance between the linings and the drum.

The free stroke must be:

drum brakes—5/8 to 3/4 inch (16 to 19 mm);

disc brakes—7/8 to 1-1/8 inch (22 to 29 mm).

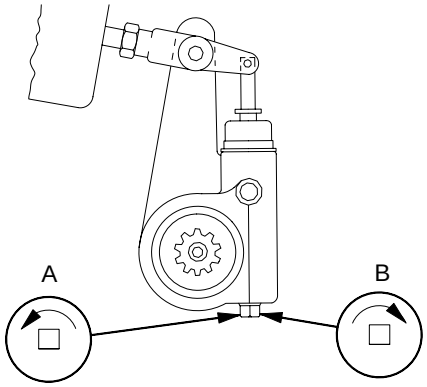


If the free stroke is incorrect, turn the adjusting nut one-eighth turn, as shown in **Fig. 11.** Measure the stroke again, and adjust until it is correct.

5. Measure the brake chamber stroke, and adjust as needed.

5.1 With the brakes fully released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 12**, Ref. A.

5.2 Build air pressure to 100 psi (689 kPa). Shut down the engine. Fully apply the brakes, then measure the distance from the bottom of the brake chamber to the center of the large clevis pin.

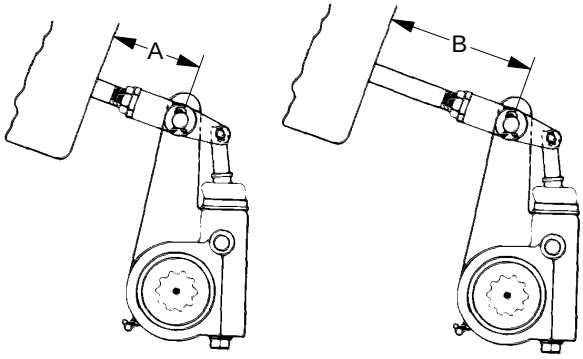


Removal and Installation

09/27/94 f420180a

NOTE: For a drum brake, A minus B must equal 5/8" to 3/4" (16 to 19 mm). For a disc brake, A minus B must equal 7/8" to 1-1/8" (22 to 29 mm).

Fig. 10, Measuring Free-Stroke



07/05/95 f420181a

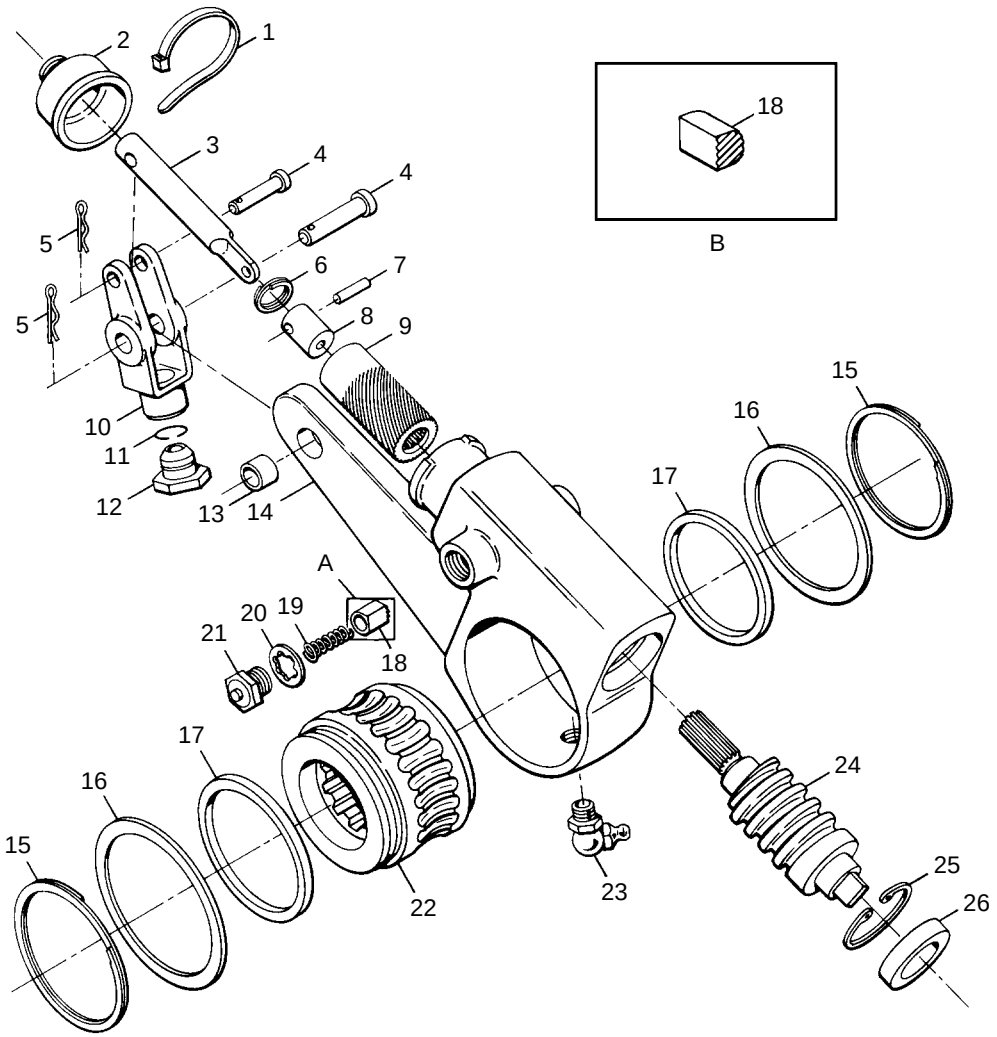
A. Shorten stroke.
B. Lengthen stroke.

Fig. 11, Turn the Adjusting Nut

See Fig. 12, Ref. B. The difference between the measurements is the brake chamber stroke.

5.3 The brake chamber stroke must be less than the measurements shown in the appropriate table in **Specifications 400.** If needed, turn the adjusting nut to adjust the brake chamber stroke.

10/20/93 f420182a



NOTE: Measure distance *A* with the brakes released; measure distance *B* with the brakes applied.

Fig. 12, Measuring Adjusted Brake Chamber Stroke

If the stroke varies or remains greater than the specified range, check the brake components, including the camshafts, camshaft bushings, anchor pins, rollers, chamber brackets, clevis, and clevis pins. For instructions, refer to the brake section in this manual.

6. Install the pawl assembly, spring, and the pressure relief capscrew. Tighten the capscrew 15 to 20 lbf·ft (20 to 27 N·m). Or, remove the screwdriver from the pull-pawl assembly (if equipped).
7. Lube the slack adjuster through the grease fitting until the lubricant is forced out through the pressure relief fitting (or pawl slot), or through the gear splines around the inboard snap ring.
8. If a rear axle slack adjuster was installed, manually uncage the parking brake. For instructions, refer to the applicable brake chamber section in this manual.
9. Remove the chocks from the tires.

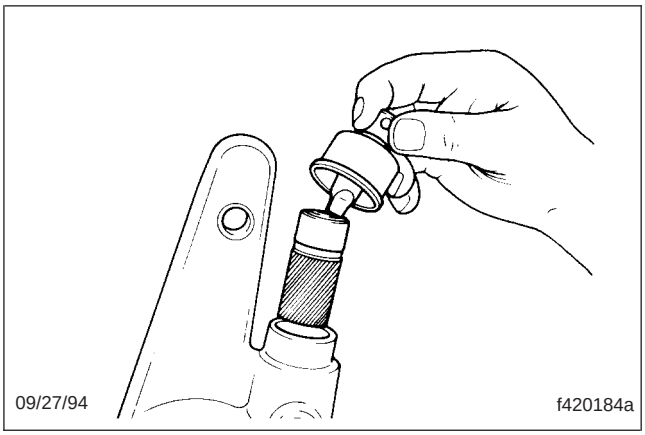
Disassembly, Cleaning and Inspection, and Assembly

1. Remove the slack adjuster. For instructions, refer to **Subject 100.**
2. Cut the boot retaining clamp, and remove the clamp from the rubber boot.
3. Remove the boot and the actuator (adjusting sleeve) from the housing. **See Fig. 2.** You may need to first work the boot off of the housing before removing the actuator.



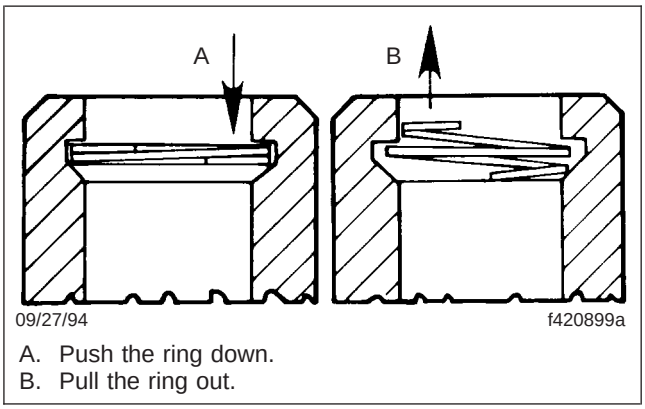


Fig. 2, Removal of the Actuator

4. Using a small screwdriver, press down the piston retaining ring and force it out of the groove **(Fig. 3).** Using pliers, unwind the ring and pull it out.

A. Push the ring down.
B. Pull the ring out.

Fig. 3, Removal of the Internal Piston Retaining Ring

5. Pull the actuator rod, piston, and pin from the actuator bore.
6. Using a small hammer and brass drift punch, remove the pin from the rod and piston. **See Fig. 4.**

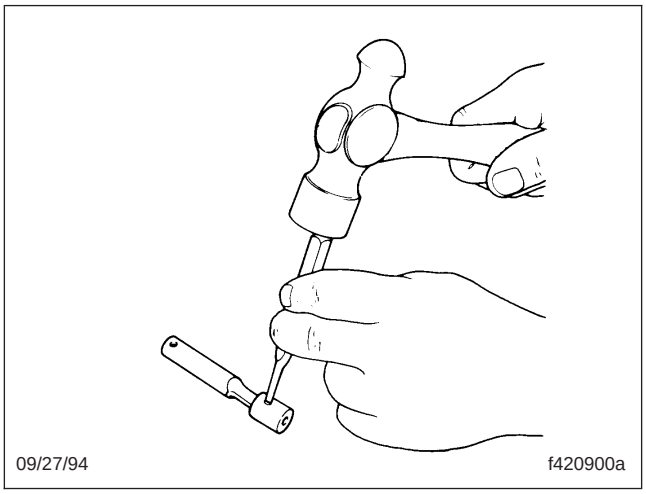

Fig. 4, Remove the Pin from the Rod and Piston

7. Using a small screwdriver, pry the grease seal from around the worm. **See Fig. 5.**

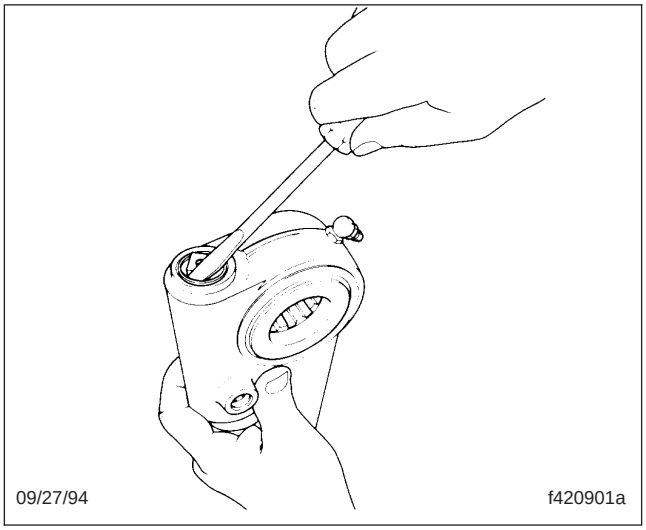

Fig. 5, Pry the Grease Seal from around the Worm

8. Using snap ring pliers, remove the retaining ring from the worm. **See Fig. 6.**

IMPORTANT: The following steps apply only to slack adusters produced before January 1993.

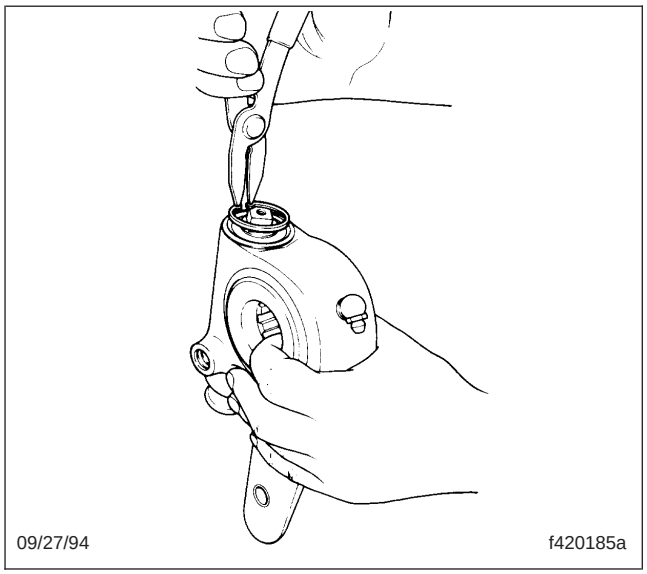

Fig. 6, Remove the Retaining Ring

On slack adjusters produced since January 1993, the gear and seals are not serviceable.

9. Using a wrench, turn the manual adjusting nut, and wind the worm out of the bore.
10. On one side of the housing, insert a small screwdriver into the notch at the end of the gear retaining ring. Remove the end of the retaining ring from the groove.

    Unwind the ring by hand and pull it out of the groove. **See Fig. 7**. Remove the thrustwasher.
11. Push the gear far enough out of the housing to remove one gear seal.

    Push the gear far enough out of the opposite side of the housing to remove the other gear seal. Remove the gear from the housing.

Cleaning and Inspection

CAUTION

CAUTION: Don't clean ground or polished parts in a hot solution tank or with water-and-alkaline solutions, such as sodium hydroxide, orthosilicates, or phosphates. Also, don't use solvent-type cleaners on any nonmetallic parts. Doing so could damage the parts.

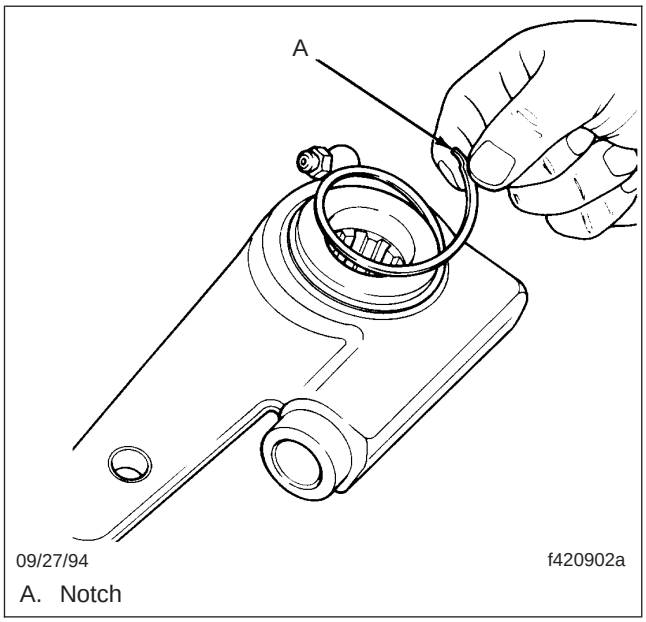

Fig. 7, Removal of the Gear Retaining Rings

1. Clean the slack adjuster parts.
   - 1.1 Clean all parts having ground and polished surfaces (such as the worm, worm gear, and inner bores of the slack housing) with solvent-type cleaners, such as emulsion cleaners, carbon tetrachloride, or petroleum solvents (excluding gasoline).
   - 1.2 Dry all parts immediately after cleaning. Use soft, clean, lint-free absorbent paper towels, or wiping rags free of abrasive material such as lapping compound, metal filings, or contaminated oil.
2. Inspect all parts for wear or damage.
   - 2.1 Inspect all parts for wear or stress. Replace as needed.
   - 2.2 Inspect the seals, and discard if they show any signs of damage.
   - 2.3 Check the condition and fit of the large clevis pin bushing in the arm of the slack adjuster. Don't remove the bushing unless it is worn or egg-shaped.
3. If storing parts for any length of time, treat them with a good rust preventative, and wrap them in

Disassembly, Cleaning and Inspection, and Assembly

special paper or other material designed to prevent corrosion.

Assembly (See Fig. 1)

IMPORTANT: The first two steps that follow apply only to slack adusters produced before January 1993. On slack adjusters produced since January 1993, the gear and seals are not serviceable.

1. Coat all parts and the gear bore with a grease recommended in the appropriate table in **Specifications 400.**
2. Install the gear into the housing.
   - 2.1 Place the gear, without the gear seals, into the housing. Keep one seal groove outside the housing.

     Make sure the gear goes straight into the bore. If needed, use a small rawhide mallet to tap the gear into place.
   - 2.2 Install a seal into the groove. **See Fig. 8.**

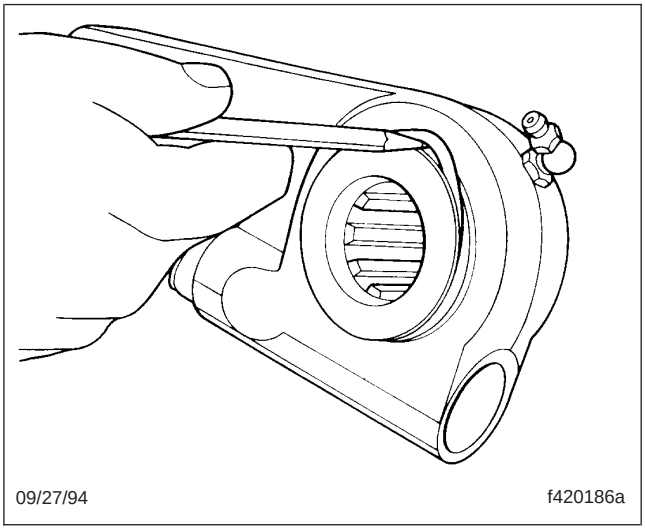

Fig. 8, Install a Seal into the Groove

CAUTION

CAUTION: Do not push the side of the gear that has the seal installed through the housing. Damage to the seal will occur when it passes the sharp edges of the intersecting worm bore.

   - 2.3 Push the gear far enough out the opposite side of the housing so you can see the other seal groove.
   - 2.4 Install the seal in the groove, and push the gear into the housing.
   - 2.5 On one side of the gear, position a thrustwasher around the gear and against the housing. Spread out the retaining ring coil. Put one end of the coil into the groove in the outer diameter of the gear. Work around the gear and press the coil into the groove.
   - 2.6 Repeat this step for the other side of the gear.
3. Install the worm into the housing.
   - 3.1 Place the worm into the bore, then turn the adjusting nut to wind the worm to the bottom of the bore.
   - 3.2 Install the retaining snap ring.
   - 3.3 Place the grease seal over the worm bore, with the lips facing outward and the metal retainer facing toward the inside of the bore. **See Fig. 9.** Using a hammer and a 1-3/16 inch seal driver, install the seal.

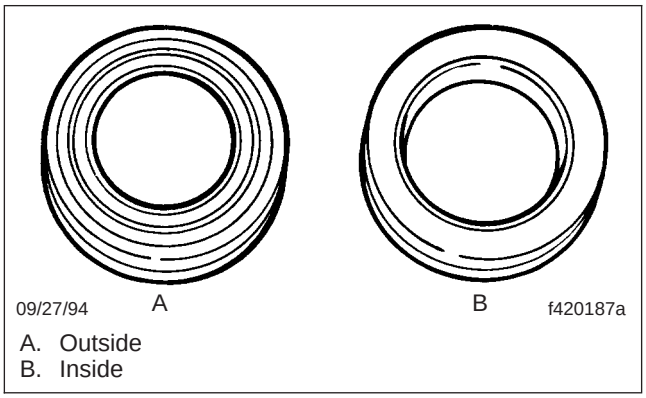

Fig. 9, Worm Seal

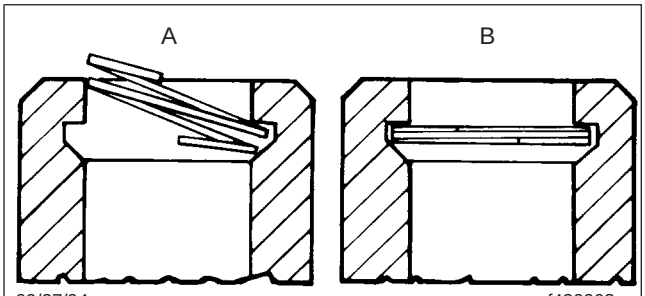
CAUTION

CAUTION: Failure to install the grease seal properly could allow contaminants to enter the housing and damage the parts.



4. Assemble the actuator, rod, and piston.

4.1 Using a small hammer and brass drift punch, install the pin that connects the piston and actuator rod.

4.2 Insert the actuator rod and piston into the actuator (adjusting sleeve).

4.3 Slide the piston retaining ring over the rod. Spread out the coils of the ring. Using a small screwdriver, press one end of the ring into the groove. **See Fig. 10.** Press on the ring and work it around the groove until it is completely seated in the groove.

See if the ring is seated correctly. You will not be able to pull the piston out of the actuator if the ring is seated correctly.

A. Start bottom coil.
B. Tuck ring into groove.

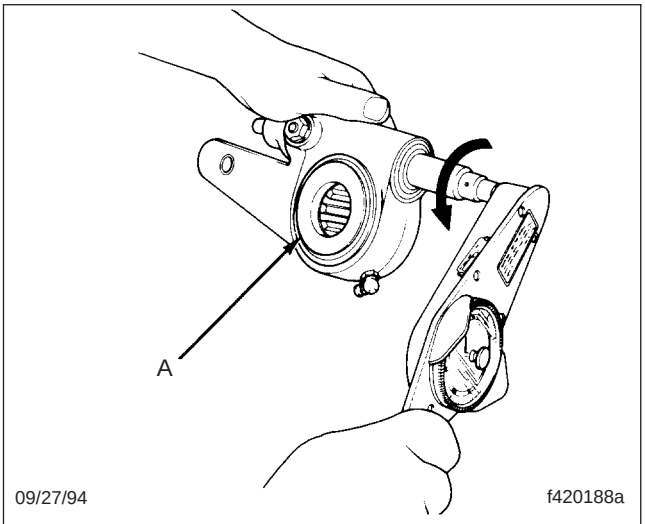


Fig. 10, Installation of the Internal Piston Retaining Ring

5. Slide the actuator assembly along the splines of the worm and into the slack housing.
6. Lubricate the actuator rod with grease, then slip the boot over the rod. Attach the boot to the housing with a silastic coating and a new retaining clamp.

   Make sure that the top of the boot fits on the round part of the rod, not the tapered part.

   Seal the top part of the boot with a silastic coating.
7. If previously removed, install a new bushing into the large clevis pin hole in the arm of the slack adjuster.
8. Lubricate the slack adjuster through the grease fitting until the lubricant is forced out through the pressure relief fitting (or pawl slot), or through the gear splines around the inboard snap ring.
9. Attach a lbf·in/N·cm torque wrench to the adjusting nut. Watch the torque scale while turning the gear 360 degrees. **See Fig. 11.** If the torque remains 25 lbf·in (280 N·cm) or less, the slack adjuster is working correctly.

   If the torque is more than 25 lbf·in (280 N·cm), the slack adjuster is not working correctly. Disassemble the slack, and check for correct assembly and alignment of parts.

A. Rotate the gear 360 degrees.

Fig. 11, Slack Adjuster Torque Check

10. Install the slack adjuster. For instructions, refer to **Subject 100.**

30	Less than 51 mm (2 inches)

* Long stroke.

Table 3, Maximum Adjusted Brake Chamber Strokes

General Description

The Haldex (SAB) automatic slack adjuster serves two main functions:

- As a lever, it converts the straight-line force of the air brake chamber push rod to torque on the brake camshaft. Rotation of the camshaft spreads the brake shoes out against the brake drum, applying the brakes.
- As an adjuster, it maintains cam brake chamber push rod stroke and lining-to-drum clearance automatically during normal use.

Principles of Operation

When the brakes are applied, the slack adjuster rotates and moves the shoes into contact with the drum. The clearance notch (**Fig. 1**, Ref. 4) corresponds to the normal lining-to-drum clearance. Different notches are available to meet the requirements of various vehicles and brake duty cycles. As the brake application continues, the rack (Ref. 3) moves upward and rotates the one-way clutch (Ref. 1) which slips in this direction.

As the brake pressure increases, the torque increase on the slack adjuster causes a relative movement between the body and the camshaft. This motion forces the worm shaft (Ref. 8) over to compress the coil spring (Ref. 7), releasing the cone clutch (Ref. 2). If the brakes are out of adjustment, any further torque will change the position of the one-way clutch in relation to the cone clutch.

When the brake begins its return stroke, the coil spring load returns to normal and the cone clutch is again engaged. The rack is pulled back to its original position in the notch. Any additional travel brought about by brake lining wear causes the rack to turn the locked one-way clutch and rotates the worm shaft through the locked cone clutch. The worm shaft then rotates the worm wheel (Ref. 6) and camshaft, adjusting the brakes.

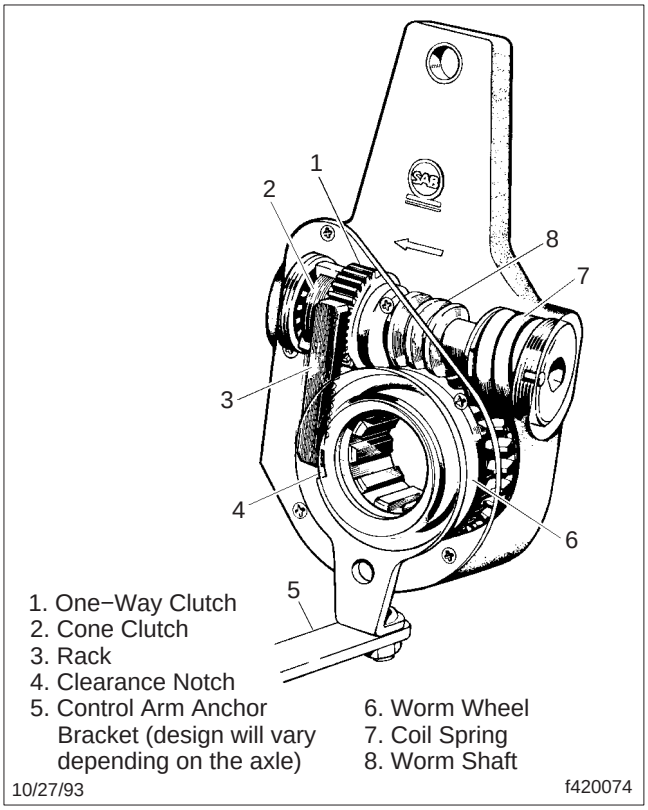

Fig. 1

Removal

1. Park on a level surface and chock the tires.
2. Release the parking brakes.

⚠ WARNING

WARNING: Before continuing, mechanically cage the power spring on each parking brake chamber to prevent the parking brakes from applying unexpectedly during the procedures. The parking brakes could suddenly apply due to a loss of air system pressure, and this could result in personal injury.

3. Remove the anchor bracket fasteners and the anchor bracket (**Fig. 1**).

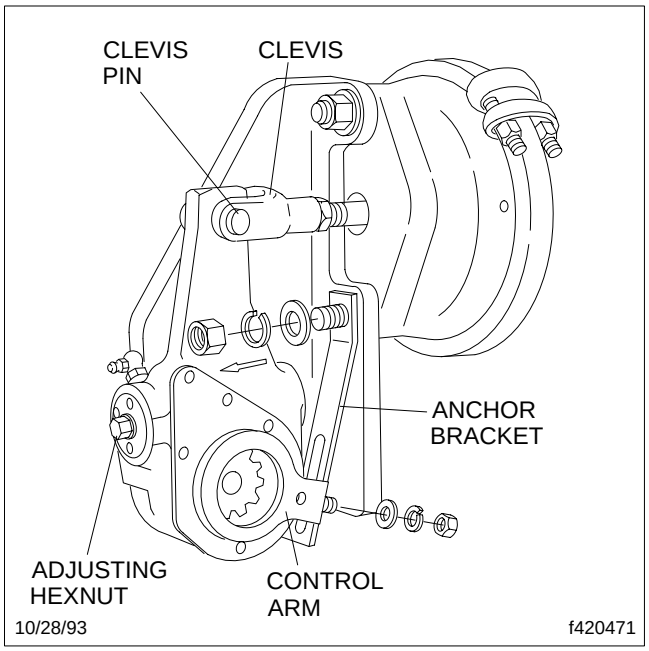

Fig. 1

4. Remove the cotter pin from the clevis pin. Remove the clevis pin.
5. Remove the snap ring holding the slack adjuster to the camshaft.
6. Turn the adjusting hexnut counterclockwise, to move the adjuster arm out of the clevis. A ratcheting sound may occur.
7. Remove the slack adjuster from the camshaft.

Installation

1. Check that the brake chamber push rod is fully released (parking brakes off).
2. Lubricate the camshaft splines with anti-corrosive grease.
3. Install the slack adjuster onto the camshaft with the adjusting hexnut (**Fig. 2**) pointing away from the brake chamber.

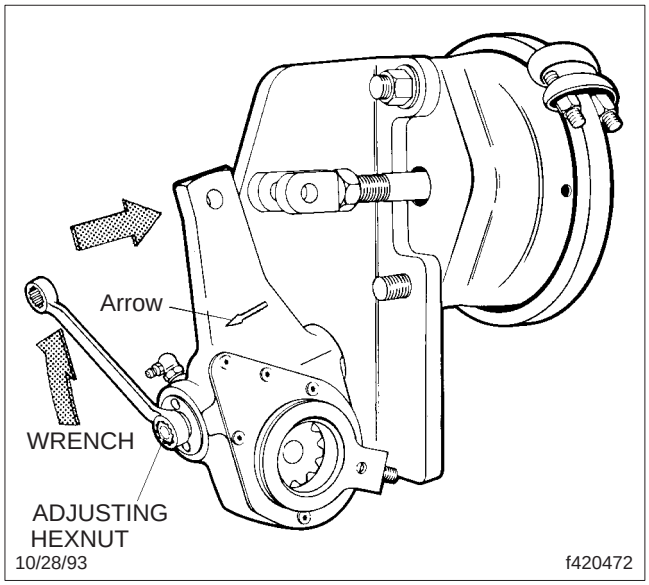

Fig. 2

IMPORTANT: When correctly installed, the brake chamber push rod pushes in the direction of the arrow (**Fig. 2**) on the adjuster arm.

4. Install the snap ring, securing the slack adjuster on the camshaft.
5. Turn the adjusting hexnut as shown in **Fig. 2** until the clevis hole lines up with the slack adjuster hole.
6. Insert the clevis pin, but do not install the cotter pin now.

IMPORTANT: Never push the slack adjuster into position. Always turn the adjusting hexnut for positioning.

7. Rotate the control arm away from the adjusting hexnut towards the brake chamber until it comes to a definite internal stop. See **Fig. 3**.

Removal and Installation

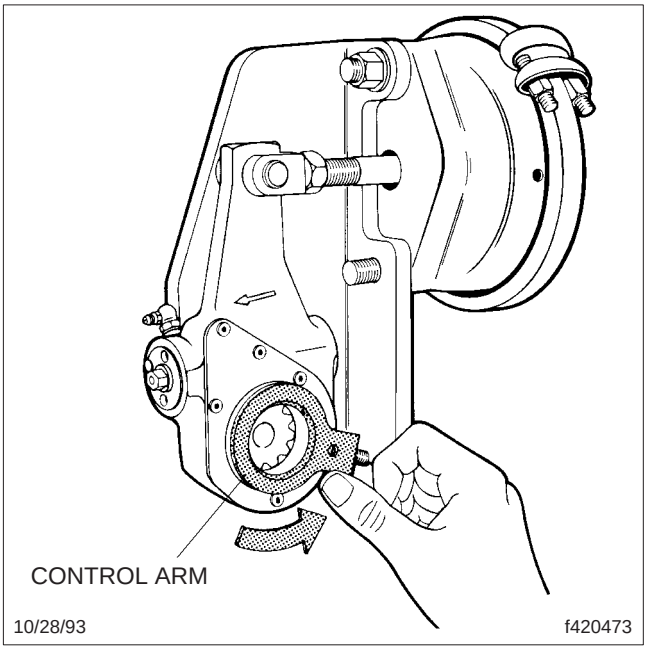

Fig. 3

IMPORTANT: Never hammer the control arm.

8. Install the anchor bracket. See **Fig. 1**.

NOTE: The anchor bracket design will vary, depending on the axle.

9. Tighten the anchor bracket fastener at the control arm 10 to 15 lbf·ft (14 to 20 N·m), making sure the control arm does not move from its position. Tighten the fastener at the brake chamber mounting stud according to the brake chamber manufacturer's specifications.
10. Adjust the brake lining clearance by turning the adjusting hexnut *clockwise* until the brake lining meets the brake drum, then back off *counterclockwise* 3/4 turn. A ratcheting sound may occur.
11. Check the installation by removing the clevis pin. Push the slack adjuster into the clevis, and then release it. See **Fig. 4**.

    If the slack adjuster hole did not stay aligned with the clevis pin hole, move the slack adjuster until the holes are aligned. Replace the clevis pin. Loosen the control arm fasteners, and move the control arm towards the brake chamber until it comes to a definite stop. Tighten the bracket fasteners.

    When the slack adjuster hole and clevis pin hole remain in alignment on release, the installation is correct.

    Insert the clevis pin in the clevis. Install and lock a new cotter pin in the clevis pin.

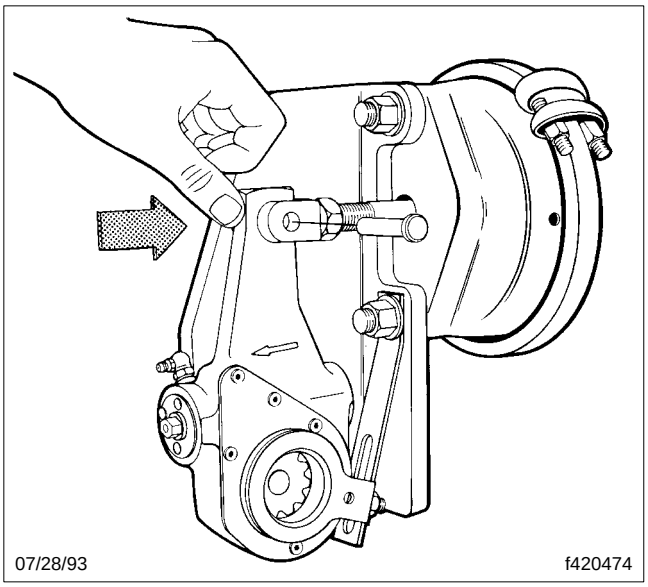

Fig. 4

⚠ WARNING

WARNING: Failure to install and lock a new cotter pin could allow the push rod to disengage from the slack adjuster, resulting in a loss of braking ability.

NOTE: Incorrect installation can cause dragging brakes.

Troubleshooting

This subject contains the following troubleshooting tables:

- Tight or Dragging Brakes
- Brake Chamber Push Rod Travel Is Excessive

Problem – Tight or Dragging Brakes

Possible Cause	Remedy
The control arm anchor bracket is not positioned properly.	See instructions under "Removal and Installation, 100."
System air pressure is too low to fully release the spring brake.	Check that the air governor cuts out at the recommended setting.
A spring brake diaphragm is ruptured or a piston seal is leaking.	Replace the diaphragm or spring brake piston seal.
A return spring in the brake chamber is broken.	Replace the spring brake return spring.
The push rod binds on the chamber housing.	Check for correct alignment and correct chamber mounting bracket. Adjust or replace parts as needed.
The air supply does not exhaust completely.	Test the air system valves for leakage and correct operation.
The brake drums are out-of-round.	Turn the brake drums, if possible. If the maximum allowable diameter of any brake drum has been exceeded, replace the drum. Also, turn or replace the other drum on the axle. For turning the drums, refer to the brake manufacturer's service manual.
Extreme differences exist in lining-to-drum clearances between shoes on the same wheel.	Check for proper operation of the brake mechanism. Lubricate or overhaul as needed.
The wheel bearings are out of adjustment.	Adjust the wheel bearings, or replace them if damaged. For instructions refer to the **front axle group** and the **rear axle group** of the vehicle service manual.
The brake shoe return spring is broken.	Replace the brake shoe return spring.

Problem – Brake Chamber Push Rod Travel Is Excessive

Possible Cause	Remedy
The control arm anchor bracket is loose, broken, or bent.	Tighten or replace the anchor bracket as required.
There is excessive wear between the anchor bracket bolt and the control arm slot.	Replace the worn parts.
The control arm assembly is damaged or worn, resulting in lateral movement between the control arm and the cover plate.	Replace the slack adjuster.
The camshaft bushings are worn.	Replace the worn camshaft bushings.
The camshaft binds.	Lubricate the camshaft or overhaul the brake mechanism as needed.
The brake chamber mounting is loose.	Tighten the brake chamber mounting fasteners.
The slack adjuster is bound against the camshaft housing. There is no end play.	Check that the correct camshaft and camshaft tube have been used and that they are assembled correctly. Overhaul the brake mechanism as needed.

Troubleshooting

Possible Cause	Remedy
The slack adjuster clutch assembly is worn.	Replace the slack adjuster.

General Description

In an S-cam type foundation brake, the final link between the air system and the foundation brake is the slack adjuster **(Fig. 1).** The arm of the slack adjuster fastens (using a yoke) to the push rod of the brake chamber, and the slack adjuster spline is installed on the brake camshaft.

Primarily, the slack adjuster is a lever, converting the linear force of the air chamber push rod into a torque that turns the brake camshaft and applies the brakes.

Standard slack adjusters contain four basic parts: the body, the worm, the gear, and the adjusting screw. The adjusting screw is provided to remove the slack caused by the wear of the brake lining.

All slack adjusters use the worm and gear principle and differ only in torque limit specifications. For example, a type 20 slack adjuster has a limit of 20,000 lbf·in; a type 30 slack adjuster has a limit of 30,000 lbf·in.

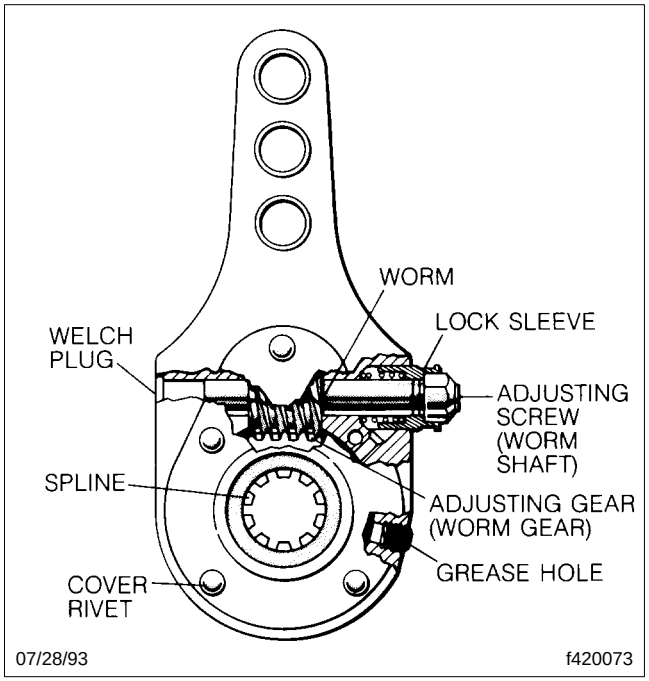

Fig. 1, Manual Slack Adjuster

Slack adjusters are produced in various arm lengths and configurations (such as "straight" and "offset"), to satisfy a variety of installation needs.

Principles of Operation

When the brakes are applied, compressed air forces the air service brake chamber diaphragm and push rod to move, rotating the slack adjuster. This in turn rotates the camshaft, causing the S-cam to spread the brake shoes, which contact the brake drum.

When the brakes are released, air pressure is exhausted from the brake chamber. The chamber return spring and the brake shoe return springs return the brake cam, camshaft, slack adjuster, and chamber push rod to the released positions.

The adjusting mechanism of a slack adjuster consists of an adjusting screw (worm shaft), worm, and slack adjuster worm gear. Turning the adjusting screw nut on the end of the worm shaft rotates the worm shaft and worm. The worm meshes with and rotates the slack adjuster worm gear, which is connected to the brake cam by a splined camshaft. The turning of the worm gear rotates the camshaft and brake cam, spreading the brake shoes, thereby compensating for brake lining wear.

Manual slack adjusters feature a positive lock mechanism to maintain the adjustment setting. This mechanism consists of a spring-loaded lock sleeve, which, when positioned properly, engages the adjusting screw nut to prevent the adjusting screw (worm shaft) from rotating.

Removal

1. Chock the tires and, if a rear-axle slack adjuster is being removed, release the parking brakes, and then cage the power spring of the parking brake chamber. For instructions, **refer to the brakes group.**

⚠ WARNING

WARNING: Possible loss of brake chamber air pressure will cause sudden application of the parking brakes, which could result in personal injury. Manually cage each parking brake chamber power spring in the release (no application) position before continuing.

2. Remove the slack adjuster from the brake camshaft.
   - 2.1 Remove the cotter pin from the brake chamber push-rod yoke pin; remove the yoke pin.
   - 2.2 Remove the snap ring and spacing washers from the end of the brake camshaft, and save them for later installation.
   - 2.3 Wipe off the adjusting screw nut and the locking sleeve area. Place a wrench or socket over the adjusting screw and depress the locking screw sleeve to disengage it. Turn the adjusting screw nut until the slack adjuster is clear of the brake camshaft.
   - 2.4 Pull the slack adjuster off the brake camshaft.
   - 2.5 Note the location and number of any remaining spacing washers from the camshaft, and then remove them. Save them for later installation.

Installation

1. Wipe the camshaft clean of any dirt or old grease.
2. As referenced earlier, install the inner camshaft washers on the camshaft.
3. Apply a thin film of fresh chassis grease to the slack adjuster splines.
4. Install the slack adjuster on the brake camshaft.
   - 4.1 Position the slack adjuster on the camshaft with the adjuster nut on the side opposite of the brake.
   - 4.2 Install the spacing washers and snap ring on the end of the camshaft.
   - 4.3 Check the slack adjuster end play, and add washers as needed to ensure a maximum end play of 1.57 mm (0.062 inch).
   - 4.4 Place a wrench or socket over the adjusting screw and depress the locking sleeve to disengage it. Rotate the adjusting screw nut until the hole in the slack adjuster arm aligns with the yoke pin hole. Install the yoke pin and lock it with a new cotter pin.
5. If a rear-axle slack adjuster was installed, manually uncage the parking brake. For instructions, **refer to the brakes group.**
6. With the parking brakes released, continue to rotate the adjusting screw until the brakes begin to drag when the drum is turned; then, back off the adjustment until the wheel turns freely. Turn the adjusting screw nut until the locking sleeve engages it.
7. Check the slack adjuster for smooth operation.
   - 7.1 Start the engine and bring the air pressure to approximately 550 kPa (80 psi).
   - 7.2 Apply the brakes, and check that the slack adjuster rotates freely and without binding.
   - 7.3 Release the brakes, and check that the slack adjuster returns to the released position without binding.
8. Check the brake chamber stroke.
   - 8.1 Bring the air pressure to approximately 550 kPa (80 psi).
   - 8.2 With the brakes released, measure distance *A* . **See Fig. 1.**
   - 8.3 Make and hold a full brake application. Measure distance *B* . **See Fig. 1.**
   - 8.4 Determine brake chamber stroke (distance *B* minus distance *A*).

Removal and Installation

8.5 Readjust the brakes if the chamber stroke exceeds the maximum stroke. **See Table 1.**

9. Remove the chocks from the tires.

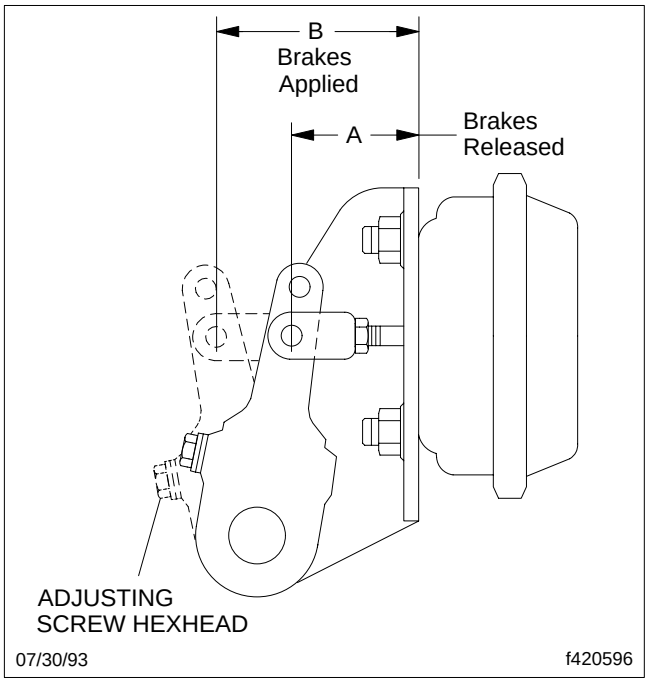

Fig. 1

Chamber Size	Maximum Chamber Stroke for Cam Brake
9	Less than 38 mm (1-1/2 inches)
12	Less than 38 mm (1-1/2 inches)
16	Less than 44 mm (1-3/4 inches)
20	Less than 44 mm (1-3/4 inches)
24	Less than 48 mm (1-7/8 inches)
24 *	Less than 51 mm (2 inches)
30	Less than 51 mm (2 inches)

* Long stroke.

Table 1, Maximum Adjusted Brake Chamber Strokes

General Description

The front and rear axle full-floating wheel hub assembly is made up of four major components: tapered wheel bearings, the wheel hub, wheel studs, and the brake drum. **See Fig. 1 and Fig. 2.**

The brake drum and lining work together as a mated friction pair, with the drum responsible for both heat absorption and dissipation. Lining performance and life largely depend on the condition of the drum and whether it can adequately absorb and dissipate heat generated by braking action.

2. Raise the vehicle until the tires clear the ground. Then place safety stands under the axle.
3. Back off the slack adjuster to release the brake shoes. For instructions, see the applicable slack adjuster section in **Group 42**.

⚠ WARNING

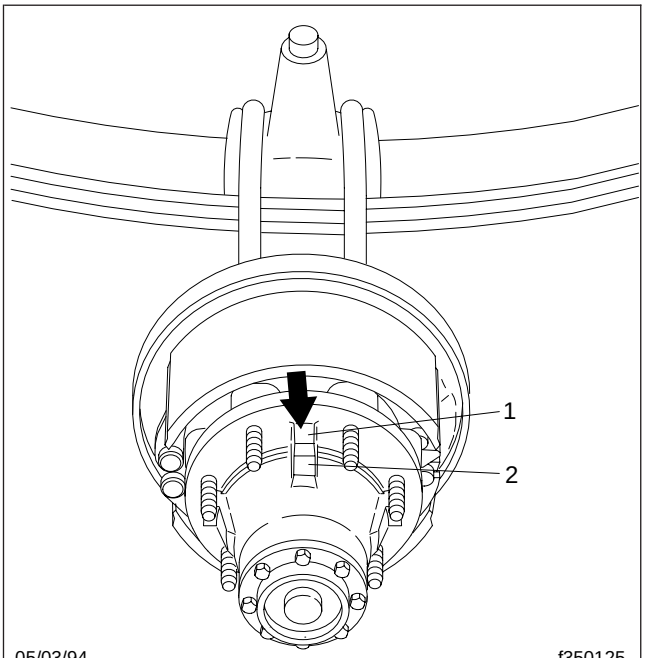
Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. Unless exposure can be reduced below legal limits, wear an air purifying respirator approved by MSHA or NIOSH at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

To reduce asbestos exposure below legal limits, apply one of the following methods: (1) An enclosed-cylinder vacuum system equipped with a High Efficiency Particulate Air (HEPA) filter; (2) A solvent spray system that keeps the asbestos-contaminated parts wet until they can be placed in a sealed and labelled plastic bag.

4. Remove wheel and tire assemblies. See **Group 40** for instructions.
5. Remove the brake drum.

   To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.
6. Inspect the drum. See **Subject 110** for instructions.

Installation



1. Install the brake drum on the wheel hub.

   1.1 On hub-piloted drums, position the brake drum on the top step of the pilot pad. One of the hub's pilot pads should be at the twelve o'clock (top center) position. See **Fig. 3**.

   IMPORTANT: If the drum is not positioned correctly, the pilot pad could be damaged when the wheel nuts are torqued.

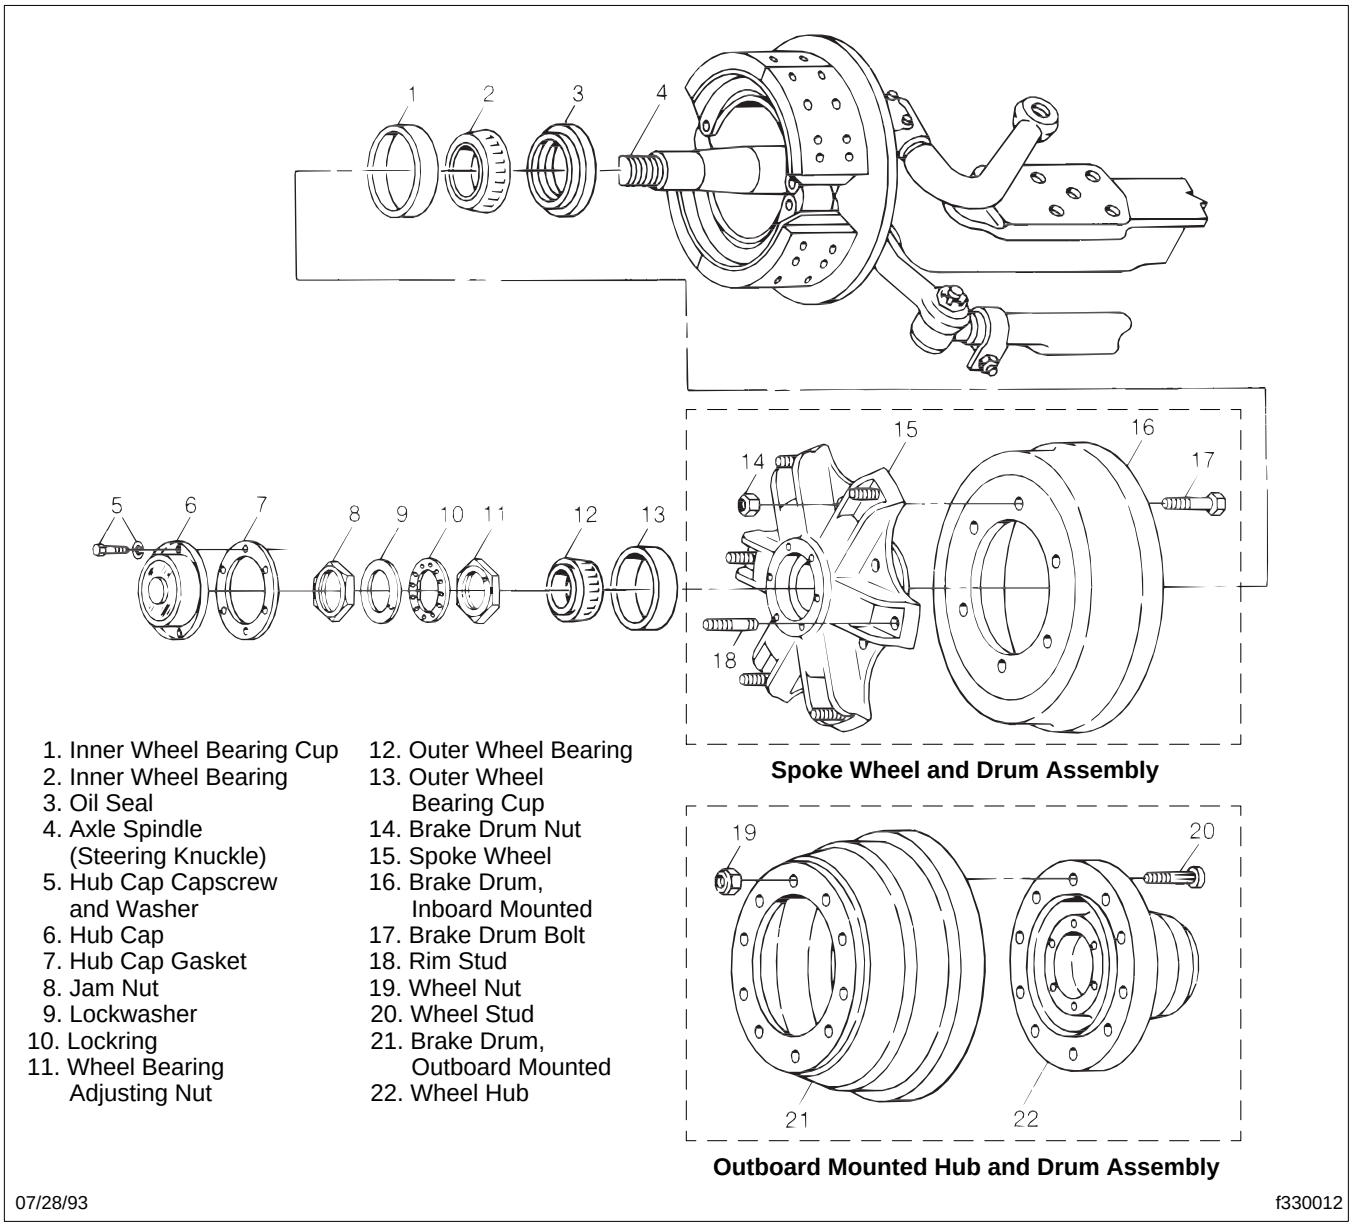
   1.2 Make sure that the pilot pads securely center the drum (space between drum and hub is equal all around the hub).

   IMPORTANT: If damage to the pads prevents the drum from centering, replace the hub. If necessary, to hold the drum in position, adjust the brakes before installing the wheels.
2. Install the wheel and tire assemblies. See **Group 40** for instructions.

NOTE: Pilot pad at 12 o'clock position

1. Drum Pilot
2. Wheel Pilot

Fig. 3, Front Axle Drum and Wheel Pilots (rear axle similar)



WARNING

If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking ability, and the hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist, could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

3. Adjust the brakes at the slack adjusters. For instructions, see Group 42 of the *Business Class Trucks Maintenance Manual*.
4. Remove the safety stands from under the axle; lower the vehicle.
5. Apply the parking brakes (if not already applied); then remove the chocks from the tires.

Inboard Mounted Drum Removal and Installation

20. Wheel Stud
21. Brake Drum, Outboard Mounted
22. Wheel Hub

Fig. 1, Typical Front Axle

1. If the front axle is being worked on, chock the rear wheels; if the rear axle is being worked on, chock the front wheels. Release the parking brakes.
2. Raise the vehicle until the tires clear the ground. Then place safety stands under the axle to be serviced. Position a jack or wheel-and-tire dolly under the tires.

Inboard Mounted Drum Removal and Installation

3. Back off the slack adjuster to release the brake shoes. For instructions, refer to the applicable slack adjuster section **in the brakes group** of this manual.
4. Remove rim and tire assemblies. Refer to the **wheels and tires group** for instructions.
5. Remove the wheel hub. Refer to the **front axle group** or the **rear axle group** for instructions.
6. Remove the brake drum nuts **(Fig. 1 and Fig. 2)** and detach the brake drum from the wheel.

WARNING

WARNING: Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

7. To minimize the possibility of creating brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag

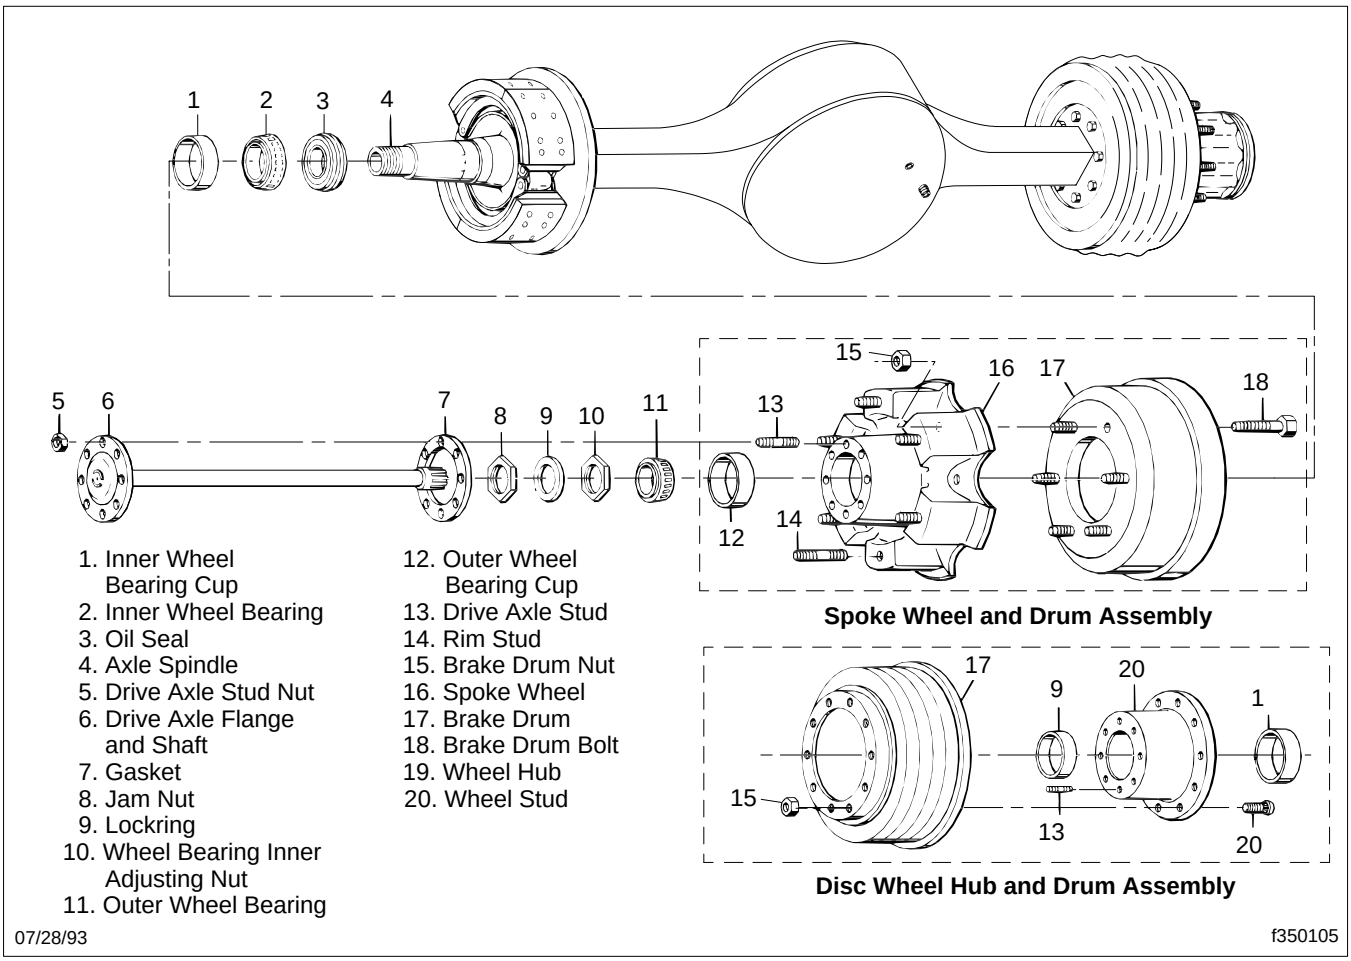

Fig. 2, Typical Drive Axle Exploded View

soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.

Installation

1. Attach the brake drum to the wheel. Install the brake drum bolts and nuts, then tighten the nuts 325 N·m (240 lbf·ft).
2. Install the hub and wheel bearings. Refer to the **front axle group** or the **rear axle group** for instructions.
3. Install the wheel and tire assembly. Refer to the **wheels and tires group** for instructions.
4. Adjust the brakes at the slack adjusters. For instructions, refer to the brakes group in the vehicle maintenance manual.
5. Remove the safety stands from under the axle; lower the vehicle.
6. Remove the chocks from under the tires.

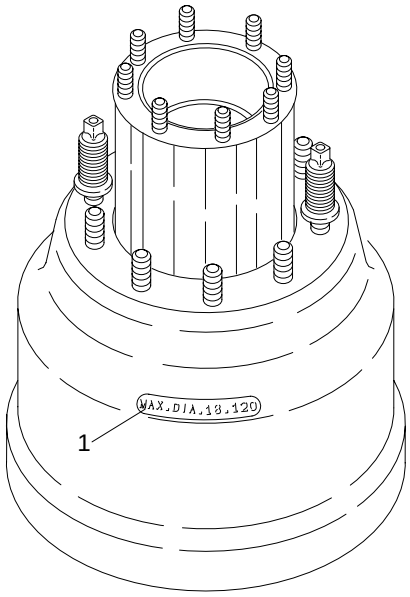
Inspection

New brake drums are purposely undersized to allow for turning, which may be needed if the drum is non-concentric when mounted on the hub. If a new drum is installed, the protective coating on the inner friction surface must first be removed with a solvent, and then rinsed with a hot water wash. Use a clean rag to remove any oily residue or metal chips from the friction surface.

If a drum must be turned or replaced, the other same-axle drum must be similarly turned or replaced to provide the same braking power on both wheels. Turned drums should not exceed the maximum allowable diameter, which is stamped on the outside surface of the drum. **Refer to Fig. 1** for a typical location of this stamp.

NOTE: Drums that have been turned should then be cleaned by using fine emery cloth followed with a hot water wash. Drums that have been renewed using emery cloth should also be cleaned with a hot water wash.

⚠ WARNING



WARNING: Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

Failure to replace drums when worn or turned to limits exceeding the maximum allowable diameter will cause drum weakness and reduced braking capacity, which can lead to distortion, higher drum temperatures, and ultimate drum breakage.

To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.

If the drums are turned or replaced, replace the brake linings. **Refer to the brakes group** for instructions.

1. Inspect the inner friction surface. If a veneered (highly glossed) or glazed surface exists, renew the drum by using 80-grit emery cloth or by turning the drums. **See Fig. 2.**

1. Maximum Diameter Stamp

07/28/93 f350012

Fig. 1

2. Inspect for heat checking, which is a form of buckling (cracking) resulting from a temperature differential in the drum wall between a relatively cool exterior and a hot friction surface. Heat checking is normal on all drums and may not reduce performance and lining life if the network of fine hairline cracks remains small. **See Fig. 3.** Examine heat checks of drums often to be sure the checks have not widened into drum weakening cracks (substantial cracks extending to the open edge of the drum). **See Fig. 4.**

   Replace the same-axle drums if substantial cracks are present, or if widening of the fine hairline cracks occurs.

Inspection

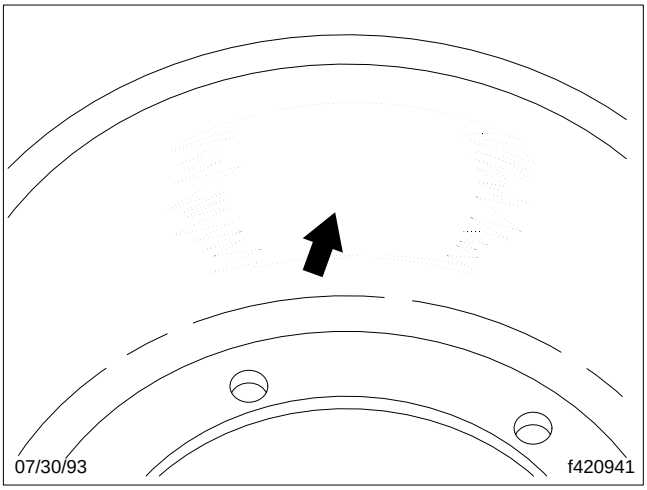


Fig. 2, Polished Drums

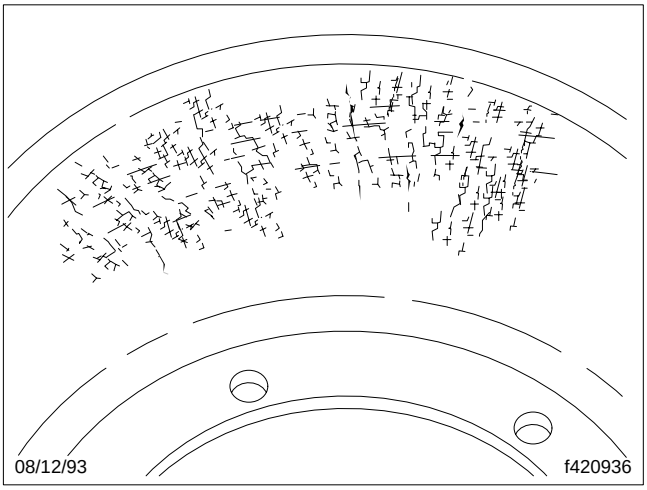

Fig. 3, Heat Checking

NOTE: If there is normal heat checking as described above, inspect the drums at least every 19 300 km (12,000 miles) thereafter. If the vehicle is not equipped with brake dust shields, inspect the drums (using a flashlight from the inboard side of the wheels) every 9700 km (6000 miles). Inspect more often under adverse operating conditions.

3. Check for a contaminated inner friction surface. If fluids are present, such as oil or grease, remove them. Locate and correct the source of the contamination. If the brake drums are contaminated with fluids, the brake linings will also be affected. Since oil-or grease-saturated linings cannot be salvaged, they must be replaced. For instructions, **refer to the brakes group.**

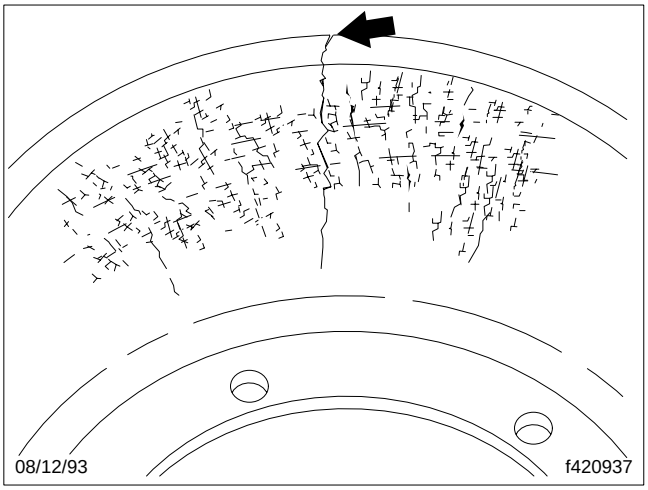

Fig. 4, Cracked Drums

WARNING

WARNING: Failure to replace fluid-contaminated brake linings could result in a partial loss of braking capacity.

4. Measure the inside diameter of the drum. If this measurement is greater than the maximum allowable diameter, replace the same-axle drums and linings. **See Fig. 5.**
5. Check for a variation in gauge readings at different points on the radius of the drum's working surface. If the variation is more than 0.25 mm (0.010 inch) at any point, the drum is out-of-round to unacceptable limits. Remachine or replace the same-axle drums. **See Fig. 5.**
6. Inspect the outside surface of the drum. Remove any accumulation of mud, dirt, or rust; foreign matter acts as an insulator, trapping heat within the drum.
7. Check for hard, slightly raised, dark-colored spots on the inner friction surface **(see Fig. 6)** or for a bluish cast on the brake parts **(see Fig 7),** both of which are caused by high temperatures. If the drums' maximum allowable diameters have not been exceeded, remachine both same-axle drums. If spots or discoloration cannot be removed, or if remachining is not possible, replace

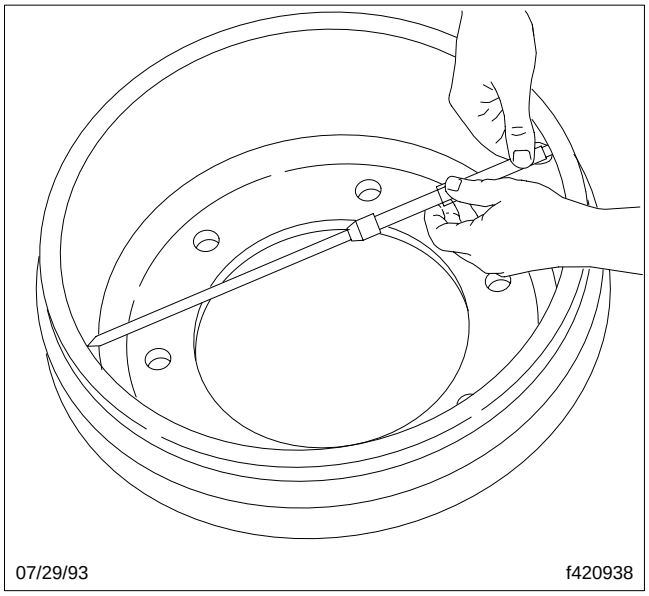

Fig. 5, Oversized Drums

the drums. Also replace the brake shoe return springs. **Refer to the brakes group** for instructions.

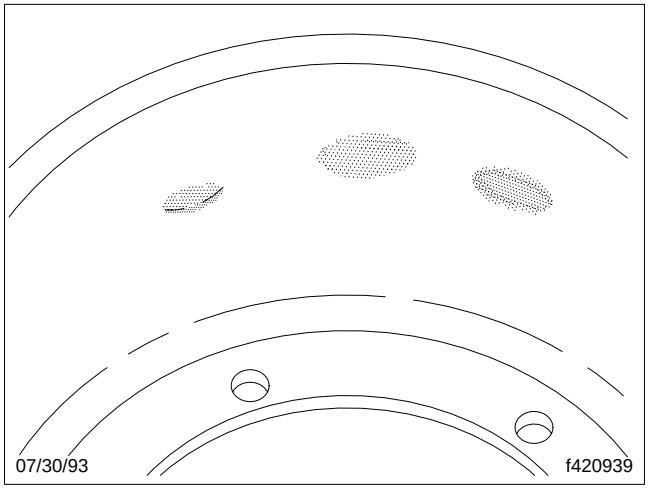

Fig. 6, Heat Spotted Drums

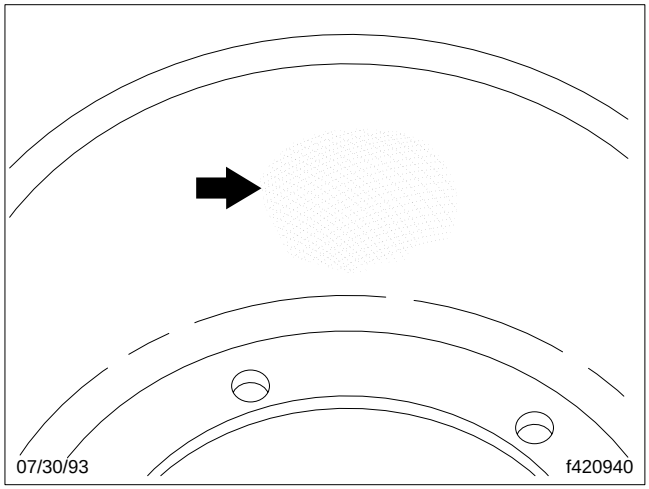

Fig. 7, Blue Drums

Specifications

This subject contains the following table:

•Fastener Torque

Description	Grade	Size	Torque N·m (lbf·ft)
Brake Drum Bolt	8	3/4-10	325 (240)

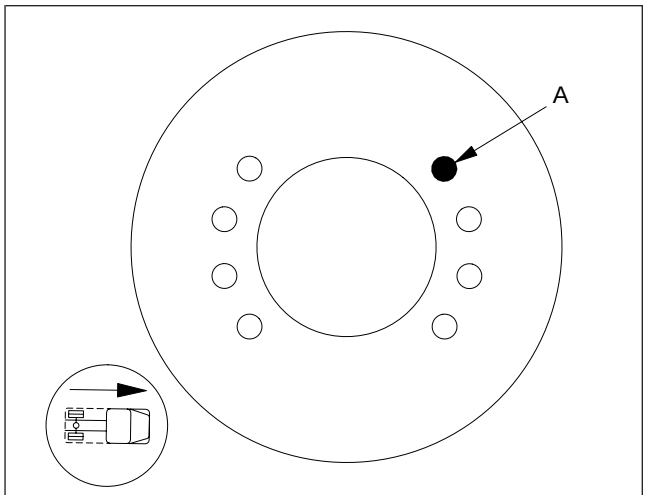

Table 1, Fastener Torque

General Description

Rockwell "Q" and "Q" Plus Series brakes are actuated by an S-type cam head, which is forged integrally with the camshaft and supported with nylon bushings. Cam pressure is applied through the cam rollers.

These brakes are used on both the front steer axle and rear axles.

Rockwell steer axles have seven holes for attaching the spider to the axle flange. There is an eighth hole left open on the brake spider, on both left and right sides of the steer axle. **See Fig. 1.** The seven holes used for attachment of the spider to the axle flange are 0.656 inch in diameter. The eighth hole is oversized at 0.687 inch in diameter.

A. Open

Fig. 1

As of March 1, 1994, Rockwell began attaching an identifying label to the web of all on-highway shoe and lining assemblies. The label is made of Mylar, and is attached with a heat-resistant adhesive. At the same time, the lining edge code changed to the new Rockwell lining designation. The new lining edge code will show the supplier lining designation and the corresponding Rockwell designation. **See Table 1.**

Vendor Code		Rockwell Designation
Abex	931–162	R301
	197	R201
	1083–7	R501
	1083–63	R401
Carlisle	E145–A	R202
	NAB–9ML	R302
	NAB10	R502
	NAB11	R402
Ferodo	NAB456	R403
	867	R203

Table 1, Edge Codes

The label will include three lines of information. **See Fig. 2.** The first line identifies the shoe as "Q PLUS" or "BRAKES" (non-Q Plus). The second line gives the new Rockwell aftermarket lining material designation. See "Rockwell Designation" in **Table 1.** The third line gives the service part number to use for replacing the shoe and lining assembly.

Principles of Operation

When the brake pedal is depressed, compressed air enters the brake chamber, causing the diaphragm to move a push rod assembly.

The push rod, which is connected to a slack adjuster, turns the slack adjuster and brake camshaft. As the camshaft turns, the S-head, which is between the brake shoe rollers, forces the brake shoes against the brake drum, and braking occurs.

When the brakes are released and air is exhausted from the brake chamber, the actuator return spring (within the brake chamber) and the brake shoe return spring, return the camshaft, brake shoes, slack adjuster, and the push rod to their released positions.

General Description and Principles of Operation

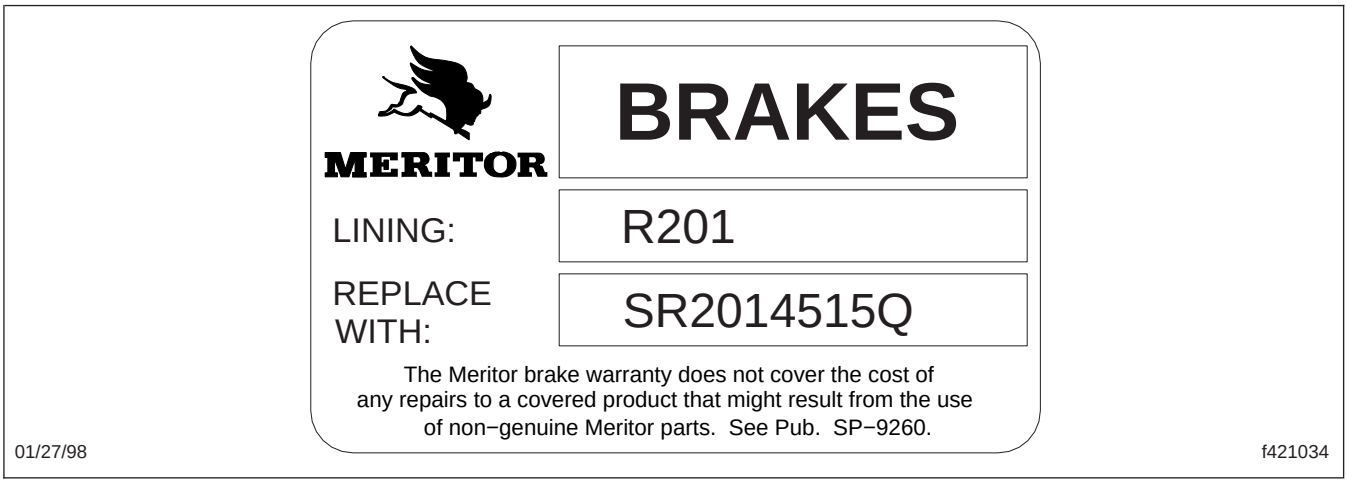

Fig. 2, Rockwell Brake Shoe Lable, Example

Safety Precautions

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Exposure to airborne brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency particulate air (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system isn't available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry.

⚠ WARNING

WARNING: Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.

Brake Shoe Removal and Installation

⚠ WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Removal

1. Park the vehicle on a level surface, apply the parking brakes, and chock the tires.
2. Raise the front or rear axle, then place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
3. Remove the wheels and brake drums. For instructions, refer to the **front axle group** or the **rear axle group** in this manual.

⚠ CAUTION

CAUTION: Before you back off automatic slack adjusters, refer to the brakes group in this manual, or to the manufacturer's service information for instructions. Failure to do so could damage the slack adjusters.

4. Back off the slack adjusters.

   On manual slack adjusters, back off each until the cam is in the start or released position.

   On automatic slack adjusters, refer to the brake section in this manual for instructions on backing off the slack adjuster.

5. If equipped with 15-inch "Q" Series brakes, go to step 6.

   If equipped with "Q" Plus Series brakes, or 16-1/2 inch "Q" Series brakes, remove the brake shoes.

   5.1 Push down on the bottom brake shoe, then pull on the roller retaining clip to remove the bottom cam roller. **See Fig. 1.**

   5.2 Lift the top brake shoe and pull on the roller retaining clip to remove the top cam roller.

   5.3 Lift the bottom shoe to release tension on the brake return spring. Remove the spring. **See Fig. 2.**

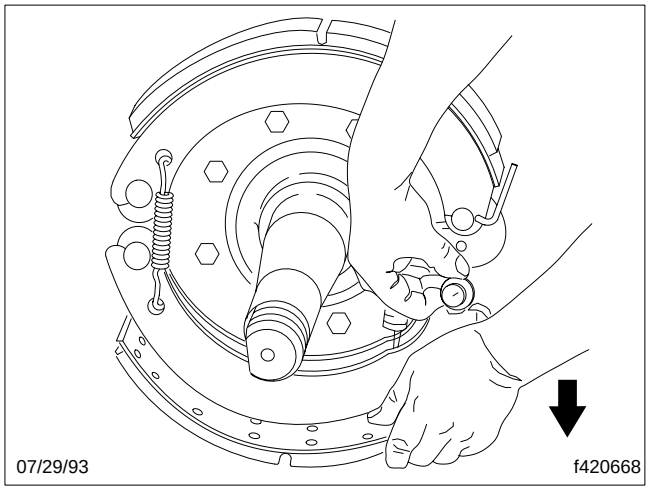

Fig. 1

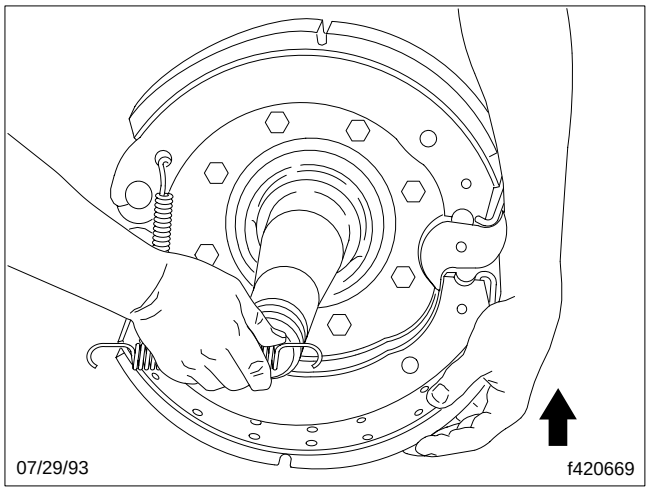

Fig. 2

   5.4 Rotate the bottom shoe to release tension on the two retaining springs. Remove the springs and the brake shoes. **See Fig. 3.**

6. If equipped with 15-inch "Q" Series brakes, remove the brake shoes.

   6.1 Push down on the bottom brake shoe, then remove the bottom cam roller.

   6.2 Lift the top brake shoe and remove the top cam roller.

Brake Shoe Removal and Installation

6.3 Remove the brake shoe return spring.

6.4 Rotate the bottom shoe to release tension on the retaining spring. Remove the spring and the brake shoes.

7. Inspect the brake shoes and linings for wear or damage. **Refer to Subject 120.**

Installation

IMPORTANT: For best brake performance, don't mix "Q" and "Q" Plus Series brakes. Use the same brake series on the entire vehicle.

1. Apply a thin film of a temperature resistant grease (Rockwell 0-616, or an equivalent) on the anchor pins where they touch the brake shoes. Also, apply a multipurpose chassis grease (Rockwell 0-617-A or 0-617-B, or an equivalent) on the retainer clips, spider, and shoe rollers where they touch the brake shoes.

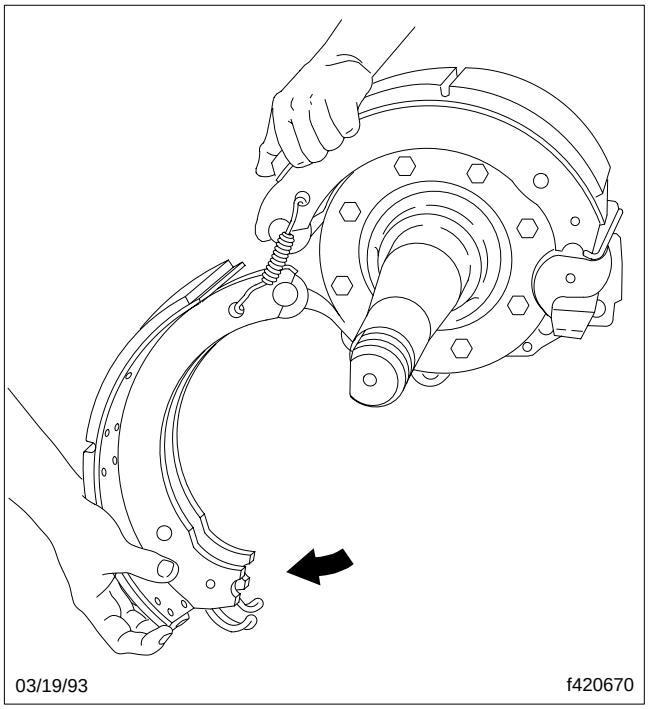

Fig. 3

IMPORTANT: Don't apply any grease on the outer diameter of the roller that touches the cam head.

2. Go to the step for installing the brake shoes on 15-inch "Q" Series brakes, if so equipped.

   If equipped with "Q" Plus Series brakes, or 16-1/2 inch "Q" Series brakes, install the brake shoes.

   2.1 Place the upper brake shoe in position on the top anchor pin. Hold the lower brake shoe on the bottom anchor pin and attach two new brake shoe retaining springs. **See Fig. 4.**

   2.2 Turn the lower brake shoe forward and attach a new brake shoe return spring. **See Fig. 5.**

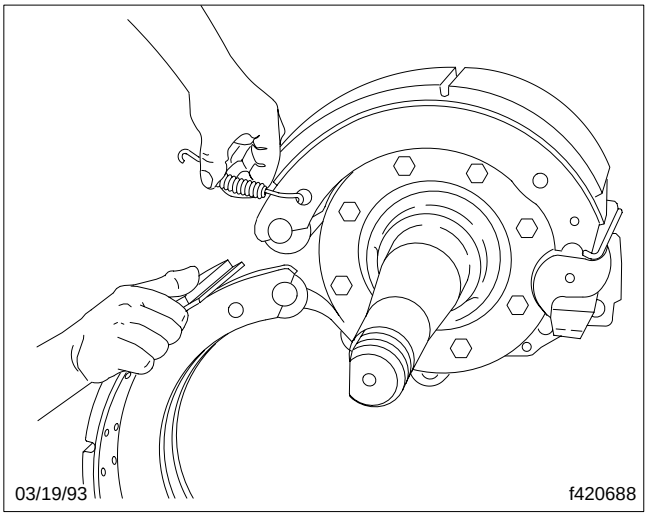

Fig. 4

   2.3 Pull each brake shoe away from the cam to allow enough space to install the cam rollers and retainers. Press the ears of the retainer together to permit the retainer to fit between the brake shoe webs. **See Fig. 6.**

   2.4 Push the retainer into the brake shoe until the ears lock in the holes in the shoe webs. **See Fig. 7.**

3. If equipped with 15-inch "Q" Series brakes, install the brake shoes.

   3.1 Install the retainer spring on the shoes and install the shoes on the anchor pins. **See Fig. 8.** Hold the bottom shoe in position and install the return spring.

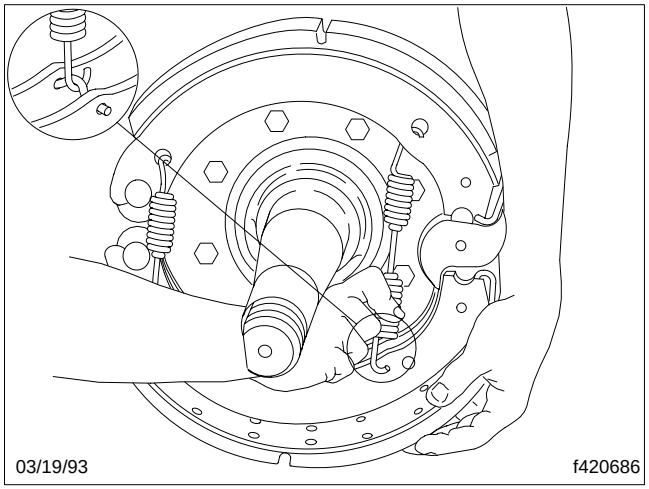

Fig. 5

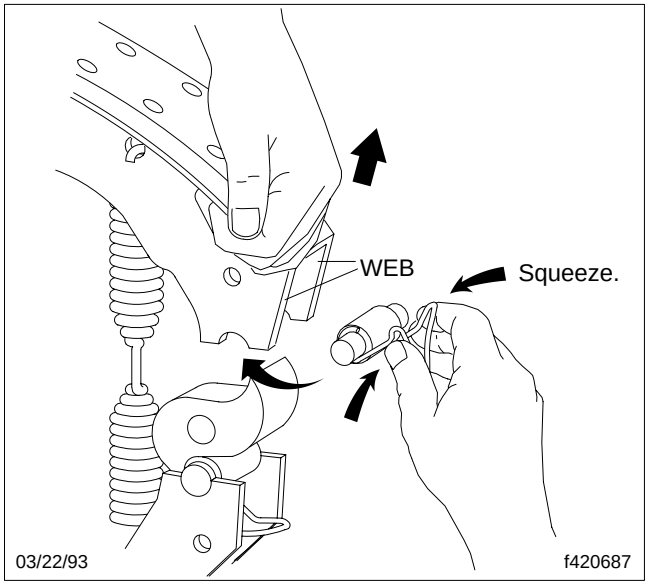

Fig. 6

3.2 Pull each shoe away from the cam to allow enough space, then install the cam rollers.

4. Install the wheels and brake drums. For instructions, refer to the **front axle group** or the **rear axle group** in this manual.

5. Adjust the brakes at the slack adjusters. For instructions, **refer to Subject 125.**

6. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

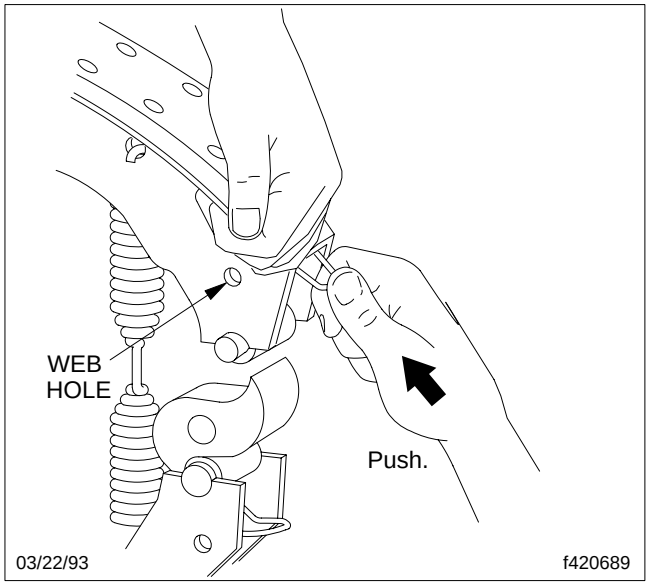

Fig. 7

⚠ WARNING

WARNING: Don't operate the vehicle until you have adjusted the brakes and checked for their proper operation. Failure to do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

7. Check for proper brake operation.

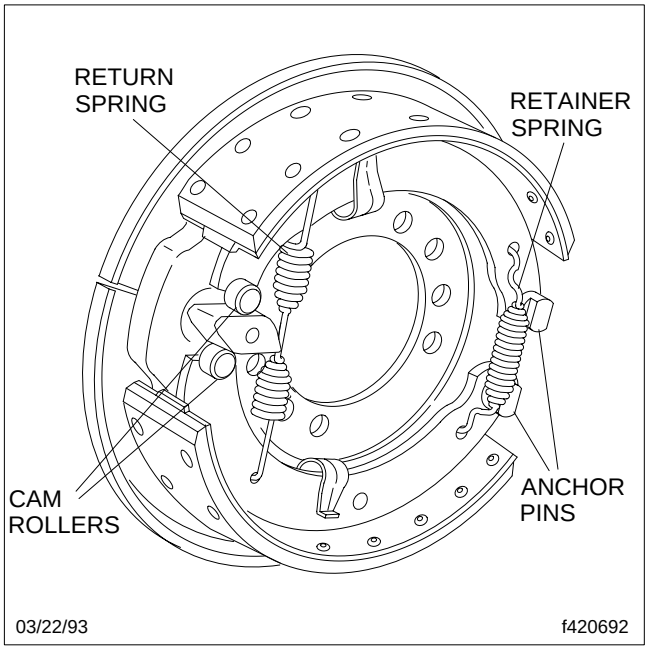
7.1 To ensure that the braking system is working correctly, make ten 60 to 30 km/h (40 to 20 mph) snubs to seat the linings.

7.2 Make ten stops from 30 km/h (20 mph) at 50 percent air pressure.

7.3 Make a full-pressure stop from 30 km/h (20 mph).

7.4 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others shows a lack of braking effort on those wheels.

Brake Shoe Removal and Installation



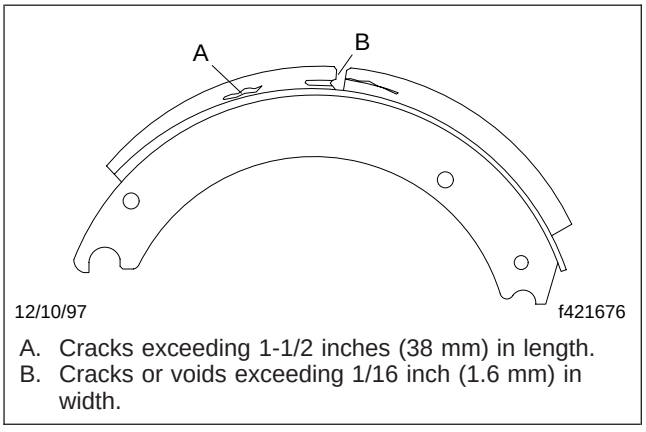


Fig. 8

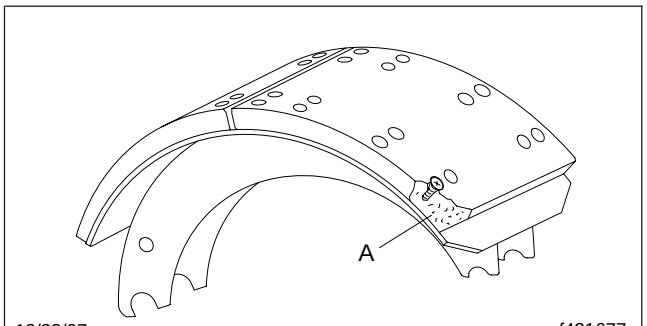
⚠ WARNING

Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.



Inspection

1. Remove the brake shoes, using the instructions in **Subject 110**.
2. Check the linings.
   - 2.1 If the linings are grease-or oil-soaked, cracked, or worn to less than 1/4-inch (6.4-mm) thickness at any point, replace them.
   - 2.2 Replace the linings if the lining surface is closer than 1/32 inch (0.8 mm) to any rivet head.
   - 2.3 The lining is considered worn-out and the vehicle should not be driven if:
     - Cracks on the lining surface exceed 1/16 inch (1.6 mm);
     - The lining edge shows cracks or voids over 1/16 inch (1.6 mm) in width and 1-1/2 inches (38 mm) in length. See **Fig. 1**;
     - Portions of the lining are missing exposing a rivet when viewed from the edge. See **Fig. 2**;

A. Cracks exceeding 1-1/2 inches (38 mm) in length.
B. Cracks or voids exceeding 1/16 inch (1.6 mm) in width.

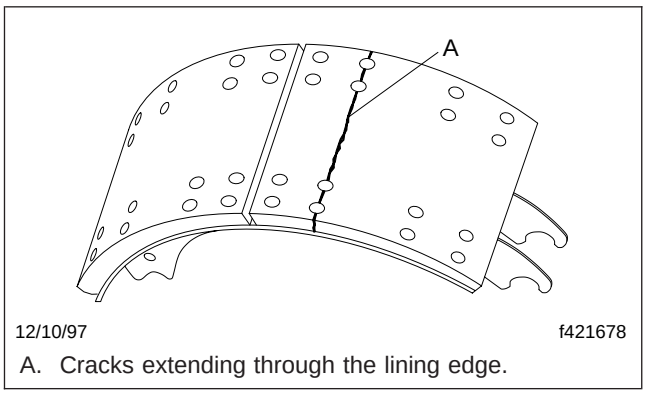


Fig. 1, Cracks and Voids

A. Exposed fastening device.

Fig. 2, Portions of the Brake Lining Missing

     - Cracks extend across the lining face and through the lining edge, or the lining is loose on the shoe. See **Fig. 3**.
   - 2.4 The vehicle is still operational but linings should be replaced as soon as possible if:
     - Horizontal or vertical cracks in the lining edge exhibit no loss of material and do not exceed 1/16 inch (1.6 mm) in width or 1-1/2 inch (38 mm) in length. See **Fig. 4**;
     - Corner portions of the lining are missing with no fastener exposed. See **Fig. 5**;
     - Surface cracks extend from hole to hole or if there is scoring and contamination from road debris. See **Fig. 6**.

A. Cracks extending through the lining edge.

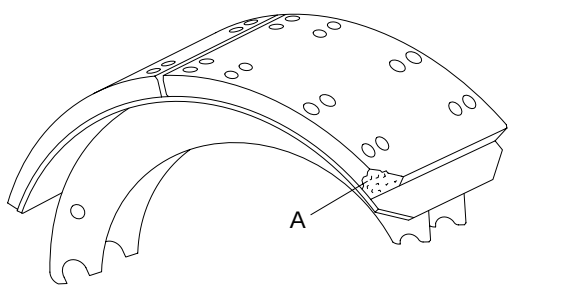

Fig. 3, Cracks in the Brake Lining

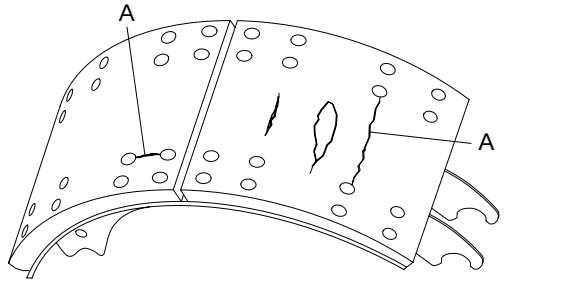
Brake Shoe and Lining Inspection



A. Cracks not exceeding 1-1/2 inches (38 mm) in length or 1/16 Inch (1.6 mm) in width.

Fig. 4, Cracks and Voids

A. Corner segment missing with no fastener exposed.

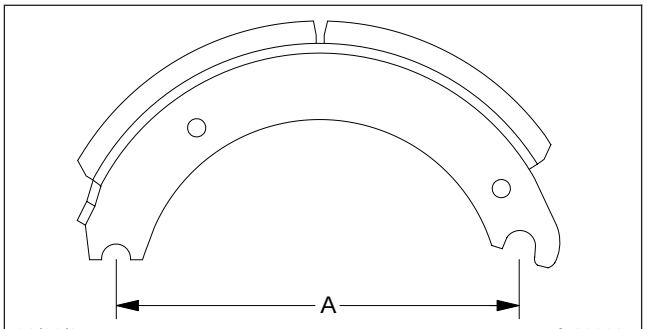


Fig. 5, Portions of the Brake Lining Missing

A. Cracks extending from hole to hole.

Fig. 6, Cracks in the Brake Lining

3. Check the shoes for bent or cracked webs or tables, broken welds, loose or out-of-round rivet or bolt holes. Replace the shoes if any of these conditions exist.
4. Check the anchor pin for looseness and camshaft roller recesses in the shoe webs for visible wear. Replace the shoe if needed.
5. Check the shoe span. Measure the distances between the centerlines of the anchor pin and the camshaft roller pin recesses in the shoe web. If the measurement is more than 12-7/8 inches (327 mm), replace the shoe. See **Fig. 7**.

A. 12-7/8 inches (327 mm)

Fig. 7, Measuring the Shoe Span

Adjustment

ROCKWELL AUTOMATIC SLACK ADJUSTER

1. Check the free-stroke.

   1.1 With the brakes fully released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 1**, Ref. *A* .

   1.2 Use a pry bar to move the slack adjuster and apply the brakes. Again, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 1**, Ref. *A* .

   1.3 The difference between the two measurements is the initial free-stroke, and sets the clearance between the linings and the drum.

   1.4 The free-stroke must be 16 to 19 mm (5/8 to 3/4 inch);

   If the free-stroke is correct, go to the step for checking brake chamber stroke.

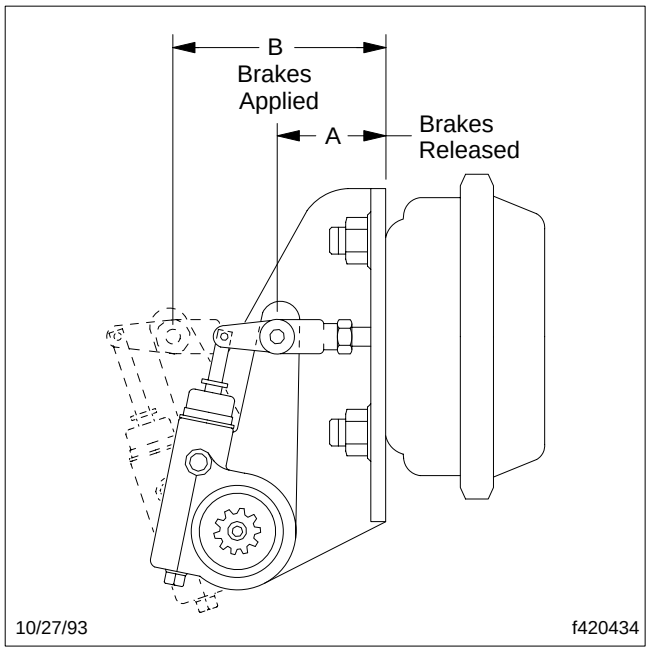

Fig. 1

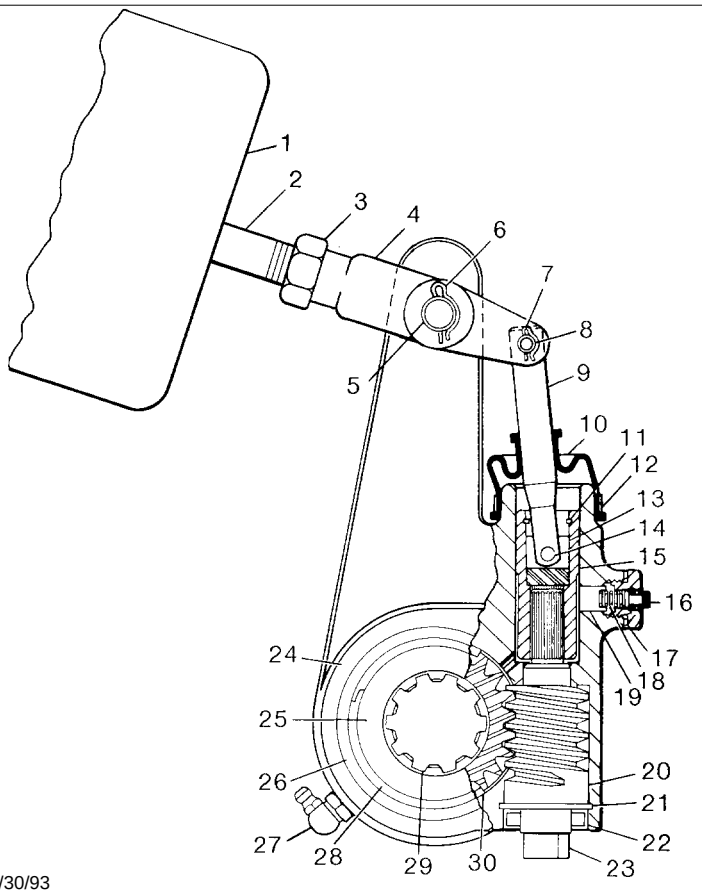
   1.5 If the free-stroke is incorrect, remove the pressure relief capscrew (**Fig. 2**, Ref. 16), spring (Ref. 18), and pawl assembly (Ref. 19) from the slack adjuster housing. If equipped with a pull-pawl assembly **(Fig. 3),** carefully insert a screwdriver and raise the relief cap about 3.2 mm (1/8 inch).

⚠ CAUTION

CAUTION: Before turning the adjusting nut, remove the pressure relief capscrew, spring, and pawl assembly. If equipped with a pull-pawl assembly, raise the relief cap about 3.2 mm (1/8 inch). Failure to do so could strip the teeth on the pawl.

   1.6 Turn the adjusting nut 1/8 turn, **as shown in Fig. 4 .** Measure the stroke again, and adjust until it is correct.



2. Check for correct brake chamber stroke.

   2.1 With the brakes fully released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 1** , Ref. *A* .

   2.2 Build air pressure to 689 kPa (100 psi). Shut down the engine. Fully apply the brakes, then measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 1** , Ref. *B* . The difference between the measurements is the brake chamber stroke.

   2.3 The brake chamber stroke must be less than the measurements shown in **Table 1.** If the brake chamber stroke is incorrect, remove the pressure relief capscrew **(Fig. 2** , Ref. 16), spring (Ref. 18), and pawl assembly (Ref. 19) from the slack adjuster housing. If equipped with a pull-pawl assembly **(Fig. 3),** carefully insert a screwdriver and raise the relief cap about 3.2 mm (1/8 inch).

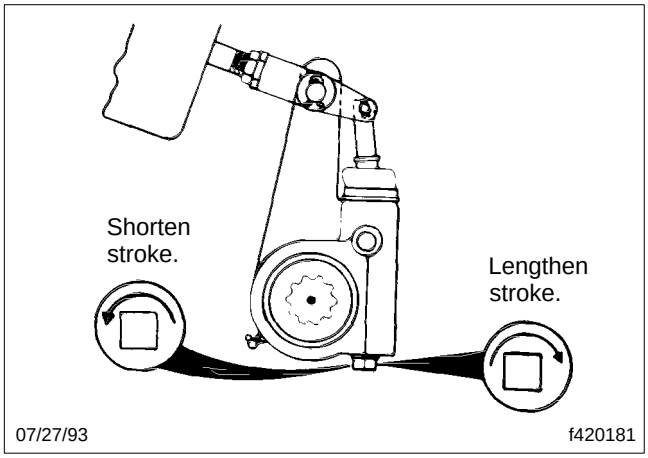

Fig. 4

Chamber Size	Stroke mm (inch)

9, 12	Less than 35 (1-3/8)
16, 20, 24	Less than 44 (1-3/4)
24 *, 30	Less than 51 (2)
36	Less than 57 (2-1/4)

* Long Stroke

Table 1, Maximum Adjusted Brake Chamber Stroke

CAUTION

CAUTION: Before turning the adjusting nut, remove the pressure relief capscrew, spring, and pawl assembly. If equipped with a pull-pawl assembly, raise the relief cap about 3.2 mm (1/8 inch). Failure to do so could strip the teeth on the pawl.

2.4 Turn the adjusting nut 1/8 turn, **as shown in Fig. 4 .** Measure the stroke again, and adjust until correct.

CAUTION

CAUTION: Don't make the adjusted chamber stroke too short. The free-stroke must not be less than 16 to 19 mm (5/8 to 3/4 inch). If the chamber stroke is too short, the linings can drag and damage the brake.

If the stroke varies or remains greater than the specified range, check the brake components. For instructions, refer to Subject 140.

2.5 If necessary, replace the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

2.6 If removed, install the pawl assembly, spring, and the pressure relief capscrew. Tighten the capscrew 20 to 27 N·m (15 to 20 lbf·ft). Or, remove the screwdriver from the pull-pawl assembly (if equipped).

HALDEX AUTOMATIC SLACK ADJUSTER

1. Turn the adjusting hexnut clockwise until the brake lining meets the brake drum, then back off counterclockwise 3/4 turn. **Refer to Fig. 5 .** There will be a ratcheting sound.
2. Measure the distance from the bottom of the air chamber to the far side of the clevis-pin hole (**Fig. 6** , Ref. *A*). Record the exact distance as measurement A. Apply and hold a 551 kPa (80 psi) brake application. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole (**Fig. 6** , Ref. *B*). Record the exact distance as measurement B. Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 2 .**

   If the stroke varies or remains greater than the specified range, check the brake components. For instructions, **refer to Subject 140.** If necessary, replace the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

Chamber Size	Stroke mm (inch)
16	19 to 44 (3/4 to 1-3/4)
20	25 to 44 (1 to 1-/34)
24	25 to 48 (1 to 1-7/8)
30	38 to 51 (1-1/2 to 2)

Table 2, Maximum Adjusted Brake Chamber Strokes With Haldex Automatic Slack Adjusters

Brake Adjustment

BENDIX MANUAL SLACK

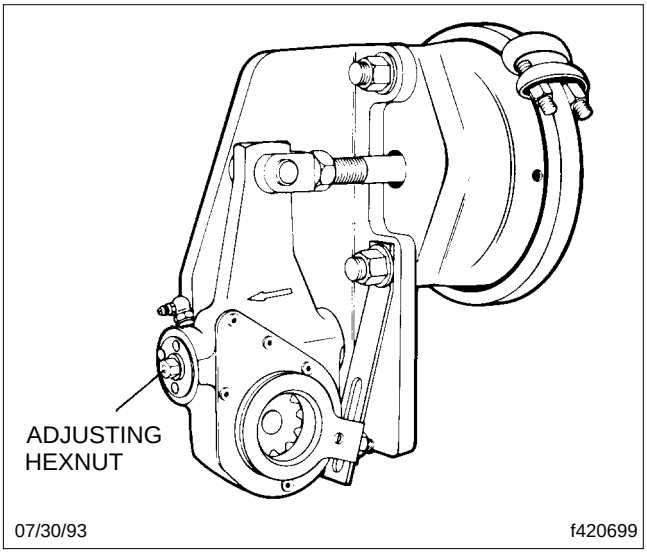

Fig. 5

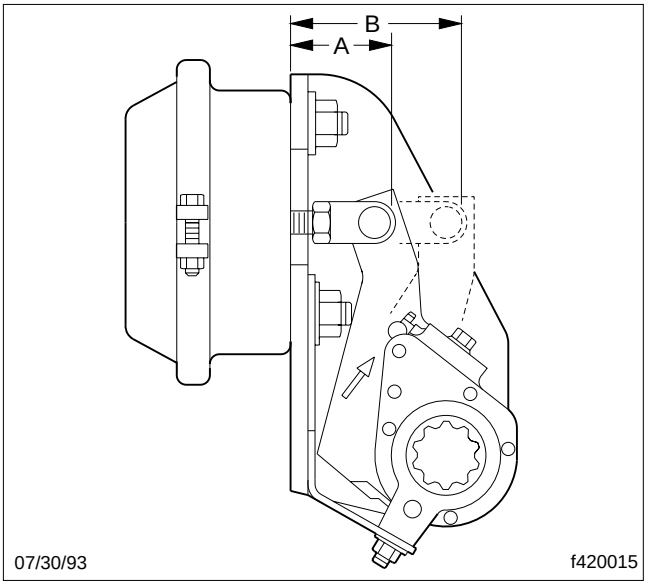

Fig. 6, Brake Stroke Check, Haldex (SAB) Automatic Slack Adjuster

ADJUSTER

1. With the parking brakes released, rotate the adjusting screw until the brakes begin to drag when the drum is turned; then, back off the adjustment until the wheel turns freely. Turn the adjusting screw nut until the locking sleeve engages it.
2. Measure the distance from the bottom of the brake chamber to the centerline of the clevis (**Fig. 7** , Ref. *A*). Record the exact distance as measurement A. Apply and hold a 551 kPa (80 psi) brake application. Measure the distance from the bottom of the brake chamber to the centerline of the clevis-pin (**Fig. 7** , Ref. *B*). Record the exact distance as measurement B. Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 3 .**
3. If the applied stroke equals or exceeds the maximum applied stroke, adjust the brakes.

   3.1 Wipe clean the adjusting screw hexhead. **Refer to Fig. 7.** Position a wrench or socket over the adjusting screw hexhead.

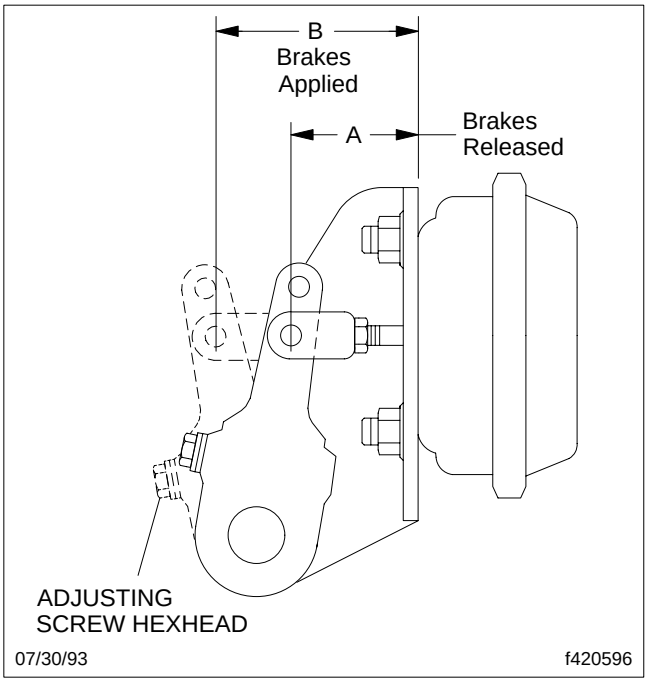

Fig. 7

Chamber Size	Stroke mm (inch)
9, 12	Less than 38 (1-1/2)
16, 20	Less than 44 (1-3/4)
24	Less than 48 (1-7/8)
24 *, 30	Less than 51 (2)

36	Less than 57 (2-1/4)

* Long Stroke

Table 3, Maximum Adjusted Brake Chamber Strokes With Bendix Manual Slack Adjusters

IMPORTANT: On slack adjusters equipped with an adjusting screw locking sleeve, wipe clean the locking sleeve area, and depress the locking sleeve when positioning the wrench or socket over the adjusting screw. Do not try to turn the adjusting screw without fully depressing the locking sleeve.

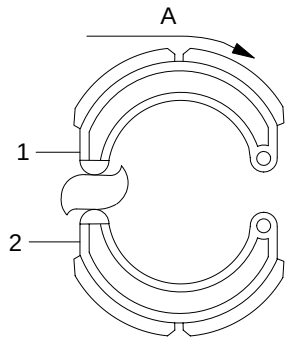
3.2 Turn the adjusting screw until it is tight; then, back off the adjustment until the drum is free. Normally, the adjusting screw will need to be backed off 2 or 3 clicks.

3.3 To see if the drum is free, strike the brake drum with a steel tool and listen for a clear ringing sound. If a dull thud is heard, the brake is dragging.

IMPORTANT: Checking the brake adjustment when the wheel is off the ground may be unreliable. Looseness or wear anywhere in the wheel bearings will cause the drum to be misaligned while the wheel is off the ground. Check the brake adjustment with the wheel on the ground.

On slack adjusters equipped with an adjusting screw locking sleeve, make sure that the locking sleeve is engaged around the adjusting screw hexhead after adjustment, thus locking the adjusting screw in place.

⚠ WARNING

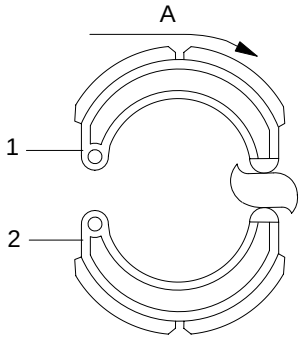


WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Replacement

IMPORTANT: For the best brake performance, don't mix brake linings between axles. When relining brake shoes, both wheel ends of each axle must have the same linings. On tandem axles, all four wheel ends must also have the same linings. However, it is not necessary for the steering axle brakes to have the same linings as the rear drive axle brakes. Also, when the minimum thickness is reached for any of the brake linings on an axle, reline both brakes on that axle at the same time.

Combination linings with different friction ratings for the primary and secondary shoes are often used. When combination linings are used, install the forward blocks on the primary shoe (following the rotation of the drum, the first shoe after passing the cam or wheel cylinder is the primary shoe).



If the cam is behind the axle, the top shoe is the primary and the lower shoe is the secondary shoe. **See Fig. 1.** If the cam is in front of the axle, the lower shoe is the primary shoe. **See Fig. 2.**

09/27/94 f420162a

1. Primary Shoe
2. Secondary Shoe

Fig. 1, Camshaft Behind Axle

09/27/94 f420683a

A. Right wheel rotation
1. Secondary Shoe
2. Primary Shoe

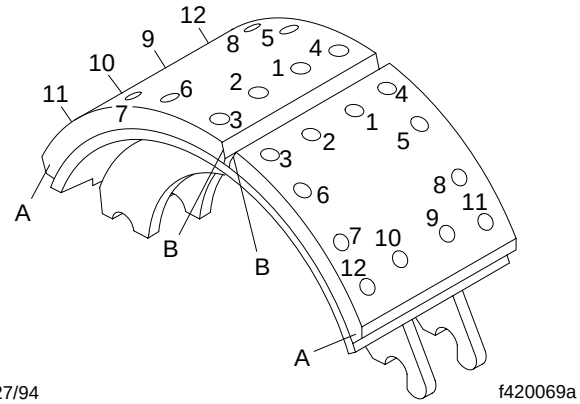
Fig. 2, Camshaft Ahead of Axle

Replacement Using Rivets

With the brake shoe removed, do the following:

1. Using a suitable riveting mandrel, push out the old rivets.

⚠ CAUTION



CAUTION: Drilling out rivets or cutting off rivet heads with a chisel can cause the rivet hole to become out-of-round. This could damage the brake shoe.

2. Clean the shoe table. For instructions, refer to **Subject 140**.
3. Align the brake shoe and lining rivet holes. Using a C-clamp, clamp the lining to the brake shoe.
4. Insert the correct sized rivets into all holes and threads, and temporarily hold them in place with masking tape.

IMPORTANT: Use rivets that have the correct material, shank diameter, length, head size, and shape. Use tubular rivets that are 1/4-inch diameter by 9/16-inch long, SAE no. 10, made of plated steel or brass.

5. Begin riveting at the center of each edge of the shoe and lining, and work toward each end. **See Fig. 3.**
6. Check for a close fit between the lining and shoe table.

Brake Shoe Lining Replacement

A. Toe
B. Heel

Fig. 3, Rivet or Bolt Attachment Sequence

Try to insert a 0.25-mm (0.010-inch) feeler gauge between the lining and shoe table along the edges. **See Fig. 4**, Ref. A. It should not be possible to insert the feeler gauge anywhere along the edge, except at each end beyond the last row of rivets. **See Fig. 5**, Ref. A. A larger clearance, up to 0.64 mm (0.025 inch), may exist in these areas.

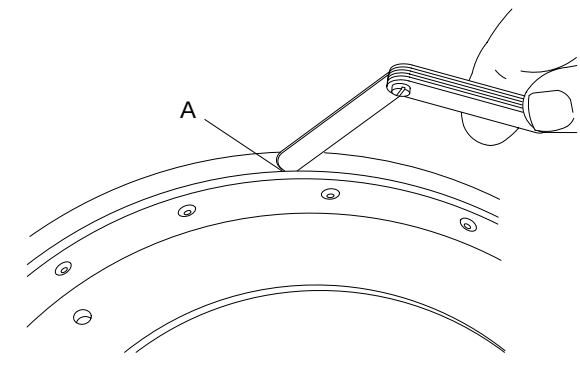


Fig. 4

7. Circle grind the brake lining to obtain the correct lining-to-drum contact. With the cam in the full-release position, the new brake linings must be ground 1.8 mm (0.070 inch) less than the drum diameter. The cam must be adjusted and the lining ground until there is an 80 percent lining-to-drum contact, which must be continuous and in the center of the lining.

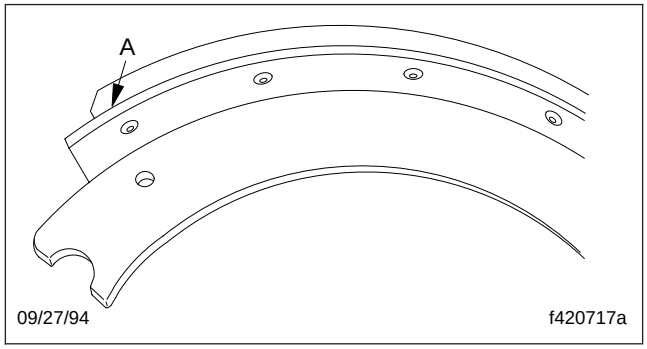

Fig. 5

Replacement Using Bolts

1. Clean the shoe table. For instructions, refer to **Subject 140**.
2. Align the brake shoe and lining bolt holes. Using a C-clamp, clamp the lining to the brake shoe.
3. Insert the correct sized bolts, and new lockwashers, into all holes and threads. Loosely install the nuts.
4. Tighten the nuts as follows in the sequence **shown in Fig. 3**: on 3/8-inch brass bolts 24 to 31 N·m (18 to 23 lbf·ft); on 1/4-inch brass bolts 900 to 1120 N·cm (80 to 100 lbf·in).
5. Circle grind the brake lining to obtain the correct lining-to-drum contact. With the cam in the full-release position, the new brake linings must be ground 1.8 mm (0.070 inch) less than the drum diameter. The cam must be adjusted and the lining ground until there is an 80 percent lining-to-drum contact, which must be continuous and in the center of the lining.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

Disassembly and Inspection

(See Fig. 1)

⚠ WARNING

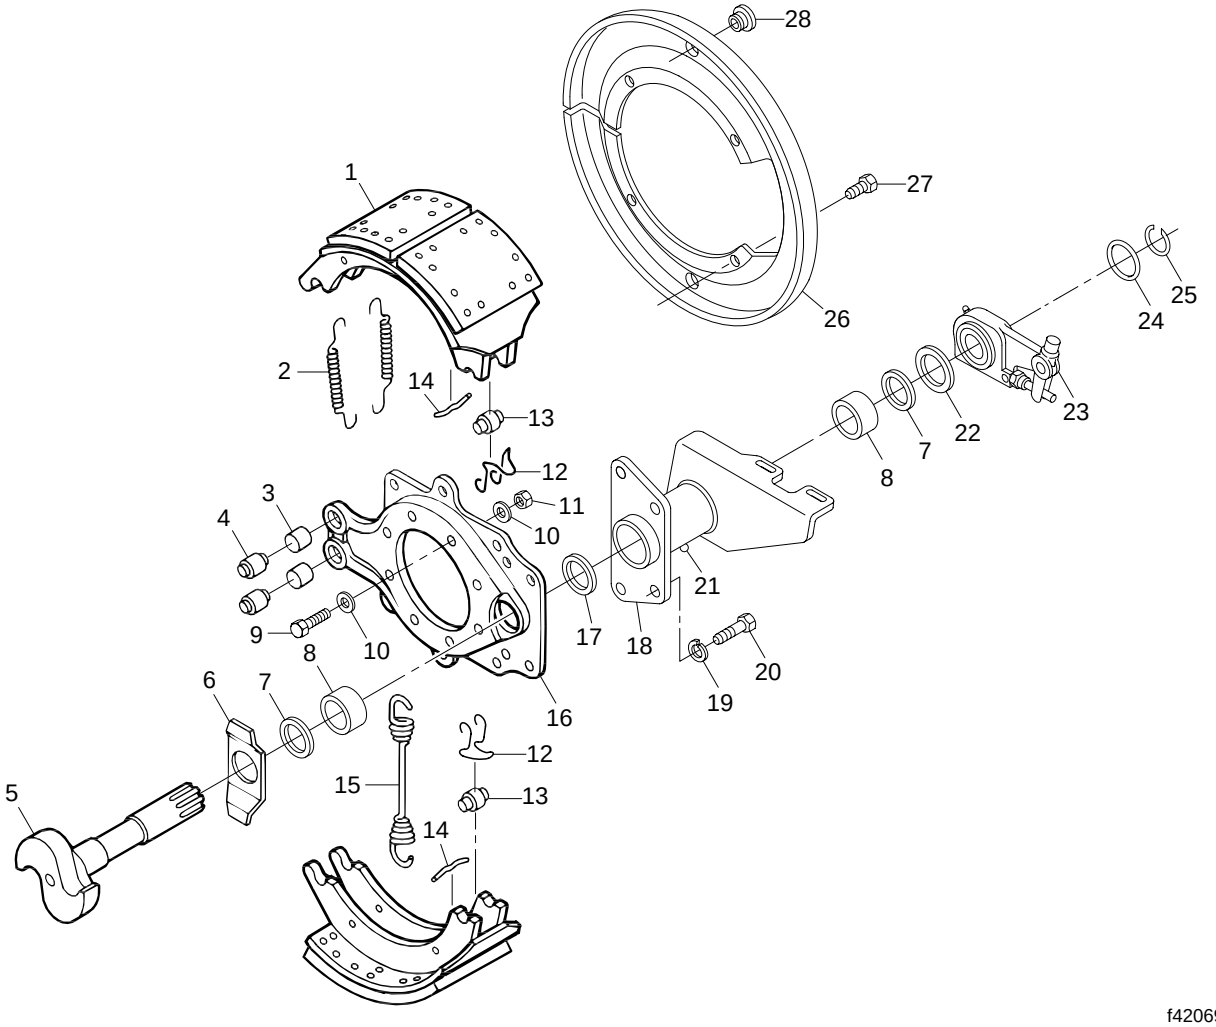
WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Check the drum for cracks, heat-checks, glazing, grooving, and run-out. **See Fig. 2.** Measure the drum diameter. Replace the drum if it exceeds the maximum diameter stamped on it. Replace cracked drums. Some drums that are glazed, grooved, or out-of-round can be repaired. For detailed instructions, refer to **Group 33** or **Group 35** in this manual.
2. Disconnect the slack adjuster from the push rod clevis. For manual slack adjusters, remove the cotter pin and clevis pin from the brake chamber push rod clevis. For automatic slack adjusters, refer elsewhere in this group, or to the slack adjuster manufacturer's service information for instructions.
3. With the brake shoes removed, use a dial indicator to measure the up-and-down and side-to-side end play of the camshaft. Replace the bushings if there is more than 0.8 mm (0.030 inch) of movement.
4. Remove the slack adjuster.
   - 4.1 For automatic slack adjusters, refer elsewhere in this group, or to the manufacturer's service information for instructions.
   - 4.2 For manual slack adjusters, while depressing the locking sleeve, turn the adjuster nut until the slack adjuster is clear of the brake chamber push rod clevis. Remove the lockring and the outer spacing washers from the camshaft. Using a suitable puller, remove the slack adjuster.

⚠ CAUTION

CAUTION: Don't hammer on the slack adjuster to remove it. Damage to the adjuster or camshaft spline may result.

5. Check the slack adjuster for damage and for binding.
   - 5.1 Check the slack adjuster clevis for cracks or bushing wear. Check the splines for chipped teeth and deformation. Replace as needed.
   - 5.2 Depress the locking sleeve, and turn the adjuster nut with a wrench at least one turn in each direction. If there is binding, or if excessive force is needed to turn the slack adjuster, replace it. For instructions, refer elsewhere in this group



IMPORTANT: If any slack adjuster problem is found, repair or replace the unit, depending on the manufacturer's recommendations.

6. Remove the camshaft by grasping its head and pulling the camshaft outboard.
7. Check the camshaft spline end for cracks, or worn or deformed splines. Replace the camshaft if damaged.
8. Check the camshaft bushing journals for wear or corrosion. Replace the camshaft if it is worn or if roughness is felt in the journal area.
9. Inspect the camshaft head for brinelling, cracking, or flat spots. Replace the camshaft if a ridge can be felt between the worn area and the cam head surface.
10. Remove the brake chamber stud nuts and lockwashers that attach the brake chamber to the camshaft support bracket.

    Check the chamber for a cracked housing, bent push rod, loose clamp ring, loose air fitting, air leaks, or clogged vent holes. Repair or replace brake chamber parts as needed.
11. Remove and inspect the camshaft support bracket. Remove and discard its gasket.

    Check the bracket for a bent, broken or cracked arm, and cracked welds. Replace the bracket if any of these conditions exist.
12. Remove and inspect the old bushing and the grease seal.
    - 12.1 Check the camshaft bushing for wear. The inner surface must be smooth; if rough or abrasive, replace the bushing.

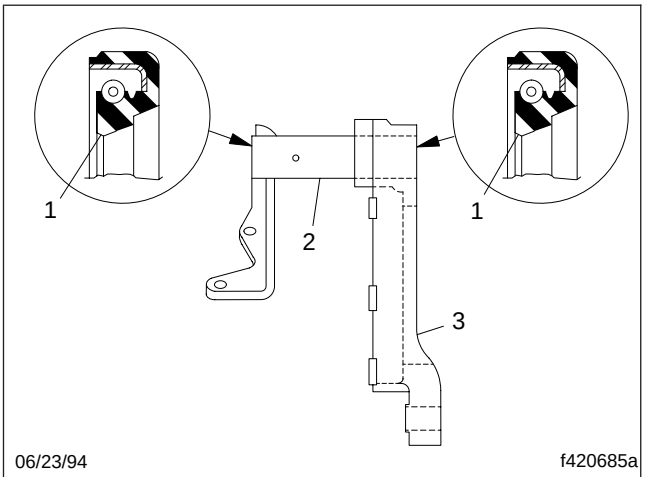
28. Plug

Fig. 1, Cam-Master Q Series Brakes

12.2 Inspect the seal. Replace it if the lip is nicked, cut, or distorted.

13. Install the new bushing or seal with a suitable piloted driver.



A. Check for diameter and for out-of-round.
B. Check for cracks, heat checks, glazing, and grooves.

Fig. 2

IMPORTANT: Grease seals are installed in both the bracket and the brake spider so that the seal lip is facing toward the slack adjuster end of the bracket tube. **See Fig. 3.**

14. Remove the spider-to-axle attaching nuts, hardened washers, and bolts. Remove the spider from the axle flange.
15. If equipped, remove the four capscrews that attach the dust shield to the spider; remove the dust shield.
16. Inspect the spider and parts for damage; replace as needed.
    - 16.1 Check for cracks at the bolt holes, cam area, and around the anchor pin. Replace if damaged.
    - 16.2 Check the anchor pin. If worn or loose, replace it.
    - 16.3 Check the anchor pin and brake spider bushings for wear. The inner surfaces must be smooth. If any surface is rough or abrasive, replace the part.
    - 16.4 Inspect the seal. Replace it if its lip is nicked, cut, or distorted.
17. Using a suitable piloted driver, install the new bushings and seal.

NOTE: The seal lip is facing toward the slack adjuster.
1. Seal Lip
2. Camshaft Support Bracket
3. Brake Spider

Fig. 3, Positioning of Seals on the Camshaft

IMPORTANT: Grease seals are installed in both the bracket and the brake spider so that the seal lip is toward the slack adjuster end of the bracket tube. **See Fig. 3.**

Cleaning

WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

After removing the brake parts being serviced, do the following:

1. Wire brush all parts exposed to mud, road dirt, and salt, including the exterior of the drum, spider, brake chamber bracket, and dust shields (if equipped). If relining the shoes, thoroughly wire-brush the shoe tables, and paint them with a rust inhibitive coating.

CAUTION

CAUTION: A thick layer of oxidation and dirt on the outside of a brake drum acts as an insulator

Brake Components Disassembly and Inspection, Cleaning, and Assembly

and may hinder normal heat dissipation. Make sure oxidation and dirt are removed by wire brushing, or damage to brake components could occur.

2. Using an industrial vacuum cleaner with a HEPA filter system, pick up excessive dust accumulation. Wipe the interior of the drums with a greaseless solvent to remove lining dust.
3. Thoroughly clean all remaining brake parts with a suitable shop solvent. Wipe dry with a clean, lint-free cloth, or use low-pressure, filtered and compressed air.

Assembly (See Fig. 1)

WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Install the dust shield, if equipped.

   Position the dust shield against the spider, and install the capscrews. Tighten the capscrews to the torque provided in **Specifications 400.**

2. Install the spider.

   Place the spider on the axle flange. Using a hardened washer under the bolt head and the nut, install the mounting fasteners. Tighten the bolts in a cross pattern to the torque provided in **Specifications 400.**

3. Install the brake chamber and bracket.

   3.1 Place the brake chamber on the mounting bracket with the chamber mounting studs through the bracket holes. Install the hardened flatwashers and locknuts. Tighten the nuts to the torque provided in **Specifications 400.**

   NOTE: If replacing a brake chamber, make sure that the new chamber is the same size and make as the brake chamber on the other side of the axle.

   3.2 Place the bracket against the spider, and install the lockwashers and capscrews. Tighten the capscrews to the torque provided in **Specifications 400.**

4. Install the camshaft and parts in the spider; install the slack adjuster.

   4.1 Apply a thin film of chassis grease on the inside of the camshaft bushings and journals. Don't grease the camshaft head area.

   4.2 Apply a thin film of rust preventive grease (Rockwell 0-637, or an equivalent) on the camshaft splines.

   4.3 Carefully slip the camshaft into the spider and the mounting bracket tube.

   4.4 Install the thick camshaft washer on the camshaft.

   4.5 Install the slack adjuster on the camshaft, with the adjuster nut on the side opposite of the brake chamber.

   4.6 Install the outer washers and snap ring.

5. Use a dial indicator to measure the end-play of the camshaft. There should be no more than 1.5 mm (0.060 inch) movement.
6. Pressure lube the camshaft bracket bushings.

   Pump multipurpose chassis grease (NLGI grade 1 or 2) into the chamber bracket until it appears at the slack adjuster end of the bracket. Use care that no grease enters the drum cavity. If grease leaks out under the camhead, the camshaft grease seal is worn or damaged, or is installed backwards.

NOTE: The use of meter-type fittings, having a maximum 276 kPa (40 psi) pressure relief at shutoff, is recommended.

7. For manual slack adjusters, while depressing the locking sleeve, turn the adjusting nut counterclockwise until the appropriate hole in the adjuster is aligned with the hole in the brake chamber push-rod clevis. For automatic slack adjusters, refer elsewhere in this group or to the manufacturer's service information.
8. Install the brake shoes. For instructions, refer to **Subject 110**.

Table 1, Torque Values

General Description

Brake chambers convert the energy of compressed air into the mechanical force and motion needed to apply the brakes. Two chambers operate the brakes, one on each side of the axle.

Each brake chamber consists of two dished metal sections: the cover assembly and the body assembly, which are separated by a nylon-neoprene diaphragm. A metal two-segment clamp ring holds the assemblies together. **See Fig. 1.**

1. Clamp Ring
2. Cover Assembly
3. Diaphragm
4. Body Assembly
5. Piston Rod Spring
6. Piston Rod Assembly
7. Piston Rod Nut
8. Clevis
9. Clevis Pin

Fig. 1, Sectional View

In front of the diaphragm are the body, piston rod assembly, and a piston rod spring. The threaded piston rod assembly extends through the bottom of the body and connects to the clevis. **See Fig. 1.**

Different sized brake chambers are identified by numbers, which specify the effective area of the diaphragm. For example, a type 16 brake chamber has 16 square inches of effective area.

Principles of Operation

The greater the air pressure admitted to the brake chamber, the greater the force applied by the piston rod. Piston rod force is determined by multiplying the delivered air pressure by the effective diaphragm area. For example, if 415 kPa (60 psi) is admitted to a type 16 brake chamber, the force on the end of the piston rod is about 436 kg (960 lb).

When the brake pedal is depressed, air pressure from the brake valve passes through the port in the brake chamber cover to move the diaphragm and piston rod assembly forward. This compresses the spring, and applies a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes.

When the brake pedal is released, compressed air behind the diaphragm exhausts through the quick release valve. The spring then allows the piston rod assembly and diaphragm to return to their previous positions.

NOTE: For both of these tests, the air system must be pressurized to at least 550 kPa (80 psi).

Operating Test

1. Chock the tires.
2. Apply the brakes. Check that each piston rod moves out promptly, without binding.
3. Release the brakes. Check that each piston rod returns to the released position promptly, without binding.
4. Check the brake chamber stroke. It should be as short as possible without causing the brakes to drag. If needed, adjust the travel of the piston rod at the slack adjuster. Refer to the vehicle maintenance manual for instructions.

Leakage Test

1. Apply the brakes and hold them on full line pressure of at least 550 kPa (80 psi).
2. Using a soap solution, coat the clamp ring. Leakage is excessive if it produces a 25-mm (1-inch) bubble within five seconds.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

3. If the leakage is excessive, tighten the clamp ring flange nuts evenly until the leakage is reduced. For acceptable torque ranges, refer to **Specifications, 400**.
4. Using a soap solution, coat the area around the piston-rod hole. No leakage is permitted. If there is leakage, replace the diaphragm. For instructions, refer to **Subject 110**.

Diaphragm Replacement

NOTE: This procedure is for service of a leaking brake chamber *diaphragm only*. If there are any other problems, refer to the applicable subjects elsewhere in this section.

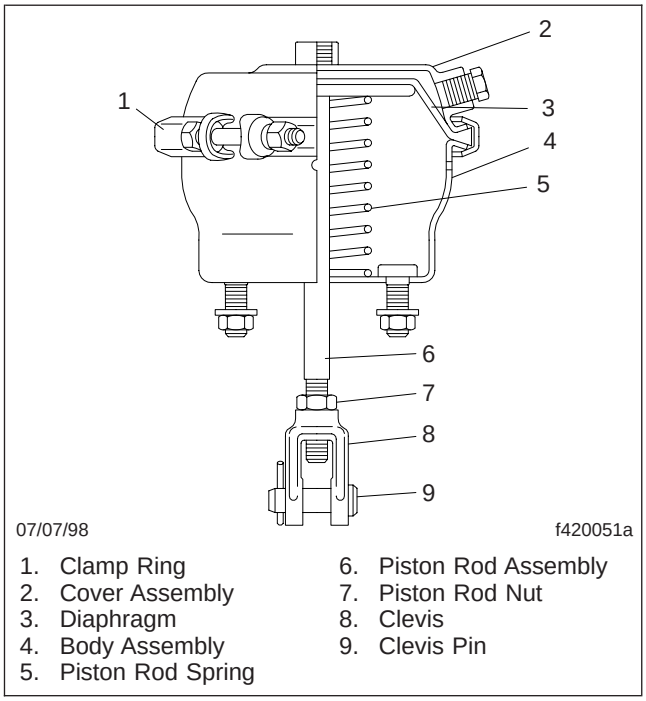
Replacement

1. Chock the tires.

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Follow the manufacturer's recommendations when working on any air device so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or compressed-air propulsion.



2. Drain the air reservoirs and lines.
3. Back off the slack adjuster; for instructions, refer to the applicable slack adjuster section in this manual. Pull out the piston rod. **See Fig. 1.** Clamp the rod at the chamber body to protect it from damage.
4. Before disassembly, mark a reference line along the chamber to allow the parts to be reassembled later in their old positions. **See Fig. 2.**
5. Replace the diaphragm.
   - 5.1 Remove one clamp ring bolt and flange nut completely and loosen the other bolt and flange nut enough to remove the clamp ring.
   - 5.2 Remove the cover assembly, and replace the diaphragm.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

   - 5.3 Position the cover assembly and clamp ring (aligning the reference marks), and install the clamp ring bolt and flange nut. Tighten the flange nuts evenly to eliminate leakage. For acceptable torque ranges, refer to **Specifications, 400**.

6. Release the clamp on the piston rod.

1. Clamp Ring

1. Chock the tires.

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at other people. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Follow the manufacturer's recommendations when working on any airdevice so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or compressed-air propulsion.

2. Drain the air reservoirs and lines.
3. Carefully disconnect the air line from the brake chamber.
4. Remove the brake chamber.

   4.1 Remove the cotter pin(s) from the clevis pin(s).

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   4.2 Remove the clevis pin(s) from the slack adjuster.

   4.3 From each mounting stud, remove any installed nuts and washers. Remove the brake chamber from the vehicle.

Installation (See Fig. 1)

1. Before installing a new chamber, be sure the new chamber is the same size and make as the brake chamber on the other side of the axle.
2. Install the brake chamber.

   2.1 Attach the brake chamber to the mounting bracket using a hardened flatwasher and prevailing torque locknut. Install the flatwasher between the locknut and the mounting bracket.

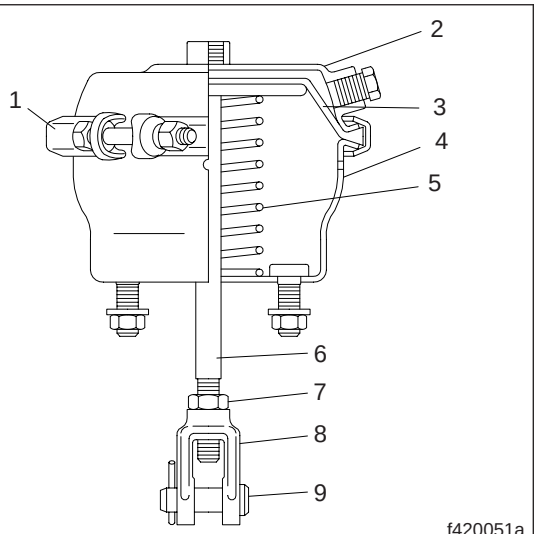
   2.2 Tighten the locknuts. **See Table 1** for the correct torque value.

Brake Chamber Removal and Installation

Description	Chamber Size (in ^{2})	Torque N·m (lbf·ft)
Brake Chamber Mounting-Stud Locknuts	12	52–58 (38–43)
	16 (7/16–14 stud)	52–58 (38–43)
	16 (1/2–13 stud)	81–88 (60–65)
	16 (1/2–20 stud)	88–95 (65–70)
	20	162–176 (120–130)
	24	162–176 (120–130)

Table 1, Mounting-Stud Locknut Torque Values

2.3 Connect the clevis pin(s) to the slack adjuster.



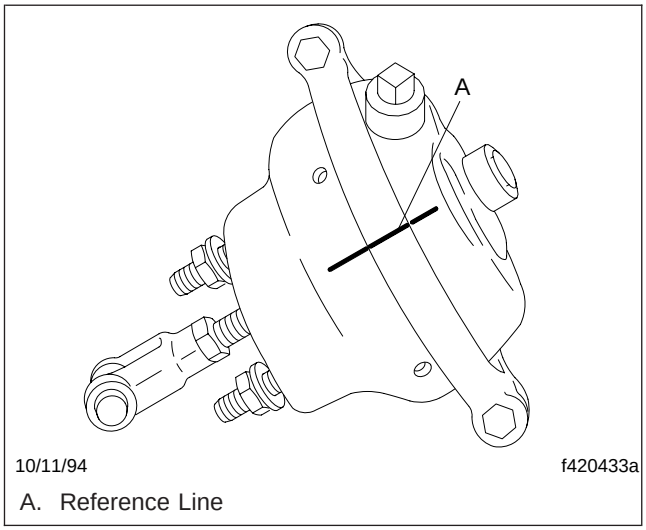
NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

2.4 Install and lock the cotter pin(s) to secure the clevis pin(s).

3. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable foundation brake section in this manual.
4. Connect the air line to the brake chamber.
   - 4.1 Check that the hoses are properly supported and, if needed, clamped to provide good clearance.
   - 4.2 Before connecting the air line, make sure the fittings are clean and free of debris.
   - 4.3 Connect the air line as follows: tighten the nut finger-tight. Using a wrench, further tighten the nut until there is resistance, then tighten one-sixth turn more.
5. Do both of the tests **in Subject 100**.
6. Remove the chocks from the tires.

Brake Chamber Disassembly, Inspection and Cleaning, and Assembly

Disassembly (See Fig. 1)



1. Clamp Ring
2. Cover Assembly
3. Diaphragm
4. Body Assembly
5. Piston Rod Spring
6. Piston Rod Assembly
7. Piston Rod Nut
8. Clevis
9. Clevis Pin

Fig. 1, Sectional View

NOTE: If the brake chamber is to be disassembled without removing the body assembly from the vehicle, first back off the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

1. Before disassembly, mark a reference line along the chamber to allow the parts to be reassembled later in their old positions. **See Fig. 2.**
2. Pull out the piston rod. Clamp the rod at the chamber body to protect it from damage.
3. Disassemble the brake chamber.
   - 3.1 Remove one clamp ring bolt and flange nut completely and loosen the other bolt and flange nut enough to remove the clamp ring.
   - 3.2 Remove the cover assembly and the diaphragm.
   - 3.3 Remove the clevis locknut and clevis from the piston rod, and release the clamp on the piston rod, being careful to contain the piston rod assembly and body until the return spring is relaxed.
   - 3.4 Remove the piston rod assembly and spring.

A. Reference Line

Fig. 2

Inspection and Cleaning

1. Clean all metal parts with cleaning solvent.
2. Inspect all parts for wear or damage; replace as needed.
   - 2.1 Check the cover and the body for dents. If any are too deep to be pounded out, replace as needed.
   - 2.2 Check the diaphragm for wear or deterioration and replace it if necessary. Midland recommends replacement of the diaphragm whenever the service brake chamber is opened for inspection.
   - 2.3 Inspect all other parts not considered serviceable. Replace if necessary.

Assembly (See Fig. 1)

1. Stand the piston rod assembly upright on a flat surface (if the chamber was removed from the vehicle).
2. Assemble the brake chamber.

Brake Chamber Disassembly, Inspection and Cleaning, and Assembly

2.1 Place the return spring on the piston rod.

2.2 Place the body on the piston rod assembly, and press the body down, working against the tension of the spring, until the body bottoms out on the flat surface. Clamp the rod at the body, making sure to protect the rod from damage. Insert the piston rod assembly through the body and clamp the rod (if the body wasn't removed from the vehicle).

2.3 Place the diaphragm in the body.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

2.4 Position the cover assembly and clamp ring (aligning the reference marks), and install the clamp ring bolt and flange nut. Tighten the flange nuts evenly to eliminate leakage. For acceptable torque ranges, refer to **Specifications, 400**.

3. Install the clevis locknut and clevis, and release the clamp on the piston rod.
4. If the brake chamber was removed from the vehicle, install it. For instructions, refer to **Subject 120**.
5. Do both of the tests found **in Subject 100**.

Description	Chamber Size (in ^{2})	Torque N·m (lbf·ft)
Brake Chamber Mounting-Stud Locknuts	12	52–58 (38–43)
	16 (7/16–14 stud)	52–58 (38–43)
	16 (1/2–13 stud)	81–88 (60–65)
	16 (1/2–20 stud)	88–95 (65–70)
	20	162–176 (120–130)
	24	162–176 (120–130)

Table 1, Mounting-Stud Locknut Torque Values

Description	Chamber Size (in ^{2})	Torque N·cm (lbf·in)
Clamp Ring Flange Nuts	12	2260 to 2820 (200 to 250)
	16	2260 to 2820 (200 to 250)
	20	1240 to 2540 (110 to 225)
	24	1700 to 2540 (150 to 225)

	16 (7/16-inch Stud)	27–41 (20–30)
	16 (1/2-inch Stud)	27–41 (20–30)
	20	45–122 (33–90)
	24	45–122 (33–90)

Table 3, Piston Rod Nut Torque Values

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

06/25/93 f420731a

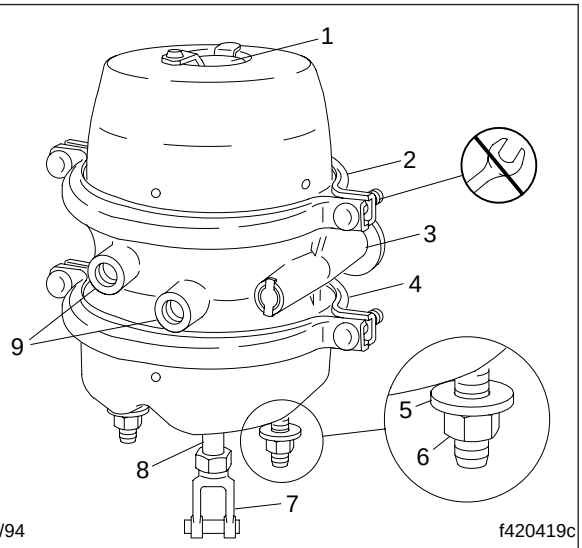
A. Do not remove this clamp ring.
1. Model E (E Series) Brake Chamber
B. Do not remove the factory-sealed clamp ring.
2. Model TR-T (TR Series) Brake Chamber

Fig. 1

IMPORTANT: On MGM "TR" Series chambers, the parking/emergency brake section is factory sealed (no clamp ring) and is a *non-serviceable* unit. On "E" Series chambers, the parking/emergency brake section is attached with a clamp ring. *Do not ever perform any service on this clamp ring.*

General Information

MGM "E" and "TR" Series tandem cam brake chambers consist of a service brake section and a parking/emergency spring brake section. **See Fig. 2** and **Fig. 3**. The service brake section is the smaller section near the clevis assembly.



In the service brake section, the flange case and non-pressure chamber contain a service return spring, piston rod assembly, and service brake diaphragm.

In the parking/emergency brake section, the flange case and the head contain a return spring, a push rod assembly, a parking (spring) brake diaphragm, a piston, a power spring, and a detachable release bolt.

All MGM brake chambers are mounted to the frame using prevailing torque locknuts and hardened flatwashers.

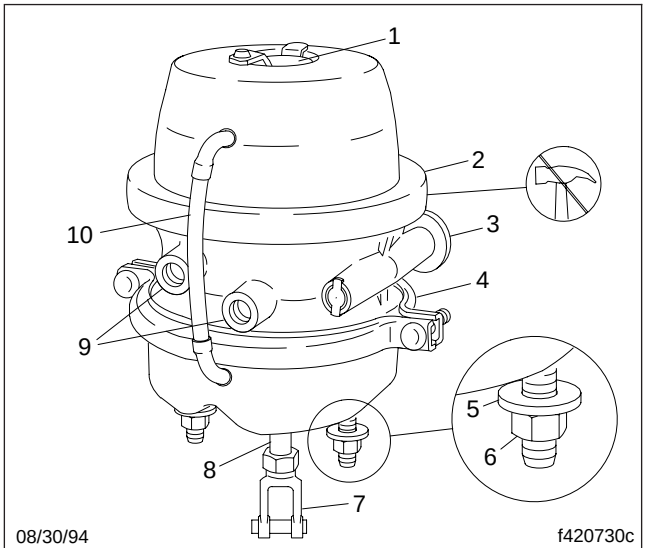
MGM "E" and "TR" Series chambers may be equipped with an external breather tube that protects the parking brake chamber from contaminants. These chambers are called Model "E-T" or "TR-T" chambers. **See Fig. 3.**

General Information and Principles of Operation

Do not remove the parking brake clamp ring.

1. End Cover Cap
2. Parking Brake Clamp Ring
3. Release Bolt Storage Pocket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

Fig. 2, Model E (E Series) Brake Chamber



Periodic maintenance of the brake chambers is required. Also, whenever the service brake chamber is disassembled (*do not attempt to disassemble the parking brake chamber*), the parts should be inspected for damage. For maintenance schedules and procedures, and for inspection of brake chamber parts, refer to the vehicle maintenance manual.

Principles of Operation

SERVICE BRAKES

As the brake pedal is depressed, compressed air enters the service brake chamber through a port. Air pressure acts upon a diaphragm, which forces the piston rod toward the non-pressure chamber, applying a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes.

Then, when the brake pedal is released, air is exhausted from the service brake chamber, and the return spring allows the diaphragm, piston rod, and slack adjuster to return to their normal positions, releasing the brakes.

Do not remove the factory-sealed clamp ring.

1. End Cover Cap
2. Factory Sealed Parking Brake Clamp Ring
3. Release Bolt Storage Pocket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports
10. External Breather Tube

Fig. 3, Model TR-T (TR Series) Brake Chamber

PARKING/EMERGENCY BRAKES

During parking brake release, compressed air enters the parking brake chamber and acts upon the diaphragm and piston, fully compressing the power spring. When the power spring is compressed, the parking brakes are released; the service brakes can then be operated at the brake pedal.

During parking brake application, air is exhausted from the parking brake chamber. The power spring releases, forcing the piston and parking brake diaphragm toward the flange case. The resulting motion on the push rod forces the service brake diaphragm and piston rod outward, applying the brakes.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

Manual Compression (Parking Brake Release)

1. Chock the tires.
2. Remove the end cover cap from the center-hole in the head of the chamber. See **Fig. 2**.

⚠ DANGER

Do not attempt to cage the power spring if the parking brake chamber is damaged severely enough to lose its structural integrity. If the power spring were to break loose, it could result in death, severe personal injury, or property damage.

A DAMAGED PARKING BRAKE CHAMBER IS EXTREMELY DANGEROUS! Only qualified service personnel should attempt to remove and disarm a damaged chamber. Using a torch, burn off the piston rod in the space between the clevis and the base of the service chamber.

Remove the chamber carefully from its bracket, and disarm it inside a suitable container. For disarming procedures, consult the MGM service manual.

3. Manually release the parking brake (cage the power spring).

   3.1 Using a hand wrench, (*don't use an impact wrench*), unscrew the release nut, and remove the nut, flatwasher, and release bolt from the storage pocket on the side of the chamber. See **Fig. 3**.

   IMPORTANT: If these parts are not stored on the chamber, they must be otherwise obtained or purchased; the parking brake cannot be manually released without them.

   3.2 Apply at least 620 kPa (90 psi) air pressure to the parking brake inlet port (set parking brake in the "release" position).

   3.3 Insert the release bolt into the center-hole in the chamber head (**see Fig. 4**). Insert the bolt until it bottoms out into the hole in the piston inside the chamber.

   IMPORTANT: If you are not absolutely sure that the formed end of the bolt has engaged the piston correctly, repeat this step. Repeat it until you are absolutely sure.

   3.4 Turn the release bolt one-quarter turn clockwise, and pull the bolt out to lock its formed end into the piston.

   IMPORTANT: If the bolt doesn't lock into the piston in less than 13-mm (1/2-inch) outward movement, repeat these steps until you are sure it does lock.

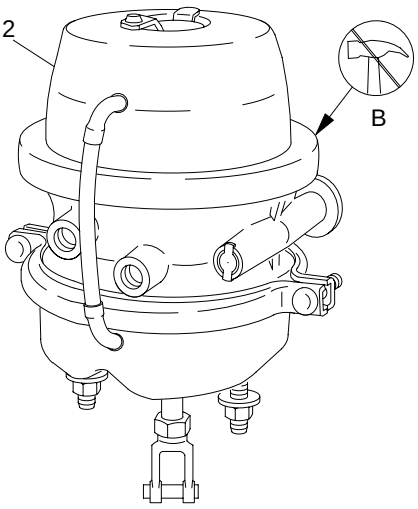
   3.5 Then, holding the bolt locked into the piston, install the flatwasher and release nut on the end of the release bolt, and turn down the nut against the flatwasher until it is finger-tight. See **Fig. 5**.

⚠ CAUTION

Don't exceed 68 N·m (50 lbf·ft) torque on the release nut; and don't use an impact wrench on this nut. Too much torque could distort the head of the chamber and prevent manual release of the parking brake.

   3.6 Using a hand wrench (*don't use an impact wrench*), turn the release nut clockwise until the bolt extends 76 mm (3 inches) above the nut. See **Fig. 6**.

   IMPORTANT: Don't exceed the 76-mm (3-inch) length.

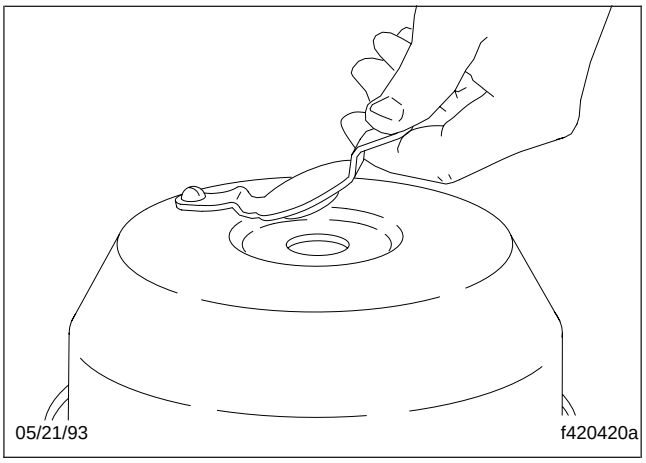


4. Once the power spring has been caged, exhaust the compressed air from the parking brake.

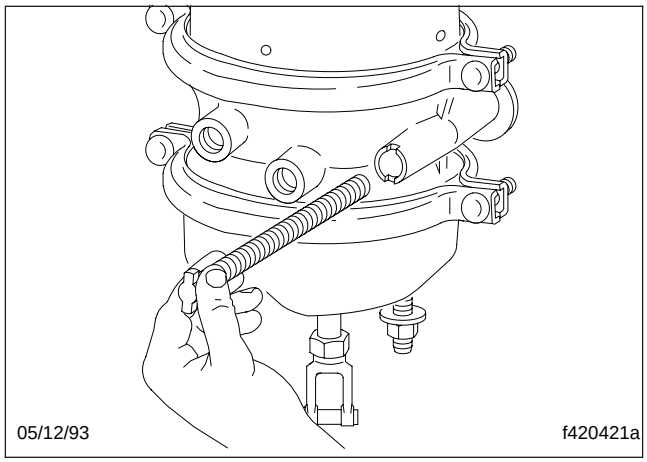
Manual Reset (Parking Brake Reset)

1. Uncage the power spring.

Power Spring Manual Compression and Reset



06/25/93 f420731a



A. Do not remove this clamp ring.
1. Model E (E Series) Brake Chamber
B. Do not remove the factory-sealed clamp ring.
2. Model TR-T (TR Series) Brake Chamber

Fig. 1

05/21/93 f420420a

Fig. 2

05/12/93 f420421a

Fig. 3

1.1 Apply at least 620 kPa (90 psi) air pressure to the parking brake inlet port (set parking brake in the "release" position).

⚠ CAUTION

Don't exceed 68 N·m (50 lbf·ft) torque on the release nut; and don't use an impact wrench on this nut. Too much torque could distort the head of the chamber and prevent manual release of the parking brake.

1.2 With air applied to the parking brake section (the parking brake control valve is in the "release" position), use a hand wrench to turn the release nut *counterclockwise* until the bolt bottoms out in the unit.

1.3 Remove the nut and flatwasher.

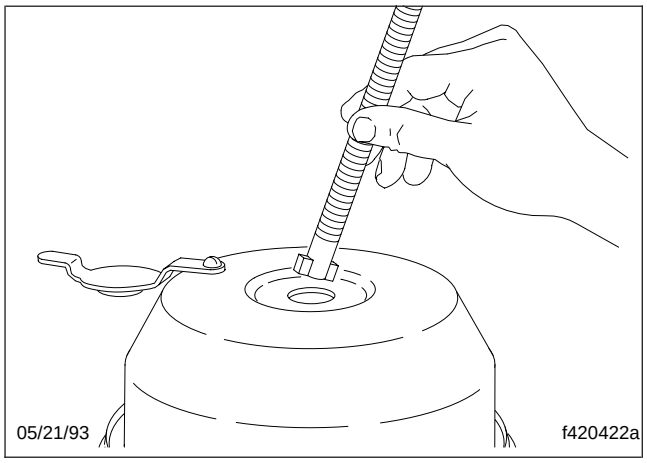


Fig. 4

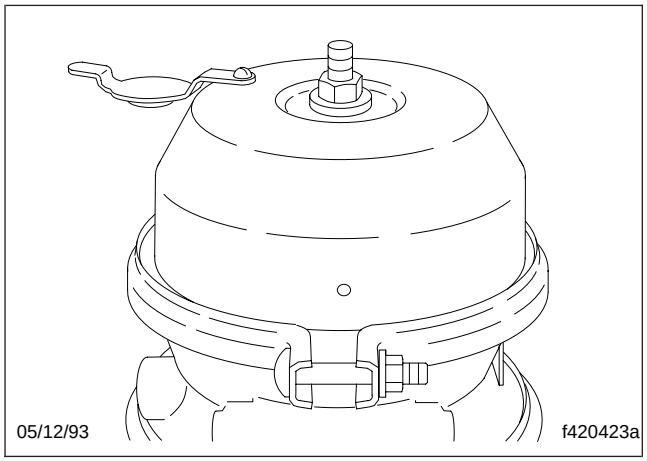

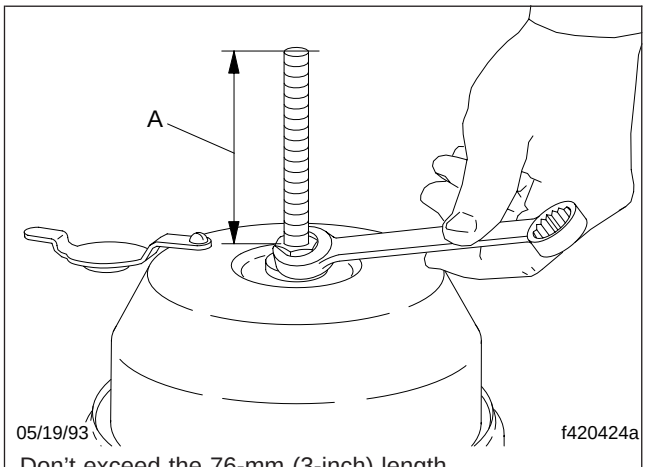

Fig. 5

1.4 Push the release bolt into the piston and turn the release bolt one-quarter turn counterclockwise to unlock its formed end from the piston. Remove the release bolt from the center-hole of the chamber.

2. Using a hand wrench (*don't use an impact wrench*), install the release bolt, flatwasher, and release nut in the storage pocket. MGM recommends 14 N·m (10 lbf·ft) torque on the nut against the flatwasher (see **Fig. 7**).

3. Snap the end cover cap in place over the center-hole in the chamber head. See **Fig. 8**.

Don't exceed the 76-mm (3-inch) length.
A. Measure this distance.

Fig. 6

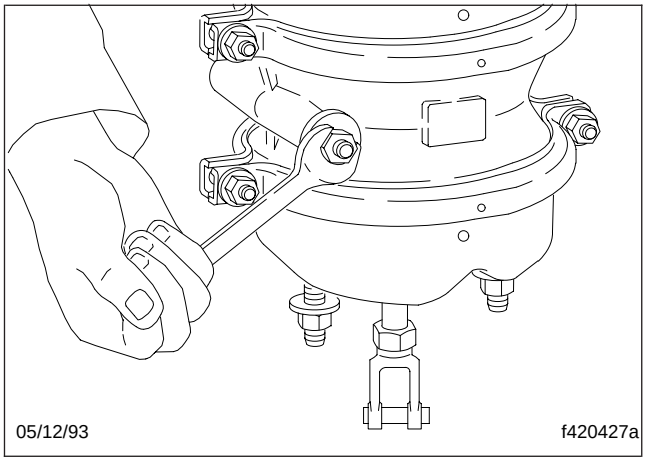

Fig. 7

CAUTION

If the external breather tube or end cover cap is missing or incorrectly installed, road dirt and debris can adversely affect the operation of the brake chamber. Once inside the chamber, dirt and debris cause the internal parts to deteriorate and shorten their lives. Operating the unit without the external breather tube or end cover cap in place voids the MGM warranty.

4. Check the plastic end cover cap periodically, and replace it with a new one at once if damaged or missing. For intervals, refer to the vehicle maintenance manual.

Power Spring Manual Compression and Reset

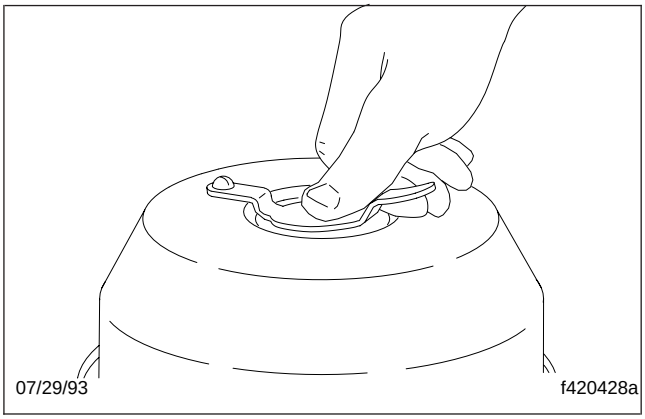

Fig. 8

5. Remove the chocks from the tires.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

Removal

1. To make removal and installation of the parking brake section easier (without removing the service brake chamber), lock off the service chamber piston rod.

   1.1 Apply the service brakes by actuating the driver's foot brake treadle valve.

   1.2 With the brakes applied, clamp a pair of locking-jaw pliers on the piston rod to lock the rod in place when the air pressure is released (see **Fig. 2**).

⚠ WARNING

Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

2. Manually release the parking brake (cage the power spring). For instructions, see **Subject 100**.

3. Mark the air lines for later reference. Then carefully disconnect them from the brake chamber.

   On chambers equipped with an external breather tube, disconnect the tube and elbow from the service brake chamber.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4. Remove the parking brake section from the service brake section.

   4.1 Using a hand wrench (*don't use an impact wrench*), remove the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

   4.2 While holding the parking brake section securely in place, remove the service clamp ring. Then remove the parking brake section from the service brake non-pressure chamber (see **Fig. 3**).

5. Remove the service brake diaphragm from the bottom of the parking brake section.

Installation

IMPORTANT: At this time, take the opportunity to inspect the parking/emergency brake section, and replace it if it shows signs of damage, corrosion, or rust. Follow the detailed inspection instructions in the vehicle maintenance manual.

1. Inspect all parts in the service (non-pressure) chamber. Replace any damaged or worn parts with genuine MGM-engineered replacement parts.

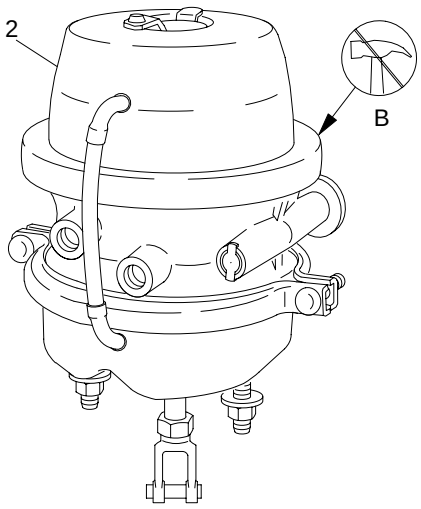
2. Place the new service brake diaphragm in the bottom recess of the parking brake section (see **Fig. 4**).

3. Install the (new, if needed) parking/emergency brake section.

   3.1 If installing a new parking brake section, be sure it is the same size and make as the old one.

   3.2 Check that the release bolt is fully extended outward. For instructions, refer to **Subject 100**.

   3.3 Install the parking brake section on the service chamber so that all mating parts are aligned straight and the air lines are positioned to mate with the vehicle air supply lines.

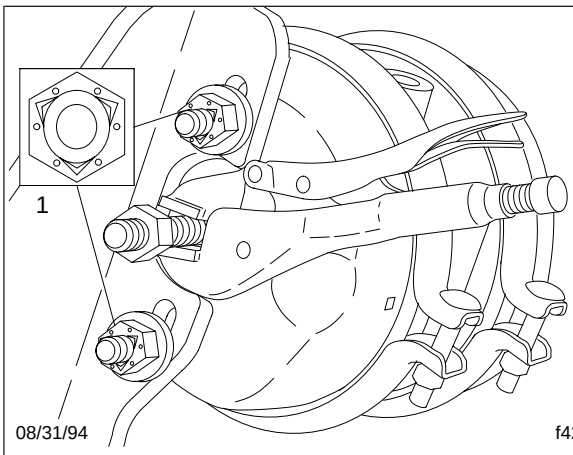


4. Install the service brake clamp ring.

   4.1 With the service brake clamp ring in place, install the clamp bolts and nuts.

   4.2 Using a hand wrench (*don't use an impact wrench*), alternately tighten each clamp nut in increments of 680 to 1360

Service Brake Diaphragm Replacement



06/25/93 f420731a

A. Do not remove this clamp ring.
1. Model E (E Series) Brake Chamber
B. Do not remove the factory-sealed clamp ring.
2. Model TR-T (TR Series) Brake Chamber

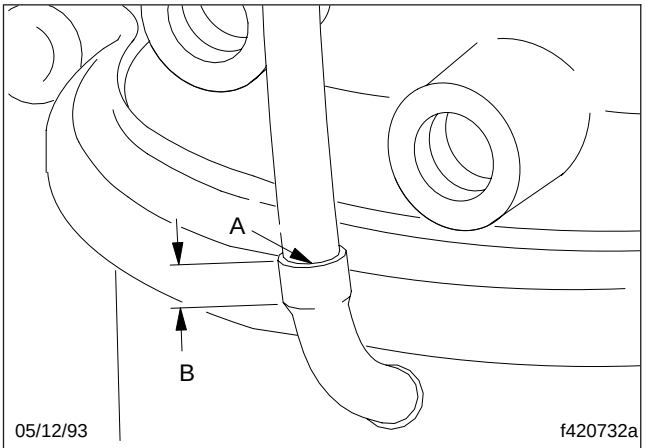
2. Service Brake Diaphragm
3. Service Brake Clamp Ring
4. Service Brake (Non-Pressure) Chamber

Fig. 4



the nuts to a final torque of 34 to 41 N·m (25 to 30 lbf·ft).

5. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 34 N·m (25 lbf·ft).
6. Using the vehicle system air, charge the parking brake with full line pressure—at least 690 kPa (100 psi). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 34 N·m (25 lbf·ft).
7. With the parking brake still charged with full line pressure, apply and hold the foot brake treadle valve down to charge the service brake chamber. Remove the locking-jaw pliers from the service piston rod so that the piston returns to a normal position in the chamber.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

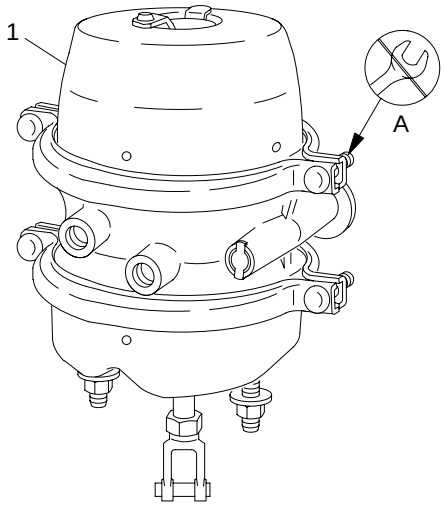
8. Test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, firmly tap the circumference of the clamp ring with a rubber mallet, and retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). MGM recommends 34 to 41 N·m (25 to 30 lbf·ft) torque on the clamp hexnuts.
9. On chambers equipped with an external breather tube, make sure that the open end of the tube is free of grease, dirt, and other debris. Then, apply a high-quality rubber cement to the tube and insert it into the elbow at least 13 mm (1/2 inch). See **Fig. 5**. Insert the tube into the service brake chamber.

05/12/93 f420732a

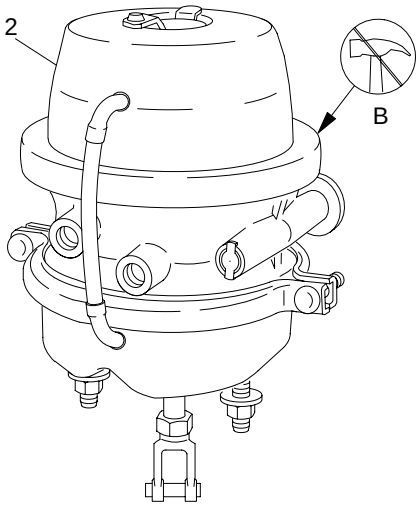
A. Apply adhesive here.
B. Check for 13 mm (1/2 ") minimum engagement.

Fig. 5

10. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the end cover cap in place. For instructions, see **Subject 100**.
11. Adjust the brakes at the slack adjuster.



Service Brake Diaphragm Replacement



IMPORTANT: After replacing any brake chamber components, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack adjuster. For instructions, see the applicable slack adjuster section in **Group 42** in this manual.

Replacement

⚠ DANGER

DANGER: Don't loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

06/25/93 f420731a

A. Do not remove this clamp ring.
1. Model E (E Series) Brake Chamber
B. Do not remove the factory-sealed clamp ring.
2. Model TR-T (TR Series) Brake Chamber

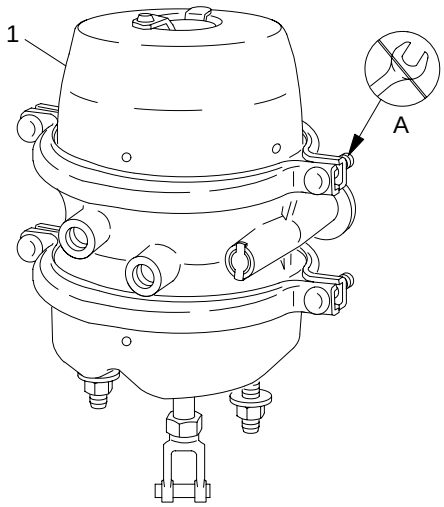


Fig. 1

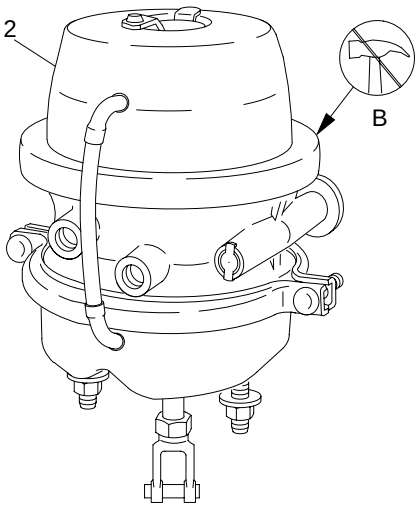


IMPORTANT: The parking/emergency brake section can be replaced as a unit. For instructions, refer to **Subject 110**.

Combination Service and Parking Brake Chamber Removal and Installation

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

06/25/93 f420731a

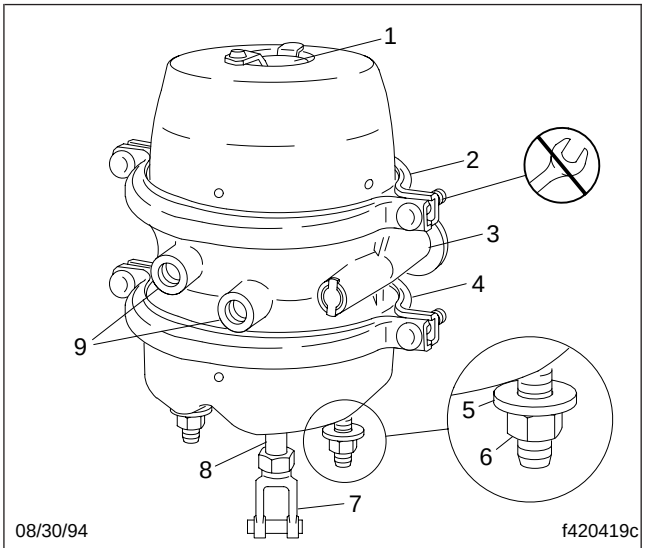
A. Do not remove this clamp ring.
1. Model E (E Series) Brake Chamber
B. Do not remove the factory-sealed clamp ring.
2. Model TR-T (TR Series) Brake Chamber

Fig. 1

Removal (See Fig. 2 or Fig. 3)

⚠ WARNING

WARNING: Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

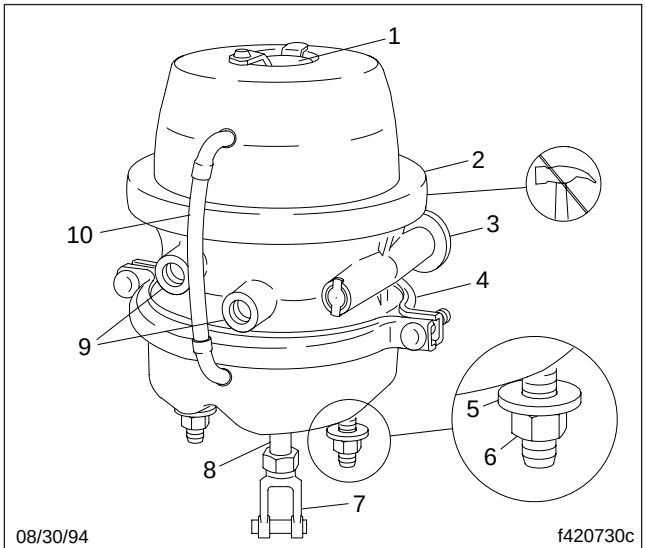


1. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100**.
2. Mark the air lines for later reference. Then carefully disconnect them from the brake chambers.
3. Remove the brake chamber from the vehicle.

   3.1 Remove the cotter pin(s) from the clevis pin(s), then remove the clevis pin(s) from the clevis. Disconnect the clevis from the slack adjuster.

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   3.2 Make sure the parking brake has been released manually (the power spring has been caged). For instructions, refer to **Subject 100**. Also, make sure that the service brake piston is fully retracted (in the brakes "OFF" position). Then, record both of the following dimensions in either mm or inches, measuring outward from



Combination Service and Parking Brake Chamber Removal and Installation

Do not remove the parking brake clamp ring.

1. End Cover Cap
2. Parking Brake Clamp Ring
3. Release Bolt Storage Pccket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

Fig. 2, Model E (E Series) Brake Chamber

Do not remove the factory-sealed clamp ring.

1. End Cover Cap
2. Factory Sealed Parking Brake Clamp Ring
3. Release Bolt Storage Pocket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports
10. External Breather Tube

Fig. 3, Model TR-T (TR Series) Brake Chamber

the base of the service brake chamber (**see Fig. 4**):

X dimension: to end of threaded piston rod

Y dimension: to centerline of (large) clevis pin

IMPORTANT: If new chambers are to be attached to manual slack adjusters, the Y dimension is the most critical measurement. When installing the new assembly, its service piston rod must be cut (**see Fig. 5**) to exactly duplicate this "rod-plus-clevis" length *after* the clevis assembly is installed on the piston rod.

If new chambers are to be attached to automatic slack adjusters, the X dimension is the most critical measurement. When installing the new assembly, its service piston rod must be cut (**see Fig. 5**) to exactly duplicate the "rod only" length *before* the clevis assembly is installed on the piston rod.

3.3 From each mounting stud, remove any installed nuts and washers. Then, cautiously remove the brake chamber from the mounting bracket.

Installation (See Fig. 2 or Fig. 3)

1. If installing a new brake chamber unit, do the following steps:

   1.1 First, make sure the power spring is caged (release bolt fully extended outward). If not, **go to Subject 100** and do the applicable steps.

   1.2 Make sure that the piston rod is the same length as the rod on the old unit (measure the rods when *both* chambers are caged).

Combination Service and Parking Brake Chamber Removal and Installation

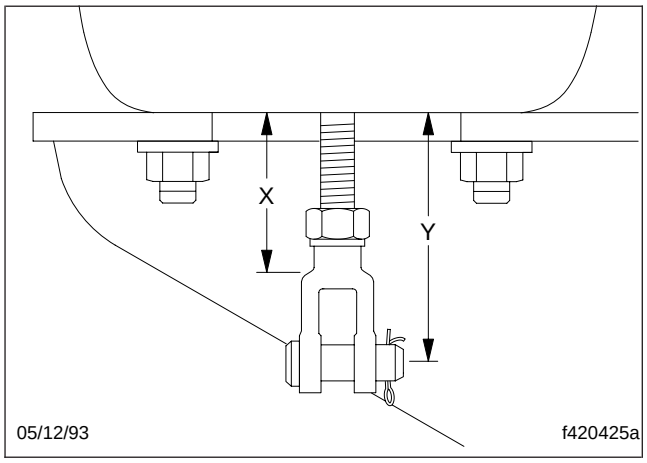


Fig. 4

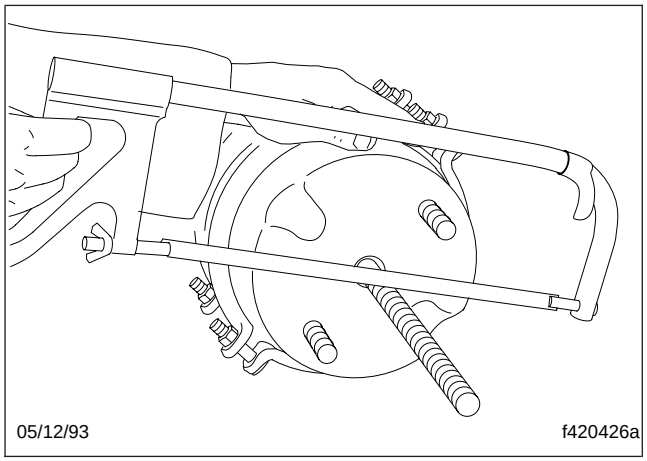

Fig. 5

1.3 Be sure the new chamber is the same size and make as the brake chamber installed on the other side of the axle.

1.4 Remove the prevailing torque locknut and hardened flatwasher from each of the mounting studs on the chamber.

2. Clean the face of the mounting bracket, and install the chamber on the bracket, paying close attention to positioning the chamber air inlet ports for correct alignment to the vehicle air lines.

⚠ WARNING

WARNING: Tighten the mounting nuts with a hand wrench, not an impact wrench. An impact wrench could damage the mounting fasteners, reducing the force of the brakes. This could result in personal injury or property damage.

3. Install one hardened flatwasher and prevailing torque locknut on each mounting stud. Using a hand wrench (*don't use an impact wrench*), tighten the nuts 136 to 156 N·m (100 to 115 lbf·ft). Make sure the flatwasher is installed between the locknut and the mounting bracket.

   On chambers equipped with an external breather tube, make sure that the tube is installed in the side of the chamber that faces away from the road surface. An improperly installed breather tube voids the MGM warranty.

4. Check mating and alignment with the vehicle air lines.

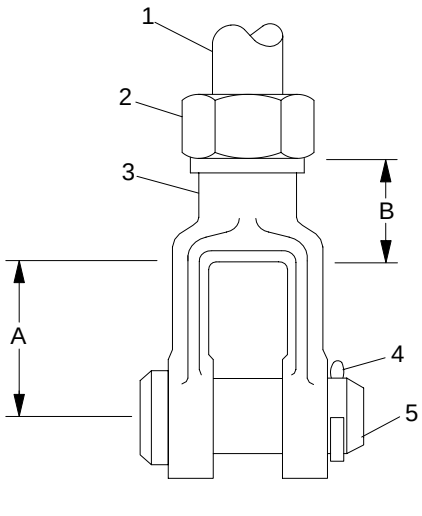
⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4.1 Using a hand wrench (*don't use an impact wrench*), loosen the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

4.2 Reposition the air inlet ports, as needed, to mate with vehicle air supply lines.

Alternately tighten each clamp nut in increments of 680 to 1360 N·cm (60 to 120 lbf·in) while constantly rechecking the alignment of mating parts.



If realignment is needed, loosen the nuts again, and repeat this substep.

4.3 Firmly tap around the circumference of the service clamp ring with a rubber mallet to ensure full seating of the clamp. Tighten the nuts to a final torque of 34 to 41 N·m (25 to 30 lbf·ft).

Combination Service and Parking Brake Chamber Removal and Installation

5. With manual slack adjusters, connect the slack adjuster to the clevis, then install the clevis pin. Insert the cotter pin in the clevis pin, and lock it in place. Check the piston-rod engagement with the clevis. At least seven threads of engagement is required; there should be 25-mm (1-inch) clearance from the centerline of the clevis pin hole to the end of the piston rod. **See Fig. 6.** Adjust if needed.

   With automatic slack adjusters, refer to the applicable slack adjuster section in **Group 42** for installation instructions.

08/20/93 f420225a

A. Minimum of 25 mm (1 inch) clearance between centerline of clevis pin hole and piston rod end.
B. Minimum of 7 threads engagement.
1. Piston Rod
2. Piston Rod Nut
3. Clevis
4. Cotter Pin
5. Clevis Pin

Fig. 6, Piston Rod Engagement With the Clevis

6. Inspect the piston rod to be sure it is working free, not binding, and is square with the chamber bottom within ±3° in any direction from zero to full stroke. If there is misalignment, make corrections by loosening the locknuts and repositioning the chamber on the mounting bracket, or by shimming the slack adjuster to the right or left on the camshaft.
7. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 34 N·m (25 lbf·ft).
8. Using the vehicle system air, charge the parking brake with full line pressure, at least 690 kPa (100 psi). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 34 N·m (25 lbf·ft).

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

IMPORTANT: If the service brake clamp ring was loosened to reposition the air inlet ports, apply air to the parking brake, and then apply and hold the foot brake treadle valve down to charge the service brake chamber. Now test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, firmly tap the circumference of the clamp ring with a rubber mallet, and retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). MGM recommends 34 to 41 N·m (25 to 30 lbf·ft) torque on the clamp hexnuts.

9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the end cover cap in place. For instructions, refer to **Subject 100**.
10. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

IMPORTANT: After replacing any brake chamber, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack

adjuster. For instructions, refer to the applicable slack adjuster section in **Group 42** in this manual.

Specifications

This subject contains the following table: •Torque Values

Description	Torque N·m (lbf·ft)
Spring Brake Release Bolt Nut (in storage pocket)	14 (10)
Service Brake Clamp Ring Nut	34-41 (25-30)
Brake Chamber Mounting Stud Nut	136-156 (100-115)
Air Hose Fitting-to-Chamber	34 (25)

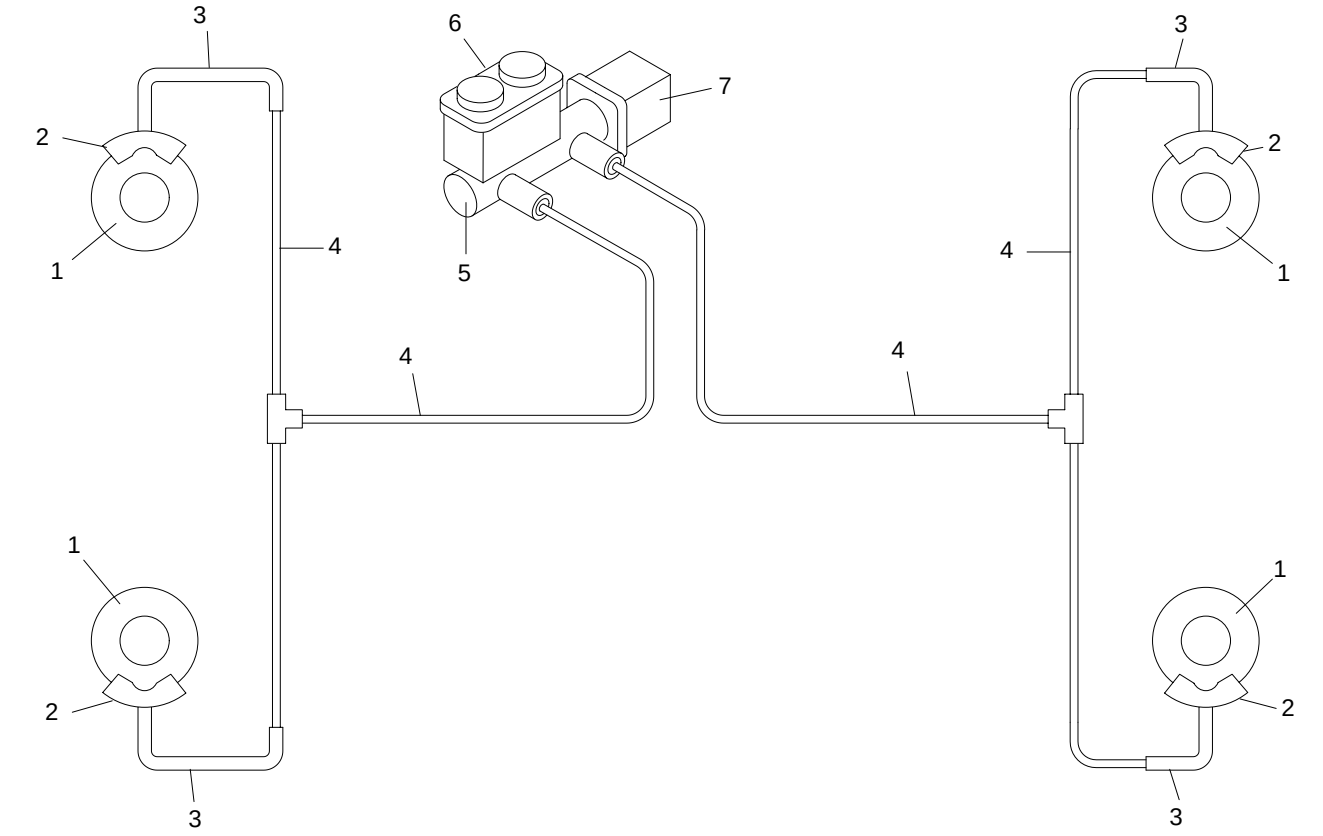


Table 1, Torque Values

General Description

The Bendix hydraulic disk brake system consists of a power booster, a master cylinder and reservoir, hydraulic lines (both rigid and flexible), a brake rotor on each wheel hub, and a brake caliper and pad assembly at each rotor. **See Fig. 1**.

- The service brake system, consisting of the master cylinder, the brake hydraulic lines, and the brake calipers. It uses DOT 3 approved brake fluid.

POWER BOOSTER **(Fig. 3)**

1. Rotor
2. Caliper and Pad Assembly
3. Flexible Brake Line
4. Rigid Brake Line
5. Master Cylinder
6. Reservoir
7. Power Booster

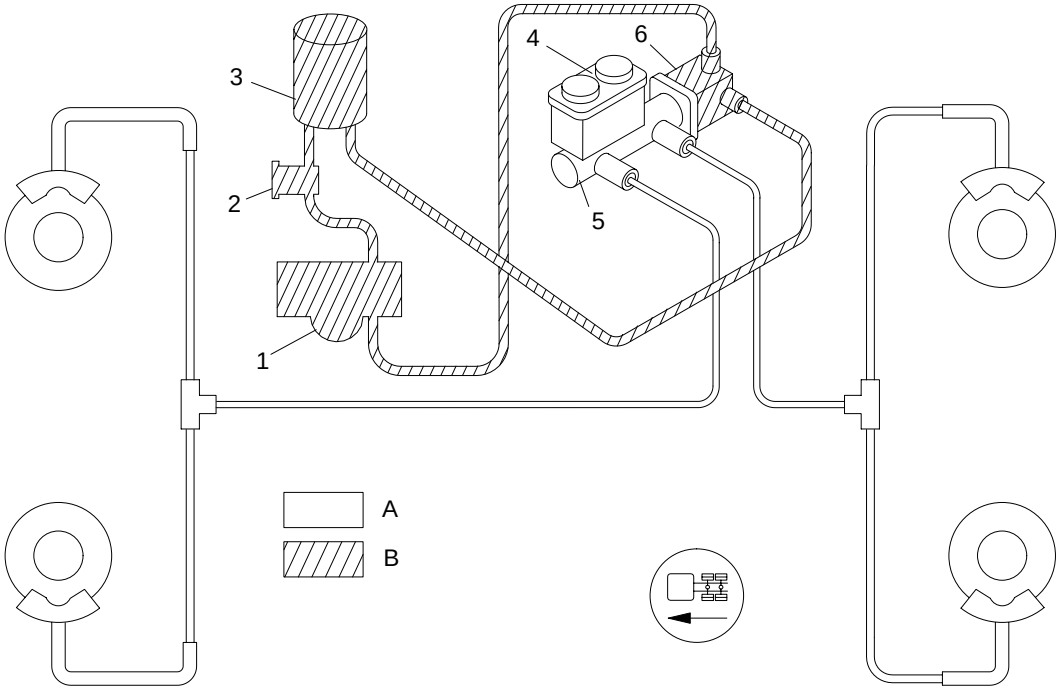

Fig. 1, Brake System Major Parts

There are two completely separate hydraulic systems, which use different and incompatible hydraulic fluids, lines, and seals (**see Fig. 2**):

- The power booster system, which provides power to the brake master cylinder, and uses power steering fluid. It is plumbed into the power steering system.

The Bendix Hydro-Max II® power booster, mounted on the firewall (Ref. 4), is attached to the rear of the master cylinder (Ref. 11). It consists basically of a reaction piston (Ref. 7), a power piston assembly (Ref. 8), an end-cap assembly (Ref. 10), and a back-up electric pump (Ref. 9).

General Description and Principles of Operation

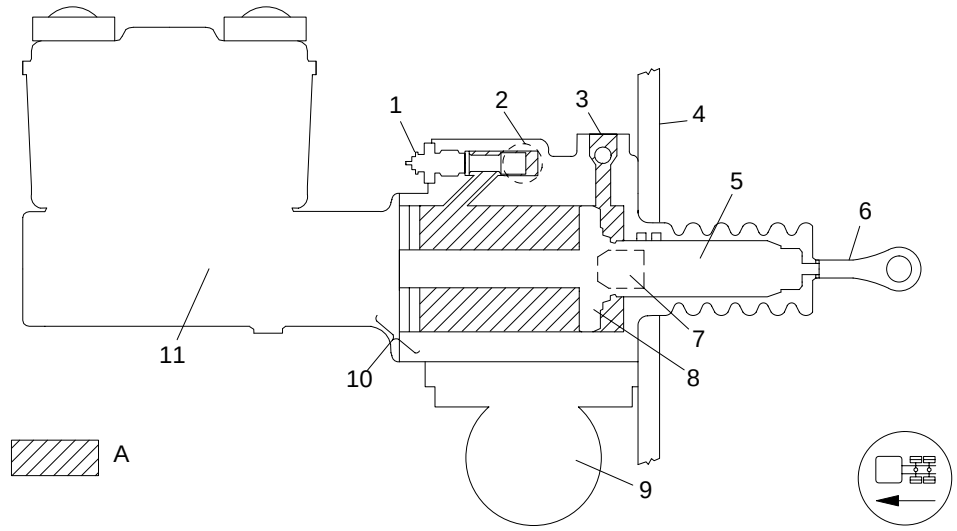
B. Brake Booster and Power Steering System (Power Steering Fluid)

1. Power Steering Gear
2. Power Steering Pump
3. Power Steering Reservoir
4. Brake Master Cylinder Reservoir
5. Brake Master Cylinder
6. Power Booster

Fig. 2, Brake System Major Parts



At the rear of the power piston—and inside it—is the reaction piston (Ref. 7). The power piston assembly (Ref. 8) is connected to the brake pedal by way of the brake pedal rod (Ref. 6). Surrounding the reaction piston is the power piston assembly (Ref. 8), the forward end of which fits through the end-cap assembly, and rests against the rear of the brake master cylinder (Ref. 11). The end-cap assembly prevents the power steering fluid in the power booster from mixing with the brake fluid in the master cylinder.

The power booster is connected to the vehicle's power steering system, which supplies it with pressurized power steering fluid. The power booster supply port (Ref. 3) is connected to the power steering pump via the steering gear, and the return port is connected to the power steering reservoir. A flow switch (Ref. 1) activates the back-up pump if, for any reason, the power steering pump doesn't supply the power booster with fluid.

MASTER CYLINDER (Fig. 4 and Fig. 5)

The brake master cylinder functions as a dual supply system: the primary system supplies pressurized brake fluid to the rear brakes; the secondary system supplies it to the front brakes. **See Fig. 4**. For safety, each system is independent of the other, so a problem with one set of brakes won't affect the function of the other.

The master cylinder, attached to the front of the power booster (**Fig. 5**, Ref. 7), consists mainly of the primary pressure chamber (Ref. 9), the primary piston/actuator assembly and return spring (Refs. 10 and 11), the primary reservoir section (Ref. 5), and the secondary pressure chamber, piston/actuator assembly, return spring, and reservoir section (Refs.

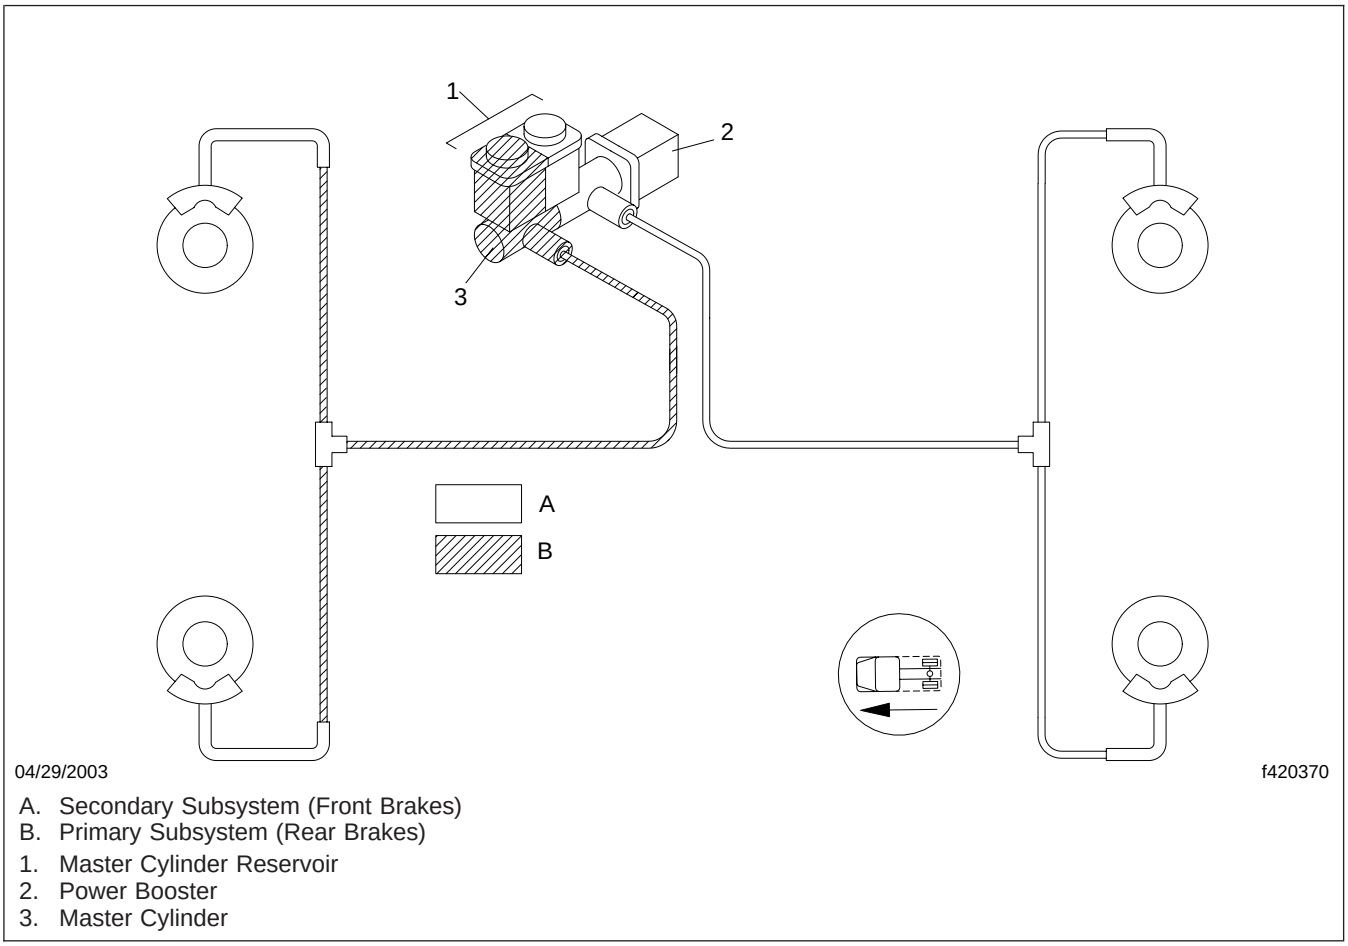
13, 12, 15, and 2). Both pressure chambers have outlet ports that connect them to either the front or rear brake caliper assemblies by way of hydraulic lines. At the bottom of each reservoir section is a compensating valve (Refs. 1 and 6), which when open, connects that reservoir section with the applicable pressure chamber in the master cylinder. A pressure differential valve operates a pressure differential switch (not shown), which activates a dash warning system, should one brake system not work.

BRAKE CALIPER ASSEMBLIES (Fig. 6 and Fig. 7)



Each brake caliper assembly, attached to a wheel, consists of a housing with dual cylinders and pistons (**Fig. 6**), a supply port (**Fig. 7**, Ref. 11), and a bleeder fitting (Ref. 10). The assembly fits over the rotor (Ref. 1) like a "U", with the pistons on the inboard face of the rotor. The caliper fits onto an anchor plate (Ref. 2) at the top and bottom, and the anchor plate is attached to the axle. The caliper is held in place on the anchor plate by a key (Ref. 4), a spring (not shown), and bolt (Ref. 5). The brake pads (Refs. 6 and 9) fit into slots in the caliper housing.

BRAKE CONTROL MODULE

The brake control module, located behind dash panel B (**see Fig. 8**), monitors electronic signals from various sensors in the brake system. If a problem is detected, the module activates the applicable warning light and buzzer on the dashboard.

The control module has nine input terminals and three output terminals (one terminal is a ground). **See Fig. 9**. The output terminals are used for the brake system pressure and parking brake warning lights (**see Fig. 10**), and a buzzer; the input terminals are connected to sensors in the brake system that detect problems.

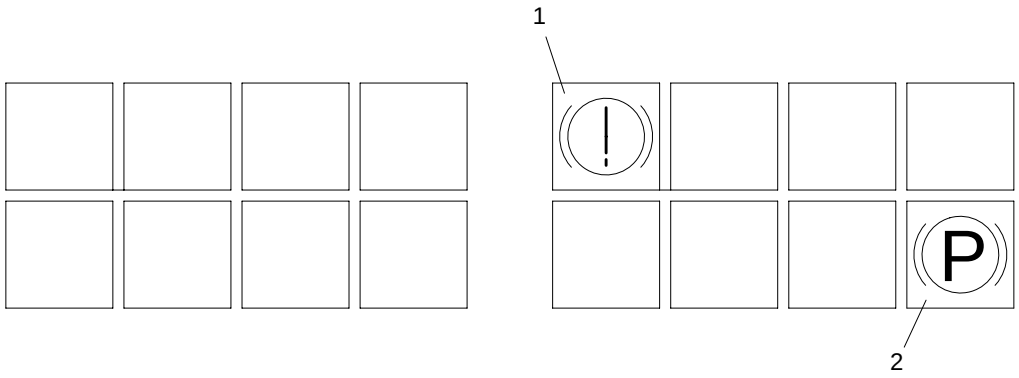
Principles of Operation (Fig. 11)

APPLYING THE BRAKES

When the brake pedal is applied, the brake pedal rod (Ref. 11) pushes the actuator pin (Ref. 10) which pushes the reaction piston (Ref. 12) forward inside the power piston (Ref. 13). This closes the pressure valve (Ref. 16), which restricts the flow of power steering fluid through the power piston (Ref. 13). The increased fluid pressure pushes the power piston forward, through the end-cap assembly (Ref. 18), and into the master cylinder primary piston/actuator assembly (Ref. 19).



As the primary piston/actuator assembly moves forward in the master cylinder, the primary compensating valve closes (Ref. 4). This closes the outlet to the primary reservoir section (Ref. 3), and causes hydraulic pressure to build up in the primary pressure chamber (Ref. 20).

The primary piston/actuator assembly continues moving forward, and moves the secondary piston/actuator assembly (Ref. 22). This closes the secondary compensating valve (Ref. 1), pressurizing the secondary pressure chamber (Ref. 23).

The primary and secondary pressure chambers are connected by outlet ports (not shown) to the primary and secondary brake lines and caliper assemblies. When pressurized brake fluid enters the caliper housings from the brake lines, the dual pistons in each caliper move outward toward the rotors, pushing the inboard brake pads against the rotors. At the same time, the caliper assemblies slide slightly inboard, causing both inboard and outboard pads to squeeze the rotors tightly, which slows down or stops the wheels.

If for any reason the power steering pump doesn't supply the power booster with fluid, the flow switch assembly (Ref. 5) turns on the electric pump (Ref. 15) and closes the return port (Ref. 6). The check valve (Ref. 8) in the power booster supply port (Ref. 7) closes, and the check valve (Ref. 14) in the electric pump opens. The electric pump then recirculates the fluid in the power booster, maintaining emergency pressure. This provides enough reserve power for the master cylinder to pressurize the brake lines.

General Description and Principles of Operation

1. Brake System Pressure
2. Parking Brake

Fig. 10

RELEASING THE BRAKES

When the brake pedal is released, a return spring (Ref. 17) in the power booster pushes the power piston and the reaction piston (inside the power piston) toward the rear of the booster housing, and away from the master cylinder primary piston/actuator assembly. This reduces the fluid pressure in the power booster.

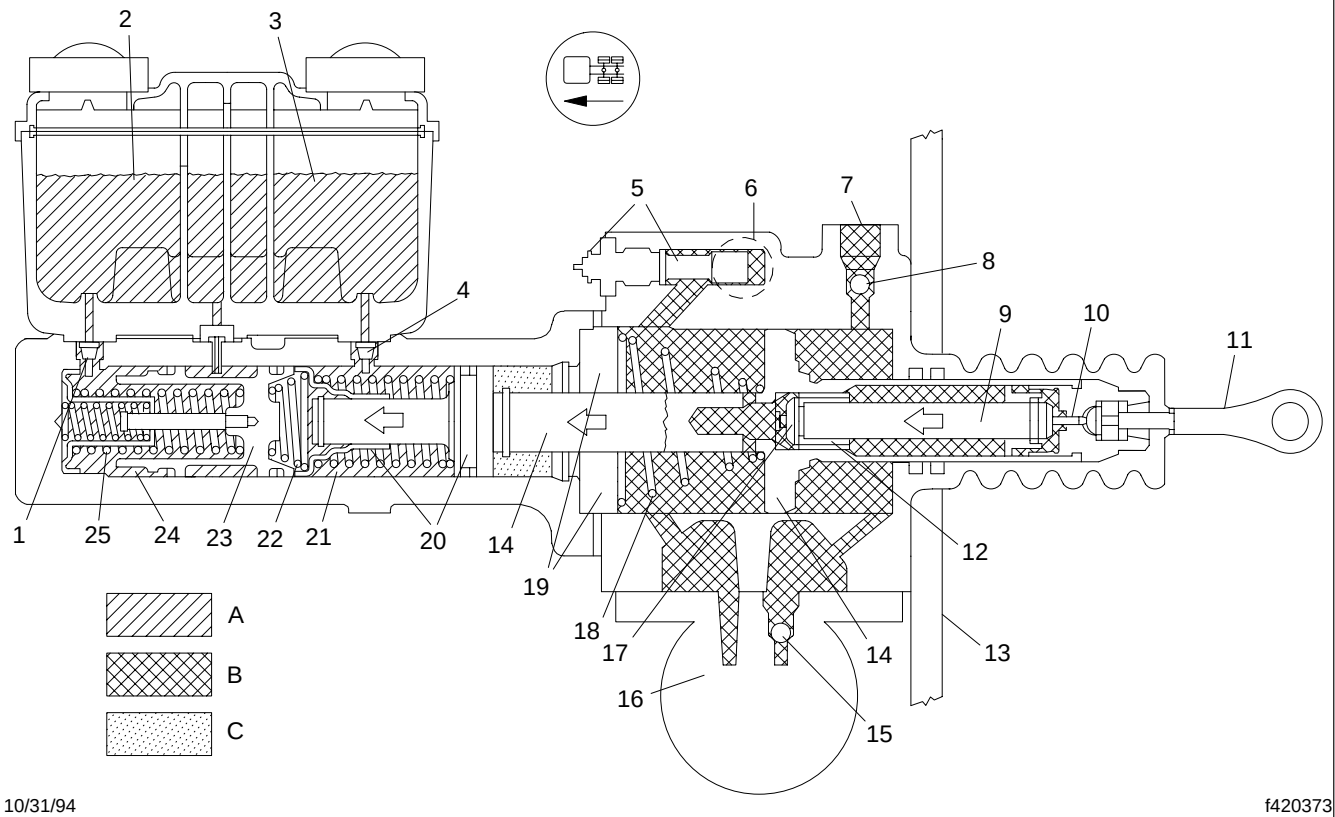
In the master cylinder, the return springs (Refs. 24 and 21) center the primary and secondary pistons. This opens up the primary and secondary compensating valves (Refs. 4 and 1), decreasing hydraulic pressure throughout the master cylinder. The pressure in the hydraulic lines drops, which allows the dual pistons in each caliper housing to retract. The calipers slide back outboard, and the brake pads no longer squeeze the rotors, allowing the rotors and wheel hubs to turn freely.

BRAKE CONTROL MODULE

The control module, which operates on 9 to 16 volts DC, is active (monitoring the hydraulic brake system) under any of the following conditions:

- When the ignition is on;
- When the brake pedal switch is powered;
- If the ignition is off, but the driver's door is open and the parking brake is not applied.

When the ignition is turned on, the control module starts a self-test mode, which lasts from about one to three seconds. The warning lights and buzzer come on, then go off if the system is working all right. The module then goes into the active mode, monitoring the hydraulic brake system. If a problem is detected, the applicable input or output terminal is activated, and a warning light and buzzer come on. The output terminals are activated as follows:



The "R" light (brake pressure) output—terminal 3—is activated when any of the following conditions exist:

- The flow switch on the power booster closes, due to a reduced flow of power steering fluid;
- The pressure differential switch on the master cylinder closes, due to a drop in pressure in either the front or rear brake system;
- The fluid level switch on the master cylinder reservoir closes, due to a drop in the fluid level;
- Too much electrical resistance is in the backup pump motor.

The "P" light (parking brake) output—terminal 2—is activated when any of the following conditions exist:

- The parking brake is applied, and the ignition is on;
- The driver's door is open, the parking brake is not applied, and the ignition is off. This condition will also cause the control module buzzer to come on.

NOTE: The vehicle is equipped with two dash buzzers: one on the control module itself, which comes on when the light "P" output (parking

brake) is activated due to the driver's door being open and the parking brake not applied; and one mounted separately from the control module, which comes on when the light "R" output (brake system pressure) is activated.

See Table 2 for information on when the input terminals are activated.

General Description and Principles of Operation

Terminal Number	Function	Circuit Number	Activated if
7	Ignition Input	388	The ignition is on.
8	Parking Brake Input	309	Parking brake is applied.
9	Relay Input	389	The ignition is on or brake pedal is depressed.
10	Door Open Input	397	Driver's door open, and parking brake not applied.
11	Pressure Differential Switch Input	36F	Pressure difference between front and rear systems becomes more than 483 kPa (70 psi).
12	Brake Pedal Input	500	Brake pedal depressed.
13	Pump Motor Input	398	Electrical resistance of backup pump motor too high.
14	Fluid Level Input	395	Fluid level of master cylinder below 25 percent capacity.
15	Flow Switch Input	393	No hydraulic flow through power booster.

Table 2

Safety Precautions

Because many brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Because medical experts believe that long-term exposure to some non-asbestos fibers could also be a health hazard, also observe the following precautions if servicing non-asbestos brake linings.

NOTE: The vehicle is originally equipped with non-asbestos brake linings.

Exposure to airborne brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

During brake servicing, wear an air purifying respirator with high-efficiency filters. The respirator and filter must be approved by NIOSH or MSHA, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency particulate air (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, or can't be used, clean the brake assembly in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with an HEPA filter system, remove dust from the brake rotors, caliper assemblies, dust shields, and brake pads. After vacuuming, remove any remaining dust using a rag soaked in water and wrung until nearly dry.

⚠ WARNING

WARNING: Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by NIOSH or MSHA. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

Hydraulic brake fluid is hazardous, and can cause blindness if it gets in your eyes. Always wear safety glasses when handling brake fluid or bleeding brake components. Brake fluid may also be a skin irritant. If you get it on your skin, wash it off as soon as possible.

Special care must be taken when disposing of used brake fluid. Put the fluid in a sealed plastic container and label it "Used Brake Fluid." Then dispose of it in an approved manner. Check with local and state regulations as to the correct disposal procedure.

Hydraulic System Bleeding

⚠ WARNING

WARNING: Before doing any of the work below, read the information under "Safety Precautions, 100". Failure to read the safety precautions, and to be aware of the dangers of brake fluid, could result in injury.

Whenever any hydraulic system fitting is loosened or disconnected, the entire system must be bled to remove any air that may have entered it.

⚠ CAUTION

CAUTION: Power steering fluid and brake fluid are incompatible. Never mix these two fluids, or serious damage to both hydraulic systems will result. Use only brake fluid for the master cylinder and brake lines. Use only power steering fluid for the power booster.

Always use new, clean brake fluid that meets DOT 3 specifications when bleeding the master cylinder and service brake system. Never reuse brake fluid, and don't use brake fluid containers for any other purpose. Keep brake fluid containers tightly closed to keep new brake fluid clean and dry.

IMPORTANT: Don't let brake fluid touch any painted surfaces, as it will remove the paint. Brake fluid may also damage certain non-metal surfaces. Don't let it get on brake pads or rotors.

PRESSURE BLEEDING, SERVICE BRAKE SYSTEM

Pressure bleeding is the preferred method for bleeding the service brake system. It requires the use of a special pressure bleeder kit, consisting of a tank, pressure pump and valve, gauge, tubing, and adapter. These are available from a number of manufacturers, and include instructions for use. **See Fig.1 .**

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Connect the pressure bleeder to the brake master cylinder reservoir, following the manufacturer's instructions.
   - 2.1 Fill the pressure bleeder with new DOT 3 approved brake fluid, then pressurize it according to the manufacturer's instructions.

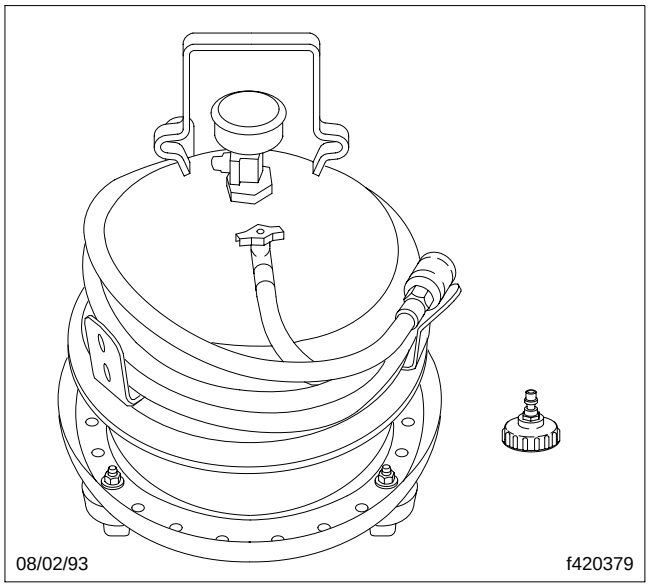

Fig. 1

   - 2.2 Using the supplied adapter, connect the pressure bleeder to the rear compartment of the master cylinder reservoir.
3. Bleed the hydraulic connections at the rear wheel calipers, starting on the right side.
   - 3.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. **See Fig.2.**
   - 3.2 Loosen the bleeder fitting about 3/4 turn, and let the brake fluid flow out of the fitting until it is free of air bubbles. **See Fig.2and Fig. 3.** Then tighten the fitting firmly.
   - 3.3 Move to the left rear caliper, and repeat steps for bleeding the caliper.

Hydraulic System Bleeding

4. Disconnect the pressure bleeder from the rear compartment of the master cylinder reservoir, then connect it to the front compartment of the reservoir.
5. Bleed the front wheel brake calipers, starting at the right side.

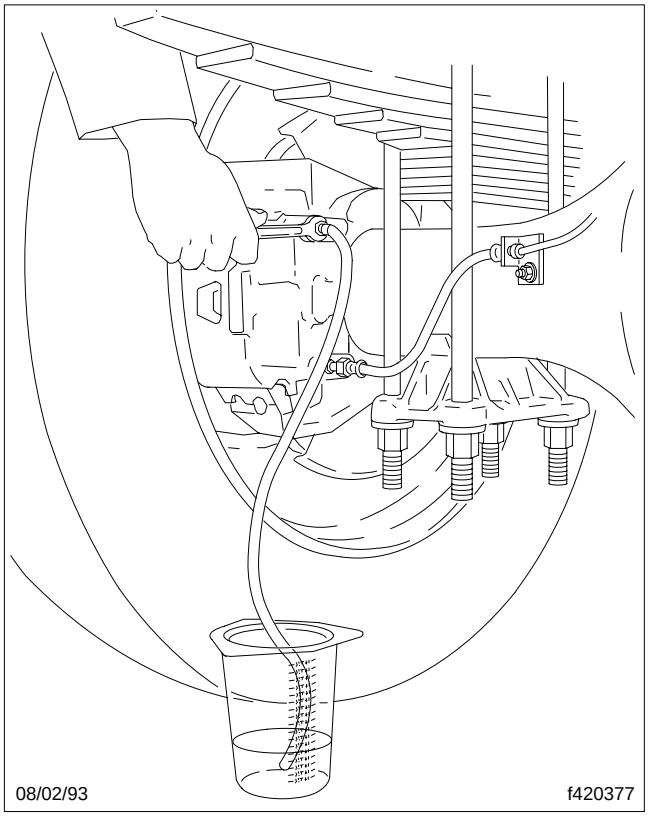

Fig. 2

5.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. **See Fig.2 .**

5.2 Loosen the bleeder fitting about 3/4 turn, and let the brake fluid flow out of the fitting until it is free of air bubbles. **See Fig.2and Fig. 3.** Then tighten the fitting firmly.

5.3 Move to the left front wheel caliper, and repeat steps for bleeding the caliper.

6. Check the brake fluid level in both compartments of the reservoir. Add new DOT 3 approved brake fluid if needed.
7. Check the operation of the brakes by depressing the brake pedal several times, until if feels firm. The brake pedal should not go all the way down to the floor. If it does, go to **"Troubleshooting, 300"** and find the problem.

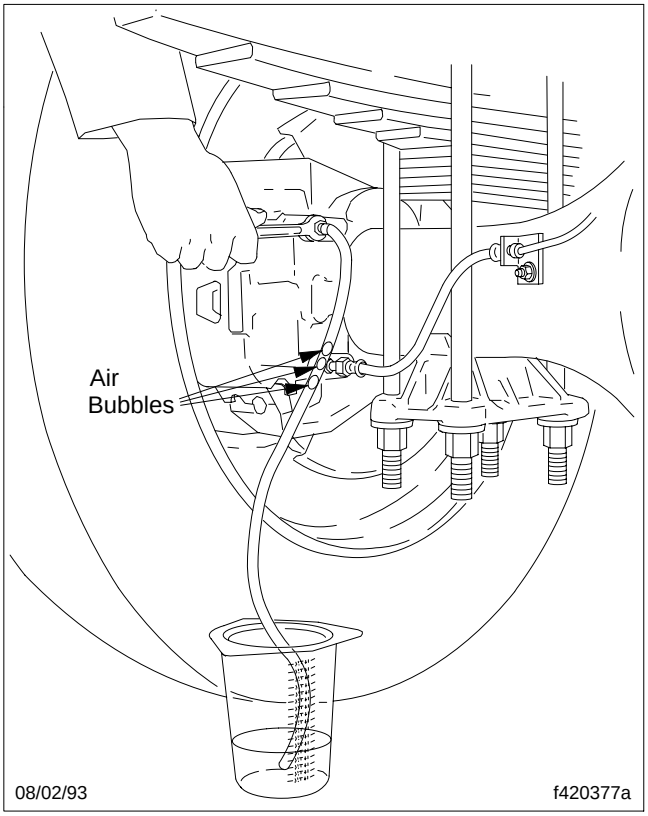

Fig. 3

8. Lower the hood and remove the chocks.

MANUAL BLEEDING, SERVICE BRAKE SYSTEM

If you don't have pressure bleeding equipment, you can use the manual bleeding procedure.

⚠ WARNING

WARNING: Read over the information under "Safety Precautions, 100" before starting the procedure below. Failure to do so may result in

either serious injury to yourself, or damage to the brake system, resulting in an accident causing serious personal injury or property damage.

IMPORTANT: Don't let the brake master cylinder run dry during manual bleeding operations. Keep the master cylinder reservoir filled with new, DOT 3 approved brake fluid. Failure to keep the brake reservoir filled could result in more air entering the system, making it impossible to effectively bleed the system.

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Bleed the master cylinder.
   - 2.1 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the rear outlet port on the master cylinder. **See Fig. 4 .** Loosen the fitting about one turn.
   - 2.2 Have someone push the brake pedal down slowly— by hand— to the floor. Brake fluid, and any air in the master cylinder, will squirt from the fitting.
   - 2.3 *With the brake pedal held down,* tighten the rear hydraulic line fitting firmly.

   IMPORTANT: Don't release the brake pedal until the fitting is tightened, or more air will get into the system.
   - 2.4 Release the brake pedal.
   - 2.5 Loosen the fitting again, and repeat steps for bleeding as required until no air escapes from the fitting, and the brake pedal feels firm.
   - 2.6 Check the level of the rear compartment of the reservoir, then add new DOT 3 approved brake fluid if needed.
   - 2.7 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the front outlet port on the master cylinder. **See Fig. 5 .** Loosen the fitting about one turn.
   - 2.8 Repeat steps as required for the front outlet port.
   - 2.9 Check the brake fluid level in the front compartment of the reservoir. Add new DOT 3 approved brake fluid if needed.
3. Bleed the hydraulic connections at the wheel calipers, starting at the right rear wheel caliper.
   - 3.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. **See Fig. 2 .**
   - 3.2 Loosen the bleeder fitting about 3/4 turn.

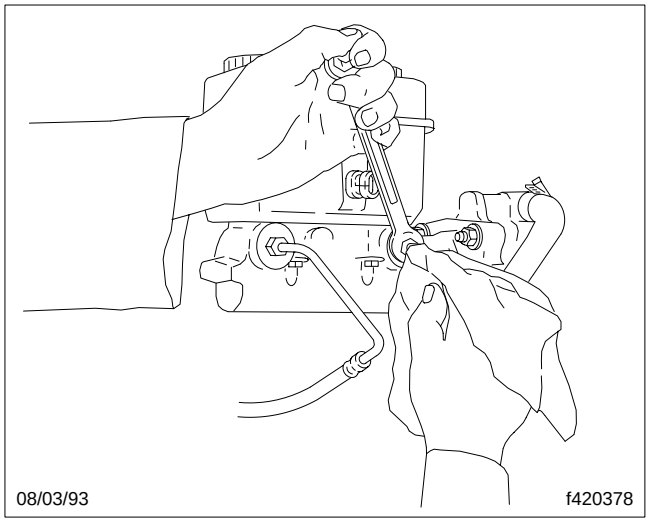

Fig. 4

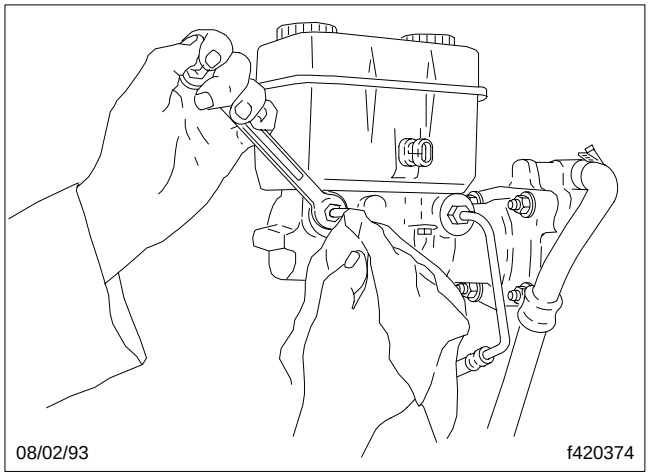

Fig. 5

Hydraulic System Bleeding

3.3 Have someone slowly push the brake pedal to the floor, then *with the brake pedal depressed,* tighten the bleeder fitting.

IMPORTANT: Make sure the brake pedal stays depressed while you tighten the fitting. If it's released before you tighten the fitting, more air will get into the system.

3.4 Release the brake pedal. Check the fluid in the tube. If there are air bubbles present **(Fig.3),** repeat steps as required until the fluid in the tube is completely free of air bubbles, **as shown in Fig.2.**

3.5 Check the brake fluid level in the reservoir. Add new DOT 3 approved brake fluid if needed.

3.6 Repeat steps for bleeding the connections for the left rear caliper, then the right front caliper, and finally for the left front caliper.

4. Lower the hood and remove the chocks.

Booster Bleeding

⚠ WARNING

WARNING: Use only clean, approved power steering fluid for the procedure below. Do not use brake fluid. Mixing brake fluid with power steering fluid will damage the seals and O-rings in the power booster, the power steering pump, and the power steering gear, resulting in possible loss of steering.

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Check the level of fluid in the power steering reservoir. **See Fig. 1 .** If needed, fill it with approved power steering fluid. **See "Specifications, 400"** for approved power steering fluid.
3. Crank the starter several times, but don't start the engine.
4. Check the fluid level in the power steering reservoir. Fill it if needed.
5. Crank the starter and check the fluid level again.
6. Check the operation of the brakes.
   - 6.1 With the engine off, depress the brake pedal. The dash warning light and buzzer should come on, and the electric motor assist should come on.
   - 6.2 Start the engine. Depress the brake pedal. The dash warning light and buzzer should not come on; neither should the electric motor. If they do, go to **"Troubleshooting, 300"** and find the problem; otherwise, stop the engine. Check the fluid level in the power steering reservoir. Fill it if needed.
7. Lower the hood, then remove the chocks.

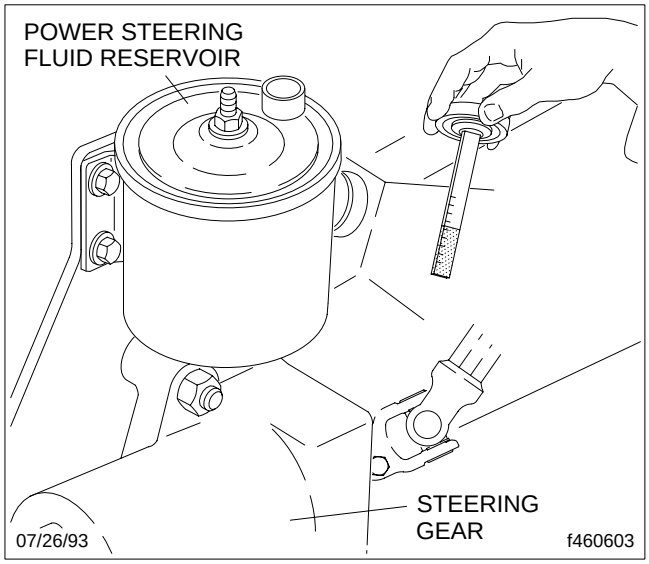

Fig. 1

Replacing Hydraulic Lines

POWER BOOSTER SYSTEM

The power booster is plumbed into the power steering system, and uses the same type of high pressure rubber hoses as that system.

The power booster has two hoses connected to it: one from the steering gear to the booster supply port, and one from the booster return port to the power steering reservoir. See **Fig. 1**.

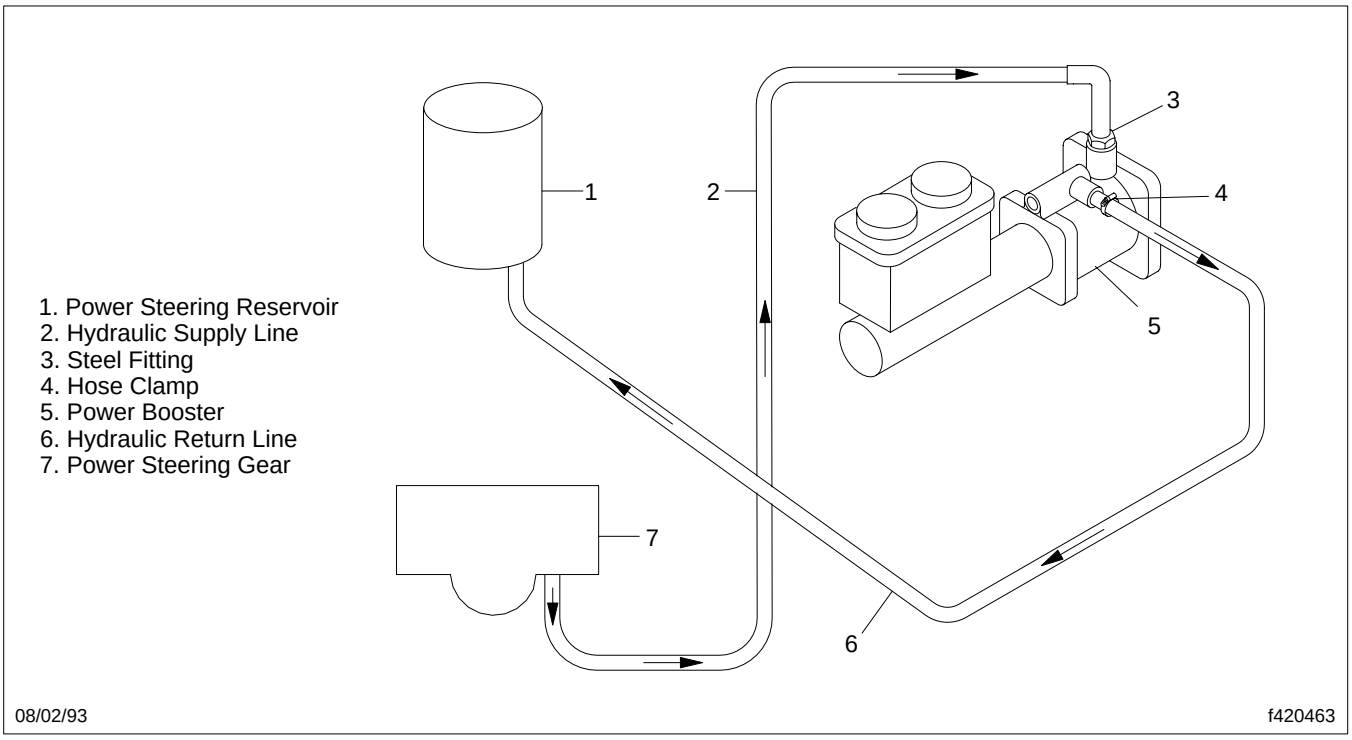

Fig. 1

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Replace the power booster hoses if they are leaking or show signs of cracking, softening, or bulging. Replace the entire hose if there are problems; don't repair it.

   2.1 Remove all hose clamps and tie straps used for routing the hose.

   2.2 Using a shop towel over the fittings to catch any power steering fluid, disconnect both ends of the hose being replaced.

   2.3 Install the new hose.

   If replacing the booster supply hose, tighten the supply port connection 22 lbf·ft (30 N·m), and the outlet connection on the power steering gear 41 lbf·ft (56 N·m).

   If replacing the booster return hose, tighten the hose clamps at the booster return fitting and the power steering reservoir firmly.

   2.4 Install the hose clamps and replace any tie straps removed above.

   Check the routing of the hose. Make sure it's away from heat sources and moving parts, such as the steering driveline.
3. Bleed the power booster system, following instructions in **Subject 115**.
4. Lower the hood, then remove the chocks.

Replacing Hydraulic Lines

SERVICE BRAKE SYSTEM

The service brake system has two types of hydraulic brake lines: rigid steel tubing and flexible rubber hose. See **Fig. 2**.

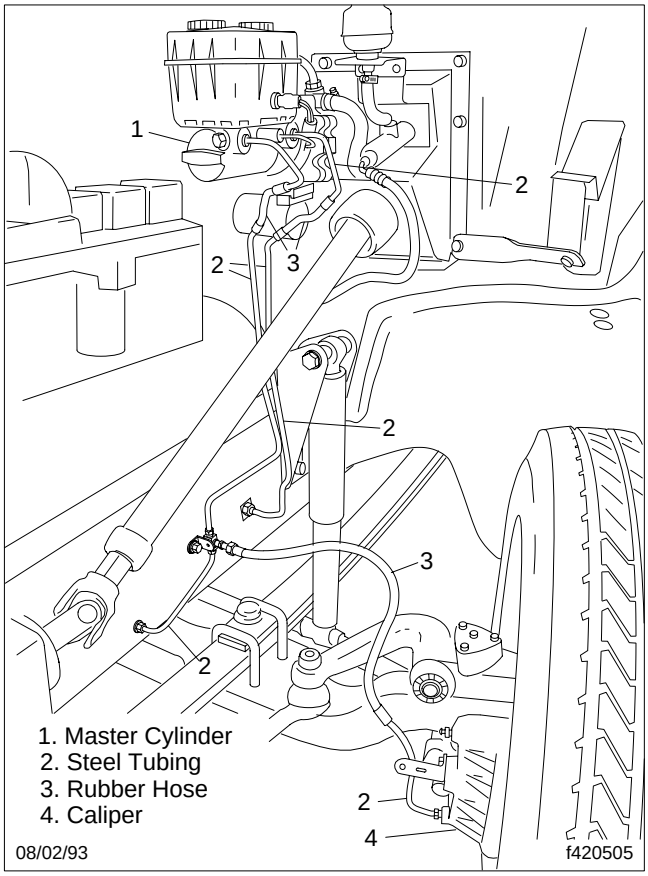

Fig. 2

The steel brake lines are 1/4-inch o.d. double-walled tubing, and run from the master cylinder to points on the chassis near each wheel. The rubber brake hoses are 1/8-inch i.d. low-expansion rubber; they connect the end of each rigid line to the caliper assembly at each wheel.

If a brake line is leaking, replace the whole section of line. Replace flexible brake hoses if they show signs of cracking, softening, or bulging.

1. Apply the parking brake and chock the tires.
2. Locate the leak in the brake line, then determine the length and configuration (if a steel line) of the section involved.
3. If necessary, loosen and remove any brackets holding the brake line to the frame or axle, so that you can remove the damaged section.
4. Put a container under the connection on one side of the leak, then disconnect the line. Plug both ends of the connection.

   Repeat at the connection on the other side of the leak.
5. Remove the plugs installed earlier, then install the new section of brake line, and tighten the connections 15 lbf·ft (20 N·m).
6. Install any brackets that were removed above.
7. Bleed the brake system, following the procedure in **Subject 110**.

Replacement

WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

IMPORTANT: When replacing brake pads, always replace them on both wheels of the axle (right and left side). If the brake pad linings are worn down to the minimum thickness of 1.6 mm (1/16 inch), you must also rebuild the calipers, as dirt has probably gotten into the caliper cylinders. Refer to **"Brake Caliper Removal and Installation, 140"** and **"Brake Caliper Rebuild, 142"** for instructions.

1. Apply the parking brake and chock the tires of the axle you will not be working on.
2. Remove the brake caliper from the wheel. Refer to **"Brake Caliper Removal and Installation, 140"** for instructions.
3. Remove the brake pads.
   - 3.1 Remove the outboard brake pad from the caliper assembly.
   - 3.2 Pull the inboard pad away from the rotor and the anchor plate. **See Fig. 1 .**
4. Using a wet rag that is wrung out until nearly dry, clean the caliper housing (especially around the piston boots), and the dust shield.
5. Check the rotor.
   - 5.1 Check the rotor surface for discoloration, cracks, scoring, and heat checking. **See Fig. 2 .**

     If the rotor is cracked, has a bluish color, or has severe heat checking, replace it. If it has minor heat checking or is scored **(refer to Fig. 2),** have it resurfaced.

     IMPORTANT: If the rotor will be 33.5 mm (1.32 inches) or less after it's resurfaced, replace it.
   - 5.2 Using a vernier caliper, check the thickness of the rotor. If it is less than 33.5 mm (1.32 inches) thick, replace it.

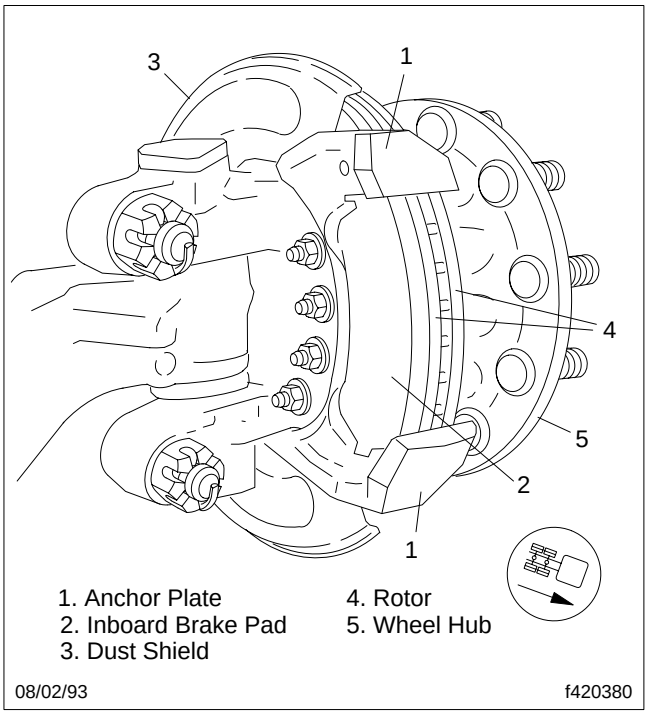

Fig. 1, Left Front Wheel Shown; Caliper Removed

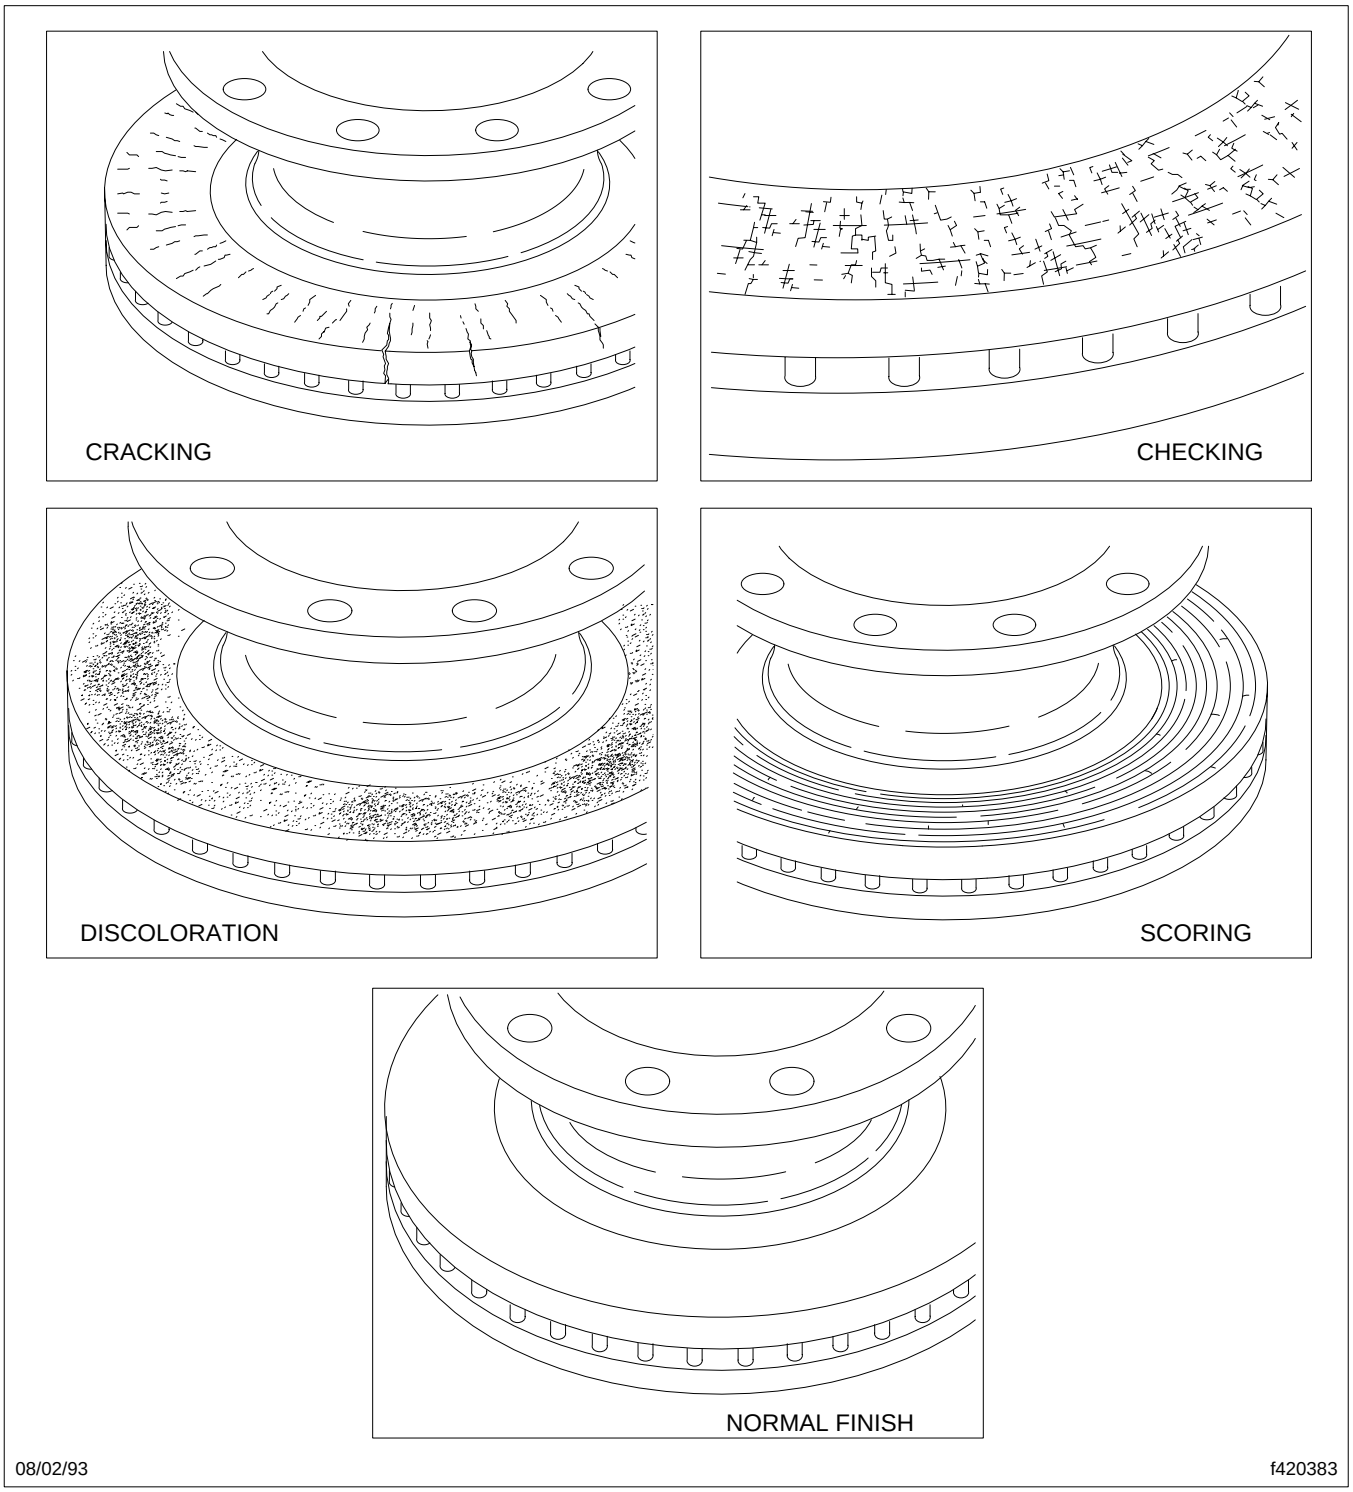
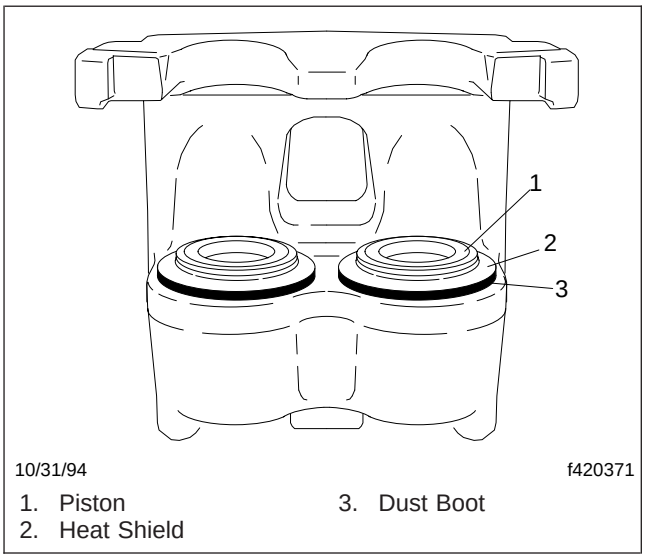
   - 5.3 Check for runout and parallelism. Refer to **"Brake Rotor Runout and Parallelism Checking, 152"** for instructions.
6. Check the caliper.
   - 6.1 Check the piston dust boots for cracks or leaks. **See Fig. 3 .** Also check the piston heat shields for damage. If a problem is found, disconnect the brake hose from the caliper, plug the hose, then rebuild the caliper, following the instructions under **"Brake Caliper Rebuild, 142."**
   - 6.2 Check the supply port and bleeder fitting **(Fig. 4)** on the caliper housing for damage or leaks. If a problem is found, replace the fitting, following the instructions under **"Brake Caliper Rebuild, 142."**
7. Clean and lubricate the sliding surfaces (V-ways) of the caliper housing and the anchor plate rails with anti-corrosion grease. **See Fig. 5 .**

Brake Pad Replacement





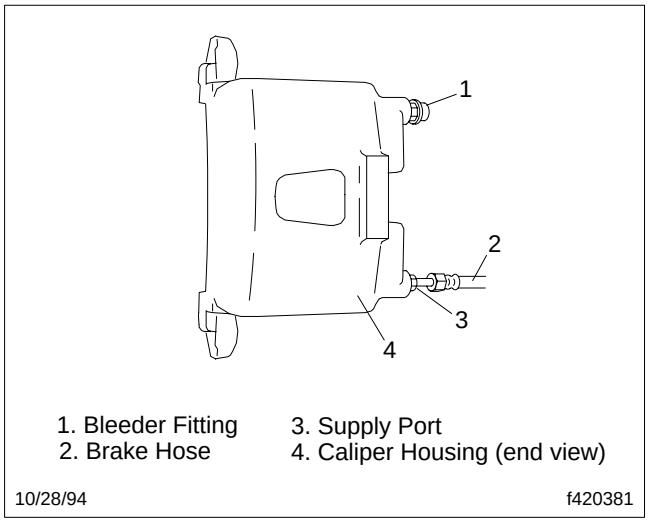


Fig. 2

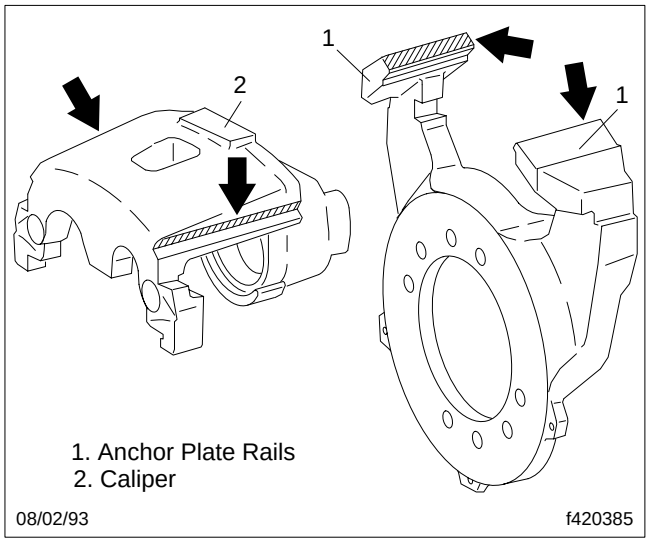
1. Piston
2. Heat Shield
3. Dust Boot

Fig. 3



1. Bleeder Fitting

4. Caliper Housing (end view)

Fig. 4

7.1 Using a fine file or emery cloth, clean the sliding surfaces (V-ways) of the caliper housing, and the corresponding surfaces of the anchor plate.

7.2 Grease the surfaces lightly with anti-corrosion grease.

8. Install the new brake pads.

1. Anchor Plate Rails
2. Caliper

Fig. 5

⚠ WARNING

WARNING: Don't get any dirt, oil, grease, or brake fluid on the brake lining material or the rotor surfaces. To do so could cause loss of brake control, which could result in an accident causing personal injury or property damage.

8.1 Install the inboard (smaller) brake pad into the mating notches of the anchor plate, **as shown in Fig. 1 .** Make sure the pad lining is facing the rotor.

8.2 Using a piece of wood and a C-clamp, push the pistons all the way into the caliper housing. **See Fig. 6 .** Be careful not to damage the piston heat shields. Remove the C-clamp and block of wood.

8.3 Install the outboard (larger) brake pad in the housing, with the pad lining facing the piston, **as shown in Fig. 7 .**

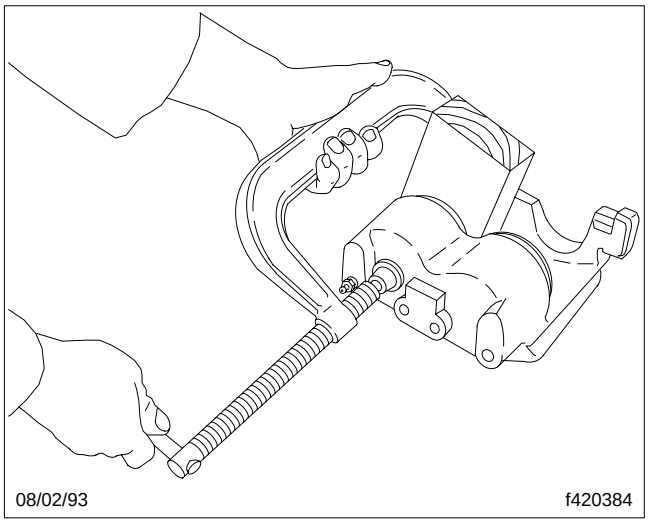
9. Install the caliper, following the instructions under **"Brake Caliper Removal and Installation, 140."**

10. Install the tires, then remove the jackstands and lower the vehicle. Remove the chocks.

11. Pump the brake pedal until it feels firm. If it doesn't get firm, check for leaks or air in the brake system. Repair any leaks, if needed, then

Brake Pad Replacement

bleed the system, following the instructions under **"Hydraulic System Bleeding, 110."**



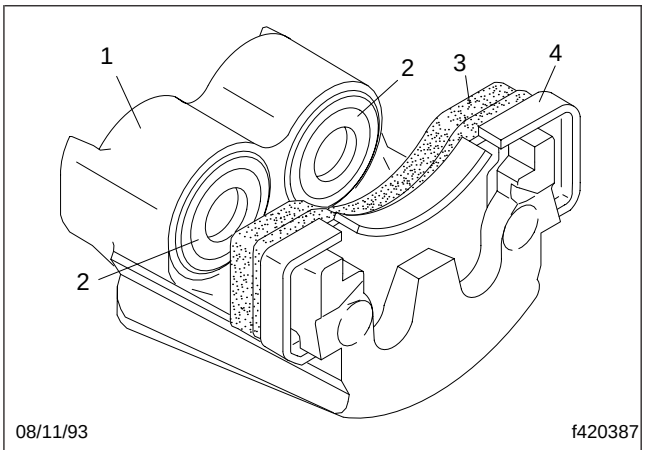


Fig. 6

1. Caliper Housing
2. Piston
3. Brake Pad Lining
4. Outboard Brake Pad

Fig. 7

⚠ WARNING

WARNING: Do not move the vehicle until the brake pedal feels firm. To do otherwise could result in loss of vehicle control, causing an accident resulting in personal injury or property damage.

12. Road test the vehicle, and seat the brake pads.

Accelerate the vehicle to 30 mph (48 km/h), then brake to a stop, using medium brake pedal pressure. *Do not slam on the brakes.*

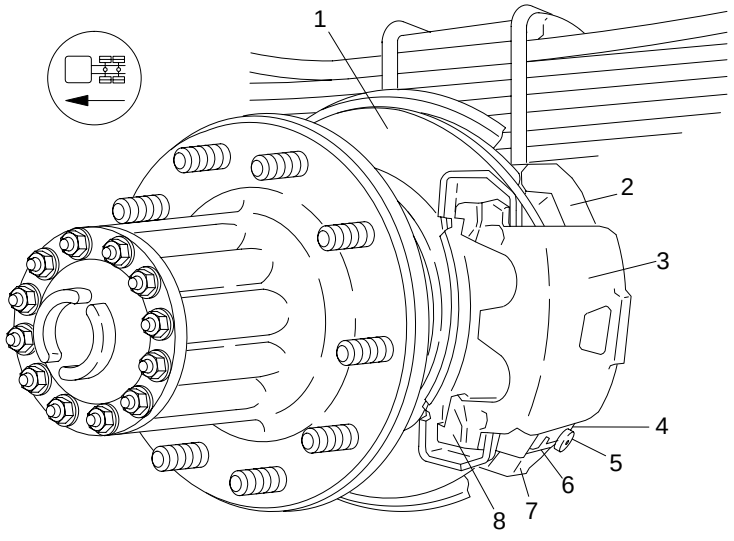
Repeat this step between 20 and 30 times, allowing a one-minute interval between brake applications.

Brake Caliper Removal and Installation

Removal

⚠ WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.



1. Apply the parking brake, chock the tires, and tilt the hood.
2. If you are removing the rear wheel caliper(s), remove half the fluid from the rear section of the master cylinder reservoir. If you are removing the front wheel caliper(s), remove half the fluid from the front section.
3. Chock the front or rear tires, depending on which axle you are working on. Then jack up the axle, and support it with jackstands.
4. Remove the tires.
5. Remove the brake caliper.
   - 5.1 If you are going to do work on the caliper, disconnect and plug the brake supply hose; otherwise, leave it attached.
   - 5.2 Remove the allen-head bolt that holds the key and spring assembly in place (on the upper anchor plate rail for the front wheel; on the lower rail for the rear wheel). **See Fig.1.**
   - 5.3 Using a punch, drive out the key and spring from between the caliper and the anchor plate rail, **as shown in Fig.2.** Save the parts.
   - 5.4 Tilt the caliper up so the outboard brake pad clears the rotor, then slide the caliper off the anchor plate rails. **See Fig.3.** Be careful not to stretch the brake hose.

     The inboard brake pad will stay in place between the upper and lower rails of the anchor plate.
   - 5.5 If the brake supply hose is attached, support the caliper with a wire, or rest it on the axle suspension. *Don't let the caliper hang by its brake hose.*
6. Remove the outboard brake pad from the caliper housing.
7. Remove the inboard brake pad from the anchor plate. **See Fig.4.**

Installation

1. Check the brake pad linings for wear and damage.
   - 1.1 Check the linings for wear. If they are 1.6 mm (1/16 inch) or less thick, replace the brake pads, following the instructions under **Subject 130.**
   - 1.2 Check the linings for pits, cracks (**see Fig.5**), separation of the material (delaminating), or other damage. Replace the brake pads if they are damaged.
   - 1.3 Check the linings for glazing. If they are glazed but not otherwise damaged, deglaze the linings, using deglazing compound. Follow the manufacturer's directions.
2. Check the caliper.
   - 2.1 Check the piston dust boots for damage or leaks. **See Fig.6.** If a problem is found, rebuild the caliper, following the instructions under **Subject 142.**
   - 2.2 Check the bleeder fitting for leaks or damage. If there are signs of leakage, check the tightness of the fitting. If the fitting is damaged, replace it. Refer to **Subject 142** for instructions.
3. Check the rotor, following the instructions under **Subject 130.**
4. Clean and lightly lubricate the sliding surfaces (V-ways) of the caliper housing and the anchor plate rails with Aeroshell Grade 5 (ES-1246) grease (don't use any type of anti-seize compound, such as Never-Seeze). **See Fig.7.**
   - 4.1 Using a fine file or emery cloth, clean the sliding surfaces (V-ways) of the caliper housing, and the corresponding surfaces of the anchor plate rails.
   - 4.2 Grease the surfaces lightly with Aeroshell Grade 5 (ES-1246) grease (don't use any

3. Brake Pad Lining
4. Outboard Brake Pad

Fig. 9

6.3 Tilt the caliper housing so that the outboard brake pad will fit over the rotor, then push the caliper down onto the anchor plate rails. **See Fig.10.**

IMPORTANT: 2.88-inch calipers have pads that are chamfered on one end. Depending on mounting location (steer axle or rear axle), make sure that the 2.88-inch calipers are installed **as shown in Fig.11.**

6.4 Assemble the spring and key **as shown in Fig.12**, then install them between the caliper housing and the anchor plate rail (the upper rail for front wheel calipers, or the lower rail for rear wheel calipers).

1. Outboard Brake Pad
2. Rotor
3. Caliper

Fig. 10

6.5 Drive the key and spring into place, using a punch and mallet. **See Fig.13.** Make sure the notch in the key lines up with the hole in the anchor plate rail.

6.6 Install the allen-head bolt, and tighten it 20 N·m (15 lbf·ft).

7. If the brake supply hose was disconnected, connect it; otherwise go to the next step and check the fluid level.

   7.1 Tighten the brake supply hose fitting 20 N·m (15 lbf·ft).

   7.2 Bleed the brake supply line to the caliper, following the instructions under **Subject 110.** If you have removed more than one brake caliper, bleed the entire brake system.

8. Check the fluid level in the master cylinder reservoir, and add the necessary amount of new DOT 3 approved brake fluid.

9. Seat the brake pads by pressing firmly on the brake pedal several times.

   If new brake pads were installed, seat them following the instructions under **Subject 130.**

10. Lower the hood, then remove the chocks.

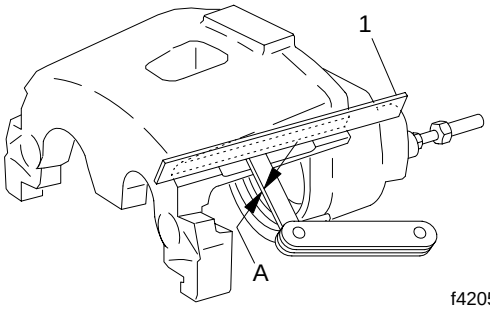
Rebuild



WARNING

WARNING: Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Apply the parking brake, then chock the tires of the axle(s) you are not working on.
2. Remove the tire.
3. Clean the outside of the caliper housing, using a damp rag.
4. Remove the caliper from the wheel, following the instructions under **Subject 140.**
5. Drain any remaining brake fluid from the caliper housing. Discard the fluid.
6. Measure the wear depth of both caliper V-ways.

   6.1 Using a wire brush, clean the V-way surfaces of the caliper housing. File smooth any deep nicks or gouges.

   6.2 Lay the caliper housing on a bench, then put a straight edge on a V-way surface, as shown in **Fig. 1 .**

10/28/94 f420598a

A. 1.27 mm (0.05 in)
1. Straightedge

Fig. 1

   6.3 Using a feeler gauge, measure the gap between the V-way surface and the straight edge. **See Fig. 1.** Record the measurement.

   Repeat this measurement for all the V-way surfaces. If any measurement is 1.27 mm (0.05 inch) or more, replace the caliper housing; otherwise, go to the step for checking caliper-to-anchor plate looseness.

7. Check for caliper-to-anchor plate looseness.

   7.1 Install the caliper on the rotor.

   7.2 Install a new key and the existing allen head bolt, but don't install the spring.

   7.3 Put a screwdriver in the gap (bumper gap) between the key and the V-way of the caliper. Pry up to seat the caliper against the sliding surfaces B and C, as shown in **Fig. 2.**

10/28/94 f420568a

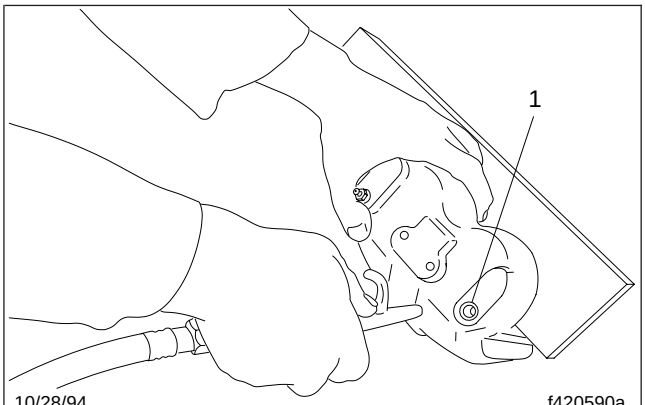
A. 3.68 mm (0.145 inch)

Fig. 2

   7.4 Using a feeler gauge, measure the bumper gap (the distance between the key and the caliper V-way). **See Fig. 2.**

   7.5 If the bumper gap is more than 3.68 mm (0.145 inch), replace the caliper, and repeat steps checking caliper-to-anchor plate looseness. If the bumper gap is more than 3.68 mm (0.145 inch) with the new caliper installed, replace the anchor plate.

   If the bumper gap is 3.68 mm (0.145 inch) or less, check **Table 1** for the correct size wear shim to install on the anchor plate. Then remove the caliper from the rotor, and go to the step for removing the pistons from the caliper housing.



Brake Caliper Rebuild

Bumper Gap mm (inch)		Shim Thickness
More than	But Not Over	
0	1.47 (0.058)	None needed
1.47 (0.058)	2.57 (0.101)	0.025
2.57 (0.101)	3.68 (0.145)	0.045
3.68 (0.145)	—	Replace the caliper

Table 1, Bumper Gap Sizes

8. Remove the pistons from the caliper housing.

8.1 Connect a compressed air line with a control nozzle to the supply port of the caliper housing. **See Fig. 3.**

1. Supply Port

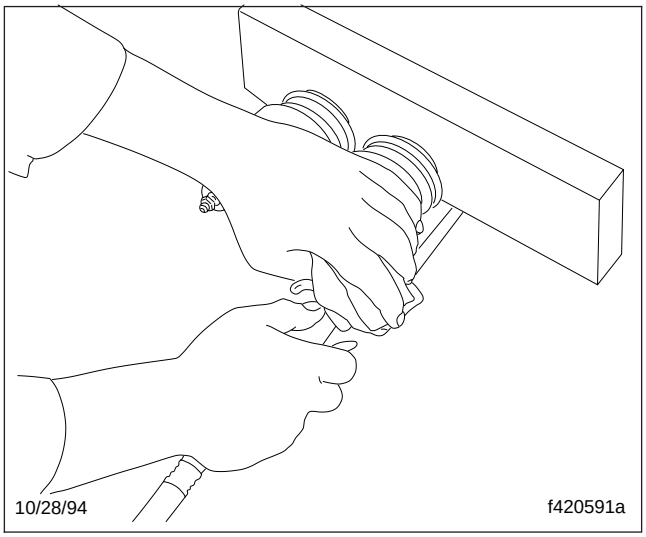
Fig. 3

8.2 Put a padded block of wood up against the outboard legs of the caliper, opposite the pistons, as shown in **Fig. 4.**

⚠ WARNING

WARNING: Be careful when using compressed air to remove the caliper pistons from their cylinders. Keep your hands away from the front of the pistons. Use only enough air pressure to ease out the pistons, or they may fly out forcibly, which could cause personal injury, or damage the pistons.

8.3 Slowly release compressed air, and ease the pistons out of the cylinders until they



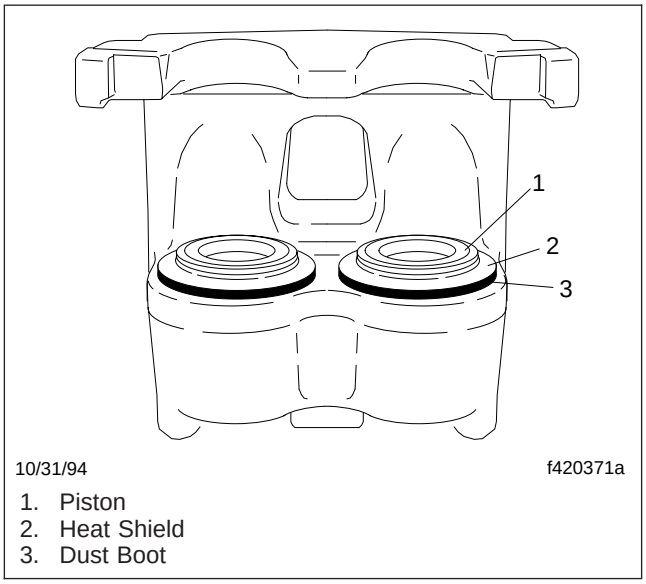


Fig. 4

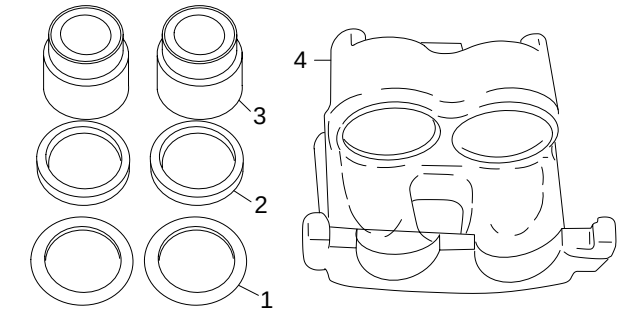
are up against the wooden block. Don't pop the pistons out.

8.4 Using tin snips, cut both piston heat shields **(Fig. 5),** then remove them from the pistons.



1. Piston
2. Heat Shield
3. Dust Boot

Fig. 5

8.5 Pry the dust boot of one of the pistons from its seat in the cylinder, then do the same for the other dust boot. Remove and discard both dust boots.

8.6 Remove both pistons from their cylinders. **See Fig. 6.**

1. Heat Shield
2. Dust Boot
3. Piston
4. Caliper Housing

Fig. 6

8.7 Remove the piston seal **(Fig. 7)** from inside each cylinder.

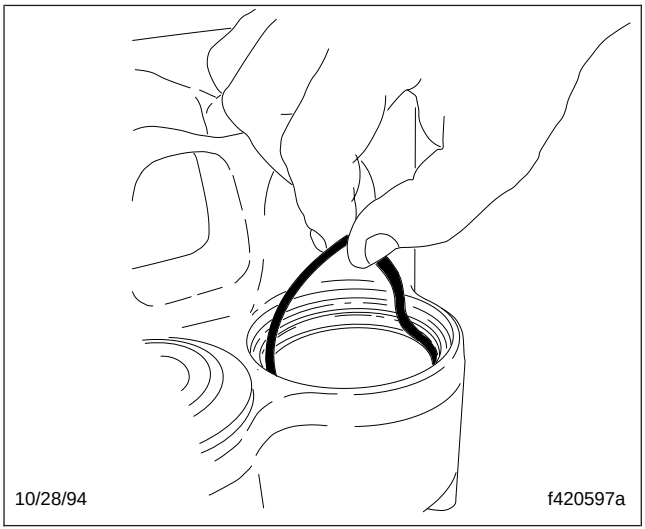


Fig. 7

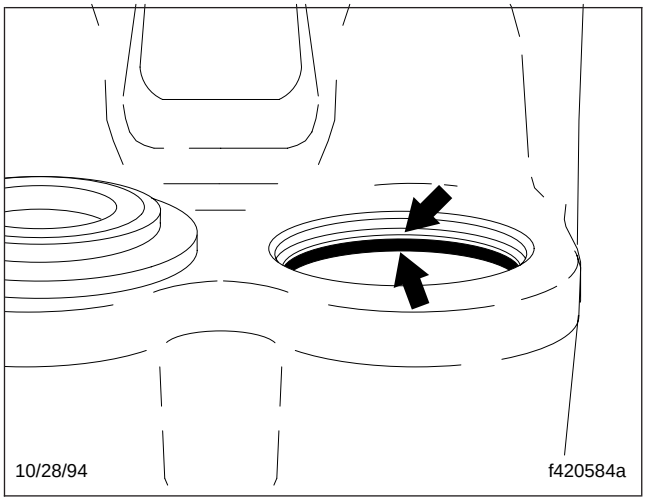
9. Using denatured alcohol, clean the pistons and the caliper housing. Clean both the outside of the caliper and the piston cylinders. Blow dry all the parts with compressed air.
10. Check the outside of the pistons for pitting, scoring, corrosion, or damage. If any problem is found, replace the piston.
11. Check the caliper seal grooves and dust boot seats for pitting. **See Fig. 8.** If pitting is found, replace the caliper housing. Clean any corrosion from the area between the seal groove and dust boot seat.



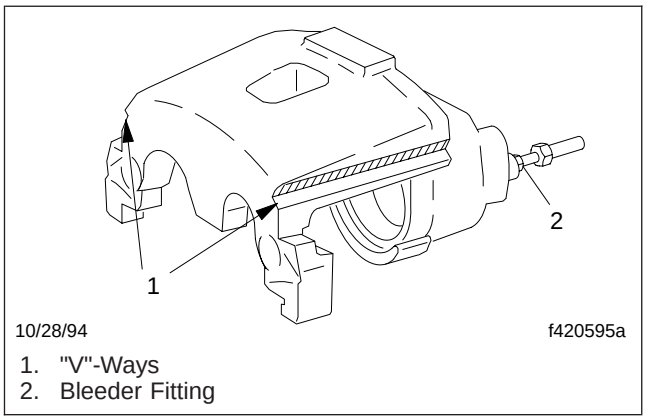


Fig. 8

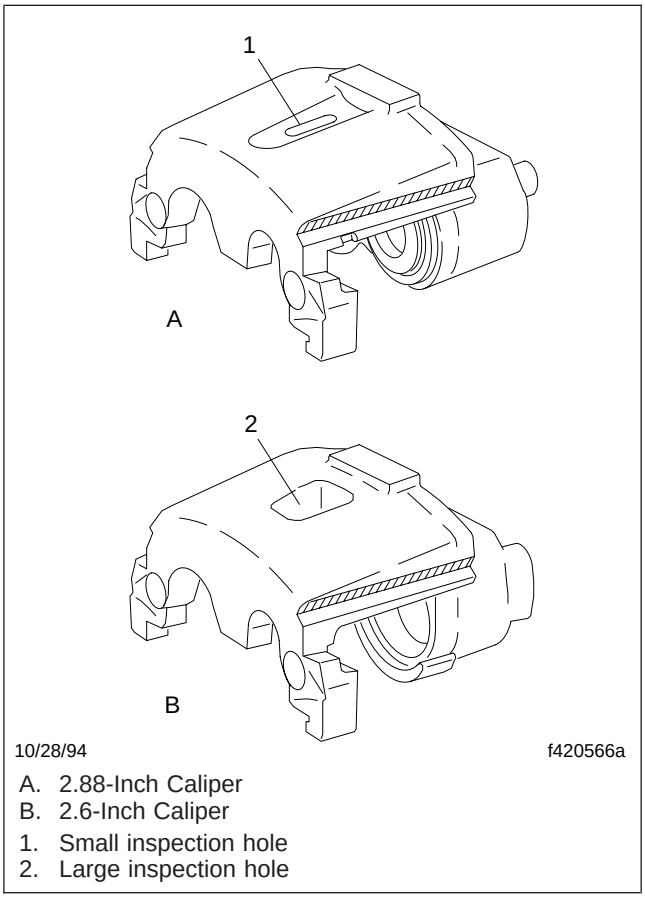
12. Check the bleeder fitting **(Fig. 9)** for damage or wear. If a problem is found, replace the fitting.

1. "V"-Ways
2. Bleeder Fitting

Fig. 9



13. Install new piston seals.

IMPORTANT: Two different types of brake calipers are used on Freightliner vehicles: calipers with 2.6 inch-diameter pistons, and those with 2.88 inch-diameter pistons. Make sure you use the right seals, dust boots, and heat shields, for the type of caliper you are rebuilding.

Brake Caliper Rebuild

To determine the type of caliper, check the inspection hole on the rear of the caliper housing. If it's large, the pistons are 2.6 inches in diameter; if the hole is small, they are 2.88 inches. **See Fig. 10.**

13.1 Coat a new piston seal with new, clean brake fluid **See Fig. 11.**

A. 2.88-Inch Caliper
B. 2.6-Inch Caliper
1. Small inspection hole
2. Large inspection hole

Fig. 10

13.2 Install a new piston seal in each of the cylinders. Make sure the seal is not twisted.

14. Install new dust boots on the pistons, as shown in **Fig. 12 .**

15. Install the pistons.

15.1 Coat the bottom half (closed end) of one of the pistons with new brake fluid. *Don't get any brake fluid on the dust boot.*

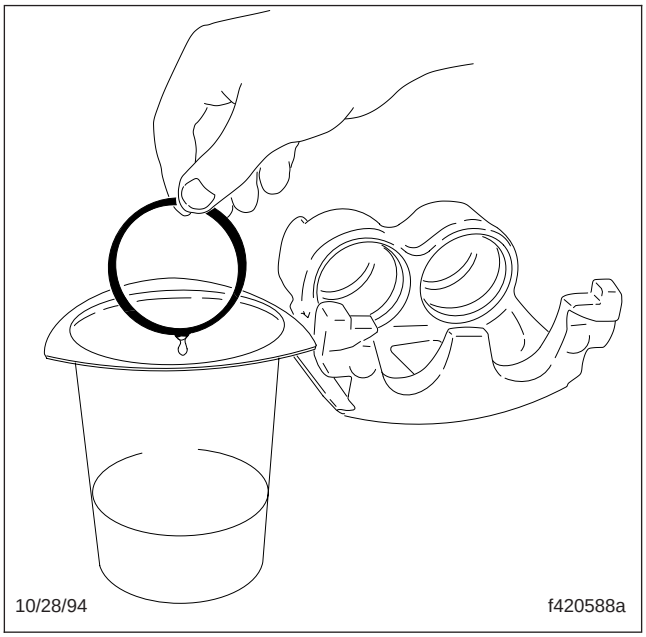


Fig. 11

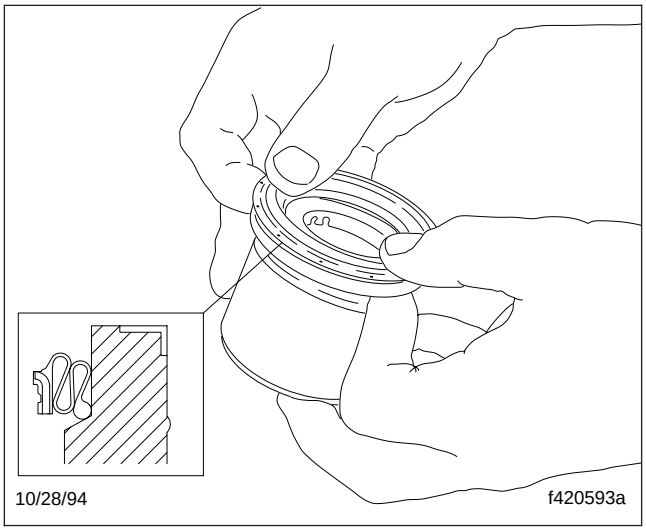

Fig. 12

15.2 Place the bottom (closed end) of the piston into its cylinder, making sure it is perfectly straight. **See Fig. 13.**

IMPORTANT: Make sure the piston is lined up in the cylinder perfectly straight before you install it; otherwise it will bind. If the piston binds in the cylinder, it will be impossible to install, and very difficult to remove.

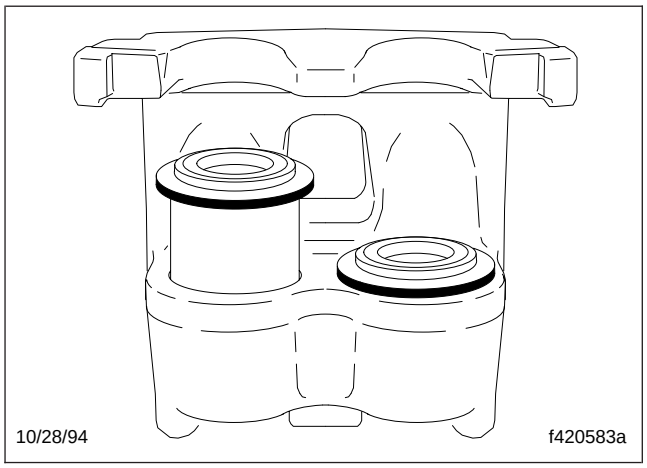

Fig. 13

15.3 Put a piece of thick metal or a block of wood over the top (open end) of the piston. Then, using a C-clamp, push the piston all the way into the cylinder until it bottoms out. **See Fig. 14.** Be careful not to damage the dust boot. If you feel resistance, the piston is in crooked. Remove it and start over.

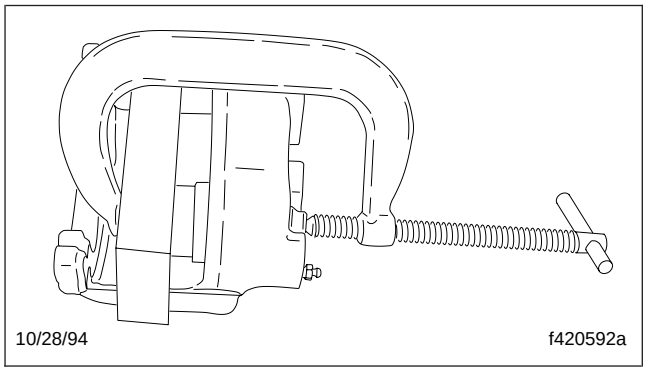

Fig. 14

15.4 Take the Kent-Moore special tool (KMS/ZTSE4275 for 2.88-inch pistons, or KMS/ZTSE4343 for 2.60-inch pistons), and put the side of the tool marked "Boot" against the dust boot. Then using the C-clamp, seat the dust boot into its groove in the cylinder.

15.5 Repeat the previous steps as needed for installing the other piston.

16. Install the heat shields on the pistons.

16.1 Put a new heat shield over the top of one piston as shown in **Fig. 15.** Make sure the heat shield is positioned correctly.

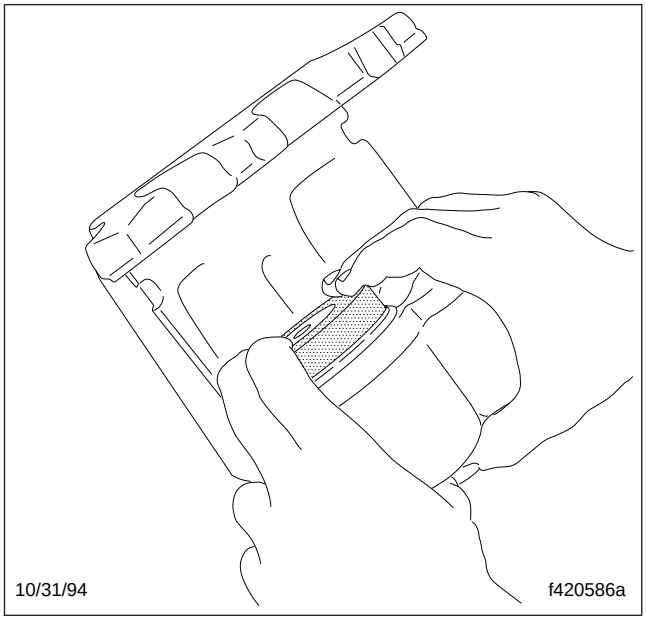

Fig. 15

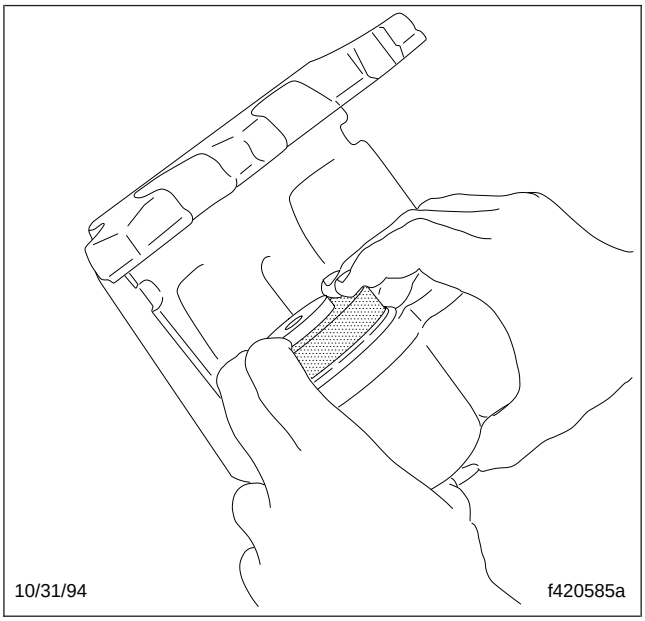
16.2 Put the side of the Kent-Moore special tool (KMS/ZTSE4275 for 2.88-inch pistons, or KMS/ZTSE4343 for 2.6-inch pistons) marked "Heat Shield" against the heat shield. **See Fig. 16.** Using the C-clamp, seat the new heat shield onto the piston.

17. If a wear shim is required, install the applicable wear shim (chosen according to **Table 1**) on the opposite anchor plate V-way from which the key and spring are installed. **See Fig. 17.**

18. Install the caliper on the rotor following the instructions under **Subject 140.**

19. Install the tire. Remove the chocks.

Brake Caliper Rebuild



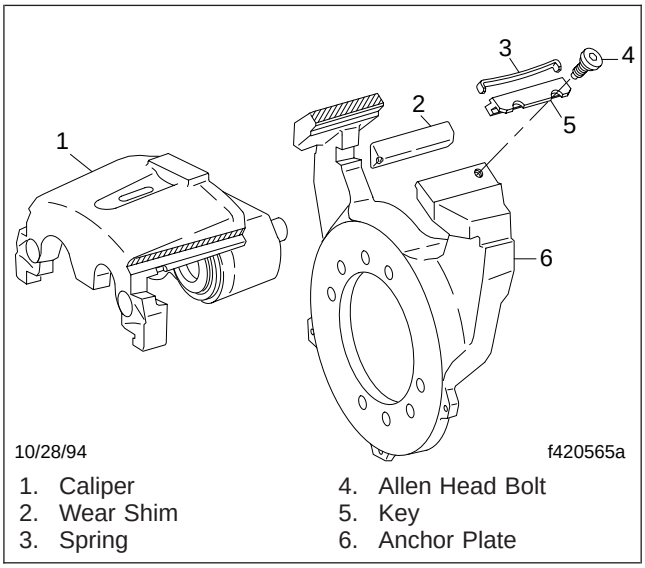


Fig. 16

6. Anchor Plate

Fig. 17

Brake Rotor Removal and Installation

⚠ WARNING

Before starting the procedure below, read the information in Safety Precautions, 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Removal

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Remove about half the brake fluid from the front section (if removing a front-axle rotor) or the rear section (rear-axle rotor) of the master cylinder reservoir. See **Fig. 1**.

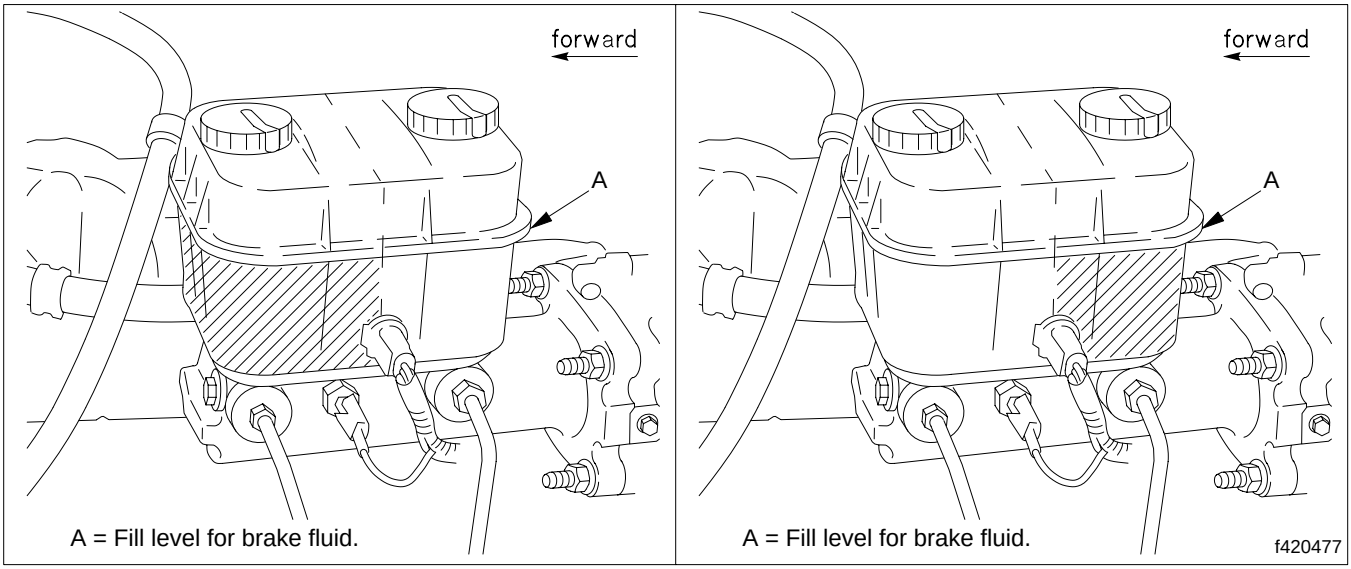

Fig. 1

3. Chock the front or rear tires, as required.
4. Jack up the vehicle, then support the axle with jackstands.
5. Remove the tire.
6. Remove the brake caliper from the rotor, following the instructions in **Subject 140**.
7. Remove the hub and rotor assembly from the axle, following the instructions in **Group 33** or **Group 35**. Put the hub on the floor so the rotor is facing up.
8. Remove the brake rotor from the wheel hub.
   - 8.1 Remove the hexbolts and washers that attach the rotor to the hub. See **Fig. 2**.
   - 8.2 Lift the brake rotor off the hub.

Installation

1. Install the rotor on the wheel hub.
   - 1.1 Position the rotor on the hub as shown in **Fig. 3**. Make sure the holes in the rotor are lined up with those of the hub.
   - 1.2 Install the mounting hexbolts and washers. Using a star pattern, tighten the hexbolts 175 N·m (130 lbf·ft). See **Fig. 4**.
2. Install the hub and rotor assembly on the axle, following the instructions in **Group 33** or **Group 35**.
3. Install the brake caliper on the rotor, following the instructions in **Subject 140**.
4. Install the tire.
5. Remove the jackstands, then lower the vehicle.
6. Fill the applicable section of the master cylinder reservoir with new DOT 3 approved brake fluid. The brake fluid level should be even with the

Brake Rotor Removal and Installation

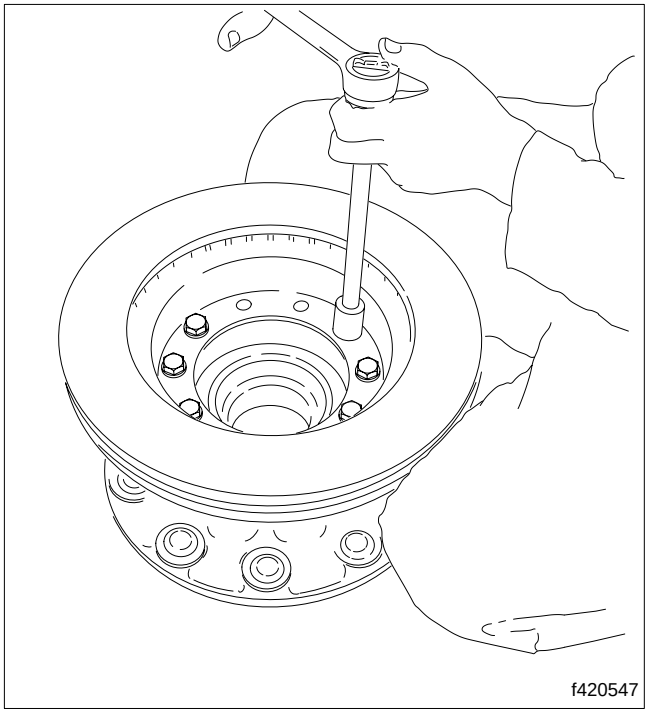

Fig. 2

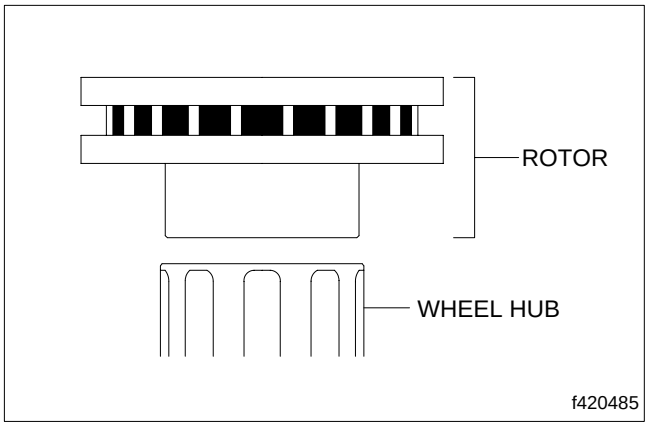

Fig. 3

raised seam on the outside circumference of the reservoir. See **Fig. 1**, Ref. A.

7. Lower the hood, then remove the chocks.

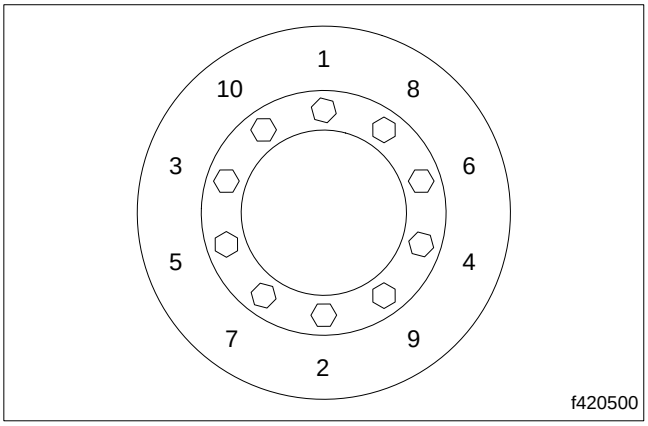

Fig. 4

Brake Rotor Runout and Parallelism Checking

Runout Checking

Brake rotor runout refers to the amount of lateral wobble the rotor has when it is turning, with the wheel bearings correctly adjusted. **See Fig. 1 .** Check the rotor runout whenever you replace the brake pads.

1. If not already done, chock the tires, jack up the axle you are working on and support it with jackstands. Then remove the wheels and tires.
2. If working on the rear axle, put the transmission in neutral.
3. Using a dial indicator, measure the amount of runout while spinning the rotor, **as shown in Fig. 2 .** Make sure the indicator is centered on the rotor face (between the outer and inner edges).
4. If the runout is more than 0.38 mm (0.015 inch), check that the rotor is securely mounted to the hub. Also check the wheel bearing end-play, following the instructions **in the front axle group** or **the rear axle group.**
5. Repeat the runout measurement. If the runout is still more than 0.38 mm (0.015 inch), replace the rotor.

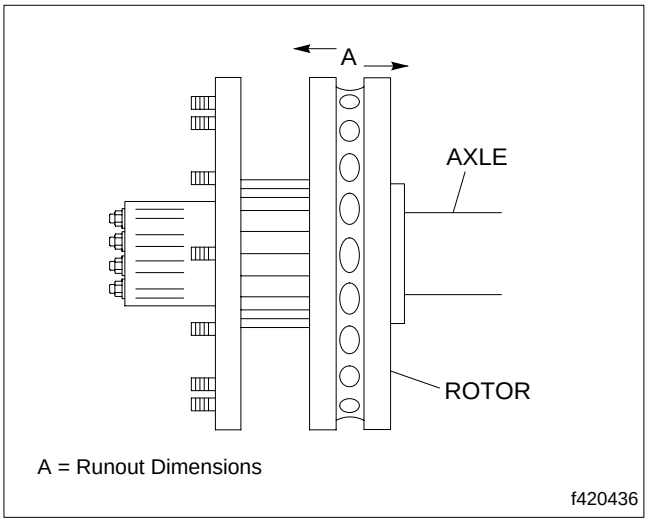

Fig. 1

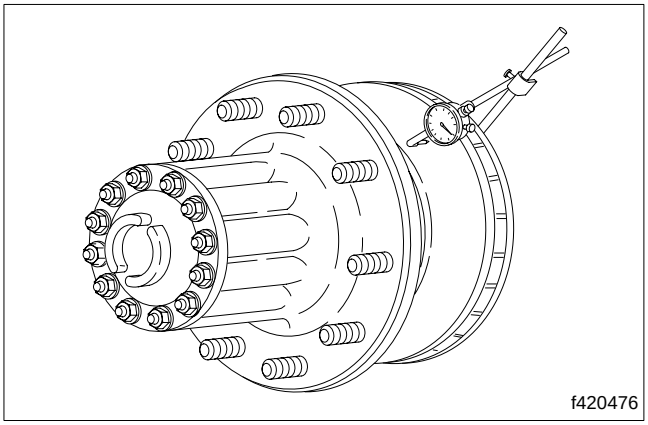

Fig. 2

Parallelism Checking

Parallelism is the difference in rotor thickness at different points around the rotor. It should be checked whenever the brake pads are replaced.

1. Using a vernier caliper or a micrometer, measure the thickness of the rotor (between the inboard and outboard faces) at four or more equally spaced points around the rotor. **See Fig. 3 .**
2. If there is a difference of more than 0.13 mm (0.005 inch) between any two measurements, have the rotor resurfaced. If resurfacing will decrease the overall thickness of the rotor to 33.5 mm (1.32 inches) or less, replace the rotor.

Brake Rotor Runout and Parallelism Checking

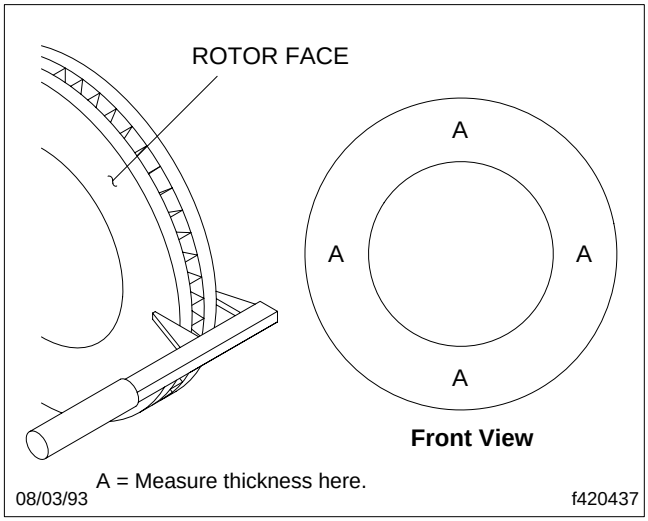

Fig. 3

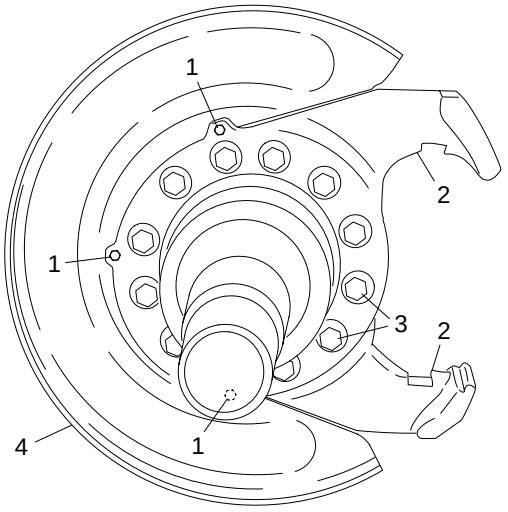


Anchor Plate Removal and Installation

Removal

1. Chock the rear or front tires, as required.
2. Jack up the vehicle, then support the axle with jackstands.
3. Remove the tire.
4. Remove the brake caliper from the anchor plate, following the instructions under **"Brake Caliper Removal and Installation, 140."**
5. Remove the wheel hub and rotor assembly from the axle, following the instructions in **the front axle group** or **the rear axle group.**
6. Remove the anchor plate from the axle.
   - 6.1 Remove the three screws holding the dust shield to the anchor plate, then remove the dust shield.
   - 6.2 Remove the hexbolts, washers, and nuts that hold the anchor plate to the axle. **See Fig. 1 .**
   - 6.3 Remove the anchor plate from the axle.

Installation

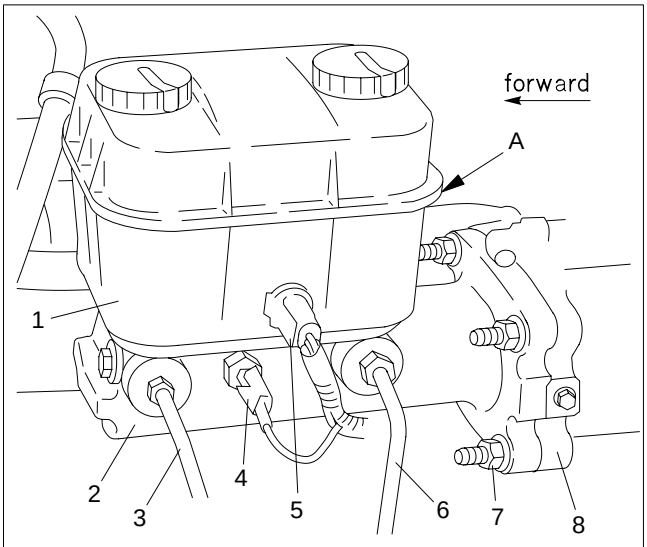
1. Install the anchor plate on the axle.
   - 1.1 Position the anchor plate in place against the outboard side of the axle flange, making sure the holes in both are lined up.
   - 1.2 From the outboard side of the anchor plate, install the hexbolts and washers, then install the nuts and remaining washers. **See Fig. 1 .** Using a star pattern, tighten the hexnuts as follows:
     - Rear Axle; 142 N·m (105 lbf·ft)
     - Front Axle Type FC; 102 N·m (75 lbf·ft)
     - Front Axle Type FD/FF; 197 N·m (145 lbf·ft)
2. Install the dust shield on the anchor plate. **See Fig. 1 .**
3. Install the wheel hub and rotor assembly onto the axle, following the instructions in **the front axle group** or **the rear axle group.**

1. Dust Shield Screws (3 qty.)
2. Anchor Plate
3. Mounting Hexbolts (12 qty.)
4. Dust Shield

08/03/93 f420554

Fig. 1

4. Install the brake caliper on the anchor plate, following the instructions under **"Brake Caliper Removal and Installation, 140."**
5. Install the tire.
6. Remove the jackstands, then lower the vehicle.
7. Remove the chocks.



Master Cylinder Removal and Installation

Removal

WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake fluid exposure could result in serious and permanent health damage.

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Disconnect the wires from the pressure differential switch (**Fig. 1** , Ref. 4) on the master cylinder, and the fluid level sensor (Ref. 5) on the reservoir.
3. Remove the accelerator cable clamp (**Fig. 2** , Ref. 2) from the L-bracket (Ref. 1) attached to the front inboard side of the master cylinder.

1. Reservoir
2. Master Cylinder
3. Front (Secondary) Circuit Brake Line
4. Pressure Differential Switch
5. Fluid Level Sensor
6. Rear (Primary) Ciruit Brake Line
7. Flanged Hexnut
8. Power Booster

A = Fill reservoir sections to this level.

08/03/93 f420479

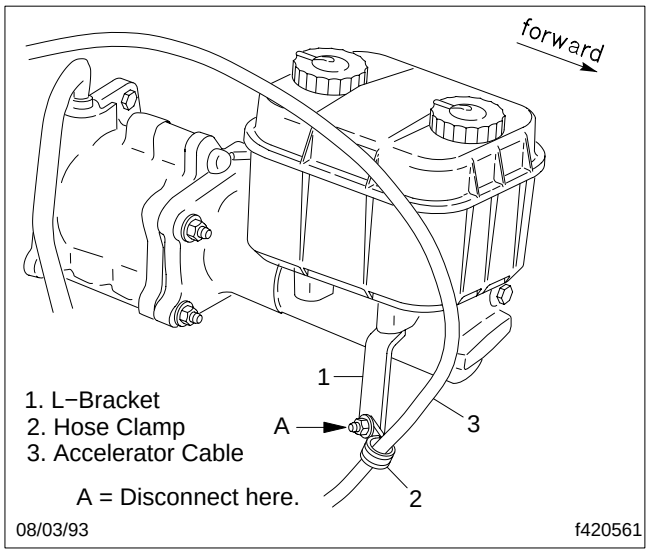


Fig. 1

CAUTION

CAUTION: Do not let the brake fluid get on any painted surface, as it will dissolve the paint. Use a rag around fittings, or put a container underneath it to catch any fluid.

4. Disconnect the brake lines from the front and rear outlet ports of the master cylinder. **See Fig. 3 .** Plug the brake lines.
5. Remove the four flanged hexnuts that attach the master cylinder to the power booster unit. **See Fig. 4 .**

   Remove the master cylinder and reservoir assembly from the vehicle. **See Fig. 5 .** Keep it upright so you don't spill any brake fluid from the reservoir.

1. L−Bracket
2. Hose Clamp
3. Accelerator Cable

A = Disconnect here.

08/03/93 f420561

Fig. 2

6. Remove the caps from the master cylinder reservoir, then carefully invert the master cylinder and reservoir assembly, and dump the brake fluid into a container. Dispose of the brake fluid in an approved manner.

Installation

1. Bench bleed the master cylinder.
   1.1 Put the master cylinder and reservoir assembly in a vise.

Master Cylinder Removal and Installation

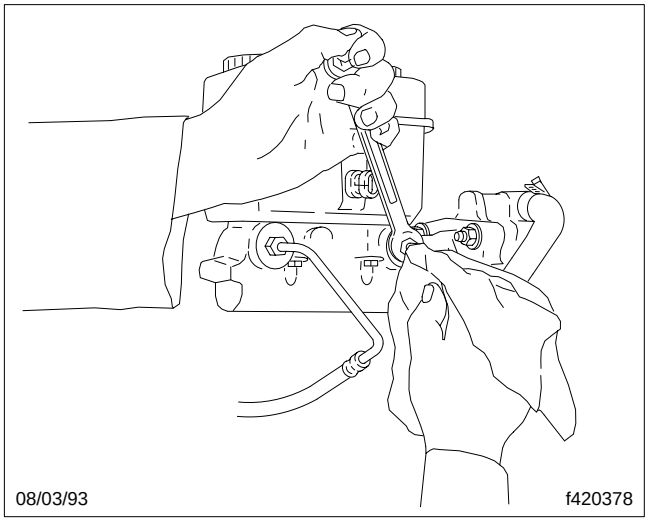

Fig. 3

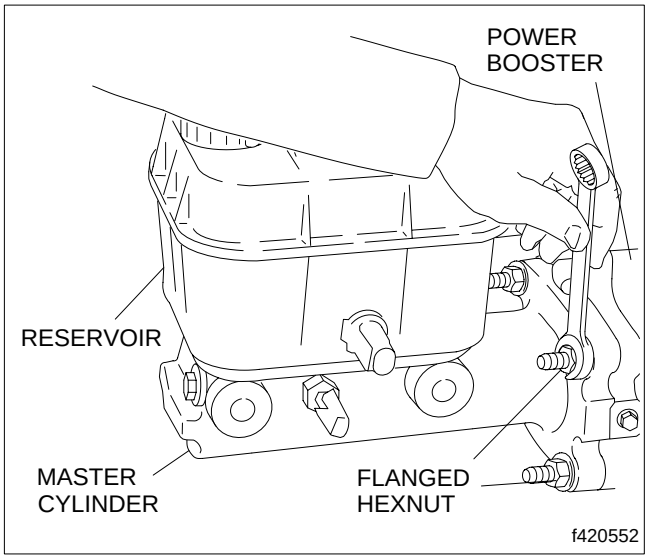

Fig. 4

1.2 Install a plastic adapter and clear rubber hose on the primary and secondary outlet ports, **as shown in Fig. 6 .**

1.3 Put the other end of each tube into its section of the reservoir, **as shown in Fig. 6 .**

1.4 Fill the reservoir sections about half-full with new DOT 3 approved brake fluid.

1.5 Using a metal rod with a rounded end, depress and release the primary piston several times.

1.6 Reposition the master cylinder in the vise, with the front (closed) end tilted slightly up. Depress and release the primary piston again until you feel increased resistance.

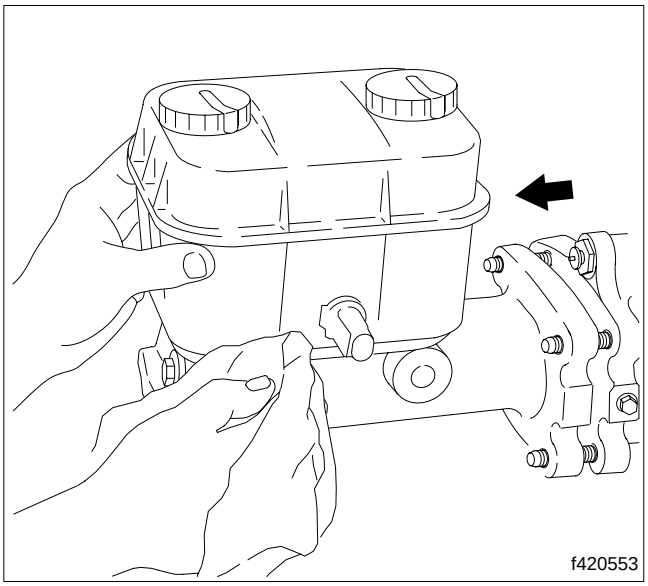

Fig. 5

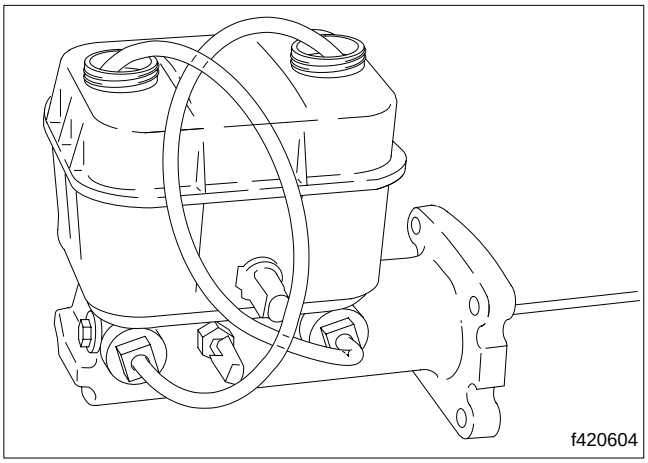

Fig. 6

2. Position the master cylinder on the front of the power booster.

3. Install the four flanged nuts on the studs of the power booster, then tighten them 34 N·m (25 lbf·ft).
4. Connect the rear brake (primary circuit) line to the rear outlet port on the master cylinder, then the front brake (secondary circuit) line to the front outlet port. Tighten the fittings 20 N·m (15 lbf·ft).
5. Connect the accelerator cable clamp (**Fig. 2** , Ref. 2) to the L-bracket (Ref. 1) on the front inboard side of the master cylinder.
6. Connect the wires to the pressure differential switch and the fluid level sensor. **See Fig. 1** , Refs. 4 and 5.
7. Fill both sections of the reservoir with new DOT 3 approved brake fluid. Fill to the raised seam on the outside of the reservoir. **See Fig. 1** , Ref. A.
8. Bleed the entire brake system, following the instructions under **"Hydraulic System Bleeding, 110."**
9. Lower the hood, then remove the chocks.

Master Cylinder Disassembly, Inspection, and Assembly

⚠ WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the dangers of brake fluid exposure could result in serious and permanent health damage.

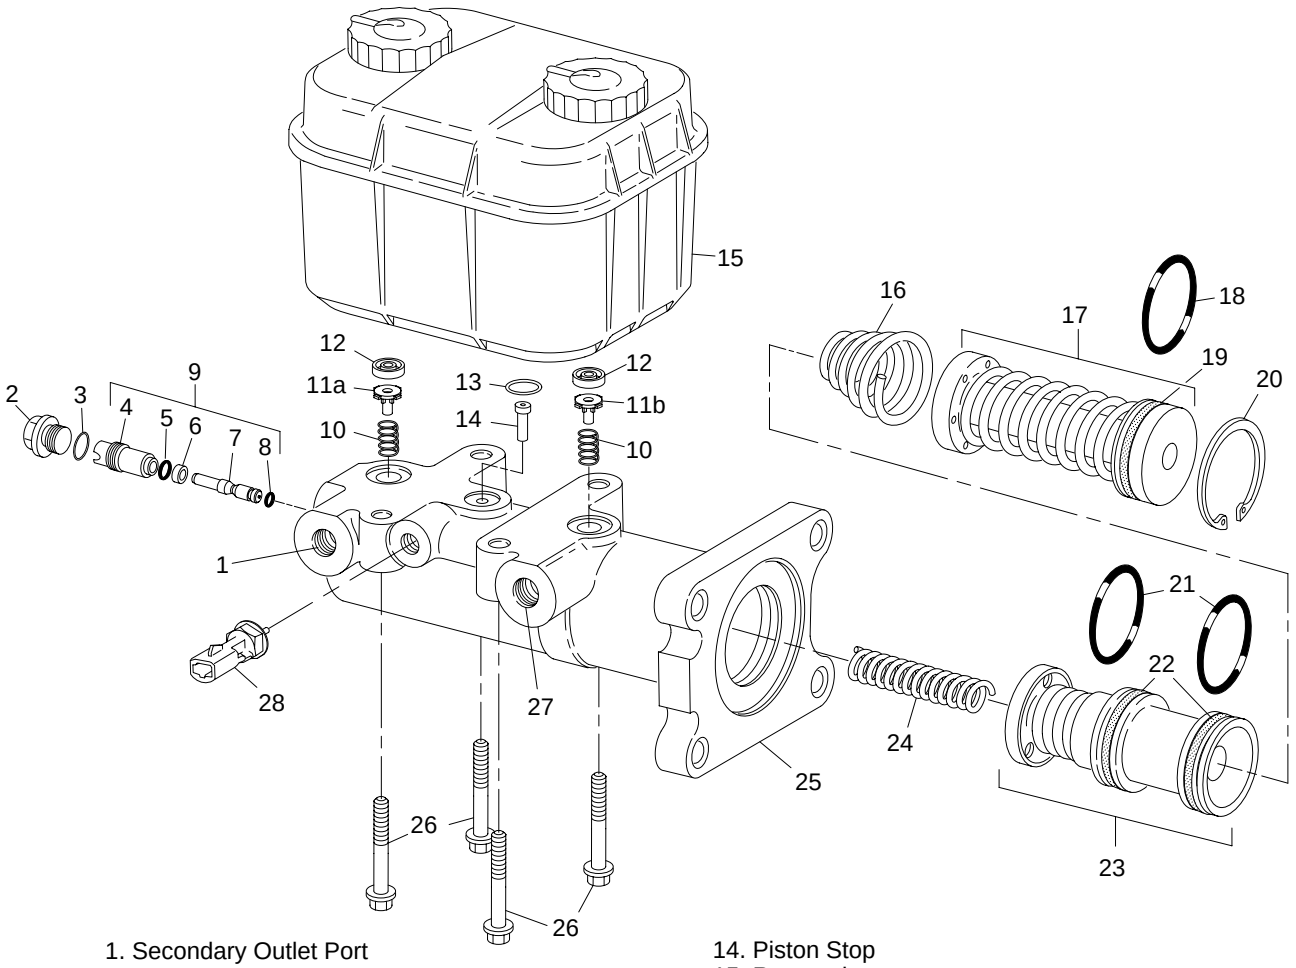
Disassembly (Refer to Fig. 1)

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Remove the master cylinder and reservoir assembly from the vehicle, following the instructions under **"Master Cylinder Removal and Installation, 170."**
3. Remove the reservoir from the master cylinder.
   - 3.1 Remove the four flanged hexbolts that attach the reservoir to the top of the master cylinder. **See Fig. 2 .** Note that one of the bolts has an L-bracket on it.
   - 3.2 Lift the reservoir off the master cylinder. Turn the reservoir over, then remove the two compensating valve seals from the bottom of it. **See Fig. 3 .**
4. Remove the small O-ring, then the two compensating valves and their springs from the top of the master cylinder housing. **See Fig. 4 and Fig. 5.**

⚠ CAUTION

CAUTION: Don't remove the piston stop at this time, or you may damage it and the piston bore in the master cylinder housing.

5. Remove the differential pressure indicator assembly from the front of the housing.
   - 5.1 Unscrew the aluminum plug at the front end of the housing. **See Fig. 6 .**
   - 5.2 Using an allen wrench, remove the nylon insert underneath the aluminum plug. **See Fig. 7 .**
   - 5.3 Remove the differential pressure switch from the side of the housing. **See Fig. 8 .**
   - 5.4 Put a compressed air hose into the port on top of the housing where the primary compensating valve was. Put a shop towel over the hole at the front end of the housing, then place the housing so that the front end is facing down toward a padded surface; keep your hands away from the front of the master cylinder housing.



⚠ WARNING

WARNING: Be careful when using compressed air to remove the differential pressure indicator assembly from the master cylinder housing. It may come out of the housing with considerable force, which could cause personal injury or damage to the part.

   - 5.5 Plug the primary circuit outlet (**Fig. 1** , Ref. 27), then release just enough air pressure to force out the brass spool, O-ring, and collar (Refs. 5, 6, and 7). Discard the O-ring.

     Remove and discard the small O-ring (Ref. 8) from the brass spool.
6. Remove the primary piston assembly from the master cylinder bore.
   - 6.1 Put the master cylinder in a vise.
   - 6.2 Using a crossbar puller, a C-clamp, or other suitable tool, push the primary piston about 13 mm (1/2 inch) into the bore. **See Fig. 9 .**
   - 6.3 With the primary piston pushed in, remove the lock ring from the open end of the bore. **See Fig. 9 .** Then remove the small piston stop from the top of the master cylinder housing. **See Fig. 10 .**
   - 6.4 Carefully release the tension on the primary piston, and ease it and its return spring out of the bore. **See Fig. 11 .**
   - 6.5 Remove and discard the pressure seal and back-up ring (**Fig. 1** , Refs. 18 and 19) from the primary piston.

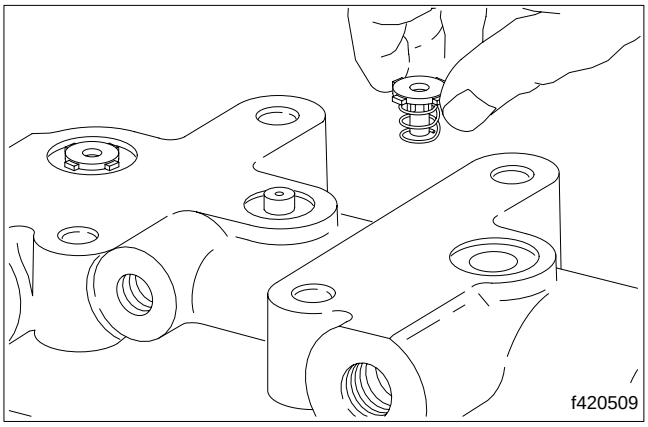

Fig. 5

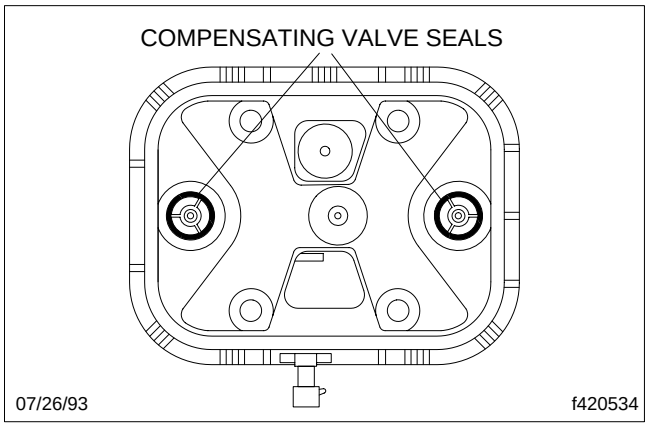

Fig. 3

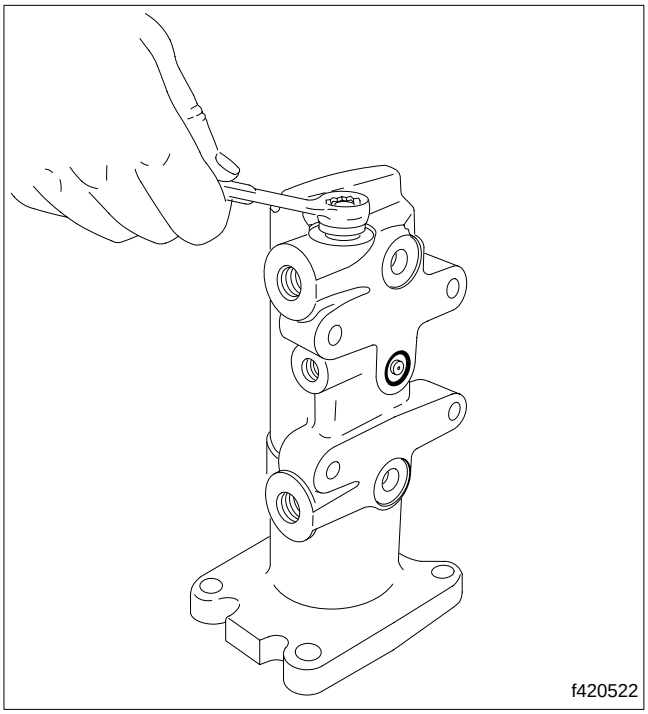

Fig. 6

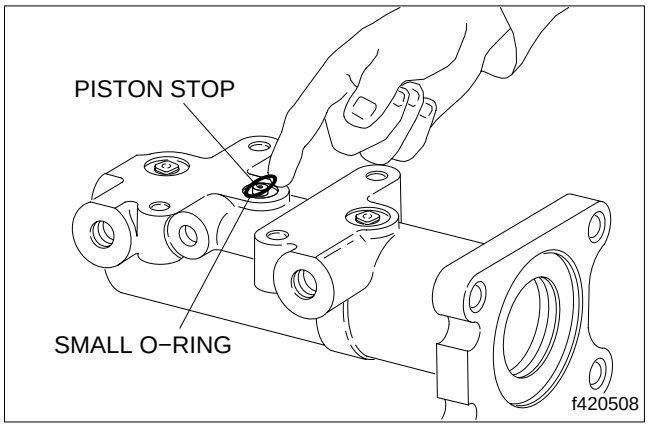

Fig. 4

⚠ WARNING

WARNING: Be careful when using compressed air to remove the secondary piston and actuator assembly from the master cylinder bore. Make sure the open end of the bore is pointed down toward a padded surface. Keep your hands away from the open end of the bore to prevent injury.

Master Cylinder Disassembly, Inspection, and Assembly

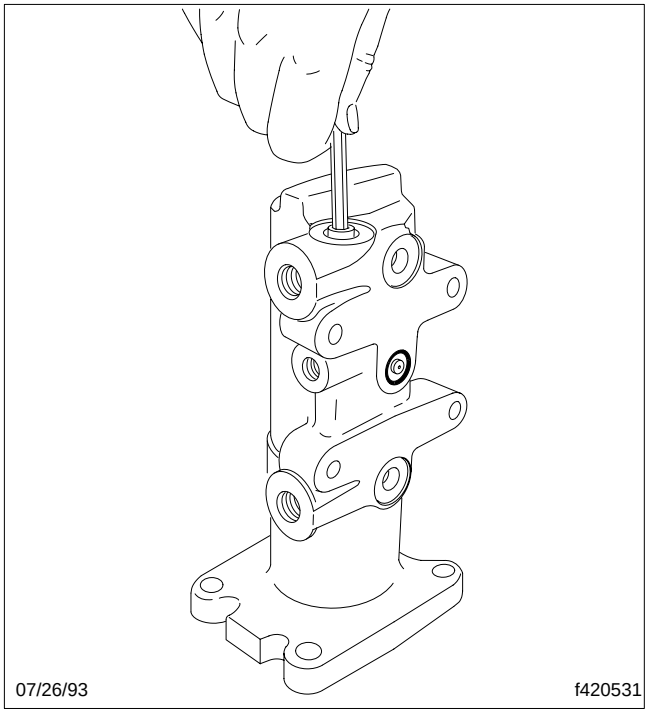

Fig. 7

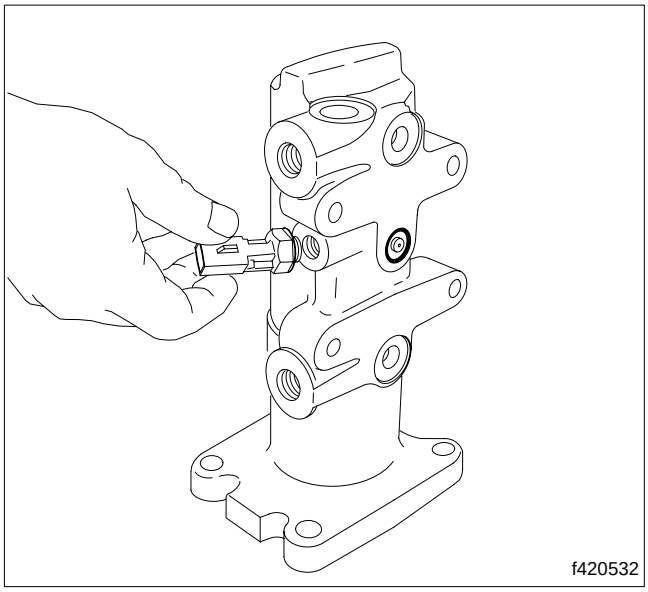

Fig. 8

7. Using compressed air, remove the secondary piston assembly from the master cylinder bore.

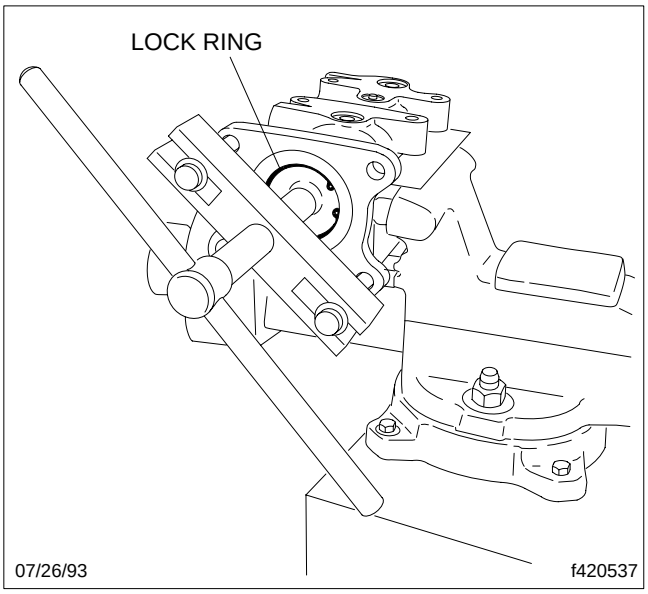

Fig. 9

7.1 Connect a compressed air hose to the front compensating valve port **(Fig. 12)** on top of the housing.

7.2 Plug the secondary outlet port (**Fig. 1** , Ref. 1) and the hole where the pressure differential indicator (Ref. 9) was on the housing.

7.3 With the open end of the housing bore facing down, and about an inch away from a padded surface, carefully apply just enough air pressure to remove the secondary piston assembly and its return spring from the bore **(see Fig. 13);** don't pop it out.

7.4 Remove and discard the pressure seal and back-up ring from the secondary piston.

Inspection

1. Check the master cylinder bore for scoring or corrosion. If the master cylinder housing is pitted, rough, or corroded, replace the entire master cylinder assembly.
2. If needed, polish any discolored or stained areas in the bore with a crocus cloth. *Don't use emery*

Master Cylinder Disassembly, Inspection, and Assembly

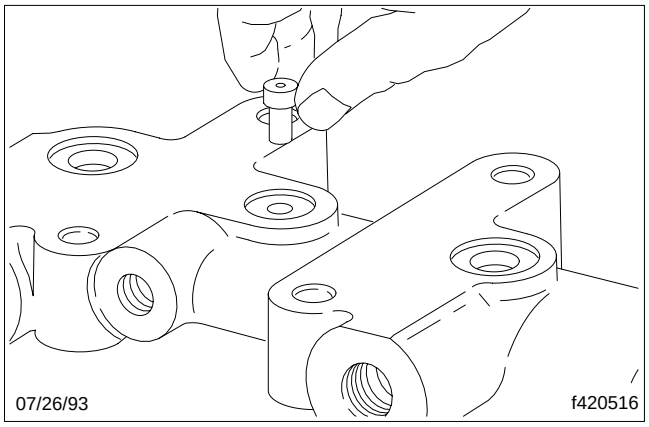

Fig. 10

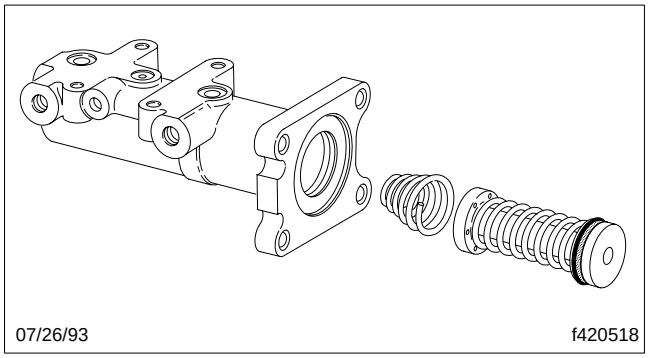

Fig. 11

cloth or sandpaper; they could scratch the bore, which could cause leakage.

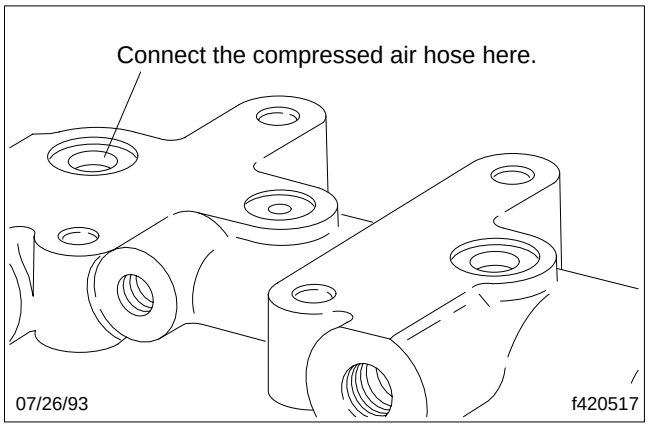

Fig. 12

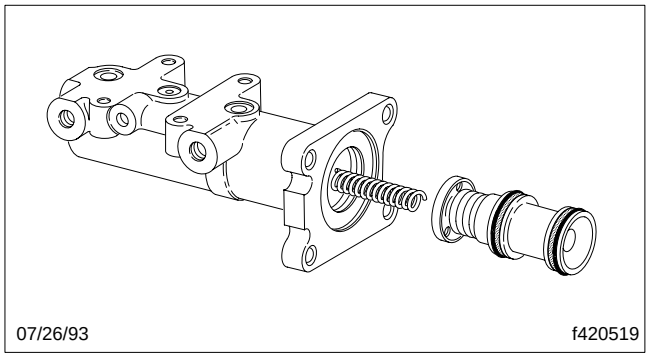

Fig. 13

Assembly (Refer to Fig. 1)

IMPORTANT: When assembling the master cylinder, use new seals and rings. Don't reuse old ones.

1. Wash all the parts and the cylinder bore in clean, new DOT 3 approved brake fluid. Discard the brake fluid afterward.
2. Install the secondary piston assembly in the master cylinder bore.
   - 2.1 Install two new pressure seals and back-up rings (**Fig. 1** , Refs. 21 and 22) on the secondary piston.
   - 2.2 Lubricate the piston assembly, the seals, and the cylinder bore **(see Fig. 14)** with clean DOT 3 approved brake fluid.
   - 2.3 Put the secondary return spring (**Fig. 1** , Ref. 24) on the actuator (flanged) end of the secondary piston assembly, then insert the piston assembly, spring end first, into the cylinder bore. **See Fig. 15 .** Push it all the way to the bottom of the bore.
3. Install the primary piston assembly in the master cylinder bore.
   - 3.1 Install a new pressure seal and back-up ring (**Fig. 1** , Refs. 18 and 19) on the primary cylinder.
   - 3.2 Lubricate the piston assembly and the seal with new DOT 3 approved brake fluid.

Master Cylinder Disassembly, Inspection, and Assembly

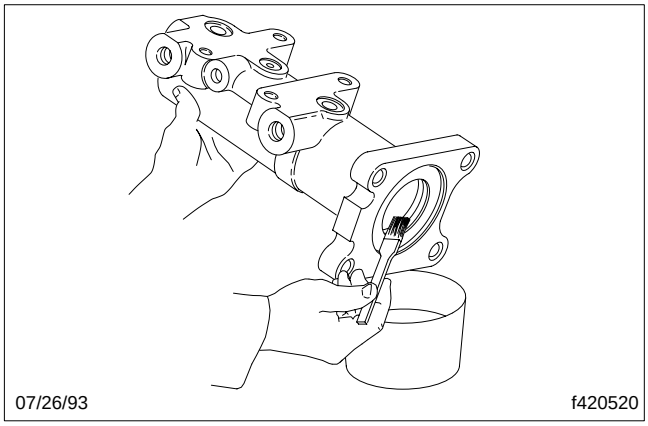

Fig. 14

3.3 Insert the small end of the primary return spring (**Fig. 1** , Ref. 16) into the master cylinder bore.

3.4 Insert the primary piston assembly into the master cylinder bore, actuator (flanged) end first. **See Fig. 16 .**

4. Put the master cylinder housing into a vise, then using a crossbar puller or a C-clamp, push the pistons far enough into the master cylinder bore to install the lock ring in its groove. **See Fig. 17 .**

5. Install the compensating valve seals on the bottom of the reservoir. **See Fig. 18 .** Make sure the seals are completely seated.

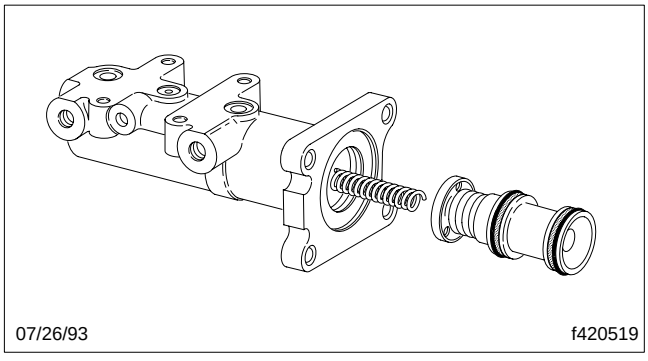

Fig. 15

6. Using a crossbar puller or a C-clamp, push the primary piston 25 mm (1 inch) into the bore. **See Fig. 19 .**

7. Install the compensating valve poppets and their springs in the top of the master cylinder housing.

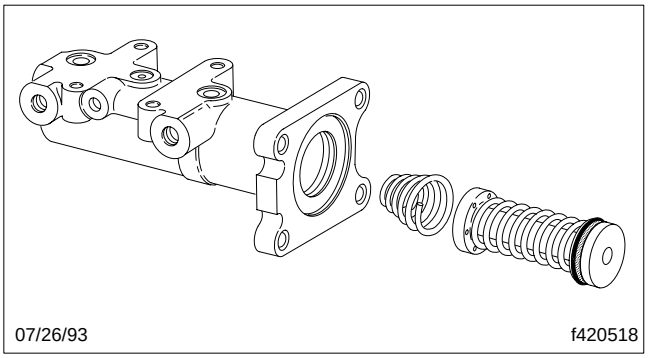

Fig. 16

Also install the piston stop and the O-ring. **See Fig. 20 .**

8. With the primary piston still pushed in, install the reservoir onto the top of the master cylinder, using the four mounting hexbolts. **See Fig. 21 .** Make sure the L-bracket goes on the front inboard (when the master

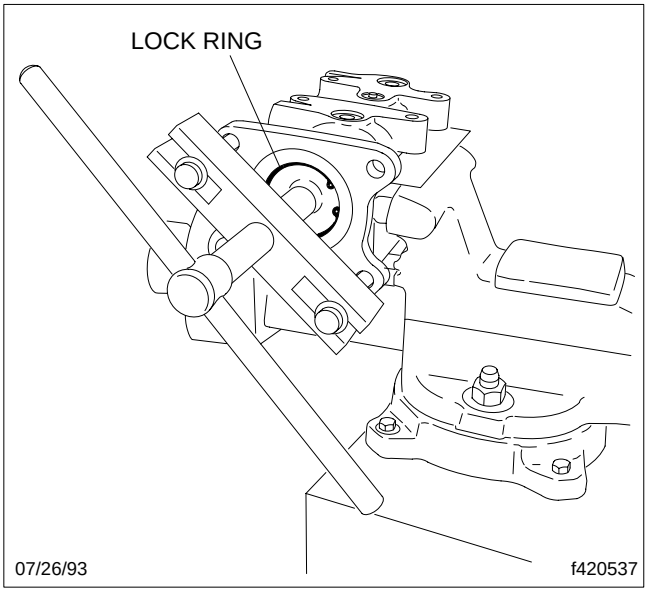

Fig. 17

9. cylinder is installed on the vehicle) mounting hexbolt. Tighten the bolts 20 N·m (15 lbf·ft).

10. Assemble the pressure differential indicator **(refer to Fig. 22).**

Master Cylinder Disassembly, Inspection, and Assembly

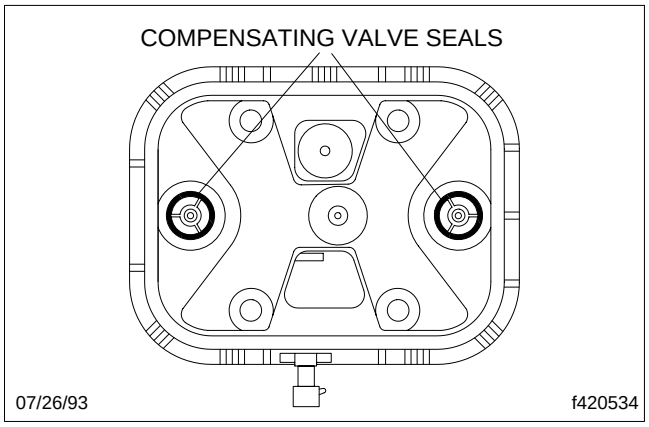

Fig. 18

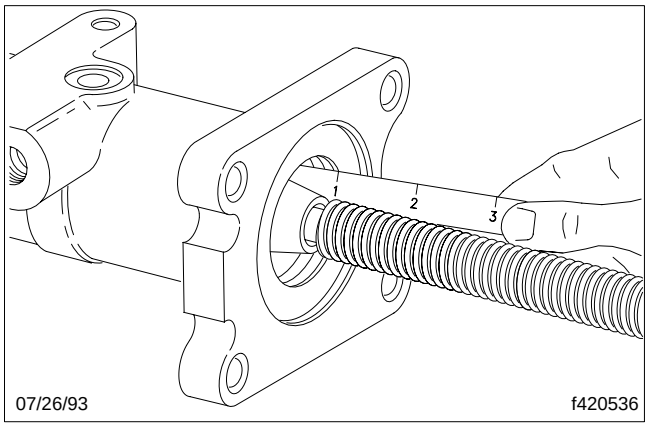

Fig. 19

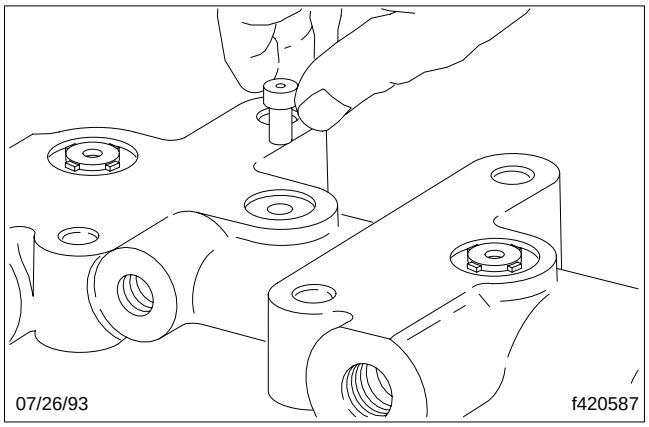

Fig. 20

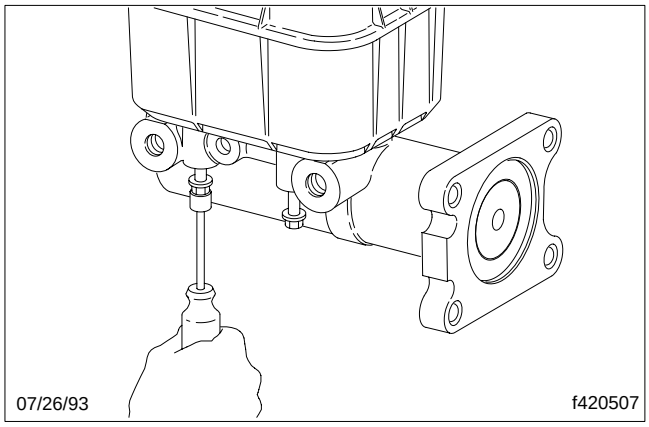

Fig. 21

10.1 Install a new small O-ring (Ref. 3) in the groove on the end of the brass spool (Ref. 4).

10.2 Install the collar (Ref. 2) on the brass spool.

10.3 Install a new large O-ring (Ref. 1) onto other end of the brass spool, and push it down onto the collar, **as shown in Fig. 22 .**

11. Install the spool and collar assembly— with the collar end up— into the hole at the front of the master cylinder housing, **as shown in Fig. 23 .** Using a small piece of wood, seat the assembly at the bottom of its hole.

12. Using an allen wrench, install the nylon insert on top of the brass spool. **See Fig. 24 .**

13. Install a new O-ring on the aluminum plug (**Fig. 1** , Refs. 3 and 2), then install the plug into the hole at the front of the master cylinder housing. Tighten the plug firmly.

14. Install the pressure differential switch in the side of the master cylinder housing, **as shown in Fig. 25 .** Tighten it finger-tight.

15. Check the operation of the compensating valves by poking a wire through the hole in the bottom of each reservoir section. The compensating valves should depress easily, about 1.5 mm (1/16 inch), then spring back. If not, remove the reservoir and install it again. Check the valves again.

Master Cylinder Disassembly, Inspection, and Assembly

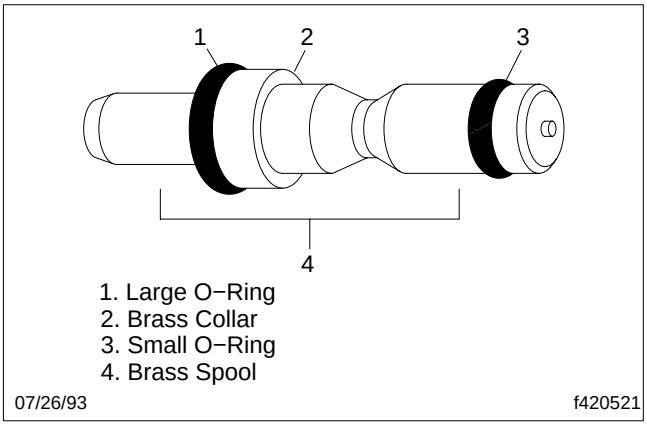

Fig. 22

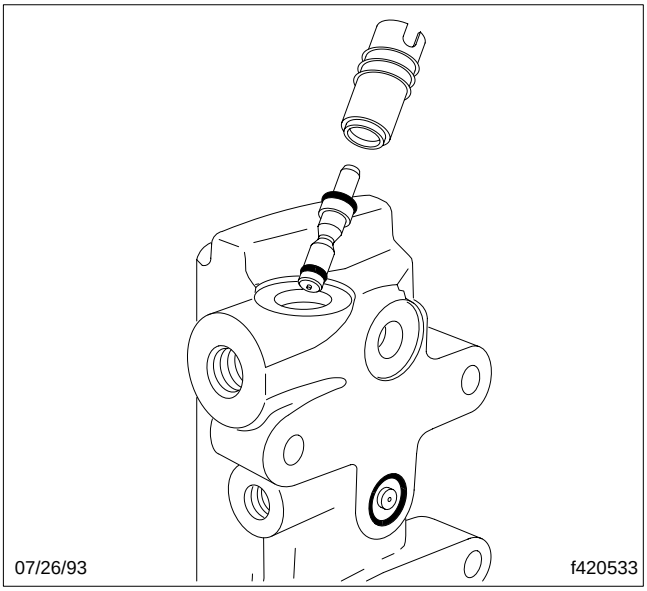

Fig. 23

16. Remove the cross-bar puller or C-clamp installed to push the primary piston into the bore.
17. Bench bleed, then install the master cylinder on the booster, following the instructions under **"Master Cylinder Removal and Installation, 170."**
18. Lower the hood, then remove the chocks.

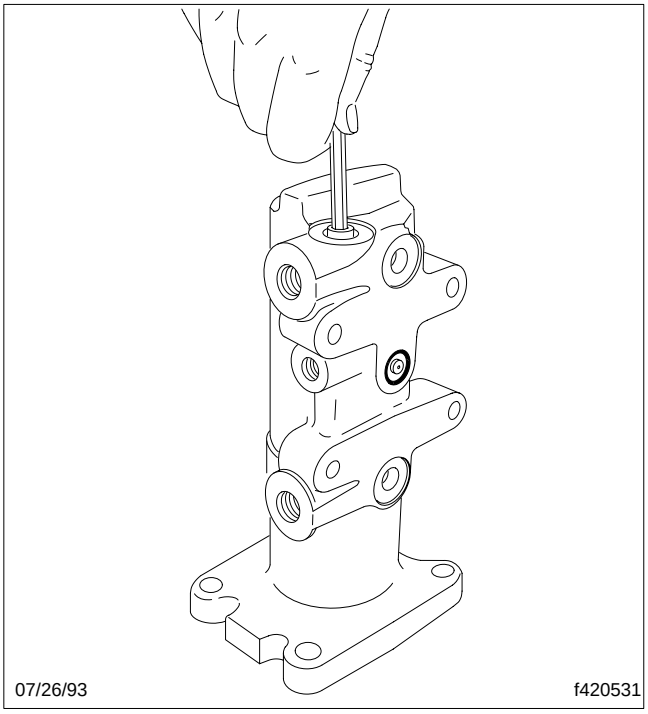

Fig. 24

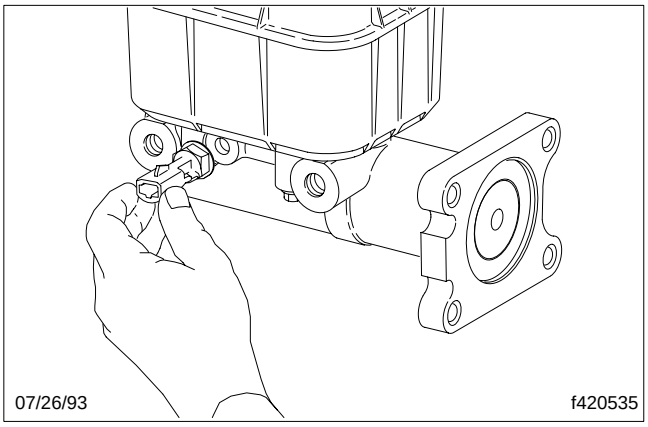

Fig. 25

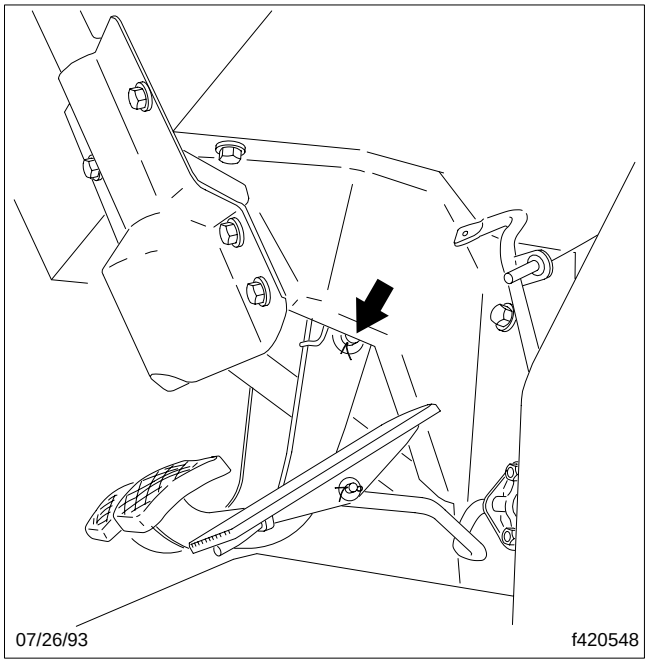
Hydro-Max II® Power Booster Removal and Installation

Removal

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Disconnect the batteries at the negative cable.
3. If not already done, disconnect the master cylinder from the power booster, following the instructions **in Subject 170.**
4. From inside the cab, disconnect the push rod from the brake pedal.
   - 4.1 Below the dash, find the clevis pin, washer, and cotter key that hold the power booster push rod to the brake pedal. **See Fig. 1 .**
   - 4.2 Remove the cotter key, washer and clevis pin.
5. Disconnect the wiring from the auxiliary electric pump assembly. **See Fig. 2 .**
6. Disconnect the wiring from the flow switch at the front of the power booster. **See Fig. 2 .**



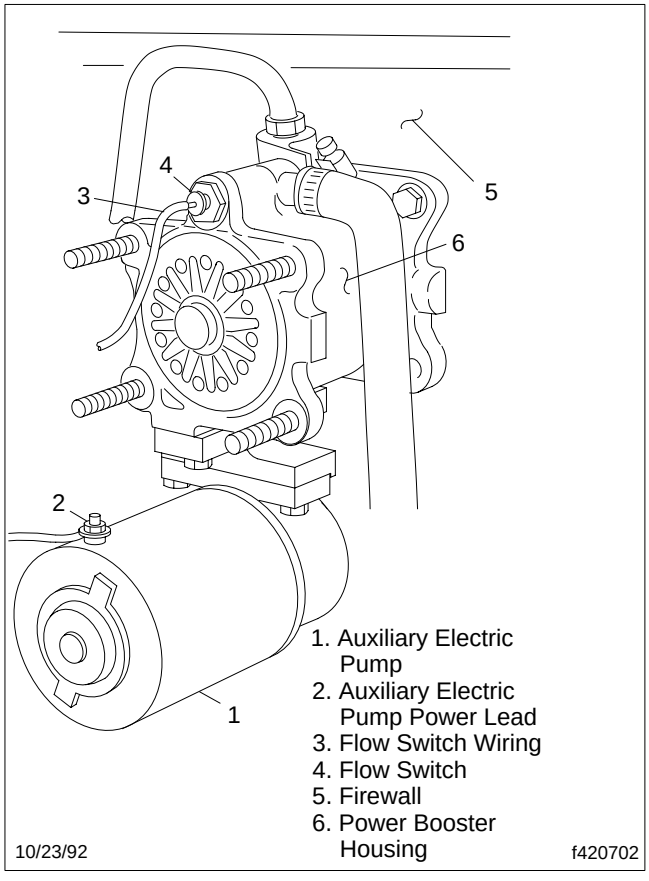


Fig. 1

7. Using a shop towel or a container to catch any power steering fluid, disconnect the hydraulic supply and return lines from the power booster. **See Fig. 3 .** Plug the lines.
8. Remove the four hexbolts and washers **(Fig. 4)** holding the power booster to the firewall, then pull the power booster straight out from the firewall, **as shown in Fig. 5 .**

Installation

1. Position the power booster on the firewall so the push rod fits through the large hole and into the cab, and the four holes in the power booster line up with those on the firewall. **See Fig. 5 .**
2. Install the four mounting hexbolts and washers. **See Fig. 4 .** Tighten them 27 N·m (15 lbf·ft).

1. Auxiliary Electric Pump
2. Auxiliary Electric Pump Power Lead
3. Flow Switch Wiring
4. Flow Switch
5. Firewall
6. Power Booster Housing

Fig. 2

3. Install the master cylinder on the power booster, following the instructions **in Subject 170.**

Hydro-Max II® Power Booster Removal and Installation

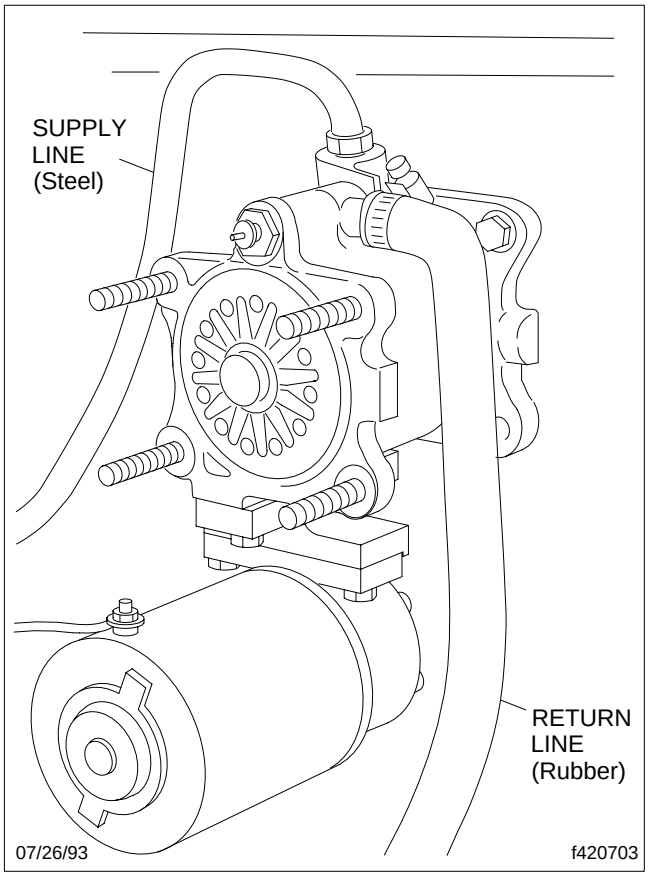

Fig. 3

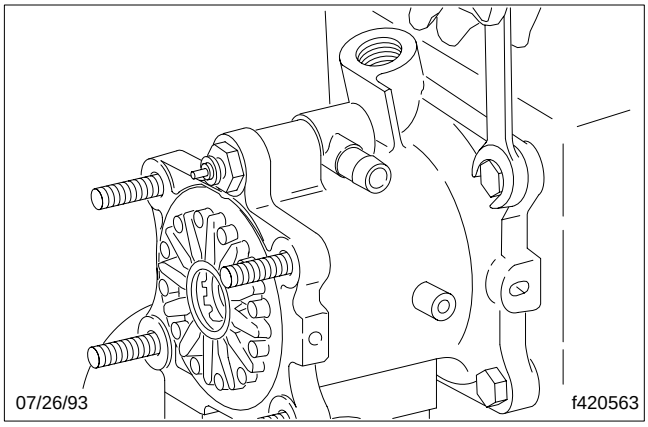

Fig. 4

4. Connect the hydraulic supply and return lines **(Fig. 3).** Tighten the supply line 20 N·m (20 lbf·ft). Tighten the hose clamp on the return line firmly.

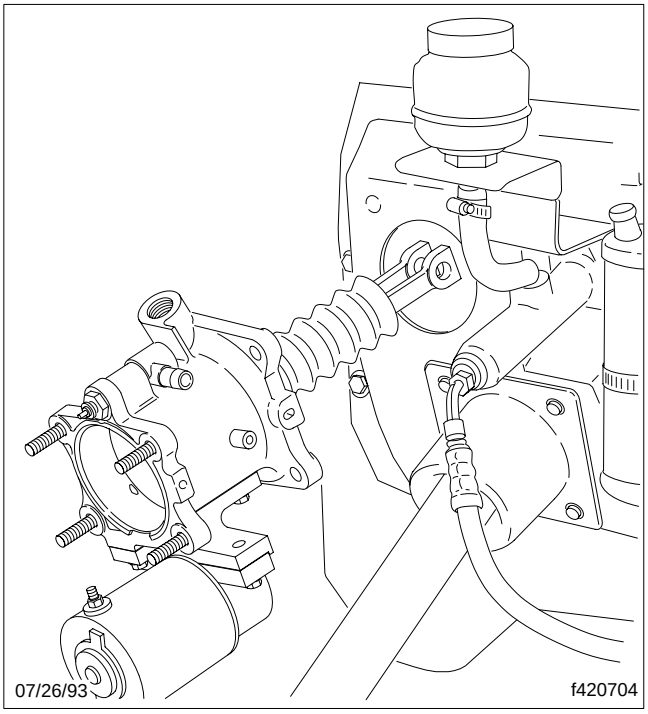

Fig. 5

5. Connect the wiring to the auxiliary electric pump assembly, and to the flow switch assembly. **See Fig. 2 .**
6. Check the fluid level in the power steering reservoir **(Fig. 6).** Add approved power steering fluid if needed. **Refer to "Specifications, 400"** for the approved power steering fluid.
7. Connect the batteries.
8. Lower the hood, then remove the chocks.
9. Bleed the power booster, following the instructions **in Subject 115.**

Hydro-Max II® Power Booster Removal and Installation

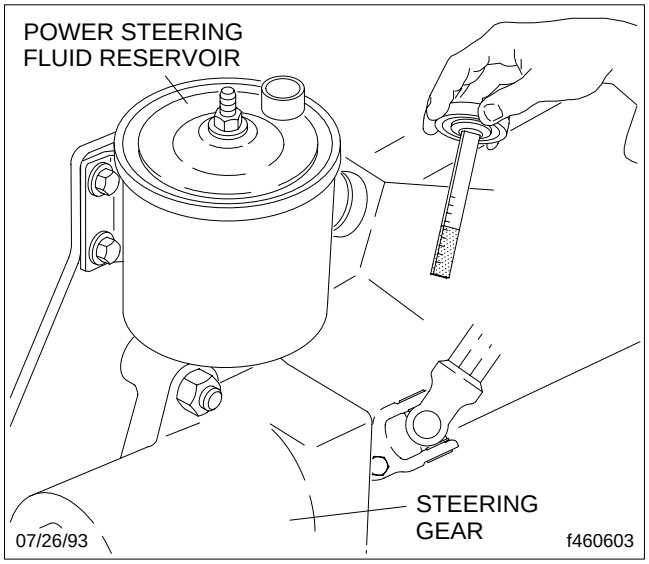

Fig. 6

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

Disassembly (Fig. 1)

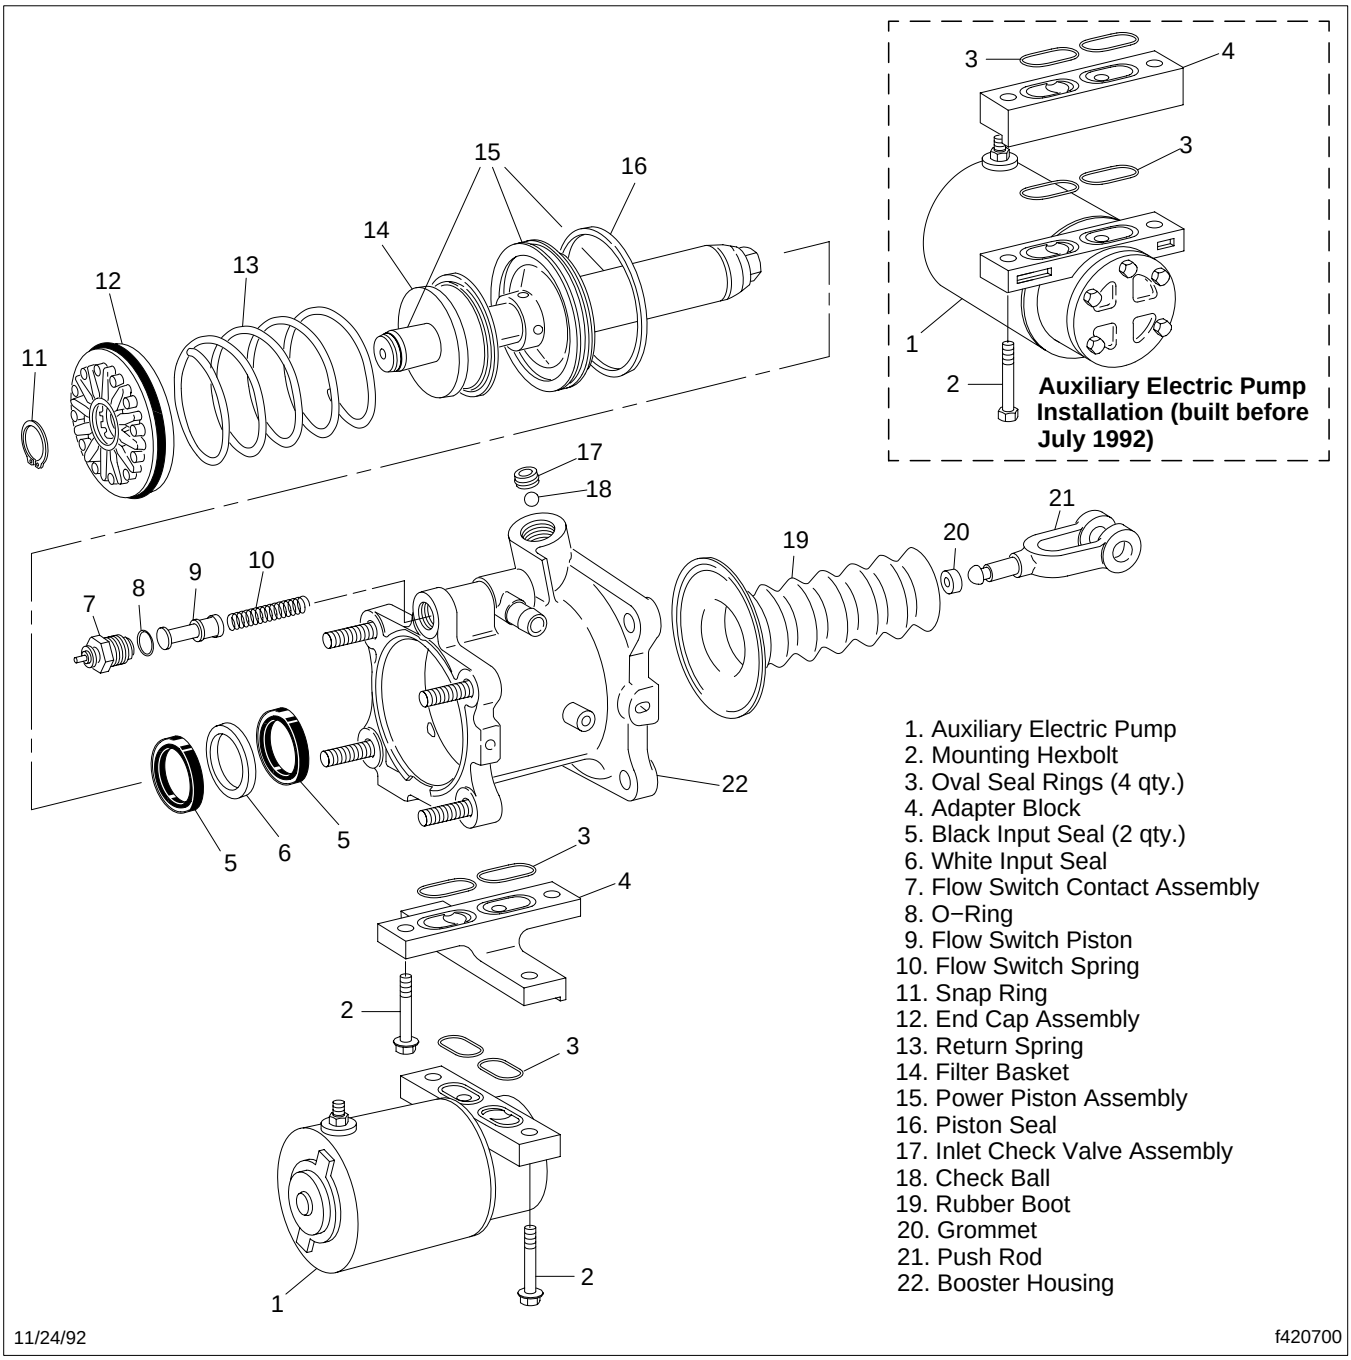

Fig. 1

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

⚠ WARNING

WARNING: Always wear safety goggles or glasses when working on the power booster. Some power booster parts are under compression (such as springs, snap-rings, and the like), and they could release with some force, possibly causing injury.

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Remove the power booster from the vehicle, following instructions in **Subject 180**.
3. Remove the auxiliary electric pump (**Fig. 1** , Ref. 1) from the power booster housing.
   - 3.1 Hold the booster and pump assembly over a container. There are about 3 cups of fluid in the assembly.
   - 3.2 Remove the two screws that hold the pump and the adapter block to the bottom of the booster. See **Fig. 2**.

     Remove the two screws that attach the pump to the adapter (if applicable).
   - 3.3 After the power steering fluid has been drained, remove and discard the oval seal rings (**Fig. 1**, Ref. 3) from the electric pump and the adapter block.
4. Remove and discard the rubber boot (**Fig. 1** , Ref. 19) from the push rod.
5. Remove push rod (**Fig. 1**, Ref. 21) from the end of the power piston (Ref. 15).
   - 5.1 Put the booster unit in a padded vise so the wrench flats at the end of the power piston are in the vise jaws, as shown in **Fig. 3**.
   - 5.2 Put a round pry bar through the eyes of the push rod clevis, then pry the push rod out of the end of the power piston. See **Fig. 3**.
   - 5.3 Remove all the plastic grommet pieces from inside the power piston end and the push rod.
6. Remove the power piston assembly and the end cap from the booster housing.

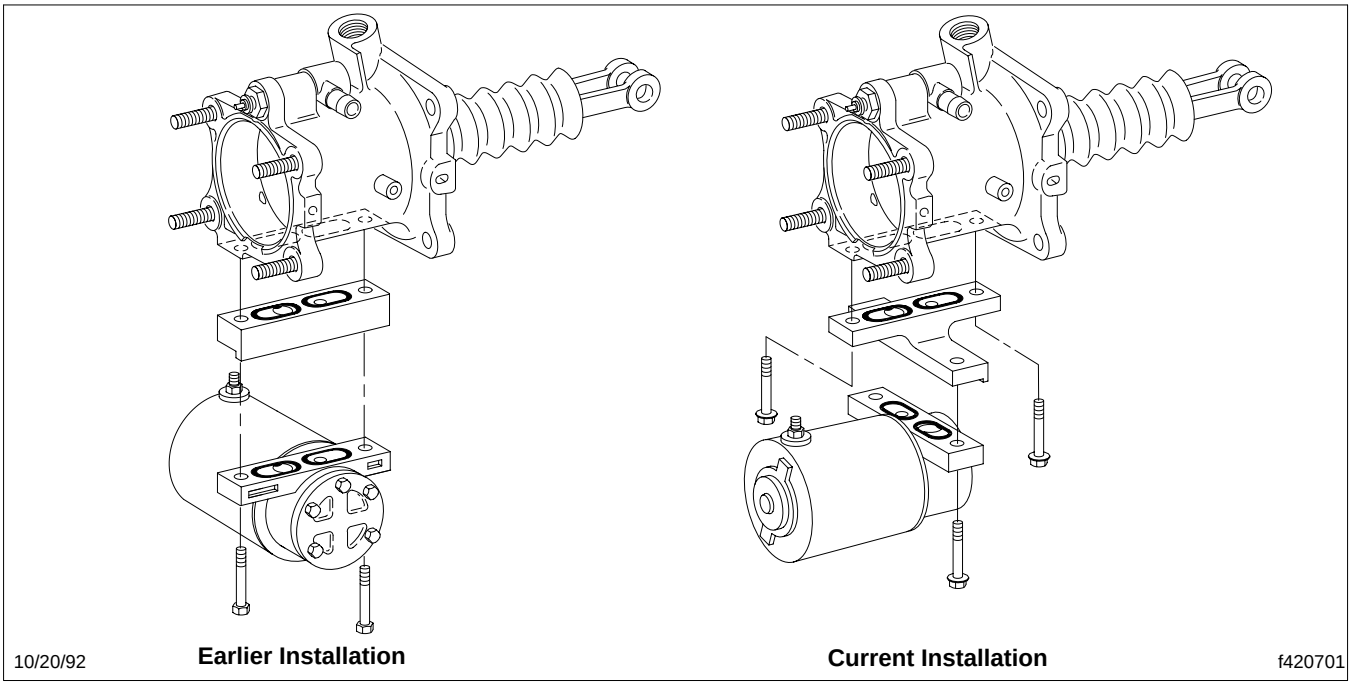

Fig. 2

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

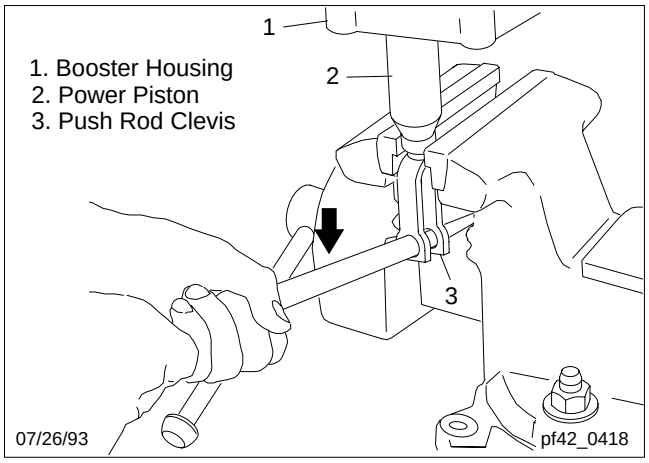

Fig. 3

6.1 Place the booster housing on a padded surface, with the end cap facing down.

6.2 Push down on the end of the power piston until the end cap and power piston come out of the front of the housing.

6.3 Pull the power piston and end cap straight out of the booster housing (see **Fig. 4**); be careful not to scratch the piston or the housing bore.

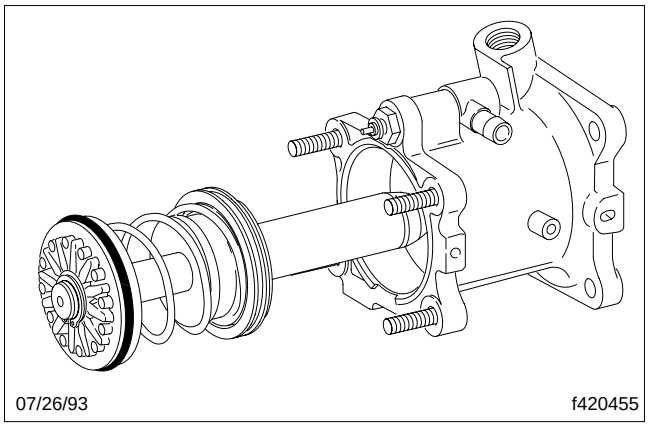

Fig. 4

7. Remove and discard the three input seals from the small bore at rear of the booster housing. See **Fig. 1**, Refs. 5 and 6.

8. Remove and discard the piston seal (Ref. 16) from the power piston.

9. Remove the end cap and the filter basket from the power piston.

9.1 Put the end cap and power piston on a padded surface.

9.2 Push down on the end cap to release the pressure on the snap ring, as shown in **Fig. 5**.

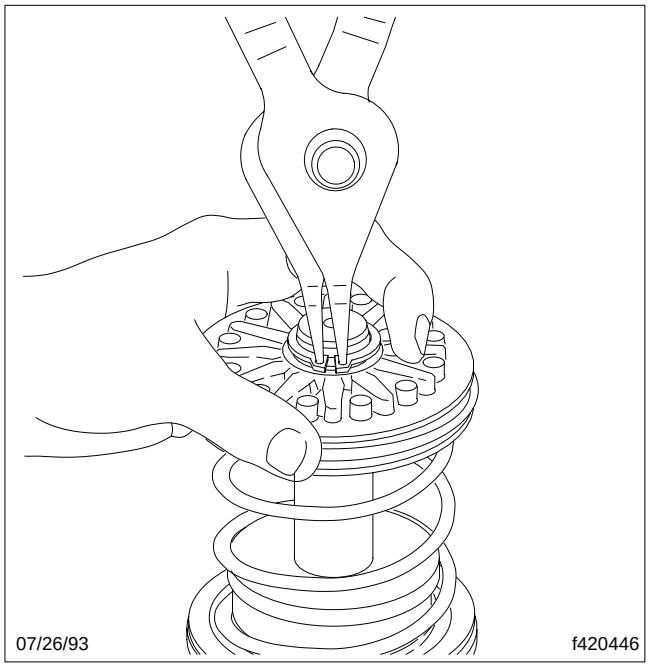

Fig. 5

9.3 Remove and discard the snap ring from the output shaft of the power piston. See **Fig. 6**.

9.4 Remove and discard the end cap and the return spring. See **Fig. 6**.

9.5 Remove the filter basket.

10. Remove the flow switch assembly from the front of the booster housing.

10.1 Unscrew the nylon flow switch contact assembly from the housing. See **Fig. 7**.

10.2 Using a small magnet, remove the flow switch piston and spring (**Fig. 8**) from the booster housing.

10.3 Remove and discard the O-ring from the nylon contact assembly.

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

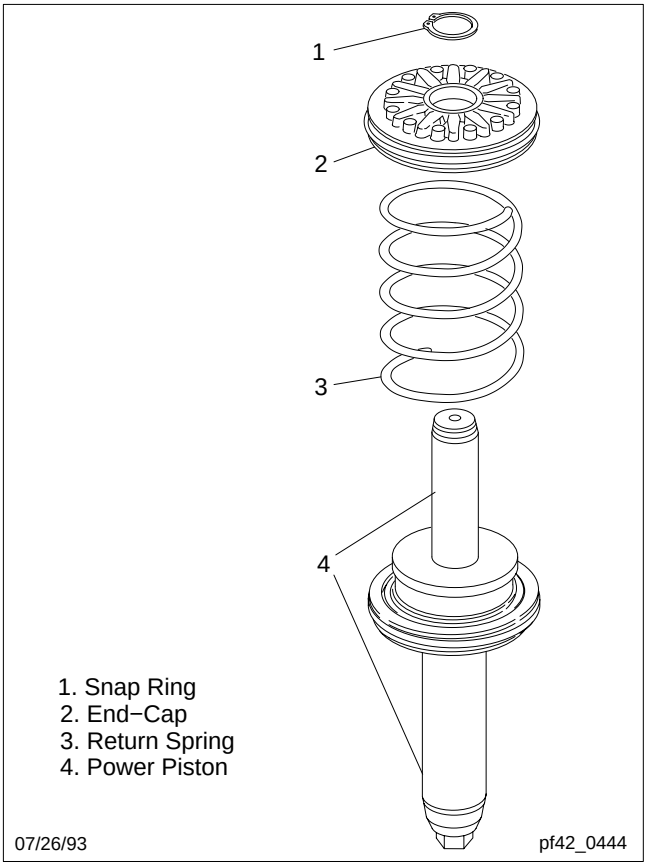

Fig. 6

11. Using a hooked piece of wire, remove the inlet check valve from the inlet port on the booster housing. Then remove the check ball. Discard both parts. See **Fig. 9**, **Fig. 10**, and **Fig. 11**.

Inspection

1. Check the power piston surface for nicks or scratches. Pay special attention to the sealing surface and the input and output shafts. See **Fig. 12**. If there is any damage, replace the power piston assembly.
2. Check the bore in the booster housing. If it is grooved, nicked, or otherwise damaged, replace the entire power booster assembly.

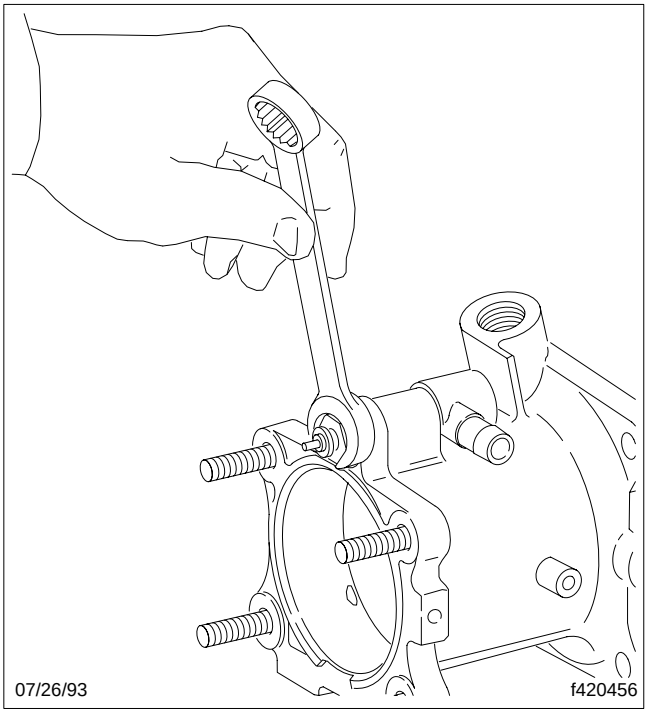

Fig. 7

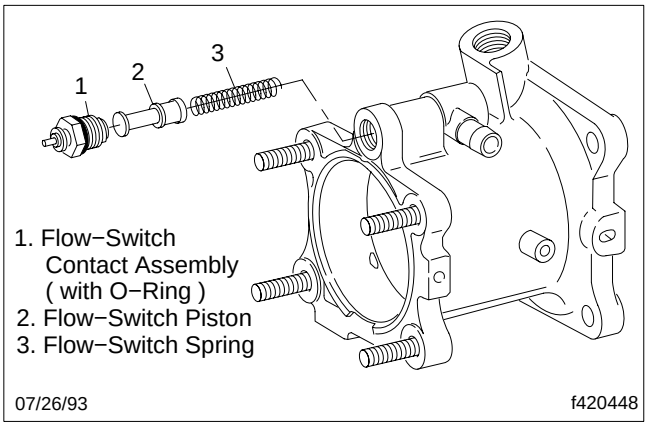

Fig. 8

Assembly (Fig. 1)

⚠ WARNING

WARNING: Use only clean Dexron II® ATF for cleaning or lubricating power booster parts. Don't use brake fluid. Using other types of fluids

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

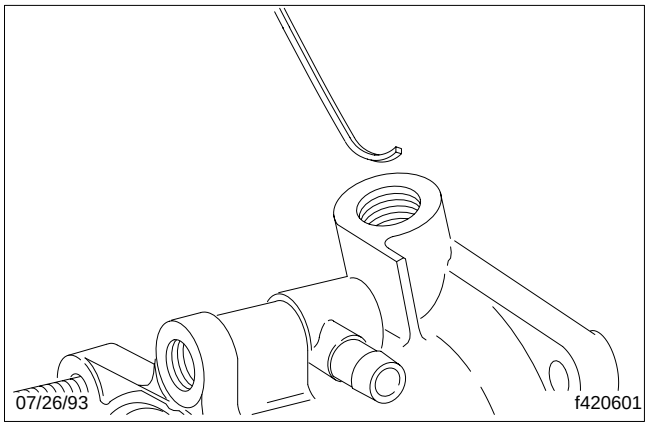

Fig. 9

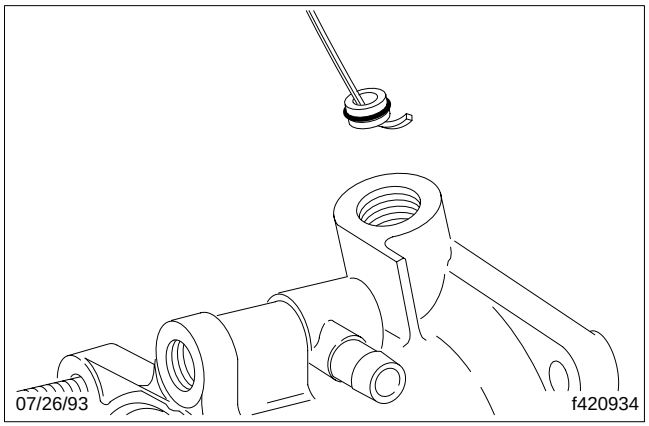

Fig. 10

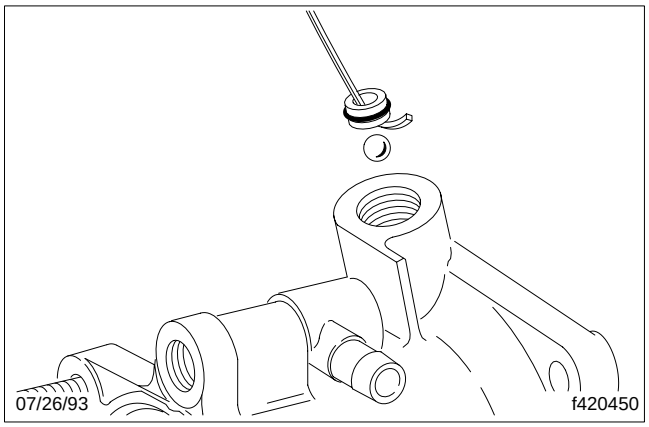

Fig. 11

may destroy seals and O-rings, which could cause the eventual loss of brake control.

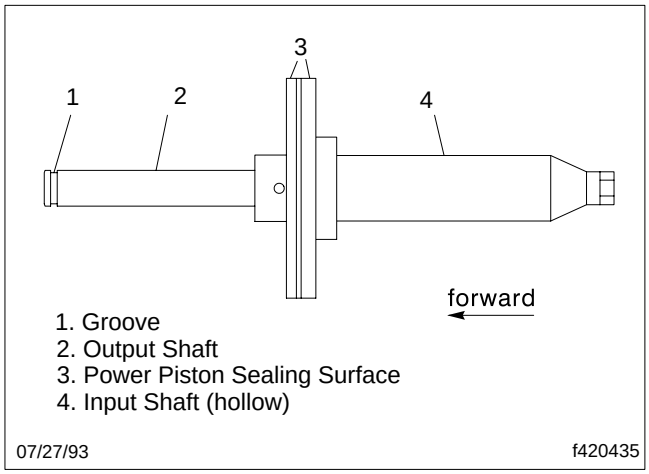

Fig. 12, Power Piston Assembly

1. Using clean power steering fluid, clean and lightly lubricate all the power booster parts.
2. Install new input seals in the small bore of the booster housing. Install the white seal between the two black ones, as shown in **Fig. 13**.

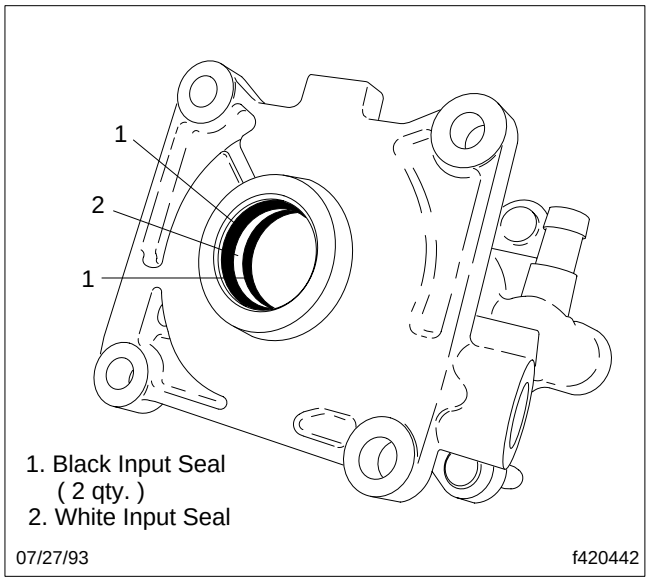

Fig. 13

3. Install a new check ball in the inlet port on top of the booster housing, then install a new inlet check valve assembly. Make sure it's seated firmly.
4. Install the flow switch assembly in the front of the booster housing. See **Fig. 14**.

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

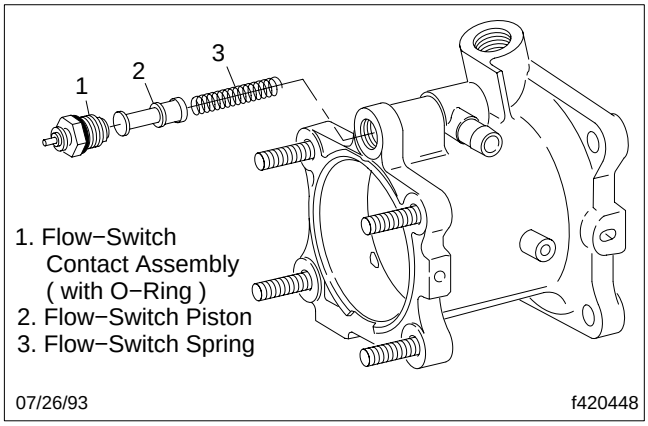

Fig. 14

4.1 Install the flow switch spring in its hole at the front of the booster housing.

4.2 Install the flow switch piston.

4.3 Install a new O-ring on the flow-switch contact assembly, then install the assembly in the hole at the front of the booster housing. Tighten it finger-tight.

5. Install a new filter basket— open end first— over the power piston output shaft, and push it up against the power piston.

6. Install the return spring on the power piston output shaft.

7. Install a new end-cap assembly on the power piston output shaft.

7.1 Install a new square cut seal on the outside diameter of the new end cap, then install a new O-ring inside the small bore of the end cap.

7.2 Lubricate the O-ring and lip seal in the end-cap hole with power steering fluid.

7.3 Carefully install the end-cap assembly (ribbed side up) on the power piston output shaft.

7.4 Keeping the end cap pushed down, install the snap ring in the groove of the power piston output shaft. See **Fig. 15**.

8. Install the power piston assembly in the booster housing.

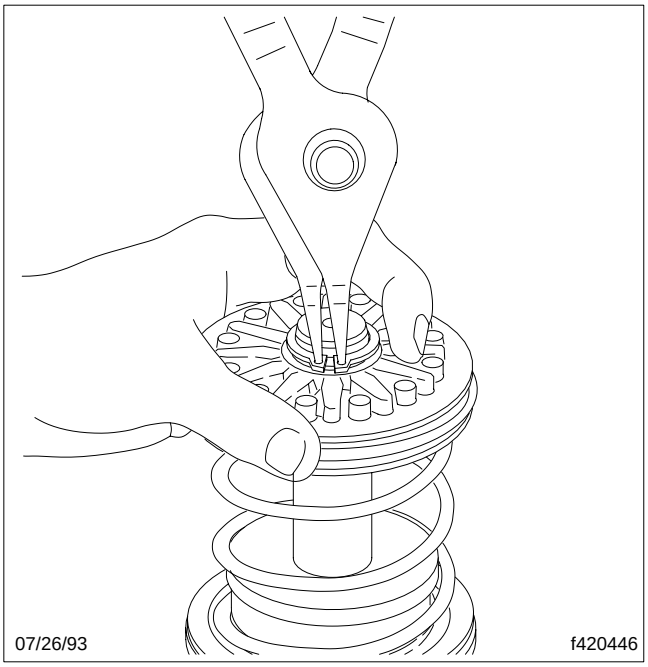

Fig. 15

8.1 Install the power piston, larger shaft first, into the large bore at the front of the booster housing.

⚠ WARNING

WARNING: Be careful not to damage the input seals in the small bore of the booster housing when you install the power piston shaft through the small bore. If these seals are damaged, the booster assembly will leak, causing loss of braking power.

8.2 Carefully work the end of the power piston shaft through the small bore of the booster housing. Use a gentle twisting motion to work the shaft past the two seals (**Fig. 13**) in the bore.

IMPORTANT: If the seals are damaged by the power piston shaft, replace them. Then repeat steps for installation of the power piston.

8.3 Seat the end cap in the large bore of the housing.

9. Install a new boot on the push rod.

Hydro-Max II® Power Booster Disassembly Inspection, and Assembly

10. Install the push rod on the end of the power piston.
    - 10.1 Install a new grommet on the push rod.
    - 10.2 Put the flats of the power piston end into a padded vise, then install the push rod and the grommet firmly into the end of the power piston.

⚠ WARNING

WARNING: Be sure the push rod is seated all the way into the power piston end. If it's not, it could become disconnected later, which could result in the loss of braking control.

11. Install new oval face seals on the mating surface of the auxiliary electric pump. See **Fig. 16**.

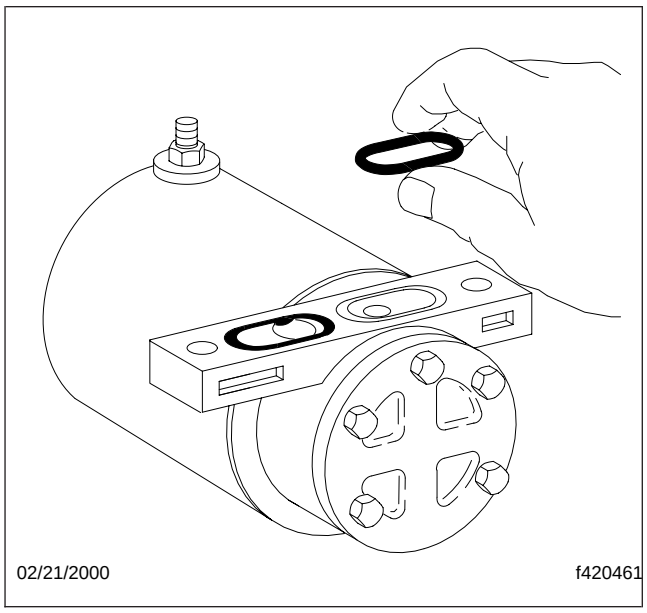

Fig. 16

12. Install the adapter block on the electric pump, with the machined lip on the block down, and hanging over the front edge of the electric pump. See **Fig. 17**. Tighten the mounting bolts 30 N·m (22 lbf·ft).
13. Install new oval face seals on the top of the adapter block, then install the adapter block and electric pump assembly on the bottom of the booster housing, as shown in **Fig. 18**. Tighten the two mounting bolts 30 N·m (22 lbf·ft).

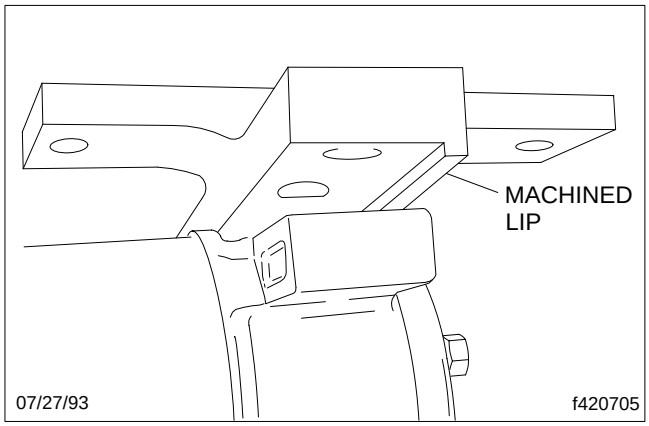

Fig. 17

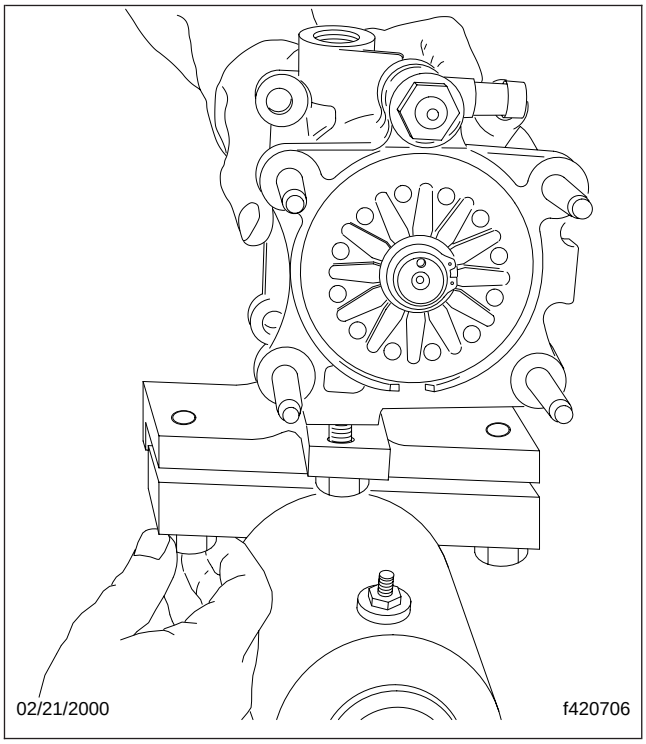

Fig. 18

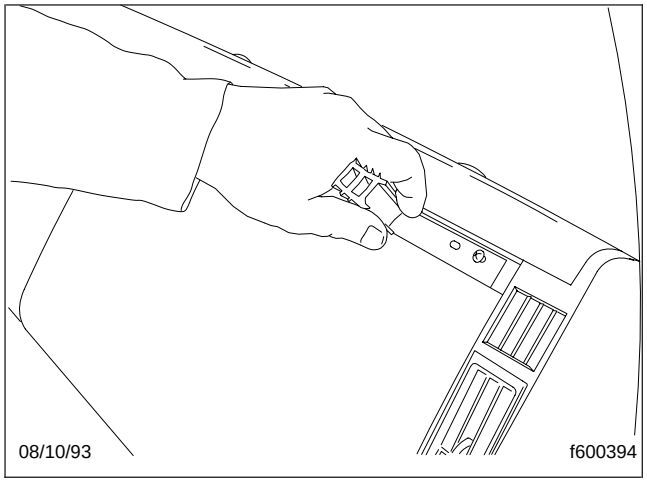
14. Install the power booster assembly on the vehicle, following instructions in **Subject 180**.

Hydraulic Brake Control Module Removal and Installation

Removal

1. Disconnect the batteries at the negative terminals.
2. Access the control module.
   2.1 Remove the extruded rubber strip from the top of the dashboard. **See Fig. 1**.



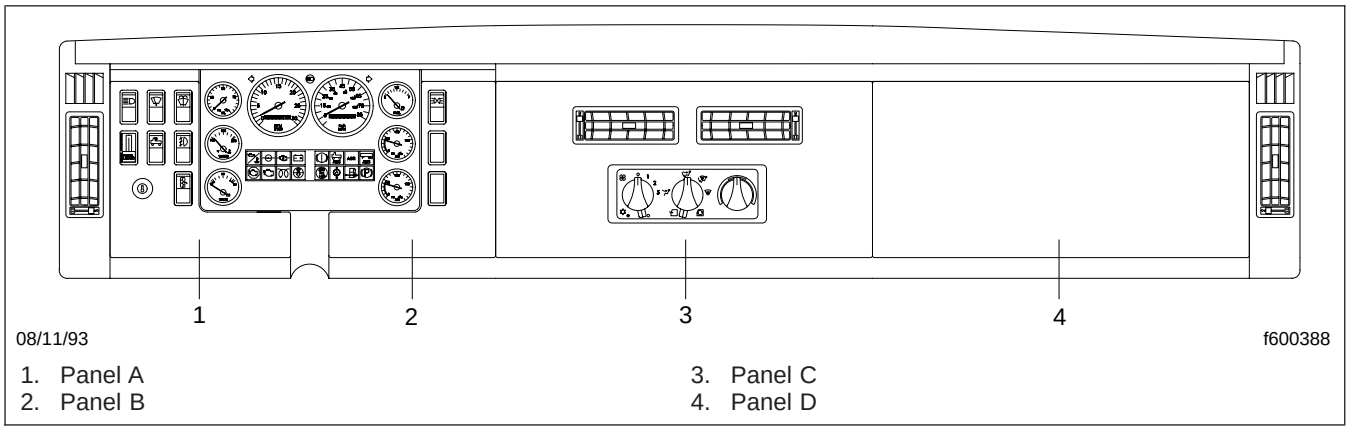


Fig. 1

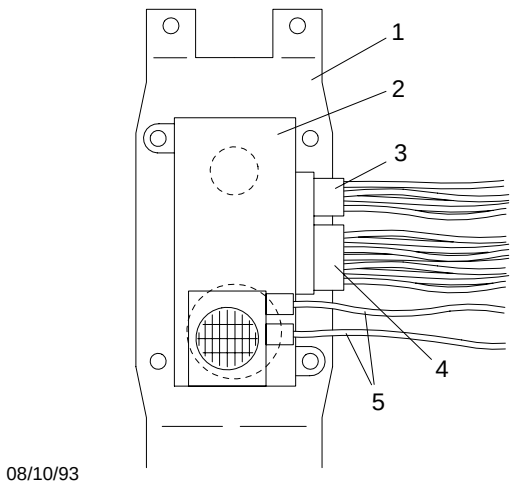
   2.2 Remove dash panels B and D. **See Fig. 2**. Mark and disconnect any electrical wires from the back of panel B.

1. Panel A
2. Panel B
3. Panel C
4. Panel D

Fig. 2

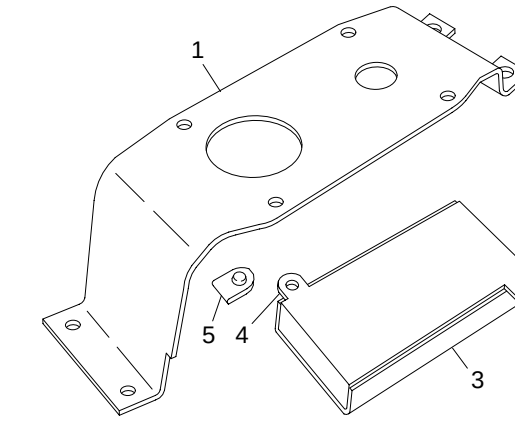
   2.3 Remove the screws from panel C, then swing it down.
3. Find the control module (**see Fig. 3**). Remove the four Torx® head screws holding the module and bracket assembly to the dash, then pull out the module and bracket assembly.



1. Steering Wheel
2. Holes
3. Control Module (mounted under bracket)
4. Mounting Bracket

Fig. 3

4. Disconnect the 9-pin connector, the 4-pin connector, and the two buzzer wires from the back of the module. **See Fig. 4**.



Hydraulic Brake Control Module Removal and Installation

1. Mounting Bracket
2. Control Module
3. 4-Pin Connector
4. 9-Pin Connector
5. Buzzer Wires

Fig. 4

5. Remove the two Torx head screws that attach the module to the mounting bracket, then remove the mounting bracket.
6. Remove and save the two clips from the ears of the module. **Refer to Fig. 5**.

1. Mounting Bracket
2. Clip (installed)
3. Control Module
4. Ear
5. Clip (removed)

Fig. 5

Installation

1. Install the two clips on the ears of the control module, then install the control module on the mounting bracket.
2. Connect the two buzzer wires to the posts on the back of the control module (it doesn't matter which wire goes to which post), then connect the 9-pin and the 4-pin connectors to the back of the control module. **See Fig. 4**.
3. Install the control module and mounting bracket assembly in the dash, using the four Torx head screws.
4. Connect any electrical wires (if present) to the back of dash panel B.
5. Swing dash panel C into place, and then install its mounting screws.
6. Install dash panels B and D.
7. Install the extruded rubber strip in the top of the dashboard.
8. Connect the batteries.

Troubleshooting Tables

Pedal

Problem—The Power Booster Works Sluggishly or Not at All

Problem—The Power Booster Works Sluggishly or Not at All	
Possible Cause	**Remedy**
Binding power booster push rod	Check the linkage between the brake pedal and the power booster push rod. Check the hole in the cab front wall through which the push rod fits. Repair or replace parts as needed.

Problem—The Auxiliary Electric Pump Runs Continuously When the Ignition Is Off and the Brake Pedal Is Not Depressed

Problem—The Auxiliary Electric Pump Runs Continuously When the Ignition Is Off and the Brake Pedal Is Not Depressed	
Possible Cause	**Remedy**
Brake pedal linkage	Check the brake pedal linkage. Repair or replace as needed.

Problem—Pedal Does Not Return, The Brakes are Dragging, Grabbing, or the Brake Action is Uneven

Problem—Pedal Does Not Return, The Brakes are Dragging, Grabbing, or the Brake Action is Uneven	
Possible Cause	**Remedy**
Brake pedal binding or restricted from returning	Check the brake pedal for a restriction. Repair as needed.

Problem—The Brake Pedal Is Hard to Depress With the Engine Running

Problem—The Brake Pedal Is Hard to Depress With the Engine Running	
Possible Cause	**Remedy**
Binding brake pedal	Check the brake pedal linkage. Repair or replace as needed.
Pedal misalignment (side-to-side)	

Wheel-End Components

Problem—Fluid Level Indicator Light Illuminated

Problem—Fluid Level Indicator Light Illuminated	
Possible Cause	**Remedy**
Brake pads worn out	Inspect the brake pads and replace as necessary in axle sets. Add fluid as required.

Troubleshooting

Problem—The Brakes Grab

Problem—The Brakes Grab	
Possible Cause	**Remedy**
Incorrect pads or loose pads on plate	Replace with the correct pads in axle sets.
Grease or brake fluid on pads	Repair grease seal or caliper as required. Replace pads in axle sets.

Problem—The Brakes Pull To the Left or Right

Problem—The Brakes Pull To the Left or Right	
Possible Cause	**Remedy**
Low tire pressure	Inflate the tires to the correct pressure.
Front wheels out of alignment	Align the front wheels. See **Section 33.00**.
Mismatched tires	Check the tire sizes and correct as needed.
Kinked brake lines	Check the routing of the brake lines and hoses. Repair or replace as needed.
Loose or not working caliper	Repair the caliper.
Oily brake pads	Replace the brake pads in axle sets.
Rear brakes not working	Check the rear brakes and repair or replace parts as needed.
Loose suspension parts	Check the front and rear suspension, and repair as needed.
Mismatched or worn brake pads	Replace the brake pads in axle sets. Repair or replace the rotor(s) as needed.
Grease on pads or rotor	Clean the parts as needed.
Caliper piston sticking	Replace caliper as required.
Caliper or anchor plate V-ways sticking	Clean V-ways and anchor plate rails thoroughly and lubricate with approved grease.

Problem—Brake Noises With the Brakes Not Applied

Problem—Brake Noises With the Brakes Not Applied	
Possible Cause	**Remedy**
Worn out front pads	Replace the pads in axle sets.
Dust or oil on rotors	Clean the rotors. Check for and repair an oil leak.

Problem—Brake Noises With the Brakes Applied

Problem—Brake Noises With the Brakes Applied	
Possible Cause	**Remedy**
Bent, damaged or incorrect brake pads installed	Install the correct brake pads in axle sets.
Loose caliper	Install wear shims, or replace worn parts as needed.

Problem—Roughness, Chattering, or Pulsating Is Felt When the Brakes are Applied

Problem—Roughness, Chattering, or Pulsating Is Felt When the Brakes are Applied	
Possible Cause	**Remedy**
Too much rotor lateral runout	Check the lateral runout on the rotors. Repair or replace as needed.
Rotor parallelism not to specifications	Check the parallelism of the rotors. Repair or replace as needed.
Incorrectly adjusted wheel bearings	Check the end play of the front and rear wheel bearings. Adjust as needed. See **Group 33** for front axles and **Group 35** for rear axles.
Brake pad installed backwards (steel side toward the rotor face)	Install the brake pad correctly.
Foreign material imbedded in pads	Replace pads in axle sets.

Problem—Too Much Effort Is Needed to Apply the Brakes (Hard Pedal)

Problem—Too Much Effort Is Needed to Apply the Brakes (Hard Pedal)	
Possible Cause	**Remedy**
Worn brake pads	Replace the brake pads in axle sets.
Stuck or binding caliper piston	Check the caliper pistons. Rebuild the caliper(s) as needed.
Fading brakes due to incorrect pads	Install the correct brake pads in axle sets.
Glazed rotors or brake pads	Replace the glazed rotors or brake pads in axle sets.
Grease or oil on brake pads or rotors	Clean the brake pads or rotors.
Overloaded vehicle	Do not exceed rated vehicle loads.

Problem—The Brakes are Dragging

Problem—The Brakes are Dragging	
Possible Cause	**Remedy**
Kinked or pinched brake lines or hoses	Check the brake lines and hoses. Repair or replace as needed.
Incorrectly installed inboard brake pad	Check the inboard brake pads. Install them correctly as needed.
Brake caliper pistons not returning	Repair or replace the caliper(s) as needed. Check the brake fluid for water. Drain, flush and fill the system if water is found.
Stuck or bound caliper pins or rails	Repair or replace the caliper(s) as needed.
Soft or swollen rubber parts caused by incorrect or contaminated brake fluid	Replace all rubber parts including calipers (which have internal rubber seals). Flush the hydraulic system and fill with approved fluid.

Problem—Excessive Pedal Travel (Low Pedal)

Problem—Excessive Pedal Travel (Low Pedal)	
Possible Cause	**Remedy**
Worn brake pads	Replace the brake pads in axle sets.
Pad and piston knockback caused by loose wheel bearings	Adjust, tighten or replace parts as necessary.

Troubleshooting

Problem—One Brake Drags

Problem—One Brake Drags	
Possible Cause	**Remedy**
Loose or worn front wheel bearings	Adjust to specifications or replace.
Worn or damaged brake hose or hydraulic tube preventing return of brake fluid	Replace worn or damaged hose or tube as necessary.
Sticking caliper piston	Repair or replace the caliper.
Swollen caliper piston seal	Replace the caliper. Flush hydraulic brake system and fill with clean, approved brake fluid.
Sticking caliper V-ways	Clean the V-ways and anchor plate rails and thoroughly lubricate with approved grease.

Hydro-Max II® Power Booster and Master Cylinder

Problem—The Auxiliary Electric Pump Does Not Work With the Engine Off and the Brake Pedal Depressed

Problem—The Auxiliary Electric Pump Does Not Work With the Engine Off and the Brake Pedal Depressed	
Possible Cause	**Remedy**
Loose, broken or disconnected wiring to flow switch on power booster	Check the wiring and repair or replace as needed.
Power booster flow switch not working	Replace the flow switch.

Problem—Fluid Level Indicator Light Illuminated

Problem—Fluid Level Indicator Light Illuminated	
Possible Cause	**Remedy**
Low fluid level	Inspect brake pads, replace as necessary in axle sets. Add fluid as required.
Fluid level indicator switch not working	Replace the master cylinder.

Problem—Silicon Floating in Master Cylinder

Problem—Silicon Floating in Master Cylinder	
Possible Cause	**Remedy**
None	This material is an assembly lubricant and is harmless.

Problem—Noise or Whistle

Problem—Noise or Whistle	
Possible Cause	**Remedy**
None	This noise is inherent in some power boosters (whistle).

Problem—Brakes Self-Apply

Problem—Brakes Self-Apply	
Possible Cause	**Remedy**
Constricted master cylinder reservoir vent	Clean the vent passage in the reservoir cap.

Problem—Pedal Does Not Return

Problem—Pedal Does Not Return	
Possible Cause	**Remedy**
Fluid contamination	Drain the system and fill with the correct type of fluid. Bleed the air from the system. Replace the power booster or master cylinder as needed. Replace the power steering reservoir filter as needed.
Master cylinder not working	Replace the master cylinder.
Binding power booster	Replace the power booster.

Problem—Soft, Spongy Brakes

Problem—Soft, Springy or Spongy Brakes	
Possible Cause	**Remedy**
Air in the hydraulic system	Bleed the brake hydraulic system and the power steering system as needed.
Poor quality brake fluid (low boiling point)	Drain the system, flush and refill with the recommended fluid.
Weak brake hoses that expand under pressure	Replace the hoses as needed.

Problem—Too Much Effort Is Needed to Apply the Brakes (Hard Pedal)

Problem—Too Much Effort Is Needed to Apply the Brakes (Hard Pedal)	
Possible Cause	**Remedy**
Overloaded vehicle	Do not exceed rated vehicle loads.
Power booster not working	Go to "System Pressure Test," under "Pressure Tests" in this subject.
Master cylinder not working	Replace the master cylinder.
Tube and hose passages blocked shut	Replace the parts containing blocked passages.

Problem—Too Much Brake Pedal Travel (Low Pedal)

Problem—Too Much Brake Pedal Travel (Low Pedal)	
Possible Cause	**Remedy**
Leak in hydraulic system	Check for and repair any leaks found in either the power booster (power steering) hydraulic system or the brake hydraulic system.
Low fluid level or leak in master cylinder	Find the cause of the low fluid level and remedy the problem. Fill the master cylinder compartments to the correct level.
Air in the hydraulic system	Bleed the brake hydraulic system and the power steering system as needed.
Plugged master cylinder cap	Clean or replace the master cylinder cap.

Troubleshooting

Problem—Too Much Brake Pedal Travel (Low Pedal)	
Possible Cause	**Remedy**
Wrong type of brake fluid in system	Drain the system and fill with the correct type of brake fluid. Bleed the air from the system.
Master cylinder not working	Replace the master cylinder.
Weak brake hoses that expand under pressure	Replace the hoses.

Problem—The Brake Pedal Travel is Decreasing

Problem—The Brake Pedal Travel is Decreasing	
Possible Cause	**Remedy**
Plugged compensating port in master cylinder	Check the compensating ports in the master cylinder through the openings at the bottom of each reservoir compartment. Unplug them if needed. If the compensating valves are stuck, remove the reservoir. Install the compensating valves correctly.
Master cylinder pistons not returning	Repair or replace the master cylinder.

Problem—The Brakes are Dragging

Problem—The Brakes are Dragging	
Possible Cause	**Remedy**
Master cylinder pistons not returning	Repair or replace the master cylinder.
Kinked or pinched brake lines or hoses	Check the brake lines and hoses. Repair or replace as needed.
Power piston in power booster not returning	Repair or replace the power booster.
Restriction or blockage inside a brake line or hose	Go to "Residual Pressure Test," under "Pressure Tests" in this subject.
Soft or swollen master cylinder seals due to brake fluid contamination	Flush out the old brake fluid and replace the master cylinder. Fill the system with new brake fluid.
Soft or swollen rubber parts caused by incorrect or contaminated brake fluid	Replace all rubber parts including calipers (which have internal rubber seals). Flush the hydraulic system and fill with approved fluid.
Trapped pressure in brake lines caused by master cylinder or power booster not fully releasing	Repair or replace the master cylinder or power booster as necessary.

Problem—The Brakes are Grabbing or the Brake Action is Uneven

Problem—The Brakes are Grabbing or the Brake Action is Uneven	
Possible Cause	**Remedy**
Power booster not working	Repair or replace the power booster.

Problem—Fluid Is Leaking Between the Power Booster and the Master Cylinder (a slight amount of moisture between the power booster and master cylinder is normal)

Problem—Fluid Is Leaking Between the Power Booster and the Master Cylinder (a slight amount of moisture between the power booster and master cylinder is normal)	
Possible Cause	**Remedy**
Worn or damaged master cylinder primary pressure seal or backup ring	Repair or replace the master cylinder.
Worn or damaged seals or O-rings in the power booster end-cap assembly	Repair or replace the power booster.

Problem—Fluid Is Leaking at the Power Booster or the Power Steering Pump

Problem—Fluid Is Leaking at the Power Booster or the Power Steering Pump	
Possible Cause	**Remedy**
Worn or damaged seals between the auxiliary electric pump and the power booster	Replace the seals.
Loose hexbolts attaching the auxiliary electric pump to the power booster	Tighten the hexbolts 22 lbf·ft (30 N·m).
Worn or damaged power booster housing	Replace the power booster.
Worn or damaged power booster flow switch seals	Repair the power booster.
Leaking master cylinder reservoir vent caps	Replace the diaphragms and the caps.
Fluid contamination	Drain the system and fill with the correct type of fluid. Bleed the air from the system. Replace the power booster or master cylinder as needed. Replace the power steering reservoir filter as necessary.
Leaking flow switch seal	Replace the O-ring.
Leaking hydraulic fittings and connections	Check the fittings and connections. Tighten and replace as necessary.

Problem—The Power Booster Works Sluggishly or Not at All

Problem—The Power Booster Works Sluggishly or Not at All	
Possible Cause	**Remedy**
Binding power booster push rod	Check the linkage between the brake pedal and the power booster push rod. Check the hole in the cab front wall through which the push rod fits. Repair or replace parts as needed.
Worn or damaged power booster	Replace or rebuild the power booster.

Auxiliary Electric Pump

Troubleshooting

Problem—Fluid is Leaking at the Power Booster or the Power Steering Pump

Problem—Fluid is Leaking at the Power Booster or the Power Steering Pump	
Possible Cause	**Remedy**
Worn or damaged seals between the auxiliary electric pump and the power booster	Replace the seals.
Worn or damaged auxiliary electric pump	Replace the auxiliary electric pump.
Loose hexbolts attaching the auxiliary electric pump to the power booster	Tighten the hexbolts 22 lbf·ft (30 N·m).
Leaking auxiliary electric pump mounting seals	Replace the seals.

Problem—The Power Booster Works Sluggishly or Not at All

Problem—The Power Booster Works Sluggishly or Not at All	
Possible Cause	**Remedy**
Leakage around the check ball in the auxiliary electric pump	Install a flow gauge on the power booster inlet port. Check the pressure with the engine on, and the brakes fully applied. If the pressure is less than 800 psi (5515 kPa), replace the auxiliary electric pump.

Problem—The Auxiliary Electric Pump Does Not Work With the Engine Off and the Brake Pedal Depressed

Problem—The Auxiliary Electric Pump Does Not Work With the Engine Off and the Brake Pedal Depressed	
Possible Cause	**Remedy**
Disconnected or damaged wiring to auxiliary electric pump	Check the wiring. Repair or replace as needed.
Dead batteries	Check the batteries. Recharge them as needed.
Out of adjustment brake switch	Check the brake switch and adjust it as needed.
Worn or damaged brake switch	Replace the brake switch.
Relay to the auxiliary electric pump not working	Check the relay. Replace it if needed.
Auxiliary electric pump not working	Check the operation of the auxiliary electric pump and replace as needed.
Open circuit	Repair the circuit.

Problem—The Auxiliary Electric Pump Runs Continuously When the Ignition Is Off and the Brake Pedal Is Not Depressed

Problem—The Auxiliary Electric Pump Runs Continuously When the Ignition Is Off and the Brake Pedal Is Not Depressed	
Possible Cause	**Remedy**
Brake light switch not working or incorrectly adjusted	Check the brake light switch and repair or replace as needed.
Relay to the auxiliary electric pump not working	Check the relay. Replace if needed.

Problem—The Auxiliary Electric Pump Runs Continuously When the Ignition Is Off and the Brake Pedal Is Not Depressed	
Possible Cause	**Remedy**
Flow switch not working	Remove the switch components, clean and inspect them for damage or contamination. Repair or replace as necessary.

Problem—The Auxiliary Electric Pump Is Working, But There Is No Boost Power to the Brakes

Problem—The Auxiliary Electric Pump Is Working, But There Is No Boost Power to the Brakes	
Possible Cause	**Remedy**
Low battery voltage	Check the batteries and recharge them as needed.
Low auxiliary electric pump voltage	Disconnect the wiring from the auxiliary electric pump. Check the voltage at the wire. If the voltage is 10 volts or less, replace the wire. If it is more than 10 volts, replace the auxiliary electric pump.

Power Steering Pump

Problem—The Brakes Are Dragging, Brakes Self-Apply or Pedal Does Not Return

Problem—The Brakes Are Dragging, Brakes Self-Apply or Pedal Does Not Return	
Possible Cause	**Remedy**
Self-applied booster (fluid flow too high)	Repair or replace the power steering pump.

Problem—Too Much Effort Is Needed to Apply the Brakes (Hard Pedal)

Problem—Too Much Effort Is Needed to Apply the Brakes (Hard Pedal)	
Possible Cause	**Remedy**
Overloaded vehicle	Do not exceed rated vehicle loads.
Low power booster supply flow	Repair or replace the power steering pump. Check the belt for tightness.
Power steering pump flow control valve not working	Repair or replace the power steering pump. Check the belt for tightness.
Power steering pump relief valve setting too low	Replace the power steering pump.
Tube and hose passages blocked shut	Replace the parts containing blocked passages.

Problem—Fluid Is Leaking at the Power Booster or the Power Steering Pump

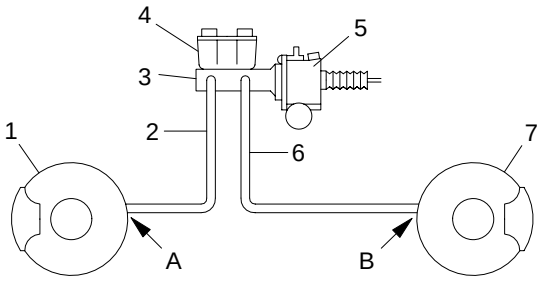
Problem—Fluid Is Leaking at the Power Booster or the Power Steering Pump	
Possible Cause	**Remedy**
Worn or damaged power steering pump	Replace the power steering pump.
Fluid contamination	Drain the system and fill with the correct type of fluid. Bleed the air from the system. Replace the power booster or master cylinder as needed. Replace the power steering reservoir filter as necessary.
Leaking hydraulic fittings and connections	Check the fittings and connections. Tighten and replace as necessary.

Troubleshooting

Problem—The Power Steering Pump Is Noisy

Problem—The Power Steering Pump Is Noisy	
Possible Cause	**Remedy**
Hydraulic supply and return lines touching chassis	Reroute the power booster supply and return lines.
Low fluid level in power steering reservoir	Fill the power steering reservoir to the correct level.
Air in power steering fluid	Bleed the power steering system.
Contaminated power steering fluid	Change the power steering fluid or replace the power steering pump.

Problem—The Power Booster Works Sluggishly or Not at All



Problem—The Power Booster Works Sluggishly or Not at All	
Possible Cause	**Remedy**
Low fluid level in power steering reservoir	Fill the power steering reservoir to the correct level.
Restriction in power steering hydraulic lines	Check all the power steering system hydraulic lines. Replace as needed.
Air in power steering hydraulic system	Bleed the power steering hydraulic system.
Worn or damaged power steering pump	Repair or replace the power steering pump.

Pressure Tests

Residual Pressure Test

1. Install two pressure gauges with a range of 0 to 50 psi (345 kPa)—one in the primary circuit (at the rear wheel), and one in the secondary circuit (at the front wheel). See **Fig. 1**.
2. Bleed the two circuits following the procedure in **Subject 110**.
3. With the ignition off, lightly apply the brakes several times. Do not apply full pressure to the brake pedal or you may damage the pressure gauges.
4. Release the brakes. Read the residual pressure on the two gauges. Record the information.
5. If the residual pressure on one or both gauges is less than 2 psi (14 kPa), go to "System Pressure Test" in this subject.

   If the residual pressure on one or both gauges is more than 2 psi (14 kPa), check the linkage between the brake pedal and the booster. Adjust or repair the linkage as needed. Repeat steps 3 and 4. If the problem is solved, go to "System Pressure Test" in this subject. If the problem is not solved, continue with the procedure.

08/10/93 f420765

B. Install gauge #1 here.
1. Front Brake
2. Secondary Circuit
3. Master Cylinder
4. Reservoir
5. Power Booster
6. Primary Circuit
7. Rear Brake

Fig. 1, Gauge Installation

6. If the check ports of the master cylinder have check valves, replace the master cylinder. Repeat steps 2 and 3. If the problem is solved, go to "System Pressure Test" in this subject. If the problem is not solved, continue with the procedure.

If the check ports of the master cylinder do not have check valves, check the hydraulic lines for internal blockage. Repair or replace lines as needed. Repeat steps 3 and 4. If the problem is solved, go to "System Pressure Test" in this subject. If the problem is not solved, continue with the procedure.

7. Check the master cylinder function. Repair or replace as needed. Go to "System Pressure Test" in this subject.

System Pressure Test

1. Install two pressure gauges with a range of 0 to 2500 psi (17 237 kPa)—one in the primary circuit (at the rear wheel), and one in the secondary circuit (at the front wheel). See **Fig. 1**.

   If you have previously done the residual pressure test, remove the two low-pressure gauges installed for that test, and replace them with the two high-pressure gauges.

2. Bleed the primary and secondary brake circuits following the procedure under **Subject 110**.

3. Make a copy of **Table 1**. Use this copy to record the results from the next step.

Test Results				
Pressure Test	**Gauge 1 (installed at rear wheel)**		**Gauge 1 (installed at front wheel)**	
Rapid Pressure Rise	Yes	No	Yes	No
Slow Pressure Rise	Yes	No	Yes	No
Highest Reading (psi)		psi		psi
Pressure Constant	Yes	No	Yes	No

Table 1, Test Results

4. Start the engine. Quickly apply the brakes using full pedal force. Hold the pedal down for 15 to 20 seconds. Record the speed of the pressure rise, the highest pressure registered on each gauge and whether the pressure stayed constant while the pedal was depressed. See **Table 1**.

5. If the pressure reading on both gauges is not within 10 percent, repair or replace the master cylinder as needed. Remove the pressure gauges. Bleed the system following the instructions in **Subject 110**.

6. If the pressure reading on both gauges is within 10 percent, but the gauges show less than 1170 psi (8067 kPa), turn off the engine; ignition on. Apply the brakes hard, hold the pedal down 15 to 20 seconds.

   If both gauges show at least 860 psi (5930 kPa), repair or replace the power booster. Remove the pressure gauges. Bleed the system following the instructions in **Subject 110**.

   If both gauges do not show at least 860 psi (5930 kPa), repair or replace the power steering pump. Bleed the system following the instructions in **Subject 110**.

7. If the pressure reading on both gauges is within 10 percent and the gauges show at least 1170 psi (8067 kPa), but the pressure came up slowly on both gauges, turn off the engine; ignition on. Apply the brakes hard, hold down the pedal 15 to 20 seconds. If there was an instant pressure rise on both gauges, repair or replace the power steering pump. Remove the pressure gauges. Bleed the system following the instructions in **Subject 110**.

   If there was not an instant pressure rise on both gauges, repair or replace the power booster. Remove the pressure gauges. Bleed the system following the instructions in **Subject 110**.

8. If the pressure reading on both gauges is within 10 percent and the gauges show at least 1170 psi (8067 kPa), but the pressure came up fast on one gauge and slowly on the other gauge, locate the restriction in the circuit having the slow gauge. Remove and install the gauge closer to the master cylinder until the pressure rises quickly. The restriction is between that point and the point of previous installation. Repair or replace the brake line as needed. Remove the pressure gauges. Bleed the system following the instructions in **Subject 110**.

9. If the pressure reading on both gauges is within 10 percent, the gauges show at least 1170 psi (8067 kPa) and the pressure came up instantly on both gauges, but there was not constant gauge pressure while the pedal was depressed, turn off the engine; ignition on. Apply the brakes hard, hold down the pedal for 15 to 20 seconds. If there is constant pressure on both gauges while the pedal is down, repair or replace the

Troubleshooting

power steering pump. Bleed the system following the instructions in **Subject 110**.

If there is not constant pressure on both gauges while the pedal is down, repair or replace the power booster. Bleed the system following the instructions in **Subject 110**.

10. If the pressure reading on both gauges is within 10 percent, the gauges show at least 1170 psi (8067 kPa), the pressure came up instantly on both gauges and there was constant gauge pressure while the pedal was depressed, but the brake pedal did not stay firm, repair or replace the master cylinder as needed. Bleed the system following the instructions in **Subject 110**.
11. If the pressure reading on both gauges is within 10 percent, the gauges show at least 1170 psi (8067 kPa), the pressure came up instantly on both gauges, there was constant gauge pressure while the pedal was depressed and the brake pedal stayed firm, remove the pressure gauges. Bleed the system following the instructions in **Subject 110**. If the problem still exists, check the foundation brakes.

Specifications

See Fig. 1 for the hydraulic brake system plumbing diagram. **See Fig. 2** for the brake control module wiring diagram.

General Description

The pressure relief valve **(Fig. 1)** protects the air brake system against excessive air pressure build-up. The valve has a spring-loaded cap and O-ring assembly which will exhaust air from the reservoir, if pressure rises above the valve's pressure setting. This setting is determined by the force of the spring.

Principles of Operation

To illustrate the operation of the pressure relief valve, note that the governor cut-out pressure on all Freightliner vehicles is set at a maximum 125 psi (862 kPa). A pressure relief valve with a setting of 150 psi (1034 kPa) is then used. Should system pressure rise to approximately 150 psi (1034 kPa), air pressure will force the cap and O-ring assembly off its seat, and allow the reservoir pressure to vent to the atmosphere. **See Fig. 2 .**

When the reservoir pressure decreases sufficiently, the spring force will seat the cap and O-ring assembly, sealing off reservoir pressure. This will occur at approximately 135 psi (931 kPa) for the 150 psi (1034 kPa) valve. Note that the desired pressure setting of the pressure relief valve is determined by the governor cut-out pressure. The opening and closing pressures of the pressure relief valve should always be higher than the governor cut-out pressure setting.

