Foreword

The purpose of this manual is to assist the service technician when the vehicle is serviced. Major drivetrain component service information is not included in this manual, but is located in each manufacturer's service manual.

Instructions and procedures are those recommended by Daimler Trucks North America LLC or the component manufacturer.

Maintenance schedules and additional service information are included in the *Business Class® Trucks Maintenance Manual*.

IMPORTANT: Descriptions and specifications in this manual were in effect at the time of printing. Daimler Trucks North America LLC reserves the right to discontinue models at any time, or change specifications and design without notice and without incurring obligation.

For additional information, please contact Daimler Trucks North America LLC, Service Systems and Documentation, P.O. Box 3849, Portland, OR 97208-3849, U.S.A. or refer to www.Daimler-TrucksNorthAmerica.com and www.FreightlinerTrucks.com.

Environmental Concerns and Recommendations

Whenever you see instructions in this manual to discard materials, you should attempt to reclaim and recycle them. To preserve our environment, follow appropriate environmental rules and regulations when disposing of materials.

NOTICE: Parts Replacement Considerations

Do not replace suspension, axle, or steering parts (such as springs, wheels, hubs, and steering gears) with used parts. Used parts may have been subjected to collisions or improper use and have undetected structural damage.

Descriptions of Service Publications

Daimler Trucks North America LLC distributes the following major service publications.

Workshop/Service Manual

Workshop/service manuals contain service and repair information for all vehicle systems and components, except for major components such as engines, transmissions, and rear axles. Each workshop/service manual section is divided into subjects that can include general information, principles of operation, removal, disassembly, assembly, installation, specifications, and troubleshooting.

Maintenance Manual

Maintenance manuals contain routine maintenance procedures and intervals for vehicle components and systems. They have information such as lubrication procedures and tables, fluid replacement procedures, fluid capacities, specifications, procedures for adjustments and for checking the tightness of fasteners. Maintenance manuals do not contain detailed repair or service information.

Driver's/Operator's Manual

Driver's/operator's manuals contain information needed to enhance the driver's understanding of how to operate and care for the vehicle and its components. Each manual contains a chapter that covers pretrip inspection and daily maintenance of vehicle components. Driver's/operator's manuals do not contain detailed repair or service information.

Parts Technical Manual

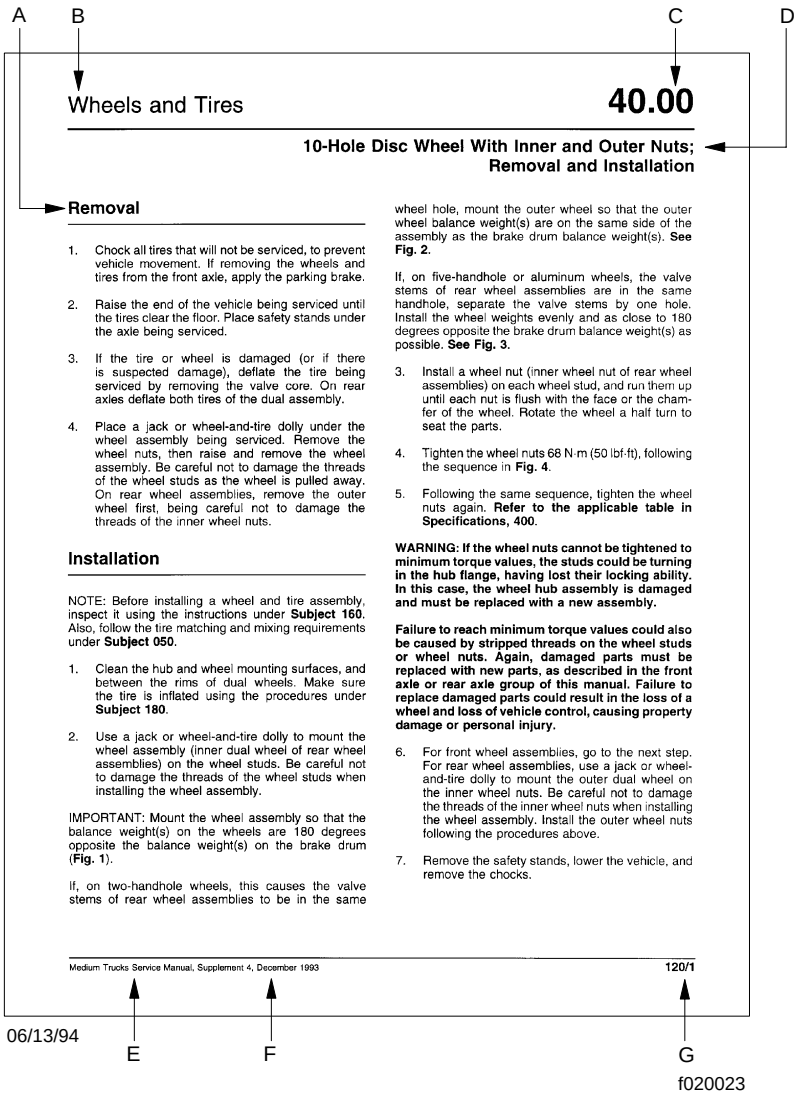
Daimler Trucks North America LLC publishes this manual to aid in the identification of serviceable replacement vehicle parts. This manual is used in conjunction with the parts book and the service parts catalog microfiche.

Service Bulletins

Service bulletins provide the latest service tips, field repairs, product improvements, and related information. Some service bulletins are updates to information in the workshop/service manual. These bulletins take precedence over workshop/service manual information, until the latter is updated; at that time, the bulletin is usually canceled. The service bulletins manual is available only to dealers. When doing service work on a vehicle system or part, check for a valid service bulletin for the latest information on the subject.

IMPORTANT: Before using a particular service bulletin, check the current service bulletin validity list to be sure the bulletin is valid.

Recall Bulletins



These bulletins pertain to special situations that involve service work or replacement of parts in connection with a recall notice. Recall bulletins pertain to matters of vehicle safety. All bulletins are distributed to dealers; customers receive notices that apply to their vehicles.

Field Service Modifications

This publication is concerned with non-safety-related service work or replacement of parts. All field service modifications are distributed to dealers; customers receive notices that apply to their vehicles.

Vehicle Receipt

Prior to signing for vehicle delivery from a transporter company, the dealer is responsible for checking for transporter-related shortages or damages, and noting these discrepancies on the transporter's delivery receipt.

The dealer is also responsible for ensuring that the vehicle was built according to the Truck Sales Order/ Invoice.

Refer to Section 3 of the Freightliner LLC *Warranty Manual* for details.

Vehicle Storage

There may be times when a vehicle is stored for long periods before customer delivery. To protect all vehicles from deterioration and weather, they must be properly maintained. Adequate protection and storage of new vehicles is the responsibility of the dealer.

Claims arising from loss and damage to improperly stored vehicles will not be reimbursed.

See Section 3 of the Freightliner LLC *Warranty Manual* for instructions on storage of new vehicles.

Pre-Delivery Information

All pre-delivery inspections and services must be performed at an authorized Freightliner LLC facility, assigned to fully qualified service personnel and recorded on the "New Vehicle Pre-Delivery Inspection" form.

Refer to Section 3 of the Freightliner LLC *Warranty Manual* for details.

It is recommended the pre-delivery inspection be performed within 30 days of vehicle receipt.

Hoses and Electrical Wiring Routing Standards

Cooling System

1. Cooling system hoses must clear all moving parts by a minimum of 1/4 inch (6 mm).
2. The 1-inch (25-mm) hose from the surge tank to the engine must be free of sumps and have allowance for engine torque.
3. Cooling system hoses should not be twisted or kinked.
4. Cooling system hoses must be routed at least six inches (152 mm) from a heat source if the heat source does not have a heat shield. If a heat shield is provided, the hose must be routed at least three inches (76 mm) from the heat source.

HVAC System

1. Cushion clamps are required to support all A/C lines. Butterfly or figure-8 clamps (two cushion clamps) may be used to prevent rubbing or chafing.
2. Tie straps may only be used to fasten together A/C lines that are parallel to each other.
3. Heater hoses that are protected with convoluted tubing may be fastened with tie straps. Otherwise, only cushion clamps or butterfly clamps may be used for heater hoses.
4. A/C lines cannot be secured to air lines, fuel lines, or electrical wires.
5. HVAC hoses should be protected from damage by routing them away from hazards of heat, wheel splash (water, gravel, ice), human traffic, and moving parts of the vehicle.
6. HVAC hoses should be routed away from sharp points and edges (such as nuts, bolts, brackets, and frame rail edges), moveable parts, and sources of abrasion, cutting, pinching, or crushing.

NOTE: If hoses are covered with convoluted tubing, they may touch any of the above.

7. Hoses that are protected with convoluted tubing may come in contact with the bends on frame rails and filters.
8. HVAC hoses must be routed at least six inches (152 mm) from a heat source if the heat source does not have a heat shield. If a heat shield is provided, the hose must be routed at least three inches (76 mm) from the heat source.
9. HVAC hoses should be clamped every 12 to 18 inches (305 to 457 mm).
10. All HVAC hoses must be routed so that regularly serviced components, such as fuel filters, fuel/water separators, oil filters, air filters, belts, and fill and drain plugs, are readily accessible for adjustment or replacement without the need to relocate or remove the hoses.

Engine Plumbing

The engine oil pressure line should not rub or chafe against the Teflon® discharge line.

Electrical Wiring

1. Wires that are bundled together should be fastened at 8- to 12-inch (203- to 305-mm) intervals. If anchor clamps are more than 12 inches (305 mm) apart, a tie strap must be used between the anchor clamps.
2. Bundles of wires that are located in an exposed area, such as under the cab or outside the frame rail, need to be fastened with heavy-duty cable ties.
3. Any wiring that will be exposed to water or heat must be covered with either loom or convoluted tubing. Loom or convoluted tubing need not butt up against Weather Pack® connectors.
4. Any wiring routed across the vehicle, on the engine crossmember, or across the rear of the engine, must be secured with a clamp or tie strap, and covered with either convoluted tubing or a loom.
5. Any wiring that may come into contact with sharp points and edges (such as nuts, bolts, brackets, and frame rail edges), moveable parts, and sources of abrasion, cutting, pinching, or crushing, must be protected by either a loom or convoluted tubing.
6. Unprotected breakouts (individual wires) of up to eight inches (203 mm) are acceptable as long as these wires are routed safely away from sharp

points and edges, moveable parts, and sources of abrasion, cutting, pinching, or crushing.

7. Gray, flame-retardant convoluted tubing may be used to protect wiring in the cab or the chassis. Black nylon convoluted tubing may only be used in the chassis.
8. All wiring must be routed so that regularly serviced components, such as fuel filters, fuel/water separators, oil filters, air filters, belts, and fill and drain plugs, are readily accessible for adjustment or replacement without the need to relocate or remove any wiring.
9. In exposed locations, such as the road light harness near the headlights, loose loops of wire must be secured with tie straps.
10. All wiring should be routed a minimum of four inches (102 mm) from the exhaust. In situations where the wiring is less than four inches (102 mm) from the exhaust, a heat shield must be placed between the wiring and the exhaust.

Battery Cables

1. Battery cables must be routed along an unobstructed path from the starter to the battery box. The cables must **not** rub or chafe on brackets, tanks, air lines or fuel lines.
2. Battery cables and electrical wiring cannot be tied or secured to fuel lines, discharge lines, or air lines.
3. Battery cables must have support brackets no more than 30 inches (762 mm) apart. Tie straps must be within six inches (152 mm) of both sides of the support brackets, and every 12 inches (305 mm) between the brackets.
4. Battery cables must have convoluted tubing from the frame bracket to the batteries, and from the frame bracket to the starter.

Fuel Lines

1. Fuel lines must not be clamped to A/C lines, battery cables, jumper cables, or any other electrical wiring.
2. Stand-off brackets or clamps may be used to prevent fuel lines from rubbing against the frame.
3. Fuel lines must be routed at least six inches (152 mm) from a heat source. If a heat shield is provided, the fuel line must be at least three inches (76 mm) from the heat source.
4. Fuel lines that are parallel may be fastened together. Fuel lines that cross or that rub on metal, plastic, or electrical parts, need to be separated with butterfly clamps.

Chassis Air Lines and Brake Hoses

1. Hoses may come in contact with each other if they are parallel, or if they are bundled together.
2. If the hoses lie on the curve or flat surface of a bracket or crossmember, they do not need convoluted tubing.
3. Brake hoses may be clamped at the top of the axle housing, and touch or lie against the axle housing in its path to the brake chamber as this assembly moves together.
4. Brake hoses must have slack between the last clamping point on the rail and brake chamber to allow for full range of suspension travel.
5. Brake hoses should have butterfly clamps at breakout points.
6. Air lines and brake hoses that are bundled together should be fastened at 8- to 12-inch (203- to 305-mm) intervals. If anchor clamps are more than 12 inches (305 mm) apart, a tie strap must be used between the anchor clamps. Tie straps may be closer than 12 inches (305 mm) apart.
7. Hoses or lines that may come into contact with the sharp edge of a bracket or frame rail are to be protected by convoluted tubing.
8. Air lines and brake hoses that are parallel may be fastened together. Air lines and brake hoses that cross or that rub on metal, plastic, or electrical parts need to be separated with butterfly clamps.
9. Nylon or STX (wire braid) chassis air lines may be fastened together to prevent rubbing, as long as the lines are stationary.

VIN for Vehicles Built through April 30, 2000

IMPORTANT: See **Subject 060** for the vehicle identification numbering system for vehicles built May 1, 2000, or later.

Federal Motor Vehicle Safety Standard 115 specifies that all vehicles sold in the U.S. be assigned a 17-character Vehicle Identification Number (VIN). Using a combination of letters and numerals, the VIN defines the manufacturer, model, and major characteristics of the vehicle. See **Table 1** for the character positions of a typical Freightliner VIN, 1FUYSTEBXVPA99999.

The VIN can be found on the Vehicle Specification Decal (see the driver's manual for decal location) and stamped on the left frame rail over the front axle about 2 inches (50 mm) from the top of the web or on the top flange of the left frame rail at frame station 30.

NOTE: For Freightliner vehicles assembled and sold in Mexico, the VIN appears on a plate or label attached to the driver's door. Also, a data card placed in the glove box shows the Mexican VIN as the "CHASSIS" number. The "CABIN" number is part of the Freightliner VIN, the last six digits of which are the Freightliner serial number.

IMPORTANT: A new VIN-code structure will be used for all vehicles built after April 30, 2000. Character positions 1 through 4 and 9 through 17 are nearly the same in both versions, but positions 5 through 8 have been assigned slightly different parameters. As a result, the build date of a vehicle must be determined before the VIN can be decoded.

For all vehicles, a check digit (9th character) is determined by assignment of weighted values to the other 16 characters. These weighted values are processed through a series of equations designed to check validity of the VIN and to detect VIN alteration.

NOTE: Always specify the VIN when ordering parts.

VIN for Vehicles Built from May 1, 2000

IMPORTANT: See **Subject 050** for the vehicle identification numbering system for vehicles built before May 1, 2000.

Federal Motor Vehicle Safety Standard 115 specifies that all vehicles sold in the U.S. be assigned a 17-character Vehicle Identification Number (VIN). Using a combination of letters and numerals, the VIN defines the manufacturer, model, and major characteristics of the vehicle. See **Table 1** for the character positions of a typical Freightliner VIN, 1FUPABAV11PA12345.

The VIN can be found on the Vehicle Specification Decal (see the driver's manual for decal location) and stamped on the left frame rail over the front axle about 2 inches (50 mm) from the top of the web or on the top flange of the left frame rail at frame station 30.

NOTE: For Freightliner vehicles assembled and sold in Mexico, the VIN appears on a plate or label attached to the driver's door. Also, a data card placed in the glove box shows the Mexican VIN as the "CHASSIS" number. The "CABIN" number is part of the Freightliner VIN, the last six digits of which are the Freightliner serial number.

IMPORTANT: A new VIN-code structure will be used for all vehicles built after April 30, 2000. As a result, the build date of a vehicle must be determined before the VIN can be decoded.

Character positions 1 through 4 and 9 through 17 are nearly the same in both versions, but positions 5 through 8 have been assigned slightly different parameters.

Another new feature is that each product line has its own model list; that is, positions 5 and 6 are will be product-specific in the new system. For example, the code AB in positions 5 and 6 for a Freightliner vehicle indicates an FLD112. Code AB in the same position for a Sterling vehicle represents an SC7000 Cargo.

For all vehicles, a check digit (9th character) is determined by assignment of weighted values to the other 16 characters. These weighted values are processed through a series of equations designed to check validity of the VIN and to detect VIN alteration.

NOTE: Always specify the VIN when ordering parts.

General Information

The majority of threaded fasteners used throughout the vehicle have U.S. customary threads (diameter and pitch are measured in inches). **See Fig. 1.** However, the engine and some items attached to the cab use metric fasteners (diameter and pitch are measured in millimeters).

Most fasteners used on the vehicle that are 1/2-inch diameter or larger are plain hex-type fasteners (non-flanged); *all* metric fasteners are non-flanged. Special hardened flatwashers are used under the bolt head, and between the part being attached and the hexnut, to distribute the load, and to prevent localized overstressing of the parts. The washers are cadmium-or zinc-plated, and have a hardness rating of 38 to 45 HRC.

Some fasteners smaller than 1/2-inch diameter are flanged fasteners, which have integral flanges that fit against the parts being fastened. The flanges eliminate the need for washers.

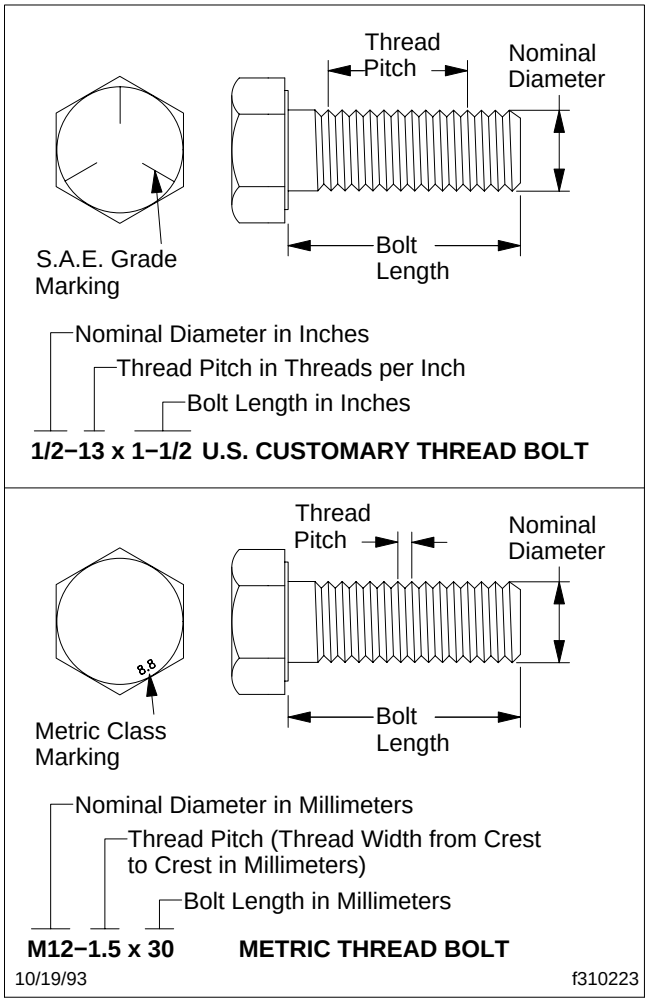

Fig. 1

Fastener Grades and Classes

Fasteners with U.S. customary threads are divided into grades established by the Society of Automotive Engineers (S.A.E.) or the International Fastener Institute (I.F.I.). The fastener grades indicate the relative strength of the fastener; the higher the number (or letter), the stronger the fastener. Bolt (capscrew) grades can be identified by the number and pattern of radial lines forged on the bolt head. **Refer to Fig. 2.** Hexnut (and locknut) grades can be identified by the number and pattern of lines and dots on various surfaces of the nut. **Refer to Fig. 3.** Nearly all of the bolts used on the vehicle are grades 5, 8, and 8.2. Matching grades of hexnuts are always used: grade 5 or grade B hexnuts are used with grade 5 bolts; grade 8, grade C, or grade G (flanged) hexnuts are used with grade 8 or 8.2 bolts.

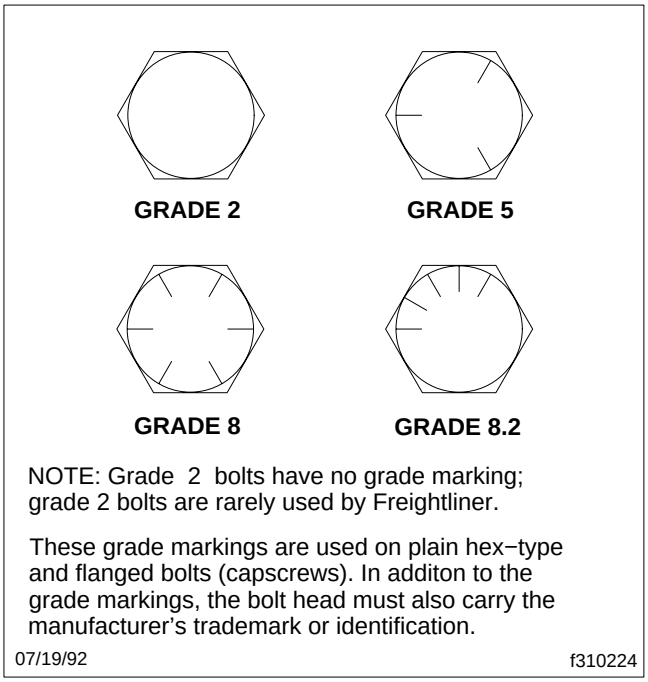

Fig. 2

General Information

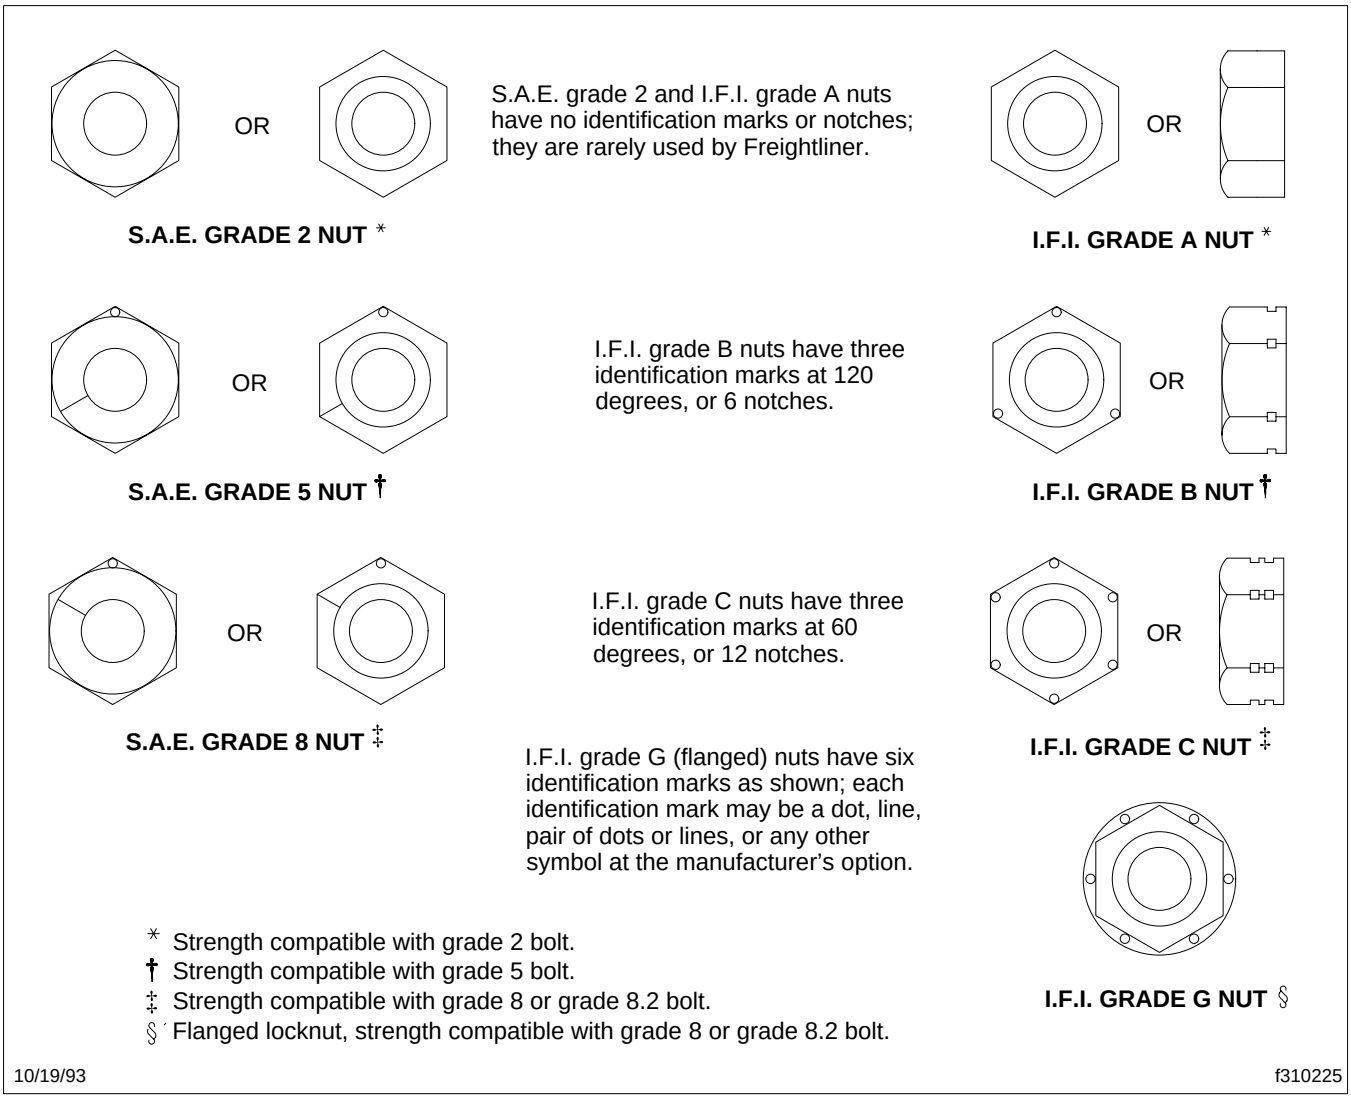

Fig. 3

Fasteners with metric threads are divided into classes adopted by the American National Standards Institute (ANSI). The higher the class number, the stronger the fastener. Bolt classes can be identified by the numbers forged on the head of the bolt. **Refer to Fig. 4.** Hexnut (and locknut) classes can be identified by the marks or numbers on various surfaces of the nut. **Refer to Fig. 5.** Class 8 hexnuts are always used with class 8.8 bolts; class 10 hexnuts with class 10.9 bolts.

Frame Fasteners

For most components attached to the frame, grade 8 and 8.2 phosphate-and oil-coated hexhead bolts and grade C cadmium-plated and wax-coated prevailing torque locknuts are used. The prevailing torque locknuts have distorted sections of threads to provide torque retention. For attachments where clearance is minimal, low-profile hexhead bolts and grade C prevailing torque locknuts are used. **See Fig. 6.**

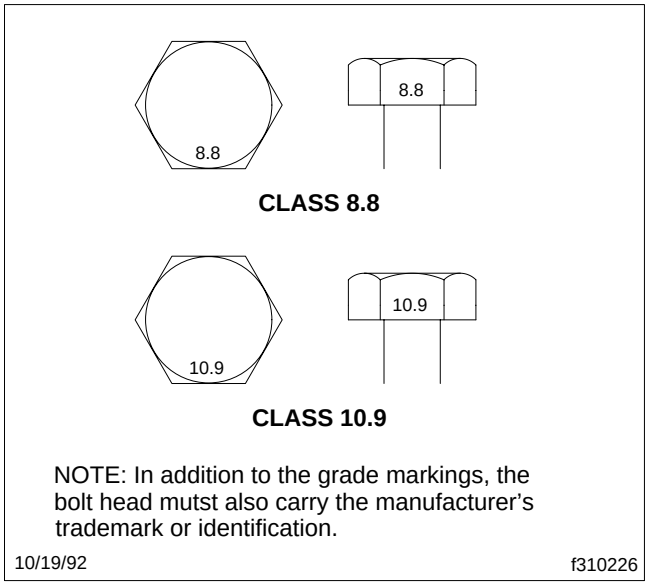

Fig. 4

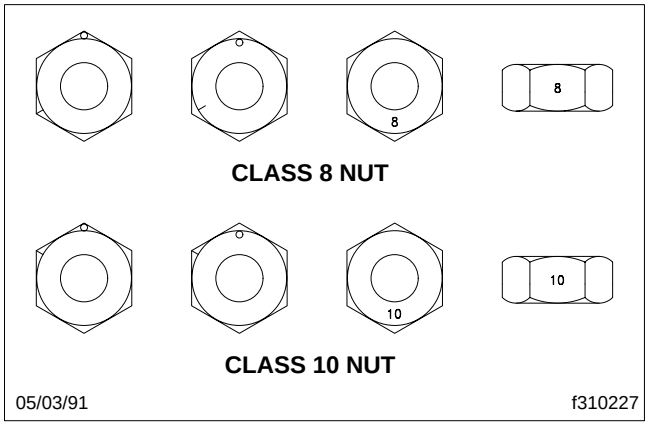

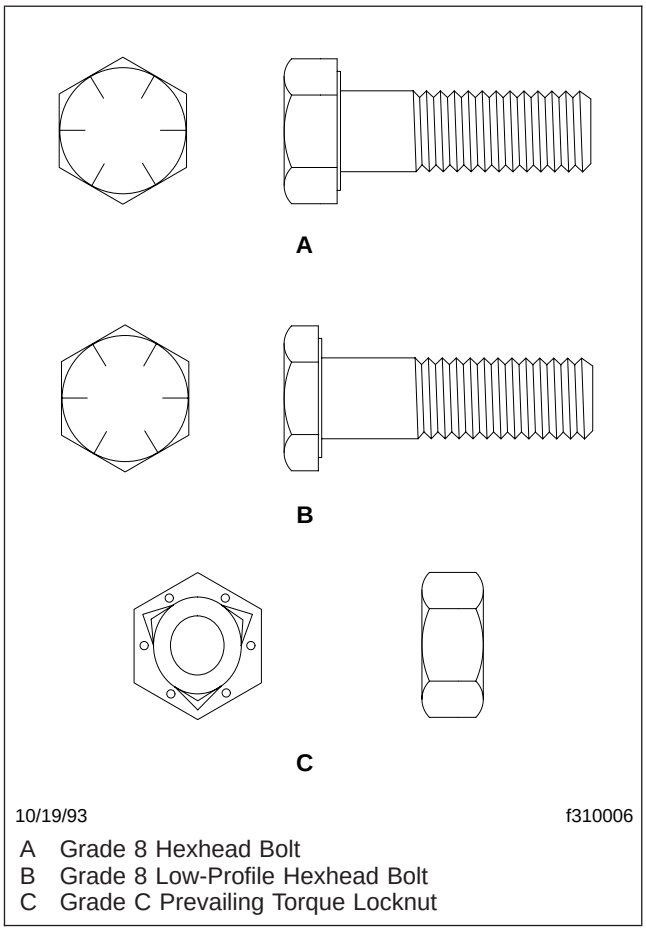

Fig. 5

Tightening Fasteners

When a capscrew is tightened to its torque value in a threaded hole, or a nut is tightened to its torque value on a bolt, the shank of the capscrew or bolt is stretched slightly. This stretching (tensioning) results in a preload that reduces fatigue of the fasteners. The torque values given in the tables in Subject 400 have been calculated to provide enough clamping force on the parts being fastened, and the correct tensioning of the bolt to maintain the clamping force.

Use of a torque wrench to tighten fasteners will help prevent overtensioning them. Overtensioning causes permanent stretching of the fasteners, which can result in breakage of the parts or fasteners.

A Grade 8 Hexhead Bolt
B Grade 8 Low-Profile Hexhead Bolt
C Grade C Prevailing Torque Locknut

Fig. 6

When torquing a fastener, typically 80 to 90 percent of the turning force is used to overcome friction; only 10 to 20 percent is used to stretch the capscrew or bolt. About 40 to 50 percent of the turning force is needed to overcome the friction between the underside of the capscrew head or nut and the washer. Another 30 to 40 percent is needed to overcome the friction between the threads of the capscrew and the threaded hole, or the friction between the threads of the nut and bolt.

The amount of torque required to tighten a fastener is reduced when the amount of friction is reduced. If a fastener is dry (unlubricated) and plain (unplated), the amount of friction is high. If a fastener is wax-coated or oiled, or has a zinc phosphate coating or cadmium plating, the amount of friction is reduced.

General Information

Each of these coatings and combinations of coatings has a different effect. Using zinc-plated hardened flatwashers under the bolt (capscrew) head and nut reduces the amount of friction. Dirt or other foreign material on the threads or clamping surfaces of the fastener or clamped part also changes the amount of friction.

Even though each different condition affects the amount of friction, a different torque value cannot be given for each different condition. To ensure they are always torqued accurately, Freightliner recommends that all fasteners be lubricated with oil (unless specifically instructed to install them dry), then torqued to the values for lubricated-and plated-thread fasteners. When locking compound or anti-seize compound is recommended for a fastener, the compound acts as a lubricant, and oil is not needed.

Fastener Replacement

When replacing fasteners, use only identical bolts, washers, and nuts; they must be the same size, strength, and finish as originally specified. Refer to the Freightliner *Service Parts Catalog* for fastener specifications.

When replacing graded (or metric class) bolts and capscrews, use only fasteners that have the manufacturer's trademark or identification on the bolt head; don't use substandard bolts. Inferior, counterfeit fasteners are difficult to identify; buy your fasteners from a reputable supplier.

Fastener Selection and Installation

When using nuts with bolts, use a grade (or class) of nut that matches the bolt.

When installing non-flanged fasteners, use hardened steel flatwashers under the bolt (capscrew) head, and under the hexnut or locknut.

For bolts 100 mm (4 inches) or less in length, make sure that at least 1-1/2 threads and no more than 16-mm (5/8-inch) bolt length extends through the nut after it has been tightened. For bolts longer than 100 mm (4 inches), allow a minimum of 1-1/2 threads and a maximum of 19-mm (3/4-inch) bolt length.

Never hammer or screw bolts into place. Align the holes of the parts being attached, so that the nut and bolt surfaces are flush against the washers, and the washers are flush against the parts.

When installing fasteners in aluminum or plastic parts with threaded holes, start the fasteners by hand, to ensure straight starting and to prevent damaged threads.

Don't use lockwashers (split or toothed) next to aluminum surfaces.

When installing studs that don't have an interference fit, install them with thread locking compound, as instructed in this subject.

When installing parts that are mounted on studs, use free-spinning (non-locking) nuts and helical-spring (split) lockwashers or internal-tooth lockwashers. Don't use locknuts, because they tend to loosen the studs during removal. Don't use plain washers (flatwashers).

Don't use lockwashers and flatwashers in combination (against each other); each defeats the other's purpose.

Use stainless steel fasteners against chrome plating, unpainted aluminum, or stainless steel.

Fastener Tightening

Before installing fasteners, clean all fastener (and parts) threads, and all surfaces being clamped.

To ensure they are always torqued accurately, Freightliner recommends that *all* fasteners be lubricated with oil (unless specifically instructed to install them dry), then torqued to the values for lubricated- and plated-thread fasteners. When locking compound or anti-seize compound is recommended for a fastener, the compound acts as a lubricant, and oil is not needed.

Bring parts and fasteners into contact, with no gaps between them, before using a torque wrench to tighten fasteners to their final torque values.

Tighten the nut, not the bolt head. This will give a truer torque reading by eliminating bolt body friction.

Always use a torque wrench to tighten fasteners, and use a slow, smooth, even pull on the wrench. Don't overtorque fasteners; overtightening causes permanent stretching of the fasteners, which can result in breakage of the parts or fasteners.

If specific torque values aren't given for countersunk bolts, use the torque value for the corresponding size and grade of regular bolt, as given in Subject 400.

Always follow the torque sequence or torque interval when provided, to ensure that clamping forces are even, and parts and fasteners aren't distorted.

Tighten frame fasteners periodically to offset the effects of "bedding in" (seating). Continued vehicle operation with loose frame fasteners could result in component, bracket, and frame damage. Refer to the Maintenance Schedule and Group 31 of the vehicle maintenance manual for intervals.

Thread Locking Compound Application

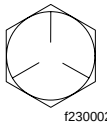
When the use of thread locking compound is recommended or desired, for studs, capscrews, and bolts

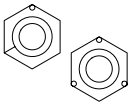
General Instructions

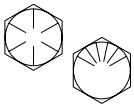
with a thread diameter of 25 mm (1 inch) or less, use Loctite® 271 or Perma-Lok® HM-128.

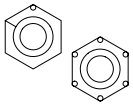
For thread diameters over 25 mm (1 inch), use Loctite 277.

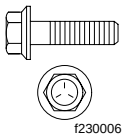
NOTE: Follow the safety precautions given on the locking compound container.

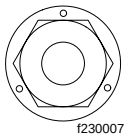


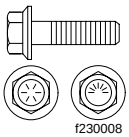


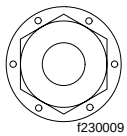












1. Clean the male and female threads of the fasteners, removing all dirt, oil, and other foreign material. If parts are contaminated, use Stoddard solvent for cleaning; then allow the fasteners to air dry for 10 minutes. Be sure solvent is completely gone before applying adhesive.
2. Transfer a small amount of the locking compound from the container to a paper cup or small non-metal dish.
3. Using a plastic brush (a metal brush will contaminate the compound), apply a small amount of compound to the entire circumference of 3 or 4 of the male threads that will be covered by the nut after it has been tightened. Be sure enough compound is applied to fill the inside of the nut threads, with a slight excess.
4. Install and torque the nut. Readjustment of the nut position is not possible after installation is complete, without destroying the locking effect.

NOTE: To disassemble the fasteners, heat the bond line to 200°C (400°F) before removing the nut. Every time the fasteners are disassembled, replace them. If any parts are damaged by overheating, replace the parts.

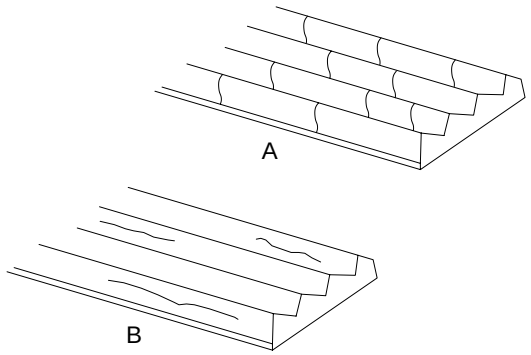
Pulley and Drive Belt Inspection

Inspection

Inspect all used drive belts (including those that are being replaced). **See Fig. 1.**

A. Glazing
B. Separating Layers
C. Streaked Sidewalls
D. Tensile Break
E. Uneven Ribs
F. Cracks

Fig. 1

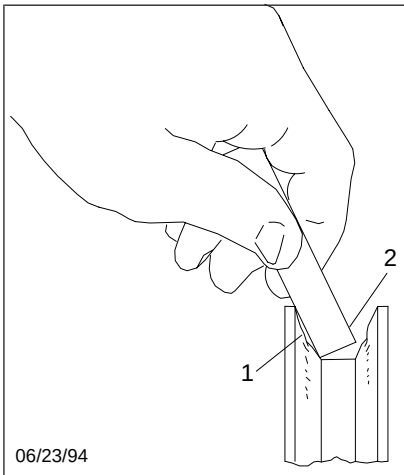


NOTE: For an installed belt, gently twist it about 90 degrees so you can see the sidewalls and bottom.

Replace a belt if any problem is found. Replace both belts of a set, at the same time. Matched belts must be from the same manufacturer.

1. Inspect for glazing (shiny sidewalls). See Ref. A. Glazing is caused by friction created when a loose belt slips in the pulleys. It can also be caused by oil or grease on the pulleys.
2. Inspect for separating layers. See Ref. B. Oil, grease, or belt dressings can cause the belt to fall apart in layers. If engine parts are leaking, repair the leaks. Do *not* use belt dressings on any belt.
3. Check for jagged or streaked sidewalls. See Ref. C. These are the result of a foreign object (such as sand or small gravel) in the pulley, or a rough pulley wall surface.
4. Check for tensile breaks (breaks in the cord body). See Ref. D. Cuts in a belt are usually caused by large foreign objects in the pulley, or by prying or forcing the belt during installation or removal.
5. On poly-V belts, check for uneven ribs. See Ref. E. Foreign objects in the pulley will erode the undercord ribs, causing the belt to lose its gripping power.
6. Inspect for cracks. See Ref. F. Small, irregular cracks are usually signs of an old belt.

   When inspecting serpentine drive belts (used on Dodge gasoline engines), look for cracks that run along the ribs. **See Fig. 2.** These are not normal. Replace any belt with cracks running along the ribs. Small cracks that run across the ribbed surface are normal.

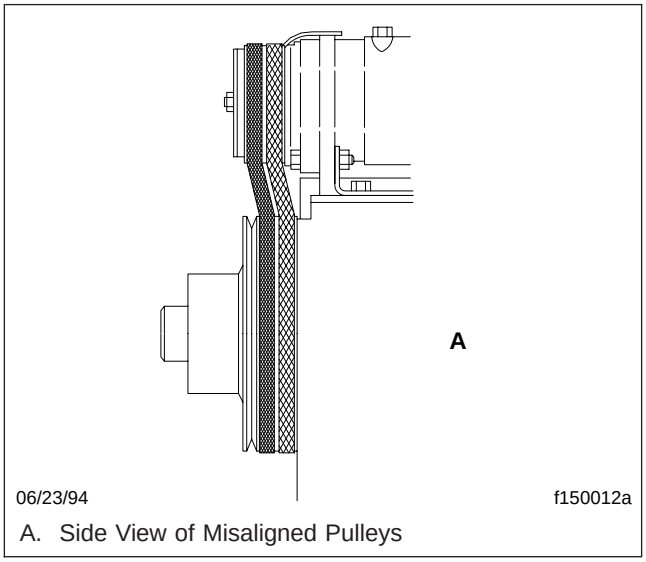


Pulley and Drive Belt Inspection

A. Normal Cracks, Belt Okay
B. Not Normal Cracks, Replace Belts

Fig. 2

7. Check all pulley bearings for roughness. Replace the bearings if they're rough.
8. Inspect all pulleys for foreign objects, oil, or grease in the grooves. Use a non-flammable cleaning solvent to remove oils. Use a wire brush to remove rust, and a file to remove burrs.
9. Inspect the pulleys for wear on the inner walls. Hold a small straightedge against the inside of the pulley walls **(Fig. 3)**, or use your little finger or fingernail to find grooves in the inner walls. If there are any grooves, replace the pulley.



1. Groove in Pulley Wall
2. Small Straightedge

Fig. 3

10. Check the alignment of pulleys. **See Fig. 4.** Use a thin straightedge that is longer than the longest span between the pulleys. Place the straightedge into the V-grooves of two pulleys at a time. The straightedge should be parallel to the outer edges of the pulleys; if not, the pulleys are misaligned.

    Pulley misalignment must not be more than 1.6 mm for each 305 mm (1/16-inch for each foot) of distance between the centers of the pulleys.

    If the pulleys are misaligned, adjust them or their brackets if possible. Replace bent or broken pulleys, pulley brackets, or shafts.

A. Side View of Misaligned Pulleys

Fig. 4

11. Check all drive component mounting parts for loose fasteners, cracks, or other damage. Tighten loose fasteners. Repair or replace cracked or damaged brackets.

Air Compressor Belt Replacement, Mercedes-Benz OM 366LA Engine

Replacement (See Fig. 1)

1. Loosen the belt tensioner.
   - 1.1 Loosen the bolt (Ref. A) in the center of the belt tensioning assembly.
   - 1.2 Loosen the pinch-bolt (Ref. B) in the tensioning assembly clamp.
   - 1.3 Back off the adjusting nut (Ref. C) until the tensioning assembly is drawn up off the air compressor belts.
2. Remove the belts from the air compressor and fan pulleys.
3. Inspect the pulleys and belts (even if installing new belts) as instructed under **"Pulley and Drive Belt Inspection, 100."**
4. Loop the belts around the fan and air compressor pulleys.
5. Tighten the belts to the correct belt tension.
   - 5.1 Tighten the adjusting nut (Ref. C) against the tensioning assembly clamp until the assembly is forced down against the belts.

     Check the belt tension while turning the nut, use your thumb to apply about 11 kg (25 lb) of force at the center of the longest belt free-span until the belt deflection equals one belt thickness per 305 mm (1 ft) of pulley-center distance.
   - 5.2 Install belt tension gauges at the center of the belts' longest free-spans.

     Turn the adjusting nut (Ref. C) against the tensioning assembly clamp to move the assembly down and tension the belts.

     Tighten the belts to 23 kg (50 lb).

   IMPORTANT: Do not overtighten the belts; too much tension shortens belt and bearing life.
   - 5.3 Tighten the tensioning assembly clamp pinch bolt (Ref. B) 80 N·m (59 lbf·ft).
   - 5.4 Tighten the bolt through the tensioning assembly (Ref. A) 80 N·m (59 lbf·ft).
6. Check the belt tension again, and adjust if needed.

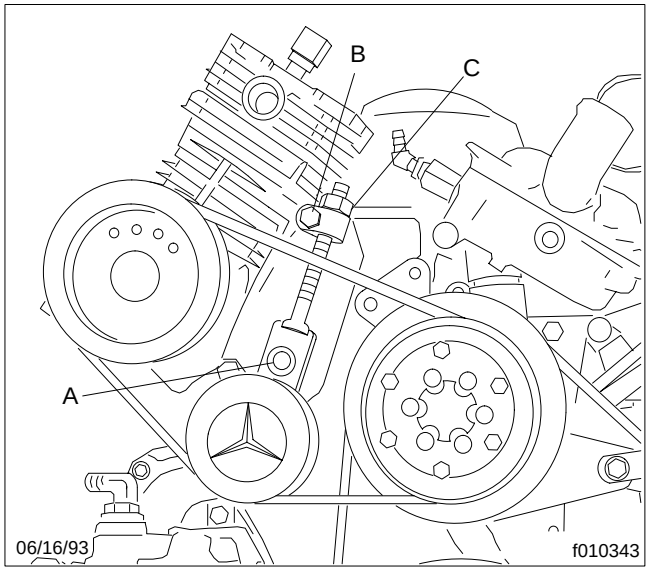


Fig. 1

7. If installing new belts, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation. If necessary, adjust the belts to 23 kg (50 lb).

Fan and Alternator Belt Replacement, Cummins B Series Engine

Replacement

1. If the vehicle is equipped with air conditioning, remove the refrigerant compressor belt. For instructions, see **Refrigerant Compressor Belt Replacement, Cummins B Series Engine, 120**.
2. Insert a 3/8-inch breaker bar in the belt tensioner (see **Fig. 1**), and rotate the tensioner up and off the belt (see **Fig. 2**).

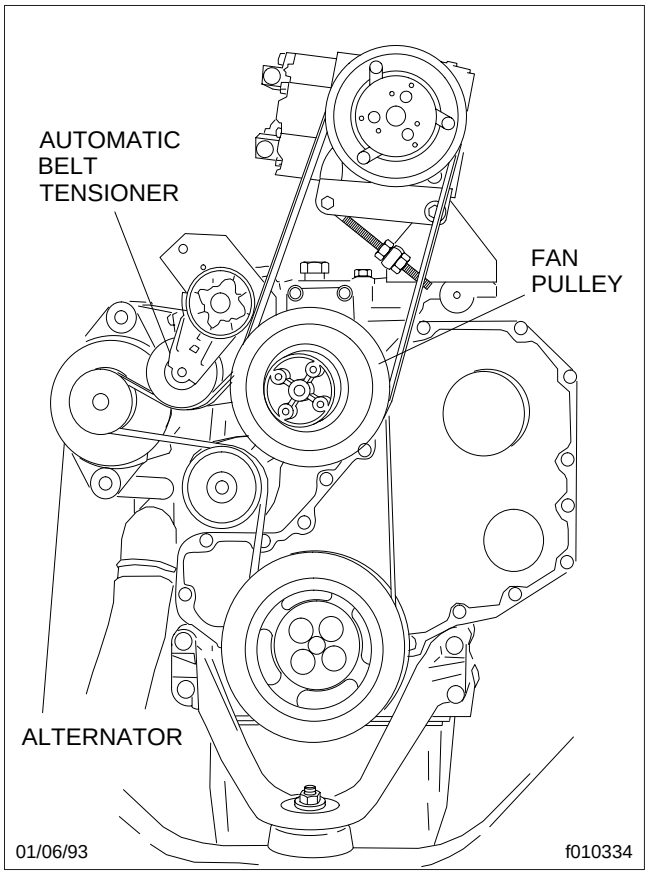

Fig. 1

3. Holding the belt tensioner up, remove the belt from the alternator pulley.
4. Slowly release the belt tensioner, and remove the breaker bar.
5. Lower the belt, and take it off the vibration damper.
6. Raise the belt, and take it off over the fan.

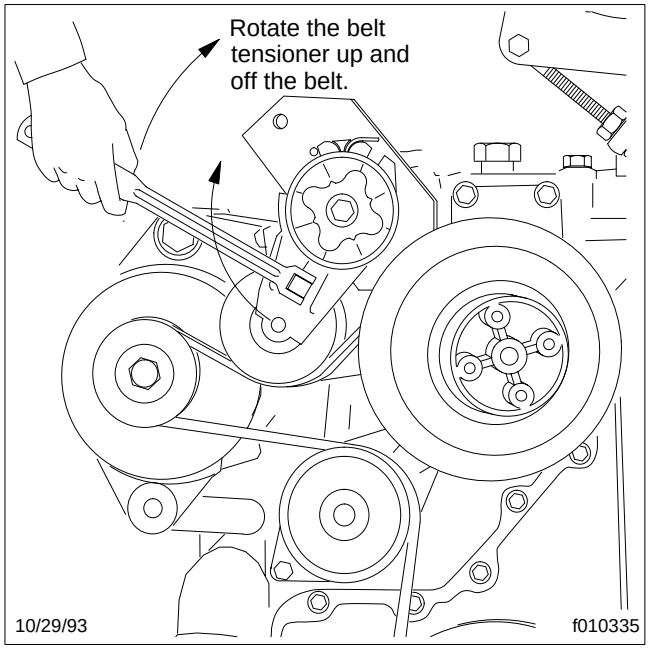

Fig. 2

7. Inspect the pulleys and the belt (even if installing a new belt) as instructed under **Pulley and Drive Belt Inspection, 100**.
8. Loop the belt around the fan and align it in the rear channel of the fan pulley (see **Fig. 2**).
9. Loop the belt down and around the vibration damper pulley.
10. Insert a 3/8-inch breaker bar in the belt tensioner (see **Fig. 2**), and rotate the tensioner up while installing the belt on the alternator pulley.
11. Slowly release the tensioner assembly onto the belt. The tensioner automatically tightens the belt to the correct tension.
12. Remove the breaker bar from the tensioner.
13. The Cummins belt tensioner automatically adjusts the fan and alternator belt to the correct tension. If the belt slips, repair or replace the tensioner. For instructions, see the *Cummins Shop Manual B Series Engines*.

Fan and Alternator Belt Replacement, Mercedes-Benz OM 366LA Engine

Replacement (See Fig. 1)

1. If the vehicle is equipped with air conditioning, remove the refrigerant compressor belt. For instructions, refer to **"Refrigerant Compressor Belt Replacement, Mercedes-Benz OM 366LA Engine, 125."**
2. If the vehicle is equipped with air brakes, remove the air compressor belt. For instructions, refer to **"Air Compressor Belt Replacement, Mercedes-Benz OM 366LA Engine, 105."**
3. Loosen the alternator mounting nut (Ref. C).
4. Back off the alternator adjusting rod nut (Ref. A).
5. Loosen the capscrew on the adjusting rod guide (Ref. B).
6. Rotate the alternator inward, and remove the belt from the alternator pulley.
7. Loop the belt down and off the vibration damper pulley.
8. Loop the belt up and off the fan pulley.
9. Inspect the pulleys and the belt (even if installing a new belt) as instructed under **"Pulley and Drive Belt Inspection, 100."**
10. Loop the belt around the fan and align it in the front channel of the large, two-channel fan pulley.
11. Loop the belt down and around the vibration damper pulley. Align the belt in the front channel of the two large pulley channels.
12. To install the belt on the alternator, rotate the alternator inward along its adjusting rod.
13. Loop the belt onto the alternator pulley, and align it in the front channel of the two alternator pulley channels.
14. Tighten the belt by turning the adjusting rod nut (Ref. A) against the adjusting rod guide until the alternator rotates outward against the belt.

    Check the tension while turning the nut, use your thumb to apply about 11 kg (25 lb) of force at the center of the longest belt free-span until the belt deflection equals one belt thickness per 305 mm (1 ft) of pulley-center distance.
15. Install a belt tension gauge at the center of the belt's longest free-span.
16. Turn the alternator adjusting rod nut (Ref. A) against the adjusting rod guide to move the alternator outward and tension the belt.
17. Tighten the belt to 75 kg (160 lb).

IMPORTANT: Do not overtighten the belt; too much tension shortens belt and bearing life.

18. Tighten the capscrew securing the adjusting rod guide (Ref. B) 80 N·m (59 lbf·ft).
19. Tighten the alternator mounting nut (Ref. C) 80 N·m (59 lbf·ft).
20. Check the belt tension again, and adjust if needed.
21. If installing a new belt, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

    If necessary, adjust the belt to 75 kg (160 lb).

Fan and Alternator Belt Replacement, Mercedes-Benz OM 366LA Engine

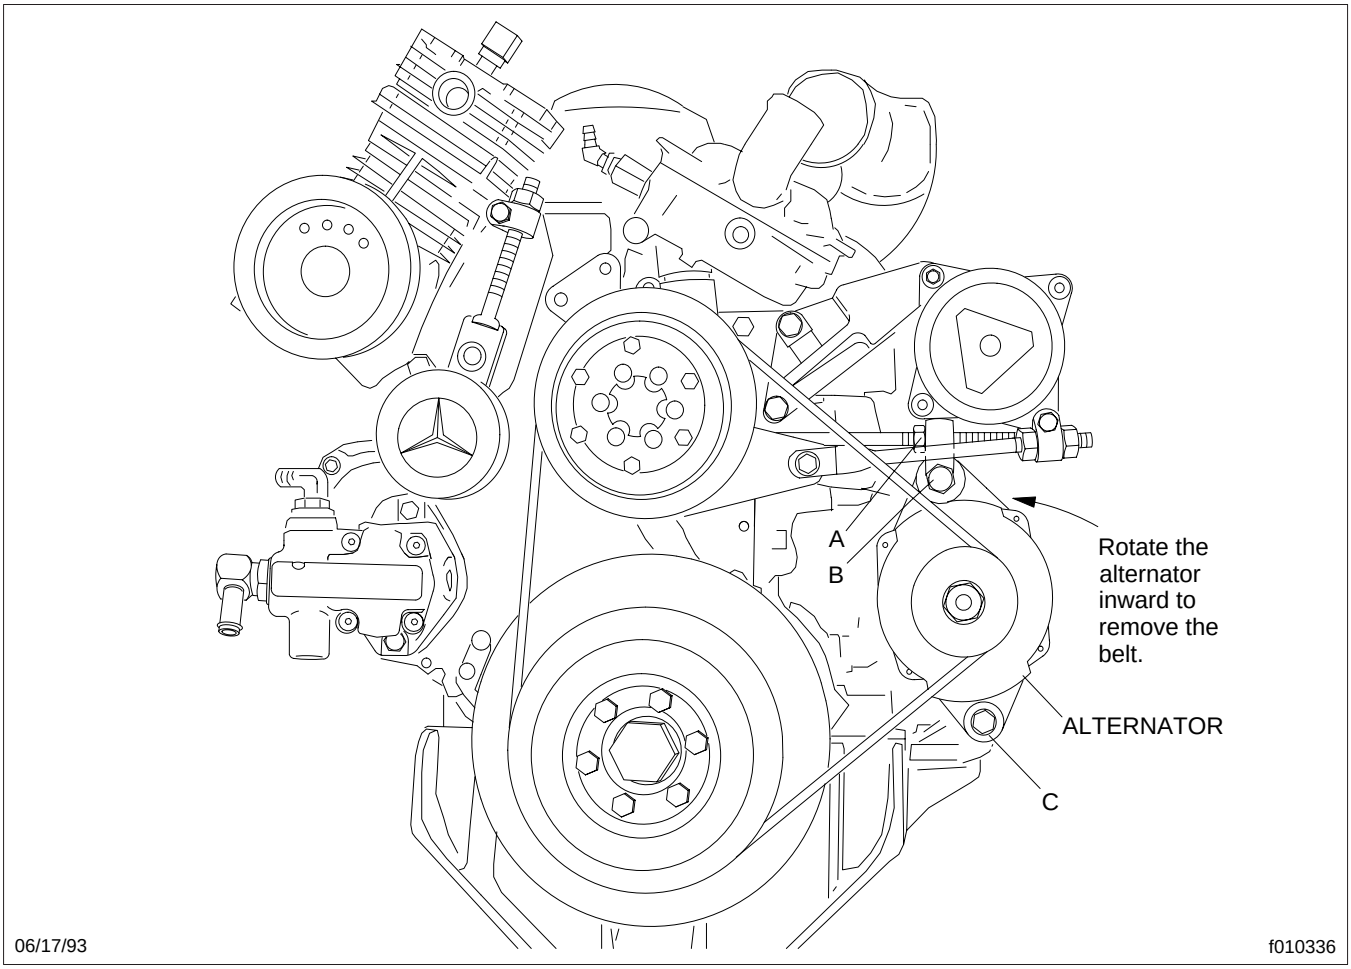

Fig. 1

Refrigerant Compressor Belt Replacement, Cummins B Series Engine

Replacement (See Fig. 1)

1. Loosen the refrigerant compressor mounting nuts (Ref. A).
2. Loosen the adjusting rod locknut (Ref. C), then back off the adjusting rod nut (Ref. B) until the belt can be removed.
3. Remove the belt. Don't pry or roll it off the pulleys.
4. Inspect the pulleys and the used belt (even if installing a new belt) as instructed under **"Pulley and Drive Belt Inspection, 100."**
5. Loop the belt around the fan and the compressor, and align it in the front channels of the pulleys.
6. Tighten the belt by turning the adjusting rod nut (Ref. B) against the compressor mount until the compressor moves up.

   Check the belt tension while turning the nut, use your thumb to apply about 11 kg (25 lb) of force at the center of the longest belt free-span until belt deflection equals one belt thickness per 305 mm (1 ft) of pulley-center distance.
7. Install a belt tension gauge at the center of the belt's longest free-span.
8. Tighten the compressor belt, by turning the adjusting rod nut (Ref. B) against the compressor mount to rotate the compressor up and away from the fan pulley. Tighten the belt to 45 kg (100 lb).

IMPORTANT: Do not overtighten the belts; too much tension shortens belt and bearing life.

9. Tighten the adjusting rod jam nut (Ref. C) against the compressor mount 80 N·m (59 lbf·ft).
10. Tighten the compressor mounting nuts (Ref. A) 80 N·m (59 lbf·ft).
11. Check the belt tension again, and adjust if needed.
12. If installing a new compressor belt, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

    If necessary, adjust the belt to 45 kg (100 lb).

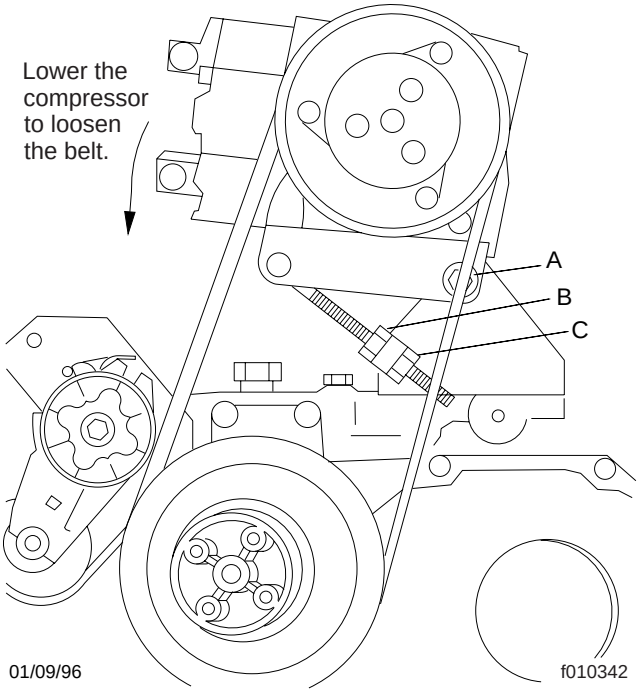

Fig. 1

Refrigerant Compressor Belt Replacement, Mercedes-Benz OM 366LA Engine

Replacement (see Fig. 1)

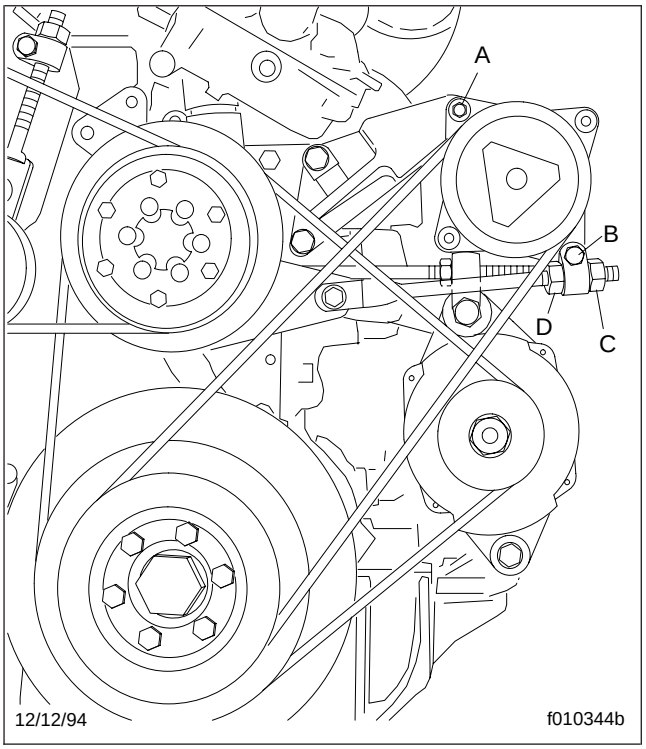

Fig. 1

1. Remove the refrigerant compressor belt.
   - 1.1 Loosen the compressor mounting nuts (Ref. A), and back off the adjusting rod nut (Ref. D).
   - 1.2 Loosen the nut on the adjusting rod guide bolt (Ref. B).
   - 1.3 Lower the compressor by sliding the guide down along the adjusting rod. Remove the belt from the compressor and vibration damper pulleys.
2. If removed, install and adjust the fan and alternator belt. For instructions, refer to **Fan and Alternator Belt Replacement, Mercedes-Benz OM 366LA Engine, 115.**
3. Inspect the pulleys and the belt (even if installing a new belt) as instructed under **Pulley and Drive Belt Inspection, 100.**
4. Loop the belt around the small vibration damper pulley.
5. Loop the belt around the compressor pulley, and align it in the rear channel of the two pulley channels.
6. Tighten the belt by turning the adjusting rod nut (Ref. D) against the adjusting rod guide until the compressor rises against the belt.

   Check the belt tension while turning the nut, use your thumb to apply about 11 kg (25 lb) of force at the center of the longest belt free-span until belt deflection equals one belt thickness per 305 mm (1 ft) of pulley-center distance.
7. Install a belt tension gauge at the center of the belt's longest free-span.
8. Turn the adjusting rod nut (Ref. D) against the adjusting rod guide to rotate the compressor upward and tension the belt.
9. For a regular V-belt, tighten the belt to 45 kg (100 lb). For a Powerband® V-belt (**see Fig. 2**), tighten the belt to 64 kg (140 lb).

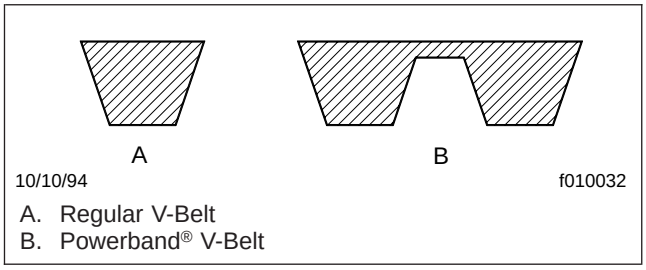

Fig. 2, Drive Belts, Cross Sections Shown

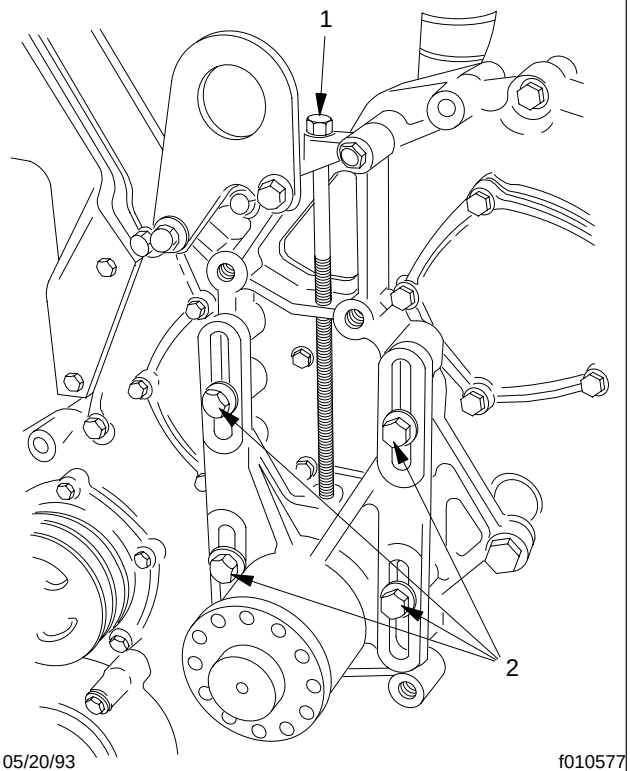
IMPORTANT: Do not overtighten the belt; too much tension shortens belt and bearing life.



10. Tighten the nut on the adjusting rod guide (Ref. B) 45 N·m (33 lbf·ft).
11. Tighten the refrigerant compressor mounting nuts (Ref. A) 45 N·m (33 lbf·ft).
12. Tighten the adjusting rod jam nut (Ref. C) 190 N·m (140 lbf·ft).
13. Check the belt tension again, and adjust if needed.
14. If installing a new belt, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

    If necessary, adjust the belt to 45 kg (100 lb).

Fan Belt Replacement, Detroit Diesel Series 50 Engine

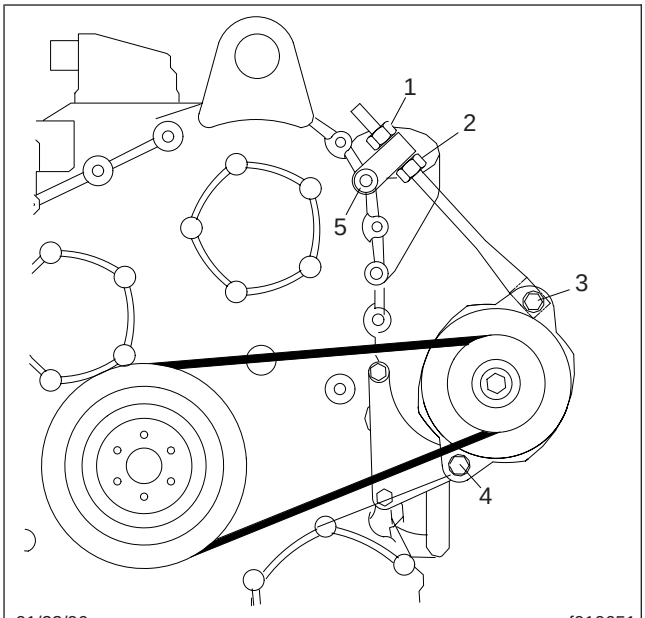
Replacement (See Fig. 1)

1. Loosen the four mounting capscrews that attach the fan hub to the engine.
2. Loosen the adjusting rod to relieve tension from the belts.
3. Remove the belts by slipping them off the pulleys and working them over one fan blade at a time. On some vehicles, it may be necessary to remove the fan blade. For instructions, refer to the engine cooling section of this manual. Don't roll or pry the belts off the pulleys; the distance between the pulley centers must be short enough to allow belt removal without using force.

1. Adjusting Rod
2. Mounting Capscrews

Fig. 1, Fan Belt Adjustment

4. Inspect the pulleys and belts (even if installing new belts) as instructed in **"Pulley and Drive Belt Inspection."**
5. Work the belts over the fan blades, one blade at a time. Install the belts on the pulleys without prying or rolling them into place.
6. While keeping the belts seated in the pulley grooves, turn the adjusting rod to increase belt tension. Use your thumb to apply about 25 lb (11 kg) of force at the center of the longest belt free-span to check the tension while turning the adjusting rod.
7. When belt deflection is about 1/2 to 3/4 inch (13 to 19 mm), install a belt tension gauge at the center of the belt's longest free-span.
8. Turn the adjusting rod to increase or decrease belt tension. Final tension must be 60 to 80 lb (27 to 36 kg).



IMPORTANT: Do not overtighten the belts; too much tension shortens belt and bearing life.

9. Tighten the fan hub mounting capscrews 75 to 83 lbf·ft (100 to 112 N·m).
10. Check the belt tension and adjust it if needed.
11. Operate the engine for about 30 minutes (or 15 miles), then check the belt tension. Check again after 8 hours (or 250 miles). Adjust belt tension as needed.

Alternator Belt Replacement, Detroit Diesel Series 50 Engine

Replacement (Refer to Fig. 1)

1. Back off the adjusting rod nut.
2. Loosen the adjusting rod guide mounting bolt.
3. Loosen the adjusting rod mounting bolt.
4. Loosen the alternator mounting bolt.
5. Turn the adjusting rod jam nut to rotate the alternator up and toward the engine. Turn the nut until the alternator is close enough to the engine to allow belt removal. Remove the belts by slipping them off the pulleys and working them over one fan blade at a time. Don't roll or pry the belts off the pulleys; the distance between the pulley centers must be short enough to allow belt removal without using force.

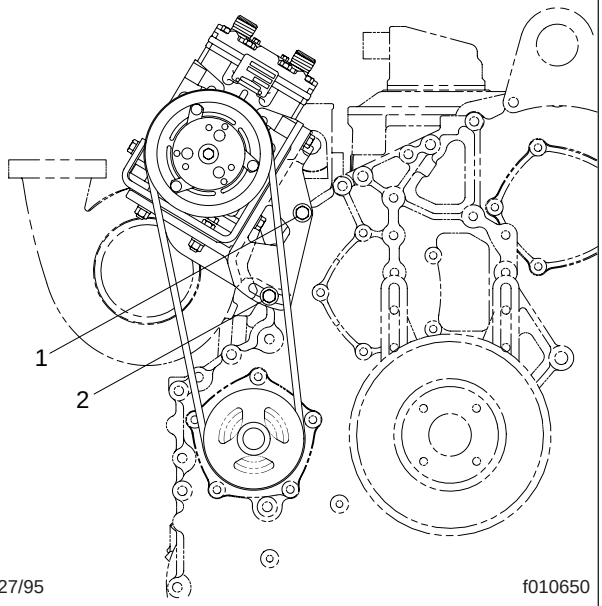
7. Work the belts over the fan blades, one blade at a time. Install the belts on the pulleys without prying or rolling them into place.
8. Install a belt tension gauge at the center of the belt's longest free-span.
9. While keeping the belts seated in the pulley grooves, turn the adjusting rod nut to rotate the alternator away from the engine and increase belt tension. Turn the adjusting rod nut until final belt tension is 60 to 80 lb (27 to 36 kg).



IMPORTANT: Do not overtighten the belts; too much tension shortens belt and bearing life.

10. Tighten the adjusting rod jam nut 176 N·m (130 lbf·ft).
11. Tighten the alternator mounting bolt and the adjusting rod mounting bolt 123 N·m (91 lbf·ft).
12. Tighten the adjusting rod guide mounting bolt 46 N·m (34 lbf·ft).
13. Operate the engine for about 30 minutes (or 15 miles), then check the belt tension. Check again after 8 hours (or 250 miles). Adjust belt tension as needed.

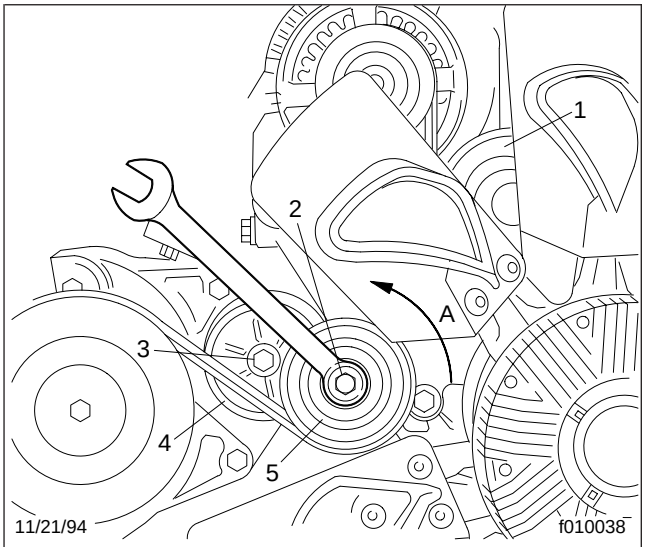
2. Rotate the compressor downward, toward the engine to allow belt removal without using force.
3. Remove the belt without prying or rolling it off the pulleys.
4. Inspect the pulleys and belts (even if installing new belts) as instructed in **"Pulley and Drive Belt Inspection."**
5. Loop the belt around the pulleys.
6. Install a belt tension gauge at the center of the belt's longest free-span.
7. While keeping the belt seated in the pulley grooves, rotate the compressor up and away from the engine until the belt is tensioned 41 to 45 kg (90 to 100 lb).



IMPORTANT: Do not overtighten the belts; too much tension shortens belt and bearing life.

8. Tighten the compressor mounting and adjustment capscrews 46 N·m (34 lbf·ft).
9. Operate the engine for about 30 minutes (or 15 miles), then check the belt tension. Check again after 8 hours (or 250 miles). Adjust belt tension as needed.

CAUTION

When installing a serpentine drive belt, route the belt correctly. If the belt is not routed correctly, the water pump pulley may rotate in the wrong direction, allowing the engine to overheat.

NOTE: If the pulley must be removed from the automatic belt tensioner: The pulley bolt has left hand threads.

4. Position the drive belt over all the pulleys *except the drive belt tensioner.* For the correct belt routing, **see Fig. 2** and **Fig. 3**.

5. Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner. Finish installing the belt. **See Fig. 1.**
6. Correct drive belt tension is required for optimum performance of belt-driven engine accessories. If the specified belt tension is not maintained, check and repair the following:

   Make sure the correct belt is installed.

   Make sure the belt is routed correctly.

   Check for worn bearings on all the engine accessory pulleys.

   Check for a loose engine accessory pulley.

   Check for misalignment between accessory pulleys.

CAUTION

When installing a serpentine drive belt, route the belt correctly. If the belt is not routed correctly, the water pump pulley may rotate in the wrong direction, allowing the engine to overheat.

4. Position the drive belt over all the pulleys *except the drive belt tensioner.* For the correct belt routing, **see Fig. 1**.
5. Insert a 1/2-inch rachet drive into the square hole in the belt tensioner, and turn the tensioner clockwise. **See Fig. 1.**
6. Position the tensioner against the belt, and remove the rachet drive from the tensioner.

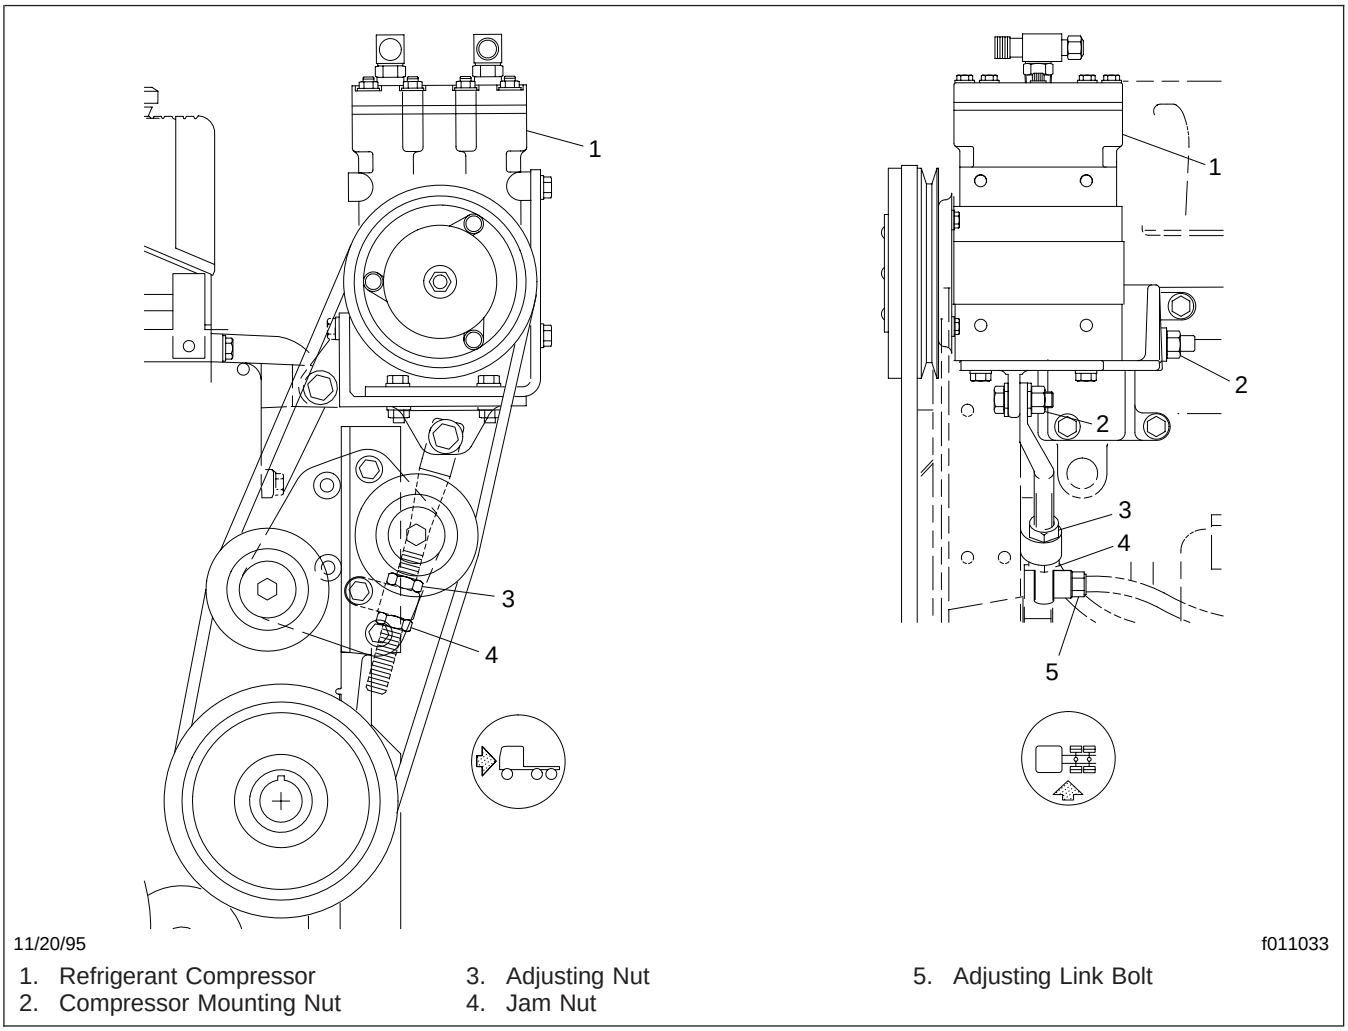
Replacement (See Fig.1or Fig.2)



1. Refrigerant Compressor
2. Compressor Mounting Nut
3. Jam Nut
4. Adjusting Nut
5. Adjusting Link Bolt

Fig. 1, Rotary-Type Compressor Installation

1. Remove the belt.
   - 1.1 Back off the adjusting nut. Loosen the mounting nuts and the adjusting link bolt just enough to allow movement of the compressor.
   - 1.2 Push the loosened compressor toward the drive pulley until the distance between them is short enough to allow belt removal without using force.
   - 1.3 Remove the belt, without prying or rolling it off of the pulleys.
2. Install the belt.
   - 2.1 Inspect the pulleys and used refrigerant compressor belt (even if a new belt is being installed) as instructed in **Subject 100**.

3. Adjusting Nut
4. Jam Nut
5. Adjusting Link Bolt

Fig. 2, Piston-Type Compressor Installation

2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.

2.3 Install the belt on the pulleys without prying or rolling it into place.

2.4 Back off the jam nut to the end of the adjusting rod.

2.5 While keeping the belt seated in the pulley grooves, turn the adjusting nut against the adjusting link to increase belt tension. Use your thumb to apply about 11 kg (25 lbs) of force at the center of the belt free-span to check the tension while turning the nut. When belt deflection equals one belt thickness per 305 mm (1 foot) of pulley-center distance, stop.

3. Adjust the belt.

3.1 If not already done, back off the adjusting link jam nut to the end of the adjusting rod, and loosen the mounting nuts and adjusting link bolt just enough to allow movement of the compressor.

3.2 Install a belt tension gauge at the center of the belt free-span.

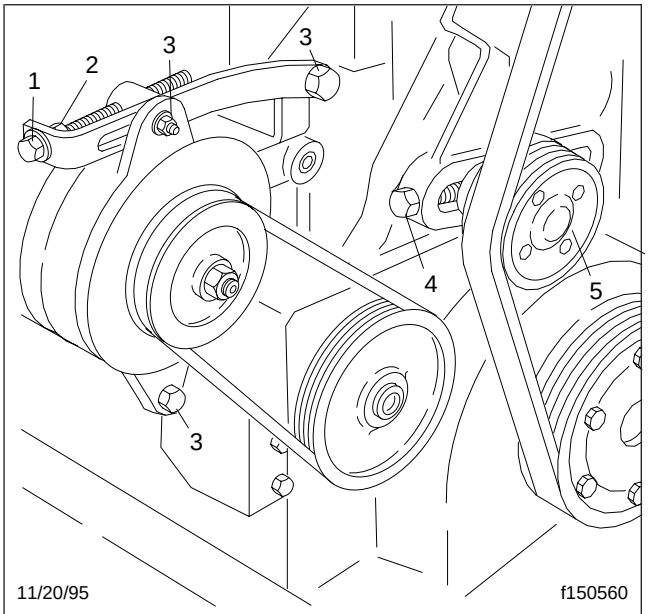
3.3 Turn the adjusting nut to adjust the tension to a reading of 59 kg (130 lbs) for a new belt, or 36 to 45 kg (80 to 100 lbs)

for a used belt. A used belt is any belt that has been in operation more than ten minutes.

IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

3.4 Tighten the adjusting link jam nut 210 N·m (155 lbf·ft).

3.5 Tighten the compressor mounting nuts 41 N·m (30 lbf·ft), and the adjusting link bolt 88 N·m (65 lbf·ft).



3.6 Check the belt tension, and adjust it if needed.

3.7 If a new refrigerant compressor belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

3.8 If the refrigerant compressor belt tension is not between 36 to 45 kg (80 and 100 lbs), adjust the tension to 45 kg (100 lbs).

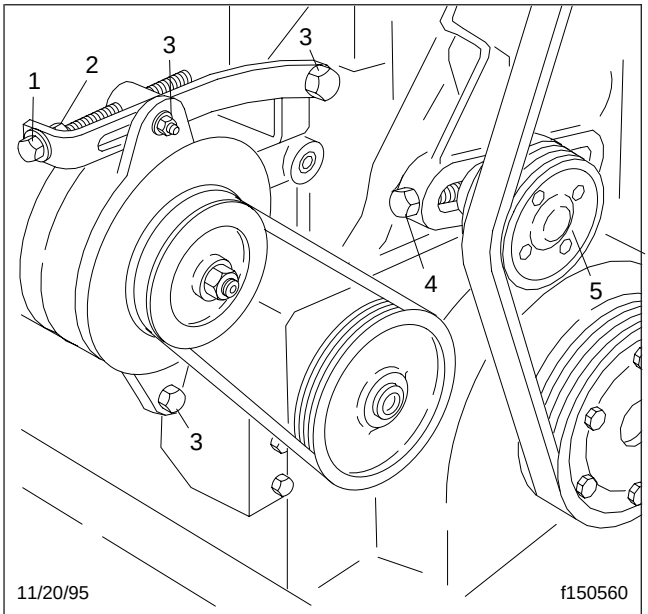
1. Adjusting Screw
2. Adjusting Screw Jam Nut
3. Alternator Mounting Fastener
4. Idler Pulley Adjustment Capscrew
5. Idler Pulley

Fig. 1, Fan and Alternator Belt Installation



1. Remove the belt.
   - 1.1 Loosen the locknut that secures the idler pulley to the fan bracket.
   - 1.2 Turn the idler pulley adjustment capscrew until there is minimal distance between the pulley centers.
   - 1.3 Remove the fan belt by slipping it off of the pulleys and working it over one fan blade at a time. Don't roll or pry the belt off of the pulleys; the distance between the pulley centers must be short enough to allow belt removal without using force.
2. Install the belt.
   - 2.1 Inspect the pulleys and used fan belt (even if a new belt is being installed) as instructed in **Subject 100**.
   - 2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.
   - 2.3 Work the belt over the fan blades, one blade at a time. Install the belt on the pulleys without prying or rolling it into place. Be sure the ribs on the belt are seated in the grooves on each pulley.
   - 2.4 While keeping the belt seated in the pulley grooves, turn the idler pulley adjustment capscrew to increase the belt tension. Use your thumb to apply about 11 kg (25 lbs) of force at the center of the belt free-span to check the tension while turning the capscrew. When belt deflection equals one belt thickness per 305 mm (1 foot) of pulley-center distance, stop.
3. Adjust the belt.
   - 3.1 If not already done, loosen the locknut that secures the idler pulley to the fan bracket.
   - 3.2 Install a belt tension gauge at the center of the belt's longest free-span.
   - 3.3 Turn the idler pulley adjustment capscrew to increase or decrease belt tension, but do not adjust the tension to the full value with the idler pulley adjustment capscrew; belt tension can increase when the idler pulley locknut is tightened. Final tension must be 36 to 45 kg (80 and 100 lbs).

   IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.

   - 3.4 Tighten the idler pulley locknut 163 to 190 N·m (120 to 140 lbf·ft).
   - 3.5 Loosen the idler pulley adjustment capscrew one-half turn, to prevent breakage.
   - 3.6 Check the belt tension, and adjust it if needed.
   - 3.7 If a new fan belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.
   - 3.8 If the fan belt tension is not between 36 to 45 kg (80 and 100 lbs), adjust the tension.

1. Remove the belt.
   - 1.1 Loosen the three mounting fasteners just enough to allow movement of the alternator.
   - 1.2 Loosen the adjusting screw jam nut.
   - 1.3 Turn the adjusting screw counterclockwise, backing off the alternator toward the drive pulley far enough to allow belt removal without using force.
   - 1.4 Remove the belt, without prying or rolling it off of the pulleys.
2. Install the belt.
   - 2.1 Inspect the pulleys and used alternator belt (even if a new belt is being installed) as instructed in **Subject 100**.
   - 2.2 Make sure the distance between the pulleys is short enough to allow belt installation without using force.
   - 2.3 Install the belt on the pulleys without prying or rolling it into place. Be sure the ribs on the belt are seated in the grooves on each pulley.
   - 2.4 While keeping the belt seated in the pulley grooves, turn the adjusting screw clockwise to increase the belt tension. Use your thumb to apply about 11 kg (25 lbs) of force at the center of the belt free-span to check the tension while turning the adjusting screw. When belt deflection equals one belt thickness per 305 mm (1 foot) of pulley-center distance, stop.
3. Adjust the belt.
   - 3.1 If not already done, loosen the adjusting screw locknut, and loosen the three mounting fasteners, just enough to allow movement of the alternator.
   - 3.2 Install a belt tension gauge at the center of the belt free-span.
   - 3.3 Turn the adjusting screw to adjust the tension to a reading of 36 to 45 kg (80 and 100 lbs).

   IMPORTANT: Do not overtighten the belt; too much tension shortens belt life and bearing life.
   - 3.4 Tighten the adjusting screw locknut 129 N·m (95 lbf·ft).
   - 3.5 Tighten the alternator mounting fastener 81 N·m (60 lbf·ft), the adjusting block nut 47 N·m (35 lbf·ft), and the adjusting arm bolt 75 N·m (55 lbf·ft).
   - 3.6 Check the belt tension, and adjust it if needed.
   - 3.7 If a new alternator belt was installed, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.
   - 3.8 If the alternator belt tension is not 36 to 45 kg (80 and 100 lbs), adjust the tension.

General Description

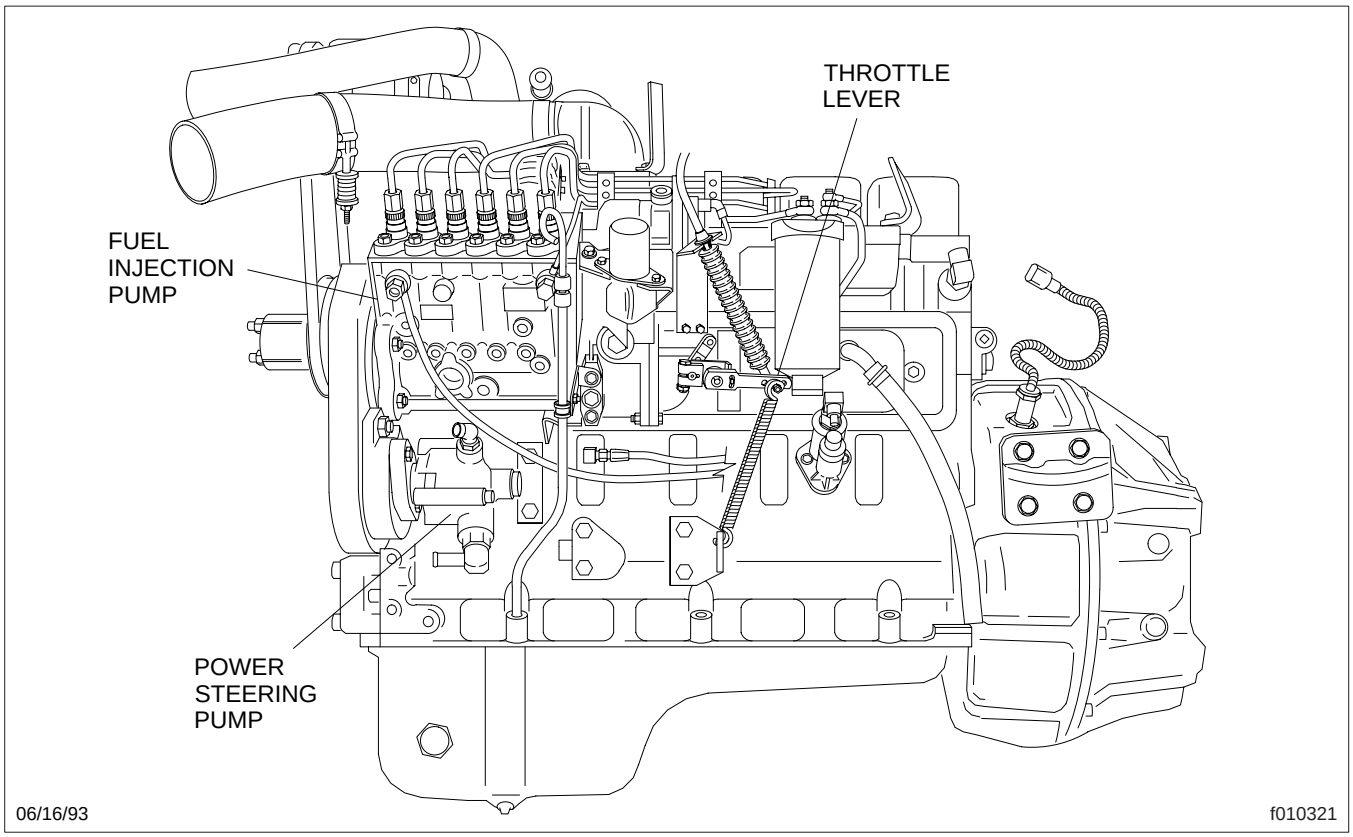

Fig. 1

The Cummins B Series engine **(see Fig. 1 and Fig. 2)** is supported by three engine mounts: two are at the rear of the engine— one on each side— and fastened to the frame rails. The other is at the front of the engine, fastened to the underslung crossmember.

Because the engine provides the main support for the transmission, removing them as an assembly is easier than disconnecting them, if the engine has to be removed.

For detailed repair procedures and other engine service not covered in this section, refer to the *Cummins B Series Operation and Maintenance Manual* , *Cummins Troubleshooting and Repair Manual B Series* , and *Cummins Workshop Manual B Series* .

General Description

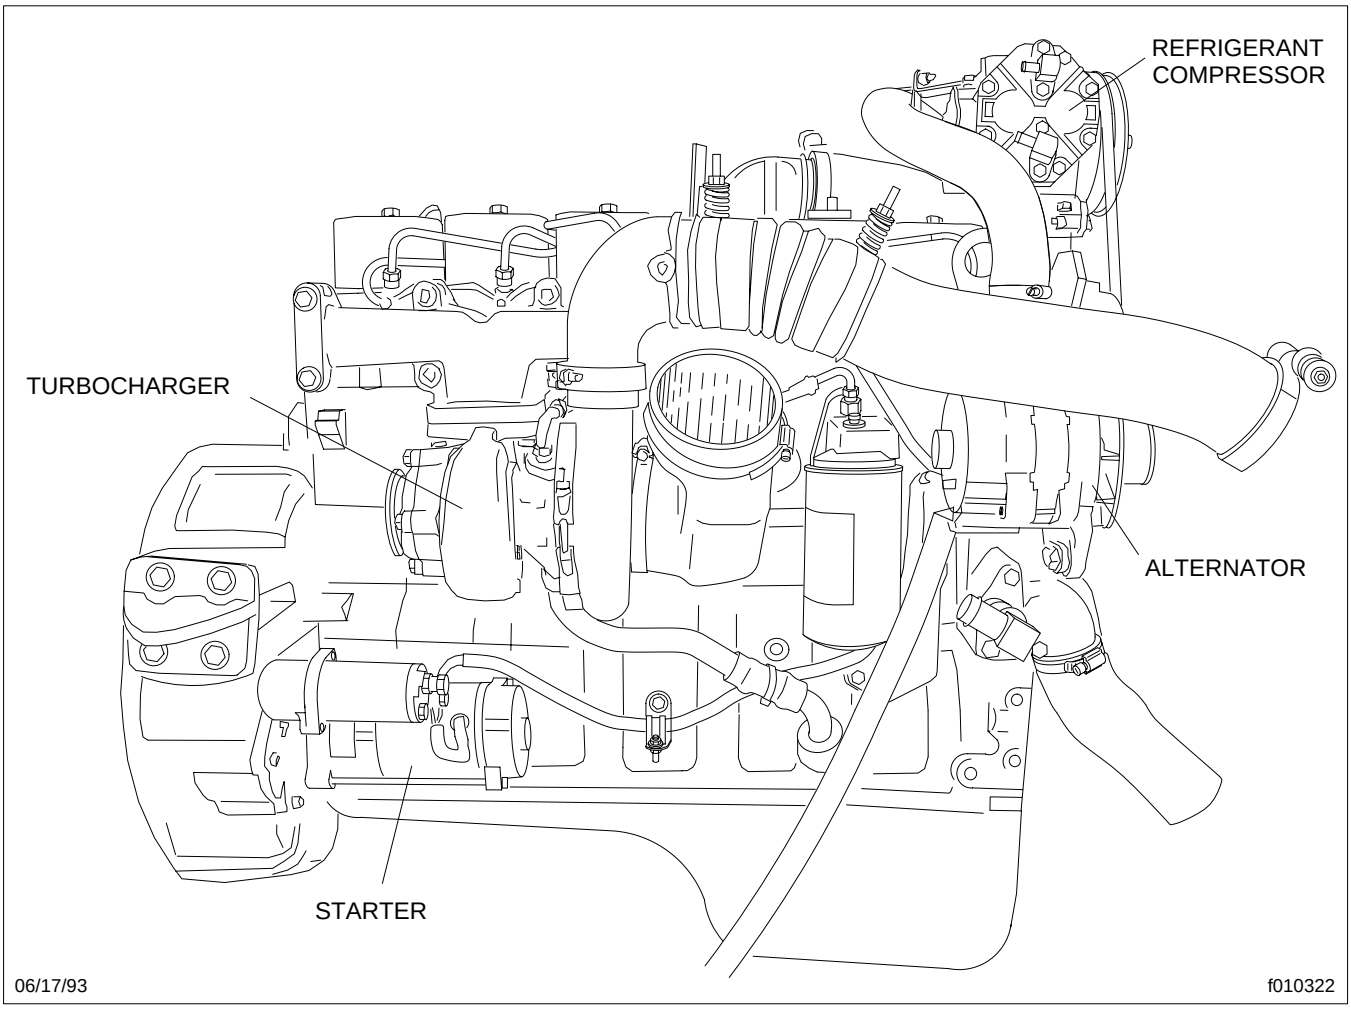

Fig. 2

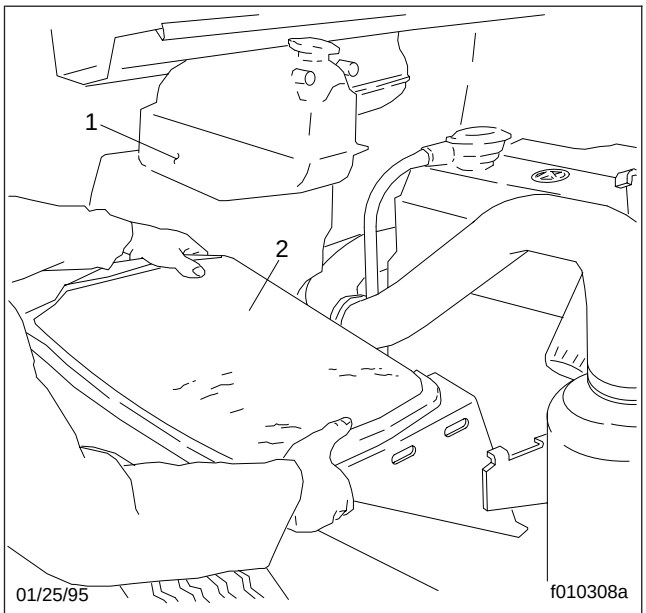
Removal



NOTE: Because the transmission is supported entirely by the engine, removing them as an assembly (as described below) is easier than disconnecting them and removing the engine only.

1. Apply the parking brakes, chock the tires, and (if applicable) drain the air system.
2. Disconnect the batteries or, if the vehicle is equipped with a battery shutoff switch, turn off the switch.
   - 2.1 Disconnect the battery ground cable at the vehicle frame.
   - 2.2 Disconnect the positive battery cable from the batteries.
3. Remove the hood and bumper. For instructions, see **Group 88**.
4. Drain the radiator.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

   - 4.1 Open the petcock at the bottom of the radiator to drain the engine coolant.
   - 4.2 Loosen the surge tank cap.
5. Remove the right fender splash shield. See **Fig. 1**.
6. Remove the air cleaner.
   - 6.1 Remove the air intake pipe from the top of the air cleaner. See **Fig. 2**.
   - 6.2 Remove the four nuts from the inside of the air cleaner mounting bracket. See **Fig. 3**.
   - 6.3 Remove the air cleaner from its mounting bracket.
7. Disconnect or remove the air intake, exhaust pipe, and hoses.
   - 7.1 If the vehicle is equipped with air brakes, disconnect the air compressor outlet line.

1. Surge Tank
2. Splash Shield

Fig. 1, Remove the Right Fender Splash Shield

   - 7.2 If the vehicle is equipped with air brakes, disconnect the two air signal lines from the air governor at the top of the compressor.
   - 7.3 Disconnect the air inlet and outlet hoses from the charge air cooler. See **Fig. 4**.
   - 7.4 Disconnect the air intake pipe from the turbocharger. See **Fig. 2**.
   - 7.5 Disconnect the V-clamp connecting the exhaust pipe to the rear of the turbocharger. Remove the pipe from the turbocharger.
8. Disconnect the coolant hoses.
   - 8.1 Disconnect the coolant inlet and outlet hoses from the radiator. See **Fig. 4**.
   - 8.2 Disconnect the vent hose from the radiator, and remove the hose bracket from the condenser mounting bolt. See **Fig. 4**.
   - 8.3 Disconnect the fill hose from the bottom of the surge tank.
   - 8.4 Disconnect the heater inlet hose at the valve near the firewall. See **Fig. 5**.

Removal and Installation

8.5 Disconnect the heater outlet hose at the firewall. See **Fig. 5**.

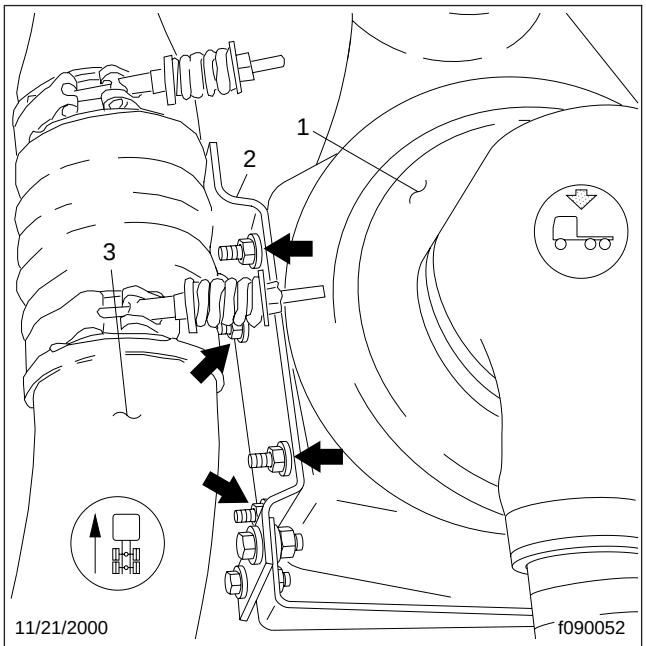
9. Remove the refrigerant compressor and condenser.

9.1 Disconnect the compressor electrical connectors.

1. Air Intake Pipe
2. Turbocharger

Fig. 2, Air Intake Pipe

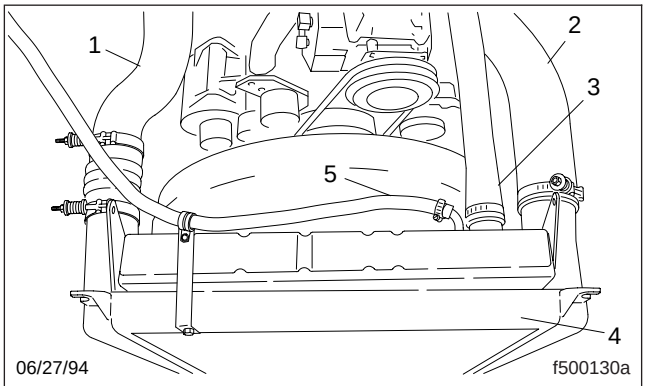
9.2 Remove the adjusting rod jam nut. See **Fig. 6**, Ref. 3.



9.3 Back off the adjusting nut (**Fig. 6**, Ref. 2), and remove the belt running between the compressor and the vibration damper.

9.4 Remove the two bolts securing the compressor to its mount. See **Fig. 6**, Ref. 1.

9.5 Remove the four bolts holding the condenser to the charge air cooler. See **Fig. 7**.



9.6 To keep the refrigerant system intact, with no leaks and no need for purging and recharging, move the condenser and the refrigerant compressor to the side at the same time. See **Fig. 8**.

9.7 Wrap the condenser in a protective blanket, or sandwich it between two sheets of cardboard or wood to prevent damage to the condenser fins. Secure the compressor and condenser out of the way with wire. See **Fig. 9**.

11. Remove the two power steering pump mounting bolts, and move the pump aside while keeping the steering fluid system intact.

12. Disconnect the engine fuel and oil system components.

12.1 Disconnect the fuel delivery line below the fuel filter. See **Fig. 13**.

12.2 Disconnect both ends of the throttle return springs. See **Fig. 13**.

12.3 Disconnect the throttle cable from the cable bracket and the engine throttle lever. See **Fig. 13**.

12.4 Disconnect the fuel return line from the injection pump. See **Fig. 14**.

12.5 Disconnect the oil pressure gauge line under the fuel injection pump. See **Fig. 14**.

12.6 Disconnect the turbocharger oil return line at the turbocharger.

13. Disconnect the engine electrical connections.

13.1 Disconnect the ground strap from the engine.

13.2 Disconnect the wires from the starter and label them for reassembly. See **Fig. 15**.

13.3 Disconnect the engine wiring harness from the rear of the alternator, then the coolant temperature sensors, the refrigerant compressor clutch, the fuel shutoff solenoid, and other applicable options.

13.4 Remove the heat shield from the wiring harness routed above the exhaust pipe.

16. Remove the engine from the vehicle.

⚠ WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

16.4 Carefully lift the engine and pull it forward to remove it from the engine compartment. See **Fig. 25**.

Installation

1. Examine all engine support components for damage and extreme wear. Replace components as necessary.
2. Install the engine in the vehicle.

⚠ WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

A. Use a crane to lift the radiator and charge air cooler.

tighten the shield bolt 15 lbf·ft (20 N·m). See **Fig. 10**.

10. Install the air conditioning components on the engine.
    - 10.1 Carefully move the refrigerant compressor and condenser back into place.
    - 10.2 Install the four bolts to hold the condenser in place over the charge air cooler. See **Fig. 7**. Tighten the bolts 15 lbf·ft (20 N·m).
    - 10.3 Position the compressor on its mount, and insert the two mounting bolts. See **Fig. 6**, Ref. A.
    - 10.4 Insert the adjusting rod through the compressor mount. See **Fig. 6**.
    - 10.5 Install the compressor drive belt on the compressor pulley and tighten the belt. For instructions, refer to "Drive Belts" in this group. Tighten the adjusting rod jam nut 59 lbf·ft (80 N·m). See **Fig. 6**, Ref. C.
    - 10.6 Tighten the compressor mounting bolt nuts 59 lbf·ft (80 N·m). See **Fig. 6**, Ref. A.
    - 10.7 Connect the compressor electrical connectors to the wiring harness.
11. Connect the coolant hoses.
    - 11.1 Connect the heater outlet hose at the firewall. See **Fig. 5**.

    - 11.4 Connect the coolant inlet and outlet hoses to the radiator. See **Fig. 4**.
    - 11.5 Connect the fill hose to the bottom of the surge tank.
12. Connect or install the air intake, exhaust pipe, and hoses.
    - 12.1 Connect the air inlet and outlet hoses to the charge air cooler. See **Fig. 4**. Tighten the hose clamps 60 lbf·in (680 N·cm).
    - 12.2 Connect the exhaust pipe to the rear of the turbocharger, and install the V-clamp that secures the pipe. Tighten the V-clamp 85 lbf·in (940 N·cm).
    - 12.3 Install the air intake pipe on the turbocharger. See **Fig. 2**.
    - 12.4 If the vehicle is equipped with air brakes, connect the air outlet line to the air compressor.
    - 12.5 If the vehicle is equipped with air brakes, connect the two air signal lines to the air governor on top of the compressor.
13. Install the air cleaner.
    - 13.1 Position the air cleaner on its bracket, and secure the cleaner with four nuts. See **Fig. 3**. Tighten the nuts 28 lbf·ft (38 N·m).
    - 13.2 Connect the air intake pipe to the top of the air cleaner. See **Fig. 2**.

Removal and Installation

14. Install the right fender splash shield. See **Fig. 1**.
15. Install the bumper and hood. For instructions, see **Group 88**.
16. Connect the batteries or, if the vehicle is equipped with a battery shutoff switch, turn on the switch.
    - 16.1 Connect the positive battery cable to the batteries.
    - 16.2 Connect the battery ground cable to the vehicle frame.
17. Fill the engine coolant system.
    - 17.1 Close the petcock on the bottom of the radiator.
    - 17.2 Fill the system with coolant at the surge tank. For coolant specifications, see the vehicle maintenance manual.
    - 17.3 Tighten the surge tank cap.
18. Start the engine and check for leaks. Eliminate any leaks.
19. After the engine has run for about 20 minutes, check the coolant level and add coolant if needed.
20. Fill and bleed the power steering system as needed. For instructions, see **Group 46**.
21. Lower the hood, and remove the chocks from the tires.

General Description

The Mercedes-Benz OM 366LA engine **(see Fig. 1 and Fig. 2)** is supported by three engine mounts: two are at the rear of the engine— one on each side— and fastened to the frame rails. The other is at the front of the engine, fastened to the underslung crossmember.

Because the engine provides the main support for the transmission, removing them as an as-sembly is easier than disconnecting them, if the engine has to be removed. To further save time and expense, the refrigerant system remains intact simply by moving the refrigerant compressor and condenser out of the way, before lifting out the engine.

For detailed repair procedures and other engine service not covered in this section, refer to the Mercedes-Benz *Engine Model OM 366LA Workshop Manual* .

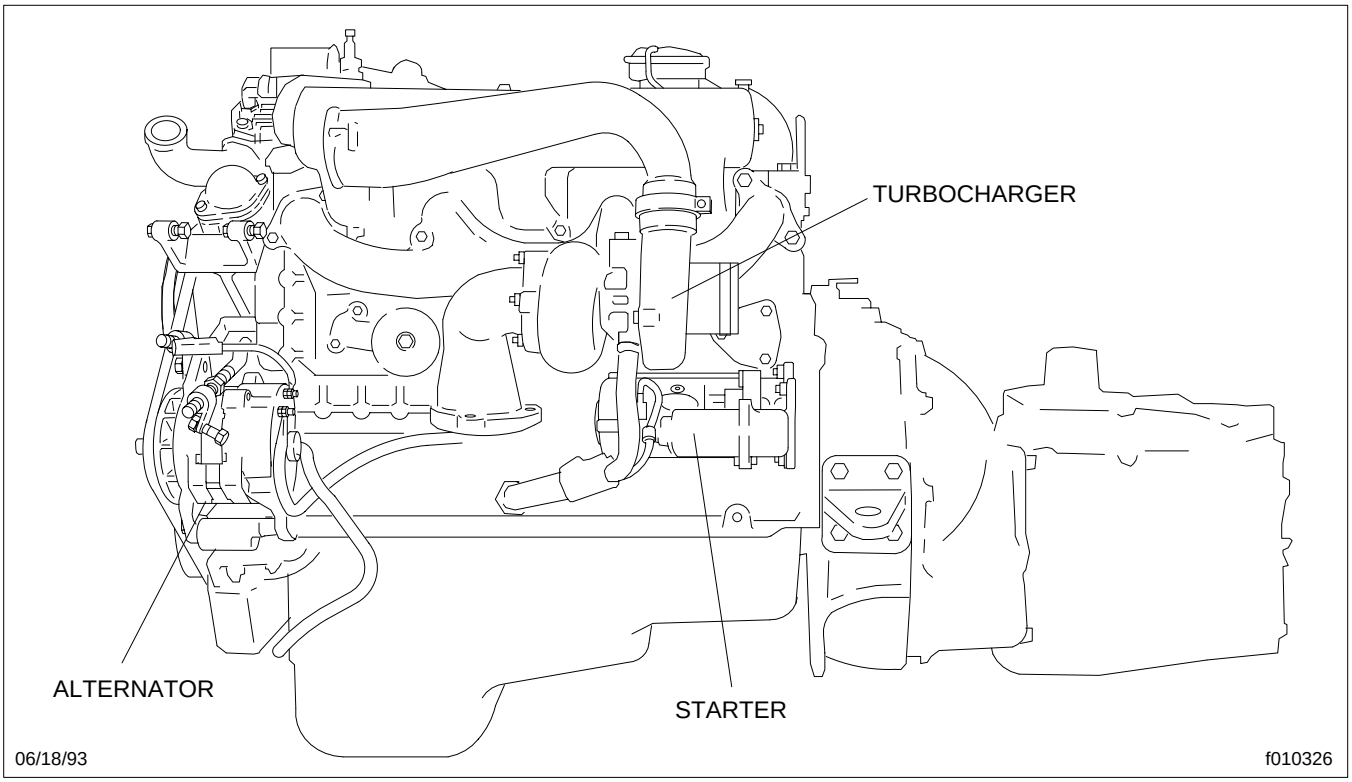

Fig. 1

General Description

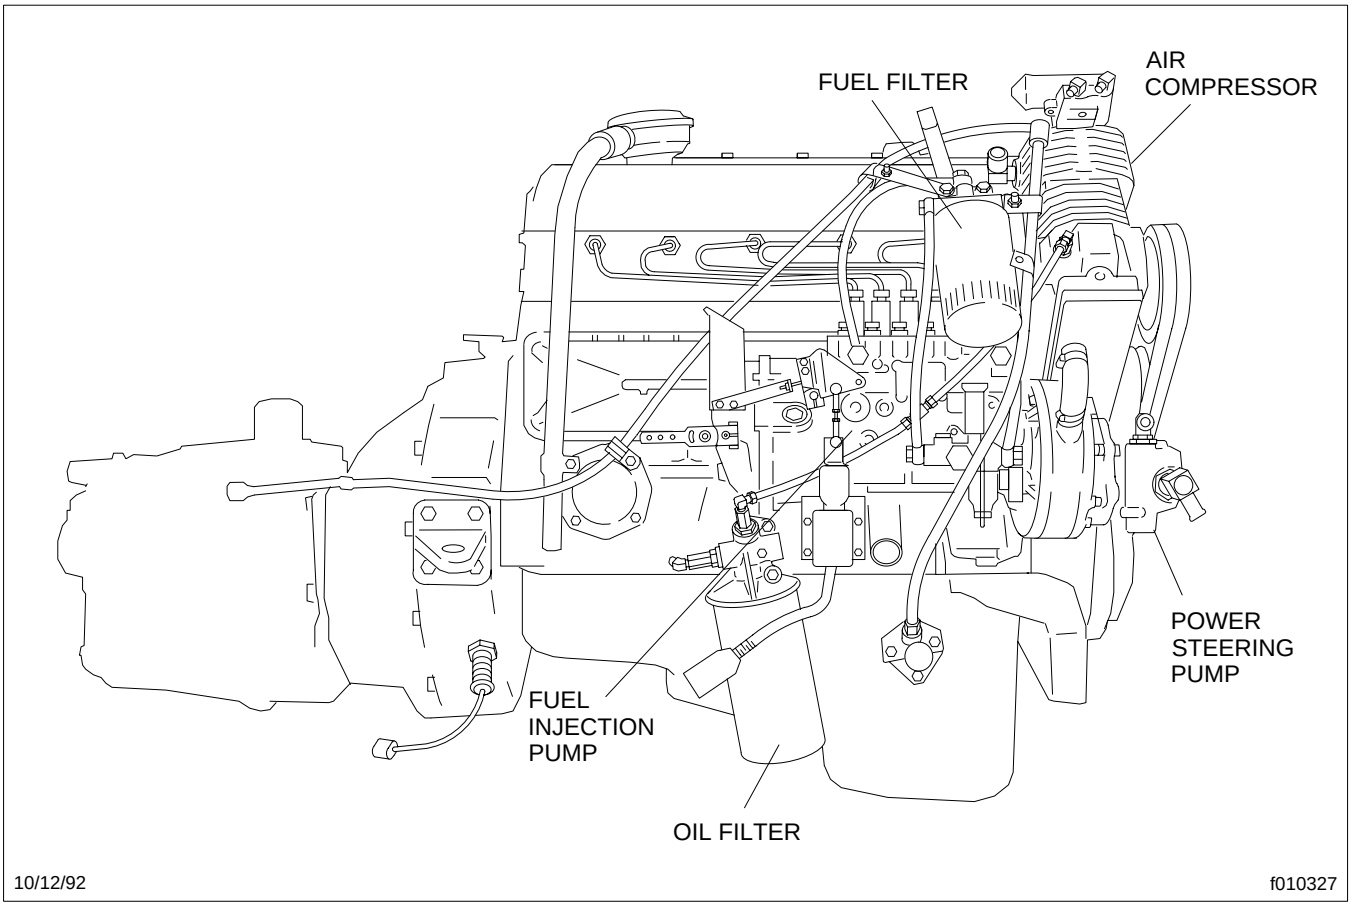

Fig. 2

Removal

NOTE: Because the transmission is supported entirely by the engine, removing them as an assembly (as described below) is easier than disconnecting them and removing the engine only.

1. Apply the parking brakes, chock the tires, and (if applicable) drain the air brake system.
2. Disconnect the batteries or, if the vehicle is equipped with a battery shutoff switch, turn off the switch.
   - 2.1 Disconnect the battery ground cable at the vehicle frame.
   - 2.2 Disconnect the positive battery cable from the batteries.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

3. Drain the radiator.
   - 3.1 Open the petcock at the bottom of the radiator to drain the engine coolant.
   - 3.2 Loosen the surge tank cap.
4. Remove the hood and bumper. For instructions, see **Group 88**.
5. Remove the right fender splash shield. See **Fig. 1**.
6. Remove the air cleaner.
   - 6.1 Remove the air intake pipe from the top of the air cleaner. See **Fig. 2**.
   - 6.2 Remove the four nuts from the inside of the air cleaner mounting bracket. See **Fig. 3**.
   - 6.3 Remove the air cleaner from its mounting bracket.
7. Disconnect or remove the air intake, exhaust pipe, and hoses.
   - 7.1 If the vehicle is equipped with air brakes, disconnect the compressor air intake hose from the air intake pipe. See **Fig. 4**.

governor on top of the air compressor. See **Fig. 5**, Ref. A.

7.3 Disconnect the compressor outlet line. See **Fig. 6**.

7.4 Remove the air intake pipe from the pipe around the rear of the engine.

7.5 Remove the air intake pipe routed around the rear of the engine to the turbocharger. Two screws secure the pipe to the rear of the engine, and a clamp holds it to the turbocharger. See **Fig. 7**.

7.6 Disconnect the air inlet and outlet hoses from the aftercooler. See **Fig. 8**.

7.7 Disconnect the exhaust pipe from the rear of the turbocharger. Remove the bracket holding the exhaust pipe to the engine. See **Fig. 9**.

8. Disconnect or remove the coolant hoses.

8.1 Disconnect the fill hose from the bottom of the surge tank and the heater inlet hose from the valve at the firewall. See **Fig. 10** and **Fig. 11**. With the heater and fill hoses attached, remove the coolant outlet hose between the engine and the bottom of the radiator. See **Fig. 12**.

8.2 Disconnect the radiator inlet hose between the engine thermostat and the radiator. See **Fig. 8**.

8.3 Disconnect the surge tank vent hose from the radiator (see **Fig. 13**), and remove the hose bracket from the condenser. Disconnect the surge tank vent hose from the engine. See **Fig. 13**.

8.4 Disconnect the heater outlet hose running between the firewall and the engine (just behind the engine thermostat). See **Fig. 14**.

9. Remove the refrigerant compressor and condenser (see **Fig. 15**).

9.1 Disconnect the compressor electrical connectors.

9.2 Remove the adjusting rod guide from the adjusting rod.

9.3 Remove the belt running between the rear pulley of the compressor and the front pulley of the vibration damper.

9.4 Remove the two bolts securing the compressor to its mount.

9.5 Remove the four bolts holding the condenser to the aftercooler. See **Fig. 16**.

9.6 To keep the refrigerant system intact, with no leaks and no need for purging and recharging, move the condenser and the

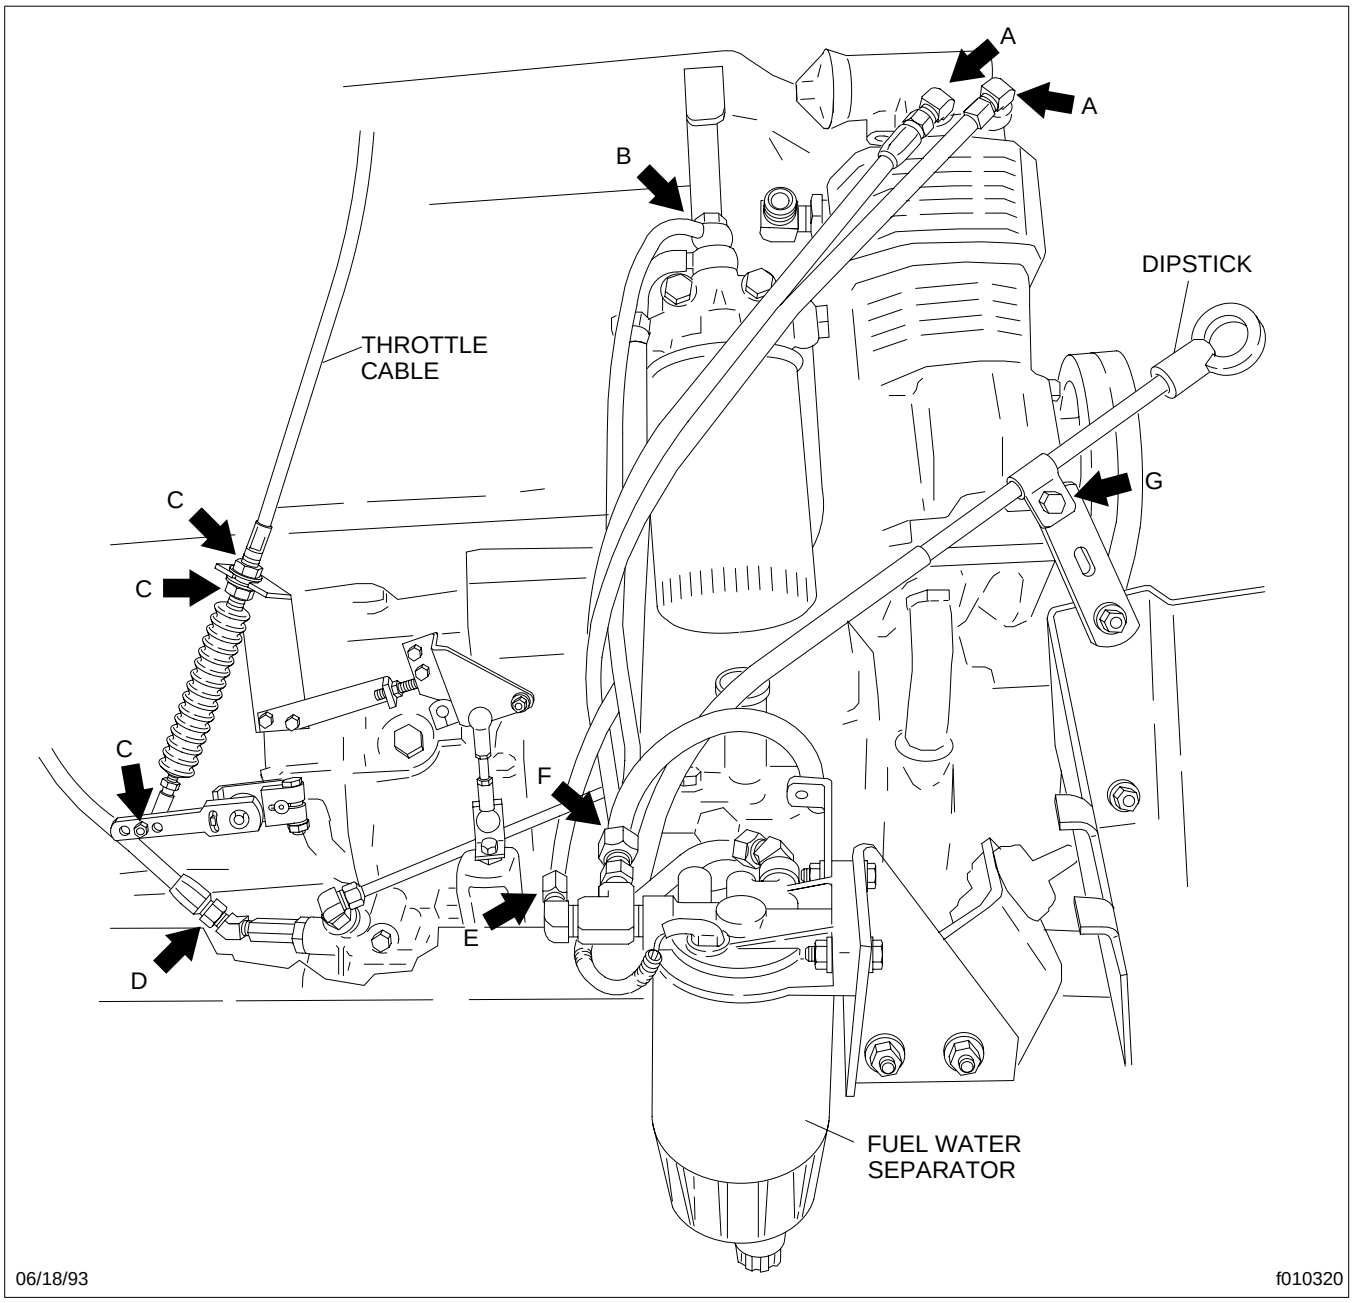

Fig. 5

refrigerant compressor to the side at the same time. See **Fig. 17**.

9.7 Wrap the condenser in a protective blanket, or sandwich it between two sheets of cardboard or wood to prevent damage to the condenser fins. Secure the compressor and condenser out of the way with wire. See **Fig. 18**.

10. Remove the radiator and aftercooler assembly.

Removal and Installation

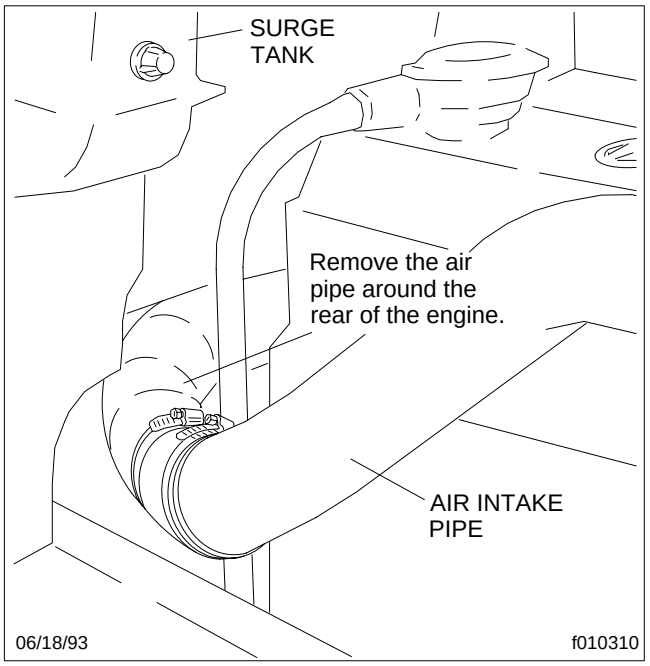

Fig. 7

10.1 Remove the left air recirculation shield to uncover the left aftercooler mounting tab. See **Fig. 19**.

10.2 Hook a lifting chain to the radiator and aftercooler assembly (see **Fig. 20**), and fasten the chain to a crane.

10.3 Remove the nuts, washers, and rubber isolators from the forward ends of the radiator struts. See **Fig. 21**.

10.4 Remove the nuts and washers from the radiator mounts. See **Fig. 21**.

10.5 Lift the radiator and aftercooler from the vehicle as a single unit. See **Fig. 20**.

11. Remove the two power steering pump mounting bolts, and move the pump aside while keeping the steering fluid system intact.

12. Disconnect the engine fuel and oil system components.

12.1 Remove the dipstick tube from the air cleaner mounting bracket. See **Fig. 5**, Ref. G.

12.2 Disconnect the throttle cable from the engine throttle arm and the throttle cable bracket. See **Fig. 5**, Ref. C.

12.3 Disconnect the oil pressure gauge line from the rear of the oil filter housing. See **Fig. 5**, Ref. D.

12.4 Disconnect the fuel return line running between the engine and the fuel water separator. See **Fig. 5** , Ref. E.

12.5 Disconnect the fuel delivery line from the fuel water separator. See **Fig. 5**, Ref. F.

12.6 Disconnect the fuel return line from the fuel filter. See **Fig. 5**, Ref. B.

12.7 Disconnect the turbocharger oil return line at the turbocharger.

13. Disconnect the engine electrical connections.

13.1 Disconnect the wiring connector for the fuel shutoff solenoid.

13.2 Remove the wiring ring terminals from the starter, and label them for reassembly. See **Fig. 22**.

13.3 Remove the alternator ground wire and engine ground strap from the frame rail.

13.4 Disconnect the engine wiring harness from the flame start (and other options as

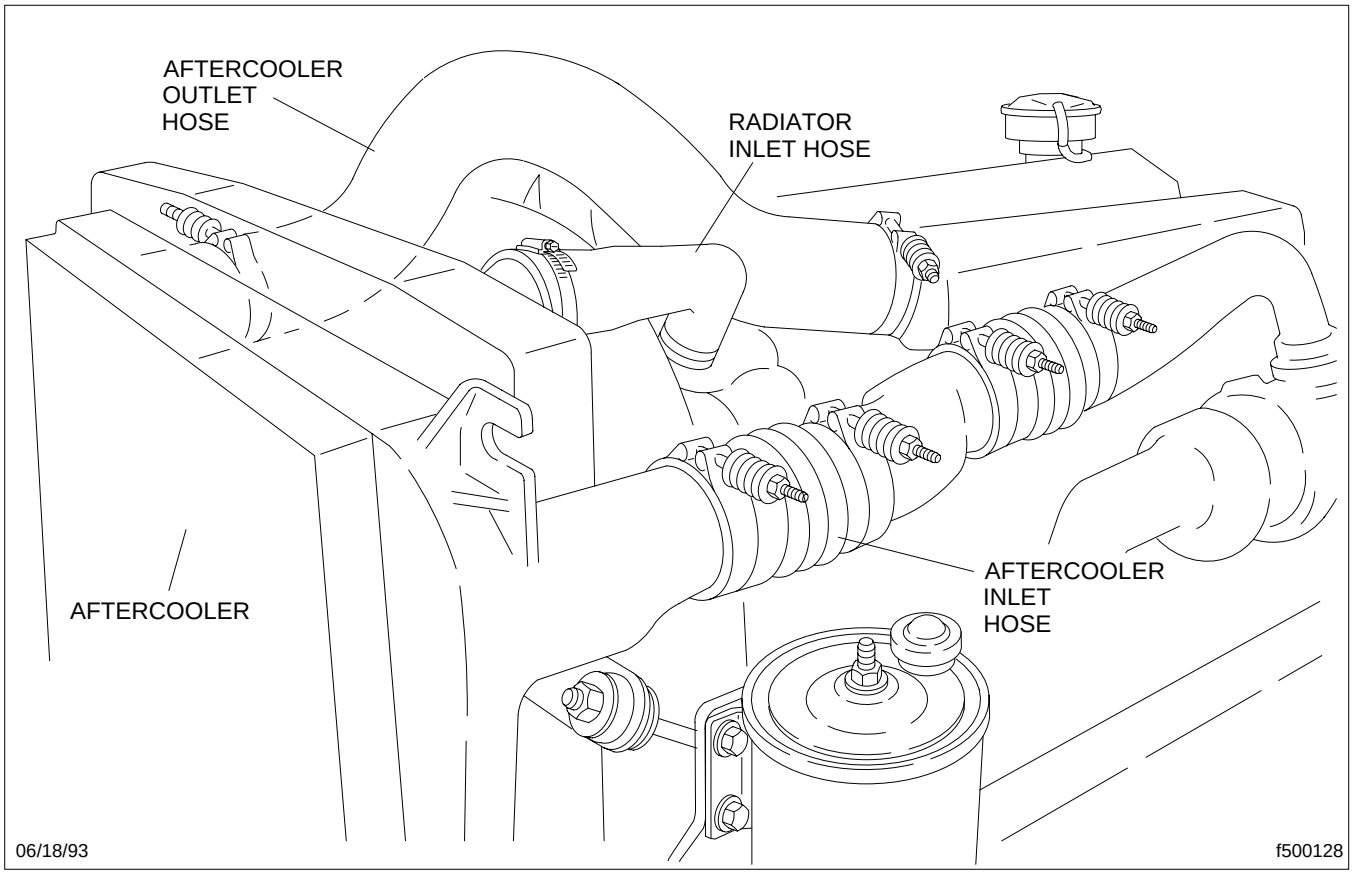

Fig. 8, Disconnect the Aftercooler Hoses and Radiator Inlet Hose

applicable), the coolant temperature sensors, and the alternator. Pull the harness off to the right side, away from the engine.

14. Disconnect the top of the left front shock absorber, and remove the top shock absorber mount from the frame rail.
15. Disconnect the transmission-mounted components.
    - 15.1 Remove the shift tower from the transmission. See **Fig. 23**. Cover the shift tower hole in the top of the transmission.
    - 15.2 Disconnect the back-up alarm sensor at the rear of the transmission. See **Fig. 24**.
    - 15.3 Disconnect the tachometer sensor at the engine flywheel. See **Fig. 24**.
    - 15.4 Disconnect the speedometer sensor at the transmission output. See **Fig. 24**.
    - 15.5 Remove the clevis pin from the clutch release lever, then remove the clutch slave cylinder from the clutch housing. See **Fig. 25**.
    - 15.6 Remove the driveshaft from the transmission output end yoke. For instructions, see **Group 41**.
    - 15.7 If the vehicle is equipped with air brakes, disconnect the air compressor outlet line from the chassis air delivery line, and remove the outlet line from the bracket mounted on the transmission bell housing. See **Fig. 24**.
16. Remove the engine from the vehicle.

Removal and Installation

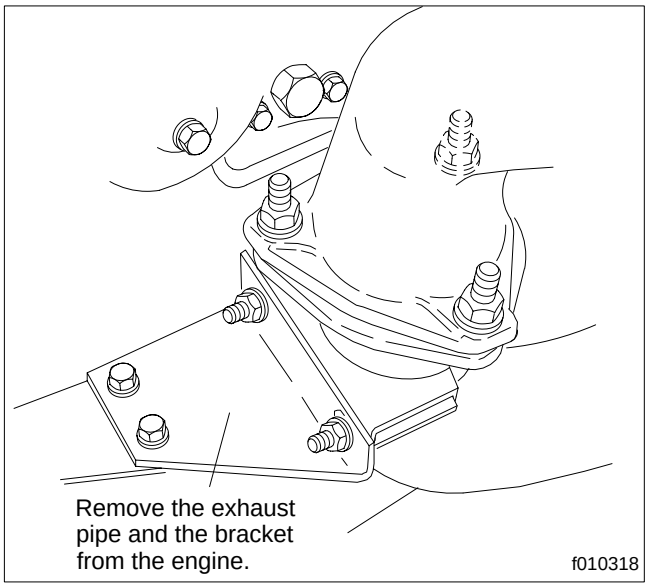

Fig. 9

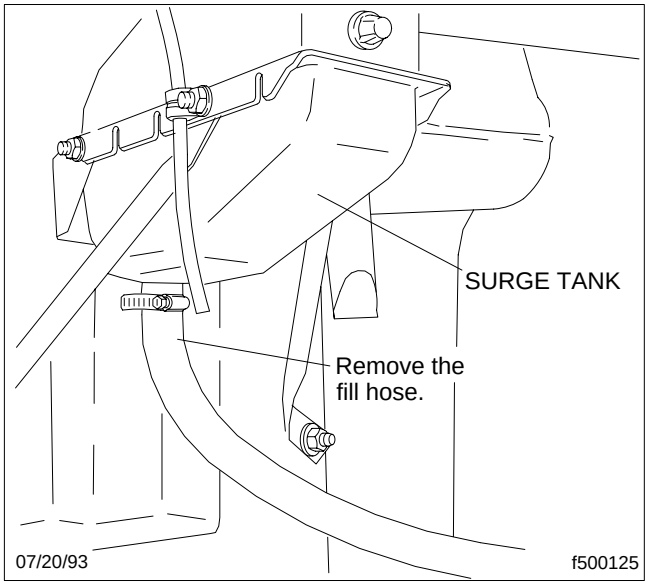

Fig. 10

⚠ WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands.

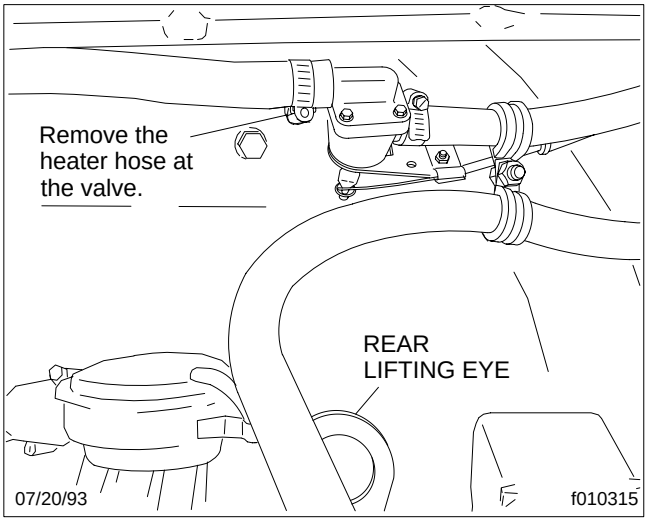

Fig. 11

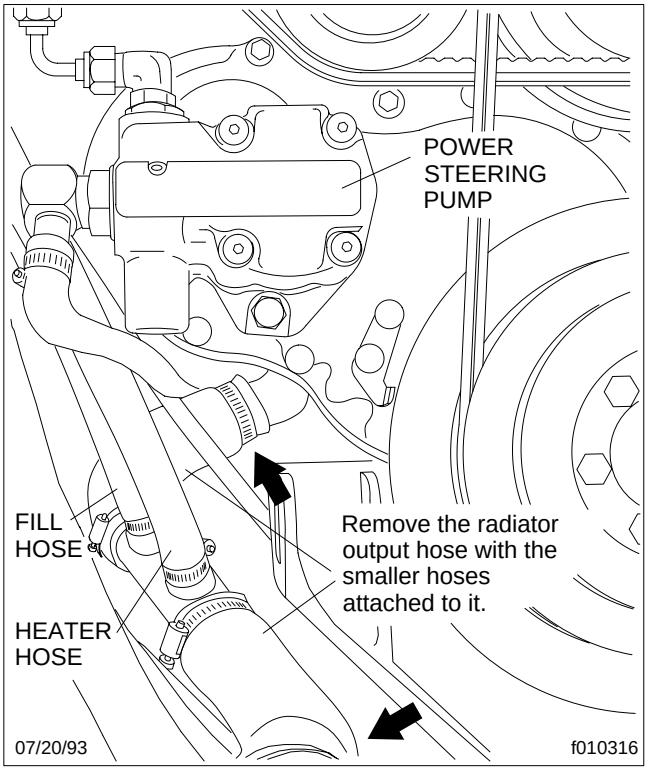

Fig. 12

An unsecured engine may fall, causing personal injury or death, and component damage.

16.1 Attach a chain to the engine lifting eye at the rear of the engine and to the lifting

hook at the front. See **Fig. 26**. Attach the chain to a crane, and raise the chain to remove any slack.

16.2 Remove the bolt from the front engine mount. See **Fig. 27**.

16.3 Remove the bolts from the two rear engine mounts. See **Fig. 28** and **Fig. 29**.

16.4 Gradually lift the engine and pull it forward to remove it from the engine compartment.

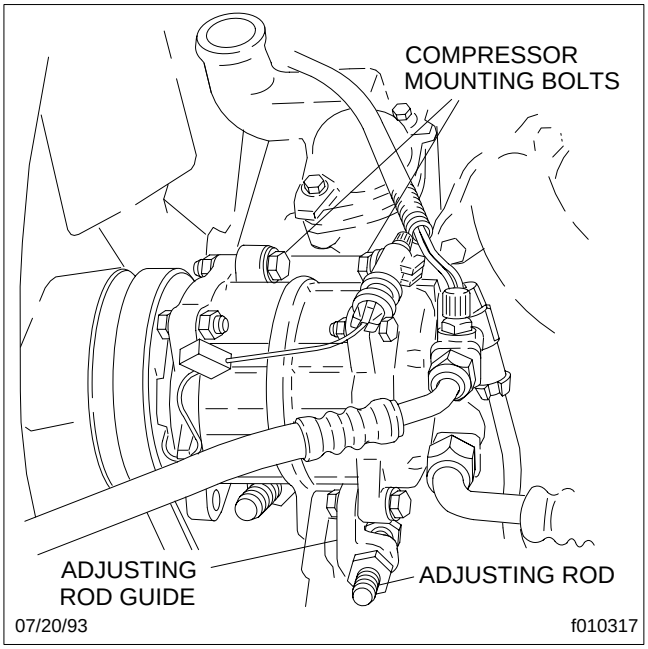

Fig. 15, Refrigerant Compressor

NOTE: If necessary to lift the engine, remove the blow-by vent from the engine cover. See **Fig. 30**.

Installation

1. Examine all engine support components for damage and extreme wear. Replace components as necessary.
2. Install the engine in the vehicle.

⚠ WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

2.1 Attach a chain to the lifting eye at the rear of the engine and to the lifting hook at the front. See **Fig. 26**. Attach the chain to a crane, and raise the chain to remove any slack.

Removal and Installation

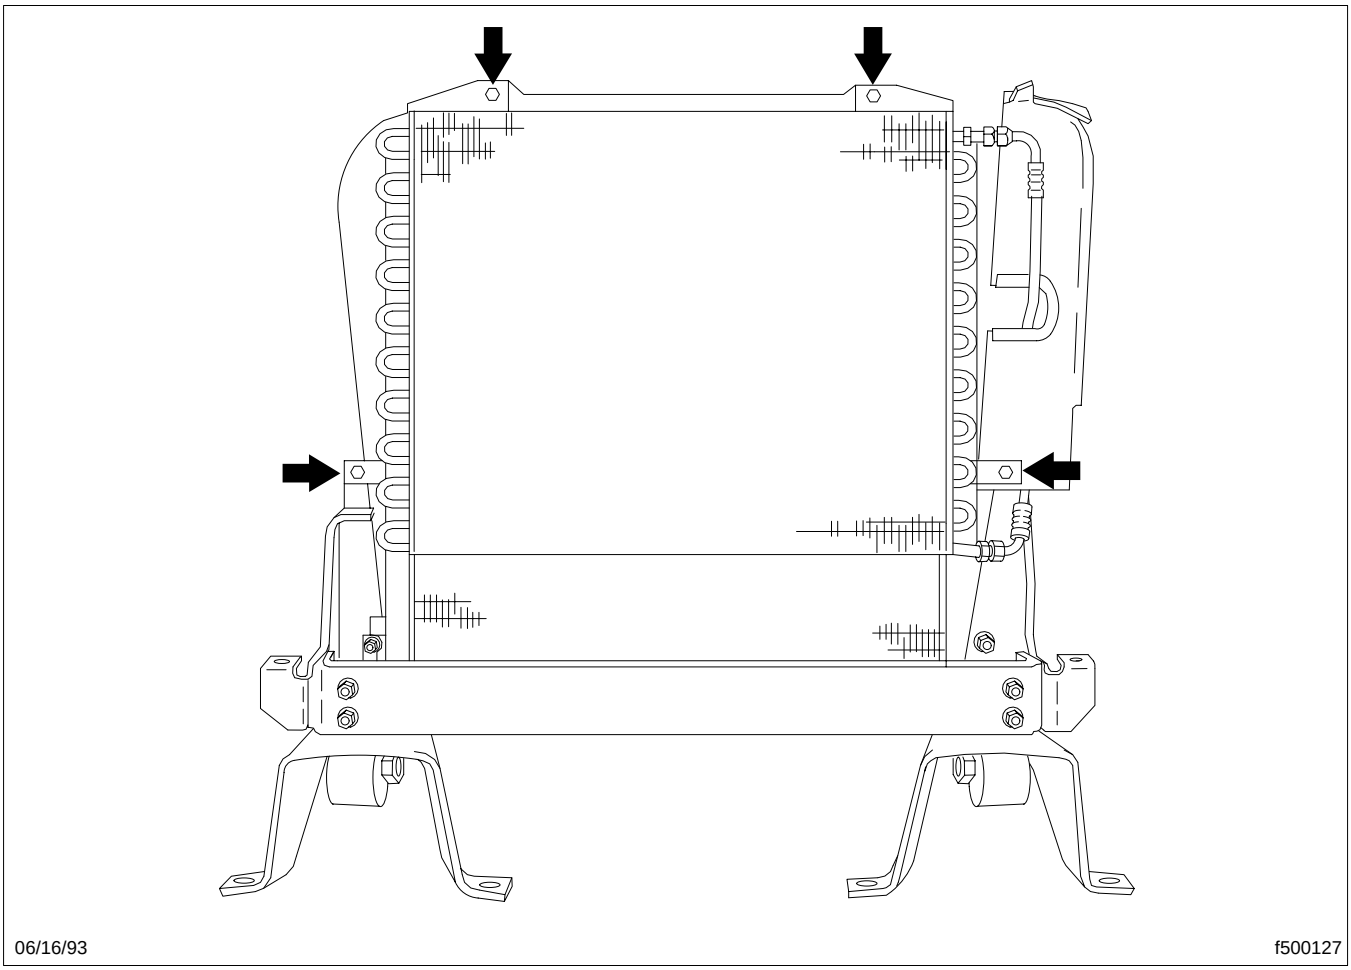

Fig. 16, Condenser Mounting Bolts

2.2 Carefully lower the engine and push it back onto the engine mounts.

2.3 Install the bolts in the two rear engine mounts, and tighten the bolts 327 N·m (241 lbf·ft).

2.4 Install the bolt in the front engine mount, and tighten it 203 N·m (150 lbf·ft).

2.5 Remove the lifting chain from the engine lifting eye and hook.

2.6 If it was removed for engine removal, install the blow-by vent on the engine cover. See **Fig. 30**.

3. Install the upper, front shock absorber mount on the left frame rail. Tighten the mounting bolts 183 N·m (135 lbf·ft). Install the shock on the mount, and tighten the shock mounting bolt 325 N·m (240 lbf·ft).

4. Connect the transmission-mounted components.

4.1 Connect the driveshaft to the transmission output end yoke. For instructions, see **Group 41**.

4.2 If the vehicle is equipped with air brakes, connect the air compressor outlet line to the chassis air delivery line, and secure the outlet line to the bracket on the transmission bell housing. See **Fig. 24**.

4.3 Connect the clutch release lever with a new clevis pin, and install the clutch slave cylinder on the clutch housing. See **Fig. 25**.

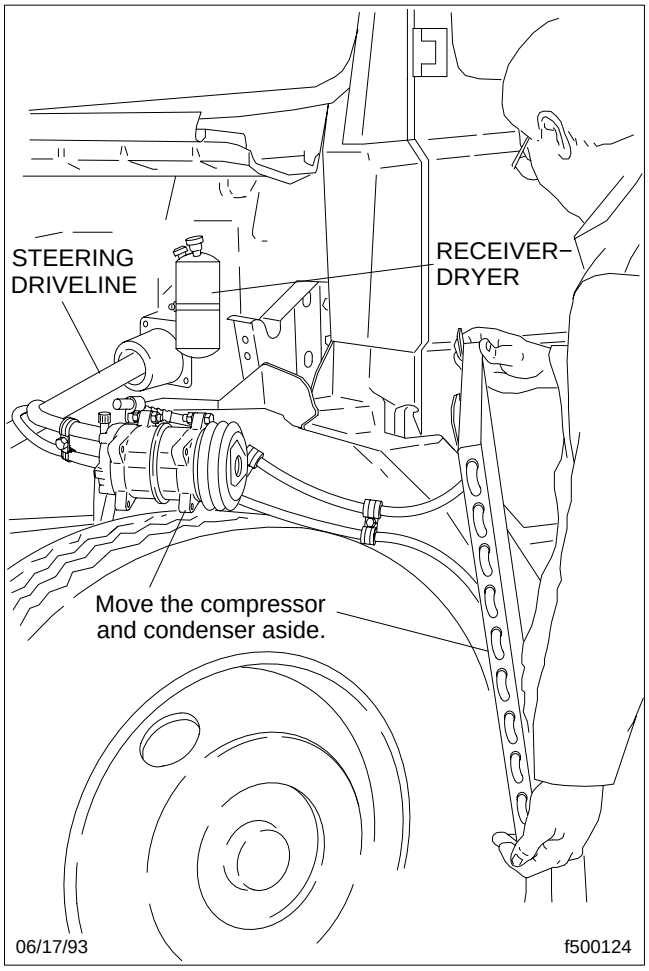

Fig. 17

4.4 Connect the speedometer sensor at the transmission output. See **Fig. 24**.

4.5 Connect the tachometer sensor at the engine flywheel. See **Fig. 24**.

4.6 Connect the back-up alarm sensor at the rear of the transmission. See **Fig. 24**.

4.7 Install the shift tower on the transmission. See **Fig. 23**.

5. Connect the engine electrical connections.

5.1 Connect the engine wiring harness at the alternator, the coolant temperature sensors, the flame start, and other options as applicable.

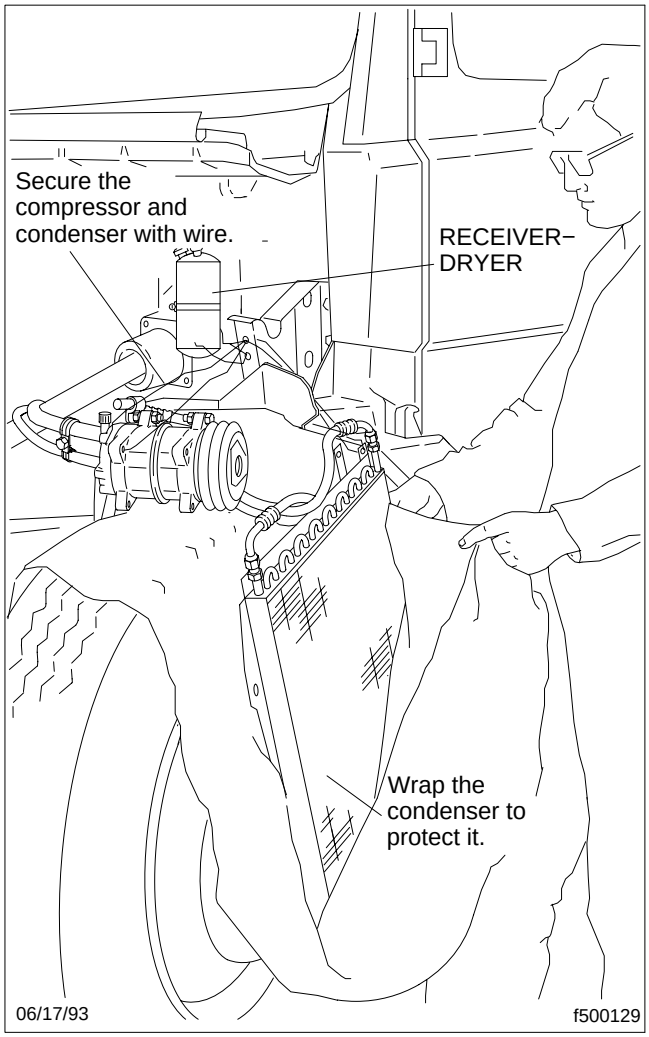

Fig. 18

5.2 Connect the alternator ground wire and the engine ground strap to the frame rail.

5.3 Connect the wiring ring terminals to the starter. See **Fig. 22**.

5.4 Connect the wiring connector to the fuel shutoff solenoid.

6. Connect the fuel and oil system components.

6.1 Connect the fuel return line to the fuel filter. See **Fig. 5**, Ref. B.

6.2 Connect the fuel delivery line to the fuel water separator. See **Fig. 5**, Ref. F.

Removal and Installation

6.5 Connect the throttle cable to the engine throttle lever and the throttle cable bracket. See **Fig. 5**, Ref. C.

6.6 Connect the dipstick tube to the air cleaner mounting bracket. See **Fig. 5**, Ref. G.

6.7 Connect the oil return line to the turbocharger.

7. Install the power steering pump on the engine, and tighten the mounting bolts 38 N·m (28 lbf·ft).

8. Install the radiator and aftercooler assembly.

8.1 Using a crane and lifting chains, lift and install the radiator and aftercooler as a single unit on the radiator mounting studs. For stability, leave the radiator attached to the crane until the radiator mounting fasteners are secure.

8.2 Install the nuts and washers on the radiator mounting studs, and tighten the nuts 40 N·m (30 lbf·ft). See **Fig. 21**.

8.3 Install the nuts, washers and rubber isolators on the radiator struts and tighten the nuts 47 N·m (35 lbf·ft). See **Fig. 21**.

8.4 Remove the lifting chains and crane from the assembly.

8.5 Install the air recirculation shield over the left aftercooler mounting tab. See **Fig. 19**. Tighten the shield bolt 20 N·m (15 lbf·ft).

9. Install the air conditioning system on the engine.

9.1 Carefully move the refrigerant compressor and condenser back into place.

9.2 Install the four bolts to hold the condenser in place over the aftercooler. See **Fig. 16**. Tighten the bolts 20 N·m (15 lbf·ft).

9.3 Position the compressor on its mount, and insert the two mounting bolts. See **Fig. 15**.

9.4 Place the adjusting rod guide on the adjusting rod.

9.5 Install the compressor drive belt on the compressor pulley and tighten the belt. For instructions, see "Drive Belts" in this group. Tighten the adjusting rod guide capscrew 45 N·m (33 lbf·ft).

9.6 Tighten the compressor mounting bolt nuts 45 N·m (33 lbf·ft).

9.7 Connect the compressor electrical connectors to the wiring harness.

10. Connect and install the coolant hoses.

10.1 Connect the heater return hose between the firewall and the engine (just behind the engine thermostat). See **Fig. 14**.

10.2 Connect the vent hose to the radiator. Secure the hose bracket at the top, right condenser mounting bolt. See **Fig. 13**.

10.3 Connect the vent hose to the engine. See **Fig. 13**.

10.4 Install the radiator inlet hose between the engine thermostat and the radiator. See **Fig. 8**.

hose, connect the shorter branch hose to the bottom of the surge tank, and connect the longer to the heater water valve at the firewall. See **Fig. 10**, **Fig. 11**, and **Fig. 12**.

11. Connect or install the air intake, exhaust pipes and hoses.

    11.1 Install the air intake pipe around the rear of the engine. See **Fig. 7**. Secure it to the engine with two screws, and clamp it to the turbocharger.

    11.2 Connect the exhaust pipe to the rear of the turbocharger. Secure the exhaust pipe bracket to the engine. See **Fig. 9**.

    11.3 If the vehicle is equipped with air brakes, connect the two air signal lines to the air governor at the top of the air compressor. See **Fig. 5**, Ref. A.

    11.4 If the vehicle is equipped with air brakes, connect the air compressor outlet line to the top of the air compressor. See **Fig. 6**.

    11.5 Connect the air inlet and outlet hoses to the aftercooler. See **Fig. 8**. Tighten the constant torque hose clamps 680 N·cm (60 lbf·in).

    11.6 Install the air intake pipe from the air cleaner to the air intake pipe routed around the rear of the engine. See **Fig. 7**. If the vehicle is equipped with air brakes,

connect the air compressor air intake hose to the air intake pipe. See **Fig. 4**.

12. Install the air cleaner.
    - 12.1 Position the air cleaner on its mounting bracket, and install the four nuts on the air cleaner mounting studs. See **Fig. 3**. Tighten the nuts 38 N·m (28 lbf·ft).
    - 12.2 Install the air intake pipe on the top of the air cleaner. See **Fig. 2**.
13. Install the right fender splash shield. See **Fig. 1**.
14. Install the bumper and hood. For instructions, see **Group 88**
15. Connect the batteries or, if the vehicle is equipped with a battery shutoff switch, turn on the switch.
    - 15.1 Connect the positive battery cable to the batteries.
    - 15.2 Connect the battery ground cable to the vehicle frame.
16. Fill the engine coolant system.
    - 16.1 Close the petcock on the bottom of the radiator.
    - 16.2 Fill the system with coolant at the surge tank. For coolant specifications, see the vehicle maintenance manual.
    - 16.3 Tighten the surge tank cap.
17. Start the engine and check for leaks. Eliminate any leaks.
18. After the engine has run for about 20 minutes, check the coolant level and add coolant if needed.
19. Fill and bleed the power steering system as necessary. For instructions, see **Group 46**.
20. Lower the hood, and remove the chocks from the tires.

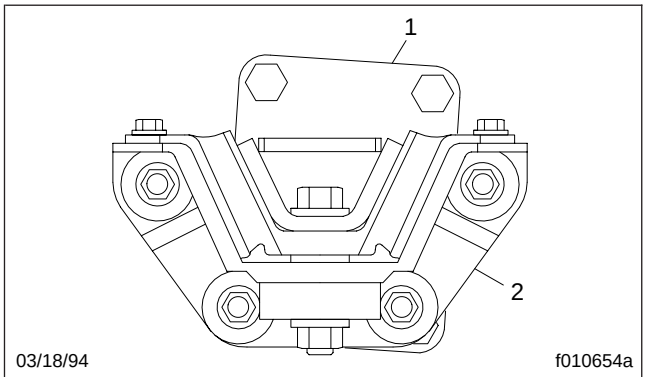
General Description

Three mounts support the engine and transmission, holding a total of almost 816 kg (1800 lb). *On diesel engines,* two of the engine mounts support the rear of the engine and transmission assembly. The third supports the front of the assembly. *On gasoline engines,* two of the engine mounts support the front of the engine and transmission assembly. The third supports the rear of the assembly.

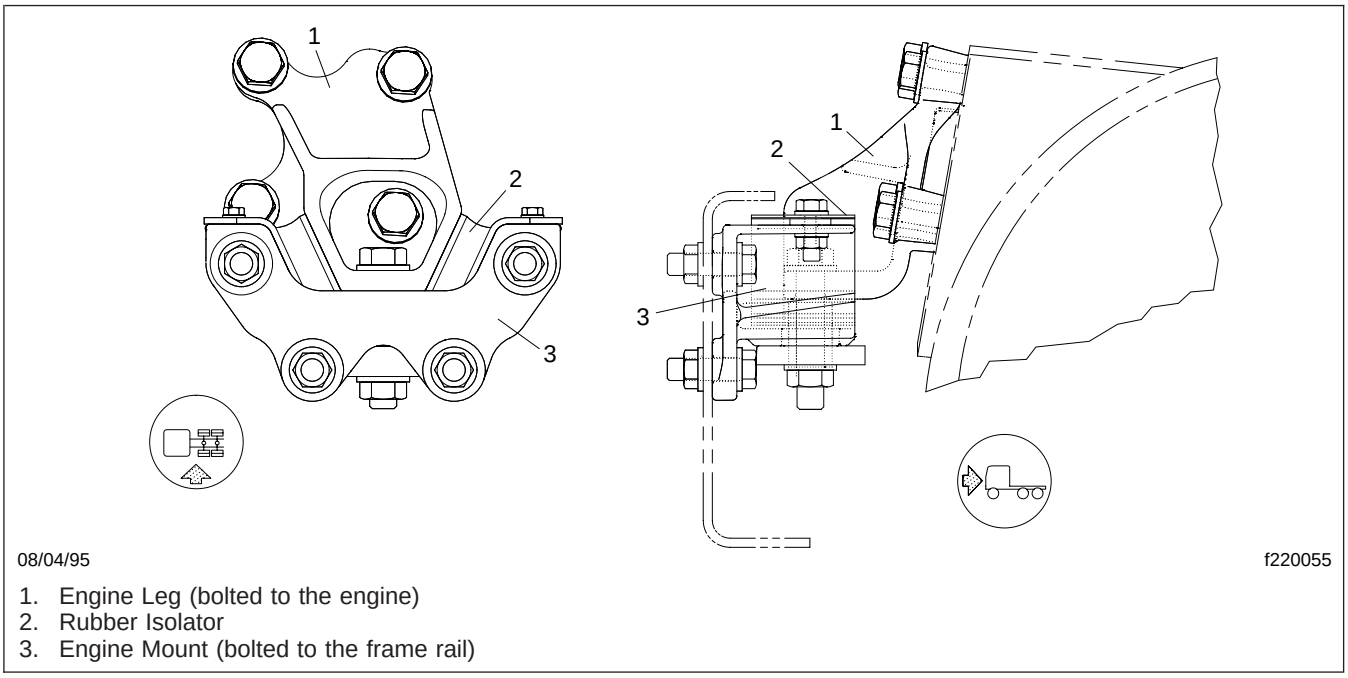


On diesel engines, each of the rear engine mounts (**Fig. 1**, **Fig. 2** or **Fig. 3**) is bolted to the inside of the frame rail near the flywheel housing. These mounts support legs which are bolted to the flywheel housing. Caterpillar, Cummins B and C series and Mercedes-Benz engines use a rear engine leg which rests flat on the mount; Detroit Diesel and Cummins M11 engines use a V-shaped rear engine leg which sets into a V-shaped rear engine mount.

NOTE: Right mount shown.
1. Rear Engine Mount

Fig. 1, Rear Engine Mount, Caterpillar, Cummins and Mercedes-Benz Engines

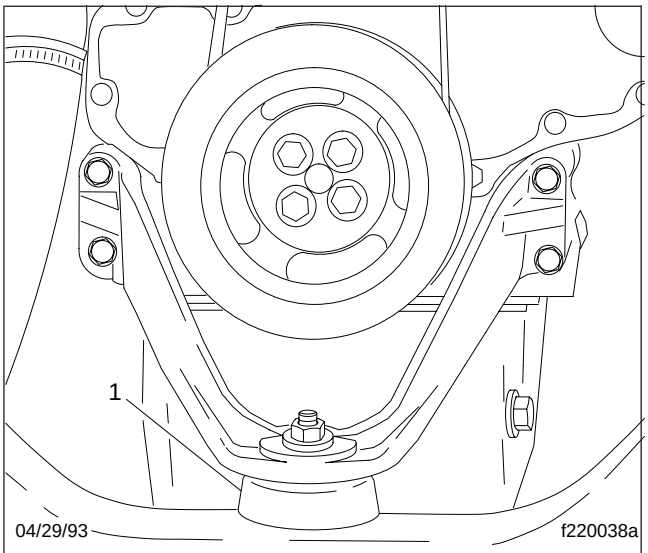
The front engine mount is an underslung crossmember under the front of the engine. It supports a bracket (**Fig. 4** and **Fig. 5**) which is bolted to the engine at each side of the vibration damper pulley.



1. Engine Leg (bolted to the engine)
2. Engine Mount (bolted to the frame rail)

Fig. 2, Rear Engine Mount, Detroit Diesel Series 50 Engine

To isolate the engine and transmission from road shock, and to isolate the vehicle frame from engine vibration, the engine mounts are sandwiched between rubber isolator cushions (sometimes called restriction pads). Steel snubbers protect the cushions from wearing on the engine support brackets, and a single bolt runs through the mount, cushions, and snubbers to hold the assembly together and hold the engine on the mount.



On gasoline engines, the forward engine mounts (**see Fig. 6**) are bolted to the inside of the frame rails near the center of each exhaust manifold. These mounts support brackets which are bolted to the engine. A bolt runs through the mount and the engine bracket to hold the two together (**Fig. 7** and **Fig. 8**), and rubber cushions (also called restriction pads) isolate the engine and transmission from road shock and isolate the vehicle frame from engine vibration. The rear engine mount is an underslung crossmember under the transmission. It supports a bracket (**Fig. 9**) bolted to the underside of the transmission. A rubber isolator pad between the bracket and the crossmember protects the transmission from road shock.

nected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

2. Disconnect the engine from the right rear engine mount.

   2.1 Place a jack under the rear of the engine, and raise the jack until it's braced against the engine.

   2.2 Remove the bolt from the right rear engine mount. Save the fasteners, rubber isolator cushions, and snubbers.

   2.3 Lift the engine slightly to take its weight off the right rear engine mount. Place engine stands under the engine to keep it off the engine mount.

3. Remove the bolts which secure the mount to the frame rail. Remove the mount from the frame rail.

   If necessary, remove the four bolts which secure the right engine support bracket to the flywheel housing, and remove the bracket from the engine.

4. Place a new engine mount against the inside of the frame rail, and secure it with bolts, washers, and nuts. Tighten the nuts as follows:

   For Caterpillar engines: tighten the nuts 61 N·m (45 lbf·ft).

   For Cummins B and C Series and Mercedes-Benz engines: tighten the nuts 108 N·m (80 lbf·ft).

   For Cummins M11 engines: tighten the nuts 183 N·m (135 lbf·ft).

   For Detroit Diesel engines: tighten the nuts 92 N·m (68 lbf·ft).

5. If removed, install the engine support bracket on the right side of the flywheel housing. Apply thread lock compound to the bracket mounting bolts, and tighten them as follows:

   On Caterpillar engines: tighten the bolts 136 N·m (100 lbf·ft).

   On Cummins B and C Series engines: tighten the bolts 75 to 88 N·m (55 to 65 lbf·ft). Cummins B Series engines used with Allison automatic transmissions have an iron flywheel housing instead of the standard aluminum housing. On B Series engines with iron flywheel housings, tighten the support bracket bolts 81 to 103 N·m (60 to 76 lbf·ft).

Rear Engine Mount Replacement, Diesel Engines

On Cummins M11 engines: tighten the bolts 327 N·m (241 lbf·ft).

On Detroit Diesel Series 50 engines: tighten the capscrews 184 N·m (136 lbf·ft).

On Mercedes-Benz OM 366LA engines: tighten the bolts 177 to 224 N·m (130 to 165 lbf·ft).

6. Inspect the engine mount rubber isolators for wear or damage and replace them if necessary.

⚠ CAUTION

CAUTION: Do not lubricate the components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

7. Install the upper isolator in the engine mount. If applicable, place the snubber on the isolator.

⚠ WARNING

WARNING: The jack used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

8. Secure the engine to the engine mounts.
   - 8.1 If not in place, set a jack under the rear of the engine and raise the jack until it is braced against the engine.
   - 8.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.
   - 8.3 Holding the lower isolator and snubber in place, install the bolt in the right rear engine mount, and secure it with the nut and hardened washer. Tighten the nut 327 N·m (241 lbf·ft).

⚠ WARNING

WARNING: The jack used to lift the engine must be capable of safely lifting and supporting two metric tons. Once the engine mount is disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

9. Disconnect the engine from the left rear engine mount.
   - 9.1 Place a jack under the rear of the engine, and raise the jack until it's braced against the engine.
   - 9.2 Remove the bolt from the left rear engine mount. Save the fasteners, rubber isolator cushions, and snubbers.
   - 9.3 Lift the engine slightly to take its weight off the left rear engine mount. Place engine stands under the engine to keep it off the engine mount.
10. Remove the capscrews which secure the mount to the frame rail. Remove the mount from the frame rail.

    If necessary, remove the four capscrews which secure the left engine support bracket to the flywheel housing, and remove the bracket from the engine.
11. Place a new engine mount against the inside of the frame rail, and secure it with bolts, washers, and nuts. Tighten the nuts as follows:

    For Caterpillar engines: tighten the nuts 61 N·m (45 lbf·ft).

    For Cummins B and C Series and Mercedes-Benz engines: tighten the nuts 108 N·m (80 lbf·ft).

    For Cummins M11 engines: tighten the nuts 183 N·m (135 lbf·ft).

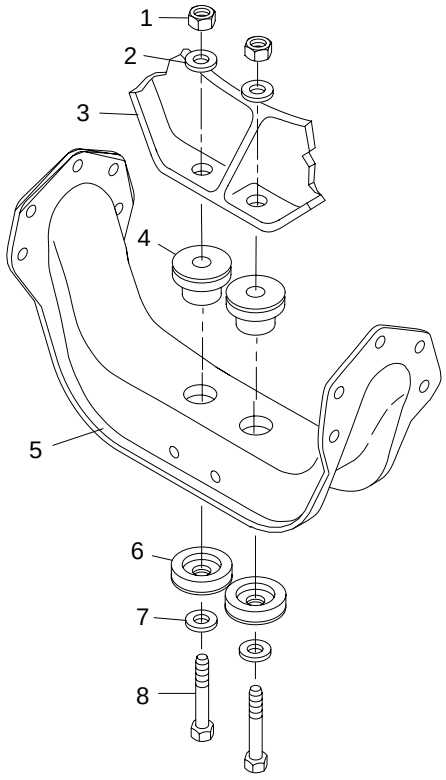
The lifting device and chain used to lift the engine must be capable of safely lifting and supporting two metric tons. Once the engine mount is disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

2. Disconnect the engine from the front engine mount.



2.1 Attach a chain to the front engine lifting hook(s), and position a lifting device to lift the engine. Attach the chain to the lifting device, and raise the chain to remove any slack.

2.2 Remove the bolt(s) from the front engine mount. Save the fasteners, rubber isolator cushions, and snubber(s).

NOTE: In order to raise the front of the engine, you may have to loosen the bolts that run through the rear engine mounts.

3. If necessary, remove the bolts which secure the engine support bracket to the front of the engine. Remove the bracket from the engine.

   On vehicles equipped with Mercedes-Benz OM 366LA engines, remove the alternator and exhaust mount fasteners that tie in with the left end of the engine support bracket.

4. If necessary, install a new engine support bracket on the front of the engine. Secure it with two bolts at each side of the vibration damper pulley, and tighten the bolts as follows:

   For Cummins B Series/ISB engines: tighten the bolts 55 to 65 lbf·ft (75 to 88 N·m).

   For Cummins C Series/ISC engines: tighten the bolts 75 to 90 lbf·ft (102 to 122 N·m).

   For Detroit Diesel Series 50 engines: tighten the bolts 118 to 148 lbf·ft (160 to 200 N·m).

For Mercedes-Benz OM 366LA engines: tighten the bolts 90 to 110 lbf·ft (122 to 150 N·m).

For MBE900 engines: tighten the bolts 100 lbf·ft (136 N·m).

On vehicles equipped with Mercedes-Benz OM 366LA engines, install the alternator and exhaust mount fasteners that tie in with the ends of the engine support bracket.

5. Inspect the engine mount rubber isolators for wear or damage and replace them if necessary.

⚠ CAUTION

Do not lubricate the components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

6. Install the upper isolator(s) in the engine mount. If applicable, place the snubber(s) on the isolator(s).

⚠ WARNING

The lifting device and chain used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

7. Secure the engine to the front engine mount.

   7.1 Attach a chain to the front engine lifting hook(s). Attach the chain to a lifting device, and raise the chain to remove any slack.

   7.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.

   7.3 Holding the lower isolator(s) and tube(s) in place, install the bolt(s) in the front engine mount and secure it with the nut(s) and washer(s). Tighten the nut(s) as follows:

   For Caterpillar engines: tighten the nuts 136 lbf·ft (184 N·m).

   For Cummins B Series/ISB engines: tighten the nuts 136 lbf·ft (184 N·m).

   For Cummins C Series/ISC engines: tighten the nuts 68 lbf·ft (92 N·m).

   For Cummins M11/ISM engines: tighten the nuts 241 lbf·ft (327 N·m).

   For Detroit Diesel engines: tighten the nuts 241 lbf·ft (327 N·m).

   For Mercedes-Benz OM 366LA engines: tighten the nuts 150 lbf·ft (203 N·m).

   For MBE900 engines: tighten the nuts 136 lbf·ft (184 N·m).

   NOTE: If you loosened the bolts that run through the rear engine mounts, tighten those bolts 241 lbf·ft (327 N·m) for all engines.

⚠ WARNING

WARNING: The jack used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

9. Secure the engine to the engine mount.

   9.1 If not in place, set a jack under the rear of the engine and raise the jack until it is braced against the engine.

   9.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.

   9.3 Holding the lower isolator in place, install the bolt in the left rear engine mount, and secure it with the nut and hardened washer. Tighten the nut 327 N·m (241 lbf·ft).

10. Remove the jack from under the engine, and remove the chocks from the tires.

snubber(s). Discard the rubber isolator cushions.

NOTE: In order to raise the front of the engine, you may have to loosen the bolts that run through the rear engine mounts.

2.3 Lift the engine slightly to take its weight off the front engine mount. Place engine stands under the engine to keep it off the engine mount.

3. Inspect the new front engine mount rubber isolators for wear or damage and replace them if necessary.

CAUTION

CAUTION: Do not lubricate the new components with oil, grease, or silicone lubricants; they will deteriorate the rubber isolators.

4. Install the upper isolator(s) in the engine mount.

WARNING

WARNING: The lifting device and chain used to lower the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mount. An unsecured engine may fall, causing personal injury or death, and component damage.

5. Secure the engine to the front engine mount.

5.1 Attach a chain to the front engine lifting hook(s). Attach the chain to a lifting device, and raise the chain to remove any slack.

5.2 Lift the engine slightly to remove the engine stands. Remove the stands, and carefully lower the engine onto the engine mount.

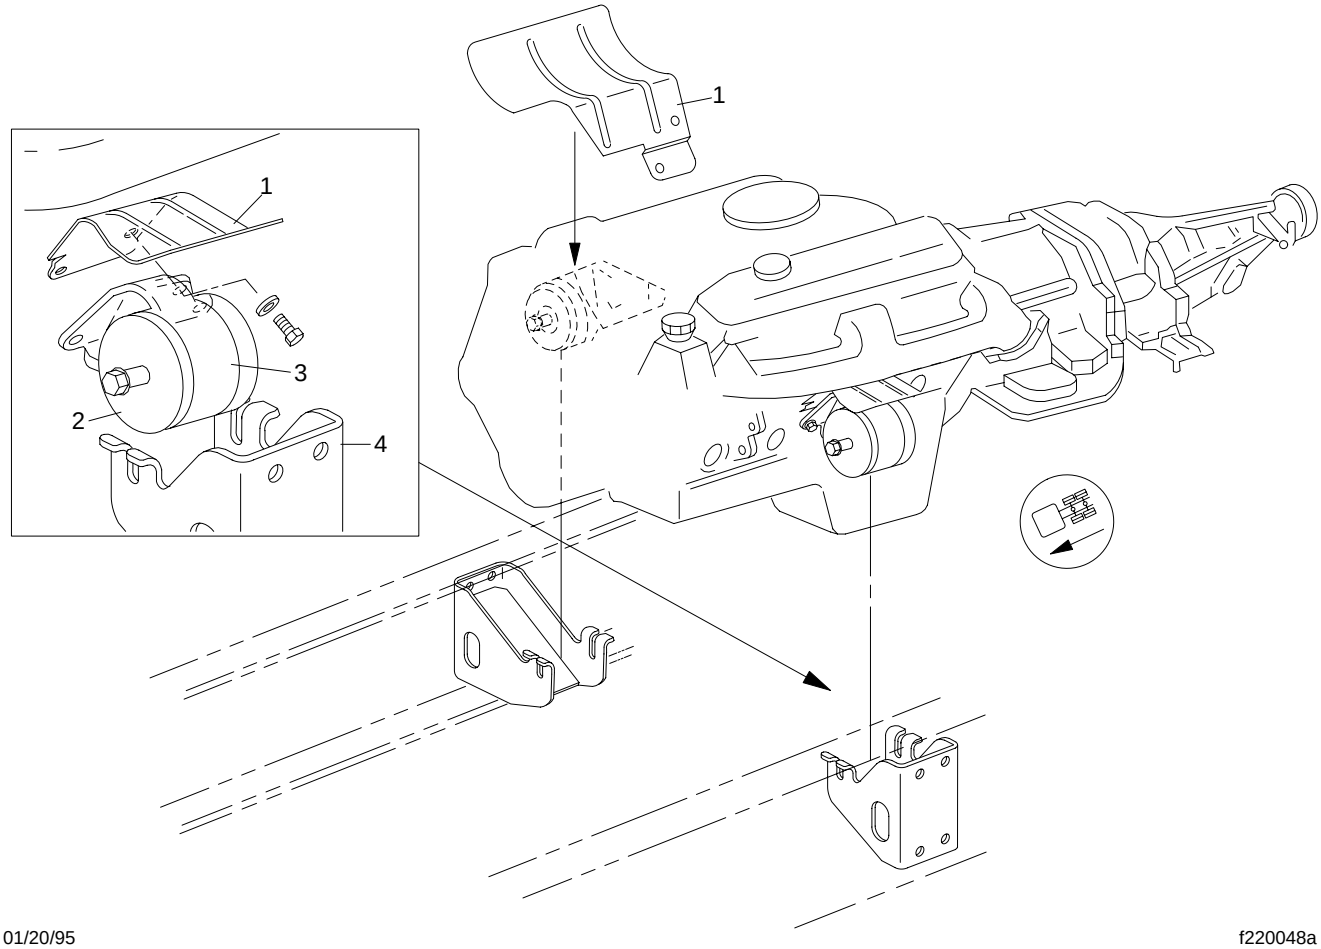
5.3 Holding the lower isolator(s) and tube(s) in place, install the bolt(s) in the front engine mount and secure it with the nut(s) and washer(s). Tighten the nut(s) as follows:

For Caterpillar engines: tighten the bolts 184 N·m (136 lbf·ft).

For Cummins B and C Series and Mercedes-Benz engines: tighten the bolts 203 N·m (150 lbf·ft).

For Cummins M11 engines: tighten the bolts 327 N·m (241 lbf·ft).

For Detroit Diesel engines: tighten the nuts 327 N·m (241 lbf·ft).



NOTE: If you loosened the bolts that run through the rear engine mounts, tighten those bolts 327 N·m (241 lbf·ft).

5.4 Remove the lifting chain from the engine lifting hook(s).

6. Remove the chocks from the tires.

2. Lift the engine slightly.

⚠ WARNING

WARNING: The crane, lifting eyes, and lifting chain used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine, or an engine lifted with unsuitable tools may fall, causing personal injury or death, and component damage.

General Description

The Phillips Temro oil pan heater keeps the crankcase oil about 32°C (90°F) warmer than the ambient air temperature. In cold weather, the heater helps prevent water from condensing in the oil, it creates a better seal in the combustion chambers for start-up, and it keeps the oil free-flowing for instant lubrication.

The heater consists of a 150-or 300-watt element that screws into the side of the engine oil pan. **See Fig. 1.** A cord plugs onto the outside end of the element, and the cord runs to a receptacle mounted below the driver's door. **See Fig. 2.**

NOTE: When a vehicle is also equipped with an engine block heater, the engine block heater is wired in tandem with the oil pan heater. The cord from the oil pan heater element, and the receptacle below the driver's door, provide power to the engine block heater.

To turn on the heater, open the spring-loaded cover on the receptacle, and connect a power source to the receptacle. The element has no thermostat. Heat dissipating from the crankcase prevents oil overheating.

Oil Pan Heater Element Removal and Installation

Removal

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Drain the oil.

⚠ WARNING

Drain the oil pan only when the oil and engine are cool. Draining it when they are hot could cause severe personal injury due to scalding.

   3.1 Place a suitable container under the oil pan drain plug.

   3.2 Remove the plug, and allow the oil to drain.

4. Unscrew the threaded cover that secures the cord to the element. See **Fig. 1**.
5. Pull the cord off the element.
6. Unscrew the element from the oil pan port.

Installation

1. Screw the element into the port until finger-tight. Then, use a wrench to tighten the element one more turn.
2. Plug the cord onto the element and secure it by screwing the threaded cover in place. See **Fig. 1**.
3. Install the oil drain plug in the crankcase, and fill the engine with oil. For recommended oil types and engine oil capacities, see the vehicle maintenance manual.
4. Start the engine and check for leaks. Repair any leaks as necessary.
5. To test the heater, plug a wattmeter into a power source, and connect the heater cord in the receptacle to the meter. A reading on the meter will indicate the heater is working.

Oil Pan Heater Element Removal and Installation

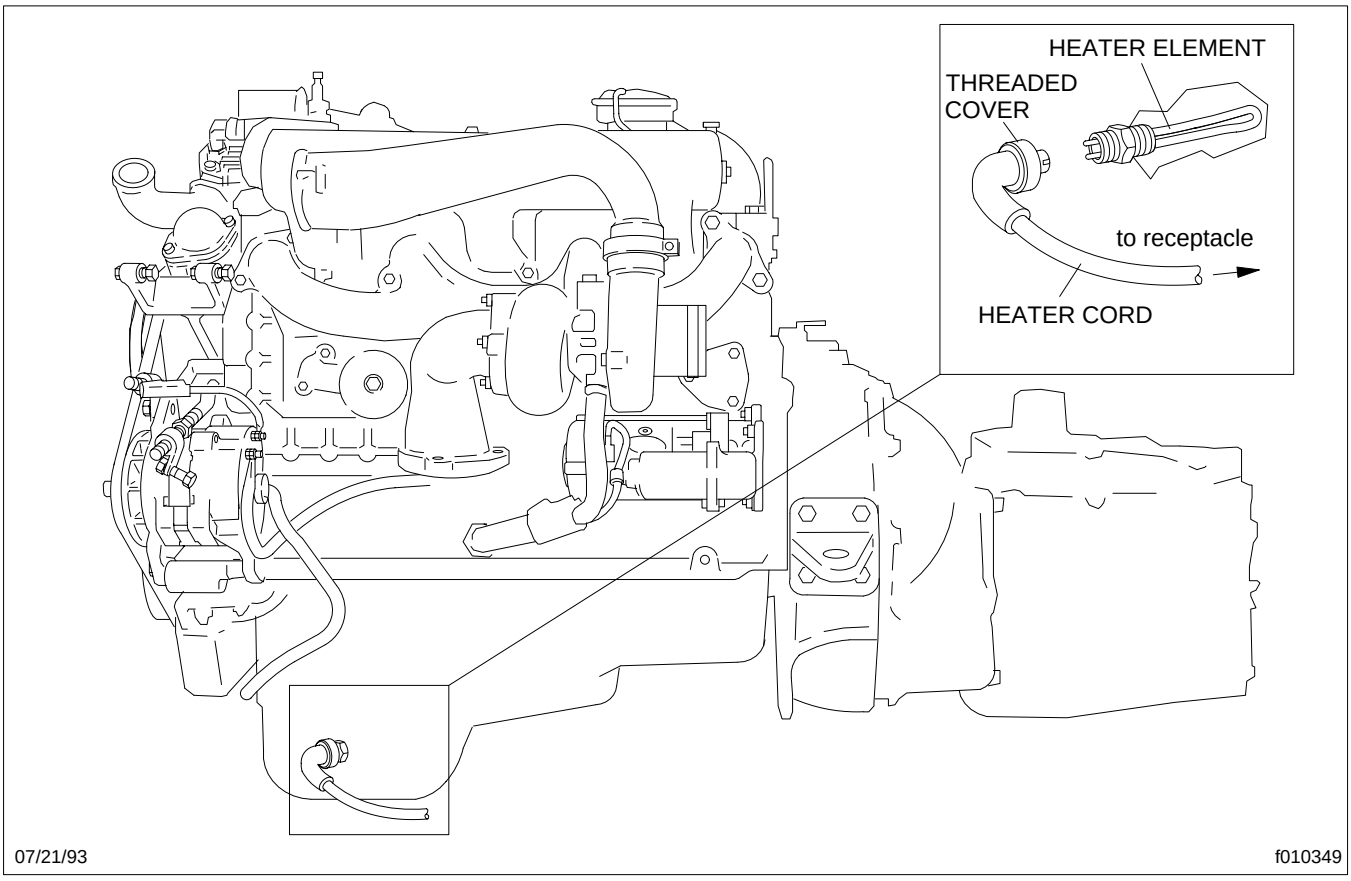

Fig. 1, Mercedes-Benz OM 366LA Engine Shown

Troubleshooting

Use the following procedures to check for the most common oil pan heater problems.

WIRING PROBLEMS

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Unscrew the threaded cover that secures the cord to the element. See **Fig. 1**. Pull the cord off the element.
4. Using an ohmmeter, check the continuity between the two poles of the element. On Cummins B Series and Mercedes-Benz OM 366LA engines, the resistance should be about 96 ohms. On Cummins C Series engines, the resistance should be about 48 ohms. If there is no reading, the element is burnt out.
5. If the element is good, check the cord. Plug the cord onto the element and secure it by screwing the cover in place. See **Fig. 1**.
6. Using an ohmmeter at the receptacle, check the continuity between the two power terminals. On Cummins B Series and Mercedes-Benz OM 366LA engines, the resistance should be about 96 ohms. On Cummins C Series engines, the resistance should be about 48 ohms. If there is no reading or a very high reading, the cord is damaged. Replace the cord.
7. Check the continuity between each power terminal and the ground terminal. There should be no ohmmeter reading. If there is a reading, replace the cord.

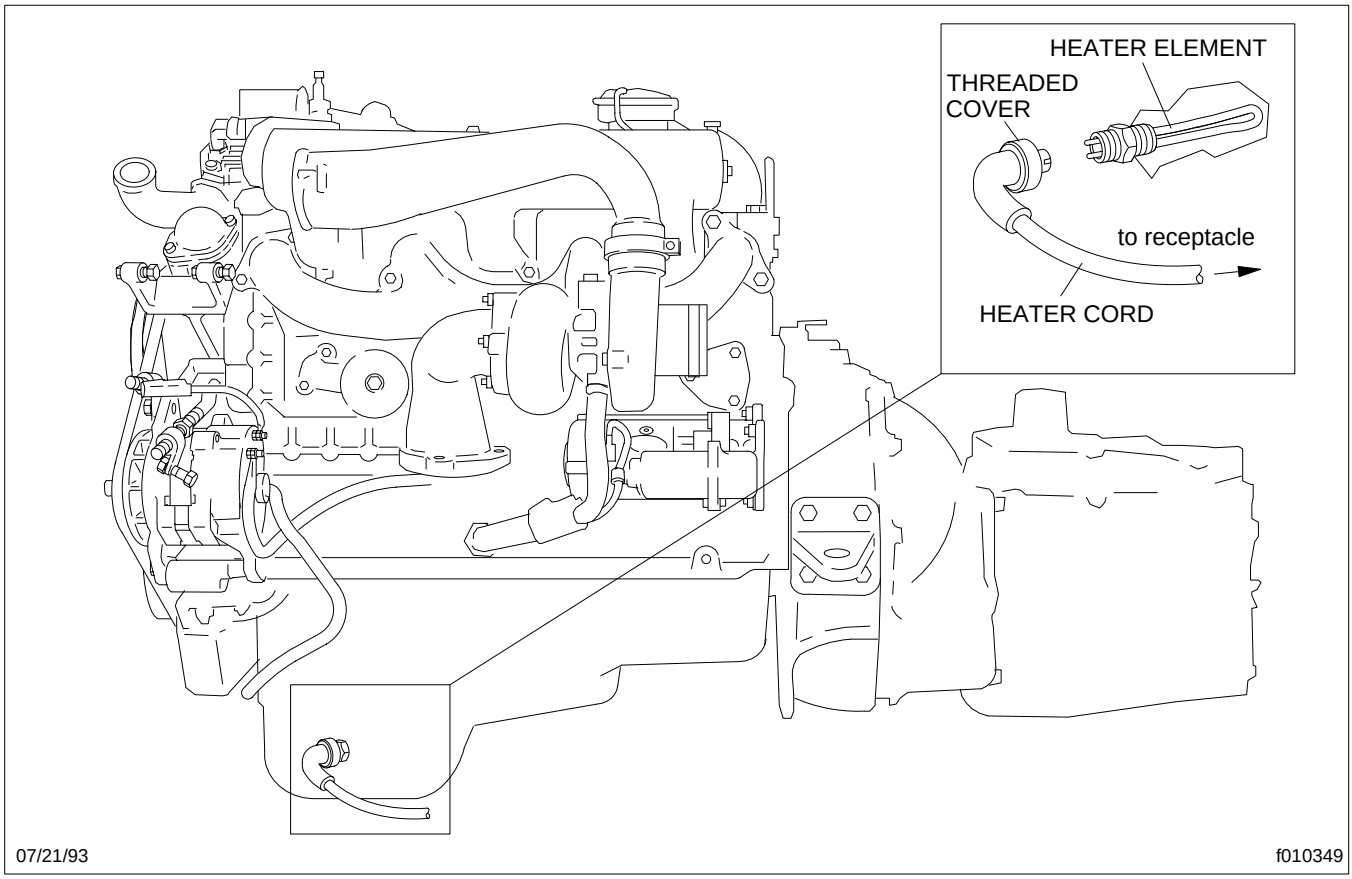

Fig. 1, Mercedes-Benz OM 366LA Engine Shown

Troubleshooting

8. Check the ohmmeter reading between the ground terminal and a good vehicle ground. The reading should be zero. If not, replace the cord.

FOULED ELEMENT

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.

⚠ WARNING

WARNING: Drain the oil pan only when the oil and engine are cool. Draining it when they are hot could cause severe personal injury due to scalding.

3. Drain the oil.
   - 3.1 Place a suitable container under the oil pan drain plug.
   - 3.2 Remove the plug, and allow the oil to drain.
4. Unscrew the threaded cover that secures the cord to the element. See **Fig. 1**. Pull the cord off the element.
5. Unscrew the element from the oil pan port.
6. Inspect the element for charred oil that may insulate it. If burnt oil is present, replace the element, and change the engine oil and oil filter.

General Description

The Phillips Temro engine block heater keeps the engine coolant about 27°C (80°F) warmer than the ambient air temperature. In cold weather, the heater helps engine starting and reduces wear on the piston walls.

When starting the engine, the diesel normally ignites on the compression stroke of each piston, when the compressed air within the cylinder reaches about 385°C (725°F). However, during cold weather starts, the heat of the compressed air dissipates into the surrounding engine block so the diesel may never reach the temperature it needs to ignite. Using the engine block heater, the engine block is already warm so heat is held in the cylinder to ignite the diesel. To reduce engine wear, the block heater warms the oil film on the piston walls and reduces piston drag caused by cold oil film.

The heater consists of an element that bolts into the side of the engine water jacket. **See Fig. 1.** A cord plugs into the outside end of the element, and the cord runs to a receptacle mounted below the driver's door. **See Fig. 2.**

NOTE: When a vehicle is also equipped with an oil pan heater, the oil pan heater is wired in tandem with the engine block heater. The cord from the engine block heater element, and the receptacle below the driver's door, provide power to the oil pan heater.

To turn on the heater, open the spring-loaded cover on the receptacle, and connect a power source to the receptacle. The element has no thermostat. Heat dissipating from the engine block prevents coolant overheating.

Engine Block Heater Element Removal and Installation

Removal

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Drain the radiator.

⚠ WARNING

WARNING: Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

   3.1 Loosen the surge tank cap.

   3.2 Open the petcock at the bottom of the radiator to drain the engine coolant.

4. Unscrew the threaded cover that secures the cord to the element. **See Fig. 1.**
5. Pull the cord off the element.
6. Remove the element from the engine block.

   On Mercedes-Benz OM 366LA engines, remove the three bolts that hold the element cover to the block, and pull out the element.

   On Cummins B Series engines, loosen the capscrew in the center of the element cover, and pull out the element.

Installation

1. Install the heater element in the engine block.

   On Mercedes-Benz OM 366LA engines, secure the element in the block with three bolts. Tighten the bolts 20 N·m (15 lbf·ft).

   On Cummins B Series engines, secure the element in the block by tightening the capscrew 13 N·m (10 lbf·ft).

2. Plug the cord into the element and secure it by screwing the threaded cord cover in place. **See Fig. 1.**
3. Fill the cooling system. For recommended coolants and coolant system capacities, refer to the vehicle maintenance manual.
4. Start the engine and check for leaks. Repair any leaks as necessary. Run the engine for half an hour to purge any air from the coolant system.
5. To test the heater, plug a wattmeter into a power source, and connect the heater cord in the receptacle to the meter. A reading on the meter will indicate the heater is working.

WIRING PROBLEMS

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Unscrew the threaded cover that secures the cord to the element. **See Fig. 1.** Pull the cord off the element.
4. Using an ohmmeter, check the continuity between the two poles of the element. The resistance should be very low, typically between 9 and 10 ohms. If there is no reading, the element has burned out, and if the reading is very high, the element is about to burn out.
5. If the element is good, check the cord. Plug the cord into the element and secure it by screwing the threaded cover in place. **See Fig. 1.**
6. Using an ohmmeter at the receptacle, check the continuity between the two power terminals. The resistance should be low, typically between 9 and 10 ohms. If there is no reading or a very high reading, the cord is damaged. Replace the cord.
7. Check the continuity between each power terminal and the ground terminal. There should be no ohmmeter reading. If there is a reading, replace the cord.

5. Remove the element from the engine block. On Mercedes-Benz OM 366LA engines, remove the three bolts that hold the element cover to the block, and pull out the element. On Cummins B Series engines, loosen the capscrew in the center of the element cover, and pull out the element.
6. Inspect the element for residue deposits, discoloration, or damage.

   Greenish residue indicates the coolant solution contains too much antifreeze. Replace the element, and refer to the vehicle maintenance manual for the recommended antifreeze/water ratio.

   Gray or black residue indicates anti-leak coolant additives have been added to the system. Replace the element, and refer to the vehicle maintenance manual for the recommended coolant additives.

   Blue or black discoloration on the element indicates the coolant system needs more coolant. Replace the element, and fill the coolant system until coolant is visible in the surge tank sight glass.

   Holes in the element indicate the coolant solution contains too little antifreeze. The weak solution is boiling inside the engine block and causing pitting of the element and block. Replace the element, and refer to the vehicle maintenance manual for the recommended antifreeze to water concentrations.

Table 1, Fastener Torques

General Description

During cold weather starts, the KBi starting fluid system injects vaporized ether into the engine manifold to help ignite the diesel fuel in the cylinders. The diesel normally ignites on the compression stroke of each piston, when the compressed air within the cylinder reaches about 385°C (725°F). However, during cold weather starts, the heat of the compressed air dissipates into the surrounding engine block so the diesel may never reach the temperature it needs to ignite. Ether ignites at 182°C (360°F). Therefore, ether vapor injected with the engine intake air ignites at the lower cylinder temperature, and the burning ether ignites the diesel.

Using the starting fluid system reduces the necessary cranking time in cold weather, and it prevents excessive wear on the battery and starter.

When the engine is cold, the KBi system begins injecting ether when the starter is cranked. The system continues injecting ether vapor into the manifold for a short time to prevent stalling. The system consists of the starting fluid cylinder, the ether injection nozzle in the engine manifold, and the engine temperature sensor. **See Fig. 1.**

The starting fluid cylinder **(see Fig. 2)** is mounted with the receiver-dryer against the firewall. It fits into the Dieselmatic® valve and Blockor® fitting which measure, hold, and release a controlled amount of fluid for each start attempt.

Ether travels through plastic tubing to the engine manifold where it sprays through the injection nozzle into the engine intake air. Inside the manifold, vaporized ether fills the cylinders and ignites.

If the weather is warm, or the engine is already warmed, the engine temperature sensor mounted in the engine water jacket prevents the KBi from injecting ether vapor. The system will inject ether only if the engine is cooler than about 4°C (40°F).

⚠ WARNING

Service starting fluid systems only in a well-ventilated area away from sparks and open flames. The ethyl ether in these systems is flammable and toxic. Wear protective gloves and glasses, and avoid breathing ether fumes. Failure to take these precautions could result in personal injury or property damage.

3. Remove the old cylinder (Ref. 1).
   - 3.1 Clean all dirt from the neck of the cylinder and the top of the Dieselmatic® valve before removing the cylinder.
   - 3.2 Loosen the cylinder clamp.
   - 3.3 Pry the dirt eliminator collar (Ref. 3) off the neck of the cylinder.
   - 3.4 Unscrew the cylinder from the Dieselmatic valve.

NOTE: If not replacing the cylinder immediately, place the valve cap (Ref. 8) in the valve to prevent dirt or other debris from entering the system.

4. Remove the old dirt eliminator collar from the valve assembly.
5. Replace the Dieselmatic valve gasket (Ref. 6). Spread the new gasket with a light film of clean oil.
6. Place a new dirt eliminator collar, adhesive-side up, on the valve assembly. Peel off the collar's paper backing (Ref. 2) to expose the adhesive.
7. Install the new cylinder.
   - 7.1 Place the new cylinder into the Dieselmatic valve and hand tighten it firmly.
   - 7.2 Slide the dirt eliminator collar up so it sticks to the cylinder.
   - 7.3 Tighten the clamp around the cylinder 680 N·cm (60 lbf·in).
8. If the ambient temperature is below 4°C (40°F), test the starting fuel system.
9. Lower the hood, and remove the chocks from the tires.

⚠ WARNING

Service starting fluid systems only in a well-ventilated area away from sparks and open flames. The ethyl ether in these systems is flammable and toxic. Wear protective gloves and glasses, and avoid breathing ether fumes. Failure to take these precautions could result in personal injury or property damage.

Do not install a starting fluid system on a vehicle with an air intake warmer, for example, a glow plug or a flame start system. An air intake warmer could prematurely ignite the starting fluid and cause an explosion in the air intake manifold resulting in personal injury and property damage.

Starting System Removal and Installation

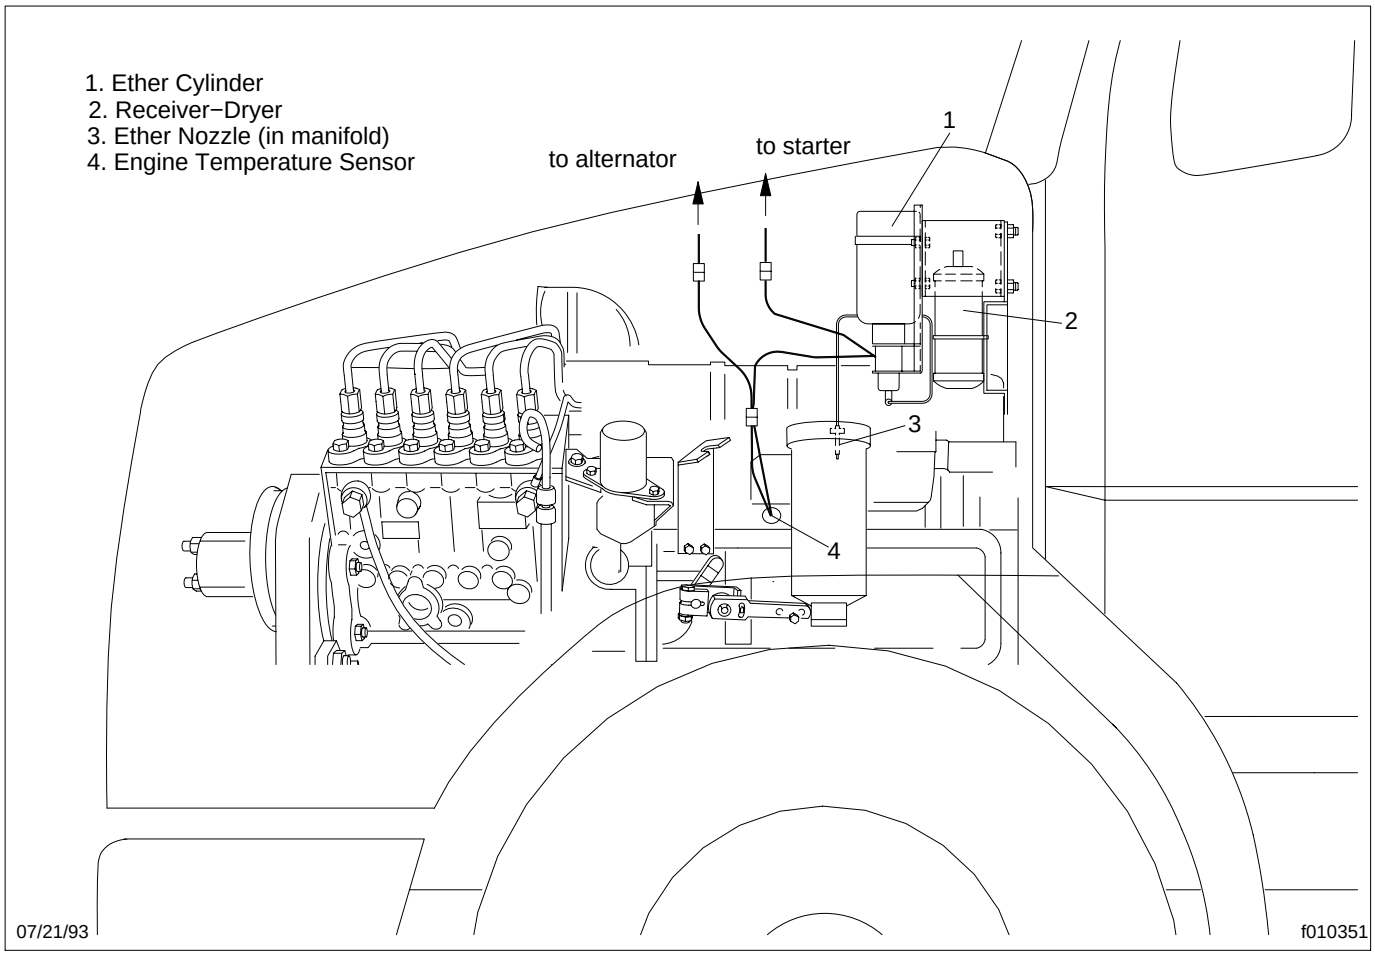

Fig. 2

1. Remove the plug in the engine intake manifold and screw the ether nozzle in place. See **Fig. 2.**
2. Install the engine temperature sensor. See **Fig. 2.**
   - 2.1 Remove the plug from the water jacket, and screw the sensor in place until finger-tight. Using a wrench, tighten the sensor one more turn.
   - 2.2 Connect the ground wire from the sensor to the alternator ground terminal.
3. Install the mounting plate and valve assembly. See **Fig. 2.**
   - 3.1 Place the mounting plate against the mounting bracket, and secure it with four bolts. Tighten the bolts 30 N·m (22 lbf·ft).
   - 3.2 Connect the ether tubing to the injection nozzle in the intake manifold. Tighten the nozzle fitting finger-tight, then, using a wrench, tighten the nozzle one more turn.
   - 3.3 Connect the black wire from the valve assembly to the engine temperature sensor.
   - 3.4 Connect the remaining wire from the assembly to the "M" terminal of the starter.
4. Install the starting fluid cylinder. See **Fig. 1.**
   - 4.1 Replace the Dieselmatic valve gasket. Spread the new gasket with a light film of clean oil.
   - 4.2 Place a new dirt eliminator collar, adhesive-side up, on the valve assembly.

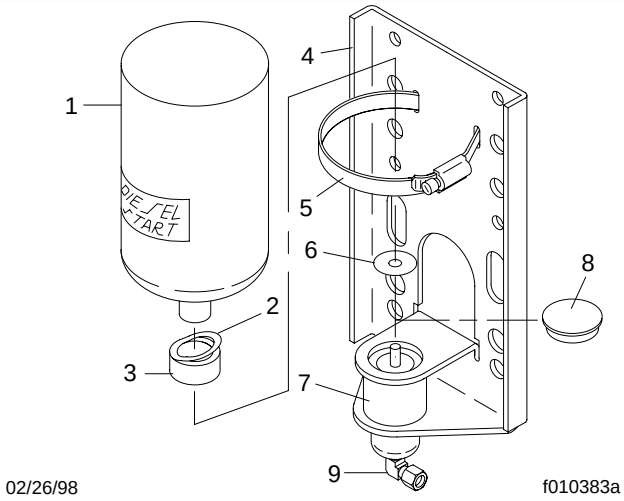
Peel off the collar's paper backing to expose the adhesive.

4.3 Place the new cylinder into the Dieselmatic valve and hand-tighten it firmly.

4.4 Slide the dirt eliminator collar up so it sticks to the cylinder.

4.5 Tighten the clamp around the cylinder 680 N·cm (60 lbf·in).

5. If the ambient temperature is below 4°C (40°F), test the starting fuel system.



Troubleshooting

Use the following procedures to check for most common problems that may prevent starting fluid delivery.

⚠ WARNING

Service starting fluid systems only in a well-ventilated area away from sparks and open flames. The ethyl ether in these systems is flammable and toxic. Wear protective gloves and glasses, and avoid breathing ether fumes. Failure to take these precautions could result in personal injury or property damage.

1. Remove the old cylinder.
   - 1.1 Clean all dirt from the neck of the cylinder and the top of the Dieselmatic® valve before removing the cylinder.
   - 1.2 Loosen the cylinder clamp.
   - 1.3 Pry the dirt eliminator collar off the neck of the cylinder.
   - 1.4 Unscrew the cylinder from the Dieselmatic valve.
   - 1.5 Remove the cylinder from the mounting plate. Cover the top of the valve after the cylinder is removed.
   - 1.6 Remove the old dirt eliminator collar from the valve assembly.
2. Weigh the cylinder to see if it is empty. See **Table 1** for the weight of each cylinder size.

Cylinder Size: oz (g)	Empty Weight: oz (g)	Full Weight: oz (g)
21 (595)	16 (455)	37 (1050)
18 (510)	15 (425)	33 (935)
8 (225)	10 (285)	18 (510)

3. Replace the Dieselmatic valve gasket. Spread the new gasket with a light film of clean oil.
4. If the cylinder is good, install it; if not, replace it.
   - 4.1 Place a new dirt eliminator collar, adhesive-side up, on the valve assembly. Peel off the collar's paper backing to expose the adhesive.
   - 4.2 Place the new cylinder into the Dieselmatic valve and hand-tighten it firmly.
   - 4.3 Slide the dirt eliminator collar up so it sticks to the cylinder.
   - 4.4 Tighten the clamp around the cylinder 680 N·cm (60 lbf·in).

CLOGGED ETHER NOZZLE

1. Disconnect the ether tubing from the nozzle, and cover the nozzle fitting. See **Fig. 2.**
2. Disconnect the black ground wire from the engine temperature sensor, and ground it.

⚠ WARNING

When testing the starting fluid system, wear protective gloves and glasses, and spray the vaporized ether into a container. Failure to do so could result in personal injury.

Troubleshooting

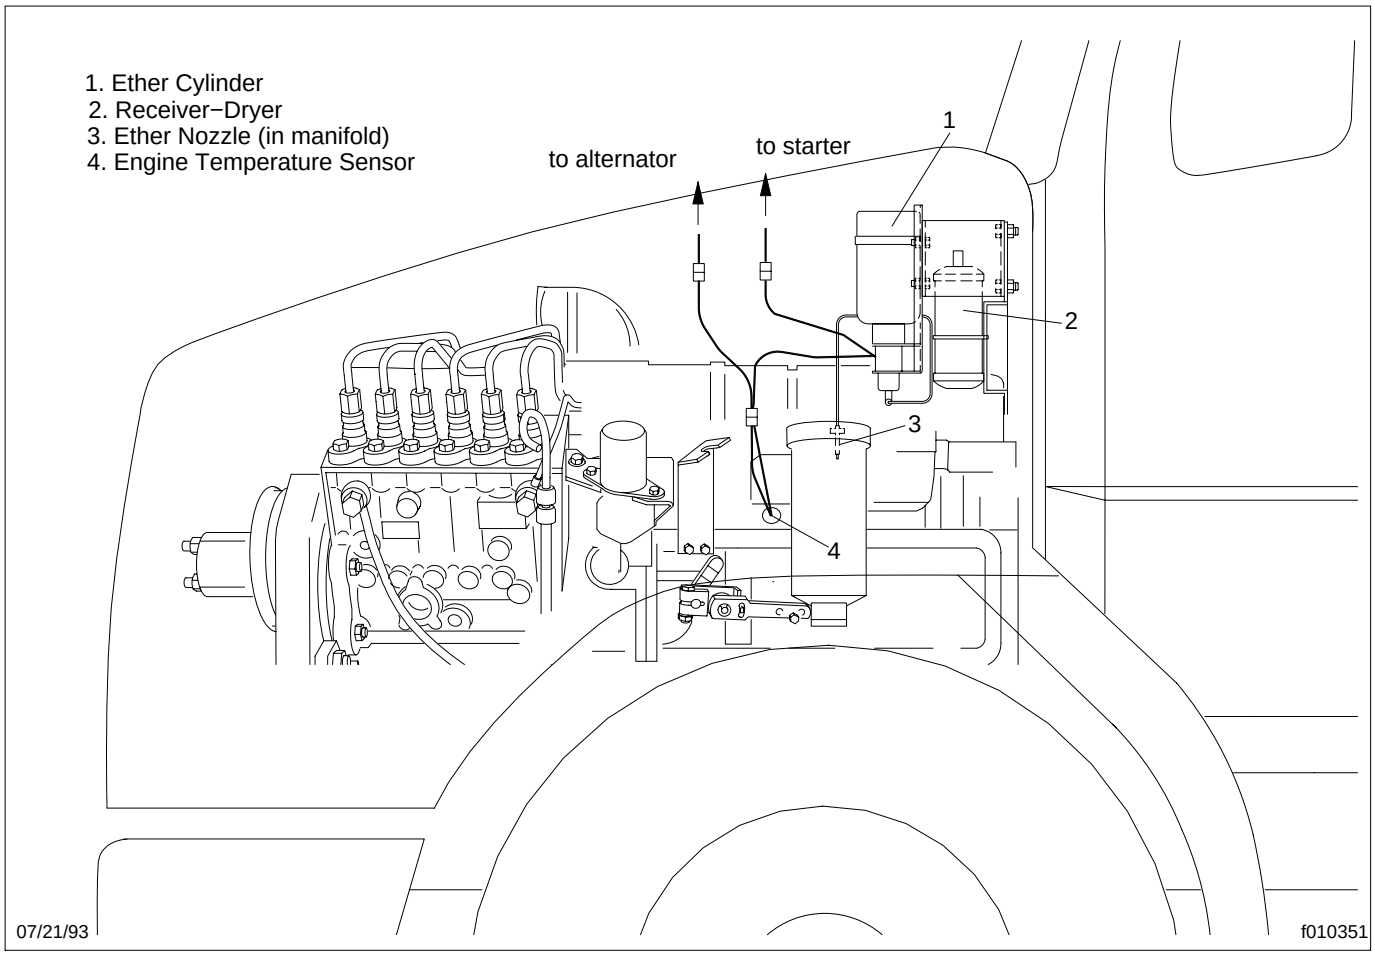

Fig. 2

3. Start the engine, and look for ether to spray from the tubing.

CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

4. If no ether sprays from the tubing, disconnect the tubing at the Blockor® fitting in the base of the cylinder assembly. See **Fig. 1.**
5. Start the engine, and look for ether to spray from the Blockor fitting in the base of the cylinder assembly.

CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

6. If ether sprays from the fitting, but not from the tubing, check for kinks or blockages in the ether tubing and the nozzle. Repair or replace the tubing and nozzle, as needed.

   If no ether sprays from the fitting or tubing, check the Blockor fitting for blockages. Repair or replace the fitting, as needed.

ELECTRICAL PROBLEMS

1. Check for a blown fuse, and for loose wiring connections, shorts, and broken wires.
2. Check that the black ground wire from the valve assembly is connected to the engine temperature sensor, and that the ground wire from the sensor is connected to the alternator ground terminal.
3. Check that the second wire from the valve assembly is connected to the "M" terminal of the starter.

⚠ WARNING

When testing the starting fluid system, wear protective gloves and glasses, and spray the vaporized ether into a container. Failure to do so could result in personal injury.

4. Test the valve.
   - 4.1 Remove the starting fluid cylinder.
   - 4.2 If the ambient air temperature is over 4°C (40°F), remove the black ground wire from the engine temperature sensor, and ground it.
   - 4.3 Crank the starter, and look for the valve plunger (see **Fig. 3**) to move up and stay up while the starter is cranked.

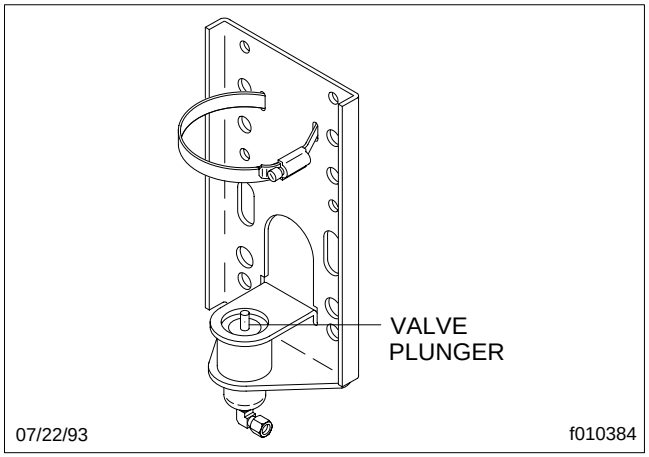

Fig. 3

⚠ CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

5. If the plunger does not move, disconnect both valve assembly wires and momentarily touch the leads across battery terminals. If the valve plunger still does not move up, replace the valve.
6. If the valve operates correctly, check the engine temperature sensor.
   - 6.1 Connect the appropriate wire to the "M" terminal of the starter.
   - 6.2 Remove the sensor from the engine water jacket, and chill it to below freezing for at least ten minutes.
   - 6.3 Install the sensor, grounding it at the alternator ground terminal.
   - 6.4 Connect the black ground wire from the valve assembly to the sensor.
   - 6.5 Crank the engine, and look for the valve plunger to move up and stay up while the starter is cranked.

⚠ CAUTION

Do this test only two times. Activating the starting fluid system in this manner more than twice could result in damage to the system.

7. If the plunger does not move, replace the sensor.

General Description

The Cummins C Series engine **(see Fig. 1 and Fig. 2)** is supported by three engine mounts: two mounts with a single rubber isolator apiece are at the rear of the engine— one on each side of the flywheel housing. The third mount is an underslung crossmember that supports the front of the engine with two rubber isolators.

For detailed repair procedures and other engine service not covered in this section, refer to the *Cummins C Series Operation and Maintenance Manual* , *Cummins Troubleshooting and Repair Manual C Series*, and *Cummins Workshop Manual C Series*.

General Description

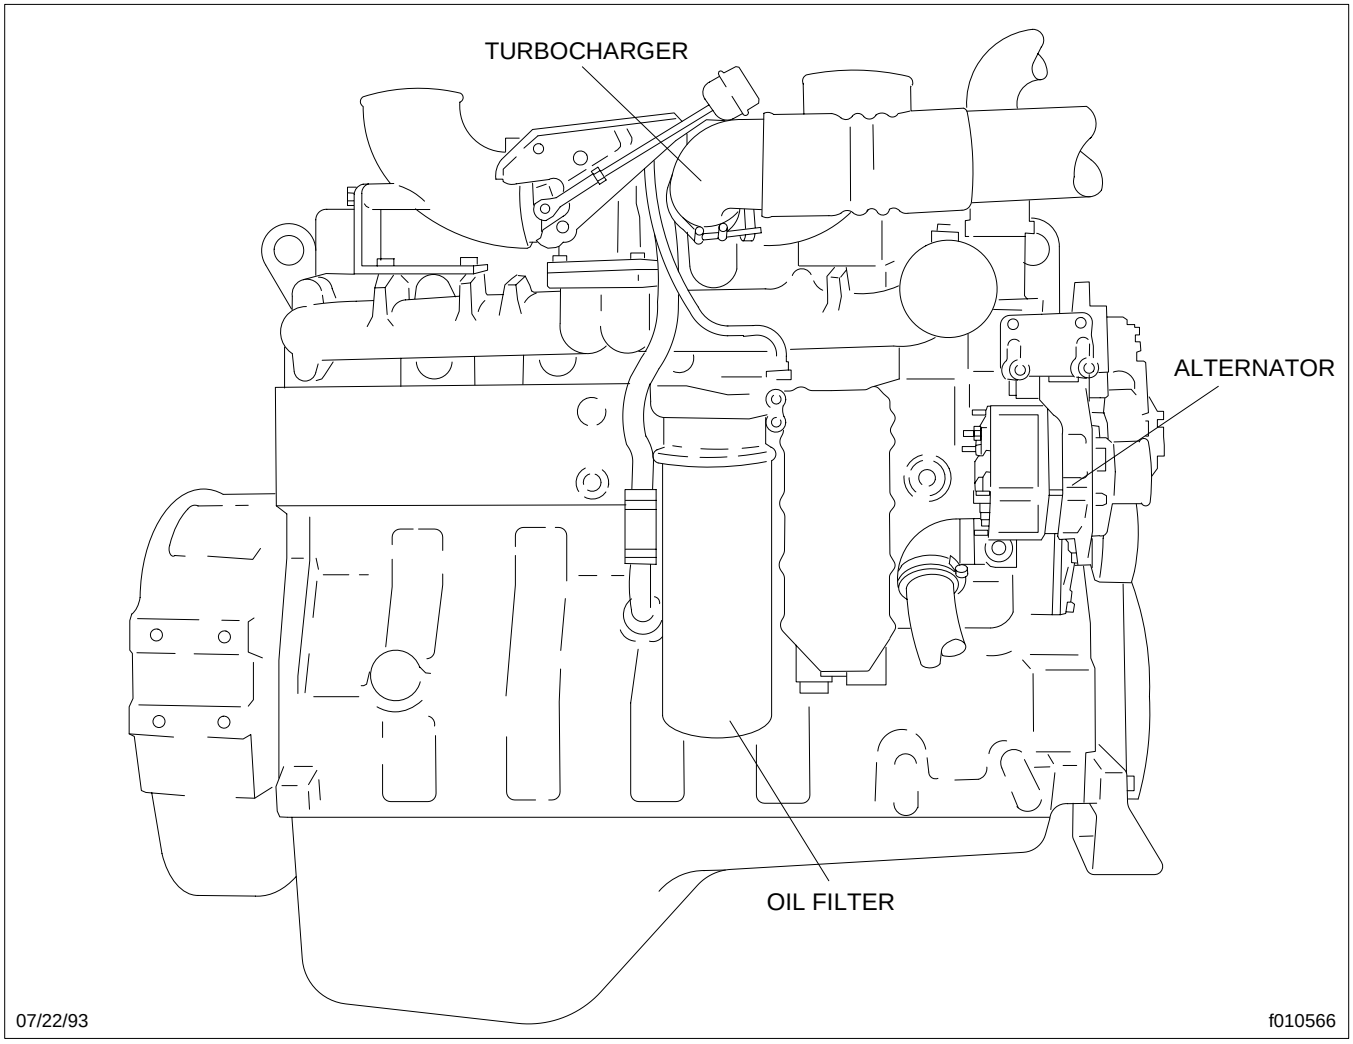

Fig. 2

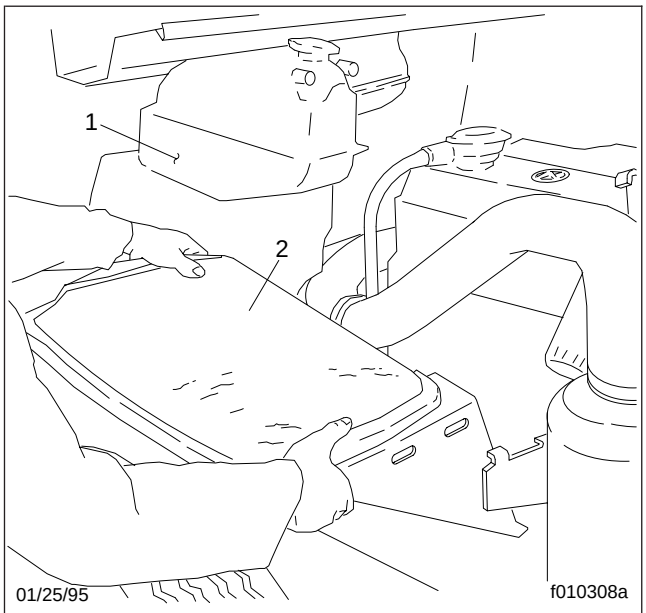


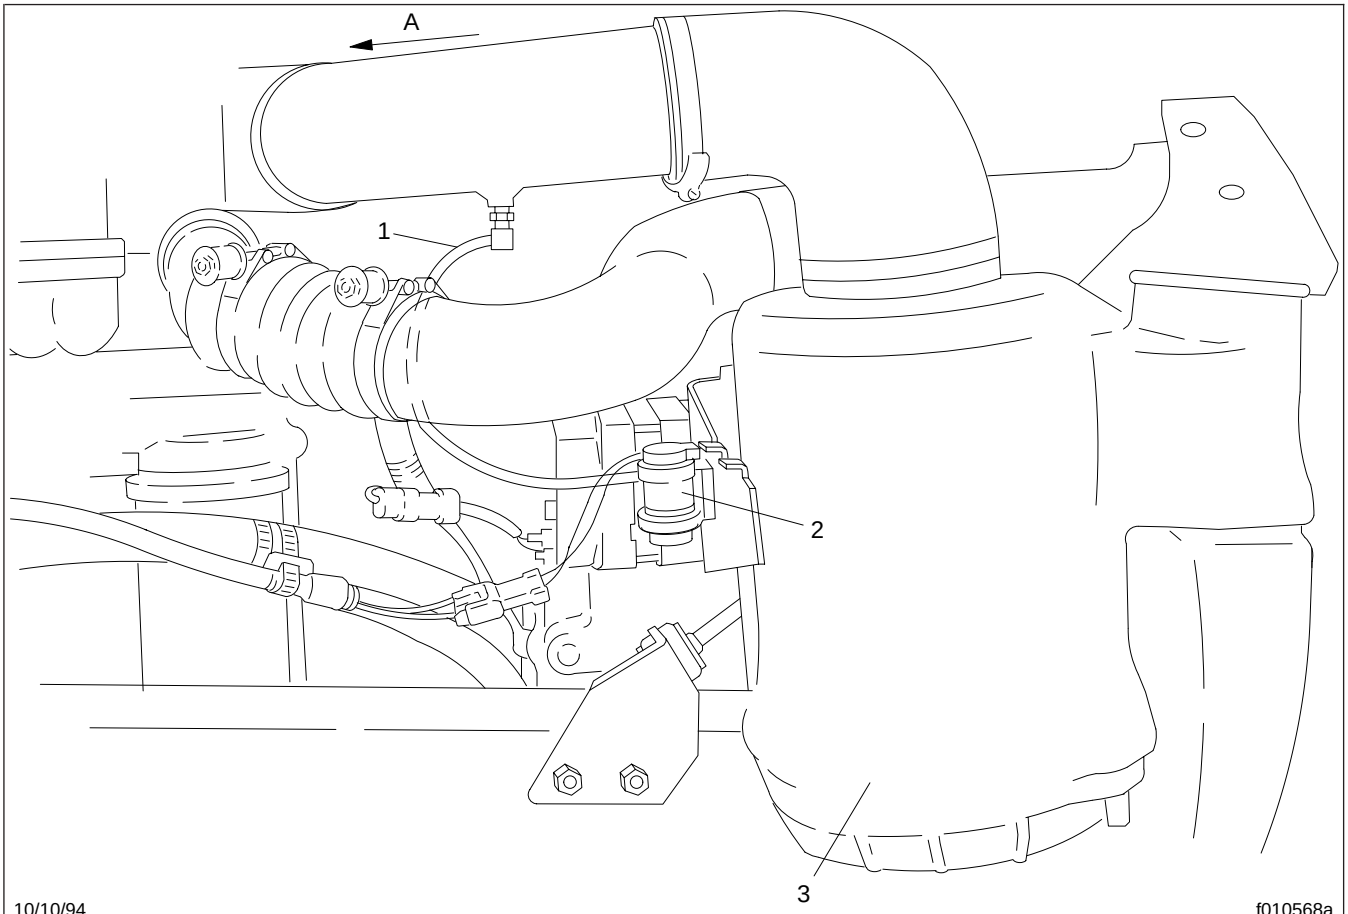
Removal

1. Apply the parking brakes, chock the tires, and (if applicable) drain the air system.
2. If the vehicle is equipped with a battery shutoff switch, turn off the switch; otherwise, disconnect the batteries.
   - 2.1 Disconnect the battery ground cable at the vehicle frame.
   - 2.2 Disconnect the positive battery cable from the batteries.
3. Remove the transmission. For instructions, see **Group 26**.
4. Remove the hood and bumper. For instructions, see **Group 88**.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

5. Drain the radiator.
   - 5.1 Open the petcock at the bottom of the radiator to drain the engine coolant.
   - 5.2 Loosen the surge tank cap.
6. Remove the right fender splash shield. See **Fig. 1**.
7. Remove the air cleaner. See **Fig. 2**.
   - 7.1 Remove the air intake ducting from the top of the air cleaner.
   - 7.2 Remove the four nuts (**Fig. 3**) from the inside of the air cleaner mounting bracket.
   - 7.3 Remove the air cleaner from the mounting bracket.
8. Disconnect or remove the air intake and exhaust ducting, and the air hoses.
   - 8.1 Disconnect the air restriction indicator hose (**Fig. 2**), and remove the air intake ducting between the air cleaner and the front of the turbocharger.



1. Surge Tank
2. Splash Shield

Fig. 1, Right Fender Splash Shield

   - 8.2 Loosen the V-band clamp (**Fig. 4**) that holds the forward end of the exhaust pipe to the rear of the turbocharger.
   - 8.3 Loosen the wide-band clamp that holds the rear end of the exhaust pipe to the flex pipe.
   - 8.4 Remove the exhaust pipe from the vehicle.
   - 8.5 Remove the air ducting between the turbocharger and the charge air cooler.
   - 8.6 Disconnect the air outlet hose from the charge air cooler.
   - 8.7 If the vehicle is equipped with air brakes, disconnect the air compressor outlet line (**Fig. 5**), and the two air signal lines (**Fig. 5**) at the air compressor and the air governor.
9. Disconnect the coolant hoses.
   - 9.1 Disconnect the coolant inlet and outlet hoses from the radiator.
   - 9.2 Disconnect the vent hoses (**Fig. 6**) from the radiator and the engine block.

Removal and Installation

A. To turbocharger.
1. Air Restriction Indicator Hose

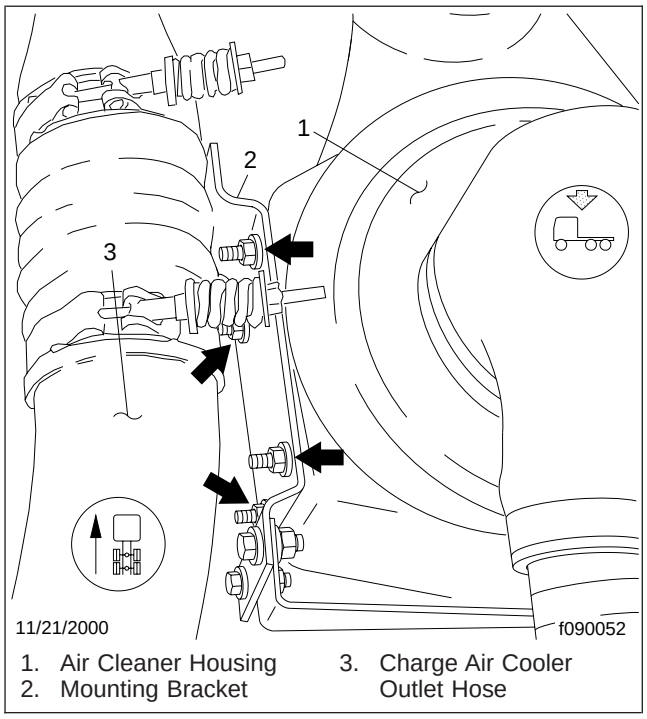
9.3 Disconnect the fill hose (**Fig. 7**) from the engine coolant inlet hose.

9.4 Disconnect the heater outlet hose (**Fig. 7**) from the engine coolant inlet hose.

9.5 Disconnect the heater inlet hose (**Fig. 8**) from the engine block.

10. Remove the refrigerant compressor and condenser.

10.1 Disconnect the compressor electrical connector.



10.2 Remove the six bolts that hold the compressor in the compressor mounting bracket.

10.3 Lower the compressor and remove the belt from the refrigerant compressor pulley.

NOTE: If replacing the engine, remove the four capscrews that hold the compressor mounting bracket to the engine, and remove the bracket for installation on the new engine.

10.4 Remove the air recirculation shield (**Fig. 9**) from the left side of the charge air cooler and radiator.

10.5 Disconnect the refrigerant lines from the stand-off bracket above the power steering fluid reservoir.

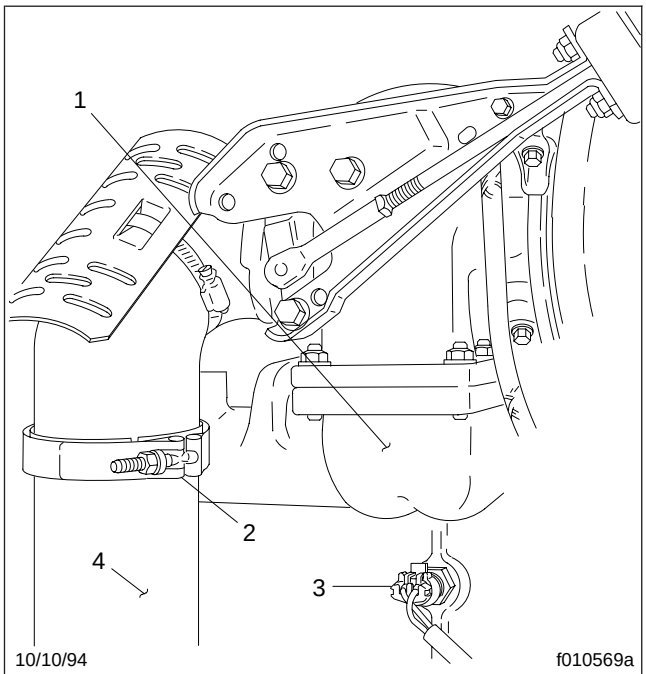
10.6 Remove the four bolts (**Fig. 9**) that hold the condenser on the charge air cooler.

10.7 To keep the refrigerant system intact, with no leaks and no need for purging and recharging, move the refrigerant compressor and condenser to the side at the same time.



10.8 Wrap the condenser in a protective blanket, or sandwich it between two sheets of cardboard or wood to prevent damage to the condenser fins. Secure the compressor and condenser out of the way with wire.

11. Remove the radiator and charge air cooler assembly.

11.1 Hook a lifting chain to the radiator and charge air cooler assembly, and fasten the chain to a crane.

11.2 Remove the nuts, washers, and rubber isolators from the forward ends of the radiator struts. See **Fig. 10**.

11.3 Remove the nuts and washers from the radiator mounts. See **Fig. 10**.

11.4 Lift the radiator and charge air cooler from the vehicle as a single unit. See **Fig. 11**.

12. Remove the two bolts that hold the power steering pump to the rear of the air compressor, and move the pump aside while keeping the steering fluid system intact.

13. Disconnect the engine fuel and oil system components.

13.1 Disconnect the fuel delivery line at the fuel transfer pump, below the fuel filter. See **Fig. 12**.

13.2 Disconnect the throttle cable from the throttle lever, and compress the push-snap fitting to remove the cable from the cable bracket. See **Fig. 5**.

13.3 Disconnect the fuel return line (**Fig. 5**) from the injection pump.

13.4 Disconnect the oil pressure gauge line from the fitting below the fuel filter.

Removal and Installation

14. Disconnect the engine electrical connections.

    14.1 Disconnect the engine ground strap from the starter.

    14.2 Disconnect the wires from the starter, and label them for reassembly.

    14.3 Disconnect the harness wiring connector at the coolant temperature sensor behind the oil filter. See **Fig. 4**.

    14.4 Disconnect the harness wiring connector at the coolant temperature sensor (**Fig. 13**) behind the alternator.

    14.5 Disconnect the harness from the alternator, and label the alternator connections for reassembly.

    14.6 Disconnect the harness wiring connector at the engine shutdown solenoid. See **Fig. 5**.

    14.7 Disconnect the wiring connector for the tachometer sensor, at the upper left side of the engine flywheel housing.

    14.8 Disconnect the engine wiring harness from any additional options, and label the wiring connectors for reassembly.

    14.9 Disconnect the harness from the stand-off bracket on the rear of the engine intake manifold.

    14.10 Pull the harness off to the left side of the engine where it will be out of the way.

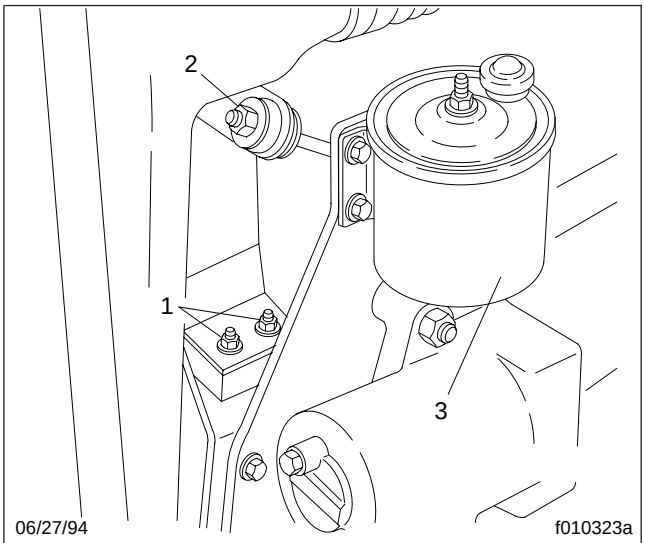
⚠ WARNING



The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

15.1 Securely attach a lifting chain to the engine. Attach the chain to a crane, and raise the chain to remove any slack.

15.2 Remove the two bolts from the front engine mount isolators.

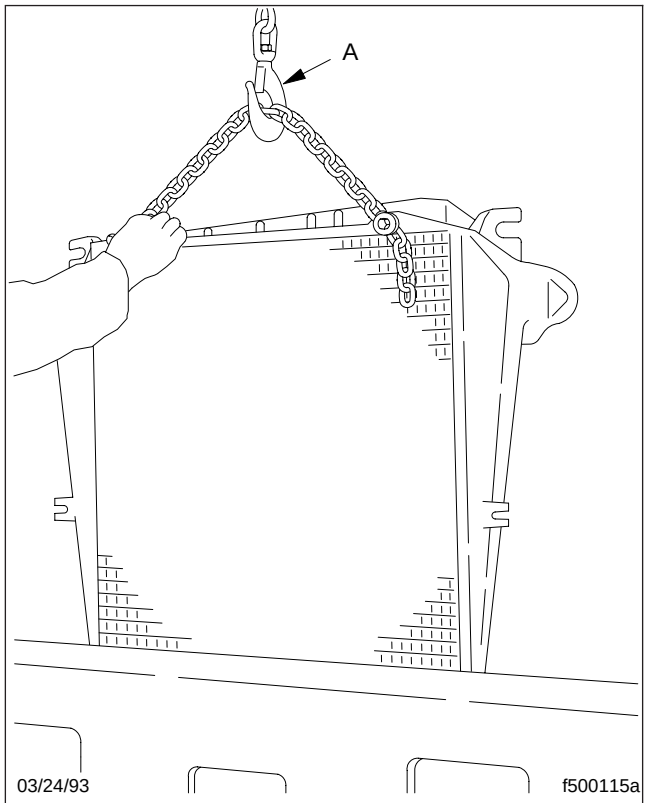
15.3 Remove the bolt from each of the two rear engine mount isolators.

Removal and Installation

1. Left Radiator Mount Nuts
2. Left Radiator Strut Nuts
3. Power Steering Fluid Reservoir

Fig. 10, Radiator Strut and Mount Fasteners

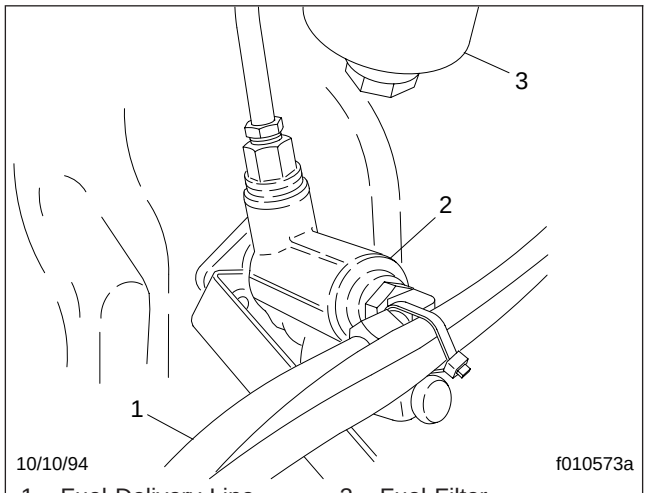
15.4 Carefully lift the engine, and pull it forward to remove it from the engine compartment.



Installation

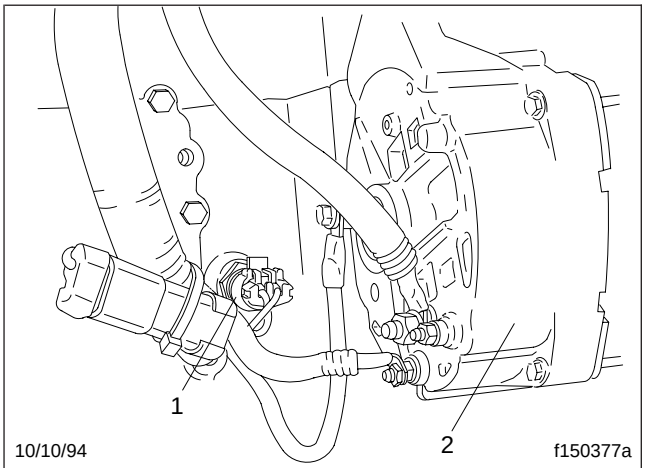
1. Examine all engine support components for damage and extreme wear. Replace components as necessary.
2. Install the engine in the vehicle.

⚠ WARNING



The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely installed on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

2.1 Securely attach a lifting chain to the engine. Attach the chain to a crane, and raise the chain to remove any slack.



A. Use a crane to lift the radiator and charge air cooler.

2.2 Lift the engine from the engine stands, and carefully lower the engine onto the engine mounts.

2.3 Install the bolts in the two rear engine mounts, and tighten them 241 lbf·ft (327 N·m).

2.4 Install the two bolts in the front engine mount, and tighten them 150 lbf·ft (203 N·m).

2.5 Remove the lifting chain from the engine.

3. Connect the engine electrical connections.

3.1 Route the engine wiring harness across the engine from the left side and connect the harness connector to the coolant temperature sensor behind the oil filter. See **Fig. 4**.

3.2 Connect the harness connector to the coolant temperature sensor behind the alternator. See **Fig. 13**.

3.3 Connect the harness to the alternator. If the alternator wires are not labeled for reassembly, see **Group 15** for alternator wiring instructions.

3.4 Connect the harness wiring connector to the engine shutdown solenoid. See **Fig. 5**.

3.5 Connect the wiring connector to the tachometer sensor, on the left side of the engine flywheel housing.

3.6 Connect the engine wiring harness to any additional options.

3.7 Connect the harness to the wiring stand-off bracket on the rear of the engine intake manifold.

3.8 Connect the wires to the starter. If the wires are not labeled for reassembly, see **Group 15** for starter wiring instructions.

3.9 Connect the engine ground strap to the starter.

4. Connect the engine fuel and oil system components.

4.1 Connect the oil pressure gauge line to the fitting below the fuel filter.

4.2 Connect the fuel return line to the injection pump. See **Fig. 5**.

4.3 Thread the throttle cable down through the throttle cable bracket, and connect the cable to the throttle lever. Compress the push-snap fitting to install the cable in the cable bracket. See **Fig. 5**.

4.4 Connect the fuel delivery line at the fuel transfer pump, below the fuel filter. See **Fig. 12**.

5. Install the power steering pump on the rear of the air compressor, and tighten the two mounting bolts 28 lbf·ft (38 N·m).

6. Install the radiator and charge air cooler assembly.

6.1 Hook a lifting chain to the radiator and charge air cooler assembly, and fasten the chain to a crane.

6.2 Lift the assembly, and carefully lower it into place on the radiator mounts. Install the nuts and washers on the radiator mounting studs. See **Fig. 10**. Tighten the nuts 30 lbf·ft (40 N·m).

6.3 Install the washers, rubber isolators, and nuts on the radiator struts. See **Fig. 10**. Tighten the nuts 35 lbf·ft (47 N·m).

Removal and Installation

6.4 Remove the lifting chain from the assembly.

7. Install the refrigerant compressor and condenser.
   - 7.1 If it was removed, install the refrigerant compressor mounting bracket, and tighten the four capscrews 27 lbf·ft (37 N·m).
   - 7.2 Carefully move the refrigerant compressor and condenser back into place.
   - 7.3 Install the four bolts that hold the condenser to the charge air cooler. See **Fig. 9**. The lower, left bolt also holds the lower end of the left air recirculation shield. Tighten the bolts 15 lbf·ft (20 N·m).
   - 7.4 Install the bolt that holds the top of the air recirculation shield, and tighten the bolt 15 lbf·ft (20 N·m).
   - 7.5 Install the refrigerant compressor on the compressor mounting bracket. Install the belt on the compressor, and lift the compressor in its bracket to tension the belt 100 lb (45 kg). Tighten the six compressor mounting capscrews 28 lbf·ft (38 N·m).
   - 7.6 Connect the compressor electrical connector.
   - 7.7 Connect the refrigerant hoses to the stand-off bracket above the power steering fluid reservoir.
8. Connect the coolant hoses.
   - 8.1 Connect the heater inlet hose to the engine block. See **Fig. 8**.
   - 8.2 Connect the heater outlet hose to the engine coolant inlet hose. See **Fig. 7**.
   - 8.3 Connect the fill hose to the engine coolant inlet hose. See **Fig. 7**.
   - 8.4 Connect the vent hoses to the radiator and the engine block. See **Fig. 6**.
   - 8.5 Connect the coolant inlet and outlet hoses to the radiator.
9. Connect or install the air intake and exhaust ducting, air hoses, and air cleaner.
   - 9.1 Connect the air outlet hose to the charge air cooler. Tighten the charge air cooler hose clamp 60 lbf·in (680 N·cm).
   - 9.2 Install the air ducting between the turbocharger and the charge air cooler, and tighten the charge air cooler hose clamp 60 lbf·in (680 N·cm).
   - 9.3 If the vehicle is equipped with air brakes, connect the air compressor outlet line and the two air signal lines to the air compressor and the air governor. See **Fig. 5**.
   - 9.4 Connect the rear of the exhaust pipe to the flex pipe, and connect the forward end of the exhaust pipe to the rear of the turbocharger. See **Fig. 4**.
   - 9.5 Tighten the wide band clamp that holds the exhaust pipe to the flex pipe.
   - 9.6 Tighten the V-band clamp that holds the exhaust pipe to the turbocharger 85 lbf·in (940 N·cm). Tap the V-band clamp all the way around with a rubber hammer, and tighten the clamp again.
   - 9.7 Position the air cleaner on its bracket, and secure the cleaner with four nuts. See **Fig. 3**. Tighten the nuts 28 lbf·ft (38 N·m).
   - 9.8 Install the air intake ducting between the front of the turbocharger and the air cleaner.
   - 9.9 Connect the air restriction indicator hose to the air intake ducting. See **Fig. 2**.
10. Install the right fender splash shield. See **Fig. 1**.
11. Install the bumper and hood. For instructions, see **Group 88**.
12. If the vehicle is equipped with a battery shutoff switch, turn on the switch; otherwise, connect the batteries.
    - 12.1 Connect the positive battery cable to the batteries.
    - 12.2 Connect the battery ground cable to the vehicle frame.
13. Fill the engine coolant system.
    - 13.1 Close the petcock on the bottom of the radiator.
    - 13.2 Fill the system with coolant at the surge tank. For coolant specifications, see the vehicle maintenance manual.

13.3 Install and tighten the surge tank cap.

14. Start the engine and check for leaks.
15. After the engine has run for about 20 minutes, check the coolant level and add coolant if needed. If a new refrigerant compressor belt was installed, check the belt tension. All new belts will lose tension after 20 minutes of operation. If necessary, tighten the belt 45 kg (100 lb).
16. Fill and bleed the power steering system as needed. For instructions, see **Group 46**.
17. Lower the hood, and remove the chocks from the tires.

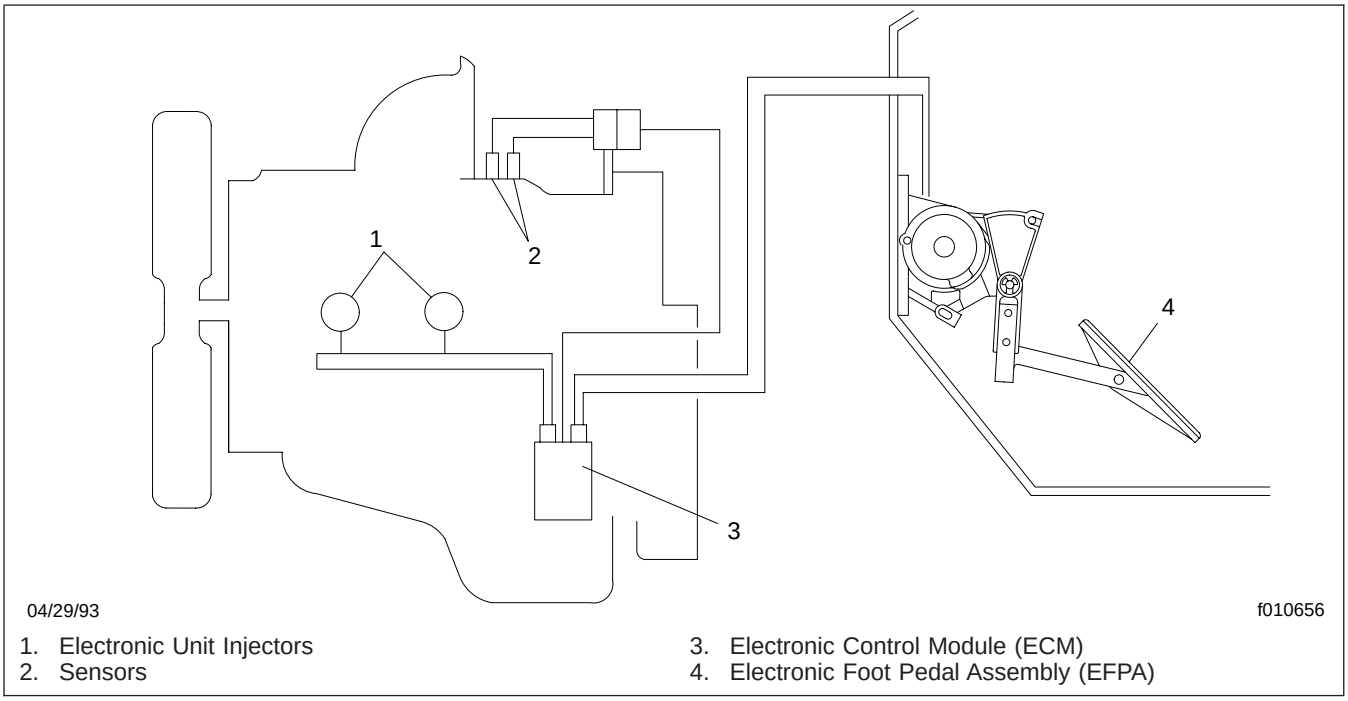
General Description and Principles of Operation

(See Fig. 1 and Fig. 2)

The DDEC II system is an electronic engine control system that is available on all Detroit Diesel Series 50 engines. The system controls engine timing and fuel injection, and monitors various engine functions. The DDEC II system is self-diagnostic, providing the operator with codes to indicate both malfunctioning components and engine-related problems. If potentially damaging engine conditions are detected, the system is capable (depending on installed options) of limiting engine operation, or completely shutting down the engine.



The driver controls the system by using the electronic foot pedal assembly (EFPA), which operates like a standard, mechanical accelerator pedal.

The "Eng Chk" light (ECL), and the "Engine Down" light inform the driver of potential problems. The ECL can also be used to read diagnostic engine codes.

ELECTRONIC CONTROL MODULE (ECM)

The electronic control module **(Fig. 3)** is the center of the system. It is a microprocessor that controls and monitors the system, sending commands to the various engine components, and receiving data from them. The ECM contains an electrically eraseable, programmable read-only memory (EEPROM), which is encoded with engine performance data such as rated horsepower, torque curve, maximum engine speed, and optional protection features.

The ECM is located on the lower left side of the engine.

3. Electronic Control Module (ECM)
4. Electronic Foot Pedal Assembly (EFPA)

Fig. 1, DDEC Components

The center of the system is a microprocessor called the electronic control module (ECM), which controls and monitors the system. The ECM receives data from the various sensors on or near the engine, and sends commands to the electronic unit injectors on the engine, thus controlling engine speed and fuel consumption.

Fig. 2, ECM Diagram

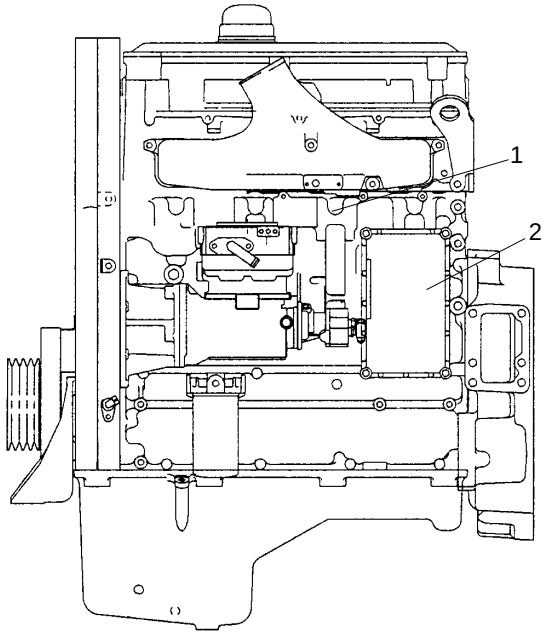
ELECTRONIC FOOT PEDAL ASSEMBLY

The electronic accelerator pedal operates similar to a mechanical accelerator pedal, controlling the amount of fuel injected into the cylinders, and thus engine speed. There is no mechanical throttle linkage in the DDEC II system.

ELECTRONIC UNIT INJECTORS

The electronic unit injectors are located under the valve cover of the engine, and are not externally visible. They are controlled by the ECM, via the electronic foot pedal assembly.

SYNCHRONOUS REFERENCE SENSOR



The synchronous reference sensor, located at the rear of the engine gear case, senses when the number one piston reaches about 45 degrees before top-dead-center (BTDC). This information is sent to the ECM, which uses it to determine engine speed.

TIMING REFERENCE SENSOR

The timing reference sensor, located near the teeth of the timing wheel, senses when each piston reaches 10 degrees before BTDC. The ECM uses this information to monitor engine rpm.

TURBO BOOST PRESSURE SENSOR (TBS)

The turbo boost pressure sensor **(Fig. 3)** , located on the intake manifold, monitors the amount of air entering the engine, and transmits this information to the ECM. The ECM uses this information to regulate the fuel supply in order to control engine smoke.

1. Turbo-Boost Pressure Sensor
2. ECM

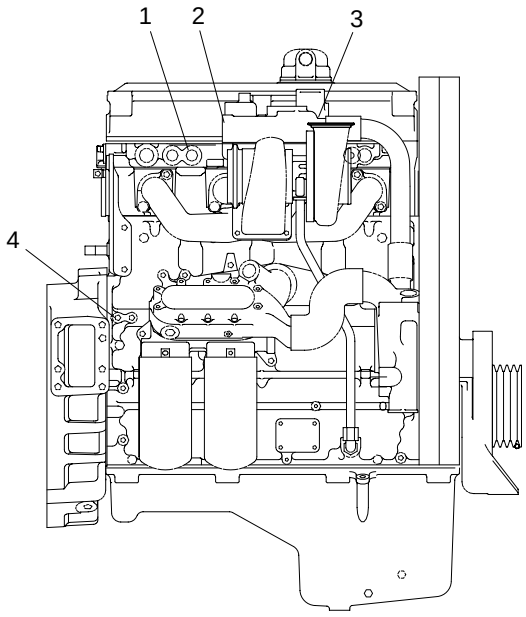

Fig. 3

OIL PRESSURE SENSOR

The oil pressure sensor (**Fig. 4**), which is connected to the main oil gallery, sends continuous electrical signals to the ECM, telling what the oil pressure is at any given speed. If a low oil pressure signal is detected by the ECM for more than seven seconds, the ECM signals the dash warning light ("Engine Down"), and if the system is so equipped, begins to shut down the engine.

OIL TEMPERATURE SENSOR

The oil temperature sensor monitors the temperature of the engine oil, and relays this information to the

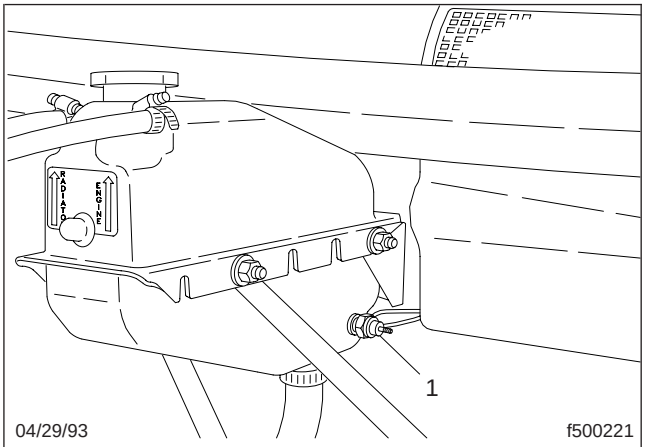
ECM. The ECM changes the engine speed according to this information, improving cold weather starts and providing faster warm-ups. If the oil temperature is too high for more than two seconds, the "Engine Down" dash light will come on, and if the vehicle is equipped with engine shutdown options, the engine will shut down.

COOLANT LEVEL SENSOR (CLS)



The coolant level sensor, which is located on the surge tank **(see Fig. 5)** , monitors the level and temperature of the coolant in the surge tank, and relays this information to the ECM. If the coolant level is too low, the ECM will turn

on the dash "Engine Down" light, and if the vehicle is equipped with an engine shutdown option, the engine will shut down.

DASH LIGHTS AND CONTROLS

There are two standard dash lights, the amber "Eng Chk" light and the red "Engine Down" light. Both are

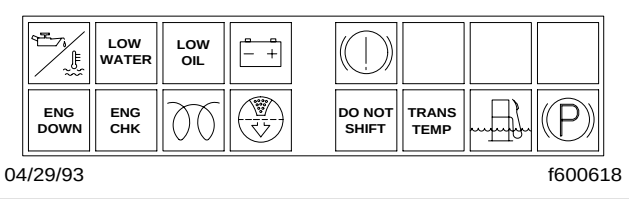
located on the dashboard lightbar **(see Fig. 6)** , and both light up when the ignition is turned on. If the DDEC II system and the engine are functioning normally, both lights will go out after three to eight seconds.



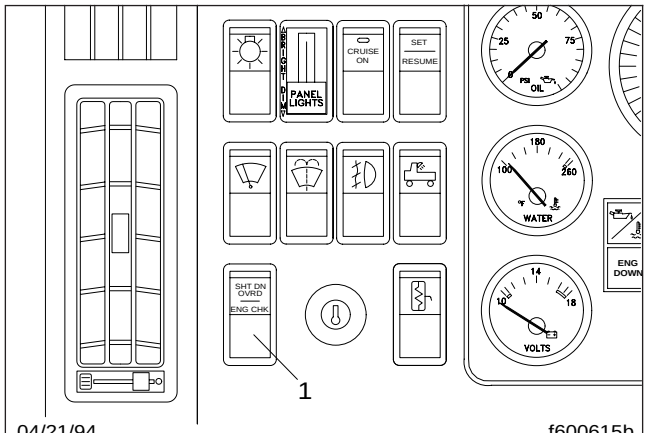


Fig. 6

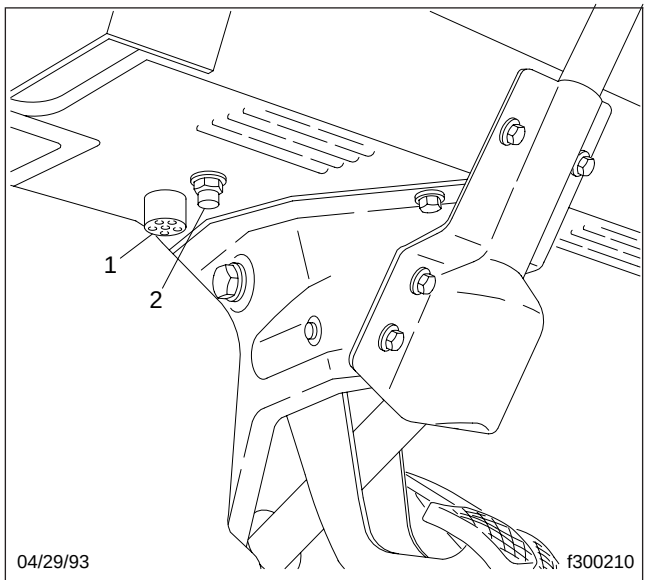
If the vehicle is equipped with cruise control, the cruise control system is connected to the main DDEC II system; it doesn't operate as a separate system. **See Fig. 7** for the location of the cruise control switches on the dash.



The "Eng Chk" button **(Fig. 8)** , on the bottom side of the lower left dash panel, is used to read the diagnostic codes from the "Eng Chk" light.

On vehicles with the engine shutdown option, an "Override" button allows the driver to get the vehicle off the road if the engine begins to shut down. It is on the left-side dash panel **(see Fig. 7)** .

General Description

This is a general description of, first, the standard features of the Detroit Diesel Electronic Control System (DDEC III) as installed on Freightliner vehicles, and second, the components that make up DDEC III. This section has a brief description of different ways to troubleshoot the DDEC III, but doesn't have the actual troubleshooting procedures. For troubleshooting procedures and specifications, refer to the *Detroit Diesel DDEC III Troubleshooting Guide*.

To tell if an engine is equipped with DDEC II or DDEC III, find the Electronic Control Module (ECM) on the left side of the engine. **See Fig. 1.** A DDEC II Electronic Control Module has two 30-pin connectors, two 5-pin connectors, and a 6-pin connector, and all five connectors plug into *one* end of the ECM.

2. Electronic Control Module (ECM)

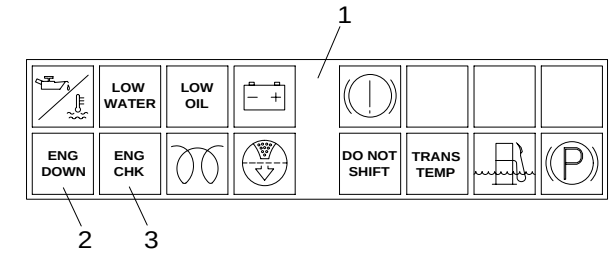
Fig. 1, Electronic Control Module Location

A DDEC III ECM has wiring harnesses plugged into *two* ends: The Detroit Diesel wiring harnesses (one 30-pin connector and two smaller connectors) plug into one end of the ECM; the Freightliner wiring harnesses (one 30-pin connector, plus a 5-pin and a 6-pin connector) plug into the opposite end of the ECM. A short, pigtail harness branches off the harness coming from the 30-pin connector on the Detroit Diesel side of the ECM. This pigtail harness wraps around the ECM and ends in a 3-pin connector near the Freightliner side. The pigtail harness connects with the Freightliner electrical engine harness.