Normally, the pressure relief valve remains inoperative and only functions if, for any reason, the reservoir pressure rises above the setting of the valve. Constant exhausting of the pressure relief valve can be caused by a faulty pressure relief valve, faulty governor, faulty compressor unloading mechanism, or a combination of any of the preceding.

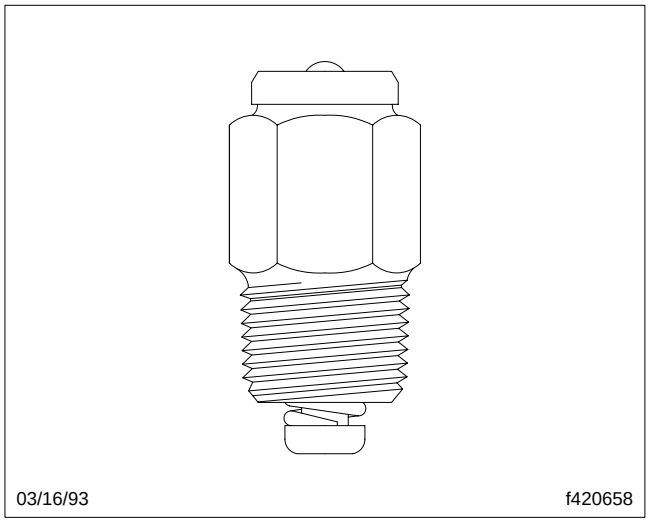

Fig. 1

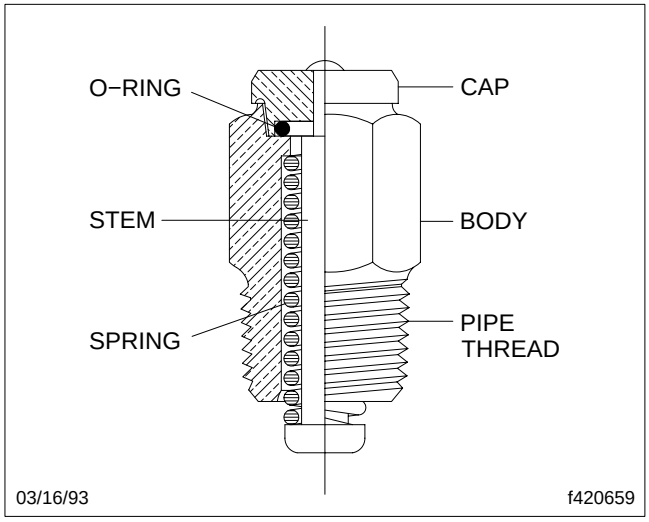

Fig. 2

Operating Check (Refer to Fig. 1)

With air pressure built up in the system, proceed as follows:

⚠ WARNING

WARNING: Wear safety goggles when exhausting the air system because debris could fly out at high speed. Failure to take all necessary precautions could result in personal injury.

1. With your index finger and thumb, pull the cap of the valve, removing the spring load from the O-ring. Air should exhaust from the valve.
2. Release the cap; the airflow should stop.

   Failure of a valve to pass the operating test indicates the valve should be replaced, using the instructions in this section.

Leakage Check

Coat the exhaust port with a soap solution. Leakage resulting in a 1-inch (2.5-cm) bubble in 5 seconds is permitted. Excessive leakage indicates dirt in the valve or a faulty O-ring or seat. The valve should be replaced, using the instructions in this section.

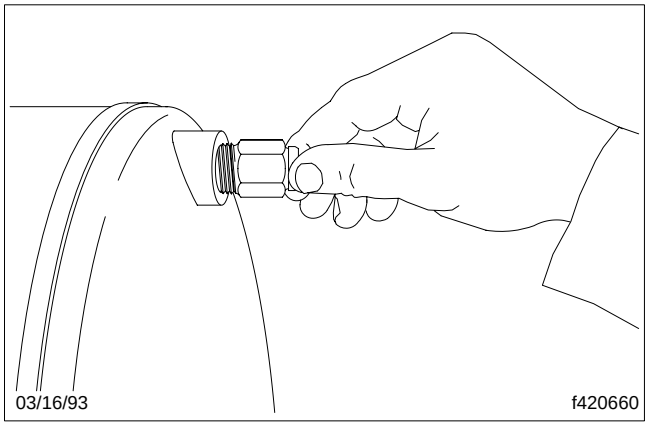

Fig. 1

Removal

1. Chock the tires, and drain the air reservoirs.
2. Using a wrench, unscrew the valve from the reservoir. **See Fig. 1 .**

Installation

1. Apply a small quantity of Loctite® 242, or an equivalent sealant, to the valve threads.

⚠ WARNING

WARNING: Make sure that excess sealant does not get inside either the male or female fittings. This would allow loose foreign material inside the plumbing, and may clog a valve. This could result in an unexpected loss of brake control, which could cause property damage or personal injury.

2. Install the valve and tighten it finger-tight. With a wrench, tighten it 1-1/2 additional turns past finger-tight.
3. Perform the operating and leakage checks on the valve and the valve fitting. For instructions, **refer to Subject 100.**

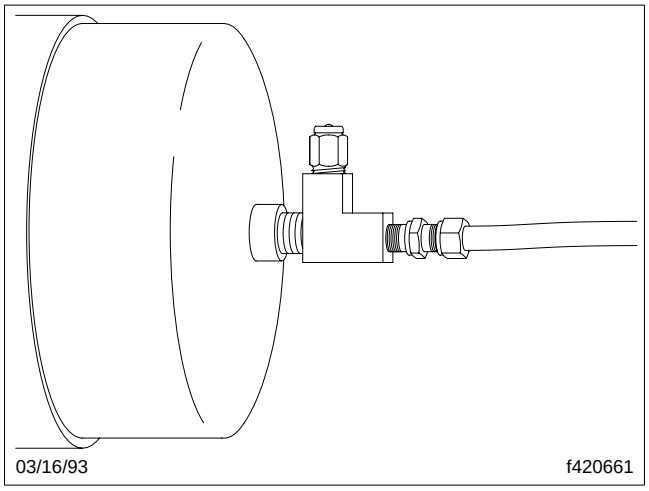

Fig. 1

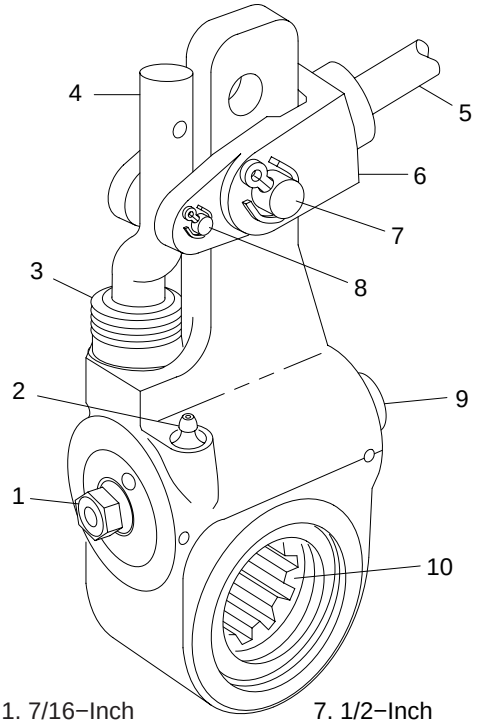
General Description



(Refer to Fig. 1)

The Gunite [1] automatic slack adjuster has two main functions:

- As a lever it converts the straight-line force of the brake chamber push rod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the drum.
- As an automatic adjuster, it maintains the lining-to-drum clearance needed for proper brake chamber push rod stroke.

The slack adjuster is installed between the brake chamber push rod and the brake camshaft. A clevis connects the brake chamber push rod to the top of the slack adjuster. The bottom of the slack adjuster is splined to the brake camshaft. The splines hold the slack adjuster internal gear to the camshaft, so the camshaft turns when the slack adjuster moves. When the brakes are applied, the brake chamber push rod moves outward forcing the slack adjuster and camshaft to rotate. This movement forces the brake shoes against the drum.

The brakes are adjusted when the slack adjuster senses an increase in the lining-to-drum clearance. The slack adjuster's internal worm shaft and ratchet shorten excessive lining-to-drum clearance. This provides maximum leverage for the brake chamber push rod. The automatic slack adjuster adjusts the brakes at the beginning of the brake application.

Fig. 1

[1] Formerly Kelsey-Hayes

IMPORTANT: This automatic slack adjuster cannot be rebuilt. If it is damaged or inoperative, replace the unit. Also, when installing or replacing a Gunite automatic slack adjuster, a new clevis must be installed.

Removal (Refer to Fig. 1)

1. Park the vehicle on a level surface, and chock the tires. If you are removing a rear slack adjuster, release the parking brake, then cage the parking brake power spring. For instructions, refer to the brake chamber section in this manual.
2. Back off the clevis jam nut.
3. Remove the cotter pins, clevis pins, and link.
4. Rotate the adjusting hexnut counterclockwise until the slack adjuster clears the clevis.
5. Remove the snap ring from the brake camshaft, then slide the slack adjuster off the camshaft.
6. Remove the clevis from the brake chamber push rod.

Installation (Refer to Fig. 2)

1. Coat the end of the brake chamber push rod, the camshaft splines, and the splines of the slack adjuster gear with an anticorrosive grease.
2. Make sure that the jam nut is on the brake chamber push rod. Tighten a new snap nut (Ref. 4) until the push rod is flush with the end of the snap nut. Do not tighten the jam nut.
3. Using the cotter pins and clevis pins, install a new clevis on the slack adjuster.
4. Using the old snap ring, install the automatic slack adjuster on the brake camshaft.
5. Turn the adjusting hexnut (Ref. 1) clockwise to rotate the slack adjuster toward the brake chamber until the clevis (Ref. 3) contacts the snap nut. Then, push the clevis and snap nut together.

⚠ WARNING

WARNING: Make sure that the snap nut contacts the clevis and that there is proper engagement. If the snap nut and clevis are not installed correctly, the brakes may not work properly. This could result in an accident causing personal injury and property damage.

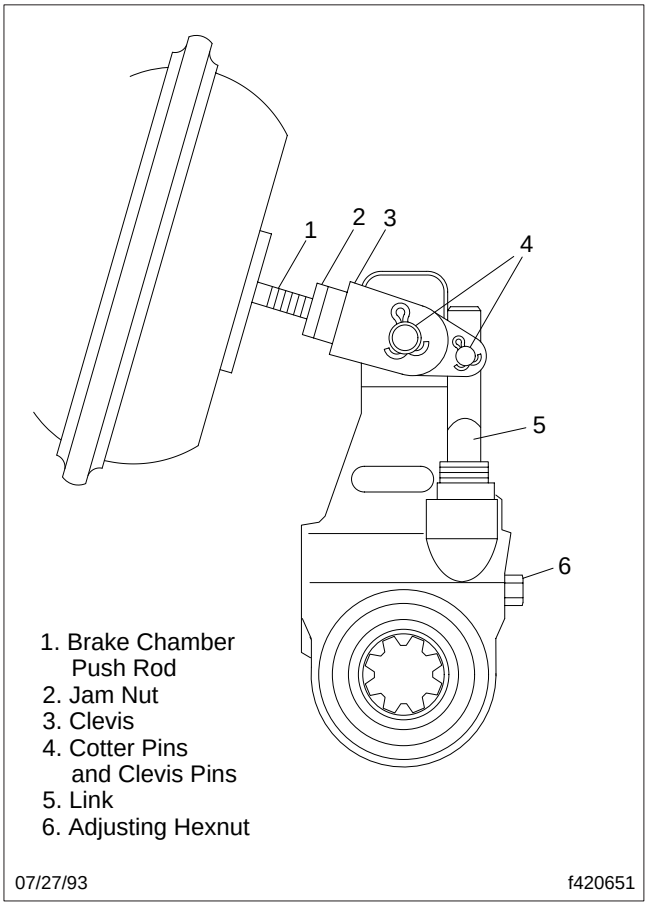

Fig. 1

⚠ CAUTION

CAUTION: Once attached to the clevis, the snap nut cannot be removed from the clevis. If the snap nut is removed, the clevis and/or snap nut will be damaged.

6. Pull on the clevis to make sure that it and the snap nut are properly engaged.
7. Using the gauge supplied with the new slack adjuster, adjust the clevis. **See Fig. 3 .**
   - 7.1 Position the 1/2-inch hole in the gauge over the end of the 1/2-inch clevis pin.

Removal and Installation

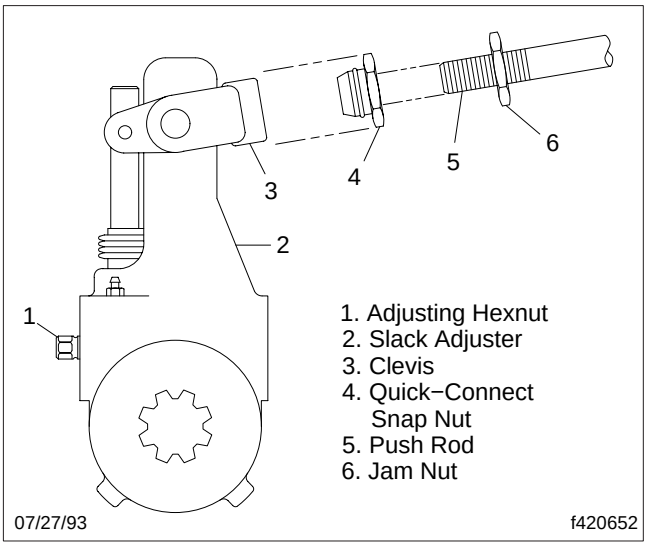

Fig. 2

7.2 Align the applicable 1/4-inch hole in the bottom of the gauge over the center hole of the camshaft.

7.3 Turn the snap nut and adjust the clevis so all of the 1/4-inch pin is visible in the notched area of the gauge. Make sure the push rod doesn't extend into the clevis opening more than 1.5 mm (1/16 inch) past the snap nut.

7.4 Tighten the jam nut.

⚠ CAUTION

CAUTION: Be sure to tighten the jam nut. Failure to do so may allow the snap nut to turn, which could prevent the automatic slack adjuster from working correctly.

NOTE: Make sure there is clearance between the slack adjuster and other vehicle components when the brakes are applied and the push rod travels its maximum stroke.

8. Set the initial free-stroke.

8.1 Turn the adjusting hexnut clockwise until the brake linings contact the drum.

8.2 Turn the adjusting hexnut counterclockwise one-half turn. There should be about 41 N·m (30 lbf·ft) resistance, and a ratcheting sound will be heard.

9. Measure the brake chamber stroke.

9.1 With the brakes fully released, use a ruler to measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 4 ,** Ref. *A* .

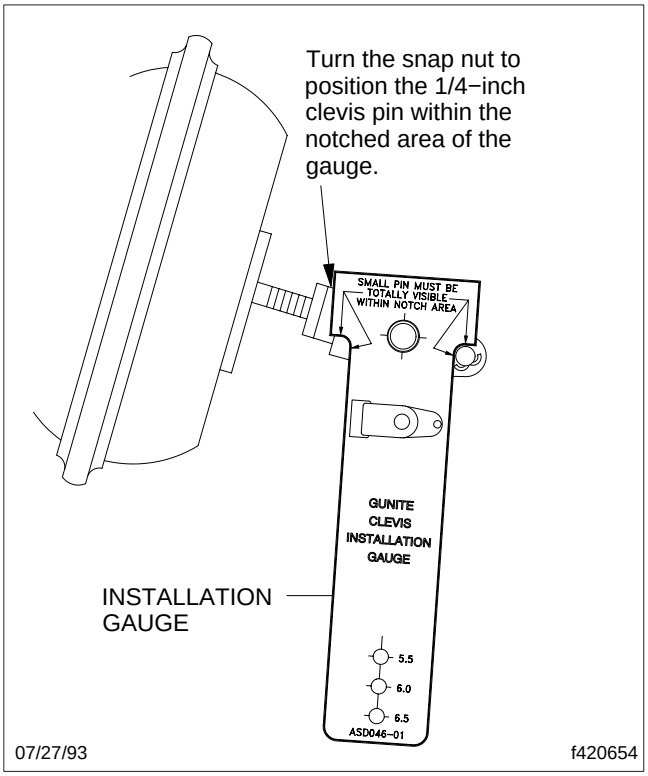

Fig. 3

9.2 Build air pressure to at least 586 kPa (85 psi). Apply the brakes, then measure the distance from the bottom of the brake chamber to the center of the large clevis pin. **See Fig. 4** , Ref. *B* . The difference between the measurements is the brake chamber stroke.

9.3 The brake chamber stroke must be less than the measurements shown in the applicable table in **"Specifications, 400."** If it isn't, check the foundation brakes for problems such as worn cams, bushings, pins and rollers, or broken springs. Repair or replace as needed. For instructions,

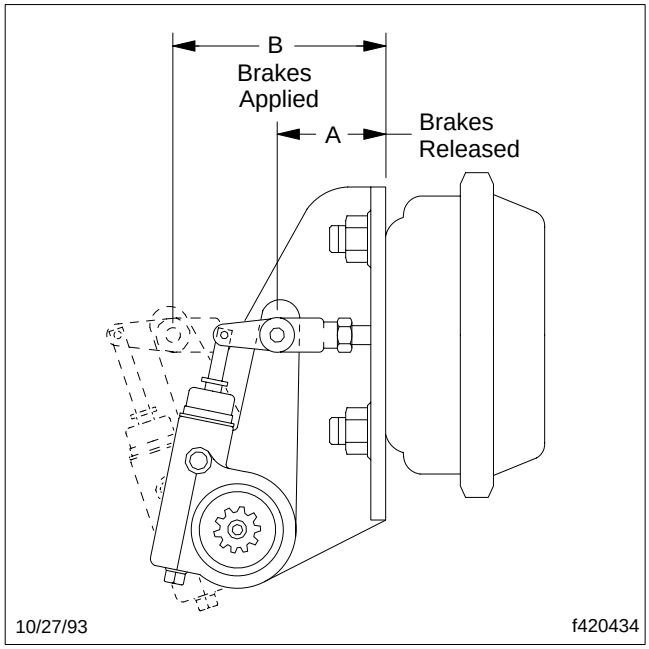

Fig. 4

refer to the foundation brake section in this manual. Then, repeat steps for setting the initial free-stroke, and measuring the brake chamber stroke.

10. If a rear axle slack adjuster was installed, manually uncage the parking brake. For instructions, refer to the brake chamber section in this manual.
11. Apply the parking brakes. Remove the chocks from the tires.

Specifications

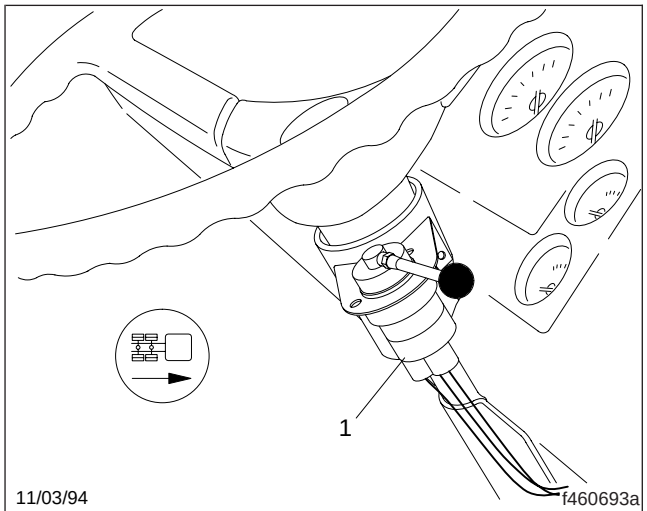
Table 2, Maximum Adjusted Brake Chamber Strokes

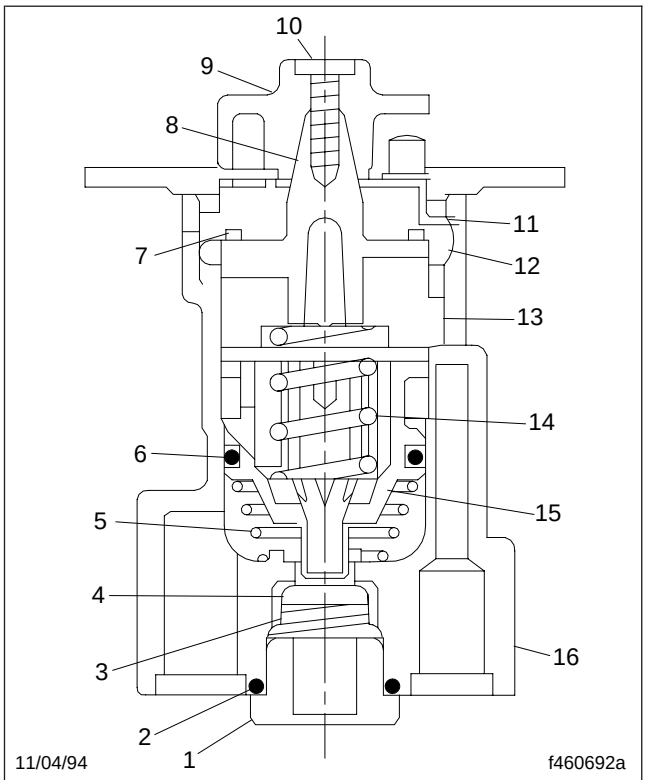


General Information

A hand-operated brake valve is included in some air brake systems for tractor units pulling trailers, in addition to the standard foot brake valve and related equipment. This valve allows the driver independent control of the trailer brakes, which can be useful when checking trailer brakes, or changing adjustable fifth wheel locations.

The brake valve is mounted on the right side of the steering column. See **Fig. 1.**

Principles of Operation (See Fig. 2)



When the valve's control handle is moved in a clockwise direction, the cam (Ref. 13) compresses the graduating spring (Ref. 14), which in turn forces the piston (Ref. 15) to move down. As the piston moves down, compressed air from the supply port flows to the delivery port, applying the trailer brakes through the trailer service line.

1. Trailer Break Control Valve

Fig. 1, Trailer Brake Control Valve Installed on the Steering Column

As air pressure builds in the trailer air system, the pressure under the piston will match the pressure of the compressed graduating spring. This moves the piston up enough to stop air flow through the valve, allowing air pressure in the trailer service brake system to remain constant.

11. Lock
12. Bearing
13. Cam
14. Graduating Spring
15. Piston
16. Body

Fig. 2, Trailer Brake Control Valve (sectional view)

When the control handle is moved counterclockwise, the cam moves up, releasing tension on the graduating spring. This allows the pressure below the piston to increase. The air pressure will then move the piston up and allow air in the service line to flow out of the exhaust port, releasing the trailer brakes.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air— it may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released. Even when compressed air has been released at the reservoirs, residual air may still be trapped in the air lines.
3. Never exceed recommended air pressure, and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood the recommended procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to the use of those tools.

⚠ WARNING

WARNING: Don't use the hand brake valve to apply the trailer brakes for parking. It is not designed for this purpose. The air could bleed out of the trailer air tank allowing the vehicle to roll, which could cause personal injury, property damage, or damage to the vehicle.

Test

1. Park the vehicle on a level surface and chock the tires.
2. Connect an accurate test gauge to the delivery port of the valve, or connect the gauge to the service hose coupling located behind the cab. When the gauge is connected to the service hose coupling, install a dummy hose coupling on the supply (emergency) hose coupling, and place the dash valve in the trailer charge position. When the valve control handle is moved to the fully applied position, the gauge should register full reservoir pressure.

NOTE: Midland valves are set to deliver full reservoir pressure. Intermediate positions should deliver proportional intermediate pressures. Upon manual release, the gauge should immediately register zero.

3. Locate the exhaust port or exhaust line and apply a soap solution.
4. With the valve in the released position, exhaust leakage should not exceed a 2.5-cm (1-inch) bubble in 5 seconds.

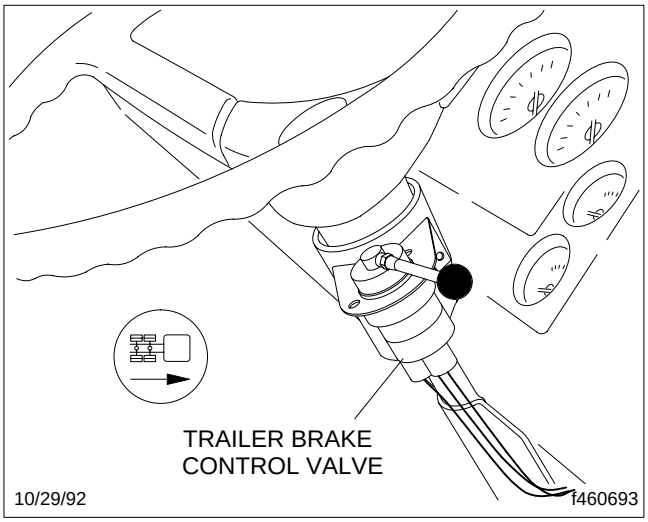
   With the valve fully applied, exhaust leakage should not exceed a 2.5-cm (1-inch) bubble in 5 seconds.
5. If the valve does not function properly or if leakage is excessive, replace the valve following the instructions **in Subject 120.**
6. Remove the chocks from the tires.

WARNING

WARNING: Before starting the procedure below, read the information in "Safety Precautions, 100." Failure to be aware of the safety precautions could result in personal injury.

Replacement (Refer to Fig. 1)

1. Chock the tires or hold the vehicle on a level surface by means other than the air brakes.
2. Drain the air system by opening both the primary and secondary reservoir drain cocks.
3. For later assembly reference, mark the three air lines connected to the valve. Disconnect the air lines from the valve.
4. Remove the two screws which hold the valve and the valve mounting bracket to the steering column. Remove the valve and the mounting bracket from the steering column.
5. Remove the three screws that attach the valve to the mounting bracket.
6. Install the mounting bracket on the new valve. Tighten the three screws firmly.
7. Position the mounting bracket and the valve on the steering column. Install and tighten the two mounting screws firmly.
8. Attach the air lines to the valve. Using two wrenches, tighten the lines firmly.
9. Do the operating and leakage test in **Subject 110.**



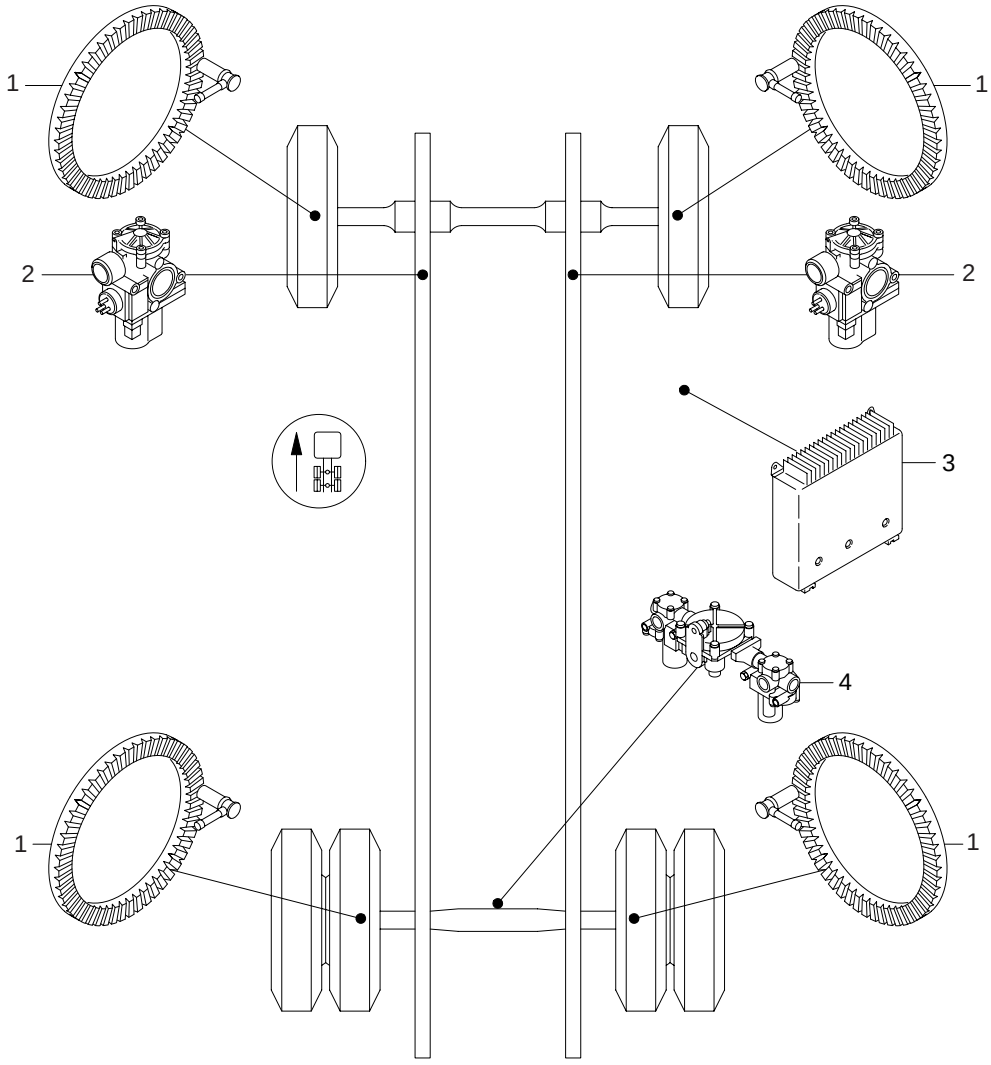


Fig. 1

General Description (See Fig. 1)

04/30/96 f421364

1. Tone Wheel and Sensor
2. Solenoid Control Valve
3. Electronic Control Unit
4. Combination Solenoid Control Valve

Fig. 1, Location of ABS Components, Four-Channel System

The WABCO Antilock Braking System (ABS) is an electronic wheel speed monitoring and control system that works with the air brake system. ABS passively monitors vehicle wheel speed at all times, and controls wheel speed during emergency stops. If equipped with Traction Control or Automatic Traction Control, wheel spin is controlled during reduced-traction situations. In normal braking applications, the air brake system is in effect.

ABS includes signal-generating tone wheels and sensors located in the wheel hubs of each sensed wheel. The sensors transmit vehicle wheel speed information to an electronic control unit. According to programmed specifications, the control unit signals

General Description and Principles of Operation

the appropriate solenoid control valve to increase, reduce, or maintain air pressure supply in the brake chamber. This prevents front and rear wheel lockup, and enhances steering control during emergency braking situations. If equipped with Traction Control or Automatic Traction Control (ATC), two additional solenoid valves are installed. During reduced-traction situations, these valves increase or reduce air pressure supply in the brake chamber to provide better traction whenever wheel spin occurs.

Principles of Operation

The ABS electronic control unit (**Fig. 2**) is a digital microcomputer that serves as the information processing and command center for the antilock braking system. The control unit receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the control unit regulates the braking force applied to each wheel by sending control signals to the solenoid control valves (**Fig. 3**).

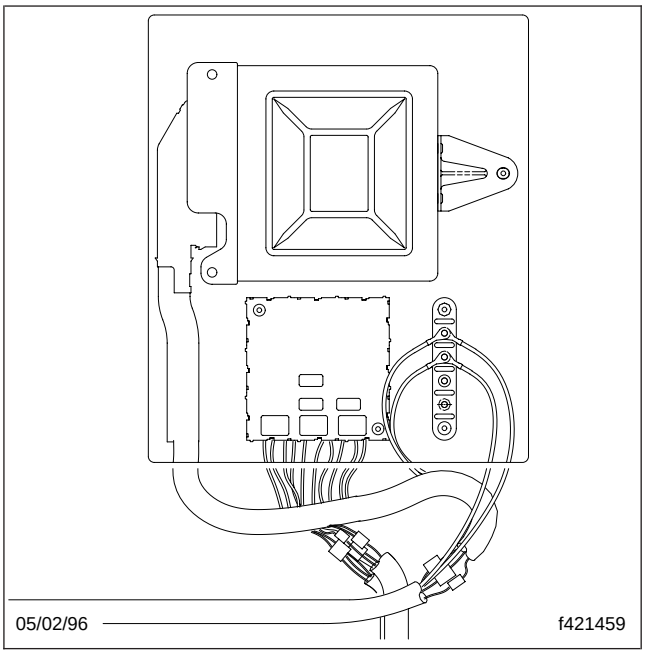

Fig. 2, Electronic Control Unit

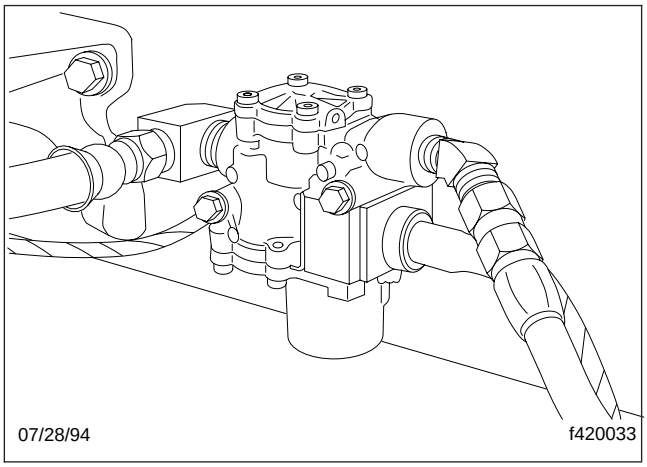

Fig. 3, Solenoid Control Valve

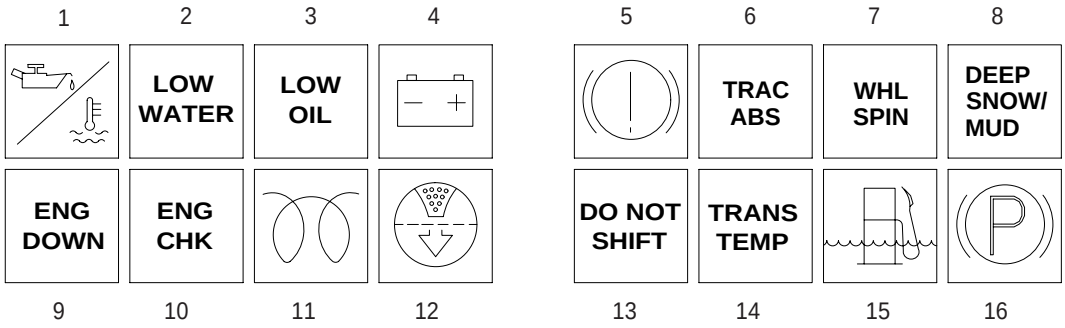
ABS MAJOR COMPONENTS

Wheel Speed Sensor

The wheel speed sensors use pulse feedback from 100-tooth tone wheels located in the front and rear axle wheel hubs. When the vehicle is moving, the teeth of the tone wheel cause interruptions in a magnetic field created by the sensor. The interruptions created in the magnetic field in turn create electrical pulses that are sent by the sensor to the electronic control unit.

Electronic Control Unit



The WABCO ABS system combines one front-axle control channel with one rear axle to form a control circuit. For example, the sensor and solenoid control valve on the left-front axle form a control circuit with the sensor and solenoid control valve on the right-rear axle.

The electronic control unit (ECU), located behind the passenger seat, contains microcomputers to monitor both control circuits. The ECU receives speed sensor pulses and interprets these signals to calculate wheel speed and a vehicle reference speed. If the calculations indicate wheel spin or lockup, the appropriate control circuit signals the solenoid control valve(s) to increase or decrease braking pressure.

The ECU contains another microcomputer that provides a safety circuit to constantly monitor the wheel sensors, traction control valves (if equipped), solenoid control valves, and the electrical circuitry. After the engine is started, the tractor warning light (TRAC

ABS) comes on. See **Fig. 4**. Once the vehicle moves faster than about 4 mph (6 km/h), the warning light goes out if all of the tractor's ABS components are working properly.

if a solenoid control valve (or combination solenoid control valve) is damaged and inoperative. As these components are an integral part of the air brake system, normal braking may be impaired or inoperative.

10. Engine Check Indicator
11. Cold-Start Manifold Heater Indicator
12. Air Cleaner Restriction Indicator
13. Do-Not-Shift Indicator
14. High Oil Temperature Warning (Automatic Transmission)
15. Water in Fuel/Water Separator Warning
16. Parking Brake Indicator

Fig. 4, Dash Warning and Indicator Lights

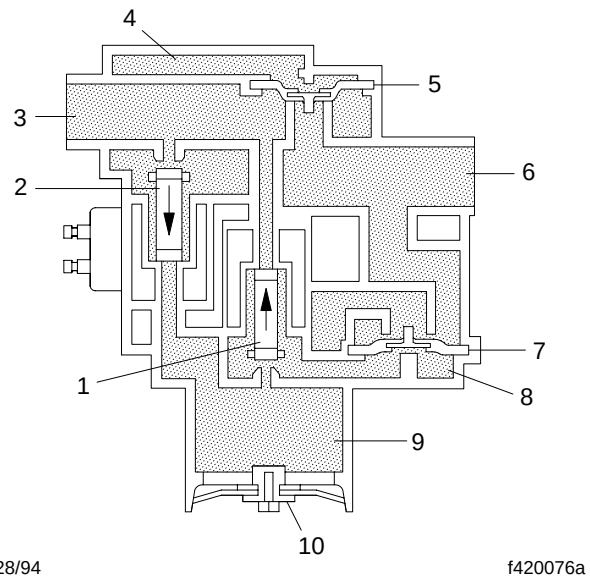
A wheel spin (WHL SPIN) indicator light (if equipped) will come on if one of the drive wheels spins during reduced-traction situations. See **Fig. 4**. Refer to the vehicle driver's manual for operating instructions.

If equipped with an electronic engine, an automatic traction control (ATC) system may be installed. On these vehicles, the ATC system automatically reduces wheel spin during reduced-traction situations.

An "ATC Function" switch (if equipped), may be used under more adverse conditions. Turning on this switch illuminates the DEEP SNOW/MUD indicator light (**Fig. 4**). The ATC system now allows some wheel spin (for example, to help burn through a thin layer of ice) during reduced-traction situations.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (a sensor, solenoid control valve, wiring connection, short circuit, etc.), the tractor warning light (TRAC ABS) comes on, and the control circuit where the failure occurred is switched to normal braking action. The remaining control circuit will retain the ABS effect. Even if the ABS system is completely inoperative, normal braking is maintained. An exception would be

IMPORTANT: If the TRAC ABS warning light does not work as described above, repair the ABS system. See **"Troubleshooting, 300"** for fault diagnosis.



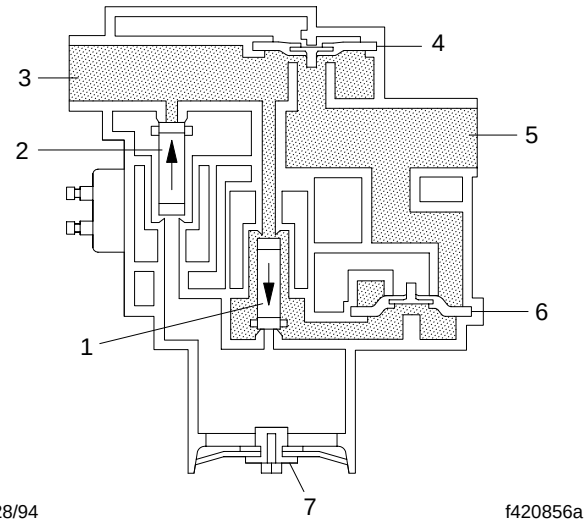
Solenoid Control Valve and Combination Valve

The solenoid control valves are attached to the frame crossmember near the brake chambers. The combination solenoid control valve (for vehicles without traction control manufactured November, 1995 or later), which includes a relay valve, is also attached to the frame crossmember near the rear brake chambers. Depending on the signal received from the electronic control unit, the control valve prevents wheel lockup by reducing, maintaining, or increasing brake chamber air pressure. During normal braking applications, compressed air flows freely to the brake chamber through the control valve.

If the electronic control unit signals indicate wheel lockup, air pressure is reduced in the brake chamber.

General Description and Principles of Operation

Solenoid valve 1 opens allowing compressed air to enter the inlet chamber and pilot chamber 1. See **Fig. 5**.

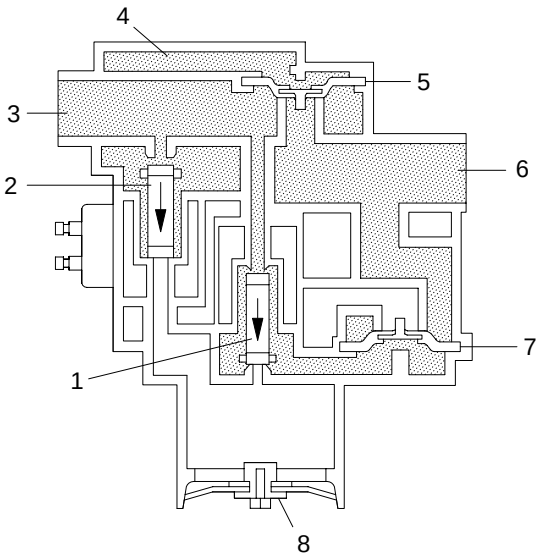


1. Solenoid Valve No. 2
2. Solenoid Valve No. 1
3. Inlet Chamber
4. Pilot Chamber No. 1
5. Diaphragm Valve No. 1
6. Delivery Chamber
7. Diaphragm Valve No. 2
8. Pilot Chamber No. 2
9. Exhaust Chamber
10. Exhaust Port

Fig. 5, Wheel Lockup Cycle

At the same time, solenoid valve 1 closes off the exhaust chamber preventing the escape of air from the inlet chamber to atmosphere. Compressed air in the inlet chamber is forced into pilot chamber 1, closing diaphragm valve 1; this prevents air passage to the delivery chamber. Solenoid valve 2 also opens allowing air to vent from pilot chamber 2 through the exhaust port. Complete venting of all air in the delivery chamber occurs as diaphragm valve 2 opens.

As wheel speed increases, the control valve alternately increases, then maintains brake pressure until the proper wheel speed is obtained, or until wheel lockup occurs and the control cycle starts again.



During the pressure increase cycle (**Fig. 6**), both solenoid valves are closed. Compressed air entering through the inlet chamber forces diaphragm valve 1 open, allowing air to pass through the delivery chamber into the brake chamber. At the same time, pressure within the control valve keeps diaphragm valve 2 closed, preventing air from releasing through the exhaust port.

Wheel Speed Sensor Replacement

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. Refer to the electrical section (wiring) in this manual for information on special terminals and connectors, and on ordering tools for them.

Front Axle

1. Chock the rear tires to prevent vehicle movement. Apply the parking brakes.
2. Gently twist and pull the sensor, to remove it from the steering knuckle (**Fig. 1**).

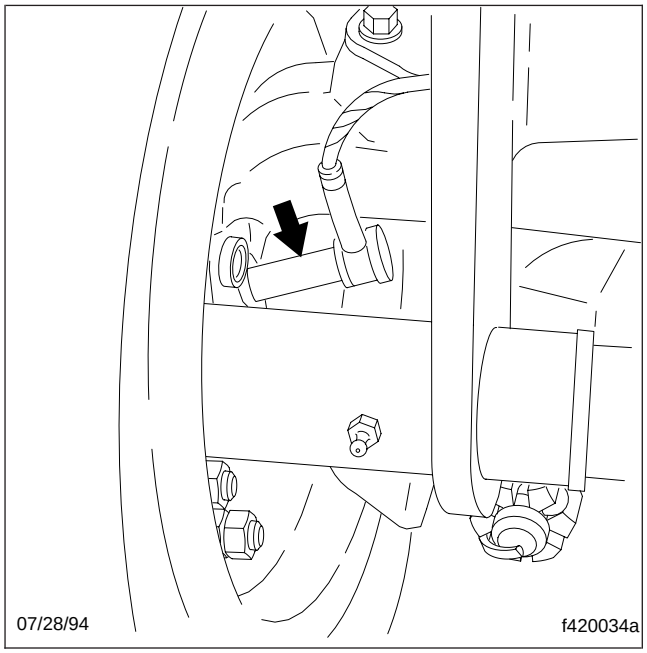

Fig. 1

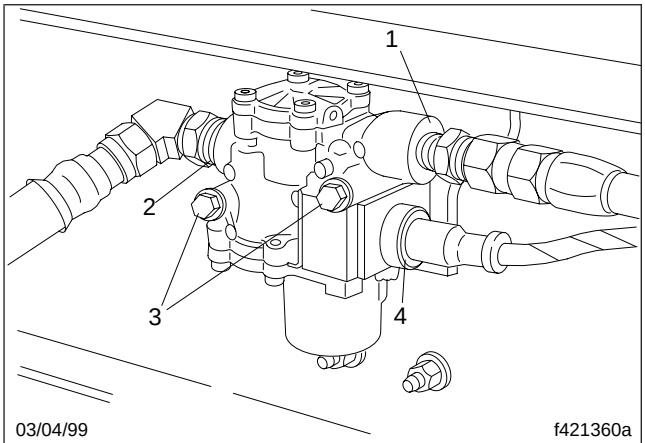
3. Remove the sensor cable from the steering knuckle top cap.
4. Disconnect the sensor cable from the chassis harness.
5. Remove the clamping bushing from the steering knuckle.
6. Connect the sensor cable to the chassis harness.
7. Attach the sensor cable to the steering knuckle top cap.
8. Press the clamping bushing into the brake spider hole until it stops.
9. Coat the sensor with Mobil HP, Valvoline EP 633, Penzoil 707L, or an equivalent. Press the sensor into the clamping bushing until it is stopped by the tone wheel.
10. Remove the chocks from the rear tires.



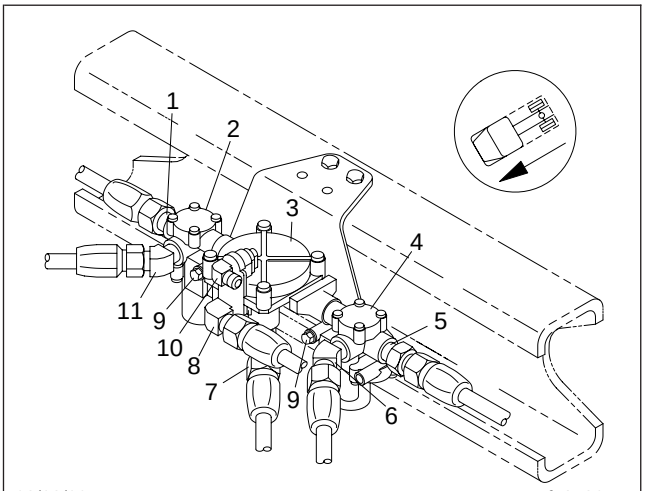
Rear Axle

1. Chock the front tires to prevent vehicle movement. Apply the parking brakes.
2. Raise the rear of the vehicle until the tires clear the ground. Place safety stands under the axle.
3. Back off the slack adjuster to release the rear axle brake shoes.
4. Remove the wheel and tire assembly from the rear axle. For instructions, refer to the wheels and tires section in this manual.
5. Remove the brake drum. For instructions, refer to the rear axle section in this manual.
6. Gently twist and pull the sensor, to remove it from the mounting block in the axle housing.
7. Remove the clamping bushing.
8. Remove the capscrew that attaches the sensor cable and the hose clamp to the axle tube.
9. Disconnect the sensor cable from the chassis harness.
10. Connect the sensor cable to the chassis harness.
11. Attach the hose clamp and sensor cable to the axle tube located between the backing plate and the spring plate.
12. Press the clamping bushing into the mounting block until it stops.
13. Coat the sensor with Mobil HP, Valvoline EP633, Penzoil 707L, or an equivalent. Push the sensor into the clamping bushing until it is stopped by the tone wheel.
14. Install the brake drum on the wheel hub.

Wheel Speed Sensor Replacement

15. Adjust the rear axle brakes. For instructions, refer to the brake section in the vehicle maintenance manual.
16. Install the wheel and tire assembly, and tighten the wheel nuts. Use the tightening sequence and torque values listed in the wheels and tires section in this manual.
17. Remove the safety stands, lower the vehicle, and remove the chocks from the front tires.

Removal (See Fig.1or Fig.2)



1. Supply Port 1 (from steer axle quick release)
2. Delivery Port 2 (to brake chamber)
3. Mounting Fasteners
4. Electrical Connection

Fig. 1, Solenoid Control Valve

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Group 54** in this manual for information on special terminals and connectors, and on ordering tools for them.

1. Chock the front and rear tires.
2. Release the pressure from the air reservoirs.
3. Disconnect the wiring from the solenoid control valves or combination solenoid control valve.
4. Mark the air lines for ease of installation. Disconnect the air lines.
5. Remove the two mounting capscrews, washers, and nuts.
6. Remove the solenoid control valves or combination solenoid control valve.

NOTE: The combination solenoid control valve can be disassembled if replacement of the relay valve or one of the solenoid control valves is needed. For disassembly and assembly instructions, see **Subject 140**.

1. Delivery Port (to right rear brake chamber)
2. Right Modulator Valve
3. Relay Valve
4. Left Modulator Valve
5. Delivery Port (to left rear brake chamber)
6. Delivery Port (to left forward brake chamber)
7. Delivery Port (to park brake quick release valve)
8. Relay Supply Port (from primary air tank)
9. Mounting Fasteners
10. Relay Control Port (from foot valve)
11. Delivery Port (to right forward brake chamber)

Fig. 2, Combination Solenoid Control Valve

Installation

IMPORTANT: It is possible for the solenoid valves to be installed backward. See **Fig.1** to be sure the valves are installed correctly.

1. Install the solenoid valves or the combination solenoid control valve.
2. Install the two mounting capscrews, washers, and nuts. Tighten the mounting nuts 15 lbf·ft (20 N·m).
3. Connect the air lines.
4. Connect the wiring to the solenoid control valves, or combination solenoid control valve.
5. Start the engine and allow the air reservoirs to fill.
6. Remove the chocks from the front and rear tires.

Replacement

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. Refer to the electrical section (wiring) in this manual for information on special terminals and connectors, and on ordering tools for them.

1. Chock the front and rear tires.
2. Disconnect the wiring from the traction control valve.
3. Disconnect the air supply and air discharge lines.
4. Remove the two mounting capscrews, washers, and nuts.
5. Remove the traction control valve.
6. Install the traction control valve using the above instructions in reverse order. Tighten the mounting nuts 24 N·m (18 lbf·ft).

Adjustment

NOTE: The following adjustment procedure requires the use of special tool T11–17556–000. Use of this tool, available through the PDCs, eliminates the time-consuming task of removing the wheel and tire assembly, and the brake drum. **See Fig. 1.**

1. Park the vehicle on level ground, set the parking brake, and shut down the engine.

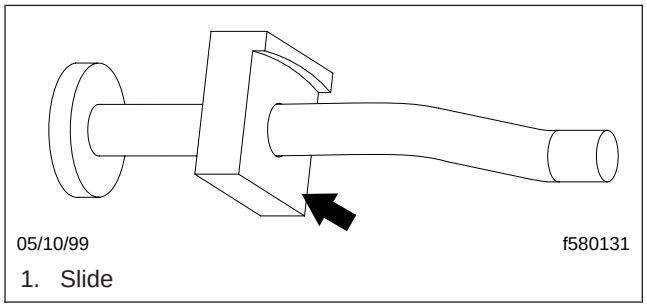


Fig. 1, ABS sensor Adjustment Tool

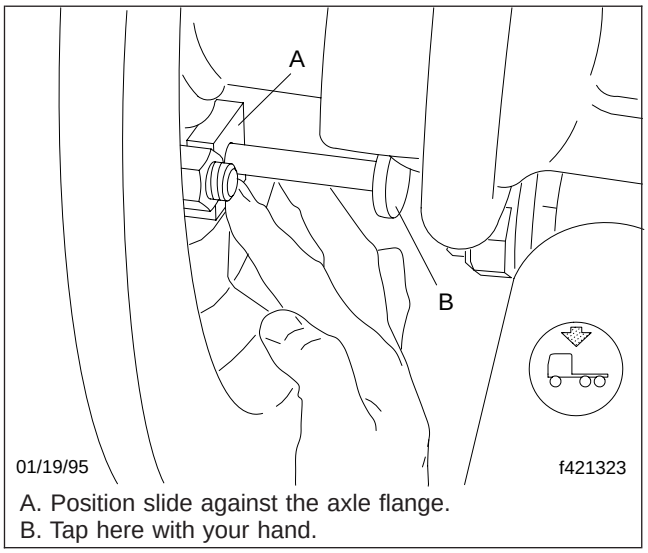
2. Chock the front tires.
3. Find the sensor access hole in the rear axle flange.
   - 3.1 View the brake drum and axle from the rear. The ABS sensor wiring harness should be visible passing through a hole in the 12 o'clock position.
   - 3.2 Find the S cam at either the 3 o'clock or 9 o'clock position.
   - 3.3 Just opposite the S cam is the sensor access hole, approximately 19 mm (3/4 inch) diameter.
4. Insert the service tool T11–17556–000 into this hole.
5. Position the slide of the tool on the axle flange to align the tool. **See Fig. 2.**
6. Tap the tool lightly with the palm of your hand. This will ensure the sensor is touching the tone wheel.
7. Remove the tool from the wheel and repeat the procedure on the other rear axle speed sensor.
8. Remove the chocks from the tires.



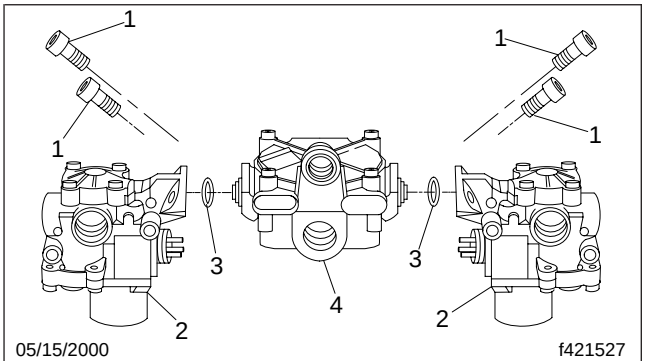


Fig. 2, Position the Tool

Combination Solenoid Control Valve Disassembly and Assembly

Disassembly (See Fig. 1)

1. Allen-Head Bolt
2. ABS Control Valve
3. O-Ring
4. Relay Valve

Fig. 1, Combination Solenoid Control Valve

1. Using a 6 mm allen-head wrench, remove the allen-head bolts.
2. Carefully separate the ABS control valve(s) from the relay valve.
3. Remove and discard the old O-rings.

Assembly (See Fig. 1)

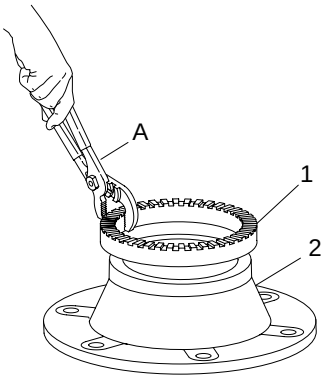
1. Lubricate the replacement O-rings with grease.
2. Plug any unused ports on the replacement valve(s).
3. Attach the ABS control valve(s) to the relay valve. Tighten the allen-head bolts 13 to 15 lbf·ft (18 to 20 N·m).

ABS Tone Ring Installation on Service Hubs

Installation

IMPORTANT: Some ABS service hubs do not have a tone ring installed on the hub. The tone ring must be ordered separately and installed on the hub before installation of the hub onto the axle. Tone rings are made of a special material and require a specific installation procedure for proper installation.

⚠ WARNING

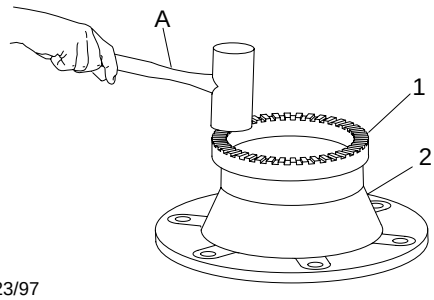


When installing an ABS system, special ABS hubs must be ordered. Machining of older hubs to accommodate the installation of tone rings can cause problems due to insufficient hub bore wall thickness. Machining an older hub with insufficient hub bore wall thickness could result in cracking, causing bearing damage and wheel loss. This could cause an accident resulting in personal injury and property damage.

1. Submerge the tone ring in boiling water or place it in an oven at 250°F (121°C) for approximately 15 minutes.

⚠ CAUTION

Do not attempt to heat the tone ring with a torch as this can damage the ring.



2. Using pliers, remove the tone ring from the boiling water or oven and center it on the machined area of the hub bore. See **Fig. 1**.
3. While the tone ring is still hot, make sure that it is properly centered on the machined surface. Using a rubber mallet, tap the tone ring until it bottoms out around the machined surface on the hub. See **Fig. 2**.
4. Install the hub on the axle. Position a dial indicator with a magnetic base so the dial indicator is against the tone ring teeth. See **Fig. 3**.
5. Rotate the hub and check the ring for runout. The runout should be less than 0.005 inch (0.13 mm). See **Fig. 4**.
6. Install the wheel. For instructions, see **Group 40** of this manual.

12/23/97 f421664

Using the Instrument Panel Blink Codes

This system has built-in diagnostics to ensure that all components are operating properly. Under normal conditions, the tractor warning light (TRAC ABS) comes on after the engine is started. Once the vehicle moves faster than about 4 mph (6 km/h) the warning light should go out if all of the tractor's ABS components are working. If the light stays on, or comes back on later, a problem within the ABS system has occurred. The vehicle can continue to be driven, but the ABS system could be partially or completely inoperative. However, normal braking ability is maintained.

To check the type of fault code recorded, stop the vehicle and turn off the engine. Then, turn on the ignition switch, but don't start the engine. If the warning light is still on, there is an "existing" system fault that must be repaired to ensure proper system operation. If the warning light is not on, an "intermittent" fault (indicating a loose connector or broken wire) has been recorded in the ECU memory.

Fault codes can be erased one at a time from the ECU memory. Erase a fault code by turning off the "ABS CHK" switch. After the WHL SPIN light stops flashing, turn off the ignition switch, then turn it back on.

NOTE: An "existing" fault code cannot be erased from ECU memory until the fault is corrected. An "intermittent" fault can be erased from ECU memory without being repaired. However, make sure that an "intermittent" fault code is recorded because it should be repaired as soon as possible if the code occurs again.

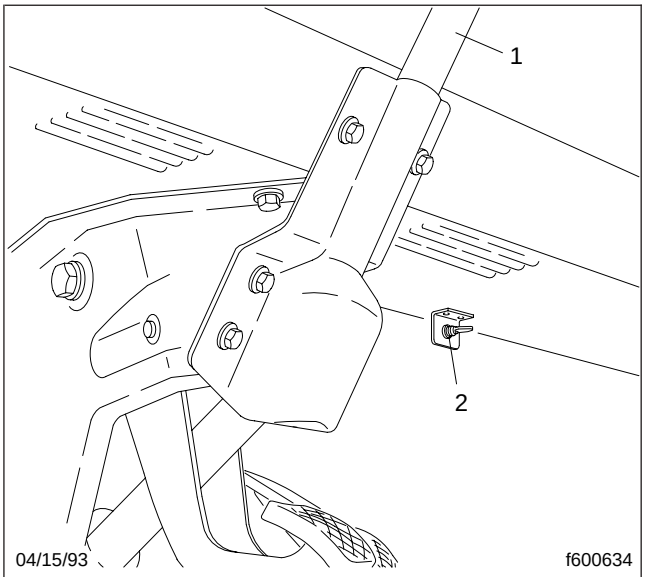
IMPORTANT: If the vehicle is equipped with an electronic engine and automatic traction control, don't turn on the "ABS CHK" switch while driving the vehicle. Activating the switch will reduce the engine speed to idle. Always park the vehicle before using the "ABS CHK" switch to read the instrument panel blink codes.

Before troubleshooting with the instrument panel blink codes, check all fuses in the control unit panel, and replace if necessary. Check the wiring to the "ABS CHK" switch and the warning lamps. See **Table 1**, and repair or replace the wiring as needed. Make sure that a charged 12-volt battery is available (the ABS system needs at least 11 volts to work).

NOTE: If troubleshooting the system with the Pro-Link 9000, use the instruction booklet that is supplied with the data cartridge.

Use the "ABS CHK" switch (**Fig. 1**) and the WHL SPIN light to display system faults. Turn on the ignition switch, then move the "ABS CHK" switch up (on position). After a five second pause, the WHL SPIN light will come on for two and one-half seconds (this is the start flash), then the diagnostic code cycle begins. After a two and one-half second pause, the three digit fault code will be displayed.

For example (**Fig. 2**), after the start flash, fault code 271 is shown by two flashes (each lasting one-half second and separated by a one-half second pause), a pause of two and one-half seconds, followed by seven flashes (each lasting one-half second and separated by a one-half second pause), another pause, followed by one flash for one-half second. After a seven and one-half second pause, the same fault code will continue to repeat beginning with the two and one-half second "start" flash and ending with a seven and one-half second pause.



Wiring Tested	Test These Pins	Volt/Ohmmeter Reading	Possible Cause	Remedy
Tractor Warning (TRAC ABS) Light	9 and 26	2 to 50 ohms (depends on bulb wattage)	Wiring light is shorted or open; or the bulb needs replacing.	Repair the wiring, or replace the bulb.
Blink Code (Whl Spin) Light	3 and 9	2 to 50 ohms (depends on bulb wattage)	Wiring light is shorted or open; or the bulb needs replacing.	Repair the wiring, or replace the bulb.

Troubleshooting

Wiring Tested	Test These Pins	Volt/Ohmmeter Reading	Possible Cause	Remedy
ABS CHK Switch	14 and 27 (also, turn the ABS CHK switch on).	0 to 2 ohms	Wiring light is shorted or open; or the switch needs replacing.	Repair the wiring, or replace the switch.

Table 1

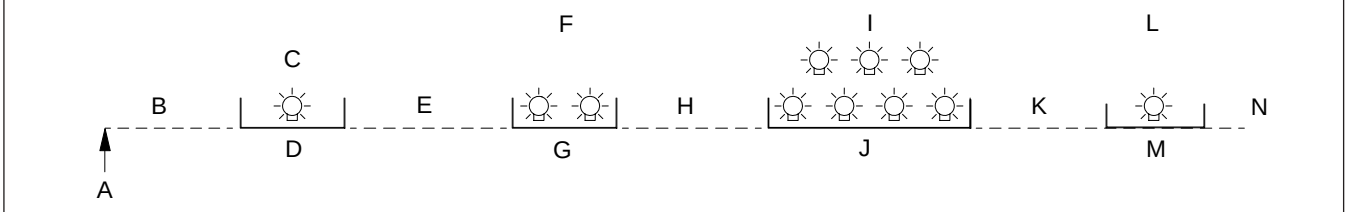
IMPORTANT: The key switch must be off when doing the tests in **Table 1**.

1. Steering Column
2. ABS Check Switch

Fig. 1

See **Fig. 3** for another example of a fault code reading.

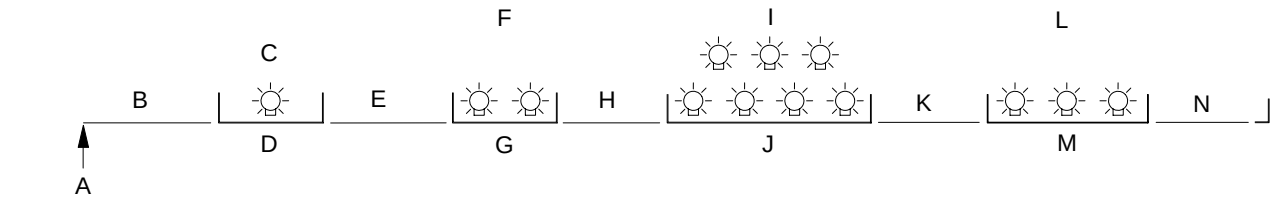
NOTE: When there are no fault codes in the ECU memory, blink code 2–0–0 is displayed.



Once a fault code has been identified, use a volt/ohmmeter to check the electrical harness at the ECU's 35-pin connector (**Fig. 4**). Connect the ohmmeter leads to the applicable pins on the connector. A Rockwell WABCO test adaptor (part number 446 300 314 0) is also available and connects to the 35-pin connector.

IMPORTANT: The ignition switch must be off when connecting or disconnecting the ECU.

After attaching the adaptor (**Fig. 5**) to the 35-pin connector, insert the leads from an ohmmeter into the numbered holes on the adaptor.



NOTE: Regardless of the ECU model installed (B3, C1, or C2), the test adaptor can be used to troubleshoot all 4-channel ABS systems.

See **Table 2** for a listing of all fault codes, pins to be tested, and the correct volt/ohmmeter readings. Repair or replace the components and/or wiring if the readings are not correct.

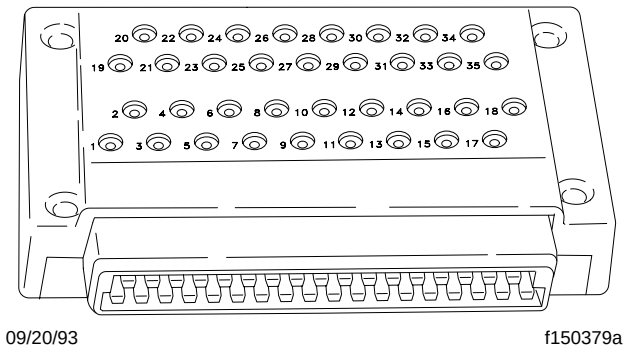

Fig. 5

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals.

See the electrical section (wiring) of this manual for information on special terminals and connectors, and ordering tools for them.

See the wiring diagram in **Subject 400**, when troubleshooting the ABS system equipped with the instrument panel blink codes. The key switch must be turned on (engine off) to activate the blink codes. However, if using the test adaptor 446 300 314 0, the key switch must be off, unless otherwise noted.

If a blink code is displayed that is not in **Table 2**, try to erase the code from ECU memory. If a fault can't be repaired, or erased from ECU memory, test the operation of the solenoid control valves and the traction control valves. For instructions, see **Table 3**. If a fault still can't be repaired, or erased from ECU memory, contact your Rockwell District Service Manager.

If necessary, start the engine and build system air pressure to at least 100 psi (689 kPa). Shut down the engine, but leave the ignition switch on.

⚠ CAUTION

CAUTION: When doing the tests in Table 3, don't leave the positive volt/ohmmeter test lead connected to pin 9 for more than 10 seconds. Momentarily touch the positive test lead to pin 9 only when you are ready to observe the reading. Leaving the test lead connected to pin 9 for more than 10 seconds could damage the solenoid or traction control valve, or the volt/ ohmmeter.

When testing the solenoid control valves or the traction control valves in **Table 3**, always connect the *positive* volt/ohmmeter test lead to pin 9. Connect the *negative* test lead to the other pin referenced in **Table 3**. Set the volt/ohmmeter to 10 amps.

NOTE: If a 10-amp capacity meter is not available, a jumper wire can be used.

Troubleshooting

IMPORTANT: The key switch must be on when doing the tests in **Table 3**.

WABCO ABS Fault Codes/Tests					
Key Switch On to Determine Fault Code			Key Switch Off to Test System		
Fault Code		Problem	Test These Pins	Volt/Ohmmeter Reading	Remedy

Specifications

Fig. 5

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

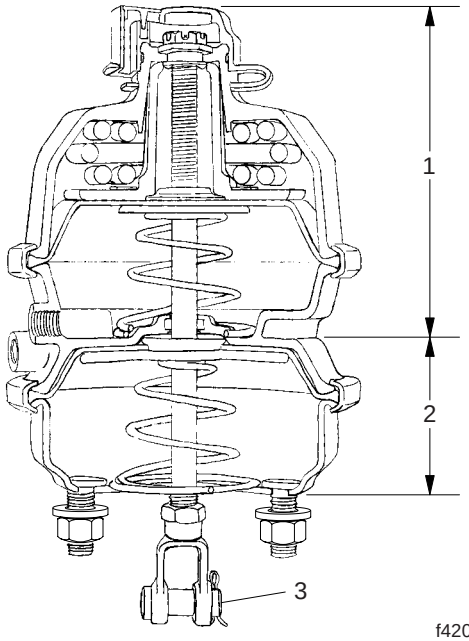
A. Do not remove this clamp ring.
1. Model L-T Brake Chamber
2. Model L Brake Chamber

Fig. 1, L Series Brake Chambers

General Information

MGM "L" series tandem cam brake chambers consist of a service brake section and a parking/emergency spring brake section. **See Fig. 2.** The service brake chamber is in the smaller section near the clevis assembly. Some installations include the service brake chamber only. **See Fig. 3.**

In the service brake section, the flange case (or pressure cap for service-only chambers) and non-pressure chamber contain a service return spring, piston rod assembly, and service brake diaphragm.



In the parking/emergency brake section, the flange case and the head assembly contain a return spring, a push rod assembly, a parking (spring) brake diaphragm, a piston, a power spring, and an integral (contained inside the chamber) release bolt and nut.

All MGM brake chambers are mounted to the frame using prevailing torque locknuts and hardened flat-washers.

To protect internal components from contaminants, MGM Model "L-T" brake chambers are equipped with an external breather tube. Model "L" employs a filtered breather cap. **See Fig. 2.**

Periodic maintenance of the brake chamber is required. Also, whenever the service brake chamber is disassembled (*do not attempt to disassemble the parking brake chamber*), the parts should be inspected for damage. For maintenance schedules and procedures, and for inspection of brake chamber parts, refer to the vehicle maintenance manual.

General Information and Principles of Operation

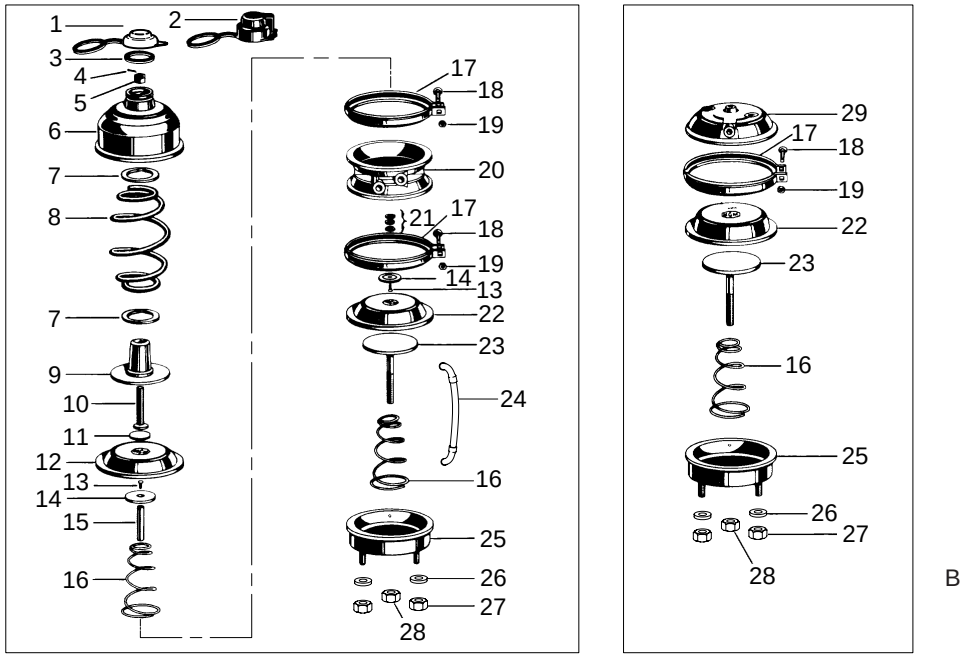
1. Parking (Spring) Brake
2. Service Brake
3. Clevis Assembly

Fig. 2, L Series Cam Brake Chambers (sectional view)

Principles of Operation

SERVICE BRAKES

As the brake pedal is depressed, compressed air enters the service brake chamber through a port. Air pressure acts upon a diaphragm, which forces the piston rod toward the non-pressure chamber, applying a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes.



Then, when the brake pedal is released, air is exhausted from the service brake chamber. The return spring allows the diaphragm, piston rod, and slack adjuster to return to their normal positions, releasing the brakes.

PARKING/EMERGENCY BRAKES

During parking brake release, compressed air enters the parking brake chamber and acts upon the diaphragm and piston, fully compressing the power spring. When the power spring is compressed, the parking brakes are released; the service brakes can then be operated at the brake pedal.

During parking brake application, air is exhausted from the parking brake chamber. The power spring releases, forcing the piston and parking brake diaphragm toward the flange case. The resulting motion on the push rod forces the service brake diaphragm and the piston rod outward, applying the brakes.

Emergency brake application automatically begins when the air pressure in the brake system drops below approximately 550 kPa (80 psi). Full emergency brake application occurs when the air pressure drops below aproximately 275 kPa (40 psi).

Fig. 3, L Series Cam Brake Chambers (exploded view)

DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

Manual Compression (Parking Brake Release)

1. Chock the tires.
2. Remove the end cap (breather cap if so equipped). See **Fig. 2**.

DANGER

Do not attempt to cage the power spring if the parking brake chamber is damaged severely enough to lose its structural integrity. If the power spring were to break loose, it could result in death, severe personal injury, or property damage.

A DAMAGED PARKING BRAKE CHAMBER IS EXTREMELY DANGEROUS! Only qualified service personnel should attempt to remove and disarm a damaged chamber. Using a torch, burn off the piston rod in the space between the clevis and the base of the service chamber.

Remove the chamber carefully from its bracket, and disarm it inside a suitable container. For disarming procedures, consult the MGM service manual.

3. Manually release the parking brake (cage the power spring).
   3.1 Apply at least 620 kPa (90 psi) air pressure to the parking brake inlet port (set parking brake in the "release" position).

CAUTION

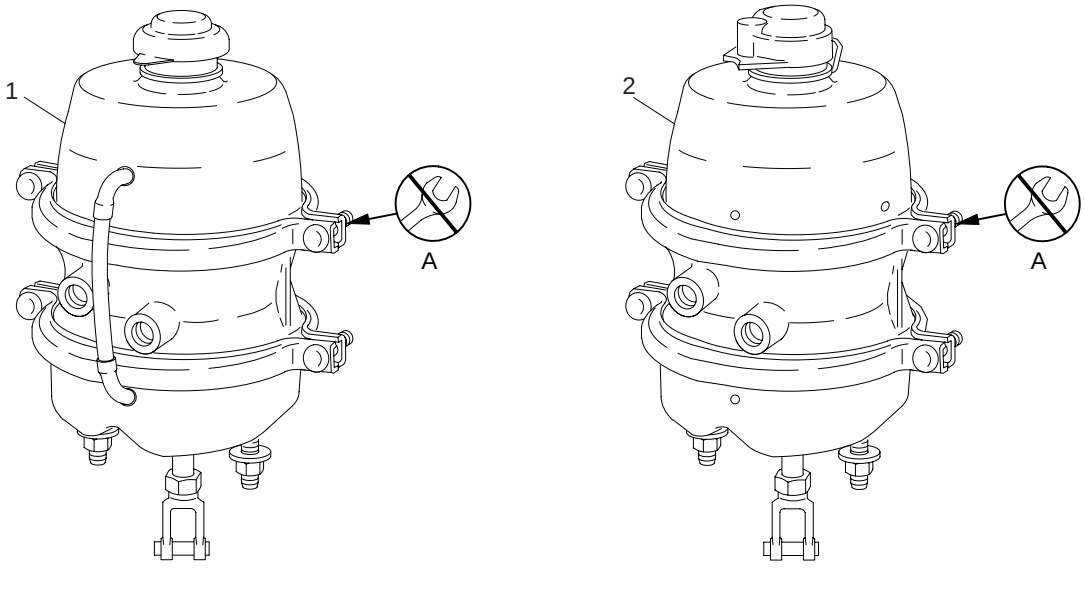
Don't exceed 68 N·m (50 lbf·ft) torque on the release bolt; and don't use an impact wrench on this bolt. Too much torque could distort the head of the chamber and prevent manual release of the parking brake.

   3.2 Using a hand wrench, (*don't use an impact wrench*), turn the release bolt *counterclockwise* until the bolt is fully extended, or about 57 to 64 mm (2-1/4 to 2-1/2 inches). See **Fig. 3**, dimension A.
4. Once the power spring has been caged, exhaust the compressed air from the parking brake.

Manual Reset (Parking Brake Reset)

1. If the threads of the release bolt are dry, coat them with a light film of low-temperature molybdenum (moly) grease.
2. Uncage the power spring.
   2.1 Apply at least 620 kPa (90 psi) air pressure to the parking brake inlet port (set parking brake in the "release" position).

CAUTION



Don't exceed 68 N·m (50 lbf·ft) torque on the release bolt; and don't use an impact wrench on this bolt. Too much torque could distort the head of the chamber and prevent manual release of the parking brake.

   2.2 Using a hand wrench (*don't use an impact wrench*), turn the release bolt *clockwise* until the bolt is fully engaged into the unit and the slotted nut bottoms out onto the head insert.
   2.3 Tighten the release bolt 61 to 68 N·m (45 to 50 lbf·ft). See **Fig. 4**.
3. Snap the end cap tightly into place. On chambers equipped with a breather cap, make sure the drain tab is pointing to the ground. Regardless of the position in which the brake chamber is installed, the arrow on the drain tab must be pointed downwards. See **Fig. 5**, Reference A.

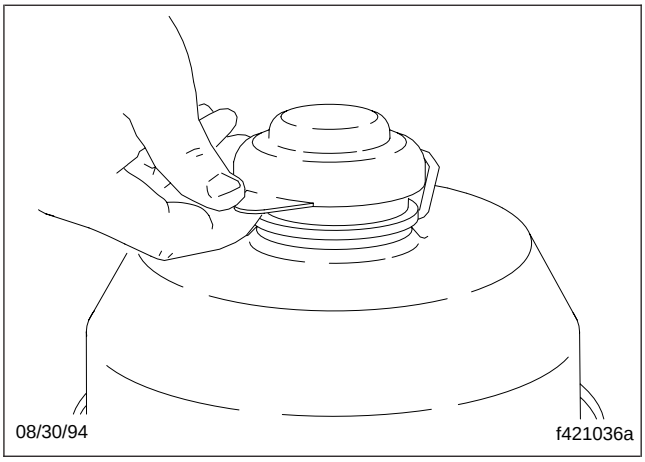
CAUTION

If the external breather tube or breather cap is missing or incorrectly installed, road dirt and debris can adversely affect the operation of the brake chamber. Once inside the chamber, dirt and debris cause the internal parts to deteriorate

Power Spring Manual Compression and Reset

A. Do not remove this clamp ring.
1. Model L-T Brake Chamber
2. Model L Brake Chamber

Fig. 1, L Series Brake Chambers



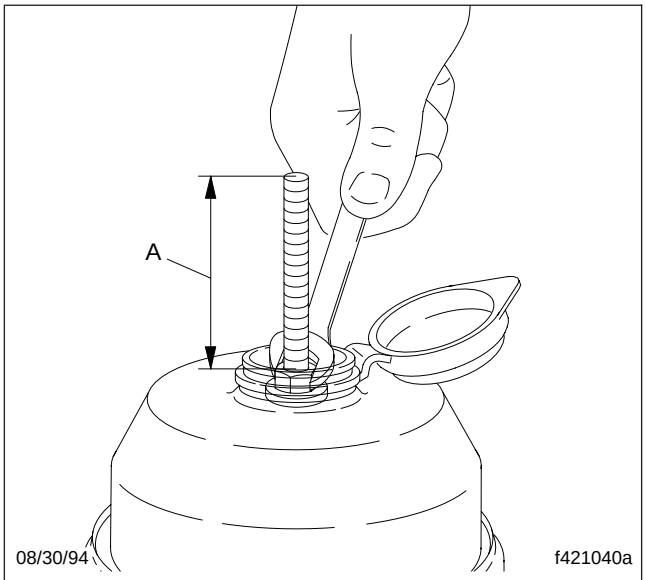


Fig. 2

and shorten their lives. Operating the unit without the external breather tube or breather cap in place voids the MGM warranty.

4. Check the breather tube or cap periodically, and replace it with a new one at once if damaged or missing. Also replace the breather cap if the foam filter is contaminated with dirt or debris. For intervals, see the vehicle maintenance manual.

Make sure the bolt extends at least 57 mm (2-1/4 inches) above the lip on the chamber head.
A. Measure this distance.

Fig. 3

5. Remove the chocks from the tires.

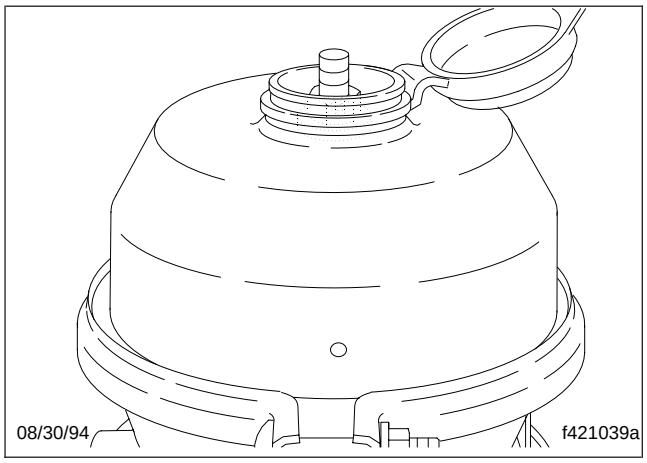

Fig. 4

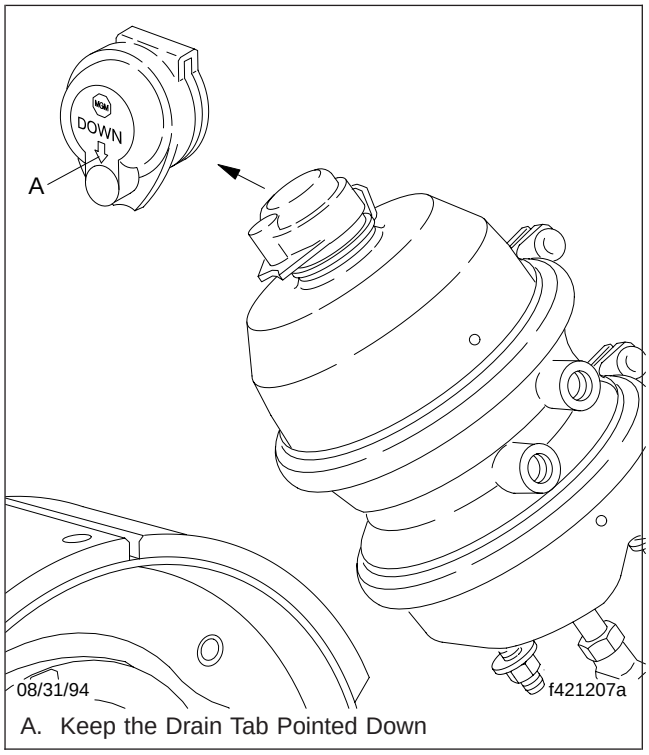

Fig. 5, Breather Cap Installation (on Model L only)

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

Removal

1. To make removal and installation of the parking brake section easier (without removing the service brake chamber), lock off the service chamber piston rod.

   1.1 Apply the service brakes by actuating the driver's foot brake treadle valve.

   1.2 With the brakes applied, clamp a pair of locking-jaw pliers on the piston rod to lock the rod in place when the air pressure is released (see Fig. 2).

⚠ WARNING

Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

2. Manually release the parking brake (cage the power spring). For instructions, see Subject 100.
3. Mark the air lines for later reference. Then carefully disconnect them from the brake chamber.

   On chambers equipped with an external breather tube, disconnect the tube and elbow from the service brake chamber.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4. Remove the parking brake section from the service brake section.

   4.1 Using a hand wrench (*don't use an impact wrench*), remove the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

   4.2 While holding the parking brake section securely in place, remove the service clamp ring. Then remove the parking brake section from the service brake non-pressure chamber (see Fig. 3).

5. Remove the service brake diaphragm from the bottom of the parking brake section.

Installation

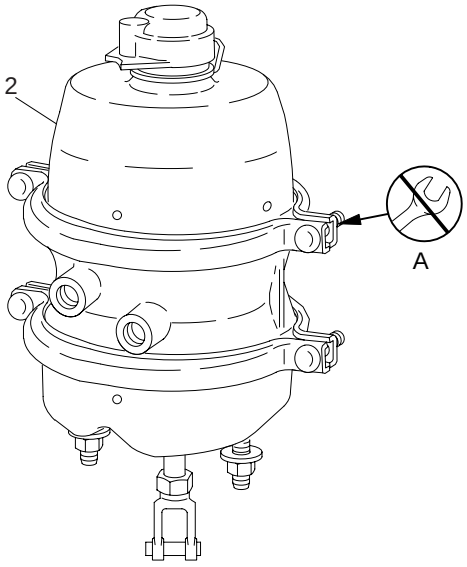
IMPORTANT: At this time, take the opportunity to inspect the parking/emergency brake section, and replace it if it shows signs of damage, corrosion, or rust. Follow the detailed inspection instructions in the vehicle maintenance manual.

1. Inspect all parts in the service (non-pressure) chamber. Replace any damaged or worn parts with genuine MGM-engineered replacement parts.
2. Place the new service brake diaphragm in the bottom recess of the parking brake section (see Fig. 4).
3. Install the (new, if needed) parking/emergency brake section.

   3.1 If installing a new parking brake section, be sure it is the same size and make as the old one.

   3.2 Check that the release bolt is fully extended outward. For instructions, refer to Subject 100.

   3.3 Install the parking brake section on the service chamber so that all mating parts are aligned straight and the air lines are positioned to mate with the vehicle air supply lines.

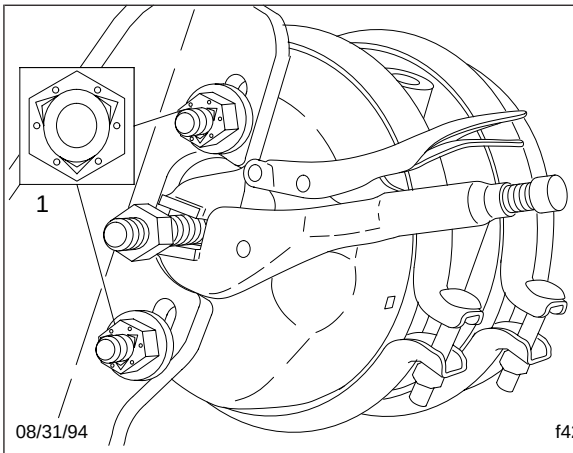


4. Install the service brake clamp ring.

   4.1 With the service brake clamp ring in place, install the clamp bolts and nuts.

   4.2 Using a hand wrench (*don't use an impact wrench*), alternately tighten each clamp nut in increments of 680 to 1360

Service Brake Diaphragm Replacement



08/30/94 f421302

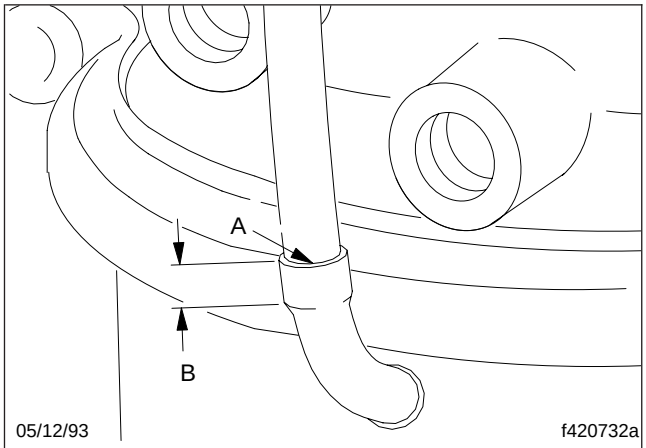
2. Service Brake Diaphragm
3. Service Brake Clamp Ring
4. Service Brake (Non-Pressure) Chamber

Fig. 4

the nuts to a final torque of 34 to 41 N·m (25 to 30 lbf·ft).

5. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 34 N·m (25 lbf·ft).

6. Using the vehicle system air, charge the parking brake with full line pressure—at least 690 kPa (100 psi). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 34 N·m (25 lbf·ft).



7. With the parking brake still charged with full line pressure, apply and hold the foot brake treadle valve down to charge the service brake chamber. Remove the locking-jaw pliers from the service piston rod so that the piston returns to a normal position in the chamber.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

8. Test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, firmly tap the circumference of the clamp ring with a rubber mallet, and retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). MGM recommends 34 to 41 N·m (25 to 30 lbf·ft) torque on the clamp hexnuts.

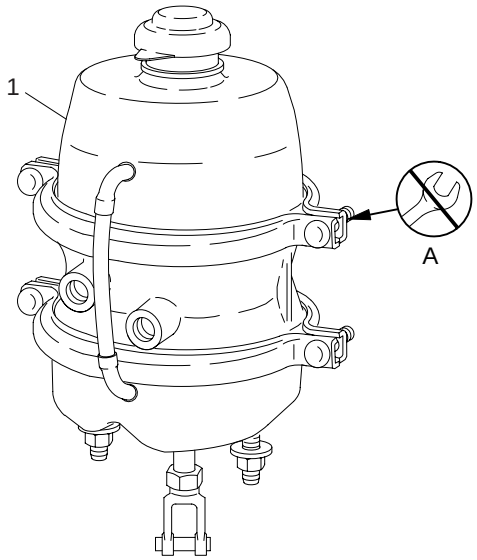
9. On chambers equipped with an external breather tube, make sure that the open end of the tube is free of grease, dirt, and other debris. Then, apply a high-quality rubber cement to the tube and insert it into the elbow at least 13 mm (1/2 inch). See **Fig. 5**. Insert the tube into the service brake chamber.

A. Apply adhesive here.
B. Check for 1/2" (13 mm) minimum engagement.

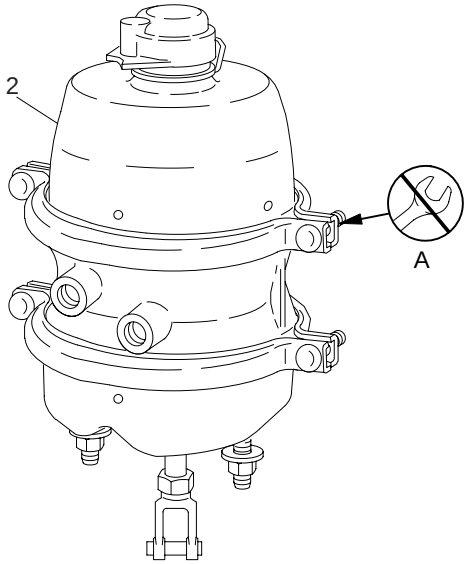
Fig. 5

10. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the end cover cap in place. For instructions, see **Subject 100**.

Service Brake Diaphragm Replacement



11. Snap the end cap into place. On chambers equipped with a breather cap, snap the breather cap into place, taking care to point the drain tab downwards. Replace the breather cap if the foam filter is contaminated with dirt or debris.
12. Adjust the brakes at the slack adjuster.



IMPORTANT: After replacing any brake chamber components, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack adjuster. For instructions, see the applicable slack adjuster section in **Group 42**.

Replacement

DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

08/30/94 f421302

A. Do not remove this clamp ring.
1. Model L-T Brake Chamber
2. Model L Brake Chamber

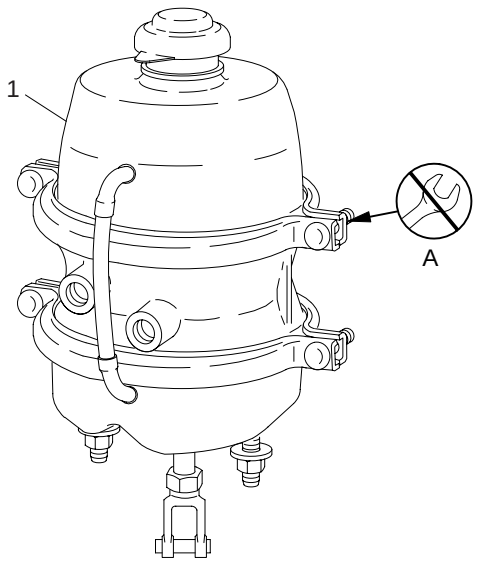


Fig. 1, L Series Brake Chambers

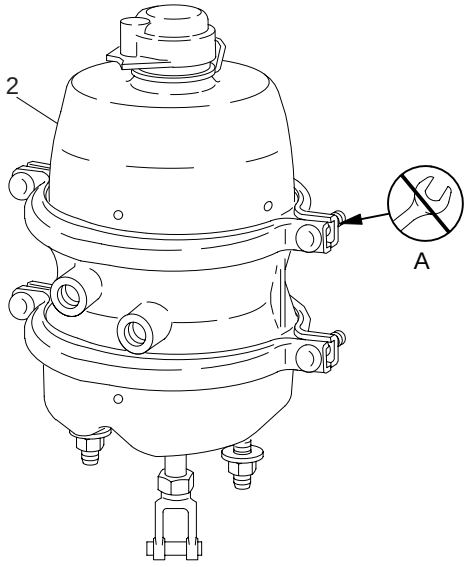


IMPORTANT: The parking/emergency brake section can be replaced as a unit. For instructions, refer to **Subject 110**.

Combination Service and Parking Brake Chamber Removal and Installation

DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

08/30/94 f421302

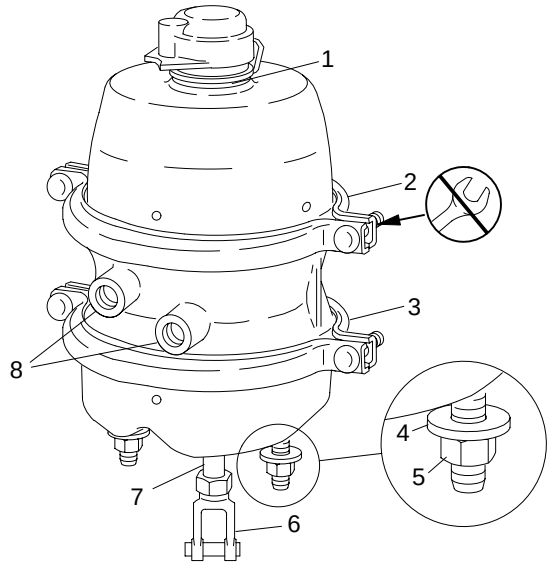
A. Do not remove this clamp ring.
1. Model L-T Brake Chamber
2. Model L Brake Chamber

Fig. 1, L Series Brake Chambers

Removal (See Fig. 2 or Fig. 3)

WARNING

WARNING: Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.



1. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100**.
2. Mark the air lines for later reference. Then carefully disconnect them from the brake chamber.
3. Remove the brake chamber from the vehicle.

   3.1 Remove the cotter pin(s) from the clevis pin(s), then remove the clevis pin(s) from the clevis. Disconnect the clevis from the slack adjuster.

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   3.2 Make sure the parking brake has been released manually (the power spring has been caged). For instructions, refer to **Subject 100**. Also, make sure that the service brake piston is fully retracted (in the brakes "OFF" position). Then, record both of the following dimensions in either mm or inches, measuring outward from

Combination Service and Parking Brake Chamber Removal and Installation

9. External Breather Tube

Fig. 3, Model L-T Brake Chamber

the base of the service brake chamber (**see Fig. 4**):

X dimension: to end of threaded piston rod

Y dimension: to centerline of (large) clevis pin

IMPORTANT: If new chambers are to be attached to manual slack adjusters, the Y dimension is the most critical measurement. When installing the new assembly, cut its service piston rod (**see Fig. 5**) to exactly duplicate this "rod-plus-clevis" length *after* the clevis assembly is installed on the piston rod.

If new chambers are to be attached to automatic slack adjusters, the X dimension is the most critical measurement. When installing the new assembly, cut its service piston rod (**see Fig. 5**) to exactly duplicate the "rod only" length *before* the clevis assembly is installed on the piston rod.

3.3 From each mounting stud, remove any installed nuts and washers. Then, cautiously remove the brake chamber from the mounting bracket.

Installation (See Fig. 2 or Fig. 3)

1. If installing a new brake chamber unit, do the following steps:

   1.1 First, make sure the power spring is caged (release bolt fully extended outward). If not, **go to Subject 100** and do the applicable steps.

   1.2 Make sure that the piston rod is the same length as the rod on the old unit (measure the rods when *both* chambers are caged).

Combination Service and Parking Brake Chamber Removal and Installation

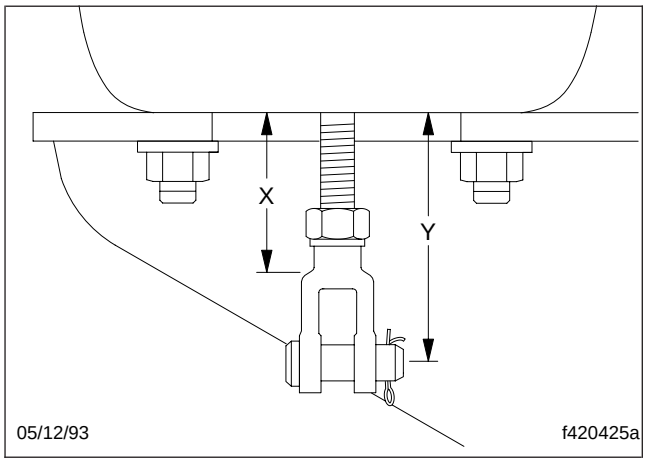

Fig. 4

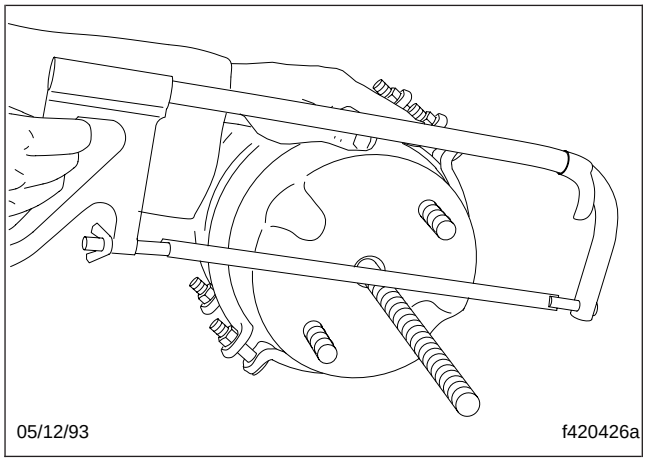

Fig. 5

1.3 Be sure the new chamber is the same size and make as the brake chamber installed on the other side of the axle.

1.4 Remove the prevailing torque locknut and hardened flatwasher from each of the mounting studs on the chamber.

2. Clean the face of the mounting bracket, and position the chamber on the bracket. Pay close attention to positioning the chamber air inlet ports for correct alignment to the vehicle air lines.

⚠ WARNING

WARNING: Tighten the mounting nuts with a hand wrench, not an impact wrench. An impact wrench could damage the mounting fasteners, reducing the force of the brakes. This could result in personal injury or property damage.

3. Install one hardened flatwasher and prevailing torque locknut on each mounting stud. Using a hand wrench (*don't use an impact wrench*), tighten the nuts 136 to 156 N·m (100 to 115 lbf·ft). Make sure that the hardened flatwasher is installed between the locknut and the mounting bracket.

   On chambers equipped with an external breather tube, make sure that the tube is installed in the side of the chamber that faces away from the road surface. An improperly installed breather tube voids the MGM warranty.

4. Check mating and alignment with the vehicle air lines.

⚠ DANGER

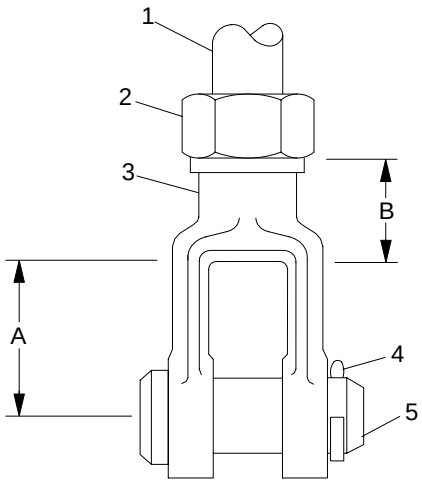
Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4.1 Using a hand wrench (*don't use an impact wrench*), loosen the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

4.2 Reposition the air inlet ports, as needed, to mate with vehicle air supply lines.

Alternately tighten each clamp nut in increments of 680 to 1360 N·cm (60 to 120 lbf·in) while constantly rechecking the alignment of mating parts.

If realignment is needed, loosen the nuts again, and repeat this substep.



4.3 Firmly tap around the circumference of the service clamp ring with a rubber mallet to ensure full seating of the clamp. Tighten the nuts to a final torque of 34 to 41 N·m (25 to 30 lbf·ft).

5. With manual slack adjusters, connect the slack adjuster to the clevis, then install the clevis pin. Insert the cotter pin in the clevis pin, and lock it in place. Check the piston-rod engagement with the clevis. At least seven threads of engagement

Combination Service and Parking Brake Chamber Removal and Installation

are required; there should be 25-mm (1-inch) clearance from the centerline of the clevis pin hole to the end of the piston rod. **See Fig. 6.** Adjust as needed.

With automatic slack adjusters, refer to the applicable slack adjuster section in **Group 42** in this manual for installation instructions.

A. Minimum clearance of 25 mm (1 inch) between centerline of clevis pin hole and piston rod end.
B. Minimum of 7 threads engagement.

1. Piston Rod
2. Piston Rod Nut
3. Clevis
4. Cotter Pin
5. Clevis Pin

Fig. 6, Piston Rod Engagement With the Clevis

6. Inspect the piston rod to be sure it is working free, not binding, and is square with the chamber bottom within ±3° from zero to full stroke. If there is misalignment, make corrections by loosening the locknuts and repositioning the chamber on the mounting bracket, or by shimming the slack adjuster to the right or left on the camshaft.
7. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 34 N·m (25 lbf·ft).
8. Using the vehicle system air, charge the parking brake with full line pressure, at least 690 kPa (100 psi). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 34 N·m (25 lbf·ft).

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

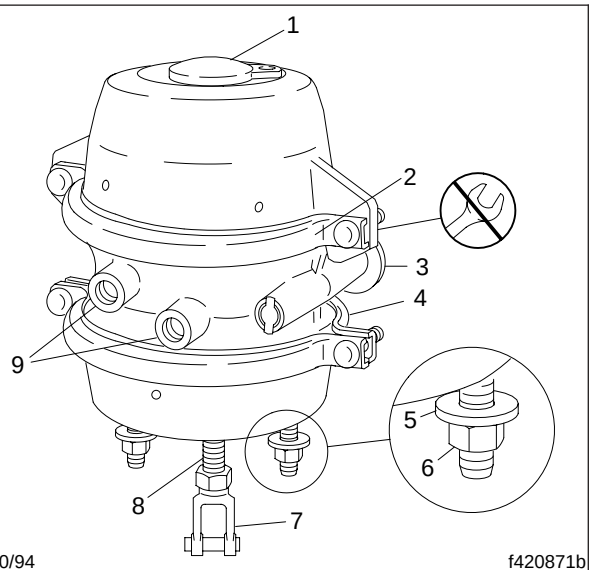
IMPORTANT: If the service brake clamp ring was loosened to reposition the air inlet ports, apply air to the parking brake, and then apply and hold the foot brake treadle valve down to charge the service brake chamber. Now test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, firmly tap the circumference of the clamp ring with a rubber mallet, and retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). MGM recommends 34 to 41 N·m (25 to 30 lbf·ft) torque on the clamp hexnuts.

9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring. For instructions, refer to **Subject 100**.
10. Snap the end cap into place. On chambers equipped with a breather cap, snap the breather cap into place, taking care to point the drain tab downwards. Replace the breather cap if the foam filter is contaminated with dirt or debris.
11. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

IMPORTANT: After replacing any brake chamber, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack

adjuster. For instructions, refer to the applicable slack adjuster section in **Group 42** in this manual.

Specifications



Description	Torque N·m (lbf·ft)
Parking Brake Release Bolt Nut	68 (50)
Service Brake Clamp Ring Nut	34-41 (25-30)
Brake Chamber Mounting Stud Locknut	136-156 (100-115)
Air Hose Fitting-to-Chamber	34 (25)

Table 1, Torque Values

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

NOTE: On some Anchorlok models, the parking/emergency brake section is factory sealed (no clamp ring) and is a *non-serviceable* unit. On other models, the parking/emergency brake section is attached with a clamp ring. *Do not ever perform any service on this clamp ring.*

08/30/94 f420871b

NOTE: On some models, the parking brake clamp ring is permanently sealed.

7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

Fig. 1

General Information

Anchorlok brake chambers consist of a service brake section and a parking/emergency spring brake section. **See Fig. 1**. The service brake section is the smaller section near the clevis assembly.

In the service brake section, the service brake chamber contains a service return spring, piston rod assembly, and service brake diaphragm.

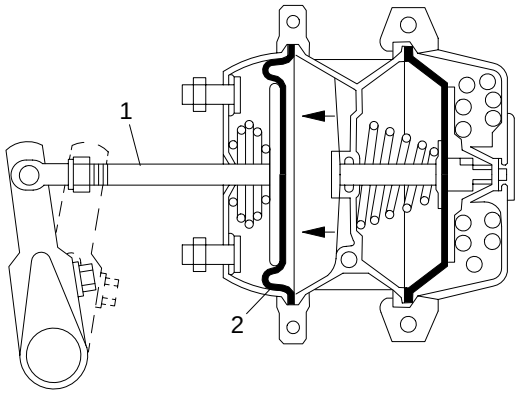
In the parking/emergency brake section, the adaptor and the chamber contain a return spring, a push rod assembly, a parking (spring) brake diaphragm, a pressure plate, a power spring, and a detachable release bolt.

All Anchorlok brake chambers are mounted to the frame using prevailing torque locknuts and hardened flatwashers.

Periodic maintenance of the brake chambers is required. Also, whenever the service brake chamber is disassembled (*do not attempt to disassemble the parking brake chamber*), the parts should be inspected for damage. For maintenance schedules and procedures, and for inspection of brake chamber parts, refer to the vehicle maintenance manual.

Principles of Operation

SERVICE BRAKES



As the brake pedal is depressed, compressed air enters the service brake chamber through a port. Air pressure acts upon a diaphragm, which forces the piston rod toward the non-pressure chamber, applying a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes. **See Fig. 2.**

Then, when the brake pedal is released (**Fig. 3**), air is exhausted from the service brake chamber, and the return spring allows the diaphragm, piston rod assembly, and slack adjuster to return to their normal positions, releasing the brakes.

PARKING/EMERGENCY BRAKES

During parking brake release, compressed air enters the parking/emergency brake chamber below the diaphragm, forcing the diaphragm against the pressure plate to compress the power spring and release the parking/emergency brake. **See Fig. 4**. During parking brake application, a control valve in the cab exhausts air from the parking/emergency brake chamber. This

1. Piston Rod Assembly
2. Service Brake Diaphragm

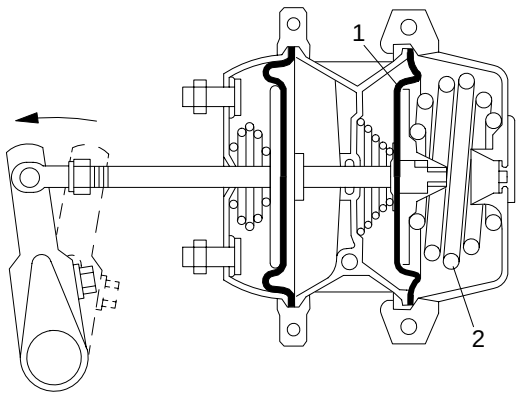
Fig. 3, Service Brakes Applied

allows the power spring to extend and apply the brakes. **See Fig. 5**.



Emergency brake application begins when air pressure in the service brake reservoir drops below about 550 to 585 kPa (80 to 85 psi). Maximum spring brake force is applied when air is entirely exhausted from the parking/emergency brake chamber.

07/02/93 f420888

Fig. 5, Parking/Emergency Brakes Applied

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

NOTE: On some models, the parking brake clamp ring is permanently sealed.

1. Dust Plug
2. Parking Brake Clamp Ring

5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

Fig. 1

Manual Compression (Parking Brake Release)

1. Chock the tires.
2. Remove the dust plug from the center-hole in the head of the chamber. **See Fig. 2.**

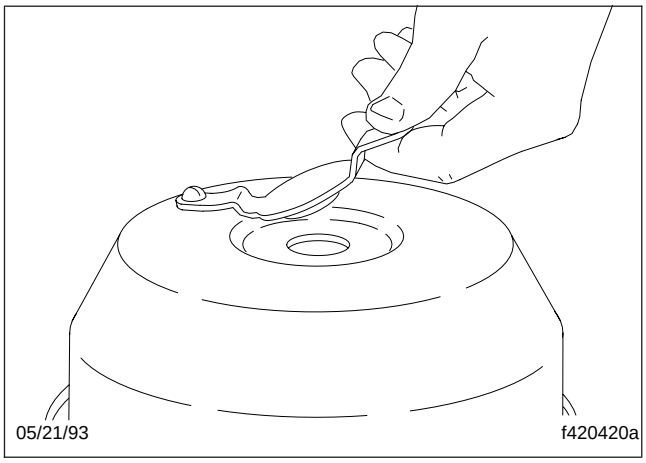

Fig. 2

⚠ DANGER

Do not attempt to cage the power spring if the safety hooks have been removed, or if the parking brake chamber is damaged severely enough to lose its structural integrity. If the power spring were to break loose, it could result in death, severe personal injury, or property damage.

A DAMAGED PARKING BRAKE CHAMBER IS EXTREMELY DANGEROUS! Only qualified service personnel should attempt to remove and disarm a damaged chamber. Using a torch, burn off the piston rod in the space between the clevis and the base of the service chamber.

Remove the chamber carefully from its bracket, and disarm it inside a suitable container. For disarming procedures, consult the Anchorlok installation instructions.

3. Manually release the parking brake (cage the power spring).

⚠ CAUTION

CAUTION: Don't use an impact wrench on this nut. Too much torque could damage the pressure plate and prevent manual release of the parking brake.

3.1 Using a hand wrench, (*don't use an impact wrench*), unscrew the release nut, and remove the nut, flatwasher, and release bolt from the storage pocket on the side of the chamber. **See Fig. 3.**

Power Spring Manual Compression and Reset

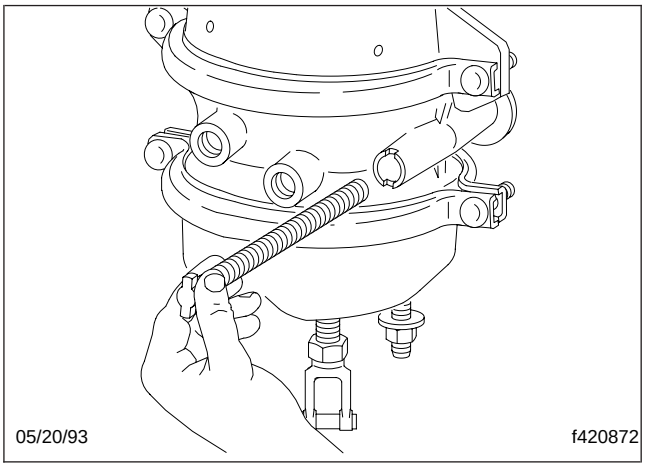

Fig. 3

IMPORTANT: If these parts are not stored on the chamber, they must be otherwise obtained or purchased; the parking brake cannot be manually released without them.

3.2 Insert the release bolt into the center-hole in the chamber head (**see Fig. 4**). Continue to insert the bolt until it bottoms out into the hole in the pressure plate inside the chamber.

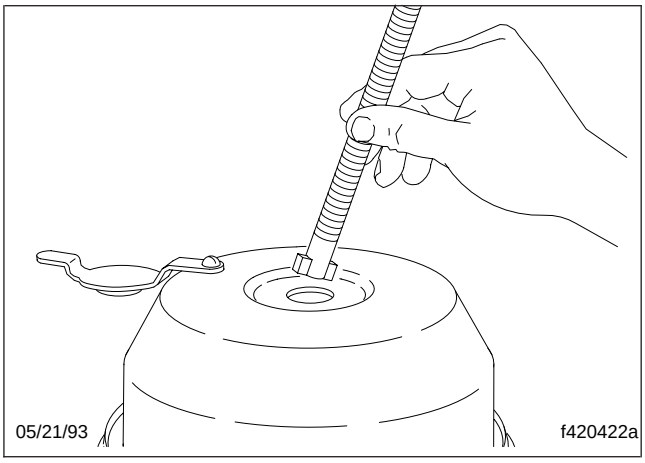

Fig. 4

IMPORTANT: If you are not absolutely sure that the formed end of the bolt has engaged the pressure plate correctly, repeat this step. Repeat it until you are absolutely sure.

3.3 Turn the release bolt one-quarter turn clockwise. Pull to seat the formed end of the release bolt in the recess of the pressure plate.

3.4 Holding the release bolt locked into the pressure plate, install the flatwasher and release nut on the end of the bolt, and turn down the nut against the flatwasher until it is finger-tight. **See Fig. 5**.

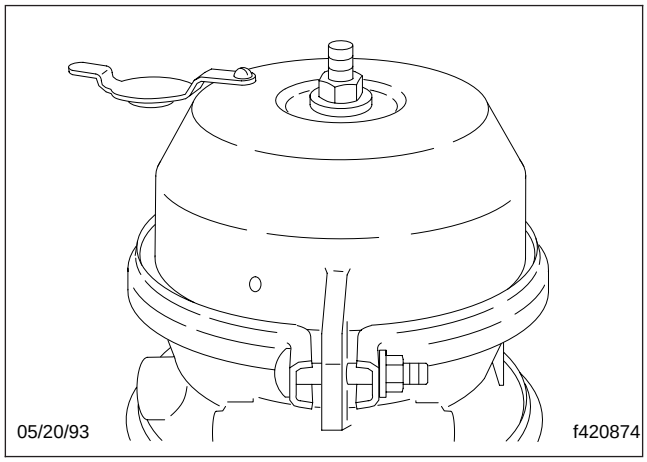

Fig. 5

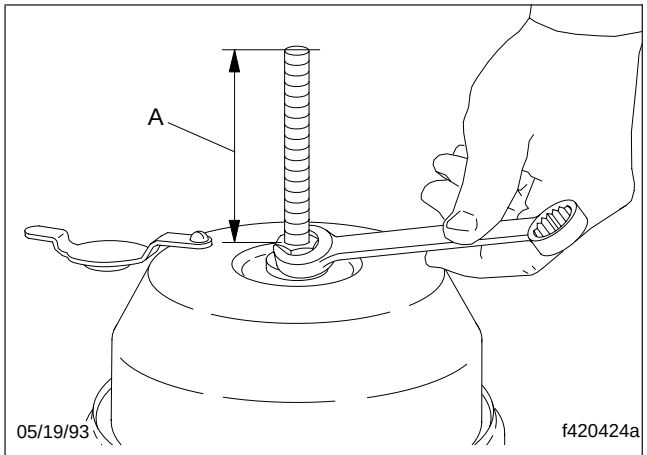
⚠ DANGER

Exhaust all air pressure before tightening the release nut more than finger-tight. Tightening this nut under pressure can damage the pressure plate and result in sudden release of the power spring, causing death or severe personal injury.

⚠ CAUTION



CAUTION: If equipped with S-cam or disc brakes, don't exceed 47 N·m (35 lbf·ft) torque on the release nut; if equipped with wedge brakes, don't exceed 27 N·m (20 lbf·ft) torque on the release nut.

3.5 Using a hand wrench (*don't use an impact wrench*), turn the release nut clockwise until the power spring is caged (**see Fig. 6**):

On parking/emergency brake chambers that are permanently sealed (no clamp ring), the bolt should extend above the nut

at least 74 mm (2.9 inches) on 24-inch chambers, or 73 mm (2.875 inches) on 30-inch chambers.

On parking/emergency brake chambers that are sealed with a clamp ring, the bolt should extend above the nut at least 71 mm (2.8 inches) on 24-inch chambers, or 69 mm (2.7 inches) on 30-inch chambers.

A. Measure this distance.

Fig. 6

IMPORTANT: Don't exceed these bolt lengths. If the bolt lengths can't be obtained without exceeding the recommended maximum torque values, replace the tandem brake chamber.

Manual Reset (Parking Brake Reset)

1. Uncage the power spring.

CAUTION

CAUTION: Don't use an impact wrench on this nut. Too much torque could damage the pressure plate and prevent manual release of the parking brake.

1.1 With air applied to the parking brake section (the parking brake control valve is in the "release" position), use a hand wrench and turn the release nut *counterclockwise* until the power spring extends back into the parking/emergency brake chamber.

NOTE: When the power spring is fully extended, force will no longer be felt on the release nut.

1.2 Remove the nut and flatwasher.

1.3 Turn the release bolt one-quarter turn counterclockwise and unlock the bolt from the receptacle in the pressure plate. Remove the release bolt from the center-hole of the chamber.

2. Install the release bolt, flatwasher, and release nut in the storage pocket. Tighten the nut 680 to 1080 N·cm (60 to 96 lbf·in). **See Fig. 7.**

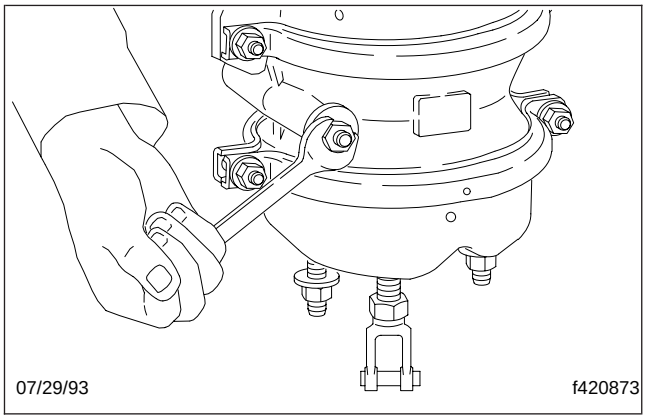


Fig. 7

3. Snap the dust plug in place over the center-hole in the chamber head. **See Fig. 8.**

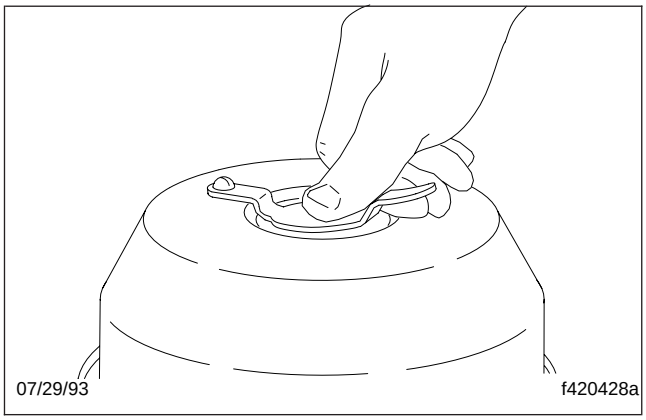

Fig. 8

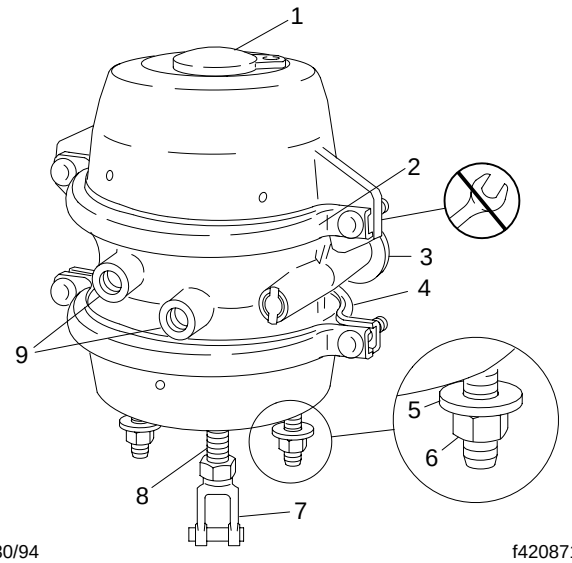
Power Spring Manual Compression and Reset



⚠ CAUTION

CAUTION: If a dust plug is missing or incorrectly installed, road dirt and debris can adversely affect the operation of the brake chambers. Once inside the chambers, dirt and debris cause the internal parts to deteriorate and shorten their lives.

4. Check the plastic dust plug periodically, and replace it with a new one at once if damaged or missing. For intervals, refer to the vehicle maintenance manual.
5. Remove the chocks from the tires.

DANGER

Don't loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

NOTE: On some models, the parking brake clamp ring is permanently sealed.

1. Dust Plug
2. Parking Brake Clamp Ring
3. Release Bolt Storage Pocket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

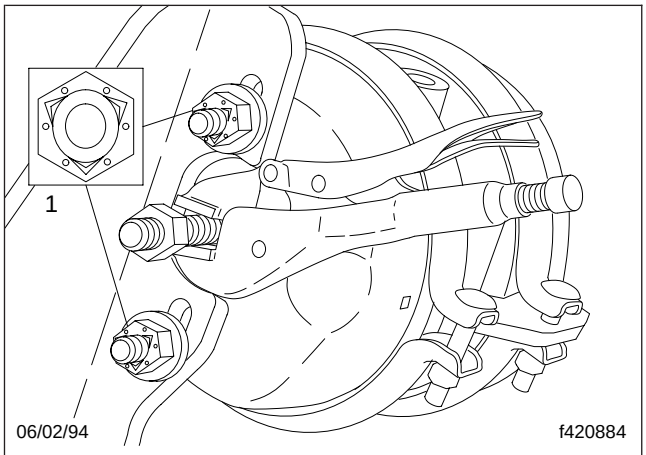


Fig. 1

Removal

1. To make removal and installation of the parking brake section easier (without removing the service brake chamber), lock off the service chamber piston rod.

   1.1 Apply the service brakes by actuating the driver's foot brake treadle valve.

   1.2 With the brakes applied, clamp a pair of locking-jaw pliers on the piston rod to lock the rod in place when the air pressure is released (see Fig. 2).

1. Prevailing Torque Locknut

Fig. 2

WARNING

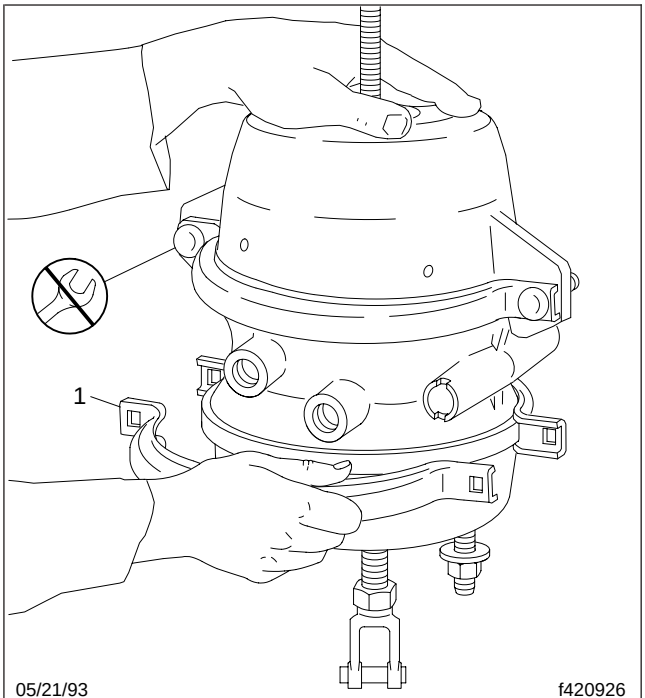
WARNING: Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

2. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100**.

3. Mark the air lines for later reference. Then carefully disconnect them from the brake chamber.

DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.



4. Remove the parking brake and adaptor from the service brake section.

   4.1 Using a hand wrench (*don't use an impact wrench*), remove the clamp nuts on

Service Brake Diaphragm Replacement

the *service* brake clamp ring (*do not disassemble the parking brake section*).

4.2 While holding the parking brake section securely in place, remove the service clamp ring. Then remove the parking brake section from the service brake non-pressure chamber (**see Fig. 3**).

1. Service Brake Clamp Ring

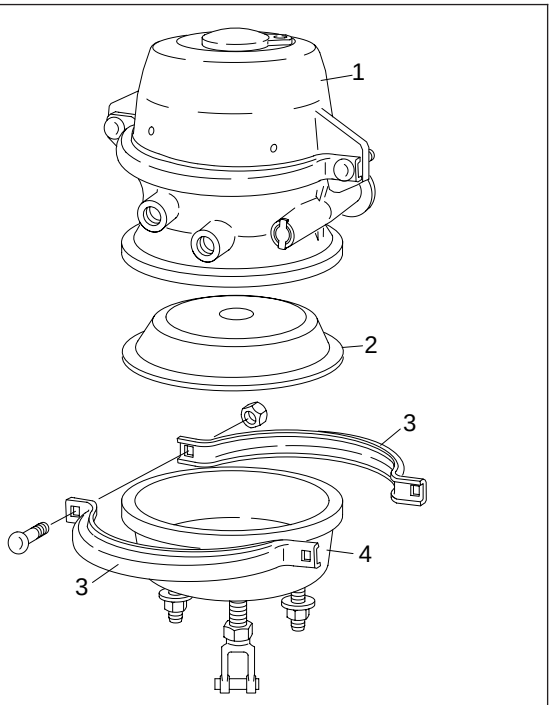


Fig. 3

5. Remove the service brake diaphragm from the bottom of the parking brake section.

Installation

IMPORTANT: At this time, take the opportunity to inspect the parking/emergency brake section, and replace it if it shows signs of damage, corrosion, or rust. Follow the detailed inspection instructions in the vehicle maintenance manual.

1. Inspect all parts in the service (non-pressure) chamber. Replace any damaged or worn parts.
2. Place the new service brake diaphragm in the bottom recess of the adaptor (**see Fig. 4**).

1. Parking/Emergency Brake and Adaptor
2. Service Brake Diaphragm
3. Service Brake Clamp Ring
4. Service Brake (Non-Pressure) Chamber

Fig. 4

3. Install the (new, if needed) parking/emergency brake section.

   3.1 If installing a new parking brake section, be sure it is the same size and make as the old one.

   3.2 Check that the release bolt is fully extended outward. For instructions, refer to **Subject 100**.

   3.3 Install the parking brake section on the service chamber so that all mating parts are aligned straight and the air lines are positioned to mate with the vehicle air supply lines.

4. Install the service brake clamp ring.

   4.1 With the service brake clamp ring in place, install the clamp bolts and nuts.

   4.2 Using a hand wrench (*don't use an impact wrench*), alternately tighten each

clamp nut in increments of 680 to 1360 N·cm (60 to 120 lbf·in) while constantly rechecking the alignment of mating parts.

If realignment is needed, loosen the nuts again, and repeat this substep.

4.3 Lightly tap around the circumference of the service clamp ring with a rubber mallet to ensure full seating of the clamp. Tighten the nuts to a final torque of 24 to 34 N·m (18 to 25 lbf·ft).

5. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 34 N·m (25 lbf·ft).

6. Using the vehicle system air, charge the parking brake with full line pressure—at least 690 kPa (100 psi). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If bubbles or leaks appear, tighten the fittings slightly, but not over 34 N·m (25 lbf·ft).

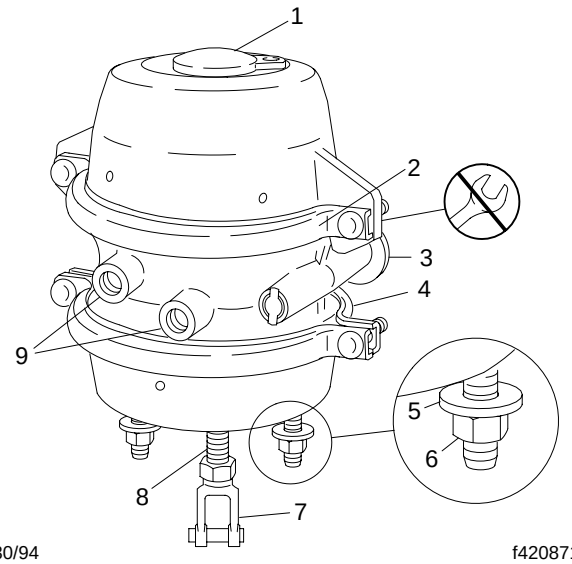
7. With the parking brake still charged with full line pressure, apply and hold the foot brake treadle valve down to charge the service brake chamber. Remove the locking-jaw pliers from the service piston rod so that the piston returns to a normal position in the chamber.

⚠ DANGER

Don't loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

8. Test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, release all air pressure from the chamber, then retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). Anchorlok recommends 24 to 34 N·m (18 to 25 lbf·ft) torque on the clamp hexnuts.

9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the dust plug in place. For instructions, refer to **Subject 100**.



10. Adjust the brakes at the slack adjuster.

IMPORTANT: After replacing any brake chamber components, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack adjuster. For instructions, refer to the applicable slack adjuster section in **Group 42** in this manual.

Replacement

DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the compression spring.

NOTE: On some models, the parking brake clamp ring is permanently sealed.

1. Dust Plug
2. Parking Brake Clamp Ring
3. Release Bolt Storage Pocket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

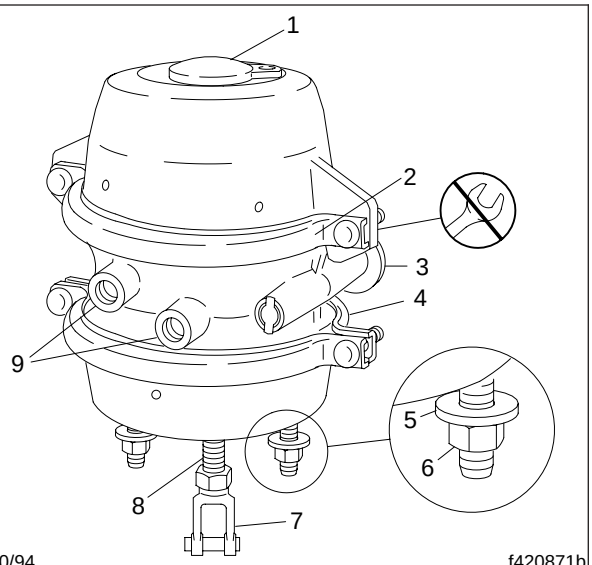


Fig. 1

IMPORTANT: The parking/emergency brake section can be replaced as a unit. For instructions, refer to **Subject 110**.

Combination Service and Parking Brake Chamber Removal and Installation

DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

NOTE: On some models, the parking brake clamp ring is permanently sealed.

1. Dust Plug
2. Parking Brake Clamp Ring
3. Release Bolt Storage Pocket
4. Service Brake Clamp Ring
5. Hardened Flatwasher
6. Prevailing Torque Locknut
7. Clevis Assembly
8. Piston Rod
9. Air Inlet Ports

Fig. 1

Removal

WARNING

WARNING: Before caging (compressing) the power spring, chock the vehicle tires and read the warnings and instructions in this section (see Subject 100). When the power spring is caged, the vehicle may be without brakes, allowing it to roll out of control, possibly resulting in personal injury or property damage.

1. Manually release the parking brake (cage the power spring). For instructions, refer to **Subject 100**.
2. Mark the air lines for later reference. Then carefully disconnect them from the brake chambers.
3. Remove the brake chamber from the vehicle.

   3.1 Remove the cotter pin(s) from the clevis pin(s), then remove the clevis pin(s) from the clevis. Disconnect the clevis from the slack adjuster.

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   3.2 From each mounting stud, remove any installed nuts and washers. Then, cautiously remove the brake chamber from the mounting bracket.

Installation

1. If installing a new brake chamber unit, do the following steps:

   1.1 First, make sure the power spring is caged (release bolt fully extended outward). If not, **go to Subject 100** and do the applicable steps.

   1.2 Make sure that the piston rod is the same length as the rod on the old unit (measure the rods when *both* chambers are caged).

   1.3 Be sure the new chamber is the same size and make as the brake chamber installed on the other side of the axle.

   1.4 Remove the prevailing torque locknut and hardened flatwasher from each of the mounting studs on the chamber.

2. Clean the face of the mounting bracket, and position the chamber on the bracket. Pay close attention to positioning the chamber air inlet ports for correct alignment to the vehicle air lines.

WARNING

WARNING: Tighten the mounting nuts with a hand wrench, not an impact wrench. An impact wrench could damage the mounting fasteners,

Combination Service and Parking Brake Chamber Removal and Installation

reducing the force of the brakes. This could result in personal injury or property damage.

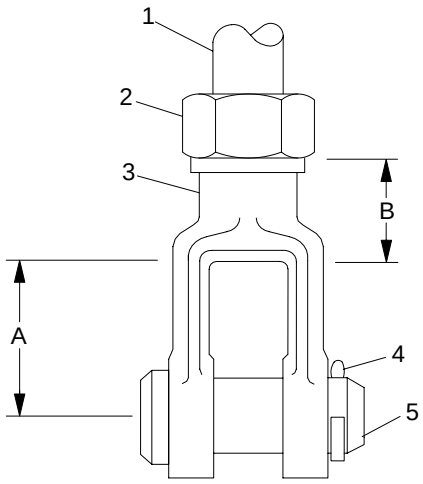
3. Install one hardened flatwasher and prevailing torque locknut on each mounting stud. Using a hand wrench (*don't use an impact wrench*), tighten the nuts 149 to 203 N·m (110 to 150 lbf·ft). Make sure that the hardened flatwasher is installed between the locknut and the mounting bracket.
4. Check proper mating and alignment with the vehicle air lines.

⚠ DANGER

Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

4.1 Using a hand wrench (*don't use an impact wrench*), loosen the clamp nuts on the *service* clamp ring (*do not disassemble the parking brake section*).

4.2 Reposition the air inlet ports, as needed, to mate with vehicle air supply lines.



Alternately tighten each clamp nut in increments of 680 to 1360 N·cm (60 to 120 lbf·in) while constantly rechecking the alignment of mating parts.

If realignment is needed, loosen the nuts again, and repeat this substep.

4.3 Lightly tap around the circumference of the service clamp ring to ensure full seating of the clamp. Tighten the nuts to a final torque of 24 to 34 N·m (18 to 25 lbf·ft).

5. With manual slack adjusters, connect the slack adjuster to the clevis, then install the clevis pin. Insert the cotter pin in the clevis pin, and lock it in place. Check the piston-rod engagement with the clevis. At least seven threads of engagement are required; there should be 25-mm (1-inch) clearance from the centerline of the clevis pin hole to the end of the piston rod. **See Fig. 2.** Adjust as needed.

With automatic slack adjusters, refer to the applicable slack adjuster section in **Group 42** for installation instructions.

08/20/93 f420225a

A. Minimum clearance of 25 mm (1 inch) between centerline of clevis pin hole and piston rod end.
B. Minimum of 7 threads engagement.

1. Piston Rod
2. Piston Rod Nut
3. Clevis
4. Cotter Pin
5. Clevis Pin

Fig. 2, Piston Rod Engagement With the Clevis

6. Inspect the piston rod to be sure it is working free, not binding, and is square with the chamber bottom from zero to full stroke. If there is misalignment, make corrections by loosening the locknuts and repositioning the chamber on the mounting bracket, or by shimming the slack adjuster to the right or left on the camshaft. If loosened, tighten the clamp nuts 24 to 34 N·m (18 to 25 lbf·ft).
7. Make sure the air hose fittings are free of grease, dirt, and other debris. Then, apply Loctite® 242 sealant, or an equivalent, to the fittings, and install, as referenced earlier. Using a hand wrench (*don't use an impact wrench*), tighten the fittings 34 N·m (25 lbf·ft).
8. Using the vehicle system air, charge the parking brake with full line pressure, at least 690 kPa (100 psi). Using only soapy water (*never any type of oil,* which could deteriorate rubber parts), check for air leaks at the air lines and fittings. If

bubbles or leaks appear, tighten the fittings slightly, but not over 34 N·m (25 lbf·ft).

⚠ DANGER

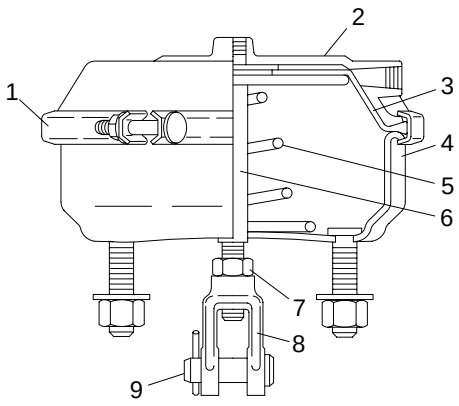
Do not loosen or remove the parking brake clamp ring (see Fig. 1) for any purpose, at any time. The parking/emergency brake section is not intended to be serviced. Serious injury or death may result from the sudden release of the power spring.

IMPORTANT: If the service brake clamp ring was loosened to reposition the air inlet ports, apply air to the parking brake, and then apply and hold the foot brake treadle valve down to charge the service brake chamber. Now test for air leaks around the circumference of the *service* brake clamp ring. If bubbles or leaks appear, release all air pressure from the chamber, then retighten the clamp nuts until leaks cease (*do not touch the parking brake section*). Anchorlok recommends 24 to 34 N·m (18 to 25 lbf·ft) torque on the clamp hexnuts.

9. With air pressure now exhausted from the service brake chamber, but held on the parking brake, reset the parking brakes by uncaging the power spring, and snap the dust plug in place. For instructions, refer to **Subject 100**.
10. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

IMPORTANT: After replacing any brake chamber, check the piston rod stroke and actuating alignment to ensure correct installation and foundation brake adjustment. No foundation brake adjustments, parking brake or service brake, can be made at the chamber and all "stroke" adjustments must be made at the slack adjuster. For instructions, refer to the applicable slack adjuster section in **Group 42** in this manual.

Specifications



Description	Torque

Table 1, Torque Values

General Description

Brake chambers convert the energy of compressed air into the mechanical force and motion needed to apply the brakes. Two chambers operate the brakes, one on each side of the axle.

Each brake chamber consists of two dished metal sections: the pressure cap and the chamber, which are separated by a nylon-reinforced diaphragm. A metal two-segment clamp ring holds the assemblies together. **See Fig. 1.**

02/28/95 f421326

2. Pressure Cap
3. Diaphragm
4. Chamber Assembly
5. Piston Rod Spring
6. Piston Rod Assembly
7. Clevis Jam Nut
8. Clevis
9. Clevis Pin

Fig. 1, Sectional View

In front of the diaphragm are the piston rod assembly, and a piston rod spring. The threaded piston rod assembly extends through the bottom of the chamber and connects to the clevis. **See Fig. 1.**

Different sized brake chambers are identified by numbers, which specify the effective area of the diaphragm. For example, a type 16 brake chamber has 16 square inches of effective area.

Principles of Operation

The greater the air pressure admitted to the brake chamber, the greater the force applied by the piston rod. Piston rod force is determined by multiplying the delivered air pressure by the effective diaphragm area. For example, if 415 kPa (60 psi) is admitted to a type 16 brake chamber, the force on the end of the piston rod is about 4270 N (960 lb).

When the brake pedal is depressed, air pressure from the brake valve passes through the port in the brake chamber pressure cap to move the diaphragm and piston rod assembly forward. This compresses the spring, and applies a straight-line force to the slack adjuster, which converts it to a rotational force. This in turn rotates the camshaft and applies the brakes.

When the brake pedal is released, compressed air behind the diaphragm exhausts through the quick release valve. The spring then allows the piston rod assembly and diaphragm to return to their previous positions.

NOTE: For both of these tests, the air system must be pressurized to at least 550 kPa (80 psi).

Operating Test

1. Chock the tires.
2. Apply the brakes. Check that each piston rod moves out promptly, without binding.
3. Release the brakes. Check that each piston rod returns to the released position promptly, without binding.
4. Check the brake chamber stroke. It should be as short as possible without causing the brakes to drag. If needed, adjust the travel of the piston rod at the slack adjuster. For instructions, refer to the applicable slack adjuster section in this group.

Leakage Test

1. Apply the brakes and hold them on full line pressure of at least 550 kPa (80 psi).
2. Using a soap solution, coat the clamp ring. Leakage is excessive if it produces a 25-mm (1-inch) bubble within five seconds.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

3. If the leakage is excessive, tighten the clamp ring flange nuts evenly until the leakage is reduced. Do not tighten more than 34 to 41 N·m (25 to 30 lbf·ft).
4. Using a soap solution, coat the area around the piston-rod hole. No leakage is permitted. If there is leakage, replace the diaphragm. For instructions, refer to **Subject 110.**

Service Brake Chamber Diaphragm Replacement

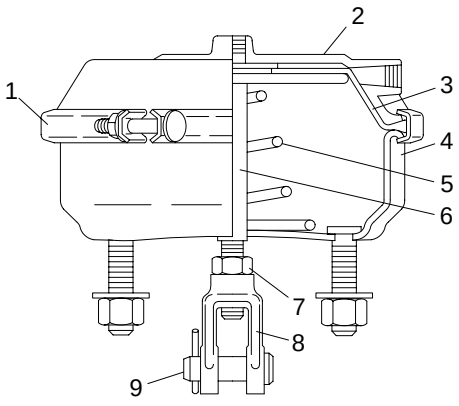
NOTE: This procedure is for service of a leaking brake chamber *diaphragm only*. If there are any other problems, refer to the applicable subjects elsewhere in this section.

Replacement

1. Chock the tires.

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.



Follow the manufacturer's recommendations when working on any air device so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or compressed-air propulsion.

2. Drain the air reservoirs and lines.
3. Back off the slack adjuster; for instructions, refer to the applicable slack adjuster section in this group. Pull out the piston rod. **See Fig. 1.** Clamp the rod at the chamber body to protect it from damage.
4. Before disassembly, mark a reference line along the chamber to allow the parts to be reassembled later in their old positions. **See Fig. 2.**
5. Replace the diaphragm.
   - 5.1 Remove one clamp ring bolt and flange nut completely and loosen the other bolt and flange nut enough to remove the clamp ring.
   - 5.2 Remove the pressure cap, and replace the diaphragm.

⚠ CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

   - 5.3 Position the pressure cap and clamp ring (aligning the reference marks), and install the clamp ring bolt and flange nut. Tighten the flange nuts evenly 34 to 41 N·m (25 to 30 lbf·ft) to eliminate leakage.
6. Release the clamp on the piston rod.
7. Do both of the tests **in Subject 100.**
8. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable brake section in this group.
9. Remove the chocks from the tires.

⚠ WARNING

WARNING: Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at other people. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in severe personal injury.

Follow the manufacturer's recommendations when working on any air device so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or compressed-air propulsion.

2. Drain the air reservoirs and lines.
3. Carefully disconnect the air line from the brake chamber.
4. Remove the brake chamber.

   4.1 Remove the cotter pin(s) from the clevis pin(s).

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

   4.2 Remove the clevis pin(s) from the slack adjuster.

   4.3 From each mounting stud, remove any installed nuts and washers. Remove the brake chamber from the vehicle.

Installation (See Fig. 1)

1. Before installing a new chamber, be sure the new chamber is the same size and make as the brake chamber on the other side of the axle.
2. Install the brake chamber.

   2.1 Attach the brake chamber to the mounting bracket using a hardened flatwasher and prevailing torque locknut. Install the flatwasher between the locknut and the mounting bracket.

   2.2 Tighten the locknuts. **See Table 1** for the correct torque value.

Description	Chamber Size (in ²)	Torque N·m (lbf·ft)
Brake Chamber Mounting-Stud Locknuts	16	47–54 (35–40)
	20	136–156 (100–115)
	24	136–156 (100–115)

Table 1, Mounting Stud Locknut Torque Values

   2.3 Connect the clevis pins to the slack adjuster.

   2.4 Install and lock the cotter pin(s) to secure the clevis pin(s).

   NOTE: Gunite and Rockwell automatic slack adjusters have two clevis pins, one large and one small, each locked by a cotter pin.

Service Brake Chamber Removal and Installation

3. Adjust the brakes at the slack adjuster. For instructions, refer to the applicable brake section in this group.
4. Connect the air line to the brake chamber.
   - 4.1 Check that the hoses are properly supported and, if needed, clamped to provide good clearance.
   - 4.2 Before connecting the air line, make sure the fittings are clean and free of debris.
   - 4.3 Connect the air line as follows: tighten the nut finger-tight. Using a wrench, further tighten the nut until there is resistance, then tighten one-sixth turn more.
5. Do both of the tests **in Subject 100.**
6. Remove the chocks from the tires.

Service Brake Chamber Disassembly, Inspection and Cleaning, and Assembly

Disassembly (See Fig. 1)

Fig. 1, Sectional View

NOTE: If the brake chamber is to be disassembled without removing the body assembly from the vehicle, first back off the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.

1. Before disassembly, mark a reference line along the chamber to allow the parts to be reassembled later in their old positions. **See Fig. 2.**

02/28/95 f421327

A. Reference Line

Fig. 2

2. Pull out the piston rod. Clamp the rod at the chamber body to protect it from damage.
3. Disassemble the brake chamber.
   - 3.1 Remove one clamp ring bolt and flange nut completely and loosen the other bolt and flange nut enough to remove the clamp ring.
   - 3.2 Remove the pressure cap and the diaphragm.
   - 3.3 Remove the clevis locknut and clevis from the piston rod, and release the clamp on the piston rod, being careful to contain the piston rod assembly and body until the return spring is relaxed.
   - 3.4 Remove the piston rod assembly and spring.

Inspection and Cleaning

1. Clean all metal parts with cleaning solvent.
2. Inspect all parts for wear or damage; replace as needed.
   - 2.1 Check the pressure cap and the chamber for dents. If any are too deep to be pounded out, replace as needed.
   - 2.2 Check the diaphragm for wear or deterioration and replace it if needed.
   - 2.3 Inspect all other parts not considered serviceable. Replace if needed.

Assembly (See Fig. 1)

1. Stand the piston rod assembly upright on a flat surface (if the chamber was removed from the vehicle).
2. Assemble the brake chamber.
   - 2.1 Place the return spring on the piston rod.
   - 2.2 Place the chamber on the piston rod assembly, and press the chamber down, working against the tension of the spring, until the chamber bottoms out on the flat surface. Clamp the rod at the chamber, making sure to protect the rod from damage. Insert the piston rod assembly

Service Brake Chamber Disassembly, Inspection and Cleaning, and Assembly

through the chamber and clamp the rod (if the chamber wasn't removed from the vehicle).

2.3 Place the diaphragm in the chamber.

CAUTION

CAUTION: Don't overtighten the clamp ring. This can distort the flange sealing surface, or the clamp ring itself.

2.4 Position the pressure cap and clamp ring (aligning the reference marks), and install the clamp ring bolt and flange nut. Tighten the flange nuts evenly 34 to 41 N·m (25 to 30 lbf·ft) to eliminate leakage.

3. Install the clevis locknut and clevis, and release the clamp on the piston rod.
4. If the brake chamber was removed from the vehicle, install it. For instructions, refer to **Subject 120.**
5. Do both of the tests found **in Subject 100.**

Specifications

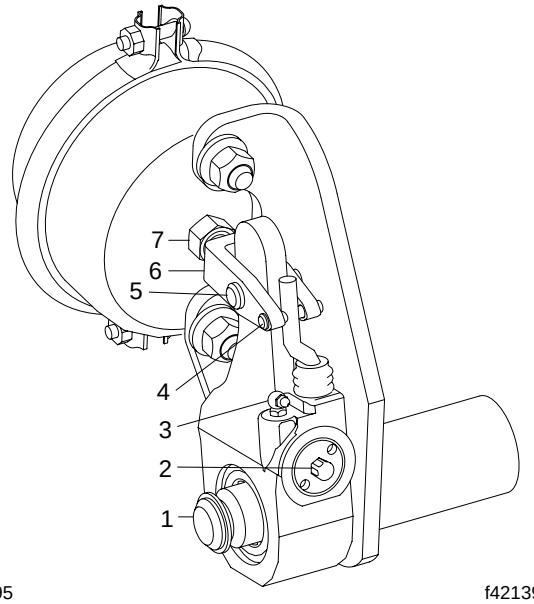
Mounting-Stud Locknut Torque Values		
Description	**Chamber Size (in ^{2})**	**Torque lbf·ft (N·m)**
Brake Chamber Mounting-Stud Locknuts	16	35 to 40 (47 to 54)
	20	100 to 115 (136 to 156)
	24	100 to 115 (136 to 156)

Table 1, Mounting-Stud Locknut Torque Values

General Information

The automatic slack adjuster has two main functions:

- As a lever it converts the straight-line force of the brake chamber push rod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the drum.
- As an automatic slack adjuster, it maintains the lining-to-drum clearance needed for proper brake chamber push rod stroke.



The slack adjuster is installed between the brake chamber push rod and the brake camshaft. A clevis connects the brake chamber push rod to the top of the slack adjuster. The bottom of the slack adjuster is splined to the brake camshaft. The splines hold the slack adjuster internal gear to the camshaft, so the camshaft turns when the slack adjuster moves.

When the brakes are applied, the brake chamber push rod moves outward forcing the slack adjuster and camshaft to rotate. This movement forces the brake shoes against the drum.

Whenever the brakes are released, the slack adjuster detects any increase in the lining-to-drum clearance. Excessive brake clearance is eliminated internally by the adjuster's one-way clutch and worm shaft, thus ensuring optimum leverage for the brake chamber push rod.

IMPORTANT: This automatic slack adjuster cannot be rebuilt. If it is damaged or inoperative, replace the unit. Also, when installing or replacing the automatic slack adjuster, a new clevis must be installed.

7. Clevis Jam Nut

Fig. 1, Slack Adjuster Mounting

1. Park the vehicle on a level surface, and chock the tires. If you are removing a rear slack adjuster, release the parking brake, then cage the parking brake power spring. For instructions, see the applicable brake chamber section in this group.
2. Back off the clevis jam nut.
3. Remove the cotter pins and clevis pins.
4. Rotate the manual adjuster shaft counterclockwise until the slack adjuster clears the clevis.
5. Remove the snap ring from the brake camshaft, then slide the slack adjuster off the camshaft.
6. Remove the clevis from the brake chamber push rod.

Installation (See Fig. 2)

A. Clevis shown cut away for clarity.

1. Camshaft
2. Installation Guide
3. 1/4" (6.4 mm) Holes
4. 1/2" (13 mm) Clevis Pin
5. Clevis
6. Clevis Jam Nut

Fig. 2, Slack Adjuster Installation Guide Use

1. Coat the end of the brake chamber push rod, the camshaft splines, and the splines of the slack adjuster gear with an anticorrosive grease.
2. Install the new clevis (with the 1/2-inch [13-mm] clevis pin) on the brake chamber push rod. Thread the clevis up to the jam nut. Do not tighten the jam nut.
3. Fit the installation guide over the camshaft splines so the 1/2-inch (13-mm) clevis-pin slot on the guide faces the brake chamber.
4. Swing the installation guide into the clevis until the slot (top or bottom) engages the 1/2-inch (13-mm) pin.
5. Check the alignment of the 1/4-inch (6.4-mm) holes in the guide and the clevis. Screw the cle-

Slack Adjuster Removal and Installation

vis on or off the push rod until the 1/4-inch (6.4-mm) clevis pin can be inserted through the clevis and the guide. Tighten the jam nut against the clevis 50 lbf·ft (68 N·m).

Remove the installation guide from the camshaft.

IMPORTANT: If the push rod extends through the clevis more than 1/16 inch (1.6 mm), remove the clevis and cut the rod to length. If the push rod does not engage a minimum 1/2 inch (13 mm) in the clevis body, cut a new push rod to length and install it. For instructions, see the applicable brake chamber section in this group.

6. Using the original snap ring, install the automatic slack adjuster on the brake camshaft.
7. Turn the manual adjuster shaft clockwise until the clevis pin holes align with the clevis. Install the 1/2-inch (13-mm) and 1/4-inch (6.4-mm) clevis pins and secure with new cotter pins.

NOTE: Make sure there is clearance between the slack adjuster and other vehicle components when the brakes are applied and the push rod travels its maximum stroke.

8. Set the initial free-stroke.
   - 8.1 Turn the adjusting hexnut clockwise until the brake linings contact the drum.
   - 8.2 Turn the adjusting hexnut counterclockwise one-half turn.
9. If a rear axle slack adjuster was installed, manually uncage the parking brake. For instructions, see the applicable brake chamber section in this group.
10. Measure the brake chamber stroke.
    - 10.1 With the brakes fully released, use a ruler to measure the distance from the bottom of the brake chamber to the centerline of the 1/2-inch (13-mm) clevis pin. See **Fig. 3**, Ref. A.
    - 10.2 Build air pressure to at least 85 psi (586 kPa). Apply the brakes, then measure the distance from the bottom of the brake chamber to the centerline of the 1/2-inch (13-mm) clevis pin. See **Fig. 3**, Ref. B. The difference between the measurements is the brake chamber stroke.

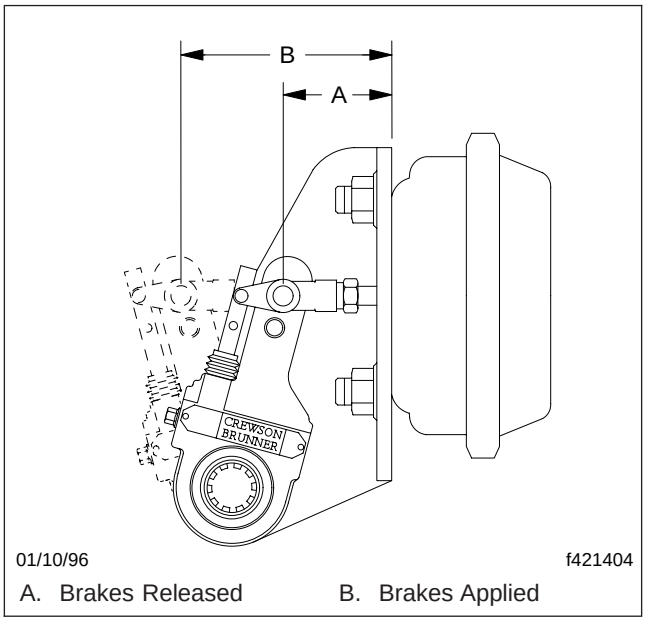

Fig. 3, Brake Stroke Check

- 10.3 The brake chamber stroke must be less than the measurements shown in **Table 1**. If it isn't, check the foundation brakes for problems such as worn cams, bushings, pins and rollers, or broken springs. Repair or replace as needed. For instructions, see the applicable brake section in this group. Then, repeat the previous steps as needed.

Chamber Size	Maximum Chamber Stroke
16	Less than 1-1/2 inches (38 mm)
20 24	Less than 1-3/4 inches (44 mm)
30	Less than 2 inches (51 mm)
36	Less than 2-1/2 inches (64 mm)

Table 1, Maximum Adjusted Brake Chamber Strokes

11. Apply the parking brakes. Remove the chocks from the tires.

General Description

The Bendix PP–DC parking brake air valve is installed on trucks with air brakes, and is used to control the rear axle parking brakes. It is a push-pull type of valve, and is mounted on the right side of the dash.

Principles of Operation

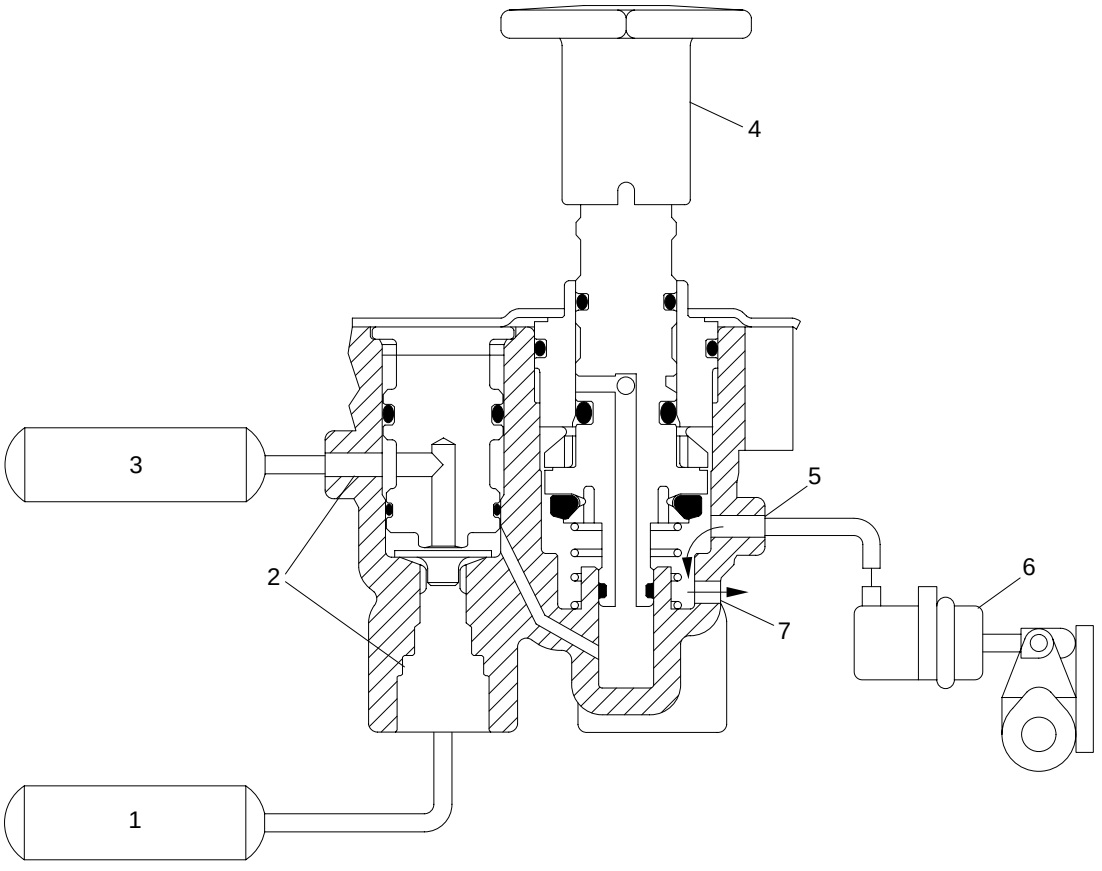
When the valve knob is pulled out, air is exhausted from the parking brake chambers, releasing the springs, and applying the parking brakes. When the knob is pushed in, air flows into the parking brake chambers from one of the reservoirs, and compresses the springs, releasing the parking brakes.

The PP–DC has a double check valve feature. The valve uses air pressure from the air system (primary or secondary) with the higher pressure for the parking brakes. If the pressure drops below 20 to 30 psi (138 to 207 kPa) in both air systems, the brakes will automatically apply. The parking brakes will not apply automatically unless pressure is lost from both systems.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

- Chock the tires and stop the engine before working under a vehicle. Keep hands away from brake chamber push rods and slack adjusters; the brakes may apply as air system pressure drops.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.



Parking Brake Hand Valve Tests

IMPORTANT: To do the following tests, connect two separate 120 psi (827 kPa) air sources to the PP–DC supply ports. See **Fig. 1.** Tee an accurate test gauge into the supply lines, and provide for a means to control supply line pressure. Connect a small volume air source with a gauge to the delivery port.

Operating Test

1. Chock the tires.
2. Start the engine and build up the air pressure to the normal operating level.
3. With the valve knob pulled out, supply either supply port with 120 psi (827 kPa) of pressure. Push the valve knob in. Air pressure should rise in the delivery line and equal supply line pressure.

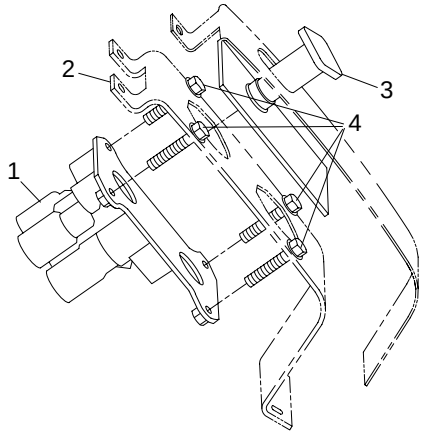
   Pull the valve knob out. Delivery pressure should exhaust to zero.
4. Build air pressure to each supply source to 120 psi (827 kPa). Decrease supply pressure at the secondary service reservoir supply port at a rate of 10 psi (69 kPa) per second.

1. Primary Service Reservoir
2. Supply Port
3. Secondary Service Reservoir
4. Valve Knob
5. Delivery Port
6. Brake Chamber
7. Exhaust Port

Fig. 1, Parking Brake Hand Valve (sectional view)

Parking Brake Hand Valve Tests

Primary supply pressure and delivery pressure should not drop below 100 psi (689 kPa). Repeat this step for decreasing primary service reservoir pressure.



5. Build air pressure to each supply source to 120 psi (827 kPa). Then, decrease both supply pressures to below 20 to 30 psi (138 to 207 kPa). The valve knob should automatically pop out when the pressure is within that range.
6. If the valve does not work as described, repair the valve or replace it following instructions under **Subject 130.**

Leak Testing

1. Chock the tires.
2. Supply the valve with 120 psi (827 kPa) from the primary reservoir supply port.
3. With the valve knob pulled out, coat the exhaust port and the plunger stem with a soapy solution. Leakage at either fitting should not exceed a 1-inch (2.5-cm) bubble every five seconds.There should be no leakage from the secondary reservoir supply port.
4. Supply the valve with 120 psi (827 kPa) from the secondary reservoir supply port. There should be no leakage from the primary reservoir supply port.
5. With the valve knob pushed in, coat the exhaust port and the plunger stem with a soapy solution. Leakage at the fittings should not exceed a 1-inch (2.5-cm) bubble every three seconds. If it does, replace or repair the valve, following instructions in **Subject 130.**

Parking Brake Hand Valve Removal and Installation

Removal (See Fig. 1)

1. Parking Brake Valve
2. Bracket
3. Knob
4. Mounting Screws

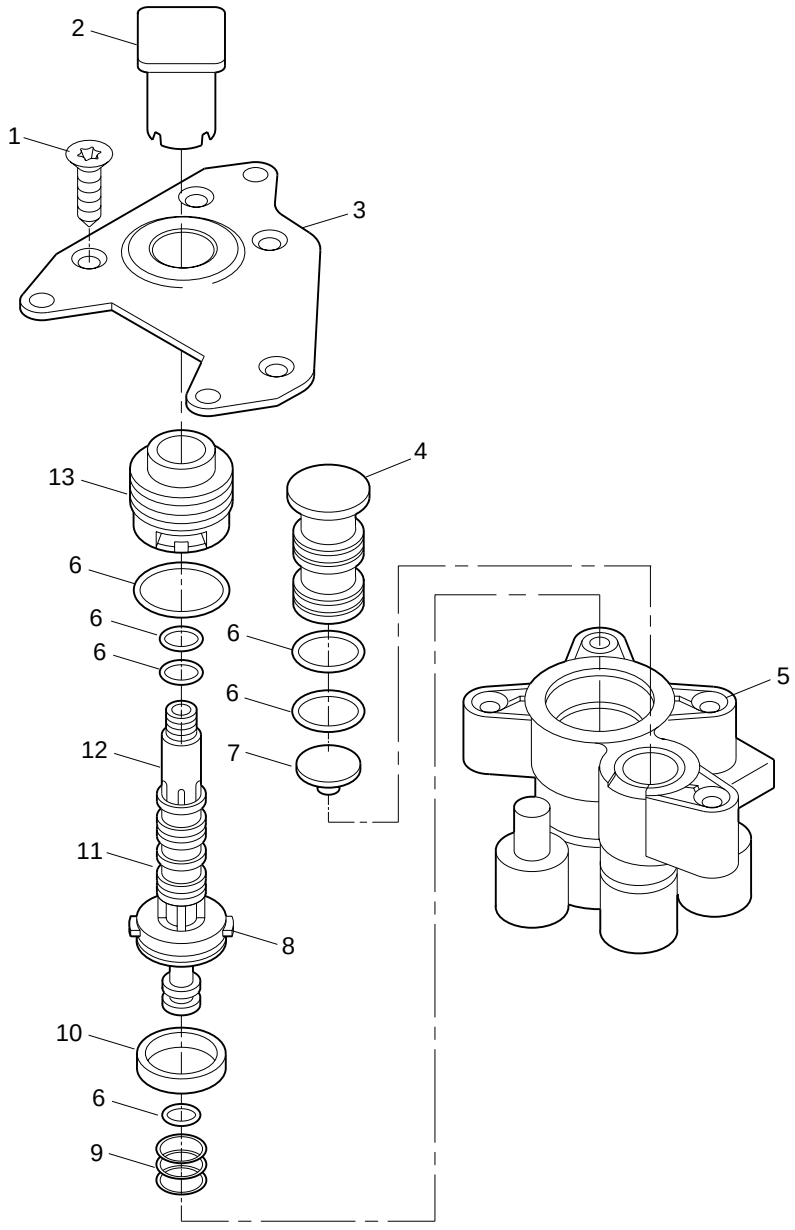
Fig. 1, Parking Brake Hand Valve Mounting

WARNING

WARNING: Review the precautions under Safety Precautions, 100 before doing any work on the parking brake valve. Failure to do so could result in personal injury.

1. Park the vehicle on a level surface, apply the parking brakes, chock the tires, and drain the air tanks.
2. Turn the valve knob (Ref. 3) counterclockwise and remove it from the valve stem.
3. Mark the air lines for later reference, then disconnect them from the valve assembly.

NOTE: The primary supply line is green; the secondary supply line is red; the exhaust line is black and 1/2-inch (13-mm) in diameter; the delivery line is black and 3/8-inch (9.6-mm) in diameter.



4. Remove the four screws (Ref. 4) that attach the valve (Ref. 1) to the bracket (Ref. 2). Remove the valve.

Installation

1. Position the valve assembly in the bracket. Install the four mounting screws.
2. Connect the air lines to the applicable fittings.
   - 2.1 Tighten the fittings hand tight.
   - 2.2 Using a wrench, tighten the fittings until the connections feel firm.
   - 2.3 Tighten the fittings an additional one-sixth turn.
3. Screw the valve knob onto the valve stem.
4. Leak test the fittings, following the instructions in **Subject 110.**

Parking Brake Hand Valve Disassembly and Assembly

11. Plunger
12. Plunger Stem
13. Guide Spool

Fig. 1, Exploded View

Parking Brake Hand Valve Disassembly and Assembly

1. Remove the valve assembly from the dash, following the instructions in **Subject 120.**
2. Put the valve assembly in a soft-jawed or padded vise.
3. Remove the screws that attach the cover to the body. Remove the cover.
4. Pull the plunger stem and remove the plunger and guide spool from the body.
5. Remove and discard the plunger spring.
6. Using a screwdriver (if needed), carefully remove the check valve seat from the body. Use care not to damage either the check valve seat or the valve body.
7. Remove and discard the check valve seat O-rings.
8. Turn the body upside down and gently tap it on a flat surface to remove the check valve. Discard the check valve.
9. Remove the guide spool from the plunger. Remove and discard the O-ring.
10. Remove and discard the O-rings from the plunger. Also, remove and discard the exhaust seal.

Assembly (See Fig. 1)

1. Clean and dry all the parts.
2. Check all the parts. Replace a part if any wear or damage is found.
3. Lightly grease all the parts—including the new parts from the maintenance kit—with Dow Corning 55 silicone pneumatic grease or equivalent.
4. Position the check valve in its seat in the body with the flat surface of the valve facing up. If needed, reach into the body to make sure that the valve is seated evenly in the bore.
5. Install the O-rings on the check valve seat and install the assembly into the body. Make sure that the check valve seat is even with the valve body surface.
6. Install the plunger spring into the body. Make sure that the spring is upright and seated properly in the body bore.

NOTE: The plunger spring should surround the protrusion or "lip" at the bottom of the body bore.

7. Install the O-rings onto the plunger, then install the plunger into the body.

   For ease of installation, line up the plunger's index tabs with the spaces in the body bore.
8. Install the O-ring on the guide spool. Install the spool over the plunger and into the body. Firmly press the guide spool into position.
9. Install the screws that attach the cover to the body. Tighten the screws 35 lbf·in (400 N·cm).
10. Install the valve in the dash, then leak test it. Follow the instructions in **Subject 120** for installation and **Subject 110** for leak testing.

General Description

The WABCO Antilock Braking System (ABS) is an electronic wheel speed monitoring and control system that works with the hydraulic brake system. See **Fig. 1**. ABS passively monitors vehicle wheel speed at all times, and controls wheel speed during emergency stops. In normal braking applications, the hydraulic brake system is in effect.

ABS includes signal-generating tone wheels and sensors located in the rotor assembly of each sensed wheel. The sensors transmit vehicle wheel speed information to an electronic control unit. During emergency braking, the control unit signals the brake pressure modulator to reduce, maintain, or increase hydraulic fluid pressure to the brake caliper housing. This prevents front and rear wheel lockup, and enhances steering control during emergency braking situations.

Principles of Operation

The ABS electronic control unit (**Fig. 2**) is a digital microcomputer that serves as the information processing and command center for the antilock braking system. The control unit receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the control unit regulates the braking force applied to each wheel by sending control signals to the brake pressure modulator (**Fig. 3**).

ABS Major Components

Wheel Speed Sensor

The wheel speed sensors use pulse feedback from tone wheels located in the front and rear axle wheel hubs. When the vehicle is moving, the teeth of the tone wheel cause changes in the magnetic field created by the sensor. The changes create an AC volatage signal that is sent by the sensor to the electronic control unit.

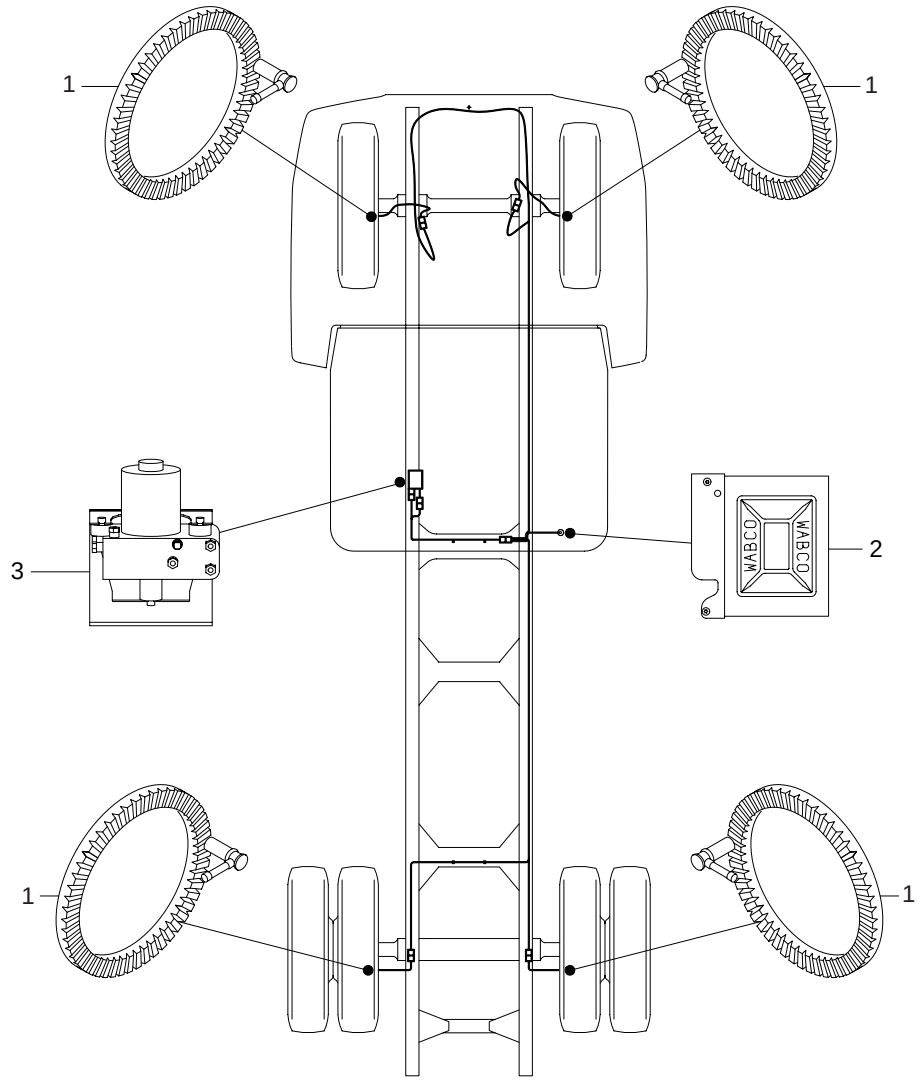
Electronic Control Unit (ECU)

The electronic control unit (ECU), located just behind the passenger's seat, contains microcomputers to monitor the front and rear control channels. The ECU receives wheel speed signals and interprets these signals to calculate wheel speed and a vehicle reference speed. If the calculations indicate a high degree of wheel slip the ECU signals the brake pressure modulator to adjust braking pressure.

The ECU contains another microcomputer that provides a safety circuit to constantly monitor the wheel sensors, the brake pressure modulator, and the electrical circuitry.

IMPORTANT: After the ignition switch is turned on, the tractor warning light (ABS) comes on for about three seconds. See **Fig. 4**. After about three seconds, the light goes out only if all of the tractor's ABS components are working correctly.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (a sensor, brake pressure modulator, wiring connection, short circuit, etc.), the tractor warning light (ABS) comes on, and the control circuit where the failure occurred is switched to normal braking action. Even if the ABS system is completely inoperative, normal braking is maintained. Refer to the vehicle driver's manual for complete operating instructions.



Brake Pressure Modulator

The brake pressure modulator is attached to the left frame rail just ahead of the center or forward rear-suspension crossmember. Depending on the signal received from the electronic control unit, the modulator prevents wheel lockup by adjusting the hydraulic fluid pressure. During normal braking applications, hydraulic fluid flows freely to the brake caliper housing through the modulator.

Within the modulator are an inlet and outlet control valve for each sensed wheel. If the electronic control unit signals indicate wheel lockup is close to occurring, fluid pressure to the brake caliper of the sensed wheel is reduced. The inlet valve of the sensed wheel closes, preventing fluid delivery to the brake caliper. At the same time, the outlet valve opens, allowing fluid to flow to an accumulator within the module. From the accumulator, a recirculation pump within the module delivers brake fluid back to the master cylinder.

As wheel speed increases, the brake pressure modulator allows increases (inlet valve opens and outlet valve closes), or maintains brake pressure until the proper wheel speed is obtained, or until wheel lockup occurs and the control cycle starts again.

Wheel Speed Sensor Replacement

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. Refer to **Group 54** (wiring) in this manual for information on special terminals and connectors, and on ordering tools for them.

Front Axle

1. Apply the parking brakes. Chock the rear tires to prevent vehicle movement.
2. Twist and pull the sensor to remove it from the sensor bracket (**Fig. 1**).

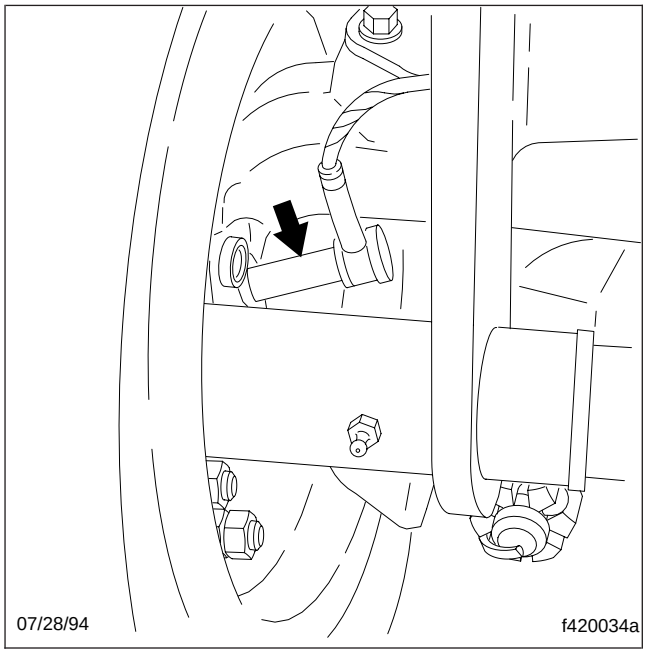

Fig. 1, Remove the Wheel Speed Sensor

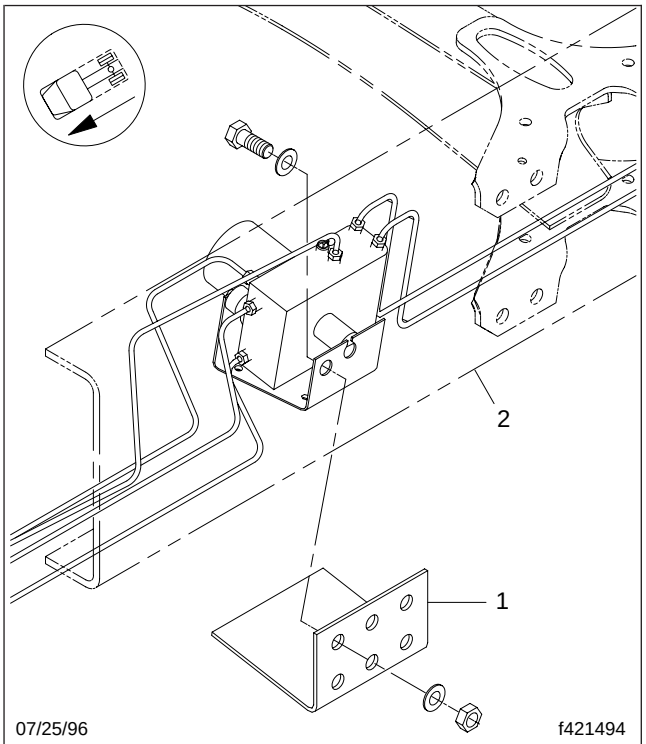
3. Remove the sensor cable clip from the top cap.
4. Disconnect the sensor cable from the chassis harness.
5. Remove the clamping bushing from the sensor bracket.
6. Connect the sensor cable to the chassis harness.
7. Attach the sensor cable to the steering knuckle top cap.
8. Press the clamping bushing into the sensor bracket at the brake spider hole until it stops.
9. Coat the sensor with Mobil HP, Valvoline EP 633, Penzoil 707L, or an equivalent. Press the sensor into the clamping bushing until it is stopped by the tone wheel.
10. Remove the chocks from the rear tires.



Rear Axle

1. Apply the parking brakes. Chock the front tires to prevent vehicle movement.
2. Raise the rear of the vehicle until the tires clear the ground. Place safety stands under the axle.
3. Twist and pull the sensor to remove it from the mounting block in the axle housing.
4. Remove the clamping bushing.
5. Remove the capscrew that attaches the sensor cable and the hose clamp to the axle tube.
6. Disconnect the sensor cable from the chassis harness.
7. Connect the new sensor cable to the chassis harness.
8. Attach the hose clamp and sensor cable to the axle tube located between the backing plate and the spring plate.
9. Press the clamping bushing into the mounting block until it stops.
10. Coat the sensor with Mobil HP, Valvoline EP633, Penzoil 707L, or an equivalent. Using your hand, push the sensor into the clamping bushing until it is stopped by the tone wheel.
11. Remove the safety stands, lower the vehicle, and remove the chocks from the front tires.

Replacement

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. Refer to **Group 54** in this manual for information on special terminals and connectors, and on ordering tools for them.

1. Chock the front and rear tires.
2. Put a container under the modulator to catch leaking brake fluid.
3. Disconnect the wiring from the modulator.
4. Mark the brake lines for ease of installation. Disconnect the lines.
5. Remove the mounting capscrews, washers, and nuts that attach the modulator and bracket assembly to the bracket on the frame rail. See **Fig. 1**.

1. Modulator Mounting Bracket
2. Left Frame Rail

Fig. 1, Brake Pressure Modulator Mounting

6. Remove the modulator and bracket assembly.

IMPORTANT: When replacing the modulator, make sure the new modulator is pre-charged.

7. Install the new modulator using the above instructions in reverse order. Tighten the modulator and bracket assembly mounting nuts 132 lbf·in (1500 N·cm). Tighten the brake line connections 108 lbf·in (1220 N·cm).
8. Bleed the brake system following the instructions in **Subject 120**.

Hydraulic System Bleeding

Whenever any hydraulic system fitting is loosened or disconnected, the entire system must be bled to remove any air that may have entered it.

⚠ CAUTION

Power steering fluid and brake fluid are incompatible. Never mix these two fluids, or serious damage to both hydraulic systems will result. Use only brake fluid for the master cylinder and brake lines. Use only power steering fluid for the power booster.

Always use new, clean brake fluid that meets DOT 3 specifications when bleeding the master cylinder and service brake system. Never reuse brake fluid, and don't use brake fluid containers for any other purpose. Keep brake fluid containers tightly closed to keep new brake fluid clean and dry.

IMPORTANT: Don't let brake fluid touch any painted surfaces, as it will remove the paint. Brake fluid may also damage certain non-metal surfaces. Don't let it get on brake pads or rotors.

Pressure Bleeding, Service Brake System

Pressure bleeding is the preferred method for bleeding the service brake system. It requires the use of a special pressure bleeder kit, consisting of a tank, pressure pump and valve, gauge, tubing, and adapter. These are available from a number of manufacturers, and include instructions for use. See **Fig. 1**.

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Connect the pressure bleeder to the brake master cylinder reservoir, following the manufacturer's instructions.
   - 2.1 Fill the pressure bleeder with new DOT 3 approved brake fluid, then pressurize it according to the manufacturer's instructions.
   - 2.2 Using the supplied adapter, connect the pressure bleeder to the rear compartment of the master cylinder reservoir.

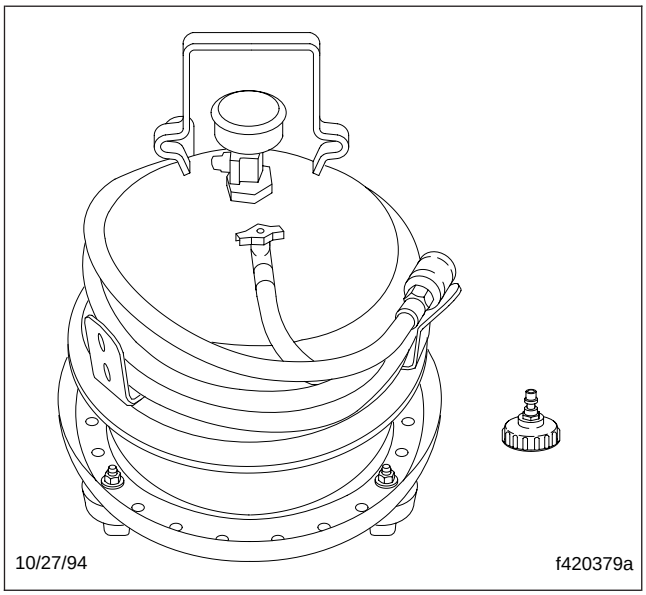


Fig. 1, Pressure Bleeder Kit

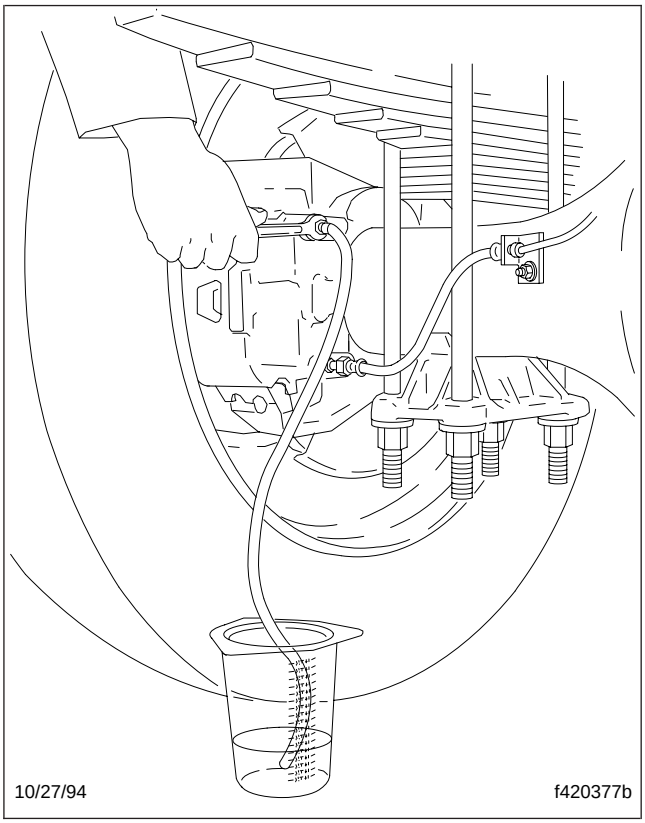
3. Bleed the hydraulic connections at the rear wheel calipers, starting on the right side.
   - 3.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.
   - 3.2 Loosen the bleeder fitting about 3/4 turn, and let the brake fluid flow out of the fitting until it is free of air bubbles. See **Fig. 2** and **Fig. 3**. Then tighten the fitting firmly.
   - 3.3 Move to the left rear caliper, and repeat steps for bleeding the caliper.
4. Disconnect the pressure bleeder from the rear compartment of the master cylinder reservoir, then connect it to the front compartment of the reservoir.
5. Bleed the front wheel brake calipers, starting at the right side.
   - 5.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.

Hydraulic System Bleeding



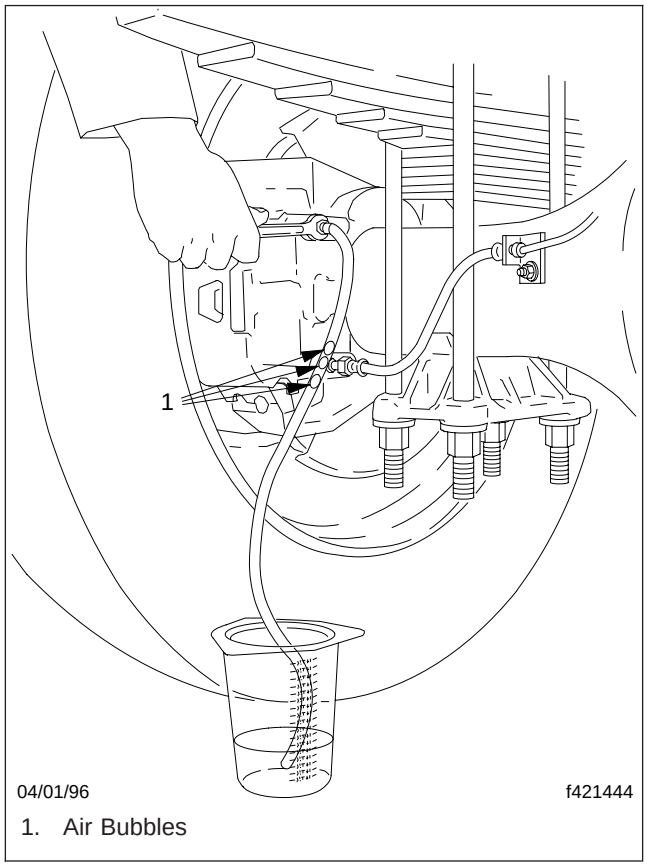


Fig. 2, Bleed the Connections at the Rear Wheel Calipers

5.2 Loosen the bleeder fitting about 3/4 turn, and let the brake fluid flow out of the fitting until it is free of air bubbles. See **Fig. 2** and **Fig. 3**. Then tighten the fitting firmly.

5.3 Move to the left front wheel caliper, and repeat steps for bleeding the caliper.

6. Check the brake fluid level in both compartments of the reservoir. Add new DOT 3 approved brake fluid if needed.
7. Check the operation of the brakes by depressing the brake pedal several times, until if feels firm. The brake pedal should not go all the way down to the floor. If it does, go to the troubleshooting subject in **Section 42.26** and find the problem.
8. Lower the hood and remove the chocks.

1. Air Bubbles

Fig. 3, Loosen the Bleeder Fitting

Manual Bleeding, Service Brake System

If you don't have pressure bleeding equipment, you can use the manual bleeding procedure.

IMPORTANT: Don't let the brake master cylinder fluid level get too low during manual bleeding operations. Keep the master cylinder reservoir filled with new, DOT 3 approved brake fluid. Failure to keep the brake reservoir filled could result in more air entering the system, making it impossible to effectively bleed the system.

1. Apply the parking brake, chock the tires, and tilt the hood.
2. Bleed the master cylinder.

2.1 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the

rear outlet port on the master cylinder. See **Fig. 4**. Loosen the fitting about one turn.

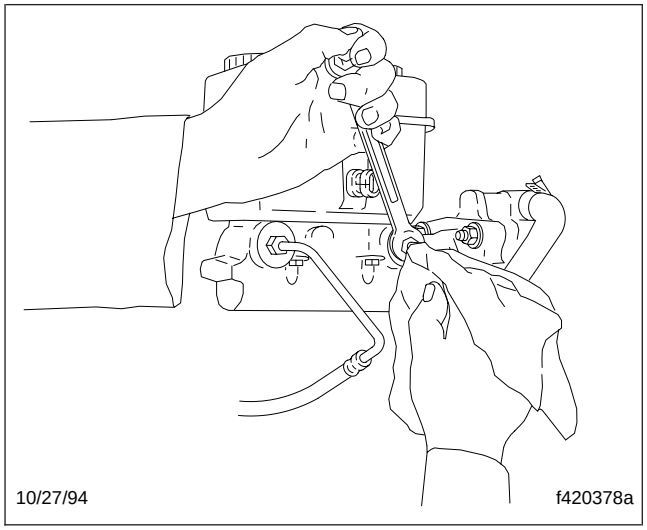

Fig. 4, Loosen the Fitting at the Rear Outlet Port

2.2 Have someone push the brake pedal down slowly—by hand—to the floor. Brake fluid, and any air in the master cylinder, will squirt from the fitting.

2.3 *With the brake pedal held down,* tighten the rear hydraulic line fitting firmly.

IMPORTANT: Don't release the brake pedal until the fitting is tightened, or more air will get into the system.

2.4 Release the brake pedal.

2.5 Loosen the fitting again, and repeat steps for bleeding as required until no air escapes from the fitting, and the brake pedal feels firm.

2.6 Check the level of the rear compartment of the reservoir, then add new DOT 3 approved brake fluid if needed.

2.7 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the front outlet port on the master cylinder. See **Fig. 5**. Loosen the fitting about one turn.

2.8 Repeat steps as required for the front outlet port.

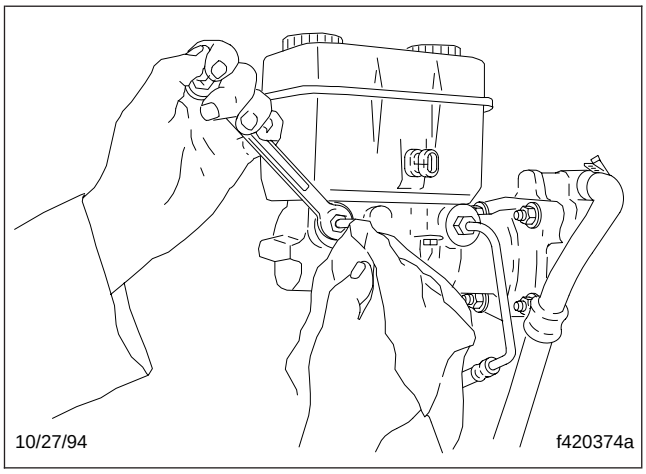

Fig. 5, Loosen the Fitting at the Front Outlet Port

2.9 Check the brake fluid level in the front compartment of the reservoir. Add new DOT 3 approved brake fluid if needed.

3. Bleed the hydraulic connections at the wheel calipers, starting at the right rear wheel caliper.

3.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.

3.2 Loosen the bleeder fitting about 3/4 turn.

3.3 Have someone slowly push the brake pedal to the floor, then *with the brake pedal depressed,* tighten the bleeder fitting.

IMPORTANT: Make sure the brake pedal stays depressed while you tighten the fitting. If it's released before you tighten the fitting, more air will get into the system.

3.4 Release the brake pedal. Check the fluid in the tube. If there are air bubbles present (**Fig. 3**), repeat steps as required until the fluid in the tube is completely free of air bubbles, as shown in **Fig. 2**.

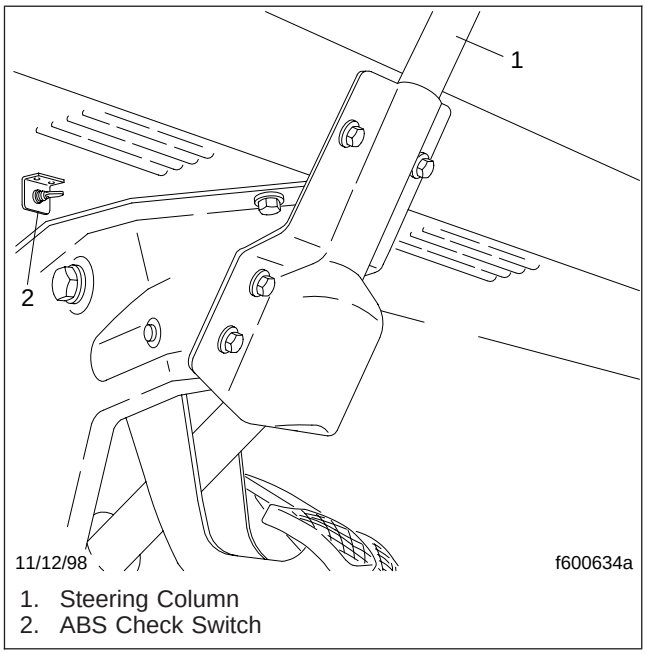
3.5 Check the brake fluid level in the reservoir. Add new DOT 3 approved brake fluid if needed.

3.6 Repeat steps for bleeding the connections for the left rear caliper, then the right front caliper, and finally for the left front caliper.

Hydraulic System Bleeding

4. Lower the hood and remove the chocks.

Troubleshooting Using the Instrument Panel Blink Codes



Using the Instrument Panel Blink Codes

This system has built-in diagnostics to ensure that all components are operating properly. Under normal conditions, the tractor warning light (ABS) comes on when the ignition is turned on. After about three seconds the light should go out if all of the tractor's ABS components are working. If the light stays on, or comes back on later, a problem within the ABS system has occurred. The vehicle can continue to be driven, but the ABS system could be partially or completely inoperative. To check the fault code recorded, stop the vehicle and turn off the engine. Then, turn on the ignition switch, but don't start the engine. If the light is still on, there is an "active" system fault that must be repaired to ensure proper system operation.

IMPORTANT: Remove the ABS light relay from the power distribution module (PDM). See **Group 54**. It is necessary to remove the relay in order to display multiple fault codes.

Use the ABS CHECK switch (see **Fig. 1**), located under the driver's left-side dash, and the ABS light to display system faults. With the ignition switch on, turn on the ABS CHK switch. The ABS light should go out. After a one-second pause, the ABS light will blink the first digit of the two-digit configuration code. This code is indicated by one long flash, a two-second pause, then one short flash (1–1). Any active fault codes will be displayed following this configuration code. There will be a two-second pause between the last configuration code flash and the first set of flashes of the fault code. The fault code will be indicated by two sets of flashes. The number of blinks displaying the first digit will be a number between one and six. After another two and one-half second pause, the second digit will be displayed. The number of blinks displaying the second digit will be a number between one and fifteen. After a two and one-half second pause, the diagnostic code cycle continues to repeat the configuration code and fault code until the fault is repaired.

For example (**Fig. 2**), after the ABS CHECK switch has been turned on, the configuration code (1–1) will blink followed by fault code 5–4, shown by five flashes, a pause of two and one-half seconds, followed by four flashes. After a two and one-half second pause, the same configuration and fault code will continue to repeat, always ending with a two and one-half second pause.

1. Steering Column
2. ABS Check Switch

Fig. 1, ABS Check Switch Location

Once a fault code has been identified, use a volt/ohmmeter to check the electrical harness at the ECU's 35-pin connector, which is located just behind the passenger's seat. Connect the ohmmeter leads to the applicable pins on each connector. See **Fig. 3** and **Table 1**, for a description of the circuit wire numbers and their location within the pin connectors.

Make the necessary repairs and clear the fault code from the ECU memory as outlined at the end of this section. If more than one fault exists, it will be displayed after the first one has been cleared from memory.

To make testing easier, use the Meritor WABCO test adaptor. See **Fig. 4**.

The Meritor WABCO test adaptor is used to service and troubleshoot the Meritor WABCO ABS system. *It can not be used with a vehicle frame-mounted ECU.* A volt ohmmeter (VOM) can determine the condition of the ABS valves, wheel end sensors and associated wiring. When used with the procedures and blink codes in *Meritor WABCO Maintenance Manual No. 38, Rev. 6/98*, it allows you to measure voltages and resistances of components in the system.

Troubleshooting Using the Instrument Panel Blink Codes

Fig. 3, ECU 35-Pin Connector

accept the tips of standard VOM cables. These tips are about 0.080 inch diameter (2 mm). Any good quality digital or analog VOM can be used. A meter with automatic polarity sensing is recommended so you do not have to worry about correct polarity of the meter leads during voltage measurements.

The test adaptor lets you access the 35-pins in the connector that attaches to the Meritor WABCO Electronic Control Unit (ECU). By inserting the probes of

06/09/97 f421604

Fig. 4, Test Adaptor

a VOM into the proper holes of the adaptor, sensor resistances, solenoid resistances, power, and grounds can be measured and compared to acceptable values. Sensor adjustment and tone ring runout can also be checked using the adaptor.

IMPORTANT: The ignition switch must be off when connecting or disconnecting the ECU.

NOTE: The blink codes are erased from ECU memory as repairs are made. Once a repair has been made, cycle the ignition to ensure the blink code does not reappear. If there are any other outstanding faults, the next blink code will be displayed.

If the ABS light does not operate correctly after the ignition is turned on (the light doesn't come on at all or it doesn't go out after about three seconds), check all circuit breakers in the control unit panel, and replace if necessary. Check the wiring to the ABS CHECK switch and the warning lamp, and repair or replace the wiring as needed. When checking the warning lamp, do the following:

- Replace the bulb.
- Check voltage potential at the socket.
- Check continuity of the wires to the socket.

When checking the switch, do the following:

Troubleshooting Using the Instrument Panel Blink Codes

- Check the resistance between the terminals while cycling the switch.
- Check the continuity of the wires to the switch.

Make sure that a charged 12-volt battery is available (the ABS system needs at least 11 volts to work).

See **Table 2** for a listing of all fault codes, pins to be tested, and the correct volt/ohmmeter readings. Repair or replace the components and/or wiring if the readings are not correct.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals.

Refer to **Group 54** in this manual for information on special terminals and connectors, and ordering tools for them.

WABCO ABS Fault Codes and Tests

Key Switch On to Determine ABS Blink Fault Code		Key Switch Off to Test System		
WABCO Fault Code	**Problem**	**Begin by Testing These Pins**	**Volt, Amp, and Ohmmeter Reading**	**Remedy**
2–0	Internal electronic control unit fault.	—	—	Replace the electronic control unit.
2–1	Internal electronic control unit fault.	—	—	Replace the electronic control unit.
2–2	Recirculation pump operates continuously.	—	—	Check the recirculation pump wiring (circuits 11 & 30), the pump relay, and the wiring connections. Repair or replace as needed.
2–3	Recirculation pump does not work.	—	—	Jump pins 9 and 11, and you should hear the pump motor run. Check the recirculation pump wiring, the relay circuit, and the pump connections.
2–4	Recirculation pump motor locked.	—	0.30 A	Jump pins 9 and 11, and you should hear the pump motor run. Check the recirculation pump wiring, the relay circuit, and the pump connections.
2–6	Stop light switch has failed.	10 and 25	—	Repair the wiring if needed (circuits 10 & 25). Also, make sure that the 35-pin connector is secure at the ECU.
2–7	Continuous power supply to the ECU with ignition off.	9 and 27	0 DCV	With the ignition off, check the valve relay and wiring connections. Repair or replace as needed.
2–8	No voltage to the inlet or outlet valve.	1, 9 and 27	12 V	Check the valve relay, the wiring (circuits 1 & 8), and the wiring connections. Repair or replace as needed.
2–9	Inlet valve supervision time exceeded.	—	—	Check the valves for normal operation. If okay, clear the faults.
2–10	Modulator reference ground interrupted.	31	—	Repair or replace wiring (circuit 31) as needed. Check the chassis ground circuit.

Troubleshooting Using the Instrument Panel Blink Codes

WABCO ABS Fault Codes and Tests				
Key Switch On to Determine ABS Blink Fault Code		**Key Switch Off to Test System**		
WABCO Fault Code	**Problem**	**Begin by Testing These Pins**	**Volt, Amp, and Ohmmeter Reading**	**Remedy**
2–11	Recirculation pump cycle time is excessive.	—	—	Check the recirculation pump operation. If okay, clear the fault.
2–12 Right Front (RF) 2–14 Left Front (LF)	Wheel speed signal is erratic.	(RF), pins 17 and 34 * (LF), pins 15 and 32 *	above 0.20 volt AC	A damaged tone wheel, a sensor needs adjustment, or there is excessive hub runout. Repair or replace as needed.
2–13 Left Rear (LR) 2–15 Right Rear (RR)	Wheel speed signal is erratic.	(LR), pins 18 and 35 * (RR), pins 16 and 33 *	above 0.20 volt AC	A damaged tone wheel, a sensor needs adjustment, or there is excessive hub runout. Repair or replace as needed.
3–0 Right Front (RF)	On the steer axle, there is an open circuit in the RF inlet control valve and/or wiring to the modulator connection.	6 and 27	5 to 7.5 ohms 1.6 amps †	Check the inlet control valve wiring (circuit 6). Repair or replace wiring as needed.
3–1 Right Front (RF)	On the steer axle, there is an open circuit in the RF outlet control valve and/or wiring to the modulator connection.	7 and 27	3 to 5 ohms 2.5 amps †	Check the outlet control valve wiring (circuit 7). Repair or replace wiring as needed.
3–2 Left Front (LF)	On the steer axle, there is an open circuit in the LF inlet control valve and/or wiring to the modulator connection.	23 and 27	5 to 7.5 ohms 1.6 amps †	Check the inlet control valve wiring (circuit 23). Repair or replace the wiring as needed.
3–3 Left Front (LF)	On the steer axle, there is an open circuit in the LF outlet control valve and/or wiring to the modulator connection.	24 and 27	3 to 5 ohms 2.5 amps †	Check the outlet control valve wiring (circuit 24). Repair or replace the wiring as needed.
3–4 Right Rear (RR)	On the rear axle, there is an open circuit in the RR inlet control valve and/or wiring to the modulator connection.	4 and 27	5 to 7.5 ohms 1.6 amps †	Check the inlet control valve wiring (circuit 4). Repair or replace the wiring as needed.
3–5 Right Rear (RR)	On the rear axle, there is an open circuit in the RR outlet control valve and/or wiring to the modulator connection.	5 and 27	3 to 5 ohms 2.5 amps †	Check the outlet control valve wiring (circuit 5). Repair or replace the wiring as needed.

6–12 Right Front (RF) 6–14 Left Front (LF)	Wheel speed signal is missing.	pins 17 and 34 pins 15 and 32	Above 0.2 volts AC	The gap is too large, adjust the sensor.

Troubleshooting Using the Instrument Panel Blink Codes

WABCO ABS Fault Codes and Tests				
Key Switch On to Determine ABS Blink Fault Code		Key Switch Off to Test System		
WABCO Fault Code	**Problem**	**Begin by Testing These Pins**	**Volt, Amp, and Ohmmeter Reading**	**Remedy**
6–13 Left Rear (LR) 6–15 Right Rear (RR)	Wheel speed signal is missing.	pins 18 and 35 pins 16 and 33	Above 0.2 volts AC	The gap is too large, adjust the sensor.

* After connecting the volt/ohmmeter test leads, rotate the applicable tire at about 30 rpm (1 revolution every 2 seconds).
† Desired readings are with the battery potential at approximately 12.5 volts.

Table 2, WABCO ABS Fault Codes and Tests

Refer to the wiring diagram in **Specifications 400** when troubleshooting the ABS system. The key switch must be turned on (engine off) to activate the blink codes.

If a fault still can't be repaired, or erased from ECU memory, contact your Meritor District Service Manager, or call Meritor WABCO at 1-800-535-5560.

ERASING A FAULT FROM THE ECU MEMORY

NOTE: An existing fault cannot be erased until it has been corrected.

Meritor WABCO recommends that you erase all faults from the ECU memory after they have been noted and corrected.

Faults can only be erased one at a time. A fault is erased from the ECU memory by doing the following:

1. Turn the ignition switch on.
2. Turn the blink code switch on.
3. Wait until the blink code begins to flash.
4. Turn the blink code switch off.
5. Wait for the ABS lamp to stop flashing.
6. Turn the ignition switch off, then back on.
7. Turn the blink code switch off, then back on.
8. Check for additional faults. If they are present, repair and clear them.

When all faults are repaired and cleared, only the configuration code (1–1) will be displayed.

See **Fig. 1** for a full view of the wiring diagram for troubleshooting 4S/4M ABS systems using instrument panel blink codes. See **Fig. 2**, or **Fig. 3** for partial (detailed) views of the wiring diagram. See **Fig. 4** for a plumbing diagram of the hydraulic ABS system.

General Information

The Allied Signal/Bendix TP–3DC is a tractor protection valve which includes an integral double check valve. The TP–3DC serves two purposes. First, as required by Federal law, the valve protects the tractor brakes in the event of trailer breakaway or a severe air system leak. Second, when used with a dash-mounted trailer supply control valve, the TP–3DC valve can be used to shut off the trailer control line before the trailer is disconnected.

The TP–3DC also includes an integral single check valve which prevents air from getting trapped in the trailer control line. Trapped air in this line could cause service/spring brake compounding and, if the trailer is parked with air applied, a trailer roll-away situation.

On Business Class vehicles, the TP–3DC tractor protection valve is mounted under the left rear cab corner (see **Fig. 1**).

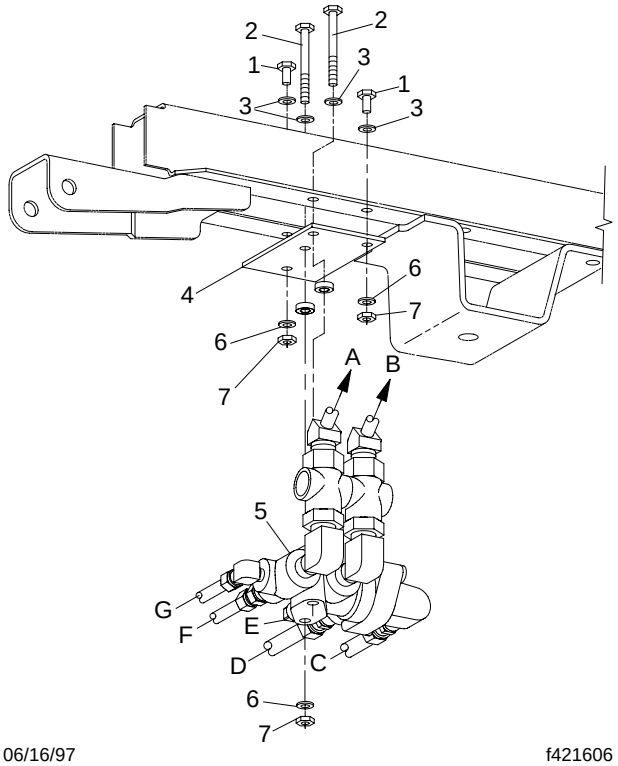
TP–3DC valve port designations and internal components are shown in **Fig. 2**.

Principles of Operation

INITIAL CHARGE **(See Fig. 3)**

Pushing in the red trailer air supply knob (Ref. 1) on the instrument panel causes air to flow into the TP–3DC valve at the tractor supply port (Ref. 2). Air flows through the valve housing, exiting via the auxiliary supply port (if used) and the trailer supply port (Ref. 4), to pressurize the trailer brake system and release the trailer parking brakes.

As air pressure builds in the trailer supply circuit, the single check valve (Ref. 5) seats, and the valve plunger (Ref. 16) begins to move (against spring pressure) toward the guide (Ref. 8). When pressure reaches about 45 psi (310 kPa), the plunger bottoms against the guide and the inlet valve is open.



The TP–3DC valve is in the "run" mode, and ready to receive and deliver a service brake application from either the foot valve or the hand valve.

SERVICE BRAKE APPLICATION

(See Fig. 4)

When the foot pedal is pressed, air flows to the TP–3DC valve tractor control primary (Ref. 10) and secondary (Ref. 13) ports. If the trailer control valve (Ref. 14) is also used, the external double check (Ref. 12) delivers the higher pressure (trailer control or foot valve secondary) to the TP–3DC Tractor Control secondary port.

Inside the TP–3DC valve, the higher pressure (primary or secondary) moves the diaphragm (Ref. 9) to seal off the port at the lower pressure.

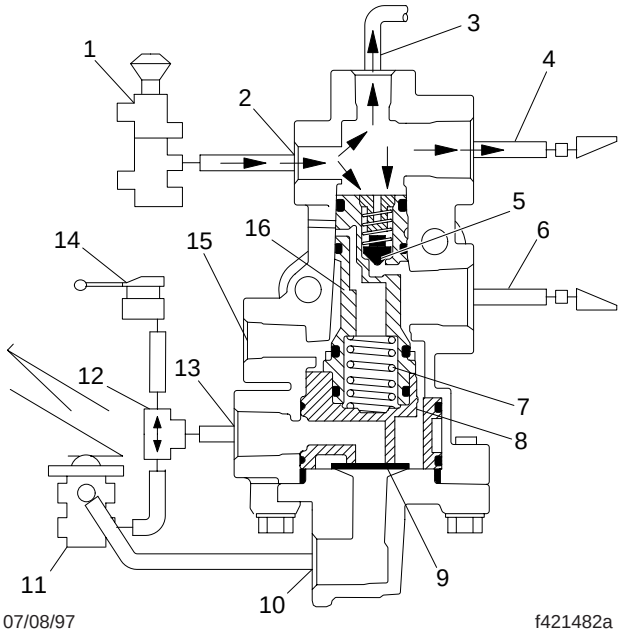
12. Stop Lamp Switch
13. Plunger

Fig. 2, TP–3DC, Sectional View



With the plunger bottomed against the guide and the inlet valve open (as described earlier), the higher pressure air flows through the valve to the trailer control port (Ref. 6) and the stop lamp switch, applying the brakes and activating the stop lamps.

NOTE: While air pressure also reaches the TP–3DC single check valve, the valve stays closed because supply pressure is acting on the other side.

SERVICE BRAKE RELEASE

(See Fig. 5)

When the foot pedal is released, air stops flowing into the TP–3DC valve at the tractor control primary (Ref. 10) or secondary (Ref. 13) port. At the same time, air in the trailer control line (Ref. 6) returns to the valve, flowing back through the open inlet valve.

Fig. 3, Initial Charge

The air forces the diaphragm (Ref. 9) to seat, sealing off the tractor control primary port. The air then exits the valve at the tractor control (secondary) port (Ref. 13) and flows to the foot valve or hand valve where it is exhausted.

TRACTOR PROTECTION **(See Fig. 6)**

If the red trailer air supply knob on the instrument panel is pulled out (or if a large leak develops in the trailer supply circuit), pressure in the trailer supply circuit (and the auxiliary supply circuit, if used) is vented. When pressure drops to about 20 to 30 psi (138 to 207 kPa), the pressure can no longer over-

come the spring force inside the TP–3DC valve and the inlet valve closes.

With the inlet valve closed, air pressure from the brake foot or hand control valves will not reach the trailer control circuit when the brakes are applied.

ANTI-COMPOUNDING **(See Fig. 7)**

If the red trailer air supply knob on the instrument panel is pulled out while the service brakes are applied, the single check valve (Ref. 5) in the TP–3DC prevents simultaneous spring and service brake application. As pressure in the trailer supply circuit drops, the spring (Ref. 7) in the TP–3DC valve forces the inlet valve closed (as described above in "Tractor Protection." Safety Precautions

When working on or around air brake systems and components, observe the following precautions.

1. Chock the tires and stop the engine before working under the vehicle. Releasing air from the system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not correctly disassembled. Use only correct tools and observe all precautions regarding use of those tools.

Leakage Test

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100.**

1. Chock the tires, start the engine, and run it until the air system is fully charged.
2. Shut down the engine and place the trailer air supply valve in the emergency position.
3. Disconnect the trailer control line hose coupling and apply a soap-water solution to the coupling.
4. With tractor reservoirs charged to at least 100 psi (689 kPa) make and hold a full service brake application using either the foot valve or the trailer control valve. Leakage at the hose coupling should not exceed a 1-inch (2.5-cm) bubble in five seconds.
5. Release the service brake application and place the trailer supply valve in the "run" position. Connect the trailer control valve to a test gauge.
6. Make a service brake application and note that service air pressure is present at the trailer control line hose coupling.
7. Disconnect the air line at the TP–3DC tractor control port (primary), plug the line, and apply a soap-water solution to the valve.
8. Make a service brake application and check for leakage at the open tractor control port. Leakage should not exceed a 1-inch (2.5-cm) bubble in five seconds.
9. Reconnect the air line to the tractor control port (primary) and disconnect the air line at the tractor control port (secondary). Then, plug the disconnected line and apply a soap-water solution to the valve.
10. Make and service brake application and check for leakage at the open tractor control port. Leakage should not exceed a 1-inch (2.5-cm) bubble in five seconds.

IMPORTANT: If the valve does not function as described, or if leakage is excessive, repair or replace the valve.

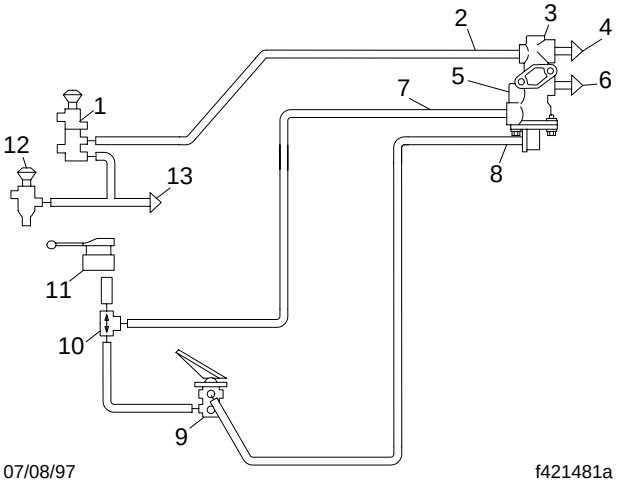
Removal

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.

1. Chock the tires, and open the air reservoir drain cocks to bleed the air from the system.
2. Remove the trailer hose assemblies from the TP–3DC valve. Disconnect the tractor service and supply lines. Mark the lines for later assembly reference. Cap the air lines tightly to keep out contaminants.
3. Remove the fasteners attaching the TP–3DC valve to the vehicle, and remove the valve.

Installation

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.



1. Place the TP–3DC valve on the vehicle, and attach it with bolts, washers, and nuts. Tighten the nuts 11 to 15 lbf·ft (15 to 20 N·m).

NOTE: The delivery line from the trailer air supply valve is connected to the tractor emergency port of the TP–3DC valve. See **Fig. 1**. The delivery line from the brake valve (double check valve) is connected to the tractor service port of the TP–3DC valve. Trailer hose assemblies are installed in the trailer emergency and trailer service ports of the TP–3DC valve.

2. Remove the caps from the air lines, and depending on the type of air hose, use the following instructions to connect the air hoses to the TP–3DC valve:

   If equipped with nylon tube air hoses, connect the hose fittings to the valve ports, and tighten the nuts finger-tight. Then, using a wrench, tighten the nuts at least two turns, or until no threads show on the fitting.

   If equipped with wire braid hoses, connect the hose fittings to the valve ports, and hand-tighten the nuts. Using a wrench, tighten the nuts until there is resistance. Tighten one-sixth turn more. Do not overtighten.

14. Plunger O-Ring
15. Valve Body

Fig. 1, Exploded View of TP–3DC Valve

IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.

1. Remove the valve from the vehicle, retaining the mounting hardware. For instructions, see **Subject 120**.
2. Scribe a line across the valve cover (Ref. 2) and valve body (Ref. 15) to ensure proper alignment during assembly.
3. Remove the two 1/4-inch screws (Ref. 1) which secure the valve cover to the valve body and

Disassembly, Cleaning and Inspection, and Assembly

allow the valve spring to expand until the valve cover can be removed.

4. Remove the cover O-ring (Ref. 3) and discard it.
5. Remove the diaphragm (Ref. 4) from the valve body and discard it.
6. Remove the guide (Ref. 5) from the valve body.
7. Remove the O-rings (Refs. 7 and 8) from the guide and discard them.
8. Remove the valve spring from the plunger, then the plunger from the valve body.
9. Remove the O-rings (Refs. 9, 13, and 14) from the plunger and discard them.
10. Remove the collar (Ref. 11) and the O-ring (Ref. 12) from the plunger. Discard the O-ring, but keep the collar.

Cleaning and Inspection

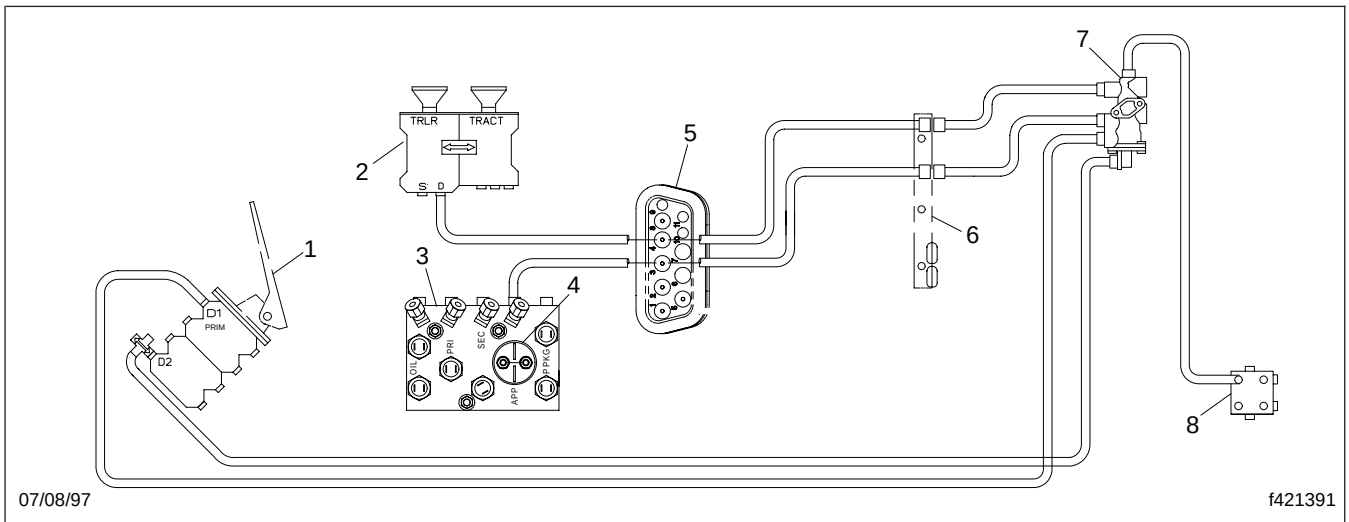
IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the TP–3DC valve in cleaning solvent, then dry them using compressed air.
2. Examine the cover, body, guide, and plunger for corrosion, excessive wear, cracks, or other damage. If any of these conditions are found on a part, replace the part with a new one.
3. Check the spring for distortion and corrosion. If the spring is distorted or corroded, replace it.
4. Check the valve body bores for deep scratches or gouging

Assembly



IMPORTANT: Before working on or around air brake systems and components, review **Safety Precautions, 100**.

1. Lubricate the O-rings, O-ring grooves, body bores, and all sliding parts with the lubricant provided in the overhaul kit (Bendix silicone lubricant #291126 or equivalent).
2. Install the O-rings (Refs. 9, 13, and 14) on the plunger.
3. Install the O-ring (Ref. 12) on the plunger and then the collar (Ref. 11) over the O-ring. Make sure that the collar is fully seated and firmly in place over the O-ring.
4. Install the plunger into the valve body and the spring (Ref. 6) into the plunger.
5. Install the O-rings (Refs. 7 and 8) in their grooves on the guide.
6. Align the indexing tab on the guide with the notch in the valve body and install the guide in the valve body.
7. Place the diaphragm (Ref. 4) in its recess on the guide.
8. Place the O-ring (Ref. 3) on the cover.
9. Place the cover on the guide and press them down, against spring pressure, until the cover is seated against the valve body.
10. Install the two 1/4-inch screws and tighten them 30 to 60 lbf·in (340 to 675 N·cm).
11. Install the TP–3DC valve on the vehicle following the instructions in **Subject 120**.

See **Fig. 1** for a TP–3DC plumbing diagram.

General Information

The QR–1C quick release valve **(Fig. 1)** is a dual function valve. Its primary function is to speed up the release of air pressure from the service brake chambers. Additionally, the valve works as an anti-compound device. The double check valve feature prevents a service and parking brake application from occuring at the same time.

1. Supply Port
2. Balance Port
3. Delivery Port
4. Exhaust
5. Cap Nut
6. Sealing Ring
7. Double Check Diaphragm
8. Body
9. Quick Release Diaphragm
10. Cover

Fig. 1, QR-1C Valve and Cross Section

The QR–1C valve is generally mounted near the rear axle. A balance line from the relay valve delivery port (port 2 on the WABCO combination valve) is connected to the balance port on top of the QR–1C quick release valve; the two side ports are for brake chamber connections; the supply port is connected to the delivery port of the parking brake control valve, and the exhaust port is located at the bottom of the valve.

Principles of Operation **(See Fig. 1)**

Parking Brakes Released

When the parking brakes are released, air from the parking brake control valve flows through the QR–1C valve. This forces the double check diaphragm and the quick release diaphragm to flex and seal the balance and exhaust ports. Air flows into the inlet ports of the parking brake chambers from the QR–1C valve delivery ports.

Parking Brakes Applied

When the parking brakes are applied, supply line air pressure to the QR–1C valve is exhausted through the parking brake control valve. As air pressure is exhausted from one side of the double check diaphragm and the quick release diaphragm, both diaphragms flex in the opposite direction to open the balance and exhaust ports. Parking brake pressure is released at the exhaust port of the QR–1C valve while a small amount of air trapped between the two diaphragms is released through a relay valve or the foot valve exhaust port.

Anti-Compounding

When a service brake application is made with the parking brakes applied, service air enters the balance port and flows through the QR–1C valve into the inlet ports of the parking brake chambers. This prevents application of the service and parking brakes at the same time. Service air passing through the QR–1C valve flexes the double check and quick release diaphragms, sealing the supply and exhaust ports. When the service brake application is released, air is exhausted from the parking brakes.

Safety Precautions

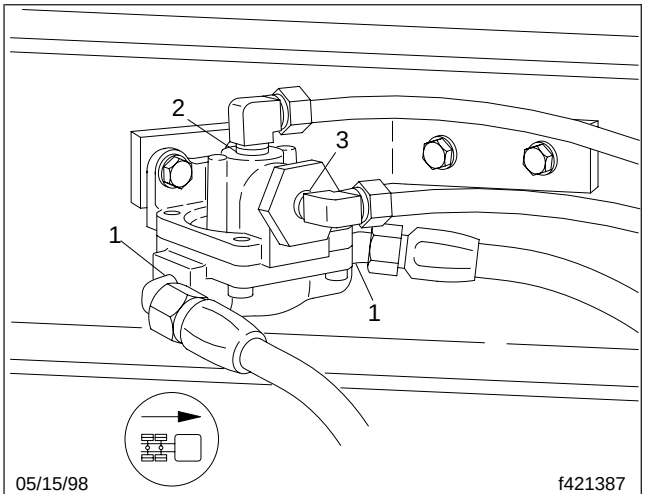
When working on or around air brake systems and components, observe the following precautions.

1. Chock the tires and stop the engine before working under a vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they may apply as air system pressure drops.
2. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
3. Never exceed recommended air pressure and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
4. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use only proper tools and observe all precautions pertaining to use of those tools.

QR–1C Quick Release Valve Operating and Leakage Tests

Operating and Leakage Tests

⚠ WARNING



Before working on or around air brake systems and components, review the safety precautions in Subject 100. Failure to do so could result in personal injury.

The following tests should also be performed after repairing or replacing the QR–1C valve to ensure that it is functioning properly.

1. Chock the tires.
2. Drain the air system.
3. Release the parking brakes.
4. Remove the air line from the valve balance port. Build system air pressure to 120 psi (827 kPa). Coat the exhaust and balance ports with a soap solution; leakage of a one-inch bubble in five seconds at either port is allowable. Install the air line at the balance port.
5. Apply the parking brakes. Step on the foot brake; the QR–1C valve should exhaust air at the exhaust port.
6. Drain the air system.
7. Remove the air line from the valve supply port. Build system air pressure to 120 psi (827 kPa). With the foot valve depressed, coat the supply port and the seam between the body and cover with a soap solution; leakage of a one-inch bubble in five seconds at the supply port is allowable. No leakage between the body and cover is permitted. Install the air line at the supply port.
8. If the valve does not function properly, or if leakage is excessive, repair or replace it following the instructions in this section.

QR–1C Quick Release Valve Removal and Installation

Removal (See Fig. 1)

NOTE: Valve mounting inside the left frame rail shown.

1. Delivery Port
2. Balance Port
3. Supply Port

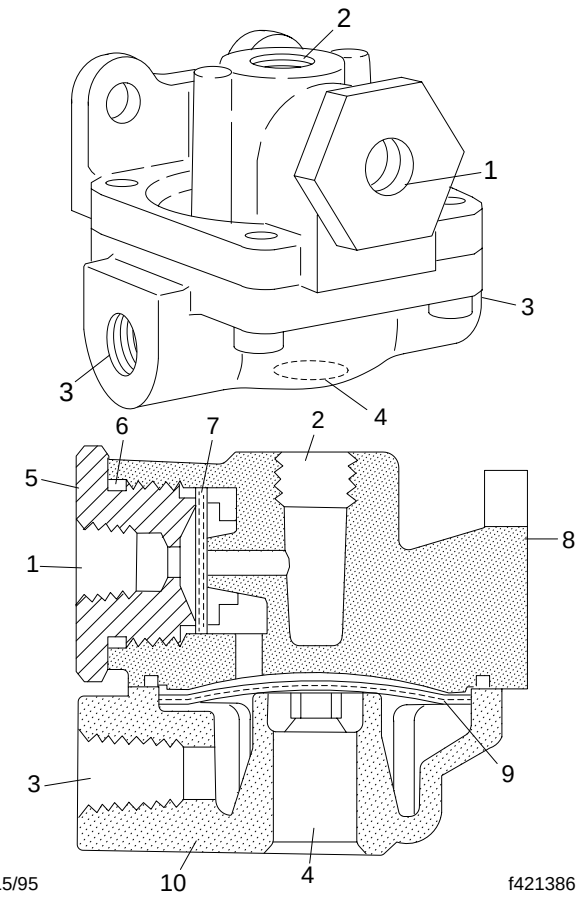
Fig. 1, QR-1C Valve Mounting (plumbing and location will vary depending on vehicle configuration)

WARNING

Before working on or around air brake systems and components, review the safety precautions in Subject 100. Failure to do so could result in personal injury.

1. Chock the tires or hold the vehicle by means other than air brakes.
2. Drain the air brake system.
3. Mark and disconnect the air lines from the quick release valve.
4. Remove the mounting bolts and the valve.

Installation (See Fig. 1)



WARNING

Before working on or around air brake systems and components, review the safety precautions in Subject 100. Failure to do so could result in personal injury.

1. Install the quick release valve with the exhaust port facing down. Securely tighten the mounting bolts.
2. Connect the air lines to the quick release valve in the locations previously marked.
3. Perform the operating and leakage tests in **Subject 110.**

QR–1C Quick Release Valve Disassembly, Cleaning and Inspection, and Assembly

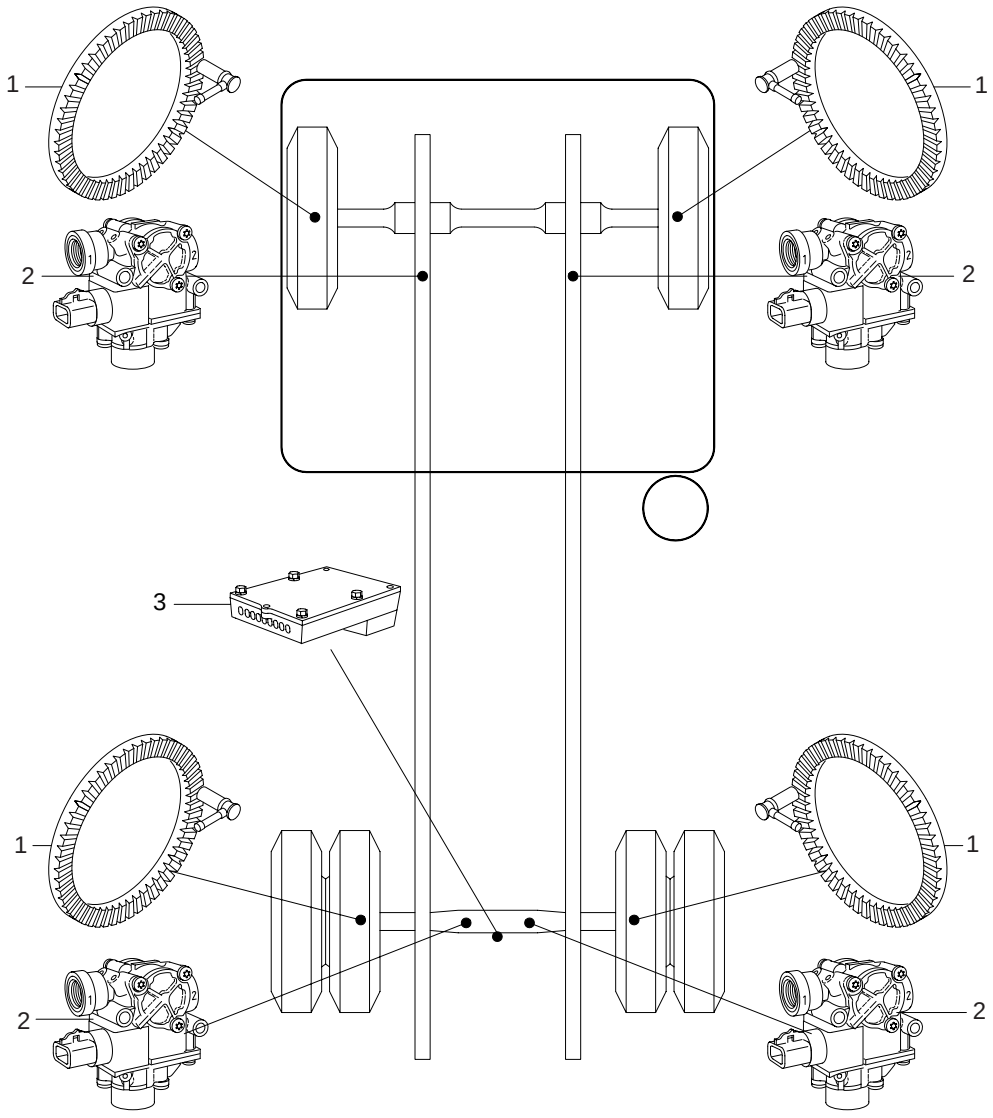
2. Balance Port
3. Delivery Port
4. Exhaust
5. Cap Nut
6. Sealing Ring
7. Double Check Diaphragm
8. Body
9. Quick Release Diaphragm
10. Cover

Fig. 1, QR-1C Valve and Cross Section

1. Remove the quick release valve from the vehicle following the instructions in **Subject 120.**
2. Mark the valve body and cover for ease of installation.
3. Remove the cap nut at the supply port. Remove the sealing ring from the cap nut.
4. Remove the double check diaphragm.
5. Remove the four screws holding the valve cover on the valve body.
6. Separate the cover from the body and remove the sealing ring and the quick release diaphragm.



Cleaning and Inspection

1. Clean all metal parts in mineral spirits. Wipe all rubber parts clean.
2. It is recommended that all rubber parts and any other part showing signs of wear or deterioration be replaced with genuine Bendix parts.

Assembly

1. Install the sealing ring on the cap nut.
2. Install the double check diaphragm in the valve body.
3. Install the cap nut. Tighten the nut 150 to 400 lbf·in (1700 to 4520 N·cm).
4. Install the quick release diaphragm in the cover.
5. Install the valve cover on the body. Tighten the screws 30 to 60 lbf·in (340 to 680 N·cm) evenly and securely.
6. Install the quick release valve, following the instructions in **Subject 120.**
7. Do the operating and leakage test as instructed in **Subject 110.**

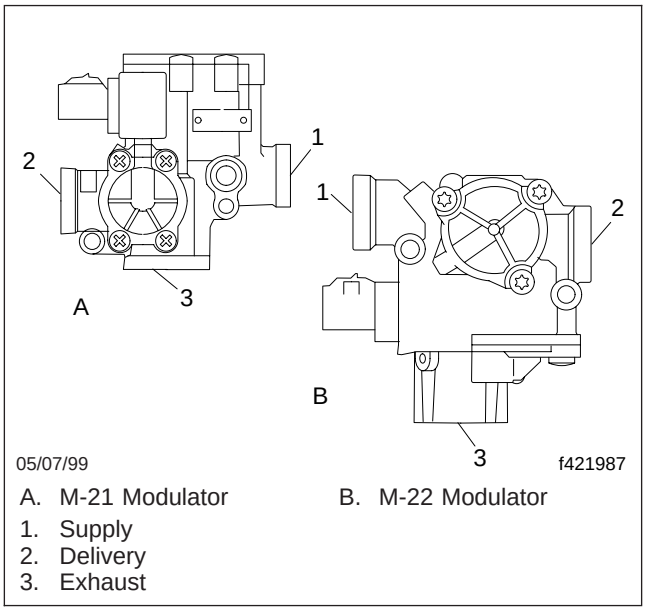
07/02/97 f421526

1. Tone Wheel and Sensor
2. Modulator Assembly
3. Electronic Control Unit (ECU)

Fig. 1, Location of ABS Components, Four-Channel System

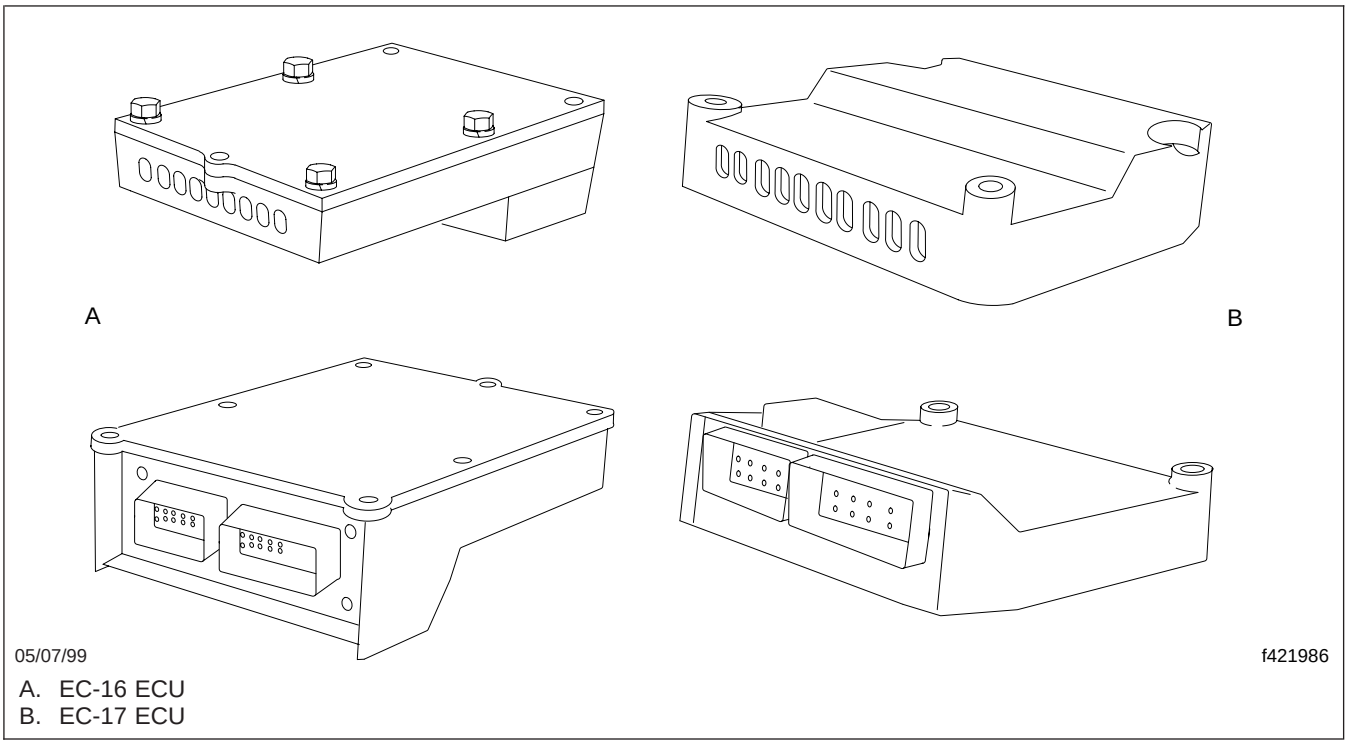
The Bendix® antilock braking system (ABS) is an electronic wheel-speed monitoring and control system that works with the standard air brake system. ABS passively monitors vehicle wheel speed at all times, and controls wheel speed during emergency



General Information

stops. In normal braking applications, the standard air brake system is in effect.

ABS includes signal-generating tone wheels and sensors located in the wheel hubs of each sensed wheel. The sensors transmit vehicle wheel speed information to an electronic control unit (ECU). According to programmed specifications, the ECU signals the appropriate modulator assembly to increase, reduce, or maintain air pressure supply in the brake chamber. This prevents front and rear wheel lockup, and enhances steering control during emergency braking situations.



Principles of Operation

The ABS electronic control unit (ECU) (**Fig. 2**) is a digital microcomputer that serves as the information processing and command center for the ABS. The ECU receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the ECU regulates the braking force applied to each wheel by sending control signals to the modulator assembly (**Fig. 3**).

Fig. 2, EC-16 and EC-17 ABS Electronic Control Units

ABS MAJOR COMPONENTS

Wheel Speed Sensor

The wheel speed sensors use pulse feedback from 100-tooth tone wheels located in the front and rear axle wheel hubs. When the vehicle is moving, the teeth of the tone wheel cause interruptions in a magnetic field created by the sensor. The interruptions created in the magnetic field in turn create electrical pulses that are sent by the sensor to the ECU.

Electronic Control Unit (ECU)

The ECU receives speed sensor pulses and interprets these signals to calculate wheel speed and a vehicle reference speed. If the calculations indicate wheel slip or lockup, the appropriate control circuit signals the modulator assembly to increase or decrease braking pressure.

There are three versions of the ECU. The older versions (EC-15 and EC-16) are factory programmed with vehicle particulars, such as the number of speed sensors, if the traction control feature was enabled and the type of traction control (torque limiting, differential braking, or both).

The current, self-configuring ECU (EC-17) can be most easily identified while installed on the vehicle. Identification can be made by observing the reaction of the diagnostic display when the ignition is turned on and power is applied to the ECU. The current configuration of the ECU is displayed via the troubleshooting LEDs and occurs during the normal self-test sequence. Only the LEDs that correspond to the sensors identified during the self-configuration will illuminate. If all antilock components are working properly, the red LEDs will turn off and the single, green, VLT LED will be illuminated. This configuration review is repeated each time the ignition is turned on.

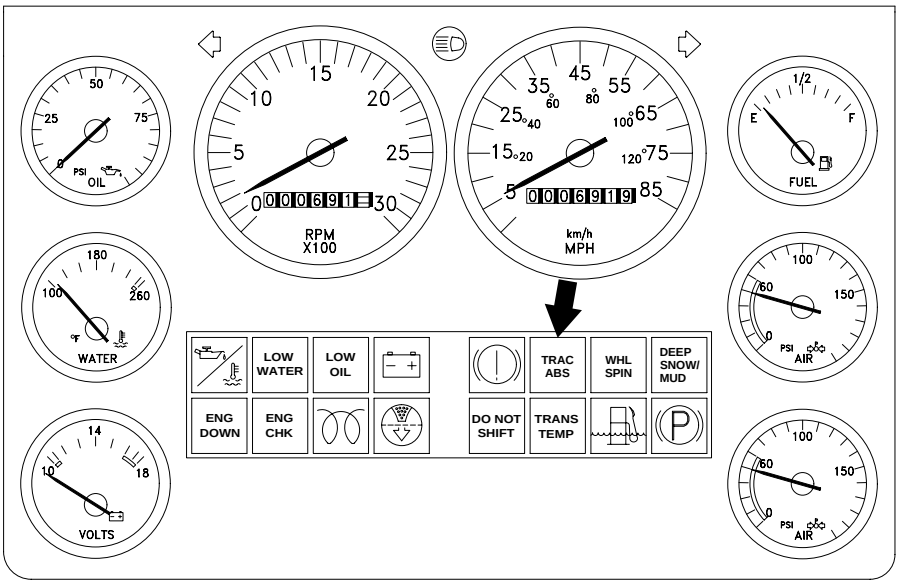
IMPORTANT: The LED display is optional on the EC-17. The EC-17N control unit does not have an LED display and the AlliedSignal Bendix Diagnostic Communication Interface (DCI) must be used for diagnostics or reconfiguration.

On the older versions of the ECU, *all* diagnostic LEDs will illuminate and then go out if all antilock components are working properly. During normal operation, all the red LEDs will be off and the single, green, VLT LED will be illuminated. See **Troubleshooting, 300** for more information on the LED display.

The ECU contains a safety circuit to constantly monitor the wheel sensors, modulator assemblies, and the electrical circuitry. After the ignition is switched on, the tractor warning light (TRAC ABS) comes on. See **Fig. 4**. On vehicles with newer ECUs, the TRAC ABS light will go out shortly after the ignition is turned on. On vehicles with the older ECUs, the TRAC ABS light will stay lit until the vehicle reaches 7 mph (11 km/h). The TRAC ABS light will stay on if the tractor's ABS components are not working properly.

When vehicle power is supplied to the EC-17, a modulator "chuff" test is performed. When the brake pedal is depressed while the ECU is powered up, the modulator "chuff" test can be heard. This test will verify if the modulator is connected correctly and is functional. The modulators will exhaust air in the sequence of right front, left front, right rear and left rear. If they do not follow this sequence, proceed with modulator troubleshooting. See **Troubleshooting, 300**.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (a sensor, modulator assembly, wiring connection, short circuit, etc.), the TRAC ABS light comes on, and the control circuit where the failure occurred is switched to normal braking action. Remaining control circuits will retain the ABS effect. Even if the ABS system is completely inoperative, normal braking is maintained. The vehicle is not disabled.



IMPORTANT: If the ABS warning lights do not work as described above, there is a possible system malfunction. If this occurs, the vehicle will continue to have normal braking ability, but without ABS. Service the ABS as soon as possible. See **Troubleshooting, 300** for fault diagnosis.

Modulator Assembly

To ensure proper operation, ABS solenoid/modulator valves must be plumbed properly. If the valve plumbing is removed during service, care must be taken to ensure the air lines are plumbed to the correct valve ports when reinstalled.

Depending on the signal received from the ECU, the modulator assembly prevents wheel lockup by reducing, maintaining, or increasing brake chamber air pressure. During normal braking applications, com-

General Information

05/10/99 f601812

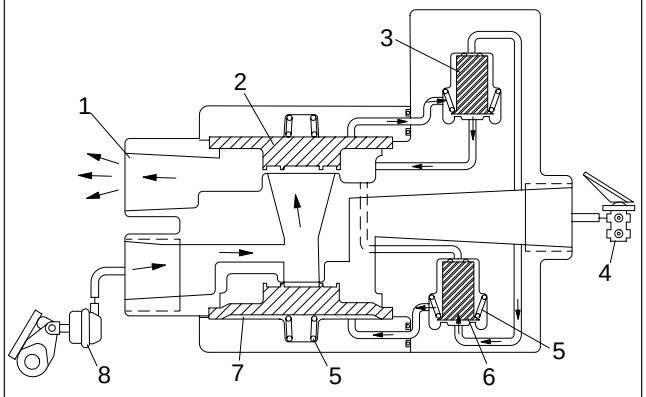


Fig. 4, TRAC ABS Indicator Light

pressed air flows freely to the brake chamber through the modulator assembly.

If the ECU receives signals indicating wheel lockup during a brake application, the ECU energizes both the supply and exhaust solenoids in the modulator assembly. See **Fig. 5**. Energizing the supply solenoid causes its exhaust to close and its inlet to open. With the inlet of the supply solenoid open, application air is permitted to flow to the control side of the supply diaphragm. Air pressure acting on the supply diaphragm causes it to close the supply diaphragm and prevent further delivery of air to the brake chamber.

Energizing the exhaust solenoid closes its inlet and opens its exhaust. By closing the exhaust solenoid inlet, application air is prevented from flowing to the control side of the exhaust diaphragm. Air pressure, which was present on the control side of the exhaust diaphragm flows out the exhaust port of the modulator assembly. With control air pressure removed from the exhaust diaphragm, brake application air forces the exhaust diaphragm to unseat which allows it to flow out the modulator exhaust port.

As wheel speed increases, the modulator assembly alternately increases, then maintains brake pressure until the proper wheel speed is obtained, or until wheel lockup occurs and the control cycle starts again.

3. Exhaust Solenoid Energized
4. Brake Valve
5. Spring
6. Supply Solenoid Energized
7. Supply Diaphragm
8. Brake Chamber

Fig. 5, Wheel Lockup

During the pressure increase cycle (**Fig. 6**), brake application air enters the supply port of the modulator assembly and flows to, and through, the open ex-

haust solenoid, then to the exhaust diaphragm. Air pressure, along with spring force, seats the exhaust diaphragm on the exhaust passage thus preventing the escape of service air. At the same time, application air flows to the supply diaphragm and forces it away from its seat. Air flows past the open supply and out the modulator assembly delivery port to the service brake chambers.

2. Exhaust Diaphragm
3. Exhaust Solenoid
4. Brake Valve
5. Spring
6. Supply Solenoid
7. Supply Diaphragm
8. Brake Chamber

Fig. 6, Pressure Increase

If maintaining brake air pressure (**Fig. 7**), the ECU energizes the supply solenoid and de-energizes the exhaust solenoid. This seats both diaphragms and prevents further exhaust of brake chamber air pressure and prevents the application air from flowing out of the delivery port to the brake chamber.

Replacement

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Group 54** of this manual for information on special terminals and connectors, and on ordering tools for them.

FRONT AXLE

1. Chock the rear tires to prevent vehicle movement. Apply the parking brakes.
2. Twist and pull the sensor to remove it from the steering knuckle (see **Fig. 1**).

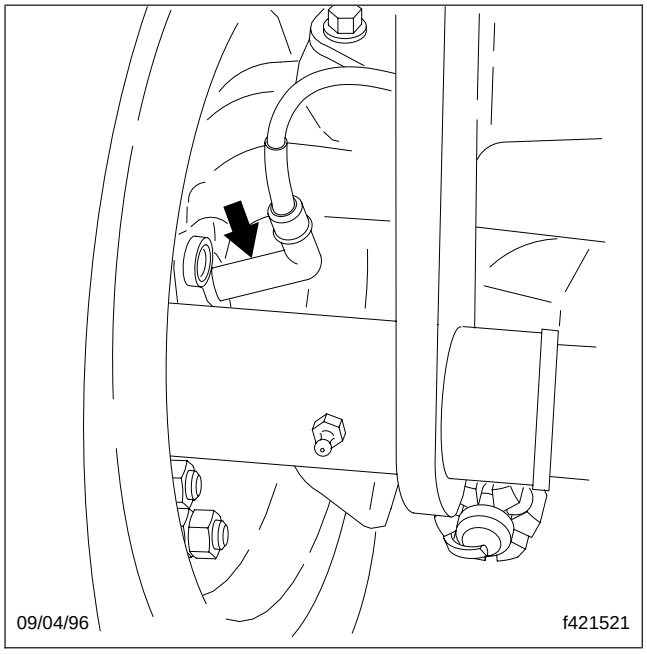

Fig. 1, Wheel Speed Sensor

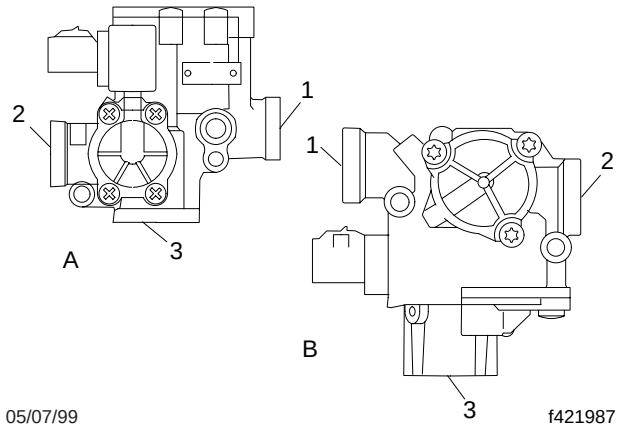
3. Remove the sensor cable from the steering knuckle top cap.
4. Disconnect the sensor cable from the chassis harness.
5. Remove the clamping bushing from the brake spider hole.
6. Connect the sensor cable to the chassis harness.
7. Attach the sensor cable to the steering knuckle top cap.
8. Push the clamping bushing into the brake spider hole until it stops.
9. Coat the sensor with Mobil HP, Valvoline EP 633, Penzoil 707L, or an equivalent grease. Push the sensor into the clamping bushing until it is stopped by the tone wheel.
10. Remove the chocks from the rear tires.

REAR AXLE

1. Chock the front tires to prevent vehicle movement. Apply the parking brakes.
2. Raise the rear of the vehicle until the tires clear the ground. Place safety stands under the axle.
3. Back off the slack adjuster to release the rear axle brake shoes.
4. Remove the wheel and tire assembly from the rear axle. For instructions, see **Group 40** of this manual.
5. Remove the brake drum. For instructions, see **Group 35** of this manual.
6. Twist and pull the sensor to remove it from the mounting block in the axle housing.
7. Remove the clamping bushing.
8. Remove the capscrew that attaches the sensor cable and the hose clamp to the axle tube.
9. Disconnect the sensor cable from the chassis harness.
10. Connect the sensor cable to the chassis harness.
11. Attach the hose clamp and sensor cable to the axle tube located between the backing plate and the spring plate.
12. Push the clamping bushing into the mounting block until it stops.
13. Coat the sensor with Mobil HP, Valvoline EP633, Penzoil 707L, or an equivalent grease. Push the sensor into the clamping bushing until it is stopped by the tone wheel.
14. Install the brake drum on the wheel hub.
15. Adjust the rear axle brakes. For instructions, see **Group 42** of this manual.

Wheel Speed Sensor Replacement

16. Install the wheel and tire assembly, and tighten the wheel nuts. Use the tightening sequence and torque values listed in **Group 40** of this manual.
17. Remove the safety stands, lower the vehicle, and remove the chocks from the front tires.



Replacement

WARNING

Reversal of supply and delivery air lines plumbed to the modulator could cause the vehicle brakes to lock up, and remain locked, during a hard brake application. Locked brakes may cause the vehicle to slide or cause loss of steering and/or stability, possibly resulting in vehicle damage or personal injury.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Group 54** of this manual for information on special terminals and connectors, and on ordering tools for them.

1. Chock the front and rear tires.
2. Release the pressure from the air reservoirs.
3. Disconnect the wiring from the modulator assembly.
4. Disconnect the air supply line (**Fig. 1**) and the air discharge line.

A. M-21 Modulator
B. M-22 Modulator
1. Supply
2. Delivery
3. Exhaust

Fig. 1, M-21 and M-22 Modulator Assemblies

IMPORTANT: Modulator porting is reversed on the M-21 modulator.

5. Remove the two mounting capscrews and nuts.
6. Remove the modulator assembly.
7. Position the modulator assembly and install the two mounting capscrews and nuts. Tighten the mounting nuts 18 lbf·ft (24 N·m).
8. Connect the air supply line (**Fig. 1**) and the air discharge line.

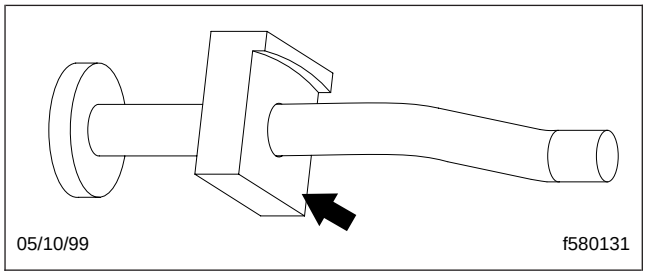
IMPORTANT: Modulator porting is reversed on the M-21 modulator.

9. Connect the wiring to the modulator assembly.
10. Remove the chocks from the front and rear tires.

Adjustment

NOTE: The following adjustment procedure requires the use of special tool T11–17556–000. Use of this tool, available through the PDCs, eliminates the time-consuming task of removing the wheel and tire assembly, and the brake drum. See **Fig. 1**.

1. Park the vehicle on level ground, set the parking brake, and shut down the engine.



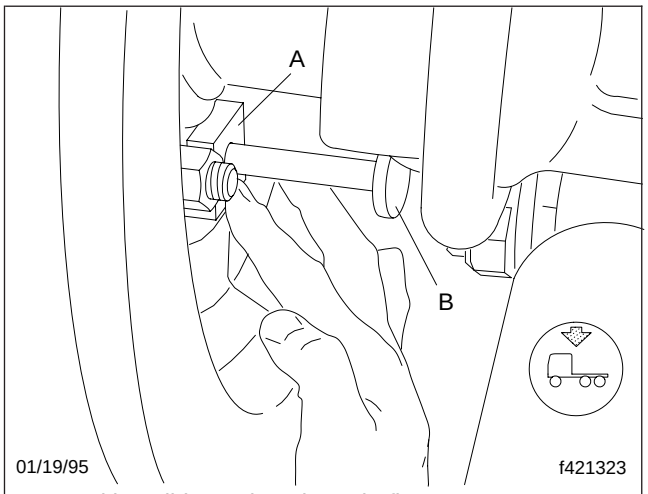


Fig. 1, ABS Sensor Adjustment Tool Slide

2. Chock the front tires.
3. Find the sensor access hole in the rear axle flange.
   - 3.1 View the brake drum and axle from the rear. The ABS sensor wiring harness should be visible passing through a hole in the 12 o'clock position.
   - 3.2 Find the S-cam at either the 3 o'clock or 9 o'clock position.
   - 3.3 Just opposite the S-cam is the sensor access hole, approximately 3/4 inch (19 mm) diameter.
4. Insert the service tool T11–17556–000 into this hole.
5. Position the slide of the tool on the axle flange to align the tool. See **Fig. 2**.
6. Tap the tool lightly with the palm of your hand. This will ensure the sensor is touching the tone wheel.
7. Remove the tool from the wheel and repeat the procedure on the other rear axle speed sensor.
8. Remove the chocks from the tires.

A. Position slide against the axle flange.
B. Tap here with your hand.

Fig. 2, Position the Tool

Using the Electronic Control Unit (ECU) Panel Lights (LEDs)

This system has built-in diagnostics to ensure that all components are operating properly. After the ignition is turned on, the tractor warning light (TRAC ABS) comes on. On vehicles with newer ECUs, the TRAC ABS light will go out shortly after the ignition is turned on. On vehicles with the older ECUs, the TRAC ABS light will stay lit until the vehicle reaches 7 mph (11 km/h). The TRAC ABS light will go out if the tractor's ABS components are working properly. See "Electronic Control Unit (ECU)" in **Subject 050** for more information. If the light stays on, or comes back on later, a problem within the ABS system has occurred. The vehicle can continue to be driven, but the ABS system could be partially or completely inoperative. However, normal braking ability is maintained. To check the type of fault code recorded, stop the vehicle and turn off the engine. Then, turn on the ignition switch, but do not start the engine. If the warning light is still on, there is a system fault that must be repaired to ensure proper system operation. Faults are displayed by the ECU panel lights. See **Fig. 1**. If the warning light is not on, an "intermittent" fault has occurred. An intermittent fault could involve a power surge, taking the system out of voltage range for a moment. In such cases, the problem basically corrects itself; the ECU memory is cleared and the system is restored to full ABS capability.

NOTE: LED lamps are not serviceable.

Following is a list of the faults displayed by the ECU panel lights (**Fig. 1**). Once a fault has been recorded, turn on the ignition switch, but do not start the engine.

- FRT (front): This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the right (RHT) or left (LFT) display light, and the modulator (MOD) or sensor (SEN) display light.
- MID (middle or forward sensed rear axle on 6S/4M systems only): This red lighted display indicates the location of a malfunctioning sensor or its wiring. This light will always come on with either the RHT or LFT display light, and the SEN display light.

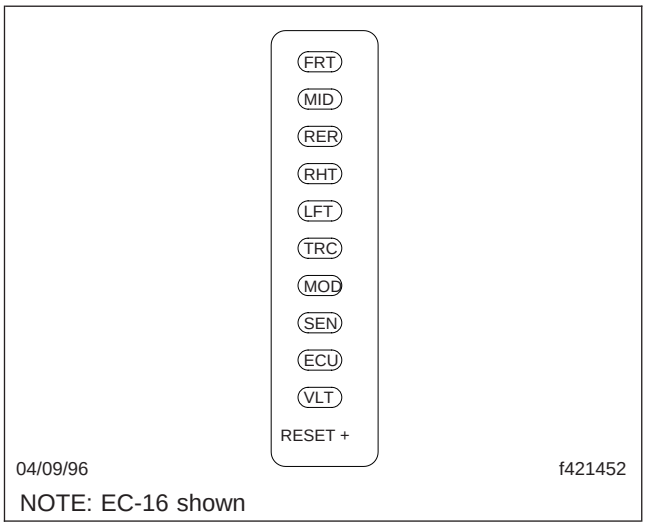

Fig. 1, ECU Panel Lights (LEDs)

- RER (rear): This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the RHT or LFT display light, and the MOD or SEN display light.
- RHT (right): This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the FRT or RER display light, and the MOD or SEN display light.
- LFT (left): This red lighted display indicates the location of a malfunctioning component or its wiring. This light will always come on with either the FRT or RER display light, and the MOD or SEN display light.
- TRC (traction control, if equipped): This red lighted display indicates a problem within the traction control system. This light may come on by itself, or with the MOD display light (indicating a problem within the automatic traction control relay valve).
- MOD (modulator): This red lighted display indicates an open or short circuit in the solenoid(s) of one of the modulators. This light will always come on with two positioning display lights RHT or LFT plus FRT or RER. The light may also come on with the TRC display light which would indicate a problem within the automatic traction control relay valve or its wiring. Also, the red MOD light will come on if:

Troubleshooting

- The traction enable/disable switch is in the wrong position;
- Traction engine serial communication is lost;
- The traction solenoid is not connected or not operating properly.

- SEN (sensor): This red lighted display indicates an open or short circuit in the sensor circuit. This light will always come on with two positioning display lights RHT or LFT plus FRT, MID, or RER.
- ECU (electronic control unit): This red lighted display indicates that the ECU is inoperative.
- VLT (voltage): This green lighted display is always on during vehicle operation. The light indicates proper system voltage. If vehicle power is out of range (below 11 or above 17 volts), the light will flash until the power problem is corrected.
- RESET: Beneath the reset display is a magnetically sensitive switch used to clear fault codes and reset the ABS diagnostic system. This switch is also used to self-configure the ECU.

A system fault cannot be cleared from ECU memory until the fault is corrected. Once corrected, faults can be cleared one at a time from ECU memory. To clear a fault, pass a small magnet (capable of lifting a three ounce weight) over the RESET display on the ECU (**Fig. 1**). Once all of the lights on the ECU come on, remove the magnet. Holding the magnet against the RESET display for longer than 10 to 20 seconds could cause the ECU to go into a self-configuration mode.

Before troubleshooting, check all fuses in the control unit panel, and replace if necessary. Check the wiring to the warning lights. Refer to **Table 1**, and repair or replace the wiring as needed. Make sure that a charged 12-volt battery is available (the ABS system needs at least 11 volts to work).

IMPORTANT: The key switch must be on when doing the tests in **Table 1.**

Once a fault code has been identified, use a volt/ohmmeter to check the electrical harness at the ECU's 30-pin or 18-pin connector. See **Fig. 2** and **Fig. 3**. Touch the ohmmeter leads to the applicable terminals on the connector, not the ECU.

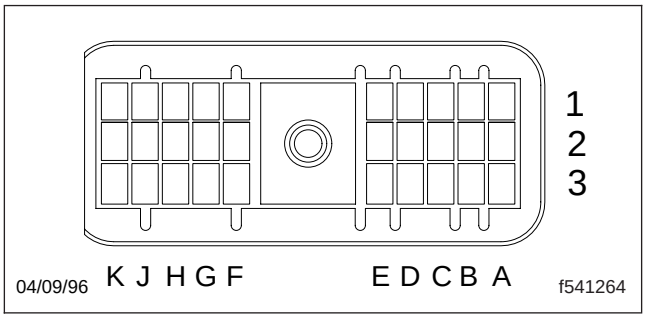

Fig. 2, 30-Pin Connector, Terminal View

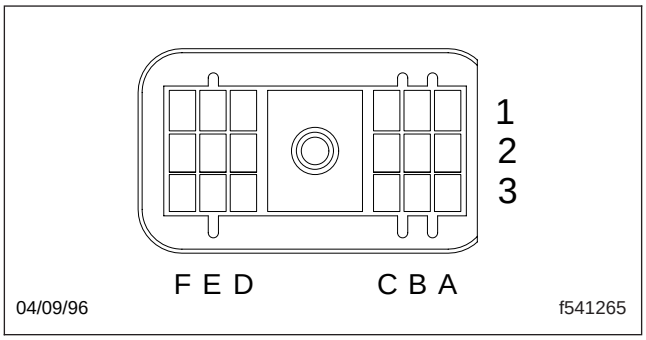

Fig. 3, 18-Pin Connector, Terminal View

IMPORTANT: The ignition switch must be off when connecting or disconnecting the ECU.

Refer to the problem charts for a listing of all diagnostic panel displays (system faults), terminals to be tested, and the correct volt/ohmmeter readings. Repair or replace the components and/or wiring if the readings are not correct.

NOTE: If a dealer has Freightliner Service Link, fault code information can be read from Service Link. For more information, see Service Bulletin 00-20.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals.

See **Group 54** of this manual for information on special terminals and connectors, and for information on ordering tools for them.

See the appropriate wiring diagram in **Specifications, 400** when troubleshooting the ABS system.

Warning Lamp Wiring Check				
Wiring Tested	**Test These Pins**	**Volt/Ohmmeter Reading**	**Possible Cause**	**Remedy**
Tractor Warning (TRAC ABS) Light	On the 30-pin connector, pins E3 and A1, E3 and A2, and E3 and A3.	Voltage should be the same as battery voltage.	Wiring to the light is shorted or open; or the bulb needs replacing.	Repair the wiring, or replace the bulb.
WHL SPIN Light (if equipped with ATC)	On the 30-pin connector, pin C2.			

Table 1, Warning Lamp Wiring Check

Problem—Battery Voltage is Too Low or Too High (Green VLT LED is Flashing)

Problem—Battery Voltage is Too Low or Too High (Green VLT LED is Flashing)	
Possible Cause	**Remedy**
Damaged ECU or unsatisfactory battery voltage and wiring continuity	If VLT or ECU is displayed, test the voltage on the 30-pin connector between battery terminals B1, K2, K3, and ground terminals A1, A2, and A3. Voltage between the terminals should be 11 to 17 volts. If the voltage readings are okay, replace the ECU. If the voltage readings are incorrect, check the battery voltage and wiring continuity. Repair or replace as needed.

Problem—Sensor Out of Adjustment, Wheel Speed Erratic, or Sensor Circuit Damage (Red SEN LED is On)

Problem—Sensor Out of Adjustment, Wheel Speed Erratic, or Sensor Circuit Damage (Red SEN LED is On)	
Possible Cause	**Remedy**
Damage to the tone wheel, wheel sensor, and/or sensor wiring to the ECU on the axle	If RHT or LFT and FRT plus SEN is displayed, measure the resistance on the 30-pin connector between terminals J1 and J2 (left front), and H2 and H3 (right front). If the readings are not 1500 to 2500 ohms, measure the resistance between the terminals at the sensor. Repair or replace as needed. If RHT or LFT and RER plus SEN is displayed, measure the resistance on the 18-pin connector between terminals F2 and F3 (left rearmost), and E2 and E3 (right rearmost). If the readings are not 1500 to 2500 ohms, measure the resistance between the terminals at the sensor. Repair or replace as needed. If RHT or LFT and MID plus SEN is displayed on the 18-pin connector, measure the resistance between terminals C2 and C3 (left rear), and B2 and B3 (right rear). If the readings are not 1500 to 2500 ohms, measure the resistance between the terminals at the sensor. Repair or replace as needed.
A sensor may be out of adjustment, or there is excessive hub runout	
Tire size is mismatched	Repair or replace as needed.

Troubleshooting

Problem—Open or Short Circuit in the Modulator, and/or Wiring to the Ground Connection (Red MOD LED is On)

Problem—Open or Short Circuit in the Modulator, and/or Wiring to the Ground Connection (Red MOD LED is On)	
Possible Cause	**Remedy**
Damage to the modulator valve and cab wiring connections on the axle	If RHT or LFT and FRT plus MOD is displayed, measure the resistance on the 30-pin connector between terminals G1 and H1 (left front), C1 and D1 (right front), F1 and H1 (left front), and C1 and E1 (right front). The resistance between the terminals should read 3.5 to 5.0 ohms. Measure the resistance between terminals G1 and F1 (left front), and D1 and E1 (right front). Resistance between the terminals should read 7 to 10 ohms. Also, there should be no continuity between any of the previously referenced terminals, and ground terminals A1, A2, A3, and J3. If the above readings are not correct, check the resistance between the pins at the modulator valve (see **Fig. 4**). Resistance between pins A and B, and B and C should be 3.5 to 5.0 ohms. Resistance between pins A and C should be 7 to 10 ohms. There should be no continuity between any of these pins and ground. Repair or replace as needed. If RHT or LFT and RER plus MOD is displayed, measure the resistance on the 18-pin connector between terminals E1 and F1 (left rear), A1 and B1 (right rear), D1 and F1 (left rear), and A1 and C1 (right rear). Resistance should read 3.5 to 5.0 ohms. Measure the resistance between terminals D1 and E1 (left rear), and B1 and C1 (right rear). Resistance between the terminals should read 7 to 10 ohms. Also, there should be no continuity between any of the previously referenced terminals, and ground terminals A1, A2, A3, and J3. If the above readings are not correct, check the resistance between the pins at the modulator valve (see **Fig. 4**). Resistance between pins A and B, and B and C should be 3.5 to 5.0 ohms. Resistance between pins A and C should be 7 to 10 ohms. There should be no continuity between any of these pins and ground. Repair or replace as needed.

Problem—Open or Short Circuit in the Traction Control Relay Valve and/or Wiring to the Ground Connection (Red

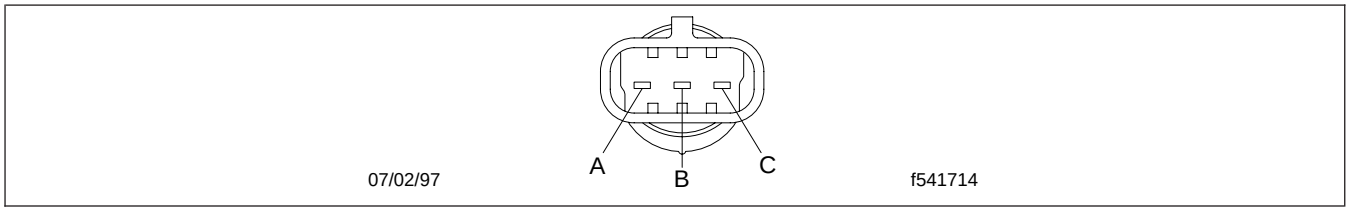

Fig. 4, Modulator Valve Connector Pin Identification

TRC LED and Red MOD LED are On)

Problem—Open or Short Circuit in the Traction Control Relay Valve and/or Wiring to the Ground Connection (Red TRC LED and Red MOD LED are On)	
Possible Cause	**Remedy**
Open or shorted circuit in the traction control relay valve and/or cab wiring connections	If TRC and MOD is displayed, measure the resistance on the 18-pin connector between terminals D2 and D3. Resistance between the terminals should be 10 to 12 ohms. Check continuity at the 30-pin connector between terminals A1, A2, A3, and terminals D2 and D3. There should be no continuity between these terminals. If the above readings are not correct, check the resistance between the pins at the connector at the relay valve. Resistance between the pins should be 10 to 12 ohms. There should be no continuity between ground pins A1, A2, and A3 (on the 30-pin connector), and the pins D2 and D3 at the valve connector. Repair or replace as needed.

Problem—J 1922 Electronic Engine Data Link is Not Working Properly (Red TRC LED is On)

Problem—J 1922 Electronic Engine Data Link is Not Working Properly (Red TRC LED is On)	
Possible Cause	**Remedy**
Damage to the data link and/or data link wiring	If TRC is displayed, check for continuity between terminals B2 and B3 on the 30-pin connector, and the two corresponding terminals on the engine's electronic control module. Repair or replace as needed.

See **Fig. 1** for a full view of the wiring diagram for the Bendix ABS system. See **Fig. 2** and **Fig. 3** for partial (detailed) views of **Fig. 1**.

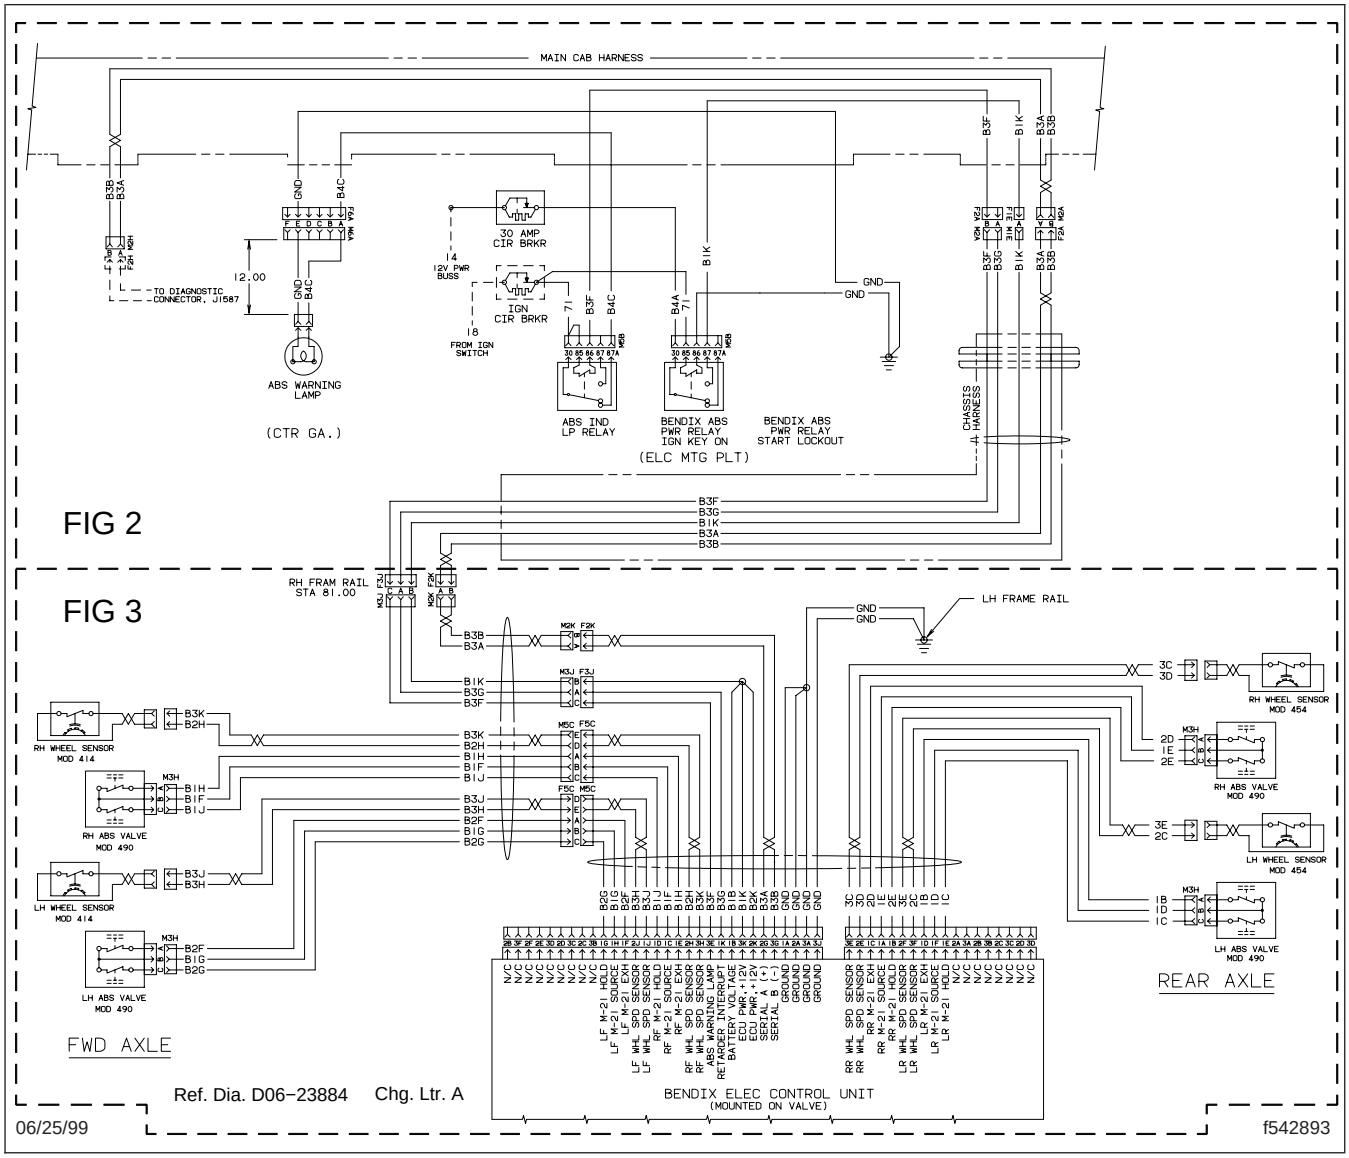

Fig. 1, Wiring Diagram for the Bendix ABS System

Specifications

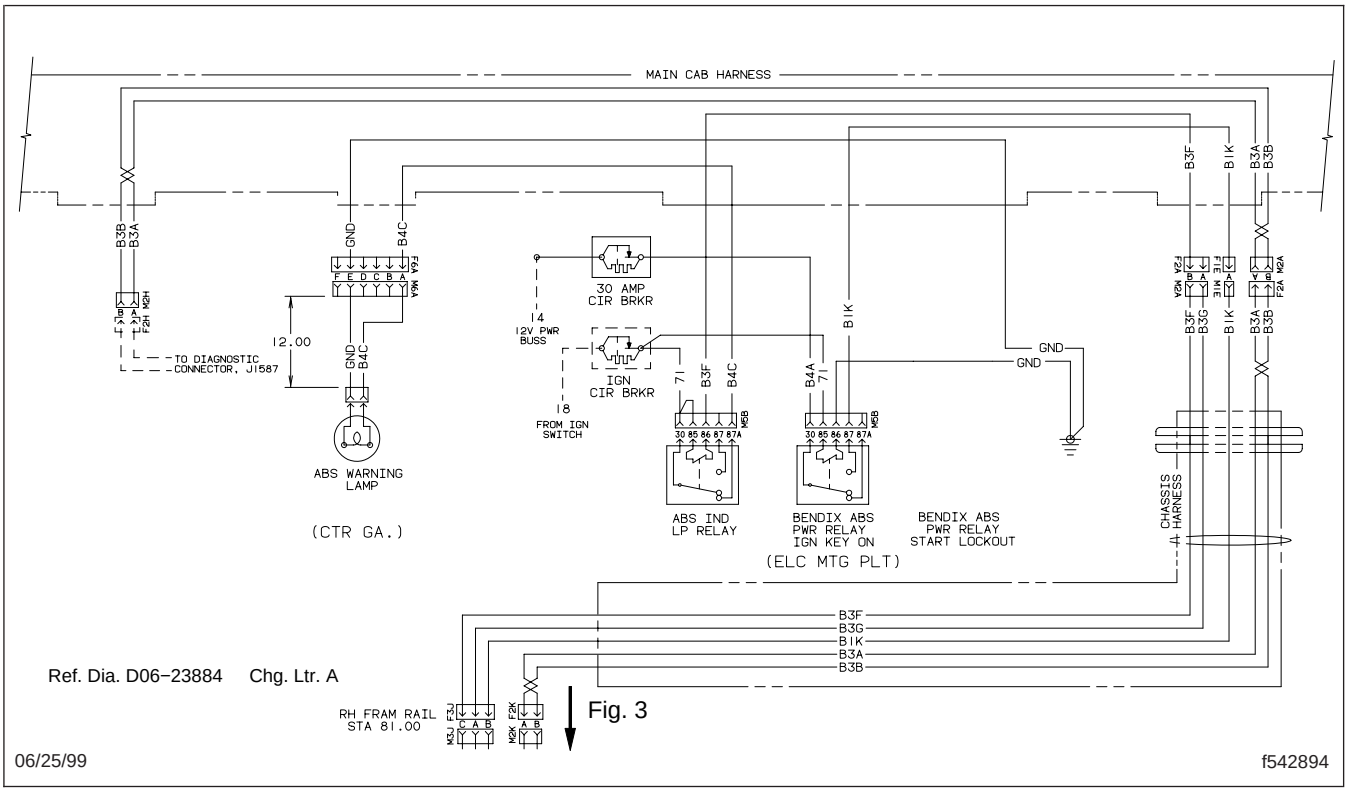

Fig. 2, Partial View of the Bendix ABS System Wiring Diagram

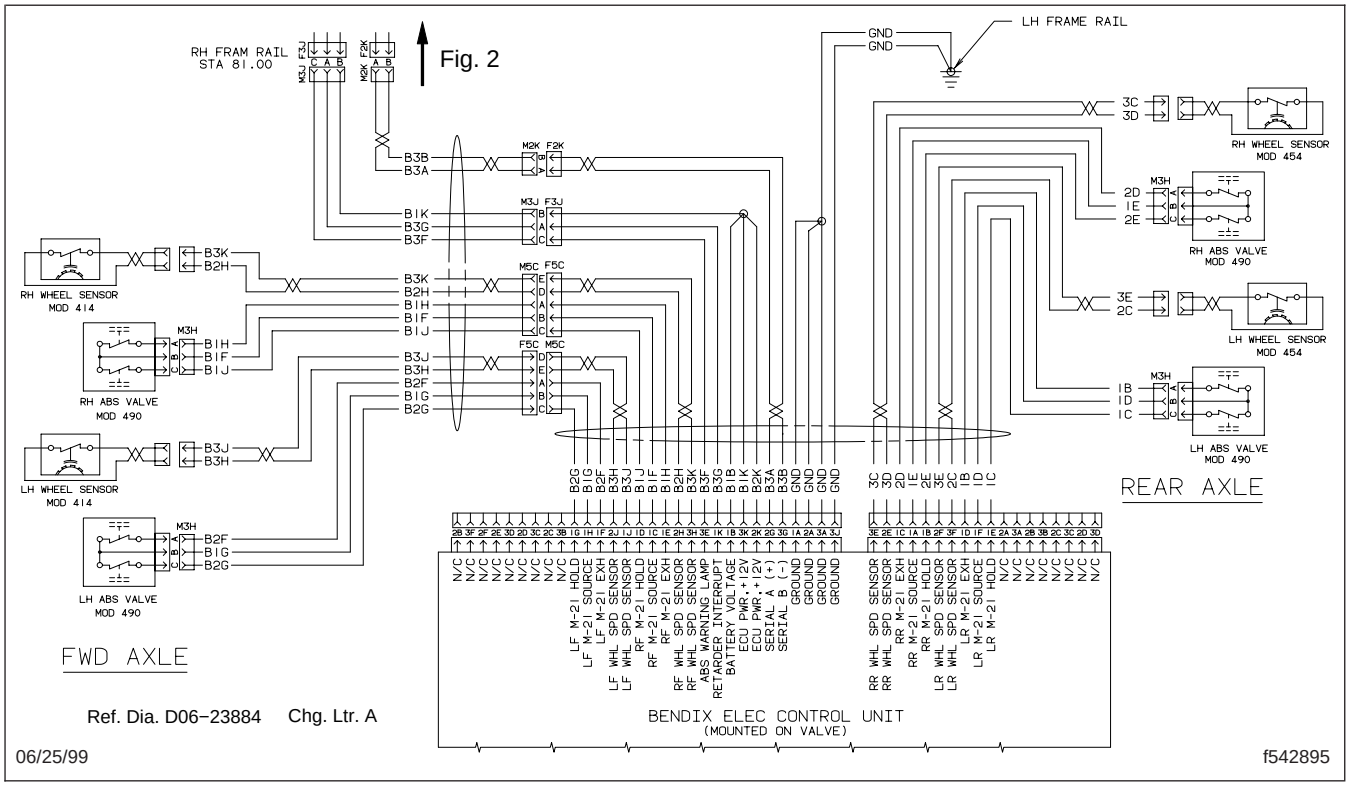

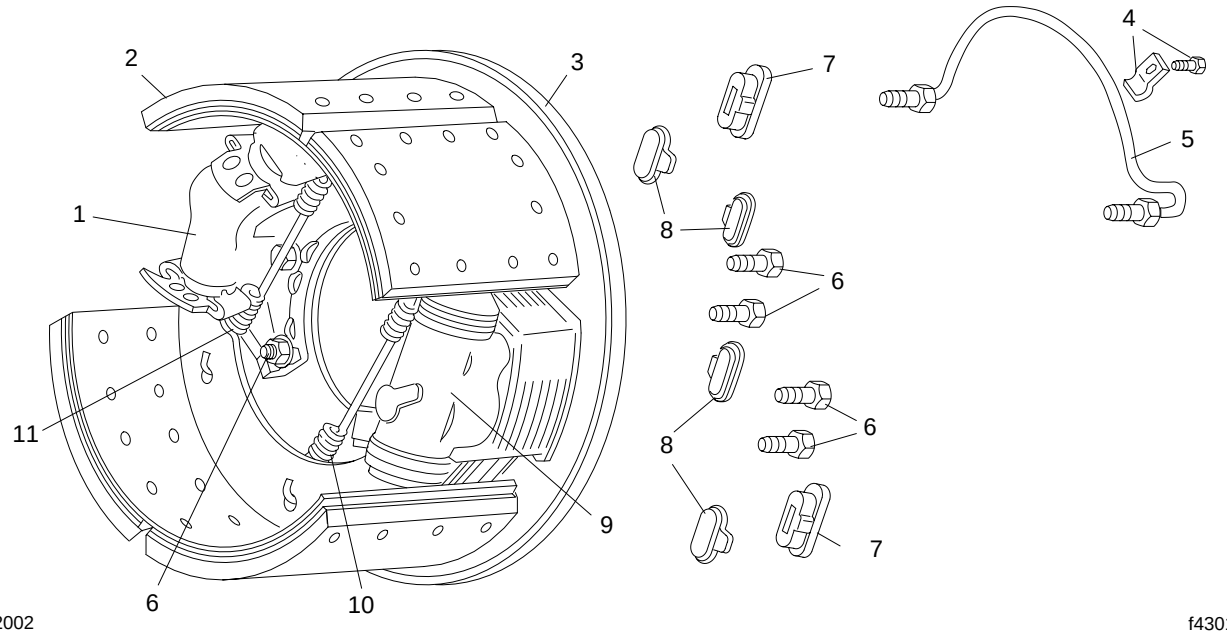

Fig. 3, Partial View of the Bendix ABS System Wiring Diagram

General Description

DURAPARK® rear hydraulic drum brakes are self-adjusting and include a parking brake function as an integral part of the brake assembly. Each DURAPARK brake consists of a backing plate, two brake shoes and lining assemblies, an adjuster cylinder, and a park cylinder. See **Fig. 1**.

- Two lining inspection holes allow for inspection and measurement of the shoe-to-drum clearance.
- Two adjuster slots provide access to the manual override wheel of the adjuster cylinder to increase or decrease the shoe-to-drum clearance. This should only be needed to set a specific shoe-to-drum clearance during initial installation or for backing the shoes off to enable a lipped drum to be removed.
- Two adjuster sight holes are used to make sure the adjusting tool is inserted in the adjusting slot correctly without damaging the dust boot on the cylinder.

NOTE: Brake configuration for spring suspensions shown.

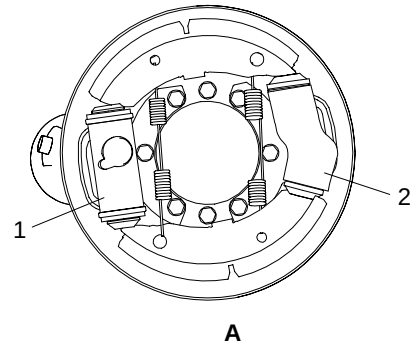
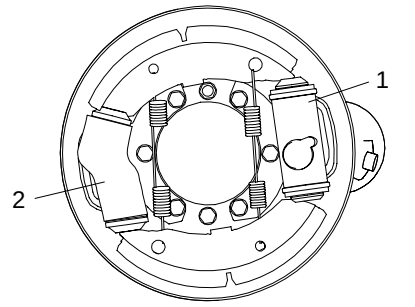
9. Park Cylinder Assembly
10. Return Spring, Orange or White
11. Return Spring, Green or Yellow

Fig. 1, DURAPARK Rear Hydraulic Drum Brake Assembly



IMPORTANT: The figures in this subject illustrate installation of brakes on vehicles with spring suspensions. On vehicles with Freightliner AirLiner suspensions, the park cylinder and adjuster cylinder positions are reversed. See **Fig. 2**.

The two cylinders are conventional wheel cylinders with special functions. The adjuster cylinder contains automatic adjusters that maintain the shoe-to-drum clearance within a specified range. The park cylinder applies and releases the brake shoes for parking.



The backing plate has six mounting holes:

NOTE: There are more than six total holes in the backing plate. Additional holes are used for mounting the ABS sensor on some applications.

2. Adjuster Cylinder

Fig. 2, DURAPARK Brake Configurations

Principles of Operation

Service Brake Operation

The adjuster and park cylinders are connected to each other through a bridge pipe. As a result, increasing the hydraulic pressure in one also increases the pressure in the other.

When the brake pedal is applied, increased hydraulic pressure in the adjuster cylinder forces two pistons outward, moving one end of each shoe toward the drum. At the same time, increased pressure in the park cylinder forces its pistons outward, moving the other end of each shoe toward the drum.

When the shoes contact the drum, they are forced around in whichever direction the drum is moving until the pistons stop against the cylinder body. Thus, regardless of forward or reverse rotation, the brake is always a two leading-shoe brake.

In the forward direction the torque load is taken by one adjuster cylinder piston bottoming in its bore, and by the park cylinder abutment piston head resting against the cylinder body. In the reverse direction, the torque is taken by the other adjuster cylinder piston bottoming and the expander piston head resting against the park cylinder body.

Parking Brake Operation

When the parking brakes are applied, the hydraulic pressure in the spring chamber is released. A spring in the parking brake chamber then forces a wedge and roller assembly into the park cylinder and forces the pistons outward, pressing the shoes against the drums.

Automatic Adjustment

In the DURAPARK brake, automatic adjustment is carried out by the adjuster cylinder. The adjuster cylinder contains two adjuster units, each unit individually adjusting the appropriate shoe. The clearance between the shoe and the drum is governed by the axial clearance (backlash) built into each adjuster mechanism.

Automatic brake shoe adjustment as the lining material wears has important advantages:

- An optimum shoe-to-drum clearance is maintained.
- Response time of the brake is kept to a minimum.
- Hydraulic brake fluid movement is kept to a minimum.
- Excessive taper wear of the lining along the shoe is avoided and lining life maximized.
- Vehicle downtime for adjustment is eliminated.

Although DURAPARK brakes adjust automatically and maintain the shoe-to-drum clearance within a specified range, correct and full adjustment occurs only when the drum is rotating. Pumping the brake pedal with the vehicle stationary will not achieve the proper adjustment.

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH.

⚠ WARNING

Hydraulic brake fluid is hazardous, and can cause blindness if it gets in your eyes. Always wear safety glasses when handling brake fluid or bleeding brake components. Brake fluid may also be a skin irritant. If you get it on your skin, wash it off as soon as possible.

Safety Precautions

Medical experts believe that long-term exposure to some brake lining fibers could be a health hazard, so the following precautions should be observed when servicing all brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

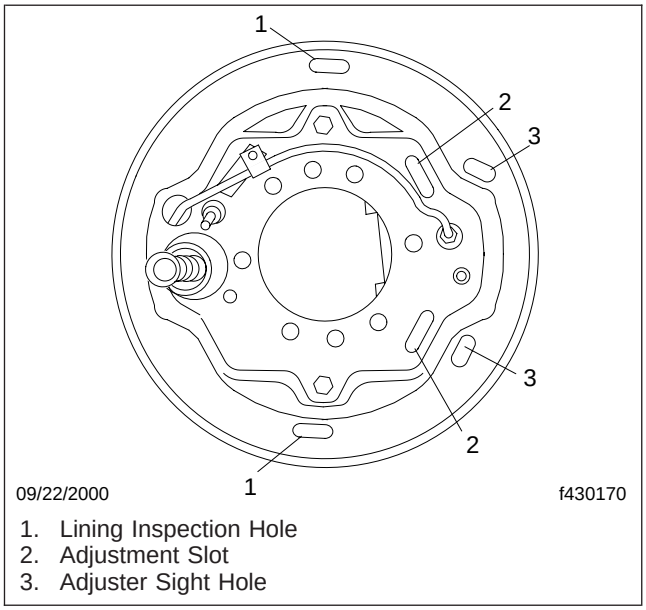
Special care must be taken when disposing of used brake fluid. Put the fluid in a sealed plastic container and label it "Used Brake Fluid." Then dispose of it in an approved manner. Check with local and state regulations as to the correct disposal procedure.

Removal

WARNING

Before doing this procedure, read the information in Safety Precautions 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Park the vehicle on a level surface and chock the front tires.
2. Make sure the parking brakes are released. Releasing the parking brakes pressurizes the spring chambers and compresses the parking brake springs. The engine must be running while the parking brakes are released.



WARNING

When work is being done on the spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

3. Carefully cage and lock the springs so that the springs cannot actuate during disassembly.
4. Set the parking brakes to release the parking brake system pressure, then shut down the engine.
5. Raise the rear axle and place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
6. Remove the wheels. For instructions, see **Section 40.00**, Subject 100.
7. Remove six rubber plugs from the backing plate. See **Fig. 1**.
   - two lining inspection hole plugs
   - two adjustment slot plugs
   - two adjuster sight hole plugs

CAUTION

When backing off the brake shoes, brake fluid will be displaced from the adjuster cylinder bore. Make sure this action does not displace other pistons on the axle.

1. Lining Inspection Hole
2. Adjustment Slot
3. Adjuster Sight Hole

Fig. 1, Backing Plate Access Holes

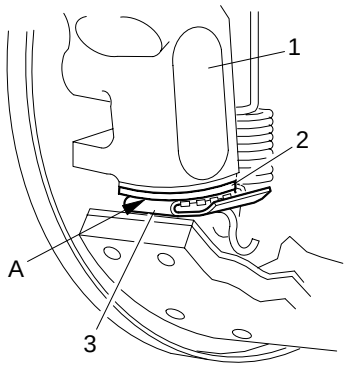
IMPORTANT: The adjustment procedures in this subject are for vehicles with spring suspensions. On vehicles with Freightliner AirLiner suspensions, the park cylinder and adjuster cylinder positions are reversed. Therefore, the adjustment procedure should be adjusted accordingly when working on a vehicle with AirLiner suspensions.

8. Back off the brake shoes.

CAUTION

Take care not to damage the dust boot with the adjusting tool.

8.1 Insert the adjusting tool (OTC part number D90T-2588-AR) in the upper adjustment slot in the backing plate. See **Fig. 3**.



IMPORTANT: A 1/16-inch gap must exist between the override wheel assembly and the dust boot. See **Fig. 2**. The 1/16-inch gap is necessary to ensure that the internal adjuster does not bottom-out in the piston, as this will prevent the adjust from operating.

8.2 With the brake shoes and return springs in place, manually back off (de-adjust) the

Brake Shoe Removal and Installation

upper brake shoe by pushing the adjusting tool to the right.

Back off the shoe enough to ensure that any drum lip will clear the brake shoes during drum removal. View the clearance through the lining inspection holes.

06/26/2001 f430267

A. 1/16-inch gap between override wheel assembly and dust boot.
1. Adjuster Cylinder
2. Dust Boot
3. Override Wheel Assembly

Fig. 2, Gap Measurement at Cylinder

8.3 Move the adjusting tool to the lower adjustment slot.

8.4 Back off the lower brake shoe by pushing the adjustment tool to the left.

9. Remove the brake drums. For instructions, see **Section 35.01**, Subject 100.

CAUTION

Do not apply service or parking brakes after the brake drums are removed. The unrestricted brake shoe movement may damage the cylinders.

IMPORTANT: Additional de-adjustment can be done at this time before the brake shoes are removed. Once the shoes are removed, the previous procedure cannot be used to de-adjust the adjuster cylinder.

CAUTION

When removing the brake shoes, do not allow the brake shoe assembly to contact the dust boots on the adjuster or park cylinder. To do so could damage the boots.

10. Remove the brake shoes. Vehicles with rotated brakes are those equipped with AirLiner suspensions.

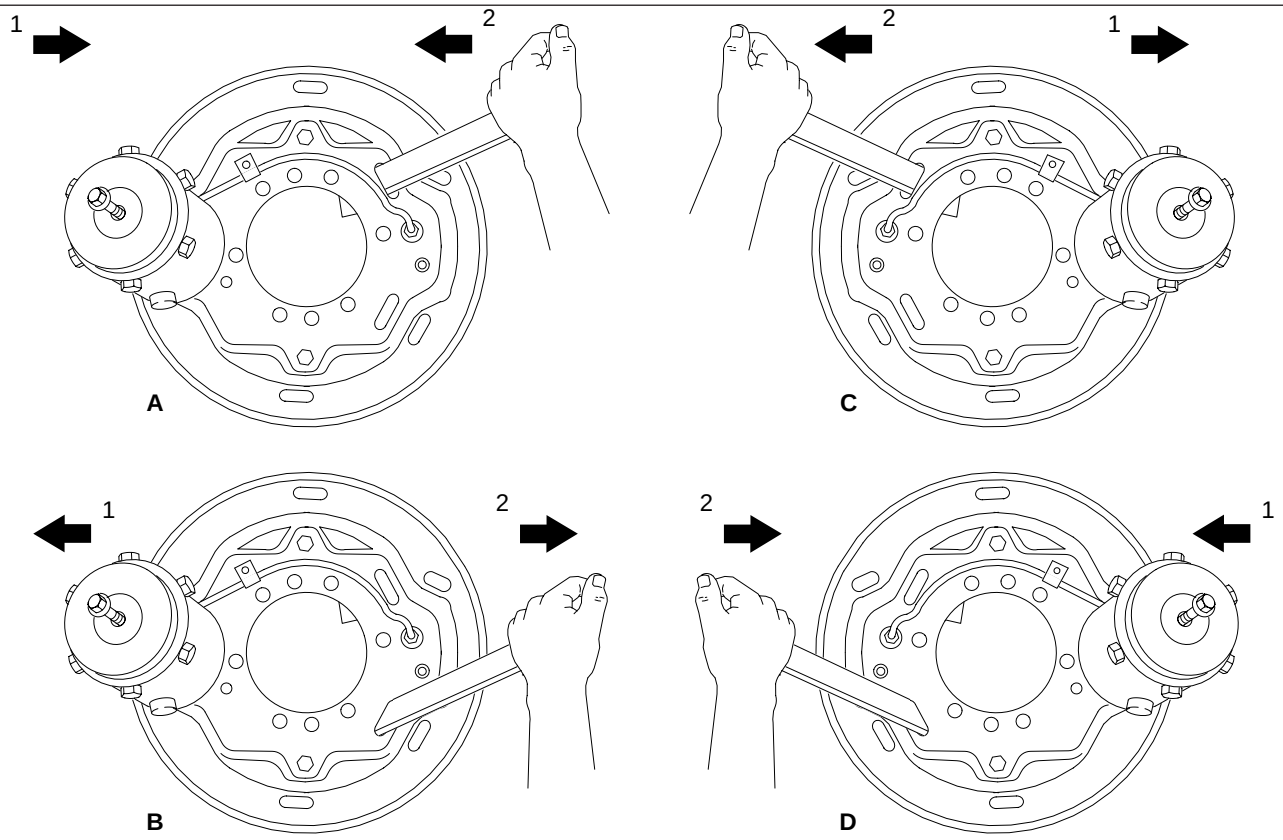
10.1 Place a durable load plate (at least 4 x 1 x 1/8-inch) against the brake lining on the adjuster cylinder end of the upper shoe (lower shoes on rotated brake). See **Fig. 4**.

10.2 Using a 12-inch (or larger) adjustable wrench to grip the shoe and load plate, lift the upper shoe (lower shoe for rotated brake) out of the slot on the top of the adjuster cylinder.

10.3 Rotate the shoe slightly outboard, then lower it with the shoe web resting as far down on the protective shield (next to the slot) as possible. This reduces the tension on the spring for the next step. Remove the wrench and load plate.

10.4 Insert the spring tool, OTC part number 7462 or equivalent (**Fig. 5**), in the loop on the lower end of the adjuster cylinder return spring. See **Fig. 6**. Unhook the spring from the lower shoe.

10.5 Place the load plate against the brake lining on the park cylinder end of the lower shoe (upper shoe for rotated brake).



CAUTION

Do not allow the brake shoe or web to contact the dust boot on the park cylinder. To do so could damage the boot.

10.6 Using the adjustable wrench to grip the lower shoe (upper shoe for rotated brake) and load plate, lower the shoe out of the slot on the bottom of the park cylinder.

10.7 Rotate the shoe outboard, then place the shoe on the end of the park cylinder. Remove the wrench and load plate.

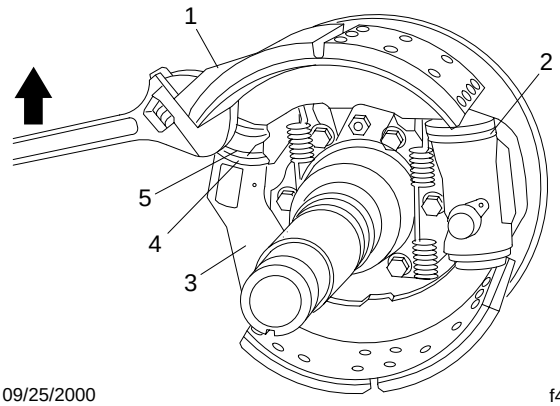
10.8 While supporting the lower shoe (upper shoe for rotated brake), unhook the lower end of the park cylinder return spring. Re-

NOTE: Arrows on the back plate indicate the adjustment direction.

A. Left wheel, upper shoe
B. Left wheel, lower shoe
C. Right wheel, upper shoe
D. Right wheel, lower shoe

1. Increase Lining-to-Drum Clearance
2. Decrease Lining-to-Drum Clearance

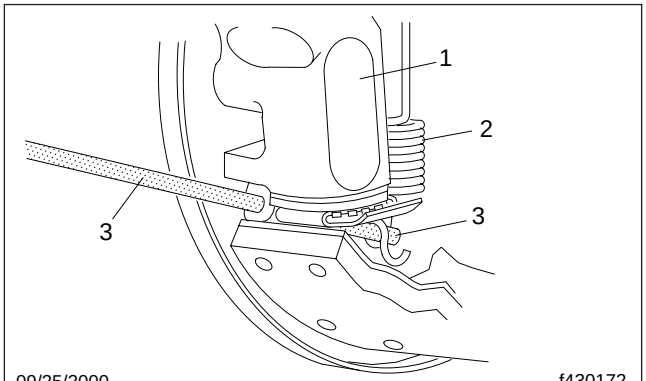
Fig. 3, Brake Shoe Adjustment (vehicles with spring suspensions)



move the lower shoe (upper shoe for rotated brake).

10.9 Remove the upper shoe (lower shoe for rotated brake).

IMPORTANT: Do not de-adjust the adjuster cylinder with the shoes removed. If further de-adjustment is required, contact your district service manager for technical support.



11. Remove and discard the return springs.
12. Secure both lower pistons to pervent them from falling out of the housing.
13. Inspect the dust boots for damage; replace as needed. The dust boots can be replaced without removing either cylinder from the backing plate.
    - To replace a dust boot on the park cylinder, remove and replace the dust boot on the top (expander) piston or bottom (abutment) piston. No disassembly is required.
    - To replace a dust boot on the adjuster cylinder, remove the slotted cap (manual override wheel assembly) from the applicable end of the adjuster cylinder. See **Fig. 7**.

Brake Shoe Removal and Installation

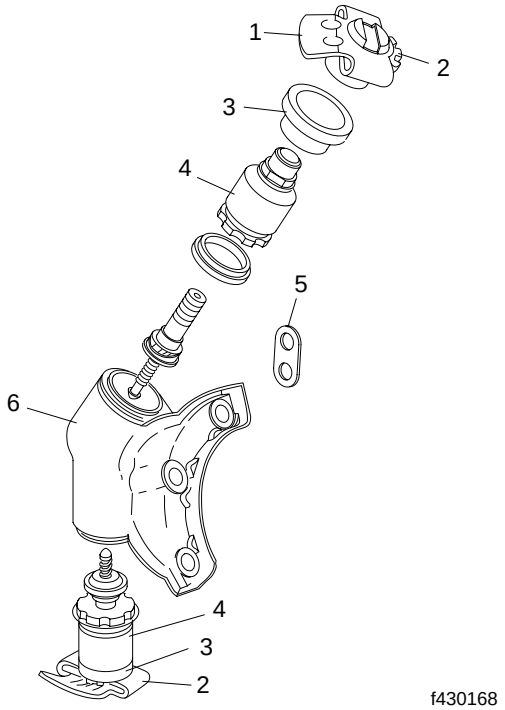
1. Adjuster Cylinder
2. Return Spring
3. Spring Tool
4. Return Spring Loop

Fig. 6, Unhook the Return Spring



NOTE: OTC part number 7462. The tool can be made from 3/8-inch (9.5-mm) tool steel.

A. Tool head, 3/8-inch (10 mm) diameter tool steel.
B. Tool guide, 1 x 1 x 1/8-inch (25 x 25 x 3-mm) tool steel.

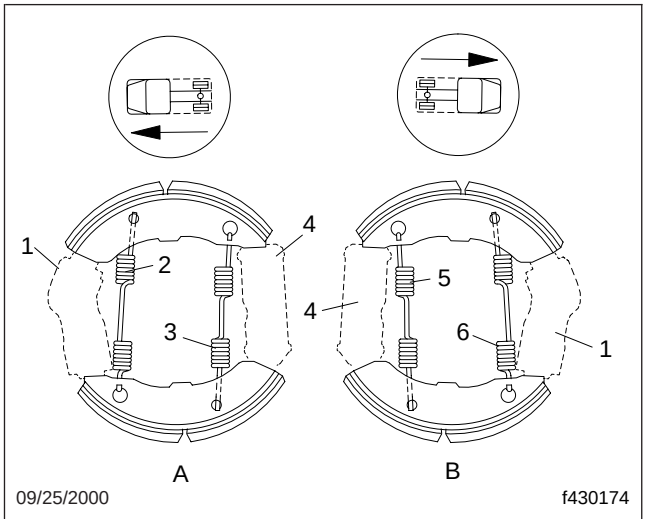
Fig. 5, Spring Tool

The manual override wheels are snapped onto the pistons. Pull to remove, being careful not to remove the piston. Install a new dust boot and snap the cap back on the housing.

1. Protective Shield
2. Slotted Cap (Manual Override Wheel Assembly)
3. Dust Boot
4. Piston
5. Gasket
6. Housing

Fig. 7, Adjuster Cylinder

14. Inspect the brake shoes and linings for wear or damage. For instructions, see **Subject 120**.



Installation

⚠ WARNING

When installing new brake shoes, always install new return springs. Also, turn or replace the drums according to the manufacturer's recommendations.

IMPORTANT: Use the same brake series on both ends of the axle.

1. Arrange the brake shoe assemblies on the floor in the positions you will view them on the vehicle. See **Fig. 8**. Although all four shoes are identical, they are not symmetrical and must be correctly oriented to the adjuster and park cylinders.

NOTE: If the springs cannot be identified by color, the springs with a loop at the bottom are next to the adjuster cylinders and the straight center section of the spring is closest to the front of the vehicle. When the top J-hook on a park cylinder spring is installed, the opening in the lower hook faces forward.

A. Left-side brake.
B. Right-side brake.
1. Adjuster Cylinder
2. Green Return Spring
3. Orange Return Spring
4. Park Cylinder
5. White Return Spring
6. Yellow Return Spring

Fig. 8, Brake Shoe Assembly Orientation (spring suspensions)

2. Hook the return springs in the upper shoe from the underside of the web. Leave the bottom of the springs free.
3. Install the brake shoes.
   3.1 Lift the upper shoe and springs. Place the shoe webs in the slots on the top of the adjuster and park cylinders.

Brake Shoe Removal and Installation

NOTE: The following is a seesaw procedure to provide anchor points for installing the return springs.

3.2 Hold the lower shoe near (not under) the park cylinder and install the free end of the return spring in the lower shoe web.

3.3 Place the other end of the lower shoe web in the slot on the bottom of the adjuster cylinder.

3.4 Place the load plate against the brake lining on the park cylinder end of the lower shoe.

3.5 Using the adjustable wrench to grip the lower shoe and load plate, press the shoe down far enough to place the web in the slot on the bottom of the park cylinder.

3.6 Move the load plate to the adjuster cylinder end of the lower shoe.

3.7 Using the adjustable wrench, press the shoe down just far enough to remove the web from the slot on the bottom of the adjuster cylinder. Allow the web to rest against the protective shield at the base of the adjuster cylinder.

3.8 Insert the spring tool in the loop at the bottom of the return spring. See **Fig. 6**. Hook the return spring in the lower shoe web.

3.9 Using the load plate and adjustable wrench, press the shoe down and place the web in the slot on the bottom of the adjuster cylinder again.

4. Install the brake drums. For instructions, see **Section 35.01**, Subject 100.

⚠ WARNING

Always wear safety glasses when handling brake fluid or bleeding brake components. Hydraulic brake fluid is hazardous and can cause blindness if it gets in your eyes. Brake fluid may also be a skin irritant. If you get it on your skin, wash it off as soon as possible.

IMPORTANT: Use only new brake fluid.

5. Fill the master cylinder reservoir, if needed, with new brake fluid that meets DOT 3 specifications. Cover the reservoir.
6. Make two slow, hard applications of the brake foot pedal to center the shoes. Repeat before each evaluation of the shoe-to-drum clearance.
7. Manually adjust the upper and lower shoes. See **Subject 160** for instructions.
8. Start the engine and check the brake pedal travel. If the pedal travel is excessive, shut down the engine and bleed the hydraulic system. For instructions, see **Subject 170**.
9. Install the six rubber plugs in the backing plate.
10. Start the engine and run it long enough to pressurize the parking brake system. The parking brake should still be in the released position. Shut down the engine.
11. Manually uncage the power spring in the parking brake chamber. For instructions, refer to the applicable brake chamber section in this manual.
12. Install the wheels. For instructions, see **Section 40.00**, Subject 100.
13. Rotate each wheel by hand to verify that the parking brakes are fully released.
14. Apply the parking brake and check that the wheels cannot be rotated by hand.
15. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

16. Before you put the vehicle in service, check for proper brake operation in a safe area.

16.1 Start the engine and release the parking brake.

16.2 Apply and release the brakes several times to check for leaks and proper operation.

16.3 Perform several low-speed stops to ensure correct parts replacement and full vehicle control.

Inspection

WARNING

Before starting this procedure, read the information in Safety Precautions 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

1. Remove the rear brake shoes. Refer to **Subject 110** for instructions.
2. Inspect the rear brake shoe linings. If the linings are grease- or oil-soaked, cracked, or worn to the lining wear groove, replace them.

NOTE: The lining wear groove is approx. 3/8-inch (9.5 mm) thick.

3. Check the shoes for bent or cracked webs or tables, broken welds, loose rivets, or out-of-round rivet holes. Replace the shoes if any of these conditions exist.

Replacement

WARNING

Before starting this procedure, read the information in Safety Precautions 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

IMPORTANT: Vehicle brake systems require the correct lining material to perform as originally designed. The type of lining material that is specified for the vehicle is based on several technical considerations and Department of Transportation (DOT) braking performance regulations. To ensure fewer relines and greater compatibility with the vehicle's brake system, use the same quality of friction lining material that was installed at the factory.

Always reline both wheels of a single axle and all wheels of a tandem axle at the same time.

Always install the same linings and drums on both wheels of a single axle and all four wheels of a tandem axle. It is not necessary for the steering axle brakes to have the same linings as the rear drive axle brakes.

When the minimum thickness is reached for any of the brake linings on an axle, reline both brakes on that axle at the same time.

NOTE: Replace the return springs each time the brakes are relined.

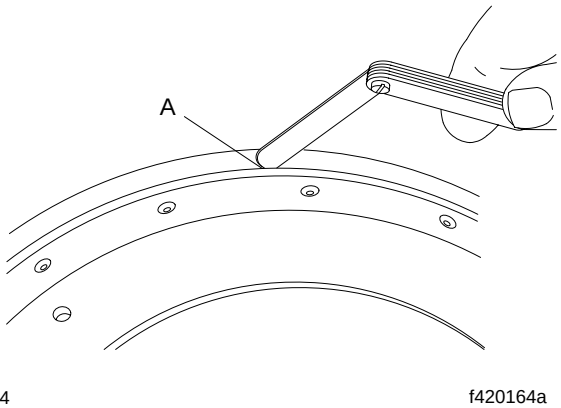
1. Remove the brake shoes. For instructions, see **Subject 110**.

CAUTION

Drilling out rivets or cutting off rivet heads with a chisel can cause the rivet hole to become out-of-round. This could damage the brake shoe.

2. Using a suitable riveting mandrel, push out (do not drill out) the old rivets.
3. Clean the shoe table. For instructions, see **Subject 150**, "Cleaning."

CAUTION



Make sure that the replacement lining material conforms to FMSI 1308, a standard for lining size and shape only. Use of an improper FMSI lining specification or friction material type may cause brake dragging or grabbing, or improper brake performance.

4. Align the brake shoe and lining rivet holes. Using a C-clamp, clamp the lining to the brake shoe.

IMPORTANT: Use rivets supplied with Meritor lining kits.

5. Insert the rivets into all the holes in the new block. Temporarily hold them in place with masking tape.
6. Secure the rivets in the correct sequence. Start with two of the middle holes and work toward the ends in a crisscross pattern.
7. Check for a close fit between the lining and shoe table.

   Try to insert a 0.010-inch (0.254-mm) feeler gauge between the lining and shoe table along the edges. See **Fig. 1**. It should not be possible to insert the gauge anywhere along the edge, except at each end beyond the last row of rivets. A larger clearance may exist in these areas.

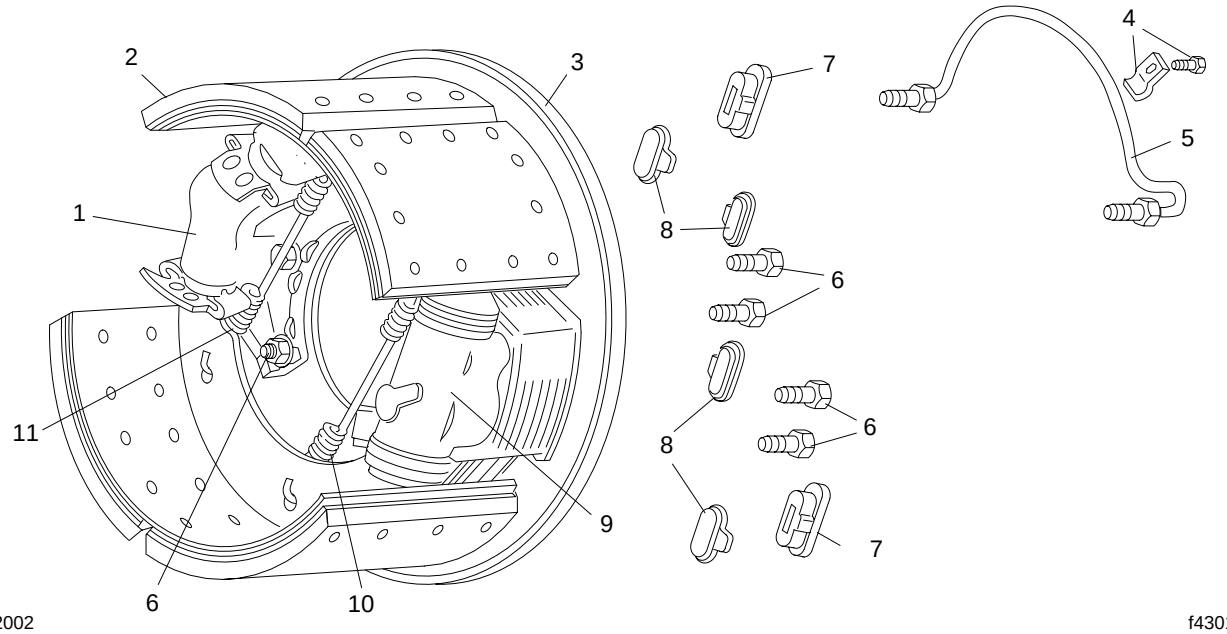
A. The clearance between the brake lining and shoe table must be less than 00.010-inch (0.254-mm).

Fig. 1, Check Fit Between Lining and Shoe Table

8. Remove the C-clamp and masking tape.

Brake Shoe Lining Replacement

IMPORTANT: Always adjust the brakes after replacing the linings. For instructions, see **Subject 160**.



Adjuster and Park Cylinder Removal and Installation

⚠ WARNING

Before starting this procedure, read the information in Safety Precautions 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Clyinder Removal

1. Remove the brake shoes. For instructions, see **Subject 110**.
2. Remove the bridge pipe retaining clip and screw from the backing plate. See **Fig. 1**.
   - 3.2 Remove the parking brake spring chamber. See **Section 42.25** for instructions.
   - 3.3 Remove three 9/16–18 bolts, hexnuts, and washers securing the park cylinder to the backing plate and axle flange.
   - 3.4 Remove the two 7/32-inch Allen-head bolts (if installed) securing the park cylinder to the backing plate. Discard the Allen-head bolts; they were originally installed for shipping.
   - 3.5 Remove the park cylinder and gasket from the backing plate. Discard the gasket.

1. Adjuster Cylinder Assembly
2. Brake Shoe and Lining
3. Backing Plate
4. Retaining Clips and Screw
5. Bridge Pipe
6. Cylinder Mounting Bolts
7. Manual Override Access Plug
8. Inspection Plugs
9. Park Cylinder Assembly
10. Return Spring, Orange (LH brake) or White (RH brake)
11. Return Spring, Green (LH brake) or Yellow (RH brake)

Fig. 1, DURAPARK Rear Hydraulic Drum Brake Assembly

3. Remove the park cylinder.
   - 3.1 Clean the bridge pipe and disconnect it from the cylinder.
4. Remove the adjuster cylinder.
   - 4.1 Clean the bridge pipe and disconnect it from the cylinder.

Adjuster and Park Cylinder Removal and Installation

4.2 Remove three 9/16–18 bolts, hexnuts, and washers securing the adjuster cylinder to the backing plate and axle flange.

4.3 Remove the two 7/32-inch Allen-head bolts (if installed) securing the park cylinder to the backing plate. Discard the Allen-head bolts; they were originally installed for shipping.

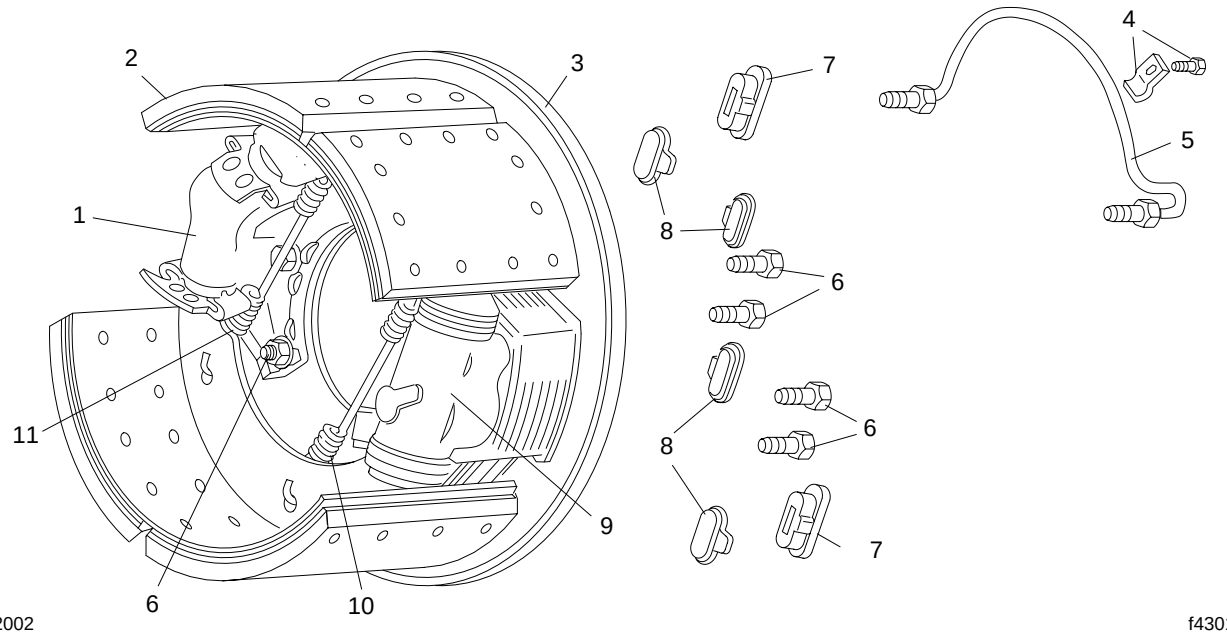
4.4 Remove the adjuster cylinder and gasket from the backing plate. Discard the gasket.

Clyinder Installation

1. Install the adjuster cylinder.
   1.1 Using a new gasket, install the adjuster cylinder on the backing plate. Insert three 9/16–18 x 1-1/2 inch bolts through the axle flange, backing plate, and cylinder housing.
   1.2 Secure the bolts with hardened washers and 9/16–18 hexnuts. Torque the nuts 135 to 160 lbf·ft (185 to 215 N·m).
   1.3 Connect the bridge pipe to the cylinder. Torque the capscrew 10 to 15 lbf·ft (14 to 20 N·m).
2. Install the park cylinder.
   2.1 Using a new gasket, install the park cylinder on the backing plate. Insert three 9/16–18 x 1-1/2 inch bolts through the axle flange, backing plate, and cylinder housing.
   2.2 Secure the bolts with hardened washers and 9/16–18 hexnuts. Torque the nuts 135 to 160 lbf·ft (185 to 215 N·m).
   2.3 Connect the bridge pipe to the cylinder. Torque the capscrew 10 to 15 lbf·ft (14 to 20 N·m).
   2.4 Install the parking brake spring chamber. See **Section 42.25** for instructions.
3. Install the bridge pipe retainer and screw on the backing plate.
4. Install the brake shoes, drums, and wheels. For instructions, see **Subject 110**.

WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.



5. Bleed the hydraulic brake system. For instructions, see **Subject 170**.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

⚠ WARNING

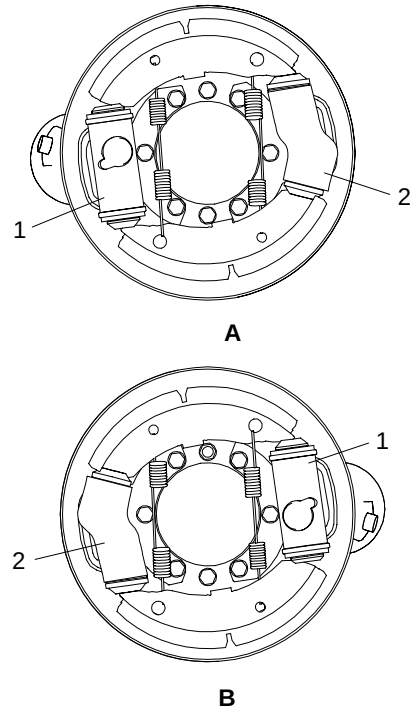
Before starting this procedure, read the information in Safety Precautions 100. Failure to be aware of the dangers of brake lining dust exposure could result in serious and permanent health damage.

Figure 1 shows a DURAPARK® rear hydraulic drum brake.

1. Adjuster Cylinder Assembly
2. Brake Shoe and Lining
3. Backing Plate
4. Retaining Clips and Screw
5. Bridge Pipe
6. Cylinder Mounting Bolts
7. Manual Override Access Plug
8. Inspection Plugs
9. Park Cylinder Assembly
10. Return Spring, Orange (LH brake) or White (RH brake)
11. Return Spring, Green (LH brake) or Yellow (RH brake)

Fig. 1, DURAPARK Rear Hydraulic Drum Brake Assembly

IMPORTANT: The figures and instructions in this subject illustrate installation of brakes on vehicles with spring suspensions. On vehicles with Freightliner AirLiner suspensions, the park cylinder and adjuster cylinder positions are reversed. See **Fig. 2**.



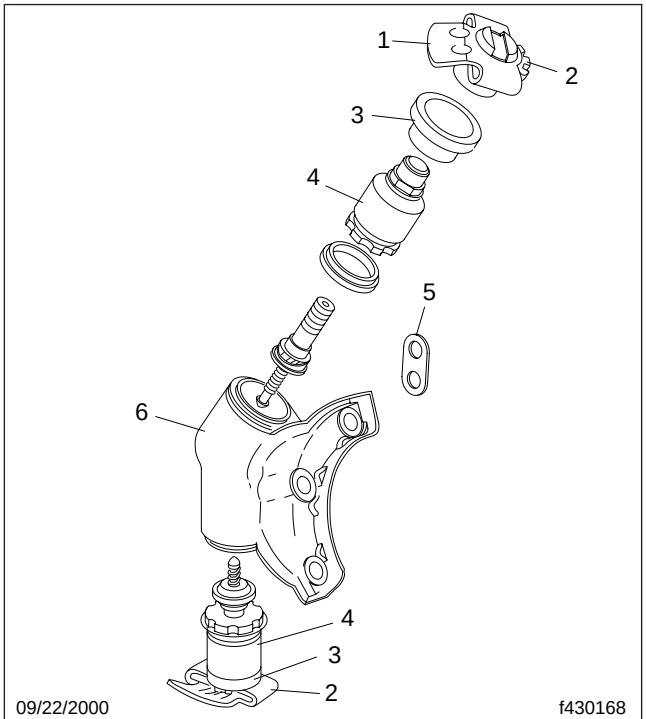
Disassembly

Adjuster Cylinder

Refer to **Fig. 3** while performing the following procedures.

1. Park the vehicle on a level surface, shut down the engine, and chock the tires.
2. Remove the adjuster cylinder. See **Subject 140**.

Brake Components Disassembly and Inspection, Cleaning, and Assembly



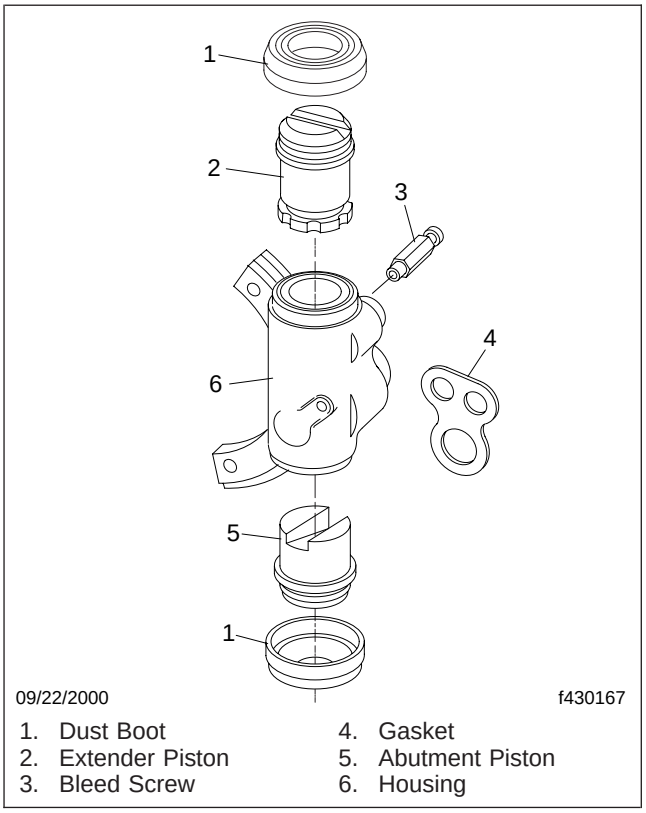
A. Standard Brake Configuration
B. AirLiner Suspension Configuration
1. Park Cylinder
2. Adjuster Cylinder

Fig. 2, DURAPARK Brake Configurations

3. Remove and inspect the manual override wheels. Clean the manual override wheels by soaking them in clean DOT 3 heavy duty brake fluid. Remove the dust boots from the housing. Discard the boots.
4. Remove the pistons and adjuster assemblies from housing, being careful not to cock them and scratch the housing bore. Inspect the pistons. Replaced if any pitting, peeling, or scoring is found. Some discoloration of the piston diameter may be apparent. This is the natural result of brake actuation over a period of operation.
5. Remove the adjuster shaft from the piston. Keep the adjuster shafts and pistons together as sets.

IMPORTANT: Do not remove the drive ring from the adjuster shaft.

6. Remove the seals from the pistons. Use care not to score the seal groove. Discard the seal.



1. Protective Shield
2. Slotted Cap (Manual Override Wheel Assembly)
3. Dust Boot
4. Piston
5. Gasket
6. Housing

Fig. 3, Adjuster Cylinder

Park Cylinder

Refer to **Fig. 4** while performing the following procedures.

1. Park the vehicle on a level surface, shut down the engine, and chock the tires.
2. Remove the park cylinder. See **Subject 140**.
3. Place the cylinder in a soft jawed vise.
4. Remove the bleed screw
5. Remove the dust boots from the housing and discard the boots.
6. Remove the abutment piston.
7. Remove the Allen-head 5/32-inch stop pin from the housing.

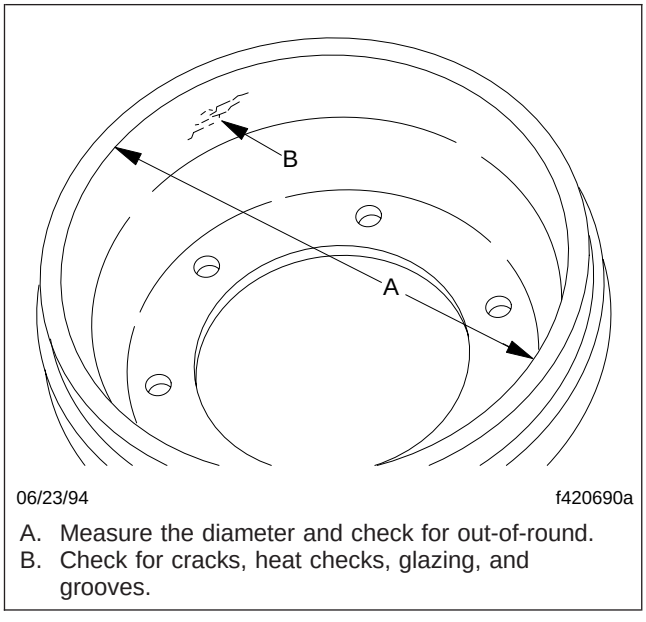
1. Dust Boot
2. Extender Piston
3. Bleed Screw
4. Gasket
5. Abutment Piston
6. Housing

Fig. 4, Park Cylinder

8. Push the expander piston and the handbrake piston out of the housing.
9. Remove and discard the seals and O-ring from the pistons.
10. Press down on the wedge assembly sleeve and return spring to remove the pin from the shaft. Slowly release the wedge return spring and remove the sleeve and return spring from the shaft.
11. Remove the snap ring that retains the shaft, retainer and washer in the housing. Remove the wedge and roller assembly.

Inspection and Cleaning

After removing the brake parts being serviced, do the following:



Brake Drums and Chambers

CAUTION

Do not clean ground or polished metal parts in a hot solution tank or with water, steam, or alkaline solutions. These solutions will cause parts to corrode.

IMPORTANT: Do not apply brake grease or corrosion-preventive materials to the brake linings or the brake drum.

1. Inspect the drum.
   - 1.1 Check the drum for cracks. Replace any cracked drum.
   - 1.2 Using a drum caliper or other measuring device, measure the inside diameter of the drum in several places. Replace the drum if it exceeds the maximum diameter stamped on it.
   - 1.3 Check the drum for heat checks, glazing, grooving, run-out, and out-of-round. See **Fig. 5**. Some drums that are glazed, grooved, or out-of-round can be repaired. For detailed instructions, see **Section 35.01**.

A. Measure the diameter and check for out-of-round.
B. Check for cracks, heat checks, glazing, and grooves.

Fig. 5, Check the Drum

Brake Components Disassembly and Inspection, Cleaning, and Assembly

2. Check the brake chamber for a cracked housing, loose fittings, and leakage. Repair or replace parts as needed.
3. Wire brush all parts that have been exposed to mud, road dirt, and salt, including the exterior of the drum.

   If relining the shoes, thoroughly wire-brush the shoe tables and paint them with a rust-inhibitive coating.

⚠ CAUTION

A thick layer of oxidation and dirt on the outside of a brake drum acts as an insulator and may hinder normal heat dissipation. Make sure oxidation and dirt are removed by wire brushing, or damage to brake components could occur.

4. Using a wire brush, remove any rust or corrosion from the backing plate.
5. Using an industrial vacuum cleaner with a HEPA filter system, remove any dust accumulation from the brake parts.
6. Wipe the inside of the drums with a damp rag to remove lining dust.
7. Prepare the brake parts for assembly.

   7.1 Thoroughly clean all the brake parts.

   For ground or polished metal parts, use a cleaning solvent to clean the parts and surfaces.

   For rough metal parts, use a cleaning solvent or a weak alkaline solution in a hot solution tank to clean the parts. If a hot solution tank is used, leave the rough parts in the hot solution tank until they are completely cleaned and heated. Remove the rough parts from the hot solution tank and wash them with water until the alkaline solution is removed.

   7.2 Thoroughly dry all the brake parts with a clean, lint-free cloth or paper towel, or use low-pressure filtered and compressed air.

⚠ WARNING

All worn or damaged brake parts must be replaced. If the brakes are assembled with worn or damaged parts, they may not perform to their capacity and a brake failure could occur, which could cause personal injury and property damage.

   7.3 Inspect all the brake parts for wear or damage. It is very important that all the parts be carefully inspected before they are assembled. Repair or replace any worn or damaged parts.

   7.4 For parts that will be assembled, apply a thin layer of brake grease to the parts after they have been cleaned, dried, and inspected to protect them from corrosion.

   If the parts will be stored, apply a special material that prevents corrosion and rust on all surfaces. The parts should be stored in special paper (or other material) that prevents corrosion and rust.

Adjuster Cylinder

Refer to **Fig. 3** while performing the following procedures.

1. Wash all parts with clean DOT 3 heavy duty brake fluid. Placed the cleaned parts on a clean sheet of paper.
2. Clean the adjust shaft hole in the piston.

   2.1 Fill the threaded hole half-full with new brake fluid.

   2.2 Cover the hole and shake the piston vigorously.

   2.3 Rapidly turn the piston upside down and drain the brake fluid.

   IMPORTANT: Do not use a cleaning brush on any of the parts.

NOTE: Some discoloration of the bore surface near the mouth of the cylinder may be apparent. This is the natural result of brake actuation over a period of operation.

3. Inspect the cylinder bore and pistons for evidence of corrosion, ridges or scoring. If

scratches or scoring are present in the bore, hosing is allowed. However, the bore diameter must not be larger than 1.75 inches (44.5 mm) after honing. If larger than specified, replace the cylinder housing. Hone the cylinder bore using a 220 spring loaded wheel cylinder stone that gives a smooth finish. If any defects are present after honing the cylinder housing much be replaced.

Clean the cylinder bore with isopropyl alcohol to remove all honing residue.

Park Cylinder

Refer to **Fig. 4** while performing the following procedures.

1. Inspect all three pistons. Replace the pistons if any pitting, peeling, or scoring is found. Some discoloration of the piston diameter may be apparent. This is the natural result of the brake actuation over a period of operation.
2. Inspect the wedge components for any signs of wear, replace as needed.
3. Wash all parts in clean DOT 3 heavy duty brake fluid.

NOTE: Some discoloration of the bore surface near the mouth of the cylinder may be apparent. This is the natural result of brake actuation over a period of operation.

4. Inspect the cylinder bore and pistons for evidence of corrosion, ridges or scoring. If scratches or scoring are present in the bore, honing is allowed. However, the bore diameter must not be larger than 1.75 inches (44.5 mm) after honing. If larger than specified, replace the cylinder housing. Hone the cylinder bore using a 220 spring loaded wheel cylinder stone that gives a smooth finish. If any scoring is present after honing, the housing must be replaced.

IMPORTANT: Clean the cylinder bore with the isopropyl alcohol to remove all honing residue.

Assembly

Adjuster Cylinder

Refer to **Fig. 3** while performing the following procedures.

⚠ WARNING

The use any mineral based grease will cause contamination of the seals and may result in brake failure. Use only the specified lubricants.

1. Coat the adjuster shaft threads with new brake fluid.
2. Assemble piston and adjuster shaft, adjuster shaft must turn freely and smoothly without roughness or drag over its full length. Turn the adjuster shaft all the way in then back out one full turn. This will insure the shaft is not locked in the piston.

NOTE: It is essential that the adjuster shaft rotates freely in the piston to allow for the initial self-adjuster movement to take place. If the shaft binds or does not rotate freely in the piston, replace the piston and adjuster assembly.

3. Coat the new seal with the clean DOT 3 heavy duty brake fluid. Install the new seal in the groove on the piston so that the lip seal faces toward the adjuster shaft.
4. Lubricate the pistons and seals with clean DOT 3 heavy duty brake fluid. Install the piston assemblies into the cylinder bores.
5. Lubricate the inside of the dust boot with synthetic lube provided with the adjuster cylinder parts kit available from Meritor.

⚠ WARNING

The use of any mineral based grease will cause contamination of the seals and may result in brake failure. Use only the specified lubricants.

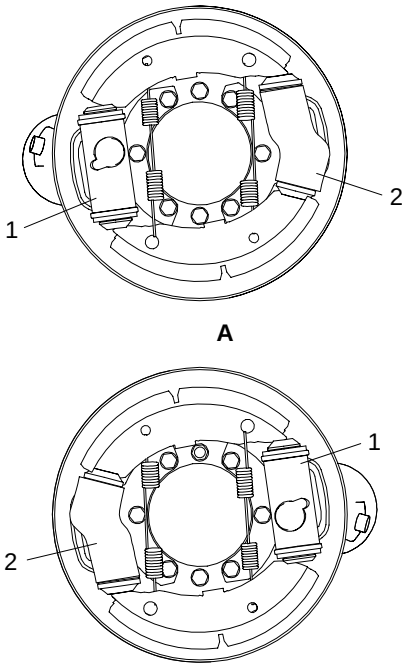
6. Install the dust boot onto the housing.
7. Install the manual override wheel.

NOTE: Be sure the tappet head ears are properly located in the corresponding flats in the piston.

8. Install the adjuster cylinder. See **Subject 140**.

Park Cylinder

Refer to **Fig. 4** while performing the following procedures.



Brake Components Disassembly and Inspection, Cleaning, and Assembly

WARNING

The use any mineral based grease will cause contamination of the seals and may result in brake failure. Use only the specified lubricants.

1. Assemble and install the wedge assembly into the housing.
2. Coat the outside diameter and the ramp of the abutment piston with synthetic grease included in the seal kit. Install the abutment piston into the bore the ramp engages the wedge and roller assembly. Install a new dust boot over the abutment piston and onto the housing.
3. Coat the handbrake piston ramp and O-ring with grease and install the O-ring onto the piston.
4. Coat the seals with clean DOT 3 heavy duty brake fluid. Install the seal on the handbrake piston so that the seal lip faces away from the wedge and roller slot. Install the seal on the expander piston so the seal lip faces away from the shoe web slot.
5. Install the handbrake piston into the bore, aligning the slot on the side of the piston with the stop pin hole.
6. Install the stop pin. Tighten to 16 lbf·ft (21.5 N·m).
7. Install the expander piston into the bore. Install a new dust boot over the expander piston onto the housing.
8. Install the park brake cylinder. See **Subject 140**.

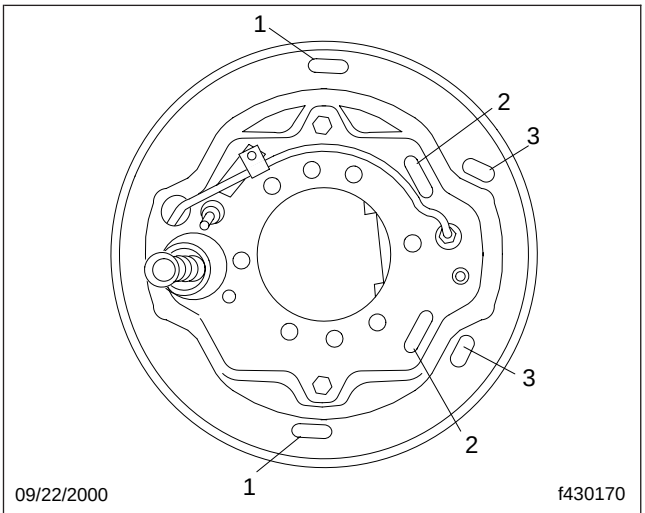
IMPORTANT: The figures and instructions in this subject illustrate installation of brakes on vehicles with spring suspensions. On vehicles with Freightliner AirLiner suspensions, the park cylinder and adjuster cylinder positions are reversed. See **Fig. 1**.

A. Standard Brake Configuration
B. AirLiner Suspension Configuration
1. Park Cylinder
2. Adjuster Cylinder

Fig. 1, DURAPARK Brake Configurations

Pre-Adjustment Checks

1. Park the vehicle on a level surface and chock the front tires.
2. Make sure the parking brakes are released. Releasing the parking brakes pressurizes the spring chambers and compresses the parking brake springs. The engine must be running while the parking brakes are released.



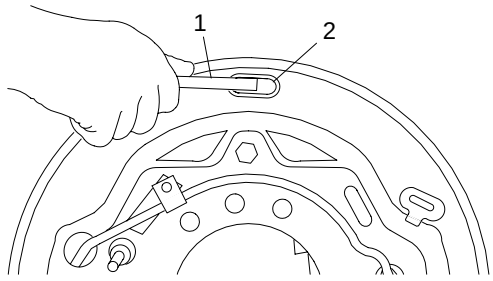
⚠ WARNING

When work is being done on the spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury.

3. Carefully cage and lock the springs so that the springs cannot actuate during disassembly.
4. Set the parking brakes to release the parking brake system pressure, then shut down the engine.
5. Raise the rear axle and place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.

Shoe-to-Drum Clearance Measurement

1. Center the shoes in the drum by making two slow, hard applications and releases of the service brakes.
2. Remove the rubber plugs from the inspection holes in the backing plate. See **Fig. 2**.



1. Lining Inspection Hole
2. Adjustment Slot
3. Adjuster Sight Hole

Fig. 2, Backing Plate Access Holes

Manual Brake Adjustment

NOTE: Make sure the feeler gauge is on the lining surface, not in the area between the two lining blocks.

3. Insert feeler gauges between the lining and the drum, about half way across the width of the lining. See **Fig. 3**.

1. Feeler Gauge
2. Lining Inspection Hole

Fig. 3, Clearance Measurement

NOTE: The clearance between the drum and brake lining may vary from top to bottom, and from the left side of the vehicle to the right. This is normal and does not indicate that service is required.

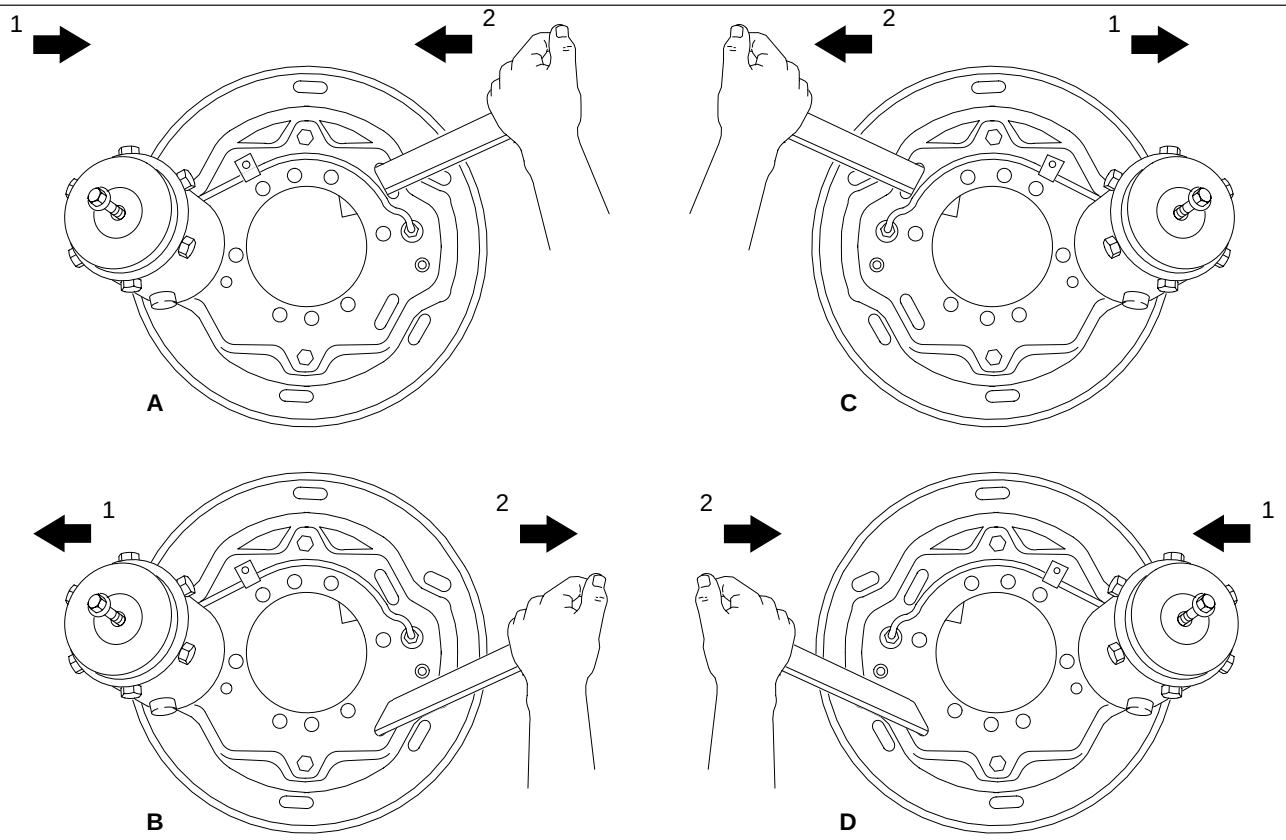
4. If the shoe-to-drum clearance meets either of the following criteria, do not adjust the brake.
   - The shoe-to-drum clearance should be 0.020 to 0.050 inch (0.508 to 1.27 mm).
   - If it is not, add the clearance for the top and bottom shoes. The sum should be 0.040 to 0.100 inch (1.016 to 2.54 mm).
5. If the shoe-to-drum clearance does not meet the criteria above, manually adjust the brakes. Otherwise, skip to "Assembly and Test."

Manual Adjustment

IMPORTANT: The adjustment procedures in this subject are for vehicles with spring suspensions. On vehicles with Freightliner AirLiner suspensions, the park cylinder and adjuster cylinder positions are reversed. Therefore, the adjustment procedure should be adjusted accordingly when working on a vehicle with AirLiner suspensions.

⚠ CAUTION

Take care not to damage the dust boot with the adjusting tool.



1. Insert the adjusting tool (OTC part number D90T-2588-AR) in the upper adjustment slot on the back side of the backing plate. See **Fig. 4**.
2. Manually adjust the upper shoe by pushing or pulling the adjusting tool (OTC part number D90T-2588-AR) in the direction shown in **Fig. 4**.
   - Adjust burnished shoes to 0.020 inch (0.508 mm) clearance.
   - Adjust new shoes to 0.030 inch (0.732 mm) clearance.
3. Insert the adjusting tool in the lower adjustment slot on the backing plate. Repeat the previous procedure to adjust the lower shoe.

Assembly and Test

1. With the parking brake still in the released position, start the engine to pressurize the parking brake system.
2. Manually uncage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this manual.
3. Rotate each wheel by hand to make sure the hydraulic system has fully released the parking brakes.
4. Apply the parking brakes and verify that the wheels cannot be rotated by hand.
5. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.
6. With the engine running, release the parking brakes.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking

NOTE: Arrows on the back plate indicate the adjustment direction.

A. Left wheel, upper shoe
B. Left wheel, lower shoe
C. Right wheel, upper shoe
D. Right wheel, lower shoe

1. Increase Lining-to-Drum Clearance
2. Decrease Lining-to-Drum Clearance

Fig. 4, Brake Shoe Adjustment (vehicles with spring suspensions)

ability, which could cause personal injury or death, and property damage.

7. Before you put the vehicle in service, check for proper brake operation in a safe area.

   7.1 Drive the vehicle slowly and check the service and parking brakes.

   7.2 Apply and release the brakes several times to check for air leaks and proper operation.

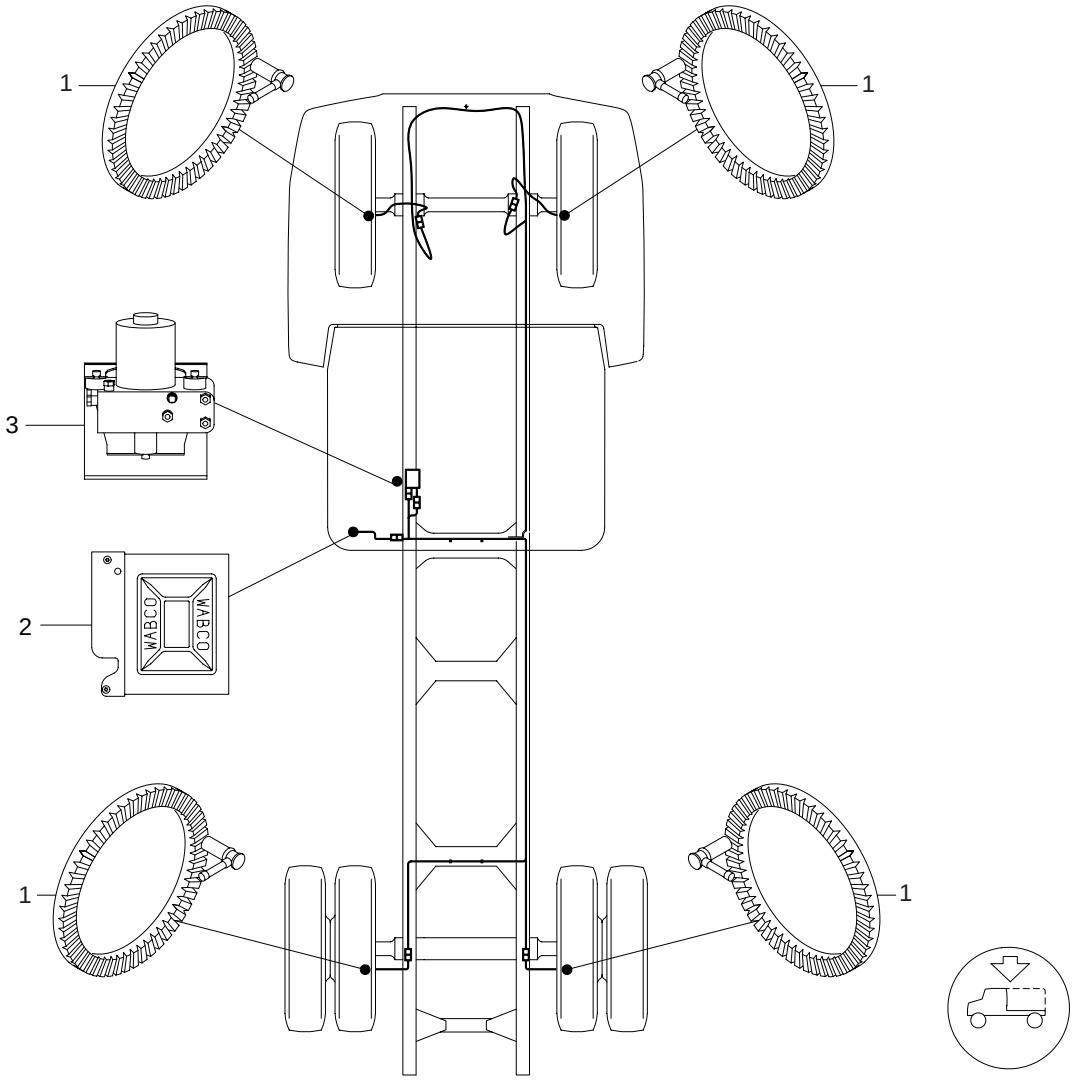
   7.3 Perform several low-speed stops to ensure correct parts replacement and full vehicle control.

System Bleeding

NOTE: The following manual bleed procedure has been proven to be more effective than using pressure bleed equipment when working with Durapark brakes. Please use only the following manual pressure bleed procedure.

IMPORTANT: The ignition must remain off for the entire bleed procedure.

1. Fill the reservoir with DOT 3 hydraulic fluid.



IMPORTANT: Do not allow the brake master cylinder fluid to fall below the minimum level during the bleeding operation. Keep the master cylinder reservoir filled with new DOT-3 approved brake fluid as specified by the original equipment manufacturer. Failure to keep the brake reservoir level above minimum could result in more air entering the system, making it impossible to effectively bleed the system.

2. Place a wrench on the right rear bleeder fitting. Attach a length of clear plastic tubing to the bleeder fitting. The tube must fit tight over the fitting.
3. Submerge the opposite end of the tubing in a container of clean brake fluid.

NOTE: Both the tubing and container must be able to withstand the effects of brake fluid.

4. Press the brake pedal. Loosen the bleeder fitting until the fluid begins to flow (about 3/4 turn) while pressing the brake pedal through its maximum available stroke. Continue to press on the brake pedal for 5 to 8 seconds after the brake fluid stops flowing from the bleeder fitting.
5. Tighten the bleeder fitting firmly, then release the brake pedal. The bleeder fitting must be tightened prior to releasing the brake pedal. Failure to perform the operations in this sequence will result in the discharged fluid and air being drawn back into the system.
6. Repeat steps 4 and 5 several times until the discharged fluid is clear and free of bubbles.
7. Repeat steps 2 through 6 for the left rear brake, right front brake, and then left front brake in this sequence.
8. Check the fluid level in the reservoir and fill if required. Replace reservoir cap and dispose of used brake fluid.
9. Remove the chocks from the tires.

General Information

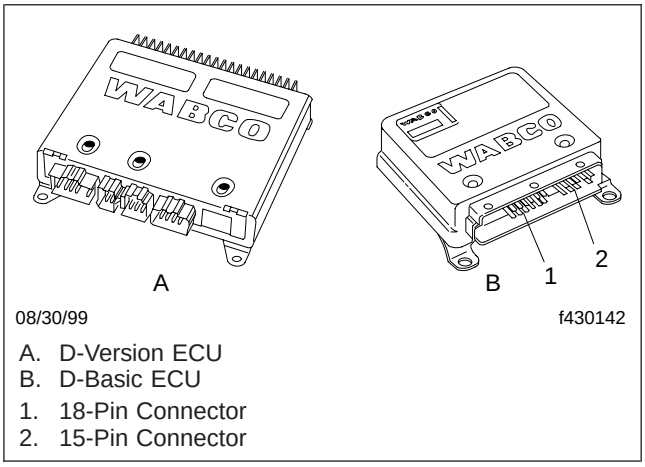
04/05/2001 f422013b

1. Tone Wheel and Sensor
2. Electronic Control Unit
3. Brake Pressure Modulator

Fig. 1, Location of ABS Components, Four-Channel System

The Meritor WABCO Antilock Braking System (ABS) is an electronic wheel speed monitoring and control system that works with the hydraulic brake system. See **Fig. 1**. ABS passively monitors vehicle wheel speed at all times, and controls wheel speed during emergency stops.

D-version hydraulic ABS is used on vehicles built since February 19, 1999. To determine the hydraulic



General Information

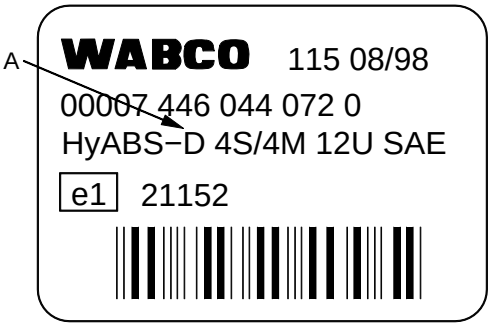
ABS version installed on the vehicle, look at the ABS electronic control unit (ECU). D-version ECUs have three connectors. See **Fig. 2**. The ECU version can also be determined by the letter designation printed on part number identification tag. See **Fig. 3**.

ABS includes signal-generating tone wheels and sensors located in the rotor assembly of each sensed wheel. The sensors transmit vehicle wheel speed information to the electronic control unit. During emergency braking, the control unit signals the brake pressure modulator to reduce, maintain, or increase hydraulic fluid pressure to the brake caliper housing. This prevents wheel lockup, and enhances steering control during emergency braking situations.

Principles of Operation

The ABS electronic control unit (**Fig. 2**) is a digital microcomputer that serves as the information processing and command center for the antilock braking system. The control unit receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the control unit regulates the braking force applied to each wheel by sending control signals to the brake pressure modulator. See **Fig. 4**.

08/30/99 f430142

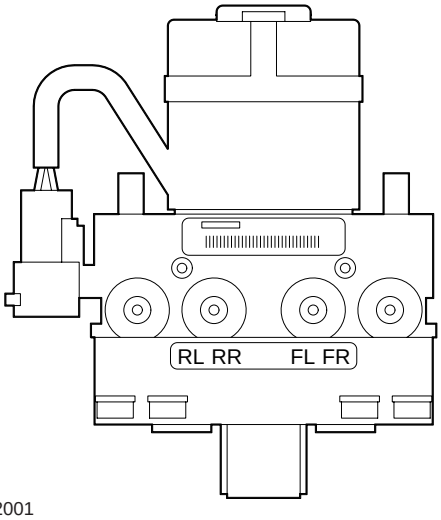


A. D-Version ECU
B. D-Basic ECU
1. 18-Pin Connector
2. 15-Pin Connector

Fig. 2, Electronic Control Unit

ABS Major Components

Wheel Speed Sensor



The wheel speed sensors use pulse feedback from tone wheels located in the front and rear axle wheel hubs. When the vehicle is moving, the teeth of the tone wheel cause changes in the magnetic field created by the sensor. The changes create an AC voltage signal that is sent by the sensor to the electronic control unit.

04/27/2000 f080097

A. Version Designation

Fig. 3, ECU Identification Tag ("D" Version Shown)

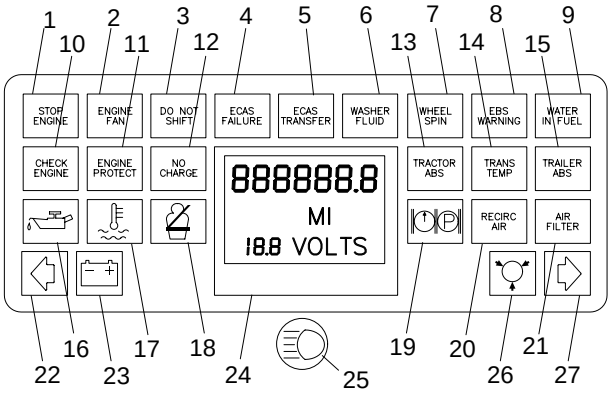
04/03/2001 f543727

Fig. 4, Brake Pressure Modulator, "D" Basic Version

Electronic Control Unit (ECU)

The electronic control unit (ECU), located just behind the driver's seat, contains a microcomputer to monitor the front and rear control channels. The ECU receives wheel speed signals and interprets these signals to calculate wheel speed and a vehicle reference speed. If the calculations indicate a high degree of wheel slip the ECU signals the brake pressure modulator to adjust braking pressure.

The ECU contains another microcomputer that provides a safety circuit to constantly monitor the wheel sensors, the brake pressure modulator, and the electrical circuitry.



IMPORTANT: After the ignition switch is turned on, the tractor warning light (ABS) comes on for about 3 seconds. See **Fig. 5**. After about 3 seconds, the light goes out only if all of the tractor's ABS components are working correctly.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (a sensor, brake pressure modulator, wiring connection, short circuit, etc.), the tractor warning light (ABS) comes on, and the control circuit where the failure occurred is switched to normal braking action. Even if the ABS system is completely inoperative, normal braking is maintained. Refer to the vehicle driver's manual for complete operating instructions.

Brake Pressure Modulator

The brake pressure modulator is attached to the left frame rail just ahead of the center or forward rear-suspension crossmember. Depending on the signal received from the electronic control unit, the modulator prevents wheel lockup by adjusting the hydraulic fluid pressure. During normal braking applications, hydraulic fluid flows freely to the brake caliper housing through the modulator.

Within the modulator are an inlet and outlet control valve for each sensed wheel. If the electronic control unit signals indicate wheel lockup is close to occurring, fluid pressure to the brake caliper of the sensed wheel is reduced. The inlet valve of the sensed wheel closes, preventing fluid delivery to the brake caliper. At the same time, the outlet valve opens, allowing fluid to flow to an accumulator within the module. From the accumulator, a recirculation pump within the module delivers brake fluid back to the master cylinder.

08/02/2000 f610231a

Typical installation shown. Location of legends installed in the top row may vary, and other legends may be specified.

1. Stop Engine Warning (Cummins engine only)
2. Eng. Fan On Indicator, Optional

Fig. 5, Level I ICU Dash Message Center

General Information

As wheel speed increases, the brake pressure modulator allows increases (inlet valve opens and outlet valve closes), or maintains brake pressure until the proper wheel speed is obtained, or until wheel lockup occurs and the control cycle starts again.

If maintaining brake pressure, both valves are closed, preventing fluid delivery and maintaining fluid pressure.

Replacement

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals.

Front Axle

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires to prevent vehicle movement.
2. Twist and pull the sensor to remove it from the sensor bracket. See **Fig. 1**.

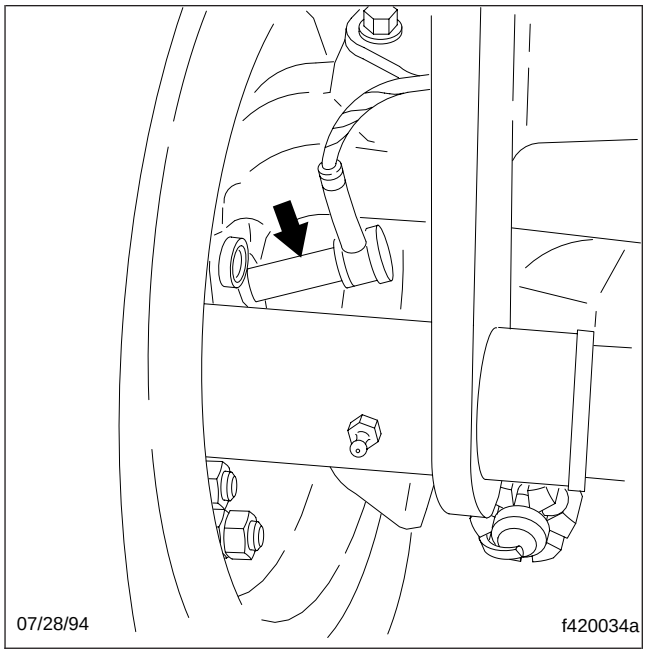

Fig. 1, Remove the Wheel Speed Sensor

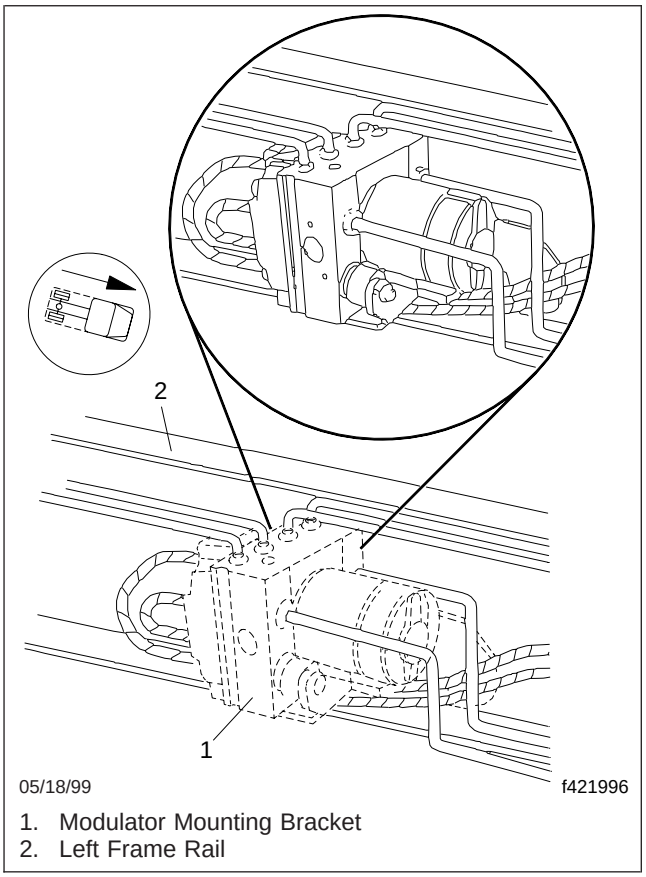


3. Remove the sensor cable clip from the top cap.
4. Disconnect the sensor cable from the chassis harness.
5. Remove the sensor spring clip from the sensor bracket.
6. Connect the sensor cable to the chassis harness.
7. Attach the sensor cable to the steering knuckle top cap.
8. Coat the sensor spring clip and the sensor with Mobil HP, Valvoline EP 633, Penzoil 707L or an equivalent.
9. Press the sensor spring clip into the sensor bracket at the brake spider hole until it stops. Make sure the spring clip tabs are on the inboard side of the vehicle.
10. Press the sensor into the sensor spring clip until it is stopped by the tone wheel.
11. Remove the chocks from the rear tires.

Rear Axle

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the front tires to prevent vehicle movement.
2. Twist and pull the sensor to remove it from the mounting block in the axle housing.
3. Remove the sensor spring clip.
4. Remove the capscrew that attaches the sensor cable and the hose clamp to the axle tube.
5. Disconnect the sensor cable from the chassis harness.
6. Connect the new sensor cable to the chassis harness.
7. Attach the hose clamp and sensor cable to the axle tube located between the backing plate and the spring plate.
8. Press the sensor spring clip into the mounting block until it stops.
9. Coat the sensor with Mobil HP, Valvoline EP633, Penzoil 707L or an equivalent. Using your hand, push the sensor into the sensor spring clip until it is stopped by the tone wheel.
10. Remove the chocks from the front tires.

Brake Pressure Modulator Removal and Installation

Removal

1. Modulator Mounting Bracket
2. Left Frame Rail

Fig. 1, Brake Pressure Modulator Mounting, "D" Basic Version

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Group 54** for information on special terminals and connectors and on ordering tools for them.

See **Fig. 1** for the "D" basic version modulator.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the front and rear tires.
2. Put a container under the modulator to catch leaking brake fluid.
3. Disconnect the wiring from the modulator.

⚠ CAUTION

The modulator assembly contains hydraulic brake fluid, a caustic substance. Remove the brake lines and modulator carefully so that fluid does not leak and cause skin irritation or damage to components.

4. Mark the brake lines for ease of installation. Disconnect the lines.
5. Remove the mounting capscrews, washers and nuts that attach the modulator and bracket assembly to the bracket on the frame rail.
6. Remove the modulator and bracket assembly.

Installation

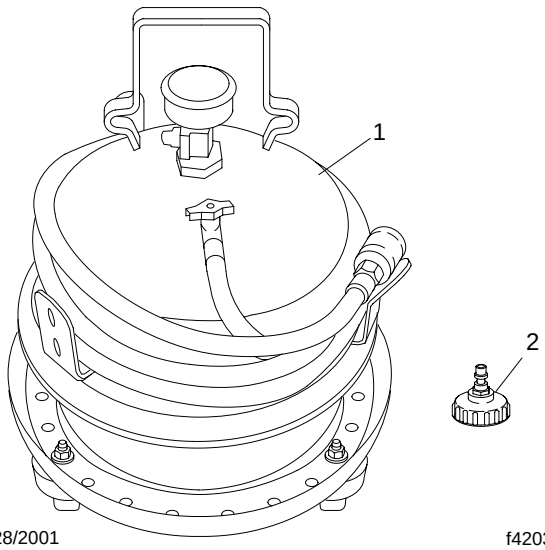
1. Install the modulator and bracket assembly. Install the mounting capscrews, washers and nuts that attach the modulator and bracket assembly to the bracket on the frame rail. Tighten the modulator and bracket assembly mounting nuts 132 lbf·in (1500 N·cm).
2. Connect the brake lines. Tighten the two small adapters (M10XI) 108 lbf·in (1200 N·cm). Tighten the four large adapters (M12XI) 132 lbf·in (1500 N·cm).
3. Connect the wiring to the modulator.
4. Bleed the brake system following the instructions in **Subject 120**.
5. Remove the chocks from the tires.

Bleeding

⚠ WARNING

Failure to bleed the system whenever any hydraulic system fitting is loosened or disconnected will allow air to remain in the system. This will prevent the hydraulic pressure in the brake system from rising enough to apply the brakes properly. This will cause the stopping distance to increase and can result in serious personal injury.

Properly discard hydraulic brake fluid that is removed from the brake system. Hydraulic brake fluid that is removed can be contaminated and can cause damage, loss of braking and serious personal injury.



Power steering fluid and brake fluid are incompatible. Use only brake fluid for the master cylinder and brake lines. Use only power steering fluid for the power booster. Never mix these two fluids or serious damage to both hydraulic systems will result. The wrong hydraulic brake fluid will damage the rubber parts of the brake caliper and can cause damage, loss of braking and serious personal injury.

Always use new, clean brake fluid that meets DOT 3 specifications when bleeding the master cylinder and service brake system. Never reuse brake fluid, and don't use brake fluid containers for any other purpose. Keep brake fluid containers tightly closed to keep new brake fluid clean and dry.

IMPORTANT: Do not let brake fluid touch any painted surfaces, as it will remove the paint. Brake fluid may also damage certain non-metal surfaces. Do not let fluid get on brake pads or rotors.

Pressure Bleeding

Pressure bleeding is the preferred method for bleeding the service brake system. It requires the use of a special pressure bleeder kit, consisting of a tank, pressure pump and valve, gauge, tubing and adapter. These are available from a number of manufacturers and include instructions for use. See **Fig. 1**.

1. Pressure Bleeder
2. Adaptor

Fig. 1, Pressure Bleeder Kit

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the batteries. The ignition must remain off for the entire bleed procedure.
3. Open the hood.
4. Connect the pressure bleeder to the brake master cylinder reservoir following the manufacturer's instructions.
   - 4.1 Fill the pressure bleeder with new DOT 3 approved brake fluid. Pressurize it according to the manufacturer's instructions.
   - 4.2 Using the supplied adapter, connect the pressure bleeder to the rear compartment of the master cylinder reservoir.
5. Bleed the hydraulic connections at the rear wheel calipers, starting on the right side.
   - 5.1 Put a wrench on the bleeder fitting at the caliper. Attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.
   - 5.2 Loosen the bleeder fitting by about a 3/4 turn and let the brake fluid flow out of the

Hydraulic System Bleeding

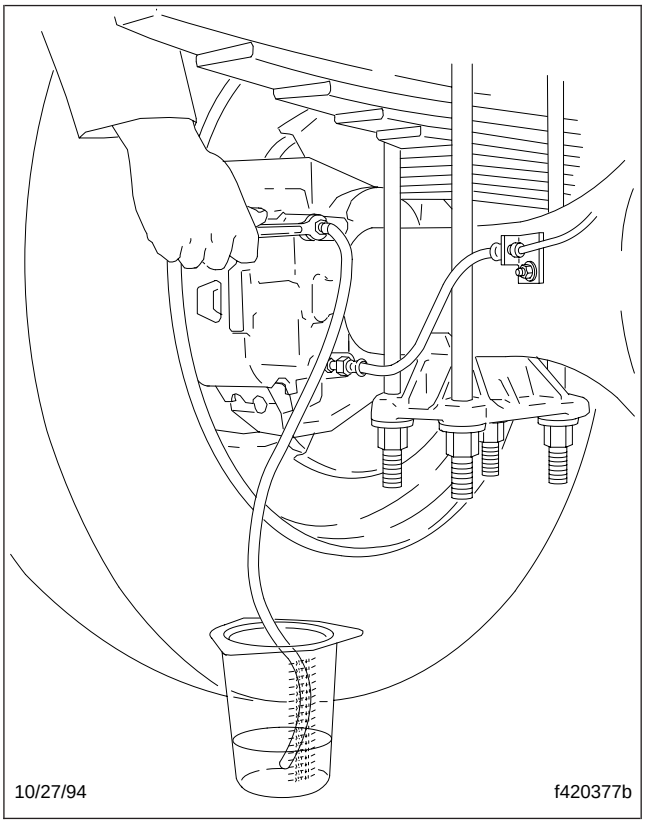


Fig. 2, Bleed the Connections at the Rear Wheel Calipers

fitting until it is free of air bubbles. Tighten the fitting firmly.

5.3 Move to the left rear caliper and repeat steps for bleeding the caliper.

6. Disconnect the pressure bleeder from the rear compartment of the master cylinder reservoir. Connect it to the front compartment of the reservoir.
7. Bleed the front wheel brake calipers, starting at the right side.

7.1 Put a wrench on the bleeder fitting at the caliper. Attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.

7.2 Loosen the bleeder fitting by about a 3/4 turn and let the brake fluid flow out of the fitting until it is free of air bubbles. Tighten the fitting firmly.

7.3 Move to the left front wheel caliper and repeat steps for bleeding the caliper.

8. Check the brake fluid level in both compartments of the reservoir. Add new DOT 3 approved brake fluid if needed.
9. Check the operation of the brakes by depressing the brake pedal several times until if feels firm. The brake pedal should not go all the way down to the floor. If it does, see "Troubleshooting" in **Section 42.26**, Subject 300 and find the problem.
10. Close and latch the hood.
11. Connect the batteries.
12. Remove the chocks from the rear tires.

Manual Bleeding

If you do not have pressure bleeding equipment, you can use the manual bleeding procedure.

IMPORTANT: Do not let the brake master cylinder fluid level get too low during manual bleeding operations. Keep the master cylinder reservoir filled with new, DOT 3 approved brake fluid. Failure to keep the brake reservoir filled could result in more air entering the system, making it impossible to effectively bleed the system.

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Open the hood.
3. Disconnect the batteries. The ignition must remain off for the entire bleed procedure.
4. Bleed the master cylinder.

4.1 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the rear outlet port on the master cylinder. See **Fig. 3**. Loosen the fitting about one turn.

4.2 Have someone push the brake pedal down slowly by hand to the floor. Brake fluid and any air in the master cylinder will squirt from the fitting.

4.3 *With the brake pedal held down*, tighten the rear hydraulic line fitting firmly.

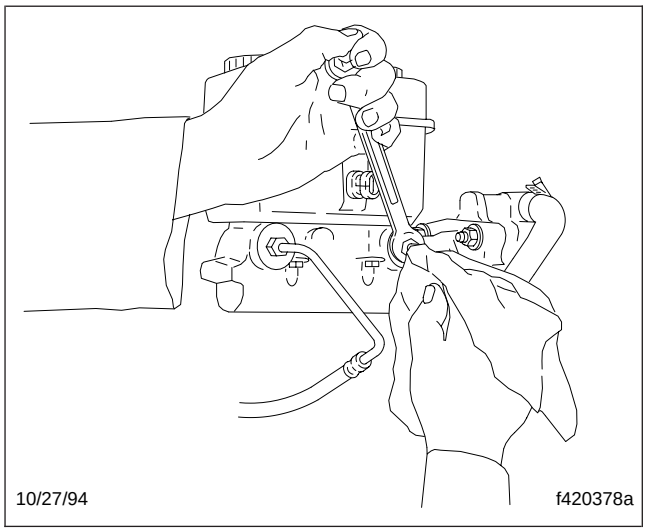

Fig. 3, Loosen the Fitting at the Rear Outlet Port

IMPORTANT: Do not release the brake pedal until the fitting is tightened or more air will get into the system.

4.4 Release the brake pedal.

4.5 Loosen the fitting again and repeat the steps for bleeding as required until no air escapes from the fitting and the brake pedal feels firm.

4.6 Check the fluid level of the rear compartment of the reservoir. Add new DOT 3 approved brake fluid if needed.

4.7 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the front outlet port on the master cylinder. See **Fig. 4**. Loosen the fitting about one turn.

4.8 Repeat steps as required for the front outlet port.

4.9 Check the brake fluid level in the front compartment of the reservoir. Add new DOT 3 approved brake fluid if needed.

5. Bleed the hydraulic connections at the wheel calipers, starting at the right rear wheel caliper.

5.1 Put a wrench on the bleeder fitting at the caliper. Attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.

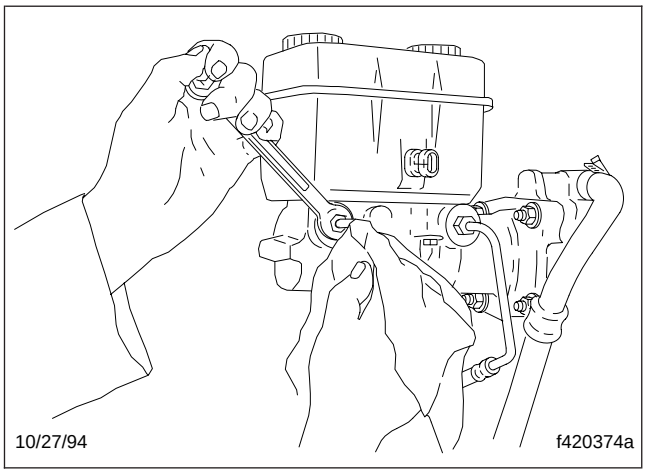

Fig. 4, Loosen the Fitting at the Front Outlet Port

5.2 Loosen the bleeder fitting by about a three-quarter turn.

5.3 Have an assistant slowly push the brake pedal to the floor. *With the brake pedal depressed*, tighten the bleeder fitting.

IMPORTANT: Make sure the brake pedal stays depressed while you tighten the fitting. If it is released before you tighten the fitting, more air will get into the system.

5.4 Release the brake pedal. Check the fluid in the tube. If there are air bubbles present, repeat steps as required until the fluid in the tube is completely free of air bubbles.

5.5 Check the brake fluid level in the reservoir. Add new DOT 3 approved brake fluid if needed.

5.6 Repeat the steps for bleeding the connections for the left rear caliper, the right front caliper and the left front caliper.

6. Close and latch the hood.

7. Connect the batteries.

8. Remove the chocks from the rear tires.

Voltage Check

NOTE: Along with the following, the voltage can also be checked using the Meritor WABCO PC Diagnostics-Toolbox Software.

IMPORTANT: Voltage must be between 9.5 and 14 volts for the 12-volt hydraulic ABS to function properly.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Turn the ignition on.
3. Check the voltage between 12 and 1, and pins 12 and 2, on the 18-pin connector.
4. If voltage is not between 9.5 and 14 volts, verify proper wiring connections. Make corrections as required.
5. Remove the chocks from the rear tires.

ABS Indicator Light

If the ABS indicator light does not come on after the ignition is turned on, check the bulb. Complete further diagnostics in **Troubleshooting 300**.

ABS Blink Code Switch

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires to prevent vehicle movement.
2. Check the resistance between the terminals while cycling the switch. There should be minimal resistance, if any, while the switch is in the momentary on position and infinite (high) resistance in its normal position, or off.
3. Remove the chocks from the rear tires.

Sensor Voltage Output Test

IMPORTANT: Sensor output voltage must be at least 0.2 volts AC at 30 rpm.

⚠ WARNING

Block the wheels to prevent the vehicle from moving. Support the vehicle with safety stands. Do not work under a vehicle supported only by jacks. Jacks can slip and fall over. Serious personal injury can result.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the front and rear tires.
2. Turn the ignition off.
3. Release the parking brakes.
4. To measure voltage at the pins on the sensor connector, disconnect the sensor from the chassis harness.
5. Raise the vehicle off of the ground. Put safety stands under the axle.
6. Rotate the wheel by hand at 30 rpm (1/2 revolution per second).
7. Measure the voltage across the two pins at the sensor connector.
8. If the voltage is not greater than 0.2 volts AC, adjust the sensor and recheck. If the voltage is still not greater than 0.2 volts AC, replace the sensor.
9. Apply the parking brakes.
10. Remove the safety stands and lower the vehicle.
11. Remove the chocks from the rear tires.

Sensor Resistance

IMPORTANT: The sensor resistance must be between 900 and 2000 ohms. Measure resistance at the sensor connector or at the pins on the ECU connector.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires to prevent vehicle movement.
2. Turn the ignition off.
3. Measure resistance at the sensor connector. Disconnect the sensor from the chassis harness.
4. Measure the resistance across the two pins at the sensor connector.

Component Tests

5. If the measurement is not between 900 and 2000 ohms, replace the sensor.
6. Remove the chocks from the rear tires.

Troubleshooting

Meritor WABCO PC Diagnostics-Toolbox Software

The Meritor WABCO PC Diagnostics-Toolbox Software can be used to diagnose hydraulic antilock brake system (ABS) faults. This software is packaged with the CD ServiceLink and provides J1587 fault codes and on-screen information to assist in troubleshooting. Toolbox software must be used to reconfigure the ECU. The D version ECU does not allow reconfiguration through the blink code switch. See *Meritor WABCO Maintenance Manual No. 39, Rev. 1/00*.

Servicelink

ServiceLink can be used to troubleshoot the Meritor WABCO hydraulic ABS. J1587 fault codes can be read by connecting the vehicle to the ServiceLink computer.

J1587 Fault Codes

See **Table 1** for a listing of J1587 fault codes.

Instrument Panel Blink Codes

This system has built-in diagnostics to ensure that all components are operating properly. The ABS warning light in the instrument control unit comes on when the ignition is turned on. After about 3 seconds the light goes out if all of the ABS components are working correctly. If the light stays on, or comes back on later, a problem within the ABS has occurred. The vehicle can continue to be driven, but the ABS could be partially or completely inoperative. To check the fault code recorded, stop the vehicle and turn off the engine. Turn on the ignition switch, but do not start the engine. If the light stays on, there is an "active" system fault that must be repaired to ensure proper system operation. See **Table 2** for a listing of instrument panel blink codes.

Table 2, Blink Code Cross Reference

Use the ABS CHECK switch (**Fig. 1**), located behind the driver's seat, and the ABS light to display system faults. With the ignition switch on, hold the ABS switch ON for 1 second. The ABS light should go out. After a 1-second pause, the ABS light will blink any active or stored fault codes. Each fault code will be indicated by two sets of flashes. The number of blinks displaying the first digit will be a number between one and eight. After a 1-1/2 second pause, the second digit will be displayed. The number of blinks displaying the second digit will be a number between one and eight. After a 4-second pause, the diagnostic code cycle continues to repeat the active fault code until the fault is repaired.

A. ABS Check Switch (access through opening in cover)
1. ABS ECU Cover

Fig. 1, ABS ECU Check Switch Location (behind driver's seat)

IMPORTANT: Active fault codes must be corrected before you can see stored faults.

For example, after the ABS CHECK switch has been turned on, the fault code 2–3 will blink, shown by two

flashes, a pause of 1-1/2 seconds, followed by three flashes. After a 4-second pause, the same fault code will continue to repeat, always ending with a 4-second pause.

- If it is an active fault, the same fault code will repeat until the ignition switch is turned off. See **Fig. 2**.
- If it is a stored fault, the next fault in the ECU memory will be displayed after the 4-second pause. See **Fig. 3**. The last fault stored in memory is displayed first; each stored fault is displayed only once.
- If there are no fault codes in the ECU memory, blink code 1–1 is displayed, meaning the system is clear. See **Fig. 4**.

Once a fault code has been identified, use a digital multimeter (DMM) to check the electrical harness at the electronic control unit (ECU) connectors or the modulator assembly connectors. Connect the meter leads to the applicable pins on each connector. See **Fig. 5** and **Table 3** for a description of the circuit wire numbers and their location within the pin connectors.

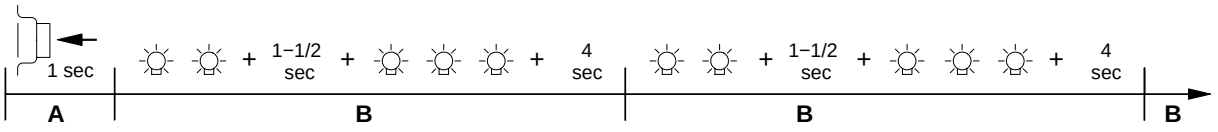
NOTE: In the harness connector, there is a jumper in Pin 15 that jumps Pin 12 to Pin 18 when the connector is disconnected from the ECU. This will cause the ABS lamp to illumincate if the connector is disconnected.

See **Fig. 6** for pin-out locations at the brake pressure modulator.

IMPORTANT: The ignition switch must be off when connecting or disconnecting the ECU.

NOTE: The active blink codes are erased from ECU memory as repairs are made. Once a repair has been made, cycle the ignition to ensure the blink code does not reappear. If there are any other outstanding faults, the next blink code will be displayed.

If the ABS light does not operate correctly after the ignition is turned on (the light does not come on at all or it does not go out after about 3 seconds), check all circuit breakers in the control unit panel and replace if necessary. Check the wiring to the ABS CHECK switch and the warning light and repair or replace the wiring as needed. When checking the warning light:



- Replace the bulb;
- Check for a fault in the warning lamp circuit, use a lamp test in Meritor PC-based diagnostics;

When checking the switch:

- Check the resistance between the terminals while cycling the switch;

The ABS system needs between 9.5 and 14 volts.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Group 54** for information on special terminals and connectors and ordering tools for them.

05/18/2000 f151013

NOTE: An active fault code repeats until the ignition switch is turned off.

A. Press the ABS CHECK switch for one second, then release. The ABS light goes out. After a 1-second pause, blink codes start.
B. Blink code 2–3: two blinks, a 1.5-second pause, three blinks, and a 4-second pause.

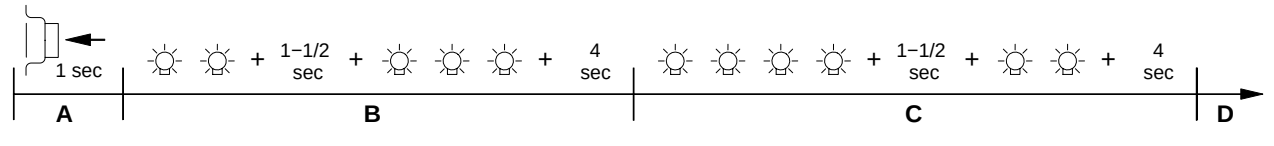


Fig. 2, Active Fault Codes Repeat (Blink Code 2-3 Shown)

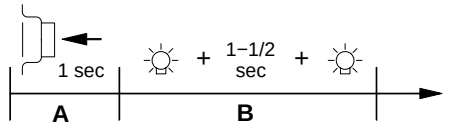
Make the necessary repairs and clear the fault code from the ECU memory. If more than one active fault exists, it will be displayed after the first one has been cleared from memory.

A DMM can determine the condition of the ABS valves, wheel end sensors and associated wiring.

See the wiring diagrams in **Specifications 400** when troubleshooting the ABS system. If a fault cannot be repaired or erased from ECU memory, contact your

Troubleshooting



05/18/2000 f151014

NOTE: The last fault stored is displayed first; each stored fault is displayed only once.

A. Press the ABS CHECK switch for one second, then release. The ABS light goes out. After a 1.5-second pause, blink codes start.
B. The newest stored fault is displayed (blink code 2–3 is shown).
C. The second newest stored fault is displayed if one exists (blink code 4–2 is shown).
D. The third newest stored fault is displayed if one exists.

Fig. 3, Stored Fault Codes Display in Sequence

05/18/2000 f151012

A. Press the ABS CHECK switch for one second, then release. The ABS light goes out. After a 1-second pause, blink codes start.
B. Blink code 1–1: one blink, a 1-1/2 second pause, and 1 blink (system okay code).

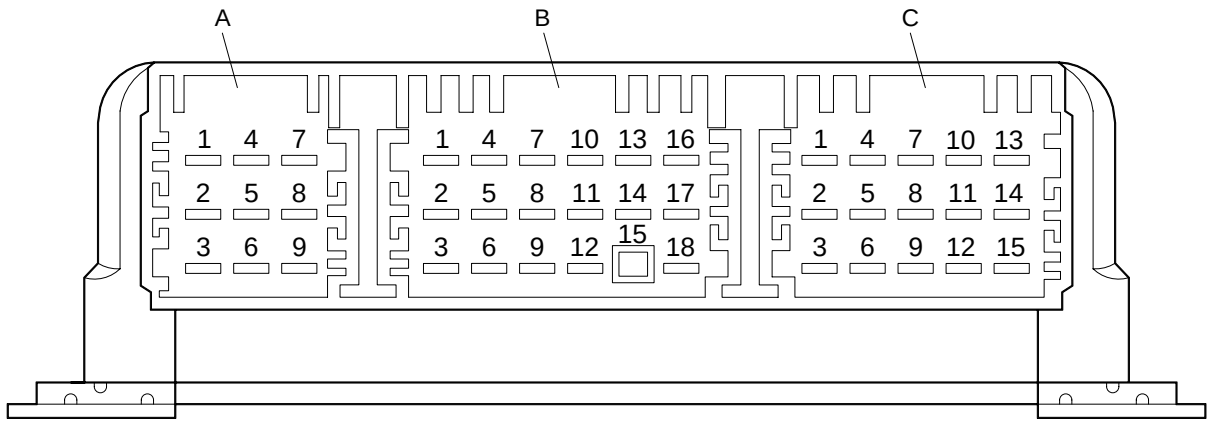


Fig. 4, No Faults, System OK

Erasing a Fault from the ECU Memory

NOTE: An active fault cannot be erased until it has been corrected.

Meritor WABCO recommends that you erase all faults from the ECU memory after they have been noted and corrected.

Stored faults are erased from the ECU memory by doing the following:

01/11/2000 f422100

A. 9-Pin ECU Connector
B. 18-Pin ECU Connector
C. 15-Pin ECU Connector

Fig. 5, "D" Basic ECU

District Service Manager or call Meritor WABCO at 1-800-535-5560.

1. Turn the ignition switch on.
2. Press the blink code switch on and hold for 3 seconds.

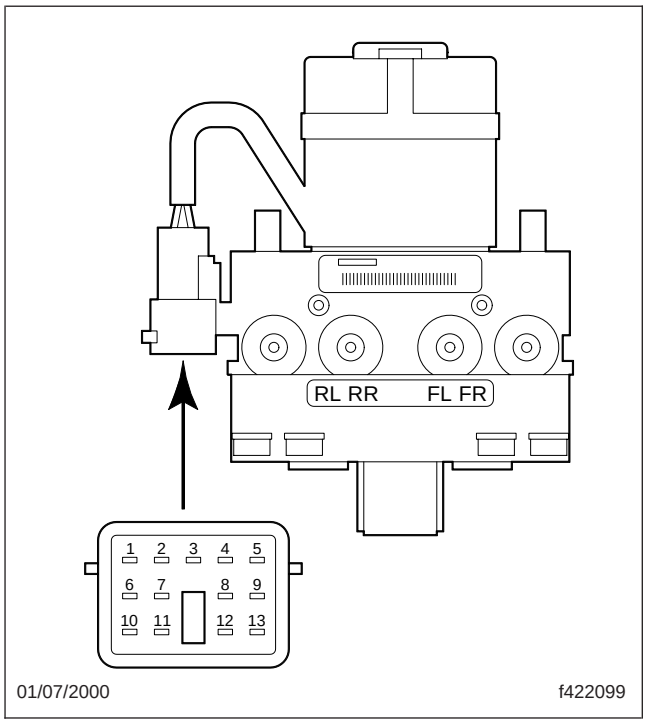

Fig. 6, Pin Locations at the Brake Pressure Modulator

3. Release the blink code switch.
4. If the ABS light flashes eight times and the system status code is repeated (Code 2), all stored faults have been successfully cleared. Turn the ignition OFF.

   Turn the ignition ON. The ABS light stays on because the system is looking for a wheel speed. Drive the vehicle above a speed of 4 mph (6 km/h). Once the ECU senses a wheel speed the light will go out. If the light remains on, there are still active faults.

   If the ABS light does not flash eight times, just flashing Code 2, active faults still exist. Repair the active fault and repeat the procedure to clear the fault codes.

Reset Memorized (Learned Components)

The ECU learns whether or not a retarder relay circuit is present. Once the ECU has detected a retarder circuit, it expects to see it every time the vehicle is powered up and will monitor the circuit for faults. If the ECU senses a resistance on the retarder circuit it will automatically learn that the retarder circuit exists. If an engine retarder circuit does not exist, but the ECU has detected one and is indicating faults, something may have been connected (a multimeter, etc.) to the retarder circuit during testing. Moisture, faulty circuit wiring, or moving an ECU from one vehicle to another can also cause the ECU to mistakenly detect a non-existent retarder circuit. If necessary, use the "Reset Memorized" command in the Meritor WABCO PC Diagnostics-Toolbox Software to clear the ECU memory of this component. For instructions, see *Meritor WABCO Maintenance Manual No. 39, Rev. 1/00*.

Troubleshooting Tables

J1587 Fault 136s001 Left Front Wheel Sensor							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	001	01	Incorrect sensor air gap	1. Adjust the sensor. Check the AC voltage across the two pins at the sensor connector while rotating the left front wheel 30 rpm.	Voltage greater than 0.2 VAC	Sensor adjustment solved the problem. Clear the stored faults and drive the vehicle 4 mph (6 km/h).	3-2
					Voltage less than 0.2 VAC	Check for excessive wheel bearing end play. Repair as necessary.	
136	001	02	Intermittent open circuit or incorrect sensor resistance NOTE: This SAE J1587 fault code can also be caused by incorrect or mixed tire size (see information in TEST 4 below). The only way to determine the exact fault is to use blink code diagnostics. If blink code is 5-1, 5-2, 5-3 or 5-4, perform TEST 4 below.	2. Measure the resistance across Pins 1 and 2 of the 9-pin EC3 ECU connector (Circuits 377LF+ and 377LF–).	Resistance reading between 900 and 2000 ohms	Check for intermittent, loose or poor connections in Circuits 377LF+ and 377LF– and repair as necessary. If the problem persists, suspect the ECU is at fault.	4-2
					Resistance reading below 900 or above 2000 ohms	Go to TEST 3.	
				3. Disconnect the sensor at the sensor connector. Measure the resistance at the sensor connector (on the sensor side).	Resistance reading between 900 and 2000 ohms	Check the wiring between the ECU and the wheel sensor (Circuits 377LF+ and 377LF–). Repair as necessary. Go to TEST 4.	
					Resistance reading below 900 or above 2000 ohms	Replace the wheel sensor.	

Troubleshooting

J1587 Fault 136s001 Left Front Wheel Sensor							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	001	02	Incorrect or mixed tire size NOTE: This SAE J1587 fault code can also be caused by an intermittent open circuit or incorrect sensor resistance. The only way to determine the exact fault is to use blink code diagnostics. If blink code is 5-1, 5-2, 5-3 or 5-4, perform TEST 4. If blink code is 4-2, perform TESTS 2 and 3.	4. Check for tire size deviation in excess of 16 percent. Mixed tire sizes can cause this fault.	Tire size correct and size varies no more than 16 percent.	Check blink codes. If blink code 4-2 then perform TEST 2 and TEST 3 above if not already done. Verify fault and check ECU if problem cannot be verified	5-1 5-2 5-3 5-4
					The tire size varies more than 16 percent	Install the correct size tires.	
136	001	05	Open circuit	5. Measure the resistance across Pins 1 and 2 of the 9-pin EC3 ECU connector (Circuits 377LF+ and 377LF–).	Resistance reading between 900 and 2000 ohms	Check for intermittent, loose or poor connections in Circuits 377LF+ and 377LF– and repair as necessary. If the problem persists, suspect the ECU is at fault.	4-2
					Resistance reading below 900 or above 2000 ohms	Go to TEST 6.	
				6. Disconnect the sensor at the sensor connector. Measure the resistance at the sensor connector (on the sensor side).	Resistance reading between 900 and 2000 ohms	Check the wiring between the ECU and the wheel sensor (Circuits 377LF+ and 377LF–). Repair as necessary.	
					Resistance reading below 900 or above 2000 ohms	Replace the wheel sensor.

Troubleshooting

J1587 Fault 136s004 Right Rear Wheel Sensor							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	004	01	Incorrect sensor air gap	1. Adjust the sensor. Check the AC voltage across the two pins at the sensor connector while rotating the right rear wheel 30 rpm.	Voltage greater than 0.2 VAC	Sensor adjustment solved the problem. Clear the stored faults and drive the vehicle 4 mph (6 km/h).	3-3
					Voltage less than 0.2 VAC	Check for excessive wheel bearing end play. Repair as necessary.	
136	004	02	Intermittent open circuit or incorrect sensor resistance	2. Measure the resistance across Pins 3 and 6 of the 9-pin EC3 ECU connector (Circuits 377RR+ and 377RR–).	Resistance reading between 900 and 2000 ohms	Check for intermittent, loose or poor connections in Circuits 377RR+ and 377RR– and repair as necessary. If the problem persists, suspect the ECU is at fault.	4-3
					Resistance reading below 900 or above 2000 ohms	Go to TEST 3.	
				3. Disconnect the sensor at the sensor connector. Measure the resistance at the sensor connector (on the sensor side).	Resistance reading between 900 and 2000 ohms	Check the wiring between the ECU and the wheel sensor (Circuits 377RR+ and 377RR–). Repair as necessary.	
					Resistance reading below 900 or above 2000 ohms	Replace the wheel sensor.	

J1587 Fault 136s004 Right Rear Wheel Sensor							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	004	05	Open circuit	4. Measure the resistance across Pins 3 and 6 of the 9-pin EC3 ECU connector (Circuits 377RR+ and 377RR–).	Resistance reading between 900 and 2000 ohms	Check for intermittent, loose or poor connections in Circuits 377RR+ and 377RR– and repair as necessary. If the problem persists, suspect the ECU is at fault.	4-3
					Resistance reading below 900 or above 2000 ohms	Go to TEST 5.	
				5. Disconnect the sensor at the sensor connector. Measure the resistance at the sensor connector (on the sensor side).	Resistance reading between 900 and 2000 ohms	Check the wiring between the ECU and the wheel sensor (Circuits 377RR+ and 377RR–). Repair as necessary.	
					Resistance reading below 900 or above 2000 ohms	Replace the wheel sensor.	

Table 7, J1587 Fault 136s004 Right Rear Wheel Sensor

Troubleshooting

J1587 Fault 136s013 Retarder							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	013	03	Short to power	1. Disconnect the 15-pin EC2 connector at the ECU. With the ignition ON, measure the voltage between Pin 12 of the 15-pin EC2 ECU connector and a good chassis ground.	Voltage is zero	Check for intermittent short to power in Circuit 376R. If the problem persists, suspect the ECU is at fault.	7-3
					Voltage not zero	Check for short to power in Circuit 376R. Repair as necessary.	
136	013	05	Open circuit	2. Disconnect the 15-pin EC2 connector at the ECU. With the ignition OFF, measure the resistance between Pin 12 of the 15-pin EC2 ECU connector and a good chassis ground.	Resistance is 59 to 71 ohms	If problem persists, suspect ECU is at fault	
					Resistance is 71 to 680 ohms	Check for poor or loose connections in circuit 376R and GND. If resistance is right at 680 Ohms, the retarder relay coil is open.	
					Resistance is greater than 680 ohms	If resistance is right at 680 Ohms then the retarder relay is open. If greater than 680 Ohms the retarder relay coil and its resistor are both open, or circuit 376R is open, or retarder relay coil ground circuit is open. repair as necessary. *	
136	013	06	Short to ground	3. Disconnect the 15-pin EC2 connector at the ECU. With the ignition OFF, measure the resistance between Pin 12 of the 15-pin EC2 ECU connector and a good chassis ground.	Resistance is 59 to 71 Ohms	If problem persists, suspect ECU is at fault	
					Resistance below 59 ohms	Check circuit 376R for short to ground, check for shorted retarder relay coil and resistor. Repair as necessary. *	

* NOTE: The retarder relay has a 680 Ohm resistor in parallel with the coil. Proper resistance across the coil terminals (85 and 86) should be approximately 59 to 71 Ohms (this is the combined resistance through both the coil and the resistor). If the resistor is open, the resistance across the coil terminals will be approximately 72 Ohms ±7 Ohms. If the relay coil is open, the resistance across the coil will be approximately 680 Ohms.

Table 8, J1587 Fault 136s013 Retarder

J1587 Fault 136s014 Power							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	014	03	Voltage supplied to ECU with ignition OFF This fault is caused by a malfunction to the internal relay to power the solenoid valves.	—	—	Replace ECU NOTE: If diagnosed by blink code 8-2, there may be another cause. See troubleshooting information under J1587 fault code 136 s251 before condemning the ECU.	8-2 *
136	014	04	No voltage supplied to ECU with ignition ON	2. Disconnect the 18-pin ECU connector. Measure the voltage between pin 8 (circuit 376A) and a good ground. Repeat test measuring the voltage between pin 1 (circuit 376B) and a good ground. NOTE: If the vehicle has a battery shut-off switch, make sure it is on. The above test assumes that the batteries are fully charged and have a nominal voltage reading of 12-volts at the batteries.	Voltage between 9.5 and 14 volts at both pins	Check for intermittent faults in circuits 376A and 376B. Check ECU ground circuit. If problem circuit fault can not be found and problem persists, replace the ECU.	8-1 *
					Voltage below 9.5 volts at either pin	Check the 25A and 40A ABS fuses. Check circuits 376A and 376B for open circuit or poor connection. Repair as necessary.	

* There is additional troubleshooting information for this blink code in Table 21.

Table 9, J1587 Fault 136s014 Power

Troubleshooting

J1587 Fault 136s023 ABS Warning Lamp							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	023	05	Open circuit or low current	1. Disconnect the 18-pin EC1 connector from the ECU. Turn the ignition ON.	ABS lamp illuminates	Check for intermittent wiring connections in Circuit 376L. If the wiring is OK, suspect the ECU is at fault.	7-4
					ABS lamp does not illuminate	Go to TEST 2.	
				2. Turn the ignition OFF and disconnect the 18-pin EC1 connector from the ECU. Measure the resistance between pin 18 of the EC1 connector and a good chassis ground.	Resistance is near zero Ohms	Go to TEST 3.	
					Resistance is above zero Ohms	Check the ground circuit (GRD6) between pin 12 of the 18-pin EC1 connector and ground splice S1. NOTE: There is a shorting bar in the 18-pin connector between pins 12 and 18. This bar should make contact between these pins when the connector is disconnected, thus providing the ground path to the ABS warning lamp.	
				3. Replace the ABS lamp in the ICU with a known good one. Leave the 18-pin EC1 connector disconnected. Turn the ignition ON.	ABS lamp illuminates	Replace the ABS lamp.	
					ABS lamp does not illuminate	Go to TEST 4.	
				4. Disconnect the B connector from the back of the ICU (leave the 18-pin EC1 connector disconnected). Measure the resistance between pin B11 of the ICU B connector and a good ground.	Resistance is near zero Ohms	Check the ICU, replace as necessary.	
					Resistance is above zero Ohms	Check circuit 376L between the ICU and the ABS ECU. Repair as necessary.	

Table 10, J1587 Fault 136s023 ABS Warning Lamp

J1587 Fault 136s030 Recirculation Pump Relay							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	030	03	Relay shorted to power	1. Disconnect the 15-pin EC2 connector. With the ignition ON, measure the voltage between pin 15 and a good chassis ground.	Voltage is zero	If the problem persists, suspect the ECU is at fault.	7-8
					Voltage is not zero	Circuit 376H is shorted to power. Repair as necessary.	
136	030	05	Relay open circuit	2. Disconnect the 15-pin EC2 connector. Measure the resistance between pin 15 and a good chassis ground.	Resistance is 59 to 71 Ohms	If the problem persists, suspect the ECU is at fault.	
					Resistance is 71 to 680 Ohms	Check for poor or loose connections in circuit 376H & GRND5. If the resistance is 680 Ohms, the relay coil is open.	
					Resistance is greater than 680 Ohms	If resistance is right at 680 Ohms then the relay coil is open, If greater than 680 Ohms either the relay coil and its resistor are both open, or circuit 376H is open, or relay coil ground circuit is open (GND5). Repair as necessary. *	
136	030	06	Relay short to ground	3. Disconnect the 15-pin EC2 connector. Measure the resistance between pin 15 and a good chassis ground.	Resistance between 59 and 71 ohms	If the problem persists, suspect the ECU is at fault.	
					Resistance below 50 or above 200 ohms	Check circuit 376H for short to ground, check for shorted relay coil and resistor. Repair as necessary. *	
136	030	07	Pump relay sticks, pump continues to run when ECU deactivates the relay NOTE: The problem may be intermittent and a new relay may be required to correct the fault.	4. If the fault is active, disconnect the 15-pin EC2 connector from the ECU. With the ignition ON, check to see if the recirculation pump is running.	Pump is OFF	ABS pump relay may be intermittently sticking. Try a new relay and verify that problem is solved.	
					Pump is ON	ABS pump relay is sticking. Replace relay.	

* The ABS pump relay (Siemens VF7-41F11) has a 680 Ohm resistor in parallel with the coil. Proper resistance across the coil terminals (85 and 86) should be approximately 59 to 71 Ohms (this is the combined resistance through both the coil and the resistor). If the resistor is open, the resistance across the coil terminals will be approximately 72 Ohms ±7 Ohms. If the relay coil is open, the resistance across the coil terminals will be approximately 680 Ohms.

Table 11, J1587 Fault 136s030 Recirculation Pump Relay

Troubleshooting

J1587 Fault 136s042 Left Front Inlet Solenoid Valve							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	042	03 05 06	Shorted to power Open circuit Shorted to ground NOTE: Check for an open circuit in the wiring between the ECU and the modulator valve. Check the ground circuit to the modulator valve.	1. Measure the resistance across pins 2 and 3 of the 15-pin EC2 connector (circuits 378LFI and GRD7).	Resistance is 6.5±0.5 Ohms.	Check for intermittent wiring connections. If the wiring is OK, suspect the ECU is at fault.	2-2
					Resistance is not 6.5±0.5 Ohms	Go to TEST 2.	
				2. Check the ground circuit by measuring the resistance between pin 3 of the 15-pin EC2 connector and a good chassis ground.	Resistance is near zero Ohms	Go to TEST 3.	
					Resistance is above zero Ohms	Check and repair the ground circuit.	
				3. Measure the resistance in circuit 378LFI between the modulator connector pin 12 and the 15-pin ECU2 connector pin 2.	Resistance is near zero Ohms	Go to TEST 4.	
					Resistance is above zero Ohms	Repair circuit 378LFI.	
				4. With the modulator valve connector removed, measure the resistance across pins 8 and 12 (on the modulator).	Resistance is 6.5±0.5 Ohms.	Repeat tests 1 - 4. Problem may be intermittent. If wiring is OK, suspect the ECU is at fault	
					Resistance is not 6.5±0.5 Ohms	Replace modulator valve

MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	051	03 05 06	Shorted to power Open circuit Shorted to ground NOTE: Check for an open circuit in the wiring between the ECU and the modulator valve. Check the ground circuit to the modulator valve.	1. Measure the resistance across pins 10 and 3 of the 15-pin EC2 connector (circuits 378RRO and GRD7).	Resistance reading 3.5±0.5 ohms	Check for intermittent wiring connections. If the wiring is OK, suspect the ECU is at fault.	2-3
					Resistance reading not 3.5±0.5 ohms	Go to TEST 2.	
				2. Check the ground circuit by measuring the resistance between pin 3 of the 15-pin EC2 connector and a good chassis ground.	Resistance is near zero Ohms	Go to TEST 3.	
					Resistance is above zero Ohms	Check and repair the ground circuit.	
				3. Measure the resistance in circuit 378RRO between the modulator connector pin 10 and the 15-pin ECU2 connector pin 10.	Resistance is near zero Ohms	Go to TEST 4.	
					Resistance is above zero Ohms	Repair circuit 378RRO.	
				4. With the modulator valve connector removed, measure the resistance across pins 10 and 8 (on the modulator).	Resistance reading 3.5±0.5 ohms	Repeat tests 1 - 4. Problem may be intermittent. If wiring is OK, suspect the ECU is at fault.	
					Resistance reading not 3.5±0.5 ohms	Replace modulator valve.	

Table 19, J1587 Fault 136s051 Right Rear Outlet Solenoid Valve

Troubleshooting

J1587 Fault 136s054 Recirculation Pump							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	054	03	Recirculation pump on without being activated by ECU NOTE: In this case the ECU is sensing voltage on the pump monitor circuit (pin 8 of the 18-pin EC1 connector) when the pump relay was not activated by the ECU (pin 15 of the 15-pin EC2 connector).	1. Remove the 15-pin EC2 connector from the ECU. With the ignition ON, measure the voltage between pin 15 and a good chassis ground.	Voltage is zero.	Check the ECU and verify the fault.	7-7
					Voltage is not zero.	Go to TEST 2.	
				2. Remove the ABS pump relay and repeat TEST 1.	Voltage is zero.	Check pump relay; it may be sticking or shorted.	
					Voltage is not zero.	Check for a short to power in Circuit 376A causing the pump to run when it should not be. Repair as necessary.	
136	054	04	Recirculation pump does not switch on when activated by the ECU NOTE: In this case the ECU does not sense voltage on the pump monitor circuit (pin 8 of the 18-pin EC1 connector) when the pump relay was activated by the ECU (pin 15 of the 15-pin EC2 connector).	3. Remove both the 18-pin EC1 and 15-pin EC2 connectors from the ECU. With the ignition ON, Link pin 2 of the 18-pin EC1 connector to pin 15 of the 15-pin EC2 connector while measuring the voltage between pin 8 of the 18-pin EC1 connector and a good chassis ground. Note: the pump should run (do not hold for more than one minute).	Voltage is between 9.5 and 14 volts.	Check for intermittent connections in circuit 376A, check pump relay for intermittent operation. Repair as necessary.	
					Voltage is below 9.5 or above 14 volts.	Check circuit 376A, check the pump relay. Repair as necessary.	
136	054	07	Recirculation pump sticks or is locked NOTE: In this case, the ECU senses high current on the pump monitor circuit (pin 8 of the 18-pin EC1 connector) indicating the pump motor is locked.	4. Remove both the 18-pin EC1 and 15-pin EC2 connectors from the ECU. With the ignition ON, momentarily link pin 2 of the 18-pin EC1 connector to pin 15 of the 15-pin EC2 connector. Note: the pump should run (do not hold for more than one minute).	Pump runs	Repeat the test to verify. If the fault persists, suspect a problem with the ECU.	
					Pump does not run	Replace the recirculation pump.	

Table 20, J1587 Fault 136s054 Recirculation Pump

J1587 Fault 136s055 ECU							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	055	02	Reference to ground interrupted	1. With the ignition OFF, measure the voltage between pin 3 of the 15-pin EC2 connector (circuit GRD7) and a good chassis ground.	Voltage is zero	Go to TEST 2.	2-7
					Voltage is not zero	Check the ground circuit for a short to positive voltage.	
				2. Measure the resistance between pin 3 of the 15-pin EC2 connector and a good chassis ground.	Resistance near zero ohms	Check ECU ground circuit (GRD7) for intermittent or loose connection. Check pump and modulator ground circuits for intermittent or poor connections. If problem persists, suspect the ECU is at fault.	
					Resistance above zero ohms	Check ground circuit GRD7, pump ground, and modulator ground. Repair as necessary	

Table 21, J1587 Fault 136s055 ECU

J1587 Fault 136s251 Low Voltage							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	251	03	Voltage too high NOTE: Voltage to the ABS ECU must be between 9.5 and 14 volts to function properly.	1. Disconnect the 18-pin EC1 connector. Start the engine, run it at governed speed while measuring voltage between pins 2 and 12.	Voltage between 9.5 and 14 volts	Check the electrical system. If the problem persists, suspect the ECU is at fault.	8-2 *
					Voltage below 9.5 or above 14 volts	Check the batteries and charging system for malfunction. Repair as necessary.	

Troubleshooting

J1587 Fault 136s251 Low Voltage							
MID	**SID**	**FMI**	**Problem**	**Test**	**Test Result**	**Action**	**Blink Code**
136	251	04	Low voltage to ABS solenoid valves NOTE: Voltage to the ABS ECU must be between 9.5 and 14 volts to function properly.	2. Disconnect the 18-pin EC1 connector. Start the engine, run it at idle while measuring voltage between pins 2 and 12.	Voltage between 9.5 and 14 volts	Verify that the batteries were not drained or the charging system was not overloaded when the fault occurred. If the problem persists, suspect the ECU is at fault.	8-1 *
					Voltage below 9.5 or above 14 volts	Check the batteries and charging system for malfunction. Repair as necessary.	

* There is additional troubleshooting information under 136s014 for this blink code (**Table 8**).

General Information

Bosch hydraulic pin slide disc brakes are two piston sliding caliper brakes for use at both front and rear wheels. See **Fig. 1**. Each pin slide caliper disc brake wheel installation is comprised of three major components. See **Fig. 2**.

taches to and slides on sealed pins located in an anchor plate. The anchor plate is mounted on the steering knuckle flange on front axles or on the axle flange on rear axles. Two sizes of calipers are used: 66mm Twin (2 piston) and 73mm Twin (2 piston). See **Fig. 3**.

pers covering the anchor plate pad abutments. Inboard and outboard disc brake pads may be chamfered, and if so are marked with an arrow and the word "FORWARD" for proper installation. Brake pads may not be interchangeable inner to outer, so correct location is required during assembly.

Anchor Plate Assembly

The anchor plate includes lubricated floating guide pins sealed by rubber boots and anchor plate pad abutments protected by stainless steel slippers. A tie bar which spans the anchor plate abutment arms is used on 73mm pin slide disc brake installations only. A splash shield on the back of the rotor helps protect the brake assembly from road contamination. Bosses are provided for mounting an antilock brake system speed sensor. See **Fig. 4**.

Safety Precautions

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by NIOSH or MSHA. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

Because many brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Because medical experts believe that long-term exposure to some non-asbestos fibers could also be a health hazard, also observe the following precautions if servicing non-asbestos brake linings.

NOTE: The vehicle is originally equipped with non-asbestos brake linings.

Exposure to airborne brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

During brake servicing, wear an air purifying respirator with high-efficiency filters. The respirator and filter must be approved by NIOSH or MSHA, and worn during all procedures.

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency particulate air (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, or can not be used, clean the brake assembly in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with an HEPA filter system, remove dust from the brake rotors, caliper assemblies, dust shields, and brake pads. After vacuuming, remove any remaining dust using a rag soaked in water and wrung until nearly dry.

⚠ WARNING

Hydraulic brake fluid is hazardous, and can cause blindness if it gets in your eyes. Always wear safety glasses when handling brake fluid or bleeding brake components. Brake fluid may also be a skin irritant. If you get it on your skin, wash it off as soon as possible.

Special care must be taken when disposing of used brake fluid. Put the fluid in a sealed plastic container and label it "Used Brake Fluid." Then dispose of it in an approved manner. Check with local and state regulations as to the correct disposal procedure.

IMPORTANT: During service procedures, keep grease and other foreign material away from caliper assemblies, disc brake pads, brake rotors and external surfaces of the hub. Handle parts carefully to avoid damage to the caliper, rotor, disc brake pads or brake lines.

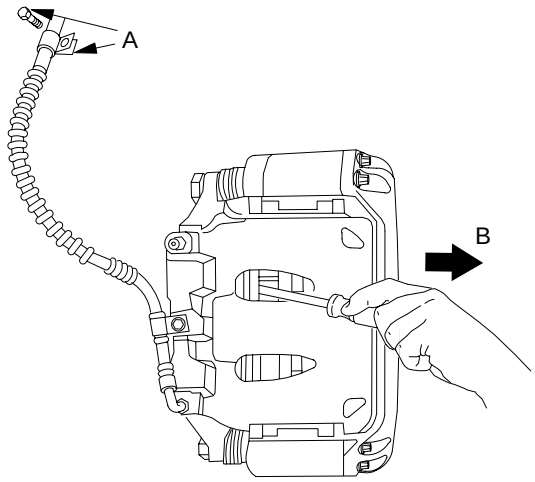
Brake Pad Removal, Inspection and Installation

⚠ WARNING

Before starting the procedures below, read the information in Subject 100. Failure to do so could result in serious and permanent health damage.

IMPORTANT: It is recommended that all disc brake pads on the vehicle be replaced at the same time. This will maintain balanced braking. If complete replacement is not desirable or necessary, make sure that at a minimum all disc brake pads on one axle (both ends) are replaced at the same time.

Removal



1. Park the vehicle on a level surface. Shut down the engine and apply the parking brake.
2. Open the hood.
3. If removing rear axle wheel pads, remove about half of the fluid from the rear section of the master cylinder reservoir. If removing front axle wheel pads, remove about half of the fluid from the front section.
4. Chock the front or rear tires, depending on which axle is being worked on. Jack up the axle and support it with jackstands.
5. Remove the tires.
6. Visually inspect all brake pad linings. Lining pads should be replaced when the remaining lining reaches 3/16-inch (5-mm) thickness or less.

⚠ CAUTION

Care must be taken when positioning the pry bar. Incorrect positioning of the pry bar could result in damage to the caliper.

7. Insert a pry bar in one of the rotor cooling fin slots and pry the caliper outboard, pushing the caliper pistons into the piston bores. See **Fig. 1**.
8. On front axles only, remove the brake line retaining clip from its support mounting. This will allow the brake line hose to hang free. See **Fig. 1**.

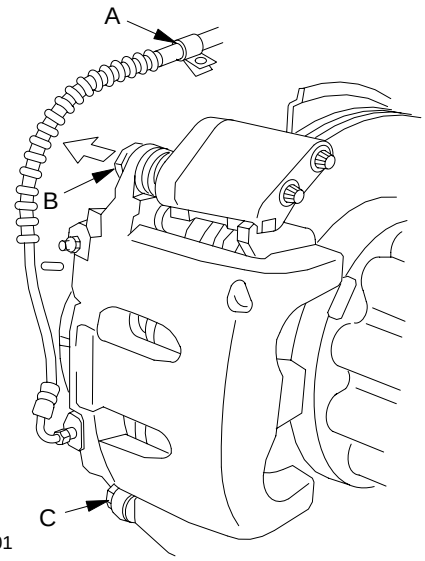
IMPORTANT: When servicing disc brake pads only, loosen and remove the upper (top) caliper pin mounting bolt. Do not loosen the lower (bottom) pin mounting bolt.

A. Remove this screw and clip on front axles only.
B. Move the caliper outboard to push the pistons in.

Fig. 1, Piston Retraction and Brake Line Clip Removal

9. Remove only the upper (top) pin mounting bolt. See **Fig. 2**.

⚠ CAUTION



Do not pull on the guide pins. This may dislodge the guide pin boot from the guide pin or anchor plate grooves, which could damage the guide pin boot.

10. Swing the caliper assembly away from the rotor by carefully rotating the caliper on the lower pin mounting bolt and guide pin. See **Fig. 3**. Do not allow the brake line hose to become pinched or kinked.
11. Remove the inboard and outboard disc brake pads from the anchor plate pad abutment slippers.

IMPORTANT: Do not mark on the pad face.

12. If the original disc brake pads are to be reused, be sure to mark them in some manner so that they are installed in the same location.

Brake Pad Removal, Inspection and Installation

A. Make sure this clip is detached from the support bracket.
B. Loosen and remove the upper pin mounting bolt.
C. Do not loosen the lower pin mounting bolt.

Fig. 2, Remove Upper Pin Mounting Bolt

Inspection

IMPORTANT: Do not damage or dislodge the guide pin boots while cleaning the machined surfaces.

1. Inspect the machined surfaces of the caliper, guide pin mounting face, and anchor plate. If rust or corrosion is present, use a hand-held wire brush to clean the surfaces.
2. Inspect the caliper, piston seals, and pistons for leakage or damage. If leakage or damage is found, repair or replace the piston(s) as required.
3. Inspect the anchor plate for damage to the mating surfaces at the anchor plate pad abutment slippers and guide pin heads. If damage is found, repair or replace as required.
4. Inspect the rotor for scoring, warping, cracks bluing, heat spots or other damage. See **Fig. 4**. If any damage is found, repair or replace the rotor. For instructions, see **Subject 140**.

Installation

1. Position a metal plate across both caliper pistons. Use a C-clamp to push both pistons into the caliper to provide clearance for the new disc brake pads. See **Fig. 5**.