FEATURES

The Detroit Diesel Electronic Control System (DDEC III) controls and monitors Detroit Diesel Series 50 engines installed in Freightliner vehicles. DDEC III, first offered with Detroit Diesel 1994 engines, can protect the engines from serious damage caused by:

- High Coolant Temperature
- High Oil Temperature
- Low Coolant Level
- Low Oil Pressure



If coolant or oil temperatures rise too high, or if coolant level or oil pressure drop too low, dash warning lights will light and a buzzer will sound. If this engine condition continues, the standard DDEC III system is programmed to shut down the engine.

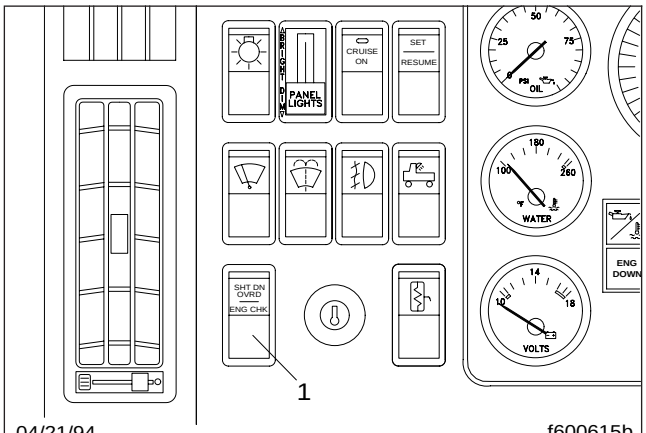
The brain of the DDEC III system is an electronic control module (ECM). The ECM receives information from the engine sensors provided on the engine by Detroit Diesel, and information from the electronic throttle pedal, vehicle speed sensor, and coolant level sensor provided by Freightliner. Comparing this information with the calibration tables in its memory, the ECM controls the fuel timing and quantity of fuel that the electronic unit (fuel) injectors deliver to the engine. This control improves fuel economy and lowers exhaust emissions.

The DDEC III system also provides limiting and variable speed governing. The Limiting Speed Governor fuels the engine according to the driver's use of the throttle. An optional Variable Speed Governor will hold the engine at a constant requested speed (within engine capabilities) regardless of load changes such as hills or winds. The Variable Speed Governor is usually used to provide steady, even power to a PTO (controlled with the cruise control switches while the vehicle is parked), and it will hold the engine speed constant without increased use of the hand throttle or throttle pedal.

General Description

While controlling fuel delivery to the unit injectors, the ECM also monitors sensor reports about oil temperature, fuel temperature, etc. If any of the sensors report a problem, the ECM activates first the "Engine Check" light and then the "Engine Down" light in the warning and indicator light module. **See Fig. 2.** The Engine Check light will come on if the problem is minor enough that it can be solved as soon as convenient. If the problem resolves itself, for example, if the coolant temperature drops back down into the acceptable range, the Engine Check light will go out. However, if the problem gets worse: For example, if the coolant or oil temperature continues to rise, the ECM will reduce engine power by cutting the fuel to the injectors. As the problem gets worse, the ECM will continue to cut fuel until engine power is reduced by 30 percent. At that point, (if the engine is programmed with the shutdown option) the ECM will turn on the Engine Down light. Thirty seconds after that, the ECM will shut down the engine by not delivering any fuel to the injectors.

02/10/94 f600618a



1. Warning and Indicator Light Module
2. Engine Down Light
3. Engine Check Light

Fig. 2, DDEC III Light Module

NOTE: If the driver cannot move the vehicle to safety within thirty seconds, the driver must press the Shutdown Override/Engine Check switch immediately after the Engine Down light comes on. Pressing the switch just before shutdown will keep the engine running for thirty more seconds.

If the engine is not programmed to shut down, the ECM will continue to cut fuel delivery to the injectors until the engine is running at 40 percent of original power.

After an emergency engine shutdown, the Shutdown Override/Engine Check switch allows the driver to re-start the engine for thirty seconds and move the vehicle to a new location. Turn the ignition off and then on, and press the override switch. **See Fig. 3.** For additional time, the driver must press the override switch again, every thirty seconds. Emergency engine warning, power derate, and engine shutdown are standard on engines equipped with DDEC III, but an engine can be programmed to give a warning and then cut engine power without shutting down. To reprogram engine options, contact your nearest Freightliner or Detroit Diesel dealer.

1. Shutdown Override/Engine Check Switch

Fig. 3, Shutdown Override/Engine Check Switch

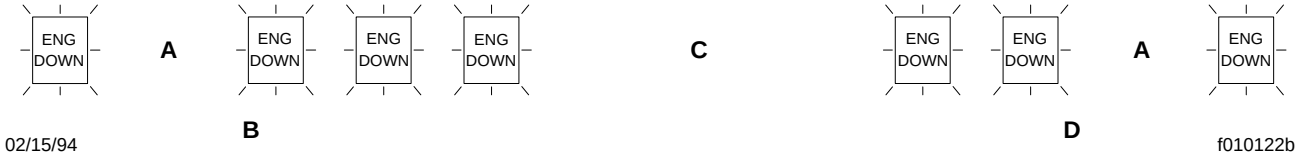
Diagnostics

If the DDEC III reports an engine problem, you have two ways to diagnose it:

- Press the Shutdown Override/Engine Check switch (on the left dash panel) and watch the codes flashed by the Engine Check and Engine Down light. Two types of flash codes represent engine problems. The first type, active codes, represent existing problems and keep the Engine Check or Engine Down light lighted. The second type, historical codes, represent problems that are logged in the ECM but are not active.

  If the Engine Check light and Engine Down light stay on, the engine has a problem, and the DDEC III has a flash code ready to represent that problem. To read the flash code, turn on the ignition or idle the engine, and wait for five seconds. Then press and hold the Shutdown Override/Engine Check switch. The En-

gine Down light will flash a number of times to represent the code for the problem. For example, the code 13 would be one Engine Down light flash followed by a pause, then three more flashes. If the engine has more than one problem, a code for each of the problems will flash with a pause of several seconds between them. **See Fig. 4.** After all the active codes have flashed, or if there are no active codes, the Engine Down light will flash code 25. After that, the Engine Check light will flash any historical codes for problems that are not active but are logged in the ECM. After all the historical codes have flashed, or if there are no historical codes, the Engine Check light will flash code 25. For the meaning of the flash codes, refer to the *Detroit Diesel DDEC III Troubleshooting Guide*.



while the engine is idling and rev the engine slightly. Ninety seconds before the engine shuts down, the Engine Check light will flash. Step on the throttle pedal and rev the engine during this time, and the engine will idle indefinitely.

COMPONENTS

Electronic Control Module

The Electronic Control Module (ECM) is mounted on the lower left side of Detroit Diesel Series 50 engines. Four wiring harnesses connect to the ECM. Two Detroit Diesel harnesses plug into one end of the ECM; two Freightliner harnesses plug into the opposite end.

On the Freightliner end, the first harness, the power harness, runs from the batteries to the ECM, and

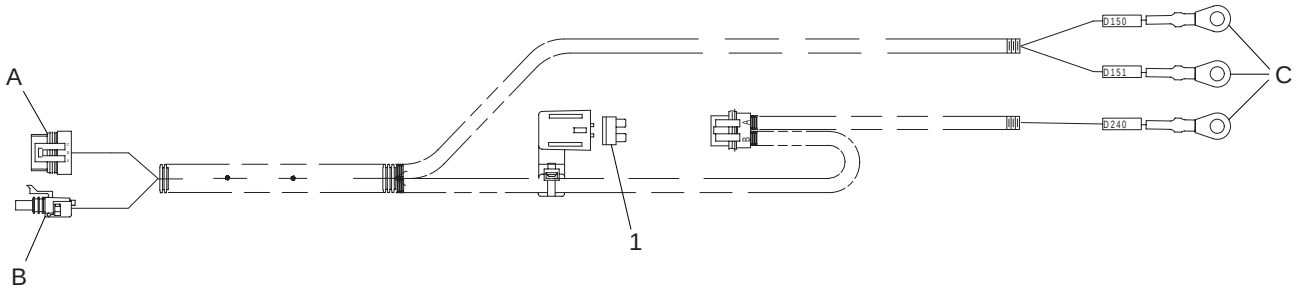
- Use a hand-held Diagnostic Data Reader (DDR) equipped with a DDEC III cartridge. With the ignition turned on or the engine idling, connect the reader to the Deutsch six-pin connector under the lower, left dash panel. If using a DDR, choose reader Mode 01 to read the active codes, and choose Mode 02 to read the historical codes.

Idle Shutdown Timer



The same system that shuts down the engine during a problem also shuts down the engine if the customer requests the optional idle shutdown time. With an idle shutdown timer, the engine automatically shuts down after idling for a predetermined number of minutes. That length of time can be set anywhere between two minutes and 99 minutes. To start the engine after the idle shutdown timer has shut it down, turn the key all the way off, then turn the key on. To make the engine idle longer than the predetermined length of time, release and immediately reapply the parking brake, or press the throttle pedal

includes a single 15 amp fuse. **See Fig. 5** and **Fig. 6**. The fuse is mounted on the battery box, and if the fuse fails, the engine will not run. At the engine, the five-pin power harness connector plugs into the ECM, and the harness's single-pin connector plugs into a connector on the Freightliner electrical engine wiring harness.

NOTE: Before troubleshooting the DDEC III system, make sure the fuses and circuit breaker for the power harness and the ignition circuit are good.

The second harness, the Freightliner electrical engine wiring harness, connects the ECM and the sensors installed by Freightliner (the low coolant level sensor and the vehicle speed sensor) to the cab wiring. **See Fig. 6** and **Fig. 7**. This engine wiring harness also connects the ECM to the tachometer. Three of the wiring harness's connectors plug into the ECM. Two of these connectors, the 30-pin connector and the six-pin connector plug into the Freightliner end of the ECM; the third connector, the

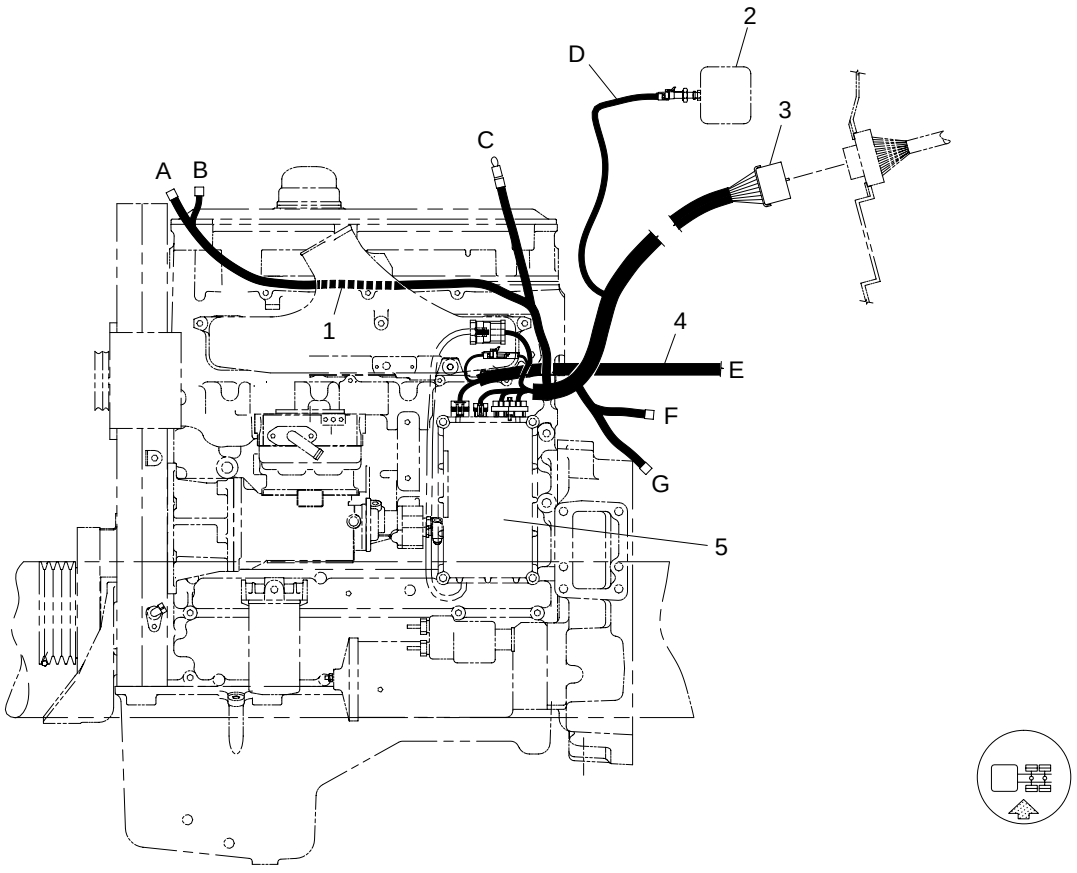
3-pin connector, plugs into a short pigtail harness that is routed around from the opposite end of the ECM. A fourth connector near the ECM, plugs into the single-pin connector on the power harness. At the firewall, the cab interface connector plugs the harness into the cab wiring harness. The low coolant level sensor branch of the harness plugs into the sensor in the radiator surge tank. The vehicle speed sensor branch of the harness plugs into the sensor at the transmission output.

On the Detroit Diesel end of the ECM are one 30-pin connector and two smaller connectors.

The 30-pin connector is on the third wiring harness: The harness that connects the ECM to the turbo boost pressure sensor, the timing and synchronous reference sensors, the temperature sensors for the air, oil, fuel, and coolant, and pressure sensors for the fuel, oil, and coolant. **See Fig. 8.** This harness includes a smaller pigtail harness that runs from the Detroit Diesel end of the ECM and ends in a 3-pin connector near the Freightliner end. This pigtail harness connects to a 3-pin connector at the end of the Freightliner electrical engine wiring harness.



The two smaller wiring connectors plugged into the Detroit Diesel end of the ECM belong to the fourth wiring harness. This harness connects the ECM to the electronic fuel injectors.

A fifth wiring harness, the Freightliner non-electronic component wiring harness (**Fig. 9** and **Fig. 10**), connects cab and chassis wiring at the bulkhead connectors to parts within the engine compartment, including:

- The air conditioning pressure switch
- The magnetic switch
- The starter
- The back-up light and alarm switch
- The transmission oil temperature sender
- The ether start system
- The fan solenoid
- The alternator
- The ammeter shunt

The ECM makes continuous self-diagnostic checks and monitors the DDEC III system from ignition through all engine operating modes. The ECM contains an Electronically Erasable Programmable Read Only Memory (EEPROM), which controls the basic engine functions, including:

- Rated Speed and Power
- Fuel Injection Timing
- Engine Governing
- Torque Shaping
- Cold Start Logic
- Transient Fuel Delivery
- Diagnostics

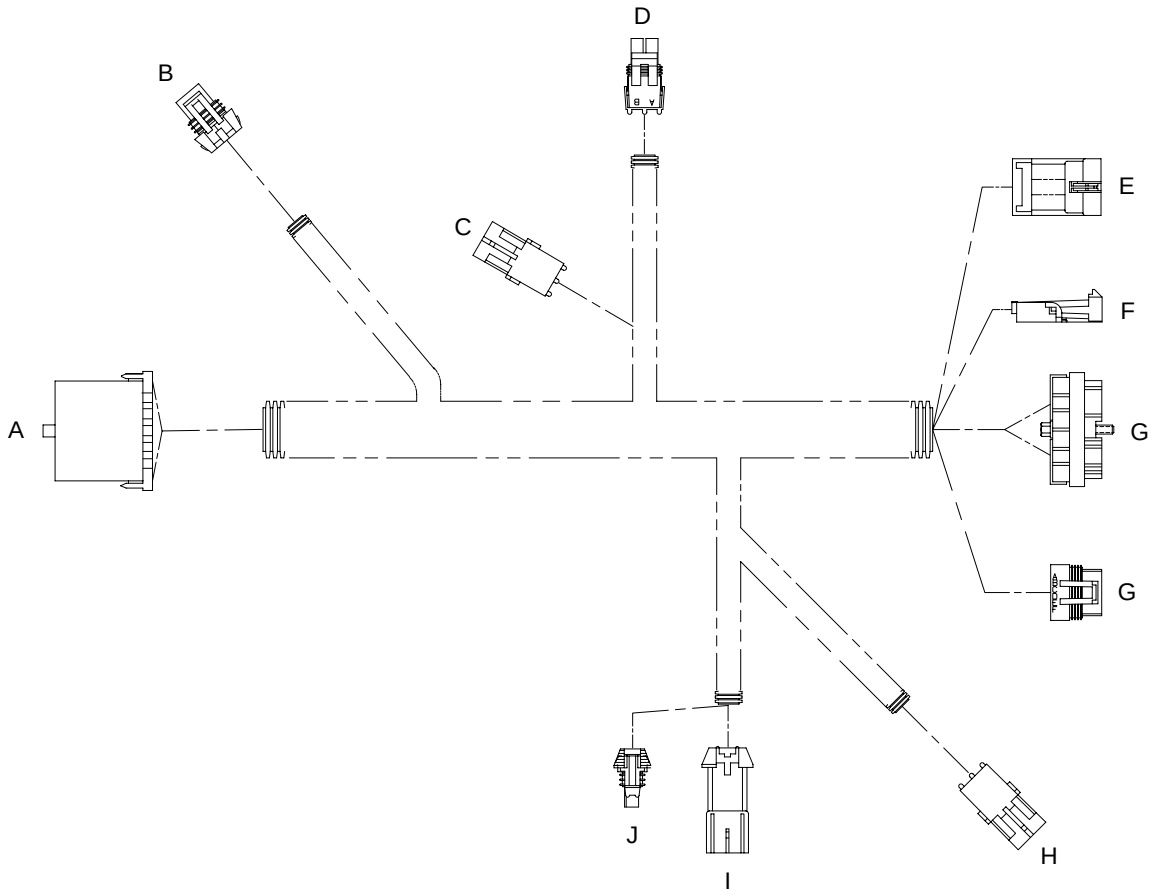
- Engine Protection

For precise fuel delivery and improved fuel economy, the control logic uses calibration tables to determine the duration and timing of fuel delivery to the electronic unit injectors.



ECM Programming

In production, Freightliner programs the Electronically Erasable Programmable Read Only Memory (EEPROM) with the standard engine operating features and any options the customer has specified. Currently, the standard program includes engine shutdown, but the option is available to only cut engine power in emergency situations. To re-program the EEPROM, take the vehicle to the nearest Freightliner or Detroit Diesel dealership.

Electronic Unit Injectors

The Electronic Unit (fuel) Injectors (EUI) operate the same as Detroit Diesel mechanical unit injectors: the cam/rocker arm system powers the high fuel delivery pressure. However, on the EUI, a solenoid controlled

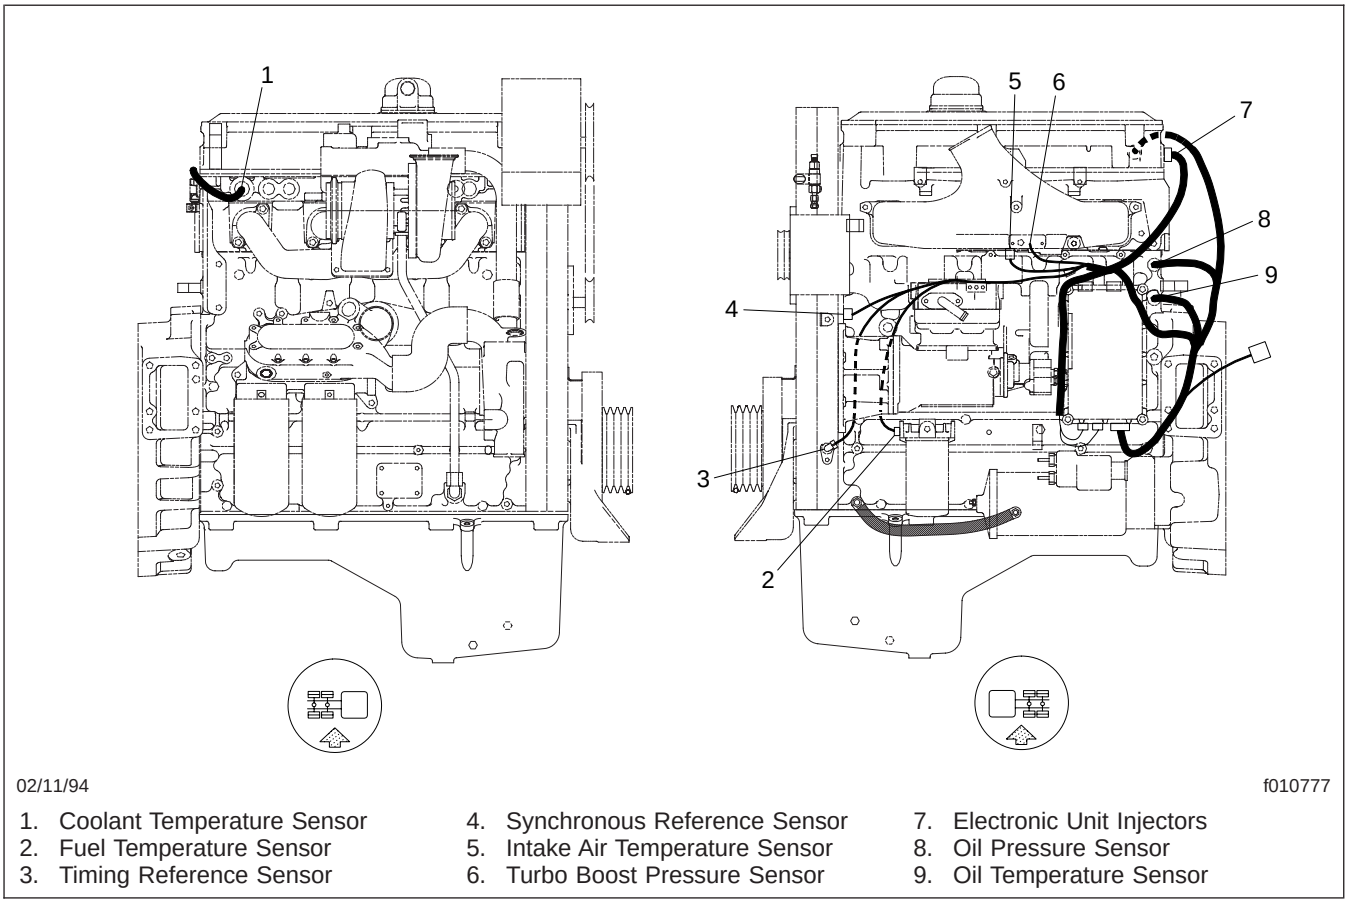
by the ECM controls fuel injection timing and fuel quantity. When the solenoid valve closes, fuel injection begins. When the solenoid opens, fuel injection ends. As long as the ECM keeps the solenoid closed, the unit injector injects fuel into the cylinder.



Timing and Synchronous Reference Sensors

The timing reference sensor (TRS) tells the ECM the engine rpm. This sensor is installed in front of the air compressor, below the air compressor drive.

See Fig. 8. The synchronous reference sensor (SRS) indicates a specific cylinder in the firing order. It is installed in front of the air compressor, above the air compressor drive.

Turbo Boost Pressure Sensor

The Turbo Boost Sensor (TBS) is installed in the side of the air intake manifold, and monitors the pressure of the engine intake air after it has been pressurized by the turbocharger and cooled by the aftercooler.

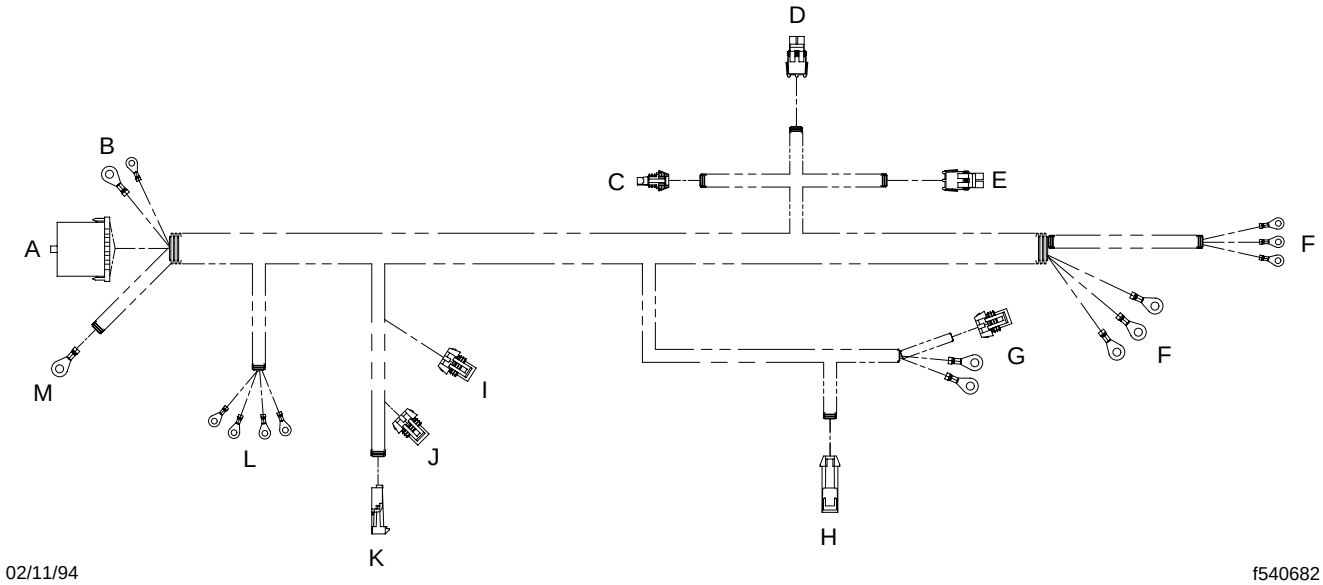
See Fig. 8. The ECM uses information from the TBS to control engine smoke.

Oil Pressure Sensor (See Fig. 8)



The oil pressure sensor is installed in the engine block, right below the rear end of the air intake manifold. This sensor tells the ECM the engine oil pressure in the gallery, and the ECM compares this pressure to the engine rpm. **See Fig. 11.** If oil pressure falls too low in relation to engine rpm, the ECM turns on the Engine Check light and Engine Down light, and an engine oil pressure switch turns on the low oil pressure warning light and buzzer. Thirty seconds later, the ECM shuts down the engine (if the engine is programmed with shutdown protection).

Fuel, Air, Coolant, and Oil Temperature Sensors (See Fig. 8)

The fuel temperature sensor, installed in the secondary fuel filter, measures fuel temperatures for the ECM to use when calculating fuel consumption and fuel input compensation. If the fuel temperature rises above 100°F (38°C), the ECM will increase fuel delivery to the injectors. This increase in volume compensates for the warmer, less dense fuel. If the fuel temperature rises to 140°F (60°C), the ECM will no longer increase the fuel delivery to the injectors. The ECM drops fuel delivery back to the original rate because, at this temperature, the fuel and engine are too hot.

The intake air temperature sensor, installed in the under-side of the air intake manifold, reports engine intake air temperature to the ECM so the ECM can

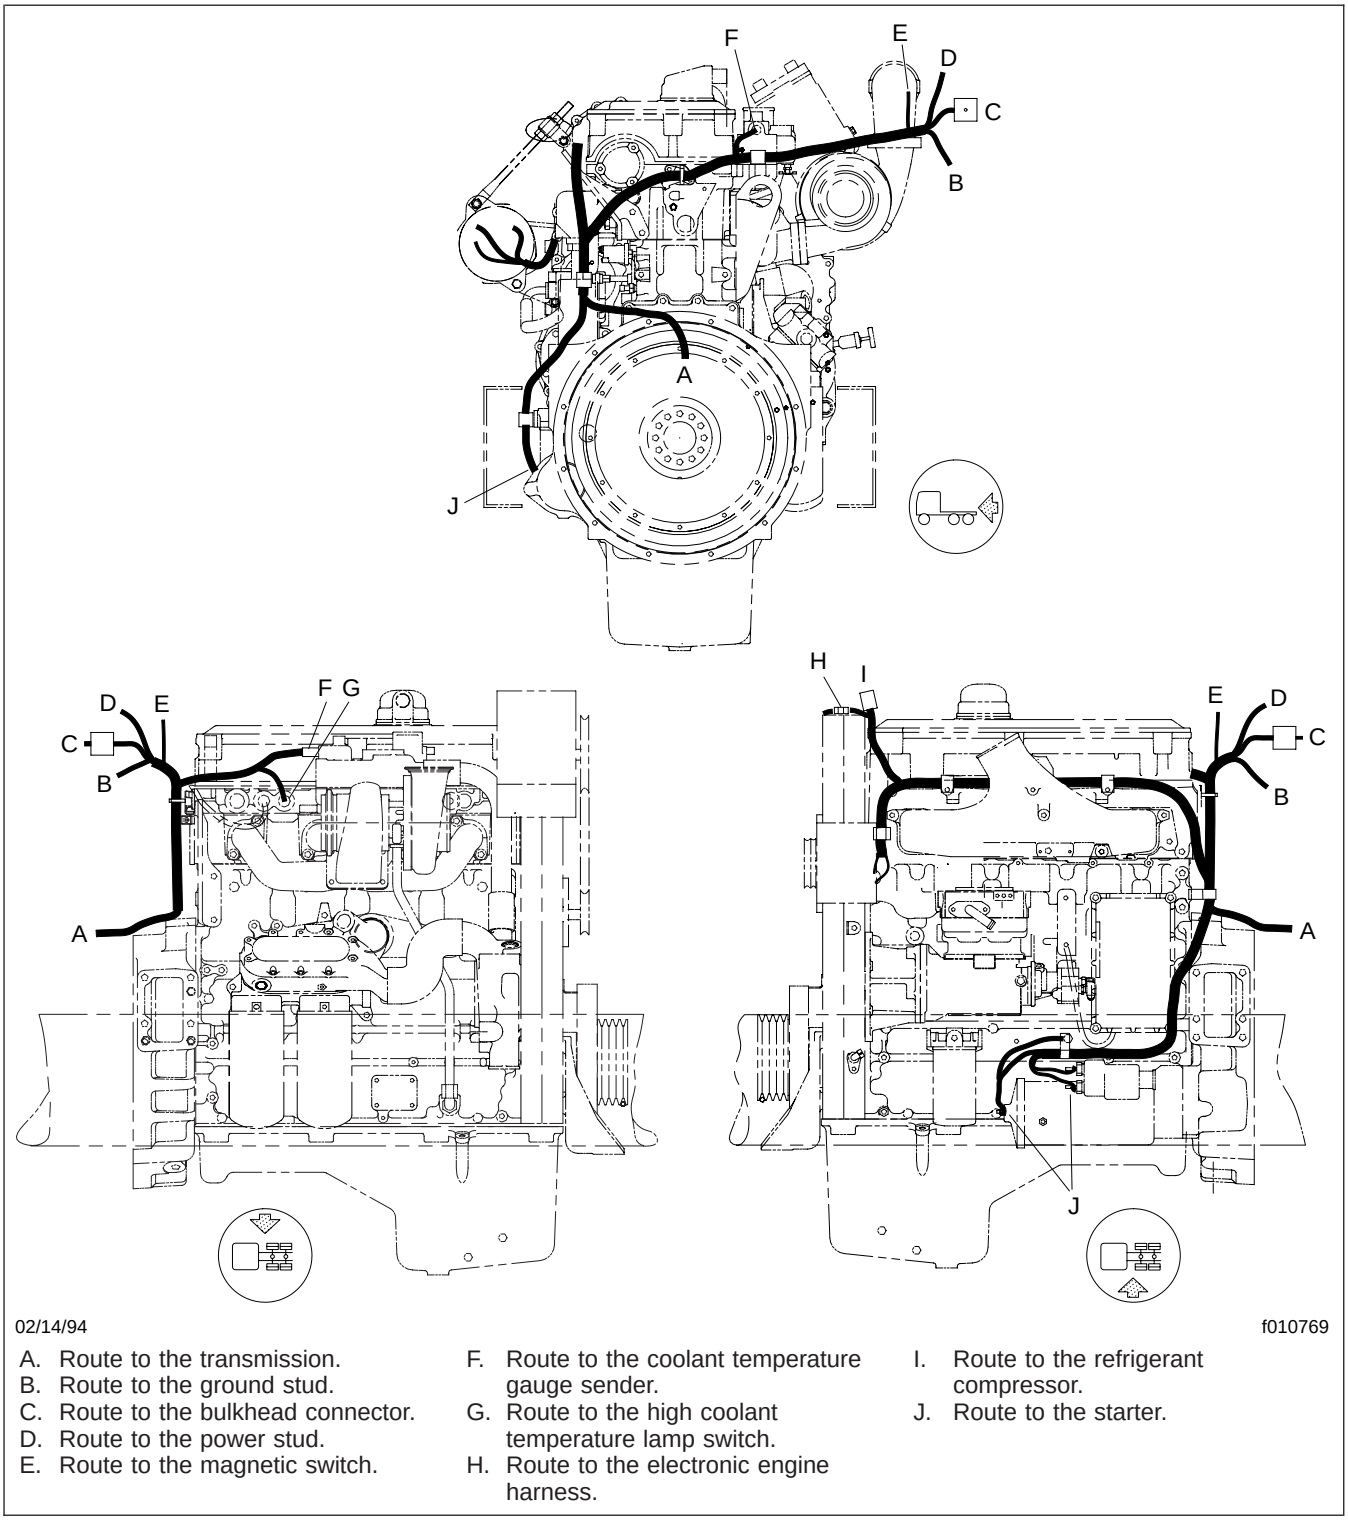
vary the hot idle speed and injection timing for better cold starts and less white smoke.

The coolant temperature sensor, installed in the coolant jacket above the rear end of the exhaust manifold, tells the ECM if coolant temperature exceeds 217°F (103°C). At that temperature, a coolant temperature switch turns on the high coolant temperature light and buzzer, and the ECM turns on the Engine Check light and begins to cut engine power. If the coolant reaches 223°F (106°C), the ECM turns on the Engine Down light and shuts down the engine (if the engine is programmed with shutdown protection).

The oil temperature sensor is installed below the oil pressure sensor, below the rear end of the intake air manifold. **See Fig. 8.** It reports oil temperature to the ECM so the ECM can vary idle speed and injection timing for better cold starts and less white smoke. If oil temperature exceeds 250°F (121°C), the ECM activates the Engine Check light and begins to cut engine power. If the oil temperature reaches 260°F (127°C) the ECM turns on the Engine Down light and shuts down the engine (if the engine is programmed with shutdown protection).



Throttle Position Sensor

The throttle position sensor is part of the electronic foot pedal assembly. Freightliner uses the Williams Electronic throttle pedal with DDEC III systems. There is no mechanical throttle linkage.

NOTE: Williams throttle pedals made to work with DDEC II will work with DDEC III, but the reverse is not true.

Coolant Level Sensor (See Fig. 12)

Freightliner installs the coolant level sensor in the radiator surge tank. The coolant grounds the sensor, so if the coolant level drops below the sensor for more than seven to ten seconds, the low coolant level warnings begin. The warning means more than 10% of the engine coolant is missing, and this early

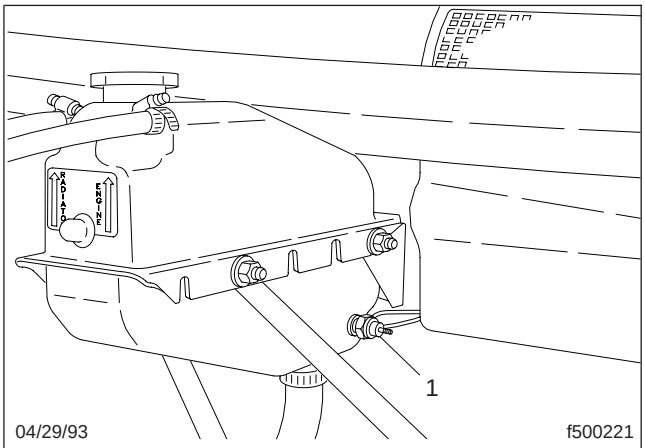
warning will prevent coolant aeration and water jacket cavitation.



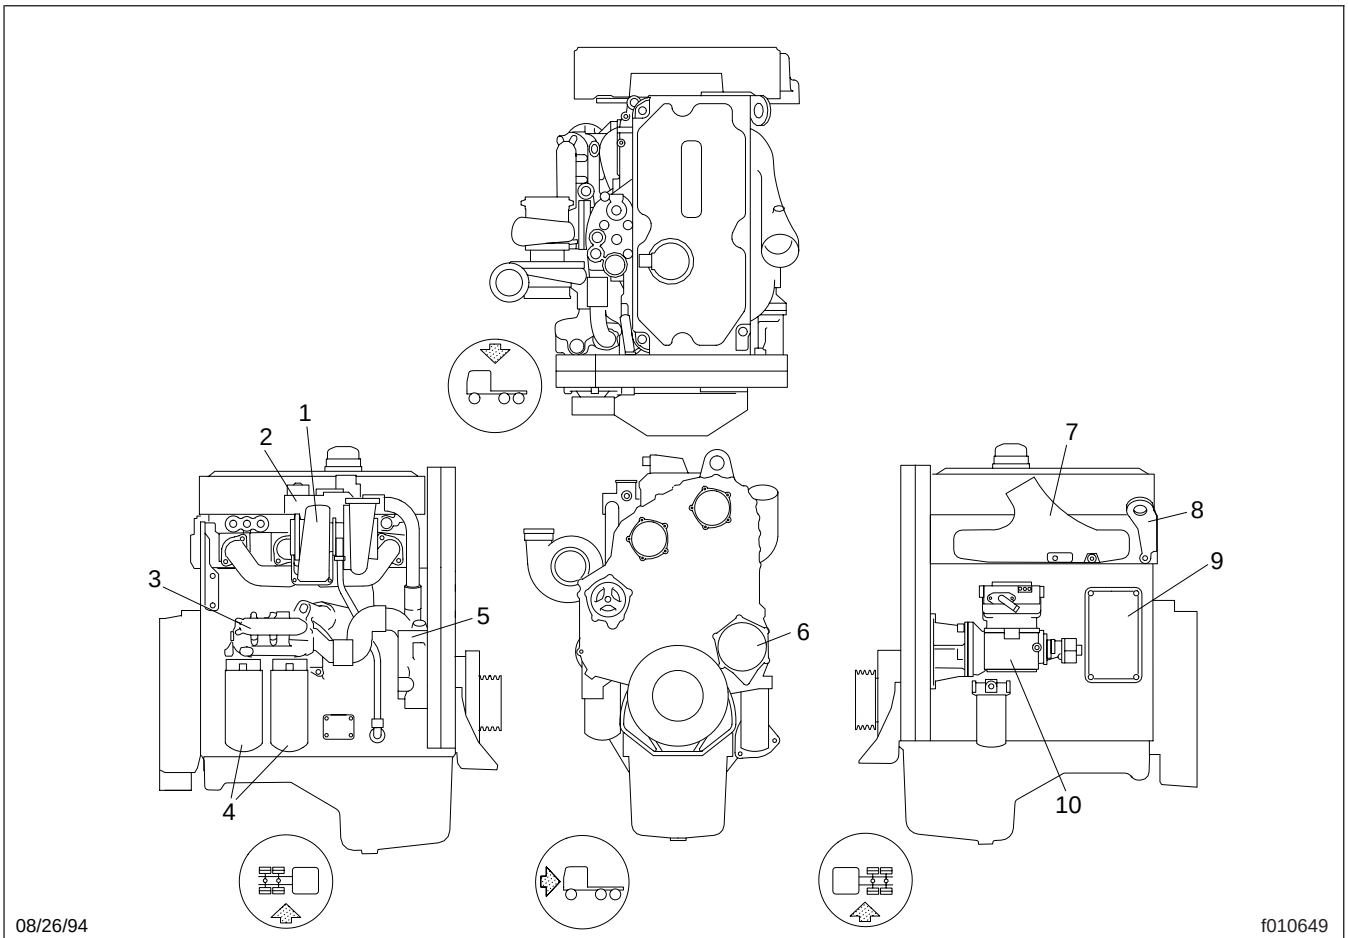


Fig. 12, Sensor Location in Surge Tank

NOTE: If a vehicle is equipped with an optional transmission retarder, and the ECM is reprogrammed by Detroit Diesel, the low coolant level warning light may come on when the transmission retarder is on. For these two functions (coolant level and transmission retarder), Freightliner uses different pin locations on the 30-pin ECM connectors than are specified by Detroit Diesel. This is not a problem because Freightliner also programs the ECM; however, if Detroit Diesel reprograms the ECM, the coolant level and transmission retarder functions will be switched back to the connector pins that Detroit Diesel specifies. If this happens, the low coolant level warning light will come on when the transmission retarder is on. If Detroit Diesel reprograms the ECM for a new exhaust brake, the low coolant level light may stay on continuously. For specific circuits and wiring schematics, refer to the DDEC section in **Group 54** of this manual.

Vehicle Speed Sensor

The vehicle speed sensor is installed in the transmission output, and sends vehicle speed signals to the speedometer and to the ECM. The ECM uses this signal for cruise control and for vehicle speed limiting.

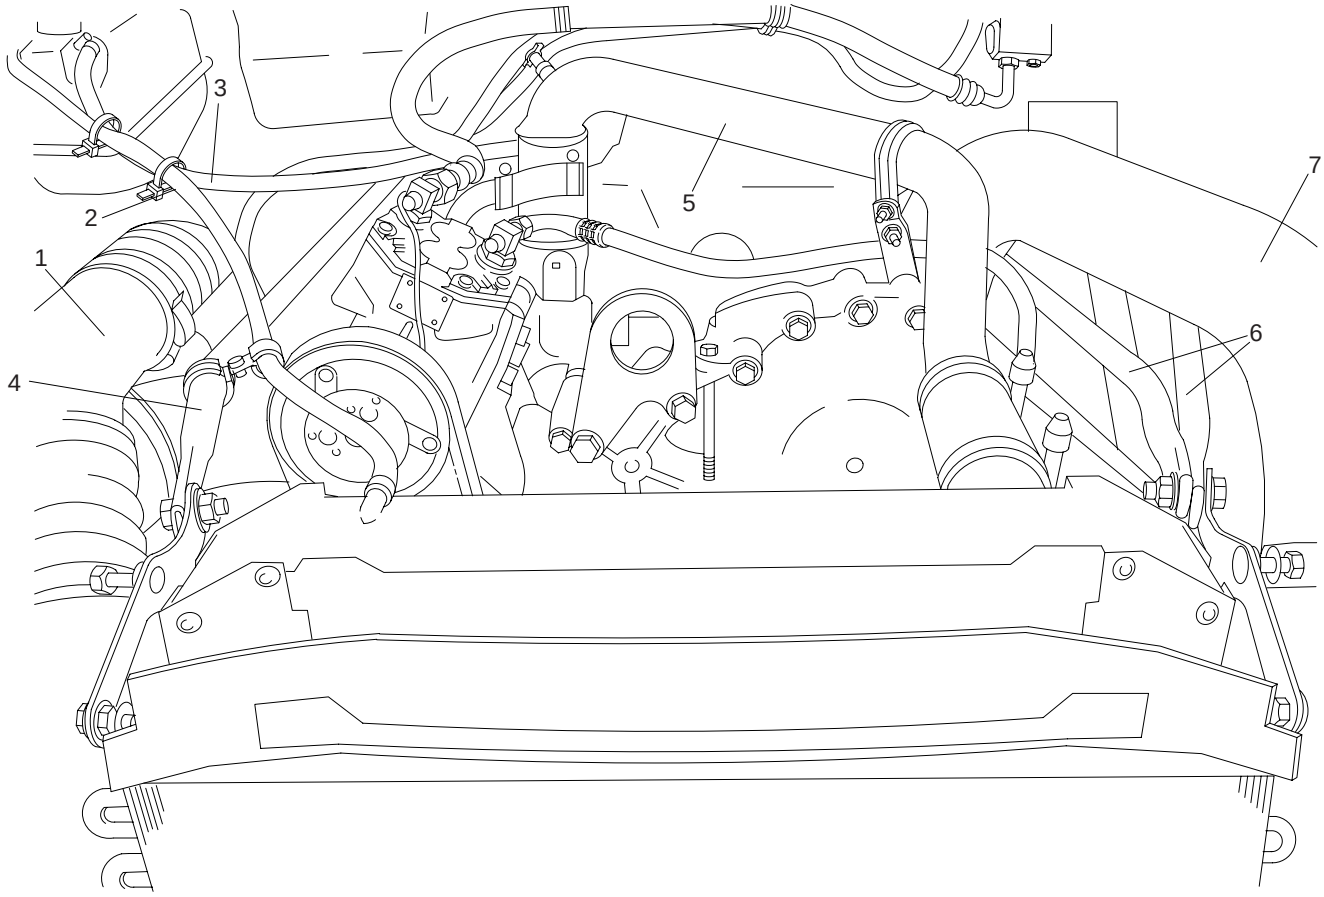
   - 2.1 Disconnect the battery ground cable at the vehicle frame.
   - 2.2 Disconnect the positive battery cable from the batteries.
3. Disconnect the transmission. For instructions, refer to **Group 26** in this service manual.

NOTE: To remove the transmission from a Detroit Diesel Series 50 engine in a Medium Truck, it may be necessary to remove the air regulator from the transmission and lower the transmission or raise the rear of the vehicle so that the transmission will clear the crossmember directly behind it.

Removal and Installation

4. Remove the hood, bumper and left front half-fender. For instructions, refer to the cab group in the vehicle service manual.

⚠ WARNING



Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

5. Drain the radiator.
   - 5.1 Open the coolant drain at the bottom of the radiator.
   - 5.2 Loosen the surge tank cap.
   - 5.3 To drain the coolant from the engine block, remove the water jacket plug at the bottom of the water pump, on the inboard side of the coolant inlet from the radiator.
6. Remove the right fender splash shield.
7. Remove the air cleaner and intake air ducting. See **Fig. 2** and **Fig. 3**.
   - 7.1 Remove the hoses and convoluted tubing that run between the turbocharger and the aftercooler, and between the aftercooler and the engine intake manifold. Cover the turbocharger inlet with a clean shop rag.
   - 7.2 Remove the ducting that runs between the air cleaner and the turbocharger.
   - 7.3 Disconnect the right-side air recirculation shield from the radiator, and remove the shield with the air cleaner. See **Fig. 4**.
   - 7.4 Remove the fasteners that hold the air cleaner mounting bracket to the frame rail, and remove the bracket and the air cleaner housing, together.
8. Remove the exhaust ducting.
   - 8.1 Loosen the V-band clamp that holds the forward end of the exhaust ducting to the rear of the turbocharger. See **Fig. 3**.
   - 8.2 Loosen the clamp that holds the rear end of the exhaust ducting to the exhaust flex pipe.
   - 8.3 Remove the exhaust duct support bracket that shares mounting fasteners with the rear engine lifting eye, and remove the exhaust duct and bracket from the vehicle.

⚠ WARNING

After removing the exhaust duct support bracket, re-install all the engine lifting eye fasteners and tighten them securely. If the fasteners are not re-installed and tightened, the engine lifting eye will be unstable. Lifting the engine with an unstable lifting eye can lead to the engine falling, possibly causing personal injury and property damage.

   - 8.4 Install the rear lifting eye fasteners and tighten them securely.
9. Disconnect the coolant hoses. See **Fig. 2** and **Fig. 3**.
   - 9.1 Disconnect the coolant inlet and outlet hoses from the radiator.
   - 9.2 Disconnect the vent hoses from the radiator and the engine.
   - 9.3 Disconnect the coolant fill pipe from the top of the water pump.
   - 9.4 Disconnect the heater outlet hose from the oil cooler.
   - 9.5 Disconnect the heater inlet hose from the bottom of the water pump, near the radiator outlet hose.
10. Relocate the refrigerant compressor.
    - 10.1 Disconnect the compressor clutch electrical connector.
    - 10.2 Remove the clamps that secure the refrigerant lines within the engine compartment.
    - 10.3 Remove the two bolts that hold the refrigerant compressor mounting bracket to the engine. See **Fig. 5**.
    - 10.4 To keep the refrigerant system intact, with no leaks and no need for purging and recharging, carefully move the refrigerant compressor over the left frame rail, and secure it out of the way with tie straps. See **Fig. 6**.

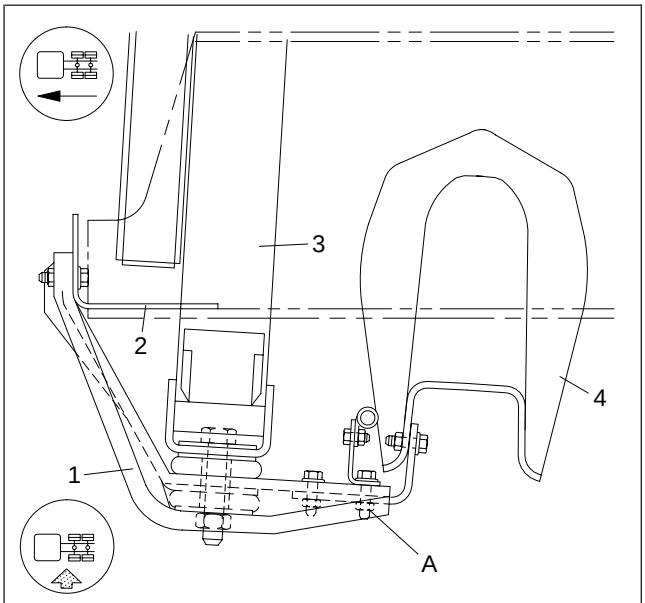

Fig. 16, Front Crossmember

19.2 Remove the fasteners that hold the front crossmember to the frame rails. See **Fig. 18**. Then, pull the crossmember forward until it's free of the frame rails.

20. Attach a three-point lifting chain to the engine, and lift the engine enough to take all weight off of the front engine mount. See **Fig. 19**.

⚠ WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

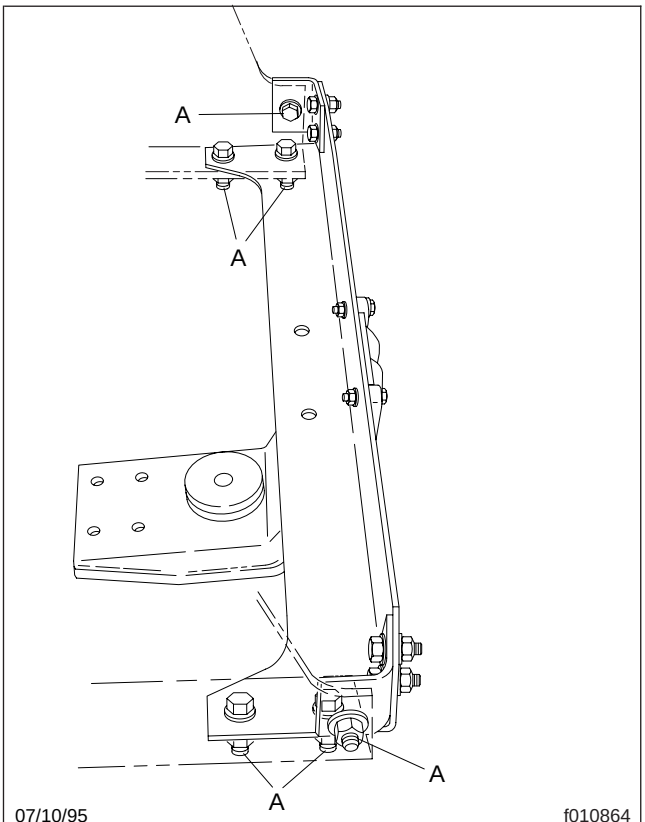
4. Underslung Crossmember (Front Engine Mount)

Fig. 17, Radiator Support Bracket Fasteners

20.1 Attach the chain to the existing lifting hooks at the front and the rear of the engine.



20.2 With all three engine lifting points connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.

21. Disconnect the engine from the rear engine mounts.

21.1 With the engine securely supported by the crane, lifting chains, and the engine stands, disconnect the rear engine legs from the engine mounts mounted on the frame rails.

21.2 On each engine leg, remove the nut from the bolt that runs down through the engine leg, rubber isolators, and engine mount. Save the fasteners and isolators.

22. Disconnect the engine from the front engine mount. See **Fig. 20**.

A. To remove or install the front crossmember, remove or install these capscrews.

Fig. 18, Front Crossmember Fasteners

22.1 Remove the nuts from the bolts that fasten the front engine bracket to the underslung crossmember.

22.2 Using the crane, lift the engine until all weight is removed from the front engine mount.

22.3 Remove the bolts and washers that hold the front engine bracket to the crossmember, and save the nuts, bolts, washers, and isolators.

23. Remove the underslung crossmember.

23.1 Remove the fasteners that hold each end of the crossmember to the frame rails. See **Fig. 21**.

23.2 Pull the crossmember forward to remove it from the vehicle.

Removal and Installation

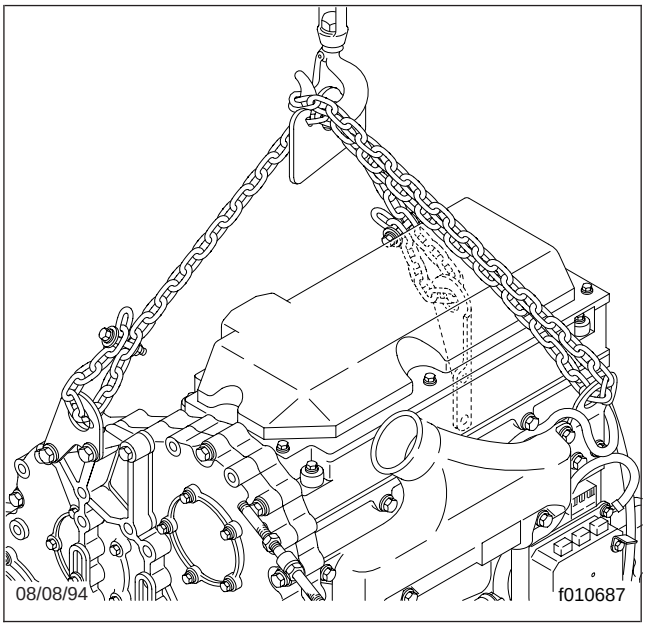


Fig. 19, Three-Point Lifting Chain

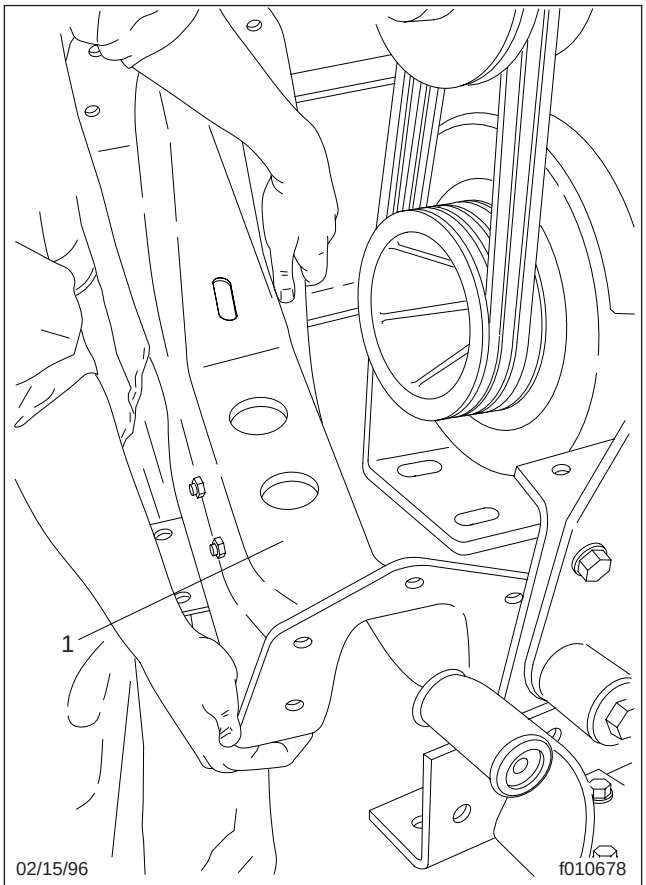
24. Remove the engine from the vehicle.

    24.1 Using the crane, lift the engine and pull it forward.

    24.2 Once the engine is clear of the vehicle, place the engine on engine stands.



Installation

1. Install the underslung crossmember that serves as the front engine mount. See **Fig. 21**. Tighten the crossmember-to-frame rail fasteners 68 lbf·ft (92 N·m), and place the upper isolators in the engine mount holes.

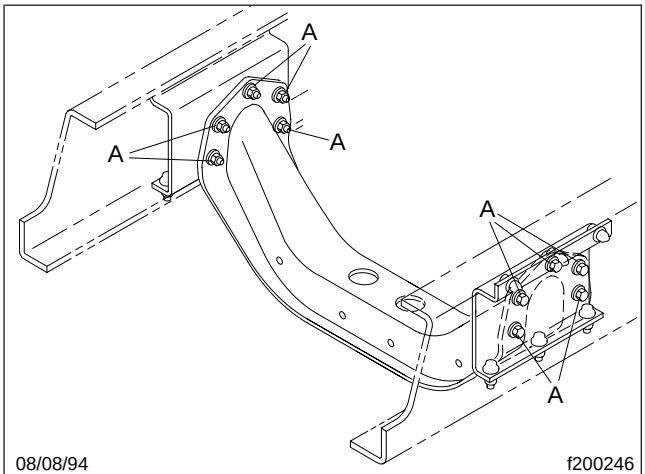
⚠ WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine stands are removed, do not get under the engine until it is securely supported on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

2. Attach a three-point lifting chain to the engine, and lift the engine off the engine stands. See **Fig. 19**.

1. Underslung Crossmember (Front Engine Mount)

Fig. 20, Front Engine Mount



3. Install the engine in the engine compartment.

    3.1 Place the upper rubber isolators in the rear engine mounts.

    3.2 Using the crane, place the engine in the engine compartment. Keeping the front of the engine raised, slightly, push the engine back until it rests squarely on the two rear engine mounts.

    3.3 For the rear engine mounts, run a bolt down through each engine leg, the upper isolator, the engine mount, and the lower isolator. Install a nut on each bolt, and tighten each nut finger-tight.

    3.4 Using the crane, lower the engine until it rests squarely on the front engine mount.

A. To remove or install this crossmember, remove or install these capscrews.

Fig. 21, Underslung Crossmember

3.5 Run the bolts down through the front engine support bracket, the upper isolator, the engine mount, and the lower isolator. Install the nut on each bolt, and tighten each nut 241 lbf·ft (327 N·m).

3.6 Tighten the nuts on the rear engine mount bolts 241 lbf·ft (327 N·m).

3.7 With the engine securely installed on all three engine mounts, remove the crane.

4. Install the front crossmember and the underslung radiator mount. See **Fig. 17**.

4.1 Position the front crossmember between the frame rails so that it is aligned with the fastener holes. Install the capscrews, washers, and nuts removed and tighten the nuts 136 lbf·ft (184 N·m).

4.2 Use 3/8-16 1.37-inch bolts, washers and nuts to fasten the rear of the underslung radiator support bracket to the forward edge of the bracket fastened to the underslung crossmember. Tighten the nuts 28 lbf·ft (38 N·m).

5. Install the windshield wiper pan. See **Fig. 15**.

5.1 Position the pan by tucking it up under the lower edge of the windshield trim.

5.2 Install the fresh air intake snorkel.

5.3 Install the screws that hold the pan to the firewall.

5.4 Install the surge tank. For instructions, refer to the engine cooling group of this manual.

5.5 Install the wiper arms. For instructions refer to the cab group of this manual.

6. Install the power steering pump. See **Fig. 5**.

7. Remove the tie straps that hold the alternator against the engine, and adjust the alternator drive belt to the correct tension. For adjustment instructions, refer to the drive belt section in this service manual group.

8. Install the fan blades on the engine. For the applicable fastener torque, refer to **Group 20** of this service manual.

9. Connect the engine electrical connectors.

9.1 Connect the wiring harness to the coolant temperature gauge sensor. See **Fig. 14**.

9.2 Connect the wiring harness to the coolant temperature warning light switch. See **Fig. 14**.

9.3 Connect the wiring harness to the tachometer sensor on the engine flywheel housing.

9.4 Connect the wiring harness to the ECM. See **Fig. 13**.

9.5 Connect the wiring harness to the starter motor and solenoid.

9.6 Connect the wiring harness to the alternator. See **Fig. 12**.

9.7 Install the horn and horn stand-off bracket. See **Fig. 11**.

10. Connect the fuel and oil components.

10.1 Connect the oil pressure gauge sensor line behind the alternator.

10.2 Connect the fuel supply line at the fuel transfer pump. See **Fig. 10**.

11. Install the radiator and aftercooler assembly.

NOTE: Before lifting the radiator and aftercooler, be sure the upper radiator isolator is in the underslung radiator mount.

Removal and Installation

11.1 Hook a lifting chain to the top of the radiator and aftercooler assembly, and fasten the chain to a crane. Lift the radiator and aftercooler, and position the assembly on the radiator mount. See **Fig. 8**.

11.2 Install the lower radiator isolator, and install the nut on the radiator mounting stud. Tighten the nut 241 lbf·ft (327 N·m).

11.3 Install the right-side radiator brace strut.

11.4 Remove the lifting chains from the radiator and aftercooler assembly.

12. Connect the air compressor. See **Fig. 7**.

12.1 Connect the air outlet line to the top of the compressor.

12.2 Connect the two air signal lines to the air governor.

13. Install the refrigerant compressor and condenser.

13.1 Remove the tie straps and protective coverings, and carefully move the compressor and condenser back into their operating positions.

13.2 Install the fasteners that hold the condenser to the aftercooler. Tighten the fasteners 15 lbf·ft (20 N·m).

13.3 Install the fasteners that hold the compressor mounting bracket to the engine. See **Fig. 5**. Connect and adjust the compressor drive belt. For instructions, refer to the drive belt section in this manual.

13.4 Connect the radiator brace rods to the top left corner of the radiator. See **Fig. 2**. Tighten the mounting fasteners 68 lbf·ft (92 N·m).

13.5 Secure the power steering and refrigerant lines with clamps.

13.6 Install the left-side air recirculation baffle on the radiator.

14. Connect the coolant hoses. See **Fig. 2** or **Fig. 3**.

14.1 Connect the heater inlet hose to the bottom of the water pump.

14.2 Connect the heater outlet hose to the oil cooler.

14.3 Connect the coolant fill pipe to the top of the water pump.

14.4 Connect the vent hoses to the radiator and the engine.

14.5 Connect the coolant inlet and outlet hoses to the radiator.

15. Install the exhaust ducting.

15.1 Remove the lower mounting bolt from the rear engine lifting eye, and install the exhaust duct support bracket and the length of duct between the turbocharger and the exhaust flex pipe.

15.2 Connect the duct to the exhaust flex pipe, and tighten the wide band clamp.

15.3 Connect the duct to the rear of the turbocharger and tighten the V-band clamp 85 lbf·in (940 N·cm). See **Fig. 3**.

16. Install the air cleaner and air intake ducting.

16.1 Position the air cleaner on its mounting bracket, and secure it with four nuts and washers. Tighten the nuts 28 lbf·ft (38 N·m).

16.2 Fasten the right-side air recirculation shield to the air cleaner housing.

16.3 Install the hose and metal duct between the air cleaner and the turbocharger.

16.4 Install the hoses and convoluted tubing between the turbocharger and the aftercooler, and between the aftercooler and the engine intake manifold. Tighten the constant-torque hose clamps 60 lbf·in (680 N·cm).

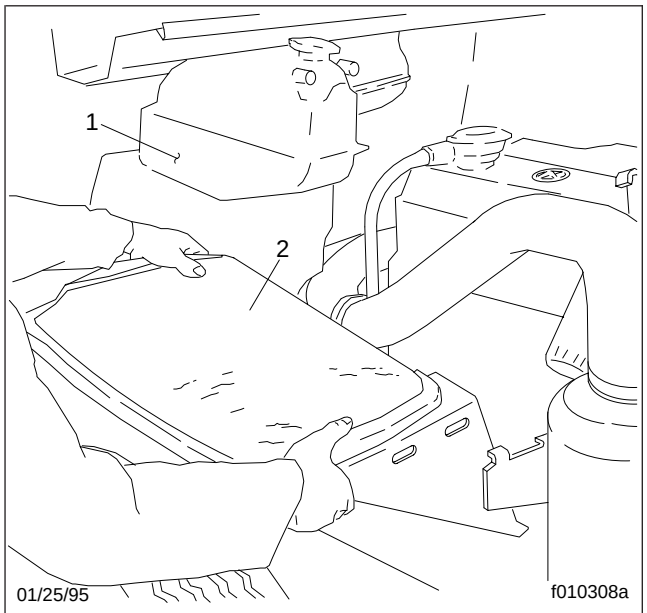
17. Install the right fender splash shield.

18. Make sure the coolant drains in the water pump and the radiator are closed, and then fill the engine and cooling system with coolant. Refer to the vehicle maintenance manual for the correct coolant type and quantity.

19. Install the hood, bumper, and left front half-fender. For instructions, refer to the applicable group in this service manual.

20. Install the transmission on the engine. For instructions, refer to **Group 26** in this service manual.

21. Connect the batteries, or if applicable, turn on the battery shutoff switch.
22. Start the engine, and check for leaks. Repair any leaks found.
23. Test drive the vehicle.



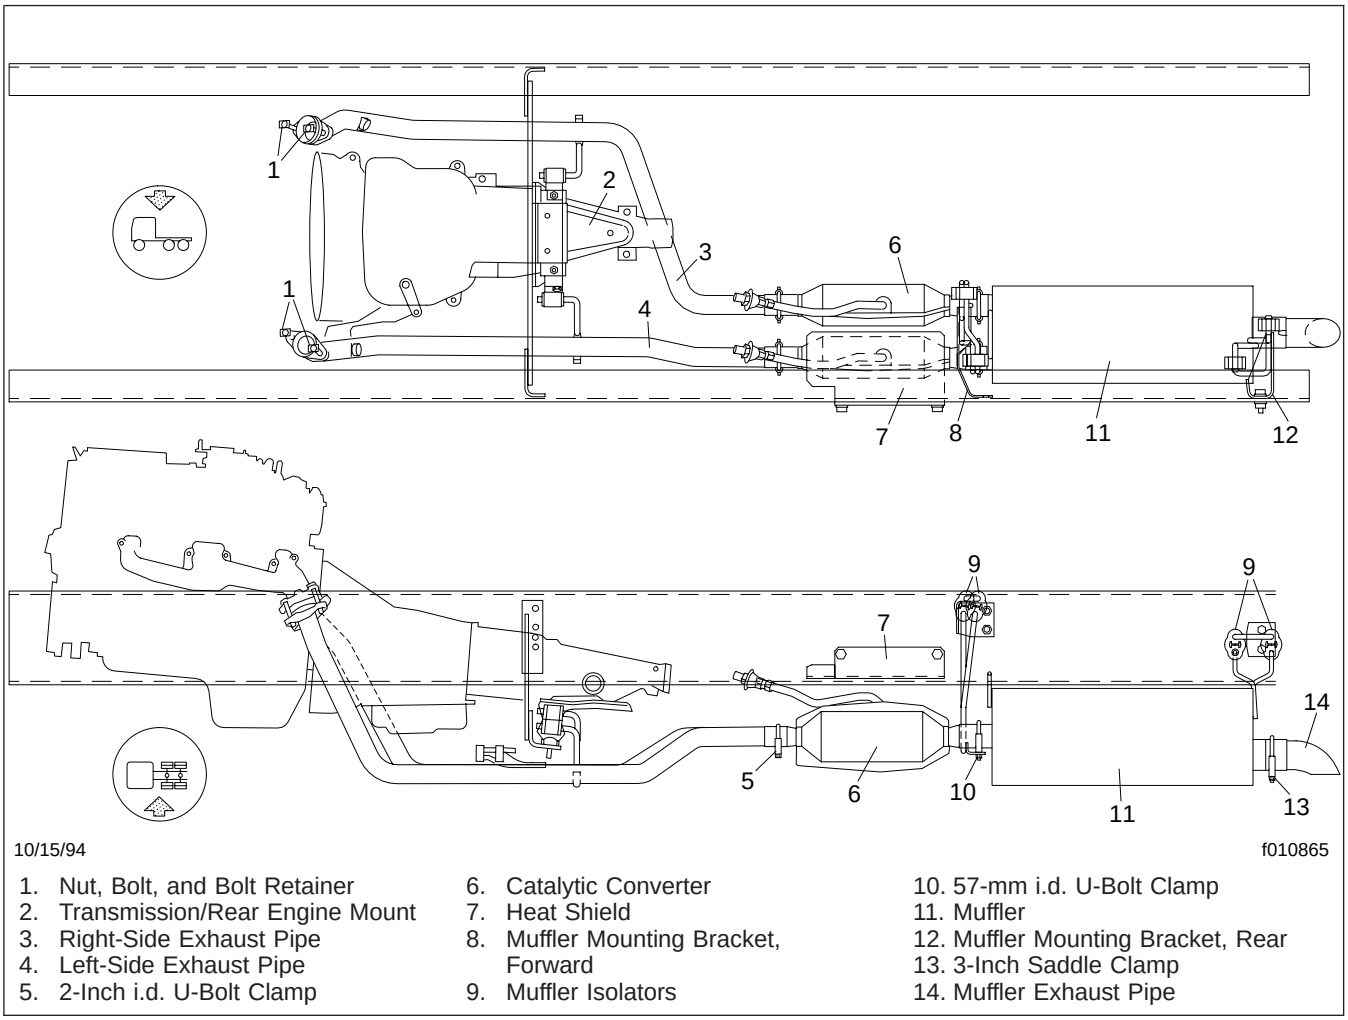
Removal

WARNING

WARNING: The fuel system is under pressure whether or not the engine is running or shut down. Always release the pressure from the fuel system before servicing any fuel supply or fuel return system component. Servicing a pressurized system could cause fuel to spray, leading to personal injury or property damage.

IMPORTANT: Before beginning this procedure, get a Chrysler fuel pressure gauge tool set 5069. You will need these tools to release the fuel system pressure.

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Disconnect the batteries.
3. Remove the hood. For instructions, see **Group 88**.
4. Remove the right fender splash shield. See **Fig. 1**.



1. Surge Tank
2. Splash Shield

Fig. 1, Right Fender Splash Shield, Typical Installation

5. Remove right and left bumper extensions.
6. Use engine stands to support the rear of the engine, and remove the transmission. See **Group 26** for instructions. Removing the transmission requires removing the exhaust pipes. See **Fig. 2**.
7. Disconnect the air outlet hose from the air injection pump. See **Fig. 3**.
8. Remove the horn and bracket assembly from the right frame rail.
9. Remove the air cleaner housing. See **Fig. 4** . For complete removal instructions, see **Group 09**.
10. Disconnect the throttle cable from the throttle body cam. See **Fig. 5**.
    - 10.1 Remove the tie strap that holds the cable housing to the refrigerant line.
    - 10.2 Roll the throttle body cam, by hand, from idle to full throttle. Slip the pin on the end of the cable from the hole in the throttle body cam, and remove the cable from the cam. See **Fig. 6**.
    - 10.3 Loosen the cable clamp nuts on either side of the throttle body mounting bracket. See **Fig. 7**. Lift the cable out of the bracket, and move the cable aside.
11. Remove the fan blade and the fan shroud. See **Fig. 8**.
    - 11.1 Loosen the six self-tapping screws that hold the fan shroud to the rear of the radiator, and move the shroud back against the engine.
    - 11.2 Place a bar or screwdriver between the water pump pulley bolts to keep the pulley from turning. Then, use a wrench to turn the fan hub nut counterclockwise as viewed from the front of the vehicle.

      Unscrew the fan hub nut from the engine shaft, and remove the fan clutch from the engine.
    - 11.3 Remove the fan and the fan shroud as a unit.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.

12. Remove the radiator. See **Fig. 9**.

12.1 Drain the radiator; then mark and disconnect the coolant hoses and vent hose from it.

12.2 Disconnect the hoses from the transmission oil cooler.

12.3 Remove the hose standoff bracket from the rear stud on the left-side radiator mount.

12.4 Support the transmission oil cooler and refrigerant condensor; then remove the four nuts that hold the cooler and condenser to the front of the radiator. Remove the transmission oil cooler, and set it aside. Keep it upright to avoid spilling any transmission fluid. Swing the condenser to the side, and out of the way.

12.5 Remove the bolts that attach the bottom of the air recirculation shields to the radia-

tor side-channels; then remove the shields. See **Fig. 10**.

12.6 Remove the hose bracket from the right-side radiator strut.

12.7 Disconnect the left-side radiator strut from the framerail bracket.

12.8 From underneath the vehicle, mark, then disconnect the coolant hoses from the engine oil cooler. See **Fig. 11**.

12.9 Remove the four nuts holding the radiator to the radiator-mount studs; then remove the radiator.

13. Disconnect the coolant hoses from the water pump. See **Fig. 12**.

14. Remove the accessory drive belt.

14.1 Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner. See **Fig. 13**.

14.2 Remove the engine accessory drive belt.

15. Disconnect the wiring from the engine.

15.1 Disconnect the 60-pin connector from the power train control module on the bulkhead.

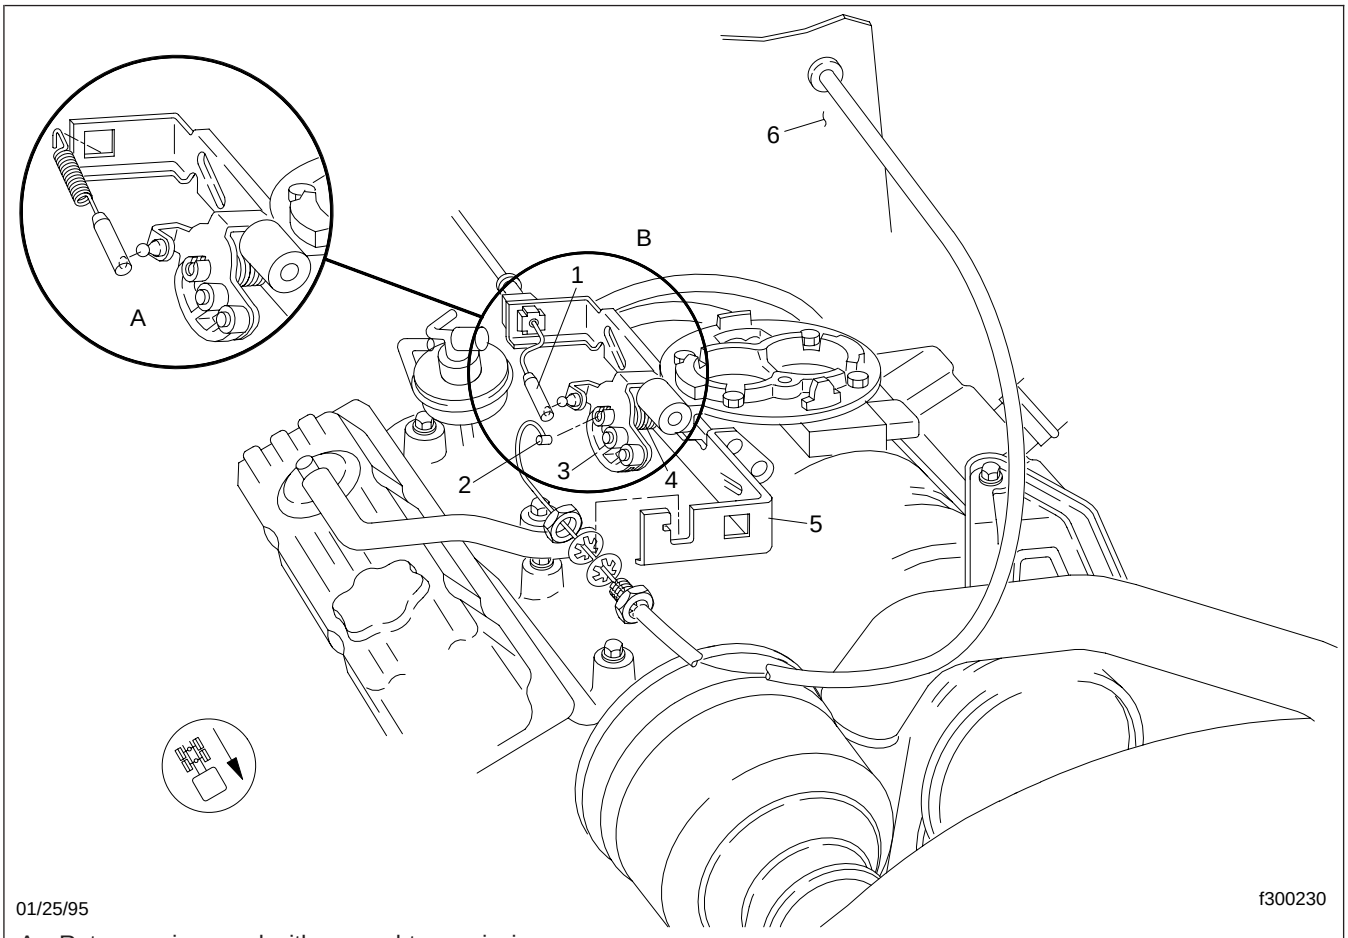
15.2 Mark, then disconnect the three multi-pin connectors and one single-pin connector at the rear, right side of the engine.

15.3 Disconnect the ground strap from the engine block.

15.4 Mark, then disconnect the wiring from the starter motor.

16. Disconnect the heater hoses. See **Fig. 14** .

16.1 Disconnect the heater supply hose at the rear of the engine.



16.2 Disconnect the heater return hose from the front of the engine.

⚠ WARNING

WARNING: The fuel system is under pressure whether or not the engine is running or shut down. Always release the pressure from the fuel system before servicing any fuel supply or fuel return system component. Servicing a pressurized system could cause fuel to spray, leading to personal injury or property damage.

17. If not already done, release the pressure from the fuel system, and disconnect the fuel line at the engine.

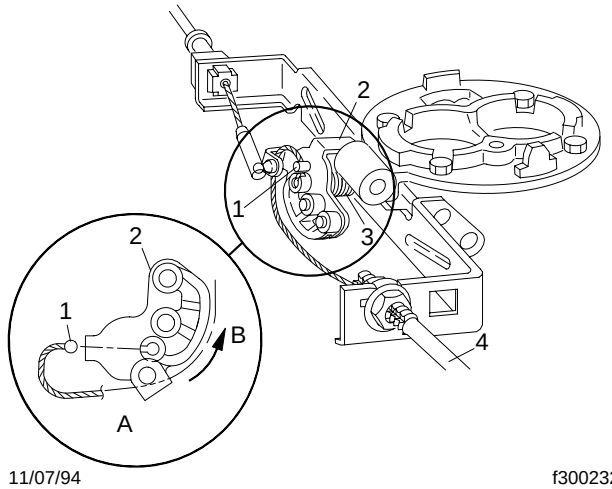
⚠ WARNING

WARNING: Wear eye protection when releasing fuel system pressure, and do not let fuel spill onto the engine intake or exhaust manifolds. Place shop towels under and around the pressure port to absorb fuel when the pressure is released. Spilled fuel or lack of eye protection could lead to personal injury or property damage.

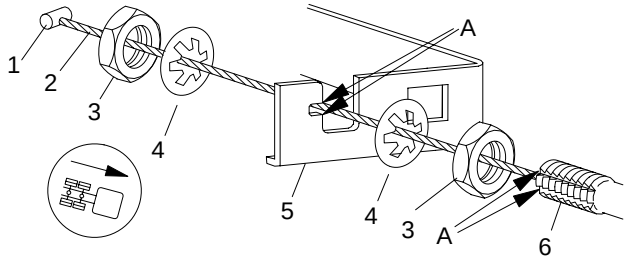


17.1 If not already done, disconnect the negative battery cable.

17.2 Remove the fuel tank caps to release fuel tank pressure.

17.3 Unscrew the protective plastic cap from the pressure test port (schrader valve) on the fuel rail. See **Fig. 15**.

17.4 Obtain the fuel pressure gauge/hose assembly from a Chrysler fuel pressure gauge tool set 5069. Remove the gauge from the hose.



17.5 Place the gauge end of the hose into an approved gasoline storage container.

17.6 Place a shop towel under the test port.

17.7 To release the fuel system pressure, screw the other end of the hose onto the fuel pressure test port.

17.8 After the fuel pressure has been released, remove the hose from the test port, and install the protective cap on the fuel test port.

17.9 Disconnect the fuel supply lines from the fuel racks.

18. Disconnect the power steering hoses from the power steering pump; then remove the hose bracket from the radiator strut bracket. Move the hoses and bracket out of the way.

19. Remove the refrigerant compressor. See **Fig. 16**.

19.1 Loosen the five bolts that hold the compressor to the engine.

19.2 Mark and disconnect the wiring from the compressor.

19.3 Leaving the refrigerant hoses attached to the compressor, lift it off the engine, and move it to the side.

20. From underneath the vehicle, disconnect the oil pressure sensor line from the rear of the engine. See **Fig. 17**.

21. Attach the lifting chains to the engine.

⚠ WARNING

WARNING: The crane, lifting eyes, and lifting chain used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine, or an engine lifted with unsuitable tools may fall, causing personal injury or death, and component damage.

21.1 Remove and save the upper inboard hexbolt from the power steering pump bracket; then install a 3/8-inch x 1-3/4-inch hexbolt and lifting eye in its place. Tighten the bolt firmly. See **Fig. 18**.

21.2 At the rear right-side of the engine, use a 3/8 x 1-1/4 inch hexbolt to install a second lifting eye in one of the blank holes on the engine head. See **Fig. 17**.

21.3 Attach a lifting chain to the lifting eyes.

Removal and Installation

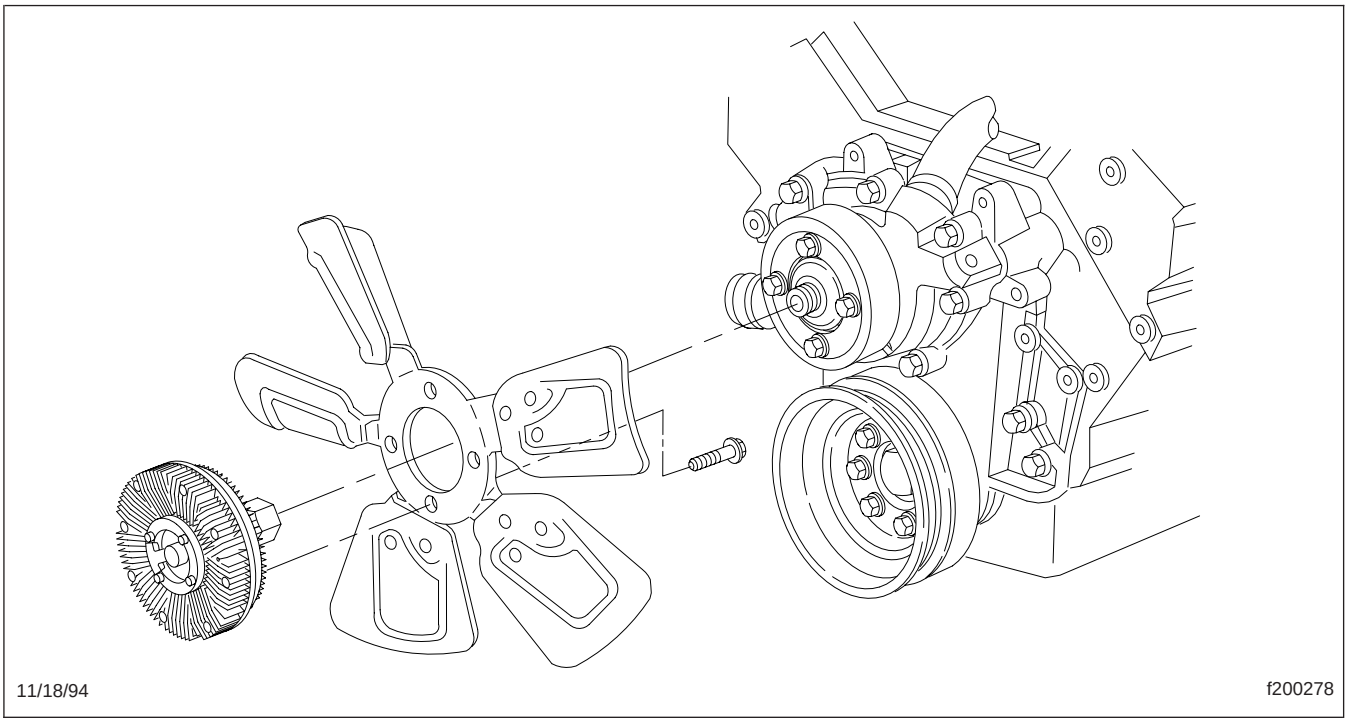

Fig. 8, Fan Clutch Mounting for Dodge Magnum V-8 Engine

21.4 Attached the chain to a suitable lifting device, and raise the chain to remove any slack.

22. Disconnect the engine from the engine mounts.

22.1 Remove the nut and washer from each of the two bolts that run through the engine legs, rubber isolators, and engine mounts.