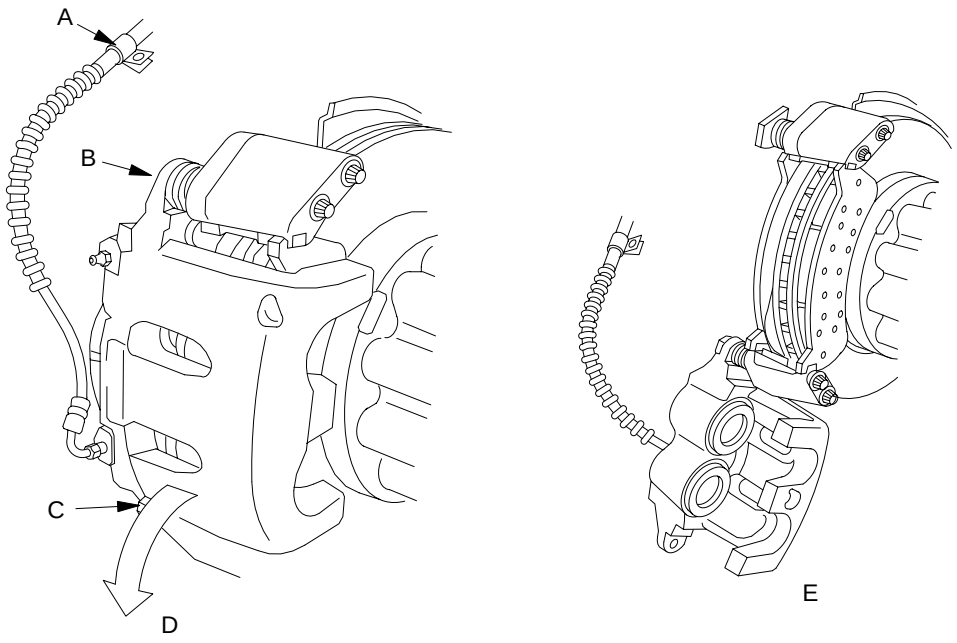
CAUTION

When replacing disc brake pads, make sure to use the same lining material on both axle ends. Mixing lining types can result in unbalanced braking, increased pad wear, or degraded stopping performance.

IMPORTANT: Inboard and outboard brake pads may not be interchangeable. The word "Forward" and a forward rotor rotation direction arrow may appear on each pad backing plate. Orient the pads as indicated by the arrow.

2. Position the inboard and outboard disc brake pads onto the anchor plate pad abutment slippers with the lining facing toward the rotor. See **Fig. 6**.

CAUTION



Use care when positioning the caliper over the disc brake pads, rotor, and upper guide pin head to avoid tearing, cutting, or dislodging the piston boots or guide pin boot.

3. Carefully rotate the caliper closed about the lower pin mounting bolt and guide pin. Do not allow the brake line hose to become pinched or kinked. Align the flat on the upper guide pin head with the flat on the caliper upper guide pin boss. See **Fig. 7**.

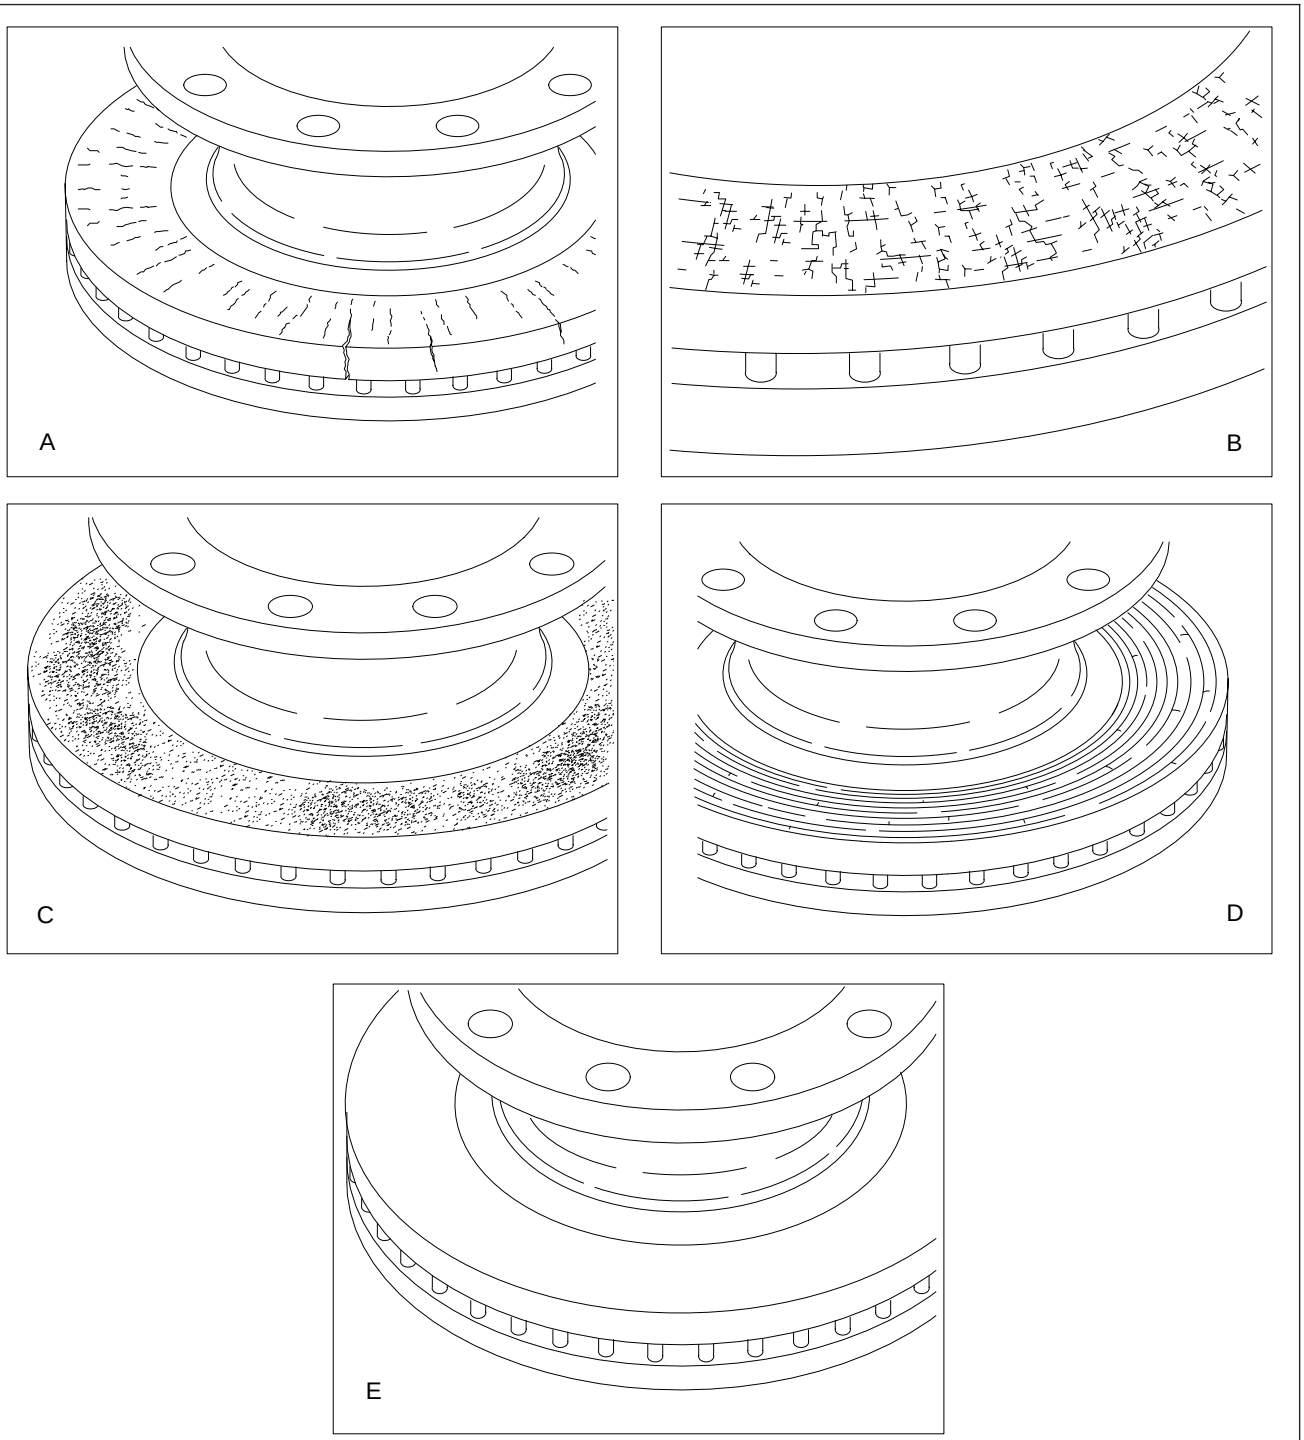
CAUTION

Always tighten caliper pin mounting bolts in the proper sequence. Do not overtighten caliper pin mounting bolts. Increased brake drag may result from incorrect tightening.

IMPORTANT: If the lower mounting bolt was loosened, see **Fig. 8** before tightening either the upper or lower mounting bolt.

A. Make sure this clip is detached from the support bracket.
B. Guide pin bolt has been removed.
C. Do not loosen the lower pin mounting bolt.
D. Swing the caliper down until it stops.
E. Caliper in the lowered position.

Fig. 3, Open Caliper to Access Brake Pads and Pistons



4. Hold the caliper in the closed position with the caliper upper guide pin boss hole aligned with the threaded hole in the upper guide pin head. Hand thread the pin mounting bolt. Tighten the bolt 70 to 80 lbf·ft (95 to 108 N·m). See **Fig. 8**.
5. On front axles only, install the previously removed brake line retaining clip. Make sure the brake line hose is not pinched or kinked.
6. Visually inspect all components serviced. Make sure the mounting pins are torqued according to the specifications in this procedure. Make sure the pads are seated and positioned to slide along the pad abutment slippers.
7. Install the tires, remove the jackstands and lower the vehicle.
8. Check the fluid level in the master cylinder reservoir and add the necessary amount of new DOT 3 approved brake fluid.
9. Pump the brake pedal until it feels firm. If it does not get firm, check for leaks or air in the brake system. Repair any leaks, if needed, then bleed the system, following the instructions in **Subject 170**.

⚠ WARNING

Do not move the vehicle until the brake pedal feels firm. To do otherwise could result in loss of vehicle control, causing an accident resulting in personal injury or property damage.

10. Close the hood and remove the chocks from the tires.
11. Road test the vehicle and seat the brake pads.
    - 11.1 Accelerate the vehicle to 30 mph (48 km/h), then brake to a stop, using medium brake pedal pressure. *Do not slam on the brakes.*
    - 11.2 Repeat this step between 20 and 30 times, allowing a 1-minute interval between brake applications.

Brake Caliper Removal and Installation

WARNING

Before starting the procedures below, read the information in Subject 100. Failure to do so could result in serious and permanent health damage.

Removal

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine.
2. Open the hood.
3. If removing the rear wheel caliper(s), remove half the fluid from the rear section of the master cylinder reservoir. If removing the front wheel caliper(s), remove half the fluid from the front section.
4. Chock the front or rear tires, depending on which axle is being worked on. Jack up the axle and support it with jackstands.
5. Remove the tires.
6. On front axles only, remove the brake line retaining clip from its support mounting. This will allow the brake line hose to hang free. See Fig. 1.

A. Make sure this clip is detached from the support bracket.
B. Loosen and remove the upper pin mounting bolt.
C. Do not loosen the lower pin mounting bolt.

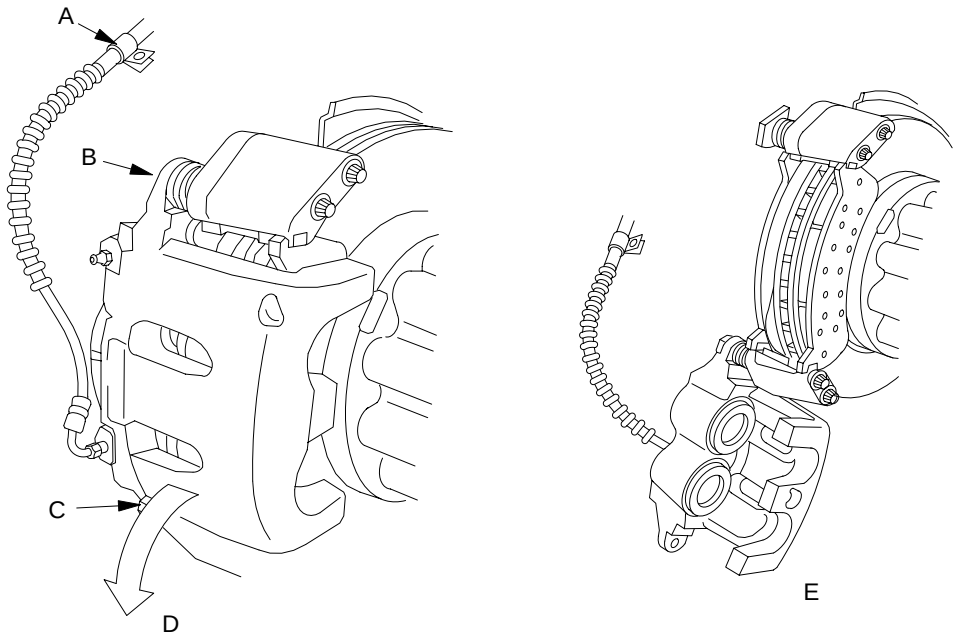
Fig. 1, Remove Upper Pin Mounting Bolt

7. Remove the upper (top) guide pin mounting bolt. See Fig. 1.

CAUTION

Do not pull on the guide pins. This may dislodge the guide pin boot from the guide pin or anchor plate grooves, which could damage the guide pin boot.

8. Swing the caliper assembly away from the rotor by carefully rotating the caliper on the lower pin mounting bolt and guide pin. See Fig. 2. Do not allow the brake line hose to become pinched or kinked.
9. Disconnect the brake fluid line from the caliper. See Fig. 3.
10. Remove the lower guide pin mounting bolt and remove the caliper from the anchor plate.



Installation

CAUTION

Use isopropyl alcohol to clean brake seals, boots, and pistons. Do not soak components for an extended period of time.

1. Clean contamination, dirt and debris from the exterior of the caliper, machined faces and around the caliper piston boots.
2. Visually inspect the caliper for brake fluid leakage or damage to pistons or piston boots. If there is leakage or damage, the caliper should be repaired or replaced. For repair instructions, see Subject 130.
3. Make sure the pistons are fully retracted into the caliper. Piston boots must be fully seated in the piston boot groove and boot grooves in the caliper face.
4. Position the caliper on the anchor plate with the caliper lower guide pin boss hole aligned with the threaded hole in the lower guide pin head. Hand thread the pin mounting bolt through the caliper and into the anchor plate.

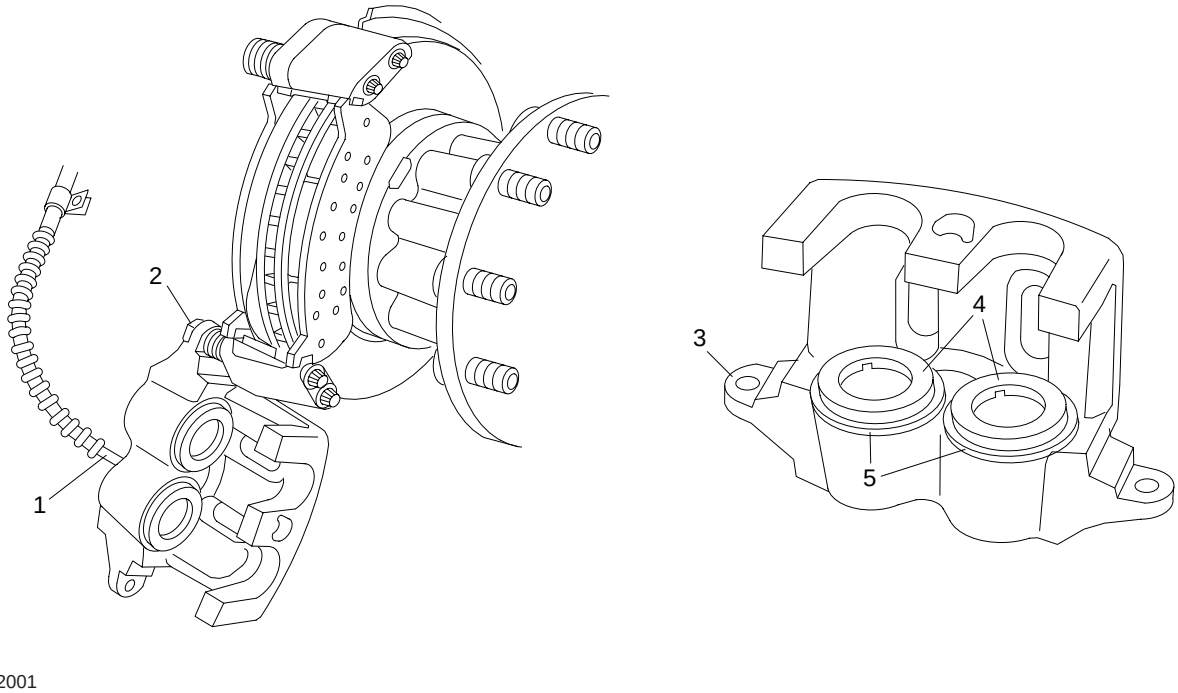
Brake Caliper Removal and Installation

A. Make sure this clip is detached from the support bracket.
B. Guide pin bolt has been removed.
C. Lower Guide Pin Bolt
D. Swing the caliper down until it stops.
E. Caliper in the lowered position.

Fig. 2, Open Caliper

⚠ CAUTION

Use care when positioning the caliper over the disc brake pads, rotor, and upper guide pin head to avoid tearing, cutting, or dislodging the piston boots or guide pin boot.



5. Carefully rotate the caliper closed about the lower pin mounting bolt and guide pin. Do not allow the brake line hose to become pinched or kinked. Align the flat on the upper guide pin head with the flat on the caliper upper guide pin boss. See **Fig. 4**.

⚠ CAUTION

Always tighten caliper pin mounting bolts in the proper sequence. Do not overtighten caliper pin mounting bolts. Increased brake drag may result from incorrect tightening.

IMPORTANT: See **Fig. 5** before tightening either the upper or lower mounting bolt.

6. Hold the caliper in the closed position with the caliper upper guide pin boss hole aligned with the threaded hole in the upper guide pin head. Hand thread the upper pin mounting bolt. Tighten the bolts 70 to 80 lbf·ft (95 to 108 N·m) in the order shown in **Fig. 5**.
7. On front axles only, install the previously removed brake line retaining clip. Make sure the brake line hose is not pinched or kinked.
8. If the brake supply hose was disconnected, connect it.
   - 8.1 Tighten the brake supply hose fitting 15 lbf·ft (20 N·m).
   - 8.2 Bleed the brake supply line to the caliper, following the instructions in **Subject 170**. If you have removed more than one brake caliper, bleed the entire brake system.
9. Install the tires, remove the jackstands and lower the vehicle.

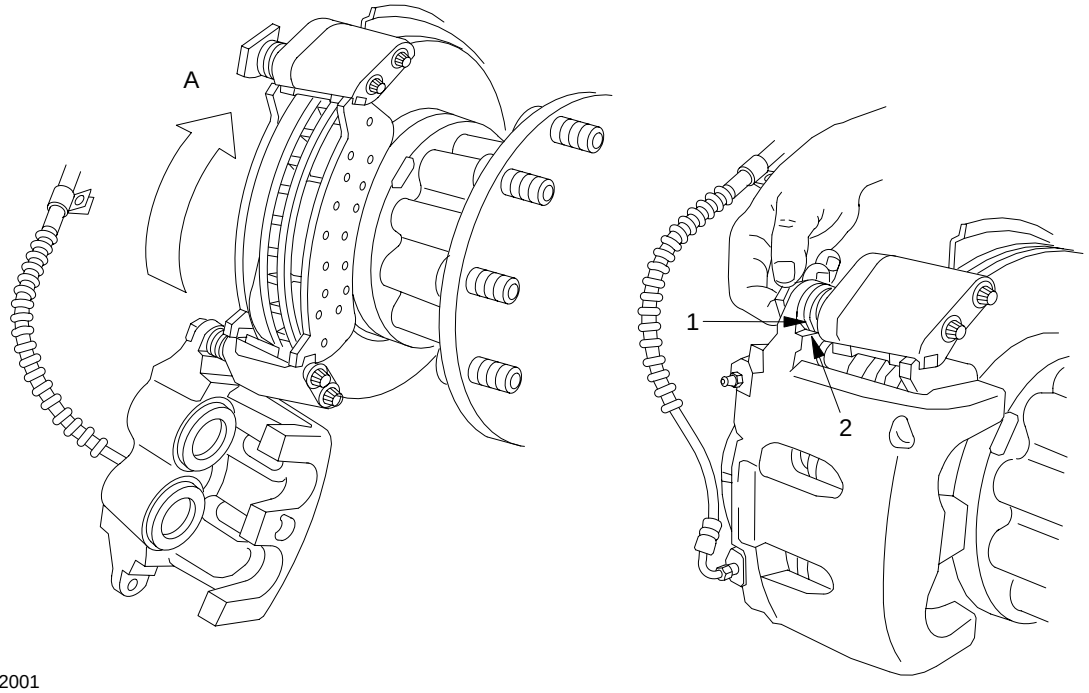
1. Brake Line
2. Lower Guide Pin Bolt
3. Machined Face
4. Pistons
5. Piston Boots

Fig. 3, Remove Caliper From Anchor Plate

10. Check the fluid level in the master cylinder reservoir and add the necessary amount of new DOT 3 approved brake fluid.
11. Close and latch the hood.
12. Remove the chocks from the tires.

⚠ WARNING

Do not move the vehicle until the brake pedal feels firm. To do otherwise could result in loss of vehicle control, causing an accident resulting in personal injury or property damage.



13. Seat the brake pads by pressing firmly on the brake pedal several times.

    If new brake pads were installed, road test the vehicle to seat the brake pads.

    13.1 Accelerate the vehicle to 30 mph (48 km/h), then brake to a stop, using medium brake pedal pressure. *Do not slam on the brakes.*

    13.2 Repeat this step between 20 and 30 times, allowing a 1-minute interval between brake applications.

Brake Caliper Removal and Installation

A. Swing the caliper up into position.
1. Flat on Guide Pin
2. Flat on Caliper

Fig. 4, Close Caliper Over Brake Pads and Rotor

A. Front Brakes and Forward-Mount Rear Brakes
1. Tighten First
B. Rear Brakes
2. Tighten Second

Fig. 5, Tightening Sequence for Caliper Mounting Bolts

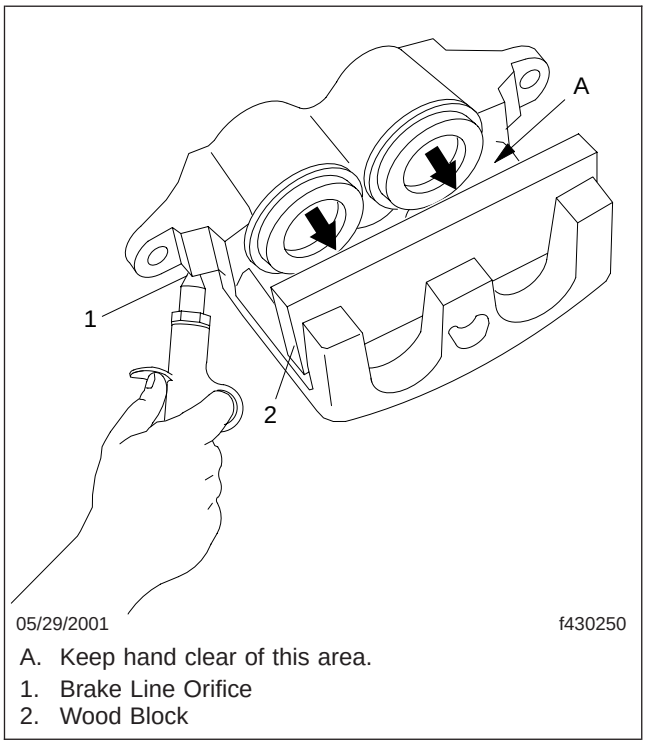
WARNING

Before starting the procedure below, read the information in Subject 100. Failure to do so could result in serious and permanent health damage.

CAUTION

Use isopropyl alcohol to clean brake seals, boots, and pistons. Do not soak components for an extended period of time.

IMPORTANT: When using compressed air, use air lines that are completely free of oil and moisture.



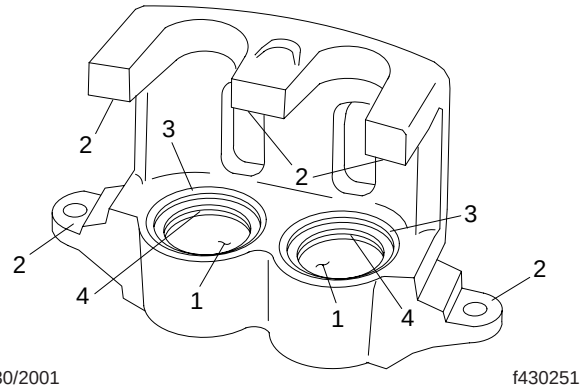
Rebuild

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine.
2. Open the hood.
3. Remove the caliper. For instructions, see Subject 120.
4. Clean contamination, dirt and debris from the exterior of the caliper, machined faces and around the caliper piston boots.
5. Drain all fluid from the caliper.
6. Place a block of wood between the caliper and piston faces. Leave approximately 1 to 1.5 inch clearance between the pistons and the block of wood. See Fig. 1.

WARNING

Always wear eye protection. Use just enough air pressure to ease the piston from the caliper bore. Keep hands clear of the piston face to avoid possible injury if the piston pops from its bore. Cover the pistons with a shop cloth to prevent brake fluid spray as the piston clears the bore.

7. Cover the pistons with a shop cloth to prevent brake fluid spray. Use an air blow gun to carefully apply low air pressure into the open caliper port to slowly push the pistons out of the caliper bores. The pistons should push out beyond the seal compression.



A. Keep hand clear of this area.
1. Brake Line Orifice
2. Wood Block

Fig. 1, Remove Pistons from Caliper Bore

8. Remove the block of wood and remove each piston from its piston boot.
9. Remove each piston boot from its boot groove in the caliper.
10. Using your fingers or a wooden or other non-metallic device, remove and discard the seals from the caliper bores. Do not nick, scratch or otherwise scar the piston bores or seal grooves.
11. Inspect the caliper for damage to the piston bores and boot grooves. If damage is found, repair or replace the caliper.
12. Check the machined surfaces of the caliper that come in contact with the guide pin heads, pistons, piston seals, piston boots and brake pads. See Fig. 2. If any rust or corrosion is present at these locations, carefully clean the surfaces with a hand-held wire brush.
13. Clean the caliper, caliper piston bores and fluid ports with solvent. Use compressed air to clean out and dry grooves and passages. If the piston bores are not clean, wipe out the bores with a clean, dry cloth and use 320 to 400 grit emery

Brake Caliper Rebuild

1. Bores
2. Machined Surface
3. Boot Groove
4. Seal Groove

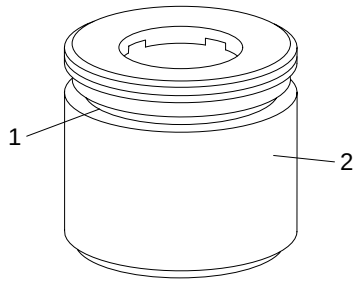

Fig. 2, Caliper Machined Surfaces

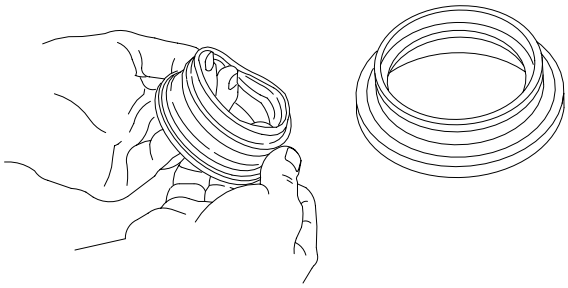
cloth to lightly clean the piston bores. Using a pick-type tool, make sure the caliper piston seal and boot grooves in the caliper are free of all foreign material.

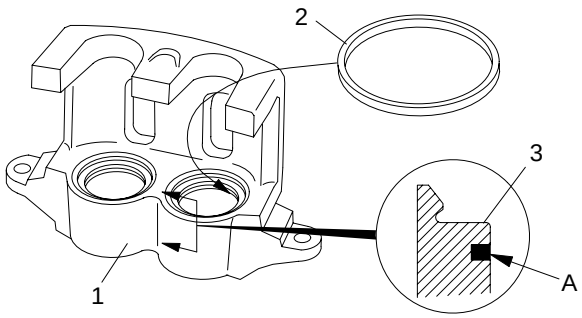
14. Inspect the caliper piston bores and piston seal and boot grooves. Make sure they are free of foreign matter, pitting, scoring or corrosion. If damage or defects are found, repair or replace the caliper.
15. Inspect the tube seats in the caliper fluid ports. Make sure they are free of foreign matter and are in good condition. Replace tube seats if damaged.
16. Clean caliper pistons with isopropyl alcohol. Visually inspect each piston for pitting, scoring or excessive wear. If damage or defects are found, replace the piston. If foreign material is found in the caliper piston boot groove, use a fiber brush to remove it. See **Fig. 3**.
17. Clean the piston boots with isopropyl alcohol and visually inspect both the inside and the outside of the piston boot for cracks, tears, holes and flexibility. See **Fig. 4**. If damage or defects are found, the boot must be replaced.

NOTE: All brake parts must be clean and completely dried of cleaning fluids before assembly.



18. Dip new piston seals in clean DOT 3 or DOT 4 hydraulic brake fluid. Install the piston seal in the piston seal groove of the caliper piston bores. See **Fig. 5**.

05/30/2001 f430252



1. Piston Boot Groove
2. Piston

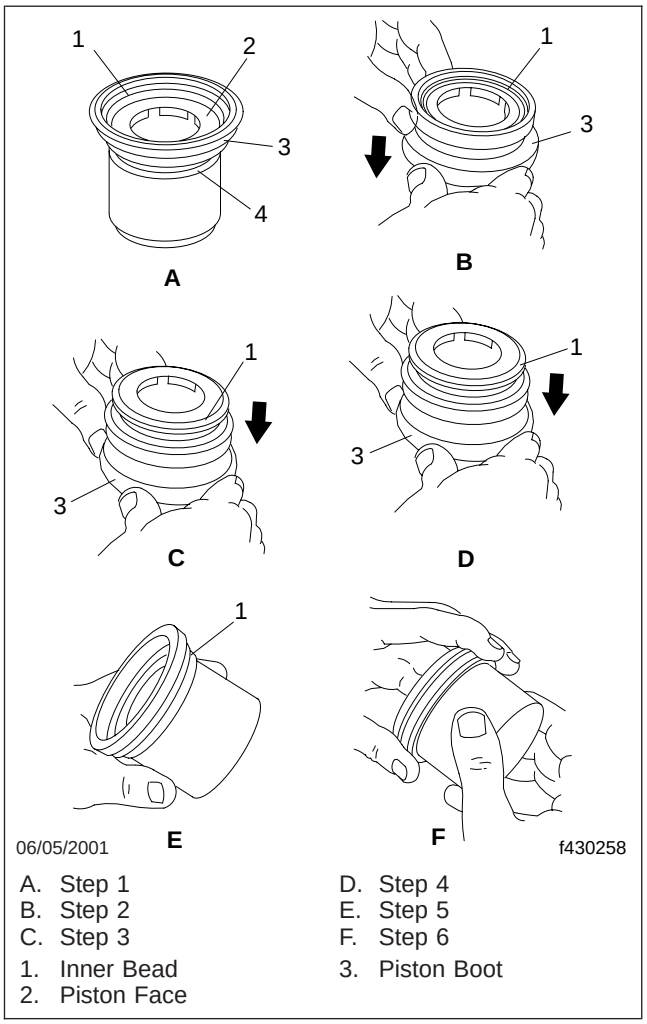
A. Make sure the seal is seated squarely in the groove.

1. Caliper
2. Caliper Bore Seal
3. Seal Land

Fig. 5, Piston Seal Installation

19. With the piston seal positioned on the groove, gently work around the groove with clean fingers



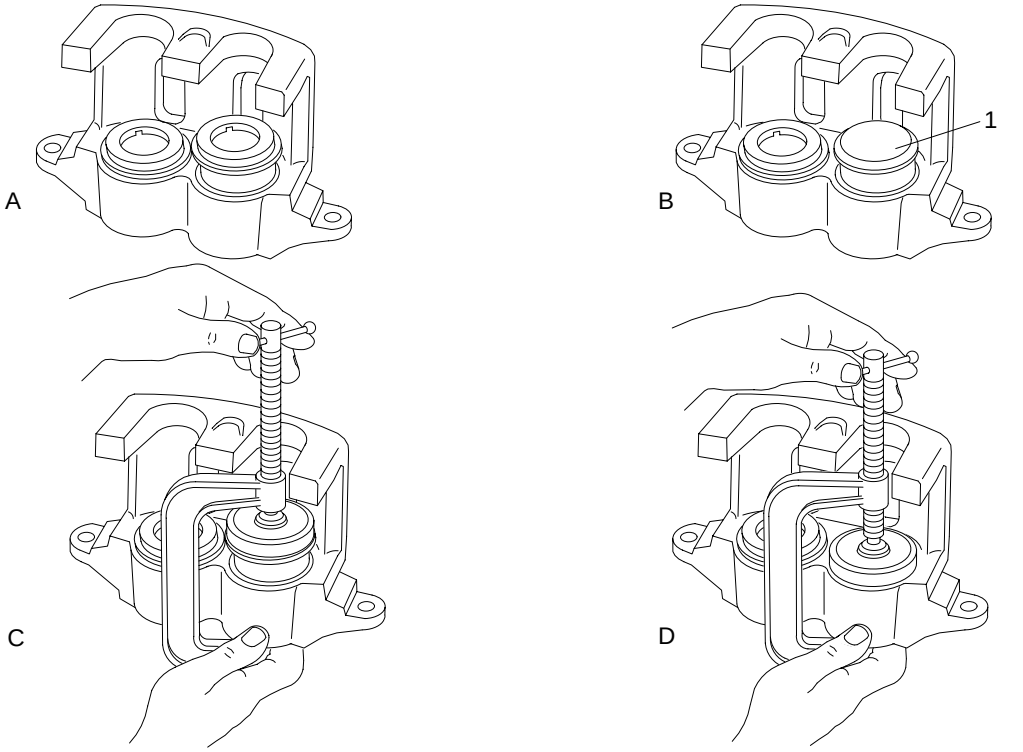
until the seal is properly seated into the groove. Make sure the seal is not twisted or rolled.

IMPORTANT: Use only silicone grease on the seal bead. Other greases may cause the seal to swell (grow) and impair proper piston movement.

20. Apply a thin film of silicone grease to the caliper bore seal land between the piston boot and seal grooves. Apply the grease around the entire circumference of the caliper bore.

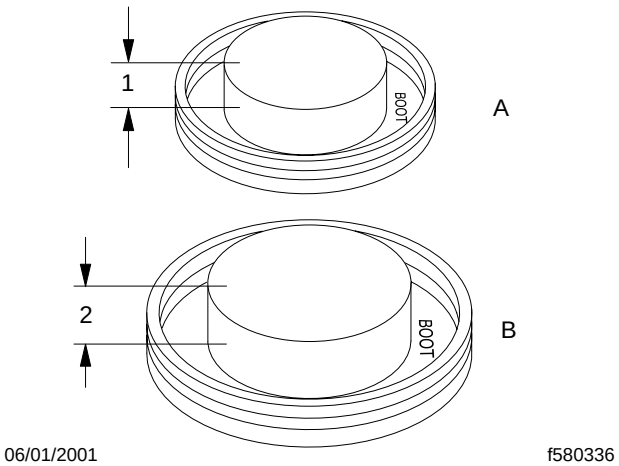
NOTE: Clean DOT 3 or DOT 4 hydraulic brake fluid may be used on the boot inner bead and outer ring to ease assembly. Do not use any other lubricant.

21. Position the boot on top of the caliper piston with the boot flange properly oriented. See **Fig. 6**. Carefully pull the piston boot down over the top of the piston until the inner bead of the boot is seated in the piston boot groove. Return the boot to the collapsed or folded position. Make sure the boot is fully seated in the piston boot groove by grasping the piston boot flange and rotating the piston back and forth.
22. Apply DOT 3 or DOT 4 hydraulic brake fluid to the outside of the caliper piston and carefully position the piston with the piston boot into the caliper piston bore. See **Fig. 7**.
23. Position the caliper piston and boot installation tool (ZTSE4417 for 66mm brakes, ZTSE4418 for 73mm brakes) on top of a piston and piston boot so the word "Boot" is on the underside of the tool, toward the piston. See **Fig. 8**. Make sure to use the correct tool for the pistons being installed.
24. Using a "C" clamp or arbor press, gently press the piston past the piston seal and partially into the bore. Avoid cocking or binding the piston during installation. Continue to press the piston and piston boot into the bore until they are fully seated into the caliper.
25. Remove the "C" clamp or arbor press. Make sure the piston boot flange ring is fully seated into the top groove of the piston bore in the caliper face.
26. Repeat the procedure for the other piston.



A. Step 1
B. Step 2
C. Step 3
D. Step 4
E. Step 5
F. Step 6
1. Inner Bead
2. Piston Face
3. Piston Boot

Fig. 6, Installing Piston Boot to Piston



27. Inspect the caliper prior to installing it on its anchor plate. Pistons must be fully retracted into the caliper. Piston boots must be fully seated in the piston boot groove and boot grooves in the caliper face.
28. If the caliper bleed screw was removed, make sure that a bleed screw has been installed in the upper brake fluid port.
29. Install the caliper on the anchor plate. For instructions, see **Subject 120**.

Brake Caliper Rebuild

A. Position the piston square in the bore.
B. Position the installation tool.
C. Press the piston into the bore.
D. Seat the piston in the bore.

Brake Rotor Removal and Installation

⚠ WARNING

Before starting the procedures below, read the information in Subject 100. Failure to do so could result in serious and permanent health damage.

Removal

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the tires.
2. Open the hood.
3. Remove about half the brake fluid from the front section (if removing a front-axle rotor) or the rear section (rear-axle rotor) of the master cylinder reservoir. See **Fig. 1**.

A. Fill level for brake fluid.

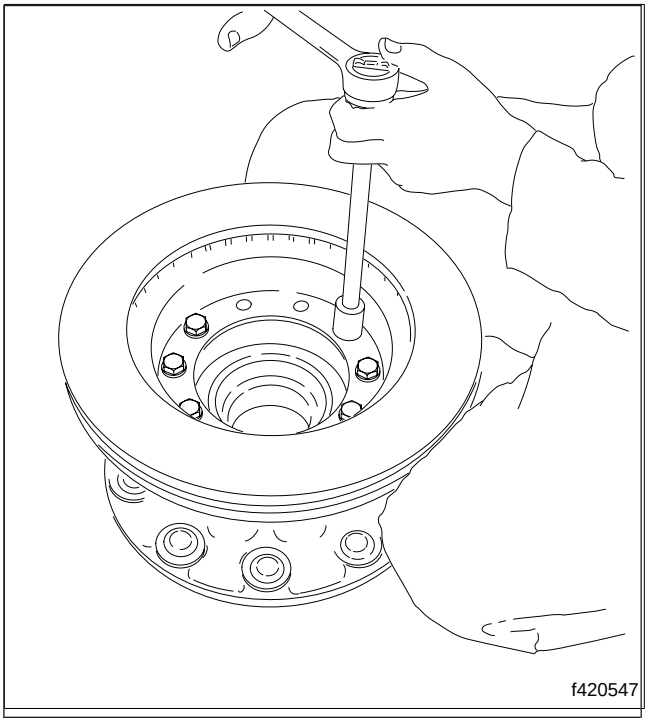
Fig. 1, Master Cylinder Reservoir

4. Chock the front or rear tires, as required.
5. Jack up the vehicle. Support the axle with jack-stands.
6. Remove the tire.
7. Remove the brake caliper from the rotor, following the instructions in **Subject 120**.
8. Remove the hub and rotor assembly from the axle, following the instructions in **Group 33** for the front axle or **Group 35** for the rear axle. Put the hub on the floor so the rotor is facing up.
9. Remove the brake rotor from the wheel hub.
   - 9.1 Remove the hexbolts and washers that attach the rotor to the hub. See **Fig. 2**.
   - 9.2 Lift the brake rotor off the hub.

Installation

1. Visually inspect the rotors for scoring, warping, cracks, bluing or heat spots, or other damage. See **Fig. 3**. If signs of damage are found, the rotor should be resurfaced or replaced.
2. Install the rotor on the wheel hub.
   - 2.1 Position the rotor on the hub as shown in **Fig. 4**. Make sure the holes in the rotor are lined up with those of the hub.
   - 2.2 Install the mounting hexbolts and washers. Using a star pattern, tighten the hexbolts 130 lbf·ft (175 N·m). See **Fig. 5**.
3. Install the hub and rotor assembly on the axle, following the instructions in **Group 33** for the front axle or **Group 35** for the rear axle.

Brake Rotor Removal and Installation



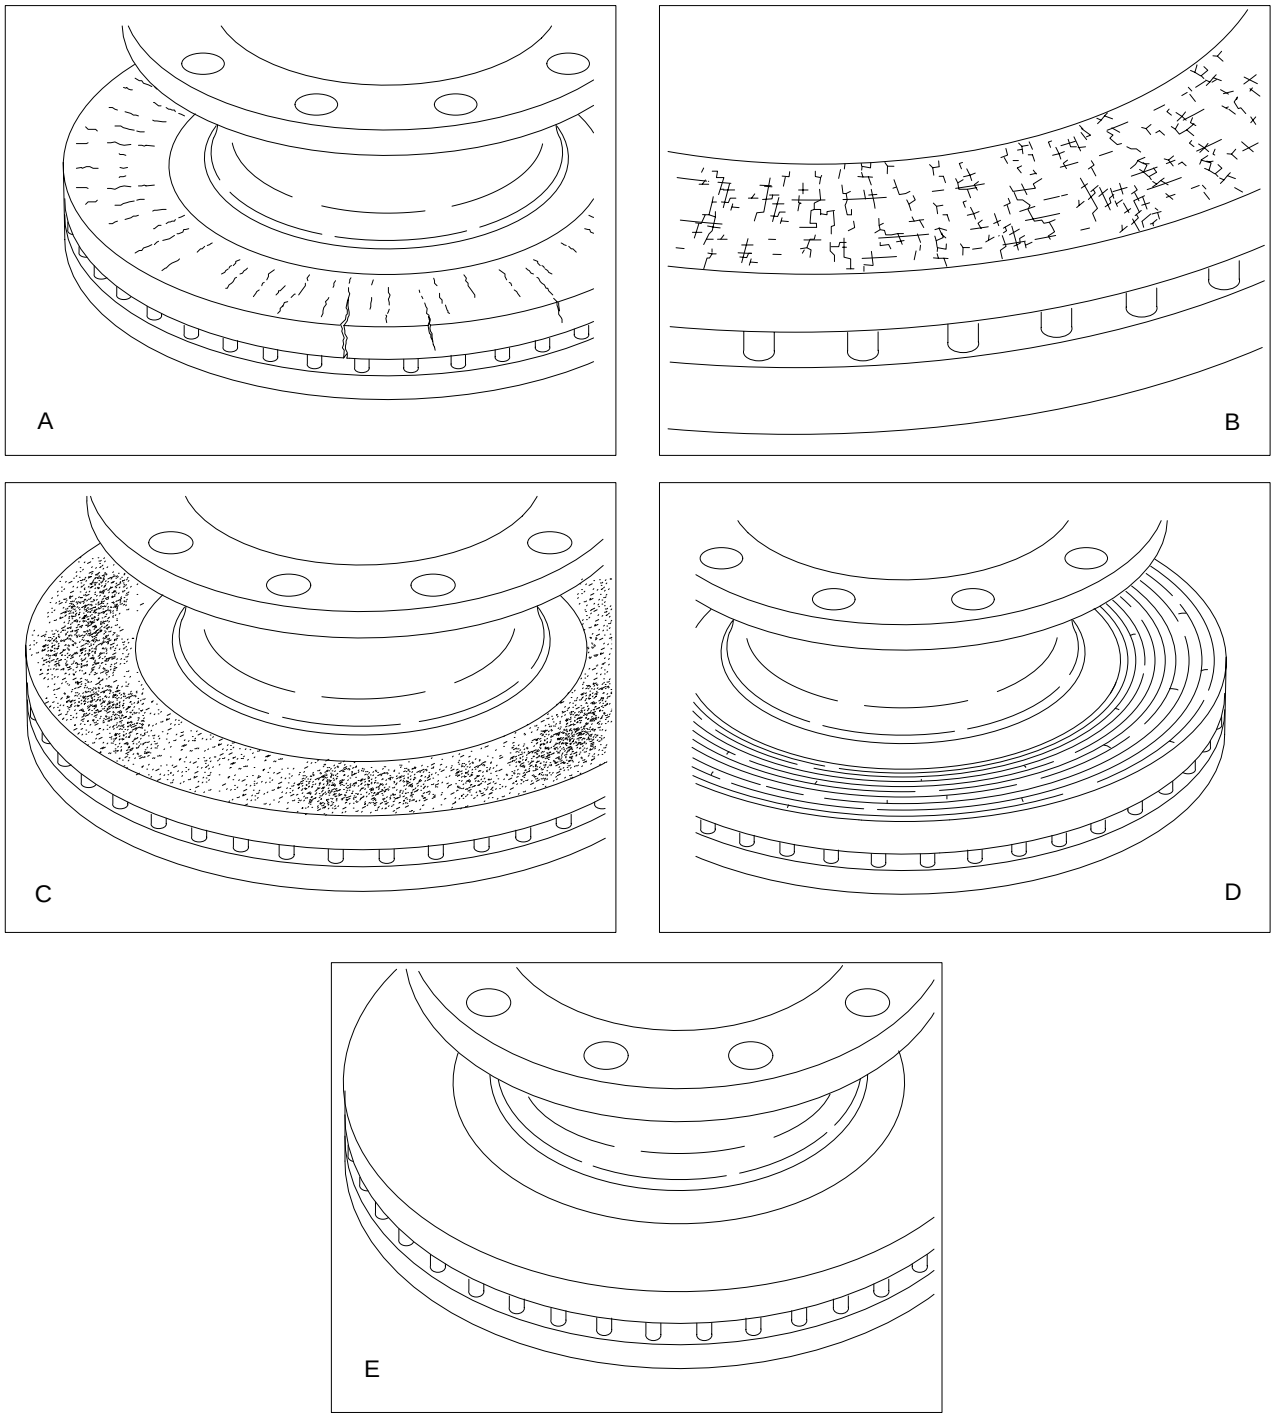


Fig. 2, Rotor-to-Hub Fasteners

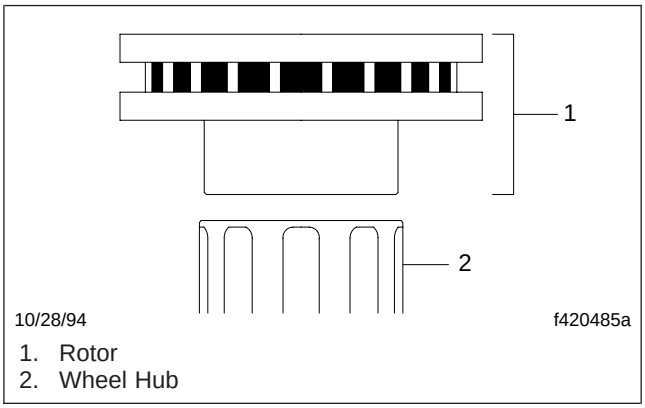

4. Check rotor runout and parallelism. For instructions, see **Subject 150**.
5. Install the brake caliper on the rotor, following the instructions in **Subject 120**.
6. Install the tire.
7. Remove the jackstands. Lower the vehicle.
8. Fill the applicable section of the master cylinder reservoir with new DOT 3 approved brake fluid. The brake fluid level should be even with the raised seam on the outside circumference of the reservoir. See **Fig. 1**.
9. Close and latch the hood.
10. Remove the chocks from the tires.

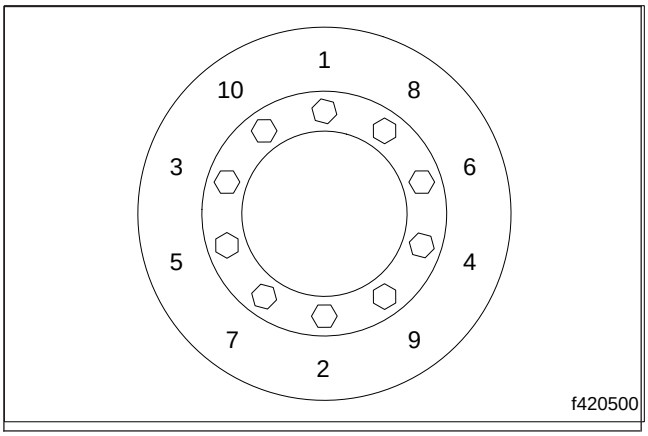
Fig. 4, Rotor-to-Hub Position



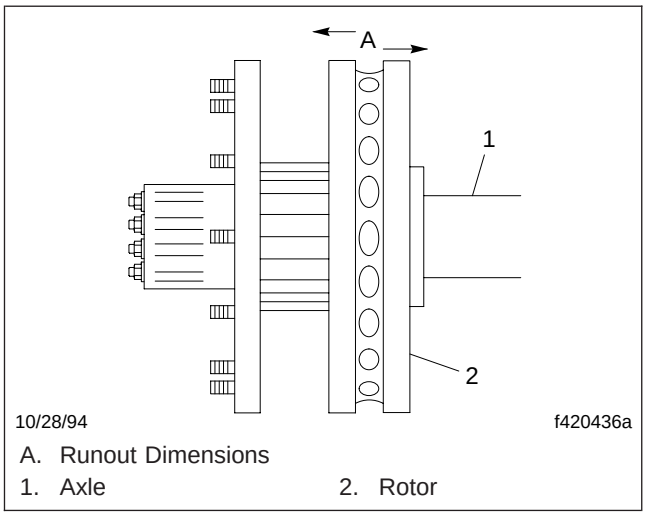


Fig. 5, Tightening Pattern

Brake Rotor Runout and Parallelism Check

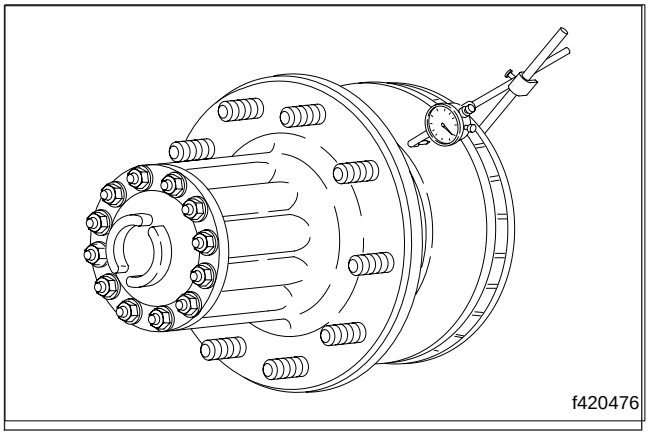
Runout Check

Brake rotor runout refers to the amount of lateral wobble the rotor has when it is turning, with the wheel bearings correctly adjusted. See **Fig. 1**. Check the rotor runout whenever you replace the brake pads.

1. If not already done, chock the tires, jack up the axle you are working on and support it with jackstands. Remove the wheels and tires.
2. If working on the rear axle, put the transmission in neutral.
3. Using a dial indicator, measure the amount of runout while spinning the rotor, as shown in **Fig. 2**. Make sure the indicator is centered on the rotor face (between the outer and inner edges).
4. If the runout is more than 0.015 inch (0.38 mm), check that the rotor is securely mounted to the hub. Also check the wheel bearing end-play, following the instructions in **Group 33** for the front axle or **Group 35** for the rear axle.
5. Repeat the runout measurement. If the runout is still more than 0.015 inch (0.38 mm), replace the rotor.

A. Runout Dimensions
1. Axle 2. Rotor

Fig. 1, Brake Rotor Runout



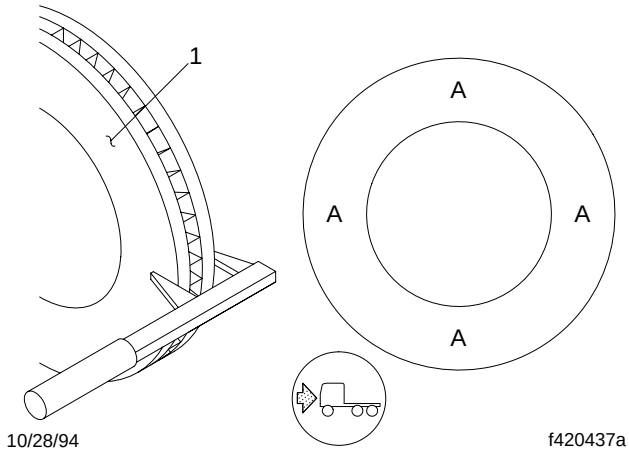


Fig. 2, Measure Runout

Parallelism Check

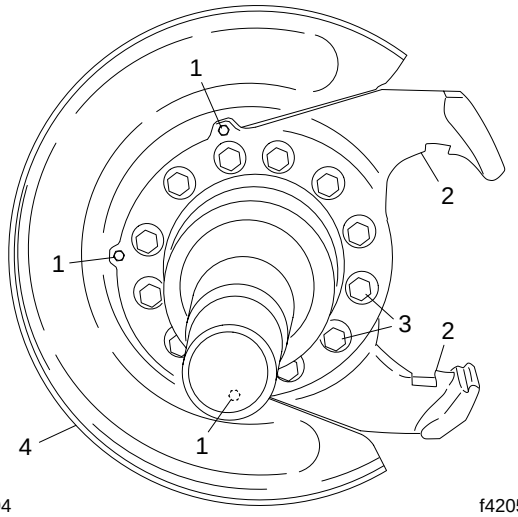
Parallelism is the difference in rotor thickness at different points around the rotor. It should be checked whenever the brake pads are replaced.

1. Using a vernier caliper or a micrometer, measure the thickness of the rotor (between the inboard and outboard faces) at four or more equally spaced points around the rotor. See **Fig. 3**.
2. If there is a difference of more than 0.005 inch (0.13 mm) between any two measurements, have the rotor resurfaced. If resurfacing will decrease the overall thickness of the rotor to 1.32 inches (33.5 mm) or less, replace the rotor.

Brake Rotor Runout and Parallelism Check

A. Measure thickness here.
1. Rotor Face

Fig. 3, Measure Rotor Thickness

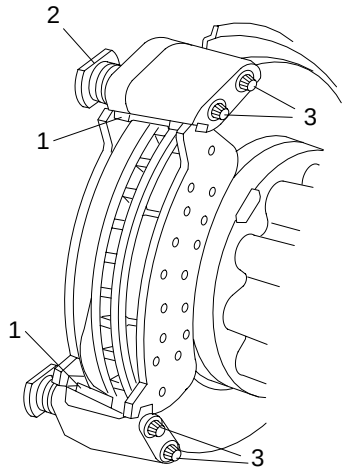


Anchor Plate Disassembly, Clean and Inspection, and Assembly

WARNING

Before starting the procedures below, read the information in Subject 100. Failure to do so could result in serious and permanent health damage.

Disassembly



1. Park the vehicle on a level surface. Chock the rear or front tires, as required.
2. Jack up the vehicle. Support the axle with jackstands.
3. Remove the tire.
4. Remove the brake caliper from the anchor plate following the instructions in Subject 120.
5. Remove the tie bar from the anchor plate on 73mm brakes, or remove the plugs from the anchor plate on 66mm brakes.
6. Remove the brake pads from the anchor plate. For instructions, see Subject 110.
7. Remove the wheel hub and rotor assembly from the axle, following the instructions in Group 33 for the front axle or Group 35 for the rear axle.
8. Remove the anchor plate from the axle.
   - 8.1 Remove the three screws holding the dust shield to the anchor plate and remove the dust shield.
   - 8.2 Remove the hexbolts, washers and nuts that hold the anchor plate to the axle. See Fig. 1.
   - 8.3 Remove the anchor plate from the axle.
9. Remove contamination, dirt and debris from the exterior of the anchor plate.
10. Remove the brake pad abutment slipper using a blunt nose drift pin or screwdriver and a light hammer. Avoid marring the anchor plate abutment surfaces. See Fig. 2.
11. Remove the guide pins and guide pin boots by pulling out the guide pin with a slight twisting motion.
12. Remove the splash shield and antilock braking system sensor bracket from the anchor plate. See Fig. 3.

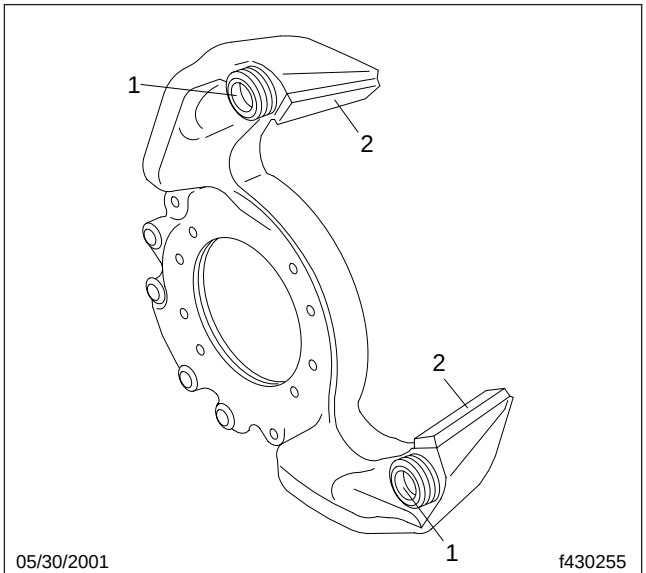
Fig. 2, Anchor Plate Components

Clean and Inspection

1. Clean the anchor plate with a brush and solvent. Make sure the anchor plate abutments, anchor plate tie bar mounting surfaces, axle flange

Anchor Plate Disassembly, Clean and Inspection, and Assembly

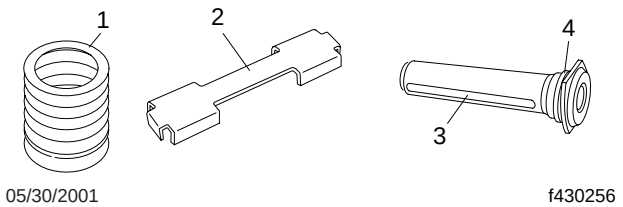


A. Driver Side Front Backing Plate Assembly (66mm brakes)
B. Driver Side Front Backing Plate Assembly (73mm brakes)
C. Driver Side Rear Backing Plate Assembly (typical)
1. Sensor Bracket
2. Anchor Plate

Fig. 3, Splash Shield and Sensor Mounting Bracket

mounting surface and anchor plate boot grooves are clean and free of any rust or corrosion. See **Fig. 4**. Use a hand-held wire brush to clean these surfaces. It is important to clean these areas of the anchor plate. Also make sure the tie bar bolt hole threads are clean and free of foreign matter.

2. Clean the guide pin bores with a bore brush and solvent. Use compressed air to clean out and dry guide pin bores. Check the guide pin bores for excessive wear. Replace the anchor plate, if necessary.
3. Clean the guide pin boots with isopropyl alcohol. Do not use solvent to clean the boots. Inspect each guide pin boot for cracks, tears, holes and flexibility. If damage is found, the boot must be replaced. See **Fig. 5**.
4. Clean the guide pins with isopropyl alcohol. Make sure the guide pins, and the threads in the guide pins, are free of foreign matter and corrosion. Use compressed air to clean out and dry guide pins and bolt threads in the guide pins. Check the guide pins for wear. Replace them if excessive wear is detected.



1. Guide Pin Bore and Boot Groove
2. Pad Abutment Slipper Mounting

Fig. 4, Anchor Plate Machined Surfaces

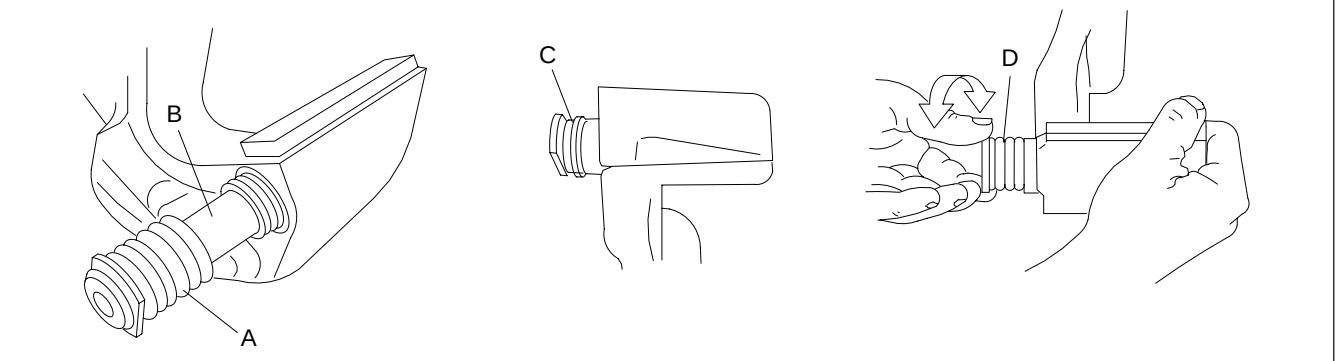
5. Inspect the pad abutment slippers for damage or wear and clean them with solvent. Replace them if damaged or excessive wear is detected.

Anchor Plate Disassembly, Clean and Inspection, and Assembly

05/30/2001 f430256

1. Guide Pin Boot
2. Pad Abutment Slipper
3. Guide Pin
4. Boot Groove

Fig. 5, Loose Anchor Plate Components



6. Visually inspect the anchor plate for worn or damaged slippers, and damaged or dislodged guide pin boots. If signs of wear or damage are found, the anchor plate should be repaired or replaced.

Assembly

NOTE: All brake parts must be clean and completely dry of cleaning fluids before assembly.

1. Uniformly apply Aeroshell Grade 5 grease to the entire guide pin bore and on the guide pin shaft. Use 1/8 ounce (3 grams) of grease to thoroughly lube each guide pin and guide pin bore set. See **Fig. 6**.
2. Apply a thin coat of Aeroshell Grade 5 grease to the inside opening at each end of the boot.
3. Slide the guide pin into the guide pin boot.
4. Insert the guide pin with the boot into the anchor plate guide pin bore until the boot is completely compressed.
5. Rotate the guide pin 1/4 to 1/2 turn back and forth in order to seat the guide pin boot.
6. Inspect the guide pin boot to make sure the boot is fully seated all around the guide pin and the anchor plate retaining grooves.
7. Install an anchor plate pad abutment slipper onto each anchor plate abutment. See **Fig. 7**. Use a soft brass or other light hammer to be sure the slipper is seated on the abutment. Avoid marring anchor plate abutment slipper surfaces.
8. Install the splash shield and antilock braking system sensor bracket to the anchor plate.

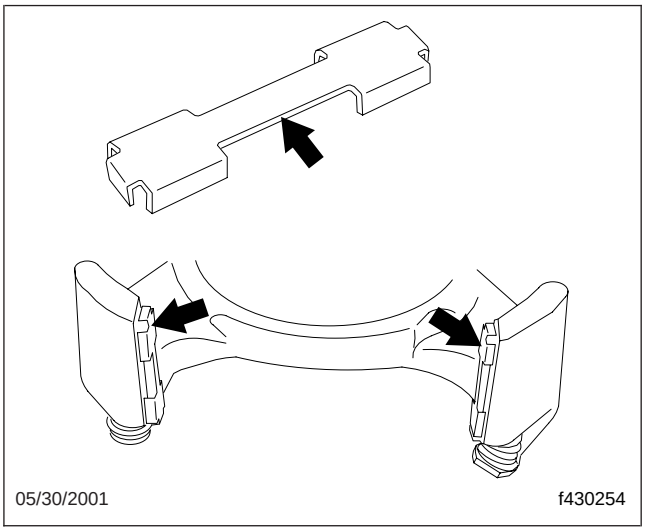
   When installing the splash shield and sensor bracket on the anchor plate for 66mm front and all rear brakes, the splash shield and sensor bracket are mounted on the inboard side of the anchor plate and the five bolts are installed from the inboard side. Tighten the bolts 12 to 16 lbf·ft (17 to 21 N·m).

06/01/2001 f430261

A. Lube the inside of the boot, both ends.
B. Apply Aeroshell Grade 5 grease to the bore and the pin.
C. Boot and pin in place.
D. Twist to seat in the groove.

Fig. 6, Install Guide Pins and Boots

Anchor Plate Disassembly, Clean and Inspection, and Assembly



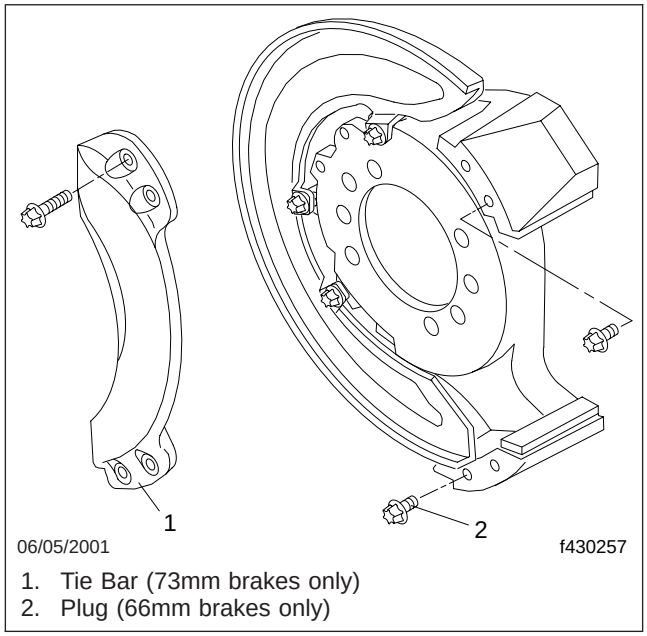


Fig. 7, Pad Abutment Slipper

For 73mm front brakes, the splash shield and sensor bracket are mounted on the outboard side of the anchor plate and the five bolts are installed from the outboard side. Tighten the bolts 12 to 16 lbf·ft (17 to 21 N·m).

9. Remove all traces of dirt, grease and oil from the knuckle and axle brake flange.
10. Install the anchor plate on the axle.
    - 10.1 Position the anchor plate against the outboard side of the axle flange, making sure the holes in both are lined up.
    - 10.2 From the outboard side of the anchor plate, install the hexbolts and washers. Install the nuts and remaining washers. See **Fig. 1**. Using a star pattern, tighten the hexnuts as follows:
      - Rear Axle; 105 lbf·ft (142 N·m)
      - Front Axle Type FC; 75 lbf·ft (102 N·m)
      - Front Axle Type FD/FF; 145 lbf·ft (197 N·m)
11. Install the dust shield on the anchor plate. See **Fig. 1**.
12. Install the wheel hub and rotor assembly onto the axle, following the instructions in **Group 33** for the front axle or **Group 35** for the rear axle.
13. On 66mm brakes, install the four bolt plugs into the anchor plate face. Tighten 16 to 27 lbf·ft (22 to 37 N·m). See **Fig. 8**.

    On 73mm brakes, install the anchor plate tie bar and the four tie bar bolts to the anchor plate face. Tighten 40 to 50 lbf·ft (54 to 68 N·m).

1. Tie Bar (73mm brakes only)
2. Plug (66mm brakes only)

Fig. 8, Plugs and Tie Bar

14. Install the brake caliper on the anchor plate following the instructions in **Subject 120**.
15. Install the brake pads into the anchor plate. For instructions, see **Subject 110**.
16. Install the tire.
17. Remove the jackstands. Lower the vehicle.
18. Remove the chocks.

Bleeding

⚠ WARNING

Before starting the procedure below, read the information in Subject 100. Failure to do so could result in serious and permanent health damage.

Whenever any hydraulic system fitting is loosened or disconnected, the entire system must be bled to remove any air that may have entered it.

⚠ CAUTION

Power steering fluid and brake fluid are incompatible. Never mix these two fluids or serious damage to both hydraulic systems will result. Use only brake fluid for the master cylinder and brake lines. Use only power steering fluid for the power booster.

Always use new, clean brake fluid that meets DOT 3 specifications when bleeding the master cylinder and service brake system. Never reuse brake fluid and do not use brake fluid containers for any other purpose. Keep brake fluid containers tightly closed to keep new brake fluid clean and dry.

IMPORTANT: Do not let brake fluid touch any painted surfaces, as it will remove the paint. Brake fluid may also damage certain non-metal surfaces. Do not let it get on brake pads or rotors.

Pressure Bleeding

NOTE: Pressure bleeding is the preferred method for bleeding the service brake system. It requires the use of a special pressure bleeder kit, consisting of a tank, pressure pump and valve, gauge, tubing and adapter. These are available from a number of manufacturers and include instructions for use. See **Fig. 1**.

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Open the hood.

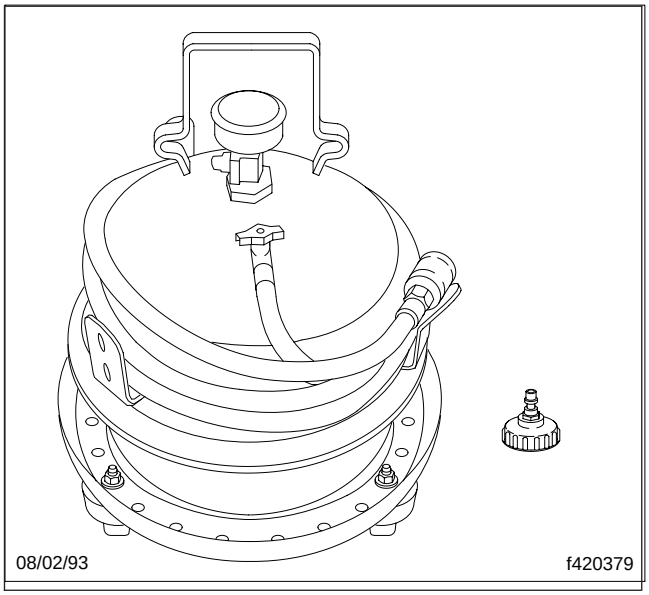

Fig. 1, Pressure Bleeder Kit

3. Connect the pressure bleeder to the brake master cylinder reservoir following the manufacturer's instructions.
   - 3.1 Fill the pressure bleeder with new DOT 3 approved brake fluid. Pressurize it according to the manufacturer's instructions.
   - 3.2 Using the supplied adapter, connect the pressure bleeder to the rear compartment of the master cylinder reservoir.
4. Bleed the hydraulic connections at the rear wheel calipers starting on the right side.
   - 4.1 Put a wrench on the bleeder fitting at the caliper. Attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.
   - 4.2 Loosen the bleeder fitting about 3/4 turn and let the brake fluid flow out of the fitting until it is free of air bubbles. Tighten the fitting firmly.
   - 4.3 Move to the left rear caliper and repeat steps for bleeding the caliper.
5. Disconnect the pressure bleeder from the rear compartment of the master cylinder reservoir. Connect it to the front compartment of the reservoir.

System Bleeding

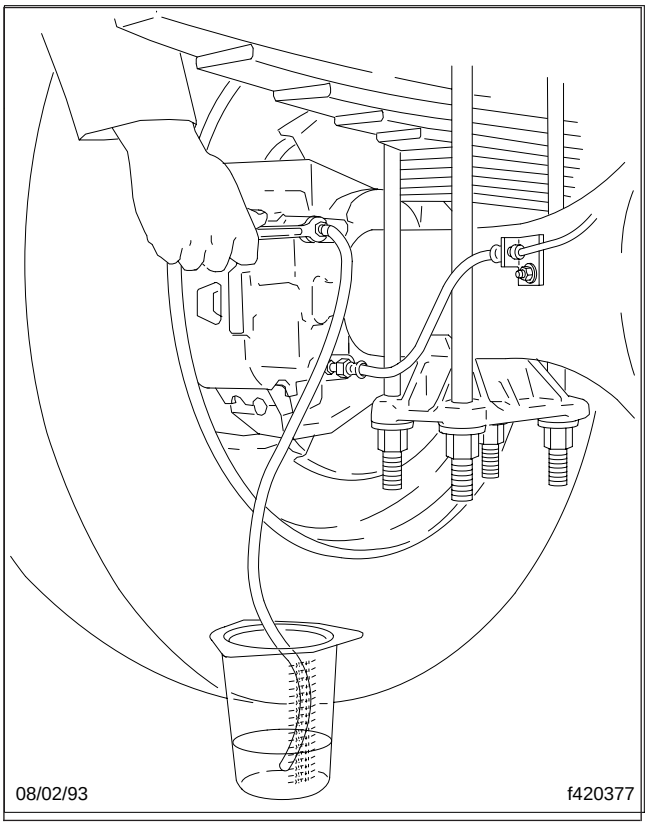

Fig. 2, Bleed the Hydraulic Connection

6. Bleed the front wheel brake calipers starting at the right side.
   - 6.1 Put a wrench on the bleeder fitting at the caliper. Attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.
   - 6.2 Loosen the bleeder fitting about 3/4 turn and let the brake fluid flow out of the fitting until it is free of air bubbles. Tighten the fitting firmly.
   - 6.3 Move to the left front wheel caliper and repeat steps for bleeding the caliper.
7. Check the brake fluid level in both compartments of the reservoir. Add new DOT 3 approved brake fluid if needed.
8. Check the operation of the brakes by depressing the brake pedal several times, until if feels firm. The brake pedal should not go all the way down to the floor. If it does, see **Troubleshooting, 300** and find the problem.
9. Close and latch the hood.
10. Remove the chocks from the rear tires.

Manual Bleeding

NOTE: If you do not have pressure bleeding equipment, you can use the manual bleeding procedure.

⚠ WARNING

Read over the information in Subject 100 before starting the procedure below. Failure to do so may result in either serious injury to yourself, or damage to the brake system, resulting in an accident causing serious personal injury or property damage.

IMPORTANT: Do not let the brake master cylinder run dry during manual bleeding operations. Keep the master cylinder reservoir filled with new, DOT 3 approved brake fluid. Failure to keep the brake reservoir filled could result in more air entering the system, making it impossible to effectively bleed the system.

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Open the hood.
3. Bleed the master cylinder.
   - 3.1 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the rear outlet port on the master cylinder. See **Fig. 3**. Loosen the fitting about one turn.
   - 3.2 Have someone push the brake pedal down slowly by hand to the floor. Brake fluid, and any air in the master cylinder, will squirt from the fitting.
   - 3.3 *With the brake pedal held down*, tighten the rear hydraulic line fitting firmly.

   IMPORTANT: Do not release the brake pedal until the fitting is tightened, or more air will get into the system.

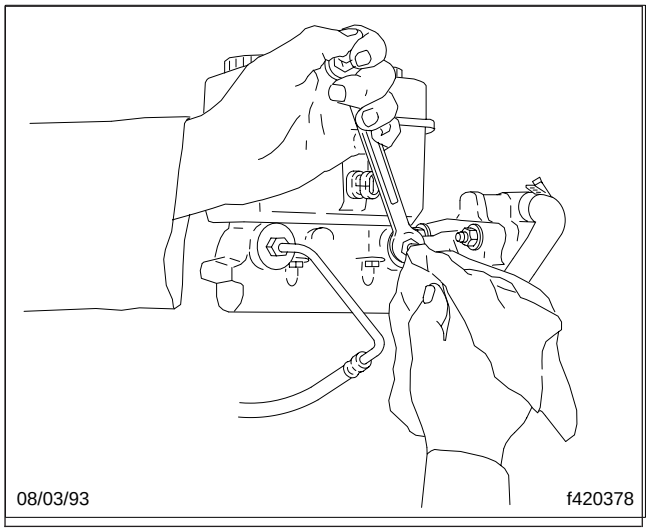

Fig. 3, Rear Outlet Port

3.4 Release the brake pedal.

3.5 Loosen the fitting again, and repeat steps for bleeding as required until no air escapes from the fitting, and the brake pedal feels firm.

3.6 Check the level of the rear compartment of the reservoir, then add new DOT 3 approved brake fluid if needed.

3.7 Using a wrench (and a rag to absorb leaking brake fluid), loosen the fitting at the front outlet port on the master cylinder. See **Fig. 4**. Loosen the fitting about one turn.

3.8 Repeat steps as required for the front outlet port.

3.9 Check the brake fluid level in the front compartment of the reservoir. Add new DOT 3 approved brake fluid if needed.

4. Bleed the hydraulic connections at the wheel calipers, starting at the right rear wheel caliper.

4.1 Put a wrench on the bleeder fitting at the caliper, then attach a length of clear tubing to the bleeder fitting. Make sure the tube fits snugly. Submerge the tubing in a container of clean brake fluid. See **Fig. 2**.

4.2 Loosen the bleeder fitting about 3/4 turn.

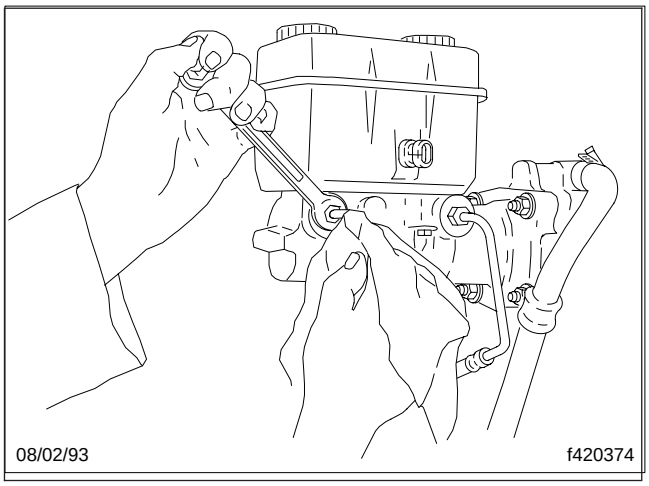

Fig. 4, Front Outlet Port

4.3 Have someone slowly push the brake pedal to the floor. *With the brake pedal depressed*, tighten the bleeder fitting.

IMPORTANT: Make sure the brake pedal stays depressed while you tighten the fitting. If it is released before you tighten the fitting, more air will get into the system.

4.4 Release the brake pedal. Check the fluid in the tube. If there are air bubbles present, repeat the steps as required until the fluid in the tube is completely free of air bubbles.

4.5 Check the brake fluid level in the reservoir. Add new DOT 3 approved brake fluid if needed.

4.6 Repeat the steps for bleeding the connections for the left rear caliper, the right front caliper and the left front caliper.

5. Close and latch the hood.

6. Remove the chocks from the rear tires.

Troubleshooting Tables

Problem—Noise and Chatter

Problem—Noise and Chatter	
Possible Cause	**Remedy**
Bent, damaged or incorrect pads	Replace with the correct pads in axle sets.
Worn out lining plates (plates rubbing rotor)	Resurface or replace the rotor. Replace the pads in axle set.
Rotor polished or linings glazed	Remove the polish or glaze.
Foreign material embedded in linings	Replace the pads in axle sets.
Excessive rotor thickness variations or lateral runout	Resurface or replace the rotor.

Problem—Brakes Grab

Problem—Brakes Grab	
Possible Cause	**Remedy**
Incorrect pads or pads loose on plate	Replace with the correct pads in axle sets.
Grease or brake fluid on linings	Repair the grease seal or caliper. Replace the pads in axle sets.
Loose caliper at anchor plate pins	Tighten to specifications.
Excessive rotor lateral runout	Check the bearing adjustment. Resurface or replace the rotor.

Problem—Vehicle Pulls to One Side

Problem—Vehicle Pulls to One Side	
Possible Cause	**Remedy**
Incorrect pads or loose lining on plates	Replace with the correct pads in axle sets.
Grease or brake fluid on linings	Repair the grease seal or caliper. Replace the pads in axle sets.
Loose caliper or anchor plate	Tighten to specifications.
Caliper piston sticking	Repair or replace the piston or replace the caliper.
Caliper guide pins sticking	Repair or replace the guide pins and boots. Clean the pin bores and lubricate.
Excessive rotor lateral runout	Check the bearing adjustment. Resurface or replace the rotor.

Problem—Pulsating Brake Pedal

Problem—Pulsating Brake Pedal	
Possible Cause	**Remedy**
Worn or damaged front wheel bearings	Replace the wheel bearings.
Excessive variation in rotor thickness	Resurface or replace the rotor.

Troubleshooting

Problem—Springy or Spongy Pedal

Problem—Springy or Spongy Pedal	
Possible Cause	**Remedy**
Excessive rotor lateral runout	Resurface or replace the rotor.
Poor quality brake fluid (low boiling point)	Drain and clean the system. Refill with the approved brake fluid.
Weak brake hoses that expand under pressure	Replace the hoses.
Air in hydraulic system	Bleed the system. For instructions, see **Subject 170**.

Problem—All Brakes Drag (or Both Brakes on Same Axle)

Problem—All Brakes Drag (or Both Brakes on Same Axle)	
Possible Cause	**Remedy**
Binding brake pedal	Free-up and lubricate the pedal.
Soft or swollen rubber parts caused by incorrect or contaminated brake fluid	Replace rubber parts. Flush the system and refill with approved brake fluid. For instructions, see **Subject 170**.
Trapped pressure in brake lines caused by master cylinder and/or booster not fully releasing	Repair or replace the master cylinder and/or booster as necessary.

Problem—One Brake Drags

Problem—One Brake Drags	
Possible Cause	**Remedy**
Loose or worn front wheel bearings	Adjust to specifications or replace.
Defective brake hose or hydraulic tube (preventing return of fluid)	Replace the hose or tube.
Sticking caliper piston	Repair or replace the caliper.
Swollen caliper piston seal	Replace the seal. Drain and flush the system. Refill with the approved brake fluid.
Sticking caliper guide pin(s)	Repair or replace the pin(s). Lubricate the pins and boots.

Problem—Low Pedal

Problem—Low Pedal	
Possible Cause	**Remedy**
Leak in hydraulic brake system	Check the master cylinder, calipers, hoses and tubes. Replace as necessary.
Air in hydraulic brake system	Bleed the system. For instructions, see **Subject 170**.
Poor quality brake fluid (low boiling point)	Drain the system. Flush and refill with approved brake fluid.
Weak brake hoses that expand under pressure	Replace the defective hoses.
Pad and piston knockback caused by loose wheel bearings	Adjust or tighten parts or replace faulty parts as necessary.

Table 5, Component Specifications

General Information

The R–12 (see **Fig. 1**) and R–14 (see **Fig. 2**) relay valves are control relay stations in the air brake system to speed the application and release of the brakes. Mounted at the rear of the vehicle, they are operated by remote control and give about the same amount of air pressure to the brake chambers as they receive from the service brake foot valve or other source.

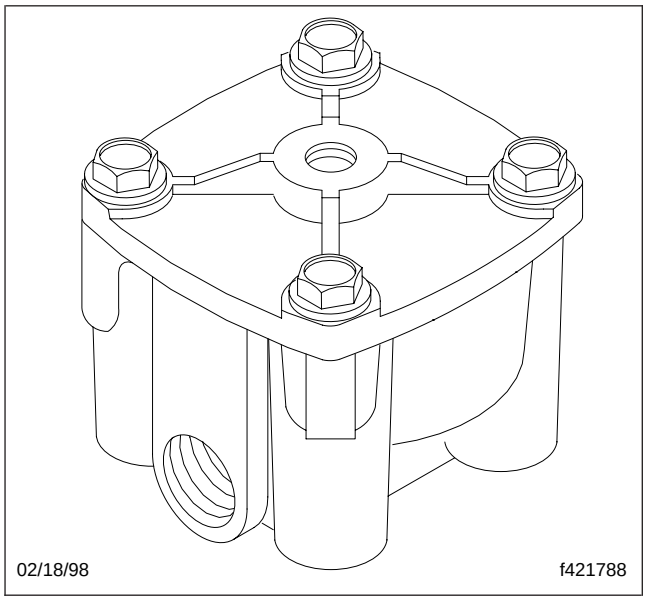

Fig. 1, R-12 Relay Valve

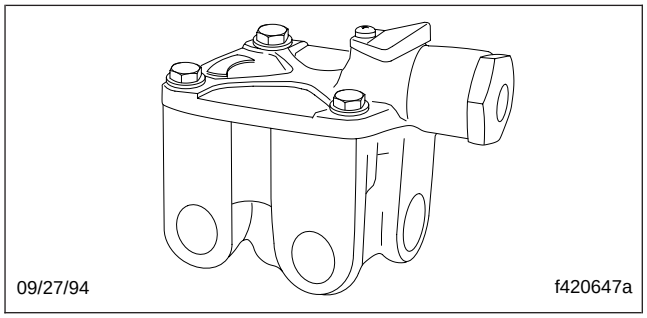

Fig. 2, R-14 Relay Valve

The valves are piston operated and have an insert-type inlet and exhaust valve that can be serviced.

Principles of Operation

See **Fig. 3 and Fig. 4** for sectional views of the R–12 and R–14 relay valves.

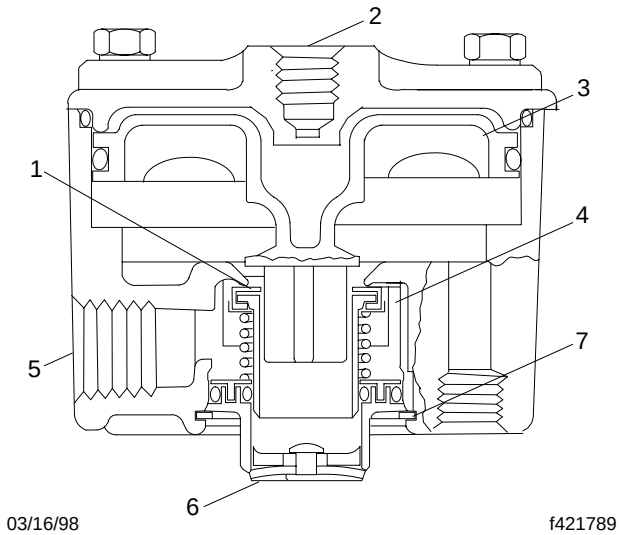
Application

Air pressure delivered to the service port enters the small cavity above the relay piston and moves the piston down. The exhaust seat moves down with the piston and seats on the inner or exhaust portion of the inlet/exhaust valve, sealing off the exhaust passage. At the same time, the outer or inlet portion of the inlet/exhaust valve moves off its seat, permitting supply air to flow from the reservoir, past the open inlet valve and into the brake chambers.

Balance

The air pressure being delivered by the open inlet valve also is effective on the bottom area of the relay piston. When air pressure beneath the piston equals the service air pressure above, the piston lifts slightly and the inlet spring returns the inlet valve to its closed position. The exhaust remains closed as the service line pressure balances the delivery pressure. As delivered air pressure is changed, the valve reacts to the change, holding the brake application at the same level.

Exhaust or Release



When air pressure is released from the service port and air pressure in the cavity above the relay piston is exhausted, air pressure beneath the piston lifts the piston, and the exhaust seat moves away from the exhaust valve, opening the exhaust passage. With the exhaust passage open, air pressure in the brake chambers is permitted to exhaust through the exhaust port, releasing the brakes.

Anti-Compounding (Simultaneous Service and Park Application), R–14 Valve

An "anti-compound" feature allows the R–14 valve to be used as either a service or spring brake relay valve. An exhaust cover is installed that protects the 1/8-inch balance port when the R–14 anti-compound feature is not in use. See **Fig. 4**.

In applications where the R–14 is used to control spring brake chambers, the anti-compound feature

Fig. 3, R-12 Relay Valve (sectional view)

may be used. To use, the exhaust cover of the quick release portion of the R–14 is removed and a line is installed, which is connected to the delivery port of the service brake valve or relay valve. With no air pressure at the service port of the R–14, the parking brakes apply. When a service brake application is made, air from the service brake valve enters the exhaust port of the quick release of the R–14 and moves the diaphragm, blocking the service port. Air then proceeds into the cavity above the relay piston, forces the piston down, closing the exhaust and opening the inlet to deliver air to the spring brake cavity.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

A. Chock the tires and stop the engine before working under the vehicle. Releasing air from the system may cause the vehicle to roll. Keep hands away from brake chamber push rods and slack adjusters; they will apply as air pressure drops.

B. Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.

C. Never exceed recommended air pressure, and always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.

D. Never attempt to disassemble a component until you have read and understood recommended procedures. Some components contain powerful springs and injury can result if not correctly disassembled. Use only correct tools and observe all precautions regarding use of those tools.

Operation Test

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Start the vehicle and build the brake system to cut-out pressure, about 130 psi (827 kPa).
2. Using a soap and water solution, check all air line fittings on the valve for leakage. If the fittings or air lines are leaking, replace the fittings. For instructions, see **Section 42.03**.
3. Make several service brake applications and check for prompt application and release of the brakes.
4. If brake response is slow, troubleshoot the brake system. For instructions, see **Section 42.02** . If the valve is malfunctioning, repair or replace it.

Leakage Test

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Start the vehicle and build the brake system to cut-out pressure, about 130 psi (827 kPa).
2. Using a soap and water solution, check for inlet valve and O-ring leakage.
   - 2.1 Make this check with the service brakes released when the R–12 or R–14 is used to control the service brakes.
   - 2.2 Make the check with the spring brakes (parking brakes) applied when the R–14 is used to control the spring brakes.
3. While holding a full service brake application, apply a soap solution to the exhaust port. Leakage at the exhaust port should not exceed a 1-inch (2.5-cm) bubble in three seconds.

NOTE: If the anti-compound feature is in use, the line attached to the balance port must be disconnected to perform this test.

4. Coat the outside of the valve where the cover joins the body to check for O-ring leakage; no leakage is permitted.
5. If the R–14 is used to control the spring brakes, release the parking brake, apply a soap solution to the balance port. Leakage at the balance port should not exceed a 1-inch (2.5-cm) bubble in three seconds.

IMPORTANT: If the valves do not function as described in the above test, or if leakage is excessive, replace it. For instructions, see **Subject 120**.

Relay Valve Removal and Installation

Removal

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Chock the tires, and drain the air system.
2. Remove all air hoses from the valve. Cap the hoses and mark them for reassembly.
3. Remove the valve mounting bolts. Remove the valve.

Installation

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

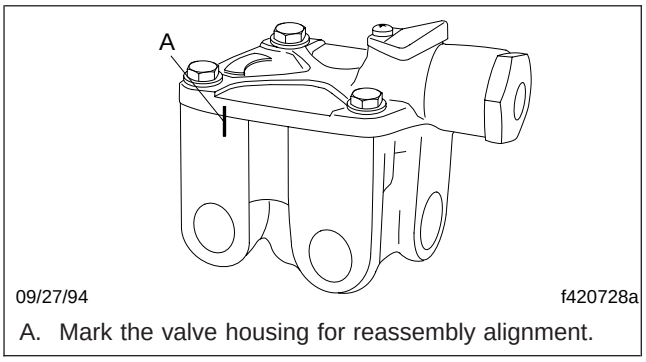
1. Attach the valve to the vehicle, using the bolts, washers, and nuts. Tighten the nuts 132 to 180 lbf·in (1500 to 2040 N·cm).
2. Remove the caps from the air lines, then depending on the type of air hose, do one of the following.

   Nylon Tubing: Connect the air line fittings to the valve ports, and tighten the nuts finger-tight. Using a wrench, tighten the nuts at least two turns, or until one thread shows on the fittings.

   Wire Braid Hoses: Connect the hose fittings to the valve ports, and hand-tighten the nuts. Using a wrench, tighten the nuts until resistance is felt. Tighten one-sixth turn more. Do not overtighten.
3. Close the air reservoir drain cocks. Start the vehicle engine to pressurize the air system.
4. Test the valve following the instructions in **Subject 110**.

Relay Valve Disassembly, Cleaning and Inspection, and Assembly

Disassembly



IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Remove the valve from the vehicle. For instructions, see **Subject 120**.

NOTE: Prior to disassembly, draw an alignment mark across the valve cover and body, for reassembly alignment. See **Fig. 1**.

2. Disassemble the valve.

   2.1 Referring to **Fig. 2**, remove the four cover capscrews and integral lockwashers.

A. Mark the valve housing for reassembly alignment.

Fig. 1, Valve Marked for Reassembly (R-14 valve shown)

   2.2 Remove the valve cover and O-ring.

   2.3 Remove the relay piston, and the O-ring.

   2.4 While depressing the exhaust cover, remove the retainer ring; slowly remove the exhaust cover and the valve spring. Remove the O-rings from the exhaust cover.

   2.5 Remove the inlet/exhaust valve. Remove the valve retainer from the inlet/exhaust valve.

3. On R–14 valves, remove the Phillips screw and the exhaust cover. Then, remove the service port capnut, the O-ring, and the diaphragm located inside the service port.

Cleaning and Inspection

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

IMPORTANT: Before working on or around air brake systems and components, see **Safety Precautions, 100**.

1. Wash all metal parts of the valve in cleaning solvent. Dry the metal parts of the disassembled valve with compressed air.
2. Wipe all rubber parts clean with a clean cloth. Examine all rubber parts for cracks, tears, or other deterioration. If any rubber parts are worn, cracked, torn, or otherwise damaged, replace them with new parts.
3. Examine all metal parts for wear, cracks, or other damage. If any metal parts are worn, cracked, or otherwise damaged, replace them with new parts.
4. Check the springs for distortion and corrosion. If the springs are distorted or corroded, replace them.
5. Inspect the exhaust seat of the quick release diaphragm in the R–14 cover and make sure all internal air passages in the area are open, clean, and free of nicks and scratches.

Assembly

IMPORTANT: Before working on or around air brake systems and components, refer to **Safety Precautions, 100**.

1. Lubricate the O-rings and all sliding parts with Dow Corning 55-M pneumatic grease or equivalent. Assemble the valve (see **Fig. 2**).

   1.1 Install the O-ring on the relay piston.

   1.2 Install the inner and outer O-rings on the exhaust cover.

   1.3 Install the O-ring on the valve cover.

   1.4 Install the relay piston in the body, taking care not to damage the piston O-ring.

Relay Valve Disassembly, Cleaning and Inspection, and Assembly

19. Diaphragm
20. O-Ring
21. Capnut

Fig. 2, R-14 Valve (R-12 similar)

1.5 Noting the reference mark made during disassembly, secure the valve cover with four capscrews and lockwashers. Torque the capscrews 80 to 120 lbf·in (900 to 1360 N·cm).

1.6 Install the valve retainer and spring on the inlet/exhaust valve assembly. Install the inlet/exhaust valve assembly in the body.

1.7 Install the exhaust cover. While depressing the exhaust cover, install the retaining

ring, making sure the retaining ring is completely seated in the groove.

1.8 On R–14 valves, place the diaphragm in the service port making sure it is positioned between the guide ribs. Install the service port cap nut and O-ring, then tighten it to 150 lbf·in (1700 N·cm).

1.9 Position the exhaust cover, then install the Phillips screw and tighten it to 25 lbf·in (280 N·cm).

2. Install the relay valve on the vehicle following the instructions in **Subject 120**.

3. Test the valve following the instructions in **Subject 110**.

Specifications

Valve Cover Capscrews	80–120 (900–1360)
Valve Mounting Capscrews	132–180 (1500–2040)
Service Port Capnut	150 (1700)
Phillips Screw, no. 10–24	25 (280)

Table 1, Torque Values

General Description

The steering driveline connects the steering column and jacket assembly to the steering gear by means of a telescoping shaft with integral yokes, an upper and a lower end yoke, and a pair of universal joints. **See Fig. 1.**

ternally splined lower section. The telescoping shaft eases installation and removal of the steering column, steering driveline, and steering gear. It also compensates for changes in distance between the steering column and steering gear, which occur when the relative positions of the frame rails and cab change during vehicle operation.

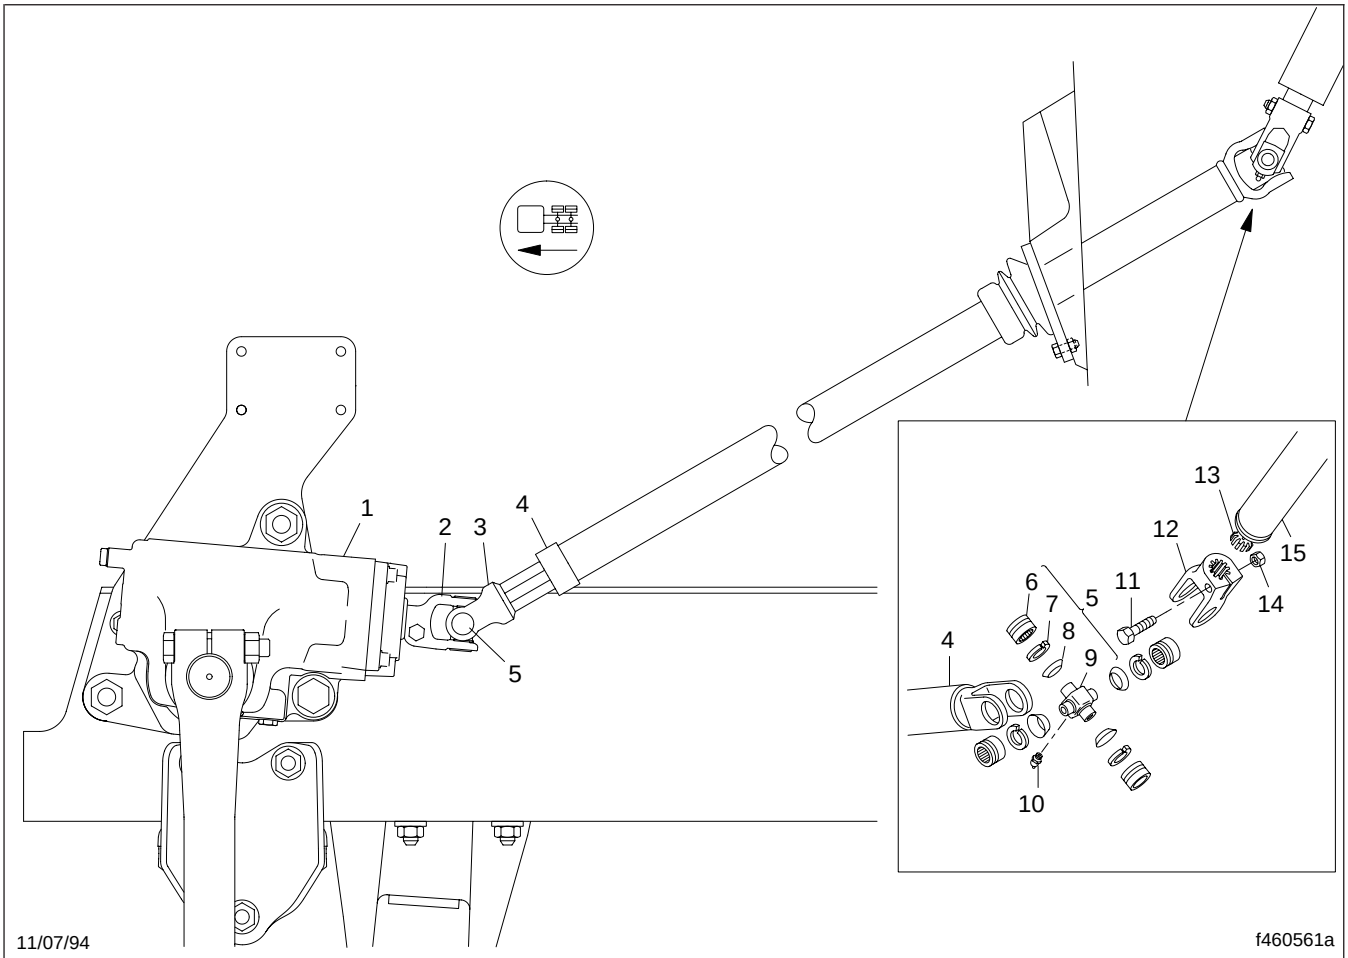
The driveline shaft consists of a tubular upper section, splined on the inside, which mates with an ex-



The upper end yoke is internally serrated to match the external serrations at the end of the steering col-

General Description

umn shaft; the lower end yoke is internally serrated to match the external serrations on the steering gear input shaft. Each end yoke is secured to its respective shaft by a pinch bolt that engages a notch in the shaft.

The universal joint at each end of the steering driveline allows the transfer of steering motion from the steering column shaft, to the steering driveline, and to the steering gear input shaft, even though the driveline is at an angle to both of the other shafts. Each universal joint cross rides in four needle bearing cups, two carried in the end yoke, and two carried in the steering driveline's integral yoke. The needle bearing cups are held in place in each yoke by snap rings.

14. Pinch-Bolt Nut
15. Upper Column and Jacket Assembly

Fig. 1, Steering Driveline

NOTE: It is not necessary to loosen the steering wheel and column assembly to do this procedure.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations will be done.
2. Apply the parking brakes, and chock the tires. Tilt the hood.
3. Disconnect the lower end yoke.
   - 3.1 Remove the pinch-bolt nut and pinch bolt from the lower end yoke. **See Fig. 2.** Discard the nut.

Removal and Installation

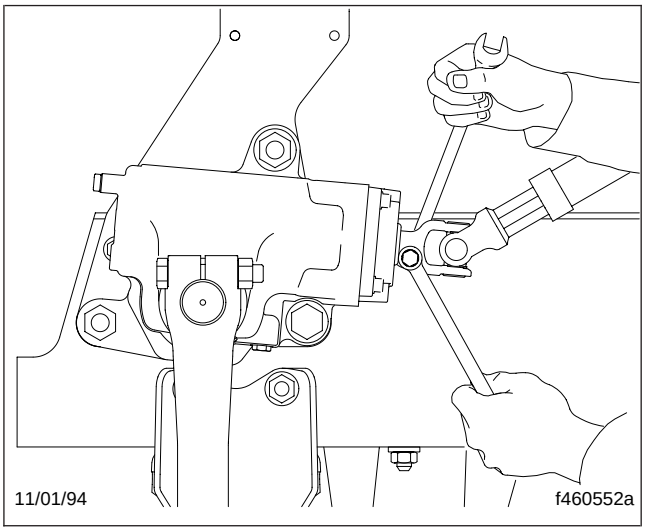

Fig. 2

3.2 Remove the yoke from the steering gear input shaft. **See Fig. 3.** Don't turn the steering gear input shaft when removing the lower end yoke. Push the driveline shaft into the driveline tube, as you remove the lower end yoke.

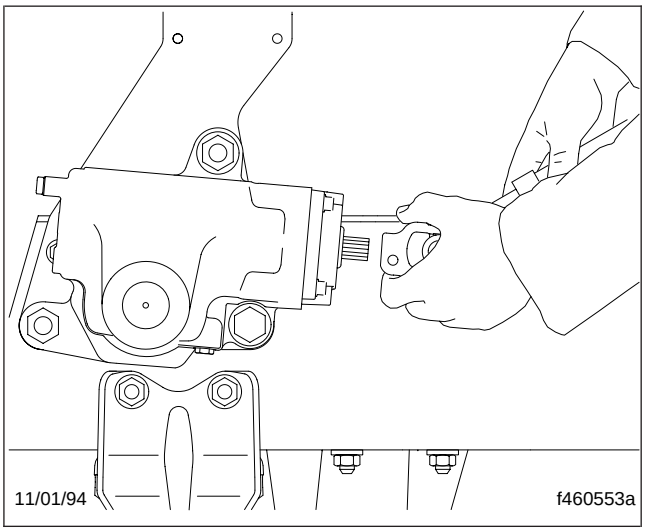

Fig. 3

4. Disconnect the upper end yoke.

4.1 Remove the four screws holding the steering driveline boot to the firewall. **See Fig. 4.**

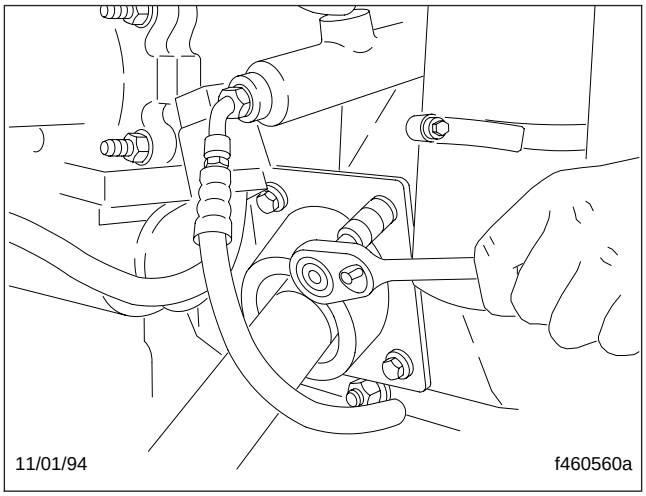

Fig. 4

4.2 Slide the boot down the steering driveline. **See Fig. 5.**

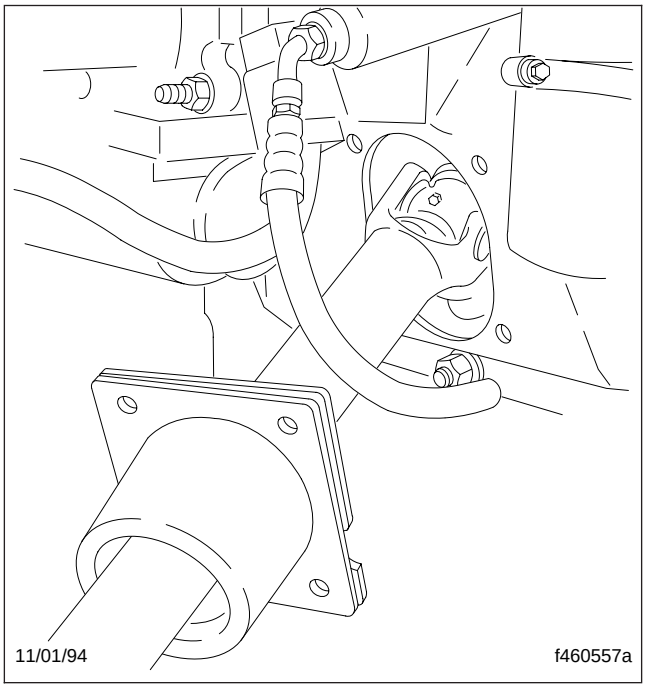

Fig. 5

4.3 Remove the pinch-bolt nut and pinch bolt from the upper end yoke. **See Fig. 6.** Discard the nut.

4.4 Remove the upper end yoke from the steering column shaft. **See Fig. 7.**

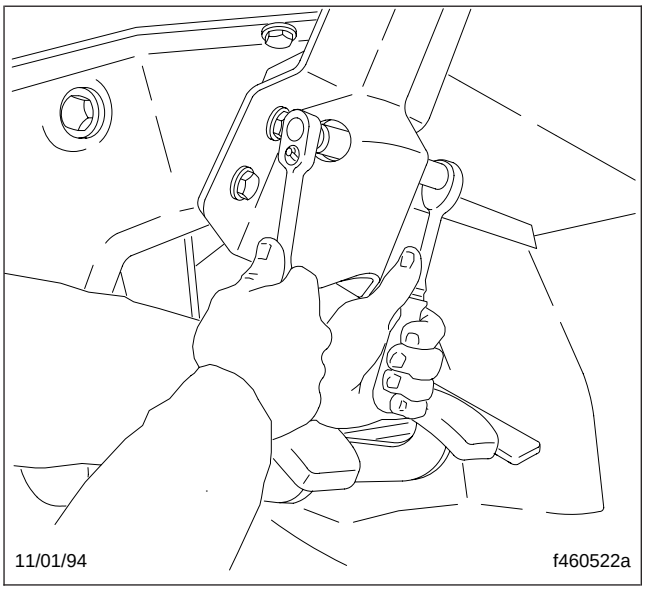

Fig. 6

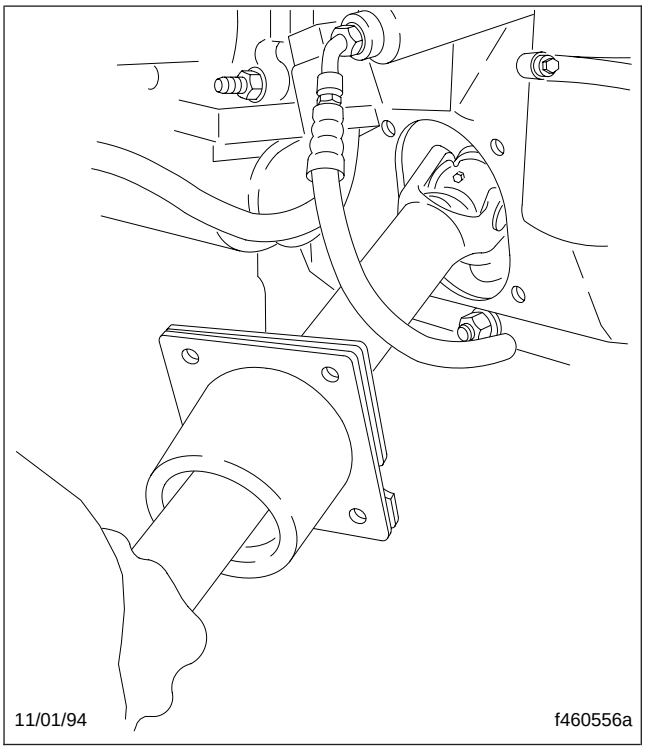

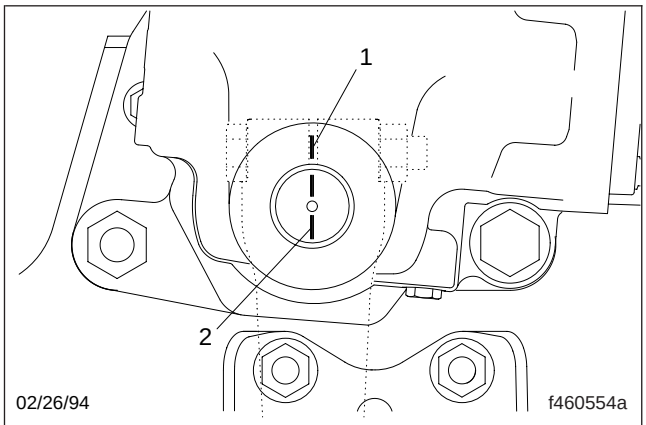

Fig. 7

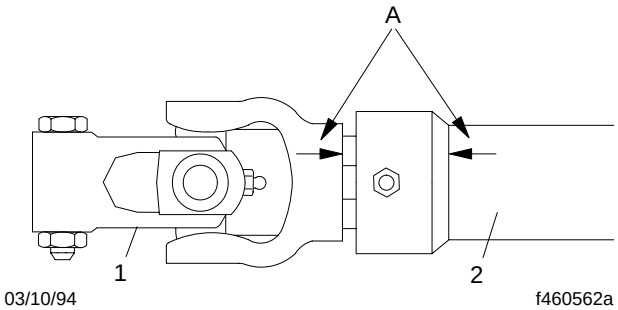
Installation (See Fig. 1)



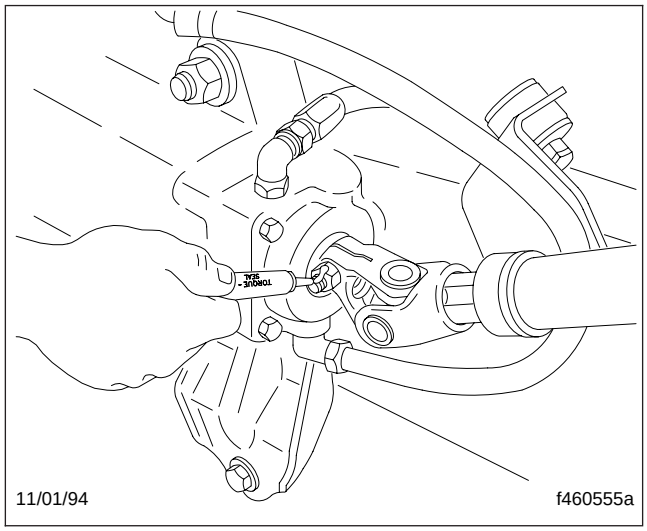
1. Clean the steering gear input shaft, steering column, and end yokes.
   - 1.1 Thoroughly clean the end yokes, the steering column shaft, and the steering gear input shaft with a clean, dry cloth.
   - 1.2 Apply a thin film of grease to the yoke splines. Use lithium-based grease, NLGI grade 2.
2. Slide the upper end yoke onto the steering column shaft, then install the end yoke pinch bolt. Before installing the pinch-bolt nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new pinch-bolt nut, and tighten it 75 to 88 N·m (55 to 65 lbf·ft).
3. Apply white Torque Seal F-900 to the exposed pinch-bolt thread and to the locknut.
4. Before attaching the lower end yoke to the steering gear input shaft, be sure the front tires are straight ahead, and the steering gear is centered with the timing mark on the end of the sector shaft in line with the mark on the housing trunnion. **See Fig. 8 .** Also, be sure the arrows on the driveline shaft and the driveline tube are aligned. **See Fig. 9.**

1. Timing Mark (Housing Trunnion)
2. Timing Mark (Sector Shaft)

Fig. 8

Removal and Installation

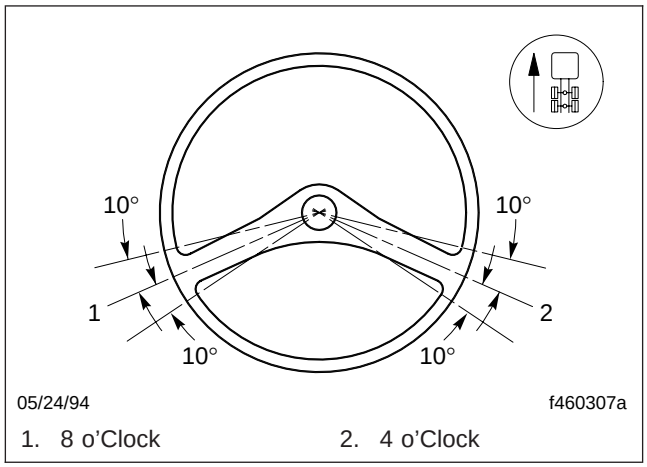
03/10/94 f460562a



A. Align arrows.
1. Lower End Yoke
2. Driveline Tube and Yoke Assembly

Fig. 9

⚠ CAUTION



CAUTION: If the arrow on the driveline shaft is not aligned with the arrow on the driveline tube, the U-joints will not be correctly oriented. Assembling the driveline with the U-joints incorrectly oriented could cause binding at the U-joints.

5. Install the lower end yoke on the steering gear input shaft. Before installing the pinch-bolt nut, make sure the pinch bolt is centered in the steering gear input shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a *new* pinch-bolt nut, and tighten it 75 to 88 N·m (55 to 65 lbf·ft).
6. Apply white Torque Seal F-900 to the exposed pinch bolt thread and to the locknut. **See Fig. 10.**
7. Lubricate the driveline tube and both U-joints with lithium-based grease, NLGI grade 2. Apply until grease appears at the lower end of the tube splines and all four U-joint cross seals.
8. Align the steering wheel spokes.
   - 8.1 With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be pointing within ±10 degrees of the 4 o'clock and 8 o'clock positions. **See Fig. 11.**
   - 8.2 If not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

11/01/94 f460555a

Fig. 10

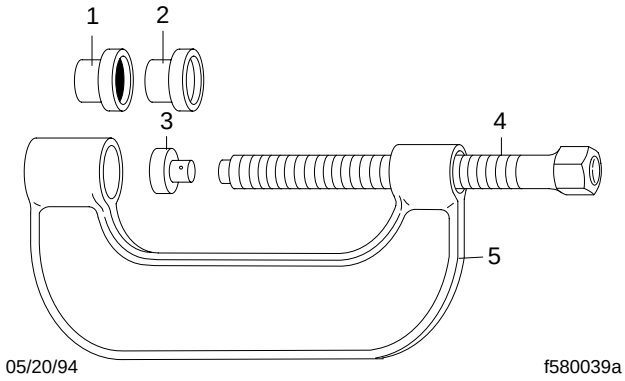
05/24/94 f460307a

1. 8 o'Clock 2. 4 o'Clock

Fig. 11

9. Lower the hood, and secure the hood latches. Leave the parking brakes applied and the chocks at the rear tires.
10. Raise the front of the vehicle, so that the front tires are off the ground, then place safety stands under the frame.

⚠ WARNING



WARNING: Driving a vehicle with hard steering or binding in the steering system is hazardous and could result in partial or complete loss of steering control during vehicle operation.

11. Turn the steering wheel through full travel, checking for hard steering or binding. If there is difficulty, check the assembly and installation of the driveline parts. If the cause is not the driveline, refer to the applicable steering gear section in this group.
12. Remove the safety stands, lower the vehicle to the ground, and remove the chocks.

Disassembly

1. Remove the steering driveline from the vehicle. Refer to **Subject 100** for instructions.
2. Slide the driveline shaft and yoke assembly out of the driveline tube and yoke assembly.
3. Remove the steering driveline U-joint.

   3.1 Clamp the frame of a U-joint tool **(Fig. 1)** in a vise.

1. Bushing Adaptor
2. Bearing Driver
3. Expansion Plug
4. Pressure Screw
5. Frame

Fig. 1, Universal Joint Tool

   3.2 Wearing safety goggles, remove the needle bearing cup snap rings from the needle bearing cups by pushing an open end of each snap ring with a screwdriver.

⚠ WARNING

WARNING: Snap rings can become potentially harmful projectiles when they are being removed. Wear safety goggles to prevent eye injury.

   3.3 Select a U-joint tool expansion plug of slightly smaller diameter than the needle bearing cup, and place it on the pressure screw. Select a bushing adapter of slightly larger inside diameter than the needle bearing cup, and place it on the opposite end of the tool.

   3.4 Place the integral yoke of the driveline tube in the U-joint tool. Position the bushing adapter to receive a needle bearing cup, and place the expansion plug against the opposite needle bearing cup.

   3.5 Tighten the pressure screw to press one needle bearing cup out of the driveline yoke, then remove the cup. In some cases, it might be necessary to give the pressure screw a sharp blow with a brass hammer while the screw is under pressure.

   3.6 Reverse the driveline tube and yoke assembly, and press against the U-joint cross to force out the other needle bearing cup.

   3.7 Remove the driveline tube and yoke assembly from the U-joint tool, then remove the upper end yoke and the U-joint cross from the driveline yoke.

   3.8 Place the upper end yoke in the U-joint tool. Position the bushing adapter to receive a needle bearing cup, and place the expansion plug against the opposite needle bearing cup.

   3.9 Tighten the pressure screw to press one needle bearing cup out of the upper end yoke, then remove the cup. In some cases, it might be necessary to give the pressure screw a sharp blow with a brass hammer while the screw is under pressure.

   3.10 Reverse the upper end yoke in the U-joint tool, and press against the U-joint cross to force out the other needle bearing cup.

   3.11 Remove the upper end yoke from the U-joint tool, then remove the U-joint cross from the upper end yoke.

4. Repeat the applicable steps above for the driveline shaft and yoke assembly and the lower end yoke.

Assembly

1. Install the steering driveline U-joint.

   1.1 Clamp the frame of a U-joint tool **(Fig. 1)** in a vise.

   1.2 Select a U-joint tool expansion plug of a slightly smaller diameter than the needle

Disassembly and Assembly

bearing cup, and place it on the pressure screw. Place a bearing driver on the opposite end of the tool.

1.3 Position the U-joint cross in the upper end yoke so that the U-joint cross lube fitting points toward one of the yoke ears.

1.4 Make certain the U-joint cross seals are in place on the needle bearing cups, then start both needle bearing cups into the yoke ears from the outside. Place the upper end yoke in the U-joint tool with the bearing driver against one of the needle bearing cups and the expansion plug against the opposite needle bearing cup.

1.5 Tighten the pressure screw, making sure that both needle bearing cups press straight and true into the yoke ears. Work the U-joint cross during this operation to ensure free movement. If the needle bearing cups don't seat correctly, or if the U-joint binds, give the yoke shoulder near each cup a sharp blow with a brass hammer.

1.6 Press the needle bearing cup on the screw end of the U-joint tool all the way in, until there is enough clearance to insert a new needle bearing cup snap ring. Insert the snap ring, and fully seat it in its groove.

⚠ WARNING

WARNING: Use new snap rings when assembling the U-joints. Used snap rings are often distorted and overstressed from disassembly. Also, snap rings not fully seated in their grooves could work loose, resulting in a hazardous vehicle operating condition.

1.7 Reverse the upper end yoke in the U-joint tool, and push the other needle bearing cup until there is clearance to insert the other snap ring. Insert the snap ring, then remove the upper end yoke from the U-joint tool.

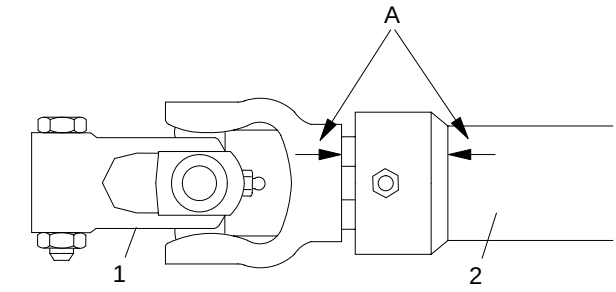
1.8 With the U-joint cross lube fitting facing away from the base of the upper end yoke, position the U-joint cross and the upper end yoke in the driveline tube and yoke assembly.

NOTE: The U-joint cross lube fitting should face away from the base of the upper end yoke to provide access for lubrication when the steering driveline is installed on the vehicle.

1.9 Make certain the U-joint cross seals are in place on the needle bearing cups, then start both needle bearing cups into the yoke ears. Place the driveline tube and yoke assembly in the U-joint tool with the bearing driver against one of the needle bearing cups and the expansion plug against the opposite needle bearing cup.

1.10 Tighten the pressure screw, making sure that both needle bearing cups press straight and true into the yoke ears. Work the U-joint cross during this operation to ensure free movement. If the needle bearing cups don't seat correctly, or if the U-joint binds, give the yoke shoulder near each cup a sharp blow with a brass hammer.

1.11 Press the needle bearing cup on the screw end of the U-joint tool all the way in, until there is enough clearance to insert a needle bearing cup snap ring. Insert the snap ring. Reverse the driveline tube and yoke assembly in the U-joint tool and push the other needle bearing cup until there is clearance to insert the other snap ring. Insert the snap ring.



2. Remove the driveline tube and yoke assembly from the U-joint tool.

3. Repeat the applicable steps above for the lower end yoke and the driveline shaft and yoke assembly.

4. Slide the lower driveline shaft into the driveline tube, so that the arrow on the driveline shaft yoke is aligned with the arrow on the driveline tube. **See Fig. 2.**

⚠ CAUTION

CAUTION: If the arrow on the driveline shaft yoke isn't aligned with the arrow on the driveline tube, the U-joints will be out of phase. Assembling the driveline with the U-joints out of phase could result in binding at the U-joints.

A. Align arrows.
1. Lower End Yoke
2. Driveline Tube and Yoke Assembly

Fig. 2

5. Install the steering driveline in the vehicle. Refer to **Subject 100** for instructions.

Specifications

Description	Grade	Size	Torque N·m (lbf·ft)
End Yoke Pinch-Bolt Nut	8 or 8.2	7/16–20 UNF	75 to 88 (55 to 65)

Table 1, Torque Values

General Description

The drag link is nonadjustable, with non-removable socket ball studs at both ends. **See Fig. 1**.

The drag link connects the pitman arm to the front axle steering arm. The socket ball studs, one located at each end, rotate to allow for changing angles between the pitman arm and steering arm as the vehicle is steered and the suspension articulates.

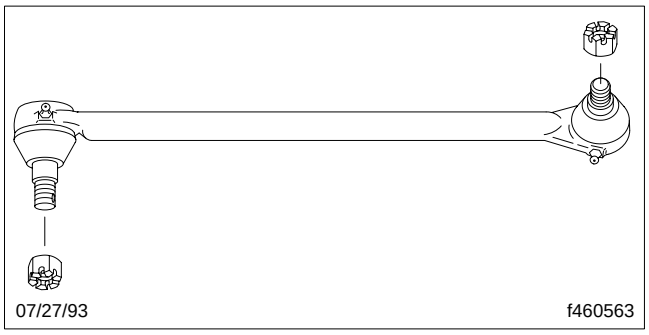


Fig. 1

Removal

1. If ball stud wear or looseness is suspected, check for wear of the ball studs before removing the drag link. Refer to **Subject 110** for instructions.
2. Position the tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations are to be performed. *Do not turn the steering wheel at any time while the drag link is still attached to both the pitman arm and the axle steering arm.* If the steering wheel is turned, the front tires will not be straight ahead.
3. Apply the parking brakes, and chock the rear tires.
4. Release the hood latches, and tilt the hood.
5. Remove the left-hand bumper extension or rotate it out of the way. See **Fig. 1**.

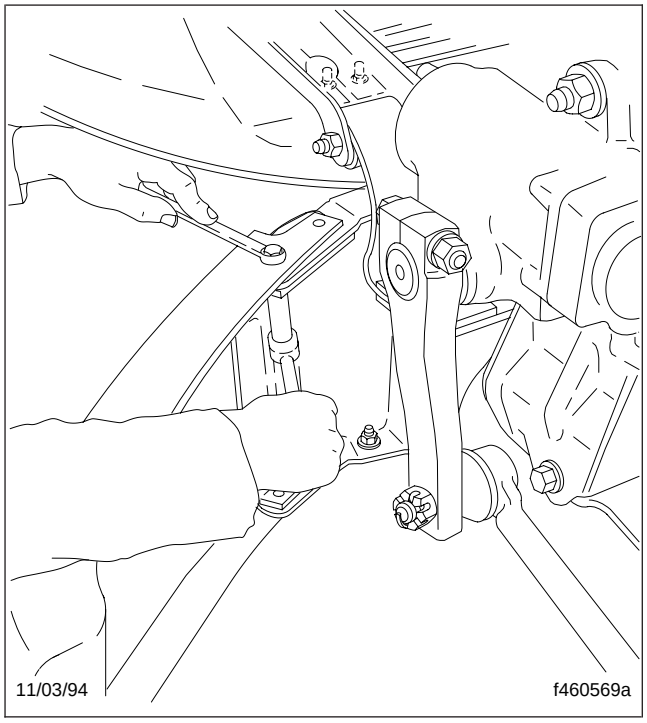

Fig. 1, Moving the Bumper Extension

6. Remove the drag link from the vehicle.
   - 6.1 At both ends of the drag link, remove the cotter pins and loosen the nuts on the socket ball studs. See **Fig. 2** and **Fig. 3**. Be sure the nuts are loosened far enough to allow use of a ball stud removal tool.

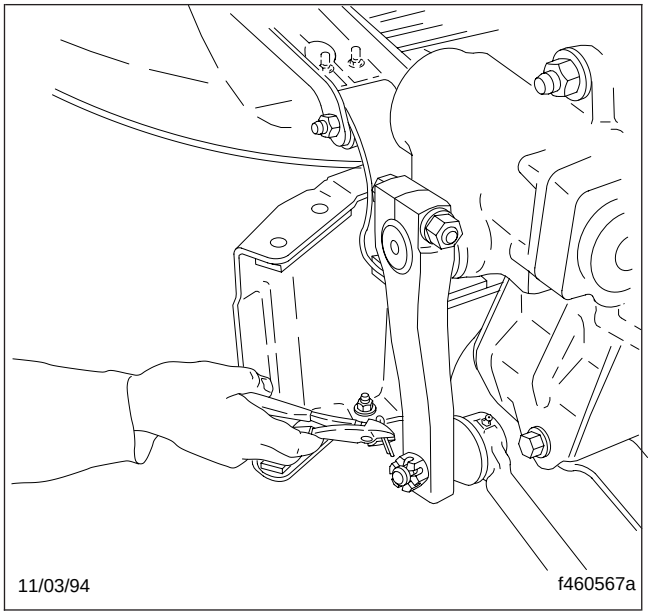

Fig. 2, Remove the Cotter Pin

   - 6.2 Using a ball stud removal tool, loosen the drag link from the pitman arm and the axle steering arm. See **Fig. 4**, **Fig. 5**, and **Fig. 6**.
   - 6.3 Remove the nuts and drag link.

IMPORTANT: Do not steer the gear with the linkage removed; unintended setting of the automatic poppets may result.

Installation

1. Before installing the drag link, check for damage or wear. Replace parts as needed.
   - 1.1 Check the ball stud covers or dust caps for extreme wear, cuts, or other damage; replace the covers (seals) if needed.
   - 1.2 Inspect the socket ball studs, ball stud nuts, drag link rod, and grease fittings for wear or damage. Replace the components as needed.
2. Install the drag link.

Removal and Installation

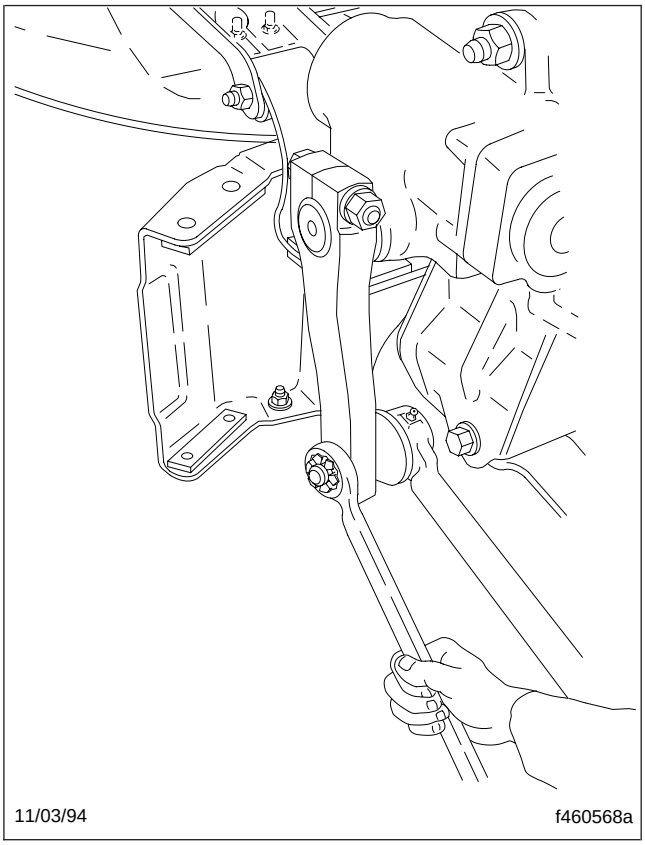

Fig. 3, Loosen the Nut

2.1 When installing the drag link, if needed, slightly turn the steering wheel to change the distance between the pitman arm and the steering arm.

2.2 Tighten the ball stud nuts as follows:

- 5/8–18, 60 to 115 lbf·ft (81 to 156 N·m)
- 3/4–16, 90 to 170 lbf·ft (122 to 230 N·m)
- 7/8–14, 160 to 300 lbf·ft (217 to 407 N·m)

2.3 If required, continue tightening each nut until a slot on the nut aligns with the hole in the ball stud. *Don't back off the nut when locating the cotter pin hole.*

2.4 Install new cotter pins through the ball studs and nuts, and lock the cotter pins in place.

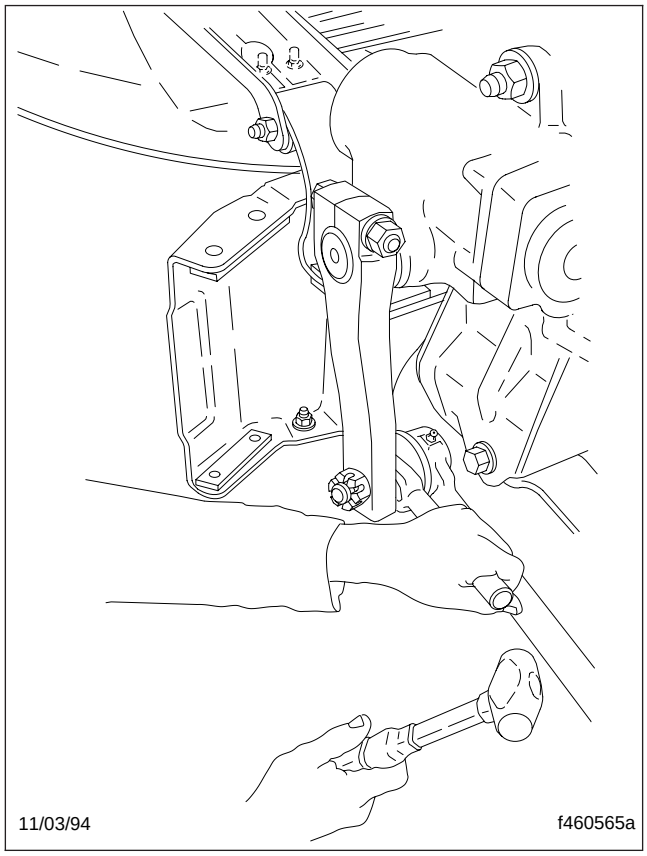

Fig. 4, Loosening the Drag Link from the Pitman Arm

⚠ WARNING

Failure to install and lock new cotter pins in the ball studs and nuts could result in disengagement of the parts and loss of steering control.

3. Wipe the dirt from the grease fittings. Apply chassis grease until the old grease is forced out.
4. Install the left-hand bumper extension.
5. Lower the hood, and fasten the hood latches.
6. Align the steering wheel spokes. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be pointing within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 7**. If not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

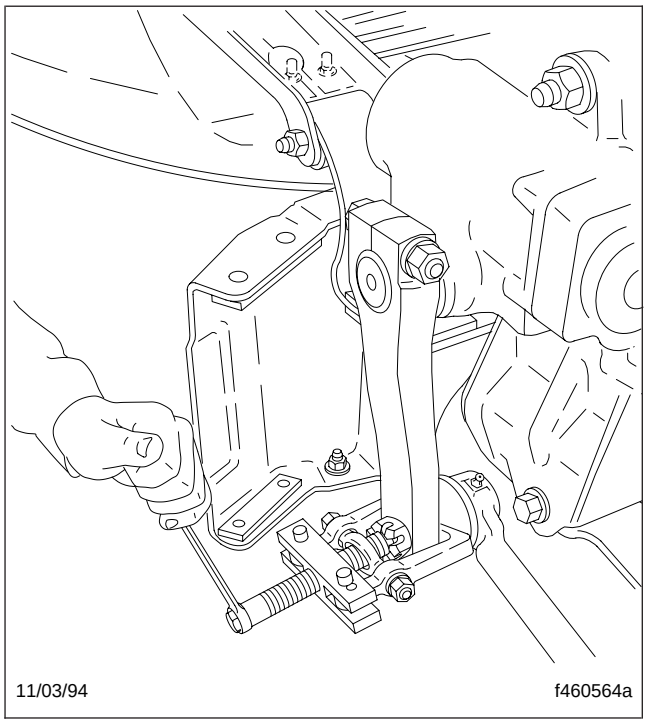

Fig. 5, Loosening the Drag Link from the Pitman Arm

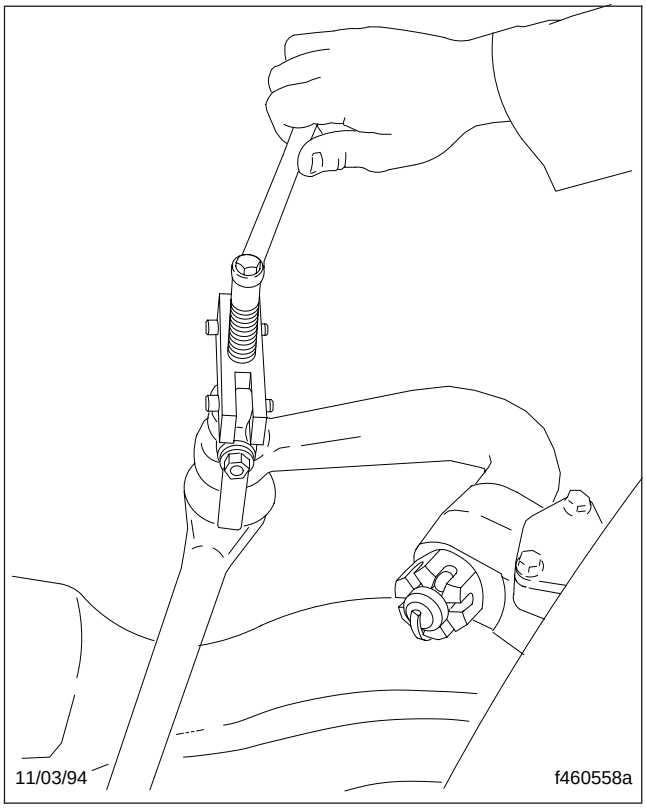

Fig. 6, Loosening the Drag Link from the Axle Steering Arm

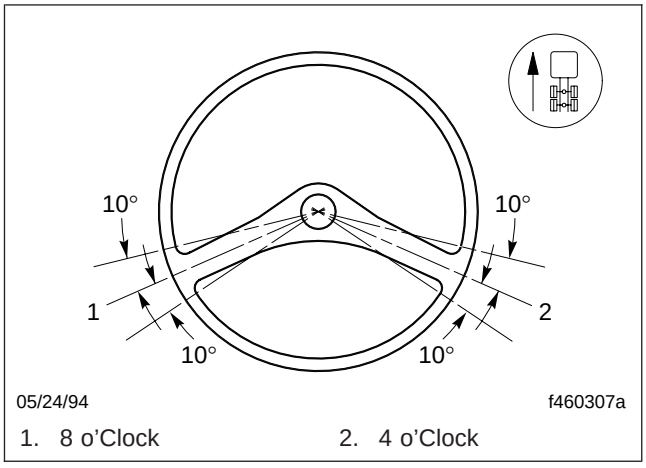

Fig. 7, Proper Steering Wheel Position (with the tires straight ahead)

Testing

Check for wear of the drag link ball stud end, and nut tightness as follows:

Have someone gently turn the steering wheel back and forth. Check for looseness between the ball stud end, and both the pitman arm and steering arm. Also check for looseness of the ball stud nut.

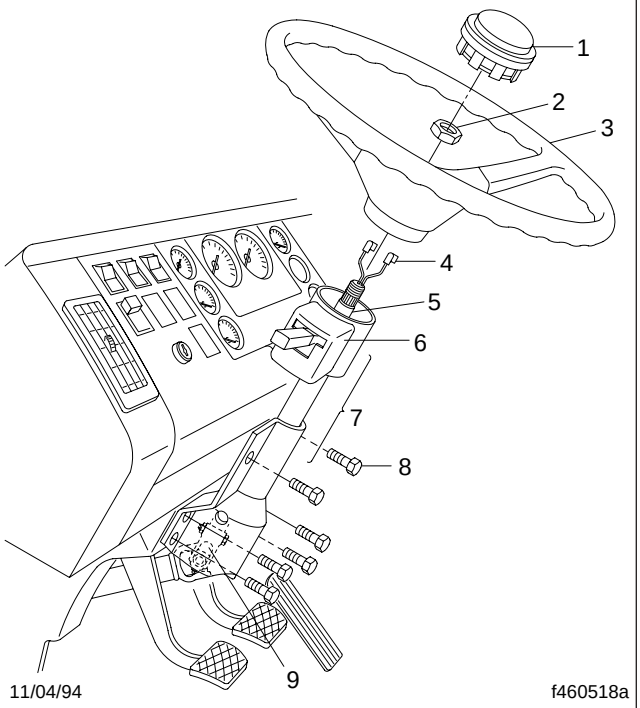
If the ball stud *end* is loose, replace the drag link. If the ball stud *nut* is loose, replace the nut and cotter key. Tighten the ball stud nut as follows:

- 5/8–18, 60 to 115 lbf·ft (81 to 156 N·m)
- 3/4–16, 90 to 170 lbf·ft (122 to 230 N·m)
- 7/8–14, 160 to 300 lbf·ft (217 to 407 N·m)

Grasp the drag link near the pitman arm end, push and pull laterally to check for axial looseness in the ball stud end. If there is looseness, replace the drag link. For instructions, refer to **Subject 100**. If there is 1/8 inch (3 mm) looseness or more, do not drive the vehicle until the drag link is replaced.

Grasp the drag link near the steering arm end. Push and pull vertically to check for axial looseness in the ball stud end. If there is looseness, replace the drag link. For instructions, refer to **Subject 100**. If there is 1/8 inch (3 mm) looseness or more, do not drive the vehicle until the drag link is replaced.

Grease the drag link until the old grease is purged.



Specifications

Torque Values	
Nut Size	**Torque lbf·ft (N·m)**
5/8–18	60–115 (81–156)
3/4–16	90–170 (122–230)
7/8–14	160–300 (217–407)

Table 1, Torque Values

General Information

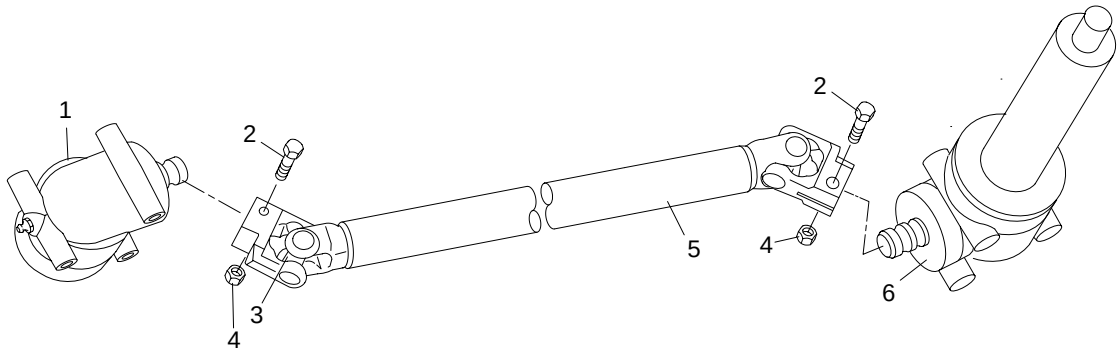
The steering wheel is cushioned and has two spokes. A horn button is mounted in the center of the steering wheel. See **Fig. 1**.

1. Horn Button
2. Steering Wheel Nut
3. Steering Wheel
4. Horn Wires
5. Steering Shaft
6. Turn Signal Switch
7. Tube Assembly
8. Steering Column Mounting Capscrews
9. Driveline End Yoke

Fig. 1, Steering Column Assembly, Left-Hand Drive

A turn signal switch is attached to the left side of the column, just below the steering wheel. If the vehicle is equipped with the optional trailer brake air switch, it is installed on the right side of the column.

The major parts of the steering column assembly are the shaft, the bearings, and the tube assembly.



On vehicles with right-hand drive, a traverse shaft and two miter boxes connect the steering column with the steering driveline on the left side of the vehicle. See **Fig. 2**.

The steering shaft is installed in the tube assembly and held in place by the bearings. The upper end of the shaft is threaded. Below the threads are splines that correspond to those in the steering wheel.

On left-hand-drive vehicles the lower end of the shaft is splined for the steering driveline end yoke and has a groove for the pinch bolt. On right-hand-drive vehicles the lower end of the shaft is attached to a 90-degree miter box that has a splined output shaft on the left (inboard) side that attaches to the end yoke of the traverse shaft. A second 90-degree miter box connects the traverse shaft with the steering driveline.

On left-hand-drive vehicles, the steering column assembly is held in place by capscrews that attach the bracket end of the assembly to the lower dash and the pedal support bracket. On right-hand-drive vehicles, the steering column assembly is held in place by capscrews that attach the lower mounting plate to the lower dash and the clutch pedal box.

Steering Wheel Removal and Installation

Removal

1. Put the front wheels in the straight ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the place where the work will be done.

   Don't turn the steering wheel at any time during the removal procedure.
2. Apply the parking brake and chock the tires.
3. Disconnect the batteries at the negative terminal.
4. Using a small screwdriver, carefully pry out the horn button. Disconnect the two wires from it. **See Fig. 1.**

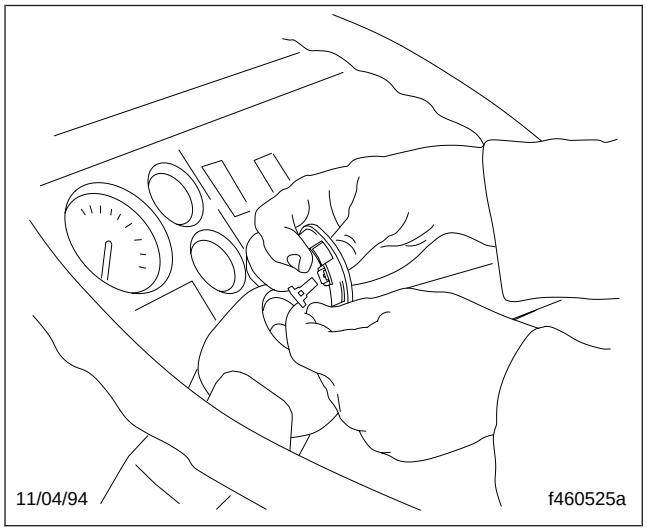

Fig. 1, Pry out the Horn Button

5. Using a deep socket to avoid damaging the wires, remove the steering wheel nut. **See Fig. 2.**
6. Using 1/4-inch sheet metal stock, make a wire protector about 4 cm x 1.5 cm (1-5/8 inches x 5/8 inch), like the one shown in **Fig. 3.** Then put it over the end of the steering column.
7. Using a steering wheel puller, remove the steering wheel from the steering column. **See Fig. 4.**

IMPORTANT: When you set the steering wheel aside, be careful not to damage the turn signal self-cancelling pin on the underside of the wheel. **See Fig. 5.**

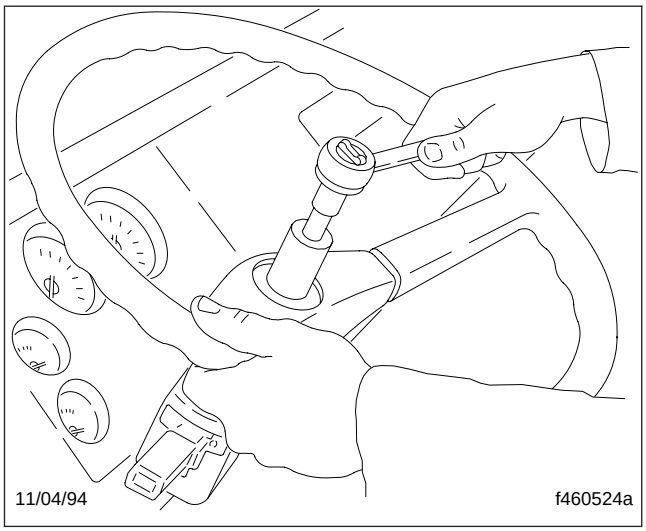

Fig. 2, Remove the Steering Wheel Nut

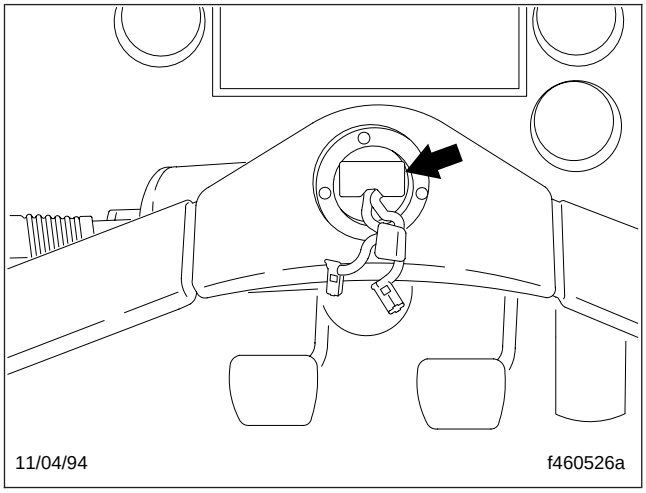

Fig. 3, Make a Wire Protector

Installation

1. Make sure the front tires are pointed straight ahead and the steering gear is centered.
2. Put the steering wheel on the steering column so that the spokes are within 10 degrees of the 4 o'clock and 8 o'clock positions. **See Fig. 6.**
3. Thread the two horn wires through the steering wheel nut, then install the nut. Tighten it 81 N·m (60 lbf·ft).

Steering Wheel Removal and Installation

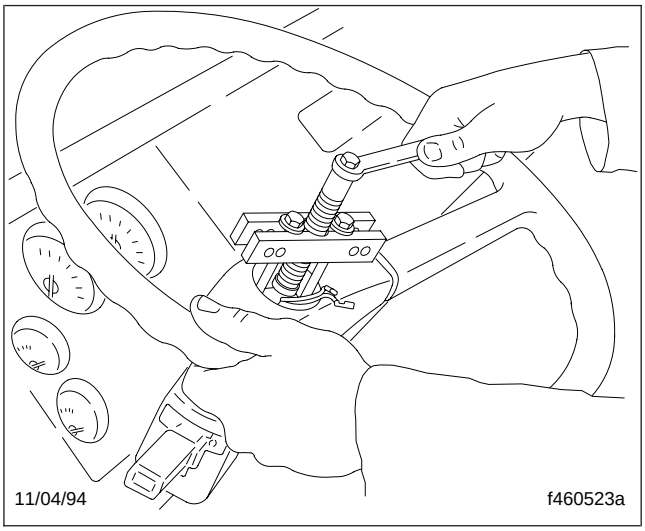

Fig. 4, Remove the Steering Wheel from the Column

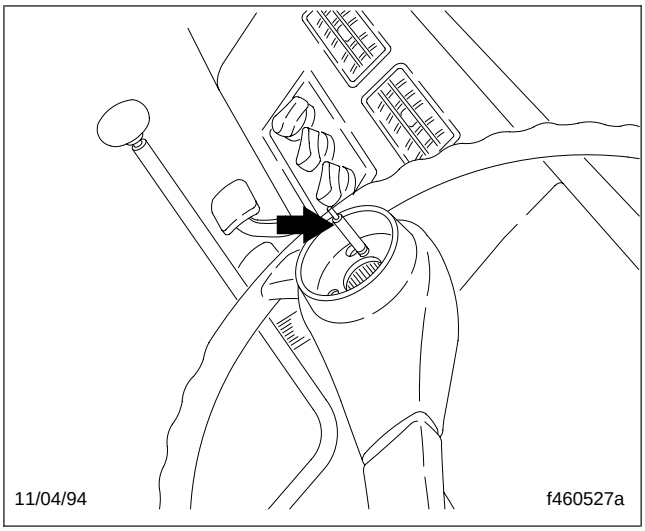

Fig. 5, Turn Signal Self-Cancelling Pin

4. Connect the two wires to the horn button. Pack the horn wires with dielectric grease.

NOTE: The horn wires may be connected to either terminal.

5. Install the horn button in the steering wheel hub so the logo on it is aligned with the steering wheel spokes. **See Fig. 7.**

6. Take the vehicle for a test drive to make sure the steering wheel is on correctly. If it isn't, remove it and install it again.

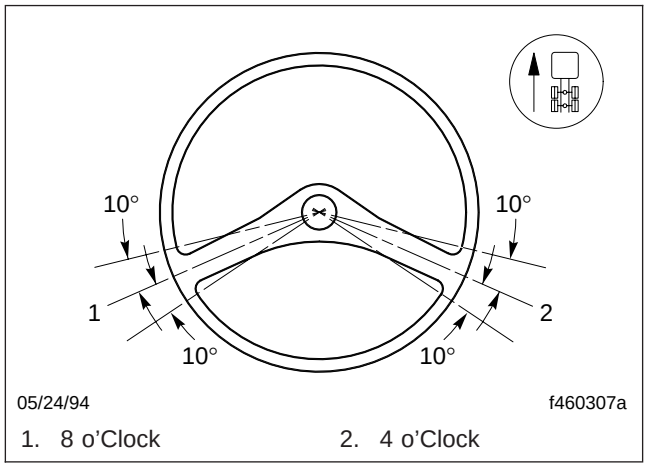

Fig. 6, Center the Steering Wheel

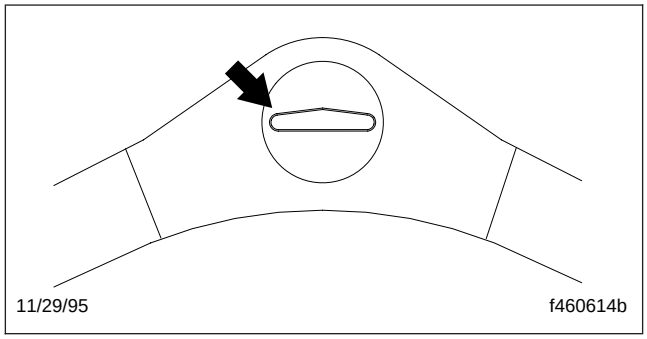

Fig. 7, Align the Logo

Left-Hand Drive (LH DR)

REMOVAL

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service work will be done. *Do not move the tires from the straight-ahead position during removal or at any time while the steering column is removed.*
2. Apply the parking brakes and chock the tires.
3. Remove the steering wheel, following the instructions in **Subject 100**.
4. Remove the plastic cover from the turn signal switch on the left (outboard) side of the steering column. See **Fig. 1**.

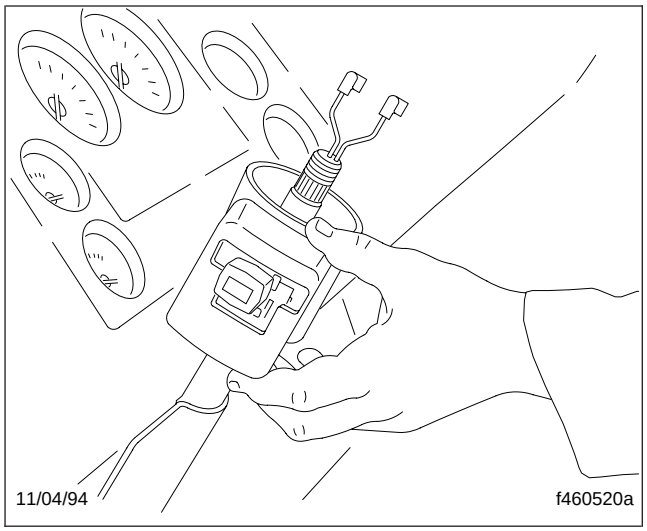

Fig. 1, Removing the Plastic Cover

5. Remove the two allen-head screws that attach the turn signal switch to the steering column (see **Fig. 2**), then swing the turn signal switch up and out of the way.
6. Disconnect the horn wire. See **Fig. 3**.
7. If installed, remove the trailer brake air lines from the switch mounted on the right (inboard) side of the steering column. Mark the lines for ease of installation. See **Fig. 4**.
8. Remove and discard the pinch bolt and nut from the steering driveline yoke. See **Fig. 5**.

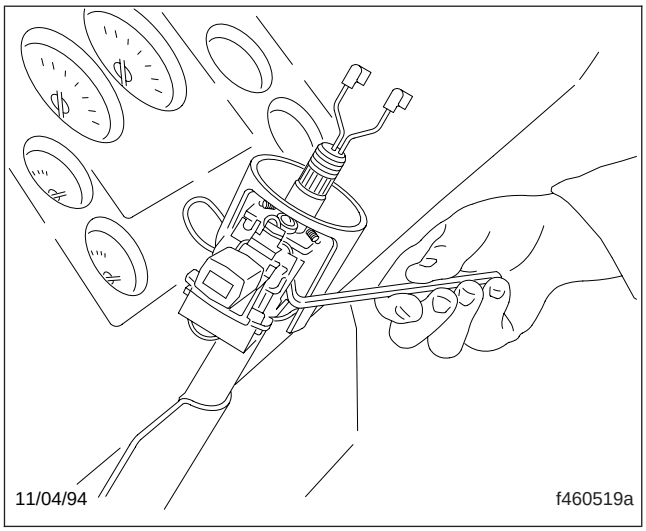

Fig. 2, Removing the Mounting Screws

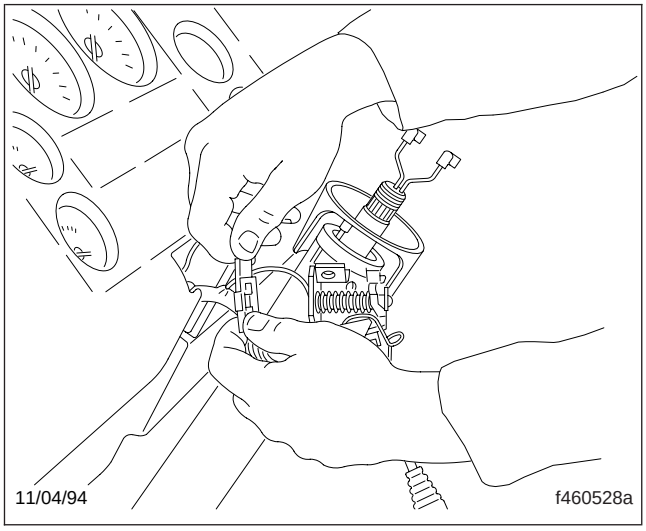

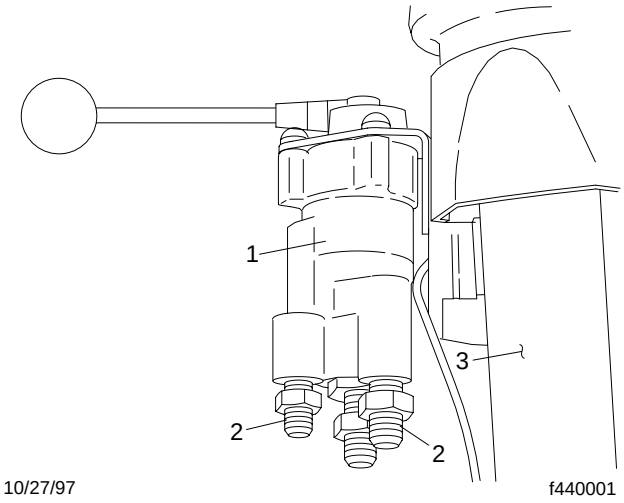

Fig. 3, Disconnecting the Horn Wire

9. Remove the six capscrews that attach the steering column bracket to the lower dash and to the pedal support bracket. See **Fig. 6**.
10. Disconnect the steering column from the steering driveline U-joint yoke.

INSTALLATION

1. Connect the lower steering column to the steering driveline.
   1.1 Slide the steering driveline U-joint yoke onto the lower end of steering column.

Steering Column Removal and Installation

This switch is mounted on the right side of the steering column on both LH DR and RH DR.

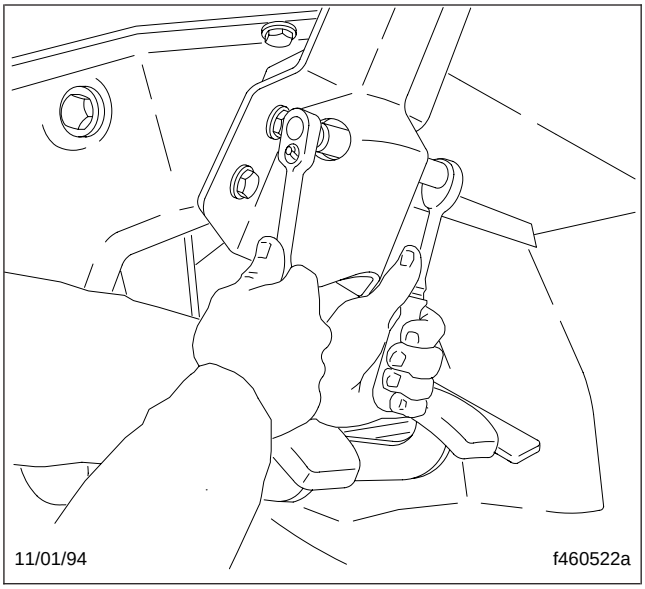

Fig. 5, Removing the Steering Driveline Pinch Bolt

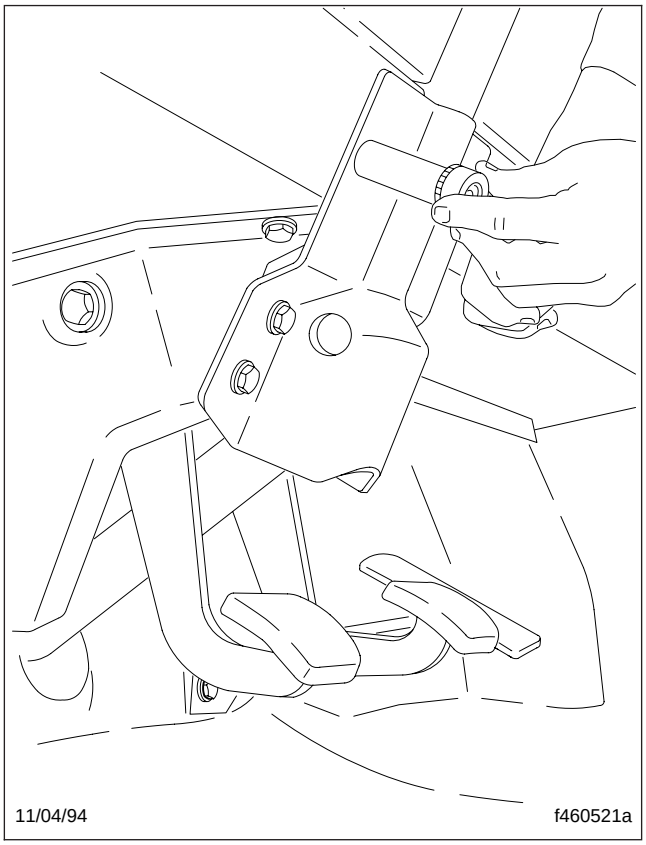
1.2 Install a new pinch bolt and nut. Tighten the nut 37 lbf·ft (50 N·m), then apply white Torque Seal F-900® to the exposed threads of the pinch bolt.



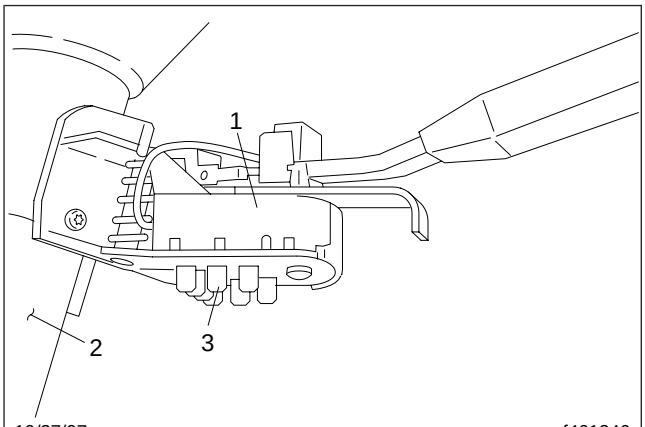


Fig. 6, Removing the Steering Column Mounting Capscrews (LH DR)

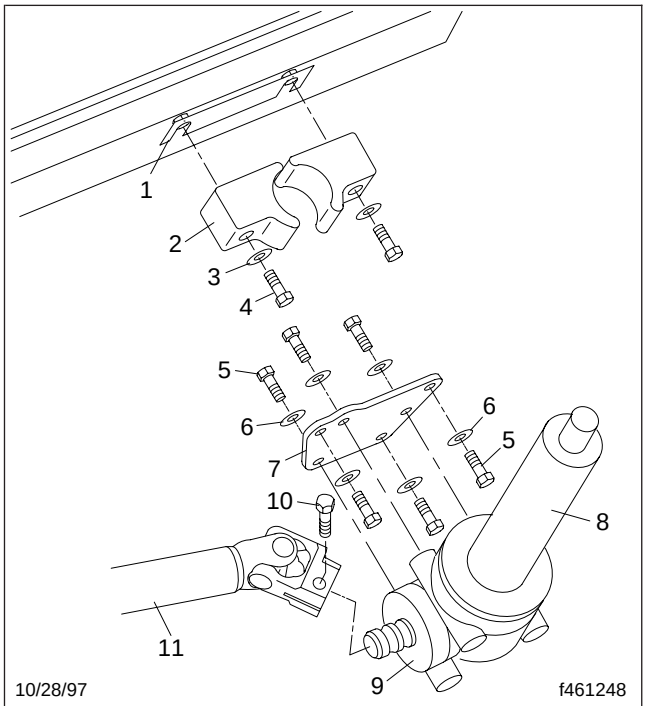
2. Line up the holes in the steering column bracket with those in the lower dash and the pedal support bracket.
3. Install the six capscrews (see **Fig. 5**), and tighten them in stages to a final torque of 40 lbf·ft (54 N·m).
4. Connect the horn wire, as shown in **Fig. 3**.
5. Install the turn signal switch on the left (outboard) side of the steering column. See **Fig. 2**. Tighten the screws firmly.
6. Install the trailer brake air lines, as marked. See **Fig. 4**.
7. Install the steering wheel, following the instructions in **Subject 100**.

Right-Hand Drive (RH DR)

REMOVAL

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service work will be done. *Do not move the tires from the straight-ahead position during removal or at any time while the steering column is removed.*
2. Apply the parking brakes and chock the tires.
3. Remove the steering wheel, following the instructions in **Subject 100**.
4. Remove the plastic cover from the turn signal switch on the left (inboard) side of the steering column. Disconnect the electrical connector and pull the turn signal harness down and out of the way. See **Fig. 7**.



This switch is mounted on the left side of the steering column on both LH DR and RH DR.

1. Switch
2. Steering Column
3. Connector

Fig. 7, Turn Signal Switch Electrical Connector

5. Disconnect the horn wire. See **Fig. 3**.
6. If installed, remove the trailer brake air lines from the switch mounted on the right (outboard) side of the steering column. Mark the lines for ease of installation. See **Fig. 4**.
7. Remove the three 3/8–16 capscrews attaching the steering column cover to the RH miter box.
8. Remove and discard the pinch bolt and nut from the traverse shaft. See **Fig. 8**.

8. Steering Column
9. RH Miter Box
10. Pinch Bolt, 7/16–20
11. Traverse Shaft

Fig. 8, Steering Column Removal, Right-Hand Drive

9. Remove the two steering column supports. Remove the support shim behind them.
10. Remove the six 3/8–16 capscrews and lockwashers that attach the steering column to the lower mounting plate and underdash panel. See **Fig. 6**.
11. Remove the steering column from the dash.

INSTALLATION

1. Position the steering column so that the bolt holes on the lower mounting plate line up with the holes on the pedal box.
2. Install the six capscrews and lockwashers attaching the steering column and lower mounting plate

Steering Column Removal and Installation

to the pedal box and underdash panel (see **Fig. 8**). Tighten all six capscrews 28 lbf·ft (38 N·m).

3. Attach the two steering column supports to the dash.
   - 3.1 Install the support shim between the supports and the dash.
   - 3.2 Install the two grade 10.9 M10 capscrews and lockwashers.
   - 3.3 Tighten the two capscrews 34 lbf·ft (46 N·m).

NOTE: Allow the turn signal switch harness to come out the left (inboard) side of the steering column.

4. Connect the steering column to the traverse shaft.
   - 4.1 Slide the traverse shaft U-joint yoke onto the splined shaft of the miter box, as marked on removal.
   - 4.2 Install a new pinch bolt and nut. Tighten the nut 60 lbf·ft (81 N·m), then apply white Torque Seal F-900® to the exposed threads of the pinch bolt.
5. Install the steering column cover to the RH miter box. Tighten the three 3/8–16 capscrews 28 lbf·ft (38 N·m).
6. Install the turn signal harness to the connector on the turn signal switch on the left (inboard) side of the steering column. See **Fig. 2**. Tighten the screws firmly and install the plastic cover.
7. Install the trailer brake air lines, as marked. See **Fig. 4**.
8. Connect the horn wire, as shown in **Fig. 3**.
9. Install the steering wheel, following the instructions in **Subject 100**.
10. Remove the chocks from the tires.

Disassembly (See Fig. 1)

1. Remove the steering wheel, following the instructions **under Subject 100**.
2. Remove the steering column assembly, following the instructions **under Subject 110**.
3. Unscrew the horn contact assembly (Ref. 4) from the side of the steering column.
4. Remove the retaining ring (Ref. 1) holding the upper shaft bearing (Ref. 2) in place, then remove the bearing. Remove the second retaining ring from the shaft.
5. Remove the retaining ring holding the lower shaft bearing (Ref. 6) in place, then remove the bearing.
6. Slide the shaft out of the bracket and bearing tube assembly (Ref. 5).

Assembly (See Fig. 1)

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using a solvent, clean all the parts, then check them. If any are worn or damaged, replace them.
2. Grease the bearings, using a lithium based bearing grease.
3. Install the shaft (Ref. 3) into the bracket and bearing tube assembly.
4. Install a retaining ring in the lower groove on the upper part of the shaft, then install the upper bearing. Install a second retaining ring on top of the bearing.
5. Install the lower bearing on the shaft, then install the lower retaining ring.
6. Screw the horn contact assembly into the side of steering column assembly.
7. Install the steering column assembly and the steering wheel, following the instructions in this section.

Steering Column Disassembly and Assembly

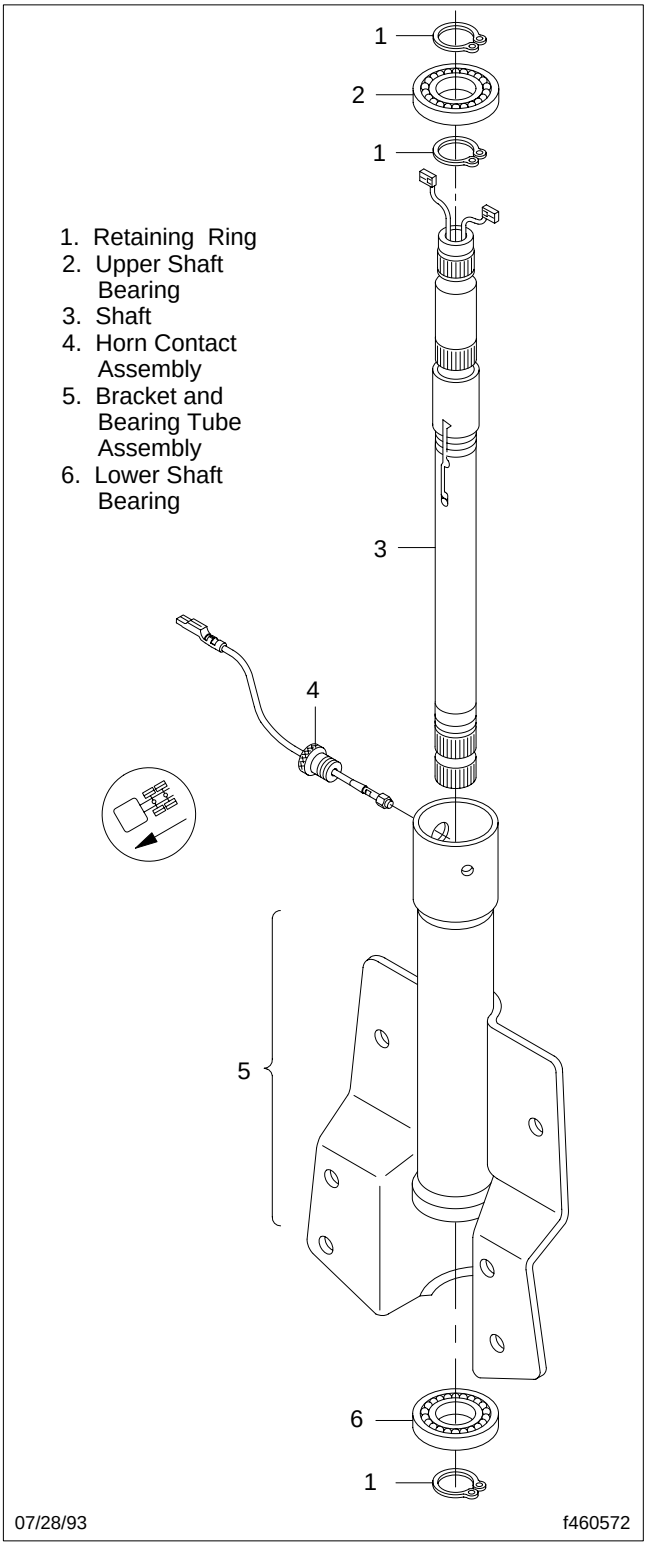

Fig. 1

Horn Contact Assembly Replacement

Replacement

1. Disconnect the horn wire from the wire lead-ing to the back of the dash. **See Fig. 1**.

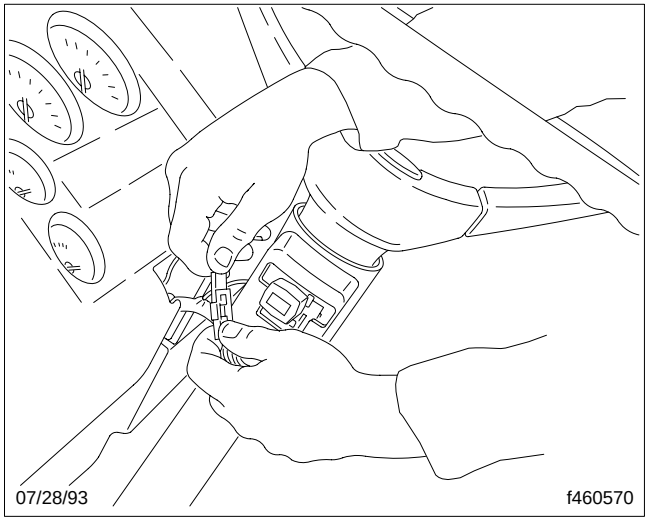

Fig. 1

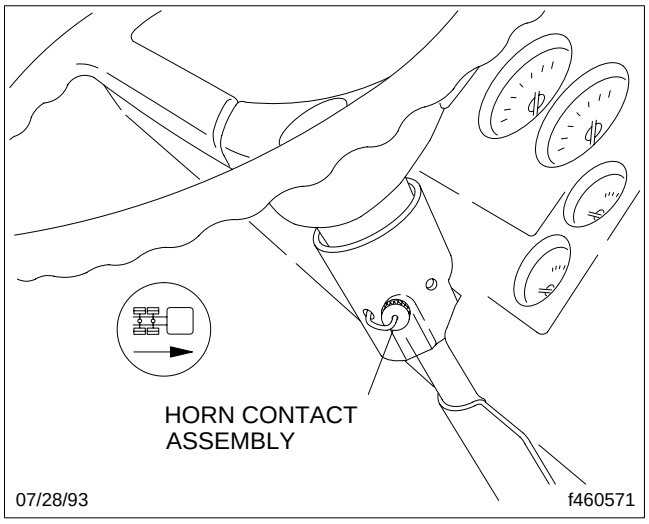
2. Unscrew the horn contact assembly from the right-hand side of the steering column, and dis-card it. **See Fig. 2**.



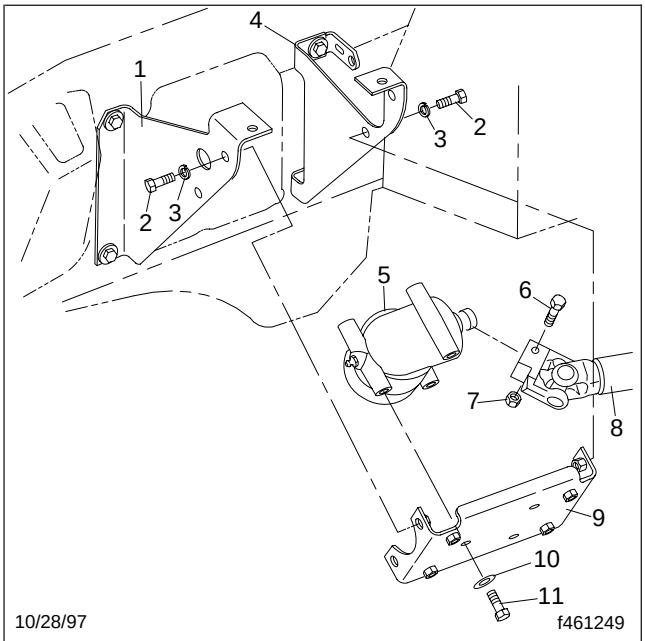


Fig. 2

3. Install a new horn contact assembly into the right-hand side of the steering column. Screw in the assembly firmly.
4. Connect the horn wire to the wire leading to the back of the dash.
5. Check the horn. If it doesn't work, heck the wir-ing to the horn, the horn itself, and the horn but-ton. Repair or replace parts as needed.

Traverse Shaft Removal and Installation, RH DR

Removal

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service work will be done. *Do not move the tires from the straight-ahead position during removal or at any time while the traverse shaft is removed.*
2. Apply the parking brakes and chock the tires.
3. Remove the dash kick panel. Remove the two shims inside the panel.
4. Remove the face plate. See **Fig. 1**.

10/28/97 f461249

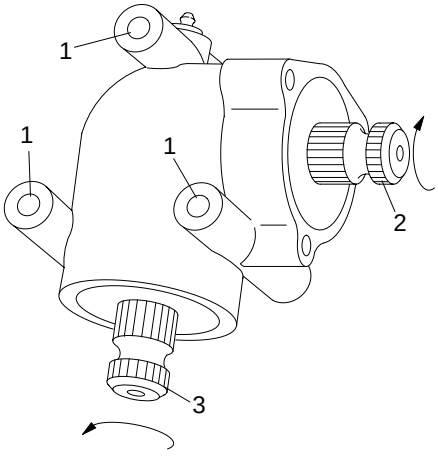
11. Miter Box Mounting Lockwasher

Fig. 1, Face Plate and Miter Box Removal

4.1 Remove the four face plate mounting capscrews and lockwashers.

4.2 Remove the three miter box mounting capscrews and lockwashers.



5. Remove the two pinch bolts that attach the LH miter box to the steering linkage.

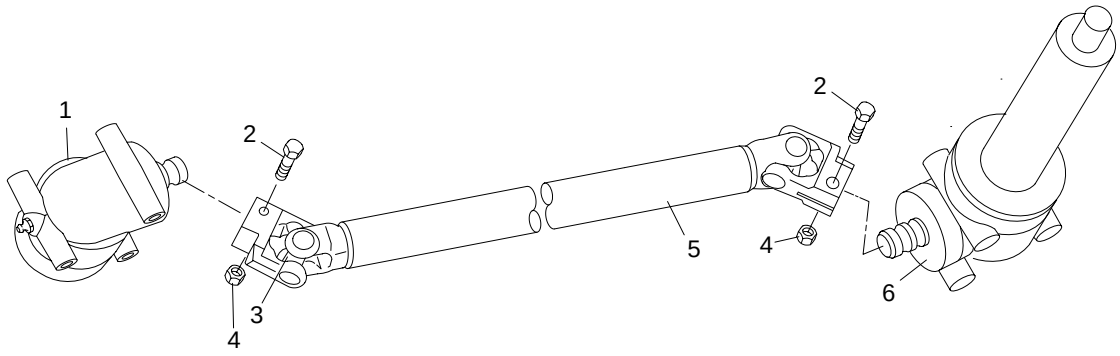
5.1 Remove the pinch bolt and prevailing torque hexnut that connect the output shaft of the miter box to the steering driveline. Mark the splines for later assembly.

5.2 Remove the pinch bolt and prevailing torque hexnut that connect the input shaft of the miter box to the traverse shaft. Mark the splines for later assembly.

5.3 Discard the pinch bolts and nuts.

6. Remove the miter box from the vehicle. See **Fig. 2**. Take care not to damage the splined input (clockwise) or output (counterclockwise) shafts.

11/06/97 f461247



IMPORTANT: The input and output shafts turn in opposite directions. Be sure to install them correctly.

1. Threaded Hole, 3/8–16
2. Input (clockwise) Shaft
3. Output (counterclockwise) Shaft

Fig. 2, LH Miter Box

7. Remove and discard the pinch bolt and prevailing torque hexnut that attach the RH miter box to the traverse shaft. See **Fig. 3**.
8. Remove the traverse shaft from the vehicle. See **Fig. 3**. To gain clearance, loosen the upper bolts on the electrical power center (EPC) panel.

Traverse Shaft Removal and Installation, RH DR

1. LH Miter Box
2. Pinch Bolt, 7/16–20
3. U-Joint
4. Prevailing Torque Hexnut
5. Traverse Shaft
6. RH Miter Box

Fig. 3, Traverse Shaft Pinch Bolts

Installation

1. Position the traverse shaft through the EPC panel. Install new pinch bolts and prevailing torque hexnuts into the end yokes of the U-joints at each end of the shaft, but do not tighten.
2. Install the LH miter box. See **Fig. 2**.

⚠ CAUTION

The two shafts of the LH miter box turn in opposite directions. If they are not installed correctly, the steering linkage can be damaged when the wheels are turned.

   2.1 Using the alignment marks made on removal, install the input (clockwise) shaft of the miter box onto the traverse shaft.

   2.2 Using the alignment marks made on removal, install the output (counterclockwise) shaft of the LH miter box onto the steering driveline.

3. Connect the traverse shaft to the RH miter box. See **Fig. 3**).
4. Tighten the new pinch bolts and nuts. See **Fig. 3**.

   4.1 Tighten each nut 60 lbf·ft (81 N·m).

   4.2 Apply white Torque Seal F-900® to the exposed threads of the pinch bolts.

5. Install the face plate as shown in **Fig. 1**. Tighten the LH miter box and face plate mounting capscrews 28 lbf·ft (38 N·m)
6. Line up the shims inside the dash kick panel. Install the dash kick panel.
7. Tighten the bolts loosened on the EPC panel.
8. Remove the chocks from the tires.

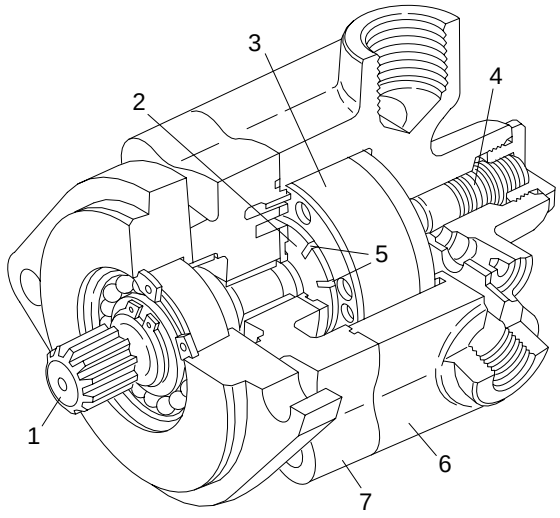
General Information



The LuK Automotive Hydraulics VT 7 Series power steering pump supplies power steering fluid for the operation of the power steering gear, and in vehicles so equipped, for the hydraulic brake power booster.

On Cummins B and C Series engines, the pump is mounted on the driver's side of the engine, at the rear of the gear case. It is powered by an adaptor gear in the engine.

On Detroit Diesel Series 50 engines, the pump is mounted on the driver's side of the engine at the front of the engine gear case.

On Dodge Magnum engines, the pump is mounted on the driver's side of the engine and is belt driven by the crankshaft pulley.

The main components of the power steering pump are the housing, driveshaft, cam ring, rotor, vanes, and control valve. See **Fig. 1**.

4. Control Valve
5. Vane
6. Housing
7. Flange Assembly

Fig. 1, Power Steering Pump Components

Principles of Operation

The driveshaft, powered by the adaptor gear in the engine gear case or by the crankshaft pulley, turns the rotor, which is inside the cam ring. As the rotor turns, centrifugal force pushes the vanes out toward the surface of the cam ring. As fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port, and into the system. The fluid operates the steering gear, and if the vehicle is so equipped, the hydraulic brake power booster. Eventually the fluid returns to the power steering reservoir, then back to the power steering pump. See **Fig. 2**

If the system pressure gets too high, a poppet inside the control valve is forced off its seat, shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump instead of going to the outlet port. When the system pressure drops to the correct level, the poppet seats, closing off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port, then into the power steering system.

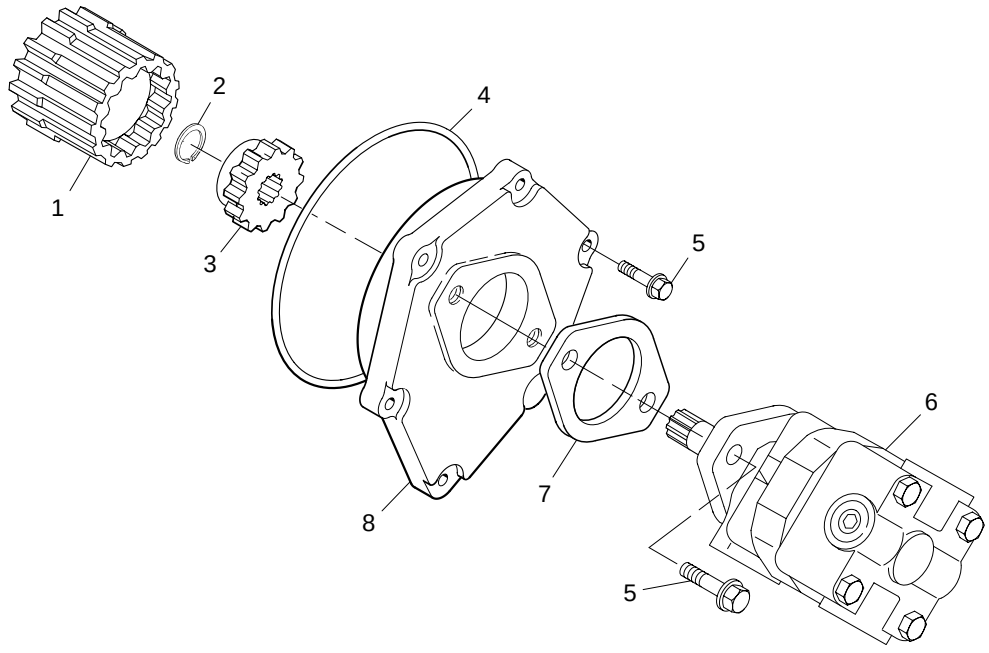
Fig. 2, Power Steering Pump Fluid Flow



Removal

1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Open the hood.
3. Clean all dirt from around the fittings and hose connections.
4. Put a container under the pump, then disconnect the hoses from the fittings on the pump. Plug the hoses and cap the fittings to keep out dirt and to prevent fluid from leaking.
5. On Cummins engines, remove the pump.
   - 5.1 Remove the capscrews that attach the pump to the engine accessory drive mounting flange.
   - 5.2 Pull the pump straight out from the engine. Keep it level to avoid spilling fluid.
6. On Detroit Diesel Series 50 engines, remove the pump.
   - 6.1 Remove the capscrews that attach the pump to the adaptor flange. See **Fig. 1**.
   - 6.2 Slide the pump out of the coupling. Remove the sprocket from the shaft if necessary.
   - 6.3 Check around the adaptor flange for oil leaks. If there are leaks, remove the adaptor flange from the engine. Remove all old gasket material.
7. On Dodge Magnum engines, remove the pump.
   - 7.1 Loosen the nut from the pulley hub. See **Fig. 2**.
   - 7.2 Loosen the capscrews on the pulley assembly.
   - 7.3 Turn the belt tensioner counterclockwise to loosen the drive belt.
   - 7.4 Remove the capscrews from the pulley assembly, and remove the pulley assembly.
   - 7.5 Remove the bearing washer and nut from the pulley hub.
   - 7.6 Using an appropriate puller, remove the pulley hub.
   - 7.7 Remove the capscrews that attach the pump to the mounting bracket, and remove the pump.
8. Turn the pump upside down over a container and let the fluid drain out.
9. Discard the gasket from the pump mounting flange.

Installation

1. Using engine oil, lightly lubricate a new gasket and the pump shaft.
2. Install the pump.
   - 2.1 On Cummins engines, install a new gasket on the pump mounting flange, then place the pump on the engine accessory drive mounting. Install the washers and capscrews, and tighten them 27 to 32 lbf·ft (37 to 43 N·m).
   - 2.2 On Detroit Diesel Series 50 engines, make sure the clip is installed in the sprocket and that the coupling and sprocket are installed on the engine accessory drive. If the adaptor flange was removed, use engine oil to lightly lubricate a new O-ring. Install the O-ring on the flange, and install the flange on the engine. Cross tighten the capscrews 22 to 25 lbf·ft (30 to 34 N·m). Install the new gasket on the pump mounting flange, then position the pump on the adaptor flange. Turn the pump or shaft as needed to mesh the shaft with the sprocket. Install the capscrews and tighten them 27 to 32 lbf·ft (37 to 43 N·m).
   - 2.3 On Dodge Magnum engines, position the pump on the mounting bracket. See **Fig. 2**. Install the capscrews and tighten them 27 to 32 lbf·ft (37 to 43 N·m). Using an appropriately sized driver to protect the pump shaft, tap the pulley hub onto the pump shaft. Loosely install the bearing washer and nut. Position the pulley assembly and loosely install the six capscrews. Turn the belt tensioner counterclockwise and slip the belt over the pulley. Tighten the nut on the pulley hub 59 to 74 lbf·ft (80 to 100 N·m). Tighten the

capscrews on the pulley assembly 16 lbf·ft (22 N·m).

3. Connect the inlet hose (from the power steering reservoir) to the inlet port. Tighten it 20 lbf·ft (27 N·m).
4. Connect the outlet hose (from the power steering gear) to the outlet port. Install the hose clamp and tighten it firmly.
5. Bleed the power steering system.
   - 5.1 Check the fluid level in the power steering reservoir and if needed, fill it to the correct level with the approved power steering fluid in **Specifications 400**.
   - 5.2 Start the engine and let it idle for several minutes.
   - 5.3 Turn the wheels to a full-left and full-right turn. Repeat about three times.
   - 5.4 Check the fluid level in the power steering reservoir. If needed, add fluid. For approved power steering fluid, see **Specifications 400**.
   - 5.5 Shut down the engine.
6. Close the hood and remove the chocks from the tires.

Disassembly

WARNING

Wear safety goggles or glasses when disassembling the power steering pump. Some of the parts are held in place by springs or snap rings, which can release with considerable force, possibly causing injury.

CAUTION

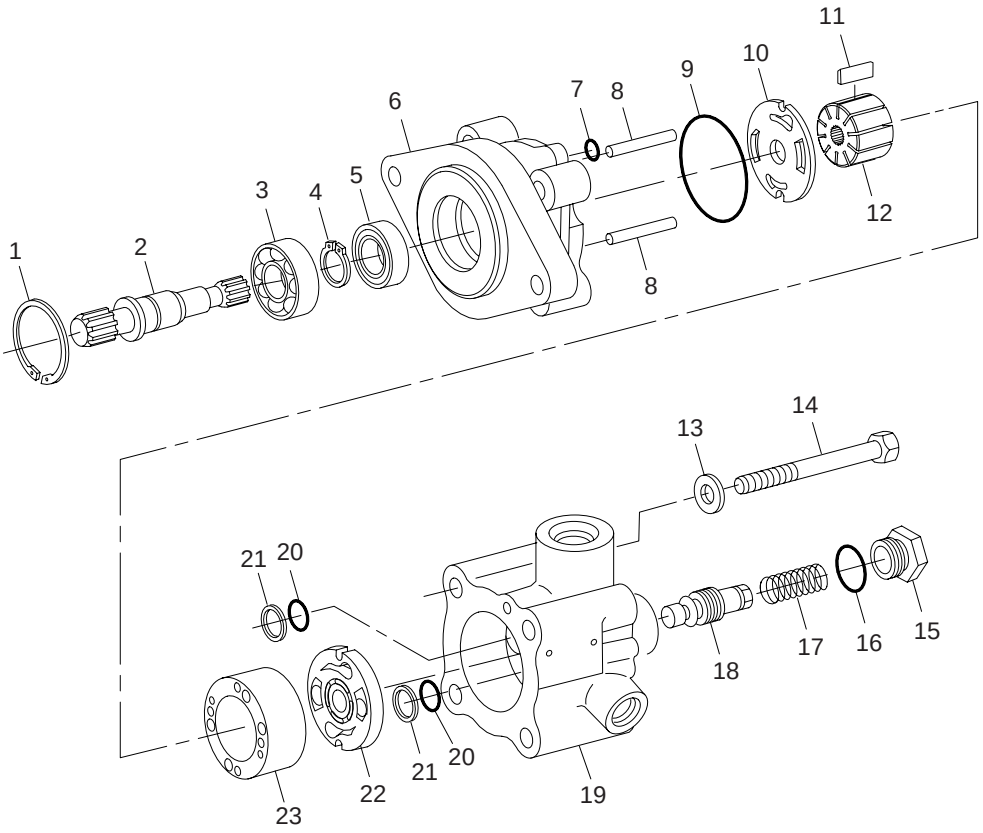
Be careful when working on the pump housing; it is aluminum, and can be easily damaged. When putting it in a vise, pad the vise jaws. Tighten the vise just enough to hold the pump.

1. Remove the power steering pump from the engine following the instructions in **Subject 100**.
2. Carefully remove the end plug and spring from the pump body. See **Fig. 1**.
3. Remove the control valve from the pump body. Be careful not to scratch the control valve.
4. Remove and discard the O-ring from the plug.
5. Put the pump housing in a padded vise, and remove the capscrews that attach the housing to the flange assembly.
6. Remove the flange assembly from the pump housing.
7. Remove the pressure plate from the flange assembly.
8. Remove the cam ring.
9. Remove the rotor and vanes.
10. Remove the wear plate.
11. Remove the two guide pins from the seats.
12. Remove the large O-ring from the flange assembly.
13. Remove the driveshaft from the flange assembly.
    - 13.1 Remove the snap ring holding the shaft bearing in place.
    - 13.2 Put the flange assembly in a vise, then carefully tap out the driveshaft.
14. Check the driveshaft bearing. If it is damaged or worn, remove it from the driveshaft. If it is not damaged or worn, go to the next step.
    - 14.1 Remove the small snap ring from the driveshaft.
    - 14.2 Being careful to push only on the inner ring of the bearing, press the bearing off the driveshaft.
15. Remove and discard the shaft seal from the flange assembly.
16. Remove and discard the two O-rings and backup rings from the pump housing.

Inspection

1. Using a solvent compatible with the power steering fluid, clean all the parts. Then, using filtered compressed air, dry all the parts.
2. Check all the parts. Replace any that are damaged or worn.
3. Check the vanes on the rotor for damage or too much play in the rotor slots. If you can move the vanes from side to side in the slots, replace the whole rotor assembly.
4. Check the control valve.

   If obvious damage or wear is present, replace the control valve. If the control valve does not need replacing, continue with the next step.



CAUTION

When putting the control valve in a vise, put only the end opposite the hex end of the control valve into the vise. Do not clamp the sealing surfaces (outer rings), or you will damage the valve.

5. Carefully put the control valve in a padded vise. See **Fig. 2**. Do not damage the sealing surfaces.

   Test the torque of the end plug. It should be 6 to 8 lbf·ft (8 to 11 N·m). If it is not, replace the control valve.
6. Coat the control valve with approved power steering fluid specified in **Specifications 400**. Then install it in the bore in the pump housing.

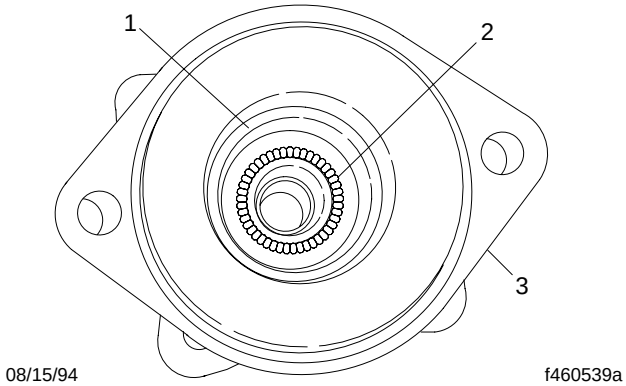
7. Spin the control valve all the way around in the bore while moving it in and out. If there is any binding, replace the control valve.

Assembly



NOTE: To correctly install the driveshaft seal and bearing, it is necessary to make suitable drivers from tubular stock. Refer to **Specifications 400** for the applicable dimensions.

1. Coat all the parts in the approved power steering fluid specified in **Specifications 400**.
2. Using a suitable driver, install the shaft seal into the bore in the flange assembly. Make sure the spring side of the seal faces the flange. See **Fig. 3**. Seat the seal firmly against the shoulder in the bore.

A. Clamp vise here.
1. Hex End
2. Sealing Surfaces

Fig. 2, Control Valve Components

1. Shaft Seal
2. Garter Spring
3. Flange

Fig. 3, Seal Placement

CAUTION

When installing the driveshaft bearing, make sure that pressure is exerted only on the inner race of the bearing. Do not use any pressure on the outer race, or you may damage the bearing assembly.

3. If it was removed, install a new bearing on the driveshaft using a suitable driver and an arbor press.

   Install the small snap ring in the groove on the driveshaft with the sharp edge facing toward the bearing.

4. Install the driveshaft and bearing assembly in the flange assembly.

   4.1 Lubricate the shaft with power steering fluid.

   4.2 Slide the driveshaft into the bore of the flange assembly, being careful not to damage the shaft seal.

   4.3 Install the large snap ring into the groove in the flange assembly.

5. Using approved power steering fluid specified in **Specifications 400**, lubricate the new O-rings and backup rings, then install them in the pump housing.
6. Put the flange assembly in a padded vise, then install a new large O-ring in the flange assembly.
7. Install a new small O-ring in the flange assembly.
8. Install the two guide pins in their seats in the flange assembly.
9. Install the wear plate, bronze side up, on the flange assembly.
10. Install the rotor on the driveshaft.
11. Install the vanes, rounded edges outboard, in the rotor. Make sure that none of them are binding.
12. Install the cam ring over the rotor, on the flange assembly, and over the guide pins. Make sure that the arrow on the face of the cam ring is pointing in the direction of the shaft rotation. With the flange held shaft side down, the arrow should be pointing in a counterclockwise direction (left). See **Fig. 4**.
13. Install the pressure plate, bronze side down, on the rotor and cam ring assembly.
14. Lining up the mounting holes, install the pump housing over the flange assembly.
15. Install the capscrews and washers in the pump housing. Tighten them in a cross pattern 29 to 37 lbf·ft (40 to 50 N·m).
16. Install the control valve in the pump housing.

CAUTION

Make sure you install the control valve correctly in the bore. If it is installed backwards, the power steering pump will not work and will quickly overheat, which could cause severe damage to the pump.

16.1 Lubricate the control valve, then install it, with the hex end up, into the bore in the pump housing. See **Fig. 5**.

08/15/94 f460544a

A. Insert this end first.
1. Hex End

Fig. 5, Control Valve Installation

16.2 Install the spring over the hex end of the control valve.

16.3 Install a new O-ring on the end plug, then install the end plug. Tighten it 33 to 40 lbf·ft (45 to 54 N·m).

17. Install the power steering pump on the engine following the instructions in **Subject 100**.

Problem—The Power Steering Pump Doesn't Deliver Fluid

Problem—The Power Steering Pump Doesn't Deliver Fluid	
Possible Cause	**Remedy**
The pump driveshaft is broken, or not engaging.	Remove the pump. Repair or replace parts as needed.
The control valve is stuck open.	Remove and disassemble the pump. Clean the control valve in a solvent. Install the control valve, then check for any binding in its bore. If the control valve binds or feels gritty when you move it, replace it.
One or more rotor vanes is stuck.	Remove and disassemble the pump. Check the rotor and vanes for dirt or damage. If damaged, replace the rotor and vane assembly. If dirty, clean the rotor and vanes in a solvent, then assemble the parts and check for free vane movement. If the problem persists, replace the rotor and vane assembly.
Incorrect power steering fluid is used.	Check for the type of fluid used. If it is incorrect, drain, flush, and fill the system with power steering fluid. For approved power steering fluid, see **Specifications 400**.
The pump intake port is blocked.	Drain and flush the system. Fill the system with power steering fluid. For approved power steering fluid, see **Specifications 400**.
The air vent in the power steering reservoir is clogged, or the filter is dirty.	Remove the filter cap from the reservoir, then clean the air slot. Check the filter and replace it if needed.
A power steering hose is kinked or blocked.	Repair or replace the hose.

Problem—The Power Steering Pump Is Making Noise

Problem—The Power Steering Pump Is Making Noise	
Possible Cause	**Remedy**
The intake line or filter is plugged.	Drain the system. Clear the intake line if needed, then check the filter. Replace it if needed. Fill the system with power steering fluid. For approved power steering fluid, see **Specifications 400**.
There is an air leak at the pump connections, the fittings, the reservoir connections, or the shaft seal.	Check all the connections by pouring power steering fluid over them, then listen for a reduction in sound. Tighten all the connections as needed. If the problem persists, remove the pump, then disassemble it and replace the shaftseal.
The pump driveshaft is misaligned.	Remove and disassemble pump. Replace the shaft seal and bearing.

General Information

The TRW TAS40, TAS55, TAS65, and TAS85 power steering gears use pressurized hydraulic fluid to help the driver turn the front wheels. All four models mount on the left frame rail, and all operate in the same way.

The difference between the four gears is size. The TAS40 can be installed on vehicles with front axle capacities up to 9000 pounds (4086 kg). The TAS55 is for vehicles with front axle capacities up to 12,000 pounds (5448 kg), the TAS65 is for front axle capacities up to 14,300 pounds (6500 kg), and the TAS85 is for front axle capacities up to 18,000 pounds (8200 kg).

All four gears use more pressurized fluid when the driver turns the steering wheel quickly than when the driver turns the steering wheel slowly, but the minimum amount of power steering fluid is different for each model. With the driver turning the steering wheel 1-1/2 turns per second, the TAS40 needs at least 2.2 gallons (8.3 liters) of fluid per minute . At the same turning speed, the TAS55 needs 2.6 gpm (9.8 L/min), the TAS65 needs 3.0 gpm (11.4 L/min), and the TAS85 needs 3.6 gpm (13.6 L/min).

⚠ CAUTION

Never steam clean or high-pressure wash the steering gear. Internal damage to gear seals and ultimately the steering gear can result.

Principles of Operation

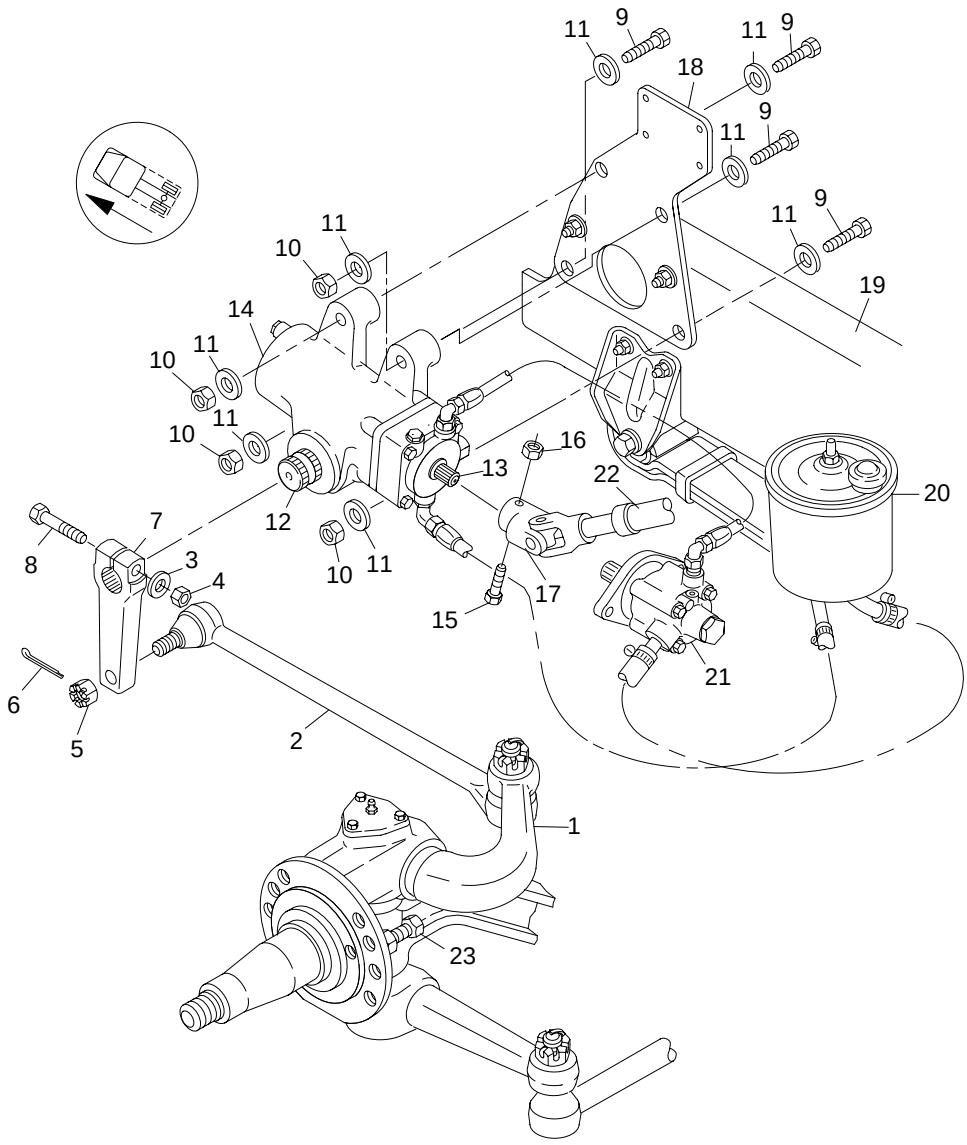
When the driver turns the steering wheel, that force travels down through the steering driveline to the steering gear input shaft. See **Fig. 1** and **Fig. 2**. The input shaft turns the worm shaft which moves the rack piston forward or backward in the gear housing by means of a series of recirculating balls in the spiral channels of the worm shaft. See **Fig. 3**.

Grooves in the rack piston mesh with teeth in the sector shaft, and as the piston slides back and forth, it turns the sector shaft. The sector shaft swings the pitman arm. The pitman arm pulls or pushes the drag link, and the drag link moves the axle steering arm, steering the vehicle.

Pressurized power steering fluid helps the worm shaft slide the rack piston forward or backward in the gear housing.

The input shaft is not connected directly to the worm shaft. Instead, a thin bar, the torsion bar, holds the input shaft to the worm shaft. The outside end of the torsion bar is fastened to the input shaft, and the inside end is fastened to the worm shaft; thus, the force of the driver turning the steering wheel travels from the input shaft to the worm shaft through the torsion bar.

With the force of the driver alone, the front axle would be difficult to steer. The weight on the front wheels, the friction of the tires against the road, and the inertia of the vehicle traveling in its current direction all combine to hold the sector shaft and the rack piston in place.



To overcome this resistance, the steering gear has a valve for directing pressurized hydraulic fluid either in front of the rack piston or behind it, thus using the fluid to push the rack piston in the direction the worm shaft is trying to slide it.

The torsion bar controls the hydraulic fluid. As the driver turns the steering wheel to turn the input shaft, and the front wheels resist turning and hold the rack piston and worm shaft in place, the torsion bar connecting the input shaft and worm shaft twists slightly. That twisting aligns holes in the hydraulic control valve with channels that carry hydraulic fluid. Depending on the direction the driver turns the steering wheel—the direction the torsion bar twists—the valve aligns the channels to direct hydraulic fluid in front of the rack piston or behind it. The fluid provides the extra force the worm shaft needs to overcome the resistance from the front wheels, and the worm shaft can then slide the rack piston in the gear housing.

The rack piston slides, and turns the sector shaft. The sector shaft swings the pitman arm. The pitman arm pulls or pushes the drag link. The drag link moves the axle steering arm, and the front wheels turn.

As the front wheels reach the axle stop—the farthest the wheels can turn in that direction—a poppet (unloading valve) in the rack piston trips to prevent steering gear damage. The tripped poppet reduces steering fluid pressure, heat generated by the power steering fluid pump, and outside forces from acting on the steering linkage.

dampen the shock before it can move up the worm shaft to the steering driveline and the steering wheel.

Sector Shaft Adjustment

1. Position the sector (output) shaft at its center of travel by turning the steering wheel until the alignment mark on the sector shaft is at a right angle to the input shaft centerline, and in line with the timing mark on the end of the housing trunnion. See **Fig. 1**.

1. Housing Trunnion Timing Mark
2. Sector Shaft Timing Mark

Fig. 1, Timing Mark Placement

2. Disconnect the drag link from the pitman arm. Do not turn the input shaft/valve/worm assembly more than 1-1/2 turns in either direction from its center of travel while the drag link is disconnected from the pitman arm. Turning the input shaft more than 1-1/2 turns from center will cause misadjustment of the automatic poppets. This may require the installation of a service poppet adjustment tool to manually reset the poppets.
3. With the sector shaft in the center position, grasp the pitman arm and gently try to move it back and forth. Fingertip force is adequate to detect lash (free play) of a loose sector shaft. See **Fig. 2**. There should be no movement of the input shaft or sector shaft. Loosen the sector shaft adjusting screw jam nut. See **Fig. 3**. If no lash was detected, turn the shaft adjusting screw counterclockwise until lash is detected.
4. To adjust, move the adjusting screw clockwise until no lash is felt at the pitman arm. Use no more than 10 lbf·ft (14 N·m) of torque. Slowly turn the adjusting screw clockwise an additional one-eighth turn. Hold the adjusting screw in place and tighten the jam nut 40 to 45 lbf·ft (54 to 61 N·m).

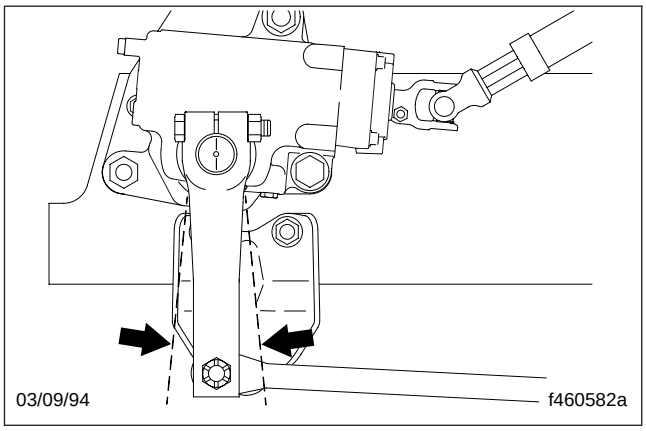

Fig. 2, Free Play Check

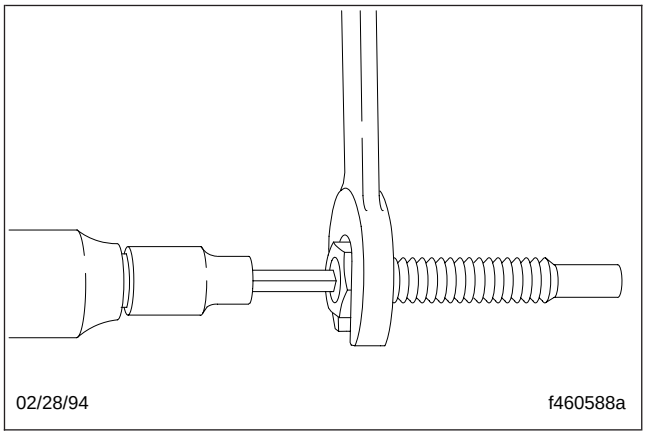

Fig. 3, Jam Nut

5. Again, check the pitman arm for lash. Turn the steering wheel one-quarter turn each side of center. No lash should be felt. If lash exists, readjust the sector shaft.
6. Connect the drag link to the pitman arm. For instructions, refer to the applicable section in this group.

Poppet Valves Adjustment

TAS40, TAS55, TAS65, and TAS85 steering gears have automatic poppet valves that reset themselves if the axle stops are reset for increased steering travel. However, if the axle stops are reset for **de-**

In-Vehicle Adjustments

creased steering travel, the poppet valves must be reset manually, through the use of a special service poppet adjusting screw and sealing jam nut kit, unless they were reset for automatic adjustment while the steering gear was disassembled.

Use the following procedure for manually resetting the poppet valves.

1. Verify correct axle stop adjustment. For instructions, refer to **Group 33**.

IMPORTANT: The axle stops must be set so that there are at least 1-3/4 steering wheel turns from a straight-ahead position to both a full-left and a full-right turn; otherwise the poppet valves will not work.

2. If both axle stops were set for increased travel, the steering gear poppets have reset automatically and gear adjustments are complete. No further action is required.

   If either axle stop was set for decreased travel, the steering gear poppets must be set manually. Continue with the following steps.

3. Install the steering gear manual poppet adjusting screw.

   3.1 Screw the special poppet adjusting screw (from TRW kit number 021407-X1) into the nonsealing end of the sealing jam nut, until the drive end of the screw is flush with the nut. See **Fig. 3**.

   3.2 With the vehicle unloaded, the engine off, and the front wheels in the straight-ahead position, remove and discard the poppet fixed stopscrew and washer from the lower end of the steering gear housing. See **Fig. 4**.

NOTE: With the wheels straight ahead and the timing marks on the sector shaft and gear housing aligned, the steering gear is centered. See **Fig. 1**.

   3.3 Using an Allen wrench turn the adjusting screw and nut, without rotating the nut, into the steering gear housing until the nut is firmly against the housing. See **Fig. 5**. Tighten the nut 33 to 37 lbf·ft (45 to 50 N·m).

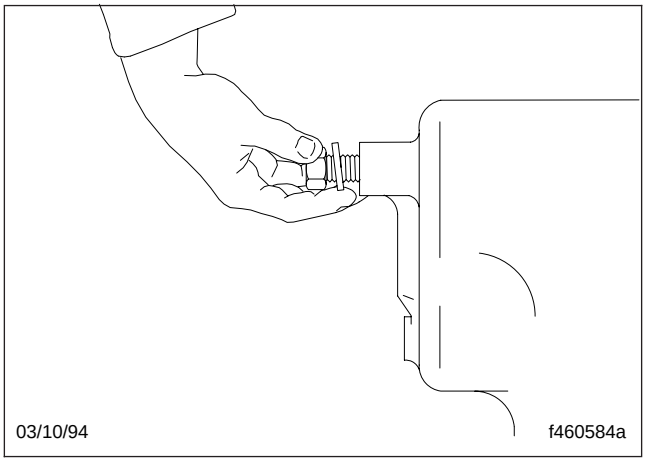

Fig. 4, Poppet Fixed Stopscrew

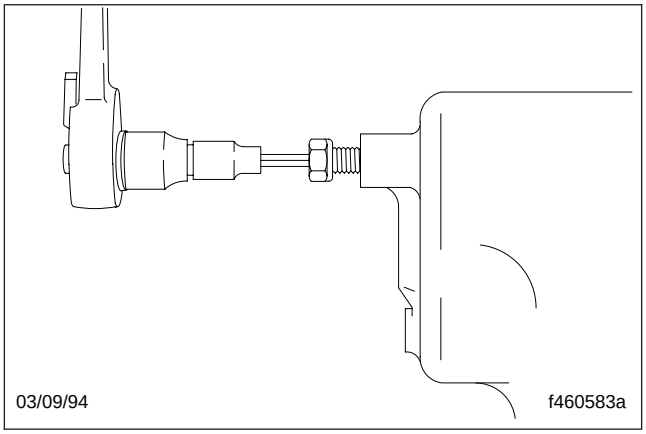

Fig. 5, Stopscrew Adjustment

NOTE: It may be necessary to move the sector shaft slightly from the straight-ahead position to assemble the service adjusting screw as instructed and then return it to straight ahead.

4. Adjust the poppets manually.

   4.1 Check the fluid level and fill the power steering reservoir with the power steering fluid specified in **Specifications 400**.

   4.2 Make sure the engine is off.

   4.3 Place a jack under the center of the front axle, and raise the steer tires off the ground.

   4.4 Turn the steering wheel to the right until the axle stopscrew contacts the axle stop,

or the end of the gear travel is reached. This pushes out the left-hand turn poppet to prepare it for setting. See **Fig. 6**.

1. Adjustable Poppet Screw

Fig. 6, Stopscrew Contact

4.5 Turn the steering wheel to the left until the left-hand stop makes contact. This sets the left-turn poppet. Release the steering wheel and do not steer again until the adjusting screw has been backed out and the sealing nut tightened.

4.6 Loosen the sealing nut on the gear housing and back out the adjusting screw until it is 1 to 1-1/16 inches (25 to 27 mm) beyond the sealing nut. See **Fig. 7**. Tighten the sealing nut 33 to 37 lbf·ft (45 to 50 N·m).

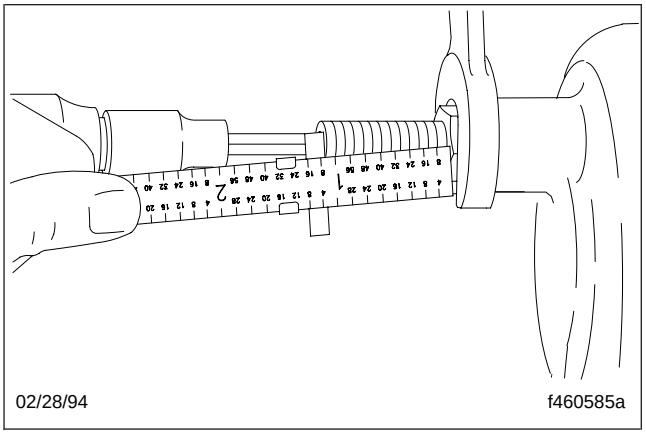

Fig. 7, Backing Out the Adjusting Screw

IMPORTANT: Make sure the adjusting screw does not protrude more than 1-1/16 inches (27 mm) beyond the sealing nut.

4.7 Have someone turn the steering wheel all the way to the right and hold it in place when the axle stops are contacted.

4.8 With the steering wheel held in place, loosen the sealing nut one turn, and while holding the sealing nut, turn the adjusting screw using an Allen wrench. Do not force the screw. Use one or two fingers and turn the Allen wrench until it comes to a stop. When this happens contact has been made with the poppet seat; **do not turn it any further**. Back out the screw 3-1/4 turns. Have the steering wheel released at this time.

4.9 While holding the adjusting screw in place, tighten the sealing nut firmly against the gear housing. See **Fig. 8**. Tighten it 33 to 37 lbf·ft (45 to 50 N·m).

Check the adjusting screw. If it extends more than 1-1/16 inches (27 mm) from the sealing nut, loosen the sealing nut, and turn the adjusting screw in as needed. Tighten the sealing nut 33 to 37 lbf·ft (45 to 50 N·m). See **Fig. 7** and **Fig. 8**.

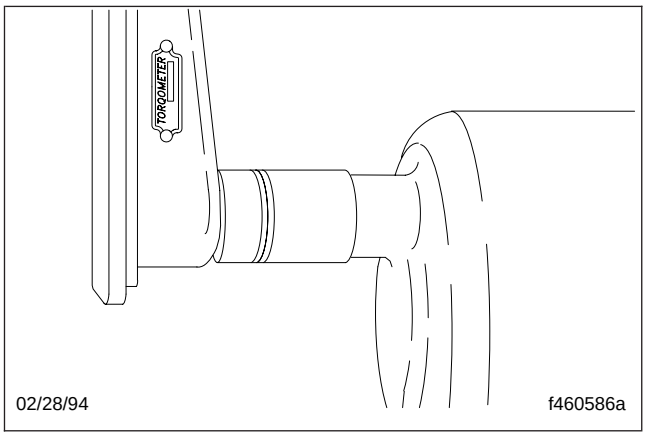

Fig. 8, Tighten the Sealing Nut

⚠ WARNING

If the adjusting screw protrudes more than 1-1/16 inches (27 mm) from the sealing nut, the screw could fall out of the steering gear, resulting in loss of power steering. This could cause an accident resulting in serious personal injury or property damage.

IMPORTANT: Once the poppet adjusting screw and sealing nut are in place and the poppet valves have been manually adjusted,

the adjustment procedure must be repeated if steering travel is either increased or decreased in the future.

Removal

IMPORTANT: Before removing the steering gear, see the troubleshooting procedures in **Section 46.11, Subject 300**.

1. Verify correct axle stop adjustment. For instructions, refer to **Group 33**. Ensuring correct axle stop adjustment now will eliminate the possibility of resetting steering gear poppet valves after the gear is reinstalled.
2. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where the work is to be done. Apply the parking brakes and chock the tires.
3. Remove the left-hand bumper extension.
4. Clean all outside dirt from around the fittings and hose connections.
5. Drain the power steering system. Disconnect all hydraulic lines from the gear, marking the lines for later assembly reference. Seal the lines and the fittings to keep out dirt.
6. Disconnect the pitman arm from the steering gear sector shaft.
   - 6.1 Remove the pinch bolt, washer, and nut from the pitman arm. Discard the pinch bolt and nut. See **Fig. 1** or **Fig. 2**.
   - 6.2 Remove the pitman arm using a suitable puller, and swing the pitman arm and drag link out of the way.
7. Disconnect the steering driveline from the steering gear input shaft.
   - 7.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

CAUTION

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

   - 7.2 Remove the lower end yoke from the input shaft.
8. Clean the entire assembly before removing the gear.

WARNING

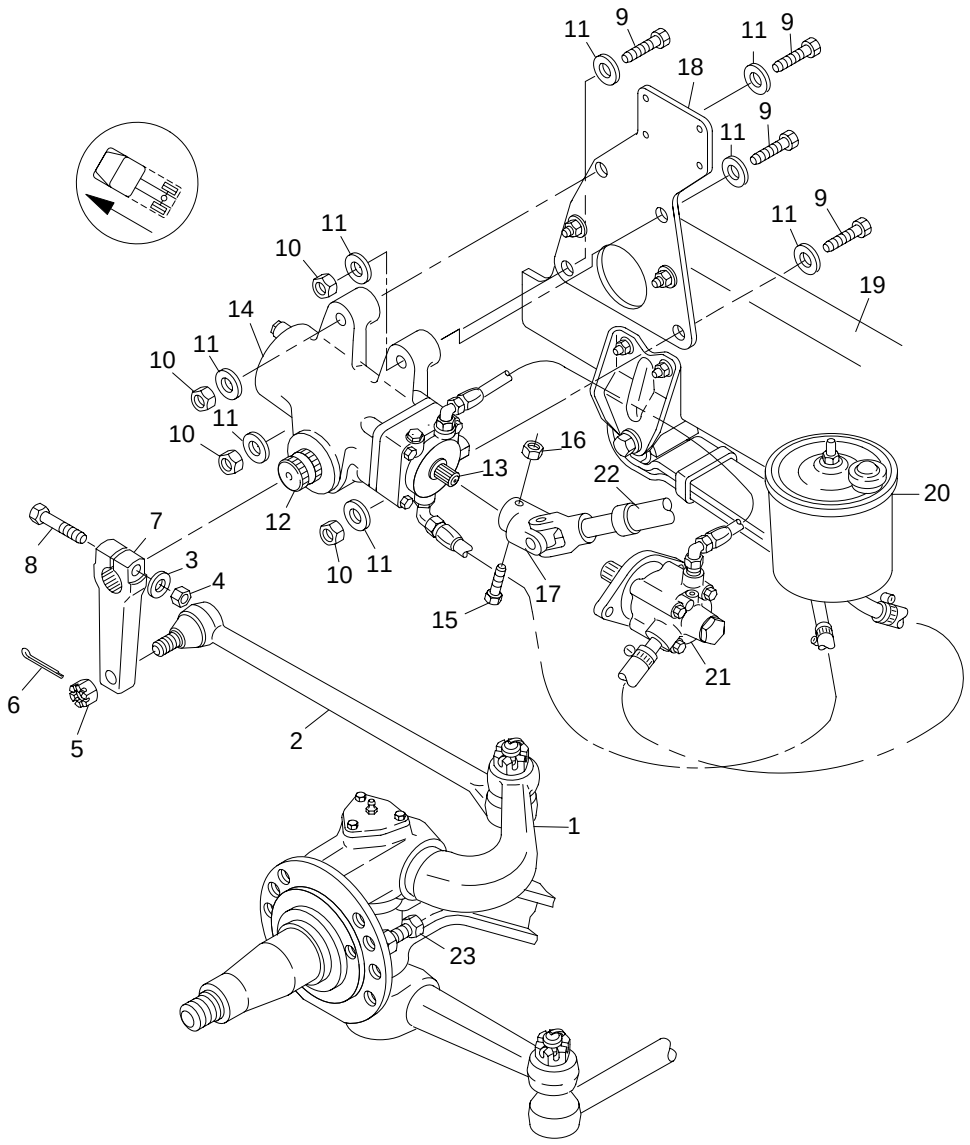
The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

9. Remove the fasteners that attach the steering gear to the frame rail. Remove the steering gear.

Installation

1. Install the steering gear and fasteners as shown in **Fig. 3** or **Fig. 4**.

   Torque the 7/8–14 fasteners 278 to 352 lbf·ft (377 to 477 N·m).
2. If not previously done, center the steering gear. The sector (output) shaft alignment mark must be at a right angle to the steering gear input shaft centerline. Make sure the steering gear remains centralized as the service work continues.
3. Install the pitman arm.
   - 3.1 Position the pitman arm on the steering gear, aligning the timing mark as shown in **Fig. 5**.



WARNING

Never leave a chisel wedged in the pitman arm slot. When using a chisel to spread the slot in the pitman arm, maintain a firm grip on the chisel at all times. Otherwise the chisel may fly loose, which could cause an injury.

NOTE: The pitman arm may not fit over the splines on the sector shaft without spreading the slot in the arm. Use a ball-peen hammer to drive a chisel into the slot. Hold the chisel in place. Install the pitman arm on the sector shaft. Remove the chisel from the slot.

   - 3.2 Install a new pinch bolt, washer, and nut. Tighten the nut to one of the following torque specs:
     - 120 to 140 lbf·ft (163 to 190 N·m) for a 5/8–14 nut
     - 215 to 245 lbf·ft (291 to 332 N·m) for a 3/4–16 nut

4.1 Clean the steering gear input shaft and the inside of the driveline yoke.

4.2 Apply a thin film of grease to the yoke spline.

Steering Gear Removal and Installation

1. 7/8–14 x 4-1/2 Capscrew, Grade 8
2. 7/8 Inch ID Hardened Washer
3. 7/8–14 Nut
4. 7/8–14 x 4 Capscrew, Grade 8

Fig. 3, Steering Gear Installation, TAS40/55/65

4.3 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut to one of the following torque specs:

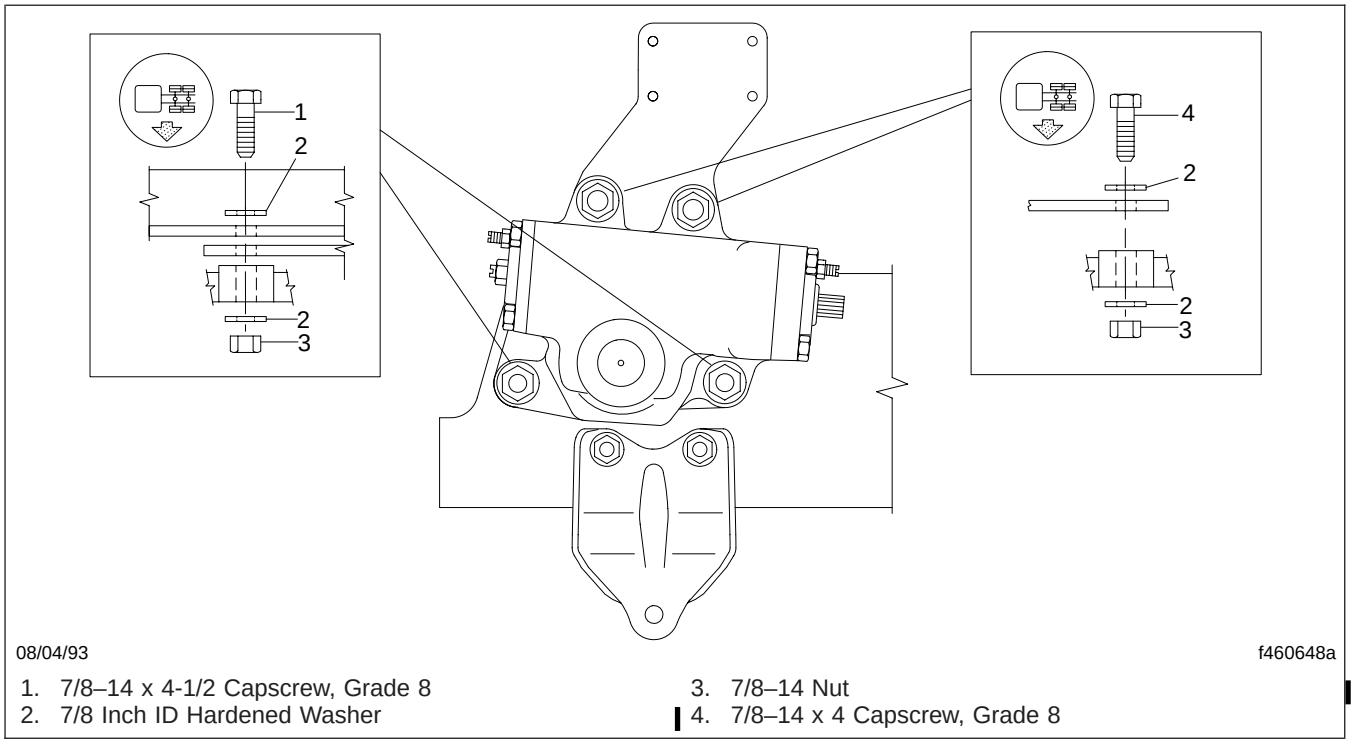
- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

4.4 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and to the nut.

5. Connect the hydraulic lines.

5.1 If they were removed, attach the hydraulic line elbow fittings to the steering gear. Tighten the fittings 38 lbf·ft (51 N·m). Tighten the pressure line fitting jam nut 41 lbf·ft (56 N·m).

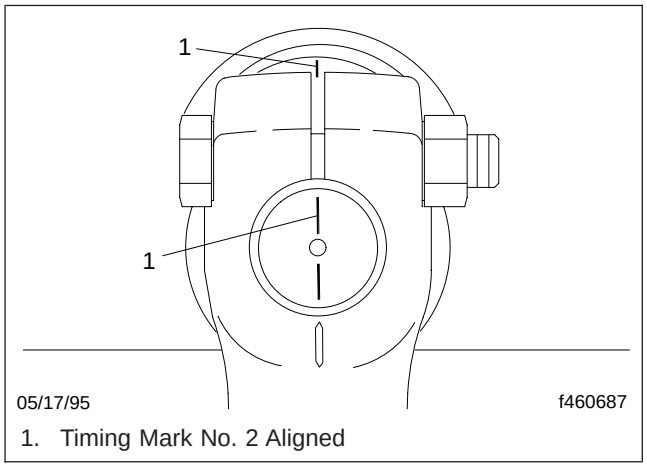
5.2 Remove the plugs from the hydraulic lines. Connect the lines to the steering gear as previously marked. Tighten the nut on each fitting finger-tight. Then, use a wrench to tighten the nut until there is firm resistance. Tighten one-sixth turn more.



6. Fill and bleed the steering system.

IMPORTANT: Do not turn the steering wheel until instructed. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

6.1 Fill the power steering reservoir with the power steering fluid specified in **Specifications 400** until nearly full. Crank the starter for 10 seconds without allowing the engine to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed. Repeat this procedure three times, each time checking and filling the reservoir.



6.2 Start the engine and let it idle for two minutes. Shut down the engine, and check the fluid level in the reservoir.

6.3 Start the engine again. Steer the vehicle from full-left to full-right, several times. As necessary, add fluid to the full line on the reservoir dipstick.

1. 7/8–14 x 4-1/2 Capscrew, Grade 8
2. 7/8 Inch ID Hardened Washer
3. 7/8–14 Nut
4. 7/8–14 x 4 Capscrew, Grade 8

Fig. 4, Steering Gear Installation, TAS85

1. Timing Mark No. 2 Aligned

Fig. 5, Typical Pitman Arm and Timing Marks

IMPORTANT: If the poppet adjuster seat and sleeve assemblies were not set for automatic adjustment during the assembly of the steering gear, **and** if the axle stops have been adjusted for **decreased** steering travel or the steering gear is installed on a different vehicle, the poppets must be set manually following the procedure in **Subject 100**.

7. Go to **Subject 140** and do the checks as instructed.
8. Install the left-hand bumper extension.
9. Test drive the vehicle or take a ride with the driver.

   Check the steering wheel spoke position. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 6**. If not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

Steering Gear Removal and Installation

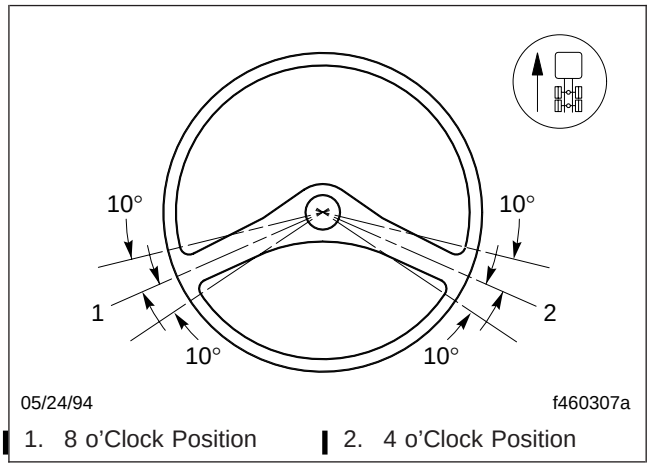


Fig. 6, Steering Wheel Centered

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

Disassembly

Be sure that required tools are available before beginning the service procedures described here. See the special tools table in **Specifications 400**. The special tools required for disassembly and assembly of the steering gear components are available from the SPX Kent-Moore or an affiliated dealer.

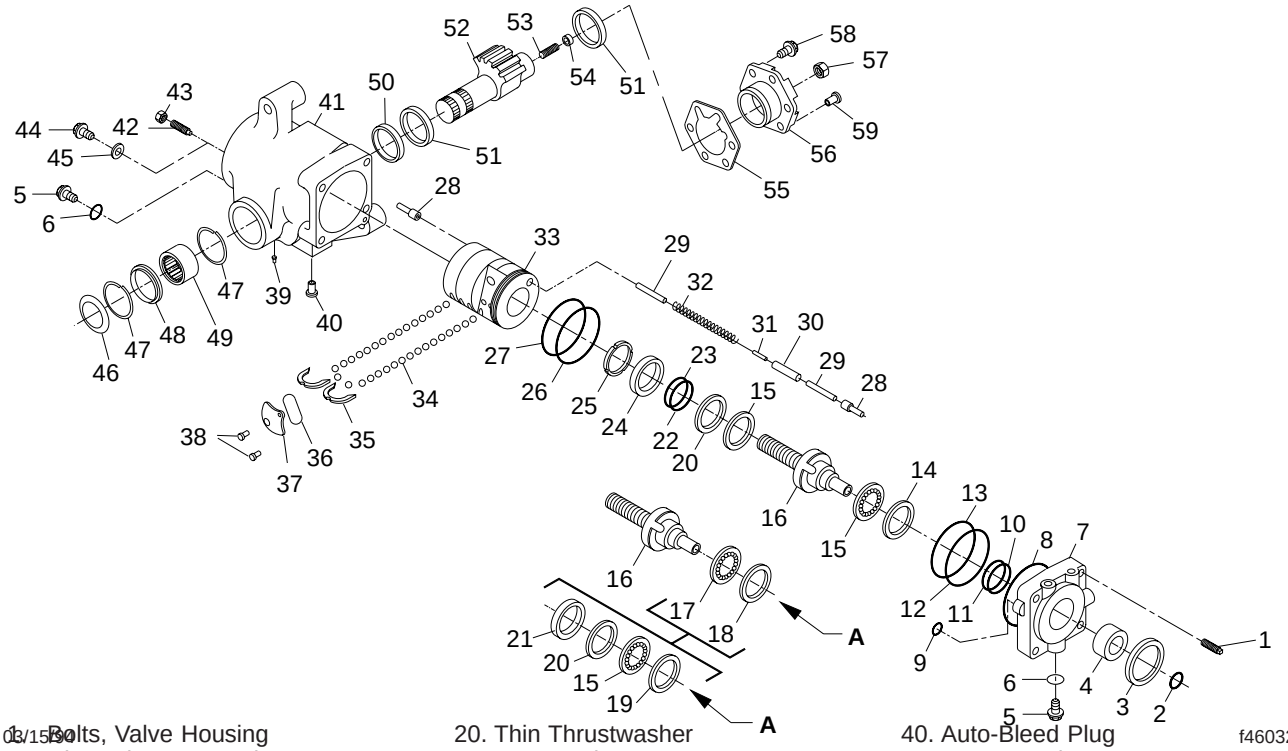
IMPORTANT: When the sector shaft is disconnected from the vehicle steering linkage, do not allow the input shaft to move more than 1-1/2 turns from the straight-ahead position. If the input shaft moves more than 1-1/2 turns, the initial setting of the poppet valves will be changed.

Make sure that the steering gear is placed on a clean surface. Clean and dry the gear before disassembly. As the gear is disassembled, clean all parts in a clean, petroleum-based solvent, and blow-dry them only.

Never steam clean or high-pressure wash the hydraulic steering components. Do not force or abuse closely fitted parts. Doing so could cause damage to steering system parts.

Keep each part separate to avoid nicks and burrs. Discard all seals, O-rings, and gaskets, and replace them with new parts.

See **Fig. 1** for an exploded, assembly drawing of the steering gear.



1. Place the steering gear in a vise so that the output shaft is horizontal. Clamp the gear at the mounting flange.
2. Put a basin under the hydraulic ports, and remove both hydraulic port plugs from the gear.
3. Using a 3/4-inch or 11/16-inch socket wrench, turn the input shaft so that the timing mark on the end of the sector shaft is lined up with the timing mark on the end of the housing trunnion. See **Fig. 2**.
4. Remove sector shaft/side cover assembly.
   - 4.1 Using a small screwdriver, remove and discard the water seal from the housing trunnion. See **Fig. 3**. Remove any dirt, paint, or corrosion from the sector shaft with a piece of fine emery cloth. See **Fig. 4**.
   - 4.2 Tape the splines and the bolt groove of the sector shaft, using one layer of masking tape. See **Fig. 5**.
   - 4.3 Using a 3/4-inch socket, remove the jam nut from the sector shaft adjusting screw. See **Fig. 6**.
   - 4.4 Put a container under the side cover to catch any drainage, then remove the special bolts from the side cover. See **Fig. 7**.

     IMPORTANT: These special bolts are equipped with either an integral ring or washer on the underside of the head. See **Fig. 8**. If replacing one or more bolts, use bolts of the same **type and length** as those that were removed. Do not use a substitute; do not mix different types of bolts.
   - 4.5 Remove the side cover and the sector shaft assembly as a unit from the steering gear housing. See **Fig. 9**. If necessary, start the removal by tapping the end of the sector shaft with a rubber or wooden mallet. Remove and discard the side cover gasket.
5. Disassemble the sector shaft/side cover assembly.
   - 5.1 Using a screwdriver, screw the sector shaft adjusting screw into the side cover and remove. See **Fig. 10**.
   - 5.2 Remove the sector shaft from the side cover.
   - 5.3 Remove the side cover seal.

     IMPORTANT: Be careful when you are removing the side cover seal or you may damage the side cover bore, the DU bushing (if a TAS40/55/65 model), or the bearing (if a TAS85 model).
   - 5.4 Screw a 1/2–20 x 3 bolt into the hole in the side cover where the sector shaft adjusting screw was.

     Make sure the bolt is in far enough so that it will support a rolling head (lady-foot) type pry bar. See **Fig. 11**.
   - 5.5 With the pry bar supported by the bolt end, pry up the side cover seal and re-

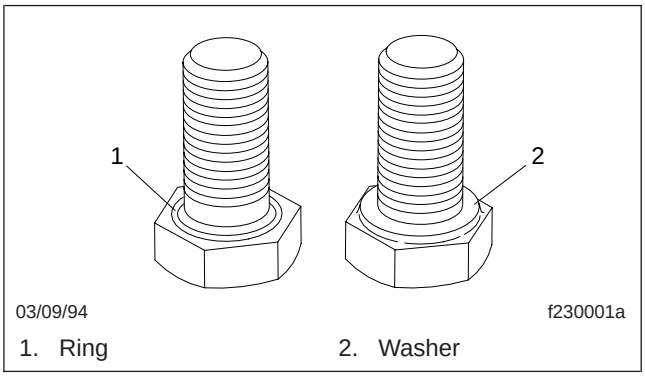

Fig. 8, Bolts With Ring or Washer

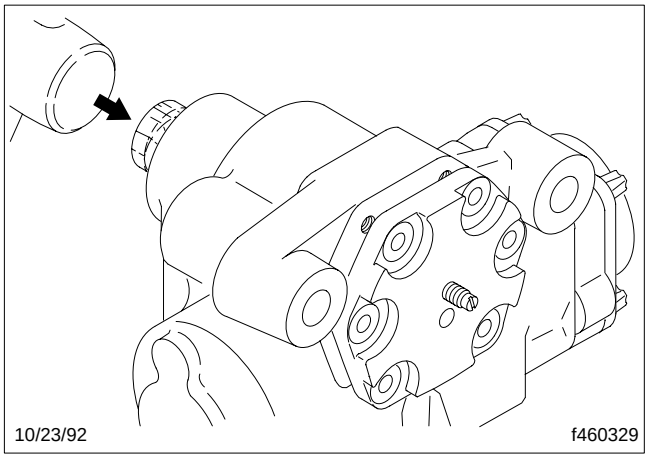

Fig. 9, Remove the Side Cover and Sector Shaft Assembly

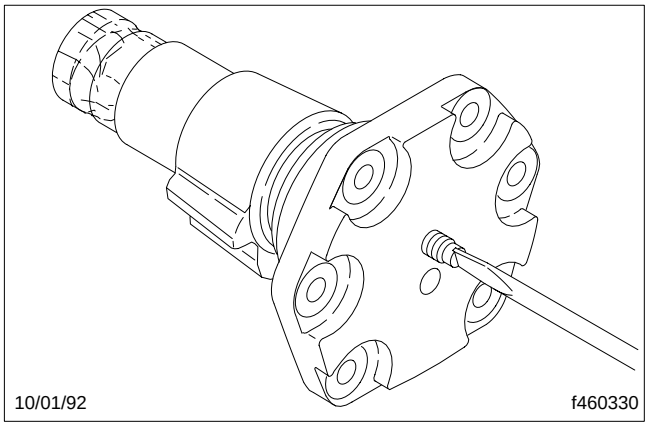

Fig. 10, Disassemble the Sector Shaft/Side Cover Assembly

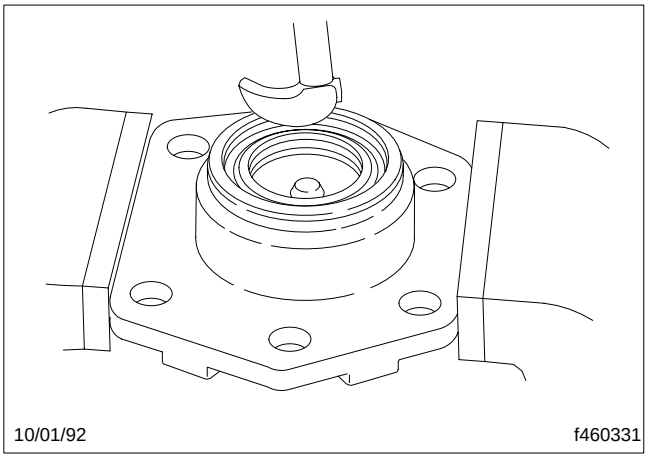

Fig. 11, Rolling Head Pry Bar

6. Remove the adjusting screw if required. Removal is required only if deemed necessary after the inspection procedure.

   6.1 Put the sector shaft in a padded vise and, using a chisel, unstake the adjusting screw retainer. See **Fig. 12**.

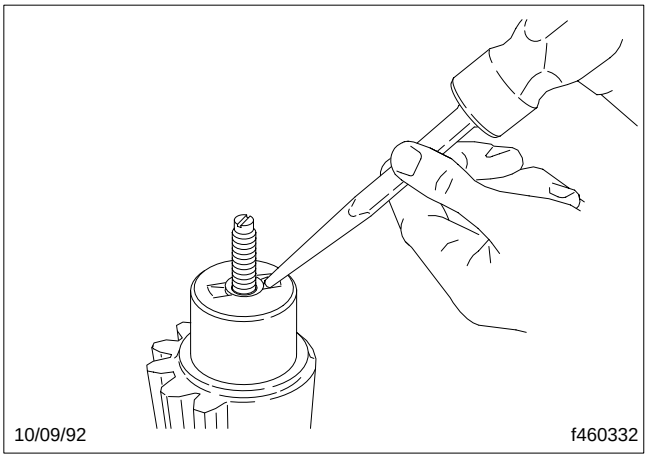

Fig. 12, Unstake the Adjusting Screw Retainer

   6.2 Unscrew the retainer and remove it from the sector shaft.

   6.3 Remove the adjusting screw. Discard the retainer.

7. If equipped with relief valve components, remove the relief valve cap, the O-ring, and the two-piece relief valve from the valve housing. Discard the O-ring.

8. Remove the input shaft, valve housing, and rack piston.

   8.1 Remove and discard the dirt and water seal from the input shaft. Clean the exposed part of the input shaft, using a fine grade emery cloth. See **Fig. 13**.

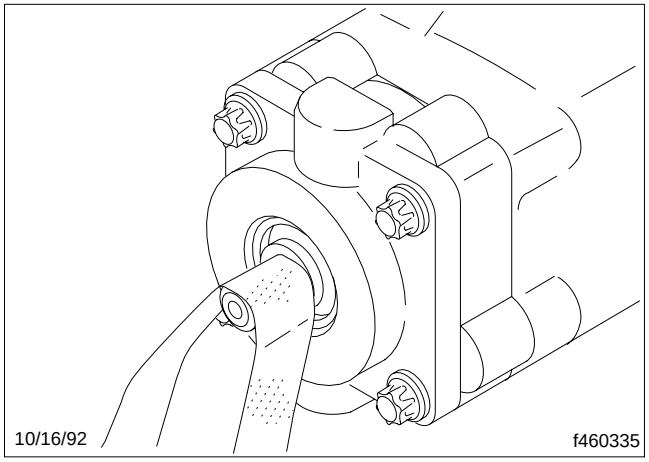

Fig. 13, Clean the Input Shaft

   8.2 Using an E-16 Torx® socket wrench, remove the four valve housing bolts. See **Fig. 14**.

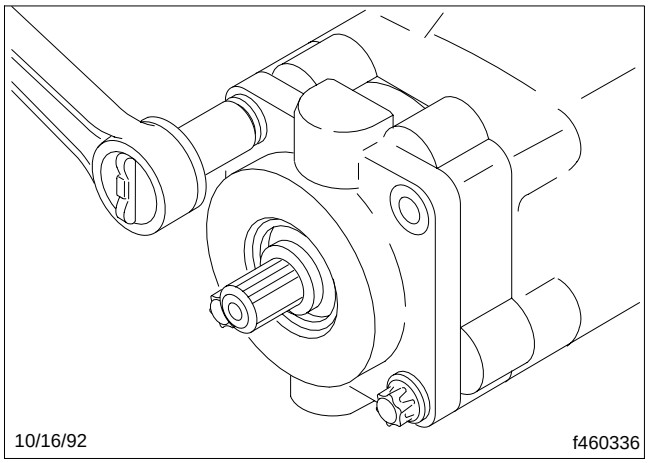

Fig. 14, Remove the Valve Housing Bolts

   8.3 Remove the valve housing from the main gear housing, together with the worm shaft and rack piston assembly. See **Fig. 15**. Set the assembly on a clean bench.

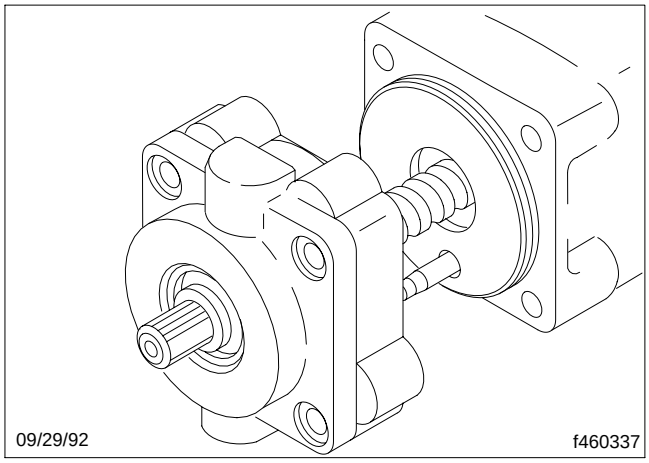

Fig. 15, Remove the Valve Housing

   8.4 Remove and discard the seal rings from the valve housing.

   IMPORTANT: If you are not going to remove, reset, or replace the poppet valves on the steering gear, make sure that the setting for them is not accidentally changed. Mark the gear, identifying the vehicle from which it was removed, and note that the poppet valve adjustments are for that particular vehicle.

9. Remove the steel balls.

   9.1 Remove the two sealing screws holding the ball return guide cap to the rack piston. See **Fig. 16**.

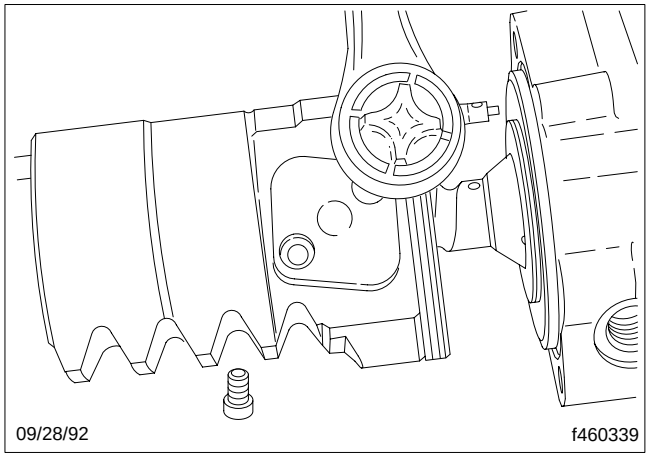

Fig. 16, Remove the Sealing Screws

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

9.2 Remove the cap and its seal. See **Fig. 17**. Discard the two screws and the seal.

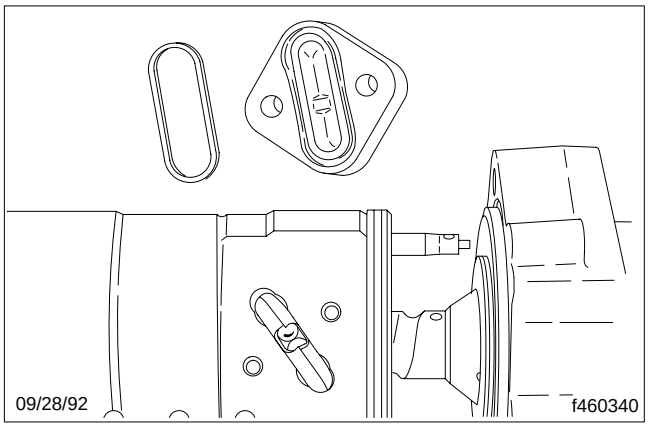

Fig. 17, Remove the Cap and Seal

9.3 Remove the ball return guide halves from the rack piston by carefully prying up on them with a screwdriver. See **Fig. 18**.

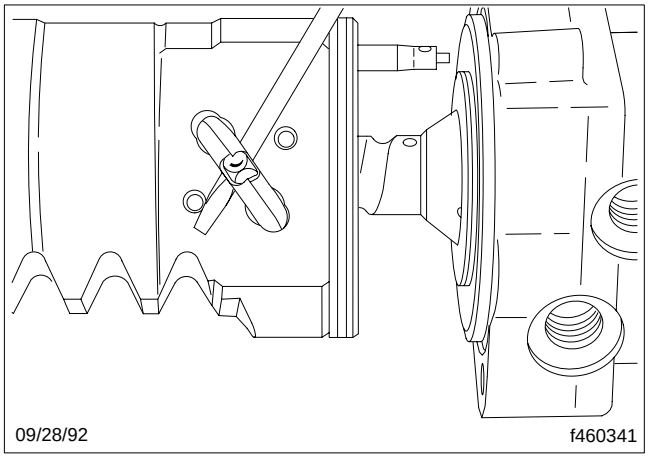

Fig. 18, Remove the Ball Return Guide Halves

9.4 Remove the 29 (TAS40), 31 (TAS55), 32 (TAS65), or 34 (TAS85) steel balls from the rack piston by turning the worm shaft until all of them are out. See **Fig. 19**. **Do not lose any of these balls or you will have to replace the entire set.**

10. Remove the worm shaft and valve housing assembly from the rack piston. See **Fig. 20**.

11. Cut and remove the Teflon® seal ring and the O-ring from the rack piston. See **Fig. 21**.

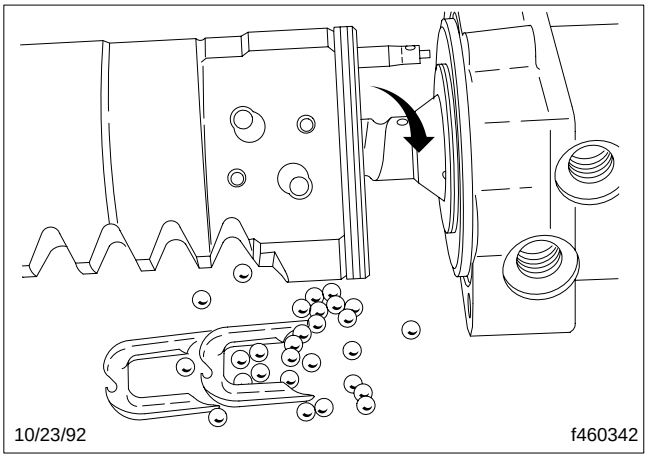

Fig. 19, Remove the Steel Balls

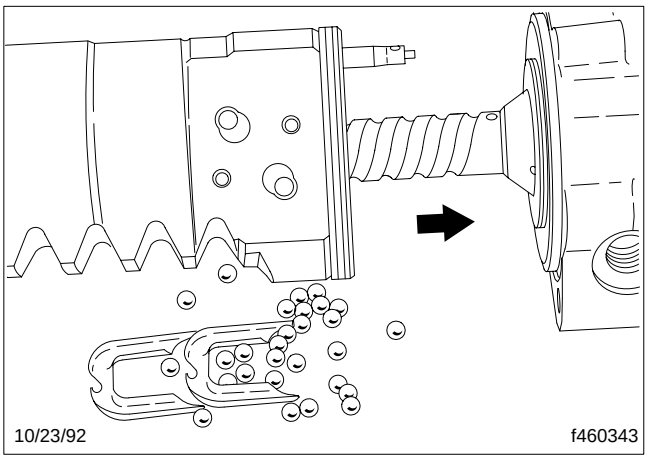

Fig. 20, Remove the Worm Shaft and Valve Housing Assembly

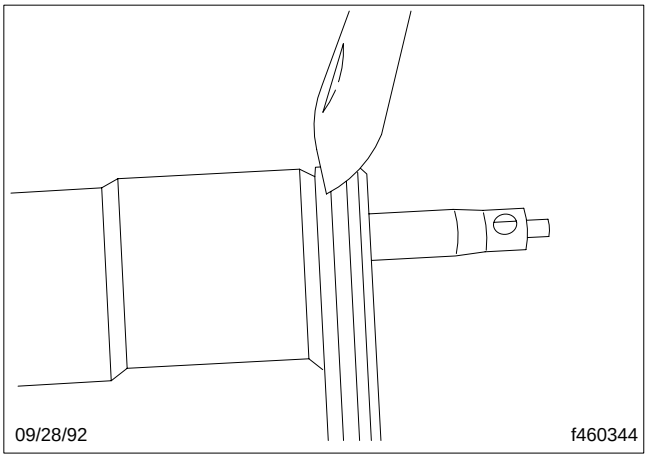

Fig. 21, Remove the Seal Ring and the O-Ring

12. If replacing poppet assemblies, remove the poppet valve assemblies.

    IMPORTANT: Do not use special tool J38713 on a rack piston that does not have a counterbore in the hole for the seat and sleeve assembly.

    12.1 Put the rack piston in a padded vise.

    12.2 Slide the special tool J38713 (preferred) or J36452 over the poppet adjuster seat, then turn the tool so that its prongs fit into the slot on the threaded adjustment sleeve. See **Fig. 22**. Hit the end of the tool firmly four or five times with a 16 oz. hammer to loosen the Loctite®. See **Fig. 23**.

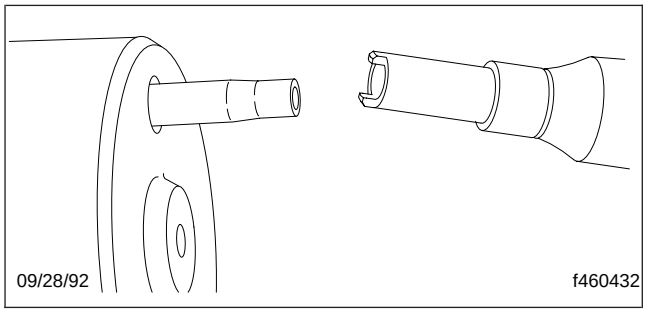

Fig. 22, Slide the Tool Over the Poppet Adjuster

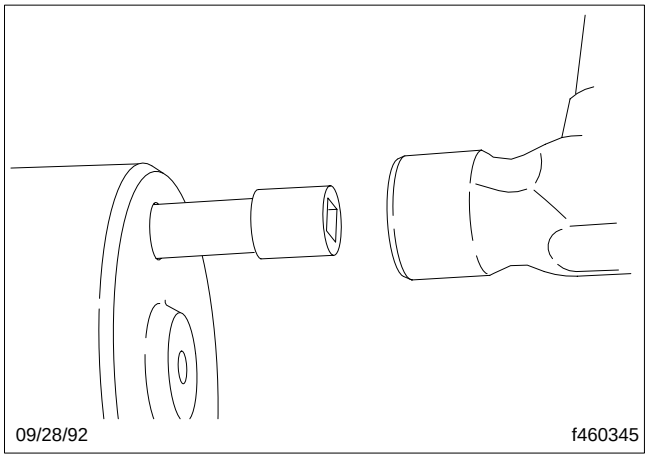

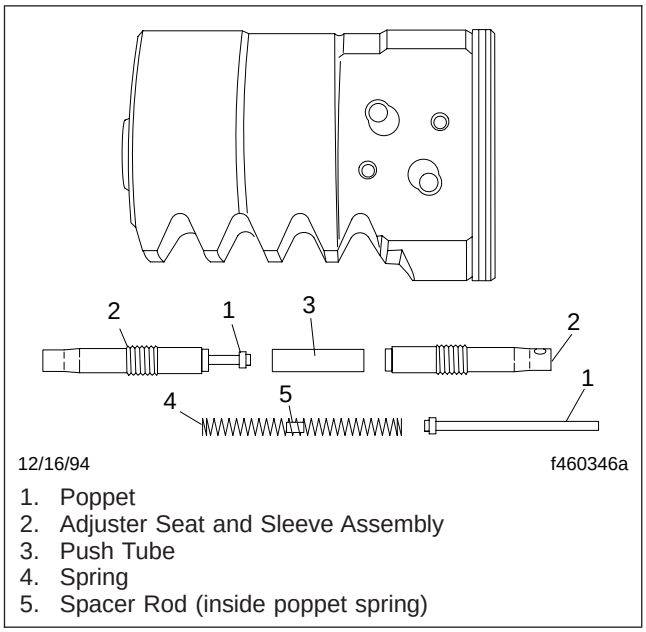

Fig. 23, Use the Tool to Loosen the Loctite®

    12.3 Using a breaker bar, unscrew the adjuster seat and sleeve assemblies from the rack piston. If the assembly will not loosen, hit the end of the tool several more times with a hammer.

    12.4 Remove both poppets, and the spring, spacer rod, and push tube. See **Fig. 24**.

    Repeat the above steps for the other poppet adjuster seat and sleeve assembly.

1. Poppet
2. Adjuster Seat and Sleeve Assembly
3. Push Tube
4. Spring
5. Spacer Rod (inside poppet spring)

Fig. 24, Remove the Poppets Spring, Spacer Rod, and Push Tube

13. Disassemble the valve housing if needed.

    IMPORTANT: Do not disassemble the valve housing unless you find signs of extreme heat, internal leakage, bearing damage or roughness, or if the worm shaft preload adjustment is needed.

    13.1 Put the worm shaft and valve housing assembly into a padded vise, with the worm shaft in a vertical position as shown in **Fig. 25**.

    13.2 Unstake the adjuster locknut, using a punch. See **Fig. 25**.

    13.3 Using special tools J37464 and J37070 with a breaker bar, unscrew the adjuster locknut, then the bearing adjuster from the valve housing. See **Fig. 26**.

    NOTE: The bearing adjuster has either two slots or two drill points on its face. Special

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

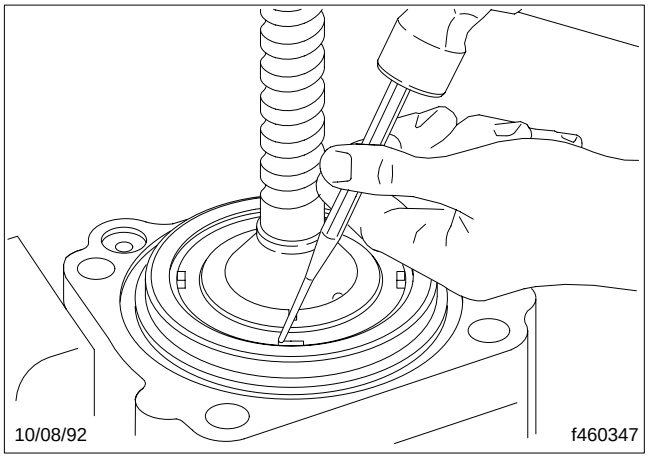

Fig. 25, Unstake the Adjuster Locknut

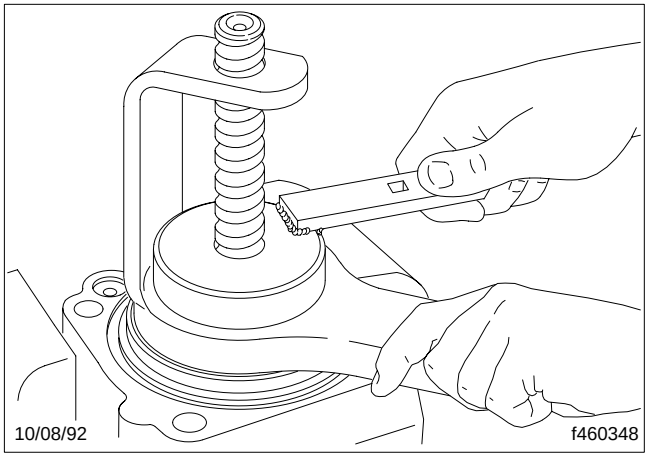

Fig. 26, Unscrew the Adjuster Locknut

tool J37070 can be used for removing and installing either style of bearing adjuster. See **Fig. 26**.

13.4 Remove and discard the seal ring and the O-ring from the bearing adjuster. See **Fig. 27**.

13.5 Remove the thin washer, thrust bearing, input shaft, rotary valve, and worm shaft assembly from the valve housing. See **Fig. 28**.

IMPORTANT: Do not disassemble the input shaft or worm shaft assembly any further. These are not serviceable.

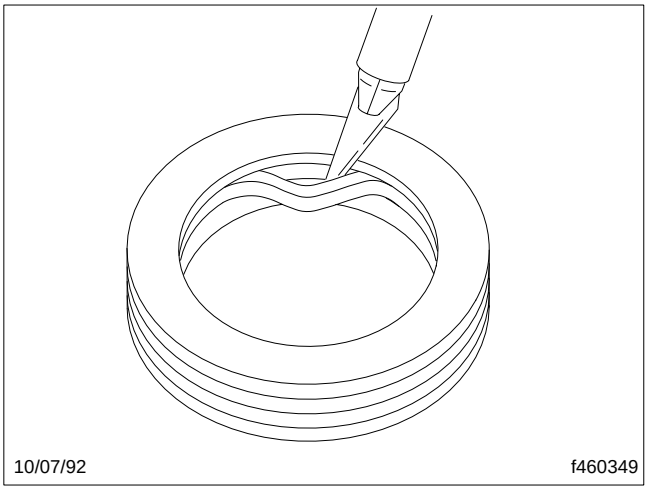

Fig. 27, Remove the Seal Ring

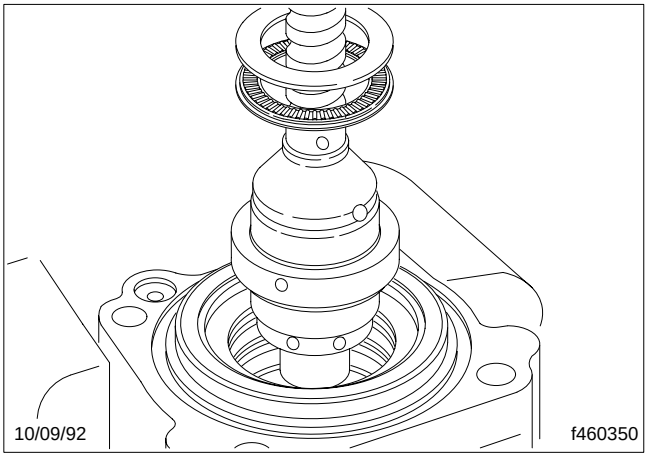

Fig. 28, Remove the Washer, Thrust Bearing, Input Shaft, Rotary Valve, and Worm Shaft Assembly

13.6 Remove the roller thrust bearing assembly and the thick thrustwasher from the valve housing. See **Fig. 29**.

13.7 Using a small knife, a probe, or a pick, remove and discard the seal rings and O-rings from the valve housing. See **Fig. 30**.

13.8 Turn the valve housing over and remove the retaining ring. See **Fig. 31**.

13.9 Using a 1-1/8 inch socket, tap out the seal from the valve housing. See **Fig. 32**. Discard the seal.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

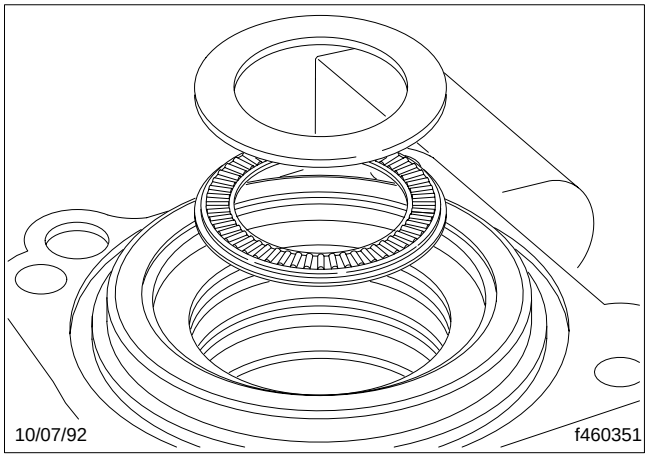

Fig. 29, Remove the Roller Thrust Bearing Assembly

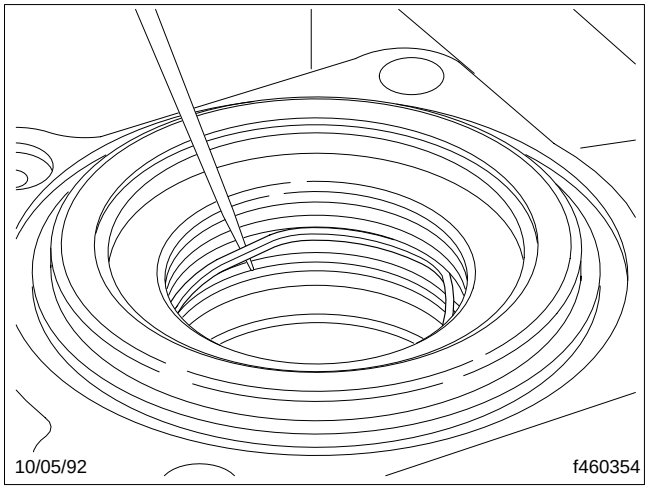

Fig. 30, Remove the Seal Rings and O-Rings

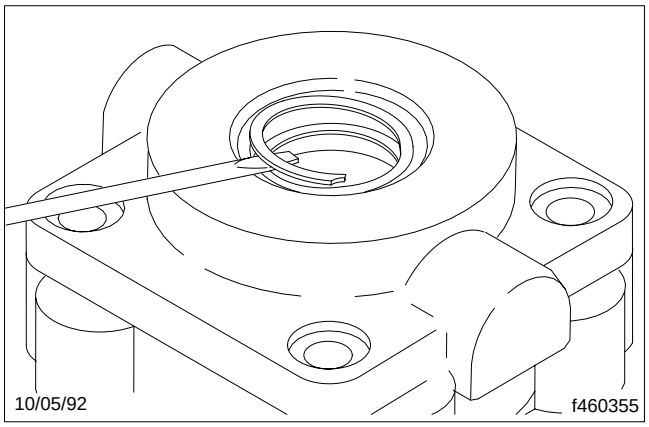

Fig. 31, Remove the Retaining Ring

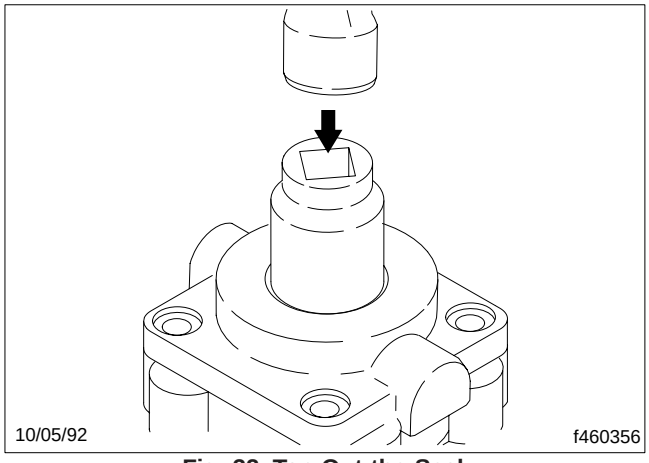

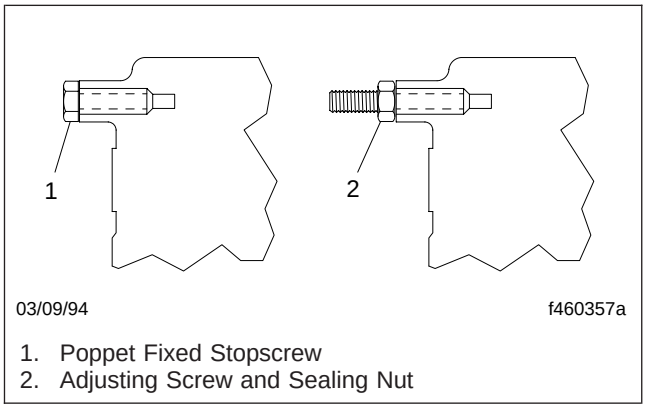

Fig. 32, Tap Out the Seal

13.10 If replacing either of the auxiliary port plugs, remove them. Be sure to remove and discard the O-rings.

14. Disassemble the housing.

NOTE: The steering gear is equipped with either a poppet fixed stopscrew, or an adjusting screw and sealing nut. See **Fig. 33**.

14.1 If the poppet fixed stopscrew needs replacement, remove it.

1. Poppet Fixed Stopscrew
2. Adjusting Screw and Sealing Nut

Fig. 33, Steering Gear Adjusting Screws

14.2 If the adjusting screw and sealing nut need replacing, remove them.

14.3 Remove the retaining ring from the output end of the housing trunnion. See **Fig. 34**.

14.4 Remove and discard the dirt seal. See **Fig. 35**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

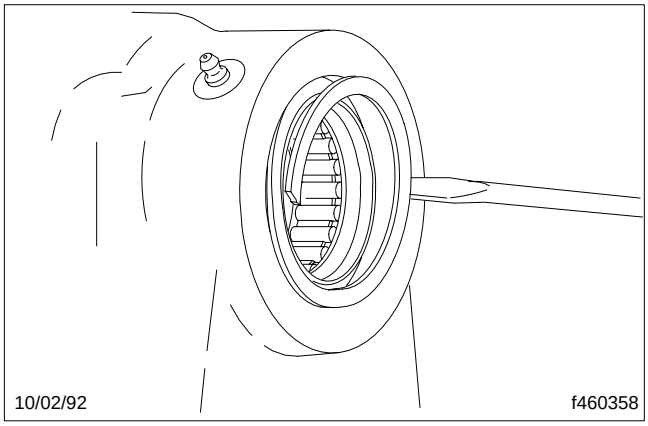

Fig. 34, Remove the Retaining Ring

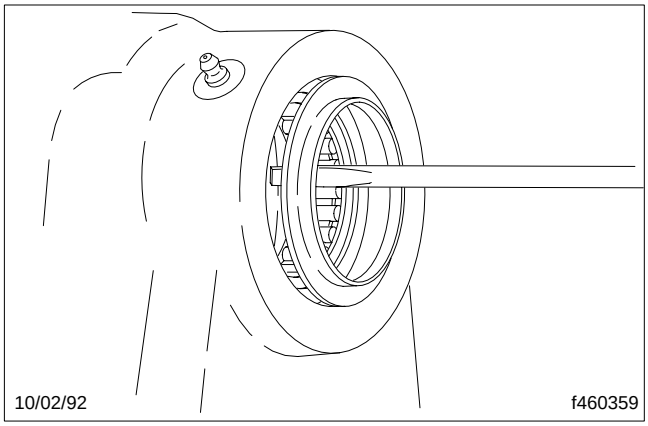

Fig. 35, Remove the Dirt Seal

14.5 Insert a screwdriver into the gear housing, and carefully push the seal and the spacer washer out of the other end of the bearing bore. See **Fig. 36**. Be careful not to damage the sealing area of the bore. Discard the seal.

14.6 If replacing the roller bearing in the housing, remove it using special tool J37705 (TAS40), J37071 (TAS55/65), or J38779 (TAS85). Press the roller bearing out of the trunnion end of the housing from the side of the bore where the side cover was attached. See **Fig. 37**.

14.7 If replacing the retaining ring, remove it through the trunnion end opposite the end where the side cover was attached. See **Fig. 38**. Be careful not to damage the pressure seal bore area.

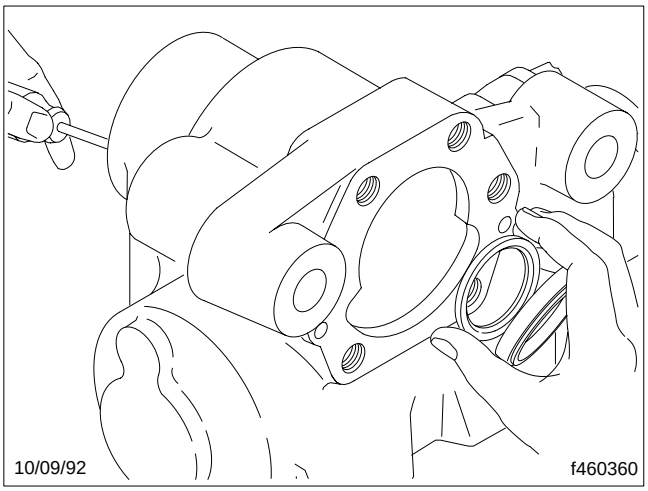

Fig. 36, Remove the Seal and Spacer Washer

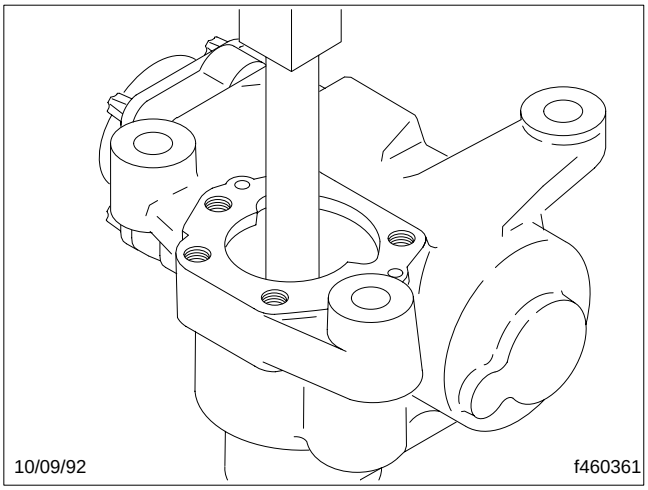

Fig. 37, Press the Roller Bearing Out of the Housing

Inspection

All sealing surfaces and seal cavities must be free of nicks and corrosion. If any part is nicked or corroded where sealing occurs, the part must be replaced to ensure proper sealing.

Wash all parts in a clean petroleum-based solvent. Blow-dry them with air.

1. Inspect the rack piston teeth for cracks and wear. See **Fig. 39**. If a step can be detected by running your fingernail horizontally across the teeth surfaces, the rack piston, the sector shaft, and the set of steel balls must be replaced.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

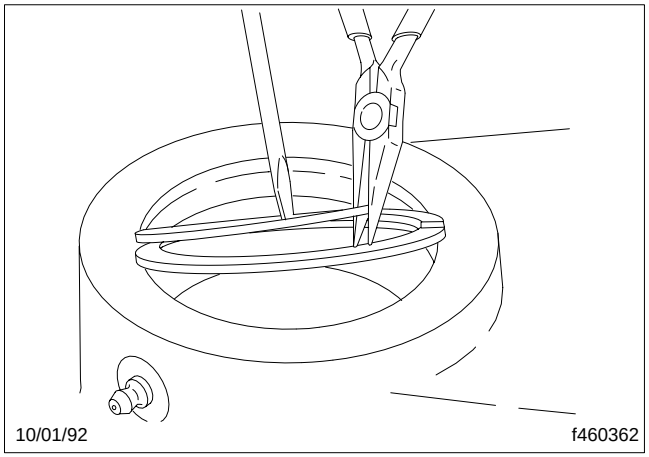

Fig. 38, Remove the Retaining Ring

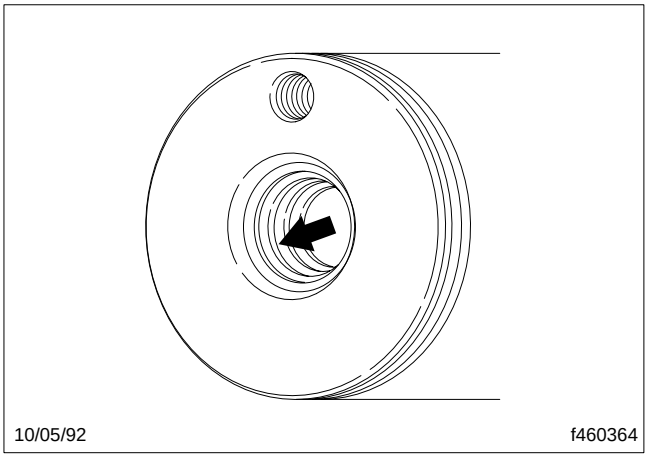

Fig. 40, Inspect the Rack Piston

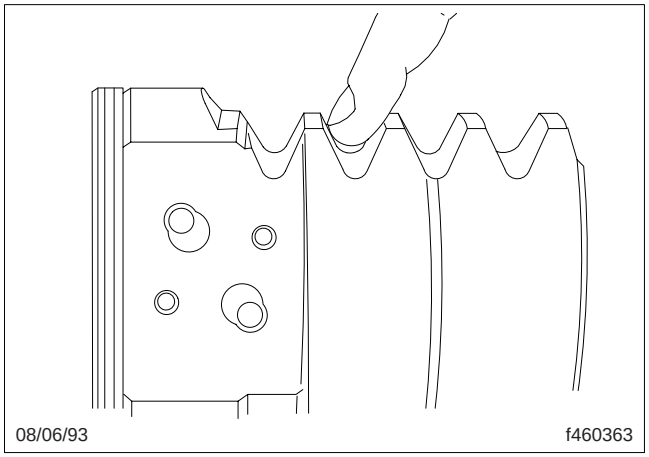

Fig. 39, Inspect the Rack Piston Teeth

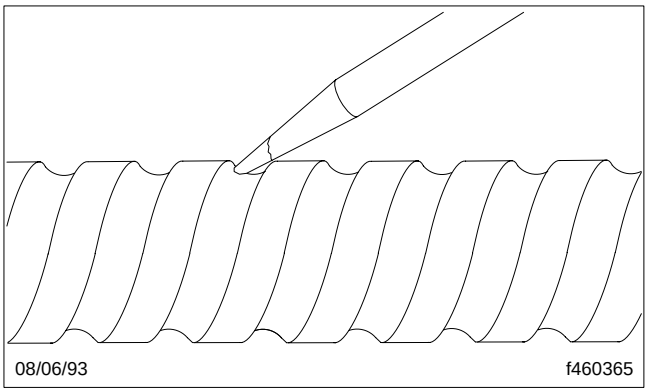

Fig. 41, Inspect the Worm Shaft

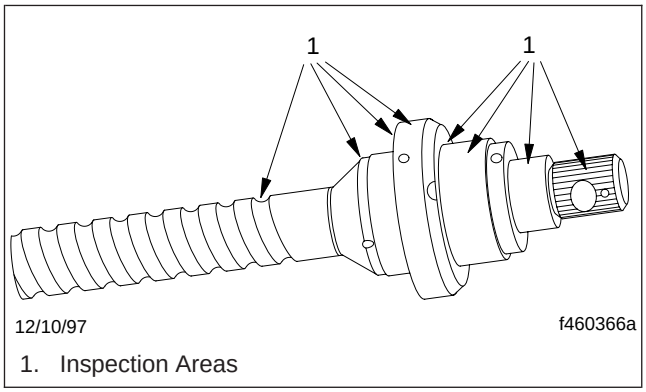

Fig. 42, Inspection Areas on the Upper Worm Shaft

2. Inspect the rack piston internal ball-track grooves for brinelling (dents) or spalling (flaking). See **Fig. 40**. If either condition exists, replace the rack piston, the valve/worm shaft assembly, and the set of 29 (TAS40), 31 (TAS55), 32 (TAS65), or 34 (TAS85) steel balls.
3. Inspect the worm shaft ball-track grooves for brinelling or spalling. See **Fig. 41**. If either condition exists, replace the worm/input shaft assembly, the rack piston, and the set of steel balls. Inspect the upper shaft-seal area near the input shaft serrations for nicks. Run your fingernail across the sealing surface to detect steps. See **Fig. 42**.
4. Inspect the housing cylinder bore. See **Fig. 43**. Minor scoring marks running lengthwise through the bore are normal, and should not be compared to the scoring that might be found in the cylinder bores of an internal combustion engine. Replace the housing only if it has been tested for internal leakage, and it is determined that the

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

scoring is the cause of internal leakage greater than 1 gpm (3.8 L/min). For troubleshooting procedures, see **Section 46.11, Subject 300**.

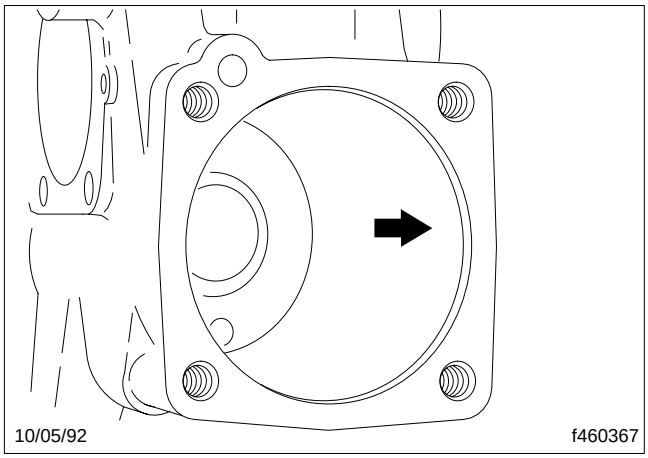

Fig. 43, Inspect the Housing Cylinder Bore

NOTE: In evaluating this test, make sure that internal leakage of more than 1 gpm (3.8 L/min) can be attributed only to the housing and not to the seals in the worm shaft, rack piston, and valve assembly.

5. Inspect the housing faces for nicks that would prevent proper sealing. See **Fig. 44**. Replace the gear housing if these nicks cannot be easily removed with a fine-toothed flat file without changing the dimensional characteristics.

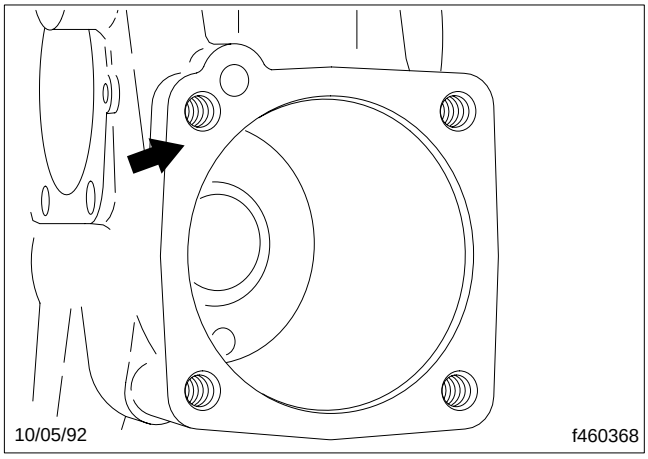

Fig. 44, Inspect the Housing Faces

6. Inspect the housing roller bearing for brinelling or spalling. If either condition exists, replace the housing bearing. See **Fig. 45**.

   For a TAS40/55/65 steering gear, inspect the side cover bushing. If the clearance between the bushing and the sector shaft is more than 0.008 inch (0.20 mm), replace the side cover and bushing assembly. See **Fig. 46**.

   For a TAS85 steering gear, inspect the side cover bearing for brinelling or spalling. If the bearing is damaged, replace the side cover and bearing assembly.

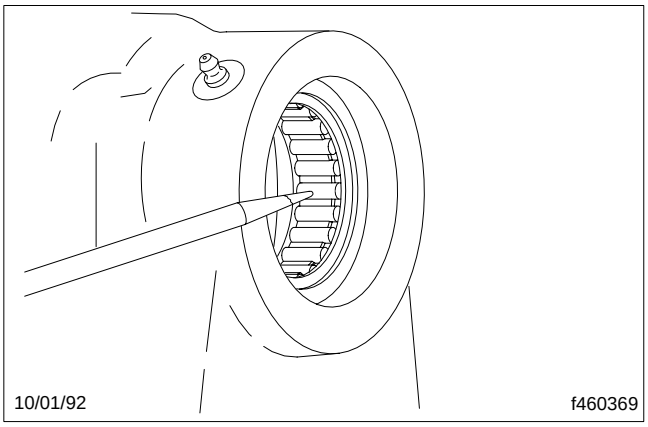

Fig. 45, Inspect the Housing Roller Bearing

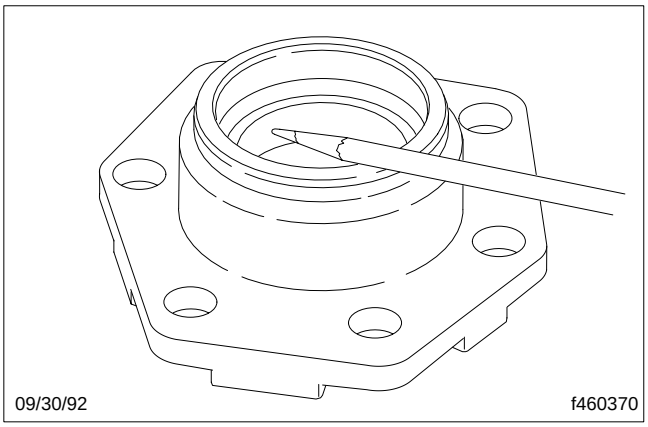

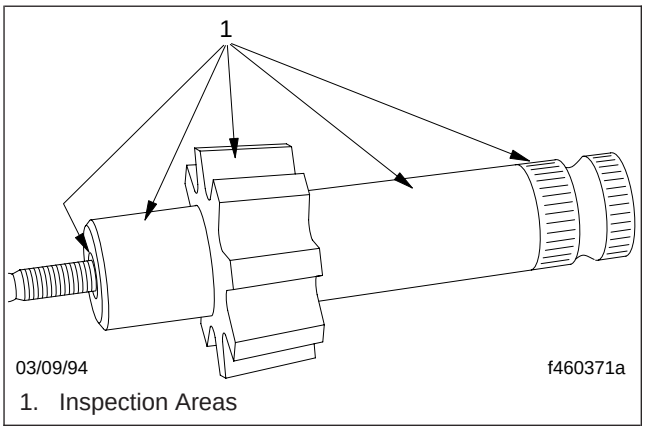

Fig. 46, Inspect the Side Cover Bushing

7. Inspect the sector shaft bearing sealing areas for brinelling or spalling. See **Fig. 47**. Run your fingernail across these areas to detect steps. Also, inspect for cracks. If any of these conditions exist, replace the sector shaft.

1. Inspection Areas

Fig. 47, Inspect the Sector Shaft Bearing Sealing Areas

8. Check the sector shaft assembly for damaged adjusting screw threads. Make sure the adjusting screw retainer is locked in place and has no cracks. The adjusting screw must turn by hand with no end play (lash). If the adjusting screw is damaged, replace it and its retainer.
9. Inspect the thrust bearing rollers for any deterioration. Inspect the thrustwashers for brinelling, spalling, or cracks. See **Fig. 48**. Replace any part if these conditions are detected.

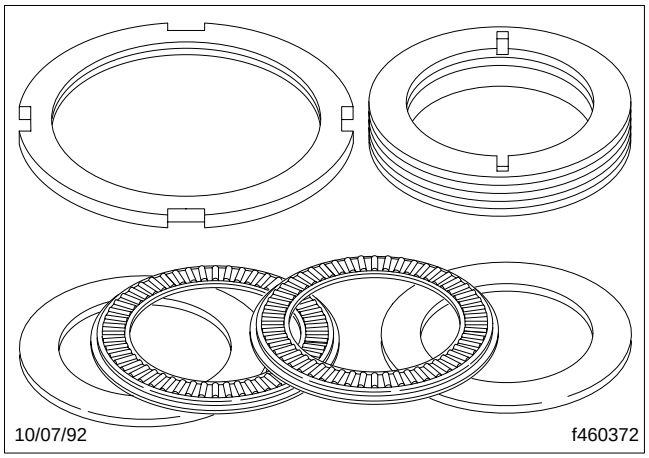

Fig. 48, Thrust Bearing Rollers

Assembly

IMPORTANT: Be sure that required tools are available before beginning the service procedures described here. See the special tools table in **Specifications 400**. The special tools required for disassembly and assembly of the steering gear parts are available from the SPX Kent-Moore or an affiliated dealer.

After inspection, clean all parts again in a clean petroleum-based solvent and blow-dry them with air.

All seals, seal rings, and gaskets must be replaced with new ones each time the gear is disassembled. Individual seals, seal rings, and gaskets—as well as complete seal kits—are available from Freightliner parts distributors.

1. If required, install a new sector shaft roller bearing; otherwise, go on to the next step.
   - 1.1 Put the gear housing on its side with the trunnion end of the bore facing up as shown in **Fig. 49**.

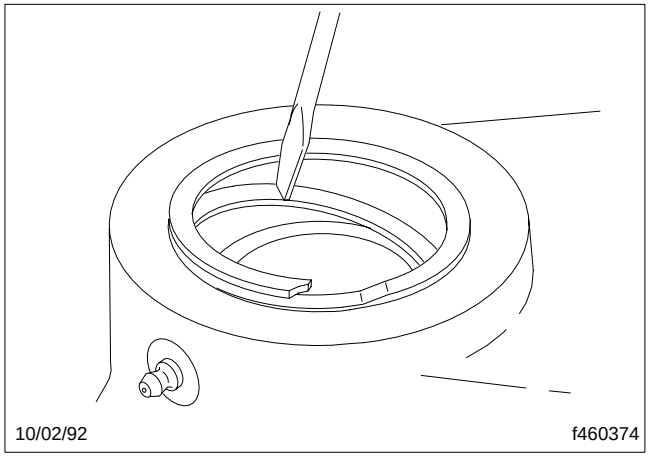

Fig. 49, Install the Retaining Ring

   - 1.2 Install the retaining ring in the groove closest to the side cover end of the bore. See **Fig. 49**. Then lubricate the bore.
   - 1.3 Place the new roller bearing on the housing bore with the lettered side of the bearing shell facing up.
   - 1.4 Using the installation end of the special tool, press the roller bearing into the housing until it seats against the retaining ring. See **Fig. 50**.
2. Install the sector shaft seals.
   - 2.1 Put the gear housing on its side with the side cover end of the bore facing up as shown in **Fig. 51**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

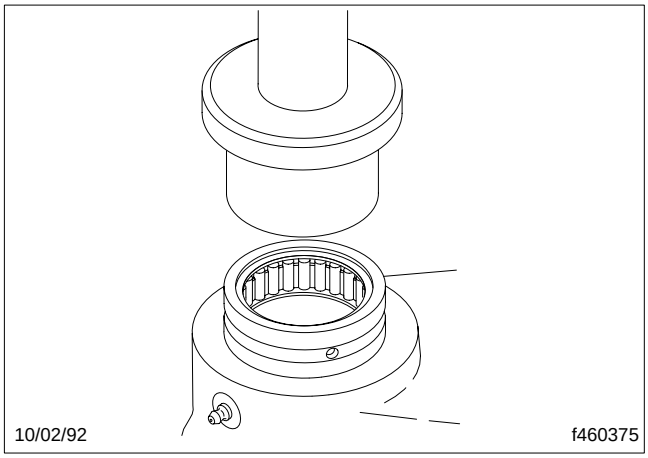

Fig. 50, Press the Roller Bearing into the Housing

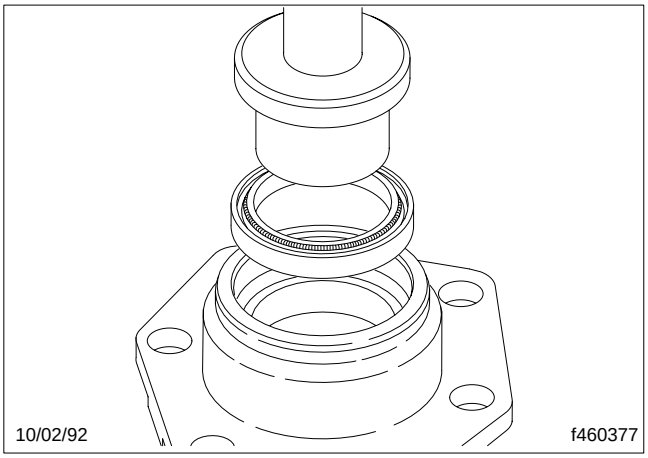

Fig. 52, Attach the New Seal to the Tool

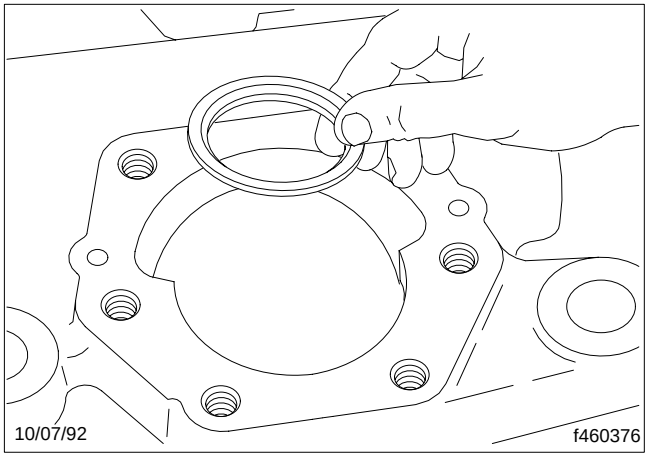

Fig. 51, Install the Washer in the Bore

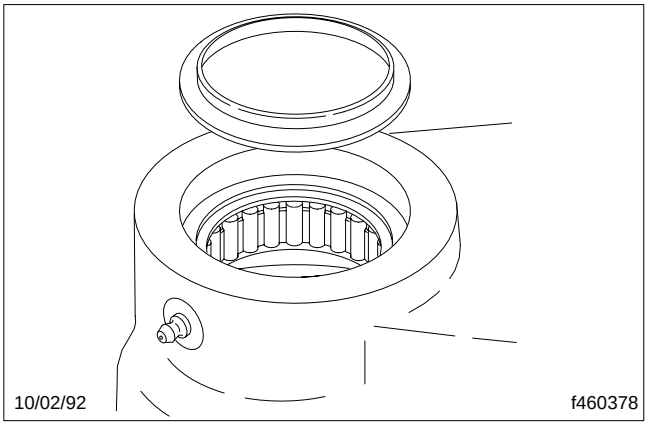

Fig. 53, Install the New Seal

2.2 Install the washer in the bore with the small diameter end of it facing the roller bearing retaining ring. See **Fig. 51**.

2.3 Put the new seal on special tool J37705 (TAS40), J37071 (TAS55/65), or J38779 (TAS85) so that the lip of the seal with the garter spring is toward the shoulder of the tool. See **Fig. 52**.

2.4 From the side cover end of the bore, press the new seal onto the washer (and the roller bearing below it) with a force of 100 to 800 lbf (445 to 3560 N).

2.5 Turn the gear housing over so that the trunnion end of the bore is up. Install the new dirt seal against the roller bearing with the lip facing up. See **Fig. 53**.

2.6 Install the second retaining ring seating it firmly into the groove in the bore. See **Fig. 54**.

2.7 Pack the area between the dirt seal and the pressure seal (including the roller bearing) with Mobil Temp® 1 grease or equivalent. See **Fig. 55**.

3. Assemble the valve housing.

3.1 Put the valve housing in a vise so the input/worm shaft can be installed with the worm shaft up.

3.2 Lubricate and install a new O-ring in the valve housing. See **Fig. 56**.

3.3 Lubricate a new large diameter O-ring and a new seal ring, then install them in the valve housing. See **Fig. 56** and **Fig. 57**.

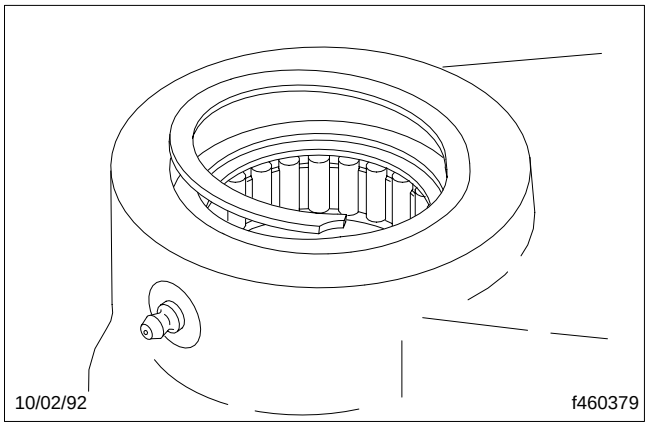

Fig. 54, Install the Second Retaining Ring

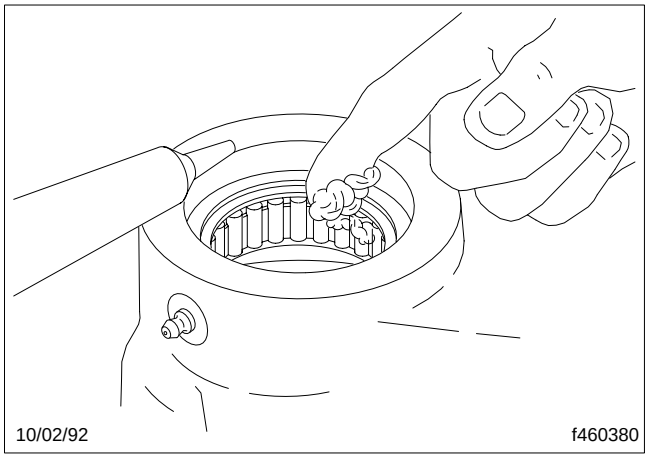

Fig. 55, Lubricate the Area Between the Seals

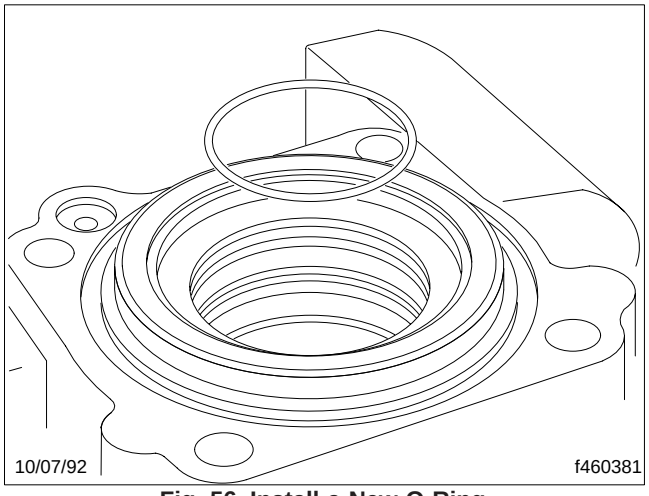

Fig. 56, Install a New O-Ring

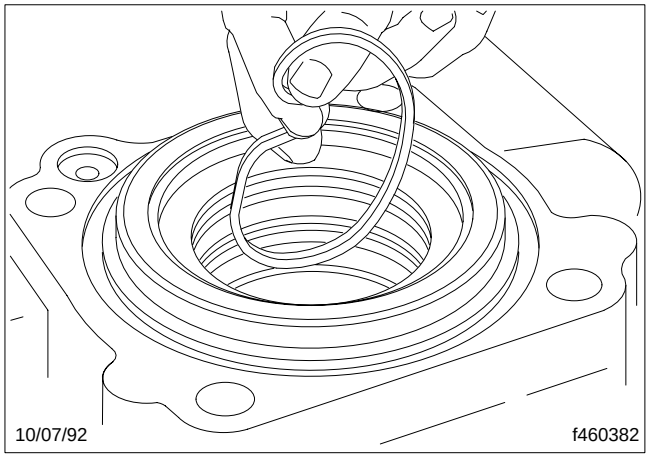

Fig. 57, Installing a New O-Ring

3.4 Install the roller thrust bearing and the thick thrustwasher on the input-shaft thrust face. See **Fig. 58**.

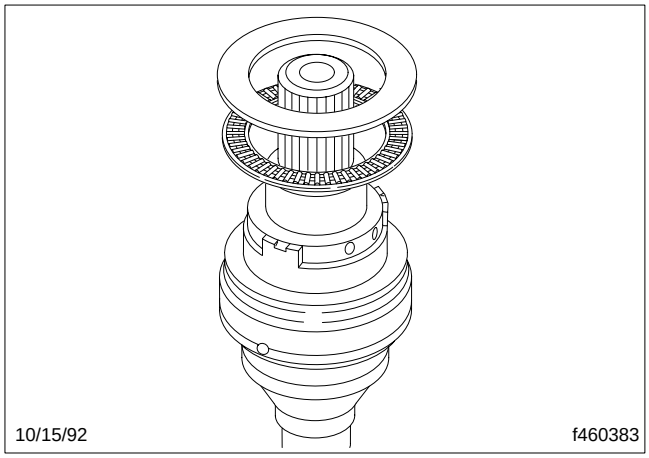

Fig. 58, Installing the Roller Thrust Bearing and Thrustwasher

3.5 Install a new seal ring on the input shaft and against the thick thrustwasher. See **Fig. 1**.

3.6 Lubricate, then install the input shaft/valve/worm assembly in the valve housing seating it firmly. See **Fig. 59**.

3.7 Lubricate, then install a second thrust bearing and thin washer over the worm shaft. See **Fig. 60**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

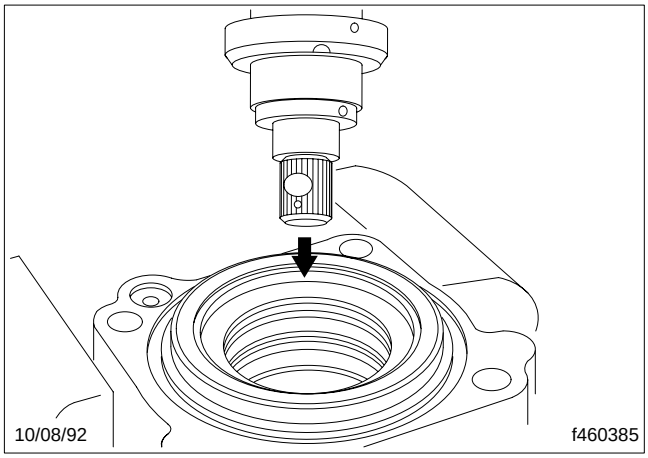

Fig. 59, Install the Input Shaft/Valve/Worm Assembly

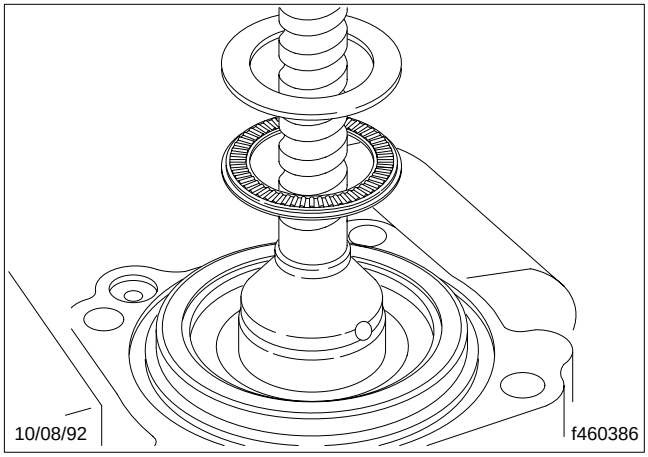

Fig. 60, Installing a Second Thrust Bearing

3.8 Lubricate the new O-ring and seal ring. Install the O-ring, then the seal ring in the groove of the bearing adjuster. See **Fig. 61**.

3.9 Making sure the bearing adjuster threads are clean and free of any stake burrs, lubricate and then install the bearing adjuster over the worm shaft and into the valve housing.

3.10 Using a torque wrench and bearing adjuster tool J37070, tighten the valve adjuster 11 to 15 lbf·ft (15 to 20 N·m), then back it off 1/4 to 1/2 turn. See **Fig. 62**.

3.11 Turn the valve housing over in the vise so that the worm shaft is facing down.

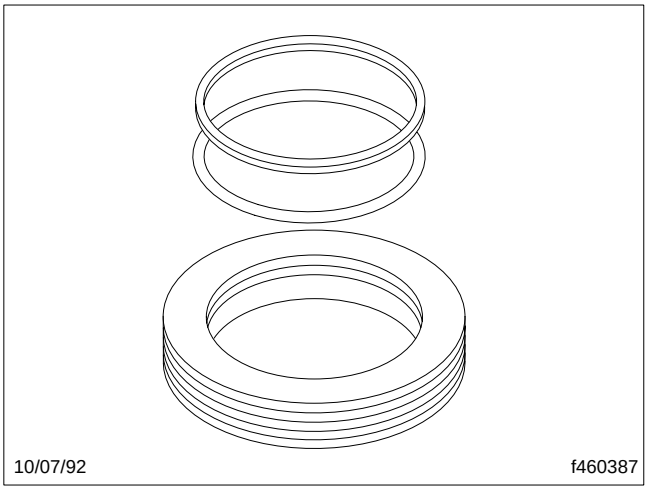

Fig. 61, Installing the O-Ring and Seal Ring

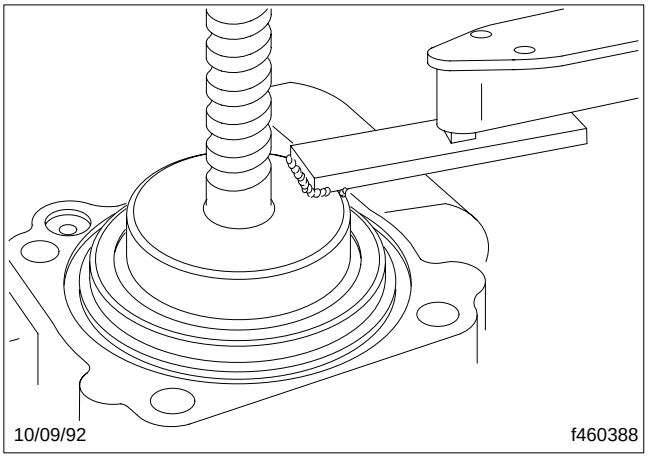

Fig. 62, Tighten the Valve Adjuster

3.12 Using an inch-pound torque wrench, check the torque needed to turn the input shaft slowly 360 degrees clockwise and counterclockwise. Tighten the bearing adjuster until the torque needed to turn the input shaft increases by 5 to 10 lbf·in (60 to 120 N·cm). See **Fig. 63**.

3.13 Turn the valve housing over in the vise again so that the worm shaft is facing up.

3.14 Oil and install the locknut on the bearing adjuster and, using special tools J37070 and J37464, tighten the locknut 101 to 122 lbf·ft (137 to 165 N·m) while holding the bearing adjuster. See **Fig. 64**.

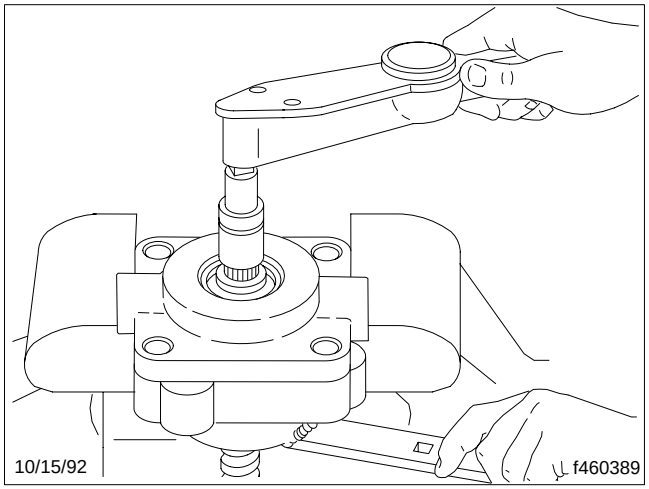

Fig. 63, Checking the Torque

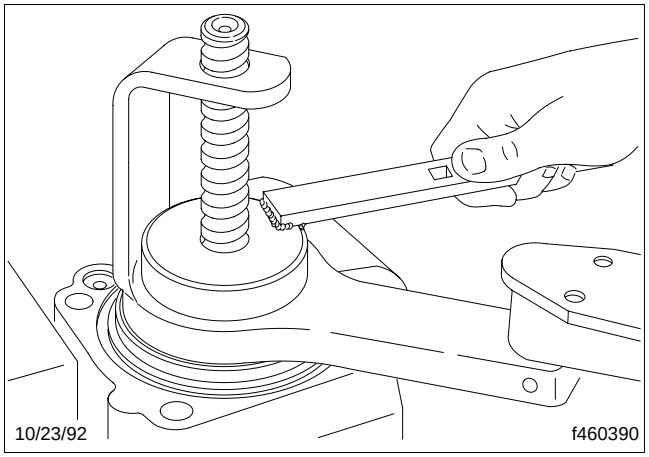

Fig. 64, Installing the Locknut on the Bearing Adjuster

3.15 Check the torque needed to turn the input shaft again. If the torque has not increased 5 to 10 lbf·in (60 to 120 N·cm), remove the locknut from the bearing adjuster and repeat the steps above beginning with tightening the valve adjuster, then backing it off.

3.16 Using a punch, stake the locknut to the valve housing at two opposite slots in the locknut. Stake each slot in the most clockwise corner as shown in **Fig. 65**.

3.17 Stake the locknut to the bearing adjuster at two places 180 degrees apart. See **Fig. 65**. Do not use a spot that was staked before.

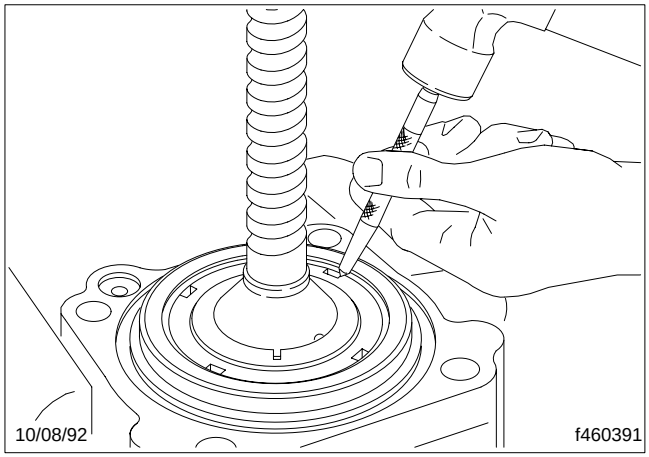

Fig. 65, Stake Each Slot

3.18 Check the torque needed to turn the input shaft. If the torque is not greater than 5 to 10 lbf·in (60 to 120 N·cm) the torque previously noted, unstake the locknut from the bearing adjuster and repeat the steps above beginning with tightening the valve adjuster, then backing it off.

NOTE: The torque needed to turn the input shaft must not be more than 22 lbf·in (240 N·cm).

3.19 Oil the new seal rings and install them in the valve housing. See **Fig. 66**.

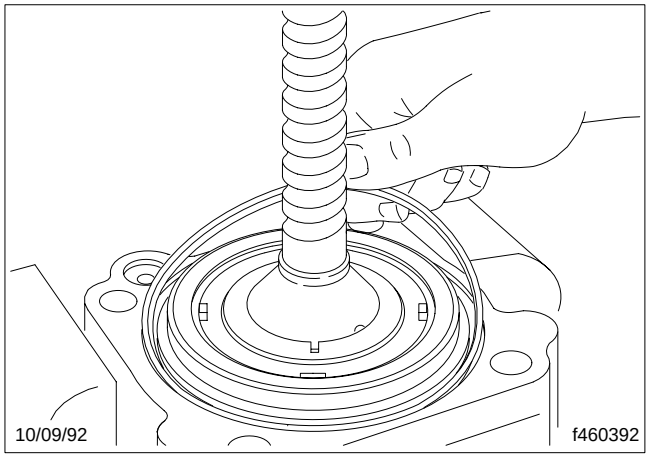

Fig. 66, Installing New Seal Rings

4. Reset the automatic poppet valves.

IMPORTANT: Make sure the poppet adjuster seat and sleeve assemblies and the

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

threaded holes in the rack piston are free of Loctite®. Use 7/16-20 thread chasers to remove the Loctite®.

4.1 Turn the poppet adjuster seat and sleeve assembly so that it is in the **opposite** direction in which it was installed, and loosely screw it into the threaded hole in the rack piston. See **Fig. 67**.

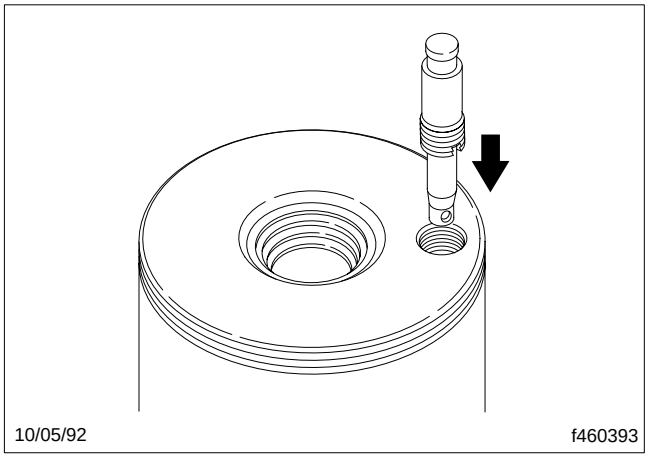

Fig. 67, Installing the Poppet Adjuster Seat and Sleeve Assembly in the Rack Piston

4.2 Press the adjuster seat into the adjuster sleeve with a force of 500 to 2500 lbf (2224 to 11 120 N) until the shoulder on the seat bottoms on the sleeve. See **Fig. 68** and **Fig. 69**.

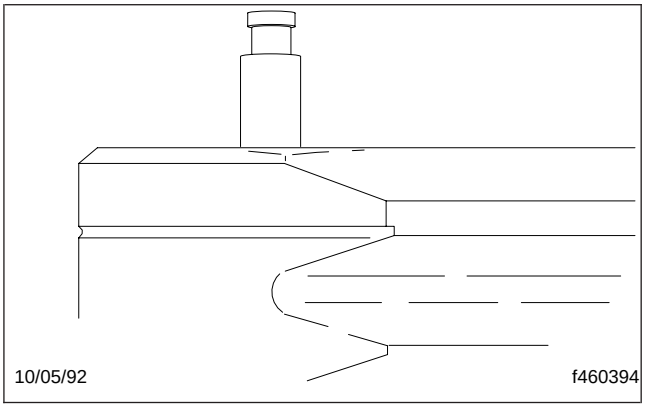

Fig. 68, The Adjuster Seat in the Adjuster Sleeve

4.3 Remove the adjuster seat and sleeve assembly from the rack piston.

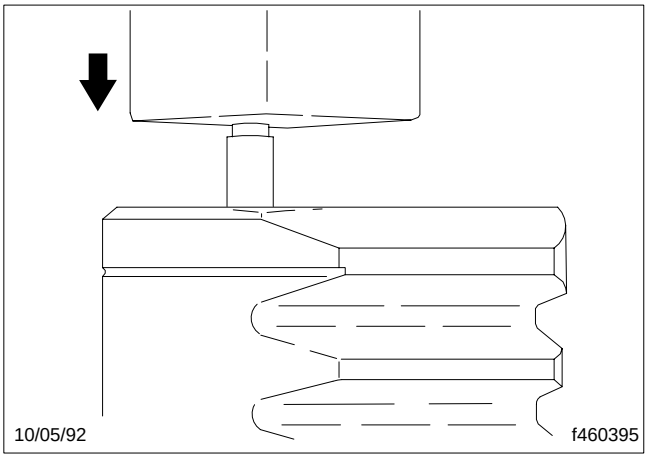

Fig. 69, Installing the Adjuster Seat into the Adjuster Sleeve

4.4 Repeat the previous steps for the other poppet adjuster seat and sleeve assembly.

5. Install the rack piston seal. Install a new backup O-ring and new Teflon® seal ring on the rack piston. See **Fig. 70**. Do not stretch them more than necessary when installing them.

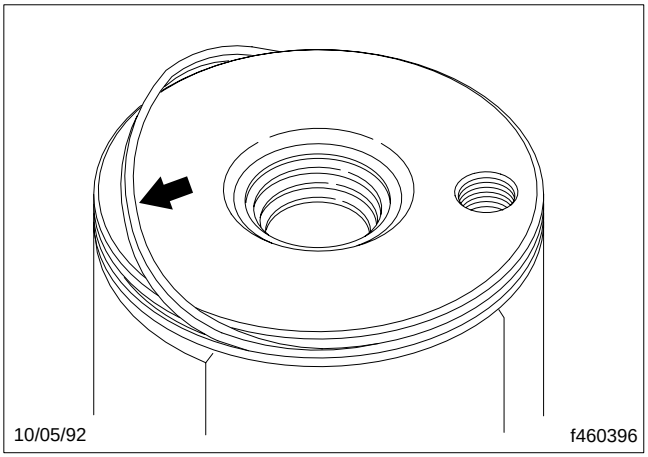

Fig. 70, Installing the Rack Piston Seal

6. Install the automatic poppets.

NOTE: If you are installing new poppet adjuster seat and sleeve assemblies, they may already have Dri-Loc® 200 on them. If so, more Loctite® is not needed.

6.1 Apply Locquic primer T to the threaded poppet holes in the rack piston and to the threads on the poppet adjuster seat and

sleeve assemblies. Let dry for ten minutes, then apply Loctite® RC680 to the same threads. See **Fig. 71**.

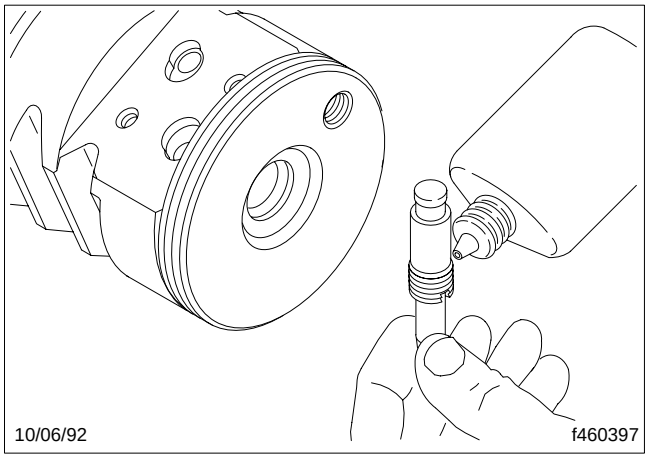

Fig. 71, Apply Primer to the Threaded Poppet Holes

6.2 Place the rack piston in a padded vise, and install a poppet adjuster seat and sleeve assembly, slotted end out, into the threaded hole at one end of the rack piston. See **Fig. 72**.

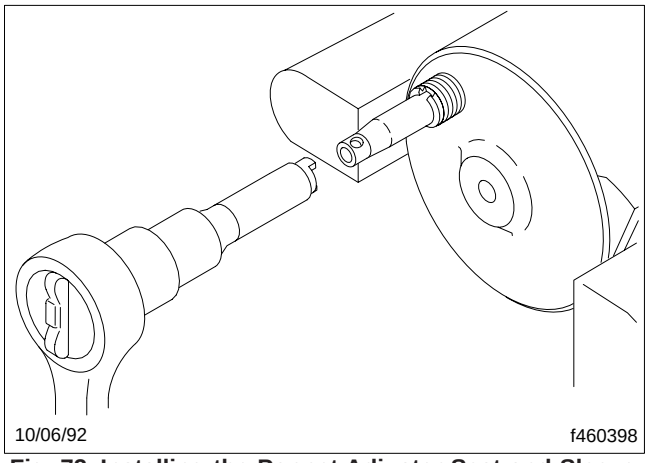

Fig. 72, Installing the Poppet Adjuster Seat and Sleeve Assembly into the Rack Piston

6.3 In the other end of the hole, install the poppet assembly parts in the following order: one poppet, the poppet spring, the nylon spacer rod, the push tube, the other poppet, and the other poppet adjuster seat and sleeve assembly. See **Fig. 73**.

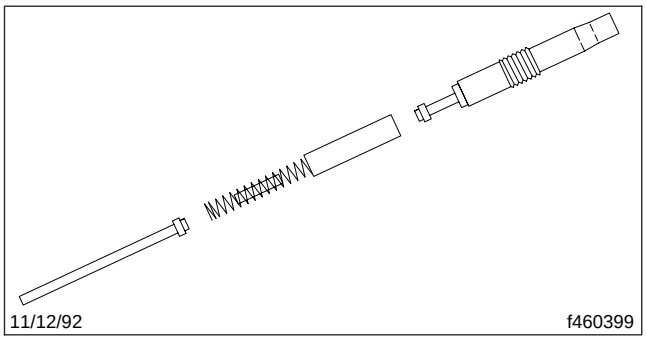

Fig. 73, Installing the Poppet Assembly Parts

6.4 Using special tool J36452 or J38713 (preferred), tighten both poppet adjuster seat and sleeve assemblies using one of the following torque specs:

- 10 lbf·ft (14 N·m) for a TAS40/55/65 steering gear
- 18 lbf·ft (24 N·m) for a TAS85 steering gear

7. Install the worm shaft and valve housing assembly into the rack piston.

7.1 Put the rack piston on a clean, cloth-covered bench with the worm end of the piston near the edge of the bench and the ball guide holes facing up.

NOTE: When made to the correct dimensions to raise and support the piston, a wooden V-block will make the following steps easier.

7.2 Insert the worm shaft and input shaft assembly into the worm end of the rack piston close to the maximum depth without the valve housing contacting the upper poppet. See **Fig. 74**.

7.3 Line up the grooves in the worm shaft with the ball guide holes in the rack piston. Make sure the valve housing extends over the edge of the bench or the rack piston is put on a V-block so that the valve housing and worm shaft can turn freely.

8. Install the steel balls.

8.1 Install new ball return guide halves in the rack piston. See **Fig. 75**. Make sure they are correctly seated.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

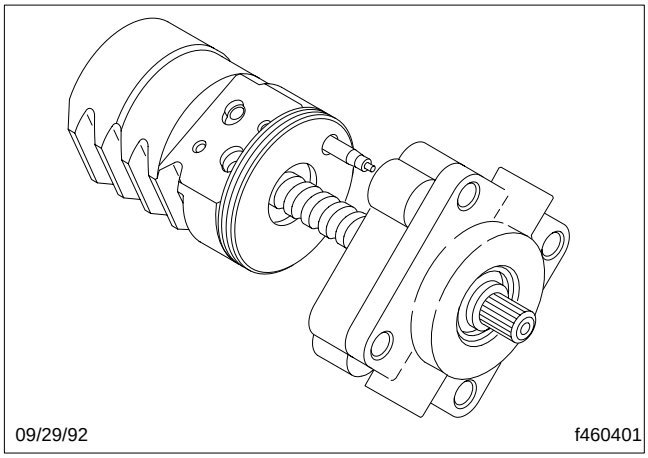

Fig. 74, Inserting the Worm Shaft and Input Shaft Assembly into the Rack Piston

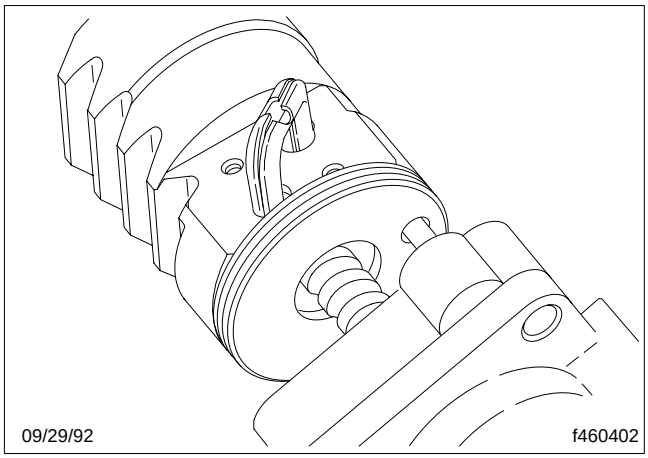

Fig. 75, Installing the New Ball Return Guide Halves

NOTE: The worm gear may have to be rotated slightly to seat guide halves. Left-hand ball return guide halves are copper-plated; right-hand guide halves are not. Make sure the correct new ball return guide halves are installed by comparing them with the old ones. Then discard the old ones.

8.2 Insert the 29 (TAS40), 31 (TAS55), 32 (TAS65), or 34 (TAS85) steel balls in the ball return guide hole as shown in **Fig. 76**. As the balls are dropped into the guide, turn the worm shaft so that the balls are pulled down into its grooves.

8.3 If the ball guide halves rise up at any time during or after the installation of the steel balls, remove all of the balls and the input shaft/valve/worm assembly from the rack piston. Repeat the previous steps beginning with inserting the worm shaft and input shaft assembly into the worm end of the rack piston.

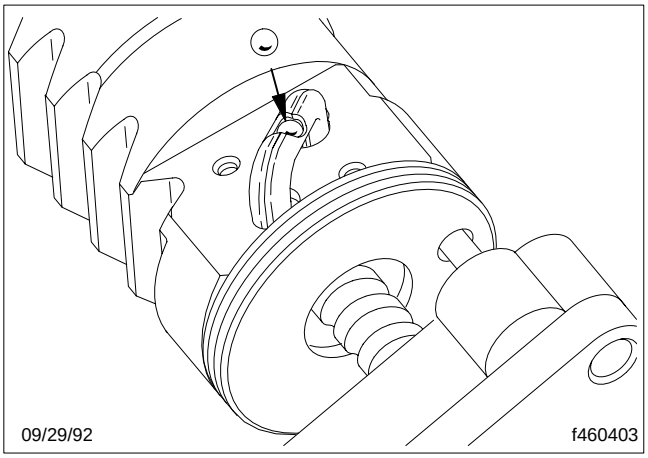

Fig. 76, Inserting the Steel Balls in the Return Guide Hole

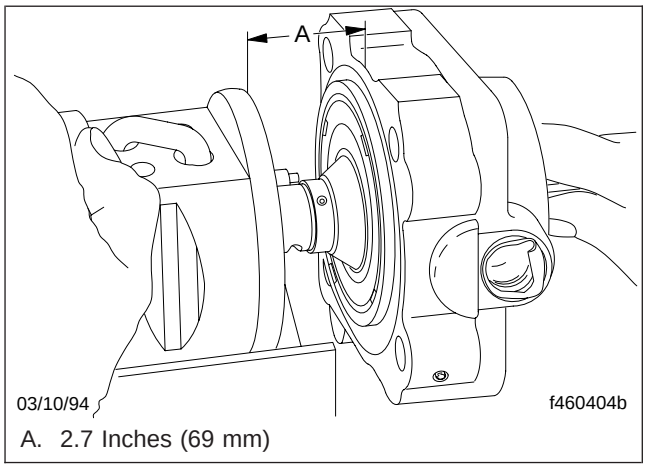

IMPORTANT: Do not let the valve housing pilot face touch the poppet adjuster or move more than 2.7 inches (69 mm) from the upper end of the rack piston. See **Fig. 77**. If this happens, the poppet adjuster could be incorrectly preset or the worm could be backed out beyond the closed ball loop.

8.4 Lubricate the new seal for the ball return guide cap and install it in the groove in the cap. See **Fig. 78**.

8.5 Using a 5/32 inch Allen socket and two new 5/32 inch Allen head screws (or a T-30 Torx socket and two new Torx head screws), install the ball return guide cap on the rack piston. Make sure the seal makes full contact with the rack piston surface. Tighten the fasteners alternately once or twice, to a final torque of 14 to 22 lbf·ft (19 to 30 N·m).

8.6 To ensure that the steel balls have been correctly installed, turn the worm shaft from one end of travel to the other without allowing the valve housing to contact the poppet adjuster and without moving the valve housing pilot face more than 2.7

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

A. 2.7 Inches (69 mm)

Fig. 77, Maximum Distance Between the Valve Housing Pilot Face and the Upper End of the Rack Piston

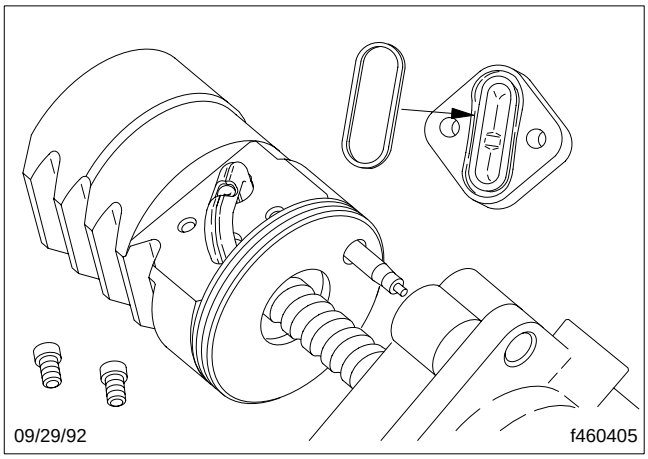

Fig. 78, Install the Seal in the Ball Return Guide

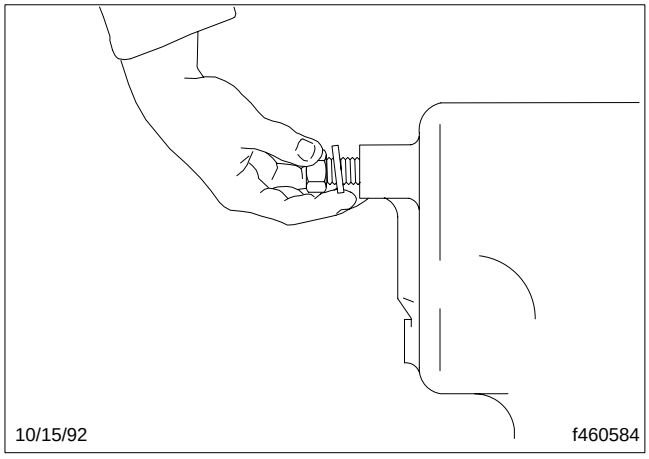
inches (69 mm) from the input end (upper end) of the rack piston. See **Fig. 77**.

8.7 If the worm shaft does not turn, remove all of the steel balls, and install them again.

9. Install the poppet stopscrew. If the poppet stopscrew is being replaced, install the new one and its washer in the gear housing. See **Fig. 79**. Tighten it 38 to 42 lbf·ft (52 to 57 N·m).

10. Preset the poppet adjusting screw, if equipped.

10.1 If the service poppet adjusting screw and the service sealing jam nut are being used for automatic poppet adjustment, turn the adjusting screw into the jam nut until 1.03



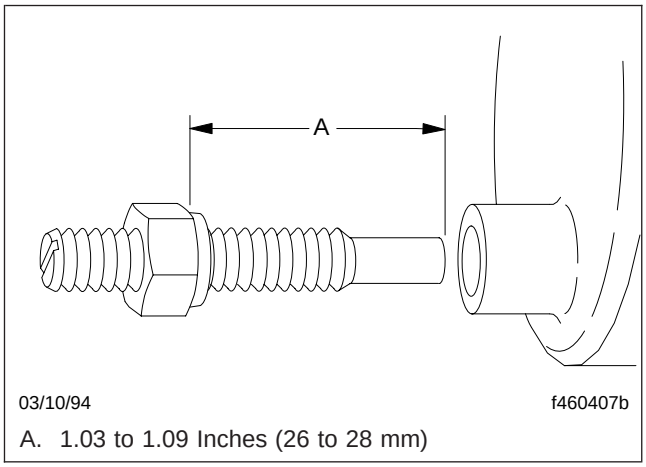


Fig. 79, Installing the Poppet Stopscrew

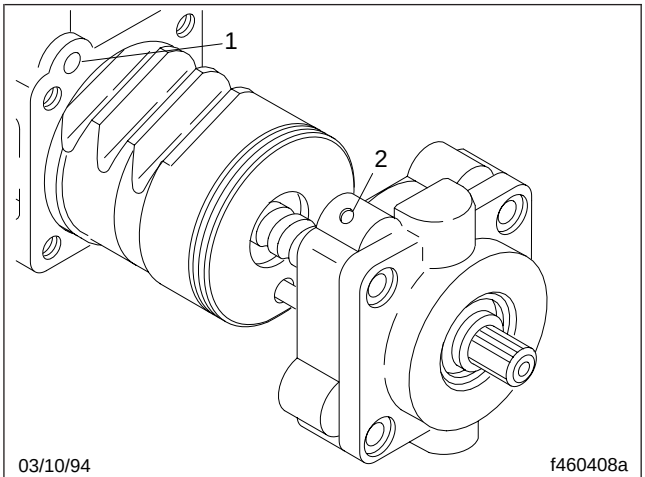
to 1.09 inches (26 to 28 mm) protrudes from the bottom of the jam nut. See **Fig. 80**.

A. 1.03 to 1.09 Inches (26 to 28 mm)

Fig. 80, Turn the Adjusting Screw into the Jam Nut

10.2 Install the assembly into the gear housing. Tighten the jam nut 33 to 37 lbf·ft (45 to 50 N·m).



11. Install the rack piston/valve housing assembly into the gear housing.

11.1 Put clean oil on the rack piston Teflon® seal ring and into the bore of the gear housing. Position the rack piston on the worm gear with a gap of 10 to 13 mm (3/8 to 1/2 inch) between the valve housing and the upper poppet adjuster seat and sleeve assembly.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

IMPORTANT: This gap is to ensure that the poppets do not make contact with anything while the steering gear is being assembled.

11.2 Install the rack piston and worm shaft assembly in the gear housing, being careful not to damage the seal ring on the rack piston. Do not let the poppet adjuster sleeve assemblies bottom out inside the gear housing. Install the piston with the rack teeth toward the sector shaft hole in the housing. See **Fig. 81**. Be sure the valve housing cylinder feed hole lines up with the gear housing feed hole.

1. Gear Housing Feed Hole
2. Valve Housing Cylinder Feed Hole Boss

Fig. 81, Installing the Rack Piston and Worm Shaft Assembly in the Gear Housing

11.3 Using an E-16 Torx socket wrench, install and tighten the four valve housing bolts using one of the following torque specs:

- 75 to 85 lbf·ft (102 to 115 N·m) for a TAS40/55/65 steering gear
- 108 to 128 lbf·ft (146 to 174 N·m) for a TAS85 steering gear

12. Install the relief valve components, if equipped.

12.1 Assemble a new O-ring on the relief valve cap.

12.2 Assemble the small end of tapered spring onto the pin on the other part of the relief valve and insert the assembly, tapered spring end first, into the relief valve cap cavity. See **Fig. 82**.

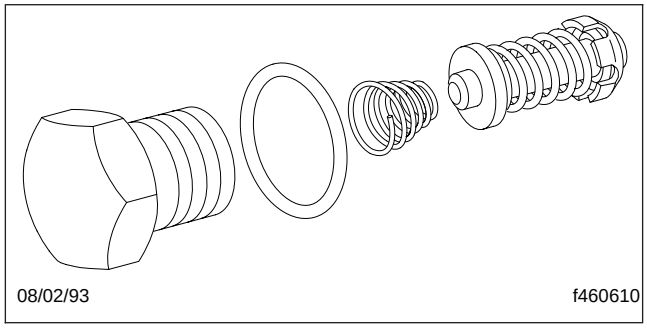


Fig. 82, Assemble the Spring and Pin into the Relief Valve Cap

12.3 Turn the relief valve cap as assembled into the valve housing and torque it to 30 lbf·ft (41 N·m). See **Fig. 83**.

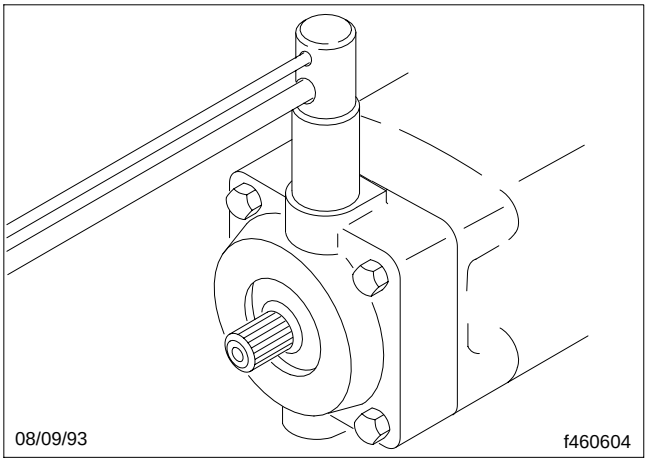

Fig. 83, Turn the Relief Valve Cap into the Valve Housing

13. If the sector shaft adjusting screw is being replaced, do the following. Otherwise go to the next step and install the sector shaft/side cover components.

13.1 Coat the end of the new adjusting screw with wheel bearing grease and, with the sector shaft in a padded vise, insert the new adjusting screw into the recess in the sector shaft end.

13.2 Install a new sector-shaft screw retainer in the sector shaft. Adjust the retainer so that the sector shaft adjusting screw can be

turned freely by hand. It should have a maximum end play of 0.002 inch (0.05 mm).

13.3 Stake the sector-shaft screw retainer to the slots in the sector shaft. See **Fig. 84**. Check the adjusting screw again for free movement and end play.

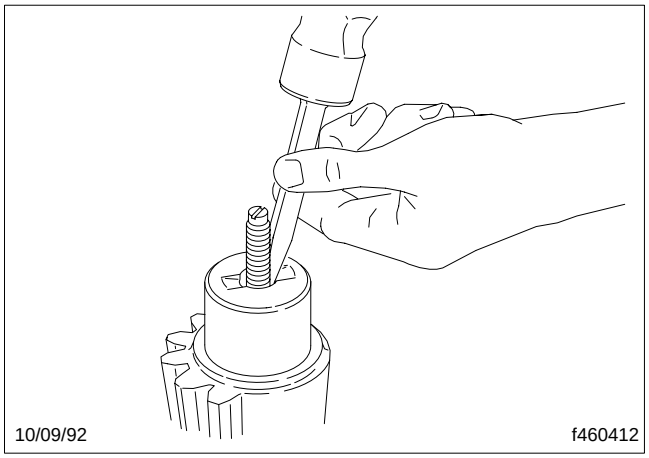

Fig. 84, Stake the Sector-Shaft Screw Retainer to the Sector Shaft

14. Install the sector shaft/side cover components.

14.1 For a TAS40/55/65 steering gear, lightly oil the side cover DU bushing. Do not grease it. See **Fig. 85**.

For a TAS85 steering gear, heavily grease the side cover bearing with Mobile Temp 1 or 2 grease. Do not oil it.

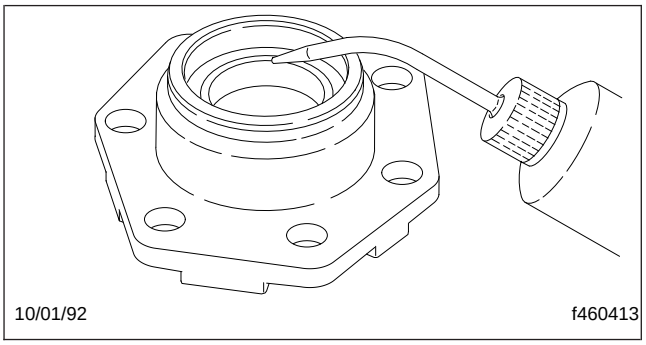

Fig. 85, Oil the Side Cover DU Bushing

14.2 Put a new seal on special tool J37705 (TAS40), J37071 (TAS55/65), or J38779 (TAS85) so that the garter spring is against the shoulder of the tool. See **Fig. 86**. Press the new seal into the side cover with a force of 100 to 800 lbf (445 to 3560 N). Make sure the seal is seated against the bottom of the counterbore.

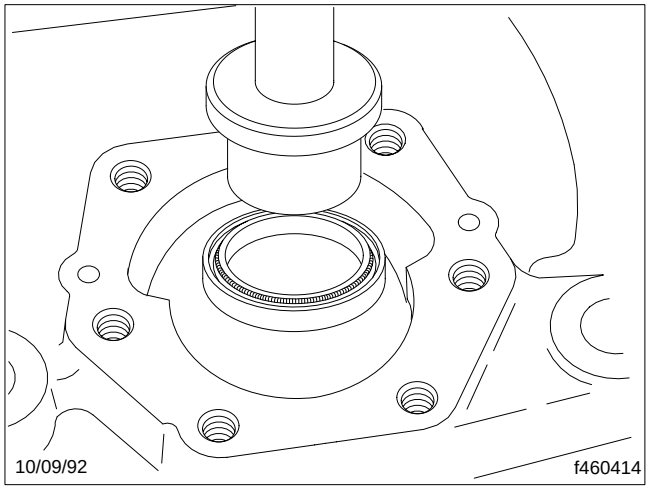

Fig. 86, Put a New Seal on the Tool

14.3 For a TAS40/55/65 steering gear, lightly oil the short bearing end of the sector shaft.

For a TAS85 steering gear, heavily grease the short bearing end of the sector shaft.

Insert the sector shaft into the side cover. Screw the sector shaft adjusting screw counterclockwise into the side cover until the screw seats. See **Fig. 87**. Then rotate the adjusting screw clockwise one turn so that the side cover rotates freely on the sector shaft.

14.4 Install the sector-shaft adjusting screw jam nut onto the sector-shaft adjusting screw a few threads. See **Fig. 88**. Final adjustment will be made later.

14.5 Press a new rubber plug into the hole provided in the side cover until the plug is flush. See **Fig. 89**.

15. Install the sector shaft/side cover assembly.

15.1 Apply clean grease to a new side cover gasket and install it on the side cover. See **Fig. 90**. Apply enough grease to hold the gasket in place.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

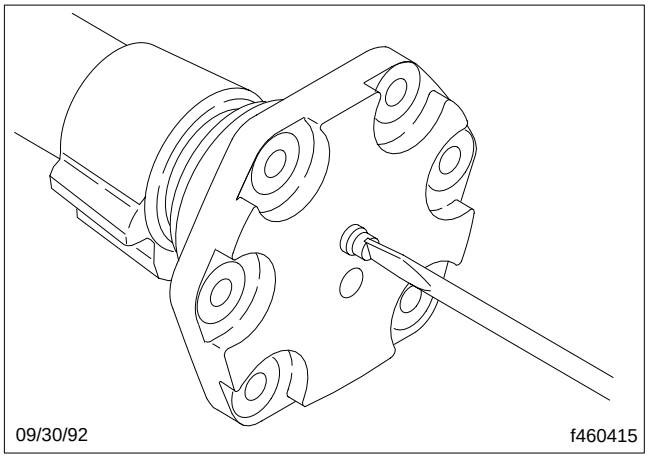

Fig. 87, Screw the Sector Shaft Adjusting Screw into the Side Cover

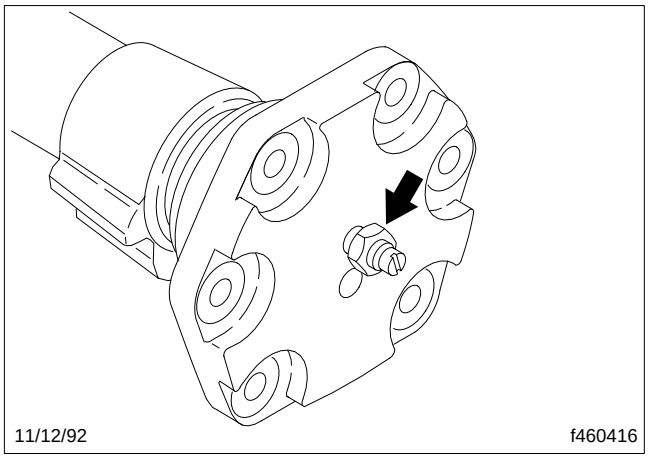

Fig. 88, Install the Jam Nut Onto the Sector-Shaft Adjusting Screw

15.2 There are four teeth on the rack piston. Turn the input shaft as needed to position the rack piston so that the tooth space identified by the pencil in **Fig. 91** (it is the third space between the second and the third tooth), is in the center of the sector shaft opening. See **Fig. 92**. This will center the rack piston in the opening.

15.3 Remove all tape from the sector shaft splines. Retape the splines and the bolt groove with **one** layer of masking tape.

15.4 Install the sector shaft and side cover as an assembly in the gear housing. See **Fig. 93**. Make sure the center tooth of the

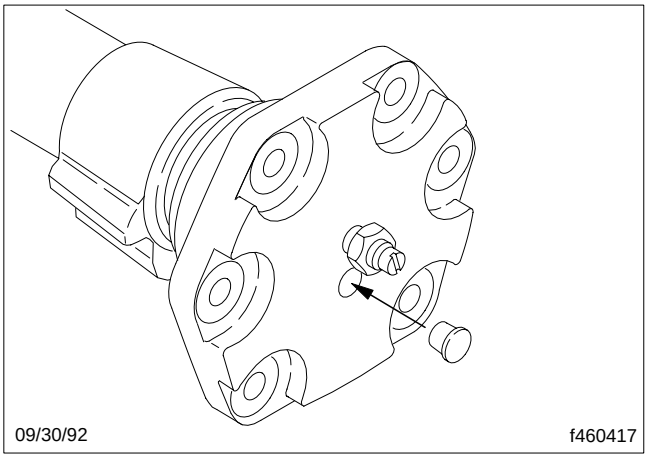

Fig. 89, Install a New Plug into the Side Cover

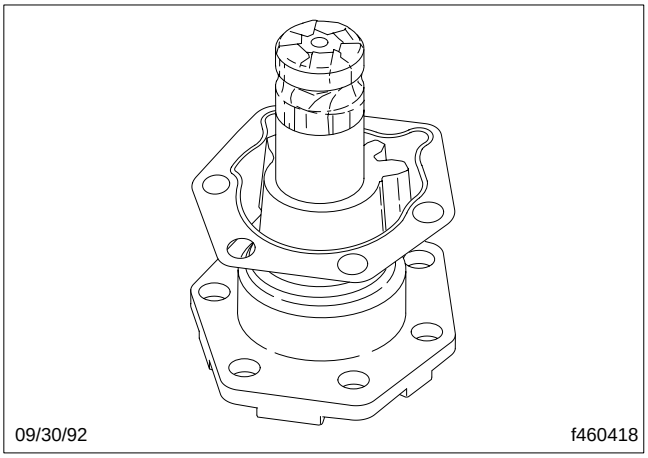

Fig. 90, Install a New Gasket on the Side Cover

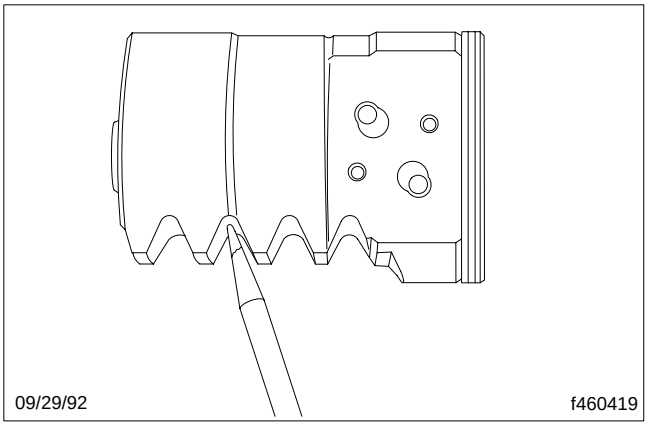

Fig. 91, Positioning the Rack Piston

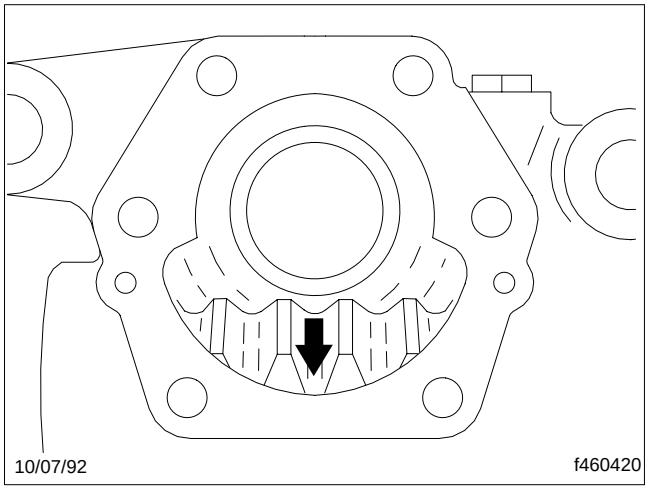

Fig. 92, Positioning the Rack Piston

sector engages the center space (between the second and third teeth) of the rack piston.

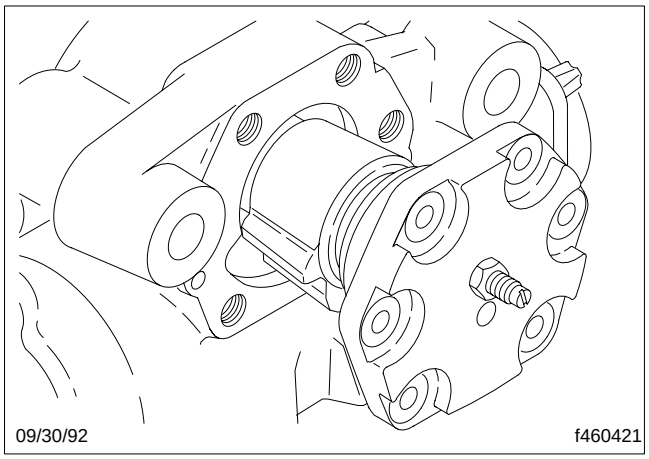

Fig. 93, Install the Sector Shaft/Side Cover Assembly in the Gear Housing

15.5 Install the special side cover bolts in the side cover. Using the torque pattern shown in **Fig. 94** or **Fig. 95**, tighten the bolts using one of the following torque specs:

- 118 lbf·ft (160 N·m) for lubricated bolts or 160 lbf·ft (217 N·m) for dry bolts on a TAS40 steering gear
- 170 lbf·ft (230 N·m) for lubricated bolts or 230 lbf·ft (312 N·m) for dry bolts on a TAS55/65/85 steering gear

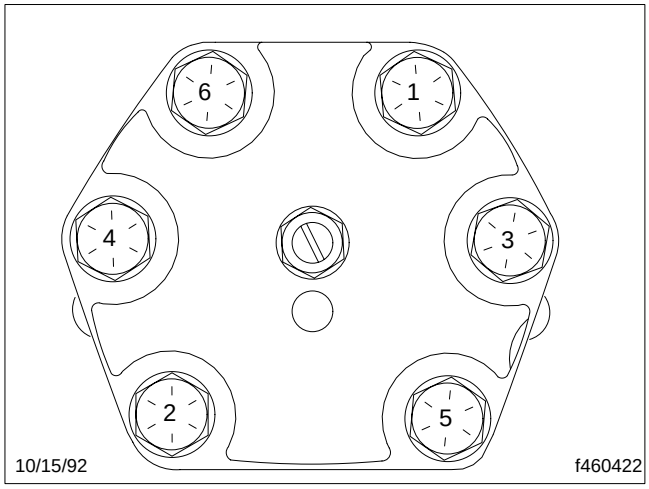

Fig. 94, Tightening Sequence

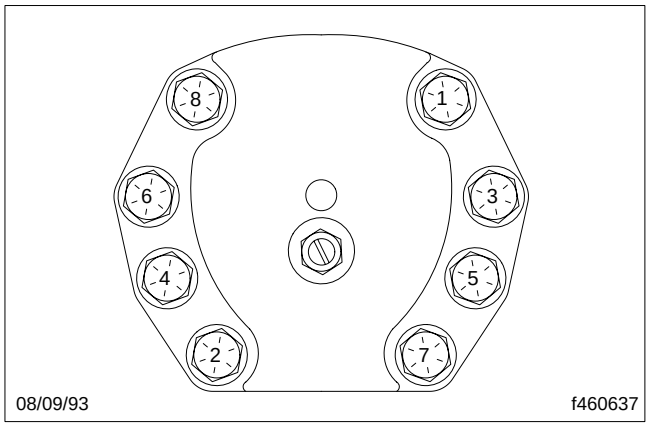

Fig. 95, Tightening Sequence

16. Install the sector shaft seal.

    Remove the tape from the sector shaft and pack the end of the housing trunnion area at the sector shaft with Mobil Temp 1 or 2 grease or equivalent. Put grease on the new trunnion dirt seal and install it over the sector shaft and into the trunnion bore. See **Fig. 96**.

17. Install the input shaft seals and retaining ring.

    IMPORTANT: Make sure the input shaft seal is installed squarely in the seal bore.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

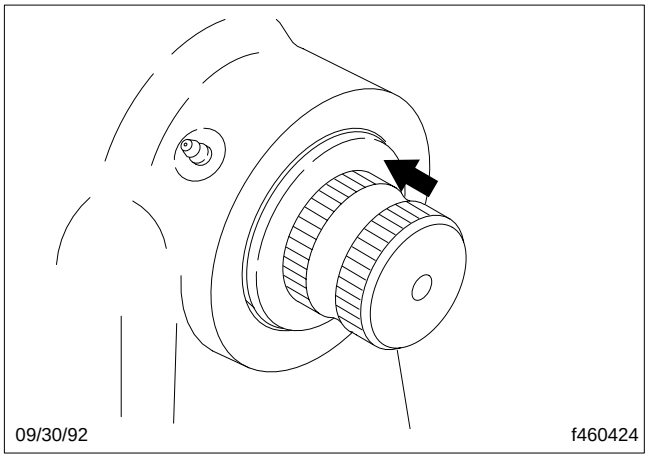

Fig. 96, Install the Sector Shaft Seal

17.1 Apply clean grease to the new input shaft seal. Then place it—garter spring side first—over the input shaft. Using special tool J37073 and a mallet, tap the seal installer tool until the tool shoulder is square against the valve housing. See **Fig. 97**. Remove any seal material that may have sheared off in the retaining groove.

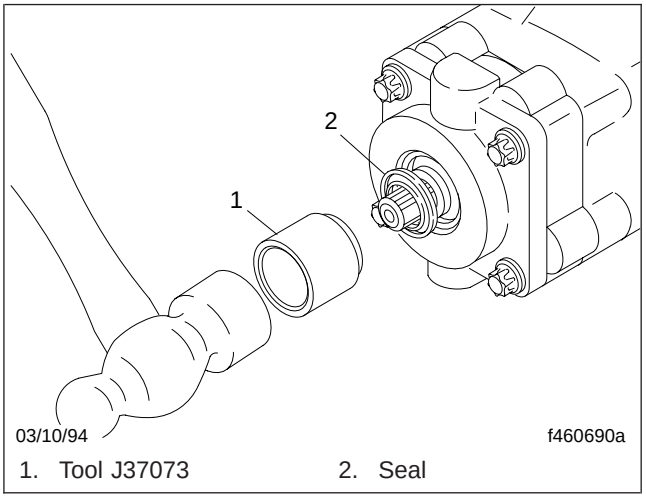

Fig. 97, Tap the Seal Installing Tool Against the Valve Housing

17.2 Install a new retaining ring into its groove in the valve housing. See **Fig. 98**.

17.3 Pack the end of the valve housing bore (around the input shaft) with Mobil Temp 1 or 2 grease or equivalent. Apply grease to the new dirt and water seal and install it

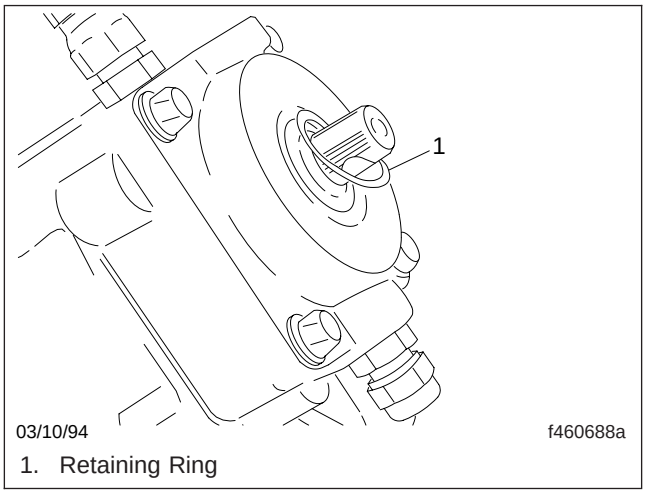

Fig. 98, Install a New Retaining Ring

over the input shaft. Seat the dirt and water seal in the groove behind the serrations of the input shaft and against the valve housing. See **Fig. 99**.

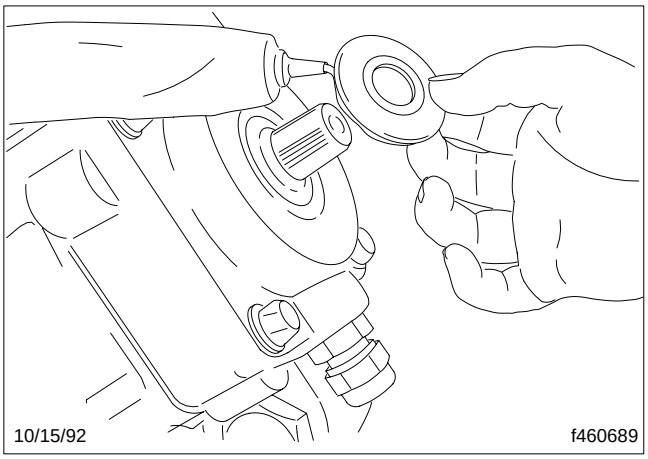

Fig. 99, Install the Dirt and Water Seal

18. Install the grease fitting and auxiliary port plug.

18.1 If the grease fitting is being replaced, install a new one in the gear housing using a piece of metal tubing over the head of the new fitting as shown in **Fig. 100**. Tap the new grease fitting in place.

18.2 If the auxiliary port plugs were removed, install new O-rings on them and install the plugs in the gear housing. Tighten them 25 to 35 lbf·ft (34 to 47 N·m).

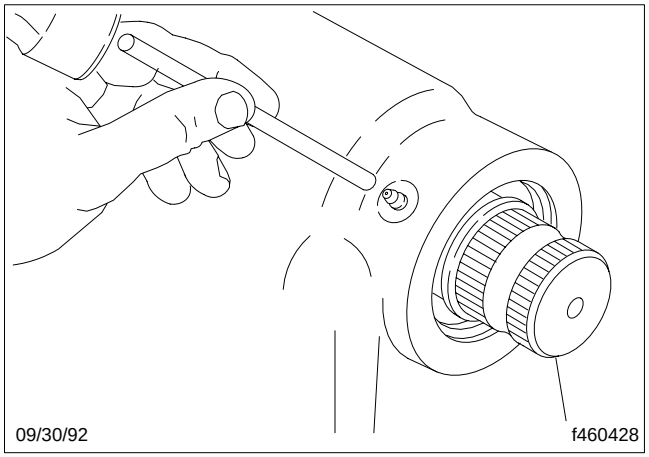

Fig. 100, Tap the Grease Fitting in Place

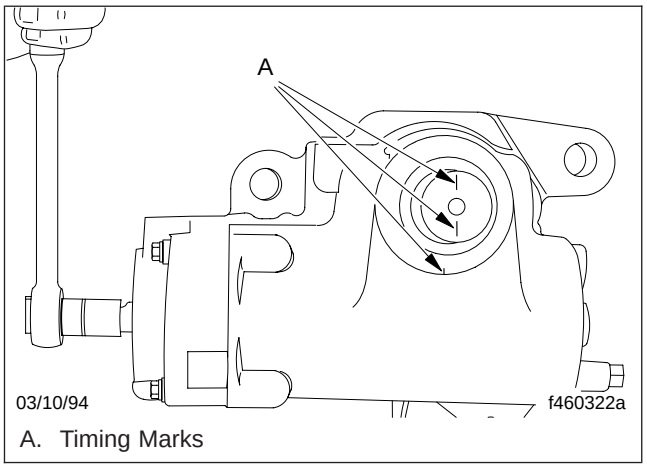

Fig. 101, Line Up the Timing Marks

Final Adjustments

Before installing the steering gear on the vehicle, make these adjustments.

NOTE: Worm shaft preload adjustment was done when the input shaft was installed in the valve housing during the assembly procedure.

1. Adjust the sector shaft preload.

   1.1 Center the steering gear by turning the input shaft until the timing mark on the end of the sector shaft is in line with the timing mark on the end of the housing trunnion. See **Fig. 101**. Use a 12-point, 11/16 or 3/4 inch socket wrench to turn the input shaft. If the input shaft is turned more than 1-1/2 turns from the center position, you will have to either disassemble the gear to adjust the poppets again or install the special poppet adjusting screw kit 021407-X1.

   NOTE: If new or reset poppets are in the gear, they will be moved when the input shaft is turned less than one rotation in either direction from the center position. This will not affect the function of the poppets.

   1.2 With the adjusting screw nut loose, adjust the sector shaft adjusting screw while turning the input shaft 180 degrees each side of center until the input shaft reaches a torque of 45 to 50 lbf·in (500 to 560 N·cm). See **Fig. 102**. Use a 12-point socket and an inch-pound torque wrench to turn the input shaft.

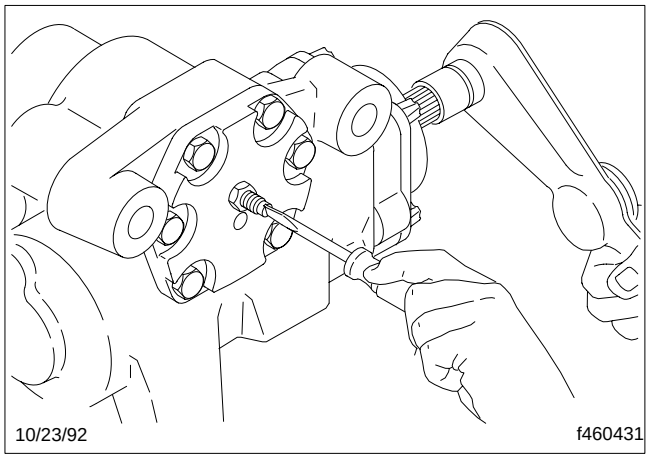

Fig. 102, Adjust the Sector Shaft Adjusting Screw

   1.3 Back out the sector shaft adjusting screw one-half turn. Note the torque needed to turn the input shaft through 180 degrees each side of center.

   1.4 Tighten the sector shaft adjusting screw so that the torque noted in the above substep is increased by 6 to 8 lbf·in (60 to 100 N·cm). Then, while holding the adjusting screw in place, tighten the sector shaft adjusting screw jam nut 40 to 45 lbf·ft (54 to 61 N·m).

2. Check the torque needed to turn the input shaft. If it is more than 40 lbf·in (452 N·cm), readjust the input shaft.

Removal

1. Disconnect the return line from the steering gear and plug the line. See **Fig. 1**. Also cap the return port of the gear with a high pressure fitting.

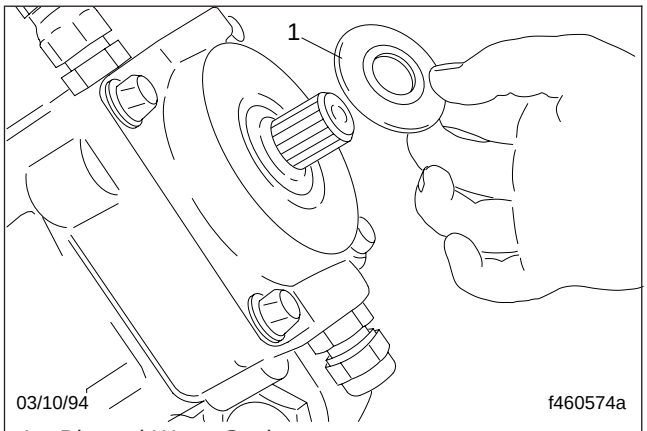
A. Cap the return line and the return port.

Fig. 1, Disconnect the Return Line

2. Disconnect the steering driveline from the steering gear input shaft.

   2.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

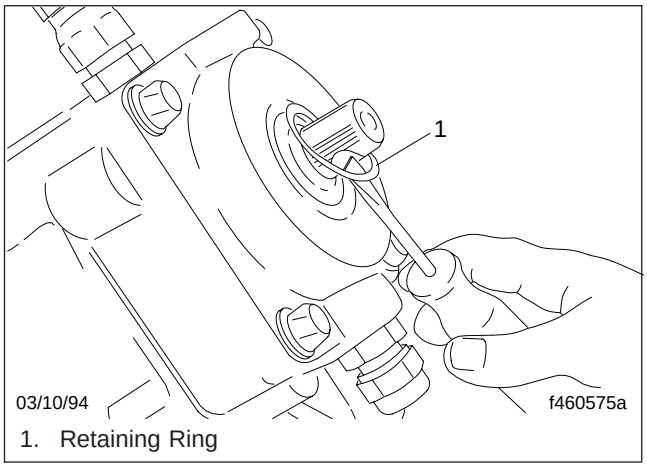
CAUTION



Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

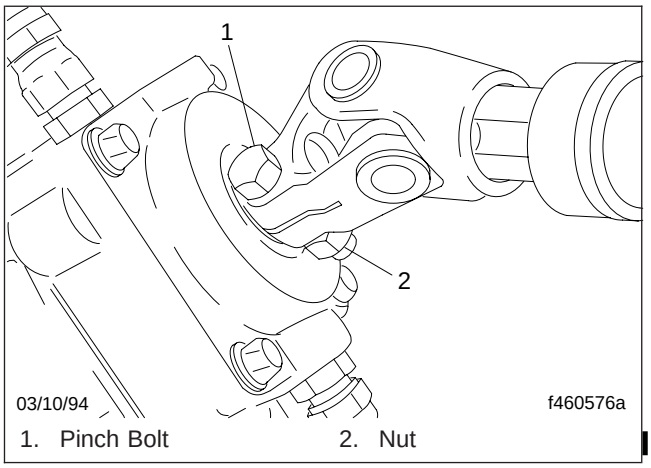
   2.2 Remove the lower end yoke from the input shaft. Do not turn the steering gear input shaft when removing the lower end yoke. Push the driveline shaft into the driveline tube as you remove the lower end yoke.

3. Remove the dirt and water seal from the steering gear. See **Fig. 2**.



4. Wipe out the grease and then remove the spiral retaining ring. See **Fig. 3**. Use a screwdriver inserted into the notch formed in the end of the ring.

5. Slip the input yoke back on the input shaft with the pinch bolt installed but not tightened. **Fig. 4**

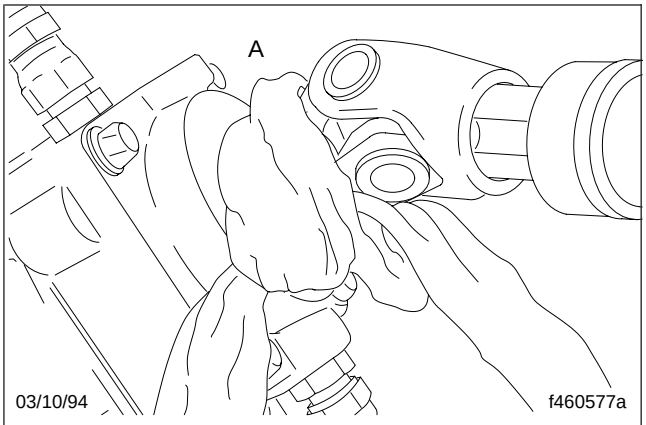


1. Dirt and Water Seal

Fig. 2, Remove the Dirt and Water Seal

1. Retaining Ring

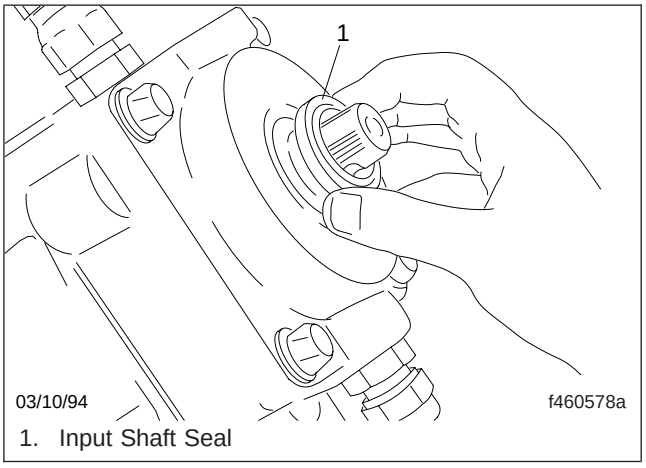
Fig. 3, Remove the Retaining Ring



1. Pinch Bolt 2. Nut

Fig. 4, Install the Pinch Bolt

Input Shaft Seal Removal and Installation

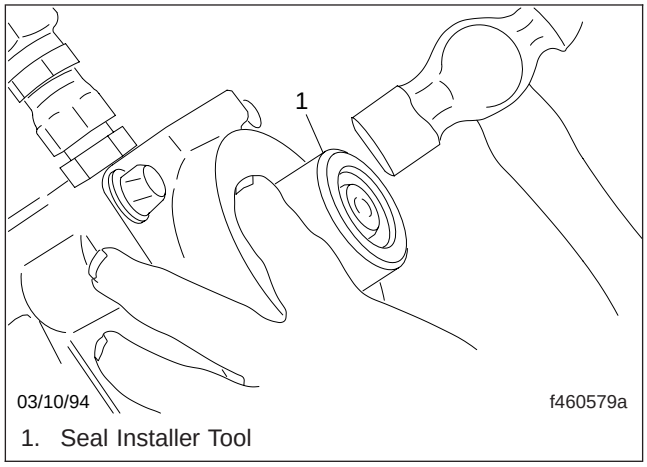


6. Tie or wrap a shop towel around the input shaft area and place a drip pan under the vehicle to catch the oil. See **Fig. 5**.

A. Cover the input shaft area.

Fig. 5, Shop Towel Covering the Input Shaft

7. Add the power steering fluid specified in **Specifications 400** as necessary to the fill line on the dipstick.
8. With the vehicle in neutral, momentarily turn the starter (quickly turn off the engine if it starts).
9. Remove the shop towel, pinch bolt, and input yoke.
10. Remove the seal. See **Fig. 6**.

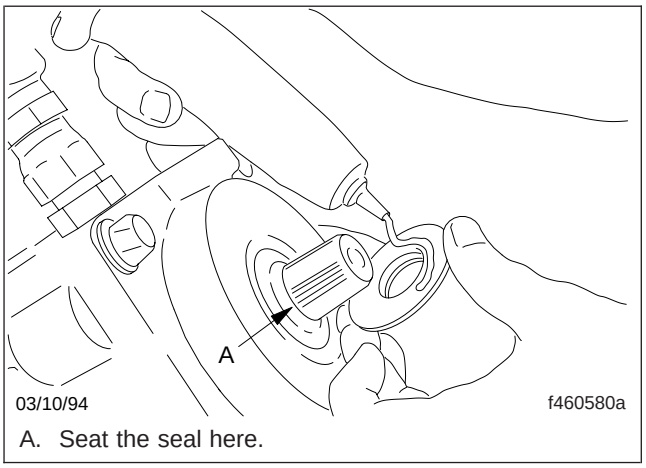


1. Input Shaft Seal

Fig. 6, Remove the Input Shaft Seal

11. Check the seal area of the valve housing for any seal fragments. Remove any that are found.
12. Check the seal for heat damage. If the seal is stiff, brittle, and not pliable like the new seal, it is probably heat damaged. You need to determine and fix the cause of excessive heat in the vehicle. For troubleshooting procedures, see **Section 46.11, Subject 300**.

Installation



1. Put clean grease on the new input shaft seal and place it over the input shaft, garter spring side first. See **Fig. 6**. Place seal installer tool J37073 over the input shaft and against the seal, small diameter end first. See **Fig. 7**. Tap the seal installer tool until the tool shoulder is square against the valve housing. Remove any seal material that may have sheared off in the seal bore or retaining ring groove.

1. Seal Installer Tool

Fig. 7, Position the Seal Installer Tool

2. Insert the new retaining ring into the groove.
3. Pack the end of the valve housing bore around the input shaft with clean high temperature industrial grease (Mobil Temp 1 or 2 or equivalent). Apply more of the grease to a new dirt and water seal and install it over the input shaft. See **Fig. 8**. Seat it in the groove behind the serrations and against the valve housing.
4. Connect the steering driveline to the steering gear input shaft.
   4.1 Clean the input shaft and the inside of the driveline yoke.

A. Seat the seal here.

Fig. 8, Install the Dirt and Water Seal

4.2 Apply a thin film of grease to the yoke splines. Use lithium-based grease, NLGI grade 2.

4.3 Slide the yoke on the input shaft and install the a new pinch bolt. Before installing the nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new nut and tighten it to one of the following torque specs:

- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

4.4 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and to the nut.

5. Connect the return line to the steering gear return port.

6. Fill and bleed the steering system.

IMPORTANT: Do not turn the steering wheel in the following steps until instructed. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

6.1 Fill the power steering reservoir with the steering fluid specified in **Specifications 400** until nearly full.

Crank the engine for 10 seconds without allowing it to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed.

Repeat this procedure three times, each time checking and filling the reservoir.

6.2 Start the engine and let it idle for two minutes. Shut down the engine and check the fluid level in the reservoir.

6.3 Start the engine again. Steer the vehicle from full left to full right several times. As needed, add fluid to the full line on the reservoir dipstick.

Post-Service Checks |

After power steering components have been worked on and before the vehicle is placed into service, make the following checks.

⚠ WARNING

Failure to make the following checks could result in damage to the power steering system. This could cause a loss of hydraulic assist, which could cause personal injury or property damage.

1. With the engine turned off and warm, check the power steering reservoir fluid level.
2. Check for air in the system.
   - 2.1 Place a thermometer in the power steering reservoir. Then warm the hydraulic system to normal operating temperature of 125° to 135°F (51° to 57°C) by operating the engine at low idle while turning the steering wheel through several full-left and full-right turns.
   - 2.2 With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level (a sign that air is trapped in the system). If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as needed. Bleed the air from the system.
3. At full-left and full-right wheel cuts, be sure the axle stops (on the rear-side of the spindle) are set so there is at least 1/2-inch (13-mm) clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be 3/4 inch (19 mm). If clearance is less than this, reset the axle stops.
4. Check that the automatic poppets or the manual poppet adjusting screw (if equipped) are set correctly. If needed, adjust them. For instructions, see **Subject 100**.
5. If there are still problems with the power steering system, see **Section 46.11, Subject 300**. Otherwise, go to the next step.
6. Test drive the vehicle or take a ride with the driver.

   Check the steering wheel spoke position. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 1**. If they are not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

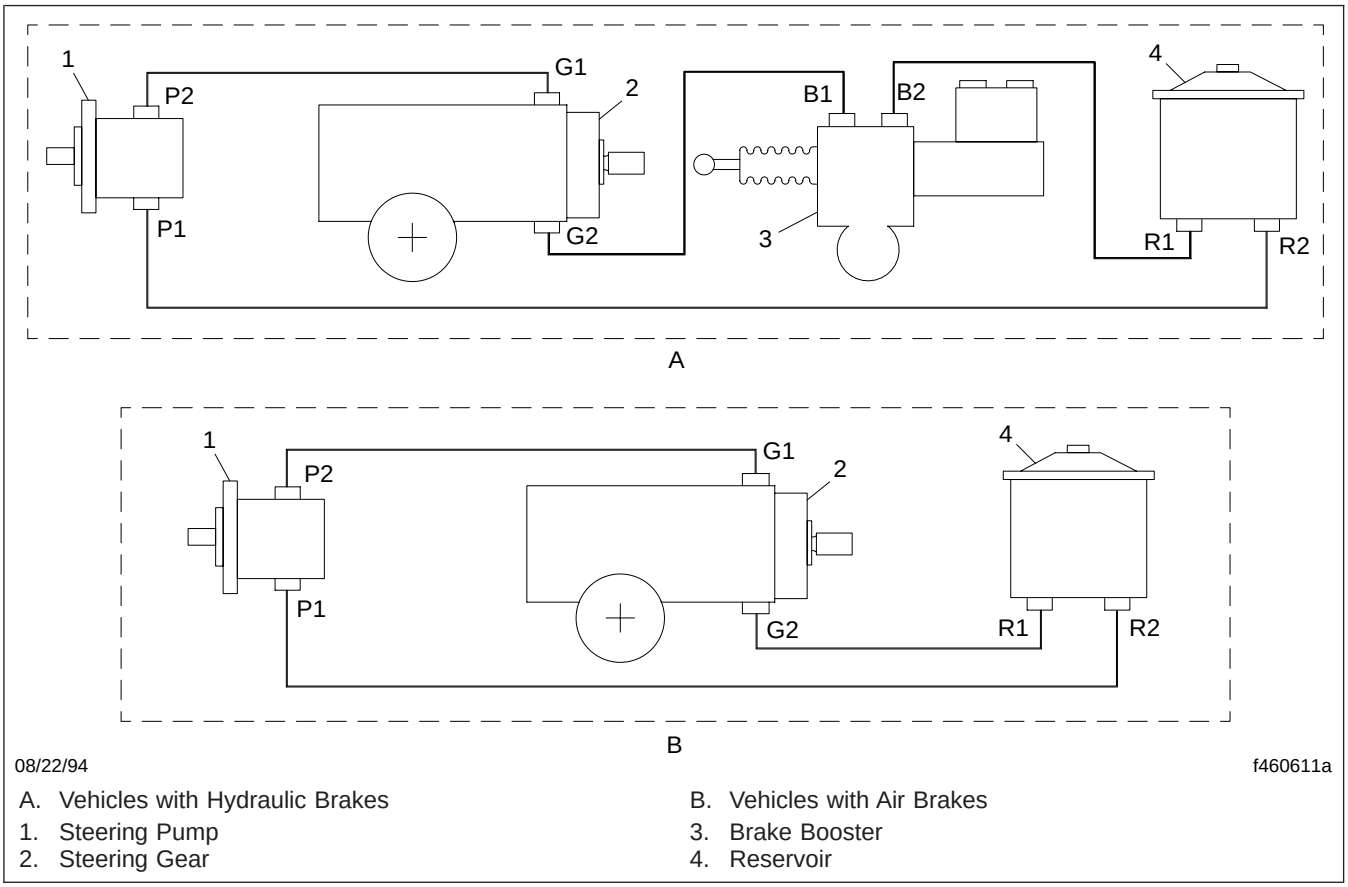
⚠ WARNING

Fill only with approved clean power steering fluid. Any mixture or any unapproved fluid could lead to seal deterioration and leaks. Any fluid leak could eventually cause loss of power steering assist.



Approved Power Steering Fluids	
Fluid Type	**Approved Fluid**
Automatic Transmission Fluid*	Dexron® II Dexron® III
Heavy-Duty Engine Oil* IMPORTANT: Do not use heavy-duty engine oil in vehicles built from November 4, 2002. **⚠ WARNING** **Do not use heavy-duty engine oil in vehicles equipped with a Hydro-Max® brake booster. Engine oil is not compatible with the seals in the brake booster. If the vehicle is equipped with a Hydro-Max brake booster, use only automatic transmission fluid in the power steering system. Failure to follow this precaution could cause loss of hydraulic brake assist, possibly resulting in personal injury and property damage.**	Union 10W–40 Texaco 10W–40 Chevron 10W–40 Mobil Super 10W–40 Union 15W–40 Shell Rotella T 30W

* Do not mix engine oil with automatic transmission fluid (ATF). Use the same lubricant for parts as is in the power steering system.

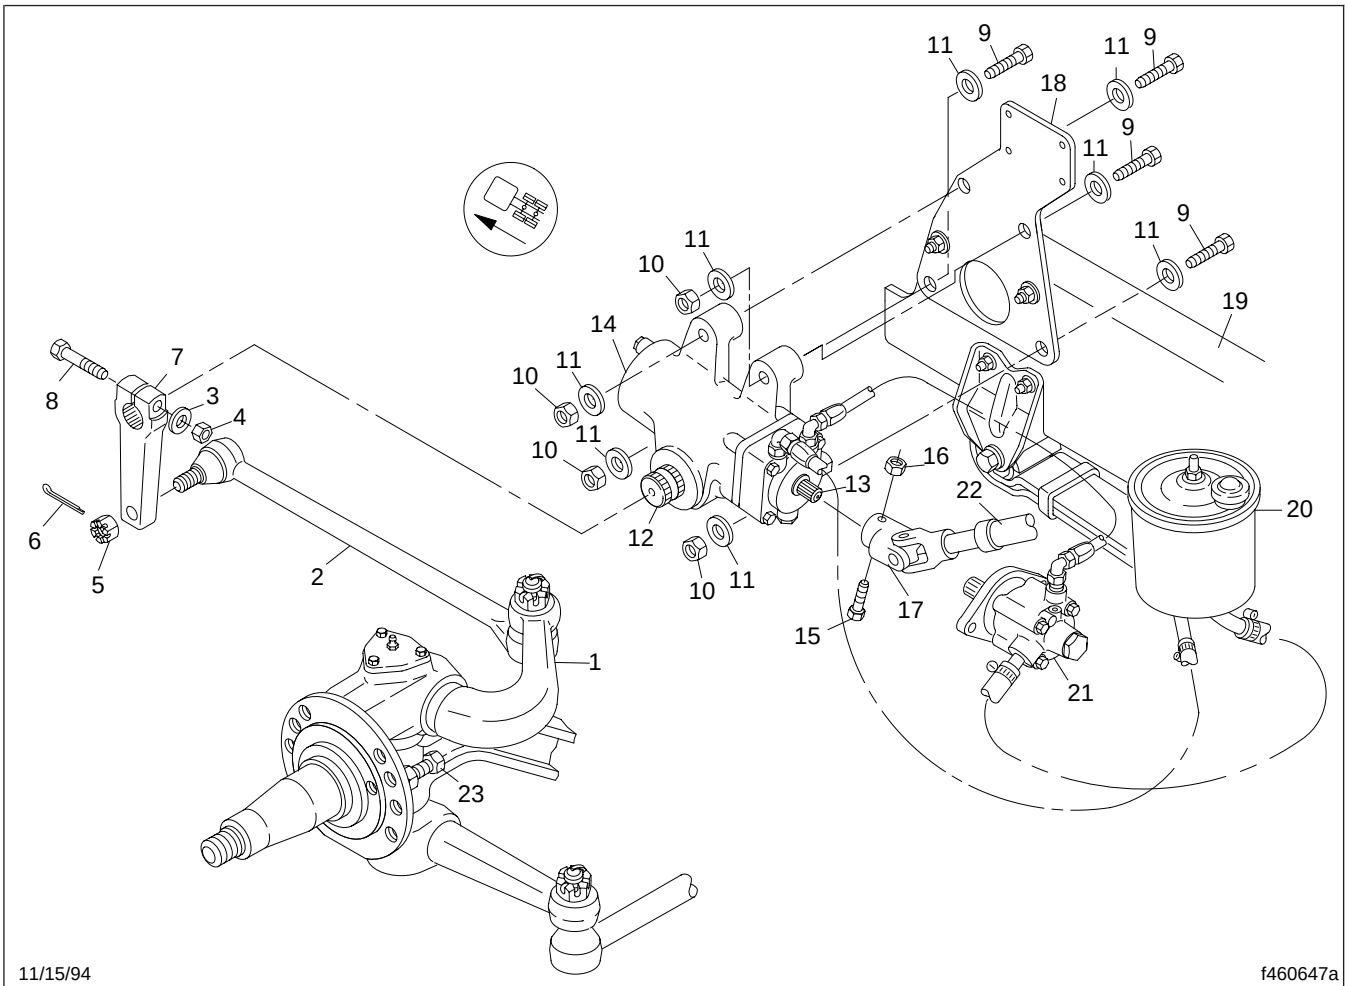
Fig. 1, Steering System Plumbing Diagram

General Information

The TRW HFB70 power steering gears can be installed on vehicles with front axle capacities up to 16,000 pounds (7257 kg). The steering gear is mounted on the vehicle frame rail. The steering gear incorporates a manual steering mechanism, hydraulic control valve, and a hydraulic power cylinder. The control valve is a rotary design, which directs oil flow from the power steering pump to the upper or lower cylinder cavity. See **Fig. 1**.

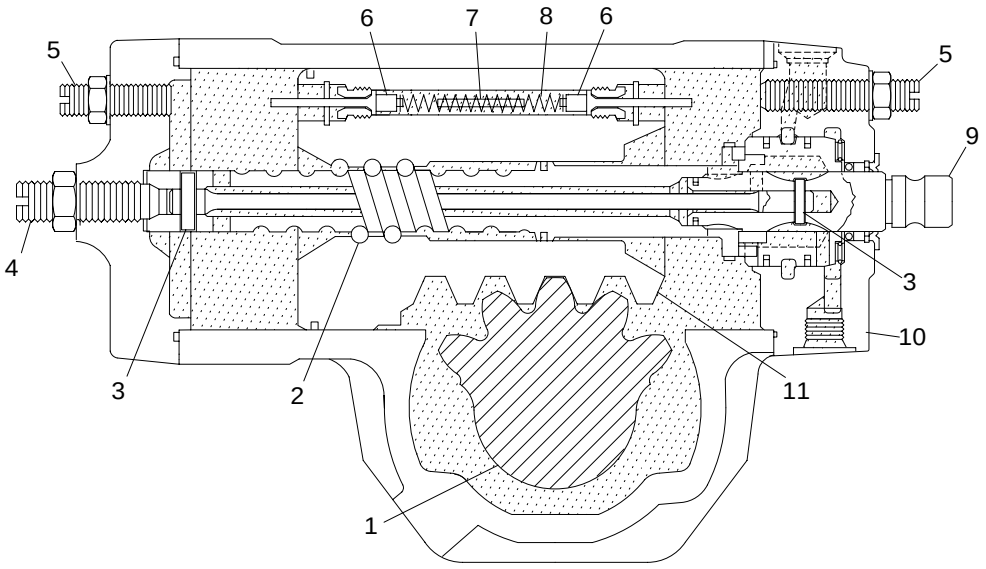
Principles of Operation



When the steering wheel is turned, force is transmitted from the steering wheel to the steering gear input shaft. A torsion bar, pinned at one end to the input shaft and at the other to the worm shaft, turns with the input shaft and exerts a rotational force on the worm shaft. In response, the worm shaft, acting through the recirculating ball mechanism, tries to move the rack piston up or down (as applicable) in the gear housing cylinder bore. See **Fig. 2**.

The movement of the rack piston is resisted by its engagement to the sector shaft, which is linked to the steered wheels. Because of this resistance, the torsion bar is twisted by the input shaft, thereby actuating the control valve. Pressurized fluid, directed by the control valve to the upper or lower cylinder cavity (depending on the direction or turn), assists in moving the rack piston up or down in the cylinder bore. The rack piston then turns the sector shaft to steer the vehicle.

If the steered wheels receive a shock load, the shock forces are transmitted through the sector shaft to the rack piston and on to the worm shaft. The internal construction of the steering gear causes the control valve to send high-pressure fluid to the correct cylinder cavity to resist the shock forces. By absorbing the shock forces hydraulically, the steering gear prevents kickback at the steering wheel.



On each end of the rack piston is a poppet (unloading valve). The appropriate poppet will trip as the steered wheels approach the axle stop for that direction of turn. The tripped poppet reduces pressure in the gear, heat generated by the pump, and outside forces acting on the steering linkage.

Sector Shaft Adjustment

1. Position the sector (output) shaft at its center of travel by turning the steering wheel until the alignment mark on the sector shaft is at a right angle to the input shaft centerline, and in line with the timing mark on the end of the housing trunnion. See **Fig. 1**.

1. Sector Shaft Timing Mark
2. Housing Trunnion Timing Mark

Fig. 1, Align the Timing Marks

2. Disconnect the drag link from the pitman arm. For instructions, refer elsewhere in this group.
3. With the sector shaft centered, grasp the pitman arm and gently try to move it back and forth. Fingertip force is adequate to detect lash (free play) of a loose sector shaft. See **Fig. 2**. There should be no movement of the input shaft or sector shaft. If there is no lash, no adjustment is needed.

   If there is lash, loosen the sector shaft adjusting screw jam nut and turn the adjusting screw clockwise until the sector shaft and rack piston are in contact. Use no more than 10 lbf·ft (14 N·m) of torque. Then turn the adjusting screw counterclockwise one turn. At this point, there should be lash at the pitman arm.
4. To adjust, slowly turn the adjusting screw clockwise until no lash is felt at the pitman arm. Hold the adjusting screw in place and tighten the jam nut 40 to 45 lbf·ft (54 to 61 N·m).

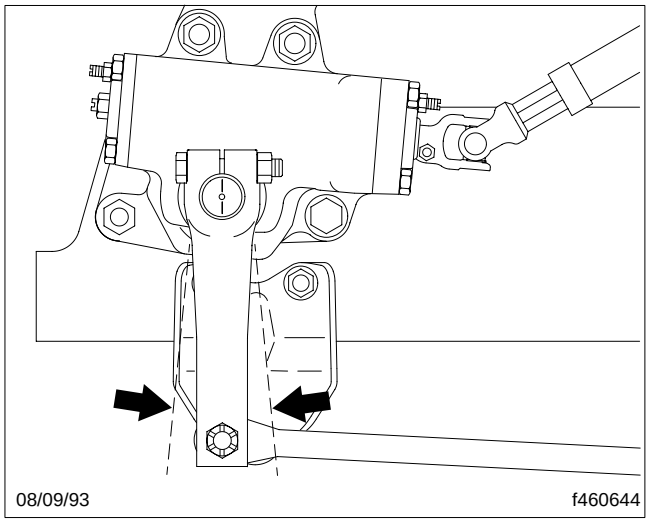

Fig. 2, Check the Free Play

5. Again check the pitman arm for lash. Turn the steering wheel one-quarter turn each side of center. No lash should be felt. If lash exists, readjust.
6. Connect the drag link to the pitman arm. For instructions, refer elsewhere in this group.

Poppet Valves Adjustment

1. Check the settings of the axle stops and adjust them if necessary. For instructions, refer to the front axle section in this manual.
2. Install a flow meter kit in the supply line from the pump to the steering gear. Make sure that the flow meter can be pressurized. Warm the power steering fluid to an operating temperature of 125° to 135°F (51° to 57°C).
3. Loosen both of the poppet valve adjusting screw jam nuts.
4. With the engine at idle, have someone turn the steering wheel to the full-lock right position. Check the pressure gauge.

⚠ CAUTION

If power steering pump relief pressure is reached while the steering wheel is at full lock, release the steering wheel from this position. Do not allow the pump relief pressure to be maintained for

In-Vehicle Adjustments

longer than five seconds, or damage to the pump may result.

IMPORTANT: When the steering wheel is at the full-lock position, make sure the stop screw on the back of the wheel spindle contacts the axle boss. Failure to maintain contact while adjusting the poppet valve could cause incorrect adjustment.

5. If the pressure gauge reading is less than 2000 psi (13 800 kPa), back out the poppet valve adjusting screw until the relief pressure reading is 1960 psi (13 514 kPa).

NOTE: The right-turn poppet valve adjusting screw is at the rear of the steering gear.

6. If system pressure exceeds the maximum pump relief pressure, repair the power steering pump. Refer elsewhere in this group for pump repair instructions.
7. Release the steering wheel from the full-lock right position enough to allow insertion of a 1/16- to 1/8-inch (1.6- to 3.2-mm) thick flatwasher between the axle beam and the right-side axle stop pin.
8. Bring the steering wheel back to the full-lock right position against the flatwasher. While holding the poppet valve adjusting screw jam nut in place with a wrench, immediately screw in the poppet valve adjusting screw until the pressure gauge reading drops by 200 to 400 psi (1379 to 2758 kPa).

   While holding the poppet valve adjusting screw in place, tighten the jam nut 12 to 18 lbf·ft (16 to 24 N·m).
9. With the engine at idle, have someone turn the steering wheel to the full-lock left position. Check the pressure gauge. Adjust the other poppet valve adjusting screw using the applicable steps above.

NOTE: The left-turn poppet valve adjusting screw is on the front of the steering gear.

Removal

IMPORTANT: Before removing the steering gear, see **Section 46.11, Subject 300** to identify the problem.

1. Verify correct axle stop adjustment. For instructions, refer to the front axle section in this manual. Ensuring correct axle stop adjustment now will eliminate the possibility of resetting steering gear poppet valves after the gear is reinstalled.
2. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where the work is to be done. Apply the parking brakes and chock the tires.
3. Remove the left-hand bumper extension.
4. Clean all outside dirt from around the fittings and hose connections.
5. Drain the power steering system. Disconnect all hydraulic lines from the gear, marking the lines for later assembly reference. Seal the lines and the fittings to keep out dirt.
6. Disconnect the pitman arm from the steering gear sector shaft. See **Fig. 1**.
   - 6.1 Remove and discard the pinch bolt, washer, and nut from the pitman arm.
   - 6.2 Using a suitable puller, remove the pitman arm and swing the pitman arm and drag link out of the way.
7. Disconnect the steering driveline from the steering gear input shaft.
   - 7.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

CAUTION

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

   - 7.2 Remove the lower end yoke from the input shaft.
8. Clean the entire assembly before removing the gear.

WARNING

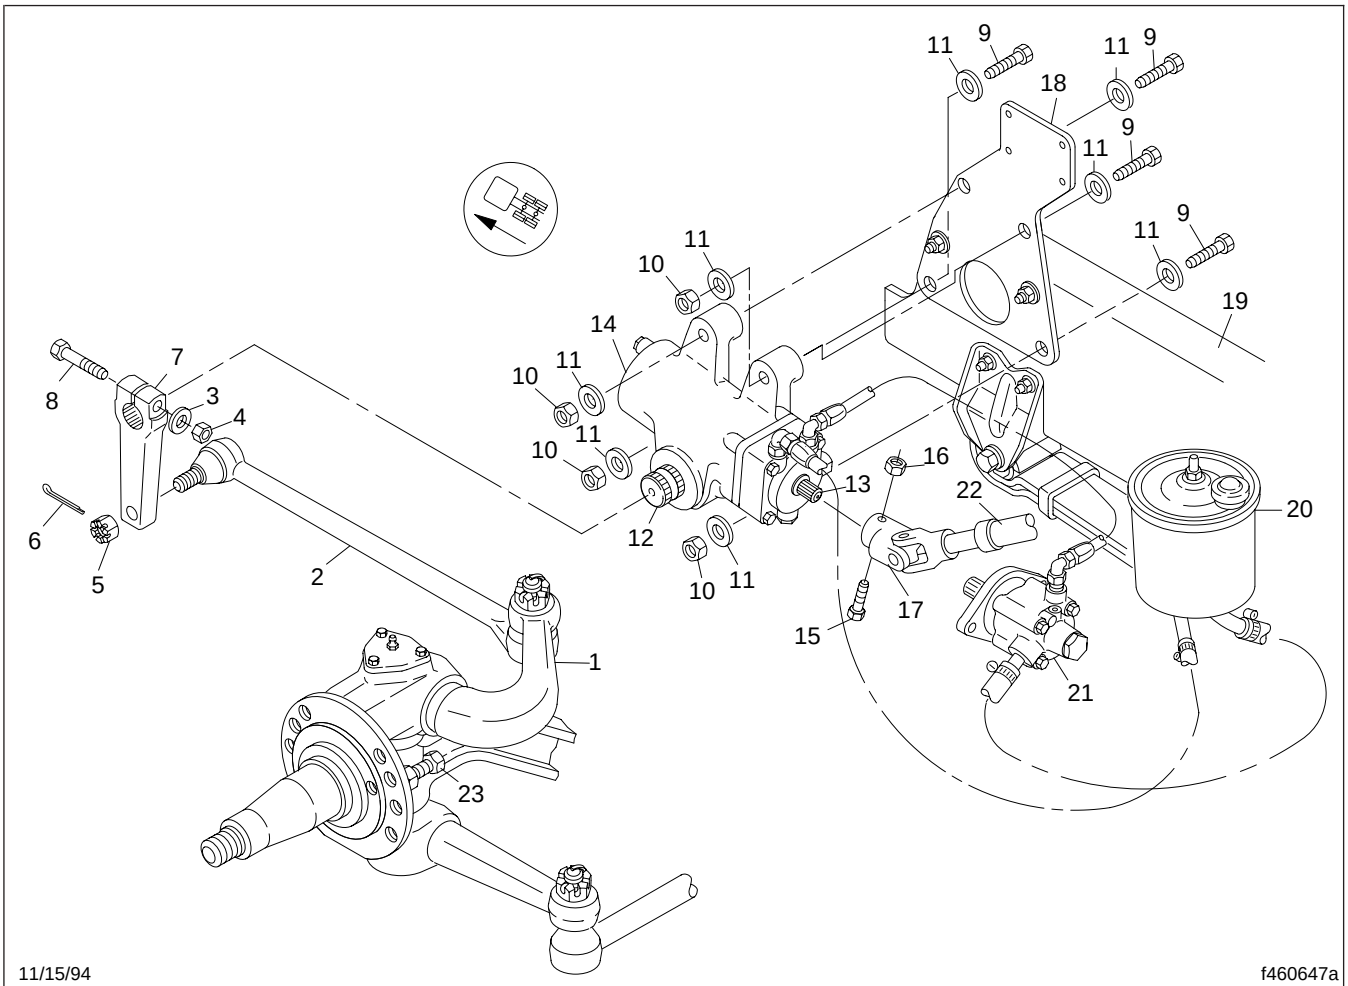
The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

9. Remove the fasteners that attach the steering gear to the frame rail. Remove the steering gear.

Installation

1. Install the steering gear and fasteners as shown in **Fig. 2**.

   Tighten the fasteners 427 lbf·ft (579 N·m).
2. If not previously done, center the steering gear. The sector (output) shaft alignment mark must be at a right angle to the steering gear input shaft centerline. Make sure the steering gear remains centralized as the service work continues.
3. Install the pitman arm.
   - 3.1 Position the pitman arm on the steering gear, aligning the timing mark as shown in **Fig. 3**.



WARNING

Never leave a chisel wedged in the pitman arm slot. When using a chisel to spread the slot in the pitman arm, maintain a firm grip on the chisel at all times. Otherwise the chisel may fly loose, which could cause an injury.

   NOTE: The pitman arm may not fit over the splines on the sector shaft without spreading the slot in the arm. Use a ball-peen hammer to drive a chisel into the slot. Hold the chisel in place. Install the pitman arm on the sector shaft. Remove the chisel from the slot.

   - 3.2 Install a new pinch bolt, washer, and nut. Tighten the nut 215 to 245 lbf·ft (292 to 332 N·m).
   - 3.3 Apply torque seal, OGP F900WHITE, to the exposed threads and to the nut.
4. Connect the steering driveline to the steering gear input shaft.
   - 4.1 Clean the steering gear input shaft and the inside of the driveline yoke.

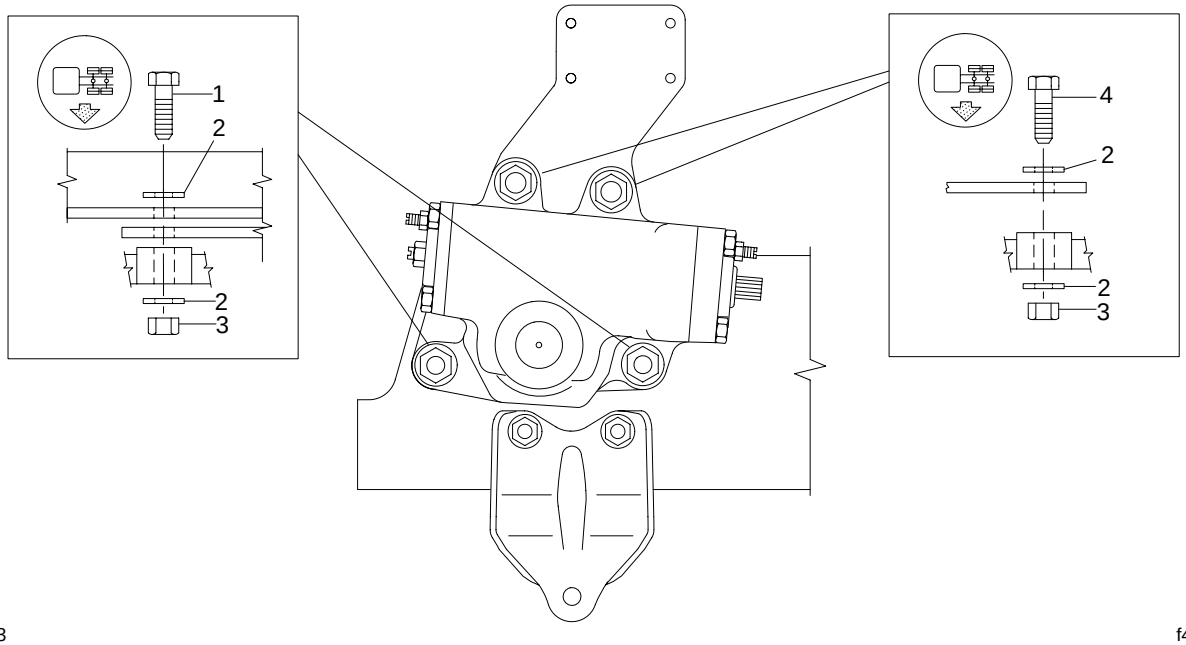
21. Power Steering Pump
22. Steering Driveline
23. Axle Stop

Fig. 1, TRW HFB70 Power Steering Installation

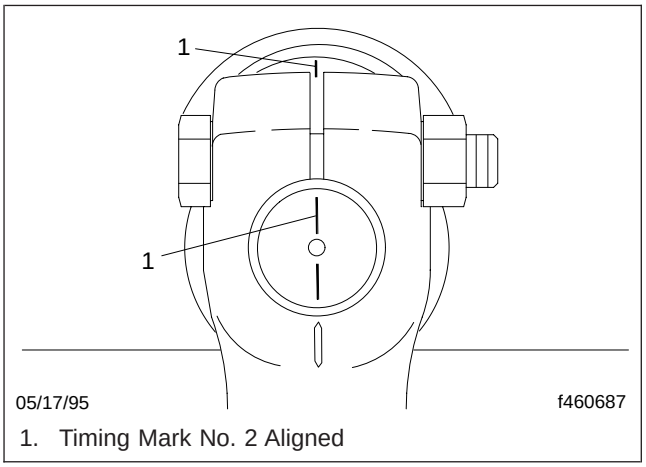
4.2 Apply a thin film of grease to the yoke spline.



4.3 Slide the yoke on the input shaft and install a new pinch bolt and nut. Tighten the nut to one of the following torque specs:

- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bot and nut

4.4 Apply torque seal, OGP F900WHITE, to the exposed threads and to the nut.



5. Connect the hydraulic lines.

5.1 If they were removed, attach the hydraulic line elbow fittings to the steering gear.

1. 7/8–14 x 4-1/2 Capscrew, Grade 8
2. 7/8 Inch ID Hardened Washer
3. 7/8–14 Nut
4. 7/8–14 x 4 Capscrew, Grade 8

Fig. 2, Steering Gear Mounting (top view)

1. Timing Mark No. 2 Aligned

Fig. 3, Typical Pitman Arm and Timing Marks

Tighten the fittings 38 lbf·ft (51 N·m). Tighten the pressure line fitting jam nut 41 lbf·ft (56 N·m).

5.2 Remove the plugs from the hydraulic lines. Connect the lines to the steering gear as previously marked. Tighten the nut on each fitting finger-tight. Then use a wrench to tighten the nut until there is firm resistance. Tighten one-sixth turn more.

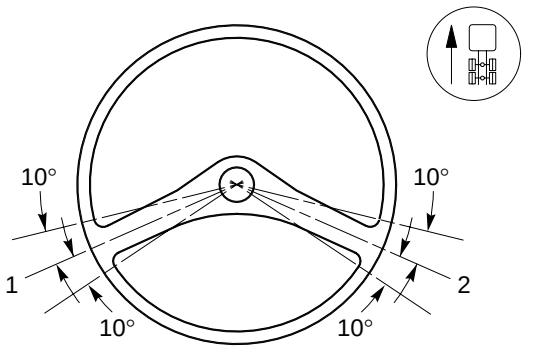
6. Fill and bleed the steering system.

   IMPORTANT: Do not turn the steering wheel until instructed in the following steps. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

   6.1 Fill the power steering reservoir with the steering fluid specified in **Specifications 400** until nearly full. Crank the starter for 10 seconds without allowing the engine to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed. Repeat this procedure three times, each time checking and filling the reservoir.

   6.2 Start the engine and let it idle for two minutes. Shut down the engine and check the fluid level in the reservoir.

   6.3 Start the engine again. Steer the vehicle from full left to full right several times. As



Steering Gear Removal and Installation

necessary, add fluid to the full line on the reservoir dipstick.

NOTE: Adjust the poppets following the procedure in **Subject 100**.

7. Go to **Subject 150** and do the checks as instructed.
8. Install the left-hand bumper extension.
9. Test drive the vehicle or take a ride with the driver.

   Check the steering wheel spoke position. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 4**. If not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

1. 8 o'Clock Position
2. 4 o'Clock Position

Fig. 4, Steering Wheel Centered

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

Disassembly

IMPORTANT: The special tools required for disassembly and assembly of the steering gear parts are available from SPX Kent-Moore or an affiliated dealer. See the special tools Table in **Specifications 400** to be sure that you have the required tools before beginning the service procedures.

Make sure that the steering gear is placed on a clean surface. Clean and dry the gear before disassembly. As the gear is disassembled, clean all parts in a clean, petroleum-based solvent, and blow-dry them only.

Keep each part separate to avoid nicks and burrs. Discard all seals, O-rings, and gaskets, and replace them with new parts.

See **Fig. 1** for an exploded, assembly drawing.

1. Clamp the gear mounting bosses in a vise, so that the gear's input shaft is horizontal. Rotate the input shaft to position the alignment mark on the sector shaft halfway between two trunnion cover bolts and pointing up. See **Fig. 2**.
2. Remove and discard the pinch bolt and nut from the pitman arm. Using a suitable puller, remove the pitman arm.
3. Remove the protective boot, the grease fittings, and the dirt and water seal from the trunnion cover. See **Fig. 3**. Discard the boot and the seal.
4. Using a fine grade of emery paper, remove any paint or corrosion from the nonserrated area of the sector shaft. Loosen the sector shaft adjusting screw jam nut.
5. Remove the four trunnion cover bolts and washers. See **Fig. 4**. Remove the trunnion cover. Remove and discard the trunnion cover O-ring, the Teflon® backup washer, and the two-piece sector shaft seal. See **Fig. 5**.
6. Tape the serrations and bolt groove of the sector shaft, using **one**layer of masking tape. See **Fig. 6**.
7. Prepare for fluid to drain, then remove the eight special bolts from the side cover.

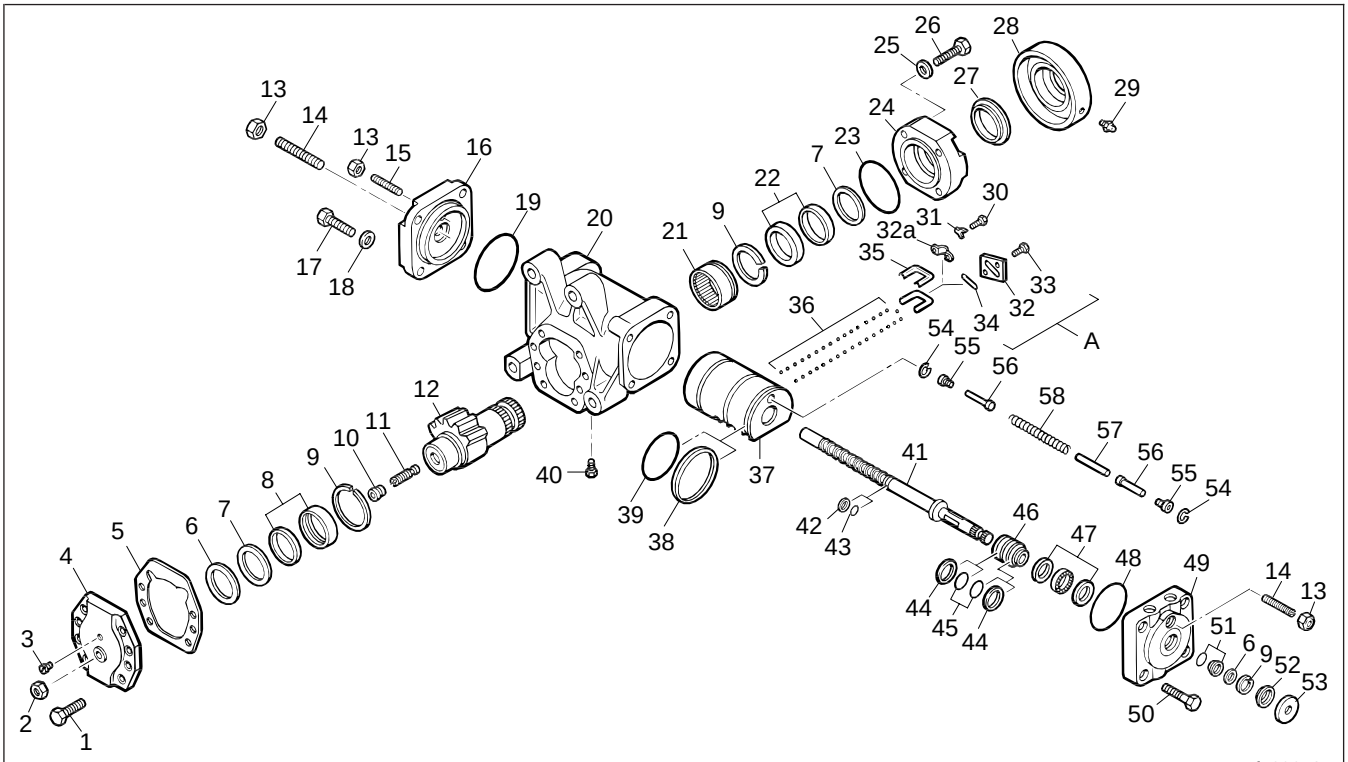
IMPORTANT: These special bolts are equipped with either a ring or washer-design on the underside of the head. See **Fig. 7**. If replacing one or more bolts, use bolts that are the same **type and length** as those that were removed. Do not use substitutes.

8. Begin to remove the side cover and sector shaft as an assembly. See **Fig. 8**. As a means of starting the removal of the side cover and sector shaft assembly, a soft hammer or wooden handle may be used. Stop removal when the bearing rolls in the housing bearing are half exposed. Coat the bearing rolls with grease. See **Fig. 9**.

IMPORTANT: Be sure that no rolls are lost during disassembly. If one or more of the rolls is lost, the entire bearing must be replaced. If the bearing is identified as BR-970, there are 41 rolls. If the bearing is identified as BR-970-1, there are 42 rolls.

NOTE: The housing bearing may have caged (retained) rolls, which do not require special precautions. However, if the bearing rolls are not caged, remove this assembly slowly or it may come out too quickly to allow the bearing rolls in the housing bearing race to be retained. Follow the shaft end with bearing tool J26743 to retain the rolls, or when the rolls are half exposed, coat them with grease to retain them in the housing bearing. See **Fig. 9**.

NOTE: The number on the housing bearing may not be visible while it is in place.



9. Finish removing the side cover and sector shaft as an assembly. Remove and discard the side cover gasket.
10. If the housing bearing race is damaged or if one or more of the rolls are lost, replace the housing bearing.

    10.1 Using bearing mandrel J26743, apply pressure from the side cover opening and press the bearing and retaining ring out through the trunnion cover opening and away from the cylinder bore.

    NOTE: Maintain firm, square contact between the housing and the base of the press to avoid damaging the housing bearing bore.

    10.2 Remove the retaining ring from the bearing and discard the bearing.

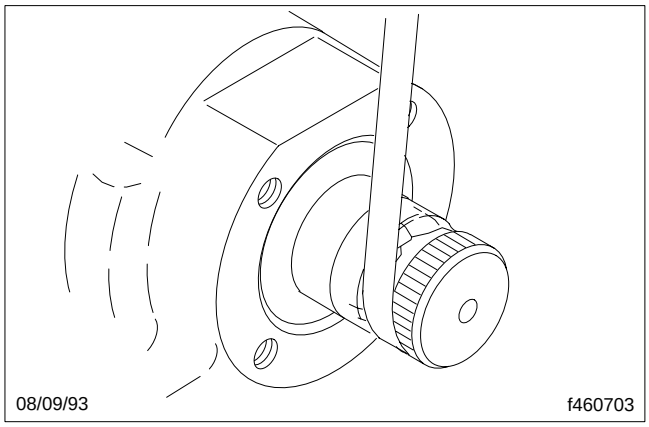

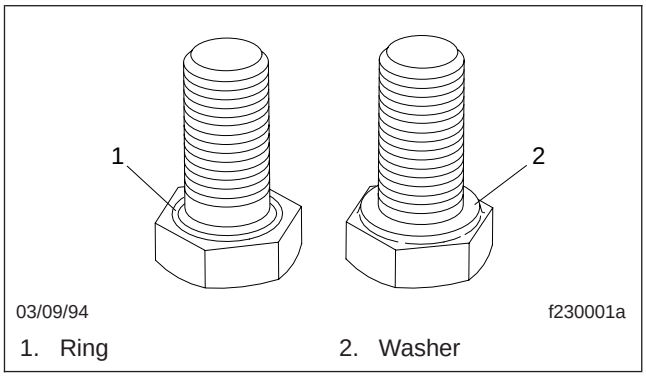

Fig. 6, Tape the Serrations and Bolt Groove

1. Ring
2. Washer

Fig. 7, Bolts With Ring or Washer

11. Remove the sector shaft adjusting screw jam nut.
12. Screw the sector shaft adjusting screw through the side cover. See **Fig. 10**. Place the side cover exterior side down and lift the sector shaft out vertically. See **Fig. 11**.

IMPORTANT: This will allow the side cover bearing rolls to fall into the side cover where

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

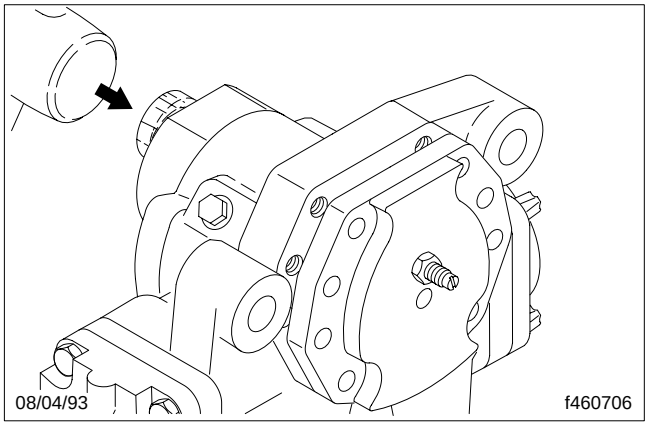

Fig. 8, Remove the Side Cover and Sector Shaft

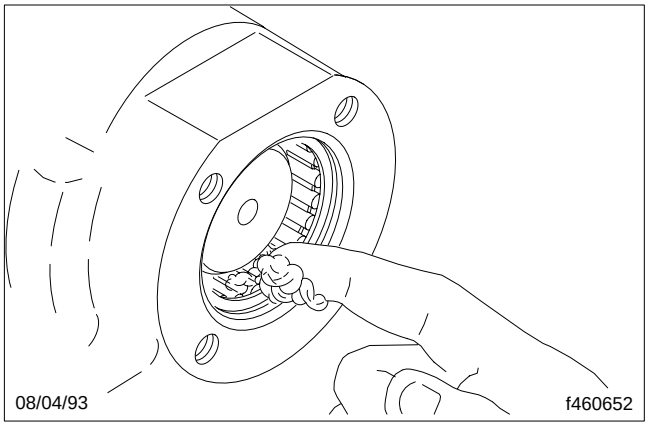

Fig. 9, Lubricate the Bearing Rollers

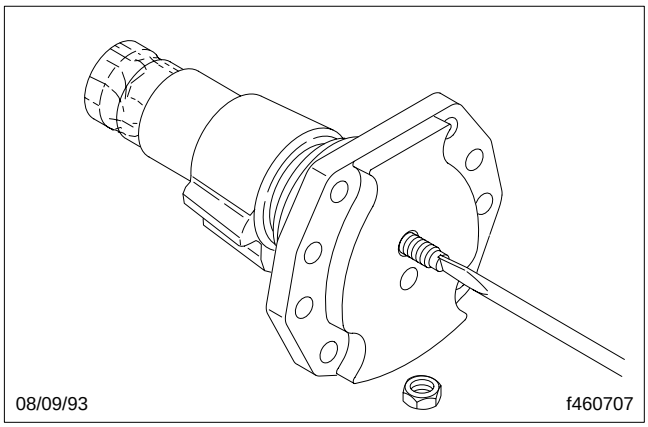

Fig. 10, Sector Shaft Adjusting Screw

they can easily be collected. Immediately collect all of the side cover bearing rolls and count them. Do not lose any rolls during disassembly, or the complete side cover assembly will have to be replaced.

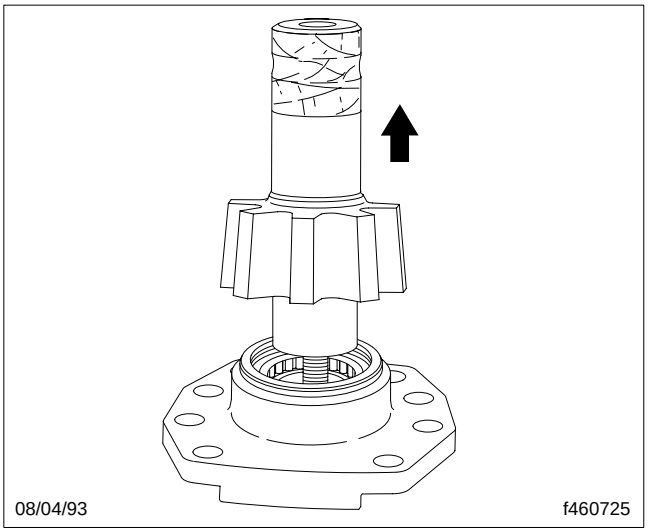

Fig. 11, Lift the Sector Shaft Out Vertically

13. Remove the side cover retaining ring, the two-piece side cover seal, the Teflon® backup washer, and the steel backup washer from the side cover. See **Fig. 12** and **Fig. 13**. Discard the two-piece seal and the Teflon® backup washer. Remove and discard the rubber plug.

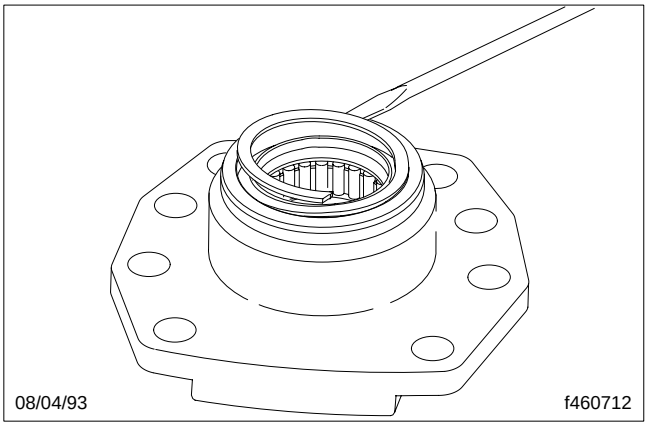

Fig. 12, Remove the Retaining Ring

14. Loosen the worm shaft preload adjusting screw jam nut. Loosen the worm shaft preload adjusting screw about two turns. See **Fig. 14**. Loosen the poppet adjusting screw jam nut and the poppet adjusting screw about two turns.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

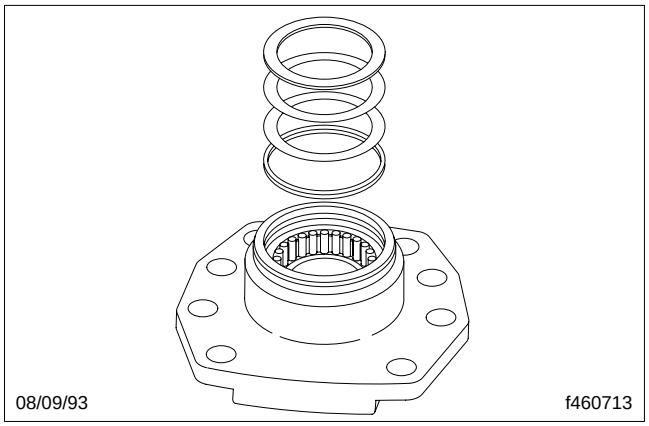

Fig. 13, Remove the Retaining Ring, Seal, and Washers

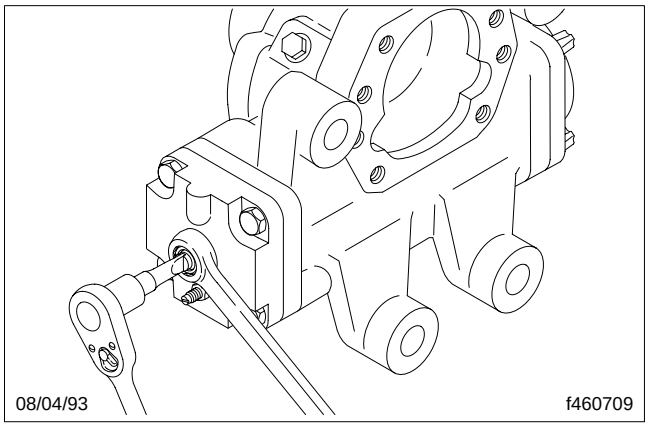

Fig. 14, Loosen the Jam Nut and Adjusting Screw

15. Remove the four end cover bolts. See **Fig. 15**. Prepare for some fluid to drain, then remove the end cover. See **Fig. 16**.

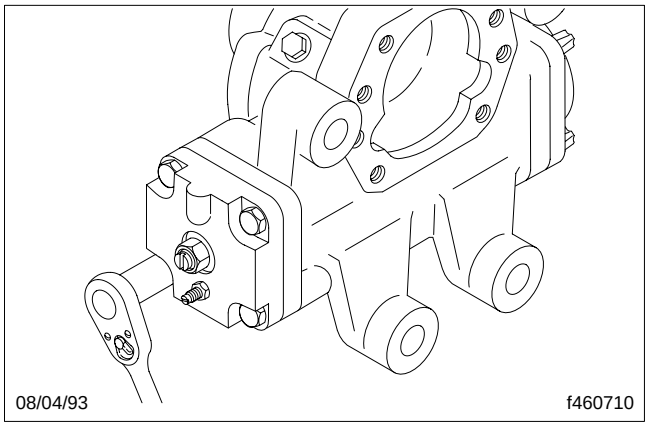

Fig. 15, Remove the End Cover Bolts

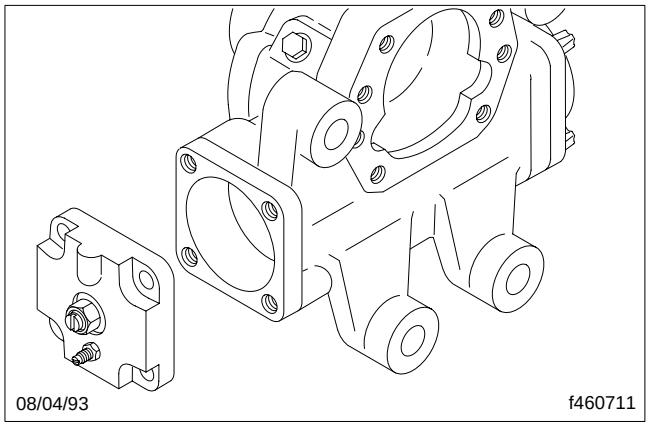

Fig. 16, Remove the End Cover

16. Remove and discard the end cover O-ring. See **Fig. 17**.

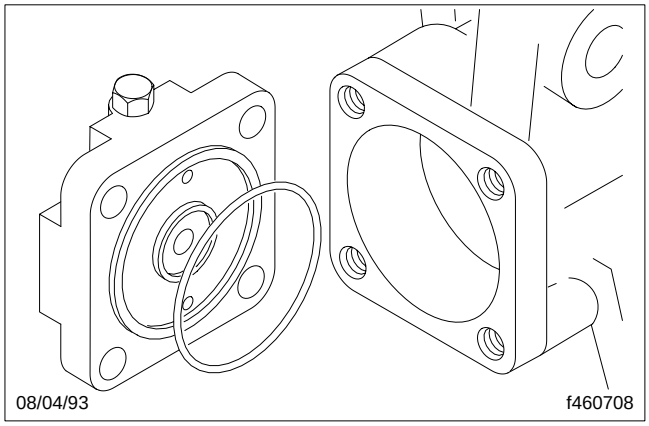

Fig. 17, Remove the O-Ring

17. Using a fine grade of emery paper, clean any paint or foreign material from the nonserrated area of the input shaft. See **Fig. 18**.
18. Loosen the valve housing poppet adjusting screw jam nut and poppet adjusting screw about two turns.
19. Remove the four valve housing bolts. See **Fig. 19**. Prepare for some fluid to drain, then remove the valve housing. See **Fig. 20**.
20. If the valve sleeve is still in the housing, remove it. See **Fig. 21**.
21. Remove the first thrustwasher, the thrust bearing, and the second thrustwasher from the valve housing. See **Fig. 22**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

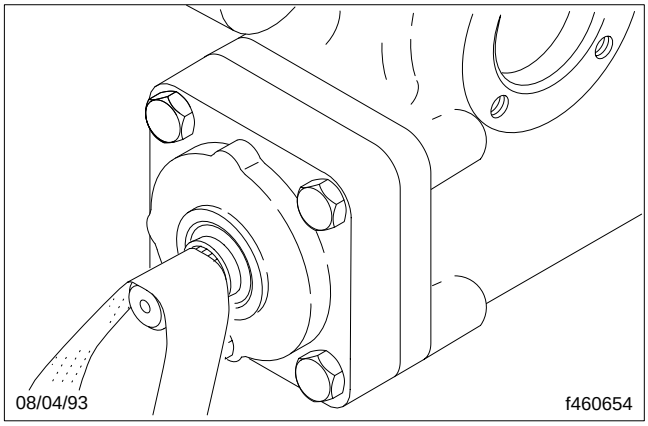

Fig. 18, Clean the Input Shaft

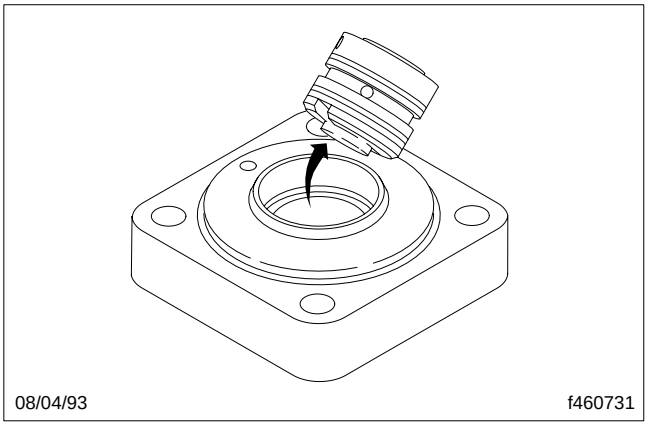

Fig. 21, Remove the Valve Sleeve

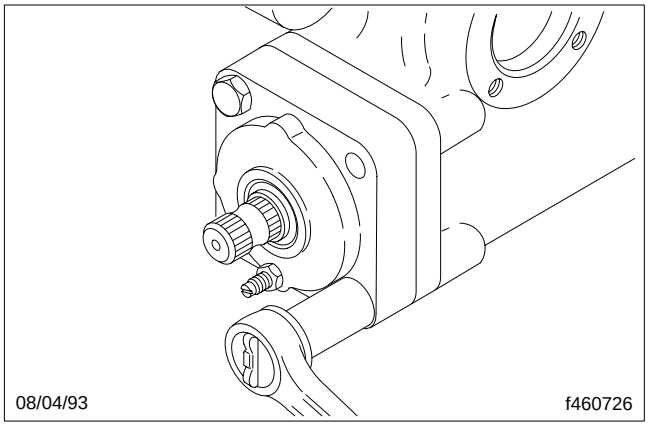

Fig. 19, Remove the Valve Housing Bolts

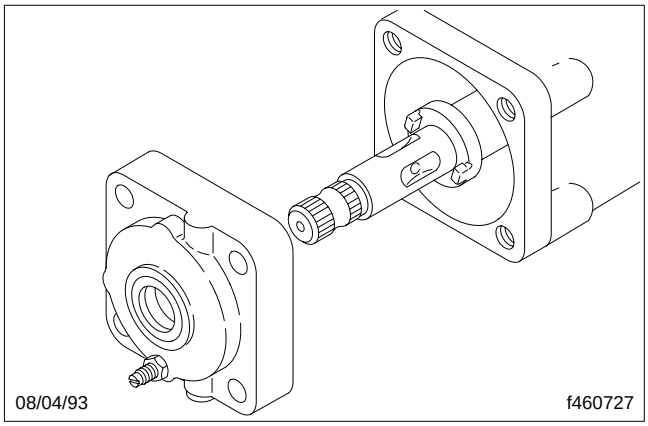

Fig. 20, Remove the Valve Housing

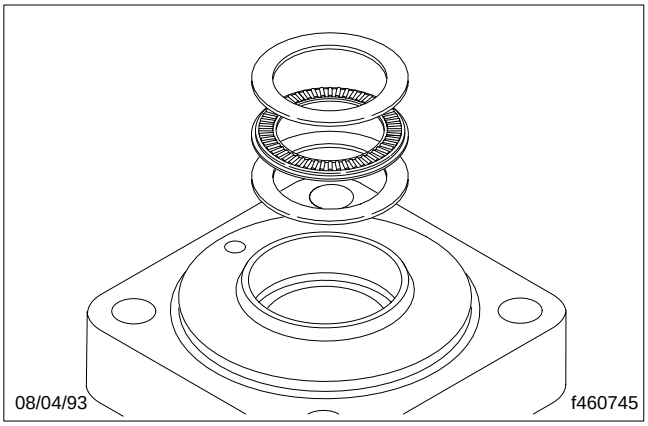

Fig. 22, Remove the Thrustwashers and Thrust Bearing

NOTE: The first thrustwasher may stay on the end of the valve sleeve. If so, remove it from the sleeve.

22. Remove and discard the valve housing O-ring.
23. Remove and discard the valve housing the dirt and water seal. See **Fig. 23**.
24. Remove the valve housing retaining ring. See **Fig. 24**.
25. Remove the steel backup washer and the two-piece input shaft seal from the valve housing. See **Fig. 25**. Discard the shaft seal.
26. Remove and discard the two Teflon® seal rings from the valve sleeve. See **Fig. 26**.
27. Remove and discard the two backup O-rings from the grooves in the valve sleeve. See **Fig. 27**.

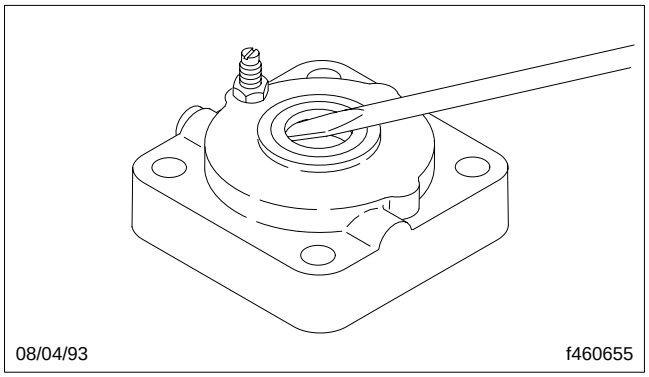

Fig. 23, Remove the Dirt and Water Seal

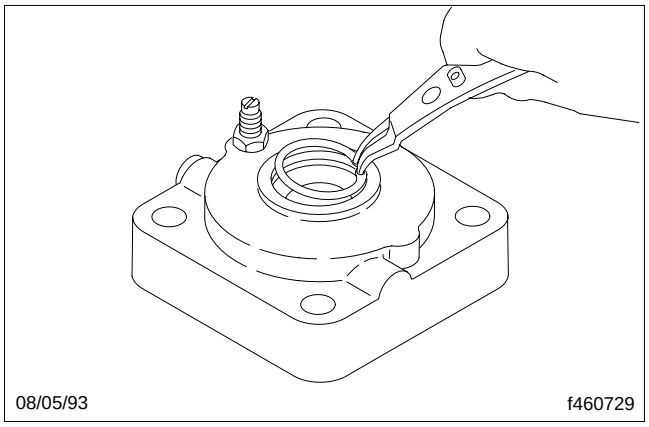

Fig. 24, Remove the Valve Housing Retaining Ring

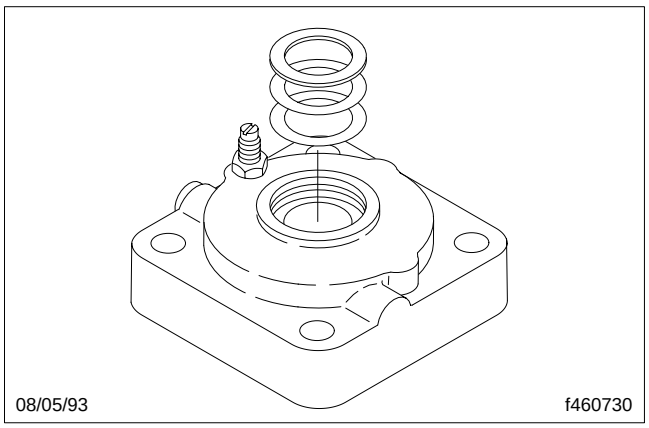

Fig. 25, Remove the Washer and Seals

28. Remove the rack piston and worm shaft from the gear housing as an assembly. See **Fig. 28**.

NOTE: The worm shaft portion of the assembly will be inside the rack piston with the input shaft portion of the worm protruding from the rack. Be careful when removing this assembly from the housing. Removing the rack piston assembly from the long end of the housing prevents the Teflon® rack piston seal from getting caught in the sector shaft cavity.

29. Set the rack piston and worm shaft assembly on a clean rag, to keep the piston from rolling.

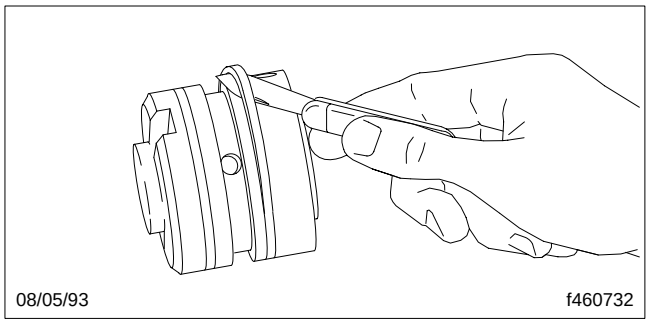

Fig. 26, Remove the Seal Rings

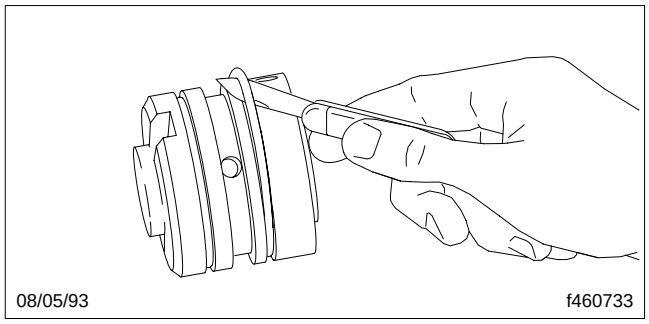

Fig. 27, Remove the O-Rings

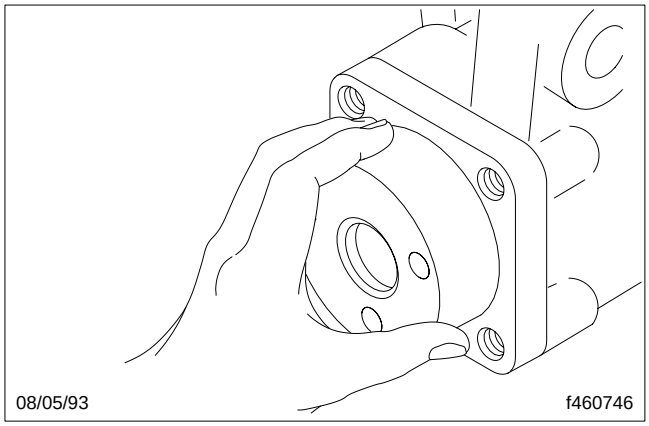

Fig. 28, Remove the Rack Piston and Worm Shaft

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

30. For rack pistons with a ball return guide clip, bend the tangs down on the two ball return guide clip locking tabs. See **Fig. 29**. Remove the two bolts, the locking tabs, and the guide clip. Discard the locking tabs. See **Fig. 30**.

    For rack pistons with a ball return guide cap, remove the two Allen head screws, the ball return guide cap, and the ball return guide cap seal. See **Fig. 31** and **Fig. 32**. Discard the screws and the cap seal.

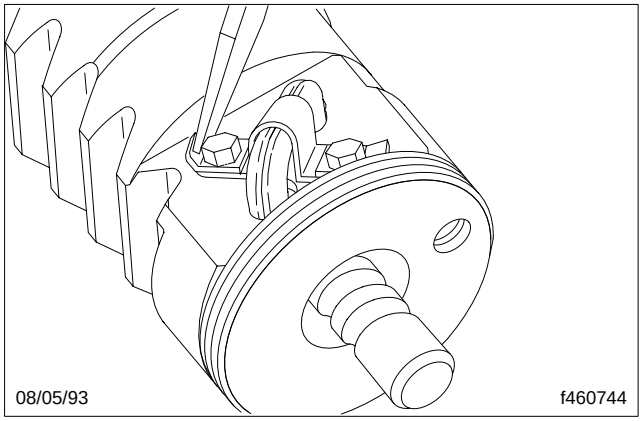

Fig. 29, Bend the Tangs

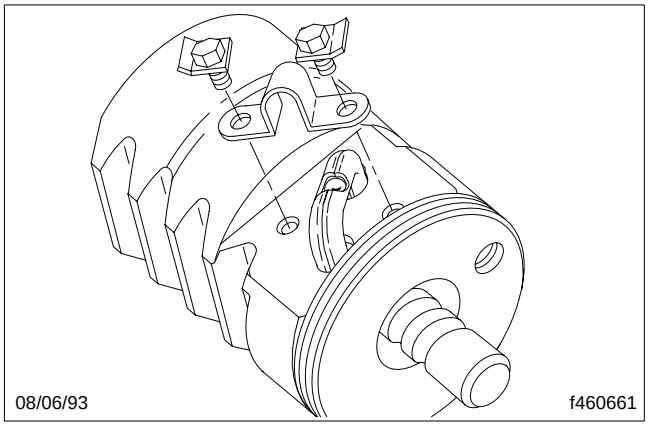

Fig. 30, Remove the Bolts, Tabs, and Guide Clip

31. Remove the halves of the ball return guide. See **Fig. 33**. Then remove the 34 steel balls from the rack piston by rotating the worm shaft until the balls fall out. See **Fig. 34**. **Do not loose any of these balls or you will have to replace the entire set**.

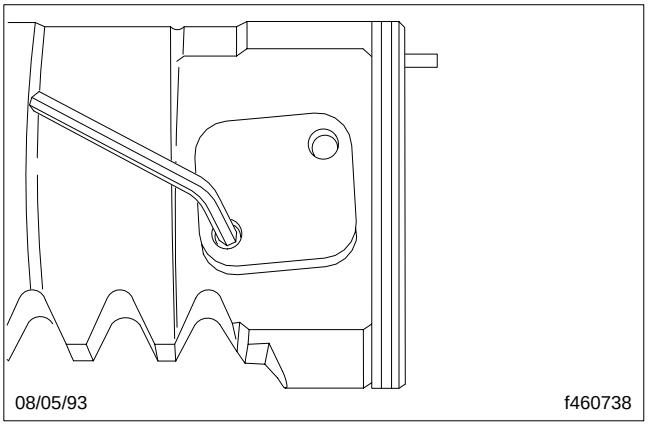

Fig. 31, Remove the Allen Head Screws

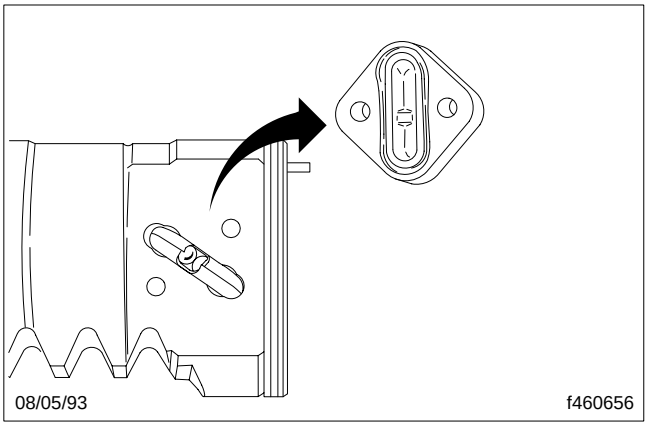

Fig. 32, Remove the Return Guide Cap Seal

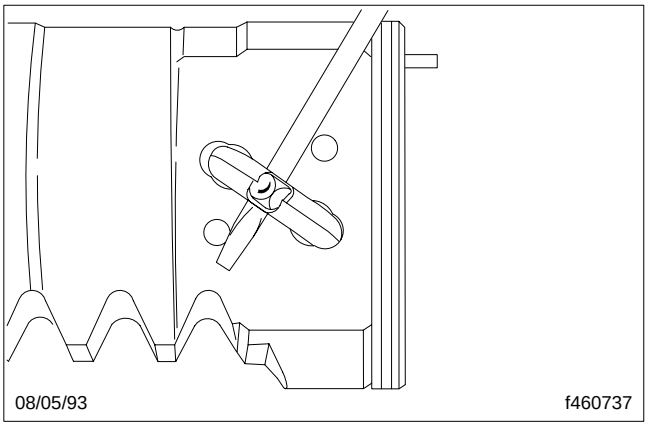

Fig. 33, Remove the Ball Return Guide Halves

NOTE: The ball return guide is closely fitted with the rack piston. It may be necessary to remove

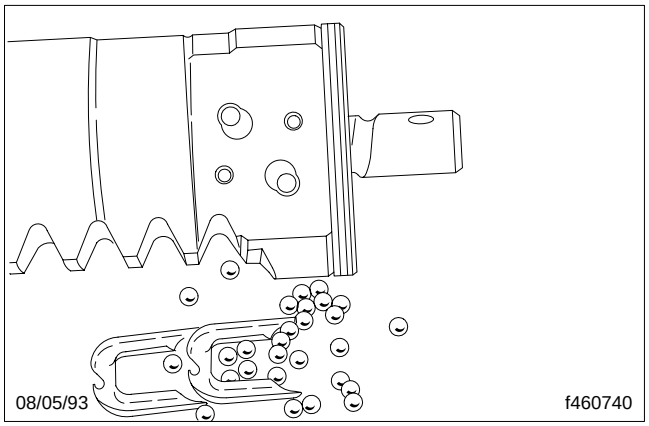

Fig. 34, Remove the Steel Balls

the halves by carefully inserting a screwdriver between the rack and the guide.

32. Remove the worm shaft from the rack piston. See **Fig. 35**.

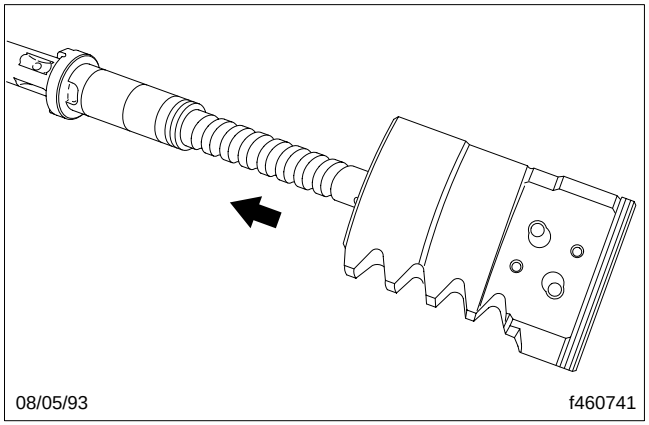

Fig. 35, Remove the Worm Shaft

33. Remove and discard the rack piston seal ring and the backup O-ring. See **Fig. 36** and **Fig. 37**.

34. Remove and discard the worm shaft seal ring and O-ring. See **Fig. 38**.

IMPORTANT: Do not disassemble the input shaft or worm shaft assembly any further. These are not serviceable. See **Fig. 39**.

35. The poppets will usually not require servicing. If it is necessary to service the poppets, position the rack piston in a soft-jawed vise. Remove the two poppet retaining rings, two poppet seats, two

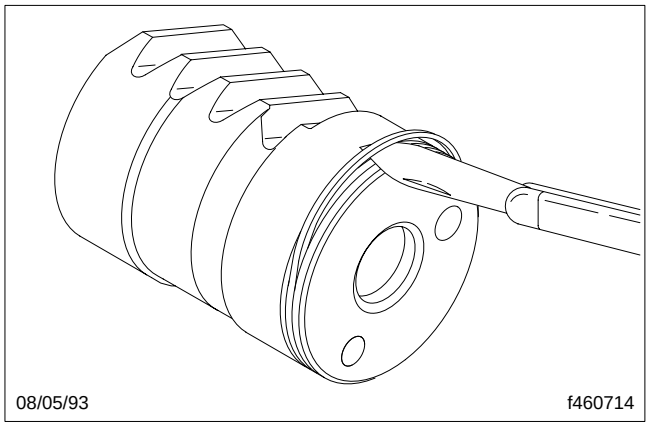

Fig. 36, Remove the Seal Ring

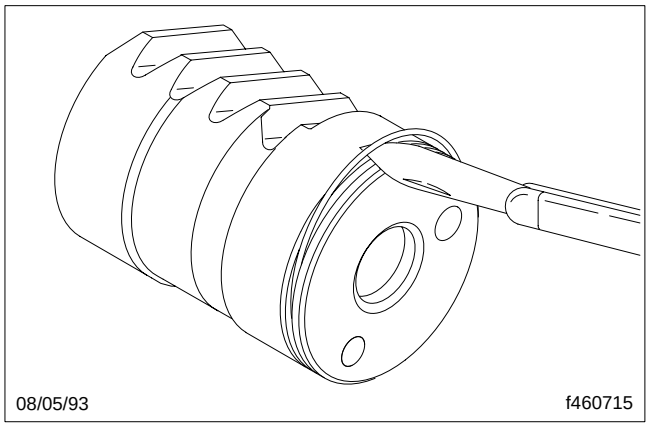

Fig. 37, Remove the O-Ring

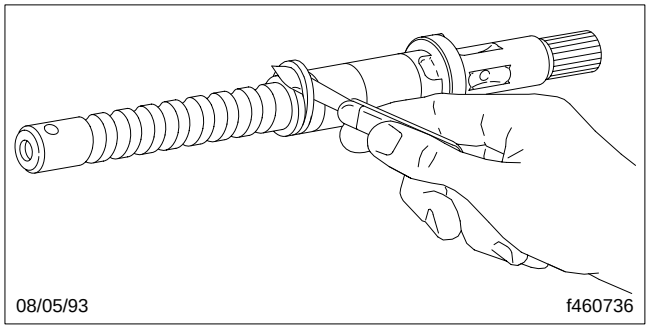

Fig. 38, Remove the Seal Ring and O-Ring

poppets, the nylon spacer rod, and the poppet spring. See **Fig. 40**, **Fig. 41**, and **Fig. 42**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

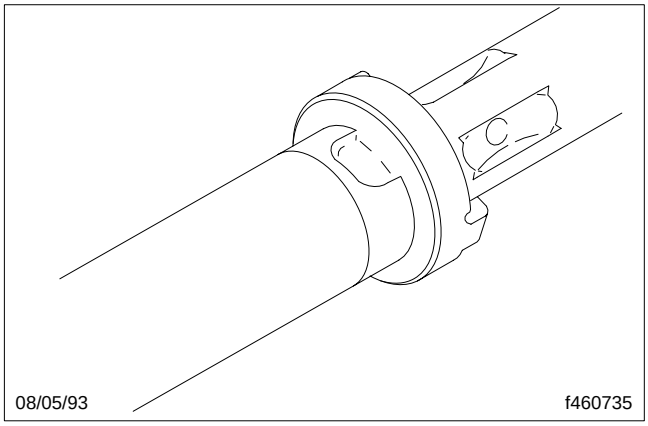

Fig. 39, Input Shaft/Worm Shaft Assembly

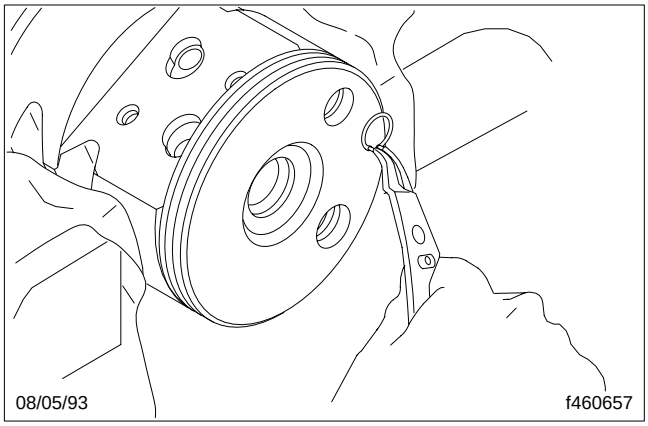

Fig. 40, Remove the Poppet Retaining Rings

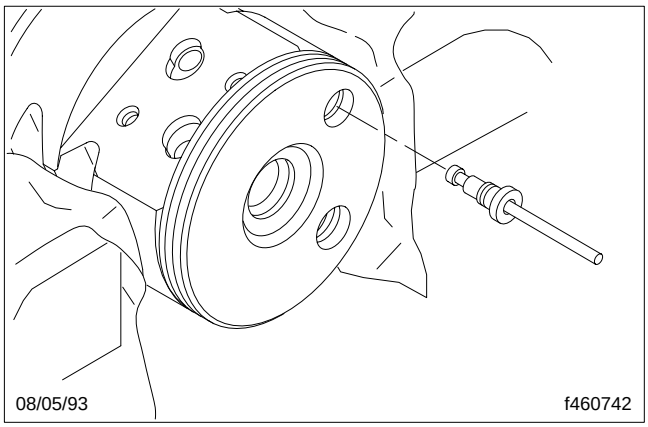

Fig. 41, Remove the Poppet Seats

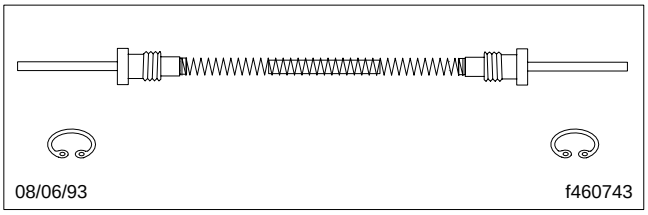

Fig. 42, Remove the Poppets, Spacer Rod, and Spring

Inspection

All sealing surfaces and seal cavities must be free of nicks and corrosion. If any part is nicked or corroded where sealing occurs, replace the part to ensure proper sealing.

Wash all parts in clean petroleum-based solvent, then blow-dry them.

1. Inspect the rack piston teeth for cracks and wear. See **Fig. 43**. If a step can be detected by running your fingernail horizontally across the teeth surfaces, replace both the rack piston and the sector shaft.

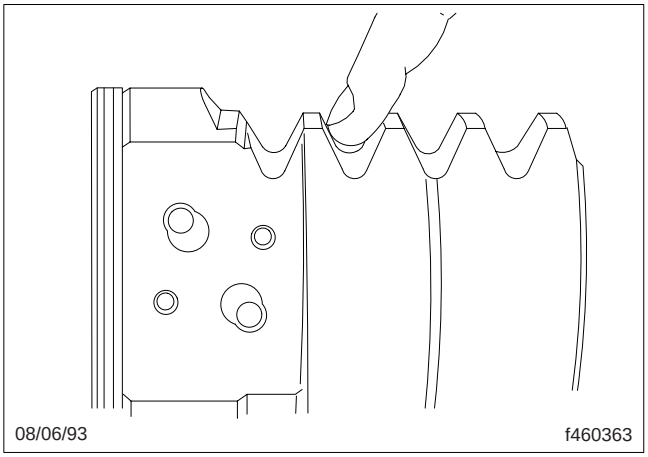

Fig. 43, Inspect the Rack Piston Teeth

2. Inspect the rack piston internal ball-track grooves for brinelling (dents) or spalling (flaking). See **Fig. 44**. If either condition exists, replace the rack piston, the worm shaft/input shaft assembly, the set of 34 steel balls, and the valve sleeve.
3. Inspect the worm shaft ball-track grooves for brinelling or spalling. See **Fig. 45**. If either condition exists, replace the worm shaft/input shaft assembly, the rack piston, the set of 34 steel balls, and the valve sleeve. Inspect the upper

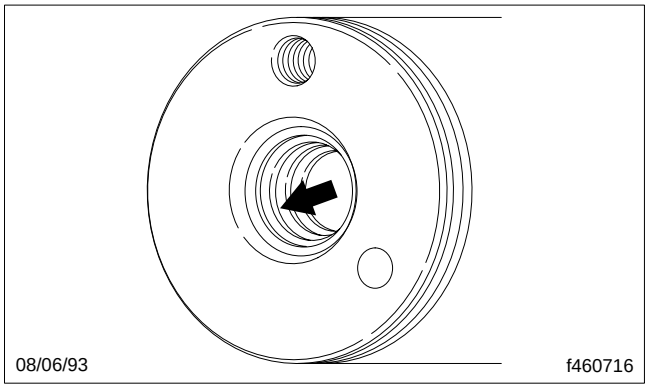

Fig. 44, Inspect the Rack Piston Internal Grooves

shaft seal area near the input shaft serrations for nicks. Run your fingernail across the sealing surface to detect steps. See **Fig. 46**.

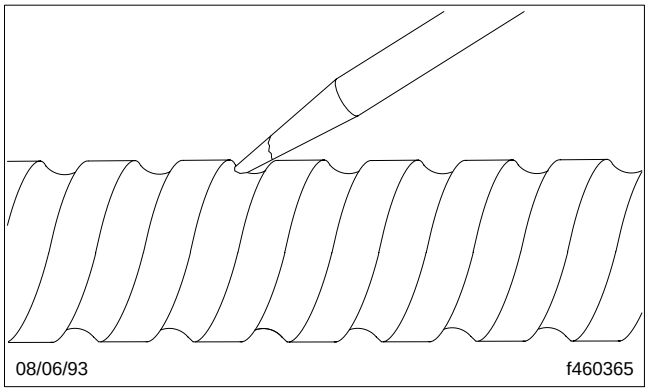

Fig. 45, Inspect the Worm Shaft

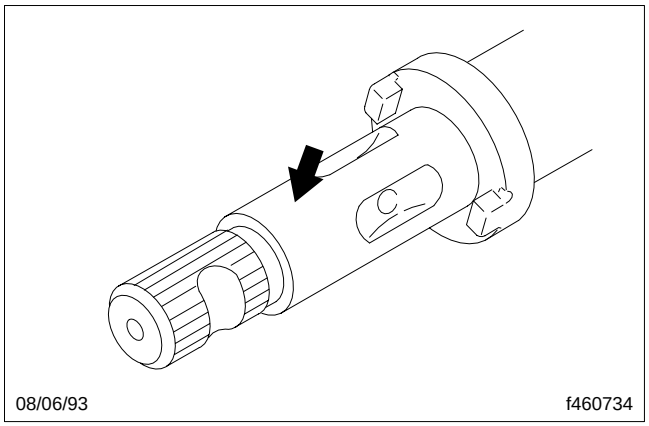

Fig. 46, Inspect the Sealing Surface

NOTE: The input shaft is pinned to the worm shaft by the torsion bar pin. The assembly is flexible and may appear slightly bent at this joint. See **Fig. 47**. This slight bend is normal.

4. Inspect the housing cylinder bore. See **Fig. 48**. Minor scoring marks running lengthwise through the bore are normal, and should not be compared to the scoring that might be found in the cylinder bores of an internal combustion engine. Replace the housing only if it has been tested for internal leakage, and it is determined that the scoring is responsible for internal leakage greater than 1.5 gpm (5.7 L/min). For troubleshooting procedures, see **Section 46.11, Subject 300**.

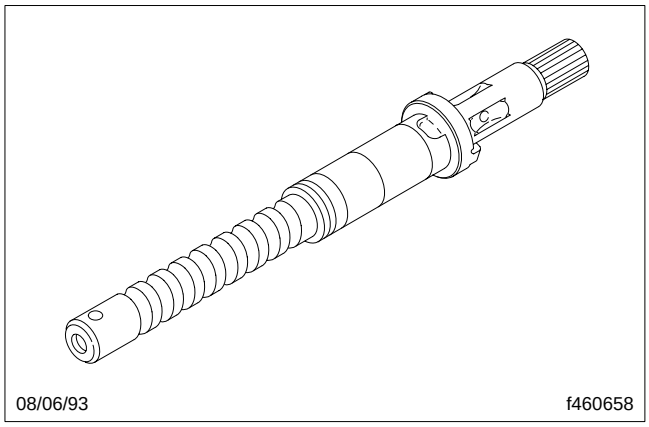

Fig. 47, Input Shaft/Worm Shaft Assembly

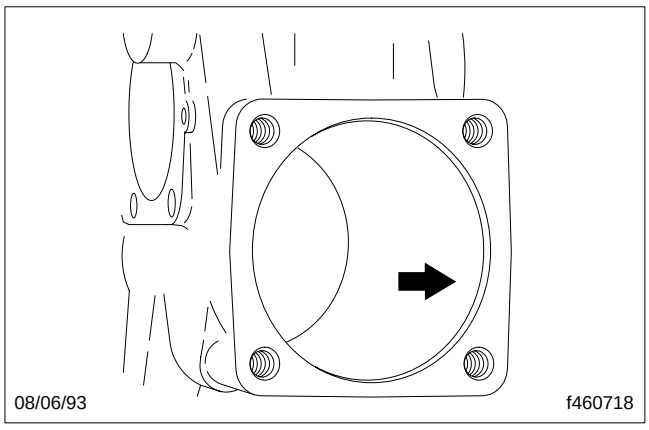

Fig. 48, Inspect the Housing Cylinder Bore

NOTE: In evaluating the results of this test, make sure that internal leakage exceeding 1.5 gpm (5.7 L/min) is attributed only to the housing, and not to the seals in the worm shaft, rack piston, and valve assembly.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

5. Inspect the housing faces for nicks that would prevent proper sealing. See **Fig. 49**. Replace the gear housing if these nicks cannot be easily removed with a fine-toothed flat file without changing the dimensional characteristics.

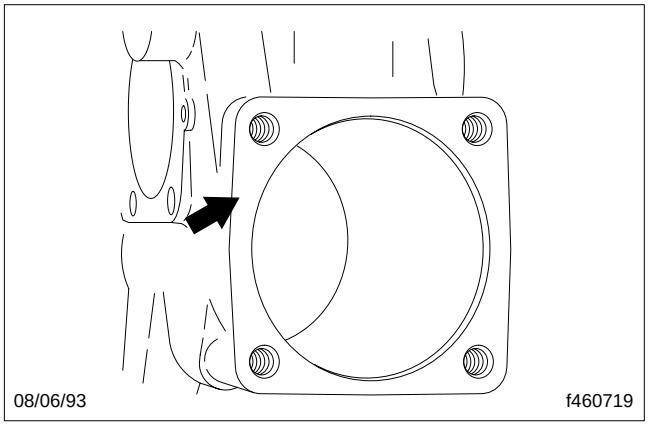

Fig. 49, Inspect the Housing Faces

6. Inspect the housing bearing for brinelling or spalling. If either condition exists, replace the housing bearing. See **Fig. 50**.

   Inspect the side cover bearing for brinelling or spalling. If the side cover bearing is damaged, replace the complete side cover assembly. See **Fig. 51**.

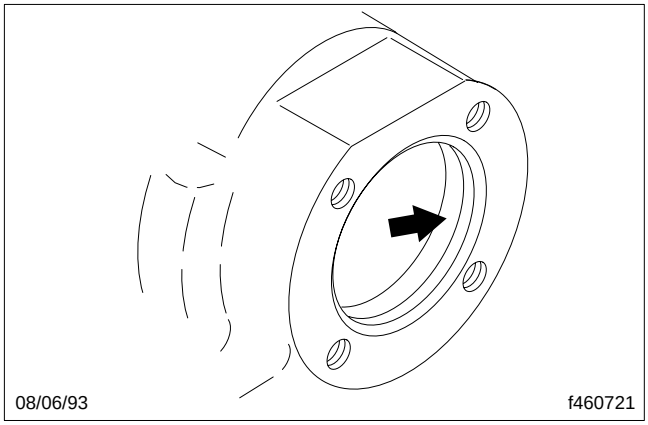

Fig. 50, Inspect the Housing Bearing

7. Inspect the sector shaft bearing sealing areas for brinelling or spalling. See **Fig. 52**. Run your fingernail across these areas to detect steps. Also inspect for cracks. If any of these conditions exist, replace the sector shaft.

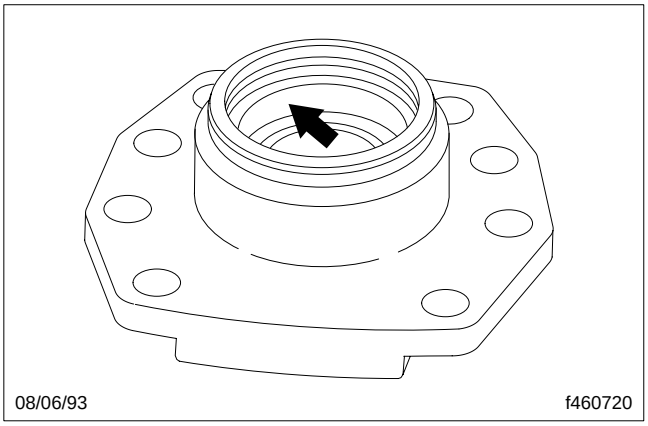

Fig. 51, Inspect the Side Cover Bearing

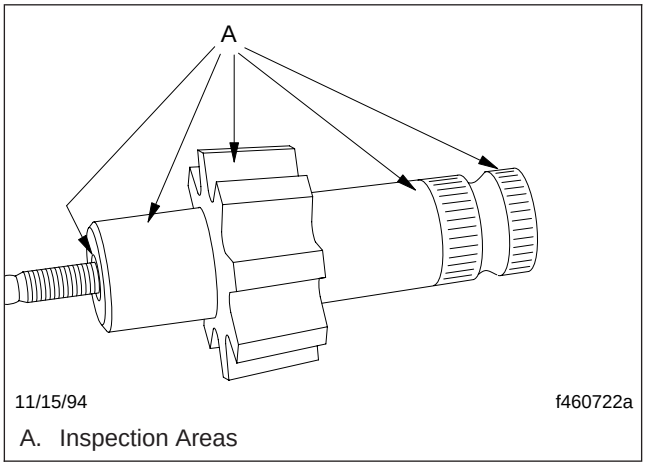

Fig. 52, Sector Shaft Bearing

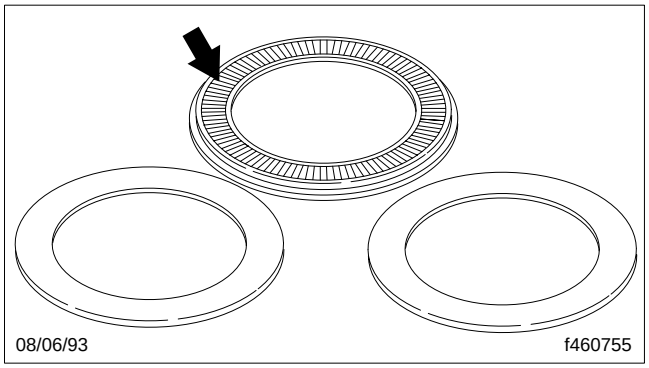
8. Check the sector shaft assembly for damaged adjusting screw threads. Make sure the adjusting screw retainer is locked in place and has no cracks. The adjusting screw must turn by hand with no end play (lash). If the adjusting screw is damaged, replace it and its retainer.

9. Inspect the thrust bearing rollers for any deterioration. Inspect the two thrustwashers for brinelling, spalling, or cracks. See **Fig. 53**. Replace any part if these conditions are detected.

Assembly

IMPORTANT: The special tools required for disassembly and assembly of the steering gear parts are available from SPX Kent-Moore or an



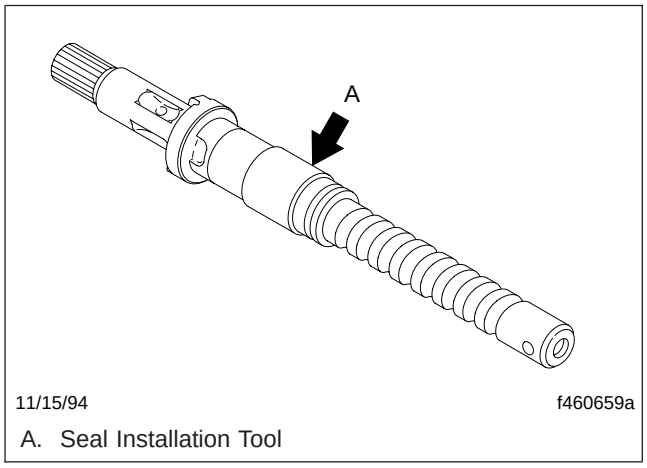


Fig. 53, Thrust Bearing Rollers and Thrustwashers

affiliated dealer. See the special tools Table in **Specifications 400** to be sure that you have the required tools before beginning the service procedures.

Replace all seals, seal rings, and gaskets with new ones each time the gear is disassembled. Individual seals, seal rings, and gaskets—as well as complete seal kits—are available from Freightliner part distributors.

1. Using seal installation tool J26739, assemble the new worm shaft backup O-ring, then the new Teflon® worm shaft seal ring. See **Fig. 54** and **Fig. 55**. Compress the seal ring with compression tool J26740 and set the worm shaft aside for 10 minutes. See **Fig. 56**.

A. Seal Installation Tool

Fig. 54, Worm Shaft Backup O-Ring

2. If installing a new housing bearing, install the retaining ring into the groove on the bearing's outside diameter. Then press the bearing into the housing from the trunnion side, using bearing mandrel J26743 against the lettered end of the bearing shell so the retaining ring end is away from the housing bore. See **Fig. 57**. Be sure the bearing mandrel is clean. Be sure the housing is square with the press base and that the bearing is not cocked.

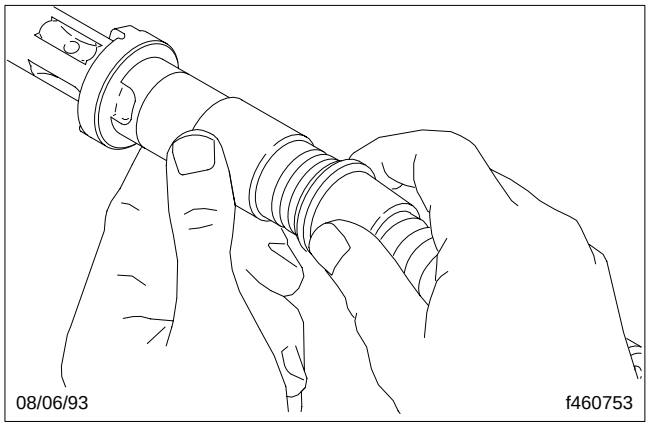

Fig. 55, Worm Shaft Seal Ring

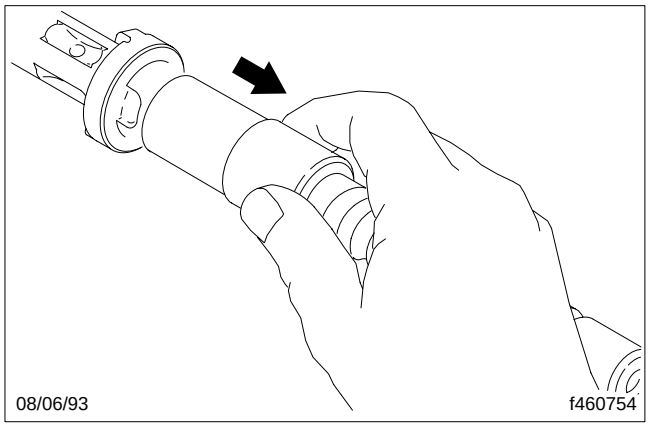

Fig. 56, Compress the Seal Ring

3. Whether or not a new bearing race was installed, apply a generous amount of clean grease to the bearing race to retain the bearing rolls. Then place the bearing rolls into the bearing race. Be sure that the rolls have been counted correctly and the quantity matches the quantity required for the housing bearing part number.

NOTE: If bearing BR-970 is being installed, install 41 rolls. If bearing BR-970-1 is being installed, install 42 rolls.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

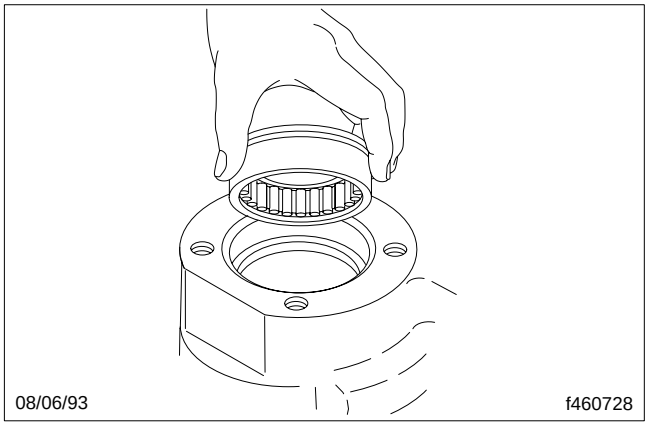

Fig. 57, Press the Bearing into the Housing

4. Install a new rack piston backup O-ring and a new Teflon® rack piston seal ring. See **Fig. 58** and **Fig. 59**. Do not stretch these rings when installing them. After they are installed, coat them with a liberal amount of grease.

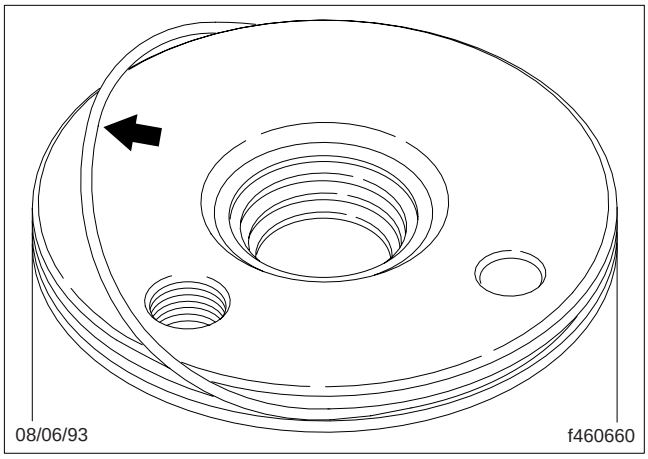

Fig. 58, Install the Backup O-Ring

5. Install the parts of the poppet assembly in the following order: one poppet seat, then (from the other end of the poppet hole in the piston) one poppet, the poppet spring, the nylon spacer rod, the other poppet, and the other poppet seat. See **Fig. 60**, **Fig. 61**, and **Fig. 62**.
6. Tighten the poppet seats 20 to 25 lbf·ft (27 to 34 N·m). Install both retaining rings.
7. If more than 10 minutes have passed since installing the worm shaft seal and ring, grease the sealing surface inside the rack piston and install

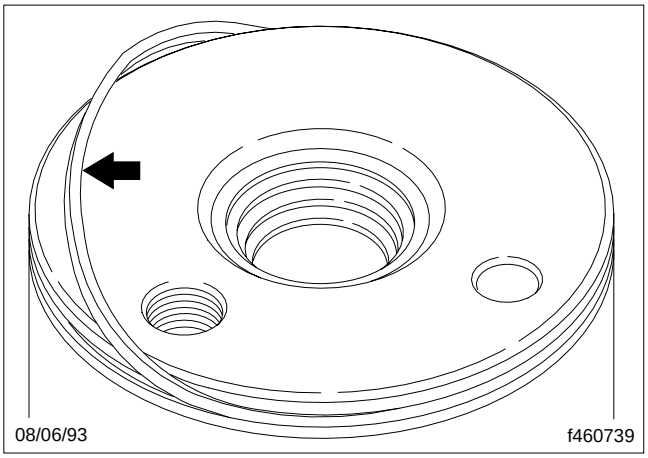

Fig. 59, Install the Seal Ring

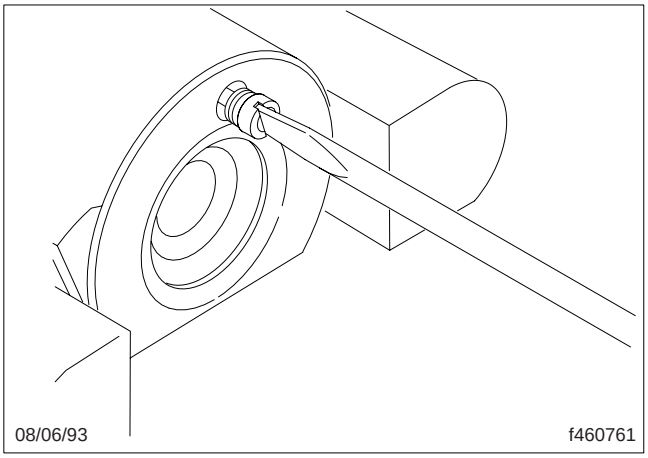

Fig. 60, Install the Poppet Assembly

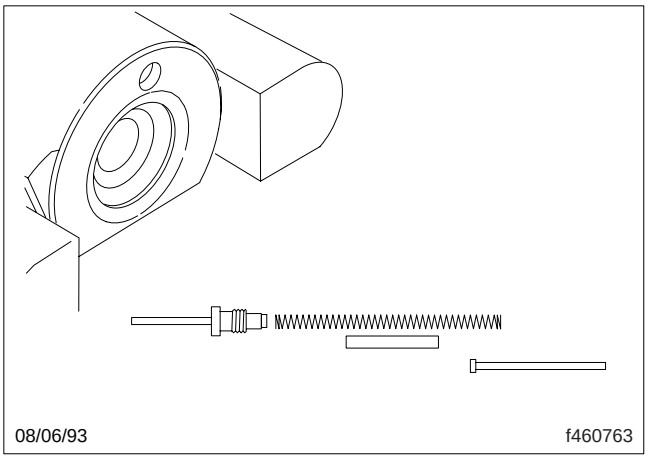

Fig. 61, Poppet, Spring, and Spacer Rod

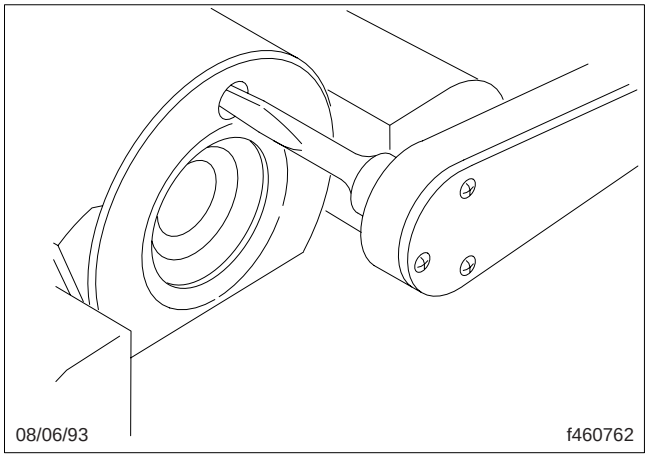

Fig. 62, Poppet and Poppet Seal

the worm shaft/input shaft assembly into the rack piston. See **Fig. 63**.

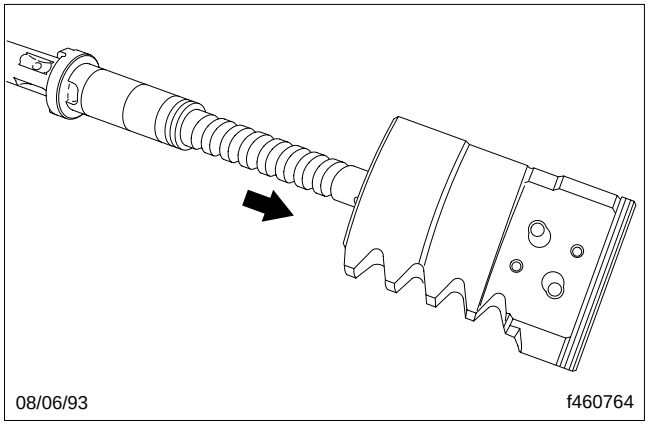

Fig. 63, Install the Worm Shaft/Input Shaft Assembly

8. Install the ball return guides.

   8.1 For ball return guides with a hole in the top, install the guides in the rack piston. Make sure they are seated.

   8.2 Place the 34 balls in the ball return guides and rack piston. Drop them through the hole provided in the ball return guides. As the balls are dropped into the guide, turn the worm shaft to pull them down into the grooves. See **Fig. 64**.

   8.3 For ball return guides without a hole in the top, insert the eraser end of a pencil into one hole of the rack piston as far as it will go. Drop 22 of the 34 balls into the other hole of the rack piston. See **Fig. 65**. Turn the worm shaft to advance the balls toward the other hole. There will be resistance after the 22nd ball is dropped. A ball will be visible at the base of each hole. Remove the pencil.

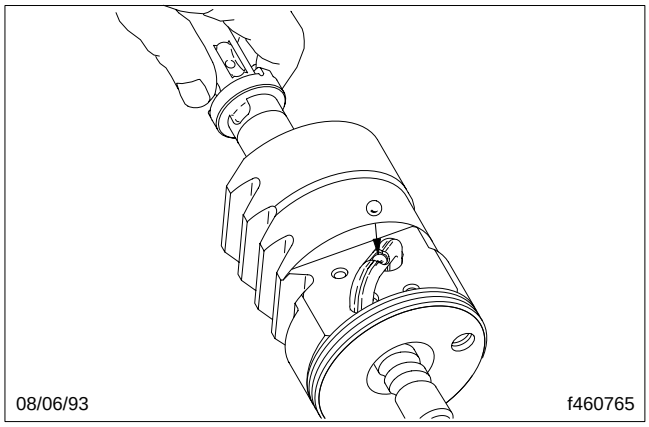

Fig. 64, Install the Steel Balls

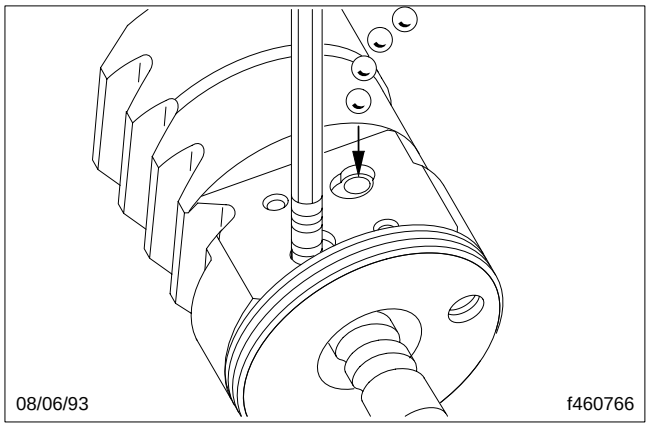

Fig. 65, Install the Steel Balls

   8.4 Apply a generous amount of clean grease on the ball return guides and insert the remaining 12 balls into a guide half. See **Fig. 66**. Join the guide halves and install in the rack piston.

9. If equipped with the ball return guide clip, assemble it and make sure that both bolt hole faces are in full contact with the rack piston surface. Install the two locktabs and the two bolts. Tighten the bolts 14 to 22 lbf·ft (19 to 30 N·m). See **Fig. 67** and **Fig. 68**. Bend the locking tabs up against the bolt head flats. See **Fig. 69**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

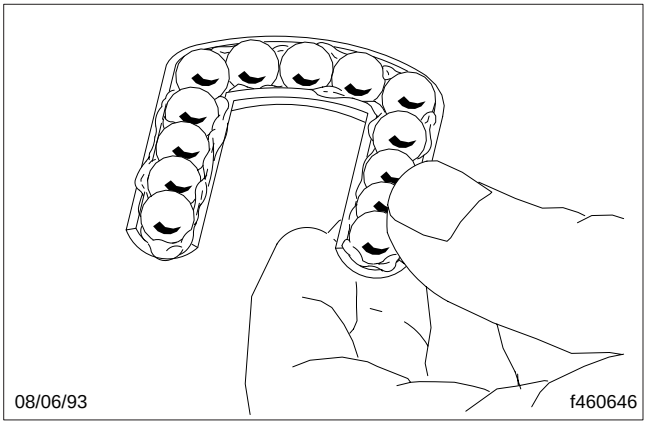

Fig. 66, Steel Balls in a Guide Half

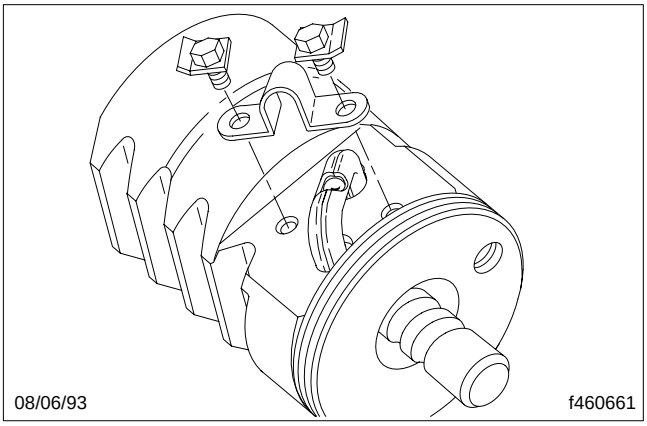

Fig. 67, Install the Ball Return Guide Clip

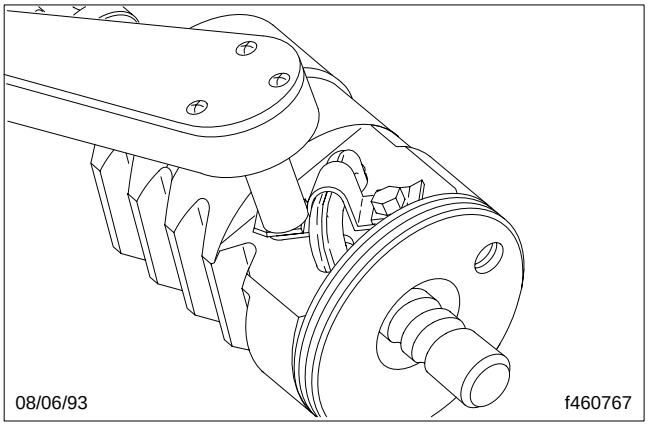

Fig. 68, Tighten the Bolts

10. If equipped with the ball return guide cap, grease the cap seal and install the seal in the ball return guide cap groove. Install the guide cap so that the seal is in full contact with the rack piston surface. Install two new Allen head screws and tighten them 14 to 22 lbf·ft (19 to 30 N·m). See **Fig. 70** and **Fig. 71**.

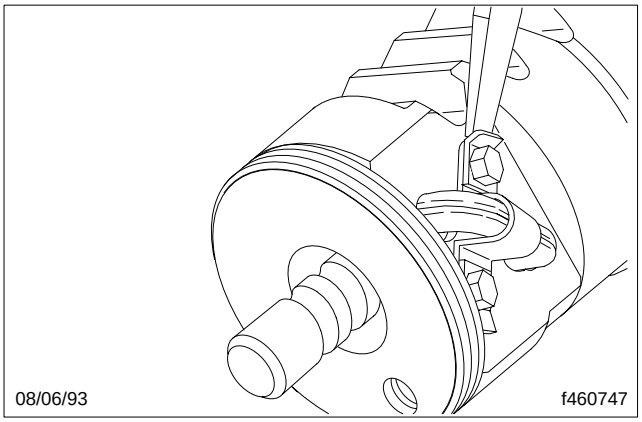

Fig. 69, Bend the Locking Tabs

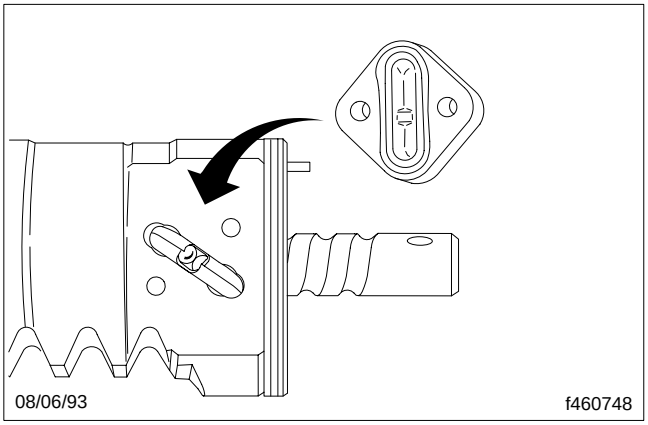

Fig. 70, Install the Ball Return Guide Cap

11. Apply a generous amount of clean grease to the Teflon® rack piston seal and to the housing cylinder bore. See **Fig. 72**. Install the rack piston and worm shaft as an assembly in the gear housing, so that the Teflon® rack piston seal goes in last. See **Fig. 73**.

NOTE: To ease the later assembly of the sector shaft, turn the rack piston and worm shaft assembly in the housing so that the rack teeth are exposed in the sector shaft cavity of the housing.

12. Install the worm shaft adjusting screw jam nut on the nonslotted end of the worm shaft preload ad-

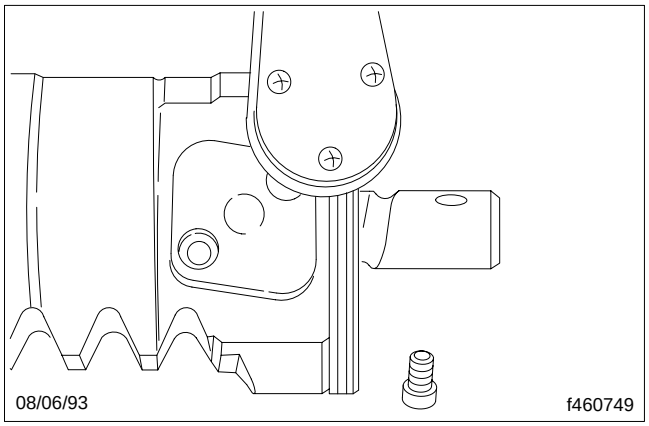

Fig. 71, Tighten the Allen Head Screws

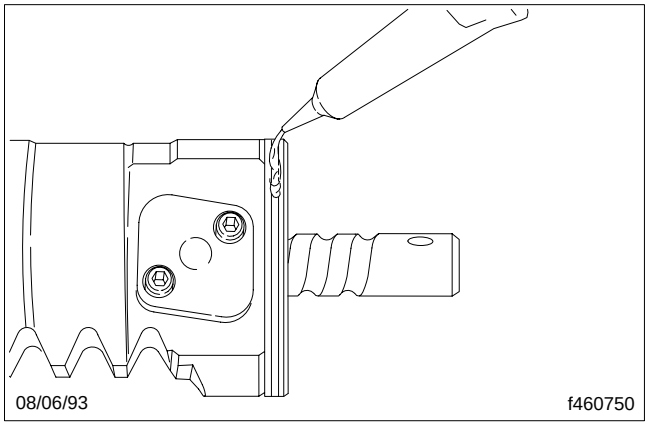

Fig. 72, Lubricate the Seal and Housing Cylinder Bore

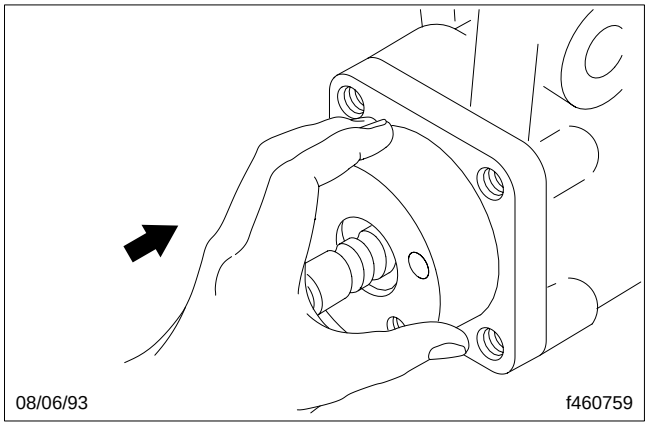

Fig. 73, Install the Rack Piston/Worm Shaft Assembly

justing screw so that the seal on the jam nut faces the end cover.

13. Assemble and install one poppet valve adjusting screw and jam nut in the same manner. Assemble the other poppet valve adjusting screw jam nut onto the poppet valve adjusting screw.

NOTE: The poppet valve adjusting screws may not be of the same length. If not, insert the shorter adjusting screw into the end cover a few turns.

14. Install the worm shaft preload adjusting screw in the end cover a few turns.

15. Grease the end cover O-ring groove and install the new end cover O-ring. See **Fig. 74**.

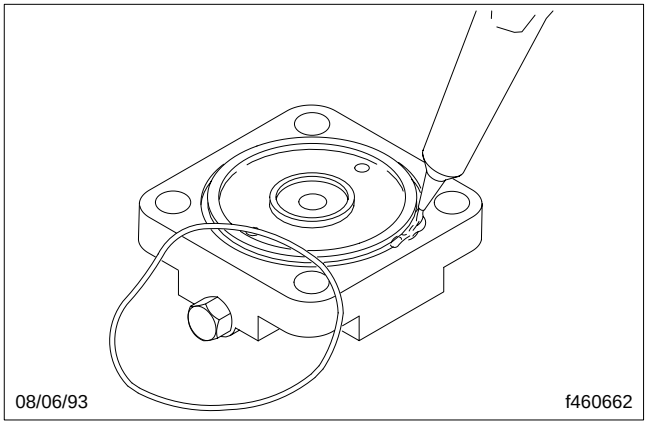

Fig. 74, Lubricate the End Cover O-Ring Groove

NOTE: When installed, the O-ring should extend slightly above the machined surface of the end cover.

16. Position the end cover so that the poppet adjusting screw is aligned with the end of the poppet. See **Fig. 75**.

    Make sure the rack piston teeth are fully visible in the sector shaft cavity of the housing. This ensures proper location of the poppets so that the poppet adjusting screw will contact the poppets.

    Install the four end cover bolts and tighten 150 to 170 lbf·ft (203 to 230 N·m). See **Fig. 76**.

17. Grease two new valve-sleeve backup O-rings and two new Teflon® seal rings. Install the backup O-rings on the valve sleeve. See **Fig. 77**. Then use seal installation tool J26741 to install the seal rings on the valve sleeve. See **Fig. 78**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

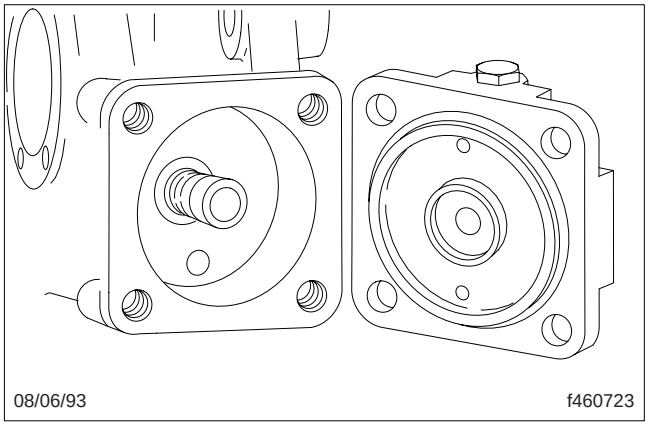

Fig. 75, Position the End Cover

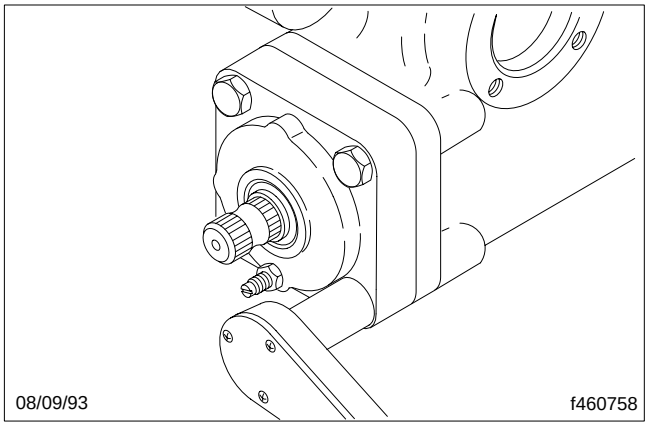

Fig. 76, Install the End Cover Bolts

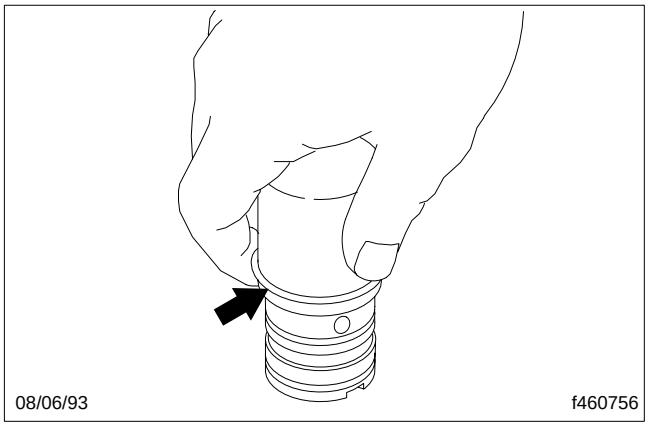

Fig. 77, Install the O-Rings on the Valve Sleeve

18. Using special tool J26742, compress the Teflon® seal rings. See **Fig. 79**. Leave the tool on for 10 minutes.

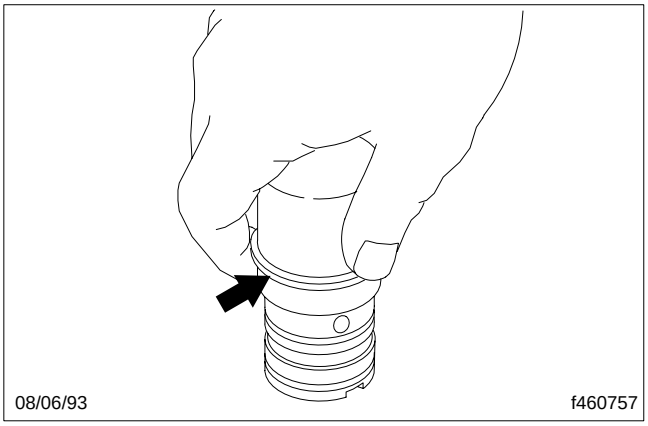

Fig. 78, Install the Seal Rings on the Valve Sleeve

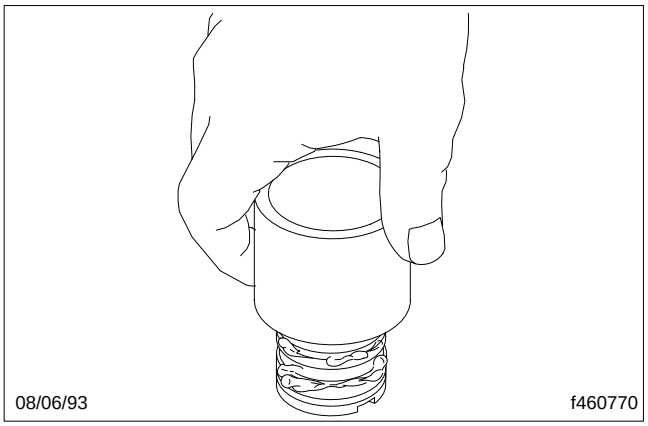

Fig. 79, Compress the Seal Rings

19. Turn the poppet valve adjusting screw into the valve housing 4 or 5 turns. Final adjustments will be made later.

20. Apply clean grease to the O-ring groove in the valve housing. Install a new valve housing O-ring in the groove. See **Fig. 80**.

NOTE: When installed, the valve housing O-ring should extend slightly above the machined surface of the valve housing.

21. Apply a generous amount of clean grease to one thrustwasher. Install the thrustwasher into the valve housing. Be sure the washer is centered. See **Fig. 81**.

22. Apply a generous amount of clean grease to the thrust bearing. Install the bearing in the valve housing and onto the first thrustwasher. Be sure the bearing is centered. See **Fig. 82**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

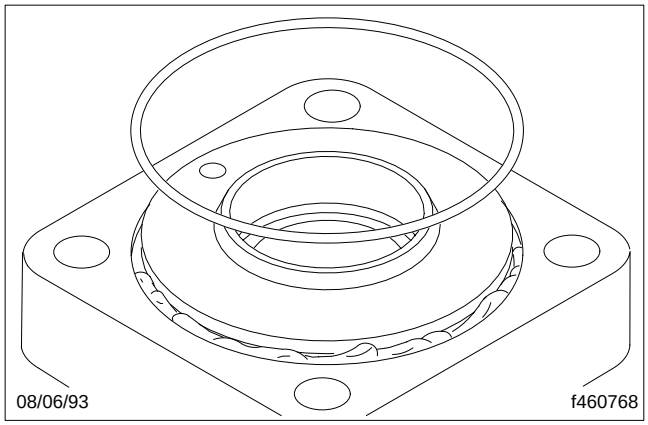

Fig. 80, Install the Valve Housing O-Ring

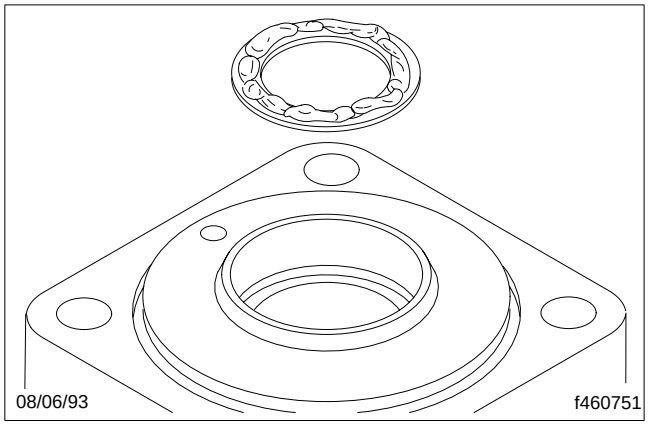

Fig. 81, Install the Thrustwasher in the Valve Housing

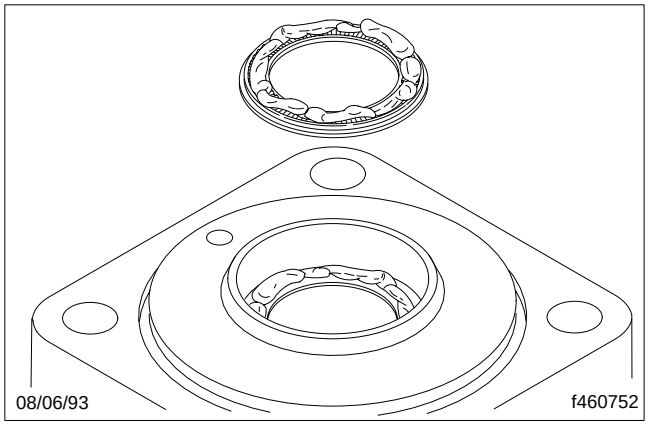

Fig. 82, Install the Bearing in the Valve Housing

23. Remove the compression tool from the valve sleeve. Apply more grease to the valve sleeve seals. Grease the thrustwasher face on the end of the valve sleeve that is without the drive slots. Place the second thrustwasher on this face. See **Fig. 84**.

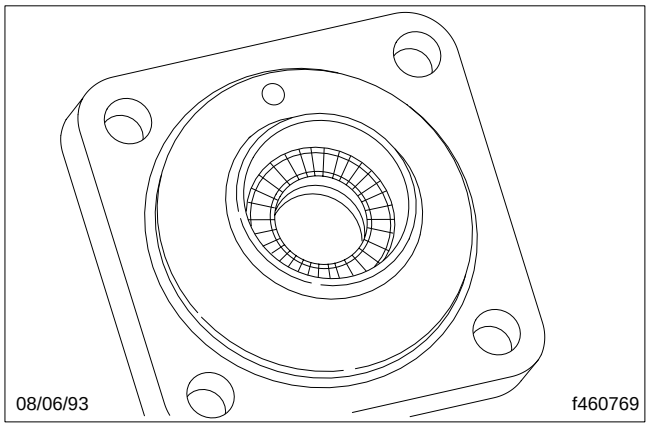

Fig. 83, Thrustwasher and Thrust Bearing

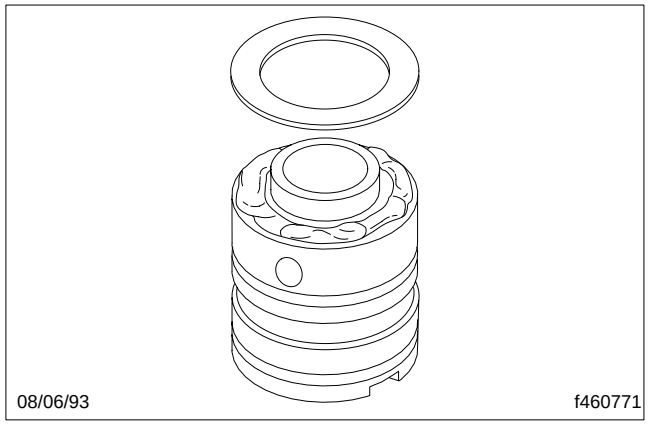

Fig. 84, Install the Second Thrustwasher

24. Install the valve sleeve and the attached thrustwasher into the valve housing. See **Fig. 85**. When the valve sleeve is in place, it should measure between 0.370 and 0.400 inch (9 and 10 mm) above the face of the valve housing to the end of the valve sleeve nose. See **Fig. 86**.
25. Move the rack piston flush with the open end of the gear housing. Turn the worm shaft until it extends out of the rack piston as far as it will go.
26. Locate the timing mark (a faint punched mark on the chamfered edge of the valve sleeve or an indented mark on the front of the sleeve). See **Fig. 87**. Locate the timing mark on the worm shaft. See **Fig. 88**.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

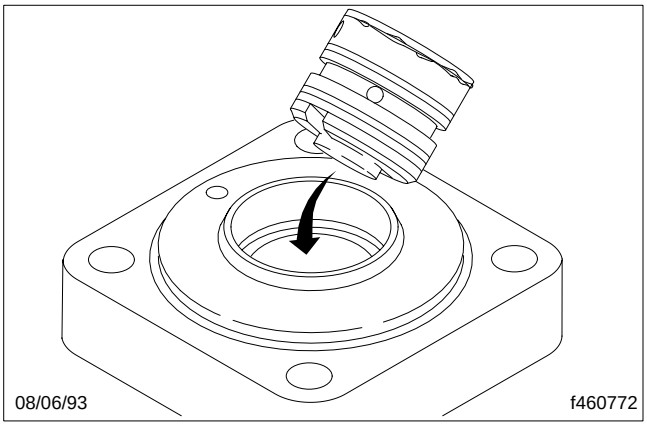

Fig. 85, Install the Sleeve into the Valve Housing

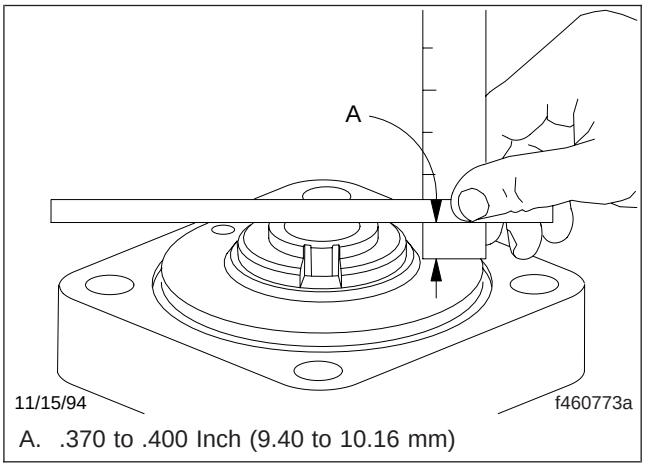

Fig. 86, Measure the Placement of the Valve Sleeve

Grasp the valve housing and valve sleeve as an assembly with your thumbs on the valve housing and your fingers applying pressure on the valve sleeve to keep it in the valve housing. See **Fig. 89**.

Align the previously located timing marks. See **Fig. 87** and **Fig. 88**. Place the valve housing and valve sleeve as an assembly on the input-shaft end of the worm shaft until the drive lugs are fully engaged. See **Fig. 90**.

NOTE: Valve sleeves are identified with and matched to a right- or left-hand lead of the worm screw. Because the screw has a right-hand thread (that is, goes into the rack piston when turned clockwise), the valve sleeve will have the letter R stamped between the seal

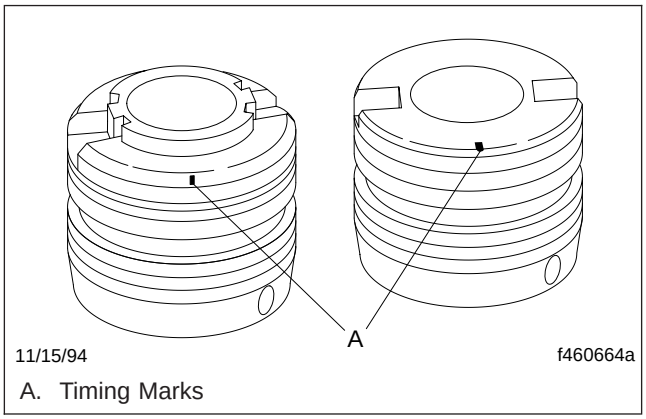

Fig. 87, Locate the Timing Marks

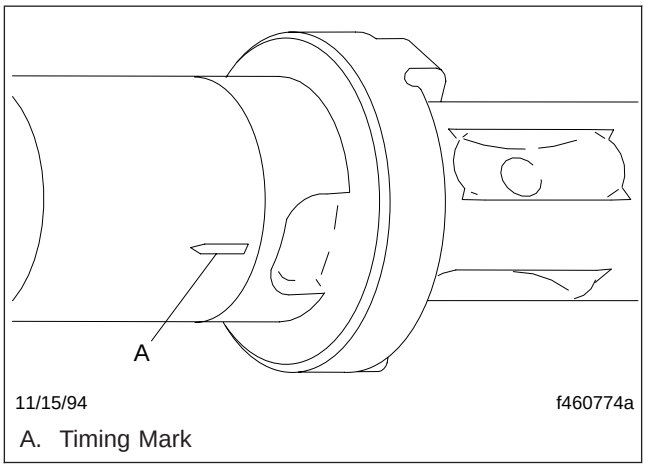

Fig. 88, Timing Mark on the Worm Shaft

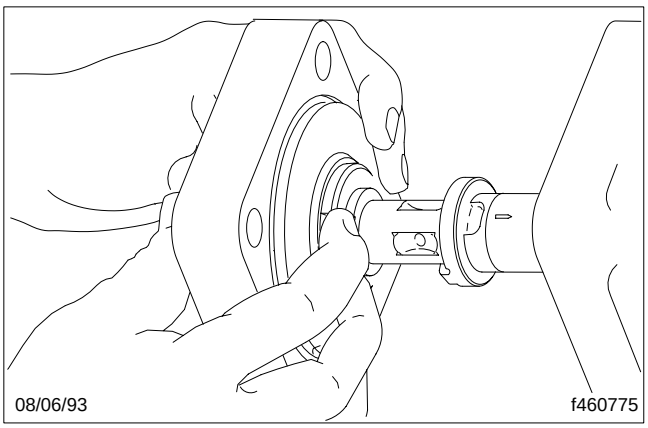

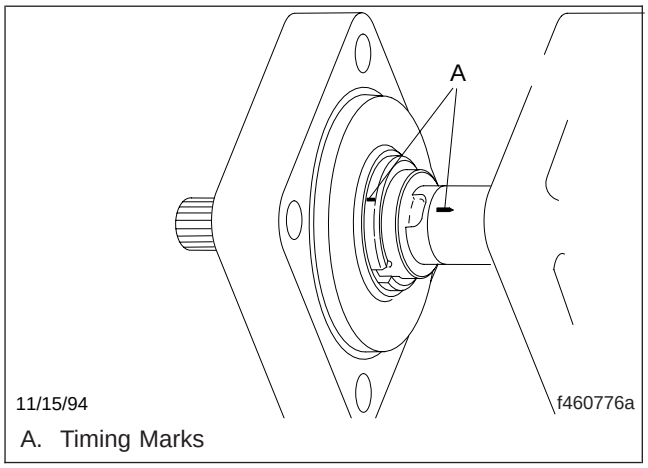

Fig. 89, Valve Housing and Valve Sleeve

lands. For a left-hand worm lead (which will come out of the rack piston when turned clock-

A. Timing Marks

Fig. 90, Install the Valve Housing/Valve Sleeve Assembly on the Worm Shaft

wise), the mating valve sleeve has no identifying letter or has the letter L stamped between the seal lands.

27. Maintain pressure on the valve end of the valve housing to ensure continued engagement of the drive lugs and thrust bearing package. See **Fig. 91**. While maintaining this pressure, turn the valve housing and align the poppet adjusting screw with the poppet in the rack piston. While continuing pressure, turn the input shaft to bring the valve housing into contact with the gear housing face.

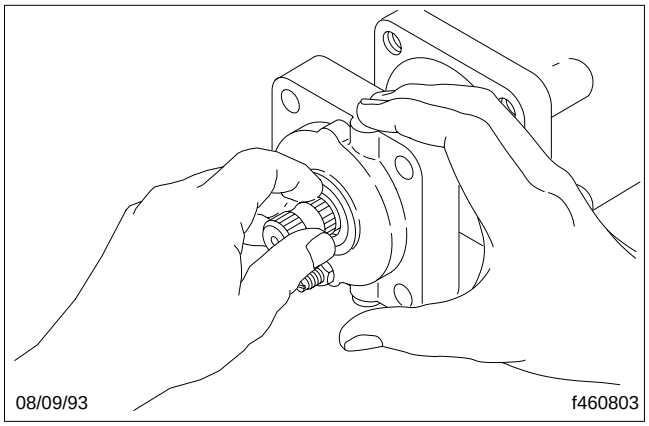

Fig. 91, Valve Housing

28. Install the four valve housing bolts in the valve housing, and tighten them 145 to 155 lbf·ft (197 to 210 N·m). See **Fig. 92**.

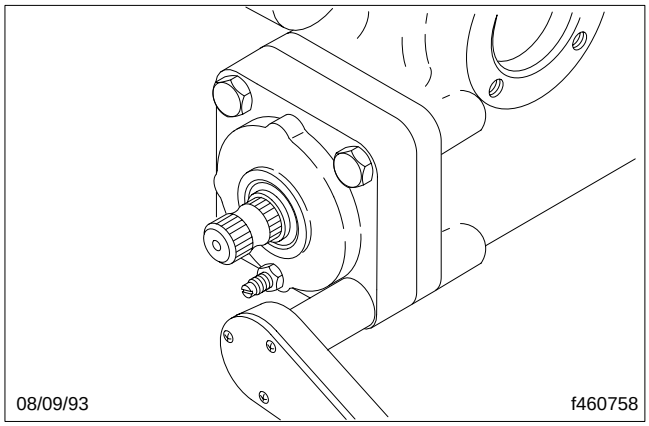

Fig. 92, Install the Valve Housing Bolts

29. Apply a generous amount of clean wheel bearing grease (do not substitute another type of grease) to the bearing race inside the side cover.

30. Insert the bearing rolls into the side cover bearing race. See **Fig. 93**. If equipped with bearing BR-970, insert 41 rolls. If equipped with bearing BR-970-1, insert 42 rolls.

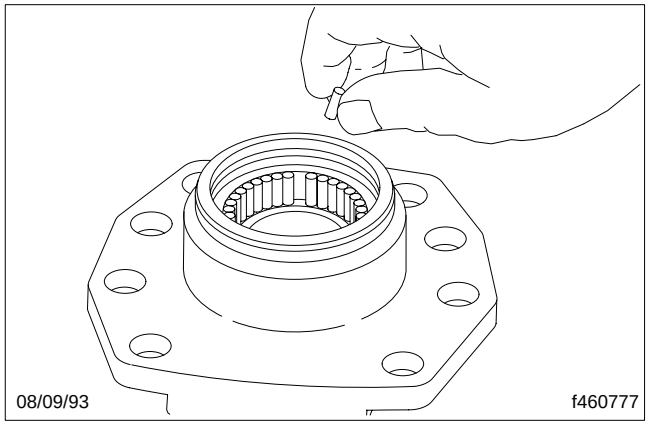

Fig. 93, Insert the Bearing Rolls into the Side Cover Bearing Race

NOTE: Apply clean wheel bearing grease to loose rolls to retain them in the bearing race.

31. Install the steel backup washer, a new Teflon® backup washer, and a new two-piece side cover seal in the side cover. See **Fig. 94**.

NOTE: In newer seal kits and on some units, the Teflon® backup washer is an integral part of the two-piece seal.

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

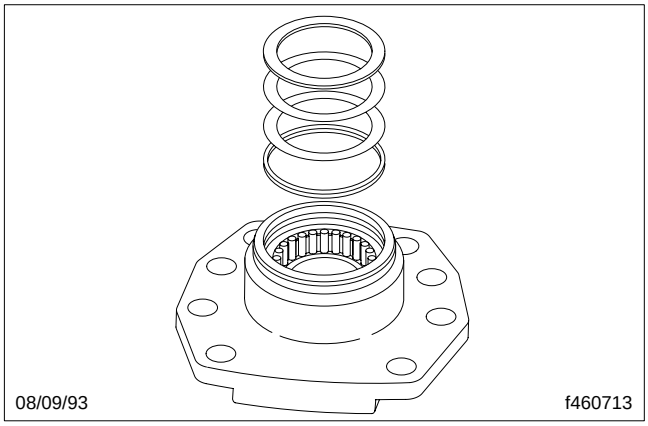

Fig. 94, Install the Washers and the Side Cover Seal

32. Assemble the two-piece seal so that the words OIL SIDE are visible after it is installed.
33. Install the side cover retaining ring in the ring groove of the side cover. See **Fig. 95**.

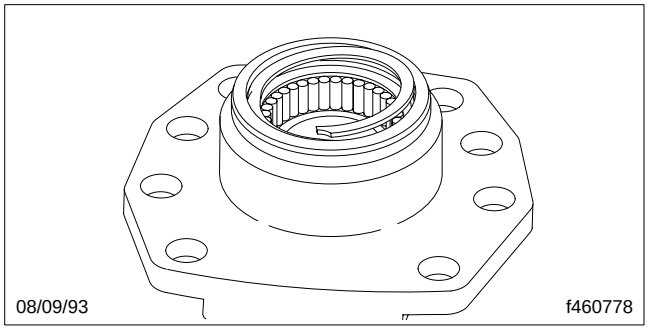

Fig. 95, Install the Retaining Ring

34. Apply a generous amount of clean grease to the short bearing area of the sector shaft. Insert the sector shaft into the side cover. Turn the sector shaft adjusting screw into the side cover, until it seats. See **Fig. 96**. Then back out the adjusting screw one turn, so that the side cover turns freely on the sector shaft.
35. Install the sector shaft adjusting screw jam nut onto the sector shaft adjusting screw a few threads. Final adjustment will be made later.
36. Press a new rubber plug into the hole provided in the side cover until the plug is flush. See **Fig. 97**.
37. Apply clean grease to a new side cover gasket and install it on the side cover. See **Fig. 98**. Apply enough grease to hold the gasket in place.

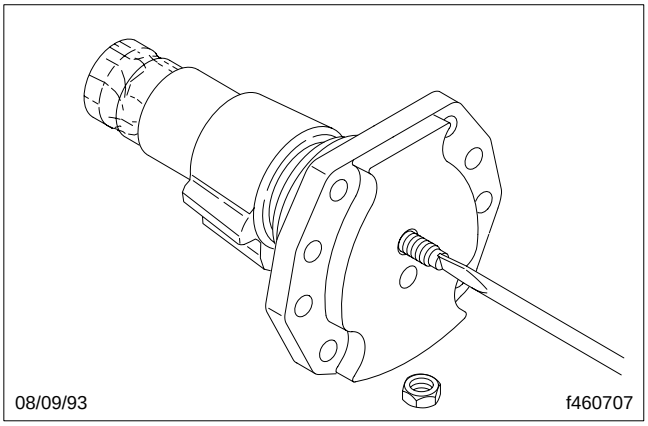

Fig. 96, Install the Sector Shaft Adjusting Screw

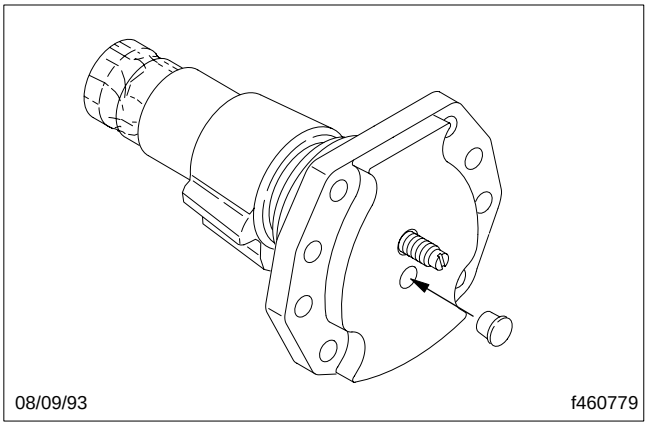

Fig. 97, Install a New Plug in the Side Cover

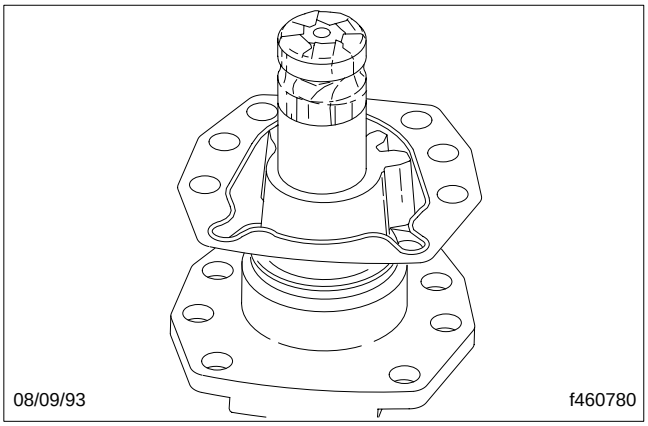

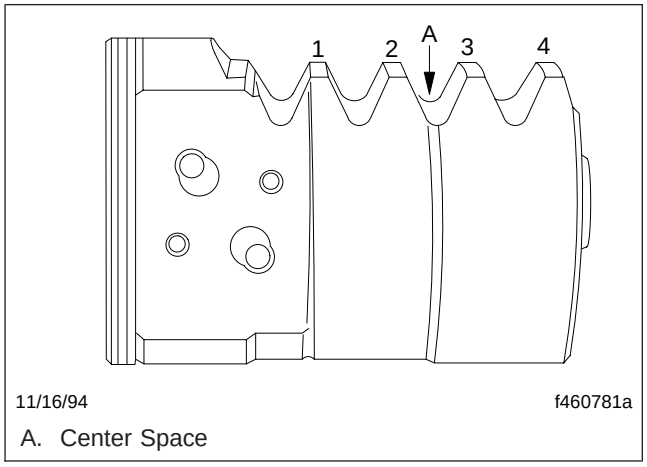

Fig. 98, Install the Side Cover Gasket on the Side Cover

38. There are four teeth on the rack piston. See **Fig. 99**. Position the rack piston so that the tooth

space identified by the pencil in **Fig. 100** (it is the space between the second and the third tooth) is in the center of the sector shaft opening.

A. Center Space

Fig. 99, Rack Piston Teeth

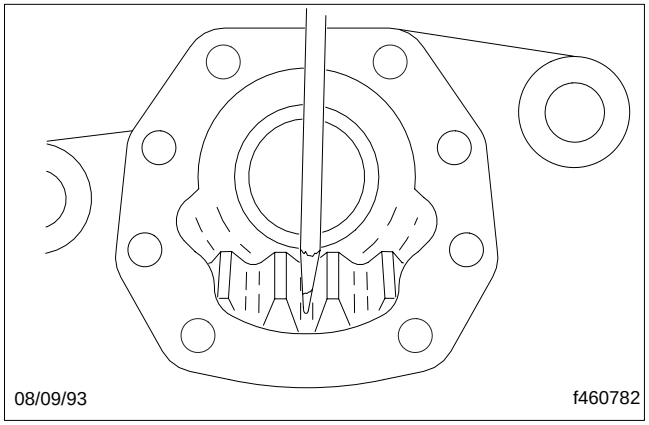

Fig. 100, Position the Rack Piston

39. With the rack piston centered, tighten the worm shaft adjusting screw 15 to 20 lbf·ft (20 to 27 N·m). Then loosen the adjusting screw 1/4 to 1/2 turn and note the torque required to rotate the input shaft 90 degrees each side of center. See **Fig. 101**. Loosen the adjusting screw if the noted input shaft torque exceeds 15 lbf·in (169 N·cm). Return the rack piston to the center position.
40. Remove any tape on the sector shaft serrations. Retape the serrations and bolt groove with **one** layer of masking tape. Install the sector shaft and side cover as an assembly into the gear housing. Make sure that the center tooth of the sector shaft engages the center space (between the second and third teeth) of the rack piston.

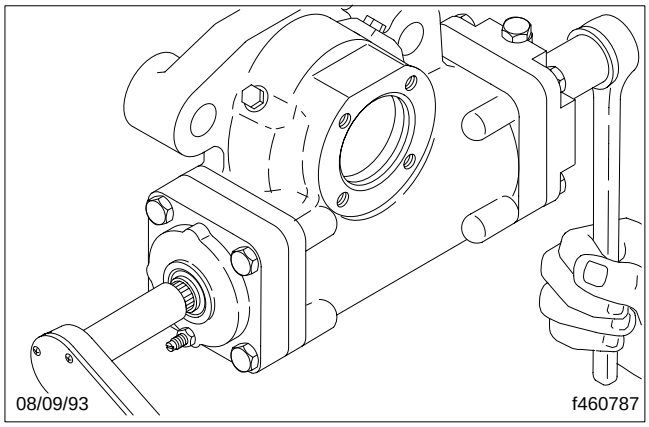

Fig. 101, Loosen the Adjusting Screw

41. Install the eight special side cover bolts into the side cover and tighten them 150 to 170 lbf·ft (203 to 230 N·m).
42. Place the trunnion cover on a bench with the exterior side down. Install a new Teflon® backup washer.
43. Install a new two-piece sector shaft seal so that the words OIL SIDE are visible after the seal is in place. See **Fig. 102**.

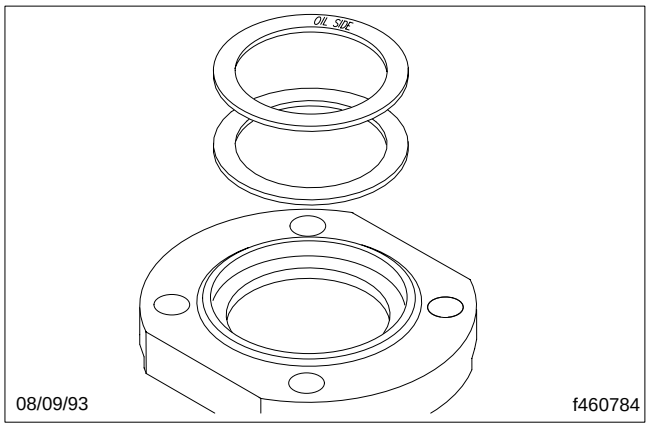

Fig. 102, Install the Sector Shaft Seals

44. Grease a new trunnion cover O-ring and install it in the trunnion cover O-ring groove.
45. Inspect the housing bearing to make sure that all the bearing rolls are in place. Then install the trunnion cover. See **Fig. 103**. Install the four

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

trunnion cover bolts and tighten them 15 to 22 lbf·ft (20 to 30 N·m). See **Fig. 104**. Pack the cavity around the seal area of the sector shaft with Mobil Temp 1 or 2 grease or an equivalent.

Using a suitable blunt-end drift, install a new dirt and water seal. Install a new protective boot on the sector shaft and trunnion cover. Locate the boot grease fitting hole toward the input shaft end of the gear assembly. See **Fig. 105**. Insert the grease fitting into the protective boot.

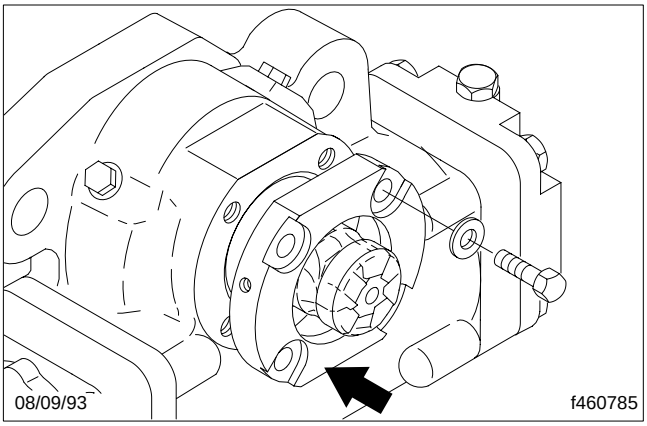

Fig. 103, Install the Trunnion Cover

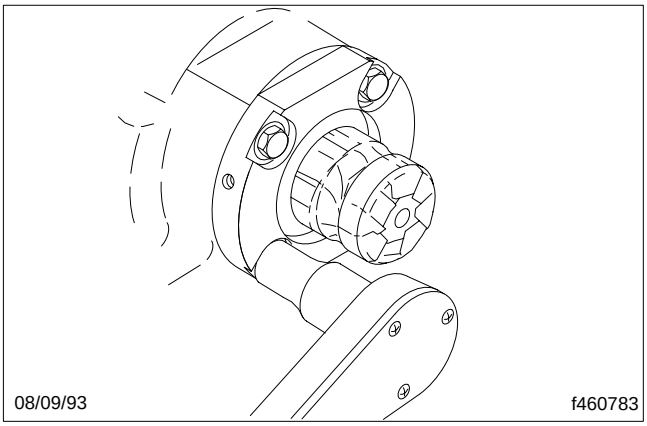

Fig. 104, Install the Trunnion Bolts

46. Apply clean grease to the input shaft seal assembly (seal and O-ring) and to the input shaft. Install a new two-piece input shaft seal (with the flat side out), and the steel backup washer, using seal driving tool J28490. See **Fig. 106** and **Fig. 107**. Install the retaining ring.

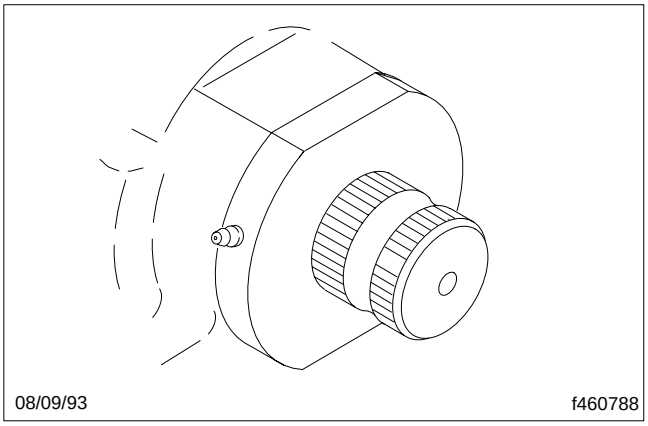

Fig. 105, Position the Grease Fitting Hole

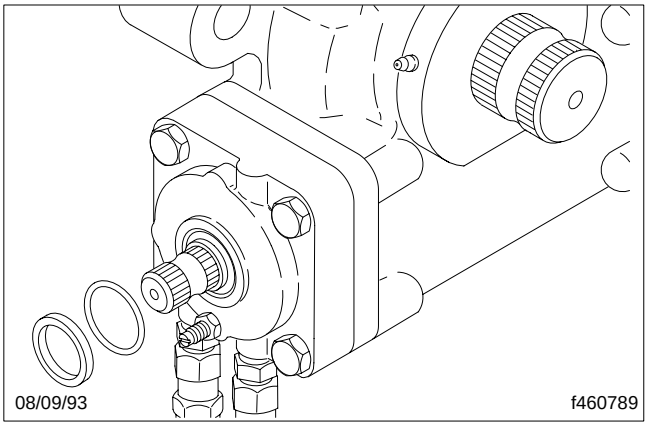

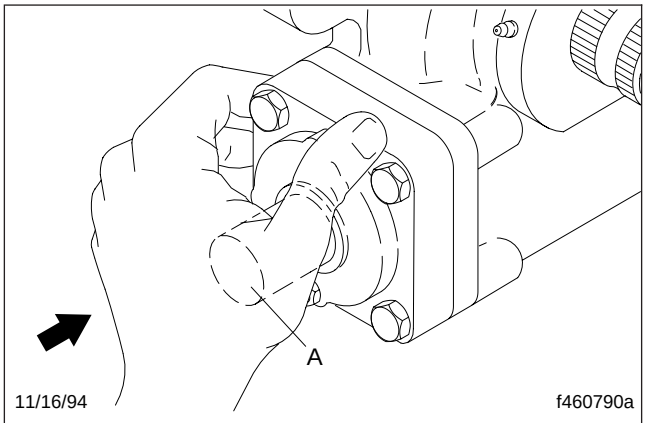

Fig. 106, Install the Input Shaft Seal and Washer

A. Seal Driving Tool J28490

Fig. 107, Install Input Shaft Seal and Backup Washer

47. Pack the area around the input shaft with clean water-resistant grease and install the dirt and water seal, using seal driving tool J28490 or a suitable blunt-end drift.
48. Apply clean grease to the cupped side of the new seal protector and install it, cupped side in, on the input shaft and into the serration relief groove. See **Fig. 108**.

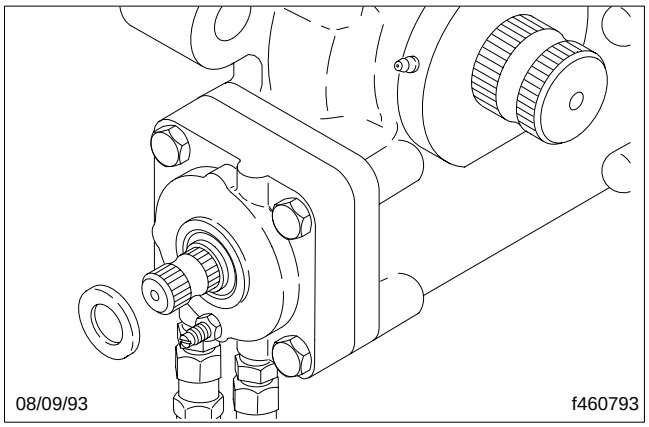

Fig. 108, Install the Seal Protector on the Input Shaft

49. Install the manual bleed screw (if equipped) and tighten it 27 to 33 lbf·in (305 to 373 N·cm).

Final Adjustments

Before installing the steering gear on the vehicle, make these adjustments.

NOTE: Worm shaft preload adjustment was done when the input shaft was installed in the valve housing during the assembly procedure.

1. To center the steering gear, turn the input shaft until the timing mark on the end of the sector shaft is at a right angle to the input shaft. See **Fig. 109**.

NOTE: Use a 12-point socket and an inch-pound torque wrench to turn the input shaft.

2. Adjust the sector shaft adjusting screw while turning the input shaft 180 degrees each side of center until the input shaft reaches a torque of 25 to 30 lbf·in (280 to 340 N·cm). See **Fig. 110**.
3. Back out the sector shaft adjusting screw one turn. Note the torque now required to turn the input shaft 180 degrees each side of center. Then tighten the adjusting screw to increase the noted torque by 2 to 4 lbf·in (23 to 45 N·cm).

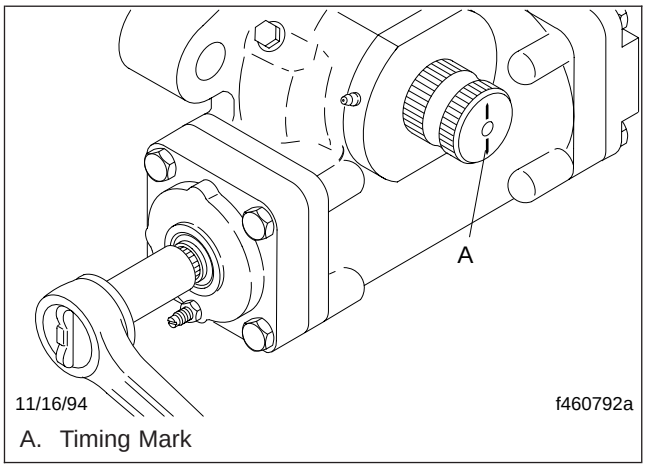

Fig. 109, Center the Steering Gear

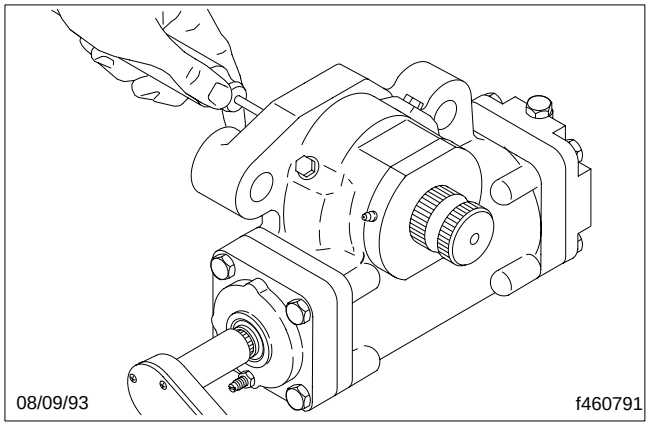

Fig. 110, Adjust the Sector Shaft Adjusting Screw

4. Tighten the sector shaft adjusting screw jam nut 40 to 45 lbf·ft (54 to 61 N·m). The torque now required to turn the input shaft should not exceed 20 lbf·in (226 N·cm) at any point in the steering gear travel. If it does exceed 20 lbf·in (226 N·cm), repeat the previous steps beginning with the procedure of backing out the adjusting screw one turn and noting the torque required to turn the input shaft 180 degrees.
5. While turning the input shaft back and forth slightly, adjust the worm shaft preload adjusting screw to increase the maximum noted input torque by 10 to 15 lbf·in (113 to 169 N·cm). Make sure that the worm shaft adjusting screw

Steering Gear Disassembly, Inspection, Assembly, and Final Adjustments

jam nut does not contact the end cover while making this adjustment.

Tighten the jam nut 70 to 80 lbf·ft (95 to 108 N·m). Be sure that the adjusting screw does not move.

6. The torque now required to turn the input shaft should not exceed 35 lbf·in (395 N·cm). If it does exceed 35 lbf·in (395 N·cm), repeat the previous step.

Removal

1. Disconnect the return line from the steering gear and plug the line. See **Fig. 1**. Also cap the return port of the gear with a high pressure fitting.

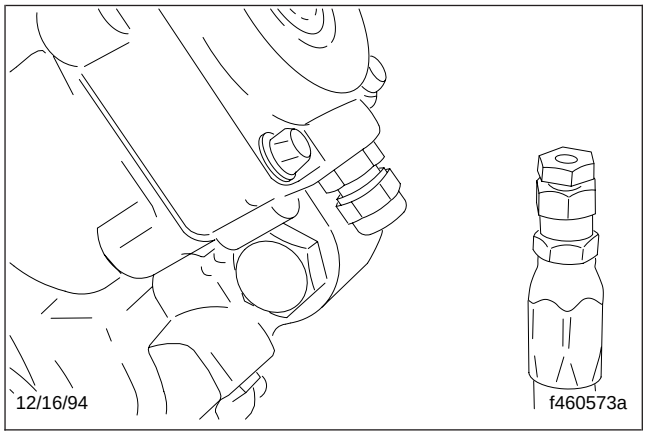

Fig. 1, Disconnect the Return Line

2. Disconnect the steering driveline from the steering gear input shaft.
   - 2.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

⚠ CAUTION

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

   - 2.2 Remove the lower end yoke from the input shaft. Do not turn the steering gear input shaft when removing the lower end yoke. Push the driveline shaft into the driveline tube as you remove the lower end yoke.

3. Remove the dirt and water seal from the steering gear. See **Fig. 2**.
4. Wipe out the grease and then remove the spiral retaining ring. See **Fig. 3**. Use a screwdriver inserted into the notch formed in the end of the ring.
5. Slip the input yoke back onto the input shaft with the pinch bolt installed, but not tightened. See **Fig. 4**.

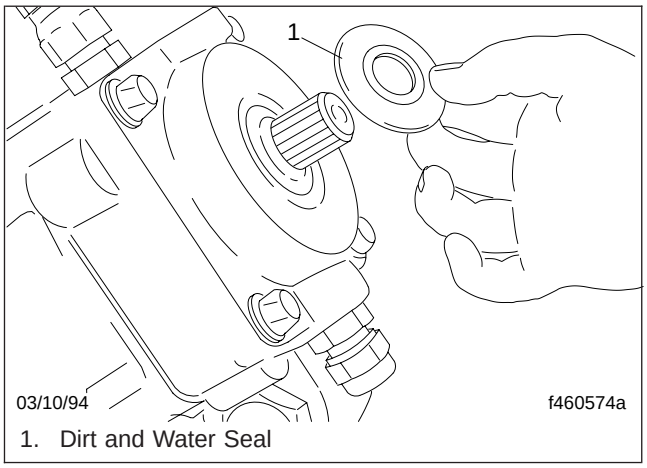

Fig. 2, Remove the Dirt and Water Seal

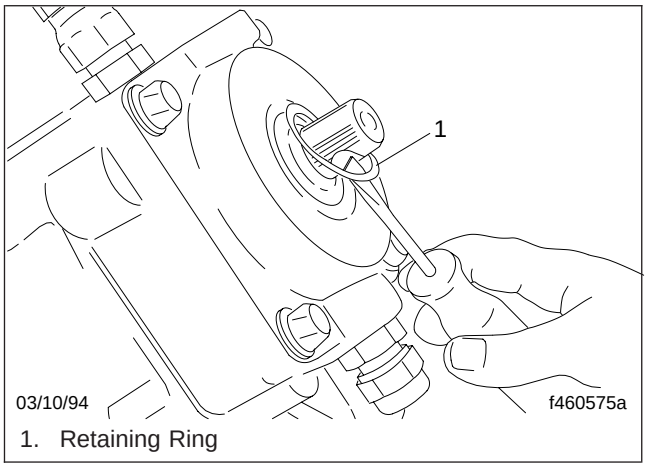

Fig. 3, Remove the Retaining Ring

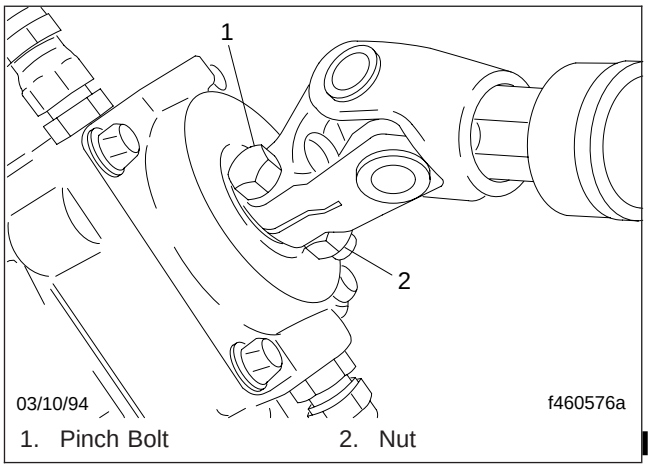

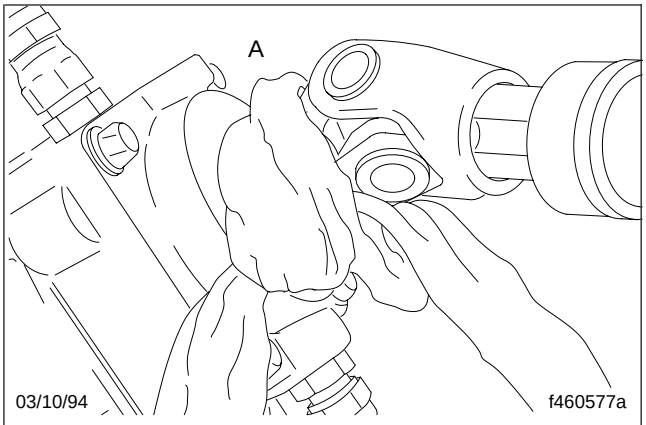

Fig. 4, Install the Pinch Bolt

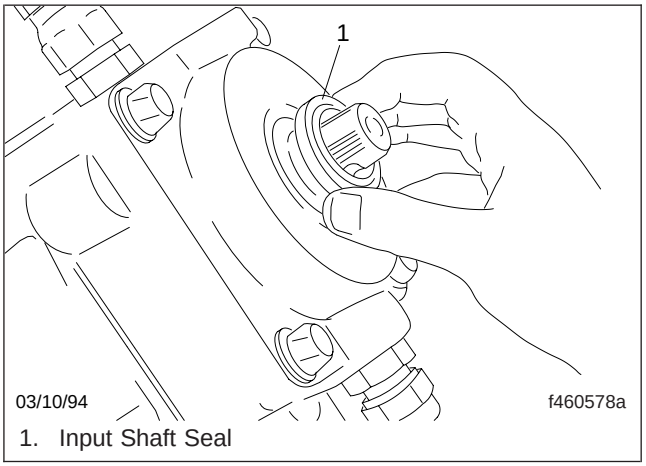
Input Shaft Seal Removal and Installation

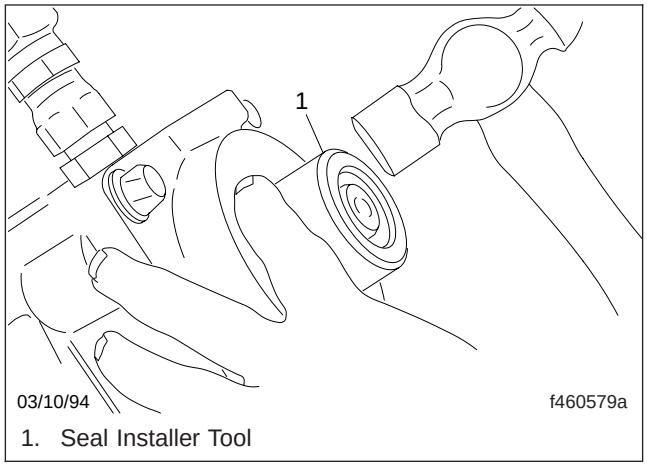


6. Tie or wrap a shop towel around the input shaft area and place a drip pan under the vehicle to catch the oil. See **Fig. 5**.

A. Cover the input shaft area.

Fig. 5, Shop Towel Covering the Input Shaft

7. Add the power steering fluid specified in **Specifications 400** as necessary to the fill line on the dipstick.
8. With the vehicle in neutral, momentarily turn the starter (quickly turn off the engine if it starts).
9. Remove the shop towel, pinch bolt, and input yoke.
10. Remove the seal. See **Fig. 6**.

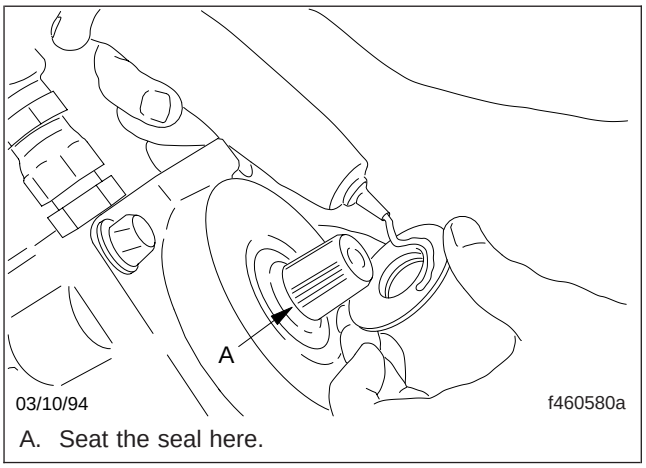


1. Input Shaft Seal

Fig. 6, Remove the Input Shaft Seal

11. Check the seal area of the valve housing for any seal fragments. Remove any that are found.
12. Check the seal for heat damage. If the seal is stiff, brittle, and not pliable like the new seal, it is probably heat damaged. You need to determine and fix the cause of excessive heat in the vehicle. For troubleshooting procedures, see **Section 46.11, Subject 300**.

Installation



1. Put clean grease on the new input shaft seal and place it over the input shaft, garter spring side first. See **Fig. 6**. Place seal installer tool J37073 over the input shaft and against the seal, small diameter end first. See **Fig. 7**. Tap the seal installer tool until the tool shoulder is square against the valve housing. Remove any seal material that may have sheared off in the seal bore or retaining ring groove.

1. Seal Installer Tool

Fig. 7, Position the Seal Installer Tool

2. Insert the new retaining ring into the groove.
3. Pack the end of the valve housing bore around the input shaft with clean high temperature industrial grease (Mobil Temp 1 or 2 or equivalent). Apply more of the grease to a new dirt and water seal and install it over the input shaft. See **Fig. 8**. Seat it in the groove behind the serrations and against the valve housing.
4. Connect the steering driveline to the steering gear input shaft.
   4.1 Clean the input shaft and the inside of the driveline yoke.

A. Seat the seal here.

Fig. 8, Install the Dirt and Water Seal

4.2 Apply a thin film of grease to the yoke splines. Use lithium-based grease, NLGI grade 2.

4.3 Slide the yoke on the input shaft and install a new pinch bolt. Before installing the nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new nut and tighten it to one of the following torque specs:

- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 77 N·m) for an M10 x 1.25 pinch bolt and nut

4.4 Apply torque seal, OGP F900WHITE, to the exposed bolt threads and to the nut.

5. Connect the return line to the steering gear return port.

6. Fill and bleed the steering system.

IMPORTANT: Do not turn the steering wheel in the following steps until instructed. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

6.1 Fill the power steering reservoir with the steering fluid specified in **Specifications 400** until nearly full.

Crank the engine for 10 seconds without allowing it to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed.

Repeat this procedure three times, each time checking and filling the reservoir.

6.2 Start the engine and let it idle for two minutes. Shut down the engine and check the fluid level in the reservoir.

6.3 Start the engine again. Steer the vehicle from full-left to full-right several times. As needed, add fluid to the full line on the reservoir dipstick.

Sector Shaft Seal Removal and Installation

Removal

NOTE: For clarity, the figures in this subject show the steering gear mounted on a mock-up frame and steering driveline.

If there is a leak in the trunnion cover area, remove the trunnion cover and replace the sector shaft seal package.

1. Place the front tires in a straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations are to be performed. Apply the parking brakes and chock the tires.
2. Remove and discard the pinch bolt, washer, and nut from the pitman arm.

NOTE: If factory alignment marks are not present, use a marking pen or paint to make a reference mark on the pitman arm and the sector (output) shaft.

3. Using a suitable puller, remove the pitman arm. Swing the pitman arm and drag link out of the way.
4. Remove the protective boot, the grease fitting, and the dirt and water seal from the trunnion cover. See **Fig. 1** and **Fig. 2**. Discard the protective boot and the dirt and water seal.

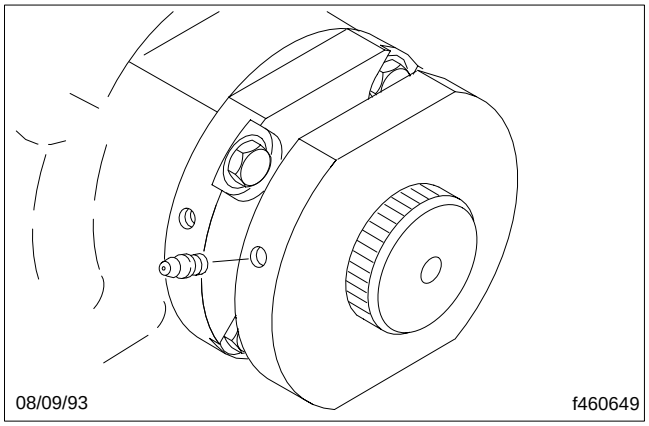


Fig. 1, Grease Fitting

5. Clean the nonserrated area of the sector shaft with a fine grade of emery paper as shown in **Fig. 3**. Be sure to remove any paint.

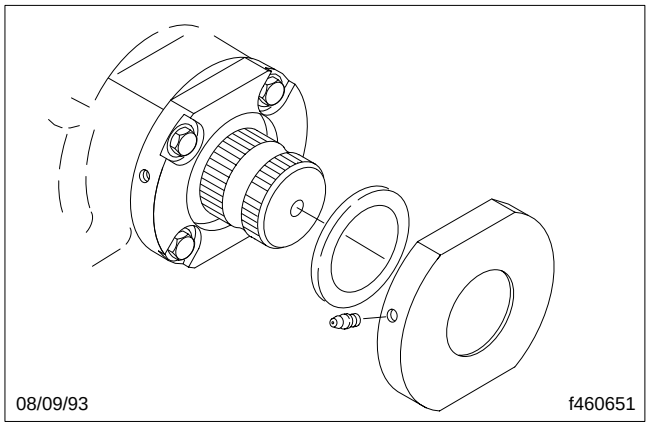

Fig. 2, Protective Boot

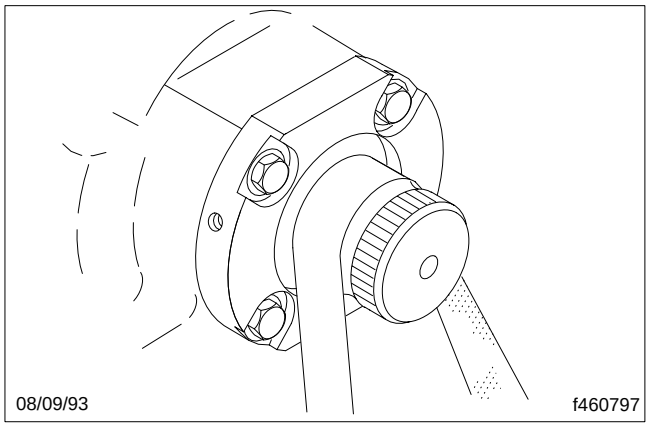

Fig. 3, Clean the Shaft Area

6. Remove the four trunnion cover bolts and trunnion cover as shown in **Fig. 4**. Remove and discard the sector shaft seal package, consisting of the Teflon® backup washer, the two-piece sector shaft seal, and the trunnion cover O-ring. See **Fig. 5**.

Installation

1. Clean the trunnion cover in petroleum-based solvent and inspect its seal cavity and sealing face for nicks or corrosion. Replace the trunnion cover with a new one if these conditions exist.
2. Place the trunnion cover on a bench to install the new seal package. Start with the new Teflon® backup washer. Install the new two-piece sector shaft seal so that the words OIL SIDE are visible after the seal is in place. See **Fig. 6**.

Sector Shaft Seal Removal and Installation

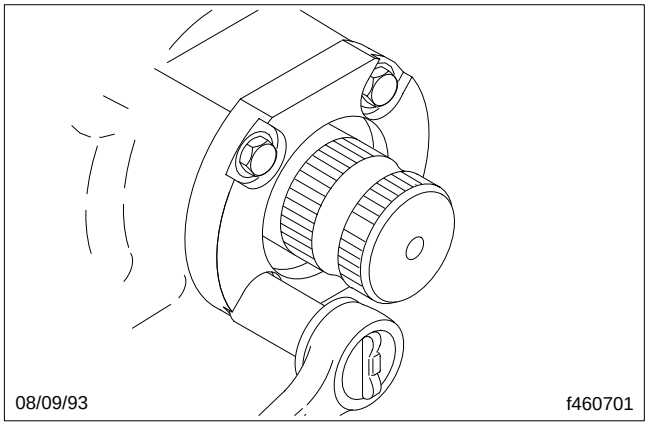

Fig. 4, Removing the Trunnion Cover Bolts

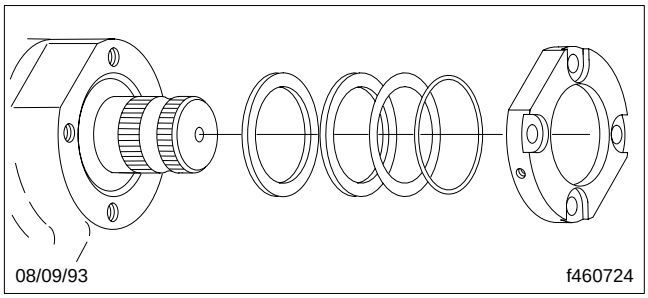

Fig. 5, Trunnion Cover and Seals

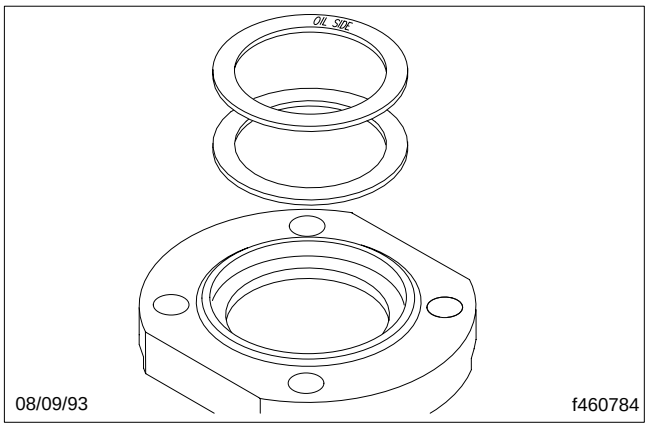

Fig. 6, Sector Shaft Seal Installation

⚠ WARNING

The words OIL SIDE must be visible after the seal is in place, as shown in Fig.6. If not, the seal will malfunction. This could cause a loss of power steering assist and result in an accident possibly causing personal injury or property damage.

3. Grease the new trunnion cover O-ring and install it in the cover groove.
4. Cover the serrations of the sector shaft with one layer of masking tape to avoid damaging the seals during trunnion cover installation. See **Fig. 7**.

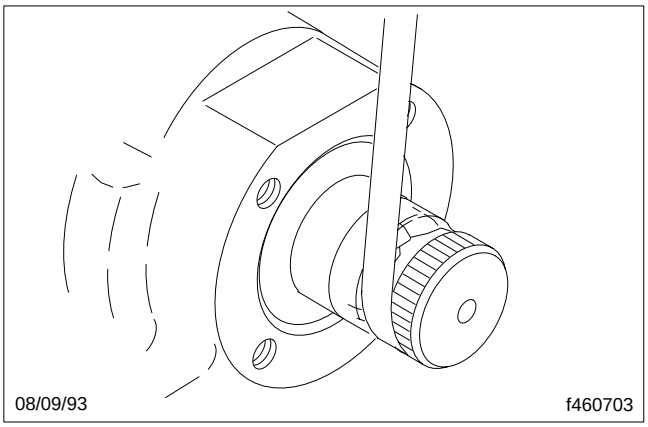

Fig. 7, Masking Tape Cover

5. Install the trunnion cover. See **Fig. 8**.

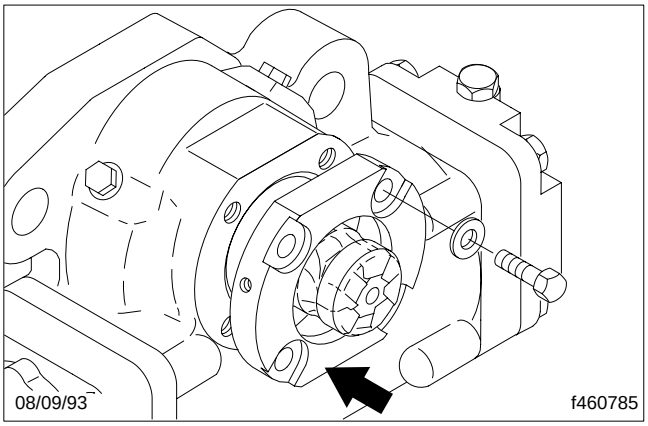

Fig. 8, Trunnion Cover, Installation

6. Install the four trunnion cover bolts. Torque the bolts 15 to 22 lbf·ft (20 to 30 N·m). See **Fig. 9**. Pack the cavity around the seal area of the sector shaft with Mobil Temp® 1 or 2 grease or an equivalent. Install a new dirt and water seal using a suitable blunt-end drift as shown in **Fig. 10**.
7. Grease the new protective boot inside the smaller diameter ring, and install it on the sector shaft. See **Fig. 11**. Position the protective boot

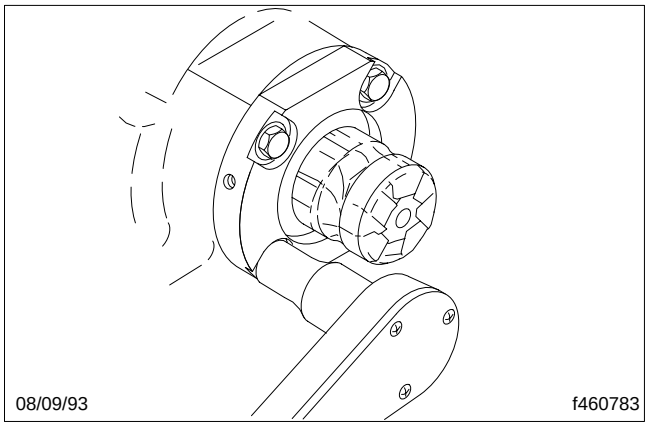

Fig. 9, Tighten Trunnion Cover Fasteners

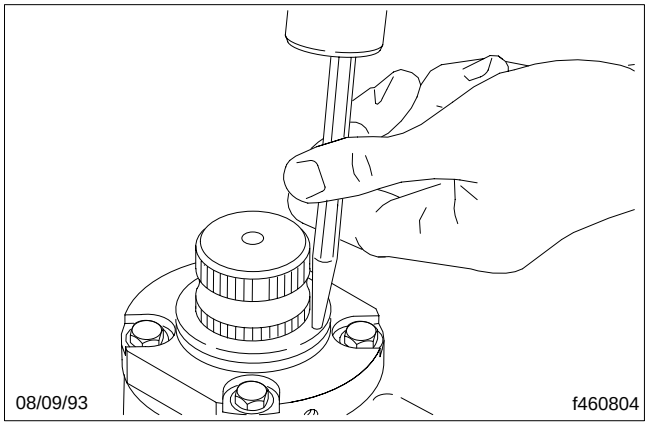

Fig. 10, Dirt and Water Seal Installation

so that the grease fitting hole faces toward the input shaft end of the gear assembly.

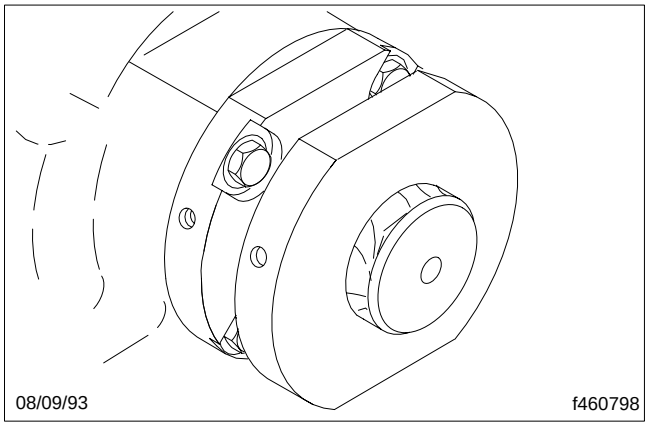

Fig. 11, Boot Installation

8. Insert the grease fitting into the protective boot. Remove the tape from the sector shaft.
9. Attach the pitman arm to the sector shaft. Be sure that the mark on the pitman arm aligns with the mark on the sector shaft. See **Fig. 12**.

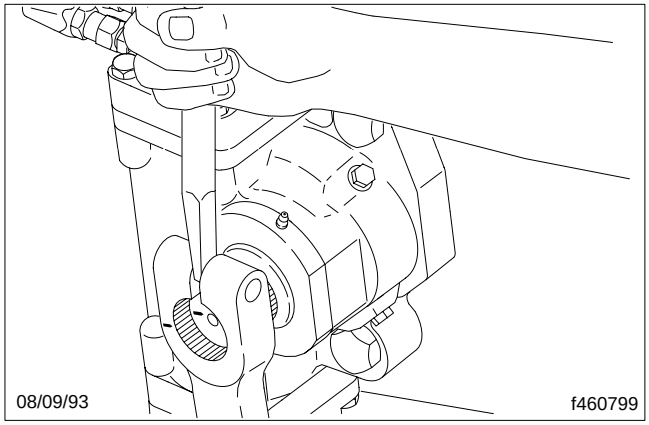

Fig. 12, Pitman Arm Installation

⚠ WARNING

Never leave a chisel wedged in the pitman arm slot. When using a chisel to spread the slot in the pitman arm, maintain a firm grip on the chisel at all times. Otherwise, the chisel may fly loose, which could cause an injury.

NOTE: The pitman arm may not fit over the splines on the sector shaft without spreading the slot in the arm. Use a ball-peen hammer to drive a chisel into the slot. Hold the chisel in place. Install the pitman arm on the sector shaft. Remove the chisel from the slot.

10. Install a new pinch bolt, washer, and nut. See **Fig. 13**. Tighten the nut 215 to 245 lbf·ft (290 to 332 N·m).
11. Fill and bleed the steering system.

    IMPORTANT: Do not turn the steering wheel until instructed in the following steps. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

    11.1 Fill the power steering reservoir with the steering fluid specified in **Specifications 400** until nearly full.

Sector Shaft Seal Removal and Installation

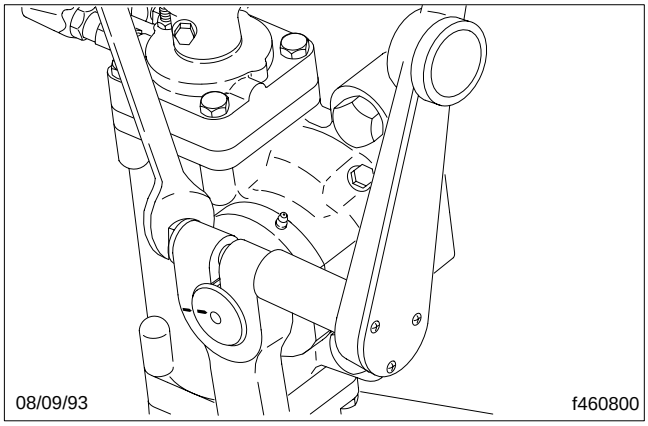

Fig. 13, Pinch Bolt Installation

Crank the engine for 10 seconds without allowing it to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed.

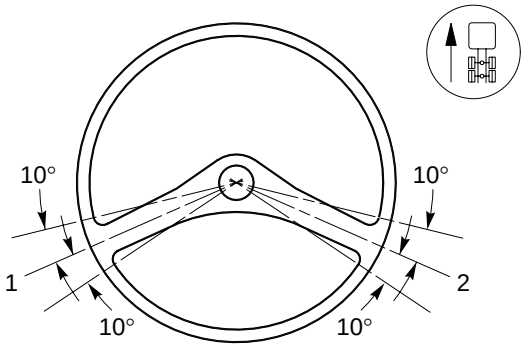
Repeat this procedure three times, each time checking and filling the reservoir.

11.2 Start the engine and let it idle for two minutes. Shut down the engine and check the fluid level in the reservoir.

11.3 Start the engine again. Steer the vehicle from full left to full right several times. As needed, add fluid to the full line on the reservoir dipstick.

NOTE: If needed, remove air from the system by adjusting the poppets. For instructions, see **Subject 100**.

Post-Service Checks |



After power steering components have been worked on and before the vehicle is placed into service, make the following checks.

⚠ WARNING

Failure to make the following checks could result in damage to the power steering system. This could cause a loss of hydraulic assist, which could cause personal injury or property damage.

1. With the engine turned off and warm, check the power steering reservoir fluid level.
2. Check for air in the system.
   - 2.1 Place a thermometer in the power steering reservoir, then warm the hydraulic system to normal operating temperature of 125° to 135°F (51° to 57°C) by operating the engine at low idle while turning the steering wheel through several full-left and full-right turns.
   - 2.2 With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level (a sign that air is trapped in the system). If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as needed. Bleed the air from the system.
3. At full-left and full-right wheel cuts, be sure the axle stops (on the rear-side of the spindle) are set so there is at least 1/2-inch (13-mm) clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be 3/4 inch (19 mm). If clearance is less than this, reset the axle stops.
4. If there are still problems with the power steering system, see the troubleshooting procedures in **Section 46.11, Subject 300**. Otherwise, go to the next step.
5. Test drive the vehicle or take a ride with the driver.

Check the steering wheel spoke position. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 1**. If they are not, remove the steering wheel and install it in the correct position. For instructions, see the applicable section in this group.

1. 8 o'Clock Position
2. 4 o'Clock Position

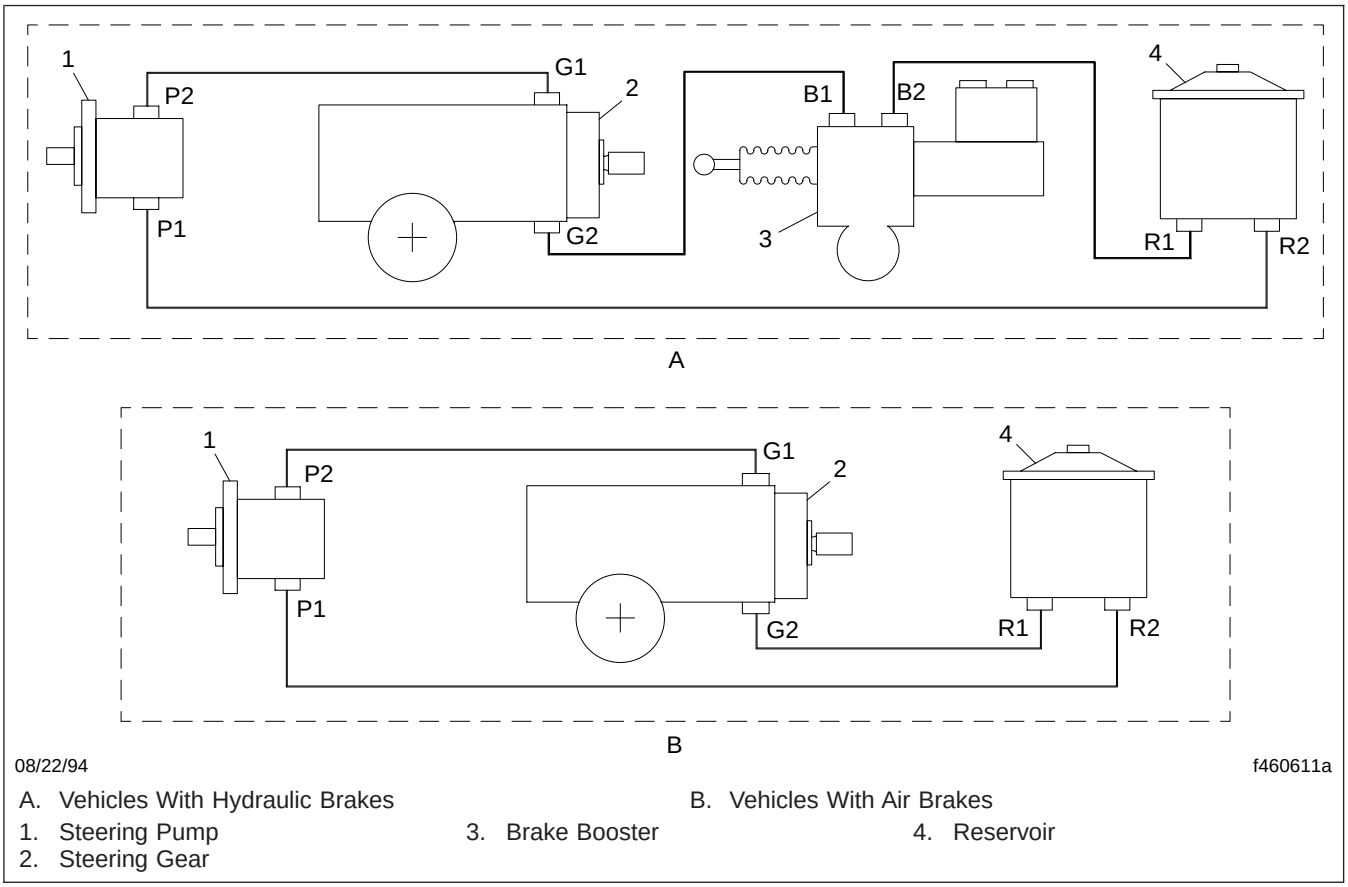
* Torque values are for a plain capscrew with a phosphate- and oil-coated locknut with a hardened washer.

Table 2, Steering Gear Torque Values

⚠ WARNING

Fill only with approved clean power steering fluid. Any mixture or any unapproved fluid could lead to seal deterioration and leaks. Any fluid leak could eventually cause loss of power steering assist.



Specifications

Approved Power Steering Fluids	
Fluid Type	**Approved Fluid**
Automatic Transmission Fluid*	Dexron® II Dexron® III
Heavy-Duty Engine Oil* IMPORTANT: Do not use heavy-duty engine oil in vehicles built from November 4, 2002. **⚠ WARNING** **Do not use heavy-duty engine oil in vehicles equipped with a Hydro-Max® brake booster. Engine oil is not compatible with the seals in the brake booster. If the vehicle is equipped with a Hydro-Max brake booster, use only automatic transmission fluid in the power steering system. Failure to follow this precaution could cause loss of hydraulic brake assist, possibly resulting in personal injury and property damage.**	Union 10W–40 Texaco 10W–40 Chevron 10W–40 Mobil Super 10W–40 Union 15W–40 Shell Rotella T 30W

* Do not mix engine oil with automatic transmission fluid (ATF). Use the same lubricant for parts as is in the power steering system.

Table 3, Approved Power Steering Fluids

2. Steering Gear
3. Brake Booster
4. Reservoir

Fig. 1, Steering System Plumbing Diagram

General Description (Refer to Fig. 1)

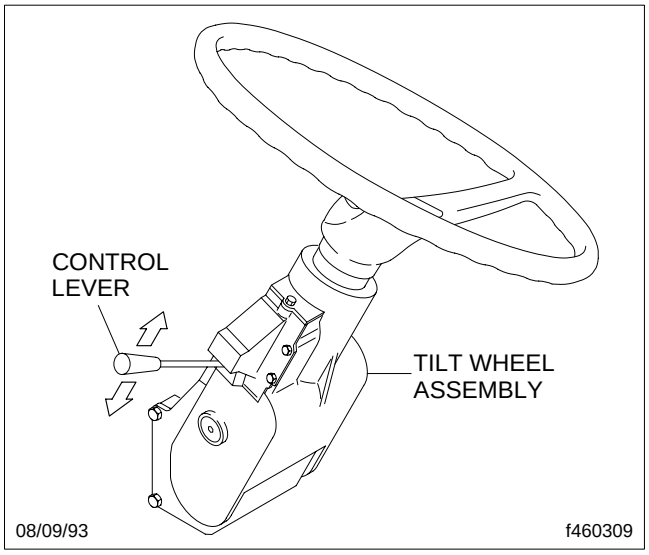

Fig. 1

The tilt/telescoping steering column has a tilt range of 15 degrees, and a telescoping range of 67 mm (2-5/8 inches). A control lever is located just below the turn signal switch. For operating instructions, refer to the vehicle driver's manual.

The upper end of the steering column assembly is threaded for the steering wheel nut, and just below the threads are splines that correspond to those in the steering wheel hub. At the lower end, the shaft is splined for the steering driveline end yoke, and has a groove for the end-yoke pinch bolt.

The steering column assembly is held in place by six hexbolts that attach the assembly to the lower dash and the pedal support bracket.

Steering Wheel Removal and Installation

Removal

1. Put the front wheels in the straight ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the place where the work will be done.

   Don't turn the steering wheel at any time during the removal procedure.
2. Apply the parking brake and chock the tires.
3. Disconnect the batteries at the negative terminal.
4. Using a small screwdriver, carefully pry out the horn button. Disconnect the two wires from it. **See Fig. 1.**

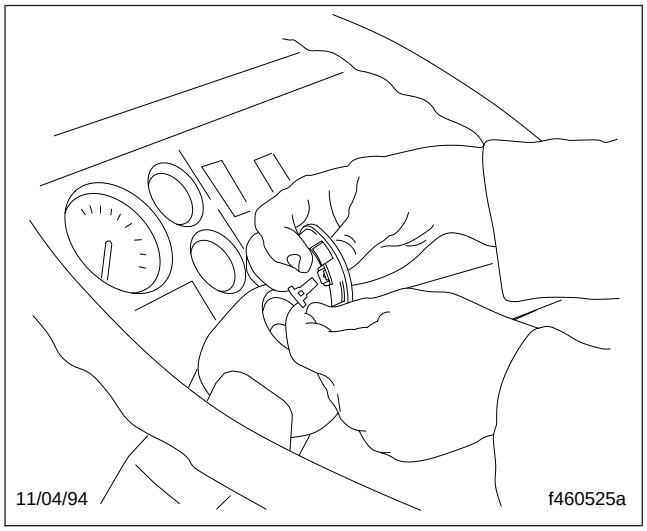

Fig. 1, Pry out the Horn Button

5. Using a deep socket to avoid damaging the wires, remove the steering wheel nut. **See Fig. 2.**
6. Using 1/4-inch sheet metal stock, make a wire protector about 4 cm x 1.5 cm (1-5/8 inches x 5/8 inch), like the one shown in **Fig. 3.** Then put it over the end of the steering column.
7. Using a steering wheel puller, remove the steering wheel from the steering column. **See Fig. 4.**

IMPORTANT: When you set the steering wheel aside, be careful not to damage the turn signal self-cancelling pin on the underside of the wheel. **See Fig. 5.**

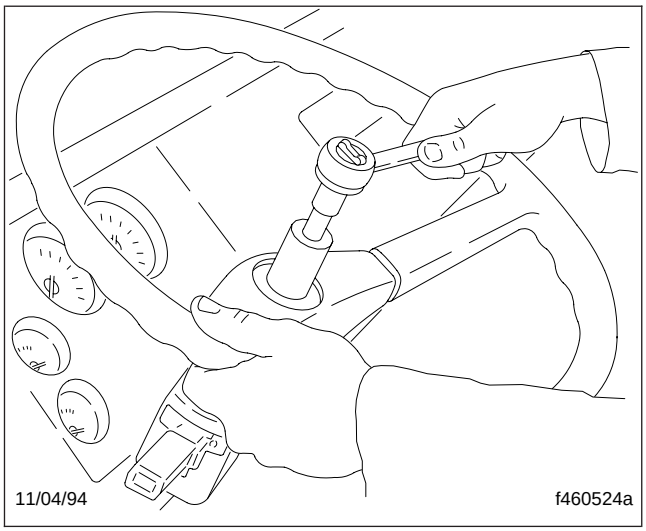

Fig. 2, Remove the Steering Wheel Nut

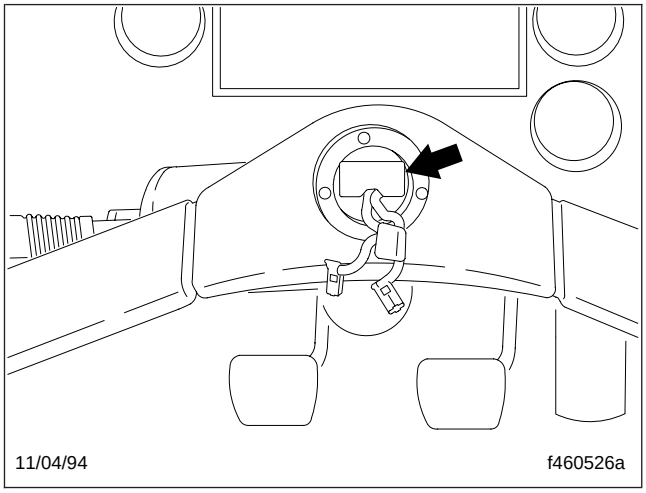

Fig. 3, Make a Wire Protector

Installation

1. Make sure the front tires are pointed straight ahead and the steering gear is centered.
2. Put the steering wheel on the steering column so that the spokes are within 10 degrees of the 4 o'clock and 8 o'clock positions. **See Fig. 6.**
3. Thread the two horn wires through the steering wheel nut, then install the nut. Tighten it 81 N·m (60 lbf·ft).

Steering Wheel Removal and Installation

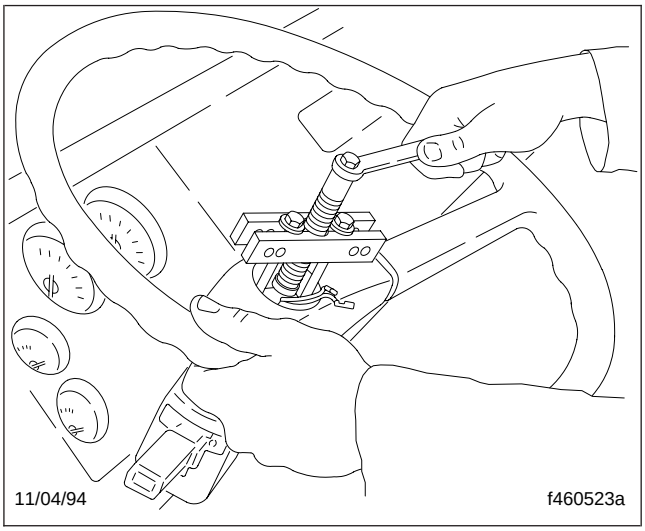

Fig. 4, Remove the Steering Wheel from the Column

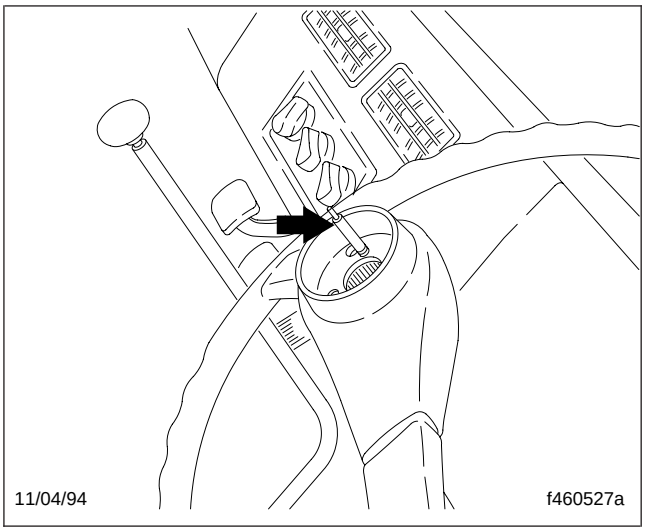

Fig. 5, Turn Signal Self-Cancelling Pin

4. Connect the two wires to the horn button. Pack the horn wires with dielectric grease.

NOTE: The horn wires may be connected to either terminal.

5. Install the horn button in the steering wheel hub so the logo on it is aligned with the steering wheel spokes. **See Fig. 7.**

6. Take the vehicle for a test drive to make sure the steering wheel is on correctly. If it isn't, remove it and install it again.

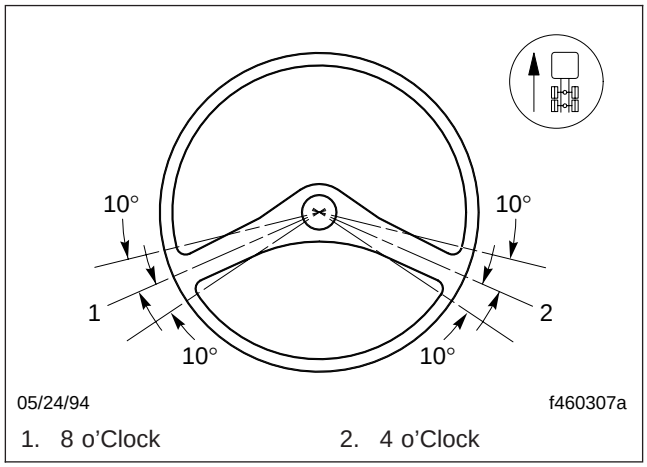

Fig. 6, Center the Steering Wheel

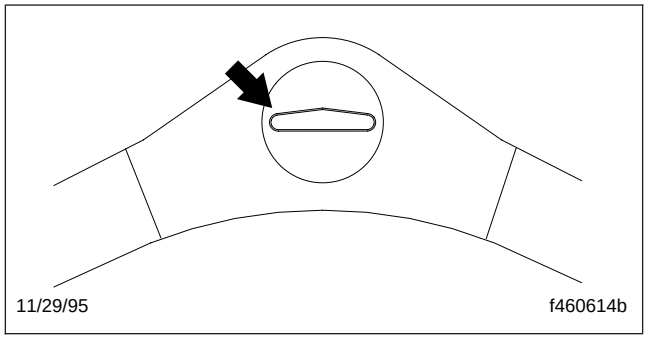

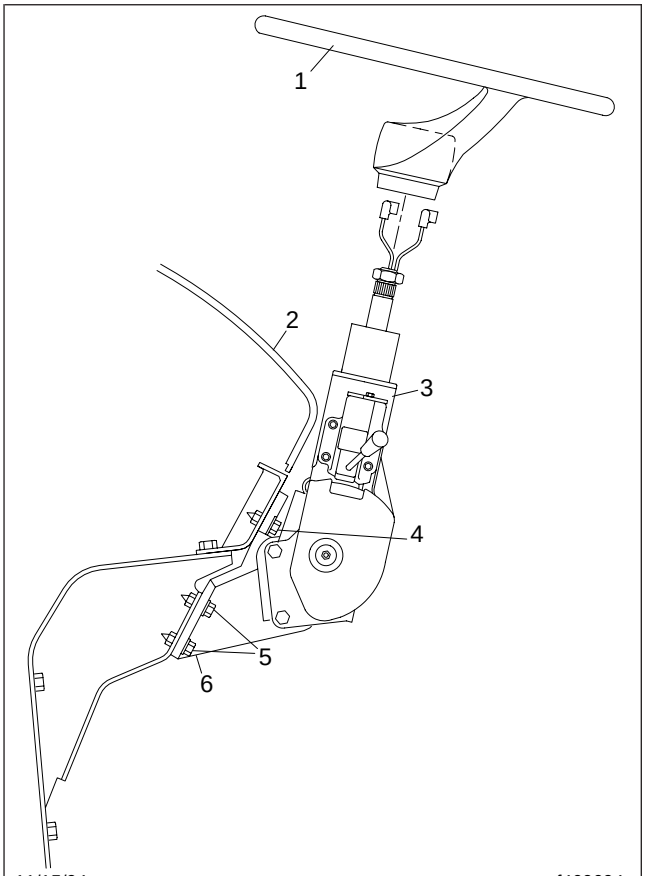

Fig. 7, Align the Logo

Removal (See Fig. 1)

1. Steering Wheel
2. Instrument Panel
3. Tilt Steering Column Assembly
4. Upper Mounting Hexbolts
5. Lower Mounting Hexbolts
6. Steering Column Mounting Bracket

Fig. 1, Steering Column Assembly

1. Park the vehicle on a level surface. Make sure the front tires are pointing forward. Apply the parking brakes. Shut down the engine. Chock the tires.

IMPORTANT: Once the vehicle is parked, do not turn the steering wheel at any time during the following procedures.

2. Disconnect the batteries.
3. Remove the plastic cover from the turn signal switch on the left side of the steering column.
4. Remove the two allen-head screws that attach the turn signal switch to the steering column. Swing the turn signal switch up and out of the way.
5. Disconnect the horn wire.
6. Remove and discard the pinch bolt and nut from the steering driveline yoke.
7. Remove the four hexbolts that attach the steering column bracket to the lower dash and to the pedal support bracket.
8. Disconnect the steering column from the steering driveline U-joint yoke.
9. Loosen the two upper mounting bracket hexbolts. Remove the steering column assembly from the vehicle.
10. If replacing the column, remove the steering wheel. For instructions, see **Subject 100**.

Installation (See Fig. 1)

1. Install the steering wheel. For instructions, see **Subject 100**.
2. Wipe the end of the column shaft with a clean, dry cloth.
3. Slide the upper end yoke onto the column shaft. Install a new end yoke pinch bolt. Before installing the pinch-bolt nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install and tighten a new pinch-bolt nut. For the proper torque, see **Specifications, 400**.
4. Apply torque seal OGP F900WHITE to the exposed pinch-bolt threads and to the locknut.
5. Align the upper mounting bracket holes with the upper mounting bracket hexbolts. Position the column assembly under the lower dash.
6. Line up the four lower holes in the steering column bracket with those in the lower dash and the pedal support bracket.
7. Install the four hexbolts and tighten them in stages to a final torque of 40 lbf·ft (54 N·m).
8. Connect the horn wire.

Steering Column Removal and Installation

9. Install the turn signal switch on the left side of the steering column. Tighten the screws firmly. Install the plastic cover.
10. Connect the batteries.
11. Remove the chocks from the tires.
12. Test drive the vehicle and make sure the steering column assembly operates smoothly. If it does not operate smoothly, repeat the service operations.

Disassembly (Refer to Fig. 1)

WARNING

WARNING: All steering mechanisms are critical safety items. Because of this, follow the instructions in this subject to the letter. Failure to do so may result in loss of steering, which could cause an accident resulting in personal injury or property damage.

Wear eye protection during disassembly of the tilt steering wheel column assembly. Parts of the assembly are spring-loaded, and could be ejected, which could result in serious eye injury.

NOTE: If replacing only the control lever (Ref. 36), spring cover plate (Ref. 33), actuator housing (Ref. 35), spring (Ref. 31), cam actuator (Ref. 38), pivot pin (Ref. 39), lockpin (Ref. 30), anti-rattle spring (Ref. 37), plate (Ref. 29), spring and wedgelock (Refs. 28 and 40), and spring and lockbar (Refs. 27 and 41), it is not necessary to remove the steering wheel and column assembly from the vehicle.

1. To minimize spring tension within the column assembly, hold the control lever all the way down, then move the steering wheel to the upright (non-tilt) position; release the control lever.

   Pull up the control lever and move the steering wheel up until it stops; release the control lever.

2. Remove the steering wheel from the column assembly. **Refer to Subject 100 for instructions**.

3. Remove the steering column assembly from the vehicle. **Refer to Subject 110 for instructions**.

4. Unscrew the control lever (Ref. 36).

5. Remove the 10-24 x 5/8-inch tapping screw (Ref. 32) from the spring cover plate (Ref. 33). Remove the plate.

6. Remove the four self-tapping screws (Refs. 32 and 34) from the actuator housing and bushing assembly (Ref. 35). Remove the actuator housing.

NOTE: On some tilt/telescoping column assemblies, two of the self-tapping screws (Ref. 32) are 5/8-inch long, and the other two screws (Ref. 34) are 7/8-inch long.

7. Remove the spring (Ref. 31), cam actuator (Ref. 38), pivot pin (Ref. 39), lockpin (Ref. 30), and anti-rattle spring (Ref. 37).

8. Remove the disengagement plate (Ref. 29), spring and wedgelock (Refs. 28 and 40), and spring and lockbar (Refs. 27 and 41).

   Remove all grease from the wedgelock/ lockbar cavity.

9. Detach the springs (Refs. 43 and 45) from the main housing assembly (Ref. 26). Remove the upper spring cover (Ref. 42).

10. Remove the four bolts (Ref. 8) from the support bracket (Ref. 25) and lower bearing housing (Ref. 21).

11. Remove the spring (Ref. 18) from the jacket tube (Ref. 16).

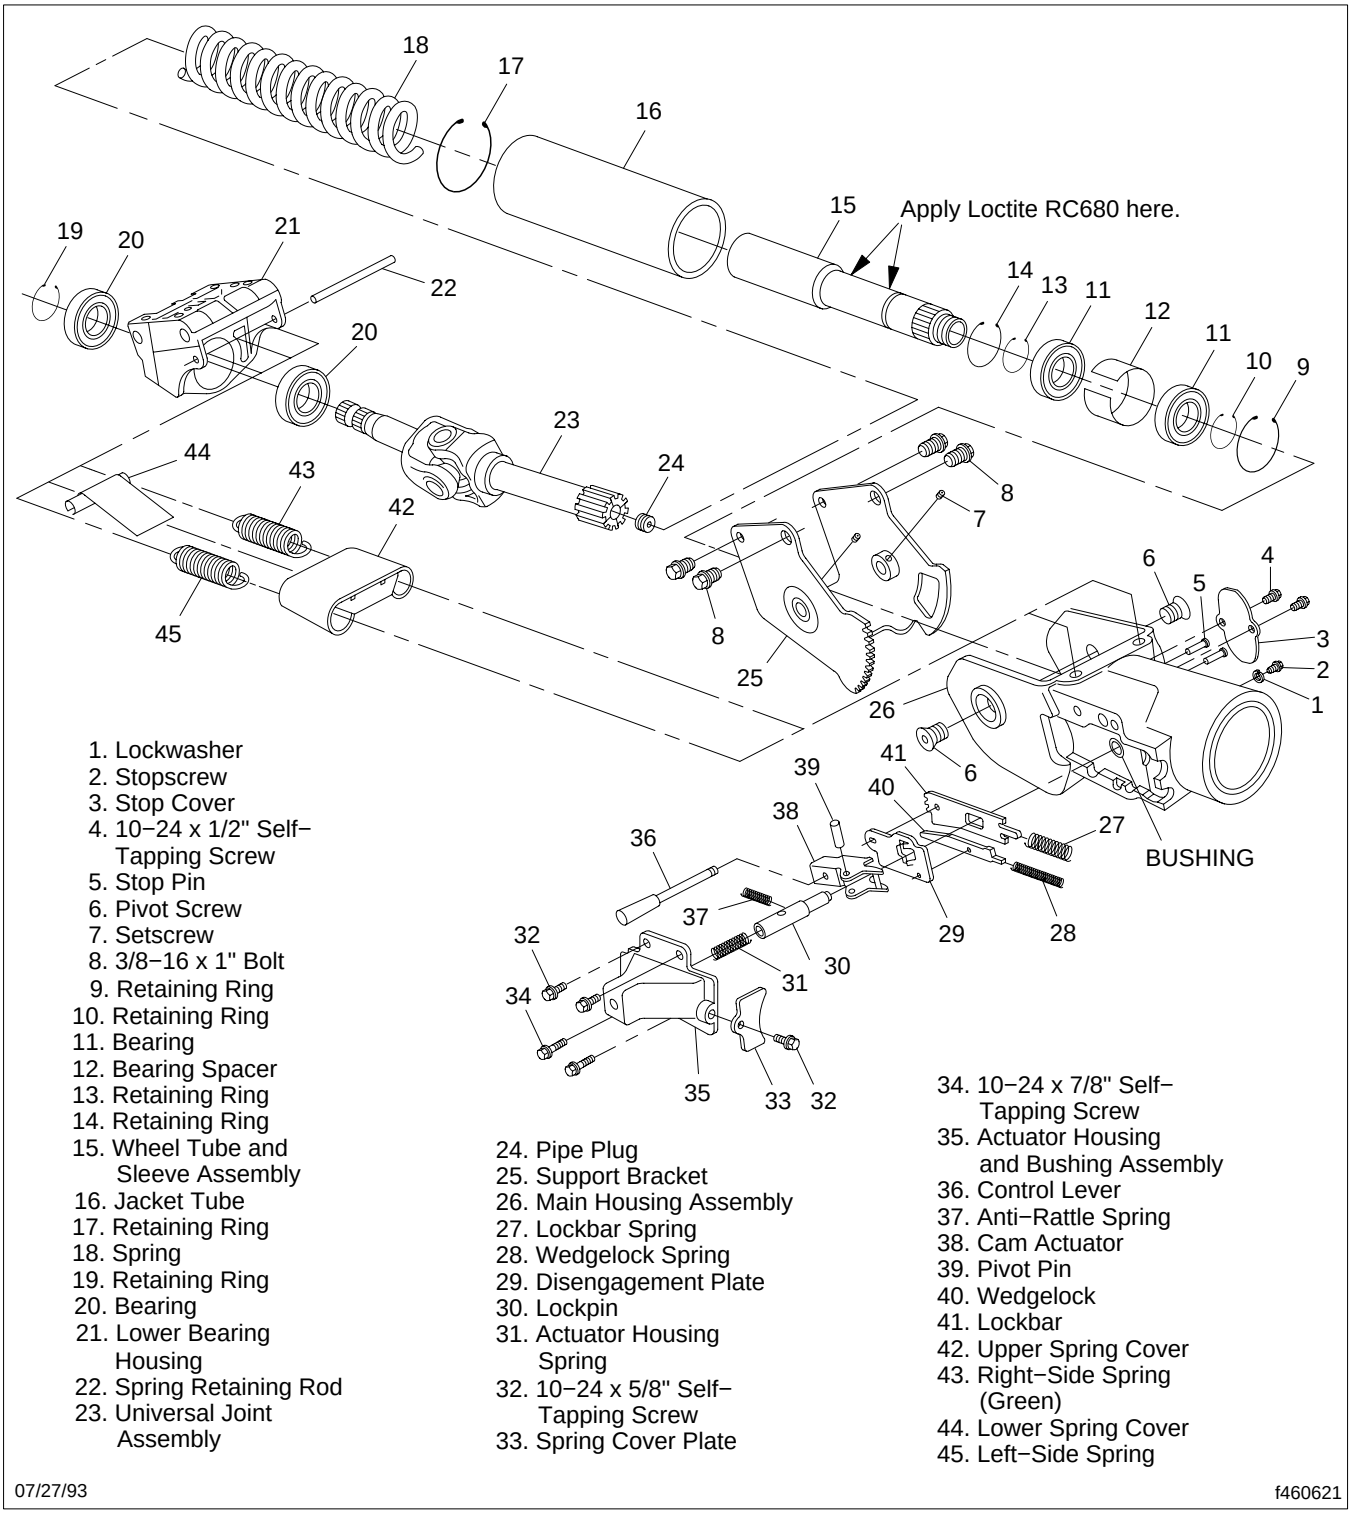
12. Remove the lower spring cover (Ref. 44), springs (Refs. 43 and 45), and spring retaining rod (Ref. 22) from the lower bearing housing.

13. Remove the retaining ring (Ref. 19) from the lower end of the universal joint assembly (Ref. 23). Remove the universal joint assembly from the lower bearing housing.

14. Using a suitable bearing puller, remove the bearings (Ref. 20) from the lower bearing housing.

    Using a 3/16-inch allen wrench, remove the pipe plug (Ref. 24) from the end of the universal joint assembly.

15. Remove the stopscrew (Ref. 2) and lockwasher (Ref. 1) from the main housing assembly (Ref. 26).



16. Push the wheel tube and jacket tube (Refs. 15 and 16) out through the lower end of the main housing assembly.

17. Remove the two retaining rings (Refs. 9 and 10) from the top end of the wheel tube and sleeve assembly and the jacket tube.

CAUTION

CAUTION: Keep the jacket tube clean and free of lubricant. Also, don't dent or scratch the jacket

tube. Dents or scratches could restrict the telescoping action of the tilt steering column assembly.

18. Insert a 20 x 2 cm (8 x 3/4-inch) rod into the splined sleeve end of the wheel tube. Using a press, press out the wheel tube and sleeve assembly. Remove the retaining ring (Ref. 14).
19. Using a suitable bearing removal tool, press the bearings (Ref. 11) off of the wheel tube and sleeve assembly. Remove the retaining ring (Ref. 13).
20. Remove the self-tapping screws (Ref. 4), stop cover (Ref. 3), and the stop pins (Ref. 5) from the main housing assembly.
21. Remove the setscrews (Ref. 7) from the support bracket. Remove the two pivot screws (Ref. 6), then separate the support bracket (Ref. 25) from the main housing.

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

NOTE: For ease of removal, it may be necessary to heat the setscrews and pivot screws. Don't exceed 260°C (500°F) as the material hardness of these fasteners will be affected.

22. Using a petroleum-based solvent, clean the pivot screws, setscrews, and the internal threads of the support bracket.

Assembly (Refer to Fig. 1)

⚠ WARNING

WARNING: Wear eye protection during assembly of the tilt steering wheel column assembly. Parts of the assembly are spring-loaded, and could be ejected, which could result in serious eye injury.

1. Position the support bracket (Ref. 25) in the main housing (Ref. 26). Make sure that the bracket teeth are on the same side of the housing as the cam actuator (Ref. 38).
2. Install but don't tighten the pivot screws (Ref. 6). Insert a 13 x 76 mm (1/2 x 3 inch) bolt and nut through the center of the support bracket, between the bracket flanges.

   Back off the nut to spread the flange bosses against the main housing and provide clearance for installation of the lower bearing housing (Ref. 21).

   Remove the pivot screws (Ref. 6).
3. Apply a light coating of lithium grease under the head of each pivot screw (Ref. 6) then, apply Loctite RC680 to the threads of the pivot screws.

NOTE: Use care and avoid getting any grease on the pivot screw threads, or Loctite RC680 under the pivot screw head.

4. First tighten the pivot screw on the cam-actuator side of the housing 460 to 500 N·cm (40 to 45 lbf·in). Install and tighten the other pivot screw 460 to 500 N·cm (40 to 45 lbf·in).
5. Apply Loctite RC680 to the threads of the setscrews (Ref. 7). Install the setscrews and tighten them 560 to 680 N·cm (50 to 60 lbf·in).

NOTE: Use care and avoid getting any Loctite RC680 under the setscrew head.

6. Remove the 1/2 x 3-inch bolt and nut from the support bracket.
7. Install two new retaining rings (Refs. 13 and 14) on the top end of the wheel tube and sleeve assembly (Ref. 15).
8. Apply Loctite RC680 around the wheel tube in the bearing support area. Install a new bearing (Ref. 11) against the upper retaining ring.
9. Install the bearing spacer (Ref. 12). Install a new bearing (Ref. 11) until it clears the upper retaining ring groove. Install a new retaining ring (Ref. 10).
10. Insert the wheel tube and sleeve assembly (Ref. 15) into the jacket tube (Ref. 16). Align the split in the bearing spacer (Ref. 12) with the screw hole in the top end of the jacket tube.
11. Using a tubular bearing installation tool, apply pressure against the outer race of the upper bearing and press the wheel tube and sleeve assembly into the jacket tube.

Column Disassembly and Assembly

Install retaining rings (Refs. 9 and 17) in the grooves of the jacket tube.

12. Place the jacket tube assembly spring-end down on a pedestal that is about 10 cm (4 inches) high and 6 cm (2-1/4 inches) in diameter. Make sure that the cutouts on the lower collet in the main housing assembly are aligned with the holes for the lockpin (Ref. 30) and stopscrew (Ref. 2).
13. Slide the main housing assembly down over the jacket tube assembly. As the upper end of the jacket tube approaches the upper tapered collet of the main housing, push the collet down with a screwdriver (or other suitable tool) to pilot the wheel tube assembly into the housing bore.
14. Align the jacket tube's guide slot with the stopscrew (Ref. 2) hole in the main housing assembly (Ref. 26). Install the lockwasher and stopscrew (Refs. 1 and 2). Tighten the stopscrew 14 to 20 N·m (10 to 15 lbf·ft).
15. Press a new bearing (Ref. 20) into each end of the lower bearing housing (Ref. 21).
16. Slide the shaft of the universal joint assembly (Ref. 23) into the lower bearing housing until it seats against the lower bearing.

    Install the retaining ring (Ref. 19) on the universal joint shaft.
17. Install the pipe plug (Ref. 24) in the slotted end of the universal joint shaft. Tighten the pipe plug finger-tight.

NOTE: Don't overtighten the pipe plug. Overtightening will make it difficult to install the universal joint shaft in the wheel tube and sleeve assembly (Ref. 15).

18. Install the spring retaining rod (Ref. 22) in the lower bearing housing.
19. Hook one end of the green spring (Ref. 43) on the right side of the spring retaining rod (Ref. 22). Hook one end of the other spring (Ref. 45) on the left side of the spring retaining rod.
20. Clamp the serrated end of the wheel tube and sleeve assembly (Ref. 15) in a soft-jawed vise.
21. Push all the way down on the jacket tube (Ref. 16), then install the spring (Ref. 18).
22. Install the universal joint assembly (Ref. 23) through the spring (Ref. 18) and into the wheel tube and sleeve assembly (Ref. 15). Make sure that a slot in the splined shaft of the universal joint assembly aligns with the wide groove in the splined sleeve of the wheel tube and sleeve assembly.
23. Holding down on the universal joint assembly, align the lower bearing housing (Ref. 21) and support bracket (Ref. 25) screw holes. Install the bolts (Ref. 8). Tighten them 34 to 47 N·m (25 to 35 lbf·ft).
24. Position the lockbar (Ref. 41) on the main housing. Make sure that the lockbar locating pin is out, and that the teeth mesh with the support bracket teeth.
25. With the tapered end pointing towards the support bracket teeth, place the wedgelock (Ref. 40) on the main housing, under the lockbar.
26. Position the disengagement plate (Ref. 29) over the lockbar and wedgelock locating pins.
27. Insert the lockpin (Ref. 30) into the cam actuator (Ref. 38). Make sure that the spring hole in the cam and lockpin are facing each other.

    Insert the pivot pin (Ref. 39) through the cam actuator and lockpin. Check that the pivot pin is flush at the bottom of the cam actuator.
28. Attach one end of the anti-rattle spring (Ref. 37) to the lockpin, and the other end to the cam actuator.

    Lightly oil the lockpin assembly. Insert the lockpin into the bushing on the main housing assembly. Make sure that the ears on the cam actuator (Ref. 38) fit under the raised tabs on the disengagement plate (Ref. 29).
29. Insert the actuator housing spring (Ref. 31) into the end of the lockpin (Ref. 30). Using four self-tapping screws (Refs. 32 and 34), attach the actuator housing (Ref. 35) to the main housing. Tighten the screws 460 to 680 N·cm (40 to 60 lbf·in).

NOTE: On some tilt/telescoping column assemblies, two of the self-tapping screws (Ref. 32) are 5/8-inch long, and the other two screws (Ref. 34) are 7/8-inch long.

30. Attach the lockbar and wedgelock springs (Refs. 27 and 28). Install the spring cover plate (Ref. 33) over the lockbar and wedgelock springs.

Tighten the self-tapping screw (Ref. 32) 460 to 680 N·cm (40 to 60 lbf·in).

31. Screw the control lever (Ref. 36) into the cam actuator (Ref. 38).
32. Push down on the control lever and tilt the steering column all the way down. Release the control lever.
33. Snap the lower spring cover (Ref. 44) onto the retaining rod, between the springs.
34. Slide the upper spring cover (Ref. 42) over the springs, engaging the slot on the lower spring cover.
35. Push down on the control lever, then tilt the steering column all the way up. Release the control lever. Using a suitable spring assembly tool, hook the loose ends of the springs (Refs. 43 and 45) in the holes of the main housing assembly (Ref. 26).
36. Insert and lightly tap the stop pins (Ref. 5) to seat them into the holes lettered "D" and "K."
37. Install the stop cover (Ref. 3) with the self-tapping screws (Ref. 4). Tighten the screws 460 to 680 N·cm (40 to 60 lbf·in).
38. Push the jacket tube (Ref. 16) and wheel tube assembly (Ref. 15) all the way down. Using a 3/16-inch allen wrench that is 30-cm (12-inches) long, tighten the pipe plug (Ref. 24) just enough to keep the jacket tube and wheel tube assembly in position when the lockpin (Ref. 30) is disengaged.

    Loosen the pipe plug about a one-eighth turn to allow the wheel tube assembly to telescope freely under spring tension.
39. Check the operation of the tilt/telescoping column assembly as follows:

    39.1 Unlock the column assembly by pushing and holding the control lever all the way down. Tilt the column to any position, then release the control lever to lock it in place. Tilt the column to several other positions to ensure proper operation.

    39.2 Unlock the column assembly by pulling and holding the control lever all the way up. Move the column up or down to any position, then release the control lever to lock it in place. Telescope the column to several other positions to ensure proper operation.

    If the column telescoping action is sluggish or sticks, spray a small amount of Tri-Flow lubricant, or an equivalent, on the jacket tube (Ref. 16) while the column is all the way up.

NOTE: The tilt/telescoping column assembly must sit at room temperature for 24 hours to allow the Loctite RC680 to dry.

40. Install the tilt/telescoping column assembly. **Refer to Subject 110 for instructions**.
41. Install the steering wheel. **Refer to Subject 100 for instructions**.

Horn Contact Assembly Replacement

Replacement

1. Disconnect the horn wire from the wire lead-ing to the back of the dash. **See Fig. 1**.

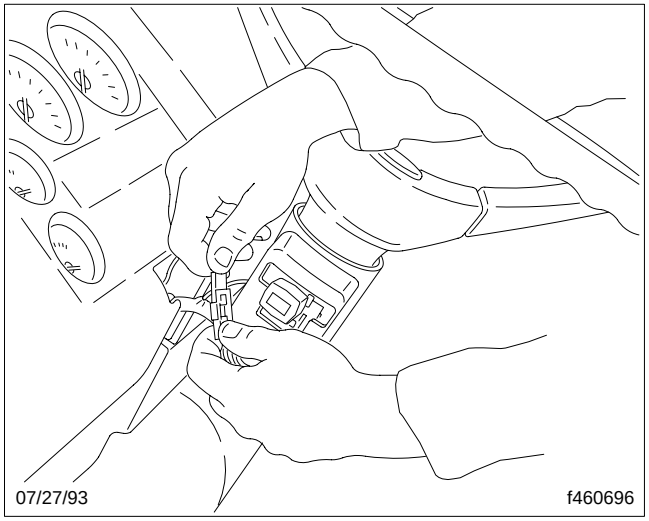

Fig. 1

2. Unscrew the horn contact assembly from the right-hand side of the steering column, and dis-card it. **See Fig. 2**.

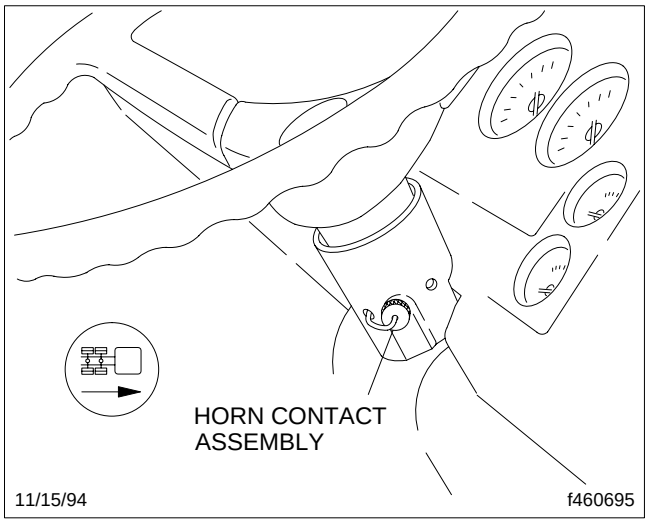

Fig. 2

3. Install a new horn contact assembly into the right-hand side of the steering column. Screw in the assembly firmly.
4. Connect the horn wire to the wire leading to the back of the dash.
5. Check the horn. If it doesn't work, check the wir-ing to the horn, the horn itself, and the horn but-ton. Repair or replace parts as needed.

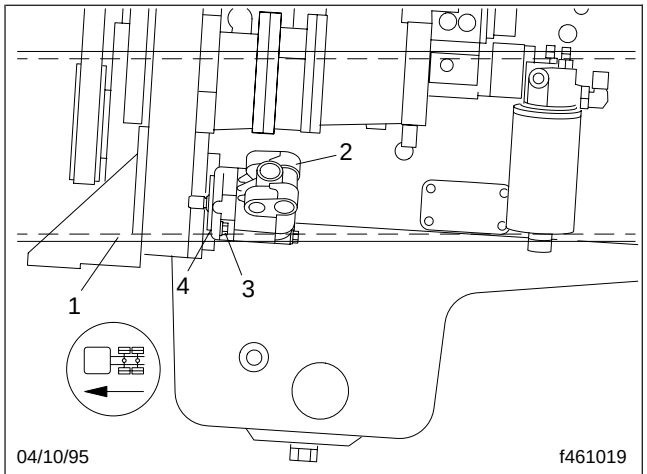
Table 1, Fastener Torques

General Information

The TRW PS Series power steering pump supplies power steering fluid for the operation of the power steering gear.

The main parts of the power steering pump are the housing, input shaft, cam ring, rotor, vanes, control valve, and cover assembly.



Principles of Operation

The input shaft, powered by the adaptor gear in the engine gear case or by the crankshaft pulley, turns the rotor, which is inside the cam ring. As the rotor turns, centrifugal force pushes the vanes out toward the surface of the cam ring. As fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port and into the system. The fluid operates the steering gear. Eventually the fluid returns to the power steering reservoir, then back to the power steering pump.

If the system pressure gets too high, a relief valve inside the control valve is forced off its seat, shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump instead of going to the outlet port. When the system pressure drops to the correct level, the relief valve seats, closing off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port and then into the power steering system.

Removal

1. Apply the parking brake, chock the tires, then tilt the hood.
2. Clean all outside dirt from around the fittings and hose connections.
3. Put a container under the pump, then disconnect the hoses from the fittings on the pump. Plug the hoses and cap the fittings to keep out dirt and to prevent fluid from leaking.
4. Remove the pump.
   - 4.1 Remove the mounting capscrews and washers that attach the pump to the engine accessory drive mounting flange. See **Fig. 1**. Hold the pump as you remove the second mounting bolt.

1. Frame Rail
2. Steering Pump
3. M10 x 35 Capscrew and 7/16-inch Washer
4. Gasket

Fig. 1, TRW PS Series Power Steering Pump Mounting

   - 4.2 Pull the pump straight out from the engine. Keep it level to avoid spilling fluid.
5. Turn the pump upside down over a container and let the fluid drain out.
6. Discard the gasket from the pump mounting flange.

Installation

1. Using engine oil, lightly lubricate a new gasket and the pump shaft.
2. Install the pump.
   - 2.1 Install a new gasket on the pump mounting flange, then place the pump on the engine's accessory drive mounting.
   - 2.2 Install the washers and capscrews, and tighten them 46 N·m (35 lbf·ft).
3. Connect the inlet hose (from the power steering reservoir) to the inlet port. Tighten it 35 N·m (26 lbf·ft).
4. Connect the outlet hose (from the power steering gear) to the outlet port.
5. Bleed the power steering system.
   - 5.1 Check the fluid level in the power steering reservoir and if needed, fill it to the correct level.
   - 5.2 Start the engine and let it idle for several minutes.
   - 5.3 Turn the wheels to a full-left and full-right turn. Repeat about three times.
   - 5.4 Check the fluid level in the power steering reservoir. Add fluid as necessary to the full line on the reservoir dipstick.
   - 5.5 Shut down the engine.
6. Close the hood and remove the chocks from the tires.

Steering Pump Disassembly, Inspection, and Assembly

CAUTION

Be careful when working on the pump housing; it is aluminum, and can be easily damaged. When putting the pump in a vise, pad the vise jaws and clamp only the cover. Tighten the vise just enough to hold the pump.

Disassembly

WARNING

Wear safety goggles or glasses when disassembling the power steering pump. Some of the parts are held in place by springs or snap rings, which can release with considerable force, possibly causing injury.

NOTE: Prepare for fluid drainage before disassembling the pump.

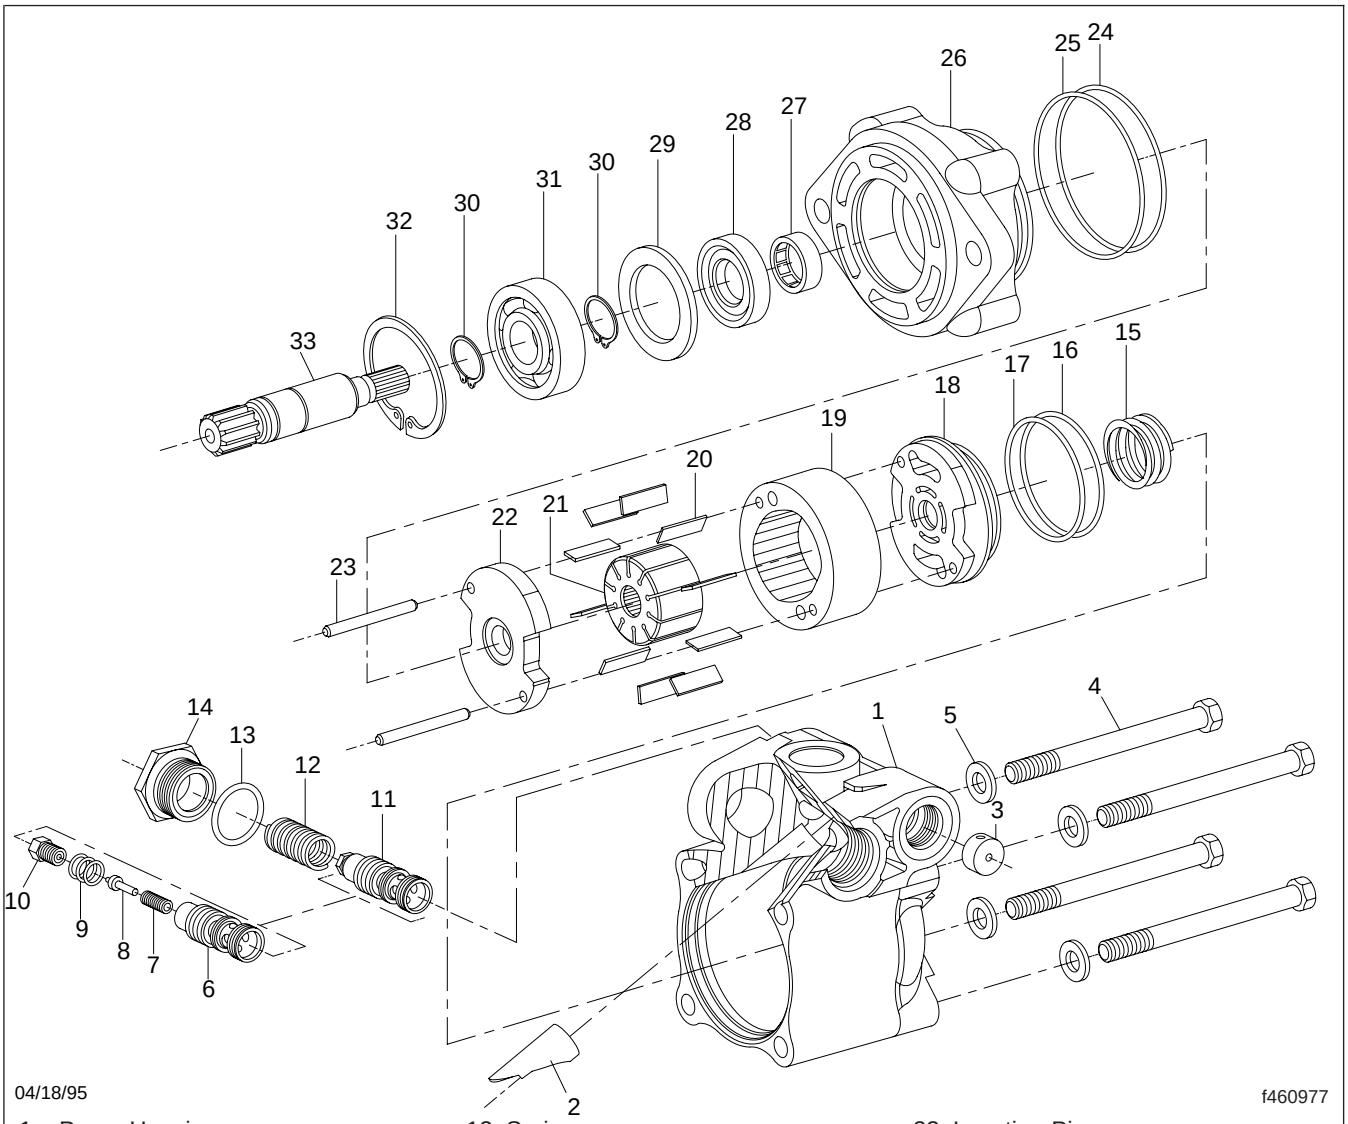
1. Remove the power steering pump from the engine, following the instructions in **Subject 100**.
2. Carefully remove the end plug from the pump housing. Remove the spring if it did not come out with the end plug. See **Fig. 1**, **Fig. 2**, and **Fig. 3**.
3. Remove and discard the O-ring from the plug.

IMPORTANT: TRW does not recommend disassembly of the control valve spool assembly.

4. Remove the control valve spool assembly by hand or by pushing it with a small rod. See **Fig. 4**. Do not push on the small screen in the relief valve seat assembly.
5. Using a solvent-proof marker, make a mark across the housing and the cover. See **Fig. 5**. Remove the four screws and washers holding the housing and the cover together. See **Fig. 6**. Using a twisting motion, separate the housing from the cover.
6. Remove the spring. See **Fig. 7**.
7. Using a solvent-proof marker, draw a line across the top plate and the bottom plate. See **Fig. 8**.
8. Holding the cam ring in place, remove the top plate. See **Fig. 9**. Remove and discard the O-ring and backup O-ring.
9. Holding the bottom plate in place, remove the cam ring. Note and record whether the dots near the locating pin holes on the cam ring are up or down. See **Fig. 10**.
10. Look for wear on the outside edge of the vanes. Note and record the direction of the wear for assembly. Carefully remove the rotor and vanes, as the vanes will slip from their slots in the rotor. See **Fig. 11**.
11. Remove the locating pins. See **Fig. 12**. Make marks on the outside of the cover (not on the sealing surface) to note from which holes the locating pins were removed.
12. Remove the bottom plate. See **Fig. 13**.
13. Turn the cover over and remove the large retaining ring. See **Fig. 14.**
14. Press out the input shaft and ball bearing assembly. See **Fig. 15**.
15. Remove the spacer from the cover. See **Fig. 16**.
16. Using care not to damage the bore, remove the shaft seal. See **Fig. 17**.

Inspection

1. Using a solvent compatible with the power steering fluid, clean all the parts. Then use filtered, compressed air to dry all the parts.



NOTE: Replace any parts that are damaged or worn.

2. Inspect the housing for cracks, stripped threads, a damaged valve bore, and damaged sealing areas. See **Fig. 18**.
3. Inspect the cover for nicks in the O-ring seal grooves. Make sure that the seal drain hole is open and that the seal bore is free of nicks and other damage. See **Fig. 19**.

   Make sure that the surface on which the bottom plate rests is flat and free of nicks and other damage.
4. Check that the needles roll freely in the needle bearing. If needed, replace the needle bearing.

   4.1 Place the cover in a press with the flange side down. Using an 11/16-inch socket,

press the needle bearing out of the cover. See **Fig. 20**.

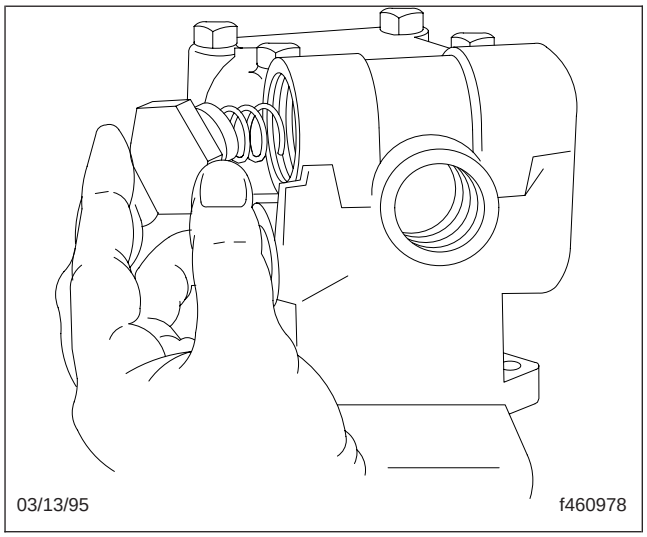

Fig. 2, Remove the End Plug

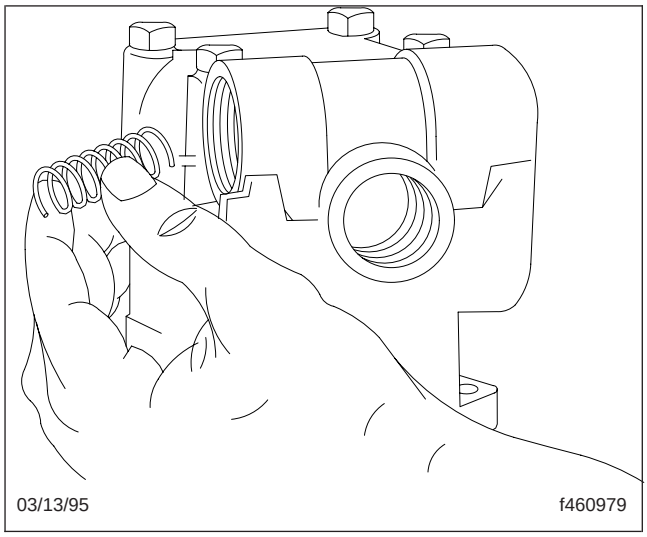

Fig. 3, Remove the Spring

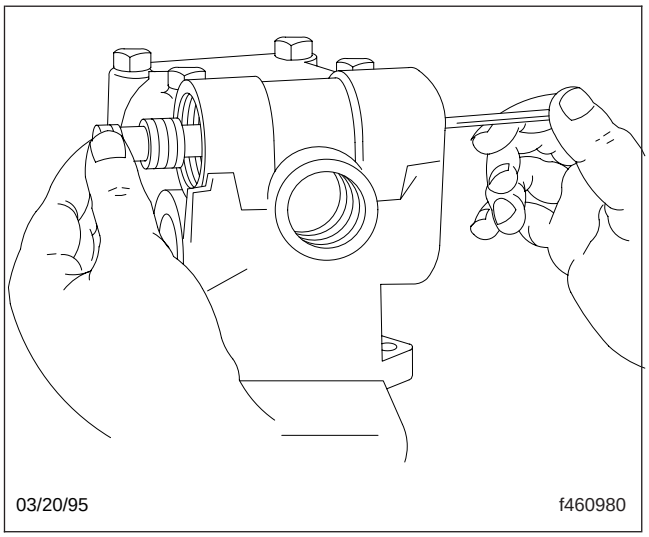

Fig. 4, Remove the Control Valve Assembly

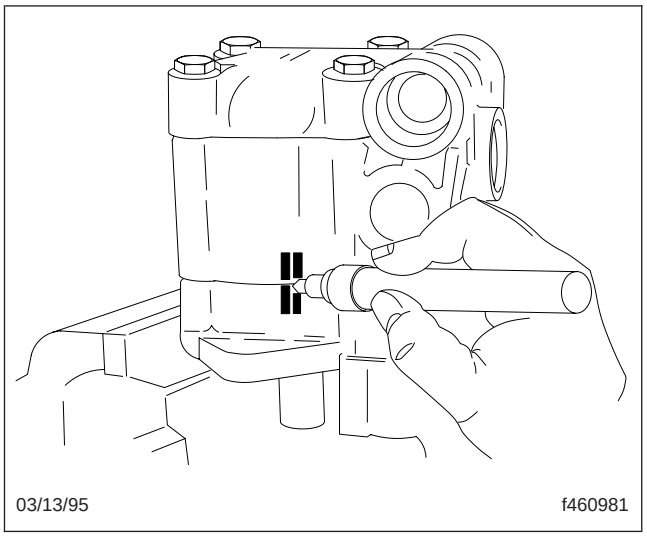

Fig. 5, Mark the Housing and the Cover

CAUTION

Make sure that the press is clean and free of debris. Debris could damage the face of the cover, which will affect pump operation.

4.2 Put the cover in a clean press with the flange side up. Make sure that the lettered side of the needle bearing is facing toward the press.

4.3 Using a 7/8-inch deep socket, press the new needle bearing into the cover until it is flush with the inside surface of the cover. See **Fig. 21**.

5. Inspect the top plate for seal area nicks and abnormal wear or erosion. A polished pattern from the rotor and vanes is normal; grooves you can feel with your fingernail are not normal.

6. Look for abnormal wear, erosion, or surface damage on the inside of the cam ring.

Steering Pump Disassembly, Inspection, and Assembly

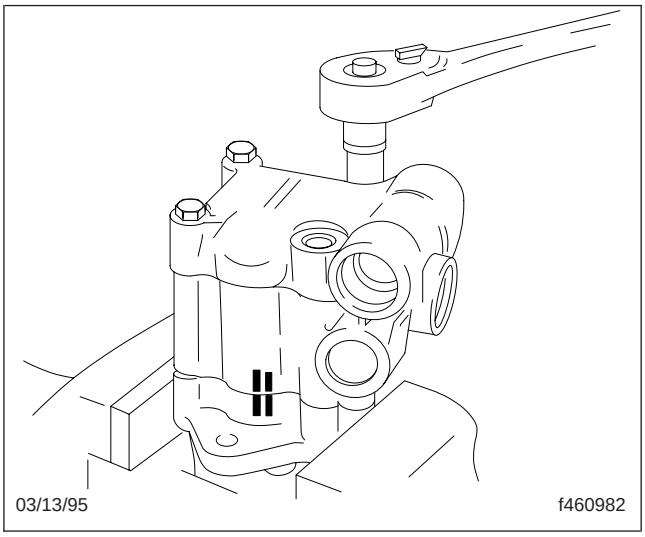

Fig. 6, Remove the Screws and Washers

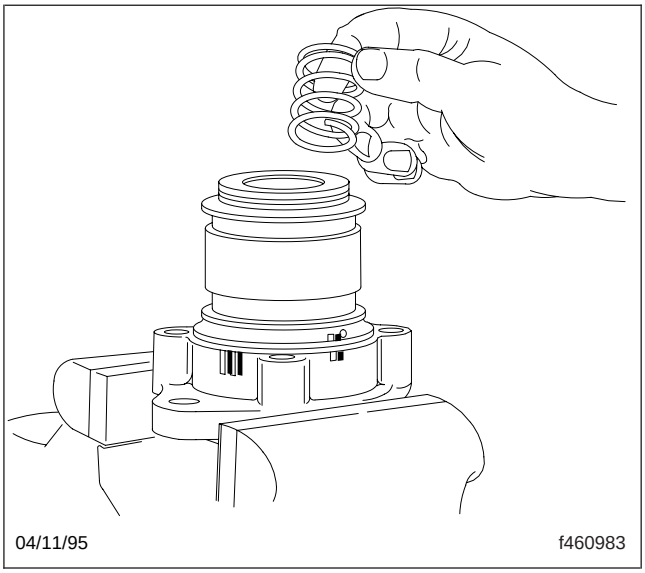

Fig. 7, Remove the Spring

7. Check the vanes on the rotor for damage or too much play in the rotor slots. See **Fig. 22**. If you can move the vanes from side-to-side in the slots, replace the whole rotor assembly.

NOTE: If the vanes are removed, make sure they are installed with the rounded edge out.

8. Check the bottom plate for abnormal wear patterns.

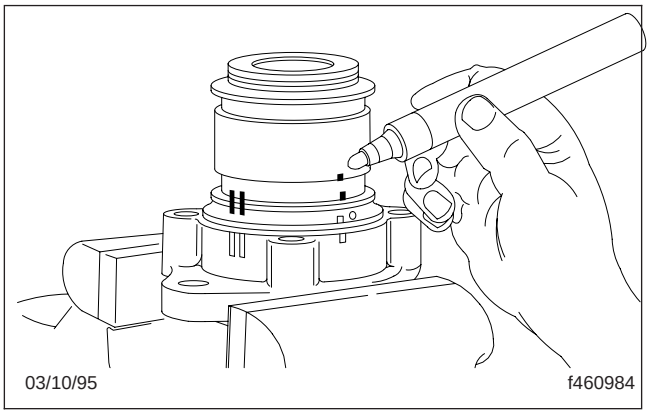

Fig. 8, Mark the Top Plate and the Bottom Plate

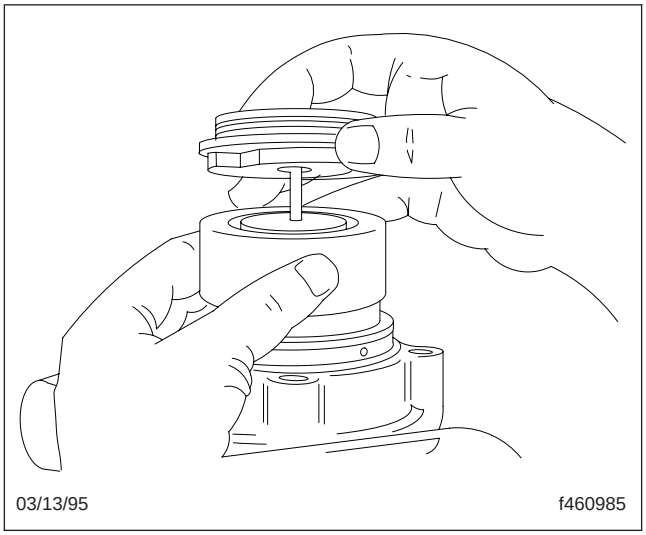

Fig. 9, Remove the Top Plate

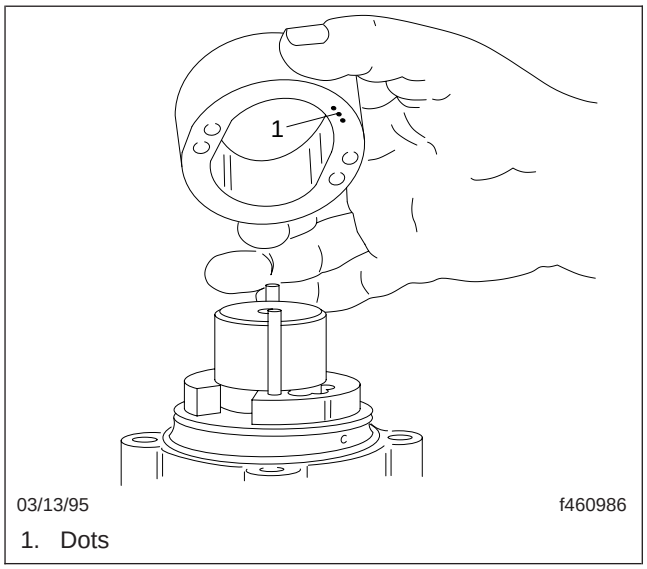

9. Check the input shaft for damaged splines and abnormal wear grooves around the seal area. See **Fig. 23**. Replace the input shaft if there are grooves that can be detected with your fingernail.

   9.1 Remove the retaining ring (engine drive end) from the shaft. See **Fig. 24**.

   Remove the Woodruff key, if equipped.

   9.2 Applying pressure to the engine drive end of the input shaft, press the input shaft from the ball bearing. See **Fig. 25**.

   9.3 Press the new input shaft (from the small splined end) into the ball bearing until the shaft bottoms out on the retaining ring. See **Fig. 26**.

1. Dots

Fig. 10, Check Whether the Dots Are Up or Down

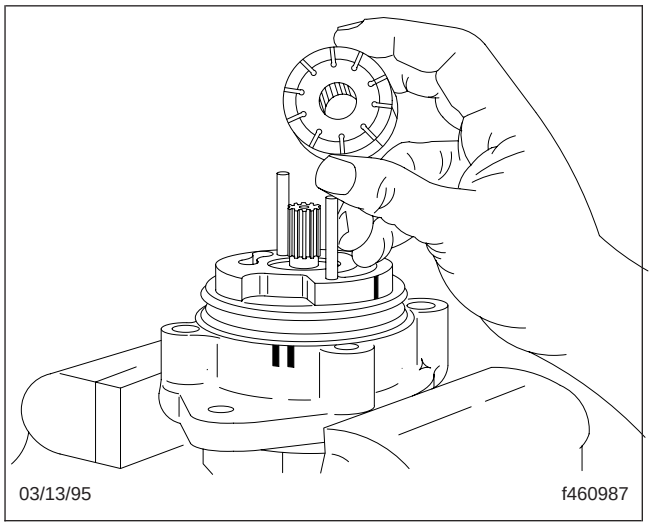

Fig. 11, Remove the Rotor and Vanes

9.4 Install the retaining ring on the input shaft with the sheared edge pointing away from the bearing. Make sure that the retaining ring is properly seated.

IMPORTANT: TRW does not recommend disassembly of the control valve spool assembly.

10. Check the control valve spool assembly for wear or chipping. If needed, back-flush with air and solvent. Check the assembly for nicks or burrs.

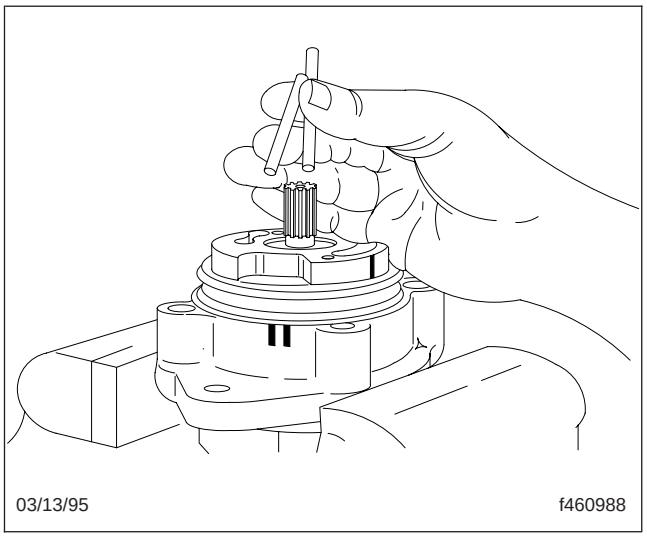

Fig. 12, Remove the Locating Pins

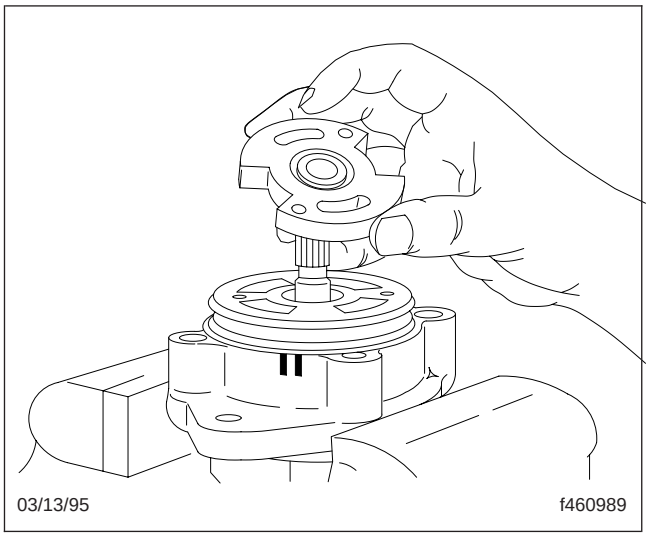

Fig. 13, Remove the Bottom Plate

Assembly

CAUTION

Make sure that the press is clean and free of debris. Debris could damage the face of the cover, which will affect pump operation.

1. Coat the outside surface of the shaft seal with a petroleum-based chassis grease. With the lettered side facing toward the needle bearing,

Steering Pump Disassembly, Inspection, and Assembly

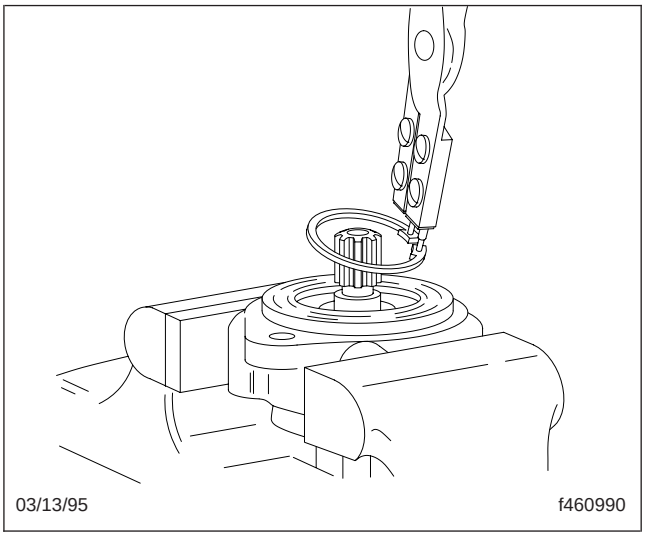

Fig. 14, Remove the Large Retaining Ring

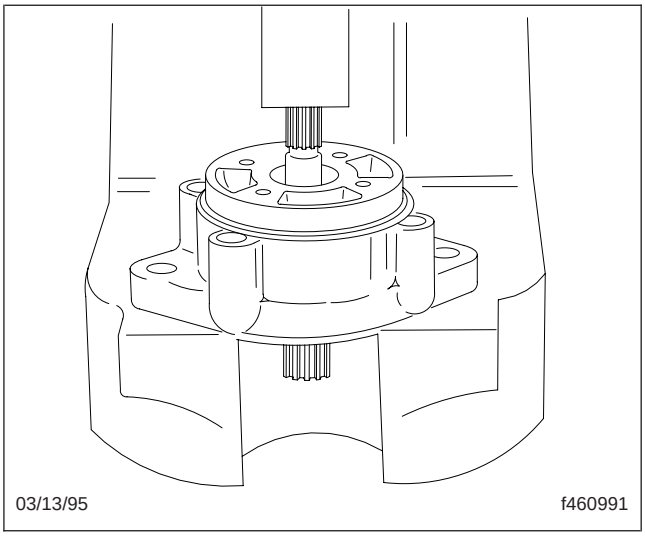

Fig. 15, Press Out the Input Shaft and Ball Bearing Assembly

press the seal into the cover. See **Fig. 27**. The installed seal should be flush with, or just below, the sealing surface on the cover.

2. Grease the inside surface of the shaft seal using a petroleum-based chassis grease.
3. Install the spacer. See **Fig. 16**. Make sure that it lies flat.

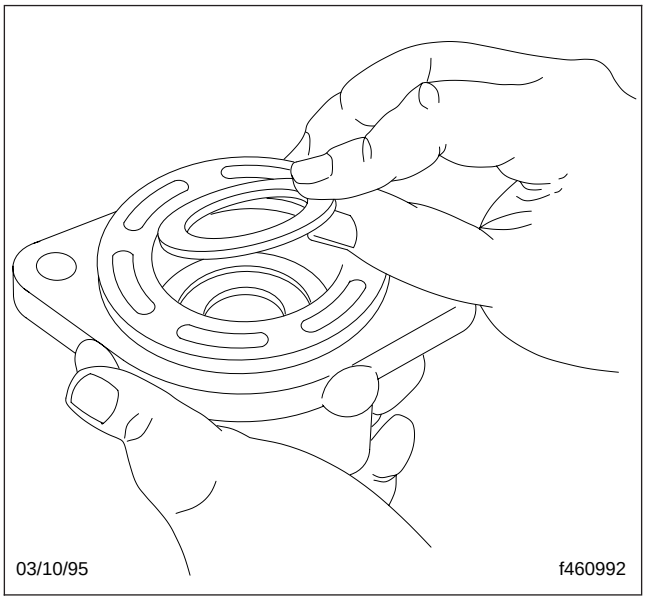

Fig. 16, Remove the Spacer

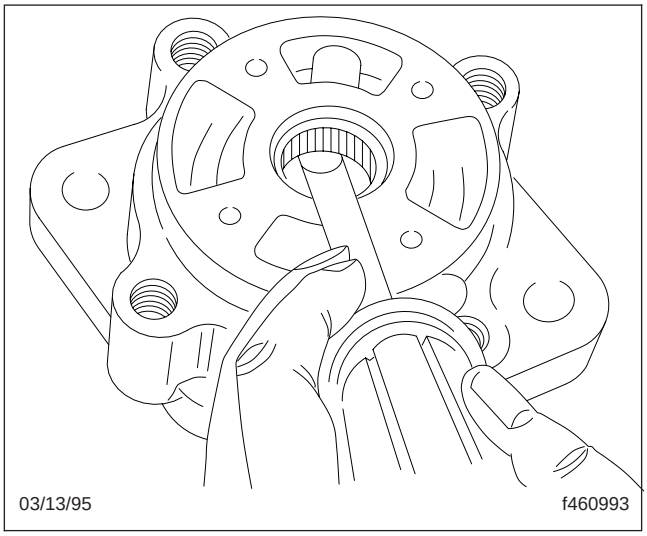

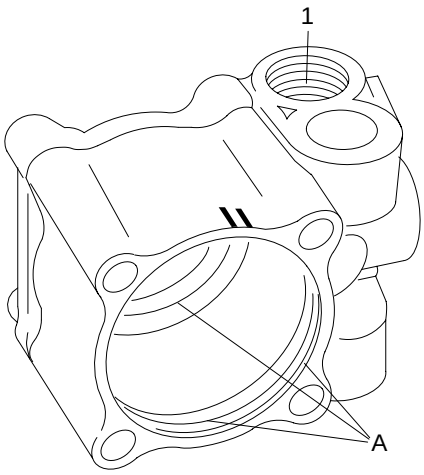

Fig. 17, Remove the Shaft Seal

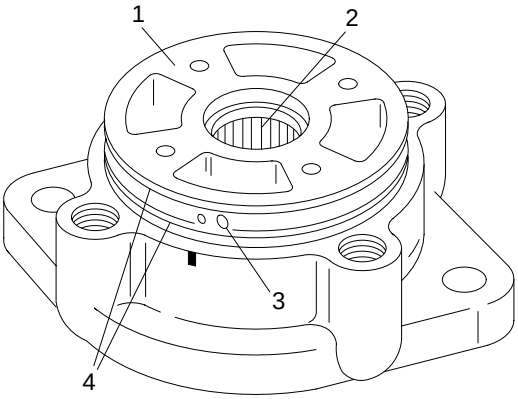
CAUTION



Do not allow the splines to contact the shaft seal. The splines could damage the shaft seal.

4. Insert the input shaft (small splined end first) into the cover. Do not allow the splines to contact the shaft seal. Insert the shaft into the seal by hand until the ball bearing contacts the cover.

3. Seal Drain Hole
4. Seal Grooves

Fig. 19, Inspect the Cover

Using a 7/8-inch socket, press the shaft and bearing into the cover. See **Fig. 28**.

CAUTION

When placing the cover in a padded vise, do not use excessive clamping force. This could damage the cover.

5. Place the cover in a padded vise and install the large retaining ring with the sheared edge out.

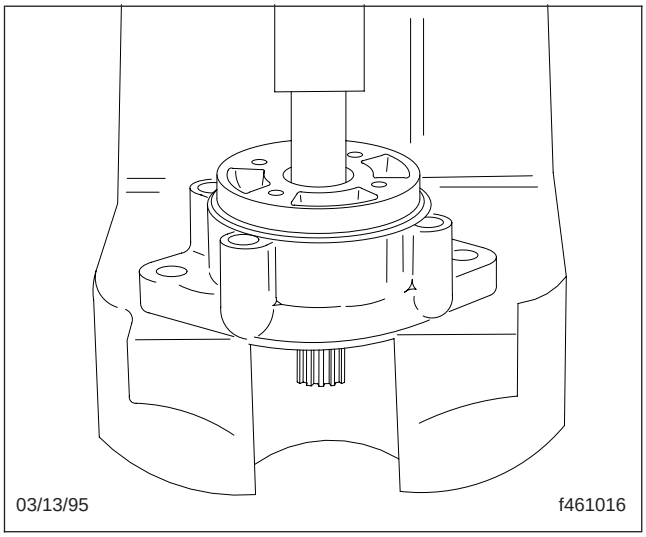

Fig. 20, Press the Needle Bearing Out of the Cover

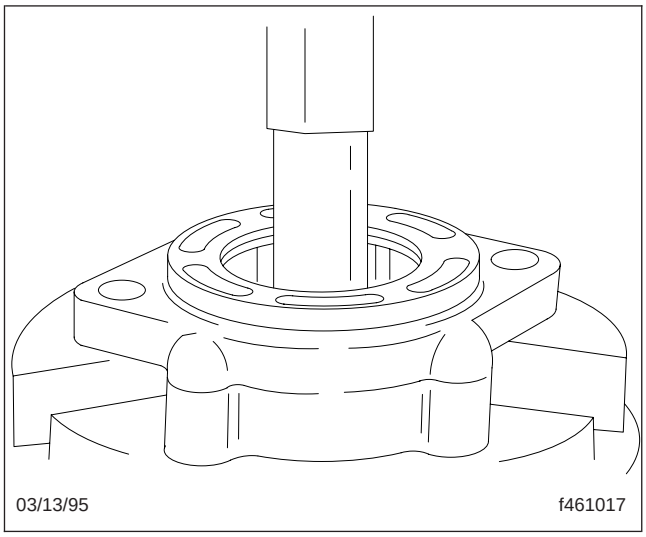

Fig. 21, Press a New Needle Bearing into the Cover

Turn the cover assembly over.

6. Install the new large and small O-rings in the cover. Make sure that they are seated properly. See **Fig. 29**.
7. Using the marks made during disassembly as a guide, install the locating pins.

IMPORTANT: In one of the four cutouts in the cover there is a bar. When installed, the bottom plate must cover this bar.

Steering Pump Disassembly, Inspection, and Assembly

A. Splines
B. Shaft Seal Area

Fig. 23, Check the Input Shaft

8. Install the bottom plate with the pockets facing up. See **Fig. 30**. Make sure that the marks made during disassembly are aligned.

9. Install the cam ring with the dots facing up or down as noted during disassembly. Make sure that the cam ring is flush with the bottom plates large outside diameter and that the marks made during disassembly are aligned. See **Fig. 31**.

10. Install the rotor and vanes. Make sure that squared edge on each vane points toward the center of the rotor. See **Fig. 32**.

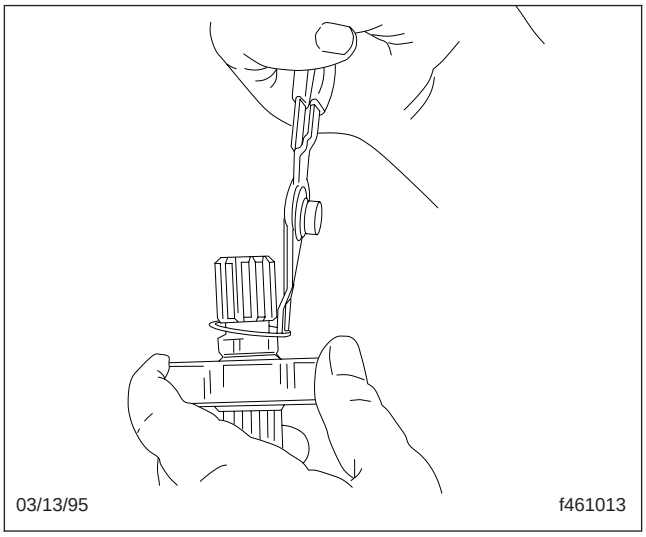

Fig. 24, Remove the Retaining Ring

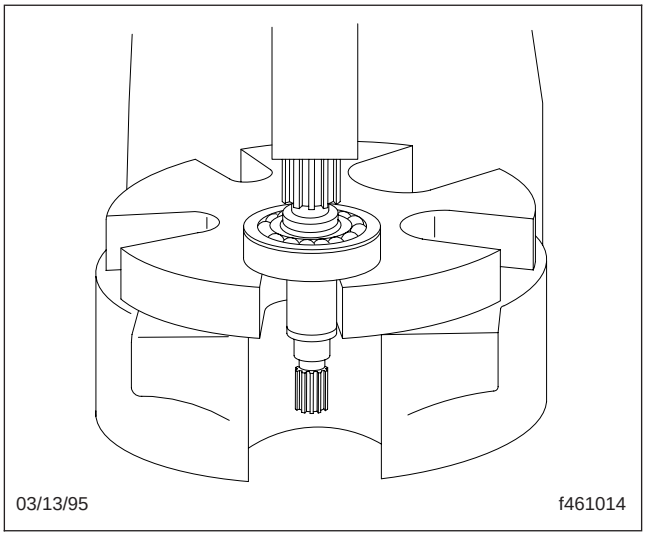

Fig. 25, Press the Input Shaft

11. Install the top plate with the pin holes down. Make sure that the locating pins are engaged in the pin holes, not the pockets. See **Fig. 33**.

    Make sure that the top plate is flush with the cam and that the marks made during disassembly are aligned.

NOTE: The backup O-ring will fit tighter on the top plate after loosely wrapping (no twisting) it around two fingers, then allowing it to unwrap.

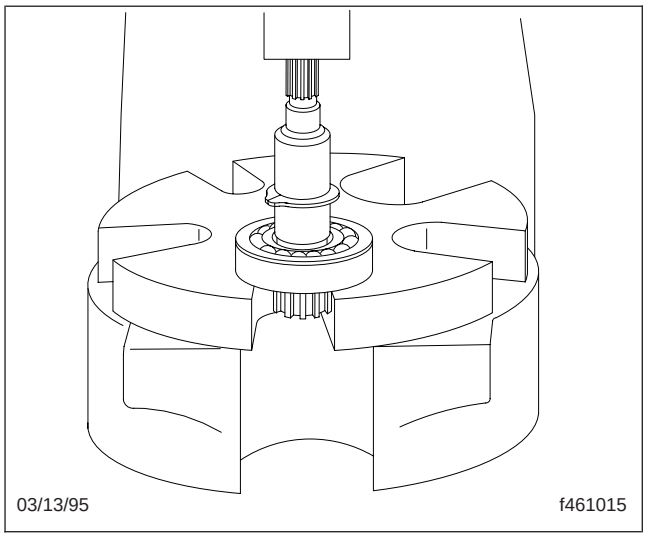

Fig. 26, Press the New Input Shaft

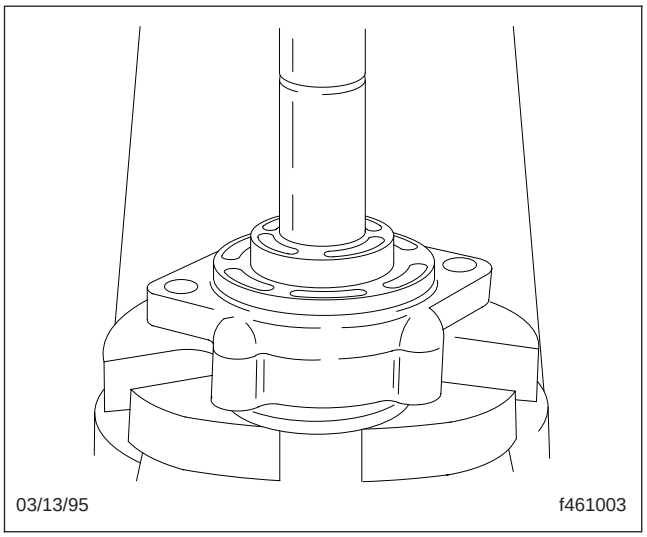

Fig. 28, Press the Shaft and Bearing into the Cover

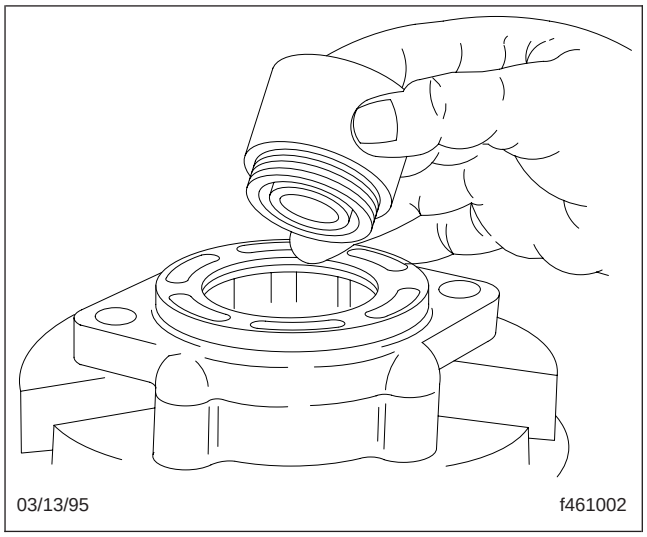

Fig. 27, Install the Seal in the Cover

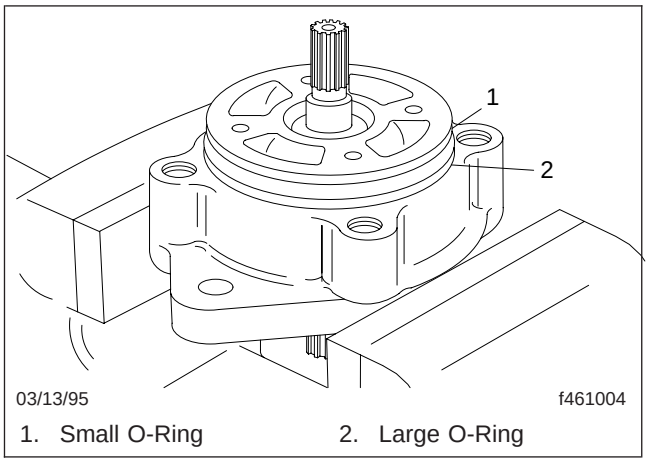
12. Install the backup O-ring on the top plate. Seat the O-ring at the bottom of the groove.
13. Install a new O-ring (without allowing it to roll) on the top plate. Seat the O-ring at the top of the groove.
14. Grease both the O-ring and the backup O-ring. See **Fig. 34**.



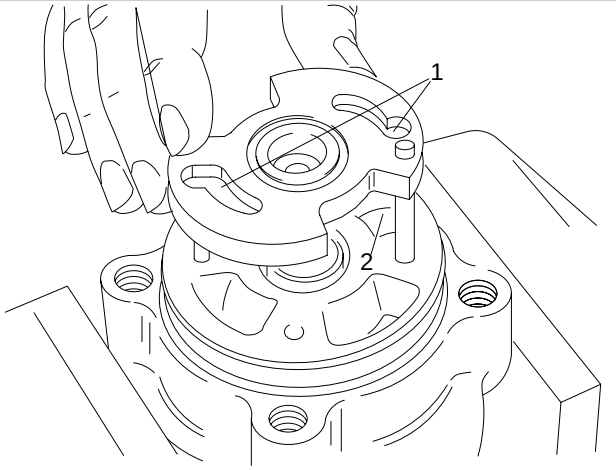


Fig. 29, Install the O-Rings

CAUTION

The housing may have sharp edges. Use care to not cut your finger when applying grease to the housing.

15. Grease the sealing areas of the housing. See **Fig. 35**.
16. Place the spring on the top plate.
17. Place the housing over the cover assembly. Make sure that the marks made during disassembly are aligned. See **Fig. 36**.

The driveline shaft consists of a tubular upper section, splined on the outside, which mates with an internally splined lower section. The telescoping shaft eases installation and removal of the steering column shaft; the lower end yoke is internally serrated to match the external serrations on the steering gear

General Description

input shaft. Each end yoke is secured to its respective shaft by a pinch bolt that engages a notch in the shaft.

The universal joint at each end of the steering driveline allows the transfer of steering motion from the steering column shaft, to the steering driveline, and to the steering gear input shaft, even though the driveline is at an angle to both of the other shafts. Each universal joint cross rides in four needle bearing cups, two carried in the end yoke, and two carried in the steering driveline's integral yoke. The needle bearing cups are held in place in each yoke by snap rings.

Removal (See Fig. 1)

14. Upper End Yoke Pinch Bolt and Nut
15. Fixed Steering Column Assembly

Fig. 1, Steering Driveline Installation

NOTE: It is not necessary to loosen the steering wheel and column assembly to do this procedure.

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations will be done.
2. Apply the parking brakes, and chock the tires. Tilt the hood.
3. Disconnect the lower end yoke.
   - 3.1 Remove the pinch-bolt nut and pinch bolt from the lower end yoke. **See Fig. 2.** Discard the nut.
   - 3.2 Remove the yoke from the steering gear input shaft. Don't turn the steering gear

Steering Driveline Removal and Installation

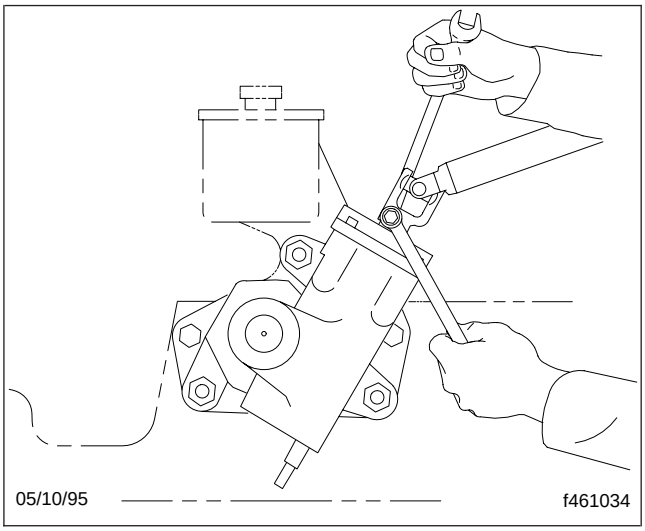

Fig. 2, Disconnect the Lower End Yoke

input shaft when removing the lower end yoke. Push the driveline shaft into the driveline tube, as you remove the lower end yoke.

4. Disconnect the upper end yoke.

   NOTE: One of the screws must be removed from inside the cab. **See Fig. 3,** Ref. A.

   4.1 Remove the four screws holding the upper steering driveline boot to the firewall.

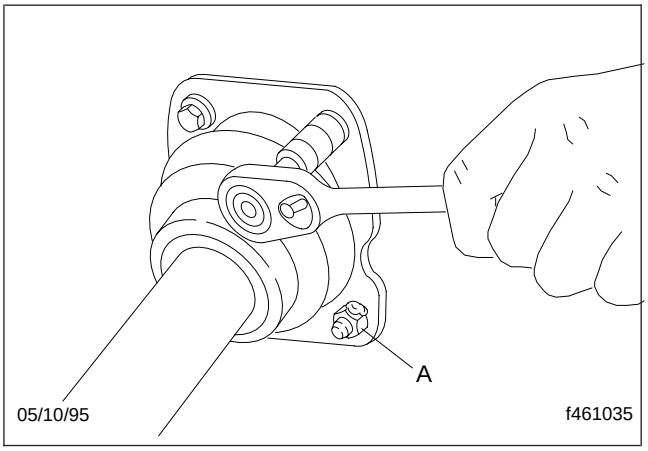

Fig. 3, Remove the Steering Driveline Boot Fasteners

   4.2 Remove the pinch-bolt nut and pinch bolt from the upper end yoke. **See Fig. 4.** Discard the nut.

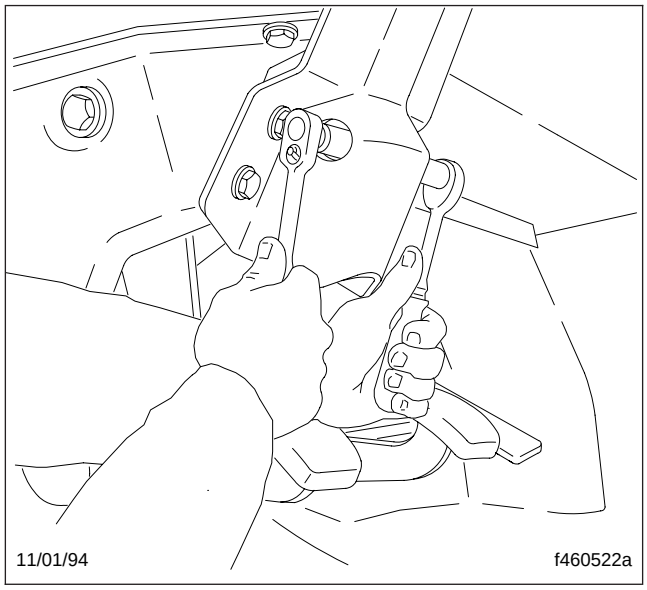

Fig. 4, Remove the Pinch-Bolt Nut and Pinch Bolt from the Upper End Yoke

   4.3 Remove the upper end yoke from the steering column shaft.

5. Remove the driveline from the engine compartment.

Installation (See Fig. 1)

1. Clean the steering gear input shaft, steering driveline, and end yokes. Do not separate the steering driveline.

   1.1 Thoroughly clean the end yokes, the steering driveline, and the steering gear input shaft with a clean, dry cloth.

   1.2 Apply a thin film of grease to the yoke splines. Use lithium-based grease, NLGI grade 2.

2. Make sure that the upper steering driveline boot is in position on the inner tube.

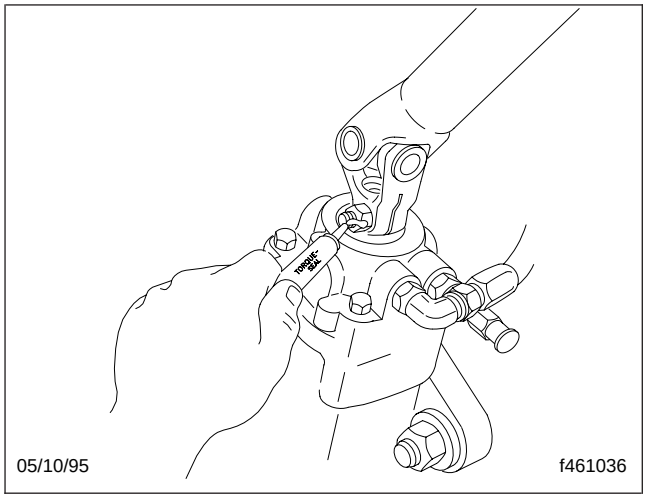
3. Slide the driveline's upper end yoke onto the steering column shaft, then install the end yoke pinch bolt. Before installing the pinch-bolt nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new pinch-bolt nut, and tighten it 75 to 88 N·m (55 to 65 lbf·ft).

4. Apply white Torque Seal F-900 to the exposed pinch-bolt thread and to the locknut.
5. Install the four screws that attach the upper steering driveline boot to the firewall.
6. Before attaching the lower end yoke to the steering gear input shaft, be sure the front tires are straight ahead, the steering gear is centered, the arrows on the driveline inner tube and the outer tube are aligned, and the driveline slides freely.

CAUTION

CAUTION: If the arrow on the driveline inner tube is not aligned with the arrow on the outer tube, the U-joints will not be correctly oriented. Assembling the driveline with the U-joints incorrectly oriented could cause binding at the U-joints.

7. Install the lower end yoke on the steering gear input shaft. Before installing the pinch-bolt nut, make sure the pinch bolt is centered in the steering gear input shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a *new* pinch-bolt nut, and tighten it 75 to 88 N·m (55 to 65 lbf·ft).
8. Apply white Torque Seal F-900 to the exposed pinch bolt thread and to the locknut. **See Fig. 5.**



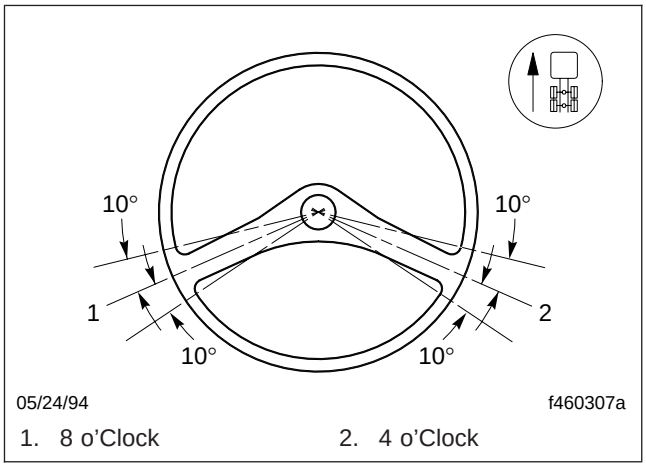


Fig. 5, Apply White Torque Seal F-900

9. Using a hand-type grease gun, lubricate the driveline tube at the lower end yoke assembly with lithium-based grease, NLGI grade 2. Apply until grease appears at all four U-joint cross seals.
10. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be pointing within ±10 degrees of the 4 o'clock and 8 o'clock positions. **See Fig. 6.**

    If not, remove the steering wheel and install it in the correct position. For instructions, refer to the applicable section in this group.

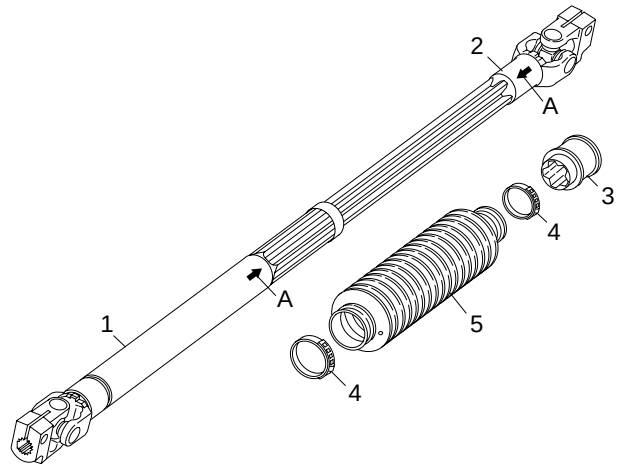
1. 8 o'Clock 2. 4 o'Clock

Fig. 6

11. Lower the hood, and secure the hood latches. Leave the parking brakes applied and the chocks at the rear tires.
12. Raise the front of the vehicle so that the front tires are off the ground, then place safety stands under the frame.

WARNING

WARNING: Driving a vehicle with hard steering or binding in the steering system could result in partial or complete loss of steering control during vehicle operation, possibly causing personal injury and property damage.



13. Turn the steering wheel through full travel, checking for hard steering or binding. If there is difficulty, check the assembly and installation of the driveline parts. If the cause is not the driveline, refer to the applicable steering gear section in this group.

Steering Driveline Removal and Installation

14. Remove the chocks from the tires, and secure the hood.

Steering Driveline Boot and Adaptor Replacement

Replacement (See Fig. 1)

A. Alignment Arrows
1. Outer Tube (to the steering gear)
2. Inner Tube (to the steering column)
3. Adaptor
4. Clamp
5. Boot

Fig. 1, Steering Driveline

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations will be done.
2. Apply the parking brakes, and chock the tires. Tilt the hood.
3. Disconnect the lower end yoke.
   - 3.1 Remove the pinch-bolt nut and pinch bolt from the lower end yoke. Discard the nut.
   - 3.2 Remove the yoke from the steering gear input shaft. Don't turn the steering gear input shaft when removing the lower end yoke. Push the driveline outer tube into the inner tube as you remove the lower end yoke.
4. Slide the inner tube out of the outer tube. Leave the adaptor in place.
5. Using pliers, remove the clamps that secure the boot on the outer tube and inner tube.
6. Discard the boot, clamps, and the adaptor.
7. Using a clean, dry cloth, clean the splined section of the inner tube.
8. Place the adaptor over the inner tube. Align the arrows on the adaptor and the inner tube.
9. Clamp the small end of the new boot on the adaptor.
10. Apply a thin film of grease to the splined portion of the inner tube. Use lithium-based grease, NLGI grade 2.

⚠ CAUTION

CAUTION: If the arrow on the driveline inner tube is not aligned with the arrow on the outer tube, the U-joints will not be correctly oriented. Assembling the driveline with the U-joints incorrectly oriented could cause binding at the U-joints.

11. Align the arrows on the driveline inner tube and the outer tube.
12. Slide the inner tube into the outer tube.
13. Clamp the boot on the outer tube (just above the formed section).
14. Stroke the driveline several times to ensure that the boot and adaptor are firmly in place, and that the driveline slides freely.
15. Before attaching the lower end yoke to the steering gear input shaft, be sure the front tires are straight ahead, the steering gear is centered, the arrows on the driveline inner tube and the outer tube are aligned, and the driveline slides freely.
16. Install the lower end yoke on the steering gear input shaft. Before installing the pinch-bolt nut, make sure the pinch bolt is centered in the steering gear input shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a *new* pinch-bolt nut, and tighten it 75 to 88 N·m (55 to 65 lbf·ft).
17. Apply white Torque Seal F-900 to the exposed pinch bolt thread and to the locknut. **See Fig. 2.**
18. Remove the chocks from the tires, and secure the hood.

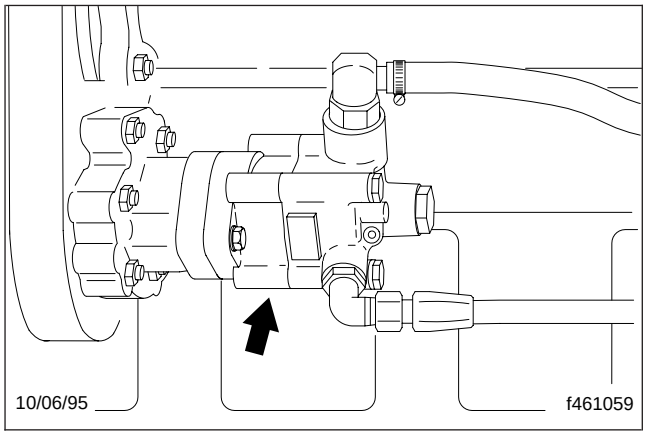
Description	Grade	Size	Torque N·m (lbf·ft)
End Yoke Pinch-Bolt Nut	8 or 8.2	7/16–20 UNF	75 to 88 (55 to 65)

Table 1, Torque Values

General Information

The LuK Automotive Hydraulics LF 73 power steering pump supplies power steering fluid for the operation of the power steering gear.

The pump, used on Cummins B and C series engines, is mounted on the driver's side of the engine, at the rear of the gear case or the air compressor. It is powered by an adaptor gear in the engine. See **Fig. 1**.



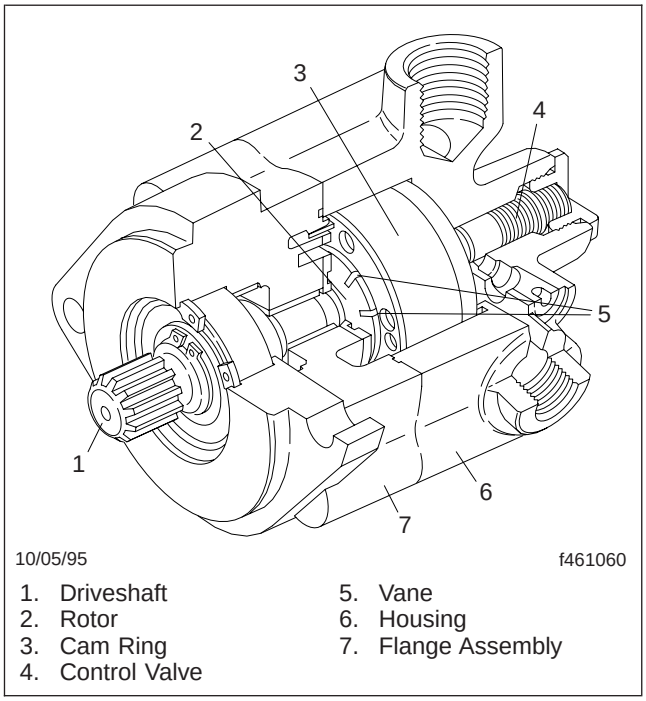


Fig. 1, Power Steering Pump

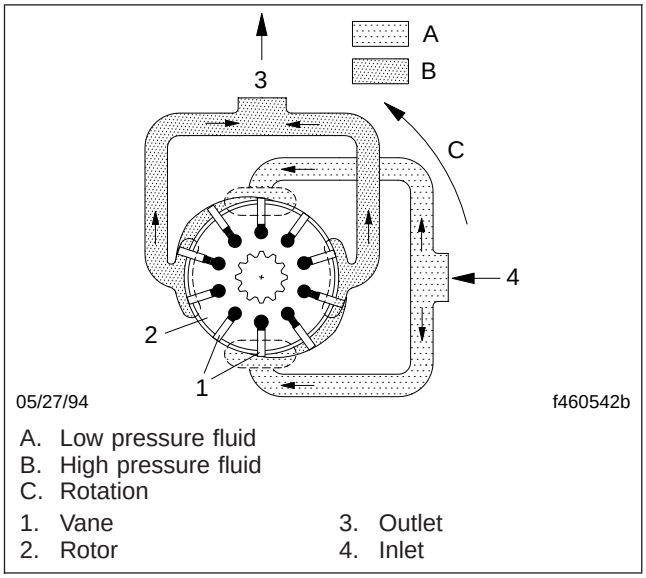
The main parts of the power steering pump are the housing, driveshaft, cam ring, rotor, vanes, and control valve. See **Fig. 2**.

Principles of Operation



The driveshaft, powered by the adaptor gear in the engine gear case, turns the rotor, which is inside the cam ring. As the rotor turns, centrifugal force pushes the vanes out toward the surface of the cam ring. As fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port and into the system. The fluid operates the steering gear. Eventually the fluid returns to the power steering reservoir, then back to the power steering pump. See **Fig. 3**.

If the system pressure gets too high, a poppet inside the control valve is forced off its seat shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump instead of going to the outlet port. When the system pressure drops to the correct level, the poppet seats, closing off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port and then into the power steering system.

2. Rotor
3. Outlet
4. Inlet

Fig. 3, Pump Fluid Flow Diagram

Removal

1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Open the hood.
3. Clean all dirt from around the fittings and hose connections.
4. Put a container under the inlet port of the pump, then disconnect the hose from the fitting. Plug the hose to keep out dirt and to prevent fluid from leaking.

   Repeat this step at the pump outlet port.
5. Remove the capscrews that attach the pump to the engine accessory drive mounting flange. See **Fig. 1**. Slide the pump out of the shaft sleeve and remove the pump from the engine.

02/15/2000 f461079

1. Gasket
2. Pump
3. Washer
4. Capscrew

Fig. 1, Power Steering Pump Mounting

Installation

1. Using engine oil, lightly lubricate a new gasket and the pump shaft.
2. Install the new gasket on the pump mounting flange, then place the pump on the engine accessory drive mounting. Turn the pump or shaft as needed to mesh the shaft with the shaft sleeve. Seat the pilot of the pump mounting flange in the accessory drive mounting, without applying unnecessary force. Install the washers and capscrews. Tighten the capscrews 27 to 32 lbf·ft (37 to 43 N·m).
3. Connect the hoses to the pump inlet and outlet ports.
4. Check the fluid level of the power steering reservoir and add fluid if necessary. Start the engine and let it idle for two minutes. Do not turn the steering wheel; doing so can cause air to enter the system.

   Turn off the engine and check the fluid level in the reservoir.
5. Start the engine again. To remove air from the system, steer the vehicle from full left to full right several times.

   Add fluid as necessary to the full line on the reservoir dipstick.
6. If the steering gear does not have a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Repeat this step and add fluid as necessary until there are no bubbles in the reservoir.

   If the steering gear is equipped with a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Then loosen the manual bleed screw about one turn and look for clear fluid or fluid mixed with bubbles at the threaded area of the bleed screw. Repeat this step and add fluid as necessary until only clear fluid shows. Tighten the manual bleed screw 27 to 33 lbf·in (305 to 373 N·cm). If necessary, fill the reservoir to the full line on the dipstick.
7. Close the hood and remove the chocks from the tires.

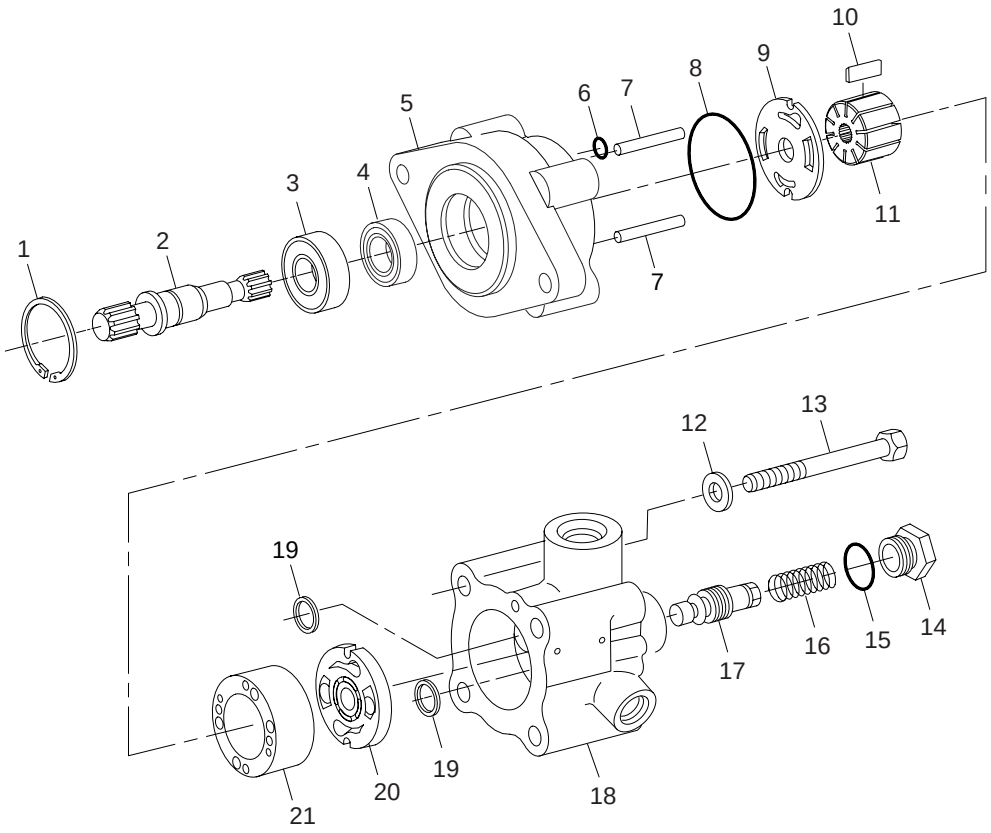
⚠ CAUTION

Be careful when working on the pump housing; it is aluminum, and can be easily damaged. When putting it in a vise, pad the vise jaws. Tighten the vise just enough to hold the pump.

Replacement

⚠ WARNING

Wear safety goggles or glasses when disassembling the power steering pump. Some of the parts are held in place by springs or snap rings, which can release with considerable force, possibly causing injury.



NOTE: The shaft seal kit contains a replacement seal for LF and VT series pumps. The seal for the LF series pump is smaller.

1. Remove the power steering pump from the engine following the instructions in **Subject 100**.
2. Carefully remove the end plug and the spring from the pump body. See **Fig. 1**.
3. Remove the control valve from the pump body. Be careful not to scratch the control valve.
4. Remove and discard the O-ring from the plug.
5. Put the pump housing in a padded vise and remove the capscrews that attach the housing to the flange assembly.
6. Remove and discard the combination O-rings/backup rings from the pump housing.
7. Remove the pressure plate, guide pins, cam ring, rotor, vanes, and wear plate as a unit and set it aside.
8. Remove and discard the small and large O-rings from the flange assembly.
9. Remove the snap ring that holds the shaft seal in place. Discard the snap ring.
10. Put the flange assembly in a vise with the inner end of the shaft pointing up. Carefully tap out the driveshaft.
11. Remove and discard the shaft seal.
12. Clean all the parts using a solvent compatible with the power steering fluid. Then, using filtered compressed air, dry all the parts.
13. Coat all the parts with clean power steering fluid. For approved power steering fluids, see **Specifications 400**.
14. Place the spacer over the outer (drive) end of the shaft with the cupped side of the spacer facing the inner end of the shaft.
15. Using power steering fluid, lubricate the new shaft seal. Carefully place the seal over the outer (drive) end of the shaft up against the spacer. The lettered side of the seal should be visible.

NOTE: To correctly install the driveshaft seal, it is necessary to make a suitable driver from tubular stock. See **Fig. 2** for the applicable dimensions.

16. Using a suitable driver, install the shaft seal into the bore in the flange assembly. Make sure the spring side of the seal faces the flange. See **Fig. 3**. Seat the seal firmly against the shoulder in the bore.
17. Install the small snap ring in the groove on the driveshaft with the sharp edge facing toward the bushing.
18. Put the flange assembly in a padded vise with the drive end of the shaft pointing up. Install a new large O-ring in the flange assembly.
19. Install a new small O-ring in the flange assembly.
20. Install the pressure plate, guide pins, cam ring, rotor, vanes, and wear plate as a unit. Make sure that the two guide pins are seated in the flange assembly.
21. Using power steering fluid, lubricate the new combination O-ring/backup rings. Install the rings in the pump housing with the black side facing the housing and the white, plastic side exposed.
22. Install the pump housing over the flange assembly lining up the mounting holes.
23. Install the capscrews and washers in the pump housing. Tighten them in a cross pattern 29 to 37 lbf·ft (40 to 50 N·m).
24. Install the control valve in the pump housing.

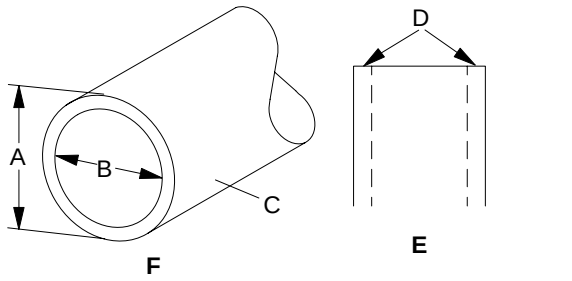
Fig. 1, Power Steering Pump Assembly

⚠ CAUTION

Make sure you install the control valve correctly in its bore. If it is installed backwards, the power steering pump will not work and will quickly overheat, which could cause severe damage to the pump.

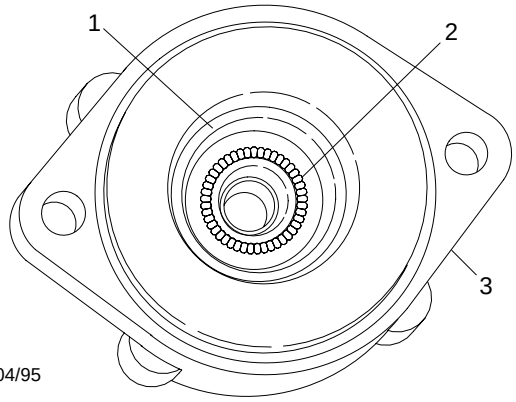


24.1 Lubricate the control valve with power steering fluid, then install it—with the hex end up—in the bore in the pump housing. See **Fig. 4**.

24.2 Install the spring over the hex end of the control valve.

24.3 Install a new O-ring on the end plug, then install the end plug. Tighten it 33 to 40 lbf·ft (45 to 55 N·m).

25. Turn the shaft by hand. It should turn smoothly and without binding.



26. Install the power steering pump on the engine. For instructions, see **Subject 100**.

Table 5, Pressure Settings

General Information

The LuK Automotive Hydraulics LF 80 power steering pump supplies power steering fluid for the operation of the power steering gear.

The power steering pump, used on the MBE900 engine, is mounted on the air compressor. See **Fig. 1**. The power steering pump is powered by a cross plate in the air compressor.

The main parts of the power steering pump are the housing, driveshaft, cam ring, rotor, vanes, and control valve.

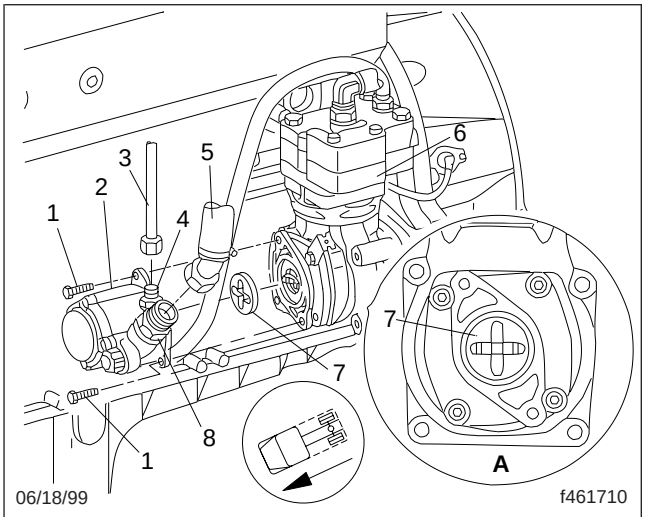
6. Air Compressor
7. Cross Plate
8. Inlet Port

Fig. 1, Power Steering Pump Mounting

Principles of Operation

The power steering pump driveshaft is driven by the air compressor, which is powered by the adaptor gear in the engine gear case. As the pump driveshaft turns the pump rotor, centrifugal force throws the vanes out against the surface of the cam ring. As fluid enters the cam ring through the inlet port, the rotor vanes force it out through the outlet port and into the system. The fluid enters the steering gear providing the gear with enough fluid to steer the vehicle. Eventually the fluid returns to the power steering reservoir and then back to the power steering pump. See **Fig. 2**.



1. Low Pressure Area
2. Ring Contour
3. Rotor
4. Vane
5. High Pressure Area

Fig. 2, Power Steering Pump, Section View

If the system pressure gets too high, a poppet inside the control valve is forced off its seat shunting fluid into a relief passage connected to the inlet port. The fluid then recirculates inside the pump instead of going to the outlet port. When the system pressure drops to the correct level, the poppet seats, closing off the relief passage to the inlet port. The fluid flow returns to normal, flowing from the inlet port to the outlet port and then into the power steering system.

Replacement

1. Turn off the engine, apply the parking brakes, chock the tires, and open the hood.
2. Clean the dirt from around the inlet and outlet ports and from the hose connections. See **Fig. 1**.

A. Cross plate shown installed on the air compressor.

1. Capscrew	5. Inlet Hose
2. Steering Pump	6. Air Compressor
3. Outlet Hose	7. Cross Plate
4. Outlet Port	8. Inlet Port

Fig. 1, Power Steering Pump Mounting

3. Put a container under the steering pump. Disconnect the inlet hose and fitting and the outlet hose and fitting from the inlet and outlet ports. Drain the fluid. Plug the hoses to keep out dirt.
4. Remove the capscrews and washers that attach the steering pump to the air compressor. Remove the steering pump from the air compressor.
5. Remove the cross plate and inspect it for excess wear. See **Fig. 1**.
6. Before installing a new steering pump, make sure the cross plate aligns with the air compressor shaft. See **Fig. 1**.
7. Attach the steering pump to the air compressor using capscrews and washers. Tighten the capscrews 27 to 32 lbf·ft (37 to 43 N·m).
8. Connect the inlet and outlet hoses and fittings to the steering pump inlet and outlet ports.
9. Add fluid to the power steering reservoir. Start the engine and let it idle for two minutes. Do not turn the steering wheel; doing so can cause air to enter the system.

   Turn off the engine and check the fluid level in the reservoir.
10. Start the engine again. To remove air from the system, steer the vehicle from full left to full right several times.

    If necessary, add fluid to the full line on the reservoir dipstick.
11. If the steering gear does not have a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Repeat this step and add fluid as necessary until there are no bubbles in the reservoir.

    If the steering gear is equipped with a manual bleed screw, turn the steering wheel from full lock to full lock two or three times with the engine running at idle. Then loosen the manual bleed screw about one turn and look for clear fluid or fluid mixed with bubbles at the threaded area of the bleed screw. Repeat this step and add fluid as necessary until only clear fluid shows. Tighten the manual bleed screw 27 to 33 lbf·in (305 to 373 N·cm). Refill the reservoir if necessary to the full line on the dipstick.
12. Close the hood and remove the chocks from the tires.

Table 5, Pressure Settings

General Information

A new Checklist for Troubleshooting Power Steering System Performance, form SD-94, has been developed to include the new high-pressure power steering gears as well as the power steering pumps. Use form SD-94, dated 9/17/04, and the following troubleshooting procedures when troubleshooting the power steering system.

You are required to fill out the applicable sections of form SD-94 when submitting a warranty claim on a power steering gear. It is recommended that you fill out the applicable sections of form SD-94 when submitting a warranty claim on a power steering pump. See **Fig. 1** and **Fig. 2** for a sample of form SD-94.

Form SD-94 can be downloaded from the internet through www.AccessFreightliner.com.

- Key in your user name and password.
- Click on Applications.
- Click on ServicePro®.
- Cancel the Vehicle Identification window.
- Click on Service Solutions.
- Click on Symptoms Search.
- At the bottom of the screen, enter 2005 in the Enter Solution Number field.
- Click on the SD-94 attachment.

Dealers can order form SD-94 through the TAO electronic mail system.

- At the TAO Mail Menu, key in B for bulletin boards.
- Tab down to Pub-Forms-FTL and key in L for list.
- At Freightliner Manuals Order Form, key in U.

If you don't have access to the TAO electronic mail system, contact Publishing Distribution at 503-745-7343.

Troubleshooting Procedures

Steps 1 through 3 are typically related to routine maintenance procedures. Some of these inspections and procedures can be found in the Pretrip Inspection and Daily Maintenance chapter in the *Business Class® Trucks Driver's Manual*; some of these inspections and procedures can be found in the *Business Class® Trucks Maintenance Manual*.

1. Check the tire pressure and load.

   1.1 Check that the front tires are inflated to the correct pressure, and the tire pressure is equal on both sides. Correct the pressure if needed.

   Low pressure causes increased steering effort due to friction with the road surface. Unequal tire pressure causes unequal friction between the tire and the road. This can cause pulling to one side. Check the tires for damage or abnormal wear.

   1.2 Check that the rear tires are inflated to the correct pressure, and the tire pressure is equal on both sides. Correct the pressure if needed.

   1.3 Check that the tire sizes are correctly matched, and whether duplex or oversized tires (that were not originally specified for the vehicle) have been installed.

   Extra tire width causes increased steering effort due to extra friction with the road surface. If the axle stops were turned out to reduce wheel cut due to a change in tires, the power steering gear poppets/plungers will need to be adjusted.

   1.4 Determine whether the vehicle is operated at or over the rated load.

   Increased load causes greater steering effort. Make sure the vehicle is being operated within rated capacities.

2. Check the lubrication and condition of the fifth wheel, if so equipped.

   Check to see if the fifth wheel is adequately lubricated. A dry fifth wheel plate makes it difficult to change direction. Check the plate surface for burrs, gouges, and irregularities.

3. Check for loose and binding components. Check whether any steering components need maintenance or adjustment.

   3.1 Check for proper lubrication of the drag link, tie rods, and knuckle pins. Apply lubrication as needed.

Troubleshooting Procedures

FREIGHTLINER® LLC
A DaimlerChrysler Company

Checklist for Troubleshooting Power Steering System Performance

To be used with the troubleshooting and diagnostic checks.

Date _____ Work order No. _____

Evaluation performed by _____ □ Dealership □ Fleet □ Independent

Vehicle Identification
Vehicle model _____ Serial No. _____ Date in service _____
Mileage _____ Mileage when steering complaint first occurred _____
Vehicle application _____ Normal steering axle load _____

Steering System Description
Steering pump mfr. _____ Model No. _____
Steering gear mfr. _____ Model No. _____ Date code _____
Slave steering gear mfr. (optional) _____ Model No. _____ Date code _____
Reservoir capacity: □ 2 quarts (1.9 liters) □ 4 quarts (3.8 liters) □ 9 quarts (8.5 liters)
Type of fluid: □ ATF □ 10 W □ 10W−30 □ 10W−40 □ Other:_____

List complaint: _____
_____
_____

The numbers below correspond to the steps in the troubleshooting procedures, Subject 300. Refer to Subject 300 for definitions, explanations, and instructions.

1. **Check tire pressure and load:**
   - Front tire pressure correct and even on both sides? □ Yes □ No
   - Rear tire pressure correct and even on both sides? □ Yes □ No
   - Oversized front tires? □ Yes □ No
   - Operated at excessive load? □ Yes □ No

2. **Check fifth wheel lube and condition:** □ N/A □ OK □ Not OK

3. **Check for loose and binding components:**
   - Lubrication of drag link, tie rods, and knuckle pins? □ Yes □ No
   - COE steering column bearings bind? □ N/A □ Yes □ No
   - Steering driveline U-joints bind? □ Yes □ No
   - Steering driveline phasing OK? □ Yes □ No
   - Sector shaft adjustment OK? □ Yes □ No
   - Front tire self−return OK? □ Yes □ No
   - Fasteners and components worn or loose? □ Yes □ No

4. **Power steering temperature and hydraulic checks:**
   - 4.2. Check for correct fluid level. □ Fluid OK □ Added fluid
   - 4.5. Record initial fluid temperature. □ °F □ °C _____

5. **Power steering hydraulic system:**

Install a Power Steering System Analyzer (PSSA) between the pump high-pressure line and the steering gear. Run the engine at idle and use the load valve to raise the fluid temperature to 180°F (82°C).

- 5.1. Record total system back pressure. □ psi □ kPa _____
  See troubleshooting and diagnostic checks if greater than 100 psi (689 kPa).

SD−94 (9/17/04)

10/14/2004 f020157

Fig. 1, Checklist for Troubleshooting Power Steering System Performance, Front Page

5.2. Check for erratic pump response while momentarily closing and opening the load valve. ◻ OK ◻ Not OK

5.3. Pump relief pressure. ◻ psi ◻ kPa _____

5.4. Pump relief valve operated correctly at idle. ◻ OK ◻ Not OK

5.5. Pump relief valve operated correctly at 1500 rpm. ◻ OK ◻ Not OK

5.6. Partially close the load valve until the pressure gauge reads approximately 1800 psi (12 410 kPa) or 2300 psi (15 858 kPa) for high-pressure steering gears. Record flow rate with engine at idle and with the appropriate load applied. ◻ gpm ◻ L/min ____

5.7. Record flow rate with engine at 1500 rpm and no load applied. ◻ gpm ◻ L/min ____

5.8. Run engine at governed speed until fluid temperature stabilizes. Record the maximum fluid temperature. Do not exceed 250°F (121°C). ◻ °F ◻ °C _____

5.9. Steering gear internal leakage:
Primary gear: 1.0 gpm (3.8 L/min) max ◻ gpm ◻ L/min Left _____ Right _____
(optional) Slave gear or ram: 1.0 gpm (3.8 L/min) max Left _____ Right _____
(optional) Slave gear or ram: 1.0 gpm (3.8 L/min) max Left _____ Right _____
(optional) Slave gear or ram: 1.0 gpm (3.8 L/min) max Left _____ Right _____

6. Steering gear poppet adjustment:
6.2. Poppet relief pressure. ◻ psi ◻ kPa Left _____ Right _____

7. Abnormal power steering noise:
7.1. If not already done, check for proper fluid level. ◻ Fluid OK ◻ Too low ◻ Too high
7.2. Check fluid condition. ◻ Fluid OK ◻ Discolored ◻ Foamy ◻ Other _____
7.3. Hissing at less than full turn. ◻ Yes ◻ No

8. Check for leaks and restrictions, and test the system back pressure:
8.1. Check for kinked or collapsed hoses. ◻ Yes ◻ No
8.1. Check for leaking fittings. ◻ Yes ◻ No
8.1. Check for leaking seals. ◻ Yes ◻ No

8.2. Install a low−pressure gauge− 200 to 300 psi (1379 to 2068 kPa)—in the appropriate locations within the power steering system to determine the following values.

8.3. Fill out the fields below using instructions found in substep 8.3 of the diagnostic checks.

Pump outlet	P2: _____	P2 max: 100 psi (689 kPa)	◻ OK	◻ Not OK
		140 psi* (965 kPa)	◻ OK	◻ Not OK
Gear inlet	G1: _____	P2 − G1 max: 12 psi	◻ OK	◻ Not OK
Gear outlet	G2: _____	G1 − G2 max 55 psi	◻ OK	◻ Not OK
Booster inlet*	B1: _____	G2* − B1 max: 12 psi	◻ OK	◻ Not OK
Booster outlet*	B2: _____	B1* − B2 max: 40 psi	◻ OK	◻ Not OK
Reservoir inlet	R1: _____	B2* − R1 max: 12 psi	◻ OK	◻ Not OK
Reservoir outlet	R2: _____	G2 − R1 max: 12 psi	◻ OK	◻ Not OK
Pump inlet	P1: _____	R1 − R2 max: 4 − 8 psi	◻ OK	◻ Not OK
		R2 − P1 max: 12 psi	◻ OK	◻ Not OK

SD-94 (9/17/04)

10/14/2004 f020158

Fig. 2, Checklist for Troubleshooting Power Steering System Performance, Back Page

Troubleshooting Procedures

Chock the rearmost tires. With the engine shut down, turn the steering wheel and check for looseness or binding. Make sure all components are free to move, but are not excessively loose.

3.2 Check the COE steering column bearings for binding. Lubricate them if needed.

3.3 Check the steering driveline U-joints for looseness or binding. Lubricate them if needed.

3.4 Check for correct steering phasing where applicable. The U-joints should line up. Reset the phasing if needed.

NOTE: On older COEs, the steering U-joints do not line up.

3.5 Check the sector shaft adjustment.

- With the vehicle on the ground and the front tires pointed straight ahead, turn the steering wheel until slight motion is observed at the front wheels.
- Align a reference mark on the steering wheel to a rule, then slowly turn the steering wheel in the opposite direction until motion is again detected at the wheels.
- Measure the lash (free play) at the rim of the steering wheel.

  Excessive lash exists if steering wheel movement exceeds 2-1/2 inches (64 mm) with a 20-inch (508-mm) steering wheel, or 2-1/4 inches (57 mm) with an 18-inch (457-mm) steering wheel.

3.6 Check that the front wheels self-return without binding.

- With the engine off, chock the rearmost tires and place the front tires on radius plates (turntables).
- Disconnect the drag link from the steering arm.
- By hand, pull the tire to one axle stop and release. The tire should self-return to almost straight ahead.
- Repeat in the opposite direction.
- If the tire does not return to near straight ahead, check for binding or a lack of lubrication in the steering axle kingpin bushings or tie rod linkage.
- Connect the drag link and tighten the castle nut, then install a new cotter pin.

3.7 Inspect all suspension fasteners and components for wear and looseness.

4. Prepare the power steering system for temperature and hydraulic checks.

NOTE: The hydraulic power steering system is tested with a Power Steering System Analyzer (PSSA), and with the hydraulic fluid at operating temperature. The part number for the PSSA is J-26487. The part number for the adapter kit is J-28593. The PSSA and adapter kit are available from SPX Kent-Moore. See **Fig. 3**.

A PSSA is a combination of a flow meter, a shutoff valve, and a pressure gauge. The PSSA will allow you to measure flow and pressure, and provide a load on the pump in the hydraulic lines of the steering system.

4.1 Park the vehicle outside to reduce noise and exhaust in the shop.

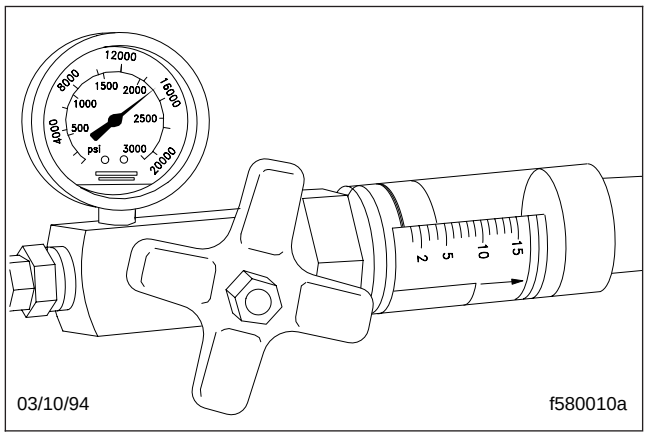

Fig. 3, Power Steering System Analyzer

4.2 Record on form SD-94 whether the fluid level was okay or if fluid was added.

4.3 Install the PSSA between the pump high-pressure line and the steering gear.

4.4 Fill and bleed the steering system as needed.

4.5 Determine the initial power steering fluid temperature.

- Place a temperature gauge in the fluid reservoir.
- Record the initial temperature on form SD-94, and leave the temperature gauge in the reservoir to monitor the fluid temperature throughout these tests.

NOTE: Power steering system checks must be done with the power steering fluid at operating temperature, approximately 180°F (82°C). Maintain this temperature throughout the following tests.

CAUTION

Do not leave the load valve fully closed for longer than five seconds. Doing so could damage the power steering system.

4.6 If not already done, raise the power steering fluid temperature to normal operating temperature.

- Run the engine at idle.
- Partially close the load valve on the PSSA until the pressure gauge reads 1000 psi (6895 kPa).
- Open the valve when the fluid temperature reaches about 180°F (82°C).

5. Test the power steering hydraulic system.

5.1 Check the total system back pressure.

- Run the engine at idle.
- Make sure the PSSA load valve is fully open.
- Read the pressure gauge on the PSSA.
- Record the total system back pressure on form SD-94.

NOTE: If the total system back pressure is greater than 100 psi (689 kPa) on a vehicle with air brakes, or 140 psi (965 kPa) on a vehicle with hydraulic brakes, back pressure is excessive. Go to step 8 to find the restriction in the system.

CAUTION

Do not leave the load valve closed for longer than five seconds during the following test. Doing so could damage the power steering system.

5.2 Check for erratic pump response.

- Slowly close the load valve.
- When the valve is completely closed, read the pressure gauge.
- Open the valve.

  If the pressure rises rapidly, appears to be uncontrolled, or rises above the typical relief pressure, open the load valve immediately. See **Table 1** or **Table 2** for relief pressures.
- Indicate on form SD-94 whether the pump response was erratic or not.

  If the response was erratic, replace the pressure relief valve in the pump or the power steering pump as required. For instructions, refer elsewhere in this group. After replacing the pressure relief valve, repeat substeps 5.1 and 5.2. Make sure the temperature is at about 180°F (82°C). If the pressure was consistent, go to substep 5.3.

5.3 Check the pump relief pressure.

- Slowly close the load valve.
- When the valve is completely closed, read the pressure gauge.
- Open the valve.

Troubleshooting Procedures

Minimum Measured Pump Flow and Relief Pressure at Engine Idle		
Gear Make and Model*	**Flow at 1800 psi (12 500 kPa)**	**Typical Relief Pressure**
TRW TAS40 or HFB52	1.8 gpm (6.8 L/min)	2175 ± 100 psi (15 000 ± 700 kPa)
TRW TAS55	2.2 gpm (8.3 L/min)	
TRW TAS65 or HFB64	2.6 gpm (9.8 L/min)	
TRW TAS85 or HFB70	3.2 gpm (12.1 L/min)	
TRW TAS65 With RCS65	5.6 gpm (21.1 L/min)	
TRW TAS65 With Linear Cylinder	6.1 gpm (23.1 L/min)	
TRW TAS85 With RCS65	6.6 gpm (25.0 L/min)	
TRW TAS85 With Linear Cylinder	6.1 gpm (23.1 L/min)	
HFB70 With RCB70	6.6 gpm (25.0 L/min)	
HFB70 With RCB64	6.1 gpm (23.1 L/min)	
HFB70 With Linear Cylinder	6.1 gpm (23.1 L/min)	
Sheppard MD83	2.1 gpm (8.1 L/min)	
Sheppard M100	3.0 gpm (11.4 L/min)	
Sheppard M110 With Slave 110 and Dual TRW Right-Side Rams	5.6 gpm (21.2 L/min)	

* On vehicles with TRW TAS steering gears and hydraulic brakes, the typical relief pressure is 2375 ± 100 psi (16 000 ± 700 kPa).

Table 1, Minimum Measured Pump Flow and Relief Pressure at Engine Idle

Minimum Measured Pump Flow and Relief Pressure for High-Pressure Gears at Engine Idle		
Gear Make and Model	**Flow at 2300 psi (16 000 kPa)**	**Typical Relief Pressure**
TRW THP45	1.5 gpm (5.7 L/min)	2683 ± 100 psi (15 000 ± 700 kPa)
TRW THP60 or PCF60	2.3 gpm (8.7 L/min)	
TRW THP60 With Linear Cylinder	5.8 gpm (22.0 L/min)	
TRW THP60 With RCH45	6.3 gpm (23.8 L/min)	

Table 2, Minimum Measured Pump Flow and Relief Pressure for High-Pressure Gears at Engine Idle

- Record the relief pressure on form SD-94.

If the pump relief pressure matches the relief pressure in **Table 1** or **Table 2**, it is acceptable. Go to the next substep.

If the pump relief pressure does not match the relief pressure in **Table 1** or **Table 2**, refer to the pump manufacturer's service literature to verify the exact relief pressure for the power steering pump being diagnosed.

If the pump relief pressure does not match the relief pressure in **Table 1** or **Table 2** or the pump manufacturer's specifications, replace the pressure valve if not done previously, or replace the power steering pump. After replacing the pressure relief valve in the pump, repeat substeps 5.1 and 5.2.

If the pump relief pressure does not match the relief pressure in **Table 1** or **Table 2** and the relief valve was previously replaced, replace the pump. For instructions, refer else-

where in this group. After replacing the pump, evaluate the pump's performance by repeating step 5.

5.4 Test the pump relief valve reaction at idle.

- Run the engine at idle.
- Note the flow rate with the load valve open.
- Close the load valve until the pump relief pressure is reached. The flow rate should drop to zero.
- Smoothly and quickly open the load valve and note the flow rate. Repeat this action three times. It should return to the flow rate noted above.
- Record on form SD-94 whether the relief valve operated correctly or not.

  If the flow rate returns smoothly and quickly, the relief valve is acceptable. Go to the next substep.

  If the flow rate does not return smoothly and quickly, the pump relief valve is not working correctly. Replace the relief valve if not done previously, or replace the power steering pump.

5.5 Test the pump relief valve reaction at 1500 rpm.

- Run the engine at 1500 rpm.
- Note the flow rate with the load valve open.
- Close the load valve until the pump relief pressure is reached.
- Smoothly and quickly open the load valve and note the flow rate. Repeat this action three times. It should return to the flow rate noted above.
- Record on form SD-94 whether the relief valve operated correctly at 1500 rpm.

  If the flow rate returns immediately, the relief valve is acceptable. Go to the next step.

  If the flow rate does not return immediately, the pump relief valve is not working correctly. Replace the relief valve if not done previously.

5.6 Test the flow of the pump at idle with a load applied.

- Run the engine at idle.
- Slowly close the load valve until the pressure gauge reads 1800 psi (12 410 kPa).
- Read the flow gauge and record the flow rate on form SD-94.

  NOTE: For high-pressure steering gears, use 2300 psi (15 858 kPa) as the test load pressure. See **Table 1** or **Table 2** for minimum flow rate.

- Open the load valve.

5.7 Test the maximum flow of the pump with no load applied.

- Run the engine at 1500 rpm.
- Read the flow gauge and record the maximum flow on form SD-94.

  If the flow rate is below the minimum as indicated in **Table 1** or **Table 2**, repair or replace the pump. For instructions, refer elsewhere in this group.

  If the flow rate is above 8 gpm (30 L/min), replace the flow control and relief valve in the pump, or replace the power steering pump as required. For instructions, refer elsewhere in this group.

CAUTION

Do not allow the temperature to exceed 250°F (121°C) during the following test. If this temperature is exceeded, stop the test and record the last noted temperature on form SD-94.

5.8 Record the maximum fluid temperature.

- Run the engine at governed speed.
- Observe the power steering fluid temperature until it stabilizes.
- Record on form SD-94 the maximum power steering fluid temperature.

Troubleshooting Procedures

If the temperature does not exceed 250°F (121°C) during the test, excessive system heat is probably not the cause of the complaint.

If at any time during the test the temperature exceeded 250°F (121°C), the system is operating at excessive temperature levels, and steering system performance and life may be affected. Damage to hoses, seals, and other components may result if the vehicle is operated at excessive steering system temperatures.

Excessive steering system backpressure or excessive pump flow may be the cause of the over temperature problem. Go to step 8 if you suspect a restriction in the system.

If excessive heat continues to be a problem, a cooler may need to be added to the system.

⚠ WARNING

Keep fingers clear of the stop bolt and spacer block during the following test. Make sure that the spacer block contacts the axle stop squarely. Contact that is not square could break the stop bolts or eject the spacer block, which could cause serious personal injury.

⚠ CAUTION

While running the following test, do not hold the steering wheel in the full-turn position for more than five seconds. Doing so could damage the pump.

NOTE: The following substeps check for excessive internal leakage in the steering gear(s). Make sure the fluid temperature is approximately 180°F (82°C) and the vehicle is stationary with the front wheels pointing forward.

5.9 Test the steering gear internal leakage.

- Run the engine at idle with the load valve open.
- Place an unhardened steel spacer, 1-inch (25-mm) thick, between the axle and the stop bolt at one side of the axle. See **Fig. 4**.

  The spacer should have an extension or handle long enough to keep fingers clear of the axle stop area. A brazing rod or welding rod works well for this purpose.

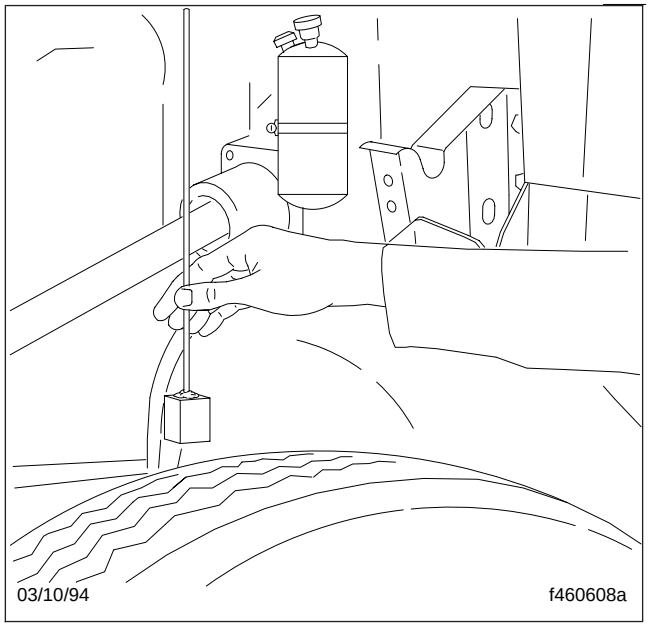

Fig. 4, Position the Steel Spacer

- Have someone turn the steering wheel until the stop bolt contacts the spacer block. See **Fig. 5**.
- Apply a 20-pound (89-newton) force on the steering wheel.
- Read the internal leakage rate on the flow meter. Record this value on form SD-94.
- Repeat substep 5.9 (beginning with placing the spacer between the axle and the axle stop) for the opposite turn.

  The maximum permissible internal leakage for a single gear is 1.0 gpm (3.8 L/min). If leakage is greater in either turning direction, replace the

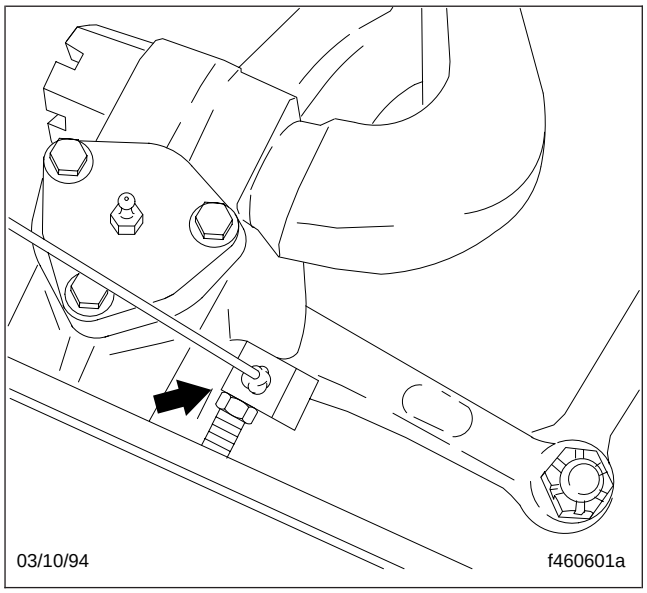

Fig. 5, Steel Spacer Contacting the Axle Stop

steering gear components as needed.

For systems with two or more steering gears and/or linear cylinders, the total acceptable internal leakage is 1.0 gpm (3.8 L/min) for each steering gear/ram in the system. For example, for a dual-gear system (two steering gears) the total acceptable internal leakage is 2.0 gpm (7.6 L/min).

If the leakage is more than 2.0 gpm (7.6 L/min) on a dual-gear system, isolate the auxiliary cylinder from the system.

- Disconnect the auxiliary cylinder hydraulic lines at the main gear auxiliary ports.
- Plug the main steering gear ports with suitable steel or high-pressure plugs or caps.
- Direct the disconnected lines into a drain pan.
- Repeat the internal leakage test.

If the internal leakage is less than 1 gpm (3.8 L/min), repair or replace the auxiliary gear or linear cylinder.

If the internal leakage is greater than 1 gpm (3.8 L/min), repair or replace the main gear.

- Remove the plugs and connect the hoses.
- Fill the power steering reservoir to the proper level.

6. Check the steering gear poppet relief valve and stop bolt adjustment.

   NOTE: Poppets limit the steering assist when the front wheels approach the stop bolts. Improper adjustment can apply excessive force to the steering linkage or loss of assist as the steering wheel approaches either full-left or full-right turns.

   6.1 Check the steering system for adequate turn angle.

   - Make sure the stop bolt settings limit the steering travel so there is 1/2-inch (13-mm) clearance from all stationary components, and 3/4-inch (19-mm) clearance from all moving components.
   - Make sure the pitman arm is situated on the steering gear sector shaft correctly.

⚠ CAUTION

If power steering pump relief pressure is reached while the steering wheel is at full lock, release the steering wheel from this position. Do not allow the pump relief pressure to be maintained for longer than five seconds or damage to the pump may result.

   6.2 Check the poppet relief pressure.

   - Set up a system for hydraulic checks as done in step 4.
   - Make sure the fluid temperature is at approximately 180°F (82°C) and the vehicle is stationary on the ground with the front wheels pointing forward.
   - Run the engine at idle with the load valve open.

Troubleshooting Procedures

- Turn the steering wheel to either full-lock position.
- Note the pressure gauge reading.
- Repeat the previous three instructions for the opposite turn.
- Record the poppet relief pressure on form SD-94 for both turns.

The pressure should drop slightly before the steering stops are contacted. If the pressure increases (from contact with the steering stops), the poppets/plungers must be manually reset. For poppet reset instructions, refer elsewhere in this group.

If the pressure is relieved and assist is lost when the wheel is too far from the axle stop, adjust the automatic poppet valve following the instructions in the next substep.

6.3 Adjust the poppet valves.

- Turn the steering wheel to the full-lock position.
- Apply a 20-pound (89-newton) force on the steering wheel while in the full-lock position.
- Repeat the previous two instructions for the opposite turn.

If the poppets (TRW gears only) have been adjusted or reset properly, and after subsequent vehicle operations loss of assist continues to occur when the wheel is too far from the axle stop, the poppets have become loose due to previous incorrect poppet adjustment and must be replaced. After poppet replacement and adjustment, test again for correct poppet relief function and record the pressure on form SD-94.

7. Check for abnormal power steering noise.

NOTE: Noise from the power steering system does not necessarily mean there is a problem. Some noises are normal and are the result of proper operation.

7.1 If not already done, check for proper fluid level. Record the results on form SD-94.

7.2 Check the condition of the power steering fluid and record the condition on form SD-94.

7.3 Check if a hissing sound is heard at less than full turn. If a hissing sound is heard, check the steering gear poppet and the axle stop adjustment and record the result on form SD-94. For adjustment instructions, see step 6.

See **Table 3** and **Table 4** for possible causes and remedies for common noises associated with the power steering system and power steering pump.

8. Check for leaks and restrictions, and test the system back pressure.

8.1 Check for leaks and restrictions.

- Run the engine at idle.
- Inspect all hoses and fittings for signs of kinked or collapsed hoses, or leaking fittings.
- Inspect all external seals.
- Repair all leaking fittings and replace parts as needed.
- Replace any leaking seals.
- Inspect the seal bores and sealing surfaces for scrapes or burrs. Make sure the seals are installed correctly using the recommended tools as found elsewhere in this group.
- Indicate on form SD-94 if there were any kinked or collapsed hoses, or leaking fittings or seals.

If you replaced the steering gear input shaft seal and found it to be excessively hard, test the system operating temperature, substep 5.8, if not already done.

Power Steering System Noise	
Possible Cause	**Remedy**
Growling or other abnormal steering noise	Check the fluid level. Check for air bubbles and foam. Check for hose and fitting leaks. Add fluid if needed. If there is air in the fluid, check for inlet tube and hose leaks. Correct all leaks.
A change from the usual pump sound	Check the power steering fluid reservoir. Check for air bubbles and foam in the fluid. If there is air in the fluid, check for inlet tube and hose leaks. Correct all leaks.
Clicking noise during a turn	Check for loose steering components. Check the front suspension for insufficient spring pin shims. Tighten any loose steering components. Add front spring pin shims if needed.
Hissing when the steering wheel is at or near full turn	Fluid flowing past a poppet valve makes a hissing noise. This is normal. No action is needed.

Table 3, Power Steering System Noise

Power Steering Pump Noise	
Possible Cause	**Remedy**
The intake line is plugged.	Drain the system. Clear the intake line if needed. Fill the system.
There is an air leak at the pump connections, the fittings, the reservoir connections, or the shaft seal.	Check all the connections by pouring power steering fluid over them, and listen for a reduction in sound. Tighten all the connections as needed. If the problem persists, remove the pump, disassemble it, and replace the shaft seal.
The pump input shaft is misaligned.	Remove and disassemble the pump. Replace the shaft seal and bearing.

Table 4, Power Steering Pump Noise

⚠ CAUTION

Do not move the steering wheel or allow the system pressure to exceed the rating of the gauge during the following test, or damage to the gauge could occur.

8.2 Test the system back pressure.

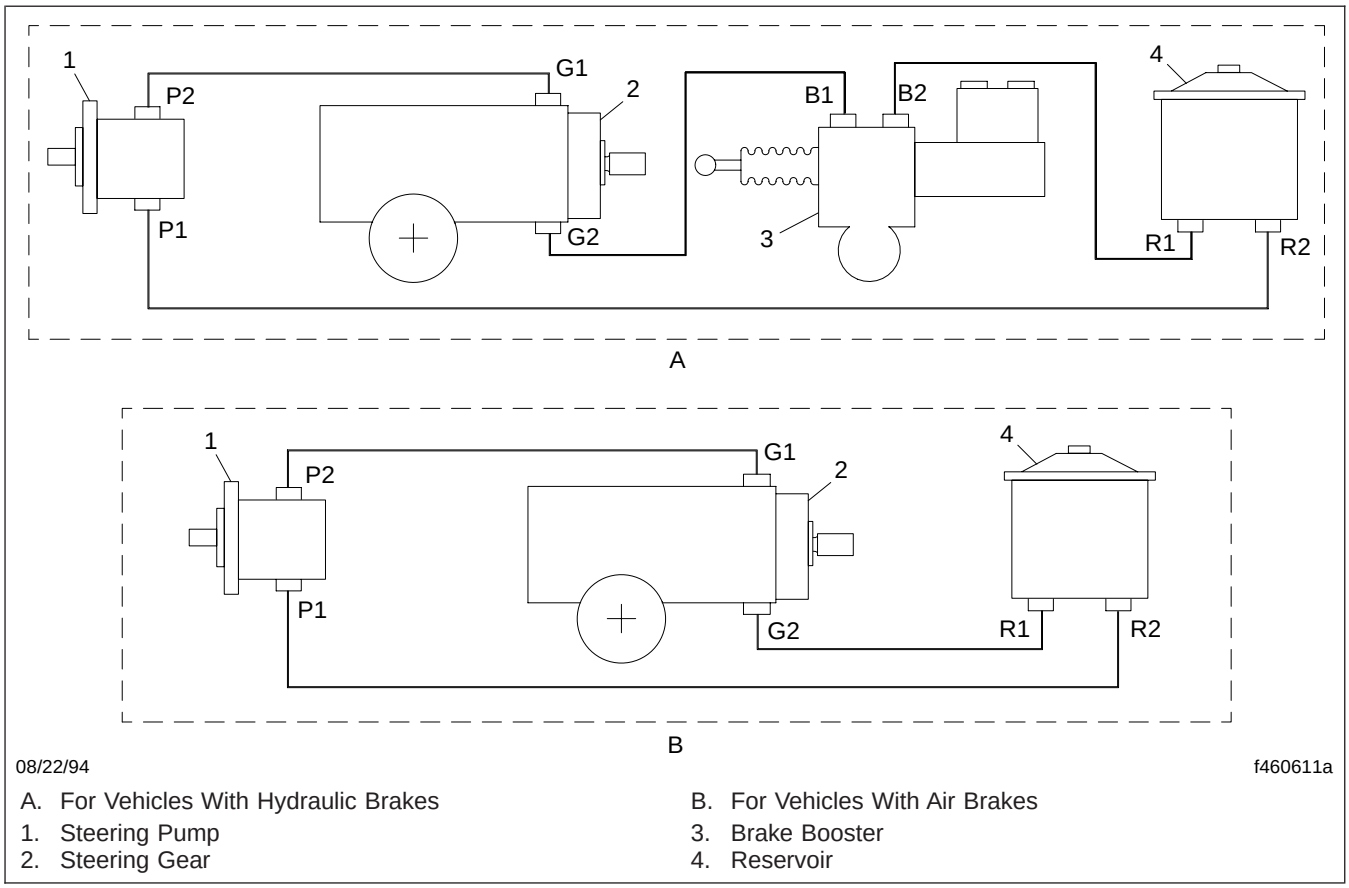
- Install a low-pressure gauge—200 to 300 psi (1379 to 2068 kPa) maximum—between the pressure line and the pump.
- Run the engine at idle and check for correct fluid level. If necessary, add fluid. If bubbles or foam appear in the reservoir, check the hose fittings for looseness or leaks.
- With the engine at idle, read the total system back pressure on the pressure gauge. Record the value on form SD-94.
- If the total system back pressure is greater than 100 psi (689 kPa), or 140 psi (965 kPa) for a vehicle with hydraulic brakes, go to the next substep. If the pressure between the pressure line and pump is less, restriction is not a problem.

8.3 Determine the restriction of the individual components by subtracting the values shown in **Table 5**. Record the values on form SD-94.

The component at fault can be identified by checking pressure at key locations in the steering system. With the engine at idle, use the low-pressure gauge and hose connection adaptors necessary to measure pressure at all locations identified in **Fig. 6**. Each time the gauge moves to a new location, make sure that the fluid

Troubleshooting Procedures

level is correct and air is removed from the system by running the engine at idle and checking the fluid level.



- Install the low-pressure gauge between the pump outlet and the pump-to-gear hose. Record this value as P2.
- Install the low-pressure gauge between the pump-to-gear hose and the steering gear inlet port. Record this value as G1.
- Install the low-pressure gauge between the steering gear outlet port and the gear-to-reservoir hose. Record this value as G2.
- Install the low-pressure gauge between the gear-to-reservoir hose and the reservoir inlet port. Record this value as R1.
- Install the low-pressure gauge between the reservoir outlet port and the reservoir-to-pump hose. Record this value as R2.
- Record the total system back pressure as determined in substep 8.2 as P1.

NOTE: For a vehicle with hydraulic brakes, perform similar procedures as those in substep 8.3. Record the pressure at the booster inlet as B1, and at the booster outlet as B2.

If any component exceeds the maximum allowable restriction listed for each component, refer to the applicable action to take in **Table 5**.

Total System and Component Restrictions		
Total System and Component Pressure-Check Location	**Maximum Allowable Restriction**	**Action to Take**
P2 = total system (pump outlet)	Hydraulic brakes: 140 psi (965 kPa) Air brakes: 100 psi (689 kPa)	Check pressure at the key locations.
P2–G1 = hose: pump-to-gear	12 psi (83 kPa)	Check for a kinked or plugged hose. Replace the hose if necessary.
G1–G2 = steering gear	55 psi (379 kPa)	The gear rotary valve is damaged. Replace the gear. See instructions elsewhere in this group.
G2–B1 = hose: gear-to-booster	12 psi (83 kPa)	Check for a kinked or plugged hose. Replace the hose if necessary.
G2–R1 = hose: gear-to-reservoir	12 psi (83 kPa)	Check for a kinked or plugged hose. Replace the hose if necessary.
B1–B2 = booster	40 psi (276 kPa)	Check the internal booster filter for contaminants. Check for contaminants causing binding or blockage of poppet and check valves within the booster.
B2–R1 = hose: booster-to-reservoir	12 psi (83 kPa)	Check for a kinked, collapsed, or plugged hose. Replace the hose if necessary.
R1–R2 = reservoir	2 qt: 4 psi (28 kPa)	Replace the filter. Check for internal blockage.
R2–P1 = hose: pump supply	12 psi (83 kPa)	Check for a kinked, collapsed, or plugged hose. Replace the hose if necessary.

Fig. 6, Plumbing Diagrams

General Information

The fuel system delivers fuel from the fuel tanks to the engine. It consists of the engine fuel system components, the fuel tank(s) and tank mounting components, and the fuel lines and (if so equipped) shutoff valve.

The engine fuel system components include fuel filters, injectors, fuel transfer pumps, and a fuel governor. For service and maintenance procedures, refer to the applicable engine manufacturer's service and maintenance manuals.

The fuel tanks are held in place by metal straps and brackets that transfer the load to the vehicle frame. On some installations, cab-access and chassis-access step assemblies attach to the fuel tanks and tank brackets.

In diesel engine installations, fuel suction and return lines made of polyester-braid-reinforced nylon tubing bring fuel from the tank to the engine, and return surplus fuel from the engine to the tank. Dual-tank installations have single suction and return lines with a crossover fuel line (a flexible, wire-braid-reinforced hose) to equalize the level of fuel in the tanks. A shutoff valve in the crossover line attaches to the bottom fitting of the primary tank, and shuts off fuel flow to or from the secondary tank.

A dual suction/dual return fuel system has been added to late model vehicles. This system provides equal fuel levels in both fuel tanks without the need of a low crossover line. This system also reduces the tendency for fuel to gel in cold weather.

NOTE: EquiFlo fuel systems are not available on vehicles equipped with the Chrysler gasoline engine.

⚠ WARNING

On gasoline engines, release the fuel system pressure before servicing the fuel system. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.

Gasoline engines are equipped with a returnless fuel system in which the fuel is held under constant pressure, even when the engine is shut down. While this eliminates the need for a return line, it makes it necessary to drain the fuel system pressure before servicing the fuel system.

The returnless fuel system also requires special high-pressure lines, tubes and fittings, which cannot be interchanged with diesel fuel lines, tubes or fittings.

Standard equipment for diesel engines includes a fuel level gauge sender in the primary tank, with an electric fuel level gauge mounted in the cab instrument panel. For gasoline engines, a float and sensing unit on the fuel pump module send data to the electric fuel gauge.

Tank-Mounted Step Assembly Removal and Installation

Removal

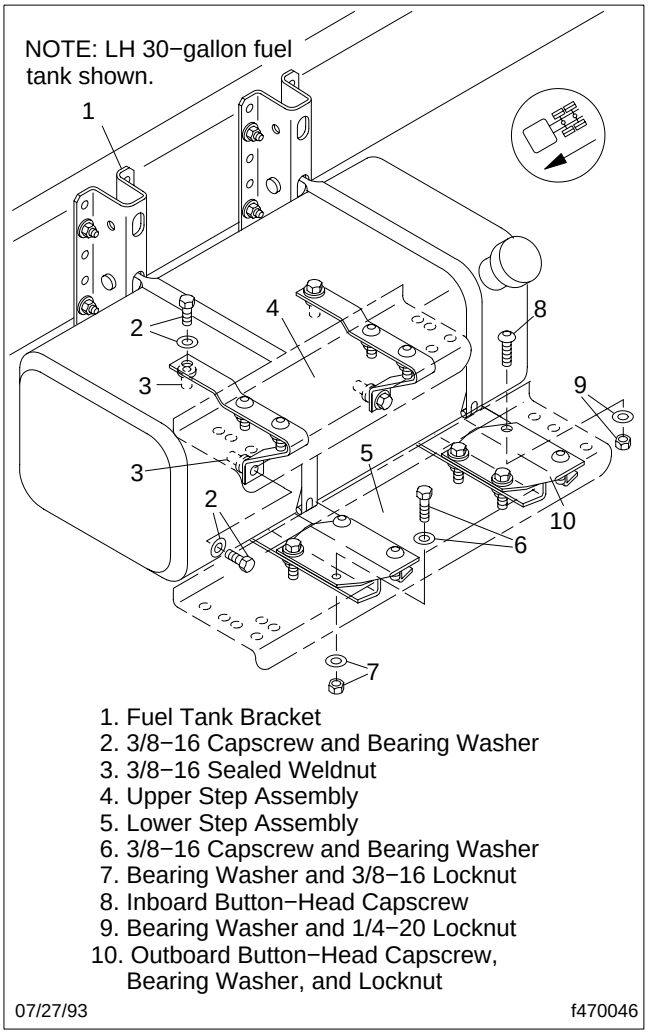
CAB-ACCESS STEP (Refer to Fig. 1)

To remove a *single-level* step, or the *lower step* of a *dual-level* installation (Ref. 5), remove the locknuts, bearing washers, and capscrews (Refs. 6 and 7) that attach the bottom of the step brackets to the fuel tank brackets (Ref. 1). Also, to remove the lower step from a 45-gallon *long* fuel tank, remove the *inboard* button-head capscrews, bearing washers, and locknuts (Refs. 8 and 9) that attach the step and step brackets to the fuel tank brackets. Don't remove the outboard fasteners (Ref. 10) that attach the step to the step brackets. Remove the step.

To remove the *upper step* of a *dual-level* installation (Ref. 4), remove the capscrews and bearing washers (Ref. 2) that attach the step brackets to the sealed weldnuts (Ref. 3) on the fuel tank. Remove the step.

CHASSIS-ACCESS STEP

(Refer to Fig. 2)



1. Remove the capscrews and bearing washers (Ref. 2) that attach the step clamps (Ref. 3) to the top of the fuel tank.
2. Remove the step. Remove the step clamps and fasteners from the step.

Installation

CAB-ACCESS STEP (Refer to Fig. 1)

NOTE: The procedures below are for step *assemblies* ; if the step and its brackets have been disassembled, use the procedures below to install the brackets, then **refer to Fig. 3,** or **Fig. 4** to position the step on the brackets.

To install a *single-level* step, or the *lower step* of a *dual-level* installation (Ref. 5), on the right-hand side of the vehicle, position the step brackets against the rear flanges of the outboard ends of the fuel tank brackets; on the left-hand side of the vehicle, position the step brackets against the front flanges of the fuel tank brackets. Install the capscrews, bearing washers, and locknuts (Refs. 6 and 7) that attach the step brackets to the tank brackets. Tighten the locknuts 38 N·m (28 lbf·ft). Also, for a lower step on a 45-gallon long fuel tank, install the inboard button-head capscrews, bearing washers, and locknuts (Refs. 8 and 9). Tighten the locknuts 10 N·m (7 lbf·ft).

2. 3/8−16 Capscrew and Bearing Washer
3. 3/8−16 Sealed Weldnut
4. Upper Step Assembly
5. Lower Step Assembly
6. 3/8−16 Capscrew and Bearing Washer
7. Bearing Washer and 3/8−16 Locknut
8. Inboard Button−Head Capscrew
9. Bearing Washer and 1/4−20 Locknut
10. Outboard Button−Head Capscrew, Bearing Washer, and Locknut

Fig. 1, Tank-Mounted Cab-Access Step Installation (dual-level steps shown)

To install the *upper step* of a *dual-level* installation (Ref. 4), align the fastener holes of the upper step brackets with the sealed weldnuts (Ref. 3) on the top and outboard side of the fuel tank. Install the capscrews and bearing washers (Ref. 2) that attach the step brackets to the fuel tank. Tighten the capscrews 35 N·m (26 lbf·ft).

Tank-Mounted Step Assembly Removal and Installation

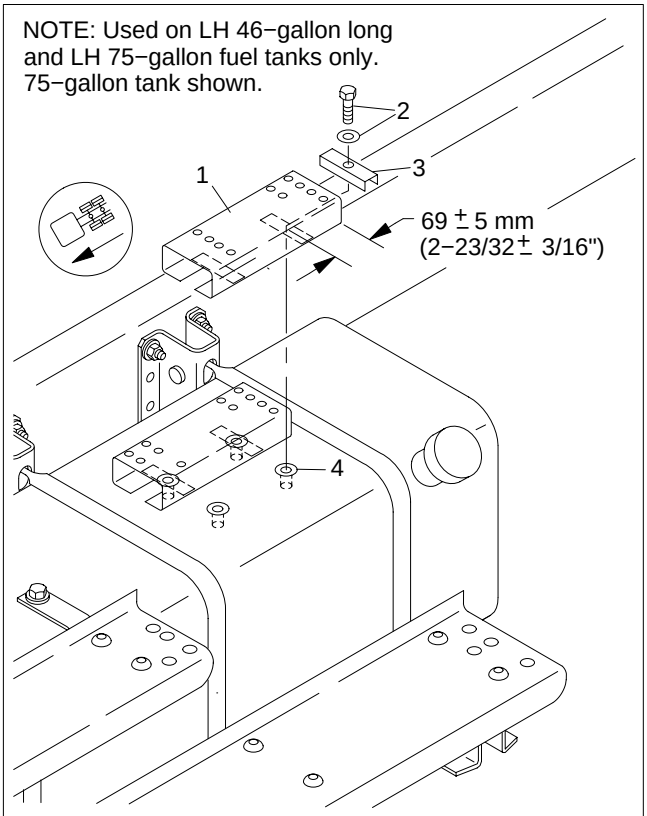

Fig. 2, Tank-Mounted Chassis-Access Step Installation

CHASSIS-ACCESS STEP

(Refer to Fig. 2)

1. Install the step clamps, capscrews, and bearing washers (Refs. 3 and 2) on the fuel tank; leave the fasteners loose. Turn the step clamps so they point to the front and rear of the truck (parallel to the frame rail).
2. Install the step on the fuel tank so the distance from the rear of the step to the center of the step clamp is 69 ± 5 mm (2-23/32 ± 3/16 inches).
3. Turn the step clamps so they point from side to side, and the ends are positioned over both bottom flanges of the step.
4. Tighten the step clamp capscrews 35 N·m (26 lbf·ft).

Tank-Mounted Step Assembly Removal and Installation

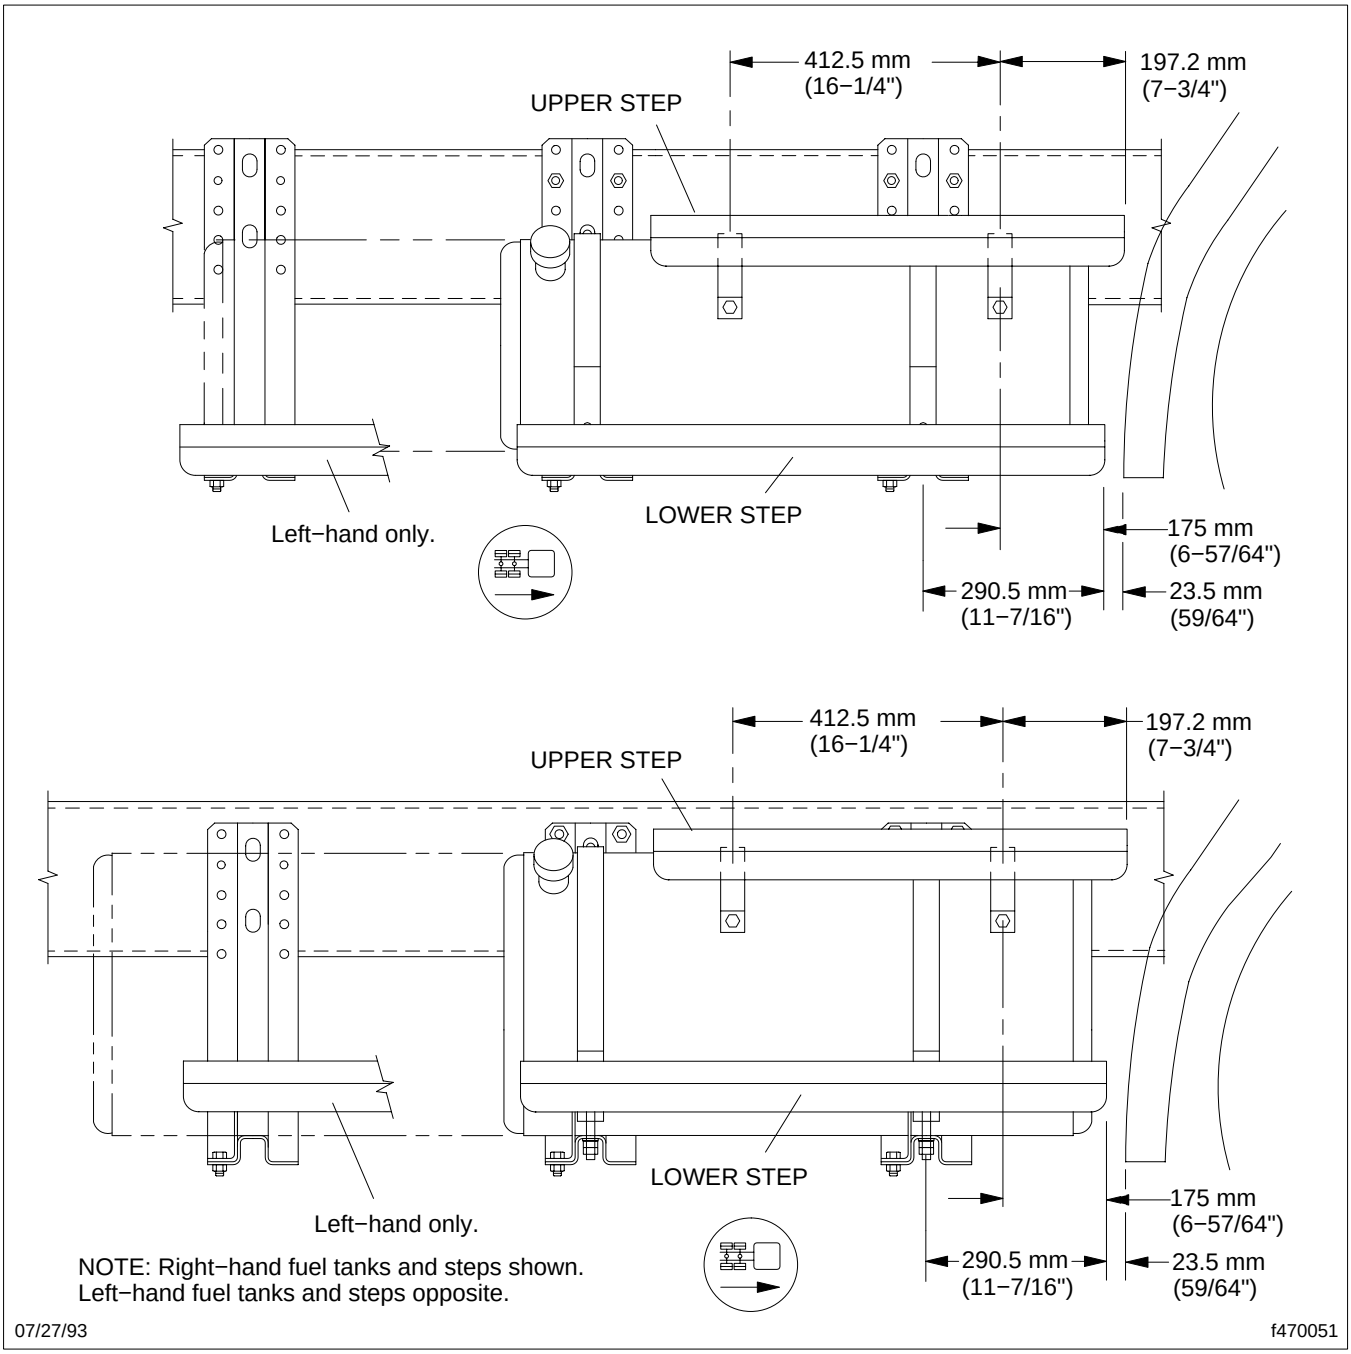

Fig. 4, Dual-Level Cab-Access Step Positioning

Removal (See Fig. 1, Fig. 2, Fig. 3, Fig. 4, or Fig. 5)

⚠ WARNING

Damaged fuel tanks must be replaced. A repaired fuel tank may not meet U.S. Federal strength, leakage, and venting standards required for all fuel tanks. A repaired fuel tank may be more likely to spill fuel or be ruptured in a vehicle accident, which could lead to personal injury or property damage.

If a damaged tank is found, use the following procedure:

1. Park the vehicle on level ground. Apply the parking brakes and chock the tires.
2. Remove the cab-access step(s); see **Subject 100**.

⚠ WARNING

Do not drain fuel near, or allow fuel vapor near, open flame or intense heat. Doing so is a dangerous practice, and creates a severe fire hazard. This could lead to personal injury, or property damage.

NOTE: Dual suction/dual return fuel systems on Business Class vehicles are not equipped with shut-off valves.

3. On a single-tank installation or a dual suction/dual return fuel system, place a suitable container under the fuel tank and remove the drain plug.

   On a dual-tank installation with a shut-off valve, place a suitable container under the fuel tank, close the fuel shutoff valve located on the primary fuel tank, then remove the drain plug.

   If the fuel is to be re-used, store it in a clean container to protect it from contaminants.
4. Disconnect the fuel return and suction lines from the tank; then cap the lines to prevent fuel spillage.

   On a dual-tank installation with a fuel crossover line, disconnect the fuel crossover line from the bottom of the tank that is to be removed; then cap the line.
5. If removing a single or primary tank, disconnect the wires from the fuel level gauge sender. See **Fig. 6.**
6. Remove the tank straps and isolators. See **Fig. 7.**

   6.1 Remove the nuts and washers from the tank strap T-bolts at the outboard end of the tank brackets.

   6.2 Remove the cotter pins and clevis pins from the inboard end of the tank straps. Remove the tank straps and isolators.
7. Using a fork lift, remove the fuel tank.
8. Inspect the tank straps, isolators, and brackets for wear and damage. Replace worn or damaged parts with new parts.

⚠ WARNING

Failure to replace worn or damaged parts could result in loss of a fuel tank and spilling of fuel, which could cause property damage or personal injury.

9. When replacing a fuel tank, remove all parts necessary to install the new fuel tank. Inspect the parts, and replace them as needed. Install all necessary components on the new fuel tank before installation.

   9.1 Remove and clean all pipe plugs, fittings and lines, then transfer the components to the new fuel tank. Coat all tapered pipe plug and fitting threads with Loctite® 592, or an equivalent sealer.

   9.2 Inspect the vent line, then transfer it to the new fuel tank.

   9.3 Transfer the chassis-access steps to the new tank, if so equipped; see **Subject 100.**

   9.4 If a single or primary fuel tank is being replaced, transfer the fuel level gauge sender and gasket to the new fuel tank. Install the machine screws until contact is made with the sender unit. Use a star pattern (see **Fig. 8**) to distribute the torque evenly around the sender unit.

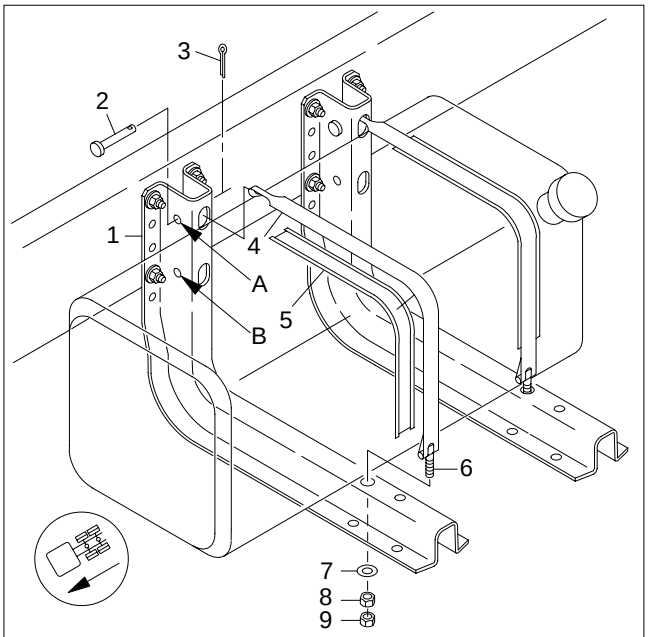
3. 100 Gallon Tank
4. 30 Gallon
5. 45 Gallon Long Tank

Fig. 9, Fuel Tank Positioning

Fuel Tank Strap Replacement

Replacement (Refer to Fig. 1)

1. Apply the vehicle parking brakes and chock the tires.
2. Remove the cab-access step(s); **refer to Subject 100.**
3. Remove the fuel tank strap and isolator (Refs. 4 and 5).
   - 3.1 Remove the nuts and washer (Refs. 9, 8, and 7) from the tank strap T-bolt (Ref. 6) at the outboard end of the tank bracket.
   - 3.2 Remove the cotter pin and clevis pin (Refs. 3 and 2) from the tank strap eye at the inboard end of the tank bracket.
4. Inspect the isolator and clevis pin for wear or damage; replace if needed.



WARNING

WARNING: Failure to replace worn or damaged parts could result in loss of a fuel tank and spilling of fuel, which could cause property damage or personal injury.

5. Install the isolator and the new tank strap on the tank.
   - 5.1 Install the clevis pin (Ref. 2) through the inboard end of the tank bracket and tank strap. Install and lock a new cotter pin (Ref. 3) in the clevis pin.

   IMPORTANT: Fuel tanks can be damaged by overtightening the fuel tank straps.

   - 5.2 Install a bearing washer and two nuts on the tank strap T-bolt. Tighten the first nut 20 N·m (15 lbf·ft).
   - 5.3 While holding the first nut stationary with a wrench, tighten the jam nut 41 N·m (30 lbf·ft).
6. Install the cab-access step(s); **refer to Subject 100.**
7. Remove the tire chocks.

1. Fuel Tank Bracket
2. Tank Strap Clevis Pin
3. Clevis Pin Cotter Pin
4. Fuel Tank Strap

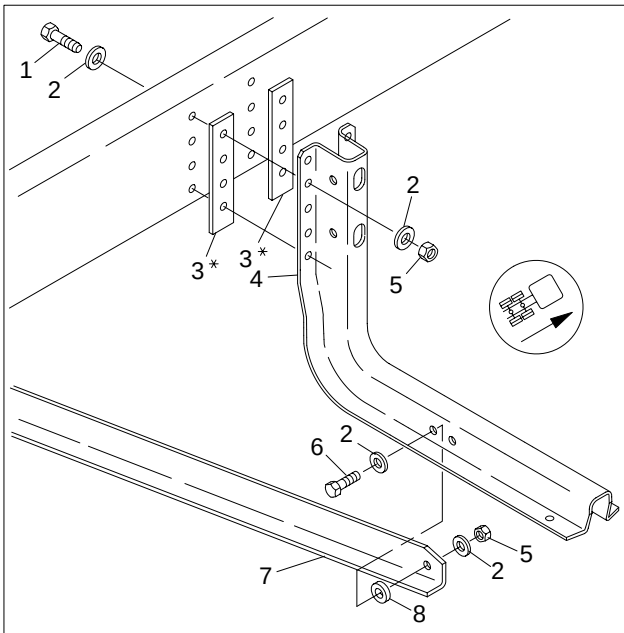
B. Use for 45−gallon long tank or 30−gallon tank.



07/27/93 f470049

Fig. 1

Fuel Tank Bracket Replacement

Replacement (Refer to Fig. 1)

1. Remove the fuel tank; **refer to Subject 110.**
2. If the fuel tank bracket has a compression brace (Ref. 7) attached, remove the locknut, washers, spacer (Ref. 8), and capscrew that attach the brace to the bracket.
3. Remove the locknuts, hardened washers, and capscrews that attach the fuel tank bracket to the frame rail. Remove the bracket, and if so equipped, the fuel tank bracket spacers (Ref. 3).
4. From inside the frame rail, install the two upper capscrews and hardened washers. If so equipped, install the fuel tank bracket spacers onto the outboard ends of the capscrews. Position the new tank bracket on the capscrews, then install the two upper hardened washers and locknuts, finger-tight.
5. Install the two lower sets of fasteners. Tighten all of the locknuts 92 N·m (68 lbf·ft).
6. If a compression brace (Ref. 7) was attached to the bracket, install the capscrew, hardened washers, spacer (Ref. 8), compression brace, and locknut, **as shown in Fig. 1 .** Tighten the locknut 92 N·m (68 lbf·ft).
7. Install the fuel tank; **refer to Subject 110.**

1. 1/2−13 Capscrew
2. Bearing Washer
3. Fuel Tank Bracket Spacer *
4. Fuel Tank Bracket
5. 1/2−13 Locknut
6. 1/2−13 Capscrew
7. Compression Brace
8. Compression Brace Spacer

* Used with 14,000 and 16,000 lb front suspension when frame reinforcement isn't used.

07/27/93 f470057

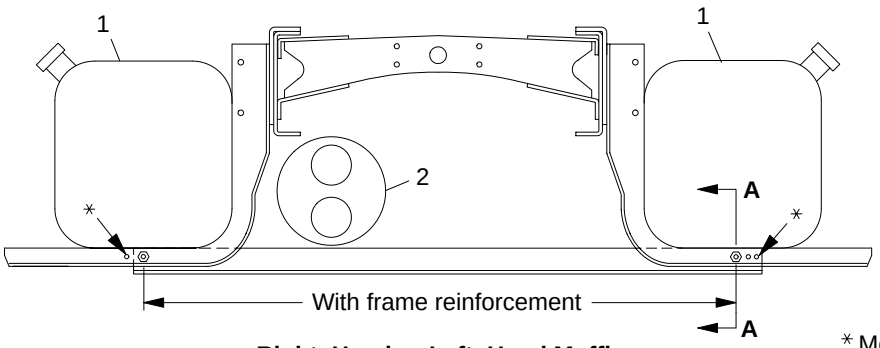


Fig. 1

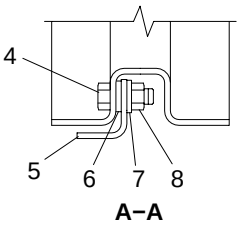
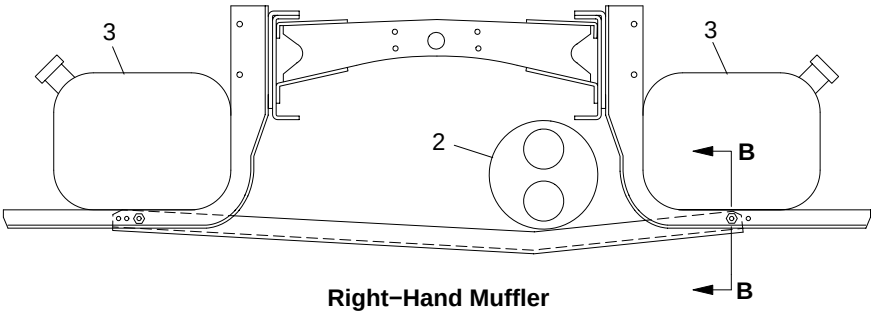
Compression Brace Replacement



Replacement (Refer to Fig. 1)

1. Apply the vehicle parking brakes and chock the tires.
2. Remove the fasteners and clamps that attach the fuel crossover line to the compression brace.
3. Remove the locknuts, bearing washers, spacers (Ref. 6), and capscrews that attach the compression brace to the fuel tank brackets. Remove the compression brace.
4. Position the new compression brace, **as shown in Fig. 1 .** Install the capscrews, bearing washers, spacers, and locknuts, in the indicated mounting holes.
5. Tighten the locknuts 92 N·m (68 lbf·ft).
6. Install the clamps and fasteners that attach the fuel crossover line to the compression brace. Tighten the fasteners snugly.
7. Remove the chocks.

Compression Brace Replacement



Right−Hand or Left−Hand Muffler

Fig. 1

Diesel Fuel Lines

GENERAL GUIDELINES

If diesel fuel lines are worn, damaged, or deteriorated, replace them. Use the following guidelines for installing and routing them.

- Fuel lines must be free of droops, sharp bends, and kinks in the lines.
- Fuel lines must not extend more than 2 inches (5 cm) below the fuel tank unless they are completely enclosed in a protective housing.
- Fuel lines must be routed in a continuous upward slope from the fuel tank to prevent high and low spots in the hoses.
- Fuel lines must be routed at least six inches (15 cm) from exhaust pipes
- Heat shields and/or hose insulation must be used to protect any section of fuel line that is less than six inches (15 cm) from a heat source.
- Fuel lines must be routed to allow routinely serviceable components such as dipsticks, filters, and water separators to be readily accessed without the need to disconnect the fuel lines.
- Fuel lines must be secured to prevent chafing, kinking, or other damage.
- Fuel lines must be long enough to allow movement of the parts to which they are attached.
- Coat all pipe threads (tapered threads) with Loctite® 592, or an equivalent.
- Finger-tighten pipe fittings; then tighten one and one half turns. Tighten more if necessary to seal.
- Fuel lines and fittings must be free of leaks, to prevent fuel loss or entry of air into the line, which may result in a loss of prime by the engine fuel system.
- Drains or other bottom fittings must not extend more than 3/4 inch (19 mm) below the lowest part of the fuel tank or sump.

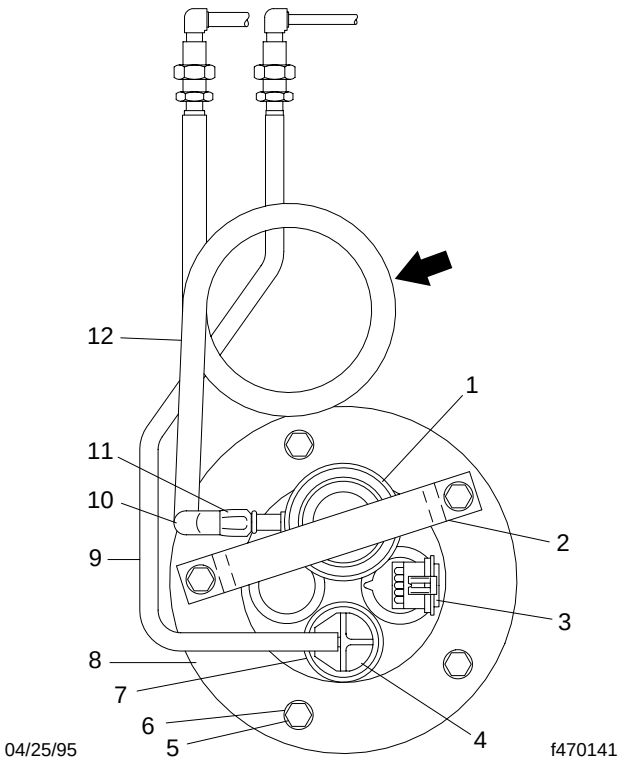
Gasoline Fuel Lines and Clamps

GENERAL GUIDELINES FOR LINES AND CLAMPS

The gasoline-powered engines used on Freightliner vehicles use a fuel injection system. This system requires fuel lines, tubes and clamps of special construction.

The fuel lines and tubes must withstand higher fuel pressures and the possibility of contaminated fuel in this system. Only lines and tubes marked EFM/EFI may be used.

The hose clamps on fuel-injected vehicles are of a special rolled-edge construction. This prevents the edge of the clamp from cutting into the hose and causing leaks. Do not use other types of clamps.



Inspect the fuel system using the following guidelines.

⚠ WARNING

WARNING: Release the fuel system pressure before servicing any fuel system lines, tubes, or fittings. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.

1. Release the fuel system pressure. For instructions, refer to **Subject 170**.
2. Inspect all fuel lines to be sure they are free from sharp bends or kinks, and are not in contact with other vehicle components so as to cause scuffing or abrasion. Replace any bent or kinked lines.
3. Secure all fuel lines to prevent chafing, kinking, or other damage.
4. Check the length of all fuel lines. They must be long enough to allow movement of the parts to which they attach. Check that the fuel supply line is looped correctly where it attaches to the fuel pump module. See **Fig. 1.**
5. Inspect all fuel lines, clamps, couplings, and fittings for leaks. Inspect all clamps, couplings, and fittings for security. Immediately replace any component that shows signs of failure, or damage that could lead to failure. Tighten new clamps 15 lbf·in (170 N·cm).

Fuel Line Routing

Loop the fuel supply line as shown.

1. Fuel Filter/Pressure Regulator
2. Fuel Pump Guard Bracket
3. Pump/Gauge Electrical Connector
4. Pressure Relief/Rollover Valve
5. 5/16–18 Clamp Ring Mounting Capscrew (Grade 8)
6. Hardened Flatwasher
7. Rollover Valve Grommet
8. Fuel Pump Mounting Clamp Ring
9. Evaporative Canister Line
10. 90° Elbow
11. Fuel Supply Line Fitting
12. Fuel Supply Line

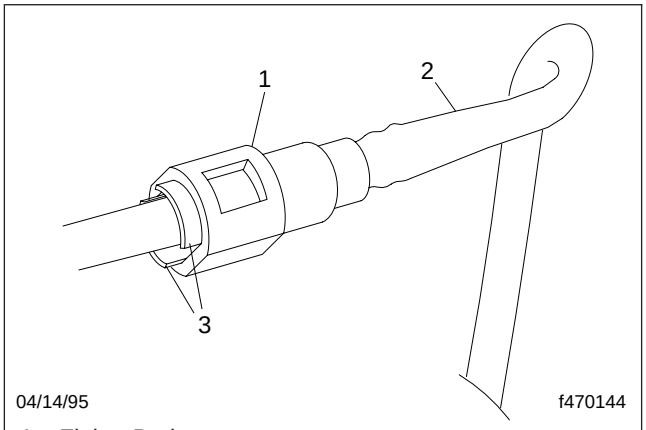


Fig. 1, Fuel Supply Line

6. Be sure that all nylon fuel tubes are properly routed, not pinched, and far enough away from sources of heat. Replace as necessary.

IMPORTANT: Never attempt to repair a nylon fuel tube.

QUICK-DISCONNECT FITTINGS

Gasoline fuel lines are equipped with quick-disconnect fittings to allow easy and fast connections. These fittings contain a plastic retainer with two external tabs, one on each side of the fitting. See **Fig. 2.**

1. Fitting Body
2. Fuel Line
3. Plastic Retainer Tab

Fig. 2, Quick-Disconnect Fitting

1. Disconnect the batteries.

WARNING

WARNING: Release the fuel system pressure before servicing any fuel system quick-disconnect fittings. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.

2. Release the fuel system pressure. For instructions, refer to **Subject 170**
3. Clean the fitting of any foreign material such as grease or oil.
4. To disconnect the line at the fuel rail, squeeze the two tabs on the plastic retainer against the sides of the fitting, using finger pressure only. Remove the line and fitting body, leaving the retainer on the fuel rail.

NOTE: To remove the plastic retainer, if necessary, very carefully release it from the component using two small screwdrivers. Inspect the retainer after removal for cracks or damage.

5. Inspect the plastic retainer and the body of the quick-connect fitting for damage. Replace if necessary.

IMPORTANT: Do not attempt to replace any interior components (O-rings, spacers) of the quick-disconnect fitting. If repair is needed, replace the complete fitting.

6. Check the condition of the fitting and the component. Clean all parts with a lint-free cloth. Lubricate them with clean engine oil.
7. To connect, insert the fitting into the component and into the plastic retainer. When you hear a click, the connection has been made. Pull firmly on the fuel tube to make sure the connection is locked.

NOTE: A locked fitting should resist a pull of approximately 15 to 30 lbf (65 to 130 N).

8. Connect the batteries.
9. Start the engine and check for leaks.

Priming

Before priming the system, make sure there is enough fuel in the tank(s). Don't fill them to more than 95 percent of capacity.

⚠ WARNING

WARNING: Federal regulations prohibit filling a fuel tank to more than 95 percent of its capacity. A tank with air space is much less likely to rupture in an accident than one that has little or no air space. Fuel tank rupture could result in fuel spillage and a hazardous condition.

Don't crank the starter more than 30 seconds at a time during any of the following procedures; wait 2 minutes after each try to allow the starter to cool, or starter damage may occur.

1. If the engine is equipped with a priming pump, use it to prime the fuel transfer pump.
   - 1.1 Operate the priming pump plunger until there is resistance.
   - 1.2 Push the plunger in and tighten it by hand.
   - 1.3 Start the engine; if it doesn't start, more priming is needed. Once the engine has started, it may run rough; if so, run the engine at low idle until it runs smoothly.
2. If the engine isn't equipped with a priming pump, pressurize the fuel in the fuel tank, to prime the fuel transfer pump.
   - 2.1 Remove the fuel tank cap from the primary tank.
   - 2.2 Loosen the fuel supply line at the fuel transfer pump.
   - 2.3 While someone else looks for a constant fuel flow at the loosened fuel supply line, partially block the fuel tank opening with a clean rag, and use an air hose to apply no more than 35 kPa (5 psi) air pressure to the fuel tank.
   - 2.4 When the fuel flow is constant, remove the air hose and rag, and tighten the fuel supply line.

IMPORTANT: To prevent fuel loss or entry of air into a fuel line, make sure that all fuel line connections are tight.

- 2.5 Start the engine. Once the engine has started, it may run rough. If this occurs, run the engine at low idle until it runs smoothly.

Gasoline Fuel Tank Removal and Installation

Removal

If there is any damage to the fuel tank, *replace* it; *do not repair* fuel tanks.

⚠ WARNING

WARNING: Damaged fuel tanks must be replaced. A repaired fuel tank will not meet the strength, leakage, and venting standards required by U.S. Federal regulations for original and replacement fuel tanks. A repaired fuel tank may be more likely to rupture from impact, possibly causing fire and resulting in personal injury or property damage.

1. Apply the vehicle parking brakes and chock the tires.

IMPORTANT: The gasoline-powered engine uses a returnless fuel system. Even when the engine is shut down, the fuel system is under constant pressure.

2. Release the pressure on the fuel system.

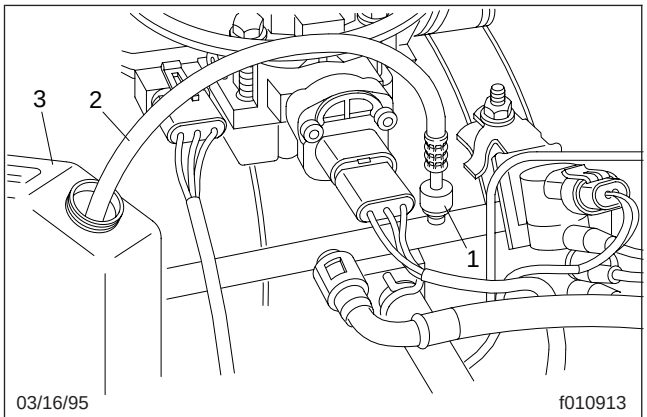
   2.1 Disconnect the batteries.

   2.2 Remove the fuel tank filler cap. This releases fuel tank pressure.

   IMPORTANT: Do not allow gasoline to spill onto the engine intake or exhaust manifolds. To absorb the gasoline, place shop towels under and around the pressure port when the pressure is released from the fuel rail.

   2.3 Unscrew the protective plastic cap from the pressure test port on the fuel rail (**see Fig.1**).

⚠ WARNING



WARNING: Always wear proper eye protection when releasing fuel system pressure. Fuel squirted or splashed into the eyes can cause injury.

   2.4 Obtain fuel pressure gauge tool set #5069. To order this tool set, call the Kent-Moore Tool Company at 1-800-328-6657. Remove the gauge from the hose. Place one end of the hose into an approved gasoline container. Place a shop towel under the test port. **See Fig.2.**

1. Fuel Rail
2. Fuel Line
3. Test Port Protective Cap

Fig. 1, Pressure Test Port

1. Test Port
2. Test Hose
3. Vented Gasoline Can

Fig. 2, Release Fuel System Pressure

   2.5 Screw the other end of the hose onto the fuel pressure test port and allow the gasoline to run into the container until the pressure is fully released.

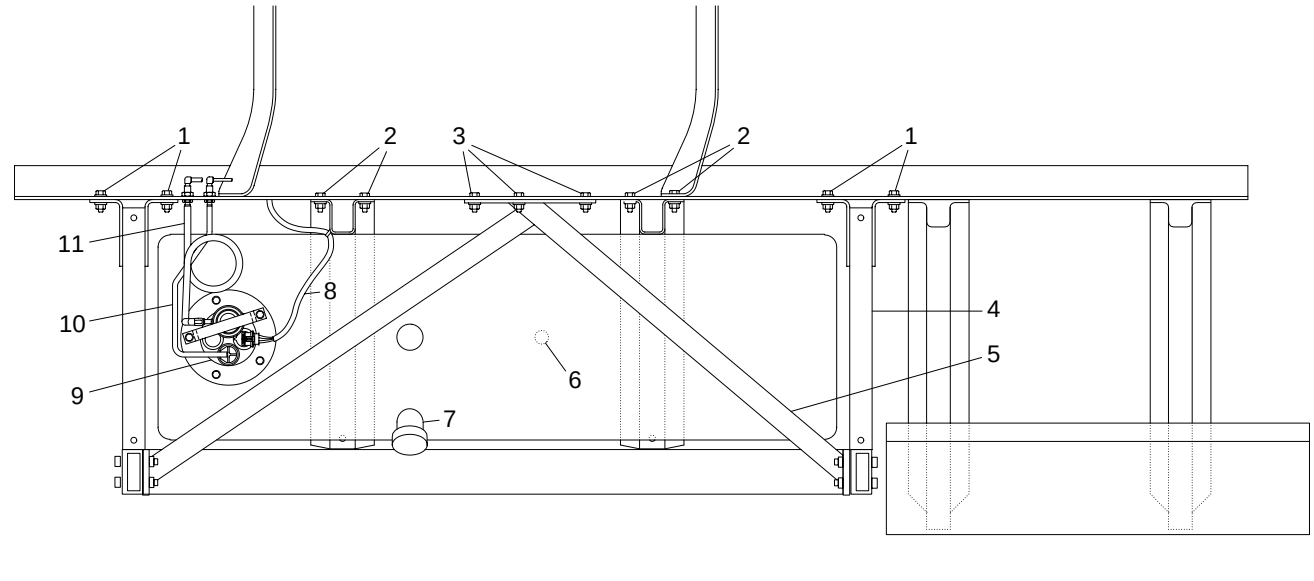
   2.6 Remove the hose from the test port and return it to tool set #5069.

   2.7 Install the protective cap on the test port.

Gasoline Fuel Tank Removal and Installation

WARNING

WARNING: Gasoline is highly flammable. Do not drain gasoline near, or expose gasoline vapor to, open flame or intense heat. This could lead to personal injury or property damage by fire.



3. Remove the drain plug (**see Fig.3**, Ref. 6). Drain the fuel tank.

   If the gasoline is to be saved, store it in a clean container, and protect it from contaminants. Move the container away from the work area.

First determine the vehicle's configuration, and then refer to the appropriate removal method below.

Vehicles with Open Frame

1. Disconnect the electrical connector and fuel lines from the fuel pump module. Then, remove the fuel pump module from the tank. For a detailed removal procedure, refer to **Subject 100** in the Chrysler fuel pump module section.
2. Remove the mounting locknuts and capscrews.

05/04/95 f470143

8. Electrical Cable
9. Fuel Pump Module
10. Evaporative Canister Line
11. Fuel Supply Line

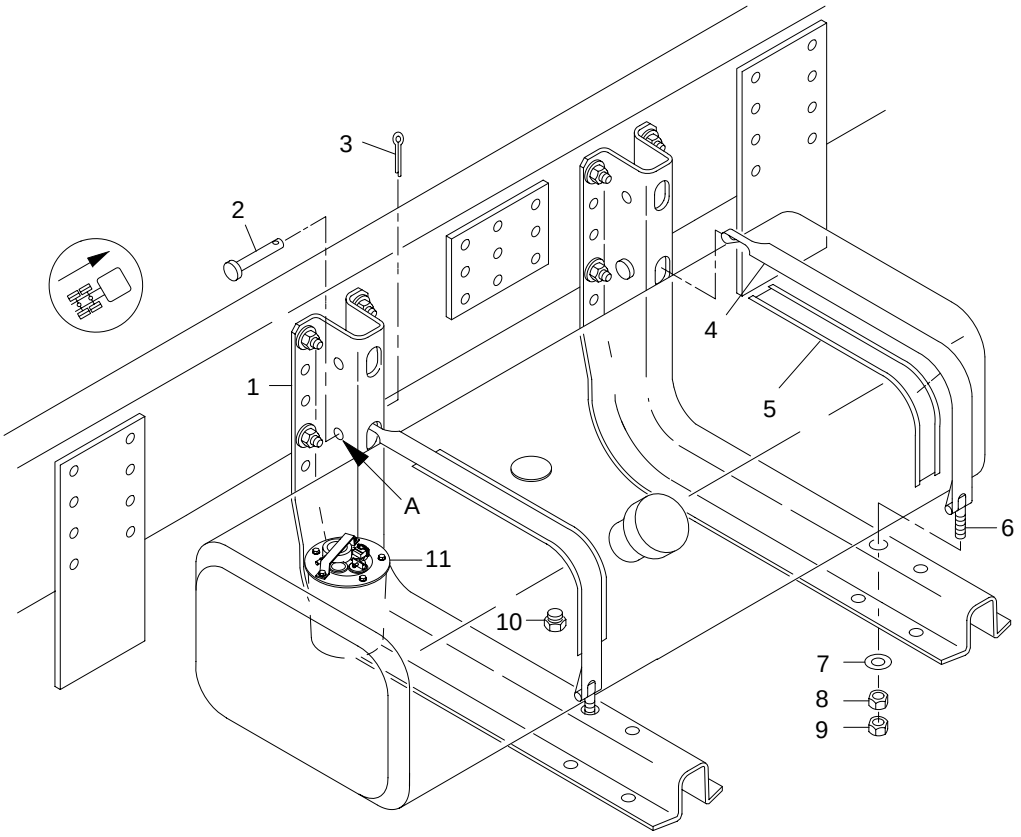

Fig. 3, Rectangular Fuel Tank (installed)

IMPORTANT: The removal of the fuel tank is affected by the configuration of the vehicle. The three configurations are:

- open frame;
- box with a bolted tank assembly;
- box with Huckbolted tank assembly.

3. Remove the top brace bolts from the top brace bracket and the outboard end of each end bracket. Remove the top braces (upper cage assembly) from the vehicle.
4. Remove the tank straps and isolators. **See Fig.4.**

   4.1 From each tank strap T-bolt (Ref. 6), fastened to the outboard end of the tank brackets, remove the nuts and bearing washers (Refs. 9, 8, and 7).

09/18/95 f470142

NOTE: Lower cage assembly removed for clarity.

A. Use the lower set of holes in the tank bracket for attaching the fuel tank straps.

8. 1/2–13 Hexnut
9. 1/2–13 Jam Nut
10. Drain Plug
11. Fuel Pump Module

Fig. 4, Fuel Tank Removal and Installation

4.2 Remove the cotter pins and clevis pins (Refs. 3 and 2) from the inboard end of each tank strap. Remove the tank straps and isolators.

5. Lift the fuel tank out of the fuel tank cage.

6. Inspect the tank straps, isolators, and brackets for wear and damage.

⚠ WARNING

WARNING: Replace worn or damaged parts. Failure to replace worn or damaged parts could result in loss of a fuel tank and spilling of fuel, which could cause personal injury or property damage.

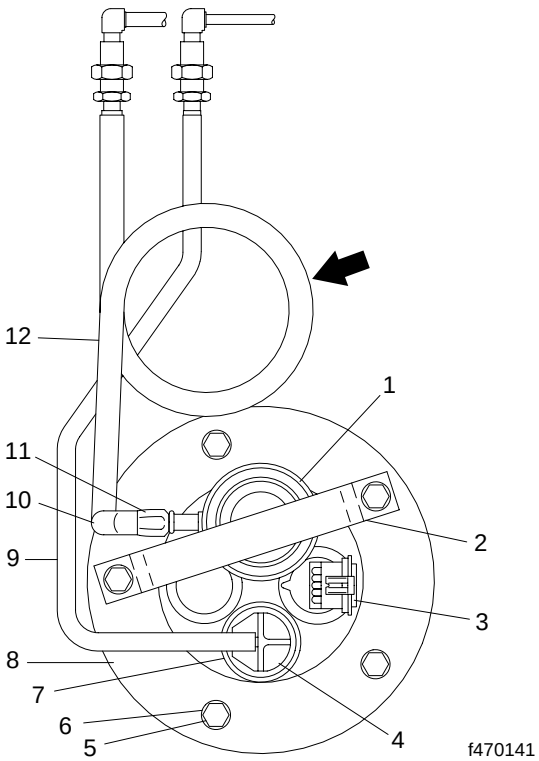
7. If a fuel tank is being replaced, remove parts from the old tank that will be needed on the new tank. Inspect the parts, and replace them if necessary. Install them on the new tank. If neces-

Gasoline Fuel Tank Removal and Installation

sary, install near the fuel filler neck a new decal reading "unleaded fuel only."

7.1 Remove and clean all pipe plugs and fittings, and transfer them to the new tank. Clean all parts with a lint-free cloth. Lubricate them with clean engine oil.

IMPORTANT: Loop the fuel supply line during the next step in the installation procedure. **See Fig.5.**



7.2 Install the fuel pump module to the new tank. **See Fig.5.** For a detailed installation procedure, refer to **Subject 100** in the Chrysler fuel pump module section. Securely and evenly tighten the clamp ring mounting capscrews 20 N·m (15 lbf·ft).

Vehicles With Box and Bolted Fuel Tank Assemblies Installed

1. Disconnect the electrical connector and fuel lines from the fuel pump module. Then, remove the fuel pump module from the tank. For a detailed removal procedure, refer to **Subject 100** in the Chrysler fuel pump module section.
2. Remove the fuel tank cage. To do so, use the following instructions:
   - 2.1 Support the cage assembly with a forklift or other lifting device;
   - 2.2 Unbolt the cage assembly from the frame rail;
   - 2.3 Remove the cage from the vehicle.
3. Remove the tank straps and isolators. **See Fig.4.**
   - 3.1 From each tank strap T-bolt (Ref. 6), fastened to the outboard end of the tank brackets, remove the nuts and bearing washers (Refs. 9, 8, and 7).
   - 3.2 Remove the cotter pins and clevis pins (Refs. 3 and 2) from the inboard end of each tank strap. Remove the tank straps and isolators.

NOTE: Do not remove the fuel tank brackets.

4. Remove the fuel tank from the vehicle.
5. Inspect the tank straps, isolators, and brackets for wear and damage.

NOTE: It is important to loop the fuel supply line as shown.

1. Fuel Filter/Pressure Regulator
2. Fuel Pump Guard Bracket
3. Pump/Gauge Electrical Connector
4. Pressure Relief/Rollover Valve
5. 5/16–18 Clamp Ring Mounting Capscrew (Grade 8)

8. Fuel Pump Mounting Clamp Ring
9. Evaporative Canister Line
10. 90° Elbow
11. Fuel Supply Line Fitting
12. Fuel Supply Line

Fig. 5, Fuel Pump Module (Top View)

WARNING

WARNING: Replace worn or damaged parts. Failure to replace worn or damaged parts could result in loss of a fuel tank and spilling of fuel, which could cause personal injury or property damage.

6. If a fuel tank is being replaced, remove parts from the old tank that will be needed on the new tank. Inspect the parts, and replace them if necessary. Install them on the new tank. If necessary, install near the fuel filler neck a new decal reading "unleaded fuel only."

    6.1 Remove and clean all pipe plugs and fittings, and transfer them to the new tank. Clean all parts with a lint-free cloth. Lubricate them with clean engine oil.

    6.2 Install the fuel pump module to the new tank. **See Fig.5.** For a detailed installation procedure, refer to **Subject 100** in the Chrysler fuel pump module section. Securely and evenly tighten the clamp ring mounting capscrews 20 N·m (15 lbf·ft).

Vehicles With Box and Huckbolted Fuel Tank Assemblies Installed

1. Disconnect the electrical connector and fuel lines from the fuel pump module. Then, remove the fuel pump module from the tank. For a detailed removal procedure, refer to **Subject 100** in the Chrysler fuel pump module section.

NOTE: Use a gas cutting torch and a grinder to remove the Huckbolts.

2. To prepare the fuel tank and the vehicle for removal of the Huckbolts, use the following instructions:

    2.1 Flush the fuel tank with water for several minutes;

    2.2 Fill the fuel tank with water;

    2.3 Flush the adjacent portion of the vehicle and the surrounding area with water;

    2.4 Allow the water on the vehicle and the work area to dry.

⚠ WARNING

WARNING: Do not use a flame or a grinder near a gasoline tank unless the tank has been flushed and filled with water, and the surrounding area has been flushed with water. Otherwise, an explosion or fire could result, causing serious person injury or death.

    2.5 Burn and grind seven of the nine Huckbolts attaching the fuel tank brackets. (Leave one Huckbolt holding each bracket). Work on either side of the frame rail, whichever offers the best access;

    2.6 Install a nut and bolt to hold each bracket before removing the last Huckbolts;

    2.7 Remove the last Huckbolts with the torch and grinder;

    2.8 Drain the water from the tank, and position a forklift or other lifting device under the tank.

3. Remove the tank straps and isolators. **See Fig.4.**

    3.1 From each tank strap T-bolt (Ref. 6), connected to the outboard end of the tank brackets, remove the nuts and bearing washers (Refs. 9, 8, and 7).

    3.2 Remove the cotter pins and clevis pins (Refs. 3 and 2) from the inboard end of each tank strap. Remove the tank straps and isolators.

    3.3 Remove the temporary bolts holding the brackets.

4. Lower the fuel tank out of the fuel tank cage. Remove the fuel tank from the vehicle.

NOTE: During the lowering procedure, the fuel tank may need to be rotated slightly so that the filler tube clears the cage assembly.

5. Inspect the tank straps, isolators, and brackets for wear and damage.

⚠ WARNING

WARNING: Replace worn or damaged parts. Failure to replace worn or damaged parts could result in loss of a fuel tank and spilling of fuel, which could cause personal injury or property damage.

6. If a fuel tank is being replaced, remove parts from the old tank that will be needed on the new tank. Inspect the parts, and replace them if necessary. Install them on the new tank. If necessary, install near the fuel filler neck a new decal reading "unleaded fuel only."

Gasoline Fuel Tank Removal and Installation

6.1 Remove and clean all pipe plugs and fittings, and transfer them to the new tank. Clean all parts with a lint-free cloth. Lubricate them with clean engine oil.

6.2 Transfer the fuel pump module to the new tank. **See Fig.5.** For a detailed installation procedure, refer to **Subject 100** in the Chrysler fuel pump module section. Securely and evenly tighten the clamp ring mounting capscrews 20 N·m (15 lbf·ft).

7. If the old tank, which was filled with water, is to be installed, ensure that it is dry before installation. Mop out the interior of the tank with shop towels, and then direct shop air into the tank until dry.

Installation

1. Depending on the vehicle's configuration, lower or lift the fuel tank into its approximate installed position. **See Fig.3.**

   Make sure the fuel filler neck is outboard.

   On vehicles where the Huckbolts and the brackets were removed, install the brackets along with the fuel tank. Replace the Huckbolts with fuel tank bracket mounting locknuts and Grade 8 capscrews. Tighten each nut 68 lbf·ft (92 N·m).

2. Install the isolators and tank straps. **See Fig.4.**

   2.1 Install a clevis pin (Ref. 2) through the inboard end of each tank bracket and tank strap. Use the lower hole in the tank bracket. Install and lock a new cotter pin (Ref. 3) in each clevis pin.

   IMPORTANT: Fuel tanks can be damaged by overtightening the fuel tank straps.

   2.2 Install a bearing washer and two nuts on each tank strap T-bolt. Tighten the first nuts 20 N·m (15 lbf·ft).

   2.3 While holding the first nut stationary with a wrench, tighten each jam nut 41 N·m (30 lbf·ft).

3. On open-framed vehicles, install the top braces onto the fuel tank cage end brackets and the frame rail. Install all bolts with the nuts facing toward the fuel filler cap. Tighten the bolts 68 lbf·ft (92 N·m). **See Fig.3.**

   On vehicles with a box or container (bolted cage), install the fuel tank cage to the frame rail. Use a forklift or other lifting device to support the cage during installation. Tighten the bolts 68 lbf·ft (92 N·m).

4. Attach the wires to the electrical connector on the fuel pump module. Check the connector for tightness.

5. Make certain the fuel lines are clean. Loop the fuel supply line as shown **in Fig.5**. Then connect the fuel lines to their fittings on the fuel tank. For general guidelines, refer to **Subject 150**.

6. Add clean unleaded gasoline to the fuel tank. Be sure the fuel tank has a decal reading "Unleaded fuel only" located near the fuel filler neck. Replace the filler cap.

7. Remove the tire chocks.

Specifications

This subject contains the following table:

•Fastener Torques

Refer to Fig. 1 for fuel tank positioning. Refer to Fig. 2 for single-level cab-access step positioning. Refer to Fig. 3 for dual-level cab-access step positioning.

General Description

The Freightliner/Racor fuel/water separator (**Fig. 1**) removes water and solid contaminants from diesel fuel. Installed between the fuel tank and the fuel transfer pump, the separator has an optional ignition-controlled fuel heater to prevent ice and wax in the diesel from clogging fuel filters.

1. Fuel Filter
2. Collection Bowl
3. Water Sensor Probe
4. Drain

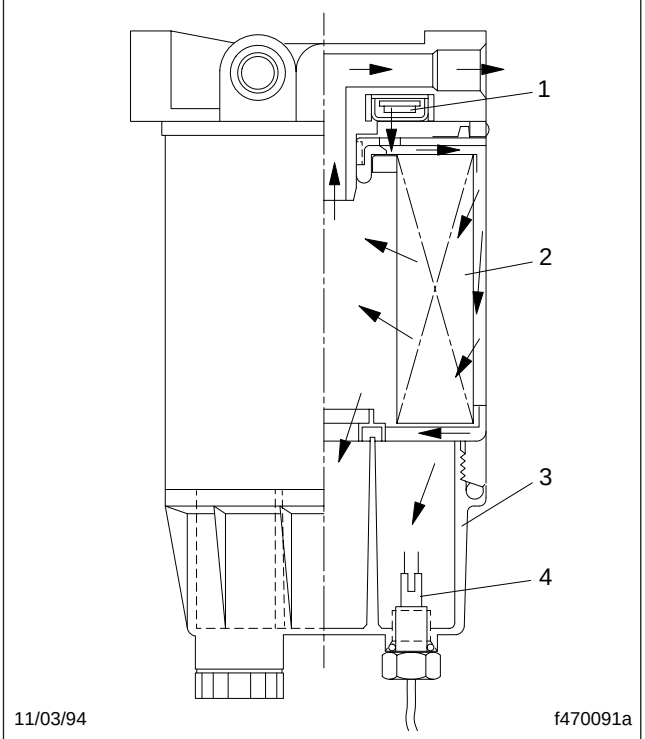

Fig. 1, Fuel/Water Separator

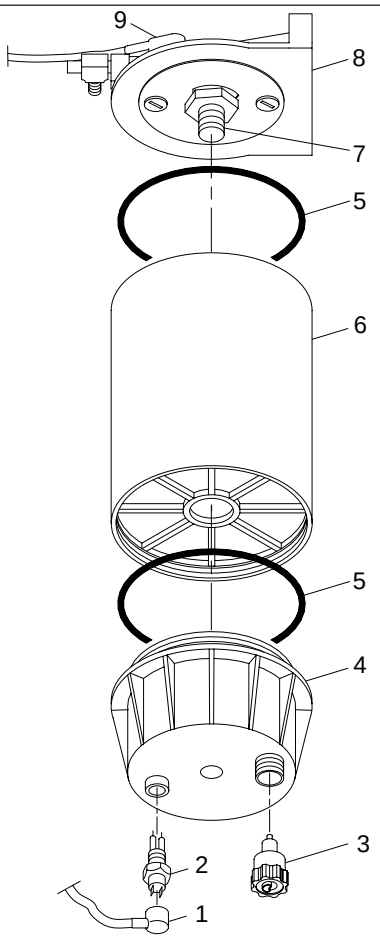
The separator is mounted on the frame rail.

Principles of Operation

Diesel fuel enters at the top of the separator (**Fig. 2**), flowing down past the heater element (if so equipped), and on to the top of the filter element. As the fuel flows down the sides of the element, the heavier contaminants and some water fall directly to the collection bowl below the element. The filter element itself contains a resin that repels water, forcing any remaining water to bead against or within the element and fall to the collection bowl. As the fuel passes from the outside to the inside of the filter element, the last traces of water collect on the inner surface of the element and fall to the collection bowl.

The filtered fuel is drawn out through the top of the separator, and the water and solid contaminants remain in the collection bowl. As the water collects, it completes the circuit between the two prongs of the water sensor probe. A warning light in the cab alerts the operator to drain the bowl.



1. Heater Element
2. Filter Element
3. Collection Bowl
4. Water Sensor Probe

Fig. 2, Fuel Flow Through the Separator

Replacement (See Fig. 1)

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Drain the fuel/water separator.
   - 2.1 Place a suitable container under the separator.
   - 2.2 Turn the drain counterclockwise to remove it.

   IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground. On all types of separators, stop draining fluid when you see fuel come out of the separator drain valve.
3. Disconnect the wiring connector from the water sensor probe.
4. Remove the bowl from the element.
5. Remove the element from the adapter fitting and the mounting head.
6. Install the bowl on the bottom of the new filter element.
7. Install the drain by turning it clockwise into the bottom of the bowl.
8. Lubricate the O-ring in the top of the filter element with clean motor oil or diesel fuel.
9. Fill the element and bowl assembly with clean fuel.
10. Install the new filter element on the mounting head. Tighten the element 72 lbf·in (820 N·cm).
11. Connect the wiring connector to the water sensor probe.
12. Start the engine and check for leaks. Repair any leaks.
13. Lower the hood, and remove the chocks from the tires.

1. Wiring Connector
2. Water Sensor Probe
3. Self-Venting Drain
4. Bowl
5. Filter Element O-Ring
6. Filter Element
7. Adaptor Fitting
8. Mounting Head

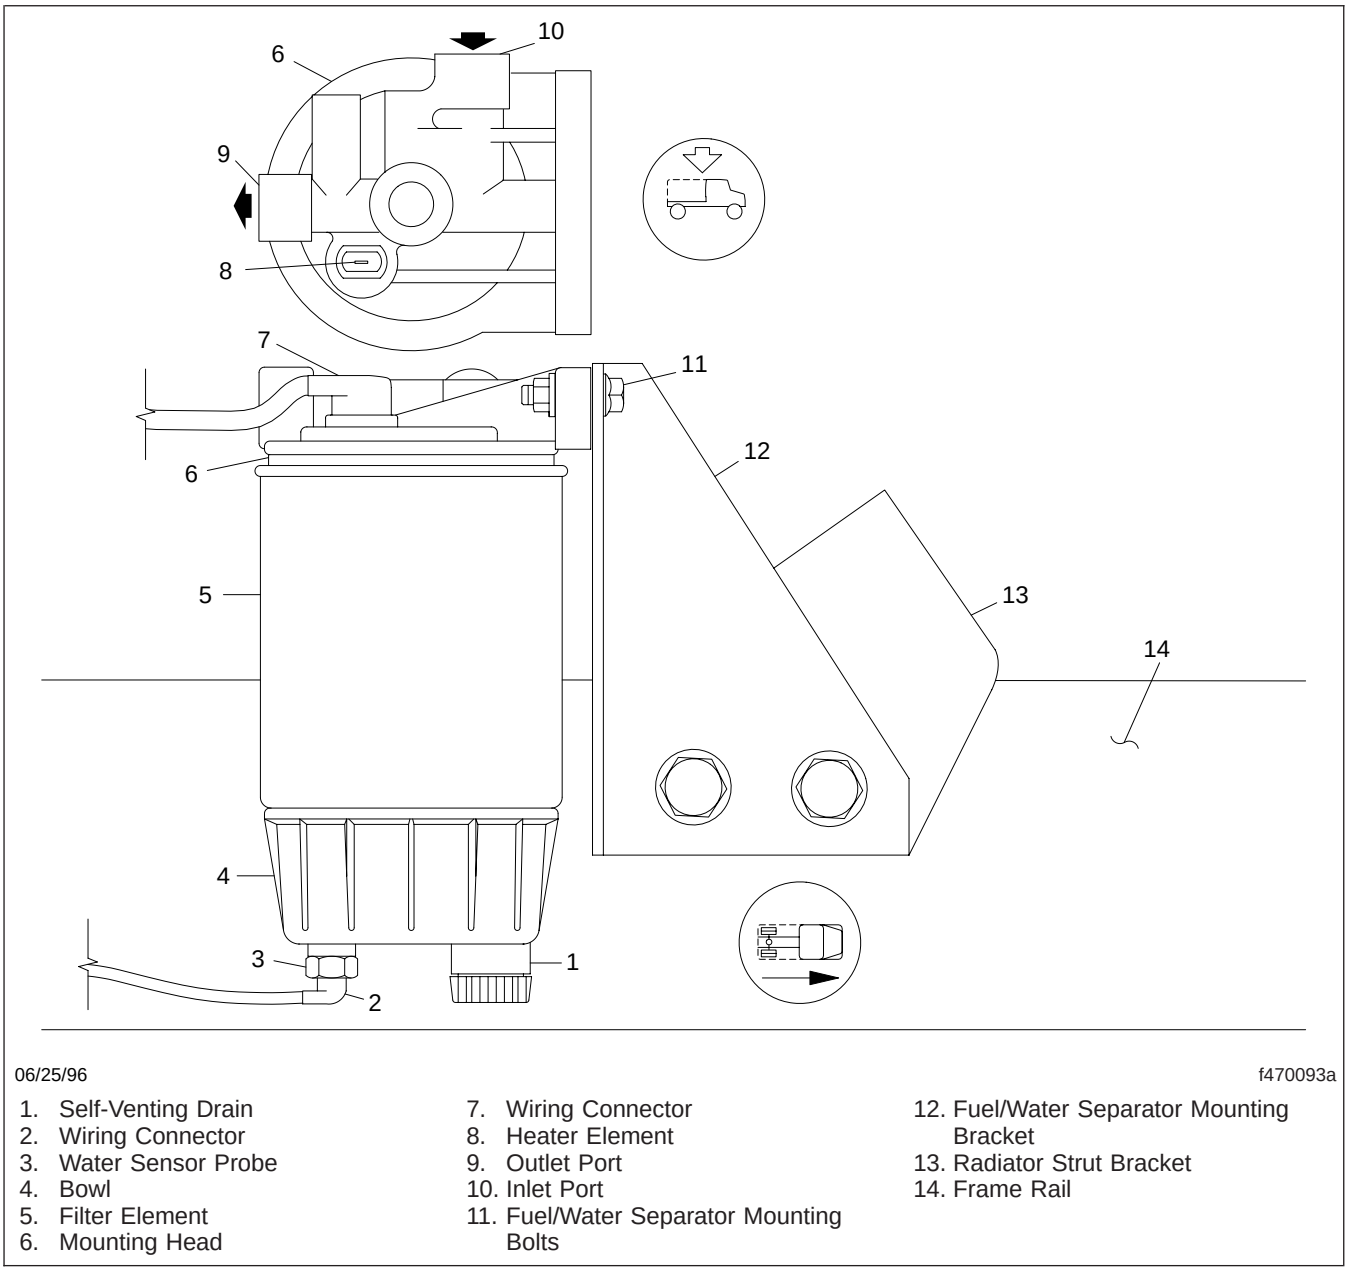
10. Wiring Connector

Fig. 1, Fuel/Water Separator Assembly With Heater



1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Drain the fuel/water separator.
   - 2.1 Place a suitable container under the separator.
   - 2.2 Turn the drain counterclockwise to remove it.

   IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground. On all types of separators, stop draining fluid when you see fuel come out of the separator drain valve.
3. Disconnect the wiring connector from the water sensor probe.
4. Remove the bowl from the element.
5. Remove the element from the adapter fitting and the mounting head.
6. Remove the brass adapter fitting from the mounting head.
7. Disconnect the wiring connector from the heater element.
8. Remove the heater element from the mounting head.
9. Clean the inside surface of the mounting head, and install the new heater element with a new, lubricated element O-ring.
10. Apply Loctite 271 (or equivalent) to the adapter fitting threads, and install the adapter on the mounting head. Tighten the adapter 30 lbf·ft (40 N·m).
11. Connect the wiring connector to the element.
12. Install the bowl on the bottom of the replacement filter element.
13. Screw the drain into the bottom of the bowl.
14. Lubricate the O-ring in the top of the filter element with clean motor oil or diesel fuel.
15. Fill the element and bowl assembly with clean fuel.
16. Install the replacement filter element on the adaptor fitting. Tighten the element 72 lbf·in (820 N·cm).

Heater Element Replacement

17. Connect the wiring connector to the water sensor probe.
18. Start the engine and check for leaks. Repair any leaks.
19. Lower the hood, and remove the chocks from the tires.

Replacement (See Fig. 1)

1. Self-Venting Drain
2. Wiring Connector
3. Water Sensor Probe
4. Bowl
5. Filter Element
6. Mounting Head
7. Wiring Connector
8. Heater Element
9. Outlet Port
10. Inlet Port
11. Fuel/Water Separator Mounting Bolts
12. Fuel/Water Separator Mounting Bracket
13. Radiator Strut Bracket
14. Frame Rail

Fig. 1, Fuel/Water Separator Mounting

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Drain the fuel/water separator.

2.1 Disconnect the fuel lines from the separator, and mark the lines for reassembly.

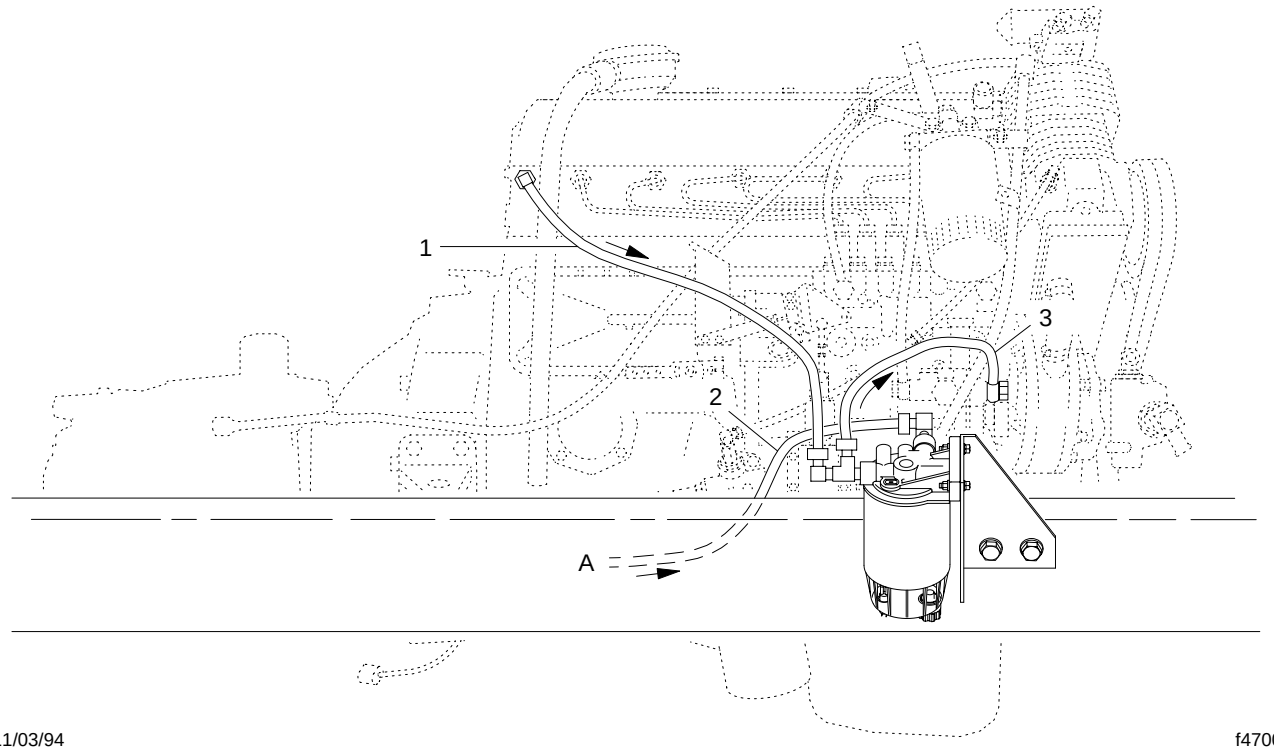
Fuel/Water Separator Replacement

2.2 Place a suitable container under the separator.

2.3 Turn the drain counterclockwise to remove it.

IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground. On all types of separators, stop draining fluid when you see fuel come out of the separator drain valve.

3. Remove the wiring connectors from the water sensor probe and the heater element.
4. Remove the fuel/water separator mounting bolts, and remove the separator from its mounting bracket.
5. Place the new separator against the mounting bracket, and secure it with the mounting bolts. Tighten the bolts 40 lbf·ft (55 N·m).
6. Remove the bowl and the filter element, as a unit, from the new separator.
7. Using clean motor oil or diesel fuel, lubricate the O-ring in the top of the filter element.
8. Make sure the drain in the bowl is closed, then fill the filter element and bowl assembly with clean fuel.
9. Install the element on the mounting head, and tighten the element 72 lbf·in (820 N·cm).
10. Connect the fuel lines to the separator.
11. Connect the wiring connectors to the water sensor probe and the heater element.
12. Prime the fuel system. With the filter element and bowl assembly full of clean fuel, crank the engine until it starts. This serves to prime the fuel system.
13. Start the engine and check for leaks. Repair any leaks.
14. Lower the hood, and remove the chocks from the tires.



Troubleshooting

1. Turn the ignition to "Accessory." The high water light should come on for 2 to 5 seconds, then go off.
2. With the ignition still on, disconnect the wiring connector from the water sensor probe, and run a jumper wire from one connector terminal to the other. The high water light should come on. If it does not, check all wiring connections. Check that power is on, and that the separator is grounded. Check for damaged wiring in the sensor probe circuit. For a diagram of the sensor circuit, see **Specifications, 400**. If the circuit is intact and undamaged, replace the sensor probe.
3. Repeat the above steps to test the new sensor probe.
4. Connect the wiring connector to the sensor probe.

General Information

On all gas-powered engines, the fuel pump module is installed in the top of the fuel tank. **See Fig. 1.**

1. Fuel Supply Line Connection
2. Fuel Filter/Pressure Regulator
3. Electric Fuel Pump
4. Sensing Unit
5. Float
6. In-Tank Fuel Filter
7. Electrical Connector
8. Pressure Relief/ Rollover Valve
9. Ribbed Cover

Fig. 1, Fuel Pump Module

The fuel pump module contains the following:

- A combination fuel filter and pressure regulator
- An electric fuel pump
- A separate in-tank fuel filter
- A fuel gauge sensing unit and float
- A fuel supply line connection

Also mounted in the fuel pump module is a pressure relief/rollover valve that is designed to prevent fuel leakage during a rollover. Molded on the ribbed cover of this valve is a barbed connection. A flexible line attaches this barb to the evaporative canister.

The fuel pump module is suspended in fuel inside the fuel tank. Fuel is drawn in through the separate in-tank filter in the base of the module.

The electric fuel pump is located inside the fuel pump module. It is equipped with a permanent magnet electric motor which pushes the fuel into the filter/pressure regulator.

The fuel pump is located inside a 1-liter (1.1-quart) plastic reservoir that remains full while the engine is running. In the bottom of the reservoir, there is a valve that closes whenever the fuel level in the tank drops below approximately 25 mm (1 inch). This will supply fuel from the reservoir to prevent cavitation of the pump.

A check valve installed in the fuel outlet prevents pressure drain-back through the pump. This maintains constant fuel pressure even when the engine is not running and helps to start the engine more easily.

IMPORTANT: The fuel system is under constant pressure. Before performing any service on the fuel pump module, be sure to release the fuel system pressure. For procedures, refer to **Subject 130**.

The electric fuel pump is not serviceable. If the fuel pump needs replacement, replace the entire fuel pump module. For procedures, refer to **Subject 100**.

The fuel filter/pressure regulator is a mechanical device not controlled by the Powertrain Control Module. It is calibrated to maintain fuel system pressure at approximately 240 to 310 kPa (35 to 45 psi) and contains an internal diaphragm, calibrated springs, a fuel return valve, and an internal fuel filter.

The electric fuel pump supplies fuel through a fuel inlet in the base of the pressure regulator. If fuel pressure exceeds 310 kPa (45 psi), the internal diaphragm closes, forcing the excess fuel back into the tank. No separate fuel return line is needed.

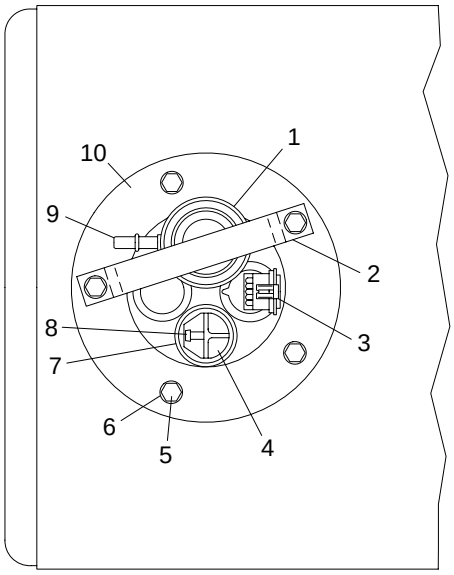
The fuel filter/pressure regulator and the pressure relief/rollover valve can be replaced without removing the fuel pump module. For procedures, refer to **Subject 110** and **Subject 120**. If the fuel pump module has to be removed for any reason, replace the entire module. Do not attempt to disassemble the sensing unit, float, or in-tank fuel filter.

Fuel Pump Module Removal and Installation and In-Tank Fuel Filter Replacement

Removal

1. Apply the parking brakes and chock the tires. Disconnect the batteries.

⚠ WARNING



WARNING: Release the fuel system pressure before removing the fuel pump module. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire. Always wear proper eye protection when releasing the fuel system pressure. Fuel squirted into the eyes can cause serious injury, including blindness.

2. Release the fuel system pressure and drain the fuel tank. For instructions, see **Subject 130**.

⚠ WARNING

WARNING: Gasoline is flammable and can ignite if exposed to open flame, intense heat, or other ignition source. Do not drain fuel near, or expose fuel vapor to open flame or intense heat. Exposure to open flame, intense heat, or other ignition source could start a fire, possibly resulting in personal injury or property damage. When working on a fuel system, have a fire extinguisher within easy reach.

3. Disconnect the fuel supply line from the filter/pressure regulator, and the evaporative canister line from the rollover valve. Disconnect the electrical connector. See **Fig. 1**.
4. Remove the fuel pump module from the fuel tank.
   - 4.1 Clean the top of the fuel pump module to prevent dirt from falling into the fuel tank.
   - 4.2 Remove the two 5/16–18 grade 8 capscrews holding the fuel pump guard bracket in place. Remove the guard bracket, capscrews and hardened flatwashers.
   - 4.3 Remove the other three 5/16–18 grade 8 capscrews holding the fuel pump clamp ring in place. Remove the capscrews and hardened flatwashers.

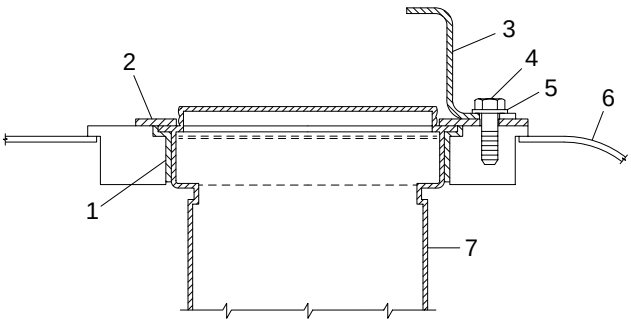
Fig. 1, Fuel Pump Module (top view)

   - 4.4 Remove the fuel pump module from the fuel tank. See **Fig. 2**.
   - 4.5 Remove the fuel pump module gasket from the fuel tank. See **Fig. 3**. Discard the old gasket.
5. Replace the in-tank fuel filter on the fuel pump module. See **Fig. 2**.
   - 5.1 Use an appropriate tool to pry back the retaining tabs.
   - 5.2 Remove the in-tank fuel filter.
   - 5.3 Install the new filter into the retaining tabs until the filter is firmly seated.



Fuel Pump Module Removal and Installation and In-Tank Fuel Filter Replacement

4. 5/16–18 Clamp Ring Mounting Capscrew (Grade 8)
5. Hardened Flatwasher
6. Fuel Tank
7. Fuel Pump Module

Fig. 3, Fuel Pump Module Mounting (cutaway view)

Installation

1. Check that the sensing unit, the electrical wires, the float, and the in-tank fuel filter are properly installed. See **Fig. 2**.
2. Install a new fuel pump module gasket in the opening in the fuel tank. See **Fig. 3**.
3. Position the fuel pump module in the opening in the fuel tank. Make sure the filter/pressure regulator is on the side facing the frame rail (see **Fig. 1**). Apply a light coat of silicone spray to the gasket, if necessary to ease installation.

NOTE: Using silicone spray on the mounting gasket will prevent the gasket from bunching, or deforming. The spray will evaporate and not affect the fuel.

4. Secure the fuel pump module in the fuel tank.

   IMPORTANT: Use only grade 8 capscrews.

   4.1 Install the fuel pump clamp ring over the fuel pump module. To hold it in place, install three capscrews with hardened flatwashers. Use the holes not intended for the guard bracket. Do not tighten the capscrews yet.

   4.2 Install the fuel pump guard bracket over the filter/pressure regulator. Fasten it in place with the remaining two capscrews and hardened flatwashers.

   4.3 Tighten all five capscrews 15 lbf·ft (20 N·m).

5. Connect the fuel lines to the fittings on the filter/pressure regulator and the rollover valve. Attach the electrical connector. See **Fig. 1**.
6. Return clean unleaded gasoline to the fuel tank.
7. Connect the battery, start the engine, and check for fuel leaks. Also check that the fuel gauge is working properly. Correct any fuel leaks with the engine OFF.
8. Remove the chocks from the tires.

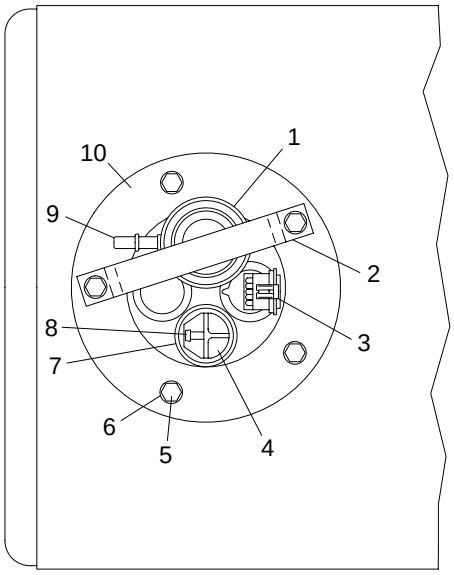
Fuel Filter/Pressure Regulator Removal and Installation

Removal

It is not necessary to remove the fuel pump module to replace the fuel filter/pressure regulator.

1. Apply the parking brakes and chock the tires. Disconnect the batteries.

⚠ WARNING



WARNING: Release the fuel system pressure before removing the fuel filter/pressure regulator. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.

2. Release the fuel system pressure. For instructions, refer to **Subject 130**.
3. Remove the fuel supply line from the fuel filter/pressure regulator. If necessary for convenient access, remove the evaporative canister line from the rollover valve and disconnect the electrical connector. **See Fig. 1.**
4. Remove the fuel pump guard bracket.
   - 4.1 Unscrew the two 5/16–18 grade 8 capscrews holding the fuel pump guard bracket in place.
   - 4.2 Remove the guard bracket, the two capscrews, and the two hardened flatwashers.
5. Remove the filter/pressure regulator from the fuel pump module.

⚠ CAUTION

CAUTION: Do not pull up the filter/regulator more than 7.5 centimeters (3 inches) from the fuel pump module. Pulling it any further could cause damage to the coiled fuel tube.

- 5.1 Twist the filter/regulator and pull straight up to free it from the rubber grommet attaching it to the fuel pump module. **See Fig. 2.**
- 5.2 Release the snap ring holding the convoluted fuel tube cover. Slide the fuel tube cover away from the plastic fuel tube until the fuel tube clamp is exposed. **See Fig. 3.**

03/17/95 f470135

1. Fuel Filter/Pressure Regulator
2. Fuel Pump Guard Bracket
3. Pump/Gauge Electrical Connector

5. 5/16–18 Clamp Ring Mounting Capscrew (Grade 8)
6. Hardened Flatwasher
7. Rollover Valve Grommet
8. Evaporative Canister Barb
9. Fuel Supply Line Connection
10. Fuel Pump Mounting Clamp Ring

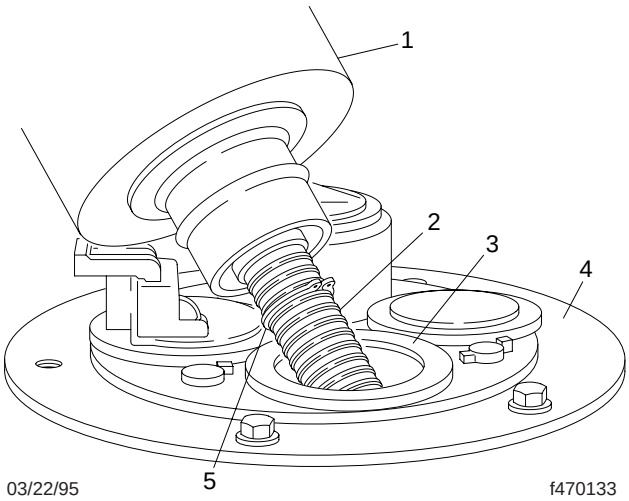

Fig. 1, Fuel Pump Module (Top View)

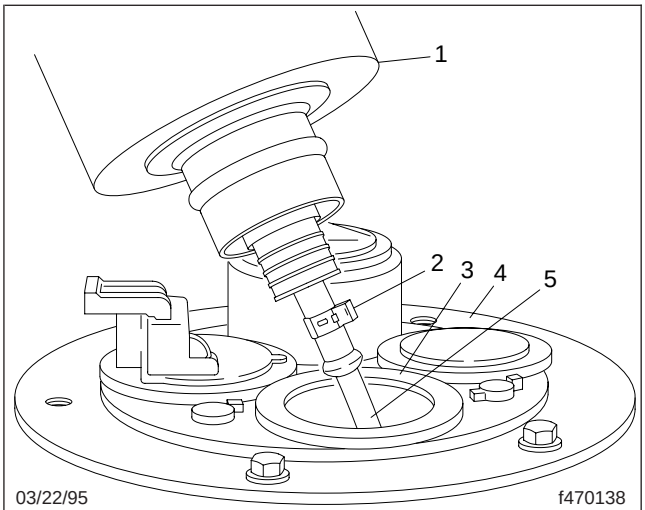
- 5.3 Gently cut the fuel tube clamp, taking care not to damage the fuel tube. Discard the fuel tube clamp.
- 5.4 Pull downward gently on the fuel tube to remove it from the filter/regulator. Remove the filter/regulator unit from the fuel pump module.

Installation



1. Slide a new clamp onto the plastic fuel tube.
2. Attach the filter/regulator to the fuel tube. Be sure the fuel supply line fitting near the top of the filter unit is positioned to allow easy attachment of the fuel supply line.

Fuel Filter/Pressure Regulator Removal and Installation

1. Fuel Filter/Pressure Regulator
2. Fuel Tube Cover
3. Rubber Grommet
4. Fuel Pump Mounting Clamp Ring
5. Snap Ring

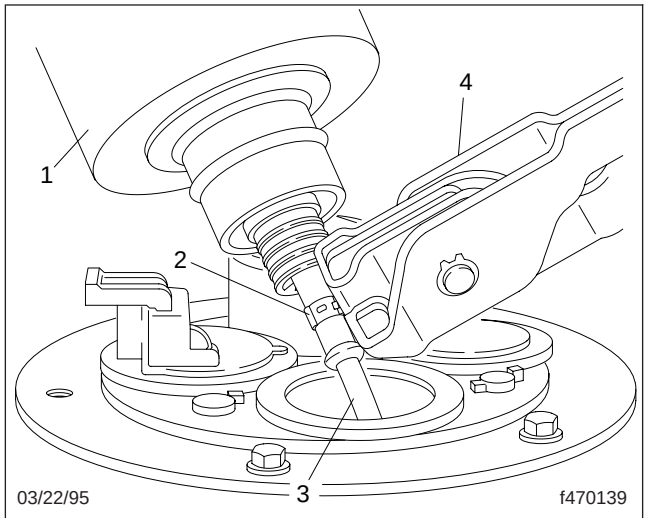


Fig. 2, Snap Ring and Fuel Tube Cover

1. Fuel Filter/Pressure Regulator
2. Fuel Tube Clamp
3. Rubber Grommet
4. Fuel Pump Mounting Clamp Ring
5. Nylon Fuel Tube

Fig. 3, Fuel Tube and Clamp

3. Tighten the fuel tube clamp using the special hose clamp pliers, Kent Moore tool number C-4124, or equivalent. To order this tool, call the Kent-Moore Tool Company at 1-800-328-6657. **See Fig. 4.** Do not use conventional side cutters to tighten this type of clamp.

1. Fuel Filter/Pressure Regulator
2. Fuel Tube Clamp
3. Nylon Fuel Tube
4. Hose Clamp Pliers, Tool C-4124

Fig. 4, Tightening the Fuel Tube Clamp

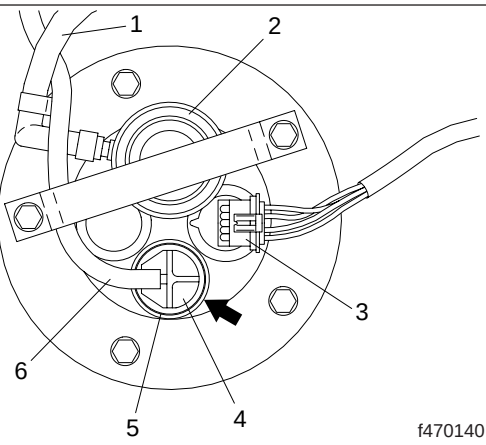
4. Slide the fuel tube cover into place and install the snap ring.
5. Press the filter/regulator by hand into the rubber grommet. As you do, check the positioning of the fuel supply fitting.
6. Connect the fuel lines to the fittings on the fuel filter/pressure regulator and the rollover valve. Attach the electrical connector. **See Fig. 1.**
7. Install the fuel pump guard bracket.

   IMPORTANT: Use only grade 8 capscrews.

   7.1 Install the fuel pump guard bracket over the filter/pressure regulator. Fasten it in place with two 5/16–18 grade 8 capscrews and hardened flatwashers.

   7.2 Tighten both capscrews 15 lbf·ft (20 N·m).
8. Fill the fuel tank with unleaded gasoline.
9. Connect the batteries. Then remove the chocks from the tires and release the parking brake.

Pressure Relief/Rollover Valve Removal and Installation



Removal

1. Apply the parking brakes and chock the tires. Disconnect the batteries.

⚠ WARNING

WARNING: Release the fuel system pressure before removing the pressure relief/rollover valve. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.

2. Release the fuel system pressure. For instructions, refer to **Subject 130**.
3. Remove the evaporative canister line from the rollover valve. **See Fig. 1.**

Remove the evaporative canister line. Wedge a screwdriver at the arrow, between the fuel pump module and the grommet. Do not wedge anything between the rollover valve and the grommet.

1. Fuel Supply LIne
2. Fuel Filter/Pressure Regulator
3. Electrical Connector
4. Pressure Relief/Rollover Valve
5. Rollover Valve Grommet
6. Evaporative Canister LIne

Fig. 1, Fuel Pump Module, Top View

4. Remove the pressure relief/rollover valve from the fuel pump module.

⚠ CAUTION

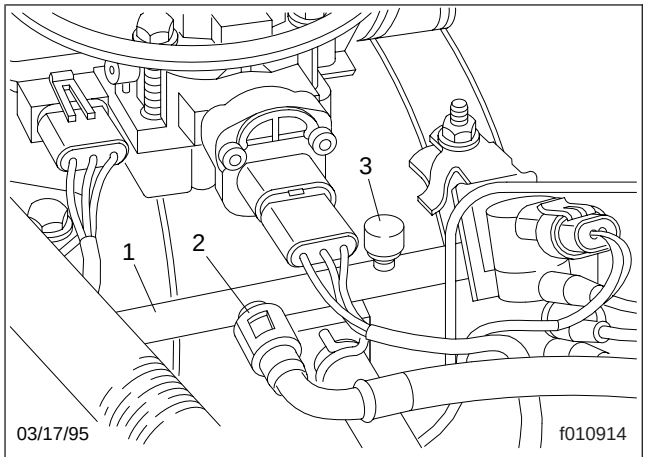
CAUTION: Do not wedge anything between the rollover valve and the grommet. This may cause damage to the valve unit.

4.1 Wedge the blade of a standard screwdriver between the rubber rollover valve grommet and the surface of the fuel pump module. **See Fig. 1.**

4.2 Using a second screwdriver as a support, pry both the valve and the grommet out of the fuel pump module.

5. Remove the grommet from the rollover valve.

5.1 Place the valve upright on a flat surface. Push down on the grommet.



5.2 Peel the grommet off the valve. Discard the old grommet.

Installation

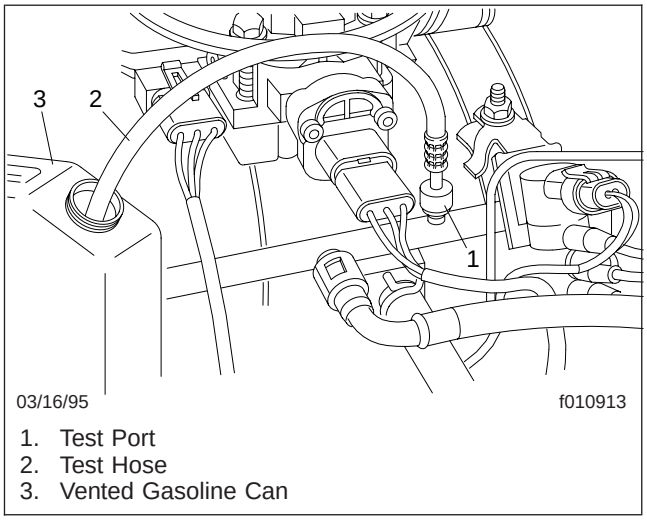
1. Install a new rollover valve grommet in the fuel pump module. Work it around the curled lip on the surface of the module.
2. Lubricate the grommet, using power steering fluid.
3. Push the valve downward through the grommet and into the fuel pump module.
4. Be sure the evaporative canister line fitting on the rollover valve is positioned to allow easy attachment of the evaporative canister line. If necessary, twist the valve into a better position.
5. Connect the fuel supply line to the fitting on the fuel filter/pressure regulator and the evaporative canister line to the fitting on the rollover valve. Connect the electrical connector. **See Fig. 1.**
6. Fill the fuel tank with unleaded gasoline.
7. Connect the batteries. Remove the chocks from the tires and release the parking brake.

Release

1. Disconnect the batteries.
2. Remove the fuel tank filler cap. This releases fuel tank pressure.
3. Unscrew the protective plastic cap from the pressure test port on the fuel rail (**see Fig. 1**).

1. Fuel Rail
2. Fuel Supply Line
3. Test Port Protective Cap

Fig. 1



WARNING

WARNING: Always wear proper eye protection when releasing the fuel system pressure. Fuel squirted or splashed into the eyes can cause injury.

4. Obtain Kent-Moore fuel pressure gauge tool set #5069. To order this tool set, call the Kent-Moore Tool Company at 1-800-328-6657. Remove the gauge from the hose. Place one end of the hose into an approved gasoline container. Place a shop towel under the test port. **See Fig. 2.**

IMPORTANT: Do not allow fuel to spill onto the engine intake or exhaust manifolds. To absorb fuel, place shop towels under and around the pressure port when the pressure is released from the fuel rail.

5. Screw the other end of the hose onto the fuel pressure test port and allow the fuel to run into the container until the pressure is fully released.

1. Test Port
2. Test Hose
3. Vented Gasoline Can

Fig. 2

6. Remove the hose from the test port and return it to tool set #5069.
7. Install the protective cap on the test port.
8. Install the filler cap on the fuel tank.

Troubleshooting Tests

To test fuel system pressure, do tests NTC-3A and -B in the Chrysler Powertrain Diagnostic Procedures Manual.

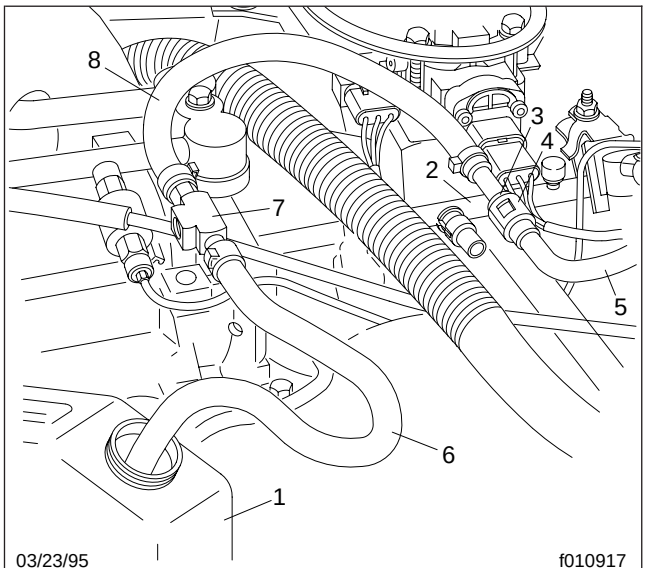
For additional fuel pump module troubleshooting procedures, see tests NS-4A through -C and NS-5A and -B in the Chrysler Powertrain Diagnostic Procedures Manual.

FUEL PUMP CAPACITY TEST

NOTE: Before running this test, verify fuel pump pressure by doing fuel system pressure test NTC-3A in the Chrysler Powertrain Diagnostic Procedures Manual.

⚠ WARNING

WARNING: Release the fuel system pressure before testing the fuel pump capacity. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.



1. Release the fuel system pressure. For instructions, refer to **Subject 130**. Do not drain the fuel tank.
2. Connect Kent-Moore special tool part #6631, the fuel line pressure test adapter. **See Fig. 1.** To order this tool, call the Kent-Moore Tool Company at 1-800-328-6657.

   NOTE: Use Kent-Moore special tool part #6631 only with 3/8-inch i. d. hose.

   2.1 Disconnect the fuel supply line at the fuel rail. Squeeze the plastic retainer tabs against the sides of the quick-connect fitting, using fingers only.

   2.2 Into the disconnected end of the fuel supply line, insert the hose attached to one end of Kent-Moore special tool part #6631, the fuel line pressure test adapter. Insert the hose attached to the other end of special tool #6631 into an approved vented gasoline container, at least 7.5 liters (two gallons) in capacity.

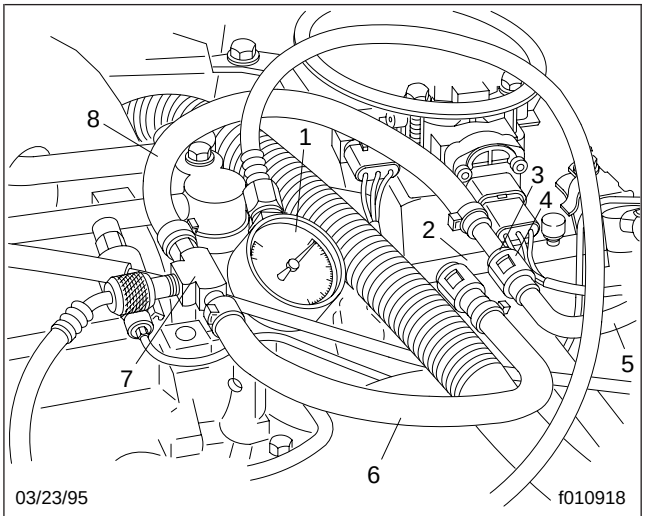
   NOTE: Be sure the "T" end of special tool #6631 is capped.

1. Vented Gasoline Can
2. Fuel Rail
3. Plastic Retainer Tab
4. Quick-Connect Fitting
5. Fuel Supply Line
6. Test Hose (to Vented Gas Can)
7. Kent-Moore Special Tool Part #6631
8. Test Hose (to Fuel Supply Line)

Fig. 1, Fuel Pump Capacity Test

3. Activate the fuel pump and pressurize the system using the DRB scan tool. For procedures, refer to the Chrysler Powertrain Diagnostic Procedures manual.
4. Check that the fuel pump delivers at least 2 liters (2.1 quarts) per minute.

FUEL PRESSURE LEAKDOWN TEST



Use this test to diagnose low fuel pressure when a hot engine that has been shut down only a short time requires an abnormally long period of cranking to restart it. Low fuel pressure may be caused by leaks in the fuel injectors or fuel rail, fuel lines, or the check valve in the fuel pump module.

Troubleshooting

WARNING

WARNING: Release the fuel system pressure before testing fuel pressure leakdown. Otherwise fuel could spray out, possibly resulting in severe personal injury and property damage, including fire.

1. Release the fuel system pressure. For instructions, refer to **Subject 130**. Do not drain the fuel tank.
2. Connect Kent-Moore special tool part #6631, the fuel line pressure test adapter. **See Fig. 2.**

1. Fuel Pressure Test Gauge (from Gauge Set #5069)
2. Fuel Rail
3. Plastic Retainer Tab
4. Quick-Connect Fitting
5. Fuel Supply Line
6. Test Hose (to Fuel Rail)
7. Kent-Moore Special tool part #6631
8. Test Hose (to Fuel Supply Line)

Fig. 2, Fuel Pressure Leakdown Test

NOTE: Use special tool #6631 only with 3/8-inch i. d. hose.

2.1 Disconnect the fuel supply line at the fuel rail. Squeeze the plastic retainer tabs against the sides of the quick-connect fitting, using fingers only.

2.2 Into the disconnected end of the fuel supply line, insert the hose attached to one end of Kent-Moore special tool part #6631. Insert the hose attached to the other end of special tool #6631 into the fuel rail.

3. Connect the fuel pressure test gauge from Kent-Moore gauge set, part #5069, to the test port on Kent-Moore special tool part #6631.

IMPORTANT: To ensure the accuracy of the test results, check that the fittings on special tool #6631 and gauge set #5069 are in good condition and do not leak.

4. Check the fuel system for pressure leakdown.

4.1 Start the engine and bring it to the normal operating temperature of 82°C (180°F).

4.2 Check that the test gauge climbs to normal operating pressure of 240-310 kPa (35-45 psi).

4.3 Shut down the engine.

4.4 Check the test gauge. If the pressure falls below 165 kPa (24 psi) in less than five minutes, go to the next step.

5. Check the fuel injectors and fuel rail for leakage.

5.1 Again, start the engine and bring it to the normal operating temperature of 82°C (180°F).

5.2 Shut down the engine.

5.3 Clamp off the rubber hose leading from special tool #6631 to the fuel rail. If the pressure now holds at or above 165 kPa (24 psi), check the fuel injectors and the fuel rail for leaks. If the pressure continues to fall, go to the next step.

6. Check the fuel lines and the fuel pump module for leakage.

6.1 Now clamp off the rubber hose leading from the fuel supply line to special tool #6631. If the pressure now holds at or above 165 kPa (24 psi), check the fuel lines for leaks.

6.2 If no leaks are found in the fuel lines, replace the fuel pump module.

Specifications

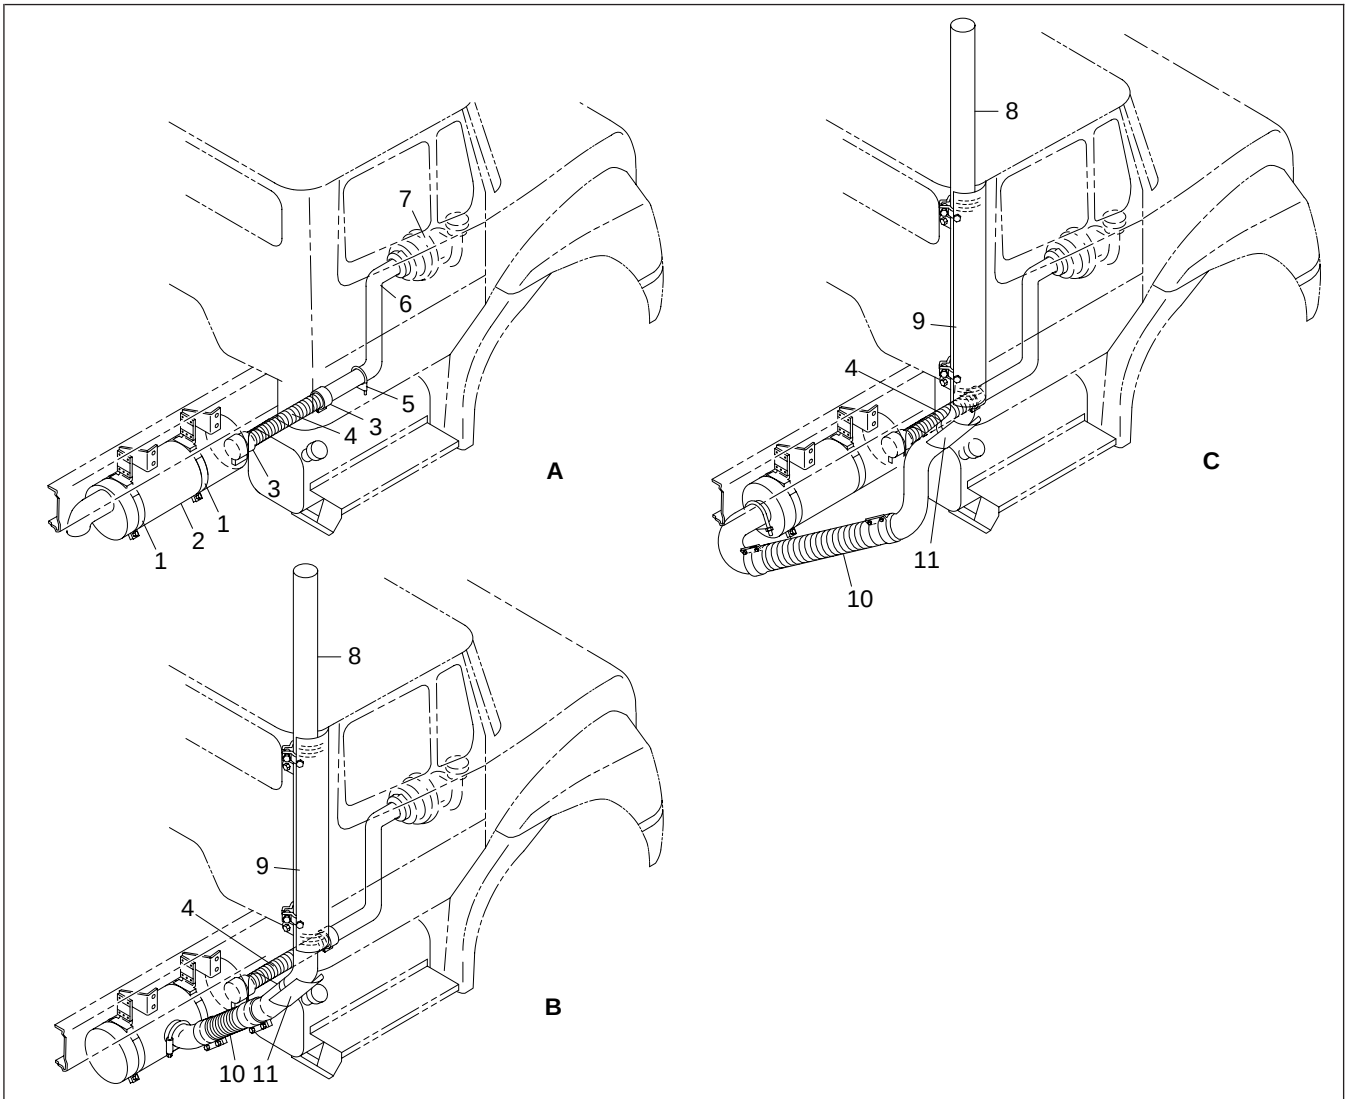
Description	Pressure kPa (psi)
Operating Pressure	240–310 (35–45)
Bypass Pressure	620 (90)

Table 2, Fuel System Pressures

General Description

(See Fig.1or Fig.2)

The exhaust system routes hot exhaust gas away from the cab, and reduces engine exhaust noise. Vehicles (except FL112s) have a horizontally mounted muffler on either the left or right side of the vehicle, and are available with either a horizontal outlet or vertical exhaust stack.



FL112 vehicles have either a horizontally mounted muffler with a horizontal outlet, (see **Fig.3** and **Fig.4**), or a vertical muffler with a stack (see **Fig.2**).

System components include the engine outlet exhaust pipe, muffler, muffler mounting components, saddle clamps, wide-band exhaust clamps, flex pipe, exhaust stack, and exhaust system heat shields.

Most exhaust installations consist of an engine exhaust pipe, sometimes called the turbo pipe, mounted to the rear of the turbocharger and secured with a V-clamp. On Cummins M11 and C8.3 engines, Detroit Diesel Series 50, Caterpillar 3126, and OM 366LA engines, a section of this pipe is flex pipe. On Cummins M11 engines, a bracket attached to the frame rail uses a saddle clamp to hold and support the engine exhaust pipe as it runs to the muffler. See **Fig.3**. A wide-band clamp holds the exhaust pipe to the muffler.

A horizontal muffler hangs from brackets mounted inside the frame rail web. See **Fig.1** or **Fig.5**. A vertical muffler bolts to an upright. See **Fig.2**. All exhaust components attach to either the engine or the chassis frame rails, so there is no need to allow for movement between the cab and chassis.