22.2 Back out the bolts.

23. Lift the engine from the vehicle. Lower it onto suitable stands.

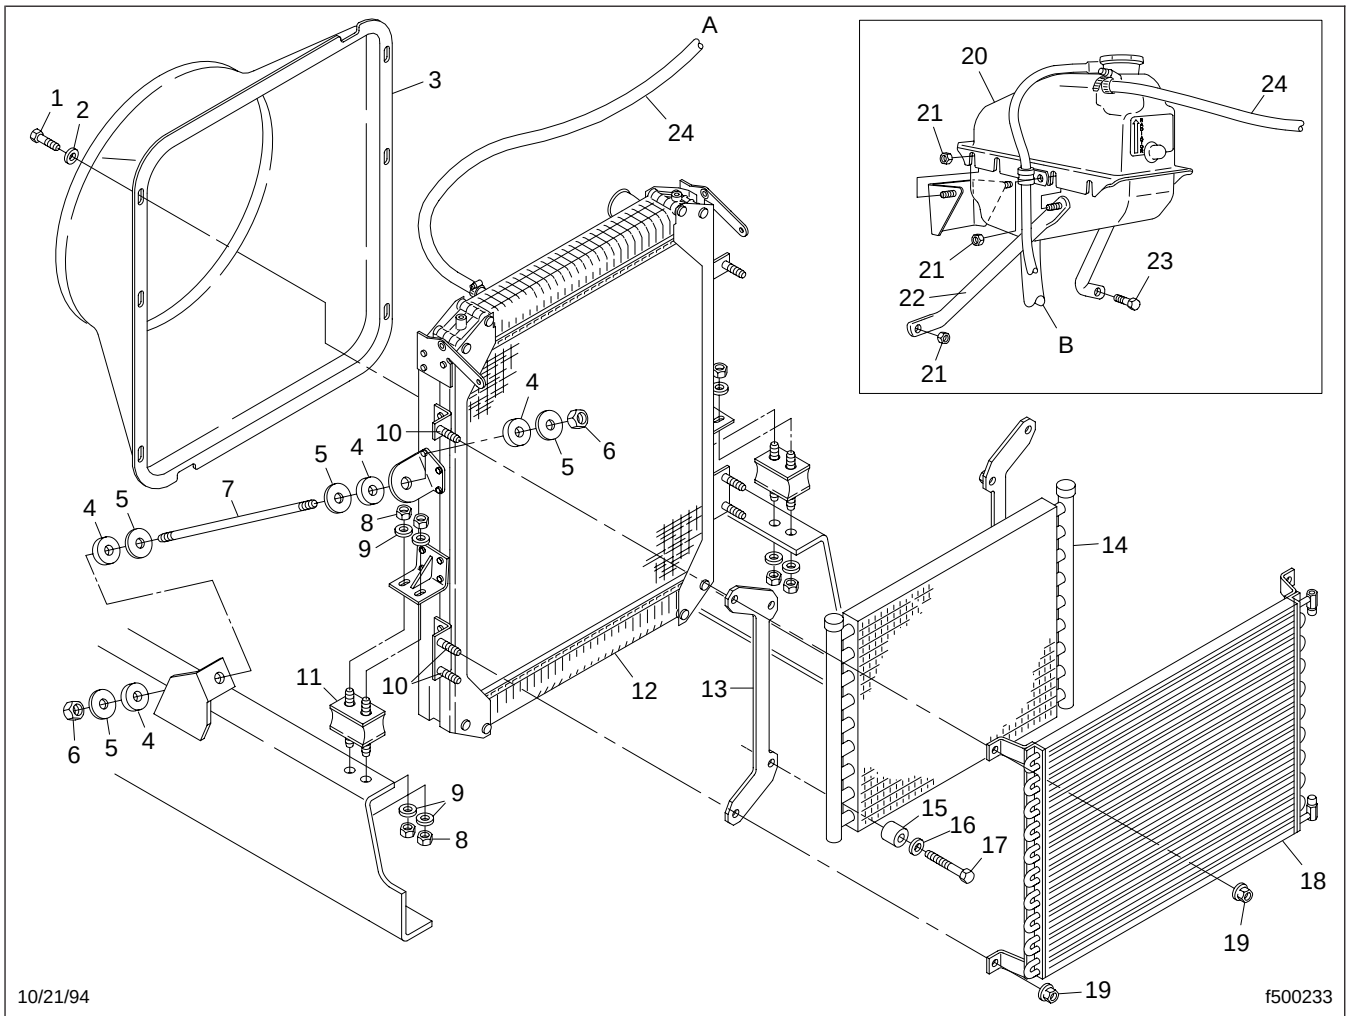
Installation

WARNING

WARNING: The crane, lifting eyes, and lifting chain used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine, or an engine lifted with unsuitable tools may fall, causing personal injury or death, and component damage.

1. Install the engine on the engine mounts.

1.1 With an engine stand in place to support the rear of the engine, lower the engine into the engine compartment so the engine legs align with the engine mounts.



1.2 Run bolts through the engine mounts, rubber isolators, and engine legs. See **Fig. 19** and **Fig. 20**.

1.3 Secure each bolt with a flatwasher and nut, and torque each nut 54 to 68 N·m (40 to 50 lbf·ft).

1.4 Install the transmission. See **Group 26** for instructions.

1.5 Remove the lifting eyes and chains from the engine.

1.6 Install the bolt removed earlier from the power steering pump bracket on the front of the engine.

⚠ CAUTION

CAUTION: Make sure the drive belt is installed correctly. Incorrect installation could cause the water pump pulley to rotate in the wrong direction, which could result in extensive damage to the engine from overheating.

10. Install the accessory drive belt. For belt routing instructions, see **Section 01.00**.
    - 10.1 Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner. See **Fig. 13**.
    - 10.2 Install the belt.

14. Put the fan and clutch assembly inside the fan shroud; then install the fan and clutch assembly onto the fan pulley. Tighten the nut 57 N·m (42 lbf·ft).
15. Install the radiator.
    - 15.1 Install the radiator onto the four mounting-bracket studs.
    - 15.2 Install the rear ends of the radiator support struts in the holes of the brackets on the frame rail.
    - 15.3 Install a rubber isolator, washer and nuts on the end of each strut. Tighten the nuts 47 N·m (35 lbf·ft).
    - 15.4 Install the four radiator mounting locknuts and washers, and tighten them 40 N·m (30 lbf·ft).
16. Install the fan shroud onto the radiator side channels, using the six self-tapping screws and washers
17. Install the air recirculation shields, the transmission oil cooler, and the condenser in front of the radiator. The upper mounting studs attach all three components to the radiator.
18. Connect the hoses to transmission oil cooler.
19. Install the transmission oil cooler hose stand-off bracket onto the rear stud of the driver's side radiator mounting bracket.
20. Connect the coolant hoses to the radiator. See **Fig. 22**.
21. Install the hose from the power steering reservoir to the power steering pump.
22. Connect the heater supply and return hoses.
23. Install the horn and mounting bracket assembly on the right frame rail. Make sure the nuts are facing outboard. Connect the wiring to the horn.
24. Install the air filter assembly and its gasket onto the throttle body. Make sure the stud on the intake manifold fits into the hole at the front underside of the air filter.
25. From behind the engine, connect the oil pressure sensor line to the engine. See **Fig. 17**.
26. Install the hood. See **Group 88** for instructions.
27. Install the bumper extensions.
28. Close the hood, then remove the chocks from the tires.

Removal

NOTE: For engine wiring diagrams, refer to the applicable section in **Group 54**. For trouble-shooting procedures, refer to **Section 54.02** for the Kysor Warning and Engine-Shutdown System.

1. Apply the parking brakes, chock the tires, and drain the air system.
2. Disconnect the batteries.
   - 2.1 Disconnect the battery ground cable at the vehicle frame.
   - 2.2 Disconnect the positive battery cable from the batteries.
3. Remove the hood and bumper. For instructions, refer to **Group 88** in this service manual.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

4. Drain the radiator.
   - 4.1 Place a suitable container under the driver's side corner of the radiator. See **Fig. 1**.
   - 4.2 Remove the surge tank cap.
   - 4.3 Unscrew the plug in the bottom of the radiator.

     After the coolant has drained, screw the plug into the radiator, and tighten it firmly.
5. Remove the air cleaner housing.
   - 5.1 Remove the right fender splash shield. See **Fig. 2**.
   - 5.2 Remove the air compressor intake hose that runs from the engine air intake hose to the compressor. See **Fig. 3**.
   - 5.3 Remove the air intake hoses that run between the air cleaner housing and the turbocharger, and remove the hoses that run between the turbocharger and the charge air cooler, and between the charge air cooler and the engine.

   Leave the A-shaped bracket that held the air intake piping to the top of the engine.
   - 5.4 Disconnect the vent lines from the radiator and the engine, and move the lines aside.
   - 5.5 Remove the radiator inlet hose from the radiator and the engine.
   - 5.6 Disconnect the radiator outlet hose from the bottom of the radiator.
   - 5.7 Disconnect the wiring to the horn.
   - 5.8 Disconnect the radiator right-hand strut from the air cleaner housing bracket.
   - 5.9 Disconnect the right-side air recirculation shield from the radiator. This includes disconnecting the two push-type fasteners that hold the shield to a bracket attached to the top of the radiator. See **Fig. 4**.

6. Remove the radiator.

6.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser. See **Fig. 5**.

6.2 Remove the condenser mounting fasteners, and move the condenser aside.

6.3 Remove the left-side air recirculation shield from the radiator/charge air cooler assembly.

6.4 Disconnect the right-side radiator strut from the radiator.

6.5 Attach a lifting chain to the two rear hood attachment studs at the top of the radiator, and attach the chain to a lifting crane. See **Fig. 6**.

6.6 Disconnect the radiator/charge air cooler from its framerail mounts.

6.7 Remove the fasteners that hold the fan shroud to the radiator, and move the shroud back against the engine.

6.8 Lift the radiator/charge air cooler assembly from the vehicle.

7. Move the refrigerant compressor aside.

7.1 Disconnect the compressor wiring.

7.2 Remove the accessory drive belt. For instructions, refer to **Section 01.00** in this service manual.

7.3 Remove the compressor mounting fasteners, and move the compressor aside.

7.4 Use tie straps to secure the refrigerant compressor and condenser out of the way.

8. Disconnect the heater hoses.

8.1 Disconnect the heater return hose from the water pump, and move the hose aside. See **Fig. 7**.

   - 9.2 Disconnect the ground strap from the alternator.
   - 9.3 Disconnect the wiring from the alternator.
   - 9.4 Disconnect the wiring from the receiver-drier.
   - 9.5 Disconnect the wiring from the fan clutch.
   - 9.6 Disconnect the wiring from the coolant temperature sensors.
   - 9.7 Unplug the lower wiring harness connector from the electronic control module. See **Fig. 11**.
10. Disconnect the power steering components.
    - 10.1 Place a suitable container under the power steering fluid reservoir, and remove the hoses from the bottom of the reservoir. Allow the fluid to drain completely.
    - 10.2 At the power steering fluid pump, disconnect the hose that runs from the pump to the steering gear.
    - 10.3 Secure any loose, disconnected hoses to the engine with tie straps.
11. Disconnect the air lines from the air governor on top of the air compressor.
12. At the fuel/water separator, disconnect the fuel delivery line that runs to the engine.
13. Disconnect the forward end of the clutch rod, and tie strap the rod to the engine.
14. Remove the windshield wiper pan. See **Fig. 12**.
    - 14.1 Remove the windshield wiper arms. For instructions, refer to **Group 82** of this manual.
    - 14.2 Remove the screws that hold the wiper pan to the firewall.
    - 14.3 Remove the surge tank. For instructions, refer to **Group 20** in this manual.
    - 14.4 Remove the fresh air intake snorkel with the wiper pan.
    - 14.5 Remove the wiper pan by pulling the pan down, out from under the lower edge of the windshield trim.
15. Disconnect the air line from the fan clutch solenoid. See **Fig. 13**.
16. Remove the shift tower. For instructions, refer to **Group 26** in this service manual.
17. Remove the exhaust ducting.
    - 17.1 Loosen the V-band clamp that holds the forward end of the exhaust ducting to the rear of the turbocharger.
    - 17.2 Under the cab, disconnect the exhaust pipe from the saddle clamp mounted on the flywheel housing. See **Fig. 14**.
18. Disconnect the driveline from the transmission.
    - 18.1 Place a stand under the driveline, and disconnect the driveline from the transmission. For instructions, refer to **Group 41** in this service manual.
    - 18.2 Place a second stand under the driveline, and disconnect the driveline midship bearing bracket. See **Fig. 15**. For instructions, refer to **Group 41** in this service manual.

until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

20. Remove the engine from the vehicle.

20.1 Attach the chain to the existing lifting eyes at the front and the rear of the engine. See **Fig. 18**.

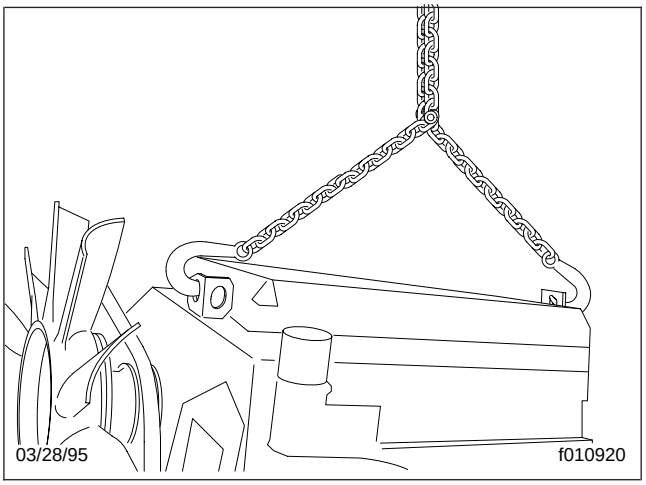

Fig. 18, Lifting Chain Installed

20.2 With the engine lifting eyes connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.

20.3 With the engine securely supported by the crane and lifting chains, disconnect the rear engine legs from the engine mounts on the frame rails.

On each engine leg, remove the nut from the bolt that runs down through the engine leg, rubber isolators, and engine mount. Save the fasteners and isolators.

20.4 Remove the nuts from the bolts that fasten the front engine support bracket to the underslung crossmember. See **Fig. 19**.

20.5 Using the crane, lift the engine and pull it forward.

20.6 Once the engine and transmission are clear of the vehicle, place the engine on engine stands.

Installation

⚠ WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely supported on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

1. Install the engine and transmission in the vehicle.
   - 1.1 Attach the chain to the existing lifting eyes at the front and the rear of the engine.
   - 1.2 With the two engine lifting eyes connected by chain to the crane, lift the engine, and position it in the engine compartment.
   - 1.3 Connect the engine to the rear engine mounts, and tighten each bolt that runs down through the engine leg, rubber isolators, and engine mount 327 N·m (241 lbf·ft).
   - 1.4 Assemble the lower isolator under the underslung crossmember and the front engine support bracket, and secure the front engine mount with nuts and washers. Tighten the nuts 184 N·m (136 lbf·ft).
   - 1.5 Once the engine is securely installed in the vehicle, remove the lifting chains.
2. Under the engine and transmission, connect all engine and transmission components.
   - 2.1 Connect the wiring to the speedometer sensor at the transmission output.
   - 2.2 Connect the wiring harness connectors to the back-up alarm switch and the neutral start switch on the transmission top cover.
   - 2.3 Connect the fuel supply line to the junction plate mounted on top of the transmission.
   - 2.4 Connect the fuel return line to the back of the engine block.
   - 2.5 Connect the wire-braid air compressor outlet line to the chassis air supply line.
   - 2.6 Route and clamp the battery cable.
3. Connect the driveline.
   - 3.1 Connect the driveline to the transmission. For instructions, refer to **Group 41** in this manual.
   - 3.2 Connect the driveline midship bearing bracket. For instructions, refer to **Group 41** in this manual.
4. Install the exhaust ducting.
   - 4.1 Under the engine, connect the exhaust pipe to the saddle clamp mounted on the flywheel.
   - 4.2 Tighten the V-band clamp that holds the forward end of the exhaust ducting to the rear of the turbocharger 85 lbf·in (940 N·cm).
5. Install the windshield wiper pan. See **Fig. 12**.
   - 5.1 Position the pan by tucking it up under the lower edge of the windshield trim.
   - 5.2 Install the fresh air intake snorkel.
   - 5.3 Install the screws that hold the pan to the firewall.
   - 5.4 Install the surge tank. For instructions, refer to **Section 20.01** of this manual.
   - 5.5 Install the wiper arms. For instructions refer to **Group 82** of this manual.
6. Connect the air line to the fan clutch solenoid. See **Fig. 13**.
7. At the left side of the engine, connect the air lines to the air governor on top of the air compressor.
8. At the fuel/water separator, connect the fuel delivery line that runs to the engine.
9. Connect the forward end of the clutch rod, and remove any tie straps that hold the rod to the engine.
10. Connect the power steering components.
    - 10.1 Connect the hoses to the bottom of the power steering fluid reservoir.
    - 10.2 At the power steering fluid pump, connect the hose that runs from the pump to the steering gear.
    - 10.3 With all the hoses connected, fill the power steering fluid reservoir.
11. Connect the engine wiring.
    - 11.1 Connect the wiring to the starter.
    - 11.2 Connect the ground strap to the alternator.
    - 11.3 Connect the wiring to the alternator.
    - 11.4 Connect the wiring to the receiver-drier.

Engine Removal and Installation

11.5 Connect the wiring to the fan clutch.

11.6 Connect the wiring to the coolant temperature sensors.

11.7 Plug the lower wiring harness connector into the electronic control module.

12. Connect the heater hoses.

12.1 Connect the heater return hose to the water pump.

12.2 Connect the heater supply hose to the rear of the engine block.

13. Install the refrigerant compressor.

13.1 Connect the compressor wiring.

13.2 Install the compressor mounting fasteners. For instructions, refer to **Group 83** in this manual.

13.3 Install the accessory drive belt. For instructions, refer to **Section 01.00** in this manual.

14. Install the radiator.

14.1 Attach a lifting chain to the two hood attachment studs at the top of the radiator, and attach the chain to a lifting crane.

14.2 Lift the radiator/charge air cooler assembly, and position it on the radiator mounts.

14.3 Install the radiator/charge air cooler on its framerail mounts. For instructions, refer to **Section 20.01** in this manual.

14.4 Install the fan shroud on the radiator.

14.5 Connect the vent lines to the radiator and the engine.

14.6 Install the radiator inlet hose between the radiator and the engine.

14.7 Connect the radiator outlet hose to the bottom of the radiator.

14.8 Install the condenser on the radiator and charge air cooler.

14.9 Route the refrigerant lines between the compressor and the condenser, and secure the lines with clamps and stand-off brackets.

14.10 Install the driver side air recirculation shield.

15. Install the air cleaner housing.

15.1 As a unit, position the air cleaner housing, the housing bracket, the right-side air recirculation shield, and the horn on the vehicle.

15.2 Install the four 3/4-inch bolts that hold the air cleaner housing mounting bracket to the frame rail. For instructions, refer to **Group 09** in this service manual.

15.3 Connect the radiator right-hand strut to the air cleaner housing bracket.

15.4 Connect the right-side air recirculation shield to the radiator. This includes connecting the two push-type fasteners that hold the shield to a bracket attached to the top of the radiator.

15.5 Connect the air intake hoses that run between the air cleaner housing and the turbocharger, and connect the hoses that run between the turbocharger and the charge air cooler, and between the charge air cooler and the engine. Clamp the hoses to the A-shaped bracket on top of the engine.

15.6 Install the air compressor intake hose that runs from the engine air intake hose to the compressor.

15.7 Install the right fender splash shield. See **Fig. 3**.

15.8 Connect the wiring to the horn.

16. Install the shift tower.

17. Fill the radiator.

18. Install the hood and bumper. For instructions, refer to **Group 88** in this service manual.

19. Connect the batteries.

20. Remove the chocks from the tires.

21. Start the engine, and check for leaks. Repair any leaks found.

22. Test drive the vehicle.

Removal

IMPORTANT: To remove the Cummins M11 engine from a Freightliner FL112 vehicle, you'll need a special lifting bracket for the rear of the engine.

1. Apply the parking brakes, chock the tires, and drain the air system.
2. Disconnect the batteries.
3. Remove the hood, bumper, and the left-side half fender. For instructions, refer to **Group 88** in this service manual.
4. Remove the hood tilt-assist bracket mounted on the front closing crossmember. For instructions, refer to **Group 88** in this service manual.
5. Remove the transmission. For instructions, refer to the applicable section in **Group 26** in this service manual.
6. Remove the air cleaner housing and the brackets that hold the housing to the bulkhead. See **Fig. 1**. This includes removing the heat shield between the cleaner and the turbocharger. For instructions, refer to **Group 09** in this service manual.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

7. Drain the radiator.
   - 7.1 Place a suitable container under the left side corner of the radiator.
   - 7.2 Remove the surge tank cap.
   - 7.3 Unscrew the plug in the bottom of the radiator.

     After the coolant has drained, screw the plug into the radiator, and tighten it firmly.
8. Move the air conditioning components out of the way without breaking the refrigerant lines. See **Fig. 2**.
   - 8.1 Free the refrigerant lines from all routing clamps and stand-off brackets between the compressor and the condenser.
   - 8.2 Free the refrigerant lines from all routing clamps and stand-off brackets between the receiver- drier and the condenser.
   - 8.3 Remove the condenser mounting fasteners, and move the condenser aside.
   - 8.4 Remove the refrigerant compressor and move the compressor aside.
   - 8.5 Use tie straps to secure the refrigerant compressor and condenser out of the way.
9. Remove the air recirculation shields around the radiator and charge air cooler. For instructions, refer to **Group 09** in this service manual.
10. Remove the radiator and charge air cooler. For instructions, refer to **Group 20** in this service manual.
11. Remove the radiator mounting bracket from the front closing crossmember.
12. Disconnect or remove the remaining ducts and lines. See **Fig. 3**.
    - 12.1 If not already removed, remove the air duct between the turbocharger and the air cleaner.
    - 12.2 Disconnect the vent line from the engine, and move the line aside.
    - 12.3 Disconnect the two air signal lines from the air governor on top of the compressor.
    - 12.4 Disconnect the outlet line from the air compressor.
    - 12.5 Disconnect the air line to the fan clutch solenoid, and free the line from routing clamps.
    - 12.6 Disconnect the heater return hose from the radiator outlet pipe, and free the hose from the clamps that route it along the left frame rail. See **Fig. 4**.
    - 12.7 Disconnect the heater supply hose. See **Fig. 4**.
    - 12.8 Disconnect the oil pressure sensor line beneath the receiver-drier.

Engine Removal and Installation

13. Remove the windshield wiper pan. See **Fig. 5** .
    - 13.1 Remove the surge tank and mounting bracket from the bulkhead. For instructions, refer to **Group 20** in this service manual.
    - 13.2 Remove the windshield wiper arms. For instructions, refer to **Group 82** of this manual.
    - 13.3 Remove the screws that hold the wiper pan to the firewall.
    - 13.4 Remove the fresh air intake snorkel with the wiper pan.
    - 13.5 Remove the wiper pan by pulling the pan down, out from under the lower edge of the windshield trim.
14. Remove the windshield wiper linkage. For instructions, refer to **Group 82** in this service manual.
15. Label and disconnect the wiring.
    - 15.1 Disconnect the two engine harness bulkhead connectors.
    - 15.2 Disconnect the wiring from the power stud on the bulkhead.
    - 15.3 Disconnect the wiring from the ground stud on the bulkhead.
    - 15.4 Remove the two screws that hold the magnetic switch to the bulkhead, and remove the switch without disconnecting the wires from it.
    - 15.5 Disconnect the starter ground cable from the frame rail.
    - 15.6 Disconnect the power cables from the starter and the starter solenoid.
16. Without breaking the power steering fluid lines, remove the power steering pump, and move it aside. For instructions, refer to **Group 46** in this service manual.
17. Under the engine, disconnect or remove the remaining components.
    - 17.1 Remove the flex pipe section of exhaust ducting that attaches to the turbocharger.

⚠ WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands.

An unsecured engine may fall, causing personal injury or death, and component damage.

18. Remove the engine from the vehicle.

    NOTE: If the engine is equipped with a compression brake, remove the valve cover. For instructions, refer to the engine manufacturer's service literature.

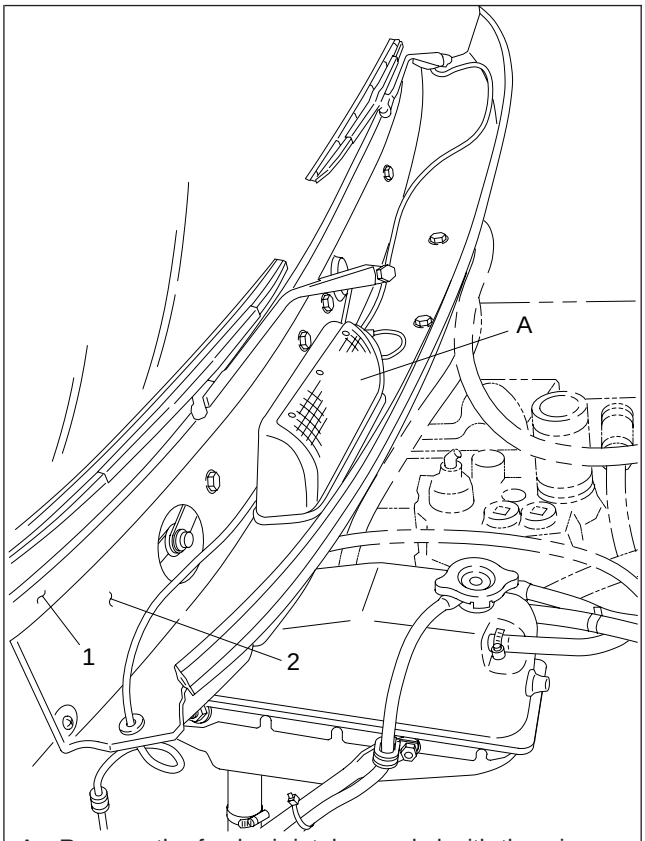
18.2 Attach the chain to the existing lifting eye at the front and the special lifting bracket at the rear of the engine.

18.3 With the two engine lifting points connected by chain to the crane, raise the crane enough to tighten the chains, but not enough to lift the front of the vehicle.



18.4 Remove the nuts from the bolts that fasten the front engine support bracket to the underslung crossmember.

18.5 Using the crane, lift the engine slightly and remove the upper isolator from the front engine mount.

18.6 Using the crane, lift the engine and pull it forward.

WARNING

The crane and lifting chains used to install the engine must be capable of safely lifting and supporting two metric tons. Once the engine is removed from the engine stands, do not get under the engine until it is securely supported on the engine mounts. An unsecured engine may fall, causing personal injury or death, and component damage.

1. Install the engine in the vehicle.
   - 1.1 If not already attached. Install the special lifting bracket on the rear of the engine.
   - 1.2 Attach the chain to the existing lifting eye at the front and the special lifting bracket at the rear of the engine.
   - 1.3 With the two engine lifting points connected by chain to the crane, lift the engine, and position it in the engine compartment.
   - 1.4 Connect the engine to the rear engine mounts, and tighten the bolt that runs down through each engine leg, rubber isolators, and engine mount 327 N·m (241 lbf·ft).
   - 1.5 Assemble the lower isolator under the underslung crossmember and the front engine bracket, and secure the front engine mount with nuts and washers. Tighten the nuts 184 N·m (136 lbf·ft).
   - 1.6 Once the engine is securely installed in the vehicle, remove the lifting chains and the special lifting bracket.
   - 1.7 If the valve cover was removed, install it. For instructions, refer to the engine manufacturer's service literature.
2. Connect and install components under the engine.
   - 2.1 Connect the exhaust flex pipe to the forward end of the exhaust piping.
   - 2.2 Connect the two fuel return lines to the equiflow bracket. For instructions, refer to **Group 47** of this service manual.
3. Without breaking the power steering fluid lines, install the power steering pump. For instructions, refer to **Group 46** in this service manual.
4. Connect the wiring. For wiring harness information, refer to **Group 54** in this service manual.
   - 4.1 Connect the two engine harness bulkhead connectors.
   - 4.2 Connect the wiring to the power stud on the bulkhead.
   - 4.3 Connect the wiring to the ground stud on the bulkhead.

4.4 Install the magnetic switch on the bulkhead.

4.5 Connect the starter ground cable to the frame rail.

4.6 Connect the power cables to the starter and the starter solenoid.

5. Install the windshield wiper linkage. For instructions, refer to **Group 82** in this service manual.
6. Install the windshield wiper pan. See **Fig. 5** .
   - 6.1 Position the pan by tucking it up under the lower edge of the windshield trim.
   - 6.2 Install the fresh air intake snorkle.
   - 6.3 Install the screws that hold the pan to the firewall.
   - 6.4 Install the surge tank. For instructions, refer to **Group 20** of this service manual.
   - 6.5 Install the wiper arms. For instructions refer to **Group 82** of this manual.
7. Connect or install the ducts and lines. See **Fig. 3**.
   - 7.1 Install the V-band clamp that holds the forward end of the flex pipe exhaust ducting to the rear of the turbocharger. Tighten it 85 lbf·in (940 N·m).
   - 7.2 Install the air duct between the turbocharger and the air cleaner.
   - 7.3 Connect the vent line to the engine.
   - 7.4 Connect the two air signal lines to the air governor on top of the compressor.
   - 7.5 Connect the outlet line to the air compressor.
   - 7.6 Connect the air line to the fan clutch solenoid.
   - 7.7 Connect the heater return hose to the radiator outlet pipe. See **Fig. 4**.
   - 7.8 Connect the heater supply hose. See **Fig. 4**.
   - 7.9 Connect the oil pressure sensor line beneath the receiver-drier.
8. Install the radiator mounting bracket on the front closing crossmember.
9. Install the radiator, fan shroud, and charge air cooler. For instructions, refer to **Group 20** in this service manual.
10. Install the air recirculation shields around the radiator and charge air cooler. For instructions, refer to **Group 09** in this service manual.
11. Install the air conditioning components without breaking the refrigerant lines. See **Fig. 2**.
    - 11.1 Install the condenser. For instructions, refer to **Group 83** of this service manual.
    - 11.2 Install the refrigerant compressor. For instructions, refer to **Group 83** of this service manual. For instructions on installing the compressor drive belts, refer to **Section 01.00** in this service manual group.
    - 11.3 Route and clamp the refrigerant lines between the compressor and the condenser.
    - 11.4 Route and clamp the refrigerant lines between the receiver-drier and the condenser.
12. Install the air cleaner housing. For instructions, refer to **Group 09** in this service manual. Connect the intake air ducting to the air cleaner and the charge air cooler.
13. Install the transmission. For instructions, refer to the applicable section in **Group 26** in this service manual.
14. Install the hood tilt-assist bracket mounted on the forward closing crossmember. For instructions, refer to **Group 88** in this service manual.
15. Install the hood, bumper, and the left-side quarter fender. For instructions, refer to **Group 88** in this service manual.
16. Fill the radiator.
17. Connect the batteries.
18. Start the engine, and check for leaks. Repair any leaks found.
19. Test drive the vehicle.

General Information and Principles of Operation

This system electronically controls the two grid heating elements in the air intake manifold to assist in cold weather starts and to improve cold engine running. The electric grid heater system works in a preheat and post-heat mode. The preheat mode heats the intake air prior to starting the engine to aid in starting. The post-heat mode heats the intake air after starting to improve cold engine running. This system can be used on naturally aspirated and turbocharged engines.

The grid heater system benefits include:

- Quicker starting
- Smoother engine running after starting
- Replacement of ether as a starting aid
- Extended starter and battery life through less cranking

The grid heater starting aid will not operate unless the intake manifold temperature sensor senses a temperature below 45°F (7°C). This system is compatible with a 12-volt electrical system only, and is not compatible with a 24-volt system.

Current draw is 95 amperes per element. To prevent excessive drain on the batteries, the electric grid heater controller has incorporated a battery monitoring feature. If the battery voltage dips too low, the grid heater controller will interrupt the post-heat cycle, preventing further drain on the batteries. This battery protection feature is activated only on vehicles with weak or drained batteries.

The following is a summary of normal operations:

1. Turn the key switch to ON (intake manifold temperature sensor must read a temperature below 45°F (7°C).
2. While the wait-to-start (WTS) light is ON, the grid is in the preheat mode, see **Table 1**.
3. When the WTS light goes out, the engine is ready to start.
4. Start the engine within 10 seconds after the WTS light goes off.
5. After the engine starts, the grid is in the post-heat mode.

1. Set the parking brake, shut down the engine, and chock the tires. Disconnect the batteries.
2. Remove the air intake tube from the intake elbow by loosening the clamps.
3. Disconnect all three electrical cables from the grid heater block by removing the retaining capscrews.

IMPORTANT: Note the orientation of the heater grid block before removal, to ensure correct installation.

4. Remove the four mounting capscrews; then remove the intake elbow and the grid heater block. It may be necessary to pry between the grid heater block and the manifold to break the seal between them.
5. Place a clean cloth into the intake manifold opening to prevent any contaminants from entering.
6. Clean any gasket material or sealant from the grid heater mounting surface.

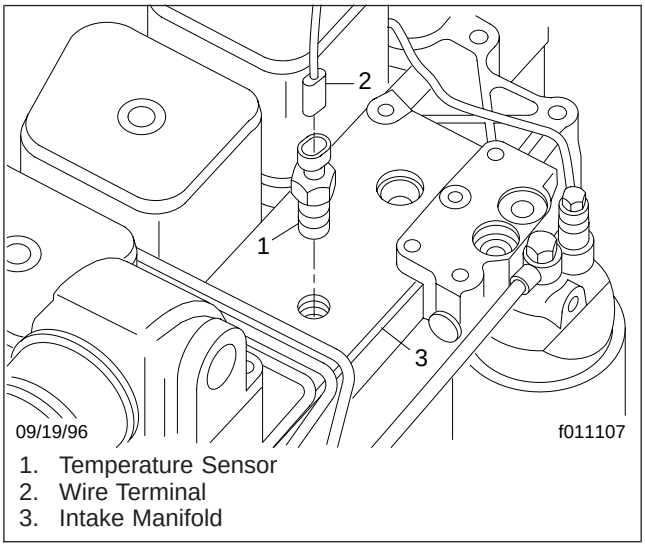
Installation (See Fig. 1)

1. Remove the cloth from the intake manifold and carefully check the manifold to ensure that there are no foreign objects remaining.
2. Place a new gasket on the grid heater block mounting surface.
3. Position a new grid heater block on the mounting surface and place a gasket on the grid heater block. Place the intake elbow on the grid heater block and secure with the mounting capscrews. Be sure to secure the negative grid heater block cable (Ref. 1) under a capscrew. Torque the mounting capscrews to 18 lbf·ft (24 N·m).
4. Connect the positive electrical cables to the grid heater block.

NOTE: The electrical cables should be secured within 6 inches of any connection to avoid connector or ring terminal damage.

5. Position the intake tube on the intake elbow, with the intake couple and clamps in place. Tighten the clamps 75 lbf·in (800 N·cm).
6. Connect the batteries and remove the chocks from the tires.

Temperature Sensor Replacement



Removal (See Fig. 2)

1. Set the parking brake, shut down the engine, and chock the tires. Disconnect the batteries.
2. Disconnect the wire terminal from the sensor.
3. Remove the sensor by unscrewing it from the manifold.

Installation

1. Install the temperature sensor in the intake cover. Tighten it 25 lbf·in (35 N·m).

Component Replacement

1. Temperature Sensor
2. Wire Terminal
3. Intake Manifold

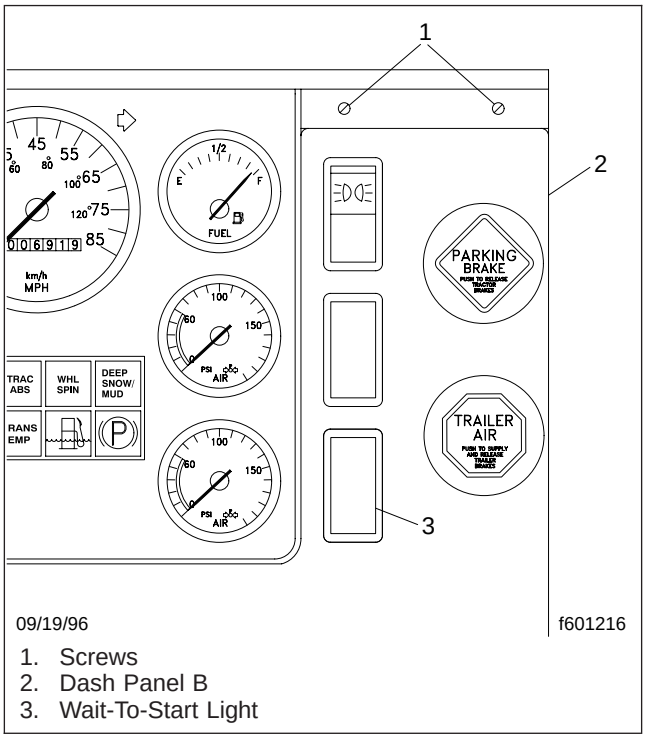
2. Connect the wire to the sensor.
3. Connect the batteries and remove the chocks from the tires.



Wait-to-Start Light Assembly Replacement

Removal (See Fig. 3)

1. Set the parking brake, shut down the engine, and chock the tires. Disconnect the batteries.
2. Loosen the dashboard panel B by removing the mounting screws.
3. Being careful not to damage the connecting wires, allow the panel to come away from the dashboard.
4. Disconnect the wires at the wait-to-start light assembly.
5. Remove the light assembly by removing the mounting screws.

Installation (See Fig. 3)

1. Position a replacement wait-to-start light assembly in the dash opening and secure it with the mounting screws.
2. Connect the wire to the light assembly.

1. Screws
2. Dash Panel B
3. Wait-To-Start Light

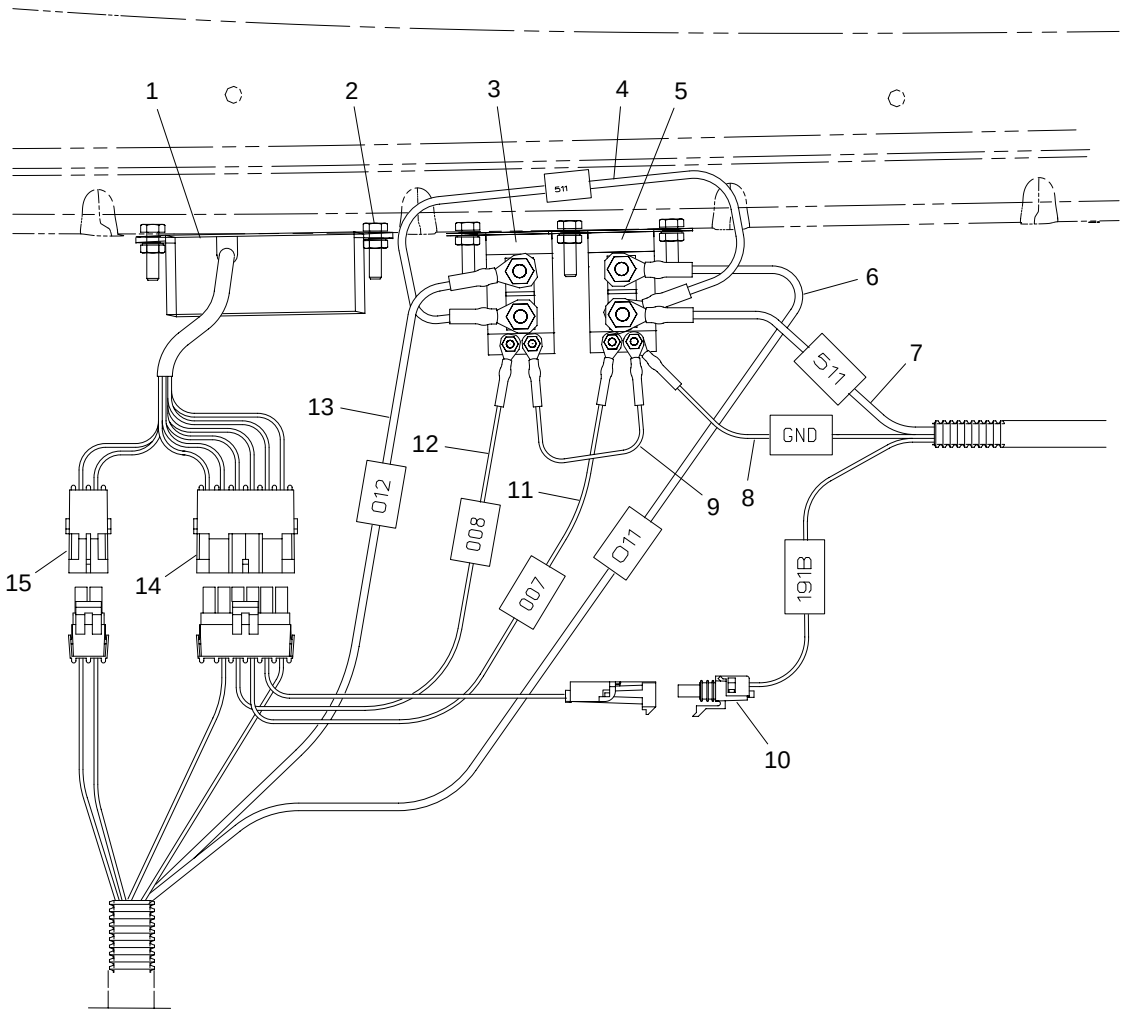
3. Install the dashboard panel B and secure it with the mounting screws.
4. Connect the batteries and remove the chocks from the tires.



Air Intake Heater Control Module Replacement

Removal (See Fig. 4)

1. Set the parking brake, shut down the engine, and chock the tires. Disconnect the batteries.
2. Working under the hood, disconnect the main module connector and the temperature sensor connector at the intake heater module.
3. Remove the module by removing the mounting fasteners.

Installation (See Fig. 4)

1. Position the intake heater control module on the air intake tray.

Air Intake Heater Relay #1 Replacement

Removal (See Fig. 4)

1. Set the parking brake, shut down the engine, and chock the tires. Disconnect the batteries.

Component Replacement

2. Working under the hood, disconnect the cables (Ref. 4, 6, 7, 8, and 9) and the controller module wire (Ref. 11) from the relay.
3. Remove the relay by removing the mounting fasteners.

Installation (See Fig. 4)

1. Position the relay on the air intake tray.
2. Install the fasteners.
3. Connect the cables (Ref. 4, 6, 7, 8, and 9) and the wire (Ref. 11) to the relay.
4. Connect the batteries and remove the chocks from the tires.

Air Intake Heater Relay #2 Replacement

Removal (See Fig. 4)

1. Set the parking brake, shut down the engine, and chock the tires. Disconnect the batteries.
2. Working under the hood, disconnect the cables (Ref. 4, 9 and 13) and the controller module wire (Ref. 12) from the relay.
3. Remove the relay by removing the mounting fasteners.

Installation (See Fig. 4)

1. Position the relay on the air intake tray.
2. Install the fasteners.
3. Connect the cables (Ref. 4, 9 and 13) and the wire (Ref. 12) to the relay.
4. Connect the batteries and remove the chocks from the tires.

Troubleshooting Procedures

1. Preheat Cycle—The key switch should be in the ON position. The wait-to-start (WTS) light will come on indicating that the system is in the preheat mode. When the light goes out the engine is ready to start. The engine must be cranked within 10 seconds after the WTS light goes out.

   Post-Heat Cycle—With the engine running, if white smoke is present or if the engine is running rough due to cold conditions, the operator can use the post-heat cycle. The key switch should be in the ON position. When the intake manifold heater system switch is in the ON position, the WTS light will flash indicating that the system is in the post-heat mode. See **Table 1** for operating times at given temperatures.

2. Wait-To-Start Light—Do not attempt to start the engine while the wait-to-start light is ON. When the air temperature rises above 59°F (15°C), the WTS light will go out, indicating that the engine will start. The engine must be cranked within ten seconds after the WTS light goes out, or the intake air should be warmed again. If the WTS light flashes at the rate of once per second, there is an open in the system's wiring circuit.

3. Temperature Sensor—The temperature sensor, or thermistor, is mounted in the intake manifold and sends varying resistance values to the electronic control module (ECM). The ECM in turn controls the wait-to-start light and the heater solenoids.

4. Wiring Harness—If the engine does not have a shutdown solenoid, or if it has a timer module for the shutdown solenoid, the three-pin connector "Tee" will be wired to the vehicle. The connectors on the harness have letter designations. "A" connects to the vehicle power. "B" connects to the "S" terminal on the ignition switch. "C" is the ground wire.

   If a problem is suspected in the wiring harness, check for loose connections. Also check for abrasions, and broken or worn wires. Replace or repair as necessary.

5. Contactors—The contactors, or relay coils, close the circuits to the air intake heater grid when the switch is moved to the ON position, the ignition switch is ON, and the temperature sensor senses a temperature below 59° F (17° C).

6. Fusible Links, 110A—The air intake heater system is protected by two 110 ampere fusible links—one for each of the grid heater elements. If either of the grid heater elements is suspected of not operating, both fusible links should be checked for continuity. The current draw is 95 amperes per element.

7. Controller Module—If a malfunction is suspected in the air intake heater control module, first check the wiring harness. The controller operates between 6.5 volts and 16 volts. Check the connectors for good connections. Check pin J2A for 12-volt signal.

NOTE: The controller will cancel post-heat if it senses a voltage below 9.5 volts during preheat or a delay of 10 seconds or more between the wait-to-start light going off and the start of cranking. An open in the circuit will also be detected by the controller and will also result in a cancellation of the post-heat operation.

8. Ground Circuits—Check pin J1B for ground to the controller and check the ground strap to the grid for high resistance. Repair or replace as necessary.

Troubleshooting Table

Problem—Wait-To-Start (WTS) light will not function

Problem—Wait-To-Start (WTS) light will not function	
Possible Cause	**Remedy**
The bulb is damaged or burned out.	Replace the bulb.
There is no power to the light.	Check the voltage to the bulb socket. If there is no voltage, check the connections and wiring from the key switch to the WTS light switch and to the light socket. Check the ground circuit from the controller. Repair as necessary. The WTS light will flash once every second if the temperature sensor detects an open circuit.

Problem—Temperature Sensor Appears Inoperative

Problem—Temperature Sensor Appears Inoperative	
Possible Cause	**Remedy**
The temperature sensor has failed.	Check the resistance across the temperature sensor pins J1A and J1B at room temperature and in an ice bath, 32°F (0°C). The resistance should be approximately 800 ohms at room temperature and 2000 ohms in the ice bath. Check the resistance to ground for an open circuit. NOTE: Make resistance checks with the key switch in the ON position to make sure there are no ground problems. Replace as necessary.
The circuit is open.	Check the circuitry connections and wiring for continuity. Replace or repair as necessary.

Problem—Relays or Contactors Appear Inoperative

Problem—Relays or Contactors Appear Inoperative	
Possible Cause	**Remedy**
The relays or contactors have failed.	An audible click should be heard from the relays or contactors during operation. Replace as necessary. Check the resistance at the relay terminals and ground. If resistance is too high, replace the relay.

Problem—Insufficient Ground Connections

Problem—Insufficient Ground Connections	
Possible Cause	**Remedy**
The circuit is open.	Check pin J1B for ground to the controller, and check the ground strap to the grid for high resistance. Repair or replace the wiring as necessary.

Problem—Controller is Malfunctioning

Problem—Controller is Malfunctioning	
Possible Cause	**Remedy**
The circuit is open.	Check pin J2A for a 12-volt signal. Inspect the wiring harness for shorting, chafing, or burning. Repair or replace the wiring as necessary. NOTE: The controller operates between 6.5 volts and 16 volts.
Low or no voltage to the controller.	The controller operates between 6.5 volts and 16 volts. Check connectors for good connections. Replace the controller if necessary.
The controller is inoperative.	The controller will cancel post-heat if it senses a voltage below 9.5 volts during preheat, a ten second delay or more between the WTS light OFF and cranking, or an open temperature circuit.

Removal

1. Apply the parking brakes, chock the tires, and (if applicable) drain the air system.
2. Disconnect the battery cables at the batteries.
3. Remove the hood. For detailed instructions, see **Section 88.00**, Subject 140.
4. Drain the oil. See **Fig. 1** for the location of the oil drain plug.

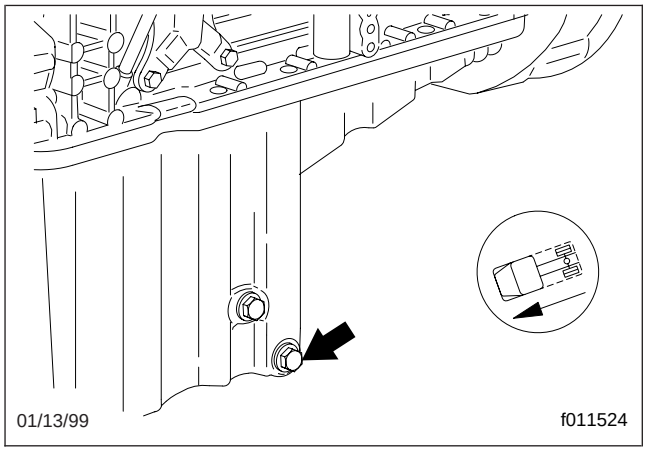

Fig. 1, Oil Drain Plug

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

5. Drain the coolant from the radiator. See **Fig. 2**.
6. Remove the coolant hose standoff bracket.
7. When the coolant has fully drained, remove all the coolant hoses from the engine. See **Fig. 3** for the coolant delivery hoses from the surge tank, **Fig. 4** for the upper coolant hose, and **Fig. 5** for the lower coolant hose.
   - 7.1 Remove the two small-diameter hoses attached to the surge tank, one going to the engine, the other to the radiator. These are the hoses that were attached to the standoff bracket.
   - 7.2 Remove the 2-inch (50-mm) inside diameter upper coolant hose attached to the front end of the crankcase, near the cylinder head.
   - 7.3 Remove the lower coolant hose assembly.
   - 7.4 Plug the openings with a clean shop towel.
8. Remove the intake air circulation pipes and hoses. See **Fig. 5**.
   - 8.1 Remove the crossover hose from the charge air inlet pipe to the charge air cooler (cold air).

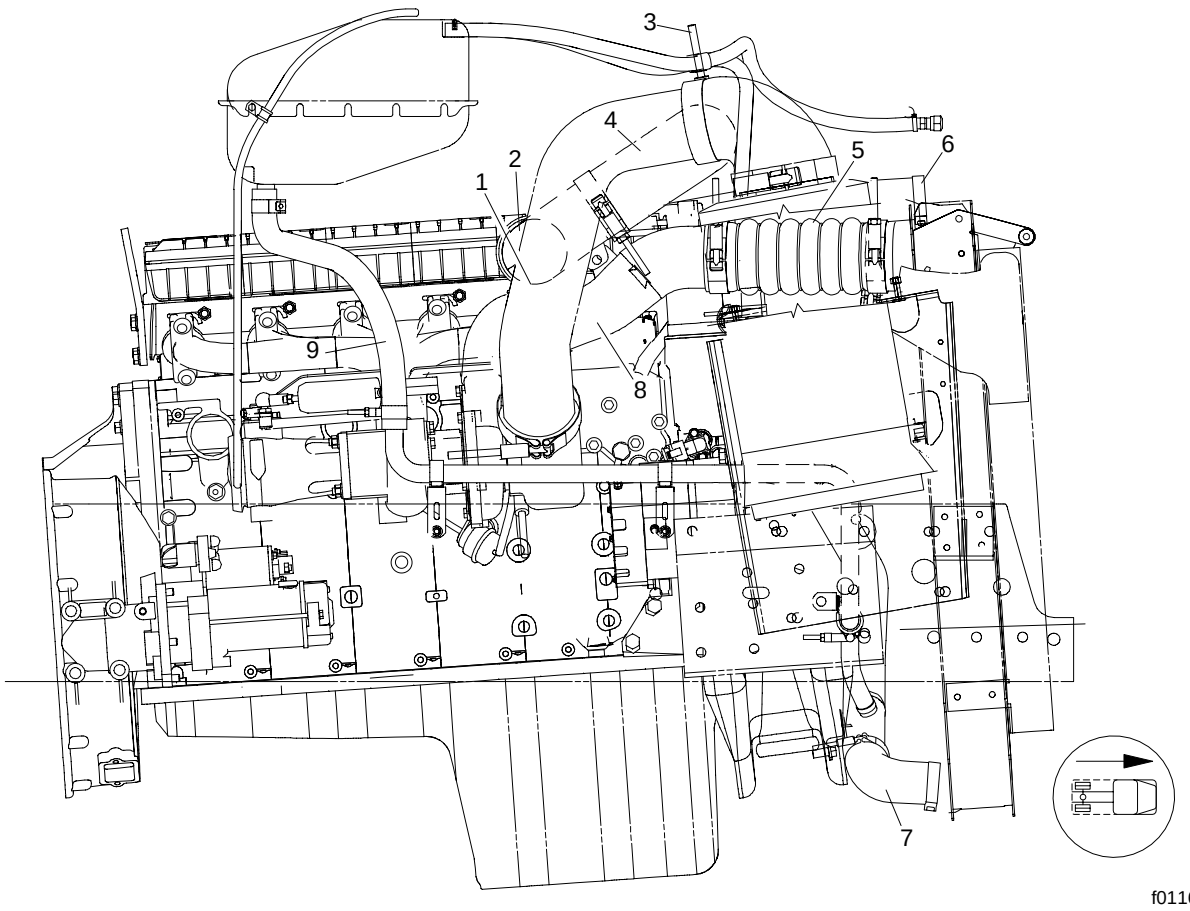
8.2 Remove the convoluted hose from the turbo outlet pipe to the charge air cooler (warm air).

8.3 Remove the pipe from the air cleaner to the turbo inlet (air cleaner pipe).

8.4 Remove the crankcase breather hose from the crankcase inlet tubing.



8.5 Remove the air compressor inlet hose between the air cleaner pipe and the air compressor inlet tubing.

8.6 For ease of installation, mark the outlets on each pipe with a paint pen.

8.7 Plug the openings with a clean shop towel.

IMPORTANT: Leave all air conditioning hoses attached to avoid depressurizing the A/C system.

9. Remove the air conditioning (A/C) condenser. See **Fig. 6**. Wrap the condenser, with hoses attached, in a protective blanket, and secure it out of the way.
10. Remove the charge air cooler. See **Fig. 7**. For detailed procedures, see the instructions in **Section 09.01**, Subject 100.
11. Remove the radiator assembly. See **Fig. 7**. For detailed procedures, see the instructions for frame-rail mounted radiators in **Section 20.01**, Subject 100.
12. Release the tension on the poly-V belt. See **Fig. 8**.
13. Disconnect the fuel lines from the fuel filter housing. See **Fig. 9**.
14. Remove the refrigerant compressor. See **Fig. 10**.
15. Disconnect the electrical connectors from the engine.
    - 15.1 Disconnect the engine harness connector from the PLD (engine control unit). See **Fig. 11**.
    - 15.2 Disconnect the fan solenoid connector. This connector is along the left-hand side, between the PLD and the air compressor. See **Fig. 12**.
    - 15.3 Disconnect the exhaust brake solenoid connector, if installed. This connector is on the left-hand side near the PLD. See **Fig. 12**.
16. Disconnect the power steering pump from the air compressor. Secure it, with the lines attached, up and out of the way. See **Fig. 13**.
17. Remove the air line from the exhaust brake, if installed. See **Fig. 14**.
18. Disconnect the exhaust pipe. See **Fig. 15**.
19. Remove the starter and engine ground strap. Set the starter out of the way.
    - 19.1 Remove the ground strap from the engine to the chassis.
    - 19.2 Remove the starter mounting bolts.
    - 19.3 Move the starter up and out of the way, with the cables attached. Tie the starter in place.
20. Remove the electrical leads from the back of the alternator. See **Fig. 16**.
21. Remove the transmission. For procedures, see **Group 26**.
22. Remove the hydraulic clutch line, if installed. See **Fig. 17**.
23. Remove the rain tray and wiper arms.

CAUTION

To avoid damage to the crankcase breather valve cover, make sure the chains on the front lifting eye provide adequate clearance.

To avoid damage to the wiper conlink, make sure the chains on the rear lifting fixture do not contact the conlink when the engine is lifted.

24. Attach a lifting hoist to the engine. Run the chains through the front lifting eye and rear lifting fixture. See **Fig. 18** for attachment to the front lifting eye and **Fig. 19** for attachment to the rear lifting fixture.
25. Loosen the engine mounts. See **Fig. 20** for the front engine mount and **Fig. 21** for the rear engine mounts.
    - 25.1 Loosen the front engine mounting bolt where it attaches to the front crossmember.
    - 25.2 Loosen the four rear engine mounting capscrews that attach the mount to the engine.

Engine Removal and Installation

Remove the four mounting bolts.

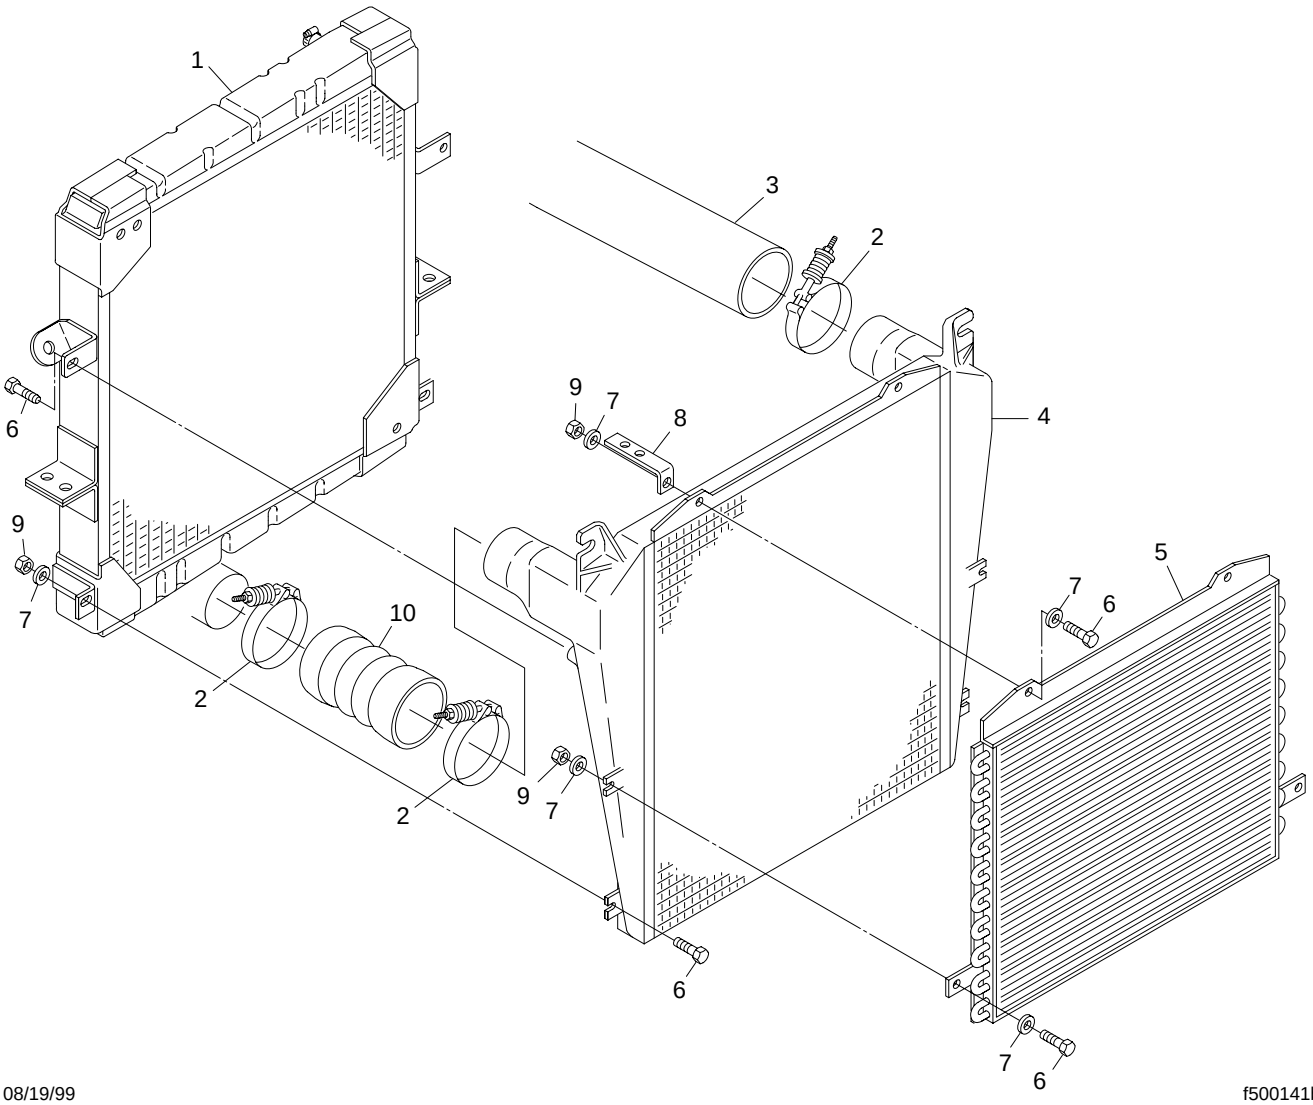
1. Air Conditioning (A/C) Condenser
2. Charge Air Cooler
3. Condenser Inlet
4. Condenser Outlet

Fig. 6, A/C Condenser

26. Support the rear of the engine with a jack.
27. Remove both rear engine mounts. For proper clearance, remove both ends of the mount.
28. Remove the front crossmember to obtain proper clearance for removal of the engine. See **Fig. 22**.

⚠ WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.



29. Remove the engine from the vehicle. See **Fig. 23**.
    - 29.1 Raise the hoist slightly until it is holding the full weight of the engine.
    - 29.2 Lower the engine just enough to allow it to move forward until it can be lifted without hitting the frontwall or wiper conlink.
    - 29.3 Pull the engine forward and up to clear the vehicle. If a new engine is to be installed, transfer all needed components from the old engine to the new engine.

Installation

⚠ WARNING

The crane and lifting chains used to remove the engine must be capable of safely lifting and supporting two metric tons. Once the engine mounts are disconnected, do not get under the engine until it is securely supported on engine stands. An unsecured engine may fall, causing personal injury or death, and component damage.

1. Using the hoist as removed, lower the engine into the engine compartment until the rear of the engine is resting on the jack used during removal. Check clearances on all sides, as removed.
2. Install the front crossmember. Tighten the locknuts on the mounting bolts 60 lbf·ft (81 N·m).
3. Install the front engine mounting bolt, isolator, and nut. Tighten the nut 136 lbf·ft (184 N·m).
    - 3.1 Position the isolator on the crossmember.
    - 3.2 Move the engine on the hoist until it rests directly on the isolator.
    - 3.3 Insert the bolt through the crossmember, isolator, and engine. Install and tighten the nut.
4. Install both rear engine mounts. See **Fig. 21** and **Fig. 24**.
    - 4.1 Install the engine mounts on the frame-mounted brackets. Tighten the mounting bolts 241 lbf·ft (347 N·m).
    - 4.2 Lower the jack under the rear of the engine slightly, until the holes in the timing case line up with the holes in the engine mounts.
    - 4.3 Insert the engine mounting capscrews and tighten them 155 lbf·ft (210 N·m).

25. Install the rain tray and wiper arms.

26. If removed, install the hydraulic clutch line and bleed the hydraulic clutch system. For detailed instructions, see **Section 25.03**, Subject 140.

27. Install the hood. For detailed instructions, see **Section 88.00**, Subject 140.

28. Install the coolant drain plug. Fill the radiator with coolant. Make sure the coolant drain plug is tight and is not leaking.

29. Install the oil drain plug and tighten it 48 lbf·ft (65 N·m). Fill the engine with oil. Make sure the oil drain plug is tight and is not leaking.

30. Connect the battery cables to the batteries.

31. Turn on the ignition keyswitch and test the engine for good operation. Pay attention to oil pressure, coolant temperature, warning lights, fluid leaks, and any other signs of a problem.

32. Remove the chocks from the tires.

Table 1, Torque Values, Engine Removal and Installation

General Information

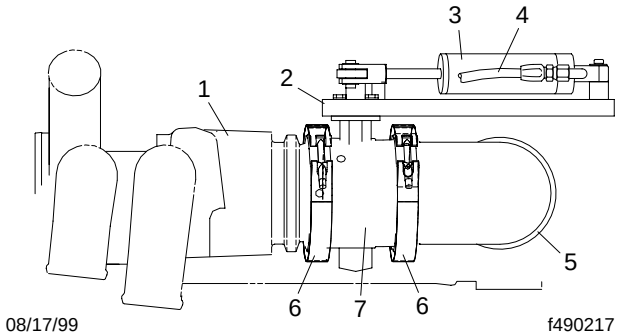
The Jacobs exhaust brake uses exhaust back pressure to help slow the vehicle. It supplements the vehicle's standard service brakes to supply more efficient braking action, even with heavy loads. It is virtually silent during operation, and provides retarding power proportional to the engine rpm; that is, the higher the engine rpm, the higher the retarding horsepower.

The exhaust brake is installed in the exhaust line between the turbocharger (or turbocharger exhaust pipe) and the main exhaust pipe. The major components of the exhaust brake include a butterfly valve and an air cylinder. When the air cylinder is pressurized, a pushrod rotates an actuating lever to close the butterfly plate. A solenoid valve controls the air released to the air cylinder from the secondary air tank.

When the valve restricts the flow of exhaust gas, back pressure increases inside the engine. This higher back pressure creates resistance against the pistons, which slows the crankshaft's rotation and helps control the speed of the vehicle.

The Jacobs exhaust brake has a cast-iron housing and a butterfly plate that resists extremely high temperatures. The exhaust brake requires no adjustment or maintenance because the valve's orifice is fixed and the air cylinder is sealed to prevent contamination. The unit can be deactivated by pressing a switch on the dash.

Removal

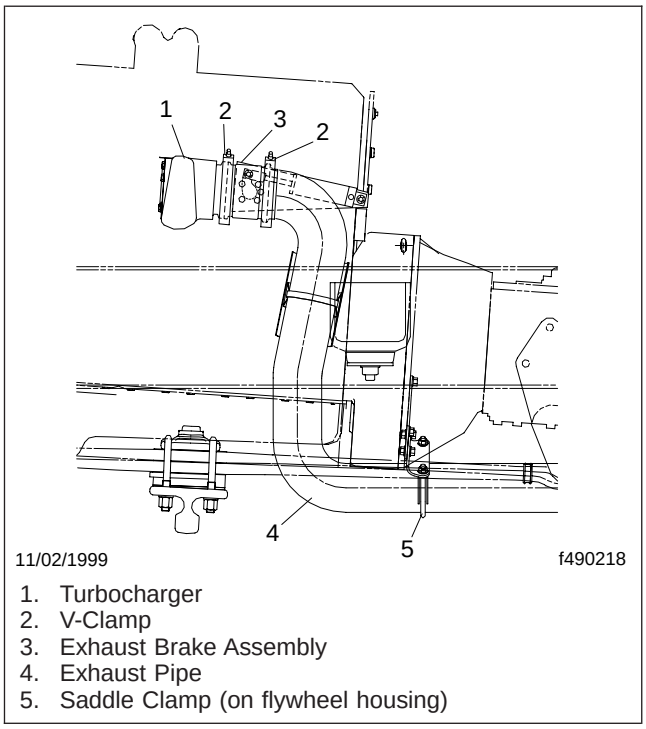


NOTE: The position of the exhaust brake and the location of the solenoid valve depend on the configuration of the vehicle. The following procedure and the illustrations are for a typical installation and may differ slightly for your application.

1. Park the vehicle, set the parking brakes, and shut down the engine. Chock the rear tires.
2. Drain the air tanks. For instructions, see **Group 42**.

⚠ WARNING

Do not work on or near the exhaust components while they are hot. To do so could result in serious personal injury from burns. Let the exhaust piping cool before you work on it.



3. Disconnect the air line from the exhaust brake cylinder. See **Fig. 1**.

- 4.3 Loosen and remove the two V-clamps securing the exhaust piping to each side of the exhaust brake. Your vehicle may have the exhaust brake connected directly to the turbocharger without a short connecting pipe.
- 4.4 Pull the exhaust piping apart and remove the exhaust brake. Discard the gasket on the inlet side of the exhaust brake.

Installation

1. Connect the exhaust brake to the exhaust piping.
   - 1.1 Install a new gasket on the exhaust brake inlet.

     If the short turbocharger exhaust pipe was removed, install a new gasket on the inlet side of the exhaust pipe before reinstalling it.
   - 1.2 Install the exhaust brake between the turbocharger (or short turbocharger exhaust pipe) and the main exhaust pipe, aligning the marks made during removal. See

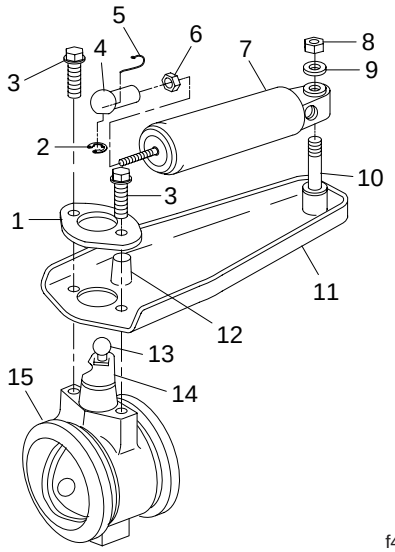
1.3 Install the two V-clamps. Tighten each clamp 4 lbf·ft (5 N·m).

1.4 Install the saddle clamp on the exhaust pipe and secure it to the flywheel housing. Tighten the hexnuts on the saddle clamp 24 lbf·ft (33 N·m).

2. Connect the air line from the solenoid to the air cylinder. See **Fig. 1**. Tighten the connection firmly.
3. Make sure the wiring and air lines are not kinked, and are protected from abrasion and potentially hot surfaces.
4. Test the exhaust brake.
   - 4.1 Start the engine.
   - 4.2 Turn the exhaust brake switch to On.
   - 4.3 Bring the engine up to the governed rpm and release the throttle. The brake should actuate, then turn off at about 900 rpm.
5. Remove the chocks from the tires.

Replacement

NOTE: The air cylinder is the only replaceable part on the exhaust brake. Air cylinder replacement kits are available through the Caterpillar distribution system. If there is a problem with any other part, replace the entire exhaust brake assembly.



1. Park the vehicle, set the parking brakes, and shut down the engine. Chock the rear tires.
2. Drain the air tanks. For instructions, see **Group 42**.

⚠ WARNING

Do not work on or near the exhaust components while they are hot. To do so could result in serious personal injury from burns. Let the exhaust piping cool before you work on it.

3. Disconnect the air line from the exhaust brake cylinder.
4. If the configuration of your vehicle provides enough clearance to remove the air cylinder from the exhaust brake housing, go to the next step.

   If access to the air cylinder is restricted, remove the entire exhaust brake assembly from the exhaust piping. See **Subject 100** for instructions.
5. Remove the air cylinder from the exhaust brake. See **Fig. 1**.
   - 5.1 Mark the air cylinder bracket below the air supply port on the air cylinder.
   - 5.2 Loosen the jam nut between the air cylinder and the ball-and-socket joint.
   - 5.3 Remove the safety clip from the socket.
   - 5.4 Pry the socket off the ball stud on the actuating lever.
   - 5.5 Remove the locknut and washer securing the air cylinder on the pivot stud. Remove the air cylinder from the bracket.
   - 5.6 Unscrew the socket and jam nut from the threaded rod on the air cylinder.
   - 5.7 Note the orientation of the air supply fittings on the air cylinder. Remove and save the fittings. Discard the air cylinder.

6. Install the new air cylinder on the exhaust brake.
   - 6.1 Install the air supply fittings in the same orientation on the new air cylinder.

   NOTE: The socket in the air cylinder kit has the internal snap ring already installed.
   - 6.2 Install the jam nut and socket on the threaded rod on the air cylinder, but do not tighten.
   - 6.3 Slide the air cylinder bushing onto the pivot stud on the air cylinder bracket. Make sure the air supply port is aligned with the mark you made on the bracket during disassembly.
   - 6.4 Install the washer and locknut on the pivot stud, but do not tighten.
7. Adjust the socket.
   - 7.1 Move the actuating lever clockwise until it contacts the positive stop. See **Fig. 1**. Hold the lever in this position.

Air Cylinder Replacement

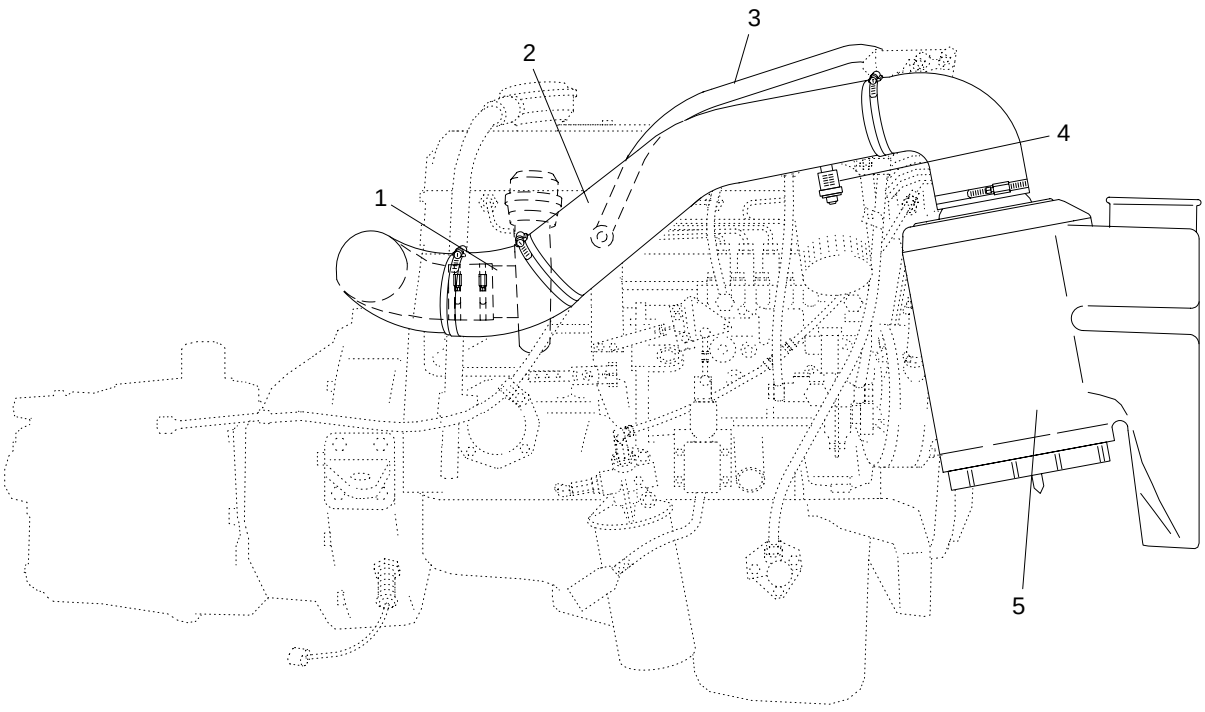
7.2 Turn the socket on the threaded rod until the pocket is aligned with the ball stud on the exhaust brake housing. Then, tighten the socket one additional turn on the air cylinder threaded rod.

NOTE: The additional turn on the socket provides the required small preload on the spring in the air cylinder. If too much preload is applied (more than 1-1/2 turns), the butterfly plate will not fully close, resulting in poor exhaust brake performance.

7.3 Press the socket on the ball of the actuating lever until it snaps in place.

7.4 Make sure the spring preload in the air cylinder holds the actuating lever tightly against the positive stop. If there is any free play in the actuating lever, readjust the socket.

8. From the air cylinder side of the socket, insert the safety clip through the holes in the socket. Snap the loop on the end of the clip into the groove in the body of the socket.
9. Tighten the jam nut against the socket 13 lbf·ft (18 N·m).
10. Tighten the prevailing-torque locknut on the pivot stud until there is no free play of the cylinder on the stud.
11. Install the exhaust brake in the exhaust piping if it was removed at the start of this procedure. See **Subject 100** for instructions.
12. Connect the air line from the solenoid to the air cylinder. Tighten the connection firmly.
13. Make sure the wiring and air lines are not kinked, and are protected from abrasion and potentially hot surfaces.
14. Test the exhaust brake.
    14.1 Start the engine.
    14.2 Turn the exhaust brake switch to On.
    14.3 Bring the engine up to the governed rpm and release the throttle. The brake should actuate, then turn off at about 900 rpm.
15. Remove the chocks from the tires.



General Information

An average diesel engine needs over 10,000 gallons (38 000 liters) of clean air for each gallon (3.8 liters) of fuel burned. So complete combustion occurs in each engine cylinder, more clean air than is needed is present in each cylinder. The air intake system routes this supply of outside air through an air cleaner, which filters out dirt, dust, abrasive particles, and other foreign material from the intake air, without restricting air flow. From there, the air intake ducting routes this clean air to the engine turbocharger.

The air intake ducting consists of a high-temp plastic housing for the air cleaner, followed by aluminum tubes and neoprene hoses. Stainless steel hose clamps fasten all the components together in one of six configurations depending on which engine is used. See **Fig.1 , Fig.2 , Fig.3 , Fig.4 , Fig.5,** and **Fig.6**.

On some engines, a lock-up air restriction indicator (see **Fig.7)** is attached to the intake ducting near the air cleaner. As an option, an air restriction indicator or gauge mounts in the dashboard. Nylon tubing connects the remote-mounted indicator or gauge to the ducting. The air restriction indicator or gauge indicates when the air cleaner element needs to be replaced. The amount of allowable air restriction varies with engine type.

On vehicles equipped with a Bendix AirMaster® air compressor, the compressor air inlet hose mounts to the air intake pipe just past the air restriction indicator.

General Instructions

WARNING

WARNING: Do not operate the engine with any under-hood component of the air intake system removed; serious physical injury can occur if the turbocharger impeller is touched when it is rotating.

All air intake components and connections must be air-and water-tight. Dirt or dust entering the engine can cause internal engine damage. Much of the dirt and dust are silicates, which fuse into abrasive glass-like particles when exposed to engine combustion. These particles can grind piston rings, pistons, and cylinder liners.

IMPORTANT: Replace damaged components with new, identical parts. Neoprene hoses and nylon ducts that have been enlarged, extended, or otherwise modified, are not acceptable for installation between the air cleaner and the engine.

To avoid chafing, air intake ducting must not contact other parts.

Removal

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Disassemble the air intake ducting. **Refer to Fig. 1.**
   - 3.1 Loosen the clamp (Ref. 8) that holds the elbow (Ref. 7) to the top of the air cleaner, and remove the elbow from the cleaner.
   - 3.2 Loosen the clamp (Ref. 6) that holds the elbow to the forward end of the air intake pipe (Ref. 5), and remove the elbow from the pipe.
   - 3.3 Loosen the clamp (Ref. 4) that holds the pipe to the elbow (Ref. 3) at the forward side of the turbocharger, and remove the pipe from the elbow.
   - 3.4 Loosen the clamp (Ref. 2) that holds the elbow to the forward side of the turbocharger, and remove the elbow from the turbocharger.

Installation

1. Replace any damaged parts with new identical parts.
2. Assemble the air intake ducting. **Refer to Fig. 1.**
   - 2.1 Install the new or undamaged elbow (Ref. 3) on the forward side of the turbocharger, and loosely install the clamp (Ref. 2).
   - 2.2 Install the new or undamaged air intake pipe (Ref. 5) in the elbow at the forward side of the turbocharger, and loosely install the clamp (Ref. 4).
   - 2.3 Install the new or undamaged elbow (Ref. 7) on the forward end of the air intake pipe, and loosely install the clamp (Ref. 6).
   - 2.4 Install the elbow on the top of the air cleaner, and tighten all hose clamps.
3. Lower the hood.
4. Remove the chocks from the tires.

Removal

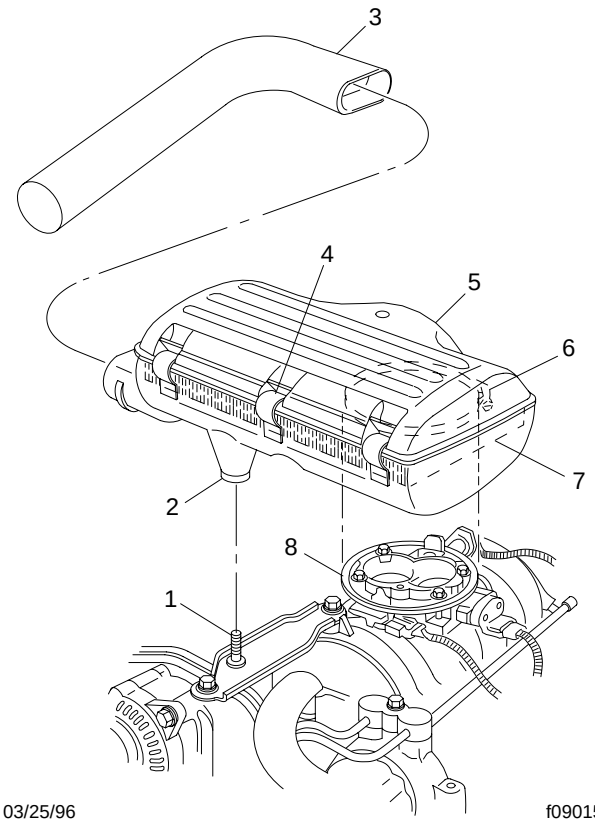
Dodge Magnum V-8

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Disconnect the air inlet tube at the side of the air cleaner housing. **See Fig. 1.**
4. Loosen, but do not remove the band-type screw clamp that attaches the housing to the top of the throttle body. Note the clamp positioning tabs on the air cleaner housing.
5. Disconnect the air pump hose at the air cleaner housing.

NOTE: The bottom-front of the air cleaner housing is equipped with a rubber grommet. A mounting stud is attached to the intake manifold, and is used to position the air cleaner housing into the grommet.



6. Lift the assembly from the throttle body while slipping the assembly from the mounting stud.
7. Check the condition of the gasket at the throttle body (and replace as necessary).
8. Unlatch the three spring clips at the top of the air cleaner housing, and tilt the housing cover up and rearward for removal of the cover.
9. Remove the air cleaner element from the air cleaner housing.

Dodge Magnum V-10

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.

NOTE: A small amount of engine oil wetting the inside of the air cleaner housing is normal. When servicing, wipe out the oil from the housing.

3. Loosen the clamp, and remove the air inlet tube at the front of the air cleaner housing cover. **See Fig. 2.**

5. Push down on the air cleaner housing at the rubber grommet to seat the housing at the intake manifold.
6. Tighten the throttle body-to-air cleaner housing clamp 400 N·cm (35 lbf·in).
7. Install the air inlet tube at the inlet on the air cleaner housing.
8. Close the hood.
9. Remove the chocks from the tires.

Dodge Magnum V-10

1. Clean the inside of the air cleaner housing.
2. If the removal of the housing is necessary, remove the four housing-to-throttle body nuts.
3. After re-installing the housing, tighten the four nuts to 1084 N·cm (96 lbf·in).
4. Position the air cleaner element into the air cleaner cover, and latch the spring clips to seal the cover to the housing.
5. Install the air inlet tube at the air cleaner housing.
6. Install and tighten the clamp at the air inlet tube.
7. Close the hood.
8. Remove the chocks from the tires.

General Information

The charge air cooler (CAC) is attached to the front of the radiator, behind the condenser. **See Fig. 1.** It is similar to a radiator: outside ambient air passing through the CAC core cools the engine's intake air charge.

Air leaving the turbocharger is compressed, which heats it to about 135° to 162°C (275° to 325°F), depending on the ambient temperature and boost. The CAC reduces this temperature to the engine manufacturer's specified air intake temperature before the air reaches the engine intake manifold. Lower tem-

Charge Air Cooler Inspection and Leakage Test

Inspection

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Check the charge air cooler (CAC) convoluted hoses and the inlet and outlet piping for holes or other damage. Also check for loose or damaged constant-torque hose clamps. Replace damaged parts. If hose clamps are loose, turn them so their tightening screws are under the hoses or facing inboard; then tighten the screws 45 lbf·in (500 N·cm).
3. Check the CAC core fins. If the fins are bent, use a small pair of needle-nose pliers or a small screwdriver to straighten them.
4. Check the CAC core for clogged fins. Use compressed air or water to dislodge any material restricting airflow through the core.
5. Perform the "CAC Core Leakage Test."

Leakage Test

Charge air coolers are designed in such a way that they may leak an insignificant amount of air. The allowable leakage mentioned in **Table 1** represents a loss of less than 0.1 percent of charge airflow. Based on this rate, there should be no measurable loss of performance.

Leakage Rate Specifications		
Engine	**Pressure Drop in 15 Seconds psi (kPa)**	**Start Pressure psi (kPa)**

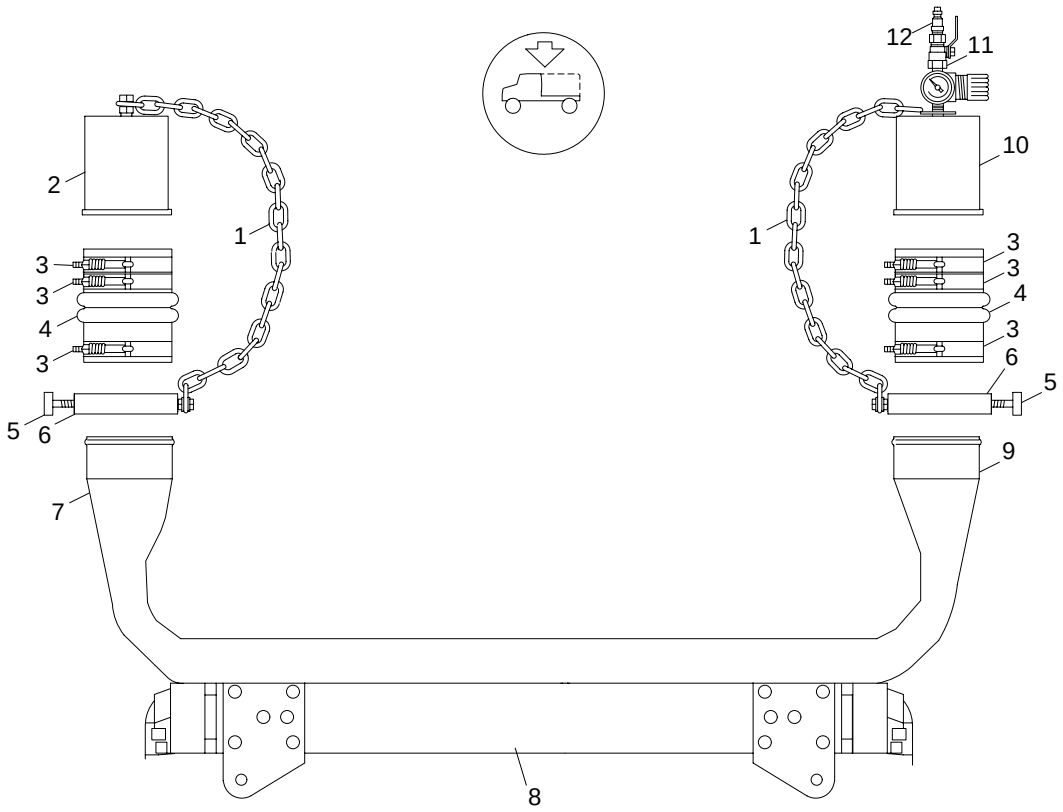
Table 1, Leakage Rate Specifications

The CAC core leakage test should be performed using a charge air cooler test kit, part number 5039, which can be purchased from Kent-Moore/SPX at 1.800.328.6657.