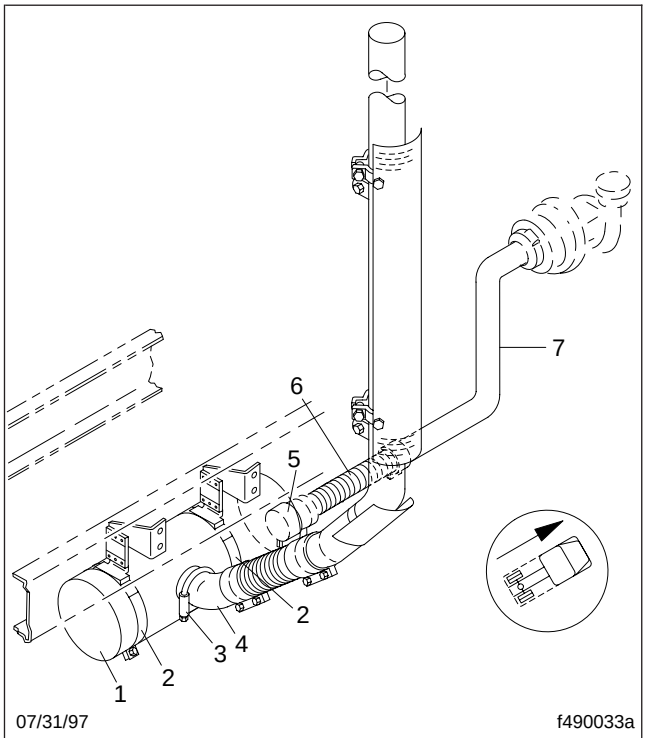
Replacement

NOTE: The mufflers on Freightliner Business Class vehicles can be mounted either horizontally or vertically. Use the following replacement procedure that applies to your vehicle.

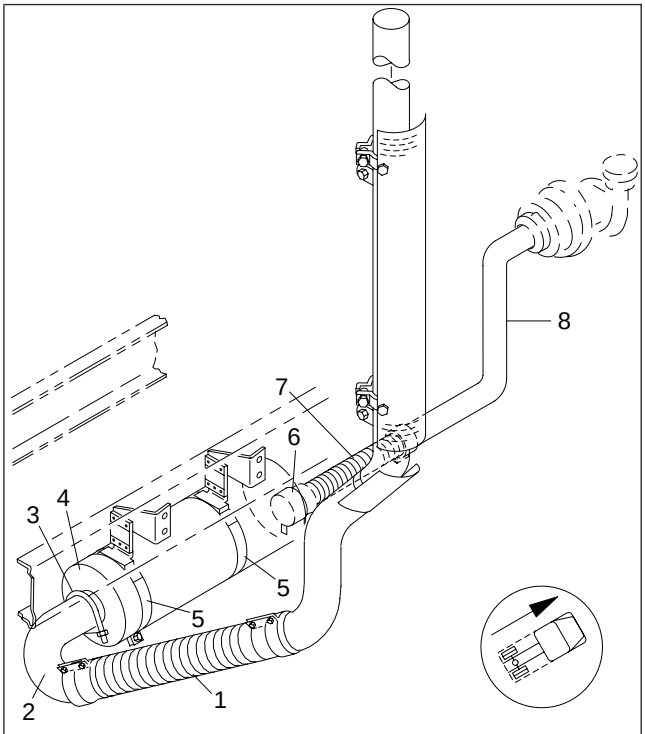


HORIZONTALLY MOUNTED MUFFLERS (See Fig. 1, Fig. 2 , and Fig. 3)

NOTE: The exhaust flex pipe (Ref. 4) may not be present on early model vehicles.

1. Muffler Mounting Band
2. Muffler
3. Wide-Band Exhaust Clamp
4. Exhaust Flex Pipe (except Cummins B 5.9 engines)
5. Muffler Inlet Exhaust Pipe

Fig. 1, Exhaust System Without a Stack, All Models Except FL112



NOTE: This configuration is on vehicles built to August 2, 1996. The exhaust flex pipe (Ref. 6) may not be present on early model vehicles.

1. Muffler
2. Muffler Mounting Band
3. Saddle Clamp
4. Muffler Outlet Exhaust Pipe
5. Wide-Band Exhaust Clamp
6. Exhaust Flex Pipe (except Cummins B 5.9 engines)
7. Muffler Inlet Exhaust Pipe

Fig. 2, Exhaust System With a Stack, Side Outlet, All Models Except FL112

1. Remove the muffler.
   - 1.1 Remove and discard the wide-band exhaust clamp from the muffler inlet connection.
   - 1.2 On vehicles with a vertical exhaust stack, remove the saddle clamp from the muffler outlet connection. Pull the muffler outlet exhaust pipe out of the muffler outlet tube.
   - 1.3 Remove the bolts and locknuts on the front and rear muffler mounting bands. Remove the mounting bands. Remove the muffler.
2. Install the muffler.
   - 2.1 Slide the new muffler's inlet tube over the muffler inlet exhaust pipe.
   - 2.2 Install the front and rear muffler mounting bands. Install the bolts and locknuts on the mounting bands, but do not tighten them at this time.

Muffler Replacement

07/31/97 f490143

NOTE: This configuration is on vehicles built from August 2, 1996. The exhaust flex pipe (Ref. 7) may not be present on early model vehicles.

1. Flex Pipe
2. Rear Exhaust Outlet
3. Saddle Clamp
4. Muffler (catalytic converter on some engine models)
5. Muffler Mounting Band Muffler
6. Wide-Band Exhaust Clamp
7. Exhaust Flex Pipe (except Cummins B 5.9 engines)
8. Muffler Inlet Exhaust Pipe

Fig. 3, Exhaust System, Rear Outlet, All Models Except FL112

2.3 On vehicles with a vertical exhaust stack, slide the muffler outlet exhaust pipe into the muffler outlet tube.

2.4 Coat the lap joint area with chassis grease, so the clamp will slide freely without scratching the surface of the pipe.

2.5 Wrap a new wide-band exhaust clamp by hand around the lap joint. Place the large end of the clamp around the muffler inlet tube, and the small end around the inlet exhaust pipe.

2.6 Install the fasteners in the clamp. Starting from the larger end of the clamp, alternately tighten the fastener in three increments to a final torque of 50 to 60 lbf·ft (68 to 81 N·m).

Clean any excess chassis grease from around the clamp.

2.7 Install the saddle clamp U-bolt on the muffler outlet tube (where applicable). Tighten the saddle clamp flanged nuts alternately in three increments to a final torque of 24 lbf·ft (33 N·m).

2.8 Tighten the muffler mounting band fasteners until the band ears touch; then, tighten the fasteners two full turns or until the ears are in full contact, whichever occurs first.

2.9 Run the engine, and check for exhaust leakage at the exhaust clamp joints. Replace the wide-band exhaust clamps if they leak.

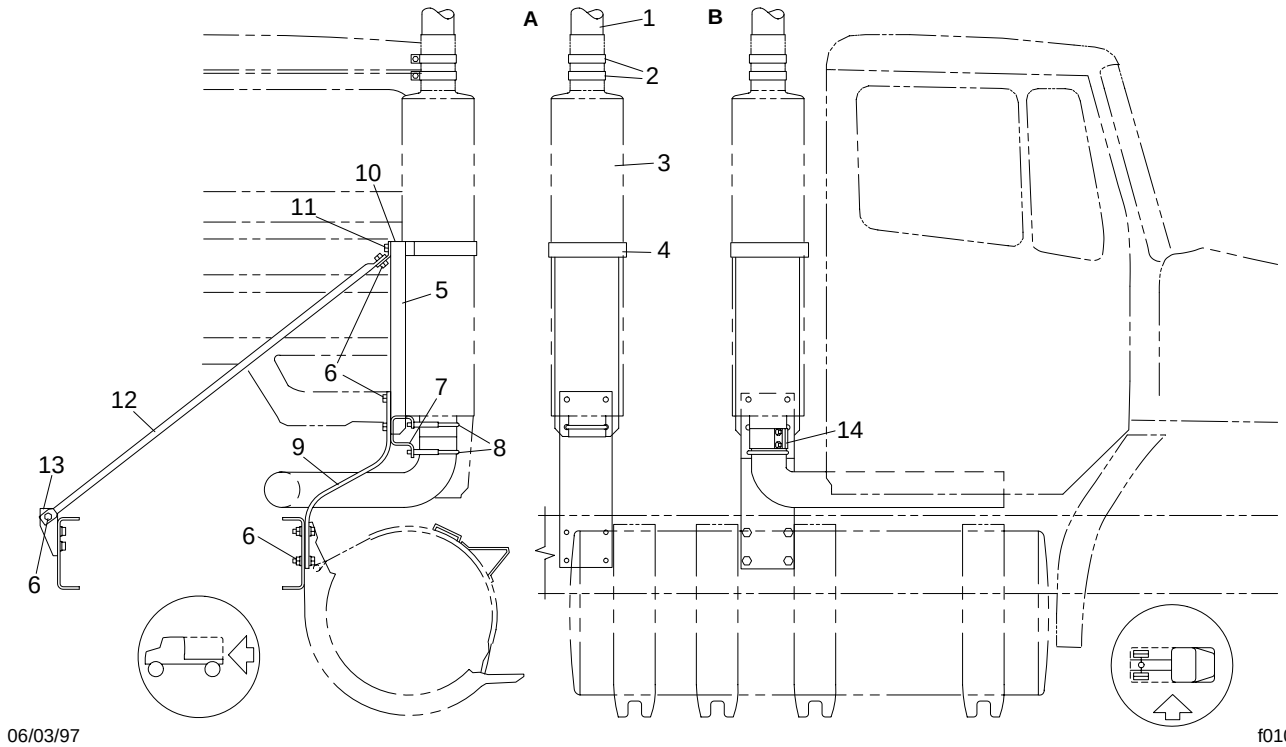
VERTICALLY MOUNTED MUFFLERS

(See Fig. 4)

1. Remove the muffler.

1.1 Loosen the saddle clamp that holds the stack on the muffler, and remove the stack.

1.2 Loosen the saddle clamp that holds the base of the muffler to the support channel.



1.3 Loosen the wide-band clamp that connects the muffler to the exhaust pipe.

1.4 Remove the two bolts that hold the muffler mounting band to the muffler support channel.

1.5 Lift the muffler out of the lower saddle clamp.

2. Install the muffler.

2.1 Place the muffler in the support channel, and hold it in place while installing a new wide-band clamp to connect the muffler with the exhaust pipe.

A. Muffler Position, FL112 Conventional with Extended Cab

B. Muffler Position, FL112 Conventional with Day Cab

1. Exhaust Stack
2. Narrow-Band Clamp (2 qty.)
3. Muffler
4. Muffler Mounting Band
5. Support Channel
6. Nut, Washer, and Capscrew, 5/8–11, Grade 8
7. Lower Muffler Mounting Bracket
8. Saddle Clamp, 5-Inch
9. Upright Muffler Mounting Bracket
10. Upper Brace Bracket
11. Nut, Washer, and Capscrew, 1/2–13
12. Brace
13. Lower Brace Bracket
14. Wide-Band Clamp

Fig. 4, Vertical Exhaust Mounting, FL112

2.2 Coat the lap joint area with chassis grease, so the clamp will slide freely without scratching the surface of the pipe.

2.3 Wrap a new wide-band exhaust clamp by hand around the lap joint. Place the large end of the clamp around the muffler inlet, and the small end around the exhaust pipe.

2.4 Install the fasteners in the clamp. Starting from the larger end of the clamp, alternately tighten the fastener in three increments to a final torque of 50 to 60 lbf·ft (68 to 81 N·m).

Clean any excess chassis grease from around the clamp.

2.5 Install the saddle clamp at the bottom of the muffler, and tighten the clamp 24 lbf·ft (33 N·m).

2.6 Install the capscrews, washers and nuts that hold the muffler mounting band to the support channel, and tighten the capscrews 68 lbf·ft (92 N·m).

2.7 Install the stack, and secure it with two narrow-band clamps. Tighten the clamps 50 lbf·ft (68 N·m).

Muffler Replacement

2.8 Run the engine, and check for exhaust leakage at the exhaust clamp joints. Replace the wide-band exhaust clamps if they leak.

Wide-Band Exhaust Clamp Replacement

Replacement

1. Remove and discard the leaking or damaged wide-band exhaust clamp.
2. Grease the lap joint area.
3. Hand-form a new wide-band exhaust clamp around the lap joint, with the larger end of the clamp around the larger diameter tubing, and the smaller end of the clamp around the smaller diameter tubing. Position one third to one half of the exhaust clamp width onto the larger diameter tubing, or completely cover the slots in the larger tubing.
4. Install the fasteners in the clamp. Starting from the larger end of the clamp, alternately tighten the fasteners in three increments to a final torque of 68 to 81 N·m (50 to 60 lbf·ft).
5. Run the engine, and check for exhaust leakage at the exhaust clamp joint. Replace the wide-band exhaust clamp if it leaks.

Exhaust Stack Shield Replacement

Replacement

1. Remove the four capscrews that attach the exhaust shield to the exhaust shield clamps, and remove the exhaust shield.
2. Position the new exhaust shield against the clamps, and install all four capscrews. Tighten the capscrews to 18 N·m (13 lbf·ft).

Specifications

Description	Grade	Size	Torque N·m (lbf·ft)
Wide-Band Exhaust Clamp	—	—	68-81 (50-60)
Saddle Clamp U-Bolt	—	3/8-16	33 (24)
Exhaust Stack Shield Capscrews	302 SS	5/16-18	18 (13)

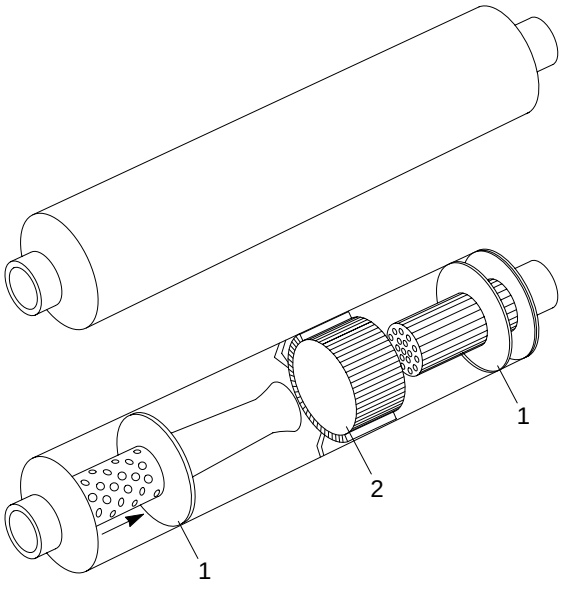


Table 1, Fastener Torques

General Information

To clean vehicle exhaust and reduce exhaust noise, Freightliner uses mufflers and catalytic converters with some engines. On diesel engines, including the Cummins B and C series, and the Mercedes Benz 210 and 230 horsepower OM 366LA, Freightliner uses a combined catalytic converter and muffler in the same housing (can). On gasoline engines, Freightliner uses a separate catalytic converter and muffler.

Exhaust pipes route the exhaust from the engine to the catalytic converter.

Diesel engines use a combined catalytic converter and muffler. The converter consists of three sections: a muffler section, the catalytic converter, another muffler section. **See Fig. 1.**

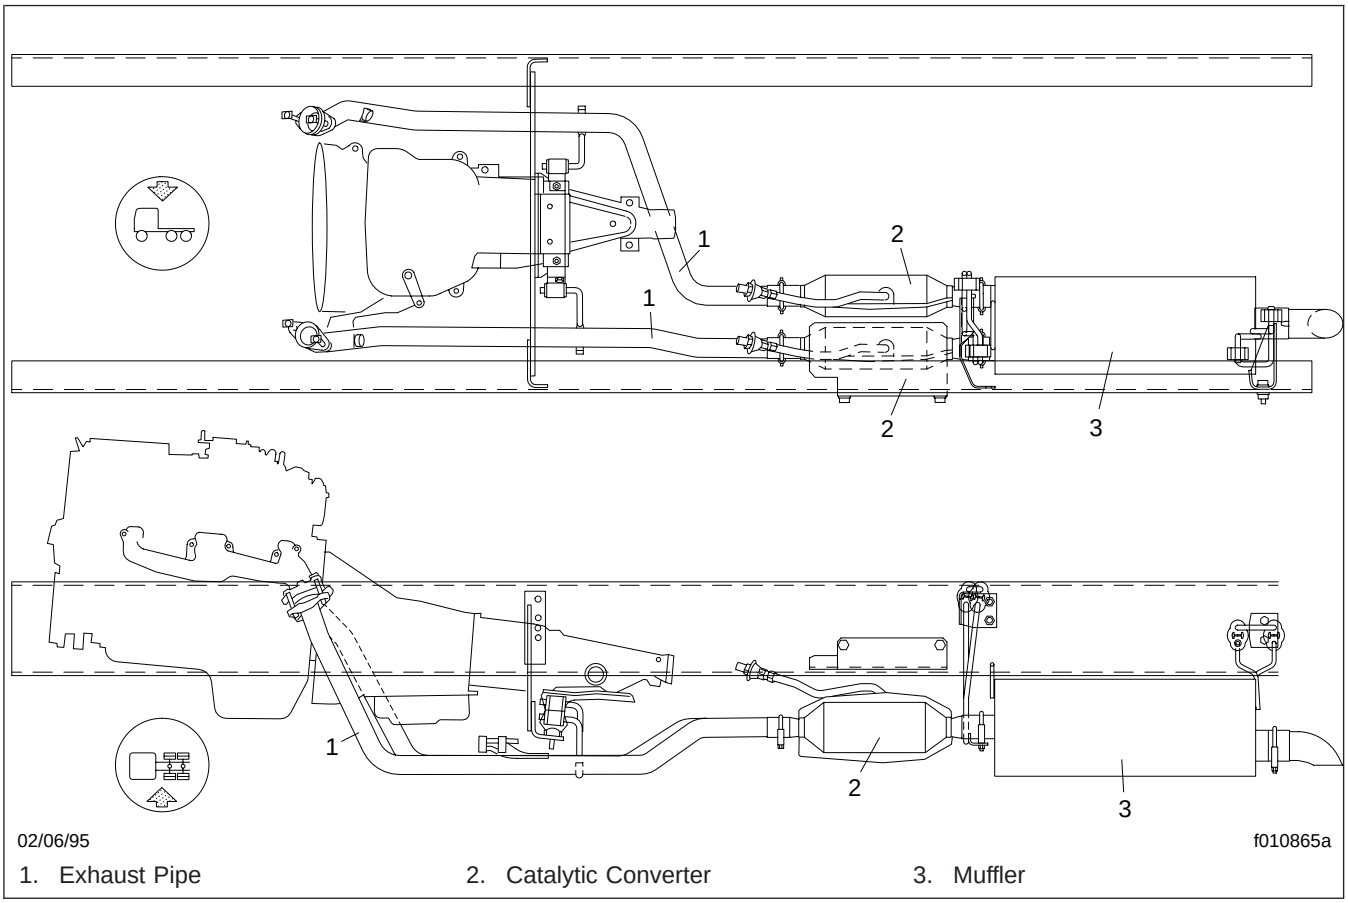
01/27/94 f490058

NOTE: This combined muffler and catalytic converter is used with diesel engines.

1. Baffle
2. Substrate

Fig. 1, Typical Catalytic Converter Muffler

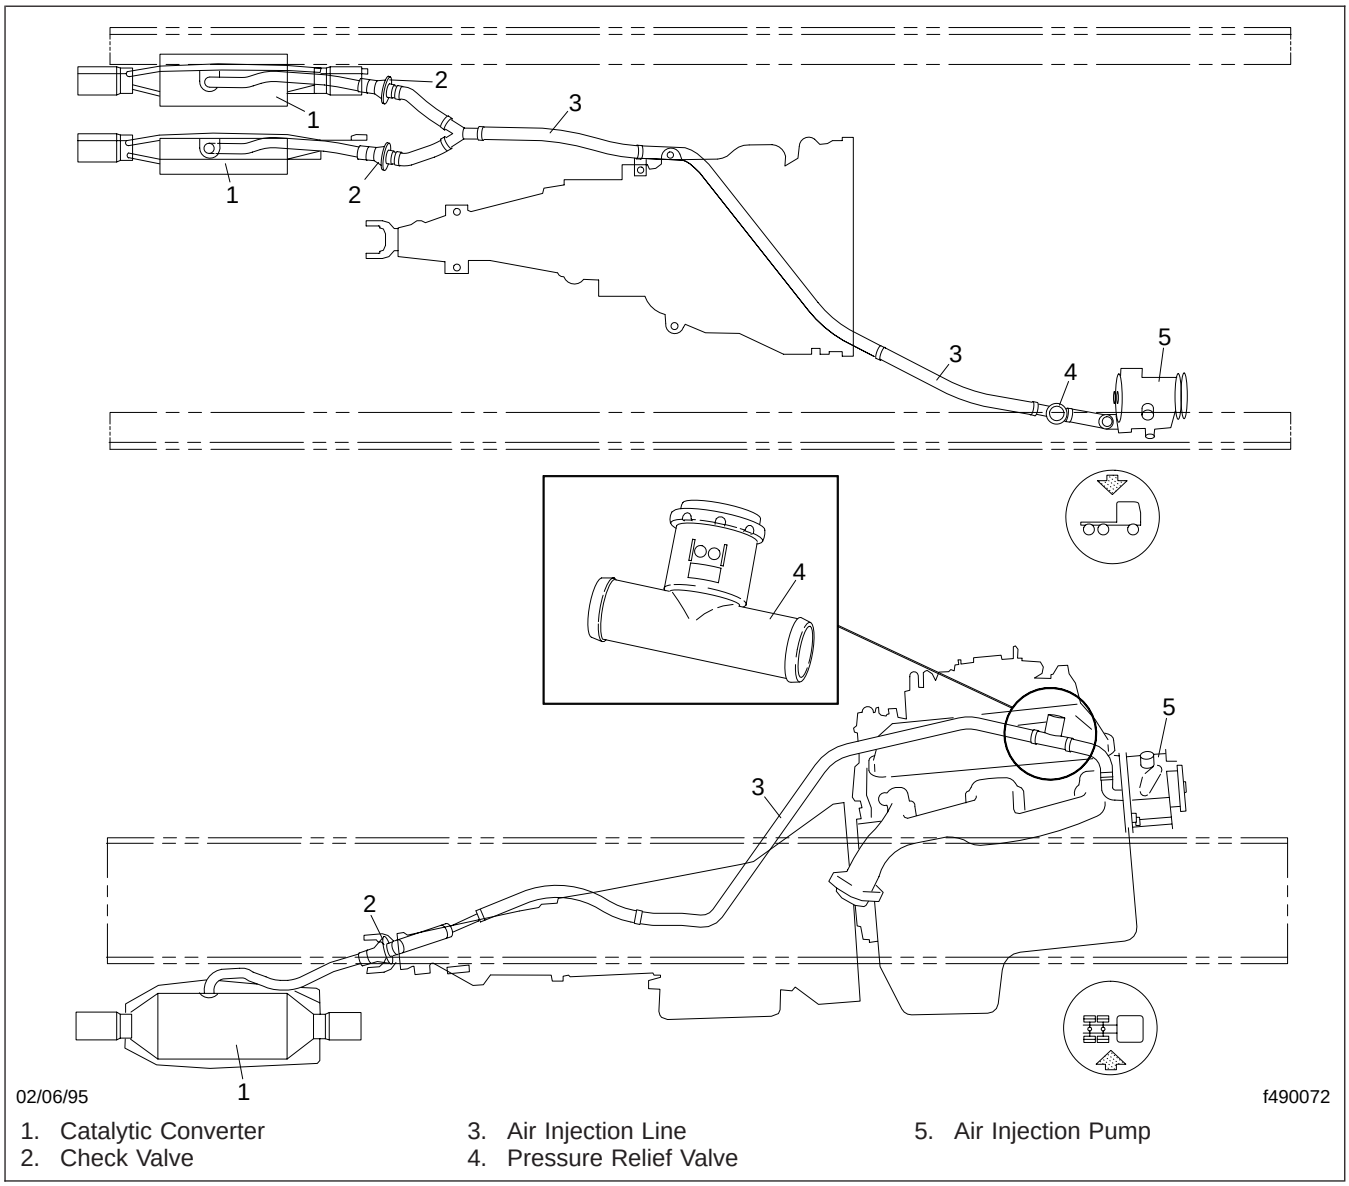
Inside the converter, a series of baffles dampens the noise of the exhaust by breaking the sound waves into shorter lengths. Then the exhaust is channeled through the catalytic converter, a section of fine ceramic honeycomb called the substrate. The substrate is coated with gold, and the heat of the exhaust heats the gold plate. Once the catalytic converter is warmed to operating temperature, the hot gold plate ignites any unburned fuel and oil in the exhaust. The remaining fuel and oil burn, and the cleaned exhaust passes through another section of baffles that further muffle any noise. After the second muffler section, the exhaust vents to the atmosphere.



Although the catalytic converter muffler is the same size as a standard muffler assembly, the converter muffler weighs about 50 percent more. A standard muffler may weigh about 9 kg (20 lbs), while a converter muffler the same size will weigh 15 kg (33 lbs). To be fully effective, the gold plate on the ceramic honeycomb of the substrate must stay clean so that it can contact and burn any fuel and oil in the exhaust. A layer of pollutants on the gold plate will insulate it and allow unburned fuel and oil to pass through the catalytic converter muffler. To prevent pollution build-up on the gold plate, the muffler is built with aluminized stainless steel which is thicker and heavier than the aluminized steel used in standard mufflers.

Gasoline engines use separate catalytic converters and mufflers. Engine exhaust is routed from each exhaust manifold, back, to two separate catalytic converters on the forward end of the muffler. **See Fig. 2.**

To help the converters burn any residual oil and fuel, an air injection pump on the engine pumps air through lines to the catalytic converters. **See Fig. 3.** A pressure relief valve on the air injection line will open if pressure in the injection line is too high. Check valves at the catalytic converters keep hot exhaust from backing up the air injection lines into the injection pump and engine. After passing through the converters, the exhaust passes through the muffler. The catalytic converters, muffler, and exhaust pipes are suspended from the frame rails and transmission by rubber isolators (**see Fig. 4**) or straps (**Fig. 5**) that allow the exhaust system to move as necessary under normal vehicle operation.



All catalyst muffer installations are certified to be in compliance with 1994 EPA standards. Use parts specified by PartsPro® when replacing any of the exhaust system components.

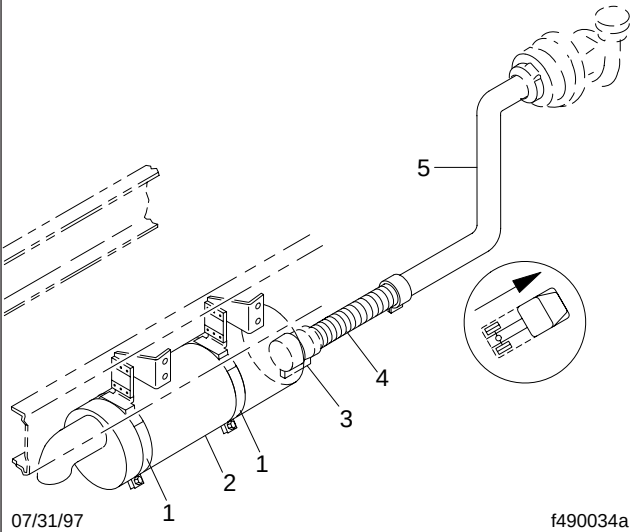

Fig. 5, Muffler Mounting with Straps, Dodge Magnum Engine

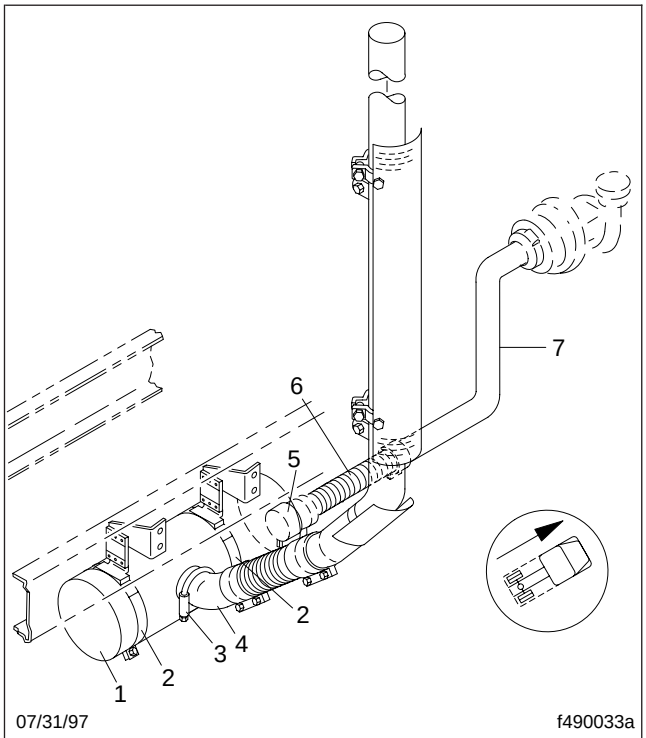
Replacement

NOTE: The mufflers on Freightliner Business Class vehicles can be mounted either horizontally or vertically. Use the following replacement procedure that applies to your vehicle.

Horizontally Mounted Mufflers

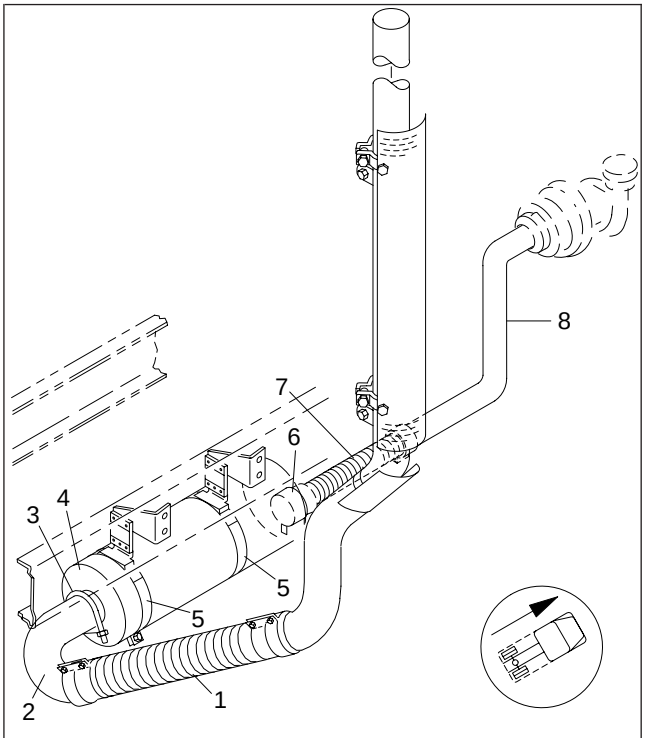


(See Fig. 1, Fig. 2 , and Fig. 3)

NOTE: The exhaust flex pipe (Ref. 4) may not be present on early model vehicles.

1. Muffler Mounting Band
2. Muffler
3. Wide-Band Exhaust Clamp
4. Exhaust Flex Pipe (except Cummins B 5.9 engines)
5. Muffler Inlet Exhaust Pipe

Fig. 1, Exhaust System Without a Stack, All Models Except FL112



NOTE: This configuration is on vehicles built to August 2, 1996. The exhaust flex pipe (Ref. 6) may not be present on early model vehicles.

1. Muffler
2. Muffler Mounting Band
3. Saddle Clamp
4. Muffler Outlet Exhaust Pipe
5. Wide-Band Exhaust Clamp
6. Exhaust Flex Pipe (except Cummins B 5.9 engines)
7. Muffler Inlet Exhaust Pipe

Fig. 2, Exhaust System With a Stack, Side Outlet, All Models Except FL112

1. Remove the muffler.
   - 1.1 Remove and discard the wide-band exhaust clamp from the muffler inlet connection.
   - 1.2 On vehicles with a vertical exhaust stack, remove the saddle clamp from the muffler outlet connection. Pull the muffler outlet exhaust pipe out of the muffler outlet tube.
   - 1.3 Remove the bolts and locknuts on the front and rear muffler mounting bands. Remove the mounting bands. Remove the muffler.
2. Install the muffler.
   - 2.1 Slide the new muffler's inlet tube over the muffler inlet exhaust pipe.
   - 2.2 Install the front and rear muffler mounting bands. Install the bolts and locknuts on the mounting bands, but do not tighten them at this time.

Muffler Replacement

07/31/97 f490143

NOTE: This configuration is on vehicles built from August 2, 1996. The exhaust flex pipe (Ref. 7) may not be present on early model vehicles.

1. Flex Pipe
2. Rear Exhaust Outlet
3. Saddle Clamp
4. Muffler (catalytic converter on some engine models)
5. Muffler Mounting Band Muffler
6. Wide-Band Exhaust Clamp
7. Exhaust Flex Pipe (except Cummins B 5.9 engines)
8. Muffler Inlet Exhaust Pipe

Fig. 3, Exhaust System, Rear Outlet, All Models Except FL112

2.3 On vehicles with a vertical exhaust stack, slide the muffler outlet exhaust pipe into the muffler outlet tube.

2.4 Coat the lap joint area with chassis grease, so the clamp will slide freely without scratching the surface of the pipe.

2.5 Wrap a new wide-band exhaust clamp by hand around the lap joint. Place the large end of the clamp around the muffler inlet tube, and the small end around the inlet exhaust pipe.

2.6 Install the fasteners in the clamp. Starting from the larger end of the clamp, alternately tighten the fastener in three increments to a final torque of 50 to 60 lbf·ft (68 to 81 N·m).

Clean any excess chassis grease from around the clamp.

2.7 Install the saddle clamp U-bolt on the muffler outlet tube (where applicable). Tighten the saddle clamp flanged nuts alternately in three increments to a final torque of 24 lbf·ft (33 N·m).

2.8 Tighten the muffler mounting band fasteners until the band ears touch; then, tighten the fasteners two full turns or until the ears are in full contact, whichever occurs first.

2.9 Run the engine, and check for exhaust leakage at the exhaust clamp joints. Replace the wide-band exhaust clamps if they leak.

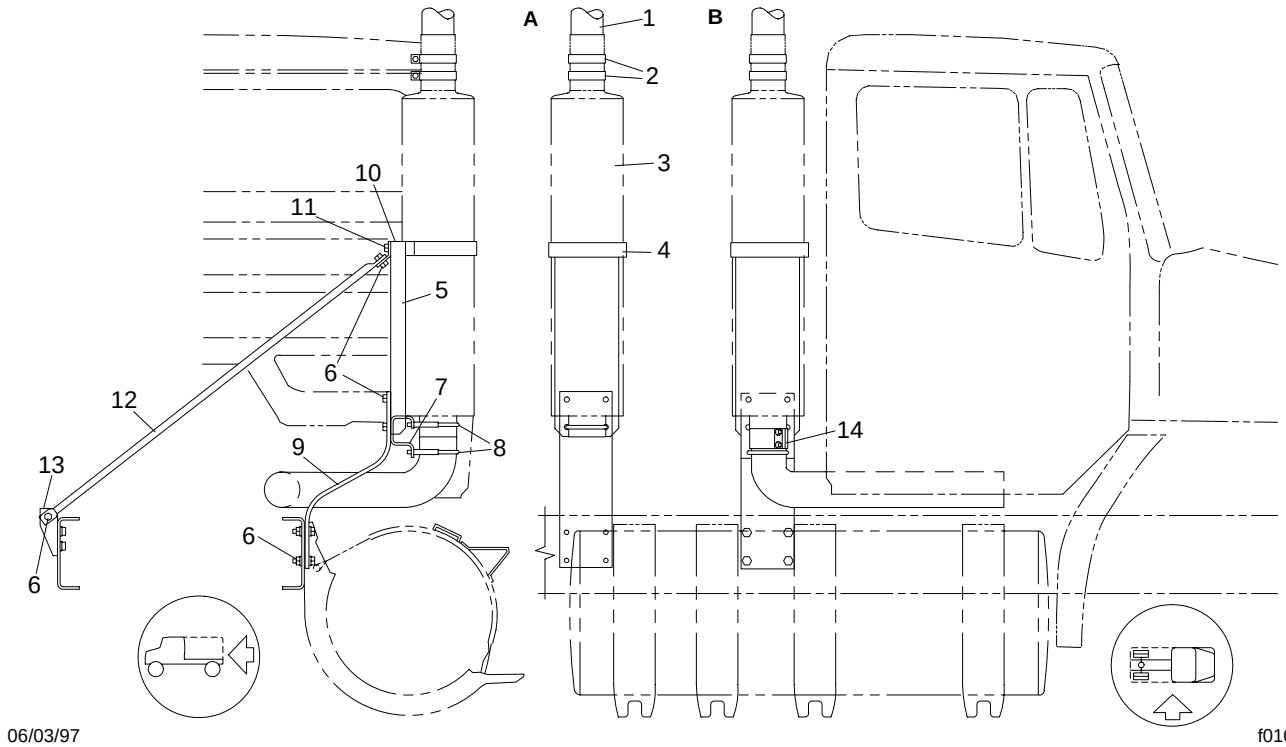
Vertically Mounted Mufflers (See Fig. 4)

1. Remove the muffler.

1.1 Loosen the narrow-band clamps that hold the stack on the muffler, and remove the stack.

1.2 Loosen the saddle clamp that holds the base of the muffler to the support channel.

1.3 Loosen the wide-band clamp that connects the muffler to the exhaust pipe.



1.4 Remove the two bolts that hold the muffler mounting band to the muffler support channel.

1.5 Lift the muffler out of the lower saddle clamp.

2. Install the muffler.

2.1 Place the muffler in the support channel, and hold it in place while installing a new wide-band clamp to connect the muffler with the exhaust pipe.

2.2 Coat the lap joint area with chassis grease, so the clamp will slide freely without scratching the surface of the pipe.

A. Muffler Position, FL112 Conventional with Extended Cab

B. Muffler Position, FL112 Conventional with Day Cab

1. Exhaust Stack
2. Narrow-Band Clamp (2 qty.)
3. Muffler
4. Muffler Mounting Band
5. Support Channel
6. Nut, Washer, and Capscrew, 5/8–11, Grade 8
7. Lower Muffler Mounting Bracket
8. Saddle Clamp, 5-Inch
9. Upright Muffler Mounting Bracket
10. Upper Brace Bracket
11. Nut, Washer, and Capscrew, 1/2–13
12. Brace
13. Lower Brace Bracket
14. Wide-Band Clamp

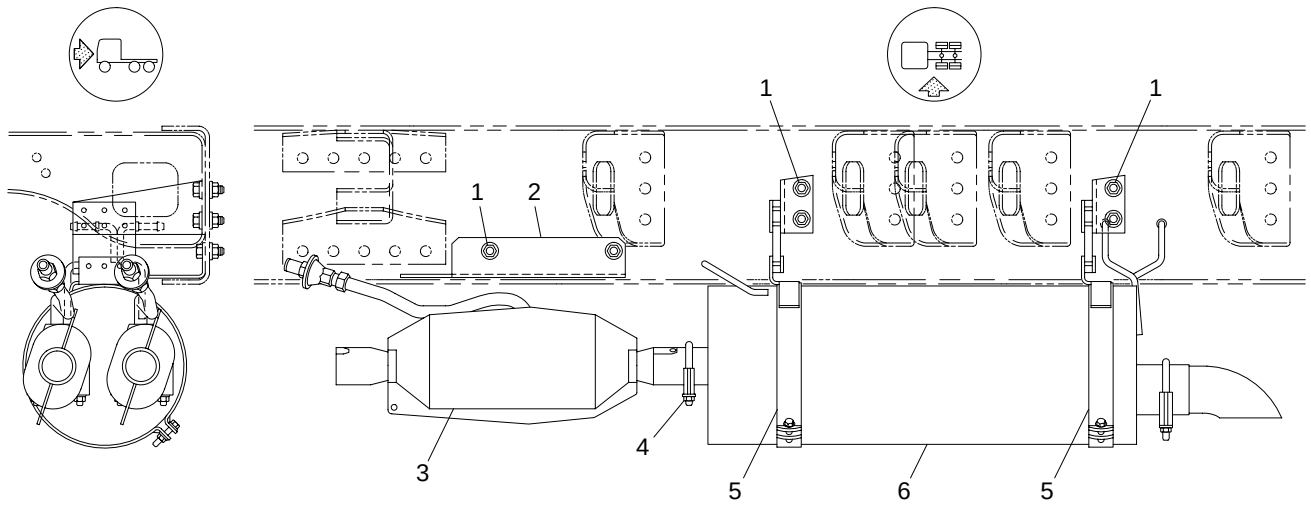
Fig. 4, Vertical Exhaust Mounting, FL112

2.3 Wrap a new wide-band exhaust clamp by hand around the lap joint. Place the large end of the clamp around the muffler inlet, and the small end around the exhaust pipe.

2.4 Install the fasteners in the clamp. Starting from the larger end of the clamp, alternately tighten the fastener in three increments to a final torque of 50 to 60 lbf·ft (68 to 81 N·m).

Clean any excess chassis grease from around the clamp.

2.5 Install the saddle clamp at the bottom of the muffler, and tighten the clamp 24 lbf·ft (33 N·m).



2.6 Install the capscrews, washers and nuts that hold the muffler mounting band to the support channel, and tighten the capscrews 68 lbf·ft (92 N·m).

2.7 Install the stack, and secure it with two narrow-band clamps. Tighten the clamps 50 lbf·ft (68 N·m).

2.8 Run the engine, and check for exhaust leakage at the exhaust clamp joints. Replace the wide-band exhaust clamps if they leak.

Muffler Removal and Installation, Gasoline Engines

Removal (See Fig.1 or Fig.2)

01/09/96 f490129

1. Capscrew, 1/2–13 x 1.75 inch, grade 8; Washer; Hexnut, 1/2–13
2. Heat Shield
3. Catalytic Converter
4. U-Bolt Clamp, 57.15 mm diameter
5. Muffler Support Assembly
6. Muffler

Fig. 1, Muffler Mounting with Straps, Dodge Magnum Engine

1. Park the vehicle, apply the parking brakes, and shut down the engine.
2. Loosen the two saddle clamps that hold the catalytic converters to the front of the muffler.
3. *If removing a muffler supported by straps (* **Fig.1***) do this step, if removing a muffler supported by rubber isolators (* **Fig.2***) go to the next step.*

   Remove the capscrews that hold the bands of the muffler support assemblies together. Then lower and remove the muffler.
4. To remove a muffler supported by rubber isolators, support the muffler, and remove the two bolts that hold the rear exhaust system mounting bracket to the frame rail.
5. Pull the muffler back, away from the catalytic converters, and remove it.
6. If replacing the muffler, remove the rubber isolators and the rear exhaust system mounting bracket from the old muffler.

Installation

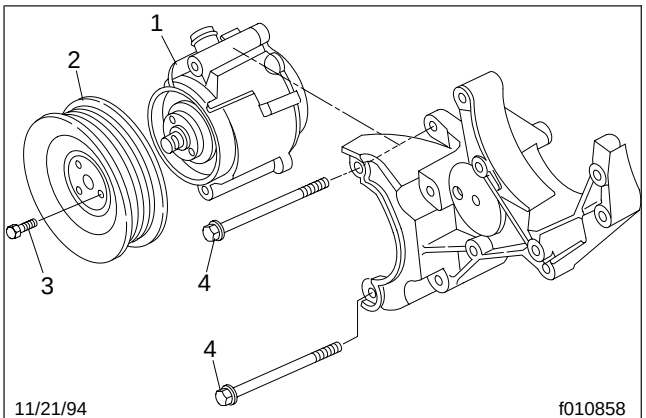
1. *If installing a muffler supported by straps (* **Fig.1***) do this step, if installing a muffler supported by rubber isolators (* **Fig.2***) go to the next step.*

   To install a muffler supported by straps, position the muffler in the bands of the support assemblies, then close the bands with capscrews and tighten the capscrews 13 N·m (10 lbf·ft). Now, go to the last step in this procedure.
2. To install a muffler supported by rubber isolators, first install the rubber isolators and the rear exhaust system mounting bracket on the new muffler.
3. Position the muffler in the vehicle so that it mates with the catalytic converters.
4. Install the two bolts that hold the rear exhaust system mounting bracket to the frame rail, and tighten the bolts firmly.

Muffler Removal and Installation, Gasoline Engines

1. Rubber Isolator
2. Exhaust System Mounting Bracket
3. Muffler

Fig. 2, Muffler Mounting with Rubber Isolators, Dodge Magnum Engine



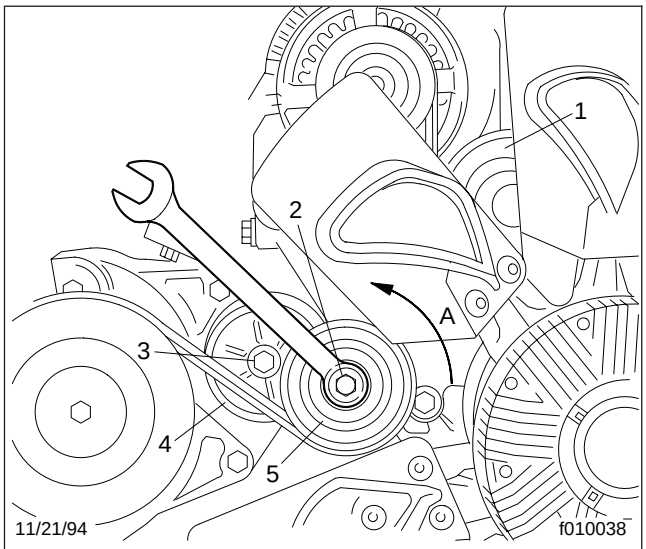
5. Tighten the saddle clamps to seal the muffler-catalytic converter joints.

Air Injection Pump Removal and Installation, Gasoline Engines

Removal

NOTE: The air injection pump does not have any internal serviceable parts.

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Disconnect both the hoses at the air injection pump.
4. Loosen (but do not remove at this time) the three 10 mm air pump pulley mounting bolts. **See Fig. 1.**



1. Air Injection Pump
2. Pump Pulley
3. Pulley Mounting Bolt
4. Pump Mounting Bolt

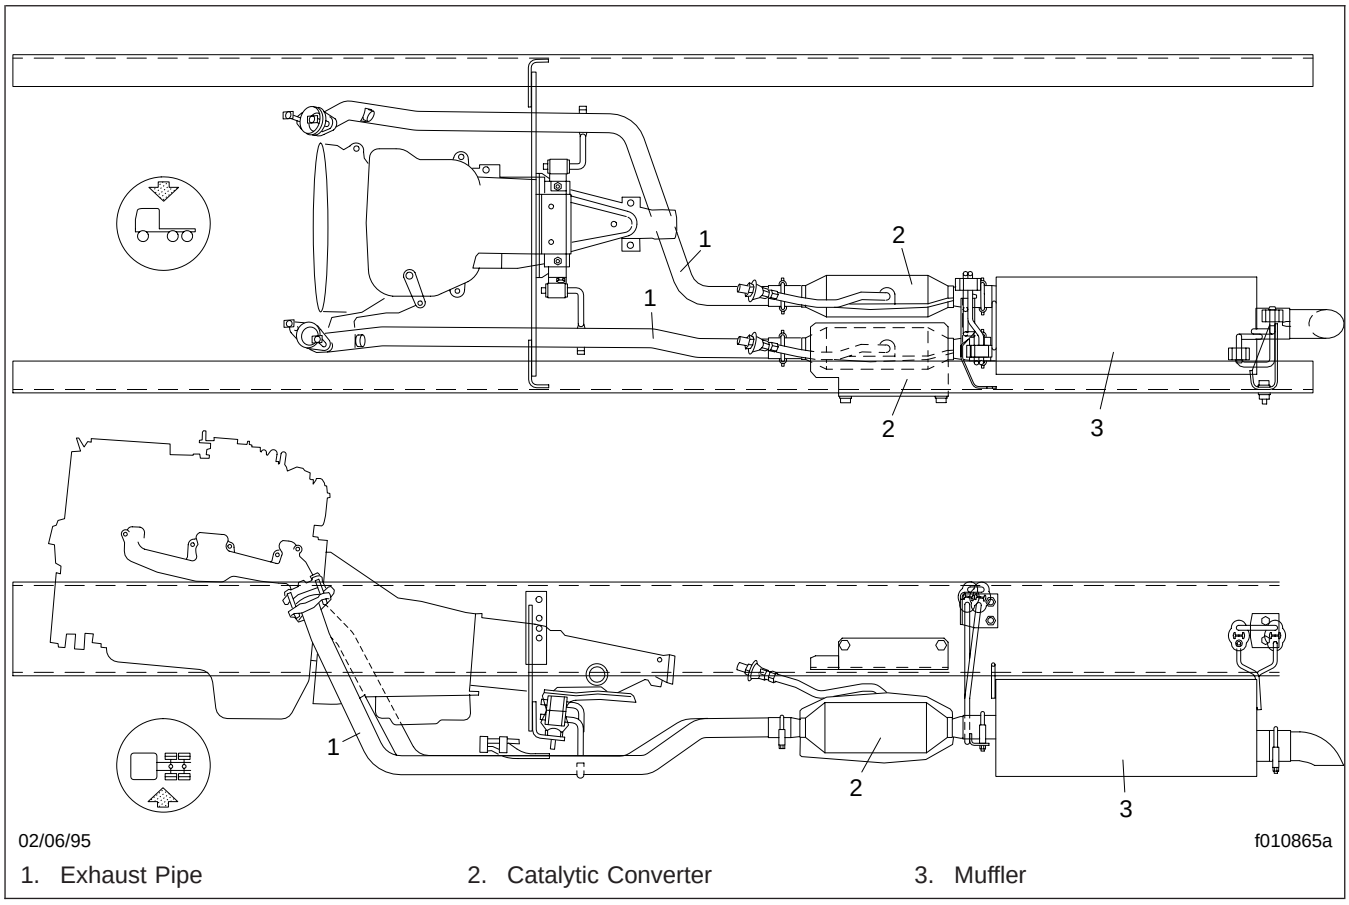
Fig. 1, Pump Mounting

5. Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner and remove the engine accessory drive belt. **See Fig. 2.**
6. Remove the three air pump pulley bolts and remove the pulley from the pump.
7. Remove the two 14 mm air pump mounting bolts, and remove the pump from the mounting bracket. **See Fig. 1.**

Installation

1. Position the air injection pump on the mounting bracket.

A. Turn counterclockwise to remove the belt.



1. Idler Pulley
2. Tensioner Pulley Bolt
3. Tensioner Mounting Bolt
4. Tensioner
5. Tensioner Pulley

Fig. 2, Relieving Belt Tension

2. Install the two 14 mm pump mounting bolts. **See Fig. 1.** Tighten the mounting bolts 40 N·m (30 lbf·ft).
3. Install the pump pulley and three 10 mm pulley mounting bolts. Tighten the bolts finger tight.
4. Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner. Install the engine accessory drive belt. **See Fig. 2.**
5. Tighten the pump pulley mounting bolts 1180 N·cm (105 lbf·in).
6. Connect the two hoses to the air pump.
7. Lower the hood, and remove the chocks from the tires.

Catalytic Converter Removal and Installation, Gasoline Engines

Removal (See Fig.1 or Fig.2)

1. Exhaust Pipe 2. Catalytic Converter 3. Muffler

Fig. 1, Muffler Mounting with Rubber Isolators, Dodge Magnum Engine

1. Park the vehicle, apply the parking brakes, and shut down the engine.
2. *If the muffler is mounted with rubber isolators (* **Fig.1***), remove the muffler. For instructions, refer to* **Subject 105***.*

   If the muffler is mounted with straps (**Fig.2***), loosen the U-bolt clamps that hold the catalytic converters to the muffler.*
3. Loosen the clamps that hold the air injection lines to the catalytic converters. Then, disconnect the lines from the converters.
4. Loosen the saddle clamps that hold the catalytic converters to the exhaust pipes, then pull the converters back and remove them.

Installation

1. Position the catalytic converters on the exhaust pipes, but don't tighten the saddle clamps yet.
2. *If the muffler is mounted with rubber isolators (* **Fig.1***), install the muffler. For instructions, refer to* **Subject 105***.*

   If the muffler is mounted with straps (**Fig.2***), connect the catalytic converters to the muffler, and tighten the U-bolt clamps to seal the connection.*
3. Tighten the saddle clamps to seal the joint between the exhaust piping and each catalytic converter.

Catalytic Converter Removal and Installation, Gasoline Engines

01/09/96 f490129

1. Capscrew, 1/2–13 x 1.75 inch, grade 8; Washer; Hexnut, 1/2–13
2. Heat Shield
3. Catalytic Converter
4. U-Bolt Clamp, 57.15 mm diameter
5. Muffler Support Assembly
6. Muffler

Fig. 2, Muffler Mounting with Straps, Dodge Magnum Engine

4. Connect the air injection lines to the catalytic converters, and tighten the hose clamps.

Specifications

Description	Grade	Size	Torque N·m (lbf·ft)

Saddle Clamp U-Bolt	—	3/8–16	33 (24)
Exhaust Stack Shield Capscrews	302 SS	5/16–18	18 (13)
Mounting Band Fasteners	—	—	14 (10)

Table 1, Fastener Torques

General Information and Principles of Operation

The Freightliner engine warning system is an optional system that alerts the driver to any problem associated with low oil pressure, high coolant temperature, and low coolant level. If a problem occurs in one of these systems, an indicator light will illuminate on the dashboard and a buzzer will sound.

The warning light and buzzer for the low oil pressure and high coolant temperature are activated by switches. The warning light and buzzer for the low coolant level are activated by a probe and a module.

NOTE: The low oil pressure switch and the high coolant temperature switch activate the same warning light.

- If the engine oil pressure drops below a predetermined level, the warning light comes on and the buzzer sounds. The pressure that triggers the warning light and buzzer is given in **Table 1.**

Engine Model	Switching Pressure bar (psi)	Switch Position	
		Engine Off (Ignition Off)	Engine Running
MB OM 366LA	0.7 (10)	NC *	Open
Cummins B5.9	0.7 (10)	NC *	Open

* NO = normally open; NC = normally closed. A normally open switch is open; a normally closed switch is closed when the engine is shut down and all electrical power is off.

Table 1, Low Oil Pressure Switch

- If the engine overheats, the warning light comes on and the buzzer sounds. The temperature that triggers the warning light and buzzer varies with engine type. **See Table 2.**

Engine Model	Switching Temperature°C (°F)	Switch Position	
		Ignition Off	Ignition On
MB OM 366LA	96 (205)	NO *	Open
Cummins B5.9	99 (210)	NO *.	Open

* NO = normally open; NC = normally closed. A normally open switch is open; a normally closed switch is closed when the engine is shut down and all electrical power is off.

Table 2, High Coolant Temperature Switch

- If the coolant level drops below a probe in the cooling system, the low coolant light comes on and the buzzer sounds. As an antislosh feature, the probe must be exposed for more than five seconds before the warnings are activated.

Because power is supplied to these circuits through the ignition switch, turning the ignition switch off also shuts off the warning system.

ENGINE FUNCTIONS

The low oil pressure switch controls a ground activated circuit: The switch is normally closed (NC). [1] During normal operation, the switch is held open by the engine oil pressure. If the oil pressure drops below a predetermined point **(see Table 1),** the switch closes and connects wire 34 to ground. This completes the circuit, activating the warning light and buzzer.

The coolant temperature switch also controls a ground activated circuit, but the switch is normally open (NO). [1] If the coolant temperature rises above a predetermined point **(see Table 2),** the switch closes and connects wire 18C to ground. This completes the circuit, activating the warning light and buzzer.

The coolant level warning system consists of a probe and a module. The probe is located in the surge tank and uses the coolant as a conductor to ground. If the coolant level drops below the probe for longer than 5 seconds, the module, which controls a normally open (NO) [1] switch, will close the switch and connect wire 150G to ground. This completes the circuit, activating the low coolant level warning light and the buzzer.

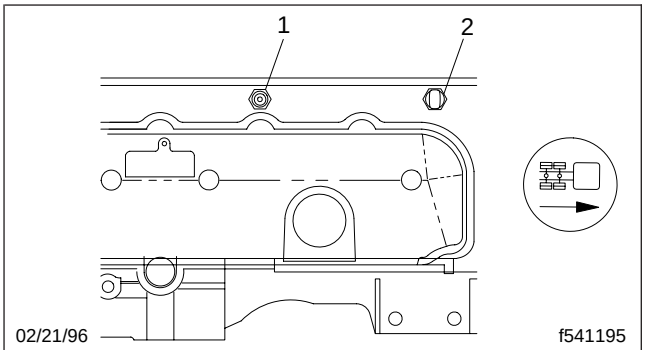
[1] NO = normally open; NC = normally closed. A normally open switch is open; a normally closed switch is closed when the engine is shut down and all electrical power is off.

Low Coolant Level Control Module Replacement

Replacement

1. The control module is located behind the right-side upper dashboard panel, above the electrical center. Access it by removing the rubber trim piece on the right side of the dashboard and the two screws that connect the dashboard cover to the dashboard.
2. Disconnect the vehicle harness 5-pin connector from the module (only 4 pins are used), then remove the low coolant level module from the mounting bracket.
3. Install the new low coolant level module and connect the 5-pin connector.
4. Install the dashboard cover and tighten the screws securely; then install the trim piece.

Replacement



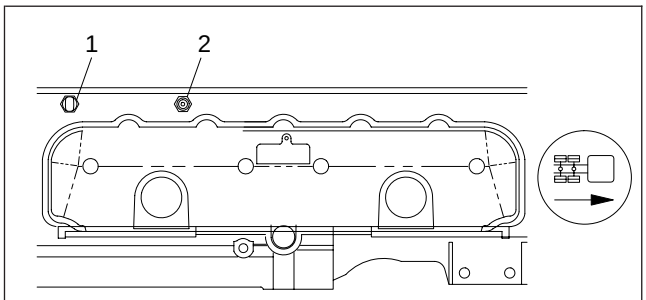
HIGH COOLANT TEMPERATURE SWITCH

1. Turn off the ignition switch and let the engine cool. Remove the surge tank cap to release the system pressure.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.

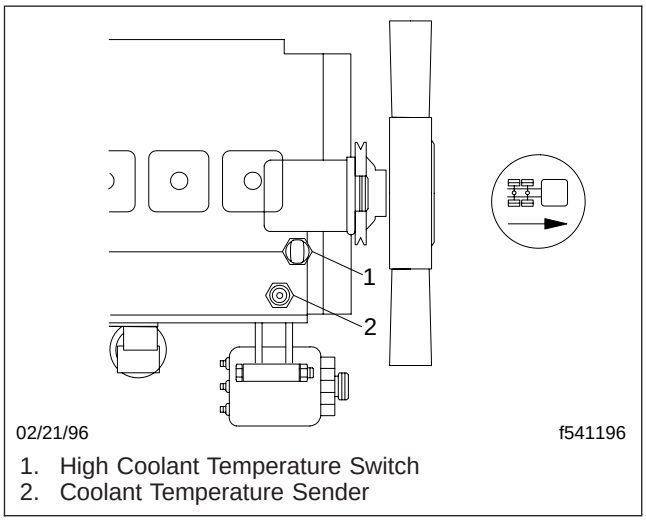
2. Drain the coolant from the engine.
3. Disconnect wire 18C from the high coolant temperature switch (see **Fig. 1**, **Fig. 2**, **Fig. 3**, **Fig. 4**, **Fig. 5,** , **Fig. 6**, **Fig. 7**, and **Fig. 8**); then remove the switch.



1. Coolant Temperature Sender
2. High Coolant Temperature Switch

Fig. 1, OM 366LA, Forward Mounted Coolant Temperature Sender and High Coolant Temperature Switch

4. Install the new switch and tighten it one-half turn past finger-tight. Connect wire 18C to the switch.
5. Add coolant to the system as needed; then install the cap. Start the engine and check the system to be sure there are no coolant leaks.



LOW COOLANT LEVEL PROBE

1. Turn off the ignition switch and let the engine cool. Remove the surge tank cap to release the system pressure.

1. High Coolant Temperature Switch
2. Coolant Temperature Sender

Fig. 2, OM 366LA, Rear Mounted Coolant Temperature Sender and High Coolant Temperature Switch

1. High Coolant Temperature Switch
2. Coolant Temperature Sender

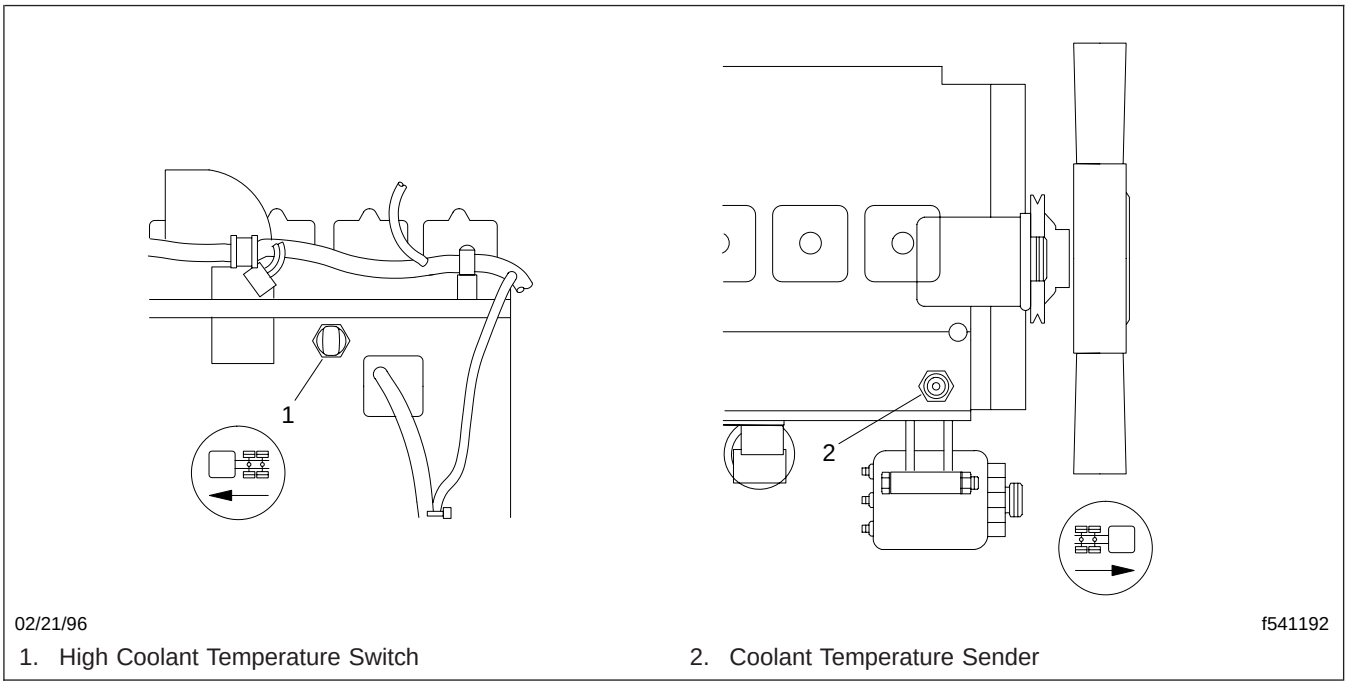


Fig. 3, Cummins B Series with Top Mounted Coolant Temperature Sender and High Coolant Temperature Switch

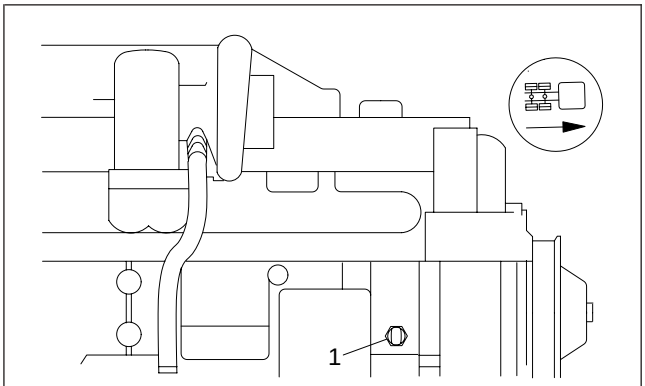
⚠ WARNING

WARNING: Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.



2. Drain the coolant from the surge tank.
3. Disconnect wire 173 and the ground wire (if equipped) from the low coolant level probe, located in the inboard side of the surge tank (see **Fig. 9**); then remove the probe.

Switch (Sensor) Replacement

1. High Coolant Temperature Switch
2. Coolant Temperature Sender

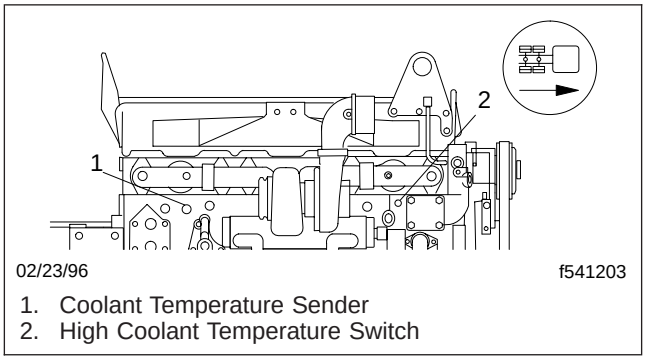


Fig. 4, Cummins B Series with Side Mounted Coolant Temperature Sender and Top Mounted High Coolant Temperature Switch

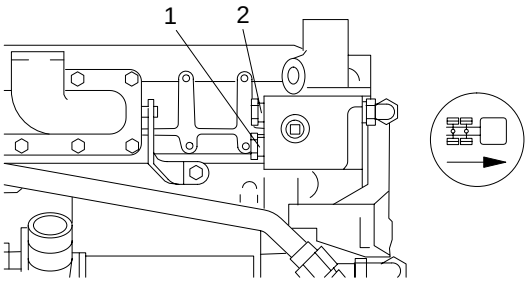
1. Coolant Temperature Sender, and High Coolant Temperature Switch

Fig. 5, Cummins C Series

4. Install the new probe and tighten it one-half turn past finger-tight. Connect wire 173 to the probe.
5. Add coolant to the system as needed; then install the cap.

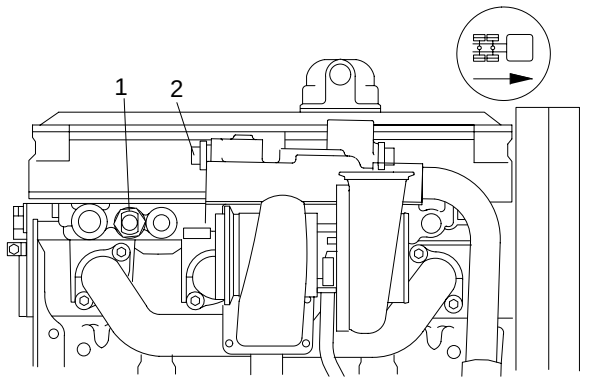


1. Coolant Temperature Sender
2. High Coolant Temperature Switch

Fig. 6, Cummins M11

6. Start the engine and check that the low coolant level warning light and buzzer do not come on. Check the system to be sure there are no coolant leaks.

LOW OIL PRESSURE SWITCH

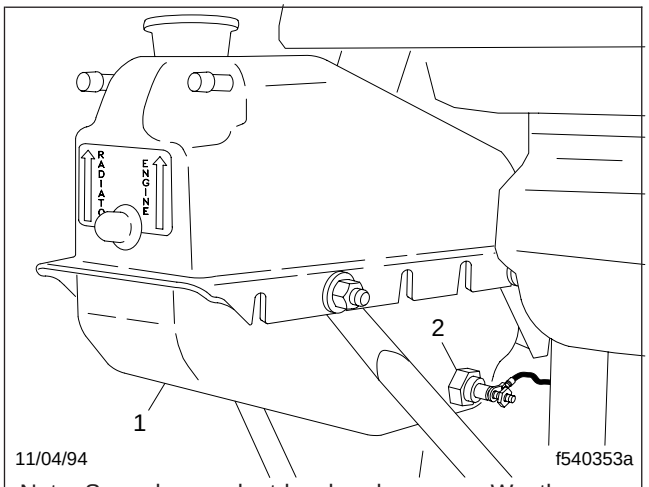


NOTE: The low oil pressure warning switch is located on a tee on the air-oil manifold located behind the left side of the dash panel. Access it by removing the rubber trim piece and the two

02/20/96 f541190

1. Coolant Temperature Sender
2. High Coolant Temperature Switch

Fig. 7, Caterpillar 3126



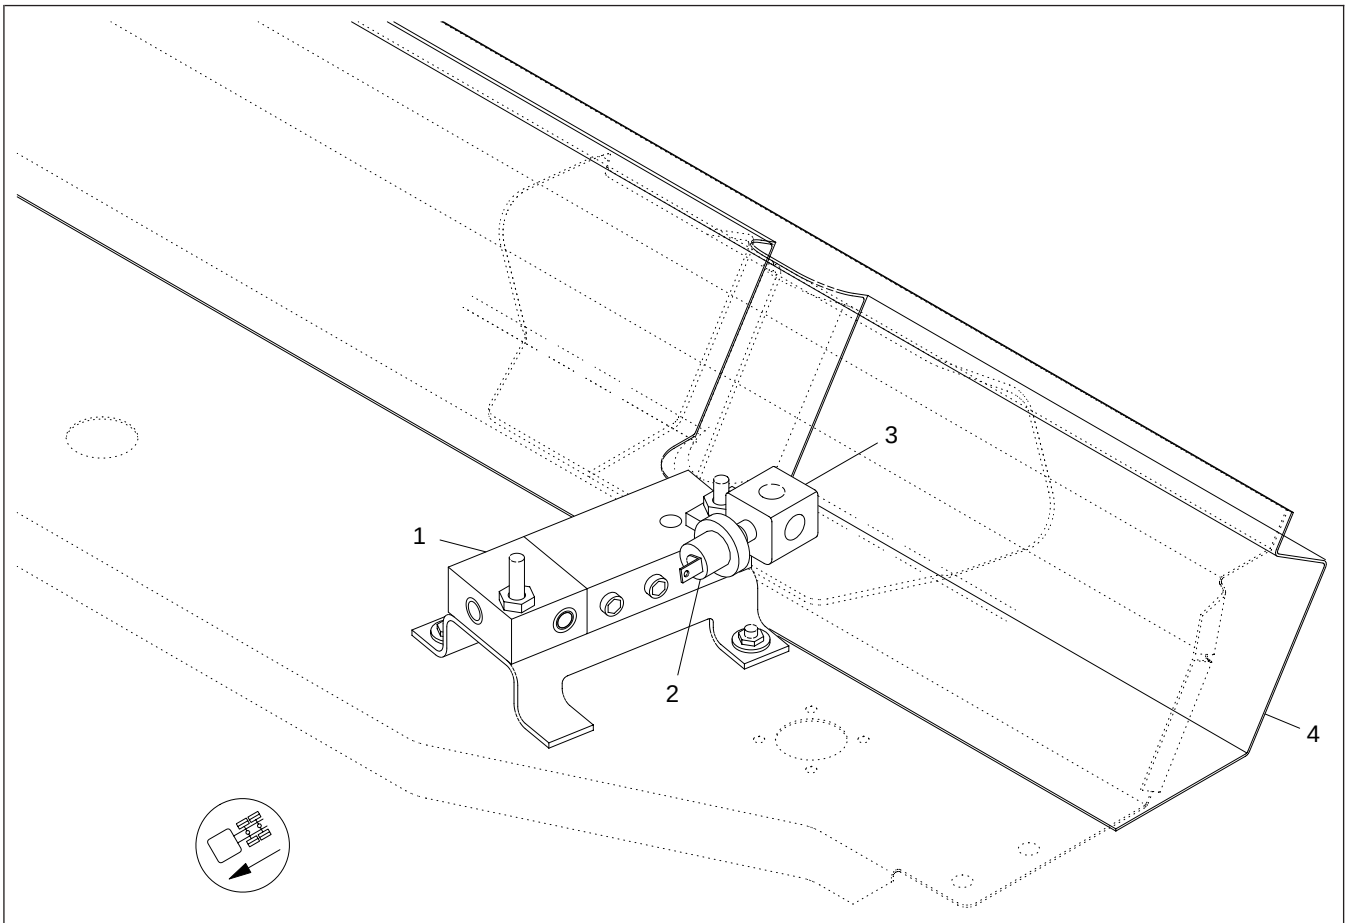
10/01/96 f541194

1. High Coolant Temperature Switch
2. Coolant Temperature Sender

Fig. 8, Detroit Diesel 50 Series

screws that connect the dashboard cover to the dashboard.

1. Turn off the ignition switch.
2. Disconnect wire 34 from the switch. (see **Fig. 10**, Ref. 2),. then remove the switch.
3. Install the new switch and tighten it one-half turn past finger-tight. Connect wire 34 to the switch.
4. Start the engine and check that the warning light and buzzer shut off when the oil pressure reaches approximately 10 psi (69 kPa). Check the system to be sure there is no oil leakage.



11/04/94 f540353a

Note: Some low coolant level probes use a Weather Pack® connector. The low coolant level probe may also have a ground wire attached to its body.

1. Surge Tank
2. Low Coolant Level Probe

Fig. 9, Low Coolant Level Probe

Switch (Sensor) Replacement

11/07/94 f540351a

NOTE: For clarity, other air/oil fittings, lines, and switches are not shown.

Fig. 10, Low Oil Pressure Switch

Troubleshooting

This subject contains the following troubleshooting tables:

- Warning Light Comes On But the Buzzer Does Not Sound
- Buzzer Sounds But the Warning Light Does Not Come On
- Buzzer Does Not Sound and Light Does Not Come On When the Systems Are Known to Be Operating Incorrectly
- Warning Light or Buzzer or Both Stay On When the Systems Are Known to Be Operating Correctly

Problem—Warning Light Comes On But the Buzzer Does Not Sound

Possible Cause	Remedy
The buzzer assembly is damaged.	Replace the buzzer assembly.
There is a break in the wiring between the fuse and the buzzer assembly, or between the buzzer assembly and the switch (or low coolant level module, if equipped).	Repair or replace the wiring as needed.

Problem—Buzzer Sounds But the Warning Light Does Not Come On

Possible Cause	Remedy
One or more of the warning lights is loose or damaged.	Check each bulb and replace as needed.
There is a break in the wiring between the fuse and the warning lights, or between the warning lights and the switch (or low coolant level module, if equipped).	Repair or replace the wiring as needed.

Problem—Buzzer Does Not Sound and Light Does Not Come On When the Systems Are Known to Be Operating Incorrectly

Possible Cause	Remedy
The fuse is damaged.	Replace the fuse.
A switch (or the low coolant level module, and/or probe, if equipped) is damaged.	Replace the damaged switch, module, or probe, as needed.
There is a short or break in the wiring from the fuse to both the buzzer assembly and the warning light.	Repair or replace the wiring as needed.

Problem—Warning Light or Buzzer or Both Stay On When the Systems Are Known to Be Operating Correctly

Possible Cause	Remedy
A switch (or the low coolant level module, and/or probe, if equipped) is damaged.	Replace the damaged switch, module, or probe, as needed.
The circuits are closing to ground due to a short in the wiring from the warning lights or the buzzer assembly to the switches (or low coolant control module and/or probe, if equipped).	Repair or replace the wiring as needed.

Specifications

This subject contains the following tables:

- Low Oil Pressure Switch
- High Coolant Temperature Switch

For the Freightliner warning system wiring diagram, see **Fig. 1** .

Engine Model	Switching Pressure psi (bar)	Switch Position	
		Engine Off (Ignition Off)	Engine Running
All Engines	10 (0.7)	NC *	Open

* NO = normally open; NC = normally closed. A normally open switch is open when the engine is shut down. A normally closed switch is closed when the engine is shut down.

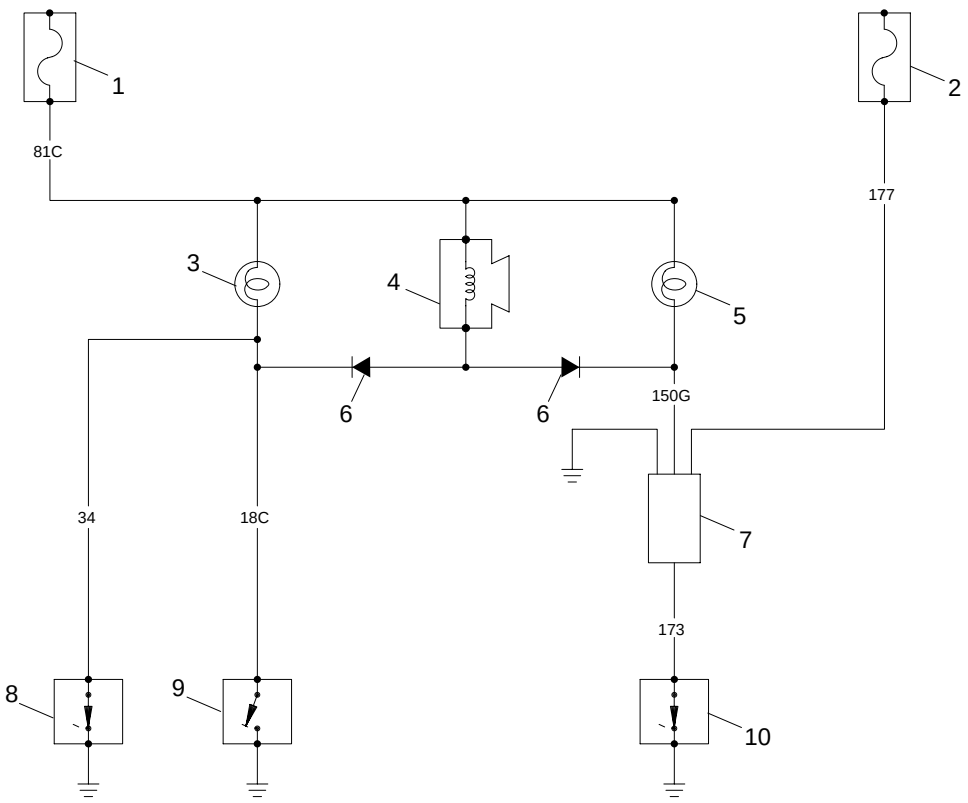

Table 1, Low Oil Pressure Switch

Engine Model	Switching Temperature°F (°C)	Switch Position	
		Ignition Off	Ignition On
MB OM 366LA	205 (96)	NO *	Open
Cummins B5.9	215 (101)	NO *	Open
Cummins C Series	215 (101)	NO *	Open
Cummins M11	220 (104)	NO *	Open
Caterpillar 3126	225 (107)	NO *	Open
DDEC 50 Series	215 (101)	NO *	Open

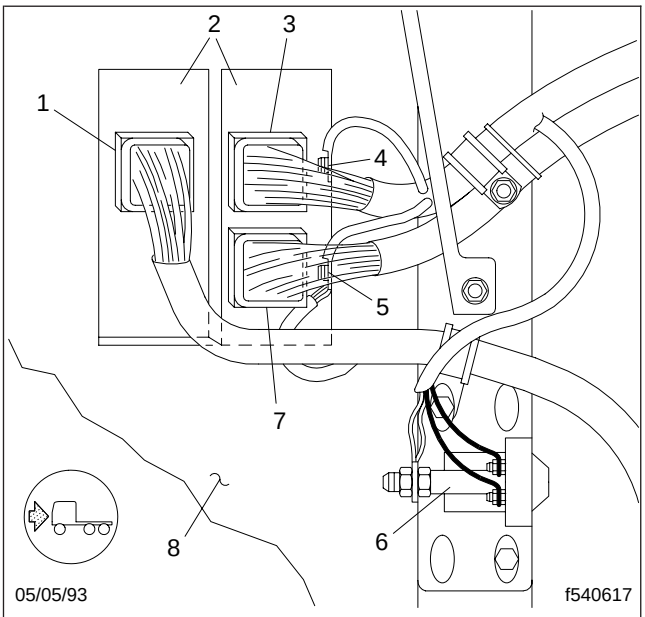
* NO = normally open; NC = normally closed. A normally open switch is open when the engine is shut down. A normally closed switch is closed when the engine is shut down. Also, see **Fig. 1**.

Table 2, High Coolant Temperature Switch

Specifications

1. 10 Amp Fuse (ignition controlled)
2. 15 Amp Fuse (accessory controlled)
3. Low Oil Pressure/High Coolant Temperature Light
4. Warning Buzzer
5. Low Coolant Level Light
6. Diode
7. Low Coolant Level Module
8. Low Oil Pressure Switch
9. High Coolant Temperature Switch
10. Low Coolant Level Probe

Fig. 1, Freightliner Warning System Wiring Diagram (key off)

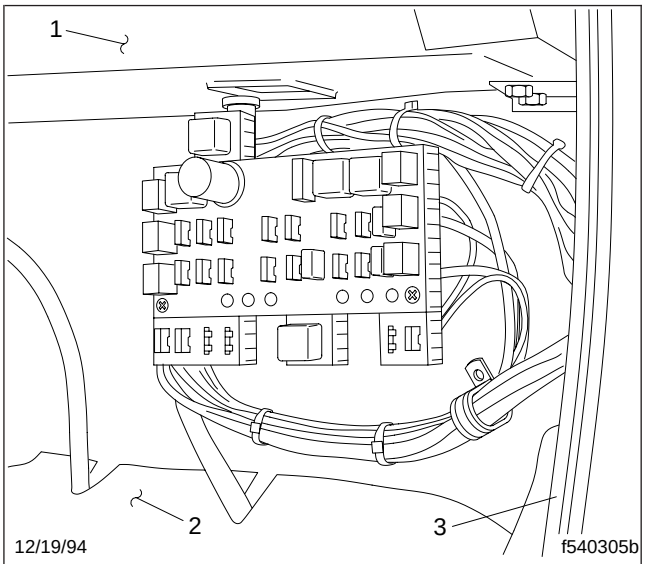


General Information

A 21.5 by 28 cm (8-1/2 by 11 inch) clear-coated white vinyl card, with the standard vehicle wiring diagram printed on one side, and the wire number code identification printed on the other, is placed in the storage console of each vehicle. This standard vehicle wiring diagram is shown in **Specifications, 400**. It shows the wiring circuits for all standard and standard-option electrical components and systems. Wiring diagrams that cover specific systems are included in Specifications, 400, of the applicable sections throughout this service manual.

The wire number code identification is shown in a table in **Specifications, 400**. It is a listing by circuit number of the vehicles' standard and standard-option electrical components and systems, with a brief circuit description for each.

Most of the vehicle wiring is included in just three major wiring harnesses: the engine harness (varies by engine), the chassis harness, and the main cab harness. A fourth major wiring harness is used with vehicles having an electronic engine. The main cab harness is joined to the engine harness(es) and the chassis harness at two (or, three for electronic engines) 28-pin bulkhead connectors attached to a junction plate on the passenger's side of the firewall. See **Fig. 1**. Additional harnesses are used for variable and optional components. The insulation on each wire is marked every two to three inches with its circuit number. All exterior wiring connections use weather-proof Metri-Pack® connectors.



On vehicles with left-hand drive, the electrical power center, containing the relays and fuses or circuit breakers, is located on an expandable panel under the passenger-side of the dash, near the 28-pin frontwall harness connectors. On vehicles with right-hand drive, the electrical power center is located under the center dash skirt panel. See **Fig. 2** for a typical electrical power center. Standard protection for circuits is provided by plug-in blade-type fuses; optional protection is by automatic-reset circuit breakers. For identification of all fuses, circuit breakers, and relays, see **Specifications 400**.

1. 28-pin Chassis Connector (to main cab harness connector inside cab)
2. Junction Plate
3. 28-pin Engine Connector (to main cab harness connector inside cab)
4. Power (positive) Stud
5. Ground Stud
6. Magnetic Switch
7. 28-pin Electronic Engine Connector (to main cab harness connector inside cab)
8. Bulkhead (passenger-side of engine compartment)

Repair and Replacement

IMPORTANT: Before you repair or replace any damaged electrical system parts, find and correct the cause of the damage; otherwise it could occur again.

Wiring insulation can be damaged from heat (internal or external), chafing, kinking, breaking, cracking, or saturation with oil or grease.

Discolored wire insulation (brown) is caused by long-term overheating of the wire itself. Melted insulation is usually caused by an external heat source.

Repair or replace damaged wiring. The choice depends on the type of damage and the wire size. **See Table 1 .** If the wire is 12 gauge or larger, replace it.

Type of Damage	Remedy
Broken wire	Repair or replace *
Kinked wire	Replace
Oil-soaked insulation	Replace
Cracked insulation	Repair if minor, otherwise replace
Melted insulation	Replace
Worn or missing insulation	Repair or replace †
Discolored insulation	Replace

* Repair the break by soldering the two broken ends together, if there is enough slack in the wire; otherwise solder in a new section of wire. See "Repairing Broken Wire" for instructions.
† Repair the damage if the area is two inches (51 mm) or less in length; otherwise, replace the section of wiring.

Table 1

REPAIRING DAMAGED WIRE INSULATION

1. Using shrink tubing, cover the damaged area. Overlap the damaged area at least 3/4 inch (20 mm) on both sides.

IMPORTANT: Don't repair the insulation if the wire underneath is also damaged. Remove and replace the damaged section.

2. If the insulation is chafed, find the source of chafing, and reroute the wiring away from it. If this isn't possible, either cover the sharp edge with protective vinyl trim 48–02188–001, or use convoluted tubing to protect the insulation.
3. Cover the repaired section of wiring with plastic convoluted tubing.

REPLACING DAMAGED WIRE

⚠ CAUTION

CAUTION: Never replace a wire with a smaller gauge wire. Wire gauge is selected by electrical load and current capabilities, and overheating may occur if a wrong gauge wire is used.

1. Replace damaged wire using a solder splice. See "Repairing Broken Wire" for instructions. Use only solder splices. If the damaged wire is 12 gauge or larger, replace the entire section of wire.
2. If the insulation has been discolored, find out what is causing the wire to overheat, and correct it.
3. If the insulation has been melted, check the routing of the wiring and find the problem. Reroute the wiring if possible, and secure it with clamps. If rerouting is not possible, use a heat shield to protect the wire.

REPAIRING ELECTRICAL CONNECTIONS

1. Find the cause of the damage or corrosion, and correct the problem.
2. Clean corroded connectors with a wire brush, using a solution of baking soda and water. Replace any damaged connectors.
3. Spray any exposed connectors (such as ground terminals) with dielectric red enamel. **See Table 2** for approved brands.

Material	Approved Brand(s)
Dielectric Red Enamel Spray	3-M® 1602
	IVI® Spray-Sealer
	Spray-On® B-6-665

Table 2

Wiring Repair and Replacement

REPAIRING BROKEN WIRE

IMPORTANT: The following procedure is the only approved method of repairing broken wires on Freightliner vehicles. This procedure (solder splicing) is done using solder repair kit ESYES66 404, and is for 14-or 16-gauge wire. Don't repair wire that is 12 gauge or larger; replace it.

1. Strip the ends of the wire to be repaired. Make sure the stripped ends are 3/8-to 1/2-inch (10-to 13-mm) long.
2. If repairing an exterior wire, slip a 3-inch (75-mm) long piece of shrink tube over one end of the wire. **See Fig. 1** , Ref. 4.
3. Slip a solder sleeve from kit ESYES66 404 over one end of the wire. **See Fig. 1** , Ref. 3.
4. Using a suitable crimp tool and a crimp splice from the kit, crimp the ends of the wire as follows **(see Fig. 2):**
   - 4.1 Insert a stripped wire end into the crimp splice until it touches the wire stop (Ref. 1) in the middle of the crimp splice.
   - 4.2 Center the crimping tool between the wire stop and the end of the crimp splice, then crimp the wire.
   - 4.3 Repeat steps for crimping the other wire end.
5. Check the crimp, making sure the crimping tool impression is on both ends of the crimp splice.
6. Slide the solder sleeve over the crimp splice so the solder ring is over the center of the crimp splice **(see Fig. 3),** then apply 250°F (121°C) heat until the solder flows into the splice crimp, and the plastic sleeve has shrunk completely against the wire.
7. If shrink tubing was installed to repair an exterior wire, slide it over the splice; then apply 250°F (121°C) heat to it until it's completely shrunk against the wire insulation. Some of the sealant material should be bubbling out from the ends of the shrink tube.

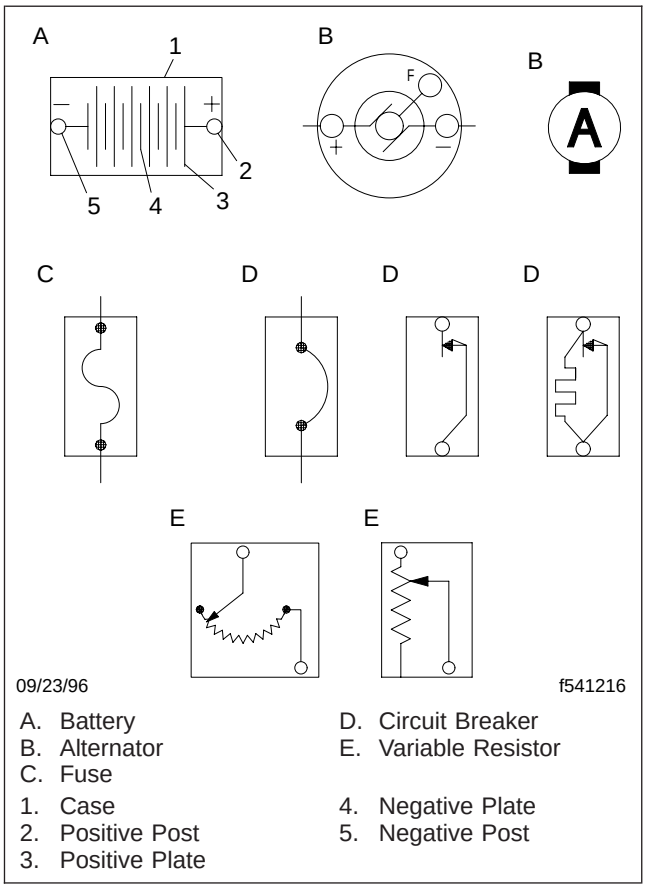
A Vehicle Electrical System – The Basics

NOTE: This subject is intended to provide a brief review of the electrical symbols and theory necessary for basic troubleshooting. For comprehensive coverage of electrical theory and practice as it applies to motor vehicles, refer to Freightliner Self-Paced Training Basic Electricity Units SDF–006 (Volts, Ohms & Amps), SDF–007 (Magnetism), SDF–008 (Symbols & Diagrams) & SDF–009 (Terms).

The vehicle electrical system can be divided into four basic categories: power suppliers, power controllers, directional controllers, and appliances. Every system has these four categories, in one form or another.

Power Suppliers



Everyone knows that the battery (see **Fig. 1**, Ref. A for symbol) is a very important source of electrical power in a motor vehicle. A typical battery (wet cell) is an electro-chemical device consisting of metal plates (usually lead) and an acid-water solution (sulfuric acid). The battery has both positive and negative plates, which are stacked together like a deck of cards, but not allowed to touch each other. The chemical reaction that takes place inside the battery results in an electron build-up on one set of plates, and an electron deficit on the other set of plates. The electrons will follow any available pathway to get from one set of plates to the other.

The alternator (Ref. B), on the other hand, converts mechanical power supplied by the engine into electrical power. The alternator produces power whenever the engine is running, to operate lights, motors, etc., and also to keep the battery fully charged.

There may be other "power suppliers" in the vehicle electrical system, too, but they are something different and we won't discuss them here. Basically, they take power supplied by the battery/alternator and modify it somehow (usually reduce the voltage) for use in an electronic subsystem (like engine control or ABS).

Power Controllers

Power controllers such as fuses and circuit breakers (Refs. C and D) are the "safety valves" in an electrical system. If too many electrons flow through the

4. Negative Plate
5. Negative Post

Fig. 1, Symbols, Power Suppliers and Controllers

fuse or circuit breaker, it gets hot and either melts (fuse) or its contacts open (circuit breaker) to open the power pathway in a controlled manner. The fuse or circuit breaker is the built-in "weak link" in a circuit; it is supposed to interrupt the flow of electrons before other parts of the circuit are damaged.

The rheostat or variable resistor (Ref. E) is also a power controller. A rheostat is a device that is specifically designed to reduce electron flow (current) in a circuit. A good example of a common rheostat is the instrument panel illumination bulb dimmer (I/P dimmer, for short). The I/P dimmer takes battery voltage and, by restricting the flow of electrons, reduces the voltage available "downstream" of the rheostat. So, as you increase rheostat resistance by twisting the I/P dimmer knob, you lower voltage to the illumination bulbs and they burn less brightly.

Troubleshooting

Directional Controllers

The electrons stored on the battery plates need pathways to complete their circuit. The vehicle electrical system provides pathways in the form of wires, terminals, the cab, the frame, component cases or housings, and even fasteners (screws, bolts, washers). The important thing about pathways is that they provide very easy routes for the electrons to take; very little energy is lost or consumed as the electrons travel along. The materials most commonly used as power pathways are copper (wiring), aluminum (cab structure, frame rails, component housings), steel (cab structure, frame rails), and cast iron (engine block, transmission case).

It's not desirable or practical to operate all electrical equipment at the same time. For instance, you want the starting motor to operate only when starting the engine, and you want to be able to turn off the headlights. Switches and relays (see **Fig. 2**, Refs. A and B for symbols) work like drawbridges, closing and opening to allow and interrupt the flow of electrons in a circuit. Typically, switches are used in low power circuits, and relays are used in moderate to high power circuits.

Appliances

Appliances are the reason we create power sources, power controllers, and directional controllers — we want electrons to go somewhere and do something for us. Electric motors, light bulbs, heating elements (for mirrors), solenoids, solid-state devices (like radios and control modules), and gauges (see Refs. C to H for symbols) all do something for us when they use those electrons. Electric motors turn shafts, light bulbs provide illumination, heating elements melt ice or evaporate condensation, solenoids provide linear motion, etc. From an electrical standpoint, appliances fit into our discussion here because a large voltage drop occurs as the electrons travel through the appliance.

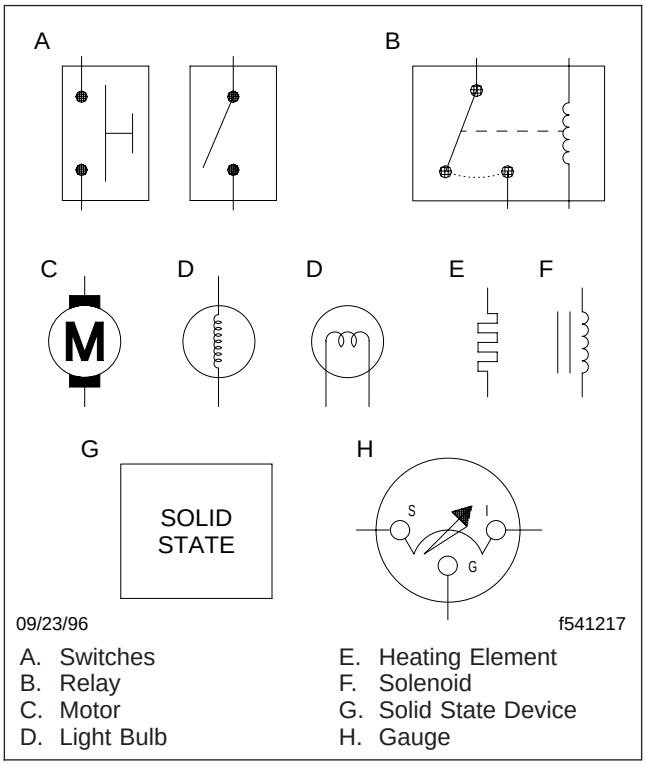

Fig. 2, Symbols, Directional Controllers and Appliances

Troubleshooting Tools

Here are some of the tools used during electrical troubleshooting:

Voltmeter

A DC voltmeter (see **Fig. 3**) is used to measure circuit voltage. Connect the black (–) lead to ground and the red (+) lead to the place where you want to measure voltage.

Ohmmeter

An ohmmeter (see **Fig. 4**) is used to measure circuit resistance and check continuity. When checking circuit resistance, the circuit's normal power source must be removed by disconnecting the battery or pulling a fuse or circuit breaker. If this isn't done, there's a good chance that the ohmmeter will be damaged.

A battery inside the ohmmeter supplies the voltage necessary to make resistance measurements.

Volt-Ohm-Milliammeter (VOM)

The VOM is simply three separate devices combined into one. It's a voltmeter, an ohmmeter, and an ammeter. Typically, you operate a rotary switch on the VOM to select the type of measurement you want to make; when measuring current flow (ammeter function) you often have to connect the positive (+) lead to a different port on the VOM.

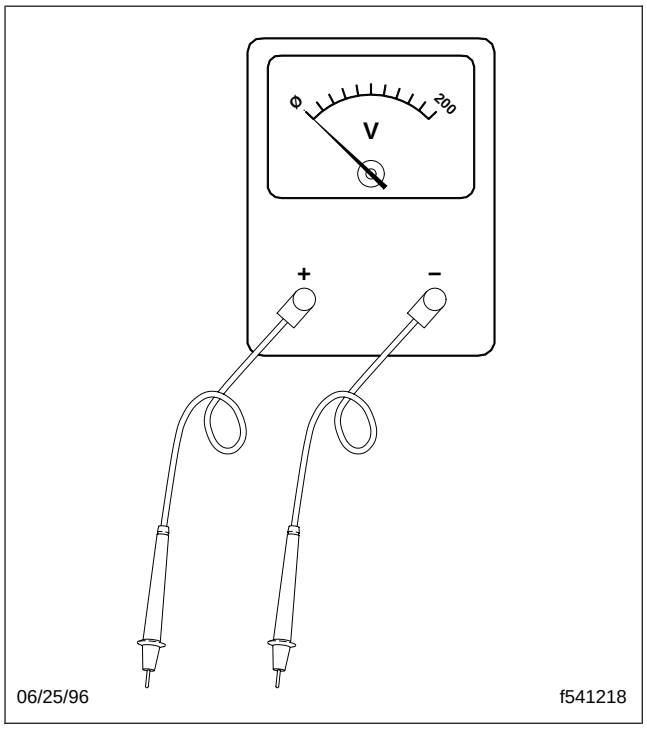

Fig. 3, Voltmeter

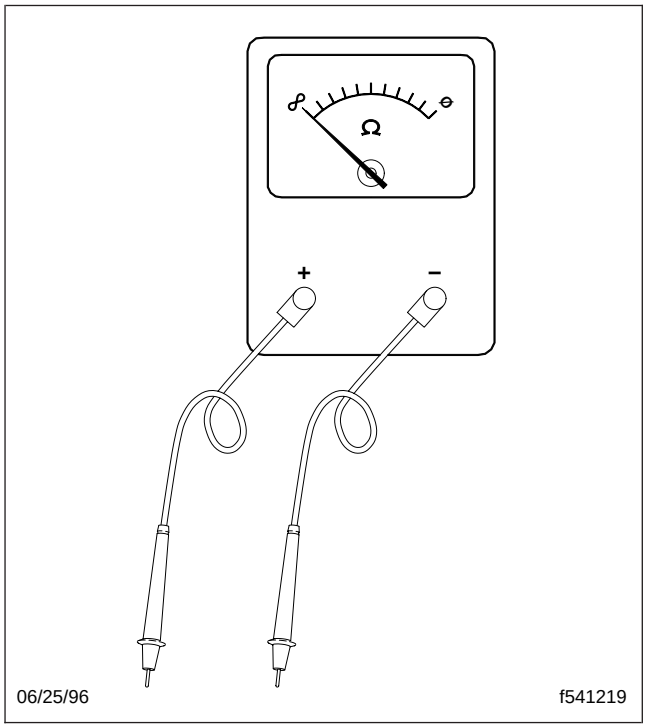

Fig. 4, Ohmmeter

A very common modern alternative to the VOM is the Digital Volt-Ohm Millammeter or DVOM. See **Fig. 5**. This tool is a solid-state version of the VOM and usually has a large, easy to read, digital LCD display instead of a needle.

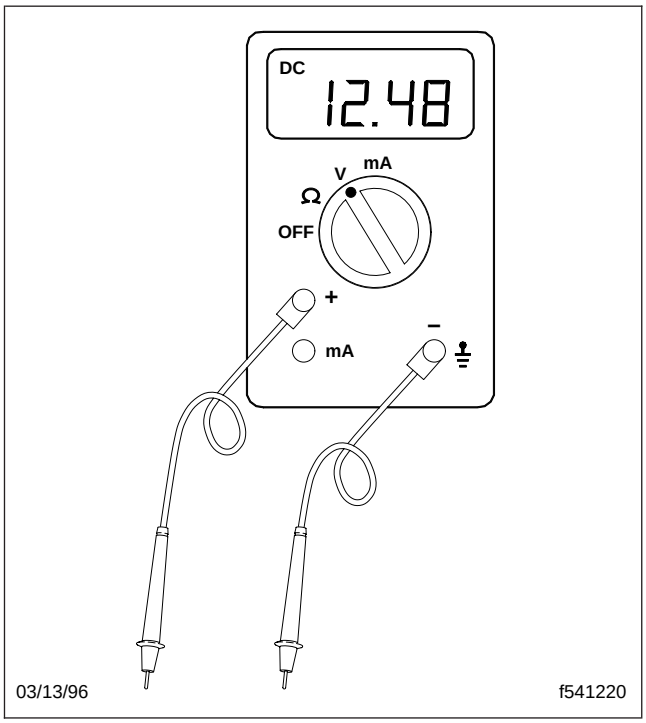

Fig. 5, Digital Volt-Ohm-Milliammeter (DVOM)

Jumper Wire

A jumper wire (see **Fig. 6**, Ref. A) is simply a length of wire with an alligator clip or test probe at each end. You can use a jumper wire to connect two points of a circuit, bypassing (or jumping over) fuses, switches, etc.

NOTE: Never connect a jumper wire across an appliance! This would be a short circuit from battery to ground and could cause an injury or a fire.

Actually, it's a good idea to use a fused jumper wire (Ref. B) at all times. That way an accidental short will blow the fuse, protecting both you and the rest of the circuit.

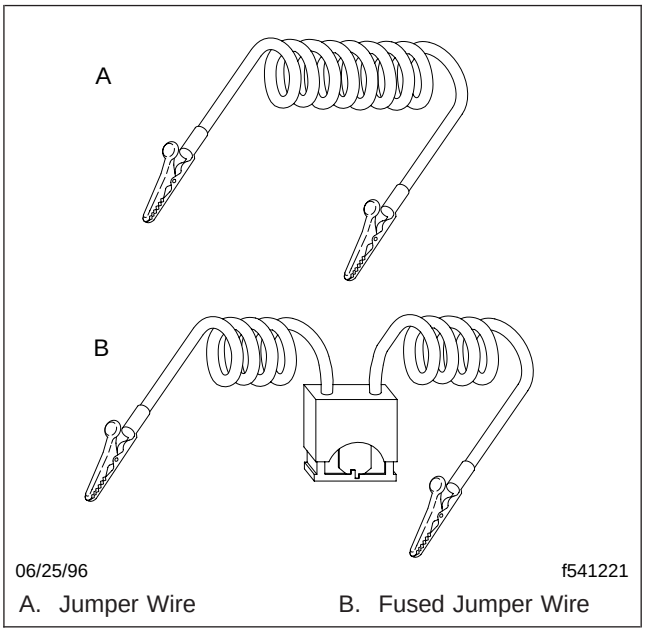

Fig. 6, Jumper Wires

Test Lamp

A test lamp (see **Fig. 7**) is a 12V (or 24V, if appropriate) light bulb with a length of wire attached to each terminal. The test lamp can be used for quick, but imprecise, voltage checks.

Typically, the bulb is enclosed in a clear plastic handle (screwdriver-like) with a pointed metal probe coming out one end and a wire coming out the other end. Clamp the wire to a good ground and touch the metal probe to the desired test point. If enough voltage is present, the bulb will illuminate.

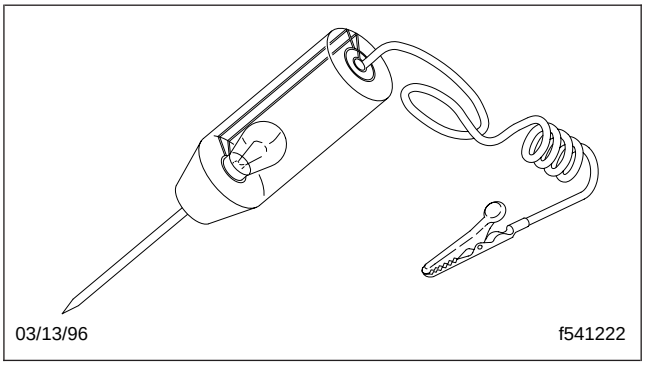

Fig. 7, Test Lamp

A Sample Circuit

See **Fig. 8** for a sample circuit. Notice that every one of the categories discussed previously is present: power supplier (the battery, Ref. A), power controller (the circuit breaker, Ref. B), directional controllers (wiring and switch, Ref. C), and appliance (electric motor, Ref. D). This kind of circuit is called a series circuit; all the parts are arranged, one after the other, in series. There's only one possible path the electrons can take. This is a simple circuit, but it is also typical.

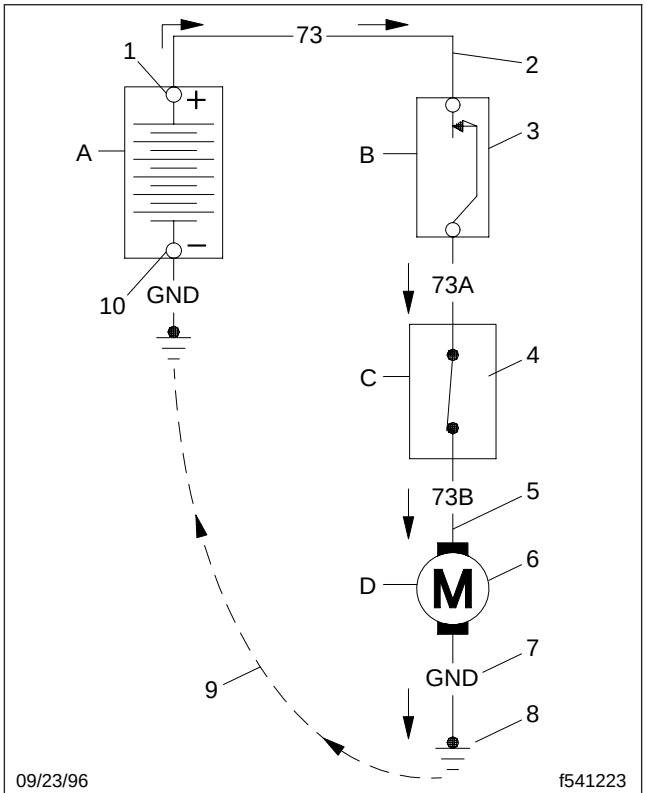

Fig. 8, Sample Circuit Number One

The circuit starts at the battery positive terminal (Ref. 1) follows wire 73 (Ref. 2) to the circuit breaker (Ref.

3), and continues on to the switch (Ref. 4). When the switch contacts are closed, the circuit continues through the switch and wire 73B (Ref. 5) to the electric motor (Ref. 6). So long as the motor is operative (isn't damaged or burned-out) the circuit continues through the motor to the GND wire (Ref. 7) and on to the chassis ground point (Ref. 8). Although it isn't usually shown on a schematic, the circuit actually continues through chassis metal (Ref. 9) back to the battery negative terminal (Ref. 10).

Troubleshooting the Sample Circuit

To find out what's wrong if the switch is closed, but the motor doesn't run, work around the circuit, checking for voltage at key points. If voltage is present, keep going; if voltage isn't present, find out why:

Is the battery dead? Check battery voltage using a voltmeter. See **Fig. 9**. Connect the voltmeter red (+) lead to the battery (+) terminal and the voltmeter black (–) lead to the battery (–) terminal. Voltage should be at least 12 volts. Low or no voltage could mean that there is corrosion between the battery post and terminal. If the battery terminals are loose or obviously corroded, fix them. If not, loosen the clamp bolts and disconnect the terminals. Soft, shiny or greyish metal should be present on both the battery post and the inside of the terminal, not hard, dark and scaly metal. Clean the battery posts and the terminals, if necessary. If the terminal connections seem to be okay, the battery needs to be charged, or the battery should be replaced.

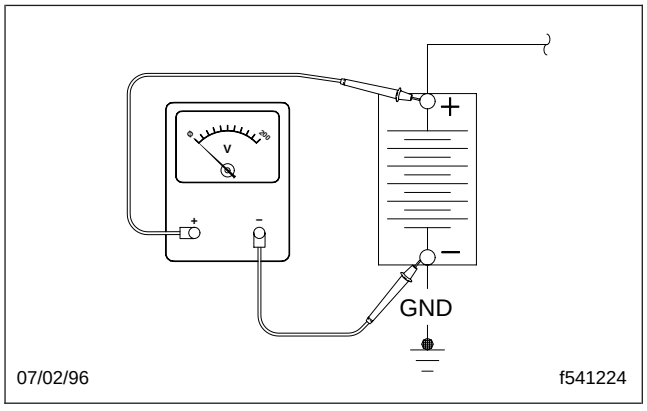

Fig. 9, Checking Battery Voltage

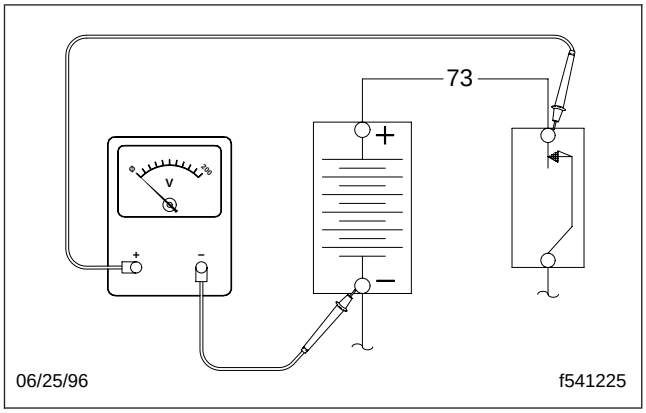
Is battery voltage present at the circuit breaker? Check, using a voltmeter. See **Fig. 10**. Connect the voltmeter red (+) lead to the circuit breaker (the side fed by the battery) and the voltmeter black (–) lead to the battery (–) terminal. Again, voltage should be at least 12 volts. If it isn't, the problem may be a broken wire 73, or an inadequate or damaged crimp where a wire terminal is connected to wire 73 (see **Fig. 11**).



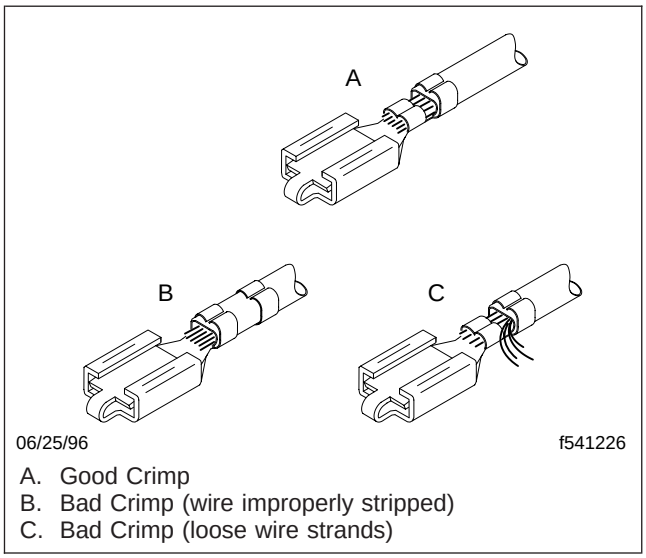


Fig. 10, Voltage Check at Circuit Breaker

A. Good Crimp
B. Bad Crimp (wire improperly stripped)
C. Bad Crimp (loose wire strands)

Fig. 11, Good and Bad Crimps

Is battery voltage present at the other end of the circuit breaker? See **Fig. 12**. If not, the circuit breaker is faulty and should be replaced.

Is battery voltage present at the switch? See **Fig. 13**. If it isn't, possible causes again include a broken wire or inadequate/damaged terminal crimps.

Is battery voltage present at the switch outlet when the switch is closed? See **Fig. 14**. If not, the switch is faulty and should be replaced.

Troubleshooting

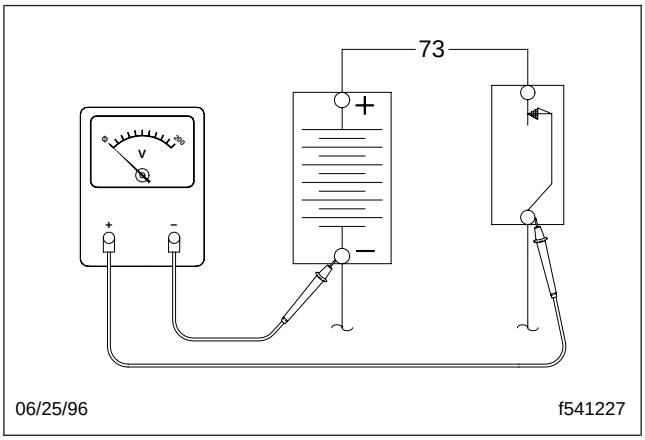

Fig. 12, Voltage Check after Circuit Breaker

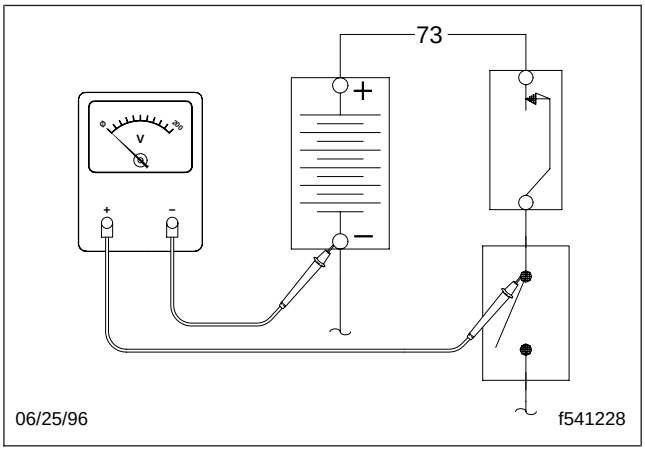

Fig. 13, Voltage Check at the Switch

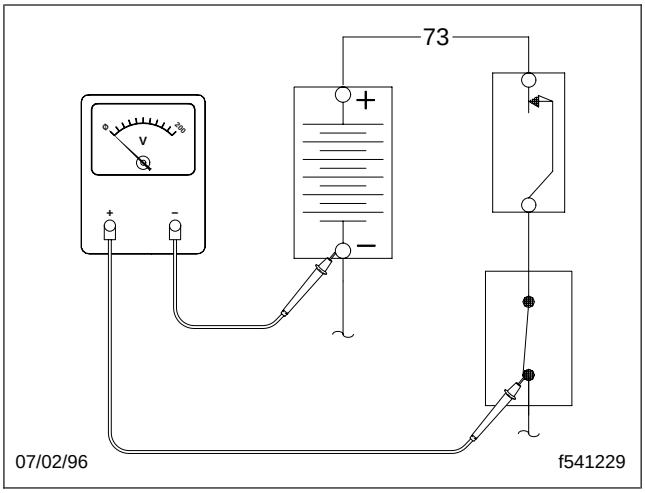

Fig. 14, Voltage Check after the Switch

Is battery voltage present at the motor? See **Fig. 15**. If not, wire 73B could be broken or an inadequate/ damaged terminal crimp could be the cause.

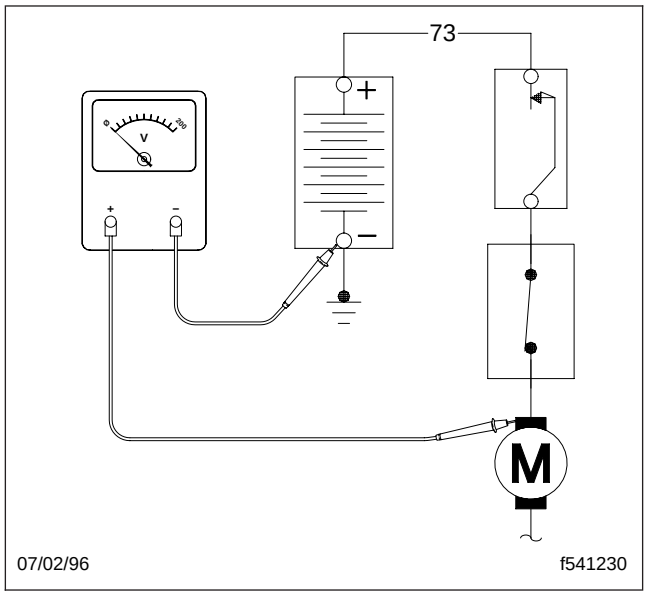

Fig. 15, Voltage Check at the Motor

Is the motor obviously damaged or burned-out? If it is, replace it. If it doesn't appear to be, continue troubleshooting.

If voltage is present at all the points mentioned above, perhaps the ground circuit is faulty. Note that voltage tests are performed only on parts of the circuit that appear before the appliance. This is because a large voltage drop occurs across the appliance and, unless you know exactly what voltage should be present after the appliance, a voltage measurement won't be very meaningful.

The most commonly used method for troubleshooting ground circuits is checking circuit resistance with an ohmmeter.

NOTE: One very important thing to remember when checking circuit resistance with an ohmmeter is that voltage must not be present in the circuit being tested, or the ohmmeter will be damaged. A battery inside the ohmmeter provides all the voltage necessary to make the resistance measurement. Make sure the appropriate power switch for the circuit being tested is off. For circuits receiving battery voltage all the

time, shut off power using the main disconnect switch or, if necessary, disconnect the batteries.

Check circuit resistance between the GND wire terminal and the vehicle frame or body. See **Fig. 16**. Resistance should be very low; usually less than one ohm for this type of connection. If resistance is more than five ohms, there is a problem that needs to be corrected. The cause could be a loose screw securing the terminal to the frame or body, or corrosion between the terminal and the frame or body. Make sure that the bare metal of the frame or body is exposed at the ground point — paint, rust, grease, and dirt can act as an insulator, causing high resistance.

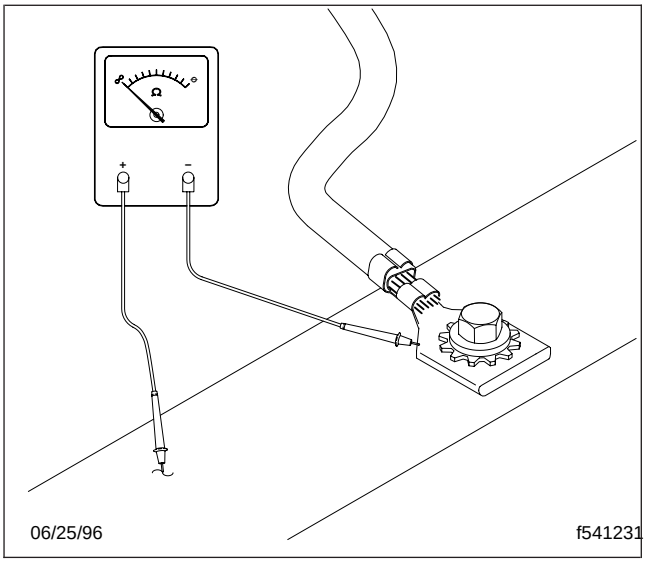

Fig. 16, Resistance Check at the Ground Point

Check circuit resistance between the motor ground terminal and the vehicle frame or body. See **Fig. 17**. Again, resistance should be very low — if it is more than 5 ohms, there's a problem. Inspect for damaged or inadequate crimps where a wire is connected to a terminal. See **Fig. 11**. Check for corrosion at connections and check for a damaged wire.

At some point during the steps outlined above, you should have discovered the cause of the problem. If you didn't, the motor may be malfunctioning; replace it. If the new motor doesn't work, go back to the beginning, checking voltage and resistance readings again.

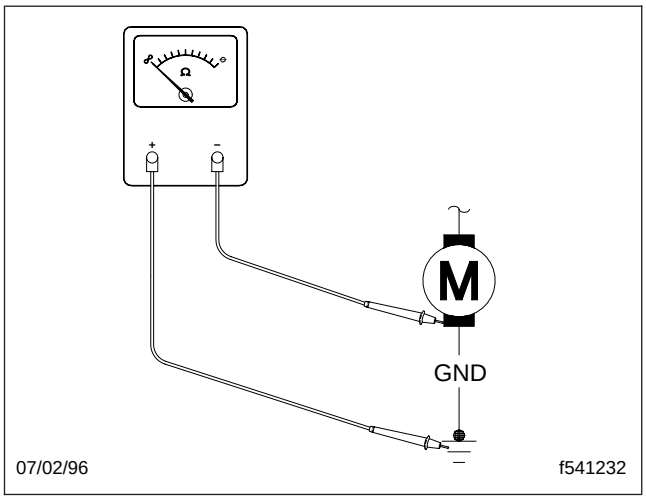

Fig. 17, Resistance Check of Ground Circuit

Short Cuts

Sometimes, it may be very difficult to access voltage measurement points in the circuit. In those cases, it makes sense to check the easy-to-access points first, regardless of their position in the circuit; check the battery terminals, fuse, and motor.

Or, check voltage at the motor first with the switch turned on; if voltage is present at the motor, it must be present at the battery, circuit breaker, and switch, so you can skip those voltage tests.

The same strategy applies to the resistance tests; if low resistance is measured between the motor and the frame, there's no point in measuring resistance between the GND wire terminal and the frame. Use short cuts whenever it makes sense, not just when access to a component is a problem.

Troubleshooting Steps

Take an orderly approach to electrical troubleshooting. Follow the same set of steps every time to improve your chances of a quick, accurate diagnosis:

Step 1 – Verify that the problem exists.

Using information provided by the owner/operator of the vehicle, operate the system and see all the symptoms for yourself. The owner/operator complaint may be inaccurate or misleading. Also, you may no-

tice symptoms that the owner/operator didn't notice or didn't think were important enough to report.

Step 2 – Narrow down the possible causes of the problem.

Perform basic checks to quickly eliminate possible causes. Are the battery terminals loose or corroded? Is the alternator belt loose? Any obvious damage to the vehicle? Blown fuses? Loose or corroded ground wires? Lenses showing that moisture is trapped inside a lamp?

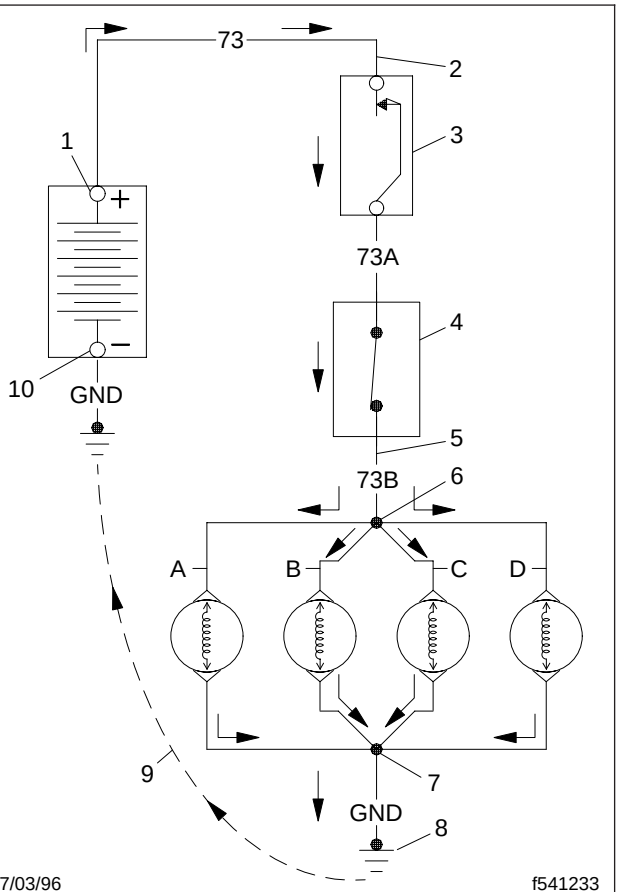
If you don't find anything, check the wiring schematics or service bulletins for clues. What other component/system shares a fuse/circuit breaker or ground point with the faulty component/system? Is that component/system operating properly?

Step 3 – Test for the cause of the problem.

Use the appropriate test equipment and procedures to zero in on the cause of the problem. Check for voltage. Check for continuity. Check for appropriate resistance values. Check for appropriate current flow.

Step 4 – Verify that you have located the cause of the problem.

If you think a switch is faulty, use jumper wires to bypass the switch and verify that the component now operates. Likewise for a suspected bad ground - run a jumper directly from the component to the frame or cab. If you think that one shorted lamp is blowing a fuse or tripping a breaker, disconnect that lamp and verify that the rest now operate normally. Connect a known good component without actually removing the old one, if possible — does the component operate?



Step 5 – Make the necessary repairs.

Perform any repairs or parts replacement necessary.

Step 6 – Verify that the problem is gone.

Operate the system to make sure that all symptoms are gone. Just as important, make sure that no new symptoms have appeared.

Fig. 18, Sample Circuit Number Two

The following circuit (see **Fig. 18**) is a little more complicated than the first one. This one includes parallel circuits. Most of the parts in the circuit are arranged, one after the other, just like the parts in the series circuit we looked at earlier. The light bulbs, however, aren't arranged one after the other; they appear side by side or "in parallel."

In parallel circuits, the electrons are not limited to following just one path back to the battery — they

can follow any of several parallel paths. Many vehicle illumination circuits are parallel circuits where several bulbs come on at the same time.

So, the circuit starts at the battery positive terminal (Ref. 1) follows wire 73 (Ref. 2) to the circuit breaker (Ref. 3), and continues on to the switch (Ref. 4). When the switch contacts are closed, the circuit continues through the switch and wire 73B (Ref. 5) to the splice (Ref. 6). Up to this point we've been tracing a series circuit.

Assuming that resistance in each of the bulb circuits is equal, an equal number of electrons will travel down each of the four bulb circuits (Refs. A, B, C, & D). If all the light bulb filaments are intact (none of the bulbs are burned-out), electrons travel through the bulbs and their individual GND wires to the ground splice (Ref. 7) and on to the chassis ground point (Ref. 8). Although it isn't usually shown, the circuit actually continues through chassis metal (Ref. 9) back to the battery negative terminal (Ref. 10).

Troubleshooting the Sample Circuit

Let's look at two possible circuit failures — none of the bulbs illuminate when the switch is closed, and some, but not all, of the bulbs illuminate when the switch is closed.

None of the Bulbs Operate — if none of the bulbs illuminate, it's very possible that the problem is in the series part of the circuit — the part of the circuit that is just like the circuit we looked at earlier. So, the troubleshooting steps are exactly the same. Work around the circuit, checking for voltage at key points. If voltage is present, keep going; if voltage isn't present, find out why. Review "A Sample Circuit" if necessary.

Unlike the first sample circuit in which we checked for voltage at the electric motor, this sample circuit has an extra "component" — the splice which feed the individual bulb circuits. Check for battery voltage at the splice. See **Fig. 19**. If battery voltage isn't present, wire 73B could be broken or an inadequate/ damaged terminal crimp could be the cause.

If voltage is present at the splice, lack of voltage is not likely to be the cause of the problem, since the splice is the transition point between the series circuit and the parallel circuit. If voltage is present at the splice, that would mean that all four circuits leading to the bulbs would have to be faulty or all four bulbs would have to be burned out and that's unlikely.

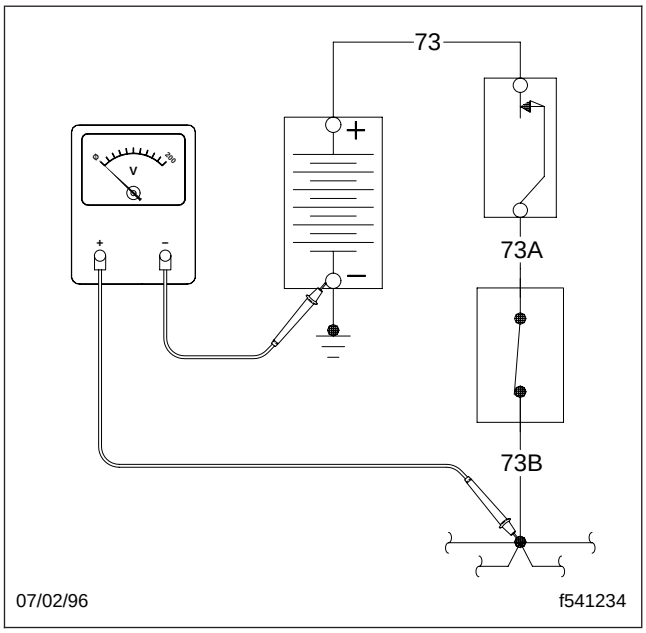

Fig. 19, Checking for Power at the Splice

Check the ground circuit instead. Review "A Sample Circuit" if necessary.

NOTE: Remember, when checking circuit resistance with an ohmmeter, voltage must not be present in the circuit being tested, or the ohmmeter will be damaged. A battery inside the ohmmeter provides all the voltage necessary to make the resistance measurement. Make sure the appropriate power switch for the circuit being tested is off. For circuits receiving battery voltage all the time, shut off power using the main disconnect switch or, if necessary, disconnect the batteries.

The ground circuit of this sample circuit, like the power circuit, has an extra "component," and it's the ground splice. Check circuit resistance between this ground splice and the vehicle frame or body. See **Fig. 20**. Again, resistance should be very low — if it is more than 5 ohms, there's a problem. Inspect for damaged or inadequate crimps where a wire is connected to a terminal and check for a damaged wire.

If you still haven't found the cause, check the individual bulb ground circuits that run between each bulb and the ground splice. But if none of the bulbs are working, it means that all four of the circuits are faulty (which is very unlikely).

Troubleshooting

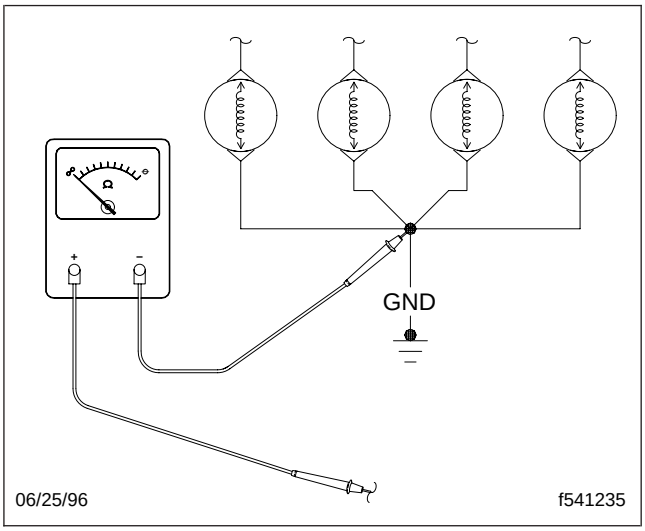

Fig. 20, Checking the Shared Ground Circuit

Check resistance between each bulb socket ground terminal and the ground splice. See **Fig. 21**. Resistance between each terminal and the splice should be very low.

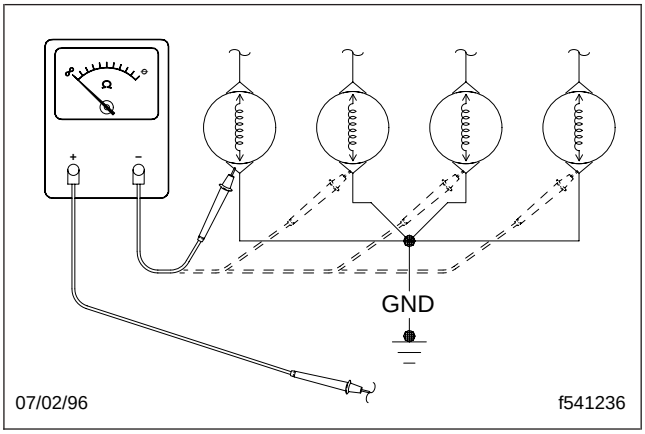

Fig. 21, Checking the Individual Ground Circuits

Some, But Not All of the Bulbs Operate — This kind of failure is a lot easier to troubleshoot since most of the possible circuit faults are immediately eliminated.

If even just one of the bulbs is operating, you can skip voltage tests all the way up to the circuit 73B splice; if one of the bulbs is operating, voltage must be reaching the splice. And, you can assume that the shared ground circuit between the ground splice and the actual ground point is also intact for the same reason.

The problem, then, must be in the individual power or ground circuits for each non-functioning bulb, or the bulb itself.

So, check for battery voltage at the circuit 73B terminal for each of the non-functioning bulbs. If battery voltage is present, use the DVOM to check resistance between the bulb socket ground terminal and the ground splice.

Specifications

To identify circuit numbers, see **Table 1** for circuits 1 through 61A. See **Table 2** for circuits 71 through 319, and see **Table 3** for circuits 320 through 503.

To identify fuses, relays, and circuit breakers on vehicles with left-hand drive (LH DR), see **Table 4** for positions 1 through 25 and **Table 5** for positions 26 through 50.

To identify relays and circuit breakers on vehicles with right-hand drive (RH DR), see **Table 6** for positions 1 through 29 and **Table 7** for positions 30 through 55.

See **Fig. 1** for a standard vehicle wiring diagram. For detailed (partial) views of the standard vehicle wiring diagram, see **Fig. 2** or **Fig. 3**.

See **Fig. 4** for the revised (as of April 3, 1998) standard left-hand-drive (LH DR) vehicle wiring diagram. For detailed (partial) views of the revised (as of April 3, 1998) standard (LH DR) vehicle wiring diagram, see **Fig. 5** or **Fig. 6**. See **Fig. 7** for the revised (as of April 3, 1998) standard (LH DR) vehicle wiring diagram wire code numbers.

See **Fig. 8** for the right-hand-drive (RH DR) vehicle wiring diagram. For detailed (partial) views of the RH DR vehicle wiring diagram, see **Fig. 9** or **Fig. 10**. See **Fig. 11** for the RH DR vehicle wiring diagram wire code numbers.

General Description and Principles of Operation

The Kysor warning and engine shutdown system electronically monitors engine oil pressure, coolant temperature, and coolant level. If the oil pressure drops below a preset level, the low oil pressure light comes on, and a warning buzzer sounds. If the oil pressure drops to a preset critical level, the engine shutdown light comes on, and the voltage to the fuel control circuit is interrupted, shutting down the engine.

If engine coolant temperature rises above a preset level, a warning light comes on, and a buzzer sounds. The temperature that triggers the warning light and buzzer varies with engine type. If the temperature continues to rise to critical levels, the engine shutdown light comes on, and the voltage to the fuel control circuit is interrupted, shutting down the engine.

If the coolant level drops below the level of a sensor in the cooling system, the low water level light comes on, and a buzzer sounds. After 30 seconds the system shuts down the engine.

All shutdown features have an automatic override: if it is necessary to move the vehicle to a safe location after a shutdown, just crank the engine— it will run for about 30 seconds and then shut down again.

The Kysor warning and engine shutdown system provides a driver circuit for the temperature gauge. This circuit uses the same temperature sensor as the alarm and shutdown functions.

When the ignition switch is turned on, the engine function light will turn on and the buzzer will sound momentarily.

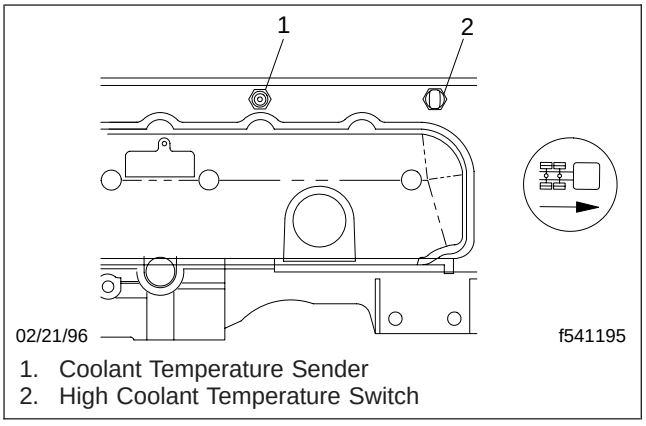
The warning buzzer is triggered by the start circuit. After the engine is cranked, releasing the start switch activates the buzzer. Therefore, during a normal start, the buzzer sounds after releasing the starter until the engine oil pressure and the air pressure reach normal operating values.

Circuit overload protection is built into the Kysor warning and engine shutdown system. If an overload is detected on an output circuit, that par-ticular circuit shuts down. To restore full function, remove the overload; turn the ignition switch off, then on again. Intermittent shorts in the output circuits will cause intermittent false engine shutdown.

Replacement

1. The warning and shutdown control module is located behind the right-side upper dashboard panel, above the electrical center. Access it by removing the rubber trim piece on the right side of the dashboard and the two screws that connect the dashboard cover to the dashboard.
2. Replace the control module.
   - 2.1 Disconnect the 15-pin wiring connector from the warning and shutdown control module.
   - 2.2 Remove the two mounting bolts and the module.
   - 2.3 Position the new module on the mounting bracket then install the two mounting bolts.
   - 2.4 Connect the 15-pin wiring connector.
3. Install the dashboard cover and tighten the screws securely; then install the trim piece.

Replacement

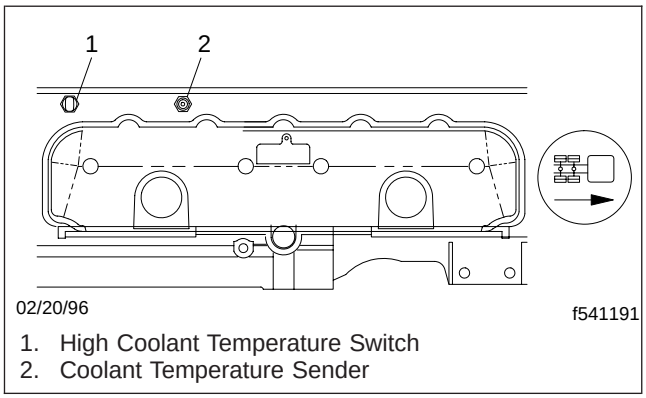


HIGH COOLANT TEMPERATURE SWITCH

1. Turn off the ignition switch and let the engine cool. Remove the surge tank cap to release the system pressure.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.



2. Drain the coolant from the engine.
3. Disconnect wires 18C and 324 from the high coolant temperature switch (see **Fig. 1**, **Fig. 2**, **Fig. 3**, **Fig. 4**, **Fig. 5**, **Fig. 6**, **Fig. 7**, or **Fig. 8**); then remove the switch.

1. Coolant Temperature Sender
2. High Coolant Temperature Switch

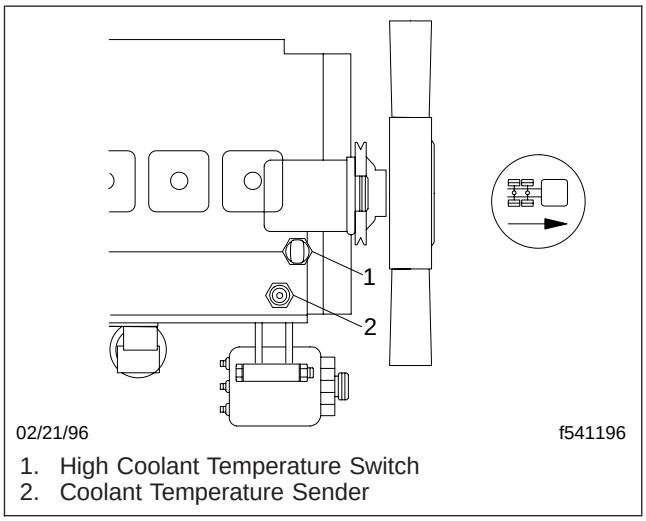


Fig. 1, OM 366LA, Forward-Mounted Coolant Temperature Sender and High Coolant Temperature Switch

4. Install the new switch and tighten it one-half turn past finger-tight. Connect wires 18C and 324 to the switch.
5. Add coolant to the system as needed; then install the cap. Start the engine and check the system to be sure there are no coolant leaks.

1. High Coolant Temperature Switch
2. Coolant Temperature Sender

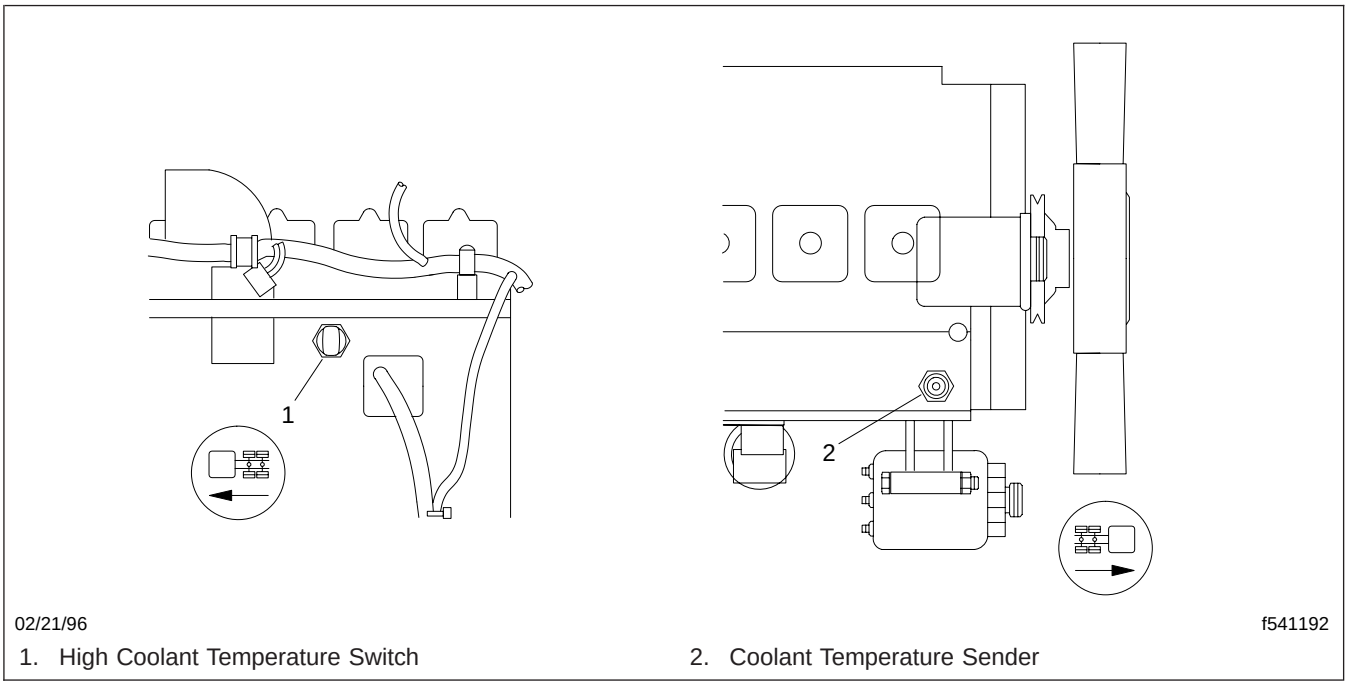
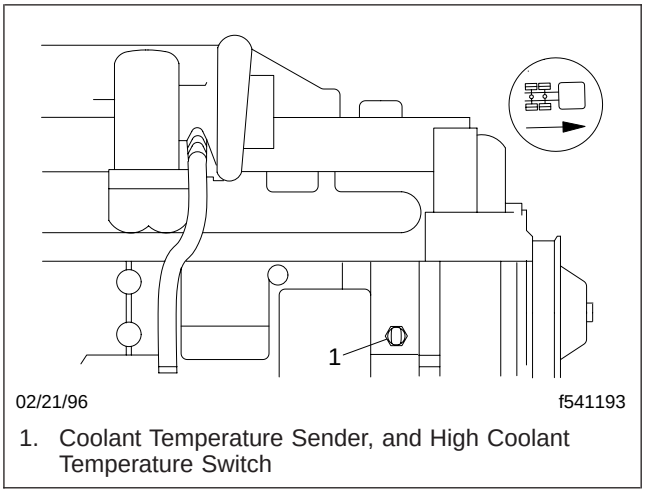
LOW COOLANT LEVEL PROBE



1. Turn off the ignition switch and let the engine cool. Remove the surge tank cap to release the system pressure.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.



2. Drain the coolant from the surge tank.

Switch (Sensor) Replacement

LOW OIL PRESSURE WARNING SWITCH

NOTE: The low oil pressure warning switch is located on a tee on the air-oil manifold located behind the left side of the dash panel. Access it by removing the rubber trim piece and the two screws that connect the dashboard cover to the dashboard.

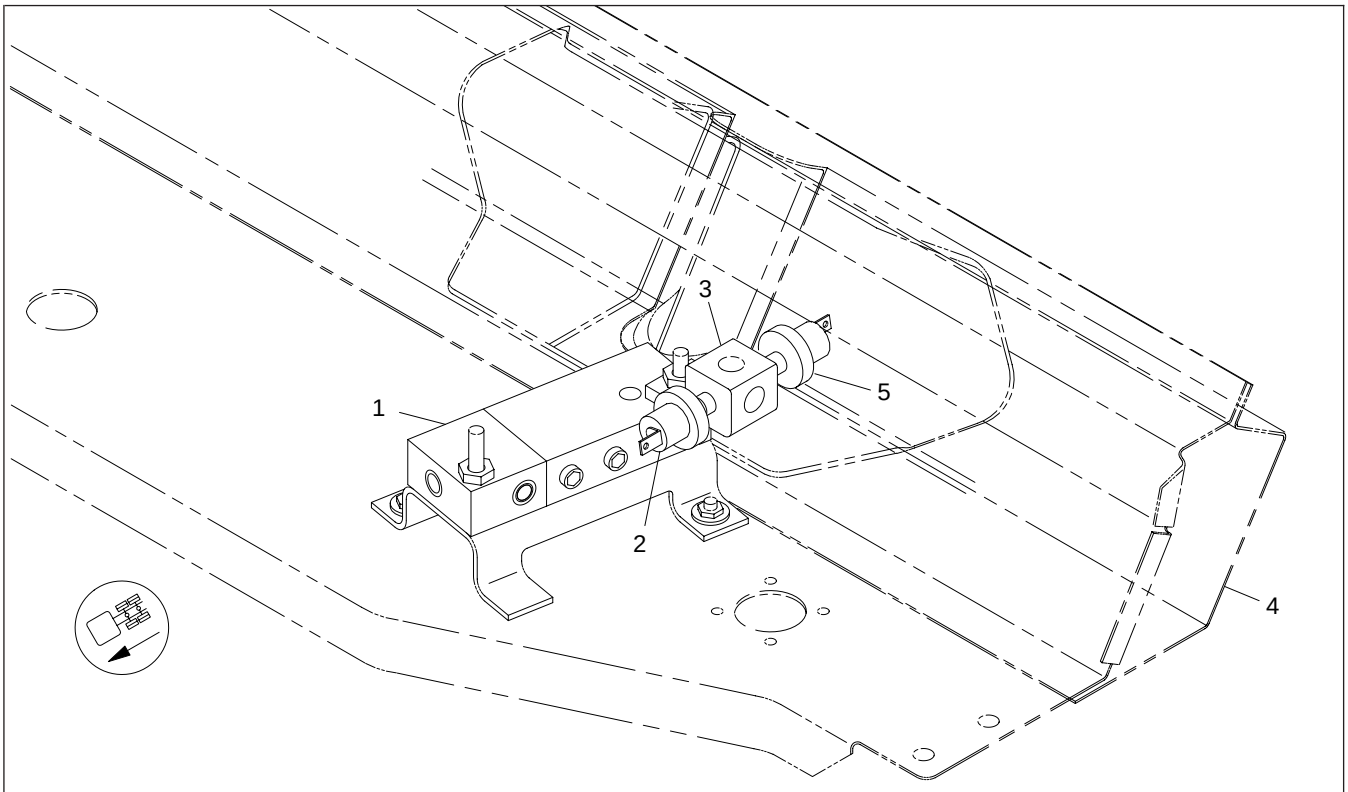
1. Turn off the ignition switch.
2. Disconnect wire 34 from the switch (see **Fig. 10**, Ref. 2), then remove the switch.
3. Install the new switch and tighten it one-half turn past finger-tight. Connect wire 34 to the switch.

11/04/94 f540353a

Note: Some low coolant level probes use a Weather Pack® connector. The low coolant level probe may also have a ground wire attached to its body.

1. Surge Tank
2. Low Coolant Level Probe

Fig. 9, Low Coolant Level Probe



4. Start the engine and check that the warning light and buzzer shut off when the oil pressure reaches approximately 10 psi (69 kPa). Check the system to be sure there is no oil leakage.
5. Install the dash panel.

LOW OIL PRESSURE SHUTDOWN SWITCH

NOTE: The low oil pressure shutdown switch is located on a tee on the air-oil manifold located behind the left side of the dash panel. Access it by removing the rubber trim piece and the two screws that connect the dashboard cover to the dashboard.

1. Turn off the ignition switch.
2. Disconnect wire 325 from the switch (see **Fig. 10**, Ref. 5). Remove the switch.
3. Install the new switch and tighten it one-half turn past finger-tight. Connect wire 325 to the switch.
4. Start the engine and check that the warning light and buzzer shut off when the oil pressure reaches approximately 10 psi (69 kPa). Check the system to be sure there is no oil leakage.

Troubleshooting Procedures

ENGINE PROTECTION FEATURES

The Engine Run switch must be on for the fuel solenoid (or other fuel control) to turn on. The Engine Run switch is controlled by five separate inputs to the Kysor warning and engine shutdown system. The test procedure for each input and an explanation of how each one functions are presented below.

1. *Ignition Switch On*—Connect a voltmeter to the fuel solenoid wire 99, and turn on the ignition switch. The voltmeter should register at least 12 volts for 25 to 35 seconds; then, the voltage should drop to zero.

2. *Starter Engage*—Turn on the ignition switch and measure the voltage as above. After the voltage drops to zero, briefly engage the starter. There should be 12 volts at the fuel solenoid again for 25 to 35 seconds. Then, the voltage should drop to zero. This feature is operated by voltage in wire 150R, which has voltage only when the engine is being cranked.

3. *Coolant Level Sensing*—Disconnect wire 173 from the coolant level sensor in the surge tank. Start the engine. The LOW WTR light and the warning buzzer should be on. The engine should shut down 30 seconds after it starts, and the SHUTDOWN light should come on at the same time.

   Reconnect wire 173 to the coolant level sensor.

   This circuit sends a current through wire 173 to the low coolant sensor. When the circuit is grounded through the coolant, the system interprets this as a normal condition. Excessive coolant loss uncovers the sensor and breaks the circuit to ground. This causes the warning and shutdown control module to turn on the low coolant warning and to shut down the engine. An open circuit in wire 173 causes a false low coolant warning and shutdown. If wire 173 shorts to ground, the protection feature doesn't operate.

4. *Temperature Sensing*—Disconnect wires 18C and 324 from the temperature switch. Start the engine. The overheat indicator light should be on and the warning buzzer should sound. The engine should shut down 20 to 40 seconds after starting, and the SHUTDOWN light should come on at the same time.

   This circuit monitors the temperature switch continuity through wires 324 and 18C. If wire 18C or 324 shorts to ground, the high temperature alarm and shutdown features won't work. The engine could overheat and would probably be damaged.

IMPORTANT: Perform the temperature sensing test at every scheduled vehicle service to ensure that there are no problems with circuit 18C or 324. Reconnect wires 18C and 324 to the temperature switch.

5. *Low Oil Pressure Sensing*

   5.1 Warning Light

   Disconnect wire 34 from the low oil pressure warning sensor. Start the engine. The low oil pressure light should come on and the warning buzzer should sound. Circuit 34 is ground-seeking at the warning switch, which is normally open. The warning switch opens and interrupts the ground to wire 34 if oil pressure falls below the switch setpoint. When wire 34 loses ground, the oil pressure warning turns on, so an open circuit in wire 34 would cause a false low oil pressure warning. A short to ground in wire 34 would prevent the low oil pressure warning from working. This would occur when the ignition switch is first turned on: the low oil pressure symbol would not light until the starter is engaged. During normal start up, the low oil pressure indicator should light and the buzzer should sound when the key is turned on.

   5.2 Engine Shutdown

   Leave wire 34 disconnected from the low oil pressure warning switch. Disconnect wire 325 from the low oil pressure shutdown switch. Start the engine. The low oil pressure symbol and the buzzer should be on. The SHUTDOWN light should come on 20 to 40 seconds after start up, and the engine should shut down at the same time. Circuit 325 is similar to 34 in that it seeks ground through the normally open shutdown switch; if that ground is lost due to low oil pressure or an open circuit, the Kysor warning and shutdown control module shuts down the engine. If

Troubleshooting

circuit 325 shorts to ground, the low oil pressure shutdown feature will not work.

Troubleshooting Table

ENGINE PROTECTION FEATURES

For troubleshooting of the Kysor warning and engine shutdown system, see the following table.

Kysor Warning and Engine Shutdown System Troubleshooting

Kysor Warning and Engine Shutdown System Troubleshooting	
Problem	**Remedy**
The water temperature/oil pressure indicator does not light when engine coolant temperature is high.	Check the indicator bulb, the water temperature switch and wire 18C. See **Fig. 1**.
The water temperature/oil pressure indicator does not light when oil pressure is low.	Check the indicator bulb, the low oil pressure switch and wire 34. See **Fig. 2**.
The water temperature/oil pressure indicator is on when the oil pressure and coolant temperature are normal.	Check the low oil pressure switch, the water temperature switch, wire 34 and wire 18C. See **Fig. 3**.
The engine cranks but will not start. The engine shutdown indicator is on while the starter is cranking.	Check wire 150R, wire 150Q, and wire 373. See **Fig. 4**.
The engine shuts down; the engine shutdown indicator is not on as the engine begins to lose rpm.	Check the fuel solenoid relay, fuel pump and wire 373. See **Fig. 5**.
The engine shuts down with the water level and engine shutdown indicators on.	Check the coolant level switch and wire 173. See **Fig. 6**.
The water level indicator does not come on when the coolant level is low.	Check the coolant level switch and wire 173. See **Fig. 7**.
The engine starts, but the engine shuts down after 20 to 40 seconds.	Check the alarmstat, the oil pressure shutdown switch, wire 324 and wire 325. See **Fig. 8**.
The engine shutdown indictor does not come on when the engine shuts down.	Check the engine shutdown indicator relay. See **Fig. 9**.
The engine shutdown indicator is on, but the engine does not shut down.	Check the engine shutdown relay and wire 373. See **Fig. 10**.
The warning buzzer does not sound with high water temperature, but the water temperature/oil pressure indicator does light.	Check the warning buzzer and warning buzzer wiring. See **Fig. 11**.
The warning buzzer does not sound with low oil pressure, but the water temperature/oil pressure indicator does light.	Check the warning buzzer and warning buzzer wiring. See **Fig. 12**.

Troubleshooting

Kysor Warning and Engine Shutdown System Troubleshooting	
Problem	**Remedy**
The warning buzzer sounds without the water temperature/oil pressure indicator or the water level indicator lighting.	Check the warning buzzer and warning buzzer wiring. See **Fig. 13**.
The warning buzzer does not sound and the water temperature/oil pressure indicator does not light briefly after the starter is disengaged.	Check wire 81C. See **Fig. 14**.
The warning buzzer does not sound, but the water temperature/oil pressure indicator lights briefly after the starter is disengaged.	Check the warning buzzer and associated wiring. See **Fig. 15**.

For a wiring diagram of the Kysor warning and engine shutdown system, see **Fig. 1**.

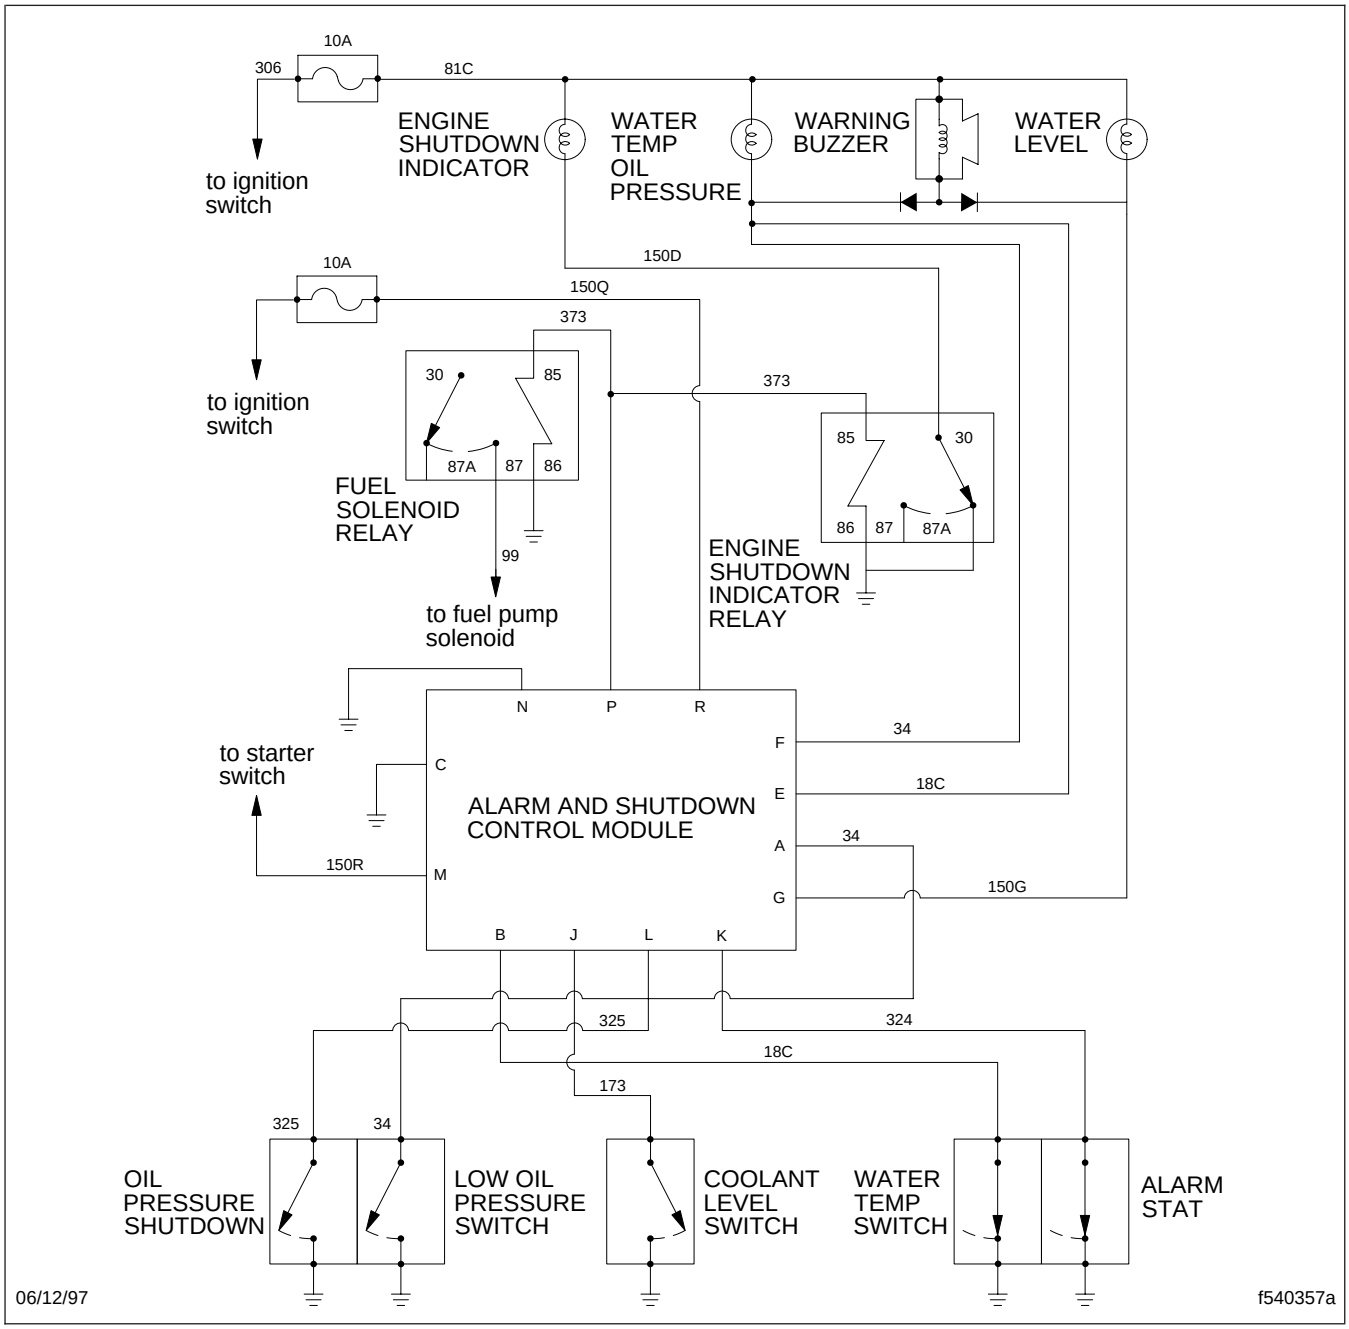

Fig. 1, Wiring Diagram, Kysor Warning and Engine Shutdown System

General Information

ALL LEAD-ACID BATTERIES

Maintenance-free lead-acid batteries, both liquid-electrolyte batteries and gel cells, are electrochemical devices which store chemical energy. When the battery is connected to an external load, such as a starter, the chemical energy is converted into electrical energy and current flows through the circuit.

The modern automotive battery has three functions:

- To supply power to the starter and ignition system so the engine can be cranked and started.
- To stabilize the voltage in the electrical system by reducing temporary high voltages in the electrical system. These high transient voltages could damage other electrical components if they were not protected by the battery.
- To supply extra power when the vehicle's electrical load requirements go beyond what the charging system can supply, or when the engine is not running.

All lead-acid batteries use plates made of two unlike metals held apart by separators. One of the metals becomes the positive plate, the other the negative plate. These plates are then grouped in pairs, alternating negative and positive. The groups are connected in series, and each plate group (cell) produces about two volts. Thus, a battery with six cells is a 12-volt battery. See **Fig. 1**.

In conventional liquid-electrolyte batteries (wet cells), each battery contains a group of plates immersed in a solution of electrolyte (dilute sulfuric acid). In a gel cell battery, the electrolyte is a solid gel, not a liquid.

Maintenance-free wet cells use calcium rather than antimony to improve grid strength. Calcium reduces the tendency for the battery to produce gas at normal charging voltages. Therefore, little water is lost, unless the battery has been charged at a very high rate. There are no filler caps in the cover. The battery is sealed, except for small vent holes in the cover. The vents allow the escape of gases produced in the battery.

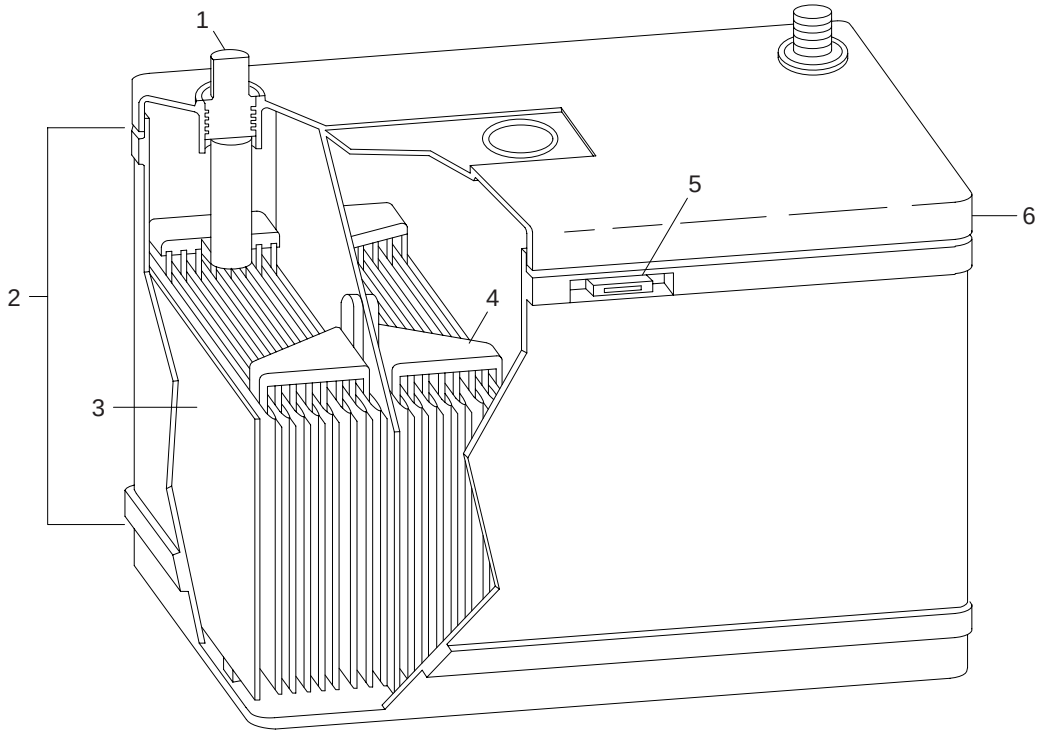
Electrical energy is produced in each cell by chemical changes in the plates (and in the electrolyte whenever a battery is discharged). See **Fig. 2**. A battery produces maximum electrical energy only when the cells are fully charged. As the cells discharge, chemical changes in the plates gradually reduce the potential electrical energy available. Recharging the battery with an opposite flow of direct current reverses the chemical changes within the cells and restores them to their active state. See **Fig. 3**.

NOTE: Liquid-electrolyte batteries must be kept in an upright position to prevent electrolyte leakage. Tipping a wet cell beyond a 45-degree angle in any direction can allow a small amount of electrolyte to leak out the vent holes.

In standard installations, the batteries are contained in a carrier below the left-hand door. See **Fig. 4**.

Only good care can ensure long battery life. Proper testing will indicate the battery condition. For more information, see **Subject 140**.

GEL CELLS (ISOLATED BATTERY SYSTEM)



The purpose of an isolated battery system is to prevent the starting batteries from becoming discharged by overuse of accessories when the vehicle is not operating. When the engine is running, the isolated battery is charged like the starting batteries. When the engine is shut down, the isolator relay disconnects the starting batteries from the accessory power circuits, directing the entire load to the isolated battery. The starting batteries can start the vehicle even if the isolated battery is completely drained.

Since March 1, 1996, vehicles with battery isolator systems are equipped with the Freightliner gel cell as the isolated battery.

A gel cell is a lead-acid electric storage battery with the following features:

- It is pressurized and sealed using special vents, and therefore *it should never be opened*.
- The only maintenance it needs is periodic cleaning of the terminals and tightening of the cable connectors.
- It uses a thixotropic gelled electrolyte that liquefies when stirred or shaken, but returns to a solid state when allowed to rest.
- It never needs filling, because it uses a special recombination technique to replace the oxygen and hydrogen normally lost in a standard wet

General Information

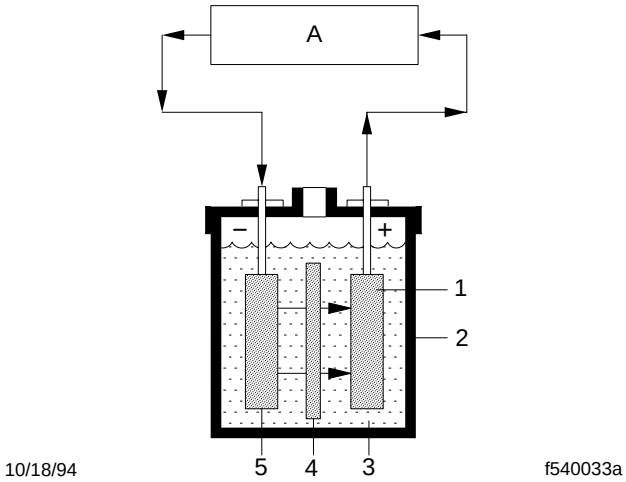
4. Intercell Connection
5. Vent Hole
6. Plastic Cover

Fig. 1, Typical Maintenance-Free 12-Volt Battery

cell, particularly when used in deep-cycle applications.

- It is non-spillable, and can be operated in virtually any position (upside-down installation is not recommended).

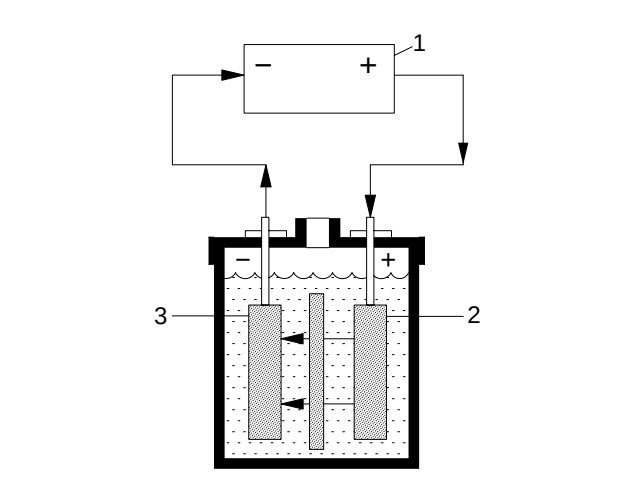


At 14 volts, a gel cell has a very high charge acceptance rate. Because a truck charging system operates at approximately 14 volts, under normal conditions a gel cell should never need to be recharged with an external charger.

CAUTION

Do not attempt to charge a gel cell with a standard battery charger. All standard battery chargers supply at least 16 volts to the battery. This will damage the gel cell.

Neither type of maintenance-free battery (see **Fig. 1**) needs additional water during normal service life.



A gel cell is a "recombinant" battery. The oxygen that is normally produced at the positive plate (in all lead-acid batteries) recombines (in a gel cell) with the hydrogen given off at the negative plate. The recombination of hydrogen and oxygen produces water (H_2O), which replenishes the moisture in the battery. Therefore, the gel cell is maintenance-free, as it never needs added water.

1. Batteries

Fig. 4, Typical Battery Installation

Selecting a Replacement

Long and trouble-free service is assured when the reserve capacity of the battery is equal to or exceeds 160 minutes and the cold cranking amp (CCA) rating of each replacement battery is at least 625 amperes. The CCA rating of the battery is a measure of its ability to supply high cranking power to the cranking motor at 0°F (–18°C).

The use of an undersized battery may cause poor performance and early failure. It may also cause damage to or reduced life of the starter. With falling temperatures, battery power decreases while the need for engine cranking power increases. Subzero temperatures reduce the capacity of a fully charged battery to 45 percent of the normal power, and at the same time, increase cranking load to 3-1/2 times the normal warm-weather load.

Batteries of a greater capacity should be considered if the electrical load has been increased through the addition of accessories, or if driving conditions are such that the charging system cannot keep the batteries charged.

IMPORTANT: Don’t replace a battery with one designed for automobiles and light trucks. The cold cranking amp (CCA) rating may be the same or higher, but the plates are lighter, and the battery won’t provide the reserve life that is needed. Also, these batteries don’t have the extra vibration protection or temperature resistance required on a heavy-duty vehicle.

Storage

Always store batteries in an upright position. Don't store liquid-electrolyte type batteries on their sides, as electrolyte may escape through the vent holes.

Maintain inventory levels in balance with demand and always rotate battery stock on a strict first-in, first-out basis. To protect against self-discharge, check the date codes stamped on the battery cartons and on the batteries themselves.

IMPORTANT: One of the major causes of problems with replacement batteries is failure to follow the first-in, first-out stock procedure.

Roller racks provide the best way to store batteries. If loaded properly from the back, they insure that the oldest battery of a particular type will always appear in the front.

Mark the racks clearly, both front and back, to ensure that the same battery type will go in the same rack every time.

If roller racks are not available, use wooden shelving reachable from both the front and the back. Otherwise, old batteries must be removed, to put new batteries in the back.

Never stack batteries on top of one another. If nothing else is available, simple battery storage racks can be made from loose, flat boards.

Maintenance-free batteries can have a shelf life of up to twelve months or more, depending upon storage temperatures, before charging is needed.

NOTE: Batteries in vehicles that are not in service are considered to be in storage. When a vehicle is to be out of service for 30 days or more, disconnect the negative ground terminal of each battery to prevent self-discharge caused by various components.

To minimize self-discharge, store batteries in as cool a place as possible, away from heat ducts in winter, and shielded from direct sunlight in summer.

The best storage conditions are in clean, dry areas where ambient temperatures are stable between 32° and 80°F (0° and 27°C). Storage in temperatures above 80°F (27°C) is not recommended, as this increases the rate of self-discharge. Avoid temperatures below 32°F (0°C) to prevent freezing if a battery becomes discharged.

General Safety Precautions

⚠ WARNING

Keep sparks, flames, burning cigarettes, etc. away from batteries. Batteries generate explosive gases, which could cause a battery to explode, causing serious personal injury, including blindness.

When charging the batteries, gas forms in each cell and escapes through the vent holes. In poorly ventilated areas, the gas lingers around the battery several hours after it has been charged. The gas is explosive around sparks, flame, or other intense heat; if ignited, it could cause the battery to explode. Follow these precautions when charging the batteries:

1. Wear safety glasses or a face shield when working with batteries. When many batteries are handled, wear rubber gloves and an apron to protect clothing.
2. Make sure that the area is well ventilated.

⚠ WARNING

Do not install any lead-acid battery in a sealed container or enclosure. Allow hydrogen gas caused by overcharging to escape. Exploding hydrogen gas can cause blindness or other bodily injury.

3. Make certain that the charger cable leads are clean and making good connections. A poor connection could cause an electrical arc which could ignite the gas mixture and explode the battery.
4. Do not break live circuits at the terminals because a spark usually occurs at the point where a live circuit is broken. Use care when connecting or disconnecting booster leads or cable clamps on chargers.
5. Don't smoke near batteries that are being charged or have recently been charged. Keep the batteries away from open flames or sparks.
6. If the battery is frozen, let it reach room temperature before trying to charge it. Check for leaks and cracks before charging the battery. Replace the battery if leaks or cracks are seen.
7. Take care that tools or metal objects do not fall across the battery terminals.

⚠ CAUTION

If a metal object connects an ungrounded battery terminal to a nearby metal part of the vehicle which is grounded, it could short out the batteries, causing sparks and possible property damage.

Battery Electrolyte Safety Precautions

⚠ WARNING

Protect skin and eyes from battery electrolyte (acid). Electrolyte is corrosive and could result in serious personal injury if splashed on your skin or in your eyes.

If electrolyte is splashed on your skin or in your eye, force the eye open, rinse it with cool, clean water for about five minutes, and call a doctor immediately. Do not add eye drops or other medication unless advised by the doctor.

If electrolyte is swallowed, drink several large glasses of milk or water. Follow with milk of magnesia, a beaten raw egg, or vegetable oil. Call a doctor immediately.

Use extreme care to avoid spilling or splashing electrolyte. Electrolyte spilled or splashed on your body or clothing should be neutralized with baking soda or household ammonia and then rinsed with clean water.

Electrolyte can also damage painted or unpainted metal vehicle parts. If electrolyte is spilled or splashed on any metal surface, neutralize and rinse it with clean water.

To prevent possible skin burns, do not wear watches, rings, or other jewelry while performing maintenance work on the batteries.

Battery Safety Precautions

⚠ WARNING

Do not apply pressure to the end walls of a plastic-case battery. This could cause electrolyte to squirt from the vents, possibly resulting in serious injury to skin or eyes.

When handling plastic-case batteries, use a battery carrier. If one is not available, lift these batteries with your hands placed at opposite corners of the battery.

Gel Cell Charging Precautions

GEL CELLS ARE SENSITIVE TO OVERCHARGING

⚠ CAUTION

To avoid shortening the life of a gel cell, carefully regulate the charging voltage—between 13.8 and 14.1 volts. Use only a reliable, automatic, temperature-sensing, voltage-regulated charger. Use only the gel cell charging procedures in Subject 150. *Never* use a constant current charger. *Never* leave any battery, including a gel cell, on a trickle charger.

Because gel cells normally give off little or no hydrogen gas, they do not cause explosions unless extremely overcharged. This is why they are safe around sensitive electronic equipment, and do not cause surrounding metals to corrode.

However, gel cells are very sensitive to overcharging. If overcharged, the oxygen and hydrogen are produced too rapidly and are vented away. Since they are no longer present inside the battery, they cannot recombine to form water. The water loss to the battery is permanent.

⚠ CAUTION

Never overcharge a gel cell. If a gel cell is charged to more than 14.1 volts, it will dry out and be unable to perform.

CONTINUAL UNDERCHARGING CAN DAMAGE GEL CELLS

In many respects, undercharging is as harmful as overcharging. In an undercharged state, the positive grids corrode and the plates shed, dramatically shortening battery life.

Furthermore, an undercharged battery works harder (is more heavily loaded) than a fully-charged battery. This also shortens its life.

IMPORTANT: The warranty is void if the battery is improperly charged. Use only a charger that limits voltage to no more than 14.1 volts and no less than 13.8 volts at 68°F (20°C). The charger must be temperature-sensing to prevent over- or undercharging caused by temperature changes.

CHECK FOR VENT BLOCKAGE

Because the gel cell operates under internal pressure, it is normal for it to bulge slightly, particularly at higher temperatures, which make the polypropylene case more pliable. Severe bulging indicates a battery with a blocked vent. Bulging (swollen) gel cells should be taken out of service.

DO NOT CHARGE GEL CELLS ON THE VEHICLE

Because the gel cell is an isolated battery, it needs to be connected directly to the charger. To properly charge the gel cell, it must be removed from all electrical loads. The best way to accomplish this is to remove it from the vehicle.

Emergency (Jump) Starting

⚠ WARNING

Before jump starting a vehicle, read the instructions in Subject 120. Failure to follow the safety precautions could result in personal injury.

⚠ CAUTION

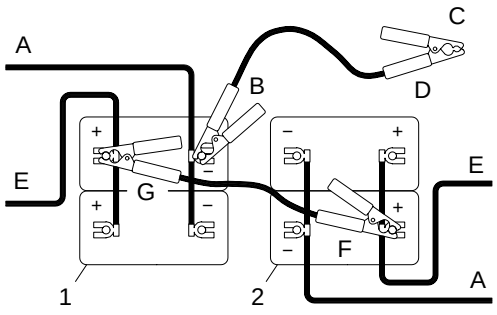
Do not attempt to charge gel cells (isolated batteries) with jumper cables. The gel cell requires a special charger and should be removed from the vehicle before charging. To avoid damage, follow the manufacturer's instructions.

Handle both the charged and the discharged batteries carefully when using jumper cables. Follow the procedure below, being careful not to cause sparks.

⚠ CAUTION

Make sure the starting systems on both vehicles have the same voltage outputs, and make connections as described below. Otherwise, the starter or the charging system could be damaged.

IMPORTANT: At no time during this operation should the vehicles touch each other, as this could establish a ground connection and offset the benefits of this procedure.



⚠ WARNING

Use the following procedure when jump starting. Incorrect battery handling procedures could result in battery explosion and severe personal injury, including blindness.

1. Apply the parking brakes. Turn off the lights, heater, and all other electrical loads.

IMPORTANT: If the vehicles are exposed to traffic, activate the warning flashers on the booster vehicle.

2. For your first connection, attach one end of the jumper cable to the positive terminal of the booster battery. For your second connection, attach the opposite end of the same cable to the positive terminal of the discharged battery. See Fig. 1 and Fig. 2.

10/18/94 f540303a

If the vehicle is equipped with an isolated battery system, make sure that the connections are made to the starting set of batteries, not to the gel cell(s).

NOTE: This procedure is for negative-ground vehicles only.

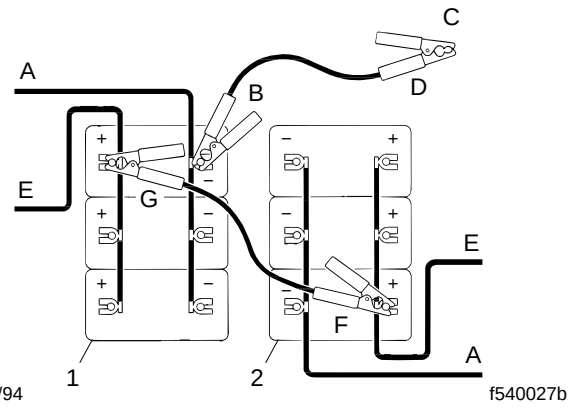
1. Booster Battery
2. Discharged Starting Battery

Fig. 1, Jumper Connections, Two-Battery System



3. For your third connection, attach one end of the other jumper cable to the negative terminal of the booster battery. For the fourth connection, attach the opposite end of that cable to a ground at least 12 inches (300 mm) from the battery of the vehicle being started. See Fig. 1 and Fig. 2. The vehicle frame is usually a good ground.

IMPORTANT: The final ground connection must provide good electrical conductivity and current-carrying capacity. To prevent sparks and explosions of hydrogen gas, don't connect directly to the negative post of the discharged battery.

4. Make sure that the clamps from one cable do not touch the clamps on the other cable. Don't lean over the batteries when making connections.

5. Make sure that everyone is standing away from the vehicles. Start the engine of the vehicle with the booster batteries. Wait a few minutes, then attempt to start the engine of the vehicle with the discharged batteries.

Emergency (Jump) Starting a Battery

If the vehicle is equipped with an isolated battery system, make sure that the connections are made to the starting set of batteries, not to the gel cell(s).

NOTE: This procedure is for negative-ground vehicles only.

A. To Ground
B. Third Connection
C. To Frame
D. Fourth Connection
E. To Starter
F. Second Connection
G. First Connection
1. Booster Battery
2. Discharged Starting Battery

Fig. 2, Jumper Connections, Three-Battery System

Don't operate the starter longer than 30 seconds. Wait at least two minutes between starting attempts to allow the starter to cool. If the engine doesn't start after several attempts, check for the cause.

6. After starting, allow the engine to idle. Disconnect the ground connection from the vehicle with the discharged battery. Then disconnect the opposite end of the cable.
7. Disconnect the other cable from the discharged battery first, then disconnect the opposite end.

General Information

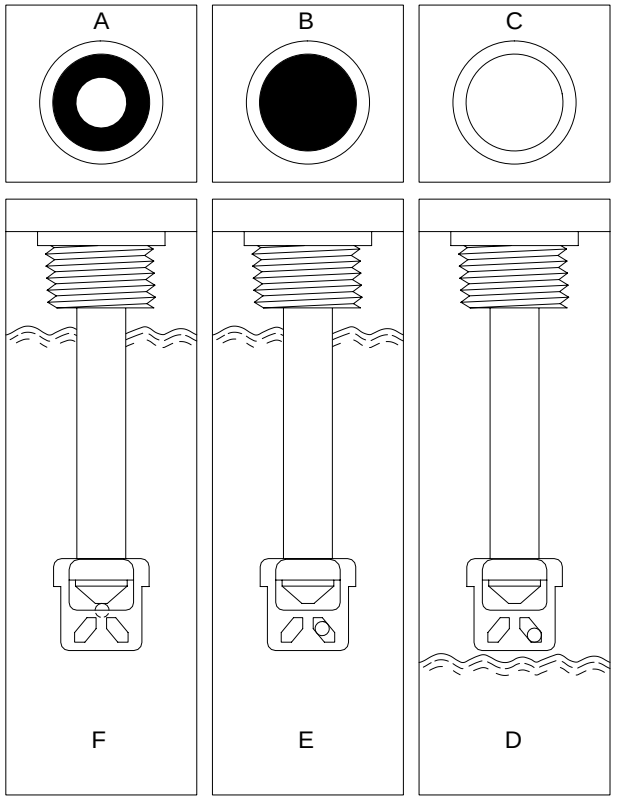
WARNING

Before testing a battery, see "Battery Safety Precautions" in this section. Failure to follow the safety precautions could result in personal injury.

Test any maintenance-free battery that does not hold a charge to see if it needs to be replaced, or if the problem lies elsewhere in the electrical system. Accuracy of the test depends on variables such as temperature and age of the battery. Follow the recommended testing instructions listed below.

IMPORTANT: Two types of battery tests are discussed in this subject. The first test uses the Midtronics Micro740 battery tester, and must be used by all U.S. and Canadian dealers for battery warranty claims. The second test is a load test using a carbon pile type tester and should **not** be used by U.S. or Canadian dealers for battery warranty claims.

Visual Inspection



Check for obvious damage such as a cracked or broken case that could permit loss of electrolyte. If there is physical damage replace the battery. Find the cause of the damage and correct it as needed.

On maintenance-free batteries without a built-in hydrometer, perform the Midtronics PowerSensor Micro740 test or the load test.

On maintenance-free batteries with a built-in hydrometer, check the sight glass. If a green dot shows in the sight glass, test the battery. If the sight glass is dark, recharge the battery, then test it. See **Subject 150**. If the sight glass is clear, replace the battery. See **Fig. 1**.

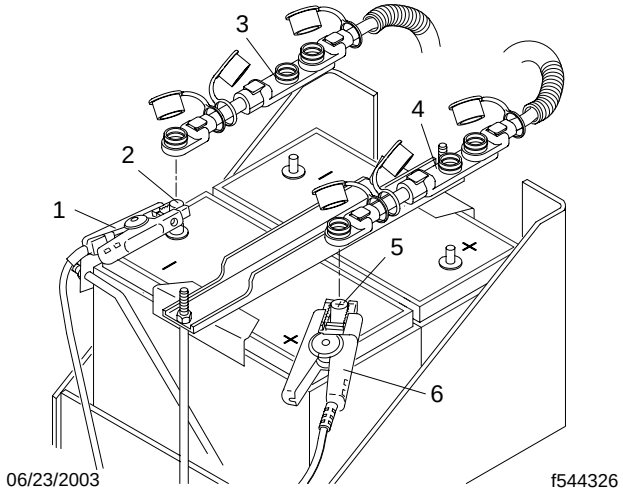
Prior to Testing

1. Clean the battery terminals with a soft wire brush before testing.
2. At the start of the test, make sure all vehicle accessory loads are off and the ignition is in the off position.

A. Green Dot
B. Dark
C. Clear
D. Dead Battery
E. 65% or Less of Charge
F. 65% or More of Charge

Fig. 1, Built-In Hydrometer or Charge Indicator (on optional batteries only)

Midtronics PowerSensor Micro740 Test



NOTE: This test must be used by all U.S and Canadian dealers for battery warranty claims.

Every battery in a pack of two or more must be disconnected before testing. If more than one battery is selected to be tested, the analyzer will test the first battery, then prompt you to connect to the next battery after the test has been completed. If the analyzer detects that the batteries are connected, it will remind you to disconnect the pack before starting the test.

Battery Testing

Connecting the Midtronics Tester

1. Screw an adapter onto the negative-terminal stud and one onto the positive-terminal stud. See **Fig. 2**.

1. Negative-Terminal Clamp
2. Negative-Terminal Stud Adaptor
3. Negative-Terminal Battery Jumper
4. Positive-Terminal Battery Jumper
5. Positive-Terminal Stud Adaptor
6. Positive-Terminal Clamp

Fig. 2, Battery Connection

IMPORTANT: For accurate test results, connect the clamps to the lead adaptors or to the lead bases of threaded studs. Lead stud adaptors are included with the Micro740. Do not connect the clamps directly onto the threaded studs or an inaccurate test result may occur.

2. Connect the red clamp to the positive-terminal stud adaptor.
3. Connect the black clamp to the negative-terminal stud adaptor.
4. Rock the clamps back and forth to ensure a secure connection. Both sides of the clamp must be firmly connected to the adaptors before testing. If the test message CHECK CONNECTION appears, clean the terminals and/or reconnect the clamps.

Battery Test

NOTE: If the analyzer displays a test message after you start the test, see *Test Messages* to determine the cause and remedy.

1. Use the arrow buttons at the top of the keypad to scroll to menu choices. Select BATTERY TEST. Press ENTER to select.
2. Enter the number of batteries being tested (1 to 6) and press ENTER to select.
3. Select the rating system; CCA, SAE, EN, IEC, DIN, or JIS then press ENTER.
4. Select the appropriate rating value (see **Table 1**) then press ENTER.
5. If the analyzer detects that the temperature of the battery may make a difference in the results it will ask you to select whether the battery temperature is above or below 32°F (0°C). It will resume the test after you make the selection and press ENTER.
6. At the end of the test, the Micro740 will display one of the following results from **Table 2** and the measured voltage and CCA, if applicable.

   If the result is REPLACE BATTERY or BAD CELL—REPLACE the analyzer will prompt you to press ENTER to generate a battery code.

   When the prompt BAT.SERIAL # appears enter the battery serial number. Use the ARROW buttons to scroll to the correct digit, then press ENTER to select it and move to the next digit. Pressing the BACK button will move the cursor back one space. When finished, press ENTER.
7. Turn on the printer and align the analyzer transmitter with the printer receiver. Press and hold the MENU button. Select PRINT RESULTS from the option menu by using the arrow buttons and pressing ENTER. It will take about 30 seconds to print all test results, which are displayed simultaneously on the screen.

Battery Rating Systems		
Rating System	**Description**	**Value Range**
CCA	Cold Cranking Amps, as specified by SAE. The most common rating for cranking batteries at 0°F (-18°C)	100 to 1700 A
SAE	European labeling of CCA	100 to 1700 A
EN	Europa-Norm	100 to 1700 A
IEC	International Electrotechnical Commission	100 to 1000 A
DIN	Deutsche Industrie-Norm	100 to 1000 A
JIS	Japanese Industrial Standard: (shown on a battery as a combination of numbers and letters, for example: 80D26)	43 values from 26A17 to 245H52

Table 1, Battery Rating Systems

Battery Test Results	
Result	**Recommendation**
Good Battery	Return to service.
Good—Recharge	The battery is good, but has an insufficient state of charge. Fully charge the battery and return to service.
Charge and Retest	The battery has a very low state of charge. Fully charge the battery and retest. Failure to fully charge the battery before retesting may cause false readings.
Replace Battery	Replace the battery and generate a test code.
Bad Cell—Replace	Replace the battery and generate a test code.

Table 2, Battery Test Results

Test Messages

Test Message—SYSTEM NOISE	
Possible Cause	**Remedy**
The analyzer has detected computer or ignition noise and will attempt to retest.	Make sure all vehicle loads are off and the ignition is in the off position. The analyzer will automatically retest when it no longer detects system noise
You may be testing too close to a noise source.	Move away from any high-current device and retest.
Battery charge is too low to test properly.	Recharge the battery and retest. If the message reappears, replace the battery.
Poor connection at battery terminal.	Connect the battery cables and retest.

Test Message—NON 12-VOLT BATTERY DETECTED	
Possible Cause	**Remedy**
You are attempting to test both batteries in a 24-volt system at the same time.	Disconnect the batteries and test each one individually.

Battery Testing

Test Message—INTERNAL ERROR, SERVICE REQUIRED	
Possible Cause	**Remedy**
The analyzer has detected a hardware or software problem.	See the Midtronics Micro740 *Instruction Manual*.

Test Message—REVERSE CONNECTION	
Possible Cause	**Remedy**
The clamps are connected in reverse polarity. i.e., Red to negative (–), and black to positive (+).	Disconnect the clamps and reclamp to proper polarity. i.e., Red to positive (+), and black to negative (–).

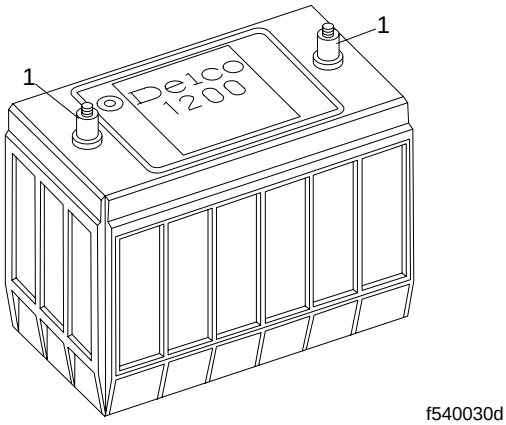
Test Message—UNSTABLE BATTERY	
Possible Cause	**Remedy**
Batteries that are very weak or that have just been charged may have sufficient electrical activity to alter test results. The analyzer will automatically retest when the battery has stabilized. Fully charged batteries should stabilize quickly.	Charge weak batteries and then retest.

Test Message—CHECK CONNECTION	
Possible Cause	**Remedy**
Poor connection. Both sides of the clamps must be firmly connected before testing.	Clean the battery terminals using a wire brush and a mixture of baking soda and water. Inspect and clean the clamps. Liberally apply baking soda and water with a clean cloth and thoroughly rub the jaw and spring. Use a soft wire brush to remove corrosion buildup. Rinse with water and let dry.

Load Test

NOTE: This test must **not** be used by U.S and Canadian dealers for battery warranty claims.

1. Test each battery separately, either installed or removed. Disconnect the battery cables from the battery, ground cable first.



⚠ WARNING

Before charging a battery, see "Battery Safety Precautions" in this section. Failure to follow the safety precautions could result in personal injury.

When charging batteries, always wear eye protection. During charging, batteries give off explosive hydrogen gas. Exploding gas can cause blindness or other bodily injury.

2. Before beginning the load test, check the open circuit voltage (OCV) of each battery. If the voltage is below 12.4 volts, charge the battery on a shop charger for at least 2 hours. If the voltage is above 12.4 volts, proceed to the next step. See **Subject 150** for battery charging instructions.
3. Connect the tester leads to the battery terminals following the tester manufacturer's instructions. Batteries with sealed terminals require adaptors

to provide a place for attaching the tester's leads. See **Fig. 3**.

1. Terminal Stud Adaptor

Fig. 3, Sealed Battery

4. Check the rated CCA of the battery. Apply a load equal to one-half the rated CCA across the terminals for 15 seconds to remove the surface charge from the battery. Remove the load and wait 15 seconds for the battery to recover.

   Example: For a battery rated at 620 CCA, apply a load of 310 amperes across the terminals.

5. Estimate the battery temperature by touch and by the ambient temperature the battery was exposed to before this test, then find the voltage in **Specifications 400** that must be maintained while the battery supplies a specified electrical load.

   Example: At 70°F (21°C) the battery must supply 9.6V minimum.

6. Apply the specified test load to the battery for 15 seconds. The test load (amperes) is equal to one-half of the cold-cranking amperes of the 0°F (–18°C) rating of the battery.

7. Read the terminal voltage at the end of 15 seconds with the load still connected. Do not keep the load attached for a longer period of time before reading the voltage, as this would alter the test results.

8. Remove the load after 15 seconds and note the tester reading.

If the voltage drops below the minimum listed in the table replace the battery.

If the voltage is the same or greater than the minimum listed in the table the battery is capable of further service.

Charging a Conventional Battery

To ensure the general well being of the electrical system, the starting battery(s) should be kept at a high state of charge. In particular, if operating a vehicle with undercharged battery(s), the alternator can be overworked and may cause premature failure.

To charge a conventional liquid-electrolyte battery (wet cell), apply a charge rate in amperes for several hours. For example, a 10-ampere charge rate for five hours would produce a 50 ampere-hour charge to the battery.

General Guidelines for Charging Batteries

When charging multiple batteries on one charger, group batteries that have similar voltages and are of similar age. If not, the group will only charge as fast as the battery with the lowest state of charge. Batteries below 5 volts should be charged individually.

Important: Do not overcharge maintenance-free batteries. Overcharging causes excessive loss of water from the electrolyte and eventual battery damage.

Refer to **Table 1**, **Table 2**, **Table 3**, and **Table 4** for determining how long to charge the batteries.

Batteries below 11.8 volts should be charged at no more than 10 amps for a minimum of 24 hours per battery. Check after the first hour and ensure that the battery is not getting hot.

If after using the above charging method you receive a Charge and Retest result from a Midtronics battery tester and the voltage is above 11.8 volts, continue to charge normally. If the battery voltage is below 11.8 volts, condemn the battery.

Recharge Time Using Shop Charger for a Single Battery					
Voltage	State of Charge	Charger Maximum Rate			
		50 Amps	30 Amps	20 Amps	10 Amps
12.6	100%	Ready to Use			
12.4	75%	0.6 hrs	0.9 hrs	1.3 hrs	2.5 hrs
12.2	50%	1.2 hrs	1.9 hrs	2.7 hrs	5.1 hrs
12.0	25%	1.8 hrs	2.9 hrs	4.3 hrs	7.8 hrs
11.8	0%	2.5 hrs	4.0 hrs	5.7 hrs	10.7 hrs

Table 1, Recharge Time Using Shop Charger for a Single Battery

Recharge Time Using Shop Charger for a Two Battery System					
Voltage	State of Charge	Charger Maximum Rate			
		50 Amps	30 Amps	20 Amps	10 Amps
12.6	100%	Ready to Use			
12.4	75%	1.2 hrs	1.8 hrs	2.6 hrs	5.0 hrs
12.2	50%	2.4 hrs	3.8 hrs	5.4 hrs	10.2 hrs
12.0	25%	3.6 hrs	5.8 hrs	8.6 hrs	15.4 hrs
11.8	0%	5.0 hrs	8.0 hrs	11.4 hrs	21.4 hrs

Table 2, Recharge Time Using Shop Charger for a Two Battery System

Battery Charging

Recharge Time Using Shop Charger for a Three Battery System					
Voltage	State of Charge	Charger Maximum Rate			
		50 Amps	30 Amps	20 Amps	10 Amps
12.6	100%	Ready to Use			
12.4	75%	1.8 hrs	2.7 hrs	3.9 hrs	7.5 hrs
12.2	50%	3.6 hrs	5.7 hrs	8.1 hrs	15.3 hrs
12.0	25%	5.4 hrs	8.7 hrs	12.9 hrs	23.1 hrs
11.8	0%	7.5 hrs	12.0 hrs	17.1 hrs	32.1 hrs

Table 3, Recharge Time Using Shop Charger for a Three Battery System

Recharge Time Using Shop Charger for a Four Battery System					
Voltage	State of Charge	Charger Maximum Rate			
		50 Amps	30 Amps	20 Amps	10 Amps
12.6	100%	Ready to Use			
12.4	75%	2.4 hrs	3.6 hrs	5.2 hrs	10.0 hrs
12.2	50%	4.8 hrs	7.6 hrs	10.8 hrs	20.4 hrs
12.0	25%	7.2 hrs	11.6 hrs	17.2 hrs	31.2 hrs
11.8	0%	10.0 hrs	16.0 hrs	22.8 hrs	42.8 hrs

Table 4, Recharge Time Using Shop Charger for a Four Battery System

On optional batteries with built-in hydrometer (charge indicator), the battery is sufficiently charged when the green dot in the hydrometer is visible. Gently shake or tilt the battery at hourly intervals during charging to mix the electrolyte and check to see if the green dot appears. Do not tilt the battery beyond a 45-degree angle.

If the green dot does not appear after a 75 ampere-hour charge, continue charging for another 50 to 75 ampere-hours. If the green dot still does not appear, replace the battery.

NOTE: Batteries with built-in hydrometers (charge indicators) cannot be charged if the indicator color is clear or light yellow; this indicates low electrolyte level. Replace these batteries.

Refer to the following steps to charge a wet cell battery.

1. Clean the battery terminals.

NOTE: If the battery is cold, let it warm up. This will allow a normal charging rate.

2. Make sure that the charger is turned off.
3. Connect the charger to the battery following the manufacturer's instructions. Rock the charger lead clamps to make sure there is a good connection.
4. Turn on the charger and slowly increase the charging rate until the recommended ampere value is reached.

IMPORTANT: If the battery feels hotter than 125°F (52°C), or if rapid gassing or spewing of electrolyte occurs, lower the charging rate or stop charging the battery and allow it to cool.

5. After the battery(s) has charged for the recommended time, turn the charger off.
6. Disconnect the charger cables from the battery.

NOTE: If the vehicle is equipped with an isolated battery system, be sure that both battery systems are charged.

7. If the engine does not crank satisfactorily when a charged battery is installed, test the battery using

a Midtronics™ battery tester. For instructions, see **Subject 140**.

If the battery passes the Midtronics test, check the fuel, ignition, cranking, and charging systems to find and correct the problem.

If the battery does not pass the Midtronics test, replace it.

Gel Cell Charging

CAUTION

To avoid shortening the life of a gel cell, carefully regulate the charging voltage—between 13.8 and 14.1 volts.

It is hard to determine how long to charge a gel cell. Recharging time depends on the following factors:

- Depth of discharge
- Temperature
- Size and efficiency of the charger
- Age and condition of the battery

Because the chemical charging reaction slows down as it nears completion, about 60% of the total charging time will be spent bringing the battery from 10.5 volts under load (11.8 volts with no load) to 90% of full charge (12.92 volts, including surface charge). The other 40% of the time is required to charge the remaining 10% (full charge = 13.0 volts, including surface charge).

Example: If it takes 3-1/2 hours to charge a battery to 90%, it will take another 2-1/2 hours to bring it to full (100%) charge.

See **Table 5** for a list of estimated charging times to 90% of full charge. See **Table 6** for a list of estimated charging times to 100% of full charge. All charging times are based on the initial charge current accepted by the battery, using an automatic, temperature-sensing, voltage regulating charger set at 13.8 volts (2.30 to 2.35 volts per cell) on a totally discharged battery (at 11.80 to 12.00 volts, with no load).

Charging Time to 90% of Full Charge			
Battery	Initial Amps Needed to Recharge In		
	13 Hours	6 Hours	3-1/2 Hours
G27	8	21	41
G31*	9	24	45

* Freightliner uses the G31 (Group 31) gel cell.

Table 5, Gel Cell Charging Guide (90% charge)

HOW TO USE THESE CHARTS: Read amps about one minute after the charger is first turned on. Use this initial reading to estimate the approximate charging time.

Example: If a G31 battery reads about 24 amps charge current when first turned on, the battery will be at 90% charge in about six hours, and will be fully charged (100%) in about ten hours.

Charging Time to 100% of Full Charge			
Battery	Initial Amps Needed to Recharge In		
	22 Hours	10 Hours	6 Hours
G27	8	21	41
G31*	9	24	45

* Freightliner uses the G31 (Group 31) gel cell.

Table 6, Gel Cell Charging Guide (100% charge)

To charge a gel cell, do the following steps:

1. Remove the gel cell from the vehicle.
2. Clean the battery terminals.

NOTE: If the gel cell is cold, let it warm up to 68°F (20°C). This will allow a normal charging rate.

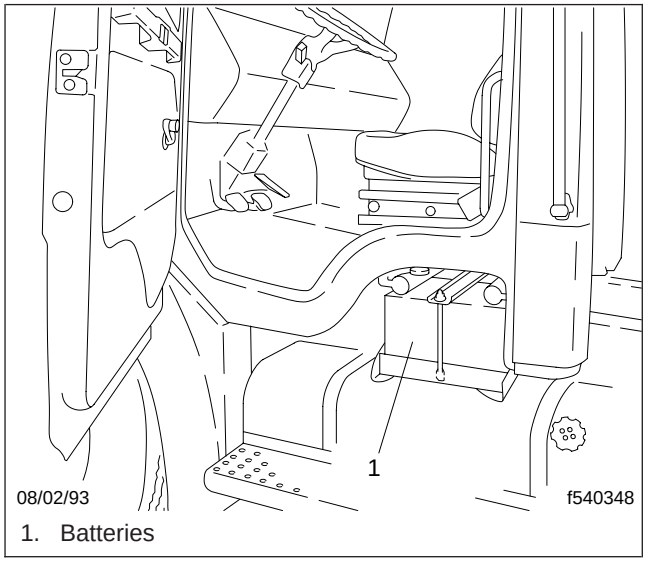
3. Make sure that the charger is turned off.
4. Connect the charger leads directly to the battery following the charger manufacturer's instructions. Rock the charger lead clamps to make sure there is a good connection.
5. Turn on the charger and set the charging rate between 13.8 and 14.1 volts (2.30 to 2.35 volts per cell).

Battery Charging

6. After about one minute, check the initial charge current. To charge to 90% of full charge, see **Table 5** to determine the approximate time of completion. To charge to 100% of full charge, see **Table 6** to determine the approximate time of completion.

IMPORTANT: If the battery feels hotter than 125°F (52°C), or if rapid gassing occurs, stop charging the battery and allow it to cool.

7. When finished, turn the charger off.
8. Disconnect the charger cables from the battery.



Battery Removal, Cleaning and Inspection, and Installation

WARNING

Before doing any of the following procedures, read the instructions in Subject 120. Failure to follow the safety precautions could result in personal injury.

Removal

1. Before working on the battery box, make sure all electrical loads (lights, ignition, accessories) are turned off.
2. For assembly reference, note the locations of the battery positive and negative terminals in relation to surrounding components.
3. Remove the battery retainer assembly; then remove the batteries from the carrier. See Fig. 1.

1. Batteries

Fig. 1, Typical Battery Installation

Cleaning and Inspection

1. Inspect all battery cables and inter-connectors for wear, and replace them if necessary. Remove corrosion from cables, terminals, and battery posts with a wire brush and a solution of baking soda and water. Rinse thoroughly with clean water, and dry.
2. Clean and tighten the battery ground cable at the weld stud on the frame rail. There are two locations to service. First, at the battery, and, second, at the engine behind the left wheel. Inspect and ensure that the nut is a self-locking type and that a flat washer is used. Do not use a split-lock washer or star washer. Torque the nut 15 to 18 lbf·ft (20 to 24 N·m). Seal the area with red dielectric spray enamel sealant.
3. Inspect the retainer assembly and battery box. Replace worn or damaged parts. Remove any corrosion with a wire brush, and wash with a weak solution of baking soda and water. Rinse with clean water, and dry. Paint the retainer assembly, if needed, to prevent rusting.
4. Be sure foreign objects, such as stones, bolts, and nuts, are removed from the battery box.

Installation

1. Be sure that the battery to be installed has a sufficient capacity to cover the electrical needs of the vehicle. For more information, see Subject 100.

CAUTION

Using an under-capacity battery will result in poor performance and premature battery failure, resulting in damage or reduced life of the starter.

2. Be sure the battery is at full charge when installed. If the battery has been in storage for some time, or if the installation is being made in subfreezing temperatures, give the battery a boost-charge before installing it. For instructions, see Subject 150.
3. Place the batteries in the carrier with the terminals in the proper position, as referenced earlier. The batteries should rest level in the carrier.
4. Install the battery retainer assembly, and tighten it until the batteries are secure. See Fig. 1.

CAUTION

Do not overtighten the battery retainer assembly. Overtightening could damage the batteries.

5. To provide corrosion protection, apply pumpable dielectric grease, part no. 48–02349–000, liberally to the terminal pads, then install the inter-

Battery Removal, Cleaning and Inspection, and Installation

connectors. For a list of approved suppliers, see **Specifications, 400**.

IMPORTANT: Many electrical components are located outside of the cab in areas subjected to harsh weather, road spray, etc. Some components also have exposed metal electrical terminals, which, when subjected to harsh conditions, may suffer corrosion at the electrical connection. Spray dielectric sealant on all exposed electrical terminals, and use dielectric grease on all covered terminals.

6. Connect the battery cables to the batteries; check for correct polarity with respect to the vehicle. Connect the ground cable last.

CAUTION

Reversed polarity may cause serious damage to the electrical system.

7. Tighten all battery connections to the torque specifications listed on the battery. Generally those are 10 to 15 lbf·ft (14 to 20 N·m). Proper torque is important for electrical system operation.
8. Start the engine, and check the operation of the charging system. If needed, adjust or repair the charging system to obtain the correct charging output. For instructions, see the appropriate section in **Group 15**.

CAUTION

Make sure all battery posts are covered with protective caps. Failure to do so could cause the battery box cover to short across the posts.

Troubleshooting

If the starting batteries test good, but fail to perform satisfactorily in service, check for the following causes:

1. Accessories were left on overnight.
2. A slipping alternator belt, high resistance in the wiring, or an inoperative voltage regulator is causing the batteries to discharge.
3. The electrical load is exceeding the charging system capacity.
4. Wires in the electrical system are shorted or pinched.
5. There are loose or damaged battery cable-to-terminal connections.
6. The batteries are still connected in a vehicle that has been out of service. Small current drains of accessories that are connected all the time can discharge the batteries in six to eight weeks. Batteries left in a discharged condition for a prolonged period of time are subject to freezing and may become difficult to charge.

Problem—The Starting Batteries Are Undercharged

Problem—The Starting Batteries Are Undercharged	
Possible Cause	**Remedy**
The drive belt is loose.	Check the drive belt. Refer to the drive belt subject in the appropriate engine section in **Group 01** for instructions. If necessary, tighten to the manufacturer's specifications. Start the engine and check the alternator voltage and output. Refer to the troubleshooting subject in the appropriate alternator section **in Group 15** for instructions.
The drive belt is damaged or missing.	Check the drive pulleys for locked bearings. Repair or replace any damaged components. Replace the drive belt and start the engine. Check the alternator voltage and output. Refer to the troubleshooting subject in the appropriate alternator section **in Group 15** for instructions.
The batteries are undercharged.	Do a load test on the batteries. Refer to **Subject 140** for instructions. Charge or replace batteries as needed. If the batteries were discharged, start the engine and check the alternator voltage and output. Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.
The cranking circuit is broken.	If the batteries were fully charged and passed the load test, check the cranking circuit. Make repairs as needed. Start the engine to verify the repair.
The control circuit is broken.	Check the starter wiring. Make repairs as needed. Start the engine to verify the repair.
The starter is cold.	Perform a cold weather starting test.
The battery cables do not deliver sufficient voltage to the starter.	Check the available cranking voltage.
The starter ring gear or pinion gear is damaged.	Visually check the ring and pinion gears.
The starter is damaged.	Replace the starter.
The alternator is malfunctioning.	Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.

Troubleshooting

Problem—The Starting Batteries Are Undercharged	
Possible Cause	**Remedy**
The isolator relay is not operating correctly (optional battery isolator system only).	Replace the isolator relay with an exact replacement continuous duty relay.

Problem—The Starting Batteries Are Overcharged

Problem—The Starting Batteries Are Overcharged	
Possible Cause	**Remedy**
The voltage regulator is damaged.	Run engine at approximately 2000 RPM. Using a digital voltmeter, check the voltage at the alternator. Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions. If the voltmeter reads 15.5V or above, replace the alternator.
The dash voltmeter is broken.	Run engine at approximately 2000 RPM. Using a digital voltmeter, check the voltage at the alternator. Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions. If the voltmeter reads below 15.5V, check and, if necessary, replace the dash voltmeter.
The batteries are overheated.	Check battery temperatures. If 120°F (49°C) or above, connect cool, fully charged batteries and recheck the voltage at the alternator. Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions. If 119°F (48°C) or below, load test the batteries. Refer to **Subject 140** for instructions.
The batteries need replacing.	Check battery temperatures. If 119°F (48°C) or below, load test the batteries. Refer to **Subject 140** for instructions.

Specifications

Minimum Permissible Voltages	
Ambient Temperature °F (°C)	Minimum Voltage (After 15 seconds at 300 amps)
	12-Volt
70 (21) and Above	9.6
60 (16)	9.5
50 (10)	9.4
40 (4)	9.3
30 (–1)	9.1
20 (–7)	8.9
10 (–12)	8.7
0 (–18)	8.5

Table 1, Minimum Permissible Voltage at Various Ambient Temperatures

Charging Rates for Starting Batteries				
Rated Battery Capacity (reserve minutes)	Slow Charge *		Fast Charge †	
	Hours @	Amperes	Hours @	Amperes
180	30	5	7-1/2	20
	15	10	5	30
			2-1/2	45

* Slow charging is recommended for completely charging the batteries.

† An emergency boost charge, which consists of a high charging rate, can be obtained by reducing the fast-charge time to half, while maintaining the same recommended ampere charge may be used to crank an engine.

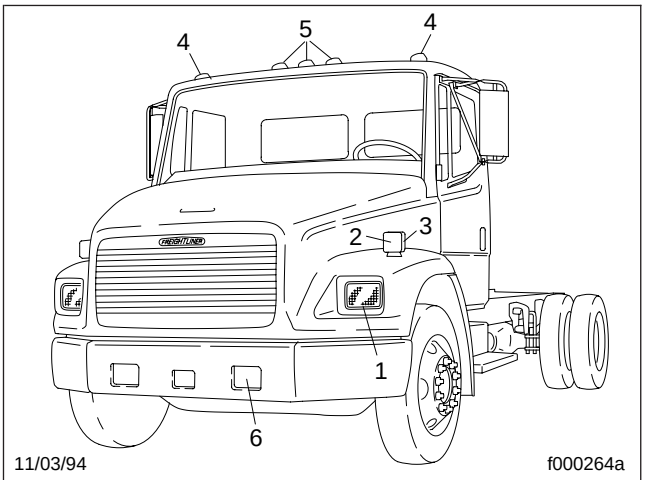
Reserve Capacity	Cold Cranking Amps (CCA)
180 minutes	750

Table 4, Standard Battery Specifications

General Information

NOTE: On FL112 vehicles, the headlights and front turn signal lights are mounted together in bezels attached to the hood. See **Fig. 1**. Road lights are normally mounted underneath the front bumper. If the vehicle has an air dam and tow hooks (which mount in the holes in the front bumper), rectangular cutouts are provided in the air dam to accommodate the road lights. If the vehicle has an air dam, but does not have tow hooks, the road lights are mounted in the holes in the front bumper.



1. Headlight/Turn Signal Bezel
2. Road Light
3. Air Dam
4. Front Bumper

Fig. 1, Headlights and Road Lights (FL112 only)

Fig. 2 shows the exterior lighting system of the Short Conventional. In the front of the vehicle are headlights, fender-mounted turn-signal lights, and side-marker lights. On the roof of the cab there are clearance and identification lights. At the rear of the vehicle are the taillights, stoplights with turn signals, and backup lights. Optional fog lights are mounted in the front bumper.

NOTE: The fog lights will operate only if the low-beam headlights are turned on. The fog lights won't operate if the high-beam headlights are already on, and switching from low beams to high beams will switch off the fog lights. Also, with daytime running lights, the fog lights can be turned on any time the daytime running lights are on.

The instrument panel features fully lighted gauges and labels for switches and controls. The steering column-mounted turn-signal switch has the headlight dimmer switch built into it. A dome light is mounted in the rear center of the cab roof.

1. Headlight
2. Signal Light
3. Side Marker Light and Reflector
4. Clearance Light
5. Identification Lights
6. Fog Light

Fig. 2, Exterior Lighting (all but FL112)

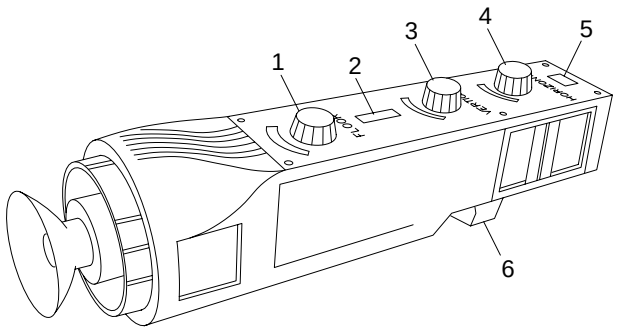
On the dash is a marker light interrupt switch designed to allow the driver to blink the vehicle marker lights without turning off the headlights. When activated, the marker, taillight, front turn signal, and dash panel lights all blink. The marker light interrupter operates only with the headlights ON; it will not operate when only the parking lights are on.

Daytime running lights are a standard feature on vehicles built to operate in Canada; they are an option on other vehicles.

On Freightliner vehicles with this feature, switching on the ignition and releasing the parking brake automatically activates the headlight low beams at reduced voltage as daytime running lights.

Sure Power daytime running lights operate until the parking brakes are applied; then they will switch off. Turning on the regular headlights overrides the day-

General Information



time running lights. Vehicles so equipped cannot be driven without the headlights or daytime running lights on.

The Sure Power model 1323F daytime running light (DRL) module turns on the low beam headlights at reduced voltage when the engine is operating. It does this by sensing when the ignition switch is on and the parking brake is released.

The DRL module applies approximately 86 percent of normal operating voltage to the low beam filaments. Model 1323F has a left and right low beam output. The voltage will vary from approximately 10.5 volts with the engine stopped to 12.5 volts with the engine running.

The 1323F module is designed to conform to the CMVSS 108 and FMVSS 108 specifications for low beam operation. In addition to turning on the low beams at reduced voltage, the module also provides an ACTIVE LOW (ground) signal to the dimmer relays, thereby forcing the dimmer relays into the high beam position. This is necessary to prevent the DRL module from feeding the remaining light circuitry. When the DRL module is deactivated, the dimmer relays return to normal operation.

Headlight aim can be checked and adjusted most easily, using the Hopkins mechanical aimer. The aimer attaches to the headlight with a vacuum cup activated by pushing the piston handle located on the base of the aimer. See **Fig. 3**.

1. Floor Slope Dial
2. Level Vial
3. Vertical Dial
4. Horizontal Dial
5. Split Image View Port
6. Piston Handle

Fig. 3, Headlight Aimer

To adjust the horizontal aim, turn the horizontal adjusting screw on the headlight until the split image aligns in the split image view port. To adjust the vertical aim, turn the vertical adjusting screw on the headlight until the bubble is centered in the level vial.

Headlight Replacement

1. Remove the headlight bezel. See **Fig. 1**.
2. Remove the retaining ring screws.
3. Remove the retaining rings.
4. Remove the lamp from the housing; then disconnect the wiring connector from the back of the lamp.
5. To provide corrosion protection, coat the prongs/base of the new lamp with dielectric grease. For approved electrical terminal lubricants, see the applicable table in **Specifications 400**.
6. Push the wiring connector onto the prongs at the rear of the new lamp.
7. Place the new lamp in the headlight housing.
8. Place the retaining ring over the lamp and install the retaining ring screws; then tighten the screws securely.
9. Check and, if necessary, adjust the headlight aim as described in **Subject 130**.
10. Install the headlight bezel.

Front Turn Signal/Side Marker Bulb Replacement

1. Remove the lens-to-housing attaching screws. See **Fig. 2** and **Fig. 3**.
2. Remove the bulb from the socket.
3. To provide corrosion protection, coat the base of the new bulb with dielectric grease. For approved lubricants, see the applicable table in **Specifications 400**. Install the new bulb.
4. Check for proper operation.
5. Install the lens and attaching screws.

Clearance\Identification Light Bulb Replacement

1. Using a screwdriver, unsnap the lens from the base to gain access to the bulb. See **Fig. 4**.
2. Remove the bulb.

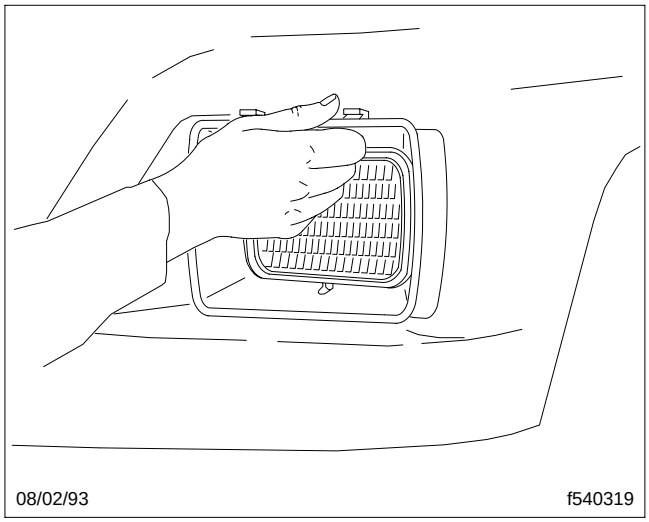

Fig. 1, Bezel Removal

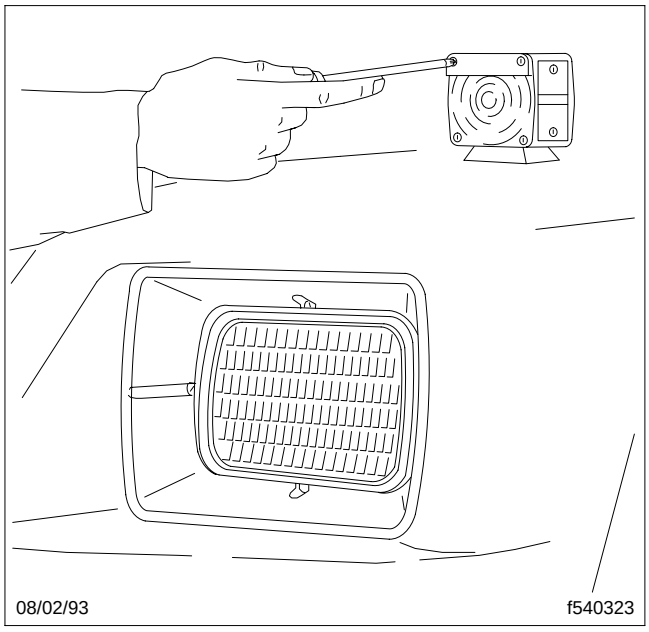

Fig. 2, Attaching Screws Removal

3. To provide corrosion protection, coat the base of the new bulb with dielectric grease.

   For approved electrical terminal lubricants, see the applicable table in **Specifications 400**.
4. Install the new bulb and test for proper operation.
5. Install the lens on the base, making sure that it is fully seated.

Exterior Light Replacement

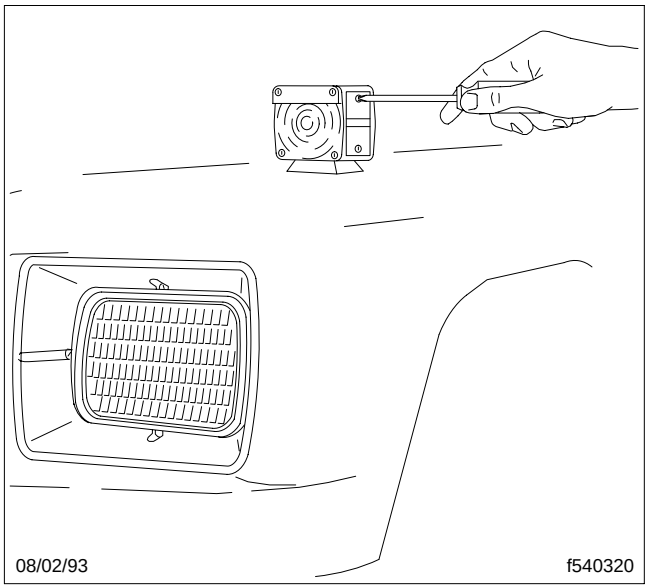

Fig. 3, Attaching Screws Removal

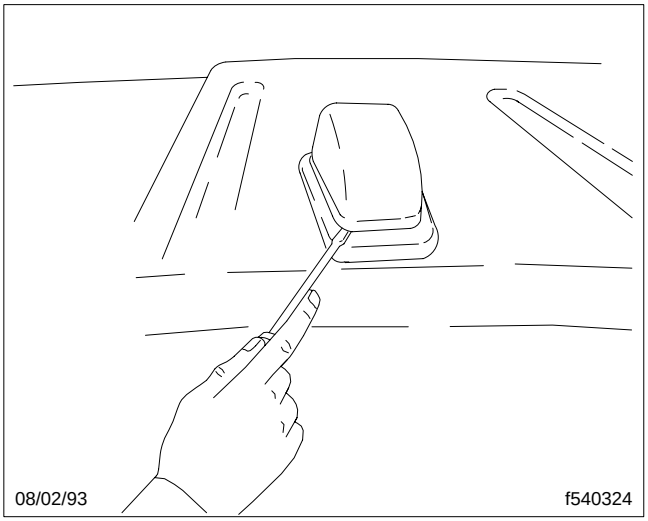

Fig. 4, Snapping Open the Lens

Fog Light Replacement, Per-Lux

1. Gain access to the front of the light assembly by removing the mounting bracket locknut. Remove the light assembly from the mounting bracket. See **Fig. 5**.
2. Remove the crosshead screws from both sides of the lens retainer.
3. Separate the lens retainer and louver from the main housing. Pull the lamp from the housing, and disconnect the blade connectors from the blade terminals on the bulb. See **Fig. 6**.
4. To provide corrosion protection, coat the blade terminals on the new bulb with dielectric grease. For approved electrical terminal lubricants, see the applicable table in **Specifications 400**.
5. Install the blade connectors on the terminals of the new lamp. Place the unit in the housing and test it for proper operation.
6. Place the lens and louver over the lamp. Make sure the word "TOP" appears on the top of the lamp. See **Fig. 7**. If not properly installed, the beam from the light will be directed upward instead of down.

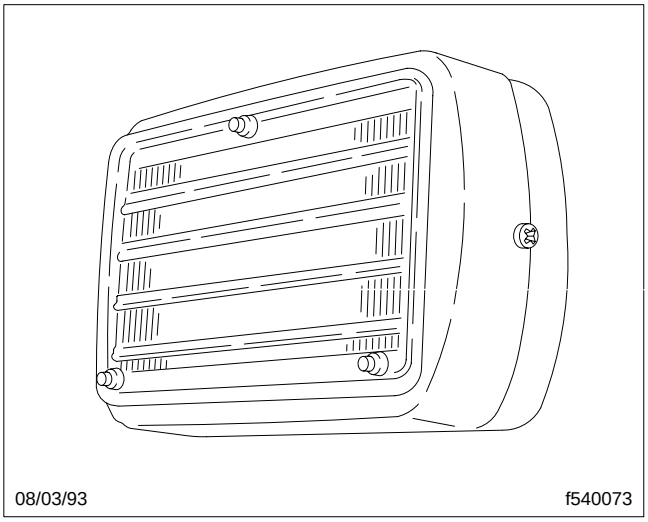

Fig. 5, Per-Lux Fog Light

7. Place the lens retainer over the louver. Install the crosshead screws.
8. Place the fog light assembly in the mounting bracket. Install the locknut. Make sure the lamp is aimed directly ahead. Then, tighten the locknut 75 lbf·ft (102 N·m).

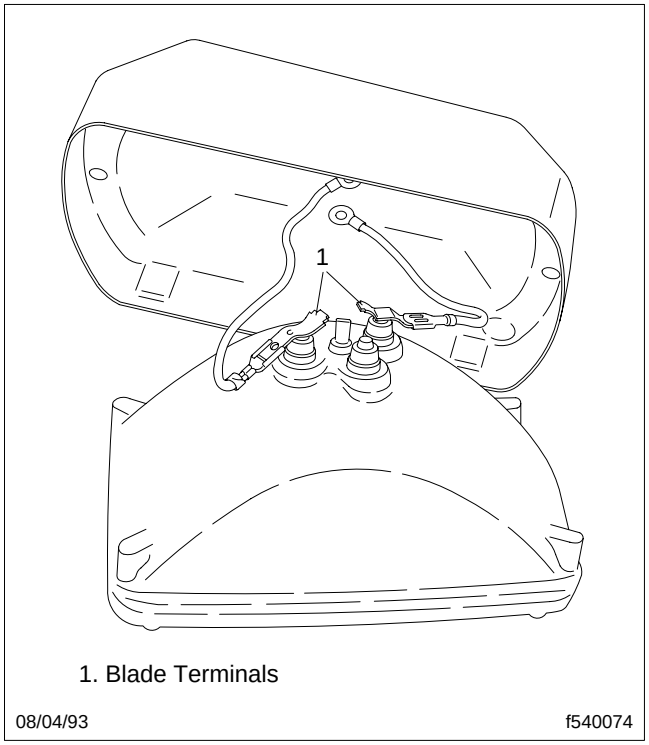

Fig. 6, Blade Terminal Removal

Stoplight and Taillight Replacement

1. Remove the screws attaching the lens to the light housing. See **Fig. 8**.
2. Press in on the bulb and turn it counterclockwise to release it from the socket. See **Fig. 9**.
3. To provide corrosion protection, coat the base of the new bulb with dielectric grease. For approved electrical terminal lubricants, see the applicable table in **Specifications 400**.
4. Press the new bulb into the socket, and turn it clockwise to lock it in place. Test the bulb for proper operation.
5. Install the lens on the housing. Fasten it in place with the attaching screws. Do not overtighten the screws or you will crack the lens.

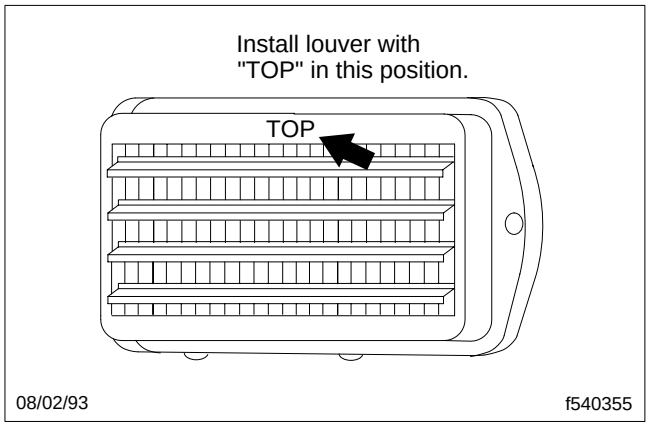

Fig. 7, TOP Position on Lamp

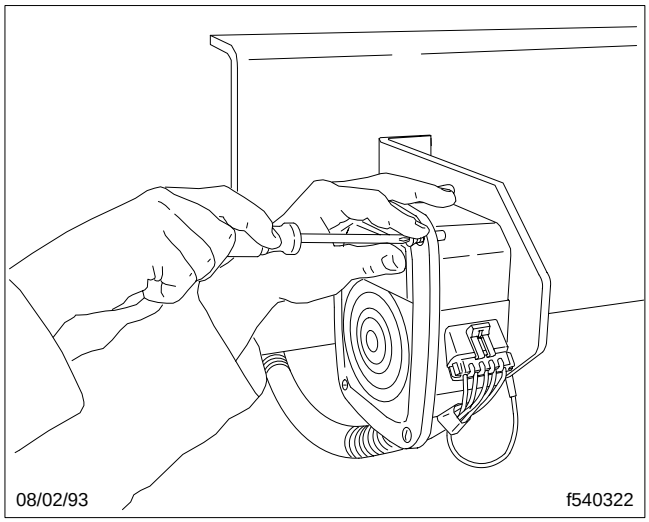

Fig. 8, Lens Removal

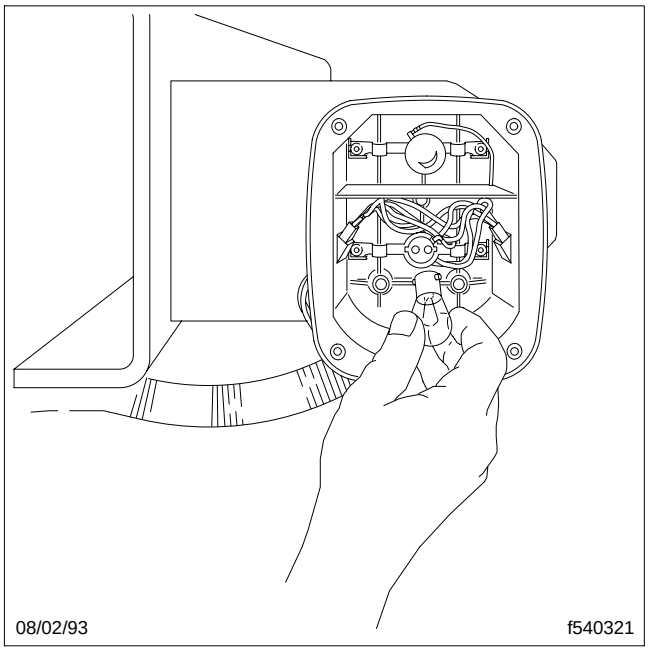
FL112 Headlight Replacement

1. Remove the two Phillips-head screws that attach the headlight/turn signal bezel to the hood. See **Fig. 10**. Pull the bezel away from the hood.
2. Remove the three Phillips-head screws that secure the headlamp retaining ring and the lamp to the bezel.
3. Disconnect the wire harness from the headlamp and remove the lamp.
4. To provide corrosion protection, coat the prongs/base of the new lamp with dielectric grease. For approved electrical terminal lubricants, see the applicable table in **Specifications 400**.

Exterior Light Replacement



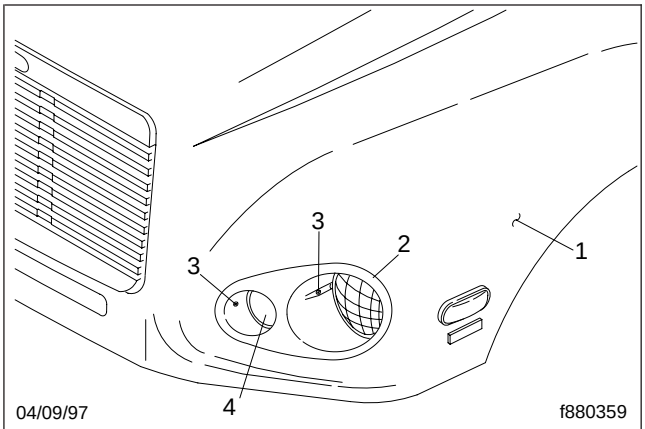


Fig. 9, Bulb Removal

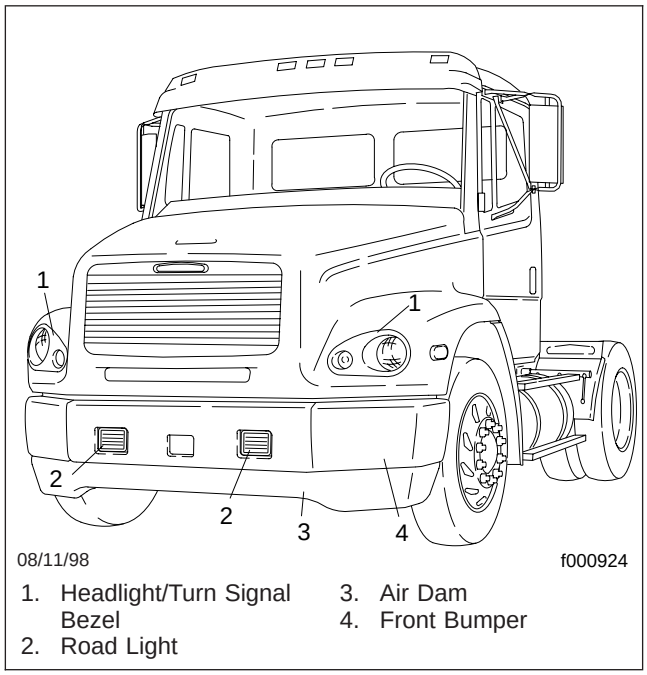

1. Hood
2. Headlight/Turn Signal Bezel
3. Mounting Screw
4. Turn Signal

Fig. 10, Headlight/Turn Signal Bezel Attachment (FL112 only)

5. Connect the wire harness to the new lamp and place it in position in the bezel.
6. Place the retaining ring over the lamp and install and tighten the three Phillips-head screws securely.
7. Insert the bezel into position in the hood and install and tighten the two Phillips-head screws securely.
8. Check and, if necessary, adjust the headlight aim as described in Group 54 of the *Business Class Trucks Maintenance Manual*.

FL112 Road Light Replacement

(See Fig. 11)

1. Headlight/Turn Signal Bezel
2. Road Light
3. Air Dam
4. Front Bumper

Fig. 11, Headlights and Roadlights (FL112 only)

1. Remove the two fasteners that attach the triangular road light mounting plate to the front bumper.
2. Disconnect the wire harness from the road light.
3. Remove the single fastener attaching the road light to the mounting plate.
4. Attach the mounting plate to the new road light with the single fastener and tighten it securely.
5. Connect the wire harness to the new road light.
6. To provide corrosion protection, coat the pins and base of the connector with dielectric grease. For approved electrical terminal lubricants, see the applicable table in **Specifications 400**.

7. Place the road light, with the attached mounting plate, in position on the bumper. Install the two fasteners and tighten them securely.
8. Wipe the lens with a clean cloth to remove any dirt or skin oil.
9. Test the light for proper operation.
10. Check the alignment of the light. Make sure the light is pointing forward and slightly toward the shoulder side of the road.

Instrument Panel Bulb Replacement

1. Loosen the cross-head screws through access holes in the instrument panel cover. **See Fig.1.**
2. Pull the panel out of the dash to provide access to the back of the panel, **as shown in Fig.2.**
3. Remove the bulb holder by twisting it 1/8 turn counterclockwise and pulling it away from the panel. Remove the bulb by pulling it straight out.
4. Install the new bulb and replace the bulb holder. Test the bulb for proper operation.
5. Place the instrument panel back in the dash, making sure that none of the wires are pinched, kinked, or otherwise incorrectly positioned. Install the screws.

Rocker Switch Bulb Replacement

1. Remove the vinyl extrusion trim from the groove above the switch panel.
2. Remove the screws from the top of the panel. Swing the panel out and lift it from the slots.
3. Unplug the wiring connector from the back of the switch. Pull the bulb holder from the switch and replace the bulb; then install the bulb holder in the switch. Reconnect the wiring harness to the switch.
4. Check the bulb for proper operation. Install the panel and the vinyl extrusion trim.

Temperature Control Panel Bulb Replacement

1. Remove the vinyl extrusion trim from the groove above the switch panel.
2. Remove the screws from the top of the panel. Swing the panel out.

NOTE: Both dash panels on either side may have to be removed to allow removal of the center panel.

3. Remove the bulb holder and replace the bulb.

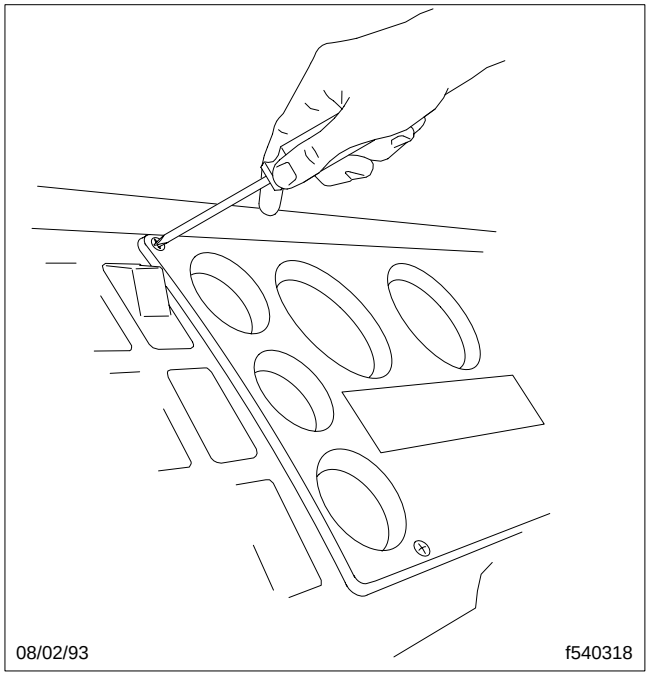

Fig. 1

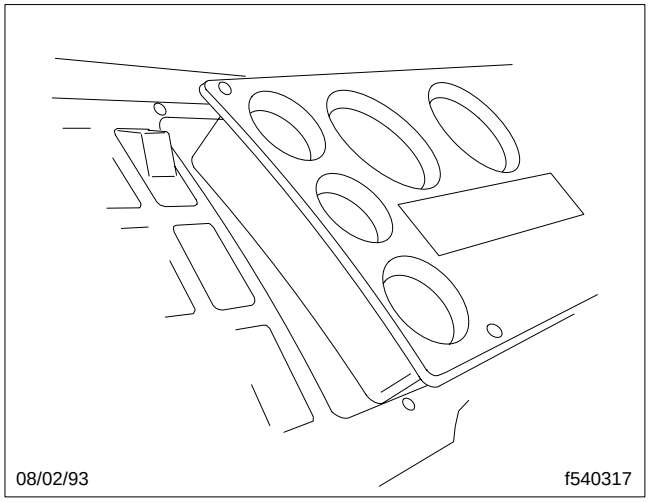

Fig. 2

4. Check the bulb for proper operation; then install the bulb holder.
5. Install the dash panels and the vinyl extrusion trim.

Interior Light Replacement

Headlight Dimmer, Hazard Light, and Turn Signal Switch Replacement

1. By hand, remove the turn signal switch cover.
2. Remove the two allen head screws that fasten the switch to the steering column.
3. Disconnect the wiring harness connector from the switch.
4. Reverse the procedure to install the new switch.

Dome Light Replacement

1. Unsnap the lens from the housing to gain access to the bulb; use a screwdriver to press in the prong on one side of the housing. **See Fig.3.**
2. Press in on the bulb and turn it counterclockwise to release it from the socket. **See Fig.4.**
3. Press the new bulb into the socket; then turn it clockwise to lock it in place. Test the bulb for proper operation.
4. Install the lens on the housing; be sure that it is fully seated.

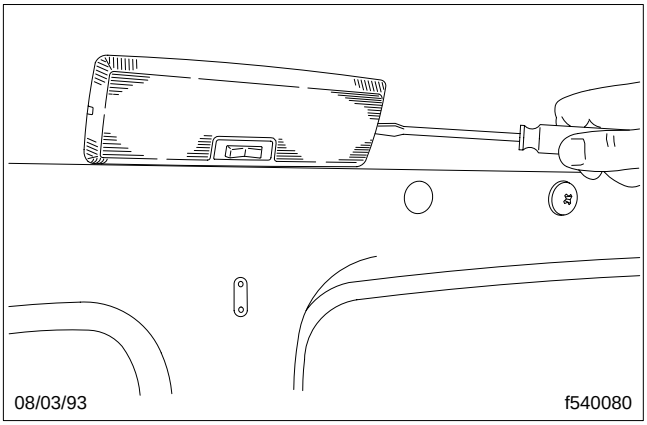

Fig. 3

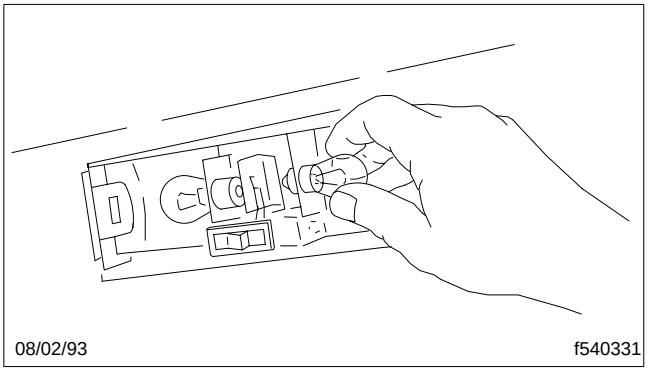

Fig. 4

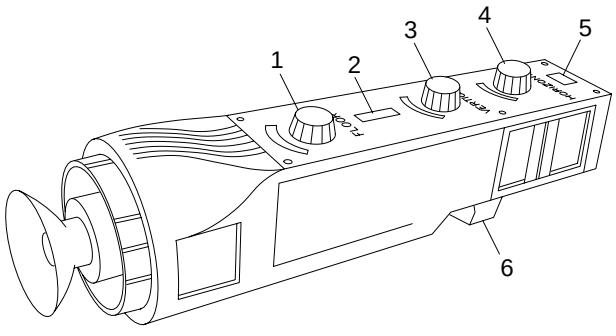
Headlight Aim Checking and Adjusting



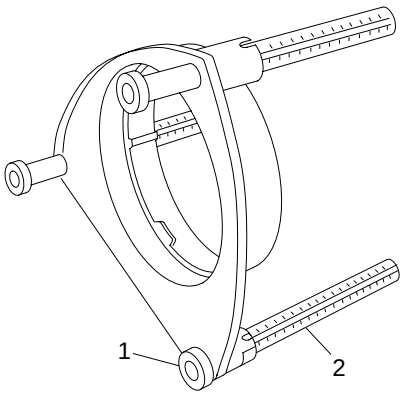
Before checking or adjusting the headlight aim, do the following:

- Remove large amounts of mud or ice from the undersides of the fenders.
- Check the springs for sagging or broken leaves. Check the suspension for proper functioning of the leveling mechanism.
- Clean the headlight lenses and aiming pads.
- Check the bulbs for burnout and broken aiming pads. Switch the beams from low to high to make sure they switch properly.
- With the vehicle unloaded, check that the tires are inflated to the recommended air pressure.

Checking

For a quick check to see if the headlights need aiming, do the following procedure.

1. Move the vehicle onto a flat surface that has been calibrated for slope. Shut down the engine, set the parking brake, and chock the tires.
2. Attach a headlight aimer to each headlight. See **Fig. 1**.



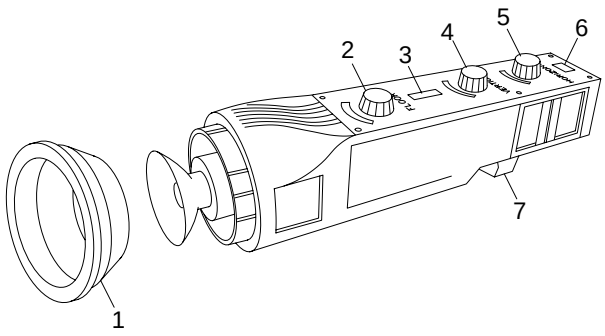
04/11/97 f580162

1. Floor Slope Dial
2. Level Vial
3. Vertical Dial
4. Horizontal Dial
5. Split Image View Port
6. Piston Handle

Fig. 1, Headlight Aimer

2.1 Attach the black universal adaptor to the aimer. Set the adjustment rods to "0" (zero). See **Fig. 2**.

On FL112 model vehicles, attach the seven-inch circular adaptor to the aimer. See **Fig. 3**.



04/14/97 f580165

Set the adjustment rods to "0" (zero).

1. Adaptor Foot
2. Adjustment Rod

Fig. 2, Universal Adaptor

07/02/97 f580175

2. Floor Slope Dial
3. Level Vial
4. Vertical Dial
5. Horizontal Dial
6. Split Image View Port
7. Piston Handle

Fig. 3, Seven-Inch Circular Adaptor

NOTE: On older FL70s with sloping headlights, set the adjusting rods to the values marked on the headlights. See **Fig. 4**.

2.2 Align the adaptor with the aiming pads on the headlight lens.

Headlight Aim Checking and Adjusting

04/14/97 f580167

NOTE: On standard rectangular headlights, set all three adjusting rods to "0" (zero).
Turn rod clockwise to lock in an odd number; turn rod counterclockwise to lock in an even number.

A. The inboard lower adjustment rod is always set to "0" (zero).
B. Set the outboard lower adjustment rod to to the horizontal adjustment value on the headlight. *Example:* "11H."
C. Set the upper adjustment rod to to the vertical adjustment value on the headlight. *Example:* "17V."

Fig. 4, Aiming Pad Alignment

2.3 Push the piston handle on the base of the aimer forward to engage the vacuum cup. Immediately pull the handle backward until it locks. See **Fig. 5**.

2.4 Do the same procedure with the other aimer.

3. Check the floor slope dial for the correct setting. See **Fig. 6**.

4. Check the horizontal aim. See **Fig. 7**.

4.1 Turn the horizontal dial until the split image is in alignment.

4.2 If the horizontal dial scale on either aimer reads more than "4," re-aim the headlight.

NOTE: If adjustment is required, see the procedures under "Adjusting" below.

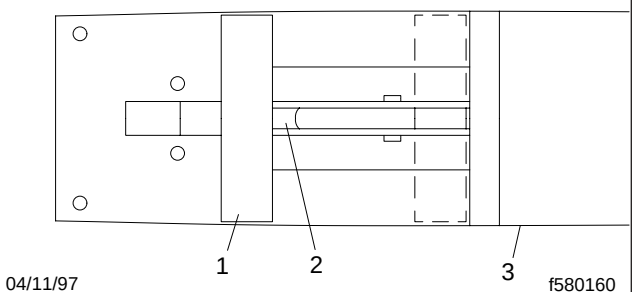
5. Check the vertical aim. See **Fig. 8**.

5.1 Turn the vertical dial until the level vial is centered.

5.2 If the vertical dial scale on either aimer reads more than "4," re-aim the headlight.

NOTE: If adjustment is required, see the procedures under "Adjusting" below.

6. Remove the two headlight aimers. Hold each aimer securely, and then press the vacuum release button.

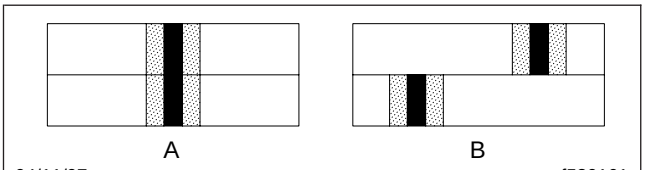


7. Remove the chocks from the tires.

Adjusting

If the headlights need adjusting, do this procedure.

1. If not already there, move the vehicle onto a flat surface that has been calibrated for slope. Shut



Headlight Aim Checking and Adjusting

To attach, push the piston handle forward to engage the vacuum cup. Immediately pull the handle backward until it locks.
To remove, press the vacuum release button.

down the engine, set the parking brake, and chock the tires.

4. Adjust the horizontal aim. See **Fig. 7**.

   4.1 Set the horizontal dial to "0" (zero).

Headlight Aim Checking and Adjusting

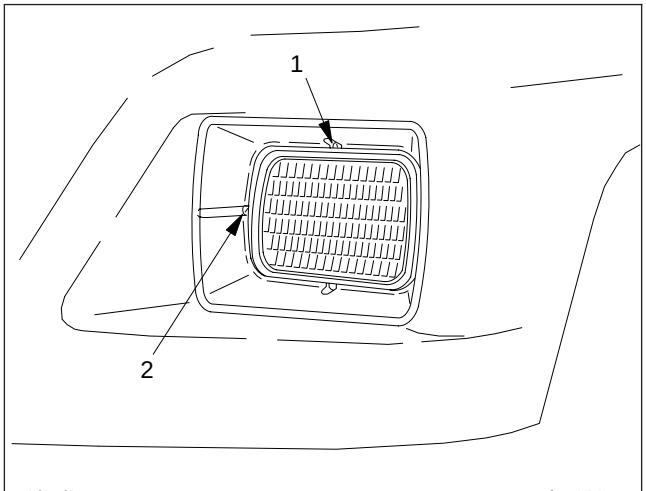
07/28/97 f580177

Set the vertical dial to "0" (zero).

A. Bubble Not Centered
B. Bubble Centered
1. Level Vial
2. Vertical Dial

Fig. 8, Vertical Aim Level Vial

4.2 Look in the viewing port for the split image target lines. If necessary, rotate either or both aimers until the lines are visible.



4.3 Turn the horizontal adjustment screw as needed to make the split image appear as one solid line. See **Fig. 9**.

IMPORTANT: To avoid backlash, make the final adjustment by turning the screw clockwise.

4.4 Do the same procedure for the other headlight.

5. Adjust the vertical aim. See **Fig. 8**.

5.1 Set the vertical dial to "0" (zero).

10/05/94 f540307a

1. Vertical Adjustment
2. Horizontal Adjustment

Fig. 9, Headlight Adjustment Screws

5.2 Turn the vertical adjustment screw as needed to center the bubble in the level vial between the lines. See **Fig. 9**.

IMPORTANT: To avoid backlash, make the final adjustment by turning the screw clockwise.

5.3 Do the same procedure for the other headlight.

6. Recheck the horizontal alignment on both aimers. Readjust if necessary.

7. Remove both headlight aimers. While holding the aimer securely, press the vacuum release button. See **Fig. 5**.

8. Remove the chocks from the tires.

Troubleshooting Table

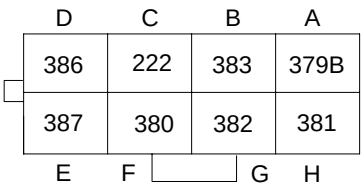
Problem—Daytime Running Lights Are Not Operating Correctly

Possible Cause	Remedy
The DRL module connectors are not making proper contact.	Disconnect and inspect the connectors. Check the headlights for proper operation. Reconnect the module and retest.
The wiring, relay or switch does not work.	Correct the wiring or switch fault. Retest.
The DRL input levels are incorrect. Refer to **Table 1** for the voltage levels at the harness connector.	Correct the wiring, relay, or switch problem. Retest.
Tests in **Table 2** indicate that the DRL module has a problem.	Replace the DRL module and retest.

Testing the DRL System

See **Specifications 400** for the wiring diagrams of the DRL and the vehicle lighting systems. To test the operation of the daytime running lights (DRLs):

1. With the ignition key OFF, the headlight circuit works normally.
2. When the key ON, and the parking brake set or the headlight switch is ON, the headlights work as normal and will switch between high and low beams when the dimmer switch is toggled.



NOTE: The low beams will not turn fully off, however, if the key is ON with either the parking brakes released, or the headlight switch OFF, because the system is in the DRL mode.

3. With the key ON, the headlight switch OFF, and the parking brake released, the DRL module activates the low beam circuit only (through pins D and E) at approximately 86 percent of nominal voltage. The DRL voltage will range between 10.5 VDC with the engine stopped and 12.5 VDC with the engine running.

   NOTE: When the DRL system is active, pin C of the DRL module grounds and causes both dimmer relays to switch to the high beam position. This position prevents electricity from flowing from pins D and E of the DRL module to all the lights normally activated by the headlight switch. Only the low beams and the fog lamps can receive power in the DRL mode.

4. Disconnect the electrical connector from the DRL module. Perform the voltage tests on the harness connector as described in **Table 1** to make sure that the DRL module is receiving the correct inputs.
5. Connect the harness connector to the DRL module connector. Perform the tests described in **Table 2**. When the DRL system is active and the engine is not running, the DRL module must cause the voltages shown in the table at the locations specified.

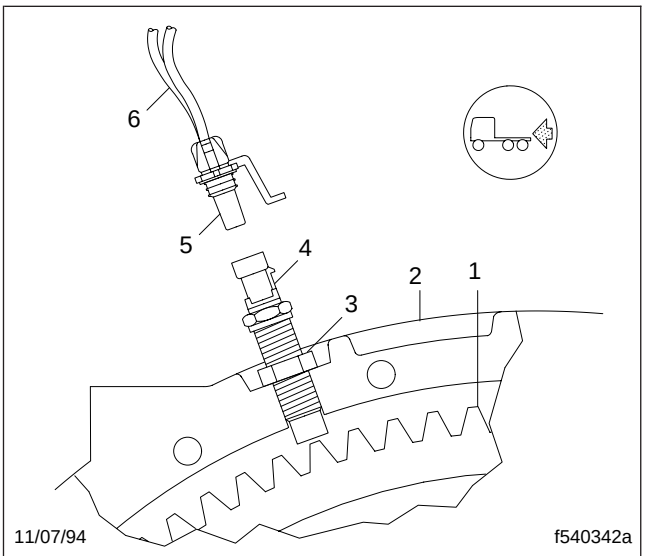
General Information

The Ametek electronic tachometer consists of a dash-mounted gauge (tachometer head), a magnetic sensor mounted on the flywheel housing, and the electrical wires that provide power to the tachometer and complete the circuit between the components.

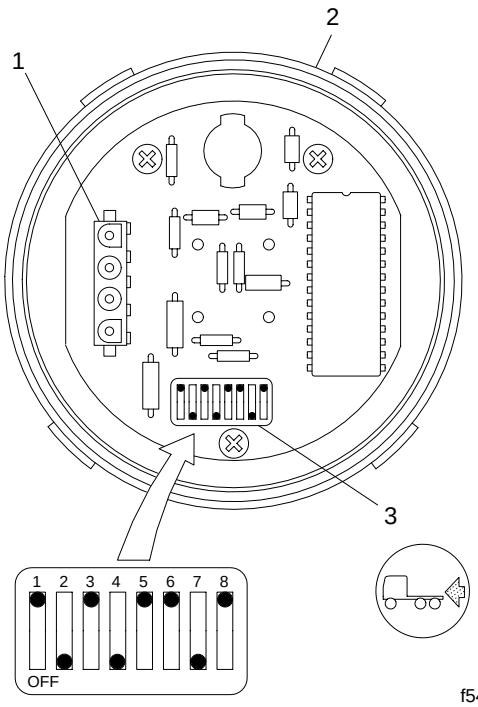
The tachometer head registers engine speed in revolutions per minute (rpm). It is used as a guide for shifting, and keeping the engine in the proper speed range. An optional tachometer is equipped with a 7-wheel hourmeter that records total hours of engine operation. See **Fig. 1**.



The magnetic sensor is mounted with its magnetic end extending through a threaded bore in the flywheel housing. It stops a little over 1/32 inch (1 mm) from the teeth of the flywheel ring gear. See **Fig. 2**.

1. Ametek Electronic Tachometer
2. Engine Hourmeter
3. Instrument Panel

Fig. 1, Tachometer/Hourmeter Location



When the engine is running, the teeth of the turning flywheel ring gear generate electrical pulses in the sensor's magnetic field. These pulses tell the tachometer head how fast the engine is turning. For the tachometer head to interpret the pulses as engine speed, it must be programmed (calibrated) for the number of teeth on the flywheel ring gear. At the back of the tachometer head are 8 DIP switches (rocker switches). See **Fig. 3**. The tachometer is calibrated by positioning the rocker switches on or off to correspond to the code determined for the number of teeth on the ring gear. A new tachometer head must be calibrated before it is installed.

Removal

1. Remove the instrument panel.

   1.1 By hand, remove the vinyl extrusion trim (**Fig. 1**, Ref. 7) on the sides of the instrument panel.

   1.2 On vehicles built after late January/early February 1997, remove the four Torx-head screws from the instrument panel.

09/16/97 f600386a

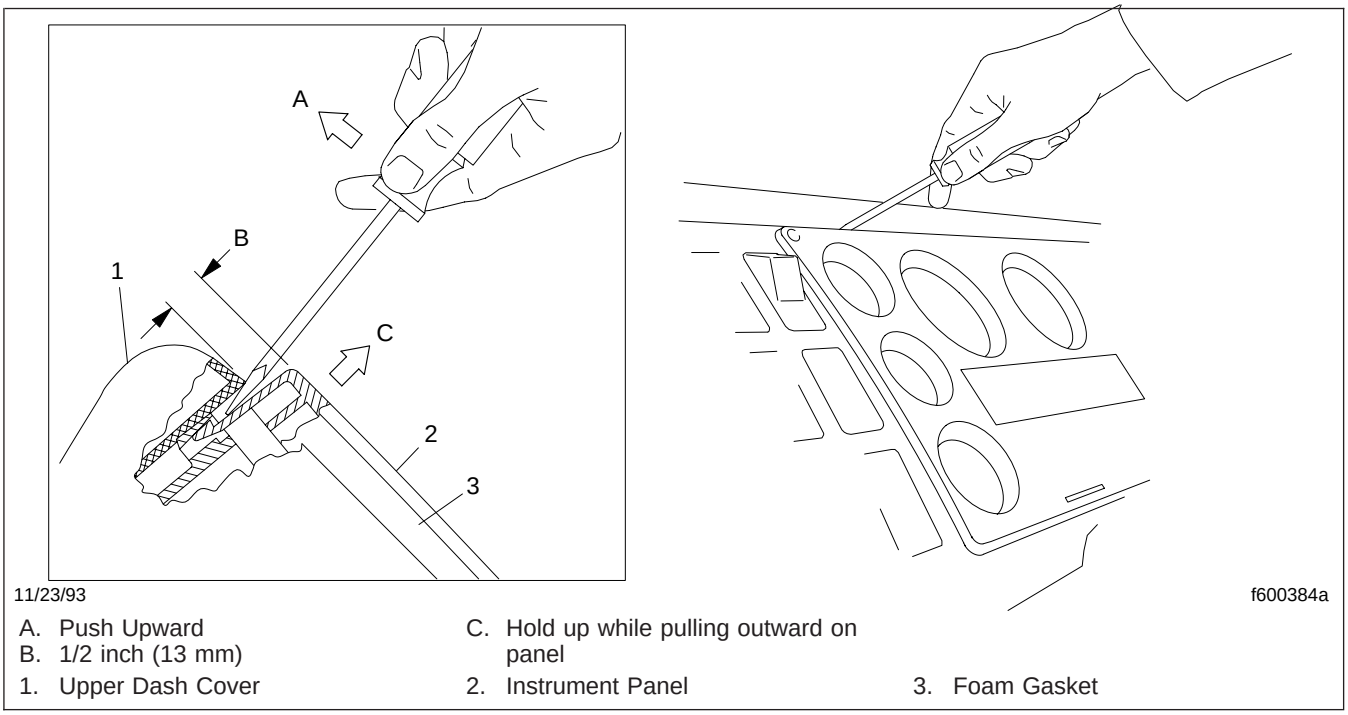
6. Opening in Foam Gasket
7. Vinyl Extrusion Trim
8. Gauge Blank (block-off plug)
9. Slot in Panel
10. Torx-Head Screws

Fig. 1, Instrument Panel



NOTE: Vehicles manufactured after late January/early February 1997, use spring-loaded Torx®-head screws to fasten the instrument panel (see **Fig. 1**, Ref. 10). This is in lieu of locking tabs.

1.3 On vehicles built earlier, insert a stubby plain-tip screwdriver in an opening in the foam gasket (see **Fig. 1**, Ref. 6), gently pry down the panel locking tab (**Fig. 1**,

Tachometer Head Removal and Installation

Ref. 5). Hold up on the screwdriver, while pulling that corner of the panel out about 1/2-inch (13 mm) from the upper dash cover. See **Fig. 2**. Use care not to damage the foam gasket.

2.2 Use your thumbs to gently, simultaneously press the locking tabs away from the bosses on the tachometer case. See **Fig. 5**. Then, lift the tachometer head away from the gauge housing.

A. Push Upward
B. 1/2 inch (13 mm)
C. Hold up while pulling outward on panel
1. Upper Dash Cover
2. Instrument Panel
3. Foam Gasket

Fig. 2, Upper Dash Cover

1.4 Repeat the above step for the other upper corner, then tilt the top of the panel out about 1 inch (25 mm). Work the bottom of the panel out of the dash. If the bottom of the panel won't move, use a screwdriver to pry up the locking tabs at the bottom of the panel. See **Fig. 3**.

1.5 Work the panel off the dash, using care not to damage the foam gasket.

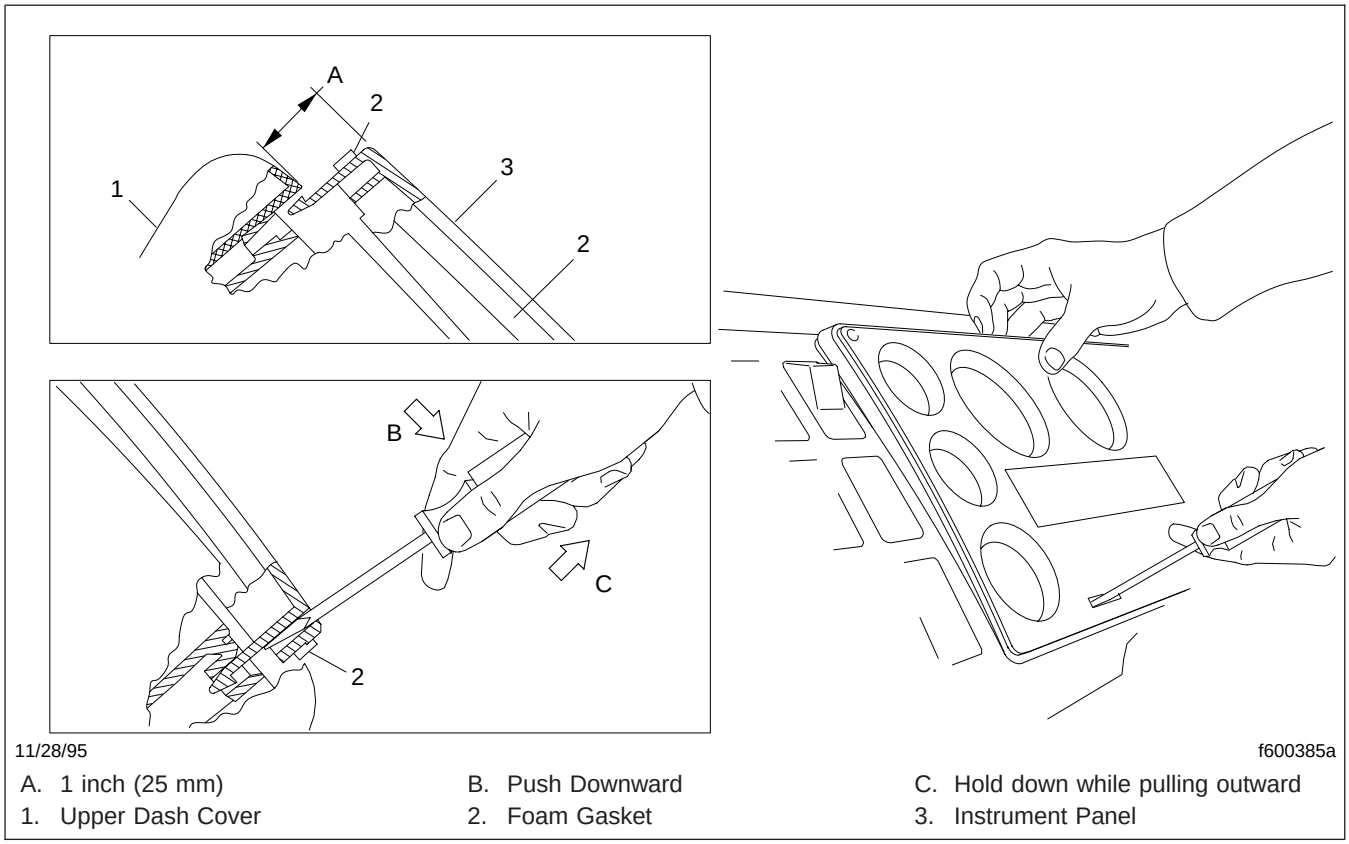
2. Remove the tachometer head from the dashboard.

IMPORTANT: Don't touch the tachometer face or pointer.

2.1 Lift out the right-hand turn signal indicator-light tunnel and the right-hand warning-light separator. See **Fig. 4**.

2.3 Install the right-hand turn signal indicator-light tunnel and right-hand warning-light separator.

2.4 Squeeze the connector release tabs while pulling the harness half of the Mate-N-Lok connector, to disconnect it from the back of the tachometer head. See **Fig. 6** and **Fig. 7**.



Installation

NOTE: Before installing the tachometer head, be sure it is calibrated; see **Subject 110**.

1. Install the tachometer head in the dashboard.

1.1 Connect the wiring harness to the tachometer head. See **Fig. 6**. Be sure the upper and lower lock tabs are locked.

Tachometer Head Removal and Installation

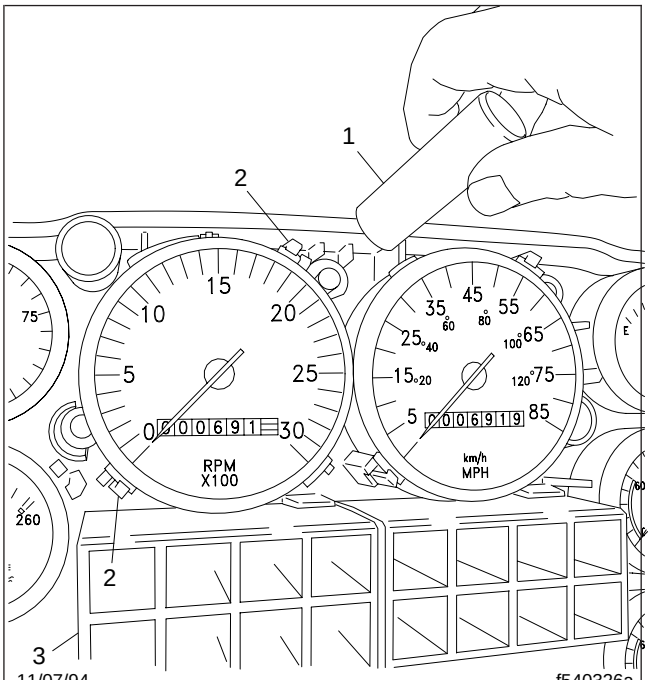
A. 1 inch (25 mm)
B. Push Downward
C. Hold down while pulling outward
1. Upper Dash Cover
2. Foam Gasket
3. Instrument Panel

Fig. 3, Panel Removal

1.2 Line up the bosses on the tachometer case with the locking tabs on the gauge housing. Feed the wiring harness through the opening in the gauge housing, and press the tachometer head into place until the locking tabs are locked over the bosses. See **Fig. 4**.

2. Install the instrument panel. See **Fig. 1**.

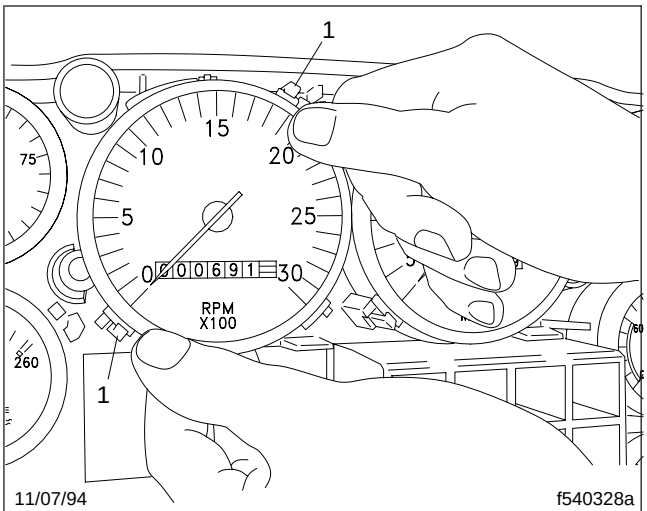
2.1 Position the instrument panel against the dash. See **Fig. 1**



2.2 On vehicles built after late January/early February 1997, install the four spring-loaded Torx-head screws and tighten them until firm.

On vehicles built earlier, lock the four locking tabs, by pushing alternately, starting with the lower corner, against the bottom and top corners of the panel, until the face of the panel is flush with the rest of the instrument panel.

IMPORTANT: Don't push against the lenses of the gauge blanks.



2.3 Install the vinyl extrusion trim (See **Fig. 1**, Ref. 7) on both sides of the panel.

A. Squeeze the release tabs, then pull out on the connector to remove.

Fig. 7, Wiring Harness and Tachometer Head (disconnected)

Calibration

Always calibrate a new tachometer head before installing it.

1. See **Table 1** to determine the tachometer calibration setting.

Tachometer Calibration Settings								
Engine	**S1**	**S2**	**S3**	**S4**	**S5**	**S6**	**S7**	**S8**
Cummins 6BTA	ON	OFF	ON	OFF	ON	ON	OFF	ON
Mercedes-Benz OM 366LA	ON	OFF	ON	OFF	ON	OFF	ON	OFF
Cummins C	ON	OFF	OFF	OFF	ON	OFF	ON	OFF
All Electronic Engines	OFF	OFF	OFF	OFF	ON	ON	OFF	OFF

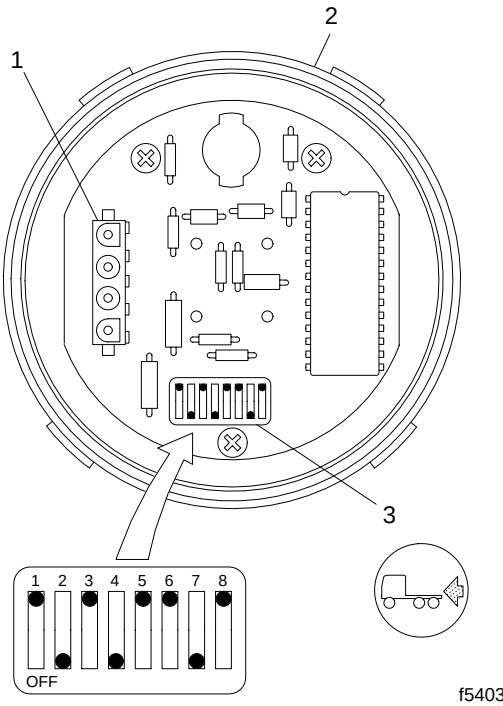

Table 1, Tachometer Calibration Settings

2. Set the positions of the eight rocker (DIP) switches to ON or OFF as indicated by the calibration code. See **Fig. 1**.

   A 0 (zero) indicates OFF, and a 1 (one) indicates ON. Using a scribe, an awl, or a straightened paper clip, depress the top of the rocker switch to set it to ON; depress the bottom to set it to OFF.

   For example, to match the calibration code 10101101, the number 1 rocker switch is ON (top is depressed), the number 2 switch is OFF (bottom is depressed), number 3 is ON, 4 is OFF, 5 and 6 are ON, 7 is OFF, and 8 is ON. See **Fig. 1**.

3. Remove the old tachometer and install the new calibrated tachometer; see **Subject 100.**

NOTE: Example shows switches set for calibration code 10101101: S1=ON, S2=OFF, S3=ON, S4=OFF, S5=ON, S6=ON, S7=OFF, and S8=ON. The black dot shows which end to press in.

1. Mate-N-Lok Connector Half
2. Tachometer Head
3. DIP Switches

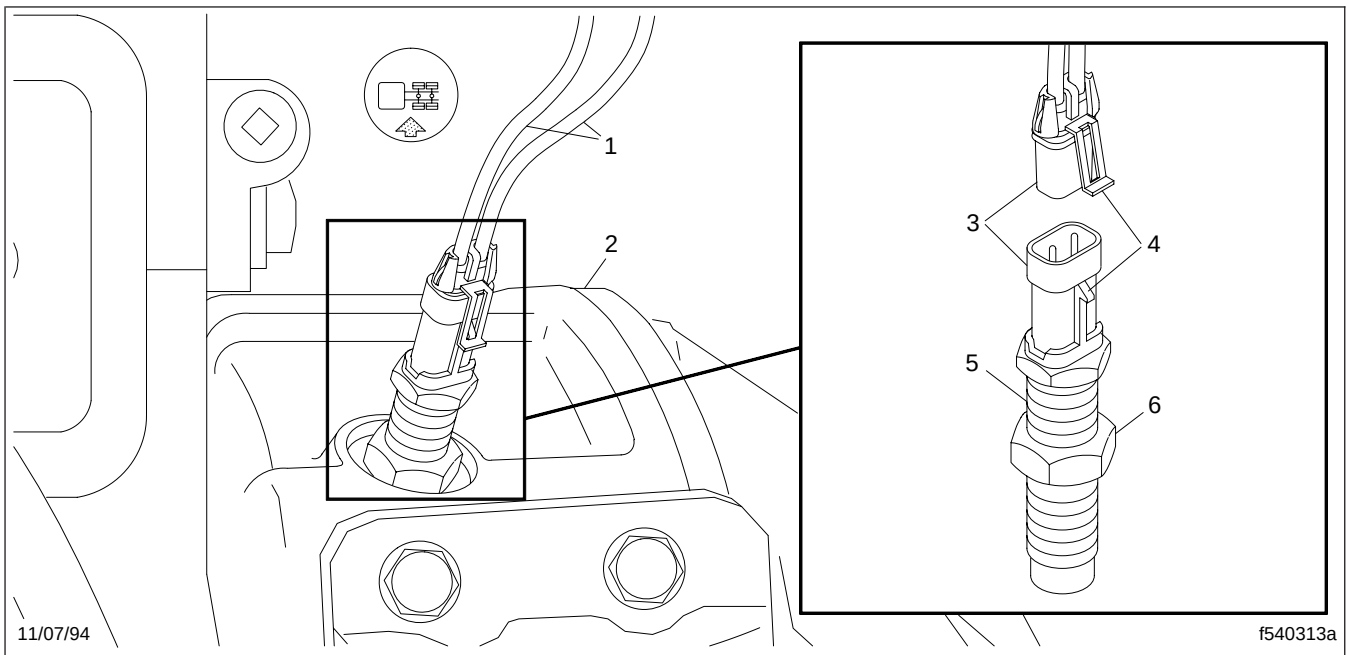

Fig. 1, Rear View of the Tachometer Head

Replacement and Adjustment

1. Apply the parking brakes, shut down the engine, and chock the tires.
2. Remove the magnetic sensor.
   - 2.1 Disconnect the Metri-Pack® connector from the magnetic sensor. See **Fig. 1**.
   - 2.2 Loosen the magnetic sensor jam nut. See **Fig. 2**. Turn the magnetic sensor out of the flywheel housing.
3. Adjust the new sensor. See **Fig. 3**.
   - 3.1 Back off to the outboard end of the new magnetic sensor.
   - 3.2 Turn the sensor by hand into the flywheel housing until it bottoms out on the teeth of the flywheel ring gear.
   - 3.3 Back out the sensor three-quarters of a turn. See **Fig. 3**.
4. Install the new sensor.
   - 4.1 While holding the sensor in place to keep it from turning, tighten the jam nut 18 lbf·ft (25 N·m).

IMPORTANT: Maintain the correct sensor adjustment, or the tachometer reading will not be correct.

   - 4.2 Connect the wiring to the sensor and be sure the Metri-Pack connector is locked in place. See **Fig. 1**.
5. Remove the chocks from the tires.
6. Test drive the vehicle and check that the tachometer is operating. If there is no tachometer reading, the magnetic sensor was probably not adjusted correctly; readjust the sensor.

Troubleshooting Procedures

Tachometer malfunctions are usually one of two types: the tachometer does not operate at all, or the tachometer readings are inaccurate.

INACCURATE TACHOMETER

Inaccurate tachometer readings may occur whenever a new tachometer head is installed. Calibrate the tachometer head using the procedure in **Subject 110**.

Inaccurate readings will also occur if the magnetic sensor is not adjusted correctly. Before troubleshooting the system, make sure the magnetic sensor is correctly adjusted. For instructions, see **Subject 120**. Also, make sure the batteries are fully charged.

THE TACHOMETER DOES NOT OPERATE

1. Test the magnetic sensor's output voltage.

   NOTE: To receive an accurate tachometer reading, a minimum of one volt AC output is needed from the magnetic sensor.

   1.1 Disconnect the Metri-Pack® connector from the magnetic sensor. See **Fig. 1**. Make sure that both halves of the connection are free of corrosion and moisture.

   1.2 Connect the leads of an AC voltmeter to the pins of the magnetic sensor. See **Fig. 2**.

   1.3 Run the engine at idle speed, and check the voltage output from the sensor. Then shut down the engine.

   If the voltage is less than one volt, and the sensor was correctly adjusted before troubleshooting the system, the magnetic sensor is damaged; replace it.

   If the voltage is at least one volt, continue the procedure.

2. Connect the leads of an ohmmeter to the pins of the magnetic sensor. See **Fig. 3**. The resistance should measure 876 ± 88 ohms.

   NOTE: Resistance will vary on optional sensors. Contact the manufacturer for the acceptable sensor resistance.

   If the resistance is outside the acceptable range, replace the sensor; see **Subject 120**.

   If the resistance is in the acceptable range, connect the wiring to the sensor and be sure the Metri-Pack connector is locked in place. See **Fig. 1**. Then go on to check the wiring between the magnetic sensor and the tachometer head.

3. Check the wiring between the magnetic sensor and the tachometer head. See **Fig. 4**.

   3.1 Remove the tachometer head from the dash and disconnect the wiring harness from the tachometer head; see **Subject 100**.

   3.2 Check for an open or short circuit by inserting the ohmmeter leads in towers 2 and 4 of the wiring harness half of the Mate-N-Lok connector (for wiring circuit numbers 162 and 163, respectively). See **Fig. 4**. The resistance should measure 876 ± 88 ohms.

   NOTE: Resistance will vary on optional sensors. Contact the manufacturer for the acceptable sensor resistance.

   3.3 If the resistance is outside the acceptable range, the problem is in the wiring between the tachometer head and the magnetic sensor. Repair or replace the damaged wiring. Then install the tachometer head; see **Subject 100**.

   If the resistance is in the acceptable range, connect the wiring harness to the tachometer head and be sure the Mate-N-Lok connector is locked in place. Then go on to check the battery voltage at the tachometer head.

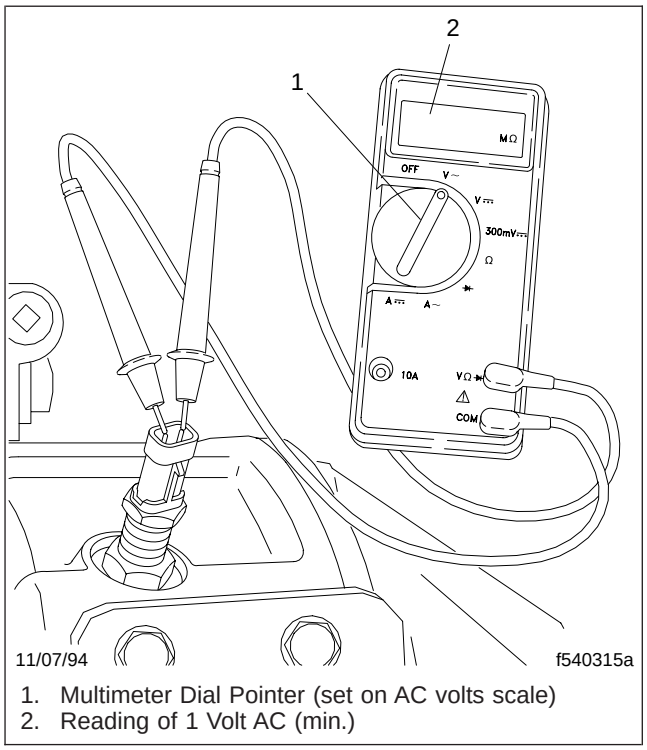
4. Check the battery voltage at the tachometer head. See **Fig. 5**.

   4.1 With the ignition switch on, touch the probes of a DC voltmeter to pins 1 and 3 on the front side of the rear plate of the tachometer head (where the pins of the connector extend through the rear plate). See **Fig. 5**. Touch the negative (black) probe to pin 1, and the positive (red) probe to pin 3. The voltmeter should read 9 to 16 volts DC.

Troubleshooting

1. Tachometer Wiring
2. Flywheel Housing
3. Metri-Pack Connector Halves
4. Connector Lock Halves
5. Magnetic Sensor
6. Jamnut

Fig. 1, Metri-Pack Connector



4.2 If the voltage *is* between 9 and 16 volts DC, but the tachometer readings are *not* accurate, then the tachometer head, not the wiring, is causing inaccurate readings. Disconnect the voltmeter and turn off the ignition switch. Replace the tachometer head; see **Subject 100**.

If the voltage is *not* between 9 and 16 volts DC, check the wiring between the ignition switch and the tachometer head, and between the tachometer head and ground. Disconnect the voltmeter and turn off the ignition switch. Repair or replace the damaged wiring. Install the tachometer head; see **Subject 100**.

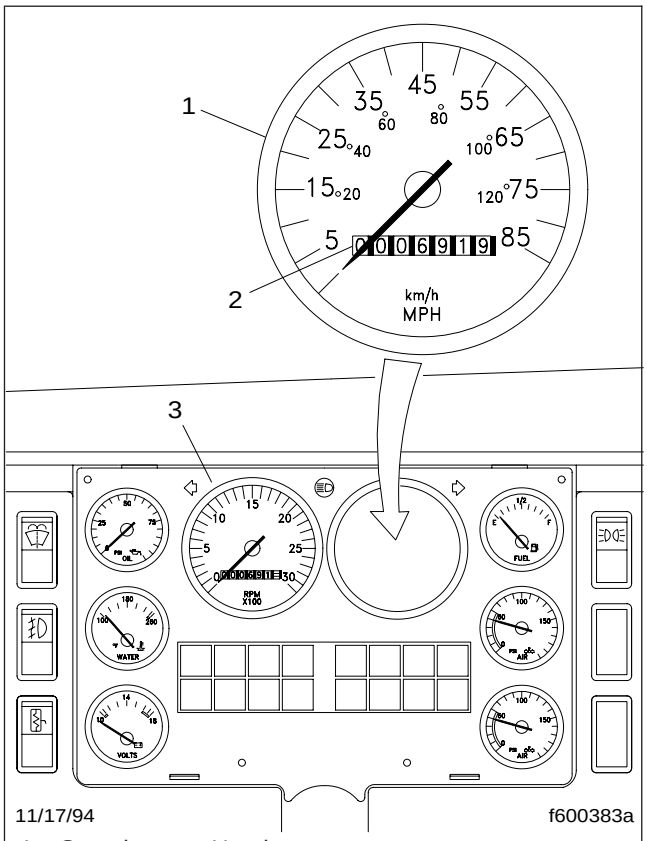
Fig. 1, Tachometer Wiring Diagram

General Information

The Ametek electronic speedometer consists of a dash-mounted gauge (speedometer head), a transmission-mounted magnetic sensor, and the electrical wires that provide power to the speedometer and complete the circuit between the components.

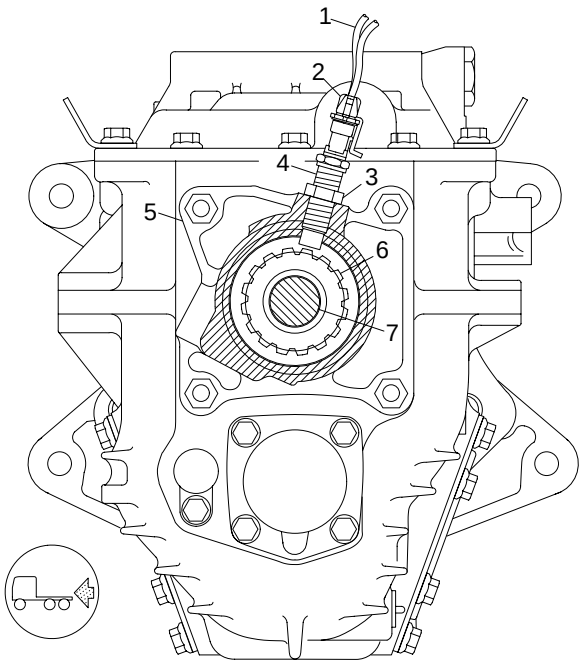


A vehicle built for use in the U.S.A. has a speedometer head that registers vehicle speed in miles per hour (mph) on its outer (major) scale and in kilometers per hour (km/h) on its inner (minor) scale, and records total distance traveled in miles on a 7-wheel odometer. See **Fig. 1**. A speedometer head for a vehicle built for use in Canada, registers vehicle speed in km/h on the outer scale (and mph on the inner scale), and has a 7-wheel odometer that records distance in kilometers.

The magnetic sensor is mounted with its magnetic end extending through a threaded bore in the transmission bearing cover. It stops a little over 1/32-inch (1 mm) from the teeth of a standard 16-tooth spacer gear located under the cover, on the inboard end of the transmission output shaft. See **Fig. 2**.

When the vehicle is moving, the teeth of the turning spacer gear generate electrical pulses in the sensor's magnetic field. These pulses tell the speedometer head how fast the transmission output shaft is turning. For the speedometer head to interpret the pulses as vehicle speed and distance traveled, it must be programmed (calibrated) for the components with which the vehicle is equipped.

At the back of the speedometer head are 10 DIP switches (rocker switches). See **Fig. 3**. The speedometer is calibrated by positioning the rocker switches on or off to correspond to the code determined for the specific combination of the number of teeth on the transmission spacer gear, the axle reduction ratio, and the tire size (tire revolutions per mile). For each possible combination, there is a different calibration code.



A new speedometer head must be calibrated before it is installed. Whenever different tires are installed on the vehicle, the speedometer head must be recalibrated.

Removal

1. Remove the instrument panel.

   1.1 By hand, remove the vinyl extrusion trim (**Fig. 1**, Ref. 7) on the sides of the instrument panel.

   1.2 On vehicles built after late January/early February 1997, remove the four Torx-head screws from the instrument panel.

A. Sectional Detail (left-side view)
B. Sectional Detail (left-side view)

7. Vinyl Extrusion Trim
8. Gauge Blank (Block-Off Plug)
9. Slot in Panel
10. Torx-head Screws

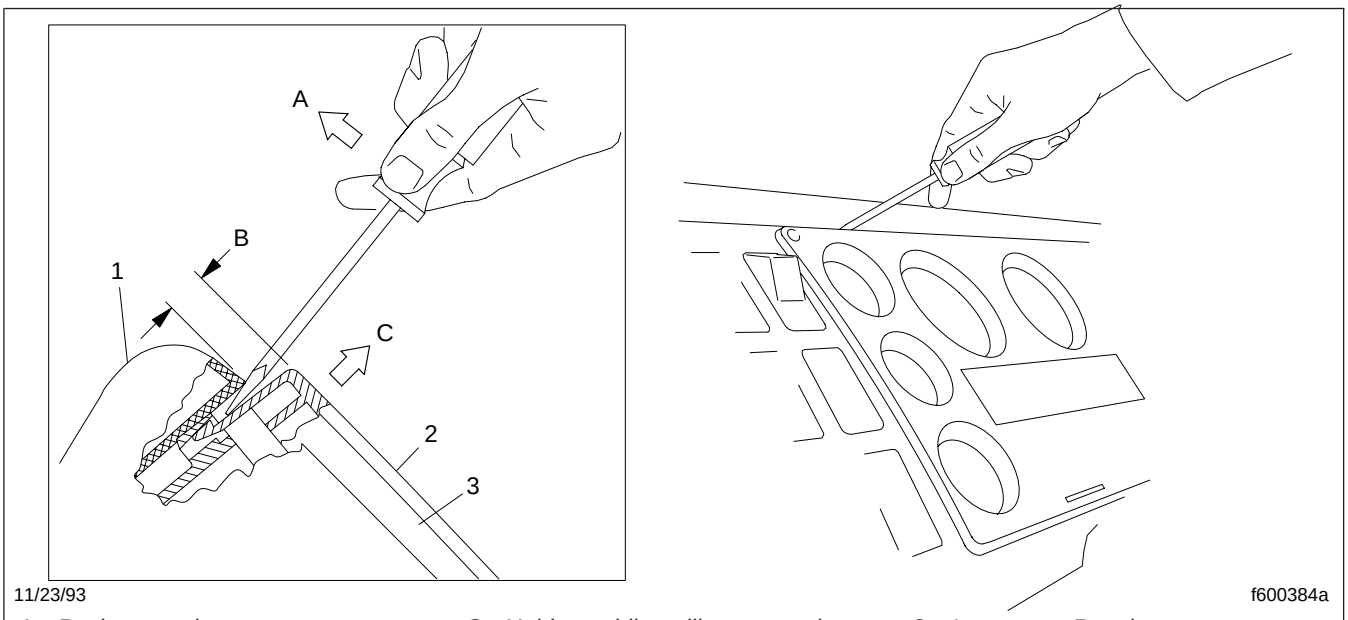

Fig. 1, Instrument Panel

NOTE: Vehicles manufactured after late January/early February 1997, use spring-loaded Torx®-head screws to fasten the instrument panel (see **Fig. 1**, Ref. 10). This is in lieu of locking tabs.

1.3 On vehicles built earlier, insert a stubby plain-tip screwdriver in an opening in the foam gasket (see **Fig. 1**, Ref. 6), gently pry down the panel locking tab (**Fig. 1**,

Speedometer Head Removal and Installation

Ref. 5). Hold up on the screwdriver, while pulling that corner of the panel out about 1/2 inch (13 mm) from the upper dash cover. See **Fig. 2**. Use care not to damage the foam gasket.

A. Push upward.
B. 1/2-inch (13 mm)
C. Hold up while pulling outward on panel.
1. Upper Dash Cover
2. Instrument Panel
3. Foam Gasket

Fig. 2, Upper Dash Cover

1.4 Repeat the above step for the other upper corner, then tilt the top of the panel out about 1 inch (25 mm). Work the bottom of the panel out of the dash. If the bottom of the panel won't move, use a screwdriver to pry up the locking tabs at the bottom of the panel. See **Fig. 3**.

Work the panel off the dash, using care not to damage the foam gasket.

2. Remove the speedometer head from the dashboard.

IMPORTANT: Don't touch the speedometer face or pointer.

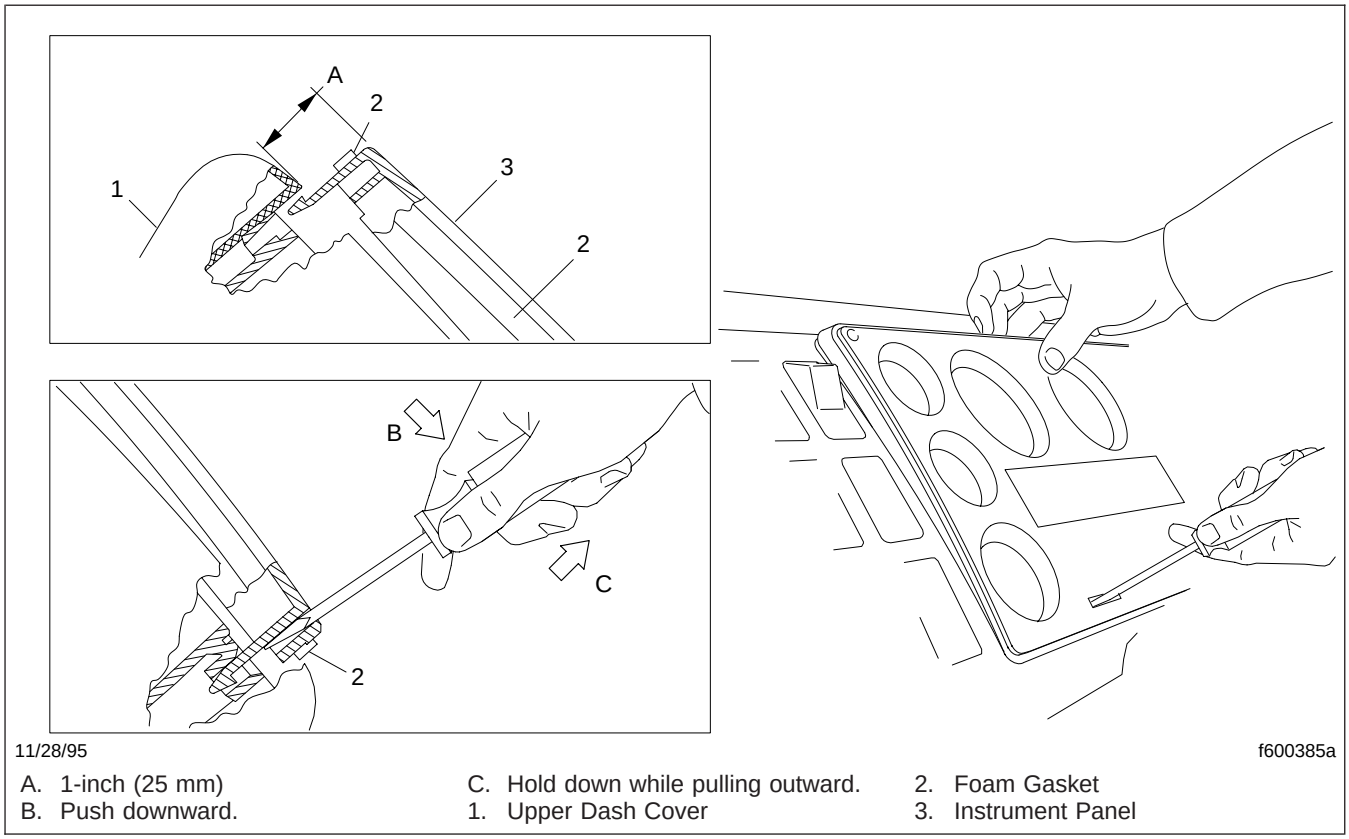
2.1 Lift out the right-hand turn signal indicator-light tunnel and the right-hand warning-light separator. See **Fig. 4**.

2.2 Use your thumbs to gently, simultaneously press the locking tabs away from the bosses on the speedometer case. See **Fig. 5**. Then, lift the speedometer head away from the gauge housing.

2.3 Install the right-hand turn signal indicator-light tunnel and right-hand warning-light separator.

2.4 Squeeze the connector release tabs while pulling the harness half of the Mate-N-Lok connector, to disconnect it from the back of the speedometer head. See **Fig. 6** and **Fig. 7**.

Installation



NOTE: Before installing the speedometer head, be sure it is calibrated; see **Subject 110**.

1. Install the speedometer head in the dashboard.

1.1 Connect the wiring harness to the speedometer head. See **Fig. 6**. Be sure the upper and lower lock tabs are locked.

1.2 Line up the bosses on the speedometer case with the locking tabs on the gauge

Speedometer Head Removal and Installation

A. 1-inch (25 mm)
B. Push downward.
C. Hold down while pulling outward.

2. Foam Gasket
3. Instrument Panel

Fig. 3, Panel Removal

housing. Feed the wiring harness through the opening in the gauge housing, and press the speedometer head into place until the locking tabs are locked over the bosses. See **Fig. 4**.

2. Install the instrument panel. See **Fig. 1**.

   2.1 Position the instrument panel against the dash. See **Fig. 1**

   2.2 On vehicles built after late January/early February 1997, install the four spring-loaded Torx-head screws and tighten them until firm.

   On vehicles built earlier, lock the four locking tabs, by pushing alternately, starting with the lower corner, against the bottom and top corners of the panel, until the face of the panel is flush with the rest of the instrument panel.

IMPORTANT: Don't push against the lenses of the gauge blanks.

   2.3 Install the vinyl extrusion trim (See **Fig. 1**, Ref. 7) on both sides of the panel.

Calibration

Recalibrate the speedometer head whenever different tires (brand, size, or tread design) are installed. Always calibrate a new speedometer head before installing it.

1. Determine the speedometer calibration setting.

   1.1 Look on the sidewall of the vehicle's rear tires to find their size, manufacturer, and tread design. Contact the tire dealer or manufacturer to get the revolutions per mile (rev/mi) for those tires.

   1.2 Find the rear axle ratio (AR) on the vehicle specification decal, or on the identification plate attached to the axle housing.

   1.3 Calculate the number of electronic pulses per mile (pulses/mi) that are being sent to the speedometer, by multiplying the tire revolutions per mile (rev/mi) by the rear axle ratio (AR), then multiply the answer by the number of impulses (n) sent to the speedometer for each revolution of the transmission output shaft.

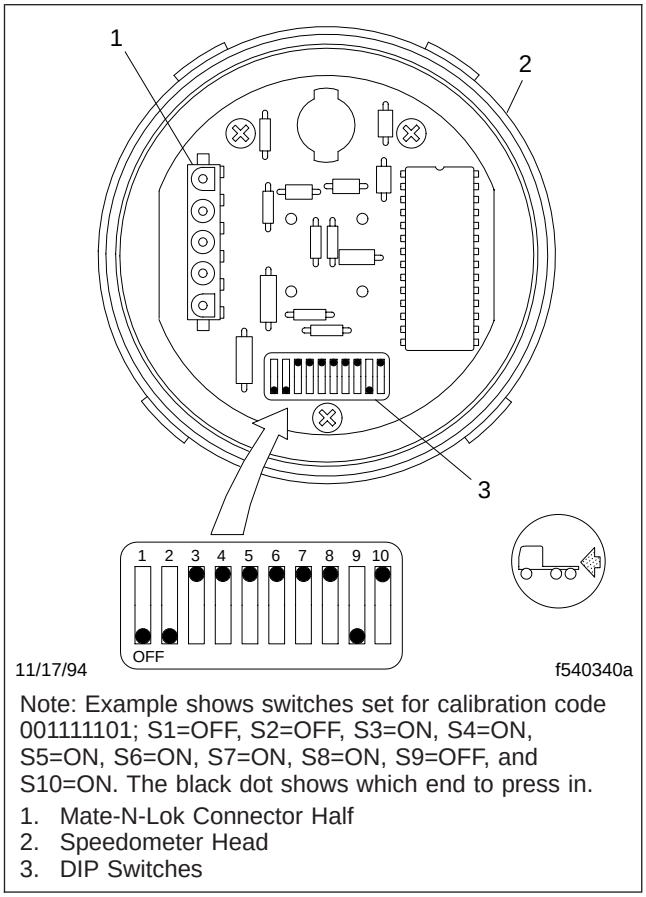
   NOTE: For all manual and automatic transmissions *n* equals 16 (there are 16 teeth on the transmission's speedometer impulse gear).

   1.4 Thus, rev/mi x AR x n = pulses/mi.

   For example, if the vehicle is equipped with Michelin 275/80R22.5 XZA-1 Pilote radial tires (516 rev/mi) and 3.91 rear axle ratio (3.91 AR), calculate pulses/mi as follows:

   516 (rev/mi) x 3.91 (AR) x 16 (n) = 32280 pulses/mi.

   1.5 Find the number in the "pulses per mile" column of the applicable table in **Specifications, 400** that comes closest to the calculated pulses per mile; then find the corresponding calibration code across from it in the other column.



Using the calculation example, the corresponding calibration code for 32280 pulses/mi is 1011000010.

2. Remove the speedometer head from the dash; see **Subject 100.**
3. Set the positions of the ten rocker (DIP) switches to ON or OFF as indicated by the calibration code. See **Fig. 1**.

   A 0 (zero) indicates ON, and a 1 (one) indicates OFF.

   Using a scribe, an awl, or a straightened paper clip, depress the top of the rocker switch to set it to ON; depress the bottom to set it to OFF.

   Using the calculation example, the number 1 rocker switch is OFF (bottom is depressed), the number 2 switch is ON (top is depressed), number 3 is OFF, 4 is OFF, and so on, see **Fig. 1**.
4. Install the speedometer head; see **Subject 100.**.

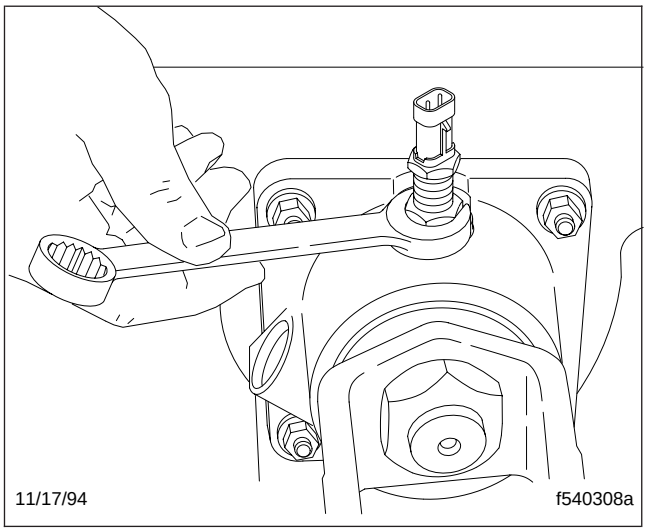
Note: Example shows switches set for calibration code 001111101; S1=OFF, S2=OFF, S3=ON, S4=ON, S5=ON, S6=ON, S7=ON, S8=ON, S9=OFF, and S10=ON. The black dot shows which end to press in.

1. Mate-N-Lok Connector Half
2. Speedometer Head
3. DIP Switches

Fig. 1, Rear View of the Speedometer Head

Replacement and Adjustment

1. Apply the parking brakes, shut down the engine, and chock the tires.
2. Remove the magnetic sensor.
   - 2.1 Disconnect the Metri-Pack® connector from the magnetic sensor. See **Fig. 1**.
   - 2.2 Loosen the magnetic sensor jam nut. See **Fig. 2**. Turn the magnetic sensor out of the transmission bearing cover. If the sensor O-ring wasn't removed with the sensor, remove the O-ring from the bearing cover.
3. On Rockwell transmissions, install a new O-ring on the magnetic sensor. If installing a new sensor, leave the plastic cap on the end of the sensor. The cap serves as a gap gauge when installing the sensor. See **Fig. 1**.
4. Adjust the sensor. See **Fig. 3**.



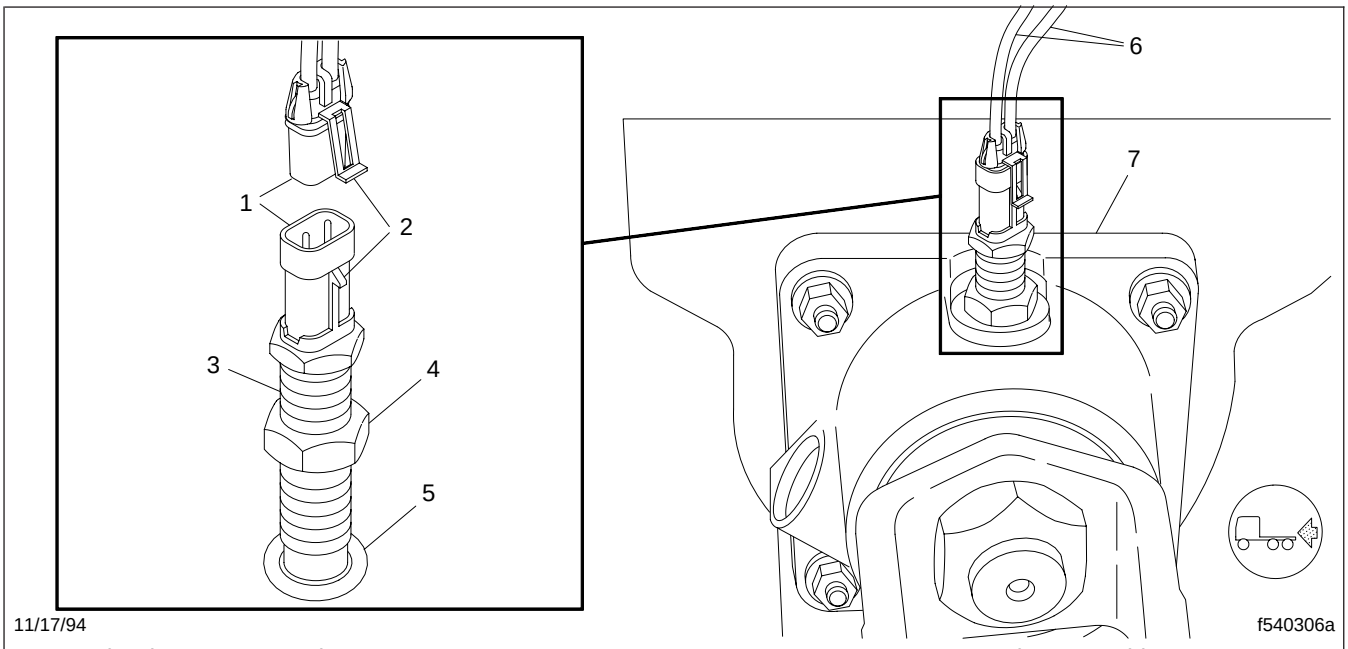


Fig. 2, Loosen the Magnetic Sensor Jam Nut

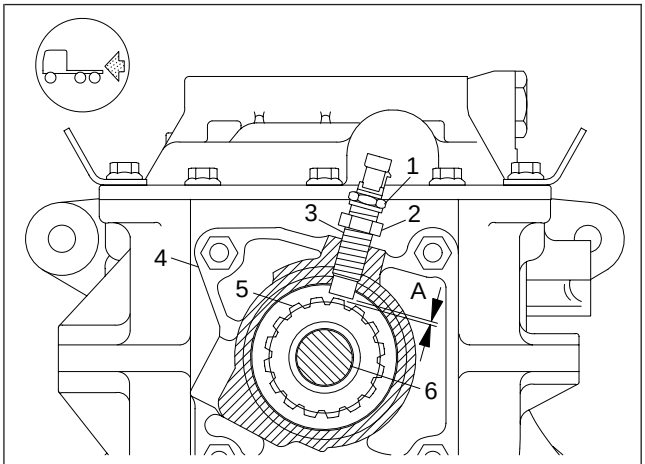

- 4.1 Back off the jam nut to the outboard end of the new magnetic sensor.
- 4.2 Turn the sensor by hand into the transmission bearing cover until it bottoms out on the gear teeth.

6. Transmission Output Shaft

Fig. 3, Cutaway View of an Installed Sensor

4.3 If the magnetic sensor is installed without the plastic shim (gap gauge) back out the sensor three-quarters of a turn to adjust the gap.

NOTE: If the sensor was installed with the plastic cap (gap gauge), do not back out the sensor three-quarters of a turn since the gap has been set by the plastic cap.

5. Install the sensor. See **Fig. 1**

5.1 Holding the sensor in place to keep it from turning, tighten the jam nut 18 lbf·ft (25 N·m).

IMPORTANT: Maintain the correct sensor adjustment, or the speedometer reading won't be correct.

5.2 Connect the wiring to the sensor and be sure the Metri-Pack connector is locked in place. See **Fig. 1**.

6. Remove the chocks from the tires.

7. Test drive the vehicle and check that the speedometer is operating correctly. If there is no speedometer reading, the magnetic sensor was probably not adjusted correctly. Readjust the sensor.

Troubleshooting Procedures

INACCURATE SPEEDOMETER

Incorrect speedometer readings may occur whenever a new speedometer head or new tires are installed. In each case, calibrate the speedometer head using the procedure in **Subject 110**.

1. Test the accuracy of the speedometer head.

NOTE: Testing the accuracy of speedometer head readings is best done by commercial services specializing in such tests. If these commercial services aren't available, do the following odometer reading test.

2. Drive the vehicle over a measured mile to test the accuracy of the odometer.

An inaccurate odometer reading indicates incorrect speedometer head calibration. Calibrate the speedometer head; see **Subject 110**. Again check the accuracy of the odometer.

Inaccurate readings will also occur if the magmetic sensor is not adjusted correctly. Before troubleshooting the system, make sure the magnetic sensor is correctly adjusted. For instructions, see **Subject 120**. Also, make sure the batteries are fully charged.

THE SPEEDOMETER DOES NOT OPERATE

1. Check the resistance of the magnetic sensor.

   1.1 Disconnect the Metri-Pack® connector from the magnetic sensor. See **Fig. 1**. Make sure that both halves of the connection are free of corrosion and moisture.

   1.2 Connect the leads of an ohmmeter to the pins of the magnetic sensor. See **Fig. 2**. The resistance should measure 876 ± 88 ohms.

   If the resistance is outside the acceptable range, replace the sensor; see **Subject 120**.

   If the resistance is in the acceptable range, connect the wiring to the sensor and be sure the Metri-Pack connector is locked in place. See **Fig. 1**. Then go on to check the wiring between the magnetic sensor and the speedometer head.

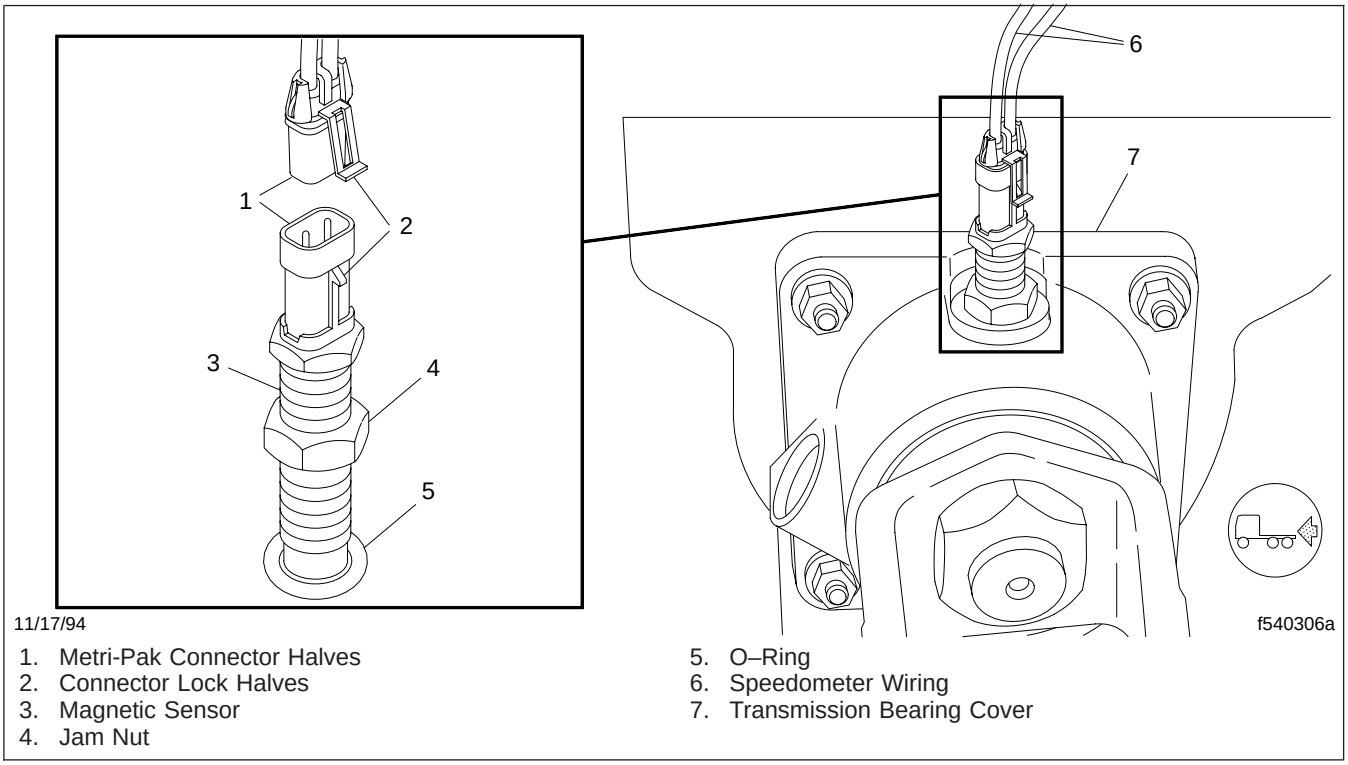
2. Check the wiring between the magnetic sensor and the speedometer head. See **Fig. 3**.

   2.1 Remove the speedometer head from the dash and disconnect the wiring harness from the speedometer head; see **Subject 100** .

   2.2 Check for an open or short circuit by inserting the ohmmeter leads in towers 2 and 4 of the wiring harness half of the Mate-N-Lok connector (for wiring circuit numbers 117 and 118, respectively). See **Fig. 3**. The resistance should measure 876 ± 88 ohms.

   2.3 If the resistance is outside the acceptable range, the problem is in the wiring between the speedometer head and the magnetic sensor. Repair or replace the damaged wiring. Then install the speedometer head; see **Subject 100**.

   If the resistance is in the acceptable range, connect the wiring harness to the speedometer head and be sure the Mate-N-Lok connector is locked in place. Then go on to check the battery voltage at the speedometer head.



3. Check the battery voltage at the speedometer head. See **Fig. 4**.

   3.1 With the ignition switch on, touch the probes of a DC voltmeter to pins 1 and 3 on the front side of the rear plate of the speedometer head (where the pins of the connector extend through the rear plate). See **Fig. 4**. Touch the negative (black) probe to pin 1, and the positive (red) probe to pin 3. The voltmeter should read 9 to 16 volts DC.

   3.2 If the voltage is between 9 and 16 volts DC, but the speedometer readings are not accurate, then the speedometer head, not the wiring, is causing inaccurate readings. Disconnect the voltmeter and turn off the ignition switch. Replace the speedometer head; see **Subject 100**.

   If the voltage is not between 9 and 16 volts DC, check the wiring between the

General Information

All 12-volt starting systems are equipped with a heavy-duty starter relay, or magnetic switch. See **Fig. 1**. The magnetic switch is attached to the front-wall, on the right side of the vehicle. When the starter button is pushed, the magnetic switch closes, connecting electrical current to the starter solenoid, which engages the starter motor pinion with the engine flywheel ring gear, and then energizes the starter motor.

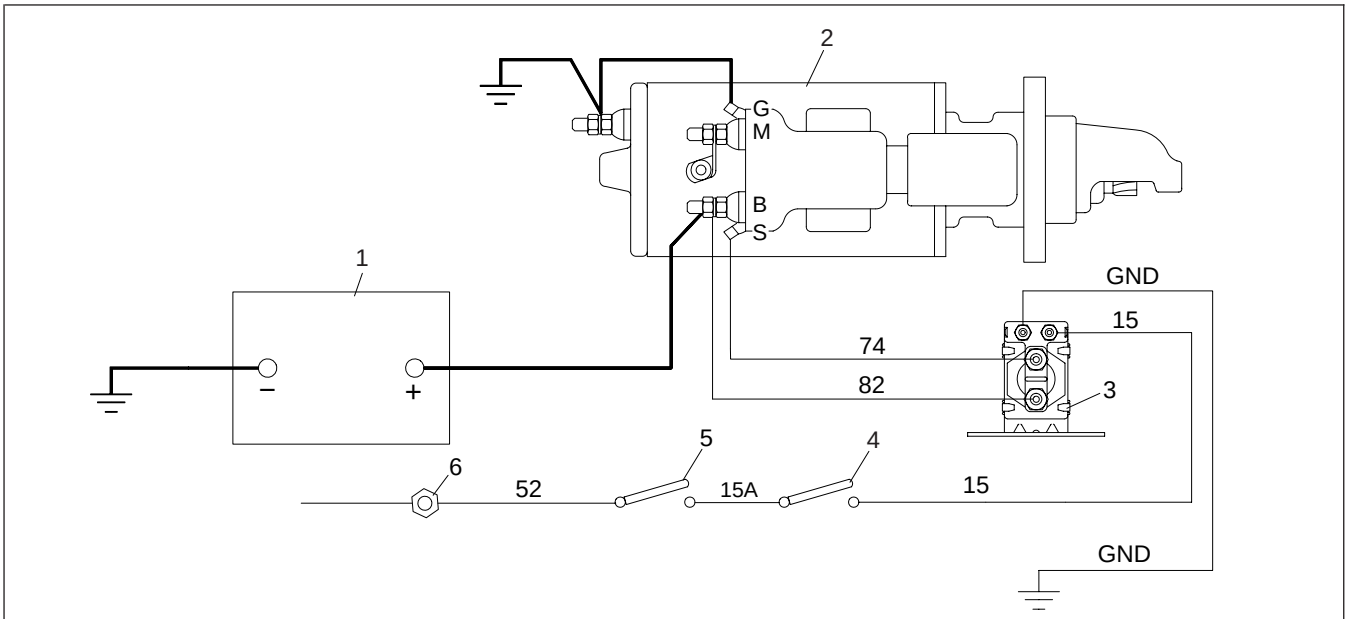
1. Coil Terminal (to ground)
2. Coil Terminal (to ignition switch)
3. Switch Terminal (to solenoid)
4. Switch Terminal (to starter BAT terminal)

Fig. 1, Magnetic Switch

The magnetic switch consists of a winding, mounted around a hollow cylinder containing a movable core or plunger, with a contact disk that is assembled onto the plunger.

When the winding is energized, plunger movement causes the contact disk to be held tightly against the two main switch terminals; this closes the circuit between these terminals, and activates the starting motor. When the winding is de-energized, a return spring causes the plunger to return to its original position, opening the circuit to the starter motor.

Preliminary Checks



Before replacing the magnetic switch, or repairing or replacing any of the starting and charging circuits, do the preliminary checks and the magnetic switch circuit test in **Troubleshooting 300**.

Replacement

NOTE: The magnetic switch cannot be disassembled. If the switch does not work, replace it.

1. Apply the parking brakes, and chock the tires.
2. Disconnect the batteries and tilt the hood.
3. Mark the wires for later reference, then disconnect the wires that are attached to the magnetic switch. See **Fig. 1**.
4. Remove the magnetic switch.
   - 4.1 Remove the two large terminal nuts.
   - 4.2 Remove the two small terminal nuts.
   - 4.3 Disconnect the wires from the terminal switch.
   - 4.4 Remove the magnetic switch mounting nuts, lockwashers, and bolts.
5. Install the new magnetic switch.
   - 5.1 Install the new magnetic switch, using the mounting bolts, lockwashers, and nuts just removed. Tighten the nuts securely.
   - 5.2 Connect the wires to the magnetic switch.
   - 5.3 Install and tighten the nuts securely.

   NOTE: Tighten # 10 nuts to a maximum of 40 lbf·in (460 N·cm) and 5/16-inch nuts to a maximum of 95 lbf·in (1080 N·cm).
6. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1**.

Magnetic Switch Replacement

Protectant Material	Approved Brands
Spray-On Application	MMM 1602 IVI–Spray Sealer, Red Electric Grade; order from the PDC
Brush-On Application	Glyptal 1201EW– Low VOC, Red; order at www.glyptal.com or 1-800-GLP-1201

Table 1, Approved Dielectric Red Enamel

7. Connect the batteries and lower the hood.
8. Remove the chocks from the tires.

Preliminary Checks

Before replacing the magnetic switch, or repairing or replacing any of the starting and charging circuits, do these preliminary checks and the "Magnetic Switch Circuit Test."

1. Apply the parking brakes, and chock the tires.
2. Check the condition of the batteries. Follow the battery testing procedure in **Section 54.03**. Be sure the batteries are fully charged.

NOTE: The wiring, switches, and starter motor cannot be checked if the batteries are damaged or discharged.

3. Check the starting motor, ignition switch, and solenoid for damage or wear. Repair or replace the component(s), as needed.

Magnetic Switch Circuit Test

Before replacing the magnetic switch, or repairing or replacing any of the starting and charging circuits, do this test.

1. Apply the parking brakes, and chock the tires.
2. Check the condition of the batteries. Follow the battery testing procedure in **Section 54.03**. Be sure the batteries are fully charged.

NOTE: The wiring, switches, and starter motor cannot be checked if the batteries are damaged or discharged.

3. Check the starting motor, ignition switch, and solenoid for damage or wear. Repair or replace the component(s), as needed.
4. Check the wiring and the magnetic switch for wear or damage. See **Section 54.01, Specifications 400**.
5. Check the circuit between the magnetic switch and the starter "B" terminal (circuit 82) for correct voltage.

   5.1 Disconnect the circuit running from the starter "S" terminal to the magnetic switch (circuit 74).

   5.2 Connect a voltmeter to the magnetic switch terminal where the circuit from the starter "B" terminal is connected (circuit 82).

   5.3 If the voltmeter reading is 0 volt, check for an open circuit.

   If the voltmeter reading is less than 12.0 volts, check for corroded or loose connections.

   If the voltmeter reading is 12.0 volts or more, go to the next step.

   5.4 Repair or replace any damaged wires.

6. Check the magnetic switch ground circuit (circuit GND).

   6.1 Connect an ohmmeter between the magnetic switch ground terminal and a known good ground.

   6.2 If the ohmmeter reading is more than 0.5 ohm, check for corroded or loose connections.

   6.3 Repair or replace any damaged wires.

7. Check the magnetic switch ignition wiring (circuit 15) for correct voltage.

   NOTE: This check requires two persons.

   7.1 Have one person turn on the ignition keyswitch and hold in the start button.

   7.2 Have the other person connect a voltmeter between the magnetic switch terminal where the ignition circuit is connected (circuit 15) and a known good ground.

   7.3 If the voltmeter reading is 0 volt, check for an open in circuit 15.

   If the voltmeter reading is less than 11.0 volts, check for corroded or loose connections.

   Repair or replace any damaged wires, circuit breakers, or relays.

   7.4 If the voltmeter reading is 11.0 volts or more, go to the next step.

8. Check the circuit between the magnetic switch and the starter "S" terminal (circuit 74) for correct voltage.

Troubleshooting

NOTE: This check requires two persons.

8.1 Have one person turn on the ignition keyswitch and hold in the start button.

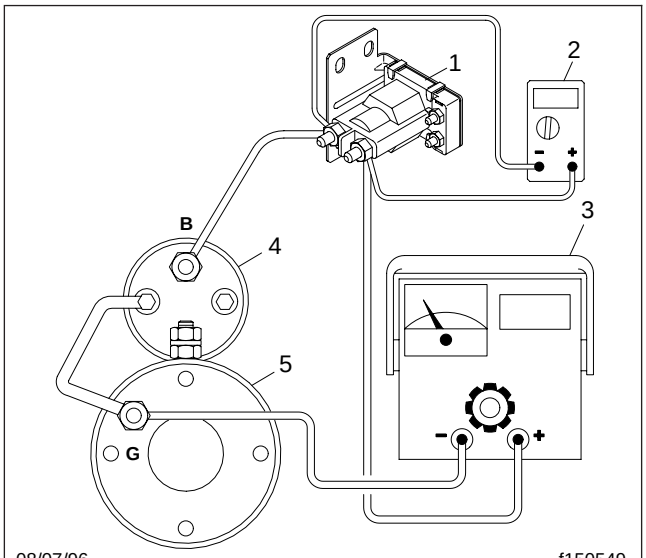
8.2 Have the other person connect a voltmeter between the magnetic switch terminal where the circuit from the starter "S" terminal is connected (circuit 74) and a known good ground.

8.3 If the voltmeter reading is less than 12.0 volts, replace the magnetic switch.

Magnetic Switch Contactor Test

The cranking circuit includes the battery, starter solenoid, cranking motor, magnetic switch, and ignition keyswitch.

If there is excessive voltage loss in the cranking circuit, the starter may not engage the flywheel at all, or it may drop out too soon when battery voltage goes down. In this case, check the cranking circuit and starter solenoid for voltage loss.



If the magnetic switch closes during the cranking circuit test and the starter wiring test, also check the magnetic switch contactors for voltage loss.

1. Disconnect the lead from the magnetic switch to the "S" (solenoid) terminal on the starter (leave as in "Starter Wiring Test").
2. Connect this lead to the positive lead of a carbon pile tester. Connect the negative lead of the carbon pile to the starter "G" (ground) terminal (leave as in "Starter Wiring Test").
3. Set a digital voltmeter on the low scale and connect the positive lead to the magnetic switch terminal to which the carbon pile is already connected. Connect the negative lead to the other large terminal on the magnetic switch. See **Fig. 1**.
4. Start the engine and check the voltage.

   NOTE: This check requires two persons.

   4.1 Have one person turn on the ignition keyswitch and hold in the start button.

   4.2 Have the other person read the voltage on the voltmeter. It should read 0 volt.

1. Magnetic Switch
2. Digital Voltmeter
3. Carbon Pile
4. Starter Solenoid
5. Cranking Motor

Fig. 1, Magnetic Switch Contactor Test

5. Turn on the carbon pile and adjust it to a 100-amp load.

   5.1 Now read and record the voltage on the voltmeter. Turn off the carbon pile.

   5.2 If the voltage reads 11.8 volts or greater, the magnetic switch contactors are OK.

   If the voltage reads less than 11.8 volts, replace the magnetic switch.

Specifications

For a typical magnetic switch wiring diagram, see **Fig. 1**.

General Information

An air restriction gauge **(Fig. 1)** indicates how much air filter capacity has been used and how much remains. It registers the actual maximum restriction of the filter element (or elements, if two air cleaners are installed) when the engine is operating at full load. The yellow indicator inside the air restriction gauge retains the reading so that the remaining capacity can be read even after the engine is shut down.

The air restriction gauge and tap fittings sometimes become plugged from moisture or engine vapors, possibly causing an incorrect reading.

IMPORTANT: Most engine degreasers are harmful to the polycarbonate (Lexan) plastics that are used in air restriction gauges. When cleaning an engine or other components, avoid getting degreaser on these plastic parts.

The air restriction gauge is mounted on the air cleaner intake piping **(see Fig. 2).** A gauge mounted on the air cleaner or intake piping has a push-type reset button located at the end opposite the mounting fitting.

NOTE: Avoid opening the air cleaner and disturbing the seals or filter element until the yellow indicator shows maximum restriction ("red line") **(see Fig. 3).** When this occurs, the air cleaner needs to be serviced; however, immediate engine shutdown is not necessary.

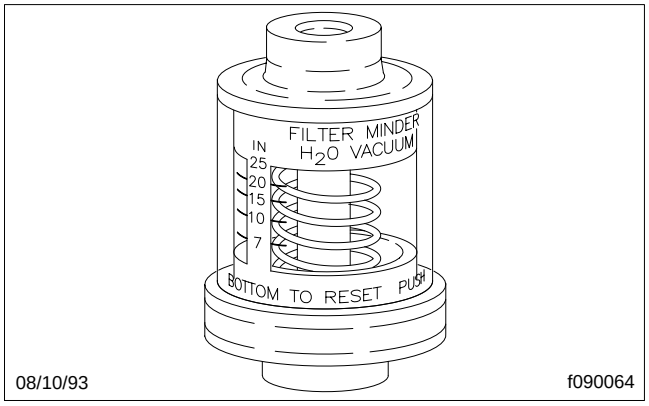

Fig. 1, Air Restriction Gauge

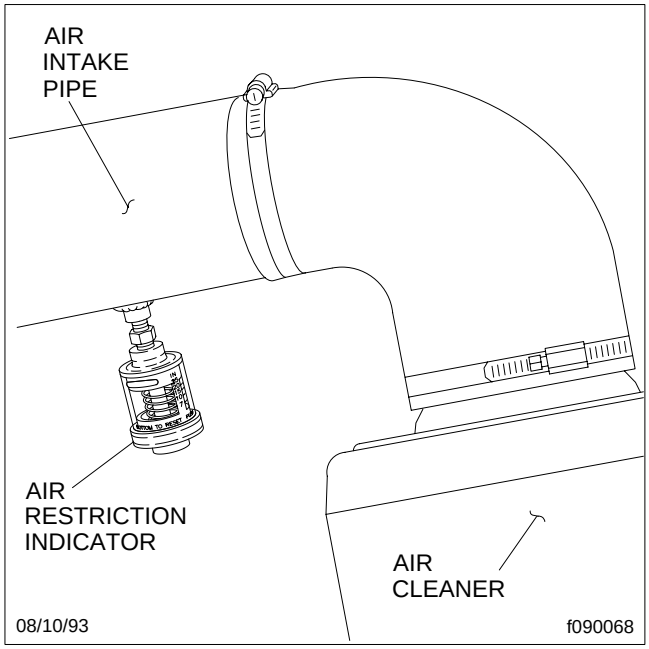

Fig. 2, Air Restriction Gauge Mounted on the Intake Piping

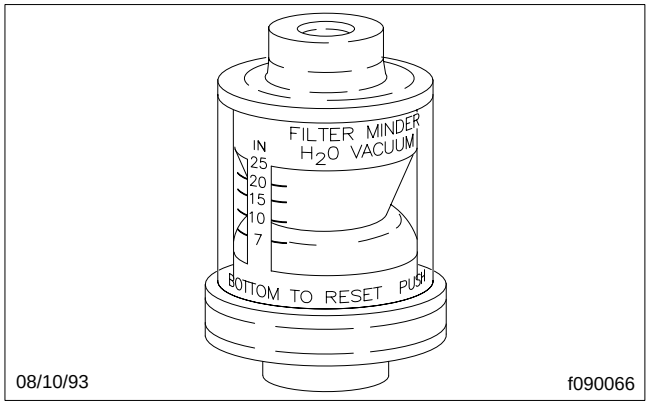

Fig. 3, Maximum Restriction

Replacement

AIR INTAKE PIPE MOUNTED

1. Chock the tires, then tilt the hood. For instructions, refer to the vehicle driver's manual.
2. Using a wrench, unscrew the gauge from the air intake piping.
3. Install the new air restriction gauge using the instruction above, in reverse order.

NOTE: The fitting in the intake pipe is a special fitting incorporating an orifice and a filter. Be sure that the correct fitting is installed.

Problem—No Restriction Reading

Problem—No Restriction Reading	
Possible Cause	**Remedy**
The gauge leaks.	Remove the air restriction gauge. Apply a vacuum to the gauge until the yellow indicator reaches the red line. With your thumb on the mounting fitting, close the end of the gauge airtight. Hold in the reset button. The yellow indicator will drop slightly and then not move unless the gauge has a leak. If the gauge is functioning properly, install it and press the reset button. If the yellow indicator continues to move, replace the air restriction gauge. Repeat the troubleshooting procedure to verify that the new gauge does not leak. When the gauge is functioning properly, install it and press the reset button.
The air cleaner or intake pipe fitting is plugged.	Remove the obstruction.
Engine airflow is too low to generate a reading.	Turbocharged engines must be at full load to pull full engine airflow. Restrictions can be simulated by gradually closing off air intake. If there is still no restriction reading, check for leaks in the gauge or vacuum hose, as appropriate, and take corrective action.
The safety filter, if equipped, is plugged.	Do not clean the safety filter. Replace it with a new one.

Problem—High Restriction Readings

Problem—High Restriction Readings	
Possible Cause	**Remedy**
The element is plugged.	Anytime a high restriction is noted, it should be verified by resetting the restriction indicator and checking it again after several hundred miles of normal operation. Install a new filter element.
The intake screens or ducts are plugged.	Check the system upstream from the air restriction gauge and remove any debris. Check for damage or improper installation, and take necessary corrective action.
Heavy snow or rain.	Temporary high restriction can occur during a rain or snow storm and disappear after drying out. Anytime a high restriction is noted, it should be verified by resetting the restriction indicator and checking it again after several hundred miles of normal operation.

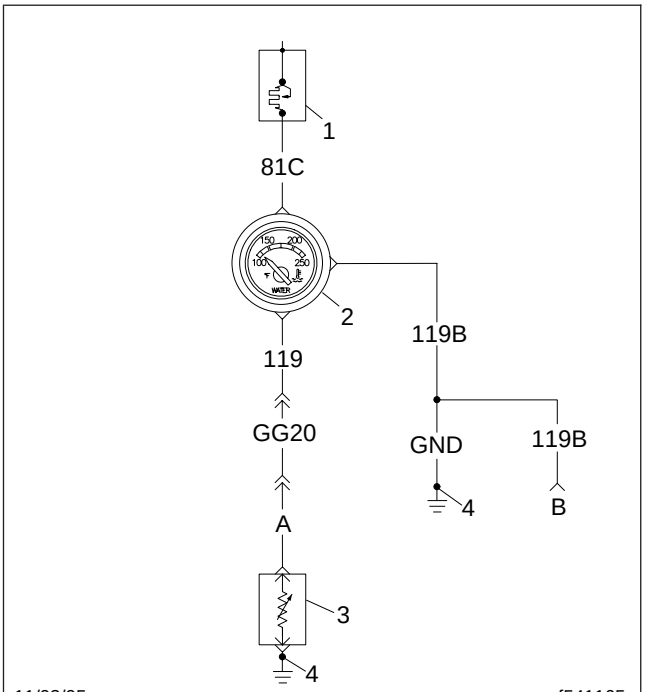
General Information

The Ametek coolant temperature gauge system is standard equipment on all vehicles. The system consists of a dash-mounted gauge (electrical type), an engine-mounted temperature sender, and the electrical wires that connect these components. Circuitry is similar, but not identical, for diesel and gasoline powered vehicles. See **Fig. 1** and **Fig. 2**.



1. Power Supply Circuit Breaker
2. Coolant Temperature Gauge
3. Coolant Temperature Sender
4. Ground Point

Fig. 1, Engine Coolant Temperature Gauge System, Diesel Engines

The coolant temperature gauge is a cross-coil electric gauge with a 90-degree sweep. The gauge body is made of clear plastic and has a painted face. A light bulb fitted to the gauge mounting panel illuminates the gauge face from behind. The gauge is easily removed and installed from the front of the instrument panel.

Vehicles built for use in North America have a gauge that registers coolant temperature in degrees Fahrenheit (°F). Vehicles built for export out of North America have a gauge that registers coolant temperature in degrees Celsius (°C).

The coolant temperature sender is threaded into a fitting on the engine, where its tip comes in direct contact with engine coolant. The specific location

A. This wire is violet with a yellow stripe.
B. Circuit 119B ends at a connector and is not used.
1. Power Supply Circuit Breaker
2. Coolant Temperature Gauge
3. Coolant Temperature Sender
4. Ground Point

Fig. 2, Engine Coolant Temperature Gauge System, V-8 Gasoline Engines

varies according to engine manufacturer and model, but is usually near the thermostat.

Diesel engines are fitted with a two-terminal coolant temperature sender (see **Fig. 3**); V-8 gasoline engines are fitted with a similar single-terminal sender.

The coolant temperature sender is a temperature sensitive resistor (thermistor) whose electrical resistance decreases as coolant temperature increases. In other words, the resistance across the sensor terminals is high when the engine is cold (about 400 ohms) and drops as the engine warms up (resistance is about 50 ohms when the engine is hot).

General Information

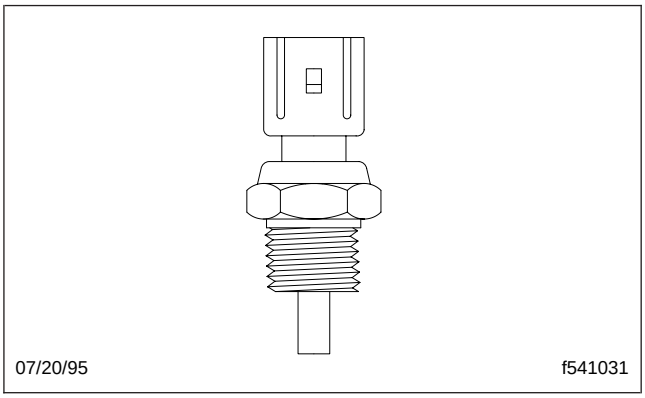


Fig. 3, Two-Terminal Coolant Temperature Sender, Diesel Engines

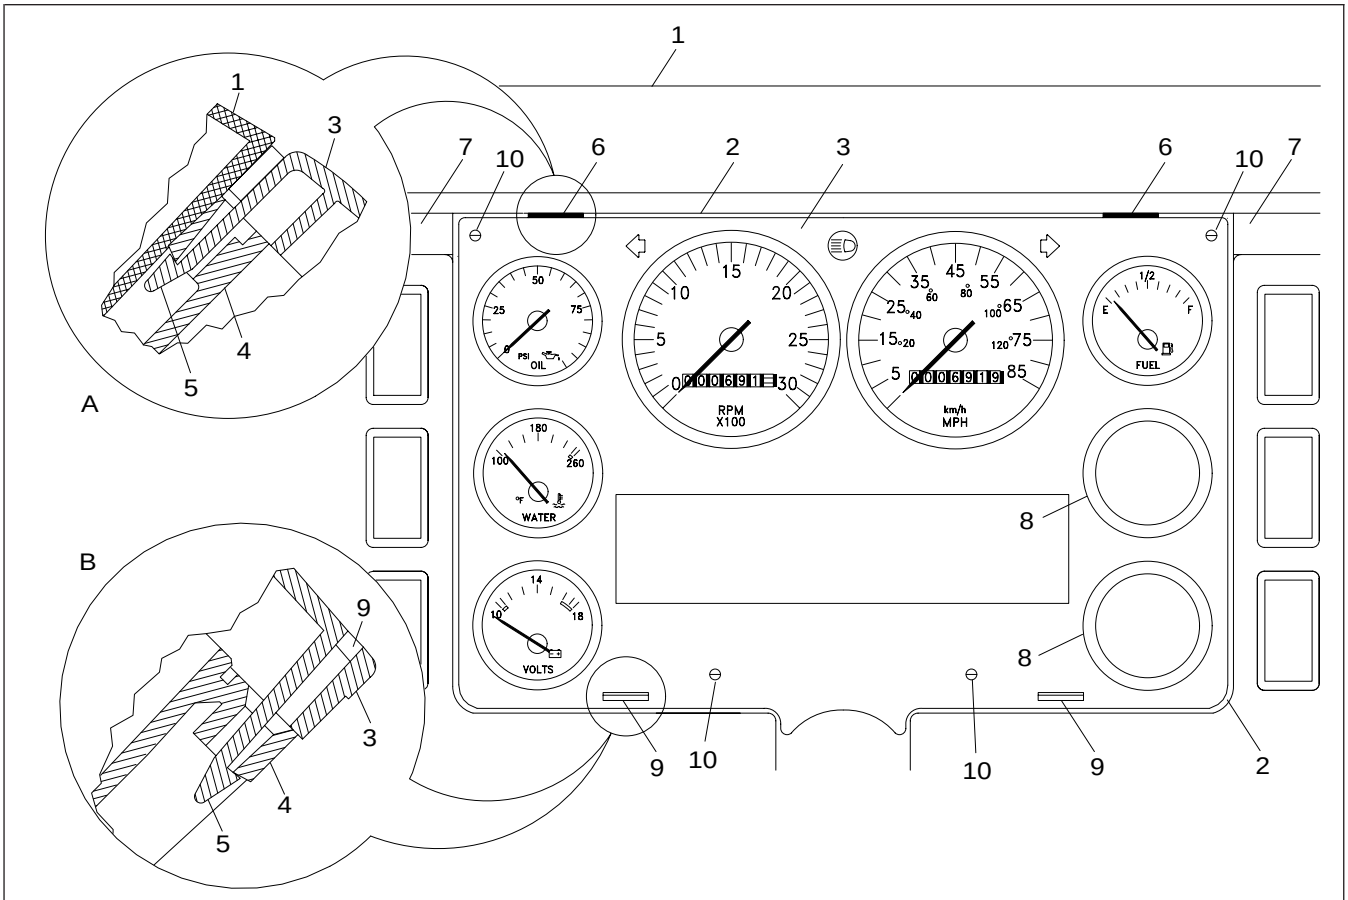
Coolant Temperature Gauge Removal and Installation



Removal

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Disconnect the batteries.
3. Remove the instrument cluster bezel. See **Fig. 1**.

3.1 If present, remove the four Torx-head screws from the bezel.

3.2 By hand, remove the vinyl extrusion trim (see **Fig. 1**, Ref. 7) on each side of the instrument cluster bezel.

3.3 Insert a stubby, flat-tipped screwdriver

A. Sectional Detail (Left Side View of Upper Left-Hand Locking Tab)

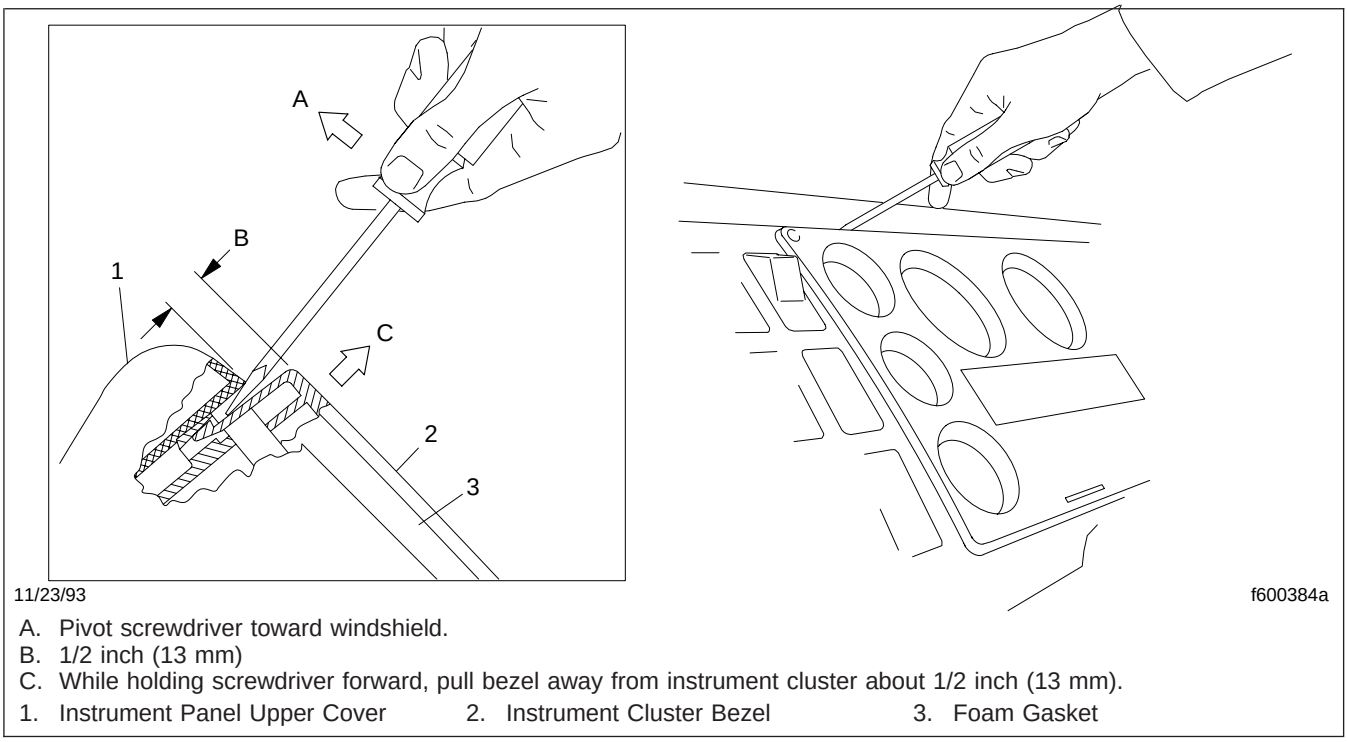
6. Opening in Foam Gasket
7. Vinyl Extrusion Trim
8. Gauge Blank (Block-Off Plug)
9. Slot in Bezel
10. Location of Torx-Head Mounting Screw

Fig. 1, Instrument Cluster Bezel Details

NOTE: On some vehicles, the bezel is also secured to the instrument panel with four Torx®-head screws (**Fig. 1**, Ref. 10).

into the opening above the upper left-hand corner of the instrument cluster bezel (see **Fig. 1**, Ref. 6) and release the bezel locking tab (Ref. 5) by gently pivot-



Coolant Temperature Gauge Removal and Installation

ing the screwdriver handle toward the vehicle windshield. See **Fig. 2**.

While keeping pressure on the screwdriver, use your other hand to pull the corner of the bezel away from the instrument panel about 1/2 inch (13 mm).

The gauge illumination bulb will remain in the gauge mounting panel; do not remove the bulb unless it must be replaced. See **Fig. 4**.

Installation

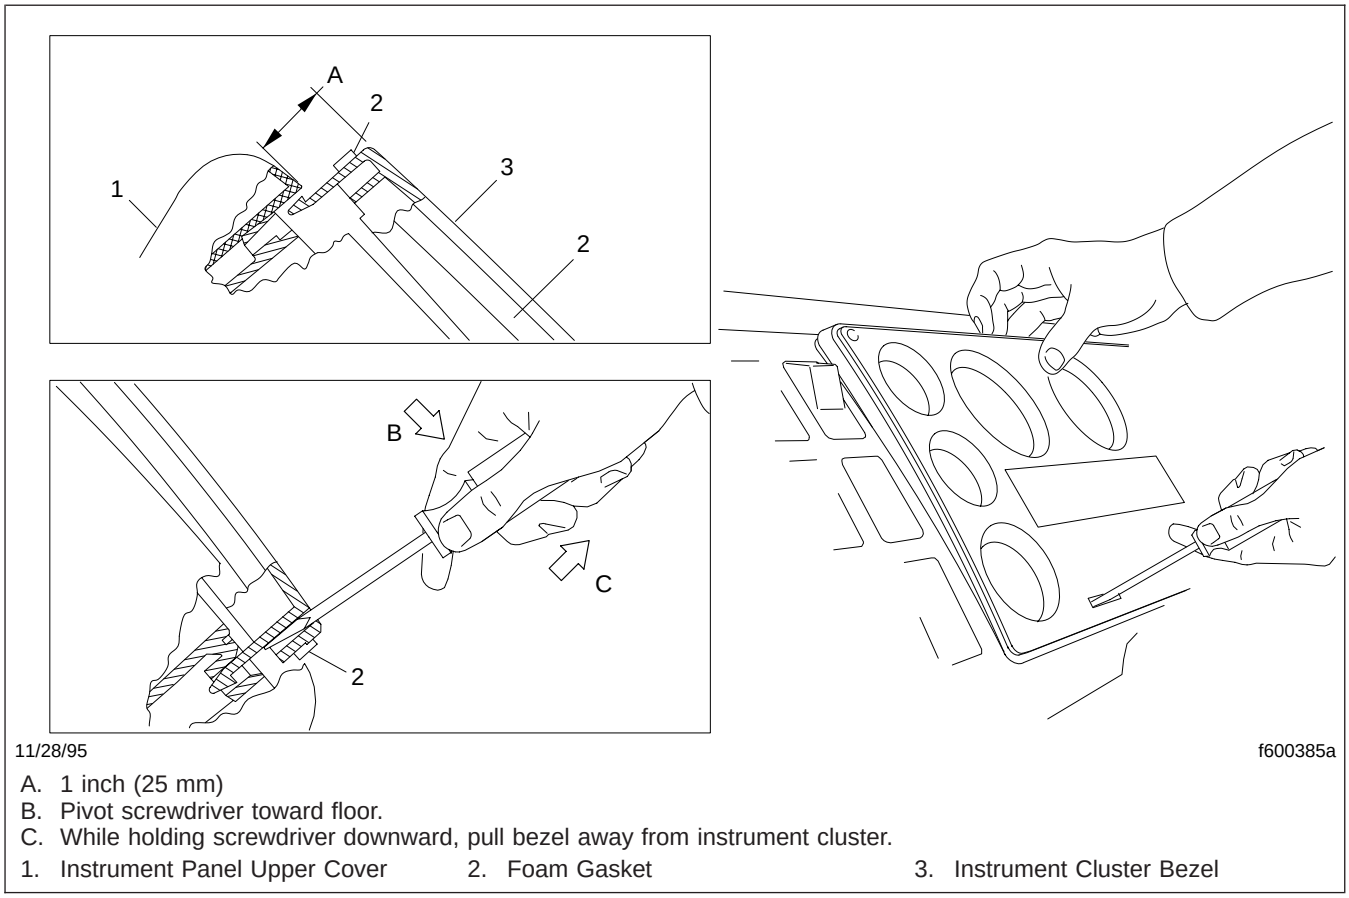
A. Pivot screwdriver toward windshield.
B. 1/2 inch (13 mm)
C. While holding screwdriver forward, pull bezel away from instrument cluster about 1/2 inch (13 mm).
1. Instrument Panel Upper Cover 2. Instrument Cluster Bezel 3. Foam Gasket

Fig. 2, Releasing the Bezel Upper Edge

3.4 Repeat the previous step for the upper right-hand corner of the bezel.

3.5 With both corners released, tilt the entire top edge of the bezel away from the instrument panel about 1 inch (25 mm) and try to work the bottom edge of the bezel loose.

If the bottom of the bezel won't come loose, use the screwdriver to release the locking tabs at the bottom edge of the bezel. See **Fig. 3**.



Set the bezel aside.

4. Remove the coolant temperature gauge from the gauge mounting panel by grasping the gauge firmly and pulling it straight out of the mounting panel.

1. Position the coolant temperature gauge over the gauge mounting panel, making sure that the panel terminals line up with the gauge sockets.
2. Push the gauge into place until it seats against the mounting panel.
3. Position the instrument cluster bezel against the instrument panel. Starting with the lower corners, alternately push against the bottom and top corners of the bezel, until all four locking tabs are locked and the face of the bezel is flush with the surfaces of the instrument panel. Don't push against the gauge lenses or gauge blanks (block-off plugs).

NOTE: On some vehicles, the bezel is also secured to the instrument panel with four Torx®-head screws (**Fig. 1**, Ref. 10).

Coolant Temperature Gauge Removal and Installation

2. Gauge Mounting Panel
3. Panel Electrical Terminals
4. Illumination Bulb and Socket
5. Gauge Electrical Socket

Fig. 4, Coolant Temperature Gauge Installation View

Coolant Temperature Sender Removal and Installation

Removal

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Open the hood and locate the coolant temperature sender. Sender location varies according to engine manufacturer and model, but is usually near the coolant thermostat. **See Fig. 1**, **Fig. 2**, **Fig. 3**, **Fig. 4**, **Fig. 5**, **and Fig. 6.**

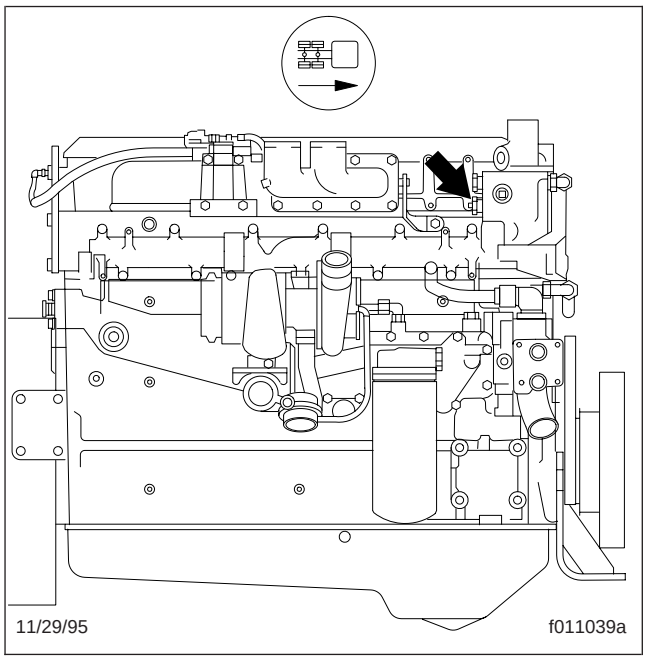

Fig. 1, Coolant Temperature Sender Location, Caterpillar 3126 Engine

⚠ WARNING

WARNING: Don't drain the cooling system while the engine is hot. To avoid personal injury from scalding coolant, wait until the engine has cooled down before draining the system.

3. Drain coolant from the system until the coolant level drops below the coolant temperature sender location.
   - 3.1 With the engine cool, loosen the radiator cap to release pressure from the radiator, then tighten the cap.
   - 3.2 Place a clean drain pan under the drain plug or petcock located at the bottom of the radiator left end-tank. **See Fig. 7.** Remove the drain plug or open the petcock. If necessary, use a deflector to channel coolant away from the front springs and into the drain pan.

     On some Caterpillar and Detroit Diesel Engines, the radiator drain plug is located on the forward end of the coolant outlet pipe. **See Fig. 8.** On these vehicles, re-

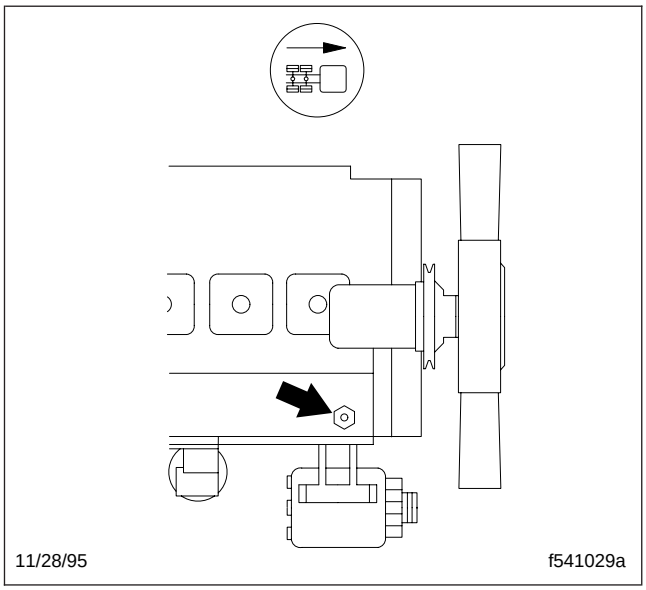

Fig. 2, Coolant Temperature Sender Location, Cummins B Series Engine

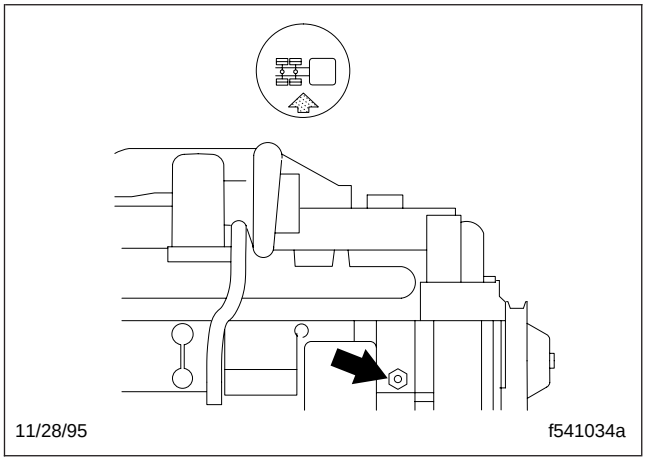

Fig. 3, Coolant Temperature Sender Location, Cummins C Series Engine

Coolant Temperature Sender Removal and Installation

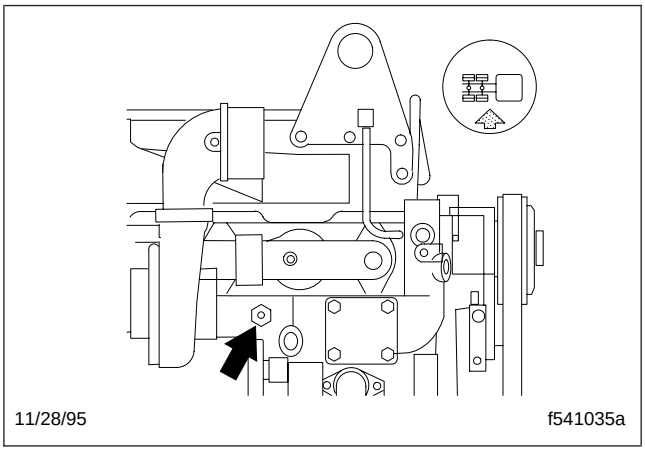

Fig. 4, Coolant Temperature Sender Location, Cummins M11 Engine

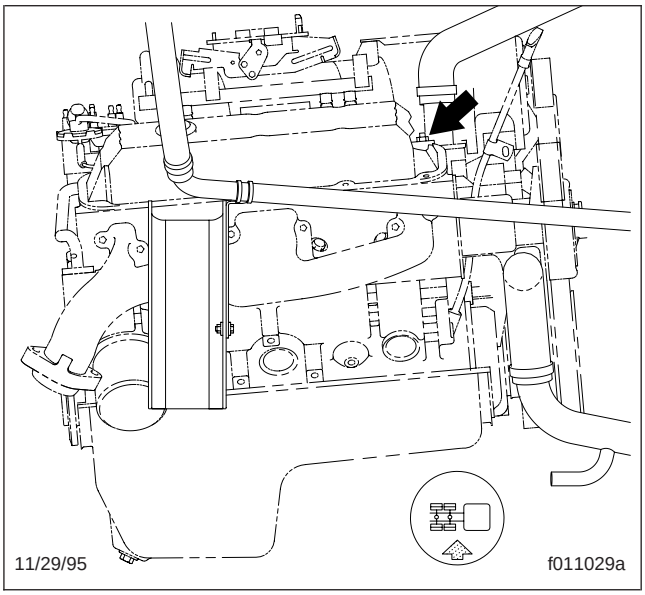

Fig. 5, Coolant Temperature Sender Location, Dodge Magnum Engine

move the aerodynamic cover to access the drain plug.

3.3 Install the drain plug or tighten the petcock.

4. Unplug the wiring harness connector from the coolant temperature sender, and remove the sender from the engine.

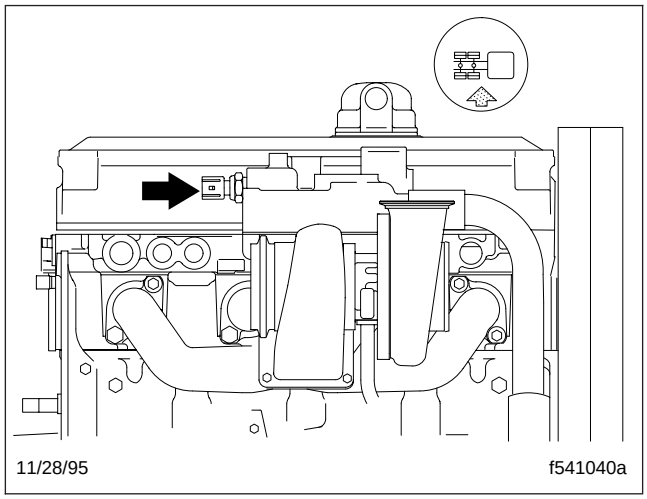

Fig. 6, Coolant Temperature Sender Location, Detroit Diesel 50 Series Engine

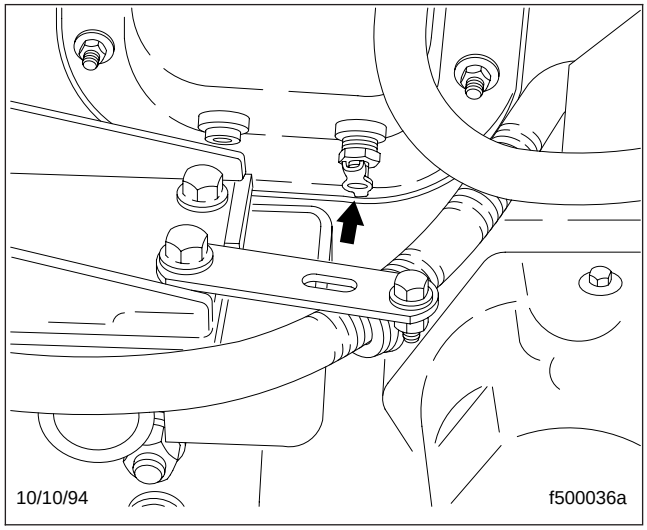

Fig. 7, Radiator Drain Location, Typical

Installation

1. Clean old sealant residue from the threads of the coolant temperature sender opening.
2. Apply pipe thread sealant to the threads of the new coolant temperature sender, and install the sender in the engine opening. Tighten the sender until it is snug.
3. Connect the vehicle wiring harness to the sender.

Coolant Temperature Sender Removal and Installation

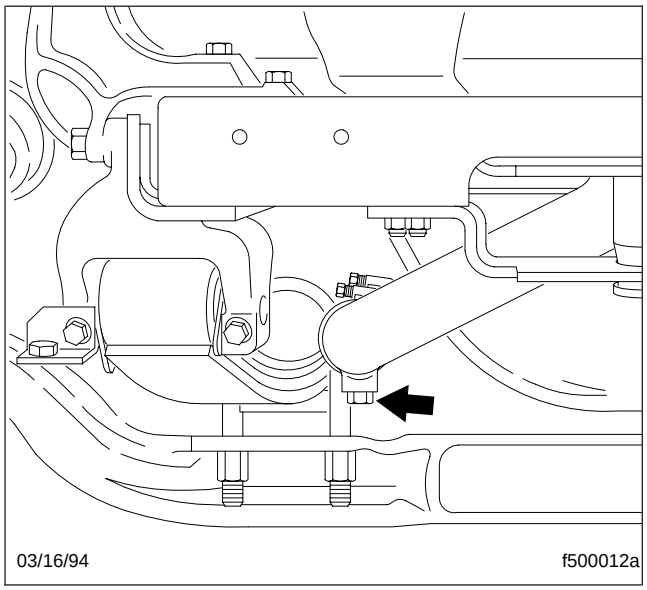

Fig. 8, Radiator Drain Location, Some Caterpillar and Detroit Diesel Engines

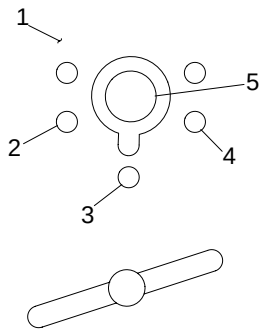
4. Fill the cooling system.
5. Start the engine, check for leaks, and check that the coolant temperature gauge is operating properly.
6. Remove the chocks from the tires.

Troubleshooting Procedures



Coolant temperature gauge malfunctions are usually one of two types: the gauge does not operate at all (always shows that the engine is cold), or the coolant temperature indicated by the gauge is believed to be incorrect.

Before proceeding with any troubleshooting when an inaccurate gauge or sender is suspected, confirm that the coolant level is correct and the engine thermostat and fan clutch are operating properly. Simply removing the radiator cap and inserting a thermometer may reveal that the problem is not in the gauge system, but in the cooling system itself. For cooling system troubleshooting, see **Group 20**.

Malfunctions that would cause a totally inoperative coolant temperature gauge include open circuits in the gauge, sender, or wiring. To isolate the cause of an inoperative coolant temperature gauge, follow the troubleshooting procedures in the order given.

1. Switch off the ignition and unplug the wiring harness connector from the coolant temperature sender.
2. Switch on the ignition and observe the gauge needle; it should remain at the left end of the scale (low temperature indicated).
3. Switch off the ignition and, using a jumper wire, connect the sender wiring harness terminal to ground (if a one-terminal sender is used) or short the sender wiring harness terminals together (if a two-terminal sender is used).
4. Switch on the ignition again and watch the gauge needle; it should move immediately to the extreme right or "hot" end of the scale.
5. If the gauge operates as described in the previous steps, it is functioning properly and the wiring to the gauge is okay. The problem is in the sender; replace it following the instructions in **Subject 110** and verify that the gauge operates properly.

   If the gauge does not function as described previously, continue troubleshooting with the following steps:
6. Switch off the ignition, unground (or remove the jumper wire from) the wiring harness connector and reconnect it to the coolant temperature sender.
7. Remove the instrument cluster bezel and the coolant temperature gauge. If necessary, refer to **Subject 100**.
8. Identify the coolant temperature gauge terminals that are part of the gauge mounting panel. See **Fig. 1**.

02/22/99 f601090

1. Gauge Mounting Panel
2. Ground Terminal
3. Ignition Power Terminal
4. Sender Signal Terminal
5. Gauge Illumination Bulb

Fig. 1, Coolant Temperature Gauge Connection

9. Check the coolant temperature gauge ground circuit wiring for an open circuit.

   9.1 With the ignition switch turned off, connect the leads of an ohmmeter between the cab metal (an unpainted bolt or screw attached directly to cab structure works well) and the ground circuit terminal (see **Fig. 1**. Ref. 2) in the gauge mounting panel.

   9.2 Resistance should be less than one ohm. If it is, go to the next step. If resistance is higher than one ohm, verify that you have good connections at both the terminal and the cab metal.

   9.3 If the connections are good, but resistance is still greater than one ohm, locate the damaged section of wiring between the terminal and ground. Repair the damage by splicing in a length of replacement wiring following the instructions in this group.

Troubleshooting

10. Check the signal circuit between the coolant temperature gauge and the sender.

    10.1 With the gauge removed from the gauge mounting panel, connect one ohmmeter lead to the mounting panel signal terminal (see **Fig. 1**. Ref. 4) and the other lead to the mounting panel ground terminal (Ref. 2).

    10.2 If the harness and sender are good, resistance will depend upon engine temperature and should be, approximately, no more than 400 ohms for a cold engine and at least 50 ohms for a hot engine.

    NOTE: The resistance values are approximations only. Test the sensor in place, on the engine. For the purpose of the resistance test, a cold engine is one which has been sitting overnight, or for a minimum of two hours. A hot engine is one which has reached operating temperature, a minimum of 180°F (82°C).

    10.3 If resistance is within specifications, go to the next step. If resistance is too low, temporarily unplug the sender and recheck resistance. If resistance is still too low, find and repair the short to ground in circuit 119 (119, GG20, and Violet/Yellow on V-8 gasoline engines). If resistance is too high, unplug the sender, connect the sender wiring harness terminal to ground (if a one-terminal sender is used) or short the sender wiring harness terminals together (if a two-terminal sender is used), and recheck resistance. If resistance is still too high, find and repair the poor connection or damaged wire in circuit 119 (119, GG20, and Violet/Yellow on V-8 gasoline engines).

11. Check for battery voltage at the coolant temperature gauge terminal in the gauge mounting panel.

    11.1 Turn the ignition switch on.

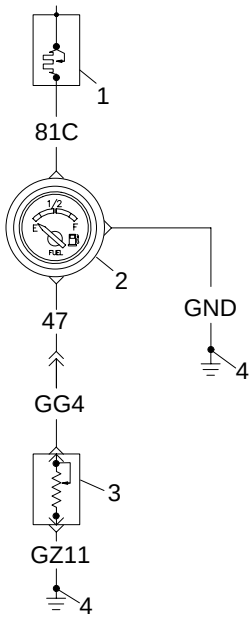
    11.2 Connect a voltmeter (set on 20 volt scale, DC voltage) to the gauge terminals in the gauge mounting panel as follows; positive (red) probe to the ignition power circuit (see **Fig. 1**. Ref. 3) and the negative (black) probe to the ground circuit (Ref. 2). The voltmeter should read between 9 and 16 volts DC.

    11.3 If voltage is between 9 and 16 volts, the gauge itself is malfunctioning, and must be replaced. For instructions, refer to **Subject 100**. If the voltage reading is not within the limits mentioned above, check the circuit breaker that supplies power to the gauge. If the circuit breaker is okay, locate and repair the damage to the power circuit. General wire repair information can be found elsewhere in this group.

General Information

The Ametek fuel level gauge system consists of a dash-mounted gauge (electrical type), a fuel tank-mounted fuel level sender, and the electrical wires that connect these components. Circuitry is similar, but not identical for diesel and gasoline powered vehicles. **See Fig. 1** and **Fig. 2**.

09/07/95 f541044



1. Power Supply Circuit Breaker
2. Fuel Level Gauge
3. Fuel Level Sender
4. Ground Point

Fig. 1, Fuel Level Gauge System, Diesel Engines

The fuel level gauge is a cross-coil electric gauge with a 90-degree sweep. The gauge body is made of clear plastic and has a painted face. A light bulb fitted to the gauge mounting panel illuminates the gauge face from behind. The gauge is easily removed and installed from the front of the instrument panel.

On diesel engine-equipped vehicles, the fuel level sender (**see Fig. 3**) is mounted inside the fuel tank (right hand tank on dual tank vehicles) and is serviced by removing a plate fitted to the top of the tank.

On gasoline engine-equipped vehicles, the fuel level sender (**see Fig. 4**) is also mounted inside the fuel tank, but is part of the fuel pump module. The module is made up of an electric fuel pump, an inlet filter,

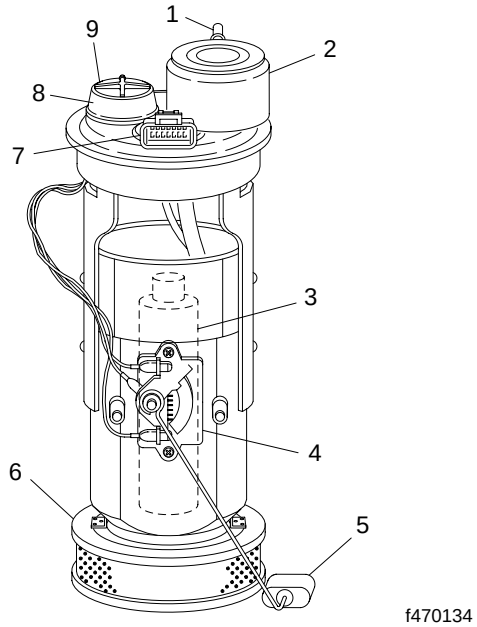
2. Fuel Level Gauge
3. Fuel Level Sender
4. Ground Point

Fig. 2, Fuel Level Gauge System, V-8 Gasoline Engines

a combination outlet filter/pressure regulator, a pressure relief/rollover valve, and the fuel level sender.



07/25/95 f541045

Fig. 3, Fuel Level Sender, Diesel Engine

The fuel level sender consists of a float and arm fitted to a variable resistor; the float rests on the fuel surface and, as the fuel level drops, the float drops with it. When the fuel tank is full, fuel level sender resistance is about 30 ohms for diesels and 10 ohms for gasoline senders. When the tank is about half full, sender resistance is about 103 ohms for diesel senders and 32 ohms for gasoline senders. When the tank is empty, resistance is about 245 ohms for diesels, 100 ohms for gasoline senders.

General Information

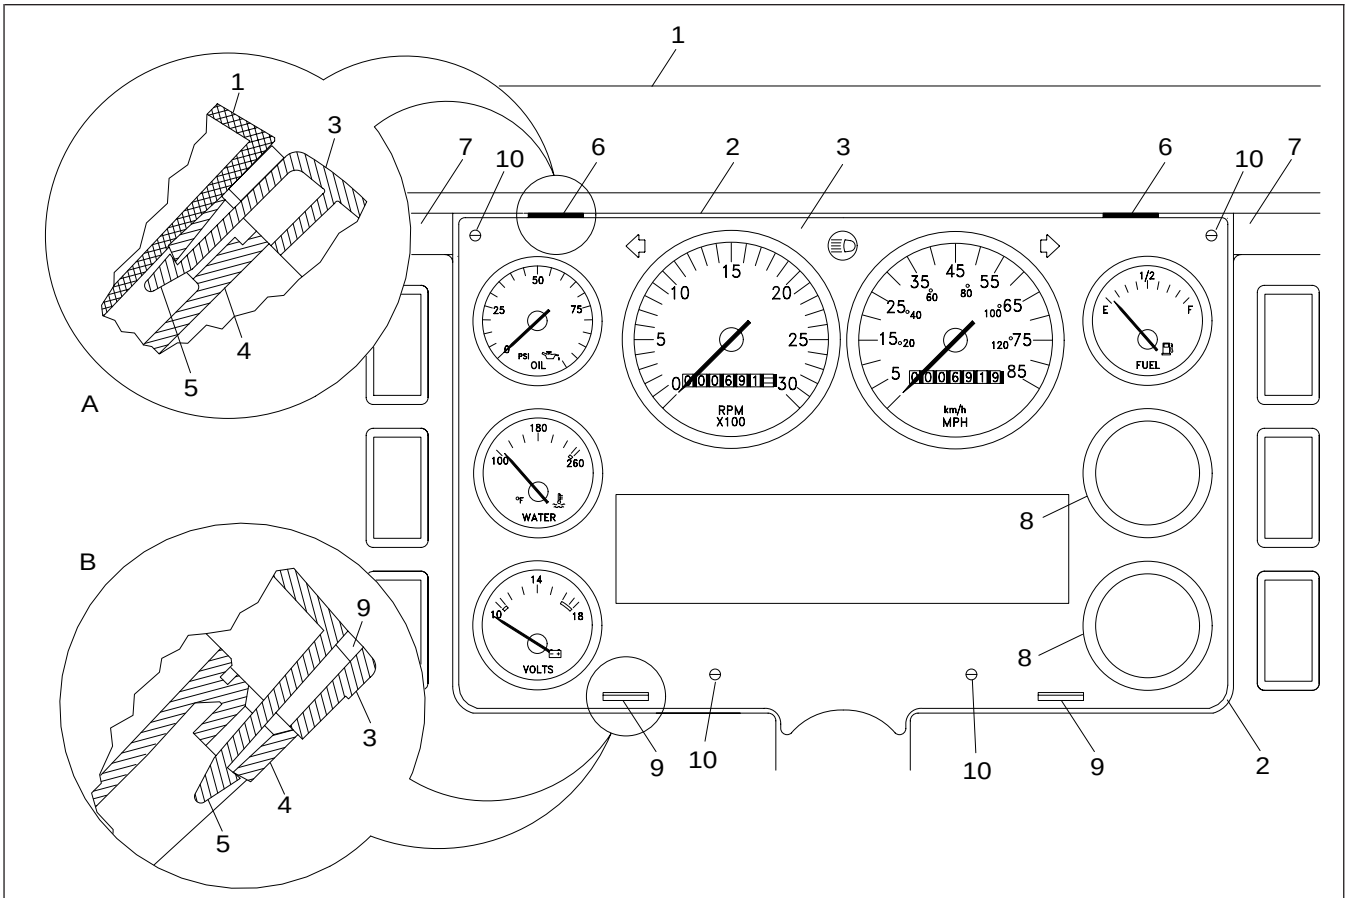
Fig. 4, Fuel Level Sender, Gasoline Engine



Removal

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Remove the instrument cluster bezel. See **Fig. 1**.

3.1 If present, remove the four Torx-head screws from the bezel.

3.2 By hand, remove the vinyl extrusion trim (see **Fig. 1**, Ref. 7) on each side of the instrument cluster bezel.

3.3 Insert a stubby, flat-tipped screwdriver

A. Sectional Detail (Left Side View of Upper Left-Hand Locking Tab)
B. Sectional Detail (Left Side View of Lower Left-Hand Locking Tab)

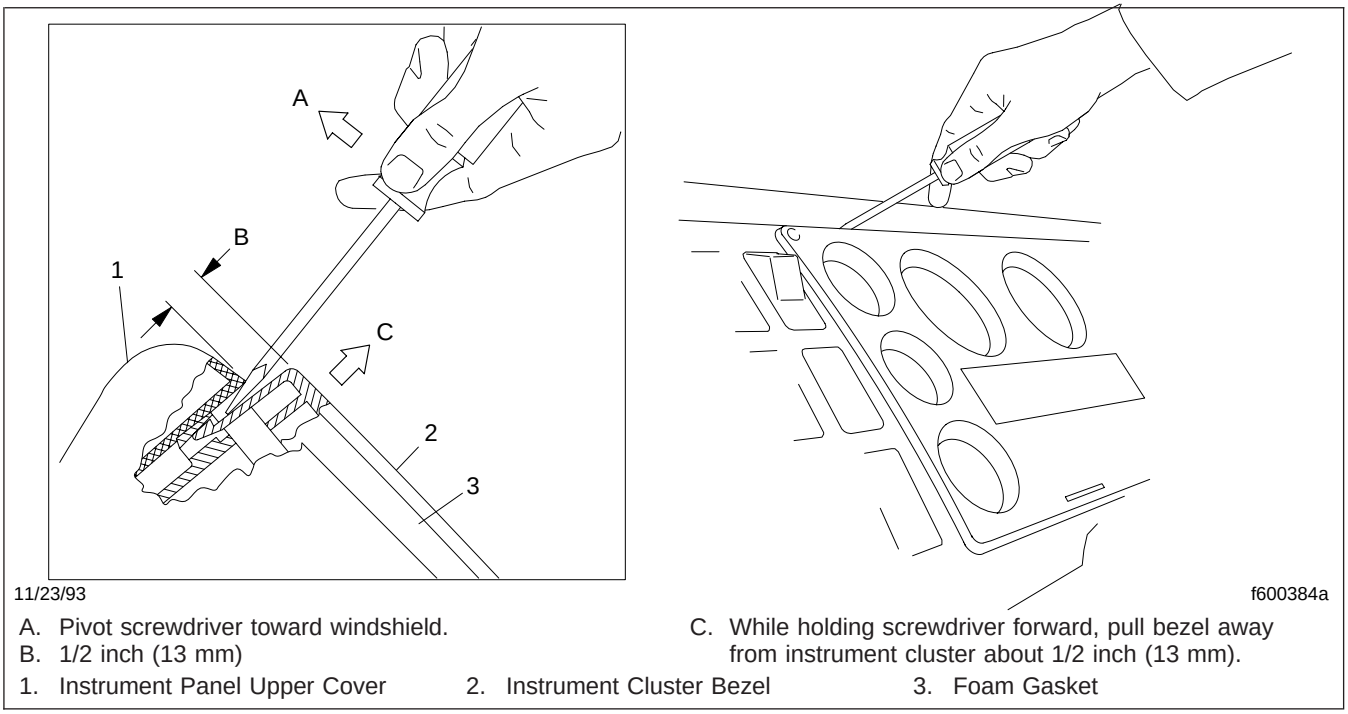
2. Foam Gasket
3. Instrument Cluster Bezel
4. Gauge Mounting Panel
5. Bezel Locking Tab
6. Opening in Foam Gasket
7. Vinyl Extrusion Trim
8. Gauge Blank (Block-Off Plug)
9. Slot in Bezel
10. Location of Torx-Head Mounting Screw

Fig. 1, Instrument Cluster Bezel Details

NOTE: On some vehicles, the bezel is also secured to the instrument panel with four Torx®-head screws (**Fig. 1**, Ref. 10).

into the opening above the upper left-hand corner of the instrument cluster bezel (see **Fig. 1**, Ref. 6) and release the bezel locking tab (Ref. 5) by gently pivot-



Fuel Level Gauge Removal and Installation

ing the screwdriver handle toward the vehicle windshield. See **Fig. 2**.

While keeping pressure on the screwdriver, use your other hand to pull the corner of the bezel away from the instrument panel about 1/2 inch (13 mm).

The gauge illumination bulb will remain in the gauge mounting panel; do not remove the bulb unless it must be replaced. See **Fig. 4**.

Installation

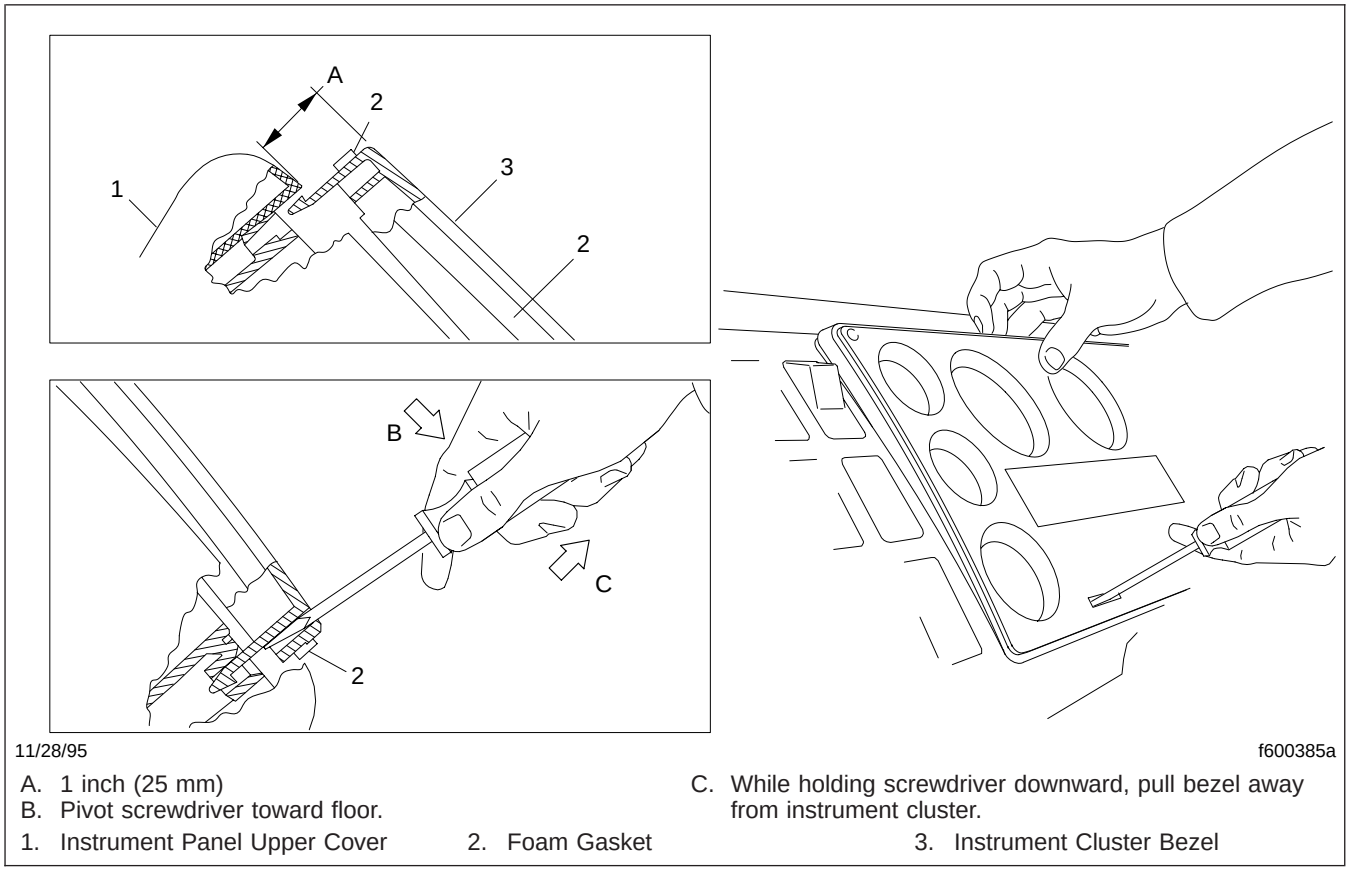
A. Pivot screwdriver toward windshield.
B. 1/2 inch (13 mm)
C. While holding screwdriver forward, pull bezel away from instrument cluster about 1/2 inch (13 mm).
1. Instrument Panel Upper Cover
2. Instrument Cluster Bezel
3. Foam Gasket

Fig. 2, Releasing the Bezel Upper Edge

3.4 Repeat the previous step for the upper right-hand corner of the bezel.

3.5 With both corners released, tilt the entire top edge of the bezel away from the instrument panel about 1 inch (25 mm) and try to work the bottom edge of the bezel loose.

If the bottom of the bezel won't come loose, use the screwdriver to release the locking tabs at the bottom edge of the bezel. See **Fig. 3**.

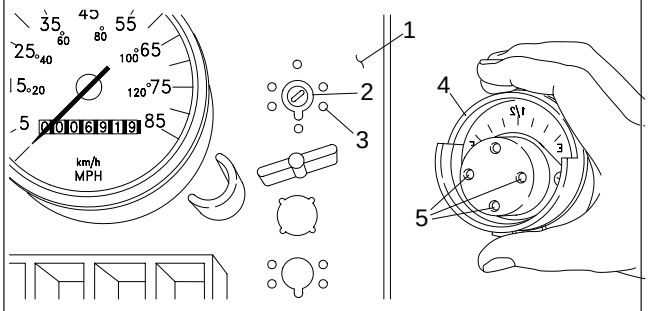


Set the bezel aside.

4. Remove the fuel level gauge from the gauge mounting panel by grasping the gauge firmly and pulling it straight out of the gauge mounting panel.

1. Position the gauge over the gauge mounting panel, making sure that the panel terminals line up with the gauge sockets.
2. Push the gauge into place until it seats against the mounting panel.
3. Position the instrument cluster bezel against the instrument panel. Starting with the lower corners, alternately push against the bottom and top corners of the bezel, until all four locking tabs are locked and the face of the bezel is flush with the surfaces of the instrument panel. Don't push against the gauge lenses or gauge blanks (block-off plugs).

NOTE: On some vehicles, the bezel is also secured to the instrument panel with four Torx®-head screws (**Fig. 1**, Ref. 10).



4. If removed, install the screws in the instrument cluster bezel.
5. Install the vinyl extrusion trim on both sides of the bezel.
6. Connect the batteries.
7. Start the engine and verify that the fuel level gauge is operating properly.
8. Remove the chocks from the tires.

A. 1 inch (25 mm)
B. Pivot screwdriver toward floor.
C. While holding screwdriver downward, pull bezel away from instrument cluster.

Fuel Level Sender Removal and Installation

Removal

NOTE: On gasoline engine equipped vehicles, the fuel level sender is serviced by replacing the entire fuel pump module assembly. For information, refer to **Group 47**.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. If necessary, remove any fairings or skirts blocking access to the top of the fuel tank (right hand fuel tank on dual tank vehicles).
3. Use masking tape and a felt-tipped marker to label the fuel sender wires; this will ease reassembly.
4. Remove the screws securing the fuel level signal and ground wires to the fuel level sender, then disconnect the wires from the sender. **See Fig. 1.**

1. Ground Wire
2. 10-24 Machine Screw
3. Circuit 47
4. 10-32 Hexnut and Split Lockwasher
5. 10-32 Machine Screw
6. Fuel Level Sender
7. Gasket
8. Fuel Tank

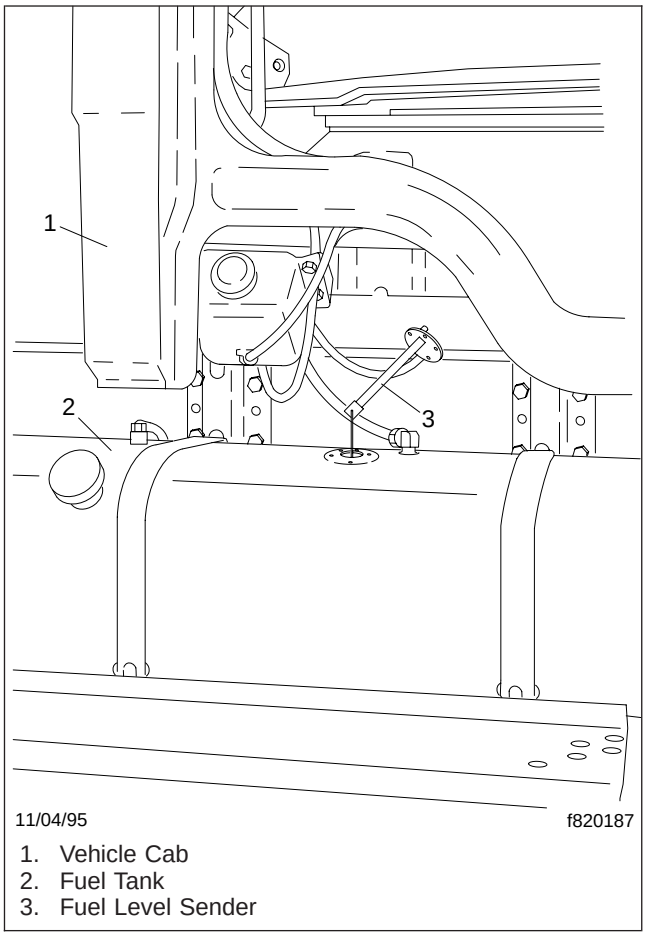

Fig. 1, Fuel Level Sender Mounting, Diesel Engines

5. Using a felt-tipped permanent marker, make alignment marks on both the fuel level sender plate and the fuel tank; this will simplify the assembly process.

⚠ WARNING

WARNING: Do not service the fuel system in the presence of sparks, open flames, or intense heat. These could ignite the fuel, possibly causing severe burns.

6. Remove the screws securing the fuel level sender to the fuel tank and carefully withdraw the sender and gasket from the tank. **See Fig. 2.** Be careful to avoid bending the float arm or damaging the float itself. The sender assembly *can* be removed from the tank opening without being damaged by tilting and rotating the sender as it is being withdrawn.

1. Vehicle Cab
2. Fuel Tank
3. Fuel Level Sender

Fig. 2, Fuel Level Sender Removal/Installation, Diesel Engines

Fuel Level Sender Removal and Installation

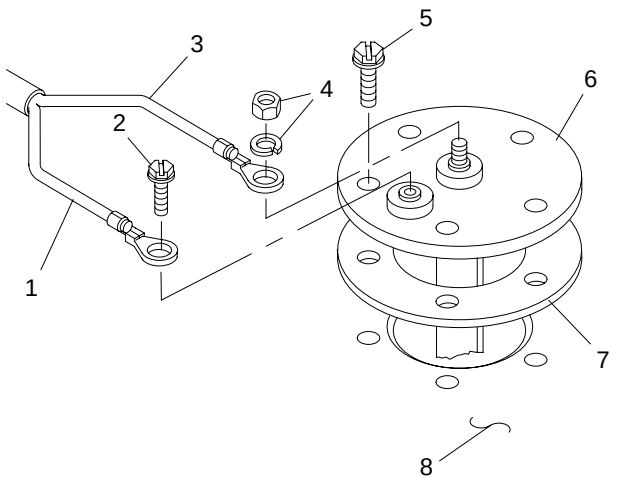
Installation

NOTE: If the fuel level sender is being replaced with a new unit, be sure to "transfer" the sender alignment mark from the old sender to the new sender.

1. Make sure the gasket is in place on the fuel sender assembly and insert the fuel level sender into the fuel tank, being careful to avoid damage to the float or float arm.
2. Rotate the sender assembly as necessary to line up the alignment marks made earlier, install the sender mounting screws, and tighten them. **See Fig. 1.**
3. Connect the vehicle wiring harness to the sender. Circuit 47 ("47" marked directly on the wire) must be connected to the insulated post at the center of the sender plate. The ground wire (marked "GND") must be connected to the remaining terminal post. **See Fig. 1.**
4. Start the engine, check for leaks, and check that the fuel level gauge is operating properly.
5. Install any side skirts or fairings that were removed to access the fuel level sender.
6. Remove the chocks from the tires.

Troubleshooting Procedures

Fuel level gauge malfunctions are usually one of two types: the gauge does not operate at all (always shows that the tank is empty), or the fuel level indicated by the gauge is believed to be incorrect.

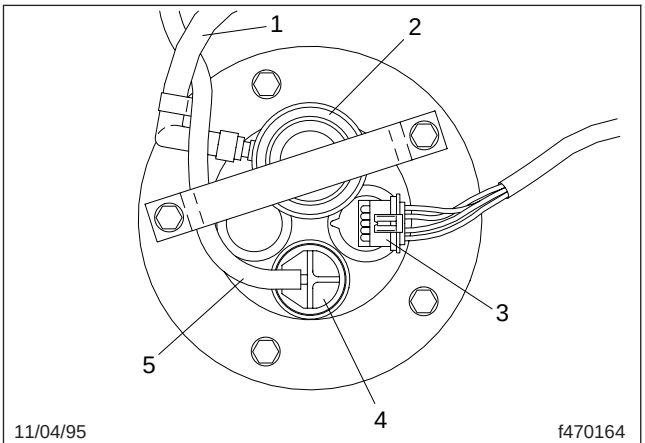


Before proceeding with any troubleshooting when an inaccurate gauge or sender is suspected, confirm the actual fuel level by inserting a clean dipstick into the tank (right hand tank on dual tank vehicles since this tank contains the sender).

If the vehicle is equipped with dual fuel tanks, check to see that the fuel level is approximately the same in both tanks. If the levels are different, check for problems with the fuel equalizing line and/or valve. For fuel tank and line information, refer to **Group 47**.

A possible, but unlikely, cause of incorrect gauge readings is that the wrong gauge is installed. Diesel engine gauges and gasoline engine gauges are not the same, but look very similar. Confirm that the proper gauge is installed by checking the part number label on the gauge.

Malfunctions that would cause a totally inoperative fuel level gauge include open circuits in the gauge, sender, or wiring. To isolate the cause of an inoperative fuel level gauge, follow the troubleshooting procedures in the order given.



1. Switch off the ignition and disconnect the fuel level signal circuit from the fuel level sender.
   - 1.1 Remove side skirts or fairings, if necessary, to access the top of the fuel tank (right hand tank on dual tank vehicles).
   - 1.2 On diesel engine powered vehicles, remove the screw securing the signal wire (marked "47") to the insulated center terminal of the fuel level sender, disconnect the wire from the terminal, and prop up the wire so it can't touch the sender or the tank itself. **See Fig. 1.**
   - 1.3 On gasoline engine powered vehicles, unplug the electrical connector at the fuel pump module. **See Fig. 2.**
2. Switch on the ignition and observe the gauge needle; it should remain at the left end of the scale (empty tank indicated).
3. Switch off the ignition and, using a jumper wire, connect the fuel level gauge signal wire terminal

(circuit 47) to the sender ground terminal. **See Fig. 1** (diesel engine) or **Fig. 3** (gasoline engine).

1. Wiring Harness Connector
2. Fuel Pump Motor Power (circuit A61)
3. Fuel Level Gauge Signal (circuit 47)
4. Fuel Level Gauge Ground (circuit Z11)
5. Fuel Pump Motor Ground (circuit Z13)

Fig. 3, Fuel Pump Module Connector Terminals

4. Switch on the ignition again and watch the gauge needle; it should move immediately to the extreme right or "full" end of the scale.

5. If the gauge operates as described in the above steps, it is functioning properly and the wiring to the gauge is okay. The problem is in the sender; replace it following the instructions in **Subject 110** and verify that the gauge operates properly.

   If the gauge does not function as described above, continue troubleshooting with the following steps:

6. Check the fuel level sender ground circuit.

   6.1 Switch off the ignition and disconnect the jumper previously installed between the sender signal and ground wires.

   6.2 Connect one lead of an ohmmeter to an exposed part of the frame, and connect the remaining lead to the sender ground terminal. Resistance should be very low—less than 5 ohms. Higher resistance indicates a problem in the ground circuit. Look for a loose wire, corrosion at the terminal, or a damaged wire.

   6.3 If the sender ground circuit checks out, leave the sender signal wire or fuel pump module connector disconnected and continue with the following steps:

7. Remove the instrument cluster bezel and the fuel level gauge. If necessary, refer to **Subject 100**.

8. Identify the fuel level gauge terminals that are part of the gauge mounting panel. **See Fig. 4.**

1. Gauge Mounting Panel
2. Ground Terminal
3. Ignition Power Terminal
4. Sender Signal Terminal
5. Illumination Bulb

Fig. 4, Fuel Level Gauge Connection

9. Check the fuel level gauge ground circuit wiring for an open circuit.

   9.1 With the ignition switch turned off, connect the leads of an ohmmeter between the cab metal (an unpainted bolt or screw attached directly to cab structure works well) and the ground circuit terminal in the gauge mounting panel. **See Fig. 4**, Ref. 2.

   9.2 Resistance should be very low—less than 5 ohms. If it is, go to the next step. If resistance is higher than 5 ohms, verify that you have good connections at both the terminal and the cab metal.

   9.3 If the connections are good, but resistance is still greater than 5 ohms, locate the damaged section of wiring between the terminal and ground. Repair the dam-

age by splicing in a length of replacement wiring following the instructions in this manual.

10. Check the signal circuit between the fuel level gauge and sender.
    - 10.1 With the gauge still removed from the gauge mounting panel, connect one ohmmeter lead to the mounting panel signal terminal (**see Fig. 4**, Ref. 4) and the other lead to the harness connector signal wire (still disconnected) at the fuel level sender (diesel) or fuel pump module (gasoline). **See Fig. 1** or **Fig. 3**.
    - 10.2 Resistance should be very low—less than 5 ohms. If it is, continue troubleshooting. If resistance is too high, locate and repair the loose connection or damaged section of wire between the fuel level gauge and the sender.
    - 10.3 Check the sender signal wire for a short to ground by measuring resistance between the gauge mounting panel signal terminal (gauge still removed) and a good ground. The ohmmeter should indicate infinite resistance. Any other reading means that the signal wire is shorted to ground. Look for a pinched, chafed or otherwise damaged circuit 47 between the gauge and the sender.
11. Check for battery voltage at the fuel gauge power terminal in the gauge mounting panel.
    - 11.1 Turn the ignition switch on.
    - 11.2 Connect a voltmeter (set on 20 volt scale, DC voltage) to mounting panel terminals as follows; positive (red) probe to the ignition power terminal (**see Fig. 4**, Ref. 3) and the negative (black) probe to the ground terminal (Ref. 2). The voltmeter should read between 9 and 16 volts DC.
    - 11.3 If voltage is between 9 and 16 volts DC, the gauge itself is malfunctioning, and must be replaced. For instructions, refer to **Subject 100**. If the voltage reading is not between 9 and 16 volts DC, check the circuit breaker that supplies power to the gauge. If the circuit breaker is okay, locate and repair the damage to the power circuit. General wire repair information can be found elsewhere in this manual.
12. Install the fuel level gauge and instrument cluster bezel. Connect the fuel level sender wires (diesel) or fuel pump module connector (gasoline). Make sure that the gauge is now operating properly.

4. Remove the transmission fluid temperature gauge from the dash.
   - 4.1 Using finger pressure, release the locking clip on the side of the gauge.
   - 4.2 Grasp the gauge firmly and pull it straight out of the mounting panel.

IMPORTANT: Don't touch the transmission fluid temperature gauge face or pointer.

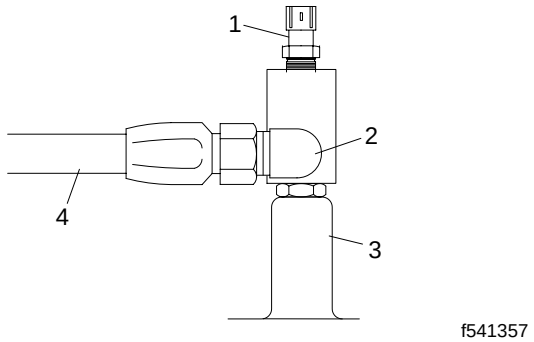
Installation

1. Install the transmission fluid temperature gauge.
   - 1.1 Grasp the gauge firmly and insert it in the mounting panel.
   - 1.2 Make sure the gauge is firmly seated and that the locking clip is holding it in place.
2. Install the instrument cluster bezel.
3. Remove the chocks from the tires.

Transmission Fluid Temperature Sensor Removal and Installation

Removal

1. Shut down the engine, apply the parking brake, and chock the tires.



⚠ WARNING

Do not service the temperature sensor until the transmission case has cooled. Touching a hot transmission case could result in burns to fingers and hands.

⚠ CAUTION

Automatic transmissions are sensitive to contamination of any kind. To prevent transmission damage, make sure that no dirt enters the system.

2. Remove the sensor from the transmission case. See **Fig. 1**.

02/22/99 f541357

1. Temperature Sensor
2. 90° Elbow
3. Outlet Port
4. Outlet Line to Cooler

Fig. 1, Transmission Fluid Temperature Sensor

2.1 Clean dirt and oil from the area around the sensor.

2.2 Disconnect the electrical connector from the sensor. Unscrew the sensor from the transmission outlet port.

2.3 To prevent contamination of the automatic transmission fluid (ATF), cover the hole with a shop towel.

Installation

1. Install the transmission fluid temperature sensor in the outlet port of the transmission case.

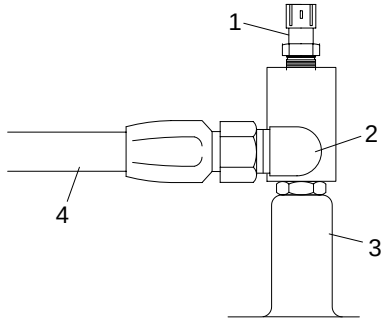
   1.1 Remove the shop towel and install the sensor into the port.

   1.2 Tighten the sensor to 18 lbf·ft (25 N·m).

2. Connect the wiring to the transmission fluid temperature sensor.
3. Start the engine and check for leaks.
4. Remove the chocks from the tires.
5. Test drive the vehicle to check the transmission fluid temperature gauge for correct operation.

Troubleshooting Procedures

Transmission temperature gauge malfunctions are usually one of two types: the gauge does not operate at all (it always shows that the transmission is cold), or the transmission temperature indicated by the gauge is incorrect.



Malfunctions that would cause a totally inoperative transmission temperature gauge include open circuits in the gauge, sensor, or wiring. To isolate the cause of a faulty transmission temperature gauge system, follow the troubleshooting procedures in the order given.

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the rear tires.

⚠ WARNING

Do not touch the transmission case until the case has cooled. Touching a hot transmission case could result in burns to fingers and hands.

2. Turn the ignition key to the OFF position and remove the electrical connector from the transmission temperature sensor. See **Fig. 1**.

02/22/99 f541357

1. Temperature sensor
2. 90° Elbow
3. Transmission Outlet Port
4. Outlet Line to Cooler

Fig. 1, Transmission Temperature Sensor Connection

3. Check the sensor unit with the electrical connector disconnected.

   3.1 Operate the vehicle until the transmission is at operating temperature. Carefully avoiding touching the hot transmission case, put the ohmmeter probes on the temperature sensor terminals. The ohmmeter reading should be less than 200 ohms when the transmission oil is hot.

   3.2 When the transmission cools to about 80° F (25° C) or less, connect one probe of an ohmmeter to one of the terminals on the sensor and the other probe to the other terminal. The ohmmeter reading should be at least 500 ohms. If the readings are not as indicated, replace the transmission temperature sensor, following the instructions in Group 54.16, **Subject 110** and verify that the gauge operates properly.

4. If the sensor readings are within specifications, turn the ignition key to the ON position and, with the electrical connector to the sensor disconnected, observe the gauge needle. The gauge needle should remain at the left end of the scale (low temperature indicated). If not, find and repair the short circuit in the wiring or gauge.

5. Test the wiring harness and gauge.

   5.1 Turn the ignition key to the OFF position and connect both terminals in the harness connector together with a jumper.

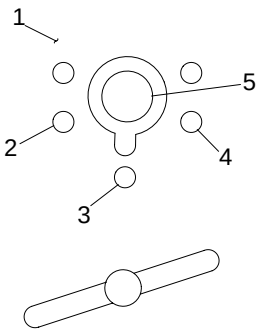
   5.2 Turn the ignition key to the ON position again and watch the gauge needle; it should move immediately to the extreme right or "hot" end of the scale.

   If the gauge needle moves to full scale in this test, the gauge unit and the wiring to the gauge are functioning properly or the problem is intermittent.

   Turn the ignition key to the OFF position, remove the jumper from the wiring harness connector and reconnect the harness connector to the transmission temperature sensor.

   IMPORTANT: If the problem is intermittent, test the current carrying capacity of the wires and pins and replace any damaged parts.

   5.3 If the gauge needle stays at the low end of the scale with the jumper connected, test the harness ground circuit by connecting the jumper from ground to the



Troubleshooting

sensor harness connector terminal for circuit 30. The gauge needle should move to the full scale position.

If the gauge now indicates full scale, the other wire in the sensor harness (from the harness connector to ground) is not making a good connection. Fix the wire problem and retest. If the gauge needle remains at the low end of the scale during this check, the gauge or the wire (circuit 30) from the sensor to the gauge has a problem.

6. If the previous tests indicate that the wiring and the sensor are good, check the gauge mounting panel and gauge.

   Remove the instrument cluster bezel and the transmission temperature gauge. If necessary, refer to Group 54.16, **Subject 100**. See **Fig. 2** to identify the transmission temperature gauge terminals .

02/22/99 f601090

1. Gauge Mounting Panel
2. Ground Terminal (–)
3. Ignition Power Terminal (+)
4. Sensor Signal Terminal
5. Gauge Illumination Bulb

Fig. 2, Transmission Temperature Gauge Connection

7. Check the ground circuit wiring of the transmission temperature gauge.

   7.1 With the ignition key in the OFF position, connect the probes of an ohmmeter between the cab metal (an unpainted bolt or screw attached directly to cab structure works well) and the ground circuit terminal (see **Fig. 2**) in the gauge mounting panel.

   7.2 The resistance should be less than 1 ohm. If it is, go to the next step. If the resistance is higher than 1 ohm, verify that you have good connections at both the terminal and the cab metal.

   7.3 If the connections are good, but the resistance is still greater than 1 ohm, locate the damaged section of wiring between the gauge ground terminal and ground. Repair the damage by splicing in a length of replacement wiring following the instructions in this group.

8. Check the signal circuit between the transmission temperature gauge and the sensor.

   8.1 With the gauge removed from the gauge mounting panel, connect one ohmmeter lead to the sensor signal terminal (see **Fig. 2**) and the other lead to the mounting panel ground terminal.

   8.2 If the harness and sensor are good, the resistance will depend upon the transmission fluid temperature. The resistance should be more than 500 ohms for a cold transmission and less than 200 ohms for a transmission at operating temperature.

   8.3 If the sensor resistance at this test point is within specifications, the sensor and the wiring are functioning correctly. If the resistance is not with specifications, go to the next step to test for power to the gauge.

9. Check for battery voltage at the transmission temperature gauge terminal in the gauge mounting panel.

   9.1 Turn the ignition key to the ON position.

   9.2 Connect a voltmeter (set on the 20 volt scale, DC voltage) to the gauge terminals in the gauge mounting panel as follows; positive (red) probe to the ignition power terminal (see **Fig. 2**) and the negative (black) probe to the ground terminal. The voltmeter should read between 9 and 16 volts DC.

9.3 If the voltage is between 9 and 16 volts, the gauge itself is malfunctioning, and must be replaced. For instructions, refer to Group 54.16, **Subject 100**. If the voltage reading is not within the limits mentioned above, check the circuit breaker that supplies power to the gauge. If the circuit breaker is functioning correctly, locate and repair the damage to the power circuit.

IMPORTANT: The level I ICU is also known (on ServiceLink) as the ICU3.

General Description

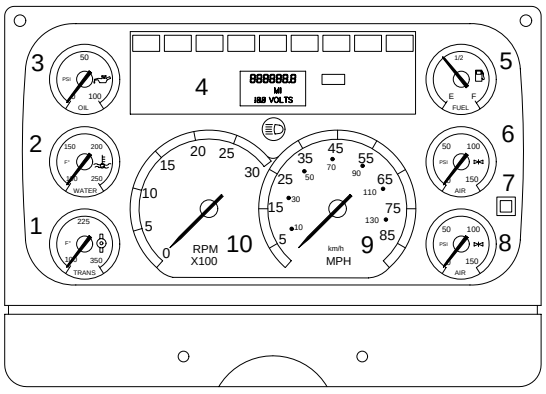
This section covers the instrumentation control unit, level I (level I ICU).

LEVEL I ICU (ICU3)

The level I ICU (ICU3) is a basic electronic dashboard that accepts input from the fuel level sensor, the transmission temperature sensor (if installed), and the J1587 datalink. The information is processed by a micro-computer and displayed on electronic gauges driven by stepper motors. Only air gauges operate mechanically.

The following gauges are available:

- Speedometer
- Tachometer (optional)
- Engine Oil Pressure
- Coolant Temperature
- Fuel Level
- Transmission Fluid Temperature (optional)
- Primary Air Pressure (optional)
- Secondary Air Pressure (optional)



The transmission fluid temperature gauge is required on vehicles with automatic transmissions.

The speedometer and tachometer are large-faced electronic gauges located below the dash message center. See **Fig. 1**.

The other gauges are small-faced gauges on the driver's instrument panel, to either side of the speedometer and tachometer. The engine oil pressure, coolant temperature, transmission fluid temperature, and fuel level gauges are electronic; the air pressure gauges are mechanical. The level I ICU can not drive gauges located on the auxiliary instrument panel.

The following items are replaceable:

- air pressure gauges
- light bulbs
- lens/mask assembly
- mode/reset button

06/02/99 f610205b

1. Transmission Fluid Temperature Gauge
2. Coolant Temperature Gauge
3. Engine Oil Pressure Gauge
4. Dash Message Center
5. Fuel Level Gauge
6. Primary Air Pressure Gauge
7. Optional Mode/Reset Push Button
8. Secondary Air Pressure Gauge
9. Speedometer
10. Tachometer

Fig. 1, Level I ICU Gauge Layout (typical)

- top row warning and indicator lenses
- back cover

DASH MESSAGE CENTER

The heart of the level I ICU is the dash message center. It has two parts: a set of 26 warning and indicator lights similar to those found on a conventional lightbar, and a dash driver display screen. The dash driver display screen is a 1-line by 7-character liquid crystal display (LCD) that is normally used to display the odometer reading. In addition, there is a separate voltmeter display underneath the odometer display.

The information that can be provided by the message center includes:

- odometer readings
- trip miles
- trip engine hours
- a listing of active faults

With the optional Mode/Reset button, you can switch the odometer to display either miles or kilometers,

General Information

invoke the trip odometer and trip engine hours, and call up diagnostic messages (active faults).

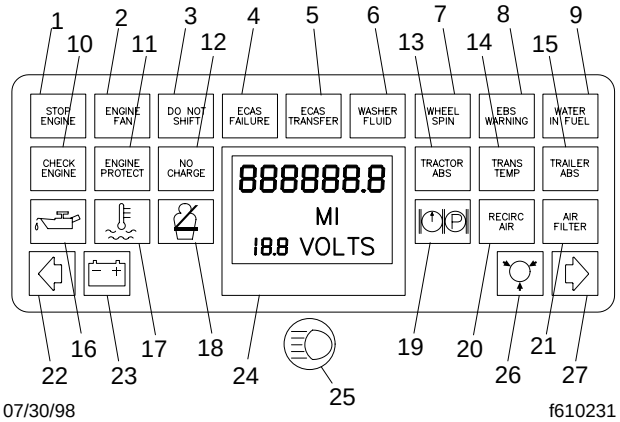
WARNING AND INDICATOR LIGHTS

There are spaces on the level I ICU for 26 warning and indicator lights. See **Fig. 2** for a typical installation.

There are four rows of lights. The lights in the top row are all optional and may be installed in any order, except for two lights that are typically installed at a fixed position.

- Position 1: Stop Engine Warning (Red)—installed on vehicles with Cummins engines only
- Position 7: Wheel Spin Indicator (Amber)

NOTE: Positions 1 through 8 are ground-activated circuits; position 2 can be activated with the ignition switch in the OFF position; position 9 is power-activated.



On the other three rows, the lights are installed at fixed positions that do not vary. Some lights are optional; if an optional light is not requested, the position is blank (does not light up).

The following fixed-position lights are standard:

- Check Engine Indicator (Amber)
- Low Engine Oil Pressure Warning (Red)
- High Coolant Temperature Warning (Red)
- Fasten Seat Belt Warning (Red)
- Left Turn Signal (Green)
- Low Battery Voltage Indicator (Amber)
- Tractor ABS Indicator (Amber)
- Parking Brake On Warning (Red)
- Recirculated Air Indicator (Amber)
- Low Air Pressure Warning (Red)
- Right Turn Signal (Green)
- High Beams On Indicator (Blue)
- Engine Protection Warning (Red)

The following fixed-position lights are optional:

- Alternator No Charge Indicator (Amber)

Typical installation shown. Location of legends installed in the top row may vary, and other legends may be specified.

1. Stop Engine Warning (Cummins engine only)
2. Engine Fan On Indicator (optional)
3. Do Not Shift Indicator (optional)
4. ECAS Failure Warning (optional)
5. ECAS Transfer Indicator (optional)
6. Low Washer Fluid Indicator (optional)
7. Wheel Spin Indicator (optional)
8. EBS Warning (optional)
9. Water In Fuel Indicator (optional)
10. Check Engine Indicator
11. Engine Protection Warning
12. Alternator No Charge Indicator (optional)
13. Tractor ABS Warning
14. Transmission Temperature Warning (optional)
15. Trailer ABS Warning (optional)
16. Low Engine Oil Pressure Warning
17. High Coolant Temperature Warning
18. Fasten Seat Belt Warning
19. Parking Brake On Warning
20. Recirculated Air Indicator
21. Air Restriction Indicator (optional)
22. Left Turn Signal
23. Low Battery Voltage Warning
24. Dash Driver Display Screen
25. High Beams On Indicator
26. Low Air Pressure Warning
27. Right Turn Signal

Fig. 2, Dash Message Center, Level I ICU (ICU3)

- High Transmission Temperature Warning (Amber)—installed on vehicles with automatic transmissions
- Trailer ABS Indicator (Amber)—installed on vehicles designed to be used with a trailer
- Air Restriction Indicator (Amber)

The following lights are optional and their installed location may vary anywhere in the top row:

- Engine Fan On Indicator (Amber)
- Do Not Shift Indicator (Amber)
- ECAS Failure Warning (Red)
- ECAS Transfer Indicator (Amber)
- Low Washer Fluid Indicator (Amber)
- EBS (Electronic Braking System) Warning (Red)
- Water In Fuel Indicator (Amber)

Other optional lights may be specified.

All light bulbs are replaceable in the field, including gauge light bulbs and warning/indicator light bulbs.

Principles of Operation

IGNITION SEQUENCE

When the ignition keyswitch is turned on, the level I ICU (ICU3) runs through the ignition sequence. See **Fig. 3**. If the headlights are turned on, the screen displays the odometer and waits for the ignition to be turned on.

IMPORTANT: When the ignition keyswitch is first turned on, all the electronic gauges complete a full sweep of their dials, the warning and indicator lights light up, and the buzzer sounds for three seconds.

The following warning and indicator lights go on during the ignition sequence:

- Low Engine Oil Pressure Warning
- High Coolant Temperature Warning
- Low Air Pressure Warning
- Parking Brake On Warning
- Low Battery Voltage Indicator
- Fasten Seat Belt Warning
- All engine warning lights, including Engine Protection, Check Engine, and Stop Engine (on Cummins only)
- All ABS warning lights, including Wheel Spin, Tractor ABS, and Trailer ABS (if installed)

NOTE: While the engine and ABS warning lights go on during the ignition sequence, they are not controlled by the level I ICU, but by their own system ECU (electronic control unit).

Once the ignition keyswitch has been turned on, the ICU performs a self-test, looking for active faults. During the first half of the self-test, all segments of the display illuminate as follows: "888888.8." During the second half of the self-test, the software revision level is displayed.

If there are no active faults, the screen displays the odometer.

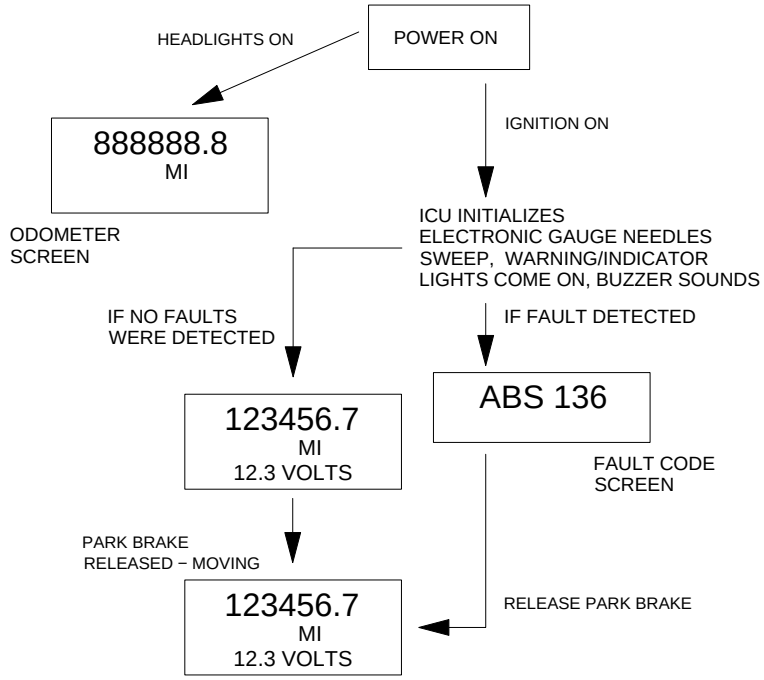
If, however, the level I ICU has received active fault codes from other devices, it displays the three-letter acronym and MID number for each for three seconds, one after the other, until the parking brake is released or the ignition keyswitch is turned off.

The screen displays a code, called the message identifier (MID), indicating the ECU or system that is not functioning properly.

For a complete list of possible screen displays, see **Specifications 400**.

NOTE: If the level I ICU receives a message from an ECU that has not been pre-programmed into the ICU's memory, it displays "SYS ###" instead, where ### is replaced by the MID of the broadcasting device.

Once the parking brake is released, the level I ICU displays the odometer again.



ODOMETER

The odometer is set to display in either miles or kilometers, depending on the primary scale of the speedometer. The legend, either "MI" or "KM," illuminates between the odometer and the volts display when the engine is running or the headlights are turned on.

The odometer is a seven-digit display with a decimal point, until the vehicle has traveled 999,999.9 miles or kilometers (km). At one million miles (km), the odometer rolls over to "1000000," without the decimal point, and can continue up to 9,999,999. The odometer only displays significant figures (no leading zeros).

IMPORTANT: Although the odometer uses data supplied by the engine ECM to update its count,

General Information

During the first half of the self-test, all segments of the display illuminate. During the second half of the self-test, the software revision level is displayed.

NOTE: If there is more than one fault, the level I ICU displays them, one after another, changing every three seconds, until the park brake is released.

Fig. 3, Level I ICU Ignition Sequence

it keeps its own mileage starting from zero, when it was first installed. The ICU odometer may not match the engine ECU odometer. This may occur if the engine has been operated with the ICU disconnected, as may occur during factory break-in or engine service, or if the ICU has been replaced.

BUZZER

The buzzer sounds during the ignition sequence and whenever one of the following conditions exist:

- The engine oil pressure falls below the preset level, which is 5 to 9 psi (35 to 60 kPa) on most engines.
- The coolant temperature rises above the preset level, which is 215°F (101°C) on Caterpillar and Detroit Diesel engines; 220°F (104°C) on Cummins engines; and 189°F (87°C) on MBE900 engines.
- The air pressure falls below the preset level of approximately 70 psi (483 kPa).
- The parking brake is set with the vehicle moving at a speed greater than 2 miles per hour.

IMPORTANT: The level I ICU is also known (on ServiceLink) as the ICU3.

Replacement

The instrumentation control unit, level I (level I ICU) is a self-contained one-piece unit, including housing, gauges, and the dash message center. See **Fig. 1**.

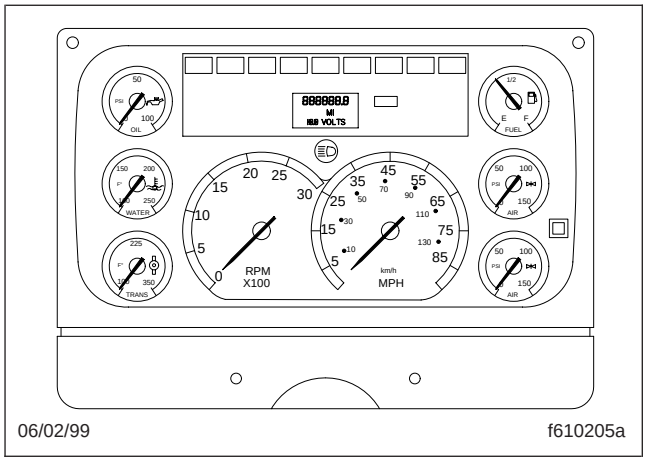


Fig. 1, Level I ICU

1. Reduce air pressure in the primary and secondary air systems to 25 psi (172 kPa) or less.

CAUTION

Electronic components of the level I ICU (ICU3) are vulnerable to damage from static electricity. If available, wear a wrist grounding strap connected to a ground in the cab or workbench. If a grounding strap is not available, touch a grounded component immediately before doing any work which could bring a tool or body part in contact with level I ICU circuitry.

2. Remove the four fasteners from the level I ICU bezel. See **Fig. 2**. Fasteners used on the level I ICU are T25 Torx-head dog-point screws. See **Fig. 3**.

CAUTION

Do not forcibly pull the driver's panel from the dash. This may dislodge wires from the harness

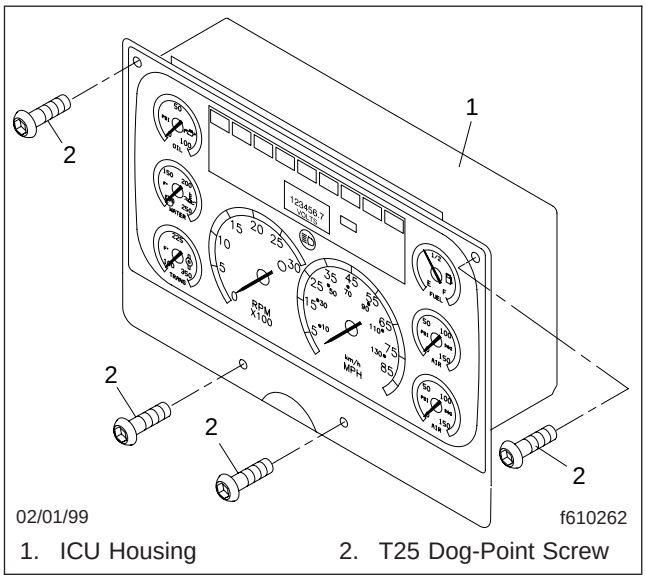

Fig. 2, Level I ICU Installation

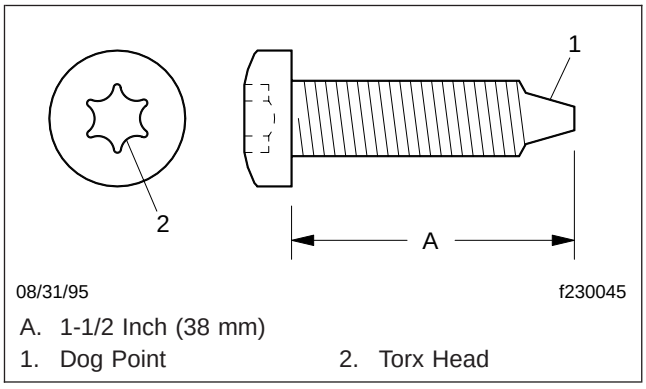

Fig. 3, Dog-Point Screw

electrical connectors on the back of the ICU housing and damage the wires, the ICU, or the dash.

3. Pull the old ICU away from the dash. Pull the top of the unit towards you until the back of the housing is free, then pull up to remove the rest of the unit.

4. Remove the connectors from the back of the housing.

   4.1 From behind the ICU housing, disconnect the two electrical connectors in the center of the housing.

Level I Instrumentation Control Unit Replacement

4.2 Disconnect all air hoses. Hoses and connectors are color-coded for ease of installation.

5. Remove the old ICU from the vehicle. See **Fig. 2**.
6. Install the level I ICU on the dash. See **Fig. 2**.
   - 6.1 Connect the air hoses to the air gauges, as removed.
   - 6.2 Connect the two electrical connectors, as removed.
   - 6.3 Place the new level I ICU in the dash and install the fasteners.
7. Turn on the ignition and test the operation of the new level I ICU. All the electronic gauges should make one complete sweep and return to their normal indicating positions; the warning and indicator lights should turn on, then off.

   If any gauges are not working properly, the level I ICU will need to be serviced or replaced.

NOTE: Mechanical (air) gauges do not make a sweep.

Replacement

1. Reduce air pressure in the primary and secondary air systems to 25 psi (172 kPa) or less.

CAUTION

To avoid damaging the ICU, please read and follow the cautions in Subject 100 regarding grounding the ICU and forcibly pulling it from the dash.

2. Remove the level I ICU. See **Fig. 1**. For detailed instructions, see **Subject 100**.

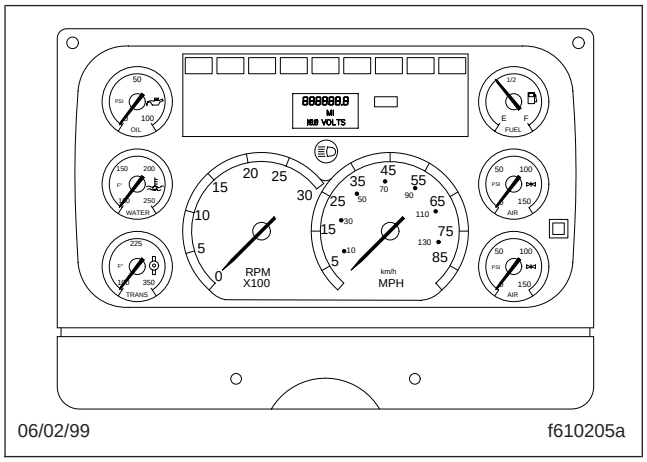

Fig. 1, Level I ICU

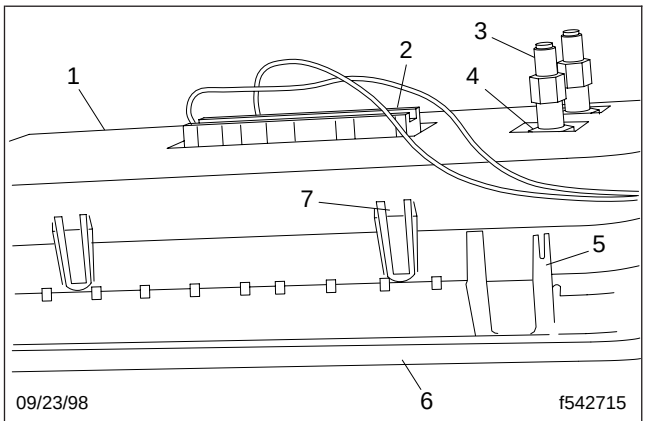


CAUTION

Use extreme care to avoid breaking the clips when prying them off the ICU housing. The clips are under tension and are easy to damage.

3. Using a thin-bladed screwdriver, very carefully pry the nine large white clips away from the sides of the ICU housing. It is helpful to use a small thin piece of metal, such as a spade terminal, to hold each clip away from the housing after it has been gently levered off its pawl. Remove the bezel from the ICU housing. See **Fig. 2**.

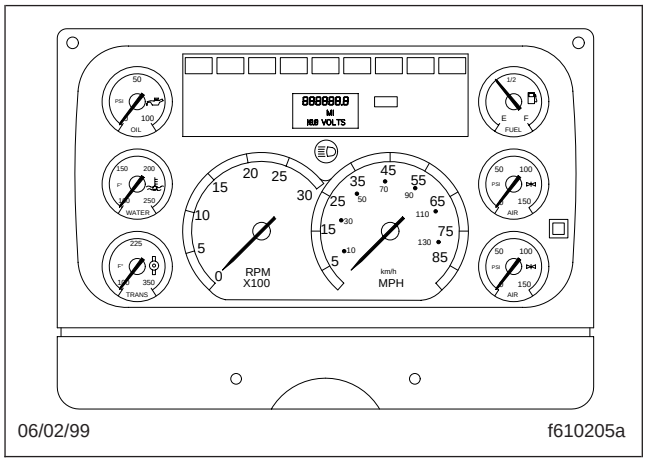
4. From the back of the ICU housing, remove the quick-disconnect fitting and nut from the threaded tube coming out the back of the air gauge.

5. Remove the old air gauge from the ICU.

1. ICU Housing
2. Electrical Connector
3. Quick-Disconnect Fitting
4. Nut
5. Bezel Clip (white)
6. Bezel
7. Back Cover Clip (black)

Fig. 2, Air Pressure Gauge Installation

6. Install the new air gauge.
   - 6.1 Insert the new gauge into the hole in the ICU housing.
   - 6.2 Tighten the nut on the threaded tube.
   - 6.3 Install the quick-disconnect fitting.
7. Position the bezel on the ICU housing. Fasten the nine white clips to the sides of the ICU housing.
8. Install the level I ICU. For detailed instructions, see **Subject 100**.
9. Start the engine and verify the proper operation of the new gauge as the air pressure builds up.



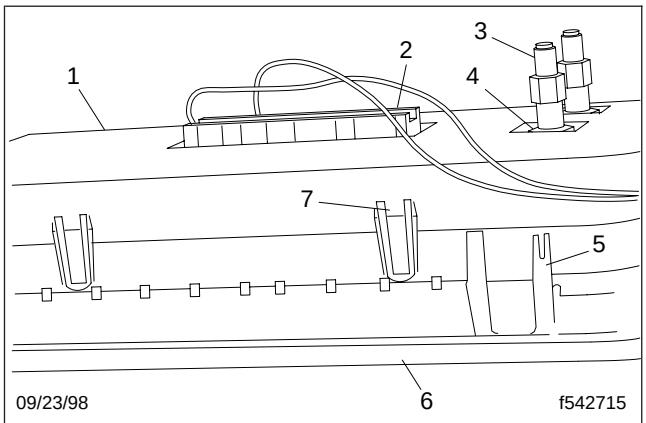
Replacement

1. Reduce air pressure in the primary and secondary air systems to 25 psi (172 kPa) or less.

CAUTION

To avoid damaging the ICU, please read and follow the cautions in Subject 100 regarding grounding the ICU and forcibly pulling it from the dash.

2. Remove the level I ICU. See **Fig. 1**. For detailed instructions, see **Subject 100**.

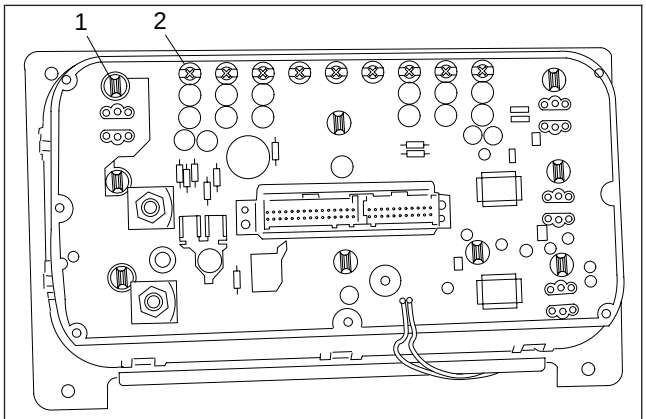


06/02/99 f610205a

Fig. 1, Level I ICU

CAUTION

Use extreme care to avoid breaking the clips when prying them off the ICU housing. The clips are under tension and are easy to damage.



3. Pry off the four small black clips from the sides of the ICU housing. See **Fig. 2**.
4. Remove the two screws from the back of the housing, one on the middle of each side, and remove the back cover from the ICU housing.
5. Remove the burnt-out light bulb(s). See **Fig. 3**.
   - 5.1 To remove gauge light bulbs, twist the bulb base 1/4-turn counter-clockwise, then pull out.

09/23/98 f542715

09/29/98 f542716

1. Gauge Light Bulb Base
2. Warning and Indicator Light Bulb Base

Fig. 3, Light Bulb Installation

   - 5.2 To remove warning/indicator light bulbs, use a small screwdriver to twist out the bulb base behind the affected light.
6. Install the new light bulb(s).
   - 6.1 To install gauge light bulbs, twist the bulb holder into the slot from which the old one was removed.

Light Bulb Replacement

6.2 To install warning/indicator light bulbs, insert the new bulb base into the proper slot and use a small screwdriver to tighten it.

NOTE: LEDs must be installed with correct polarity. Insert the LED into the socket, rotating and pushing gently until it touches the contacts. If it lights, push it the rest of the way into the socket. Otherwise, pull it out, rotate it 1/2 turn, and check for lighting again. If it still doesn't light, you need to push it further into the socket, the socket isn't getting power, or you may have a bad LED.

7. Position the back cover on the ICU housing. Fasten the four black clips to the sides of the ICU housing.
8. Install the two screws on the back of the housing, one on the middle of each side.
9. Install the level I ICU. For detailed instructions, see **Subject 100**.
10. Turn on the ignition keyswitch. Check all bulbs for correct operation.

IMPORTANT: The level I ICU is also known (on ServiceLink) as the ICU3.

The two connectors are pink and plug into pins located in the center of the unit, on the back. Connector #1 has 24 cavities, numbered A1 through A12, and B1 through B12. Connector #2 has 32 cavities, numbered C1 through C16, and D1 through D16.

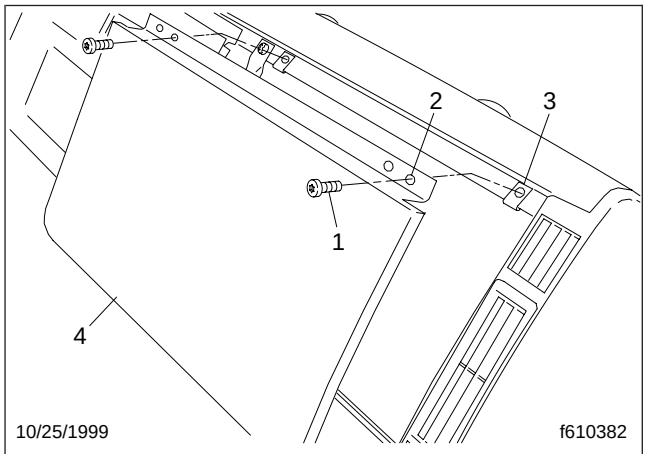
Vehicle Control Unit Removal and Installation

Removal



1. Remove the vinyl extrusion trim at the top of the passenger's-side dash panel. See **Fig. 1**.

Left-hand drive is shown; right-hand drive is similar.
1. Passenger's-Side Dash Panel
2. Vinyl Extrusion Trim

Fig. 1, Passenger's-Side Dash Panel

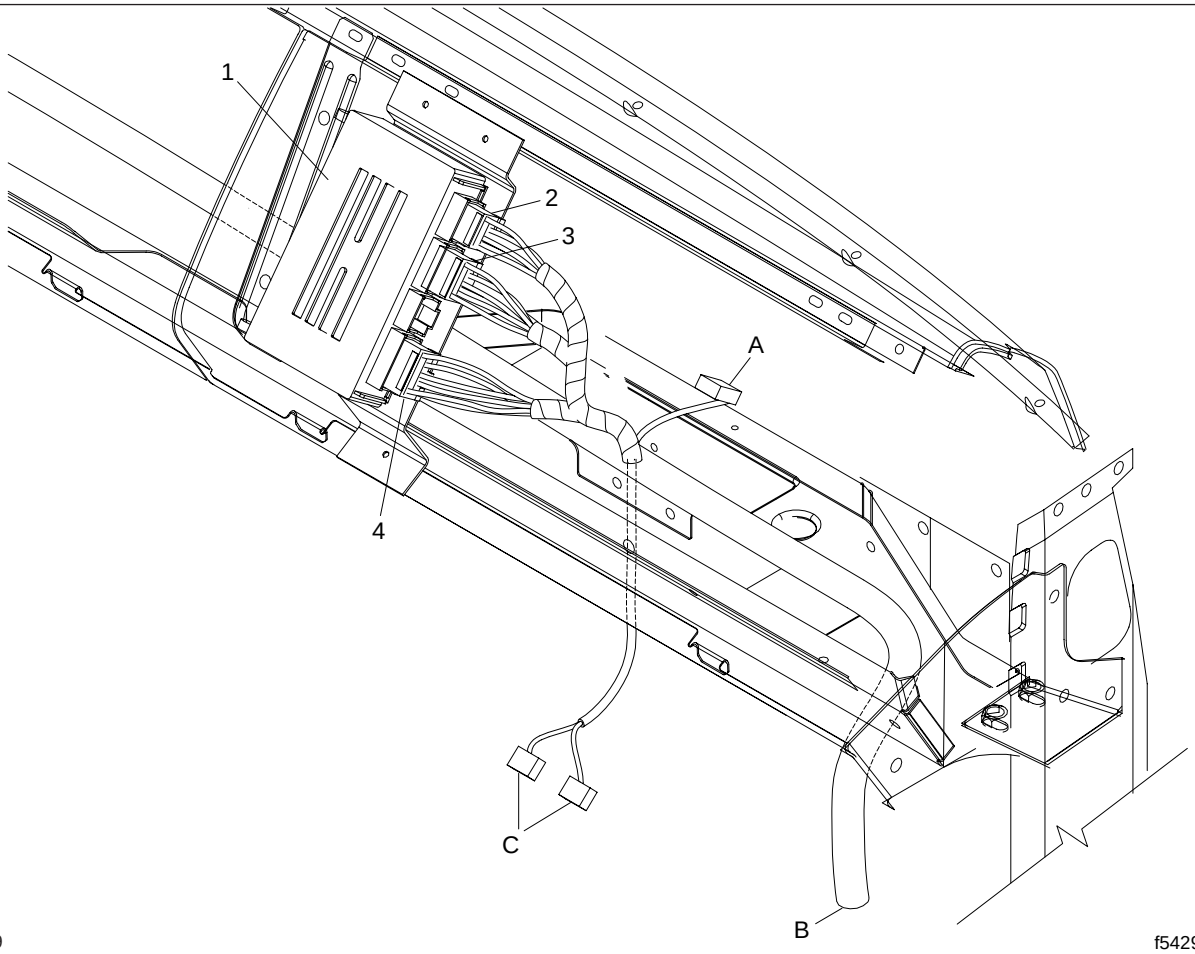
2. Using a T25 torx-head screwdriver, remove the two mounting screws along the top edge of the dash panel. See **Fig. 2**.

1. T25 Torx-Head Screw
2. Hole in Panel
3. Spring Clip
4. Passenger's-Side Dash Panel

Fig. 2, Dash Panel Mounting

3. Disconnect the three electrical connectors (violet, gray, and brown) by pressing the release at the bottom of each connector. See **Fig. 3**.
4. Push on the VCU (vehicle control unit) case in the direction away from the connectors to loosen the clips on the back of the box. See **Fig. 4**.

Installation



1. Install the VCU. Push in until the clips are firmly seated.
2. Connect the violet, gray, and brown electrical connectors to the VCU, as removed.

IMPORTANT: The connectors cannot be installed on the wrong plug location on the VCU, because they each have different numbers of pins. Connector VC2 is not used at this time.

- Connector VC1 has 21 pins.
- Connector VC3 has 18 pins.
- Connector VC4 has 15 pins.

3. Install the passenger's-side dash panel and tighten the two mounting screws until firm.
4. Install the vinyl extrusion trim at the top of the panel.

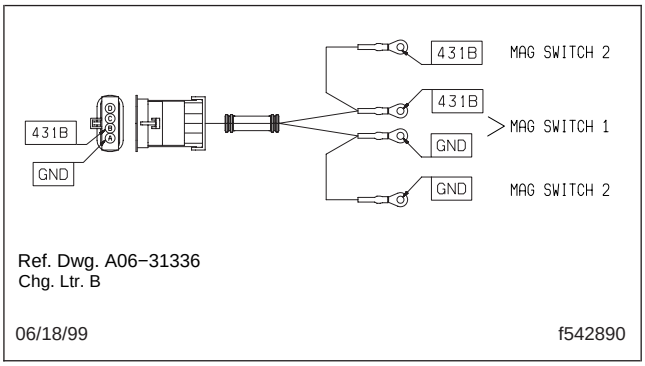
Fig. 4, Freightliner MBE900 Engines, Engine Side Wiring Harness

Harness Wiring



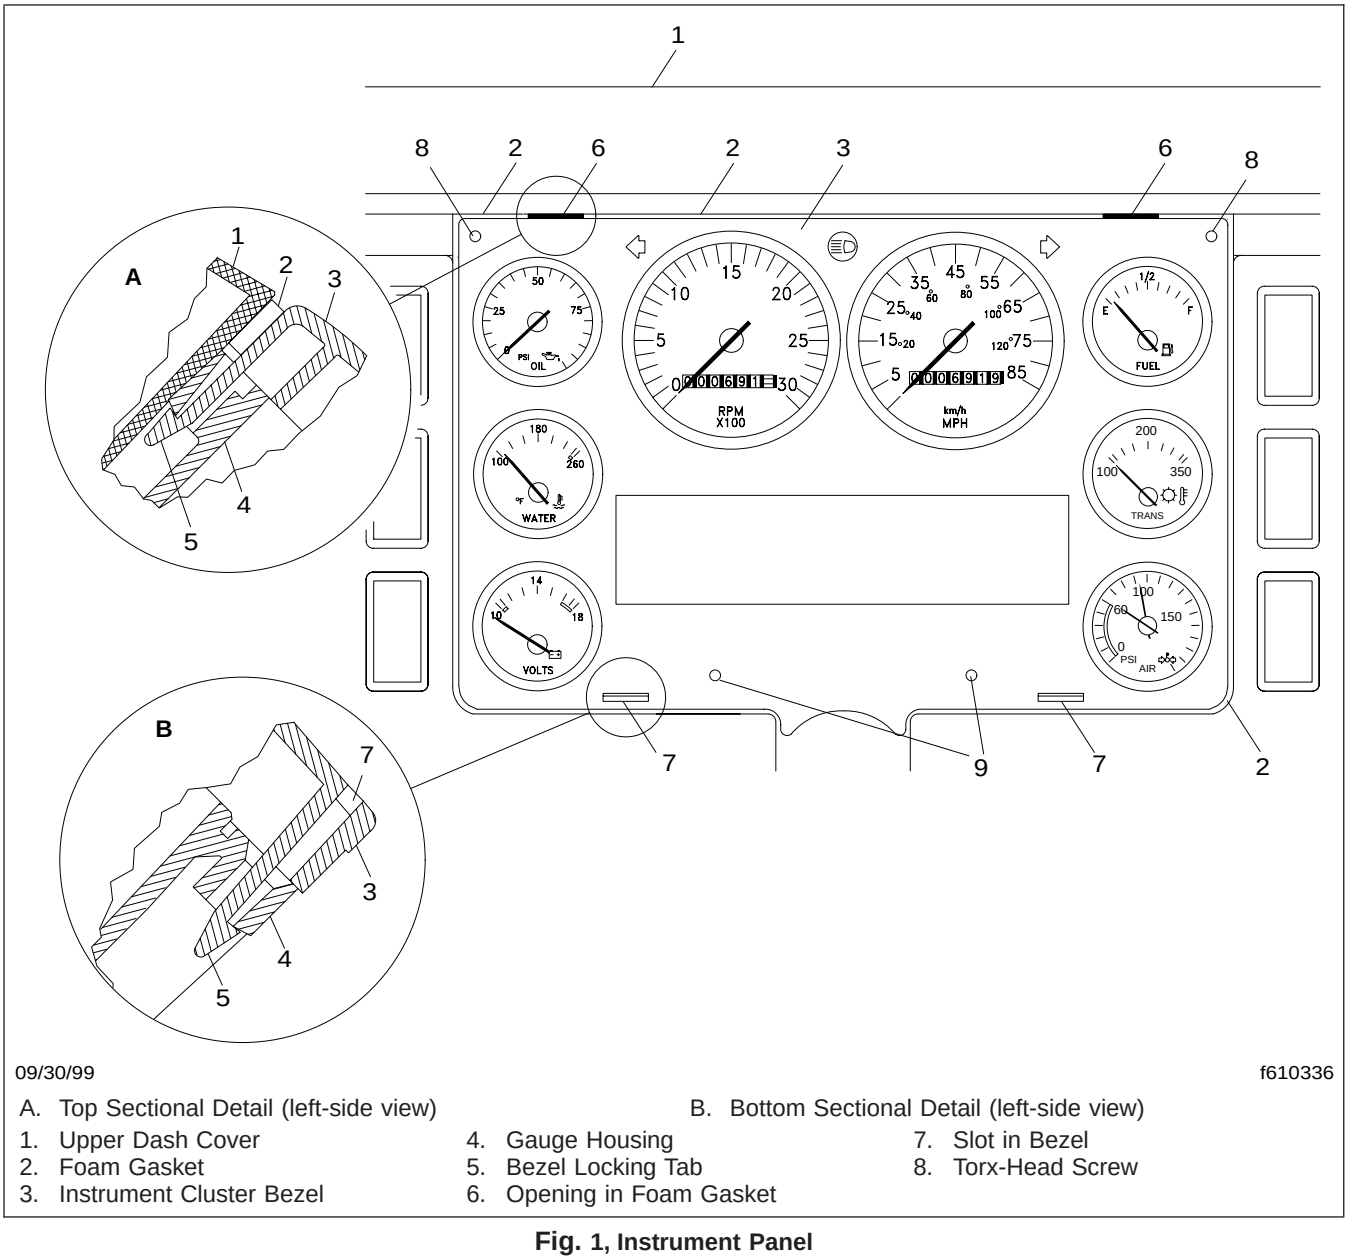


Fig. 5, Freightliner MBE900 Engines, Grid Heater Harness

General Description

The voltmeter is located in the lower left instrument panel. The voltmeter indicates battery voltage level, and should read 12.8 volts to 14.6 volts (or higher) when the engine is running. When the engine is being started, battery voltage will be lower than normal. Once the engine has been started, battery voltage will be temporarily higher than normal as the batteries are being recharged. If the voltmeter indicates a low or high voltage for an extended period of time, check the charging system and batteries.

Removal

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the batteries.
3. Remove the instrument cluster bezel. See **Fig. 1**.
   - 3.1 Remove the four Torx®-head screws from the bezel.
   - 3.2 Remove the instrument panel from the dash.
   - 3.3 Remove the bezel and set it aside.

6. Opening in Foam Gasket
7. Slot in Bezel
8. Torx-Head Screw

Fig. 1, Instrument Panel

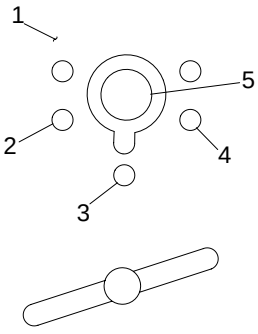
Voltmeter Removal and Installation

4. Remove the voltmeter from the gauge mounting panel by firmly grasping the gauge and pulling it straight out of the mounting panel.

   The gauge illumination bulb will remain in the gauge mounting panel; do not remove the bulb unless it must be replaced.

Installation

1. Position the voltmeter over the gauge mounting panel, making sure that the panel terminals line up with the gauge sockets.
2. Push the gauge into place until it seats against the mounting panel.
3. Position the instrument cluster bezel against the instrument panel.
4. Install the Torx-head screws in the instrument cluster bezel and tighten until firm.
5. Connect the batteries.
6. Start the engine and verify that the voltmeter is operating properly.
7. Remove the chocks from the tires.



Troubleshooting Procedures

Voltmeter gauge malfunctions are usually one of two types: the gauge does not operate at all, or the gauge is believed to be incorrect.

Before proceeding with any troubleshooting when an inaccurate gauge is suspected, confirm the actual battery voltage and charging voltage with a known good voltmeter.

Malfunctions that would cause a totally inoperative voltmeter include open circuits in the gauge or wiring.

1. Remove the instrument cluster bezel and the voltmeter gauge. For instructions, see **Subject 100**.
2. Identify the voltmeter terminals that are part of the gauge mounting panel. See **Fig. 1**.

02/22/99 f601090

1. Gauge Mounting Panel
2. Ground Terminal
3. Ignition Power Terminal (12 volts)
4. Not Used
5. Illumination Bulb

Fig. 1, Voltmeter Connection

3. Check the voltmeter gauge ground circuit wiring for an open circuit.
   - 3.1 With the ignition switch turned off, connect the leads of an ohmmeter between the cab metal (an unpainted bolt or screw attached directly to cab structure works well) and the ground circuit terminal in the gauge mounting panel. See **Fig. 1**, Ref. 2.
   - 3.2 Resistance should be very low—less than 5 ohms. If it is, go to the next step. If resistance is higher than 5 ohms, verify that you have good connections at both the terminal and the cab metal.
   - 3.3 If the connections are good, but resistance is still greater than 5 ohms, locate the damaged section of wiring between the terminal and ground. Repair the damage by splicing in a length of replacement wiring following the instructions in this manual.
4. Check for battery voltage at the voltmeter gauge power terminal in the gauge mounting panel with the ignition switch in the on position.
   - 4.1 Turn the ignition switch on.
   - 4.2 Connect a voltmeter (set on 20 volt scale, DC voltage) to mounting panel terminals as follows; positive (red) probe to the ignition power terminal (see **Fig. 1**, Ref. 3) and the negative (black) probe to the ground terminal (Ref. 2). The voltmeter should read between 9 and 16 volts DC.
   - 4.3 If voltage is between 9 and 16 volts DC, the gauge itself is malfunctioning, and must be replaced. For instructions, see **Subject 100**. If the voltage reading is not between 9 and 16 volts DC, check the circuit breaker that supplies power to the gauge. If the circuit breaker is okay, locate and repair the damage to the power circuit. General wire repair information can be found elsewhere in this group.
5. Install the voltmeter gauge and instrument cluster bezel. Make sure that the gauge is now operating properly.

General Information

The Short Conventional cab is supported at four points on the vehicle chassis. **See Fig. 1.**

Isolators, located at each of the four support points, cushion the cab from shock by absorbing energy as they are compressed. Each front support point has an upper and lower, solid, synthetic rubber isolator.

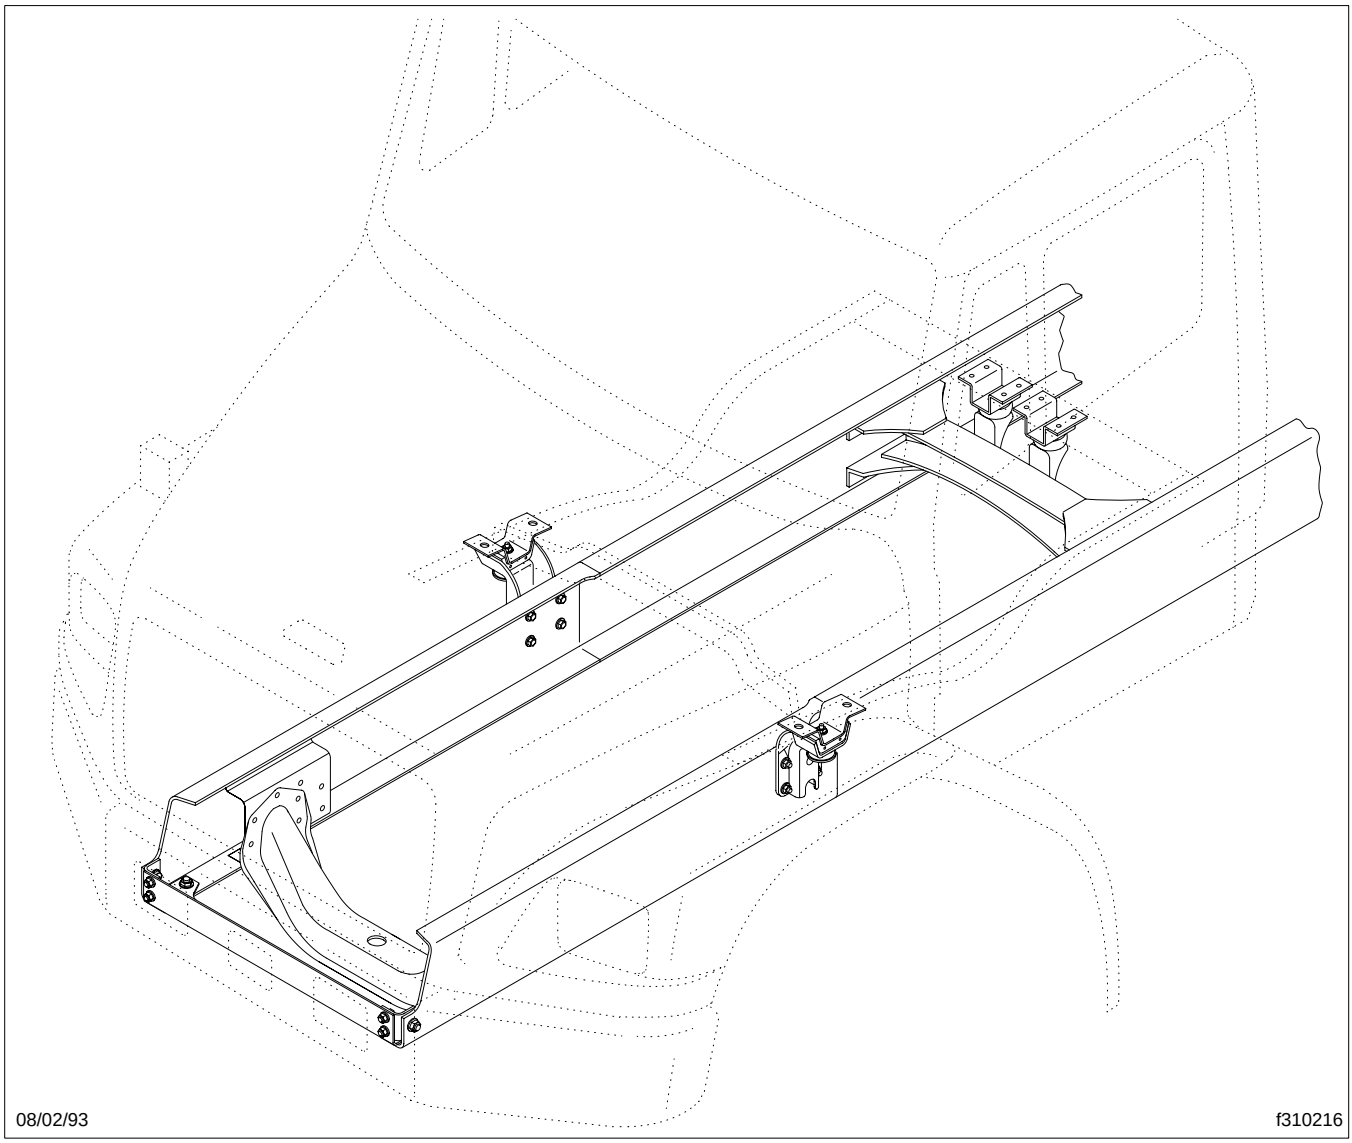


Fig. 1

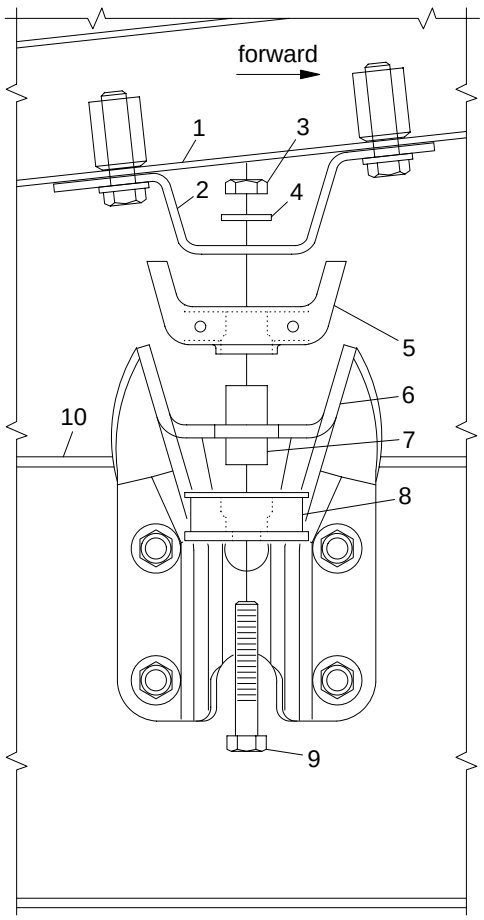
The front of the cab has a cab mounting bracket at each side, directly above a cab support bracket attached to the outboard side of each frame rail. The rear of the cab is mounted on a pair of cab support brackets attached near the center of a frame crossmember.

Each rear support point has either an upper and lower solid rubber isolator or a single hydraulic isolator. Solid rubber upper isolators are fastened between the cab mounting brackets and cab support brackets, to compress when the cab and chassis are forced toward each other. Solid rubber lower isolators

General Information

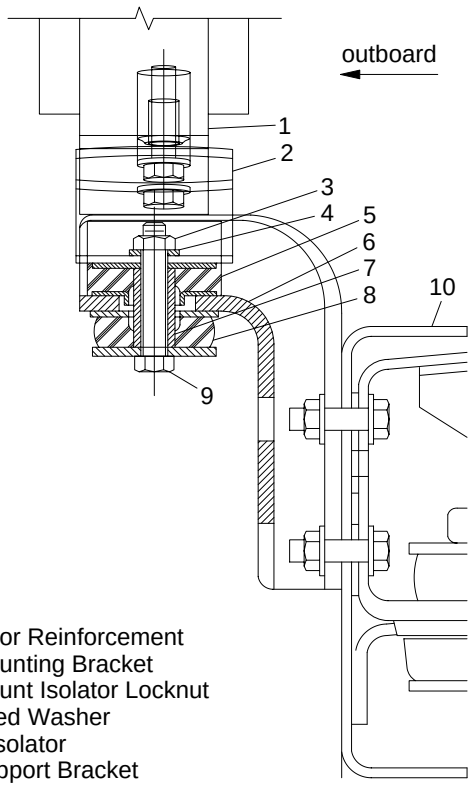
are attached to the bottom of the cab support brackets, to compress when the cab and chassis are forced away from each other.

The hydraulic isolators are fastened between the cab mounting brackets and cab support brackets; they absorb energy both as they are compressed and stretched.



Replacement

NOTE: Don't replace only one isolator or a pair of isolators; as a set, replace the upper and lower isolators on both sides of the front of the vehicle.



1. Tilt the hood; refer to the vehicle driver's manual.
2. Remove the half fenders; **refer to the hood group** for instructions.
3. Remove the old isolators. **Refer to Fig. 1 .**
   - 3.1 From each side of the cab, remove the locknut, hardened washer, bolt, lower isolator, and spacer.
   - 3.2 Use a jack to raise the front of the cab about 13 mm (1/2 in).
   - 3.3 Remove the upper isolator from each cab support bracket.
4. Install the new isolators. **Refer to Fig. 1 .**
   - 4.1 Inspect the original locknuts, hardened washers, bolts, and spacers. If any wear, distortion, or other damage is found, replace the part.
   - 4.2 Install the new upper isolator in each cab support bracket.
   - 4.3 Lower the cab until the cab mount brackets just contact the top of the upper isolators.
   - 4.4 Install a spacer and bolt in one of the new lower isolators, then install these parts at the bottom of one of the cab support brackets. Install a hardened washer and locknut.

     Repeat this for the other side of the cab.
   - 4.5 Lower the cab, and remove the jack.
   - 4.6 Tighten the locknuts 92 N·m (68 lbf·ft).
5. Install the half fenders; **refer to the hood group** for instructions.

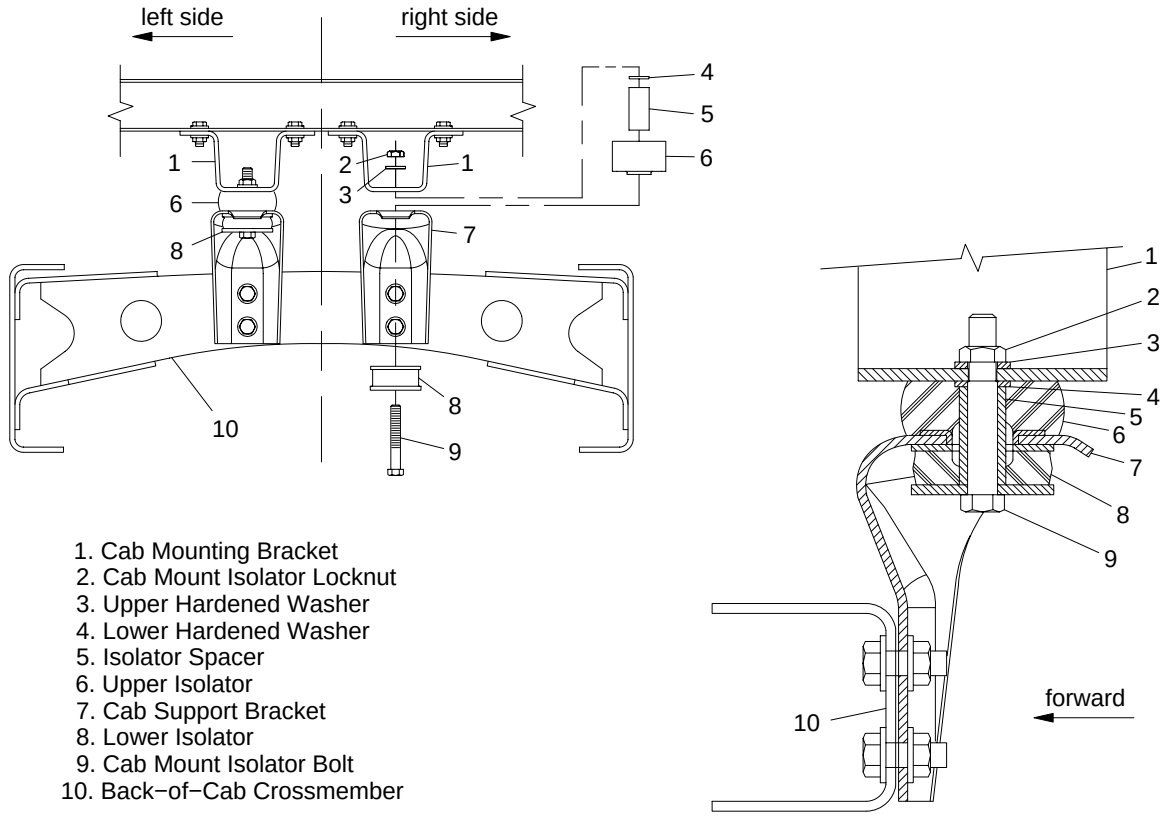
Rear Mount Solid Rubber Isolator Replacement



Replacement

NOTE: Don't replace only one isolator or a pair of isolators; as a set, replace the upper and lower isolators on both sides of the rear of the vehicle.

1. Tilt the hood; refer to the vehicle driver's manual.
2. Remove the old isolators. **Refer to Fig. 1 .**
   - 2.1 From each side of the cab, remove the locknut, upper hardened washer, bolt, lower isolator, and spacer.
   - 2.2 Use a jack to raise the rear of the cab about 25 mm (1 in).
   - 2.3 Remove the upper isolator and lower hardened washer from each cab support bracket.
3. Install the new isolators. **Refer to Fig. 1 .**
   - 3.1 Inspect the original locknuts, hardened washers, bolts, and spacers. If any wear, distortion, or other damage is found, replace the part.
   - 3.2 Install the new upper isolator and the lower hardened washer on each cab support bracket.
   - 3.3 Lower the cab until the cab mount brackets just contact the top of the upper isolators.
   - 3.4 Install a spacer and bolt in one of the new lower isolators, then install these parts at the bottom of one of the cab support brackets. Install a hardened washer and locknut.

     Repeat this for the other cab support bracket.
   - 3.5 Lower the cab, and remove the jack.
   - 3.6 Tighten the locknuts 92 N·m (68 lbf·ft).

Rear Mount Hydraulic Isolator Replacement

Replacement

NOTE: Don't replace only one isolator; replace both isolators at the rear of the vehicle as a set.

1. Tilt the hood; refer to the vehicle driver's manual.
2. Remove the old isolators. **Refer to Fig. 1 .**
   - 2.1 From each side of the cab, remove the locknut and hardened washer from the upper and lower studs on the isolator.
   - 2.2 Using a jack, raise the rear of the cab about 25 mm (1 in).
   - 2.3 Remove the isolator from each cab support bracket.
3. Install the new isolators. **Refer to Fig. 1 .**
   - 3.1 Inspect the original locknuts and hardened washers. If any wear, distortion, or other damage is found, replace the part.
   - 3.2 Install each new isolator with the blue-colored stud pointing up.
   - 3.3 Lower the cab and remove the jack.
   - 3.4 Install the hardened washers and locknuts. Tighten the locknuts 92 N·m (68 lbf·ft).

Rear Mount Hydraulic Isolator Replacement

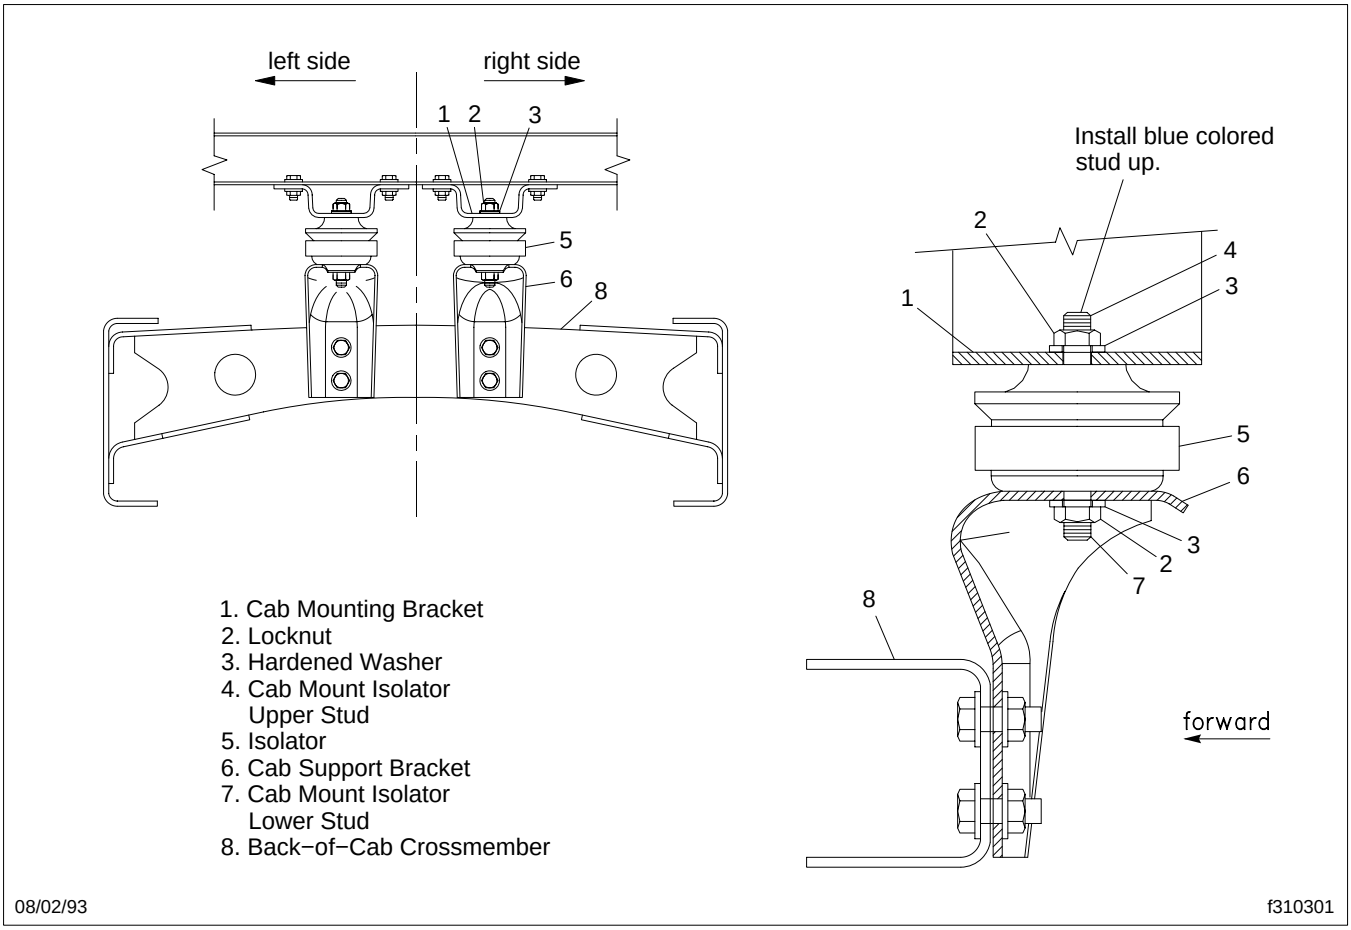

Fig. 1

Replacement

NOTE: Don't replace only one front cab mount; replace both front mounts as a set.

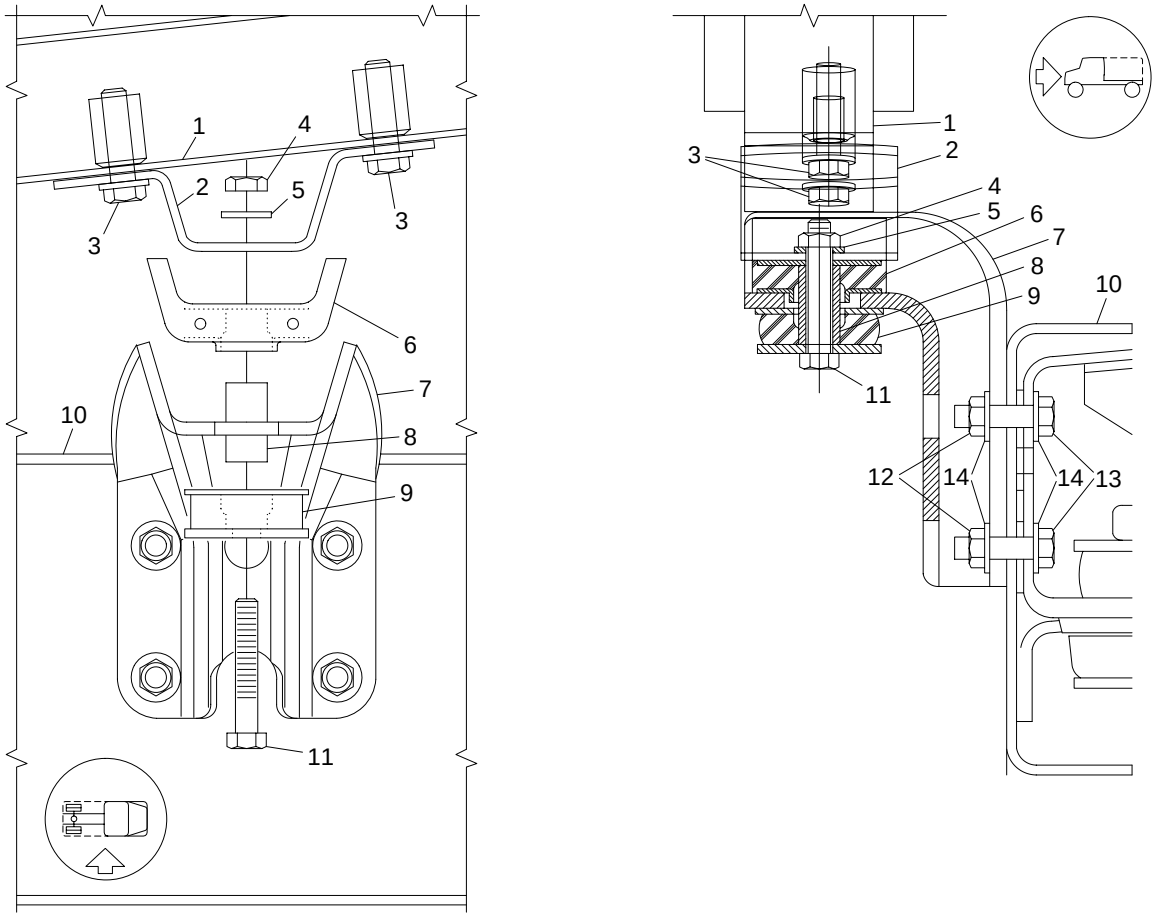
Front Cab Mounts

1. Park the vehicle on a level surface. Apply the parking brake; then chock the tires.
2. Tilt the hood; see the vehicle driver's manual.
3. Remove the half fenders; see **Group 88** for instructions.
4. Remove the cab mount assembly.
   - 4.1 Remove the isolator bolt. See **Fig. 1.**
   - 4.2 Place a bottle jack between the frame rail and cab deck; then raise the cab about 1-1/2 inches (40 mm).

   NOTE: The four frame-rail mounting bracket bolts go through the engine mounts.

   - 4.3 Place a jack under the transmission bell housing; then jack up the bell housing just enough to support the engine.
   - 4.4 Remove the four bolts from the cab support bracket along with the bracket.
   - 4.5 Remove two capscrews from the cab mounting bracket along with the bracket.
5. Install the cab mount assembly. See **Fig. 1.**
   - 5.1 Apply Loctite® 272 or equivalent to the cab mounting bracket capscrews. With the new cab mounting bracket separated from the cab mount assembly, position the cab mounting bracket; then install the two capscrews with washers. Tighten each capscrew 75 lbf·ft (100 N·m).
   - 5.2 Position the cab support bracket; then install the four capscrews, locknut, and hardened washers in the lower bracket assembly. Tighten each capscrew 190 lbf·ft (260 N·m).
   - 5.3 Position the upper isolator on the cab support bracket.
   - 5.4 Lower the cab until the cab mounting bracket just contacts the top of the upper isolator.
   - 5.5 Install a spacer and bolt and hardened washer in the lower isolator; then install these parts at the bottom of the cab support bracket. Install the hardened washer and locknut.
6. Install the half fenders; see **Group 88** for instructions.
7. Remove chocks from the tires.

FL106 and FL112 Front Cab Mounts



NOTE: FL106 and FL112 front cab mounts built after July 7, 1995 are slightly different. See **Fig. 2**.

1. Park the vehicle on a level surface. Apply the parking brake; then chock the tires.
2. Tilt the hood; see the vehicle driver's manual.
3. Remove the half fenders; see **Group 88** for instructions.
4. Remove the cab mount assembly.
   - 4.1 Remove the isolator bolt. See **Fig. 3**.
   - 4.2 Place a bottle jack between the frame rail and cab deck; then raise the cab about 1-1/2 inches (40 mm).
   - 4.3 Place a jack under the transmission bell housing; then jack up the bell housing just enough to support the engine.

   NOTE: Four of the five cab support bracket bolts go through the engine mount.

   - 4.4 Remove the five bolts from the cab support bracket along with the bracket itself.
   - 4.5 Remove three capscrews from the cab support bracket along with the bracket itself.
5. Install the new cab mount assembly. See **Fig. 3**.
   - 5.1 Apply Loctite® 272 or equivalent to the cab mounting bracket M14–1.5 capscrews. With the cab mounting bracket separated from the cab mount assembly, position the cab mounting bracket; then install three (driver's side) or two (passenger's side) capscrews with washers. Tighten each capscrew 75 lbf·ft (100 N·m).

Fig. 1, Early-Style Front Cab Mount Assembly

5.2 Position the cab support bracket; then install the five capscrews, locknuts and hardened washers. Tighten each capscrew 190 lbf·ft (260 N·m).

5.3 Position the upper isolator on the cab support bracket.

5.4 Lower the cab until the cab mount bracket just contacts the top of the upper isolator.

5.5 Install the isolator spacer, isolator bolt and hardened washer in the lower isolator; then install these parts at the bottom of the cab support bracket. Install the hardened washer and locknut.

6. Repeat procedure for the other side of the cab.
7. Lower the cab, and remove the jack under the cab and the jack under the bell housing.
8. Install the half fenders; see **Group 88** for instructions.

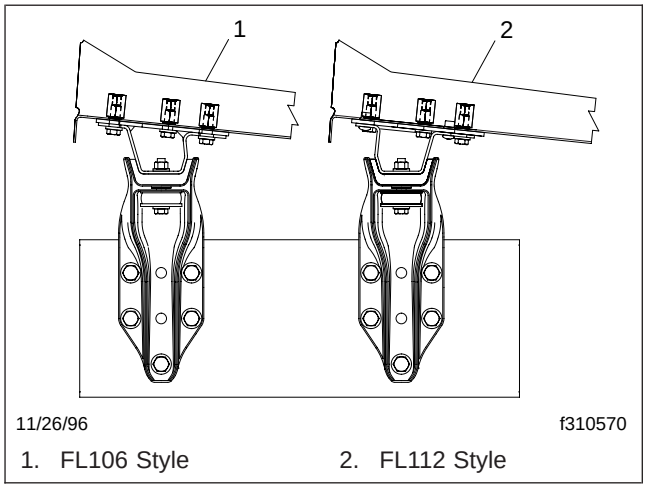

Fig. 2, Driver's-Side Cab Mount Assemblies, FL106 and FL112 Vehicles Built After July 7, 1995 (passenger's side similar)

9. Remove the chocks from the tires.

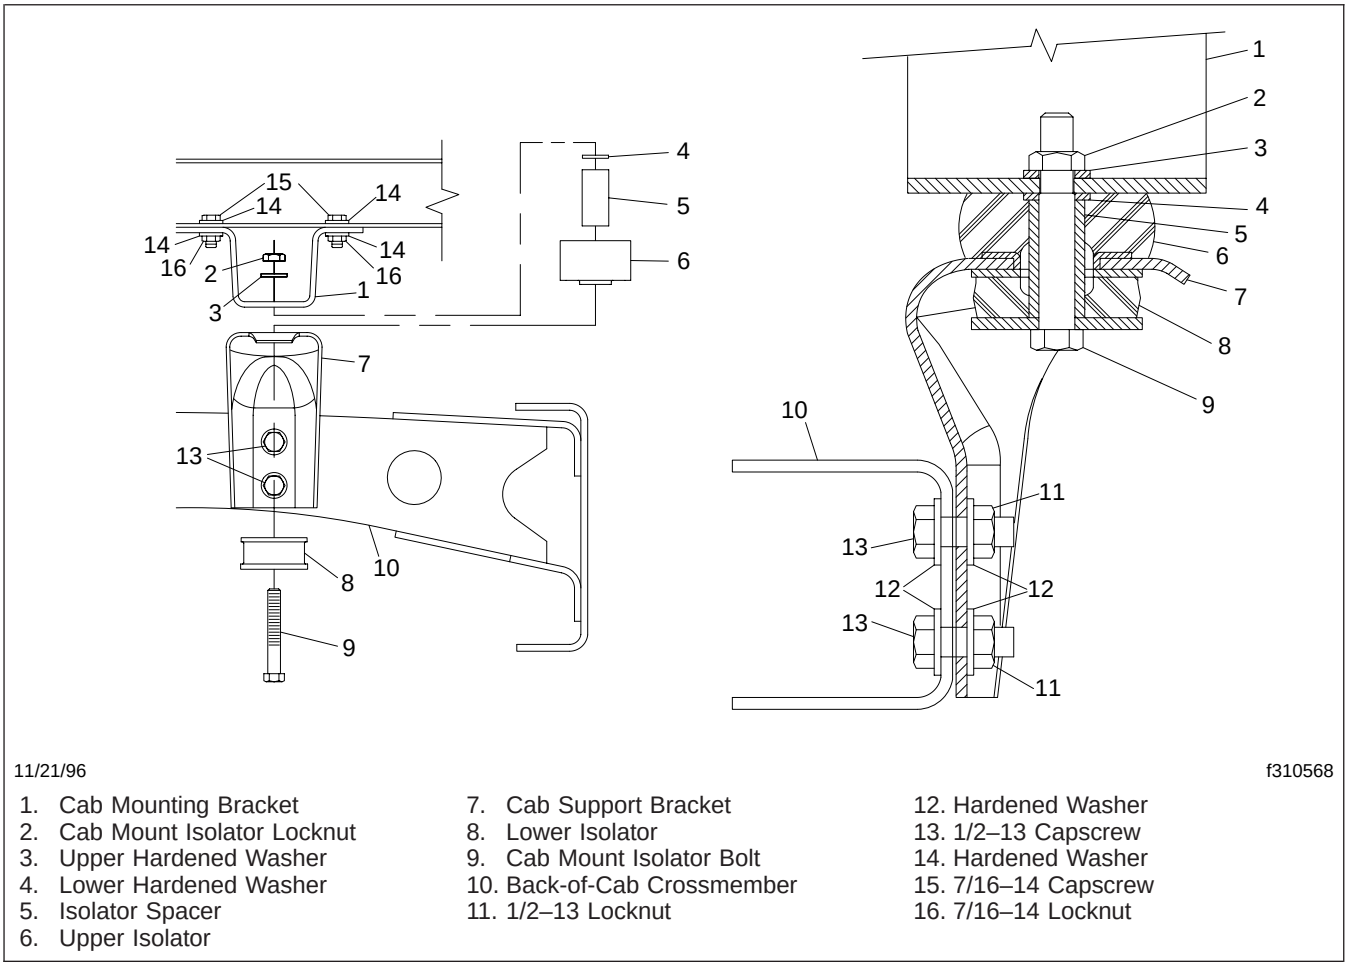
Rear Solid Rubber Isolator Mount Replacement

Replacement

NOTE: Don't replace only one rear cab mount; replace both mounts at the rear of the vehicle as a set.

1. Park the vehicle on a level surface. Apply the parking brake; then chock the tires.
2. Tilt the hood; refer to the vehicle driver's manual.
3. Remove the cab mounts. See **Fig. 1.**

3.1 From each side of the cab, remove the locknut, upper hardened washer, isolator bolt, lower isolator, and isolator spacer.



3.2 Using a jack, raise the rear of the cab about 1 inch (25 mm).

3.3 Remove the upper isolator and lower hardened washer from each cab support bracket.

3.4 Remove the two capscrews, hardened washers, and locknuts from the cab support bracket along with the cab support brackets.

3.5 Remove the two cab mounting bracket capscrews, hardened washers and locknuts along with each cab mounting bracket.

4. Install the new rear cab mounts. See **Fig. 1 .**

Fig. 1, Rear Rubber Isolator Cab Mount

Rear Solid Rubber Isolator Mount Replacement

4.1 Inspect the original locknuts and hardened washers. If any wear, distortion, or other damage is found, replace the part.

4.2 Install the cab mounting brackets, capscrews, hardened washers and locknuts. Tighten each capscrew to 65 lbf·ft (90 N·m).

4.3 Install the cab support brackets, capscrews, hardened washers and locknuts. Tighten each capscrew to 95 lbf·ft (130 N·m).

4.4 Install the upper isolator and lower hardened washer at each cab support bracket.

4.5 Lower the cab until the cab mount brackets just contact the top of the upper isolators.

4.6 Install a spacer and bolt in one of the new lower isolators, then install these parts at the bottom of one of the cab support brackets. Install a hardened washer and locknut.

Repeat this for the other cab support bracket.

4.7 Lower the cab, and remove the jack.

4.8 Tighten the upper and lower isolator stud locknuts 65 lbf·ft (90 N·m).

4.9 Remove chocks from the tires.

Rear Hydraulic Isolator Mount Replacement

Replacement

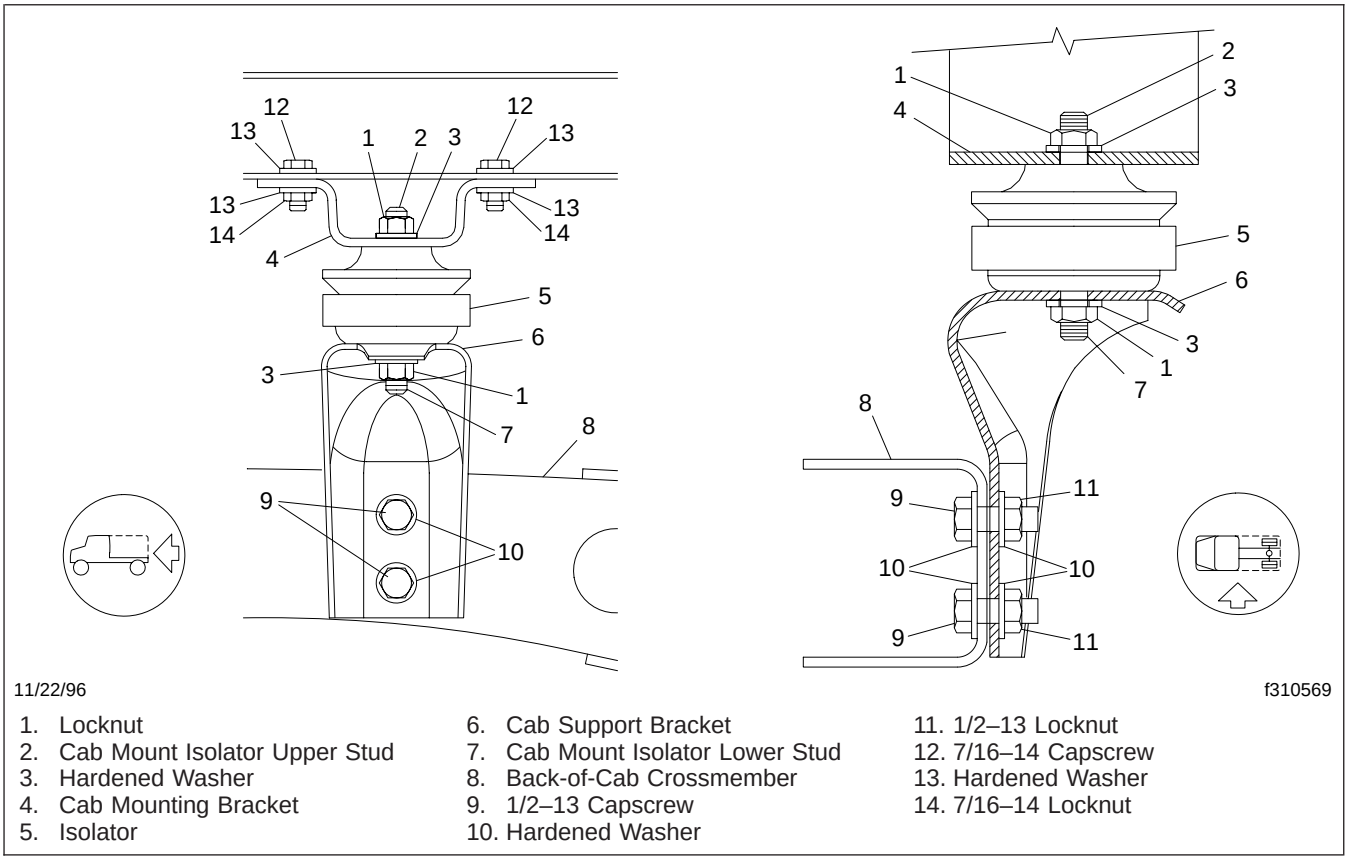
NOTE: Don't replace only one rear cab mount; replace both mounts at the rear of the vehicle as a set.

1. Park the vehicle on a level surface. Apply the parking brake; then chock the tires.
2. Tilt the hood; see the vehicle driver's manual.
3. Remove the cab mounts. See **Fig. 1.**

3.1 From each side of the cab, remove the locknut and hardened washer from the upper and lower studs on the isolator.

3.2 Using a jack, raise the rear of the cab about 1 inch (25 mm).

3.3 Remove the isolator from each cab support bracket.



3.4 Remove the two capscrews, hardened washers and locknuts from the cab support bracket along with the cab support brackets.

3.5 Remove the two cab mounting bracket capscrews, hardened washers and locknuts along with each cab mounting bracket.

4. Install the new rear cab mounts. See **Fig. 1 .**

4.1 Inspect the original locknuts and hardened washers. If any wear, distortion, or other damage is found, replace the part.

4.2 Install the cab mounting brackets, capscrews, hardened washers and locknuts. Tighten each capscrew to 65 lbf·ft (90 N·m).

Fig. 1, Rear Hydraulic Isolator Cab Mount

Rear Hydraulic Isolator Mount Replacement

4.3 Install the cab support brackets, capscrews, hardened washers and locknuts. Tighten each capscrew to 95 lbf·ft (130 N·m).

4.4 Install each new isolator with the blue-colored stud pointing up.

4.5 Lower the cab and remove the jack.

4.6 Install the hardened washers and isolator stud locknuts. Tighten the locknuts 68 lbf·ft (90 N·m).

4.7 Remove chocks from the tires.

Specifications

Fastener Torques			
Description	**Size**	**Grade**	**Torque lbf·ft (N·m)**
Front Isolator Locknut	1/2–13	8	68 (92)
Rear Solid Rubber Isolator Locknut	1/2–13	8	68 (92)
Rear Hydraulic Isolator Locknut	1/2–13	8	68 (92)
Rear Cab Mounting Bracket Capscrew	7/16–14	8	65 (88)

Front Cab Mounting Bracket Hexnut	1/2–13	8	68 (92)
Front Cab Support Bracket Capscrew	5/8–11	8	190 (258)

Table 1, Fastener Torques

General Description

The windshield is a single curved piece of glass, available clear or tinted. Both types include a permanent, black band at the base of the windshield to mask dash components.

The cab rear windows are two flat pieces of glass, available clear or tinted. One-piece rubber retainers hold the rear windows and the windshield in the cab and seal the joints between the glass and the cab shell.

Removal (Refer to Fig. 1)

CAUTION

CAUTION: When replacing a cracked windshield glass, it is very important that you find the cause of glass breakage, and correct the condition before installing a new windshield. If not removed, a small obstruction or high spot somewhere around the windshield opening may crack or break the replacement windshield, especially when the glass is exposed to high winds, pressure, temperature extremes, and vehicle motion.

IMPORTANT: At least two people are required to remove a windshield.

1. Protect the paint finish and instrument panel inside the cab. Using tape and paper around the windshield opening and outside surfaces, lay suitable covering across the hood and fenders. Before removing the windshield, mark the windshield retainer and the windshield opening flange with the location of the break on the edge of the window.
2. Remove the windshield wiper arms.
   - 2.1 Remove the nut that holds each wiper arm on each wiper motor splined pivot shaft.
   - 2.2 Gently pull each wiper arm off its pivot shaft.

IMPORTANT: When handling the windshield glass, wear heavy protective gloves to prevent cutting your hands.

3. If replacing the windshield glass but not the retainer **(refer to Fig. 2)** loosen the lip of the windshield retainer from the flange along the top and at the sides by applying controlled pressure to the edge of the glass. At the same time, use a putty knife to lift the retainer over the flange. Remove the windshield.

   If replacing the windshield retainer or both the glass and the retainer, cut off the lip of the old retainer from the inside of the cab before applying pressure to the edge of the glass. **Refer to Fig. 2.** This will ease removal of the glass.

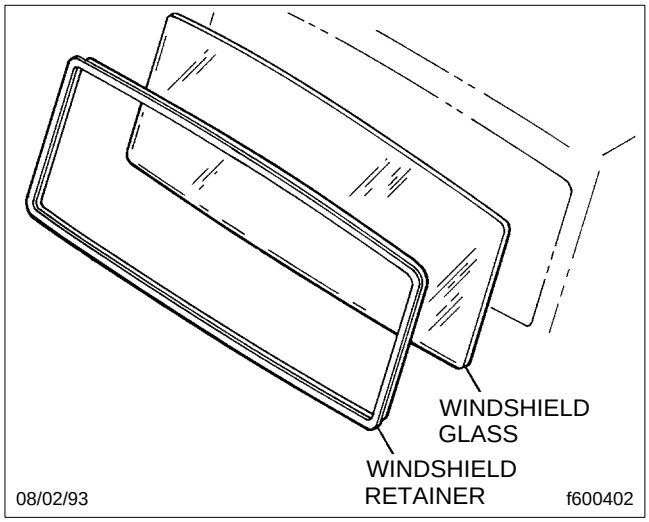

Fig. 1

Installation

CAUTION

CAUTION: When handling the windshield glass, use care not to nick or splinter the edges of the glass. Chipped edges could cause future breaks.

IMPORTANT: At least two people are required to install a windshield.

1. Remove all sealant from the flange around the windshield opening. **See Fig. 3.**
2. If a stress crack occurred, thoroughly check the windshield opening flange and retainer before installing a replacement windshield.

   Check for the following conditions at the previously marked point of fracture on the windshield opening flange:

   - Chipped edges on the glass.
   - High spots or obstructions in the flange and surrounding surfaces.
   - High spots or obstructions in the windshield retainer.

   Correct any areas on the flange that need to be fixed.
3. Install the retainer on the glass.

Windshield Removal and Installation

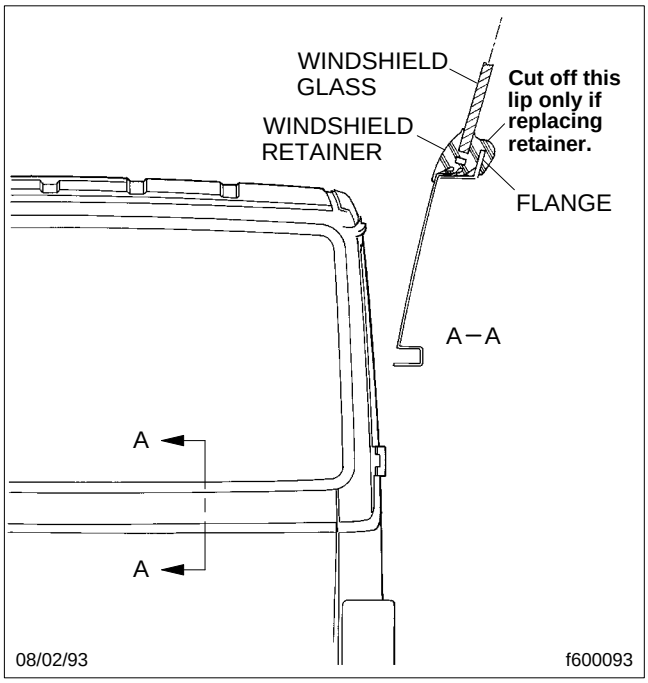

Fig. 2

4. Install a 3-mm (1/8-inch) nylon cord around the edge of the retainer **(refer to Fig. 4),** leaving a loop at the top and loose ends at the bottom.

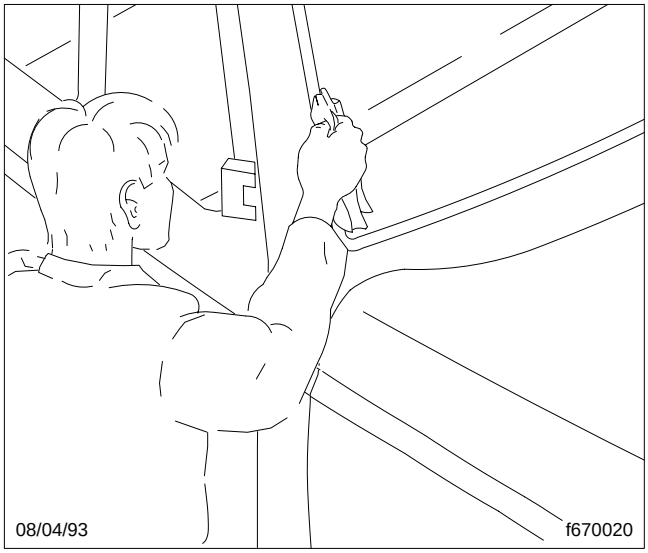

Fig. 3

5. Make sure the protective covering is over the front fenders and hood.

6. Place the windshield and retainer assembly in the windshield opening.

7. With one person lightly pushing in on the windshield, have another person pull on the loose ends of the cord until each is within 51 mm (2 inches) of its respective upper corner. **See Fig. 5.**

8. Finish seating the corners by pulling both ends of the cord at the same time at each corner. This will position the upper corners.

9. Be sure the windshield and retainer are properly positioned in relation to each other.

10. Install the windshield wiper arms.

    10.1 Place each arm on its splined pivot shaft. Be careful the splines within the hole at the base of the arm are aligned with the splines on the pivot shaft. **See Fig. 6.**

    10.2 Install and tighten the wiper arm nuts 19 N·m (14 lbf·ft).

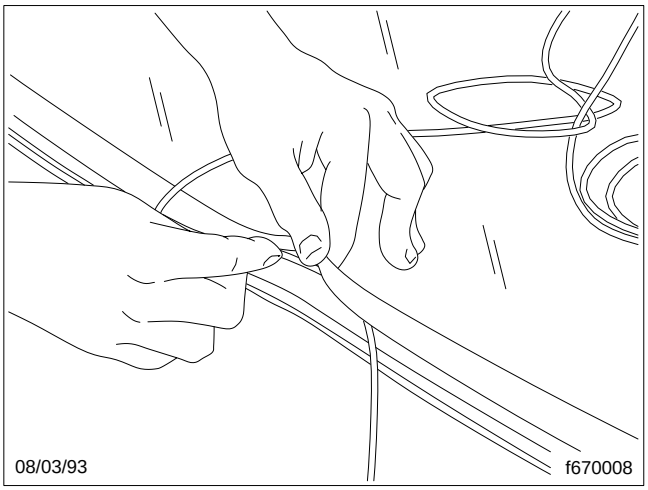

Fig. 4

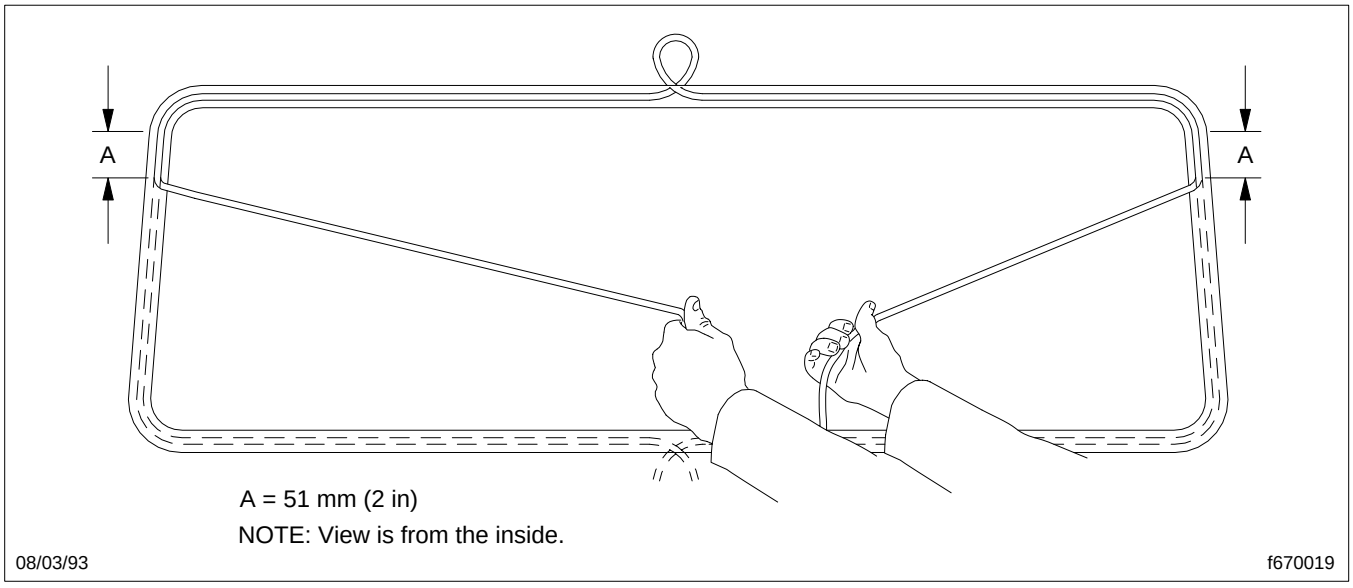

A

Fig. 6

Rear Window Removal and Installation

Removal (Refer to Fig. 1 and Fig. 2)

CAUTION

CAUTION: When replacing a broken rear window, it is very important that you find the cause of glass breakage, and correct the condition before installing a new window. If not removed, a small obstruction or high spot somewhere around the window opening may break the replacement glass, especially when it is exposed to high winds, pressure, temperature extremes, and vehicle motion.

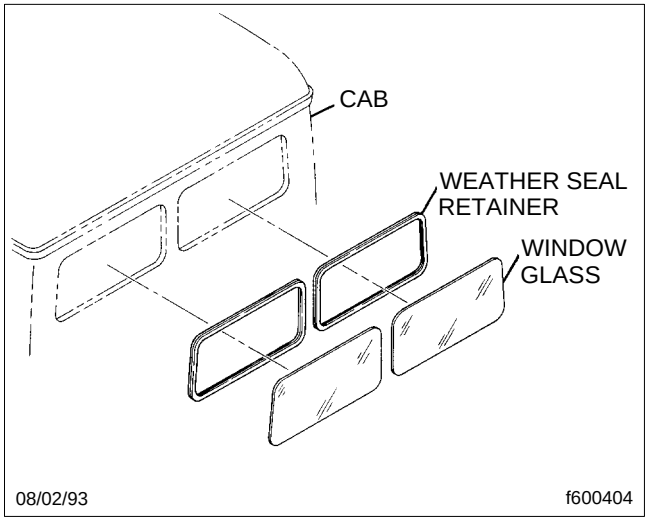

Fig. 1

1. Protect the paint finish and cab interior, using tape and paper around the window opening and outside surfaces. Before removing the window, mark the weather-seal retainer and the opening with the location of the break at the edge of the window.

IMPORTANT: When handling the window glass, wear heavy protective gloves to prevent cutting your hands.

2. Loosen the lip of the weather-seal retainer from the flange along the top and at the sides by applying firm, controlled pressure to the edge of the glass. At the same time, use a putty knife to lift the retainer over the window opening flange. Remove the window glass.

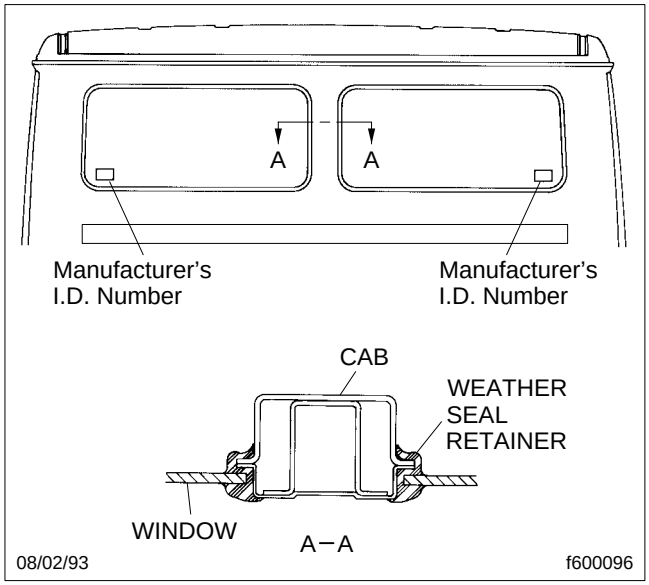

Fig. 2

Installation

CAUTION

CAUTION: When handling the window glass, use care not to nick or splinter the edges of the glass. Chipped edges could cause future breaks.

IMPORTANT: Two people are required to install a rear window glass.

Thoroughly check the window opening flange and the weather-seal retainer for alignment and roughness before installing a replacement glass. To check the alignment, hold the replacement glass up to the opening and use it as a guide.

1. Remove all sealant from the window opening flange.
2. Check for the following conditions at the previously marked point of fracture on the window opening flange:
   - Chipped edges on the glass.
   - High spots or obstructions in the window opening flange.
   - High spots or obstructions in the weather-seal retainer.

Rear Window Removal and Installation

Correct any areas on the window opening that need to be fixed.

3. With the window supported and centered in the opening, check the relationship of the glass to the opening.
4. Mark any areas on the flange to be fixed, remove the glass, and correct as necessary.
5. Install the retainer on the glass.
6. Install a 3-mm (1/8-inch) nylon cord around the edge of the retainer, leaving a loop at the top and loose ends at the bottom. **See Fig. 3.**

NOTE: Make sure the reinforcement plate **(see Fig. 4 and Fig. 5)** is in place between the interior trim panel and the cab back skin along the lower edge of the window opening.

7. Place the window and retainer assembly in the opening.

   The rear window glass is not a rectangle: The upper edge of the glass is slightly shorter than the lower edge. If installing a left-side (driver's-side) window, locate the glass in the opening so that the manufacturer's I.D. number is in the lower left corner. If installing a right-side (passenger's side) window, locate the glass in the opening so that the manufacturer's I.D. number is in the lower right corner. **Refer to Fig. 2.**

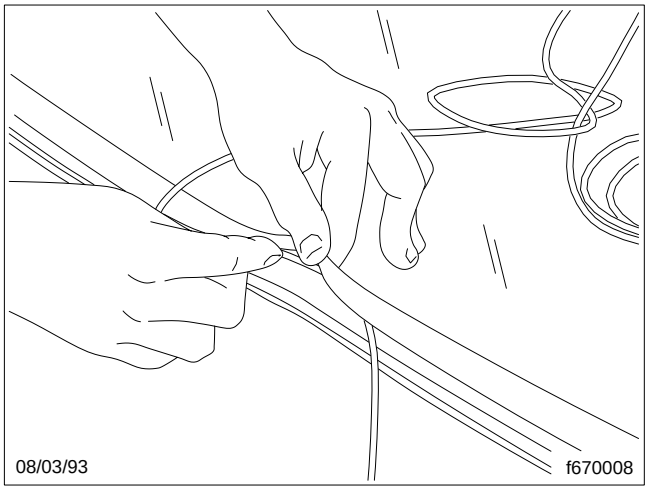

Fig. 3

8. With one person lightly pushing in on the window, have another person pull on the loose ends of the cord until each is within 51 mm (2 inches) of its respective upper corner.
9. Pull on the loop until the cord is within 51 mm (2 inches) of the upper corners.
10. Finish seating the corners by pulling both ends of the cord at the same time at each corner. This will position the upper corners.
11. Be sure the window and retainer are correctly positioned in relation to each other.

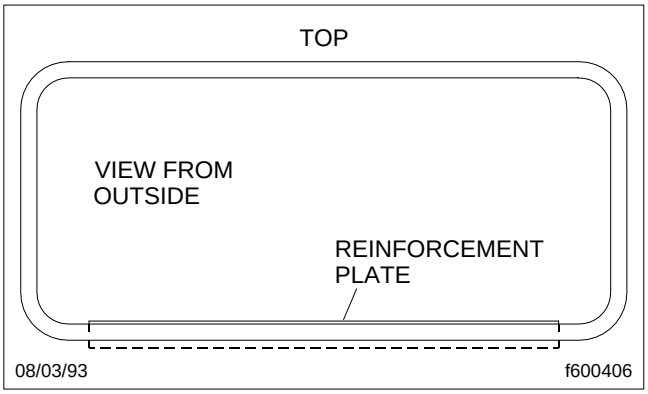

Fig. 4, Window Opening Frame

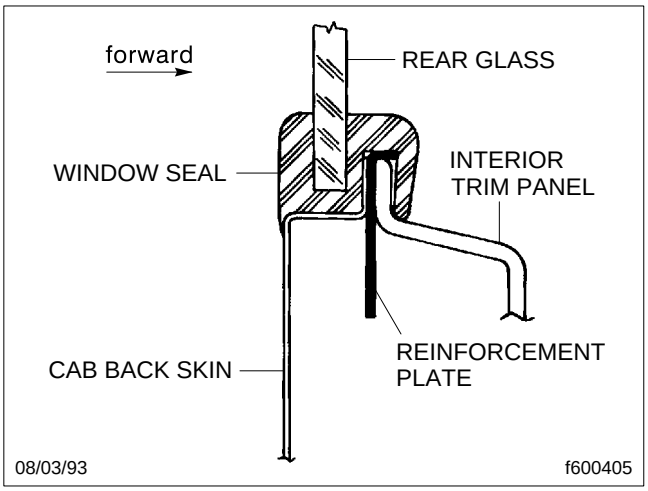

Fig. 5, Bottom Reinforcement Plate and Window Assembly, Installed

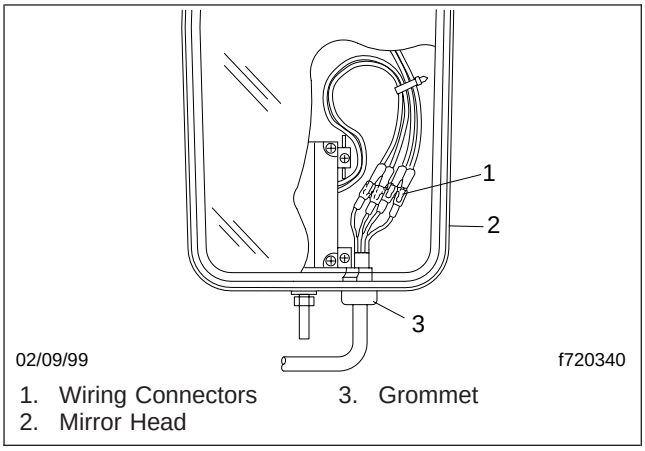
Specifications

Description	Grade	Size	Torque N·m (lbf·ft)
Wiper Arm Nuts	8.8	M6 x 1	19 (14)

Table 1, Fastener Torques

General Information

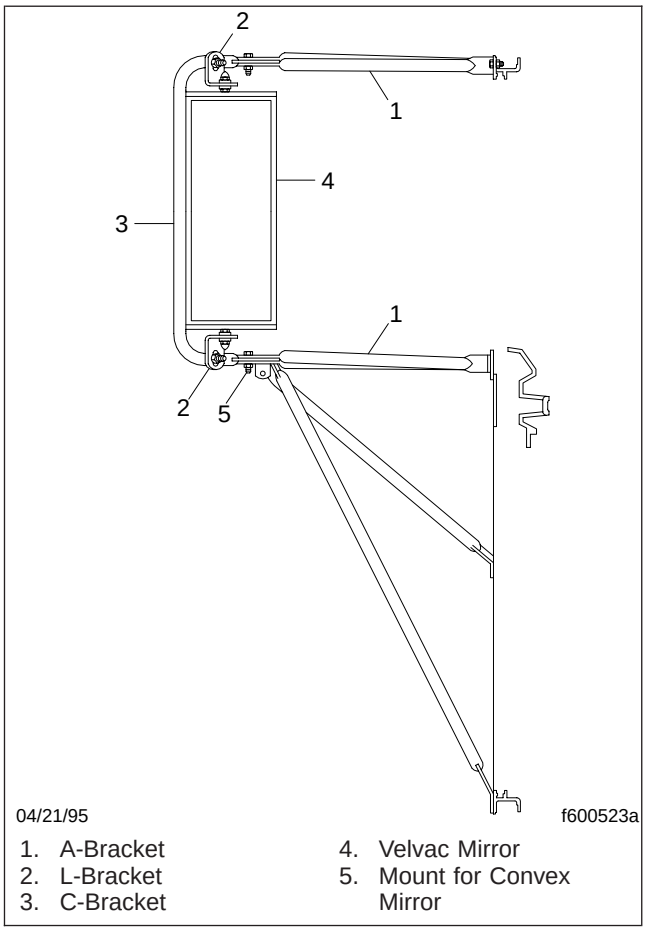


The Velvac mirror is an 8 by 16 inch (20 by 40 cm) electrically heated, remote-controlled mirror with marker lights. Using switches that mount in the cab, a driver can remotely adjust the position of each mirror. The mirror is rotated by an electric motor mounted to a slip clutch. The slip clutch allows for manual adjustment of the mirrors without damage to the electric motor or drive gears. A temperature-controlled heater heats the mirror surface to remove moisture and ice. Marker lights on the mirrors signal the widest points of the vehicle to oncoming traffic.

Removal

1. Apply the parking brake and chock the tires.
2. Disconnect the batteries.

NOTE: Most repairs to the Velvac mirrors can be made with the mirror head still mounted to the brackets on the vehicle.



3. Using pliers or a grommet tool, depress the grommet tab and remove the plastic grommet for the mirror wiring harness from the bottom of the mirror head. See **Fig. 1**.

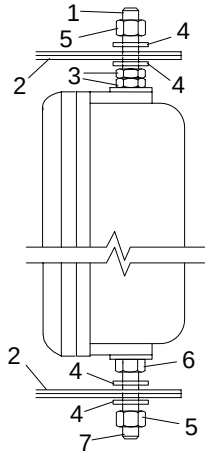
1. Wiring Connectors
2. Mirror Head
3. Grommet

Fig. 1, Disconnecting the Wiring

4. Pull the wires through the hole for the grommet so that the wire connectors are outside the mirror head. Disconnect all the electrical connectors at the mirror.
5. If a convex mirror is mounted on the bottom shaft of the Velvac mirror, remove the convex mirror.
6. Remove the nuts securing the L-brackets to the C-bracket and remove the Velvac mirror from the vehicle. See **Fig. 2**.
7. Using a 1/2 inch backup wrench to prevent the jam nuts at the top of the mirror head from turning on the shaft, remove the locknut from the top shaft. Remove the washers and L-bracket from the top shaft.
8. Using a 9/16 inch backup wrench to prevent the nut at the bottom of the mirror head from turning, remove the locknut from the bottom shaft. Remove the washers and L-bracket from the bottom shaft. See **Fig. 3**.

1. A-Bracket
2. L-Bracket
3. C-Bracket
4. Velvac Mirror
5. Mount for Convex Mirror

Fig. 2, Typical Mirror Mounting Arrangement



IMPORTANT: Do not allow the lower nut next to the mirror head to turn on the bottom shaft when removing the locknut. The torque on this nut is set at the factory.

Installation

1. Install a flatwasher on top of the two jam nuts on the top shaft of the mirror head. Install the top L-bracket and another flatwasher. Install a hexnut with a split lockwasher onto the top shaft.

IMPORTANT: Use a backup wrench on the jam nuts to prevent the jam nuts from turning on the top shaft of the mirror. These jam nuts have

Velvac Mirror Removal and Installation

1. 5/16–18 Thread
2. Clamp
3. Jam Nuts
4. Flatwasher
5. Locknut
6. Large Nut
7. Motor Shaft

Fig. 3, Typical Mirror Mounting Arrangement

been tightened at the factory and must not rotate when tightening the top L-bracket locknut. The top shaft must be free to rotate onthe mirror head.

2. With a backup wrench on the jam nuts, tighten the locknut that holds the L-bracket on the top shaft as follows:
   - 60 to 80 lbf·in (680 to 900 N·cm) for the non-motorized mirrors
   - 125 to 200 lbf·in (1410 to 2260 N·cm) for the motorized mirrors
3. Install a flatwasher on the bottom shaft of the mirror head. Install the bottom L-bracket and another flatwasher. Install the hexnut with a split lockwasher onto the bottom shaft.

IMPORTANT: Use a backup wrench on the nut next to the mirror head to prevent the nut from turning on the bottom shaft of the mirror. The nut was tightened at the factory and must not rotate when tightening the bottom L-bracket locknut. If the nut has loosened, tighten it only until the bottom shaft starts turning with the nut.

4. With a backup wrench on the nut next to the mirror head, tighten the locknut that holds the L-bracket on the bottom shaft 14 lbf·ft (19 N·m).
5. Connect the wires from the mirror to the wiring harness according to the color code chart in **Table 1**.

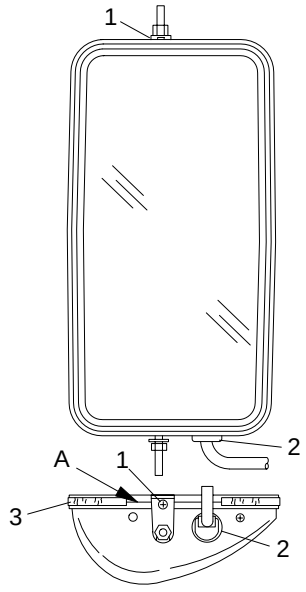
Mirror Wiring Color Code	
Mirror Head	**Harness**
Red (heater +)	Red
Black (heater, light –)	Black
Blue (light +)	Blue
White (motor)	White
Green (motor)	Green

Table 1, Mirror Wiring Color Code

6. Slide the plastic grommet to its original position on the jacket of the mirror harness. Using pliers or a grommet tool, push the grommet and harness into the hole in the bottom of the mirror head. Make sure that the grommet tab locks the grommet in place.
7. Install the convex mirror (if removed) on the end of the lower A-bracket.

⚠ WARNING

Grab only the mirror head when turning the mirror by hand. Do not apply force to the mirror glass or the glass could break and cause injury.



8. Rotate the mirror head by hand to make sure that there is clearance.
9. Connect the batteries.
10. Test the operation of all the mirror functions using the switches inside the cab. The mirror should be warm to the touch within 5 minutes of starting the mirror heater.
11. Remove the chocks from the tires.

Replacement

1. Apply the parking brake, and chock the tires.
2. Disconnect the batteries.

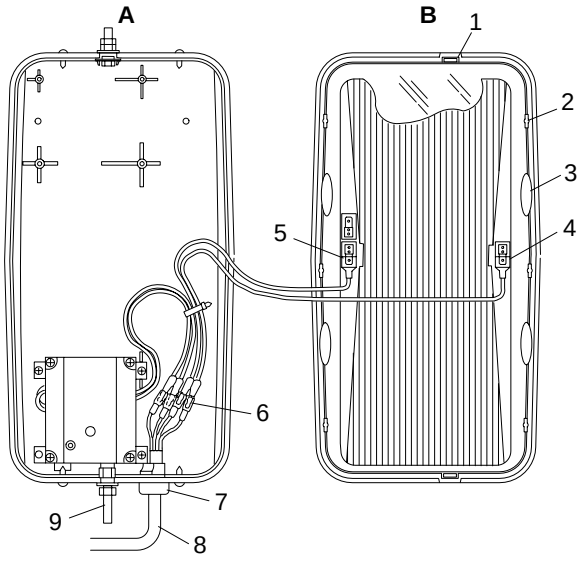
NOTE: The motor in the Velvac mirror can be replaced with the mirror head still mounted to the brackets on the vehicle.

3. Remove any tape from the perimeter of the bezel. Remove the two screws on both the top and the bottom of the mirror head. See **Fig. 1**.

A. Separate bezel/mirror head here.
1. Bezel Screws
2. Grommet
3. Tape

Fig. 1, Velvac Mirror Disassembly

CAUTION



Avoid putting force on the glass or using sharp tools to separate the glass from the mirror housing. The glass can easily break and the housing can be scratched by the use of sharp tools.

4. Use your hands to carefully separate the bezel and glass assembly from the mirror housing. The plastic bezel is held in the housing by six Tinnerman® clips in the internal groove along the rear edge of the mirror housing.
5. Remove the wire connectors from the heater element on the back of the mirror glass. Put the mirror glass and heater element is a safe place.
6. Cut the tie strap and remove the wires to the mirror motor.
7. Remove the lower L-bracket from the A-bracket. Remove the locknut, L-bracket, and flatwashers from the motor shaft at the lower bracket.
8. Install two jam nuts on the motor shaft and tighten against each other. Hold a backup wrench on the outer jam nut to prevent the motor shaft from turning. Remove the large nut from the motor shaft.

NOTE: The nut on the motor shaft uses thread sealant to help it stay in position.

9. Using a Phillips screwdriver, remove the four screws that hold the motor to the housing. Lift the motor from the mirror housing.
10. Install the shaft of the new motor into its hole in the housing.
11. Install and carefully tighten the four screws that hold the motor to the housing.
12. Apply Loctite® 271 to the threads of the motor shaft nut and install it on the shaft. Tighten the nut until the shaft begins to turn.
13. Install a flatwasher, the lower L-bracket, another flatwasher, and a new nylon-insert locknut, but do not tighten the locknut.
14. Fasten the lower L-bracket to the A-bracket. Use a 9/16 inch backup wrench to prevent the shaft nut from turning and tighten the locknut on the end of the motor shaft.
15. Connect the wires from the motor to the wires of the same color in the harness. Install a tie strap in the same location as before.
16. Remove any Tinnerman clips left in the groove in the housing or on the bezel. Install new clips in the six locations on the bezel shown in **Fig. 2**.
17. Connect the black wire and the blue wire to the two terminals on the ground side of the heating element. Connect the red wire to the terminal on the other side of the element.
18. Align the tabs on the top and bottom of the bezel with the slots in the housing. Carefully and

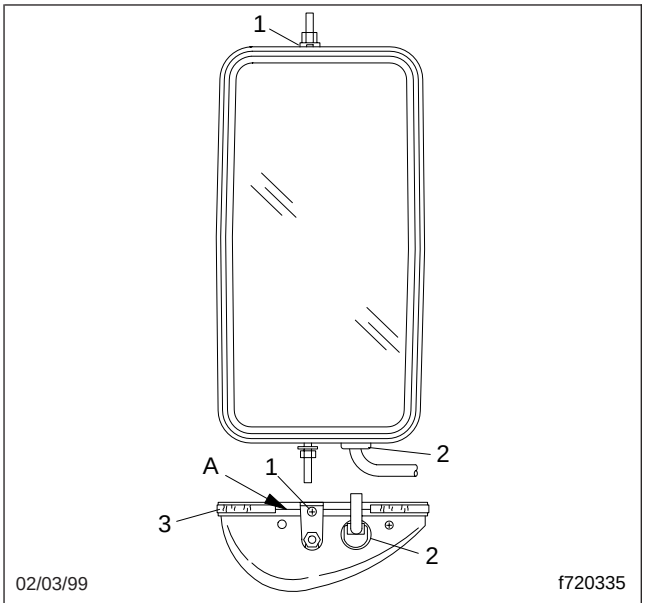
Fig. 2, Velvac Mirror Assembly

evenly press the glass and bezel assembly into the groove in the housing so that the clips firmly hold the bezel assembly in place.

19. Carefully press the glass and bezel assembly against the housing while installing the bezel mounting screws into the housing. Push down on the screwdriver while turning the screws, but do not over-tighten the screws into the plastic mirror housing.
20. Apply the tape, that was removed earlier, around the perimeter of the bezel.
21. Connect the batteries and test the mirror operation.
22. Remove the chocks from the tires.



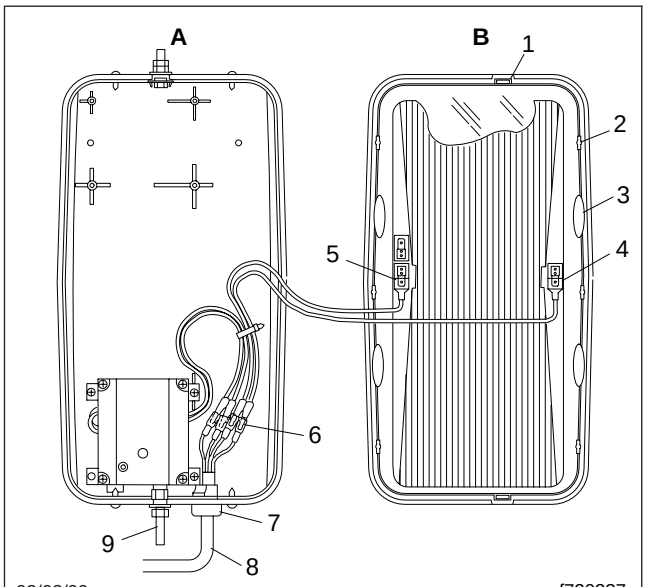
Velvac Mirror Glass and Heating Element Removal and Installation

Removal

1. Apply the parking brake, and chock the tires.
2. Disconnect the batteries.

NOTE: The heating element in the Velvac mirror can be replaced with the mirror head still mounted to the brackets on the vehicle.

3. Remove and discard any tape from the perimeter of the bezel. Remove the screws on the top and the bottom that hold the bezel to the mirror head. See **Fig. 1**.



A. Separate bezel/mirror head here.
1. Bezel Screws
2. Grommet
3. Tape

Fig. 1, Removing the Bezel

CAUTION

Avoid putting force on the glass or using sharp tools to separate the glass from the mirror housing. The glass can easily break and the housing can be scratched by the use of sharp tools.

4. Use your hands to carefully separate the bezel and glass assembly from the mirror housing. The plastic bezel is held in the housing by six Tinnerman® clips in the internal groove along the rear edge of the mirror housing. See **Fig. 2**.

A. Mirror Head
B. Glass/Heating Element and Bezel

2. Tinnerman Clips
3. Factory-applied Silicone
4. Heating Element Power Connection
5. Heating Element Ground Connection
6. Wire Connectors
7. Grommet
8. Wire Harness
9. Motor Shaft

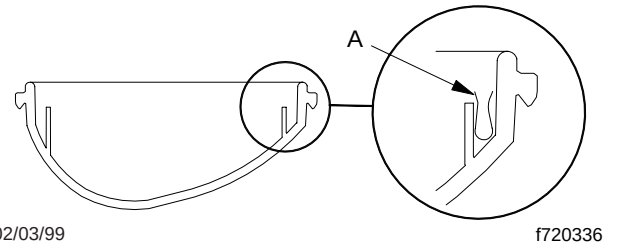

Fig. 2, Velvac Mirror Assembly

5. Remove the wire connectors from the heater element on the back of the mirror glass.
6. Peel the silicon from the bezel and remove the mirror glass and heating element.

Installation

1. Remove any Tinnerman clips left in the groove in the housing or on the bezel. See **Fig. 3**. Install new clips in the six locations on the bezel shown in **Fig. 2**.
2. Install the glass and heater element into the bezel. Apply silicon sealer four places along the glass perimeter to hold the glass to the bezel.
3. Connect the black wire and the blue wire to the two terminals on one side of the heating ele-

Velvac Mirror Glass and Heating Element Removal and Installation

A. Remove the clips from the groove in the housing.

Fig. 3, Removing the Clips

ment. Connect the red wire to the terminal on the other side of the element.

4. Align the tabs on the top and bottom of the bezel with the slots in the housing. Carefully and evenly press the glass and bezel assembly into the groove in the housing so that the clips firmly hold the bezel assembly in place.
5. Carefully press the glass and bezel assembly against the housing while installing the bezel mounting screws into the housing. Push down on the screwdriver while turning the screws, but do not over-tighten the screws into the plastic mirror housing.
6. Connect the batteries and test the mirror operation.
7. Remove the chocks from the tires.

Troubleshooting

Use the information in the following troubleshooting tables to determine the possible causes and remedies of problems with the Velvac mirrors. To test the mirror components, go to the appropriate heading in this subject.

Problem—The Mirror Will Not Rotate When the Switch Is Closed

Problem—The Mirror Will Not Rotate When the Switch Is Closed	
Possible Cause	**Remedy**
An obstruction is in the path of the mirror.	Remove the obstruction.
The motor switch does not have power.	Turn the power on.
The fuse or circuit breaker is open.	Replace the fuse or reset the circuit breaker.
The switch is not working.	Test the switch. Replace it, if necessary.
The wiring is damaged.	Check and repair the wiring.
The motor is worn.	Test the motor. Go to "Testing the Electric Motor" in this subject.

Problem—The Heater Does Not Work

Problem—The Heater Does Not Work	
Possible Cause	**Remedy**
There is no power to the heater switch.	Turn the power on.
The fuse or circuit breaker is open.	Replace the fuse or reset the circuit breaker.
The switch is not working.	Test the switch. Replace it, if necessary.
The wiring is damaged.	Check and repair the wiring.
The heating element is not working.	Test the element. Go to "Testing the Heater" in this subject.

Problem—The Mirror Will Not Stay Adjusted, Moves at High Speed, or Vibrates

Problem—The Mirror Will Not Stay Adjusted, Moves at High Speed, or Vibrates	
Possible Cause	**Remedy**
The fasteners are not tight.	Tighten the mirror mounting hardware.
The slip clutch is worn.	Test the slip clutch. Go to "Testing the Slip Clutch" in this subject.

Problem—The Glass Is Broken

Problem—The Glass Is Broken	
Possible Cause	**Remedy**
An object has struck the glass.	Replace the glass. For instructions, go to **Subject 120**.

Troubleshooting

Problem—The Glass Surface Has Scratches

Problem—The Glass Surface Has Scratches	
Possible Cause	**Remedy**
The glass was cleaned incorrectly.	Replace the glass, if necesary. Use only non-abrasive cleaners and soft cloths to clean the glass surface.

Problem—The Glass Is Distorted

Problem—The Glass Is Distorted	
Possible Cause	**Remedy**
The mounting brackets are misaligned causing the head to flex.	Align the mounting brackets.
The mirror hits an obstruction during its rotation.	Remove the obstruction.

Problem—The Marker Light Does Not Illuminate

Problem—The Marker Light Does Not Illuminate	
Possible Cause	**Remedy**
The bulb is burnt.	Replace the bulb.
The switch is not working.	Test the switch. Replace it, if necessary.
The wiring is damaged.	Check and repair the wiring.
The fuse or circuit breaker is open.	Replace the fuse or reset the circuit breaker.

TESTING THE SLIP CLUTCH

The Velvac mirror slip clutch allows the mirror head to be positioned manually without damaging the motor gear assembly. The slip clutch resistance to rotation keeps the mirror from moving unintentionally. To test the torque needed to rotate the mirror head in relation to the motor shaft, use the following procedure.

1. Apply the parking brake and chock the tires.
2. Disconnect the batteries.
3. Remove the Velvac mirror head from the vehicle. See **Subject 100** for the instructions.
4. Install two 5/16–18 jam nuts on the motor shaft of the mirror head. Using a backup wrench on one of the jam nuts, tighten the other jam nut against the first. See **Fig. 1**.
5. Use a beam-type or dial-type torque wrench on the outer jam nut. Hold the mirror head from rotating and note the reading on the torque wrench while rotating the jam nuts and motor shaft.

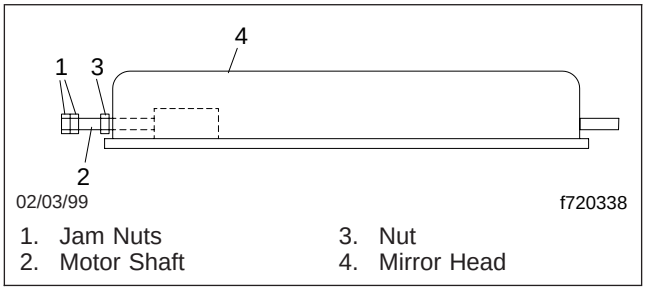

Fig. 1, Testing the Slip Clutch

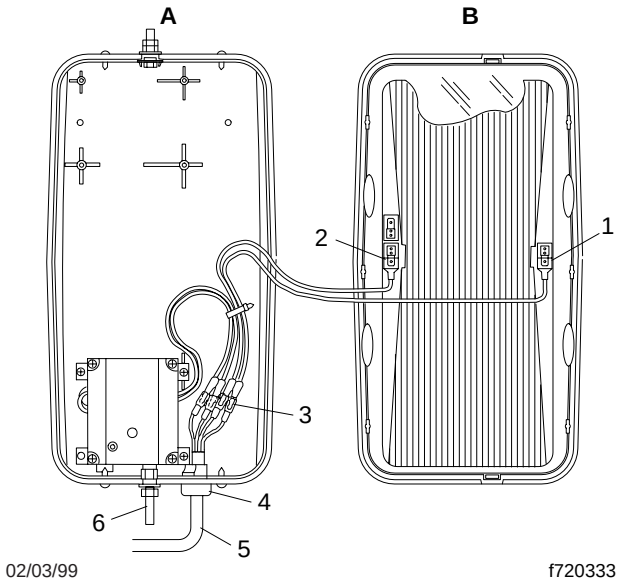
6. The torque required to turn the motor shaft in relation to the motor head must be between 60 and 110 lbf·in (680 to 1230 N·cm).
7. Replace the motor assembly if the torque needed to rotate the shaft is more than 110 lbf·in (1230 N·cm). For instructions, see **Subject 110**. If the motor shaft begins to turn at a torque value of less than 60 lbf·in (680 N·cm), tighten the large nut on the motor shaft just until the shaft begins to turn with the nut. Check the rotating torque again. Replace the motor assembly if the torque needed to turn the shaft is still not correct.



TESTING THE ELECTRIC MOTOR

To test the electric motor that rotates the mirror head, use the following procedure.

1. Apply the parking brake and chock the tires.
2. Disconnect the batteries.

NOTE: Most repairs to the Velvac mirrors can be made with the mirror head still mounted to the brackets on the vehicle.

3. Using pliers or a grommet tool, depress the grommet tab and remove the plastic grommet for the mirror wiring harness from the bottom of the mirror head. See **Fig. 2**.

A. Mirror Head
B. Glass/Heating Element and Bezel
1. Heating Element Power Connection
2. Heating Element Ground Connection
3. Wire Connectors
4. Grommet
5. Wire Harness
6. Motor Shaft

Fig. 2, Velvac Mirror Assembly

4. Pull the mirror wires through the hole for the grommet so that the wire connectors are outside the mirror head. Disconnect the electrical connectors for the white and the green wires.
5. Connect a jumper wire from the battery negative post (or a good ground) to the white wire in the mirror head.

⚠ CAUTION

The mirror head will immediately start rotating when you complete the temporary circuit. Make sure that your hands and all objects are out of the way of the mirror head before starting this test. Disconnect the wires before the mirror head can hit any object. Failure to do so could cause personal injury or damage to the mirror.

6. Temporarily touch a jumper wire from the battery positive post to the green wire in the mirror head. The motor should immediately start turning the mirror head in a clockwise direction (looking from the top).
7. Disconnect the white wire from the jumper wire connected to the battery negative post (or ground). Connect the grounded jumper to the green wire in the mirror.
8. With your hands away from the mirror head, temporarily touch a jumper wire from the battery positive post to the white wire in the mirror head. The motor should immediately start turning the mirror head in a counter-clockwise direction (looking from the top).
9. Replace the motor if it does not operate as stated above. See **Subject 110** for the motor replacement procedure.
10. Remove the jumper wires and connect the batteries.
11. Remove the chocks from the tires.

TESTING THE HEATER

To test the electric heating element in the mirror head, use the following procedure.

1. Apply the parking brake, and chock the tires.
2. Disconnect the batteries.
3. Using pliers or a grommet tool, depress the grommet tab and remove the plastic grommet for the mirror wiring harness from the bottom of the mirror head. See **Fig. 2**.
4. Pull the mirror wires through the hole for the grommet so that the wire connectors are outside

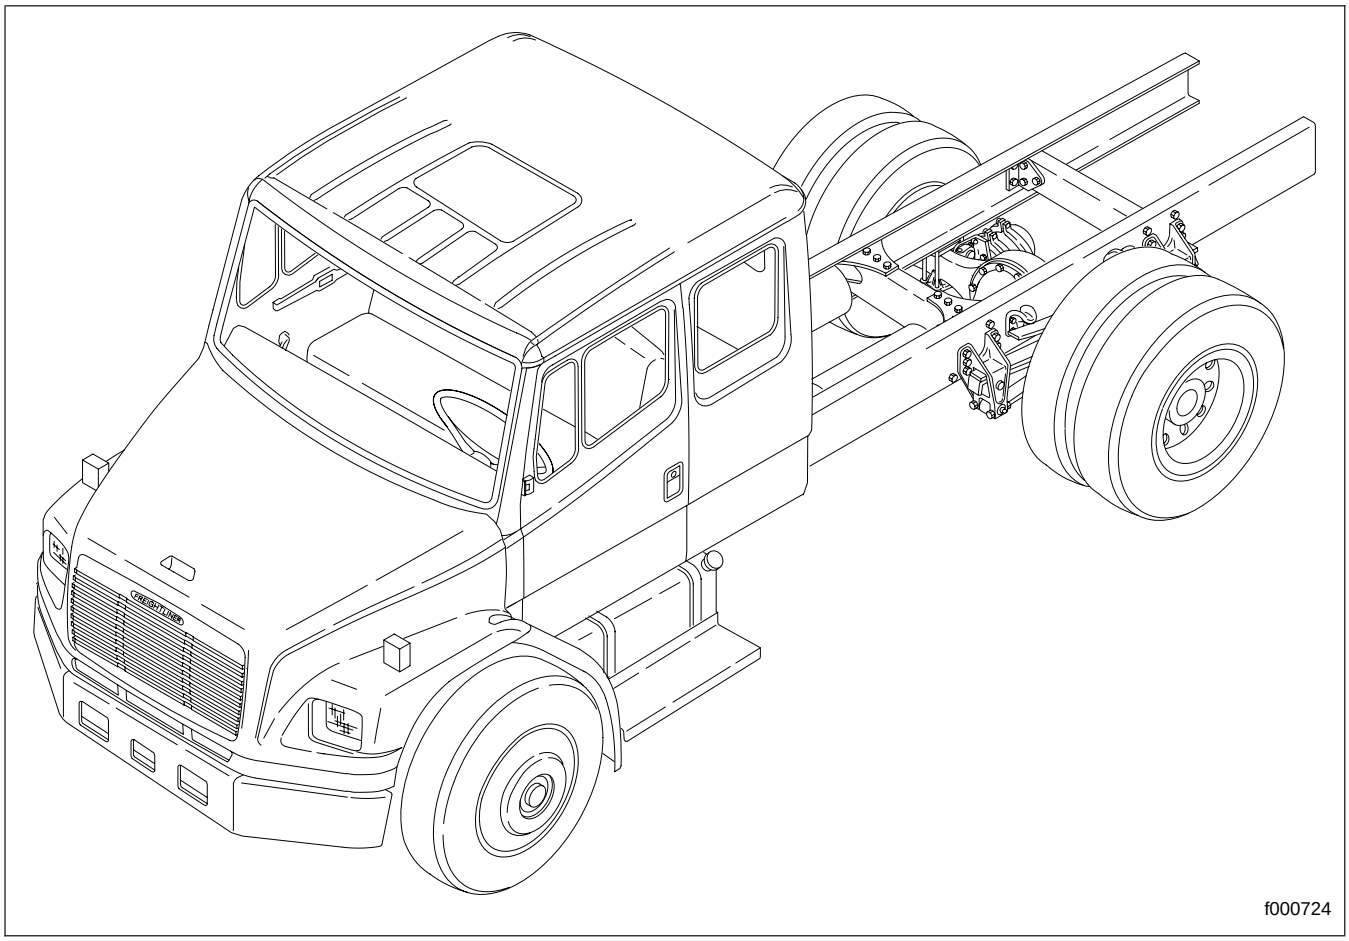
Troubleshooting

the mirror head. Disconnect the electrical connectors for the black and the red wires.

5. Test for continuity in the heater circuit by connecting one probe of an ohmmeter to the black wire from the mirror and the other probe to the red wire. The ohmmeter must indicate continuity. Replace the mirror glass/heating element if the ohmmeter indicates an open circuit.
6. Connect a jumper wire from the battery negative post (or a good ground) to the black wire in the mirror head.
7. Connect a jumper wire from the battery positive post to the red wire in the mirror head. The heating element will make the mirror glass warm to the touch within 5 minutes.
8. Replace the mirror glass and heating element assembly if it does not operate as stated above. See **Subject 120** for the heating element replacement procedure.
9. Remove the jumper wires and connect the batteries.
10. Remove the chocks from the tires.

General Information

The extended cab version of the Business Class truck or tractor includes a side window opening in each side of the cab extension. **See Fig. 1.** The window opening may contain a piece of tinted, fixed, solid tempered glass, a moveable (tip out) window assembly, or an aluminum plate. A one-piece rubber seal is used to hold the side window in the cab opening.



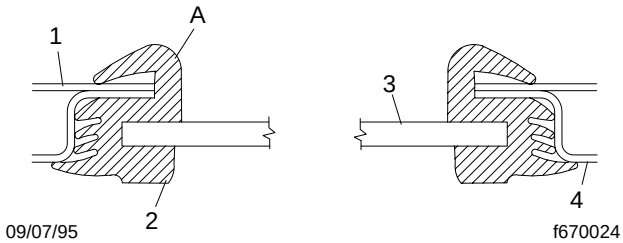


Fig. 1, Extended Cab, With Rear Side Windows

Removal and installation procedures are the same for both types of side windows: fixed, solid tempered glass, and moveable (tip out) window, as well as for the aluminum blanking plate.

The side window is retained in the cab opening by a reuseable rubber seal. **See Fig. 1.** No sealants or adhesives are used.

A. Cut this lip away from inside the cab if the seal will be replaced.
1. Cab Inner Skin
2. Window Seal
3. Side Window Glass
4. Cab Outer Skin

Fig. 1, Window Installation View

Side Window Removal

NOTE: Use an assistant to help you remove the side window. This will make the job easier, as well as reduce the possibility of accidental window breakage.

1. Protect the paint finish by taping paper around the side window opening.
2. Position your assistant outside the cab, and instruct him to apply constant, light hand pressure to the window. This will reduce the possibility of sudden window movement and dropping the window.
3. Remove the window.

   3.1 If the window seal will be replaced with a new seal, carefully cut the seal lip away from inside the cab. **See Fig. 1,** Ref. A.

   With the seal lip cut away, push the window and seal out of the cab opening.

   3.2 If the window seal will be re-used, use a windshield pick **(see Fig. 2)** to bend the seal lip away from the cab inner panel while pushing outward on the window. Start at a corner and work your way around the window until it can be pushed out of the cab opening.

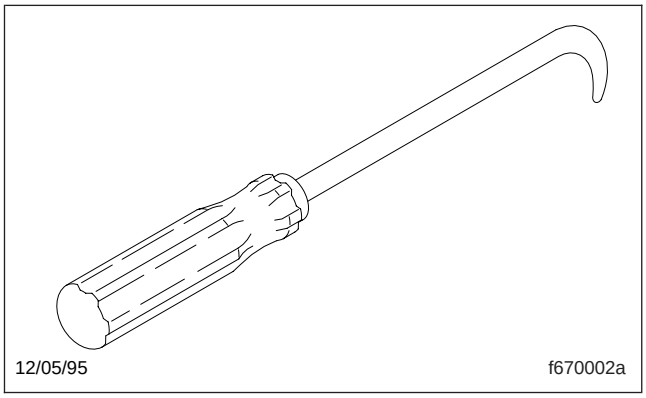

Fig. 2, Typical Windshield Pick

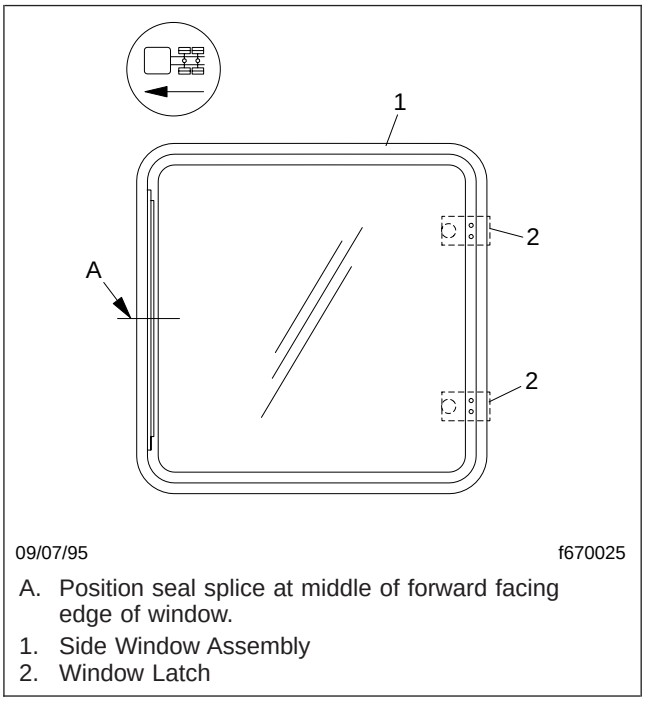
4. Separate the seal from the glass.

Side Window Installation

WARNING

WARNING: When handling side window glass, wear protective gloves to protect your hands from sharp edges and to allow a better grip. Not wearing protective gloves when handling glass could result in personal injury.



1. Clean the cab side window opening area using glass cleaner or a soap-and-water solution.
2. Lubricate the rubber window seal thoroughly with a soap-and-water solution. Make sure that all grooves in the seal are wetted.

NOTE: Before installing the window seal on the window glass or frame, be sure to position the seal splice at the middle of the forward facing edge of the window. **See Fig. 3.**

3. Stretch the rubber seal around the outside of the glass, window frame, or blanking plate.
4. Install two cords in the outside seal groove **(see Fig. 4)** as shown in **Fig. 5.** Leave the loose ends of the cords at the front and rear edges of the window.

NOTE: The cord should be a braided cotton cord (trade size number 5 minimum to number 8 maximum) with a reinforced core.

Side Window Removal and Installation

A. Position seal splice at middle of forward facing edge of window.
1. Side Window Assembly
2. Window Latch

Fig. 3, Seal Splice Location

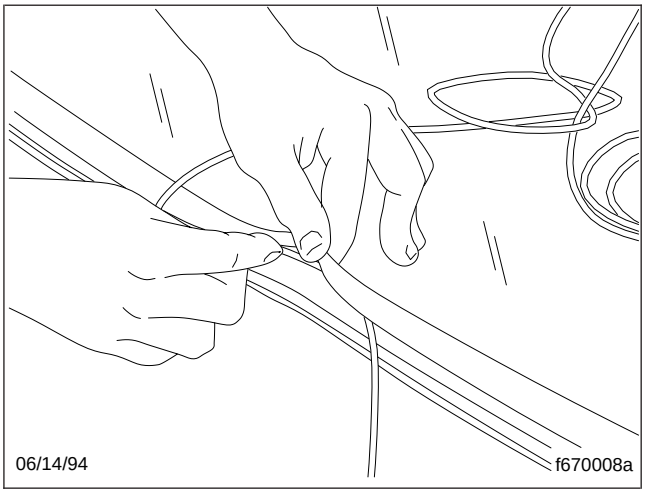


Fig. 4, Inserting Cord in Window Seal

5. Lubricate the window seal and the cord with a soap-and-water solution; then, wet the cab skin with plain clear water just before installing the window.
6. Have your assistant hold the window assembly in position against the cab window opening using light pressure. From inside the cab, pull one of the cord ends around a lower corner of the window, across the bottom, and up the other side.

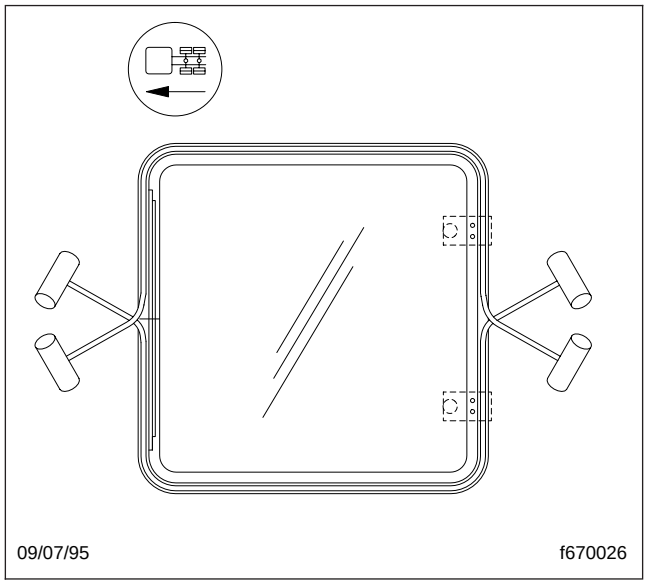

Fig. 5, Cord Installed in Window Seal

7. With the assistant maintaining pressure against the window, repeat the procedure with the other cord, going across the top of the window.
8. Using a sandbag, finish seating the glass by tapping on the glass until the glass and seal are correctly positioned. **See Fig. 1.**
9. Remove any protective paper and tape.

The tool shown in **Fig. 1**, and others, can be purchased from the following distributors:

Air Horn Valve Removal and Installation

Removal

1. Park the vehicle. Set the parking brake. Shut down the engine and chock the tires.
2. Disconnect the electrical supply.
3. Remove the left-side A-pillar cover.
4. Remove the driver's sun visor.
5. Remove the left-side speaker, or remove the speaker plug, if necessary.

NOTE: Removing the speaker or speaker plug allows access to the air horn valve and attached air lines and cables.

6. Disconnect the antenna cable, and move it aside.
7. Disconnect the air lines attached to the air horn valve. Mark the air lines for later reference.
8. Remove the fasteners that attach the air horn valve to the mounting bracket.
9. Disconnect the air horn control cable from the headliner and from the air horn valve.
10. Remove the air horn valve.

NOTE: It may be necessary to loosen the headliner above the door to allow for easier removal of the air horn valve.

Installation

1. Position the air horn valve.
2. Connect the air horn valve control cable to the air horn valve and to the headliner.
3. Attach the air horn valve to the mounting bracket.
4. Connect the air lines to the air horn valve.

⚠ CAUTION

CAUTION: Do not overtighten the air line fittings. Hand-tighten the fittings 1/2-turn after tightening begins.

5. Connect the antenna cable.
6. Install the speaker, or the speaker plug.
7. Install the sun visor, and the headliner, if loosened.
8. Install the A-pillar cover.
9. Connect the electrical supply.
10. Remove the chocks from the tires.

General Description and Principles of Operation

Freightliner designed and manufactured cab rear air-suspension systems are standard equipment on extended cab vehicles and FL112 day cabs. They are optional equipment on other day cab-equipped Business Class trucks.

The Freightliner system installed on FL112 day cab equipped vehicles mounts on top of a frame crossmember (see **Fig. 1**). The system installed on all other Business Class trucks mounts to a frame crossmember web (see **Fig. 2**).

The cab air-suspension system absorbs road shocks and compensates for changing cab loads. Both Freightliner cab air-suspension systems have the same basic parts: an air spring, a leveling valve, a shock absorber, a transverse torque arm, and top and bottom units. See **Fig. 1** and **Fig. 2**.

TOP AND BOTTOM UNITS

Both Freightliner systems are similar in design and operation. The main difference between the two systems is that the FL112 bottom unit mounts on top of a frame crossmember, while the bottom unit for other vehicles mounts to the back (web) of a frame crossmember.

For both systems, the top unit is secured to the cab rear crossmember by four bolts, and the bottom unit is secured to a frame crossmember by four bolts. See **Fig. 1** and **Fig. 2**. A transverse torque arm, which connects the bottom unit to a cab crosmember, prevents top-unit-to-bottom-unit side-to-side misalignment.

AIR SPRINGS

For both Freightliner systems, the top of the air spring has a stud which is secured to the top unit by a single nut; the bottom of the air spring is attached to the bottom unit by a single fastener as well.

Together with the leveling valve, the air spring compensates for changes in cab load by maintaining the correct distance between the rear of the cab and the frame rails.

LEVELING VALVE

All of the air in the cab air-suspension system is admitted through or exhausted from the leveling valve (**Fig. 1**, Ref. 6, and **Fig. 2**, Ref. 6). The leveling valve mounts on a bracket attached to the bottom unit. A horizontal arm connects the leveling valve control shaft to the vertical link attached to the top unit.

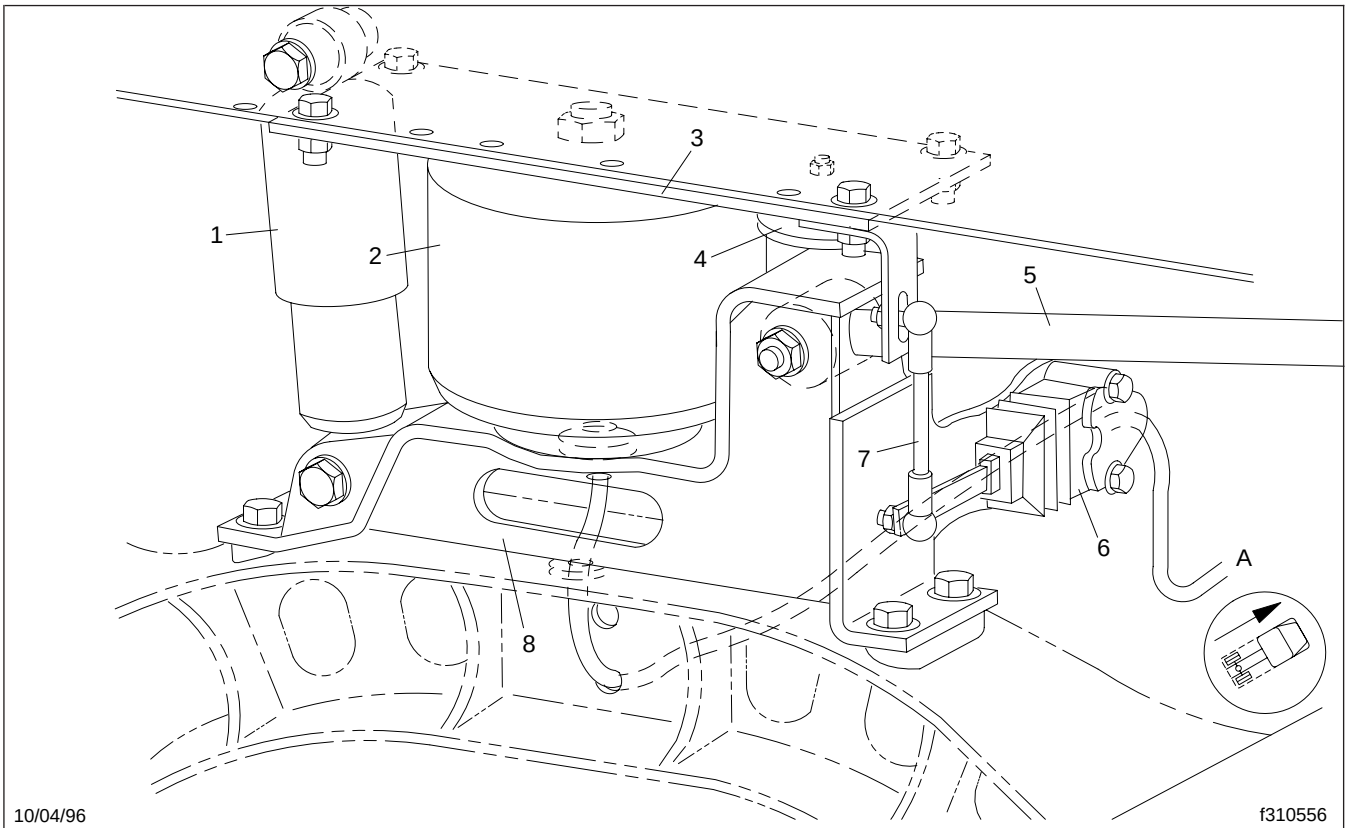
The same leveling valve (WABCO) is used on both Freightliner systems.

CAB-MOUNT STOP ASSEMBLY

The cab-mount stop assembly consists of a rubber bumper (**Fig. 1**, Ref. 4, and **Fig. 2**, Ref. 4), attached to the top unit. The bumper limits downward movement of the cab by contacting the bottom unit. If a leak occurs in the cab air-suspension system, the bumper supports the cab until the leak can be repaired.

NOTE: If a leak occurs in the cab air-suspension system, a pressure protection valve (located in the air supply line to the leveling valve) will maintain at least 65 psi (450 kPa) in the vehicle secondary air system.

SHOCK ABSORBER



On both cab air-suspension systems, a single shock absorber attaches to the cab rear crossmember at the top, and to the bottom unit at the bottom. In addition to damping cab oscillations, the shock absorber limits upward movement of the rear of the cab.

SYSTEM OPERATION

When cab load increases, the distance between the top and bottom units decreases, causing the vertical link to push down on the leveling valve horizontal arm. This rotates the leveling valve control shaft, which activates an intake valve core inside the leveling valve. Air flows through the valve and tubing into the air spring, until increasing pressure in the spring raises the cab to the correct height. As the cab reaches the correct height, the horizontal arm and the control shaft return to their neutral positions, closing the intake valve, and stopping the flow of air into the air spring.

When cab load decreases, the rear of the cab rises, causing the vertical link to pull up on the end of the horizontal arm. Rotating the leveling valve control shaft in this direction activates an exhaust valve

General Description and Principles of Operation

core. Air is exhausted from the spring until the cab lowers to the correct height. Again, the horizontal arm and control shaft return to their neutral positions as the cab reaches the correct height, and air exhausting is stopped.

When the vehicle is moving, small and abrupt movements of the cab will occur, resulting in movements of the leveling valve horizontal arm. Small movements of the arm do not activate the leveling valve because of a built-in free-travel range: a gap between the leveling valve control shaft and both of the valve cores (intake and exhaust). Abrupt movements do not activate the leveling valve because it is filled with a silicone fluid, which delays the opening of one valve core for as long as five seconds after the closing of the other.

Changes in load which result in larger movements of the horizontal arm (beyond the free-travel range) for more than five seconds will activate the leveling valve. Such changes in load occur when occupants or heavy items are added to, or removed from, the cab. Also, when the vehicle is moving forward at high speed or in a strong headwind, a major change in load occurs from the downward force applied by an optional air shield or air fairing. When these changes in load occur, the cab air-suspension system will adjust the height at the rear of the cab.

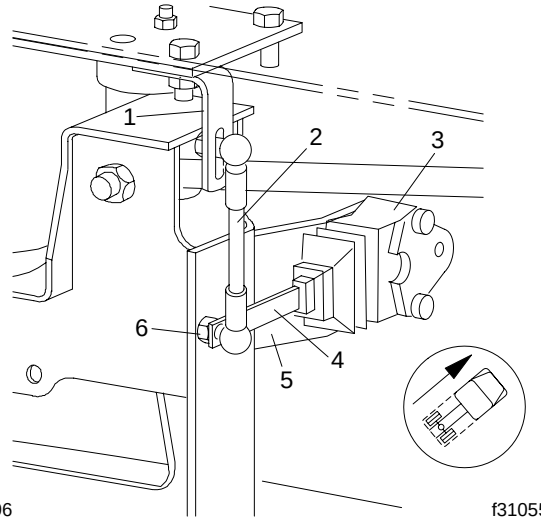
8. Bottom Unit

Fig. 2, Day Cab (except FL112) and Extended Cab Air Suspension System

Checks



To keep the cab air-suspension system operating reliably, the air system must be kept free of oil, moisture, and other foreign material. Regularly inspect and maintain the vehicle air system components. See Group 42 of the *Business Class Trucks Maintenance Manual*.

⚠ CAUTION

Failure to take precautions against the entry of oil, moisture, and other foreign material into the cab air-suspension system could eventually lead to sludge forming in the air system. Sludge could adversely affect the operation of the cab air-suspension system and other air system components.

Before replacing the leveling valve, do the following steps to see if the valve is actually damaged, or is merely out of adjustment. These steps apply to both Freightliner systems.

1. Run the engine to build up vehicle air pressure to at least 100 psi (690 kPa). Shut down the engine.
2. Chock the tires to prevent the vehicle from moving.
3. Remove the hex nut and washer securing the vertical link (lower end) to the leveling valve horizontal arm. See **Fig. 1**.
4. Push the arm down about 45 degrees for 6 to 8 seconds. If air passes through the valve and inflates the air spring, that section of the valve is okay.
5. Return the lever to the neutral position. Air should stop flowing. If so, that section of the valve is okay.
6. Pull the lever up about 45 degrees for 6 to 8 seconds. If air exhausts from the air spring, that section of the valve is okay.
7. Return the lever to the neutral position. If the air stops again in the neutral position, the valve is working correctly.
8. If the valve works as stated in all of the above steps, no further checking is needed. Connect the vertical link to the horizontal arm.

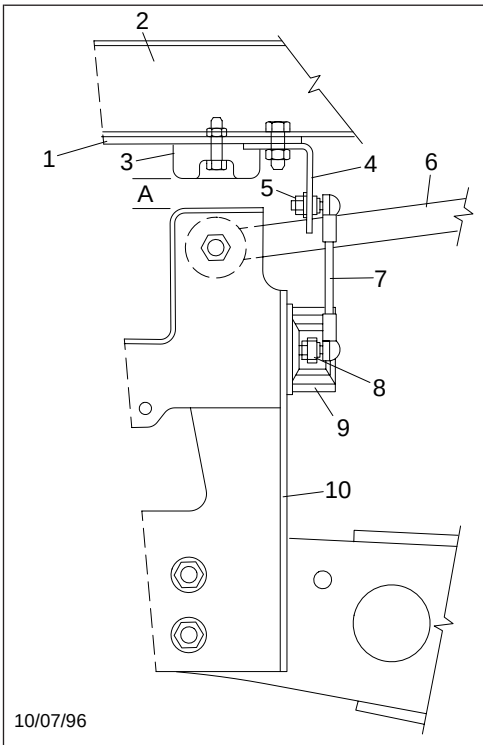
2. Vertical Link
3. Leveling Valve
4. Leveling Valve Horizontal Arm
5. Leveling Valve Mounting Bracket
6. Hex Nut

Fig. 1, WABCO Leveling Valve and Linkage

If the valve doesn't work as stated in all of the above steps, replace it. Refer to **Subject 120** for instructions.

9. If adjustment of the leveling valve is needed, refer to **Subject 110**.

Leveling Valve Adjustment



Adjustment

The leveling valve adjustment procedure is identical for both Freightliner cab rear air suspension systems.

1. Park the vehicle on a level surface and apply the parking brakes.
2. Run the engine to build up vehicle air pressure to at least 100 psi (690 kPa). Shut down the engine.
3. Chock the front tires to prevent the vehicle from moving.

IMPORTANT: Before checking leveling valve adjustment, make sure that the rubber bumper (see **Fig. 1** , Ref. 3) is present on the cab rear air suspension upper unit. If the rubber bumper is missing or in poor condition, replace it.

4. Check the leveling valve adjustment.
   - 4.1 Measure the distance from the bottom of the rubber bumper to the top of the bottom unit. It should be 3/4 to 1-1/8 inch (19 to 29 mm). **See Fig. 1** , Ref. A.
   - 4.2 If the distance is within specifications, no adjustment is needed. If it isn't, go to the next step.
5. Perform the leveling valve adjustment.
   - 5.1 Remove the hex nut (Ref. 5) securing the leveling valve control rod vertical link (upper end) to the slotted cab-mounting tab.
   - 5.2 Raise the rear of the cab by pushing down on the leveling valve horizontal arm.
   - 5.3 Insert a 7/8 inch (22 mm) spacer between the rubber bumper and the bottom unit.
   - 5.4 Lower the cab by pivoting the leveling valve lever upward until the rubber bumper contacts the spacer.
   - 5.5 Lift the flap on the side of the lever boot to expose the hole in the valve body and move the lever up and down slightly near the valve neutral position (lever horizontal) until the hole in the valve arm aligns with the hole in the valve body.
   - 5.6 Lock the leveling valve arm in the neutral position by inserting a 5/32" (4mm) pin or drill bit through the holes in the valve body and valve arm.
   - 5.7 Using a scribe or permanent ink marker, mark the vertical link upper stud centerline position on the slotted mounting tab.
   - 5.8 Remove the pin or drill bit previously inserted into the leveling valve.
   - 5.9 Push down on the leveling valve arm until enough air enters the air spring to lift the rubber bumper off the spacer.

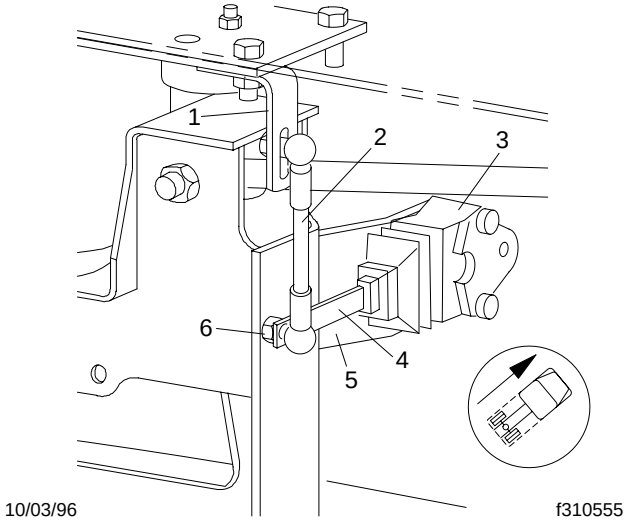
Leveling Valve Adjustment

5.10 Remove the spacer, then raise the leveling valve arm until enough air exhausts from the air spring for the rubber bumper to contact the bottom unit.

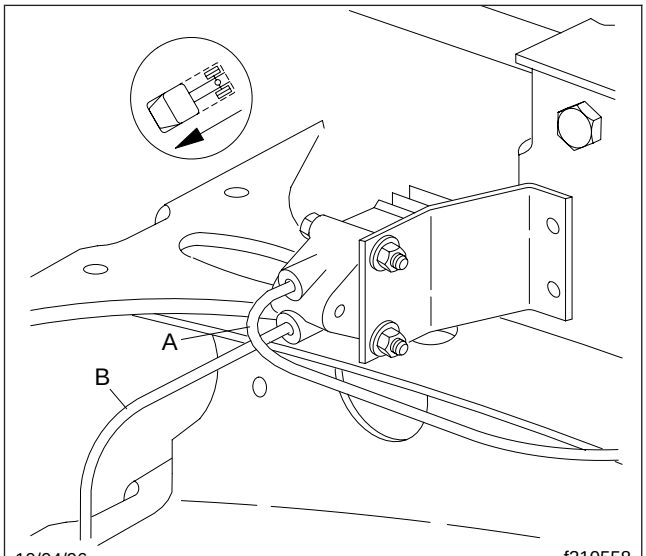


5.11 Insert the vertical link upper stud in the slotted tab and align the stud with the mark made on the tab. Let the system raise the cab, allowing about 5 seconds for the valve delay time.

5.12 Measure the distance between the rubber bumper and the bottom unit to ensure that it is between 3/4 and 1-1/8 inch (19 and 29 mm). If it is, install the vertical link hex nut and tighten it firmly. If it isn't, repeat the leveling valve adjustment procedure.

Replacement

NOTE: Before replacing the leveling valve, do the steps in **Subject 100** to see if the valve is actually damaged, or is merely out of adjustment.



1. Chock the tires to prevent the vehicle from moving.
2. Remove the leveling valve.
   - 2.1 Remove the hex nut and washer securing the leveling valve control rod vertical link (lower end) to the leveling valve horizontal arm and disconnect the arm from the link. See **Fig. 1**. Save the nut and washer for attaching the link to the new valve.

2. Vertical Link
3. Leveling Valve
4. Leveling Valve Horizontal Arm
5. Leveling Valve Mounting Bracket
6. Hex Nut

Fig. 1, WABCO Leveling Valve and Linkage

   - 2.2 Raise the leveling valve arm, and hold it there to exhaust all air from the air spring.
   - 2.3 Disconnect the air lines from the fittings on the leveling valve. See **Fig. 2**. Mark the lines for assembly reference. Cover the open ends of the air lines to prevent dirt or other foreign material from entering the system.

A. to air supply
B. to air spring

Fig. 2, Air Line Connections, WABCO Leveling Valve

   - 2.4 Remove the leveling valve mounting fasteners; then, remove the valve from its mounting bracket.
3. Install the new leveling valve.
   - 3.1 Mount the new valve on the bracket. Tighten the hexhead capscrews 18 lbf·ft (24 N·m).
   - 3.2 Connect the valve horizontal arm to the vertical link. Tighten the nut securely.
   - 3.3 Remove the covers from the air lines. Connect the air lines to the leveling valve as marked earlier or as shown in **Fig. 2**. Tighten the fitting nuts finger-tight; then, tighten them two more turns or until no threads show on the fitting body.
4. Close the drain cocks on all air reservoirs. Run the engine to build up vehicle air pressure to at least 100 psi (690 kPa).
5. Check the operation of the new leveling valve. For instructions, refer to **Subject 100**.
6. Check all air lines and connections for leaks; eliminate any found.

Leveling Valve Replacement

7. Adjust the leveling valve. Refer to **Subject 110** for instructions.

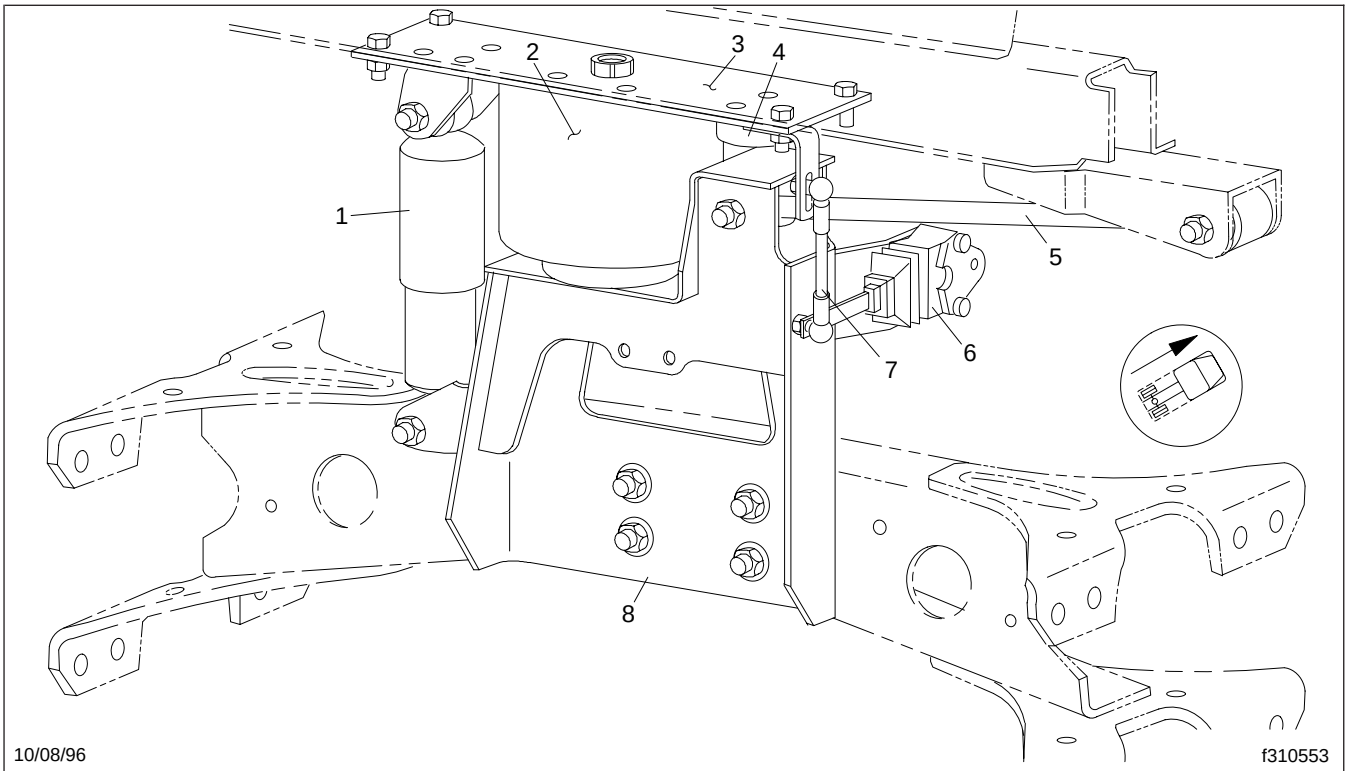
Replacement

1. Chock the front tires to prevent vehicle movement.
2. Remove the locknuts from the shock absorber upper and lower mounting bolts. See **Fig. 1**.

1. Cab Rear Crossmember
2. Shock Absorber Upper Bracket
3. Mounting Nut, Bolt
4. Shock Absorber
5. Frame Crossmember

Fig. 1, Shock Absorber Mounting

3. Remove the bolts and pull the shock absorber out of the mounting brackets.
4. Install the replacement shock absorber in the mounting brackets, and secure it with the bolts and locknuts.
5. Tighten the locknuts 45 lbf·ft (61 N·m).
6. Remove the chocks from the front tires.



Replacement

1. Chock the front tires to prevent the vehicle from moving.
2. Drain the vehicle air system. For instructions, see Group 42 of the *Business Class Trucks Maintenance Manual*.
3. Remove the four bolts securing the cab air-suspension top unit to the cab rear crossmember. The right rear bolt also secures the leveling valve linkage slotted mounting tab to the cab. See **Fig. 1**.

DANGER

Before doing the work below, block the raised cab securely. Failure to block the cab while working on the cab rear air suspension system could allow the cab to fall, possibly resulting in serious injury or death.

5. With the cab raised, place blocks of wood between the frame rails and the cab rear crossmember on both sides of the vehicle. Then, lower the bottle jack and allow the cab to rest on the blocks of wood.

1. Shock Absorber
2. Air Spring
3. Top Unit
4. Rubber Bumper
5. Transverse Torque Arm
6. Leveling Valve
7. Vertical Link
8. Bottom Unit

Fig. 1, Cab Rear Air-Suspension System

4. Using a hydraulic bottle jack and blocks of wood (for spacers, if necessary), raise the rear of the cab until the cab suspension system shock absorber reaches its end stop.
6. Remove the air spring.
   - 6.1 Raise the slotted mounting tab, vertical link, and leveling valve horizontal arm and hold it up until all air exhausts from the air spring.

Air Spring Replacement

6.2 Disconnect the air spring air supply hose from the fitting on the bottom of the air spring. Cover the end of the hose to keep out dirt, moisture, etc.

6.3 Remove the fitting from the air spring being replaced.

6.4 Remove the nuts from the air spring upper and lower mounting bosses.

6.5 Remove the air spring.

7. Install a new air spring.

7.1 With the new air spring in its installed position, install the retaining nut on the air spring lower mounting boss and tighten it 60 lbf·in (700 N·cm).

7.2 Position the top unit over the air spring, making sure that the rubber bumper is on the right-hand side of the vehicle. Install the retaining nut on the air spring upper mounting boss and tighten it 60 lbf·in (700 N·cm).

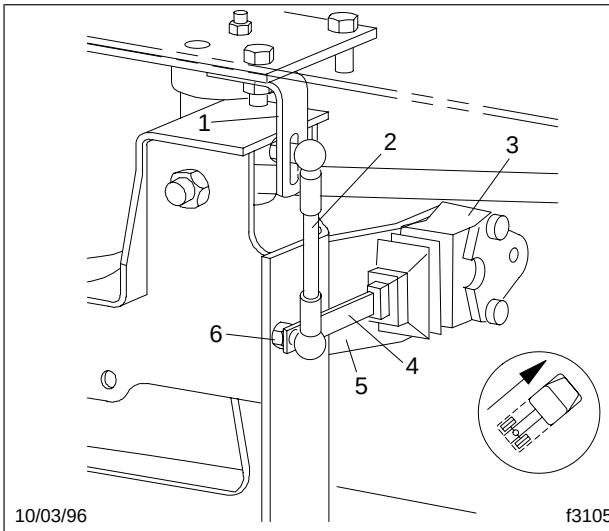
7.3 Position the leveling valve slotted mounting tab (with vertical link and leveling valve horizontal arm atteched) at the right-hand rear corner of the upper unit, then install the four bolts securing the upper unit to the cab rear crossmember. Tighten the bolts 60 lbf·ft (81 N·m)

7.4 Install the air hose fitting in the air spring. Tighten it finger-tight plus one turn. Do not apply Teflon® tape to the fitting threads.

7.5 Remove the cover from the air spring supply line and attach the line to the air spring fitting. Tighten the air line nut finger-tight plus two turns or until no threads show on the fitting.

8. Using the hydraulic bottle jack, raise the rear end of the cab just enough to remove the wooden support blocks.

9. Lower the cab and remove the jack.

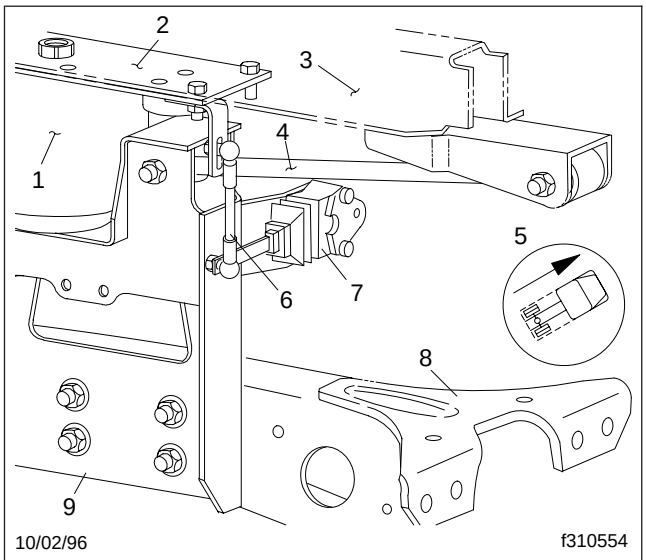


10. Start the engine and build vehicle air pressure to at least 100 psi (690 kPa).

11. Check for air leaks at the air spring and at the leveling valve. Tighten the fittings or replace the parts, if necessary.

12. Remove the chocks from the front tires.

Replacement



1. Chock the front tires to prevent the vehicle from moving.
2. Remove the hex nut securing the leveling valve arm to the vertical link. See **Fig. 1**.

1. Slotted Mounting Tab
2. Vertical Link
3. Leveling Valve
4. Leveling Valve Horizontal Arm
5. Leveling Valve Mounting Bracket
6. Hex Nut

Fig. 1, WABCO Leveling Valve and Linkage

3. Separate the leveling valve arm from the vertical link and raise the arm until the cab lowers onto its bottom stop.
4. With the cab lowered, lower the leveling valve arm to its neutral position and lock the arm there by inserting a 5/32" (4 mm) pin or drill through the hole in the valve body.
5. Remove the torque arm nuts. See **Fig. 2**.
6. Remove the torque arm bolts, then remove the torque arm from its mounting brackets.
7. Install the new torque arm in the mounting brackets and secure it with the mounting bolts and nuts.
8. Tighten the locknuts 45 lbf·ft (61 N·m).

1. Air Spring

10. Tighten the hex nut securely.
11. Remove the chocks from the front tires.

Problem—Air Spring Is Flat

Possible Cause	Remedy
Low air pressure in the secondary air system.	Check the air pressure gauge on the instrument panel. If secondary air pressure is low, run the engine until at least 70 psi (482 kPa) is indicated.
Air is leaking from the cab air-suspension system.	Check for leakage from fittings, air lines, air springs, and the leveling valve. Tighten loose fittings to stop leakage; replace worn or damaged parts. Do not use Teflon tape on fittings.
The leveling valve is out of adjustment.	Adjust the leveling valve.
The leveling valve is inoperative.	If downward movement of the arm on a properly adjusted valve fails to inflate the air spring, replace the leveling valve.
The leveling valve linkage is damaged.	Check for damage to the leveling valve vertical link and arm Repair or replace damaged linkage parts.
The air spring is punctured.	Replace the air spring. Check the area around the damaged air spring for contact with other components. Correct the problem areas as needed.
The air spring is leaking due to continual or repeated over-extension.	Check the height of the air spring. Make sure the correct height is maintained. Adjust if needed. Check for a broken shock absorber or shock bracket; replace if broken.

Problem—Air Bags Deflate Rapidly When the Engine Is Not Running

Possible Cause	Remedy
Air is leaking from the cab air-suspension system.	Check for leakage from fittings, air lines, the air spring, and the leveling valve. Tighten loose fittings to stop leakage; replace worn or damaged parts. Do not use Teflon tape on fittings.

Problem—Rear of Cab Rides Too High or Too Low

Possible Cause	Remedy
The leveling valve is out of adjustment.	Adjust the leveling valve.

Problem—Bouncy Ride

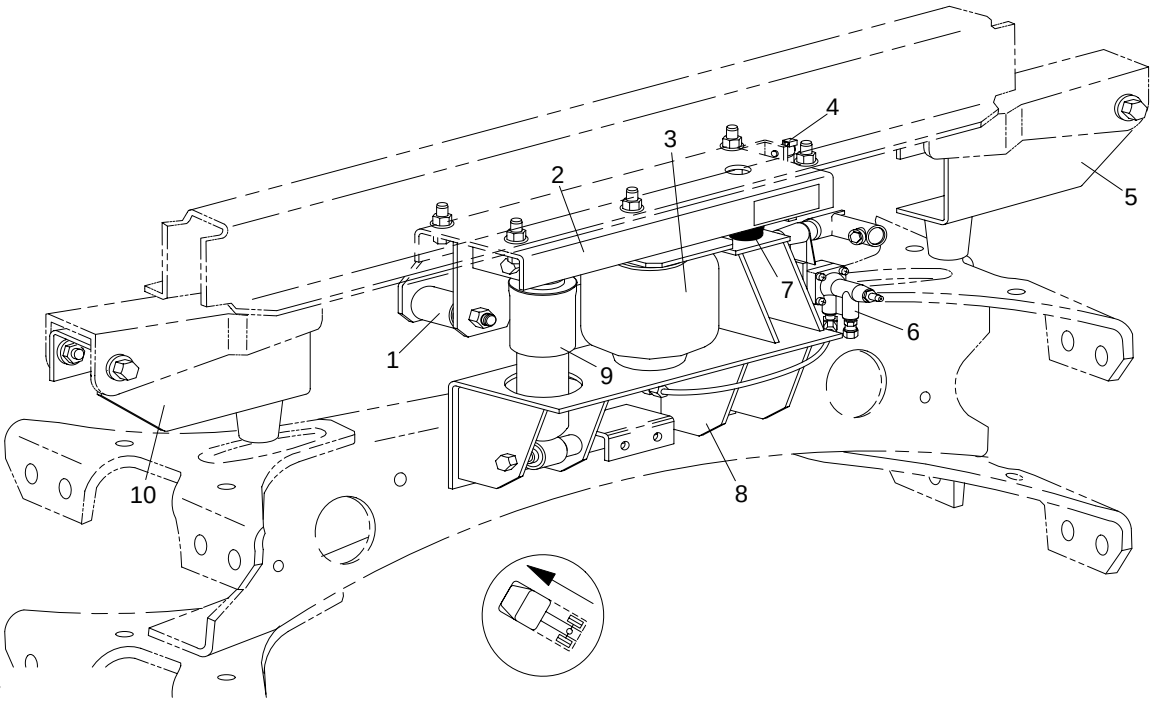
Possible Cause	Remedy
The cab air suspension shock absorber is leaking or worn out.	Replace the shock absorber.

General Description

The Link Cabmate® cab rear air-suspension system is standard equipment on Crew Cab-equipped vehicles.

The cab rear air-suspension system absorbs road shocks and compensates for changing cab loads. The cab air suspension system consists of: an air spring, a height control valve, a shock absorber, a lateral control rod, top and bottom units, and left and right outrigger-style auxiliary jounce travel limiters. See **Fig. 1**.

FL106 models equipped with the Crew Cab also use a spacer between the top unit and the cab crossmember, but do not have the auxiliary jounce travel limiters. See **Fig. 2**.

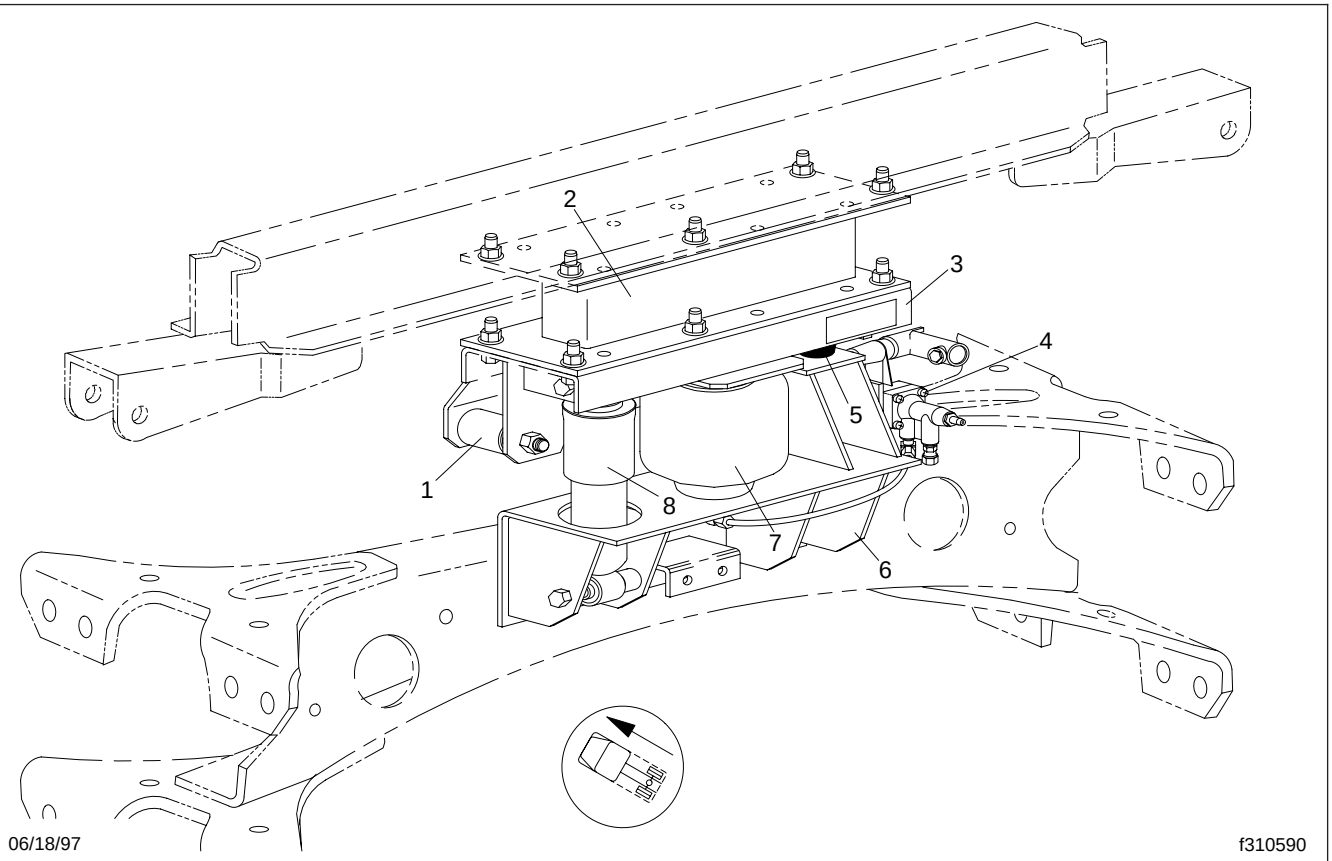


TOP AND BOTTOM UNITS

The top unit is secured to the cab rear crossmember by five bolts; the bottom unit is secured to a frame crossmember by four bolts. A lateral control rod, which connects the top and bottom units, prevents side-to-side misalignment. See **Fig. 1** and **Fig. 2**.

AIR SPRING

The top of the air spring has a threaded hole which mates with a stud welded to the top unit; the bottom of the air spring has a threaded stud and is attached to the bottom unit by a nut.



Together with the height control valve, the air spring compensates for changes in cab load by maintaining the correct distance between the rear of the cab and the frame rails.

4. Height Control Valve
5. Rubber Bumper
6. Bottom Unit
7. Air Spring
8. Shock Absorber

Fig. 2, Link Cabmate Cab Air Suspension System (FL106 models only)

HEIGHT CONTROL VALVE

All of the air in the cab air-suspension system is admitted through or exhausted from the height control valve (**Fig. 1**, Ref. 6 or **Fig. 2**, Ref. 4). The height control valve mounts on a bracket attached to the bottom unit. A horizontal arm connects the valve control shaft to the vertical linkage attached to the top unit.

CAB-MOUNT STOP ASSEMBLY

The cab-mount stop assembly consists of a rubber bumper (see **Fig. 1**, Ref. 7 or **Fig. 2**, Ref. 5) attached to the top unit. The bumper limits downward movement of the cab by contacting the bottom unit. If a leak occurs in the cab air-suspension system, the bumper supports the cab until the leak can be repaired.

NOTE: If a leak occurs in the cab air-suspension system, a pressure protection valve (located in the air supply line to the leveling valve) will maintain at least 65 psi (450 kPa) in the vehicle secondary air system.

SHOCK ABSORBER

A single shock absorber attaches to both the top and bottom units. In addition to damping cab movement, the shock absorber limits upward movement of the rear of the cab.

AUXILIARY JOUNCE TRAVEL LIMITERS

On all models except the FL106, auxiliary jounce travel limiters (see **Fig. 1**, Refs. 5 and 10) are attached to the cab rear crossmember. Each travel limiter is fitted with a rubber bumper, which contacts the top of a frame crossmember to prevent excessive cab lean.

Principles of Operation

When cab load increases, the distance between the top and bottom units decreases, causing the vertical linkage to push down on the height control valve arm. This rotates the valve control shaft, which activates an intake valve core inside the valve. Air flows through the valve and tubing into the air spring, until increasing pressure in the spring raises the cab to the correct height. As the cab reaches the correct height, the horizontal arm and the control shaft return to their neutral positions, closing the intake valve core, and stopping the flow of air into the air spring.

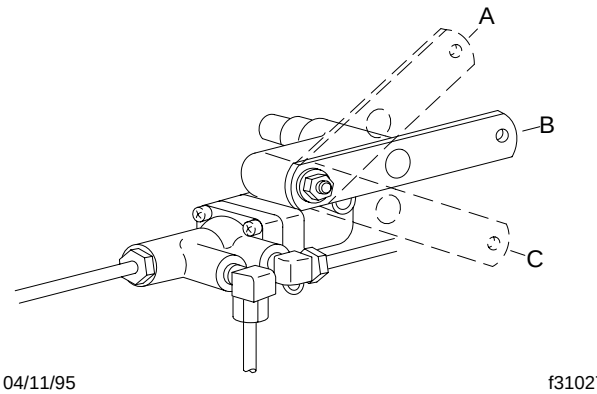
When cab load decreases, the rear of the cab rises, causing the vertical linkage to pull up on the end of the horizontal arm. Rotating the height control valve control shaft in this direction activates an exhaust valve core. Air is exhausted from the spring until the cab lowers to the correct height. Again, the horizontal arm and control shaft return to their neutral positions as the cab reaches the correct height, and air exhausting is stopped.

When the vehicle is moving, small and abrupt movements of the cab will occur, resulting in movements of the height control valve arm. Small movements of the arm do not activate the valve because of a built-in free-travel range: a gap between the height control valve control shaft and both of the valve cores (intake and exhaust). Abrupt movements do not activate the valve because it is filled with a silicone fluid, which delays the opening of one valve core for as long as five seconds after the closing of the other.

Changes in load which result in larger movements of the horizontal arm (beyond the free-travel range) for more than five seconds will activate the height control valve. Such changes in load occur when occupants or heavy items are added to, or removed from, the cab. Also, when the vehicle is moving forward at high speed or in a strong headwind, a major change in load occurs from the downward force applied by an optional air shield or air fairing. When these changes in load occur, the cab air-suspension system will adjust the height at the rear of the cab.

Checks

To keep the cab air-suspension system operating reliably, the air system must be kept free of oil, moisture, and other foreign material. Regularly inspect and maintain the vehicle air system components. For instructions, see Group 42 of the *Business Class Trucks Maintenance Manual*.



⚠ CAUTION

Failure to take precautions against the entry of oil, moisture, and other foreign material into the cab air-suspension system could eventually lead to sludge forming in the air system. Sludge could adversely affect the operation of the cab air-suspension system and other air system components.

Before replacing the height control valve, do the following steps to see if the valve is actually damaged, or is merely out of adjustment.

1. Chock the tires. Run the engine to build up vehicle air pressure to at least 100 psi (690 kPa).
2. Using a screwdriver, snap the vertical linkage off the horizontal arm attached to the height control valve.
3. Check the operation of the valve.
   - 3.1 Push the arm down about 45 degrees for 6 to 8 seconds. See **Fig. 1**, Ref. C. Air should pass through the valve and inflate the air spring.
   - 3.2 Return the arm to the neutral position. See **Fig. 1**, Ref. B. Air should stop flowing.
   - 3.3 Pull the arm up about 45 degrees for 6 to 8 seconds. See **Fig. 1**, Ref. A. Air should exhaust from the valve.
   - 3.4 Return the arm to the neutral position. The air should stops exhausting in the neutral position.
   - 3.5 If the valve works as stated in all of the above checks, no further checking is needed. Connect the vertical linkage to the valve horizontal arm.

If the valve doesn't work as stated in all of the above checks, replace it. See **Subject 120** for instructions.

A. Air Exhausts From Valve
B. Air Stops Flowing From Valve
C. Air Passes through Valve

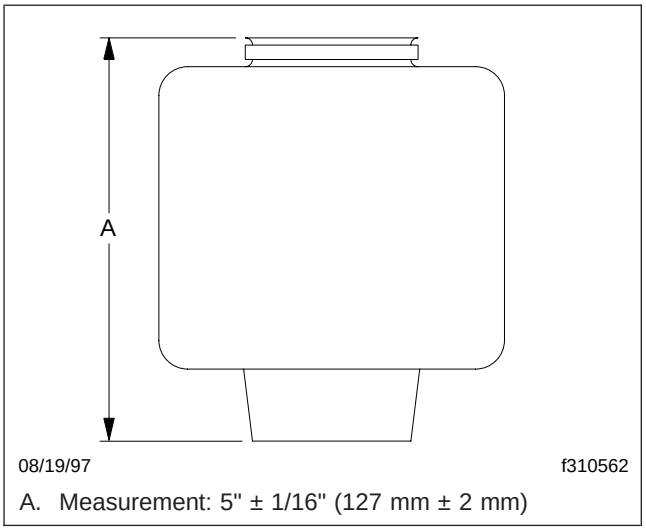


Fig. 1, Height Control Valve

4. If adjustment of the leveling valve is needed, see **Subject 110**.

Adjustment

1. Park the vehicle on a level surface and apply the parking brakes.
2. Chock the front tires to prevent the vehicle from moving.
3. Run the engine to build up vehicle pressure to at least 100 psi (690 kPa).
4. Check the height control valve adjustment.

   4.1 Measure the height of the air spring (see **Fig. 1**). It should be 5 inches ± 1/16 inch (127 mm ± 2 mm).

A. Measurement: 5" ± 1/16" (127 mm ± 2 mm)

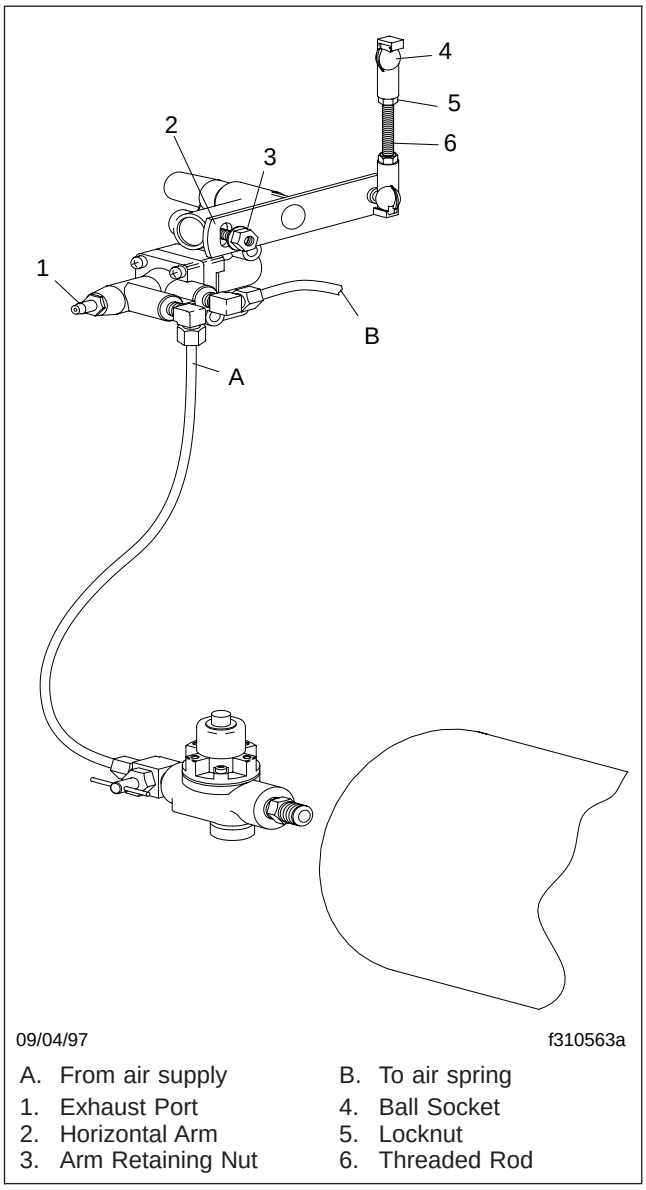

Fig. 1, Air Spring Height

   4.2 If the height is within specifications, no adjustment is needed. If it is not within specifications, go to the next step.

NOTE: If the air spring height is out of specification by more than 1/4 inch (6 mm), perform the coarse adjustment procedure. If design height is out of specification by less than 1/4 inch (6 mm), skip to the fine adjustment procedure.

5. Coarse adjustment is obtained by changing the position of the height control valve shaft, relative to the horizontal arm position.

   5.1 Loosen the retaining nut (see **Fig. 2**, Ref. 3) which secures the horizontal arm to the valve shaft.

A. From air supply
B. To air spring
1. Exhaust Port
2. Horizontal Arm
3. Arm Retaining Nut
4. Ball Socket
5. Locknut
6. Threaded Rod

Fig. 2, Height Control Valve and Linkage

   5.2 Move the height control valve shaft up or down, relative to the arm, until air spring height is within 1/4 inch (6 mm) of specifications.

   5.3 Using care to avoid moving the valve shaft, tighten the nut securing the horizontal arm to the valve shaft.

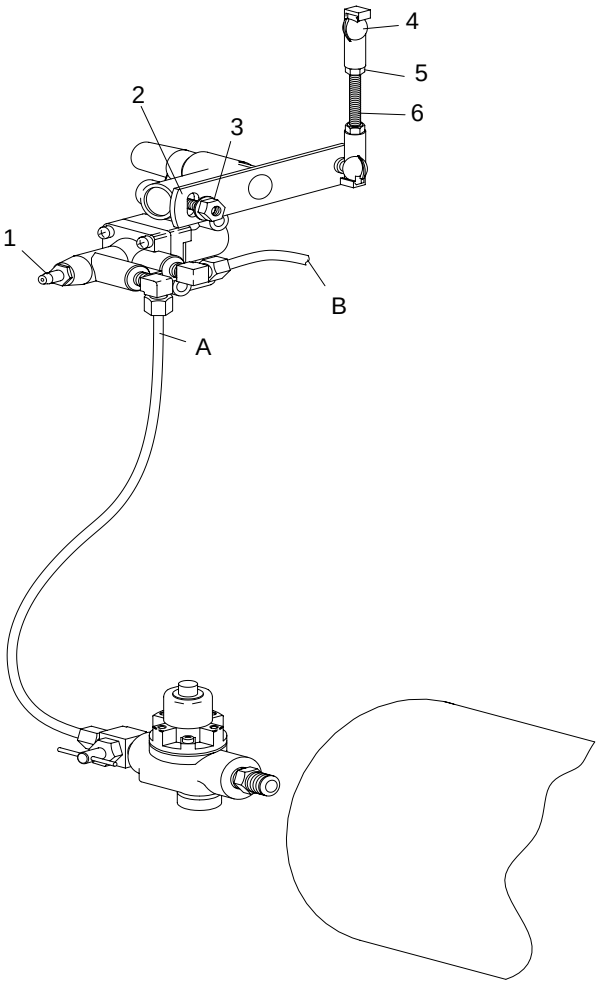
Height Control Valve Adjustment

6. When the required adjustment is less than 1/4 inch (6 mm), do the height control valve fine adjustment.

   6.1 Loosen the locknuts (**Fig. 2**, Ref. 5) securing the linkage ball sockets to the threaded rod.

   6.2 Lengthen or shorten the linkage as necessary by rotating the threaded rod in or out until the air spring design height is within specifications.

   6.3 Tighten the ball socket locknuts and recheck the air spring height. Make any corrections as needed.



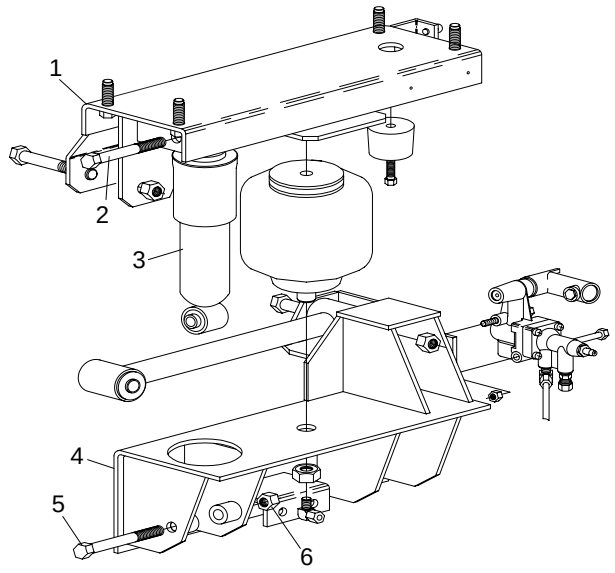
IMPORTANT: Because of a built-in delay in the height control valve, it may take as long as five seconds after making adjustments before the air spring height changes.

7. Remove the chocks from the front tires.

Replacement

NOTE: Before replacing the height control valve, do the steps in **Subject 100** to see if the valve is actually damaged, or is merely out of adjustment.

1. Park the vehicle on a level surface and apply the parking brakes.
2. Chock the front tires to prevent the vehicle from moving.
3. Drain the vehicle air system.
4. Remove the height control valve.
   - 4.1 Using a screwdriver, disconnect the vertical linkage ball socket from the height control valve horizontal arm. See **Fig. 1**, Ref. 4. Move the arm down, and hold it there to exhaust all air from the air spring.
   - 4.2 Remove the retaining nut (Ref. 3) that attaches the horizontal arm to the stud on the height control valve. Remove the arm, and save it for installation on the new valve.
   - 4.3 Disconnect the air lines from the fittings at the height control valve ports. Mark the lines for assembly reference. Cover the open ends of the air lines to prevent dirt or other foreign material from entering.
   - 4.4 Remove the height control valve mounting fasteners; then, remove the valve from its mounting plate.
5. Install the new height control valve.
   - 5.1 Mount the new valve on the plate. Tighten the hexhead capscrews 120 lbf·in (1350 N·cm).
   - 5.2 Mount the horizontal arm on the valve stud and tighten the locknut.
   - 5.3 Remove the covers from the air lines. Connect the air lines to the height control valve as marked earlier or as shown in **Fig. 1**. Tighten the fitting nuts hand-tight; then, tighten them one more turn or until no threads show on the fitting body.
6. Run the engine to build up vehicle air pressure to at least 100 psi (690 kPa).



09/04/97 f310563a

A. From air supply	B. To air spring
1. Exhaust Port	4. Ball Socket
2. Horizontal Arm	5. Locknut
3. Arm Retaining Nut	6. Threaded Rod

Fig. 1, Height Control Valve and Linkage

7. Check the operation of the new height control valve. For instructions, see **Subject 100**.
8. Check all air lines and connections for leaks; repair as needed.
9. Adjust the height control valve. See **Subject 110** for instructions.
10. Remove the chocks from the front tires.

Replacement (See 1)

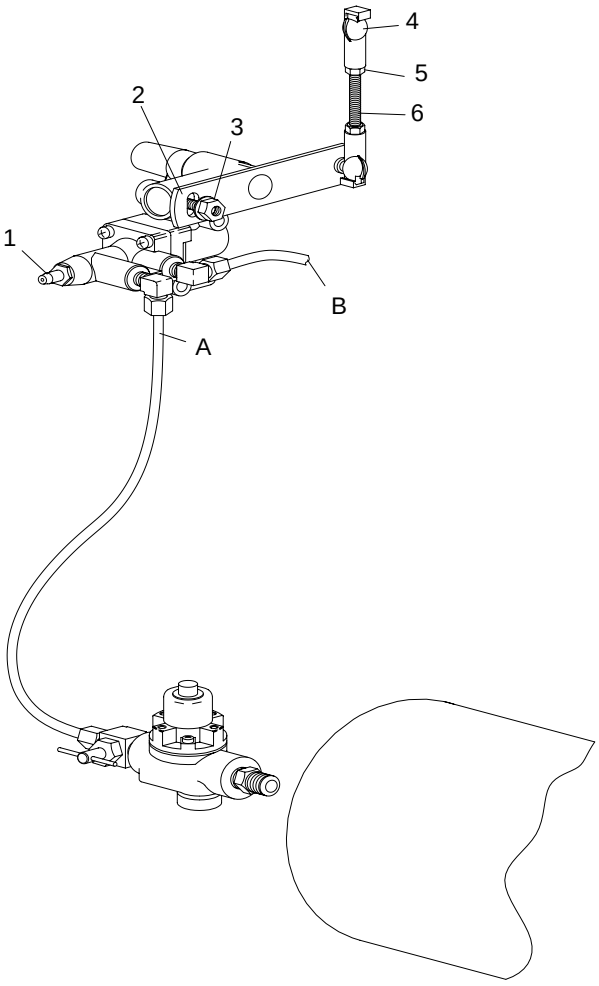
1. Top Unit
2. Upper Mounting Bolt
3. Shock Absorber
4. Bottom Unit
5. Lower Mounting Bolt
6. Locknut

Fig. 1, Shock Absorber Mounting

1. Park the vehicle on a level surface and apply the parking brakes.
2. Chock the front tires to prevent vehicle movement.
3. Remove the locknuts from the shock absorber upper and lower mounting bolts. Remove the bolts. Pull the shock absorber out of the mounting brackets.
4. Install the replacement shock absorber in the mounting brackets, and secure it with the bolts and locknuts.

NOTE: The longer bolt is used at the bottom of the shock absorber.

5. Tighten the locknuts 45 lbf·ft (61 N·m).
6. Remove the chocks from the front tires.



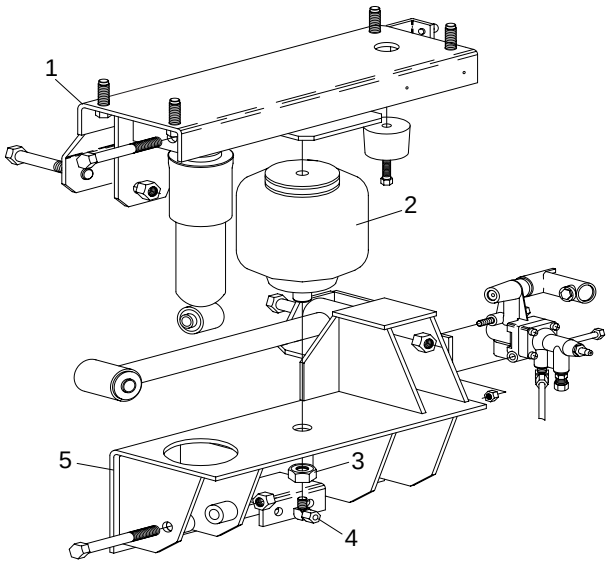
Replacement

1. Park the vehicle on a level surface and apply the parking brakes.
2. Chock the front tires to prevent the vehicle from moving.
3. Drain the vehicle air system.
4. Using a hydraulic bottle jack and blocks of wood (for spacers, if necessary), raise the rear of the cab until the cab suspension system shock absorber reaches its end stop.

⚠ DANGER

Before doing the work below, block the raised cab securely. Failure to block the cab while working on the cab rear air suspension system could result in serious injury or death.

5. With the cab raised, place blocks of wood between the frame rails and the cab rear crossmember on both sides of the vehicle. Then, lower the jack and allow the cab to rest on the blocks of wood.
6. Remove the air spring.
   - 6.1 Using a screwdriver, disconnect the ball socket (see **Fig. 1**, Ref. 4) from the height control valve arm. Move the arm up and hold it there until all air exhausts from the air spring.
   - 6.2 Disconnect the air supply hose from the fitting on the bottom of the air spring. See **Fig. 2**, Ref. 4. Cover the end of the hose to keep out dirt, moisture, etc.
   - 6.3 Unscrew the air fitting (Ref. 4) from the air spring.
   - 6.4 Remove the nut (Ref 3) securing the air spring to the bottom unit.
   - 6.5 Using both hands, grasp the air spring firmly and unscrew it from the stud on the top unit.
7. Install a new air spring.
   - 7.1 Position the new air spring under the top unit and screw it onto the top unit stud. Tighten the air spring finger-tight.



A. From air supply
B. To air spring
1. Exhaust Port
2. Horizontal Arm
3. Arm Retaining Nut
4. Ball Socket
5. Locknut
6. Threaded Rod

Fig. 1, Height Control Valve and Linkage

   - 7.2 Squeeze the air spring to extend it and insert its bottom stud through the mounting hole in the bottom unit. Install the lower mounting nut and tighten it finger-tight. Using a wrench, tighten one more turn.
   - 7.3 Install the air hose fitting (Ref. 4) in the air spring bottom stud. Tighten it finger-tight. Use a wrench to position the fitting

Air Spring Replacement

08/22/97 f310617

1. Top Unit
2. Air Spring
3. Lower Mounting Nut
4. Air Fitting
5. Bottom Unit

Fig. 2, Air Spring Mounting

so it faces rearward. Do not apply Teflon® tape to the fitting threads.

7.4 Remove the cover from the air spring supply line and attach the line to the air spring fitting. Tighten the air line nut finger-tight. Using a wrench, tighten one more turn.

8. Using the hydraulic bottle jack, raise the rear end of the cab just enough to remove the wooden support blocks.
9. Lower the cab and remove the jack.
10. Start the engine and build vehicle air pressure to at least 100 psi (690 kPa).
11. Check for air leaks at the air spring and at the height control valve. Tighten the fittings or replace the parts, if necessary.
12. Remove the chocks from the front tires.

Replacement

1. Park the vehicle on a level surface and apply the parking brakes.
2. Chock the front tires to prevent vehicle movement.
3. Drain the vehicle air system.
4. Using a screwdriver, disconnect the ball socket (see **Fig. 1**, Ref 4) from the height control valve arm.
5. Move the arm upward until all air exhausts from the air spring and the rubber bumper attached to the top unit contacts the bottom unit.
6. Remove the locknuts from the lateral control rod mounting bolts and remove the bolts. Pull the control rod out of the mounting brackets. See **Fig. 2**.
7. Install the replacement control rod in the mounting brackets, and secure it with the bolts and locknuts.

NOTE: The longer bolt is used to attach the control rod to the cab suspension top unit.

8. Tighten the locknuts 40 lbf·ft (54 N·m).
9. Connect the vertical linkage to the height control valve arm.
10. Start the engine and build vehicle air pressure to at least 100 psi (690 kPa).
11. Remove the chocks from the front tires.

Troubleshooting Tables

Problem—Air Spring Is Flat

Possible Cause	Remedy
Low air pressure in the secondary air system.	Check the air pressure gauge on the instrument panel. If secondary air pressure is low, run the engine until at least 70 psi (482 kPa) is indicated.
Air is leaking from the cab air-suspension system.	Check for leakage from fittings, air lines, air spring, and the height control valve. Tighten loose fittings to stop leakage; replace worn or damaged parts. Do not use Teflon tape on fittings.
The height control valve is out of adjustment.	Adjust the height control valve.
The height control valve is inoperative.	If upward movement of the arm on a properly adjusted valve fails to inflate the air springs, replace the height control valve.
The height control valve linkage is damaged.	Check for damage to the height control valve linkage and the arm. Repair or replace damaged linkage parts.

Problem—Air Spring Deflates Rapidly When the Engine Is Not Running

Possible Cause	Remedy
Air is leaking from the cab air-suspension system.	Check for leakage from fittings, air lines, air springs, and the height control valve. Tighten loose fittings to stop leakage; replace worn or damaged parts. Do not use Teflon tape on fittings.

Problem—Rear of Cab Rides Too High or Too Low

Possible Cause	Remedy
The height control valve is out of adjustment.	Adjust the height control valve.

Problem—Collapsed Air Spring

Possible Cause	Remedy
An air spring is punctured.	Replace the air spring. Check the area around the damaged air spring for contact with other components. Correct the problem areas as needed.
The air spring is continually or repeatedly over-extended.	Check the height of the air spring. Make sure the correct height is maintained. Adjust if needed. Check for a broken shock absorber or shock bracket; replace if broken.

Problem—Bouncy Ride

Possible Cause	Remedy
The cab air suspension shock absorber is leaking or worn out.	Replace the shock absorber.

Specifications

Tightening Torques		
Description	**Size**	**Torque**

Upper	7/16 x 3-1/4 UNF	45 lbf·ft (61 N·m)
Lower	7/16 x 3-3/4 UNF	45 lbf·ft (61 N·m)
Valve Arm Retaining Nut	1/4 UNC	84 lbf·in (940 N·cm)

Table 1, Tightening Torques

Cab Water-Leak Detection

Use the following procedure to locate areas where water may intrude into the cab.

1. With the vehicle parked, apply the parking brakes and chock the tires.
2. Prepare a wash solution of at least one-quarter cup of soap to one gallon of water in a spray bottle.
3. Close all doors, windows, and vents.
4. With the HVAC system in "Fresh Air" mode, turn the fan blower motor on high.

NOTE: Perform the leak detection test with the HVAC system in the "Fresh Air" mode only. Do not set the system in the "Recirculation" mode.

5. Spray the cab with the wash solution and look for bubbles. See **Fig. 1**. Inspect all applicable areas listed below:
    - windshield perimeter
    - visor brackets (if so equipped)
    - air horns and marker lights (if so equipped)
    - roof deflector mounts (if so equipped)
6. Mark areas of suspected leaks.

NOTE: This method of leak detection may also identify areas that will not leak water, even though those areas produce bubbles. Bubbles around door seals and along the vehicle side walls will likely not cause water intrusion issues.

If small bubbles are found in an area that is not suspected to leak, a repair may not be necessary.

7. Rinse the wash solution off the vehicle with water.
8. Turn off the fan blower motor.
9. Remove the chocks from the tires.

Cab Water-Leak Repair

If a leak is found, the repair method will depend on the area and type of leak. It may be necessary to remove some components, though most leaks should be repairable by sealing the area of the leak with silicone sealant.

Repair leaks in the windshield using the approved method. See **Section 60.01, Subject 100**.

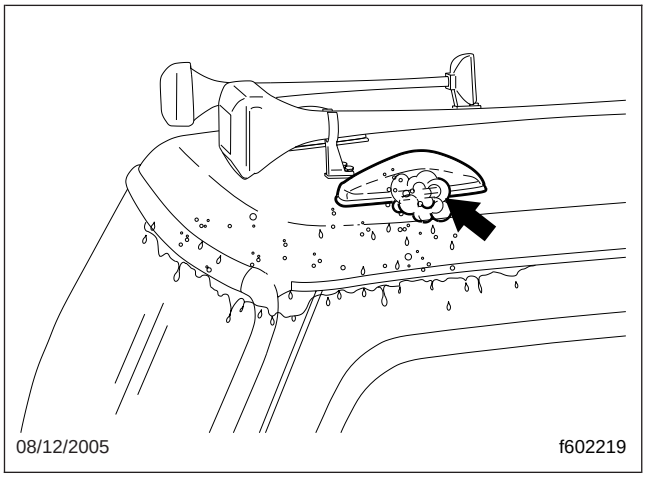

Fig. 1, Cab Water-Leak Detection with Wash Solution

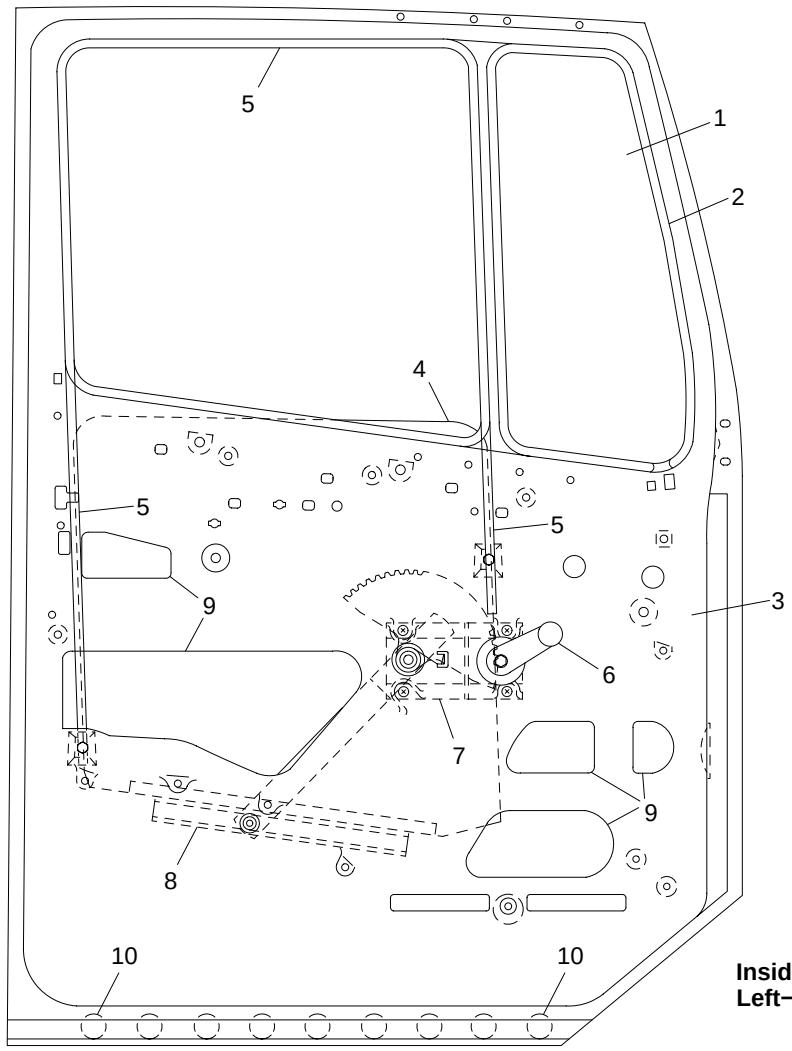
General Information

The cab door features a steel outer skin, welded to a one-piece formed steel inner panel and frame, to make a highly rigid assembly. The unitized construction provides necessary support for various parts attached to the door.

A sector-gear-and-arm window regulator assembly raises and lowers the roll-up window. **See Fig. 1** , Refs. 7 and 4. The regulator assembly bolts to the inner door panel (Ref. 3). Window up-and-down movement is guided by a channel assembly (Ref. 5). The lower portion of the channel assembly bolts to the inside of the inner door panel; screws are installed in the channel around the window opening. A glass-lift support and roller guide (Ref. 8) supports the window at its lower edge.



A fixed-position wing window is installed in each door, ahead of the roll-up window. **See Fig. 1** , Ref. 1. A one-piece weather seal (Ref. 2) surrounds each wing window opening.

A door-latch handle inside the cab is recessed in an armrest and grab-handle assembly (called the inner door handle). **See Fig. 2** , Ref. 1. A rod (Ref. 3) links the inner door handle with the latch and lock mechanisms (Refs. 6, 11, and 12) at the rear of the door frame. The flush-mounted exterior door handle assembly (Ref. 10) attaches to the door with two handle retainer clips (wedges) (Ref. 15) from the inside. The lockset tumbler (Ref. 11) is installed just above the paddle handle in the exterior door handle assembly.

Openings in the inner door panel provide easy access to the window regulator and to the latch and lock mechanisms. **See Fig. 1** and **Fig. 2.** Three sections of sound-damping material are bonded to the inside of the outer door skin. Drain holes in the bottom of the door prevent any water from collecting.

Two widely spaced hinges attach the door to the front door post of the cab door-opening frame. **See Fig. 3** , Refs. 2, 7, and 3. The hinges can be independently positioned for in-and-out, fore-and-aft, and up-and-down adjustment. A door check arm (Ref. 8) prevents the door from being opened too far. A door-latch striker pin (Ref. 11) attaches to a floating plate in the rear door post of the cab door-opening frame, and can be adjusted vertically and horizontally to correctly engage the latch assembly jaw (Ref. 9). For fore-and-aft adjustment, shims (Ref. 12) are added (or removed) behind the striker pin coned washer. The circumference of the cab door-opening frame is sealed with a strip of preformed rubber (Ref. 5).

Removal

1. Apply the parking brakes, and chock the tires.
2. Lower the roll-up window for easier handling of the door during removal.
3. Support the door frame from the bottom to prevent the door from falling or tipping.
4. If so equipped, disconnect the mirror-heat wiring. **See Fig. 1 .**

   4.1 Carefully, pull the end of the mirror-heat harness boot (Ref. 5) out of the cab door-opening frame (Ref. 4).

1. Mirror−Heat Harness
2. Upper Hinge
3. Hinge Fasteners

7. Mirror−Heat Harness Connector
8. Tie Strap

NOTE: Interior door trim panel, inner door handle assembly, and door moulding are not shown.

08/02/93 f720074

Fig. 1

   4.2 If removing the right-hand door, remove the right-hand, lower dash panel to gain access to the mirror-heat wiring harness connector.

   4.3 Separate the halves of the mirror-heat harness connector (Ref. 7). Remove any harness clamps, then feed the harness (Ref. 1) through any tie straps (Ref. 8), and through the cab door-opening frame.

5. Remove the four capscrews, flatwashers, and split lockwashers that attach the door check and hinges to the cab door-opening frame. **See Fig. 1** , Refs. 2, 3, and 6. Remove the door.

Installation

IMPORTANT: Use a support or have another person hold the door from the bottom to prevent it from falling or tipping during installation.

1. Align the hinges with their mounting holes in the door-opening frame, then install the fasteners. Tighten the capscrews just tight enough to prevent unintentional hinge movement during door adjustment.
2. If so equipped, connect the mirror-heat wiring. **See Fig. 1 .**

   2.1 Feed the mirror-heat harness (Ref. 1) into the cab through the door-opening frame, and through any tie straps (Ref. 8). Install any harness clamps, then join the halves of the harness connector (Ref. 7).

   2.2 If it was removed, install the lower right-hand dash panel.

   2.3 Install the end of the mirror-heat harness boot (Ref. 5) in the door-opening frame.

3. Adjust the door, then tighten the hinge capscrews and striker pin. **See Fig. 2 .**

   NOTE: A misaligned door can cause wind noise, poor temperature control in the cab due to drafts, water damage to the cab interior, difficult closing of the cab door, or premature wear of the door seal. The striker pin and both door hinges are attached to floating plates that move up and down and in and out so the door can be adjusted.

Door Removal and Installation

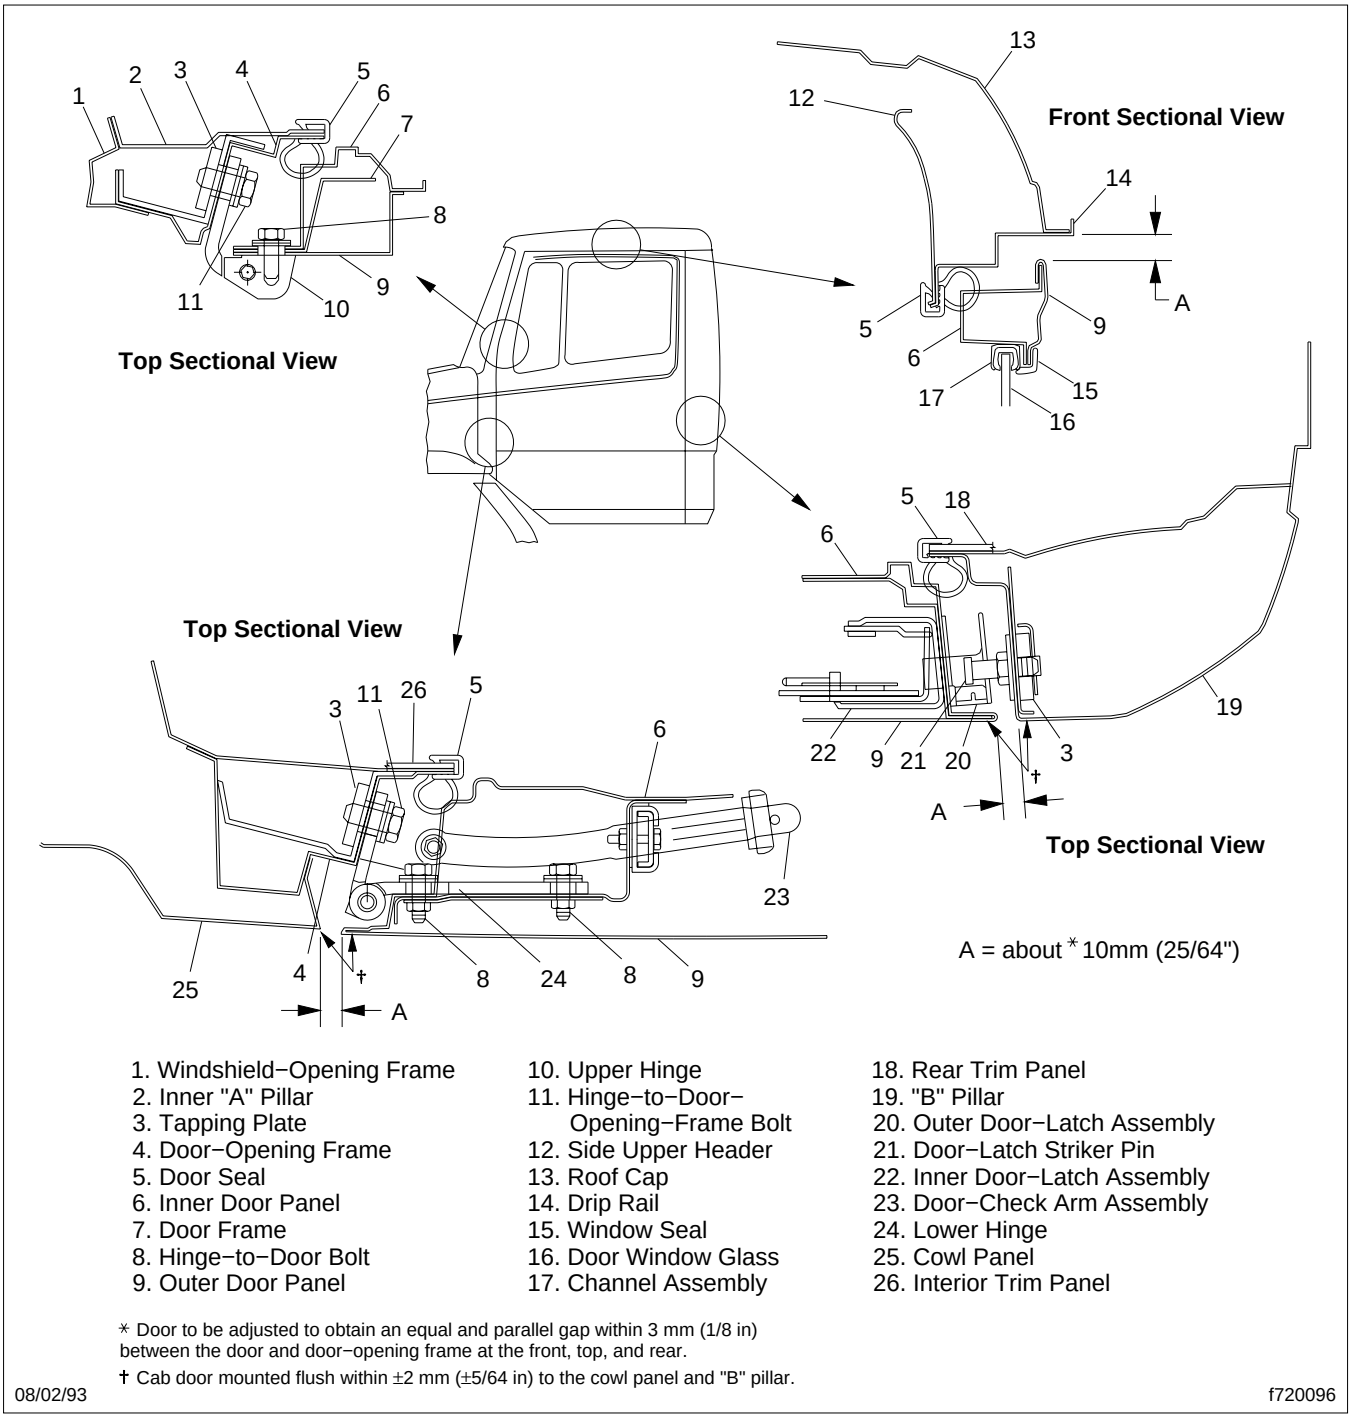

Fig. 2

3.1 Loosen the striker pin (**Fig. 2** , Ref. 21), then tighten it finger-tight.

3.2 Carefully close the door. As needed, move the door in or out until its outer sur-

face is flush, within 2 mm (5/64 in), with the surface of the cab skin at *both* its front and rear edges.

3.3 As needed, raise or lower the door until the space between the top of it and the door-opening frame is uniform, and is equal within 3 mm (1/8 in) to the spaces between the front and rear edges of the door and the door-opening frame. **See Fig. 2 .** Be careful not to disturb the in-and-out adjustment.

3.4 Without disturbing the positions of the hinges or striker pin, carefully open and support the door, then tighten the hinge capscrews 46 N·m (34 lbf·ft).

3.5 Securely tighten the striker pin. From outside the cab, partially close the door until the latch jaws are about 25 to 50 mm (1 to 2 in) from the striker pin. Be sure the striker pin will be centered in the latch jaw when the door is closed. If needed, reposition the striker pin.

3.6 Tighten the striker pin 61 N·m (45 lbf·ft), then close the door and recheck the door alignment.

4. Check the door seal (**Fig. 2** , Ref. 5) for damage or wear. If needed, replace it; **see Subject 120.**

5. Remove the chocks.

Up-and-Down Adjustment

(See Fig. 1)

From outside the cab, visually check the alignment of the door with the cab door-opening frame. See if the spaces around the top of the door are uniform, the gaps are all about 10 mm (3/8-inch), and are within 3 mm (1/8-inch) of being equal.

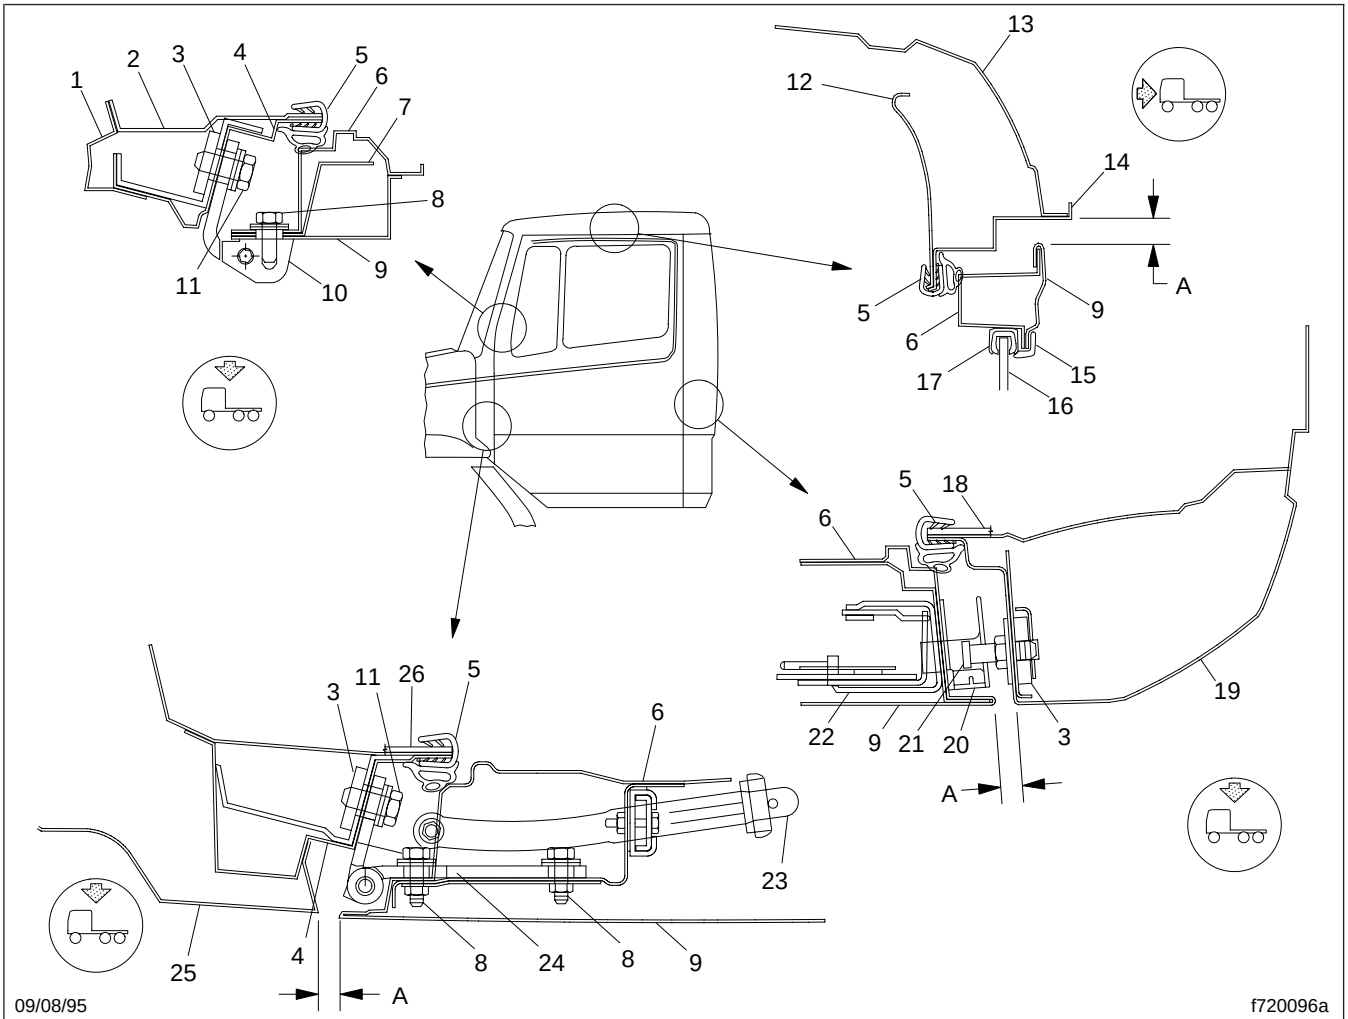
1. Mark both the vertical and horizontal positions of the latch striker pin and the two hinges before loosening them for adjustment. This will greatly simplify the procedure.
2. Loosen the striker pin, then tighten it finger-tight.
3. Loosen the capscrews that attach the hinges to the cab door-opening frame, but keep them tight enough to prevent unintentional hinge movement.
4. Carefully close the door, then raise or lower it until the space across the top of it is uniform, the gap is about 10 mm (3/8-inch), and is within 3 mm (1/8-inch) of the gaps at both the front and rear vertical edges of the door. Be careful not to disturb the in-and-out adjustments at the front or rear of the door.
5. Without disturbing the positions of the hinges or striker pin, carefully open and support the door, then tighten the hinge capscrews 46 N·m (34 lbf·ft).
6. Securely tighten the striker pin. From outside the cab, partially close the door until the latch jaws are about 25 to 50 mm (1 to 2 inches) from the striker pin. Be sure the striker pin will be centered in the latch jaw when the door is closed. If needed, reposition the striker pin.
7. Tighten the striker pin 61 N·m (45 lbf·ft), then close the door and recheck door alignment.

In-and-Out Adjustment

Poor in-and-out adjustment of the door is often indicated by hard closing of the door, wind and water leaks around the edge of the door, or premature wear of the door seal. Move the door in or out until its outer surface is flush, within ± 2 mm (± 5/64-inch), with the surface of the cab skin at *both* its front and rear edges.

1. If only the rear edge of the door needs adjusting, go on to the step for adjusting the rear edge.

   If the front edge of the door needs adjusting (**see Fig. 2**), mark the vertical and horizontal positions of the hinges before loosening them for adjustment. This will greatly simplify the procedure.
2. Loosen the capscrews that attach the hinges to the cab door-opening frame, but keep them tight enough to prevent unintentional hinge movement.
3. Carefully close the door, then move the front edge of the door in or out until its outer surface is flush, within ±2 mm (±5/64-inch), with the surface of the cab skin. Be careful not to disturb the up-and-down adjustment.
4. Without disturbing the positions of the hinges, carefully open and support the door, then tighten the hinge capscrews 46 N·m (34 lbf·ft).
5. If the rear edge of the door needs adjusting, mark the vertical and horizontal positions of the latch striker pin before loosening it for adjustment. **See Fig. 3.**
6. Loosen the striker pin, then tighten it finger-tight.
7. Carefully close the door, then move the rear edge of the door in or out until its outer surface is flush, within ±2 mm (±5/64-inch), with the surface of the cab skin. Be careful not to disturb the up-and-down adjustment.
8. Without disturbing the position of the striker pin, carefully open the door, then tighten the striker pin 61 N·m (45 lbf·ft).
9. Close the door and recheck door alignment.

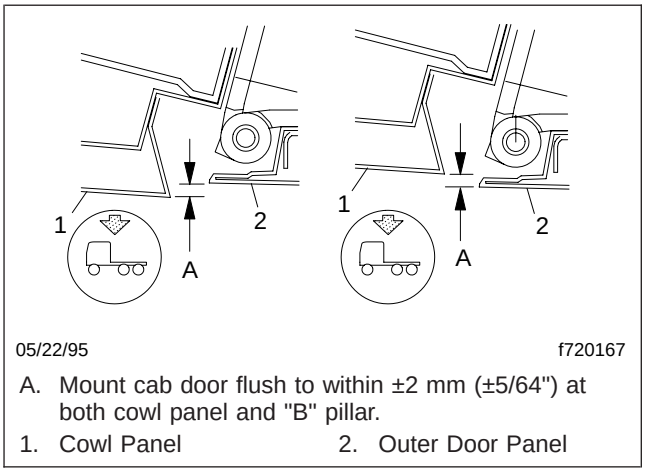


Fore-and-Aft Adjustment

(See Fig. 1)

NOTE: Although fore-and-aft adjustment of the door is possible, it should not normally be needed unless a new door is installed.

From outside the cab, visually check the alignment of the front and rear vertical edges of the door with the cab door-opening frame. See if the spaces are uniform, the gaps are about 10 mm (3/8-inch), and are within 3 mm (1/8-inch) of being equal.



Door and Latch Adjustment

A. At the front, top, and rear, check for a 10 mm (3/8-inch) gap that is parallel and equal to within 3 mm (1/8-inch).

Fig. 2, Door Adjustment (In-and-Out), at the Cowl Panel

A. Mount cab door flush to within ±2 mm (±5/64") at both cowl panel and "B" pillar.
1. Outer Door Panel 2. "B" Pillar

Fig. 3, Door Adjustment (In-and-Out), at the B Pillar

1. If the door needs adjusting, loosen the capscrews that attach the upper and lower hinges to the door, then tighten them finger-tight.
2. Gently close the door. Move the door as needed to align its front and rear vertical edges with the door-opening frame. Adjust the door until the spaces around the door are uniform, the gaps are about 10 mm (3/8-inch), and are within 3 mm (1/8-inch) of being equal.
3. Without disturbing the positions of the hinges, carefully open the door, then tighten the hinge-to-door capscrews 18 N·m (13 lbf·ft).
4. From outside the cab, partially close the door until the latch jaws are about 25 to 50 mm (1 to 2 inches) from the striker pin. Be sure the striker pin will be centered in the latch jaw when the door is closed. If needed, reposition the striker pin.
   - 4.1 Remove the striker pin.
   - 4.2 Add shims between the striker pin coned washer and the rear post of the cab door-opening frame.

   NOTE: Add only enough shims to correct the engagement of the jaws around the pin. Too many shims will cause interference between the pin and latch.
5. Tighten the striker pin 61 N·m (45 lbf·ft), then close the door and recheck door alignment.

Door Latch Adjustment

An incorrectly adjusted door latch mechanism can prevent the opening of the cab door from the outside.

If the outside door latch will not open, do the following steps:

1. First, check and adjust, if necessary, the vertical positioning of the striker pin.
2. Adjust the door latch mechanism.

STRIKER PIN ADJUSTMENT

As the door closes, watch to see if the door-latch striker pin is centered in relation to the latch jaws. **See Fig. 1.** The door should not move up or down when the latch jaws engage the striker pin. Only the center of the pin must contact the latch jaws; neither the forward end nor the hex portion of the pin should contact any part of the latch.

1. To center the striker pin vertically in the latch jaws, adjust the striker pin up or down.
   - 1.1 Loosen the pin fasteners, then tighten them finger-tight.
   - 1.2 Close the door (the latch jaws will center the pin). Move the rear of the door in or out if needed, until its outer surface is flush, within ±2 mm (±5/64 in), with the surface of the cab skin.

Door and Latch Adjustment

1.3 Carefully open the door without disturbing the position of the pin. Tighten the pin 61 N·m (45 lbf·ft), then close the door and recheck the adjustment.

2. If needed, adjust the striker pin fore and aft in the latch jaws. For procedures, see "Fore-and-Aft Adjustment."

DOOR LATCH MECHANISM ADJUSTMENT (ON VEHICLES BUILT 4/15/94 AND EARLIER)

If the outside paddle handle does not open, adjust the door latch mechanism. If needed, replace the old outside-release rod and spring clip with the revised rod, plastic retainer, and slip link.

1. Open the door and remove the interior door panel.
2. Disconnect the threaded end of the outside-release rod from the spring clip on the latch mechanism.
3. Disconnect the lower end of the outside-release rod by rotating the plastic retainer clip (**see Fig. 4**) counterclockwise to unsnap the clip from the rod.

   3.1 To move the lever into a position where the clip can be unsnapped, pull on the outside door handle.

   3.2 After unsnapping the clip, remove the rod from the door. Discard the rod.

4. Remove the spring clip that attached the rod to the inner door latch.

   4.1 Using a 3/16-inch drill bit, drill out the rivet that attaches the spring clip to the inner door latch. While drilling, place a steel plate behind the spring clip to protect the outer door panel.

   4.2 Discard the spring clip.

5. Insert a new plastic retainer clip KIC04075 4 into the rivet hole in the inner door latch. Make sure the barb of the plastic clip faces the outer door panel.
6. Insert a new outside-release rod (18–30394–000 for the left-hand door; 18–30394–001 for the right-hand door) into the release lever.

A. Door Window Opening
1. Inner Door Latch Assembly
2. Outer Door Latch Assembly

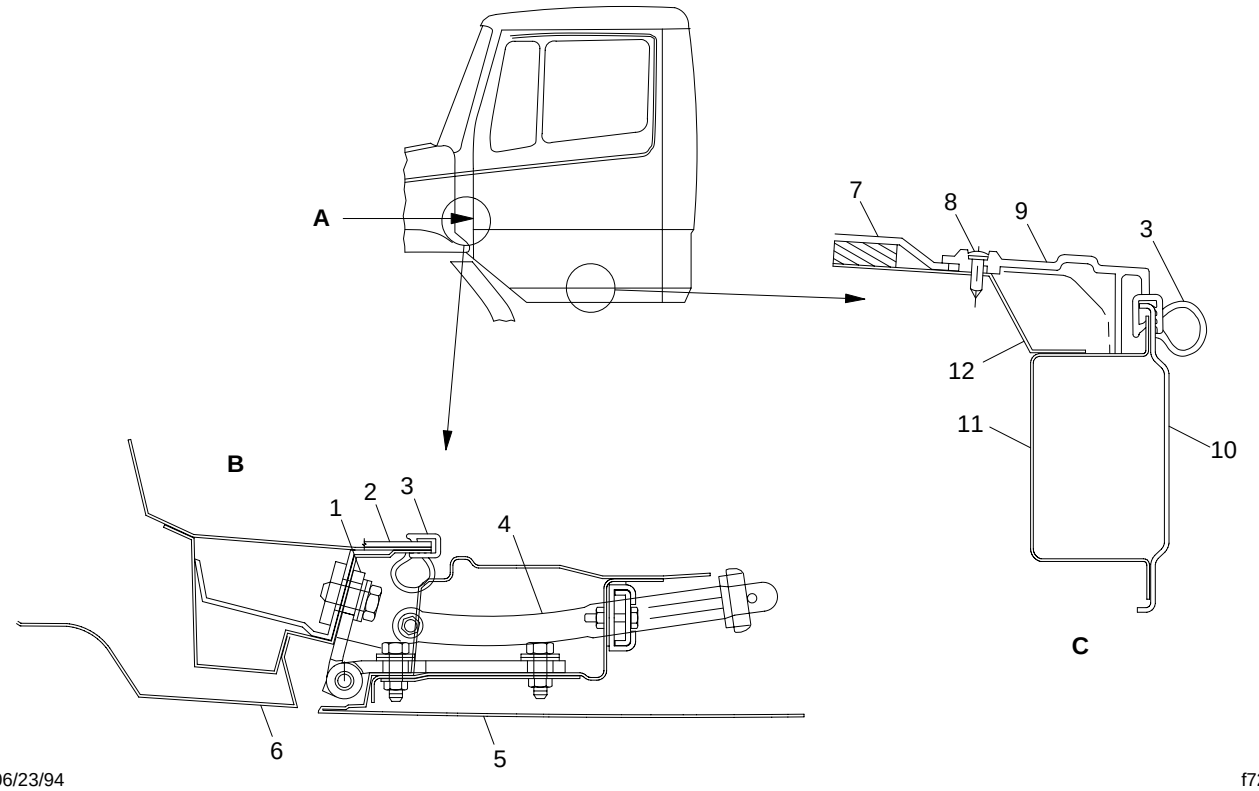
6. Slip Link
7. Release Lever
8. Exterior Door Handle Assembly
9. Lockset Tumbler Lever
10. (Inside-Release) Door-Latch Rod
11. Door Latch Rod Clips

Fig. 4, Door Latch Mechanism Interior View (Left-Hand Door)

7. Thread a slip link A18–30397–000 onto the upper end of the outside-release rod.
8. With the latch mechanism in the unlocked position, raise the arm with the newly installed plastic clip as high as possible. Adjust the slip link until it lines up with the inner door latch lever. Insert the slip link into the clip.



DOOR LATCH MECHANISM ADJUSTMENT (ON VEHICLES BUILT AFTER 4/15/94)

1. With the door still open, manually close the latch jaws. Turn the outside door handle and see if the jaws unlatch. If they don't, disconnect the slip link from the plastic clip and rotate it one or two turns lower on the rod. Repeat this procedure as necessary until the outside handle opens the latch jaws.

NOTE: The latch jaws should open at approximately 90 per cent travel of the outside door handle. If they open too soon, the mechanism can go over-center and refuse to open the door. In order to open it, the door must be locked again and then unlocked.

2. Check door latch operation with the door both locked and unlocked.
3. Install the interior panel.

Replacement (See Fig. 1)

A. Ends of Seal
B. Top Sectional View
C. Front Sectional View

1. Lower Hinge
2. Interior Trim Panel

7. Floor Mat
8. Door Sill Cover Screw
9. Door Sill Cover
10. Outer Door Sill Panel
11. Inner Door Sill Panel
12. Floor Pan

Fig. 1, Door Seal

1. Remove the three screws that attach the door sill cover to the floor pan; remove the door sill cover.
2. Pull the entire length of the old door seal from the flange of the cab door-opening frame.
3. Adjust the door so that the gap between the door and door opening is uniform. From inside the cab, use a padded block of wood and a hammer to bend the door seal flange until there is a uniform gap of 14 to 15 mm (about 9/16-inch) between the door and the door seal mounting flange.
4. Install the new door seal by pushing its open channel firmly onto the flange of the cab door-opening frame so the ends of the seal will meet at the center of the lower door hinge.

   Make sure the seal is pushed completely onto the flange all the way around the door-opening frame; there must be no creases or buckles on the sealing surface.

Door Seal Replacement

CAUTION

CAUTION: Do not stretch the door seal during installation. To do so may reduce its sealing ability, which could result in water leaks.

5. Trim the seal to length as needed, and butt the ends together.
6. Install the door sill cover, and tighten the screws snugly.

Interior Door Trim Removal and Installation

Removal (Refer to Fig. 1)

1. Remove the inner door handle assembly. **Refer to Fig.2** and **Fig.3.**
   - 1.1 Use a small hook to remove the two door handle plugs from the inner door handle assembly. **See Fig.2.**
   - 1.2 Hold the door handle so that it doesn't fall while removing the three machine screws. Gently pull the handle from the door panel.
   - 1.3 Pull straight out on the door-lock actuator and actuator guide, to disengage the barbed rivet stud that attaches the actuator to the door-lock link lever. **See Fig. 3 .**
2. Remove the window regulator handle. **See Fig.4 .**
   - 2.1 Remove the phillips screw that attaches the window regulator handle to the splined shaft. **See Fig.4 .**
   - 2.2 Pull the handle straight off the regulator splined shaft. If necessary, insert a straight-blade screwdriver under the regulator handle plate, and twist it until the handle slides off. Remove the regulator handle plate.
3. Remove the door trim panel assembly. **See Fig.5 .**
   - 3.1 Gently insert a straight-blade screwdriver under a corner of the door trim panel, and lift the panel to pull the first quarter-turn fastener out of the inner door panel. **See Fig.5 .** Use care not to damage the door trim panel.
   - 3.2 Working around the edge of the panel, pull out each of the thirteen quarter-turn fasteners, one at a time.

     If any of the quarter-turn fasteners are damaged, replace them (insert the head of the new fastener in the backing-board hole, and twist it a quarter turn).
4. Remove the door moulding and door moulding seal. **See Fig.6** and **Fig.7.**
   - 4.1 Remove the four screws and flatwashers that attach the door moulding to the door. **See Fig.6.**
   - 4.2 Remove the door moulding and door moulding seal, **as shown in Fig.7.** To prevent damaging the two positioning tabs, rotate the rear of the moulding slightly downward, and the front slightly upward, while sliding it forward and off the door.

Installation (Refer to Fig. 1)

1. Install the door moulding and door moulding seal. **See Fig. 6and Fig.7 .**
   - 1.1 Install the door moulding and door moulding seal, **as shown in Fig. 7 .** To prevent damaging the two positioning tabs, rotate the rear of the moulding upward, and the front slightly downward while sliding it backward and onto the door.
   - 1.2 Install and tighten the four screws that attach the door moulding to the door. **See Fig.6.**
2. Install the door trim panel assembly.
   - 2.1 Make sure all thirteen of the quarter-turn fasteners are correctly installed in the door panel.
   - 2.2 Working around the edge of the door trim panel, push in each of the fasteners, one at a time.
3. Install the window regulator handle and regulator handle plate. **See Fig. 4 .**
   - 3.1 Install the regulator handle plate on the splined shaft, then push the handle straight onto the shaft.
   - 3.2 Install the phillips screw, and tighten it snugly while holding the regulator handle in place to keep the splined shaft from turning. **See Fig. 4 .**
4. Install the inner door handle assembly. **See Fig. 3 .**
   - 4.1 Install the door-lock actuator and actuator guide, by engaging the barbed rivet stud that attaches the actuator to the door-lock

Interior Door Trim Removal and Installation

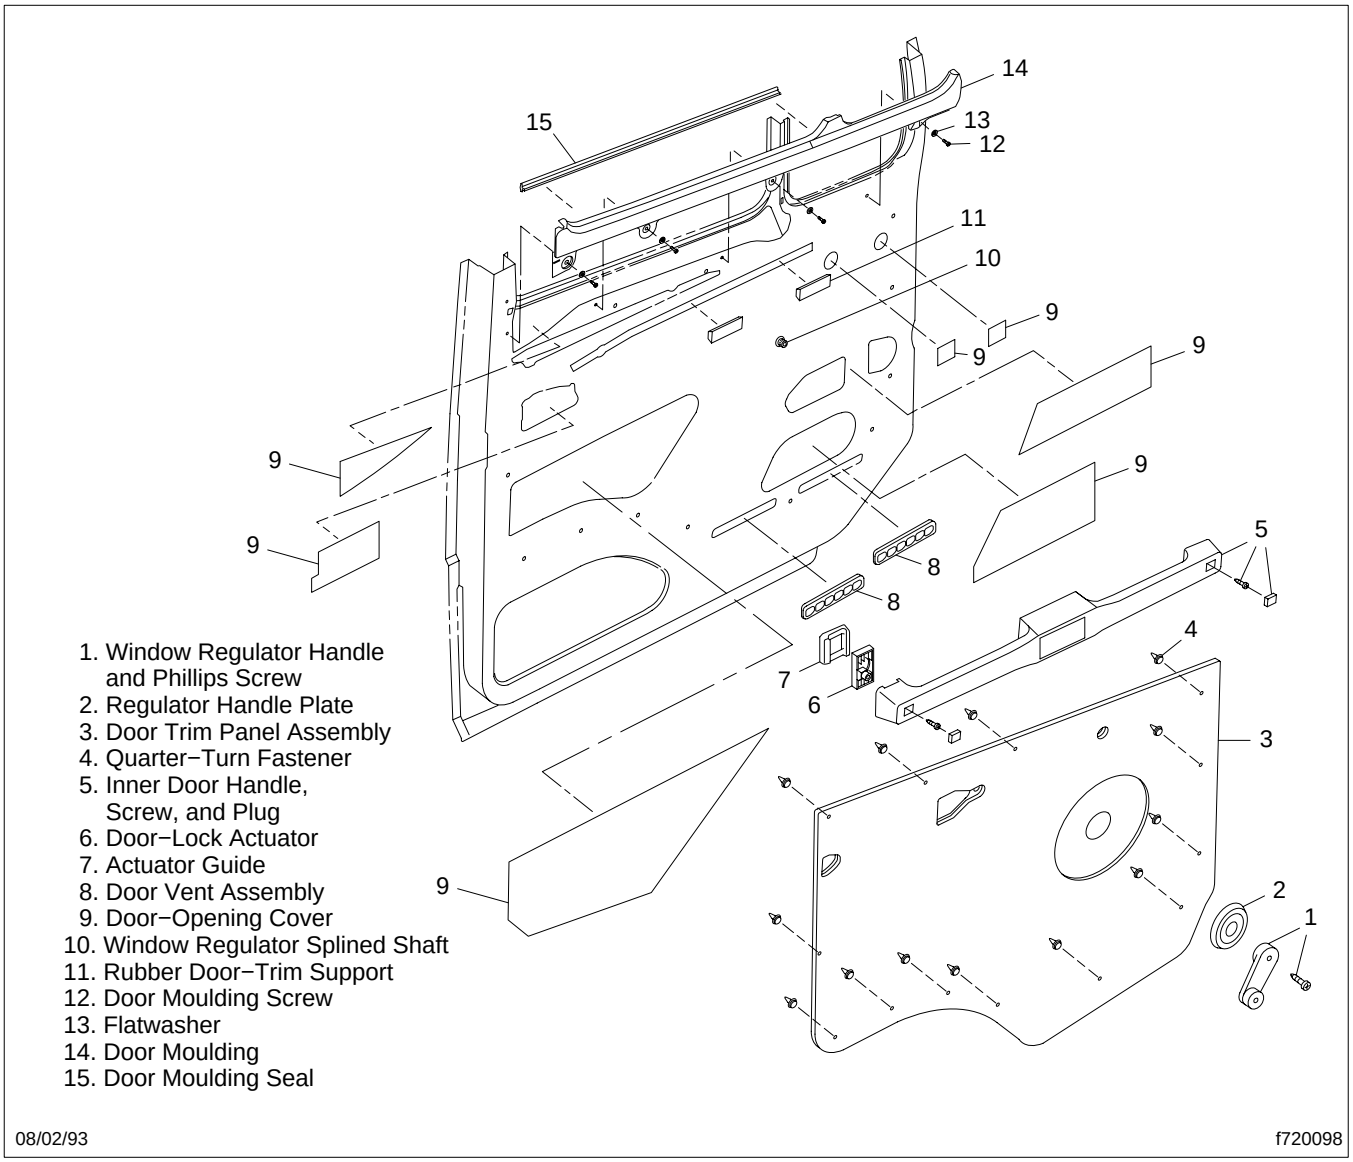

Fig. 1

link lever. **See Fig. 3 .** Hold them in place while installing the inner door handle.

4.2 While holding the inner door handle assembly in place, install and tighten the three screws.

4.3 Press the two door handle plugs into the ends of the inner door handle assembly.

Interior Door Trim Removal and Installation

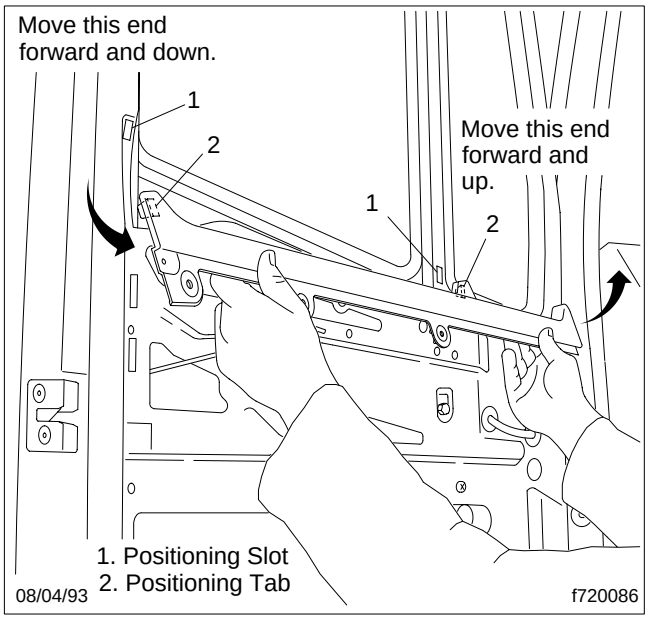

Fig. 7

Fixed Window Replacement

General Information

No special tools are needed to remove and install the glass. A thin, flat tool, such as a putty knife, can be used if a special corkscrew instrument (utilized in major body shops for window glass replacement) isn't available.

⚠ WARNING

WARNING: Use care when working around or handling glass. Wear protective gloves to eliminate the possibility of personal injury resulting from accidentally breaking or splintering the glass.

When a broken window is being replaced, it is very important that the cause of glass breakage be found, and the condition corrected before a new window is installed. If not removed, a small obstruction or high spot somewhere around the window opening may break the replacement glass, especially when it is exposed to high winds, pressure, temperature extremes, and vehicle motion.

Wing Window Replacement

(Refer to Fig. 1)

1. Remove the inner door handle assembly, window regulator handle, door trim panel assembly, and the door moulding and door moulding seal; **refer to Subject 130.**
2. Wear heavy protective gloves to prevent cutting your hands while removing all of the shattered glass from the weather seal. Using a putty knife, lift up the inside lip of the weather seal and pry it over the inner door-panel flange. If the weather seal will be re-used, take care not to damage it with the putty knife.
3. Check for high spots or obstructions in the window opening flange and the weather seal. Correct any areas on the window opening that need to be fixed. Inspect the weather seal for damage or deterioration; replace it if needed.

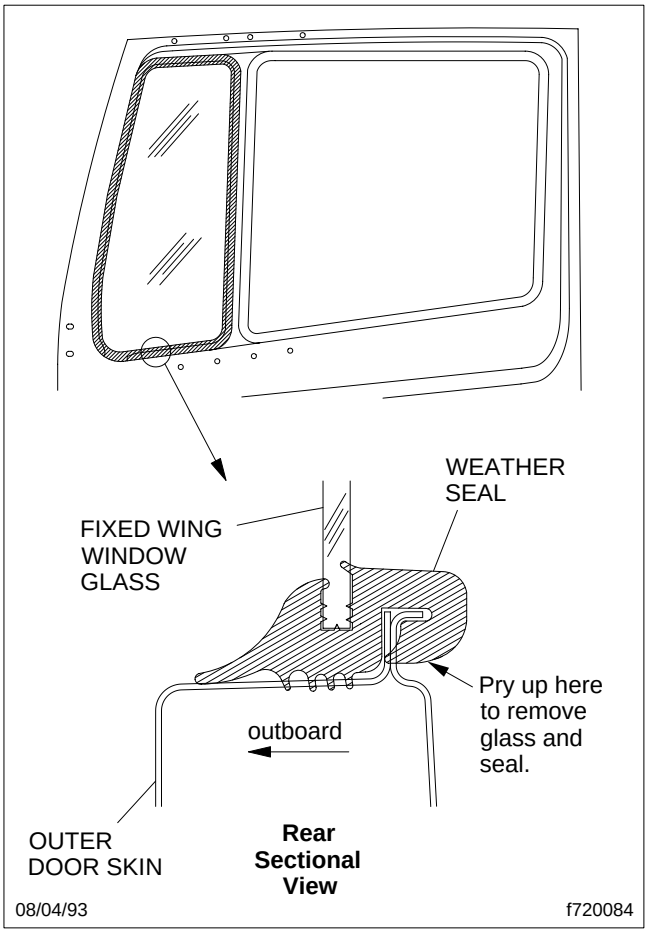

Fig. 1

⚠ CAUTION

CAUTION: When handling the new window glass, use care not to nick or splinter the edges; chipped edges could cause future breaks.

4. Using soap and water, lubricate the weather seal, then install the weather seal on the new window glass, beginning at the bottom, and ending at the upper front corner. **See Fig. 2 .**
5. Place the assembled glass and weather seal in the window opening, from the outside. With another person lightly pushing in on the glass, use a putty knife to pry the weather seal lip over the window opening flange. Begin with the upper edge, and continue down both sides, across the bottom to the lower front corner. **See Fig. 3 .**

Fixed Window Replacement

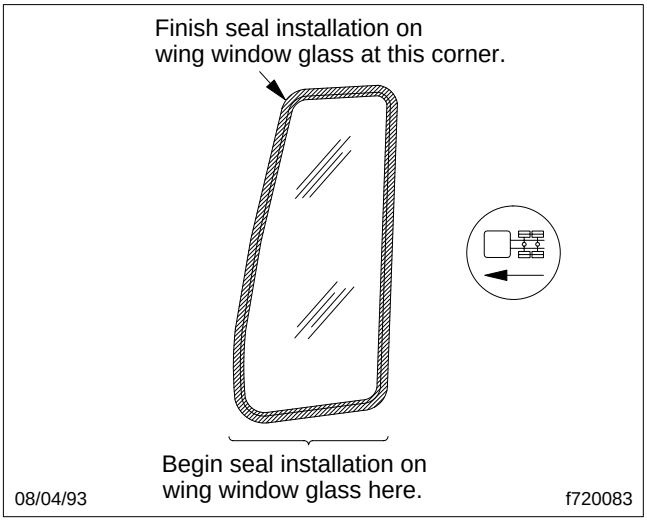

Fig. 2

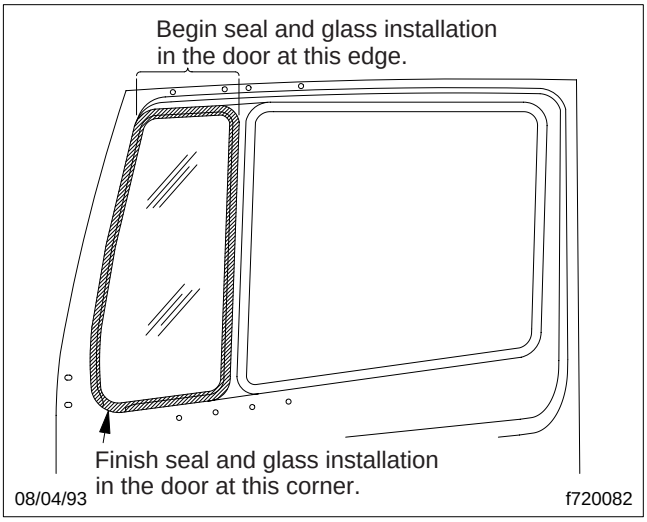

Fig. 3

IMPORTANT: To prevent cab water leaks, the weather seal should lie flat against the glass and the inner and outer door panels, and should not crease at any point, especially around the corners. Reinstall the window if the weather seal creases.

6. Install the inner door handle assembly, window regulator handle, door trim panel assembly, and the door moulding and door moulding seal; **refer to Subject 130.**

Roll-Up Window Removal and Installation

Removal (Refer to Fig. 1)

1. Remove the inner door handle assembly, window regulator handle, door trim panel assembly, and the door moulding and door moulding seal; **refer to Subject 130.**
2. Lower the roll-up window. Loosen the six screws in the window-channel seal. **See Fig. 2 .** Use needle-nose pliers to remove the screws, and be careful to keep them from falling down the window cavity.
3. Remove the two hexbolts attaching the channel to the lower portion of the inner door panel. **See Fig. 3.**
4. Pull the upper portion of the channel toward the inside until it is clear of the top of the door frame.

CAUTION

CAUTION: Failure to wear rubber gripper gloves while removing the window glass from the door

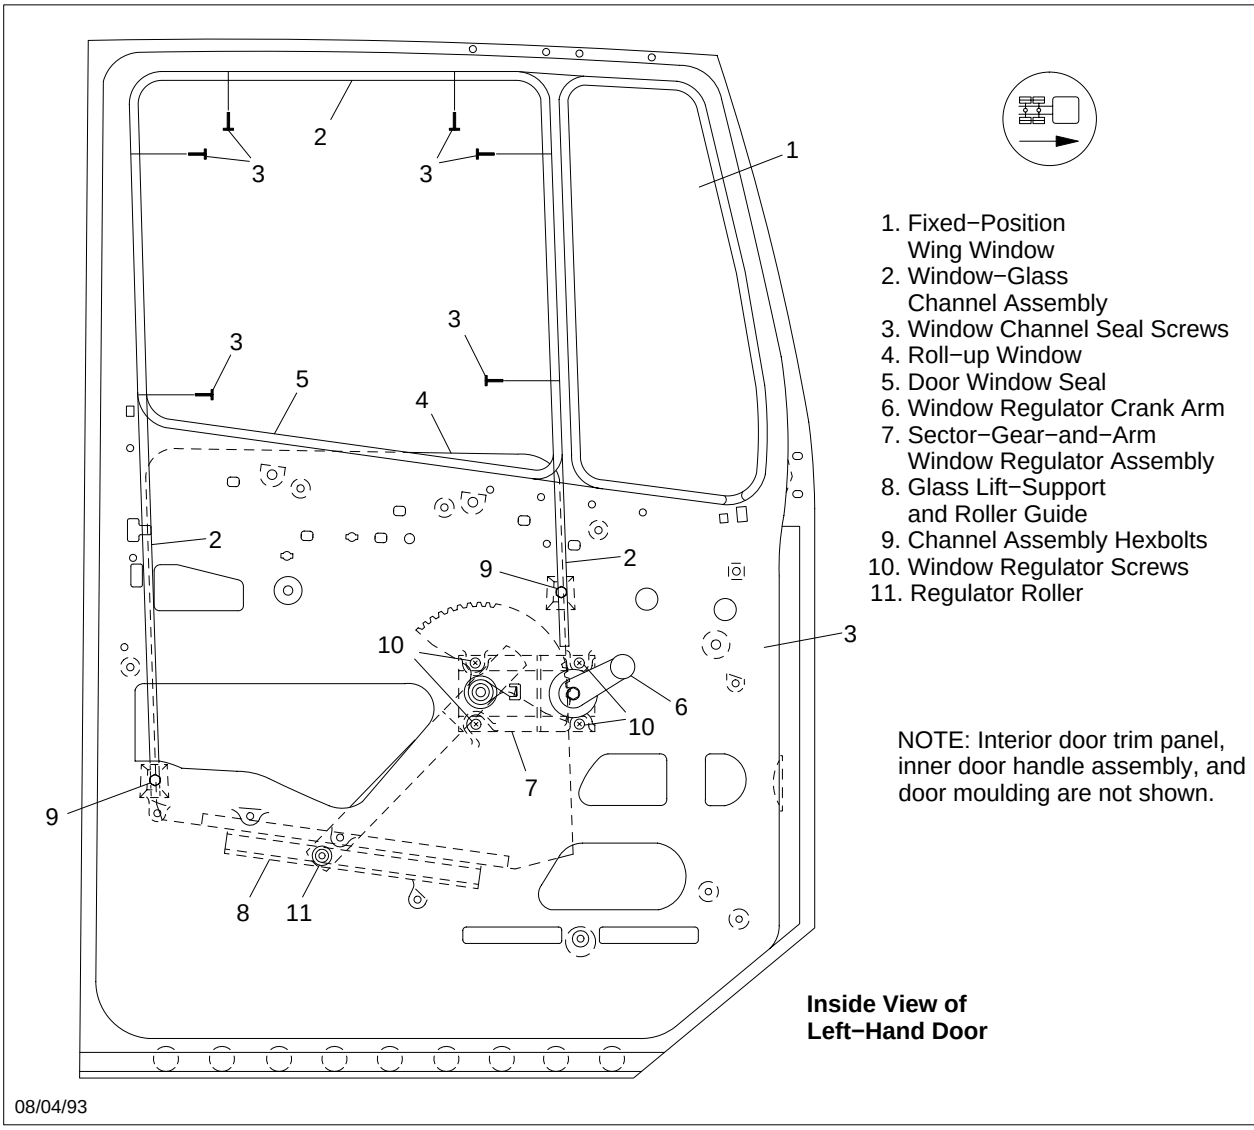

Fig. 1

Roll-Up Window Removal and Installation

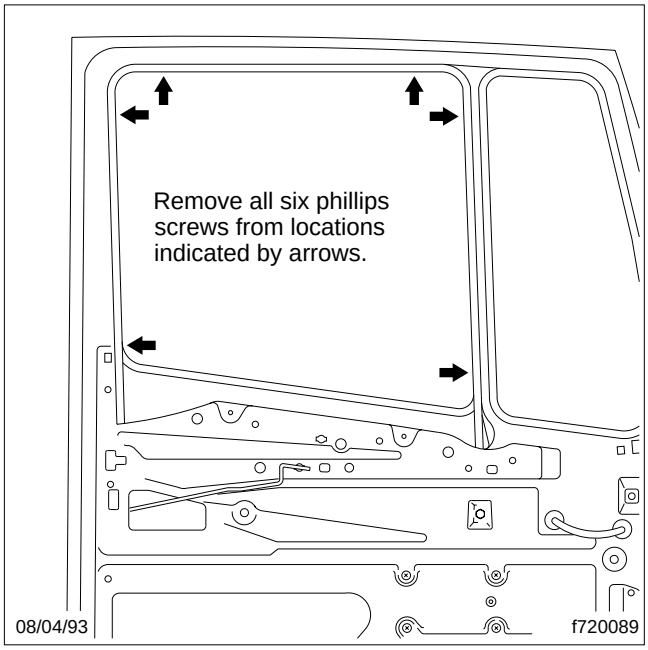

Fig. 2

could result in the glass slipping out of your hands and breaking.

IMPORTANT: Wear rubber gripper gloves when removing the window glass. Usually, service operations performed on the door will be done while the door is in a vertical position (that is, attached to the vehicle). Because of this, you will need a secure grip when handling the glass.

5. Place the window regulator handle on the splined shaft, and raise the window in the channel. Grasp the glass securely, and pull it up and in while cranking the window glass and channel out of the door. **See Fig. 4 .** Stop cranking when the window regulator roller reaches the end of the glass-lift support roller guide.
6. Carefully remove the glass and channel assembly. Leave the regulator roller arm in a vertical position.
7. Remove the window seal by pulling it off of the window opening flange.

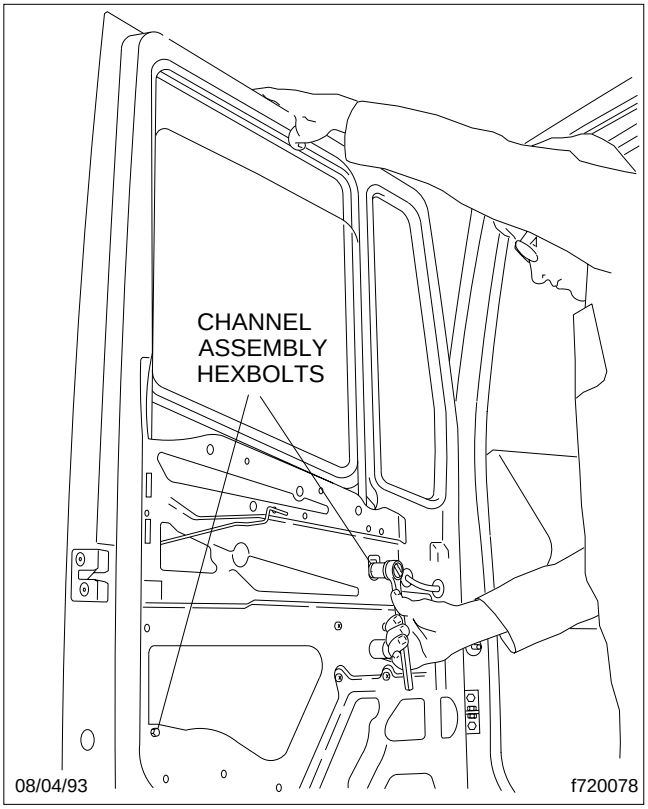

Fig. 3

Installation (Refer to Fig. 1)

1. Inspect the window channel seal, door moulding seal, and window seal for deterioration or damage; replace them if needed.
2. Install the window seal **as shown in Fig. 5 ,** by working it onto the flange of the window opening so its seal brush is at the bottom of the opening.

⚠ CAUTION

CAUTION: Incorrect positioning of the cushion in the glass-lift support can cause the glass to contact the metal, which may crack the glass.

3. Check the position of the window glass cushion in the glass-lift support. **See Fig. 6 .** The cushion must be centered in the support, with equal lengths of cushion extending beyond the ends of the support.

Roll-Up Window Removal and Installation

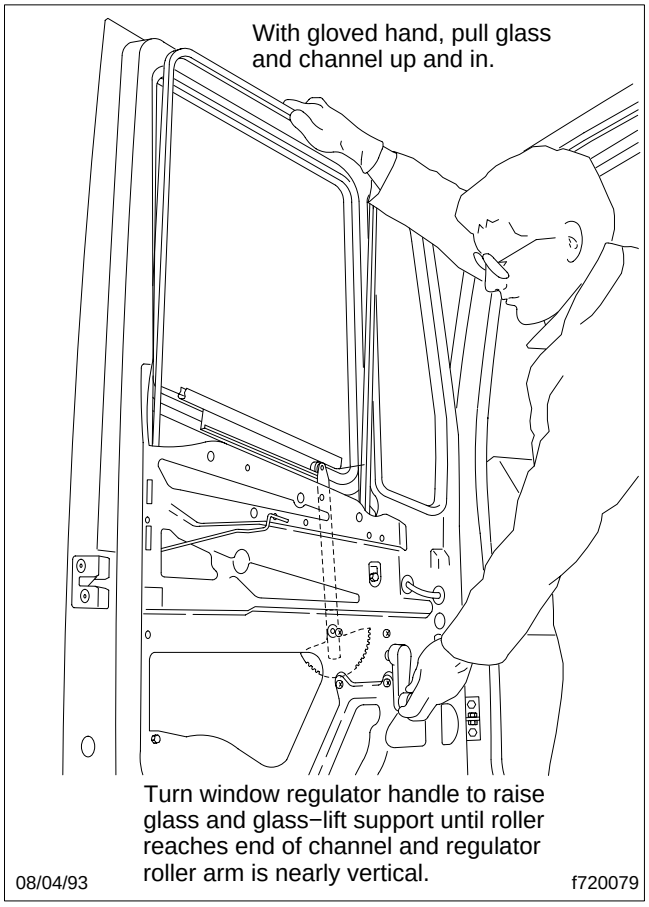

Fig. 4

Then check the position of the glass-lift support on the window glass. **See Fig. 6 .** The lowest corner of the support roller guide must be 141.0 mm (5-9/16 in) back from the lower front corner of the window glass.

4. Clean and lubricate the window regulator roller and the roller guide on the glass-lift support.
5. Place the regulator roller arm in a vertical position. Loosen the four regulator assembly mounting screws. **See Fig. 7 .**

IMPORTANT: Wear rubber gripper gloves when installing the window glass. Usually, service operations performed on the door will be done while the door is in a vertical position (that is, attached to the vehicle). Because of this, you will need a secure grip when handling the glass.

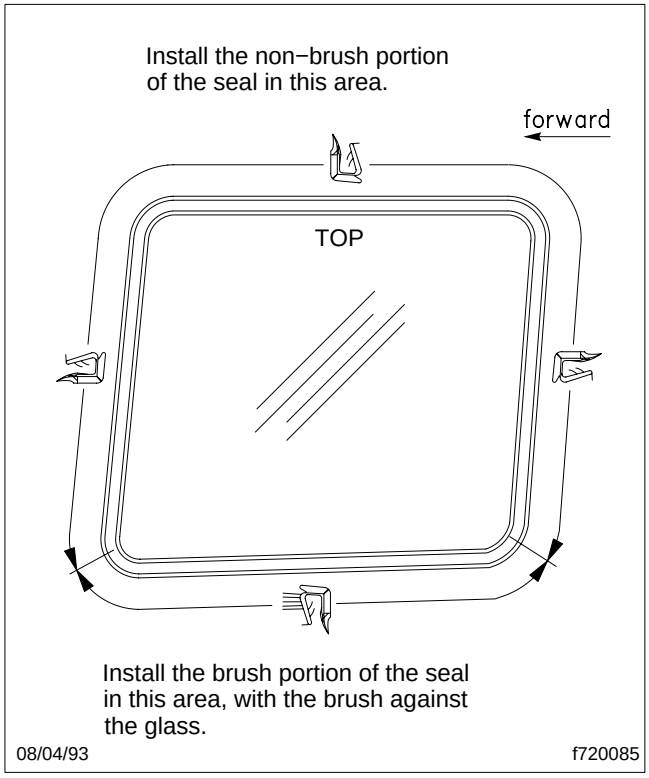

Fig. 5

CAUTION

CAUTION: Failure to wear rubber gripper gloves while installing the window glass in the door could result in the glass slipping out of your hands and breaking.

6. Grasp the glass securely, and lower the window glass and channel assembly into the door. Continue to lower the assembly until the regulator roller can be installed in the roller guide of the glass-lift support.
7. Place the regulator handle on the splined shaft, and slowly crank the glass down into the channel. Push the upper portion of the channel firmly into the window opening until it seats.
8. Install the two hexbolts attaching the channel to the lower portion of the inner door panel; don't fully tighten them at this time. **See Fig. 3 .**

   Install and tighten the six screws in the upper channel seal. **See Fig. 2.** The screw heads must not stick out into the channel. Fully tighten the

Roll-Up Window Removal and Installation

regulator screws, then tighten the two channel hexbolts 18 N·m (13 lbf·ft).

NOTE: Roll the window up and down a couple of times before fully tightening the channel screws and window regulator screws. This will help to align the window in the tracks.

9. Install the inner door handle assembly, window regulator handle, door trim panel assembly, and the door moulding and door moulding seal; **refer to Subject 130.**

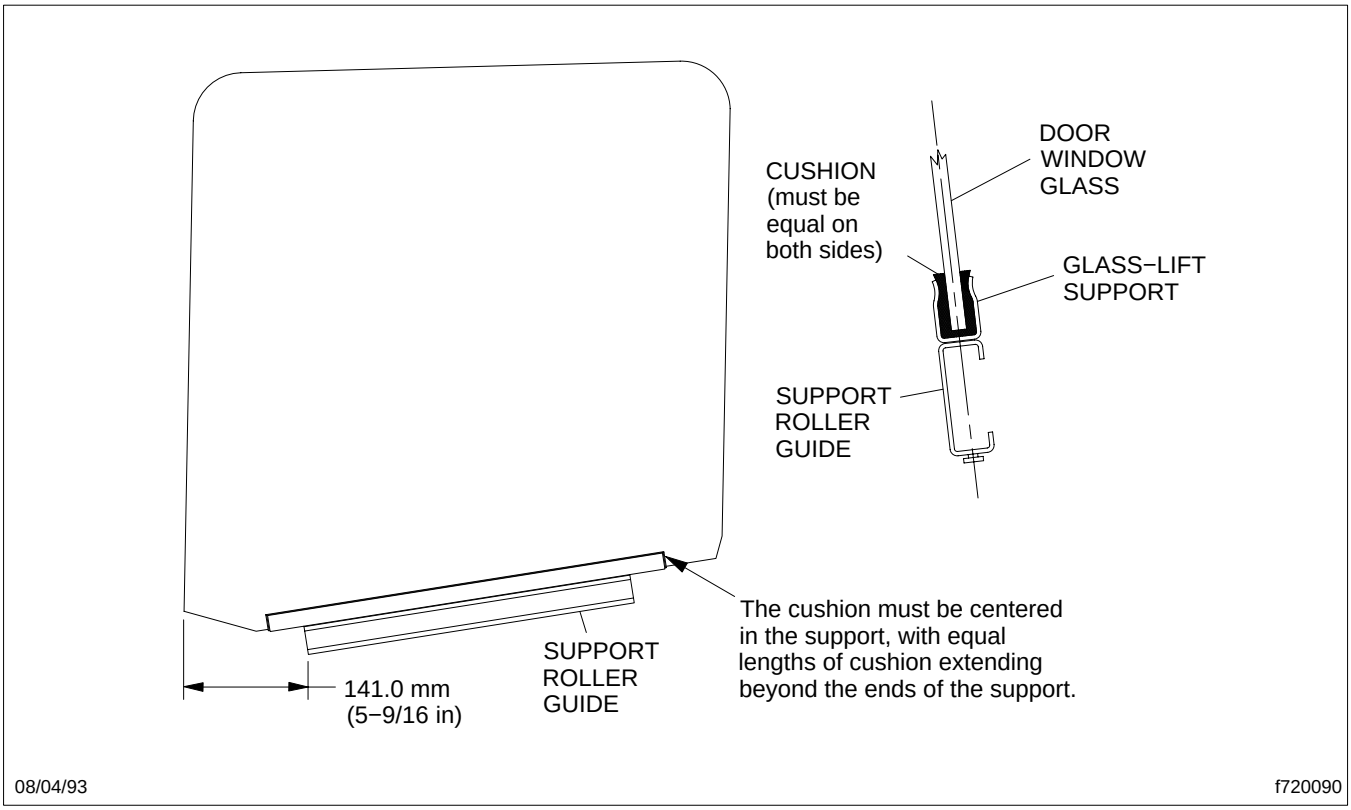

Fig. 6

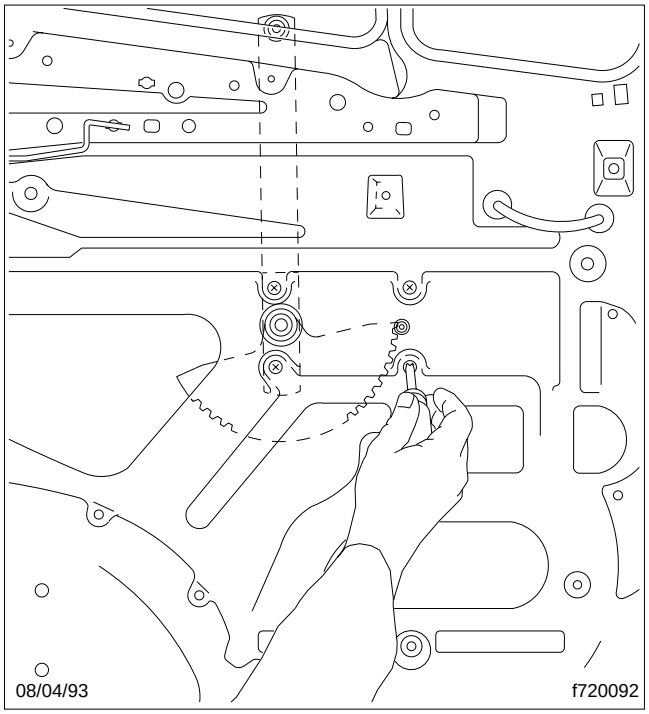
Roll-Up Window Removal and Installation



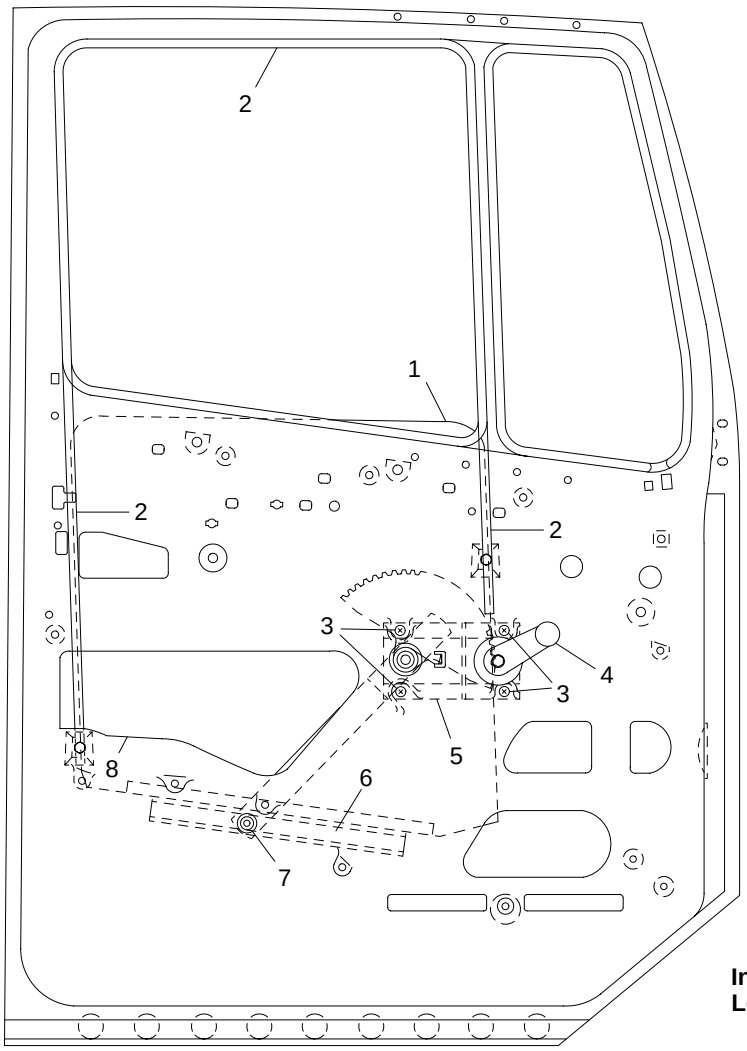


Fig. 7

Regulator Replacement

(Refer to Fig. 1)

1. Remove the roll-up window; **refer to Subject 150.**
2. Leave the regulator roller arm in a vertical position. Remove the four screws that attach the window regulator to the inner door panel. Remove the window regulator.
3. Lubricate the roller of the new window regulator.
4. Place the regulator roller arm in a vertical position, and align the regulator with the screw holes in the inner door panel while installing the four screws. Don't fully tighten the screws at this time.
5. Install the roll-up window; **refer to Subject 150.**

Fig. 1

Regulator Replacement

1. Secure the closed window to the top of the door frame using several pieces of duct tape. See **Fig. 1**.

1. Duct Tape

Fig. 1, Window Secured to Door Frame

2. Remove the inner door handle.

   2.1 Using a small hook, remove the door handle plug from the door handle. See **Fig. 2** .

   2.2 Remove the three screws that attach the door handle to the door.

   2.3 Mark the cable assemblies and switches in the door handle for assembly reference.

   2.4 Disconnect the cable assemblies from the door handle, and remove the door handle.

3. Pull straight out on the door-lock actuator and actuator guide to free the door-lock link lever from the pin on the inner door-latch plate. See **Fig. 3**.

4. Remove the inner door trim panel.

   4.1 Gently insert a straight-blade screwdriver under a corner of the door trim panel, and lift the panel to pull the first quarter-turn fastener out of the door. See **Fig. 4**. Use care not to damage the door trim panel.

Power Window Regulator Replacement

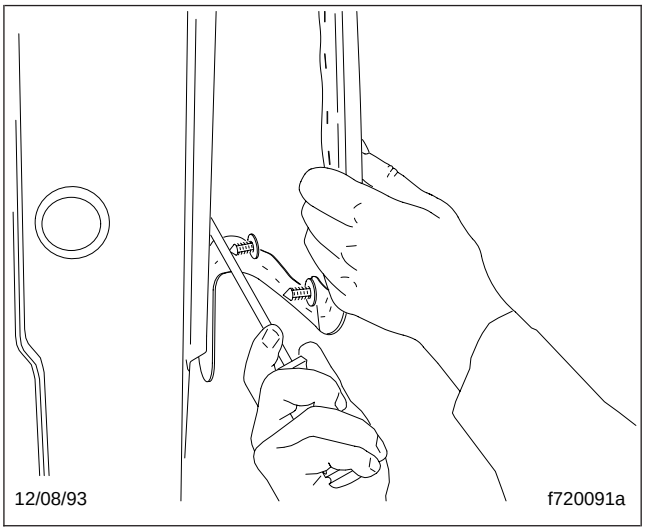

Fig. 4, Removing the Door Trim Panel

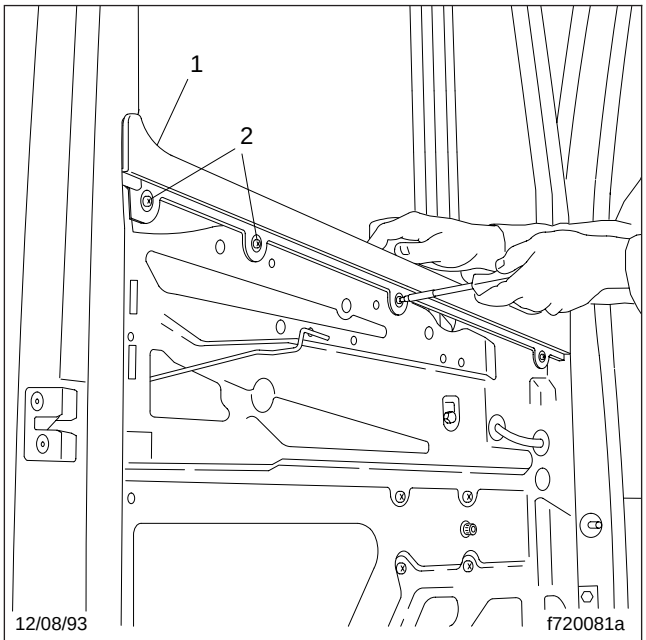
4.2 Working around the edge of the panel, pull out each of the quarter-turn fasteners one at a time. If any of the quarter-turn fasteners are damaged, replace them by inserting the head of the new fastener in the backing-board hole, and twist it a quarter turn.

5. Remove the door moulding.

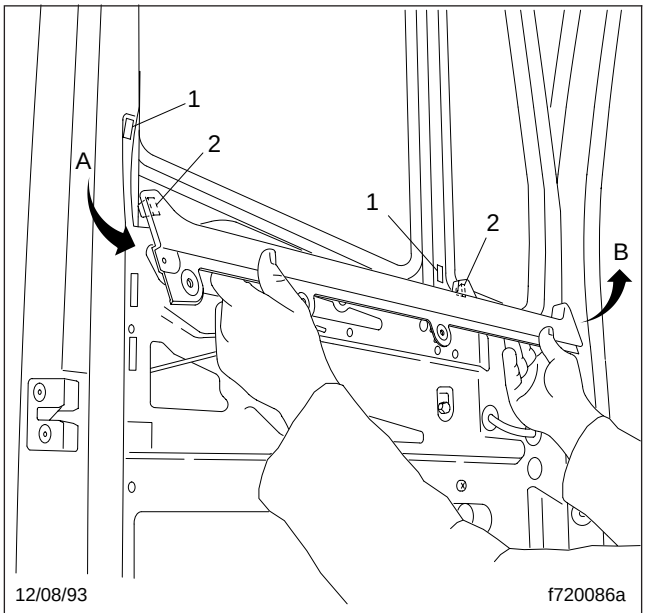
5.1 Remove the four screws and flatwashers that attach the door moulding to the door. See **Fig. 5**.



5.2 Remove the door moulding as shown in **Fig. 6**. To prevent damaging the two positioning tabs, turn the rear of the moulding slightly downward, and the front slightly upward, while sliding it forward and off the door.

6. Peel the plastic covering off of the access cutout at the rear of the door. See **Fig. 7**.

7. Remove the regulator.



7.1 Remove the four screws that attach the regulator to the door. See **Fig. 7**.

7.2 Remove the plastic fasteners that attach the lower edge of the window to the channel bracket. See **Fig. 8**. Pull the channel bracket and the cushion inside the channel bracket off the window.

1. Door Moulding
2. Screws and Flatwashers

Fig. 7, Rear Access Cutout

1. Plastic Fastener
2. Channel Bracket
3. Regulator Bracket
4. Screws

Fig. 8, Channel Bracket

7.3 Pull the channel bracket up until the bracket at the top of the regulator is above the lower window frame. Remove the two screws that attach the regulator bracket to the channel bracket. See **Fig. 8**.

7.4 Pull the regulator up until you are able to disconnect the cable assembly from the regulator. Disconnect the cable assembly and remove the regulator.

8. Install the new regulator.

8.1 Place the new regulator inside the door through the access cutout, and attach the cable assembly to the regulator.

8.2 Attach the bracket at the top of the regulator to the channel bracket using two screws. Tighten the screws 30 to 35 lbf·in (339 to 395 N·cm).

8.3 Place the cushion along the lower edge of the window; then place the channel bracket over the cushion. Attach the channel bracket to the window using plastic fasteners.

8.4 Attach the upper bracket of the regulator to the door using two screws. Tighten the screws 30 to 35 lbf·in (339 to 395 N·cm).

8.5 Attach the lower bracket of the regulator to the door using two screws. Tighten the screws 30 to 35 lbf·in (339 to 395 N·cm).

9. Press the plastic coverings back over the access cutout on the inner door.

10. Install the door moulding.

10.1 Attach the door moulding to the door. To prevent damaging the two positioning tabs, turn the rear of the moulding upward, and the front slightly downward while sliding it backward and on to the door.

10.2 Install and tighten the four flatwashers and screws that attach the door moulding to the door.

11. Feed the cable assemblies through the hole in the upper, right portion of the door trim panel.

12. Attach the door trim panel to the door only at the top of the panel.

13. Connect the cable assemblies to the switches in the door handle.

14. Install the door handle.

14.1 Install the screws in the two holes toward the front of the door handle. Tighten the screws 30 to 35 lbf·in (339 to 395 N·cm).

14.2 Install the door-lock actuator and actuator guide by placing the door-lock link lever over the pin on the inner door-latch plate. See **Fig. 3**. Hold the door-lock actuator and actuator guide in place while install-

Power Window Regulator Replacement

ing the third screw in the door handle. Tighten the screw 30 to 35 lbf·in (339 to 395 N·cm).

14.3 Press the door handle plug in to the door handle.

15. Attach the sides and lower portion of the door trim panel to the door by pushing in each of the fasteners one at a time.

Specifications

Description	Grade	Size	Torque N·m (lbf·ft)

Hinge to Door Bolt	8.8	M8	18 (13)
Window-Channel to Inner-Door-Panel Bolt	8.8	M8	18 (13)

Table 1, Fastener Torques

General Information

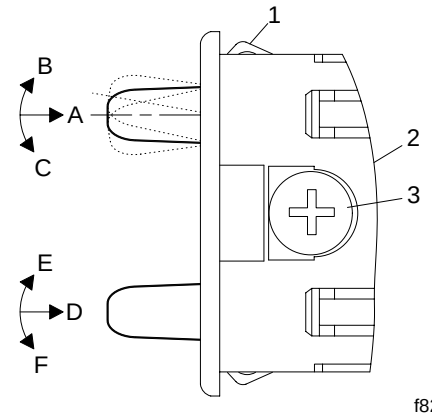
VEHICLES WITHOUT INTERMITTENT WIPERS

The windshield wiper and washer are operated by rocker switches. The windshield wiper rocker switch has two speeds: low or high. The windshield washer rocker switch will spray wash fluid on the windshield as long as the switch is depressed.

VEHICLES WITH INTERMITTENT WIPERS WITH ROCKER SWITCH AND SLIDER SWITCH CONTROLS

The windshield wiper and washer are operated by a rocker switch and a slider switch. The windshield wiper rocker switch has two speeds: low or high. The intermittent wipers are turned on by moving the slider switch up to select the desired delay interval between 2 and 10 seconds (2 and 22 seconds on early models). The windshield washer is turned on by pushing the slider switch all the way up.

VEHICLES WITH INTERMITTENT WIPERS WITH A DOUBLE-PADDLE SWITCH



The windshield wiper and washer are operated by a double-paddle switch.

The wipers have five cycles: fast, slow, mist, wash, and delay. There are six delay intervals, three seconds, five seconds (default fast), eight seconds, 12 seconds, 17 seconds (default slow), and 23 seconds. For wiper switch operation, see **Fig. 1**.

The top paddle, when pushed in, turns the wipers on or off. When pushed up, the top paddle switches the wipers to high speed; when it is pushed down, it switches them to low speed.

The bottom paddle, when pushed in momentarily (for less than 1/2 second), turns the wipers on mist (one dry cycle at low speed). When pushed in and held in (for at least 1/2 second), the bottom paddle turns on the washers for a minimum of three cycles after release. For more wash cycles, hold the bottom paddle in longer (but it will always cycle three more times after release).

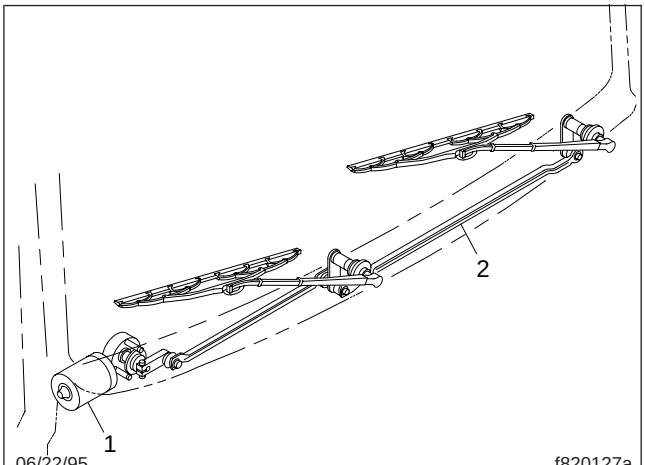
Pushing the bottom paddle up or down controls the delay cycle of the intermittent wipers. If the wipers

10/06/95 f820178

A. Push in to turn wipers on (low speed) or off.
B. Push up for high speed.
C. Push down for low speed.
D. Push in momentarily for mist cycle. Push in and hold for wash cycle.
E. Push up for fast delay. If already in delay, push up for the next faster delay.
F. Push down for slow delay. If already in delay, push down for the next slower delay.

1. Locking Clip
2. Wiper/Washer Switch
3. Light Bulb Screw

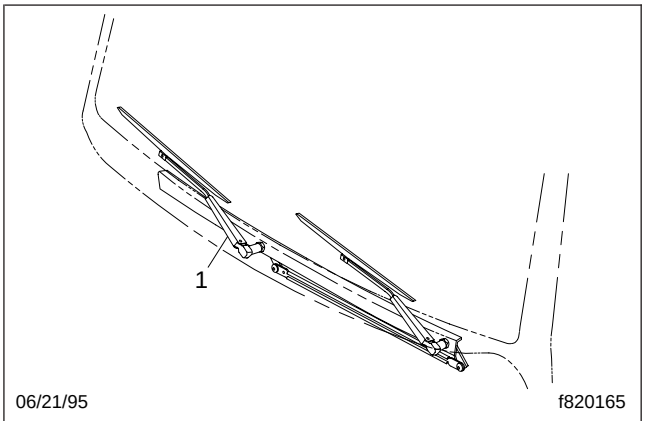
Fig. 1, Wiper/Washer Switch Operation



are not in delay, push up for default fast delay (5 seconds) or down for default slow delay (17 seconds). If the wipers are already in delay, push up for the next fastest delay or push down for the next slowest delay.

A linkage assembly joins both wiper arms to a motor that is mounted under the right-side dash panel inside the cab. See **Fig. 2**.

NOTE: Since January 6, 1995, a redesigned Sprague windshield wiper system is being installed in Business Class models. The new Sprague system has latch-mounted wiper blade arms, a higher operating speed, and slightly longer wiper arms. See **Fig. 3**.



The windshield washer reservoir is located under the cab inside the passenger's side door. See **Fig. 4**. Washer fluid is carried by a tube that runs from the reservoir, along the bottom of the cab, and up the center of each wiper arm; this is known as a wet-arm wiper system. Each tube is attached to a nozzle that is located behind the wiper blade fastening. When the washer pump is turned on, the wash spray at the

General Information

1. Wiper Motor
2. Wiper Linkage Assembly

Fig. 2, Wiper System with Nut-Attached Wiper Blade Arms (before January 6, 1995)

1. Wiper Linkage Assembly

Fig. 3, Wiper System with Latch-Mounted Wiper Blade Arms (from January 6, 1995)

windshield follows the same arc as the wiper arm. There are four jets of spray per wiper arm on the older system, and two jets per wiper arm on the newer system.

NOTE: Repair of all electrical parts in the wiper and washer system is by replacement. The parts of the wiper linkage and bracket assembly can be replaced.

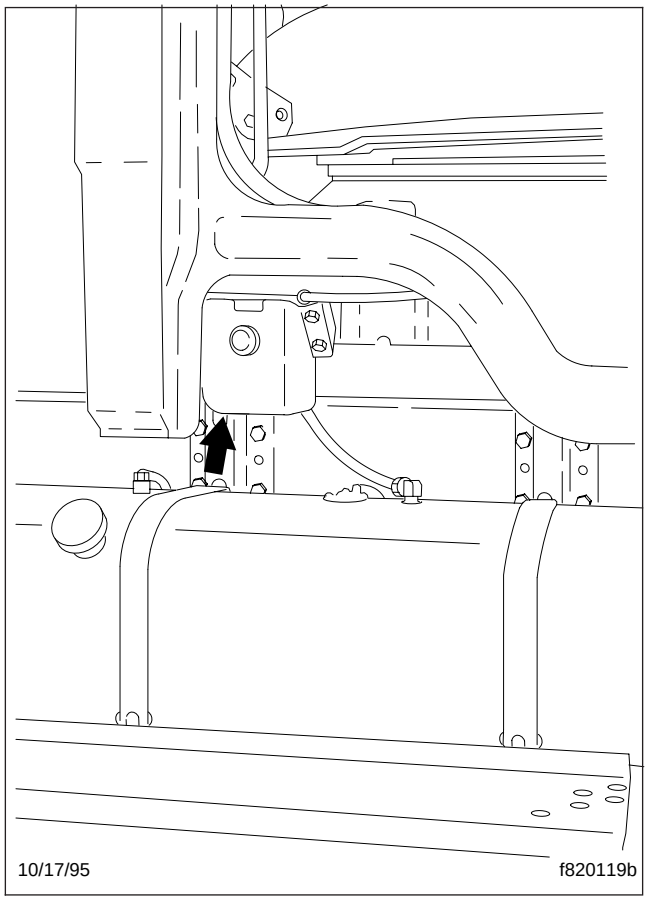


Fig. 4, Windshield Washer Reservoir

On both left-hand drive and right-hand drive vehicles, the wiper motor is installed on the passenger's side. Service procedures are the same for both types.

Wiper Motor Removal and Installation for Systems with Nut-Attached Wiper Blade Arm

Removal

1. Disconnect the batteries.
2. Remove the passenger's side dash panel to gain access to the wiper motor.
   - 2.1 Pull away the extruded rubber trim from the top of the panel.
   - 2.2 Remove the two retaining screws at the top of the panel.
   - 2.3 Lift the panel from the dash.
3. Unplug the multipin connector from the wiper motor harness.
4. Remove the plastic button plug from the access space, located on the passenger's side of the water trough, on the engine side of the firewall.
5. Loosen the pinch-bolt nut at the end of the crank; then unseat the crank from the wiper motor shaft. **See Fig. 1 .**
6. Remove the three nuts from the wiper motor mounting studs.
7. From inside the cab remove the wiper motor.

NOTE: The wiper motor is not a serviceable part.

Installation

1. Position the new wiper motor on the firewall.
2. Install the wiper motor mounting nuts. Tighten them 84 lbf·in (950 N·cm).
3. Plug the multipin connector into the wiper motor harness.
4. Connect the batteries.
5. Run the wiper motor to the park position.
   - 5.1 Turn the key switch on.
   - 5.2 Turn the wiper motor on momentarily then off. The wiper motor should stop in the park position.
   - 5.3 Turn the key switch off.
6. Install the wiper motor crank pointing to the 3 o'clock position as viewed from the engine side of the firewall. **See Fig. 1 .**
7. Tighten the crank pinch-bolt nut securely. Install the plastic button plug into the access space.
8. Test the wiper motor for correct operation.
9. Install the dash panel and retaining screws.
10. Install the extruded rubber trim on top of the panel.

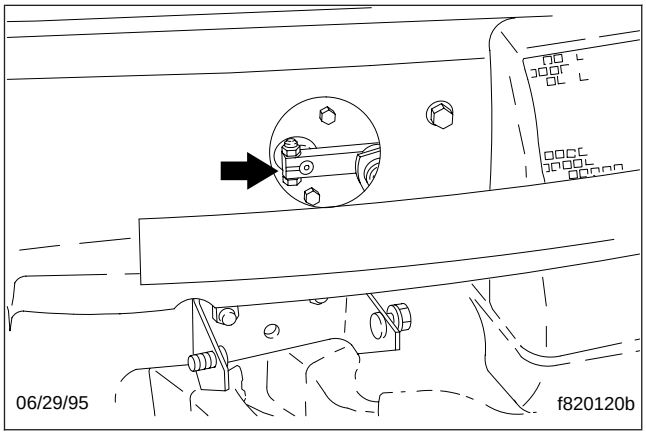

Fig. 1, Pinch Bolt

Wiper Linkage and Support Assembly Removal and Installation for Systems with Nut-Attached Wiper Blade Arm

Removal

1. Lift the wiper arm nut covers for access to the wiper arm nuts.
2. Remove the wiper arm nuts and wiper arms from the splined pivot shafts.

NOTE: Folding the arms out away from the windshield to their over-center position removes the spring tension from the wiper arm hub and eases removal of the wiper arm. **See Fig. 1 .**

3. Remove the wiper arm threaded caps from each pivot arm as shown in **Fig. 2** by turning the caps counterclockwise.
4. Disconnect the wiper washer hose and clamps as necessary to allow removal of the water trough.
5. Remove the cab air intake duct mounting screws. Remove the capscrews and sheet metal screws attaching the water trough to the wiper linkage support bracket and to the firewall. Remove the water trough and cab air duct.
6. Loosen the pinch-bolt nut; then disconnect the wiper motor crank from the wiper motor shaft. **See Fig. 3 .**
7. Remove the capscrews attaching the linkage support bracket to the cowl. **See Fig. 4 .** Remove the wiper linkage assembly. Service as required.

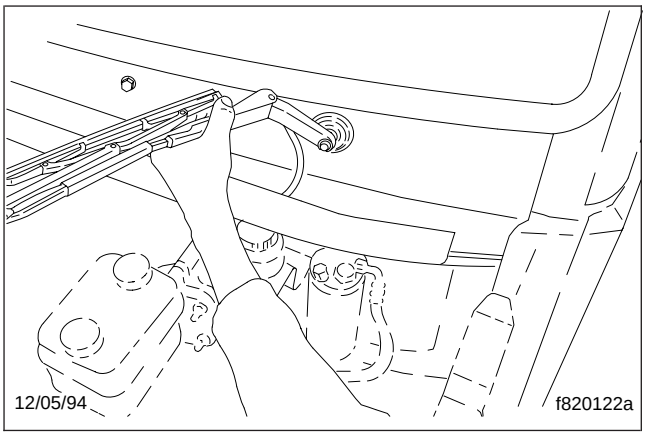

Fig. 1, Wiper Arm Removal

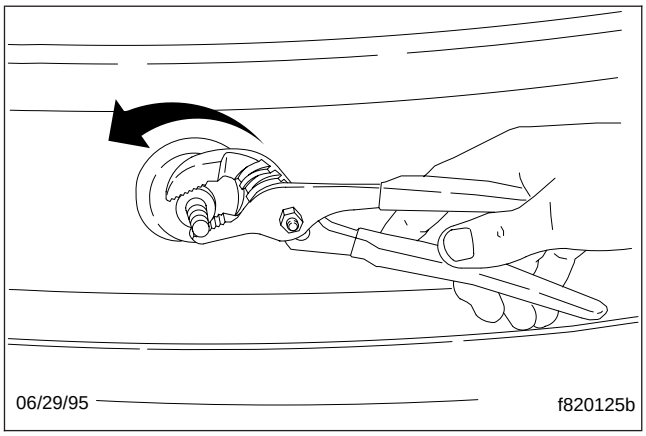

Fig. 2, Turn Caps Counterclockwise

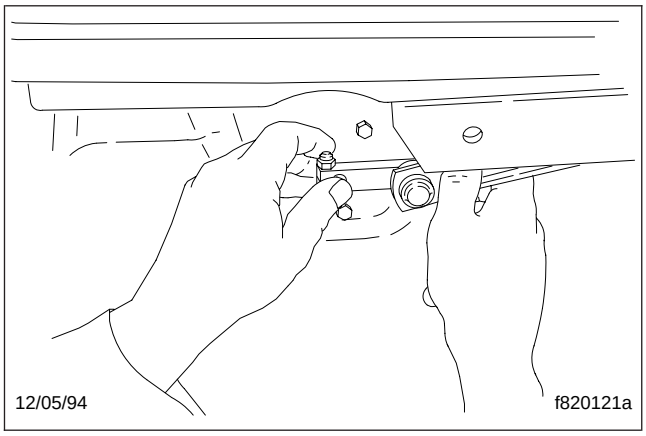

Fig. 3, Disconnect Wiper Motor Crank

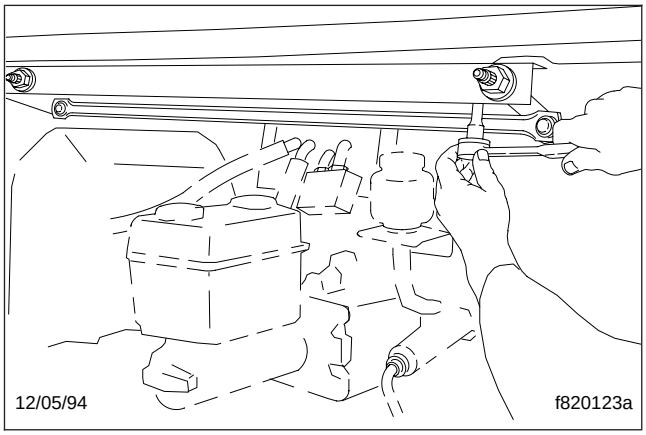

Fig. 4, Capscrew Removal

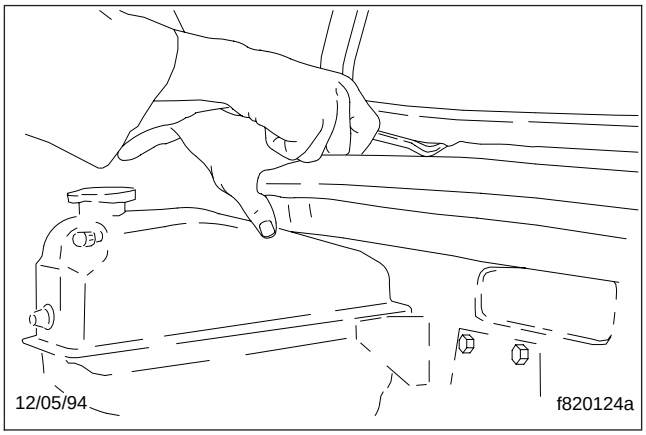
Wiper Linkage and Support Assembly Removal and Installation for Systems with Nut-Attached Wiper Blade Arm

Installation

1. Install the wiper linkage assembly. Tighten the capscrews 16 lbf·ft (21 N·m).
2. Turn the key switch on; then turn the wiper motor on and then off to position motor in the park position. Turn the key switch off.
3. Install the wiper motor crank pointing to the 3 o'clock position as viewed from the engine side of the firewall. **See Fig. 3 .**
4. Install the cab air intake duct and water trough but do not tighten the fasteners at this time.
5. Use a smooth hooked tool as shown in **Fig. 5** to slip the windshield molding over the upper edge of the water trough. Be careful not to rip the molding. Tighten the water trough capscrews 16 lbf·ft (21 N·m). Tighten the cab air intake duct fasteners. Install the sheet metal screws attaching the water trough to the firewall.
6. Install the wiper arm caps on the pivot arms.
7. With the wiper motor still in the park position, install the wiper arms so that the tips of the wiper blades are 45–55 mm (1–3/4 to 2–1/4 in) from the windshield molding. **See Fig. 6.** Tighten the nuts 13 lbf·ft (18 N·m).
8. Place the wiper arm nut covers over the wiper arm nuts.

NOTE: Conduct the following test on wet glass.

9. Run the wipers at the high speed setting to ensure that the arms do not contact the windshield frame at either end of their stroke. Adjust as necessary.



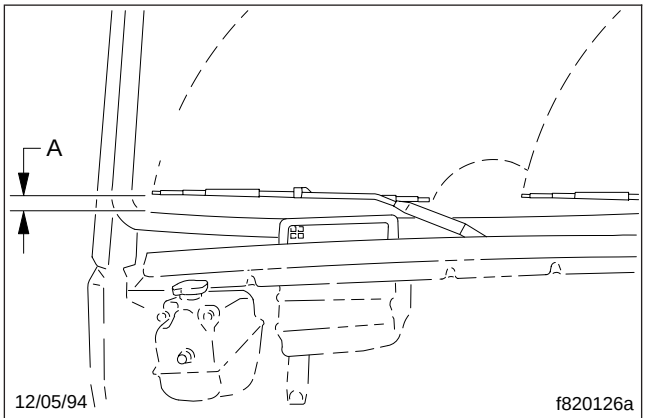


Fig. 5, Installing Windshield Molding

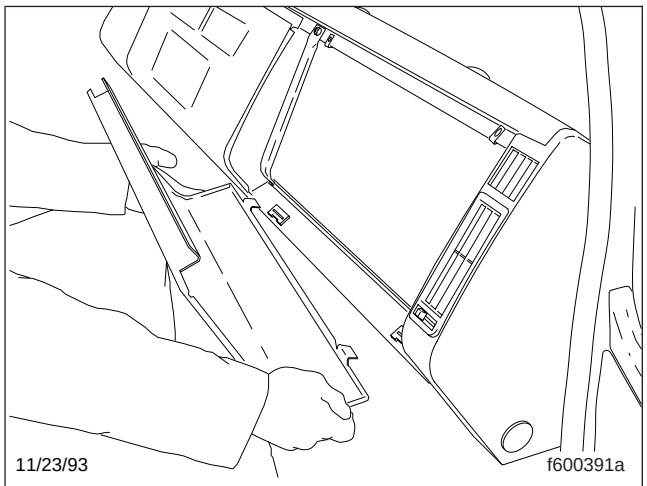
A. 1-3/4" to 2-1/4" (45 to 55 mm)

Fig. 6, Adjusting Wiper Arm Placement

Replacement



NOTE: To avoid losing washer fluid from the reservoir, you can remove the reservoir and empty it before starting this procedure, or you can place a clean bowl under it before pulling out the pump.

1. Disconnect the electrical connections and washer fluid tubing from the washer pump.
2. Unsnap the pump from the grip of the reservoir body and pull it from the reservoir.
3. Install the new pump.
4. Connect the electrical connections and washer fluid tube.
5. Fill the reservoir.
6. Test the operation of the pump.

Wiper Motor Removal and Installation for Systems with Latch-Mounted Wiper Blade Arms

Removal

1. Disconnect the batteries.
2. Remove the passenger's side dash panel (panel D) to gain access to the wiper motor. See **Fig. 1**.

Left-hand drive shown; right-hand drive opposite

Fig. 1, Removing Panel D

   2.1 Pull away the vinyl extrusion trim from the top of the panel.

   2.2 Remove the two mounting screws at the top of the panel.

   2.3 Lift the panel from the dash.

3. Unplug the multipin connector from the wiper motor harness.
4. Remove the plastic button plug from the access space, located on the passenger's side of the air intake panel on the engine side of the frontwall.
5. Remove the motor crank nut at the end of the motor shaft; then unseat the crank from the wiper motor shaft. See **Fig. 2**.
6. Remove the three nuts from the wiper motor mounting studs.
7. From inside the cab remove the wiper motor.

NOTE: The wiper motor is not a serviceable part.

Left-hand drive shown; right-hand drive opposite

Fig. 2, Motor Crank Nut

Installation

1. Position the new wiper motor on the frontwall.
2. Install the wiper motor mounting nuts. Tighten them 84 lbf·in (950 N·cm).
3. Plug the multipin connector into the wiper motor harness.
4. Connect the batteries.
5. Run the wiper motor to the park position.

   5.1 Turn the ignition keyswitch on.

   NOTE: Ensure the batteries are fully charged.

   5.2 Turn the wiper motor on momentarily, then off. The wiper motor should stop in the park position.

   5.3 Turn the ignition keyswitch off.

6. Install the wiper motor crank pointing to the 3 o'clock position as viewed from the engine side of the frontwall. See **Fig. 2**.
7. Tighten the motor crank nut securely 18 lbf·ft (25 N·m). Install the plastic button plug into the access space.
8. Test the wiper motor for correct operation, and position the wiper arms so that the wiper blades are resting horizontally on the windshield.
9. Install dash panel D and tighten the two mounting screws.

Wiper Motor Removal and Installation for Systems with Latch-Mounted Wiper Blade Arms

10. Install the vinyl extrusion trim on top of the panel.

Wiper Linkage and Support Assembly Removal and Installation for Systems with Latch-Mounted Wiper Blade Arms

Removal

1. Unlatch the wiper arm assembly from the splined pivot shafts.

NOTE: Moving the wiper arms into an unlatched position eases removal of the wiper arms. **See Fig. 1 .**

2. Remove the weather covers from each pivot shaft by turning the weather covers counterclockwise.
3. Disconnect the wiper washer hose and clamps as necessary to allow removal of the air intake panel.
4. Remove the cab air intake duct mounting screws, the capscrews, and the sheet metal screws attaching the air intake panel to the wiper linkage support bracket and to the firewall. Remove the air intake panel and cab air duct.
5. Remove the motor crank nut; then pry the wiper motor crank from the wiper motor shaft. **See Fig. 2 .**
6. Remove the hex capscrews attaching the linkage support bracket to the cowl. **See Fig. 3 .** Remove the wiper linkage assembly. Service as required.

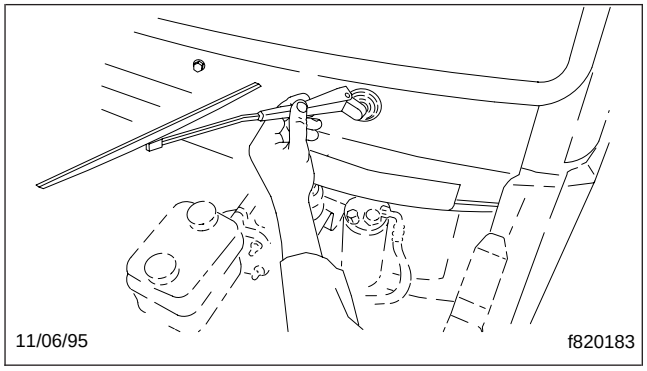


Fig. 1, Wiper Arm Removal

Installation

1. Install the wiper linkage assembly. Tighten the capscrews 16 lbf·ft (21 N·m). **See Fig. 3.**
2. Turn the key switch on; then turn the wiper motor on and then off to position motor in the park position. Turn the key switch off.

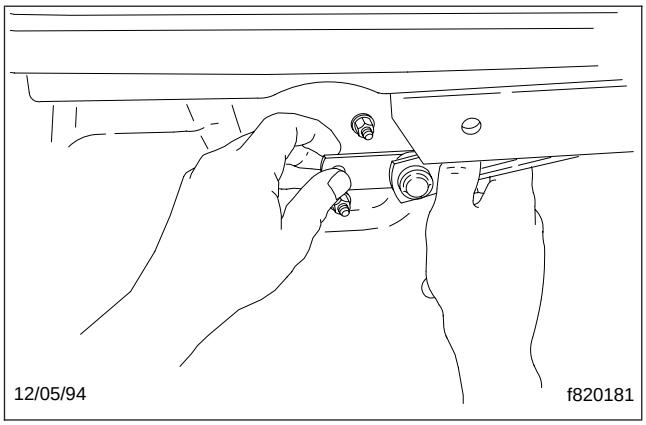

Fig. 2, Disconnect Wiper Motor Crank

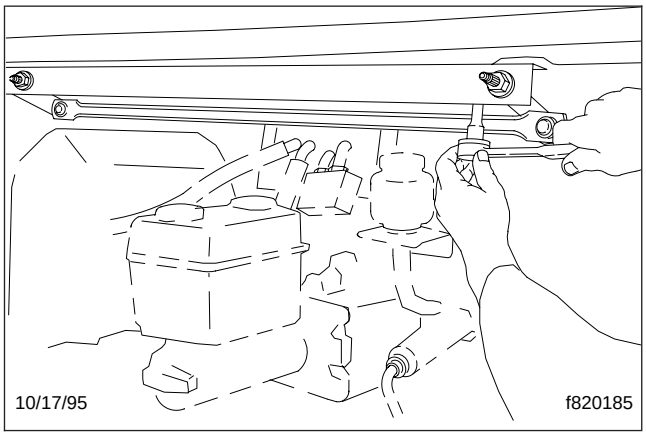

Fig. 3, Capscrew Removal

NOTE: Ensure the battery is fully charged.

3. Install the wiper motor crank pointing to the 3 o'clock position as viewed from the engine side of the firewall. **See Fig. 2 .** Tighten the motor crank nut 18 lbf·ft (25 N·m).
4. Install the cab air intake duct and air intake panel but do not tighten the fasteners at this time.
5. Use a smooth hooked tool as shown in **Fig. 4** to slip the windshield molding over the upper edge of the air intake panel. Be careful not to rip the molding. Tighten the air intake panel capscrews 16 lbf·ft (21 N·m). Tighten the cab air intake duct fasteners. Install the sheet metal screws attaching the air intake panel to the firewall.
6. Install the weather covers on the pivot shafts.

Wiper Linkage and Support Assembly Removal and Installation for Systems with Latch-Mounted Wiper Blade Arms

7. With the wiper motor still in the park position, install the wiper arms so that the wiper blades are resting horizonally on the windshield.

NOTE: Conduct the following test on wet glass.

8. Run the wipers at the high speed setting to ensure that the blades do not contact the windshield moulding or gasket at either end of their stroke. Adjust as necessary.

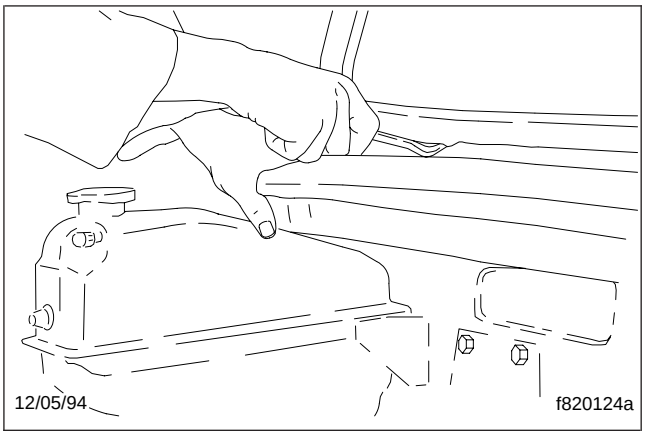

Fig. 4, Installing Windshield Molding

Troubleshooting Tables

VEHICLES WITHOUT INTERMITTENT WIPERS OR VEHICLES WITH INTERMITTENT WIPERS WITH ROCKER SWITCH AND SLIDER SWITCH CONTROLS

Problem—Wipers and Washers Do Not Operate

Problem—Wipers and Washers Do Not Operate	
Possible Cause	**Remedy**
Fuse is blown.	Check fuse. Replace if blown.
Open circuit in power supply (circuits 315 and 305).	With key on, check voltage at wiper and washer switches (circuit 315). If voltage reading is zero, take voltage readings along circuits 315 and 305 back towards ignition switch until open is located. Repair as necessary.

Problem—Washer Motor Inoperable

Problem—Washer Motor Inoperable	
Possible Cause	**Remedy**
Open circuit in switch or between switch and motor.	Make sure there is battery voltage at switch (circuit 315). At motor, check circuit 320 with washer switch closed. Battery voltage should be present. If voltage is not present, locate and repair open circuit or faulty switch.
Faulty motor.	Make sure motor has proper ground; then apply battery voltage to motor (circuit 320). If motor does not work, replace motor.

Problem—Fuses Blow Repeatedly

Problem—Fuses Blow Repeatedly	
Possible Cause	**Remedy**
Incorrect fuse.	Make sure correct fuse is being used. See **Group 54** for circuit breaker and fuse table.
Wiring or switch shorted to ground.	Remove fuse. Unplug wiper motor harness and washer motor power wire. At fuse holder, check continuity between circuit 315 and ground. Check with wiper switch in OFF, LOW and HIGH positions, and with washer switch in OFF and ON positions. Ohmmeter should read infinite in all switch positions. If ohmmeter shows continuity in any switch position, replace grounded component.
Washer motor shorted.	If the above tests reveal no problem, and if fuse blows only when using washers, replace washer motor.
Bind in linkage causing drag on wiper motor.	Disconnect wiper crank from wiper motor. Swing wiper blades away from windshield to their over-center position. Operate wiper linkage by hand. Linkage should operate freely without binding or drag. Repair or replace as necessary.
Wiper motor shorted.	Make sure motor has proper ground. If the above tests reveal no problem, and fuse still blows, replace wiper motor.

Troubleshooting

Problem—Wiper Motor Does Not Work On Low Speed

Problem—Wiper Motor Does Not Work On Low Speed	
Possible Cause	**Remedy**
Open circuit in switch or between switch and motor, or faulty motor.	At motor, check circuit 316 with switch on low speed. Battery voltage should be present. If voltage is not present, locate and repair open circuit or faulty switch. If voltage is present, replace motor.

Problem— Wiper Motor Does Not Work On High Speed

Problem—Wiper Motor Does Not Work On High Speed	
Possible Cause	**Remedy**
Open circuit in switch or between switch and motor, or faulty motor.	At motor, check circuit 318 with switch on high speed. Battery voltage should be present. If voltage is not present, locate and repair open circuit or faulty switch. If voltage is present, replace motor.

Problem—Wiper Motor Inoperable

Problem—Wiper Motor Inoperable	
Possible Cause	**Remedy**
Open in circuit 315 wire or in wiper switch.	At wiper switch, check circuit 315 for battery voltage. Battery voltage should be present. If voltage is not present, locate and repair open circuit. Check circuit 316 (low speed) or 318 (high speed) for voltage with switch in corresponding position. If no voltage, replace wiper switch.
Faulty motor.	Make sure motor has proper ground; then apply battery voltage to motor (circuit 316 for low speed, circuit 318 for high speed). If either speed is not operational, replace motor.

VEHICLES WITH INTERMITTENT WIPERS WITH ROCKER SWITCH AND SLIDER SWITCH CONTROLS

Problem—Wipers Do Not Park and Intermittent Feature Does Not Work Properly

Problem—Wipers Do Not Park and Intermittent Feature Does Not Work Properly	
Possible Cause	**Remedy**
Open circuit in wire 319.	Disconnect the wiper motor connector and check for battery voltage at pin 319. If no voltage, repair the 319 wire.
Open circuit in wire 317, intermittent wiper relay or wiper switch.	Disconnect the wiper motor connector and check for continuity between pin 316 and pin 317 at the harness side of the wiper motor connector. If no continuity, check the 317 wires, wiper switch and the intermittent wiper relay for an open.
Open circuit in wiper motor park switch.	With the wipers at mid stroke, turn the wiper switch and key switch to off. Disconnect the wiper motor connector and check for continuity between pin 317 and pin 319 at the wiper motor. If no continuity, replace the wiper motor.

Problem—Wiper Intermittent Feature Does Not Work Properly, But the Wipers Park Normally

Problem—Wiper Intermittent Feature Does Not Work Properly, But the Wipers Park Normally	
Possible Cause	**Remedy**
Open circuit in wire 319.	Disconnect the intermittent wiper relay and check for battery voltage at pin 319. If no voltage, repair the 319 wire.
Open circuit in wire 315.	Operate the washer switch to prove the 315 wire is good. If the washer does not operate, disconnect the intermittent wiper/washer switch and check for battery voltage at pin 315. If no voltage, repair the 315 wire.
Open circuit in ground wire at the intermittent wiper/washer switch.	Disconnect the intermittent wiper/washer switch and check for continuity to ground at the switch ground terminal. If no continuity, repair the ground wire.
Inoperative intermittent wiper relay or open intermittent wiper relay ground or inoperative intermittent wiper/washer switch.	Perform the above steps before this one. Disconnect the intermittent wiper/ washer switch; and with the key switch on, momentarily jumper wire 315A to wire 315 (battery voltage). If the wipers do make one pass, replace the intermittent wiper/washer switch. If the wipers do not make one pass, check the 315 wire and the intermittent wiper relay ground wire for an open; and then check the intermittent wiper relay for proper operation.

VEHICLES WITHOUT INTERMITTENT WIPERS

Problem—Wipers Do Not Park at Bottom of Stroke

Problem—Wipers Do Not Park at Bottom of Stroke	
Possible Cause	**Remedy**
Wiper crank incorrectly positioned on wiper motor shaft (wipers park in same position each time wiper switch is opened).	Disconnect wiper crank from motor shaft. Turn key switch on; then momentarily turn wiper motor on then off. Wiper motor should be at park position. Turn key switch off. Install wiper crank onto motor shaft pointing to the 3 o'clock position.
Wiper park circuit inoperable (wipers stop immediately when wiper switch is opened).	With wipers at mid-stroke, turn wiper switch and key switch off. Unplug the wiper motor wiring harness. At the wiper motor connector, connect the ground pin to ground and jump pin 316 to 317. Apply battery voltage from fused circuit to pin 319. If motor returns to park, repair open in circuit 319, or circuit 317 or replace switch as necessary. If motor does not return to park, replace motor.

VEHICLES WITH INTERMITTENT WIPERS WITH DOUBLE-PADDLE SWITCH

Problem—Wipers and Washer Not Working

Problem—Wipers and Washer Not Working	
Possible Cause	**Remedy**
The wiring is loose.	Check for and tighten any loose wiring connections.

Troubleshooting

Problem—Wipers and Washer Not Working	
Possible Cause	**Remedy**
An open or short circuit.	Check circuits 315, 315H, 315L, and 315P, the ignition circuit breaker, and both high-speed and low-speed relays. For a wiring diagram, refer to **Specifications 400**.
	Tighten loose wiring connection(s).
	Check and replace the switch.
	Check and replace broken wire(s).
The system is binding.	Free or replace the linkage.
	Free or replace the arm or blade.
The motor does not work.	Replace the motor.

Problem—The Wiper Motor Shaft Turns, But the Wiper Arms Do Not Move

Problem—The Wiper Motor Shaft Turns, But the Wiper Arms Do Not Move	
Possible Cause	**Remedy**
The drive crank is loose or disconnected.	Check the drive crank. If it's loose at the wiper motor drive shaft, clean the drive shaft splines. Replace the crank if necessary. If the crank is disconnected from the drive pivot bar, connect it and line it up correctly. For instructions, refer to **Subject 110**. If the problem persists, replace or repair parts as needed.
The linkage is loose or disconnected.	Check all the linkage connections. Repair or replace parts as needed.

Problem—Wiper Motor High Speed Not Working

Problem—Wiper Motor High Speed Not Working	
Possible Cause	**Remedy**
An open circuit.	Check circuits 315H and 315B for continuity. For a wiring diagram, refer to **Specifications 400**.

Problem—Wiper Motor Low Speed Not Working

Problem—Wiper Motor Low Speed Not Working	
Possible Cause	**Remedy**
An open circuit	Check circuits 315L and 315A for continuity. For a wiring diagram, refer to **Specifications 400**.

Problem—Washers Not Working

Problem—Washers Not Working	
Possible Cause	**Remedy**
Washer tubing disconnected.	Check the washer tubing between the washer pump and the wipers.

Problem—Washers Not Working	
Possible Cause	**Remedy**
An open circuit.	Check circuits 320 and 320A for continuity. Check the ground wire on the switch. For a wiring diagram, refer to **Specifications 400**.

Problem—Circuit Breaker Keeps Tripping

Problem—Circuit Breaker Keeps Tripping	
Possible Cause	**Remedy**
Incorrect circuit breaker installed.	Make sure correct amperage circuit breaker is installed. For the correct amperage, refer to **Specifications 400**.
Wiring is shorted to ground.	Check the wiring and the motor for shorts to ground. For a wiring diagram, refer to **Specifications 400**.
The wiper linkage is binding.	Check the linkage.

Problem—Wipers Do Not Park

Problem—Wipers Do Not Park	
Possible Cause	**Remedy**
The park circuit is not working	Check circuits 315 and 315P (blue) for continuity. Check the ground wire on the switch. For a wiring diagram, refer to **Specifications 400**.

Problem—Intermittent (Delay) Feature Not Working; High and Low Speeds are O.K.

Problem—Intermittent (Delay) Feature Not Working; High and Low Speeds are O.K.	
Possible Cause	**Remedy**
The wiper switch ground circuit is open.	Check the ground wire on the switch. For a wiring diagram, refer to **Specifications 400**.

Problem—Wipers Oversweeping

Problem—Wipers Oversweeping	
Possible Cause	**Remedy**
Worn or broken linkage component.	Replace linkage components as required.
Worn or broken pivot assembly.	Replace the pivot assembly.
Worn or broken wiper arm.	Replace the wiper arm.
The motor assembly is loose.	Secure the motor assembly.
Vehicle voltage too high.	Repair the vehicle electrical system.

Problem—Wipers Oversweeping (for Vehicles With Intermittent Wipers Built From December 5, 1997)

Problem—Wipers Oversweeping (for Vehicles With Intermittent Wipers Built From December 5, 1997)	
Possible Cause	**Remedy**
The motor assembly is loose.	Secure the motor assembly.

Troubleshooting

Problem—Wipers Oversweeping (for Vehicles With Intermittent Wipers Built From December 5, 1997)	
Possible Cause	**Remedy**
Vehicle voltage too high.	Repair the vehicle electrical system.

Specifications

For a schematic of the wiring on non-intermittent wipers, see **Fig. 1**.

For a schematic of the wiring on intermittent wipers for vehicles built before December 5, 1997, see **Fig. 2**.

For a schematic of the wiring on intermittent wipers for vehicles built from December 5, 1997, see **Fig. 3**

General Information, Description of Components, Definition of Terms, and Principles of Operation

General Information

The heater and air conditioner unit uses a common blower motor and duct work to heat or cool the cab. Airflow rate is controlled by a three-speed blower switch. Air outlets are located in the instrument panel, along the bottom of the dash, at the windshield, and also at the side windows. See **Fig. 1**.

5. Floor Outlet
6. Dash/Door Window Vent
7. Center Dash Vents

Fig. 1, Air Outlet System

When equipped with an air conditioner, temperature can be moderated by opening or closing a water regulating valve, which controls the flow of warm engine coolant to the heater core. The temperature of the air inside the cab partly depends on how much coolant is flowing through the heater core, and how much liquid refrigerant is in the evaporator coil.

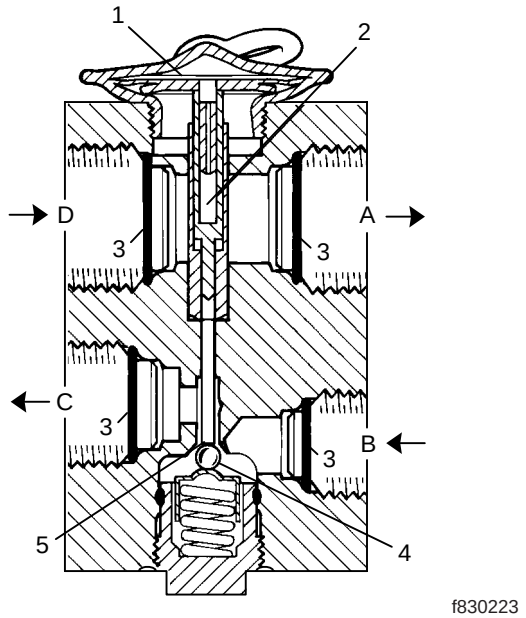
The air conditioning system also includes a cycling-clutch refrigerant compressor, a condenser, an expansion valve, an evaporator coil, a fixed-temperature thermostatic switch, and mechanically operated controls.

DESCRIPTION OF COMPONENTS

Refrigerant

Refrigerant absorbs heat from the air in the cab and releases it to the air outside the cab.

In an open container, refrigerants boil at temperatures below the freezing point of water; sealing and pressurizing refrigerant in the air conditioning system raises its boiling-point temperature.



During compressor operation, refrigerant constantly changes from a liquid to a gas. It absorbs heat (boiling) in the low-pressure evaporator coils, and it changes from a gas to a liquid as it releases absorbed heat in the high-pressure condenser.

General Information, Description of Components, Definition of Terms, and Principles of Operation

Expansion Valve

The expansion valve is a dividing point between the high-and low-pressure parts of the refrigerant system. High-pressure liquid refrigerant from the receiver-drier passes through the expansion valve and moves into the low-pressure area of the evaporator coil.

An expansion valve controls the flow rate of refrigerant in proportion to the rate of evaporation in the evaporator. If the amount of liquid in the evaporator drops off, the temperature of the gas going to the compressor rises. This causes a diaphragm in the expansion valve to react, which causes an orifice in the valve to open or close. Refer to **Fig. 2**. Through the orifice, liquid refrigerant is metered into the evaporator, as needed.

A. to compressor.
B. from receiver-drier.
C. to evaporator.
D. from evaporator.

2. Temperature Sensor
3. O-Rings
4. Metering Orifice
5. Ball and Spring

Fig. 2, Expansion Valve

Evaporator Coil

Because the evaporator coil is an area of low pressure in the system, the boiling point of refrigerant lowers, which causes it to absorb heat from the tubing walls and fins of the coils. As it absorbs heat, liquid refrigerant quickly boils and turns into a gas.

As heat is absorbed from the outside surfaces of the evaporator coil, air passing over the unit loses its heat to these cooler surfaces. Moisture in the air condenses on the outside of the coil and drains off as water (the air becomes dehumidified).

Refrigerant Compressor

"Heat" in the low-pressure gas of the evaporator coils is not heat that can be noticed by touch, because liquid refrigerant boils at a temperature much lower than the temperature at which water turns to ice. By touch, the "heated" gas in the coils is very cold. As a result, there is the problem of how to remove heat from subfreezing gas using outside air that may be higher than 100°F (38°C).

With a refrigerant compressor, low-pressure gas from the evaporator can be squeezed into a much smaller space. When the gas is compressed, the heat it contains becomes concentrated. In this way, the gas is made hotter than the outside air, without adding heat.

Another function of the compressor is to move refrigerant through the system.

Condenser

A condenser turns hot refrigerant gas, coming from the compressor, into liquid. Mounted in front of the radiator, it is made up of a coiled tube and a series of fins. Because of its location, the condenser transfers heat to air that is drawn in by the engine fan and by air that is forced into the engine compartment as the vehicle moves forward (ram air).

Receiver-Drier

Used as a reservoir and filter for liquid refrigerant from the condenser, a receiver-drier also removes water and acids from the refrigerant. The water-absorbing material (desiccant) in the unit helps stop blockages from forming in the expansion valve and in other parts of the system.

A moisture indicator shows the amount of water in the refrigerant. A sight glass (aperture) on the unit contains a specially treated element (litmus paper) that changes color, depending on the amount of water in the refrigerant. The indicator changes from a deep cobalt blue (dry) to light greyish-blue (wet) to lilac, lavender, and finally pink (very wet). Any color other than cobalt blue is considered wet. Any time

the system is evacuated (dehydrated), replace the receiver-drier.

Thermostatic Switch

The temperature of the evaporator coil is monitored by a fixed-temperature thermostatic switch.

The probe from the switch extends to the evaporator coil, and the switch is mounted on the right side of the heater and air conditioner housing. This switch disengages the compressor to prevent the evaporator coil from freezing up due to, for example, an expansion valve that is stuck open.

Binary Switch

A binary switch disengages the refrigerant compressor to protect it from harmful operating conditions. It performs two functions:

1. If refrigerant is lost or the outside temperature is too low, the binary switch will keep the compressor from operating. The switch disengages the compressor when falling pressure goes below 26 to 31 psig (179 to 214 kPa); normal compressor operation resumes when rising pressure reaches 0.1 to 3 psig (0.6 to 21 kPa) above shut-off pressure.
2. If the compressor cylinder head pressure increases to unsafe levels above 356 to 413 psig (2454 to 2847 kPa), the binary switch shuts off the compressor. Too much pressure may be caused by blocked air flow through the condenser, a plugged expansion valve or receiver-drier, or too much refrigerant in the system. When pressure falls back 57 to 11 psig (393 to 786 kPa) from shut-off pressure, the compressor resumes operation.

Heater Core

The heater core is a series of fins through which tubing is routed. When the heating system is on, engine coolant flows through the heater core tubes, heating the tubes and fins. The heat is absorbed by air that is forced through the heater core by the blower motor.

Water Regulating Valve

When opened, the water regulating valve allows engine-heated coolant to flow through the heater core.

Air Blower, Resistor Block Assembly

An air blower forces air through the heater core and evaporator coil, and into the cab. The resistor block assembly regulates the voltage to the blower motor. The voltage controls the blower motor speed. The resistor assembly has a thermal cutout which shuts off current to the blower motor in case the motor malfunctions.

DEFINITION OF TERMS

Refer to the following terms for a better understanding of the heater/air-conditioning system.

Air Conditioner A system used to control the temperature, humidity, and movement of air.

Ambient Air Temperature The temperature of air around an object; the outside temperature.

Binary Switch Disengages the refrigerant compressor to protect it from harmful operating conditions.

Blower A motor and fan used to draw air through the evaporator, and force it through the heater core and into the cab.

Blower Resistor Block Assembly Inline resistors that control the amount of voltage going to the blower motor. By controlling the voltage, you can control the fan speed.

Boiling Point The temperature at which a liquid changes to a gas. The boiling point varies with pressure.

Bulk Charging Use of large containers of refrigerant for charging a refrigerant system. Normally used for charging empty systems.

Carbon Dioxide A colorless, odorless, dry, inert gas that can be used to purge light contaminants (for example, dust) from air conditioner parts.

CFM Cubic feet per minute

Charge A specific amount of refrigerant or oil by volume or weight. Also, the act of placing an amount of refrigerant or oil in the air conditioning system.

Clutch Cycling Switch Engages or disengages the compressor depending on changes in system pressure or evaporator temperature.

Cold The absence of heat. (The lowest possible temperature is thought to be –459 °F [–273 °C].)

Compressor A device used to draw low-pressure

General Information, Description of Components, Definition of Terms, and Principles of Operation

refrigerant gas from the evaporator and squeeze it into a high-temperature, high-pressure gas. A second purpose of the compressor is to move refrigerant through the system.

Condensate Water, taken from the air, which forms on the outer surface of the evaporator.

Condenser A heat exchanger that is used to remove heat from the refrigerant, changing it from a high-pressure hot gas to a high-pressure warm liquid.

Condensing Pressure Pressure, as read from the gauge at the discharge service valve; pressure from the discharge side of the compressor into the condenser.

Contaminants Anything other than refrigerant or refrigerant oil in the system. Usually means water in the system. When water and refrigerant mix, corrosive hydrochloric acid forms.

Cycling Clutch System A system which controls compressor clutch operation in order to raise or lower the temperature in the cab.

Dehumidify To remove water from the air, at the evaporator coil.

Dehydrate To remove all traces of moisture from the refrigerant system. Normally called evacuation.

Desiccant A drying agent used in the refrigerant system (in the receiver-drier) to remove water and create an extremely dry condition.

Discharge To bleed some or all of the refrigerant from a system by opening a valve or hose connection and recovering the refrigerant from the system.

Discharge Line Connects the refrigerant compressor outlet to the condenser inlet.

Discharge Pressure Pressure of the refrigerant being discharged from the compressor; high-side pressure.

Drive Pulley A V-pulley attached to the front of the engine crankshaft. It drives the compressor clutch pulley with a belt.

Drying Agent See "Desiccant."

Duct A passageway for the transfer of air from one point to another.

Evacuate To place a high vacuum in the air-conditioning system and dehydrate or remove all traces of wet air.

Evaporate To change state from a liquid to a gas.

Evaporator Coil A component in which liquid refrigerant changes to a gas after it absorbs heat from the air. Also removes some water from the air.

Expansion Valve A device that causes a pressure-drop of the refrigerant and also regulates its flow.

Flooding A condition caused by too much liquid refrigerant going into the evaporator; usually caused by an expansion valve that is stuck open.

Flushing A process of passing liquid refrigerant through an air-conditioner component to remove dirt and water from the part. Liquid refrigerant removes heavy contamination, such as gritty dirt and large dirt build-up, which cannot be removed by purging with a gas.

Foaming Bubbles of oil and refrigerant caused by a rapid boiling out of refrigerant dissolved in the oil when the pressure is suddenly reduced. Foam in the sight glass means a very low refrigerant charge.

Freeze-Up Failure of a unit to operate properly because of ice forming at the expansion valve orifice or on the evaporator coils and fins.

Head Pressure Refrigerant pressure from the discharge side of the compressor to the condenser and expansion valves.

Heater Core A part of the heating system in which hot engine coolant flows to provide heat to the cab or to adjust the temperature produced by the air conditioner.

High-Side Service Valve A device located on the liquid line near the thermostatic expansion valve; it allows high-side pressure to be checked and other service operations to be performed.

Humidity The amount of water vapor in the air.

Hydraulic Lock The return of liquid refrigerant to the compressor, which could destroy the unit.

Hydrochloric Acid A highly corrosive substance that forms when water and refrigerant mix in a refrigerant system.

Hydrofluorocarbon The chemical name for R–134a.

Leak Detector Any device used to detect refrigerant leaks in a refrigerant system.

Liquid Pressure Pressure of refrigerant in the liquid line from the receiver-drier to the thermostatic expansion valve.

General Information, Description of Components, Definition of Terms, and Principles of Operation

Low Head Pressure High-side pressure that is lower than normal due to a system problem.

Low Suction Pressure Low-side pressure that is lower than normal due to a system problem.

Magnetic Clutch An electrical coupling device used to engage or disengage the compressor.

Manifold Device to control refrigerant flow for system test purposes; used with manifold gauges.

Manifold Gauge A calibrated instrument used for measuring system pressures.

Manifold Gauge Set A manifold that is complete with gauges and charging hoses and is used to measure or test pressure.

Micron A metric measurement of mercury; one-tenth of an inch of mercury equals 2540 microns. Measurement in microns is the only accurate way to determine the amount of pressure that is left in a refrigerant system by a high vacuum pump.

Moisture Indicator Litmus paper in a sight glass receiver-drier; shows how much water is in the system.

Nitrogen A colorless, odorless, dry, inert gas that can be used to purge light contaminants (for example, dust) from air conditioner parts.

Opacity A condition that is used to describe contamination of refrigerant oil in the compressor. Fresh refrigerant oil is clear; when contaminated, it appears cloudy or may have fine particles held in suspension.

Overcharge Too much refrigerant or oil in the system.

Phosgene Fumes Poisonous gas produced when refrigerant contacts an open flame or some other source of intense heat.

psia Pounds per square inch, absolute pressure.

psig Pounds per square inch, gauge pressure.

Purge To remove damp air, traces of refrigerant, and loose dirt from a system or part by flushing with a dry, inert gas, such as nitrogen.

Receiver-Drier A combination desiccant, filter, and storage container for liquid refrigerant.

Refrigerant–12 (R–12) A cooling agent used in automotive air conditioning systems. It is being phased out due to environmental concerns.

Refrigeration Cycle The complete circulation of refrigerant through an air conditioning system, accompanied by changes in temperature and pressure.

Refrigerant Oil Highly refined oil compatible with air-conditioning system refrigerants.

Relative Humidity The actual water content of the air in relation to the total water vapor the air can hold at a given temperature.

Resistor A voltage-dropping device, usually wire-wound, for controlling fan speed.

Schrader Valve A spring-loaded valve (similar to but not interchangeable with a tire valve) located inside the compressor service valve fitting to hold refrigerant in the system. Special adaptors must be used with the gauge hose to get into the system.

Sight Glass A window in the receiver-drier (moisture indicator) used to check the refrigerant charge.

Suction Line The line connecting the evaporator outlet to the compressor inlet.

Suction Pressure Compressor inlet pressure (the system's low-side pressure).

Suction Service Valve A device located on the suction hose near the thermostatic expansion valve that allows low-side pressure to be checked and other service operations to be performed.

Suction Side The low-pressure area of the system, extending from the expansion valve to the compressor inlet.

Thermistor A temperature-sensing resistor that is used to measure (in microns) internal system vacuum levels during evacuation.

Thermostatic Switch A temperature-sensitive switch used to control system temperature and prevent evaporator freeze-up; it does this by cycling the compressor's operation.

Thermostatic Vacuum Gauge A high-vacuum gauge sensitive to pressures ranging from atmospheric pressure to less than 1 micron, with scales reading from 25,000 microns to 1 micron.

Undercharge A system low on refrigerant, resulting in lack of cooling and possible compressor damage.

Vacuum Refers to pressure that is less than atmospheric pressure.

Vacuum Pump A mechanical device used to evacuate and place a high vacuum in the refrigerant system.

Vacuum Pump Oil Water soluble oil used in some

General Information, Description of Components, Definition of Terms, and Principles of Operation

vacuum pumps to absorb water from the refrigerant system.

Vapor The gaseous state of a material.

Water Regulating Valve A valve, mechanically operated, for controlling the flow of hot coolant to the heater core.

Principles of Operation

HEATER

Moving the temperature control toward maximum heat opens the water regulating valve, which allows engine-heated coolant to flow through the heater core. Heat absorbed by the air passing over the heater core fins is forced through ducts and into the cab.

AIR CONDITIONER

When the air conditioner is on, the motion of the compressor squeezes the refrigerant into a high-pressure, high-temperature gas. High pressure raises the condensation point of refrigerant gas, which allows the condenser to change it to a liquid. After it is compressed, refrigerant gas moves out of the discharge port of the compressor, and on to the condenser.

At the condenser, air passing over the coil's fins absorbs heat from the hot refrigerant gas and causes it to change into a liquid. The liquid moves to the receiver-drier, which filters it and removes traces of water and acids. The receiver-drier then stores the refrigerant until it is needed by the system.

From the receiver-drier, liquid refrigerant moves to the expansion valve, which meters the flow into the evaporator coil and acts as a boundary between the high-and low-pressure sides of the system. The metered release of the expansion valve greatly drops the liquid's pressure, causing it to expand. The pressure drop lowers the boiling point of the refrigerant, and causes it to evaporate quickly as it absorbs heat from air passing over the coil. The resulting cool air is forced into the cab by the blower; the heated refrigerant gas is drawn back into the compressor, where the cycle is repeated.

Safety Precautions

Whenever repairs are made to any air conditioner parts that hold refrigerant, you must discharge, purge or flush (if contaminated), evacuate, charge, and leak test the system. In a good system, refrigerant lines are always under pressure and you should disconnect them only after the air conditioning system has been discharged to a refrigerant recovery unit through the service valves on the compressor.

Refrigerants are safe when used under the right conditions. Always wear safety goggles and non-leather gloves while discharging, purging, flushing, evacuating, charging, and leak testing the system. Do not wear leather gloves; when refrigerant gas or liquid contacts leather, the leather will stick to your skin.

⚠ WARNING

Use care to prevent refrigerant from touching your skin or eyes, because liquid refrigerant, when exposed to the air, quickly evaporates and will freeze skin or eye tissue. Serious injury or blindness could result if you come into contact with liquid refrigerant.

Refrigerant splashed in the eyes should first be treated with a few drops of sterile mineral oil in the eyes, and then rinsed with a weak boric acid solution. Do not rub the eyes. Call a doctor right away.

Refrigerant splashed on the skin should be treated the same as for frostbite: gently pour cool water on the area, but do not rub the skin. Keep the skin warm with layers of soft, sterile cloth. Call a doctor right away.

Even though refrigerant does not burn, when it contacts extreme heat or flame, poisonous phosgene gas is created. This gas also is produced when an open flame leak detector is used. Phosgene fumes have an acrid (bitter) smell.

⚠ WARNING

Do not work in an area where refrigerant may contact an open flame or any burning material, such as a cigarette. When it contacts extreme heat, refrigerant breaks down into poisonous phosgene gas which, if breathed, causes severe respiratory irritation and possible severe injury or death. Do not breathe the fumes from an open flame leak detector.

You must work in an area where there is a constant flow of fresh air when the system is discharged, flushed, charged, and leak tested using an open flame leak detector.

Changes in both federal and state laws will affect the way dealerships service air-conditioning systems. Under current federal laws, refrigerant must be recovered and recycled by all users to protect the environment, and not released into the atmosphere. Many service operations not directly involving the air-conditioning system require the release of the refrigerant charge. Under the new regulations, dealerships not having the required recovery and recycling equipment (and properly trained and certified personnel) will not be allowed to do any of this service work.

Because of its very low boiling point, refrigerant must be stored under pressure. To prevent the refrigerant cans from exploding, never expose them to temperatures higher than 125°F (52°C). Never leave refrigerant cans in the sun, and do not store them in sun-exposed areas where heat can build up, such as in gloveboxes, automobile trunks, etc.

Heater Core Removal and Installation

Removal

1. Set the temperature control on the dash to its warmest setting.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

2. Drain the coolant.
3. Disconnect the batteries.
4. Remove the extruded rubber strip at the top of the dashboard. See **Fig. 1**.

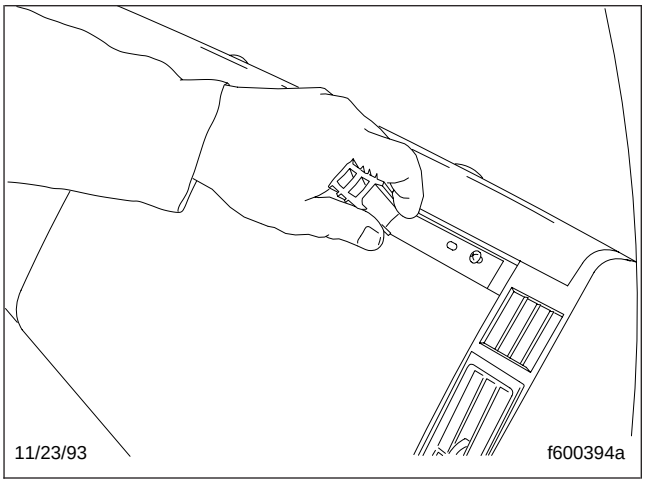

Fig. 1, Remove the Rubber Strip

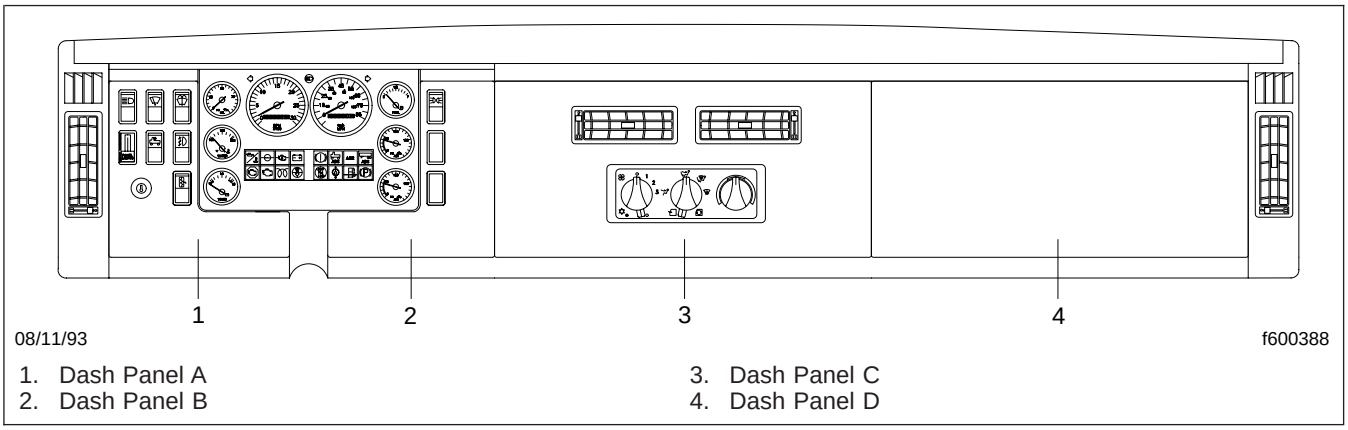

5. Remove dash panel D. See **Fig. 2** and **Fig. 3**.
   - 5.1 Remove the two screws from the top of dash panel D.
   - 5.2 Lift out the dash panel.
6. Pull out the windshield defrost duct. See **Fig. 4**.
7. Remove the parking brake knob and, if so equipped, the trailer brake knob. See **Fig. 5**. Then, remove dash panel B.
8. Remove dash panel C. See **Fig. 2**.
   - 8.1 Remove the bezel around the heater/ air-conditioner control panel.
   - 8.2 Remove the four screws (**Fig. 6**) holding the control panel to dash panel C.
   - 8.3 Remove the two screws from the top of dash panel C.
   - 8.4 Lift out the dash panel and set it aside.
9. Remove the dashboard gauge cover by pushing down on the four locking tabs. See **Fig. 7**.
10. Remove the two screws at the top of dash panel A. See **Fig. 8**.
11. Remove the dash top panel.
    - 11.1 Remove the two screws holding each dash end cap; then remove the end caps. See **Fig. 9**.
    - 11.2 Remove the screws at the base of the windshield holding the dash top panel.
    - 11.3 Remove the screw at the top of the dashboard brace (**Fig. 10**) and the screws at the top of the gauge cluster.
    - 11.4 Lift off the dash top panel. See **Fig. 11**.
12. Remove the dash side vent flexible air ducts. See **Fig. 12**.
13. Remove the air plenum.
    - 13.1 Disconnect the defrost door control cable from the face duct. See **Fig. 13**.
    - 13.2 Remove the face duct.
    - 13.3 Remove the two screws in the air plenum; then, lift out the plenum. See **Fig. 14**.
14. Disconnect the hoses from the heater core. See **Fig. 15**.

⚠ WARNING

Always wear protective gloves when handling the heater core. Failure to do so could result in serious skin cuts from the sharp edges on the heater core fins.

15. Remove the heater core. See **Fig. 16**.

Heater Core Removal and Installation

1. Dash Panel A
2. Dash Panel B
3. Dash Panel C
4. Dash Panel D

Fig. 2, Dash Panel

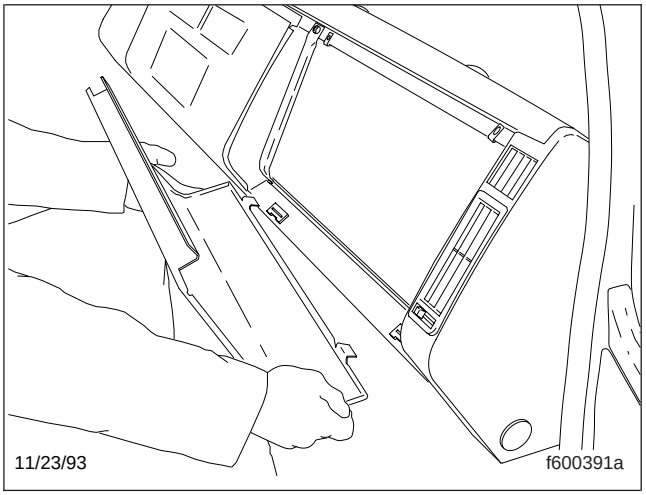

Fig. 3, Remove the Dash Panel

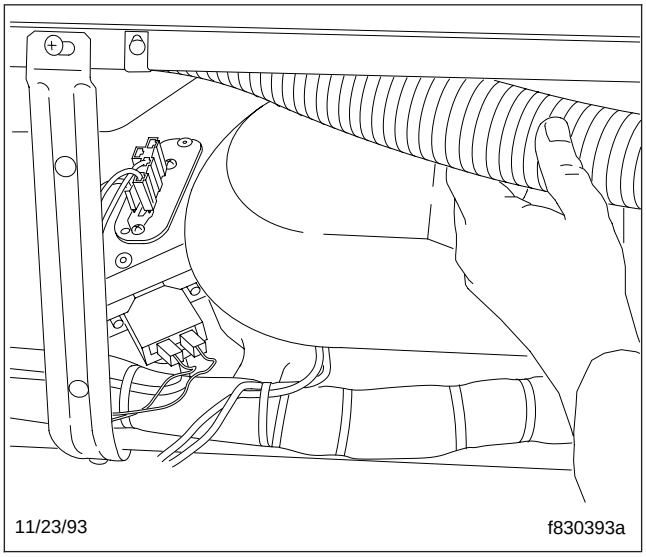

Fig. 4, Remove the Windshield Defrost Duct

Installation

⚠ WARNING

Always wear protective gloves when handling the heater core. Failure to do so could result in serious skin cuts from the sharp edges on the heater core fins.

1. Install the heater core, inserting the pipes through the holes in the firewall. See **Fig. 16**.
2. Connect the hoses to the heater core. See **Fig. 15**.
3. Check the heater core for leaks.
   - 3.1 Connect the batteries.
   - 3.2 Close the radiator drain valve.
   - 3.3 Fill the cooling system with approved coolant. See Group 20 of the *Business Class Trucks Maintenance Manual*.
   - 3.4 Start the engine and set the temperature control to the warmest setting. When the engine thermostat opens, air will be forced from the heater core as the coolant circulates. Check the coolant level again and fill as needed.
   - 3.5 Check the heater core hose connections (**Fig. 15**) for leaks. Tighten the hose clamps if needed.

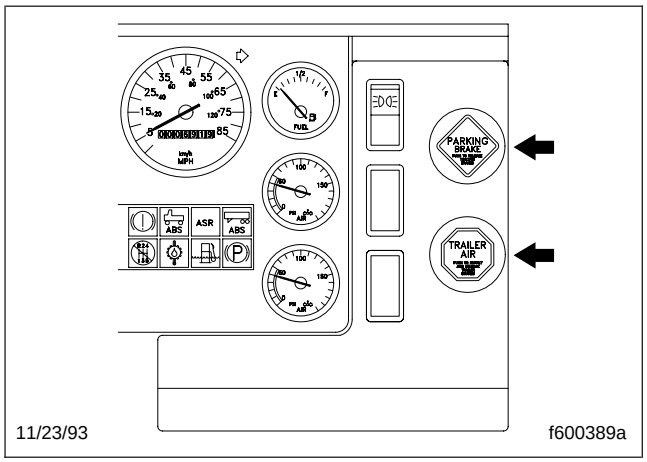

Fig. 5, Parking Brake and Trailer Brake Knobs

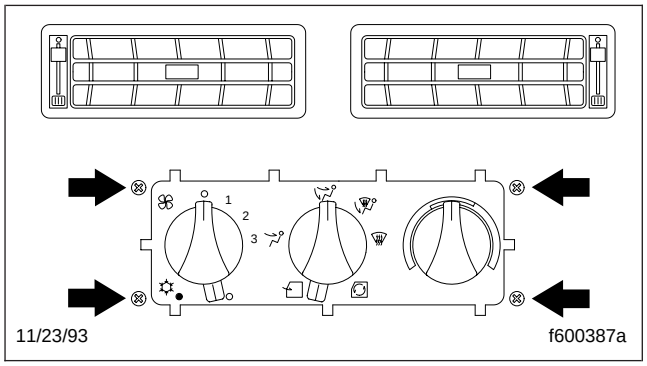

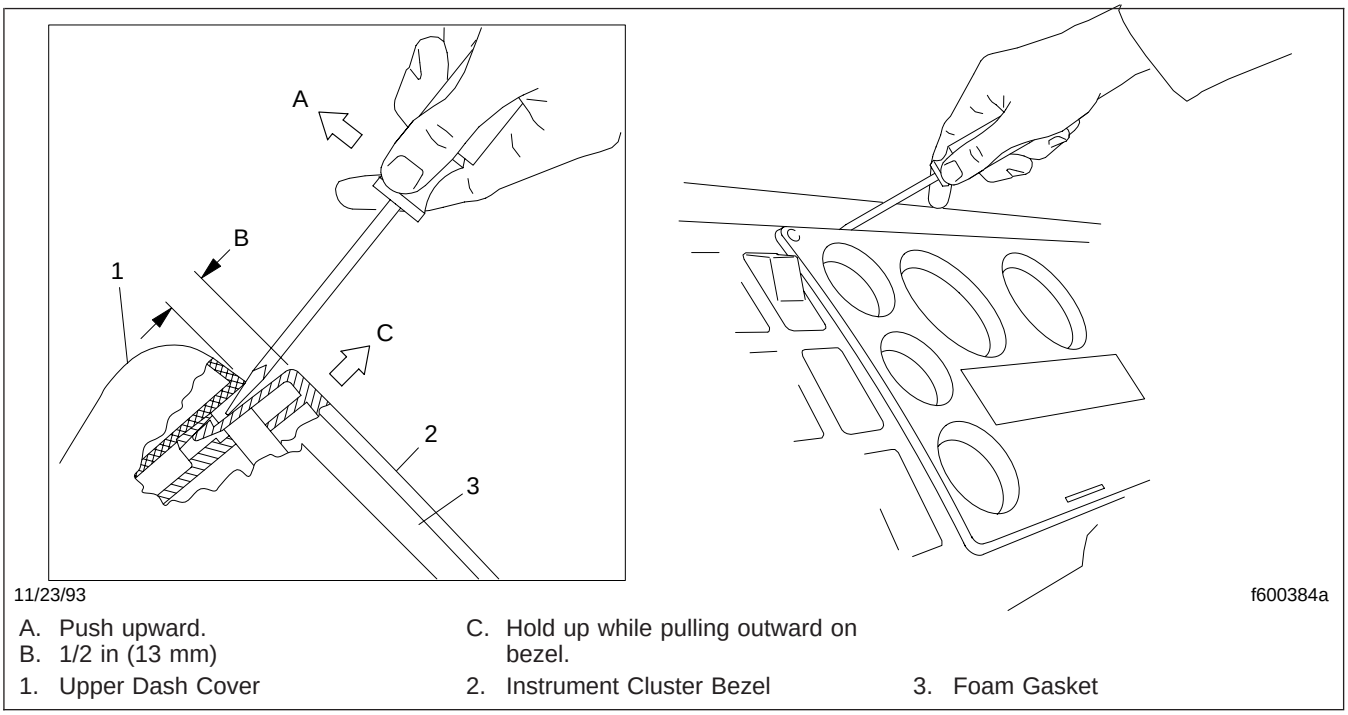

Fig. 6, Control Panel

3.6 Shut down the engine and disconnect the batteries.

4. Install the air plenum. See **Fig. 14**. Install the screws in the plenum.
5. Install the face duct. Connect the defrost door control cable and the cable sheath to the face duct. See **Fig. 13**.
6. Install the flexible air ducts to the dash side vents. See **Fig. 12**.
7. Install the dash top panel (**Fig. 11**) and the screws at the base of the windshield.
8. Install the dash end caps (**Fig. 9**) and their mounting screws (two each).
9. Install the brace screw (**Fig. 10**) and the screws at the top of the gauge cluster.
10. Install dash panel A and its two mounting screws (**Fig. 8**).
11. Install the cover over the dashboard gauges. Make sure the tabs are locked. See **Fig. 7**.
12. Install dash panel C (**Fig. 2**) and its mounting screws.
13. Install dash panel B (**Fig. 2**) and its two mounting screws. If so equipped, install the parking brake knob and the trailer brake knob.
14. Install the windshield defrost duct. See **Fig. 4**.
15. Install dash panel D (**Fig. 2** and **Fig. 3**) and its two mounting screws.
16. Install the extruded rubber strip at the top of the dashboard. See **Fig. 1**.
17. Connect the batteries.

Evaporator Coil Removal and Installation

Removal

IMPORTANT: Before replacing any refrigerant parts, read **Subject 220**. Always discharge the system before disconnecting a refrigerant line. If the system is contaminated, purge or flush it before you install replacement parts.

1. Review the information under **Safety Precautions, 100**.

⚠ WARNING

Failure to review the safety precautions, and to be aware of the dangers involved when working with refrigerant, could result in serious personal injury.

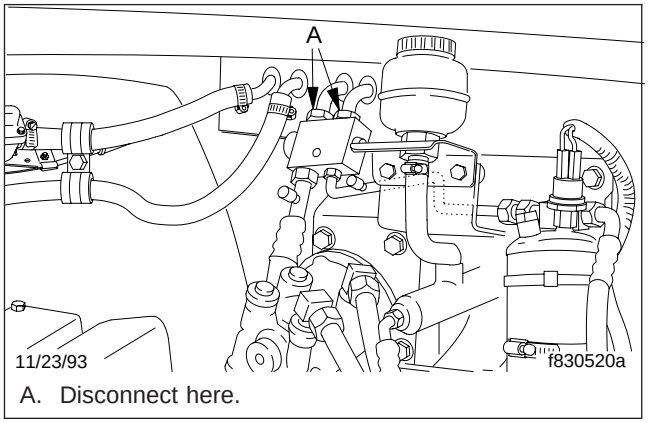
2. Disconnect the batteries.
3. Wearing protective goggles and gloves, discharge the refrigerant system. For instructions, refer to **Subject 220**.
4. Remove the heater core. Refer to **Subject 110**.

⚠ CAUTION

Water and dirt can damage the refrigerant system. Five minutes of being uncapped is the limit for any hose or component. Do not blow shop air through the refrigerant hoses; shop air is wet (humid).

5. Disconnect the evaporator coil lines from the expansion valve in the engine compartment. See **Fig. 1**. Save the O-rings if they are in good condition.
6. Cap or plug the evaporator coil lines and the expansion valve ports.

⚠ WARNING



Always wear protective gloves when handling the evaporator coil. Failure to do so could result in serious skin cuts from the sharp edges on the evaporator coil fins.

7. Lift the evaporator coil out of the housing. See **Fig. 2**.

Installation

⚠ WARNING

Always wear protective gloves when handling the evaporator coil. Failure to do so could result in serious skin cuts from the sharp edges on the evaporator coil fins.

A. Disconnect here.

Fig. 1, Evaporator Coil Lines

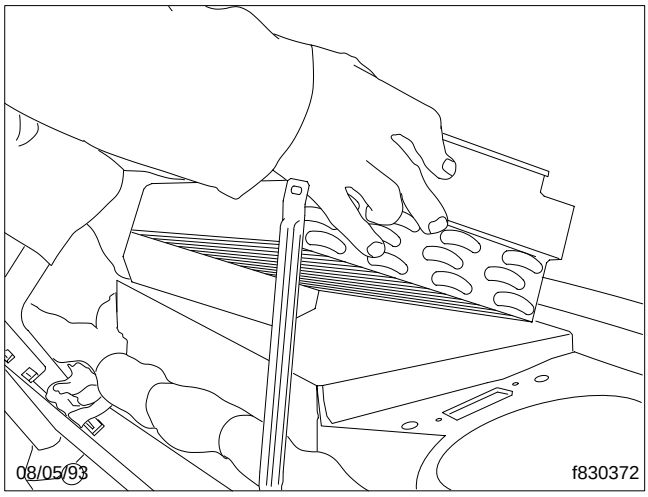


Fig. 2, Remove the Evaporator Coil

1. Wearing protective gloves, place the evaporator coil in the housing. See **Fig. 2** . Make sure the evaporator coil lines extend through the holes in the firewall.
2. Remove the caps or plugs from the evaporator coil lines and the expansion valve ports.

Evaporator Coil Removal and Installation

3. Lubricate the rubber O-rings with refrigerant oil and install them in the fittings.

NOTE: The previously removed O-rings can be used again if they are in good condition.

4. Apply Loctite® 242 or 592 to the male fitting threads; then, connect the evaporator coil

   lines to the expansion valve ports. Tighten the fittings as follows:

   - Large fitting—24 lbf·ft (33 N·m)
   - Small fitting—18 lbf·ft (24 N·m)

5. Evacuate and charge the air conditioning system with refrigerant. For instructions, refer to **Subject 220**. Be sure to add refrigerant oil to the compressor to replace that which was lost when the system was discharged. Refer to the applicable refrigerant compressor section.

NOTE: If the system will not hold a vacuum, check the evaporator coil connections for tightness or check for a missing O-ring.

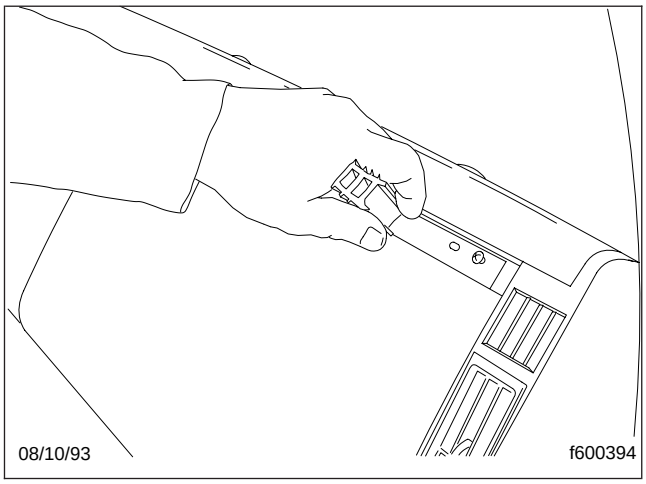
6. Install the heater core and the other removed components. Refer to **Subject 110** for instructions.

Replacement

1. Disconnect the batteries.
2. Remove the extruded rubber strip at the top of the dashboard. See **Fig. 1**.
3. Remove dash panel D. See **Fig. 2** and **Fig. 3**.
4. If so equipped, remove the parking brake knob and the trailer brake knob. Then, remove dash panel B.
5. Remove dash panel C. See **Fig. 4** .

NOTE: It isn't necessary to remove the control panel from dash panel C or to disconnect the control cables.

6. Remove the thermostatic switch. See **Fig. 5** .
   - 6.1 Disconnect the wires from the thermostatic switch.
   - 6.2 Remove the two allen-head screws holding the thermostatic switch.
   - 6.3 Carefully pull the capillary tube, which extends from the bottom of the thermostatic switch, out of the air duct.
   - 6.4 Remove the thermostatic switch.
7. Install the new thermostatic switch.
   - 7.1 Carefully insert the capillary tube into the hole in the air duct.
   - 7.2 Position the thermostatic switch and secure it with the two allen-head screws.
   - 7.3 Connect the wires to the switch.
8. Install dash panel C and its mounting screws.
9. Install dash panel B and its mounting screws. Install the parking brake knobs.
10. Install dash panel D and its mounting screws.
11. Install the extruded rubber strip at the top of the dashboard.
12. Connect the batteries.



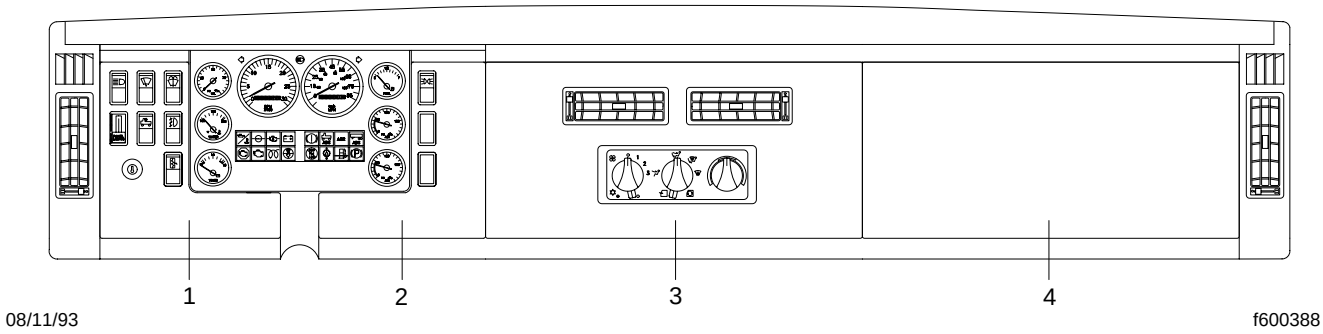


Fig. 1, Remove the Rubber Strip

3. Capillary Tube

Fig. 5, Remove the Thermostatic Switch

Replacement

1. Disconnect the batteries.
2. Remove the extruded rubber strip at the top of the dashboard. See **Fig. 1** .
3. Remove dash panel D. See **Fig. 2** and **Fig. 3** .
4. Remove the blower motor cover. See **Fig. 4** .
5. Disconnect the blower motor electrical connector. See **Fig. 5** .
6. Remove the two remaining nuts holding the blower motor (**Fig. 6**); then, lift out the blower motor.
7. Install the new blower motor. Install the two nuts. Tighten them 17 lbf·in (192 N·cm).
8. Connect the blower motor electrical lead (**Fig. 5**).
9. Install the blower motor cover. See **Fig. 4** .
10. Install and tighten the knurled thumb screw on the blower motor cover finger tight.
11. Install dash panel D (**Fig. 3**) and its two mounting screws.
12. Install the extruded rubber strip at the top of the dashboard. See **Fig. 1** .
13. Connect the batteries and check the blower operation. Refer to the vehicle driver's manual for instructions.

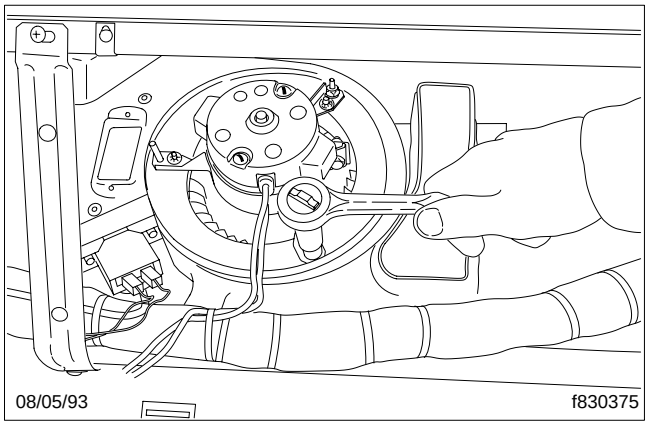

Fig. 6, Remove the Blower Motor Nuts

Replacement

1. Disconnect the batteries.
2. Remove the extruded rubber strip at the top of the dashboard. See **Fig. 1** .
3. Remove the two mounting screws from dash panel D; then, remove the panel. See **Fig. 2** and **Fig. 3** .
4. Remove the resistor block. See **Fig. 4** .
   - 4.1 Unplug the connector from the resistor block.
   - 4.2 Remove the two mounting screws.
   - 4.3 Remove the resistor block.
5. Install the resistor block with the two mounting screws; then, connect the electrical plug.
6. Connect the batteries and check the blower operation.
7. Install dash panel D and the two mounting screws.
8. Install the extruded rubber strip at the top of the dashboard.

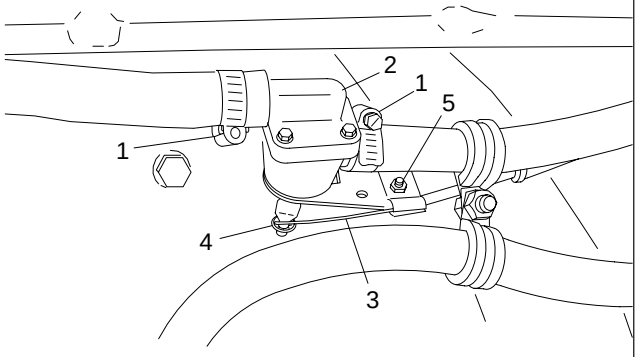
Water Regulating Valve Replacement

Replacement (See Fig. 1)



1. Tilt the hood.
2. Set the heater temperature control to the warmest setting.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

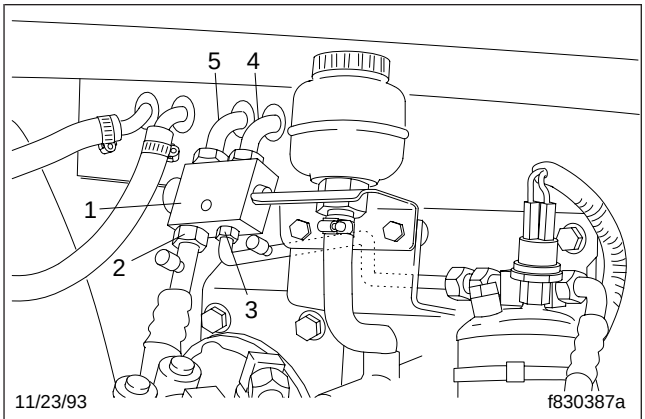
3. With the engine cold, drain enough coolant into a clean drain pan to lower the coolant level below the water regulating valve.
4. Remove the screw (Ref. 5) that holds the control cable to the valve base plate.
5. Remove the internal toothed clip (Ref. 4), and detach the control cable (Ref. 3).
6. Disconnect the heater hoses from the valve. Remove and discard the valve.
7. Install the new valve in the heater hoses. Tighten the hose clamps.
8. Slip the end of the control cable over the post on the valve control lever, and install a new internal toothed clip.
9. Adjust the control cable.
   - 9.1 Set the heater temperature control to the coolest position.
   - 9.2 Set the water regulating valve to the closed position.
   - 9.3 Slide the control cable in the clamp until the screw (Ref. 5) in the clamp lines up with the hole in the valve base plate.
   - 9.4 Tighten the screw (Ref. 5) to hold the cable in place.
   - 9.5 Check that the valve closes when the temperature control is at the coolest setting and opens toward the warmest setting.

   NOTE: The valve is fully closed or fully open before it reaches the mechanical stops at either end of its travel. After adjusting for the coolest setting, it is not necessary to adjust for the warmest setting.
10. Fill the cooling system with approved coolant. See Group 20 of the *Business Class Trucks Maintenance Manual* for instructions.
11. Start the engine. When the engine thermostat opens, air will be forced from the heater core as the coolant circulates. Check the coolant level again and fill as needed.
12. Check the valve and the hose connections for leaks. Tighten the hose clamps if needed.
13. Lower the hood.

1. Hose Clamp
2. Valve Body
3. Control Cable
4. Internal Toothed Clip
5. Cable Mounting Screw

Fig. 1, Water Regulating Valve

Replacement (See Fig. 1)



IMPORTANT: Before replacing any refrigerant parts, read **Subject 220**. Always discharge the system at the compressor before disconnecting a refrigerant line. If the system is contaminated, purge or flush it before you install replacement parts.

1. Review the information under **Safety Precautions, 100**.

⚠ WARNING

Failure to review the safety precautions, and to be aware of the dangers involved when working with refrigerant, could result in serious personal injury.

2. Tilt the hood.
3. Wearing protective goggles and gloves, discharge the refrigerant system. For instructions, refer to **Subject 220**.
4. Disconnect the four refrigerant lines from the expansion valve; then, remove and discard the valve. If the O-rings are in good condition, save them for later use.

1. Expansion Valve Body
2. Compressor Line
3. Receive-Drier Line
4. Evaporator Coil Small Line
5. Evaporator Coil Large Line

Fig. 1, Expansion Valve

⚠ CAUTION

Water and dirt can damage the refrigerant system. Five minutes of being uncapped is the limit for any hose or component.

Do not blow shop air through the refrigerant hoses; shop air is wet (humid).

5. Lubricate the rubber O-rings with refrigerant oil and install them in the fittings.

NOTE: The previously removed O-rings can be used again if they are in good condition.

6. Apply Loctite® 242 or 592 to the male fitting threads. Connect the lines from the evaporator coil to the expansion valve ports. Connect the line from the receiver-drier to the expansion valve port and the line that runs from the expansion valve port to the compressor.

   Tighten the connections as follows:

   - Evaporator coil large fitting—24 lbf·ft (33 N·m)
   - Evaporator coil small fitting—18 lbf·ft (24 N·m)
   - receiver-drier line—12 lbf·ft (16 N·m)
   - Compressor line—18 lbf·ft (24 N·m)

7. Evacuate and charge the air conditioning system with refrigerant. For instructions, refer to **Subject 220**. Be sure to add refrigerant oil to the compressor to replace that which was lost when the system was discharged. Refer to the applicable refrigerant compressor section.

NOTE: If the system will not hold a vacuum, check the connections for tightness or check for a missing O-ring.

8. Lower the hood.

Receiver-Drier Replacement

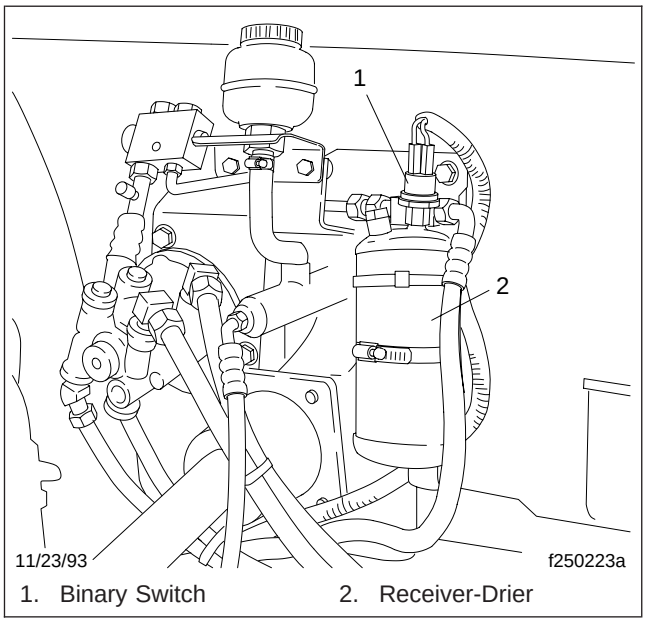
Replacement (See Fig. 1)

IMPORTANT: Before replacing any refrigerant parts, read **Subject 220**. Always discharge the system at the compressor before disconnecting a refrigerant line. If the system is contaminated, purge or flush it before you install replacement parts.

1. Review the information under **Safety Precautions, 100**.

⚠ WARNING

Failure to review the safety precautions, and to be aware of the dangers involved when working with refrigerant, could result in serious personal injury.



2. Tilt the hood.
3. Wearing protective goggles and gloves, discharge the refrigerant system. For instructions, refer to **Subject 220**.
4. Disconnect the electrical leads from the binary switch.
5. Unscrew the binary switch.
6. Disconnect the inlet and outlet lines. Use two wrenches to avoid twisting the hoses.

⚠ CAUTION

Contaminants, such as water and dirt, can damage the refrigerant system. Five minutes of being uncapped is the limit for any part. Do not blow shop air through the refrigerant hoses since shop air is wet (humid).

IMPORTANT: If the desiccant cartridge inside the old receiver-drier has fallen apart, flush the entire system and replace the expansion valve and the refrigerant compressor. Desiccant matter can't be removed from these parts. A cartridge may fall apart from too much water in the system, because of poor evacuation of the system, or from lack of care.

7. Loosen the clamp that holds the receiver-drier to the bracket on the firewall. Remove and discard the receiver-drier .

1. Binary Switch 2. Receiver-Drier

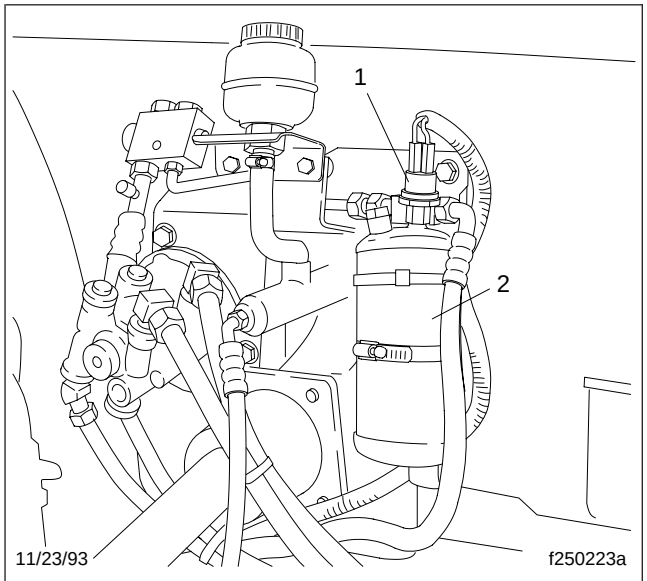


Fig. 1, Receiver-Drier

8. Mount the new receiver-drier and tighten the clamp.
9. Screw the binary switch into the receiver-drier . Tighten the switch 108 lbf·in (1220 N·cm) or one-eighth turn past hand-tight. Connect the electrical leads to the switch.
10. Connect the inlet and outlet lines to the receiver-drier . Tighten the connections 108 lbf·in (45 N·m).
11. Evacuate and charge the air conditioning system with refrigerant. For instructions, refer to **Subject 220**. Be sure to add refrigerant oil to the compressor to replace that which was lost when the system was discharged. Refer to the applicable refrigerant compressor section.
12. Lower the hood.

Replacement (See Fig. 1)

NOTE: A Schrader valve in the receiver-drier prevents loss of refrigerant when removing the binary switch.

1. Tilt the hood.
2. Disconnect the electrical leads from the binary switch.
3. Unscrew the binary switch from the receiver-drier.
4. Screw the new binary switch into the receiver-drier. Tighten the switch 108 lbf·in (1220 N·cm) or one-eighth turn past hand-tight. Connect the electrical leads to the switch.
5. Check the operation of the air-conditioning system.
6. Lower the hood.

1. Binary Switch 2. Receiver-Drier

Fig. 1, Binary Switch

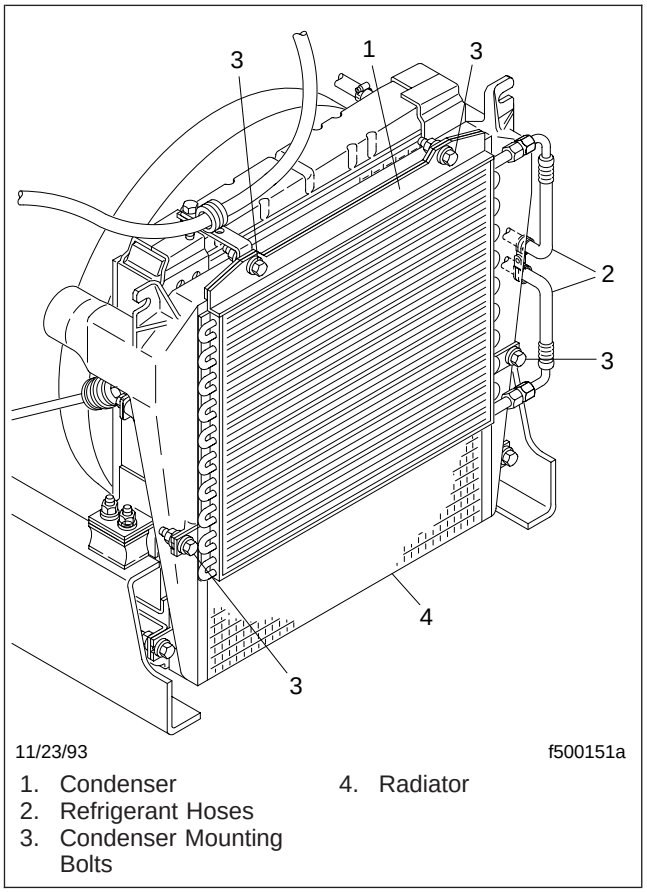
Condenser Replacement

Replacement (See Fig. 1)

IMPORTANT: Before replacing any refrigerant parts, read **Subject 220**. Always discharge the system at the compressor before disconnecting a refrigerant line. If the system is contaminated, purge or flush it before you install replacement parts.

1. Review the information under **Safety Precautions, 100**.

⚠ WARNING



Failure to review the safety precautions, and to be aware of the dangers involved when working with refrigerant, could result in serious personal injury.

2. Tilt the hood.
3. Wearing protective goggles and gloves, discharge the refrigerant system. For instructions, refer to **Subject 220**.
4. Disconnect the refrigerant hoses from the condenser. Use two wrenches to avoid damaging the condenser.

⚠ CAUTION

Contaminants, such as water and dirt, can damage the refrigerant system. Five minutes of being uncapped is the limit for any part. Do not blow shop air through the refrigerant hoses since shop air is wet (humid).

5. Cap the refrigerant hoses.
6. Remove the four condenser mounting bolts.
7. Remove the condenser.
8. Position the condenser on the radiator. Install the capscrews and tighten them 15 lbf·ft (20 N·m).
9. Remove the plugs from the new condenser. Coat the O-rings with refrigerant oil and apply Loctite® 242 or 592 to the male fitting threads.
10. Connect the refrigerant lines to the condenser. Using two wrenches, tighten the fittings 33 lbf·ft (45 N·m). *Be sure to add refrigerant oil to the compressor* , to replace that which was lost in the old condenser. Refer to the applicable compressor section.

1. Condenser
2. Refrigerant Hoses
3. Condenser Mounting Bolts
4. Radiator

Fig. 1, Condenser

11. Charge the system with refrigerant; for instructions, refer to **Subject 220**.
12. Lower the hood.

Replacement

1. Disconnect the batteries.
2. Remove the extruded rubber strip at the top of the dashboard. See **Fig. 1**.

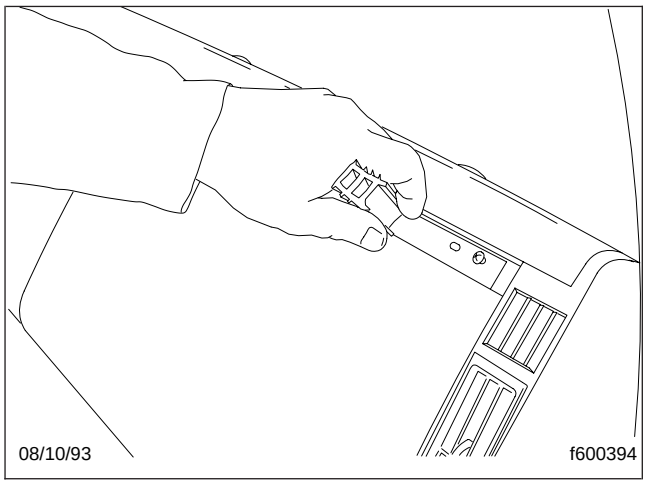


Fig. 1, Remove the Rubber Strip

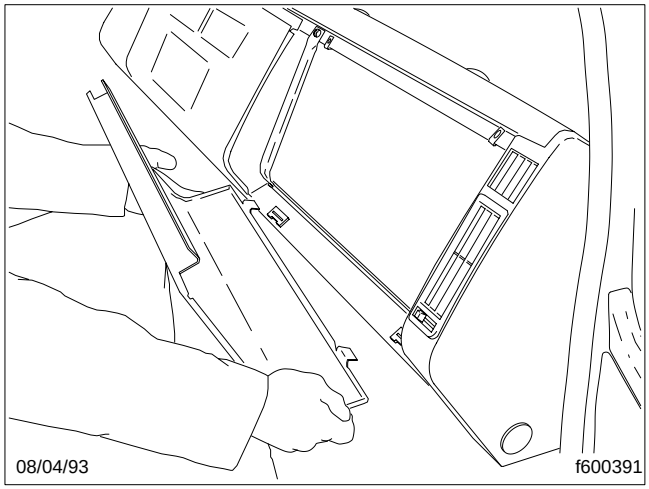
3. Remove dash panel D. See **Fig. 2** and **Fig. 3**.



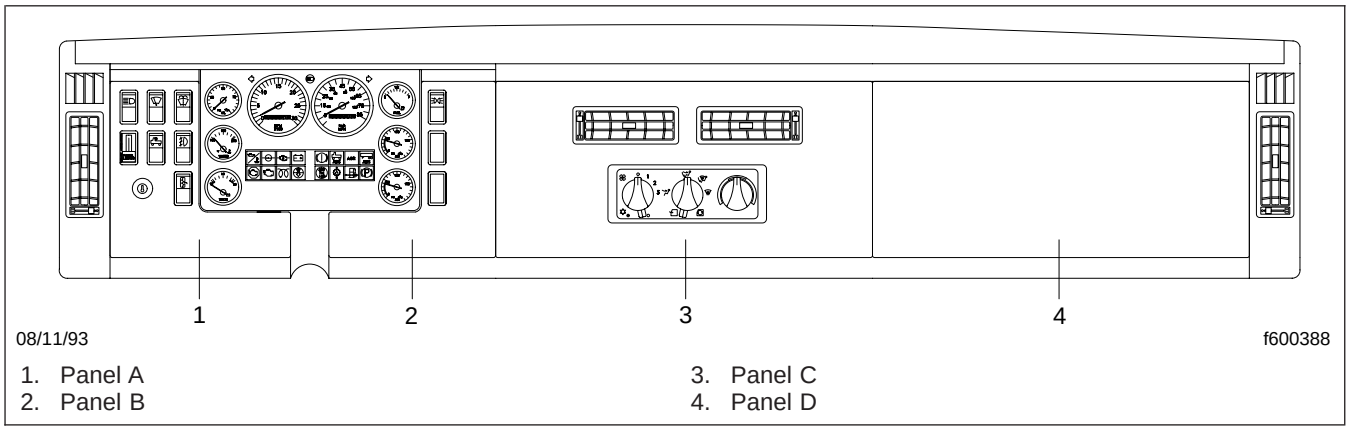


Fig. 3, Remove the Dash Panel

6.1 Gently pry the bezel from the control panel in the center of dash panel C. See **Fig. 4**.

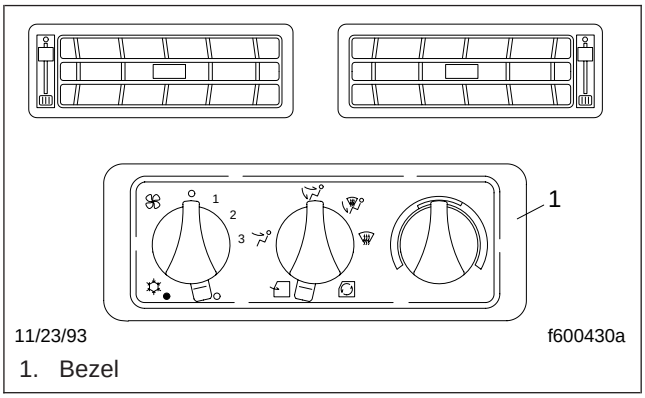
6.2 Remove the panel light and disconnect the electrical connectors from the control panel. Label the connectors so they can be installed in the same positions later.

1. Panel A
2. Panel B
3. Panel C
4. Panel D

Fig. 2, Dash Panel

4. Remove dash panel B. See **Fig. 2**.

4.1 If so equipped, remove the parking brake knob and the trailer brake knob.



4.2 Lift off the panel.

5. Remove dash panel C.
6. Remove the control panel from dash panel C.

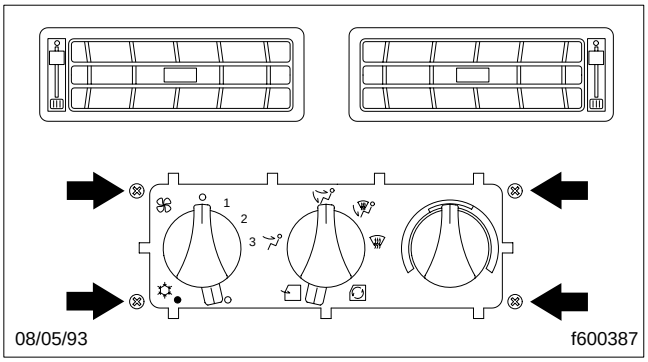
6.3 Label the control cables for later reference. See **Fig. 5**.

6.4 Remove the screws that hold the control cables to the control panel; then, disconnect the cables.

Control Panel Replacement

1. Bezel

Fig. 4, Control Panel



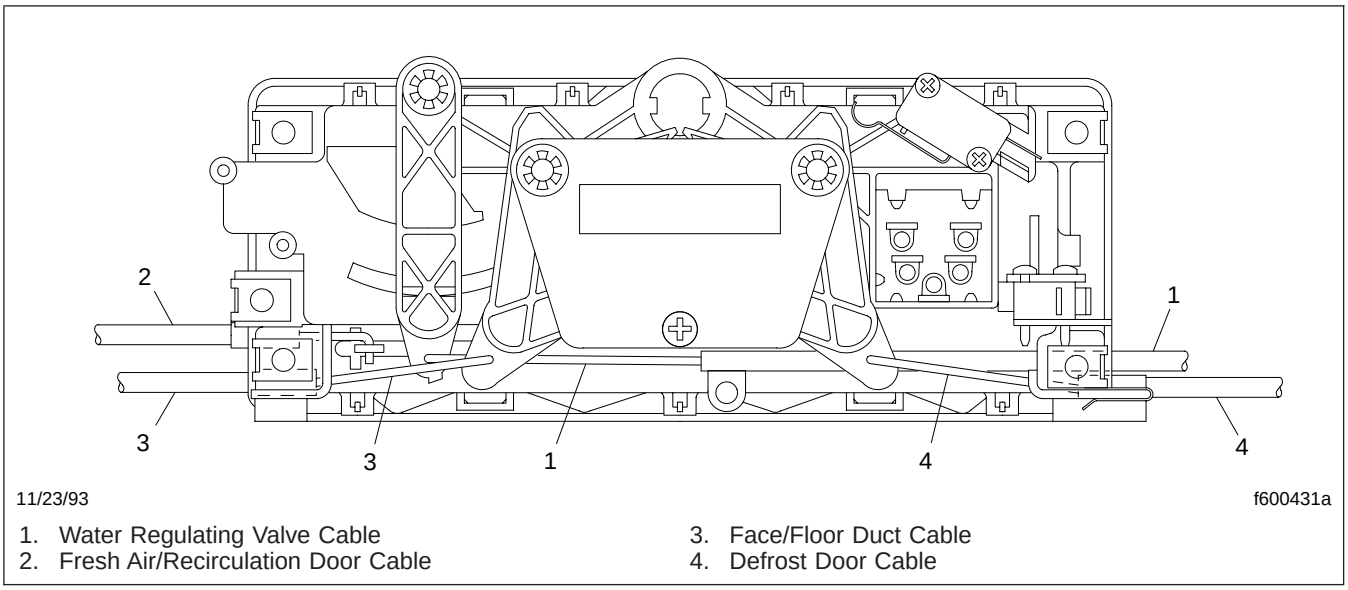


Fig. 6, Control Panel

1. Water Regulating Valve Cable
2. Fresh Air/Recirculation Door Cable
3. Face/Floor Duct Cable
4. Defrost Door Cable

Fig. 5, Control Cables

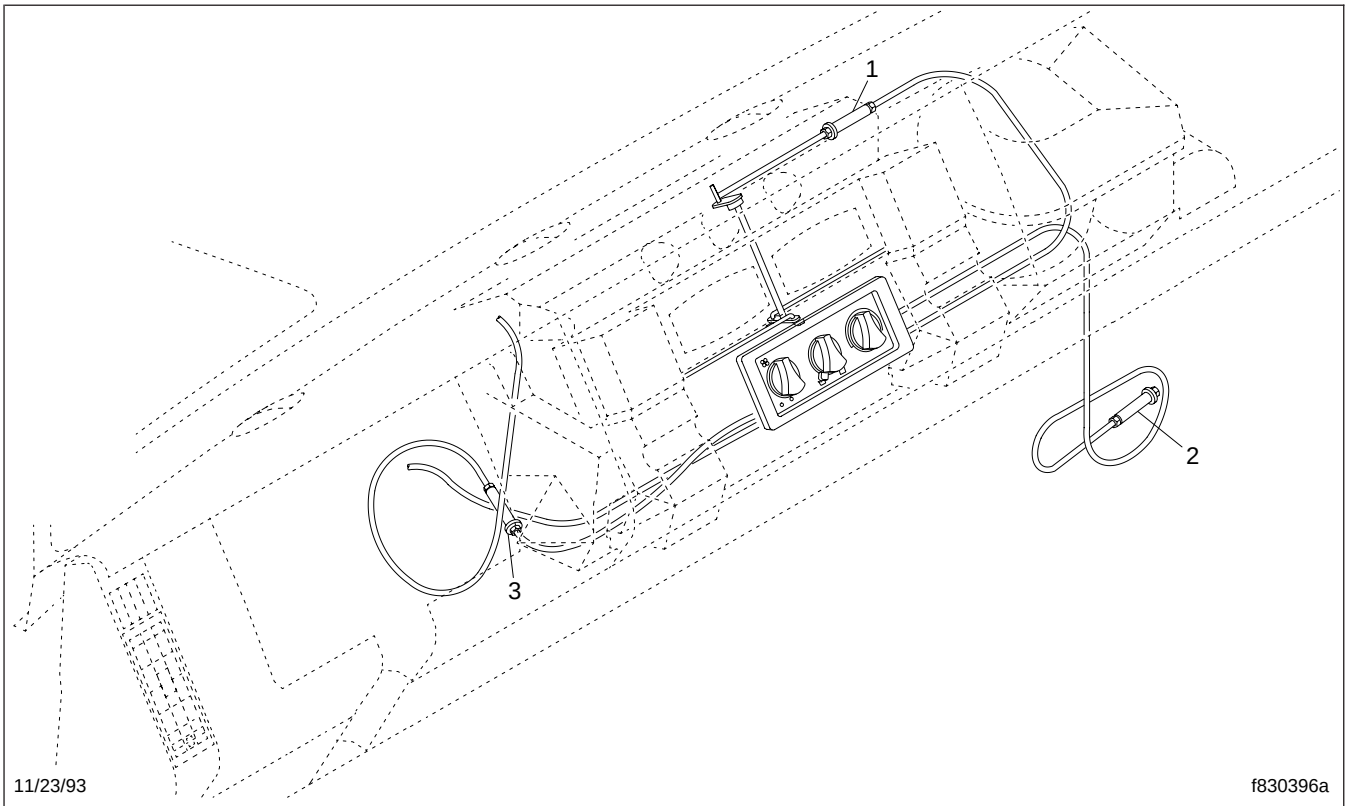
6.5 Remove the four screws holding the control panel to dash panel C. See **Fig. 6**.

6.6 Lift out the control panel.

7. Install the new control panel in dash panel C.

7.1 Position the control panel and install the four screws that mount it to the dash panel.

7.2 Attach the control cables to the control panel. Install the control cable mounting screws.



7.3 Insert the panel light and connect the wiring.

7.4 Install the bezel around the control panel.

8. Adjust the control cables. See **Fig. 5** and **Fig. 7**.

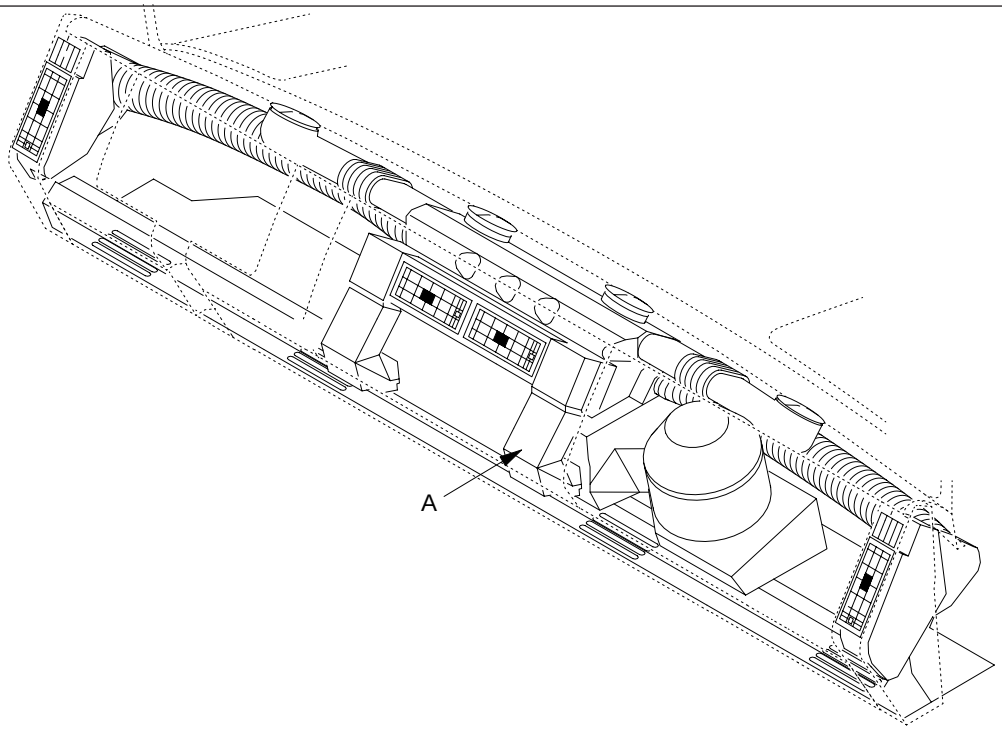
8.1 To adjust the cable (**Fig. 5**, Ref. 1) to the water regulating valve, set the dashboard control to the coolest setting (fully counterclockwise). Adjust the turnbuckle until the valve is almost at its mechanical stop in the closed position.

NOTE: The valve is fully closed or fully open before it reaches the mechanical stops at either end of its travel. After adjusting for the coolest setting, it is not necessary to adjust for the warmest setting.

1. Turnbuckle for Face/Floor Duct Door Cable
2. Turnbuckle for Fresh Air/Recirculation Door Cable
3. Turnbuckle for Defrost Duct Door Cable

Fig. 7, Turnbuckles

8.2 To adjust the fresh air/recirculation door cable (**Fig. 5**, Ref. 2), remove the kick panel under the dashboard on the passenger side for access to the door. Move the control lever to the fresh air position. Adjust the turnbuckle (**Fig. 7**, Ref. 2) under the dashboard until the door snaps into the horizontal position and closes off the opening to the cab. Move the lever to the recirculation position and make sure the door snaps open. If necessary, readjust the turnbuckle so the door is in the correct position for each control lever setting.



8.3 To adjust the face/floor duct door and defrost duct door cables (**Fig. 5**, Refs. 3 and 4), set the control knob in the twelve o'clock position. Both face/floor duct doors should be open to direct air to the floor, and the defrost duct door should be open to let air out the face ducts. Adjust the turnbuckle (**Fig. 7**, Ref. 3) on the defrost duct door cable if necessary.

Turn the control knob fully counterclockwise; the face/floor duct doors should close. Remove the bottom section of one of the floor ducts to check the door position. See **Fig. 8**. Adjust the turnbuckle (**Fig. 7**, Ref. 1) on the face/floor duct door cable if necessary.

Make sure there is a smooth transition from one cable to the other as the control knob moves through the twelve o'clock position. The defrost duct door cable should move when the control is to the right of the twelve o'clock position; the face/floor duct door cable should move when the control is to the left of the twelve o'clock position. As the control

Control Panel Replacement

knob passes through twelve o'clock, one cable should stop moving and the other cable should start to move. If the cables are adjusted incorrectly, either the control knob will lock up before reaching twelve o'clock or the control knob movement will get very stiff.

11/23/93 f830388a

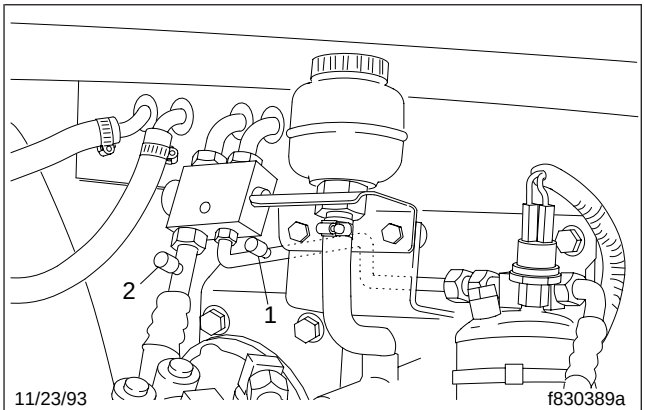
A. Remove this section of duct to check the door position.

Fig. 8, Check the Door Position

9. Install dash panel C and its mounting screws.
10. Install dash panel B. Install the parking brake knob and, if so equipped, the trailer brake knob.
11. Install dash panel D and its two mounting screws.
12. Install the extruded rubber strip at the top of the dashboard.
13. Connect the batteries.

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

Discharging



Discharging the air conditioning system removes most of the refrigerant charge in the system.

1. Tilt the hood.

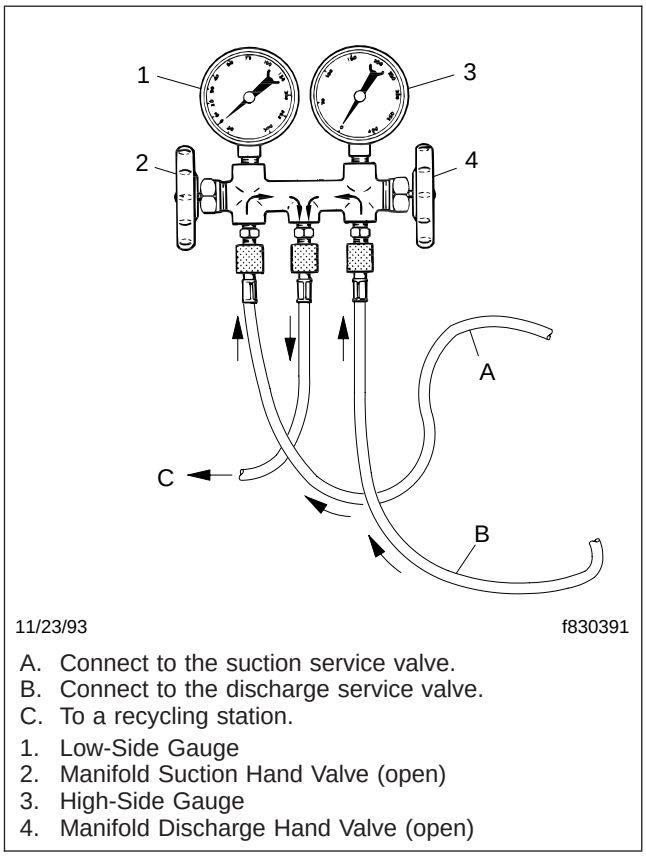
⚠ WARNING

Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions and to be aware of the dangers involved when working with refrigerant could lead to serious personal injury.

2. Remove the caps from the suction and discharge service valves. See **Fig. 1**.

1. Discharge Service Valve
2. Suction Service Valve

Fig. 1, Service Valves



IMPORTANT: The suction and discharge service valves have Schrader valves, which are similar to but not the same as tire valves. Be sure the manifold gauge set has a valve core depressor on the end of each hose.

3. Wearing protective goggles and nonleather gloves, attach a manifold gauge set to the valves. See **Fig. 2**.

   3.1 Close both manifold valves.

   3.2 Connect the manifold high-side hose to the compressor discharge service valve.

   3.3 Connect the manifold low-side hose to the compressor suction service valve.

A. Connect to the suction service valve.
B. Connect to the discharge service valve.
C. To a recycling station.
1. Low-Side Gauge
2. Manifold Suction Hand Valve (open)
3. High-Side Gauge
4. Manifold Discharge Hand Valve (open)

Fig. 2, Discharging Hookup

   3.4 Connect the manifold center hose to an Underwriters Laboratories (U.L.) approved recovery/recycling station.

4. Follow the recovery/recycling station manufacturer's instructions and recover all of the refrigerant from the system.

IMPORTANT: Always comply with all local regulations regarding R–12 disposal. You may be subject to substantial penalties for improper disposal.

5. Measure the oil in the recovery and recycling equipment. The compressor will have to be refilled with the same quantity of new refrigerant oil.

   If the system is contaminated, all of the compressor oil must be replaced with clean oil after purging and flushing the system. If the system is heavily contaminated with desiccant or grit, re-

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

place the compressor, expansion valve, and receiver-drier.

Purging and Flushing

General Information

⚠ WARNING

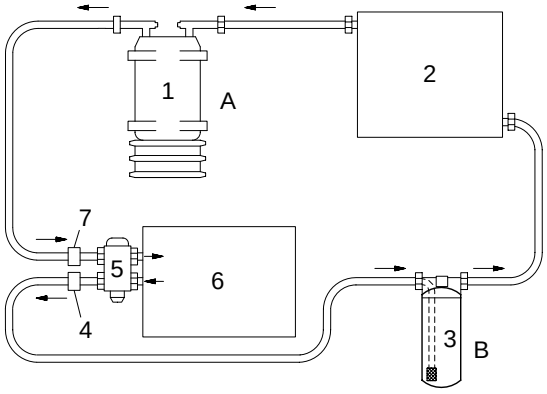
Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions and to be aware of the dangers involved when working with refrigerant could lead to serious personal injury.

Purging removes damp air, traces of refrigerant, and loose dirt from refrigerant parts by passing a stream of inert, dry gas through the parts. If left in the system, these contaminants would have a bad effect on the life and operation of the air conditioning system.

Flushing removes heavy contamination, such as gritty oil and large dirt buildup, which can't be removed by purging with gas. When a part is flushed, liquid refrigerant is forced through it. The liquid picks up the contaminants and flushes them out.

Whether to purge or flush a part depends on how much contamination there is as described above.

Normally the system always has pressure in it. Some loss of refrigerant from one season to the next is normal and does not mean that the system is dirty. If refrigerant has leaked until the system is nearly empty or if refrigerant parts show signs of internal corrosion and grit, the system is contaminated.



If the system is contaminated with moisture, purge or flush all sections of the system. Then change the oil in the compressor and replace the receiver-drier prior to evacuating and charging the system.

If the system is heavily contaminated or if desiccant has circulated through the system, replace the receiver-drier, expansion valve, and compressor.

Do not purge the receiver-drier or the compressor.

Flush the system in segments to lessen the chance of blowing deposits against a port. See **Fig. 3**.

Purge or flush the system in the opposite direction of refrigerant flow (in other words, backflush the sections).

11/23/93 f830395

NOTE: Arrows denote purge and flush points and direction of flow for gas/liquid.

A. Do not purge; instead, replace.
B. Do not purge; instead, replace.

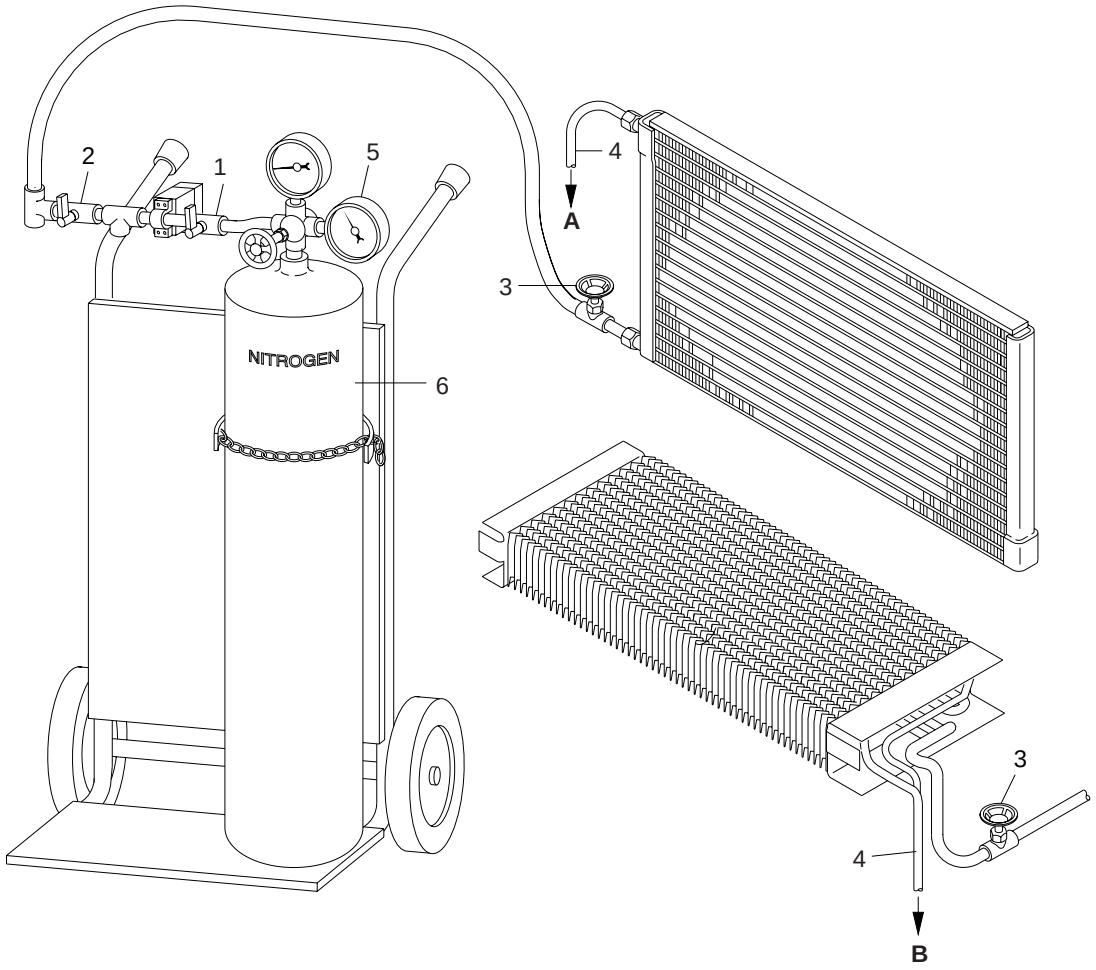
3. Receiver-Drier
4. High-Side Service Valve
5. Expansion Valve
6. Evaporator
7. Suction Service Valve

Fig. 3, Purge and Flush Points

NOTE: Dry nitrogen gas is recommended for purging, but any safe, inert, dry gas, such as carbon dioxide or argon, may be substituted. A pressure regulator is required to regulate from 0 to 200 psi (0 to 1379 kPa). Commercial cylinders of nitrogen contain pressures in excess of 2000 psi (13 790 kPa). This pressure must be reduced to 200 psi (1379 kPa) for purging.



Flushing parts with refrigerant requires a recovery/recycling station.

Purging Procedure

NOTE: Dry nitrogen gas is recommended for purging, but any safe, inert, dry gas, such as carbon dioxide or argon, may be substituted. A pressure regulator is required to regulate from 0 to 200 psi (0 to 1379 kPa). Commercial cylinders of nitrogen contain pressures in excess of 2000 psi (13 790 kPa). This pressure must be reduced to 200 psi (1379 kPa) for purging.

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

1. Discharge the system.
2. Disconnect both ends of the line or part being purged. Tightly cap the rest of the system.
3. Make sure valves 1, 2, and 3, are closed. See **Fig. 4**.
5. Connect the drain line to the inlet end of the part or line.
6. Place the outlet of the drain line into a recycling system container.
7. Adjust the nitrogen bottle regulator to 200 psi

A. To Waste Container
B. To Recycling System Container
1. Nitrogen Bottle Control Valve
2. Purging Control Valve
3. Supply Line Valve
4. Drain Line
5. Nitrogen Bottle Regulator/Gauge
6. Nitrogen Bottle

Fig. 4, Purging Station

4. Connect the supply line valve to the outlet end of the part or line.

(1379 kPa). Open the nitrogen bottle control valve and the purging control valve. Then slowly

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

open the supply line valve. Check the drain line for gas flow.

8. Let the nitrogen flow at 200 psi (1379 kPa) for 25 to 30 seconds.
9. Lower the pressure to 4 psi (28 kPa) and let it flow for 1 to 2 minutes. If the line or part was very wet, allow it to flow until there is no trace of refrigerant oil or solid bits of dirt or grit flowing from the drain tube.
10. Close the nitrogen bottle control valve and the purging control valve first, then close the supply line valve.
11. Disconnect the supply line valve and the drain line. Tightly cap both ends of the part or line.

Flushing Procedure

1. Discharge the system.
2. Disconnect both ends of the line or part being flushed. Tightly cap the lines to the rest of the system.
3. Heat R–12 in a dial-a-charge.
4. Connect the dial-a-charge outlet hose to the outlet side of the system. This will ensure that R–12 will flow in the reverse direction of normal flow.
5. Connect a line from the inlet side of the system to a recovery station or a collection bottle.

NOTE: If the system is extremely contaminated, install a receiver-drier inline as a prefilter for the recovery station.

6. Turn on the recovery station and open the outlet valve for the dial-a-charge. Allow about 2 pounds (1 kilogram) of R–12 to flow through the system.
7. Close the supply line valve and wait for the recovery station to shut off.
8. Disconnect the supply line and the drain line from the dial-a-charge and the recovery station. Connect the lines to a nitrogen bottle.
9. Purge the system and check the collection bottle or recovery station for contaminants. Repeat the process if needed.
10. Disconnect the lines from the part and tightly cap both ends of the part.

Evacuating (dehydration)

General Information

Moisture in a Refrigerant System

Moisture damages air conditioning systems in three ways.

First, water forms ice crystals at the thermostatic expansion valve. Ice crystals retard or stop the flow of refrigerant, causing a reduction or complete loss of cooling. As the expansion valve warms due to the lack of refrigerant, the ice melts and passes through the expansion valve. Then refrigerant will flow again until the ice crystals re-form. The result is intermittent cooling.

Second, water causes corrosion. Refrigerants may contain chlorine, which combined with water forms hydrochloric acid. This acid corrodes steel and copper plating.

Third, water mixes with refrigerant oil forming sludge. This reduces the lubricating ability of the oil and can plug the condenser, evaporator, and thermostatic expansion valve.

Effects of Pressure on the Boiling Points of Water

Water boils at 212°F (100°C) at an atmospheric pressure of 14.7 psi (101 kPa) (sea level). At higher elevations the atmospheric pressure is lower which allows water to boil at lower temperatures. See **Table 1** for boiling temperatures of water at converted pressures.

Similarly we can boil and remove water from the air conditioning system by lowering the system pressure to a vacuum to cause the moisture to boil at normal ambient temperatures. A vacuum pump can reduce the pressure in the system. Since the pressure is the lowest at the pump, water vapor is pulled out of the system. See **Fig. 5**. This process is called evacuation or dehydration.

Boiling Temperatures of Water at Converted Pressures		
Boiling Temperature of Water: °F (°C)	**Absolute Pressure: psi (microns)**	**Vacuum: inHg (mmHg)**
212 (100)	14.696 (759993.4)	0 (0)

Table 1, Boiling Temperatures of Water at Converted Pressures

Vacuum Pump Selection

The purpose of a high-vacuum pump is to reduce and hold a vacuum in the air conditioner system so moisture can be boiled at ambient temperature. For example, a vacuum pump capable of pulling a vacuum of 28.89 inHg (733.8 mmHg), is able to boil water at 80°F (27°C). There are various types of vacuum pumps available. Only some types are recommended for truck air conditioning evacuation.

Air pump-type vacuum pumps are designed to remove large volumes of air but do not develop high vacuum. They cannot pull more than 28 inHg (711 mmHg) which boils water at 100°F (38°C).

Compressor-type vacuum pumps come in two designs: piston-type and rotary-vane type. A piston-type compressor can typically pull a vacuum of 28.2 inHg (716.3 mmHg) which boils water at 96°F (36°C). A rotary-vane type compressor may pull a vacuum of 29.82 inHg (757.4 mmHg) which boils water at 21°F

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

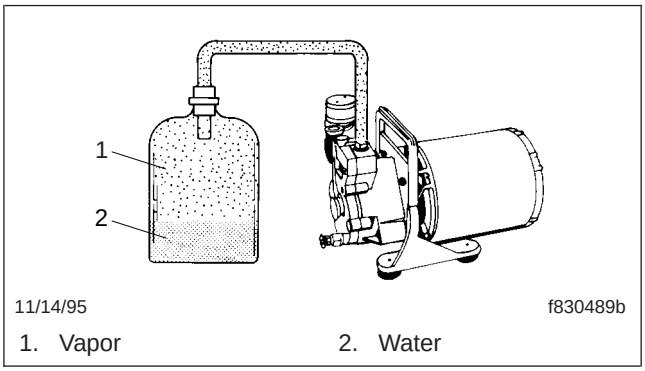

Fig. 5, Water to Vapor

(–6°C), but it is limited to pumping 0.4 to 0.8 cfm, which is too slow to handle truck air conditioners.

High-vacuum pumps are available in single-stage and two-stage models. A single-stage pump is adequate, but a two-stage pump is recommended to save time and assure complete evacuation. See **Fig. 6**.

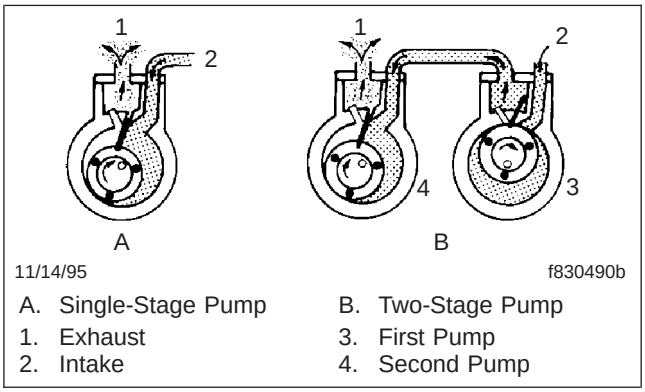

Fig. 6, Vacuum Pumps

Most single-stage high-vacuum pumps with a gas ballast will pull down to about 29.88 inHg (758.95 mmHg) which boils water at 4°F (–16°C).

A two-stage high-vacuum pump features a second pump to reach a higher vacuum than a single-stage pump. In a two-stage pump, the exhaust of the first pump discharges into the intake of the second pump. The second stage pumps at a lower pressure and therefore pulls a higher vacuum on the system than the first pump can by itself.

Two-stage high-vacuum pumps are capable of pulling down to 29.9192 inHg (759.95 mmHg) of vacuum for prolonged periods, which boils water at –60°F (–51°C).

The discharge line restriction is a factor affecting pump-down time. Pump-down time can be significantly reduced by use of larger diameter hoses, as short in length as possible.

Pumping capacity affects pump-down time. It is perfectly acceptable to use a large vacuum pump on a small system. Using too small of a pump on a large system could cause premature pump wear, or require excessive time to pull a vacuum, even though the pump may be able to draw adequate vacuum.

The suggested minimum cfm for pumps on different size air conditioners are listed in **Table 2**.

Minimum CFM for Pumps on Different Size Air Conditioners	
System Size	**Suggested High-Vacuum Pump Size**
Panel Trucks Large Window Units	2.2 cfm
Tractor/Trailers, Buses Rooftop A/C Systems	3.0 cfm
Refrigeration Van	15.0 cfm

Table 2, Minimum CFM for Pumps on Different Size Air Conditioners

Measuring Vacuum

Gauges

Vacuum can be measured with:

- A standard compound gauge;
- A closed-end manometer;
- An electronic thermistor vacuum gauge.

A standard compound gauge reads low pressures in inches of mercury. It is not suitable for measuring high vacuum.

A closed-end U-tube mercury manometer can be read with good accuracy. High vacuum readings can only be read from laboratory-style U-tube manometers.

Electronic thermistor vacuum gauges are designed for use with high vacuum pumps and can accurately

read as low as 100 microns. This gauge can use an analog scale or a digital (LED) display.

Procedure

The location of the vacuum gauge will affect the reading. The closer to the vacuum source, the lower will be the reading.

Isolate the vacuum pump with a good vacuum valve and allow the pressure in the system to stabilize before taking a final reading.

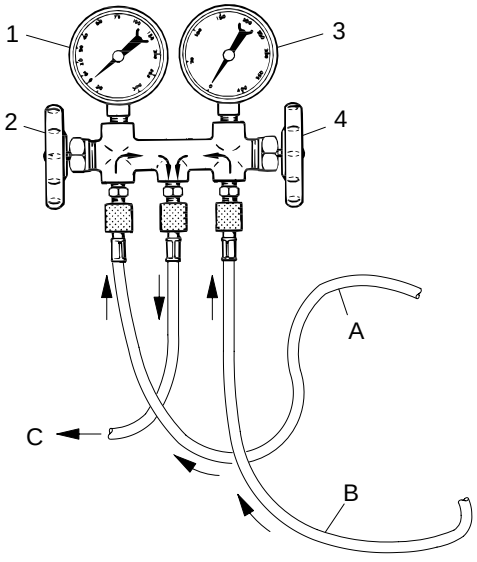
If the pressure will not stabilize, it is an indication of a leak. If it does stabilize at a vacuum which is too high (for example, 1500 microns), it is an indication of moisture and more evacuation is required.

Maintaining the Vacuum Pump

Maintenance is important for high-vacuum pumps. The oil must be changed at regular intervals to prevent moisture buildup which will cause eventual pump failure.

Pumping down for extremely wet air conditioning systems can completely saturate the pump oil.

⚠ CAUTION



Flush the vacuum pump every fourth time it is used and before storing for long periods of time. Acid will form and corrode the pump if water-laden oil remains in the pump for an extended period.

Vacuum pump oil is water soluble. This aids the pump in reaching a high vacuum by absorbing water and sealing the pump.

Only vacuum pump oil should be used as a flushing agent and lubricant. Do not use any solvent or any other oil. Clean oil should be run through the pump until it runs out clear. Oil should be added to the fill level indicated on the pump. Check the oil level before each use.

Evacuation Procedure

1. The system must be discharged and, if contaminated, purged or flushed and the compressor filled with the correct amount of refrigerant oil. Replace the receiver-drier if the system is opened.
2. Close both manifold hand valves on the manifold gauge set.
3. If using a thermistor vacuum gauge, connect the gauge between the manifold center service hose and the vacuum pump. See **Fig. 7**.

11/23/93 f830391

A. Connect to the suction service valve.
B. Connect to the discharge service valve.
C. To vacuum pump.
1. Low-Side Gauge
2. Manifold Suction Hand Valve (open)
3. High-Side Gauge
4. Manifold Discharge Hand Valve (open)

Fig. 7, Evacuation Hookup

4. Connect the manifold discharge line to the discharge service valve.
5. Connect the manifold suction line to the suction service valve.
6. Connect the center manifold line to the vacuum pump.
7. Open the manifold hand valves.
8. Turn on the vacuum pump, and open the pump control valve.
9. If using a thermistor gauge, open the thermistor gauge valve.

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

10. Allow the pump to draw to at least 29.90 inHg (759.5 mmHg).
11. Close the pump valves, and turn off the pump.
12. Allow the system to stabilize for five minutes.
13. If not using a thermistor gauge, go to the next step. If using a thermistor gauge, proceed as follows:

    13.1 If the thermistor gauge reading does not rise above 29.85 inHg (758.2 mmHg), the system is okay. Proceed to "Charging."

    13.2 If the thermistor gauge reading rises above 29.85 inHg (758.2 mmHg) and stops, there is moisture in the system. Repeat the steps above beginning with turning on the pump and opening the control valve.

    13.3 If the thermistor gauge reading rises above 29.85 inHg (758.2 mmHg) and continues to rise, add a partial charge of refrigerant and leak test the system. Repair any leaks and reevacuate the system. See "Leak Testing" for instructions.

14. If not using a thermistor gauge, proceed as follows:

    14.1 Note the low pressure gauge needle position.

    14.2 Wait 15 minutes, then check the low pressure gauge needle position again.

    14.3 If the needle has not moved, turn on the vacuum pump and open the pump control valve. Let the pump run for one hour. Go to "Charging."

    IMPORTANT: A gauge reading of over 29.85 inHg (758.2 mmHg) indicates that there is still water in the system.

    14.4 If the needle has moved, add a partial charge of refrigerant and leak test the system. Repair any leaks and reevacuate the system. See "Leak Testing" for instructions.

Charging

General Information

⚠ WARNING

Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions and to be aware of the dangers involved when working with refrigerant could lead to serious personal injury.

The recommended way of charging a system is by adding refrigerant as a gas. High-side liquid charging may cause liquid refrigerant to enter the compressor. If this happens, it may cause a hydraulic lock in the compressor and destruction of the unit.

If a charging cylinder is used—one that heats refrigerant and allows the worker to make exact refrigerant measurements—follow the instructions of the equipment manufacturer.

Gas Charging Procedure

NOTE: The system must be evacuated, with the manifold gauge set connected to the compressor, before a full charge can be added to the system.

1. Obtain enough refrigerant to fully charge the system. A full charge is 48 ounces (1362 grams) of refrigerant.

   If a tank (bulk quantity) is used, it should be set on a scale and its weight noted so that the correct amount of refrigerant enters the system. This prevents overcharging, which could damage the compressor.

   If one-pound cans of refrigerant are used, obtain enough to fully charge the system.

NOTE: Each one-pound can actually holds 14 ounces (397 grams) of refrigerant.

2. Close the manifold hand valves.
3. Connect the manifold center service hose to the refrigerant can, as shown in **Fig. 8**. Do not release the refrigerant at this time. Place the can in an upright position so that refrigerant enters the system as a gas. **Do not allow liquid refriger-**

ant to enter the compressor by tipping the refrigerant can.

A. Low-Side Hand Valve
B. High-Side Hand Valve
C. Connect to the suction service valve.
D. Connect to the discharge service valve.
1. Low-Side Gauge
2. Manifold Suction Hand Valve (open)
3. High-Side Gauge
4. Manifold Discharge Hand Valve (closed)
5. Refrigerant

Fig. 8, Gas Charging Hookup

⚠ CAUTION

If the refrigerant can is tilted during service operations, liquid refrigerant could enter the compressor through its suction port, which may damage the unit once it is turned on.

4. With the engine off, open the manifold low-side hand valve. Do not open the manifold high-side hand valve.
5. Open the valve on the refrigerant can to allow the refrigerant vapor to enter the system.

IMPORTANT: On bulk quantity tanks, larger hoses are used. These hoses alone may carry 8 ounces (227 grams) or more of refrigerant.

6. Close the valve on the refrigerant can. If a full charge did not enter the system, the rest will be added while the compressor is on.

⚠ WARNING

Any other way of warming refrigerant, such as using a torch, is dangerous and should never be tried. Using extreme heat on an refrigerant can could cause an explosion and serious bodily injury.

7. Start the engine and run it at 1500 rpm. Set the cab air conditioner controls at maximum cooling and fan speed. The refrigerant compressor must engage. Open the valve on the refrigerant can. Leave the valve open until a full charge of refrigerant has entered the system. Close the valve on the refrigerant can.