CAC CORE LEAKAGE TEST

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Connect the test equipment to the CAC core. See **Fig. 1**.
   - 2.1 Remove the inlet and outlet air piping from the convoluted hoses that attach them to the CAC air inlet and air outlet.
   - 2.2 Slip a safety ring with thumbscrew over each convoluted hose and onto the CAC air inlet and air outlet. Turn the rings so the thumbscrews are facing outboard and the safety chains are inboard. Tighten the thumbscrews securely.
   - 2.3 Install an additional constant-torque hose clamp on each convoluted hose.
   - 2.4 Install the test plug without an adapter in the CAC air inlet and turn the plug so the safety chain is inboard. Tighten both of the rearmost constant-torque hose clamps 72 lbf·in (813 N·cm).
   - 2.5 Install the test plug with adapter in the CAC air outlet and turn the plug so the safety chain is inboard. Tighten both of the rearmost constant-torque hose clamps 72 lbf·in (813 N·cm).

⚠ WARNING



Always secure the test plugs with the safety rings. Test pressures could blow an unsecured test plug out at high speed, possibly causing eye injury or other serious personal injury.

   - 2.6 If not already installed, install a test valve/gauge assembly and air chuck in the test plug with adapter.
   - 2.7 Attach a pressurized air line to the air chuck on the pressure regulator valve.
3. Test the CAC core.

⚠ WARNING

Always wear safety glasses when doing this procedure. Do not stand in front of the test plugs while the core is pressurized. A plug could sud-

denly release debris at high speed, possibly resulting in eye injury or other serious personal injury.

3.1 Open the test valve, then slowly open the pressure regulator valve and allow the charge air cooler system to gradually fill with air to the start pressure specified in **Table 1**.

3.2 Close the test valve and watch the gauge for 15 seconds. If there is more than the specified drop in the charge air cooler pressure in 15 seconds (see **Table 1**), replace the charge air cooler.

IMPORTANT: Do not attempt to repair the charge air cooler.

3.3 When testing is completed, reduce the pressure on the pressure regulator valve to bleed air from the charge air cooler.

4. Remove the test equipment (and the additional constant-torque hose clamps) from the convoluted hoses.
5. Pull the convoluted hoses and constant-torque hose clamps rearward until the hoses cover about 1-1/2 inches (38 mm) of the CAC air inlet and air outlet piping.
6. Turn the clamps so their tightening screws are under the hoses or facing inboard. Tighten the screws 45 lbf·in (500 N·cm).

7. Lower the hood and remove the chocks from the tires.

Charge Air Cooler Flushing

If the charge air cooler is suspected of being contaminated, flush the charge air cooler.

1. Turn off the engine, apply the brakes, and chock the tires.
2. Remove the charge air cooler. For instructions, see **Subject 100**.
3. Set the charge air cooler in a horizontal position with the inlet and outlet ports facing up.

⚠ CAUTION

Use only naphtha or mineral spirits to clean the charge air cooler. Do not use caustic solutions such as those that are commonly used in radiator shops. Do not use steam or high-temperature cleaning operations. Caustic solutions, steam, and high-temperature cleaning operations will damage the RTV that seals the charge air cooler tubes to the headers, which may result in leaking.

4. Pour a filtered naphtha or mineral spirits solution into the charge air cooler until it is 40 percent full.
5. Cap the inlet and outlet ports on the charge air cooler.
6. Rock the charge air cooler back and forth so that the solvent travels from one tank, through the tubes, to the other tank and back. Repeat this process ten times.

NOTE: Do not leave the solvent in the charge air cooler for more than ten minutes.

7. Remove the caps from the inlet and outlet ports
8. Drain the charge air cooler and properly dispose of the solvent.
9. Leave the caps off and allow the residual solvent to evaporate.
10. Install the charge air cooler. For instructions, see **Subject 100**.
11. Remove the chocks from the tires.

Restriction Test

After flushing the charge air cooler because of turbocharger or engine damage, test the pressure drop across the charge air cooler and air piping, as follows:

1. Remove the pipe plug from the tapped hole in the turbocharger air outlet elbow.

   Remove the pipe plug, or the nylon tube and atomizer for the ether start system (if so equipped), or the air line to the turbocharger air-pressure gauge (if so equipped), from the tapped hole in the rear left-hand side of the intake manifold.

   Install an air pressure gauge in each tapped hole.

2. Operate the engine at rated speed and horsepower; there is no need to operate the engine at its peak torque rating. While operating the engine, read both air pressure gauges.

   Because of air turbulence at the turbocharger outlet, subtract 0.3 inHg (1 kPa) from the pressure measurement taken at this point, to make it a true reading.

   From that reading, subtract the reading taken at the intake manifold. This is the pressure drop of the charge air cooler.

   If the pressure drop is more than 4 inHg (14 kPa), flush or replace the charge air cooler as needed.

General Information

The air cleaner is vertically mounted on the outside of the right frame rail, directly behind the bumper. **See Fig. 1.** Air enters through the grill and is diverted into the air cleaner housing where it passes from the outside to the inside of a replaceable, moisture-resistant, fine-mesh paper filter element **(Fig. 2).** Filtered air exits the air cleaner through an outlet port at the top of the housing.

A lock-up air restriction indicator is mounted on the underside of the air intake pipe. **See Fig. 3.** The indicator shows when the air filter element needs to be replaced. As an optional location, the air restriction indicator can be mounted in the dashboard. Nylon tubing connects the remote-mounted indicator or gauge to the air intake piping.

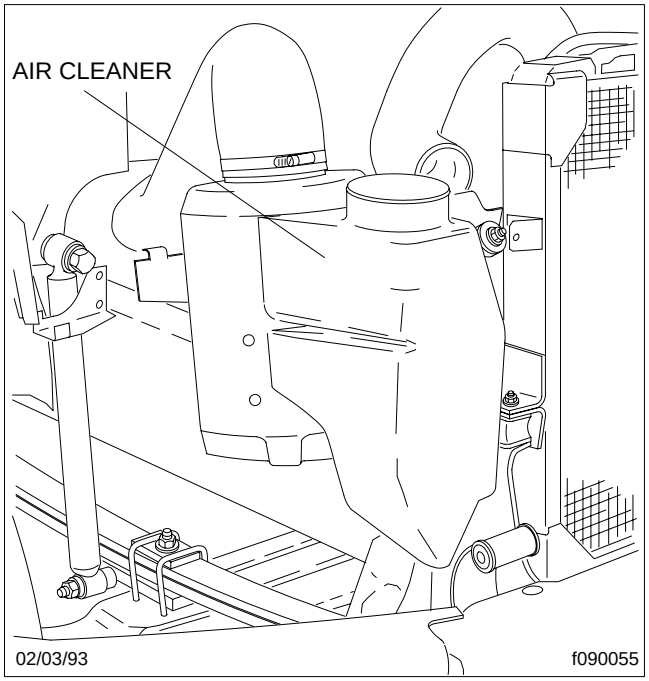

Fig. 1

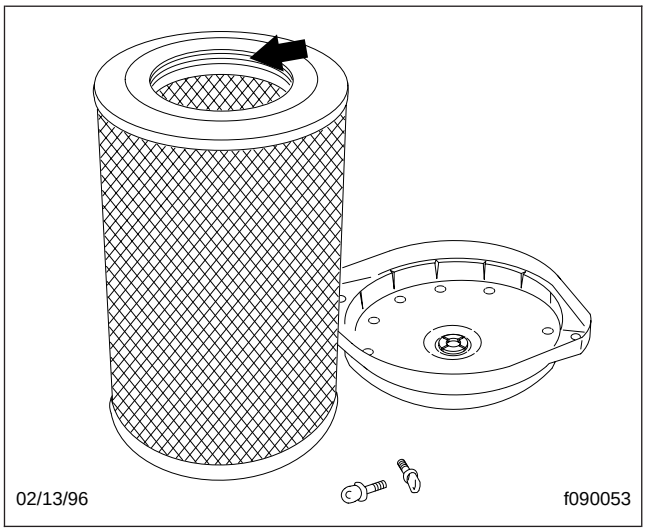

Fig. 2

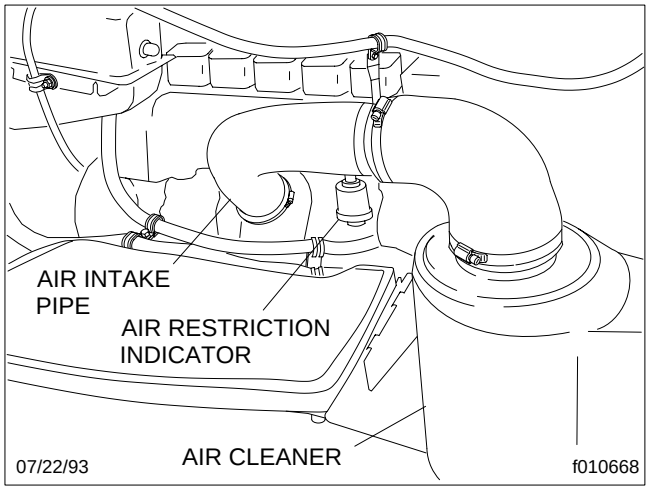

Fig. 3

Element Replacement

NOTE: Replace the air cleaner element only when it reaches the maximum restriction level allowed by the engine manufacturer; **see Subject 120**.

⚠ CAUTION

CAUTION: Do not operate the engine with the air filter element or any intake component removed — damage to the engine could occur.

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Check the seams around the air cleaner inlet and outlet ports. **See Fig. 1.** Check the outer surface of the cleaner housing for cracks, dents, or damage. If there are signs of leaks or damage, repair or replace the parts.

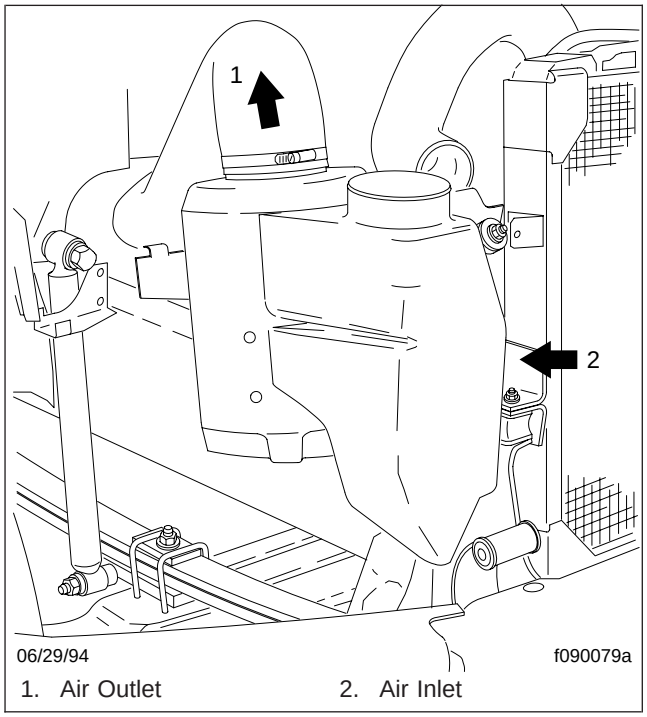

Fig. 1, Air Cleaner Housing Ports

4. Remove the two thumb screws from the bottom of the housing. **See Fig. 2.** Remove the cover.

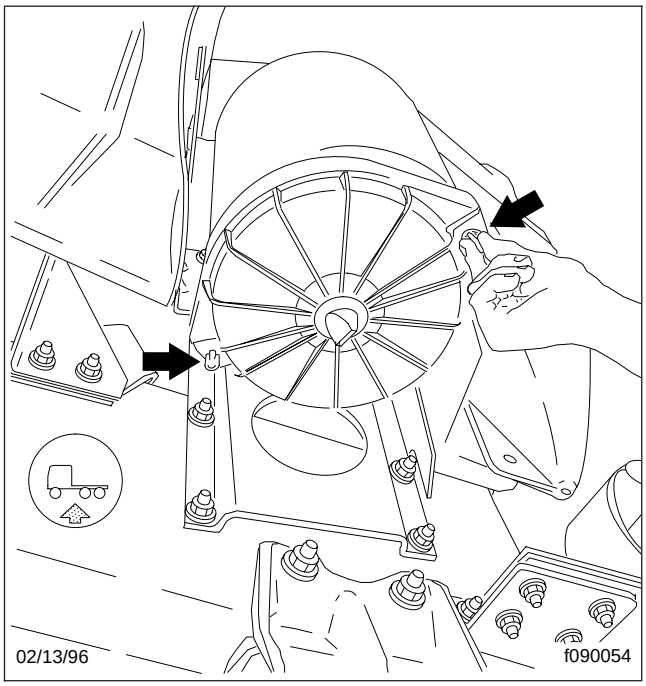

Fig. 2, Air Cleaner Housing Thumb Screws

5. Grip the base of the filter element firmly. **See Fig. 3.** Gently twist and pull the filter element down and out of the housing.
6. Inspect the element and clean the housing.
   - 6.1 Check the filter element for soot or oil. If soot is present, check for leaks in the engine exhaust system, and for exhaust from other equipment. If the element is oily, check for fumes escaping from the engine crankcase breather. Excessive oil mist shortens the life of any dry-type filter; correct the cause.
   - 6.2 Inspect the filter element radial seal surface for dust trails (from gasket leakage) **(see Fig. 4)**. Check the cleaner housing for damage or dirt build-up that may cause sealing problems. If there is leakage or damage, repair or replace the parts.
   - 6.3 Wipe the inside of the cleaner housing with a clean damp cloth.

Air Cleaner Element Replacement

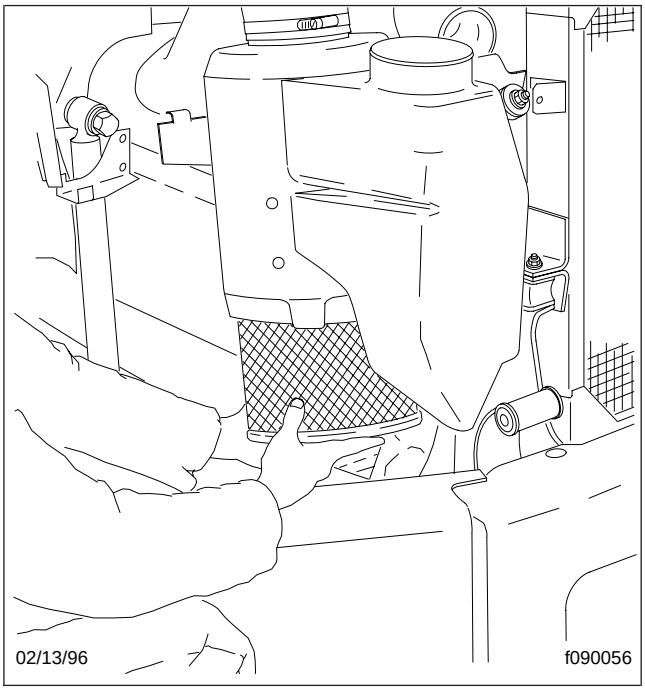

Fig. 3, Filter Element Removal/Installation

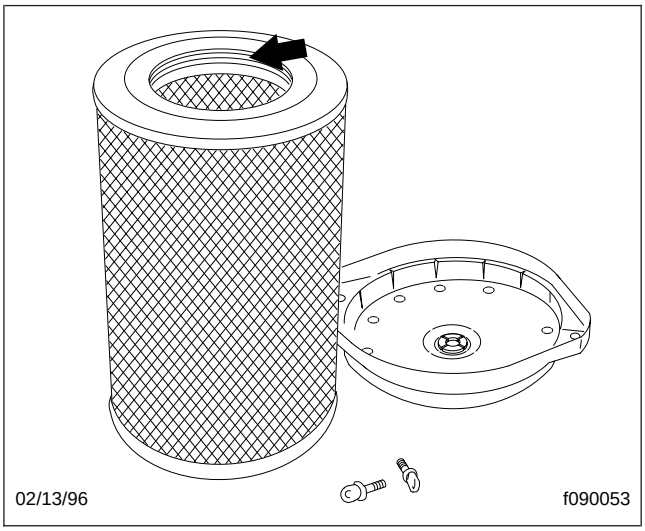

Fig. 4, Radial Seal Surface of Filter Element

⚠ CAUTION

CAUTION: Any dirt in the cleaner housing, on the clean side of the element gaskets, could be drawn into the engine, causing damage.

7. Inspect the new filter element **(see Fig. 4)** before installing it.
   - 7.1 Inspect the element for radial seal surface damage and dented metal parts. If the radial seal surface is damaged to the extent that dust might bypass it, do not use the element.
   - 7.2 Place a bright light inside the element, and rotate the element while looking through it from the outside. The light will reveal, by a bright spot, any hole or rupture. Any hole in the element will allow dust to enter the engine; do not use the element if it is damaged.
8. Position the filter element in the air cleaner housing. **See Fig. 3.** Push the element up into place until only about 2.5 cm (1 inch) still extends below the bottom of the housing.
9. Place the cover over the bottom of the element, and secure the cover with the two thumb screws.
10. Check all clamps for tightness, and all ducting and hoses for leaks; repair as necessary.
11. Lower the hood, and remove the chocks from the tires.

Replacement

CAUTION

CAUTION: All air intake components and connections must be air-and water-tight. Dirt or dust entering the engine can cause internal engine damage. Much of the dirt and dust are silicates, which fuse into abrasive glass-like particles during engine combustion. These particles can grind piston rings, pistons, and cylinder liners. Do not operate the engine with the air filter element or any air intake component removed.

IMPORTANT: Do not modify air cleaners or air intake ducting.

If the air cleaner housing has been dented or damaged, immediately check all ducting and connections to the air cleaner for leakage. Adjust or replace parts as necessary. If needed, replace the air cleaner as follows:

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.
3. Remove the air cleaner.
   - 3.1 Remove the two thumb screws securing the housing cover, and remove the cover. **See Fig. 1.**
   - 3.2 Remove the filter element from the housing; **see Subject 100**.
   - 3.3 Loosen the hose clamp connecting the air intake pipe to the elbow at the top of the air cleaner housing. **See Fig. 2.** Remove the pipe from the elbow, and cover the open end of the pipe.
   - 3.4 Remove the elbow from the top of the housing.
   - 3.5 Remove the four nuts that secure the housing to its mounting bracket. **See Fig. 3.**
   - 3.6 Take the air cleaner off its mounting bracket.
4. Install the new air cleaner.
   - 4.1 Position the air cleaner housing on its mounting bracket. Secure the housing with the four nuts, and tighten them 38 N·m (28 lbf·ft).
   - 4.2 Connect the elbow to the top of the new housing.

5. Inspect a new filter element and install it in the new air cleaner; **see Subject 100**.

Element Restriction Checking

The restriction of air flow through the air cleaner element is measured at the tap in the air transfer tube joined to the cleaner outlet.

On vehicles with an intake-duct-mounted restriction indicator (manual- or automatic-reset), the indicator is mounted in a safety fitting in the air intake piping. **See Fig. 1.**

2. Safety Fitting
3. Air Restriction Indicator
4. Reset Button

Fig. 1, Standard Intake-Duct-Mounted Manual-Reset Air Restriction Indicator

On vehicles with a dash-mounted restriction indicator (manual-reset) (**Fig. 2**) or air restriction gauge (automatic-reset) (**Fig. 3**), a hose connects the indicator or gauge to the safety fitting in the air intake piping.

On vehicles *without* an indicator or gauge, a water manometer or a service gauge must be connected to the air intake ducting to check element restriction.

- For a vehicle with a manual-reset air restriction indicator, check the indicator with the engine off to see if air restriction equals or exceeds the value shown in **Table 1** for maximum air restriction at *full load* and governed rpm. If air restriction is at or above the maximum, push the reset button on the dash-mounted or intake-duct-mounted indicator, then operate the engine at *no-load* and governed rpm, and compare the indicator reading with the value shown in **Table 1** for maximum air restriction at *no-load* and governed rpm.

Air Cleaner Element Restriction Checking

when the engine is shut down, operate the engine at *no-load* and governed rpm, and compare the gauge/indicator reading with the value shown in **Table 1** for maximum air restriction at *no-load* and governed rpm.

- For a vehicle without a gauge or indicator, test restriction with a water manometer or a service gauge. Refer to the test equipment manufacturer's literature for test procedures. Operate the engine at *no-load* and governed rpm, and compare the reading with the value shown in **Table 1** for maximum air restriction at *no-load* and governed rpm.

If air restriction equals or exceeds the value shown in **Table 1** for maximum air restriction at *no-load* and governed rpm, replace the air cleaner element; **see Subject 100**.

General Description

The Bendix AirMaster air compressor is an engine-driven, single-piston compressor which supplies compressed air to the vehicle air system.

The compressor draws air from the air intake pipe, compresses the air, and delivers it to the air system supply reservoir. The compressor runs continuously but has "loaded" and "unloaded" modes, which are regulated by the air governor and the compressor loading assembly. When the air system reaches 825 kPa (120 psi), the governor sends an air signal to the unloader assembly. The unloader assembly then holds the compressor air intake valve open so that no more compressed air is forced into the air system. As air in the system is used, its pressure drops, and at 620 kPa (90 psi), the air governor stops the signal to the compressor. Without the signal, the unloader assembly automatically closes the compressor air intake valve to force more air into the system.

On vehicles with air dryers, when the system reaches the cut-out pressure of 825 kPa (120 psi), the air governor also sends an air signal to open the sludge ejector in the air dryer.

Removal and Installation, Mercedes-Benz OM 366LA Engine

Removal (Refer to Fig. 1)

1. Apply the parking brakes, chock the tires, and drain the air system.
2. Tilt the hood.
3. Disconnect the air and oil lines from the air compressor.
   - 3.1 Disconnect the air inlet hose (Ref. 5) from the rear of the compressor head.
   - 3.2 Disconnect the air outlet pipe (Ref. 6) from the fitting at the top of the compressor.
   - 3.3 Disconnect the air signal lines (Refs. 11 and 14) from the air governor.
   - 3.4 Disconnect the oil supply line (Ref. 16) from the air compressor.
4. Remove the drive belts from the air compressor.
   - 4.1 Remove the clamp bolt (Ref. 25).
   - 4.2 Loosen the bolt (Ref. 27) in the threaded block (Ref. 31).
   - 4.3 Turn the nut at the top of the clamp (Ref. 24) to raise the adjusting assembly (Ref. 26) off the drive belts.
   - 4.4 Loop the drive belts off the adjusting assembly pulleys. Then, loop the belts off the air compressor pulleys.
5. Remove the air compressor from the engine.
   - 5.1 Remove the four air compressor mounting bolts (Ref. 17).
   - 5.2 Lift the compressor (Ref. 1) from its mounting bracket (Ref. 32).

Installation (Refer to Fig. 1)

1. Install the air compressor on the engine.
   - 1.1 Position the air compressor (Ref. 1) on its mounting bracket (Ref. 32). If necessary, hold the O-ring (Ref. 22) in place over the oil return port with white grease or petroleum jelly.
   - 1.2 Install the four air compressor mounting bolts (Ref. 17), and tighten the bolts 16 N·m (12 lbf·ft).
2. Install the drive belts on the air compressor.
   - 2.1 Loop the drive belts around the air compressor pulleys and the adjusting assembly (Ref. 26) pulleys.
   - 2.2 Turn the nut at the top of the clamp (Ref. 24) to lower the adjusting assembly (Ref. 26) onto the belts. Lower the assembly until the belts are tightened to 23 kg (50 lbs).
   - 2.3 Tighten the clamp bolt 85 N·m (63 lbf·ft).
   - 2.4 Tighten the bolt (Ref. 27) into the threaded block (Ref. 31) 100 N·m (74 lbf·ft).
3. Connect the air and oil lines to the air compressor.
   - 3.1 Connect the air signal lines (Refs. 11 and 14) to the air governor.
   - 3.2 Connect the air outlet pipe (Ref. 6) to the air compressor.
   - 3.3 Connect the air inlet hose (Ref. 5) to the air compressor.
   - 3.4 Connect the oil supply line (Ref. 16) to the air compressor.
4. Start the engine and check for leaks. Repair any leaks.
5. Lower the hood, and remove the chocks from the tires.

Removal and Installation, Mercedes-Benz OM 366LA Engine

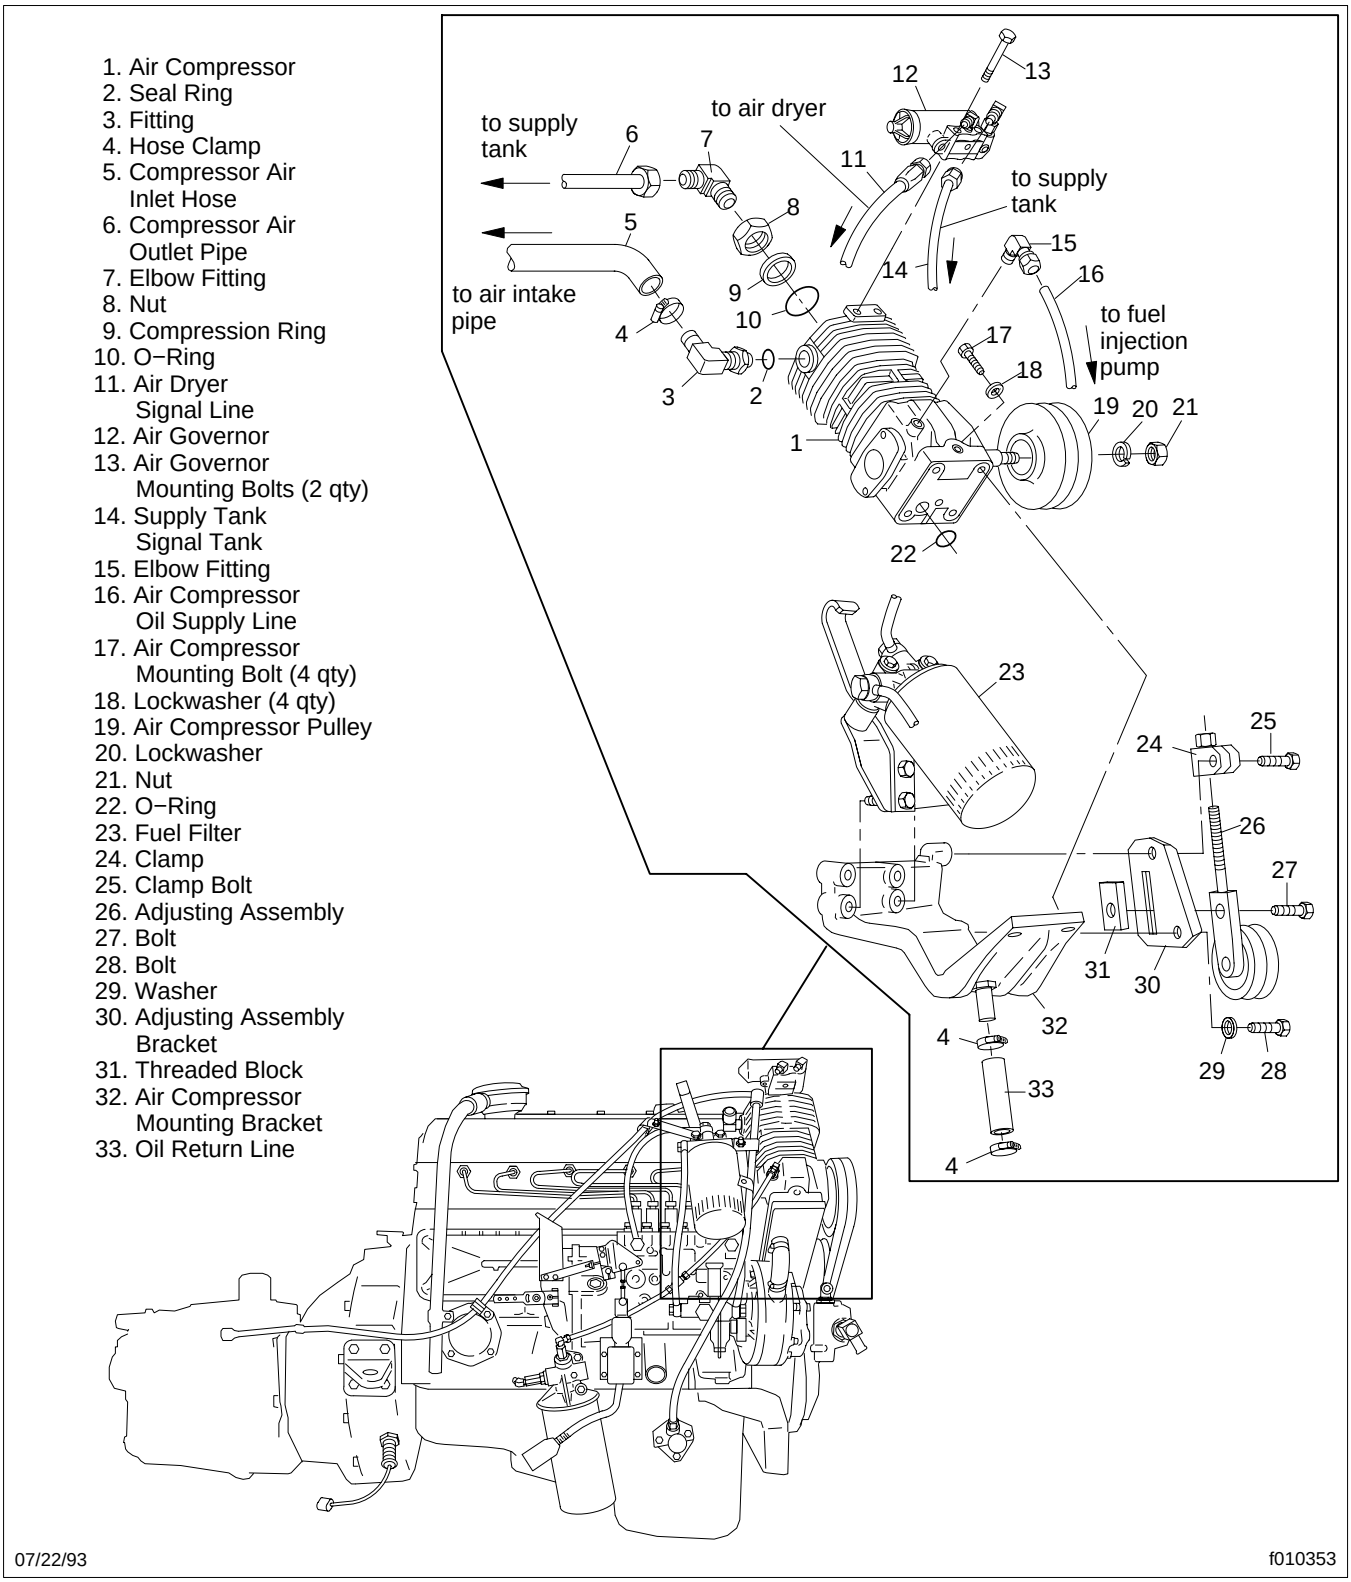

Fig. 1

Cylinder Head Disassembly, Inspection and Cleaning, and Assembly

Disassembly (Refer to Fig.1)

1. Remove the compressor from the vehicle, and place it on a suitable work surface. For instructions, **refer to "Removal and Installation from Mercedes-Benz OM 366LA Engine, 100."**
2. Remove the air governor.
3. Remove the cylinder head cover (Ref. 2).
4. Remove and discard the gasket (Ref. 9). Note the position of the gasket ear. **See Fig.2.**
5. Remove the cylinder head (Ref. 10) from the valve plate (Ref. 17).
6. Note the position of the gasket ear. **See Fig.2.** Then, remove and discard the gasket (Ref. 16).
7. Note the position of the gasket ears. **See Fig.2.** Then, remove and discard the gaskets (Ref. 18).
8. If present, remove the unloader cap (Ref. 3) from the cylinder head cover.
9. Remove the unloader piston (Ref. 4), and remove the four O-rings (Refs. 5 through 8) from the piston. Discard the O-rings.
10. Depress the spring guide (Ref. 12), and remove the C-clip (Ref. 11) from the unloader valve (Ref. 15). Discard the C-clip.
11. Remove and discard the spring guide (Ref. 12), unloader spring (Ref. 13), and unloader valve (Ref. 15) from the cylinder head.

Inspection and Cleaning

WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using a solvent, thoroughly clean all metal parts removed from the compressor.
2. Check that all air passages are clear, including the small drilling in the unloader piston. **See Fig.1**, Ref. 4.
3. Check that all mating surfaces are clean of old gasket material. Remove any old material.
4. With the piston at the top of its stroke, clean any carbon from the piston crown and the crankcase head face.

Assembly **(Refer to Fig.1)**

1. Using silicon fluid grease, lubricate the unloader piston (Ref. 4) and the O-rings (Refs. 5, 7, and 8). Fit the O-rings around the piston.
2. Lubricate the unloader cap O-ring (Ref. 6), and fit it around the cap. Lubricate the unloader bore in the cylinder head cover, and assemble the unloader piston and the unloader cap into the cover. Tighten the cap 27 N·m (20 lbf·ft).
3. Place a new unloader valve (Ref. 15) into the cylinder head (Ref. 10), and carefully thread the valve guide (Ref. 14)— with the small, tapered end down— over the unloader valve stem.
4. Place a new unloader spring (Ref. 13) and spring guide (Ref. 12) onto the valve guide. Depress the spring guide and place a new C-clip (Ref. 11) on the unloader valve stem. Release the spring and ensure the clip is securely in place.
5. Assemble the valve plate, cylinder head, cylinder head cover, and gaskets (Refs. 9 and 16), **as shown in Fig.1.**
6. Install the cylinder head assembly on the crankcase with the two gaskets (Ref. 18). For the correct placement of the gaskets, **refer to Fig.2.**
7. Install the four cylinder head bolts. Tighten the bolts diagonally, 27 N·m (20 lbf·ft).
8. Install the compressor on the engine. For instructions, **refer to "Removal and Installation from Mercedes-Benz OM 366LA Engine, 100."**
9. Install the air governor.
10. Start the engine, and check the compressor for air and oil leaks.

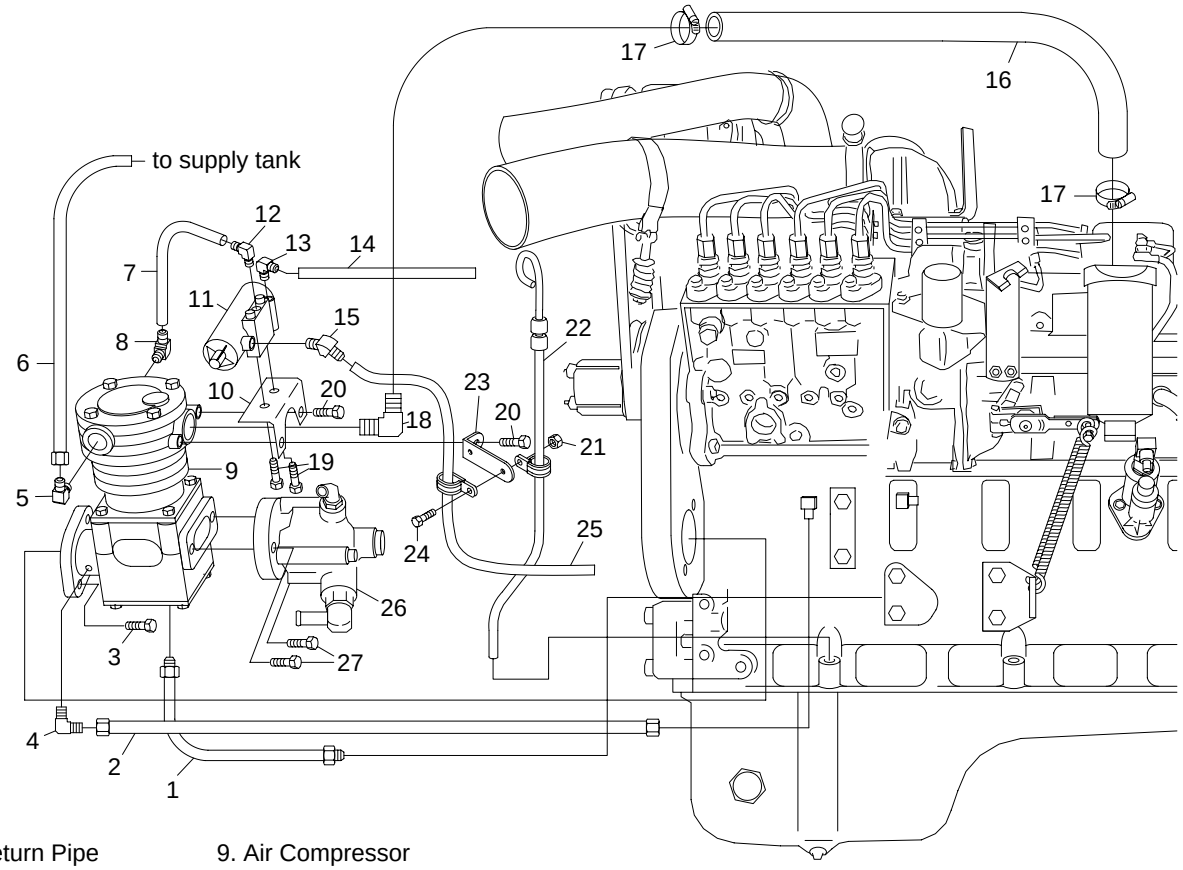
General Description

Cummins B Series engines use the Holset SS191B air-cooled air compressor, an engine-driven, single-piston compressor which supplies compressed air to the vehicle air system. The compressor draws turbo-charged, aftercooled air from the engine manifold. It compresses the air further, and delivers it to the air system supply reservoir.



The compressor runs continuously but has "loaded" and "unloaded" modes, which are regulated by the air governor and the compressor loading assembly. When the air system reaches 825 kPa (120 psi), the governor sends an air signal to the unloader assembly. The unloader assembly then holds the compressor air intake valve open so that no more compressed air is forced into the air system. As air in the system is used, its pressure drops, and at 620 kPa (90 psi), the air governor stops the signal to the compressor. Without the signal, the unloader assembly automatically closes the compressor air intake valve to force more air into the system.

On vehicles with air dryers, when the system reaches the cut-out pressure of 825 kPa (120 psi), the air governor also sends an air signal to open the sludge ejector in the air dryer.

For detailed repair procedures and other engine service not covered in this section, refer to the *Cummins SS191B Air Compressor Shop Manual* or *Cummins Single Cylinder Air Compressor Shop Manual.*

Removal (Refer to Fig. 1)

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Drain the air reservoirs.
3. Tilt the hood.
4. Carefully disconnect the air lines.
   - 4.1 Disconnect the air inlet line (Ref. 16) at the rear of the compressor head.
   - 4.2 Disconnect the air outlet line (Ref. 6) from the side of the compressor head.

Removal and Installation

4.3 Disconnect the air signal line (Ref. 7) between the compressor and the air governor.

4.4 Disconnect the air signal lines (Refs. 14 and 25) between the air governor and the chassis air system.

5. Remove the power steering pump.

5.1 Remove the butterfly clamps holding the power steering lines together.

5.2 Remove the power steering pump mounting bolts (Ref. 27).

5.3 Remove the pump from the compressor.

6. Remove the dipstick (Ref. 22) and air signal line (Ref. 25) clamps from the stand-off bracket (Ref. 23) at the rear of the air governor.

7. Remove the left air governor bracket bolt (Ref. 20) to free the stand-off bracket. Remove the bracket.

8. Disconnect the oil lines.

8.1 Disconnect the compressor oil return pipe (Ref. 1) from the engine.

8.2 Disconnect the compressor oil supply line (Ref. 2) from the air compressor.

8.3 Remove the two compressor mounting bolts (Ref. 3), then lift the compressor from the engine.

Installation (Refer to Fig. 1)

1. Install the air compressor.

1.1 Position the compressor on the engine, and secure it with the air compressor mounting bolts (Ref. 3). Tighten the bolts 73 N·m (54 lbf·ft).

1.2 If removed, install the air governor on the compressor. Install the stand-off (Ref. 23) with the left bracket bolt, and tighten both bolts 20 N·m (15 lbf·ft).

2. Connect the air compressor oil lines.

2.1 Connect the oil supply line (Ref. 2) to the compressor.

2.2 Connect the oil return pipe (Ref. 1) to the engine.

3. Install the power steering pump.

3.1 Position the pump on the air compressor, and secure it with the power steering pump mounting bolts (Ref. 27). Tighten the bolts 38 N·m (28 lbf·ft).

3.2 Clamp the power steering pump inlet and outlet lines together.

4. Connect the air compressor and air governor air lines.

4.1 Connect the air signal lines (Refs. 14 and 25) between the air governor and the chassis air system.

4.2 Connect the air signal line (Ref. 7) between the compressor and the air governor.

4.3 Connect the air outlet line (Ref. 6) to the side of the compressor head.

4.4 Connect the air inlet line (Ref. 16) at the rear of the compressor head.

5. Clamp the air signal line (Ref. 25) and the dipstick (Ref. 22) to the stand-off bracket (Ref. 23).

6. Start the engine, and check for leaks in the compressor mounting. Repair any leaks as necessary.

7. Lower the hood, and remove the chocks from the tires.

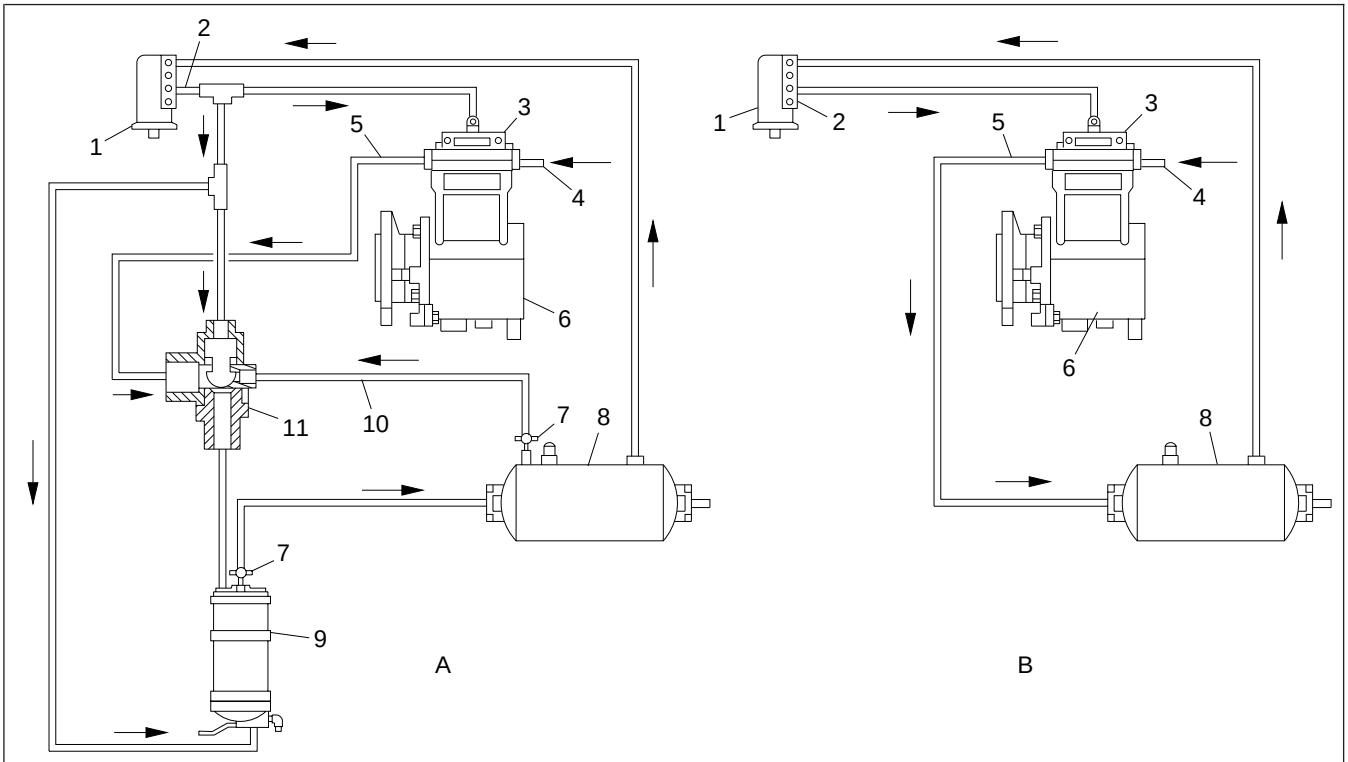
General Description

Cummins C Series engines use the Holset SS296 water-cooled air compressor, an engine-driven, piston-type compressor which supplies



compressed air to the vehicle air system. See **Fig. 1**. The compressor draws turbocharged, aftercooled air from the engine intake manifold. It compresses the air further and delivers it to the air system supply reservoir.

The compressor runs continuously but has loaded and unloaded modes, which are regulated by the air governor and the compressor loading assembly. The compressor also uses an Economy (E-type) unloader system to reduce pumping and engine boost pressure losses through the compressor intake valve while operating in the unloaded mode. If equipped with an air dryer, an Econ valve must be installed to prevent excessive oil consumption. When the air system reaches 120 psi (825 kPa), the governor sends an air signal to the unloader assembly. The unloader assembly then seals off incoming air at the intake valve so that no more compressed air enters the air system. As air in the system is used, its pressure drops and at 90 psi (620 kPa), the air governor stops the signal to the compressor. Without the signal, the compressor again pumps more compressed air into the system.

When the system reaches the cut-out pressure of 120 psi (825 kPa) on vehicles with air dryers, the air governor also sends an air signal to open the sludge ejector in the air dryer.

For detailed repair procedures and other engine service not covered in this section, refer to the *Cummins SS296 Air Compressor Shop Manual* or the *Cummins Troubleshooting and Repair Manual C Series Engines*.

Removal

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.

⚠ WARNING

WARNING: Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

3. Drain the coolant and the air reservoirs.
4. Carefully disconnect the air lines, coolant lines, and the oil supply line.
   - 4.1 Disconnect the air inlet line **(Fig. 1)** at the rear of the compressor head and at the engine.
   - 4.2 Disconnect the air outlet line **(Fig. 1)** from the front of the compressor head.
   - 4.3 Disconnect the coolant lines **(Fig. 2)** at the rear of the compressor head and at the cylinder head and engine block.
   - 4.4 Disconnect the two air signal lines between the air governor and the chassis air system.
   - 4.5 Disconnect the compressor oil supply line **(Fig. 3)** from the air compressor.

1.2 Install the mounting nuts and tighten them 77 N·m (57 lbf·ft).

1.3 Install the compressor support bracket and tighten the capscrews 47 N·m (35 lbf·ft).

2. Install the power steering pump.

   Position the pump on the air compressor, and secure it with the power steering pump mounting bolts. Tighten the bolts 47 N·m (35 lbf·ft).

3. Connect the air lines, coolant lines, and the oil supply line.

   3.1 Connect the air inlet line **(Fig. 1)** to the rear of the compressor head and to the engine.

   3.2 Connect the air outlet line **(Fig. 1)** to the front of the compressor head.

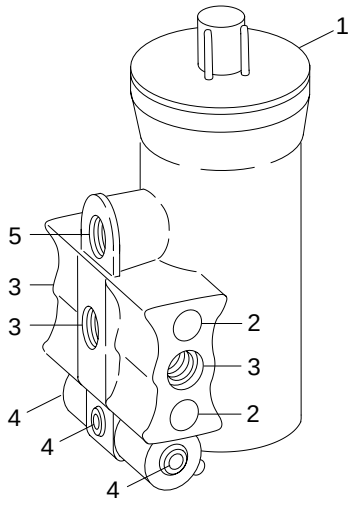
   3.3 Connect the coolant lines **(Fig. 2)** to the rear of the compressor head and to the cylinder head and engine block.

   3.4 Connect the two air signal lines between the air governor and the chassis air system.

   3.5 Connect the compressor oil supply line **(Fig. 3)** to the air compressor.

4. Fill the cooling system with approved coolant. Refer to the vehicle maintenance manual.

5. Start the engine, and check for leaks in the air lines, coolant lines, and the oil supply line. Repair any leaks as necessary.



6. Lower the hood, and remove the chocks from the tires.

General Description

The governor **(see Fig. 1),** together with the compressor unloading mechanism, automatically controls air pressure in the air brake system. It keeps the pressure between 655 and 862 kPa (95 to 125 psi), which is a preset range for all Freightliner vehicles.

The compressor runs continuously while the engine runs, but actual air compression is controlled by the D–2 governor, working with the compressor unloading mechanism.

The D–2 governor is mounted on the compressor. There are three reservoir ports, three unloader ports, and one exhaust port (all 1/8-inch NPT) on the governor.

Fig. 1

Principles of Operation

Pressurized air enters the D–2 governor at one of its reservoir ports, and acts on the area of the piston and beneath the inlet and exhaust valve. **See Fig. 2.** As air pressure builds up, the piston moves against the resistance of the pressure-setting spring. The piston and inlet and exhaust valve move up when the reservoir air pressure reaches the cut-out setting of the governor. The exhaust stem seats on the inlet and exhaust valve, and then the inlet passage opens. Reservoir air then flows by the open inlet valve, through the passage in the piston, and out the unloader port to the compressor unloading mechanism. Air also flows around the piston, and acts upon the additional area of the piston. This added force, which results from a larger area on the piston, ensures a positive action and fully opens the inlet valve.

Fig. 2

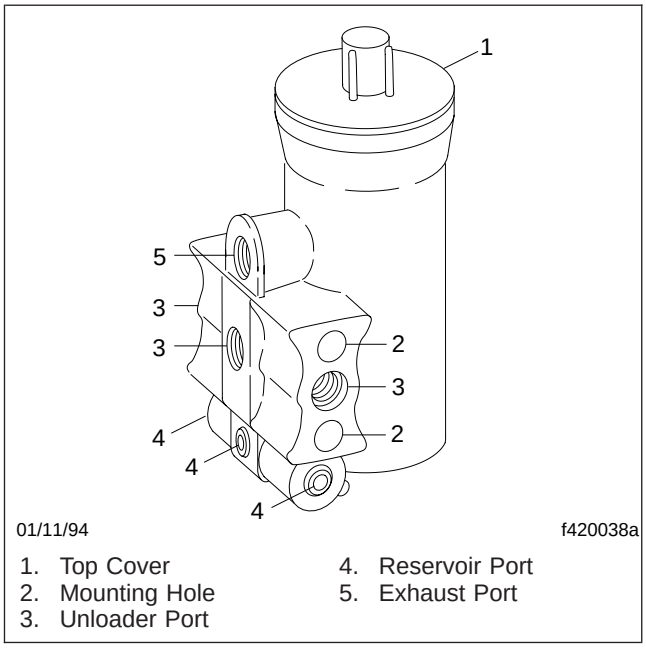
As the system reservoir air pressure drops to the cut-in setting of the governor, the force exerted on the piston is reduced so that the pressure-setting spring moves the piston down. The inlet valve closes and the exhaust opens. With the exhaust open, the air in the unloader line escapes back through the piston, through the exhaust stem and out the exhaust port.

Tests

The following test should be done whenever the vehicle air pressure is incorrect and the causes are unknown.

If the air governor doesn't work correctly or if leakage is excessive, replace it with a new or rebuilt unit, or repair it using genuine Bendix parts and the instructions in this section.

1. Apply the parking brakes and chock the tires. Tilt the hood.
2. Start the engine and build up air pressure in the air brake system.



IMPORTANT: Make sure the test gauge is registering accurately before using it to check or adjust the air governor.

3. Using a test gauge attached to the supply reservoir, check the pressure at the time the air governor cuts out. The cut-out pressure should be 120 to 130 psi (827 to 896 kPa).
4. With the engine still running, apply the brakes a few times to reduce the air pressure and observe at what pressure the air governor cuts in the compressor. The minimum cut-in pressure should be 100 psi (689 kPa).
5. If either the cut-out or cut-in pressure is incorrect, proceed to **Subject 130**.
6. Test the leakage on the air governor in both the cut-in and cut-out positions.

   6.1 With the compressor in the cut-in position, apply a soap solution to the air governor exhaust port. See **Fig. 1**. A slight bubble leakage is permitted. More leakage indicates that the inlet valve or lower piston O-ring is worn out.

   6.2 With the compressor in the cut-out position, apply a soap solution to the air governor exhaust port. See **Fig. 1**. A slight bubble leakage is permitted. More leakage indicates that the exhaust valve seat, stem, O-ring, or upper piston O-ring is worn out.

7. Lower the hood and remove the chocks from the tires.

Removal (See Fig. 1)

1. Chock the tires, then drain the air brake system. Tilt the hood.

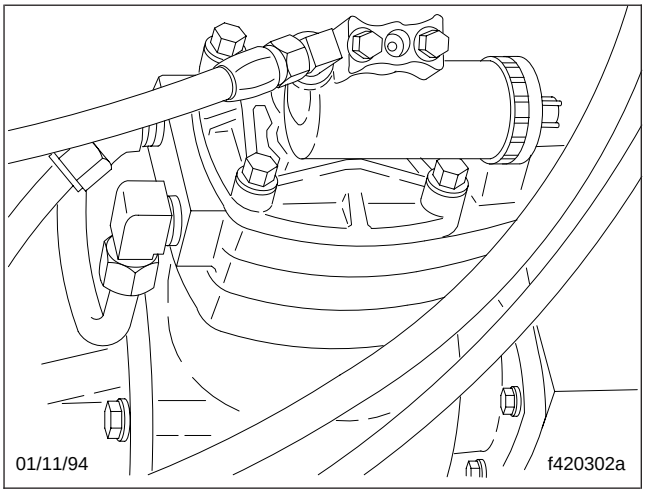

Fig. 1

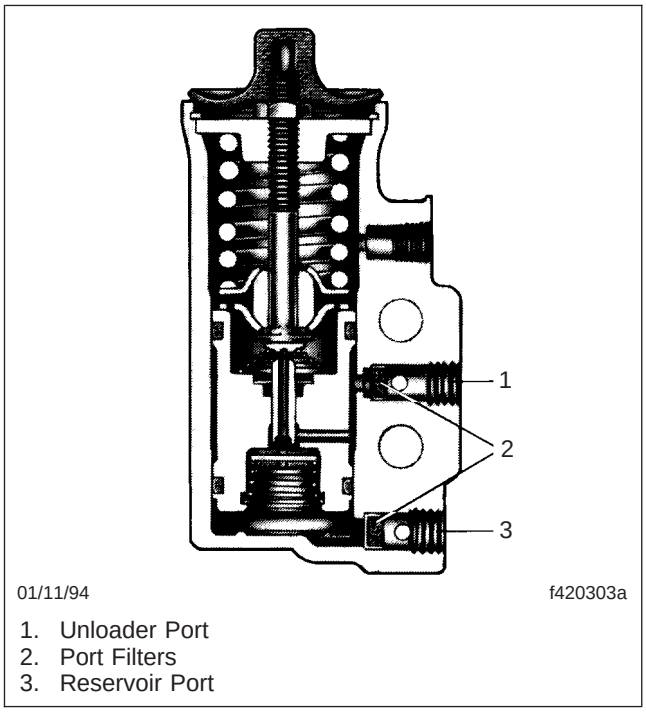
2. Disconnect the reservoir and unloader port air lines. Mark the lines for later reference. Cap the air lines tightly to keep out dirt and moisture.
3. Remove the governor mounting bolts, then remove the governor.



Installation

1. Clean the mounting pad on both the compressor and the governor block, and be sure the compressor unloading port is clear and clean.
2. Using a new governor mounting gasket, install the governor and its mounting bolts. Tighten the bolts 15 to 20 N·m (11 to 15 lbf·ft).
3. Clean the connecting lines after removing the caps, and apply Loctite® 242, or equivalent sealant in small quantities, to the reservoir and unloader fittings.

⚠ CAUTION

CAUTION: Make sure sealant doesn't get inside the fittings. Loose material inside the plumbing may clog the governor or other components, causing damage.

4. Connect the reservoir and unloader port air lines as referenced earlier. Tighten the fittings 15 to 18 N·m (11 to 13 lbf·ft).
5. Do the operating and leakage tests under **Subject 100**.
6. After the tests have been completed and the governor is operating correctly, screw the top cover on tightly until it seals the body, preventing the entry of any foreign matter.
7. If necessary, install new filters **(see Fig. 2)** in the reservoir and unloader ports. These cup-shaped filters can be installed with the head of a pencil.
8. Lower the hood. Then remove the chocks from the tires.

2. Clean the governor exterior of road dirt and grease.
3. Unscrew the top cover (Ref. 1).
4. Using a pair of retaining ring pliers, remove the spring assembly retaining ring (Ref. 16).
5. Remove the adjusting screw (Ref. 2) and spring assembly.
6. Remove the locknut (Ref. 3), then the hex-shaped upper spring seat (Ref. 15) from the adjusting screw.
7. Remove the pressure-setting spring (Ref. 14), lower spring seat (Ref. 12), spring guide (Ref. 13), and the other lower spring seat (Ref. 12) from the adjusting screw.
8. Remove the exhaust stem and its spring from the top of the piston. With the body in the inverted position, tap lightly and remove the piston.
9. Remove the inlet and exhaust valve spring (Ref. 9) and the valve (Ref. 10) from the piston.
10. Remove the two piston O-rings (Ref. 11), and with a hooked wire, remove the exhaust stem O-ring.
11. Clean or remove the unloader and reservoir port filters (Ref. 7).

Cleaning and Inspecting

WARNING

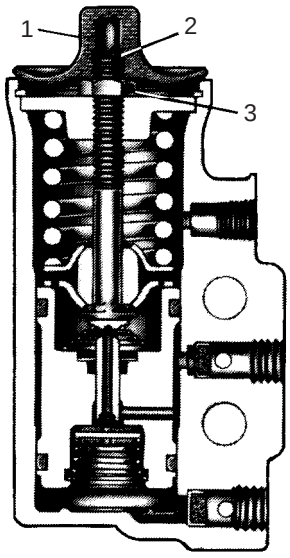
Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Clean all metal parts in mineral spirits.
2. Wipe all rubber parts dry, using a clean cloth.
3. Inspect the governor body for cracks or other damage. Be particularly careful that all air passages in the body, filters, exhaust stem, and piston are not obstructed.
4. Check the springs for cracks, distortion, or corrosion.
5. Replace all worn or damaged parts.

Assembly (See Fig. 1)

Before assembly, lubricate the lower body bore, the top of the piston, the piston grooves, piston O-rings, and the spring guide and adjusting screw with Dow Corning 55-M pneumatic grease, or equivalent.

Disassembly, Cleaning and Inspection, and Assembly



1. Install the exhaust stem O-ring (Ref. 11) in its groove in the stem bore of the piston.
2. Install the upper and lower piston O-rings (Ref. 11).
3. Drop the inlet and exhaust valve (Ref. 10) into place at the bottom of the piston.
4. Install the inlet and exhaust valve spring (Ref. 9) with the small end against the valve. Press the spring down until the larger coiled end snaps into the groove inside the piston.
5. Place the exhaust stem spring (Ref. 5) over the exhaust stem. Carefully press the stem into the stem bore of the piston.
6. Install the piston in the body.
7. Install one lower spring seat (Ref. 12), spring guide (Ref. 13), the other lower spring seat (Ref. 12), pressure-setting spring (Ref. 14), and the hex-shaped upper spring seat (Ref. 15) on the adjusting screw, in that order. Screw the upper spring seat (Ref. 15) down until the distance from the top of the seat to the bottom of the stem head is about 48 mm (1-7/8 inches).
8. Install the locknut (Ref. 3).
9. Before placing the adjusting screw and stem assembly in the governor body, check that the exhaust stem (Ref. 6) and its spring are in place in the piston.
10. Install the adjusting screw (Ref. 2) and spring assembly, and the retaining ring (Ref. 16).
11. Install the governor on the vehicle, following the instructions under **Subject 110**.

Adjustment

NOTE: An air governor with a dryer reservoir module (DRM) is not adjustable.

If the pressure settings of the governor are inaccurate or if they need to be changed, do the following:

1. Apply the parking brakes and chock the tires. Tilt the hood.
2. Remove the top cover from the governor and loosen the adjusting screw locknut. See **Fig. 1.**

3. To raise the pressure settings, turn the adjusting screw counterclockwise. To lower the pressure setting, turn the adjusting screw clockwise.

NOTE: The pressure range between cut in and cut out is not adjustable.

If these adjustments do not correct the pressure settings, repair or replace the governor using the instructions in this section.

4. Tighten the adjusting screw locknut and install the top cover.
5. Lower the hood, then remove the chocks from the tires.

General Information

The Cummins 15.2 cfm compressor is used on the ISB engine. The 18.7 cfm compressor is used on the ISC engine. Both compressors are single cylinder engine-driven, piston-type compressors which supply compressed air to operate air powered actuators on vehicles. These compressors are geared directly to the engine which serves to operate the compressor and any accessory that is connected on the rear flange. These compressors will deliver air out of the exhaust port when the unloader port is at atmospheric pressure and will stop air delivery when the unloader port is pressurized to the system pressure between 100 to 125 psi (689 to 862 kPa). A governor determines the "cut-in" (start of pumping) and "cut-out" (termination of pumping) of the compressor by supplying the proper control signal to the unloader port. The governor is sensing the pressure in the air supply tank or "wet tank." If the output air pressure is inadvertently blocked or required to exceed 250 psi (1724 kPa), the compressor will stop air delivery. The air will be recycled within the compressor and no mechanical harm will be done.

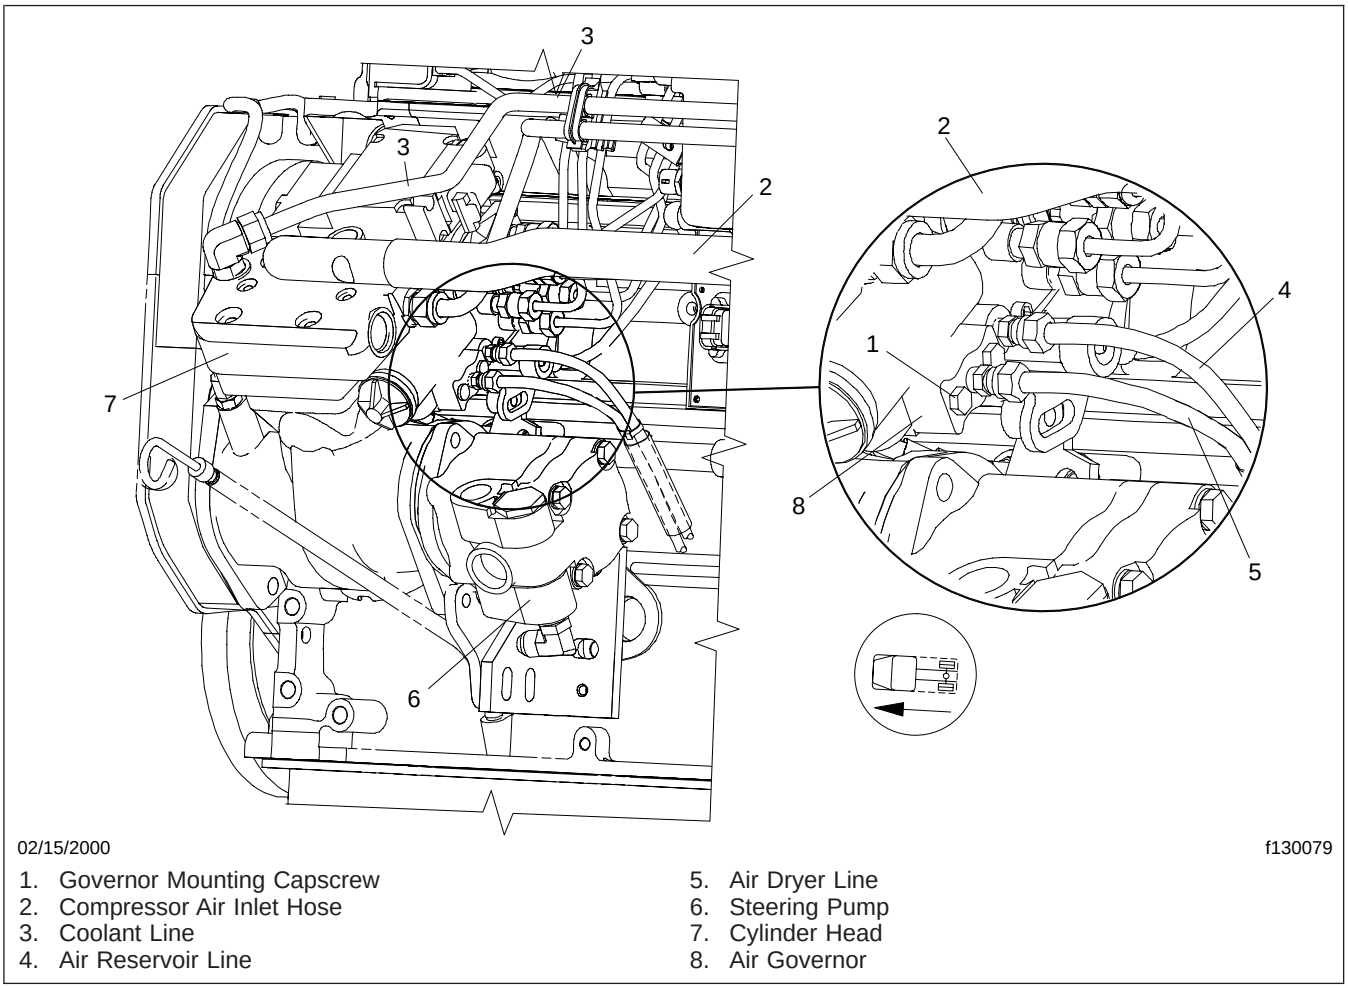
Air Compressor Removal and Installation

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Tilt the hood.
3. Drain the air reservoirs.
4. Drain the radiator coolant below the level of the air compressor. See **Group 20** in this manual for instructions.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.



5. Using a cleaning solvent, remove road dirt and grease from the outside of the air compressor, then dry the air compressor with compressed air.
6. Marking their locations and positions, disconnect all air, coolant, and oil lines attached to the air compressor and governor. Remove cushion clamps and tie straps as needed to move the lines out of the way. See **Fig. 1** and **Fig. 2**.
7. Remove the power steering pump.
   - 7.1 Remove the power steering pump mounting capscrews.
   - 7.2 Remove the power steering pump from the air compressor.
8. Remove the air compressor.
   - 8.1 Remove the air compressor support bracket. See **Fig. 3** and **Fig. 4**.
   - 8.2 Support the air compressor, and remove the nuts and washers from the front gear cover studs.
   - 8.3 Lift or lower the air compressor out of the engine compartment.
   - 8.4 Remove and discard the air compressor mounting gasket, and clean the mating surfaces.

Installation

IMPORTANT: Be sure the gasket surfaces are cleaned and not damaged.

1. Install the air compressor.
   - 1.1 Install a new gasket on the front gear cover.
   - 1.2 Position the air compressor on the front gear cover studs while aligning the compressor drive gear.
   - 1.3 Install the washers and nuts to the mounting studs and tighten 57 lbf·ft (77 N·m).
   - 1.4 Install the compressor support bracket and tighten the capscrews 35 lbf·ft (47 N·m).
2. Position the steering pump on the air compressor, and secure it with the mounting capscrews. Tighten the capscrews 35 lbf·ft (47 N·m).
3. Identify and connect all air, coolant, and oil lines to the compressor and governor. Secure the lines as needed with cushion clamps and tie straps.
4. Fill the engine cooling system. See **Group 20** for instructions.
5. Operate the engine and check for leaks.
6. Remove the chocks from the rear tires and close the hood.

Cylinder Head Replacement, 15.4 Compressor

Replacement

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Drain the air from all air reservoirs.
3. Remove the compressor from the vehicle. See **Subject 100** for instructions.
4. Mount the compressor on a suitable holding fixture.

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

5. Using a cleaning solvent, remove road dirt and grease from the outside of the compressor, then dry the compressor with compressed air.
6. Remove the cylinder head assembly, from the crankcase.

   6.1 Scribe an alignment mark across the cylinder head and upper crankcase, for assembly alignment.

   IMPORTANT: Do not use a marking method, such as chalk, that can be wiped off during assembling.

   NOTE: There is no need to remove the smaller screws.

   6.2 Note the positions of any attached components, then remove the four M8 cylinder head capscrews. Discard the capscrews. See **Fig. 1**.

   6.3 Tap the cylinder head with a soft mallet to break the gasket seal. Remove the cylinder head assembly and discard the gasket. See **Fig. 2**. Note the position of the ports with respect to the crankcase for reassembly.

   6.4 Remove the coolant and air fittings for reuse.

7. Clean the upper crankcase.

   7.1 Rotate the crankshaft until the piston is at the top of the cylinder bore.

7.2 Remove any accumulated carbon and varnish by carefully scraping, and light application of solvents. Avoid getting debris and solvents into the clearance between the piston and bore. Avoid the use of abrasive products similar to Scotch Brite because of damage and abrasive grit left behind.

Cylinder Head Replacement, 15.4 Compressor

WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

7.3 Using compressed air, blow dirt particles or gasket material from all cylinder cavities.

8. Inspect the top crankcase surface. It should be smooth and free of scratches to enable resealing on assembly.
9. Transfer the original cylinder head alignment marks to the replacement cylinder head.
10. Install the coolant and air fittings on the replacement cylinder head assembly.
11. Install the cylinder head assembly on the compressor upper crankcase.

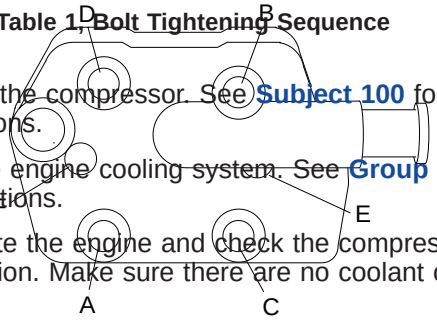
    11.1 Position the sliding valve and the guide pins in the correct direction to enter the larger diameters in the valve body and crankcase.

    11.2 Align the marks on the cylinder head and crankcase.

    11.3 Using a new cylinder head gasket, position the gasket and head assembly on the crankcase.

    Note: You should find two cover bolts loosely holding the head assembly together.

    11.4 Install new capscrews.



CAUTION

A torque angle gauge and inch pound torque wrench must be used to perform the torque-turn capscrew tightening sequence. The tightening sequence listed in Table 1 must be followed to prevent damage to the cylinder head assembly.

12. Tighten the capscrews using the bolt tightening sequence in **Table 1**.

Problem—Excessive Oil Passage

Problem—Excessive Oil Passage	
Possible Cause	**Remedy**
Restricted air intake.	Check engine air filter and replace if necessary. Check compressor air inlet for kinks and excessive bends. Repair as needed.
Restricted oil return hole in front of compressor.	Remove compressor and check the oil return hole for restrictions. Repair as needed.
Defective or worn seal in the rear bearing cap.	Replace seal.
Compressor runs loaded an excessive amount of time.	Check air lines and connections for leakage. Check for a defective governor or restricted line. Replace the governor if necessary. Repair or replace lines and connections until leakage is eliminated.
Back pressure from the engine crankcase.	Check for excessive engine crankcase pressure. Repair or replace ventilation components as necessary. NOTE: An indication of crankcase pressure is a loose or partially lifted dipstick.
Excessive engine oil pressure.	Check the engine oil pressure with a test gauge, and compare the reading to the engine specification. Do not restrict the compressor oil supply line.
Malfunctioning compressor.	Replace the compressor after making certain none of the preceding conditions exist.

Problem—Noisy Compressor Operation

Problem—Noisy Compressor Operation	
Possible Cause	**Remedy**
Loose drive coupling or gear (as indicated).	Inspect the fit of the drive coupling and gear on the compressor crankshaft. Tighten or replace the components. If the crankshaft keyway is damaged, replace the compressor.
Compressor cylinder head or discharge line restrictions.	Inspect the compressor discharge port and discharge line for carbon build-up. If carbon is detected, remove the carbon and check for proper coolant flow to the compressor. Inspect the discharge line for kinks and restrictions. Replace the discharge line as necessary.
Compressor internal engine components damaged or worn.	Replace the compressor.

Problem—Excessive Build-Up and Recovery Time

Problem—Excessive Build-Up and Recovery Time	
Possible Cause	**Remedy**
Restricted air intake.	Check engine air filter and replace if necessary. Check compressor air inlet for kinks and excessive bends. Repair as needed.

Troubleshooting

Problem—Excessive Build-Up and Recovery Time	
Possible Cause	**Remedy**
Restricted discharge or compressor discharge cavity.	Inspect the compressor discharge port and line for restrictions and carbon build-up. If carbon is detected, remove the carbon. Check for proper cooling to the compressor. Inspect the discharge line for kinks and restrictions. Replace the discharge line as necessary.
Slipping drive components.	Check for faulty drive gears and coupling, and replace as necessary.
Excessive air system leakage (not including the air compressor).	Check all valves, air lines, and connections for leakage. Repair or replace valves and lines until leakage is eliminated.
Unloader piston seized.	Check the operation of the unloading mechanism. Check for corrosion and contamination of unloader pistons. Check for correct operation of the compressor air governor. If the governor is operating properly, replace the compressor.
Damaged compressor rings, valves, and gaskets.	Replace the compressor.

Problem—Compressor Fails to Unload

Problem—Compressor Fails to Unload	
Possible Cause	**Remedy**
Malfunctioning governor.	Check the setting with an accurate test gauge. Repair or replace the air governor.
Unloader air lines from governor damaged.	Inspect the air lines to and from the governor for kinks or restrictions. Repair or replace the air lines.
Faulty or worn unloader piston or bore.	Replace the compressor.

Problem—Air in Water System/Water in Air System	
Possible Cause	**Remedy**
Internal gasket leakage.	Replace the compressor.
Internal casting porosity.	Replace the compressor.

General Information

The CS-130 alternator features a high ampere output per pound of weight, and a totally new and different regulator. A diode trio is not used. A delta stator, a rectifier bridge, and a rotor with slip rings and brushes are electrically similar to earlier models of alternators (**Fig. 1** and **Fig. 2**).

The CS stands for Charging System, and 130 denotes the outside diameter in millimeters of the stator laminations. The CS-130 features sealed bearings with lifetime lubrication in both end frames. A conventional fan mounted next to the pulley pulls air through the assembly for cooling. An internal fan mounted on the rotor pulls air through the slip ring end frame to cool the rectifier bridge and regulator. The air is expelled through openings in the end frame. No periodic maintenance on the alternator is required.

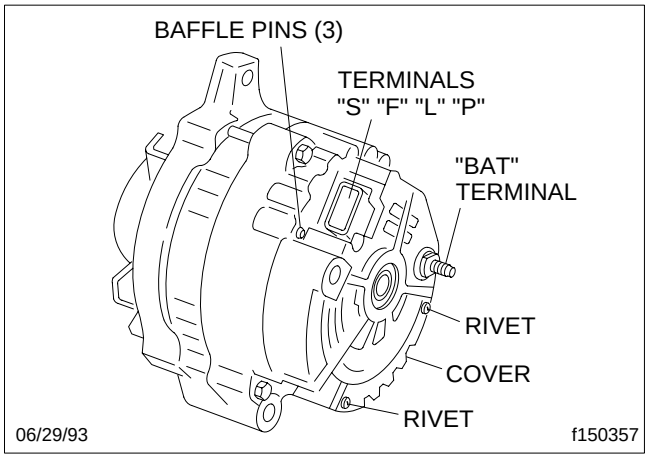

Fig. 1

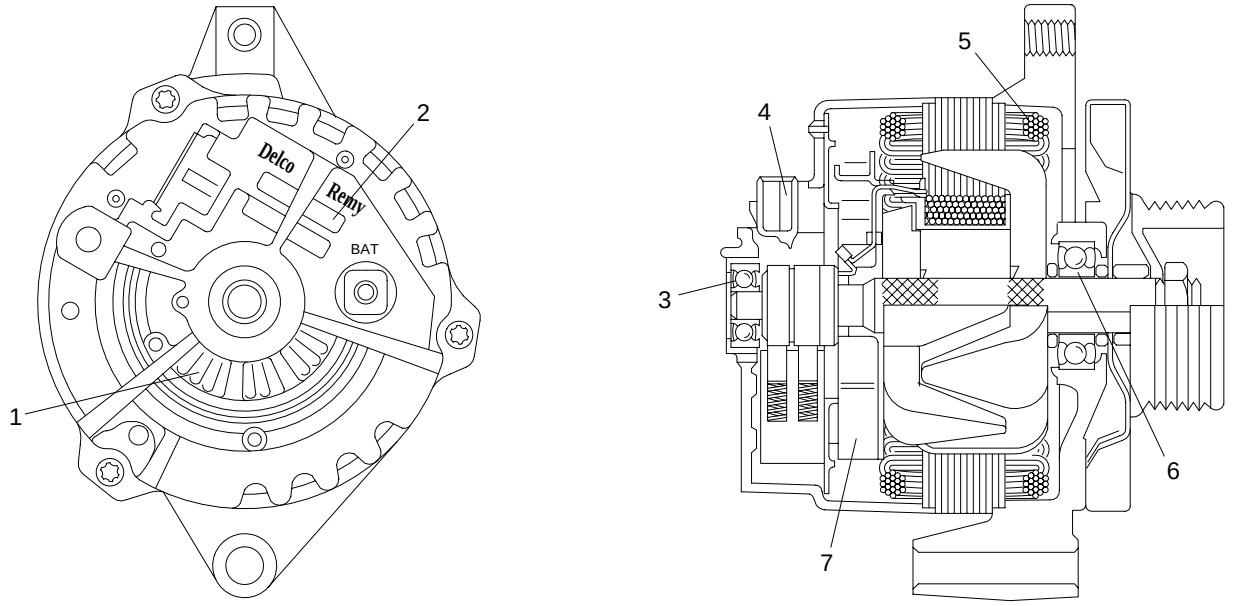
Principles of Operation



The CS-130 used on Freightliner trucks is wired with three wires connected to the alternator. The charge indicator works in much the same way as on other charging systems— the indicator light comes on when the switch is closed, and then goes out when the engine is running. If the charge indicator is on with the engine running, a charging system problem is indicated. Regardless of the problem, the indicator will glow at full brilliance. A new feature of this regulator is that it will cause the charge indicator to be on with the engine running if the system voltage is too high or too low. The regulator is temperature-compensated; that is, its voltage setting varies with temperature.

As in other alternators, the regulator limits the system voltage by controlling the rotor field current. Unlike other regulators, this regulator switches the field current on and off at a fixed frequency of about 400 cycles per second. By varying the on-off time, the correct average field current for proper system voltage control is obtained. At high speeds, the on-time may be 10%, and the off-time 90%. At low speeds with high electrical loads the on-off time may be 90% and 10% respectively.

The use of the "P" and "S" terminals is optional. The "P" terminal is connected to the stator, and may be connected externally to a tachometer or other device. The "S" terminal may be connected externally to a voltage, such as battery voltage, to sense the voltage to be controlled. For the complete circuit, see the wiring diagrams.

Where the regulator is identified with an "I" marking on the regulator case, the circuit in **Fig. 3** applies. In this circuit, both the "L" and "I" terminals serve to turn on the regulator and allow field current to flow when the switch is closed. The "I" terminal may be connected directly to the switch, or through a resistor. Both are illustrated. The "I" circuit may be used with or without the "L" circuit; that is, with or without anything connected to the "L" circuit.

Alternator Removal and Installation, Cummins B Series Engines

Removal

1. Disconnect the batteries, negative lead.
2. Disconnect and mark the battery lead wire on the alternator.
3. Disconnect the alternator wiring harness.
4. Gripping the wrench handle firmly, lift the tensioner arm and pulley; then remove the belt from the alternator pulley. **See Fig. 1.**

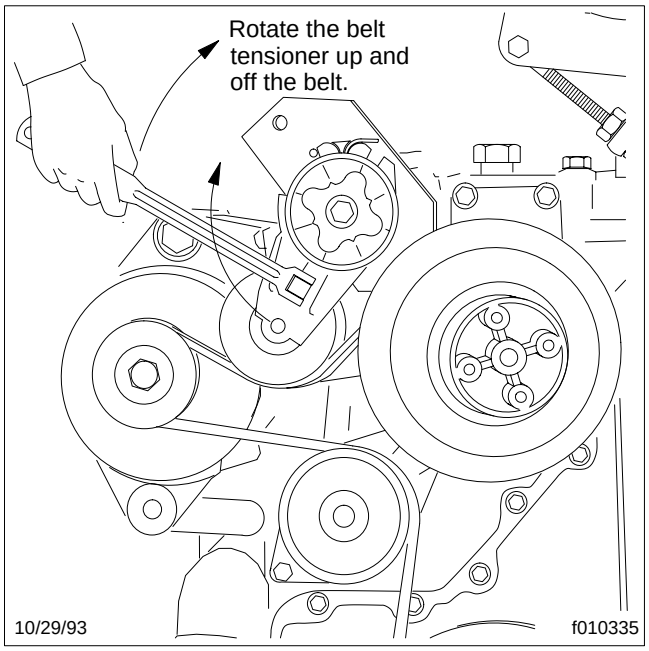

Fig. 1

5. Remove the alternator mounting bolts. Remove the alternator.

Installation

1. Check the tightness of the alternator-bracket fasteners **(Fig. 2**, Ref. 1). Tighten them 24 N·m (18 lbf·ft).
2. Position the alternator on the mounting bracket, then install the mounting bolts finger-tight.
3. Connect the alternator link **(Fig. 2**, Ref. 4) to the alternator, finger-tight.

NOTE: Make sure the alternator link is properly positioned for correct belt alignment.

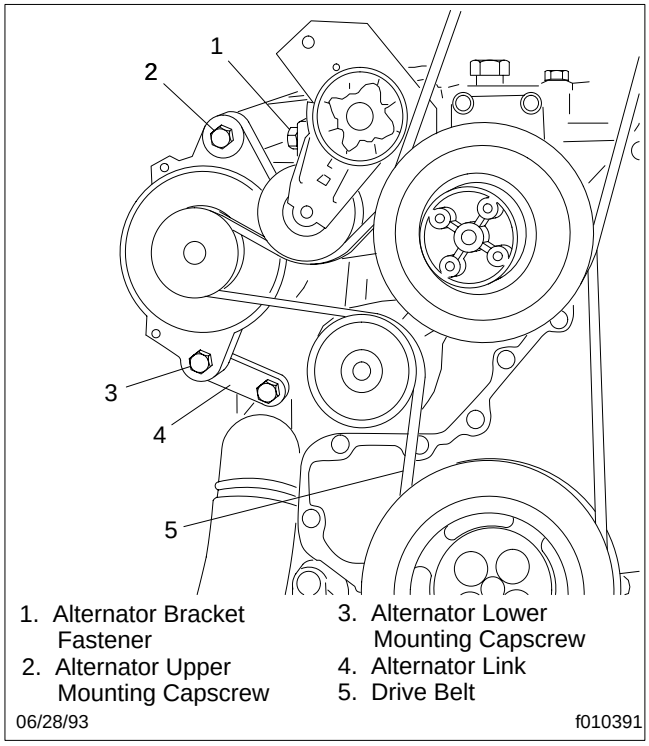

Fig. 2, Alternator and Drive Belt Installation

4. Tighten the alternator mounting capscrews as follows:
   - 8 mm: 16 N·m (12 lbf·ft)
   - 3/8-inch: 38 N·m (28 lbf·ft)
5. Lift the tensioner arm; then install the drive belt on the pulleys **(see Fig. 2).**
6. Connect the alternator wiring harness.
7. Connect the battery lead wire to the back of the alternator as previously marked. Tighten the output terminal nut maximum 8 N·m (6 lbf·ft) when attaching the cable.
8. Connect the batteries.

Disassembly (Refer to Fig. 1)

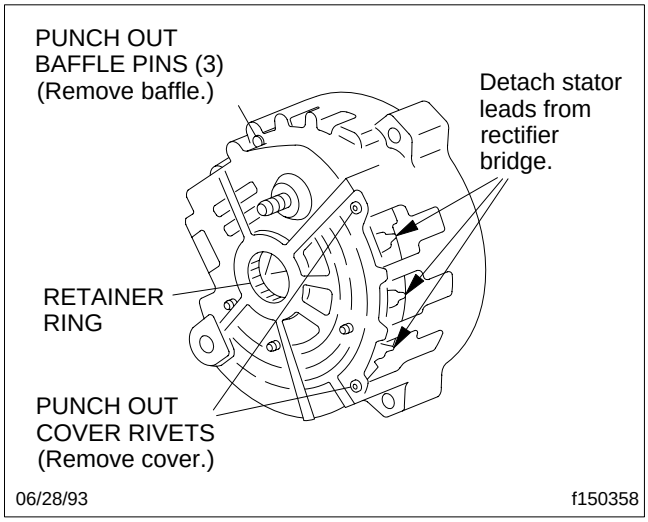

Fig. 1, Slip Ring End Frame Partially Disassembled, Bearing Removed

NOTE: If spare parts are not available, malfunctioning alternators must be replaced.

1. Remove the alternator from the vehicle. For instructions, **refer to "Removal and Installation, 100."**
2. Remove the long frame assembly bolts, and separate the drive-end frame assembly from the slip-ring end frame assembly.
3. Remove the drive-end frame from the rotor: place the rotor in a vise tightened only enough to permit removal of the shaft nut, or hold the rotor with a hex wrench in the end of the shaft when removing the nut.
4. Disassemble the slip ring end frame **(Fig. 1)** as follows:

   4.1 Punch out the cover rivets or pins and discard the cover.

   4.2 Separate the stator from the end frame assembly by cutting off the stator leads at the rectifier bridge terminals just long enough to leave adequate wire for connecting these parts if they are to be reused.