   To know when a one-pound can is empty, tap it on the bottom. A hollow ringing will be heard. **Do not tip the refrigerant can.**

NOTE: If refrigerant is slow to enter the system because of low outside temperatures, vaporization can be quickened by placing the refrigerant can in a tub of warm water no warmer than 125°F (52°C).

8. When enough refrigerant has entered the system, look at the sight glass. No frothing or bubbles should appear when the compressor is on. If frothing occurs, leak test the system.
9. While the compressor is engaged, check the operating pressures at the suction and discharge ports. See the applicable compressor section in this manual. If the operating pressures are not acceptable, see **Troubleshooting 300** for possible causes.
10. Shut down the engine. Close both manifold hand valves.
11. All of the manifold gauge hoses are under pressure. Disconnect them from the compressor and the refrigerant can. Install the caps on the compressor service valves.

Liquid Charging Procedure

NOTE: Before charging, the system must be recovered and evacuated with the recovery and

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

recycling station connected to the service and discharge port connections.

1. Obtain enough refrigerant to fully charge the system. A full charge is 48 ounces (1362 grams) of refrigerant.

   If a tank (bulk quantity) is used, it should be set on a scale and its weight noted so that the correct amount of refrigerant enters the system. This prevents overcharging, which could damage the compressor.

   If one-pound cans of refrigerant are used, obtain enough to fully charge the system.

NOTE: Most one-pound cans actually hold 14 ounces (397 grams) of refrigerant.

2. Close the manifold hand valves.
3. Disconnect the vacuum pump. Connect the manifold center service hose to the refrigerant container and purge the air from the hose.
4. With the engine off, open the manifold high-side hand valve. **Do not** open the manifold low-side hand valve. See **Fig. 9**.
5. If charging from a tank (bulk quantity), turn the tank upside down. Open the valve on the refrigerant container to allow the refrigerant liquid to enter the system.

NOTE: If refrigerant is slow to enter the system because of low outside temperatures, vaporization can be quickened by placing the refrigerant tank in a tub of warm water no warmer than 125°F (52°C).

6. Close the high-side hand valve. If a full charge did not enter the system, the rest will be added while the compressor is on.
7. Start the engine and run it at 1500 rpm. Set the cab air conditioner controls at maximum cooling and fan speed. The refrigerant compressor must engage. If charging from a tank (bulk quantity), place the tank in the upright position. Open the low-side hand valve. Leave the valve open until a full charge of refrigerant has entered the system. Close the valve on the refrigerant container. Close the low-side hand valve. Disconnect the hoses.
8. When enough refrigerant has entered the system, look at the sight glass. No frothing or bubbles should appear when the compressor is on. If frothing occurs, leak test the system.

9. While the compressor is engaged, check the operating pressures at the suction and discharge ports. See the applicable compressor section in this manual. If the operating pressures are not acceptable, see **Troubleshooting 300** for possible causes.
10. Shut down the engine.
11. All of the manifold gauge hoses are under pressure. Disconnect them from the service valves. Disconnect the hoses from the refrigerant compressor. Install the caps on the service valves.

Charge Checking

⚠ WARNING

Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions and to be aware of the dangers involved when working with refrigerant could lead to serious personal injury.

In a system that is fully charged, some bubbles will show as the compressor cycles. Very high outside temperatures may cause occasional bubbles when the compressor is running; this is normal. For additional information, see "Refrigerant Check" in **Troubleshooting 300**.

Leak Testing

General Information

⚠ WARNING

Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions and to be aware of the dangers involved when working with refrigerant could lead to serious personal injury.

Refrigerant is odorless. As a result, all of it may leak away and not be noticed until the system stops cooling. All vehicle refrigerant systems lose some refrigerant, depending on the condition of the system. High loss rates signal a need to locate and repair the leaks.

Leaks are most often found at the compressor hose connections and at the various fittings and joints in the system. Refrigerant can be lost through hose permeation. Leaks can also be traced to pinholes in the evaporator caused by acid, which forms when water and refrigerant mix.

Leak Detection

There are two ways of finding the locations of leaks:

- sight detection
- electronic leak detection

The electronic leak detection method is the recommended method and the most precise method of detecting leaks.

The sight detection method may be used to find large leaks. Many large leaks will cause oil to escape along with refrigerant at the point of the leak. A deposit of oil may be a sign of a leak. Verification of leaks must be done using the electronic leak detection method.

Freightliner recommends using only the Heated Diode type of electronic leak detector. This type of detector can be identified by its construction and power supply. It has a heated element which requires periodic replacement and uses either a 12V DC or 120V AC power supply, or has a rechargeable battery. The Heated Diode type detector is sensitive only to gases containing halogen, such as R–134a and R–12 refrigerants. It will not detect other substances and is more likely to detect all of the leaks in a system. This type has both visual and audio indicators and self-tests to confirm operation.

Recommended electronic Heated Diode type leak detectors are available from their manufacturers. See **Table 3**.

Another type of detector, the Corona Discharge type, is the kind most commonly found in service and repair shops. This detector requires very little power and can operate on as few as four AA alkaline batteries. The Corona Discharge detector is not sufficiently sensitive and will create false alarms by detecting moisture and antifreeze or solvent vapors. This type of detector is specifically **not recommended**.

When checking for leaks, always focus your attention on the lowest portion of the fitting or part being tested. Refrigerant is heavier than air and will collect at the low point. Oil will also flow toward the low point.

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

NOTE: Do not try to use a leak tester right after connecting or disconnecting service hoses. Traces of refrigerant at the fittings can falsely signal a leak. Always verify a leak by blowing shop air in to the area of the suspected leak and checking the area again.

Use the following procedures to locate A/C system refrigerant gas leaks using a heated diode type electronic leak detector.

1. Operate the electronic leak detector in accordance with the manufacturer's instructions.
2. Leak test with the engine turned off.
3. Charge the air conditioning system with sufficient refrigerant to indicate a gauge pressure of at least 50 psi (340 kPa) with the system not operating. It may not be possible to produce this amount of pressure and measure leakage if the ambient temperature is less than 59°F (15°C).
4. Be careful not to contaminate the detector probe tip if the part being tested is not clean. Wipe the part off with a dry shop towel or blow it off with shop air. Do not use cleaners or solvents as many detectors are sensitive to their chemical ingredients.
5. Visually inspect the entire refrigerant system. Look for air conditioning lubricant leakage and corrosion or damage to lines, hoses, and all other components. Inspect each questionable location carefully with the detector probe. Check all fittings, couplings, refrigerant controls, service ports (with caps installed), brazed or welded areas, and areas around attachment points and hold-downs.
6. Follow the path of the refrigerant system methodically so that no leaks are missed. If a leak is found, continue to test the rest of the system.
7. Inspect an area of possible leakage slowly and close to the part, moving completely around the part. Move the probe no faster than one to two inches (25 to 50 mm) per second and no farther away than 1/4 inch (6.4 mm) from the part.
8. If a large leak is present in either the system being serviced or the service equipment, the surrounding air will be saturated with refrigerant gas. In this situation the leak detector operates erratically and will indicate leakage without being near a possible leak source. Place a large fan so that a light breeze blows through the work area. Verify a leak by blowing shop air into the area and repeating the inspection. Pinpoint a large leak by blowing out the area often.
9. You may test the evaporator core while it is in its housing. Turn on the blower motor for a minimum of 15 seconds. Shut off the blower and wait for refrigerant gas to accumulate in the housing. Follow the detector instructions for the specific length of time to wait for the gas to accumulate. Insert the detector probe into the blower resistor block, or condensate drain hole if no water is present. If this is not possible insert the probe into the closest opening to the evaporator, such as a heater or vent duct.
10. Leak test the front seal area of the compressor. Blow shop air into the cavities in and around the clutch for at least 15 seconds. Let the compressor stand for one minute and then test for leakage. Inspect rotary type compressors (Sanden or Sel-Tec) by placing the probe near the holes at the front of the clutch. Inspect two-cylinder reciprocating type compressors (Climate Control) by placing the probe between the clutch coil and the compressor.

IMPORTANT: Be careful not to damage the clutch bearing seal with high pressure shop air.

11. Leak test repaired areas of the system after repairs have been performed. Leak test the service ports (with caps installed) after any service which disturbs the refrigerant system.

Discharging, Purging and Flushing, Evacuating, Charging, Charge Checking, and Leak Testing

Electronic Leak Detectors		
Designation	**Manufacturer**	**Comments**
D-TEK	Leybold Inficon 2 Technology Place East Syracuse NY 13057 (315) 434–1144	• Rechargeable battery • Hand-held design • Simple to operate

Table 3, Electronic Leak Detectors

Preliminary Checks

Before testing the operation of the air conditioning system, make the following checks.

1. Make sure the refrigerant compressor drive belt is not damaged and is correctly tensioned. Also check the compressor mountings for tightness. For instructions and other information, see the applicable refrigerant compressor section elsewhere in this group.
2. Using a feeler gauge, check for correct refrigerant compressor clutch clearance. For instructions, see the applicable refrigerant compressor section elsewhere in this group.
3. Check for broken, burst, or cut hoses. Also check for loose fittings on all parts.
4. Check for road debris buildup on the condenser fins. Using air pressure and a whiskbroom or a soapy spray of water, carefully clean off the condenser. Be careful not to bend the fins.
5. Check the moisture indicator sight glass for the moisture content of the refrigerant and the state of the charge. The air conditioner should be on when checking the indicator. You should make this check at the end of a day's run. Replace the charge if it is wet. If there are bubbles in the sight glass, the refrigerant charge could be low. Add more R–12 to the system. See **Subject 220** for instructions.
6. If there is not enough airflow, make sure that leaves or other debris has not entered the fresh air ports under the windshield. If debris has entered, it could clog the fins of the evaporator, and block airflow.

   Also, be sure that all ducts are connected to the dash louvers and that the air-control flaps in the heater housing are moving properly (this requires removal of the right and center dash panel).

Performance Tests

Following is a brief description of symptoms or conditions that will exist if something goes wrong in a refrigerant part.

Cooling Check

When outside temperature and humidity are high, it will take longer to cool the cab, especially if the fresh air vents are left open.

To determine if the air conditioner is cooling enough:

1. Set the engine speed at 1500 rpm.
2. Close the doors and windows.
3. Turn on the air conditioner and set the controls at maximum cooling (recirculated air) and blower speed. The compressor must be engaged during this test.
4. Allow the system to run for at least 10 minutes (longer on hot and humid days).
5. Place a thermometer inside the louver or air duct. Make sure the controls are set so that air flows out of the duct being tested.
6. Compare the measured temperature readings to the readings in **Table 1** below. If the duct's air temperature is higher than normal readings, the system is not cooling enough. For possible causes, see the troubleshooting tables.

Temperature Comparison	
Outside Temperature	**Center Vent Temperature**
60 to 80°F (16 to 27°C)	58°F (14°C) or lower
80 to 90°F (27 to 32°C)	60°F (16°C) or lower
90 to 100°F (32 to 38°C)	64°F (18°C) or lower

Table 1, Temperature Comparison

Refrigerant Check

There are four conditions to look for when checking refrigerant in the sight glass.

1. Bubbles normally show only when the system is started and then disappear after a few seconds. If these bubbles *continue all the time* the system is running, the system is merely low on (not completely out of) refrigerant. Only an occasional bubble should be seen during normal operation.
2. A clear sight glass means that the system has enough refrigerant to work properly, that it is completely out of refrigerant, or that it is overcharged.

3. A cloudy sight glass means that dirt or broken-down bits of desiccant are flowing through the system. This is a serious condition that requires a complete flushing out of the system, installation of a new receiver-drier, expansion valve, and, if the desiccant cartridge of the receiver-drier has fallen apart, installation of a new refrigerant compressor.
4. Oil streaks in the sight glass mean low refrigerant or too much oil in the system.

Receiver-Drier

The receiver-drier is normally at outside temperature. To the touch, the entire length of the unit should be the same temperature. If noticeable cool spots exist, replace the receiver-drier.

A blockage at the inlet of the unit will cause high head pressures. Outlet blockages will cause low head pressures and little or no cooling.

If the moisture indicator is not blue, the receiver-drier is saturated with water and acid, and must be replaced.

Cooling System

Although they are not physically connected, there is a close tie between a vehicle's air conditioner and its cooling system. Poor air conditioner cooling can be the result of a problem in the cooling system.

If the cooling system does not work correctly, the heat of the engine will rise to abnormal levels. The added heat will transfer to the air conditioner, other underhood parts, and maybe make its way into the cab. The added heat makes it necessary for the air conditioner to work harder and, at the same time, it reduces the air conditioner's ability to cool down the air in the cab.

See the engine cooling section for cooling system troubleshooting and to the engine manufacturer's service manual for other details about cooling system problems.

Expansion Valve

Problems that start in the expansion valve show up as follows: when stuck closed, the evaporator and the expansion valve will be at outside temperature. When stuck open, both the coil and the valve will be extremely cold with frost or ice buildup.

Because the expansion valve is very sensitive to contamination, blockages in the system tend to be found here. Usually, the contaminant is water. Less than a drop of water is all it takes to make the valve inoperative. When water reaches the valve, the extreme cold that results from the pressure drop freezes the water, forming a block of ice in the valve. After the system shuts down and the valve warms up, the ice melts, and the valve operates again, only to freeze up when the water returns.

On-and-off operation of the expansion valve means that the receiver-drier is not removing water and acids from the system. These contaminants should cause the moisture indicator's element to turn pink or white.

Refrigerant Compressor

Compressor problems usually show in one of four ways: abnormal noise, seizure, leakage, or low suction and discharge pressures.

Resonant compressor noises are not causes for alarm. Irregular noise or rattles are likely to be caused by broken parts. To check for seizure, de-energize the magnetic clutch and see if the drive plate can be turned. If it will not turn, the compressor has seized.

Low discharge pressure may be caused by not enough refrigerant, not enough belt tension, or a blockage somewhere in the system. These things should be checked before servicing the compressor.

Evaporator

The evaporator is basically trouble-free when airflow over the fins is not blocked. External or, less often, internal blockages will cause low suction pressure as well as little or no cooling.

If hydrochloric acid has formed in the system (the result when refrigerant mixes with water), it may cause pinholes to form in the evaporator. If a leak exists in the system, and it cannot be traced to other parts or fittings, suspect damage to the evaporator.

Condenser

The condenser is also usually trouble-free when road debris, such as leaves or dirt buildup, is removed. If debris cakes up, airflow over the condenser fins is blocked; air is not able to absorb enough heat to turn the hot refrigerant gas into a liquid. High head pres-

sures will result. In these cases, carefully clean off the outer surfaces of the condenser with compressed air or a soap and water solution; be careful not to bend the fins.

High head pressures will also occur if the condenser's tubing is abnormally bent, blocking the flow of refrigerant.

Less common internal blockages, such as bits of foreign material or metallic grit buildup, will stop the flow of refrigerant.

A quick test to check that poor system performance is caused by the condenser is to direct a spray of water onto the condenser while the system is running. If the air conditioner cools better because of the assist provided by the water, it is a sign that the condenser is not working.

When troubleshooting a suspected condenser problem, remember that the problem may be caused by the cooling system transferring high levels of heat to the condenser. See **Group 20** for cooling system troubleshooting and to the engine manufacturer's service manual for other details about cooling system problems.

Thermostatic Switch

Before troubleshooting the thermostatic switch, be sure there is a full charge of refrigerant in the system. The compressor will not operate, or will cycle too often, if there is not enough refrigerant in the system.

Quick or delayed cycling of the compressor may be caused by a thermostatic switch that is working, but is out of adjustment. If, after doing the tests below, the switch seems to be out of adjustment, replace it. The thermostatic switch cannot be recalibrated.

1. Be sure the compressor clutch is operating correctly. See the applicable refrigerant compressor section elsewhere in this group.
2. Expose the evaporator. See **Subject 120** for instructions.
3. Connect the batteries and start the engine. Place the air conditioner control at its coldest setting. Turn on the air conditioner and the fan.
4. Place an accurate thermometer in contact with a tube on the evaporator. Be sure the thermometer is in good contact with the tube, or you will get a wrong reading.

   When the temperature drops below 31° to 36°F (–1° to 2°C), the compressor clutch should disengage and remain this way until the temperature rises to 39° to 44°F (4° to 7°C).
5. If the compressor did not engage when the temperature was above the accepted high range, check the thermostatic switch and its wiring.

   5.1 Connect a voltmeter or a test light from one of the terminals on the thermostatic switch to ground. Repeat this test with the other terminal on the switch.

   5.2 With the engine running and the air conditioner and blower on, both terminals will show voltage when the compressor should be engaged. One terminal will show voltage when the compressor should be disengaged.

   If there is no voltage, there is a problem in the electrical system from the batteries to the thermostatic switch. Check all circuits for the cause, and repair or replace the wiring or parts.

   In all other cases where the compressor is not engaging and disengaging properly, the thermostatic switch is the cause. Replace it with a new switch.
6. Shut down the engine and, to prevent accidental electric shock or shorting during dash assembling, disconnect the batteries.
7. Assemble the dash. See **Subject 120** for instructions.

Line Restrictions

A restricted suction line causes low suction pressure at the compressor and little or not cooling. A restriction in a line between the compressor and the expansion valve can cause high discharge and low suction pressure, and insufficient cooling.

Usually, areas of ice or frost buildup mean a blockage. Parts that often freeze up are probably corroded or inoperative and should be replaced. Parts (such as the expansion valve) that freeze up once in a while may do so because of water in the system, which will cause the moisture indicator element to

turn pink. If this happens, replace the receiver-drier, purge or flush the lines and parts, and recharge the system.

Fault Analysis Flow Chart

Troubleshooting Tables

Problem—Little or No Airflow

Problem—Little or No Airflow	
Possible Cause	**Remedy**
The blower is not operating.	Check for an open circuit breaker. An open circuit breaker indicates a short in the electrical system, which must be located and repaired.
	Check the air conditioner relays for operation. Replace as necessary.
	Make sure the blower motor switch is working. Replace if necessary.
	Check the wiring to the blower motor. If any connections are loose, securely tighten them. Make sure the wiring conforms to the diagram under **Specifications 400** .
	Check the blower motor for operation. Replace if sticking or otherwise inoperative.
	Check the resistor block. Replace if necessary. **CAUTION:** Never try to by pass the fuse in the resistor block. To do so could cause the blower motor to overheat, resulting in serious damage to the heater/ air conditioning system.
There are restrictions or leaks in the air ducts.	Examine all air ducts and remove any blockages. Stop any leaks or replace any portion where the leaks cannot be stopped.
Ice has formed on the evaporator.	Defrost the evaporator before resuming operation of the air conditioner. Review "Performance Tests" in this subject for possible causes and corrective action.

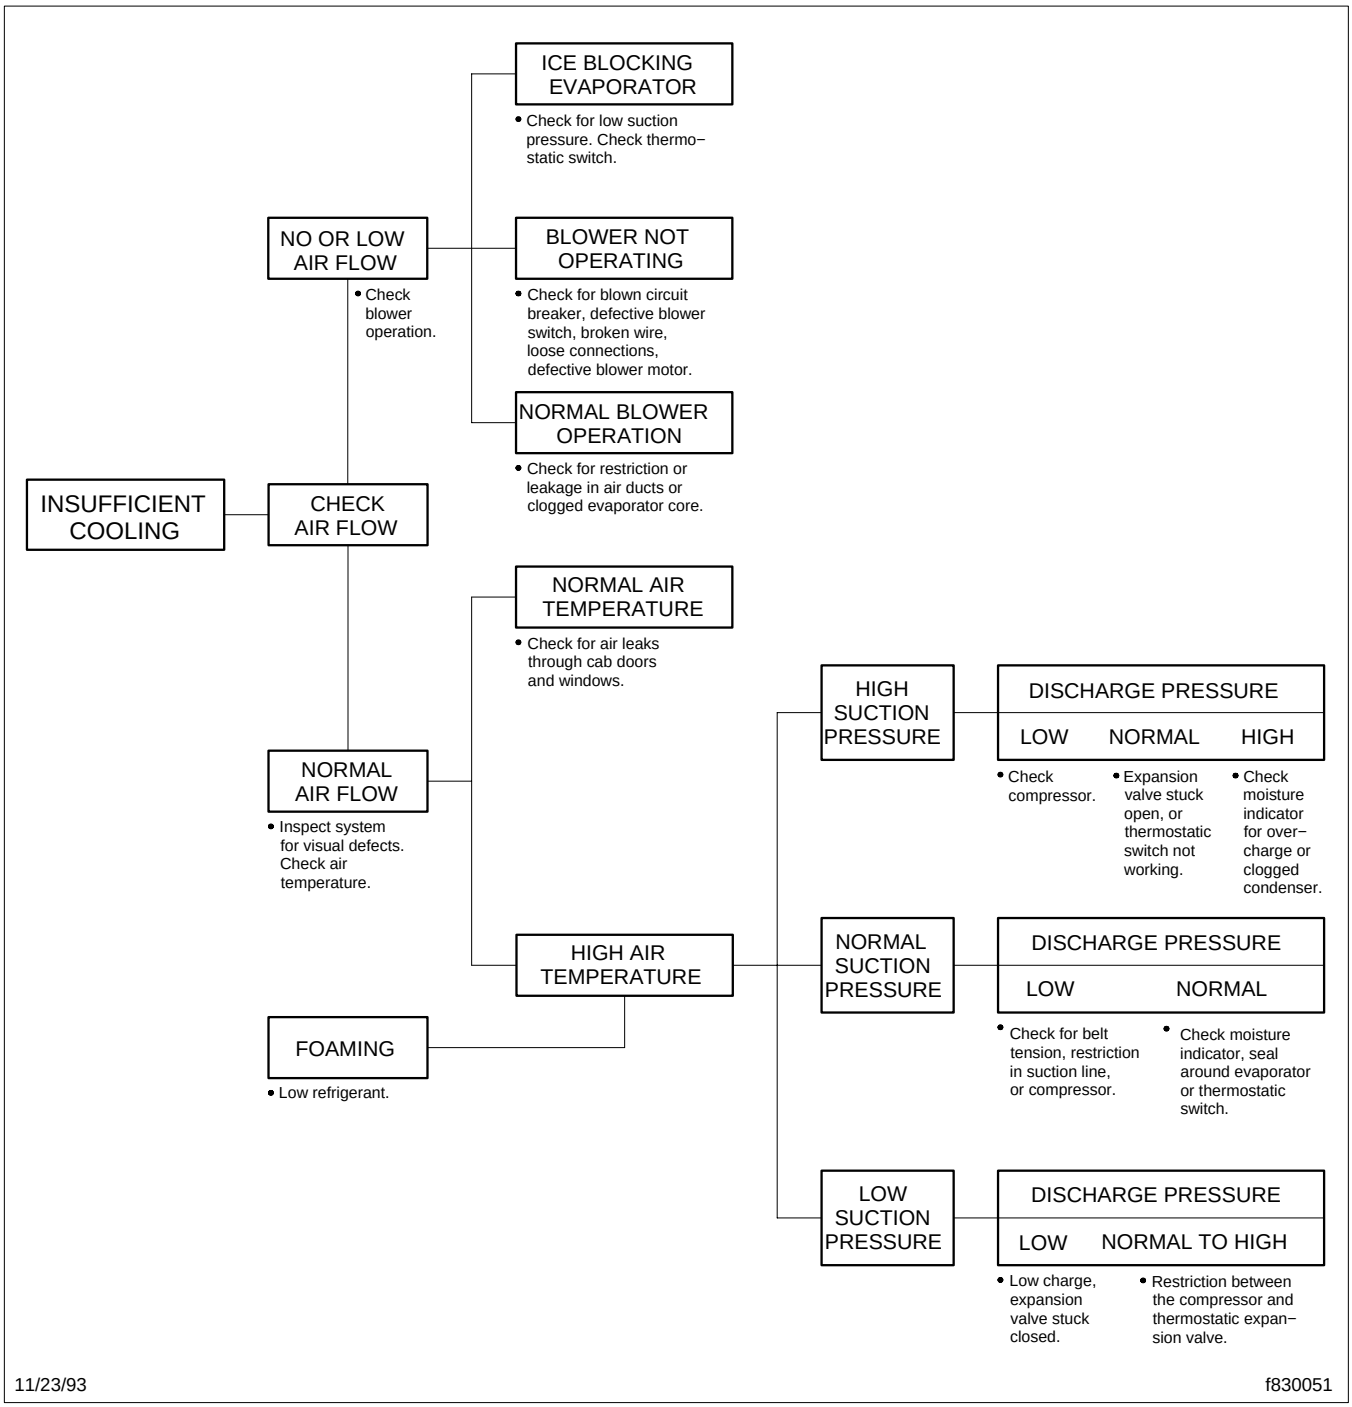

Fig. 1, Fault Analysis Flow Chart

Troubleshooting

Problem—Warm Airflow When the Air Conditioner Is On

Problem—Warm Airflow When the Air Conditioner Is On	
Possible Cause	**Remedy**
There is no refrigerant charge in the system.	Perform a leak test. Repair any leaks, purge the system, replace the receiver-drier, and add a full charge of refrigerant.
Moisture in the system.	If moisture is in the system, ice crystals may form at the expansion valve, blocking the flow of refrigerant (off and on). Discharge the refrigerant charge, purge the system, replace the receiver-drier, and add a full charge of refrigerant.
The refrigerant compressor is not operating.	If the refrigerant charge is low, charge and leak test the system. Repair any leaks.
	The refrigerant compressor clutch or drive belt needs repair or replacement. For instructions, see the refrigerant compressor section elsewhere in this group.
The air-conditioner microswitch is not working.	Replace the microswitch.
Ice has formed on the evaporator.	Defrost the evaporator before resuming operation of the air conditioner. Review "Performance Tests" in this subject for possible causes and corrective action.

Problem—Foaming in the Receiver-Drier Sight Glass

Problem—Foaming in the Receiver-Drier Sight Glass	
Possible Cause	**Remedy**
There is an insufficient refrigerant charge in the system.	Add refrigerant.
There are leaks in the system.	Perform a leak test. Stop all leaks, exhaust the old refrigerant from the system, and add a new charge.
Restriction in the line between the condenser and the receiver-drier is slowing refrigerant flow.	Remove the restrictions from the line. If water or corrosion is present, purge or flush the system, replace the receiver-drier, and add a full charge of refrigerant.

Problem—Low Evaporator Coil Outlet Pressure (Low Compressor Suction Pressure)

Problem—Low Evaporator Coil Outlet Pressure (Low Compressor Suction Pressure)	
Possible Cause	**Remedy**
The expansion valve is not working.	Replace the expansion valve. If moisture or corrosion is present, purge or flush the system, replace the receiver-drier, and add a full charge of refrigerant.
There are restrictions in the line to the expansion valve.	Remove the line restrictions. If moisture or corrosion is present, purge or flush the system, replace the receiver-drier, and add a full charge of refrigerant.
There is an insufficient refrigerant charge in the system.	Add refrigerant.

Problem—High Compressor Discharge Pressure

Problem—High Compressor Discharge Pressure	
Possible Cause	**Remedy**
Airflow through the condenser is restricted.	Remove the debris from the condenser.
There is an internal restriction in the condenser. The return tube bends should all be the same temperature.	Replace the condenser. If water or corrosion is present, evacuate the system, replace the receiver-drier, and add a full charge of refrigerant.
Air is present in the system.	Perform a leak test. Repair any leaks, evacuate the system, and add a full charge of refrigerant.
The system has too much refrigerant.	Drain some of the refrigerant charge at the discharge service valve.
Heavy frosting on the suction line suggests that the evaporator is flooded.	Defrost the evaporator coil before resuming operation of the air conditioner. If the problem recurs, there is probably moisture (ice crystals) blocking the expansion valve. Exhaust the refrigerant charge, purge the system, replace the receiver-drier, and add a full charge of refrigerant.
The engine is over-heated.	Refer to the engine manufacturer's operations manual for corrective measures.
Restriction in the compressor discharge line.	Repair or replace the line.

Problem—Evaporator Outlet Air Temperature Increases as the Compressor Discharge Pressure Drops

Problem—Evaporator Outlet Air Temperature Increases as the Compressor Discharge Pressure Drops	
Possible Cause	**Remedy**
There are leaks in the system.	Leak test the system. Repair any leaks, exhaust the old refrigerant, and add a full charge of refrigerant.
The expansion valve setting is too low.	Replace the expansion valve. Add a full charge of refrigerant.
Too much oil is in the system. An indication of this is clutch or belt slippage at governed engine speed.	Check and remove excess refrigerant oil. For instructions, refer to the refrigerant compressor section elsewhere in this group.

Problem—Compressor Operates Too Often or Continuously

Problem—Compressor Operates Too Often or Continuously	
Possible Cause	**Remedy**
There is too little refrigerant in the system.	Perform a leak test. Repair any leaks and add a full charge of refrigerant.
Ice has formed on the evaporator.	Defrost the evaporator coil before resuming operation of the air conditioner. Check the operation of the thermostatic switch and replace as necessary.
There is a restriction in the refrigerant system.	Remove the restriction from the line. If water or corrosion is present, purge or flush the system, replace the receiver-drier, and add a full charge of refrigerant.
Dirt and debris are clogging the condenser fins.	Remove all dirt and debris from the condenser fins.
The thermostatic switch is not working.	Replace the thermostatic switch.

Troubleshooting

Problem—Quick or Delayed Cycling of the Compressor

Problem—Quick or Delayed Cycling of the Compressor	
Possible Cause	**Remedy**
The thermostatic switch operates, but is out of adjustment.	Replace the thermostatic switch. Do not attempt to adjust it.
Loss of refrigerant is causing a delayed cycling of the compressor.	Leak test and add a full charge of refrigerant.

Problem—Temperature in the Cab Too Low or No Heat

Problem—Temperature in the Cab Too Low or No Heat	
Possible Cause	**Remedy**
The water regulating valve is not opened.	Turn the temperature control knob toward warm.
The water regulating valve is not opening all the way.	Adjust the water regulating valve cable.
The water regulating valve isn't working.	Replace the water regulating valve.
A heater hose is pinched or twisted.	Repair or replace the heater hose.
Coolant is leaking from the system.	Check for leakage at the heater core, and at all hose connections from the heater core to the engine. Check the radiator coolant level, as instructed in the vehicle driver's manual, and add coolant, if necessary. Check and repair any leaks at the radiator.
Dust or dirt is clogging the heater core fins.	Remove and clean the heater core.

Problem—Condensed Water Is Leaking from the Air Conditioner

Problem—Condensed Water Is Leaking from the Air Conditioner	
Possible Cause	**Remedy**
The drain tubes are plugged.	Clean the drain holes and drain tubes.

Specifications

A/C Fitting Torque Specifications*	
Hose Size	**Torque lbf·ft (N·m)**
#6	20–25 (27–34)
#8	30–35 (41–47)
#10 and #12	35–40 (47–54)

* One-inch fittings on the A/C compressor need to be torqued 21 to 27 lbf·ft (28 to 37 N·m) regardless of hose size.

General Information

The main purpose of the refrigerant compressor **(Fig. 1)** is to draw refrigerant gas from the evaporator and squeeze it into high-pressure gas. High pressure raises the condensation point of refrigerant gas, which allows the condenser to change it to a liquid so that it can be used for cooling again. A second purpose of the compressor is to move refrigerant through the air conditioning system.

The compressor is cycled by a thermostatic switch. When there is enough of a temperature drop in the cab, the switch breaks the circuit to the compressor's clutch. When the clutch is disengaged, its pulley is free-wheeling and the compressor shaft is not turning. When the clutch is engaged, it holds to the pulley, and the turning of the pulley causes the compressor shaft to turn.

Refer to the heater and air conditioner section for more information.

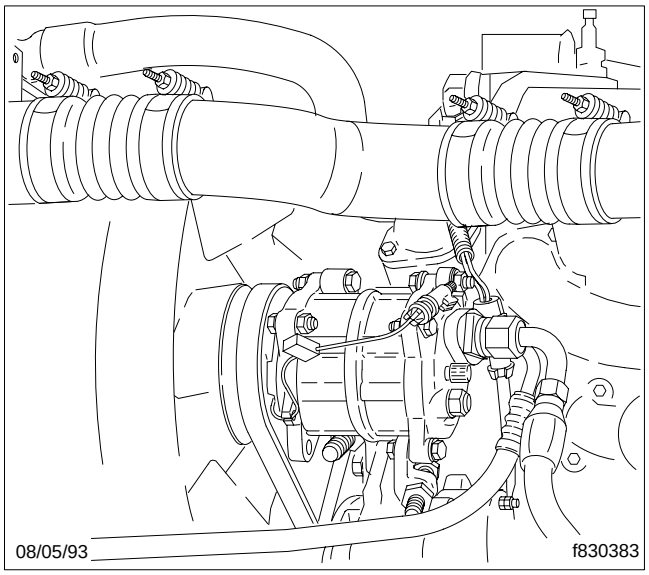

Fig. 1

Safety Precautions

Whenever repairs are made to any air conditioner parts that hold refrigerant, you must discharge, purge or flush (if contaminated), evacuate, charge, and leak test the system. In a good system, refrigerant lines are always under pressure. You should disconnect them only after the air conditioning system has been discharged to a refrigerant recovery unit through the service valves.

Refrigerants are safe when used under the right conditions. Always wear safety goggles and non-leather gloves while discharging, purging, flushing, evacuating, charging, and leak testing the system. Do not wear leather gloves; when refrigerant gas or liquid contacts leather, the leather will stick to your skin.

⚠ WARNING

WARNING: Use care to prevent refrigerant from touching your skin or eyes, because liquid refrigerant, when exposed to the air, quickly evaporates and will freeze skin or eye tissue. Serious injury or blindness could result if you come into contact with liquid refrigerant.

Refrigerant splashed in the eyes should first be treated with a few drops of sterile mineral oil in the eyes, and then rinsed with a weak boric acid solution. Do not rub the eyes. Call a doctor right away.

Refrigerant splashed on the skin should be treated the same as for frostbite: gently pour cool water on the area, but do not rub the skin. Keep the skin warm with layers of soft, sterile cloth. Call a doctor right away.

Even though refrigerant does not burn, when it contacts extreme heat or flame, poisonous gas is created.

⚠ WARNING

WARNING: Do not work in an area where refrigerant may contact an open flame or any burning material, such as a cigarette. When it contacts extreme heat, refrigerant breaks down into poisonous gas which, if breathed, causes severe respiratory irritation. If an open flame leak detector is used, follow the manufacturer's safety precautions.

If a refrigerant recovery and recycling station is available, discharge the air conditioning system into the station. Refer to the manufacturer's operating instructions.

If a refrigerant recovery and recycling station is not available, check local regulations for disposal methods.

Because of its very low boiling point, refrigerant must be stored under pressure. To prevent the refrigerant cans from exploding, never expose them to temperatures higher than 52°C (125°F). Never leave refrigerant cans in the sun, and do not store them in sun-exposed areas where heat can build up, such as in glove boxes, automobile trunks, etc.

Checks

WARNING

WARNING: Before doing any work, read the information under Safety Precautions, 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

Some special tools are needed for doing repair work on the compressor. Tool kits can be bought from the suppliers listed in **Specifications, 400**.

The checks below should be made whenever the air conditioning system is not cooling enough and the causes are unknown.

1. Be sure to check the moisture indicator, to see if moisture is the cause of the problems. The air conditioner should be on when checking the indicator; it is better to check it at the end of a day's run.
2. Check the drive belt and mounting as follows:
   - 2.1 On the drive belt, look for wear, damage, or oil. If worn, oil-soaked, or damaged, remove it and install a new one. Refer to the applicable section in **Group 01** for instructions.
   - 2.2 Check the compressor mounting parts for loose fasteners, cracks, or other damage. Tighten loose fasteners to the torque value in the applicable table in **Specifications, 400**. Repair or replace cracked or damaged brackets.
   - 2.3 Check the tension of the compressor drive belt. Refer to the applicable section in **Group 01** for instructions.
3. Check the wiring and connections to the compressor clutch. Replace damaged wiring and tighten loose connections.
4. Check for road debris build-up on the condenser coil fins. Using air pressure and a whiskbroom or a solution of soap and water, carefully clean the condenser; be careful not to bend the fins.
5. Check the refrigerant charge in the air conditioning system; for instructions, refer to the heater and air conditioner section in this group.
6. Check the suction pressure and discharge pressure of the refrigerant compressor; refer to **Subject 130**.

NOTE: For other possible causes of air conditioner problems, refer to the heater and air conditioner section in this group.

Compressor Suction and Discharge Pressure Checking

Checking

1. Read the information under **"Safety Precautions, 100."**
2. Attach a manifold gauge set to the service ports. Equip the manifold gauge set with a valve core depressor.
   - 2.1 Remove the protector caps from the service valve ports on the firewall. **See Fig. 1.**
   - 2.2 Close both of the valves on the manifold gauge set. Cap the manifold center hose.
   - 2.3 Connect the high-side hose to the discharge service port. The connection should be finger-tight.
   - 2.4 Open the high-side manifold valve one turn. Open the low-side manifold valve just enough to allow refrigerant gas to slowly escape from the low-side hose. Allow gas to escape for three seconds, then close both manifold valves.
   - 2.5 Quickly connect the low-side hose to the suction service port. The connection should be finger-tight.
3. Start the engine and set it to run at 1500 rpm.

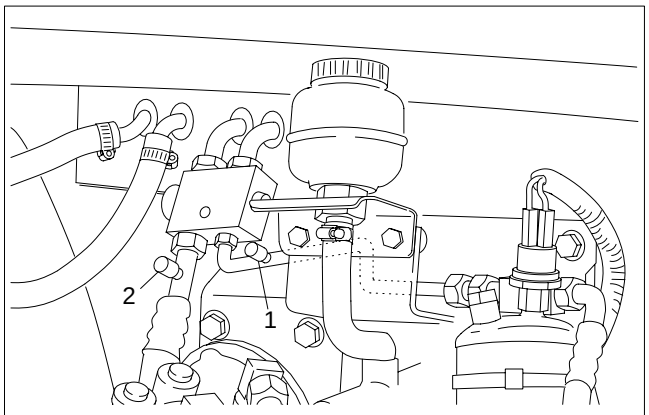

Fig. 1

4. Turn on the heater/air-conditioner blower, and set the air conditioner controls to the coldest setting, so that the compressor is operating. If the outside temperature is cooler than 21°C (70°F), *partially* block the air to the condenser.
5. Look at the manifold suction and discharge pressure gauges. The pressures on the gauges should be within the range listed in the **temperature/pressure specifications table in "Specifications, 400."**
   - 5.1 If the suction pressure is normal and the discharge pressure is too high, skip the following sub-steps and proceed.
   - 5.2 If the suction and discharge pressures are both too high, there is air in the refrigerant, or too much refrigerant in the system; check the charge; for instructions, refer to the heater and air conditioner section in this group.
   - 5.3 If the suction pressure is too high and the discharge pressure is normal, check the wiring to the thermostatic switch beside the blower motor; repair or replace the wiring, as needed. If the wiring is correct and there is power to the switch, check that the probe of the thermostatic switch is correctly installed in the evaporator coil. For instructions, refer to the heater and air conditioner section in this group. If everything checks out okay, replace the thermostatic switch at the climate control panel.
   - 5.4 If the suction pressure is too low and the discharge pressure is normal or too low, check for passage of air through the evaporator coils. If airflow is blocked, remove the blockage. If airflow is satisfactory, check for blockages in the line to the suction side of the compressor.
   - 5.5 If the suction pressure is normal or too high and the discharge pressure is too low, skip the following step and proceed.
6. If the suction pressure is normal and the discharge pressure is too high, airflow through the condenser may not be enough to carry away the heat.

   Check for dirt or debris causing reduced airflow. Also check for a blockage in the refrigerant path indicated by an icy area on the condenser or hoses.

Compressor Suction and Discharge Pressure Checking

6.1 Place a large fan in front of the radiator; place it so that the airflow goes through the condenser. After two minutes of operating the air conditioner and the fan at the same time, look at the manifold pressure gauges again. (One other procedure is to direct a spray of water onto the condenser while the system is running.)

6.2 If the discharge pressure is still too high, the lines between the compressor and the receiver-dryer are restricted, or the condenser is restricted internally. Discharge, flush, evacuate, charge, and leak test the system. If the restriction can't be removed by flushing, replace the restricted line or condenser. After flushing and before placing a vacuum in the system, *be sure to add the correct amount of refrigerant oil to the compressor* . For instructions, **refer to "Oil Check and Adding Oil to the Compressor, 150."**

7. If the suction pressure is normal or too high and the discharge pressure is too low, check for a slipping clutch or wrong-sized clutch pulley or accessory drive pulley. Replace parts as needed.

   If the suction pressure is still normal or too high and the discharge pressure is still too low, the compressor is the problem. Repair or replace the compressor.

Removal

1. Discharge the air conditioning system; for instructions, refer to the heater and air conditioner section in this group.
2. Remove the clamps holding the charge air pipe; then, remove the pipe. See **Fig. 1**.

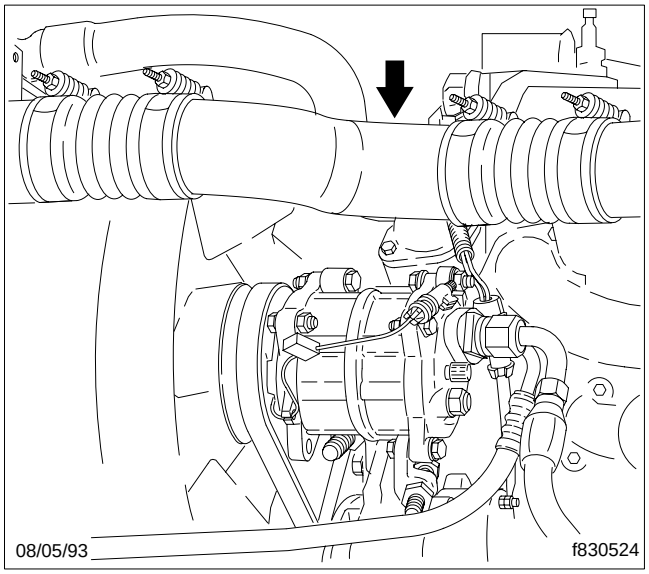

Fig. 1, Charge Air Pipe

3. Thoroughly clean the compressor around the hose connections. Disconnect the suction and discharge hoses from the compressor. Quickly cap the discharge and suction ports and plug the hoses. Under no circumstances should you leave the ports uncapped or the hoses unplugged for longer than a total of five minutes.
4. Disconnect the compressor magnetic clutch electrical wire. See **Fig. 2**.
5. Remove the V-belt.
   - 5.1 Loosen both the adjustment and jam nuts on the compressor lower mounting strut. See **Fig. 3**.
   - 5.2 Loosen the two compressor upper mounting bolts. See **Fig. 4**.
   - 5.3 Pivot the compressor down to relieve the belt tension.
   - 5.4 Remove the V-belt.

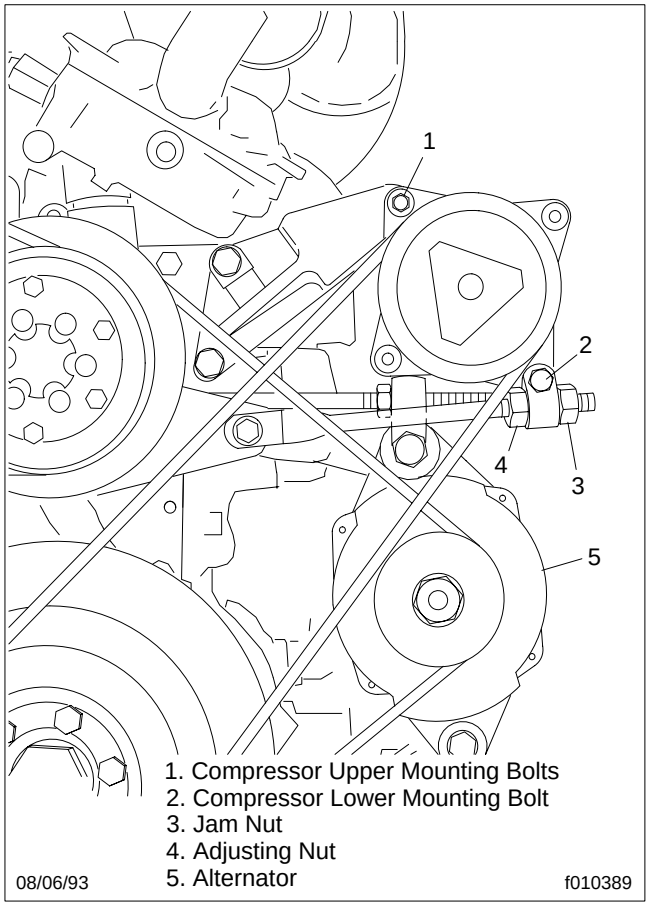

Fig. 2

6. Remove all three compressor mounting bolts (**Fig. 4**) and lift out the compressor.

Installation

IMPORTANT: A new compressor is filled with nitrogen gas and 200 mL (6.8 fl oz) of refrigerant oil. When installing a new compressor on the vehicle, do all of the steps below; if installing a used compressor, skip the following step, and proceed with the installation:

1. Flush a new compressor.
   - 1.1 Slowly release the nitrogen from the discharge side of the compressor. Be careful not to let the oil flow out.
   - 1.2 Turn the compressor several times by hand to expel the oil from the cylinders.

Compressor Removal and Installation

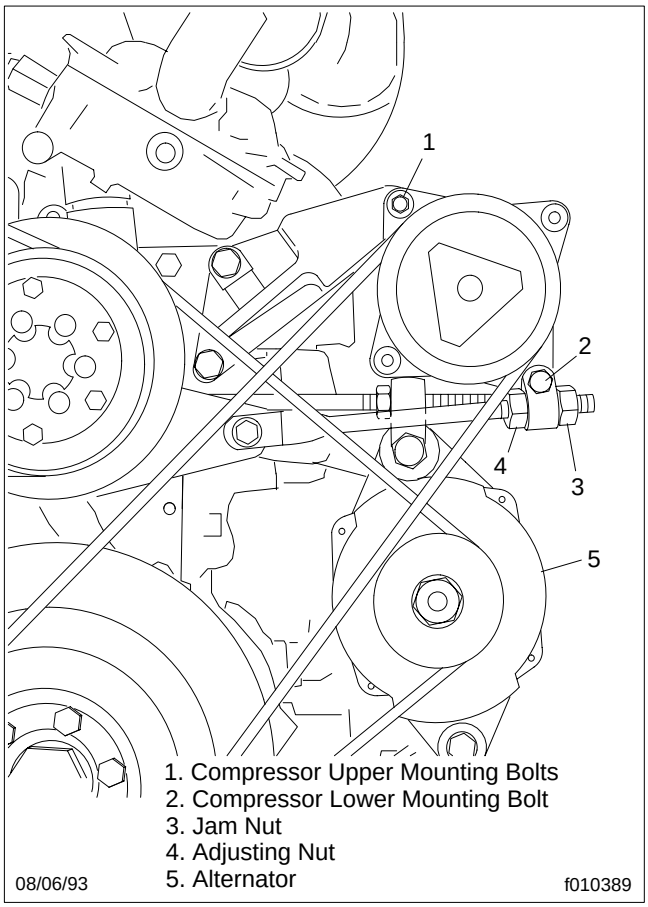

Fig. 3

1.3 When installing the compressor on a completely flushed (cleaned) system, install the compressor as it is; when installing it on a system that has not been flushed, install the compressor after adjusting the amount of oil. For instructions, refer to **Subject 150**.

2. Place the compressor in position against the mounting bracket and install the mounting bolts, washers, and nuts (**Fig. 3**, Refs. 1 and 2).

NOTE: The two long bolts go on top.

3. Hand tighten the nuts.

4. Install the V-belt. Adjust the belt tension. For instructions, the applicable section in **Group 01**.

5. Tighten the compressor mounting bolts 45 N·m (33 lbf·ft).

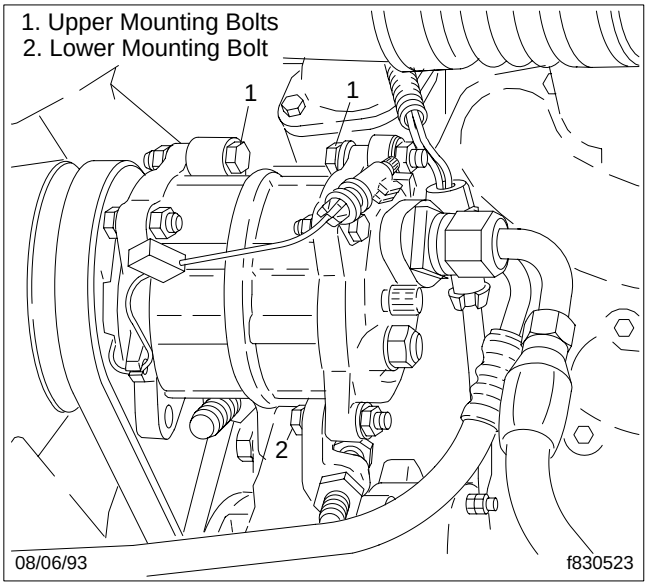

Fig. 4

6. Uncap the suction and discharge ports on the compressor. Unplug the hose connections. Check the hose connections and the surface of the suction and discharge ports. They must be clean and free of nicks, gasket residue, and other foreign material.

IMPORTANT: Under no circumstances should you leave the compressor's ports uncapped or the hoses unplugged for longer than five minutes total.

7. Attach the refrigerant hoses to the system hose connections. Tighten the suction (large) fitting 39 N·m (29 lbf·ft); tighten the discharge (small) fitting 37 N·m (27 lbf·ft).

8. Connect the compressor magnetic clutch electrical wire.

9. Evacuate, charge, and leak test the air conditioning system. For instructions, refer to the heater and air conditioner section in this group.

10. Install the charge air pipe. Tighten the constant torque hose clamps 7 N·m (5 lbf·ft).

Oil Check and Adding Oil to the Compressor

Procedure

IMPORTANT: New compressors are factory-charged with 200 mL (6.8 fl oz) refrigerant oil, which does not require periodic checking. Refrigerant oil circulates through the system with the refrigerant. The oil cannot leave the system except through a leak, when the system is discharged for service, or when a system part is replaced.

Add only FREOL DS-83P refrigerant compressor oil. Oil must be from a container that has not been opened, or that has been tightly sealed since its last use. Tubing, funnels, or other equipment used to transfer the oil should be very clean and dry.

When replacing system parts, add the following amounts of oil to the compressor, to replace that which is lost with the discarded part:

A. *Receiver-dryer*— 80 mL (2.7 fl oz);

B. *Condenser*— 30 mL (1.0 fl oz);

C. *Evaporator coil*— 20 mL (0.7 fl oz) each;

D. *Entire system*— 264 mL (8.9 fl oz). Add this amount of oil to the compressor if the entire system (including the compressor) has been discharged of refrigerant and oil, and all parts and hoses have been flushed.

When handling refrigerant oil:

- The oil should be free of water, dust, metal powder, and other foreign substances.
- Do not mix refrigerant oil with other types or viscosities of oil.
- Refrigerant oil absorbs water when exposed to the air for short periods. After use, quickly seal the oil container.

During normal operation, part of the oil recirculates with the refrigerant in the system. When checking the amount of oil in the system, first run the compressor to return the oil to the compressor.

1. Turn on the air conditioner (the compressor must be engaged), and set the blower fan at high speed.
2. With the compressor engaged, run the engine for at least 20 minutes between 800 and 1200 rpm.
3. After turning off the engine, remove the compressor from the vehicle.
4. Remove the compressor drain plug; then, drain the compressor oil into a clean container. **See Fig. 1.** Rotate the drive plate several times by hand to extract the remaining oil through the discharge-side port. About 30 mL (1 fl oz) of oil will remain in the compressor and cannot be removed without disassembling it.
5. Measure the drained oil with a measuring cylinder.
6. Check the oil for signs of contamination.
   - 6.1 Check for cloudiness or increased opacity.
   - 6.2 Check for a color change to red.
   - 6.3 Check for the presence of foreign particles (metal powder, etc.).

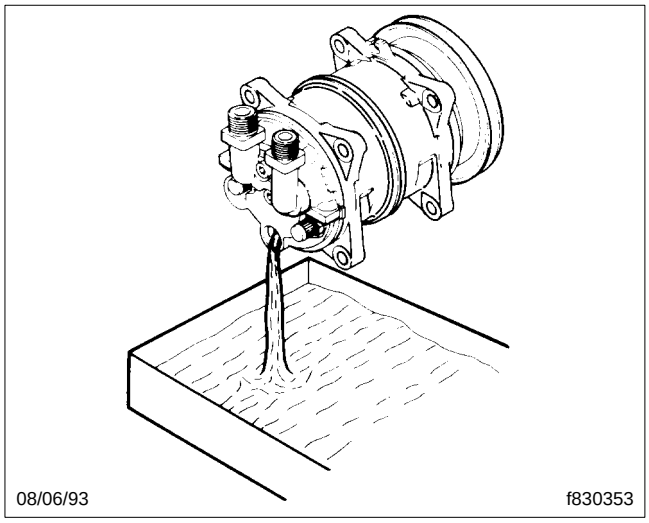

Fig. 1

NOTE: Unlike engine oil, compressor oil contains no added cleaning agent. Even after an entire season of use the oil should not become cloudy, as long as there is nothing wrong with the compressor or the way it is used.

7. If the oil is contaminated, flush all parts of the system and replace the receiver-dryer. For instructions, refer to the heater and air conditioner section in this group.

Oil Check and Adding Oil to the Compressor

8. Install the drain plug and a new O-ring lightly coated with clean compressor oil. Tighten the plug 1280 to 1460 N·cm (113 to 130 lbf·in).
9. Fill the compressor with oil through the suction-side hose fitting. **See Fig. 2. Refer to Table 1** for the charging amount.

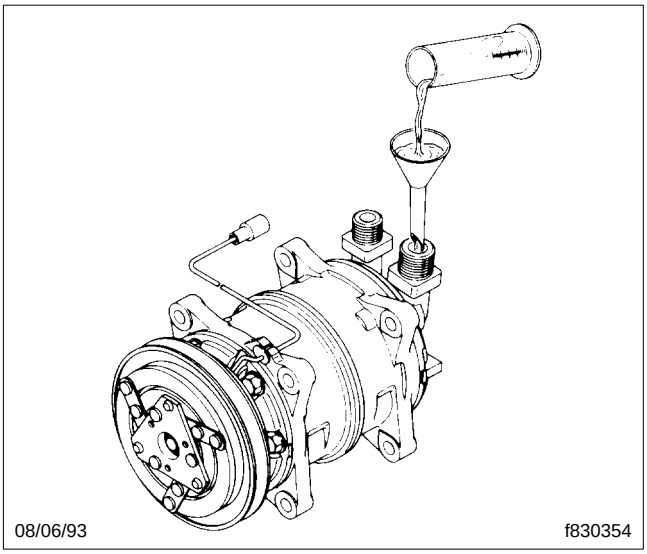

Fig. 2

Collected Amount	Charging Amount
More than 120 mL (4 fl oz)	Same as collected amount; do not exceed 264 mL (8.9 fl oz)
Less than 120 mL (4 fl oz)	120 mL (4 fl oz)

Table 1

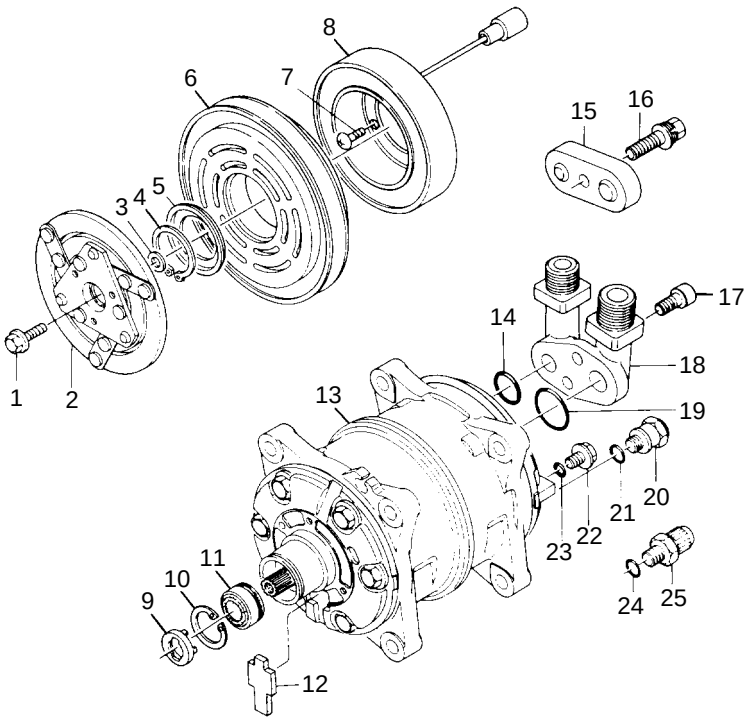
10. If an oil return operation (above) could not be done, check the compressor oil as follows:
    - 10.1 Remove the damaged compressor from the vehicle.
    - 10.2 Remove the drain plug, and drain the oil.
    - 10.3 Using a measuring cylinder, measure the drained oil.
    - 10.4 Check the oil for contamination.
    - 10.5 Fill the new compressor with oil through the suction-side connector. Refer to the table above for the correct amount of oil.
    - 10.6 Install the new compressor on the vehicle.
    - 10.7 Perform the oil return operation.
    - 10.8 Remove the compressor and check the amount of oil again.
    - 10.9 Fill the compressor with oil again. **Refer to Table 1** for the correct amount of oil.

Magnetic Clutch Assembly Removal, Inspection, and Installation

Removal

See **Fig. 1**.

NOTE: The special tools available from independent suppliers may look different from those shown in the figures below, but they are functionally identical.



1. Remove the compressor from the vehicle. For instructions, **refer to "Compressor Removal and Installation, 140."**
2. Remove the center bolt using the drive plate holder [1]to prevent drive-plate rotation. **See Fig. 2.**
3. Using the drive-plate puller [1], remove the drive plate. **See Fig. 3.** Then, remove the shims from either the driveshaft or the drive plate.
4. Using external snap-ring pliers, remove the snap ring; then, remove the cover. **See Fig. 4.**
5. Using the pulley puller and the spacer [1] positioned on the cylinder head hub, remove the pulley assembly. **See Fig. 5.**

NOTE: To avoid damaging the pulley groove, the puller claws should be hooked into (not under) the pulley groove.

6. Remove the coil's lead wire from the wire holder on the compressor; then, remove the three screws and the coil. **See Fig. 6.**

CAUTION

CAUTION: Do not hold the coil by the lead wire. This could damage the coil.

1. Bolt
2. Drive Plate
3. Shim

Fig. 1

[1] **Refer to "Specifications, 400"** for suppliers of the special tools.

Magnetic Clutch Assembly Removal, Inspection, and Installation

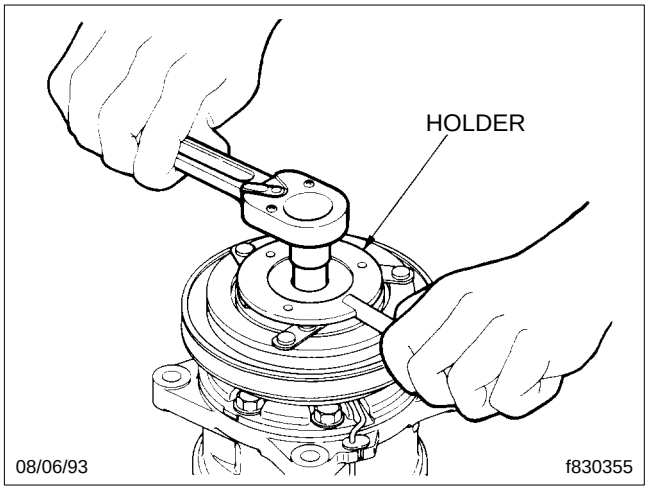

Fig. 2

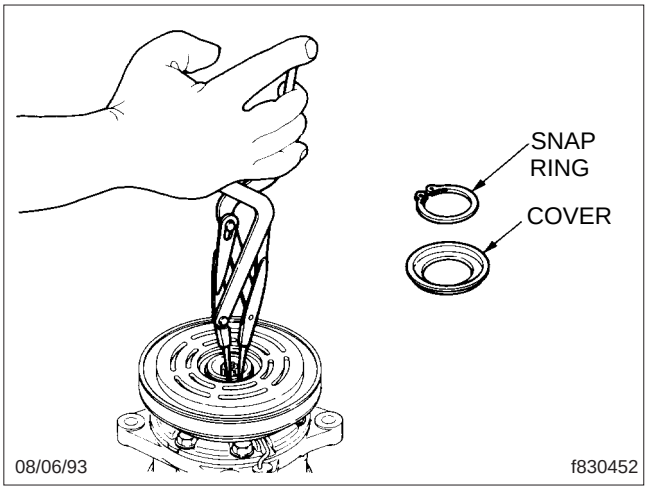

Fig. 4

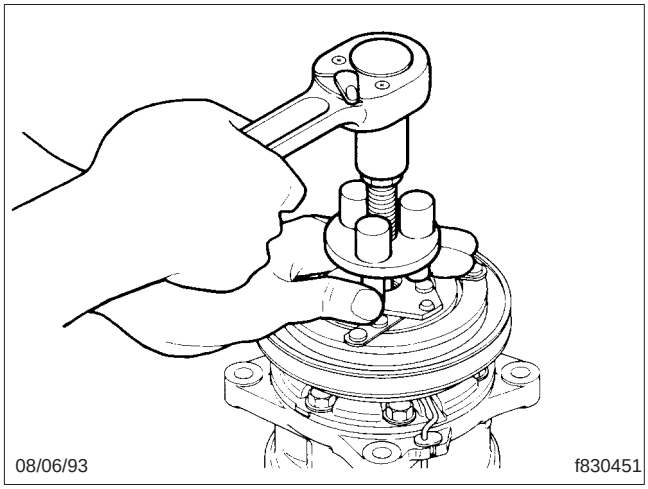

Fig. 3

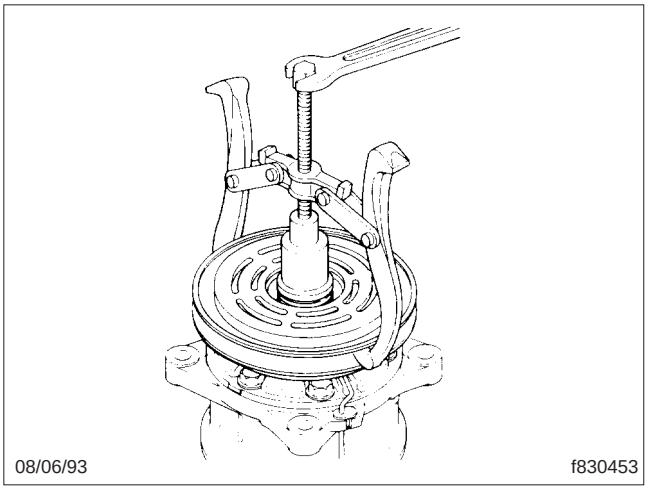

Fig. 5

Inspection (Refer to Fig. 7)

1. Inspect the drive plate. If the frictional surface shows signs of damage due to too much heat, replace the drive plate and pulley assembly.
2. Check the appearance of the pulley assembly. If the frictional surface of the pulley shows signs of too much grooving due to slippage, replace both the pulley and drive plate. Clean the frictional surfaces of the pulley assembly before installing it.
3. Check the coil for a loose connector and for cracked insulation. Replace it if necessary.

Installation

1. Make sure the felt is installed on the front cylinder head. **See Fig. 8.**
2. Install the coil on the compressor (lead wire on top).
3. Make sure the concave portion of the coil is aligned with the felt; then, tighten the mounting screws 400 to 580 N·cm (35 to 52 lbf·in). **See Fig. 8.**
4. Install the lead wire in the wire holder on the compressor.

Magnetic Clutch Assembly Removal, Inspection, and Installation

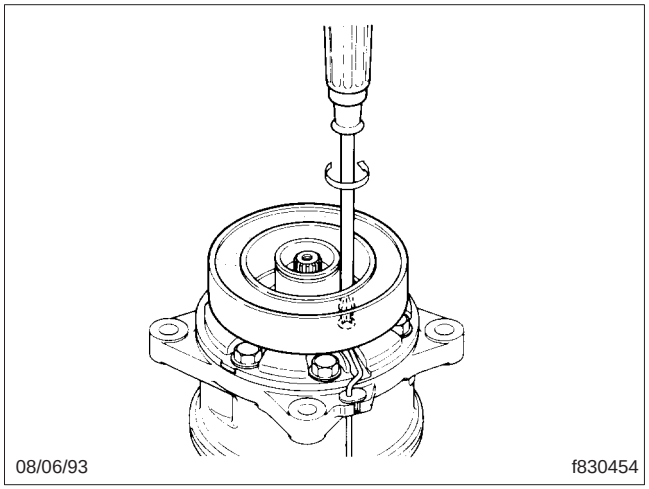

Fig. 6

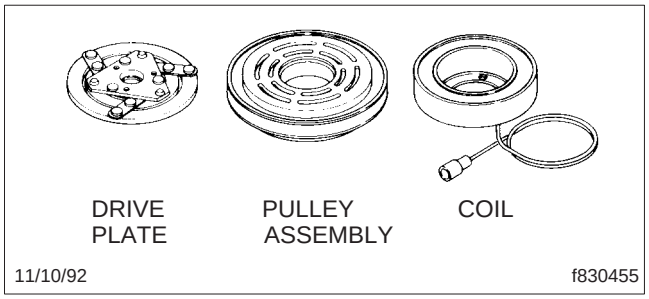

Fig. 7

5. Using the installation tool [1] and a hand press, install the pulley assembly. **See Fig. 9.** Install the bearing cover and the snap ring. **See Fig. 10.**

NOTE: The chamfered edge of the snap ring should face upward.

6. Install the drive plate on the compressor drive-shaft, together with the original shim(s). **See Fig. 11.** Press the drive plate down by hand.

7. Using the clutch holder [1] to prevent drive-plate rotation, tighten the bolt 1180 to 1360 N·cm (104 to 121 lbf·in).

NOTE: After tightening the bolt, check that the pulley turns smoothly.

8. Using a feeler gauge, check that the clutch clearance is 0.3 to 0.6 mm (0.01 to 0.02 inch). **See Fig. 12.** Adjust the clearance using shims, as necessary. Adjusting shims are available in the following thicknesses: 0.1 mm; 0.3 mm; 0.5 mm; 0.8 mm; and 2.2 mm.

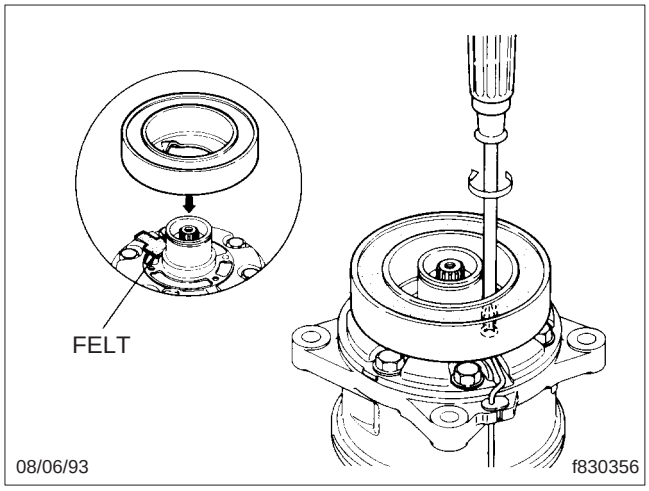

Fig. 8

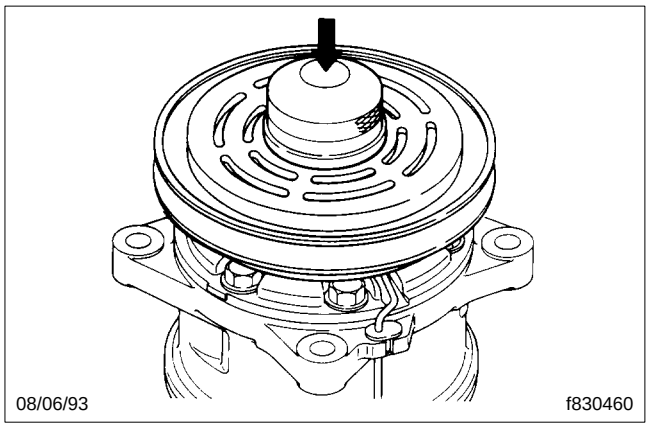

Fig. 9

9. Install the compressor on the vehicle. For instructions, **refer to "Compressor Removal and Installation, 140."**

10. Perform a running-in operation on the clutch. For instructions, **refer to "Running-In Operations, 180."**

Magnetic Clutch Assembly Removal, Inspection, and Installation

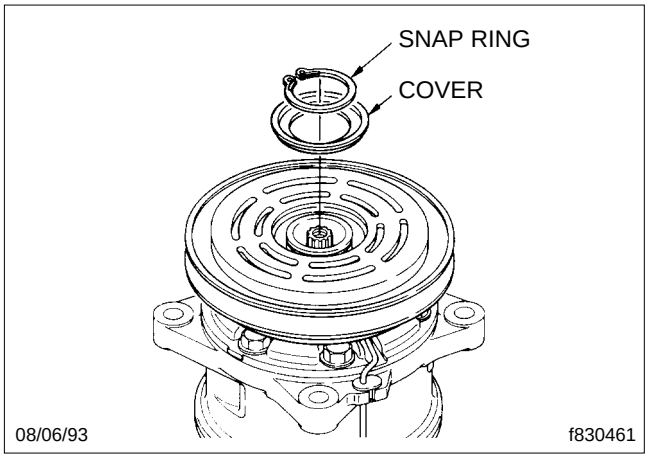

Fig. 10

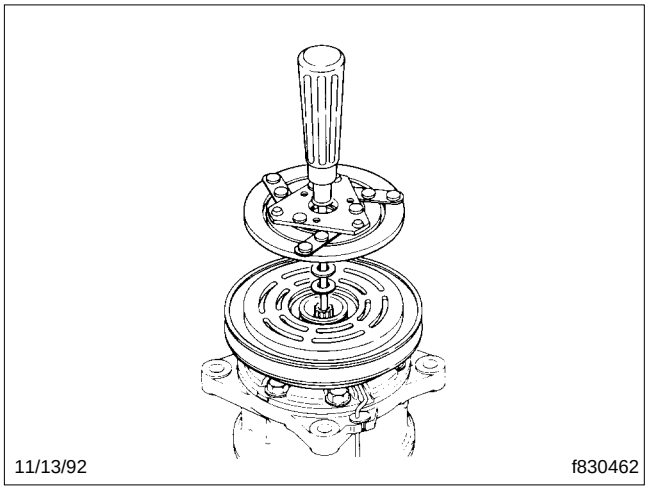

Fig. 11

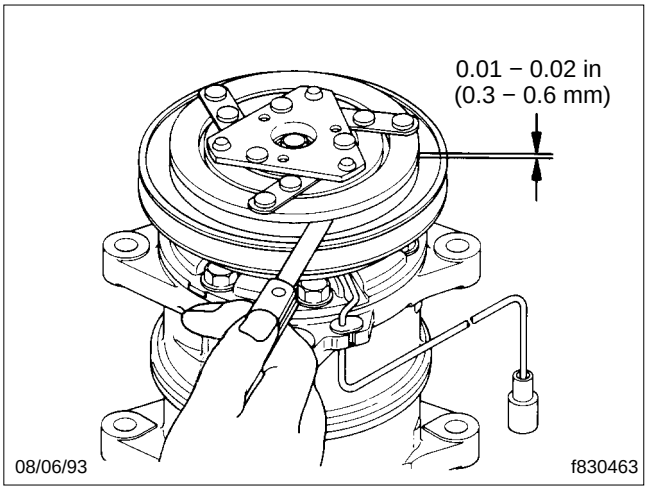

Fig. 12

Replacement

NOTE: The special tools available from independent suppliers may look different from those shown in the figures below, but they are functionally identical.

1. Remove the magnetic clutch assembly, as described in **"Magnetic Clutch Removal, Inspection, and Installation: Removal, 160."**
2. Remove the felt. **See Fig.1.**
3. Using the remover [1], remove the shaft seal cover by engaging the hook on the remover with the hook on the shaft seal cover and slowly drawing out the cover. **See Fig.1.** Discard the shaft seal cover.
4. Using internal snap-ring pliers, remove the snap ring. **See Fig.2.**
5. Using the remover [1], remove the shaft seal by engaging the hook on the remover with the hook on the shaft seal and slowly drawing out the shaft seal. **See Fig.3.**

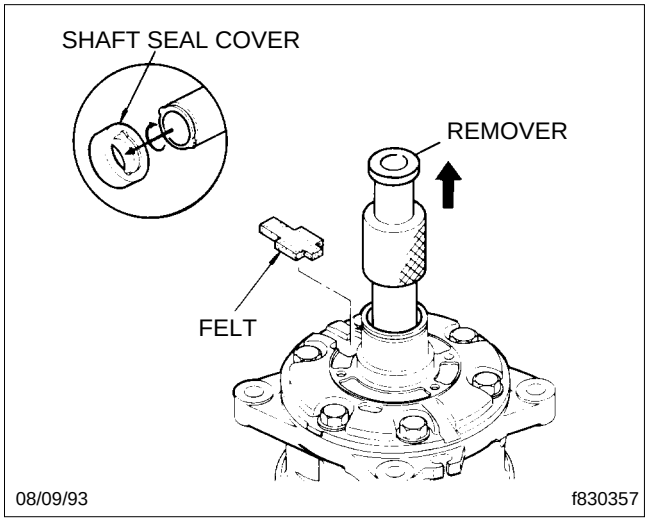

Fig. 1

NOTE: The shaft seal and shaft seal cover should not be re-used. Always use a new seal kit. Be very careful that the lip of the shaft seal to be installed is not scratched or damaged in any way. Make sure the shaft seal is free of lint and dirt, which could damage the shaft seal surface.

6. Clean the sealed section of the front cylinder head.
7. Apply clean compressor oil to the new shaft seal and to the front cylinder head. If the slip faces are dirty, clean them with thinner, dry them, and apply clean compressor oil to them.
8. Install the guide [1] onto the end of the driveshaft. **See Fig.4.**
9. Insert the shaft seal over the guide into the front cylinder head. **See Fig.5.**

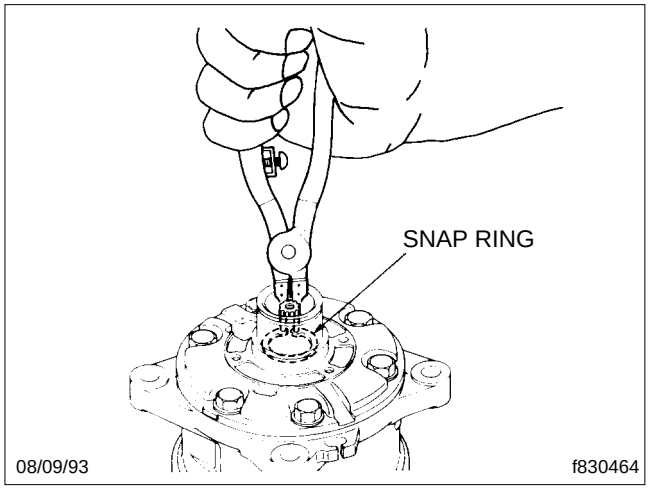

Fig. 2

10. Using the installing end of the remover [1], install the shaft seal as far as possible into the front cylinder head. **See Fig.6.** Remove the guide installed earlier from the driveshaft.
11. Using internal snap-ring pliers, install the snap ring. **See Fig.7.** Press the snap ring using the installing end of the remover [1] until a click is heard.

NOTE: When installing the snap ring, the round edge of the snap ring must face downward, **as shown in Fig.8.**

12. Fit the guide [1] onto the end of the driveshaft. **See Fig.9.** Using the installing end of the remover [1], install the shaft seal cover.

[1] **Refer to "Specifications, 400"** for suppliers of the special tools.

Shaft Seal Replacement

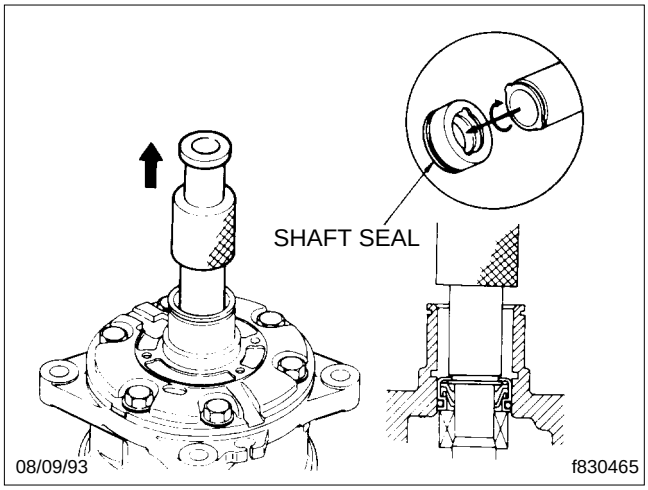

Fig. 3

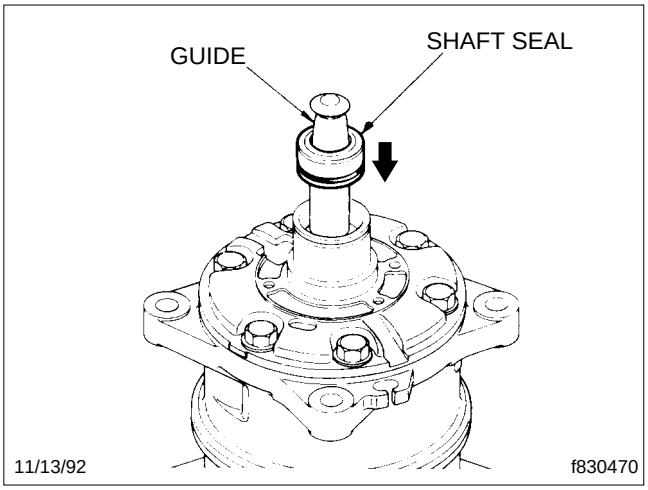

Fig. 5

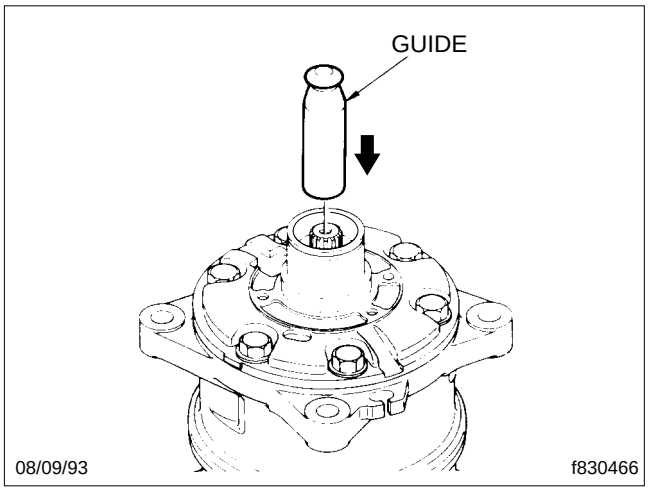

Fig. 4

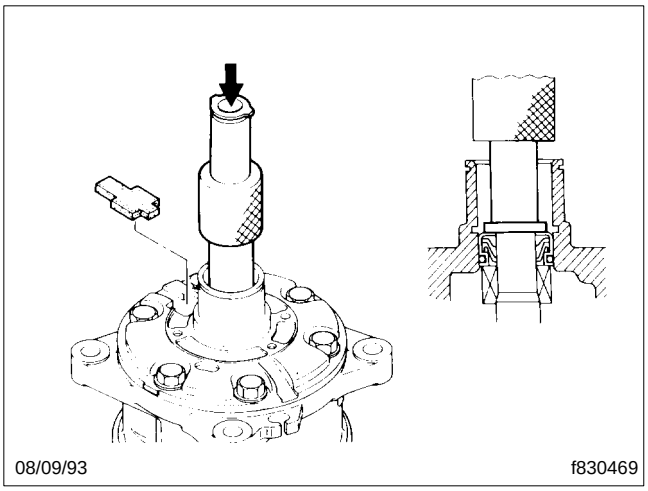

Fig. 6

NOTE: The installation position of the shaft seal cover is shown **in Fig.10.**

13. Install a new felt. **See Fig.10.**
14. Install the magnetic clutch assembly, as described in **"Magnetic Clutch Removal, Inspection, and Installation, 160."**

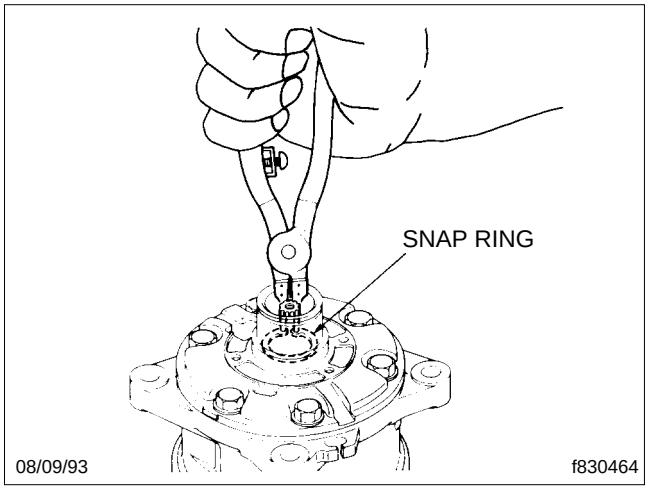

Fig. 7

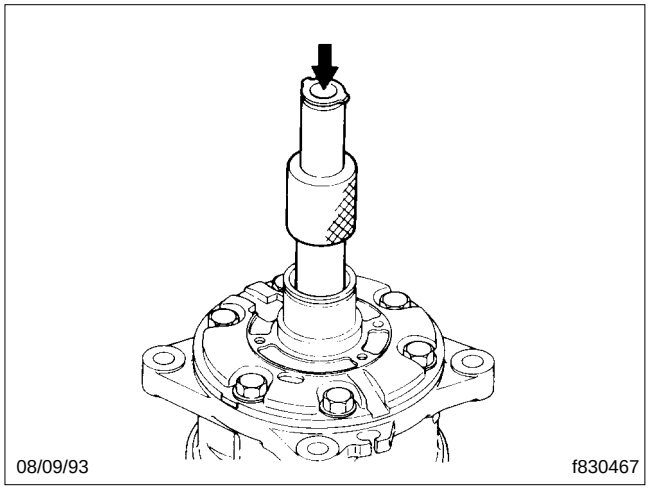

Fig. 9

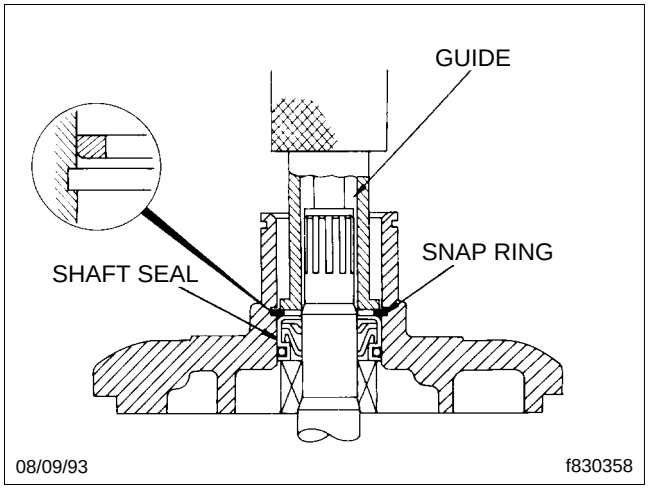

Fig. 8

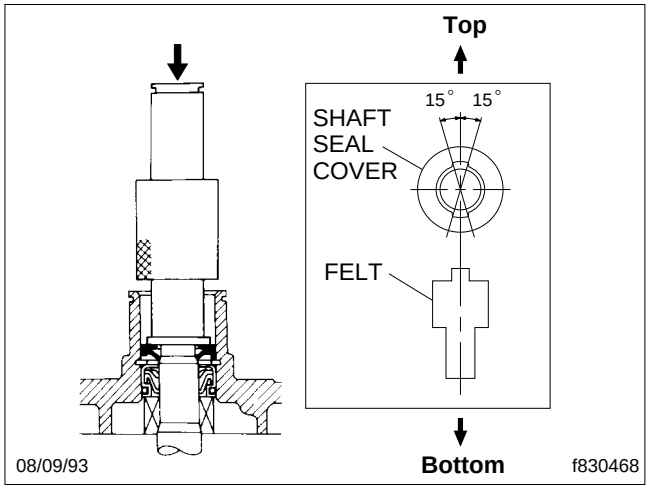

Fig. 10

Leak Test

Check the compressor for refrigerant leaks after it is repaired, as follows:

1. Install blanking caps in the suction and discharge fittings on the compressor.
2. Connect a manifold gauge set to the compressor's service ports. Close the discharge hand valve on the manifold. Fill refrigerant gas through the service port on the suction side fitting, raising the pressure to at least 482 kPa (70 psi).
3. Check the compressor for leakage using a leak detector.
4. Slowly release the refrigerant from the compressor. Remove the caps just before connecting the hoses to the compressor.

Magnetic Clutch Running-In

1. Install the compressor on the vehicle, and charge the system with refrigerant.
2. Turn on the engine and the air conditioner. Keep the compressor's speed at 500 rpm.
3. Operate the air conditioner switch on the climate control panel through the on and off cycle at least 50 times (on for 10 seconds; off for 10 seconds).

Storing a Repaired Compressor

Procedure

If it is necessary to store a repaired compressor for some time before installation, evacuate the compressor and fill refrigerant through the service port on the suction side fitting to raise the refrigerant pressure to 482 kPa (70 psi).

Special tools can be purchased from the following independent suppliers:

Classic Tool Design

Table 3, Temperature/Pressure Specifications

General Information

The main purpose of the refrigerant compressor is to draw refrigerant gas from the evaporator and squeeze it into high-pressure gas. High pressure raises the condensation point of refrigerant gas, which allows the condenser to change it to a liquid so that it can be used for cooling again. A second purpose of the compressor is to move refrigerant through the air conditioner system.

The compressor is cycled by a thermostatic switch, which is located on the blower motor housing in the cab. When there is enough of a temperature drop in the cab, the switch breaks the circuit to the compressor's magnetic clutch. When the clutch is disengaged, its pulley is free-wheeling and the compressor shaft is not turning. When the clutch is engaged, it holds to the pulley, and the turning of the pulley causes the compressor shaft to turn.

The Climate Control compressor is a two-piston design. The pistons are driven by a crankshaft and connecting rods. Refer to the heater and air conditioner section in this group for other information.

Safety Precautions

CAUTION

CAUTION: Different refrigerant oils are used in compressors on R–12 and R–134a air conditioning systems. Always use the correct refrigerant oil and never mix oils. If the wrong oil is used, or if oils are mixed, the compressor could seize due to improper lubrication.

Refrigerant R–134a Air Conditioning Systems

Whenever repairs are made to any air conditioner parts that hold R–134a refrigerant, you must recover, purge or flush (if contaminated), evacuate, charge, and leak test the system. In a good system, refrigerant lines are always under pressure and you should disconnect them only after the refrigerant charge has been recovered (discharged) at the service valves.

Refrigerant R–134a is safe when used under the right conditions. Always wear safety goggles and non-leather gloves while recovering, evacuating, charging, and leak testing the system. Do not wear leather gloves; when refrigerant gas or liquid contacts leather, the leather will stick to your skin.

WARNING

WARNING: Use care to prevent refrigerant from touching your skin or eyes, because liquid refrigerant, when exposed to the air, quickly evaporates and will freeze skin or eye tissue. Serious injury or blindness could result if you come into contact with liquid refrigerant.

Refrigerant splashed in the eyes should be rinsed with lukewarm water, not hot or cold. Do not rub the eyes. Apply a light bandage and contact a physician right away.

Refrigerant splashed on the skin should be rinsed with lukewarm water, not hot or cold. Do not rub the skin. Apply a light coat of a nonmedicated ointment, such as petroleum jelly. Contact a physician right away.

R–134a refrigerant does not burn at ambient temperatures and atmospheric pressure. However, it can be combustible at pressures as low as 139 kPa absolute (5.5 psig) at 177°C (350°F) when mixed with air concentrations that are greater than 60 percent.

WARNING

WARNING: R–134a air conditioning systems should not be pressure tested or leak tested with compressed air (R–134a may be safely pressured with dry nitrogen). Combustible mixtures of air and R–134a may form, resulting in a fire or explosion, which could cause personal injury or property damage.

You must work in an area where there is a constant flow of fresh air when the system is recovered, evacuated, charged, and leak tested. R–134a vapors have a slightly sweet odor that is difficult to detect. Frequent leak checks and air monitoring equipment are recommended to ensure a safe working environment.

IMPORTANT: When servicing an R–134a air conditioning system, use only service equipment certified to meet the requirements of SAE J2210 (R-134a recycling equipment). The equipment should be operated only by qualified personnel who are familiar with the recycling station manufacturer's instructions.

Because of its very low boiling point, refrigerant must be stored under pressure. To prevent the refrigerant containers from exploding, never expose them to temperatures higher than 52°C (125°F).

On R–134a refrigerant systems, polyalkylene glycol (PAG) or polyol ester (POE) oil is used in the compressor. When handling these oils, observe the following:

- keep the oil free of contaminants
- do not expose the a/c system or the oil container to air for long periods of time; PAG and POE oils have a high moisture absorption capacity
- use care when handling: painted surfaces, plastic parts, and other components (drive belts) could be damaged if the oil is spilled on them
- never mix the oils with other types of refrigerant oil

Safety Precautions

Refrigerant R–12 Air Conditioning Systems

Whenever repairs are made to any air conditioner parts that hold refrigerant, you must discharge, purge or flush (if contaminated), evacuate, charge, and leak test the system. In a good system, refrigerant lines are always under pressure and you should disconnect them only after the air conditioning system has been discharged to a refrigerant recovery unit through the service valves on the compressor.

Refrigerants are safe when used under the right conditions. Always wear safety goggles and non-leather gloves while discharging, purging, flushing, evacuating, charging, and leak testing the system. Do not wear leather gloves; when refrigerant gas or liquid contacts leather, the leather will stick to your skin.

⚠ WARNING

WARNING: Use care to prevent refrigerant from touching your skin or eyes, because liquid refrigerant, when exposed to the air, quickly evaporates and will freeze skin or eye tissue. Serious injury or blindness could result if you come into contact with liquid refrigerant.

Refrigerant splashed in the eyes should first be treated with a few drops of sterile mineral oil in the eyes, and then rinsed with a weak boric acid solution. Do not rub the eyes. Call a doctor right away.

Refrigerant splashed on the skin should be treated the same as for frostbite: gently pour cool water on the area, but do not rub the skin. Keep the skin warm with layers of soft, sterile cloth. Call a doctor right away.

Even though refrigerant does not burn, when it contacts extreme heat or flame, poisonous phosgene gas is created. This gas also is produced when an open flame leak detector is used. Phosgene fumes have an acrid (bitter) smell.

⚠ WARNING

WARNING: Do not work in an area where refrigerant may contact an open flame or any burning material, such as a cigarette. When it contacts extreme heat, refrigerant breaks down into poisonous phosgene gas which, if breathed, causes severe respiratory irritation. Do not breathe the fumes from an open flame leak detector.

You must work in an area where there is a constant flow of fresh air when the system is discharged, flushed, charged, and leak tested using an open flame leak detector.

Changes in both federal and state laws will affect the way dealerships service air-conditioning systems. Under current federal laws, refrigerant R–12 must be recovered and recycled by all users to protect the environment, and not released into the atmosphere. Many service operations not directly involving the air-conditioning system require the release of the refrigerant charge. Under the new regulations, dealerships not having the required recovery and recycling equipment (and properly trained and certified personnel) will not be allowed to do any of this service work.

Because of its very low boiling point, refrigerant must be stored under pressure. To prevent the refrigerant cans from exploding, never expose them to temperatures higher than 52°C (125°F). Never leave refrigerant cans in the sun, and do not store them in sun-exposed areas where heat can build up, such as in gloveboxes, automobile trunks, etc.

Pre-Service Checks

WARNING

WARNING: Before doing any work, read the information under Safety Precautions, 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

CAUTION

CAUTION: Determine if the air conditioning system is charged with refrigerant R–134a or R–12. Check the label on the radiator shroud (the side the compressor is on), the compressor identification tag, and the caution labels on system components, for verification. Service procedures are different for these refrigerant systems. Failure to properly identify the refrigerant system prior to servicing could cause component malfunction and system contamination.

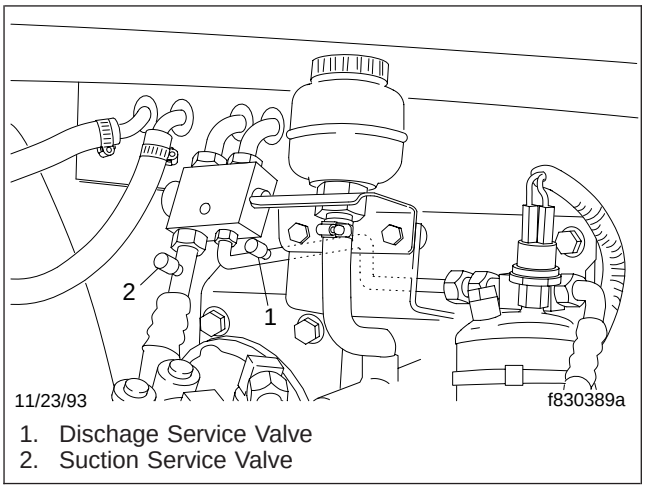
Some special tools are needed for doing repair work on the compressor. Refer to **Specifications, 400.**

The checks below should be made whenever the air conditioning system is not cooling enough and the causes are unknown.

1. Be sure to check the moisture indicator, to see if moisture is the cause of the problems. The air conditioner should be on when checking the indicator; it is better to check it at the end of a day's run.
2. Check the drive belt and mounting as follows:
   - 2.1 On the drive belt, look for wear, damage, or oil. If worn, oil-soaked, or damaged, remove it and install a new one. Refer to **Group 01** in this manual for instructions.
   - 2.2 Check the compressor mounting parts for loose fasteners, cracks, or other damage. Tighten loose fasteners to the following torque values:
     - Compressor Mounting bolt, 3/8–16: 47 N·m (35 lbf·ft)
     - Compressor mounting bracket pivot bolt, 1/2–13: 81 N·m (60 lbf·ft)
   - 2.3 Repair or replace cracked or damaged brackets.
   - 2.4 Check the tension of the compressor drive belt. Refer to **Group 01** in this manual for instructions.
3. Check the wiring and connections to the compressor clutch. Replace damaged wiring and tighten loose connections.
4. Check for road debris build-up on the condenser coil fins. Using air pressure and a whiskbroom or a solution of soap and water, carefully clean the condenser; be careful not to bend the fins.
5. Check the refrigerant charge in the air conditioning system; for instructions, refer to the applicable heater and air conditioner section in this group.
6. Check the suction pressure and discharge pressure of the refrigerant compressor; refer to **Subject 120.**

NOTE: For other possible causes of air conditioner problems, refer to the applicable heater and air conditioner section in this group.

Compressor Suction and Discharge Pressure Checking



Checking

WARNING

WARNING: Before doing any of the work below, read the information under Safety Precautions, 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Attach a manifold gauge set to the service ports. Make sure that the manifold gauge set is equipped with a valve core depressor.

   1.1 Remove the protector caps from the service valve ports on the compressor (R–12 systems), or at the firewall (R–134a systems). **See Fig. 1.**

1. Dischage Service Valve
2. Suction Service Valve

Fig. 1, Service Port Locations, R–134a System

   1.2 Make sure that the valves on the recovery and recycling station are closed. Cap the manifold center hose.

   1.3 Connect the red high-side hose to the discharge service valve, and the blue low-side hose to the suction service valve.

2. Start the engine and set it to run at 1500 rpm.

3. Turn on the heater-air conditioner blower, and set the air conditioner controls to the coldest setting, so that the compressor is operating. If the outside temperature is cooler than 70°F (21°C), *partially* block the air to the condenser.

4. Look at the manifold suction and discharge pressure gauges. The pressure on the gauges should be within the range in **Table 1** or **Table 2.**

   4.1 If the suction and discharge pressures are both too high, there is air in the refrigerant, or too much refrigerant in the system; check the charge; for instructions, refer to the applicable heater and air conditioner section in this group.

   4.2 If the suction pressure is too high and the discharge pressure is normal, check the wiring to the thermostatic switch on the blower motor housing; repair or replace the wiring, as needed. If the wiring is correct and there is power to the switch, check that the probe of the thermostatic switch is correctly installed in the evaporator coil. Refer to the applicable heater and air conditioner section in this group for instructions. If everything checks out okay, but the problem persists, replace the thermostatic switch at the climate control panel.

   4.3 If the suction pressure is too low and the discharge pressure is normal or too low, check for passage of air through the evaporator coils. If airflow is blocked, remove the blockage. If airflow is satisfactory, check for blockages in the line to the suction side of the compressor.

5. If the suction pressure is normal and the discharge pressure is too high, airflow through the condenser may not be enough to carry away the heat.

   5.1 Place a large fan in front of the radiator, so that the airflow goes through the condenser. After two minutes of operating the air conditioner and the fan at the same time, look at the manifold pressure gauges again. (One other procedure is to direct a spray of water onto the condenser while the system is running.)

   5.2 If the discharge pressure is still too high, the lines between the compressor and the receiver-drier are blocked, or the condenser is blocked internally. Discharge, flush, evacuate, charge, and leak test the system. If the blockage can't be removed by flushing, replace the blocked line or

Compressor Suction and Discharge Pressure Checking

blocked condenser. After flushing and before placing a vacuum in the system, *be sure to add the correct amount of refrigerant oil to the compressor.* For instructions, refer to **Subject 140.**

6. If the suction pressure is normal or too high and the discharge pressure is too low, check for a slipping clutch or wrong-sized clutch pulley or accessory drive pulley. Replace parts as needed.

   If the suction pressure is still normal or too high and the discharge pressure is still too low, the compressor is the problem. Repair or replace the compressor.

Outside Temperature °C (°F)	Maximum Center Vent Temperature °C (°F)	Low Pressure (suction) kPa (psi)	High Pressure (discharge) kPa (psi)
16 to 27 (60 to 80)	14 (58)	41–103 (6–15)	1138 (165)
27 to 32 (80 to 90)	16 (60)	69–124 (10–18)	1276 (185)
32 to 38 (90 to 100)	18 (64)	83–138 (12–20)	1413 (205)

Table 1, Temperature/Pressure Specifications, R–12 Systems

Relative Humidity	Outside Temperature °C (°F)	Maximum Center Vent Temperature °C (°F)	Low Pressure (suction) kPa (psi)	High Pressure (discharge) kPa (psi)
Low (40%)	24 (75)	4 (39)	97 (14)	965 (140)
	29 (85)	4 (39)	103 (15)	1145 (166)
	38 (100)	5 (40)	110 (16)	1503 (218)
High (90%)	24 (75)	3 (38)	97 (14)	896 (130)
	29 (85)	4 (39)	110 (16)	1103 (160)
	38 (100)	5 (40)	124 (18)	1517 (220)

Table 2, Temperature/Pressure Specifications, R–134a Systems

Removal

1. Recover the refrigerant from the air conditioning system; for instructions, refer to the applicable heater and air conditioner section in this group.
2. Disconnect the suction and discharge hose fittings at the compressor. **See Fig.1.**

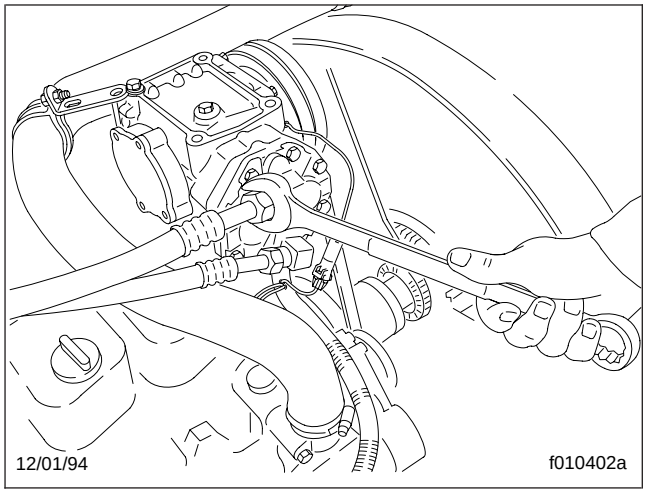


Fig. 1, Disconnect the Suction and Discharge Hose Fittings

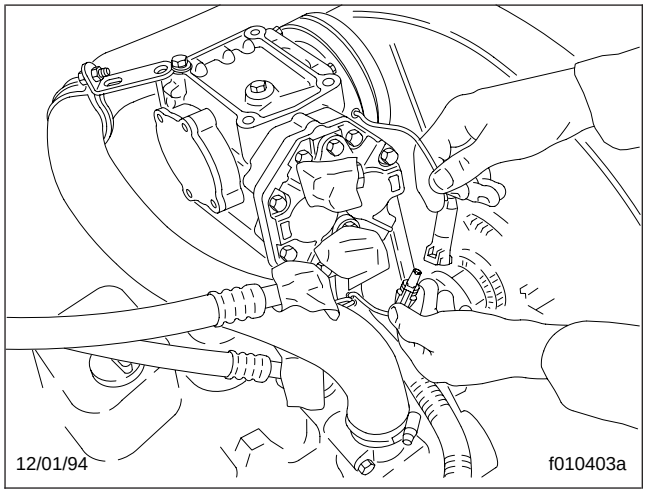
3. Plug the hoses to prevent contamination.
4. Disconnect the compressor magnetic clutch electrical connection. **See Fig.2.**



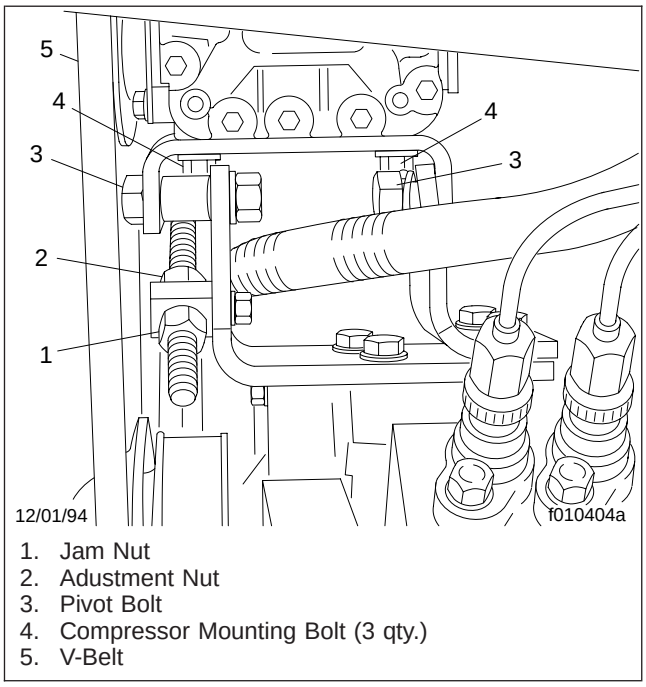


Fig. 2, Disconnect the Electrical Connection

5. Remove the V-belt. **See Fig.3,Fig. 4,or Fig.5.**

1. Jam Nut
2. Adustment Nut
3. Pivot Bolt
4. Compressor Mounting Bolt (3 qty.)
5. V-Belt

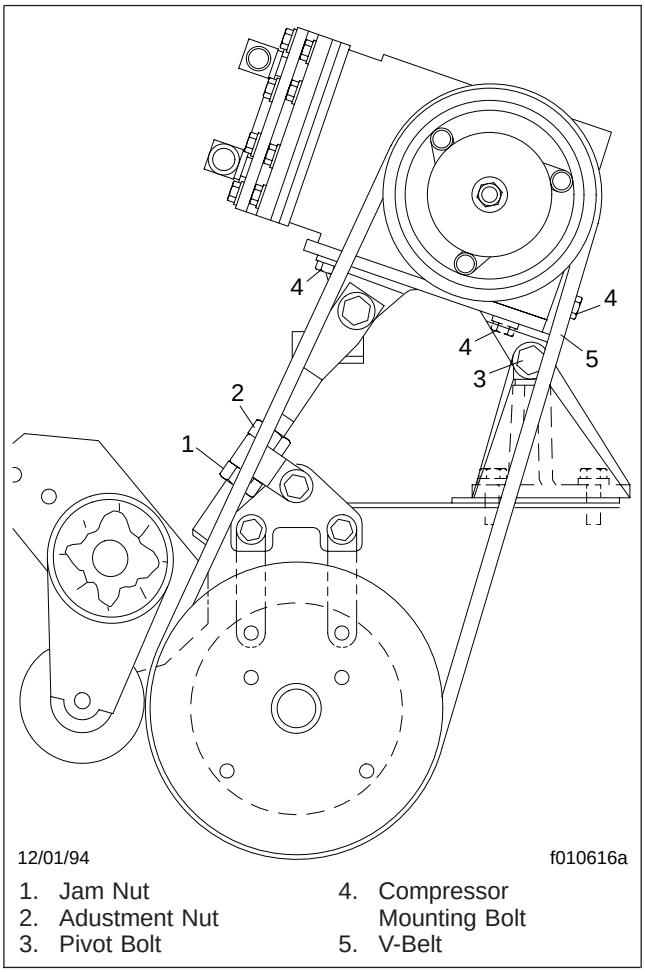
Fig. 3, Compressor Mounting on Cummins B Series Engines (earlier installations)

5.1 Loosen the compressor pivot bolts (Ref. 3).

5.2 Loosen the adjusting rod jam nut (Ref. 1), then back off the adjustment nut (Ref. 2) until the belt can be removed.

5.3 Remove the belt. Don't pry or roll it off the pulleys.

6. Remove the compressor.



6.1 Pivot the compressor mounting bracket for access to the three compressor mounting bolts (**Fig.3**, Ref. 4).

6.2 Remove the three compressor mounting bolts (Ref. 4).

On Cummins C Series engines, remove the bolt (**Fig.5**, Ref. 6) that attaches the adjusting rod to the compressor support bracket (Ref. 7).

6.3 Remove the compressor.

Compressor Removal and Installation

1. Jam Nut
2. Adustment Nut
3. Pivot Bolt
4. Compressor Mounting Bolt
5. V-Belt

Fig. 4, Compressor Mounting on Cummins B Series Engines (current installations)

Installation

IMPORTANT: A new compressor is filled with refrigerant oil and nitrogen gas. When installing a new compressor on the vehicle, do all of the steps below; if installing a used compressor, position the compressor on the mounting bracket, and begin installation.

1. To prepare a new compressor for installation, gently release the nitrogen gas from the discharge side of the compressor; be careful not to let the oil flow out. Turn the compressor shaft several times by hand to distribute oil which has settled in the cylinder.
2. Position the compressor against the mounting bracket.
3. On Cummins B Series engines, install the mounting bolts and washers to hold the compressor in place. Tighten the nuts 47 N·m (35 lbf·ft).

   On Cummins C Series engines, install the adjusting rod attachment bolt. Tighten the bolt 87 N·m (64 lbf·ft).
4. Install the V-belt.

   4.1 Position the V-belt over the pulleys.

   4.2 Adjust the V-belt tension by screwing the adjustment nut on the lower mounting strut in or out. Refer to **Group 01** in this manual for instructions.
5. Tighten the compressor pivot bolts 87 N·m (64 lbf·ft).
6. Uncap the discharge and suction ports. Unplug the suction and discharge hose connections. Check the hose connections and the surface of the discharge and suction ports. Surfaces must be clean and free of nicks, gasket residue, and other foreign matter.

IMPORTANT: Under no circumstances should you leave the compressor's ports uncapped for longer than five minutes total.

7. Connect the refrigerant hoses to the compressor. Tighten the fittings 45 N·m (33 lbf·ft).
8. Connect the electrical wire to the compressor magnetic clutch.
9. Replace the receiver-drier.
10. Check the oil in the compressor as specified in **Subject 140.**
11. Evacuate, charge, and leak test the refrigerant system. For instructions, refer to the applicable heater and air conditioner section in this manual.

1. Jam Nut
2. Adustment Nut
3. Pivot Bolt
4. Compressor Mounting Bolt
5. Fan Belt
6. Adjusting Rod Attaching Bolt
7. Compressor Support Bracket

Fig. 5, Compressor Mounting on Cummins C Series Engines

Oil Check and Adding Oil

⚠ CAUTION

Different refrigerant oils are used in compressors on R–12 and R–134a air conditioning systems. Always use the correct refrigerant oil and never mix oils. If the wrong oil is used, or if oils are mixed, the compressor could seize due to improper lubrication.

IMPORTANT: On R–12 air conditioning systems, new compressors are factory-charged with about 12.2 oz (360 mL) of refrigerant oil. On R–134a air conditioning systems, new compressors are factory-charged with about 14 oz (414 mL) of refrigerant oil. Some refrigerant oil is circulated through the system with the refrigerant, and cannot leave the system except through a leak, when the system is discharged or recovered, or when a system part is replaced.

Oil must be from a container that has not been opened, or that has been tightly sealed since its last use. Check the labelling on the compressor to determine the recommended refrigerant oil. Tubing, funnels, or other equipment used to transfer the oil should be very clean and dry.

When handling refrigerant oil:

- The oil should be free of water, dust, metal powder, and other foreign substances.
- Don't mix refrigerant oil with other types or viscosities of oil.
- Refrigerant oil absorbs moisture when exposed to the air for any period of time. After use, quickly seal the oil container.

IMPORTANT: Add the same amount of oil that is removed when the system is discharged or recovered, or when a system part is replaced. The two lists that follow provide approximate refill amounts for R–12 and R–134a air conditioning systems. Make sure you use the correct list.

The following is for R–12 air conditioning systems only:

A. Refrigerant charge—0.7 fl oz (20 mL): This amount of oil may be removed from the system each time the system loses its charge, due to routine discharging or due to a slow leak; no other parts of the system have been purged, flushed, or replaced.

IMPORTANT: The items below list oil quantities that include the amounts that are lost during discharging. Do not add an additional 0.7 fl oz (20 mL)—the amount described in the item above—to the quantities listed.

B. Receiver-drier—2.7 fl oz (80 mL);

IMPORTANT: A new receiver-drier may contain 3.4 fl oz (100 mL) of refrigerant oil, eliminating the need to add oil before installation. Confirm the oil level in a new receiver-drier; don't add any oil if it already contains 3.4 fl oz (100 mL).

C. Condenser—1.0 fl oz (30 mL);

D. Evaporator coil—0.7 fl oz (20 mL);

E. Entire system—15 fl oz (450 mL) with or without an auxiliary heater/air-conditioner. Add this amount of oil to the compressor if the entire system (including the compressor) has been discharged of refrigerant and oil, and all parts and hoses have been flushed.

The following is for R–134a air conditioning systems only:

A. Oil charge—the entire system should have *about* 14 fl oz (414 mL) of refrigerant oil. There should be 10 fl oz (296 mL) in the compressor. Each major component has *about* 2.0 fl oz (59 mL) of oil (this amount has been rounded off for ease of adding oil to the compressor). Therefore, additional oil must be added to the compressor when a major component is replaced.

NOTE: As an example, if the condenser and the receiver-drier are to be replaced, first check the oil level of the compressor. The compressor should have 10 fl oz (296 mL). Add oil if needed. Then, after replacing the condenser and the receiver-drier, add an additional 4.0 fl oz (118 mL) of oil to the compressor. The entire system should then have about 14 fl oz (414 mL).

IMPORTANT: Replacing only the amount of oil that is removed during evacuation may result in the wrong oil charge because the oil charge may have been incorrect prior to evacuation.

Oil Check and Adding Oil to the Compressor

The only way to ensure the proper oil charge is to check the oil level of the compressor with a dipstick.

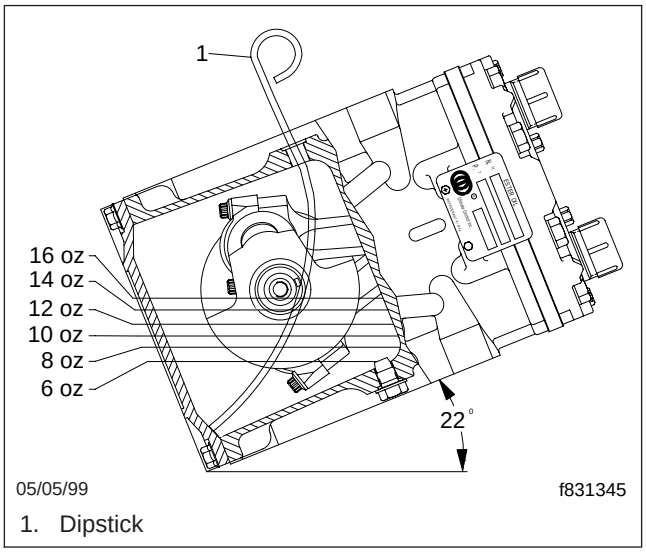
B. Receiver-drier—when the receiver-drier is replaced, *about* 2.0 fl oz (59 mL) must be added to the compressor in addition to the 10 fl oz (296 mL) that the compressor requires).

IMPORTANT: A new receiver-drier does not contain any refrigerant oil.

C. Condenser—when the condenser is replaced, *about* 2.0 fl oz (59 mL) must be added to the compressor in addition to the 10 fl oz (296 mL) that the compressor requires.

D. Evaporator coil—when the evaporator coil is replaced, *about* 2.0 fl oz (59 mL) must be added to the compressor in addition to the 10 fl oz (296 mL) that the compressor requires.

IMPORTANT: Check the compressor oil level whenever the system has been opened.



⚠ WARNING

Don't remove the oil fill plug without first recovering or discharging the system. Failure to recover or discharge the system could cause uncontrolled release of high-pressure refrigerant, which can freeze skin and eye tissue causing serious injury or blindness.

1. Remove the oil fill plug and O-ring.
2. Check the oil level with the dipstick. When the compressor is mounted vertically, use either plug; when mounted in any other orientation, use the upper plug. **Figure 1** shows the oil level with the refrigerant compressor mounted at 22 degrees. **Figure 2** shows the oil level with the refrigerant compressor mounted at 45 degrees.

   If the dipstick bottoms out before going in more than 3 inches (75 mm), it is hitting the compressor crankshaft. Rotate the drive plate by hand and insert the dipstick again until it contacts the bottom of the sump. See **Table 1** to determine the oil quantity. Add or remove oil from the compressor so that the oil charge is 10 fl oz (296 mL).

NOTE: A dipstick can be made locally or purchased from a special tools supplier. Refer to the special tools table in **Specifications 400**. If made locally, it can be formed from 1/8-inch diameter by 8-5/16 inch long stock. See **Fig. 3**. Use a nonferrous material that is not subject to corrosion. Notching the end makes it easier to see the oil depth.

1. Dipstick

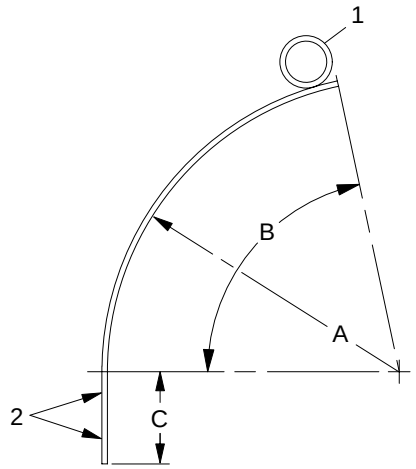


Fig. 1, Oil Level With Refrigerant Compressor Mounted at 22 Degrees

1. Dipstick

Fig. 2, Oil Level With Refrigerant Compressor Mounted at 45 Degrees

3. Being careful not to twist the O-ring, slip it over the oil fill plug threads. Insert the plug in the oil fill opening and tighten it until snug. If the plug leaks, don't attempt to stop the leak by overtightening. Leaks may be caused by dirt under the O-ring, dirt on the seat, a broken O-ring, or a damaged seat on the oil fill plug or opening. Correct the problem and install a new O-ring.

NOTE: Left-Hand Mounting: Check oil when shaft key is down. Right-Hand Mounting: Check oil when shaft key is up.

A. 4-3/4 Inches (121 mm) Radius
B. 78°
C. 1-1/2 Inches (38 mm)
1. Finger Ring
2. 12 Notches, 1/8 Inch (3.2 mm) Apart

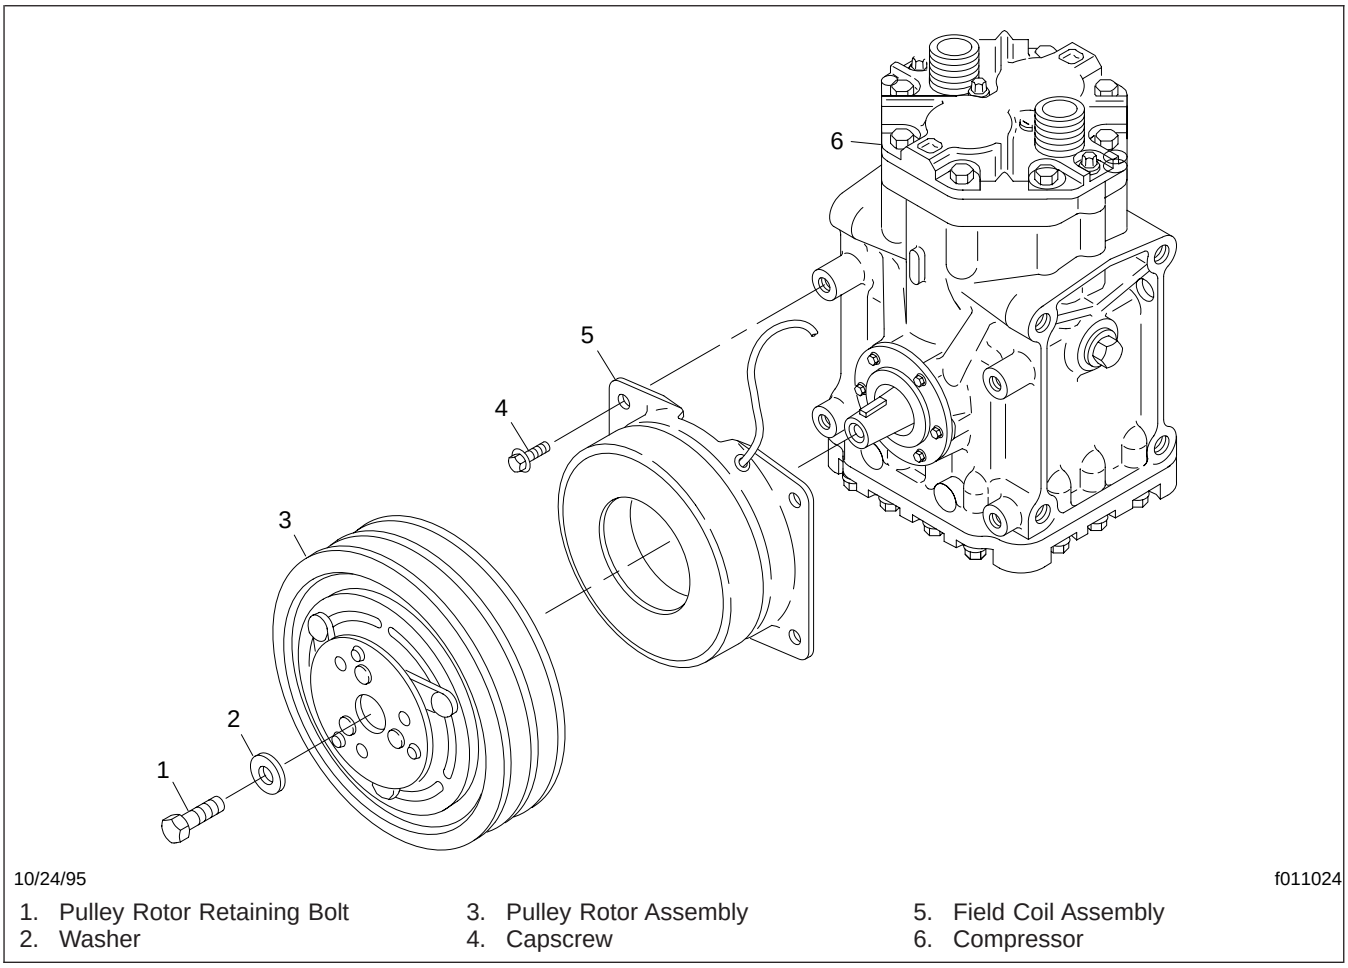

Fig. 3, Dipstick Specifications

Oil Quantity at Various Dipstick Depths				
Dipstick Depth				Oil Quantity fl oz (mL)
0-Degree Mount (horizontal) inches (mm)	22-Degree Mount inches (mm)	45-Degree Mount inches (mm)	90-Degree Mount (vertical) inches (mm)

Magnetic Clutch Removal, Inspection, and Installation

Removal (See Fig. 1)

1. Pulley Rotor Retaining Bolt
2. Washer
3. Pulley Rotor Assembly
4. Capscrew
5. Field Coil Assembly
6. Compressor

Fig. 1, Pulley Rotor and Field Coil Assemblies

1. Remove the pulley rotor assembly.
   - 1.1 Remove the 5/16-inch pulley rotor retaining bolt from the center of the pulley rotor.
   - 1.2 Install a 5/8–11 capscrew in the hub of the pulley rotor assembly.
   - 1.3 Tighten the screw to pull the pulley rotor assembly off the compressor shaft.

⚠ CAUTION

CAUTION: Do not try to remove the pulley rotor assembly by prying or hammering. This can damage the assembly.

2. Remove the field coil assembly.
   - 2.1 Disconnect the field coil electrical lead wire.
   - 2.2 Remove the four 1/4–20 capscrews holding the field coil assembly to the compressor housing.

Inspection

1. Inspect the drive plate. If the friction surface shows signs of damage due to too much heat, replace the drive plate and pulley assembly.

Magnetic Clutch Removal, Inspection, and Installation

2. Check the pulley assembly. If the friction surface of the pulley shows signs of too much grooving due to slippage, replace both the pulley and drive plate. Clean the friction surfaces of the pulley assembly before installing it.
3. Check the coil for a loose connector and for cracked insulation. Replace it, if necessary.

Installation

1. Position the field coil assembly on the compressor housing with the four screw mounting holes aligned with the bosses on the housing.
2. Apply Loctite® 262 or 680 to the four 1/4–20 capscrews (on those threads that do not already have dry Loctite on them).
3. Install the capscrews and gradually tighten them to align the coil assembly. Final torque should be 20 N·m (15 lbf·ft).
4. Taking care to properly align and seat the shaft and hub keyways, attach the pulley rotor assembly to the compressor shaft.
5. Install the 5/16–24 center bolt and washer. Tighten the bolt about 27 N·m (20 lbf·ft).
6. Turn the pulley rotor assembly by hand to make sure it moves freely without interference with the field coil assembly.
7. Connect the lead wire from the field coil to the vehicle electrical circuit.
8. Engage and disengage the clutch several times to check for correct operation.

Replacement (See Fig. 1)

1. Remove the compressor from the vehicle. For instructions, see **Subject 130**.

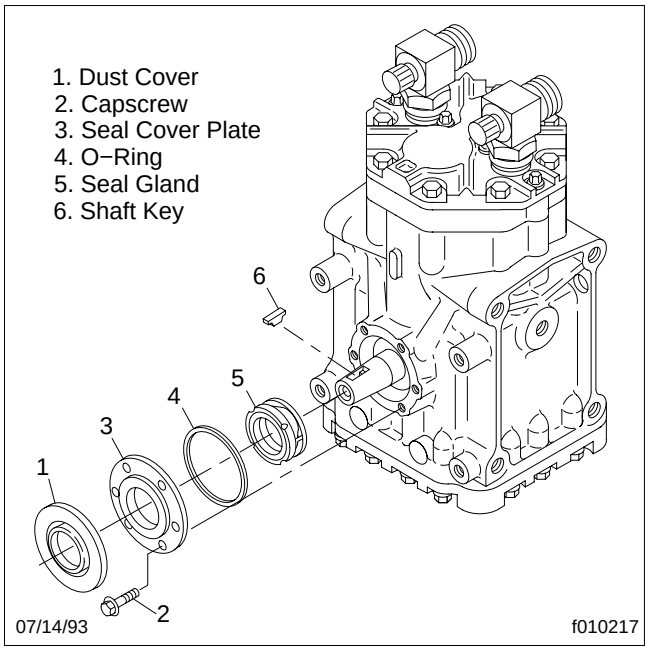

Fig. 1

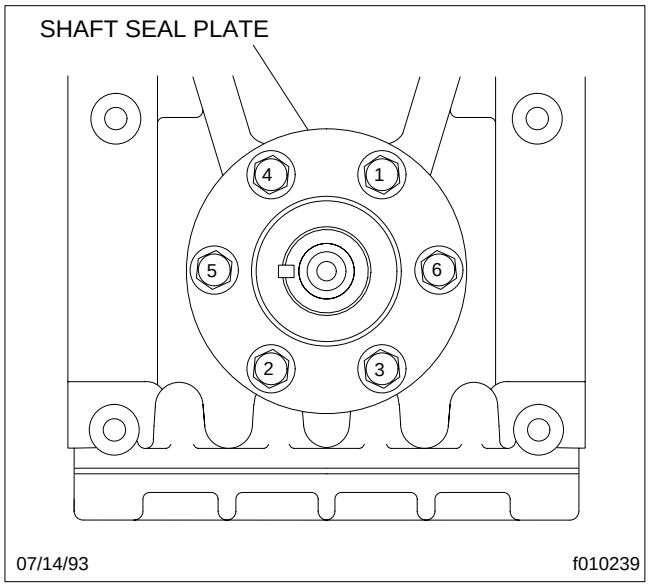
2. Remove the clutch. For instructions, see **Subject 150**.
3. Remove the seal.
   - 3.1 Remove the dust cover if present.
   - 3.2 Remove the seal cover plate. Using the seal puller, pull out and discard the seal gland. Do not use a screwdriver to pry the seal gland from the compressor shaft; this could damage the shaft. Discard all seal parts including the O-ring.
4. Clean the shaft and seal cavity with a clean lint-free cloth.
5. Install the new seal.
   - 5.1 Dip the new seal gland assembly (**Fig. 1**, Ref. 5) in refrigerant oil.
   - 5.2 Remove the carbon ring from the seal gland assembly; then, push the assembly over the end of the shaft. Make sure the carbon ring retainer is facing out. Use the seal installer tool to move the seal gland assembly into position on the shaft.
   - 5.3 Place the carbon ring in the ring retainer so the lapped surface is facing out. The indentations in the outside edge of the carbon ring must engage the driving lugs and be firmly seated in the retainer.
   - 5.4 Coat a new O-ring with refrigerant oil so it will stick; then, install it in the seal cover plate groove.
   - 5.5 Install the seal cover plate so there is equal clearance around the shaft. Install the capscrews, and tighten them 60 to 84 lbf·in (680 to 940 N·cm) in the sequence shown in **Fig. 2**.
   - 5.6 Place the dust cover on the shaft before inserting the shaft key. As the clutch bolt is tightened, the dust cover will be drawn into the proper position.
6. Install the clutch. For instructions, see **Subject 150**.



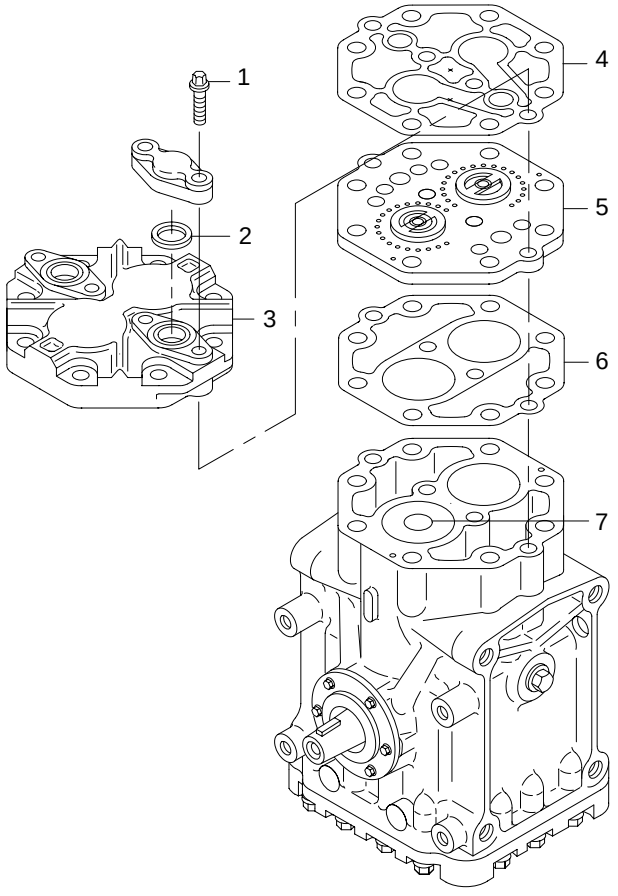


Fig. 2, Tightening Sequence

Removal (See Fig. 1)

1. Capscrew
2. O-Ring
3. Cylinder Head
4. Cylinder Head Gasket
5. Valve Plate
6. Cylinder Gasket
7. Piston

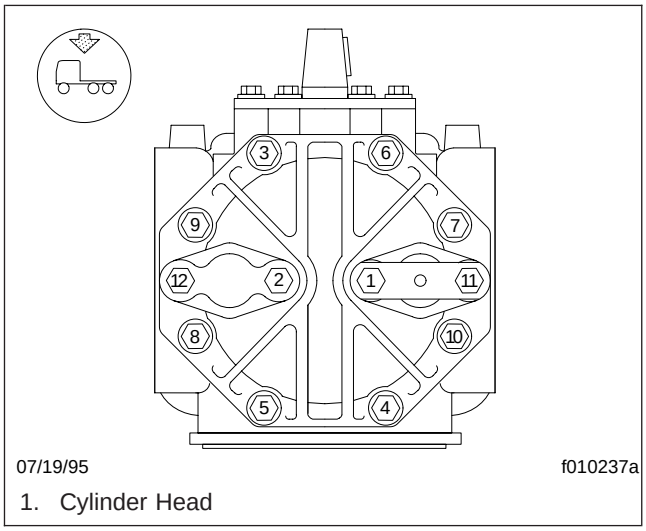

Fig. 1, Compressor Head and Valve Plate Assembly

NOTE: Before doing any work on the head and valve plate, open both service valves to release any gas pressure in the compressor. The cylinder head is made of aluminum; be careful when removing it not to damage the sealing surfaces.

1. Remove the screws from the service valves. **See Fig. 2**, Refs. 1, 2, 11, and 12.

   If equipped with flanged-type service valves, these four screws are longer than the remaining head screws.

   If equipped with Rotalock or Tube-O type valves, remove them by loosening the hexnuts which are part of the valve assembly.

1. Cylinder Head

Fig. 2, Cylinder Head Capscrew Tightening Sequence

2. Remove the remaining screws from the head.
3. Remove the valve plate and head from the cylinder by prying or tapping under the ears extending from the valve plate. If the head and valve plate adhere, hold the head and tap the valve plate ears away from the head with a soft hammer.

CAUTION

CAUTION: Do not hit or tap the head to separate it from the valve plate. Damage to the head may result.

4. Being careful not to scratch or nick the machined sealing surfaces, remove all gasket material adhering to the head, valve plate, or cylinder.

Installation

NOTE: Valves and valve plates are furnished only as a complete assembly.

Head and Valve Plate Removal and Installation

CAUTION

CAUTION: Different refrigerant oils are used in compressors on R–12 and R–134a air conditioning systems. Always use the correct refrigerant oil and never mix oils. If the wrong oil is used, or if oils are mixed, the compressor could seize due to improper lubrication.

1. Apply a thin film of clean refrigerant oil to the area of the crankcase to be covered by the cylinder gasket. Place the cylinder gasket in position on the cylinder so the dowel pins in the crankcase pass through the dowel pin holes in the cylinder gasket.
2. Apply a thin film of clean refrigerant oil to the top and bottom valve plate areas to be covered by gaskets. Place the valve plate in position on the cylinder gasket so the discharge valve assemblies are facing up and the locating dowel pins go through the dowel pin holes in the valve plate. The discharge valve assemblies are the smaller diameter ones with the restrainer over the valve reed.
3. Place the head gasket in position on the valve plate so the dowel pins go through the dowel pin holes in the gasket.
4. Apply a light film of clean refrigerant oil to the machined surface of the cylinder head which contacts the head gasket. Place the head on the cylinder head gasket so the dowel pins go into the dowel pin holes in the head.
5. Apply a thin film of clean refrigerant oil to the service valve flanges. Place a service valve gasket in position on the cylinder head service valve flanges. Place the service valves in position on the proper service valve ports (suction or discharge) and insert the four longer screws through the service valve mounting pads, the head, the valve plate, and into the crankcase.

   If equipped with Rotalock or Tube-O type valves, insert the longer screws on the inside of the service valve ports and the shorter screws on the outside.

   Insert the remaining head screws and tighten all the screws until the heads make contact.
6. Tighten the head and service valve screws 23 to 34 N·m (17 to 25 lbf·ft) in sequence. **See Fig. 2.**

Pistons, Connecting Rods, Crankshaft, and Bearing Removal and Installation

Piston and Connecting Rod Removal

The pistons and connecting rods are easily accessible after removing the head, valve plate assembly, and base plate. If the connecting rods will be reused, mark the rod, cap and crankshaft throw so the rod can be installed in exactly the same position on the crank pin.

Crankshaft and Bearing Removal

NOTE: When replacing the crankshaft, both the front (seal end) and rear main bearings should also be replaced since they may be damaged during removal.

1. Remove the four capscrews from the rear bearing cover plate.
2. Remove the cover plate by gently prying it loose from the crankcase, being careful that the housing is pulled parallel to the bearing surface.
3. Remove all components down to the crankcase, crankshaft, and seal end main bearing assembly.
4. Wash this assembly in an OSHA-approved solvent to remove all traces of oil and grease. Allow it to dry.
5. Heat the assembly in an oven set to 150°C (300°F).

CAUTION

CAUTION: Heat the complete assembly evenly in an oven. Localized heating may crack the crankcase.

6. Remove the crankshaft and ball bearing assembly from the crankcase.
7. If the crankshaft is reusable, remove the ball bearing assembly. Hold the crankshaft vertically in a vise with the flywheel end up, gripping the shaft at the unmachined center throw. Using two large screwdrivers as a pry under the bearing race, force the bearing upward and remove it from the shaft.

Crankshaft and Bearing Installation

1. Press the rear ball bearing onto the crankshaft by exerting pressure on the bearing inner race.
2. Make sure that the shaft, bearing, and recess in the crankcase are clean and free of burrs.
3. Heat the crankcase in an oven set to 150°C (300°F).

CAUTION

CAUTION: Heat the complete assembly evenly in an oven. Localized heating may crack the crankcase.

4. Using the opening in the bottom of the crankcase as a point of entry, place the seal end bearing in the recess. If necessary, apply force to the outer race to be sure that it is seated in the bottom of the recess.
5. Allow the crankcase to cool. Install the crankshaft through the rear bearing cover plate opening, and guide the flywheel end through the inner race of the ball bearing.
6. Place the crankcase so that it is completely supported on the ball bearing inner race. Then, press the shaft into place until the shaft boss contacts the inner bearing race.

CAUTION

CAUTION: If the housing is not completely supported by the inner bearing race, the bearing may be destroyed.

7. Install the rear bearing cover plate with the O-ring in the crankcase. A slight force may be required due to the small clearances between the outer race of the ball bearing and the bearing cover plate recess.
8. Install the four capscrews and tighten them 1220 to 2300 N·cm (108 to 204 lbf·in) in the sequence **shown in Fig. 1.**

Pistons, Connecting Rods, Crankshaft, and Bearing Removal and Installation

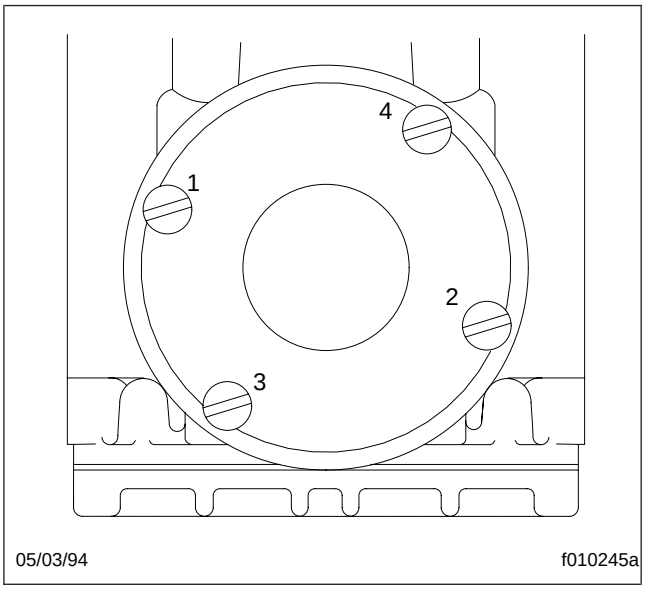

Fig. 1, Rear Bearing Cover Plate Capscrew Tightening Sequence

Piston and Connecting Rod Installation

CAUTION

CAUTION: Different refrigerant oils are used in compressors on R–12 and R–134a air conditioning systems. Always use the correct refrigerant oil and never mix oils. If the wrong oil is used, or if oils are mixed, the compressor could seize due to improper lubrication.

NOTE: When installing either the original or a new piston and connecting rod assembly, coat all bearing surfaces with clean oil of the same brand used in the crankcase.

When installing the assembly into the cylinder, the wrist pin roll pin must be positioned toward the center of the compressor. If positioned toward the outside, the roll pin may hit the crankshaft when the piston is at bottom dead center.

When installing a used connecting rod, match up the marks made during removal. When installing a new connecting rod, the dowel pins in the bearing cap must be positioned to enter the holes in the rod.

1. Install the piston and connecting rod assemblies.
2. Install the connecting rod capscrews and tighten them 16 to 22 N·m (12 to 16 lbf·ft).
3. Wipe all parts with a lint free cloth to make sure they are clean.
4. Install the base plate. Tighten the capscrews 16 to 24 N·m (12 to 18 lbf·ft) in sequence. **See Fig. 2.**

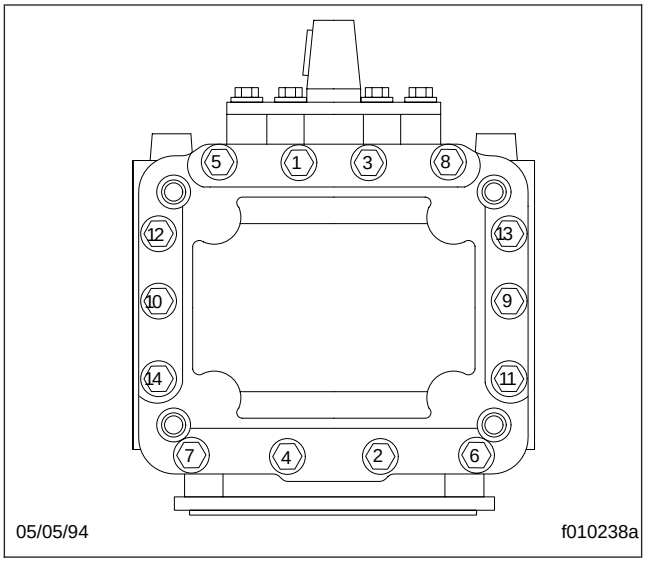

Fig. 2, Baseplate Capscrew Tightening Sequence

5. Install the head and valve plate assembly. For instructions, **Subject 170.**
6. Check the labelling on the compressor to determine the recommended refrigerant oil. Fill the crankcase with the recommended oil.
7. Close all openings to prevent the entrance of foreign material.

Specifications

Table 6, Torque Specifications for Fittings on Reciprocating Refrigerant Compressors

General Description

The heating, ventilation, and air conditioning (HVAC) unit uses a common blower motor and duct work to heat or cool the cab. Airflow rate is controlled by a three-speed blower switch. Air outlets are located in the instrument panel, along the bottom of the dash, at the windshield, and also at the side windows. See **Fig. 1**.

2. Windshield Defrost Outlets
3. Passenger's Door Window Defrost Outlet
4. Floor Outlet
5. Dash/Door Window Vent
6. Center Dash Vents

Fig. 1, Air Outlet System

Both left-hand drive (LH DR) and right-hand drive (RH DR) vehicles use the same HVAC unit. On RH DR, components are moved to the opposite side of the cab. The blower motor, on the right-hand (passenger's) side on LH DR, moves to the left-hand (passenger's) side on RH DR.

When equipped with an air conditioner, temperature can be moderated by opening or closing a water regulating valve, which controls the flow of warm engine coolant to the heater core. The temperature of the air inside the cab partly depends on how much coolant is flowing through the heater core, and how much liquid refrigerant is in the evaporator coil.

The air conditioning system also includes a cycling-clutch refrigerant compressor, a condenser, an expansion valve, an evaporator coil, a fixed-temperature thermostatic switch, and mechanically operated controls.

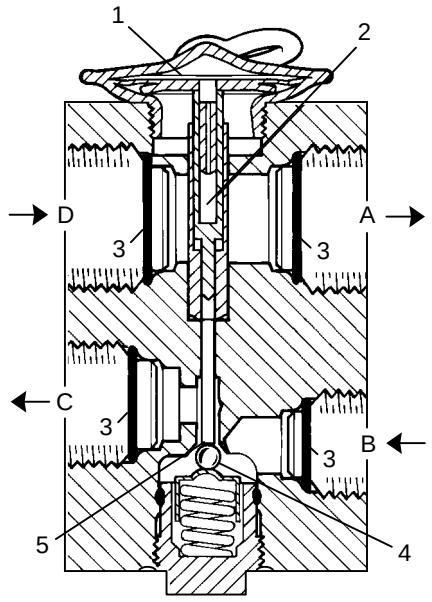
Description of Components

Refrigerant

Refrigerant absorbs heat from the air in the cab and releases it to the air outside the cab.

In an open container, refrigerants boil at temperatures below the freezing point of water; sealing and pressurizing refrigerant in the air conditioning system raises its boiling-point temperature.

During compressor operation, refrigerant constantly changes from a liquid to a gas. It absorbs heat (boiling) in the low-pressure evaporator coils, and it changes from a gas to a liquid as it releases absorbed heat in the high-pressure condenser.



Expansion Valve

The expansion valve is a dividing point between the high- and low-pressure parts of the refrigerant system. High-pressure liquid refrigerant from the

General Information

receiver-drier passes through the expansion valve and moves into the low-pressure area of the evaporator coil.

An expansion valve controls the flow rate of refrigerant in proportion to the rate of evaporation in the evaporator. If the amount of liquid in the evaporator drops off, the temperature of the gas going to the compressor rises. This causes a diaphragm in the expansion valve to react, which causes an orifice in the valve to open or close. See **Fig. 2**. Through the orifice, liquid refrigerant is metered into the evaporator, as needed.

Fig. 2, Expansion Valve

Evaporator Coil

Because the evaporator coil is an area of low pressure in the system, the boiling point of refrigerant lowers, which causes it to absorb heat from the tubing walls and fins of the coils. As it absorbs heat, liquid refrigerant quickly boils and turns into a gas.

As heat is absorbed from the outside surfaces of the evaporator coil, air passing over the unit loses its heat to these cooler surfaces. Moisture in the air condenses on the outside of the coil and drains off as water (the air becomes dehumidified).

Refrigerant Compressor

"Heat" in the low-pressure gas of the evaporator coils is not heat that can be noticed by touch, because liquid refrigerant boils at a temperature much lower than the temperature at which water turns to ice. By touch, the "heated" gas in the coils is very cold. As a result, there is the problem of how to remove heat from subfreezing gas using outside air that may be higher than 38°C (100°F).

With a refrigerant compressor, low-pressure gas from the evaporator can be squeezed into a much smaller space. When the gas is compressed, the heat it contains becomes concentrated. In this way, the gas is made hotter than the outside air, without adding heat.

Another function of the compressor is to move refrigerant through the system.

Condenser

A condenser turns hot refrigerant gas, coming from the compressor, into liquid. Mounted in front of the radiator, it is made up of a coiled tube and a series of fins. Because of its location, the condenser transfers heat to air that is drawn in by the engine fan and by air that is forced into the engine compartment as the vehicle moves forward (ram air).

Receiver-Drier

Used as a reservoir and filter for liquid refrigerant from the condenser, a receiver-drier also removes water and acids from the refrigerant. The water-absorbing material (desiccant) in the unit helps stop blockages from forming in the expansion valve and in other parts of the system.

A moisture indicator shows the amount of water in the refrigerant. A sight glass (aperture) on the unit contains a specially treated element (litmus paper) that changes color, depending on the amount of water in the refrigerant. The indicator changes from a deep cobalt blue (dry) to light greyish-blue (wet) to lilac, lavender, and finally pink (very wet). Any color other than cobalt blue is considered wet. Any time the system is evacuated (dehydrated), replace the receiver-drier.

Thermostatic Switch

The temperature of the evaporator coil is monitored by a fixed-temperature thermostatic switch.

The probe from the switch extends to the evaporator coil, and the switch is mounted on the right side of the heater and air conditioner housing. This switch disengages the compressor to prevent the evaporator coil from freezing up due to, for example, an expansion valve that is stuck open.

Fan Cycle Switch (On-Off Fan Only)

Located on the receiver-drier, the fan cycle switch activates a solenoid to turn the fan on or off, depending on refrigerant pressure.

On vehicles built before November 1994, the fan will come on if refrigerant pressure is greater than 260 ± 10 psi (1800 kPa). The fan turns off when pressure drops below 174 ± 10 psi (1200 kPa).

On vehicles built from November 1994, the fan will come on if refrigerant pressure is greater than 300 ± 10 psi (2070 kPa). The fan turns off when pressure drops below 250 ± 10 psi (1725 kPa).

Binary Switch

A binary switch disengages the refrigerant compressor to protect it from harmful operating conditions. It performs two functions:

1. If refrigerant is lost or the outside temperature is too low, the binary switch will keep the compressor from operating. The switch disengages the compressor when falling pressure goes below 26 to 31 psig (180 to 215 kPa); normal compressor operation resumes when rising pressure reaches 0.1 to 3.0 psig (0.6 to 21.0 kPa) above shutoff pressure.
2. If the compressor cylinder head pressure increases to unsafe levels above 356 to 413 psig (2455 to 2845 kPa), the binary switch shuts off the compressor. Too much pressure may be caused by blocked air flow through the condenser, a plugged expansion valve or receiver-drier, or too much refrigerant in the system. When pressure falls back 57 to 114 psig (395 to 785 kPa) from shutoff pressure, the compressor resumes operation.

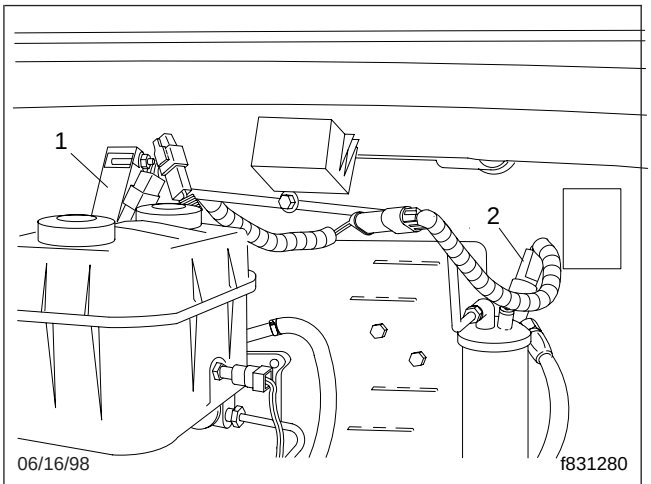
Heater Core

The heater core is a series of fins through which tubing is routed. When the heating system is on, engine coolant flows through the heater core tubes, heating the tubes and fins. The heat is absorbed by air that is forced through the heater core by the blower motor.

Water Regulating Valve

When opened, the water regulating valve allows engine-heated coolant to flow through the heater core.

Air Blower, Resistor Block Assembly



An air blower forces air through the heater core and evaporator coil, and into the cab. The resistor block assembly regulates the voltage to the blower motor. The voltage controls the blower motor speed. The resistor assembly has a thermal cutout which shuts off current to the blower motor in case the motor malfunctions.

Air Conditioning Protection and Diagnostics System (APADS™)

The APADS™ control and diagnostics system is designed to increase the life of the air conditioning system components, reduce air conditioning maintenance, and aid the diagnosis of system faults. The APADS™ control system consists of an electronic control module, high and low pressure switches, and an evaporator thermostat. The electronic control module actively monitors system conditions and controls the operation of the refrigerant compressor and the fan clutch. Refer to Principles of Operation for more information on this system.

Located under the hood on the left-hand side of the frontwall, the electronic control module registers fault codes that warn of existing or impending problems in the air conditioning system. See **Fig. 3**. Diagnostic information and system status are communicated by red and green light emitting diodes (LEDs) built into the electronic control module. Since only one blink code can be displayed, the fault code of highest priority takes precedence. For more information on fault codes, see **Troubleshooting 300**.

General Information

1. Electronic Control Module
2. High Pressure Switch

Fig. 3, APADS Control Module

APADS™ High Pressure Switch

Located on the discharge side of the refrigerant compressor, the high pressure switch signals the electronic control module to turn the fan on and to prevent operation of the refrigerant compressor in the event of a high pressure condition. When the pressure increases above 290 to 310 psi (1999 to 2137 kPa) on vehicles built before December 11, 1998 or 340 to 375 psi (2344 to 2586 kPa) on vehicles built from December 11, 1998 the electronic control module shuts down the refrigerant compressor if necessary, and turns the fan on. When the pressure returns to 250 to 270 psi (1724 to 1862 kPa), the compressor resumes normal operation and the electronic control module turns the fan off.

APADS™ Low Pressure Switch

Located on the suction side of the refrigerant compressor, the low pressure switch signals the electronic control module to shut down the refrigerant compressor in extremely cold temperatures, or if there is a loss of charge. When the pressure falls below 10 psi (69 kPa) the electronic control module shuts down the refrigerant compressor. When the pressure is above 34 psi (234 kPa) the compressor resumes normal operation.

APADS™ Evaporator Thermostat

The evaporator thermostat is the main air conditioning system control. The evaporator thermostat is wired in series with the air conditioning system on/off switch. It opens at 32°F (0°C) or below, and closes at 38°F (3°C) or above.

Definition of Terms

Refer to the following terms for a better understanding of the heater/air-conditioning system.

Air Conditioner A system used to control the temperature, humidity, and movement of air in the cab.

Air Conditioning Protection and Diagnostics System (APADS™) A system that actively monitors air conditioner conditions and controls the refrigerant compressor and the on/off fan drive. Existing or impending problems are registered as fault codes on the electronic control module.

Ambient Air Temperature The temperature of air around an object; the outside temperature.

Binary Switch Disengages the refrigerant compressor to protect it from harmful operating conditions.

Blower A motor and fan used to draw air through the evaporator, and force it through the heater core and into the cab.

Blower Resistor Block Assembly In line resistors that control the amount of voltage going to the blower motor. By controlling the voltage, you can control the fan speed.

Boiling Point The temperature at which a liquid changes to a gas. The boiling point varies with pressure.

Bulk Charging Use of large containers of refrigerant for charging a refrigerant system. Normally used for charging empty systems.

Carbon Dioxide A colorless, odorless, dry, inert gas that can be used to purge light contaminants (for example, dust) from air conditioner parts.

CFM Cubic feet per minute.

Charge A specific amount of refrigerant or oil by volume or weight. Also, the act of placing an amount of refrigerant or oil in the air conditioning system.

Clutch Cycling Switch (Thermostatic Switch) Engages or disengages the compressor depending on changes in system pressure or evaporator temperature.

Cold The absence of heat. The lowest possible temperature is thought to be –459°F (–273°C).

Compressor A device used to draw low-pressure refrigerant gas from the evaporator and squeeze it into a high-temperature, high-pressure gas. A second purpose of the compressor is to move refrigerant through the system.

Condensate Water, taken from the air, which forms on the outer surface of the evaporator.

Condenser A heat exchanger that is used to remove heat from the refrigerant, changing it from a high-pressure hot gas to a high-pressure warm liquid.

Condensing Pressure Pressure, as read from the gauge at the discharge service valve; pressure from the discharge side of the compressor into the condenser.

Contaminants Anything other than refrigerant or refrigerant oil in the system. Usually means water in the system. When water and refrigerant mix, corrosive hydrochloric acid forms.

Cycling Clutch System A system which controls compressor clutch operation in order to raise or lower the temperature in the cab.

Dehumidify To remove water from the air, at the evaporator coil.

Dehydrate To remove all traces of moisture from the refrigerant system. Normally called evacuation.

Desiccant A drying agent used in the refrigerant system (in the receiver-drier) to remove water and create an extremely dry condition.

Discharge Line Connects the refrigerant compressor outlet to the condenser inlet.

Discharge Pressure Pressure of the refrigerant being discharged from the compressor; high-side pressure; condensing pressure.

Drive Pulley A V-pulley attached to the front of the engine crankshaft. It drives the compressor clutch pulley with a belt.

Drying Agent See "Desiccant."

Duct A passageway for the transfer of air from one point to another.

Evacuate To place a high vacuum in the air-conditioning system and dehydrate or remove all traces of moisture.

Evaporate To change state from a liquid to a gas.

Evaporator Coil A component in which liquid refrigerant changes to a gas after it absorbs heat from the air. Also removes some moisture from the air.

Evaporator Thermostat (APADS™) The evaporator thermostat is the main air conditioning system control. It is used to turn off the refrigerant compressor whenever frost begins to form on the evaporator.

Expansion Valve A device that causes a pressure-drop of the refrigerant and also regulates its flow.

Flooding A condition caused by too much liquid refrigerant going into the evaporator; usually caused by an expansion valve that is stuck open.

Flushing A process of passing liquid refrigerant through an air-conditioner component to remove dirt and water from the part. Liquid refrigerant removes heavy contamination, such as gritty dirt and large dirt buildup.

Freeze-Up Failure of a unit to operate properly because of ice forming at the expansion valve orifice or on the evaporator coils and fins.

Heater Core A part of the heating system in which hot engine coolant flows to provide heat to the cab or to adjust the temperature produced by the air conditioner.

High-Side Service Valve A device located on the liquid line near the thermostatic expansion valve; it allows high-side pressure to be checked and other service operations to be performed.

High Pressure Switch (APADS™) Located on the discharge side of the refrigerant compressor, the high pressure switch signals the electronic control module to turn the fan on and to prevent operation of the refrigerant compressor in the event of a high pressure condition.

Humidity The amount of water vapor in the air.

Hydraulic Lock The return of liquid refrigerant to the compressor, which could destroy the unit.

Leak Detector Any device used to detect refrigerant leaks in a refrigerant system.

Liquid Pressure Pressure of refrigerant in the liquid line from the receiver-drier to the thermostatic expansion valve.

Low Pressure Switch (APADS™) Located on the suction side of the refrigerant compressor, the low pressure switch signals the electronic control module to shut down in extremely cold temperatures, or if there is a loss of charge.

Low-Air Pressure Switch An air operated electrical

General Information

switch that is normally open, but closes when the system pressure rises to 65 to 75 psi (450 to 515 kPa). Its purpose is to prevent the refrigerant compressor from turning on if the vehicle's air system pressure is too low to activate the cooling fan.

Low Head Pressure High-side pressure that is lower than normal due to a system problem.

Low Suction Pressure Low-side pressure that is lower than normal due to a system problem.

Magnetic Clutch An electrical coupling device used to engage or disengage the compressor.

Manifold Device to control refrigerant flow for system test purposes; used with manifold gauges.

Manifold Gauge A calibrated instrument used for measuring system pressures.

Manifold Gauge Set A manifold that is complete with gauges and charging hoses and is used to measure or test pressure.

Micron A metric unit of length equal to one-millionth of a meter; used to measure vacuum drawn from a refrigerant system by a vacuum pump.

Moisture Indicator Litmus paper in a sight glass receiver-drier; shows how much moisture is in the system.

Nitrogen A colorless, odorless, dry, inert gas that can be used to purge light contaminants (for example, dust) from air conditioner parts.

Opacity A condition that is used to describe contamination of refrigerant oil in the compressor. Fresh refrigerant oil is clear; when contaminated, it appears cloudy or may have fine particles held in suspension.

Overcharge Too much refrigerant or oil in the system.

Polyalkylene Glycol (PAG) and Polyol Ester (POE-) Highly refined synthetic oils that are used in R–134a air conditioning systems.

psia Pounds per square inch. Pressure exerted by the air at sea level. Atmospheric pressure is usually measured with a mercury barometer.

psig Pounds per square inch, gauge pressure. Any pressure above normal atmospheric pressure (14.7 psi) is referred to as gauge pressure.

Purge To remove damp air, traces of refrigerant, and loose dirt from a system or part by flushing with a dry, inert gas, such as nitrogen.

Receiver-Drier A combination desiccant, filter, and storage container for liquid refrigerant.

Recovery Removal of the refrigerant from air conditioning systems.

Recycling Removal of contaminants and moisture from R–134a using a recovery and recycling station.

Refrigerant–134a (R–134a) The cooling agent used in automotive air conditioning systems. The chemical name for R–134a is Tetrafluoroethane.

Refrigeration Cycle The complete circulation of refrigerant through an air conditioning system, accompanied by changes in temperature and pressure.

Relative Humidity The actual water content of the air in relation to the total water vapor the air can hold at a given temperature.

Resistor A voltage-dropping device, usually wire-wound, for controlling fan speed.

Suction Line The line connecting the evaporator outlet to the compressor inlet.

Suction Pressure Compressor inlet pressure (the system's low-side pressure).

Suction Service Valve A device located on the suction hose near the thermostatic expansion valve that allows low-side pressure to be checked and other service operations to be performed.

Suction Side The low-pressure area of the system, extending from the expansion valve to the compressor inlet.

Thermistor A vacuum pressure sensor that is used to measure (in microns of mercury) internal system vacuum levels after evacuation.

Thermostatic Switch A temperature-sensitive switch used to control system temperature and prevent evaporator freeze-up; it does this by cycling the compressor's operation.

Thermostatic Vacuum Gauge A high-vacuum gauge sensitive to pressures ranging from atmospheric pressure to less than 1 micron of mercury, with scales reading from 25,000 microns to 1 micron of mercury.

Undercharge A system low on refrigerant, resulting in lack of cooling and possible compressor damage.

Vacuum Refers to pressure that is less than atmospheric pressure.

Vacuum Pump A mechanical device used to evacu-

ate and place a high vacuum in the refrigerant system.

Vacuum Pump Oil Water soluble oil used in some vacuum pumps to absorb moisture from the refrigerant system.

Vapor The gaseous state of a material.

Water Regulating Valve A valve, mechanically operated, for controlling the flow of hot coolant to the heater core.

Principles of Operation

Heater

Moving the temperature control toward maximum heat opens the water regulating valve, which allows engine-heated coolant to flow through the heater core. Heat absorbed by the air passing over the heater core fins is forced through ducts and into the cab.

Air Conditioner

When the air conditioner is on, the motion of the compressor squeezes the refrigerant into a high-pressure, high-temperature gas. High pressure raises the condensation point of refrigerant gas, which allows the condenser to change it to a liquid. After it is compressed, refrigerant gas moves out of the discharge port of the compressor, and on to the condenser.

At the condenser, air passing over the coil's fins absorbs heat from the hot refrigerant gas and causes it to change into a liquid. The liquid moves to the receiver-drier, which filters it and removes traces of moisture and acids. The receiver-drier then stores the refrigerant until it is needed by the system.

From the receiver-drier, liquid refrigerant moves to the expansion valve, which meters the flow into the evaporator coil and acts as a boundary between the high- and low-pressure sides of the system. The metered release of the expansion valve greatly drops the liquid's pressure, causing it to expand. The pressure drop lowers the boiling point of the refrigerant, and causes it to evaporate quickly as it absorbs heat from air passing over the coil. The resulting cool air is forced into the cab by the blower; the heated refrigerant gas is drawn back into the compressor, where the cycle is repeated.

Air Conditioning Protection and Diagnostics System (APADS™)

After the engine is started, the electronic control module prevents operation of the refrigerant compressor for 15 seconds. After the 15 second delay, the compressor comes on for 15 seconds. This start-up cycle is accomplished with the control module ignoring all input from the thermostat. The purpose of engaging the compressor is to circulate lubricant within the compressor, which is beneficial to the system especially when it is not used frequently. If the high or low pressure switches indicate out of bound or fault conditions, the compressor is turned off after the initial 15 seconds.

The evaporator thermostat is the primary control of the air conditioning system. The refrigerant compressor will cycle at the frequency governed by the thermostat, but is limited to a maximum of one cycle per 15 seconds.

When the high pressure switch indicates a high pressure condition, the refrigerant compressor is allowed to stay on for an algorithmically determined variable period, limited to 10 seconds. The compressor is allowed to turn on after the high pressure switch resets, and the maximum cycle rate of the compressor is limited to once every 15 seconds as governed by the control logic.

When the low pressure switch indicates a low pressure condition, the refrigerant compressor is turned off. The compressor is allowed to turn on after the low pressure switch resets, and the maximum cycle rate of the compressor is limited to once every 15 seconds as governed by the control logic.

Additional air conditioning system controls performed by APADS™ include shut down of the refrigerant compressor if the supply voltage drops below 11 volts. It is allowed to turn on again after there has been a sufficient rise in system voltage. The refrigerant compressor is shut down until the next ignition cycle if any of the following faults occur:

- high pressure
- open clutch
- shorted clutch

Safety Precautions

Whenever repairs are made to any air conditioner parts that hold R–134a refrigerant, you must recover, purge or flush (if contaminated), evacuate, charge, and leak test the system. In a good system, refrigerant lines are always under pressure and you should disconnect them only after the refrigerant charge has been recovered (discharged) at the service valves.

Refrigerant R–134a is safe when used under the right conditions. Always wear safety goggles and non-leather gloves while recovering, evacuating, charging, and leak testing the system. Do not wear leather gloves; when refrigerant gas or liquid contacts leather, the leather will stick to your skin.

⚠ WARNING

WARNING: Use care to prevent refrigerant from touching your skin or eyes, because liquid refrigerant, when exposed to the air, quickly evaporates and will freeze skin or eye tissue. Serious injury or blindness could result if you come into contact with liquid refrigerant.

Refrigerant splashed in the eyes should be rinsed with lukewarm water, not hot or cold. Do not rub the eyes. Apply a light bandage and contact a physician right away.

Refrigerant splashed on the skin should be rinsed with lukewarm water, not hot or cold. Do not rub the skin. Apply a light coat of a nonmedicated ointment, such as petroleum jelly. Contact a physician right away.

R–134a refrigerant does not burn at ambient temperatures and atmospheric pressure. However, it can be combustible at pressures as low as 5.5 psig (139 kPa absolute) at 350°F (177°C) when mixed with air concentrations that are greater than 60 percent.

⚠ WARNING

WARNING: R–134a air conditioning systems should not be pressure tested or leak tested with compressed air. Combustible mixtures of air and R–134a may form, resulting in a fire or explosion, which could cause personal injury or property damage. R–134a may be safely pressured with dry nitrogen.

You must work in an area where there is a constant flow of fresh air when the system is recovered, evacuated, charged, and leak tested. R–134a vapors have a slightly sweet odor that is difficult to detect. Frequent leak checks and air monitoring equipment are recommended to ensure a safe working environment.

IMPORTANT: When servicing an R–134a air conditioning system, use only service equipment certified to meet the requirements of SAE J2210 (R-134a recycling equipment). The equipment should be operated only by qualified personnel who are familiar with the recycling station manufacturer's instructions.

Because of its very low boiling point, refrigerant must be stored under pressure. To prevent the refrigerant containers from exploding, never expose them to temperatures higher than 125°F (52°C).

On R–134a refrigerant systems, polyalkylene glycol (PAG), or polyol ester (POE) oil is used in the compressor. When handling these oils, observe the following:

- keep the oil free of contaminants
- do not expose the a/c system or the oil container to air for long periods of time; PAG and POE oils absorb moisture quickly
- use care when handling: painted surfaces, plastic parts, and other components (drive belts) could be damaged if the oil is spilled on them
- never mix the oils with other types of refrigerant oil

Heater Core Removal and Installation

Removal

⚠ WARNING

Before doing any of the work below, read the information under Subject 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Disconnect the batteries.
2. Set the temperature control on the dash to its warmest setting.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

3. Drain the coolant.
4. Remove the vinyl extrusion trim at the top of the dash. See **Fig. 1**.

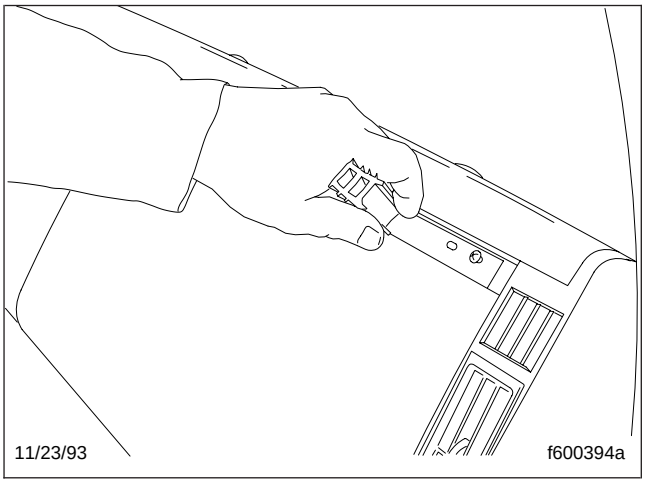


Fig. 1, Removing the Vinyl Extrusion Trim

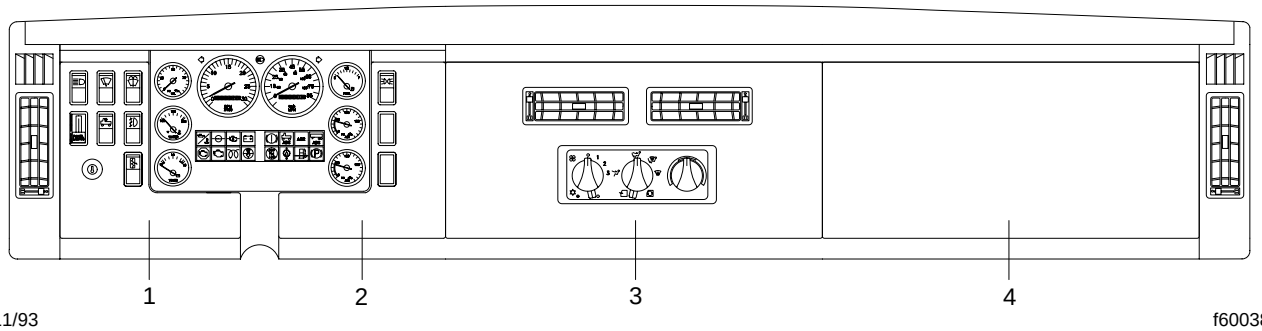
5. Remove dash panel D. See **Fig. 2** and **Fig. 3**.
   - 5.1 Remove the two screws from the top of dash panel D.
   - 5.2 Lift out the dash panel. Set it and the two mounting screws aside.
6. Pull out the windshield defrost duct. See **Fig. 4**.

NOTE: On vehicles with right-hand drive, loosen panel B. On these vehicles, the panel has enough slack that it does not need to be removed.

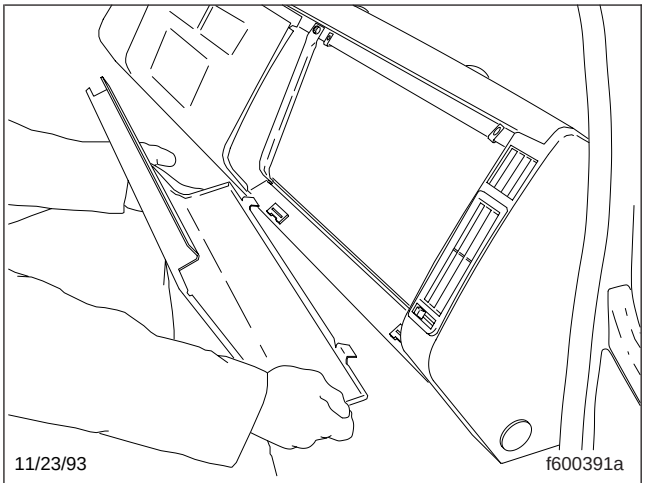


7. Remove dash panel B.
   - 7.1 Remove the knobs from the parking brake air valve and the trailer brake air valve, if so equipped. See **Fig. 5**.
   - 7.2 Remove the two mounting screws.
   - 7.3 Lift out the dash panel. Set it and the two mounting screws aside.
8. Remove dash panel C. See **Fig. 2**.
   - 8.1 Remove the bezel around the HVAC control panel.
   - 8.2 Remove and set aside the four screws (see **Fig. 6**) holding the control panel to dash panel C.
   - 8.3 Remove the two screws from the top of dash panel C.
   - 8.4 Lift out the dash panel. Set it and the two mounting screws aside.

NOTE: On vehicles with right-hand drive, loosen the instrument panel. On these vehicles, the panel has enough slack that it does not need to be removed.

9. Remove the instrument panel. See **Fig. 7**.
   - 9.1 On vehicles built after late January/early February 1997, remove the four spring-loaded Torx®-head screws.

     On vehicles built earlier, insert a screwdriver in the locking tabs and push upward to release.
   - 9.2 Pull out the panel and disconnect all the electrical connectors.
   - 9.3 Disconnect the two air pressure lines.
   - 9.4 Disconnect the oil pressure line.
10. Remove and set aside the two screws at the top of dash panel A. See **Fig. 8**.
11. Remove the upper dash cover.
    - 11.1 Disconnect the harness for the turn signal switch.



Heater Core Removal and Installation

2. Panel B
3. Panel C
4. Panel D

Fig. 2, Dash Panels

Left-hand drive shown; right-hand drive opposite

Fig. 3, Removing Panel D

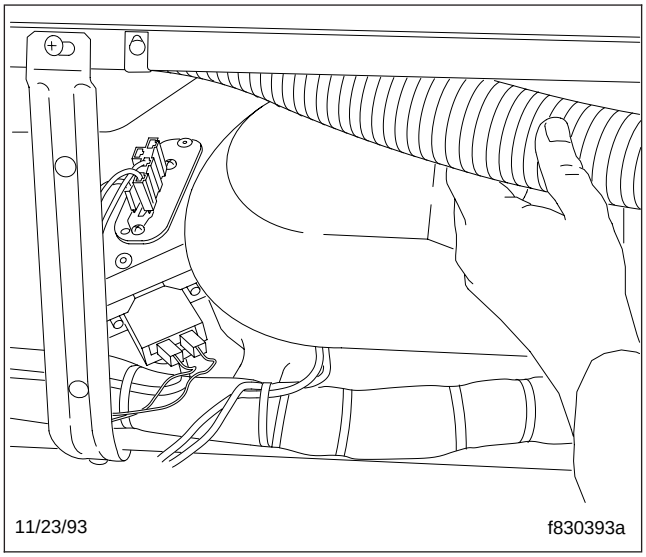

Fig. 4, Pulling Out the Windshield Defrost Duct

11.2 Pull dash panel A forward. Remove the screws holding each dash end cap; pull the end caps forward and out of the way. See **Fig. 9**.

11.3 Remove the screws at the base of the windshield holding the upper dash cover.

11.4 Remove the screw at the top of the dash brace (see **Fig. 10**) and the screws at the top of the gauge cluster.

11.5 Lift off the upper dash cover. See **Fig. 11**.

12. Disconnect the defrost door control cable from the face duct. See **Fig. 12**.

13. Remove the face duct.

14. Remove the four fasteners from the heater top cover, then set the cover aside.

15. Disconnect the hoses from the heater core. See **Fig. 13**.

⚠ WARNING

Always wear protective gloves when handling the heater core. Failure to do so could result in serious skin cuts from the sharp edges on the heater core fins.

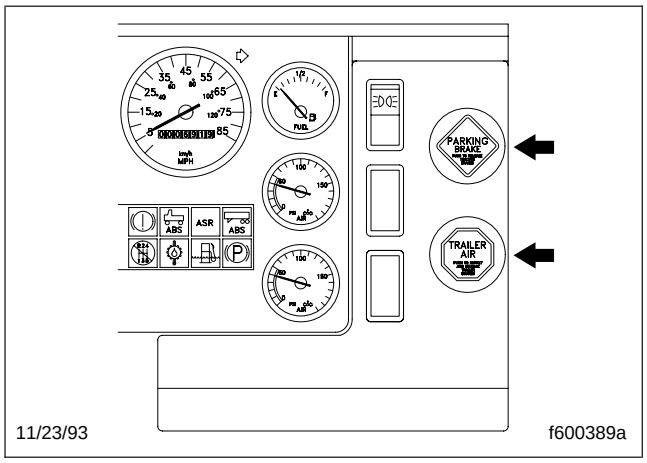

Fig. 5, Air Valve Knobs

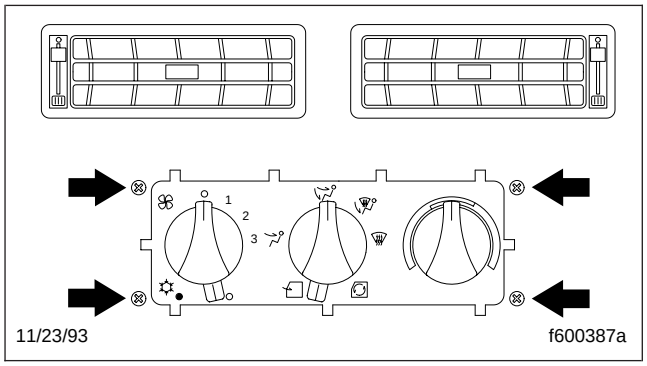

Fig. 6, HVAC Control Panel

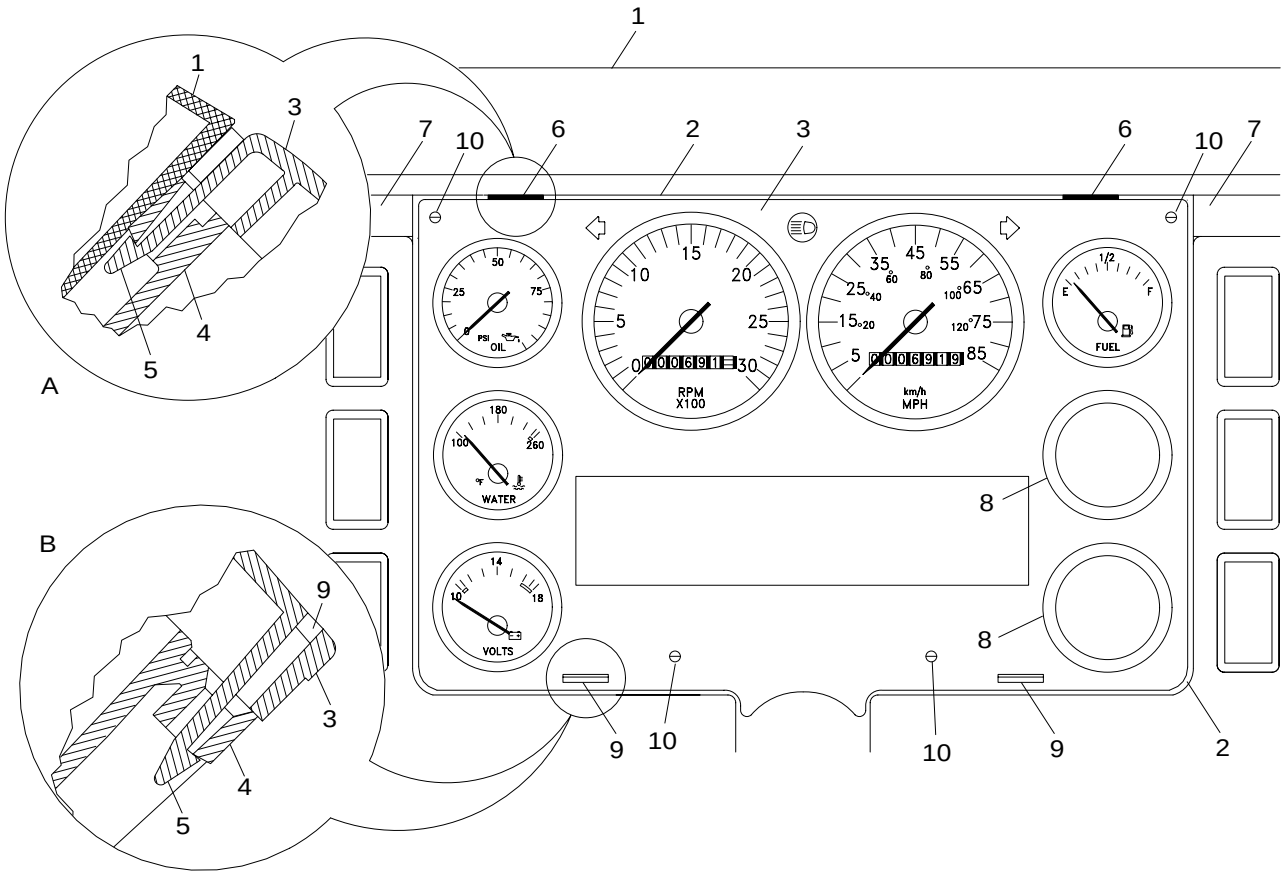
16. Remove the heater core. See **Fig. 14**.

Installation



WARNING

Always wear protective gloves when handling the heater core. Failure to do so could result in serious skin cuts from the sharp edges on the heater core fins.

1. Install the heater core, inserting the pipes through the holes in the frontwall. See **Fig. 14**.
2. Connect the hoses to the heater core. See **Fig. 13**.
3. Check the heater core for leaks.
   - 3.1 Connect the batteries.
   - 3.2 Close the radiator drain valve.
   - 3.3 Fill the cooling system with approved coolant. See the vehicle maintenance manual.
   - 3.4 Start the engine and set the temperature control to the warmest setting. When the engine thermostat opens, air will be forced from the heater core as the coolant circulates. Check the coolant level again and fill as needed.
   - 3.5 Check the heater core hose connections (see **Fig. 13**) for leaks. Tighten the hose clamps if needed.
   - 3.6 Shut down the engine and disconnect the batteries.
4. Install the heater top cover.
5. Install the face duct. Connect the defrost door control cable and the cable sheath to the face duct. See **Fig. 12**.
6. Install the upper dash cover (see **Fig. 11**) and tighten the screws at the base of the windshield.
7. Install the dash end caps (see **Fig. 9**) and their mounting screws (two each).
8. Install the brace screw (see **Fig. 10**) and the screws at the top of the gauge cluster.
9. Install dash panel A and tighten its two mounting screws (see **Fig. 8**).
10. Install the instrument panel, as removed. See **Fig. 7**.
    - 10.1 Connect the oil pressure line (brown).
    - 10.2 Connect the two air pressure lines (green on top).
    - 10.3 Connect all the electrical connectors.
    - 10.4 On vehicles built after late January/early February 1997, install the four spring-loaded Torx®-head screws.

      On vehicles built earlier, insert the locking tabs into the slots in the panel and push inward until they click into place. Make sure the tabs are locked.
11. Install dash panel C and tighten its two mounting screws (see **Fig. 2**).

Heater Core Removal and Installation

09/16/97 f600386a

On vehicles built after late January/early February 1997, remove the four spring-loaded Torx®-head screws. On vehicles built earlier, insert a screwdriver in the locking tabs and push upward to release.

4. Gauge Housing

B. Sectional Detail (bottom)
5. Panel Locking Tab
6. Opening in Foam Gasket
7. Vinyl Extrusion Trim
8. Gauge Blank (block-off plug)
9. Slot in Panel
10. Torx-Head Screw

Fig. 7, Instrument Panel Removal

12. Install dash panel B and tighten its two mounting screws (see **Fig. 2**). Install the knobs on the parking brake air valve and the trailer brake air valve, as removed.
13. Install the windshield defrost duct. See **Fig. 4**.
14. Install dash panel D and tighten its two mounting screws (see **Fig. 2** and **Fig. 3**).
15. Install the vinyl extrusion trim at the top of the dash. See **Fig. 1**.
16. Connect the wiring harness to the turn signal switch.
17. Connect the batteries.

Fig. 13, Heater Core Hoses

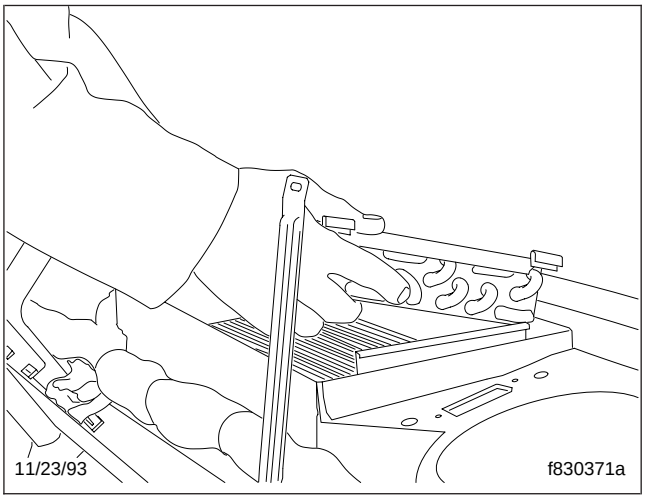

Fig. 14, Removing the Heater Core

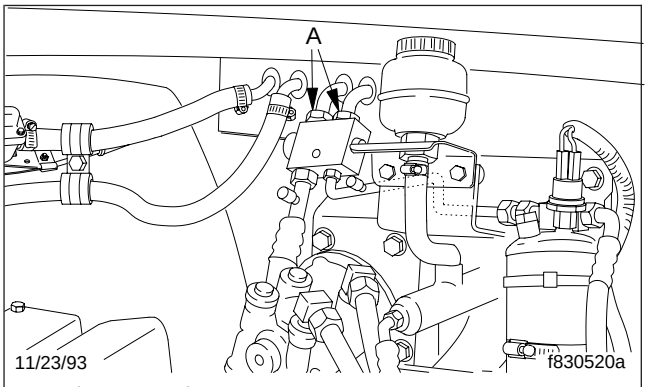
Evaporator Coil Removal and Installation

Removal

WARNING



WARNING: Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to personal injury.

1. Disconnect the batteries.
2. Wearing protective goggles and gloves, recover the refrigerant system. For instructions, refer to **Subject 220.**
3. Remove the heater core. For instructions, refer to **Subject 110.**

CAUTION

CAUTION: Water and dirt can damage the refrigerant system. Five minutes of being uncapped is the limit for any hose or component. Do not blow shop air through the refrigerant hoses; shop air is wet (humid).

4. Disconnect the evaporator coil lines from the expansion valve in the engine compartment. **See Fig. 1.** Save the O-rings if they are in good condition.

A. Disconnect here.

Fig. 1, Disconnect the Evaporator Coil Lines

5. Cap or plug the evaporator coil lines and the expansion valve ports.

WARNING

WARNING: Always wear protective gloves when handling the evaporator coil. Failure to do so could result in serious skin cuts from the sharp edges on the evaporator coil fins.

6. Lift the evaporator coil out of the housing. **See Fig. 2.**

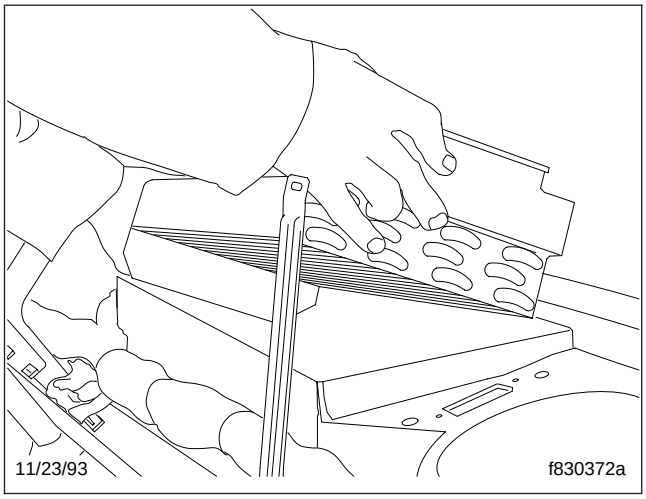


Fig. 2, Lift out the Evaporator Coil

Installation

WARNING

WARNING: Always wear protective gloves when handling the evaporator coil. Failure to do so could result in serious skin cuts from the sharp edges on the evaporator coil fins.

1. Wearing protective gloves, place the evaporator coil in the housing. **See Fig. 2.** Make sure the evaporator coil lines extend through the holes in the firewall.
2. Remove the caps or plugs from the evaporator coil lines and the expansion valve ports.
3. Lubricate the rubber O-rings with mineral oil and install them in the fittings.

NOTE: The previously removed O-rings can be used again if they are in good condition.

Evaporator Coil Removal and Installation

4. Apply Loctite 242 or 592 to the male fitting threads; then, connect the evaporator coil lines to the expansion valve ports. Tighten the fittings as follows:
    - Large fitting—33 N·m (24 lbf·ft)
    - Small fitting—24 N·m (18 lbf·ft)
5. Evacuate and charge the air conditioning system with refrigerant. For instructions, refer to **Subject 220**. Be sure to add refrigerant oil to the compressor to replace that which was lost when the system was discharged. Refer to the applicable refrigerant compressor section elsewhere in this group.

NOTE: If the system will not hold a vacuum, check the evaporator coil connections for tightness or check for a missing O-ring.

6. Install the heater core and the other removed components. For instructions, refer to **Subject 110.**
7. Connect the batteries.

Replacement

1. Disconnect the batteries.
2. Remove the vinyl extrusion trim at the top of the dash. See **Fig. 1**.

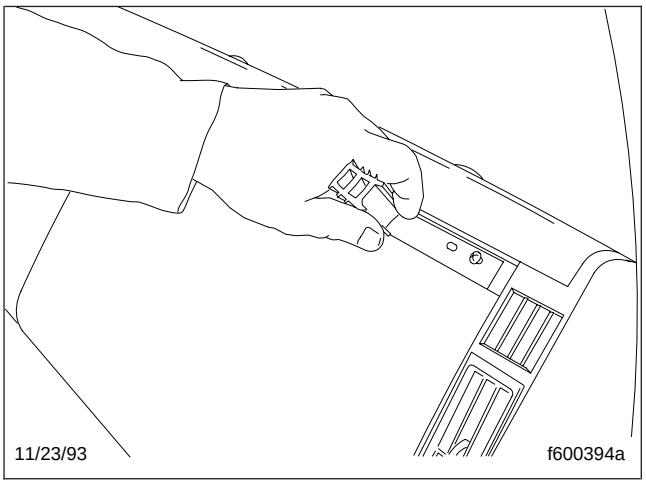

Fig. 1, Removing the Vinyl Extrusion Trim

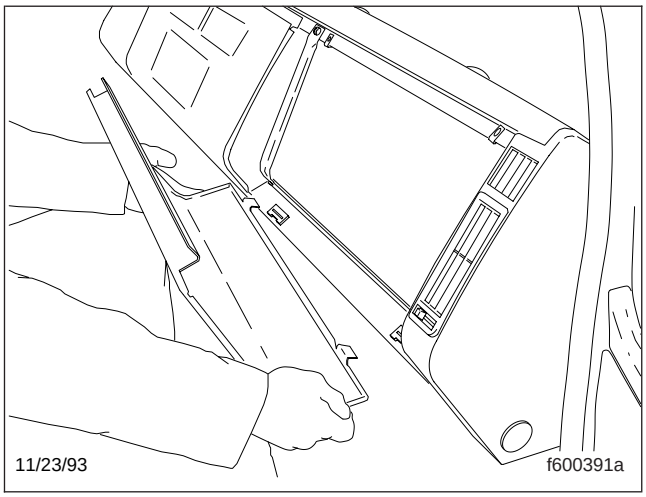
3. Remove dash panel D and set it and the two mounting screws aside. See **Fig. 2** and **Fig. 3**.



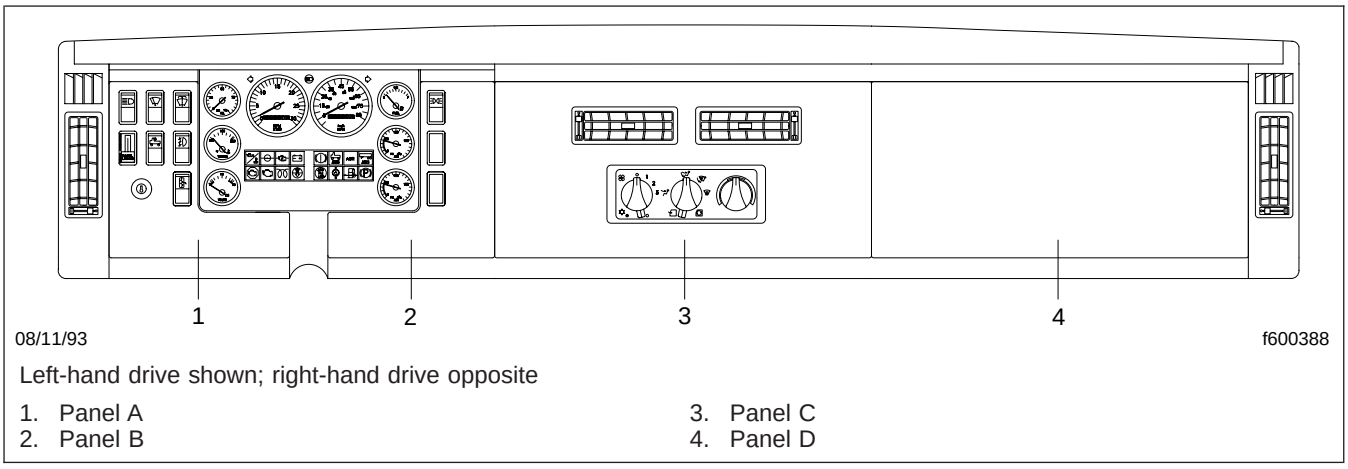


Fig. 3, Removing Panel D

4.3 If necessary in order to remove panel B, loosen the fasteners on the instrument panel. For detailed instructions, see **Subject 110**.

4.4 Lift off the dash panel. Set it and the two mounting screws aside.

5. Remove dash panel C and set it and the two mounting screws aside. See **Fig. 4**.

Left-hand drive shown; right-hand drive opposite

1. Panel A
2. Panel B
3. Panel C
4. Panel D

Fig. 2, Dash Panels

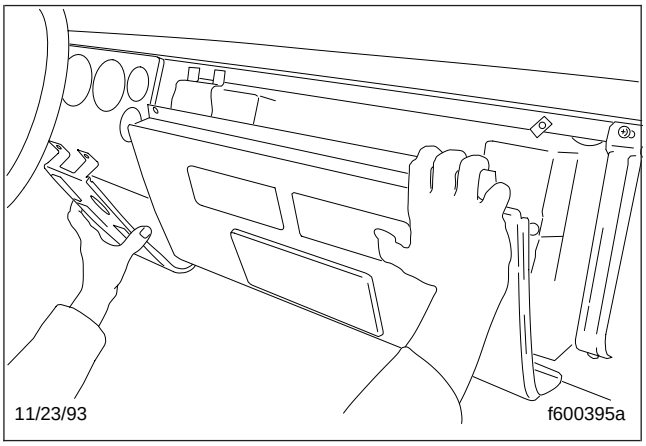
4. Remove dash panel B.

4.1 Remove the knobs from the parking brake air valve and the trailer brake air valve, if so equipped.

4.2 Remove the two mounting screws.

NOTE: It isn't necessary to remove the control panel from dash panel C or to disconnect the control cables.

Thermostatic Switch Replacement



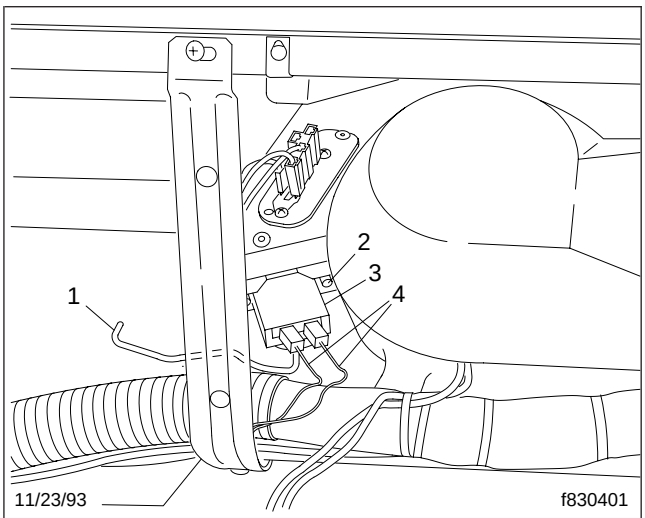


Fig. 4, Removing Panel C

6. On right-hand drive (RH DR) vehicles, detach the ignition keyswitch from panel A.
7. Remove the two screws holding the thermostatic switch to the ducting. Remove the thermostatic switch from the vehicle. See **Fig. 5**.

1. Capillary Tube
2. Allen-Head Screw
3. Thermostatic Switch
4. Thermostatic Switch Wires

Fig. 5, Thermostatic Switch

7.1 Disconnect the wires from the thermostatic switch.

7.2 Remove the two capscrews holding the thermostatic switch.

7.3 Move the air duct to access the capillary tube. Carefully pull the capillary tube, which extends from the bottom of the thermostatic switch, out of the air duct.

7.4 Remove the thermostatic switch.

8. Install the new thermostatic switch.

8.1 Carefully insert the capillary tube into the hole in the air duct.

8.2 Position the thermostatic switch and secure it to the ducting using the two screws, as removed.

8.3 Connect the wires to the switch.

8.4 Move the air duct into position.

9. On RH DR, attach the ignition keyswitch to panel A.
10. Install dash panel C and tighten its two mounting screws.
11. Install dash panel B and tighten its two mounting screws. Install the knobs for the parking brake air valve and the trailer brake air valve, as removed.
12. Install dash panel D and tighten its two mounting screws.
13. Install the vinyl extrusion trim at the top of the dashboard.
14. Connect the batteries.

Replacement

1. Disconnect the batteries.
2. Remove the vinyl extrusion trim at the top of the dash. See **Fig. 1**.

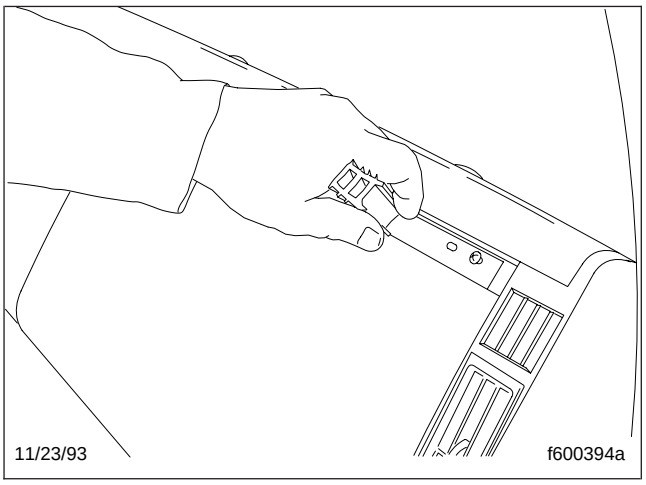

Fig. 1, Removing the Vinyl Extrusion Trim

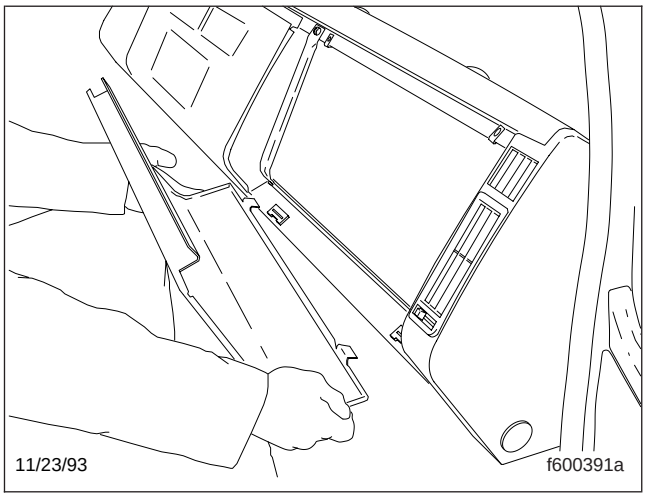
3. Remove dash panel D and set it and the two mounting screws aside. See **Fig. 2** and **Fig. 3**.



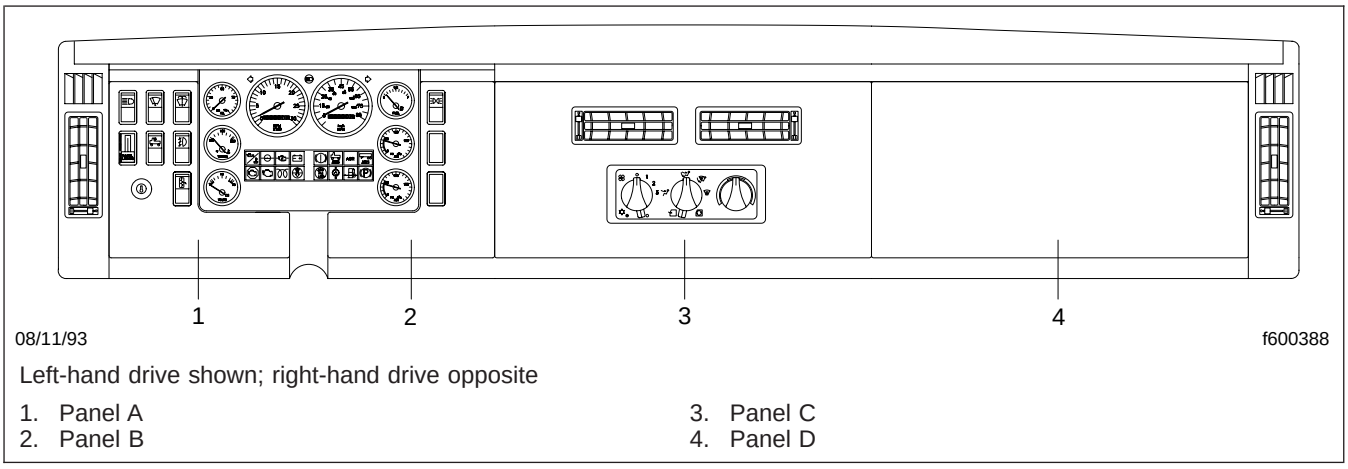


Fig. 3, Removing Panel D

7. Remove the three mounting nuts holding the blower motor (see **Fig. 6**); then, lift out the blower motor and remove it from the dash.
8. Position the new blower motor in the dash. Install the three mounting nuts and tighten them 17 lbf·in (192 N·cm).
9. Connect the blower motor electrical connector

Left-hand drive shown; right-hand drive opposite

1. Panel A
2. Panel B
3. Panel C
4. Panel D

Fig. 2, Dash Panels

4. On right-hand drive (RH DR) vehicles, remove the upper dash cover.
5. Remove the blower motor cover. See **Fig. 4**.
6. Disconnect the blower motor electrical connector. See **Fig. 5**.

(see **Fig. 5**).

10. Install the blower motor cover. See **Fig. 4**.
11. Install the knurled thumb screw on the blower motor cover finger-tight.
12. On RH DR vehicles, install the upper dash cover.

Blower Motor Replacement

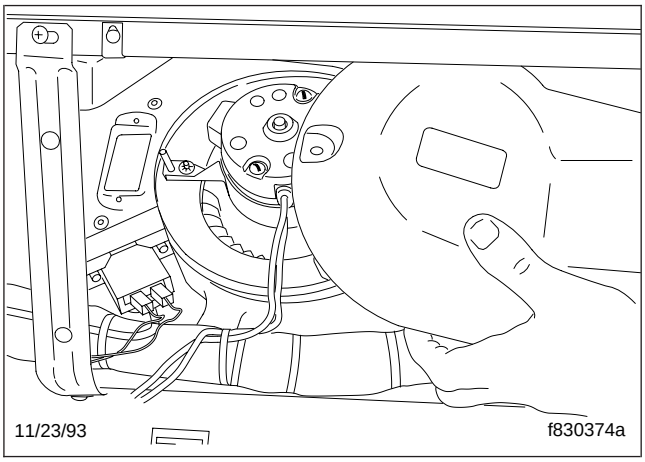

Fig. 4, Removing the Blower Motor Cover

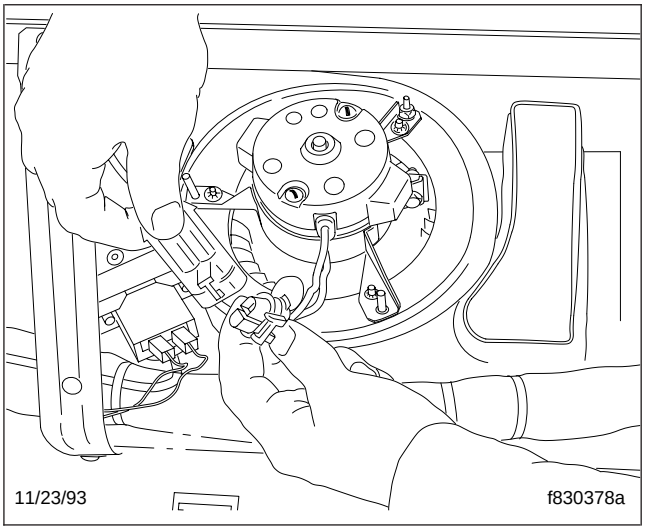

Fig. 5, Disconnecting the Electrical Connector

13. Install dash panel D (see **Fig. 3**) and tighten the two mounting screws.
14. Install the vinyl extrusion trim at the top of the dash. See **Fig. 1**.
15. Connect the batteries and check the blower operation. See the vehicle driver's manual for instructions.

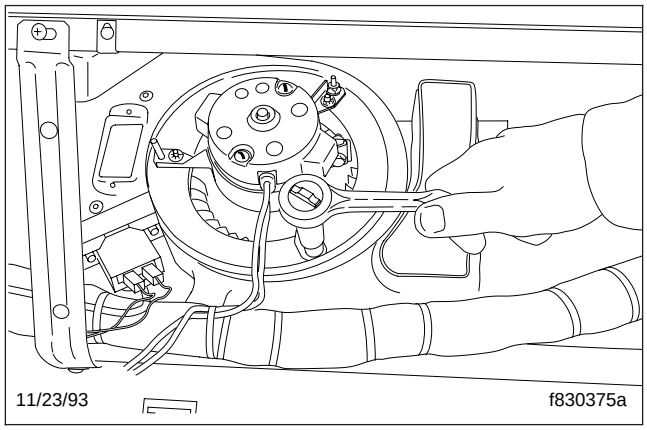

Fig. 6, Removing the Blower Motor

Replacement

1. Disconnect the batteries.
2. Remove the extruded rubber strip at the top of the dashboard. **See Fig. 1.**

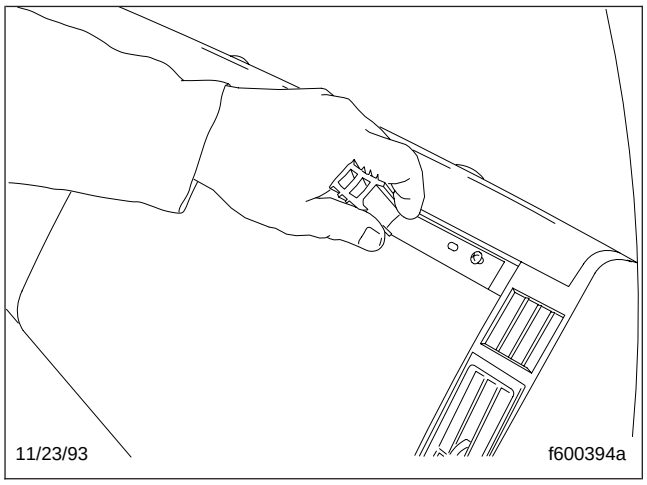

Fig. 1

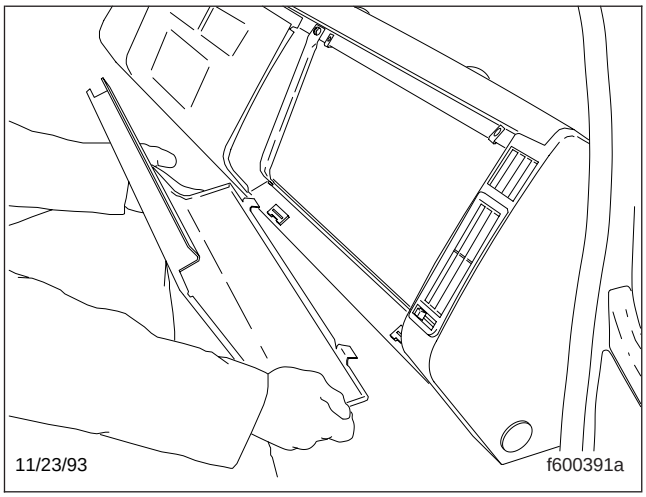
3. Remove the two mounting screws from dash panel D; then, remove the panel. See **Fig. 2** and **Fig. 3.**



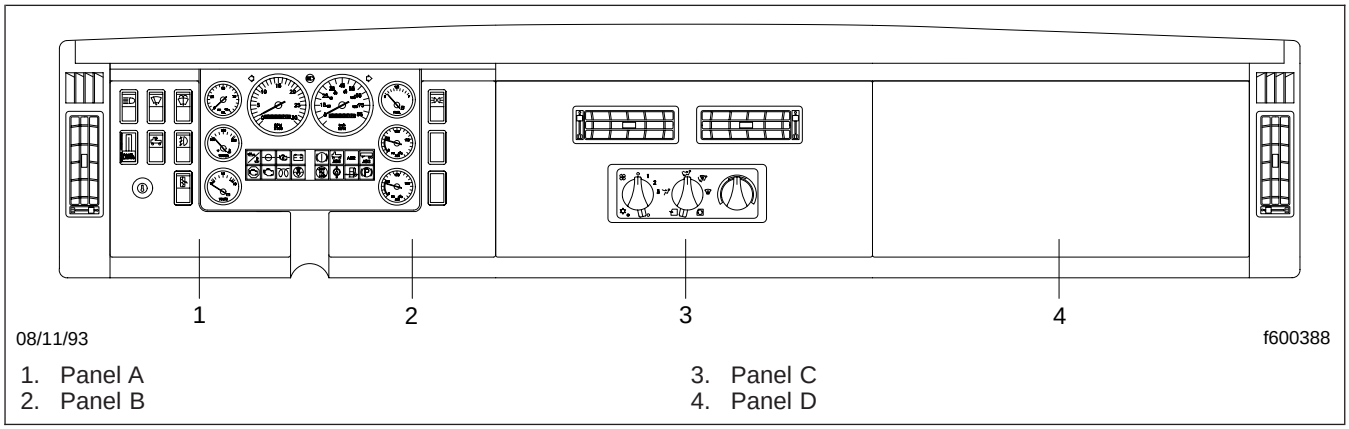


Fig. 3

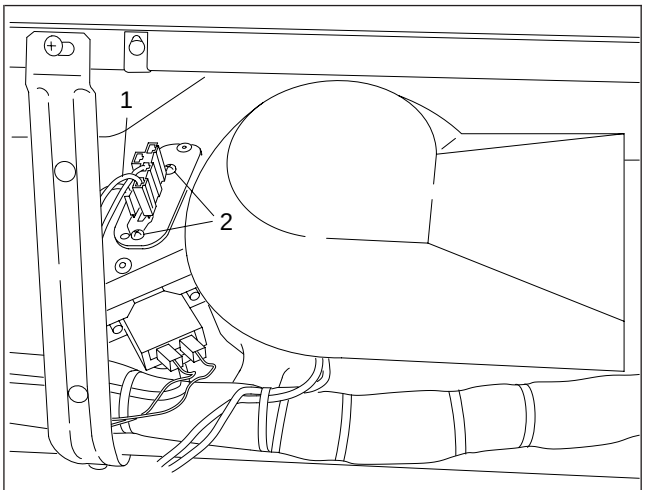
5. Install the resistor block with the two mounting screws; then, connect the electrical plug.
6. Connect the batteries and check the blower operation.
7. Install dash panel D and the two mounting screws.
8. Install the extruded rubber strip at the top of the dashboard.

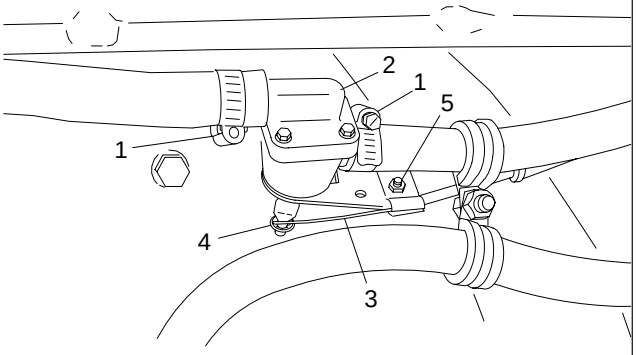


1. Panel A
2. Panel B
3. Panel C
4. Panel D

Fig. 2

4. Remove the resistor block. **See Fig. 4.**
   - 4.1 Unplug the connector from the resistor block.
   - 4.2 Remove the two mounting screws.
   - 4.3 Remove the resistor block.

Resistor Block Replacement



1. Resistor Block Wires
2. Resistor Block Mounting Screws

Fig. 4

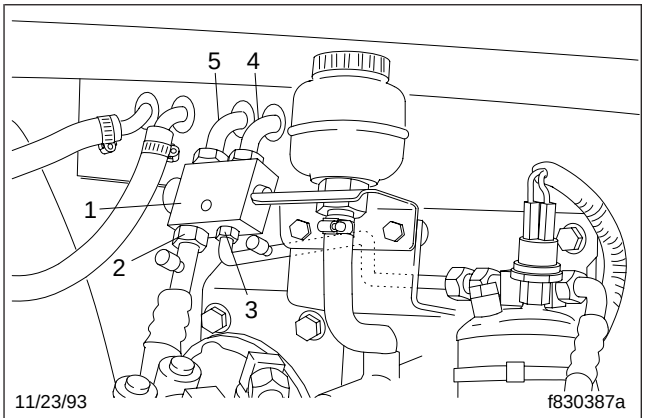
Replacement (See Fig. 1)

1. Tilt the hood.

1. Hose Clamp
2. Valve Body
3. Control Cable
4. Internal Toothed Clip
5. Cable Mounting Screw

Fig. 1

2. Set the heater temperature control to the warmest setting.



⚠ WARNING

WARNING: Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

3. With the engine cold, drain enough coolant into a clean drain pan to lower the coolant level below the water regulating valve.
4. Remove the screw (Ref. 5) that holds the control cable to the valve base plate.
5. Remove the internal toothed clip (Ref. 4), and detach the control cable (Ref. 3).
6. Disconnect the heater hoses from the valve. Remove and discard the valve.
7. Install the new valve in the heater hoses. Tighten the hose clamps.
8. Slip the end of the control cable over the post on the valve control lever, and install a new internal toothed clip.
9. Adjust the control cable.
   - 9.1 Set the heater temperature control to the coolest position.
   - 9.2 Set the water regulating valve to the closed position.
   - 9.3 Slide the control cable in the clamp until the screw (Ref. 5) in the clamp lines up with the hole in the valve base plate.
   - 9.4 Tighten the screw (Ref. 5) to hold the cable in place.
   - 9.5 Check that the valve closes when the temperature control is at the coolest setting and opens toward the warmest setting.

   NOTE: The valve is fully closed or fully open before it reaches the mechanical stops at either end of its travel. After adjusting for the coolest setting, it is not necessary to adjust for the warmest setting.
10. Fill the cooling system with approved coolant. Refer to the vehicle maintenance manual.
11. Start the engine. When the engine thermostat opens, air will be forced from the heater core as the coolant circulates. Check the coolant level again and fill as needed.
12. Check the valve and the hose connections for leaks. Tighten the hose clamps if needed.
13. Lower the hood.

Replacement (See Fig. 1)

1. Expansion Valve Body
2. Compressor Line
3. Receiver-Drier Line
4. Evaporator Coil (small line)
5. Evaporator Coil (large line)

Fig. 1, Expansion Valve

⚠ WARNING

WARNING: Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Tilt the hood.
2. Wearing protective goggles and gloves, recover the refrigerant system. For instructions, refer to **Subject 220.**
3. Disconnect the four refrigerant lines from the expansion valve; then, remove and discard the valve and the O-rings.

⚠ CAUTION

CAUTION: Water and dirt can damage the refrigerant system. Five minutes of being uncapped is the limit for any hose or component.

Do not blow shop air through the refrigerant hoses; shop air is wet (humid).

4. Lubricate the new rubber O-rings with mineral oil and install them in the fittings.
5. Apply Loctite 242 or 592 to the male fitting threads. Connect the lines from the evaporator coil to the expansion valve ports. Connect the line from the receiver-drier to the expansion valve port and the line that runs from the expansion valve port to the compressor.

   Tighten the connections as follows:

   - Evaporator coil large fitting—33 N·m (24 lbf·ft)
   - Evaporator coil small fitting—24 N·m (18 lbf·ft)
   - Receiver-drier line—16 N·m (12 lbf·ft)
   - Compressor line—24 N·m (18 lbf·ft)
6. Evacuate and charge the air conditioning system with refrigerant. For instructions, refer to **Subject 220.** Be sure to add refrigerant oil to the compressor to replace that which was lost when the system was discharged. Refer to the applicable refrigerant compressor section in this group.

NOTE: If the system will not hold a vacuum, check the connections for tightness or check for a missing O-ring.

7. Lower the hood.

Replacement (See Fig. 1)

1. Binary Switch
2. Receiver-Drier

Fig. 1, Receiver-Drier Installation

⚠ WARNING

WARNING: Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Tilt the hood.
2. Wearing protective goggles and gloves, recover the refrigerant system. For instructions, refer to **Subject 220.**
3. Disconnect the electrical leads from the binary switch and the fan control switch (if equipped).
4. Disconnect the inlet and outlet lines. Use two wrenches to avoid twisting the hoses.

⚠ CAUTION

CAUTION: Contaminants, such as water and dirt, can damage the refrigerant system. Five minutes of being uncapped is the limit for any part. Do not blow shop air through the refrigerant hoses since shop air is wet (humid).

IMPORTANT: If the desiccant cartridge inside the old receiver-drier has fallen apart, flush the entire system and replace the expansion valve and the refrigerant compressor. Desiccant matter can't be removed from these parts. A cartridge may fall apart from too much moisture in the system, because of poor evacuation of the system, or from lack of care.

5. Loosen the clamp that holds the receiver-drier to the bracket on the firewall. Remove and discard the receiver-drier.
6. Unscrew the binary switch. Remove the fan control switch (if equipped).
7. Mount the new receiver-drier and tighten the clamp.
8. If equipped with a fan cycle switch:

   On vehicles built before November 1994, apply Loctite 242 or 592 to the male threads of the coupling. Install the fan cycle switch, and tighten it 108 lbf·in (1220 N·cm) or one-eighth turn past hand-tight.

   On vehicles built from November 1994, lubricate a new O-ring with mineral oil, then install it over the male threads of the receiver-drier coupling. Install the fan cycle switch and tighten it 20 to 25 lbf·ft (27 to 34 N·m).

   Connect the wiring harness to the switch.
9. On vehicles built before November 1994, apply Loctite 242 or 592 to the male threads of the binary switch coupling. Install the binary switch, and tighten it 108 lbf·in (1220 N·cm) or one-eighth turn past hand-tight.

   On vehicles built from November 1994, lubricate a new O-ring with mineral oil, then install it over the male threads of the receiver-drier coupling. Install the binary switch and tighten it 20 to 25 lbf·ft (27 to 34 N·m).

   Connect the wiring harness to the switch.
10. Connect the inlet and outlet lines to the receiver-drier. Tighten the connections 45 N·m (33 lbf·ft).
11. Evacuate and charge the air conditioning system with refrigerant. For instructions, refer to **Sub-**

Receiver-Drier Replacement

ject 220. Be sure to add refrigerant oil to the compressor to replace that which was lost when the system was discharged. Refer to the applicable refrigerant compressor section in this group.

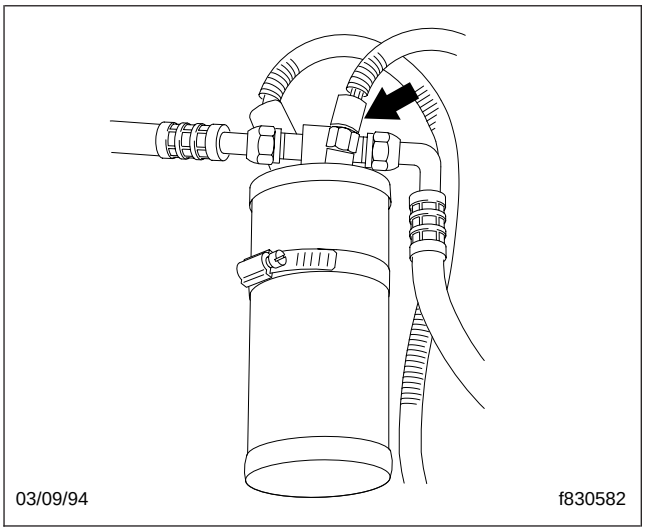
12. Lower the hood.

Replacement

⚠ WARNING

WARNING: Before doing any of the work below, read the information under Safety Precautions, 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Tilt the hood.
2. Disconnect the harness connectors and unscrew the switch from its coupling on the receiver-drier. **See Fig. 1.**



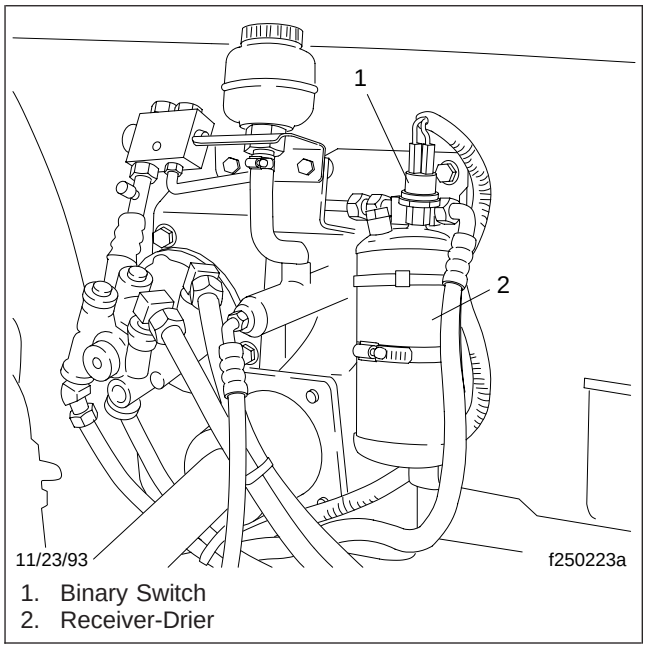


Fig. 1, Fan Cycling Switch

3. On vehicles built before November 1994, apply Loctite 242 or 592 to the male threads of the coupling. Install the fan cycle switch, and tighten it 108 lbf·in (1220 N·cm) or one-eighth turn past hand-tight.

   On vehicles built from November 1994, lubricate a new O-ring with mineral oil, then install it over the male threads of the receiver-drier coupling. Install the fan cycle switch and tighten it 20 to 25 lbf·ft (27 to 34 N·m).
4. Connect the wiring harness to the switch.
5. Check the system charge and charge the system with refrigerant if needed. Refer to **Subject 220** for instructions.
6. Lower the hood.

Replacement (See Fig. 1)

1. Binary Switch
2. Receiver-Drier

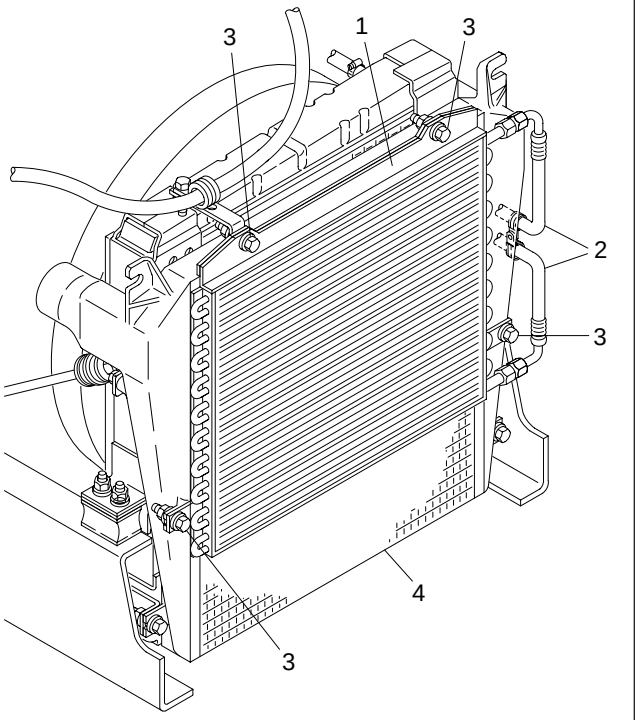

Fig. 1, Binary Switch Installation

NOTE: A Schrader valve in the receiver-drier prevents loss of refrigerant when removing the binary switch.

1. Tilt the hood.
2. Disconnect the electrical leads from the binary switch.
3. Unscrew the binary switch from the receiver-drier.
4. On vehicles built before November 1994, apply Loctite® 242 or 592 to the male threads of the binary switch coupling. Install the binary switch, and tighten it 108 lbf·in (1220 N·cm) or one-eighth turn past hand-tight.

   On vehicles built from November 1994, lubricate a new O-ring with mineral oil, then install it over the male threads of the receiver-drier coupling. Install the binary switch and tighten it 20 to 25 lbf·ft (27 to 34 N·m).
5. Check the operation of the air-conditioning system.
6. Lower the hood.

Replacement (See Fig. 1)

11/23/93 f500151a

1. Condenser
2. Refrigerant Hoses
3. Condenser Mounting Bolt
4. Radiator

Fig. 1, Condenser Installation

⚠ WARNING

WARNING: Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Tilt the hood.
2. Wearing protective goggles and gloves, recover the refrigerant system. For instructions, refer to **Subject 220.**
3. Disconnect the refrigerant hoses from the condenser. Use two wrenches to avoid damaging the condenser.

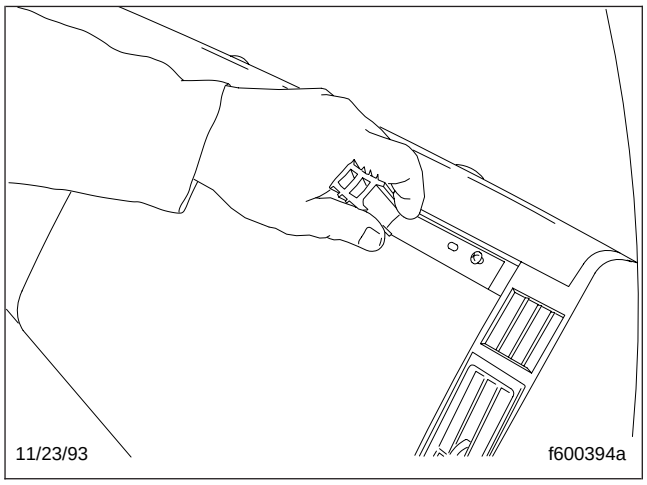
⚠ CAUTION

CAUTION: Contaminants, such as water and dirt, can damage the refrigerant system. Five minutes of being uncapped is the limit for any part. Do not blow shop air through the refrigerant hoses since shop air is wet (humid).

4. Cap the refrigerant hoses.
5. Remove the four condenser mounting bolts.
6. Remove the condenser.
7. Position the condenser on the radiator. Install the capscrews and tighten them 20 N·m (15 lbf·ft).
8. Remove the plugs from the new condenser. Coat the O-rings with mineral oil and apply Loctite 242 or 592 to the male fitting threads.
9. Connect the refrigerant lines to the condenser. Using two wrenches, tighten the fittings 45 N·m (33 lbf·ft). *Be sure to add refrigerant oil to the compressor*, to replace that which was lost in the old condenser. Refer to the applicable compressor section in this group.
10. Charge the system with refrigerant; for instructions, refer to **Subject 220.**
11. Lower the hood.

Replacement

1. Disconnect the batteries.
2. Remove the vinyl extrusion trim at the top of the dash. See **Fig. 1**.



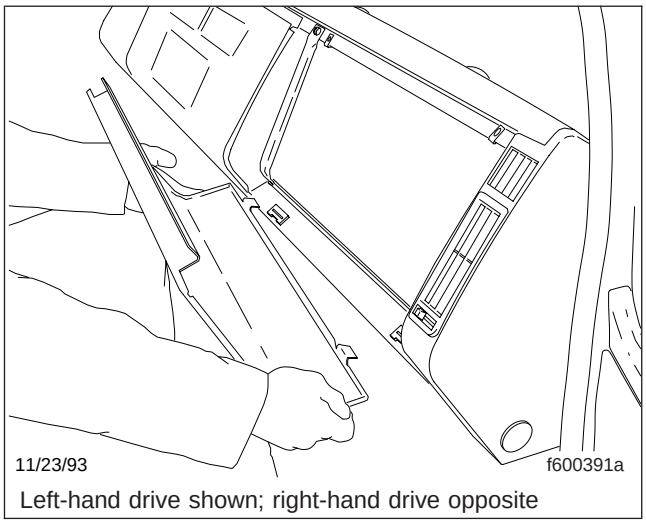


Fig. 1, Removing the Vinyl Extrusion Trim

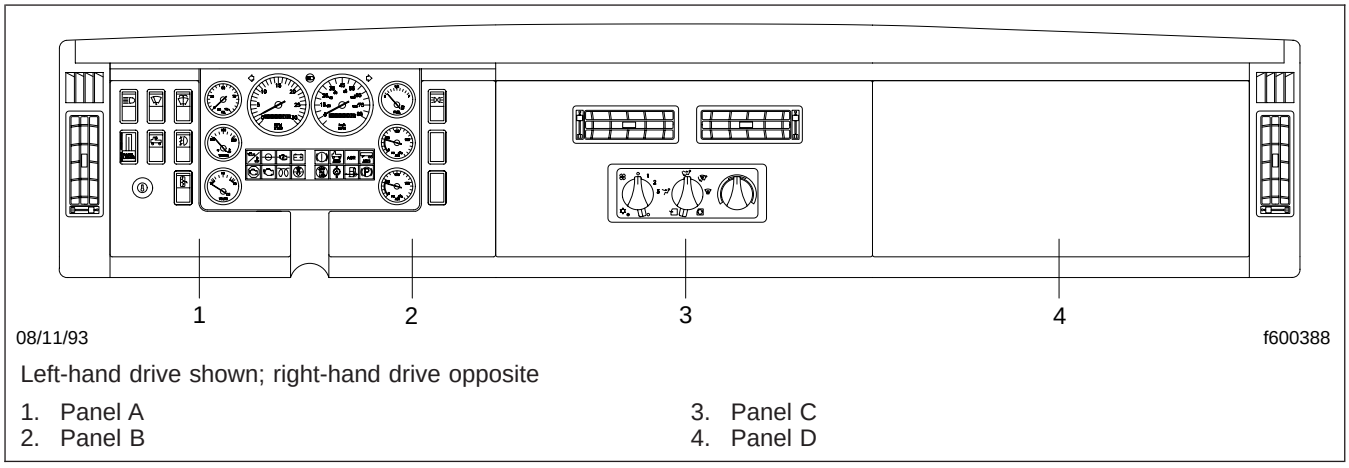
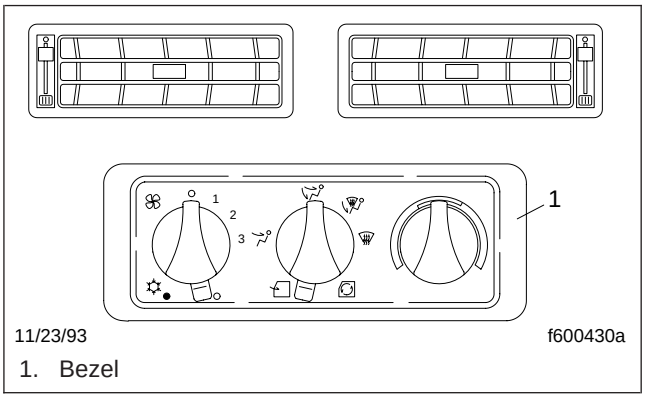


3. Remove dash panel D. Set it and its two mounting screws aside. See **Fig. 2** and **Fig. 3**.

Left-hand drive shown; right-hand drive opposite

Fig. 3, Removing Panel D

4. Remove dash panel B. See **Fig. 2**.
   - 4.1 If so equipped, remove the knobs from the parking brake air valve and the trailer brake air valve.
   - 4.2 If necessary in order to remove panel B, loosen the fasteners on the instrument panel. For detailed instructions see **Subject 110**.
   - 4.3 Lift off the panel. Set it and its two mounting screws aside.
5. Remove dash panel C.



Left-hand drive shown; right-hand drive opposite

1. Panel A
2. Panel B
3. Panel C
4. Panel D

Fig. 2, Dash Panels

   - 5.1 Gently pry the bezel from the control panel in the center of dash panel C. See **Fig. 4**.
   - 5.2 Remove and set aside the four screws holding the control panel to dash panel C. See **Fig. 5**.

Control Panel Replacement

1. Bezel

Fig. 4, HVAC Control Panel

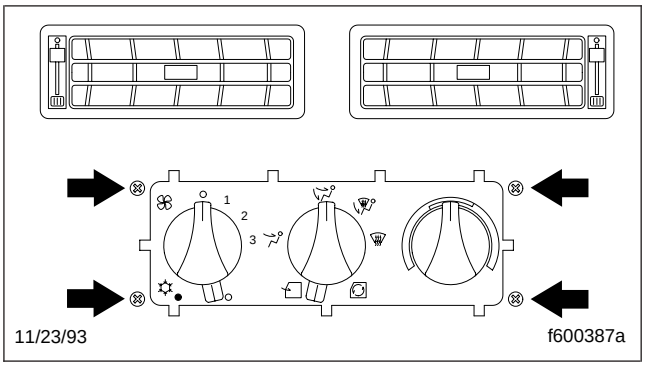


Fig. 5, Control Panel Mounting Screws

5.3 Remove the two mounting screws from the top of dash panel C.

5.4 Lift out the dash panel. Set it and the two mounting screws aside.

6. Remove the old control panel.

6.1 Remove the panel light and disconnect the electrical connectors from the control panel. Label the connectors so they can be installed in the same positions later.

6.2 Label the control cables for later reference. See **Fig. 6**.

6.3 Remove the screws that hold the control cables to the control panel; then, disconnect the cables.

6.4 Lift out the control panel.

7. Install the new control panel.

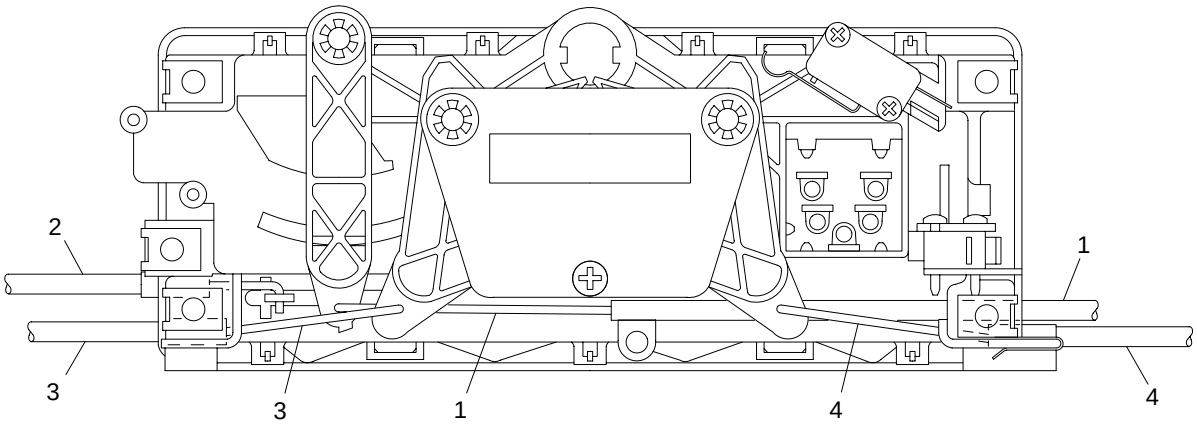
7.1 Position the control panel and install the four screws that mount it to the dash panel.

7.2 Attach the control cables to the control panel. Install the control cable mounting screws.

7.3 Insert the panel light and connect the wiring.

7.4 Install the bezel around the control panel.

8. Adjust the control cables. See **Fig. 6** and **Fig. 7**.



8.1 To adjust the cable (**Fig. 6**, Ref. 1) to the water regulating valve, set the dashboard control to the coolest setting (fully counterclockwise). Adjust the turnbuckle until the valve is almost at its mechanical stop in the closed position.

NOTE: The valve is fully closed or fully open before it reaches the mechanical stops at either end of its travel. After adjusting for the coolest setting, it is not necessary to adjust for the warmest setting.

8.2 To adjust the fresh air/recirculation door cable (**Fig. 6**, Ref. 2), remove the kick panel under the dashboard on the passenger side for access to the door. Move the control lever to the fresh air position. Adjust the turnbuckle (**Fig. 7**, Ref. 2) under the dashboard until the door snaps into the horizontal position and closes off the opening to the cab. Move the lever to the recirculation position and make sure the door snaps open. If necessary, readjust the turnbuckle so the door is in the correct position for each control lever setting.

8.3 To adjust the face/floor duct door and defrost duct door cables (**Fig. 6**, Refs. 3 and 4), set the control knob in the twelve o'clock position. Both face/floor duct doors should be open to direct air to the floor, and the defrost duct door should be open to let air out the face ducts. Adjust the turnbuckle (**Fig. 7**, Ref. 3) on the defrost duct door cable if necessary.

Turn the control knob fully counterclockwise; the face/floor duct doors should close. Remove the bottom section of one

1. Water Regulating Valve Cable
2. Fresh Air/Recirculation Door Cable
3. Face/Floor Duct Cable
4. Defrost Door Cable

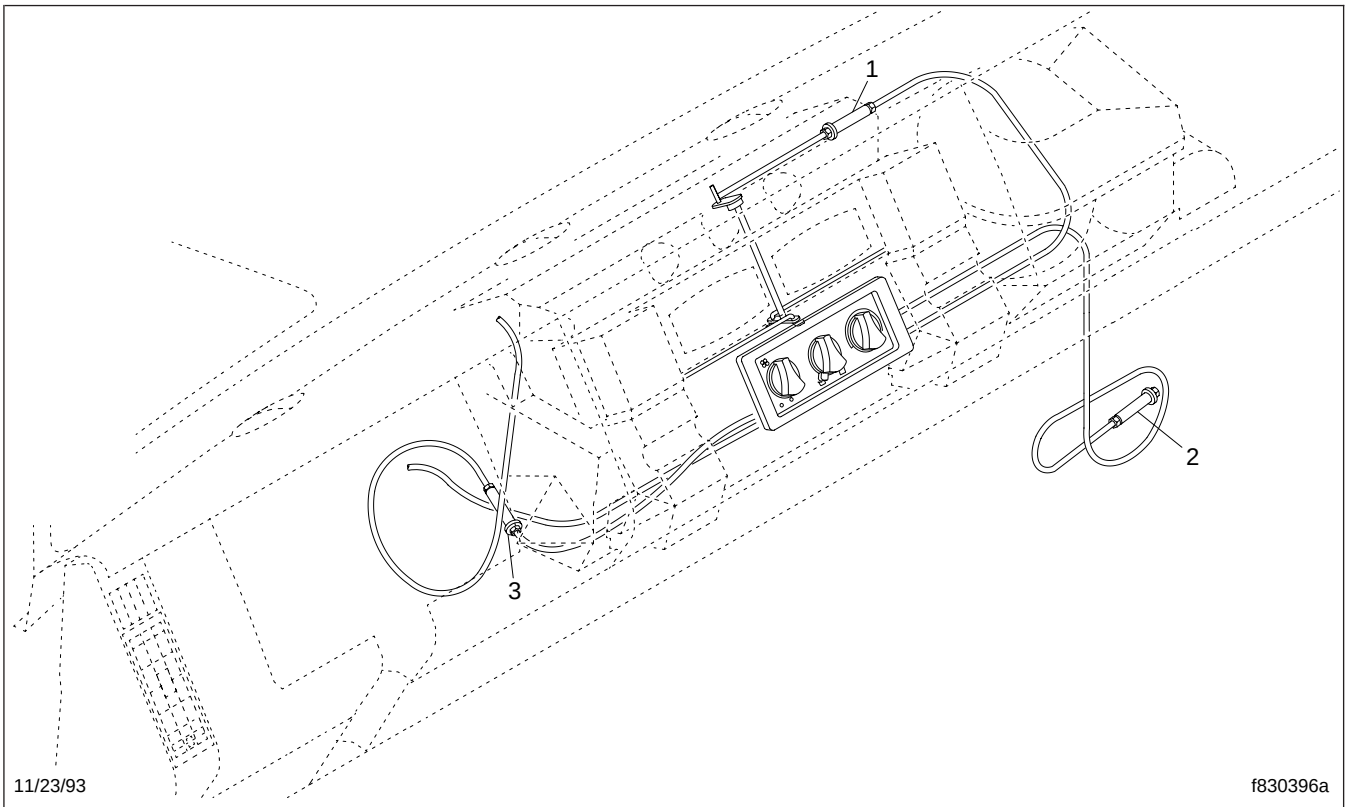


Fig. 6, HVAC Control Cables

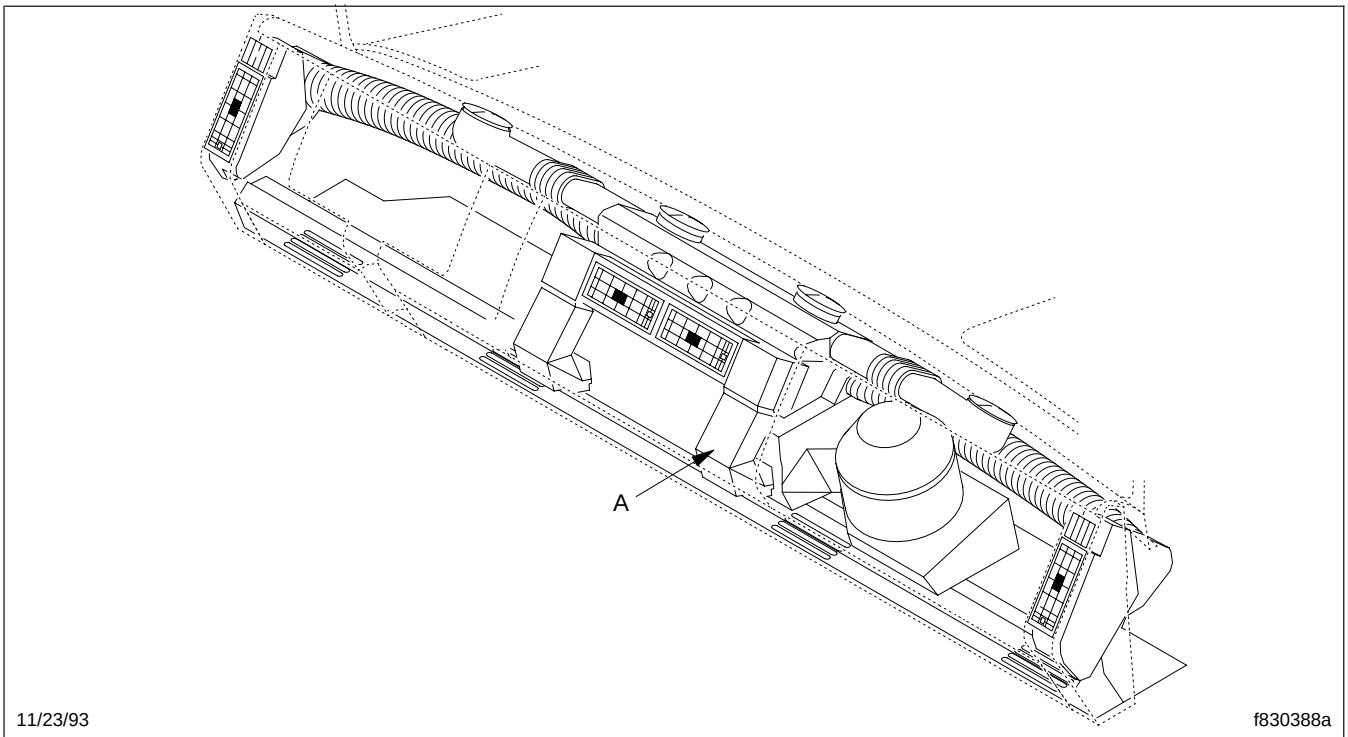
of the floor ducts to check the door position. See **Fig. 8**. Adjust the turnbuckle (**Fig. 7**, Ref. 1) on the face/floor duct door cable if necessary.

Make sure there is a smooth transition from one cable to the other as the control knob moves through the twelve o'clock position. The defrost duct door cable should move when the control is to the right of the twelve o'clock position; the face/floor duct door cable should move when the control is to the left of the twelve o'clock position. As the control knob passes through twelve o'clock, one cable should stop moving and the other cable should start to move. If the cables are adjusted incorrectly, either the control knob will lock up before reaching twelve o'clock or the control knob movement will get very stiff.

9. Install dash panel C and tighten its two mounting screws.
10. Install dash panel B and tighten its two mounting screws. Install the knobs on the parking brake air valve and the trailer brake air valve, as removed.
11. If loosened, tighten the fasteners on the instrument panel. For detailed instructions, see **Subject 110**.
12. Install dash panel D and tighten its two mounting screws.
13. Install the vinyl extrusion trim at the top of the dash.
14. Connect the batteries.



Control Panel Replacement

Left-hand drive shown; right-hand drive opposite

1. Turnbuckle for Face/Floor Duct Door Cable
2. Turnbuckle for Fresh Air/Recirculation Door Cable
3. Turnbuckle for Defrost Duct Door Cable

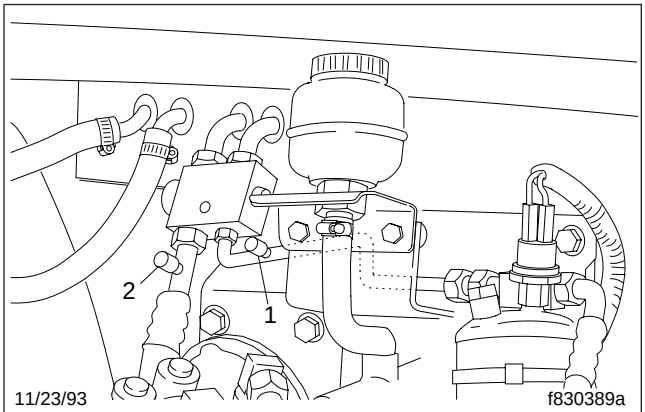
Fig. 7, Control Cable Adjustment

Left-hand drive shown; right-hand drive opposite

A. Remove this section of duct to check the door position.

Fig. 8, Duct Door Position Adjustment

Recovery, Evacuating/Recycling, Purging and Flushing, Charging, and Leak Testing



Recovery

⚠ WARNING

Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

The recovery process removes most of the refrigerant charge in the system.

1. Tilt the hood.
2. If equipped with a swashplate-type compressor, start the engine and run the air conditioning system for 5 minutes. Shut down the engine.
3. Remove the caps from the suction and discharge service valves. See **Fig. 1**.

1. Discharge Service Valve
2. Suction Service Valve

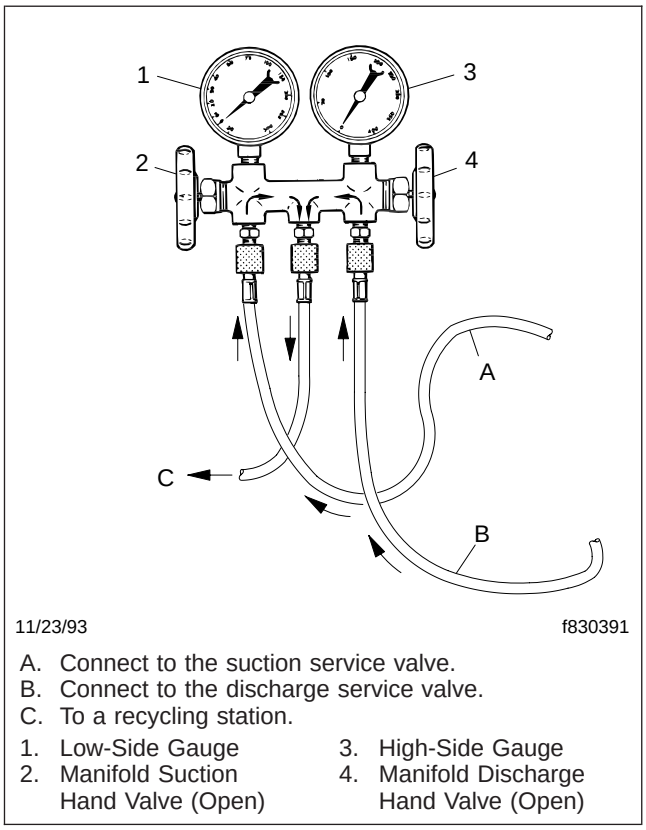


Fig. 1, Service Valves

4. Wearing protective goggles and nonleather gloves, attach the recover/recycling station's hoses to the valves. See **Fig. 2**.

   IMPORTANT: Push down firmly on the hose connectors until a clicking sound is heard. This will ensure that the coupler is locked.

   4.1 Make sure that the recovery and recycling station's valves are closed.

   4.2 Connect the red high-side hose to the discharge service valve.

A. Connect to the suction service valve.
B. Connect to the discharge service valve.
C. To a recycling station.

1. Low-Side Gauge
2. Manifold Suction Hand Valve (Open)
3. High-Side Gauge
4. Manifold Discharge Hand Valve (Open)

Fig. 2, Discharging Hookup

   4.3 Connect the blue low-side hose to the suction service valve.

   4.4 Turn the knob clockwise on each coupler to open the Schrader valves.

5. Follow the recovery and recycling station manufacturer's instructions and recover all of the refrigerant from the system.

IMPORTANT: Always comply with all local regulations regarding refrigerant disposal. You may be subject to substantial penalties for improper disposal.

6. Measure the oil recovered during this procedure. The compressor will have to be refilled with the same quantity of new refrigerant oil.

   If the system is contaminated with moisture, all of the compressor oil must be replaced with clean oil. If the system is heavily contaminated with desiccant or grit, replace the compressor, expansion valve, and receiver-drier.

Recovery, Evacuating/Recycling, Purging and Flushing, Charging, and Leak Testing

Evacuating (Recycling)

GENERAL INFORMATION

Moisture in a Refrigerant System

Water forms ice crystals at the thermostatic expansion valve. Ice crystals retard or stop the flow of refrigerant, causing a reduction or complete loss of cooling. As the expansion valve warms, due to the lack of refrigerant, the ice melts and passes through the expansion valve. Then refrigerant will flow again until the ice crystals reform. The result is intermittent cooling.

Refrigerant oil has an extremely high moisture absorption capacity. This reduces the lubricating ability of the oil, which could damage the compressor and other system components.

Effects of Pressure on the Boiling Points of Water

Water boils at 212°F (100°C) at an atmospheric pressure of 14.7 psi (sea level). At higher elevations the atmospheric pressure is lower which allows water to boil at lower temperatures. See **Table 1** for boiling temperatures of water at converted pressures.

Boiling Temperatures of Water at Converted Pressures

Boiling Temperature of Water °F (°C)	Absolute Pressure psi (microns Hg)	Vacuum inHg (mmHg)
212 (100)	14.696 (759993.4)	0 (0)
205 (96)	12.770 (660400.0)	3.92 (99.6)
194 (90)	10.169 (523881.6)	9.22 (234.2)
176 (80)	6.8699 (355269.8)	15.93 (404.6)
158 (70)	4.5207 (233786.7)	20.72 (526.3)
140 (60)	2.8900 (14958.7)	24.04 (610.6)
122 (50)	1.7987 (92555.1)	26.28 (667.5)
104 (40)	1.0700 (55336.4)	27.74 (704.6)
89 (30)	0.61540 (31826.2)	28.67 (728.2)
86 (27)	0.57010 (26220.4)	28.89 (733.8)
76 (24)	0.44435 (22979.9)	29.02 (737.1)
72 (22)	0.38856 (20094.7)	29.13 (739.9)
69 (21)	0.35084 (18143.7)	29.21 (741.9)
64 (18)	0.29505 (15258.5)	29.32 (744.7)
59 (15)	0.24720 (12783.8)	29.42 (747.3)
53 (12)	0.19888 (10285.0)	29.52 (749.8)
45 (7)	0.14746 (7625.8)	29.62 (752.3)
32 (0)	0.08858 (4579.6)	29.74 (755.4)
21 (–6)	0.05293 (2738.1)	29.81 (757.2)
6 (–14)	0.02521 (1304.0)	29.87 (758.7)
–24 (–31)	0.004905 (253.7)	29.911 (759.74)
–35 (–37)	0.002544 (131.6)	29.915 (759.84)
–60 (–51)	0.0004972 (25.7)	29.9200 (759.968)
–70 (–57)	0.0002443 (12.69)	29.92050 (759.9807)

Boiling Temperatures of Water at Converted Pressures		
Boiling Temperature of Water °F (°C)	**Absolute Pressure psi (microns Hg)**	**Vacuum inHg (mmHg)**
–90 (–68)	0.0000526 (2.72)	29.92089 (759.9906)

Table 1, Boiling Temperatures of Water at Converted Pressures

Similarly we can boil and remove water from the air conditioning system by lowering the system pressure to a vacuum to cause the moisture to vaporize at normal ambient temperatures. A vacuum pump can reduce the pressure in the system. Since the pressure is the lowest at the pump, water vapor is pulled out of the system. See **Fig. 3**. This process is called evacuation or dehydration. Also, most recover and recycling stations automatically recycle refrigerant during this process to ensure the system will be charged with the cleanest refrigerant possible.

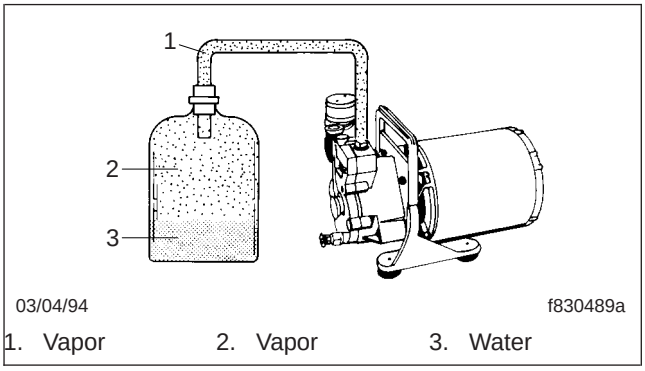

Fig. 3, Water to Vapor

Vacuum Pump Selection

The purpose of a high-vacuum pump is to reduce and hold a vacuum in the air conditioner system so moisture can be boiled at ambient temperature. For example, a vacuum pump capable of pulling a vacuum of 28.89 inHg (734 mmHg), is able to boil water at 80°F (27°C). There are various types of vacuum pumps available. Only some types are recommended for truck air conditioning evacuation.

Air pump-type vacuum pumps are designed to remove large volumes of air but do not develop high vacuum. They cannot pull more than 28 inHg (711 mmHg) which boils water at 100°F (38°C).

Compressor-type vacuum pumps come in two designs: piston-type and rotary-vane type. A piston-type compressor can typically pull a vacuum of 28.2 inHg (716.3 mmHg) which boils water at 96°F (36°C). A rotary-vane type compressor may pull a vacuum of 29.82 inHg (757 mmHg) which boils water at 21°F (–6°C), but it is limited to pumping 0.4 to 0.8 CFM, which is too slow to handle truck air conditioners.

High-vacuum pumps are available in single and two-stage models. A single-stage pump is adequate, but a two-stage pump is recommended to save time and ensure complete evacuation. See **Fig. 4**.

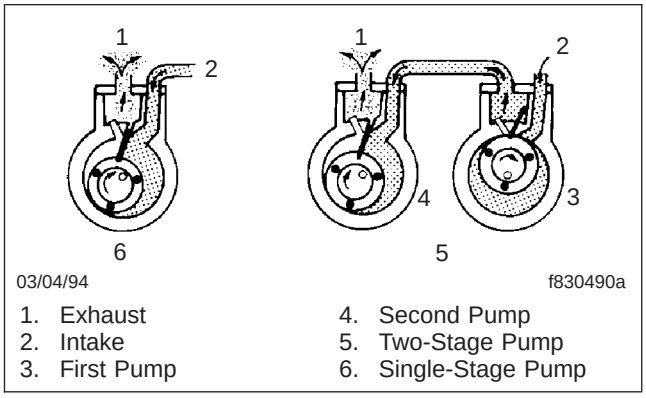

Fig. 4, Vacuum Pumps

Most single-stage high-vacuum pumps with a gas ballast will pull down to about 29.88 inHg (758.95 mmHg) which boils water at 4°F (–16°C).

A two-stage high-vacuum pump features a second pump to reach a higher vacuum than a single-stage pump. In a two-stage pump, the exhaust of the first pump discharges into the intake of the second pump. The second stage pumps at a lower pressure and therefore pulls a higher vacuum on the system than the first pump can by itself.

Two-stage high-vacuum pumps are capable of pulling down to 29.9192 inHg (759.95 mmHg) of vacuum for prolonged periods, which boils water at –60°F (–51°C).

The discharge line restriction is a factor affecting pump-down time. Pump-down time can be signifi-

cantly reduced by use of larger diameter hoses, as short in length as possible.

Pumping capacity affects pump-down time. It is perfectly acceptable to use a large vacuum pump on a small system. Using too small of a pump on a large system could cause premature pump wear, or require excessive time to pull a vacuum, even though the pump may be able to draw adequate vacuum.

The suggested *minimum* CFMs for pumps on different size air conditioners are listed in **Table 2**.

Minimum CFMs for Pumps on Different Size Air Conditioners	
System Size	**Suggested High-Vacuum Pump Size**
Panel Trucks Large Window Units	2.2 CFM
Tractor/Trailers, Buses Rooftop A/C systems	3.0 CFM
Refrigeration Van	15.0 CFM

Table 2, Minimum CFMs for Pumps on Different Size Air Conditioners

MEASURING VACUUM

Gauges

Vacuum can be measured with:

1. *Standard compound gauge.*

   A standard compound gauge reads low pressures in inches of mercury. It is not suitable for measuring high vacuum.

2. *Closed end manometer.*

   A closed end U-tube mercury manometer can be read with good accuracy. High vacuum readings can only be read from laboratory-style U-tube manometers (which are not practical for service shops).

3. *Electronic thermistor vacuum gauge.*

   An electronic thermistor vacuum gauge is designed for use with high vacuum pumps and can accurately read as low as 100 microns. This gauge can use an analog scale, a digital or LED display.

Procedure

The location of the vacuum gauge will affect the reading. The closer to the vacuum source, the lower will be the reading.

Isolate the vacuum pump with a good vacuum valve and allow the pressure in the system to stabilize before taking a final reading.

If the pressure will not stabilize, it is an indication of a leak. If it does stabilize at a vacuum which is too high (for example, 1500 microns), it is an indication of moisture, and more evacuation is required.

MAINTAINING THE VACUUM PUMP

Maintenance is important for high-vacuum pumps. The oil must be changed at regular intervals to prevent moisture buildup which will cause eventual pump failure.

Pumping down for extremely wet air conditioning systems can completely saturate the pump oil.

⚠ CAUTION

Flush the vacuum pump every fourth time it is used and before storing for long periods of time.

Vacuum pump oil is water soluble. This aids the pump in reaching a high vacuum by absorbing water and sealing the pump.

⚠ CAUTION

Acid will form and corrode the pump if water-laden oil remains in the pump for an extended period.

Only vacuum pump oil should be used as a lubricant. Do not use any solvent or any other oil. Clean oil should be run through the pump until it runs out clear. Oil should be added to the fill level indicated on the pump. Check the oil level before each use.

EVACUATION PROCEDURE

1. The system must have been recovered and the compressor filled with the correct amount of refrigerant oil. Replace the receiver-drier if the system is opened.

2. Wearing protective goggles and nonleather gloves, attach the recovery/recycling station's hoses to the valves (see **Fig. 1**).

   IMPORTANT: Push down firmly on the hose connectors until a clicking sound is heard. This will ensure that the coupler is locked.

   2.1 Make sure that the recovery and recycling station's valves are closed.

   2.2 Connect the red high-side hose to the discharge service valve.

   2.3 Connect the blue low-side hose to the suction service valve.

   2.4 Turn the knob clockwise on each coupler to open the Schrader valves.

3. Follow the recovery and recycling station manufacturer's instructions and evacuate/recycle the refrigerant system.

Purging and Flushing

GENERAL INFORMATION

⚠ WARNING

Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

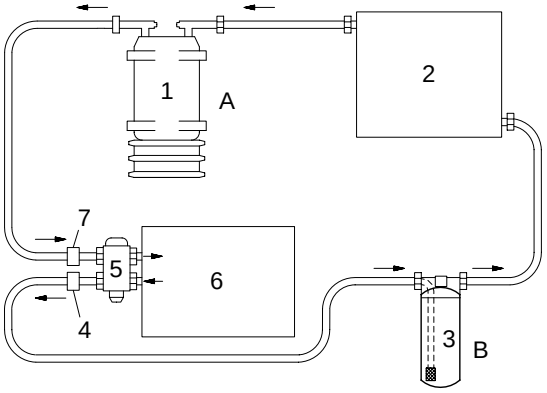
Purging removes damp air, traces of refrigerant, and loose particles from refrigerant parts by passing a stream of inert, dry nitrogen gas through the parts. If left in the system, these contaminants adversely affect the life and operation of the air conditioning system.

Flushing removes heavy contamination, such as gritty oil and large dirt buildup, which can't be removed by purging with gas. When a part is flushed, liquid refrigerant is forced through it; the liquid picks up the contaminants and flushes them out.

Whether to purge or flush a part depends on how much contamination there is, as described above.

Normally, the system always has pressure in it. Some loss of refrigerant from one season to the next is normal, and does not mean that the system is dirty. If refrigerant has leaked until the system is nearly empty, or if refrigerant parts show signs of internal corrosion and grit, the system is contaminated.

If the system is contaminated with moisture, purge all sections of the system. Then change the oil in the compressor and replace the receiver-drier prior to evacuating and charging the system.



If the system is heavily contaminated, or if desiccant has circulated through the system, replace the receiver-drier, expansion valve, and compressor.

Do not purge the receiver-drier or the compressor.

Flush the system in segments to lessen the chance of blowing deposits against a port. See **Fig. 5**.

Purge or flush the system in the opposite direction of refrigerant flow (in other words, backflush the sections).

Flushing parts with refrigerant requires a recovery and recycling station.

11/23/93 f830395

NOTE: Arrows denote purge and flush points and direction of flow for gas/liquid.

A. Do not purge; instead, replace.

Fig. 5, Purge and Flush Points

Recovery, Evacuating/Recycling, Purging and Flushing, Charging, and Leak Testing

PURGING PROCEDURE

(See Fig. 6)

NOTE: Dry nitrogen gas is recommended for purging. A pressure regulator is required to regulate between 0 to 200 psi. Commercial cylinders of nitrogen contain pressures in excess of 2000 psi (13 780 kPa); This pressure must be reduced to 200 psi (1378 kPa) for purging.

1. Recover the system refrigerant.
2. Disconnect both ends of the line or part being purged. Tightly cap the rest of the system.
3. Make sure valves 1, 2, and 3 are closed.
4. Connect the supply line valve to the outlet end of the part or line.
5. Connect the drain line to the inlet end of the part or line.
6. Place the outlet of the drain line into a recycling system container.
7. Adjust the nitrogen bottle regulator to 200 psi (1378 kPa). Open the nitrogen bottle control valve and the purging control valve. Then, slowly open the supply line valve. Check the drain line for gas flow.
8. Let the nitrogen flow at 200 psi (1378 kPa) for 25 to 30 seconds.
9. Lower the pressure to 4 psi (28 kPa) and let it flow for 1 to 2 minutes. If the line or part was very wet, allow it to flow until there is no trace of refrigerant oil or solid bits of dirt or grit flowing from the drain tube.
10. Close the nitrogen bottle control valve and the purging control valve first, then close the supply line valve.
11. Disconnect the supply line valve and the drain line. Tightly cap both ends of the part or line.

FLUSHING PROCEDURE

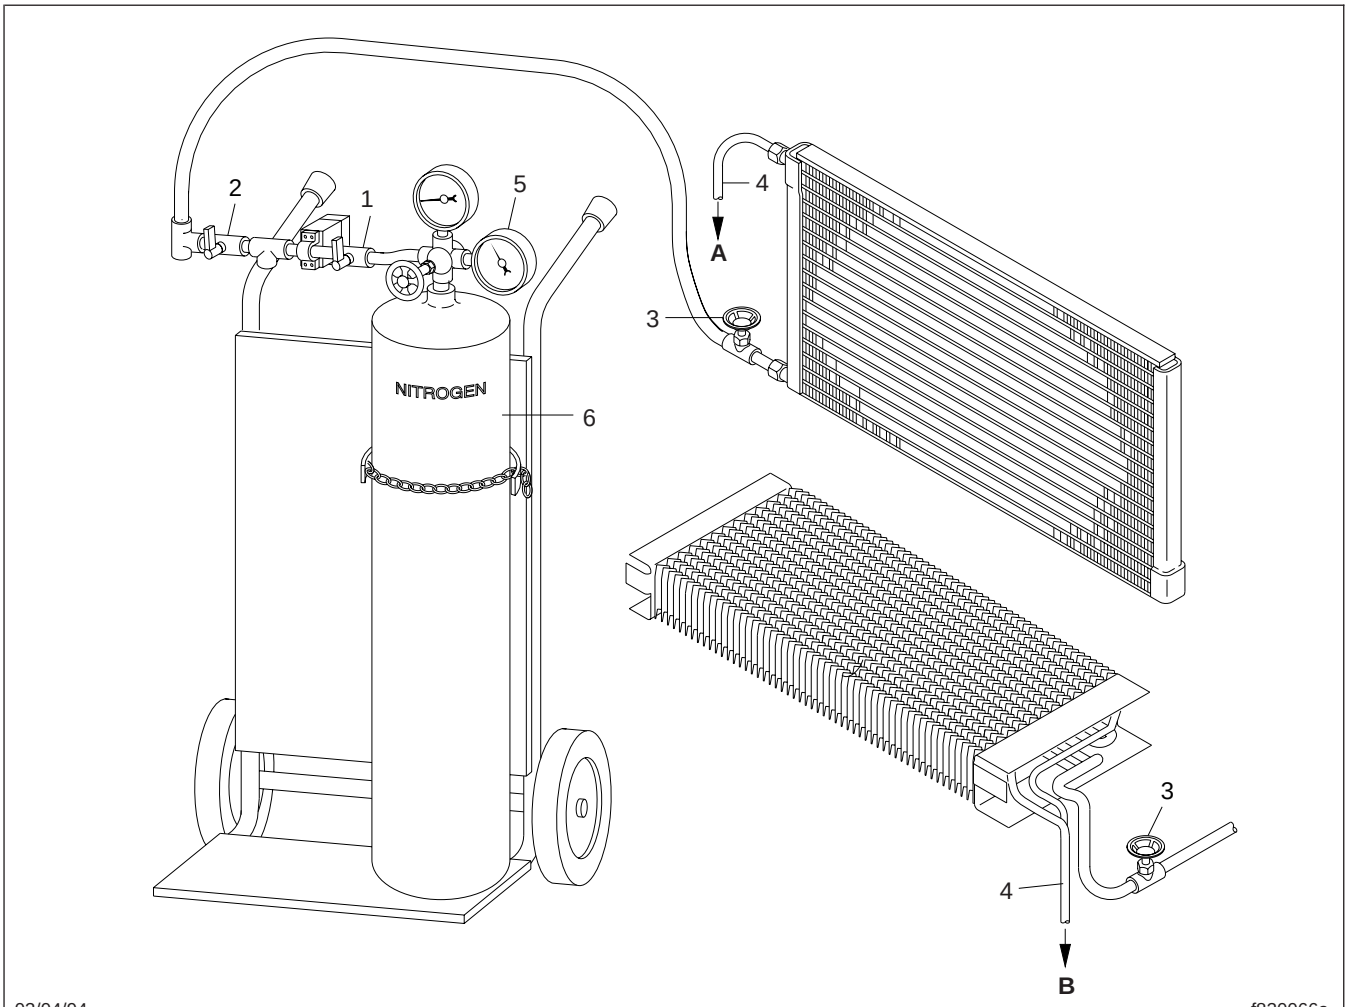
1. Recover the system refrigerant.
2. Disconnect both ends of the line or part being flushed. Tightly cap the lines to the rest of the system.
3. Heat R–134a in a charging cylinder or pressurize the refrigerant as recommended by the manufacturer.
4. Connect the charging cylinder outlet hose to the outlet side of the system (this will ensure that R–134a will flow in the reverse direction of normal flow).
5. Connect a line from the inlet side of the system to a recovery/recycling station.

NOTE: If the system is extremely contaminated, install a receiver-drier inline as a prefilter for the recovery/recycling station.

6. Turn on the recovery/recycling station and open the outlet valve for the charging cylinder. Allow about 2 pounds (1 kilogram) of R–134a to flow through the system.
7. Close the supply line valve and wait for the recovery station to shut off.
8. Disconnect the supply line and the drain line from the charging cylinder and the recovery station. Connect the lines to a nitrogen bottle.
9. Purge the system and check the collection bottle for contaminants. Repeat the process if needed.
10. Disconnect the lines from the part and tightly cap both ends of the part.

Charging

⚠ WARNING



Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

NOTE: Before charging, the system must be recovered and evacuated with the recovery and recycling station connected to the service and discharge port connections.

1. Obtain 52 oz (1.47 kg) of refrigerant to fully charge the system.

   Set the tank on a scale and weigh it so that the correct amount of refrigerant enters the system.

Recovery, Evacuating/Recycling, Purging and Flushing, Charging, and Leak Testing

A. To Waste Container
B. To Recycling System Container
1. Nitrogen Bottle Control Valve
2. Purging Control Valve
3. Supply Line Valve
4. Drain Line
5. Nitrogen Bottle Regulator/Gauge
6. Nitrogen Bottle

Fig. 6, Purging Station

This prevents overcharging, which could damage the compressor.

2. Charge the refrigerant system.

   NOTE: If equipped with a recovery, recycling, and recharging station, charge the system on the high side following the manufacturer's instructions. If charging from a bulk container, do the following.

   2.1 Turn the tank (bulk container) upside down. With the engine off, open the high-side hand valve. *Do not* open the low-side hand valve

   2.2 Allow refrigerant to enter the system until the correct charge (by weight) has entered. Then, close the high-side hand valve.

Recovery, Evacuating/Recycling, Purging and Flushing, Charging, and Leak Testing

2.3 Start the engine and run it at 1500 rpm. Set the cab air conditioner controls at maximum cooling and fan speed; the refrigerant compressor must engage.

2.4 If a full charge did not enter the system, place the tank (bulk container) in the upright position, then open the *low-side valve* to draw vapor into the system; leave the valve open until the correct weight of refrigerant has entered the system, then close the low-side valve.

NOTE: If refrigerant is slow to enter the system because of low outside temperatures, vaporization can be quickened by placing the refrigerant tank in a tub of warm water, no warmer than 125°F (52°C).

3. While the compressor is engaged, check the operating pressures at the suction and discharge ports; see the applicable compressor section in this manual. If the operating pressures are not acceptable, see **Troubleshooting 300** for possible causes.
4. Disconnect the high-side hose. With the engine running, open the low-side and high-side hose valves to recover the refrigerant from the lines.
5. Shut down the engine.

Leak Testing

GENERAL INFORMATION

⚠ WARNING

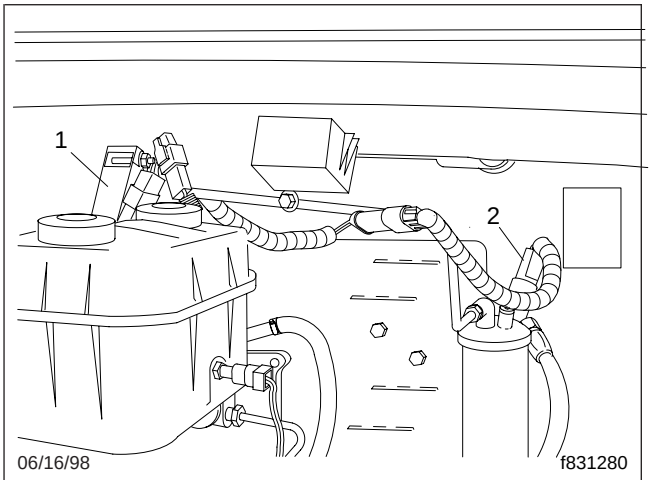
Before doing any of the work below, read the information under Safety Precautions 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

Refrigerant is odorless; as a result, all of it may leak away and not be noticed until the system stops cooling. All vehicle refrigerant systems lose some refrigerant, depending on the condition of the system. Higher loss rates signal a need to locate and repair the leaks.

Leaks are most often found at the compressor hose connections and at the various fittings and joints in the system. If unapproved replacement hoses are installed, refrigerant can be lost through hose permeation.

METHODS OF LEAK DETECTION

When checking for leaks, always focus your attention on the lowest portion of the fitting or part being tested. Refrigerant is heavier than air and will collect at the low point. Oil will also flow toward the low point. Listed in sequence from least precise to most precise, the methods for locating leaks are:

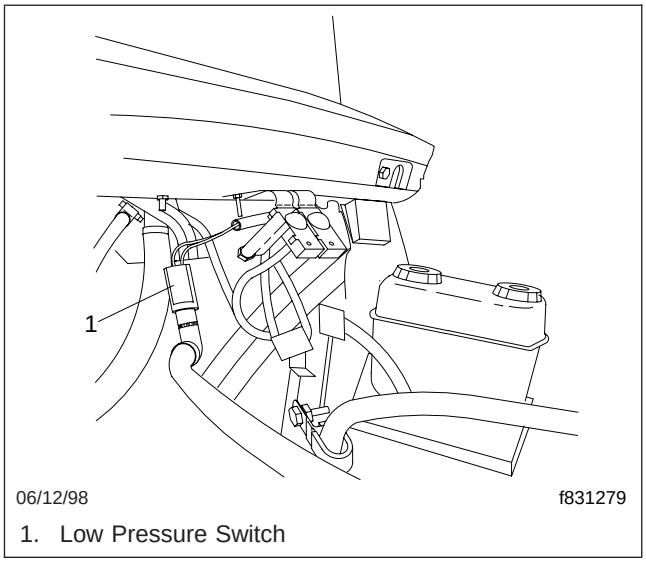


1. *Soapsuds solution*. A solution of soap and water can be squirted onto a suspected fitting or part. If the leak is large enough it will cause bubbles to form in the soapy solution at the point of the leak.
2. *Electronic leak detectors*. Electronic leak detectors are battery or 115-volt powered and rely on a very sensitive signal when a leak is found. In addition to being very precise, electronic leak detectors can be used in tight places.

NOTE: Do not try to use a leak tester right after connecting or disconnecting service hoses. Traces of refrigerant at the fittings can falsely signal a leak.

Air Conditioning Protection and Diagnostics System Electronic Control Module Replacement

Replacement



1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Open the hood.
4. Disconnect the high and low pressure switch harnesses on the Air Conditioning Protection and Diagnostics System (APADS™) electronic control module. See **Fig. 1** and **Fig. 2**.

1. Electronic Control Module
2. High Pressure Switch

Fig. 1, APADS™ Electronic Control Module

5. Remove the two bolts, washers, and nuts that fasten the APADS™ electronic control module to the mounting bracket. Keep the fasteners for installation.
6. Attach the new APADS™ electronic control module to the mounting bracket using the bolts, washers, and nuts. Tighten the bolts securely.
7. Connect the high and low pressure switch harnesses to the connectors.
8. Close the hood.
9. Connect the batteries.
10. Remove the chocks from the tires.

1. Low Pressure Switch

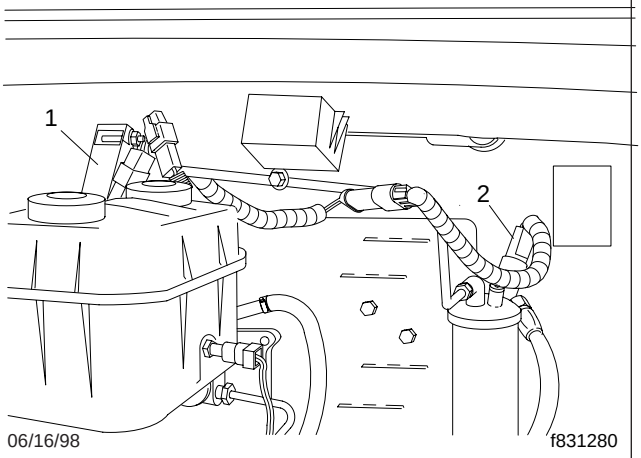


Fig. 2, APADS™ Low Pressure Switch

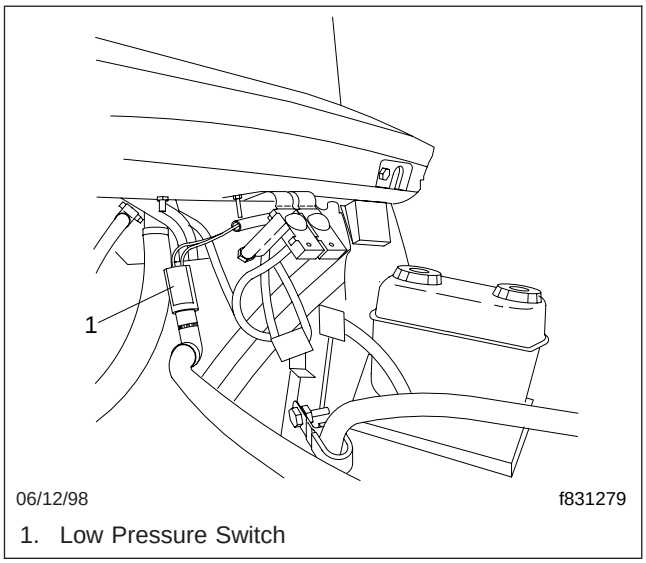
Air Conditioning Protection and Diagnostics System Pressure Switch Replacement

Replacement

NOTE: This procedure can be used for replacing both the low pressure switch and the high pressure switch.

1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Open the hood.
4. Disconnect the pressure switch harness on the Air Conditioning Protection and Diagnostics System (APADS™) electronic control module. See **Fig. 1** and **Fig. 2**.



1. Electronic Control Module
2. High Pressure Switch

Fig. 1, APADS™ High Pressure Switch

5. Remove the pressure switch from its port on the refrigerant line.
6. Lubricate a new O-ring with mineral oil, and place it on the coupling on the refrigerant line.
7. Attach the pressure switch to the port and tighten 20 to 25 lbf·ft (27 to 34 N·m).

IMPORTANT: After replacing the high pressure switch, clear the blink code by cycling the ignition switch—one cycle on, one cycle off—for four consecutive cycles.

8. Connect the pressure switch harness to the connector.

1. Low Pressure Switch

Fig. 2, APADS™ Low Pressure Switch

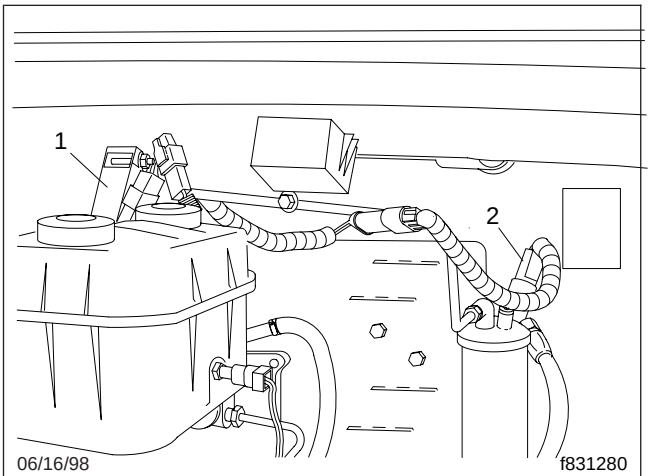
9. Close the hood.
10. Connect the batteries.
11. Remove the chocks from the tires.

Preliminary Checks

Before testing the operation of the air conditioning system, make the following checks.

1. Make sure the refrigerant compressor's drive belt is not damaged and is correctly tensioned. Also check the compressor mountings for tightness. For instructions and other information, see the applicable refrigerant compressor section elsewhere in this group.
2. Using a feeler gauge, check for correct refrigerant compressor clutch clearance. For instructions, see the applicable refrigerant compressor section elsewhere in this group.
3. Check for broken, burst, or cut hoses; also check for loose fittings on all parts.
4. Check for road debris buildup on the condenser coil fins. Using air pressure and a whiskbroom or a soapy spray of water, carefully clean off the condenser; be careful not to bend the fins.
5. Check the color of the moisture indicator sight glass. If the color is a deep cobalt blue, the refrigerant charge is dry. If the indicator is *not* blue, the system is contaminated with moisture; recover the refrigerant, evacuate the system, replace the receiver-drier, and add a full refrigerant charge.
6. If there is not enough airflow, make sure that leaves or other debris has not entered the fresh air ports under the windshield. If debris has entered, it could clog the fins of the evaporator coils, and block airflow.

   Also, be sure that all ducts are connected to the dash louvers and that the air-control flaps in the heater housing are moving properly (this requires removal of the right and center dash panel).



Performance Tests

Following is a brief description of symptoms or conditions that will exist if something goes wrong in a refrigerant part.

AIR CONDITIONING PROTECTION AND DIAGNOSTICS SYSTEM (APADS™)

The Air Conditioning Protection and Diagnostics System consists of an electronic control module, high and low pressure switches, and an evaporator thermostat. The electronic control module actively monitors system conditions and controls the operation of the refrigerant compressor and the fan clutch.

Located under the hood on the left-hand side of the frontwall (**Fig. 1**), the electronic control module registers fault codes that warn of existing or impending problems in the air conditioning system. Diagnostic information is provided by blinking red and green LEDs (light emitting diodes) built into the electronic control module. Since only one blink code can be displayed, the fault code of highest priority takes precedence. See **Table 1** for the fault code order of priority. Only the highest priority fault code is held in memory. Once the fault code is cleared, a new fault must occur to initiate a new blink code.

1. Electronic Control Module
2. High Pressure Switch

Fig. 1, APADS Control Module and Pressure Switch

A "blink" is approximately 1/4 second in duration. Once the number of blinks has been broadcast, there is a delay time of two seconds before the blink code is repeated. See **Table 2** for a description of blink codes.

The blink code is cleared by two methods:

Troubleshooting

- Cycle the ignition switch—one second on, one second off—for four consecutive cycles.
- Self-clearing based on the persistence of the fault. If a fault condition occurs once and does not repeat, the fault code is held for an extended period of time and then cleared. If the fault is repetitive, it will always be retained in memory until the problem is fixed.

For APADS™ troubleshooting information, see **Table 3**.

APADS™ Fault Code Order of Priority			
Priority	**Fault Code Name**	**Fault Description**	**LED Blinks**
1	Static low pressure	Full loss of charge	1
2	Dynamic low pressure	Partial loss of charge	1
3	High pressure	Overcharge, blocked condenser	2
4	Open clutch	Clutch wire open	3
5	Shorted clutch	Shorted clutch coil	3
6	Low pressure switch open	Cut wire to low pressure switch	4
7	High pressure switch open	Cut wire to high pressure switch	4
8	Low voltage	Low battery voltage	Rapid Green
9	No faults	No faults, module functional	Red off, Green slow blink

Table 1, APADS Fault Code Order of Priority

APADS™ Blink Codes	
Condition	**Description**
Slow Green	Unit is functioning properly
Fast Green	Low system voltage
One Red Blink	Loss of refrigerant
Two Red Blinks	Fan failure or external condenser blockage
Three Red Blinks	Voltage drop out, open or shorted wire to compressor clutch
Four Red Blinks	Open wire in pressure switch circuit

Table 2, APADS Blink Codes

APADS™ Troubleshooting Table			
Condition	**Definition**	**Possible Cause**	**Action**
Slow flashing green light.	Two seconds on, 1/2 second off.	Unit is functioning properly.	No action is needed.
Rapid flashing green light.	Low system voltage, indicates low supply voltage condition. Voltage has dropped below 11.0 volts.	Possibly caused by a damaged alternator, discharged batteries, poor ground, or an excessive electrical load.	Check voltage at the control harness by probing pins 4 (ground) and 2 (power). If voltage is less than 11.0 volts, start checking for voltage drops or a poor ground.

APADS™ Troubleshooting Table			
Condition	**Definition**	**Possible Cause**	**Action**
Ignition on, LEDs not flashing on control module or no lights on module.	Control module not receiving battery voltage.	Fuse or circuit breaker is blown.	Repair the fuse or reset the circuit breaker.
		Broken power or ground wire to control module.	Repair the wiring.
		Damaged control module.	Replace the APADS™ electronic control module, or retrofit the APADS with a binary switch. For instructions, see Service Bulletin 83–74.
Red light flashing one blink in sequence.	Low pressure fault. This is detected by monitoring the ambient temperature and switching activity of the low pressure switch.	Partial or total loss of refrigerant.	Install service gauges and the check system for leaks.
		A damaged low pressure switch.	Disconnect the low-side pressure switch connector and measure the resistance value of the switch. If the resistance shows 2.49k ohms, the switch is operating properly. If the resistance shows less than 5 ohms, replace the switch. NOTE: This check must be done with the switch installed on the vehicle, and the ignition in the off position and proper charge.
Red light flashing two blinks in sequence.	High pressure fault. The system is exhibiting abnormal high pressure activity.	Fan drive failure.	Inspect proper operation of the solenoid valve, relay, and/or related components.
		Blocked air flow through the condenser.	Remove the restriction from the condenser.
Red light flashing three blinks in sequence.	Open wire to A/C clutch. Detected by inadequate current through the compressor clutch. If no current is sensed when the A/C drive is turned on, an open connection to the clutch coil is indicated.	A break in the wiring between the control module and the A/C compressor clutch, or a break in the clutch coil.	With the use of an ohmmeter, check the resistance of the clutch coil. If the reading is less than 2.8 ohms, replace the clutch.
	Shorted wire or shorted A/C clutch. Detected by excessive current through the compressor clutch.	This indicates either a shorted clutch coil or shorted wiring to the clutch.	Locate and repair the shorted or frayed wiring between the control module and the A/C clutch.
	Fluctuating battery voltage.	Fluctuation of greater than one volt caused by a damaged voltage regulator.	Replace the alternator.

Troubleshooting

APADS™ Troubleshooting Table			
Condition	**Definition**	**Possible Cause**	**Action**
Red light flashing four blinks in sequence.	Opening in wiring harness to high or low pressure switches.	Unseated connector.	Check the connectors at the module and the pressure switch for loose pins.
		Break between wiring harness and pressure switch.	With the use of an ohmmeter, probe the yellow and yellow/black pins of the module harness. Resistance should read less than 5 ohms.
		Moisture intrusion into the connectors or switch.	Check the seals and inspect the wires for continuity.
		The use of a non-Index pressure switch.	Install the correct pressure switch.
A/C clutch is not engaging during the first 15 seconds after the ignition is turned on.	—	Unit is working. Regardless of A/C system state at start-up, the A/C clutch is disengaged for the first 15 seconds.	—
When the engine is turned on, and the A/C controls are set to the on position, the compressor is off for 15 seconds, on for 15 seconds, and then remains off indefinitely.	No voltage going to A/C compressor clutch.	Unsatisfactory A/C input signal.	Check for a break in the wiring between A/C clutch and the A/C controls.
			Check for a bad A/C on/off control switch.
			Check for a bad A/C relay.
At start-up, after 15 seconds, compressor clutch doesn't engage, but engine fan engages.	Control module sensing an opening in the high pressure switch circuit.	High-side pressure switch failure.	Check the switch by measuring the resistance value across the leads. If the resistance shows less than 1k ohms, the switch is functioning properly. If resistance is greater than 100 ohms, replace the switch.
Slow flashing green, compressor is on for a short period of time, off for 15 seconds in a repetitive sequence.	Indicates that the system is exhibiting abnormal high or low pressure activity.	Blockage on the high side of the system or in the condenser.	Repair the restriction.
		Partial loss of refrigerant.	Check the system for loss of refrigerant.
Slow flashing green light, not engaging in defrost mode or in cold weather.	—	The unit is more than likely functioning correctly. If the ambient temperature is too low, the compressor clutch is not allowed to engage because of low system pressure.	—

APADS™ Troubleshooting Table			
Condition	**Definition**	**Possible Cause**	**Action**
Slow flashing green, clutch is engaged, A/C is not cooling.	—	Inoperative blower motor.	Check for proper operation of the blower motors.
		Loose or broken compressor belts.	Tighten or replace the compressor belts.

Table 3, APADS Troubleshooting Table

COOLING CHECK

When outside temperature and humidity are high, it will take longer to cool the cab, especially if the fresh air vents are left open.

To determine if the air conditioner is cooling enough:

1. Set the engine speed at 1500 rpm.
2. Close the doors and windows.
3. Turn on the air conditioner. Set the controls at maximum cooling (recirculated air) and blower speed. The compressor must be engaged during this test.
4. Allow the system to run for at least 10 minutes (longer on hot and humid days).
5. Place a thermometer inside the louver or air duct; make sure the controls are set so that air flows out of the duct being tested.
6. Compare the measured temperature readings to the readings in **Table 4**. If the duct's air temperature is higher than normal readings, the system isn't cooling enough. For possible causes, see the troubleshooting tables.

RECEIVER-DRIER

The receiver-drier is normally at outside temperature. To the touch, the entire length of the unit should be the same temperature. If noticeable cool spots exist, replace the receiver-drier.

A blockage at the inlet of the unit will cause high head pressures; outlet blockages will cause low head pressures and little or no cooling.

If the moisture indicator is pink or white (showing that the system is wet), the receiver-drier is saturated with moisture and must be replaced.

Temperature/Pressure Specifications						
Ambient Air Temperature °F (°C)	**Humidity**		**Dash Louver Temperature °F (°C) †**	**Service Port Pressures * †**		**A/C Compressor Cycling On?**

Table 4, Temperature/Pressure Specifications

Troubleshooting

COOLING SYSTEM

Although they are not physically connected, there is a close tie between a vehicle's air conditioner and its cooling system. Poor air conditioner cooling can be the result of a problem in the cooling system.

If the cooling system does not work correctly, the heat of the engine will rise to abnormal levels. The added heat will transfer to the air conditioner, other underhood parts, and maybe make its way into the cab. The added heat makes it necessary for the air conditioner to work harder and, at the same time, it reduces the air conditioner's ability to cool down the air in the cab. Also, if the water regulating valve isn't closing all the way, heat will enter the cab, giving the impression that the air conditioning system is not working.

See **Group 20** of this manual for cooling system troubleshooting and to the engine manufacturer's service manual for other details about cooling system problems.

EXPANSION VALVE

Problems that start in the expansion valve show up as follows: when stuck closed, the evaporator coil and the expansion valve will be at outside temperature; when stuck open, both the coil and the valve will be extremely cold with frost or ice buildup.

Because the expansion valve is very sensitive to contamination, blockages in the system tend to be found here. Usually, the contaminant is water; less than a drop of water is all it takes to make the valve inoperative. When water reaches the valve, the extreme cold that results from the pressure drop freezes the water, forming a block of ice in the valve. After the system shuts down and the valve warms up, the ice melts, and the valve operates again, only to freeze up when the moisture returns.

On-and-off operation of the expansion valve means that the receiver-drier is not removing moisture from the system. This should cause the moisture indicator's element to turn white and then pink.

REFRIGERANT COMPRESSOR

Compressor problems usually show in one of four ways: abnormal noise; seizure; leakage; or low suction and discharge pressures.

Resonant compressor noises are not causes for alarm; irregular noise or rattles are likely to be caused by broken parts. To check for seizure, de-energize the magnetic clutch and see if the drive plate can be turned. If it won't turn, the compressor has seized.

Low discharge pressure may be caused by not enough refrigerant, not enough belt tension, or a blockage somewhere in the system. These things should be checked before servicing the compressor.

EVAPORATOR

The evaporator coils are basically trouble-free when airflow over the fins is not blocked. External or, less often, internal blockages will cause low suction pressure as well as little or no cooling.

If a leak exists in the system, and it cannot be traced to other parts or fittings, suspect damage to one of the evaporator coils.

CONDENSER

The condenser is also usually trouble-free when road debris, such as leaves or dirt buildup, is removed. If debris cakes up, airflow over the condenser fins is blocked; air is not able to absorb enough heat to turn the hot refrigerant gas into a liquid. High head pressures will result. In these cases, carefully clean off the outer surfaces of the condenser with compressed air or a soap and water solution; be careful not to bend the fins.

High head pressures will also occur if the condenser's tubing is abnormally bent, blocking the flow of refrigerant. Frost will appear at the point where the flow is restricted.

Less common internal blockages (bits of foreign material or metallic grit buildup) will stop the flow of refrigerant.

A quick test to check that poor system performance is caused by the condenser is to direct a spray of water onto the condenser while the system is running. If the air conditioner cools better because of the assist provided by the water, it is a sign that the condenser is not working.

When troubleshooting a suspected condenser problem, remember that the problem may be caused by the cooling system transferring high levels of heat to the condenser. See **Group 20** of this manual for cooling system troubleshooting and to the engine manufacturer's service manual for other details about cooling system problems.

THERMOSTATIC SWITCH

Before troubleshooting the thermostatic switch, be sure there is a full charge of refrigerant in the system. The compressor will not operate, or will cycle too often, if there is not enough refrigerant in the system.

Quick or delayed cycling of the compressor may be caused by a thermostatic switch that is working, but is out of adjustment. If, after doing the tests below, the switch seems to be out of adjustment, replace it (the thermostatic switch cannot be recalibrated).

NOTE: If the thermostatic switch is removed, it must be inserted at the same location of depth.

1. Be sure the compressor clutch is operating correctly. See the applicable refrigerant compressor section elsewhere in this group.
2. Expose the evaporator coil. See **Subject 120** for instructions.
3. Start the engine. Place the air conditioner control at its coldest setting. Turn on the air conditioner and the fan.
4. Place an accurate thermometer in contact with a tube on the evaporator coil. Be sure the thermometer is in good contact with the tube, or you will get a wrong reading.

   When the temperature drops below 31° to 36°F (–1° to 2°C), the compressor clutch should disengage and remain this way until the temperature rises to 39° to 44°F (4° to 7°C).
5. If the compressor did not engage when the temperature was above the accepted high range, check the thermostatic switch and its wiring.

   5.1 Connect a voltmeter or a test light from one of the terminals on the thermostatic switch to ground. Repeat this test with the other terminal on the switch.

   5.2 With the engine running and the air conditioner and blower on, both terminals will show voltage when the compressor should be engaged; one terminal will show voltage when the compressor should be disengaged.

   If there is no voltage, there is a problem in the electrical system from the batteries to the thermostatic switch. Check all circuits for the cause, and repair or replace the wiring or parts.

   In all other cases where the compressor is not engaging and disengaging properly, the thermostatic switch is the cause. Replace it with a new switch.
6. Shut down the engine and, to prevent accidental electric shock or shorting during dash assembling, disconnect the batteries.
7. Assemble the dash; see **Subject 120** for instructions.

LINE RESTRICTIONS

A restricted suction line causes low suction pressure at the compressor and little or no cooling. A restriction in a line between the compressor and the expansion valve can cause high discharge and low suction pressure, and insufficient cooling.

Usually, areas of ice or frost buildup mean a blockage. Parts that often freeze up are probably corroded or inoperative and should be replaced. Parts (such as the expansion valve) that freeze up once in a while may do so because of moisture in the system, which will cause the moisture indicator's element to turn white or pink; if this happens, recover the refrigerant charge, evacuate/recycle the system refrigerant, replace the receiver-drier, and install a new charge.

Fault Analysis Flow Chart

See **Fig. 2** for the fault analysis flow chart.

Troubleshooting Tables

Troubleshooting

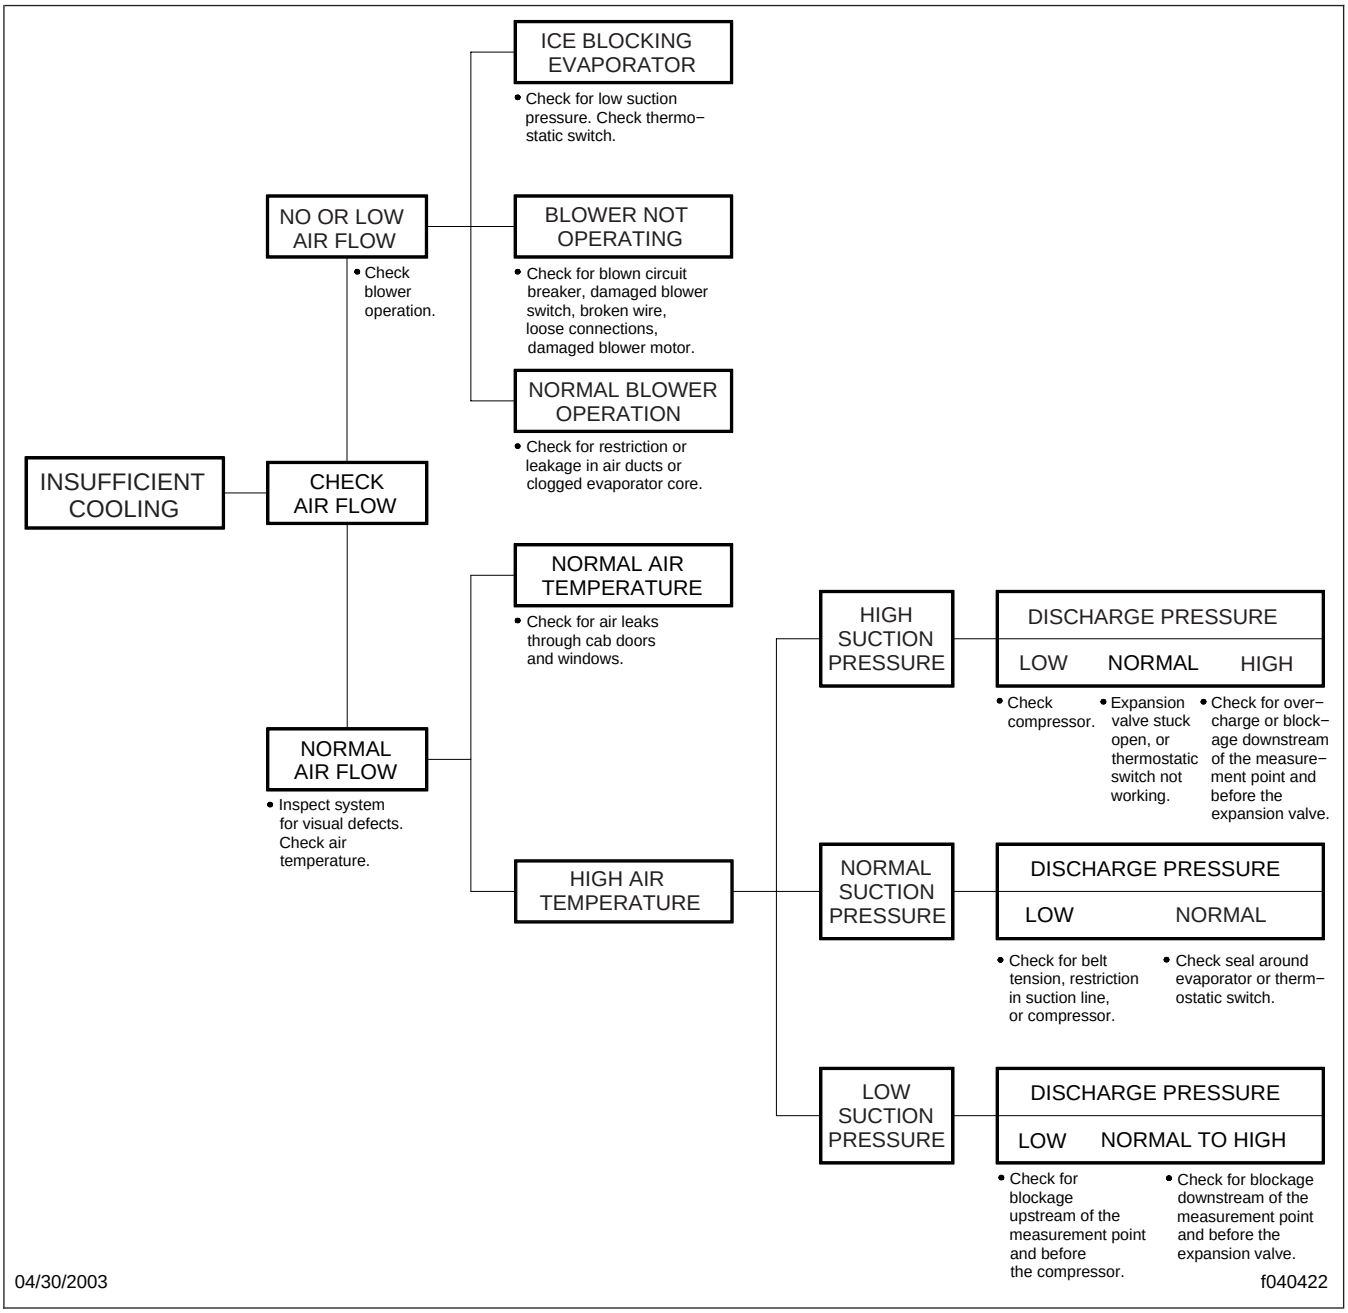

Fig. 2, Fault Analysis Flow Chart

Problem—Little or No Airflow

Problem—Little or No Airflow	
Possible Cause	**Remedy**
The blower is not operating.	Check for an open circuit breaker. An open circuit breaker indicates a short in the electrical system, which must be located and repaired.
	Check the air conditioner relays for operation. Replace, as necessary.
	Make sure the blower motor switch is working. Replace, if necessary.
	Check the wiring to the blower motor. If any connections are loose, securely tighten them. Make sure the wiring conforms to the diagram under **Specifications, 400.**
	Check the blower motor for operation. Replace if sticking or otherwise inoperative.
	Check the resistor block. Replace, if necessary. **CAUTION** **Never try to by-pass the fuse in the resistor block. To do so could cause the blower motor to overheat, resulting in serious damage to the heater/ air-conditioning system.**
There are restrictions or leaks in the air ducts.	Examine all air ducts and remove any blockages. Stop any leaks or replace any portion where the leaks cannot be stopped.
Ice has formed on the evaporator coil.	Defrost the evaporator coil before resuming operation of the air conditioner. Review "Performance Tests" in this subject for possible causes and corrective action.

Problem—Warm Airflow When the Air Conditioner Is On

Problem—Warm Airflow When the Air Conditioner Is On	
Possible Cause	**Remedy**
There is no refrigerant charge in the system.	Perform a leak test. Repair any leaks, evacuate the system, replace the receiver-drier, and add a full charge of refrigerant.
Moisture in the system.	If moisture is in the system, ice crystals may form at the expansion valve, blocking the flow of refrigerant (off and on). Recover the refrigerant charge, replace the receiver-drier, evacuate the system, and add a full charge of refrigerant.
The refrigerant compressor is not operating.	If the refrigerant charge is low, charge and leak test the system. Repair any leaks.
	The refrigerant compressor clutch or drive belt needs repair or replacement. For instructions, see the refrigerant compressor section elsewhere in this group.
The air-conditioner microswitch is not working.	Replace the microswitch.
Ice has formed on the evaporator coil.	Defrost the evaporator coil before resuming operation of the air conditioner. Review "Performance Tests" in this subject for possible causes and corrective action.

Troubleshooting

Problem—Low Evaporator Coil Outlet Pressure (Low Compressor Suction Pressure)

Problem—Low Evaporator Coil Outlet Pressure (Low Compressor Suction Pressure)	
Possible Cause	**Remedy**
The expansion valve is not working.	Replace the expansion valve.
There are restrictions in the line to the expansion valve.	Remove the line restrictions.
There is an insufficient refrigerant charge in the system.	Locate the leak. Recover the charge, replace the receiver-drier, and add a full refrigerant charge.

Problem—High Compressor Discharge Pressure

Problem—High Compressor Discharge Pressure	
Possible Cause	**Remedy**
Airflow through the condenser is restricted.	Remove the debris from the condenser.
There is an internal restriction in the condenser. (Ice buildup on the condenser or a cool spot on the line from the condenser to the receiver-drier).	Replace the condenser.
Air is present in the system.	Perform a leak test. Repair any leaks, evacuate the system, and add a full charge of refrigerant.
Heavy frosting on the suction line suggests that the evaporator coil is flooded.	Defrost the evaporator coil before resuming operation of the air conditioner.
The engine is over-heated.	See the engine manufacturer's operations manual for corrective measures.
Restriction in the compressor discharge line.	Repair or replace the line.

Problem—Evaporator Outlet Air Temperature Increases as the Compressor Discharge Pressure Drops

Problem—Evaporator Outlet Air Temperature Increases as the Compressor Discharge Pressure Drops	
Possible Cause	**Remedy**
There are leaks in the system.	Leak test the system.
The expansion valve setting is too low.	Replace the expansion valve. Add a full charge of refrigerant.
Too much oil is in the system. An indication of this is clutch or belt slippage at governed engine speed.	Check and remove excess refrigerant oil. For instructions, see the refrigerant compressor section elsewhere in this group.

Problem—Compressor Operates Too Often or Continuously

Problem—Compressor Operates Too Often or Continuously	
Possible Cause	**Remedy**
There is too little refrigerant in the system.	Perform a leak test. Repair any leaks, and add a full charge of refrigerant.
Ice has formed on the evaporator coil.	Defrost the evaporator coil before resuming operation of the air conditioner. Check the operation of the thermostatic switch, and replace as necessary.

Problem—Compressor Operates Too Often or Continuously	
Possible Cause	**Remedy**
There is a restriction in the refrigerant system.	Remove the restriction from the line.
Dirt and debris are clogging the condenser fins.	Remove all dirt and debris from the condenser fins.
The thermostatic switch isn't working.	Replace the thermostatic switch.

Problem—Quick or Delayed Cycling of the Compressor

Problem—Quick or Delayed Cycling of the Compressor	
Possible Cause	**Remedy**
The thermostatic switch operates, but is out of adjustment.	Replace the thermostatic switch. Do not attempt to adjust it.
Loss of refrigerant is causing a delayed cycling of the compressor.	Leak test and add a full charge of refrigerant.

Problem—Temperature in the Cab Too Low or No Heat

Problem—Temperature in the Cab Too Low or No Heat	
Possible Cause	**Remedy**
The water regulating valve is not opened.	Turn the temperature control knob toward "warm."
The water regulating valve is not opening all the way.	Adjust the water regulating valve cable.
The water regulating valve isn't working.	Replace the water regulating valve.
A heater hose is pinched or twisted.	Repair or replace the heater hose.
Coolant is leaking from the system.	Check for leakage at the heater core, and at all hose connections from the heater core to the engine. Check the radiator coolant level, as instructed in the vehicle driver's manual, and add coolant, if necessary. Check and repair any leaks at the radiator.
Dust or dirt is clogging the heater core fins.	Remove and clean the heater core.

Problem—Condensed Water Is Leaking from the Air Conditioner

Problem—Condensed Water Is Leaking from the Air Conditioner	
Possible Cause	**Remedy**
The drain tubes are plugged.	Clean the drain holes and drain tubes.

Specifications

WARNING

R–134a is the only refrigerant that is approved for use on Freightliner LLC vehicles. Several companies offer less expensive, hydrocarbon-based refrigerants, such as propane and methane. Use of these refrigerants will void the warranty on the vehicle's air conditioning system, cause damage to the air conditioning system, and possibly result in personal injury or property damage. Leaking air conditioning systems charged with hydrocarbon-based refrigerants pose a serious risk of fire or explosion under the hood, or inside the passenger compartment. Regardless of what the refrigerant supplier states, no vehicle built by Freightliner LLC can be safely charged with hydrocarbon-based refrigerants.

When servicing an air conditioning system, be sure to use a refrigerant identifier to ensure that the system has not been charged with something other than R–134a. This should be standard practice since there is no way to tell what services have been previously performed. Identification by service technicians will help to avoid the risk of explosion and guard against contamination of equipment when refrigerant is recovered and recycled.

General Information (See Fig. 1 or Fig. 2)

The main purpose of the refrigerant compressor is to draw refrigerant gas from the evaporator and squeeze it into high-pressure gas. High pressure raises the condensation point of refrigerant gas, which allows the condenser to change it to a liquid so that it can be used for cooling again. A second purpose of the compressor is to move refrigerant through the air conditioning system.

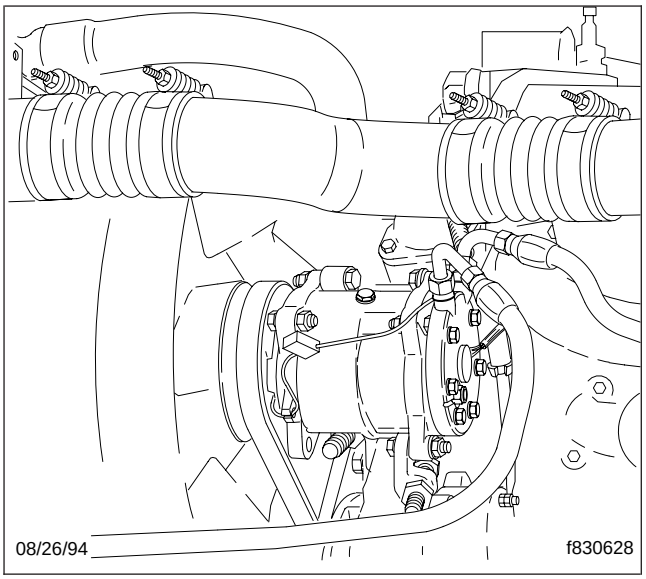

Fig. 1, OM 366LA Engine Mounting

The compressor is cycled by a thermostatic switch. When there is enough of a temperature drop in the cab, the switch breaks the circuit to the compressor's clutch. When the clutch is disengaged, its pulley is free-wheeling and the compressor shaft is not turning. When the clutch is engaged, it holds to the pulley, and the turning of the pulley causes the compressor shaft to turn.

Refer to the cab air conditioner section in this group for more information.

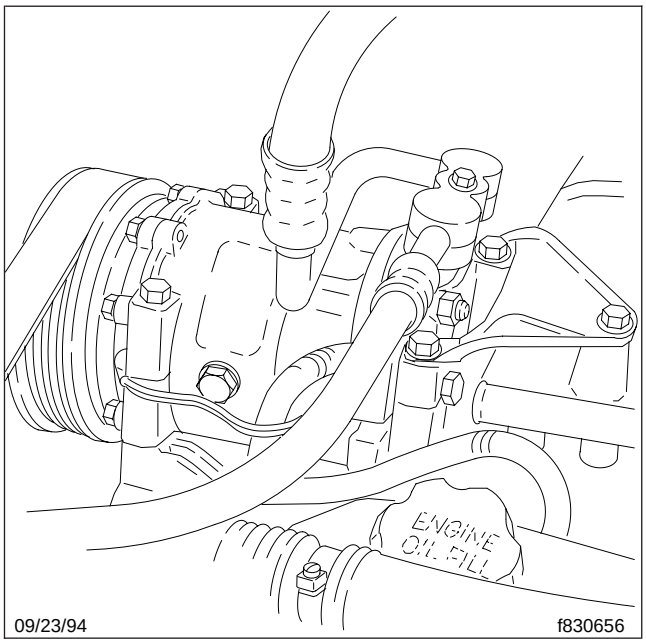

Fig. 2, Dodge Magnum Engine Mounting

Safety Precautions

Whenever repairs are made to any air conditioner parts that hold R–134a refrigerant, you must recover, purge or flush (if contaminated), evacuate, charge, and leak test the system. In a good system, refrigerant lines are always under pressure and you should disconnect them only after the refrigerant charge has been recovered (discharged) at the service valves.

Refrigerant R–134a is safe when used under the right conditions. Always wear safety goggles and non-leather gloves while recovering, evacuating, charging, and leak testing the system. Do not wear leather gloves; when refrigerant gas or liquid contacts leather, the leather will stick to your skin.

⚠ WARNING

WARNING: Use care to prevent refrigerant from touching your skin or eyes, because liquid refrigerant, when exposed to the air, quickly evaporates and will freeze skin or eye tissue. Serious injury or blindness could result if you come into contact with liquid refrigerant.

Refrigerant splashed in the eyes should be rinsed with lukewarm water, not hot or cold. Do not rub the eyes. Apply a light bandage and contact a physician right away.

Refrigerant splashed on the skin should be rinsed with lukewarm water, not hot or cold. Do not rub the skin. Apply a light coat of a nonmedicated ointment, such as petroleum jelly. Contact a physician right away.

R–134a refrigerant does not burn at ambient temperatures and atmospheric pressure. However, it can be combustible at pressures as low as 139 kPa absolute (5.5 psig) at 177°C (350°F) when mixed with air concentrations that are greater than 60 percent.

⚠ WARNING

WARNING: R–134a air conditioning systems should not be pressure tested or leak tested with compressed air. Combustible mixtures of air and R–134a may form, resulting in a fire or explosion, which could cause personal injury or property damage. R–134a may be safely pressured with dry nitrogen.

Always work in an area where there is a constant flow of fresh air when the system is recovered, evacuated, charged, and leak tested. R–134a vapors have a slightly sweet odor that is difficult to detect. Frequent leak checks and air monitoring equipment are recommended to ensure a safe working environment.

IMPORTANT: When servicing an R–134a air conditioning system, use only service equipment certified to meet the requirements of SAE J2210 (R–134a recycling equipment). The equipment should be operated only by qualified personnel who are familiar with the recycling station manufacturer's instructions.

Because of its very low boiling point, refrigerant must be stored under pressure. To prevent the refrigerant containers from exploding, never expose them to temperatures higher than 52°C (125°F).

On R–134a refrigerant systems, polyalkylene glycol (PAG) oil is used in the compressor. When handling PAG oil, observe the following:

- keep the oil free of contaminants
- do not expose the a/c system or the PAG oil container to air; PAG oil has a high moisture absorption capacity and the oil container should be immediately sealed after each use.
- use care when handling: painted surfaces, plastic parts, and other components (drive belts) could be damaged if PAG oil is spilled on them
- never mix PAG oil with other types of refrigerant oil

Pre-Service Checks

⚠ WARNING

WARNING: Before doing any work, read the information under Safety Precautions, 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

⚠ CAUTION

CAUTION: Determine whether the air conditioning system is charged with refrigerant R–134a or with R–12. Check the label on the radiator shroud (the side the compressor is on), the compressor identification tag, and the caution labels on system components for verification. Service procedures are different for these refrigerant systems. Failure to properly identify the refrigerant system prior to servicing could cause component malfunction and system contamination.

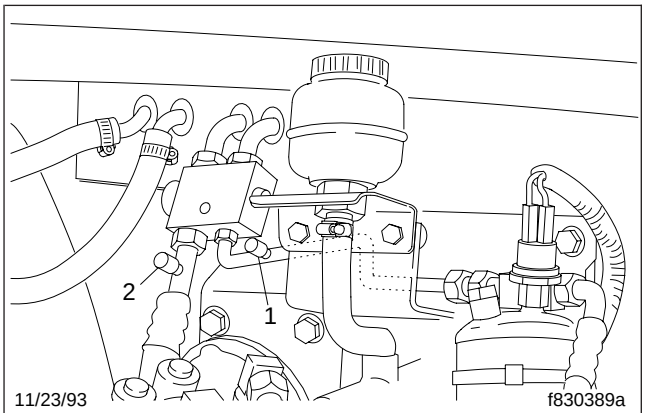
Some special tools are needed for doing repair work on the compressor. Refer to the special tools table in **Specifications 400.** Tool kits can be bought from the distributor listed under the special tools table in **Specifications 400.**

NOTE: Compressor problems usually show in one of four ways: abnormal noise; seizure; leakage; or low suction and discharge pressures. Resonant compressor noises are not causes for alarm; irregular noise or rattles are likely to be caused by broken parts. To check for seizure, de-energize the magnetic clutch and see if the drive plate can be turned. If it won't turn, the compressor has seized.

Do the following checks whenever the air conditioner system is not cooling enough and the causes are unknown.

1. Be sure to check the moisture indicator, to see if moisture is the cause of the problems. The air conditioner should be on when checking the indicator; it is better to check it at the end of a day's run.
2. Check the drive belt and mounting:
   - 2.1 On the drive belt, look for wear, damage, or oil. If worn, oil-soaked, or damaged, remove it and install a new one. Refer to the drive belt section in **Group 01** of this manual for instructions.
   - 2.2 Check the compressor mounting parts for loose fasteners, cracks, or other damage. Tighten loose fasteners to the torque value in the torque specifications table under **Specifications 400.** Repair or replace cracked or damaged brackets.
   - 2.3 Check the tension of the compressor drive belt. Refer to the drive belt section in **Group 01** of this manual for instructions.
   - 2.4 Check the compressor oil level. **Refer to Subject 140** for instructions.
3. Check the wiring and connections to the compressor clutch. Replace damaged wiring and tighten loose connections.
4. Check for road debris build-up on the condenser coil fins. Using air pressure and a whiskbroom or a solution of soap and water, carefully clean the condenser; be careful not to bend the fins.
5. Check the refrigerant charge in the air conditioner system; for instructions, refer to the section on R–134a heater and air conditioner systems in this group.
6. Check the suction pressure and discharge pressure of the refrigerant compressor; **refer to Subject 120**.
7. Check the valve plate and cylinder gasket (**Subject 170**), and the shaft seal (**Subject 160**) for damage. Replace as needed.

NOTE: For other possible causes of air conditioner problems, refer to the section on R–134a heater and air conditioner systems in this group and to the applicable fan clutch section in **Group 20** of this manual.



Checking

⚠ WARNING

WARNING: Before doing any of the work below, read the information under Safety Precautions, 100. Failure to read the safety precautions, and to be aware of the dangers involved when working with refrigerant, could lead to serious personal injury.

1. Attach a manifold gauge set to the service ports. Make sure that the manifold gauge set is equipped with a valve core depressor.

   1.1 Remove the protector caps from the service valve ports. **See Fig. 1.**

1. Discharge Service Valve
2. Suction Service Valve

Fig. 1

IMPORTANT: Push down firmly on the hose connectors until a clicking sound is heard. This will ensure that the coupler is locked.

   1.2 Make sure that the valves on the recovery and recycling station are closed. Cap the manifold center hose.

   1.3 Connect the red high-side hose to the discharge service valve, and the blue low-side hose to the suction service valve.

2. Start the engine and set it to run at 1500 rpm.

3. Turn on the heater-air conditioner blower, and set the air conditioner controls to the coldest setting, so that the compressor is operating. If the outside temperature is cooler than 21°C (70°F), *partially* block the air to the condenser.

4. Look at the manifold suction and discharge pressure gauges. The pressure on the gauges should be within the range in the temperature/pressure specifications table in **Specifications 400.**

   4.1 If the suction and discharge pressures are both too high, there is air in the refrigerant, or too much refrigerant in the system; check the charge; for instructions, refer to the section on R–134a heater and air conditioner systems in this group.

   4.2 If the suction pressure is too high and the discharge pressure is normal, check that the probe of the thermostatic switch is correctly installed in the evaporator coil. Refer to the section on R–134a heater and air conditioner systems in this group for instructions.

   4.3 If the suction pressure is too low and the discharge pressure is normal or too low, check for passage of air through the evaporator coils. If airflow is blocked, remove the blockage. If airflow is satisfactory, check for blockages in the line to the suction side of the compressor.

5. If the suction pressure is normal and the discharge pressure is too high, airflow through the condenser may not be enough to carry away the heat.

   5.1 Place a large fan in front of the radiator; place it so that the airflow goes through the condenser. After two minutes of operating the air conditioner and the fan at the same time, look at the manifold pressure gauges again. (One other procedure is to direct a spray of water onto the condenser while the system is running.)

   5.2 If the discharge pressure is still too high, the line between the compressor and the receiver-drier is blocked, or the condenser is blocked internally. Recover, flush, evacuate, charge, and leak test the system. If the blockage can't be removed by flushing, replace the blocked line or blocked condenser. After flushing and before placing a vacuum in the system, *be sure to add the correct amount of refriger-*

Compressor Suction and Discharge Pressure Checking

ant oil to the compressor. For instructions, refer to **Subject 140.**

6. If the suction pressure is normal or too high and the discharge pressure is too low, check for a slipping clutch or wrong-sized clutch pulley or accessory drive pulley. Replace parts as needed.

   If the suction pressure is still normal or too high and the discharge pressure is still too low, the compressor is the problem. Repair or replace the compressor.

Removal

1. Recover the refrigerant from the air conditioning system; for instructions, refer to the section on R–134a heater and air conditioner systems in this group.
2. If equipped with an OM 366LA engine do the following. If equipped with a Dodge Magnum engine, go to the next step.
   - 2.1 Remove the clamps holding the charge air pipe; then, remove the pipe. **See Fig. 1.**

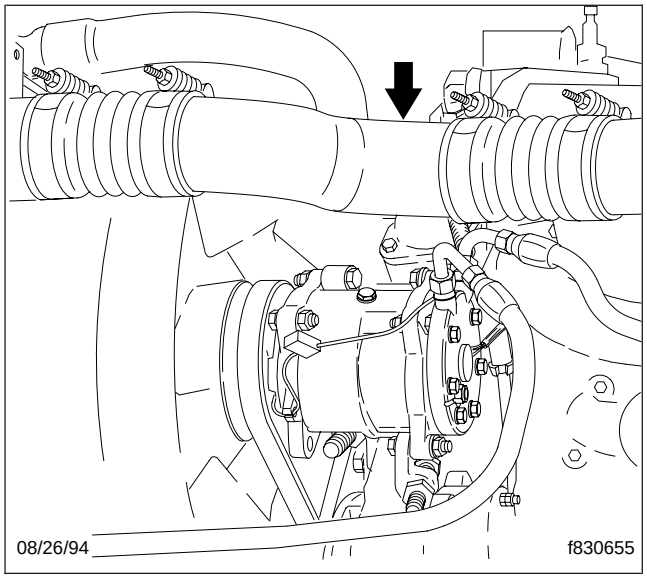


Fig. 1, Charge Air Pipe

   - 2.2 Clean the compressor around the hose connections. Disconnect all of the lines from the compressor. Quickly cap the discharge and suction ports and plug the hoses.
   - 2.3 Disconnect the compressor clutch electrical wire. **See Fig. 2.**
   - 2.4 Loosen both the adjusting and jam nuts on the compressor lower mounting strut. **See Fig. 3**, Refs. 13 and 11.
   - 2.5 Loosen the two compressor upper mounting bolts.
   - 2.6 Pivot the compressor down to relieve the belt tension.

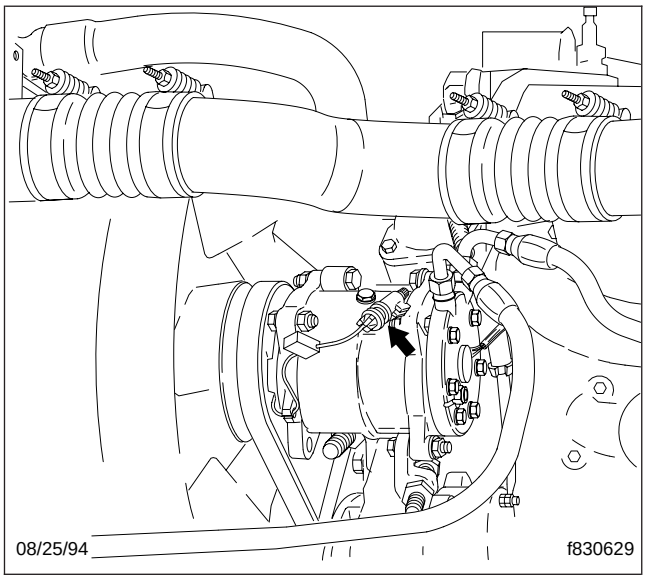

Fig. 2

   - 2.7 Remove the V-belt.
   - 2.8 Remove all three compressor mounting bolts and lift out the compressor.
3. If equipped with a Dodge Magnum engine, remove the compressor. **See Fig. 4.**
   - 3.1 Turn the belt tensioner counterclockwise to loosen the drive belt.
   - 3.2 Remove the fastener from the junction block assembly. Move the junction block assembly out of the way. Quickly cap the discharge and suction ports and plug the hoses.
   - 3.3 Cut the tie strap that secures the clutch wiring. Disconnect the wiring.
   - 3.4 Remove the five mounting fasteners, then remove the compressor.

Installation

IMPORTANT: A new compressor is filled with nitrogen gas and 200 mL (6.8 fl oz) of refrigerant oil. When installing a new compressor on the vehicle, do all of the steps below; if installing a used compressor, skip the following step, and proceed with the installation:

1. Prepare a new compressor.

Compressor Removal and Installation

1. Capscrew, M10 x 55
2. Pulley
3. Capscrew, M10 x 45
4. Lockwasher, 7/16-inch
5. Compressor Mounting Bracket
6. Capscrew, 3/8–16 x 1.75
7. Bearing Washer, 3/8-inch
8. Locknut, 3/8-inch
9. Compressor
10. Capscrew, 3/8–16 x 1.5
11. Jam Nut
12. Adjusting Rod End
13. Adjusting Nut
14. Alternator
15. Binary Switch

Fig. 3

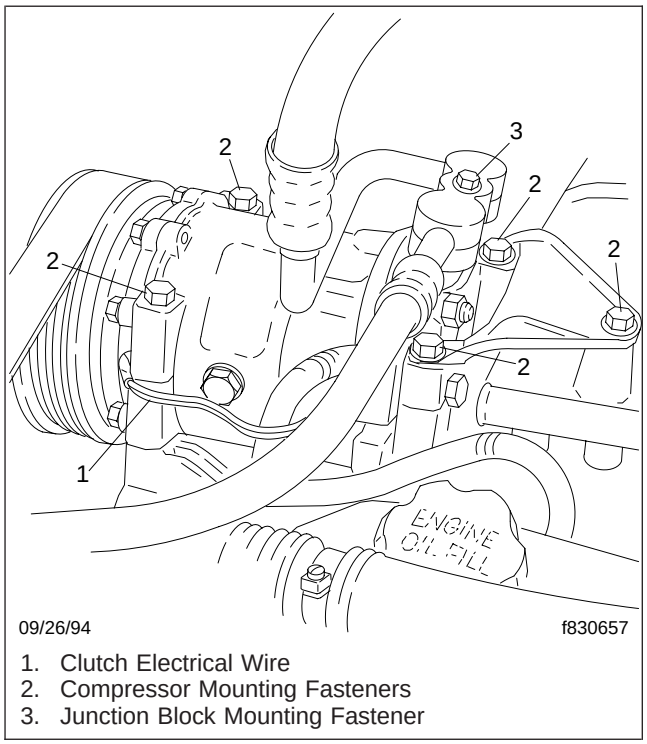
1.1 Slowly release the nitrogen from the discharge side of the compressor. Be careful not to let the oil flow out.

1.2 Turn the compressor shaft several times by hand to distribute oil which has settled in the cylinders.

2. If equipped with an OM 366LA engine, install the compressor as follows. If equipped with a Dodge Magnum engine, go to the next step.

2.1 Place the compressor in position against the mounting bracket and install the mounting bolts, washers, and nuts.

NOTE: The two long bolts go on top.



2.2 Hand tighten the nuts.

2.3 Install the V-belt. Adjust the belt tension. For instructions, refer to the applicable section in **Group 01.**

2.4 Tighten the compressor mounting bolts 45 N·m (33 lbf·ft).

2.5 Uncap the suction and discharge ports on the compressor. Unplug the hose connections. Check the hose connections and the surface of the suction and discharge ports. They must be clean and free of nicks, gasket residue, and other foreign material.

IMPORTANT: Under no circumstances should you leave the compressor's ports un-

1. Clutch Electrical Wire
2. Compressor Mounting Fasteners
3. Junction Block Mounting Fastener

Fig. 4

capped or the hoses unplugged for longer than five minutes total.

2.6 Attach the refrigerant hoses to the system hose connections. Tighten the suction (large) fitting 39 N·m (29 lbf·ft); tighten the discharge (small) fitting 37 N·m (27 lbf·ft).

2.7 Connect the compressor clutch electrical wire.

2.8 Install the charge air pipe. Tighten the constant torque hose clamps 680 N·cm (60 lbf·in).

3. If equipped with a Dodge Magnum engine, install the compressor.

3.1 Position the compressor on the mounting block.

3.2 Position the retaining bracket at the rear of the compressor.

3.3 Install the five mounting fasteners and tighten them 27 N·m (20 lbf·ft).

3.4 Uncap the suction and discharge ports on the compressor. Unplug the hose connections. Check the hose connections and the surface of the suction and discharge ports. They must be clean and free of nicks, gasket residue, and other foreign material. Replace both O-rings, then install the block assembly on the compressor. Tighten the fastener 25 N·m (19 lbf·ft).

IMPORTANT: Under no circumstances should you leave the compressor's ports uncapped or the hoses unplugged for longer than five minutes total.

3.5 Turn the belt tensioner counterclockwise and slip the belt over the pulley.

4. Evacuate, charge, and leak test the air conditioning system. For instructions, refer to the section on R–134a heater and air conditioner systems in this group.

General Information

⚠ CAUTION

Different refrigerant oils are used in compressors on R–12 and R–134a air conditioning systems. Always use the correct refrigerant oil and never mix oils. If the wrong oil is used, or if oils are mixed, the compressor could seize due to improper lubrication.

IMPORTANT: New compressors are factory-charged with about 6.8 oz (200 mL) of refrigerant oil. Some refrigerant oil is circulated through the system with the refrigerant, and cannot leave the system except through a leak, when the system is recovered, or when a system part is replaced.

Oil must be from a container that has not been opened, or that has been tightly sealed since its last use. For R–134a systems, order Sanden oil SKI/7803-1997 from your local Freightliner parts distribution center. Tubing, funnels, or other equipment used to transfer the oil should be very clean and dry.

IMPORTANT: Add the same amount of oil that is removed when the system is discharged or recovered, or when a system part is replaced. The list below contains approximate refill amounts for R–134a air conditioning systems.

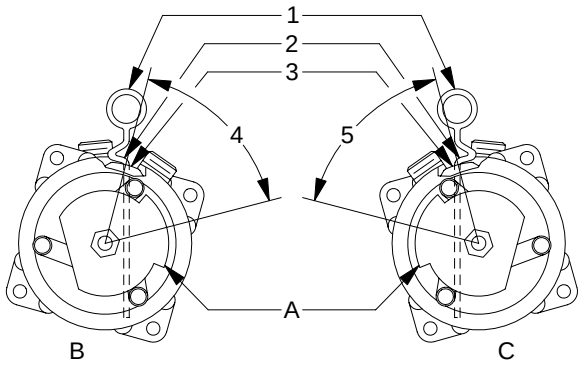
A. Refrigerant charge—0.7 fl oz (20 mL): This amount of oil may be lost from the system each time the system loses its charge, due to routine recovery or due to a slow leak; no other parts of the system have been replaced.

IMPORTANT: The items below list oil quantities that include the amounts that are lost during recovery. Do not add an additional 0.7 fl oz (20 mL)—the amount described in the item above—to the quantities listed.

B. Receiver-drier—2.7 fl oz (80 mL);

IMPORTANT: A new receiver-drier does not contain any refrigerant oil.

C. Condenser—1.0 fl oz (30 mL);



D. Evaporator coil—0.7 fl oz (20 mL);

E. Entire system—14 fl oz (414 mL) with or without an auxiliary heater/air-conditioner. Add this amount of oil to the compressor if the entire system (including the compressor) has been recovered of refrigerant and oil, and if the system has been evacuated.

When handling refrigerant oil:

- The oil should be free of water, dust, metal powder, and other foreign substances.
- Don't mix refrigerant oil with other types or viscosities of oil.
- Refrigerant oil absorbs moisture when exposed to the air for any period. After use, quickly seal the oil container.

IMPORTANT: Check the compressor oil level at the time of installation and whenever a loss of refrigerant oil has occurred.

A. Position of counterweight.
B. Mounting angle right.
C. Mounting angle left.

1. Dipstick
2. Dipstick Stop
3. Oil Fill Hole
4. 2 o'Clock
5. 10 o'Clock

Fig. 1, Checking the Oil Level

⚠ WARNING

Don't remove the oil fill plug without first recovering the system. Failure to recover the system could cause uncontrolled release of high-pressure refrigerant, which can freeze skin and eye tissue causing serious injury or blindness.

1. Run the compressor for 10 minutes with the engine at idle. Shut down the engine.

Oil Check and Adding Oil to the Compressor

2. Recover all of the refrigerant from the system.
3. Determine the mounting angle of the compressor from horizontal (oil fill plug on top).
4. Remove the oil fill plug. Using a socket wrench on the armature retaining nut, turn the shaft clockwise until the counterweight is positioned correctly. See **Fig. 1**.
5. Check the oil level with the dipstick. Make sure the angle of the dipstick stop is pointing in the right direction. See **Fig. 1**.

   Remove the dipstick and count the number of notches covered by the oil. If the number of notches covered by oil does not match the specifications for the appropriate mounting angle in **Table 1**, add or subtract oil to the midrange value. For example, if the mounting angle is zero degree, add oil until 6 notches on the dipstick are covered by oil.

Oil Specifications at Various Mounting Angles	
Mounting Angle	**Number of Notches Covered by Oil**
0°	5 to 7
10°	6 to 8
20°	7 to 9
30°	8 to 10
40°	9 to 11
50°	10 to 12
60°	11 to 13
90°	16 to 18

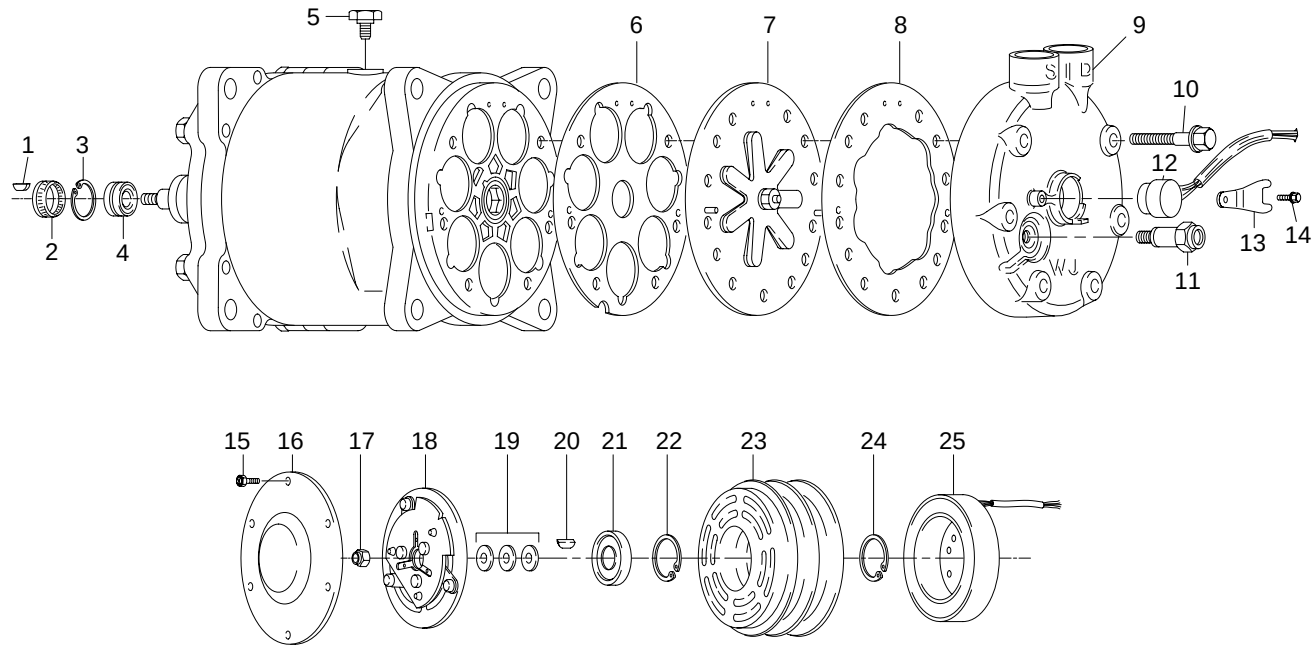


Table 1, Oil Specifications at Various Mounting Angles

NOTE: A dipstick can be made locally or purchased from a special tools supplier. Refer to the list of special tool suppliers in **Specifications 400**.

6. Being careful not to twist the O-ring, insert the plug in the oil fill opening. Tighten the plug 11 to 19 lbf·ft (15 to 25 N·m).

Clutch Assembly Removal, Inspection, and Installation

25. Field Coil Assembly

Fig. 1, Sanden SD7 Series Refrigerant Compressor

1. Remove the compressor from the vehicle. For instructions, refer to **Subject 130**.
2. Remove the six bolts that attach the drive plate cover and remove the cover.
3. Insert the pins of the drive plate spanner into the threaded holes of the drive plate. Hold the drive plate securely while removing the retaining nut. See **Fig. 2**.
4. Using the drive-plate puller, thread the three puller bolts into the drive plate. Turn the center screw clockwise to loosen and remove the drive plate. See **Fig. 3**.
5. Remove the pulley bearing dust cover (if equipped), the shaft key, and the clutch shims. Use a slotted screwdriver and hammer to tap the shaft key loose. See **Fig. 4**.
6. Using external snap-ring pliers, remove the pulley assembly snap ring.
7. Remove the pulley assembly.
   - 7.1 Insert the lip of the pulley puller jaws into the snap ring groove. See **Fig. 5**.
   - 7.2 Place the puller shaft protector over the exposed shaft.

Clutch Assembly Removal, Inspection, and Installation

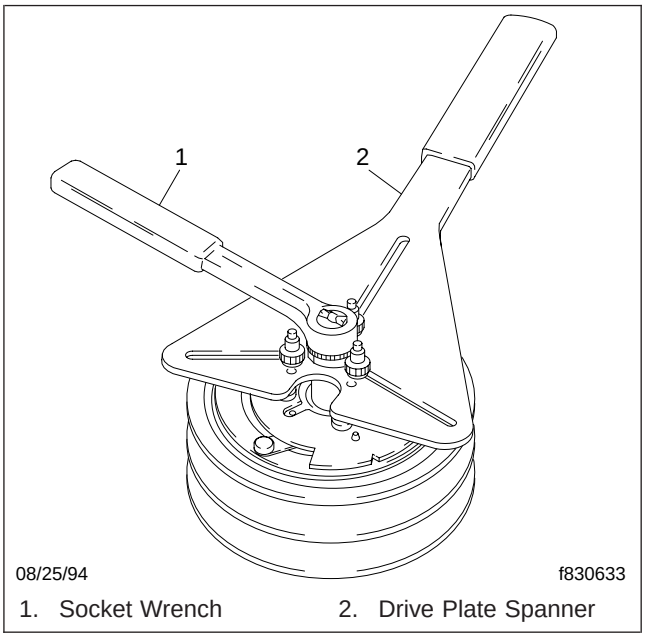

Fig. 2, Remove the Retainer Nut

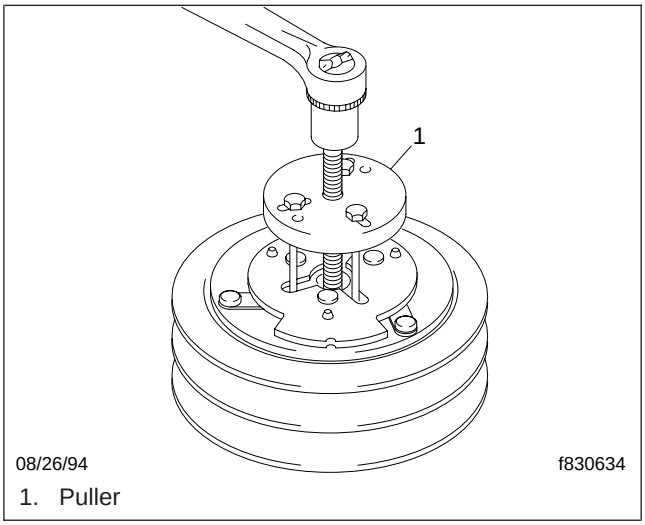

Fig. 3, Remove the Drive Plate

7.3 Align the thumb screws to the puller jaws. Tighten the screws finger tight.

7.4 Using a socket wrench, turn the puller center bolt clockwise and remove the pulley.

8. Remove the coil assembly.

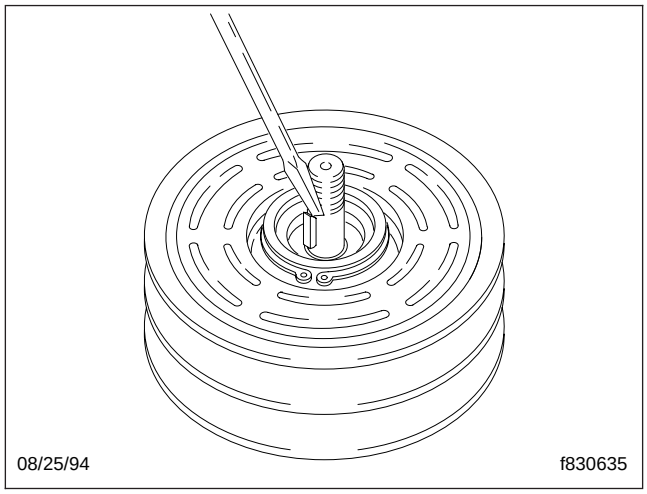

Fig. 4, Tap the Shaft Key Loose

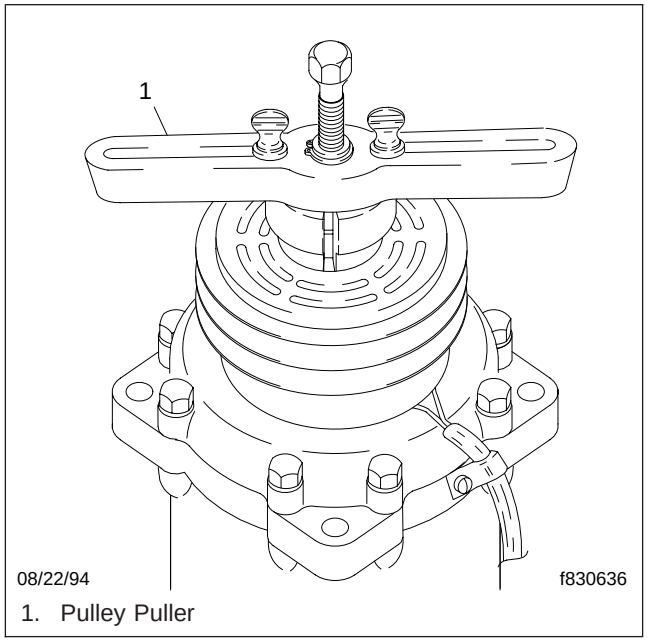

Fig. 5, Pulley Assembly

8.1 Remove the coil's lead wire from the wire holder on the compressor.

8.2 Disconnect the wiring harness.

8.3 Remove the snap ring (**Fig. 6**); then, remove the coil assembly.

Clutch Assembly Removal, Inspection, and Installation

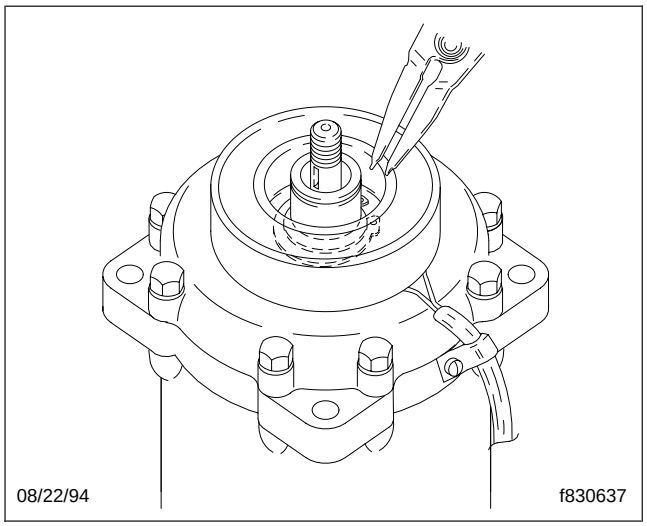

Fig. 6, Coil Assembly

Inspection

1. Inspect the drive plate. If the frictional surface shows signs ofdamage due to too much heat, replace the drive plate and pulley assembly.
2. Check the appearance of the pulley assembly. If the friction surface of the pulley shows signs of too much grooving due to slippage, replace both the pulley and drive plate. Clean the friction surfaces of the pulley assembly before installing it.
3. Check the coil for a loose connector and for cracked insulation.Replace it if necessary.

Installation

NOTE: When supporting the compressor in a vise, clamp only on the mounting ears, never on the body of the compressor.

1. Install the coil assembly.
   - 1.1 Position the coil assembly on the compressor.
   - 1.2 Install the snap ring.
   - 1.3 Attach the coil's lead wire to the wire holder on the compressor.
   - 1.4 Connect the wiring harness.
2. Install the pulley assembly.
   - 2.1 Position the pulley over the boss of the front housing.
   - 2.2 Place the pulley installer ring into the bearing bore. Make sure that the edge rests only on the inner race of the bearing, not on the seal, pulley, or outer race of the bearing.
   - 2.3 Place the driver into the ring. Using a hammer or arbor press, drive the pulley down against the front housing step. See **Fig. 7**.

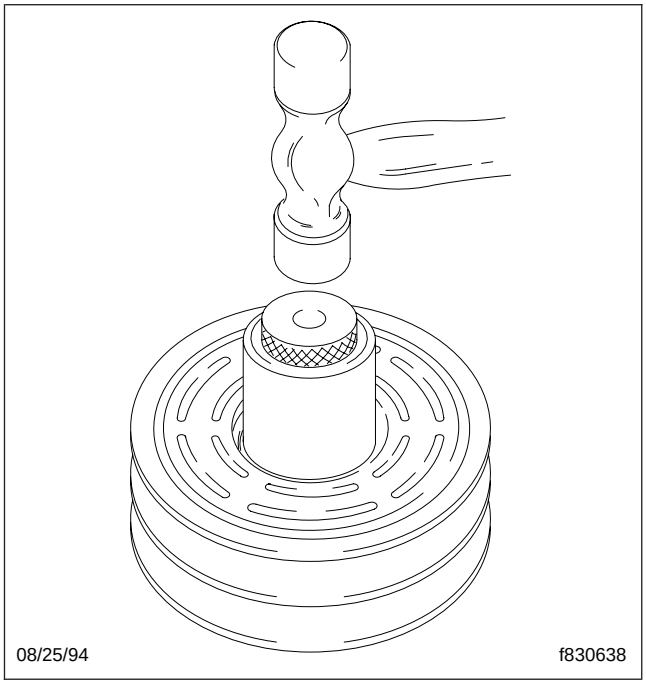

Fig. 7, Drive the Pulley Down

   - 2.4 Using internal snap ring pliers, install the pulley bearing snap ring.
   - 2.5 Using external snap ring pliers, install the pulley snap ring. If a bevel is present on the snap ring, make sure that it is facing up (away from the body of the compressor).
   - 2.6 Install the pulley bearing dust cover by gently tapping it into place.
3. Install the drive plate assembly.
   - 3.1 Using pliers, install the shaft key. See **Fig. 8**.

Clutch Assembly Removal, Inspection, and Installation

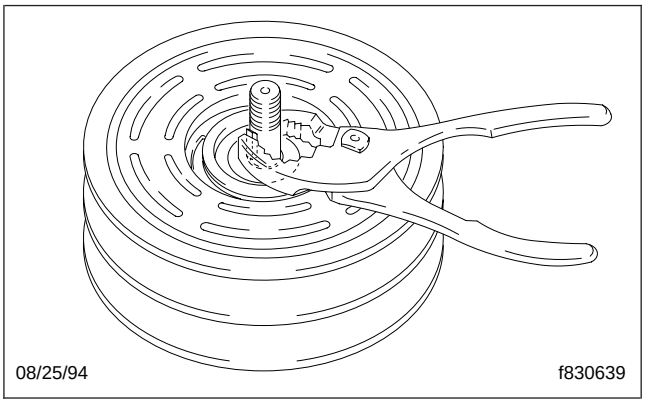

Fig. 8, Install the Shaft Key

3.2 Install the shims.

3.3 Align the keyway in the drive plate assembly with the shaft key. Using a driver, and a hammer or an arbor press, drive the assembly down over the shaft until it bottoms on the shims. See **Fig. 9**.

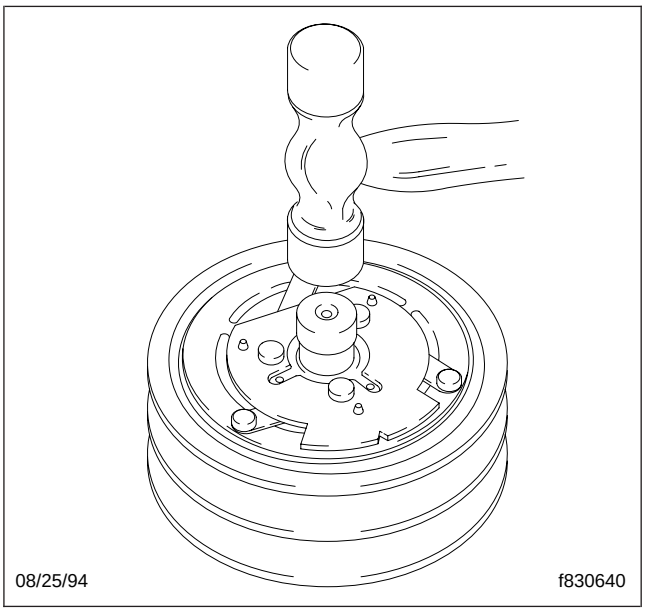

Fig. 9, Drive Plate Assembly

3.4 Install the retaining nut. Tighten the nut to the torque in **Specifications 400**.

4. Using a feeler gauge, check that the clutch clearance is 0.4 to 0.8 mm (0.02 to 0.03 inch). See **Fig. 10**. Adjust the clearance by gently tapping down on the front plate at the high spots, or gently prying up at the low spots.

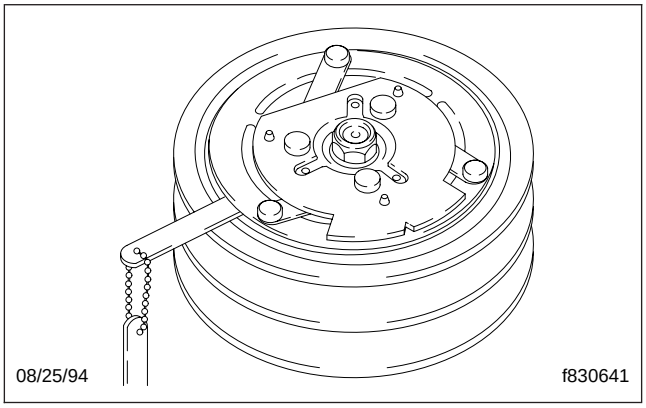

Fig. 10, Check the Clutch Clearance

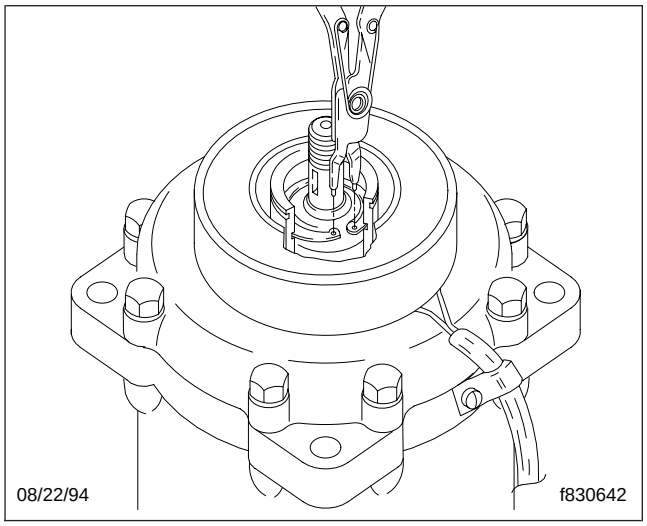
5. Install the drive plate cover. Tighten the bolts to the torque in **Specifications 400**.

6. Install the compressor on the vehicle. For instructions, refer to **Subject 130**.

Replacement

1. Remove the drive plate and pulley assemblies. For instructions, refer to **Subject 150.**
2. Using snap ring pliers, remove the felt ring retainer. **See Fig. 1.** Then remove the felt ring.



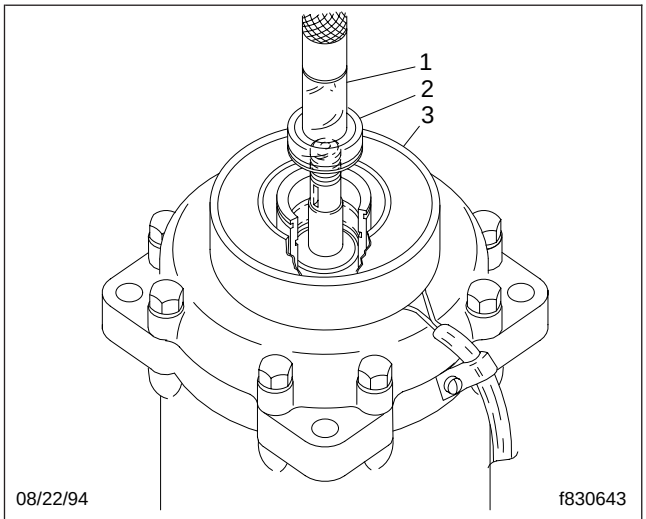


Fig. 1

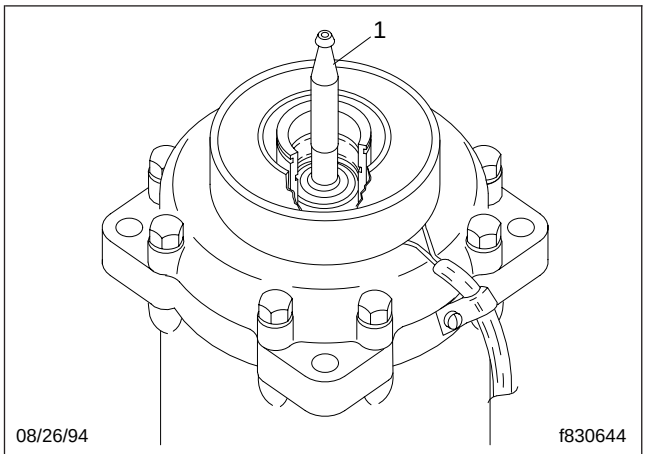
3. Using snap ring pliers, remove the shaft seal snap ring.
4. Position the shaft seal removal and installation tool on the shaft seal. Twist the tool until the hooks on the tool engage the slots in the shaft seal housing, then pull the seal out with a twisting motion. **See Fig. 2.**

NOTE: The shaft seal and felt ring should not be reused. Always use a new seal kit. Be very careful that the lip of the shaft seal to be installed is not scratched or damaged in any way. Make sure the shaft seal is free of lint and dirt, which could damage the shaft seal surface.



5. Using a non-petroleum based solvent and a lint-free cloth, clean the shaft seal cavity. Then, use dry compressed air to blow out the shaft seal cavity.
6. Position the shaft seal protective sleeve over the compressor shaft. **See Fig. 3** . Make sure that the sleeve has no scratches so that the shaft seal will not be damaged. Also, make sure that

1. Shaft Seal Removal and Installation Tool
2. Shaft Seal
3. Coil Assembly

Fig. 2

there is no gap between the end of the sleeve and the seal surface of the shaft.

1. Protective Sleeve

Fig. 3

7. Position the shaft seal removal and installation tool until the hooks on the tool engage the slots in the new shaft seal housing.
8. Place the entire assembly into clean 5GS refrigerant oil. **See Fig. 4.**
9. Insert the shaft seal over the protective sleeve, then press it down as far as possible. Twist the

Shaft Seal Replacement

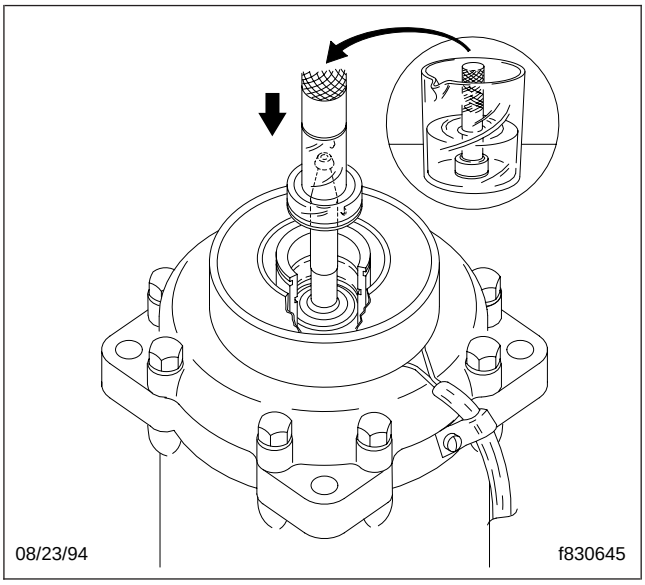


Fig. 4

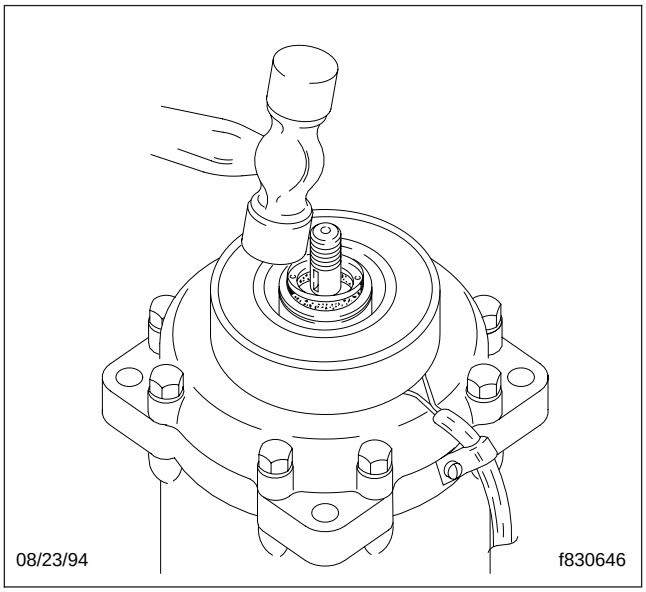

Fig. 5

removal and installation tool to remove it from the seal. Remove the tool and the protective sleeve.

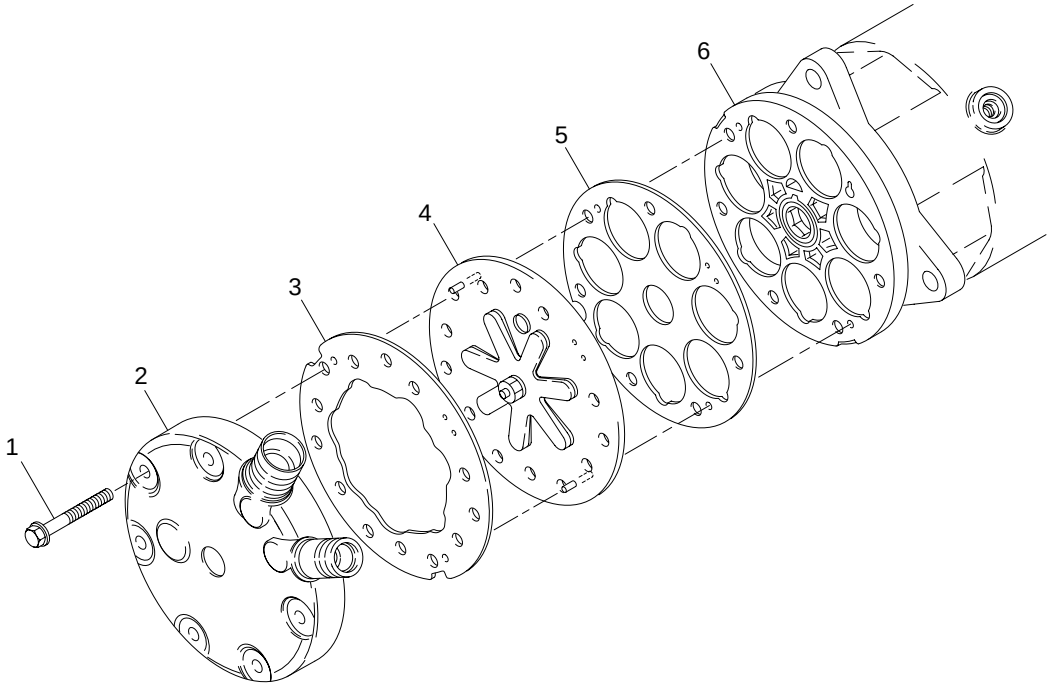
10. Using internal snap-ring pliers, install the snap ring. **See Fig. 1.** If needed, gently tap the snap ring to ensure that it is seated in the groove.

NOTE: When installing the snap ring, the beveled end of the snap ring must face away from the compressor body.

11. Gently tap the new felt ring in place. **See Fig. 5.**
12. Install the drive plate and pulley assemblies. For instructions, refer to **Subject 150.**

Head and Valve Plate Removal and Installation

Removal



NOTE: Before doing any work on the head and valve plate, open both service valves to release any gas pressure in the compressor.

1. Remove the bolts from the cylinder head. **See Fig. 1.**

⚠ CAUTION

CAUTION: Do not hit or tap the head to separate it from the valve plate. Damage to the head may result.

NOTE: It is recommended that the head gasket (located between the cylinder head and the valve plate) and the block gasket (located between the valve plate and the cylinder block) be replaced any time the cylinder head is removed.

1. Cylinder Head Bolt
2. Cylinder Head
3. Head Gasket
4. Valve Plate Assembly
5. Block Gasket
6. Compressor Body

Fig. 1

2. Remove the valve plate assembly and the cylinder head from the compressor. Use a gasket scraper to separate the cylinder head from the valve plate. **See Fig. 2**. Use care not to scratch the gasket surface of the cylinder head.
3. Being careful not to scratch or nick the machined sealing surfaces, remove all gasket material adhering to the head, valve plate, or compressor block.

Head and Valve Plate Removal and Installation

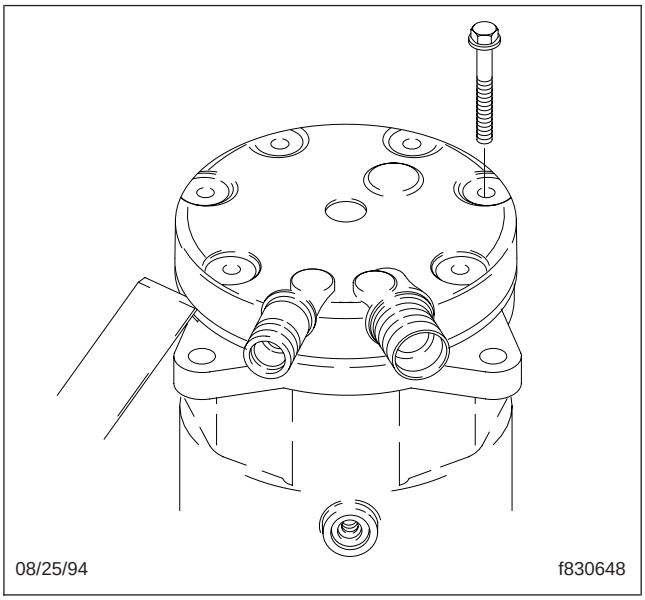


Fig. 2

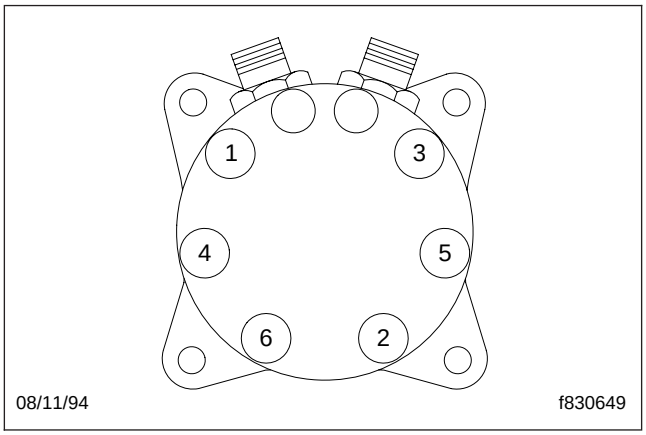

Fig. 3

Installation

1. Apply a thin film of clean 5GS refrigerant oil to the new block gasket. Place the block gasket in position on the compressor so that the pin holes in the compressor block line up with the pin holes in the block gasket.
2. Place the valve plate assembly in position on the block gasket so that the discharge valve, retainer, and the nut are facing up (away from the cylinder block). Make sure that the locating pins on the valve plate go through the pin holes in the gasket.
3. Remove all residual oil from each bolt hole on the cylinder block.
4. Apply a thin film of clean 5GS refrigerant oil to the new head gasket. Place the gasket in position over the valve plate locating pins. Make sure that the locating pins on the valve plate go through the pin holes in the gasket.
5. Place the head on the cylinder head gasket so that the dowel pins go into the dowel pin holes in the head.
6. Install the head bolts. Tighten the bolts in sequence to the values given in **Subject 400**. **See Fig. 3** for the tightening sequence.

Special tools can be purchased from the following independent suppliers:

Table 2, Temperature/Pressure Specifications

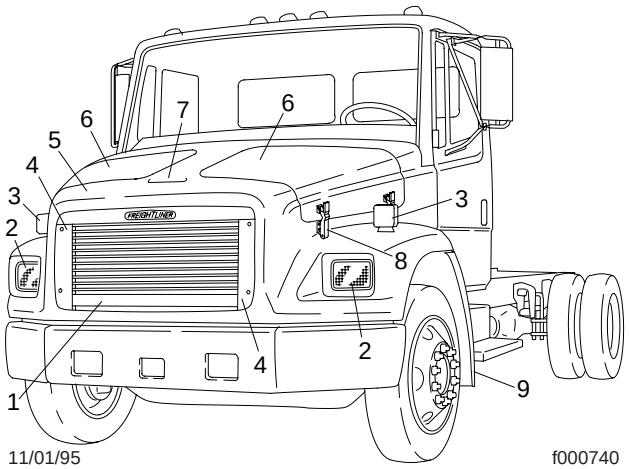
General Information

All Freightliner Business Class Trucks have a molded, fiberglass-reinforced-plastic (FRP) hood and fender assembly, and molded FRP half-fenders that mount to the cab sides. Several reinforcing members are bonded to the engine side of the hood. The argent-colored front grille is made of injection-molded plastic.

A recess in the hood, above the grille, provides the handle for hood tilting. **See Fig. 1** and **Fig. 2 .**

Most Business Class Trucks are equipped with a one-piece hood that tilts forward to allow engine access. On these one-piece hoods, the grille is mounted to the front of the hood and moves forward with the hood when the hood is tilted.

04/22/93 f000448



1. Recessed Hood-Tilt Handle
2. Injection-Molded Plastic Hood-Mounted Grille
3. Turn-Signal/Parking Lights
4. Recessed Single Headlight
5. Cab-Mounted Half-Fender

Fig. 1, Hood Features, With Hood-Mounted Grille

Less common are special application Business Class Trucks equipped with fixed-grille hoods, and trucks having fixed-grille hoods with dual engine access (butterfly) doors.

On these trucks, the grille mounts to the radiator support and does not move when the hood is tilted forward. This design provides engine access without interference problems from front-mounted sirens, lights, winches, etc.

On snow plow-equipped vehicles, the plow assembly often makes hood tilting impossible. The dual access door hood, with a hinged panel on each side of the vehicle, allows routine underhood service on these vehicles, even while the plow is installed. **See Fig. 2.**

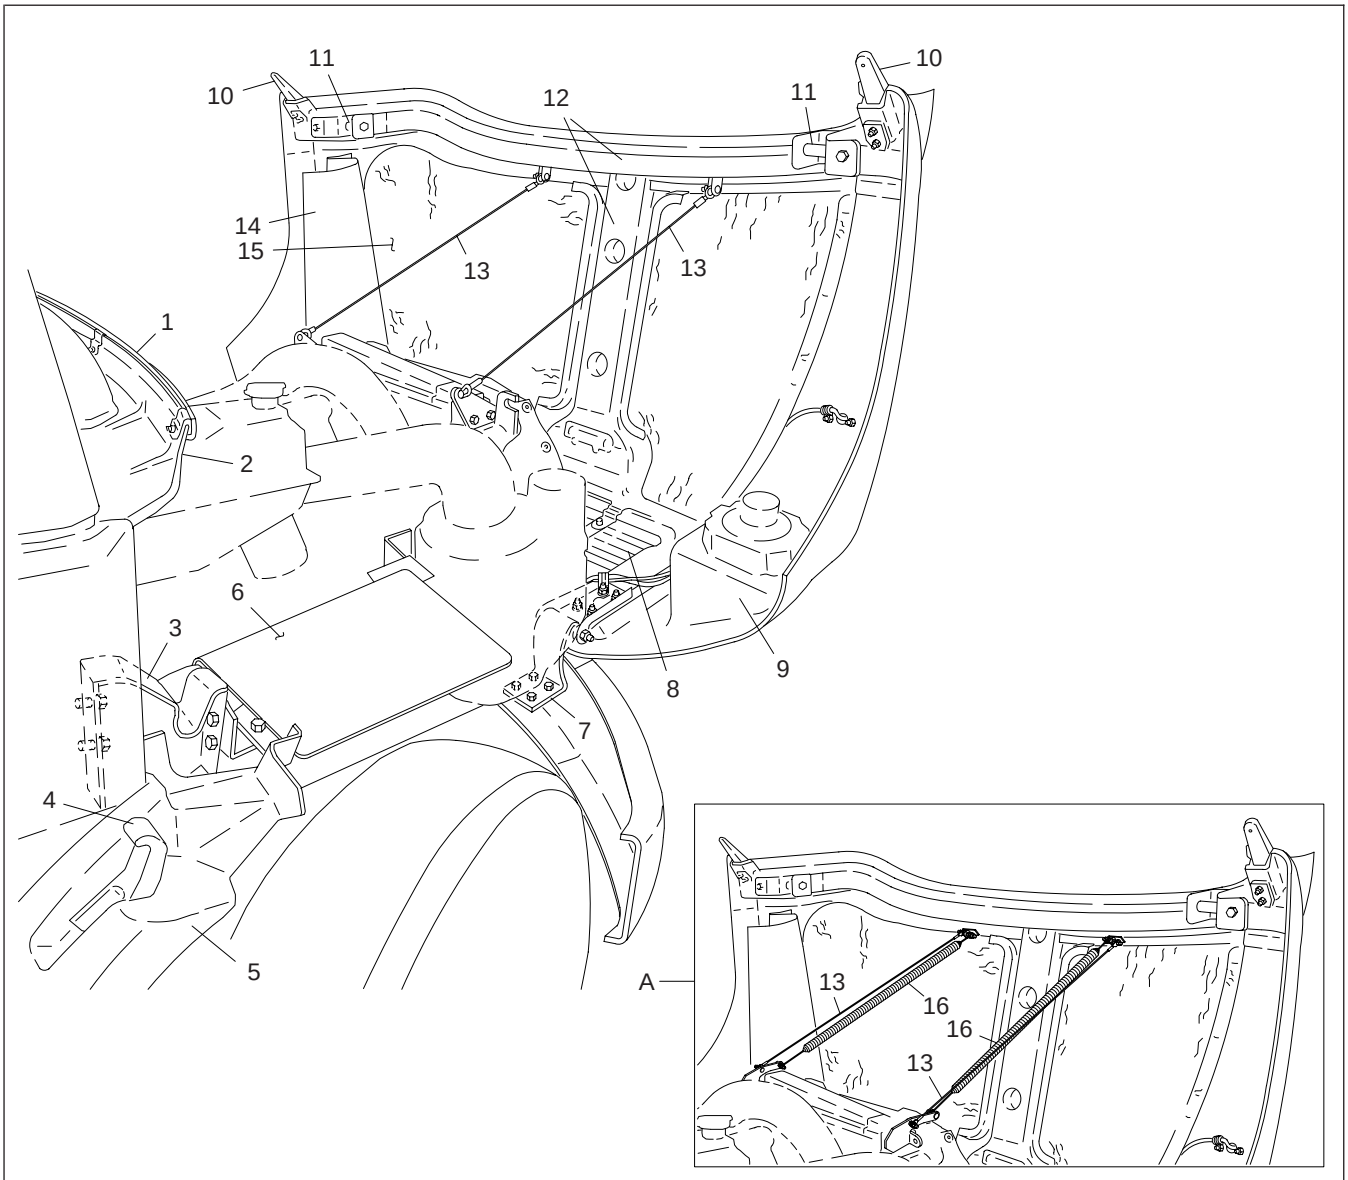
7. Recessed Hood-Tilt Handle
8. Access Door Latch
9. Cab-Mounted Half-Fender

Fig. 2, Hood Features, With Radiator-Mounted (fixed) Grille and Dual Engine Access (butterfly) Doors

The hood and half-fenders are compression molded using the preform molding process. The first step in this process is to produce a preform by spraying chopped glass fibers and resin binder in a controlled manner onto a screen that's the same shape as the male moulding die. The preform is then heated to cure the resin binder. Next, the preform is moved to a compression molding press. Resin is dispersed onto the preform; then the preform is placed onto the male half of a matched metal mold. As the halves of the mold close, the resin is distributed throughout the part, and is cured under heat and pressure.

After molding, the hood (or half-fender) is trimmed and prepared for painting. Before priming, the fiberglass reinforcements and metal parts are bonded to the hood.

General Information



At the front of the hood, brackets mounted directly behind the front bumper, at the outside of each frame rail, support the hood-hinge pivots. Stop cables limit forward travel of the hood. Newer production vehicles have a tilt-assist assembly in addition to the stop cables. **See Fig. 3.**

When in the operating position, the hood is supported at the front by the hood-hinge pivots and at the rear by hood support brackets which are attached to the cab. A groove in each bracket mates with pins attached to the inside of the hood, near each upper rear corner. The hood is held down with two rubber over-center latches, with part of the latch attached to the hood, and the other part attached to each half-fender. To prevent warm, under-hood air from entering the cab through the air conditioner/heater air-inlet, a hood seal attaches to the cowl panel, ahead of the windshield.

Both the front hood-hinge pivots and the rear hood support brackets are adjustable forward and backward, and up and down. The front pivots are also adjustable right and left.

Splash shields under the hood extend to the inboard side of the tires. The left-hand splash shield attaches to the hood, and the right-hand shield attaches to the frame and the cab bulkhead.

On the underside of the hood are several 1-inch-thick (25 mm) polyester polyurethane foam hood liners, with a polymer-film facing. The liners reduce engine noise emissions.

8. Well Nut

Fig. 1, Hood-Mounted Grille Installation

Grille Removal and Installation

REMOVAL

1. Apply the parking brakes.
2. With the hood in the normal, driving position, use a Torx screwdriver (T30) to remove the grille-to-hood screws.
3. Remove the grille.

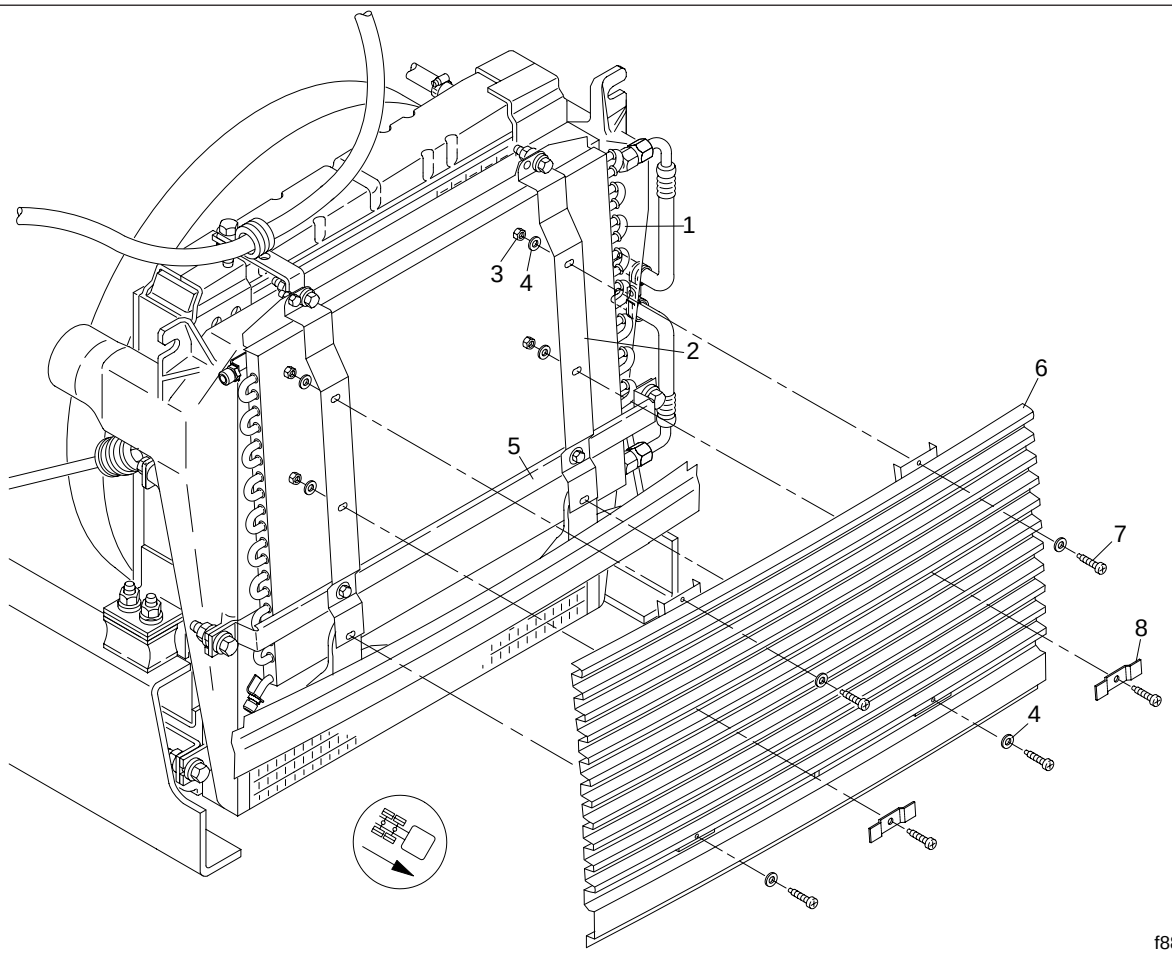
INSTALLATION

NOTE: If the grille is being replaced, transfer the nameplate and gasket to the new grille.

1. Place the grille in the hood opening and align the screw holes.
2. Install the screws and use a Torx screwdriver (T30) to tighten them securely.

Radiator-Mounted (Fixed) Grille (See Fig. 2)

REMOVAL



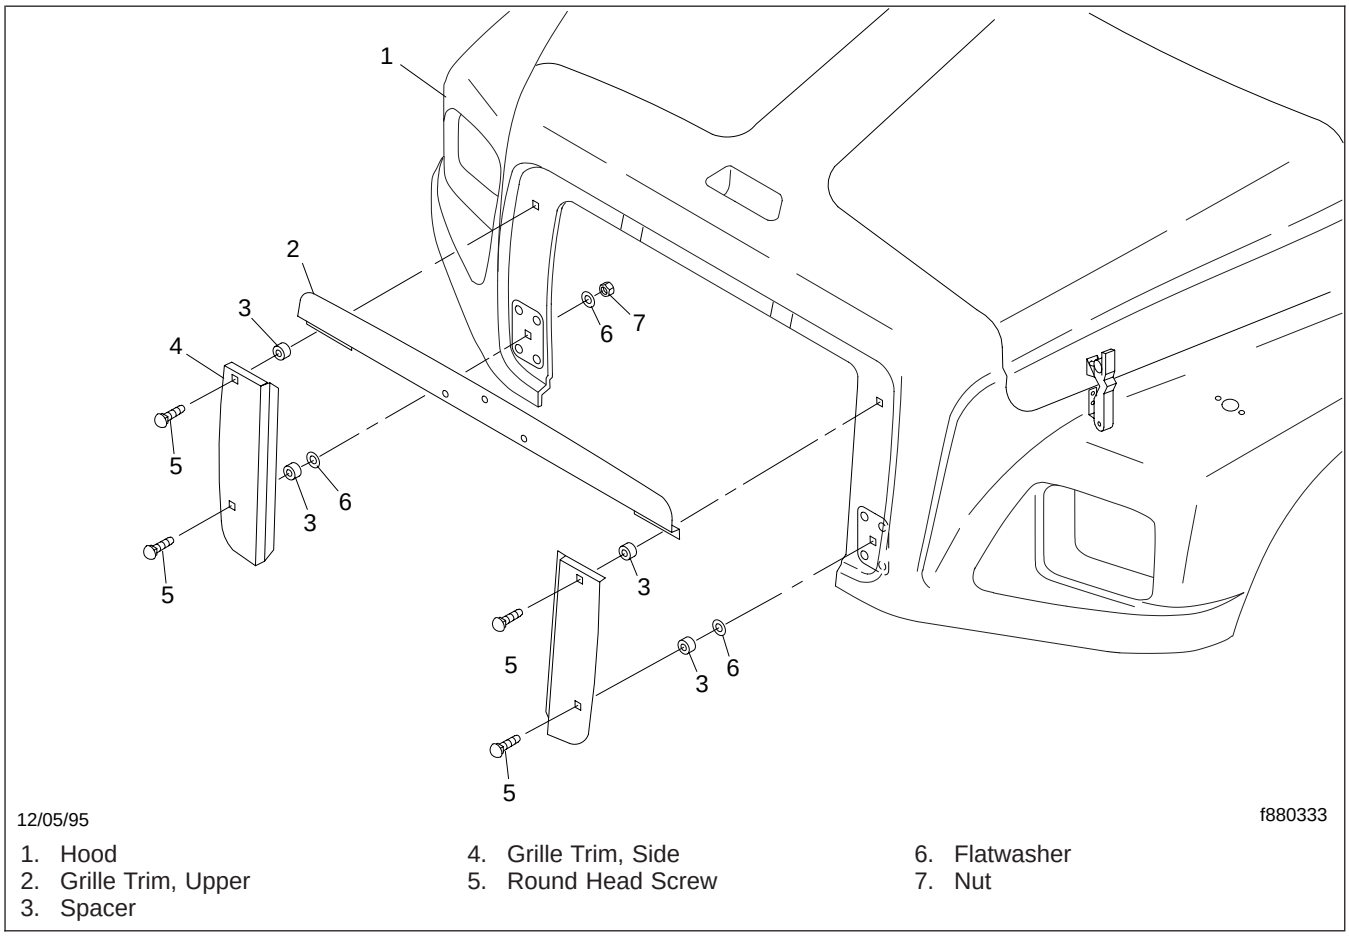
NOTE: The hood must be tilted forward to access grille fasteners. If equipment mounted on the front of the vehicle interferes with hood tilting, that equipment must be removed before attempting grille removal.

1. Apply the parking brakes.
2. Tilt the hood forward.
3. Loosen the grille retaining screws using a Phillips screwdriver, while holding the retaining screw nuts with a box wrench.
4. Remove the screws, grille retainer brackets, flatwashers, and nuts.
5. Remove the grille.

INSTALLATION

1. Position the grille against its mounting brackets and align the screw holes.
2. Insert the grille retaining screws, making sure to install flatwashers on the screws at the four corner positions and retainer brackets on the screws at the middle positions.
3. Install flatwashers and nuts on the retaining screws and tighten the screws securely using a Phillips screwdriver.

Grille Removal and Installation



NOTE: Hood assembly removed for clarity. Also, grille shown is for vehicles without front PTO. On PTO-equipped vehicles, the grille is shorter.

Grille Trim Removal and Installation (Fixed-Grille Models)

On fixed-grille versions of the Business Class Truck, three pieces of argent colored trim border the top and sides of the grille. These trim pieces are made of formed sheet steel and mount to the hood assembly. **See Fig. 1.**

1. Hood
2. Grille Trim, Upper
3. Spacer
4. Grille Trim, Side
5. Round Head Screw
6. Flatwasher
7. Nut

Fig. 1, Radiator-Mounted (fixed) Grille Trim Installation

Removal

NOTE: The hood must be tilted forward to access grille trim fasteners. If equipment mounted on the front of the vehicle interferes with hood tilting, that equipment must be removed before attempting grille trim removal.

1. Apply the parking brakes.
2. Tilt the hood forward.
3. Loosen the grille trim retaining nuts using a socket wrench, while holding the retaining screw head against the grille trim piece with your hand. (The round-head retaining screws have square shanks, which mate with square holes in the trim pieces.)
4. Remove the screws, spacers, flatwashers, and nuts.
5. Remove the grille trim.

Installation

NOTE: If the upper trim piece is being replaced, transfer the nameplate and gasket to the new trim piece.

Grille Trim Removal and Installation (Fixed-Grille Models)

1. Insert the round-head screws in the side trim pieces, and install spacers and flatwashers on the screws. **See Fig. 1.**
2. Position the upper trim piece against the hood and align the screw holes.
3. Install the grille trim side pieces on the hood.
4. Install flatwashers and nuts on the retaining screws and tighten the nuts securely using a socket wrench.

Splash Shield Removal and Installation

Removal

1. Apply the parking brakes and chock the rear tires.
2. Tilt the hood.
3. To remove the *right-hand splash shield*, remove the 1/4-turn stud that attaches the rear of the shield to its bracket on the rear hood-support bracket. See **Fig. 1**. Lift the rear of the shield about 1 in (25 mm), then pull it rearward about 1 in (25 mm). Lift it over the tire.

   To remove the *left-hand splash shield*, pull the upper edge of the splash shield sound-absorbent liner down far enough to access the splash shield rivets. Then use a drill and bit to remove the rivets and fender washers that attach the shield to the hood. See **Fig. 2**. Remove the shield.

Installation

1. To install the *right-hand splash shield*, position the tabs on the front mounting bracket in the slots in the front of the splash shield, then lower the rear of the shield until the tab on the rear inner mounting bracket is installed in the slot in the lower edge of the shield. See **Fig. 1**. Install the 1/4-turn stud.

   To install the *left-hand splash shield*, position the shield against the reinforcement under the hood, and align the rivet holes. See **Fig. 2**. At each of the six holes, position the fender washer, then install a pop rivet to attach the shield to the reinforcement. Push the splash shield sound-absorbent liner into place.
2. Lower the hood, and remove the chocks.

Splash Shield Removal and Installation

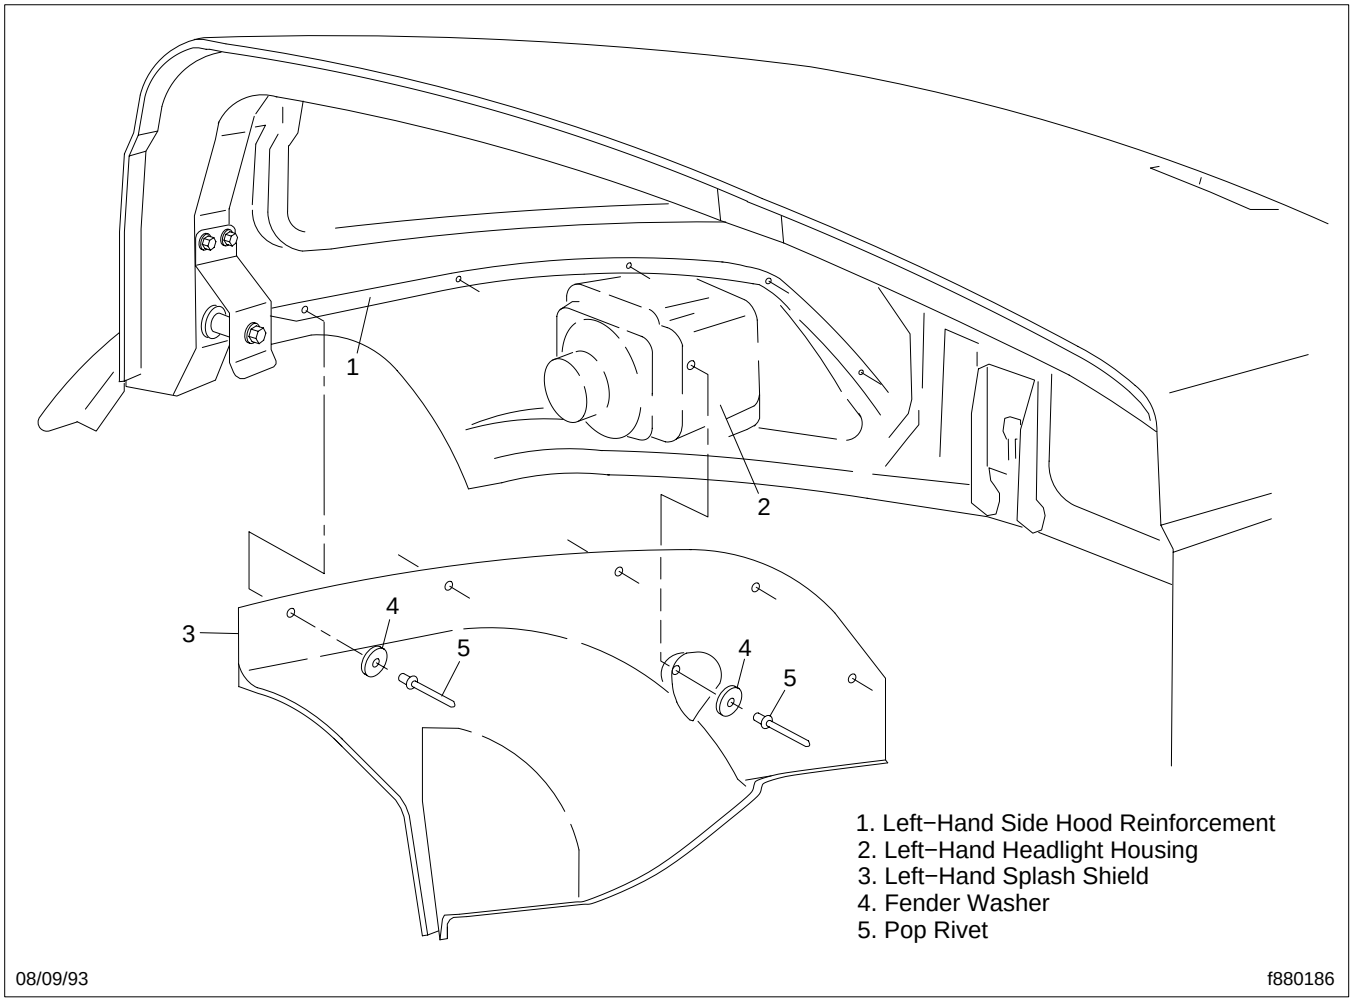

Fig. 2

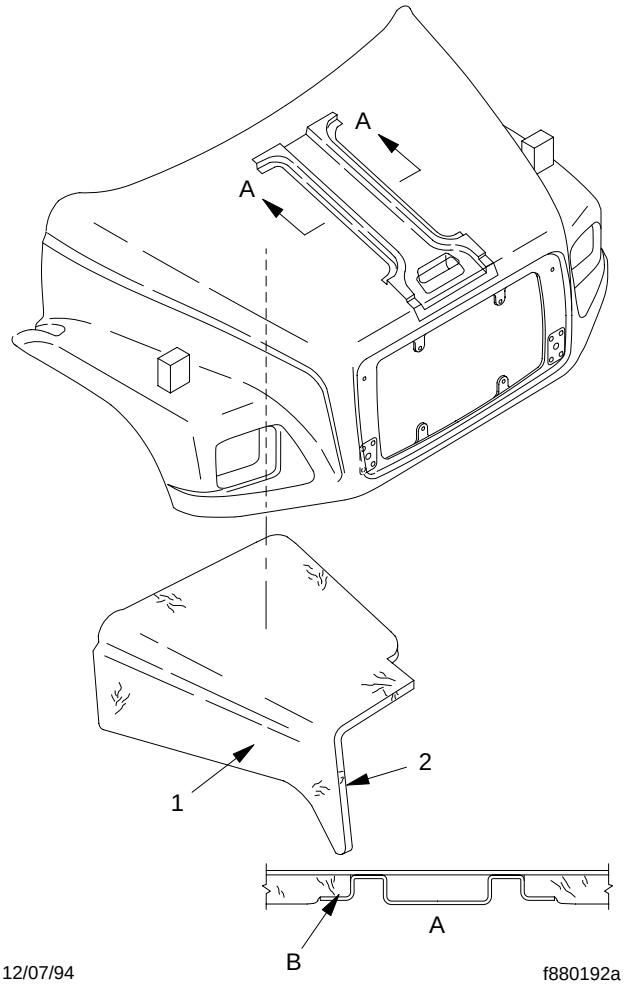
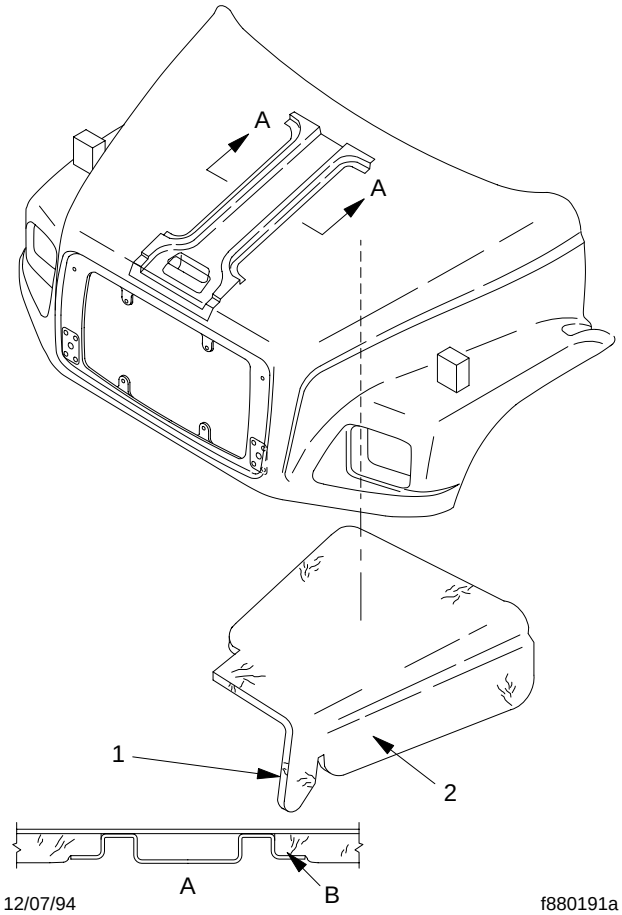


Hood Liner Replacement
(See Fig. 1 and Fig. 2)

Some Business Class Trucks equipped with diesel engines have noise insulation liners fitted to the underside of the hood. The liners are made of 1-inch-thick (25 mm) foam and have a polymer facing on both sides.

On vehicles equipped with a one-piece hood, 2 liners are attached to the underside of the hood.

On vehicles equipped with a dual access door hood, a liner is fitted to each access door.



1. Apply the parking brakes and chock the rear tires.
2. If replacing either side hood liner **(see Fig. 1 or Fig. 2),** remove the grille; if necessary, refer to **Subject 100.**
3. Tilt the hood.
4. Remove the entire liner that is being replaced.
5. Use a wire brush to clean the area that was covered by the liner; then, thoroughly steam clean the area, and allow it to air dry.
6. Push the pressure-sensitive-adhesive side of the new liner into place, starting at one edge and working the liner into place from that edge toward the opposite edge. If installing either side hood liner, start by pushing the inboard edge of the liner into the center hood reinforcement. **See Fig. 1** or **Fig. 2,** Section A-A.
7. Lower the hood. If it was removed, install the grille; refer to **Subject 100** for information.
8. Remove the chocks from the tires.

A. Cross-section view, hood center reinforcement
B. First, push the inboard edge of the liner into the center hood reinforcement.
1. Pressure-Sensitive Adhesive Backing
2. Polymer Film Facing

Fig. 1, Right-Hand Side Hood Liner

Hood Liner Replacement

A. Cross-section view, hood center reinforcement
B. First, push the inboard edge of the liner into the center hood reinforcement.
1. Polymer Film Facing
2. Pressure-Sensitive Adhesive Backing

Fig. 2, Left-Hand Side Hood Liner

Removal (See Fig. 1 and Fig. 2)

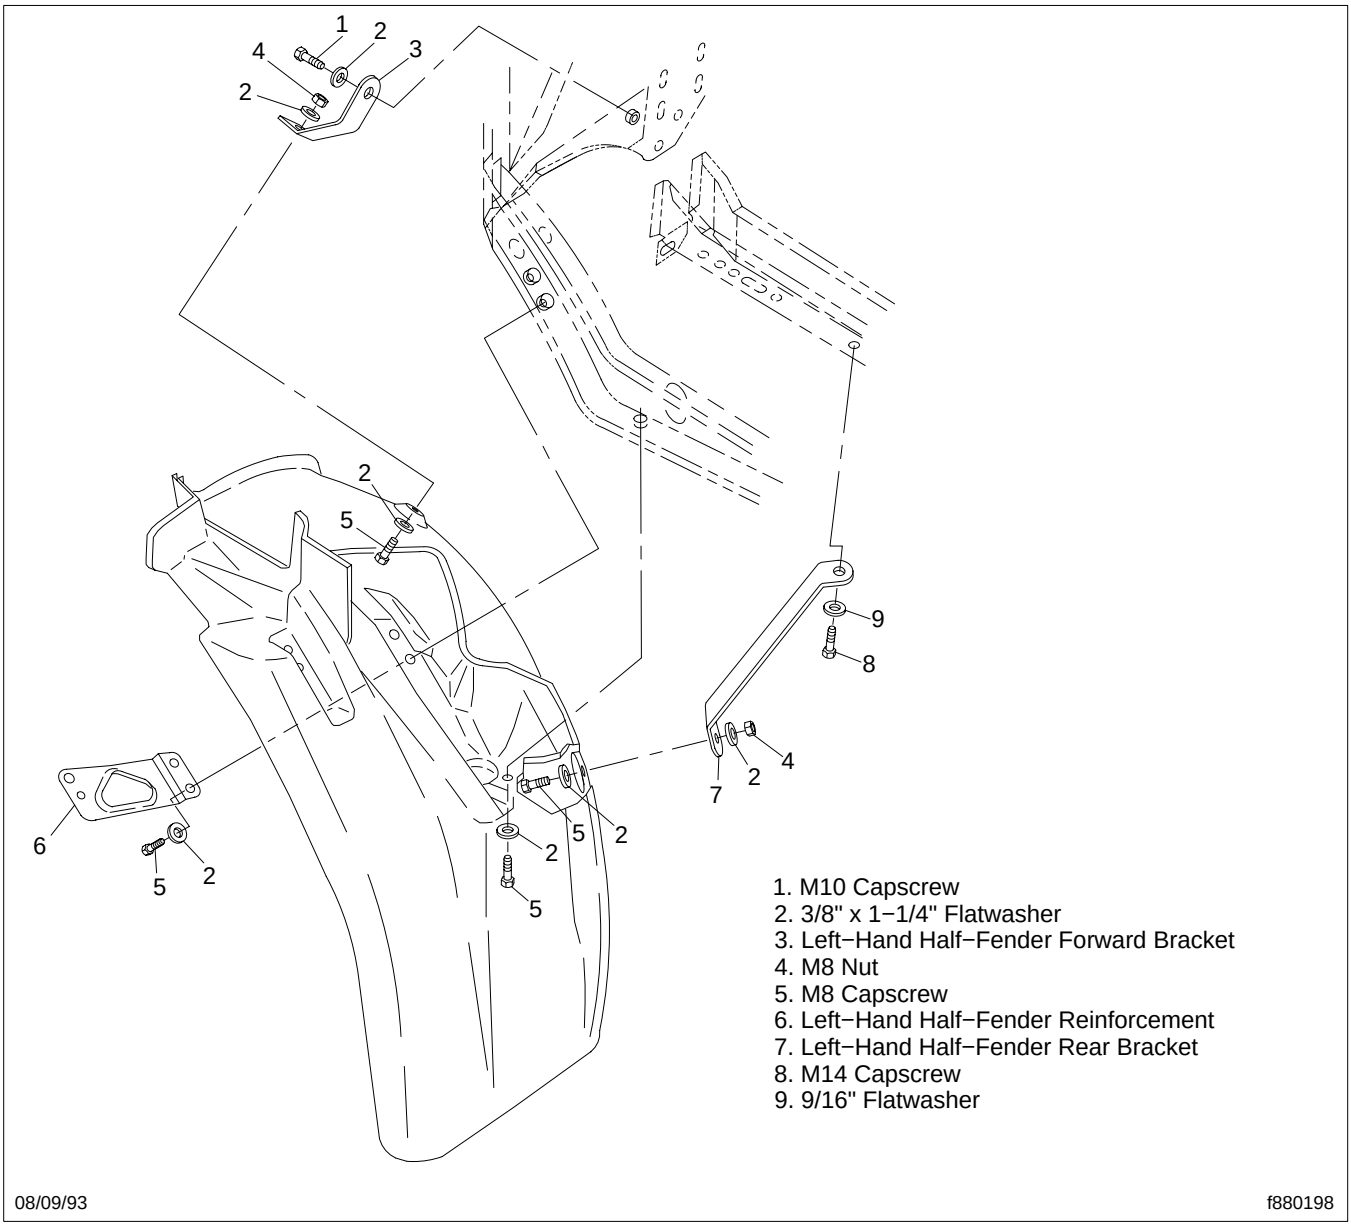


Fig. 1, Left-Hand Half-Fender Installation

1. Apply the parking brakes and chock the rear tires.
2. Tilt the hood.
3. Remove the fasteners that attach the half-fender to the forward and rear brackets.
4. Remove the fasteners that attach the half-fender to the cab. Remove the half-fender.

Half-Fender Removal and Installation

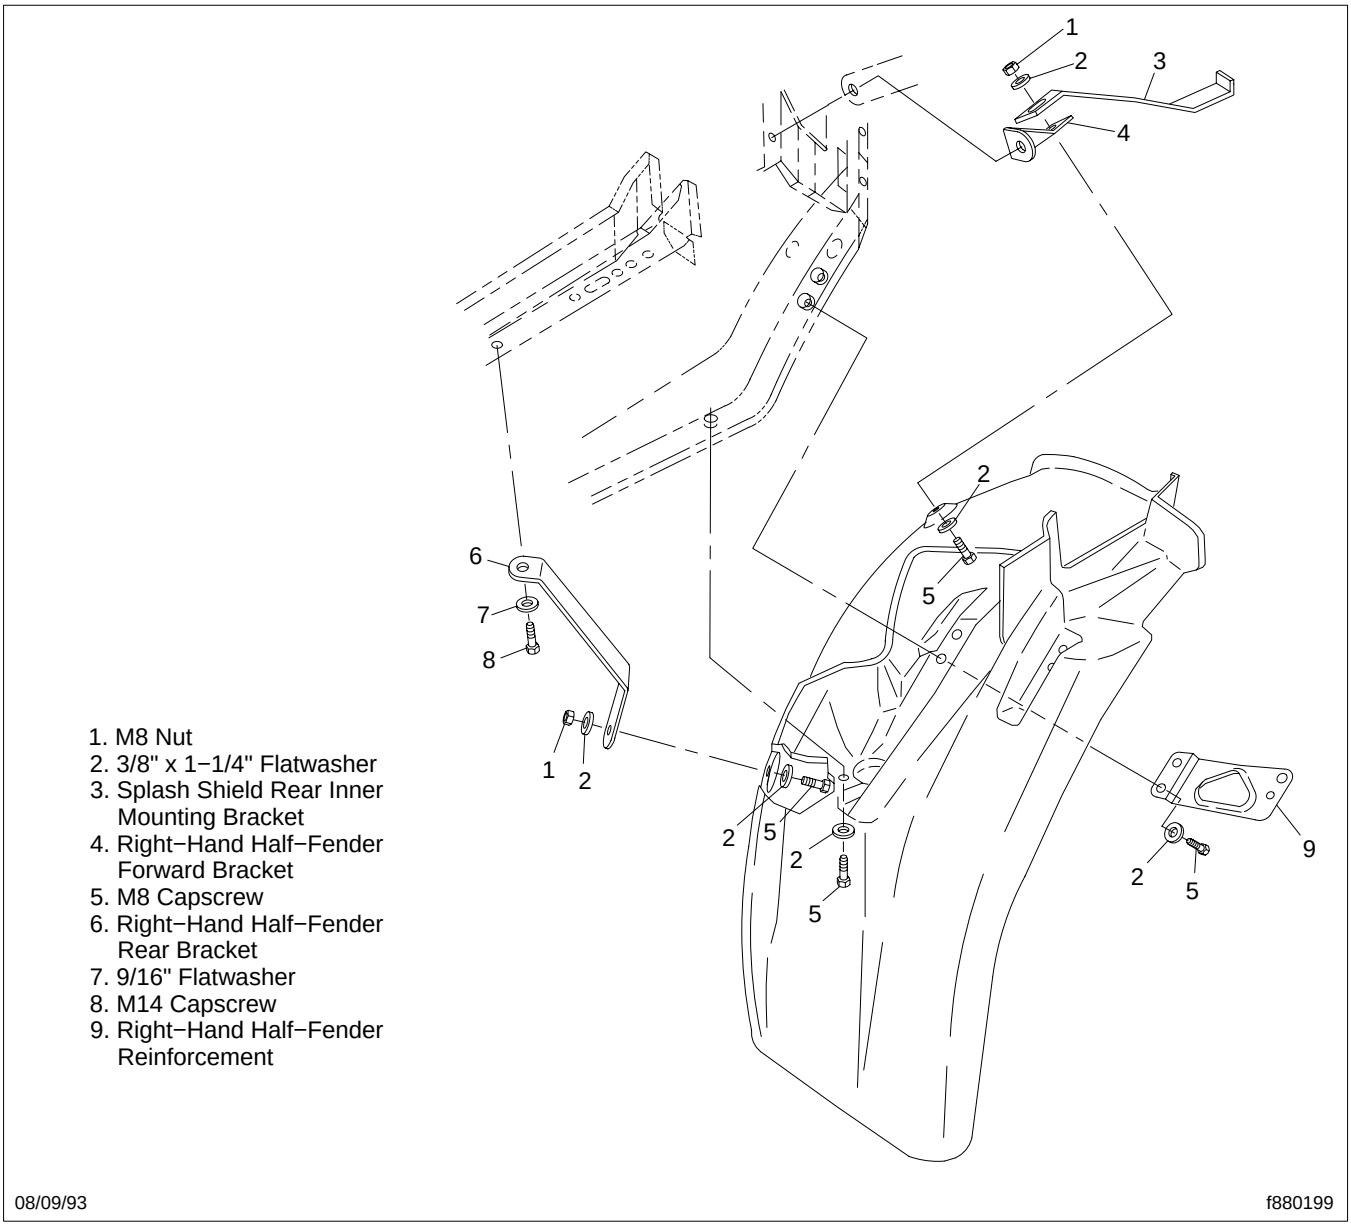

Fig. 2, Right-Hand Half-Fender Installation

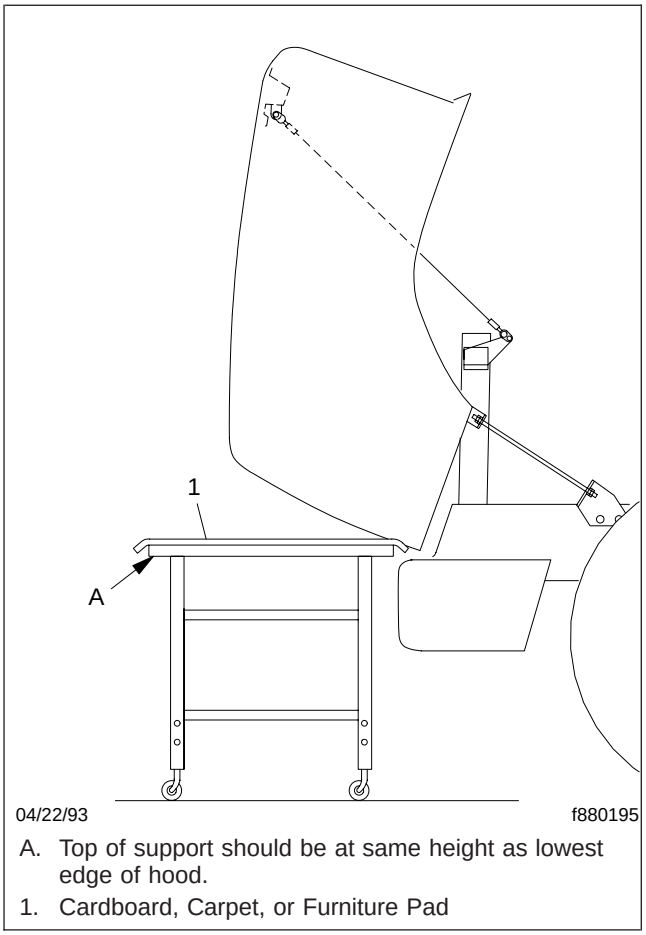
5. If the half-fender is being replaced, remove the hood latch bracket and half-fender reinforcement for installation on the new half-fender. Also, if replacing a right-hand half-fender, remove and save the splash shield rear inner mounting bracket.

Installation (See Fig. 1 and Fig. 2)



1. If the half-fender was replaced, install the hood latch bracket, half-fender reinforcement, and (if so equipped) the splash shield rear inner mounting bracket on the new half-fender. Tighten the 1/4–20 locknuts 1080 N·cm (96 lbf·in).

2. Position the new half-fender against the cab, and install, finger-tight, the fasteners that attach the fender and fender reinforcement to the cab.
3. Install the fasteners that attach the half-fender to the forward and rear brackets.
4. Tighten all M8 capscrews and nuts 21 N·m (16 lbf·ft).
5. Lower the hood, and remove the chocks.

Removal

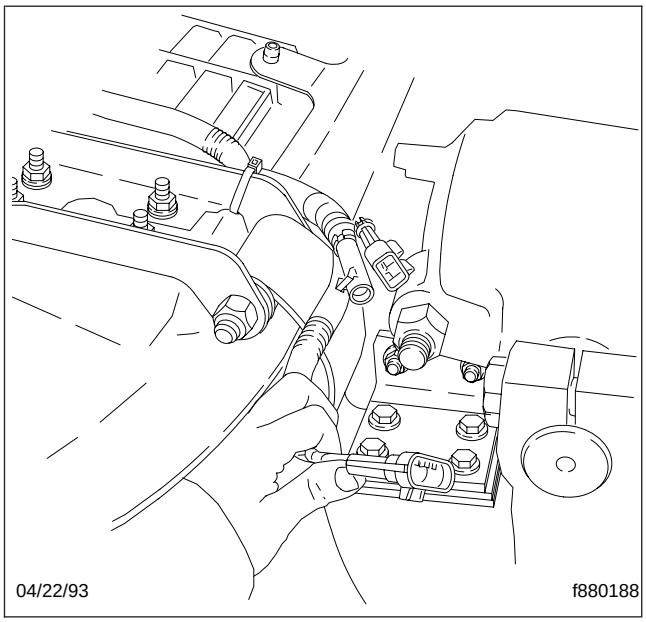
1. Apply the parking brakes and chock the rear tires.
2. Tilt the hood.
3. Place a support between the floor and the front of the hood. See **Fig. 1**.

   The support should be as wide and as long as the front of the hood, and should be the same height as the lowest edge of the hood. Place cardboard, carpet, rags, or other padding on top of the support to protect the hood.

A. Top of support should be at same height as lowest edge of hood.
1. Cardboard, Carpet, or Furniture Pad

Fig. 1

4. Disconnect the headlight and turn-signal/parking light connectors behind the bumper on both sides of the vehicle. See **Fig. 2**.



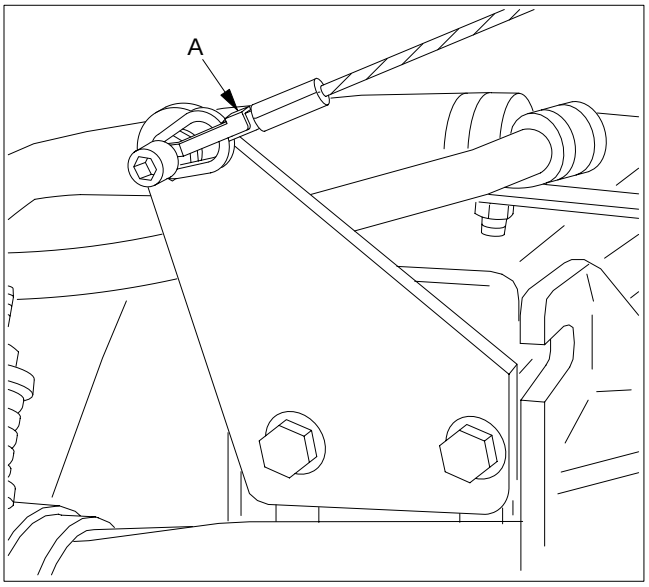


Fig. 2

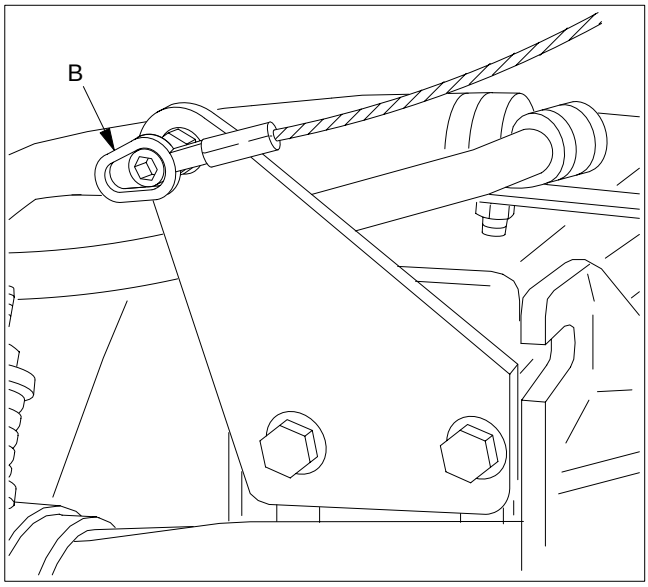
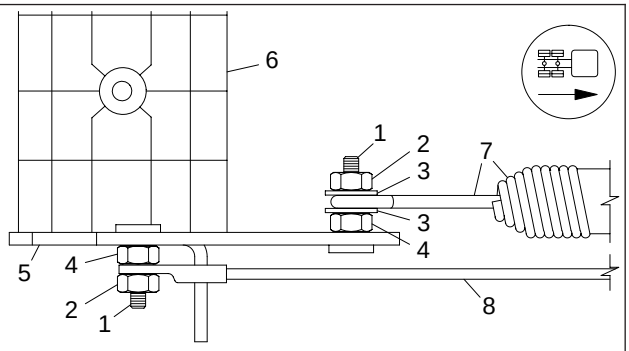


5. Lower the hood until it is balanced over the pivots to relieve tension on the stop cables (and, if so equipped, the tilt-assist assemblies). Have a co-worker hold the hood in this position.
6. Disconnect the stop cables, and if so equipped, the tilt-assist assemblies from the brackets on the radiator. See **Fig. 3** and **Fig. 4**.
7. Carefully tilt the hood onto the support.
8. Remove the prevailing torque locknuts from the hood-pivot bolts. See **Fig. 5**. Drive out both hood-pivot bolts.
9. Carefully roll or slide the hood support away from the vehicle; don't try to lift the hood.

Installation

1. With the hood in the forward-tilt position and resting on the support at about the same height as the top of the bumper, move the support and hood into alignment with the front of the vehicle. Don't try to lift the hood.
2. Align the bolt holes of the hood hinge brackets with those in the lower hood hinges. Push the hood-pivot bolts into place from the inboard side. See **Fig. 5**. Install the prevailing torque locknuts, then tighten them 130 lbf·ft (176 N·m).

Hood Removal and Installation



04/22/93 f880189

A. Remove this keeper.

B. Remove the cable eye from the allen-head bolt.

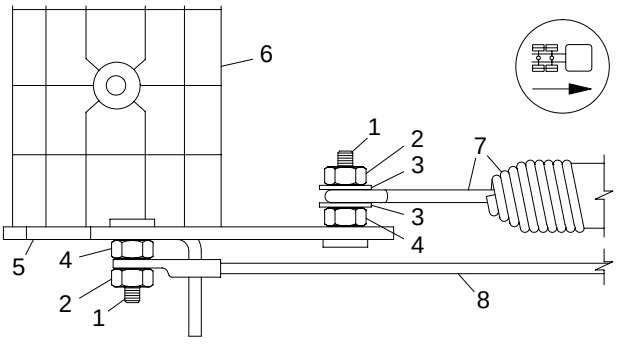
2. Locknut
3. Washers
4. Nut
5. Bracket
6. Radiator
7. Tilt-Assist Assembly
8. Stop Cable

Fig. 4, Top View

3. Lower the hood until it is balanced over the pivots, then have a co-worker hold the hood in this position.
4. Connect the stop-cable assemblies to the brackets on top of the radiator. If so equipped, install the keepers to prevent the cable eyes from coming off the ends of the allen-head bolts. See **Fig. 3**.

   If equipped with tilt-assist assemblies, install each stop cable on the stud farthest back on the radiator bracket. Install locknuts (**Fig. 4**), tighten them until all the parts are flush against each other, then back off the locknuts 1/4 turn.

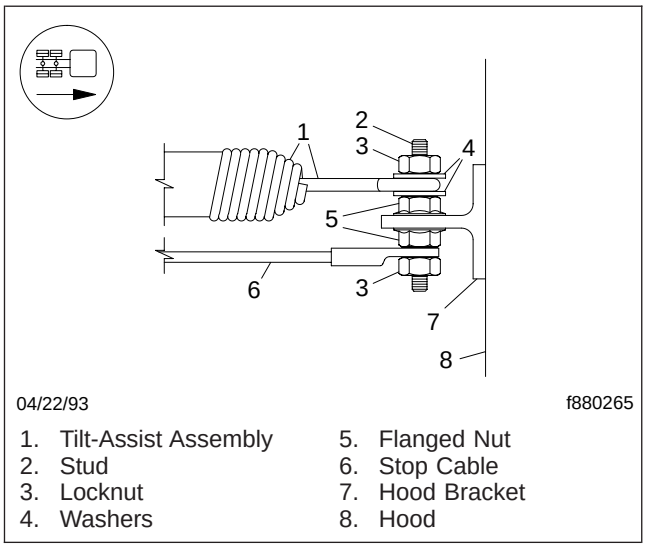
   Install each tilt-assist assembly to the forward stud on the radiator side-channel brackets, using a washer on each side of the tilt-assist cable hook, then a locknut. See **Fig. 4**. Tighten the locknuts until all the parts are flush against each other, then back off the locknuts 1/4 turn.
5. Remove the hood support from the front of the vehicle and tilt the hood all the way open.
6. Connect the headlight and turn-signal/parking light cables on both sides of the vehicle.
7. Lower the hood. Check the hood adjustment, and adjust the hood if needed. See **Subject 150** for instructions.
8. Remove the chocks from the tires.



04/22/93 f880190

Fig. 5

Replacement



1. Apply the parking brakes and chock the rear tires.
2. Tilt the hood.
3. Remove the tilt-assist assembly.
   - 3.1 Loosen and remove the locknut and washer holding the tilt-assist assembly to the bracket on the radiator side-channel. See **Fig. 1**.
   - 3.2 Loosen and remove the locknut holding the tilt-assist assembly to the stud on the hood bracket. See **Fig. 2**.
4. Remove the old tilt-assist assembly from the vehicle.

5. Bracket
6. Radiator
7. Tilt-Assist Assembly
8. Stop Cable

Fig. 1, Top View

5. Install the new tilt-assist assembly.
   - 5.1 If there is none present, install a washer on the forward stud on the radiator side-channel bracket. Hook one end of the new tilt-assist assembly over the stud. See **Fig. 1**.
   - 5.2 Install a second washer and locknut on the stud; then tighten the locknut until all parts are flush against each other. Back off the nut 1/4 turn, to allow the tilt-assist assembly to rotate.
   - 5.3 If there is none present, install a washer on the stud in the hood bracket. Hook the other end of the tilt-assist assembly over the stud .See **Fig. 2**.
   - 5.4 Install a second washer and locknut on the stud; then tighten the locknut until all the parts are flush against each other. Back off the nut 1/4 turn to allow the hood tilt-assist assembly to rotate.
6. If replacing both tilt-assist assemblies, repeat the procedure for the other side of the vehicle.
7. Lower the hood. Check the hood adjustment, and adjust the hood if needed. See **Subject 150** for instructions.
8. Remove the chocks from the tires.

2. Stud
3. Locknut
4. Washers
5. Flanged Nut
6. Stop Cable
7. Hood Bracket
8. Hood

Fig. 2, Top View

Adjustment

1. Drive the vehicle back and forth to settle the frame and suspension. Park the vehicle on a flat, level surface.
2. With the hood in the operating position, and both hood latches latched, check the gap between the top of the bumper and the bottom edge of the hood on both sides. The edges should be parallel. **See Fig. 1.**

   If the edges *are parallel*, proceed to the next step.

   If the edges are *not* parallel, adjust the height of the front of the hood.

   2.1 With the hood latched, on the side of the hood that's low, loosen the two sets of locknuts and capscrews that attach the hood-pivot support bracket to the frame rail. **Refer to Fig. 2** , Refs. 3 and 9.

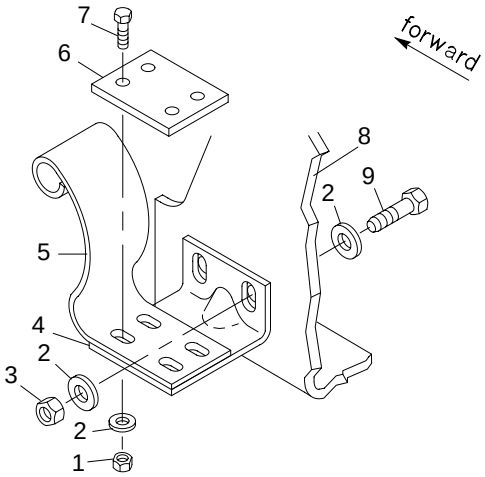
   2.2 Raise that side of the hood until both sides are parallel. From its lowest to its highest position, each hood-pivot support bracket will adjust 9.0 mm (11/32 in). Tighten the fasteners 95 N·m (70 lbf·ft).

   2.3 If you can't move that side up enough to make both sides parallel, loosen the hood-pivot support bracket fasteners on the other side of the hood, and lower that side of the hood until both sides are parallel. Tighten the fasteners 95 N·m (70 lbf·ft).

   Go to the next step.
3. With the hood in the operating position, and both hood latches latched, measure the gap between the rear vertical edge of the hood and the front outer vertical edge of the cowl at both sides of the vehicle. **Refer to Fig. 3 .** The gap should be between 10 and 16 mm (3/8 to 5/8 in).

   If the gap on both sides is within specifications, go to the step for checking the alignment of the hood/cab character lines.

   If the gap is *not* within specifications on one or both sides, adjust the fore-and-aft position of the hood.



"A" must equal "B"

08/09/93 f880183

Fig. 1

3.1 Determine the amount that the hood must be moved at one or both sides, to correct the gap.

3.2 Unlatch and tilt the hood.

8. Frame Rail
9. 1/2−13 Capscrew

08/09/93 f880184

Fig. 2

3.3 At the side(s) of the hood that must be moved, loosen the three capscrews that attach the rear hood support assembly to

Hood Alignment Adjustment

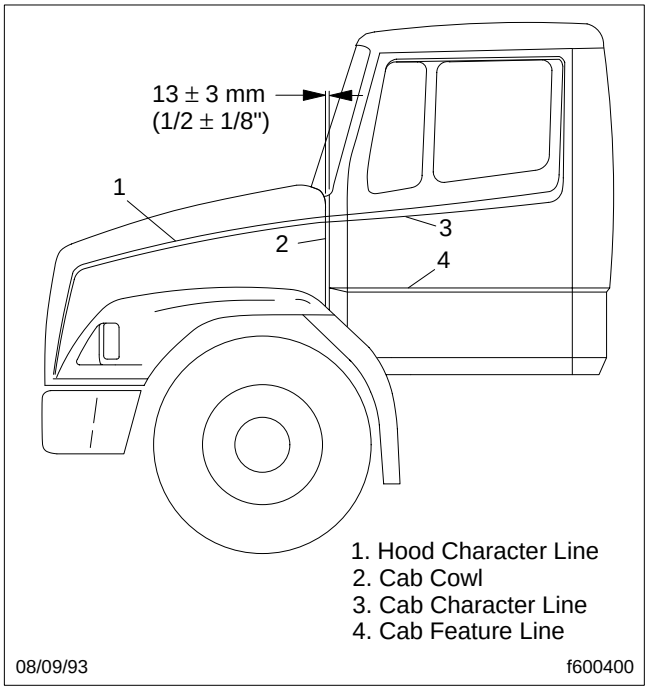

Fig. 3

the hood, just enough to allow the hood to slide fore and aft for adjustment. **Refer to Fig. 4** , Ref 3.

On the side(s) to be moved, loosen the four locknuts and capscrews that attach the lower hood-hinge pivot to the hood-pivot support bracket. **Refer to Fig. 2** , Refs. 1 and 7. Slide that side(s) of the hood fore or aft the amount determined earlier.

Tighten the lower hood-hinge pivot locknuts 55 N·m (40 lbf·ft).

3.4 Return the hood to the operating position, and fasten the latches.

3.5 Again, check the gap at both sides of the hood. **Refer to Fig. 3 .**

If the gap is *not* within specifications, repeat the above procedure.

When the gap is within specifications at both sides of the hood, go to the next step.

4. With the hood in the operating position, and both hood latches latched, check alignment of the cab and hood character lines. **Refer to Fig. 3 .** Or, if so equipped, check alignment of the cab and hood paint stripes.

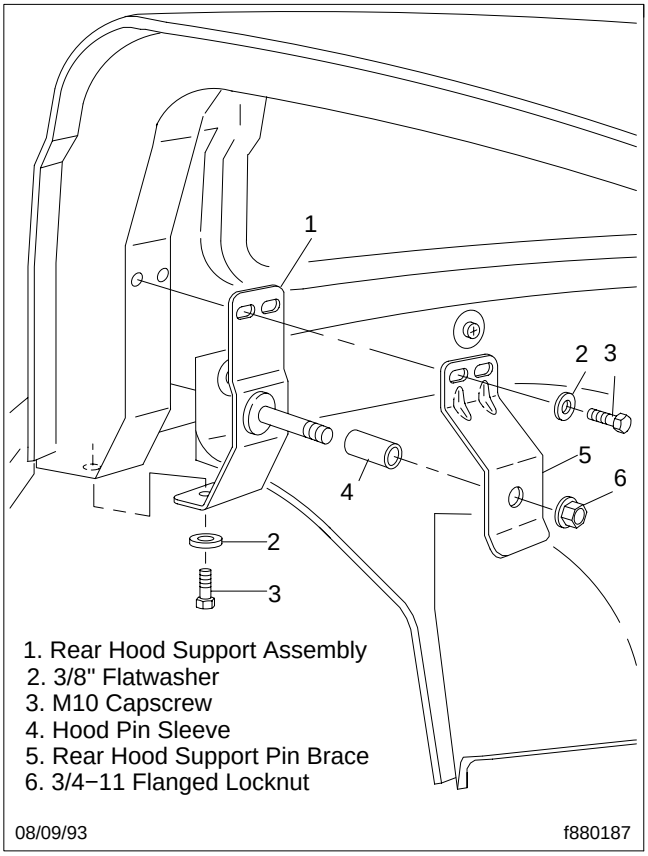

Fig. 4

If the character lines (or paint stripes) are aligned, go to the step for tightening the rear hood assembly capscrews.

If the character lines (or paint stripes) are misaligned, adjust the up-and-down position of the rear of the hood.

4.1 Unlatch and tilt the hood.

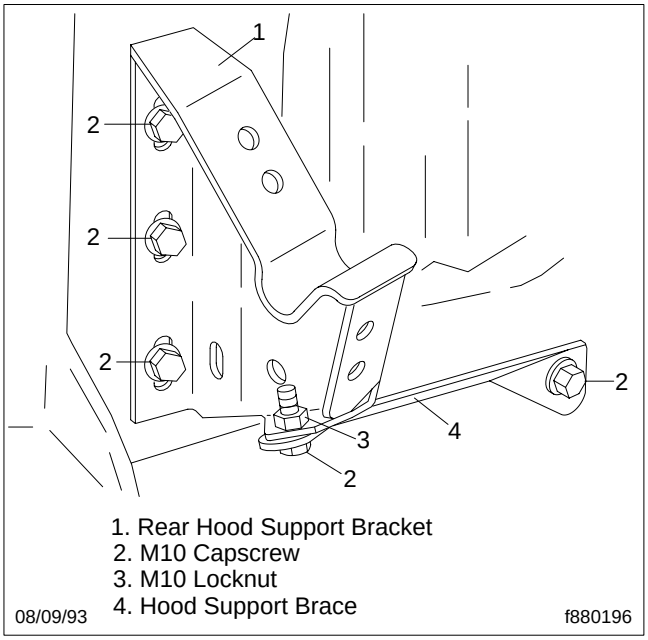
4.2 If not already done, at the side(s) of the hood that must be moved, loosen the three capscrews that attach the rear hood support assembly to the hood, just enough to allow the hood support assembly to slide fore and aft for adjustment. **Refer to Fig. 4 .**

NOTE: Complete the steps for up-and-down adjustment of one side, before doing the other side.

4.3 At the side of the hood that must be moved, loosen the capscrews that attach the rear hood support bracket and hood support brace to the bulkhead. Also, loosen the locknut that attaches the hood support brace to the rear hood support bracket. **Refer to Fig. 5 .**

4.4 Push the rear hood support bracket upward as far as it will go.

4.5 Return the hood to the operating position, but latch only the side that is *not* being adjusted.



4.6 At the side of the hood that's being adjusted, push down on the top of the hood until the character lines (or paint stripes) are aligned.

4.7 Carefully tilt the hood, without changing the position of the rear hood support bracket. Tighten 55 N·m (40 lbf·ft) the capscrews and locknuts for the rear hood support bracket and the hood support brace. **Refer to Fig. 5 .**

NOTE: If the other side of the hood needs to be adjusted, repeat required steps for up-and-down adjustment.

4.8 Go to the next step.

5. If loosened, tighten the capscrews that attach the rear hood support assembly to the hood 55 N·m (40 lbf·ft). **Refer to Fig. 4 .**

1. Rear Hood Support Bracket
2. M10 Capscrew
3. M10 Locknut
4. Hood Support Brace

Fig. 5

Repair Safety Precautions

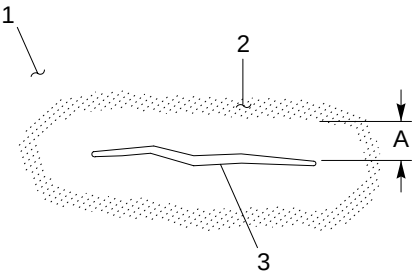
Before performing any fiberglass repairs, read the following precautions. Observe any additional precautions given by the manufacturers of the repair materials used.

1. All of the raw materials used in repairing fiberglass are harmful to the eyes and could cause blindness. Wear goggles or other protective eye shields to reduce the chances of splash contacting your eyes.
2. Wear protective gloves, as some people may have skin sensitivity to resin. Also, don't allow the hardener to contact your skin; the hardener can be a skin irritant.

IMPORTANT: In case the hardener or resin contacts your skin, wash with soap and water. If the hardener or resin should contact your eyes, rinse with plenty of water (15 minutes), and call a doctor.

3. When working with fiberglass materials, wear old clothing, since the resin may damage the cloth. Wash the clothing before wearing it again.
4. Most of the liquids involved in fiberglass repair and cleanup (especially when using acetone as a solvent) are flammable; some are also toxic. Don't perform repairs in areas where exposed (or stored) flammable liquids may contact an open flame or any burning material, such as a cigarette. Don't perform repairs in areas that are not well ventilated.

⚠ WARNING



WARNING: Do fiberglass repairs in a safe workshop area to prevent severe personal injury due to explosion of flammable liquids or breathing of toxic fumes.

5. Do not use electric tools when the fumes of flammable solvents are present. The heat or sparks generated by the tools could create a fire hazard.
6. When grinding or sanding fiberglass surfaces, wear goggles or other protective eye shields, and also use an air purifying respirator, either a throwaway type or one with a replaceable particulate filter(s). Don't breathe grinding dust or particles, otherwise irritation may occur. Also, during grinding and sanding operations, wear a disposable (paper) shop coat to keep dust and fiber slivers off your clothing.
7. Because fiberglass dust can shorten the life of electrical units, air-powered tools are preferred (for frequent use).
8. Unless fiberglass repairs are done on a regular (daily) basis, don't save leftover liquids. If liquids must be saved, store them in cool, dark areas, away from direct sunlight.

Surface Damage Repair

Surface damage refers to scratches, chips, or nicks on the outer surface of the hood or half-fender. Use the following instructions to repair surface damage:

1. Examine the damaged area. If there are cracks, see if they go all the way through the hood or half-fender. If they do, see "Structural Damage Repair" for instructions.
2. Clean the area with xylene, acetone, or an equivalent grease- and wax-removing solvent. Inspect the area closely.
3. Using 220-grit or finer sandpaper, remove all of the paint around the damaged area to a distance of about 1-1/2 inches (4 cm). See **Fig. 1**.

A. Remove paint and primer 1-1/2 inches (4 cm) around the damaged area. Use 220-grit or finer sandpaper.

1. Paint
2. Primer
3. Scratch

Fig. 1, Damaged Area with Paint and In-Mold Coating Removed

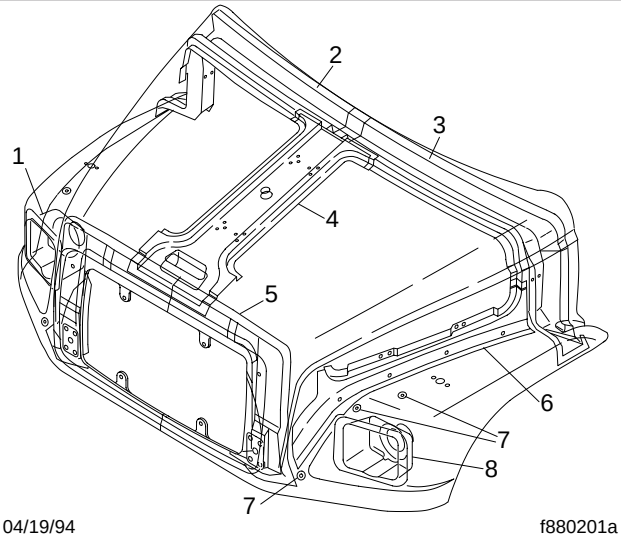
4. Using an air nozzle, blow off all dust.

5. Apply Ashland Pliogrip 7775L self-leveling urethane adhesive over the non-coated area and spread a thin layer using a squeegee applicator. Cover the entire damaged area, overlapping onto the painted surface. Leave a crowned excess of adhesive, slightly higher than the painted surface.

NOTE: When using Ashland Pliogrip 7775L, dispense the required adhesive from the cartridge in a continuous bead of uniform size and a uniform green color. Discard the initial few inches of discolored bead.

6. After the adhesive dries (about 50 minutes), sand it with a hand-held disc pad. Use 320-grit or finer sandpaper. Feather the edges of the fill so there are no visible sharp edges.
7. Clean the area with compressed air. Mask the area, then spot prime and paint it. Use Sherwin Williams BB–11 black conductive primer. See **Group 98** for spot-painting instructions.

Structural Damage Repair



The Preform FRP (fiberglass reinforced plastic) hood consists of a one-piece hood and fender assembly. Inner reinforcements are bonded to the engine-side of the hood with a structural adhesive. See **Fig. 2**. If the hood is damaged, determine which parts are affected.

If there is damage to any of the reinforcements, the damage is not repairable. For example, if the grille area of the hood is damaged so badly that the reinforcement bonded inside the grille area is also damaged, replace the entire hood assembly.

If a joint between two reinforcements, or between a reinforcement and the hood skin, has separated and there is no damage at the joint area, the parts can be rebonded. Or, if a part of the hood skin is damaged and its adjoining reinforcement(s) aren't damaged, the reinforcement can be separated from the damaged part, the damaged part can be patched, and the reinforcement(s) rebonded in place.

If a half-fender has a small crack or hole, it can be repaired; if it has a puncture or large fracture, it must be replaced.

For rebonding parts, see "Hood Reinforcement Rebonding."

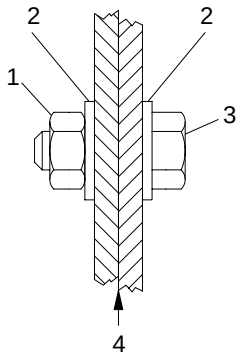
04/19/94 f880201a

1. Right-Hand Headlight Housing
2. Right-Hand Rear Hood Reinforcement
3. Left-Hand Rear Hood Reinforcement
4. Center Hood Reinforcement
5. Front Hood Reinforcement
6. Left-Hand Side Hood Reinforcement
7. Bonded Fasteners
8. Left-Hand Headlight Housing

Fig. 2, Hood Assembly Components

For damage in the form of a crack or small hole, see "Crack or Small Hole Repair."

For larger damaged areas, see "Puncture or Large Fracture Repair."



HOOD REINFORCEMENT REBONDING

1. If rebonding a joint that has partially separated, completely separate the reinforcement from the hood using a heat gun and putty knife. Remove as much of the old adhesive as possible. The heat gun will soften the adhesive and allow it to be peeled off the FRP.

   If the parts cannot be separated, work folded medium-grit sandpaper or a section of a steel hacksaw blade between the two surfaces to remove the old adhesive.
2. Scuff the surfaces with 80- to 220-grit sandpaper.
3. Clean the surfaces to be bonded with Ashland 6036 solvent or methylene chloride. Inspect the

area closely to be sure all of the old adhesive, dirt, water, grease, and oils are removed.

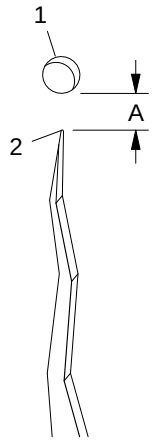
4. If replacing a large part, align the part on the hood and clamp it in place. Drill holes through the bonding surfaces and install clamping bolts in the holes. Use two washers, one on each side of the joint. See **Fig. 3**. There should be enough clamping bolts to hold the hood in place and keep the bonding surfaces together, or at least one bolt every 12 to 18 inches (30 to 45 cm). Remove the part for application of adhesive.

1. Nut
2. Washers
3. Bolt
4. Bond Joint

Fig. 3, Clamping Bolt at Bond Joint

5. Following the manufacturer's instructions, use enough adhesive to bond the parts together. Use Ashland Pliogrip urethane cartridge materials 7773 or 7779.

NOTE: When using Ashland Pliogrip 7773 or 7779, insert the two tubes of adhesive into the applicator and dispense a 3/8-inch (10 mm) diameter bead of uniform green-colored adhesive at the bonding surface. Discard any adhesive that does not show this uniform green color.



6. Within three and one half minutes (7773) or within 10 minutes (7779) of applying the bead, align the part on the hood and clamp it firmly in place. If it is a large part install the clamping bolts. Tighten the clamps or clamping bolts just enough to ensure that a uniform amount of pressure is applied along the seam. Ideally, the adhesive should be compressed to form a bondline one inch (25 mm) wide and 0.030 inch (0.76 mm) thick. This thickness can be ensured by sprinkling 0.030 inch (0.76 mm) glass beads into the adhesive before mating the parts.
7. Before it cures, remove any excess adhesive that squeezes out the edges of the bond.
8. Remove the clamps after the adhesive has cured for 30 minutes (7773) or for 60 minutes (7779).
9. If holes were drilled for clamping bolts, repair them using the instructions under "Crack or Small Hole Repair."
10. If necessary, prime and paint the repair area using the instructions under "Surface Damage Repair."

CRACK OR SMALL HOLE REPAIR

A crack (fracture) or small hole through the laminate requires repair with a fiberglass-reinforced patch.

1. Examine the damage to the hood or half-fender. Apply hand pressure all around the damaged area to check for any concealed damage.
2. If a sound-absorbent liner is present on the underside of the damaged area, peel away the liner to provide an adequate working area.
3. Clean the damaged area on both sides of the hood or half-fender with xylene, acetone, or equivalent grease- and wax-removing solvent. Inspect the area closely. All dirt, water, grease, and oils must be removed.
4. If repairing a crack, use a 1/8-inch (3-mm) diameter bit to drill a hole completely through the uncracked laminate 1/8 inch (3 mm) from each end of the crack, to prevent the crack from lengthening. See **Fig. 4**.
5. On the engine side of the hood (or underside of the half-fender), use a router bit (on a grinder or a drill) to grind away a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) outward from all sides of the damage. Taper the outside edge of the ground area. See **Fig. 5**.

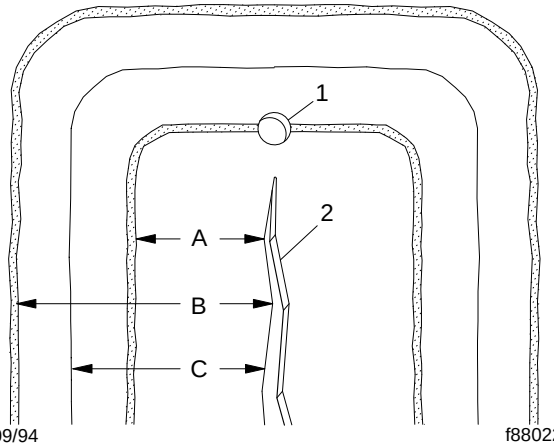
   If repairing a crack, grind outward to the drilled hole at the end of the crack, but not beyond. See **Fig. 6**, Ref. A.
6. Use 80- to 220-grit sandpaper to scuff an area at least one inch (25 mm) away from the fracture on all sides. Be sure to scuff thoroughly, since

05/04/94 f880222b

A. 1/8 inch (3 mm)
1. Drilled 1/8-inch (3-mm) Hole
2. End of Crack

Fig. 4, Drilling a Hole to Prevent the Crack From Lengthening

05/04/94 f880227b



A. Grind a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) outward in all directions from the damaged area.
1. Laminate
2. Crack
3. Slight Taper
4. Engine Side of Hood (or underside of half-fender)

Fig. 5, Recessed Area (cross-sectional view)

this will give the patch a surface to which it can stick. See **Fig. 6**, Ref. B.

7. Blow the dust away with compressed air and wipe the area with a clean cloth.

8. If necessary, align the panel sections on both sides of the crack, using weights or clamps to re-establish the original panel profile.

02/09/94 f880223a

A. Use a router to grind away a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) outward from the damage. If repairing a crack, don't grind past the hole drilled at the end of the crack.
B. Use 80- to 220-grit sandpaper to scuff the area one inch (25 mm) around the damage.
C. Cut the fiberglass cloth to fully cover the damage, and overlay about 3/4 inch (20 mm).
1. Hole 2. Crack

Fig. 6, Preparing the Damaged Area on the Engine Side of the Hood

9. With a razor-blade knife, cut a section of woven fiberglass cloth to fully cover the crack and to overlay about 3/4 inch (20 mm). See **Fig. 6**, Ref. C.

10. To bond the fiberglass cloth to the damaged panel, use Ashland Pliogrip 7775L urethane adhesive.

NOTE: When using Ashland Pliogrip 7775L, dispense the required adhesive from the cartridge in a continuous bead of uniform size and a uniform green color. Discard the initial few inches of discolored bead.

11. Lay the cut section of fiberglass cloth on the repair area, centered over the damage. Using a fiberglass roller, press the cloth down firmly into the layer of adhesive to completely saturate the glass fibers.

12. Apply another layer of adhesive over the glass cloth. Spread the adhesive evenly using the fiberglass roller.

13. After two to five minutes, the adhesive will start to jell. It may take more time when cool, less when warm.

IMPORTANT: To avoid pre-jelling or skin-over, mate the FRP parts to be bonded within one to four minutes after dispensing the adhesive.

NOTE: To get a smoother surface, press a piece of masking tape, wider than the repair, directly over the wet adhesive and smooth it before it hardens. The tape can be removed after five minutes when the adhesive has set.

14. The patch should be hard enough in 50 minutes to allow sanding to a smooth flat surface if required.

15. Repair the damage on the outside surface of the hood or half-fender, using the instructions in "Surface Damage Repair." Prime and paint both surfaces, using the instructions in **Group 98**.

PUNCTURE AND LARGE FRACTURE REPAIR (SECTION REPLACEMENT)

If a half-fender has a puncture or large fracture, replace the half-fender.

On very large damaged areas (for example, structural damage on the side surface of the hood covering an area of a square foot or more) it may be easier to do a section replacement rather than make a patch. Fenders and headlight reinforcements may be used in section replacements. Also, a second damaged hood with the needed section intact may be available as scrap.

IMPORTANT: A piece of Preform FRP laminate from a Short Conventional hood must be used for section replacement. Use of any other material may not allow the necessary bonding for the repair.

1. Push in on the area immediately surrounding and underneath the damaged area to determine the extent of damage.

2. If a sound-absorbent liner is present on the underside of the damaged area, peel away the liner to provide an adequate working area.

3. Clean the damaged area on both sides of the hood with xylene, acetone, or an equivalent grease- and wax-removing solvent. Inspect the area closely. All dirt, water, grease, and oils must be removed.

4. Using a sabre saw, cut out a large, straight-sided panel containing the damaged area. See **Fig. 7**, Ref. A.

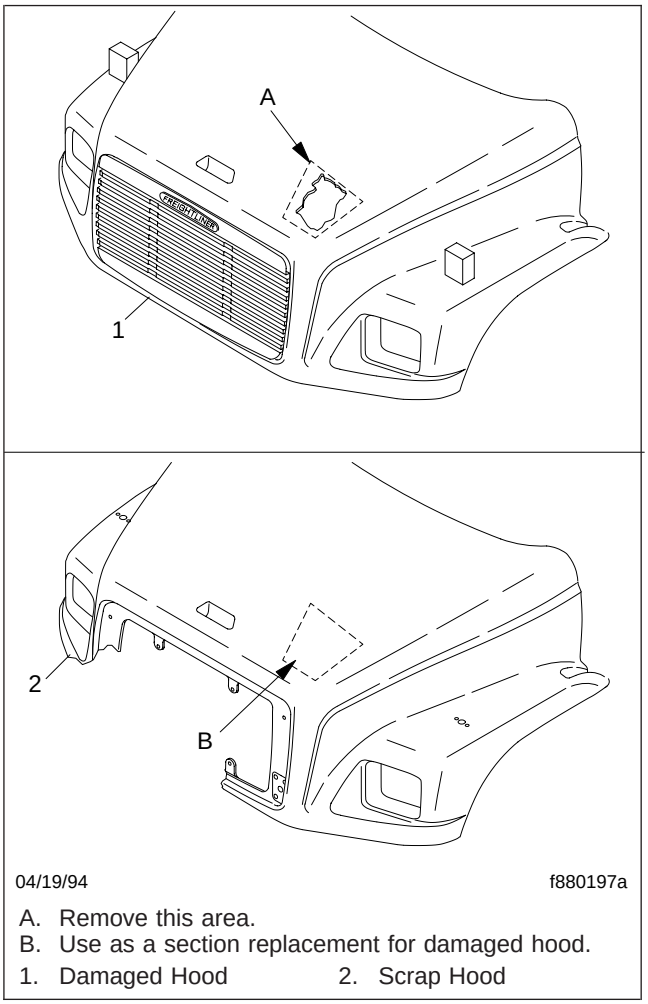
   If the damage extends to a joint where a reinforcement is bonded to the hood, completely separate the reinforcement with a heat gun and putty knife before cutting. See "Hood Reinforcement Rebonding" for instructions.

⚠ WARNING

WARNING: Wear goggles and an air purifying respirator when grinding, cutting, or sanding during all fiberglass repairs. The ground dust and particles could cause temporary or permanent damage to your eyes and, if inhaled, could cause throat or lung irritation.

5. From a scrap hood, cut a section replacement panel from the same area, only slightly larger than the cut-out in the damaged hood. See **Fig. 7**, Ref. B. Then, trim the section replacement to fit both the size and contour of the original cutout.

   If the damage is next to a headlight reinforcement, but doesn't include the reinforcement, remove the headlight reinforcement from the replacement section (scrap hood), not the damaged hood.



6. After the trimming is completed, sand the edges to allow a 1/16- to 1/8-inch (2- to 3-mm) gap around the cutout.

7. On the engine side of the hood, use a router bit (on a grinder or drill) to grind away a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) outward from all sides of the cutout area. See **Fig. 8**, Ref. A.

   Also, grind 1/2 inch (13 mm) inward from all edges on the engine side of the section replacement. See **Fig. 8**, Ref. C.

   Slightly taper the outside edge of the ground area on the hood and the inside edge of the ground area on the section replacement. See **Fig. 9**, Ref. 3.

Hood and Half-Fender Repair

A. Remove this area.
B. Use as a section replacement for damaged hood.
1. Damaged Hood
2. Scrap Hood

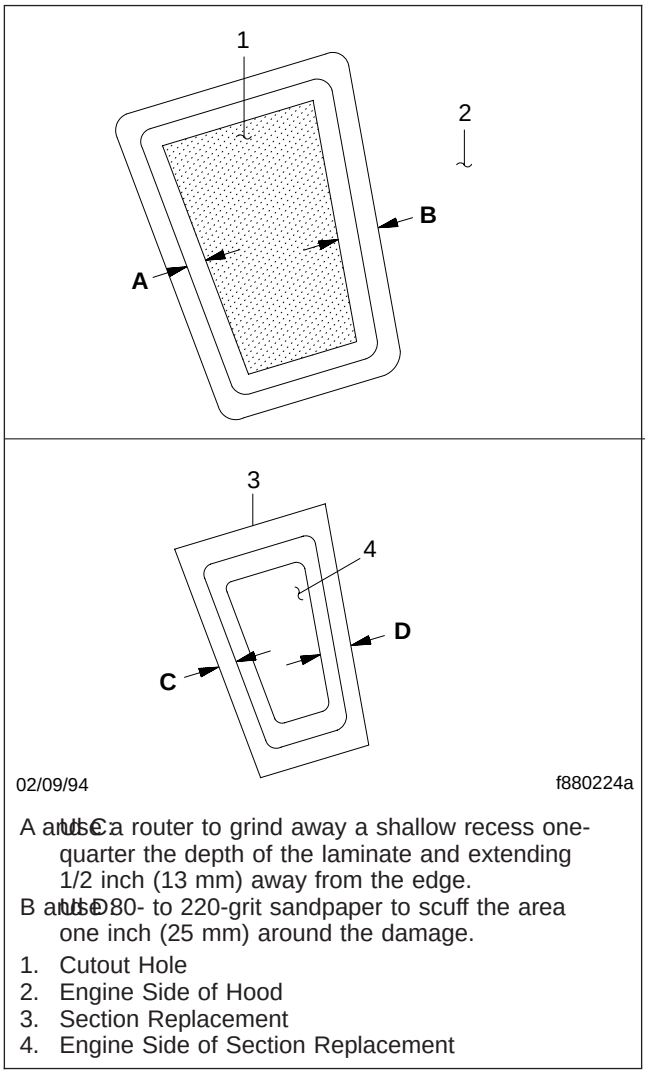


Fig. 7, Section Replacement of a Damaged Fiberglass Hood

8. Use 80- to 220-grit sandpaper to scuff an area at least one inch (25 mm) out from all sides of the cutout area. See **Fig. 8**, Ref. B.

   Also, scuff at least one inch (25 mm) in from all sides of the section replacement. See **Fig. 8**, Ref. D.

   Scuff thoroughly, since this will give the section replacement a surface to which it can stick. Be sure to completely sand off any undercoating sprayed on these areas.

9. On the outer sides of both the cutout and the section replacement, bevel the edges about 45 degrees. See **Fig. 10**.

A and C. Use a router to grind away a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) away from the edge.
B and D. Use 80- to 220-grit sandpaper to scuff the area one inch (25 mm) around the damage.
1. Cutout Hole
2. Engine Side of Hood
3. Section Replacement
4. Engine Side of Section Replacement

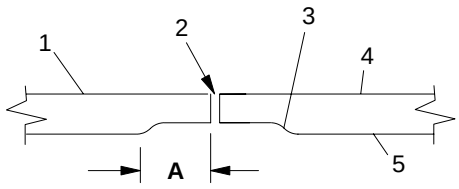

Fig. 8, Preparing the Section Replacement and Hood Cutout on the Unexposed Side

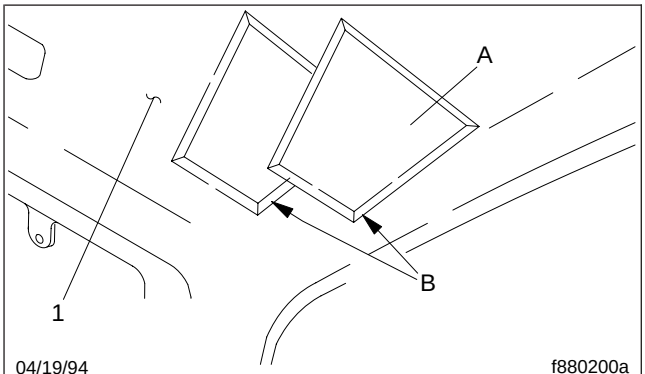
10. Gently feather the outer painted surfaces back about 1/2 inch (13 mm) beyond the edges of the repair areas (on both the cutout and the section replacement), using 220-grit or finer sandpaper.

11. Blow the dust away with compressed air, and wipe the area with a clean cloth.

12. If the section replacement is close enough to an edge, use clamps to temporarily secure it during the repair.

    If the replacement is too far from an edge to use clamps, use bond strips. See **Fig. 11**.



05/04/94 f880226b

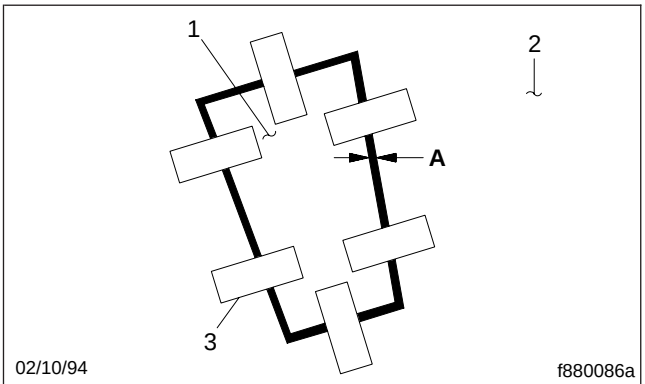
A. Grind a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) outward in all directions from the damaged area.

1. Section Replacement
2. Gap
3. Slight Taper
4. Hood
5. Engine Side of Hood

Fig. 9, Cutout Area (cross-sectional view)

04/19/94 f880200a

A. Insert section replacement.
B. Bevel outer surface edges on all sides.



1. Exposed Side of Hood

Fig. 10, Areas to be Beveled

12.1 Cut some scrap FRP into strips. Make enough strips to hold the section replacement in position; about one every six inches (15 cm). If the surface of the replacement panel is contoured or curved, use many small bond strips; larger strips could deform the curves.

12.2 On the engine side of the repair, use 220-grit sandpaper to scuff sand the areas on the hood and section replacement panels where you plan to bond the strips.

12.3 If a joint between the hood and a reinforcement was separated for the repair, rebond the joint. See "Hood Reinforcement Rebonding" for instructions.

02/10/94 f880086a

A. Gap of 1/16 inch to 1/8 inch (2 to 3 mm)

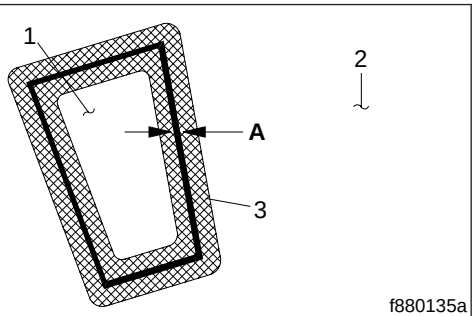
1. Section Replacement
2. Engine Side of Hood
3. Bond Strip

Fig. 11, Securing the Section Replacement to the Hood Using Bond Strips

12.4 Holding the section replacement in position, bond the strips to both hood and replacement panels in the area already scuffed. Use Ashland Pliogrip 7773 to bond the strips.

NOTE: When using Ashland Pliogrip 7773, dispense the required adhesive from the cartridge in a continuous bead of uniform size and a uniform green color. Discard the initial few inches of discolored bead.

12.5 After the adhesive has hardened, use 80- to 220-grit sandpaper to scuff the bond strips.



12.6 Blow the dust away with compressed air, and wipe the area with a clean cloth.

13. With a razor-blade knife, cut sections of woven fiberglass cloth to fully cover the gap between the cutout and the section replacement, all the way around the damaged area. The cloth should overlay about 3/4 inch (20 mm) on both sides of the gap. See **Fig. 12**.

14. To bond the fiberglass cloth to the damaged panel, use Ashland Pliogrip 7775L urethane adhesive.

NOTE: When using Ashland Pliogrip 7775L, dispense the required adhesive from the cartridge in a continuous bead of uniform size and a uni-

Hood and Half-Fender Repair

NOTE: The fiberglass cloth should overlay about 3/4 inch (20 mm) on both sides of the gap.

A. Gap of 1/16 inch to 1/8 inch (2 to 3 mm)
1. Section Replacement
2. Engine Side of Hood
3. Fiberglass Cloth

Fig. 12, Overlaying the Gap with Fiberglass Cloth

form green color. Discard the initial few inches of discolored bead.

15. Use a plastic or metal device to spread a thin layer of adhesive over the scuffed area.
16. Lay the cut sections of fiberglass cloth on the repair area, centered over the damage. Using a fiberglass roller, press the cloth down firmly into the layer of adhesive to completely saturate the glass fibers.
17. Apply another layer of adhesive over the glass cloth. Spread the adhesive evenly using the fiberglass roller.
18. After two to five minutes, the adhesive will start to jell. It may take more time when cool, less when warm.

IMPORTANT: To avoid pre-jelling or skin-over, the FRP parts to be bonded should be mated within one to four minutes after the adhesive is dispensed.

NOTE: To get a smoother surface, press a piece of masking tape, wider than the repair, directly over the wet adhesive and smooth it before it hardens. The tape can be removed after five minutes when the adhesive has set.

19. The patch should be hard enough in 50 minutes to allow sanding to a smooth flat surface, if desired.
20. Repair the damage on the outside surface of the hood and paint the surface on both sides, using the instructions in "Surface Damage Repair."

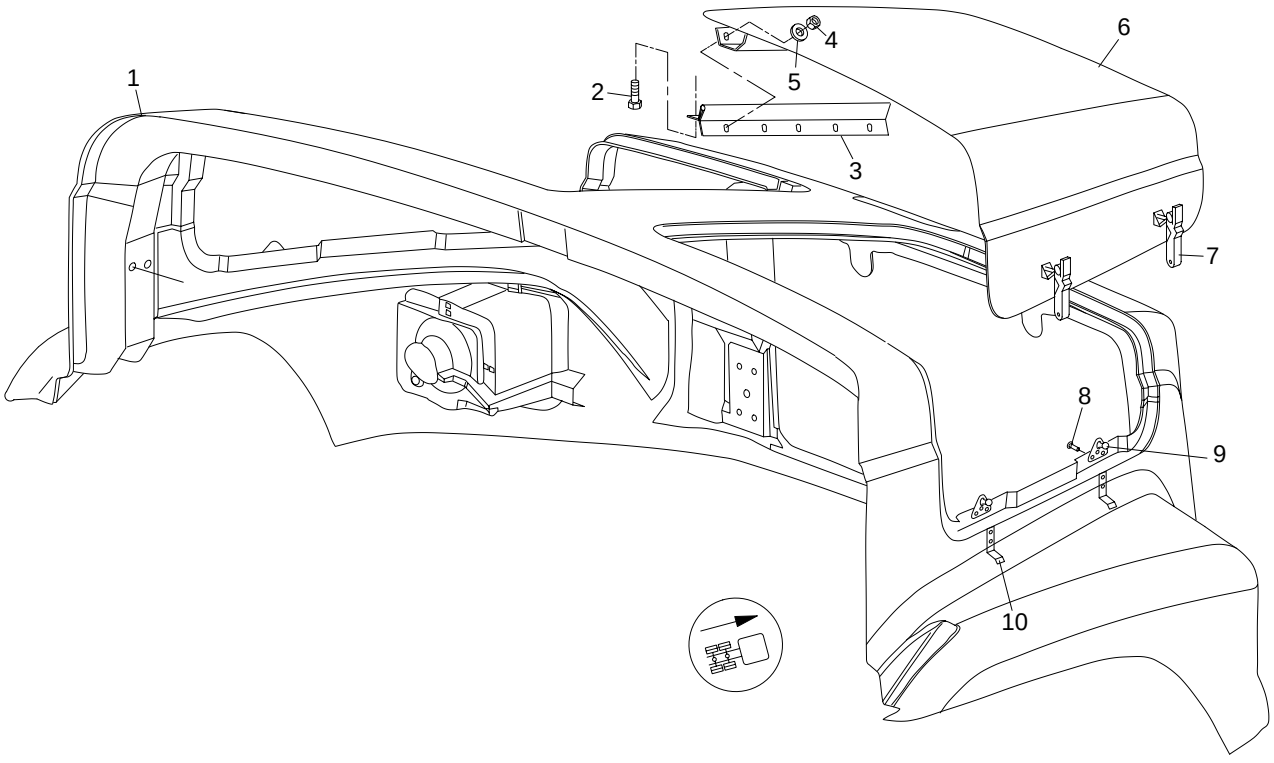
Engine Access Door Removal and Installation

Some Severe-Duty Business Class Trucks are fitted with front mounted PTOs, snow plows, etc. which limit or prevent hood opening. A hood with dual access doors is available for these applications to allow routine engine maintenance and service without requiring PTO or plow removal. This hood is sometimes referred to as the butterfly hood. **See Fig. 1.**

The access doors are made of the same fiberglass reinforced plastic (FRP) as the main hood and are attached to the hood along its centerline by piano-type hinges.

Two rubber over-center latches are fitted to each door to hold it in the closed position. A prop rod, fastened to the inside of each door, can be unclipped and used to hold the door open.

Access Door Removal



1. Apply the parking brakes and chock the rear tires.
2. Unlatch, but do not open, the door that is being removed.
3. Unlatch, open, and prop up the door that is *not* being removed.
4. Working through the open access door, remove the five bolts that secure the door hinge to the hood center reinforcement for the door that is being removed.
5. Remove the access door.

Access Door Installation

NOTE: If the access door is being replaced, transfer all mounting and latching hardware to the new door before installing it.

1. Place the access door in the hood opening.
2. Position the door, as necessary, to line up the door stop brackets and latch components.
3. Connect the latches to hold the door in place.
4. Working through the open door on the other side of the vehicle, install the five bolts that secure the door hinge to the hood center reinforcement.
5. Unlatch the newly installed door and open it to check the adjustment.
6. Remove the chocks from the tires.

Repair Tools and Materials List

SURFACE DAMAGE REPAIR

The following are required for surface damage repair:

- Xylene, acetone, or equivalent solvent
- Hand-held disc pad
- Self-leveling adhesive [1]
- Applicator squeegee
- 220- or finer grit sandpaper
- 320- or finer grit sandpaper
- Primer [2]

HOOD REINFORCEMENT REBONDING

The following are required for hood reinforcement rebonding:

- Heat gun
- Putty knife
- Hacksaw blade
- 80- to 220-grit sandpaper
- Solvent [3]
- Adhesive [4]
- Clamps, clamping bolts with washers
- Primer [2]
- 0.030 in (0.76 mm) glass beads (if needed)

CRACK OR SMALL HOLE REPAIR

The following are required for repair of cracks or small holes:

- Xylene, acetone, or equivalent solvent
- Drill and 1/8-inch (3-mm) diameter bit
- Router bit and grinder, or drill
- 80- to 220-grit sandpaper
- 220- or finer grit sandpaper
- 320- or finer grit sandpaper
- Woven fiberglass cloth
- Wooden stir stick
- Clamps
- Self-leveling adhesive [1]
- Applicator squeegee
- Hand-held disc pad
- Razor-blade knife
- Primer [2]

PUNCTURE OR LARGE FRACTURE REPAIR

The following are required for repair of punctures or large fractures:

- Suitable section of Preform FRP from scrap hood
- Xylene, acetone, or equivalent solvent
- Sabre saw
- Heat gun
- Putty knife
- Router bit and grinder, or drill
- 80- to 220-grit sandpaper
- 220- or finer grit sandpaper
- Solvent [3]
- Adhesive [4]
- Razor-blade knife
- Woven fiberglass cloth
- Wooden stir stick
- Self-leveling adhesive [1]
- Applicator squeegee
- Hand-held disc pad
- Clamps
- Primer [2]

[1] Use Ashland Pliogrip 7775L self-leveling urethane adhesive. Premeasured tubes of adhesive, mixing nozzles, and caulking gun applicators are available through Freightliner PDCs. See **Table 2** and **Table 3**.
[2] Use Sherwin Williams BB–-11 black conductive primer. Contact your local Sherwin Williams automotive paint distributor to purchase this primer.
[3] Use Ashland 6036 solvent or methylene chloride. Contact Ashland Merchandising Group, telephone (419) 289-9588, to purchase this solvent.
[4] Use Ashland Pliogrip 7700 series adhesives. Part numbers 7773 and 7779 are those products refered to in the instructions above. Part numbers 7771 and 7770 may be substituted. A heat gun or paint oven may be used to speed curing times but do not heat these adhesives above 180°F (82°C). These products are available through Freightliner PDCs. See **Table 2**.

Specifications

Fastener Torques				
Description	Size	Grade	Torque	
			lbf·in (N·cm)	lbf·ft (N·m)

Table 1, Fastener Torques

NOTE: Ashland Pliogrip 7700 and 8000 Series repair adhesives and accessories are available through Freightliner PDCs. The 7700 Series two-part urethane adhesives are specially formulated and packaged for repair of hoods and other fiber-reinforced plastics. Ashland Pliogrip 8000 Series two-part urethane adhesives are also available for those who prefer to use these earlier generation adhesives. The 7775L adhesive is a self-leveling mixture that is appropriate when a surface filler or glass fabric reinforcement repair is required.

The descriptions, working times, and curing times (sanding and repainting) of the different adhesives are shown below. See **Table 2** and **Table 4**. All working and curing times correspond to an ambient temperature of 73°F (23°C) in the workshop. Curing times may be shortened by using a heat gun or paint oven. Humidity does not affect these adhesives. All the adhesives develop the same bonding strength. Substitutions can be made to change working times.

See **Table 3** and **Table 5** for Ashland adhesive accessories.

IMPORTANT: To ensure a successful repair, do not heat these adhesives above 180°F (82°C).

7700 Series Adhesives				
Description	Part Number	Working Time in Minutes	Curing Time in Minutes	Curing Time in Hours

Table 5, 8000 Series Accessories

General Information

NOTE: The information in this section applies only to FL112 vehicles.

The hoods on these vehicles are made of fiberglass, and are manufactured by the spray-up process.

The materials used in fiberglass spray-up hoods are a combination of glass filaments, resin (the binder), catalysts (to initiate the cure), and weather resistance additives. The filaments of pure glass provide strength, dimensional stability, and heat resistance. The resin is a liquid plastic that hardens when combined with another substance, the catalyst. The resin acts as a binder to hold the filaments together; it supplies only a limited amount of additional strength to the structure.

HOOD MOUNTING AND COMPONENTS

The hood assembly mounts at the front to two hood pivot brackets, located on the outside of the frame rails, attached to the front cross-member extension. The hood pivots work in conjunction with the torsion bar tilt-assist mechanism. Two retaining straps allow a forward hood tilt adequate for vehicle service.

In the operating position, the rear of the hood is supported by hood support brackets, which are attached to the cab. These rear brackets hold the hood in the correct position for operation. The hood is held in place with latches, one on each side.

The hood pivot brackets are adjustable forward and backward and side to side. The rear hood support brackets are adjustable up and down.

Each hood assembly is equipped with an injection-molded, argent-colored grille. The grille is attached to the hood with eight fasteners. The hood is also equipped with a headlight bezel assembly, which features a headlight and turn signal/parking light combination, along with side-marker lights, on each fender.

Hood Removal, Installation, and Adjustment

Removal

1. Park the vehicle on a flat, level surface. Chock the tires.

⚠ WARNING

Do not attempt to lift the hood; it weighs about 150 lbs (68 kg). Lifting the hood could result in personal injury or damage to the hood assembly and other components.

2. Remove the grille. For removal instructions, see **Subject 110**.
3. Tilt the hood to the fully-open position.
4. Place a support between the floor and the front of the hood. The support should be as wide and as long as the front of the hood, and should be the same height as the lowest edge of the hood. Place cardboard, carpet, rags, or other padding on top of the support to protect the hood.
5. Disconnect the two headlight bezel wiring connectors at the bumper and the single connector at the side-marker light, from both sides of the hood.
6. Disconnect the two tilt-limiting assist straps by removing the fasteners attached to the inside surface of the hood. Move the hood to a less than full-tilt position to provide some slack in the straps.
7. Remove the torsion bar tilt-assist mechanism. For removal instructions, see **Subject 120**.
8. Remove the shoulder bolts from the hood hinge brackets while continuing to support the hood in position. Use a punch and hammer to tap out the shoulder bolts.
9. Carefully roll or slide the hood support away from the vehicle.

Installation

1. Position the disconnected electrical wiring out of the way to avoid interference during installation.

⚠ WARNING

Do not attempt to lift the hood; it weighs about 150 lbs (68 kg). Lifting the hood could result in personal injury or damage to the hood assembly and other components.

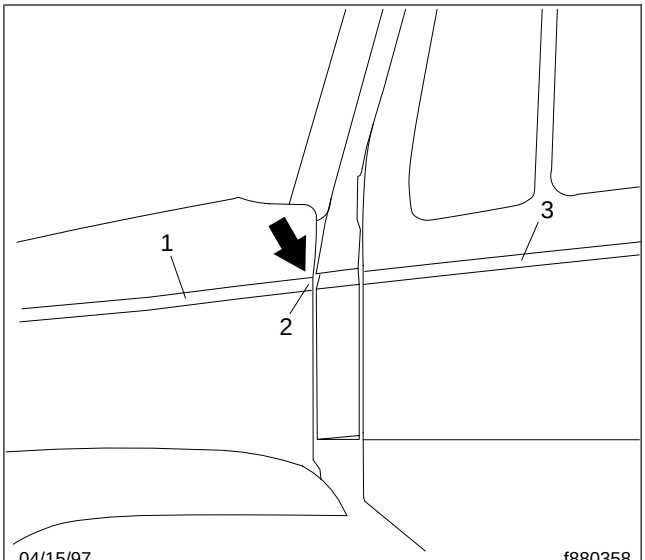
2. With the hood in the forward-tilt position and resting on the support at about the same height as the top of the bumper, move the support and hood into alignment with the front of the vehicle.
3. Apply a lubricant to the shoulder bolts and ensure that the hood pivot bushings are in position.
4. Insert the shoulder bolts and tap them into place with a mallet. Attach the nuts to the bolts. Torque the nuts to 28 lbf·ft (38 N·m).
5. Install the torsion bar tilt-assist mechanism. For installation instructions, see **Subject 120**.
6. Lower the hood until it is balanced over the pivots, then have a co-worker hold the hood in this position.
7. Connect the two tilt-limiting assist straps attached to the inside surface of the hood.
8. Tilt the hood to a full-tilt position.
9. Connect the electrical connectors to the headlight bezel assemblies.
10. Place the hood into the operating position. Latch the hood.
11. Install the grille. For instructions, see **Subject 110**.
12. Remove the chocks from the tires.

Adjustment

NOTE: If the vehicle has had damage to the chassis, the frame must be straightened before adjusting the hood.

1. Drive the vehicle back and forth to settle the frame and suspension. Park the vehicle on a flat, level surface. Chock the tires.
2. Determine whether hood adjustment is necessary by checking, with the hood in the operating position and the hood latches latched, the alignment of the hood character line with the cab

Hood Removal, Installation, and Adjustment



character line. **See Fig. 1.** The two lines should approximately match.

3. If it is determined that the hood needs to be vertically adjusted, follow these steps:

   3.1 Take note of the difference in the alignment of the character lines on the left and the right sides.

   3.2 Tilt the hood to the fully-open position.

   3.3 Slightly loosen the bolts securing one of the rear hood support brackets, which are attached to the cab frontwall. **See Fig. 2.**

1. Hood Character Line
2. Adjustment Point
3. Cab Character Line

Fig. 1, Hood Adjustment Point

   3.4 Loosen the support brace bolts at the hood support bracket.

   3.5 Loosen the support brace bolts at the cab frontwall.

   NOTE: It is also necessary to loosen or disconnect the radiator strut rod.

   3.6 Either raise or lower the bracket an amount equal to the difference in the character lines.

   3.7 Snug down the bracket mounting bolts.

   3.8 Close and latch the hood.

1. Cab Frontwall
2. Support Brace
3. Rear Hood Support Bracket
4. Bolt (support bracket)

Fig. 2, Rear Hood Support Bracket

   3.9 Inspect the alignment. If necessary, repeat the procedure until the lines are approximately the same.

   3.10 Unlatch and tilt the hood to the fully-open position.

   3.11 Tighten the mounting bolts on the rear hood support bracket, which was just adjusted, and torque them to 29 lbf·ft (40 N·m).

   3.12 Tighten the support brace bolts at the support bracket and torque them to 34 lbf·ft (46 N·m).

   3.13 Securely tighten the support brace bolts at the cab frontwall.

   3.14 Ensure that the radiator strut rod is connected to the rear hood support bracket and that the fasteners are tightened to the proper torque value. See **Section 20.01** in this manual.

   3.15 The vertical alignment adjustment should be complete.

3.16 Lower the hood and fasten the hood latches.

NOTE: The forward and aft adjustment of the hood should be not necessary as the hoods are manufactured to be adjustment-free. However, this adjustment can be performed by loosening the bolts securing the hood pivot brackets to the front crossmember extension and adjusting the position of the pivots.

Removal

1. From the front side of the grille, remove the eight Torx® head fasteners that hold the grille to the hood. **See Fig. 1.**

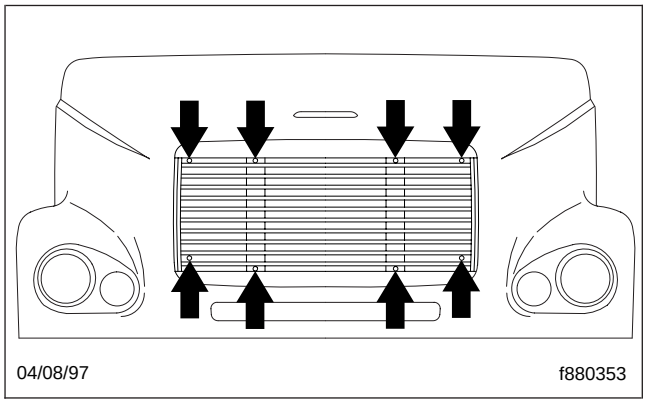


Fig. 1, Location of Grille Fasteners

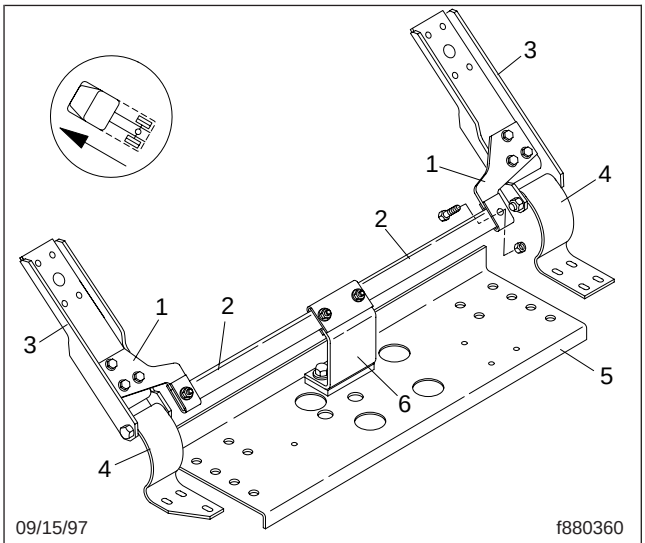
2. Remove the grille from the hood.



Installation

1. Place the grille in position on the hood with the grille fastener holes lined up with the holes on the hood.
2. Install the eight fasteners into the threaded isolators.
3. Tighten the fasteners 96 lbf·in (1080 N·cm).

Hood Torsion Bar Tilt-Assist Mechanism Removal and Installation

Removal

1. Apply the parking brakes, and chock the tires.
2. Remove the grille. See **Subject 110** for removal instructions.
3. Release the hood latches, and tilt the hood completely open.
4. Remove the three bolts in both torsion bar outer brackets. See **Fig. 1**.

1. Torsion Bar Outer Bracket
2. Torsion Bar
3. Hood Hinge Bracket
4. Hood Hinge Pivot
5. Front Closing Crossmember
6. Inner Torsion Bar Bracket

Fig. 1, Torsion Bar Tilt-Assist Mechanism

5. Loosen the bolts and nuts securing the torsion bar outer slotted ends to the outer brackets. Disconnect the outer brackets from the torsion bars.
6. Remove the bolts and nuts securing both torsion bars to the inner torsion bar bracket.
7. Remove the torsion bars.

Installation

NOTE: Tilt and support the hood at an angle of approximately 50 degrees to ease the installation of the torsion bars and the outer brackets.

1. Insert the torsion bars (drilled ends) into the inner torsion bar bracket and install the inner torsion bar bolts and nuts.
2. Attach the slotted outer ends of the torsion bars to the outer brackets.
3. Align the holes in the outer torsion bar brackets with the holes in the hood hinge brackets and install the three bolts on each side.
4. Torque the inner torsion bar bolts and nuts to 37 lbf·ft (50 N·m), the outer torsion bar bolts and nuts to 26 lbf·ft (36 N·m), and the outer bracket bolts to 37 lbf·ft (50 N·m).
5. Return the hood to the operating position and fasten both hood latches.
6. Install the grille. See **Subject 110** for installation instructions.
7. Remove the chocks from the tires.

NOTE: The torsion bar tilt-assist mechanism is not adjustable.

Repair Safety Precautions

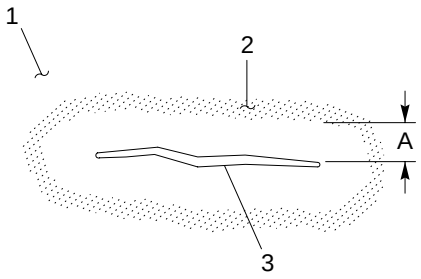
Before performing any fiberglass repairs, read the following precautions. Observe any additional precautions given by the manufacturers of the repair materials used.

1. All of the raw materials used in repairing fiberglass are harmful to the eyes and could cause blindness. Wear goggles or other protective eye shields to reduce the chances of splash contacting your eyes.
2. Wear protective gloves, as some people may have skin sensitivity to urethane adhesives.

IMPORTANT: In case the hardener or resin contacts your skin, wash with soap and water. If the hardener or resin should contact your eyes, rinse with plenty of water (15 minutes), and call a doctor.

3. When working with fiberglass materials, wear old clothing, since the resin may damage the cloth. Wash the clothing before wearing it again.
4. Most of the liquids involved in fiberglass repair and cleanup (especially when using acetone as a solvent) are flammable; some are also toxic. Don't perform repairs in areas where exposed (or stored) flammable liquids may contact an open flame or any burning material, such as a cigarette. Don't perform repairs in areas that are not well ventilated with fans or an exhaust system.

⚠ WARNING



Do fiberglass repairs in a safe workshop area to prevent severe personal injury due to explosion of flammable liquids or breathing of toxic fumes.

5. Do not use electric tools when the fumes of flammable solvents are present. The heat or sparks generated by the tools could create a fire hazard.
6. When grinding or sanding fiberglass surfaces, wear goggles or other protective eye shields, and also use an air purifying respirator, either a throwaway type or one with a replaceable particulate filter(s). Don't breathe grinding dust or particles, otherwise irritation may occur. Also, during grinding and sanding operations, wear a disposable (paper) shop coat to keep dust and fiber slivers off your clothing.
7. Because fiberglass dust can shorten the life of electrical units, air-powered tools are preferred (for frequent use).

Surface Damage Repair

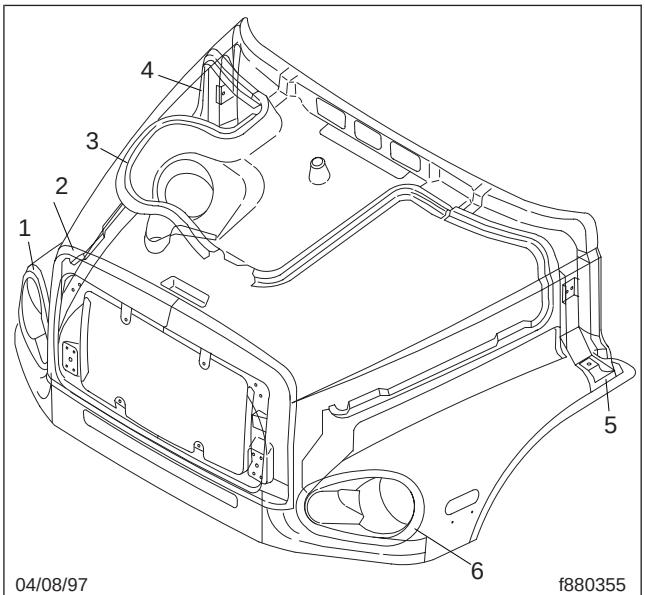
Surface damage refers to scratches, chips, or nicks on the outer surface of the hood or half-fender. Use the following instructions to repair surface damage:

1. Examine the damaged area. If there are cracks, see if they go all the way through the hood or half-fender. If they do, see "Structural Damage Repair" for instructions.
2. Clean the area with xylene, acetone, or an equivalent grease- and wax-removing solvent. Inspect the area closely.
3. Using 220-grit or finer sandpaper, remove all of the paint around the damaged area to a distance of about 1-1/2 inches (4 cm). See **Fig. 1**.

A. Remove paint and primer 1-1/2 inches (4 cm) around the damaged area. Use 220-grit or finer sandpaper.
1. Paint
2. Primer
3. Scratch

Fig. 1, Damaged Area with Paint and In-Mold Coating Removed

4. Using an air nozzle, blow off all dust.
5. Apply Ashland Pliogrip 7775L self-leveling urethane adhesive over the non-coated area and spread a thin layer using a squeegee applicator. Cover the entire damaged area, overlapping onto the painted surface. Leave a crowned excess of adhesive, slightly higher than the painted surface.



NOTE: When using Ashland Pliogrip 7775L, dispense the required adhesive from the cartridge

in a continuous bead of uniform size and a uniform green color. Discard the initial few inches of discolored bead.

6. After the adhesive dries (about 50 minutes), sand it with a hand-held disc pad. Use 320-grit or finer sandpaper. Feather the edges of the fill so there are no visible sharp edges.
7. Clean the area with compressed air. Mask the area, then spot prime and paint it. Use Sherwin Williams BB–11 black conductive primer. See **Group 98** for spot-painting instructions.

Structural Damage Repair

The Preform FRP (fiberglass reinforced plastic) hood consists of a one-piece hood and fender assembly. Inner reinforcements are bonded to the engine-side of the hood with a structural adhesive. See **Fig. 2**. If the hood is damaged, determine which parts are affected.

1. Right-Hand Headlight Housing
2. Front Hood Reinforcement
3. Rear Air Plenum Reinforcement
4. Right-Hand Side Reinforcement
5. Left-Hand Side Reinforcement
6. Left-Hand Headlight Housing

Fig. 2, Hood Assembly Components

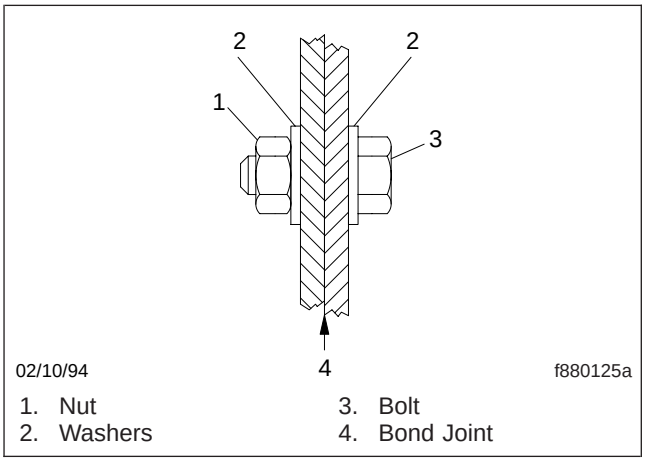
If there is damage to any of the reinforcements, the damage is not repairable. For example, if the grille area of the hood is damaged so badly that the reinforcement bonded inside the grille area is also damaged, replace the entire hood assembly.

If a joint between two reinforcements, or between a reinforcement and the hood skin, has separated and there is no damage at the joint area, the parts can be rebonded. Or, if a part of the hood skin is damaged and its adjoining reinforcement(s) aren't damaged, the reinforcement can be separated from the damaged part, the damaged part can be patched, and the reinforcement(s) rebonded in place.

If a half-fender has a small crack or hole, it can be repaired; if it has a puncture or large fracture, it must be replaced.

For rebonding parts, see "Hood Reinforcement Rebonding."

For damage in the form of a crack or small hole, see "Crack or Small Hole Repair."



For larger damaged areas, see "Puncture or Large Fracture Repair."

HOOD REINFORCEMENT REBONDING

1. If rebonding a joint that has partially separated, completely separate the reinforcement from the hood using a heat gun and putty knife. Remove as much of the old adhesive as possible. The heat gun will soften the adhesive and allow it to be peeled off the FRP.

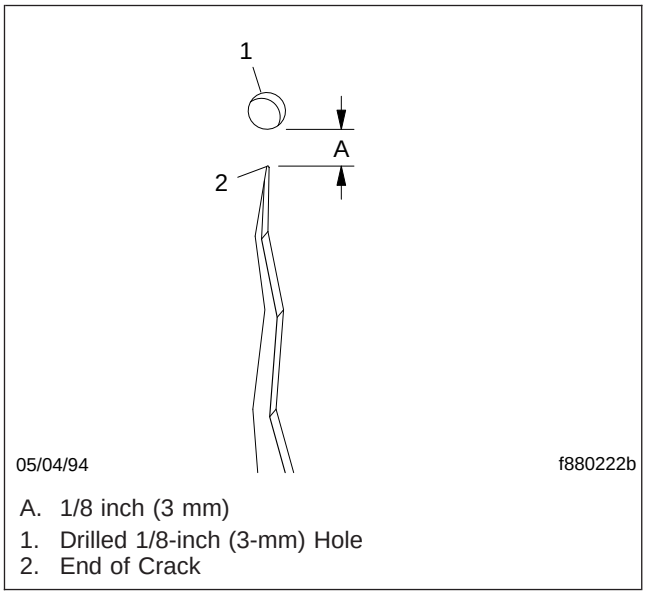
   If the parts cannot be separated, work folded medium-grit sandpaper or a section of a steel hacksaw blade between the two surfaces to remove the old adhesive.
2. Scuff the surfaces with 80- to 220-grit sandpaper.
3. Clean the surfaces to be bonded with Ashland 6036 solvent or methylene chloride. Inspect the area closely to be sure all of the old adhesive, dirt, water, grease, and oils are removed.
4. If replacing a large part, align the part on the hood and clamp it in place. Drill holes through the bonding surfaces and install clamping bolts in the holes. Use two washers, one on each side of the joint. See **Fig. 3**. There should be enough clamping bolts to hold the hood in place and keep the bonding surfaces together, or at least

one bolt every 12 to 18 inches (30 to 45 cm). Remove the part for application of adhesive.

1. Nut
2. Washers
3. Bolt
4. Bond Joint

Fig. 3, Clamping Bolt at Bond Joint

5. Following the manufacturer's instructions, use enough adhesive to bond the parts together. Use Ashland Pliogrip urethane cartridge materials 7773 or 7779.



NOTE: When using Ashland Pliogrip 7773 or 7779, insert the two tubes of adhesive into the applicator and dispense a 3/8-inch (10-mm) diameter bead of uniform green-colored adhesive at the bonding surface. Discard any adhesive that does not show this uniform green color.

6. Within three and one half minutes (7773) or within 10 minutes (7779) of applying the bead, align the part on the hood and clamp it firmly in place. If it is a large part, install the clamping bolts. Tighten the clamps or clamping bolts just enough to ensure that a uniform amount of pressure is applied along the seam. Ideally, the adhesive should be compressed to form a bondline one inch (25 mm) wide and 0.030 inch (0.76 mm) thick. This thickness can be ensured by sprinkling 0.030 inch (0.76 mm) glass beads into the adhesive before mating the parts.
7. Before it cures, remove any excess adhesive that squeezes out the edges of the bond.
8. Remove the clamps after the adhesive has cured for 30 minutes (7773) or for 60 minutes (7779).
9. If holes were drilled for clamping bolts, repair them using the instructions under "Crack or Small Hole Repair."
10. If necessary, prime and paint the repair area using the instructions under "Surface Damage Repair."

CRACK OR SMALL HOLE REPAIR

A crack (fracture) or small hole through the laminate requires repair with a fiberglass-reinforced patch.

1. Examine the damage to the hood or half-fender. Apply hand pressure all around the damaged area to check for any concealed damage.
2. If a sound-absorbent liner is present on the underside of the damaged area, peel away the liner to provide an adequate working area.
3. Clean the damaged area on both sides of the hood or half-fender with xylene, acetone, or equivalent grease- and wax-removing solvent. Inspect the area closely. All dirt, water, grease, and oils must be removed.
4. If repairing a crack, use a 1/8-inch (3-mm) diameter bit to drill a hole completely through the uncracked laminate 1/8 inch (3 mm) from each end of the crack, to prevent the crack from lengthening. See **Fig. 4**.

A. 1/8 inch (3 mm)
1. Drilled 1/8-inch (3-mm) Hole
2. End of Crack

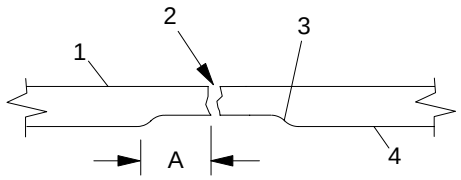


Fig. 4, Drilling a Hole to Prevent the Crack From Lengthening

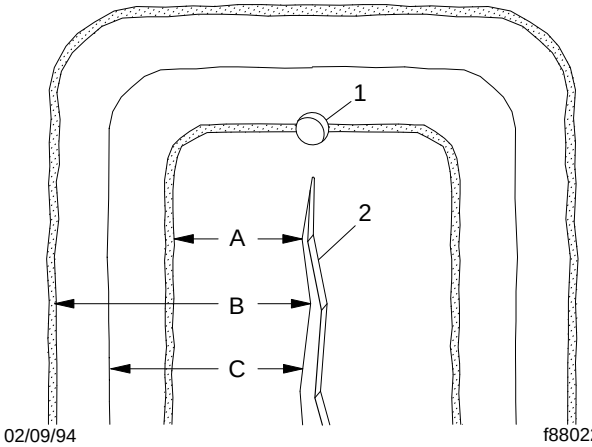
5. On the engine side of the hood (or underside of the half-fender), use a router bit (on a grinder or a drill) to grind away a shallow recess one-

Hood and Half-Fender Repair

quarter the depth of the laminate and extending 1/2 inch (13 mm) outward from all sides of the damage. Taper the outside edge of the ground area. See **Fig. 5**.

If repairing a crack, grind outward to the drilled hole at the end of the crack, but not beyond. See **Fig. 6**, Ref. A.



05/04/94 f880227b

A. Grind a shallow recess one-quarter the depth of the FRP and extending 1/2 inch (13 mm) outward in all directions from the damaged area.
1. FRP
2. Crack
3. Slight Taper
4. Engine Side of Hood (or underside of half-fender)

Fig. 5, Recessed Area (cross-sectional view)

6. Use 80- to 220-grit sandpaper to scuff an area at least one inch (25 mm) away from the fracture on all sides. Be sure to scuff thoroughly, since this will give the patch a surface to which it can stick. See **Fig. 6**, Ref. B.
7. Blow the dust away with compressed air and wipe the area with a clean cloth.
8. If necessary, align the panel sections on both sides of the crack, using weights or clamps to re-establish the original panel profile.
9. With a razor-blade knife, cut a section of woven fiberglass cloth to fully cover the crack and to overlay about 3/4 inch (20 mm). See **Fig. 6**, Ref. C.
10. To bond the fiberglass cloth to the damaged panel, use Ashland Pliogrip 7775L urethane adhesive.

NOTE: When using Ashland Pliogrip 7775L, dispense the required adhesive from the cartridge in a continuous bead of uniform size and a uniform green color. Discard the initial few inches of discolored bead.

02/09/94 f880223a

A. Use a router to grind away a shallow recess one-quarter the depth of the FRP and extending 1/2 inch (13 mm) outward from the damage. If repairing a crack, don't grind past the hole drilled at the end of the crack.
B. Use 80- to 220-grit sandpaper to scuff the area one inch (25 mm) around the damage.
C. Cut the fiberglass cloth to fully cover the damage, and overlay about 3/4 inch (20 mm).
1. Hole
2. Crack

Fig. 6, Preparing the Damaged Area on the Engine Side of the Hood

11. Lay the cut section of fiberglass cloth on the repair area, centered over the damage. Using a fiberglass roller, press the cloth down firmly into the layer of adhesive to completely saturate the glass fibers.
12. Apply another layer of adhesive over the glass cloth. Spread the adhesive evenly using the fiberglass roller.
13. After two to five minutes, the adhesive will start to jell. It may take more time when cool, less when warm.

IMPORTANT: To avoid pre-jelling or skin-over, mate the FRP parts to be bonded within one to four minutes after dispensing the adhesive.

NOTE: To get a smoother surface, press a piece of masking tape, wider than the repair, directly over the wet adhesive and smooth it before it hardens. The tape can be removed after five minutes when the adhesive has set.

14. The patch should be hard enough in 50 minutes to allow sanding to a smooth flat surface if required.
15. Repair the damage on the outside surface of the hood or half-fender, using the instructions in "Surface Damage Repair." Prime and paint both surfaces, using the instructions in **Group 98**.

PUNCTURE AND LARGE FRACTURE REPAIR (SECTION REPLACEMENT)

If a half-fender has a puncture or large fracture, replace the half-fender.

On very large damaged areas (for example, structural damage on the side surface of the hood covering an area of a square foot or more) it may be easier to do a section replacement rather than make a patch. Fenders and headlight reinforcements may be used in section replacements. Also, a second damaged hood with the needed section intact may be available as scrap.

IMPORTANT: A piece of Preform FRP from another FL112 vehicle hood must be used for section replacement. Use of any other material may not allow the necessary bonding for the repair.

1. Push in on the area immediately surrounding and underneath the damaged area to determine the extent of damage.
2. If a sound-absorbent liner is present on the underside of the damaged area, peel away the liner to provide an adequate working area.
3. Clean the damaged area on both sides of the hood with xylene, acetone, or an equivalent grease- and wax-removing solvent. Inspect the area closely. All dirt, water, grease, and oils must be removed.
4. Using a sabre saw, cut out a large, straight-sided panel containing the damaged area. See **Fig. 7**, Ref. A.

   If the damage extends to a joint where a reinforcement is bonded to the hood, completely separate the reinforcement with a heat gun and putty knife before cutting. See "Hood Reinforcement Rebonding" for instructions.

⚠ WARNING

Wear goggles and an air purifying respirator when grinding, cutting, or sanding during all fiberglass repairs. The ground dust and particles could cause temporary or permanent damage to your eyes and, if inhaled, could cause throat or lung irritation.

5. From a scrap hood, cut a section replacement panel from the same area, only slightly larger than the cut-out in the damaged hood. See **Fig. 7**, Ref. B. Then, trim the section replacement to fit both the size and contour of the original cutout.

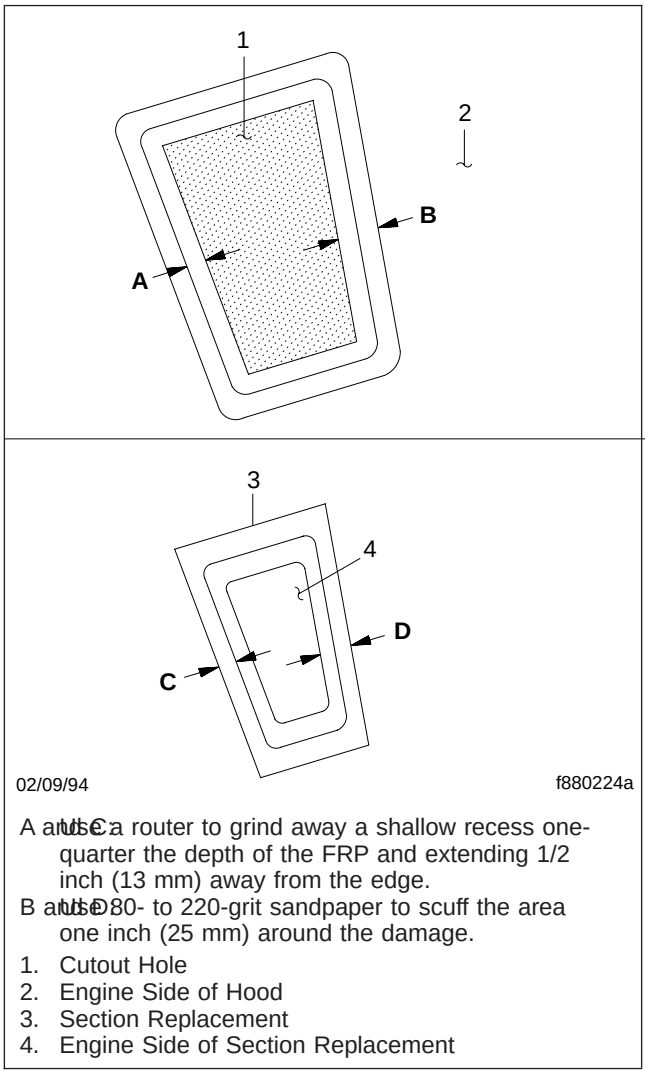
   If the damage is next to a headlight reinforcement, but doesn't include the reinforcement, remove the headlight reinforcement from the replacement section (scrap hood), not the damaged hood.
6. After the trimming is completed, sand the edges to allow a 1/16- to 1/8-inch (2- to 3-mm) gap around the cutout.
7. On the engine side of the hood, use a router bit (on a grinder or drill) to grind away a shallow recess one-quarter the depth of the laminate and extending 1/2 inch (13 mm) outward from all sides of the cutout area. See **Fig. 8**, Ref. A.

   Also, grind 1/2 inch (13 mm) inward from all edges on the engine side of the section replacement. See **Fig. 8**, Ref. C.

   Slightly taper the outside edge of the ground area on the hood and the inside edge of the ground area on the section replacement. See **Fig. 9**, Ref. 3.
8. Use 80- to 220-grit sandpaper to scuff an area at least one inch (25 mm) out from all sides of the cutout area. See **Fig. 8**, Ref. B.

   Also, scuff at least one inch (25 mm) in from all sides of the section replacement. See **Fig. 8**, Ref. D.

   Scuff thoroughly, since this will give the section replacement a surface to which it can stick. Be sure to completely sand off any undercoating sprayed on these areas.

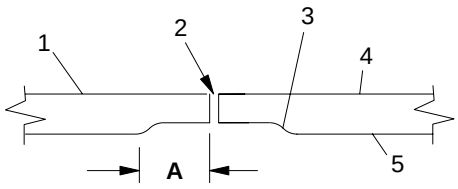


Hood and Half-Fender Repair

A. Remove this area.
B. Use as a section replacement for damaged hood.
1. Damaged Hood
2. Scrap Hood

Fig. 7, Section Replacement of a Damaged Fiberglass Hood

9. On the outer sides of both the cutout and the section replacement, bevel the edges about 45 degrees. See **Fig. 10**.
10. Gently feather the outer painted surfaces back about 1/2 inch (13 mm) beyond the edges of the repair areas (on both the cutout and the section replacement), using 220-grit or finer sandpaper.
11. Blow the dust away with compressed air, and wipe the area with a clean cloth.
12. If the section replacement is close enough to an edge, use clamps to temporarily secure it during the repair.

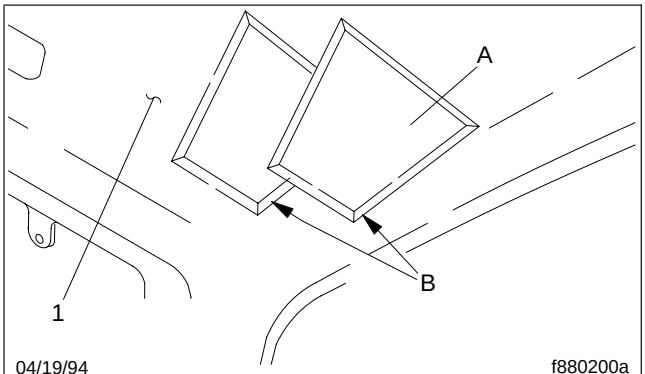


A and C. Use a router to grind away a shallow recess one-quarter the depth of the FRP and extending 1/2 inch (13 mm) away from the edge.
B and D. Use 80- to 220-grit sandpaper to scuff the area one inch (25 mm) around the damage.
1. Cutout Hole
2. Engine Side of Hood
3. Section Replacement
4. Engine Side of Section Replacement

Fig. 8, Preparing the Section Replacement and Hood Cutout on the Unexposed Side

If the replacement is too far from an edge to use clamps, use bond strips. See **Fig. 11**.

12.1 Cut some scrap FRP into strips. Make enough strips to hold the section replacement in position; about one every six inches (15 cm). If the surface of the replacement panel is contoured or curved, use many small bond strips; larger strips could deform the curves.



12.2 On the engine side of the repair, use 220-grit sandpaper to scuff sand the areas on

05/04/94 f880226b

A. Grind a shallow recess one-quarter the depth of the FRP and extending 1/2 inch (13 mm) outward in all directions from the damaged area.
1. Section Replacement
2. Gap
3. Slight Taper
4. Hood
5. Engine Side of Hood

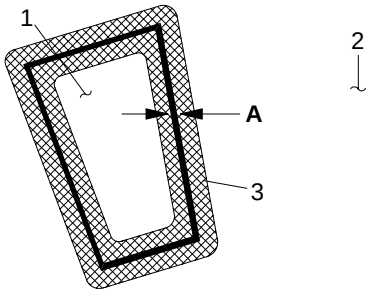
and a uniform green color. Discard the initial few inches of discolored bead.

12.5 After the adhesive has hardened, use 80- to 220-grit sandpaper to scuff the bond strips.

12.6 Blow the dust away with compressed air, and wipe the area with a clean cloth.

13. With a razor-blade knife, cut sections of woven fiberglass cloth to fully cover the gap between the cutout and the section replacement, all the way around the damaged area. The cloth should overlay about 3/4 inch (20 mm) on both sides of the gap. See **Fig. 12**.



14. To bond the fiberglass cloth to the damaged panel, use Ashland Pliogrip 7775L urethane adhesive.

NOTE: When using Ashland Pliogrip 7775L, dispense the required adhesive from the cartridge in a continuous bead of uniform size and a uniform green color. Discard the initial few inches of discolored bead.

15. Use a plastic or metal device to spread a thin layer of adhesive over the scuffed area.

16. Lay the cut sections of fiberglass cloth on the repair area, centered over the damage. Using a fiberglass roller, press the cloth down firmly into

Hood and Half-Fender Repair

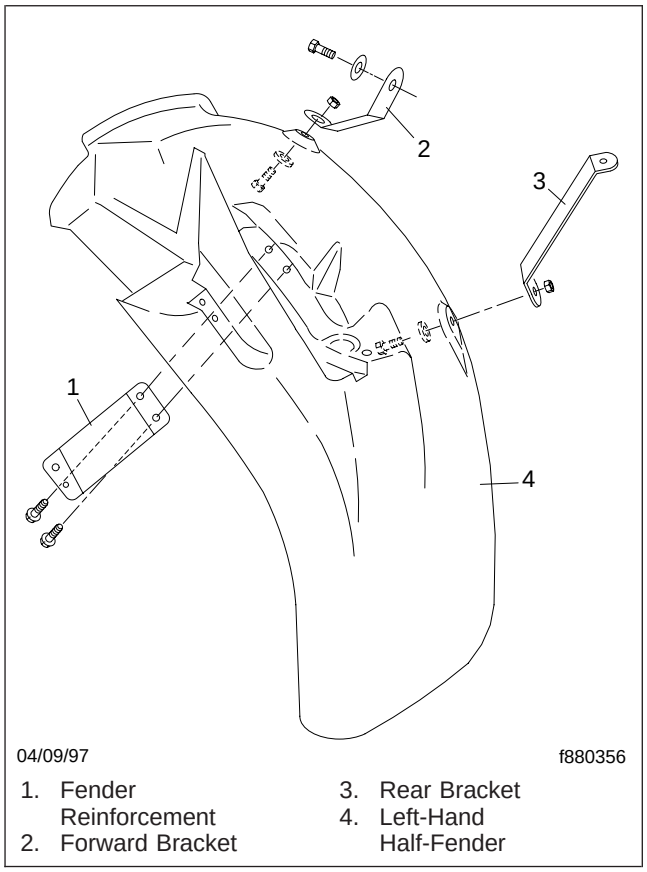
the layer of adhesive to completely saturate the glass fibers.

17. Apply another layer of adhesive over the glass cloth. Spread the adhesive evenly using the fiberglass roller.
18. After two to five minutes, the adhesive will start to jell. It may take more time when cool, less when warm.

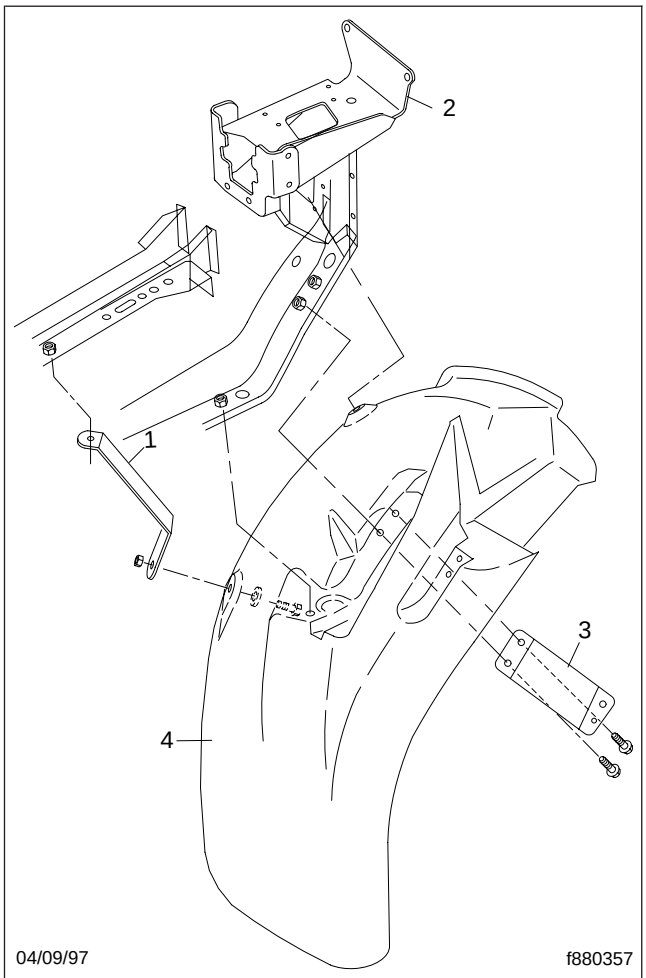


IMPORTANT: To avoid pre-jelling or skin-over, the FRP parts to be bonded should be mated within one to four minutes after the adhesive is dispensed.

NOTE: To get a smoother surface, press a piece of masking tape, wider than the repair, directly over the wet adhesive and smooth it before it hardens. The tape can be removed after five minutes when the adhesive has set.

19. The patch should be hard enough in 50 minutes to allow sanding to a smooth flat surface, if desired.
20. Repair the damage on the outside surface of the hood and paint the surface on both sides, using the instructions in "Surface Damage Repair."

Half-Fender Removal and Installation



Removal (See Fig. 1 and Fig. 2)

1. Fender Reinforcement
2. Forward Bracket
3. Rear Bracket
4. Left-Hand Half-Fender

Fig. 1, Left-Hand Half-Fender Installation

1. Apply the parking brakes and chock the tires.
2. Tilt the hood.
3. Remove the two quarter-turn fasteners and the splash shield.
4. Remove the fasteners attaching the half-fender to the forward (lower air cleaner bracket on the right-hand side) and rear brackets.
5. Remove the fasteners attaching the half-fender to the cab, which extend through the fender reinforcements.
6. If the half-fender is being replaced, remove the hood latch bracket and half-fender reinforcement for installation on the new half-fender.

1. Rear Bracket
2. Lower Air Cleaner Bracket
3. Fender Reinforcement
4. Right-Hand Half-Fender

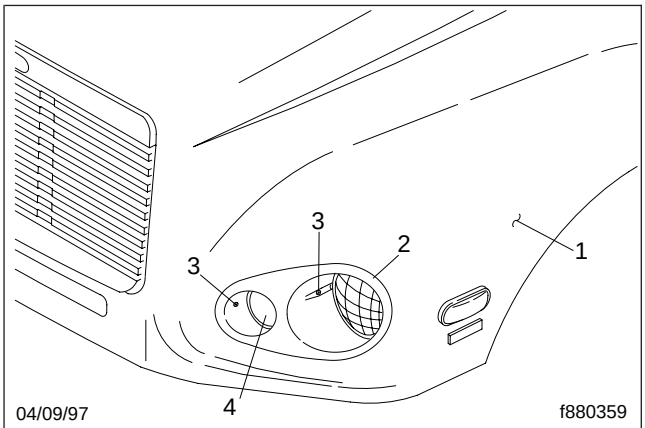
Fig. 2, Right-Hand Half-Fender Installation

NOTE: If replacing a half-fender, remove and save the splash shield rear inner mounting bracket.

7. Remove the vertical fastener in the approximate center of the half-fender, attaching the half-fender to the cab. Remove the half-fender.

NOTE: This vertical fastener is not visible unless viewed directly from below.

Half-Fender Removal and Installation



Installation (See Fig. 1 and Fig. 2)

1. If the half-fender was replaced, install the hood latch bracket, half-fender reinforcement, and the splash shield rear inner mounting bracket onto the new half-fender. Tighten the 1/4–20 locknuts 96 lbf·in (1080 N·cm).
2. Position the new half-fender against the cab. Install the fasteners which attach the fender to the cab, finger-tight only.
3. Install the fasteners that attach the half-fender to the forward bracket (lower air cleaner bracket on the right-hand side) and rear bracket.
4. Torque all the half-fender retaining M8 bolts and nuts to 14 lbf·ft (20 N·m).
5. Install the splash shield and the two quarter-turn fasteners.
6. Lower the hood, and remove the chocks.

Headlight Bezel Assembly Removal and Installation

Removal

1. Remove the two screws (**Fig. 1**) that attach the headlight bezel assembly to the hood.
2. Withdraw the bezel assembly from its opening in the hood and disconnect the turn signal harness connector.
3. Remove the headlight bezel assembly from the hood.

1. Hood
2. Headlight Bezel
3. Mounting Screw
4. Turn Signal

Fig. 1, Headlight Bezel Assembly-to-Hood Attachment

Installation

1. Connect the turn signal harness connector to the turn signal.
2. Place the headlight bezel assembly in position in its opening in the hood.
3. Install and tighten the two screws until snug.

Repair Tools, Materials

SURFACE DAMAGE

Required tools and materials:

- Xylene, acetone, or equivalent solvent
- 220- or finer grit sandpaper
- 320- or finer grit sandpaper
- Hand-held disc pad
- Self-leveling adhesive [1]
- Applicator squeegee
- Primer [2]

STRUCTURAL DAMAGE

Section Replacement (Punctures and Large Fractures)

Required tools and materials:

- Scrap FRP from a damaged hood
- Xylene, acetone, or equivalent solvent
- Saber saw
- Router bit
- Razor-blade knife
- Woven fiberglass cloth
- Clamps
- 80- to 220-grit sandpaper
- 220- or finer grit sandpaper
- 320- or finer grit sandpaper
- Hand-held disc pad
- Adhesive for bonding strips (if needed) [3]
- Self-leveling adhesive [1]
- Applicator squeegee
- Primer [2]

Crack or Small Hole

Required tools and materials:

- Xylene, acetone, or equivalent solvent
- 1/8-inch diameter drill bit
- Router bit
- Razor-blade knife
- Woven fiberglass cloth
- 80- to 220-grit sandpaper
- 220- or finer grit sandpaper
- 320- or finer grit sandpaper
- Hand-held disc pad
- Self-leveling adhesive [1]
- Applicator squeegee
- Primer [2]

HOOD COMPONENT REBONDING

Required tools and materials:

- Solvent [4]
- 80- to 220-grit sandpaper
- Clamps, clamping bolts with washers
- 0.030" (0.76 mm) diameter glass beads
- Adhesive [3]
- Primer [2]
- Heat gun
- Putty knife, hacksaw blade

Torque Values (standard and metric fasteners)				
Description	**Size**	**Grade**	**Torque lbf·ft (N·m)**	**Torque lbf·in (N·cm)**

NOTE: Ashland Pliogrip 7700 and 8000 Series adhesives and accessories are available through Freightliner dealers and PDCs. The 7700 Series adhesives are two-part urethane adhesives, specially formulated and packaged for repair of hoods and other fiber-reinforced plastics. Adhesive 7775L is a self-leveling mixture that is appropriate when a surface filler or glass fabric reinforcement repair is required. The 8000 Series adhesives are also two-part urethane adhesives, available for those who prefer to use these earlier-generation adhesives. Descriptions, working times, and curing times (sanding and repainting) for the various adhesives are shown below in **Table 2** and **Table 4**.

Ashland adhesive accessories are listed in **Table 3** and **Table 5**.

NOTE: All of the adhesives develop the same bonding strength; specific adhesives may be preferred to change working times.

NOTE: All working and curing times correspond to an ambient temperature of 73°F (23°C) in the workplace; humidity level will NOT affect working or curing times.

IMPORTANT: While a heat gun may be used to speed adhesive curing time, do not overheat the adhesive. The maximum allowable temperature is 180°F (82°C).

Table 5, 8000 Series Accessories

General Description

The Twinflow midship-mounted fire pump is a centrifugal pumping system designed to deliver large volumes of water under pressure. See **Fig. 1**.

Generally, the pump consists of the following major components:

- cast-iron pump body
- bronze impeller(s) and a stainless steel shaft
- pump gear box
- priming system
- pressure control device
- valves

There are numerous other components, such as the AutoLube and the mechanical seal.

Pump type is determined by the number of impellers on a common shaft. The impeller, which is mounted on a shaft rotated by the vehicle's engine via the driveline, provides velocity to the water causing it to build enough pressure and volume to be used for firefighting applications. See **Fig. 2**.

Bearings support and align the impeller shaft and other components. The bearings must be maintained on a scheduled basis.

The pump body is split horizontally in two sections for the ease of removal of the impeller assembly, including the bearings and the clearance rings.

The pump gear box and the impeller assembly are removable from the bottom of the vehicle in order to avoid interference with the pump plumbing and control mechanisms.

The pump has two large suction inlets, one on each side of the vehicle, though other inlets may be present. The inlets and the internal pump outlets are on opposite sides of the pump to balance forces caused by the intake and the discharge of water.

The AutoLube is built into the pump assembly to continuously force oil to the impeller shaft bushing to lubricate and cool the impeller bushing.

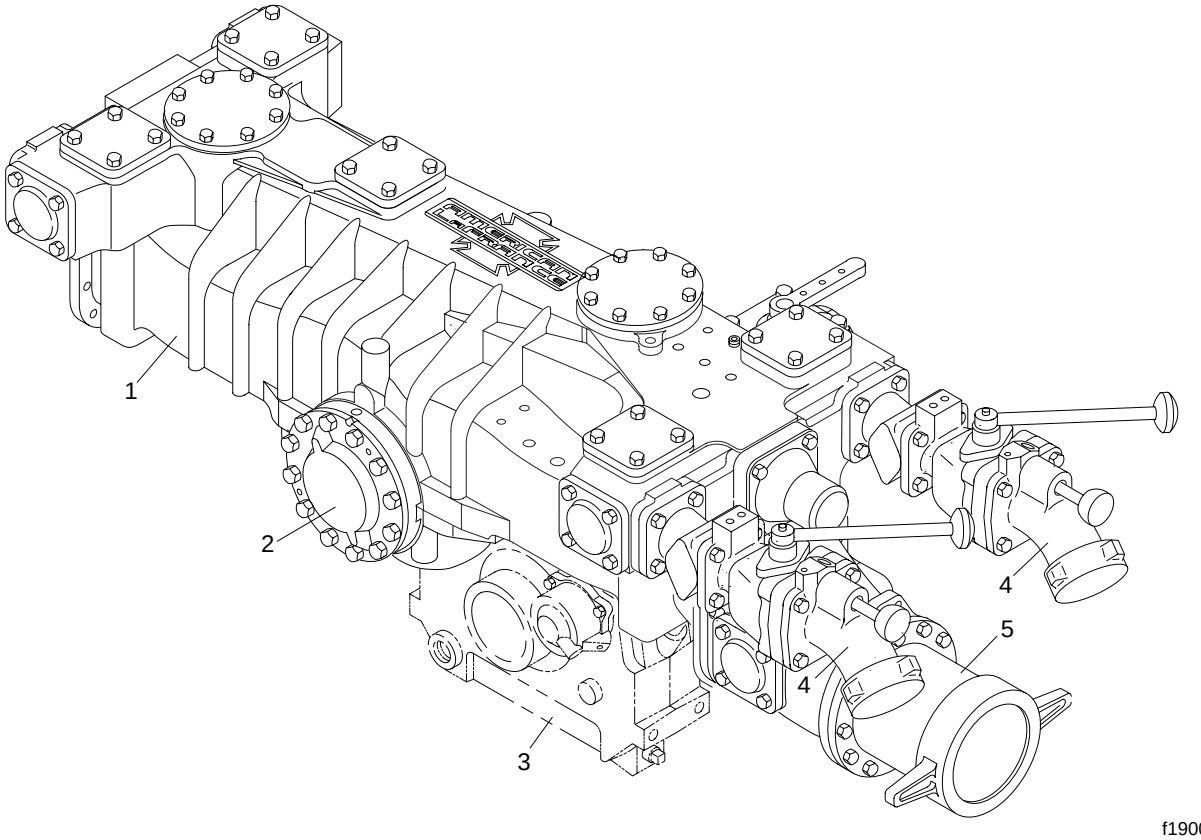
Principles of Operation

A centrifugal pump such as the Twinflow fire pump operates on the principle wherein centrifugal force is created by a rapidly spinning disk, or impeller. Water is routed to the center of the impeller, which throws the water outward from the center of the impeller. When water is confined in a closed container, in this instance, the pump body, the water pressure increases. The pressure level depends on how fast the impeller is rotating.

Water enters the spinning impeller at the intake and is confined by shrouds and vanes in the impeller, which, in turn, builds pressure.

The vanes guide the water away from the inlet to the discharge to reduce the water's turbulence and to move the water toward the outer edge of the impeller.

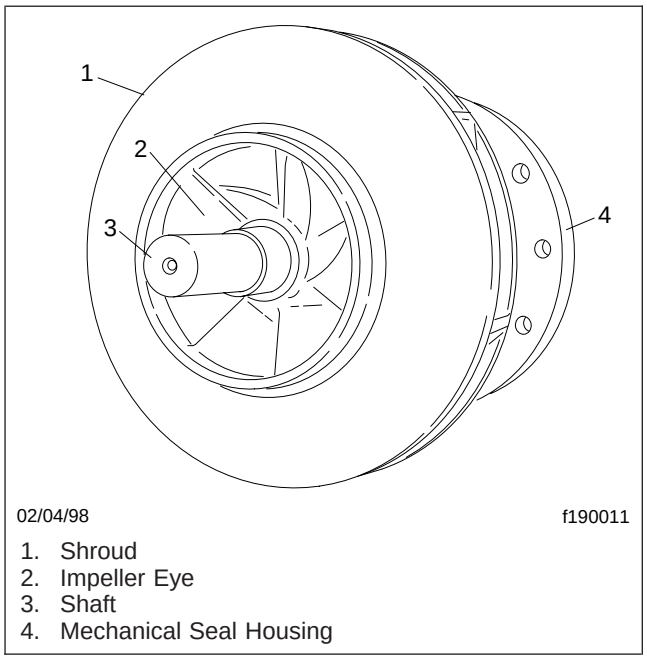
The shrouds serve as the sides of the impeller and confine the water to the centrifugal acceleration.



Single-stage pumps provide the same operating and rating-test pressures as a two-stage pump, but the two-stage pump offers additional operating (water) pressure.

The primary difference between a single-stage and a two-stage pump is that the single-stage has only one impeller and no transfer valve to switch between volume and pressure operation. A transfer valve is a two-position valve that permits the impellers in a two-stage pump to operate in parallel (volume) or series (pressure).

In two-stage pumps, the volume operation results in the pressure at the pump intake being added to the equal pressure developed by the impellers, and the amount of water sent to the discharge being the sum of the flows of the two impellers. The pressure operation features the impellers operating in series, or the output of the primary impeller supplied from the pump intake is supplied to the input of the secondary impeller. Thus, the pressure at the pump discharge is the sum of the pressures of the two impellers plus the pressure at the intake. The flow is then half of the volume operation.



In both types of pumps, the pressurized water is prevented from returning to the intake of the impeller(s) by clearance rings. Centrifugal pumps have clearance rings mounted between the spinning impeller and the pump body. Clearance rings and the hubs of the impeller(s) will, over time, become worn or pitted and may need to be replaced or machined to a smaller diameter.

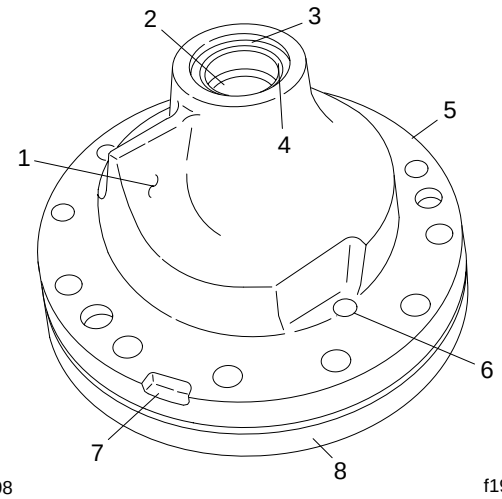
General Information

1. Pump Body
2. AutoLube
3. Gear Box
4. Discharge
5. Intake

Fig. 1, Twinflow Fire Pump (single-stage shown)

1. Shroud
2. Impeller Eye
3. Shaft
4. Mechanical Seal Housing

Fig. 2, Twinflow Fire Pump Gear Box



Replacement

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.
2. Drain the water from the pump.
3. Remove the fill and drain plugs from the AutoLube reservoir and drain the oil.
4. Use a center punch to mark the AutoLube cover and the front bearing housing for proper alignment during assembly.

CAUTION

Do not use a chisel to separate the AutoLube from the pump body because the mating surfaces may be scratched or gouged, which could result in a leak. The AutoLube is manufactured from cast metal and if it becomes necessary to pry the AutoLube apart from the pump body, pry between the AutoLube and the pump body or at the AutoLube notches.

5. Remove the 1/2–13 x 2 capscrews attaching the AutoLube to the pump body and gently pry the AutoLube from the pump body and impeller shaft.
6. Place the AutoLube face down on a work bench and remove the two 3/8–16 x 3/4 allen-head capscrews from the impeller side. Separate the two halves and remove the diaphragm.
7. Remove the seal lock ring.
8. Remove the oil seal from the inner half of the AutoLube.
9. Check the impeller shaft bushing for wear.
10. Clean the inner and outer halves of the AutoLube.
11. Clean the gasket surfaces of the AutoLube and the pump body.
12. Check for restrictions in the water passages to the rear half of the AutoLube.
13. If it is necessary to replace the impeller shaft bushing, press the bushing from the inner side of the inner half of the AutoLube (on the side opposite of the impeller). Install the bushing from the impeller side of the inner half of the AutoLube. See **Fig. 1**.

1. Cut Water
2. Bushing
3. Lock Ring
4. Seal
5. Front Bearing Housing
6. Water Passage
7. Pry Notches
8. AutoLube Cover

Fig. 1, Impeller Shaft Bushing

CAUTION

The impeller shaft bushing seats against a shoulder in the inner half of the AutoLube and can only be removed and installed as described or the AutoLube may be damaged.

14. Install the new oil seal in the inner half of the AutoLube.
15. Install the seal lock ring.
16. Position the diaphragm on the inner half of the AutoLube.
17. Line up the marks and place the outer half of the AutoLube onto the inner half. Apply Loctite® 242 to the two 3/8–16 x 3/4 allen-head capscrews. Tighten 30 lbf·ft (41 N·m).
18. Install the new gasket on the AutoLube and position the assembly (with the top up) onto the impeller shaft. Attach the AutoLube with 1/2–13 x 2 capscrews and tighten 80 lbf·ft (108 N·m).

AutoLube Seal Replacement

CAUTION

Do not damage the oil seal. A damaged oil seal could result in damage to the AutoLube assembly as well as the pump.

19. To fill the AutoLube with 90w oil, pump the oil in from the bottom plug opening until the oil spills from the top opening. This eliminates air pockets and false readings.

CAUTION

Purge the air from the AutoLube while filling it with oil or a "false-fill" situation will develop, which could cause damage to the AutoLube and other components.

20. Add water to the pump.
21. Operate the fire pump and check the AutoLube for water or oil leaks.
22. Remove the tire chocks.

Fire Pump Gearbox Removal, Disassembly, Assembly, and Installation

Removal

NOTE: For an exploded view of the fire pump body assembly, see **Fig. 1**.

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.
2. Drain the water from the pump.
3. Drain the gearbox lubricant to prevent contamination.
4. Disconnect the pressure lubrication line to the gearbox cover. Keep the line primed with lubricant.
5. Disconnect the drive shafts from the gearbox.
6. Disconnect the electrical switches and the air lines. Mark the switches and air lines for assembly.
7. Disconnect the pump gearbox cooling lines.

⚠ WARNING

The gearbox is heavy. Support the gearbox with a lifting or supporting device while removing it from the pump body. Failure to do so could result in the gearbox falling, which could result in personal injury or property damage.

NOTE: Before removing the gearbox, use a center punch to mark the rear bearing housing, the mechanical seal housing, the oil pump cover and the pump body to ensure proper alignment during reassembly.

8. Support the gearbox with an appropriate device.
9. Remove the six 1/2–13 x 1-3/4 capscrews that attach the gearbox cover to the top of the gearbox.
10. Remove the 7/16–14 x 1-1/4 capscrews that attach the gearbox to the rear bearing housing.
11. Lower the gearbox. Be sure to balance the gearbox so that it does not tip from the lowering device. See **Fig. 2**.
12. Remove the gearbox cover.

NOTE: The threaded holes may need to be cleaned.

Disassembly

1. Remove and disassemble the intermediate shaft assembly.

   1.1 Disconnect the oil suction line from the lubrication pump.

   1.2 Remove the capscrews attaching the front bearing housing to the lubrication pump. Then, remove the housing and pump assembly.

   NOTE: The rear bearing housing has threaded holes for 1/4–20 jackscrews to assist in removal.

   1.3 Remove the capscrews attaching the rear bearing housing to the lubrication pump.

   1.4 Reach into the top of the gearbox housing and remove the intermediate gear and shaft assembly. The bearing inner cups are pressed onto the shaft, so care must be taken not to damage the cups during removal.

   1.5 Using a bearing splitter, clamp the halves of the splitter onto the back edge of the intermediate shaft bearing cup. Attach a crossbar puller to the bearing splitter halves and remove the cup. Care must be taken when removing the cup to not damage the lubrication pump spline in the center of the intermediate shaft. Repeat the procedure for the opposite-side bearing cup.

   1.6 Using a gear puller with reversed jaws, remove the intermediate shaft bearing cone from the intermediate shaft rear cover.

⚠ CAUTION

Lubrication pump impeller vanes are fragile, and may break or chip. Impeller vanes are installed only one way. If removal of the vanes is necessary, note the installation direction of the vanes (rounded edge). Failure to install the vanes properly will result in pump gearbox failure.

   1.7 When disassembling the lubrication pump, be sure to note the number of gas-

kets and shims that are under the cover. Set these components aside for reassembly.

1.8 Using a centerpunch, mark the lubrication pump position, and remove the six 1/4–20 x 5/8 capscrews.

1.9 Remove the lubrication pump cover.

1.10 Remove the lubrication pump impeller and the shaft, being careful not to damage the impeller vanes.

1.11 Using a gear puller with reversed jaws, remove the intermediate shaft bearing cone from the intermediate shaft front cover. Care must be taken when removing the cup so as not to damage the lubrication pump spline in the center of the intermediate shaft cover.

2. Remove and disassemble the output shaft assembly. See **Fig. 3**.

2.1 Remove the manual shift eye from the rear of the shift yoke shaft.

2.2 Remove the detent allen-head screw, spring and detent ball from the top of the output shaft housing.

2.3 Remove the shift and interlock switches on the output shaft housing.

2.4 Remove the 7/16–14 x 2-1/4 capscrews retaining the output shaft and the housing to the gearbox housing. Carefully remove the output shaft housing by sliding the housing from the shift yoke shaft.

2.5 Remove the input shaft pilot bearing from the output shaft.

2.6 Remove the 3/4–10 x 1-1/2 capscrew retaining the rear driveline yoke to the output shaft and remove the yoke.

2.7 Remove the output shaft seal.

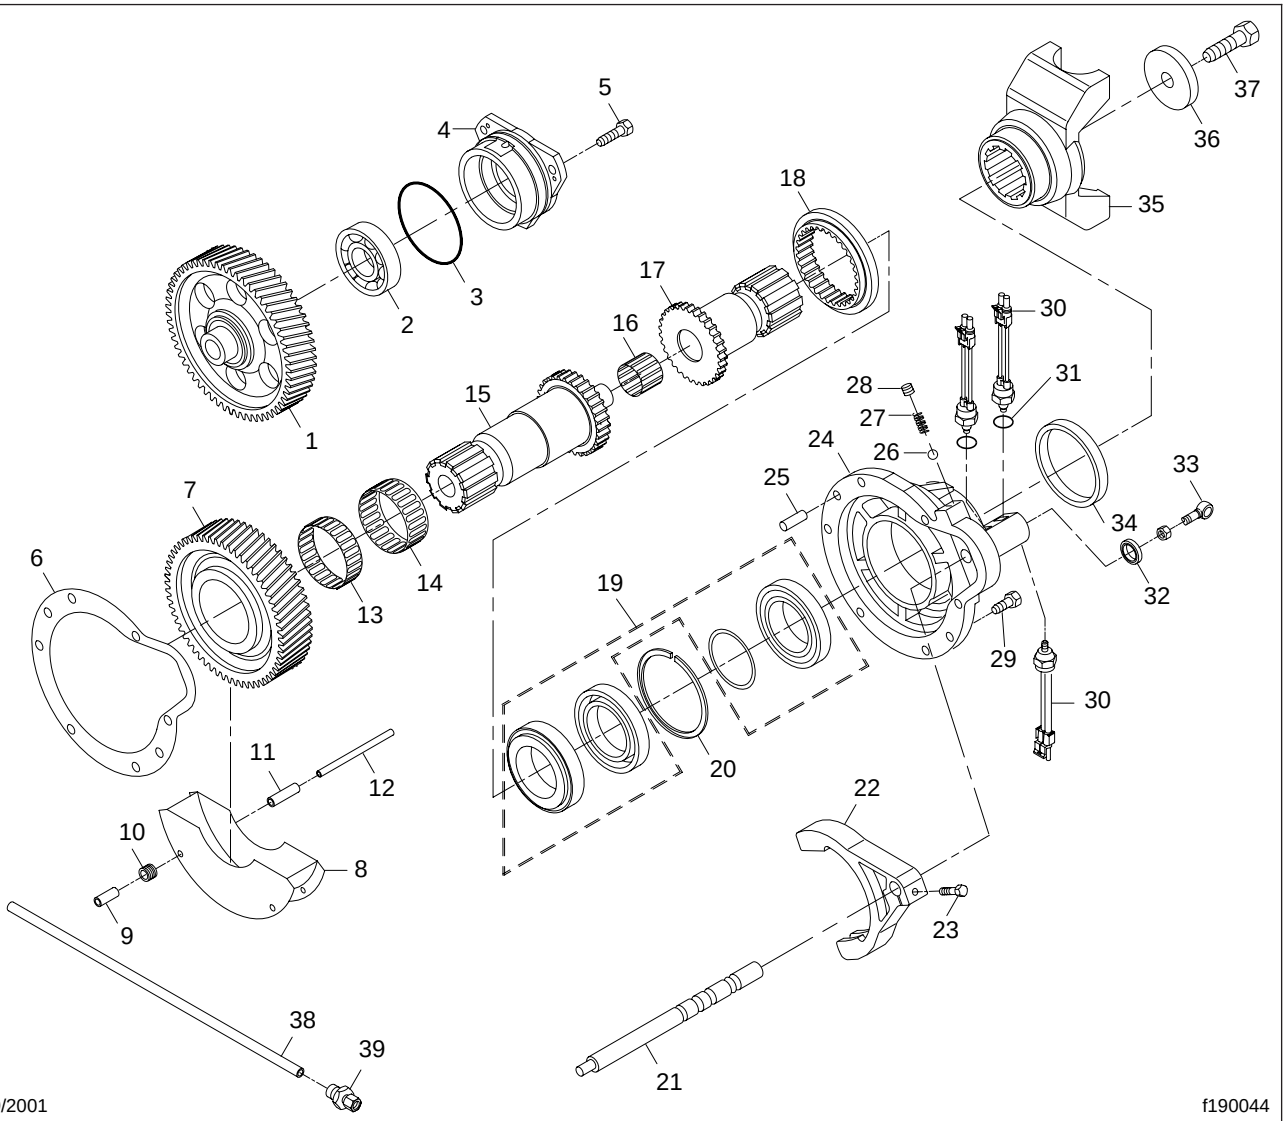
2.8 Remove the output shaft by sliding it from the output shaft housing from the rear to the front. Use caution when sliding the output shaft through the bearing cones and spacer(s).

⚠ CAUTION

Bearing cups, cones and spacers are factory pre-set for end play, and are only provided as a matched set. It is important that bearing cups, bearing cones and spacers, when removed, be kept together in matched sets. Input and output shaft bearing and spacer sets are different. Failure to keep matched sets together or to not use factory pre-set and matched bearing and spacer sets will void warranty and may result in gearbox failure.

2.9 Remove the inner and outer bearing cones.

2.10 Using a brass drift, carefully drive out the outer bearing cup from the inside out. Remove the internal retaining ring and then the spacer(s).



2.11 Using a brass drift, carefully drive out the inner bearing cup from the outside in.

2.12 Remove the shaft seal from the output shaft housing.

3. Remove and disassemble the input shaft assembly.

3.1 Remove the three 5/16–18 x 1 capscrews from the shift cylinder, and then carefully slide the shift cylinder from the piston.

Fig. 3, Rear Gearbox Assembly (exploded view)

3.2 Remove the nut and then remove the piston from the shift shaft. Remove the seal ring from the piston.

⚠ CAUTION

Do not remove the piston from the shift yoke shaft unless it is damaged (and replacement is mandatory). When installing a new piston, replace the locknut and tighten snugly, but do not overtighten as the nut can become distorted, which can cause shift failures.

3.3 Remove the shift shaft, the shift fork, and the shift ring assembly from the gearbox. Make sure the shift ring does not get dropped or damaged.

3.4 Note the location and orientation of the shift fork on the shaft, then remove the 3/8–16 x 1-1/4 screw from the shift fork and remove the fork from the shift shaft.

3.5 Remove the shift shaft support block. Then remove the seal from the support block.

NOTE: One ear of the shift yoke is machined and will fit one way. Make a note of the location of the machined ear when removing the shift yoke.

3.6 Remove the 3/4–10 x 1-1/2 capscrew attaching the front driveline yoke to the input shaft. Remove the yoke.

3.7 Remove the input shaft by sliding the input shaft from the output shaft housing opening at the rear of the gearbox. Use caution when sliding the input shaft through the bearing cones, the thrustwasher and the drive gear. Place wooden blocks to support the drive gear and to protect the windage tray, and force the shaft loose.

⚠ CAUTION

Bearing cups, cones and spacers are factory preset for end play, and are only provided as a matched set. It is important that bearing cups, bearing cones and spacers, when removed, be kept together in matched sets. Input and output shaft bearing and spacer sets are different. Failure to keep matched sets together or to not use factory pre-set and matched bearing and spacer sets will void warranty and may result in gearbox failure.

There are two bearings of different widths supporting the drive gear on the input shaft. It is important that these bearings be installed in the drive gear in the proper location. Note the location of the bearings when removed. Failure to install the bearings properly can result in gearbox failure.

3.8 Reaching through the top of the gearbox housing, carefully remove the drive gear, the inner bearing cone, and thrustwasher. Remove the drive gear bearings.

3.9 Using a magnet, remove the positioning pins from the windage tray. Then, remove the windage tray and the positioning springs.

3.10 Remove the input shaft seal.

3.11 Remove the outer bearing cone.

3.12 Using a brass drift, carefully drive out the outer bearing cup from the inside out. Remove the internal retaining ring and the spacer(s).

3.13 Using a brass drift, carefully drive out the inner bearing cup from the outside in.

4. Inspect the cooling tube for damage and leaks.
5. Remove the gearbox lubrication oil filter from the suction inlet on the gearbox housing.
6. Clean and inspect each component of the gearbox assembly. Inspect the bearing cups and the cones for wear, pitting and damage. Inspect the gear tooth surfaces for wear damage and pitting. Inspect the shift shaft block for wear. Inspect the gasket surfaces for nicks and gouges. Replace all components that are worn, damaged or pitted.

Assembly

1. Install a new transmission lubrication oil filter.
2. Assemble and install the input shaft assembly.

Fire Pump Gearbox Removal, Disassembly, Assembly, and Installation

⚠ CAUTION

Bearing cups, cones and spacers are factory pre-set for end play, and are only provided as a matched set. It is important that bearing cups, bearing cones and spacers, when removed, be kept together in matched sets. Input and output shaft bearing and spacer sets are different. Failure to keep matched sets together or to not use factory pre-set and matched bearing and spacer sets will void warranty and may result in transmission failure.

2.1 Using a brass drift or a bearing cup installation tool, install the inner bearing cup from the inside out. Then install the spacer(s) and insert the retaining ring.

2.2 Using a brass drift or a bearing cup installation tool, install the outer bearing cup from the outside in.

2.3 Coat the outer bearing cone with oil. Install the outer bearing cone.

2.4 Install the input shaft seal.

2.5 Install the windage tray positioning springs and windage tray. While holding the windage tray in place against the positioning springs, install the windage tray positioning pins.

⚠ CAUTION

There are two bearings of different widths supporting the drive gear on the input shaft. It is important that these bearings be installed in the drive gear in the proper location. The location of the bearings should have been noted when removed from the assembly. Make sure that the lubrication holes are aligned in the center of the larger bearing. Failure to install the bearings properly may result in transmission failure.

2.6 Coat the new drive bearings with oil and install in the drive gear.

2.7 Coat the inner bearing cone with oil and install. Then, install the thrustwasher.

2.8 Reaching through the top of the transmission housing, install the drive gear into position against the thrustwasher, being careful not to dislodge the windage tray.

2.9 Slide the input shaft through the output shaft housing opening at the rear of the transmission through the drive gear, the thrustwasher, and the bearing cones and spacer(s).

2.10 Install the front driveline yoke on the input shaft, being careful not to damage the input shaft seal. Apply Loctite® 242 to the 3/4–10 x 1-1/2 yoke retaining capscrew. Then install the capscrew and washer and tighten 225 lbf·ft (305 N·m).

NOTE: Apply a coat of Loctite® to all screws prior to reassembly.

NOTE: One ear of the shift yoke is machined, and it will only fit one way. Make sure the yoke is oriented on the shaft in the position noted during disassembly.

2.11 Make sure the shift fork is properly aligned (the machined side should be toward the threaded end of the shift shaft) and slide the new shift fork on the shift shaft. Align the shift fork with the groove in the shaft and secure the shift fork in place with a 3/8–16 x 1-1/4 screw. Tighten the screw 33 lbf·ft (45 N·m).

2.12 Install a new seal on the shift shaft support block. Install a new gasket on the shift shaft support block. Install the shift shaft support block and gasket in the gearbox using two 1/4–20 x 5/8 capscrews. Tighten the capscrews 96 lbf·in (1085 N·cm).

2.13 Place the shift ring into the shift fork grooves. While holding the shift ring in place, insert the shift shaft into the gearbox through the bushing. Make sure the teeth on the shift shaft ring line up with the teeth on the input shaft and gear.

2.14 Apply a light coating of grease to the new seal ring, then install the seal ring on the shift piston. Install the piston on the shift shaft end.

⚠ CAUTION

When installing the piston, use a new locknut and tighten snugly but do not overtighten. Over-

tightening the locknut may distort the piston and cause shift failures.

2.15 Secure the piston in place with a new locknut.

2.16 Apply a light coating of grease to the shift cylinder seal and install the seal in the groove on the shift cylinder.

2.17 Install the shift cylinder using three 5/16–18 x 1 screws. Tighten the screws 17 lbf·ft (23 N·m).

3. Assemble and install the output shaft assembly.

3.1 Install a new shift shaft seal in the output shaft housing.

⚠ CAUTION

Bearing cups, cones and spacers are factory pre-set for end play, and are only provided as a matched set. It is important that bearing cups, bearing cones and spacers, when removed, be kept together in matched sets. Input and output shaft bearing and spacer sets are different. Failure to keep matched sets together or to not use factory pre-set and matched bearing and spacer sets will void warranty and may result in transmission failure.

3.2 Using a brass drift or a bearing cup installation tool, install the inner bearing cup from the inside out. Install the spacer(s). Then install the retaining ring.

3.3 Using a brass drift or a bearing cup installation tool, install the outer bearing cup from the outside in.

3.4 Coat the outer bearing cone with oil and then install it.

3.5 Install the output shaft seal.

3.6 Apply a coating of oil to the inner bearing cone, and install.

3.7 Apply a coating of oil to the input shaft pilot bearing and then install the bearing into the output shaft.

3.8 Install the output shaft by sliding the shaft in through the output shaft housing from the front to the rear. Be careful when sliding the output shaft through the bearing cones and spacer(s).

3.9 Install the rear driveline yoke on the output shaft, taking care not to damage the output shaft seal. Apply Loctite® 242 to the 3/4–10 x 1-1/2 capscrew. Then, install the capscrew and washer and tighten 225 lbf·ft (305 N·m).

3.10 Install a new gasket onto the output shaft housing.

3.11 Apply Loctite® 242 to the two 7/16–14 x 2-1/4 and the four 7/16–14 x 1-3/4 capscrews. Then, install the output shaft and housing, sliding the housing onto the shift yoke shaft. Install and tighten the 2-1/4-inch capscrews 50 lbf·ft (68 N·m) and the 1-3/4-inch capscrews 53 lbf·ft (72 N·m).

3.12 Install the shift and interlock switches on the output shaft housing.

3.13 Apply Loctite® 242 to the detent allen-head screw, and install the detent ball, spring and allen-head screw.

3.14 Install the manual shift eye from the rear of the shift yoke shaft.

3.15 Rotate the input shaft to check for proper movement.

4. Assemble and install the intermediate shaft assembly.

4.1 Press a new bearing cone into the intermediate shaft rear cover, coat the cone with oil and install a new cover seal.

4.2 Press a new bearing cone into the intermediate shaft front cover, coat the cone with oil and install a new cover seal.

⚠ CAUTION

Lubrication pump impeller vanes are fragile, and may break or chip. Impeller vanes are installed only one way. If removal of the vanes is necessary, note the installation of the vanes. Failure to install the vanes properly will result in transmission failure.

IMPORTANT: To ensure proper operation of the oil pump, use the same number of gaskets and shims that were removed when the oil pump was disassembled.

Fire Pump Gearbox Removal, Disassembly, Assembly, and Installation

4.3 Install the lubrication pump impeller assembly, vanes and shaft into the front cover, aligning matchmarks. Apply Loctite® 242 to the six 1/4–20 x 5/8 capscrews and tighten 8 lbf·ft (11 N·m).

4.4 Press the new bearing cups onto the intermediate shaft, one on each side of the intermediate gear.

4.5 Reaching through the top of the transmission housing, install the intermediate gear and shaft assembly, taking care not to damage the bearing cups.

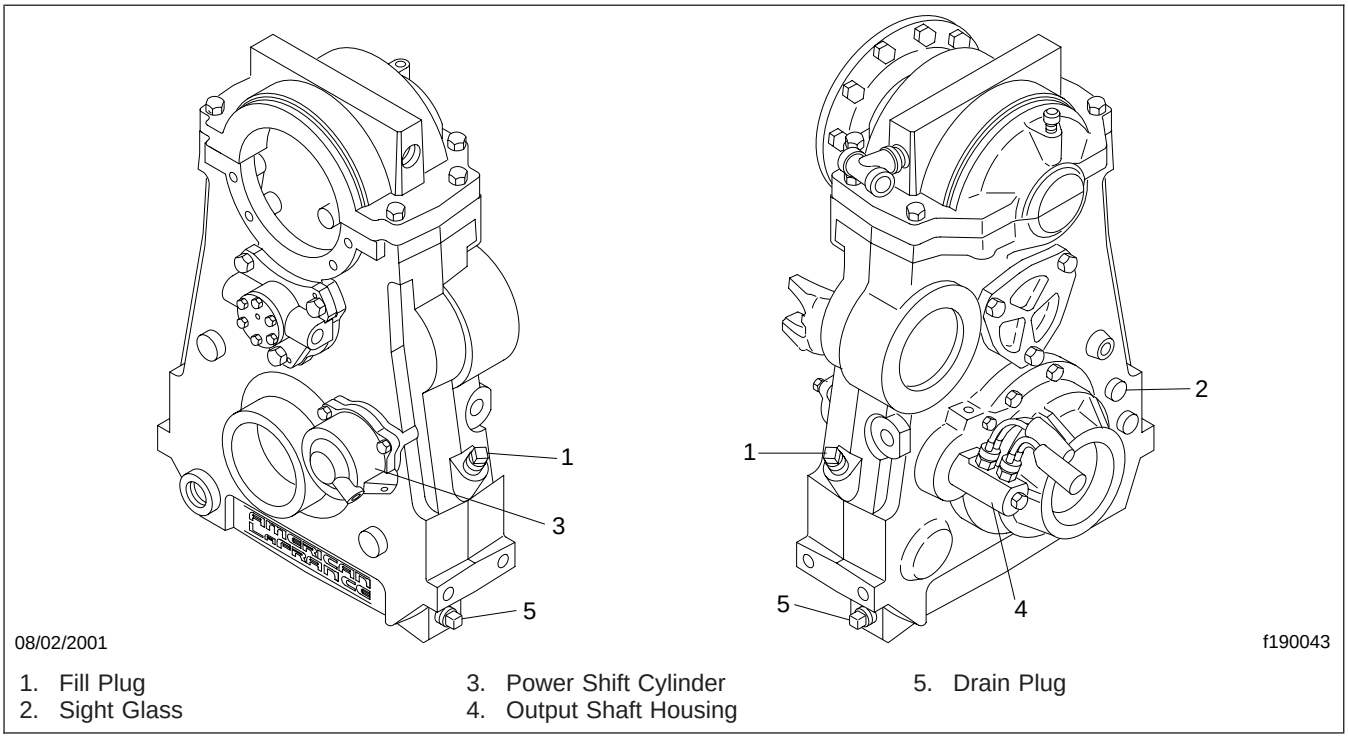
4.6 Holding the intermediate gear assembly in place, install the rear intermediate shaft cover. Apply Loctite® 242 to the three 7/16–14 x 1-1/4 capscrews and install but do not torque.

4.7 Install the front intermediate shaft cover, aligning the lubrication pump shaft spline with the intermediate shaft spline. Apply Loctite® 242 to the three 7/16–14 x 1-1/4 capscrews and tighten all six capscrews 53 lbf·ft (72 N·m).

4.8 Connect the oil suction line to the lubrication pump.

4.9 Rotate the input shaft and manually shift the transmission to check for proper movement and operation.

Installation



1. Install a new gasket on the seating surface of the rear bearing housing.

⚠ CAUTION

Properly align the rear bearing housing. If the rear bearing housing is not aligned with the matchmarks, the gear tooth mesh could be incorrect and may result in damage to the gearbox.

2. Using a lifting device, lift the gearbox into position (around the rear bearing housing). Apply Loctite® 242 to the six 1/2–13 x 1-3/4 capscrews, and attach the gearbox cover to the gearbox. Tighten finger-tight, but do not torque.
3. Apply Loctite® 242 to the twelve 7/16–14 x 1-1/4 capscrews, and insert the capscrews through the rear bearing housing cover and gasket into the gearbox. Tighten 53 lbf·ft (72 N·m).
4. Tighten the six 1/2–13 x 1-3/4 capscrews 65 lbf·ft (88 N·m).
5. Connect the pump gearbox cooling lines.
6. Connect the air lines and electrical switches.
7. Connect the drive shafts. Tighten the yoke fasteners 225 lbf·ft (305 N·m), and tighten the bearing retaining strap capscrews 40 to 48 lbf·ft (54 to 65 N·m).
8. Connect the lubrication line to the gearbox cover.
9. Fill the gearbox with the necessary lubricant. See **Fig. 4**.
10. Operate the pump and check for leaks. Verify the oil pressure at 25 to 35 psi (172 to 241 kPa) at the oil injection point.
11. Remove the chocks from the front and rear tires.

Fire Pump Gearbox Removal, Disassembly, Assembly, and Installation

1. Fill Plug
2. Sight Glass
3. Power Shift Cylinder
4. Output Shaft Housing
5. Drain Plug

Fig. 4, Fire Pump Gear Box Lubrication and Fluid Change Locations

Replacement

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.
2. Drain the water from the pump.

⚠ WARNING

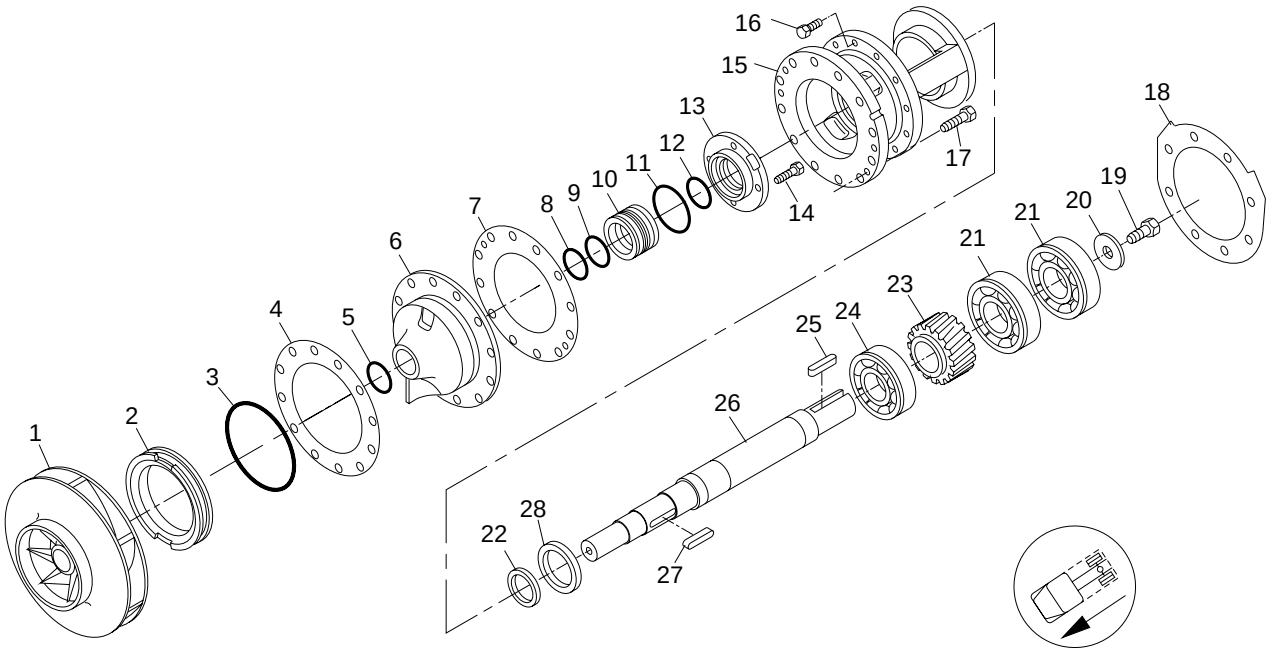
The gearbox assembly is heavy. Support the lower gearbox assembly with a lifting device. Failure to do so could result in the assembly falling, which could result in personal injury or property damage.

3. Remove the gearbox. See **Subject 110** for information.
4. Remove the 5/8–11 x 1-1/4 capscrew and bearing retaining washer from the end of the impeller shaft.
5. Remove the twelve 1/2–13 x 1-3/4 capscrews that attach the rear bearing housing to the pump body.
6. Install two 1/2–13 x 3 jackscrews into the 1/2–13 threaded holes provided in the rear bearing housing. See **Fig. 1**.
7. Use a centerpunch to mark the rear bearing housing, the mechanical seal housing, and the pump body so that the components are properly aligned during assembly.
8. Turn the two jack screws evenly, clockwise, to push the rear bearing housing from the impeller shaft and pump body.

NOTE: To prevent damage to components as the rear bearing housing is pushed from the impeller shaft, place your hands under the gear opening to catch the gear, key, and bearings.

NOTE: It may be necessary to use pry bars to gently assist in removing the inner bearings and gear.

9. Remove the jack bolts.
10. Remove the slinger from the impeller shaft.
11. Remove the four 7/16–14 x 1-1/4 capscrews from the mechanical seal cover. See **Fig. 2**. Use a center punch to mark the seal cover for proper alignment during installation.
12. Use pry bars if necessary in the provided slots to loosen the mechanical seal cover from the impeller shaft and the pump body.
13. Remove the old mechanical seal, being careful not to damage the impeller shaft. Use two small hook-tools positioned about 180 degrees apart to pull the mechanical seal from the seal cavity if necessary.
14. Clean the seal cavity and the impeller shaft.
15. Inspect the retaining ring on the shaft.
16. Remove the burrs at the gear key slot and the bearing lands, and remove the oil seal in the rear bearing housing. See **Fig. 3**.



IMPORTANT: Always replace the entire mechanical seal with a new Twinflow mechanical seal assembly.

⚠ CAUTION

When installing a new mechanical seal do not touch the sealing surface of the carbon seal ring or the metal seat while handling or installing. Oil and grease can damage the bellows of the mechanical seal. Use only a soap-and-water solution to lubricate the mechanical seal.

17. Clean the housing and the impeller shaft, and lubricate the impeller shaft and the new mechanical seal with a soap-and-water solution.
18. Install the new mechanical seal bellows over the end of the impeller shaft with the spring oriented toward the impeller. Using a soft pusher tube and keeping your fingers away from the carbon seal, carefully push the mechanical seal assembly into the mechanical seal cavity. If binding occurs, apply more soap-and-water solution to the impeller shaft and the bellows.
19. Install the steel cup and seat it into the mechanical seal cover. Lubricate with a soap-and-water solution.
20. Remove and replace the seal rings in the mechanical seal cover. Apply the soap-and-water solution to the seal rings and then slide over the

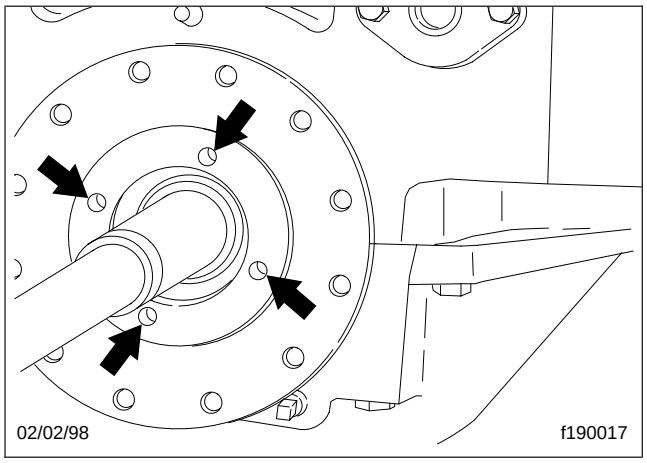
end of the impeller shaft. Make sure the mechanical seal remains seated in the bore of the cover.

21. Insert the mechanical seal cover into the mechanical seal cavity aligning it with the bolt holes and the orientation marks.
22. Insert the bolts in the mechanical seal housing to prevent the housing from rotating.
23. Install the four 7/16–14 x 1-1/4 capscrews. Tighten 53 lbf·ft (72 N·m).
24. Install the new slinger onto the impeller shaft. Then remove the retaining bolts.
25. Install the new gasket and oil seal in the rear bearing housing. Slide the housing and front bearing onto the rear impeller shaft. The bearing is a press-fit onto the impeller shaft and slip-fit in the housing.



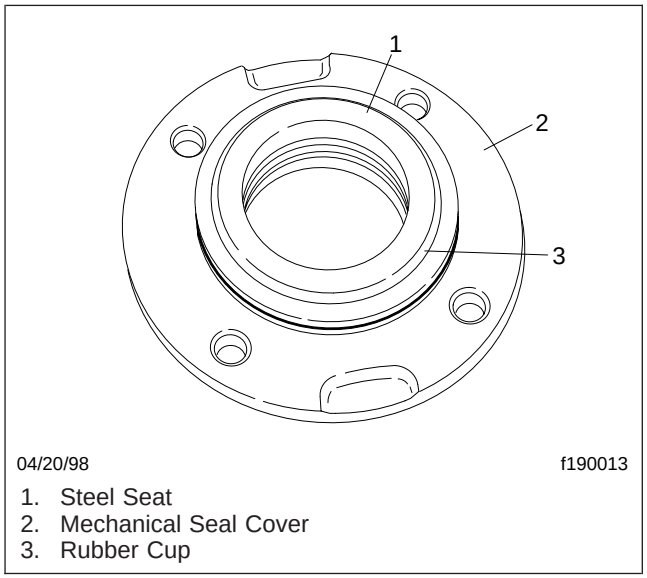


Fig. 2, Remove Four Capscrews

1. Steel Seat
2. Mechanical Seal Cover
3. Rubber Cup

Fig. 3, Mechanical Seal Assembly

IMPORTANT: Do not allow the weight of the rear bearing housing to rest on the oil seal.

26. Insert the gear through the opening in the housing and align it with the impeller shaft. Slide the housing, front bearing and gear onto the shaft. The front bearing will stop when the inner race contacts the seat on the impeller shaft.
27. Line up the keyway in the gear and install the key into the keyway.
28. Slide one of the two rear bearings onto the impeller shaft and into the housing. The rear bearings are a press-fit onto the shaft and a slip-fit in the housing.
29. Using a series of different length capscrews, install the rear bearing housing to the pump body. When it is possible, install the four capscrews (approximately 90 degrees apart). These bolts, in combination with the rear bearing, will center the housing. Double check to be sure the housing is centered and will clear the mechanical seal assembly.
30. Install the pusher bolt in the rear of the impeller shaft. Tighten the nut on the pusher bolt while holding the pusher bolt, pushing the rear bearing into the housing. Remove the pusher bolt and install the second of the two rear bearings. Then install the pusher bolt and tighten the nut while holding the pusher bolt to install the bearing.
31. Continue to tighten the nut on the pusher bolt while making sure the housing is aligned and centered. Once the pusher bolt is snug, the rear housing assembly, the gear, and the bearings should be in place. Remove the pusher bolt and rotate the impeller assembly by placing a large screwdriver between the housing and the gear. The impeller assembly should rotate.

NOTE: A new impeller will have some resistance when the impeller shaft is rotated.

32. Apply Loctite® 242 to the 5/8–11 x 1-1/4 bearing retainer capscrew. Install and tighten 80 lbf·ft (108 N·m).
33. Apply Loctite® 242 to the twelve 1/2–13 x 1-3/4 capscrews, install and tighten 80 lbf·ft (108 N·m).
34. Install the gearbox. See **Subject 110** for information.
35. Perform the annual service test on the pump. Check for leaks. Verify the oil pressure at 25 to 35 psi (172 to 241 kPa) at the oil injection point.
36. Remove the chocks from the front and rear tires.

Removal

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.
2. Drain the water from the pump.

⚠ WARNING

The gearbox assembly is heavy. Support the lower gearbox assembly with a lifting device. Failure to do so could result in the assembly falling, which could result in personal injury or property damage.

3. Remove the gearbox. See **Subject 110** for information.

⚠ WARNING

The lower pump body is heavy. Support the lower pump body and impeller assembly with a lifting device. Failure to do so could result in the lower pump body and impeller assembly falling, which could result in personal injury or property damage.

4. Remove the drain lines from the lower pump body. See **Fig. 1**.
5. Drain the oil from the AutoLube and remove the 1/2–13 x 2 capscrews from the upper half of the AutoLube and pump body.
6. Remove the 7/16–14 x 1-1/2 capscrews from the upper half of the rear bearing housing and pump body.
7. Remove the 1/2–13 x 1-1/4 capscrews from the lower pump body.

⚠ WARNING

Do not remove the four capscrews, one in each corner of the lower pump body, until the lifting device is in position. Failure to do so could result in the lower pump body and impeller assembly falling, which could result in personal injury or property damage.

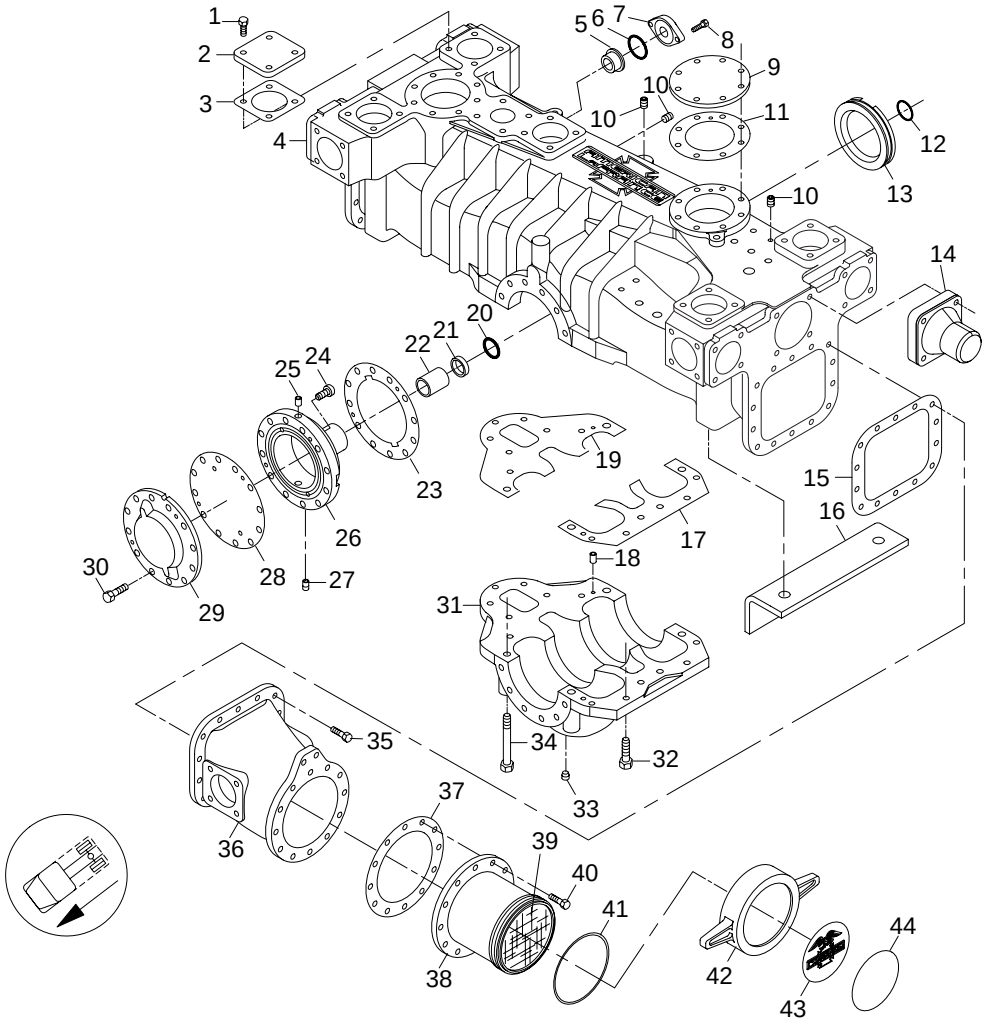
8. Position the lifting device into place with the lower pump body lifting adapter between the lifting device and the lower pump body.
9. Remove the 5/8–11 x 5 capscrews in each corner of the lower pump body.
10. Lower the lower pump body and impeller assembly. Be sure to balance the assembly so that it does not tip from the lifting device.
11. Remove the remaining capscrews from the lower half of the AutoLube, the rear bearing housing, and the lower pump body.

⚠ WARNING

The impeller assembly is heavy. Do not attempt to lift the assembly without the aid of another person or persons, or a lifting device. Failure to do so could result in the impeller assembly falling, which could result in personal injury or property damage.

12. Remove the remaining screws from the rear bearing housing and then from the lower pump body.
13. Lift the impeller assembly from the lower pump housing. See **Fig. 2**. Set the assembly aside.
14. Clean all gasket surfaces of the upper and lower pump bodies, as well as those on the AutoLube and the rear bearing housing face.
15. Clean the clearance ring and clearance ring seats in both the upper and lower pump body halves to remove all the buildup material so that the new clearance ring will seat properly.

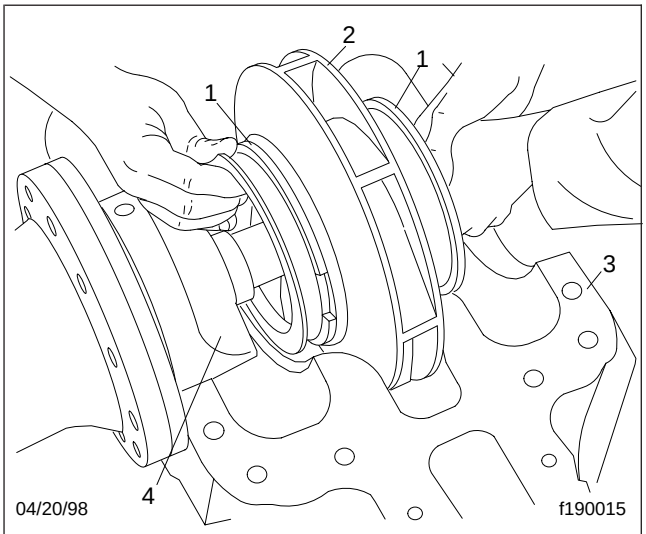
NOTE: Pitting of the clearance rings may occur from the buildup material and the effects of corrosion. Once the seats are cleaned, any pitting on the clearance rings is considered normal.



Installation

1. Install the pump body gaskets to the lower pump body, trimming as necessary to fit.

⚠ CAUTION



Failure to line up the clearance ring lock notches with the pump body tabs (as described in the next step) may result in pinched clearance rings, which could result in pump damage and pump failure.

Impeller Assembly Removal and Installation

1. Hexhead Screw, 7/16–14 x 1-1/4
2. Blank Flange
3. Flange Gasket
4. Upper Pump Body
5. Priming Valve Strainer
6. Priming Valve Plate Seal Ring
7. Priming Valve Plate

43. Medallion
44. Medallion O-Ring

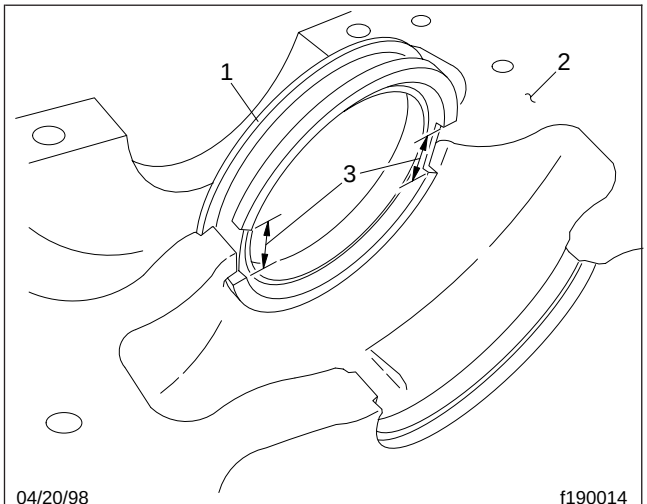

Fig. 1, Fire Pump Body Assembly (exploded view)

1. Clearance Ring
2. Impeller
3. Lower Pump Housing
4. Cut Water

Fig. 2, Lifting the Impeller Assembly from the Lower Pump Housing

2. Install the impeller assembly into the lower pump housing carefully aligning the clearance ring lock-notch with the clearance ring lock tabs in the lower pump body. Then rotate the clearance rings to one side to open up lock notches to line up with the lock tabs in the upper pump body. See **Fig. 3**.
3. Install the 1/2–13 x 1-3/4 capscrews through the rear bearing housing and the mechanical seal housing. Do not tighten.
4. Make sure the dowel pins are in the upper pump body to assist in aligning the lower pump body with the upper pump body.
5. Using a lifting device, slowly raise the lower pump body and the impeller assembly into place, making sure that the lower pump body aligns with the dowel pins and the clearance ring notches align with the clearance ring lock tabs in the upper pump body.
6. Rotate the impeller and check for freedom of movement when the lower pump body and the impeller assembly is in place.

1. Clearance Ring
2. Lower Pump Housing
3. Clearance Ring Notch

Fig. 3, Clearance Ring Mounted in Pump Housing

7. Apply Loctite® 242 and install the four 5/8–11 x 5 capscrews (one at each corner of the lower pump body). Tighten snug but do not fully torque.
8. Install the 1/2–13 x 1-3/4 screws in the rear bearing housing and mechanical seal housing. Tighten 53 lbf·ft (72 N·m).
9. Remove the lifting device.
10. Apply Loctite® 242 to the 1/2–13 x 1-3/4 lower pump body capscrews and install them. Tighten snug but do not torque.
11. Torque the 5/8–11 x 5 capscrews 150 lbf·ft (203 N·m) then, starting from the center and moving outward, tighten the lower pump body capscrews 65 lbf·ft (88 N·m).
12. Install the AutoLube. See **Subject 100** for instructions.
13. Install the gearbox. See **Subject 110** for instructions.
14. Operate the pump and check for leaks. Verify the oil pressure at 25 to 35 psi (172 to 241 kPa) at the oil injection point.
15. Remove the chocks.

Single-Stage Pump

Disassembly

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.
2. Remove the AutoLube. See **Subject 100** for instructions.
3. Remove the fire pump gear box. See **Subject 110** for instructions.
4. Remove the impeller assembly. See **Subject 130** for instructions and see **Fig. 1** for an exploded view of the assembly.
5. Place the impeller shaft on a work bench.
6. Note the orientation of the impeller vanes.
7. Remove the outer retaining ring.

WARNING

Wear protective, heat-resistant gloves while heating the impeller to remove it from the impeller shaft. Heated metal can cause injury to your hands.

CAUTION

Do not overheat the impeller. The impeller is constructed of bronze. If the impeller is overheated and turns red or blue during removal from the shaft, it has been weakened and must be replaced.

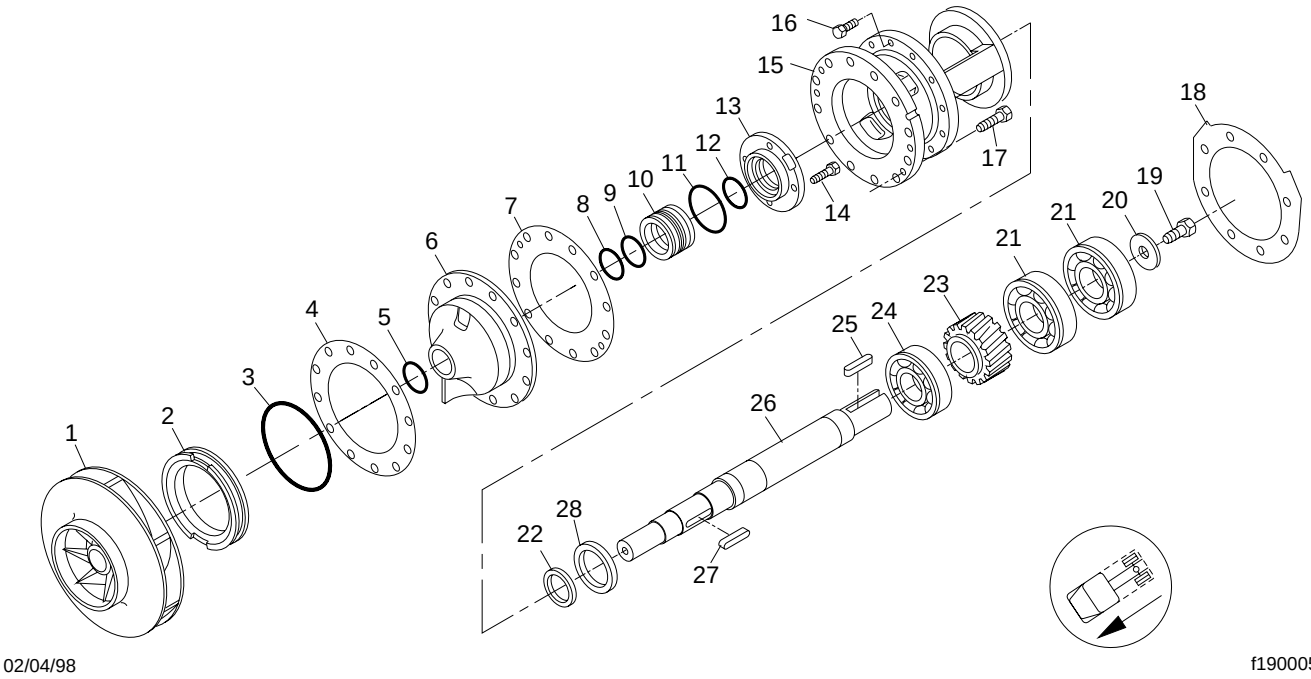
8. Using an acetylene torch, carefully heat the "eye" of the impeller for approximately two minutes.
9. When heated properly, the impeller will slide free of the shaft. If the impeller moves but does not slide free, do not immediately reheat. Allow the complete assembly to cool to room temperature then reheat and remove the impeller.
10. Allow the components to cool to room temperature.
11. Remove the inner clearance ring.
12. Remove the key.
13. Remove the inner retaining ring and slide the mechanical seal housing from the impeller shaft

Assembly

1. Clean the impeller shaft, the keyway, and the mechanical seal housing and face.
2. Check the waterway in the mechanical seal housing for restrictions.
3. Install the mechanical seal housing onto the impeller shaft.
4. Install the inner retaining ring.
5. Install the new gasket on the mechanical seal housing face.
6. Install the key into the keyway.

CAUTION

If the impeller or clearance rings are dropped, damaged, or deformed, they will need to be replaced.



7. Install the inner clearance ring.

WARNING

Wear protective, heat-resistant gloves while heating the impeller to install it onto the impeller shaft. Heated metal can cause injury to your hands.

8. Using the torch, heat the "eye" of the new impeller for approximately two minutes. Then slide the impeller onto the shaft with vanes in proper orientation. If the impeller does not fully slide onto the shaft allow the assembly to cool to room temperature before reheating.
9. Install the outer retaining ring.
10. Install the impeller assembly. See **Subject 130** for instructions.
11. Install the outer clearance ring.
12. Install the impeller shaft assembly.
13. Install the fire pump gear box. See **Subject 110** for instructions.
14. Install the AutoLube. See **Subject 100** for instructions.
15. Remove the chocks from the front and rear tires.

11. Mechanical Seal Piston Ring
12. Shaft Seal Ring
13. Mechanical Seal Cover
14. Hexhead Screw, 7/16–14 x 1-1/4
15. Rear Bearing Housing
16. Hexhead Screw, 7/16–14 x 1-1/2
17. Hexhead Screw, 1/2–13 x 1-3/4
18. Rear Bearing Housing Gasket
19. Hexhead Screw, 5/8–11 x 1-1/4
20. Rear Bearing Washer
21. Bearing (aft)
22. Pump Shaft Slinger
23. Pump Shaft Gear
24. Bearing (forward)
25. Pump Shaft Gear Key
26. Pump Shaft
27. Impeller Key
28. Drive Unit Oil Seal

Fig. 1, Impeller Shaft Assembly (exploded view)

Two-Stage Pump

Disassembly

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.
2. Remove the AutoLube. See **Subject 100** for instructions.
3. Remove the fire pump gear box. See **Subject 110** for instructions.
4. Remove the impeller assembly. See **Subject 130** for instructions.
5. Place the impeller shaft assembly on a work bench.
6. Note the position of the impeller vanes.

7. Remove the inner and the outer retaining rings and then remove the mechanical seal housing.

WARNING

Wear protective, heat-resistant gloves while heating an impeller to remove it from the impeller shaft. Heated metal can cause injury to your hands.

CAUTION

Do not overheat the impeller. An impeller is constructed of bronze. If the impeller is overheated and turns red or blue during removal from the shaft, it has been weakened and must be replaced.

8. With an acetylene torch, carefully heat the "eye" of the impellers for approximately two minutes.

IMPORTANT: Mark the impellers as to whether they are the primary or secondary impeller in relation to the AutoLube. Improper or backward installation of the impellers affects pump performance.

9. When heated properly, an impeller will slide free of the shaft. If the impeller moves but fails to slide free, do not immediately reheat. Allow the complete assembly to cool to room temperature then reheat and remove the impellers. Heat the secondary impeller and remove. Then rotate the impeller shaft assembly end for end and heat and remove the primary impeller.
10. Remove the center support bearing.
11. Remove mechanical seal housing and then the inner clearance ring.
12. Remove the key.
13. Remove the inner retaining ring and slide the mechanical seal housing from the impeller shaft.

Assembly

1. Clean the impeller shaft, the keyway, and the mechanical seal housing and face.
2. Check the waterway in the mechanical seal housing for restrictions.
3. Install the new gasket on the mechanical seal housing face.
4. Install the key into the keyway.

CAUTION

If the impellers or the clearance rings are dropped, damaged, or deformed, they require replacement.

5. Install the inner clearance ring.

WARNING

Wear protective, heat-resistant gloves while heating the impeller to install it onto the impeller shaft. Heated metal can cause injury to your hands.

6. Using the torch, heat the "eye" of each impeller for approximately two minutes. Then slide the individual impellers onto the shaft. If an impeller does not fully slide onto the shaft allow the assembly to cool to room temperature before reheating.
7. Install the outer retaining ring.
8. Install the outer clearance ring.
9. Install the impeller assembly. See **Subject 130** for instructions.
10. Install the mechanical seal housing onto the impeller shaft.
11. Install the impeller shaft assembly.
12. Install the fire pump gear box. See **Subject 110** for instructions.
13. Install the AutoLube. See **Subject 100** for instructions.
14. Remove the chocks from the front and rear tires.

Valve Removal, Disassembly, Assembly and Installation

Pilot Valve

Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front and rear tires.

1. Drain the fire pump.
2. Rotate the adjustment handwheel counterclockwise to remove the spring tension.
3. Remove the capscrew and nut attaching the adjustment handwheel to the adjustment shaft. Then remove the handwheel.

CAUTION

Identify and mark the line connections on the control body before removing. Improper connection of lines may result in the failure of the pilot valve, which could cause damage to the fire pump.

4. Remove the pump discharge pressure line and the relief valve line from the control body of the pilot valve.
5. While holding the pilot valve, remove the four 1/4–20 x 5/8 machine screws attaching the valve and cover plate to the Pump Operator's Panel, and separate the valve, plate, and the relief valve setting indicator (if equipped with PMD) from the panel.
6. Disassemble the pilot valve.
   - 6.1 Remove the four 5/16–18 x 1 allen-head capscrews securing the control body to the rear of the spring housing. Then remove the control body.

CAUTION

Do not use pliers to unscrew the control valve from the diaphragm clamp. Damage to the control valve will render the pilot valve inoperative.

   - 6.2 Unscrew the control valve from the diaphragm clamp. Remove the diaphragm washer and the diaphragm.
   - 6.3 Remove the retaining ring, the seal, and the bearing.

WARNING

Use a spring compressor to remove the pilot valve spring. The spring is under compression and could become uncompressed, which could result in personal injury.

   - 6.4 Turn the adjustment handwheel clockwise to unscrew the adjustment shaft from the adjustment nut. From the handwheel end, remove the adjustment shaft from the spring housing.
   - 6.5 Remove both springs, the adjustment nut, and diaphragm clamp as an assembly from the spring housing and then separate.
7. Clean all the pilot valve components. Inspect and lubricate with grease the threads on the adjustment shaft.
8. Assemble the pilot valve.

WARNING

Use a spring compressor to install the pilot valve spring. The spring is under compression and could become uncompressed, which could result in personal injury.

CAUTION

Always remove the pilot valve discharge pressure inlet screen, which is located in the top of the discharge side of the pump. Clean or replace as necessary. Failure to do so could render the pilot valve inoperative.

   - 8.1 Combine both springs, the adjustment nut and the diaphragm clamp as an assembly and install into the spring housing. Align the guide pin-in adjustment nut with the slot in the spring housing and the indicator plate on the PMD.
   - 8.2 Slide the adjustment shaft into the spring housing from the handwheel end. Turn the adjustment handwheel counterclockwise in order to screw the adjustment shaft into the adjustment nut until it bottoms in the diaphragm clamp. Do not put the springs under tension.

Valve Removal, Disassembly, Assembly and Installation

8.3 Lubricate the new bearing and slide the new bearing and bearing washer over the adjustment shaft into the spring body housing. Install the retaining ring. Then install the new seal washer and rotate the adjustment shaft in both directions to check for freedom of movement.

8.4 Install the new diaphragm washer and diaphragm. Screw the control valve into the diaphragm clamp.

8.5 Install the control body. Apply Loctite® 242 to the four 5/16–18 x 1 allen-head capscrews attaching the control body to the rear of the spring housing.

9. Holding the pilot valve, align the cover plate and install the four 1/4–20 x 5/8 machine screws attaching the pilot valve and cover plate to the Pump Operator's Panel.
10. Install the pump discharge pressure line and relief valve line to the control body of the pilot valve.
11. Slide the adjustment handwheel onto the adjustment shaft and then install the retaining capscrew and nut.
12. Fill the pump and test the valve for proper operation and leaks.

Transfer Valve

See **Fig. 1** for an exploded view of the transfer valve.

1. Drain the fire pump.

IMPORTANT: The transfer valve is a timed device. It is therefore important during disassembly to note the location of the transfer bracket locating pin, the transfer drum stop pin, the transfer drum sleeve locating pin, and the transfer drum stem key. It is not necessary to remove the transfer bracket locating pin, the transfer drum sleeve locating pin, or the transfer drum stop pin during disassembly.

2. Turn the adjustment handwheel clockwise until it stops. The transfer indicator should be at the top of the slotted guide in the cover plate.
3. Remove the two allen-head set screws from the transfer indicator guide. Slide the transfer indicator guide (on an adjustment stem) towards the transfer valve.
4. Remove the stem drive gear lock pin. Slide the adjustment stem from the stem drive, the support, and the transfer indicator guide, being careful not to drop or damage the transfer indicator guide and transfer indicator.
5. Remove the four 7/16–14 x 1-1/4 capscrews retaining the transfer bracket assembly to the pump body. Carefully remove the transfer bracket and the transfer valve drum.
6. Disassemble the valve.

   6.1 Remove the locating pin that secures the countershaft in place.

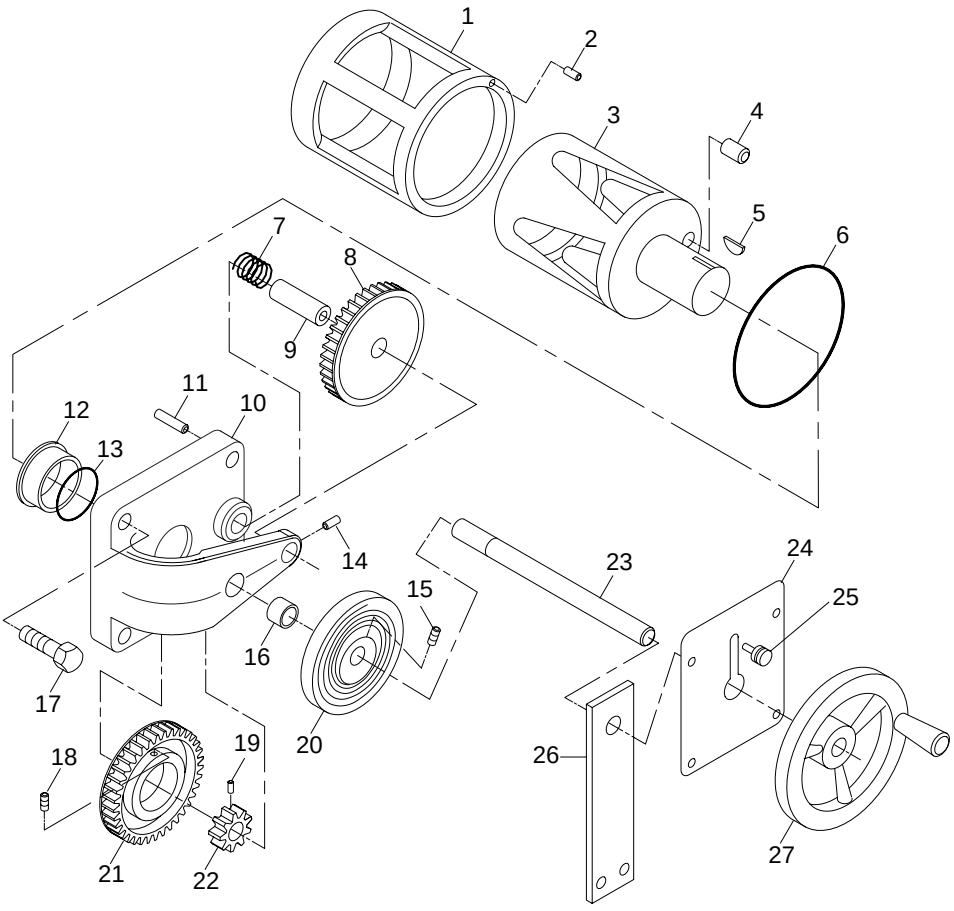
   6.2 Remove the countershaft from the countershaft gear.

   6.3 Remove the countershaft gear and the countershaft gear spring from the transfer bracket assembly.

   6.4 Remove the allen-head set screw from the transfer drum gear. Slide the transfer drum gear from the drum stem. Remove the woodruff key from the transfer drum stem.

   6.5 Separate the transfer bracket from the transfer drum by sliding it from the transfer drum stem.

   6.6 Slide the transfer drum from the transfer sleeve.



7. Assemble the valve.

   7.1 Clean and inspect all sealing surfaces, the mating surfaces of the transfer valve drum and sleeve. Clean and inspect the transfer bracket bushings and bushing surface on the transfer valve stem and the transfer valve adjustment stem.

   7.2 Install new O-ring seals on the transfer valve drum stem and the transfer valve bracket.

   7.3 Slide the transfer drum into the transfer bracket, being careful not to damage the bearing surfaces. Then rotate the transfer drum until the drum stop pin is in the correct position.

Valve Removal, Disassembly, Assembly and Installation

25. Transfer Indicator
26. Support Stem
27. Adjusting Wheel Assembly

Fig. 1, Transfer Valve

7.4 Install the woodruff key into the transfer drum stem. Install the transfer drum gear onto the transfer drum stem. Apply Loctite® 242 to the allen-head set screw and install the transfer drum gear.

7.5 Assemble the countershaft gear spring in the countershaft gear and position the assembly into place in the transfer bracket. Then install the countershaft and

Valve Removal, Disassembly, Assembly and Installation

the countershaft locating pin to lock the countershaft in place.

8. Install the transfer valve.
   - 8.1 Align the transfer drum stop pin, the transfer bracket locating pin, and the transfer drum sleeve locating pin into proper position.
   - 8.2 Install the transfer valve drum and bracket assembly into the pump body.
   - 8.3 Apply Loctite® 242 to the four 7/16–14 x 1-1/4 transfer bracket capscrews and install and tighten 53 lbf·ft (72 N·m).
   - 8.4 Slide the adjustment stem through the cover plate, the transfer indicator guide, and the support and transfer bracket.
   - 8.5 Insert the stem drive gear into place in the transfer bracket and then slide the adjustment stem through the stem drive gear.
   - 8.6 Insert the stem drive gear lock pin into place, locking the stem drive gear onto the adjustment stem.
   - 8.7 Apply Loctite® 242 to the transfer indicator guide set screws and install. Do not tighten.
   - 8.8 Turn the adjustment handwheel counterclockwise until it stops. Make sure the transfer indicator is at the top of the slotted guide toward the transfer indicator, making certain that the transfer indicator engages the transfer indicator guide in the top groove. Then tighten the inside set screw in the transfer guide indicator.
   - 8.9 Rotate the adjustment handwheel from stop to stop. The transfer indicator should move freely from the top to the bottom of the slotted guide in the cover plate.
   - 8.10 Tighten the outside set screw in the transfer indicator guide, and recheck the movement of the transfer indicator.
9. Fill the pump and test the valve for proper operation and leaks.

Back Flow Valve

1. Drain the water tank and the pump.
2. Disconnect the control linkage at the Tank-to-Pump valve.
3. Disconnect both ends of the flexible hose connecting the water tank to the tank-to-pump valve. Then slide the flexible hose toward the water tank outlet or the tank-to-pump valve plumbing.

NOTE: If the tank-to-pump valve is air-operated, drain the vehicle's air system and disconnect the supply and the return line on the valve actuator, but do not remove the actuator from the valve. Also, the tank-to-pump valve may be connected to the pump body by capscrews or studs with nuts. If studs are used, it may be necessary to remove some or all of the studs to remove the valve. If so, remove only the studs necessary to remove the valve as any studs left will assist in realigning the valve during installation.

4. Remove the eight 7/16–14 x 1-1/2 capscrews retaining the tank-to-pump valve to the pump body.
5. Remove the tank-to-pump valve and associated plumbing.

NOTE: The back flow valve is a flat butterfly plate with two pivots attached at the top. These pivots fit into two open pivot sockets in the pump body. When the gasket is removed, the back flow valve may fall out.

6. Remove the old gasket from the pump body.
7. Remove the back flow valve.
8. To install the back flow valve, first clean all of the gasket surfaces on the pump body and the tank-to-pump flange.
9. Install the back flow valve. Using two fingers, hold the pivots in the pivot sockets and check the valve for freedom of movement.
10. Install a new gasket.
11. Apply Loctite® 242 to the eight 7/16–14 x 1-1/2 capscrews and attach the tank-to-pump valve to the pump body. Tighten 53 lbf·ft (72 N·m).

12. Slide the flexible connection hose so it is evenly spaced and secured on the water tank outlet and the tank-to-pump valve plumbing.
13. Attach the tank-to-pump valve controls and linkage.
14. Fill the pump and test the valve for proper operation and leaks.

Sensing Valve

1. Disconnect the following lines at the sensing valve:
    - pilot valve discharge line
    - QG relief valve line
    - PG relief valve line
    - sensing valve pump suction line
    - drain lines
2. Remove the 7/16–14 x 2 sensing valve mounting capscrew.
3. Remove the four 5/16–18 x 1 capscrews attaching the control body to the rear of the spring housing. Remove the control body, being careful not to lose the sensing valve spring.
4. Remove the control valve from the sensing valve body.
5. Unscrew the sensing valve from the diaphragm, being careful not to damage the control valve. Remove the diaphragm.
6. Before installing the sensing valve, clean all components.

⚠ CAUTION

Always remove the sensing valve suction inlet screen. Clean or replace as necessary. The screen is located in the suction side of the pump. Failure to do so may render components inoperative.

7. Install a new diaphragm on the diaphragm clamp. Apply Loctite® to the threads on the control valve and install the control valve into the sensing valve body.
8. Install the sensing valve spring into the valve body cover.
9. Apply Loctite® 242 to the four 5/16–18 x 1 capscrews and attach the control body to the rear of the spring housing. Make sure that the sensing valve spring properly aligns with the diaphragm clamp.
10. Make sure the up arrow is aligned properly.
11. Apply Loctite® 242 to the 7/16–14 x 2 sensing valve mounting capscrew. Tighten 40 lbf·ft (54 N·m).
12. Connect all lines.
13. Fill the pump and test the valve for proper operation and leaks.

TPM Relief Valve

1. Disconnect the line to the sensing valve and drain the fire pump. Make note of the wire connections.
2. Disconnect the indicator light switch.
3. Remove the four 7/16–14 x 1-1/4 capscrews attaching the relief valve assembly to the pump body.
4. Using a twisting motion, remove the relief valve assembly.
5. To disassemble the valve, remove the indicator light switch and remove the cover retaining ring and slide the cover out of the relief valve body.
6. Apply a small amount of pressure to the relief valve piston and remove the piston retaining ring. Carefully release the pressure held to the piston by the spring.
7. Remove the relief valve from the opposite end, sliding the relief valve stem out of the piston.
8. Reach through the center hole of the piston and pull the piston out of the indicator switch end of the relief valve body. Then remove the piston spring.
9. To assemble and install the valve, first clean and inspect all components.
10. Clean all sealing surfaces and install new O-rings seals.
11. Install the relief valve into the relief valve body.

Valve Removal, Disassembly, Assembly and Installation

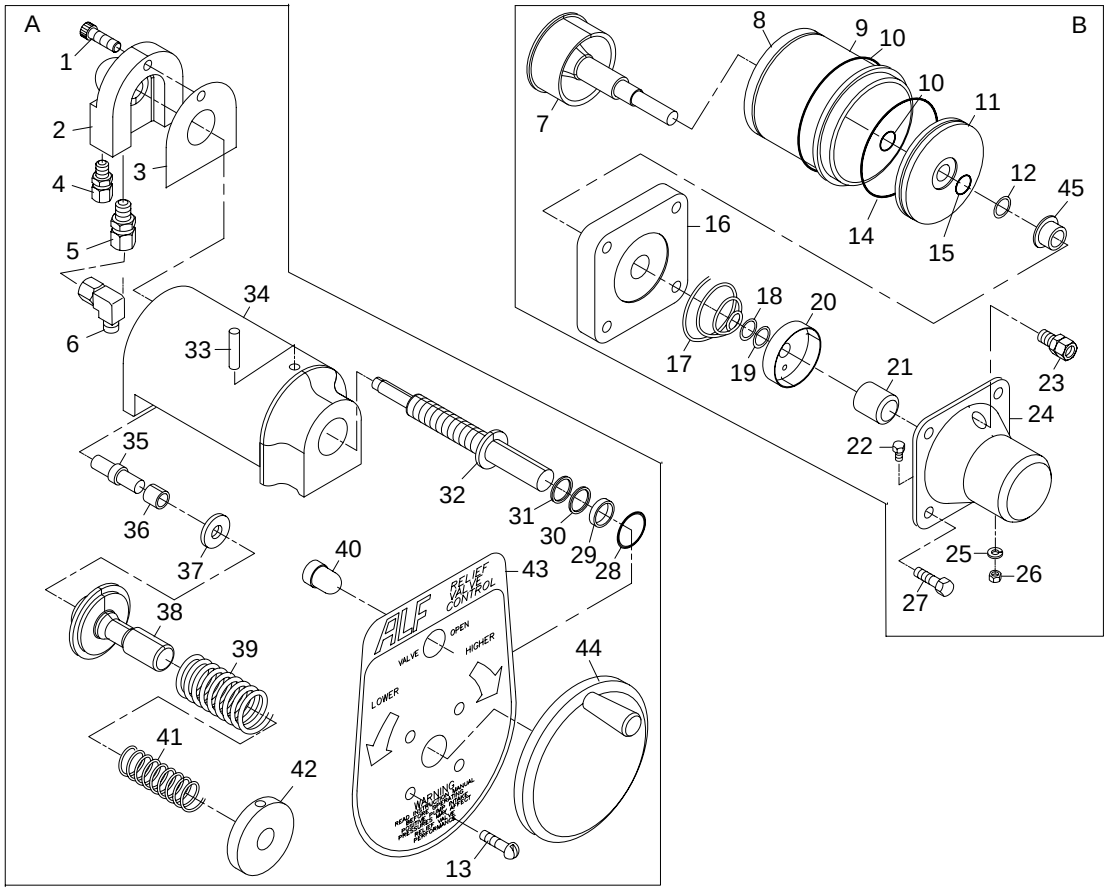
12. Install the piston spring by sliding the piston into the relief valve body while at the same time sliding the piston onto the relief valve system.
13. Apply light pressure to the piston to compress the piston spring and install the piston retaining ring.
14. Slide the cover into the relief valve body. Then install the cover retaining ring.
15. Using a powered test light, screw the indicator light switch in until the light goes out. Then turn an additional 3/4 to 1-1/4 turn. Apply Loctite® to the jamnut and tighten.
16. Slide the relief valve assembly into the pump body with the side marked "top" up, being careful not to damage the O-rings.
17. Apply Loctite® 242 to the four 7/16–14 x 1-1/4 capscrews and install the assembly in the pump body. Tighten 53 lbf·ft (72 N·m).
18. Connect the indicator light switch.
19. Fill the pump and test the valve for proper operation and leaks.

QD Relief Valve

See **Fig. 2** for an exploded view of the QD relief valve.

1. Drain the pump.
2. Note the location of the wires and disconnect the indicator light switch.
3. Disconnect the relief valve supply line from the pilot valve and drain the line.
4. Remove the two 7/16–14 x 1-1/4 capscrews attaching the relief valve indicator light switch and the mounting bracket assembly to the relief valve cover. Remove the light switch and the bracket.
5. Compress the relief valve return spring by hand and remove the E-clip and washer. Then remove the return spring.
6. Remove the two remaining 7/16–14 x 1-1/4 capscrews retaining the relief valve cover to the pump body. Using a twisting motion, carefully remove the relief valve cover.

⚠ CAUTION



Do not push the relief valve too far into the pump body as it may fall into the pump body and become lodged or damaged. The relief valve is made of brass and is easily damaged by prying or hammering. Damaged valves must be replaced.

7. Remove the retaining ring securing the relief valve piston to the relief valve. Gently push the relief valve into the pump body approximately 1 inch (25 mm) and then pull it back out in a snap-motion. This should pop the relief valve piston out of the relief valve body. Repeat if necessary.

NOTE: It is not necessary to remove the relief valve unless it is damaged. To remove the relief valve, the relief valve body will have to be removed and the complete relief valve assembly will need to be replaced as it will be necessary to pry the relief valve body from the pump body, which will likely damage it.

8. Clean and inspect all of the relief valve assembly components.
9. Clean all sealing surfaces and install new O-rings and Quad-ring seals.
10. Install the relief valve piston in the stem of the relief valve. Do not push the relief valve into the pump body. As it is necessary to start the piston onto the relief valve stem, push the piston until you can grasp the relief valve stem. Then pull the relief valve stem outward while pushing on the relief valve piston. Once the relief valve piston is seated against the shoulder of the relief valve stem, install the retaining ring.
11. Operate the relief valve by hand to check for freedom of movement.
12. Slide the relief valve cover gasket and cover over the top of the relief valve stem to align the relief valve supply line from the pilot valve in the original position. Then apply Loctite® 242 to two 7/16–14 x 1-1/4 capscrews and install opposite of each other. Tighten, but do not torque.
13. Compress and install the return spring and secure it with a washer and E-clip.
14. Align the indicator light switch mounting bracket and switch with the two empty holes in the relief

Fig. 2, QD Relief Valve

Valve Removal, Disassembly, Assembly and Installation

valve cover. Install the two remaining capscrews. Tighten all capscrews 53 lbf·ft (72 N·m).

15. Connect the relief valve supply line from the pilot valve. Also connect the drain line.
16. Connect the indicator light switch.
17. Fill the pump and test the valve for proper operation and leaks.

TPM Dump Valve

1. Drain the pump.
2. Disconnect the indicator light switch.
3. Disconnect the line to the sensing valve.
4. Remove one 7/16–14 x 2 sensing valve mounting capscrew.
5. Remove the four 7/16–14 x 1-3/4 capscrews retaining the relief valve assembly to the atmosphere dump.
6. Remove the four 7/16–14 x 1-1/2 relief valve mounting capscrews to remove the relief valve from the pump body.
7. Remove the relief valve assembly
8. Remove the four 7/16–14 x 1-3/4 capscrews retaining the relief valve cover to the relief valve body.
9. Remove the indicator light switch assembly.
10. Apply a small amount of pressure to the relief valve spring and remove the spring retaining ring and washer. Carefully release the pressure held on the spring and then remove the spring.
11. Remove the relief valve cover.
12. Remove the piston retaining ring.
13. Remove the relief valve from the opposite end, sliding the relief valve stem out of the piston.
14. Reaching through the center hole of the piston, gently pull the piston from the indicator switch end of the relief valve body.
15. Before assembling and installing the valve, clean and inspect all components of the relief valve assembly.
16. Clean all sealing gasket surfaces and install new O-rings and gaskets.
17. Install the relief valve into the relief valve body.
18. Slide the piston into the relief valve body while at the same time sliding the piston onto the relief valve stem. Then install the piston retaining ring.
19. Install the new gasket and then install the cover onto the relief valve body.
20. Install two 7/16–14 x 1-3/4 capscrews finger-tight to keep the relief valve cover aligned with the valve body.
21. Install the valve spring over the relief valve stem. Then apply pressure to the valve spring to compress the spring.
22. Install the spring washer and the retaining ring.
23. Remove the two 7/16–14 x 1-3/4 capscrews installed to keep the relief valve cover aligned with the valve body. Place the indicator switch assembly into position on the relief valve cover. Apply Loctite® 242 to the four capscrews, install, and tighten 53 lbf·ft (72 N·m).
24. Apply Loctite® 242 to the four 7/16–14 x 1-1/2 capscrews to install the new gasket for the relief valve to the pump surface.
25. Apply Loctite® 242 to the four 7/16–14 x 1-1/2 capscrews and install the new gasket and relief valve assembly to the atmosphere dump. Tighten 53 lbf·ft (72 N·m).
26. Apply Loctite® 242 to the 7/16–14 x 2 capscrew, install the sensing valve and tighten 40 lbf·ft (54 N·m). Make sure the arrow points upward.
27. Connect the indicator light switch.
28. Connect the line to the sensing valve.
29. Fill the pump and test the valve for proper operation and leaks.

Check Valves (two-stage only)

1. Drain the pump.

NOTE: There are two check valves (one on each side) in the suction side on the front of the two-stage pump body. The following procedure is used for both check valves.

2. Remove the four 1/2–13 x 1-1/4 capscrews from the check valve cover on the front side of the pump body.

3. Remove the check valve.
4. Clean the gasket surfaces and inspect the check valve pivots and pivot sockets.
5. Install the check valve.
6. Install the new gasket in the pump body.
7. Apply Loctite® to the four capscrews and secure the check valve cover to the pump body with the capscrews, being careful to align the check valve pivot with the pivot socket in the check valve cover. Tighten 53 lbf·ft (75 N·m).
8. Fill the pump and test the valve for proper operation and leaks.

SPV Priming Valve

1. Drain the pump.
2. Disconnect the 3/4-inch (19 mm) vacuum hose connecting the priming valve to the primer.
3. Remove two 7/16–14 nuts attaching the priming valve to the studs in the pump body. If the studs are damaged, replace them with 7/16–14 x 1-3/4 zinc plated studs.

NOTE: If the valve strainer and O-ring seal remains on the pump body, remove it carefully for cleaning and installation. If the valve strainer is removed as part of the priming valve, remove it from the body and set it aside. Use care as the valve strainer is easily damaged.

4. Note the location of the drain hole on the diaphragm cover and then remove the eight 5/16–18 x 3/4 capscrews securing the diaphragm cover to the valve body. Remove the diaphragm cover and the diaphragm.
5. Hold pressure on the diaphragm washer to compress the valve spring then remove the diaphragm washer retaining screw. Remove the diaphragm washer and valve spring. From the opposite side of the valve body, remove the valve.
6. Clean all the components of the priming valve and mating surfaces. Inspect the valve seat and replace if worn or damaged.
7. Install the valve into the valve body from the pump side of the body.
8. Install the valve spring and diaphragm washer onto the valve. Apply Loctite® 242 to the diaphragm washer retaining screw, compress the valve spring with the diaphragm washer, and install the valve.
9. Align the diaphragm holes with the capscrew holes in the diaphragm cover. Apply Loctite® 242 to the eight 5/16–18 x 3/4 capscrews and install the diaphragm cover and diaphragm valve body. Tighten 17 lbf·ft (23 N·m).
10. Install the valve strainer and O-ring seal onto the pump side of the priming valve.
11. Apply Loctite® 242 on the two 7/16–14 priming valve mounting nuts and install the priming valve into the pump body. Tighten 40 lbf·ft (54 N·m).
12. Connect the vacuum hose to the primer.
13. Fill the pump and test the valve for proper operation and leaks.

Troubleshooting

Lack of use causes many problems for fire pumps and fire pump components.

IMPORTANT: The entire pumping system should be exercised on a regular basis, at least weekly. This routine procedure should include all discharge valves and suction valves.

Abuse of the fire pump is rarely a problem. If the pump and pump components have been abused, indications of problems may be fairly obvious. For example, bent controls are a common indicator.

Simultaneous oil and water leaks are uncommon. Normally, a water leak indicates that a line has come loose or is broken. Gaskets are used between mating surfaces *without* sealant. If a leak is present at a gasket-mating surface, whether oil or water, the components should be disassembled and repaired.

Be certain when a device indicates it is not working that it is not asimple electrical problem, such as a burned-out indicator bulb.

Troubleshooting Tables

Problem—Pump Will Not Engage

Problem—Pump Will Not Engage Possible Cause	Remedy
Parking brake not set.	Set the parking brake.
Transmission not in neutral.	Shift transmission to neutral.
Insufficient air supply.	Repeat the recommended shift procedure: Check the air pressure gauges. This procedure requires at least 100 psi (689 kPa), and shut the engine down and check for air leaks.
Pump shift or application of parking brake attempted before apparatus was stopped.	Release the braking system momentarily and repeat the recommended shift procedure. *

* This condition is known as "Butt Tooth," which occurs when the transmission shifts and the shift gear-teeth and the teeth on the drive gear do not line up and butt up against each other. The Twinflow fire pump transmission is designed with a sliding shift collar. Therefore, the occurrence of "Butt Tooth" will be rare.

Problem—Pump Will Not Shift

Problem—Pump Will Not Shift Possible Cause	Remedy
Battery voltage low.	Turn off accessories. Check the charging system of the apparatus. Inspect the batteries. If okay, recharge and try shift again.
Interface/Interlock module not receiving proper inputs.	Check the Officers Information Center output.
Transmission not receiving lock-up input.	Check output to transmission with Prolink.

Problem—Pump Will Not Prime

Problem—Pump Will Not Prime Possible Cause	Remedy
Low battery voltage.	Increase the engine speed 1000 to 1200 rpm for temporary support for electrical system requirements and primer operation. *
Worn or damaged priming system.	Perform the "Dry Vacuum Test" which follows the troubleshooting tables in this subject. If pump is tight but primer develops less than 22 inches of vacuum, the primer pump, motor, or Priming Valve may be worn or damaged.

Troubleshooting

Problem—Pump Will Not Prime	
Possible Cause	**Remedy**
Primer not operated long enough.	Operate for 30 seconds for pump up to 1250 gpm or for 45 seconds for 1500 and up gpm pump. Add 15 additional seconds if priming from front or rear suction. Do not run primer over 45 seconds. Stop and check for causes.
Suction lifts too high.	Do not attempt lifts exceeding 22 feet, except at low elevations.
Suction strainer blocked.	Check and clean.
Air pocket in suction hose or pump.	Place suction hose lower than suction intake. Slightly open a discharge valve momentarily to release trapped air.
Air leaks.	Perform the "Dry Vacuum Test" which follows the troubleshooting tables in this subject. Then shut engine off and listen for air leaks. Pressurize the discharge side of the pump with approximately 100 psi (689 kPa) from the hydrant and check for water leaks. Check connections and gaskets.

* Electric primer does not require engine speed to be increased for operation. A primer can and will draw in excess of 300 amps and primer operation can last 45 seconds.

Problem—Pump Loses Prime

Problem—Pump Loses Prime	
Possible Cause	**Remedy**
Suction lifts too high.	Do not attempt lifts exceeding 22 feet except at low elevations.
Suction strainer blocked.	Check and clean.
Air leaks.	Check all connections and gaskets. Perform the "Dry Vacuum Test" which follows the troubleshooting tables in this subject.
Pump pressure is too low when discharge appliance is opened.	Prime the pump again. Raise pump pressure higher and open the discharge appliance slowly.

Problem—Pump Primer Does Not Operate Properly

Problem—Pump Primer Does Not Operate Properly	
Possible Cause	**Remedy**
Does not operate electrically.	Check the battery, connections, primer, and primer control. Check the control switch and solenoid on the primer. If the primer has not been used recently, it could be frozen. It should, if contact is still being made internally, show heavy current draw.
Primer is slow or lower than normal.	Check batteries, wiring, and connections. A large quantity of suction hoses or suction pipes can exceed primer capabilities. Too small diameter or too long a length of piping between primer and pump can exceed primer capabilities. Lift not to exceed 20 feet (6 m) and 10 feet (3 m) for testing. The primer pump itself may be worn out.
Pulls some prime.	The primer pump could be in need of repairs or cleaning. Check for air leaks and verify that the Priming Valve is not sticking.
Pulls full prime.	Check for air leaks. Check for clogged inlet strainer and screens. Check that the suction hose is submerged in adequate water supply. Check for air pockets and air accumulation in piping. Check for turbulence in piping. The pump impeller may be damaged or severely worn.

Problem—Insufficient Capacity or Pressure

Problem—Insufficient Capacity or Pressure	
Possible Cause	**Remedy**
Insufficient engine power.	Check engine performance.
Improperly set relief valve.	Readjust the relief valve to a higher pressure setting. If the relief valve is set too low it will open to relieve pressure and reduce capacity.
Transmission in incorrect range.	Check the transmission selector for correct range recommended for pumping procedure. Check that the Fourth range lockup has occurred. If the transmission shifts while increasing engine speed, lock up has not occurred. Check engine speed or drive shaft speed for correct transmission range and inaccurate tachometer.
Air leaks.	Perform the "Dry Vacuum Test" which follows the troubleshooting tables in this subject.
Transfer valve in incorrect position.	Transfer valve must be in the "parallel or volume" setting for capacity in the "series or pressure" setting for pressure. The transfer valve indicator may be out of adjustment. At idle, shift the transfer valve back and forth. You should hear the check valves close and see a change in pressure on the Master Pressure gauge.
Tank fill valve leaking.	Repair the leak.

Problem—Engine Speed Too High for Capacity or Pressure

Problem—Engine Speed Too High for Capacity or Pressure	
Possible Cause	**Remedy**
Impeller blockage.	Check and clean. Backflushing through the discharge side of the pump may clear the obstruction. It may require disassembly of the pump.
Worn impeller or clearance rings.	Overhaul the pump. All other possibilities should be eliminated before overhauling the pump.
Suction strainer blocked.	Clean and check.
Lift too high.	Lifts over 10 feet will cause higher engine speeds and vacuum.
Transmission in incorrect range.	Check the transmission selector for correct range for recommended pumping procedure. Check that Fourth range lockup has occurred. If the transmission shifts while increasing engine speed, lockup has not occurred. Check engine speed or drive shaft speed for correct transmission range and inaccurate tachometer.
Check Valves damaged or missing.	At idle, shift the transfer valve back and forth. You should detect a change in the engine/pump sound, hear the check valves close, and see a change in the pressure on the Master Pressure gauge. If no apparent change occurs, remove the suction inlet cap and visually inspect the check valves. Insert a broom handle in the suction inlet and gently push each check valve open and let it close. Check valves should move freely.
Tank fill valve leaking.	Repair the leak.

Troubleshooting

Problem—Relief Valve Does Not Relieve When Valves are Closed

Problem—Relief Valve Does Not Relieve When Valves are Closed	
Possible Cause	**Remedy**
Incorrect pilot valve setting.	Repeat the proper procedure for setting the relief valve.
Pilot valve inoperative.	Disassemble, clean, and lubricate. Inspect the control valve diaphragm for wear or damage.
Relief valve inoperative.	Disassemble, clean, and lubricate.

Problem—Relief Valve Does Not Recover When Valves are Opened

Problem—Relief Valve Does Not Recover When Valves are Opened	
Possible Cause	**Remedy**
Dirt in system resulting in slow or sticky operation.	Disassemble, clean and lubricate.

Problem—Unable to Attain Proper Setting

Problem—Unable to Attain Proper Setting	
Possible Cause	**Remedy**
Incorrect procedure.	Check procedure and reset.
Blocked strainer.	Disconnect the pilot valve supply line from the discharge side of pump. Remove the 90-degree fitting where the supply line connects to the pump. The strainer is attached to this fitting. Clean or replace the strainer and fitting assembly.
Dirt in pilot valve.	Disassemble, clean, and lubricate.
Hunting condition.	Insufficient water supply to the pilot valve. Check strainer and supply lines. If there is dirt in the pilot valve, disassemble, clean, and lubricate.

Problem—TPM Valve Does Not Relieve

Problem—TPM Valve Does Not Relieve	
Possible Cause	**Remedy**
Sensing valve inoperative.	Disassemble, clean, and lubricate. Inspect the control valve diaphragm for wear or damage.
PG relief valve inoperative.	Disassemble, clean, and lubricate.
PG relief valve sluggish.	Check and clean the discharge and suction strainers in the pump body.

Problem—TPM Valve Does Not Recover

Problem—TPM Valve Does Not Recover	
Possible Cause	**Remedy**
Dirt in system resulting in slow or sticky operation.	Disassemble, clean, and lubricate. Check and clean the discharge and suction strainers in the pump body.

Problem—AutoLube

Problem—AutoLube	
Possible Cause	**Remedy**
External leaks.	External leaks are the result of gasket failures. Disassemble and repair.
Internal leaks.	If water is leaking, replace the diaphragm. If oil is leaking, replace the AutoLube seal and the impeller bushing. Heavy oil usage by the AutoLube or oil present in the water when the pump master drain is opened indicates that the AutoLube seal and possibly the impeller bushing is damaged.

Problem—Mechanical Seal Leaks

Problem—Mechanical Seal Leaks	
Possible Cause	**Remedy**
Leak at mechanical seal.	If the mechanical seal is leaking it will have to be replaced. If properly cared for, the mechanical seal should be almost maintenance free. Water quality will greatly affect seal life. The most common failure of the mechanical seal is from thermal-shock. That is running the pump dry, heating up the seal and then opening to a cool or cold water supply. The seal may shatter. Check the AutoLube. If the bushing is worn or missing, the impeller shaft will wobble and fracture the mechanical seal.

Problem—Pump Gear Box Does Not Function Properly

Problem—Pump Gear Box Does Not Function Properly	
Possible Cause	**Remedy**
Water in gear box.	Locate and repair the leak. Remove and clean the gear box filter. Replace the transmission oil. Water leaking onto the input drive shaft of the pump gear box will actually be screwed into the pump transmission past the oil seals. This is not a seal problem. Be certain the slinger(s) are in place. Check the pump gear box cooling line for internal fractures. Pump gear box will fill with water and overflow through breather.
Whine in gear box.	Check the oil level. If oil is low, helical gears and/or tapered bearings will whine. Check oil pressure. If the filter is clogged, oil pressure will be low. Drain oil and check for metal. Remove filter and check for metal. If metal is detected, pump gear box will have to be disassembled for complete inspection and repairs.
Knock or rattle in gear box.	Check for gears missing teeth. Check for damaged bearings. Disassemble and repair. *

* The cause may include foreign objects, low or contaminated oil, or low oil pressure. Low oil level or pressure will result in the transmission being damaged due to overheating.

Troubleshooting

Dry Vacuum Test

1. Open all the intake valves.
2. Cap all intakes, and close and uncap all discharge valves.
3. Using the pump's priming devices, develop a vacuum of at least 22 inHg (74.5 kPa) for 30 seconds for pumps up to 1250 gpm or 45 seconds for pumps 1500 gpm or greater.
4. Reduce the maximum vacuum attained by 1 inHg (3.4 kPa) for each 1,000 ft. (305 m) of elevation of the test site above 2,000 ft. (610 m).

NOTE: The vacuum should not drop more than 10 inHg (33.9 kPa) in five minutes. Do not operate the pump priming device once the five-minute test has begun.

See **Fig. 1** for the fire pump wiring diagram.

See **Fig. 2** for the fire pump controls wiring diagram. See **Fig. 3** for a detailed view of the RH switch panel for the fire pump controls and **Fig. 4** for a detailed view of the electrical center.

General Information

The Findlay bench seat is a full-width three-person seat. **See Fig. 1 .** A lever under the driver's side allows the seat to be adjusted forward and backward. Three-point seat-belt/shoulder-harnesses are provided for the driver and the right-side passenger; a lap belt is provided for the center-seat passenger.

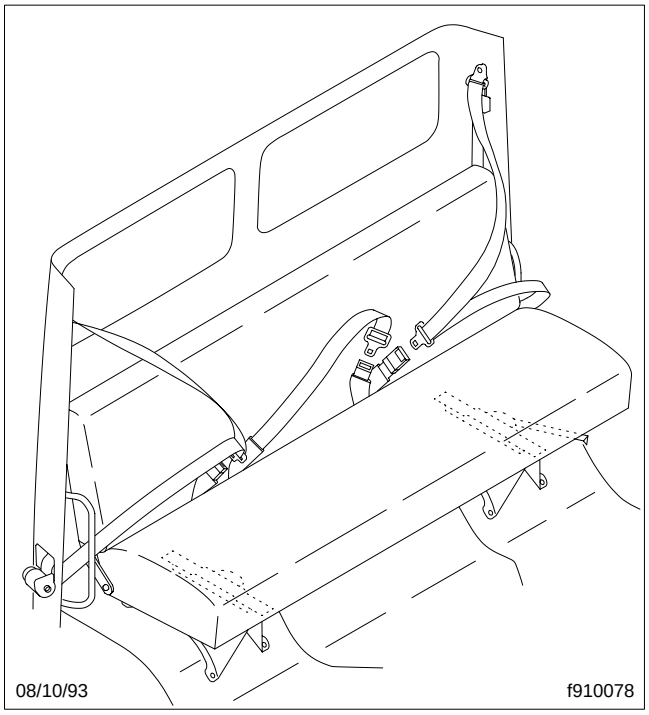

Fig. 1, Findlay 3-Person Bench Seat

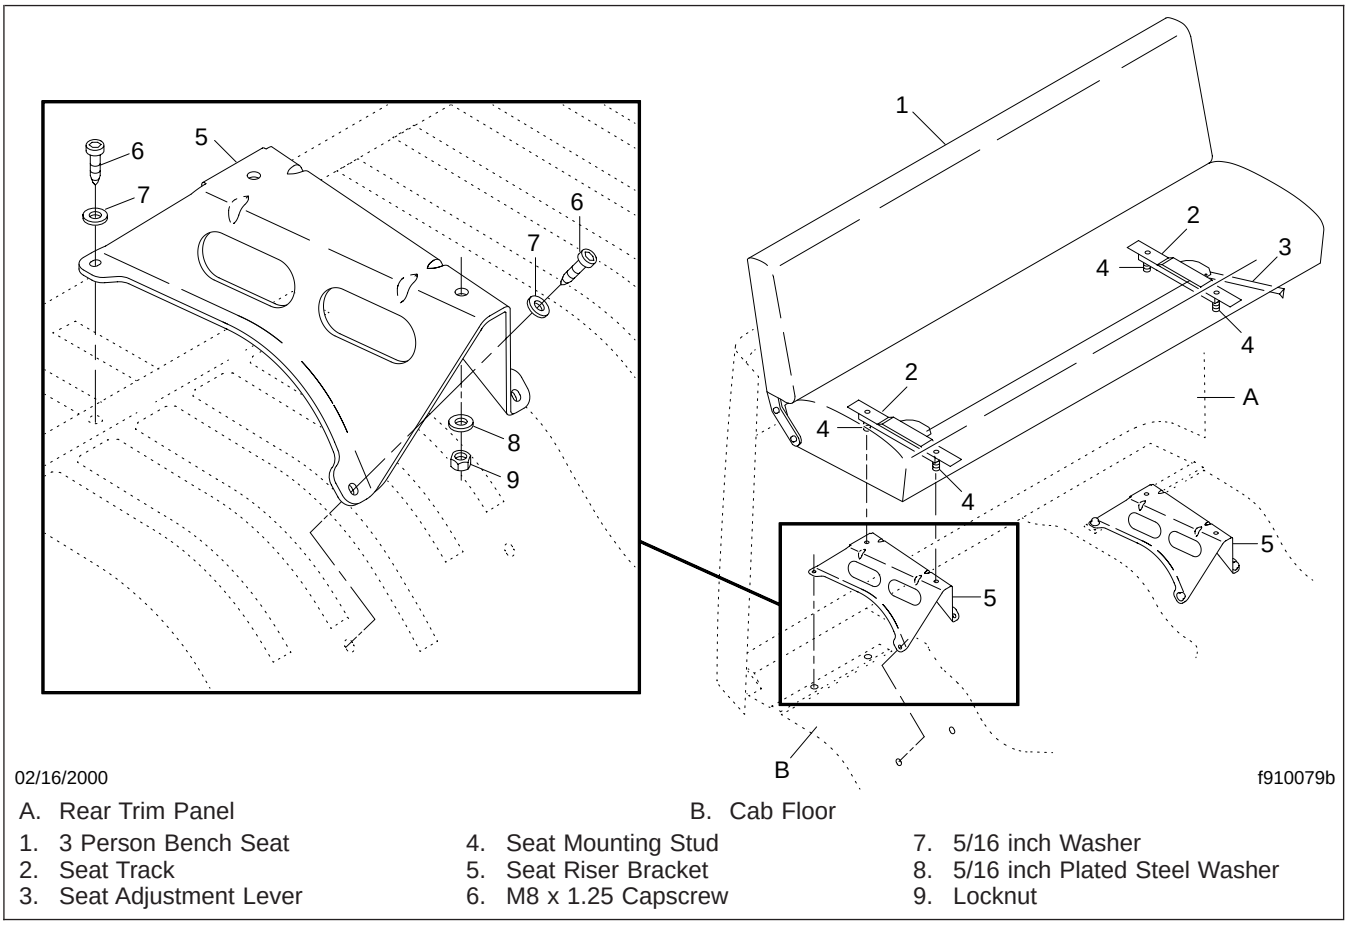

Removal

1. Slide the seat to its forward most position.
2. Push the ends of the four floor-mounted seat belt halves down through the opening between the seat back cushion and bottom cushion.
3. Remove the washers and locknuts that attach the rear of the seat tracks to the seat riser brackets. See **Fig. 1**.
4. Slide the seat to its rearmost position.
5. Remove the locknuts and washers that attach the front of the seat tracks to the riser brackets.
6. With the assistance of another person, lift the seat until the seat mounting studs clear the riser brackets; then remove the seat from the cab.

Installation

1. With the assistance of another person, position the seat in the cab, so that all four seat mounting studs are in the holes in the tops of the seat riser brackets. See **Fig. 1**.
2. Slide the seat to its rearmost position.
3. Install the washers and locknuts that attach the front of the seat tracks to the riser brackets. Tighten the locknuts 14 lbf·ft (19 N·m).
4. Slide the seat to its forwardmost position.
5. Install the washers and locknuts that attach the rear of the seat tracks to the riser brackets. Tighten the locknuts 14 lbf·ft (19 N·m).
6. Reaching through the opening between the seat back cushion and bottom cushion, pull the ends of the four floor-mounted seat belt halves onto the seat.
7. Adjust the position of the seat for driver comfort.

Specifications

This subject contains the following table: •Fastener Torques

Description	Size	Grade	Torque N·m (lbf·ft)
Seat Track Mounting Stud Locknut	5/16–24	B	19 (14)

Table 1, Fastener Torques

General Information

The National model 96 Cush-N-Aire **(Fig. 1)** and Easy-Aire **(Fig. 2)** mid-back air suspension seats offer adjustment features for height, fore and aft positioning, back cushion tilt, lumbar support, and seat cushion tilt. The air suspension and height-adjustment features are provided by an inflatable air spring (air bag).

For Cush-N-Aire seats (installed only in vehicles with air brakes), air pressure for the air spring is provided by the vehicle air system and is controlled by an air valve attached to the seat frame. **See Fig. 1 .**

For Easy-Aire seats, the air pressure is provided by and controlled by a hand pump that attaches to the side of the seat frame. **See Fig. 2 .**

Both seat styles are equipped with a shock absorber to dampen unwanted up and down motion of the seat.

For complete operating instructions, refer to the vehicle driver's manual.

08/10/93 f910093

Fig. 2, National Easy-Aire (Mid-Back) Seat, Model 96

Removal (Refer to Fig. 1 and Fig. 2)

1. For an Easy-Aire seat, hold down the pump handle (**Fig. 1** , Ref. 10) until all air is exhausted from the air spring (Ref. 21). Go to the step for removing the bolts, washers, and spacers.

   For a Cush-N-Aire seat, remove the air valve and air hoses (**Fig. 1** , Refs. 3, 1, and 8) from the seat.

   1.1 Pull the air valve knob (Ref. 6) until all air is exhausted from the air spring (Ref. 21).

   1.2 Pull up and support the rear edge of the seat cushion (Ref. 14) as needed to gain access to the air valve from the top.

   1.3 Cut off the air spring supply hose (Ref. 1) close to the air valve barbed fitting (Ref. 2); minimize hose length loss. Remove the scrap hose from the barbed fitting. Tape the hose and fitting ends to prevent dirt or other matter from entering.

   1.4 Cut the tie strap that attaches the air valve supply hose to the belt bar (Refs. 15, 8, and 16).

   1.5 Loosen the nut (Ref. 5) that attaches the air valve to the lower frame. If needed, move the fore-and-aft adjustment lever (Ref. 22) to the right, and

   slide the upper seat assembly far enough forward to allow removal of the air valve. Remove the valve (and air valve supply hose) from the lower frame, and lay it on the cab deck, behind the seat.

2. Remove the bolts, washers, and spacers that attach the seat belts and tether belts to the belt bar. **See Fig. 2** , Details *B* and *C* .

3. Remove the capscrews and washers (**Fig. 1** , Refs. 18 and 19) that attach the seat risers to the cab deck. Remove the seat from the cab.

Installation (Refer to Fig. 1 and Fig. 2)

1. Place the seat on the cab deck. Insert the socket-head capscrews through the washers (**Fig. 1** , Refs. 18 and 19) and the seat risers. Insert the forward fasteners through the left-hand hole in each seat riser (typical for driver's and passenger's seats); **refer to Fig. 2** , Detail *A*. Tighten the bolts 18 N·m (13 lbf·ft).

2. Attach the seat belts and tether belts to the belt bar, **as shown in Fig. 2** , Details *B* and *C*. Tighten the bolts 54 N·m (40 lbf·ft).

3. For a Cush-N-Aire seat, install the air valve and air hoses (**Fig. 1** , Refs. 3, 1, and 8) on the seat. **See Fig. 1** , Detail *A* .

   3.1 Attach the air valve to the lower frame (Ref. 9), with the lockwasher (Ref. 4) between the nut (Ref. 5) and the front of the valve bracket (Ref. 7); then turn the air valve so the barbed fitting (Ref. 2) is on top. Tighten the nut finger-tight. Using a wrench, tighten the nut one-half turn more.

   3.2 Install a new tie strap to attach the air valve supply hose to the belt bar (Refs. 15, 8, and 16).

   3.3 Pull up and support the rear edge of the seat cushion as needed to gain access to the air valve from the top. Unplug the air spring supply hose and air valve barbed fitting (Refs. 1 and 2), then route the hose through the tie strap (Ref. 15) attached to the track assembly latch mechanism. Push the hose onto the barbed fitting on the valve.

   3.4 Move the fore-and-aft adjustment lever (Ref. 22) to the right, and slide the upper seat assembly forward and rearward while making sure that both air hoses move without restriction. Return the seat cushion to its original position.

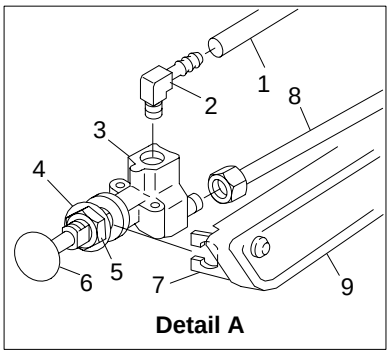
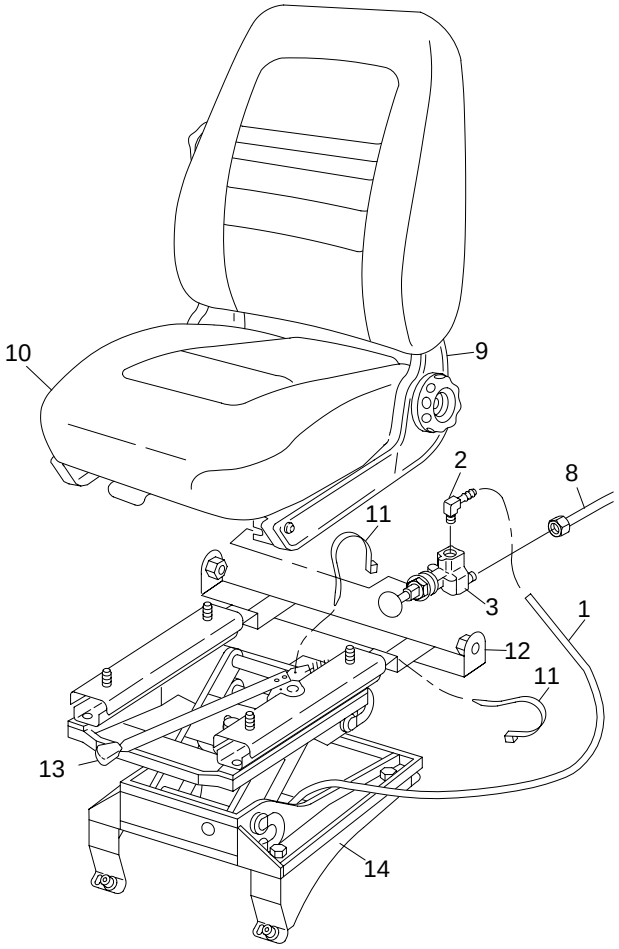
Fig. 2

Air Valve Replacement

(Refer to Fig. 1)



1. Apply the parking brakes and chock the vehicle tires. Drain all air from the vehicle air system.
2. Pull the air valve knob (Ref. 6) until all air is exhausted from the air spring.
3. Disconnect the air hoses and remove the air valve (Refs. 1, 8, and 3) from the seat.
   - 3.1 Pull up and support the rear edge of the seat cushion (Ref. 10) as needed to gain access to the air valve from the top.
   - 3.2 Cut off the air spring supply hose close to the air valve barbed fitting (Refs. 1 and 2); minimize hose length loss. Remove the scrap hose from the barbed fitting. Tape the hose end to prevent dirt or other matter from entering.
   - 3.3 Remove the air valve supply hose (Ref. 8) from the rear of the air valve; plug the hose.
   - 3.4 Loosen the nut (Ref. 5) that attaches the air valve to the lower frame. If needed, move the fore-and-aft adjustment lever (Ref. 13) to the right, and slide the upper seat assembly far enough forward to allow removal of the air valve. Remove the valve.
   - 3.5 Remove and save the air valve barbed fitting (Ref. 2).
4. Install the new air valve, and attach the air hoses.
   - 4.1 Install the air valve barbed fitting (Ref. 2) in the new air valve; position the fitting so it will point to the rear when the air valve is installed.
   - 4.2 Attach the air valve to the lower frame, with the lockwasher (Ref. 4) between the nut (Ref. 5) and the air valve bracket (Ref. 7); then turn the air valve so the barbed fitting is on top. Tighten the nut finger-tight. Using a wrench, tighten the nut one-half turn more.
   - 4.3 Unplug the air valve supply hose (Ref. 8). Route it through the tie strap attached to the belt bar (Refs. 11 and 12). Install the hose on the valve.
   - 4.4 Unplug the air spring supply hose (Ref. 1). Route it through the tie strap (Ref. 11) attached to the track assembly latch mechanism. Push the hose onto the barbed fitting on the valve.
   - 4.5 Move the fore-and-aft adjustment lever (Ref. 13) to the right, and slide the upper seat assembly forward and rearward while making sure that both air hoses move without restriction. Return the seat cushion to its original position.
5. Start the engine and allow the vehicle air system to fill. Push the air valve knob to raise the seat. Then pull the air valve knob to lower the seat. Repair any air leaks.
6. Remove the chocks.



Hand Pump Replacement

(Refer to Fig. 2)

1. Hold down the hand pump handle (Ref. 8) until all air is exhausted from the air spring.
2. Disconnect the air hose (Ref. 11), and remove the hand pump from the seat.
   - 2.1 Remove the end of the air spring supply hose from the connection on the hand pump (Refs. 11 and 12).
   - 2.2 Back off the jam nut that secures the hand pump push rod from turning in the pump clevis (Refs. 13, 14, and 6).
   - 2.3 Remove the locknut and bolt that attach the hand pump mounting ears to the pump mounting bracket (Refs. 21, 17, and 19).
   - 2.4 Unscrew the hand pump push rod from the pump clevis, and remove the pump.
3. Check the pump pivot bolt, lever, clevis, handle, and bracket (Refs. 4, 5, 6, 8, and 19) for wear or damage, and replace the parts as needed.
4. Install the new hand pump, and connect the air hose.
   - 4.1 With the jam nut (Ref. 13) turned onto the hand pump push rod (Ref. 14) as far as it

Component Replacement

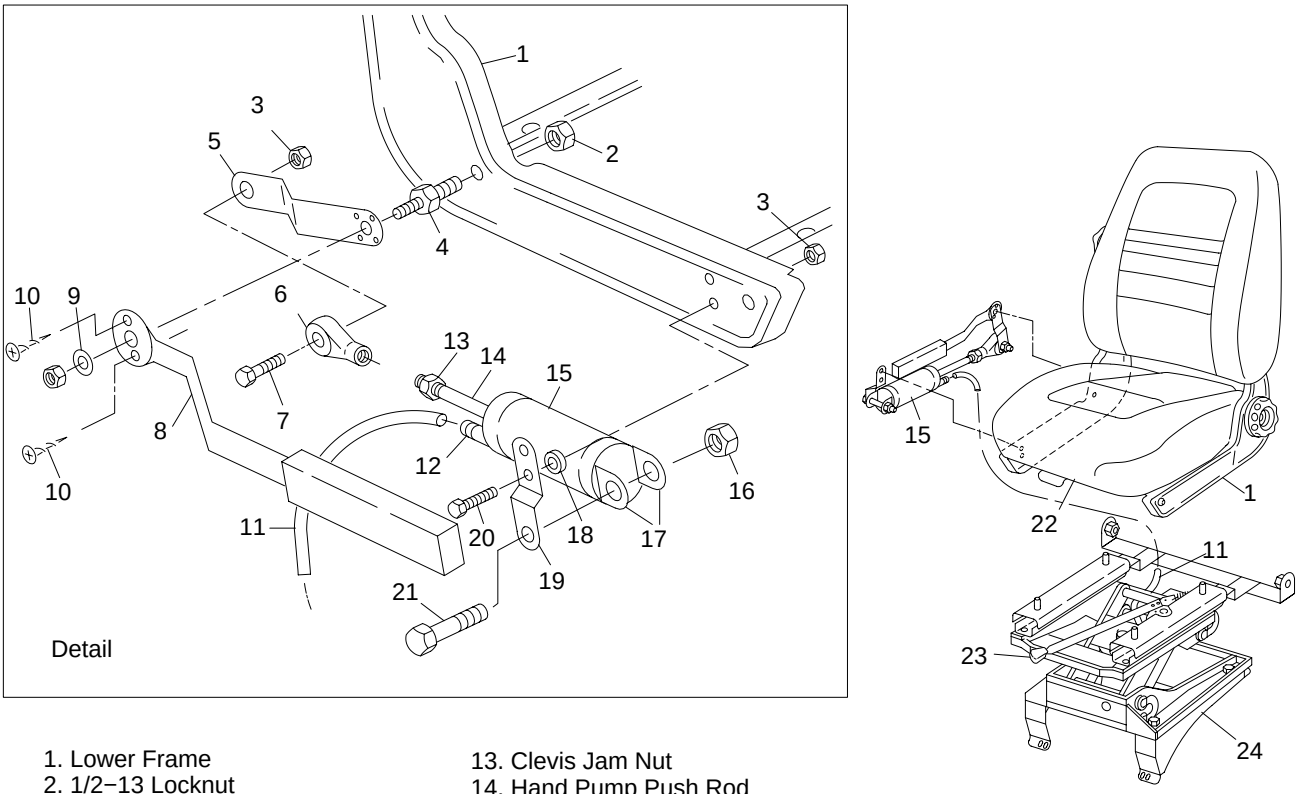
will go, screw the push rod into the pump clevis (Ref. 6) as far as it will go. Then, back it out until the air spring supply hose connection (Ref. 12) is at the bottom of the pump cylinder, and the bolt holes through the mounting ears (Ref. 17) are aligned horizontally.

4.2 Install the bolt and locknut (Refs. 21 and 16) that attach the hand pump to the pump mounting bracket. Turn the prevailing torque locknut until three threads of the bolt are showing past the nut; don't tighten it further.



4.3 Securely tighten the jam nut against the pump clevis.

4.4 Connect the air spring supply hose to the connection on the hand pump.

5. Operate the hand pump; check for and correct any air leaks.

Shock Absorber Removal and Installation (Refer to Fig. 3)

1. Move the fore-and-aft adjustment lever (Ref. 16) to the right, and slide the upper seat assembly back as far as possible.

1. Lower Frame
2. 1/2−13 Locknut

Fig. 2

2. For an Easy-Aire seat, work the hand pump (Ref. 15) until the upper seat assembly is raised to maximum height. Support the seat in this position by placing a wooden block between the lower arm and lower base. Refer to Detail *A* **in Fig. 3 ,** Refs. 9, 8, and 5. Hold down the pump handle (Ref. 14) until all air is exhausted from the air spring.

   For a Cush-N-Aire seat, push the air valve knob (Ref. 17) to raise the upper seat assembly to maximum height. Support the seat in this position by placing a wooden block between the lower arm and lower base. Refer to Detail *A* **in Fig. 3 ,** Refs. 9, 8, and 5. Pull the air valve knob until all air is exhausted from the air spring.

3. Remove the shock absorber, bushings, and spacers. See Detail *B* **in Fig. 3 .**

   3.1 Remove the nuts and bolts (Detail *B* **in Fig. 3 ,** Refs. 13 and 10) that attach the shock absorber to the upper and lower bases (Detail *A* **in Fig. 3 ,** Refs. 1 and 5). Remove the shock absorber.

Component Replacement

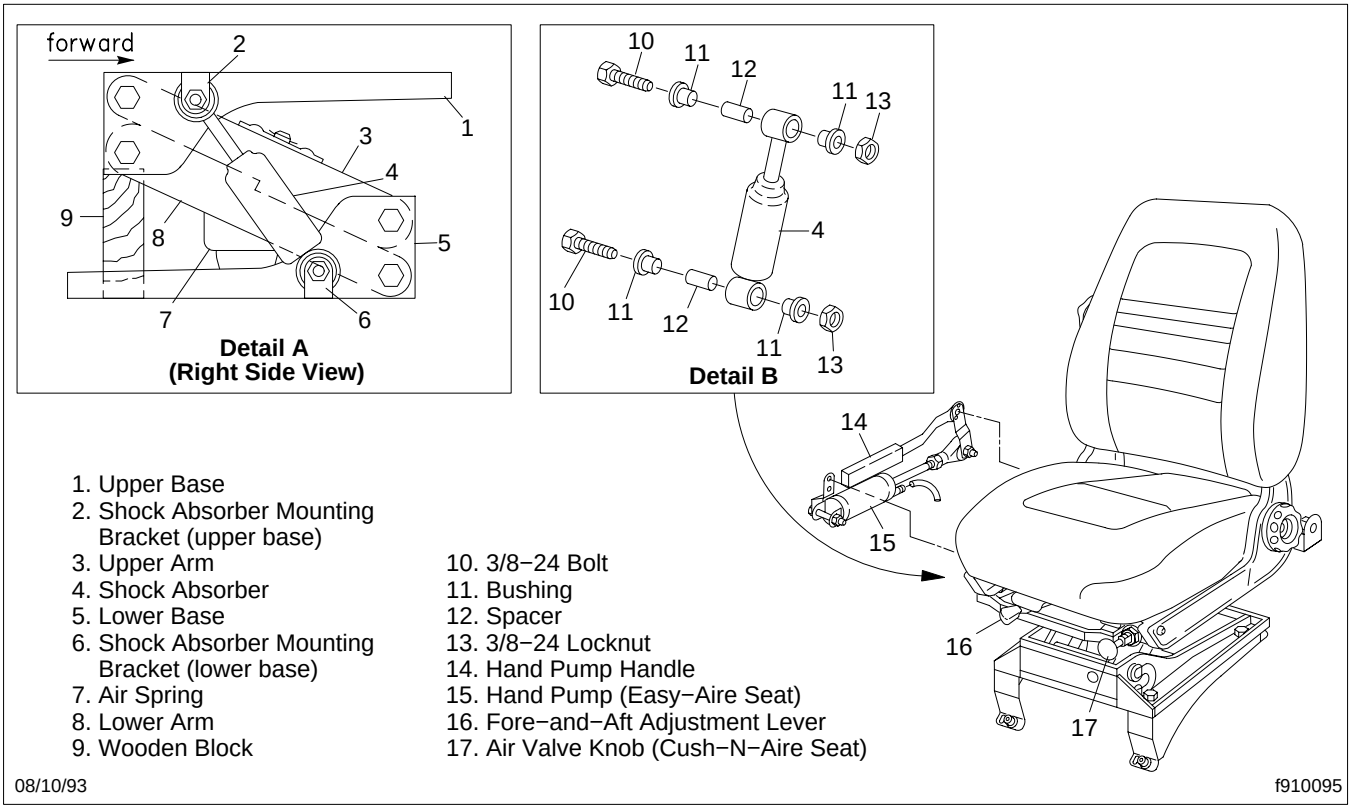

Fig. 3

3.2 Remove the bushings and spacers (Refs. 11 and 12) from the shock absorber.

4. Check the operation of the shock absorber, and replace it if needed.

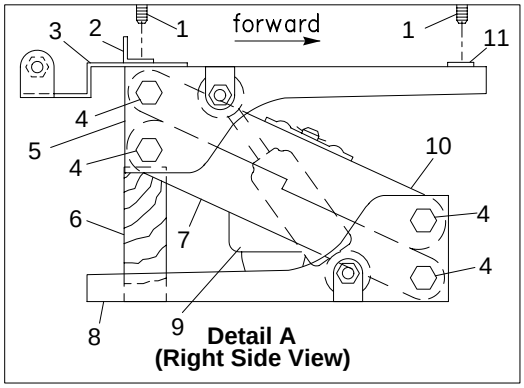
5. Install the shock absorber and new spacers and bushings.

5.1 Install new spacers and bushings in the shock absorber eyes.

5.2 Position the shock absorber so its piston-rod end is in the mounting bracket of the upper base (Detail *A* **in Fig. 3 ,** Ref. 2). Install the bolt and locknut to attach the shock absorber to the bracket. Tighten the locknut 34 N·m (25 lbf·ft).

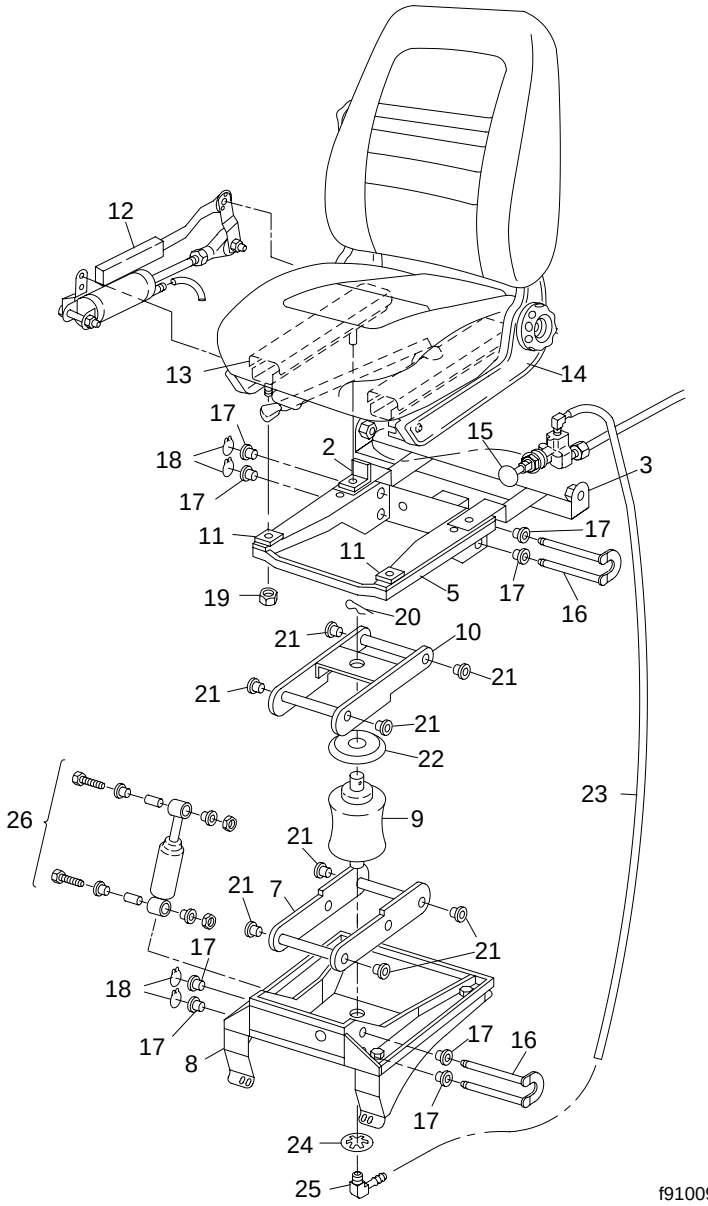
5.3 Position the cylinder end of the shock absorber in the mounting bracket of the lower base (Detail *A* **in Fig. 3 ,** Ref. 6). Install the bolt and locknut to attach the shock absorber to the lower bracket. Tighten the locknut 34 N·m (25 lbf·ft).

6. Work the hand pump (Easy-Aire seat), or push the air valve knob (Cush-N-Aire seat), to raise the seat. Remove the wooden block.



Air Spring Replacement

(Refer to Fig.4)



1. For an Easy-Aire seat, work the hand pump handle (Ref. 12) until the upper seat assembly is raised to maximum height. Support the seat in this position by placing a wooden block between the lower arm and lower base. Refer to Detail *A* **in Fig.4,** Refs. 6, 7, and 8. Hold down the pump handle until all air is exhausted from the air spring.

   For a Cush-N-Aire seat, push the air valve knob (Ref. 15) to raise the upper seat assembly to maximum height. Support the seat in this position by placing a wooden block between the lower arm and lower base. Refer to Detail *A*

in Fig.4, Refs. 6, 7, and 8. Pull the air valve knob until all air is exhausted from the air spring.

08/10/93 f910097

Fig. 4

2. Remove the seat from the vehicle as instructed **in Subject 100.**
3. Lay the seat on its side, with the wooden block still in place.
4. For an Easy-Aire seat, cut off the air spring supply hose close to the barbed 90-degree fitting at the bottom of the air spring (Refs. 23 and 25); minimize hose length loss. Remove the scrap hose from the barbed fitting, then remove the fitting from the air spring. Tape the ends of the

hose and fitting to prevent dirt or other matter from entering.

For a Cush-N-Aire seat, remove, as an assembly, the fitting and the air hose (Refs. 25 and 23) from the air spring. Tape the end of the fitting to prevent dirt or other matter from entering.

5. Pry the retaining ring (Ref. 24) from the bottom of the air spring.
6. Remove the pin clip (Ref. 20) that secures the air spring to the upper arm (Ref. 10). Remove the washer (Ref. 22) and air spring.
7. Position the new air spring in the lower base (Ref. 8), and secure it with a new retaining ring (Ref. 24).
8. Place the washer (Ref. 22) on top of the air spring, and insert the top of the air spring in the opening of the upper arm (Ref. 10). Install the pin clip (Ref. 20) on the air spring.
9. Install the air spring fitting (Ref. 25) and air hose in the bottom of the air spring.
10. Install the seat as instructed in Subject 100.
11. Work the hand pump (Easy-Aire seat), or push the air valve knob (Cush-N-Aire seat), to raise the seat. Remove the wooden block.

Base Assembly Bearing/Sleeve Replacement (Refer to Fig. 4)

1. Remove the shock absorber as instructed earlier.
2. Remove the seat as instructed **in Subject 100.**
3. For an Easy-Aire seat, cut off the air spring supply hose (Ref. 23) close to the barbed 90-degree fitting at the bottom of the air spring (Ref. 25); minimize hose length loss. Remove the scrap hose from the barbed fitting. Tape the hose and fitting ends to prevent dirt or other matter from entering.

   For either seat version, remove the four locknuts (Ref. 19) that attach the track assemblies, seat track stop, belt bar and spacers, and upper seat assembly (Refs. 13, 2, 3, 11, and 14) to the upper base (Ref. 5). Remove the upper seat assembly, track assemblies, seat track stop, and belt bar and spacers.
4. Remove the pin clip (Ref. 20) that secures the air spring to the upper arm (Ref. 10).
5. Remove the bearings and/or sleeves (Refs. 17 and 21) from the upper and lower bases and the upper and lower arms.

   5.1 If the arms are attached to the bases with pivot bolts (Ref. 4), remove all eight bolts. If the arms are attached to the bases with connected shafts held in place by snap rings (Refs. 16 and 18), use snap ring pliers to remove the four snap rings from the shaft assemblies. Then, using a drift punch, drive out the shaft assemblies from the bases.

   NOTE: Place the punch against the snap ring end of the shafts. Drive each shaft end a little at a time, as the two shafts are connected to each other on the opposite side.

   5.2 Remove the upper base, and the upper and lower arms from the air spring and lower base.

   5.3 Remove the bearings/sleeves (Ref. 21) from the upper and lower arms. Discard the bearings/sleeves.

   5.4 If so equipped, remove the sleeves/ bearings (Ref. 17) from the upper and lower bases. Discard the sleeves/ bearings.
6. Install new bearings/sleeves, as equipped.

   6.1 Install new bearings/sleeves in the upper and lower arm tubes.

   6.2 If so equipped, install new sleeves/ bearings in the upper and lower bases.

   6.3 Align the tubes of the lower and upper arms with the holes in the lower base. Be sure the notch in the lower arm is forward and up, and the notch in the upper arm is to the rear and down. See Detail *A* **in Fig.4,**

   6.4 As equipped, install and tighten the pivot bolts (Ref. 4), or install the connected shaft assembly (Ref. 16) through the lower base and the upper and lower arm forward tubes.

   6.5 Align the holes of the upper base with the rear tubes of the lower and upper arms.

6.6 As equipped, install and tighten the pivot bolts, or install the connected shaft assembly through the upper base and the upper and lower arm tubes.

6.7 For connected shaft assemblies, use snap ring pliers to install the snap rings that secure the shafts and the arms to the lower and upper bases.

7. Place the washer (Ref. 22) on the top of the air spring, and insert the top of the air spring through the upper arm. Install the pin clip (Ref. 20).

8. For an Easy-Aire seat, push the air spring supply hose (Ref. 23) onto the barbed 90-degree fitting at the bottom of the air spring (Ref. 25).

   For either seat version, set the seat base assembly upright.

9. Install the shock absorber as instructed earlier.

10. Place the belt bar and spacers, seat track stop, track assemblies, and upper seat assembly (Refs. 3, 11, 2, 13, and 14) on the upper base (Ref. 5). Install the locknuts (Ref. 19). Tighten the locknuts 20 N·m (15 lbf·ft). Remove the wooden block.

11. Install the seat as instructed **in Subject 100**.

Track Assembly Replacement

(Refer to Fig. 5)

1. For an Easy-Aire seat, work the hand pump (Ref. 21) until the upper seat assembly is raised to maximum height. Support the seat in this position by placing a wooden block between the lower base and lower arm. Refer to Detail *A* **in Fig.5,** Refs. 5, 6, and 7. Hold down the pump handle (Ref. 20) until all air is exhausted from the air spring.

   For a Cush-N-Aire seat, push the air valve knob (Detail *B* **in Fig.5,** Ref. 15) to raise the upper seat assembly to maximum height. Support the seat in this position by placing a wooden block between the lower base and lower arm. Refer to Detail *A* **in Fig.5,** Refs. 5, 6, and 7. Pull the air valve knob until all air is exhausted from the air spring.

2. Pull up and support the rear edge of the seat cushion (Ref. 19) as needed to gain access to the track assembly upper locknuts (Ref. 24).

3. For an Easy-Aire seat, remove the end of the air spring supply hose from the connection (Refs. 10 and 22) on the hand pump. Then go to step 4.

   For a Cush-N-Aire seat, remove the air valve and air hoses (Refs. 12, 10, and 18) from the seat. Refer to Detail *B* **in Fig.5.**

   3.1 Cut and remove the tie strap (Ref. 27) that attaches the air spring supply hose (Ref. 10) to the track assembly latch mechanism.

   3.2 Cut and remove the tie strap that attaches the air valve supply hose (Ref. 18) to the belt bar (Ref. 3).

   3.3 Loosen the nut (Ref. 14) that attaches the air valve to the lower frame. If needed, move the fore-and-aft adjustment lever (Ref. 26) to the right, and slide the upper seat assembly far enough forward to allow removal of the air valve.

   3.4 Remove the air valve and hoses (as an assembly), and lay them on the cab deck, behind the seat.

4. Remove the four locknuts (Ref. 24) that attach the lower frame to the top of the track assemblies. Remove the upper seat assembly (Ref. 23).

5. Remove the four locknuts (Ref. 28) that attach the track assemblies to the top of the upper base. Remove the track assemblies.

6. With the holes in the belt bar, the belt bar spacers, and the seat track stop (Refs. 3, 9, and 2) aligned with the holes in the upper base, install the new track assemblies on

   the upper base. Install and tighten the locknuts (Ref. 28) 20 N·m (15 lbf·ft).

7. Move the upper half of the track assemblies as needed to align their studs with the holes in the lower frame. Place the upper seat assembly (Ref. 23) on the track assemblies. Install and tighten the locknuts (Ref. 24) 20 N·m (15 lbf·ft).

8. For an Easy-Aire seat, connect the air spring supply hose to the connection on the hand pump (Refs. 10 and 22). Skip the following sub-steps

Component Replacement

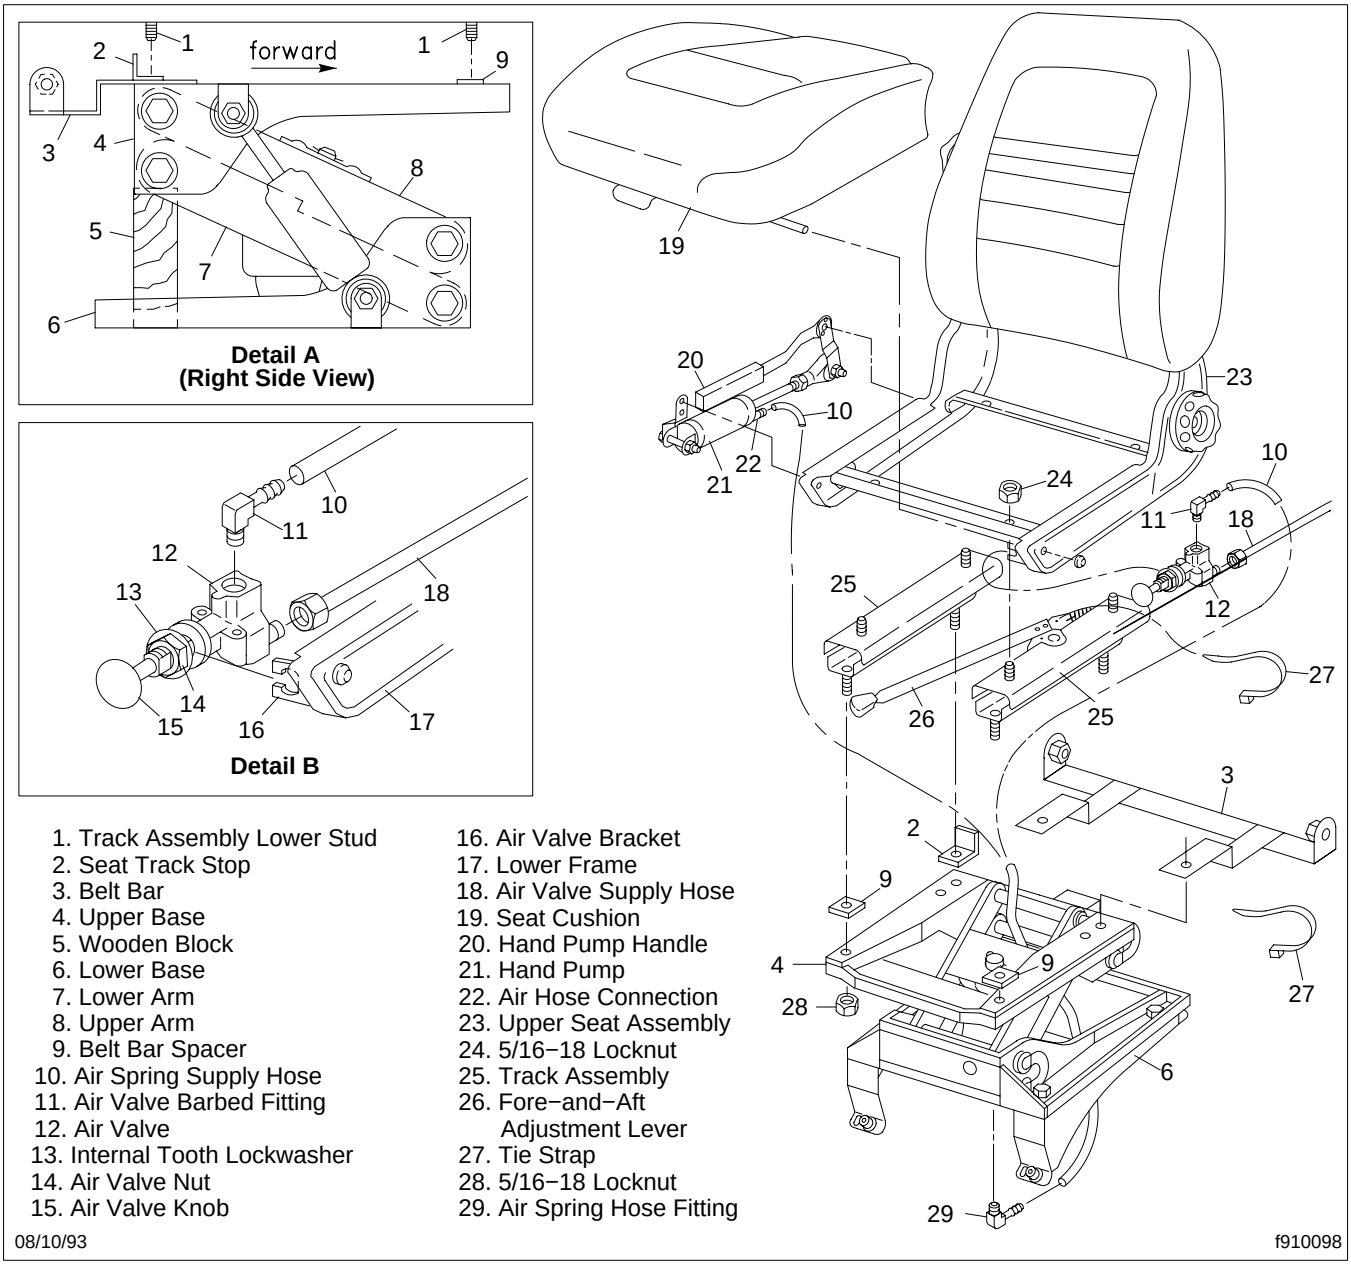

Fig. 5

for attaching the air valve and hoses on the seat, and go on.

For a Cush-N-Aire seat, install the air valve and hoses on the seat (Refs. 12, 10, and 18). Refer to Detail *B* **in Fig.5.**

8.1 Attach the air valve to the lower frame, with the lockwasher (Ref. 13) between the nut (Ref. 14) and the front of the air valve bracket (Ref. 16). Turn the air valve so its barbed fitting (Ref. 11) is on top.

8.2 Tighten the air valve nut finger-tight. Using a wrench, tighten the nut one-half turn more.

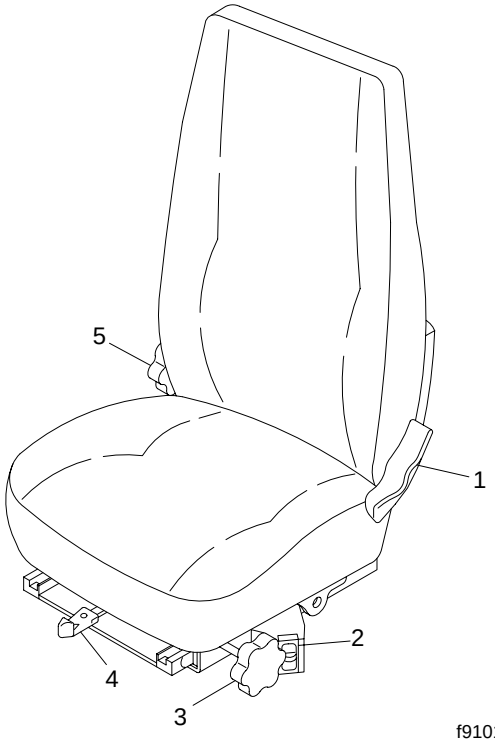
8.3 Install a new tie strap (Ref. 27) to attach the air spring supply hose (Ref. 10) to the track assembly latch mechanism.

8.4 Install a new tie strap to attach the air valve supply hose to the belt bar (Ref. 3).

9. Move the fore-and-aft adjustment lever to the right, and slide the upper seat assembly forward and rearward while making sure that the air hoses move without restriction. Return the seat cushion to its original position.

10. Work the hand pump (Easy-Aire seat), or push the air valve knob (Cush-N-Aire seat) to raise the seat. Remove the wooden block.

Specifications



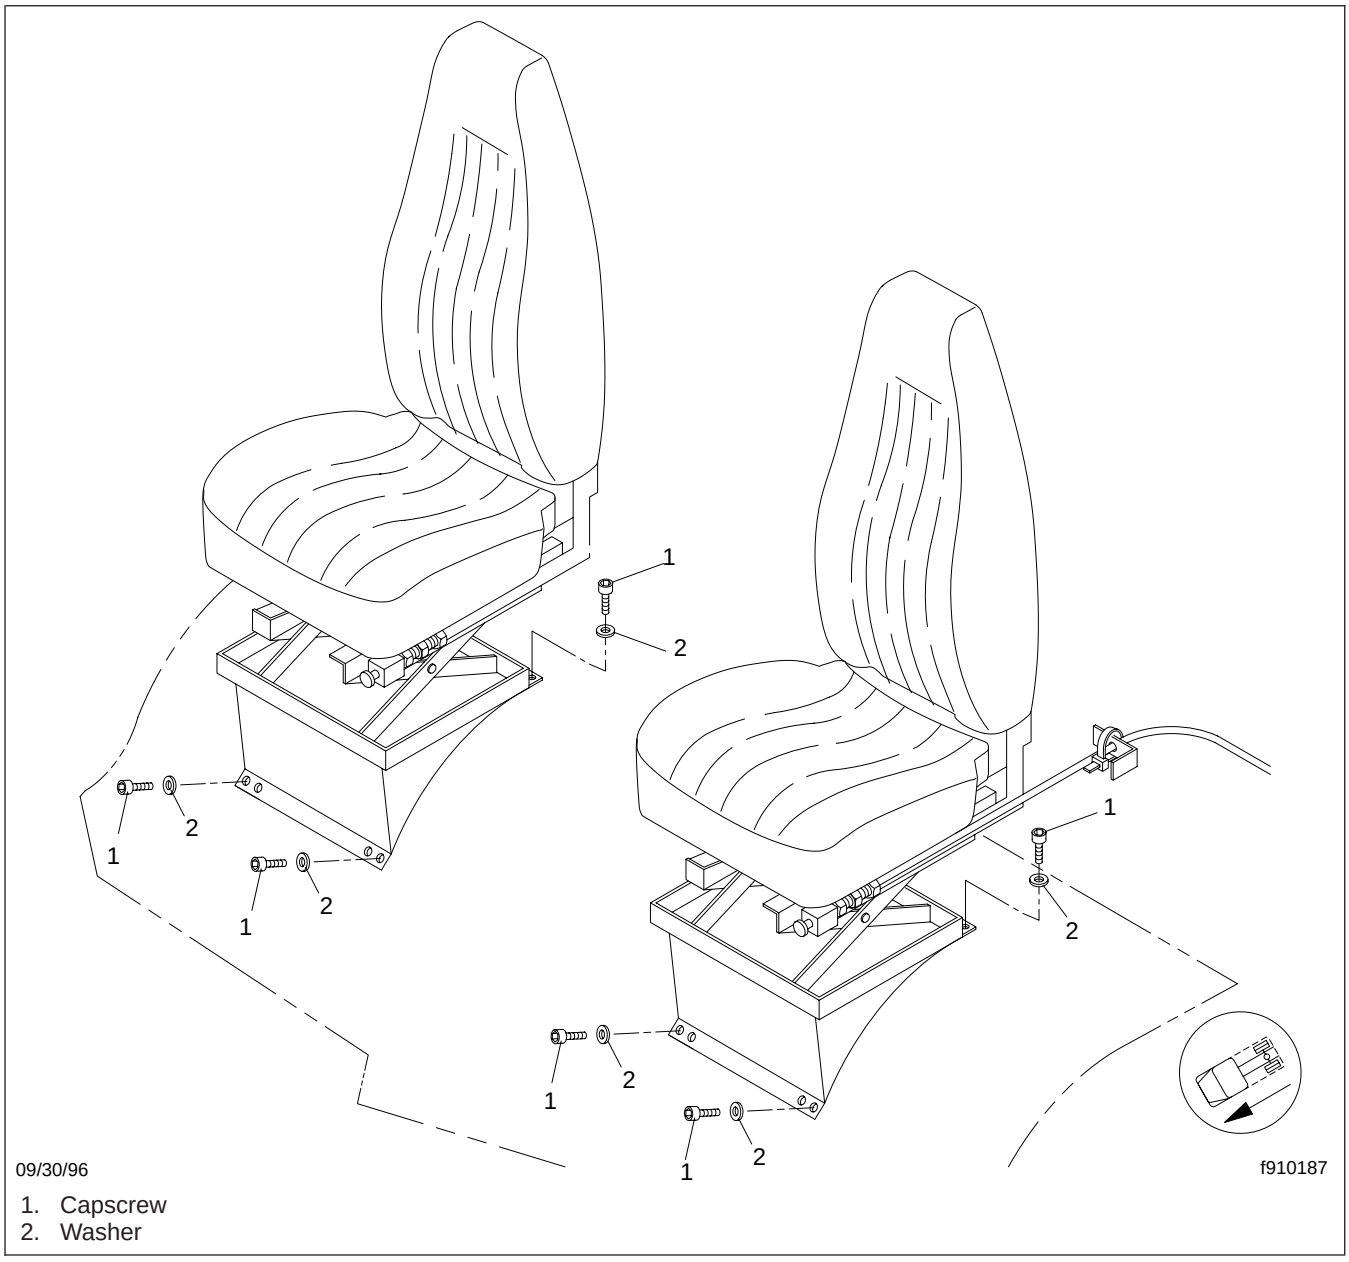
This subject contains the following table: •Fastener Torques

Description	Torque N·m (lbf·ft)
Seat Riser to Cab Deck Socket-Head Bolts	18 (13)
Seat Belt/Tether Belt to Belt Bar Bolts	54 (40)
Shock Absorber to Bracket Locknuts	34 (25)
Track Assembly to Upper Base Locknuts	20 (15)
Track Assembly to Lower Frame Locknuts	20 (15)

Table 1, Fastener Torques

General Information

The Bostrom Talladega 910 air suspension seats offer weight-height adjustment, lumbar support and a fore and aft roller track isolator system. See **Fig. 1**.



1. Back Angle Adjustment
2. Weight and Height Adjustment
3. Seat Cushion Tilt Adjustment
4. Fore and Aft Isolation and Seat Position Adjustment
5. Lumbar Adjustment

Fig. 1, Bostrom Talladega 910 Seat

For complete operating instructions, refer to the vehicle driver's manual.

Removal (See Fig. 1)

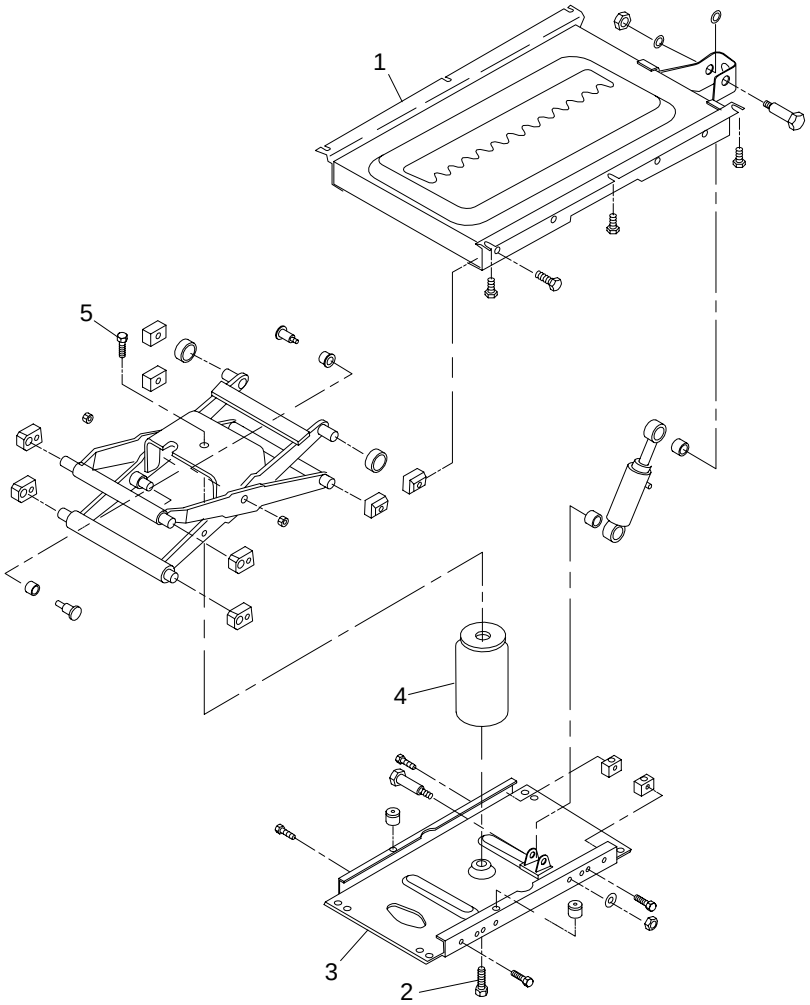
1. Capscrew
2. Washer

Fig. 1, Seat Installation

1. Apply the parking brakes, and chock the tires.
2. Push in on the top of the seat ride height switch until the seat is adjusted to its maximum height.
3. Cut a wooden block to the length required to support the seat at its maximum height, and

Seat Removal and Installation

place the block between the rear crossbars of the air suspension's inner and outer lever assemblies.



4. Drain the vehicle air reservoirs. Then push in on the bottom of the seat ride height rocker switch until all air is exhausted from the air spring.
5. Disconnect the air valve air supply hose at the quick-connect union.
6. Remove the seat belt straps and tether straps.
7. Remove the capscrews and washers that attach the seat to the cab deck. Remove the seat from the cab.

Installation (See Fig. 1)

1. Place the seat on the cab deck. Insert the capscrews through the washers and the seat base. Tighten the capscrews 27 lbf·ft (37 N·m).
2. Attach the seat belt straps and tether straps. Tighten the capscrews 40 lbf·ft (54 N·m).
3. Connect the air valve air supply hose by pressing the pneumatic tubing into the quick-connect union.
4. Start the engine and allow the air reservoirs to fill. Push in on the top of the seat ride height rocker switch until the seat is adjusted to its maximum height, then remove the wooden block that supports the seat suspension.
5. Remove the chocks from the tires.

Air Spring Removal and Installation

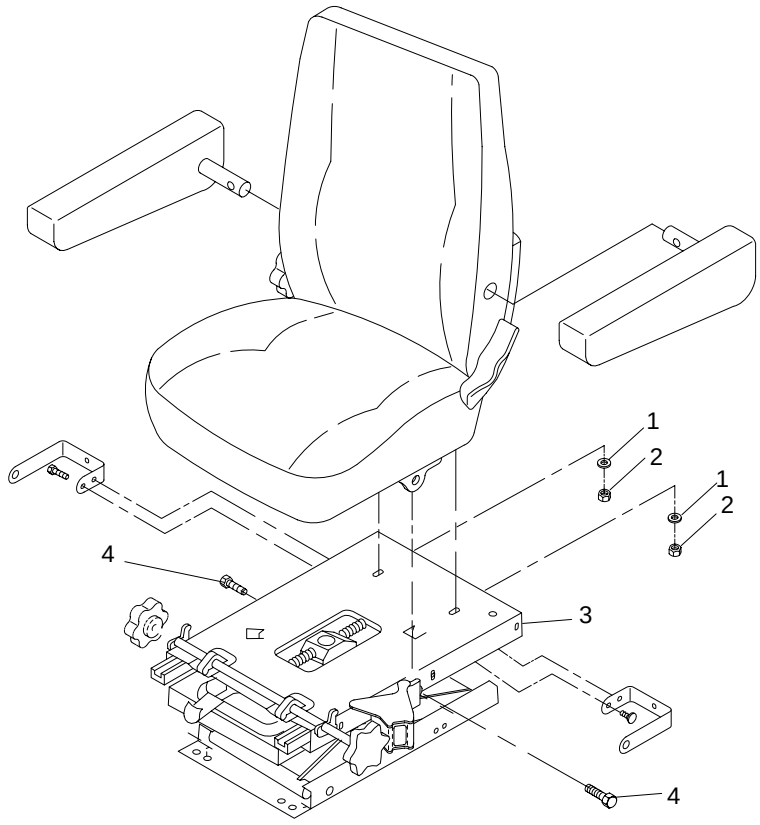
Removal (See Fig. 1)

10/04/96 f910196

1. Upper Frame
2. Bottom Screw
3. Base
4. Air Spring
5. Top Screw

Fig. 1, Bostrom Talladega 910 Seat

1. Fill the air spring so that the seat is at maximum height.
2. Block the suspension up with a spacer placed between the base and the upper frame.
3. Release the air pressure from the air spring so that the seat is supported by the spacer.
4. Remove the complete seat assembly from the vehicle using the instructions in **Subject 100**.
5. Disconnect the air line from the air spring by loosening the fitting and pullling the air line out of the fitting.
6. Remove the top and bottom screws from the air spring.
7. Remove the air spring from the suspension.



Air Spring Removal and Installation

Installation (See Fig. 1)

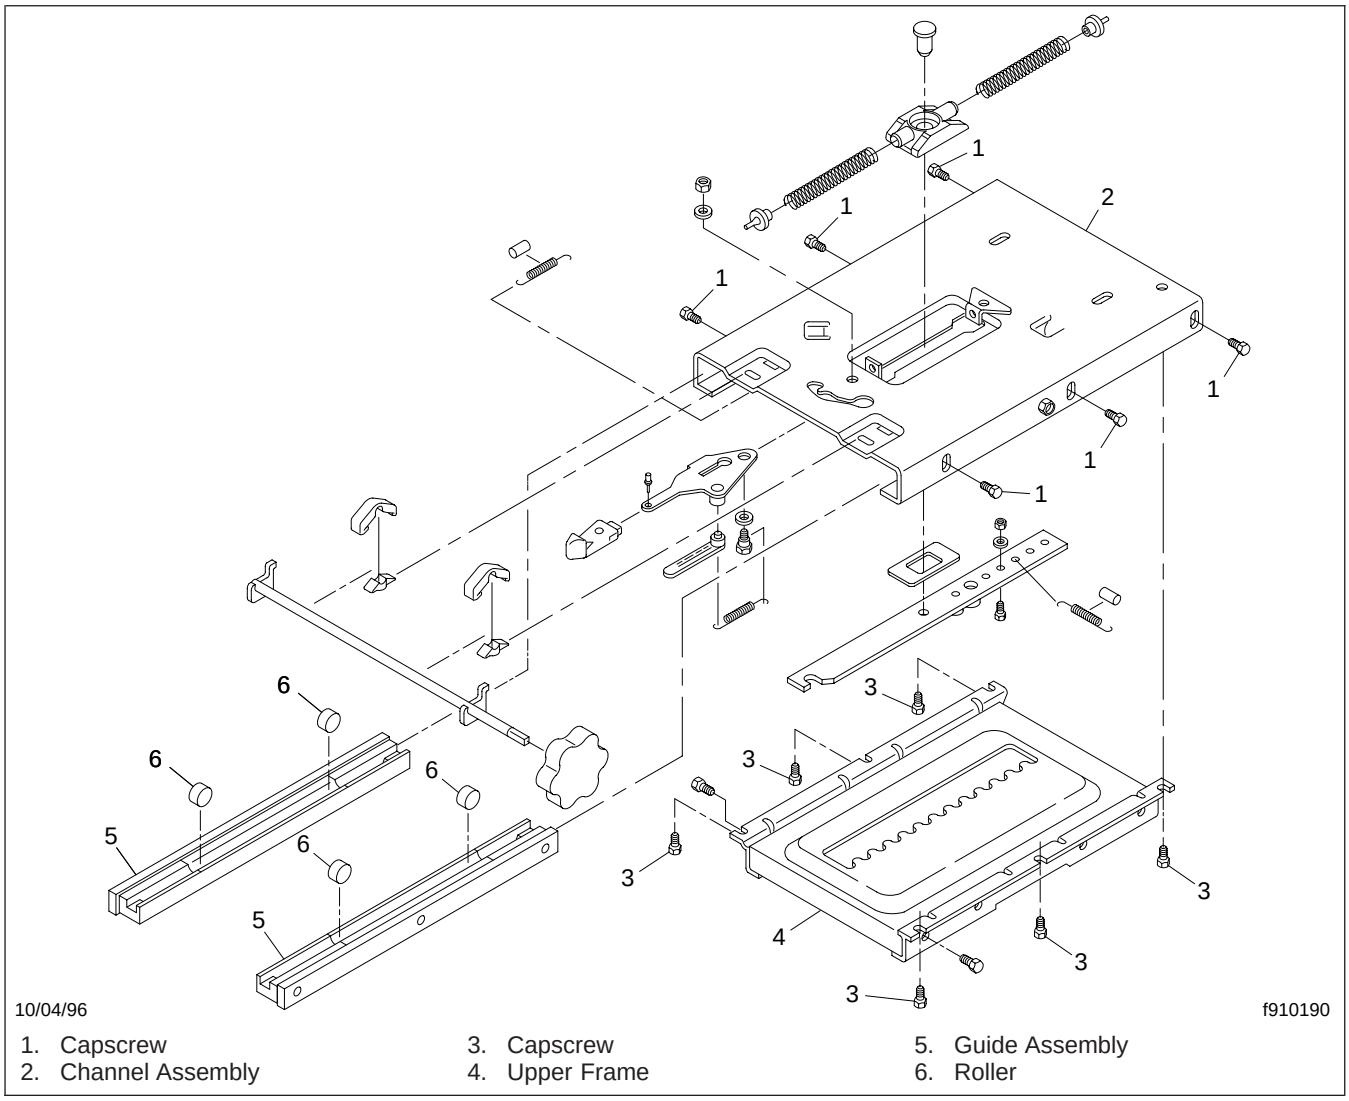
1. Position the air spring so the fitting at the bottom of the air spring is toward the front of the seat. Install the bottom screw into the air spring.
2. Tighten the bottom screw 9 to 11 lbf·ft (12 to 15 N·m).
3. Install the top screw and tighten it 15 to 19 lbf·ft (20 to 26 N·m).
4. Connect the air line to the fitting in the air spring by pushing the tube into the fitting.
5. Install the seat assembly in the vehicle, using the instructions in **Subject 100**.
6. Fill the air spring and remove the spacer block.

Seat/Back Assembly Removal and Installation

Removal (See Fig. 1)

1. Flatwasher
2. Nut
3. Channel Assembly
4. Shoulder Bolt

Fig. 1, Bostrom Talladega 910 Seat



1. Adjust the seat/back assembly to the most rearward position and remove the two nuts and flatwashers from the underside of the channel assembly.
2. Remove the two shoulder bolts from the channel assembly.
3. Disconnect the air line from the air lumbar, if equipped.
4. Remove the seat/back assembly.

Installation (See Fig. 1)

1. Place the seat/back assembly onto the channel assembly.
2. Connect the air line to the air lumbar, if equipped.
3. Install the two shoulder bolts to the channel assembly.
4. Install the two nuts and flatwashers to the underside of the channel assembly.

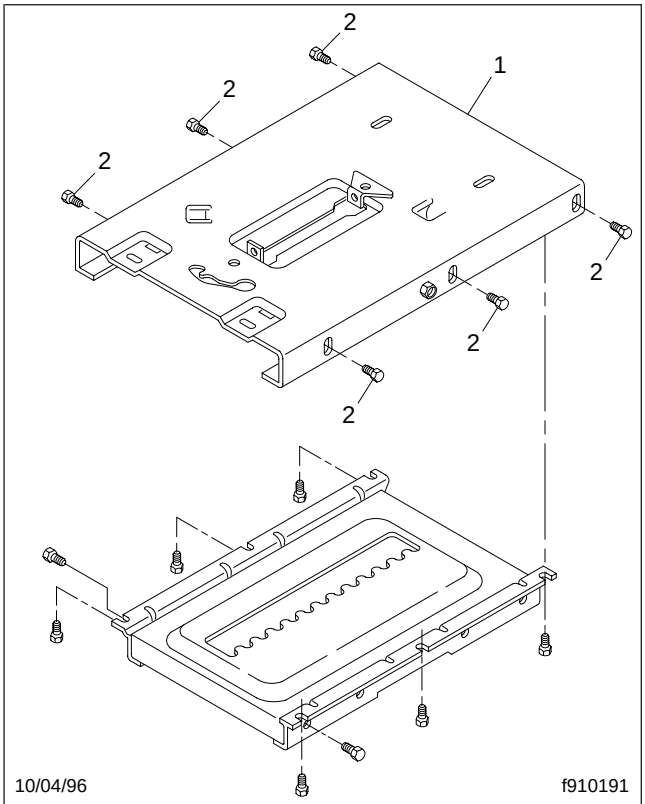
Roller Guide Removal and Installation

Removal (See Fig. 1)

1. Capscrew
2. Channel Assembly
3. Capscrew
4. Upper Frame
5. Guide Assembly
6. Roller

Fig. 1, Channel Assembly (exploded)

1. Adjust the channel assembly until the cutouts in the underside of the channel line up with the capscrews. Remove the capscrews.
2. Remove the three capscrews on each side of the channel assembly.
3. Remove both guide assemblies and the four rollers.



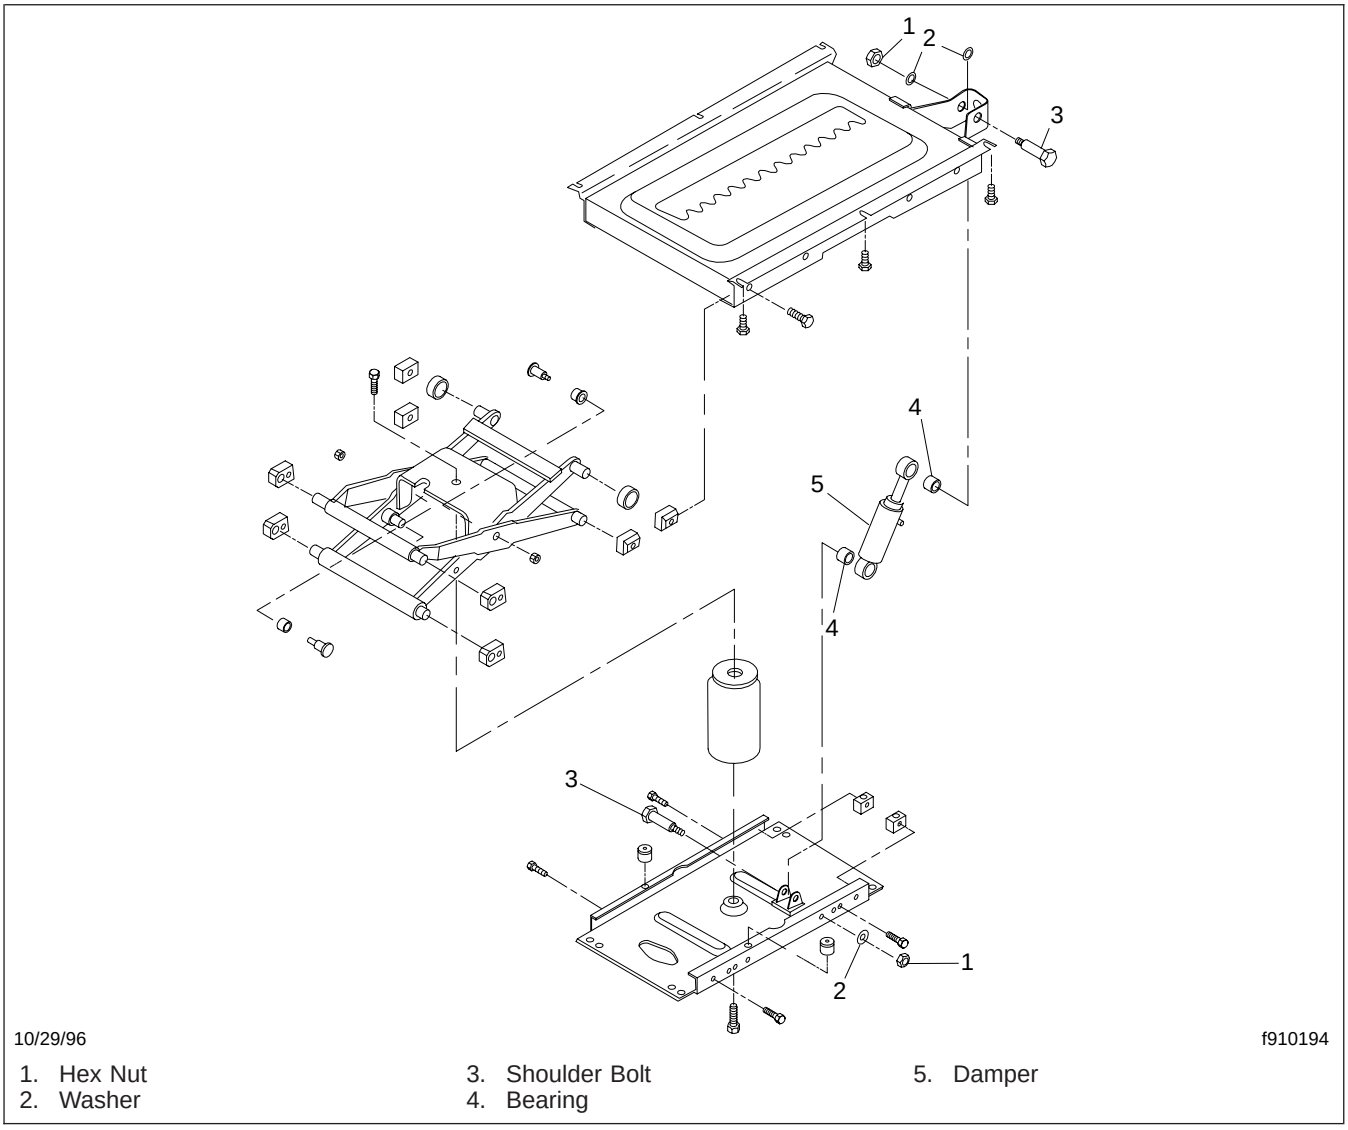
Installation (See Fig. 1)

1. Install both guide assemblies and the four rollers.
2. Install the three capscrews on each side of the channel assembly. Do not fully tighten the capscrews.

Roller Guide Removal and Installation

3. Install the center capscrews on the underside of the channel assembly. Tighten the capscrews 5 to 7 lbf·ft (7 to 9 N·m).
4. Carefully move the assembly rearward and install the front capscrew. Move the assembly forward and install the rear capscrew. Tighten the capscrews 5 to 7 lbf·ft (7 to 9 N·m).
5. Tighten the capscrews on the side of the channel assembly 5 to 7 lbf·ft (7 to 9 N·m).
6. Adjust the channel assembly using the instructions in **Subject 140**.

Adjustment (See Fig. 1)



1. Channel Assembly
2. Capscrew

Fig. 1, Bostrom Talladega 910 Seat

1. Loosen the six capscrews along the side of the channel assembly.
2. Push down on the channel assembly to adjust vertical play.
3. Retighten the six capscrews. Tighten the capscrews 5 to 7 lbf·ft (7 to 9 N·m).

Removal (See Fig. 1)

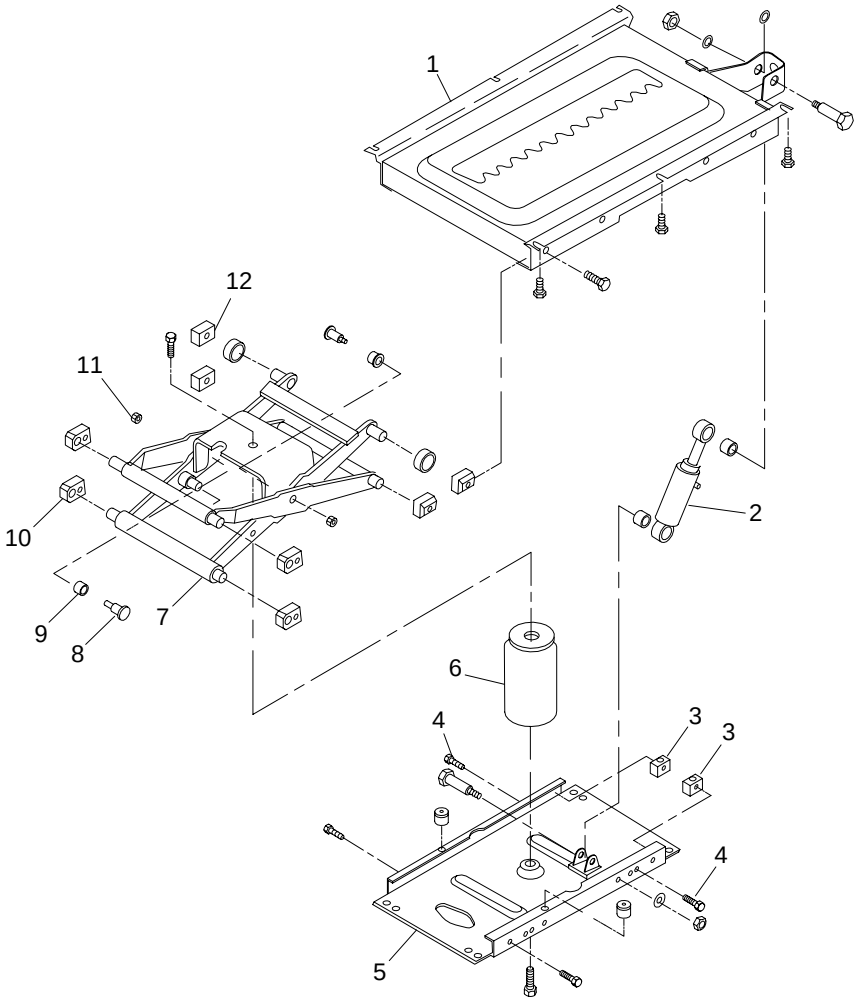
1. Hex Nut
2. Washer
3. Shoulder Bolt
4. Bearing
5. Damper

Fig. 1, Bostrom Talladega 910 Seat

NOTE: The seat/back assembly does not need to be removed.

1. Move the channel assembly to the rearmost position to provide access to the damper assembly.
2. Fill the air spring so that the seat is at maximum height.
3. Remove the shoulder bolts and hex nuts.
4. Remove the damper.

Installation (See Fig. 1)



1. Install the new damper with the flanges of the bearings to the outside of the suspension.
2. Install the thrust washers.

Damper Removal and Installation

3. Install the shoulder bolts and hex nuts.

Suspension Rebuild Bearing/Slide Block Removal and Installation

Removal (See Fig. 1)

10/04/96 f910195

1. Upper Frame
2. Damper

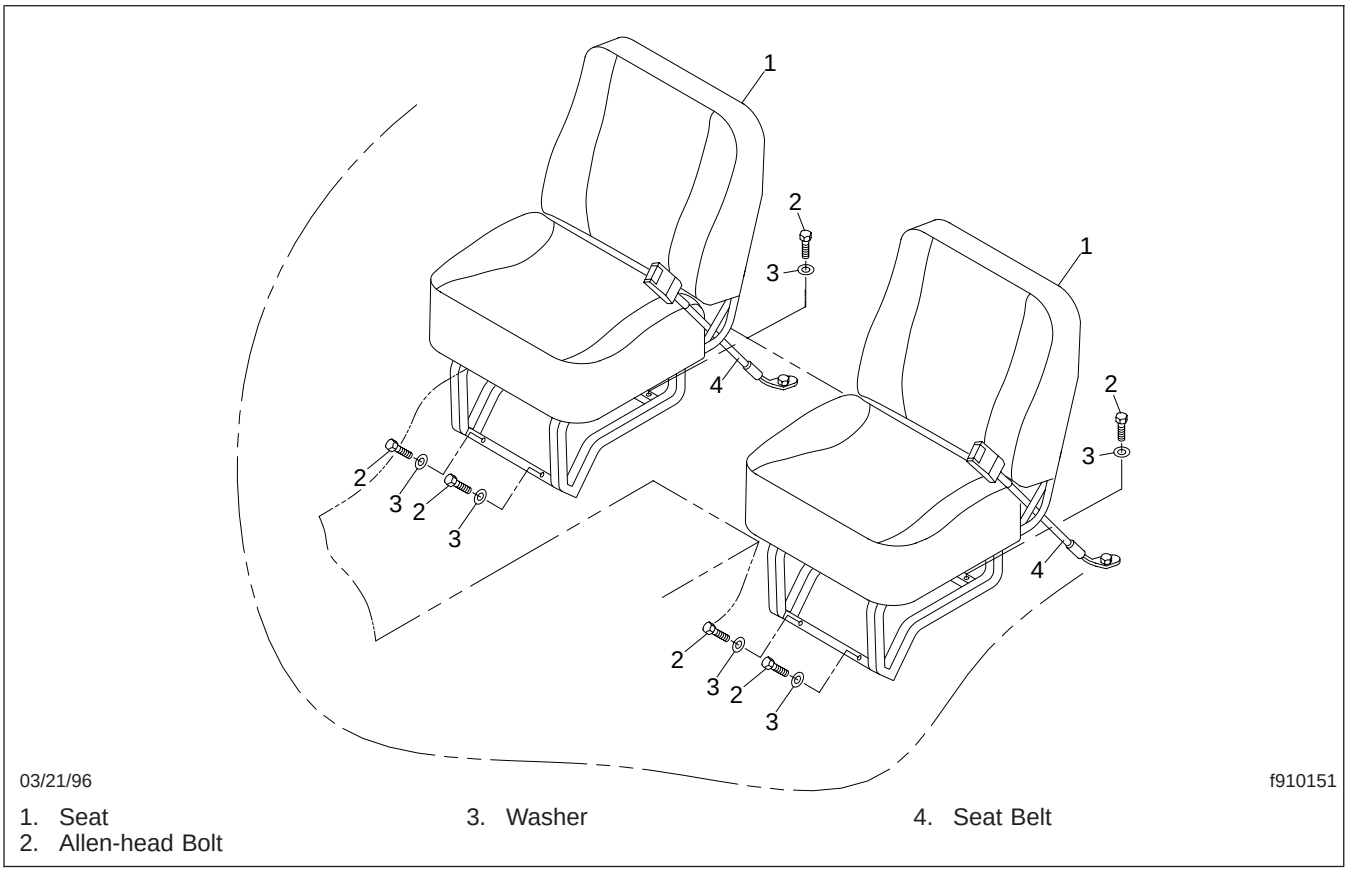
12. Slide Block

Fig. 1, Bostrom Talladega 910 Seat Suspension (exploded)

1. Bleed all the air from the supply line. Disconnect the air supply line to the seat. Using the air valve, exhaust all air from the air spring. Remove the complete seat assembly from the vehicle using the instructions in **Subject 100**.
2. Remove the seat/back assembly, using the instructions in **Subject 120**.
3. Remove the capscrews and the ICP bracket.
4. Block the suspension up with a spacer placed between the base and the upper frame.
5. Remove the air spring using the instructions in **Subject 110**. Mark the air line for reassembly.

Suspension Rebuild Bearing/Slide Block Removal and Installation

6. Remove the damper using the instructions in **Subject 150**.
7. Remove the capscrews from the upper front bearing blocks and the lower rear stop block assemblies.
8. Remove the upper frame assembly by lifting and sliding it forward off the bearing blocks and the slide blocks.
9. Remove the capscrews from the lower front bearing blocks and slide the lever assemblies forward until the bearing blocks are removed from the channel on the base. Slide the lever assemblies rearward to remove the slide blocks from the channel.
10. Remove the shoulder bolts and nuts from the pivots of the lever assemblies and inspect the bolts. If the bolts are worn, replace them.



Installation (See Fig. 1)

1. Replace the bearings at the pivots on the lever assembly by pushing out the old bearings and pressing in the new bearings. The flange of the bearings should be on the outside of the lever assembly.
2. Install the shoulder bolts and nuts into the pivots of the lever assemblies. Tighten the bolts 18 to 22 lbf·ft (24 to 30 N·m).
3. Install the new bearing blocks, spacers, and slide blocks on the levers with the beveled surfaces outward and slide the levers with blocks into the channel on the base. Tighten the screws 27 to 33 lbf·ft (37 to 45 N·m).
4. Slide the upper frame assembly over the blocks. Line up the capscrews with the bearing blocks and tighten the screws 27 to 33 lbf·ft (37 to 45 N·m).
5. Manually move the suspension up and down to make sure there are no clearance problems.
6. Block the suspension up with a spacer placed between the base and the upper frame. Install the air spring using the instructions in **Subject 110**.
7. Install the damper using the instructions in **Subject 150**.
8. Install the ICP bracket and capscrews.
9. Install the seat/back assembly using the instructions in **Subject 120**.
10. Install the seat assembly in the vehicle, using the instructions in **Subject 100**. Connect the air supply line to the seat.

Bostrom Tube Frame Seat Removal and Installation

Removal

1. Remove the four allen-head bolts attaching the seat frame to the deck of the cab.
2. Pull the seat belt from the rear of the seat frame assembly. See **Fig. 1.**

1. Seat
2. Allen-head Bolt
3. Washer
4. Seat Belt

Fig. 1, Bostrom Tube Frame Seat Assembly

3. Lift the seat from the cab deck.

Installation

1. Place the seat on the cab deck.
2. Secure the seat to the deck with the bolts and the washers. See **Fig. 1**.
3. Tighten the bolts.
4. Insert the seat belt through the rear of the seat frame assembly.

General Information

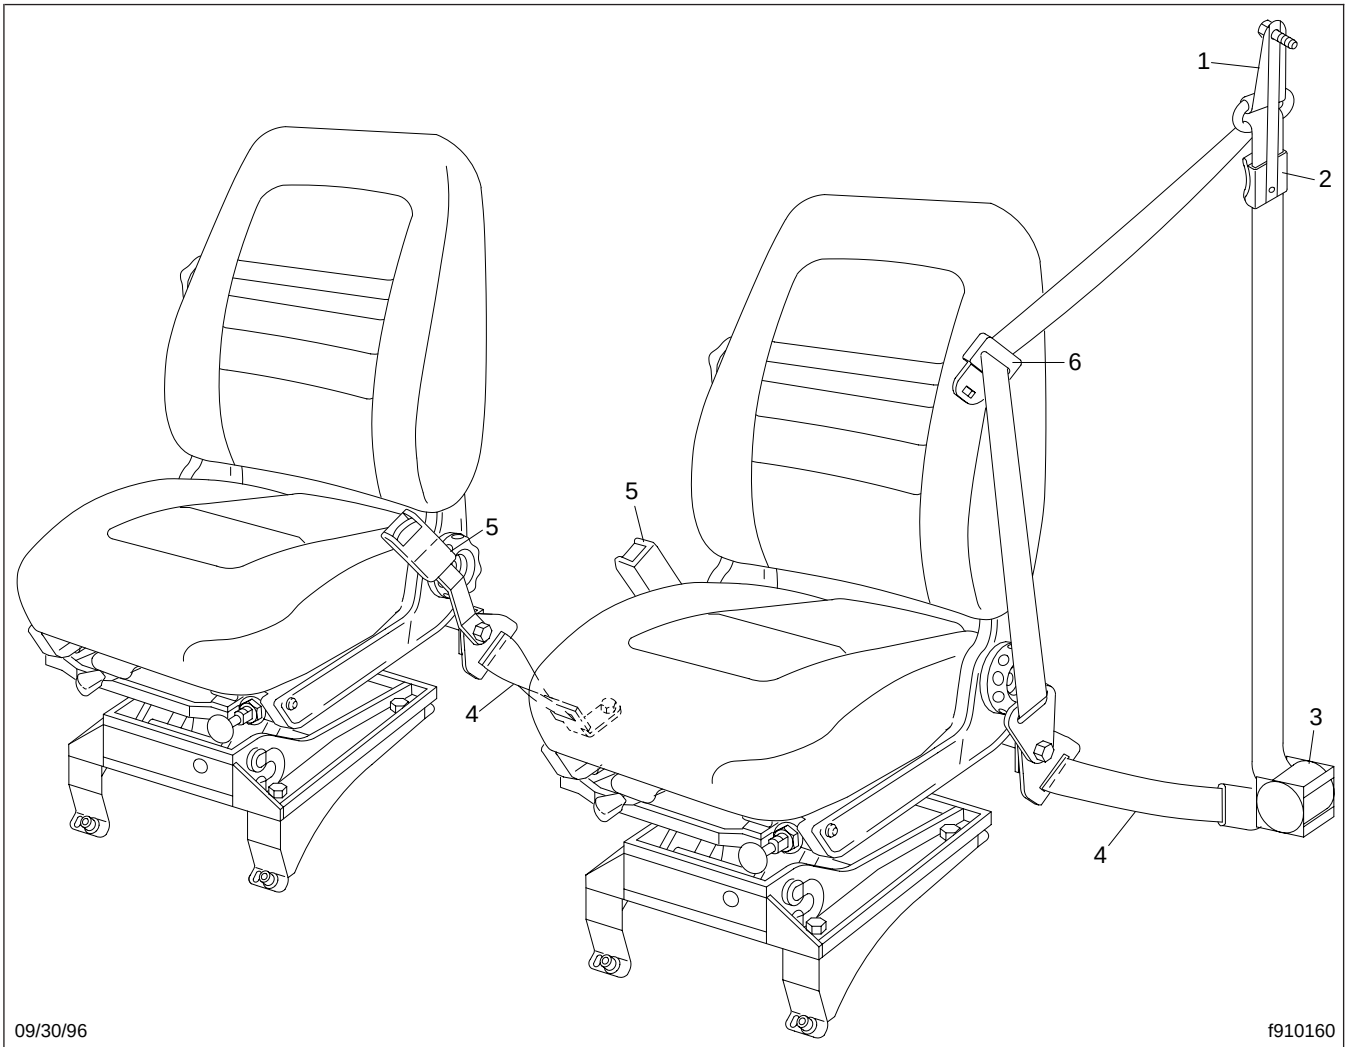
Although the three-point seat belts installed in Freightliner vehicles (See **Fig. 1**) appear similar to the seat belts used in passenger cars, there are some important differences that can affect service life.

- A heavy truck can travel more miles in a year than a car might go in its lifetime.
- There is more movement in truck seat and belt systems, especially with air ride seats.
- Trucks often operate in more severe environments than cars, such as gravel pits, cement plants, and grain elevators, where the belts are exposed to abrasive dirt and dust.

Because of these factors, truck seat belt systems need to be inspected regularly to ensure that they are in proper condition.

⚠ WARNING

WARNING: Inspect and maintain seat belts. Worn or damaged seat belts could fail during a sudden stop or crash, possibly resulting in serious personal injury or death.



⚠ CAUTION

CAUTION: Any time a vehicle is involved in an accident, the entire vehicle seat belt system must be replaced before again operating the vehicle.

IMPORTANT: When any part of a seat belt system needs replacement, the entire seat belt must be replaced, both retractor and buckle side.

IMPORTANT: Seat belts have a finite life which may be much shorter than the life of the vehicle. Regular inspections and replacement as needed are the only assurance of adequate seat belt security over the life of the vehicle.

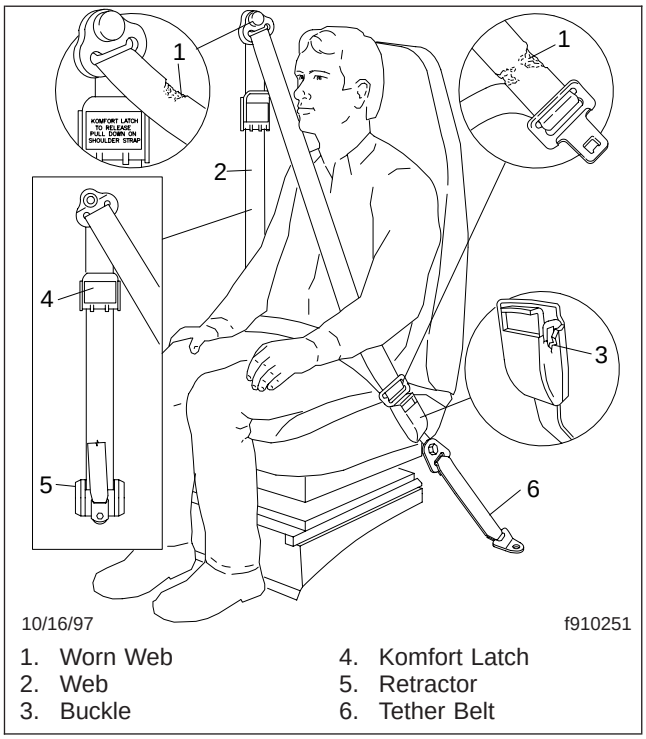
5. Retractor
6. Tether Belt

Fig. 1, Seat Belt Inspecting



IMPORTANT: Seat belts have a finite life which may be much shorter than the life of the vehicle. Regular inspections and replacement as needed are the only assurance of adequate seat belt security over the life of the vehicle.

Inspect the seat belts and tether belts (if so equipped). For right-hand-drive vehicles, see **Fig. 2**.

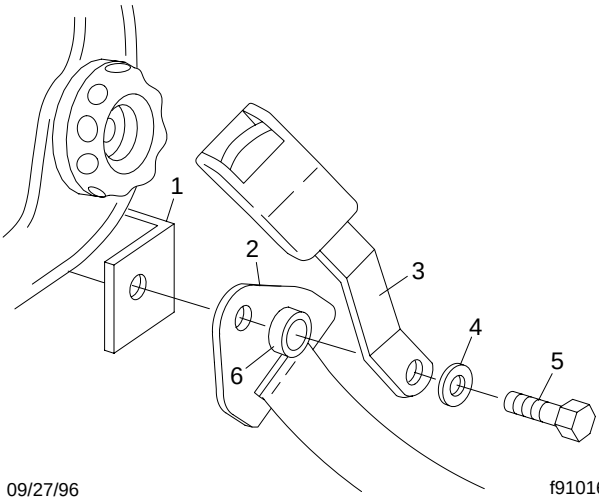
⚠ WARNING

Inspect and maintain seat belts as instructed below. Worn or damaged seat belts could fail during a sudden stop or crash, possibly resulting in serious personal injury or death.

1. Check the web for fraying, cuts, or extreme wear, especially near the buckle latch plate and in the D-loop guide area.
2. Check the web for extreme dirt or dust, and for severe fading from exposure to sunlight.

1. Worn Web
2. Web
3. Buckle
4. Komfort Latch
5. Retractor
6. Tether Belt

Fig. 2, Seat Belt Inspecting (right-hand-drive vehicle)

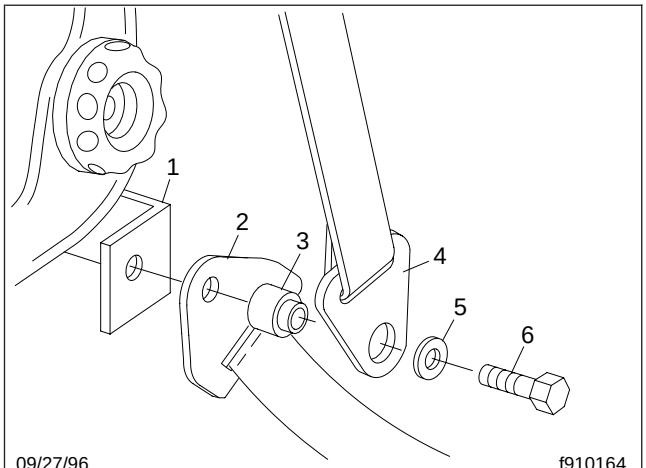


3. Check the buckle and latch for operation and for wear or damage.
4. Check the Komfort Latch™ for function and cracks or other damage.
5. Check the web retractor for function and damage.
6. Check the mounting bolts for tightness, and tighten any that are loose.

IMPORTANT: When any part of a seat belt system needs replacement, the entire seat belt must be replaced, both retractor and buckle side.

Seat Belts and Tethers Removal and Installation

Suspension Seat Removal



1. Apply the parking brakes, and chock the tires.
2. Remove the bolt and washer holding the buckle, the spacer, and the tether to the seat. Also remove the bolt holding the tether to the floor. Remove the buckle and the tether. See **Fig. 1**.

1. Mounting Bracket
2. Tether
3. Buckle
4. Washer
5. Bolt
6. Spacer

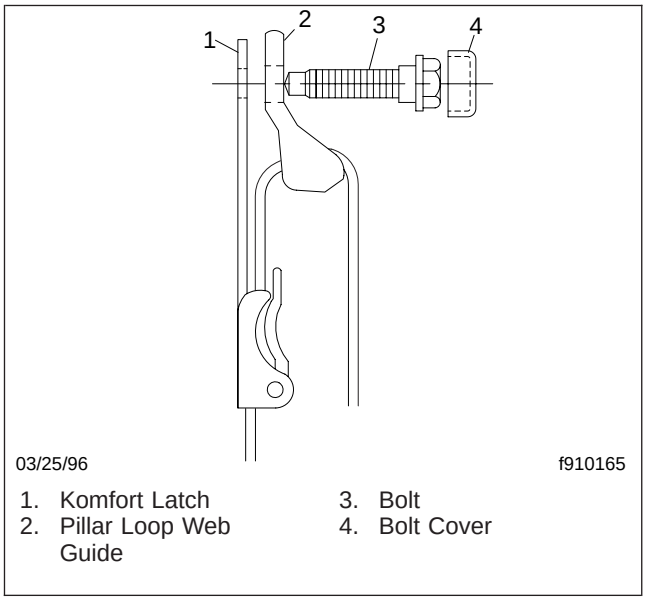


Fig. 1, Buckle Mounting

3. Remove the bolt and washer holding the seat belt, the spacer, and the inboard tether to the seat. Remove the seat belt and the tether. See **Fig. 2**.
4. Remove the bolt cover and the bolt holding the pillar loop web guide and the Komfort Latch. Remove the pillar loop web guide and the Komfort Latch™. See **Fig. 3**.
5. Remove the bolt and washer holding the outboard tether, the spacer, and the grab handle. See **Fig. 4**.
6. Remove the trim panel. Remove the bolt and washer holding the retractor. Remove the retractor.

1. Mounting Bracket
2. Tether
3. Spacer
4. Seat Belt

Suspension Seat Installation

1. Attach the retractor by inserting the bolt and washer through the retractor. Tighten 40 lbf·ft (54 N·m). Install the trim panel.

Seat Belts and Tethers Removal and Installation

03/25/96 f910166

1. Grab Handle
2. Tether
3. Washer
4. Bolt
5. Spacer
6. Trim Panel

Fig. 4, Outboard Tether Mounting

IMPORTANT: The retractor must be mounted correctly before the web will reel out of the retractor and function properly.

2. Insert the bolt and washer through the outboard tether, the spacer, and the grab handle. Tighten 40 lbf·ft (54 N·m). See **Fig. 4**.

NOTE: Install the tether belt marked "IN" on the inboard side of the seat and the tether belt marked "OUT" on the outboard side of the seat.

3. Attach the pillar loop web guide. See **Fig. 3**.

   3.1 Insert a bolt through the pillar loop web guide, the Komfort Latch™, and an optional metal spacer.

   NOTE: Some applications require a metal spacer to move the Komfort Latch/pillar loop web guide away from the vehicle cab trim (and some applications do not utilize the Komfort Latch).

   3.2 Thread the bolt into the anchor nut provided in the pillar.

   3.3 Tighten the bolt 40 lbf·ft (54 N·m). The Komfort Latch must be mounted vertically in line with the belt and remain rigid after tightening.

   IMPORTANT: The pillar loop web guide must rotate freely after assembly of the system.

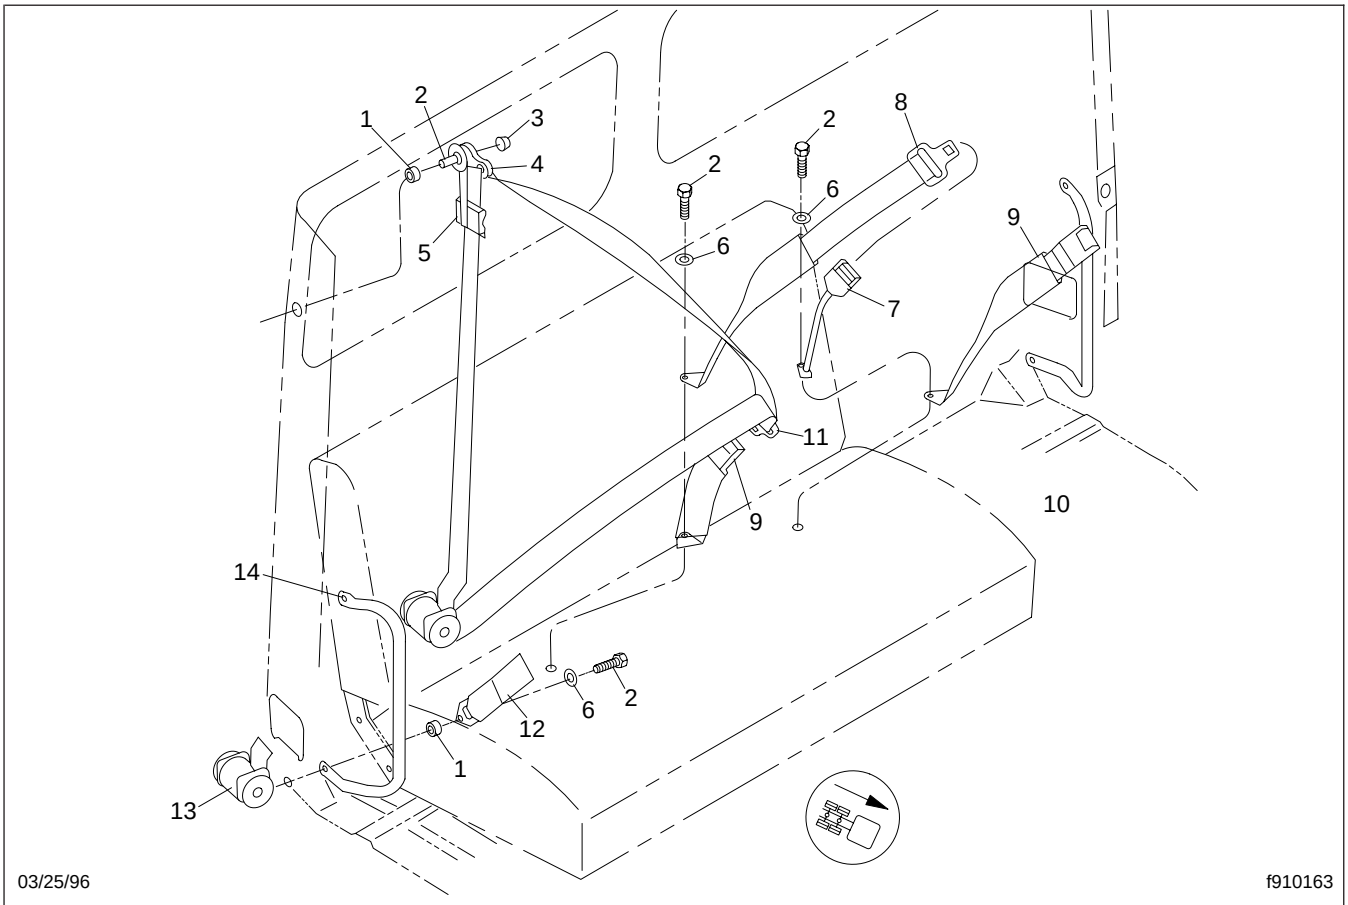
   3.4 Snap the bolt cover in place over the bolt head.

4. Attach the seat belt by inserting a bolt through the seat belt, a metal spacer, the tether, and the mounting bracket. Secure with a nut. Tighten 40 lbf·ft (54 N·m). See **Fig. 2**.

5. Attach the buckle by inserting the bolt and washer through the buckle, the tether, and the mounting bracket. Secure with a nut. Tighten 40 lbf·ft (54 N·m). See **Fig. 1**.

6. Attach the inboard tether by inserting the bolt through the tether and into the weldnut provided in the cab floor. Tighten 40 lbf·ft (54 N·m).

7. Remove the chocks from the tires.



Bench Seat and Static Seat Removal (See Fig. 5)

1. Apply the parking brakes and chock the tires.
2. Remove the bolt and washer holding the buckle (Ref. 9) and the center belt latch (passenger side with bench seat only) or the center belt buckle (driver side with bench seat only). Remove the buckle.
3. Remove the bolt and washer holding the seat belt (Ref. 12) and the grab handle (Ref. 14).
4. Remove the bolt cover. Remove the bolt and washer holding the pillar loop web guide and the Komfort Latch™. Remove the pillar loop web guide and the Komfort Latch.
5. Remove the trim panel. Remove the bolt and washer holding the retractor. Remove the retractor.

Bench Seat and Static Seat Installation (See Fig. 5)

1. Attach the retractor by inserting the bolt and washer through the retractor. Tighten 40 lbf·ft (54 N·m). Install the trim panel.

Seat Belts and Tethers Removal and Installation

NOTE: Driver side retractor and belt not shown.

1. Spacer
2. Bolt
3. Bolt Cover

12. Seat Belt
13. Retractor
14. Grab Handle

Fig. 5, Bench Seat Seat Belt Mounting

IMPORTANT: The retractor must be mounted correctly before the web will reel out of the retractor and function properly.

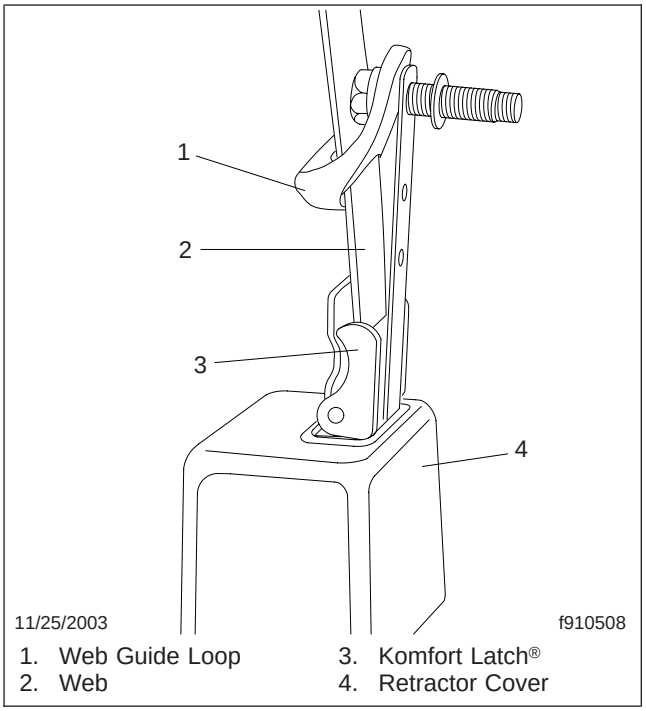
2. Attach the seat belt by inserting the bolt and washer through the belt, the spacer, and the grab handle. Tighten 40 lbf·ft (54 N·m).
3. Attach the pillar loop web guide. See **Fig. 3**.
   - 3.1 Insert a bolt through the pillar loop web guide, the Komfort Latch™, and an optional metal spacer.

NOTE: Some applications require a metal spacer to move the Komfort Latch/pillar loop web guide away from the vehicle cab trim (and some applications do not utilize the Komfort Latch).

- 3.2 Thread the bolt into the anchor nut provided in the pillar.
- 3.3 Tighten the bolt 40 lbf·ft (54 N·m). The Komfort Latch must be mounted vertically in line with the belt and remain rigid after tightening.

Seat Belts and Tethers Removal and Installation

IMPORTANT: The pillar loop web guide must rotate freely after assembly of the system.

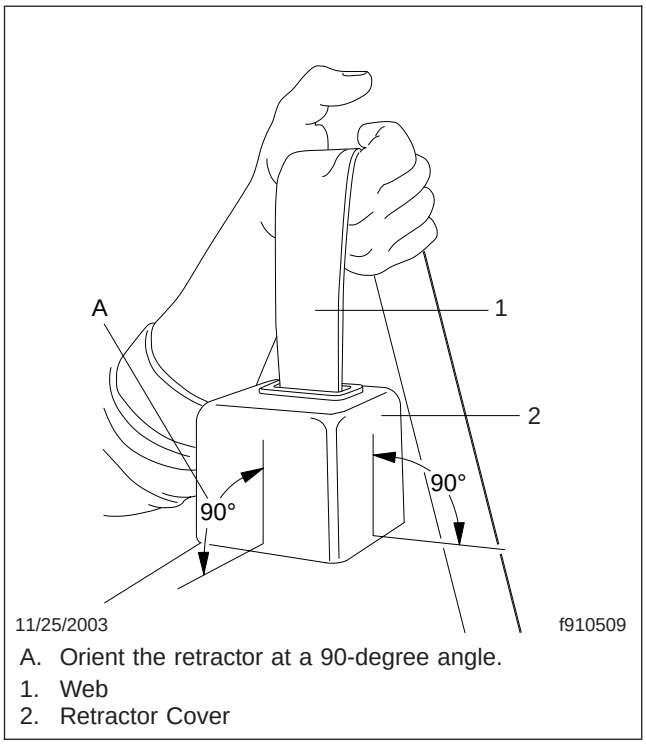


3.4 Snap the bolt cover in place over the bolt head.

4. Attach the buckle by inserting the bolt and washer through the center belt latch (passenger side) or center belt buckle (driver side) and the buckle. Tighten 40 lbf·ft (54 N·m).
5. Remove the chocks from the tires.

Unlocking an Installed Retractor

Seat belt retractors are locking up and preventing the webbing from being extracted. This condition is known as reverse lock-up and is caused by excessive webbing spooling into the retractor before installation in the vehicle.

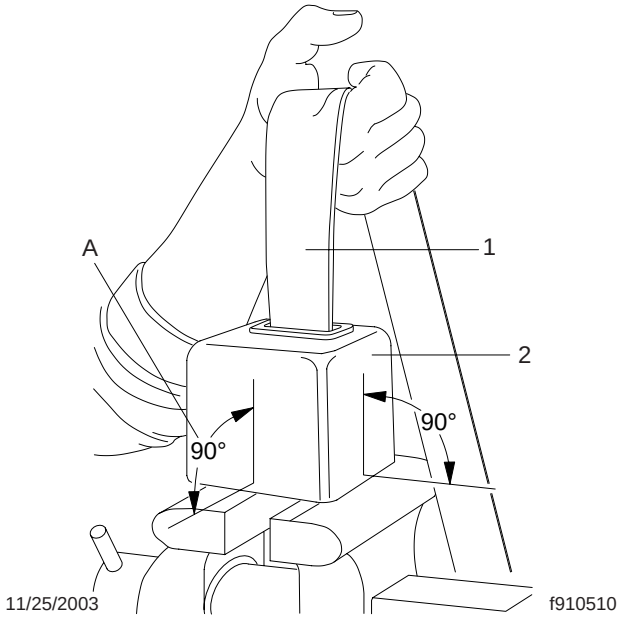


1. Park the vehicle, apply the parking brake, shut down the engine, and chock the front and rear tires.
2. Verify that the retractor is mounted in the 90-degree position. See **Fig. 1**.
3. Firmly grasp the web close to the retractor. See **Fig. 2**.

1. Web Guide Loop
2. Web
3. Komfort Latch®
4. Retractor Cover

Fig. 1, Retractor in the 90-Degree Position

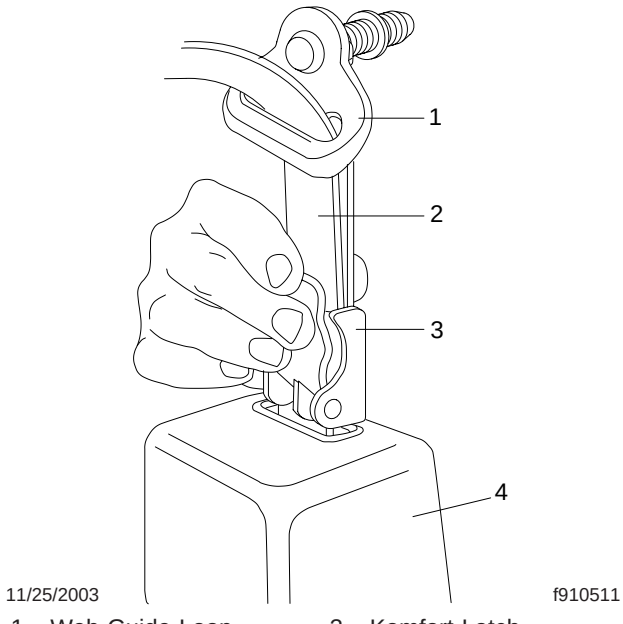
4. Pull on the web with enough force to tighten the web onto the spool until the webbing locks back onto the retractor. The retractor should unlock when tension is released.
5. Remove the chocks from the tires.



A. Orient the retractor at a 90-degree angle.
1. Web
2. Retractor Cover

Fig. 2, Firmly Grasp the Webbing

Unlocking an Uninstalled Retractor



1. Clamp the retractor in a vice at a 90-degree angle. See **Fig. 3**.
2. Pull on the web with enough force to tighten the web onto the spool.
3. Release the web. This allows 1/2-inch (12.7-mm) of the webbing to feed back into the retractor storage housing and unlock the retractor.
4. Pull all the webbing out of the retractor, and allow only 12 to 15 inches (304 to 381 mm) to retract. Lock the Komfort Latch on the web. See **Fig. 4**.

Seat Belt Retractor Unlocking

3. Komfort Latch
4. Retractor Cover

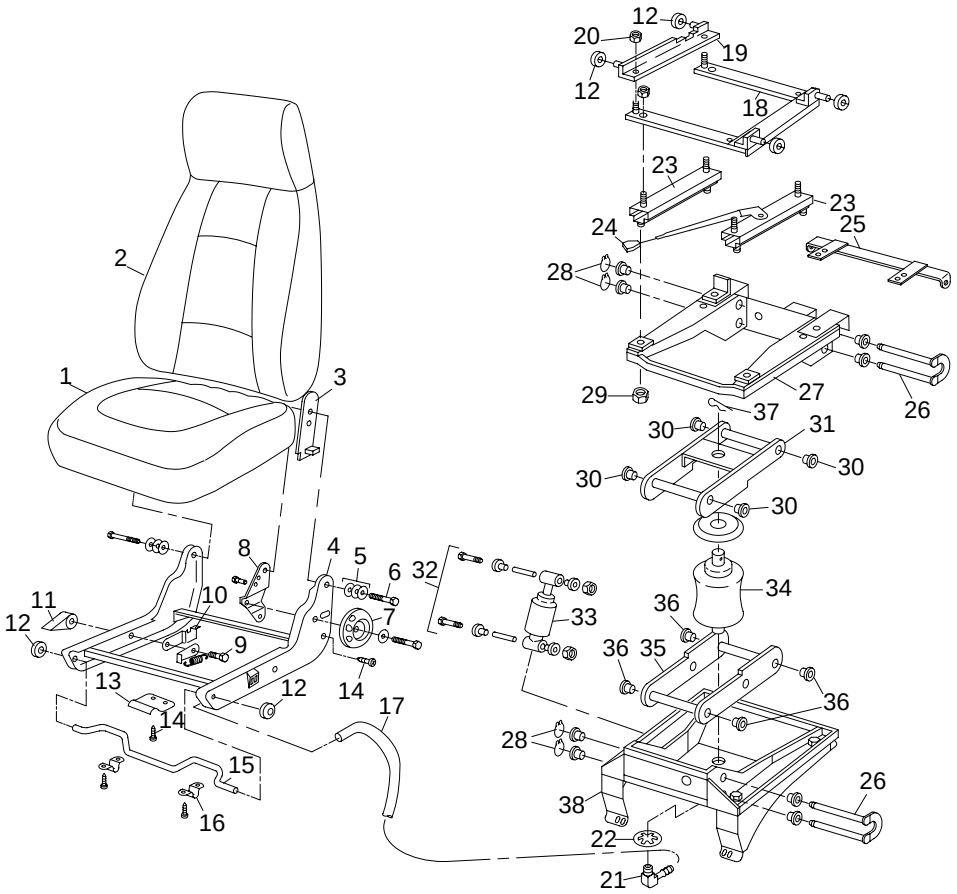
Fig. 4, Lock the Komfort Latch

Troubleshooting

Replace the entire seat belt system if any of the following problems exist. See the instructions in **Section 110**.

- cuts, fraying, or extreme wear of any area of the web (shoulder or lap belt)
- buckle and latch do not engage with a solid sounding "click" or do not release freely when the button is pushed
- Komfort Latch™ is broken or does not lock in place easily and does not release by tugging downward on the webbing
- retractor locks up at improper times or web does not flow freely to and from the retractor while vehicle is not moving
- seat belt web has been exposed to extreme sun light, dust, or dirt, causing the web color to fade and deterioration of web physical strength
- molded plastic around the buckle is deformed, cracked, or broken, exposing the internal mechanism
- molded plastic cover around the retractor is cracked or broken, exposing the internal mechanism or stored web
- metal or molded plastic area of latch is deformed, cracked, corroded, or broken
- molded plastic D-loop is deformed, cracked, or broken

If any of the following problems exist, see the instructions in **Section 110** for replacement, adjustment, tightening and torque requirement. Replace hardware with authorized parts.



- tethers are missing, not attached to seat, or hang extremely loose
- D-loop web guide does not rotate freely
- hardware is missing, rusted, corroded, or damaged
- hardware does not appear to be tight

General Information

National Cush-N-Aire II air suspension seats (see **Fig. 1**) offer adjustment features for height, fore and aft positioning, back cushion tilt, lumbar support, and seat cushion tilt. The air suspension and height-adjustment features are provided by an inflatable air spring (air bag) that receives air pressure from the vehicle air system; pressure in the air spring is controlled by a set of switches attached to the seat frame. Each seat is equipped with a shock absorber to dampen unwanted up and down motion of the seat. An isolator (Chugger-Snubber®) isolates the seat from the cab's fore and aft motion; at the side of the seat's lower frame is an isolator lockout handle that can be used whenever the isolator feature is not desired.

For a complete description of, and operating instructions for, all seat adjustment features, refer to the vehicle driver's manual.

38. Seat Base

Fig. 1, National Cush-N-Aire II Seat (exploded view)

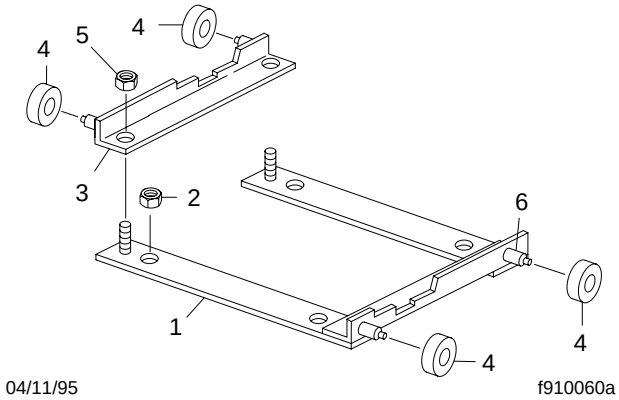
Removal (See Fig. 1)

1. Capscrew
2. Washer

Fig. 1, Seat Installation

1. Apply the parking brakes, and chock the tires.
2. Push in on the top of the seat ride height rocker switch until the seat is adjusted to its maximum height.
3. Cut a wooden block to the length required to support the seat at its maximum height, and place the block between the air suspension seat base and the rear crosstube of the lower arm.

Seat Removal and Installation



4. Drain the vehicle air reservoirs. Then push in on the bottom of the seat ride height rocker switch until all air is exhausted from the air spring.
5. Disconnect the air valve air supply hose.
6. Unscrew the capscrews that attach the seat belt straps and tether straps.
7. Remove the capscrews and washers that attach the seat to the cab deck. Remove the seat from the cab.

Installation

1. Place the seat on the cab deck. Insert the capscrews through the washers and the seat base. Tighten the capscrews 27 lbf·ft (37 N·m).
2. Attach the brackets of the seat belt straps and tether straps. Tighten the capscrews 40 lbf·ft (54 N·m).
3. Attach the air valve air supply hose.
4. Start the engine and allow the air reservoirs to fill. Push in on the top of the seat ride height rocker switch until the seat is adjusted to its maximum height, then remove the wooden block that supports the seat suspension.
5. Remove the chocks from the tires.

Isolator Assembly (Chugger-Snubber®) Replacement

Replacement (See Fig. 1)

1. Welded Bearing Support Frame
2. Locknut
3. Bearing Support Rail
4. Bearing
5. Hexnut
6. Bearing Stud

Fig. 1, Isolator Assembly

1. Remove the air spring supply hose from the seat.
2. Cut off the air spring supply hose close to the barbed fitting; minimize hose length loss. Remove the scrap hose from the barbed fitting. Tape the hose and fitting ends to prevent dirt or other matter from entering.
3. Remove the hexnuts that attach the isolator bearing support rail to the studs on the isolator bearing support frame.
4. Lift up on the side of the seat's lower frame, to slide the bearing support rail up and off the bearing support frame.

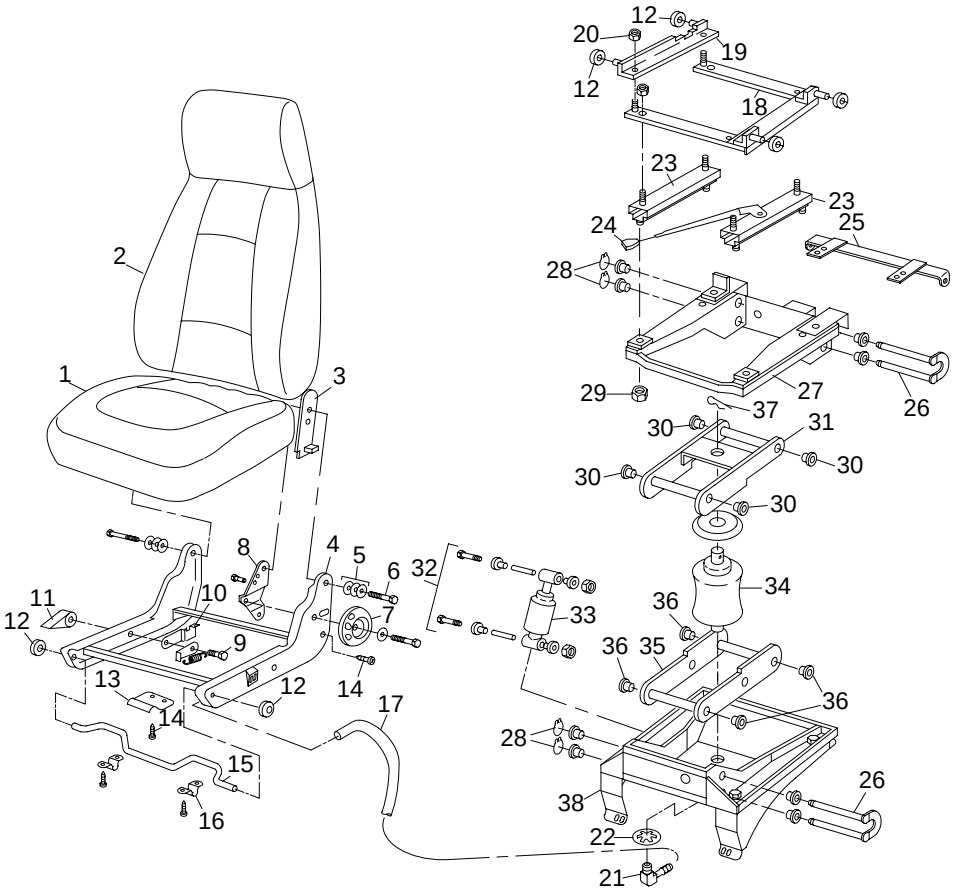
NOTE: Two of the isolator bearings will fall off when the bearing support rail is removed.

5. Push the upper seat frame toward the opposite side, to remove the other two bearings. Remove the bearings and the unattached upper seat components.
6. Remove the four 5/16–18 locknuts from the bearing support frame. Remove the bearing support frame.
7. Using a multi-purpose chassis grease, lubricate the bearing cups and new isolator bearings.
8. Install the welded bearing support frame on the track assembly. Tighten the four 5/16–18 locknuts 15 lbf·ft (20 N·m).
9. Install two of the isolator bearings on the bearing studs of the bearing support frame, then align the bearing cups on the upper seat frame over the bearings.
10. Assemble the isolator bearing support rail and the two remaining isolator bearings. With the seat cushion tilted forward, install the support rail's bearings in the upper seat frame, and lower the seat frame and support rail assembly onto the isolator bearing support frame. Install the 5/16–18 hexnuts, and tighten them finger-tight.

    Push the isolator assembly fore and aft, and check the position of the isolator bearing support rail before tightening the hexnuts. The isolator should be tight enough to eliminate side play without interfering with the fore-and-aft movement of the seat. Tighten the 5/16–18 hexnuts 15 lbf·ft (20 N·m).
11. Install the air spring supply hose.

Shock Absorber Removal and Installation

Removal



1. Move the fore-and-aft adjustment lever to the right, and slide the upper seat assembly back as far as possible.
2. Raise the upper seat assembly to maximum height. Support the seat in this position by placing a wooden block between the lower arm and the seat base.
3. Remove the shock absorber, bushings, and bearings.
   - 3.1 Remove the nuts and bolts that attach the shock absorber to the upper arm and the seat base. Remove the shock absorber.
   - 3.2 Remove the bushings and bearings from the shock absorber.

Installation

1. Check the operation of the shock absorber, and replace it if needed.
2. Install the shock absorber and new bearings and bushings.
   - 2.1 Install new bearings and bushings in the shock absorber eyes.
   - 2.2 With the upper arm blocked up, position the shock absorber so its piston-rod end is in the mounting bracket of the upper arm. Install the bolt and locknut to attach the shock absorber to the bracket. Tighten the locknut 25 lbf·ft (34 N·m).
   - 2.3 Position the cylinder end of the shock absorber in the mounting bracket of the seat base. Attach the shock absorber to the seat base. Tighten the locknut 25 lbf·ft (34 N·m).
3. Raise the seat. Remove the wooden block.

Replacement (See Fig. 1)

1. Raise the upper seat assembly to maximum height. Support the seat in this position by placing a wooden block between the lower arm and the seat base.
2. Remove the seat from the vehicle as instructed in **Subject 100**.
3. Lay the seat on its side, with the wooden block still in place.

Air Spring Replacement

4. Remove, as an assembly, the fitting and the air hose from the air spring. Tape the end of the fitting to prevent dirt or other matter from entering.
5. Pry the pin clip from the bottom of the air spring.
6. Remove the retaining ring that secures the air spring to the upper arm. Remove the air spring.
7. Position the new air spring in the seat base, and secure it with a new pin clip.
8. Insert the top of the air spring in the opening of the upper arm. Install the retaining ring on the air spring.
9. Install the air spring fitting and air hose in the top of the air spring.
10. Install the seat as instructed in **Subject 100**.
11. Raise the seat. Remove the wooden block.

Replacement (See Fig. 1)

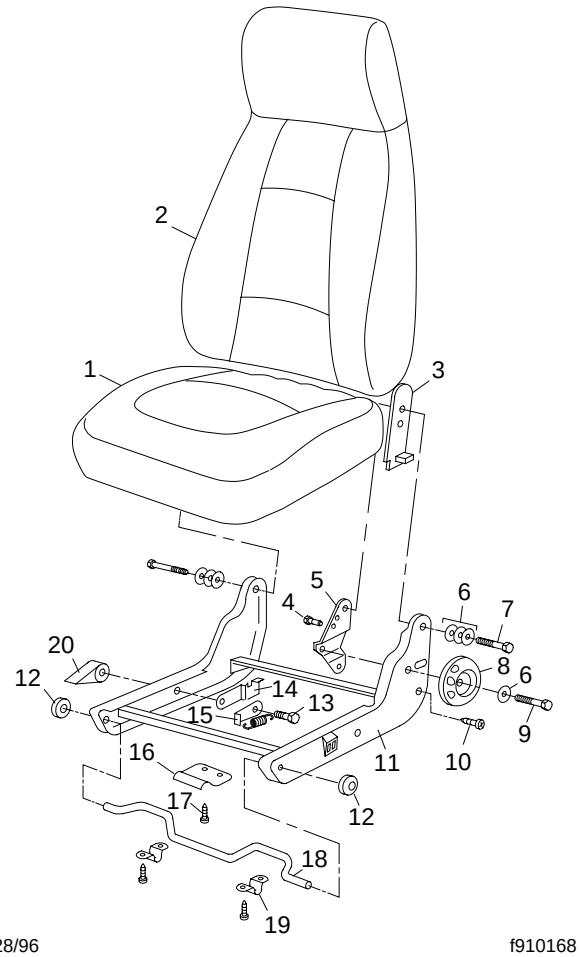
Fig. 1, National Cush-N-Aire II Seat (exploded view)

1. Remove the shock absorber as instructed in **Subject 120**.
2. Remove the seat as instructed in **Subject 100**.
3. Remove the four locknuts that attach the track assemblies, seat track stop, belt bar and bearings, and upper seat assembly to the seat sup-

Base Assembly Bearing/Sleeve Replacement

port. Remove the upper seat assembly, track assemblies, seat track stop, and belt bar and spacers.



4. Remove the retaining ring that secures the air spring to the upper arm.
5. Remove the bearings and/or sleeves from the seat support and the seat base and the upper and lower arms.
   - 5.1 Use snap ring pliers to remove the four snap rings from the connected shaft assemblies. Then, using a drift punch, drive out the shaft assemblies from the seat support and the seat base.

   NOTE: Place the punch against the snap ring end of the shafts. Drive each shaft end a little at a time; the two shafts are connected to each other on the opposite side.

   - 5.2 Remove the seat support, and the upper and lower arms from the air spring and seat base.
   - 5.3 Remove the bearings/sleeves from the upper and lower arms. Discard the bearings/sleeves.
   - 5.4 If so equipped, remove the sleeves/bearings from the seat support and the seat base. Discard the sleeves/bearings.
6. Install new bearings/sleeves, as equipped.
   - 6.1 Install new bearings/sleeves in the upper and lower arm tubes.
   - 6.2 If so equipped, install new sleeves/bearings in the seat support and the seat base.
   - 6.3 Align the tubes of the lower and upper arms with the holes in the seat base. Be sure the notch in the lower arm is forward and up, and the notch in the upper arm is to the rear and down.
   - 6.4 Install the connected shaft assembly through the seat base and the upper and lower arm forward tubes.
   - 6.5 Align the holes of the seat support with the rear tubes of the lower and upper arms.
   - 6.6 As equipped, install and tighten the pivot bolts, or install the connected shaft assembly through the seat support and the upper and lower arm tubes.
   - 6.7 For connected shaft assemblies, use snap ring pliers to install the snap rings that secure the shafts and the arms to the seat base and the seat support.
7. Insert the top of the air spring through the upper arm. Install the retaining ring.
8. Set the seat base assembly upright.
9. Install the shock absorber as instructed in **Subject 120**.
10. Place the belt bar and bearings, seat track stop, track assemblies, and upper seat assembly on the seat base. Install the locknuts, and tighten 15 lbf·ft (20 N·m).
11. Install the seat as instructed in **Subject 100**.

Upper Seat Frame Removal and Installation

Removal (See Fig. 1)

20. Cushion Adjustment Lever

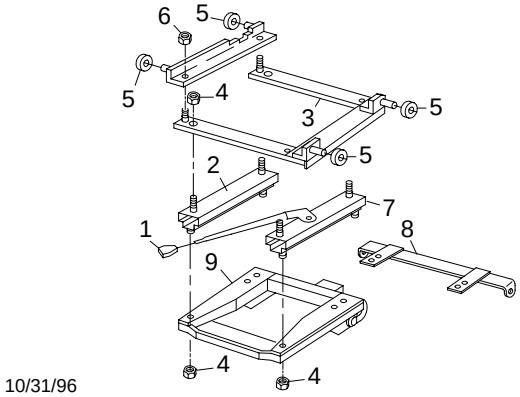

Fig. 1, Upper Seat Frame Assembly (exploded view)

1. Remove the suspension shroud (if equipped) from the seat base.
2. Remove the plastic tie strap that attaches the seat cushion to the upper seat frame assembly.
3. Remove the fasteners that attach the seat cushion to the front cushion adjustment rod. Remove the seat cushion.
4. Disconnect the air spring supply hose from the air spring.
5. Remove the four locknuts from under the top flange of the seat support assembly.
6. Remove the lower frame from the seat base.

Installation

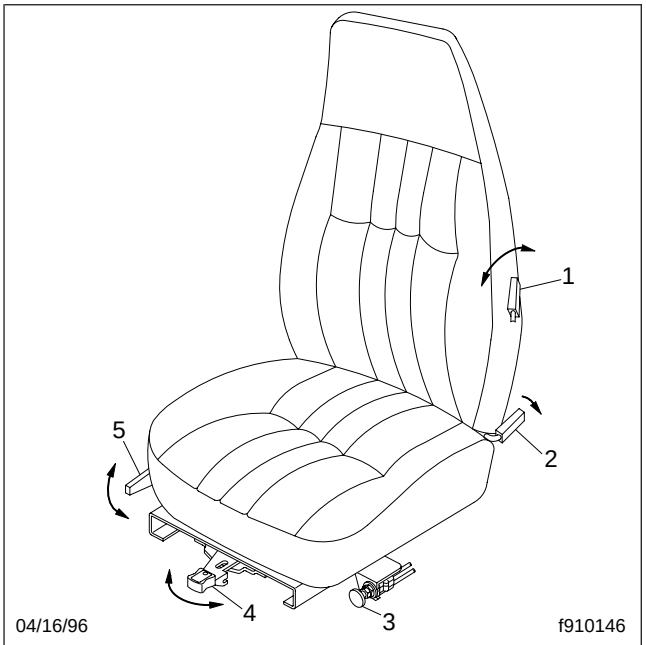
1. Place the lower frame on the seat support assembly. Install the locknuts under the top flange of the seat support assembly. Tighten the locknuts 10 lbf·ft (15 N·m).
2. Attach the air spring supply hose to the air spring. Make sure that the air hose moves without any restrictions when the seat is moved forward or rearward.
3. Position the seat cushion, then install the fasteners that attach the seat cushion to the front cushion adjustment rod.
4. Install a new plastic tie strap to secure the seat cushion to the lower frame assembly.
5. Install the suspension shroud (if equipped) on the seat base.

Replacement (See Fig. 1)

1. Fore-and-Aft Adjustment Lever
2. Right-Side Track
3. Welded Bearing Support Frame
4. Locknut
5. Bearing
6. Hexnut
7. Left-Side Track
8. Belt Bar
9. Seat Support

Fig. 1, Track Assembly (exploded view)

1. Raise the upper seat assembly to maximum height. Support the seat in this position by placing a wooden block between the lower base and lower arm.
2. Pull up and support the rear edge of the seat cushion as needed to gain access to the isolator-assembly-to-track-assembly 5/16–18 locknuts.
3. Remove the air spring supply hose from the seat.
   - 3.1 Cut and remove the tie strap that attaches the air spring supply hose to the track assembly latch mechanism.
   - 3.2 Remove the air spring supply hose (as an assembly), and lay it on the cab deck, behind the seat.
4. Remove the four 5/16–18 locknuts that attach the isolator assembly to the top of the track assemblies. Remove the upper seat assembly.
5. Remove the four 5/16–18 locknuts that attach the track assemblies to the top of the seat support. Remove the track assemblies.
6. With the holes in the belt bar, belt bar spacers, and seat track stop aligned with the holes in the seat support, install the new track assemblies on the seat support. Install and tighten the four 5/16–18 locknuts 15 lbf·ft (20 N·m).
7. Move the upper half of the track assemblies as needed to align their studs with the holes in the isolator assembly. Place the upper seat assembly on the track assemblies. Install and tighten the four 5/16–18 locknuts 15 lbf·ft (20 N·m).
8. Install the air spring supply hose.
   - 8.1 Install a new tie strap to attach the air spring supply hose to the track assembly latch mechanism.
   - 8.2 Install a new tie strap to attach the air valve supply hose to the belt bar.
9. Move the fore-and-aft adjustment lever to the right, and slide the upper seat assembly forward and rearward while making sure that the air hose moves without restriction. Return the seat cushion to its original position.
10. Raise the seat. Remove the wooden block.



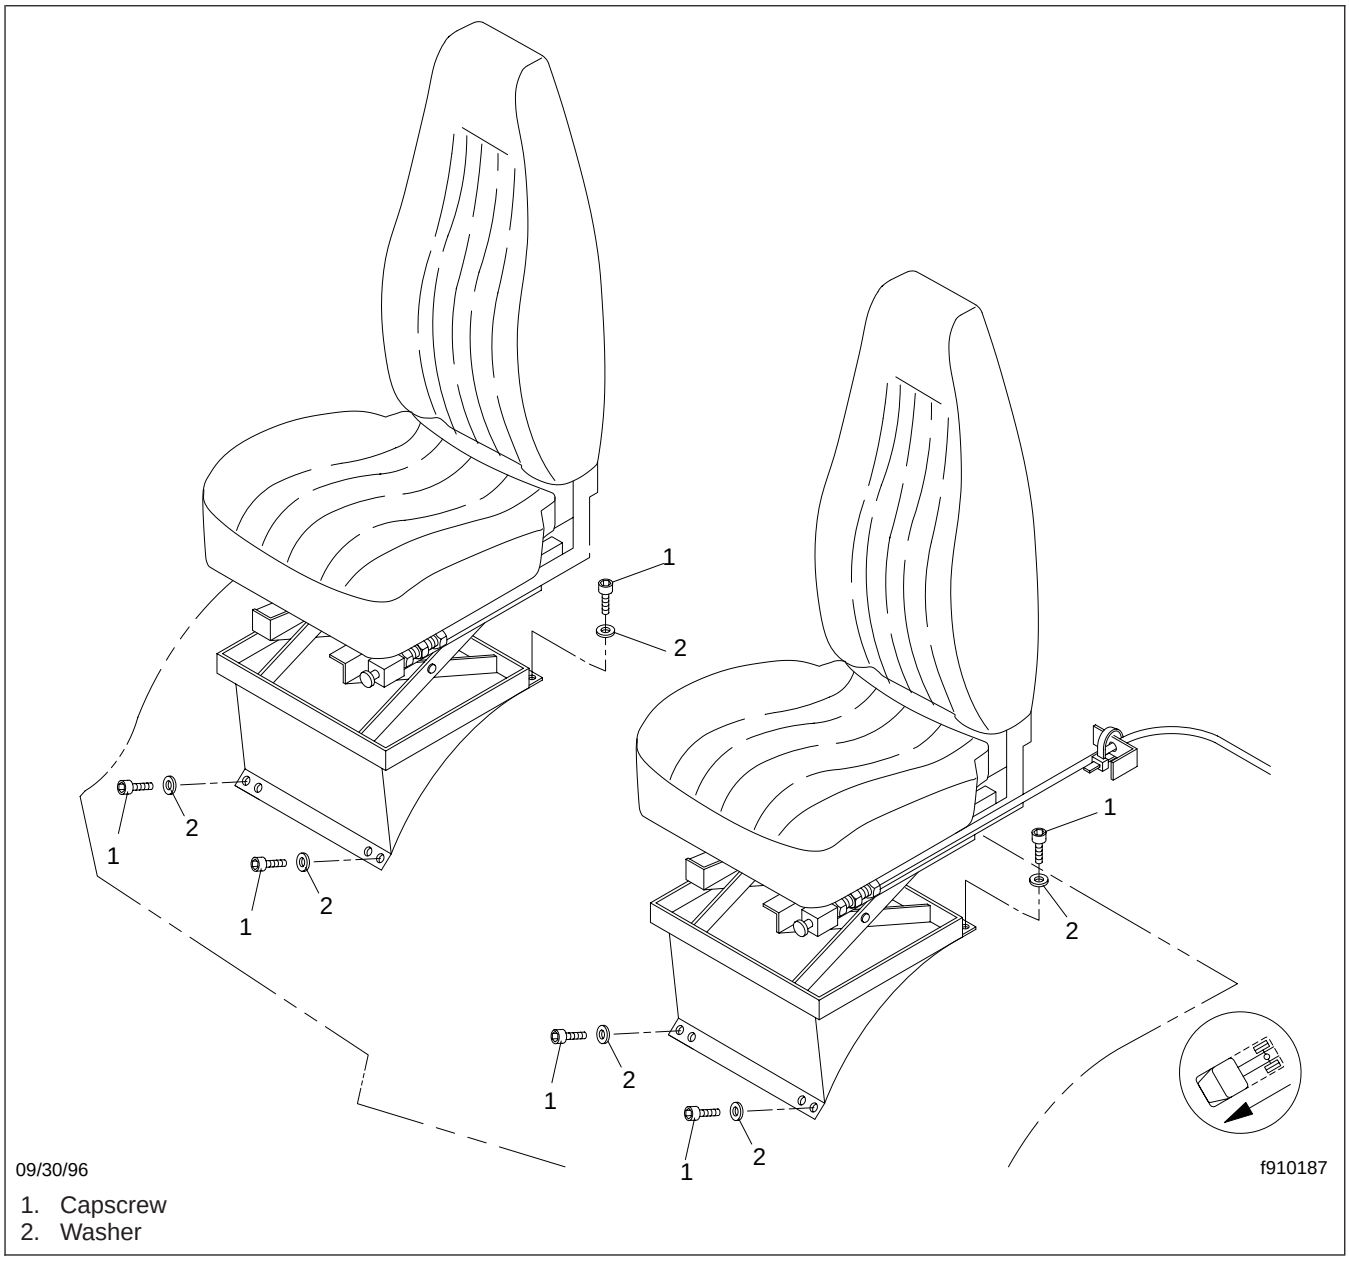
Specifications

Description	Torque: lbf·ft (N·m)
Seat Base to Cab Deck Socket-Head Bolts	13 (18)
Seat Belt/Tether Belt to Belt Bar Capscrews	40 (54)
Shock Absorber to Bracket Locknuts	25 (34)
Track Assembly to Isolator Assembly Locknuts	15 (20)
Track Assembly to Upper Seat Frame Locknuts	15 (20)

Table 1, Fastener Torques

General Information

The Bostrom 910 air suspension seats offer lumbar support, back angle adjustment, weight and height adjustment, a fore and aft roller track isolator system, and seat cushion tilt adjustment. See **Fig. 1**.



1. Lumbar Adjustment
2. Back Angle Adjustment
3. Weight and Height Adjustment
4. Fore and Aft Isolation and Seat Position Adjustment
5. Seat Cushion Tilt Adjustment

Fig. 1, Bostrom 910 Seat

For complete operating instructions, refer to the vehicle driver's manual.

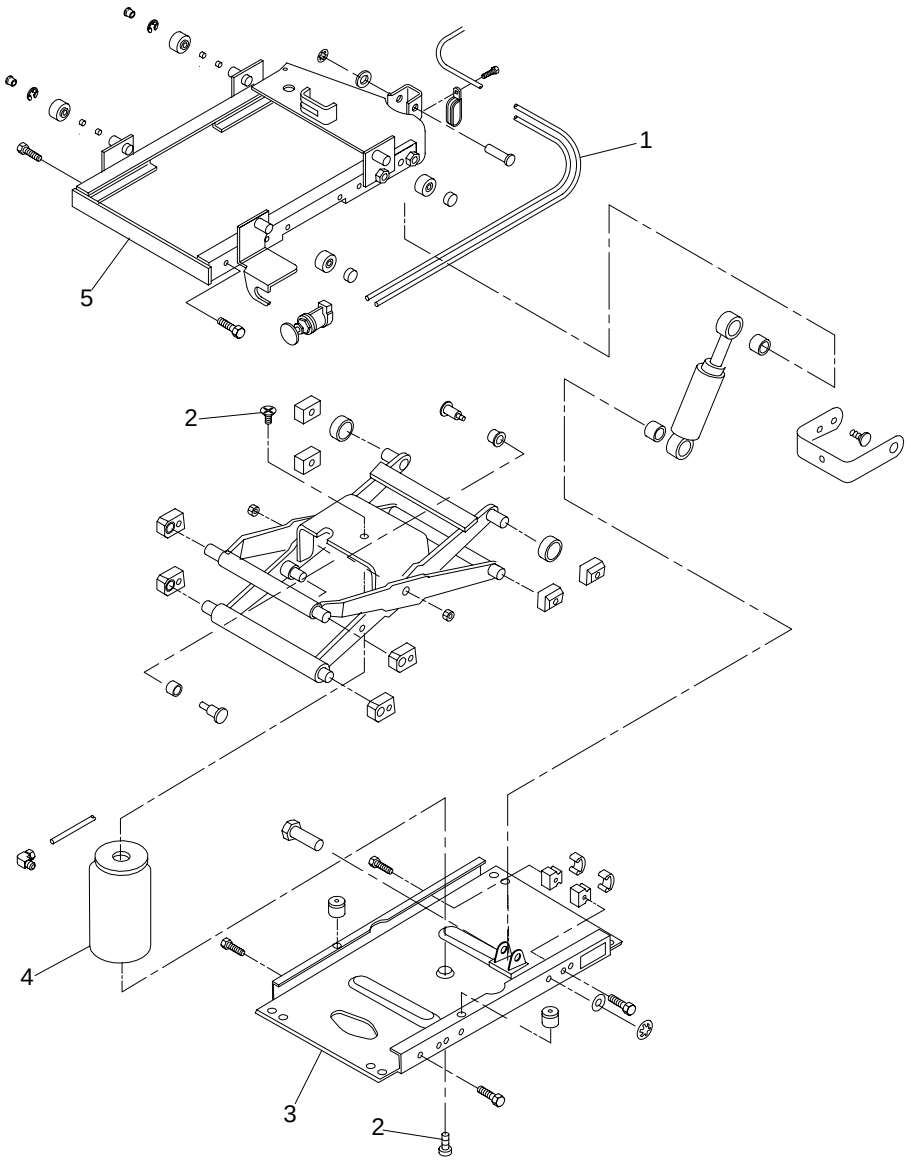
Removal (See Fig. 1)

1. Capscrew
2. Washer

Fig. 1, Seat Installation

1. Apply the parking brakes, and chock the tires.
2. Push in on the seat height adjustment valve knob until the seat is adjusted to its maximum height.
3. Cut a wooden block to the length required to support the seat at its maximum height, and

Seat Removal and Installation



place the block between the rear crossbars of the air suspension's inner and outer lever assemblies.

4. Drain the vehicle air reservoirs. Then pull out on the seat height adjustment valve knob until all air is exhausted from the air spring.
5. Disconnect the air line from the air spring assembly by pushing in the collar of the fitting while pulling the air line out of the fitting.
6. Remove the seat belt straps and tether straps.
7. Remove the capscrews and washers that attach the seat to the cab deck. Remove the seat from the cab.

Installation

1. Place the seat on the cab deck. Insert the capscrews through the washers and the seat base. Tighten the capscrews 27 lbf·ft (37 N·m).
2. Attach the brackets of the seat-belt straps and tether straps. Tighten the capscrews 40 lbf·ft (54 N·m).
3. Connect the air line to the fitting in the air spring assembly by pushing the tube into the fitting.
4. Start the engine and allow the air reservoirs to fill. Push in on the seat height adjustment valve knob until the seat is adjusted to its maximum height, then remove the wooden block that supports the seat suspension.
5. Remove the chocks from the tires.

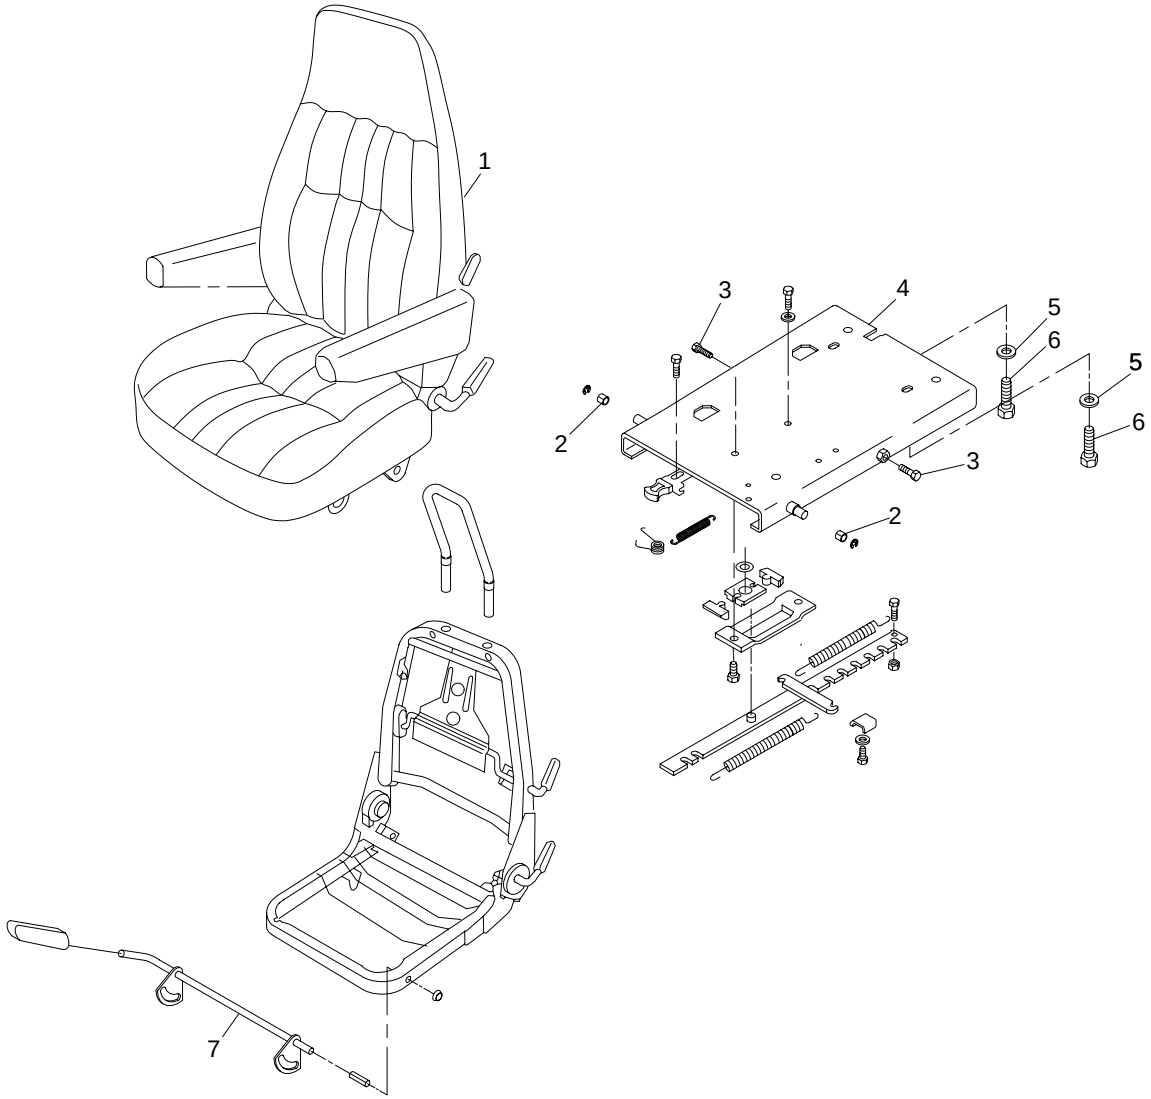
Removal (See Fig. 1)

1. Air Line
2. Screw
3. Base Riser
4. Air Spring
5. Upper Frame

Fig. 1, Bostrom 910 Seat

1. Remove the complete seat assembly from the vehicle using the instructions in **Subject 100**.
2. Remove the seat/back assembly using the instructions in **Subject 120**.
3. Remove the channel assembly using the instructions in **Subject 130**. Be careful not to lose the roller parts; they will be needed for reassembly.
4. Remove the ICP bracket.

Air Spring Removal and Installation



5. Disconnect the air line from the air spring fitting.
6. Remove the air spring screws from the air spring. Remove the air spring from the suspension.

Installation (See Fig. 1)

1. Position the air spring so the fitting at the bottom of the air spring is on the right hand side facing rearward. Install the screws into the air spring.
2. Tighten the screws 15 to 19 lbf·ft (20 to 26 N·m).
3. Connect the air line to the fitting on the air spring.
4. Attach the ICP bracket.
5. Install the channel assembly using the instructions in **Subject 130**.
6. Install the seat/back assembly using the instructions in **Subject 120**.
7. Install the seat assembly in the vehicle using the instructions in **Subject 100**.

Seat/Back Assembly Removal and Installation

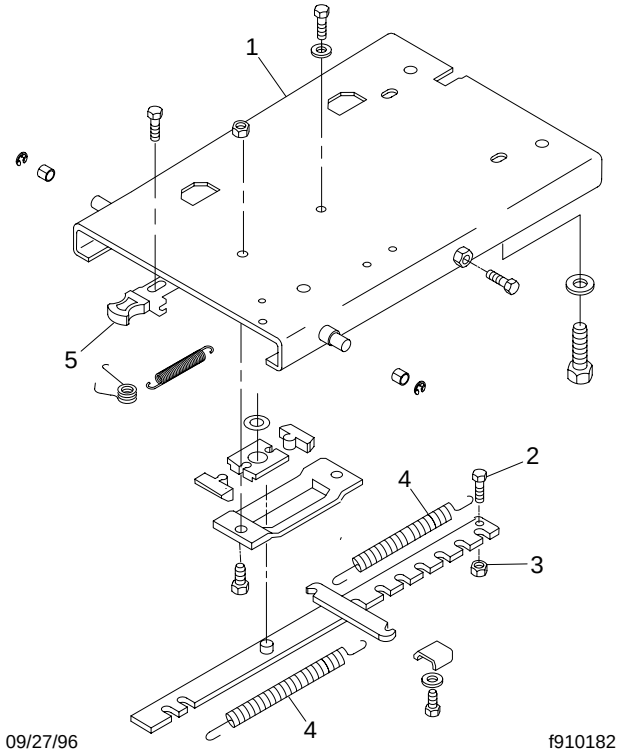
Removal (See Fig. 1)

1. Seat/Back Assembly
2. Sleeve Bearing
3. Shoulder Bolt
4. Channel Assembly
5. Flatwasher
6. Capscrew
7. Seat Tilt Cam Assembly

Fig. 1, Bostrom 910 Seat

1. Adjust the seat/back assembly to the most rearward position, then remove the two capscrews and flatwashers from the underside of the channel assembly.
2. Remove the two shoulder bolts from the channel assembly.

Seat/Back Assembly Removal and Installation



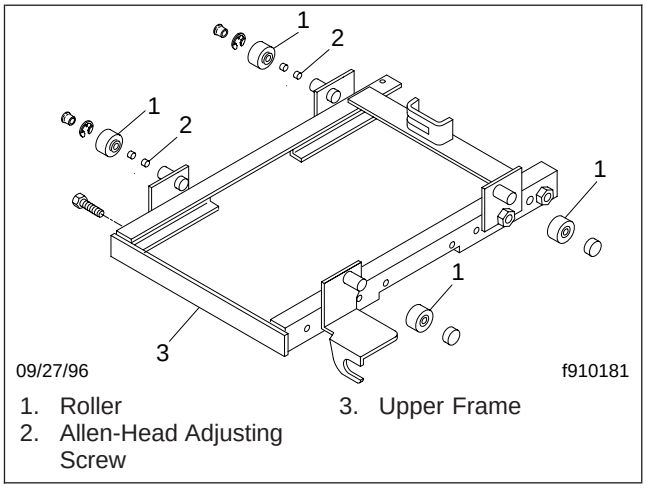
3. Move the seat/back assembly forward to disengage the seat tilt cam assembly from the sleeve bearings on the channel assembly.
4. Remove the seat/back assembly.

Installation (See Fig. 1)

1. Place the seat/back assembly onto the channel assembly.
2. Move the seat/back assembly rearward to engage the seat tilt cam assembly to the sleeve bearings on the channel assembly.
3. Install the two shoulder bolts to the channel assembly. Tighten them 18 to 22 lbf·ft (24 to 30 N·m).
4. Install the two capscrews and flatwashers to the underside of the channel assembly. Tighten them 10 to 13 lbf·ft (14 to 18 N·m).

Fore and Aft Isolation Channel Removal and Installation

Removal (See Fig. 1)

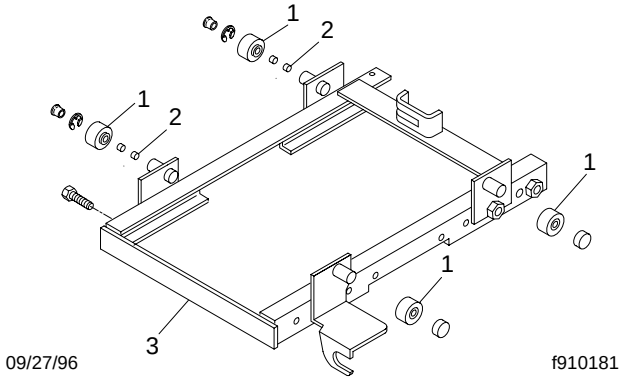


1. Channel Assembly
2. Screw
3. Nut
4. Isolator Spring
5. Isolator Handle

Fig. 1, Channel Assembly (exploded)

1. Remove the seat/back assembly using the instructions in **Subject 120**.
2. Adjust the channel assembly to the rearmost position.
3. With the isolator handle on the channel assembly in the isolation position (center position), push the channel assembly forward to expose the screw and the nut. Remove the screw and the nut and save for reassembly.
4. Move the isolator handle on the channel assembly to the fore and aft release position (outboard position). Slide the channel assembly forward past both sets of rollers. See **Fig. 2**.

NOTE: Be careful not to lose the roller parts. Either remove and save for reassembly or replace with new parts from a roller assembly kit.



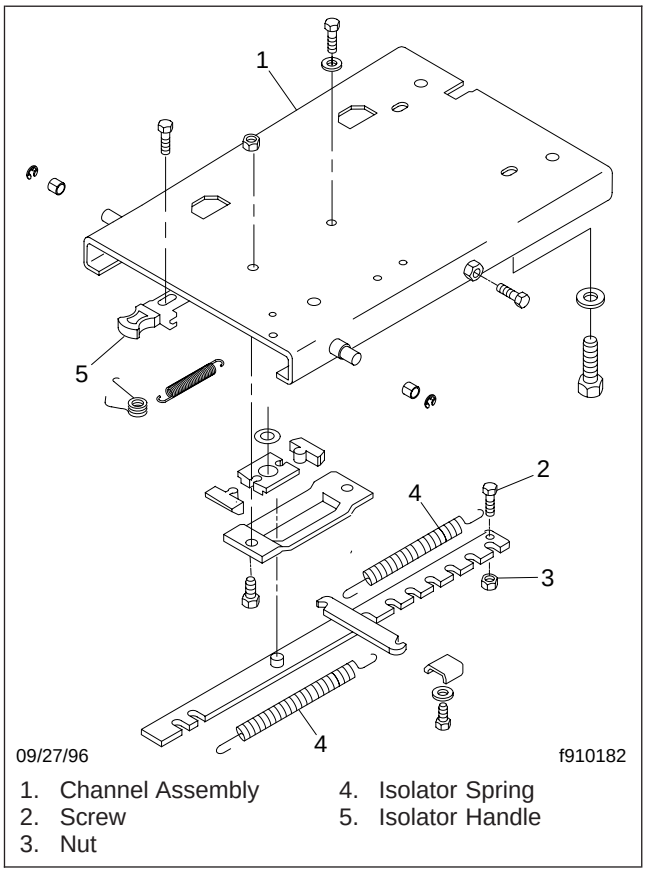
1. Roller
2. Allen-Head Adjusting Screw
3. Upper Frame

Fig. 2, Upper Frame Assembly (exploded)

Installation (See Fig. 1)

1. Slide the channel assembly rearward over both sets of rollers. The isolator handle should be in the fore and aft release position (outboard position).
2. With the isolator handle in the isolation position (center position), push the channel assembly forward to install the screw and nut.
3. Adjust lateral side play using the instructions in **Subject 140**.
4. Install the seat/back assembly using the instructions in **Subject 120**.

Adjustment (See Fig. 1)

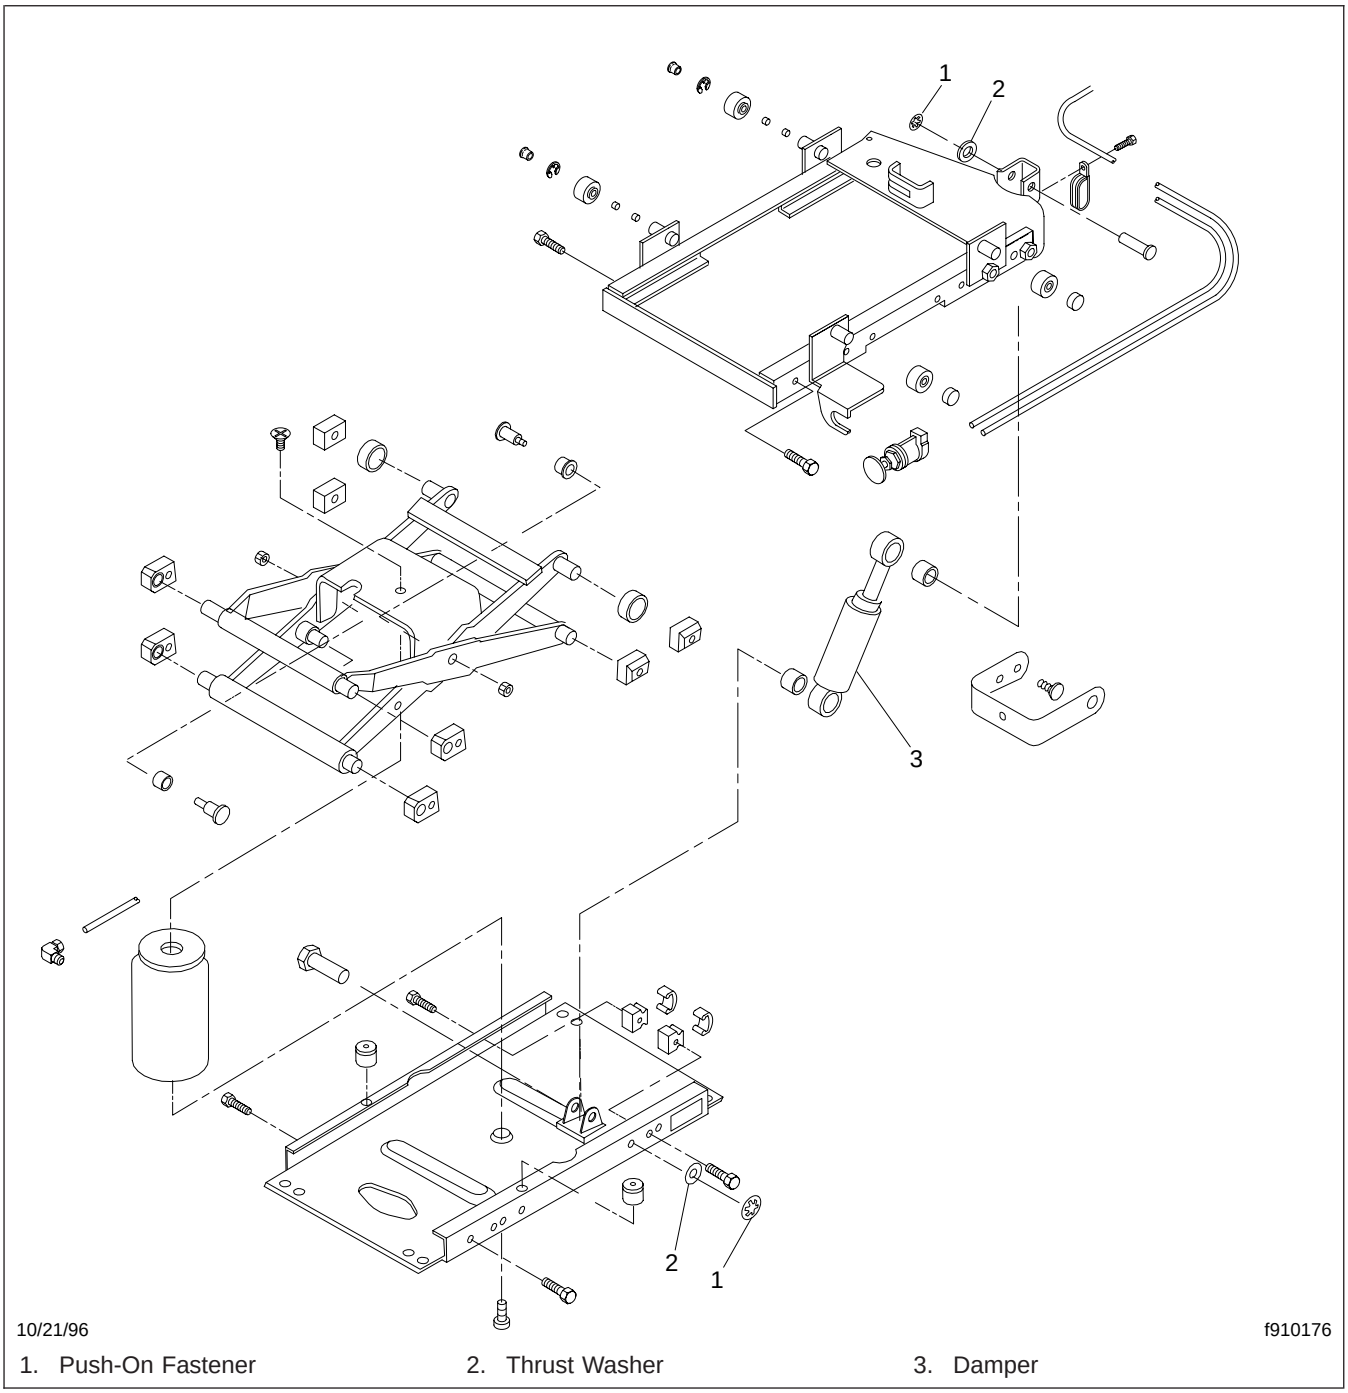


1. Roller
2. Allen-Head Adjusting Screw
3. Upper Frame

Fig. 1, Upper Frame Assembly (exploded)

1. Remove the seat/back assembly from the channel assembly, using the instructions in **Subject 120**.
2. Adjust the channel assembly until the allen-head adjusting screws in the right isolator roller shafts on the upper frame are visible in the cutouts on the inboard side of the channel assembly.
3. Use a 3 mm allen wrench (do not use a 1/8-inch allen wrench) to adjust the two allen-head screws. Turn the screws in until resistance is felt, then turn the screws 1-1/2 turns more.
4. Move the channel assembly through the entire fore and aft adjustment range to check the lateral clearance for binding. The isolator springs (see **Fig. 2**) should return the channel to the neutral position for the best ride. Friction must not exceed 10.1 lbs. (45 N) to move the channel assembly.

NOTE: To ensure the best performance, make certain the roller parts are assembled correctly.



5. Replace the seat/back assembly on the channel assembly using the instructions in **Subject 120**.

1. Channel Assembly
2. Screw
3. Nut
4. Isolator Spring
5. Isolator Handle

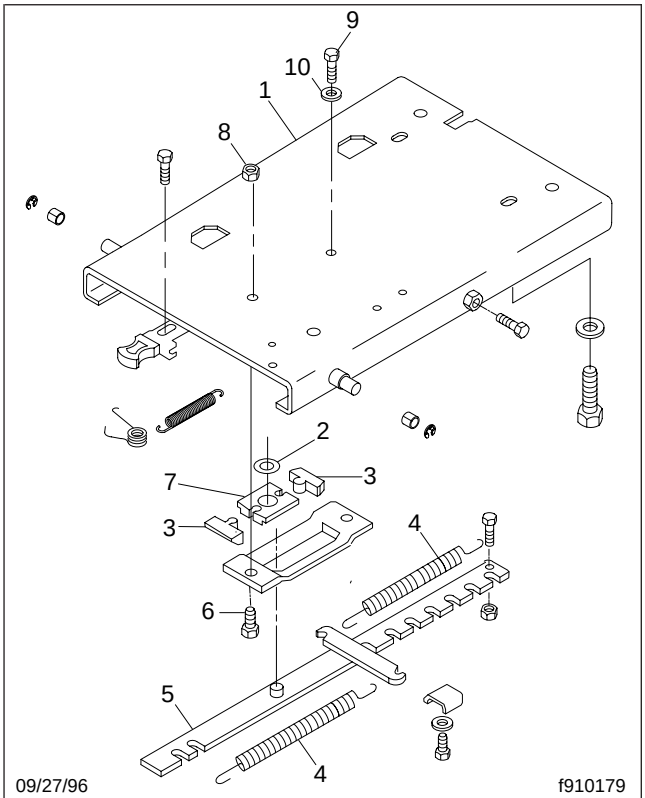
Fig. 2, Channel Assembly (exploded)

Removal (See Fig. 1)

1. Push-On Fastener
2. Thrust Washer
3. Damper

Fig. 1, Bostrom 910 Seat

Damper Removal and Installation



1. Remove the complete seat assembly from the vehicle using the instructions in **Subject 100**.
2. Remove the seat/back assembly using the instructions in **Subject 120**.
3. Remove the channel assembly using the instructions in **Subject 130**. Be careful not to lose the roller parts; they will be needed for reassembly.
4. Remove the ICP bracket.
5. Use pliers or a screwdriver to twist off the push-on fasteners. The push-on fasteners are not reusable.
6. Remove the damper assembly.

Installation **(See Fig. 1)**

1. Install the new damper.
2. Install the thrust washers and the push-on fasteners until they seat. A 1/2-inch box end wrench works well to push the fasteners on.
3. Attach the ICP bracket.
4. Install the channel assembly using the instructions in **Subject 130**.
5. Install the seat/back assembly using the instructions in **Subject 120**.
6. Install the seat assembly in the vehicle using the instructions in **Subject 100**.

Isolation Bumper Removal and Installation

Removal (See Fig. 1)

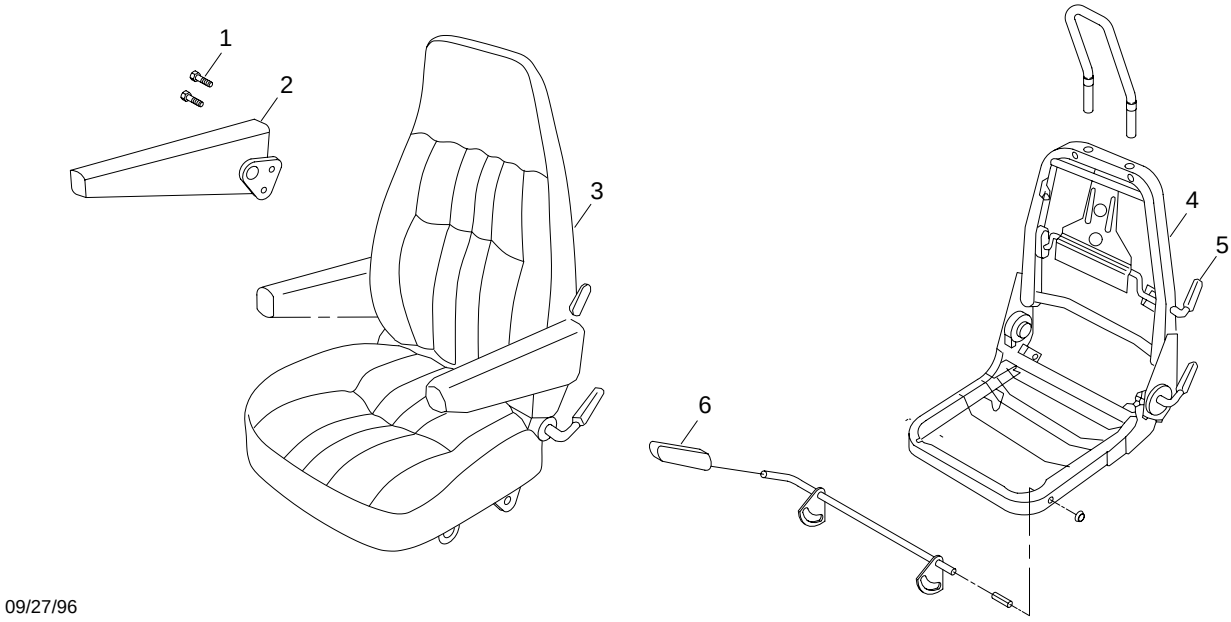
1. Channel Assembly
2. Retaining Ring
3. Isolation Bumper
4. Isolator Spring
5. Latch Bar
6. Screw
7. Pivot Block
8. Locknut
9. Screw
10. Lockwasher

Fig. 1, Channel and Isolation Bumper Assembly

1. Remove the seat/back assembly using the instructions in **Subject 120**.
2. Remove the channel assembly using the instructions in **Subject 130**.

   Be careful not to loose the roller parts; they will be needed for reassembly.
3. Remove the two isolator springs by carefully extending the springs and disconnecting them from the mounting points.
4. Slide the latch bar until the retaining ring can be seen through the hole in the channel assembly. Remove the retaining ring and keep it for reassembly.
5. Pull the latch bar free of the pivot block.
6. The rubber isolation bumpers are now accessible and can be replaced if necessary.

NOTE: The pivot block can be removed by first removing the screw and lockwasher, then remove the screw and locknut.



Installation (See Fig. 1)

1. If the pivot block was removed, install the pivot block. Tighten the bolt 14 to 18 lbf·ft (20 to 24 N·m).
2. Install the isolation bumpers.
3. Replace the latch bar on the pivot block.
4. Replace the retaining ring.
5. Replace the two isolator springs by carefully extending the springs and connecting them to the mounting points.
6. Install the channel assembly using the instructions in **Subject 130**.

   Be sure the roller parts are installed correctly on the roller pins.
7. Install the seat/back assembly using the instructions in **Subject 120**.

Back Cover/Pad Assembly Removal and Installation

Removal (See Fig. 1)

1. Armrest Fastener
2. Armrest
3. Upper Seat Assembly
4. Seat Frame Assembly
5. Lumbar Adjustment Handle
6. Seat Tilt Adjustment Handle

Fig. 1, Upper Seat Assembly

1. Remove the upper seat assembly from the suspension, using the instructions in **Subject 120**. Remove the armrests if the seat assembly has armrests.
2. Remove the back cover and pad from the seat frame assembly. Note the location of the fasteners on the existing back cover.

Installation (See Fig. 1)

1. Place a new pad over the back frame. If the seat has lumbar adjustment, make a cut in the outboard edge of the pad to fit around the handle.
2. Place the cover (inside out) over the top of the back pad. Pull down the cover until the three tie-down tabs are even with the three slots in the pad. Pull the tie-down tabs through the slots in the pad and run a short wire through all three tabs. Continue to pull the cover down completely over the pad. Tuck the front flap of the back cover between the seat cushion and the bottom of the back pad. Insert two long wires into the looped material sewn to the bottom of the cover. (One in the rear flap and one in the front flap.) Starting at the top, pull the cover down tight and hog ring the two wires at the bottom of the cover together behind the seat pad with the three tie-down tabs.

NOTE: If the seat has a high back, there will be two sets of tie-down tabs (six total with two wires) to be pulled through the back pad and wired.

3. Attach the upper seat assembly to the suspension using the instructions in **Subject 120**. Attach the armrests if the seat has armrests.

Suspension Rebuild Bearing/Slide Block Removal and Installation

Removal (See Fig. 1)

1. Remove the complete seat assembly from the vehicle using the instructions in **Subject 100**.
2. Remove the seat/back assembly using the instructions in **Subject 120**.
3. Remove the channel assembly using the instructions in **Subject 130**.

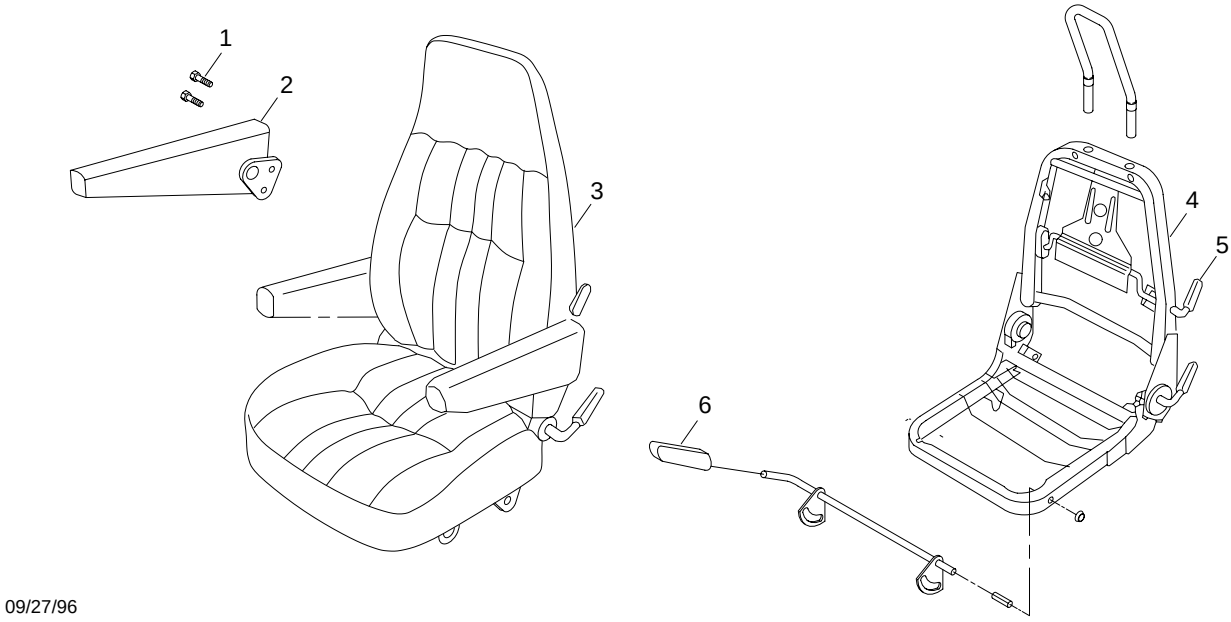
   Be careful not to loose the roller parts; they will be needed for reassembly.
4. Remove the capscrews and the ICP bracket.
5. Remove the air valve by loosening the nut on the valve and removing it from the bracket on the upper frame assembly.
6. Remove the capscrews from the upper front bearing blocks.
7. Remove the upper frame assembly by sliding it forward off of the bearing blocks and the slide blocks.
8. Remove the air spring using the instructions in **Subject 110**. Mark the air line for reassembly.
9. Remove the damper using the instructions in **Subject 150**.
10. Remove the capscrews from the lower front bearing blocks and slide the lever assemblies forward until the bearing blocks are removed from the channel on the base riser. Slide the lever assemblies rearward to remove the slide blocks from the channel.
11. Remove the shoulder bolts and nuts from the pivots of the lever assemblies and inspect the bolts. If the bolts are worn, replace them.

Installation (See Fig. 1)

1. Replace the bearings at the pivots on the lever assembly by pushing out the old bearings and pressing in the new bearings. The flange of the bearings should be on the outside of the lever assembly.
2. Install the shoulder bolts and nuts into the pivots of the lever assemblies. Tighten the bolts 18 to 22 lbf·ft (24 to 30 N·m).
3. Install new bearing blocks, spacers, and slide blocks on the levers with the beveled surfaces outward. Slide the levers with the blocks into the channel on the base riser. Tighten the screws 27 to 33 lbf·ft (37 to 45 N·m).
4. Slide the upper frame assembly over the blocks. Line up the capscrews with the bearing blocks and tighten the screws 27 to 33 lbf·ft (37 to 45 N·m).
5. Manually move the suspension up and down to make sure there are no clearance problems.
6. Block the suspension up with a spacer placed between the base riser and the upper frame. Install the air spring using the instructions in **Subject 110**.
7. Install the damper using the instructions in **Subject 150**.
8. Install the air valve onto the bracket on the upper frame.
9. Install the ICP bracket and capscrews.
10. Install the channel assembly using the instructions in **Subject 130**.

    Be sure the roller parts are installed correctly on the roller pins.
11. Install the seat/back assembly using the instructions in **Subject 120**.
12. Adjust lateral side play using the instructions in **Subject 140**.
13. Install the seat assembly in the vehicle, using the instructions in **Subject 100**.

Suspension Rebuild Bearing/Slide Block Removal and Installation



1. ICP Capscrew
2. ICP Bracket
3. Damper
4. Shoulder Bolt
5. Slide Block
6. Lever Assembly
7. Nut
8. Upper Bearing Block
9. Lower Bearing Block
10. Capscrew
11. Base Riser
12. Air Spring
13. Bearings
14. Screw
15. Air Valve
16. Upper Frame

Fig. 1, Bostrom 910 Seat (exploded)

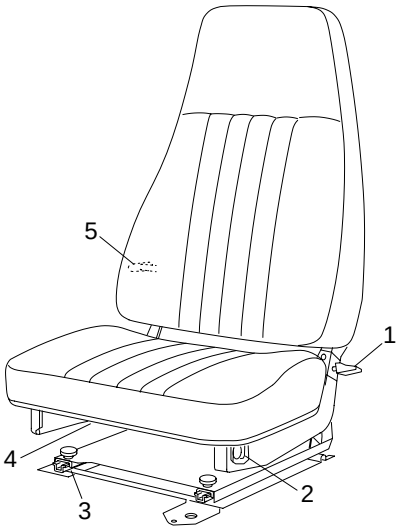
Seat Cover/Pad Assembly Removal and Installation

Removal (See Fig. 1)

1. Armrest Fastener
2. Armrest
3. Upper Seat Assembly
4. Seat Frame Assembly
5. Lumbar Adjustment Handle
6. Seat Tilt Adjustment Handle

Fig. 1, Upper Seat Assembly

1. Remove the upper seat assembly from the suspension using the instructions in **Subject 120**.
2. Remove the seat cover and pad from the seat frame assembly. Note the location of the fasteners on the existing seat cover. Do not remove the small vinyl patch from the seat tilt handle, unless it needs replacement.



Installation (See Fig. 1)

1. Place a new pad over the seat frame making sure the back edge of the pad is hooked over the rear support tube. If the seat is equipped with a seat tilt adjustment handle, make a cut in the bottom edge of the pad (right side) to fit around the handle.
2. Place the cover over the seat tilt handle and the top of the seat pad. Fold the rear half of the cover forward to expose the three tie-down tabs. Push the tie-down tabs through the holes in the foam. Reposition the cover and turn the seat over.
3. Pull the tie-down tabs tight and attach them to the center support wire (third wire from the rear). Use one hog ring per tab.
4. Insert the longest wire into the looped material sewn to the bottom of the cover. Place the shorter wire into the rear flap of the cover.
5. Pull the rear corners of the side panels rearward around the back corners of the frame. Attach the material with one hog ring per side.
6. Starting at the front of the seat cover and working rearward, hog ring the wire through the holes in the seat frame. Ten hog wires are required for the frame. Fold the rear flap down and toward the front of the seat. Pull the flap tightly and fasten it with three hog rings to the most rearward foam support wire.
7. Install the upper seat assembly onto the suspension, using the instructions in **Subject 120**.

General Information

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.

The Dura-Form air suspension seats offer lumbar support, back cushion tilt adjustment, height adjustment, a fore and aft isolator system, and seat cushion adjustment. See **Fig. 1**.

1. Back Cushion Tilt Adjustment
2. Height Adjustment
3. Isolator and Fore-Aft Adjustment
4. Seat Cushion Adjustment
5. Lumbar Support

Fig. 1, Dura-Form Seat

For complete operating instructions, see Chapter 2 of the *Business Class Trucks Driver's Manual*.

Removal

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.

1. Apply the parking brakes, and chock the tires.
2. Press the seat height adjustment rocker switch until the seat is adjusted to its maximum height.
3. If the seat is equipped with a seat suspension shroud, remove the shroud. It is held in place with Velcro and upholstery-panel fasteners.

   If the seat is equipped with a rubber bellows seat suspension cover, raise the rubber bellows.
4. Cut a wooden block to the length required to support the seat at its maximum height, and place the block between the air suspension lower base and the rear crosstube of the lower arm.
5. Drain the vehicle air reservoirs. Then, press the seat height adjustment rocker switch until all air is exhausted from the air spring.
6. Disconnect the air valve air-supply hose at the quick-connect union behind the seat.
7. Using an 11/16-inch wrench or a T50 Torx® wrench, unscrew the capscrews that attach the seat-belt straps and tether straps to the intermediate-connecting-point threaded rod.
8. Remove the capscrews and washers that attach the seat to the cab deck. Remove the seat and both mounting support channels from the cab.

Installation

1. Place the seat on the cab deck. Position a mounting support channel at the front edge, and another at the rear edge of the seat base. Insert the capscrews through the washers, the support channels, and the seat base. Tighten the capscrews 27 lbf·ft (37 N·m).
2. Attach the brackets of the seat-belt straps and tether straps to the intermediate-connecting-point threaded rod. Tighten the capscrews 40 lbf·ft (54 N·m).
3. Connect the air valve air-supply hose by pressing the pneumatic tubing into the quick-connect union behind the seat.
4. Start the engine and allow the air reservoirs to fill. Press the seat height adjustment rocker switch until the seat is adjusted to its maximum height. If the seat is equipped with a rubber bellows seat suspension cover, raise the rubber bellows. Remove the wooden block that supports the seat suspension.
5. If the seat is equipped with a seat suspension shroud, install the shroud.
6. Remove the chocks from the tires.

Air Spring Removal and Installation

Removal

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.

1. Apply the parking brakes, and chock the tires.
2. Press the seat height adjustment switch until the seat is adjusted to its maximum height.
3. Cut a wooden block to the length required to support the seat at its maximum height, and place the block between the lower housing and the upper housing.
4. Drain the vehicle air reservoirs. Then press the seat height adjustment switch until all the air is exhausted from the air spring.
5. Disconnect the 7/16-inch air fitting at the bottom of the air spring. Remove the 3/4-inch jam nut.
6. Remove the 1/2-inch hexhead bolt and lockwasher at the top of the air spring.
7. Compress the air spring and rotate it forward to lift it out.

Installation

1. Compress the air spring and install it by rotating it rearward.
2. Install the 1/2-inch hexhead bolt and lockwasher at the top of the air spring. Tighten 15 to 20 lbf·ft (20 to 27 N·m).
3. Apply pipe sealant to the threads of the elbow. Insert the tube into the fitting until the tube bottoms in the fitting, then tighten one wrench turn past finger tight. Tighten the pipe threads on the fitting 12 to 18 lbf·ft (16 to 24 N·m).
4. Connect the air fitting to the air spring with the 3/4-inch jam nut. Tighten 72 to 96 lbf·in (800 to 1100 N·cm).
5. Start the engine and allow the air reservoirs to fill. Press the seat height adjustment switch until the seat is adjusted to its maxium height, then remove the wooden block.
6. Remove the chocks from the tires.

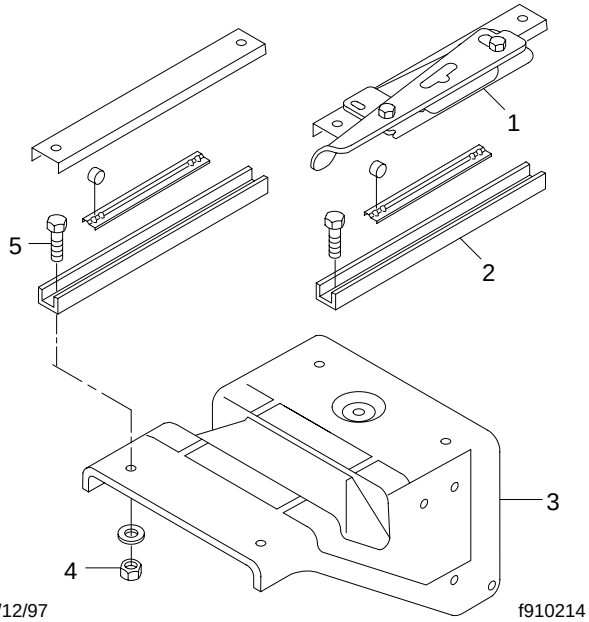
Shock Absorber Removal and Installation

Removal

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.

1. Apply the parking brakes, and chock the tires.
2. Press the seat height adjustment switch until the seat is adjusted to its maximum height.
3. Cut a wooden block to the length required to support the seat at its maximum height, and place the block between the lower housing and the upper housing.
4. Remove the 5/16-inch nut at the top of the shock absorber.
5. Remove the retaining ring and the shock pin at the bottom of the shock absorber.
6. Remove the shock absorber.

Installation



1. Install the shock absorber.
2. Install the 5/16-inch nut at the top of the shock absorber. Tighten 10 to 15 lbf·ft (14 to 20 N·m).

NOTE: The pin hole closest to the air spring is the firmer ride.

3. Install the shock pin and the retaining ring at the bottom of the shock absorber.
4. Remove the wooden block from the seat, and the chocks from the tires.

Isolator and Slides Removal and Installation

Removal (See Fig. 1)

1. Isolator Plate and Handle
2. Slide
3. Upper Housing
4. Nut
5. Screw

Fig. 1, Isolator and Slides Assembly

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.

1. Apply the parking brakes, and chock the tires.
2. Press the seat height adjustment switch until the seat is adjusted to its maximum height.
3. Cut a wooden block to the length required to support the seat at its maximum height, and place the block between the lower housing and the upper housing.
4. Remove the seat/back assembly using the instructions in **Subject 140**.
5. Using a 1/2-inch socket and a 1/2-inch wrench, remove the isolator assembly.

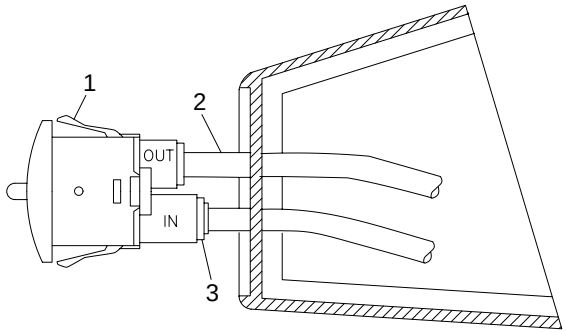
Installation (See Fig. 1)

1. Using a 1/2-inch socket or wrench and a screwdriver, install the isolator assembly.
2. Install the seat/back assembly using the instructions in **Subject 140**.
3. Remove the wooden block from the seat, and the chocks from the tires.

Seat/Back Assembly Removal and Installation

Removal

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.



1. Apply the parking brakes, and chock the tires.
2. Using a 1/2-inch socket and a 1/2-inch wrench, remove the four mounting bolts.
3. Remove the seat/back assembly.

Installation

1. Place the seat/back assembly onto the isolator assembly.
2. Using a 1/2-inch socket and a 1/2-inch wrench, install the four mounting bolts.
3. Remove the chocks from the tires.

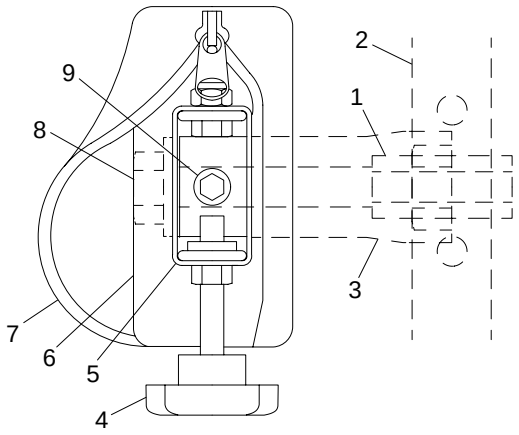
Air Valve Removal and Installation

Removal (See Fig. 1)

1. Retaining Fingers
2. Air Hose
3. Retaining Ring

Fig. 1, Air Valve Assembly

NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.



1. Apply the parking brakes, and chock the tires.
2. Drain the vehicle air reservoirs. Then press the seat height adjustment rocker switch until all air is exhausted from the air spring.
3. Reach behind and inside the air control panel and compress the two retaining fingers together on the air valve.
4. Remove the air valve by pushing it outward through the slot in the control panel.
5. Compress the gray retaining ring on the valve body inlet port toward the valve, and pull on the air hose to remove it from the valve.
6. Repeat the previous step for the outlet port.

Installation (See Fig. 1)

IMPORTANT: When installing the air lines, make sure they are connected to the same valve port they were removed from, and are firmly pressed into place. The new air line will insert approximately 1/2-inch when installed properly.

1. Install the air lines in the valve. Pull outward slightly on the new air lines to ensure a solid installation. Do not compress the air line retaining rings when verifying the installation.
2. Make sure the valve is properly oriented, and firmly press the complete valve back into the slot in the air control panel until you hear a "click." The "click" assures the valve retaining fingers are properly secured to the air control panel.
3. Start the engine and allow the air reservoirs to fill.
4. Remove the chocks from the tires.

Removal (See Fig. 1)

03/13/97 f910216

1. Coupling Nut (welded to seat frame assembly)
2. Seat Frame Assembly
3. Pivot Bar
4. Adjustment Knob
5. Armrest Tube
6. Armrest Foam
7. Armrest Cover
8. Armrest Bolt
9. Socket Head Screw

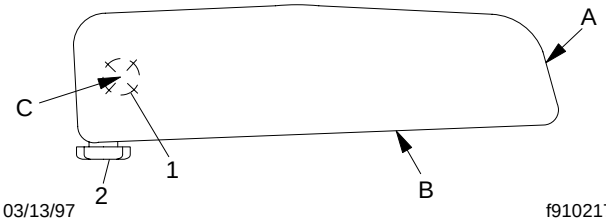


Fig. 1, Armrest, Rear View

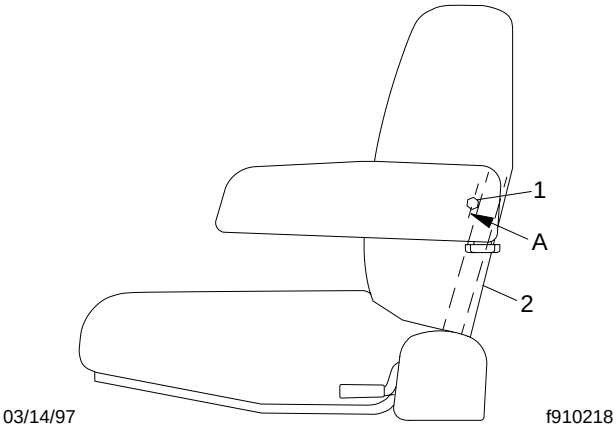
NOTE: Call Dura-Form Customer Service at 800–553–3013 to answer any questions concerning any Dura-Form seat style not covered by the information provided.

1. Apply the parking brakes, and chock the tires.
2. Unzip the armrest cover.
3. Remove the socket head screw from the pivot bar in the armrest.
4. Loosen the armrest bolt.
5. Remove the armrest.
6. Remove the pivot arm from the seat back.

Installation



1. Locate the hole in the side of the armrest foam and make an incision. See **Fig. 2**.
2. Locate the coupling nut (welded to the seat frame assembly). Make an incision in the seat back cover. See **Fig. 3**.

03/13/97 f910217

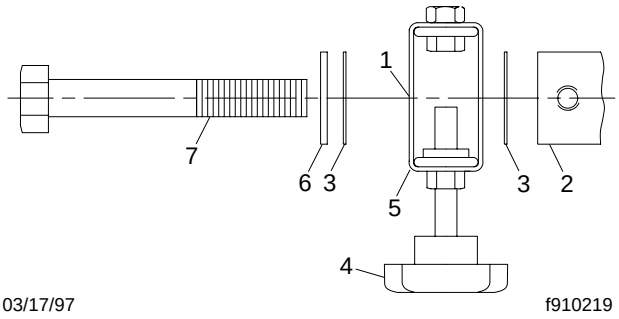
A. Front
B. Bottom
C. Place incision on this side for the left-hand armrest. Place on the opposite side for the right-hand armrest.
1. Hole
2. Adjustment Knob

Fig. 2, Armrest

03/14/97 f910218

A. Place incision on this side for the left-hand armrest. Place on the opposite side for the right-hand armrest.
1. Coupling Nut (welded to seat frame assembly)
2. Seat Back

Fig. 3, Coupling Nut Location



3. Insert the pivot bar through the incision in the seat back cover. Slide the pivot bar over the coupling nut with the hole for the socket head screw facing rearward. See **Fig. 1**.

NOTE: The seat back cover and foam will hold the pivot bar in place while the remainder of the armrest is prepared for assembly.

4. Unzip the armrest cover and assemble the armrest bolt, the metal washer, and the plastic washers through the hole in the side of the armrest tube. See **Fig. 4**. The armrest tube must be

Armrest Removal and Installation

clamped between the two plastic washers when assembly is complete.

1. Small Hole
2. Pivot Bar
3. Plastic Washer
4. Adjustment Knob
5. Armrest Tube
6. Metal Washer
7. Armrest Bolt

Fig. 4, Armrest Assembly

5. Slide the assembled armrest over the pivot bar. Tighten the armrest bolt 22 to 23 lbf·ft (29 to 31 N·m). See **Fig. 1**.

IMPORTANT: The pivot bar must be seated against the seat frame while the armrest bolt is tightened.

6. Install the socket head screw into the pivot bar. See **Fig. 1**. Tighten 10 to 16 lbf·ft (13 to 21 N·m).
7. Zip up the armrest cover.
8. Remove the chocks from the tires.

Specifications

Fastener Torques		
Description	**Size**	**Torque**
Seat Base Hexhead Capscrews	3/8–16	27 lbf·ft (37 N·m)
Intermediate-Connecting-Point Rod Capscrews	11/16	40 lbf·ft (54 N·m)
Air Spring Hexhead Bolt	1/2	15–20 lbf·ft (20–27 N·m)
Air Spring Fitting Pipe Threads	—	12–18 lbf·ft (16–24 N·m)
Air Fitting to Air Spring Jam Nut	3/4	72–96 lbf·in (800–1100 N·cm)
Shock Absorber Nut	5/16	10–15 lbf·ft (14–20 N·m)
Armrest Bolt	—	22–23 lbf·ft (29–31 N·m)
Socket Head Screw	—	10–16 lbf·ft (13–21 N·m)

Table 1, Fastener Torques

General Information

Freightliner Corporation currently applies DuPont® single-stage Imron® 5000 or two-stage (base coat and clear coat) Imron 6000 high-solids polyurethane enamel on the vehicle cab at the factory.

Black Standard Urethane or Imron 5000 is used on the vehicle chassis. The chassis includes the frame, spoke spider, running gear, and any components attached to the frame. Aluminum fuel tanks are not painted.

To meet the federal air quality regulations imposed by the EPA and local jurisdictions, these products contain lower levels of volatile organic compounds (VOCs) than earlier types (916Y, Centari®, and Imron), and are formulated free of lead and chrome.

The procedures in this section are for use with DuPont products. Unless otherwise noted, all products are manufactured by E. I. du Pont de Nemours and Company, Inc. Obtain approval from a Freightliner Regional Office for use of topcoats produced by other manufacturers.

Color-Matching

The recommended aftermarket paints for color-matching factory-applied paint are as follows:

- Cab—use Imron 5000 or Imron 6000
- Chassis—use only Imron 5000

To ensure proper gloss, durability, and color-matching of the enamel, use only Imron 5000 on panels that were previously painted with Imron 5000, and use only Imron 6000 on panels painted with Imron 6000.

To determine the correct paint number for color-matching any original finish on a vehicle, refer to the paint specification on the vehicle specification decal. Refer to the vehicle driver's manual for the location of this decal.

NOTE: The high-solids Standard Urethane applied to the chassis at the factory is sold to original equipment manufacturers (OEMs) only, and is not available for aftermarket sale. Use Imron 5000, N0001 Black, for repainting.

General Guidelines

This section provides instructions for preparing large panels or the entire cab for topcoating with DuPont® products. For spot repairs or touch-ups, see **Subject 120**.

Before topcoating, the surface must be thoroughly cleaned and sanded. Any bare areas must also be conditioned and primed.

1. Preparation materials specified for one type of surface should not be used for any other type of surface.
2. Limit intermediate coatings, such as primers, to the brand and type specified by the finish-coat manufacturer.

⚠ CAUTION

Only experienced, qualified persons using proper equipment should attempt repainting or touch-up painting. Incorrect application of chemicals or paint could damage the surface or impair the finish.

Preparation for Prime Coat

Use the cleaners and conditioners specified in each step to prepare the surface for priming. See **Specifications, 400** for a summary of the products used in this procedure.

⚠ WARNING

Do not use solvent-based cleaners on large areas of plastic or fiberglass, such as the hood. Wiping down these large areas may cause a buildup of static electricity. The resulting spark could cause a flash fire, which could result in personal injury or property damage.

1. Wash and dry the entire vehicle with a mild detergent.

⚠ WARNING

Solvents are flammable. Keep them away from heat, sparks, and open flame. Keep the container closed. Use only with adequate ventilation. Avoid breathing the vapor, or headache, nausea, and impaired reaction time and coordination may result.

2. Wipe all surfaces to be painted with a clean cloth soaked with solvent or cleaner. Remove all traces of wax, polish, grease, and silicones.
   - Metal—use DuPont Prep-Sol 3919 S.
   - Plastic—use DuPont Plastic Prep 2319 S.
   - Fiberglass—use DuPont Prep-N-Solv.

   2.1 Work on small areas at a time, wetting the surface liberally.

   2.2 Quickly wipe the surface with a clean cloth before the solvent or cleaner has a chance to dry. Change cloths frequently.
3. Feather the edge of all repaired areas, chipped surfaces, and scratches.

   3.1 Cut down the edges of broken spots with no. 220 sandpaper.

   3.2 Feather the edges by hand, using a sanding block with no. 400 sandpaper.
4. Sand the entire area to be painted. Using a sanding block and no. 400 sandpaper, remove the gloss to improve adhesion of the primer.
5. Using a clean cloth soaked with cleaner, remove any sanding dust.
   - Metal or plastic—use DuPont 3939 S lacquer and enamel cleaner.
   - Fiberglass—use a solution of one part water and one part isopropyl alcohol (IPA).
6. Treat bare metal and rusted areas.
   - Steel—use DuPont 5717 S metal conditioner.
   - Aluminum—use DuPont 225 S aluminum cleaner.

   6.1 Mix one part of the cleaner with two parts of water in a plastic bucket.

   6.2 Apply the cleaner with a cloth or sponge. If corrosion is present, work the surface with a stiff plastic brush or 3M Scotch-Brite® pad. Do not use any pads containing iron.

   6.3 While the metal is still wet, wipe thoroughly with a clean, dry cloth. Allow the

Preparing for Topcoating

surface to dry before applying a conversion coating.

7. Apply a conversion coating to all bare metal.
   - Steel—use DuPont 5718 S metal conversion coating.
   - Zinc casings or galvanized surfaces (iron or steel)—use DuPont 5718 S metal conversion coating.
   - Aluminum—use DuPont 226 S aluminum conversion coating.

   7.1 Pour the conversion coating into a plastic container (do not dilute). Using a 3M Scotch-Brite or similar non-iron abrasive pad, apply the conversion coating to the metal surface. Work only as much area as can be coated and rinsed before the solution dries.

   7.2 Leave the coating on the surface for 2 to 5 minutes. Then, rinse off the solution with cold water, or mop with a sponge or cloth rinsed frequently in clean water.

   If the metal surface dries before rinsing, reapply the conversion coating, then repeat the previous substep.

   7.3 Wipe the surface dry with a clean cloth, or air dry.

8. With paper and tape, mask all areas that are not to be painted.

Prime Coat

Prime all bare and feathered areas before topcoating. The specified primers can be used on any surface.

1. Clean all cracks and surfaces with dry compressed air.
2. Using a tack cloth, wipe all surfaces to be painted.

⚠ WARNING

Wear a positive-pressure, supplied-air, vapor and particulate respirator, approved by NIOSH or MSHA (TC-19C) when mixing or spraying primer, and until the work area has been exhausted of all vapor and spray mist. Breathing paint fumes can cause serious personal injury.

3. Prime all bare metal and feathered areas with DuPont primer.
   - Steel and aluminum—use Corlar 824 S epoxy primer.
   - Fiberglass—use Corlar 825 S epoxy primer.

   3.1 Stir the primer thoroughly.

   3.2 Mix two parts Corlar epoxy primer with one part DuPont 826 S activator.

   3.3 Reduce three parts of this mixture with one part DuPont 3602 S lacquer thinner (viscosity reading is 18 to 22 seconds in a no. 2 Zahn cup). Stir thoroughly.

   3.4 Wait 1 to 2 hours from time of mixing before using. This provides time for complete chemical induction.

   3.5 Set the air pressure at the spray gun at 45 psi (310 kPa). For pressure feed systems, set the fluid delivery at 12 to 16 ounces (350 to 470 mL) per minute.

   3.6 Hold the spray gun about 10 to 12 inches (25 to 30 cm) from the surface.

   3.7 Spray one full wet coat to give a dry film thickness of 0.7 to 1.0 mil (18 to 25 µm).

   3.8 Clean the equipment immediately after use with DuPont 3602 S lacquer thinner.

   3.9 Air dry 2 hours or force dry 20 minutes.

4. Wet sand the primer with no. 400 grit or finer sandpaper. Feather the edge into the surrounding area.
5. Dry the surface. Using a clean cloth soaked with cleaner, remove any sanding dust.
   - Metal or plastic—use DuPont 3939 S lacquer and enamel cleaner.
   - Fiberglass—use solution of 1 part water and 1 part isopropyl alcohol (IPA).

NOTE: See **Subject 110** for topcoating instructions.

General Guidelines

This section provides instructions for applying a topcoat of DuPont® enamel to full panels or the entire cab. For spot repairs or touch-ups, see **Subject 120**.

⚠ CAUTION

Only experienced, qualified persons using proper equipment should attempt repainting or touch-up painting. Incorrect application of chemicals or paint could damage the surface or impair the finish.

Do not mix additives with the finish coats unless they are specified by the finish-coat manufacturer. See **Specifications, 400** for a summary of the products used in this procedure.

Before applying any topcoat:

1. Prepare the surface for topcoating. See **Subject 100** for instructions.
2. Clean all cracks and surfaces with dry compressed air.
3. Using a tack cloth, wipe all surfaces to be painted.

After topcoating, remove the masking as follows:

- After normal air drying—remove all masking when the surface is reasonably dry.
- After forced drying—remove the masking immediately after the finish has been baked.
- After two-toning—remove the masking used for the first coat as soon as it has set up, usually in about 35 to 40 minutes. Follow the same procedure for the second color.

Imron 5000 Topcoating

Imron 5000 is a single-stage, low VOC, high-solids polyurethane enamel. It provides a durable, high-gloss surface with good chemical resistance. It requires the addition of an activator.

⚠ WARNING

Wear a positive-pressure, supplied-air, vapor and particulate respirator approved by NIOSH or MSHA (TC-19C), while spraying Imron 5000, and until the work area has been exhausted of all vapor and spray mist. Breathing paint vapor or spray mist can cause personal injury.

MIXING

1. Stir the Imron 5000 enamel thoroughly.
2. Mix three parts Imron 5000 enamel with one part of DuPont 193 S or 194 S activator. No further reduction is necessary for application.

NOTE: The pot life of the mixture is about 2 to 4 hours at 70°F (21°C), unless an accelerator is added.

3. If faster curing time is desired, add DuPont 389 S fast-dry accelerator. Add up to 2 ounces (60 mL) to 1 gallon (3.8 L) of mixed material.
4. Mix thoroughly and strain.

NOTE: The viscosity of the mixture is about 9 to 20 seconds in a no. 3 Zahn cup, depending on the color. Adding reducer could affect the color match on some metallics.

APPLICATION

1. Set the air pressure at the spray gun to 60 to 65 psi (410 to 450 kPa). For pressure feed systems, set the fluid delivery at 12 to 16 ounces (350 to 470 mL) per minute.
2. Apply the topcoating.
   - 2.1 Hold the spray gun about 10 to 12 inches (25 to 30 cm) from the surface.
   - 2.2 Using a cross-coat technique, spray one medium-wet coat in a north-to-south direction
   - 2.3 Allow 5 to 10 minutes drying time between each application. Do not sand.
   - 2.4 Apply a second medium-wet coat in an east-to-west direction.
   - 2.5 A third medium-wet coat may be needed for good coverage of some colors.
3. To air dry, allow 2 to 4 hours with accelerator 389 S, and 6 to 8 hours without the accelerator.

   To force dry, wait 15 minutes following the application of the final coat, then dry for 30 minutes at 140 to 180°F (60 to 82°C).

4. To prevent tape marking, remove all masking tape and paper immediately after the final coat is applied. Avoid contacting the freshly painted surface with masking paper.
5. Clean the equipment immediately after use with DuPont 3602 S lacquer thinner or 8685 S reducer.

RECOATING OR DECORATING

Two-toning, striping, or lettering may be applied in 4 to 6 hours if DuPont 389 S accelerator is used. Wait 10 to 12 hours if no accelerator is used.

Decals may be applied in 12 to 16 hours if 389 S accelerator is used. Wait 24 hours if no accelerator is used.

For topcoats cured over 72 hours, scuff-sand with no. 400 grit sandpaper and wipe with a clean tack cloth before recoating, striping, lettering, or applying decals.

Imron 6000 Topcoating

Imron 6000 is a two-stage, high-solids polyurethane enamel. It provides good cover with one cross-coat of the base color followed by one coat of Imron 6000 clear coat. Both the base color and clear coat require the addition of an activator.

⚠ WARNING

Wear a positive-pressure, supplied-air, vapor and particulate respirator approved by NIOSH or MSHA (TC-19C), while spraying Imron 6000, and until the work area has been exhausted of all vapor and spray mist. Breathing paint vapor or spray mist can cause personal injury.

MIXING

1. Stir the Imron 6000 base color thoroughly.
2. Mix three parts Imron 6000 base color with one part DuPont 193 S or 194 S activator. No further reduction is necessary for application.

NOTE: The pot life of the mixture is about 2 to 4 hours at 70°F (21°C), unless an accelerator is added.

3. If faster curing time is desired, add DuPont 389 S fast-dry accelerator. Add up to 2 ounces (60 mL) to 1 gallon (3.8 L) of mixed material.
4. Mix thoroughly and strain.

NOTE: For solids, the viscosity of the mixture is about 20 seconds in a DuPont M-222 (M-50) cup; for metallics, it is about 18 seconds.

APPLICATION

1. Set the air pressure at the spray gun to 60 to 65 psi (410 to 450 kPa). For pressure feed systems, set the fluid delivery at 12 to 16 ounces (350 to 470 mL) per minute.
2. Apply the topcoating.
   - 2.1 Hold the spray gun about 10 to 12 inches (25 to 30 cm) from the surface.
   - 2.2 Apply one cross-coat of the Imron 6000 base color.
   - 2.3 Flash 10 minutes minimum. Do not sand.
   - 2.4 Mix three parts DuPont 3440 S or 3480 S clear with one part DuPont 193 S or 194 S activator.
   - 2.5 Apply one coat of the activated DuPont 3440 S or 3480 S clear.
3. To air dry, allow 2 to 4 hours if DuPont 389 S accelerator is used, and 6 to 8 hours if no accelerator is used.

   To force dry, wait 15 minutes following the application of the clear coat, then dry for 30 minutes at 140 to 180°F (60 to 82°C).
4. To prevent tape marking, remove all masking tape and paper immediately after the final coat is applied. Avoid contacting the freshly painted surface with masking paper.
5. Clean the equipment immediately after use with DuPont 3602 S lacquer thinner or 8685 S reducer.

RECOATING OR DECORATING

Two-toning, striping, and lettering may be applied in 4 to 6 hours if DuPont 389 S accelerator is used. Wait 10 to 12 hours if no accelerator is used.

Decals may be applied in 12 to 16 hours if 389 S accelerator is used. Wait 24 hours if no accelerator is used.

For topcoats cured over 72 hours, scuff-sand with no. 400 grit sandpaper and wipe with a clean tack cloth before recoating, striping, lettering, or applying decals.

General Guidelines

This section provides instructions for making spot repairs or touch-ups with DuPont® enamels. Buffing may correct minor imperfections; more serious repairs require surface preparation before a topcoating can be applied. For striping, lettering, or decal application after the repair is complete, see **Subject 110**.

1. Preparation materials specified for one type of surface should not be used for any other type of surface. See **Specifications, 400** for a summary of the materials used in this section.
2. Limit intermediate coatings, such as primers, to the brand and type specified by the finish-coat manufacturer.
3. Do not mix additives with the finish coats unless they are specified by the finish-coat manufacturer.

⚠ CAUTION

Only experienced, qualified persons using proper equipment should attempt repainting or touch-up painting. Incorrect application of chemicals or paint could damage the surface or impair the finish.

Buffing Minor Imperfections

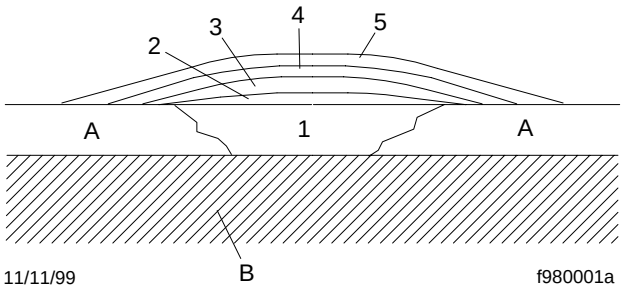
1. Clean the area carefully with a mild detergent and rinse.
2. Remove imperfections using ultra-fine or micro-fine sandpaper (1500 or 2000 grit) and water. Rinse the area with clean water, then dry.
3. Buff the area.
   - 3.1 Use a clean foam pad at low speed (about 1600 rpm) with one of the following products:
     - DuPont 1500 S
     - Meguiar's No. 2
     - 3M Finesset Two 5928
   - 3.2 Using medium pressure, buff slowly in an overlapping pattern until the imperfection has been eliminated. Repeat as necessary.
   - 3.3 Rinse the area with clean water, then dry.
4. Polish the area.
   - 4.1 Apply one of the following products with a clean pad (3M Waffle Pad):
     - DuPont 3000 S
     - Meguiar's No. 9
     - 3M 5996
   - 4.2 Using medium pressure, work small areas using an even, overlapping pattern until the gloss is restored. As the polish dries and the gloss appears, ease the pressure on the polishing pad. Repeat as necessary.

Preparing for Topcoating

1. Wash the entire panel with mild detergent. Dry with a clean, lint-free cloth.

⚠ WARNING

Solvents are flammable. Keep them away from heat, sparks, and open flame. Keep the container closed. Use only with adequate ventilation. Avoid breathing the vapor, or headache, nausea, and impaired reaction time and coordination may result.



2. Clean the area to be repaired with DuPont 3939 S solvent and quickly wipe the surface with a clean, lint-free cloth before the solvent dries. Remove all traces of wax, polish, grease, and silicones.
3. Sand or grind all dents and scratches.
4. Wet sand and the area being repaired with no. 320 grit or finer sandpaper, or a 3M Scotch-Brite® or similar non-iron abrasive pad. Feather the edge.
5. Remove the sanding dust. Use the same solvent and wipe-on, wipe-off method used earlier to clean the area.
6. Mask all areas that will not be painted.
7. Clean all cracks and surfaces with dry compressed air.
8. Using a tack cloth, wipe all surfaces to be painted.

Spot Repair

WARNING

Wear a positive-pressure, supplied-air, vapor and particulate respirator, approved by NIOSH or MSHA (TC-19C) when mixing or spraying primer, and until the work area has been exhausted of all vapor and spray mist. Breathing paint fumes can cause serious personal injury.

9. Prime all bare metal and feathered areas with DuPont primer. See **Fig. 1**.
   - Steel and aluminum—use Corlar 824 S epoxy primer.
   - Fiberglass—use Corlar 825 S epoxy primer.

NOTE: Scale exaggerated for clarity. The number of layers depends on the specific application.

A. Existing Paint
B. Panel Material (substrate)
1. Primer
2. First Color Topcoat
3. Second Color Topcoat
4. Third Color Topcoat
5. Clear Coat

Fig. 1, Spot Repair Cross-Section

9.1 Stir primer thoroughly.

9.2 Mix two parts Corlar epoxy primer with one part DuPont 826 S activator.

9.3 Reduce three parts of this mixture with one part DuPont 3602 S lacquer thinner (viscosity reading is 18 to 22 seconds in a no. 2 Zahn cup). Stir thoroughly.

9.4 Wait 1 to 2 hours from time of mixing before using. This provides time for complete chemical induction.

9.5 Set the air pressure at the spray gun to 45 psi (310 kPa). For pressure feed systems, set the fluid delivery at 12 to 16 ounces (350 to 470 mL) per minute.

9.6 Hold the spray gun about 10 to 12 inches (25 to 30 cm) from the surface.

9.7 Spray one wet coat to give a dry film thickness of 0.7 to 1.0 mil (18 to 25 µm).

9.8 Clean the equipment immediately after use with DuPont 3602 S lacquer thinner.

9.9 Air dry 2 to 4 hours or force dry 20 minutes.

10. Wet sand the primer with no. 400 grit or finer sandpaper. Feather the edge into the surrounding area.
11. If the original paint was Imron 6000, hand-rub the area around the spot repair with a medium grade compound to ensure a seamless finish.
12. Remove the sanding dust. Use the same solvent and wipe-on, wipe-off method used earlier to clean the area.
13. Wipe the repair area with a tack cloth.
14. If the finish is old, apply one coat of DuPont 222 S adhesion promoter over the entire repair area.

    14.1 Set the air pressure to 35 psi (240 kPa) at the spray gun.

    14.2 Flash for 5 to 10 minutes at 70°F (21°C) before topcoating.

Topcoating a Spot Repair

WARNING

Wear a positive-pressure, supplied-air, vapor and particulate respirator approved by NIOSH or MSHA (TC-19C), while spraying topcoating, and until the work area has been exhausted of all vapor and spray mist. Breathing topcoating vapor or spray mist can cause personal injury.

Imron 5000 Topcoating

1. Mix the Imron 5000 polyurethane enamel.

   1.1 Stir the Imron 5000 enamel thoroughly.

1.2 Mix three parts Imron 5000 base color with one part DuPont 193 S or 194 S activator. No further reduction is necessary for application.

1.3 Mix thoroughly and strain.

2. Set the air pressure at the spray gun at 60 to 65 psi (410 to 450 kPa). For pressure feed systems, set the fluid delivery at 12 to 16 ounces (350 to 470 mL) per minute.

3. For metallic topcoats only, apply one coat of DuPont 500 S urethane clear.

3.1 Mix eight parts of 500 S urethane with one part 193 activator.

3.2 Reduce the activated 500 S urethane mixture 50 percent with 8685 S reducer.

3.3 Apply a medium-wet coat of the reduced 500 S urethane over the entire repair area, and well beyond where the color will be applied.

3.4 Flash 3 minutes before applying the Imron 5000 topcoat.

4. Apply the solid color or metallic topcoating.

4.1 Hold the spray gun about 10 to 12 inches (25 to 30 cm) from the surface.

4.2 Spray one medium-wet coat over the primed area.

4.3 Flash 5 to 10 minutes.

4.4 Apply a second medium-wet coat. Extend the spray area slightly to taper the edge and avoid a visible ring.

4.5 A third medium-wet coat may be needed for good coverage of some colors. Allow each coat to flash before applying the next coat.

NOTE: A mist coat of five parts of color to three parts of 8022 S is recommended when applying metallics. Hold the gun about 18 inches (45 cm) from the surface.

5. Blend the repair area into the OEM finish.

5.1 Lower the air pressure to 15 to 20 psi (100 to 140 kPa) at the spray gun.

5.2 Empty the spray cup and refill it with DuPont 8022 S reducer or a blend of 8022 S and 8093 S.

5.3 Carefully blend the edge of the repair with even coats to melt in the overspray.

5.4 Spray one or two medium coats of the reducer over the entire area.

5.5 If a haze appears around the edge after the reducer has dried, lightly rub the edge with DuPont 1500 S one-step polish.

6. To air dry, allow 2 to 4 hours if DuPont 389 S accelerator is used, and 6 to 8 hours if no accelerator is used.

To force dry, wait 15 minutes following the application of the final coat, then dry for 30 minutes at 140 to 180°F (60 to 82°C).

7. To prevent tape marking, remove all masking tape and paper immediately after the final coat is applied. Avoid contacting the freshly painted surface with masking paper.

8. Clean the equipment immediately after use with DuPont 3602 S lacquer thinner or 8685 S reducer.

Imron 6000 Topcoating

1. Mix the Imron 6000 polyurethane enamel.

1.1 Stir the Imron 6000 base color thoroughly.

1.2 Mix three parts Imron 6000 base color with one part DuPont 193 S or 194 S activator. No further reduction is necessary for application.

1.3 Mix thoroughly and strain.

2. Set the air pressure at the spray gun at 60 to 65 psi (410 to 450 kPa). For pressure feed systems, set the fluid delivery at 12 to 16 ounces (350 to 470 mL) per minute.

3. Apply the topcoating.

3.1 Hold the spray gun about 10 to 12 inches (25 to 30 cm) from the surface.

3.2 Apply one cross-coat of the Imron 6000 base color over the primed area. No flash time is required before applying a clear coat.

3.3 Flash 10 minutes minimum. Do not sand.

Spot Repair

3.4 Mix three parts DuPont 3440 S or 3480 S clear with one part DuPont 193 S or 194 S activator.

NOTE: For best results, apply the clear coat over the entire panel. If a blend of the repair area is attempted, apply the clear coat only over the repair area, overspraying the edge slightly.

3.5 Apply one coat of the activated DuPont 3440 S or 3480 S clear.

4. Blend the 3440 S or 3480 S clear into the surrounding topcoat.

   4.1 Set the air pressure to 25 psi (170 kPa) at the spray gun.

   4.2 Apply one coat of 3401 S blending clear over the repair area only to the overspray edge.

   4.3 Flash 2 minutes. Repeat if necessary.

5. To air dry, allow 2 to 4 hours if DuPont 389 S accelerator is used, and 6 to 8 hours if no accelerator is used.

   To force dry, wait 15 minutes following the application of the final coat, then dry for 30 minutes at 140 to 180°F (60 to 82°C).

6. To prevent tape marking, remove all masking tape and paper immediately after the final coat is applied. Avoid contacting the freshly painted surface with masking paper.

7. Clean the equipment immediately after use with DuPont 3602 S lacquer thinner or 8685 S reducer.

Equipment Application Parameters

Equipment Application Parameters		
Parameter	**English Units**	**Metric Units**
Atomizing Air		
Primer	45 psi	310 kPa
Enamel	60–65 psi	410–450 kPa
Fluid Delivery	12–16 oz/min	350–470 mL/min
Booth Temperature	75°F	23°C
Spray Gun Distance	10–12 in	25–30 cm

DuPont Topcoating Materials

Step	**Topcoating Materials**	
	Imron 6000	**Imron 5000**
Mix enamel	Mix: - 3 parts Imron 6000 - 1 part 193 S or 194 S activator	Mix: - 3 parts Imron 5000 - 1 part 193 S or 194 S activator
Add accelerator (optional)	389 S accelerator (up to 2 oz/gal of activated enamel)	
Mix clear coat	Mix: - 3 parts 3440 S or 3480 S clear - 1 part 193 S or 194 S activator	—

Specifications

Step	Topcoating Materials	
	Imron 6000	Imron 5000
Pressure at gun	60–65 psi (414–448 kPa)	60 psi (414 kPa)
Equipment cleanup	3939 S lacquer and enamel cleaner or 8685 S reducer	

DuPont Spot Repair Materials

Step	Spot Repair Materials	
	Imron 6000	Imron 5000
Cleaning	3939 S lacquer and enamel cleaner	
Sanding	320 grit or finer	
Sealer primer	Mix: - 2 parts Corlar 824 S primer with 1 part DuPont 826 S activator - reduce 3 parts of mixture with 1 part DuPont 3602 S lacquer thinner	
Compound	Medium grade compound	—
Adhesion promoter	222 S adhesion promoter	
Topcoat	1 coat Imron 6000: - 3 parts base color - 1 part 193 S or 194 S activator	2 coats Imron 5000: - 3 parts enamel - 1 part 193 S or 194 S activator
Topcoat viscosity	Solids: 20 sec; Metallics: 18 sec (#2 Zahn cup)	9–20 sec (#3 Zahn cup)
Clear coat	Mix: - 3 parts 3440 S or 3480 S clear - 1 part 193 S or 194 S activator	—
Accelerator (optional)	389 S accelerator	
Blending clear	1 coat 3401 S blending clear	
Equipment cleanup	3939 S lacquer and enamel cleaner or 8685 S reducer