   4.3 Remove the stator.

   4.4 Punch out the baffle pins and remove the baffle.

   NOTE: To ensure correct assembly, carefully note the arrangement of parts; crimped, soldered, or welded connections; and location of mechanical fasteners. **See Fig. 2.**

   4.5 Remove the fasteners; then lift the brush holder, regulator, and rectifier bridge from the end frame.

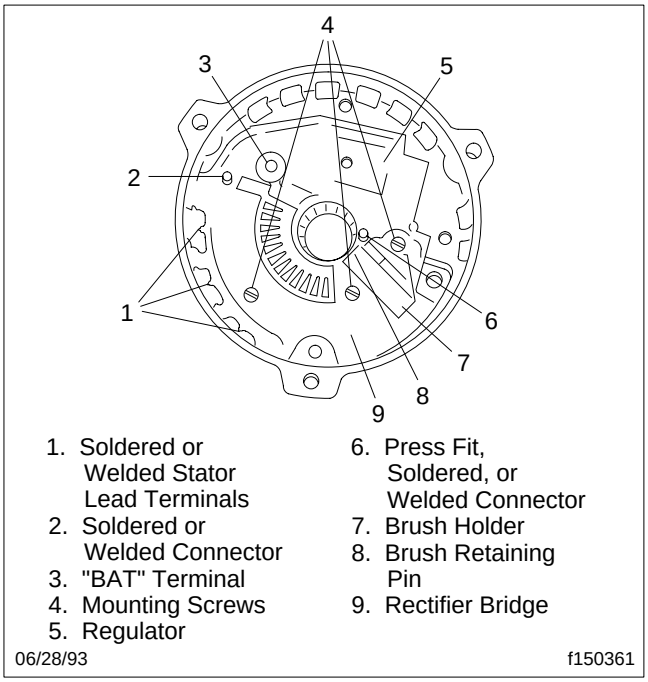

Fig. 2, View Inside the Slip Ring End Frame

   4.6 Unsolder and uncrimp the connector to disconnect the regulator from the rectifier bridge and from the brush holder.

Checking

ROTOR FIELD WINDING CHECKS

1. Connect an ohmmeter between one slip ring and the rotor. If the reading is less than one ohm, the rotor is grounded. **See Fig. 3.**
2. Check for opens by connecting the ohmmeter between the two slip rings. If the ohmmeter reading is high (infinite), the winding is open.

Disassembly, Checking, and Assembly

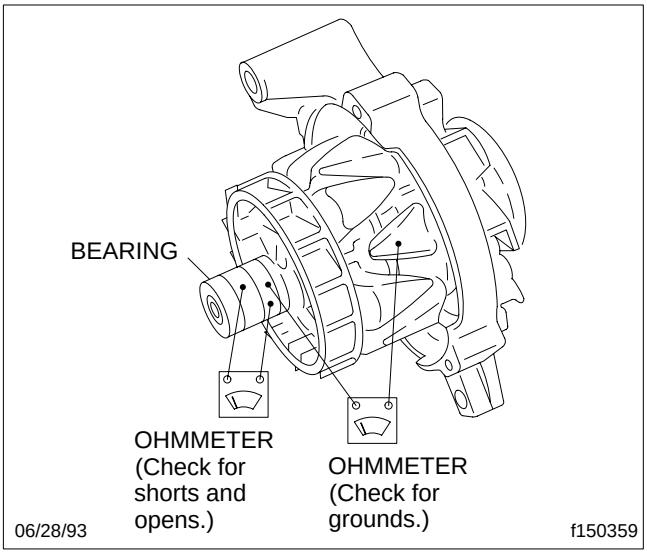

Fig. 3, Checking the Rotor

3. Check the winding for short circuits or excessive resistance by connecting a battery and ammeter in series between the two slip rings. Note the ammeter reading and refer to Delco Remy Service Bulletin 1G-188 for specifications. An ammeter reading above the specified value indicates shorted windings.

   An alternate method is to check the resistance of the field by connecting an ohmmeter between the two slip rings. If the resistance reading is below the specified value, the winding is shorted; if it is above the specified value, the winding has excessive resistance.

NOTE: The winding resistance or ammeter readings will vary slightly with winding temperature changes. If the rotor checks out okay, but the alternator fails to supply rated output, the problem is in the rectifier bridge, stator, or regulator.

STATOR CHECKS

Connect an ohmmeter between each of the stator leads and bare metal on the stator laminations. If any reading is less than 1000 ohms, the stator is grounded. **See Fig. 4.**

NOTE: An ohmmeter cannot be used to test the delta stator for shorts or opens. However, noticeable discoloration any place on the assembly usually indicates damaged stator windings.

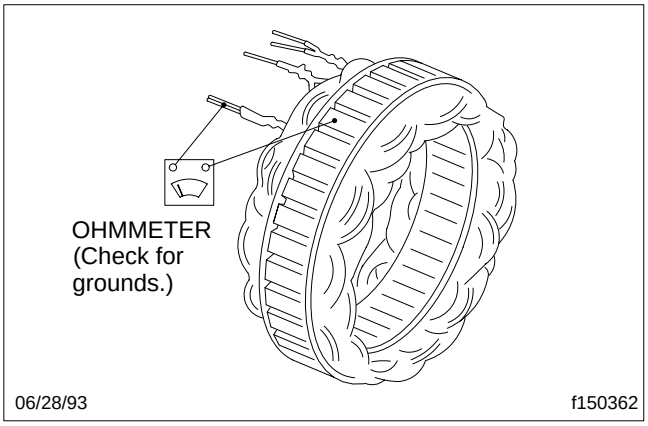

Fig. 4, Checking the Stator

RECTIFIER BRIDGE CHECK

(See Fig. 5)

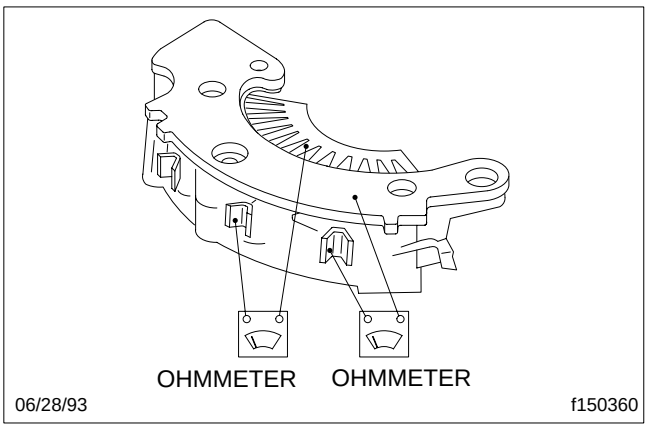

Fig. 5, Checking the Rectifier Bridge

1. To check the rectifier bridge, connect an ohmmeter (using a low scale) from the bridge terminal to the heat sink; then reverse the connections. If both readings are the same, replace the rectifier bridge.
2. Connect the ohmmeter between each of the other two terminals to the heat sink in the same manner, in order to check the other two diodes.
3. Connect the ohmmeter between each of the other three terminals and the base plate, in order to check the remaining three diodes in the rectifier bridge.

NOTE: Some digital ohmmeters cannot be used to check the diodes in the rectifier bridge. Consult the ohmmeter manufacturer's instructions to determine the ohmmeter's capabilities.

REGULATOR

The regulator cannot be checked with an ohmmeter. Use only an approved tester to test regulators of this type.

BRUSH HOLDER

If the brushes are to be re-used, clean them with a soft, dry cloth. Replace the brush holder assembly if the brushes are excessively worn.

SLIP RING SERVICING

1. If the slip rings are rough or out-of-round, turn them on a lathe to 0.05 mm (0.002 inch) maximum indicator reading. Remove only enough material to make the rings smooth and round.
2. After the slip rings are trued, or if they are only dirty, they may be cleaned and finished with 400 grain or finer polishing cloth. Spin the rotor, and hold the polishing cloth against the slip rings until they are clean. Blow away all the dust.

IMPORTANT: Turn the rotor in order to clean the slip rings evenly. Cleaning the slip rings by hand without spinning the rotor may result in flat spots on the slip rings, causing brush noise.

Assembly

1. Discard the bearing retainer ring. **See Fig. 1.**
2. Install a new ring.
3. Install a new bearing outer race; push on it until the bearing bottoms in the end frame.

NOTE: This procedure is not yet completed: See the step for installing the inner and outer races after the alternator is completely assembled.

4. Position the regulator, rectifier bridge, and brush holder on the work bench flat surface; then solder or crimp the connectors as in the original assembly. Hold the brushes in the holder with a pin.
5. To improve heat dissipation, place silicone grease 1974984 on the end frame casting under the rectifier bridge.
6. Position the assembly in the slip ring end frame; then assemble the fasteners.
7. Assemble the baffle, using a punch to drive the pins down flush with the baffle.
8. Seat the stator securely against the end frame; then solder the three stator leads to the rectifier bridge terminals.
9. Install the cover; then use a punch to drive the pins flush with the cover.
10. Push on both the inner and outer races of the slip ring end bearing to assemble the end frames together.
11. Install the long frame assembly bolts. Remove the brush holder pin.
12. With the alternator assembled, push on both the inner and outer races so the slip ring end bearing outer race is recessed 1.9 to 2.2 mm (0.07 to 0.09 inch) into the casting. **See Fig. 6.**

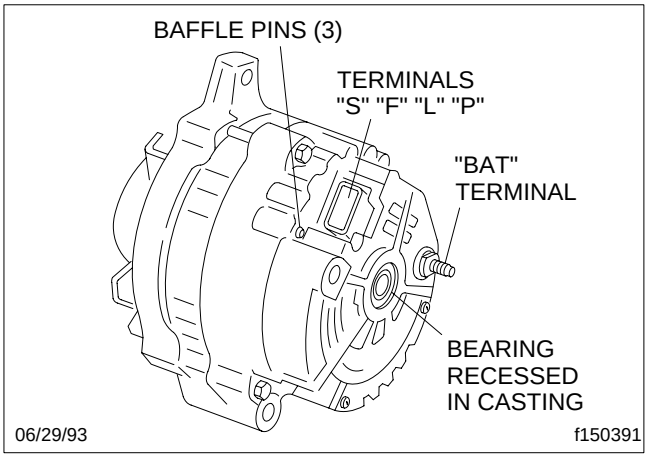

Fig. 6, Slip Ring End Bearing Assembled in the End Frame

Troubleshooting

Many alternators have been replaced that later investigation reveals were working properly. This may be due to incorrectly diagnosing the problem.

IMPORTANT: Before testing, make sure:

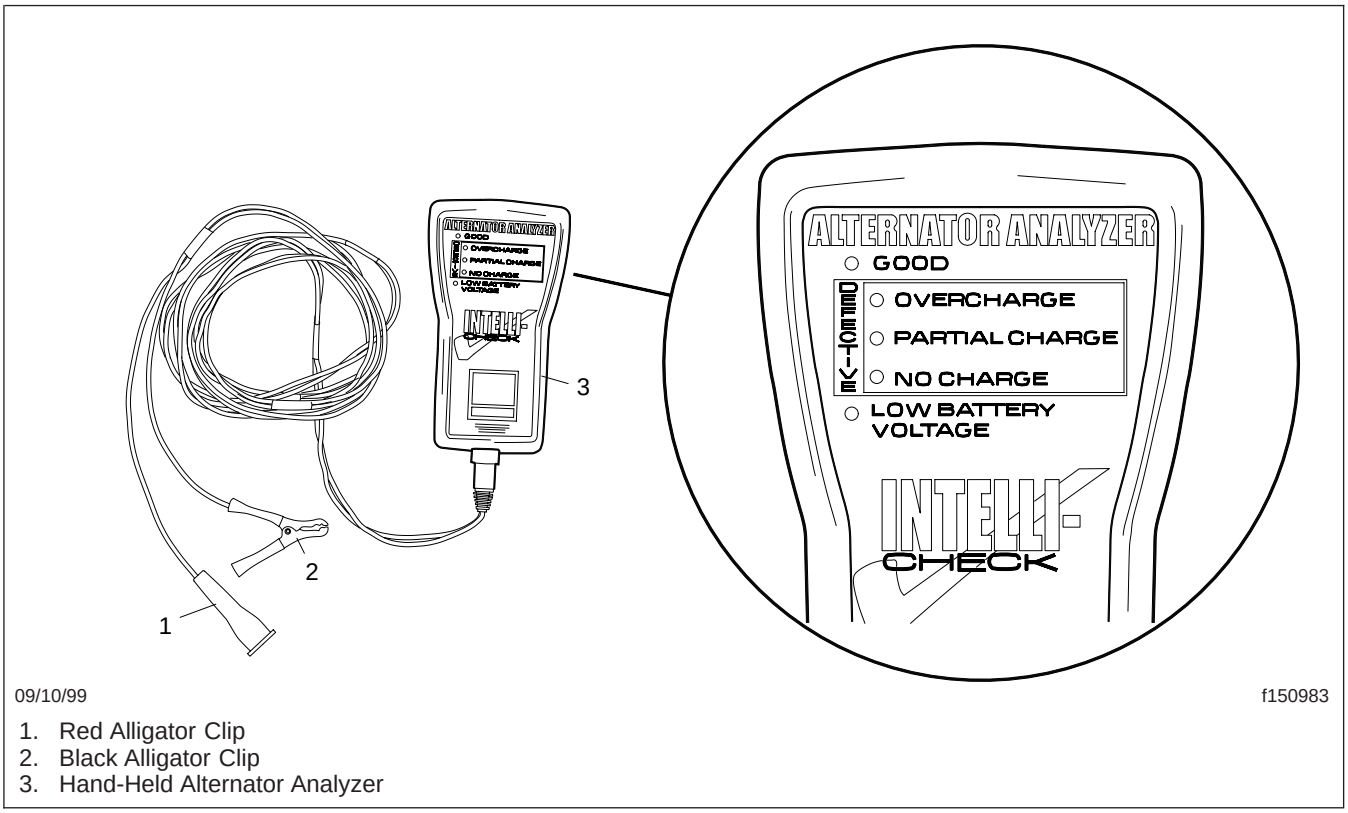
- All belts are correctly tightened;
- The wiring and terminals are clean and in good condition;
- All terminal nuts are torqued and properly protected.

Delco Remy has an alternator testing tool called the Intelli-Check Alternator Analyzer. See **Fig. 1**. This tool (DR 10457848, a single tester, or DR 10457865, a four-pack of testers) is to be used as a quick check of the alternator to see if it is working correctly.

NOTE: If you do not have the Delco Intelli-Check Tester, or if the alternator rated output is above 145 amps, or if a total vehicle charging system analysis is required, see "Alternator/Charging System Testing."

Intelli-Check Alternator Analyzer

The following information includes a pre-test procedure and operating instructions for the Delco Intelli-Check Tester, and is similar to the procedures provided by Delco with the Intelli-Check Tester.



Pre-Test Procedure (Engine Off)

1. Inspect the alternator connections to verify that all terminals are secured and tight. Verify that the sense wire is connected to the sense terminal on vehicles equipped with remote-sense alternators.
2. With the engine off, connect the red alligator clip to the output terminal of the alternator. Connect the black alligator clip to the alternator ground. An optional ground connection is to the body of the alternator. The tester LEDs will illuminate and then go off as it performs a self-test.
3. After 4 seconds the tester will activate. The following LEDs may illuminate depending on the condition of the batteries:
    - **GOOD** (green) LED indicates the battery voltage is above 12.8 and has a surface charge. The surface charge must be removed before proceeding with the alternator test. To remove the surface charge, do the following:
        A. Turn on the headlights and blower motor for 2 minutes without restarting the engine.
        B. Reset the tester by disconnecting, then reconnecting the tester alligator clips. The analyzer will again perform its self-test.
        C. Repeat the applicable steps of the Pre-Test Procedure.
    - **NO CHARGE** (red) LED indicates the battery voltage is below 12.8. This LED should illuminate for most tests. Proceed with the alternator test.
    - **LOW BATTERY VOLTAGE** (blue) LED indicates the battery voltage is below 12.35. If the batteries will start the vehicle, proceed with the alternator test. However, after completing the Intelli-Check alternator test, perform the procedures under "Alternator/Charging System Testing" to determine the condition of the rest of the charging system.

Tester Operating Instructions (Engine Running)

1. Start the engine using onboard batteries only. If the batteries will not start the engine, they must be charged for 2 hours. Start the test again after charging the batteries.
2. Verify the engine is at idle and all electrical loads are off.
3. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
    - If the **GOOD** (green) LED illuminates, proceed to the next step.
    - If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
    - If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging

system using the instructions in "Alternator/Charging System Testing."

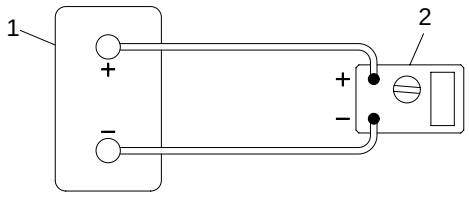
4. With the engine running, turn on all electrical loads.
5. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
6. If the **GOOD** (green) LED illuminates, the alternator is OK and the test is complete.

NOTE: If the alternator tests OK in the above tests, and the customer's complaint is reduced battery or headlight life, see "Alternator/ Charging System Testing" to completely analyze the charging system.

7. If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
8. If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing".

Alternator/Charging System Testing

Battery Open Circuit Voltage Test, Alternator Output Voltage Test and Alternator Amperage Output Test

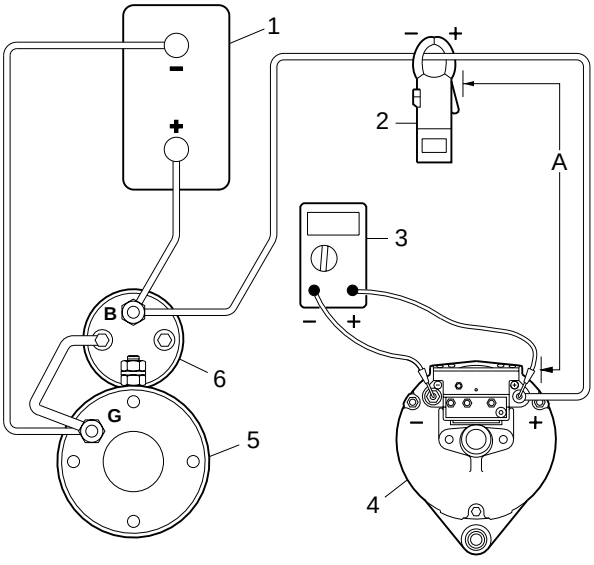


1. Use a digital volt-ohmmeter (VOM) set on the 2-20VDC (or similar) scale to test the battery open circuit voltage (OCV). With the engine shut down and the voltmeter set up as shown in **Fig. 2**, check for voltage of 12.4 volts or more.

   If the OCV is 12.4 volts or more, turn on the vehicle headlights for approximately 3 minutes.

   If the OCV is less than 12.4 volts, charge the batteries properly. For instructions, see **Group 54**.

IMPORTANT: Be sure to disconnect the batteries or remove them from the vehicle before charging.



2. Check the alternator output without a load. See **Fig. 3**.

Fig. 3, Setup 2: Alternator Output Test

2.1 Start the engine and run it at 1500 rpm for 3 to 5 minutes to stabilize the system before proceeding to the next step.

2.2 Connect the positive (+) lead of the digital voltmeter (still set on the 2-20VDC or similar scale) to the alternator (battery) terminal. Connect the negative (–) lead of the voltmeter to the alternator negative (–) ground terminal. See **Fig. 3**.

2.3 If the voltmeter reads from 13.8 to 14.2 volts, record this reading (V1) and go to the next step. If the alternator reads less than 13.8 volts and is adjustable, try to adjust the voltage regulator to 13.8 to 14.2 volts. If unable to obtain acceptable output, replace the alternator.

3. Check the alternator output under load. See **Fig. 3**.

3.1 Attach a clamp-on induction ammeter around the positive (+) wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

3.2 With the engine still running at 1500 rpm, turn on the following electrical accessories to load the alternator until the ammeter reads 60 to 75 amps.

- Both front and rear heater blowers (on HIGH)
- Headlights (high beams)
- Road lights
- Interior lights

NOTE: As an alternate method of putting load on the alternator, connect a carbon pile tester and set it to 60 to 75 amps.

3.3 Keep the voltmeter connected as in the previous step; positive (+) lead connected to the alternator positive (+) terminal; negative (–) lead connected to the alternator negative (–) terminal.

3.4 If the voltmeter reads from 13.6 to 14.2 volts, record this reading (V2) and go to the next step.

If the voltmeter reads less than 13.6 volts, replace the alternator.

4. Perform an alternator amperage output test.

4.1 Connect a carbon pile tester across the vehicle batteries as shown in **Fig. 2**.

Troubleshooting

NOTE: **Figure 2** shows a voltmeter, but the connections for the carbon pile tester are the same.

4.2 Attach a clamp-on induction ammeter around the alternator output wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

4.3 Start the engine and make sure all vehicle electrical accessories are turned off. Run it at fast speed and adjust the tester to the alternator maximum current output. Record this output value.

NOTE: Ensure that the alternator is turning at maximum available rpms and keep adjusting the tester dial until the ammeter reads its highest value.

4.4 Turn off the tester and shut down the engine.

4.5 If the output value recorded is less than 85 percent of the rated amperage output, repeat the test. If the output value recorded is still less than 85 percent of the rated amperage output, replace the alternator.

4.6 Make sure that all test instruments are removed and that the vehicle wiring is returned to its operational state.

5. To identify other problem areas within the vehicle, check the operation of the charging system. Set up the voltmeter as shown in **Fig. 2** and **Fig. 3**.

NOTE: For any load at 1500 rpm or more, battery voltage must be within 0.5 volts of the alternator voltage.

5.1 If readings at the batteries are within 0.5 volts of the readings at the alternator, the charging system is working correctly. Check other areas of the vehicle to locate the problem.

5.2 If the reading at the batteries is more than 0.5 volts lower than the reading at the alternator, do the next step.

6. Check charging system connections, cables and terminals.

6.1 Check all connections between the battery, starter and alternator for tightness and signs of corrosion. Tighten and clean as necessary.

6.2 Check all cables for breaks or partial breaks. Repair or replace as necessary.

6.3 Check each ring terminal for breakage at the point where it attaches to its wire or cable.

See **Fig. 1** for a schematic of the charging system.

General Description

The Delco Remy 21–SI series alternator (see **Fig. 1**) features a solid-state regulator that is mounted inside the end frame. The only moving part in the assembly is the rotor, which is mounted on a ball bearing at the drive end, and a roller bearing at the rectifier end. See **Fig. 2**.

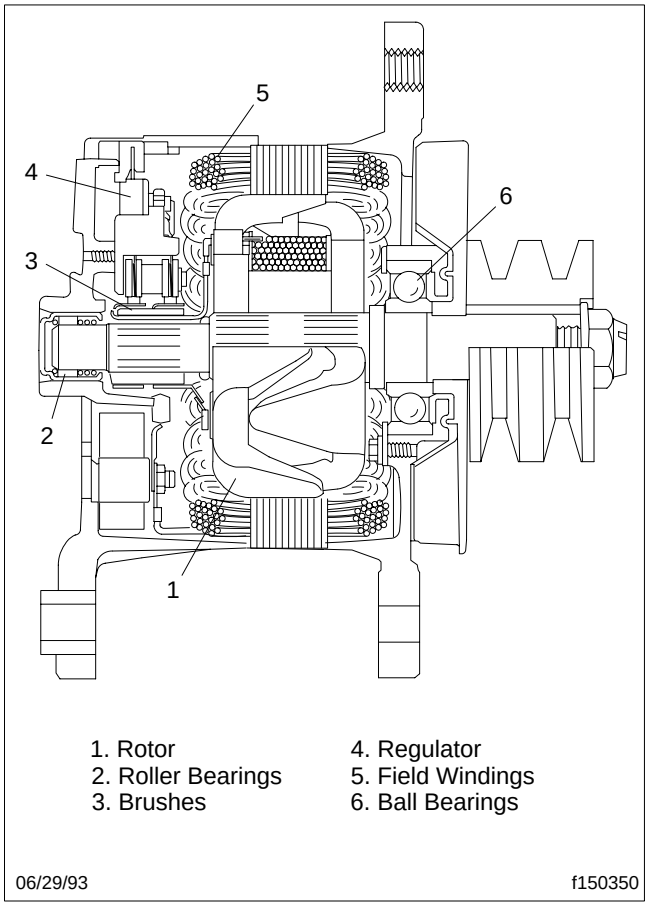

Fig. 1, 21-SI Alternator Components

All bearings are sealed so that no periodic maintenance is required. All current-carrying conductors are stationary, as are the field-winding stator components. The regulator and diodes are enclosed in a sealed compartment. A fan located on the drive end provides air flow for cooling.

Only one wire connects the alternator to the battery at the starter, along with a ground return. Since the vehicle's system is a negative ground, the output terminal connects to the starter's positive terminal.

As the rotor begins to turn, the permanent magnetism within it induces voltages in the stator windings. The voltages across the diodes cause current to flow, charging the battery.

Removal and Installation from Cummins B Series Engine

Removal

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Disconnect the batteries or, if equipped, turn off the battery shutoff switch.
3. Disconnect the wires from the alternator terminals, and label them for reassembly.
4. Remove the alternator belt.
   - 4.1 Insert a 3/8-inch breaker bar in the belt tensioner **(see Fig. 1),** and rotate the tensioner up and off the belt.
   - 4.2 Holding the tensioner up, remove the belt from the alternator pulley.
   - 4.3 Slowly release the belt tensioner, and remove the breaker bar.
5. Remove the alternator. **Refer to Fig. 2.**

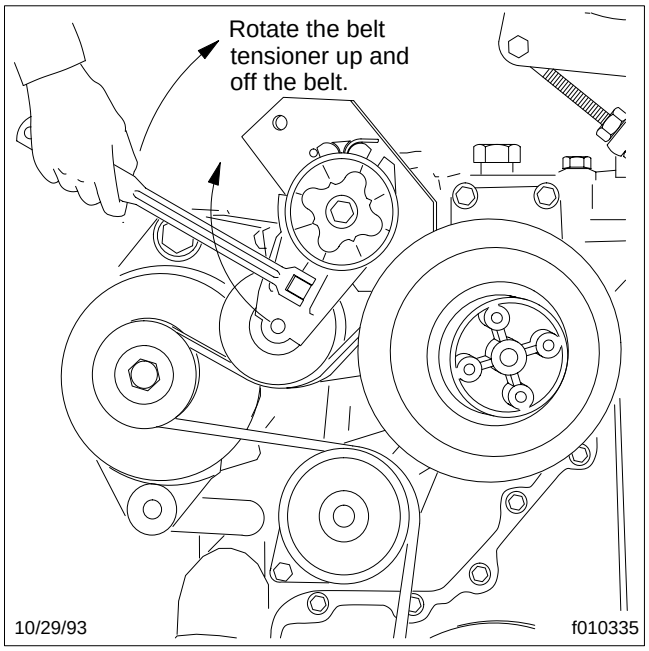

Fig. 1

   - 5.1 Remove the capscrew (Ref. 8) that secures the lower alternator mount to the link (Ref. 7).
   - 5.2 Remove the nut and washer (Refs. 5 and 4) from the pivot bolt (Ref. 1).
   - 5.3 Securely hold the alternator to prevent it from falling, and remove the pivot bolt.
   - 5.4 Remove the alternator from the vehicle.

Installation

1. Install the alternator on the alternator mount. **Refer to Fig. 2.**
   - 1.1 Position the alternator on the mount.
   - 1.2 Insert the pivot bolt (Ref. 1) through the alternator and mount.
   - 1.3 Install the washer and nut (Refs. 4 and 5) on the end of the pivot bolt.
2. Install the capscrew **(Fig. 2**, Ref. 8) to secure the lower alternator mount to the alternator link **(Fig. 2,** Ref. 7), and tighten it 21 N·m (16 lbf·ft). Tighten the nut on the end of the pivot bolt 54 N·m (40 lbf·ft).
3. Install the belt on the alternator.
   - 3.1 Insert a 3/8-inch breaker bar in the belt tensioner **(see Fig. 1),** and rotate the tensioner up while installing the belt on the alternator pulley. Make sure the belt is aligned on all pulleys.
   - 3.2 Slowly release the tensioner assembly onto the belt. The tensioner automatically tightens the belt to the correct tension.
   - 3.3 Remove the breaker bar from the tensioner.
4. Connect the wires to the alternator terminals. If the wires are not labeled, refer to the wiring diagram in **"Specifications, 400."**
5. Connect the batteries or, if equipped, turn on the battery shutoff switch.
6. Lower the hood, and remove the chocks from the tires.

Removal and Installation from Cummins B Series Engine

Removal and Installation from Mercedes-Benz OM 366LA Engine

Removal (Refer to Fig. 1)

1. Apply the parking brakes, chock the tires, and tilt the hood.

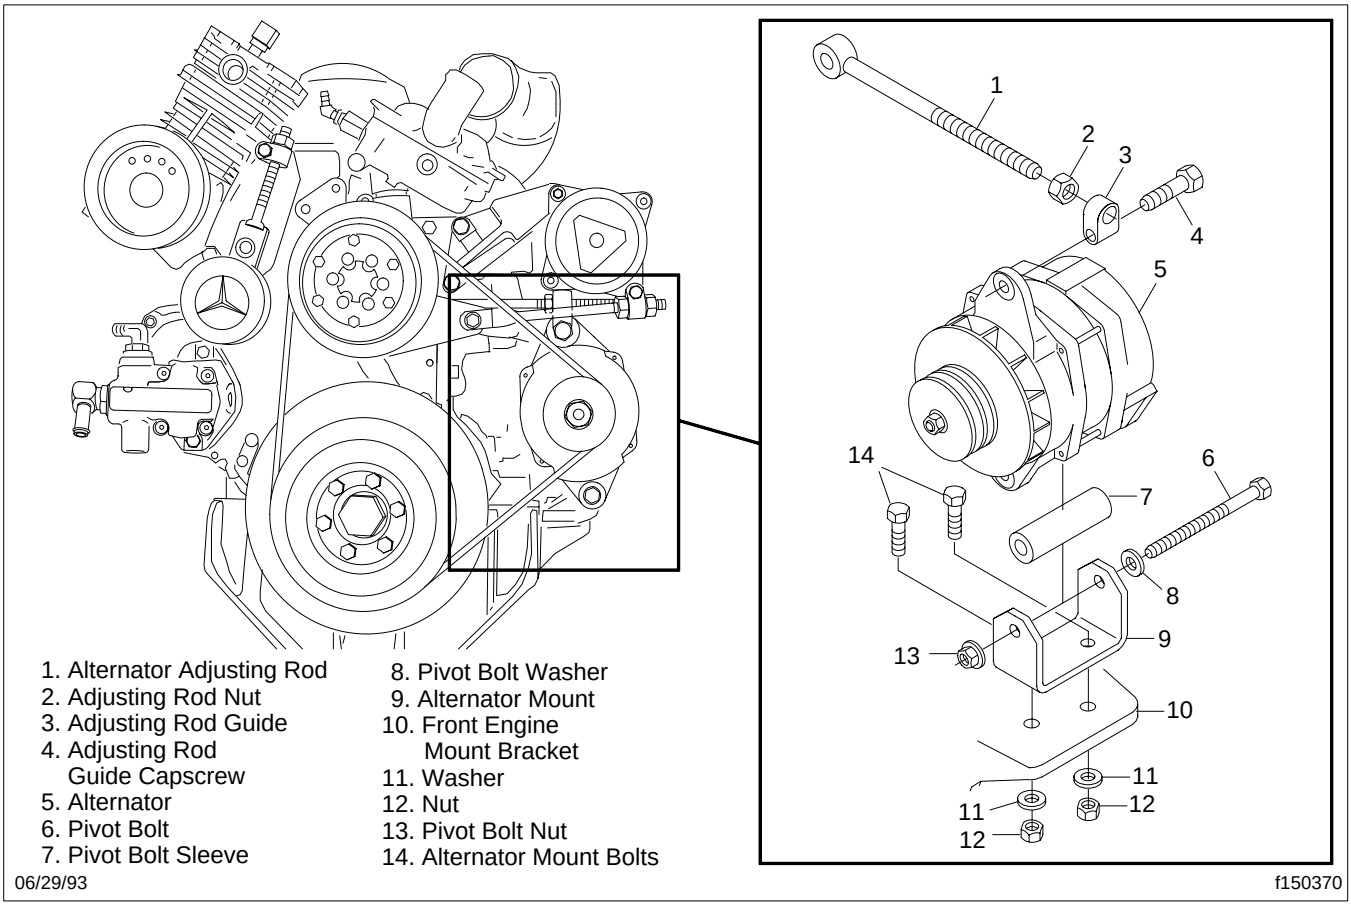

Fig. 1, Alternator Installation, Mercedes-Benz OM 366LA Engine

2. Disconnect the batteries or, if equipped, turn off the battery shutoff switch.
3. Disconnect the wires from the alternator terminals, and label them for reassembly.
4. Remove the alternator belt.
   - 4.1 Turn the adjusting rod nut (Ref. 2) clockwise to allow the adjusting rod guide (Ref. 3) to slide inward along the adjusting rod (Ref. 1).
   - 4.2 Loosen the capscrew (Ref. 4) in the adjusting rod guide.
   - 4.3 Loosen the nut (Ref. 13) on the pivot bolt (Ref. 6).
   - 4.4 Rotate the alternator inward along the adjusting rod, and remove the belt.
5. Remove the alternator.
   - 5.1 Rotate the alternator outward until the adjusting rod guide (Ref. 3) is off the adjusting rod.
   - 5.2 Remove the nut (Ref. 13) from the pivot bolt.
   - 5.3 Securely hold the alternator to prevent it from falling, and remove the pivot bolt.
   - 5.4 Remove the alternator from the vehicle.

Removal and Installation from Mercedes-Benz OM 366LA Engine

Installation (Refer to Fig. 1)

1. Install the alternator on the alternator mount (Ref. 9).
   - 1.1 Position the alternator on the mount.
   - 1.2 Hold the pivot bolt sleeve (Ref. 7) in place between the two flanges of the mount, and insert the pivot bolt (Ref. 6) through the alternator, mount, and sleeve.
   - 1.3 Install the nut (Ref. 13) on the end of the pivot bolt, and tighten the nut finger-tight.
2. Install the belt on the alternator.
   - 2.1 Rotate the alternator upward, and insert the adjusting rod (Ref. 1) through the adjusting rod guide (Ref. 3).
   - 2.2 Loop the belt on the alternator pulley, and make sure it is still aligned on the fan and vibration damper pulleys.
   - 2.3 Tighten the belt by turning the adjusting rod nut (Ref. 2) counterclockwise until the alternator rotates outward against the belt.

     Check the tension while turning the nut, use your thumb to apply about 11 kg (25 lbs) of force at the center of the longest belt free-span until the belt deflection equals one belt thickness per 305 mm (1 ft) of pulley center distance.
   - 2.4 Install a belt tension gauge at the center of the belt's longest free-span.
   - 2.5 Turn the adjusting rod nut against the adjusting rod guide to move the alternator outward until the belt tension is 75 kg (160 lbs).

IMPORTANT: Do not overtighten the belt; too much tension shortens belt and bearing life.

3. Tighten the capscrew on the adjusting rod guide (Ref. 3) 81 N·m (60 lbf·ft).
4. Tighten the nut (Ref. 13) on the pivot bolt 81 N·m (60 lbf·ft).
5. Check the belt tension again, and adjust if needed.
6. If installing a new belt, operate the engine for about 20 minutes, then check the belt tension. All new belts will lose tension after 20 minutes of operation.

   If necessary, adjust the belt to 75 kg (160 lbs).
7. Connect the wires to the alternator terminals. If the wires are not labeled, refer to the wiring diagram in **"Specifications, 400".**
8. Connect the batteries or, if equipped, turn on the battery shutoff switch.
9. Lower the hood, and remove the chocks from the tires.

Troubleshooting

Many alternators have been replaced that later investigation reveals were working properly. This may be due to incorrectly diagnosing the problem.

IMPORTANT: Before testing, make sure:

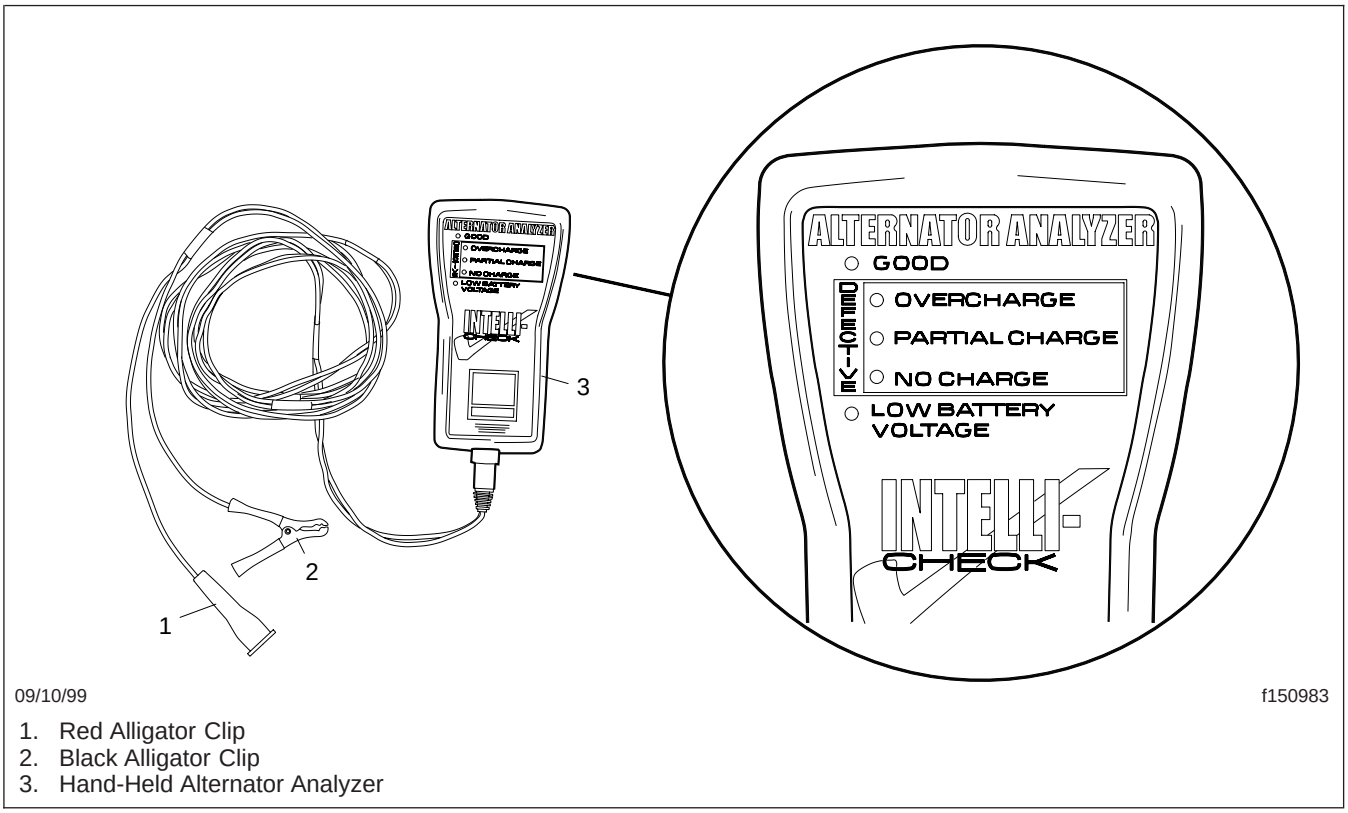
- All belts are correctly tightened;
- The wiring and terminals are clean and in good condition;
- All terminal nuts are torqued and properly protected.

Delco Remy has an alternator testing tool called the Intelli-Check Alternator Analyzer. See **Fig. 1**. This tool (DR 10457848, a single tester, or DR 10457865, a four-pack of testers) is to be used as a quick check of the alternator to see if it is working correctly.

NOTE: If you do not have the Delco Intelli-Check Tester, or if the alternator rated output is above 145 amps, or if a total vehicle charging system analysis is required, see "Alternator/Charging System Testing."

Intelli-Check Alternator Analyzer

The following information includes a pre-test procedure and operating instructions for the Delco Intelli-Check Tester, and is similar to the procedures provided by Delco with the Intelli-Check Tester.



Pre-Test Procedure (Engine Off)

1. Inspect the alternator connections to verify that all terminals are secured and tight. Verify that the sense wire is connected to the sense terminal on vehicles equipped with remote-sense alternators.
2. With the engine off, connect the red alligator clip to the output terminal of the alternator. Connect the black alligator clip to the alternator ground. An optional ground connection is to the body of the alternator. The tester LEDs will illuminate and then go off as it performs a self-test.
3. After 4 seconds the tester will activate. The following LEDs may illuminate depending on the condition of the batteries:
    - **GOOD** (green) LED indicates the battery voltage is above 12.8 and has a surface charge. The surface charge must be removed before proceeding with the alternator test. To remove the surface charge, do the following:
        A. Turn on the headlights and blower motor for 2 minutes without restarting the engine.
        B. Reset the tester by disconnecting, then reconnecting the tester alligator clips. The analyzer will again perform its self-test.
        C. Repeat the applicable steps of the Pre-Test Procedure.
    - **NO CHARGE** (red) LED indicates the battery voltage is below 12.8. This LED should illuminate for most tests. Proceed with the alternator test.
    - **LOW BATTERY VOLTAGE** (blue) LED indicates the battery voltage is below 12.35. If the batteries will start the vehicle, proceed with the alternator test. However, after completing the Intelli-Check alternator test, perform the procedures under "Alternator/Charging System Testing" to determine the condition of the rest of the charging system.

Tester Operating Instructions (Engine Running)

1. Start the engine using onboard batteries only. If the batteries will not start the engine, they must be charged for 2 hours. Start the test again after charging the batteries.
2. Verify the engine is at idle and all electrical loads are off.
3. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
    - If the **GOOD** (green) LED illuminates, proceed to the next step.
    - If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
    - If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging

system using the instructions in "Alternator/Charging System Testing."

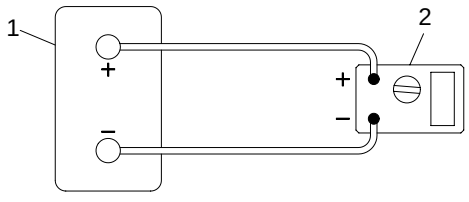
4. With the engine running, turn on all electrical loads.
5. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
6. If the **GOOD** (green) LED illuminates, the alternator is OK and the test is complete.

NOTE: If the alternator tests OK in the above tests, and the customer's complaint is reduced battery or headlight life, see "Alternator/ Charging System Testing" to completely analyze the charging system.

7. If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
8. If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing".

Alternator/Charging System Testing

Battery Open Circuit Voltage Test, Alternator Output Voltage Test and Alternator Amperage Output Test

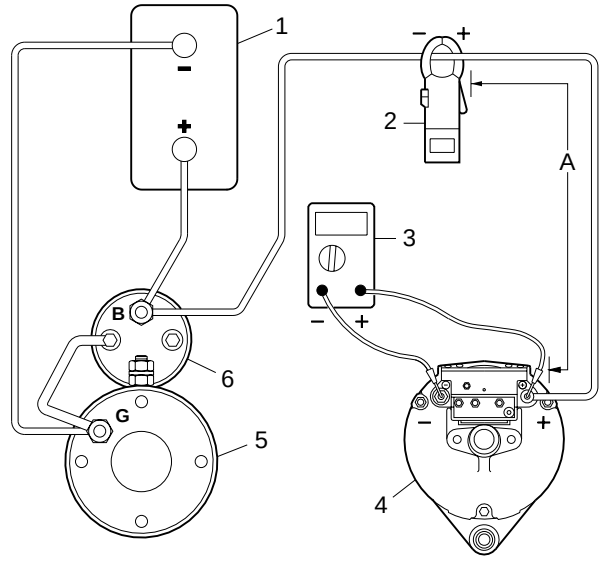


1. Use a digital volt-ohmmeter (VOM) set on the 2-20VDC (or similar) scale to test the battery open circuit voltage (OCV). With the engine shut down and the voltmeter set up as shown in **Fig. 2**, check for voltage of 12.4 volts or more.

   If the OCV is 12.4 volts or more, turn on the vehicle headlights for approximately 3 minutes.

   If the OCV is less than 12.4 volts, charge the batteries properly. For instructions, see **Group 54**.

IMPORTANT: Be sure to disconnect the batteries or remove them from the vehicle before charging.



2. Check the alternator output without a load. See **Fig. 3**.

2.1 Start the engine and run it at 1500 rpm for 3 to 5 minutes to stabilize the system before proceeding to the next step.

2.2 Connect the positive (+) lead of the digital voltmeter (still set on the 2-20VDC or similar scale) to the alternator (battery) terminal. Connect the negative (–) lead of the voltmeter to the alternator negative (–) ground terminal. See **Fig. 3**.

2.3 If the voltmeter reads from 13.8 to 14.2 volts, record this reading (V1) and go to the next step. If the alternator reads less than 13.8 volts and is adjustable, try to adjust the voltage regulator to 13.8 to 14.2 volts. If unable to obtain acceptable output, replace the alternator.

3. Check the alternator output under load. See **Fig. 3**.

3.1 Attach a clamp-on induction ammeter around the positive (+) wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

3.2 With the engine still running at 1500 rpm, turn on the following electrical accessories to load the alternator until the ammeter reads 60 to 75 amps.

- Both front and rear heater blowers (on HIGH)
- Headlights (high beams)
- Road lights
- Interior lights

NOTE: As an alternate method of putting load on the alternator, connect a carbon pile tester and set it to 60 to 75 amps.

3.3 Keep the voltmeter connected as in the previous step; positive (+) lead connected to the alternator positive (+) terminal; negative (–) lead connected to the alternator negative (–) terminal.

3.4 If the voltmeter reads from 13.6 to 14.2 volts, record this reading (V2) and go to the next step.

If the voltmeter reads less than 13.6 volts, replace the alternator.

4. Perform an alternator amperage output test.

4.1 Connect a carbon pile tester across the vehicle batteries as shown in **Fig. 2**.

Troubleshooting

NOTE: **Figure 2** shows a voltmeter, but the connections for the carbon pile tester are the same.

4.2 Attach a clamp-on induction ammeter around the alternator output wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

4.3 Start the engine and make sure all vehicle electrical accessories are turned off. Run it at fast speed and adjust the tester to the alternator maximum current output. Record this output value.

NOTE: Ensure that the alternator is turning at maximum available rpms and keep adjusting the tester dial until the ammeter reads its highest value.

4.4 Turn off the tester and shut down the engine.

4.5 If the output value recorded is less than 85 percent of the rated amperage output, repeat the test. If the output value recorded is still less than 85 percent of the rated amperage output, replace the alternator.

4.6 Make sure that all test instruments are removed and that the vehicle wiring is returned to its operational state.

5. To identify other problem areas within the vehicle, check the operation of the charging system. Set up the voltmeter as shown in **Fig. 2** and **Fig. 3**.

NOTE: For any load at 1500 rpm or more, battery voltage must be within 0.5 volts of the alternator voltage.

5.1 If readings at the batteries are within 0.5 volts of the readings at the alternator, the charging system is working correctly. Check other areas of the vehicle to locate the problem.

5.2 If the reading at the batteries is more than 0.5 volts lower than the reading at the alternator, do the next step.

6. Check charging system connections, cables and terminals.

6.1 Check all connections between the battery, starter and alternator for tightness and signs of corrosion. Tighten and clean as necessary.

6.2 Check all cables for breaks or partial breaks. Repair or replace as necessary.

6.3 Check each ring terminal for breakage at the point where it attaches to its wire or cable.

General Information

The Delco Remy 28-MT starter **(Fig. 1)** mounts at the forward face of the flywheel bell housing. On Cummins B Series engines, the starter mounts on the right side of the engine. On Mercedes-Benz OM 366LA engines, it mounts on the left.

The starter assembly **(Fig. 2)** consists of two basic parts: the solenoid and the starter motor. The shift lever and wiring connect the two parts, and the lever, motor, and solenoid are completely enclosed for protection from dirt, ice, and splash. The 28-MT starter features sealed bearings with lifetime lubrication.

The solenoid is wired to the starter relay, the alternator, and the batteries. Turning the key switch to start supplies power to the starter relay, and the relay activates the solenoid. Once activated, the solenoid plunger slides forward, moving the shift lever to engage the starter drive gear with the engine flywheel ring gear, and connecting the solenoid's battery terminal to the motor terminal.

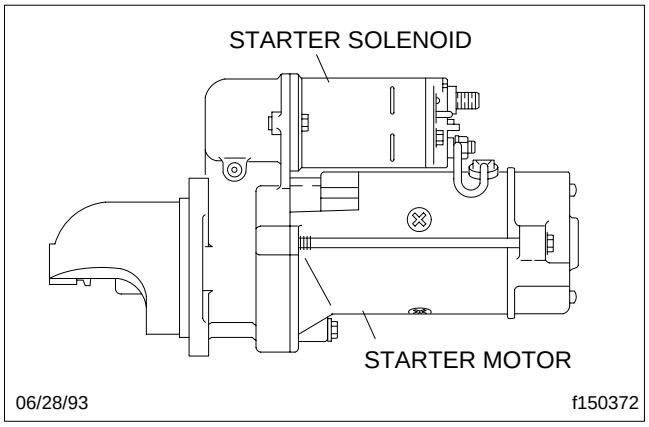

Fig. 1, Delco Remy 28-MT Starter

The motor terminal is wired to the starter motor so power from the batteries activates the starter motor after the starter drive gear engages the engine flywheel.

Once the engine starts, and the ignition stops supplying power to the starter relay, the solenoid plunger retracts, disengaging the starter motor from the engine flywheel, and cutting battery power to the starter motor.

Removal

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Disconnect the batteries or, if equipped, turn off the battery shutoff switch.
   - 2.1 Disconnect the battery ground cable at the vehicle frame.
   - 2.2 Disconnect the positive battery cable from the batteries.
3. Disconnect the wires from the starter solenoid terminals, and label them for reassembly.
4. Remove the starter from the engine.

   On Cummins B Series engines, remove the three capscrews that secure the starter to the engine. **Refer to Fig. 1.**

   On Mercedes-Benz OM 366LA engines, remove the oil return pipe from the bottom of the turbo-charger by removing the two bolts that hold the top of the pipe and the
5. pipe clamp that holds the base. **Refer to Fig. 2.** Remove the three nuts that secure the starter to the engine.

Installation

1. Install the starter on the engine.

   On Cummins B Series engines, position the starter and secure it with the three capscrews. **Refer to Fig. 1.** Tighten the capscrews 43 N·m (32 lbf·ft).

   On Mercedes-Benz OM 366LA engines, position the starter and secure it with the three nuts. **Refer to Fig. 2.** Tighten the nuts 43 N·m (32 lbf·ft). To install the oil return pipe on the bottom of the turbocharger, tighten the bolts at the top of the pipe 40 N·m (30 lbf·ft), and tighten the clamp at the base of the pipe.
2. Connect the wires to the starter terminals. If the wires were not labeled for reassembly, refer to the starter wiring diagram in **"Specifications, 400."**
3. Connect the batteries or, if equipped, turn on the battery shutoff switch.
   - 3.1 Connect the positive battery cable to the batteries.
   - 3.2 Connect the battery ground cable to the vehicle frame.
4. Lower the hood, and remove the chocks from the tires.
5. Start the engine to test the starter.

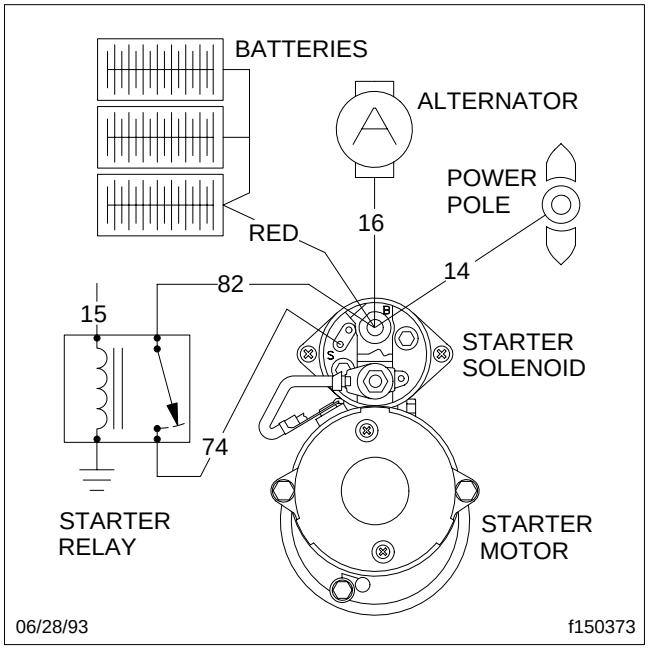

Fig. 1, Starter Wiring Diagram

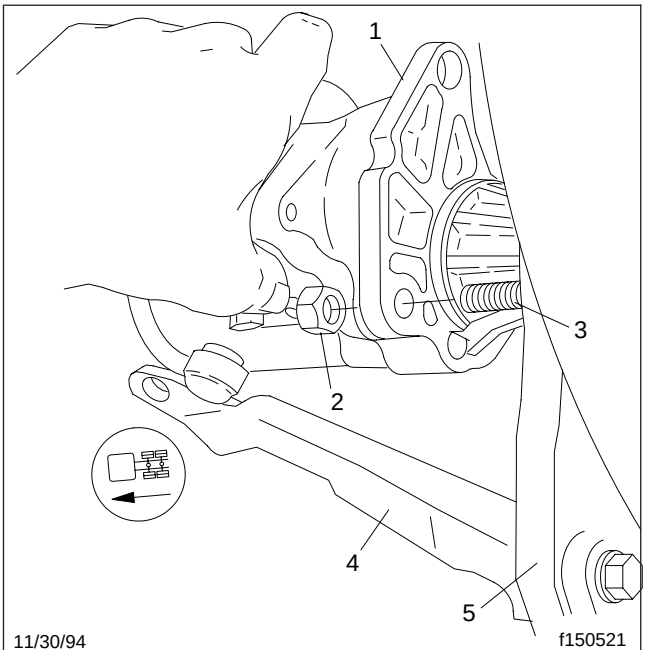
General Information

The Nippondenso starter mounts on the left-hand side of the engine directly into the transmission, through a hole in the torque converter access cover.

The starter motor incorporates a planetary gear system between the electric motor and pinion gear. This feature allows the armature to rotate at a higher speed and delivers increased torque to the drive plate ring gear or flywheel. At the same time, it reduces the size and weight of the starter.



The starter motor is activated by a solenoid mounted to the overrunning clutch housing. The starter motor and solenoid are serviced as a complete unit only. If either component fails, replace the entire assembly.

Removal

1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Disconnect the batteries.
3. Raise and support the vehicle.
4. Remove the starter from the bell housing.
   - 4.1 Remove the battery cable standoff bracket. Remove the battery cable bolt and bracket. Do not remove the clamp from the battery cable.
   - 4.2 Mark and disconnect the battery and solenoid cable leads. Remove the two starter mounting bolts and the mounting stud nut.
   - 4.3 Move the starter forward until the nose of the starter gear housing clears the hole in the torque converter access cover and the mounting flange clears the mounting stud. **See Fig. 1.**

Installation

1. Install the starter. **See Fig. 1.**
   - 1.1 Attach the battery cable leads to the starter, as previously marked. Tighten the connector on the battery lead 800 to 1240 N·cm (70 to 110 lbf·in). Tighten the connector on the solenoid lead 500 to 740 N·cm (45 to 65 lbf·in).
   - 1.2 Insert the starter gear housing into the hole in the torque converter access cover. Slip the starter into place over the starter mounting stud.
   - 1.3 Install the two starter mounting bolts and tighten them 68 N·m (50 lbf·ft). Install the starter mounting nut on the stud and tighten it 27 N·m (20 lbf·ft).
   - 1.4 Install the battery cable standoff bracket.
2. Connect the batteries.
3. Lower the vehicle and remove the supports.
4. Lower the hood and remove the chocks from the tires.
5. Start the engine to test the starter.

Replacement

The starter relay is located inside the Electrical Power Center (EPC). The EPC is underneath the dash panel on the passenger side.

1. Disconnect the batteries.
2. Remove the starter relay from the EPC.
   2.1 Remove the fasteners holding the EPC cover. Look for the starter relay on the top row of the EPC. For a typical installation, **see Fig. 1**. The exact location of the starter relay will vary depending on options installed.

   2.2 Unplug the old starter relay unit from the EPC.
3. Plug in the new starter relay. Make sure the relay is firmly seated on its mounting plate and that the electrical connections behind the panel are tight.
4. Replace the EPC cover and install the fasteners.
5. Connect the batteries.
6. Start the engine to test the starter relay.

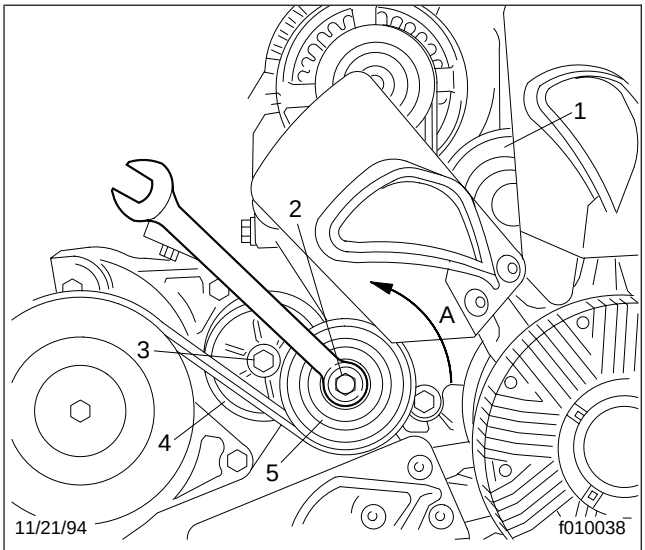
General Information

The Nippondenso alternator is driven by the engine through the serpentine accessory drive belt. It mounts directly onto the engine, on the right-hand side.

The alternator is serviced as a complete unit only. If the alternator fails for any reason, replace the entire unit.

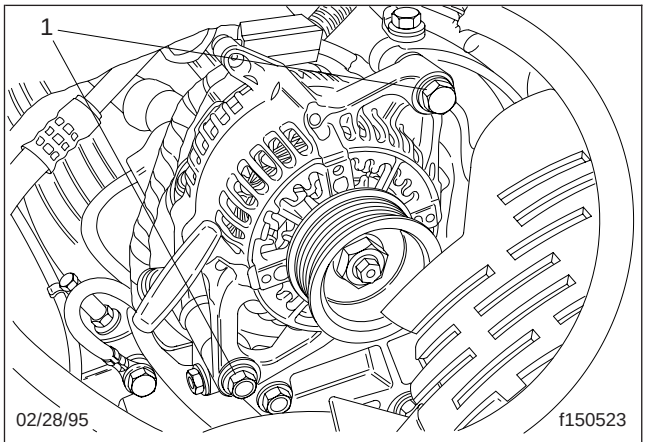


Removal

1. Apply the parking brakes, chock the tires, and tilt the hood.

⚠ WARNING

WARNING: Disconnect the negative cable from the batteries before removing the battery output wire from the alternator. Failure to do so could cause personal injury.



2. Disconnect the batteries.
3. Remove the engine accessory drive belt.
   - 3.1 Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner. **See Fig. 1.**

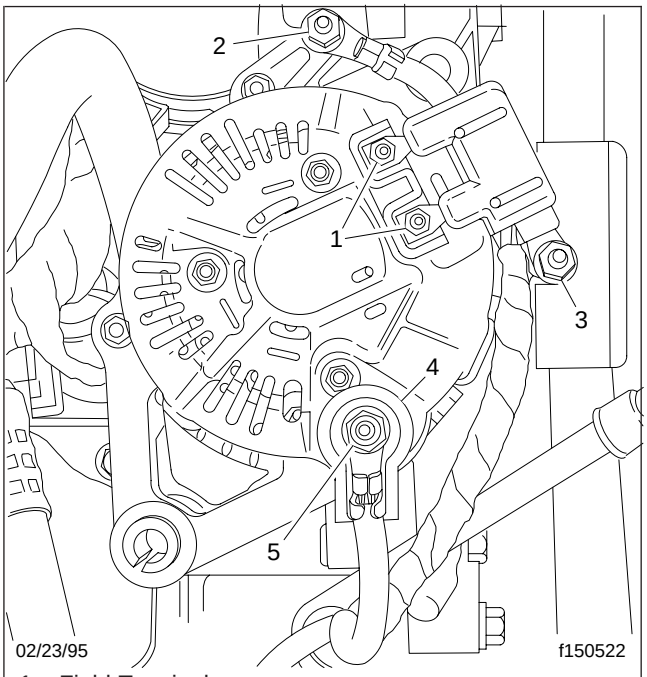
   - 4.2 From the rear (rectifier) end of the alternator, remove the nuts from the battery (positive) terminal, ground (negative) terminal, the wire harness hold-down, and the two field terminals. **See Fig. 3.**
   - 4.3 Remove the alternator.



Installation

1. Install the alternator.
   - 1.1 Attach the alternator electrical connectors to the alternator. Tighten the nuts on the field terminals 280 N·cm (25 lbf·in). Tighten all the other nuts 840 N·cm (75 lbf·in). **See Fig. 3.**
   - 1.2 Install the alternator mounting bolts. Tighten each one 41 N·m (30 lbf·ft).
2. Install the engine accessory drive belt.

⚠ CAUTION

CAUTION: When installing the serpentine accessory drive belt, route the belt correctly. If the belt is not routed correctly, the water pump pulley may rotate in the wrong direction, allowing the engine to overheat.

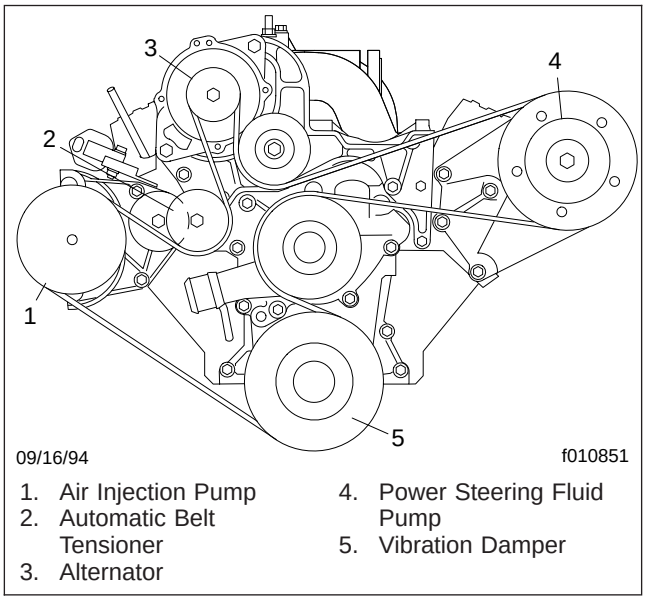
2.2 Place a 5/8-inch wrench over the pulley bolt on the automatic belt tensioner, and turn the wrench counterclockwise to relax the belt tensioner. **See Fig. 1.**

⚠ CAUTION



CAUTION: Never use a screwdriver to force the belt over a pulley rim. This can damage the synthetic fiber of the belt.

General Information

The Lestek alternator is an electromechanical device that converts mechanical force from the engine crankshaft or accessory drive, into pulsed DC electrical energy. See **Fig. 1**. A multi-poled magnet, referred to as a rotor, is spun inside a multiphased coil called a stator, that induces AC current flow in the stator coils. This AC current is then rectified using positive and negative diodes, producing a pulsed DC output which can then be used to drive electrical devices, motors, lights, etc., and charge the system batteries.

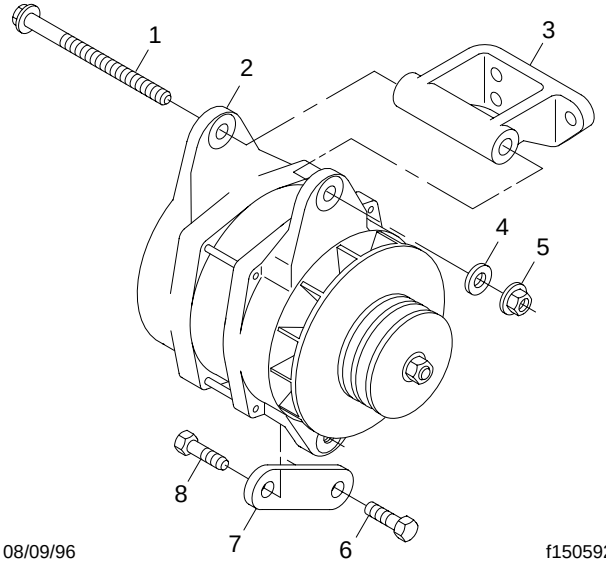
Fig. 1, Lestek Brute 190 (and 200) Alternator

The Lestek Brute 190 alternator is rated for 150 amps at engine idle and the Lestek Brute 200 is rated at 140 at engine idle. They contain a patented hand-wound Dual Delta stator. Eighteen 50-amp press-fit diodes combine for a 450-amp rectifier manufactured of high grade milled aluminum. The rotors utilize special high-flux density coils that are precision balanced for long bearing life. They use an SAE standard J180 mount, and an external regulator.

Removal

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Tilt the hood.



⚠ WARNING

Before disconnecting the batteries, read the instructions and Danger and Warning notices in Section 54.02. Keep sparks, flames, burning cigarettes, etc. away from batteries. Batteries generate explosive gases, which could cause a battery to explode, causing serious personal injury, including blindness.

3. Disconnect the batteries.
4. Mark all electrical leads and disconnect them from the alternator.
5. Remove the drive belts and note the routing. For instructions, see **Section 01.00**.
6. Remove the alternator. See **Fig. 1**.
   - 6.1 Remove the alternator mounting capscrew (Ref. 8) from the link (Ref. 7).
   - 6.2 Remove the nut and washer (Refs. 5 and 4) from the pivot bolt (Ref. 1).
   - 6.3 Securely hold the alternator to prevent it from falling, and remove the pivot bolt.
   - 6.4 Remove the alternator from the vehicle.
7. Inspect the drive belts. For instructions, see **Section 01.00**.

Installation

1. Install a new pulley, if applicable, and tighten the shaft nut to 75 lbf·ft (102 N·m).
2. Install the alternator on the pivot bracket. See **Fig. 1**.
   - 2.1 Position the alternator on the bracket.
   - 2.2 Insert the pivot bolt (Ref. 1) through the alternator and the bracket.
   - 2.3 Install the washer and nut (Refs. 4 and 5) on the end of the pivot bolt.

3. Check the torque of the alternator bracket fasteners. If necessary, tighten, see **Specifications 400**.
4. Install the alternator mounting capscrew, and tighten it 65 lbf·ft (88 N·m). Tighten the pivot nut 65 lbf·ft (88 N·m).
5. Install the drive belt on the pulley as removed. For instructions, see **Section 01.00**.

NOTE: The belt tensioner automatically adjusts the drive belt to the correct tension. If the belt slips, repair or replace the tensioner. For instructions, see the engine manufacturer's service literature.

6. Connect all leads to the back of the alternator as previously marked and tighten. See **Specifications 400**.
7. Spray any exposed terminal connectors with dielectric red enamel. See **Table 1** for approved brands.

8. Connect the batteries.
9. Before returning the vehicle to operation, test the alternator DC output voltage. For instructions, see "Alternator Voltage Output Test" in **Section 15.09, Troubleshooting 300**.
10. Lower the hood.
11. Remove the tire chocks.

Troubleshooting

Many alternators have been replaced that later investigation reveals were working properly. This may be due to incorrectly diagnosing the problem.

IMPORTANT: Before testing, make sure:

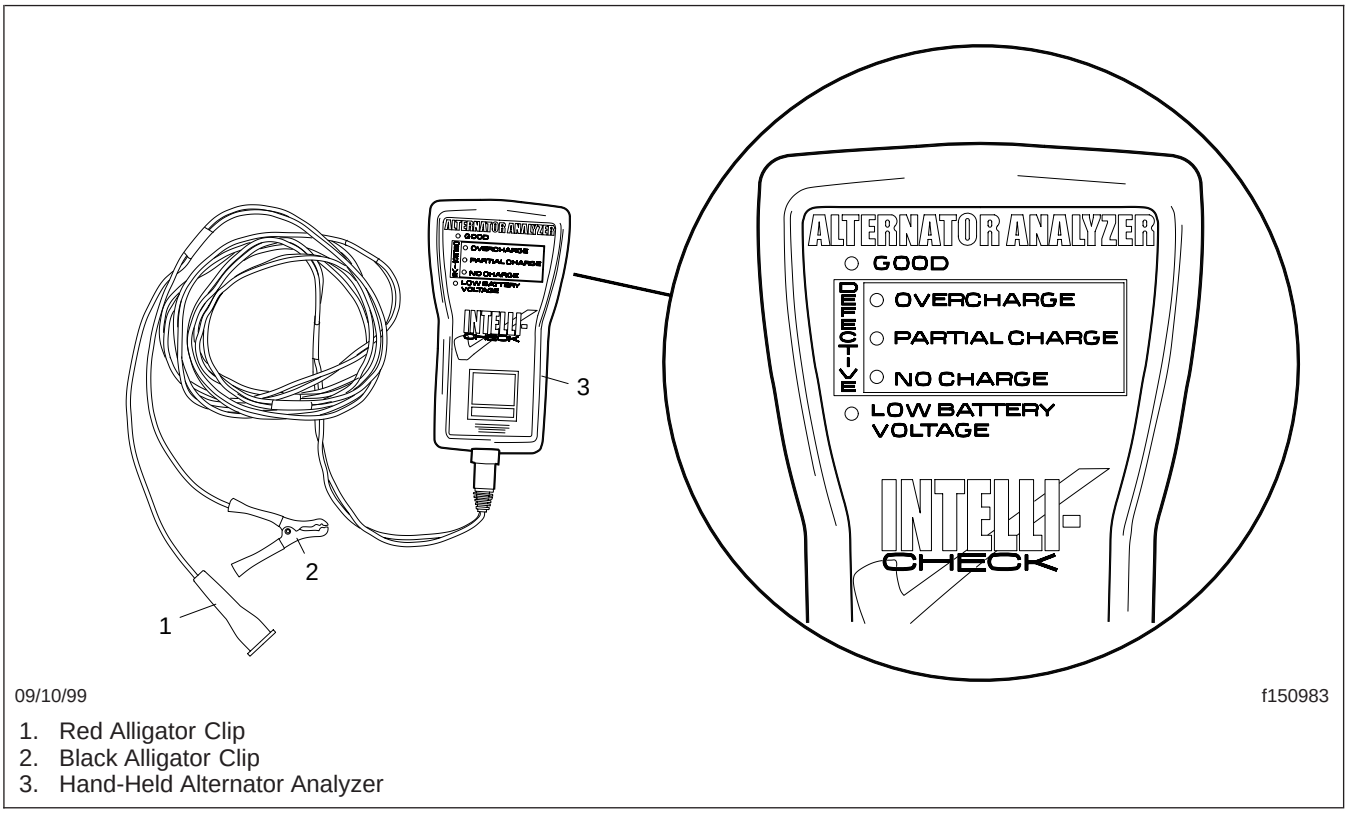
- All belts are correctly tightened;
- The wiring and terminals are clean and in good condition;
- All terminal nuts are torqued and properly protected.

Delco Remy has an alternator testing tool called the Intelli-Check Alternator Analyzer. See **Fig. 1**. This tool (DR 10457848, a single tester, or DR 10457865, a four-pack of testers) is to be used as a quick check of the alternator to see if it is working correctly.

NOTE: If you do not have the Delco Intelli-Check Tester, or if the alternator rated output is above 145 amps, or if a total vehicle charging system analysis is required, see "Alternator/Charging System Testing."

Intelli-Check Alternator Analyzer

The following information includes a pre-test procedure and operating instructions for the Delco Intelli-Check Tester, and is similar to the procedures provided by Delco with the Intelli-Check Tester.



Pre-Test Procedure (Engine Off)

1. Inspect the alternator connections to verify that all terminals are secured and tight. Verify that the sense wire is connected to the sense terminal on vehicles equipped with remote-sense alternators.
2. With the engine off, connect the red alligator clip to the output terminal of the alternator. Connect the black alligator clip to the alternator ground. An optional ground connection is to the body of the alternator. The tester LEDs will illuminate and then go off as it performs a self-test.
3. After 4 seconds the tester will activate. The following LEDs may illuminate depending on the condition of the batteries:
    - **GOOD** (green) LED indicates the battery voltage is above 12.8 and has a surface charge. The surface charge must be removed before proceeding with the alternator test. To remove the surface charge, do the following:
        A. Turn on the headlights and blower motor for 2 minutes without restarting the engine.
        B. Reset the tester by disconnecting, then reconnecting the tester alligator clips. The analyzer will again perform its self-test.
        C. Repeat the applicable steps of the Pre-Test Procedure.
    - **NO CHARGE** (red) LED indicates the battery voltage is below 12.8. This LED should illuminate for most tests. Proceed with the alternator test.
    - **LOW BATTERY VOLTAGE** (blue) LED indicates the battery voltage is below 12.35. If the batteries will start the vehicle, proceed with the alternator test. However, after completing the Intelli-Check alternator test, perform the procedures under "Alternator/Charging System Testing" to determine the condition of the rest of the charging system.

Tester Operating Instructions (Engine Running)

1. Start the engine using onboard batteries only. If the batteries will not start the engine, they must be charged for 2 hours. Start the test again after charging the batteries.
2. Verify the engine is at idle and all electrical loads are off.
3. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
    - If the **GOOD** (green) LED illuminates, proceed to the next step.
    - If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
    - If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging

Troubleshooting

system using the instructions in "Alternator/Charging System Testing."

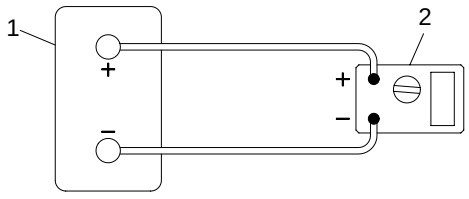
4. With the engine running, turn on all electrical loads.
5. Depress the accelerator to governed speed, hold for 10 seconds, then return to idle.
6. If the **GOOD** (green) LED illuminates, the alternator is OK and the test is complete.

NOTE: If the alternator tests OK in the above tests, and the customer's complaint is reduced battery or headlight life, see "Alternator/ Charging System Testing" to completely analyze the charging system.

7. If any LEDs illuminate indicating overcharge, partial charge or no charge (the three red lights in the **DEFECTIVE** section), replace the alternator and run the complete test again.
8. If the **LOW BATTERY VOLTAGE** (blue) LED illuminates, evaluate the charging system using the instructions in "Alternator/Charging System Testing".

Alternator/Charging System Testing

Battery Open Circuit Voltage Test, Alternator Output Voltage Test and Alternator Amperage Output Test

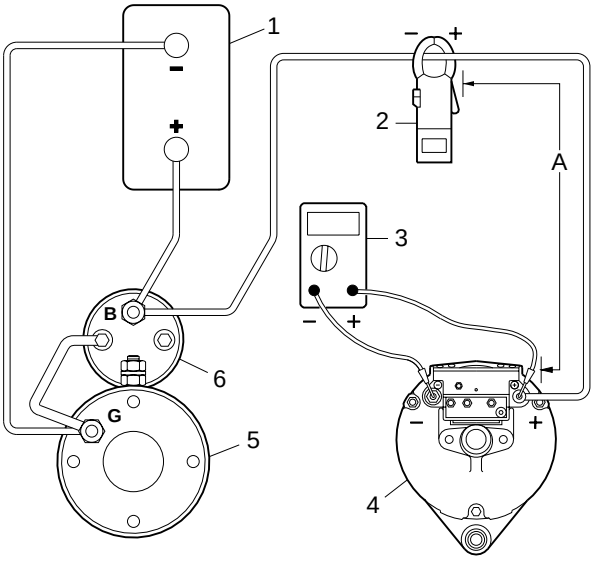


1. Use a digital volt-ohmmeter (VOM) set on the 2-20VDC (or similar) scale to test the battery open circuit voltage (OCV). With the engine shut down and the voltmeter set up as shown in **Fig. 2**, check for voltage of 12.4 volts or more.

   If the OCV is 12.4 volts or more, turn on the vehicle headlights for approximately 3 minutes.

   If the OCV is less than 12.4 volts, charge the batteries properly. For instructions, see **Group 54**.

IMPORTANT: Be sure to disconnect the batteries or remove them from the vehicle before charging.



2. Check the alternator output without a load. See **Fig. 3**.

2.1 Start the engine and run it at 1500 rpm for 3 to 5 minutes to stabilize the system before proceeding to the next step.

2.2 Connect the positive (+) lead of the digital voltmeter (still set on the 2-20VDC or similar scale) to the alternator (battery) terminal. Connect the negative (–) lead of the voltmeter to the alternator negative (–) ground terminal. See **Fig. 3**.

2.3 If the voltmeter reads from 13.8 to 14.2 volts, record this reading (V1) and go to the next step. If the alternator reads less than 13.8 volts and is adjustable, try to adjust the voltage regulator to 13.8 to 14.2 volts. If unable to obtain acceptable output, replace the alternator.

3. Check the alternator output under load. See **Fig. 3**.

3.1 Attach a clamp-on induction ammeter around the positive (+) wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

3.2 With the engine still running at 1500 rpm, turn on the following electrical accessories to load the alternator until the ammeter reads 60 to 75 amps.

- Both front and rear heater blowers (on HIGH)
- Headlights (high beams)
- Road lights
- Interior lights

NOTE: As an alternate method of putting load on the alternator, connect a carbon pile tester and set it to 60 to 75 amps.

3.3 Keep the voltmeter connected as in the previous step; positive (+) lead connected to the alternator positive (+) terminal; negative (–) lead connected to the alternator negative (–) terminal.

3.4 If the voltmeter reads from 13.6 to 14.2 volts, record this reading (V2) and go to the next step.

If the voltmeter reads less than 13.6 volts, replace the alternator.

4. Perform an alternator amperage output test.

4.1 Connect a carbon pile tester across the vehicle batteries as shown in **Fig. 2**.

Troubleshooting

NOTE: **Figure 2** shows a voltmeter, but the connections for the carbon pile tester are the same.

4.2 Attach a clamp-on induction ammeter around the alternator output wire. See **Fig. 3**.

NOTE: Locate the ammeter at least 6 inches (15 cm) away from the alternator.

4.3 Start the engine and make sure all vehicle electrical accessories are turned off. Run it at fast speed and adjust the tester to the alternator maximum current output. Record this output value.

NOTE: Ensure that the alternator is turning at maximum available rpms and keep adjusting the tester dial until the ammeter reads its highest value.

4.4 Turn off the tester and shut down the engine.

4.5 If the output value recorded is less than 85 percent of the rated amperage output, repeat the test. If the output value recorded is still less than 85 percent of the rated amperage output, replace the alternator.

4.6 Make sure that all test instruments are removed and that the vehicle wiring is returned to its operational state.

5. To identify other problem areas within the vehicle, check the operation of the charging system. Set up the voltmeter as shown in **Fig. 2** and **Fig. 3**.

NOTE: For any load at 1500 rpm or more, battery voltage must be within 0.5 volts of the alternator voltage.

5.1 If readings at the batteries are within 0.5 volts of the readings at the alternator, the charging system is working correctly. Check other areas of the vehicle to locate the problem.

5.2 If the reading at the batteries is more than 0.5 volts lower than the reading at the alternator, do the next step.

6. Check charging system connections, cables and terminals.

6.1 Check all connections between the battery, starter and alternator for tightness and signs of corrosion. Tighten and clean as necessary.

6.2 Check all cables for breaks or partial breaks. Repair or replace as necessary.

6.3 Check each ring terminal for breakage at the point where it attaches to its wire or cable.

General Description

The main function of a cooling system is to keep the engine at its optimum operating temperature. This results in the most efficient use of fuel and allows the engine oil to provide a good lubricating film. For the coolant plumbing for your vehicle, refer to the applicable figure from the list below:

- For a Cummins B Series engine, **see Fig. 1** .
- For a Mercedes-Benz OM 366LA engine, **see Fig. 2**.
- For a Detroit Diesel Series 50 engine, **see Fig. 3**.
- For a Dodge Magnum V-8 engine, **see Fig. 4**.
- For a Caterpillar CFE Series engine, **see Fig. 5**.
- For a Cummins M11 engine, **see Fig. 6**.

The cooling system is a high-flow design, where most of the coolant in a warm engine moves relatively quickly across the radiator in a single pass.

Coolant flows from the radiator to the water pump, which forces the coolant into the engine block. Inside the block, the coolant flows around and between the cylinders, then up into the cylinder head. From the head, it flows to the temperature regulator (thermostat) housing. If the engine is cool, the thermostat directs the coolant back to the water pump, and the water pump forces the coolant back into the engine. As the engine warms, the thermostat directs the coolant to the radiator. The thermostat keeps the engine temperature in the optimum range by controlling the two flows.

To prevent air and vapor from being trapped in the radiator or engine, vent lines rise from the high points where air and vapor would collect in those components. The vent lines carry any collected air to the surge tank.

Possible causes of abnormally high or low coolant temperatures are listed below. For repairs, refer to other sections of this manual or to the engine and component manufacturer's service publications.

This subject contains the following troubleshooting tables:

- Coolant Temperature Above Normal
- Coolant Temperature Below Normal

Problem—Coolant Temperature Above Normal

Possible Cause	Remedy
Coolant leakage (see possible sources below) is causing a low coolant level. External Leakage: hoses and hose connections radiator seams, core, petcock and cap block core and drain plugs water pump thermostat housing surge tank heater hoses and core temperature sending unit(s) cylinder head(s) mating (gasket) surfaces coolant filter oil cooler Internal Leakage: cylinder head gasket warped head or block surfaces cracked cylinder head or block cylinder head capscrews loose, missing, or tightened unevenly oil cooler aftercooler	Do the repairs necessary to stop the leaks. Fill to the surge tank sight glass with the correct mixture of antifreeze and water. Refer to the vehicle maintenance manual for coolant specifications.
The temperature gauge is not working.	Check the gauge wiring, circuit breaker, and sending unit. If the gauge circuit is okay, replace the temperature gauge. If the gauge circuit is broken, repair it and then check the temperature gauge operation.
The radiator, aftercooler, or condenser fins are clogged.	Clean the outside of the core and the condenser with compressed air directed from the fan side, or with water and a mild laundry soap. Straighten bent fins.
A radiator hose is collapsed or plugged.	Replace the hose(s).
A fan belt or water pump belt is loose.	Adjust belt tension.
The cooling fan shroud is damaged.	Repair or replace the shroud.
The radiator cap is incorrect or malfunctioning.	Make sure the correct radiator cap is installed. If the cap does not hold the correct pressure, replace it.
The viscous fan drive is not operating to specifications.	Check for unobstructed airflow through the radiator core, aftercooler, and condenser to the fan clutch sensor. Check that the radiator core is getting hot in front of the fan clutch (core is not internally clogged in that area) so that the sensor is getting a correct reading. If no radiator problems exist, refer to the viscous fan clutch section in this group for fan clutch inspection procedures and operation tests.
The engine oil level is incorrect.	Fill to the high (H) mark on the dipstick.
There is too much antifreeze in the system.	Clean and flush the cooling system. Refill the system with the correct mixture of antifreeze and water.
The thermostat is incorrect or inoperative.	Make sure the correct thermostat is installed in the temperature regulator housing. Test the thermostat according to the engine manufacturer's instructions. Replace it if it does not operate correctly.
The water pump is not working correctly.	Repair or replace the water pump.

Troubleshooting

Possible Cause	Remedy
The radiator core is internally plugged or damaged.	To check for blockages, warm the engine to normal operating temperature. Turn off the engine, and run your hand over the finned surface of the radiator. If there is a blockage in the radiator, it should cause an obvious temperature difference from one area of the core to another. An obvious difference between inlet and outlet temperatures is normal. If blockage is suspected, clean and flush the cooling system. Repair or replace a damaged core.
Air or combustion gases are entering the cooling system.	Check the cylinder heads, head gaskets, cylinder liners, and aftercooler for leaks. Repair or replace parts, as necessary.
The aftercooler is internally plugged or damaged.	Repair or replace the aftercooler.
The oil cooler is internally plugged or damaged.	Repair or replace the oil cooler.
The engine is receiving too much fuel.	Refer to the engine manufacturer's fuel delivery system adjustment procedures.
The wrong replacement fan was installed.	Install the correct fan.
There is exhaust blockage.	Remove the blockage.
Coolant is frozen in the radiator due to subfreezing temperatures.	Use the proper antifreeze-to-water ratio needed for winter temperatures.

Problem—Coolant Temperature Below Normal

Possible Cause	Remedy
The temperature gauge is not working.	Check the gauge circuit wires, circuit breaker, and sending unit. If the gauge circuit is okay, replace the temperature gauge. If the gauge circuit is broken, repair it and then check the temperature gauge operation.
The viscous fan drive operates continuously.	Refer to the viscous fan clutch section in this group for fan clutch inspection procedures and operation tests. Replace the fan drive if necessary.
The thermostat is incorrect or inoperative.	Make sure the correct thermostat is installed. Test the thermostat according to the engine manufacturer's instructions. Replace it if it does not operate correctly.

General Description

The main function of a cooling system is to keep the engine at its optimum operating temperature. This results in the most efficient use of fuel and allows the engine oil to provide a good lubricating film.

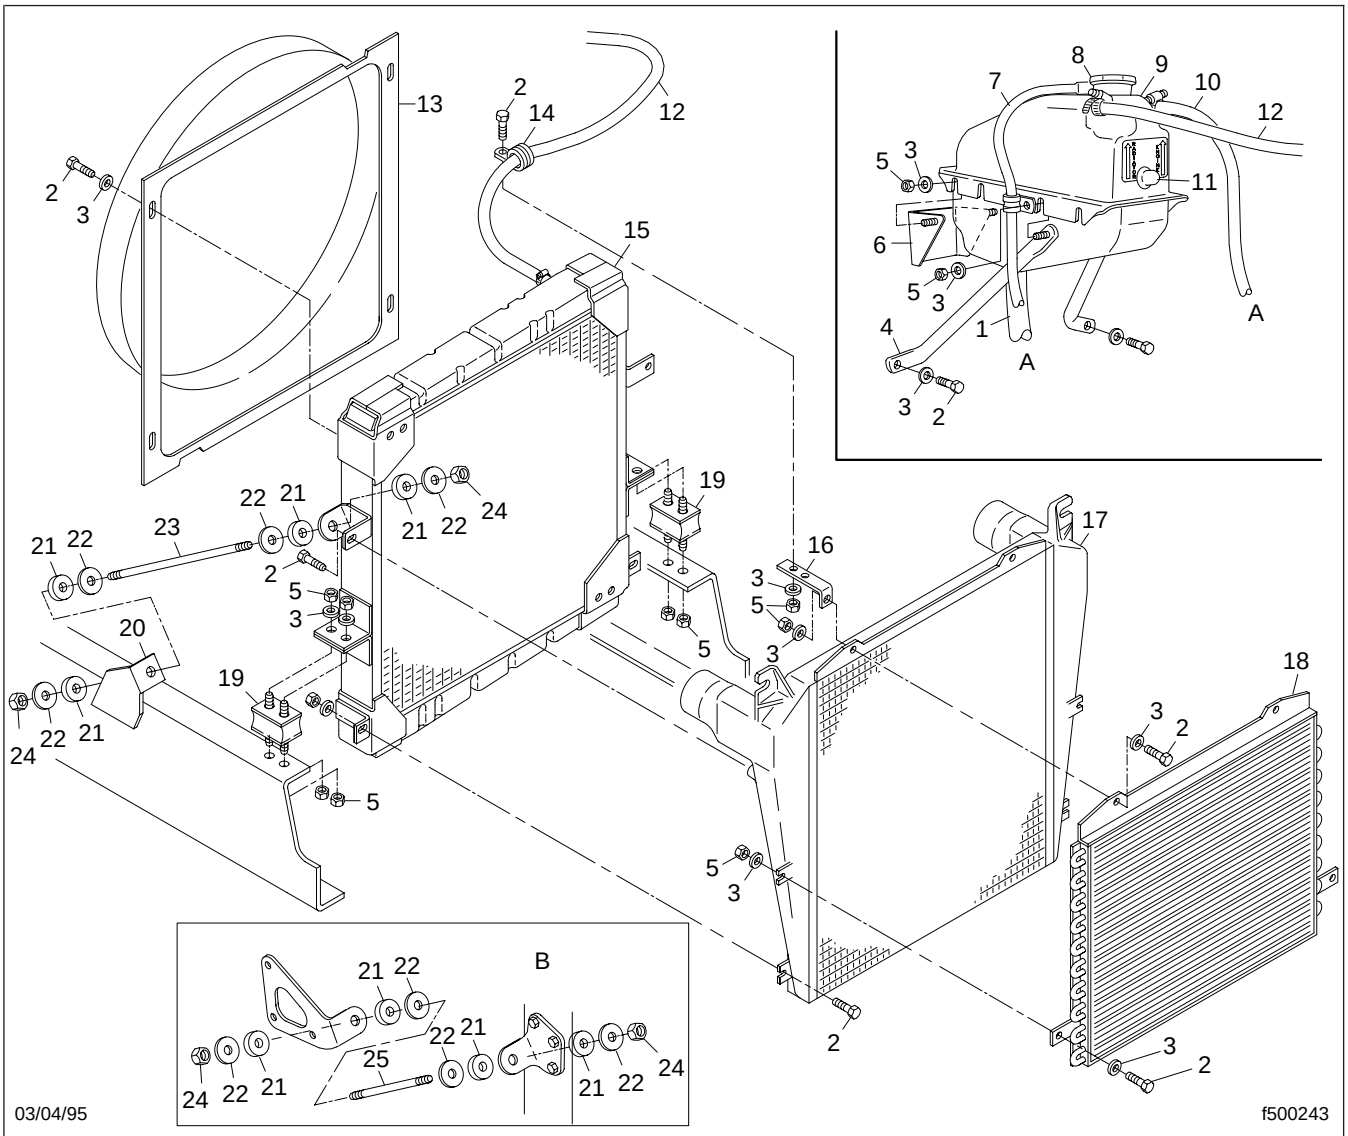
The central component of the cooling system, the radiator assembly, includes the surge tank (remote mounted on the firewall), the radiator, and the surge tank cap. **See Fig. 1**, **Fig. 2**, **Fig. 3**, or **Fig. 4.**

The surge tank provides extra reserve coolant, expansion space for heated coolant, and deaeration space. When coolant in the radiator runs low, reserve coolant stored in the surge tank flows from the tank, through the fill hose, to the water pump. As the coolant heats and expands beyond radiator capacity, excess coolant travels back through the fill hose from the water pump to the extra space in the surge tank. Any air trapped in the engine block or radiator rises to the top of the engine or radiator and escapes through the vent hoses to the surge tank.

Freightliner Medium Trucks use full-flow (or high-flow) radiators. With full-flow radiators, the coolant flows into the radiator at the left of the top tank and flows out of the radiator at the right of the bottom tank. Most of the engine coolant is routed through the radiator, and it moves relatively quickly in a single pass.

There are five sizes of two-row radiators in use:

- 695 square inches
- 720 square inches
- 850 square inches
- 1000 square inches
- 1200 square inches



The core of the smallest radiator is soldered to brass top and bottom tanks, and the tanks and radiator core are held in steel side channels that mount on the frame rails. **See Fig. 5.**

The larger radiators use glass-filled nylon top and bottom or side tanks. The edges of the radiator core header are compressed in a "dimple wave lock" crimp (**see Fig. 6**) that holds the tanks on the radiator core, and the tanks and core are held in steel channels that mount on the frame rails. On the largest radiators, with 850, 1000, or 1200 square inches of front area, the radiator is also secured by brace rods that run between the top of the radiator and the firewall. The fins of the radiator core are reinforced along their forward edge to resist damage from road debris and pressure washing.

Because crimping holds the nylon top and bottom tanks in place, the larger radiators can be disassembled and assembled.

The surge tank cap (**Fig. 1**, **Fig. 2** , **Fig. 3** , or **Fig. 4**) limits system pressure to about 9 kPa (62 psi), which raises the boiling point of the coolant. If the cooling system overheats, excess coolant is released through the overflow tube.

NOTE: There are three types of radiator installations for Medium Trucks:

- *For Caterpillar, Cummins B and C series, Dodge, and Mercedes-Benz engines using the 695- or 720-square-inch radiators,* the radiators are mounted to the frame rails.
- *For Detroit Diesel engines using the 850-square-inch radiator,* the bottom of the radiator is mounted to an underslung support. Brace rods run from the top of the radiator to the firewall to brace the radiator.
- *For Cummins M11 engines using the 1000- or 1200-square-inch radiator,* the bottom of the radiator is mounted to a bracket on the front, closing crossmember. Brace rods run from the top of the radiator to the firewall to brace the radiator.

Use the removal and installation procedures applicable to the vehicle.

Removal

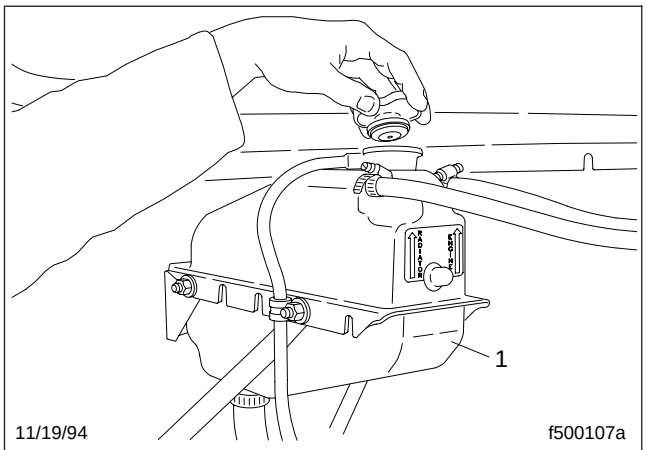
Framerail-Mounted 695- or 720-Square-Inch Radiators

1. Park the vehicle, apply the parking brakes, and chock the tires.

   Tilt the hood.

⚠ WARNING

Do not drain coolant from a hot engine. Opening the cooling system when the engine and coolant are hot can cause severe personal injury due to scalding by the hot, pressurized coolant.



2. Drain the radiator.

   2.1 Remove the radiator surge tank cap. See **Fig. 1**.

   2.2 Open the petcock at the bottom of the radiator to drain the engine coolant. See **Fig. 2.**

Installation

Framerail-Mounted 695- OR 720-Square-Inch Radiators

1. Assemble the radiator and charge air cooler assembly.
   - 1.1 On a work bench, place the radiator on the charge air cooler (**Fig. 14**), and secure it with four bolts and washers. Tighten the bolts 20 N·m (15 lbf·ft). See **Fig. 12**.
   - 1.2 Install the hood cable brackets on the radiator, and tighten the bracket bolts 540 N·cm (48 lbf·in).
   - 1.3 Install the fan shroud with the four sheet metal bolts and washers. Do not tighten the bolts.
2. Install the radiator and charge air cooler assembly.

A. Use a crane to lift the radiator and charge air cooler.

- 2.1 Secure a lifting chain to the charge air cooler, and lift the assembly with a crane.
- 2.2 Position the radiator and charge air cooler assembly on the radiator mounting studs. Secure the assembly to the mounts with nuts and washers, and tighten the nuts 40 N·m (30 lbf·ft). See **Fig. 9.**
- 2.3 Secure the radiator support struts with rubber isolators, washers, and nuts, and tighten the nuts 47 N·m (35 lbf·ft). See **Fig. 9.**
- 2.4 Remove the lifting chain from the radiator assembly.
- 2.5 Connect the coolant outlet hose at the bottom of the radiator.
- 2.6 Connect the radiator vent hose and coolant inlet hose to the radiator. See **Fig. 8.**

When working with T-bolt type hose clamps, tighten the clamps 620 N·cm (55 lbf·in). These clamps are now standard on hoses with an inside diameter greater than 51 mm (2 inches).

Breeze Constant-Torque hose clamps must be tightened to the correct torque. Properly tightened, the screw tip of the clamp should extend about 6 mm (1/4 inch) from the clamp housing, and the Belleville washer stacks must be collapsed

almost flat. Use a torque wrench to install these hose clamps correctly. The correct

installation torque for Breeze Constant-Torque hose clamps is as follows:

For Breeze Constant-Torque hose clamps with a 5/16-inch tightening screw hex: 620 N·cm (55 lbf·in).

For Breeze Constant-Torque hose clamps with a 3/8-inch tightening screw hex: 1020 N·cm (90 lbf·in).

NOTE: All hose clamp adjusters lose torque after installation, due to cold-flow of the hose material from under the clamp. Breeze Constant Torque clamps typically show a 30 percent loss of torque shortly after installation; a 50 percent loss after heat-cycling, and up to 80 percent loss after time and repeated heat cycles. However, when correctly installed, Breeze Constant-Torque clamps adjust automatically, holding enough torque to keep consistent sealing pressure. During vehicle operation and shutdown, the screw tip may adjust in and out, according to temperature and pressure changes. The torque may need to be adjusted for individual applications.

ABA Radial worm-drive hose clamps may lose 30 percent of their torque at the screw adjuster, shortly after being correctly tightened. This is due to cold-flow of the hose material, not an actual loosening of the clamp. This is the way they are designed to work, they should not be tightened further. To check the torque of an ABA clamp, it must be loosened completely, then torqued to the proper value listed in **Table 1**. Overtightening an ABA Radial worm-drive hose clamp can result in coolant leaks.

2.8 Connect the air hoses to the charge air cooler.

3. Secure the fan shroud.

3.1 Adjust the vertical clearance between the top of the fan blade and the fan shroud opening. It should be equal within 1/8 inch (3 mm) to the clearance between the bottom of the blade and the shroud opening.

Crossmember-Mounted 850- TO 1000-Square-Inch Radiators

(See Fig. 15)

1. Assemble the radiator and charge air cooler assembly.
   1.1 On a work bench, place the radiator on the charge air cooler, and secure it with four bolts and washers.
   1.2 Tighten the bolts 20 N·m (15 lbf·ft).
2. Install the radiator and charge air cooler assembly.
   2.1 Place the fan shroud in position around the fan.
   2.2 Secure a lifting chain to the charge air cooler, and lift the assembly with a crane.
   2.3 Place the upper radiator isolator and washer on the hole in the support bracket, and position the radiator and charge air cooler assembly on the support. Hold the lower radiator isolator and washer in position, and secure the assembly to the support with locknuts.

   For 850-square-inch radiators: tighten the locknuts 327 N·m (241 lbf·ft).

   For 1000-square-inch radiators: tighten the locknuts 122 N·m (90 lbf·ft).

   2.4 Secure the radiator brace rods to the top of the radiator with bolts, washers, and locknuts.

   For 850-square-inch radiators, tighten the locknuts 92 N·m (68 lbf·ft).

   2.7 Connect the radiator vent hose and coolant inlet hose to the radiator.
   2.8 Remove the seals from the coolant hose ends, connect the hoses to the radiator, and tighten the hose clamps.
   2.9 Connect the air hoses to the charge air cooler. Tighten the constant torque hose clamps 680 N·cm (60 lbf·in).
3. Secure the fan shroud.
   3.1 Adjust the vertical clearance between the top of the fan blade and the fan shroud opening. It should be equal within 1/8 inch (3 mm) of the clearance between the bottom of the blade and the shroud opening.
   3.2 Tighten the screws 1220 N·cm (108 lbf·in).
4. Install the condensor on the charge air cooler, and secure it with the four mounting bolts. Tighten the bolts 20 N·m (15 lbf·ft).
5. Route and clamp the refrigerant lines.
6. Install the hood. For instructions, refer to **Group 88** in the vehicle service manual.
7. Fill the coolant system, and install the surge tank cap.
8. Start the engine and check for coolant leaks. Repair any leaks. After idling the engine for 15 to 20 minutes, add more coolant if necessary.

9. Lower the hood, and remove the chocks from the tires.

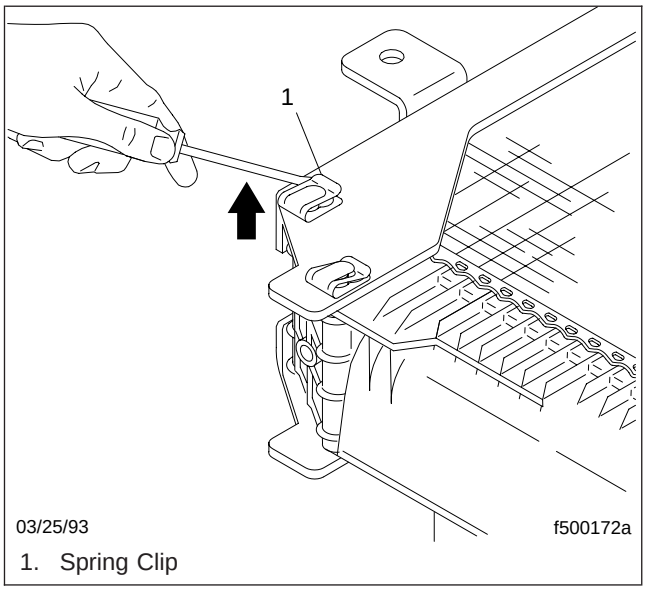
Disassembly

Before disassembling the radiator, pressure flush it and check the surge tank, following the instructions in the radiator group of the vehicle maintenance manual. Clean and check the exterior of the radiator, following the instructions in the vehicle driver's manual.

1. Remove the radiator from the vehicle; for instructions, refer to **Subject 100** .



⚠ CAUTION

CAUTION: Use care when handling or supporting the nylon top and bottom tanks. Failure to do so could damage the tanks.

2. Remove the side channels from the radiator assembly.

   2.1 Remove the eight spring clips that hold the side channel mounting pins in position. **See Fig. 1.** Insert a screwdriver blade in the open end of each clip, and pry the clip open until it clears the edge of the mounting pin. Then, slip the clip off the pin.

   2.2 Use a rubber mallet and a punch to tap out the eight mounting pins. **See Fig. 2.**

   2.3 Slip the side channels off the radiator core and tank assembly. **See Fig. 3.**

3. Leak test the radiator core and tank assembly.

Radiator Disassembly and Assembly

2. Radiator Core

Fig. 3

3.1 Securely plug all tank ports.

CAUTION

CAUTION: Don't apply a higher amount of pressure than specified below; too much pressure will damage the radiator core.

3.2 At one tank port, install a pressure regulator and gauge. Using a hand pump, apply 138 kPa (20 psi) air pressure through the port.

3.3 Submerge the radiator in a tank of water and check it for leaks. Mark any leaks for repair. If a leak is between the radiator core header and a tank, remove the tank and inspect the tank flange, the header sealing surface, and the sealing gasket. If the leak is in the core, but within 7.5 cm (3 inches) of the tank, remove the tank before repairing the leak. If the leak is in the tank, replace the tank.

4. Remove the top and bottom tanks.

4.1 Place the radiator core and tank assembly in the disassembly/assembly fixture, and clamp the assembly securely in place. **See Fig. 4**

4.2 Position the tank clamping cylinders evenly across the top of the tank. Make sure the cylinders' rubber plungers will not press against breakable fittings, such as vent tube ports.

CAUTION

CAUTION: Apply only enough pressure to compress the sealing gasket. Too much pressure will crack the nylon tank.

4.3 Apply pressure evenly across the top of the tank until the tank-to-core sealing gasket is compressed enough to show a small gap between the bottom of the dimple wave lock crimp and the tank sealing flange.

CAUTION

CAUTION: In some places, especially around the tank ports, the wave lock crimps may have to be unlocked with a screwdriver. When using a screwdriver, use care not to crack or gouge the nylon tank.

4.4 Place the T-bar into the T-bar groove in the disassembly/assembly fixture. **See Fig. 5.**

4.5 Slide the hooked-end bar over the T-bar. Place the hook over the top of the wave crimp and pull the T-bar back to unlock the crimp. **See Fig. 5 .**

4.6 Slide the hooked-end bar and the T-bar down the T-bar groove to the next wave crimp, and repeat the previous step until all the wave crimps are unlocked.

5. Once the wave crimps are unlocked, remove the tank.

5.1 Release the pressure from the tank, and move the clamping cylinders off the radiator core and tank assembly.

Radiator Disassembly and Assembly

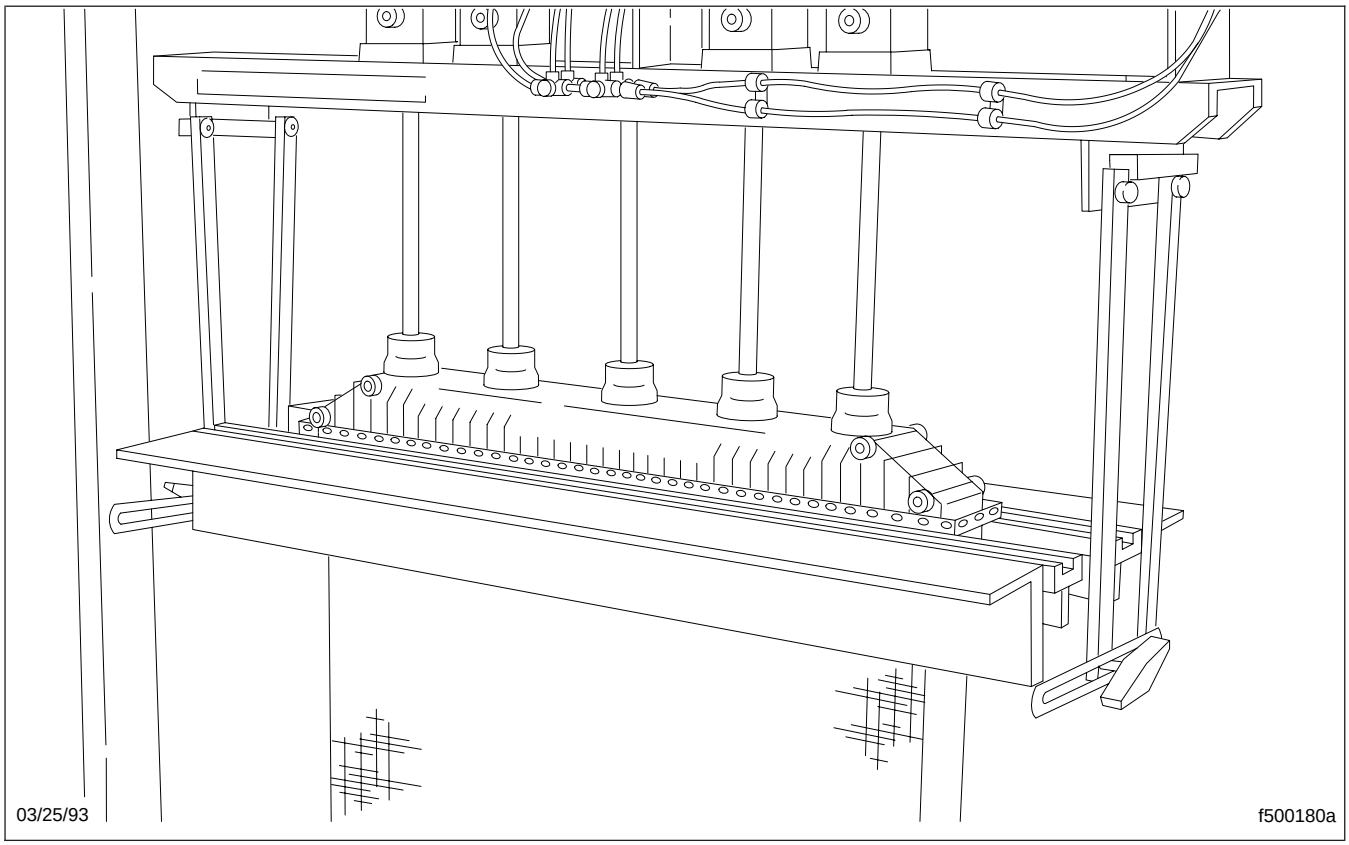

Fig. 4

CAUTION

CAUTION: If needed, use a rubber mallet or the heel of your hand and tap the side of the tank to loosen it. Do not use a screwdriver against the tank sealing flange. A screwdriver blade may damage the flange and prevent a good seal after the tank is installed.

5.2 Lift the tank from the forward side, the side opposite the tank ports. Remove the nylon tank from the radiator core. **See Fig. 6.**

5.3 Remove the sealing gasket from the sealing surface of the radiator core header. **See Fig. 7 .**

5.4 Clean the sealing surface of the radiator core header.

5.5 Repair any leaks marked during leak testing, step 3.

5.6 Repeat steps 4 and 5 to remove the opposite tank.

IMPORTANT: Check the tubes of the radiator core for scale deposits. If the radiator has been pressure-flushed, and the tubes are still clogged, the radiator should be rodded or boiled out with acid by an experienced radiator shop. Otherwise, replace the core.

Assembly

1. Install the nylon top and bottom tanks on the radiator core.

1.1 With the radiator securely clamped in the disassembly/assembly fixture, header sealing surface up, make sure the bottom of the radiator core and tank assembly is completely supported, and that the

Radiator Disassembly and Assembly

2. Gasket

Fig. 7

header sealing surface is free of any dents, tool marks, or foreign particles.

1.2 Lubricate a new sealing gasket with a soap and water solution, and position the gasket on the header sealing surface. **See Fig. 7.** To make sure the gasket is not twisted, run a finger along the gasket as it lies on the sealing surface. The mold lines of the gasket should be on the outside and inside diameters of the gasket; if you can feel a mold line cross over the top of the gasket, the gasket is twisted.

1.3 Inspect the tank sealing flange. The flange must be clean and free of defects. If the sealing flange is damaged, replace the tank.

1.4 Place the tank on the gasket, and tap the tank with a rubber mallet or the heel of your hand to seat the tank. Make sure the tank ports are facing the correct direction.

1.5 Position the tank clamping cylinders evenly across the top of the tank. Make sure the cylinders' rubber plungers will

not press against breakable fittings, such as vent tube ports. **See Fig. 4.**

CAUTION

CAUTION: Apply only enough pressure to compress the sealing gasket. Too much pressure will crack the nylon tank.

1.6 Apply pressure evenly across the top of the tank until the tank-to-core sealing gasket is compressed enough to show a small gap between the bottom of the dimple wave lock crimp and the tank sealing flange.

1.7 Place the T-bar into the T-bar groove in the disassembly/assembly fixture.

1.8 Slide the wave form bar over the T-bar, and center the bar in front of the wave crimp slot.

CAUTION

CAUTION: Do not push the wave crimp until it touches the side of the nylon tank, or the tank may crack.

1.9 Push the T-bar forward to crimp the header's edge until it almost touches the tank's side. **See Fig. 8.**

1.10 Slide the tools down the T-bar groove to the next wave crimp slot, and repeat steps 1.8 and 1.9 until all the wave crimps are crimped.

CAUTION

CAUTION: In some places, especially around the tank ports, the wave crimps may have to be crimped with a screwdriver. When using a screwdriver, use care not to crack or gouge the nylon tank.

1.11 Release the pressure from the tank, and move the clamping cylinders off the radiator core and tank assembly.

1.12 Repeat step 1 to install the opposite tank.

2. Leak test the radiator core and tank assembly. For instructions, refer to "Disassembly."

3. Install the radiator side channels.

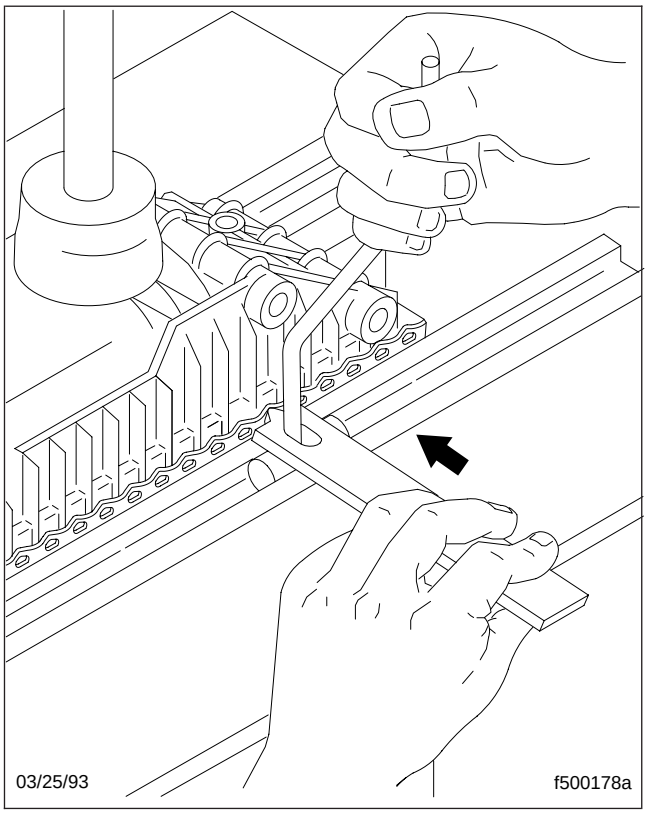

Fig. 8

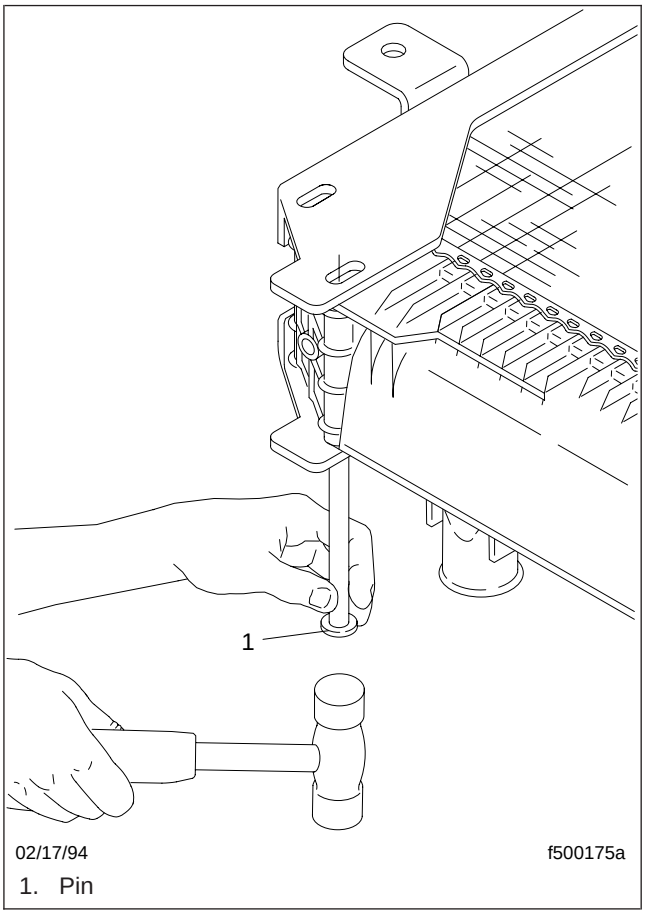
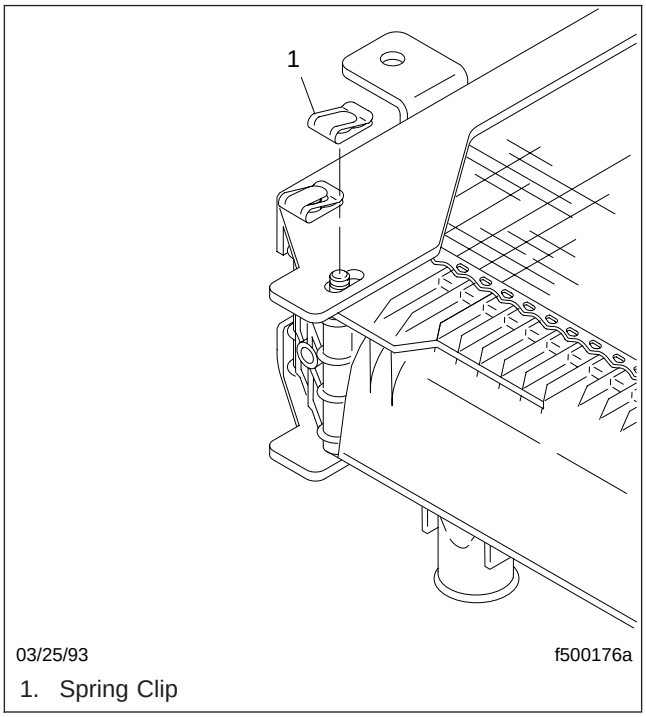


3.1 Slide the side channels onto the radiator core and tank assembly.

3.2 Using a rubber mallet and a punch, install the eight mounting pins through the side channel holes and tank bosses. **See Fig. 9.**

3.3 Install the eight spring clips to secure the mounting pins in position. **See Fig. 10.** To install each clip, place the clip over the end of the mounting pin, and slide the clip until it engages the groove in the pin and the open end of the clips snaps over the edge of the pin. If necessary, use a clamp to compress the side channel while installing the clips.



4. Install the radiator in the vehicle. For instructions, **refer to Subject 100.**

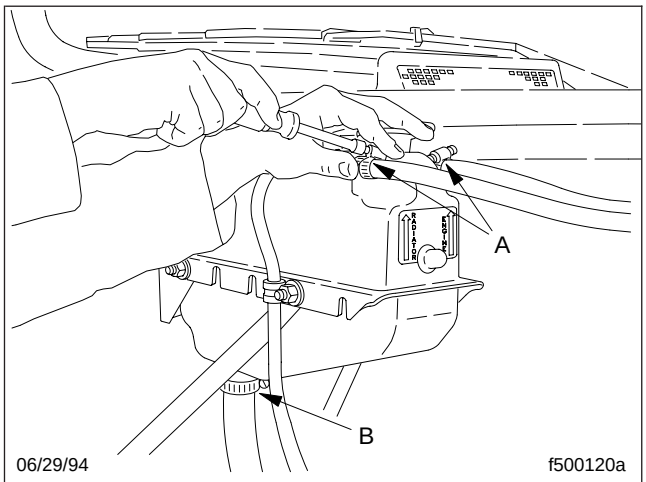
Surge Tank Removal and Installation

Removal



NOTE: In Business Class vehicles, Freightliner mounts the remote surge tank in two ways. In vehicles equipped with Cummins M11 or Detroit Diesel Series 55 engines, the surge tank is mounted on the driver's side of the bulkhead. **See Fig. 1.** In vehicles equipped with other engines, the surge tank is mounted on the passenger's side of the bulkhead. **See Fig. 2.**

B. Disconnect the fill hose.

Fig. 2, Surge Tank Mounting for All Engines Except a Cummins M11 or a Detroit Diesel Series 55 Engine

⚠ WARNING

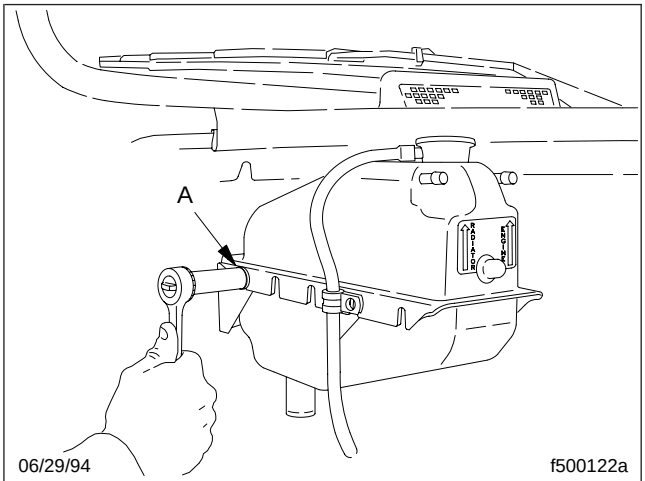
Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

3. Drain the radiator.
   - 3.1 Remove the surge tank cap.
   - 3.2 Open the petcock or remove the drain plug on the bottom of the radiator to drain the engine coolant. Drain only enough coolant to empty the surge tank.
4. Remove the surge tank.

   NOTE: Cap all the disconnected hoses to prevent the remaining coolant from spilling.

   - 4.1 Disconnect the engine and radiator vent line from the front of the surge tank.
   - 4.2 Disconnect the fill hose from the bottom of the surge tank.
   - 4.3 *On M11 and Detroit Diesel Series 55 engines,* remove the nuts that hold the tank to the bracket. **See Fig. 1.** Then, lift the tank out of the bracket.

     On other engines, remove the two surge tank support struts. **See Fig. 3.**



Surge Tank Removal and Installation

Then, loosen the surge tank mounting nuts (**see Fig. 4**), and remove the tank by lowering the front end first. **See Fig. 5.** Lift the rear end off the mounting bracket, and remove the tank.

Installation

1. If the surge tank sight glass has been removed, replace it by twisting it into the sight glass hole clockwise. Make sure the rubber seal ring is in place on the sight glass.
2. Install the surge tank.
   - 2.1 *On M11 and Detroit Diesel Series 55 engines,* place the surge tank in the bracket. **See Fig. 1.** Then, secure the tank with nuts, and tighten the nuts 30 lbf·ft (40 N·m).
   - 2.2 *On other engines,* install the surge tank on its mounting bracket by placing the two rear mounting studs in the bracket notches and installing the mounting nuts. **See Fig. 4.** Tighten the nuts 30 lbf·ft (40 N·m).
   - 2.3 Install the two support struts. **See Fig. 3.** Tighten the strut nuts 30 lbf·ft (40 N·m).
3. Connect the hoses to the tank.
   - 3.1 Connect the surge tank fill hose. **See Fig. 2.**
   - 3.2 Connect the engine and radiator vent hoses to the front of the tank.
4. Fill the coolant system, and install the surge tank cap.

5. Start the engine and check for coolant leaks. Repair any leaks.
6. Lower the hood, and remove the chocks from the tires.

Pressure Testing

1. Remove the radiator. For instructions, **refer to "Radiator Removal and Installation, 100."**
2. Pressure test the radiator as follows:
   - 2.1 Leaving the coolant inlet port open, plug the outlet, and all other ports on the radiator.
   - 2.2 Using the necessary adaptor, connect a pressure regulator and a gauge on the coolant inlet port. Use a hand pump to apply 138 kPa (20 psi) air pressure through the inlet port.

⚠ CAUTION

CAUTION: Don't apply a higher amount of air pressure; too much pressure will damage the radiator core.

   - 2.3 Submerge the radiator in a tank of water and check it for leaks. Remove the radiator from the water.
   - 2.4 Remove the plugs and testing gauge. Repair the radiator, if necessary.
3. Install the radiator. For instructions, **refer to "Radiator Removal and Installation, 100."**

NOTE: For additional troubleshooting information, refer to Section 20.00.

Visual Check

It's a sound service practice to give the cooling system a quick visual check whenever you tilt the hood. Look for signs of visible leaks (or the stains they leave), especially on the engine block. A final check is to look at the inside of the oil breather cap for signs of a milky substance —which means that coolant is leaking into the oil.

Air Conditioner Condensor and Air-to-Air Aftercooler

Since the condensor and aftercooler are right in front of the radiator, air must pass through them to get to the radiator. For the heat transfer process to take place, the fins of the radiator , the condensor, and the aftercooler must be free of blockages and deposits such as dirt or bugs. Clean the surfaces with compressed air or water and a mild laundry soap.

Also remember that because the three heat-transfer parts are so close to each other, heat will pass between them. A blocked condensor will transfer its heat to the aftercooler and a hot aftercooler will transfer its heat to the radiator.

Radiator Cap

The radiator cap is the most often ignored part in the cooling system. If it's suspect, replace it. An inspection means checking the cap with a pressure tester. A radiator cap in good condition will not open below 62 kPa (9 psi). A visual check is also in order: look for signs of deterioration on the inner gasket. Also look for cracks or breaks in the spring retainer in the cap and for corrosion or deposits on the spring itself. If the spring is not in perfect condition, it has probably lost tension; replace it.

Engine Coolant

Check the level of the coolant at the surge tank. It should be up to the sight glass.

If the engine coolant is dirty or its color is beginning to fade, change it. It should also be replaced if it has a dead fish smell.

Be sure that the mixture is correct. Refer to the maintenance manual for specifications.

Radiator

Radiator problems are limited to external leaks, which can be spotted visually, and internal blockages, assuming that there is good airflow and that the radiator is large enough to do the job.

To check for blockages, warm the engine to normal operating temperature. Shut down the engine, and pass your hand in front of the finned surface of the radiator. If there is a blockage in the radiator it should cause an obvious temperature difference from one area of the core to another. An obvious difference between inlet and outlet temperatures, however, is to be expected.

Fan

Refer to the applicable section in this group for fan and fan clutch checks.

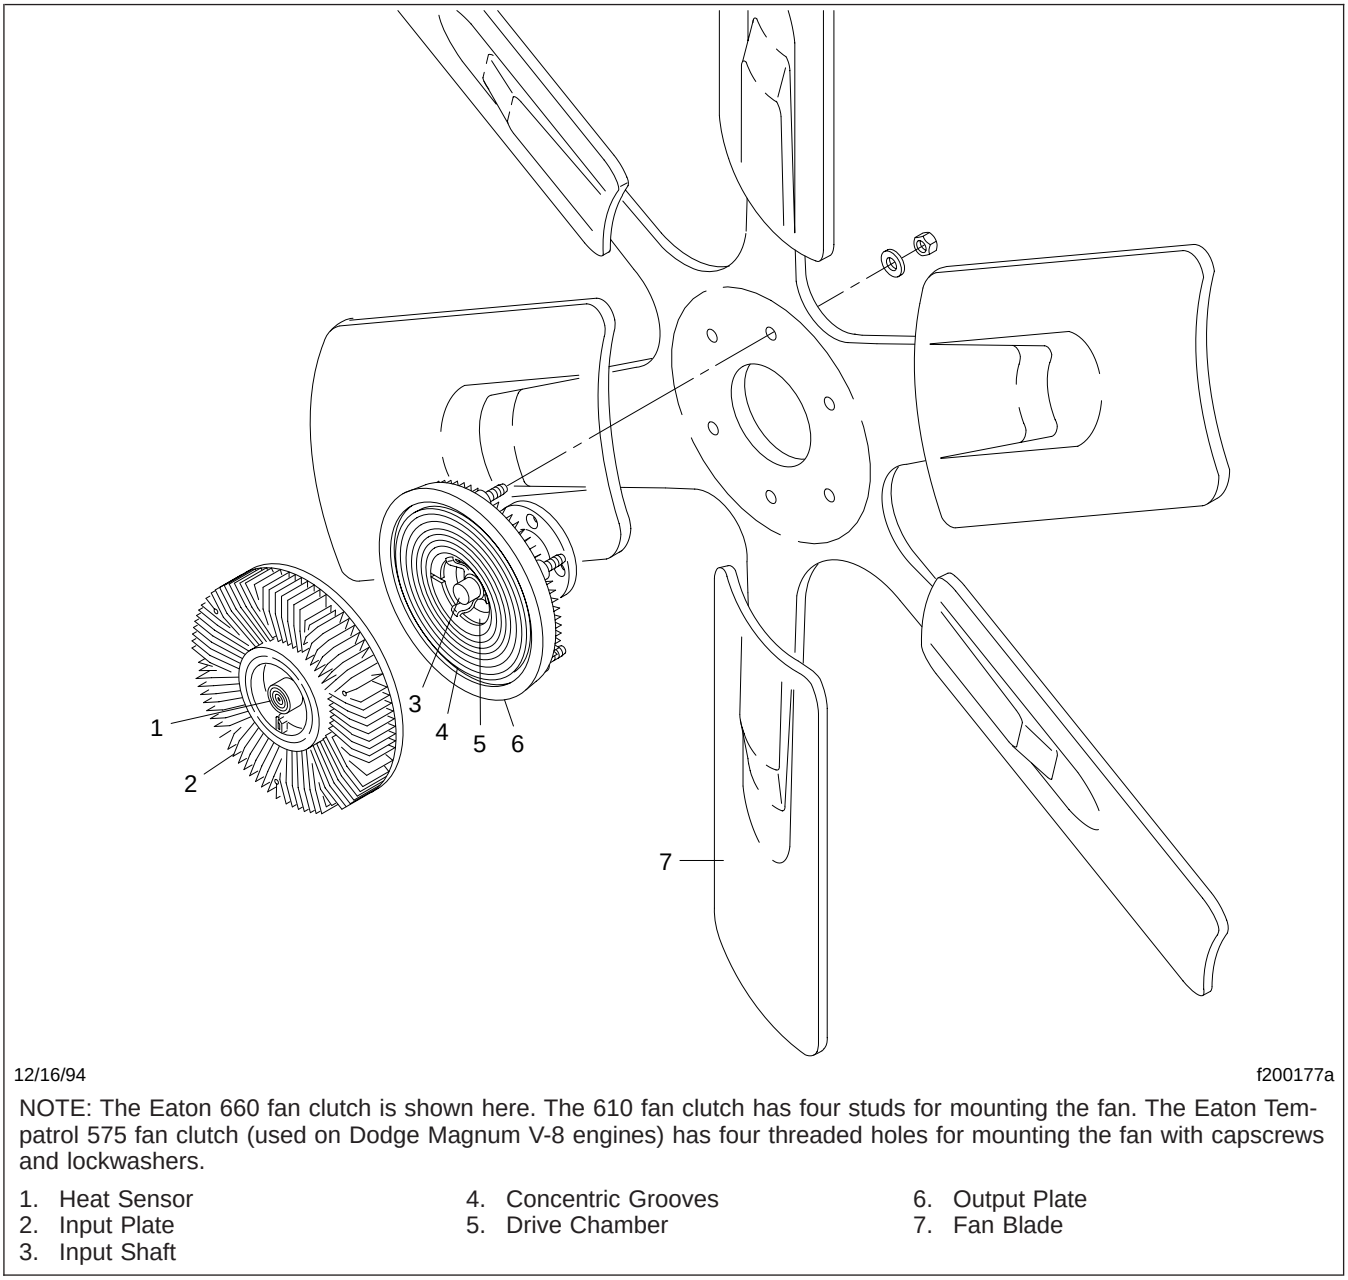
General Description (See Fig. 1)

The fan drive senses the air temperature behind the radiator core, and engages or disengages the fan depending on that temperature. An increase or decrease in the amount of heat from the radiator coolant causes a change in the air temperature behind the radiator core. A coiled metal heat sensor (Ref. 1) on the fan drive detects the temperature change; it engages the fan clutch when more cooling (airflow) is needed, and disengages it when the engine is sufficiently cooled.

The fan clutch consists of two basic parts: the input plate and shaft (Refs. 2 and 3), and the output plate (Ref. 6). The input shaft is mounted to the fan hub so it and the input plate are constantly turning as the engine runs. The output plate carries the fan blades (Ref. 7) but engages with the input plate only when extra engine cooling is needed.



When the fan is disengaged, a single bearing allows the output plate and fan to free-wheel in relation to the input shaft and plate. Both the output and input plates are lined with concentric grooves (Ref. 4) which intermesh with very close tolerance.

To engage the fan, the heat sensor on the front of the clutch opens a valve in the clutch's drive chamber (Ref. 5). The centrifugal force of the turning input plate forces the viscous (thick) silicone fluid stored in the drive chamber to flow out. The fluid flows between the concentric grooves of the input and output plates, creating friction between the two plates. As that friction increases, the output plate and fan begin to turn with the input plate. The fluid continues to spread out between more grooves, increasing the friction between the plates until they spin at about the same speed.

When air passing through the radiator is cool enough, the heat sensor disengages the fan clutch. It does this by closing the valve in the drive chamber, which stops the flow of silicone fluid to the input and output plates. For the fluid already between the plates, centrifugal force continues to push it outward until it's beyond the grooves. There, at the outer edge of the clutch, it returns through a passage in the input plate to the drive chamber.

Again, without the fluid to create friction between the two plates, the output plate and fan free-wheel in relation to the input plate and input shaft.

Fan Clutch Inspection and Operation Checking

Inspection

CAUTION

CAUTION: If the fan drive assembly is damaged, promptly replace the unit. Operating a vehicle with a seized or otherwise damaged clutch reduces fuel economy, and could cause serious engine damage.

The fan drive is only one part of the cooling system and will function well only if all other parts of the system are working right. All parts of the system should be checked if there is a cooling problem. Do all the checks in the cooling system troubleshooting section in this group, and pay special attention to the fuel flow rate and exhaust temperature. Over-fueling can cause engine overheating and high exhaust temperatures.

1. With the engine off, rotate the fan at least one full turn by hand. It should have a smooth, steady drag. If it doesn't, replace the fan clutch.
2. Check for physical damage to the fan or fan shroud.
3. Inspect the fan clutch mounting.
   - 3.1 Check the torque of the nuts holding the fan input shaft to the fan hub or mounting adapter (diesel engines), or the torque of the internally threaded fan hub nut to the engine shaft (gasoline engines). They should be tightened as follows:
     - Fan clutch input shaft to fan hub, Cummins B Series engine: 61 N·m (45 lbf·ft);
     - Fan clutch input shaft to fan hub, Cummins C Series engine: 46 N·m (34 lbf·ft);
     - Fan clutch input shaft to adapter, Mercedes-Benz OM 366LA engine: 61 N·m (45 lbf·ft);
     - Fan clutch mounting adapter to fan hub, Mercedes-Benz OM 366LA engine: 35 N·m (25 lbf·ft);
     - Internally threaded fan hub nut to engine shaft, Dodge Magnum V-8 engine: 50 to 62 N·m (37 to 46 lbf·ft).
   - 3.2 Check for wear of the fan clutch bearings. There should be no side-to-side or in-and-out movement of the fan clutch.

Operation Checking

Use the following procedure to check for correct engagement and disengagement of the fan clutch.

1. Coolant temperature in the radiator should be below 60°C (140°F) before the start of the test; the outside temperature should be above 10°C (50°F). Ideally, a temperature probe placed about 13 mm (1/2 inch) from the fan clutch sensor is needed to see if the fan clutch engages at the right temperature.
2. Disconnect any hydraulic pumps (such as the power steering pump) to prevent oil overheating.
3. Get a piece of cardboard that is large enough to block the entire front of the radiator. Cut a round 18-centimeter (7-inch) hole in the cardboard; locate the hole so that it lines up with the fan clutch. Don't put the cardboard in front of the radiator yet.

WARNING

Before starting the engine, make sure people's hands and all other objects are away from the fan blades. It is extremely dangerous to get too close to the fan blades when the engine is on, because the fan could start operating without warning. Do not try to restrict the fan blade rotation when the engine is on.

4. Turn off the air conditioner, if so equipped. Start the engine, and let it idle until the oil pressure is normal.
5. As soon as there is normal oil pressure, bring the engine up to high idle (about 80 percent of governed engine speed) and lock the throttle at this speed.

   If the engine has been idle for more than eight hours, the fan clutch may engage as soon as the engine is started. If this happens, the usual noise from the fan will be heard; the noise will stop after five minutes or less, when the fan clutch disengages.
6. After the fan clutch disengages, put the cardboard in front of the radiator.

Fan Clutch Inspection and Operation Checking

7. Look at the temperature gauge and note at what point the engine thermostat opens. As the engine warms up, the coolant temperature will rise steadily and then seem to level off after the thermostat opens. It will then start rising again, before the fan clutch engages.
8. Keep watching the coolant temperature and, if possible, the temperature of the air in front of the fan clutch, until the clutch engages. Note the temperature(s) at which the clutch engages. The fan should be fully engaged when the air at the fan clutch sensor rises to about:

   Diesel Engines: 68° to 74°C (155°to 165°F).

   Gasoline Engines: 74° to 80°C (165°to 180°F).

   With the clutch engaged, the coolant temperature will keep rising, at a slower rate, as long as the radiator is blocked with cardboard.
9. Remove the cardboard from in front of the radiator. Keep watching the coolant temperature while the clutch is engaged; you should notice a decrease after the cardboard is removed.
10. The fan should disengage when the air temperature at the fan clutch sensor drops to about:

    Diesel Engines: 49° to 54°C (120°to 130°F).

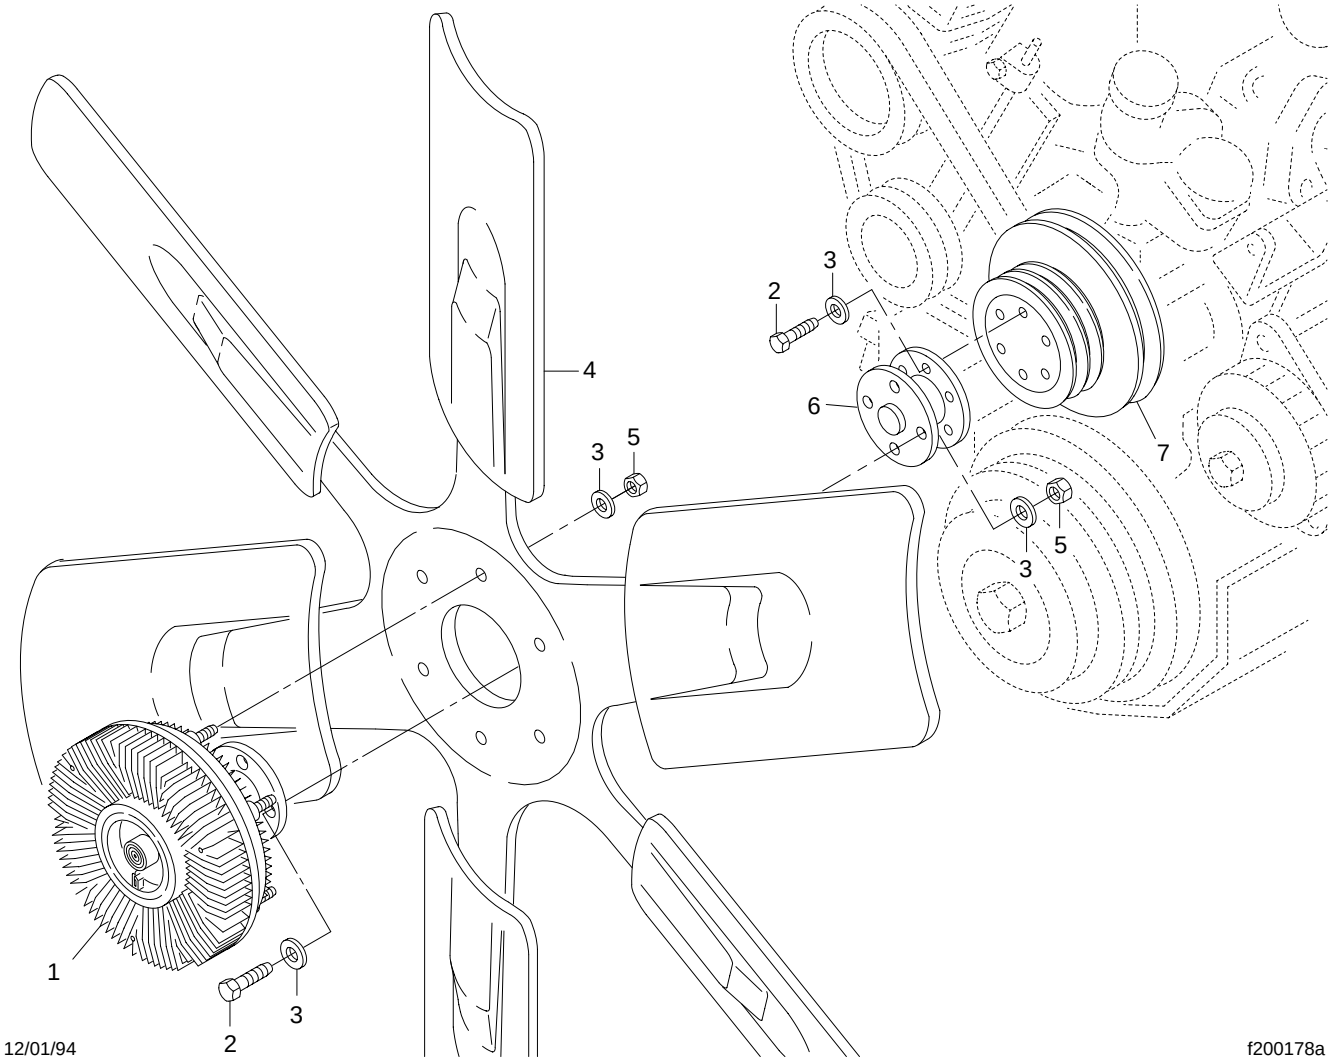
    Gasoline Engines 57° to 79°C (135°to 175°F).

    If the coolant temperature keeps rising, even though the fan is engaged and the cardboard has been removed, the fan clutch may be working okay; the problem is probably in another part of the cooling system.

IMPORTANT: If the air temperature in front of the clutch is being tested, and it does not rise as the coolant temperature rises, then the problem could be a clogged radiator or a stuck engine thermostat.

If the engine still overheats during operation, even though everything described above checks out okay, use a stroboscope to check peak fan speed. The fan speed should be at least 93 percent of the fan pulley speed when the clutch is fully engaged.

Example:



2160 = Fan pulley speed x .93 = 2009 = 93 percent of fan pulley speed

Fan speed must be at least 2009 rpm when the fan clutch is fully engaged.

Removal (See Fig. 1, Fig. 2 , or Fig. 3)

1. Shut down the vehicle, apply the parking brakes, chock the tires, and (if applicable) drain the air system.

   Disconnect the battery ground cable at the vehicle frame.
3. Tilt the hood.
4. *On diesel engines:* remove the capscrews and

If necessary, on Mercedes-Benz OM 366LA engines, remove the capscrews and lockwashers (**Fig. 1**, Refs. 2 and 3) that secure the fan clutch adapter (Ref. 6) to the fan hub. Remove the adapter from the fan hub.

5. *On gasoline engines:* place a bar or screwdriver between the water pump pulley bolts to keep the pulley from turning. Then, use a wrench to turn the fan hub nut counterclockwise as viewed from the front of the vehicle. Unscrew the fan hub nut from the engine shaft, and remove the fan clutch from the engine.
6. Remove the nuts and lockwashers (diesel engines), or capscrews and lockwashers (gasoline engines) that hold the fan blade to the clutch. Remove the blade.

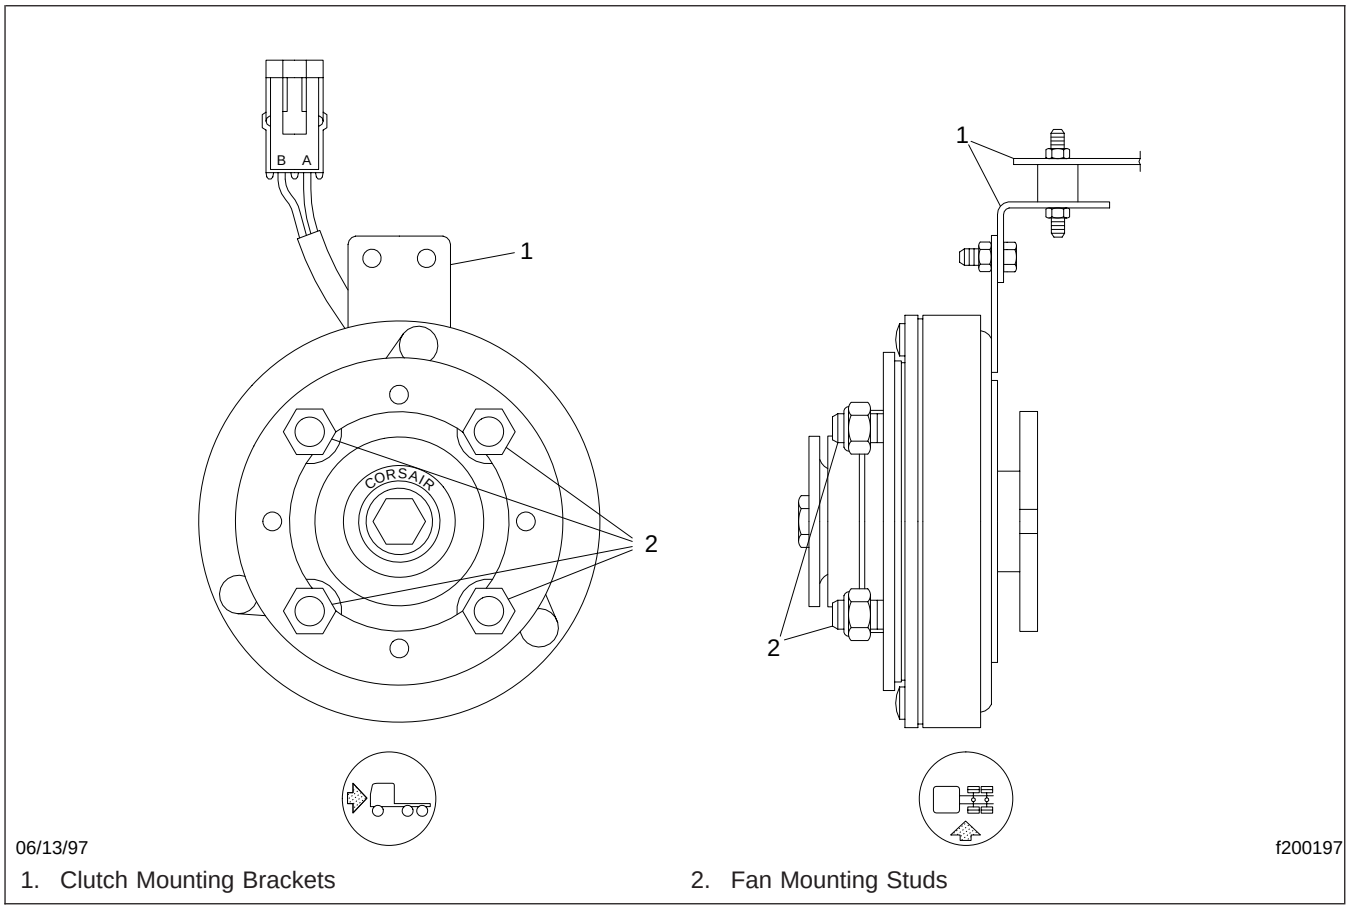
Installation (See Fig. 1, Fig. 2 , or Fig. 3)

1. Install the fan blade on the fan clutch. Tighten the fan mounting locknuts as follows:
   - Model 610: 54 N·m (40 lbf·ft);
   - Model 660: 30 N·m (22 lbf·ft);
   - Model 575: 20 to 27 N·m (15 to 20 lbf·ft).

NOTE: Use only approved fans, as specified in the *Freightliner Parts Technical Information Manual.* Never go over the maximum input speeds, and do not make changes to the engine that will raise the operating speed of the fan.



2. On Mercedes-Benz OM 366LA engines (**see Fig. 1**), if the fan clutch adapter (Ref. 6) was removed, mount it on the fan hub. Tighten the mounting capscrews 35 N·m (25 lbf·ft).
3. Install the fan clutch assembly. Tighten the fasteners as follows:
   - Mercedes-Benz OM 366LA engines (**Fig. 1**, Ref. 2): 61 N·m (45 lbf·ft);
   - Cummins B Series engines (**Fig. 2**, Ref. 2): 61 N·m (45 lbf·ft);
   - Cummins C Series engines: 46 N·m (34 lbf·ft);
   - Dodge Magnum V-8 engines (**Fig. 3**, Ref. 1): 50 to 62 N·m (37 to 46 lbf·ft).
4. Lower the hood, connect the batteries, and remove the chocks from the tires.

General Information (See Fig. 1)

Fig. 1, Horton EC450 Electromagnetic Fan Clutch

The Horton EC450 fan clutch (previously marketed as the Corsair fan clutch) is an electromagnetic on/off-style engine cooling fan clutch. The fan clutch is electrically operated, and is not connected to the vehicle's air system.

When vehicle motion (ram air effect) provides enough airflow through the radiator to keep engine coolant temperature within operating limits, the fan is disengaged by de-energizing the fan clutch. Disengaging the fan saves fuel, lowers power consumption and engine noise, and—for cold starts—allows the engine and the cab to warm up faster.

When the vehicle is stationary, or whenever extra air flow through the radiator is necessary, the fan clutch is engaged to connect the fan with the fan drive pulley and provide extra engine cooling. On most vehicles, this extra cooling is seldom needed—the clutch is deactivated and the fan is not turning 90 to 95 percent of the time.

There are several different methods of fan control depending on whether or not the vehicle is equipped with air conditioning, and whether or not it is equipped with an engine protection system.

WITHOUT AIR CONDITIONING OR ENGINE PROTECTION SYSTEM

If the vehicle isn't equipped with air conditioning or an engine protection system, a single switch (see **Fig. 2**) in the engine water jacket controls the fan clutch. The switch is "open" until engine coolant temperature rises above a preset limit, usually 200°F (93°C) or 205°F (96°C). Then, the switch closes, en-

General Information

ergizing the electromagnetic clutch, which engages the fan. When coolant temperature drops below a preset point, usually about seven degrees below the switch closing point, the switch again "opens" to deactivate the fan.

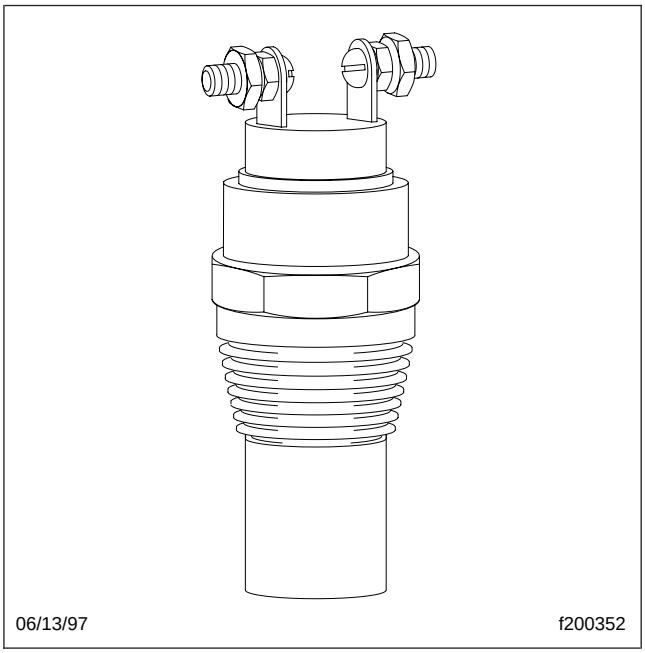

Fig. 2, Coolant Temperature Switch

WITH AIR CONDITIONING, WITHOUT ENGINE PROTECTION SYSTEM

When the vehicle is equipped with air conditioning, but not an engine protection system, coolant temperature on/off control of the fan is the same as mentioned above. With air conditioning added, however, a normally-open refrigerant pressure switch (an "override" switch), is installed on the receiver-drier. See **Fig. 3**. When refrigerant system high-side pressure rises above a preset limit, usually about 275 psi (1896 kPa) the switch closes and activates the fan, regardless of engine coolant temperature. When pressure drops to about 225 psi (1551 kPa), the switch "opens" to deactivate the fan.

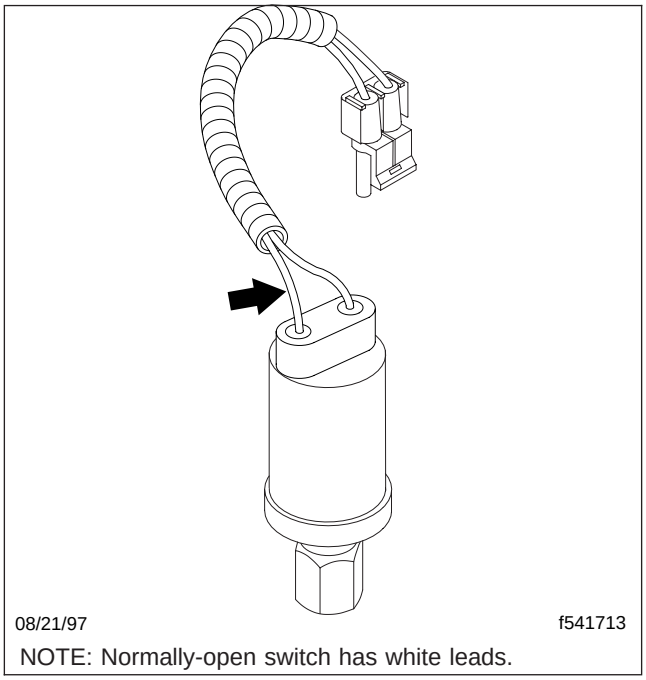

Fig. 3, A/C Override Switch, Without Engine Protection System

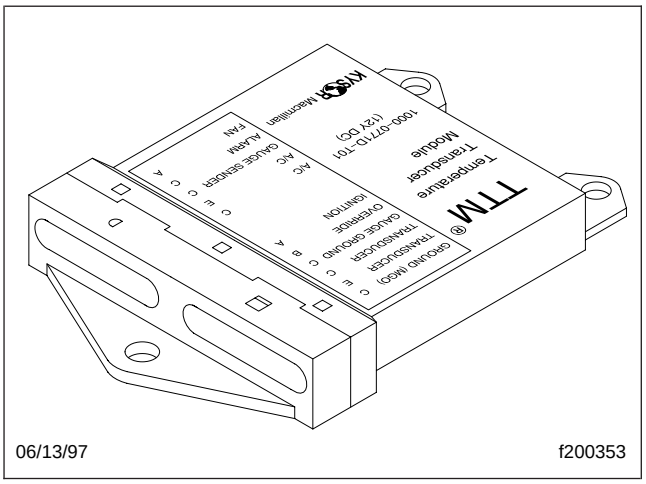
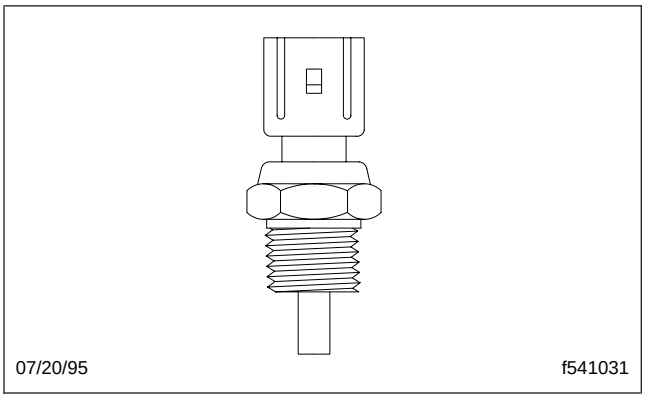


WITHOUT AIR CONDITIONING, WITH ENGINE PROTECTION SYSTEM

If the vehicle is equipped with an engine protection system, the coolant temperature sensor is installed in the engine water jacket port that would otherwise be used for the fan clutch control. Instead of finding another location for the fan switch, the method of controlling the fan (and other functions) is changed.

A Kysor Temperature Transducer Module (TTM), installed behind the instrument panel, is used to control the fan clutch, the engine protection system, and the coolant temperature gauge. See **Fig. 4**. The TTM controls all three of these functions using a single coolant temperature transducer, which is installed in the standard coolant temperature gauge sender port.

NOTE: While all TTMs look the same, they are programmed differently and are not interchangeable. Identify a particular TTM using the part number that appears on the module top surface.



The temperature transducer (**Fig. 5**) is a positive temperature coefficient (PTC) thermistor; as coolant temperature increases, transducer resistance in-

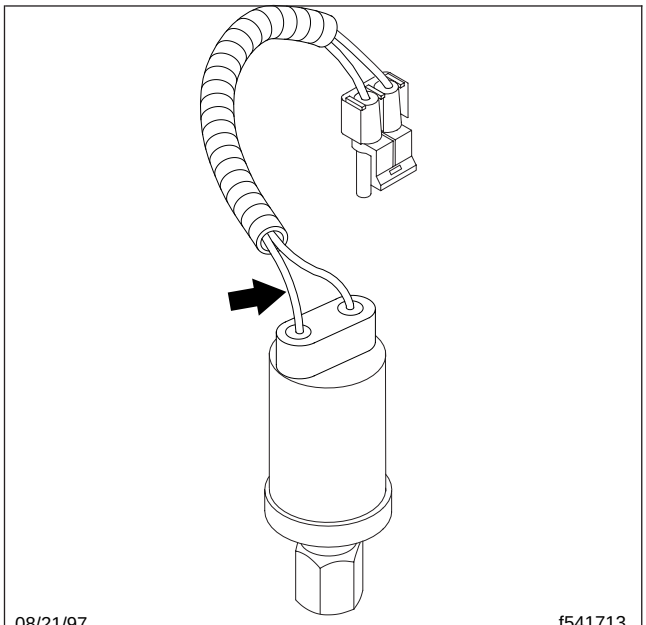
06/13/97 f200353

Fig. 4, Temperature Transducer Module (TTM)

creases. Conversely, as coolant temperature decreases, transducer resistance decreases.

07/20/95 f541031

Fig. 5, Coolant Temperature Transducer



While the TTM drives the coolant temperature gauge and the engine protection system warning lamp and/or buzzer directly, fan clutch current draw is high enough to require use of a fan clutch relay. This relay is mounted behind the instrument panel, in the fuse/relay/circuit breaker panel.

The fan circuit is wired so that the relay, when *de-energized*, is directing power to the fan clutch. When energized by the TTM, the relay interrupts power to the fan clutch.

WITH AIR CONDITIONING AND ENGINE PROTECTION SYSTEM

Fan control circuitry for a vehicle equipped with both an engine protection system and air conditioning is almost the same as fan control circuitry for a vehicle with only an engine protection system. A Kysor Temperature Transducer Module (TTM) is still installed behind the instrument panel (but in a slightly different location), and used to control the fan clutch, the engine protection system, and the coolant temperature gauge as described previously.

An A/C override switch (**Fig. 6**) also provides information to the TTM, but the switch is a *normally closed* switch. The switch contacts "open" when the refrigerant system high-side pressure rises above a preset limit, usually about 275 psi (1896 kPa). The TTM then engages the fan. When pressure drops to about 225 psi (1551 kPa), the switch closes again, but the TTM does not immediately disengage the fan. Instead, it keeps it engaged for about 36 seconds more to ensure adequate fan run time, and reduce fan cycling.

08/21/97 f541713

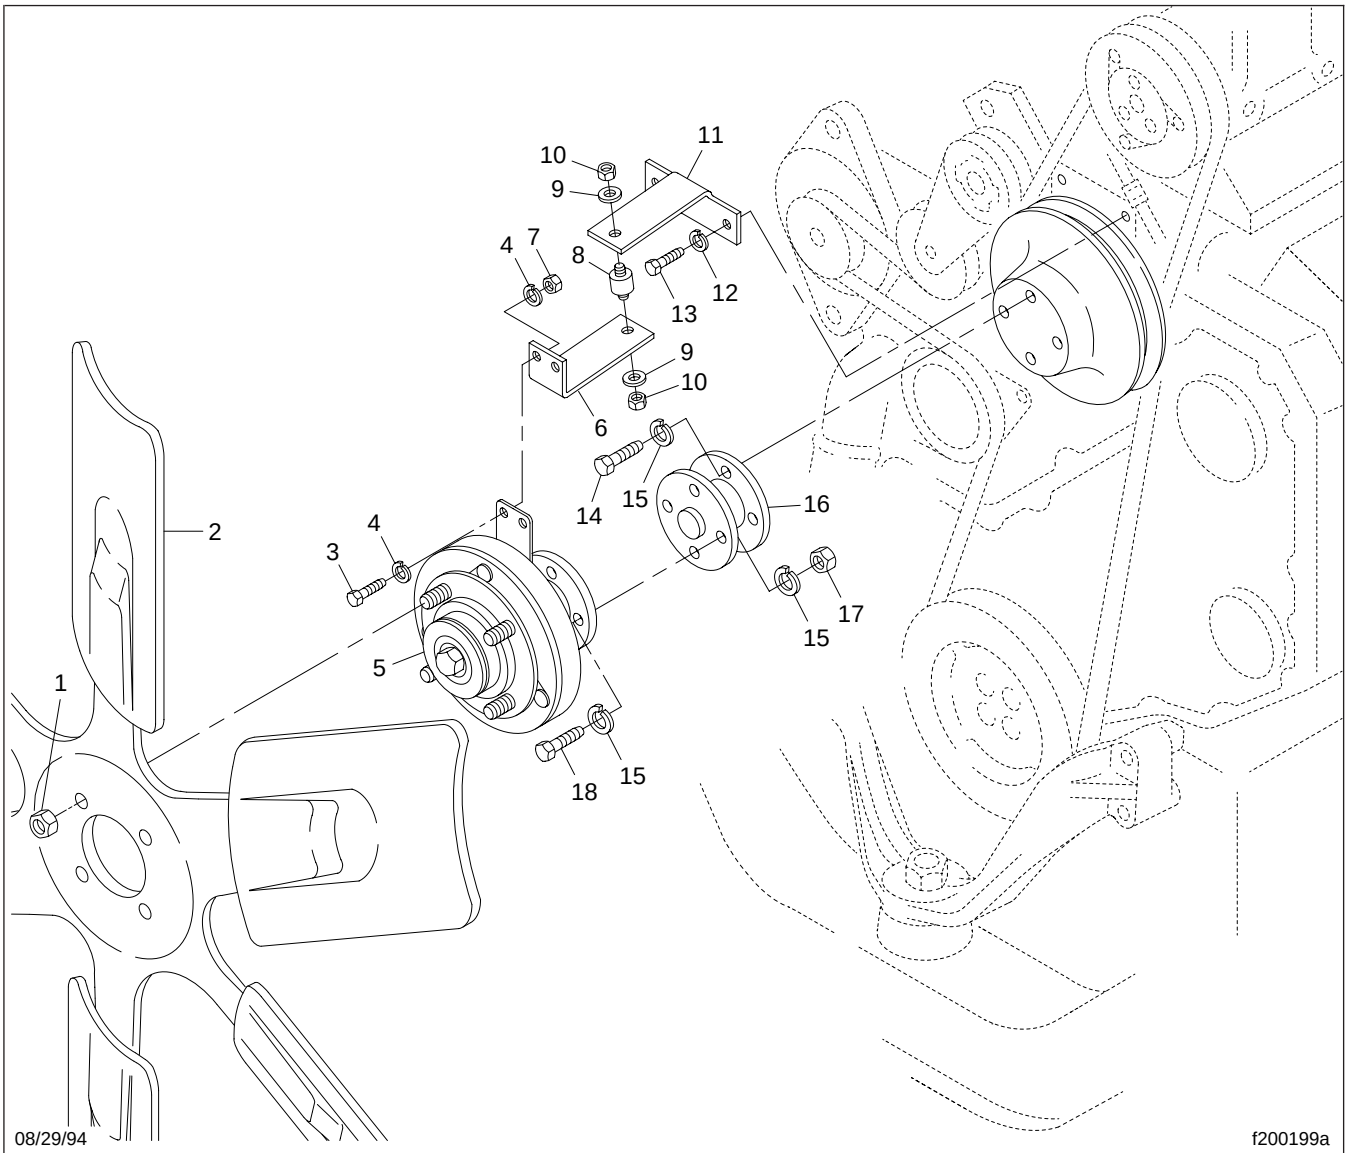
NOTE: Normally-closed switch has yellow leads.

Fig. 6, A/C Override Switch, With Engine Protection System

Additional circuitry in the TTM is used to provide override switch monitoring. If the TTM detects an in-

General Information

termittent "open" in the override switch circuit while the fan is operating, it assumes that a fault is present in the circuit. The TTM will then keep the fan engaged for about 5 minutes to alert the driver that there is a fault in the fan control circuit.



Replacement (See Fig.1 or Fig.2)

1. Apply the parking brakes, chock the tires, and (if applicable) drain the air system.
2. Disconnect the battery ground cable at the vehicle frame, or if the vehicle is equipped with a battery shutoff switch, turn off the switch.
3. Tilt the hood.
4. Remove the fan clutch.
   - 4.1 Disconnect the fan clutch field coil connector.
   - 4.2 Remove the locknuts from the fan clutch studs.
   - 4.3 Remove the fan from the fan clutch.
   - 4.4 Remove the two capscrews, lockwashers, and hexnuts that hold the clutch-side clutch mounting bracket to the fan clutch.
   - 4.5 Remove the four capscrews that hold the fan clutch to the fan clutch adaptor or the fan hub.
   - 4.6 Remove the fan clutch from the vehicle.
5. Install the new fan clutch.
   - 5.1 Position the fan clutch on the fan clutch adaptor or the fan hub.
   - 5.2 Secure the fan clutch with four capscrews. For Cummins B Series engines, use new split lockwashers. Tighten the capscrews 34 lbf·ft (46 N·m).
   - 5.3 Secure the clutch-side clutch mounting bracket to the fan clutch with two capscrews. Use new split lockwashers, and tighten the capscrews 62 lbf·in (700 N·cm).
   - 5.4 Position the fan on the fan clutch, and secure it with new locknuts.

     For a Cummins C Series engine, tighten the locknuts 16 lbf·ft (22 N·m).

     For a Cummins B Series engine, tighten the locknuts 38 lbf·ft (52 N·m).
   - 5.5 Connect the fan clutch field coil wiring to the engine wiring harness.
6. Test the fan clutch operation by running the engine until the coolant temperature is above 200°F (93°C). The fan clutch should engage.
7. Lower the hood, and remove the chocks from the tires.

Replacement

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Open the hood and locate the temperature switch/sensor. See **Fig. 1** or **Fig. 2**.

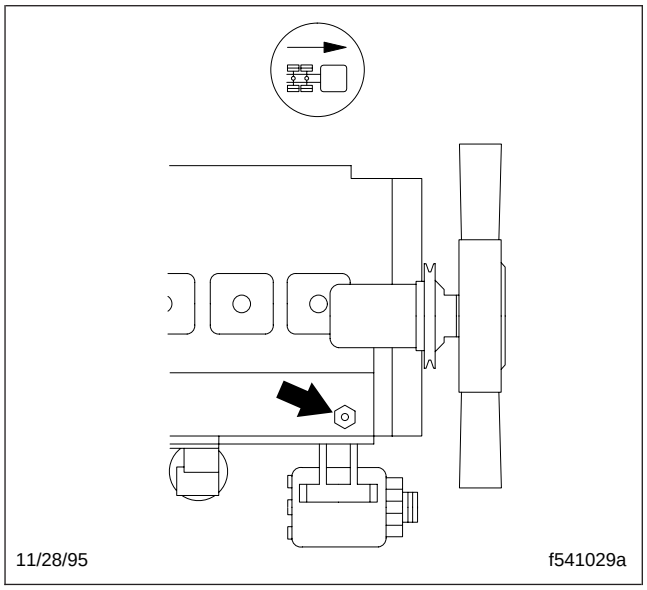

Fig. 1, Temperature Switch/Sensor Location, Cummins B Series Engine

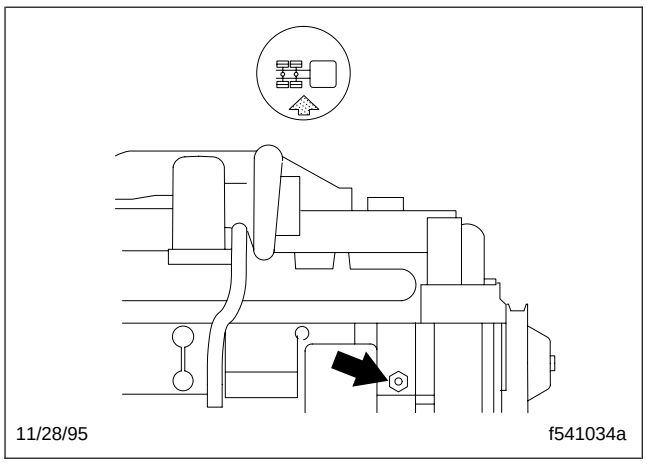

Fig. 2, Temperature Switch/Sensor Location, Cummins C Series Engine

WARNING

Do not drain the cooling system while the engine is hot. To avoid personal injury from scalding coolant, wait until the engine has cooled down before draining the system.

3. Drain coolant from the system until the coolant level drops below the temperature switch/sensor location.
   - 3.1 With the engine cool, loosen the radiator cap to release pressure from the radiator, then tighten the cap.
   - 3.2 Place a clean drain pan under the drain plug or petcock located at the bottom of the radiator left end-tank. See **Fig. 3**. Remove the drain plug or open the petcock. If necessary, use a deflector to channel coolant away from the front springs and into the drain pan.

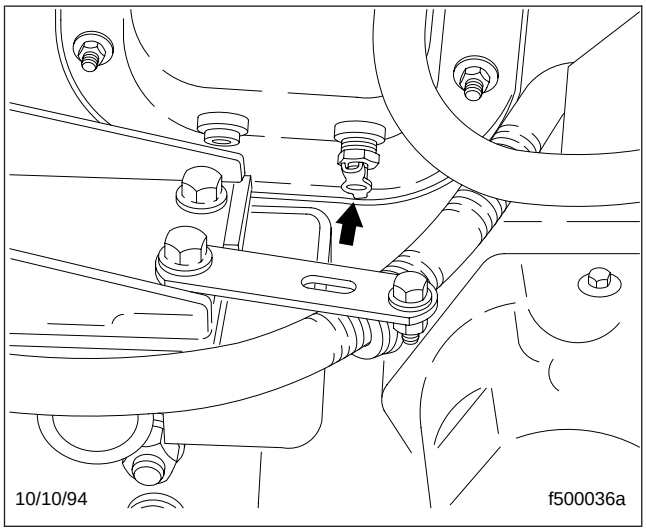

Fig. 3, Radiator Drain Location, Typical

   - 3.3 Install the drain plug or tighten the petcock.
4. Disconnect the wires from the temperature switch (or unplug the wiring harness connector from the temperature sensor), and unscrew the switch/sensor from the engine.
5. Clean old sealant residue from the threads of the switch/sensor port in the engine.

Temperature Switch/Sensor Replacement

6. Apply pipe thread sealant to the threads of the new switch/sensor, and install it in the engine port. Tighten the switch/sensor until it is snug.
7. Connect the vehicle wiring harness to the temperature switch/sensor.
8. Fill the cooling system.
9. Start the engine, check for leaks, and check that the fan clutch and coolant temperature gauge are operating properly.
10. Return the hood to the operating position.
11. Remove the chocks from the tires.

Refrigerant Pressure ("Override") Switch Replacement

Replacement

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Open the hood and locate the "override" pressure switch on the A/C receiver-drier. See **Fig. 1**.

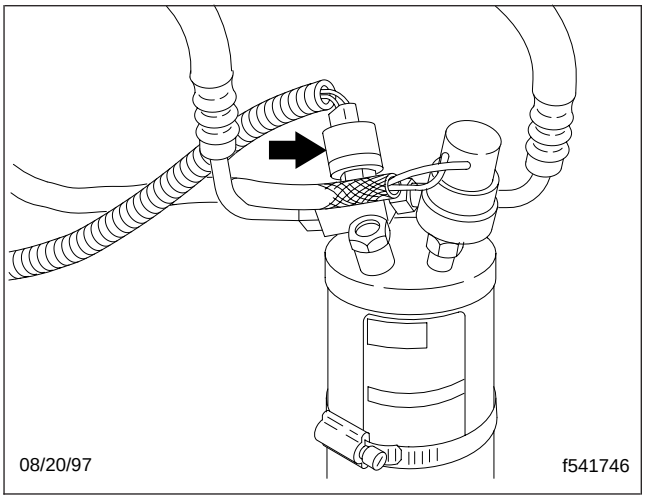

Fig. 1, Override Switch Location

NOTE: It is not necessary to recover refrigerant from the A/C system before removing the override switch. The receiver-drier fitting is equipped with a Schrader valve which closes automatically as the override switch is removed.

3. Disconnect the switch electrical connector and unscrew the switch from the receiver-drier.

IMPORTANT: Be sure that you have the correct replacement switch before installing it. Switches with yellow leads have normally-closed contacts, while switches with white leads have normally-open contacts. Installing an incorrect switch will cause the fan clutch to operate improperly.

4. Screw the override switch onto the receiver-drier fitting and tighten it securely.
5. Plug the switch connector into the vehicle wiring harness connector.
6. Start the engine, turn on the air conditioning system, and verify that the fan clutch operates properly.
7. Close the hood and remove the chocks from the tires.

Kysor Temperature Transducer Module (TTM) Removal and Installation

Removal

1. Remove the extruded rubber trim strip at the top of the dashboard. See **Fig. 1**.

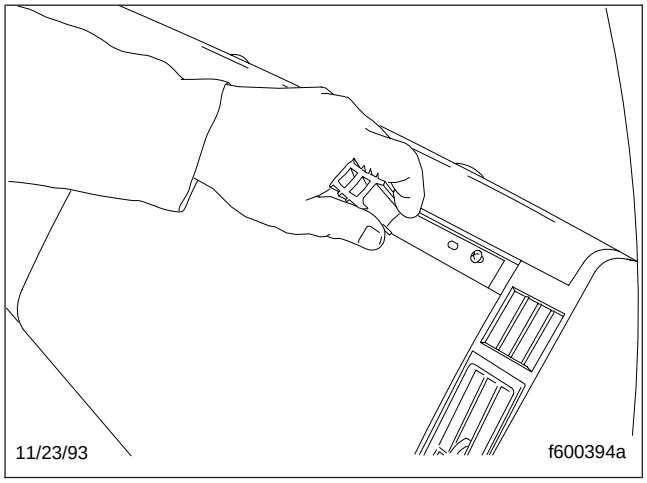

Fig. 1, Trim Strip Removal

2. Remove the right hand dash panel.
   - 2.1 Remove the two screws from the top of the right hand dash panel and pivot the top of the panel rearward.
   - 2.2 Lift out the dash panel. See **Fig. 2**.

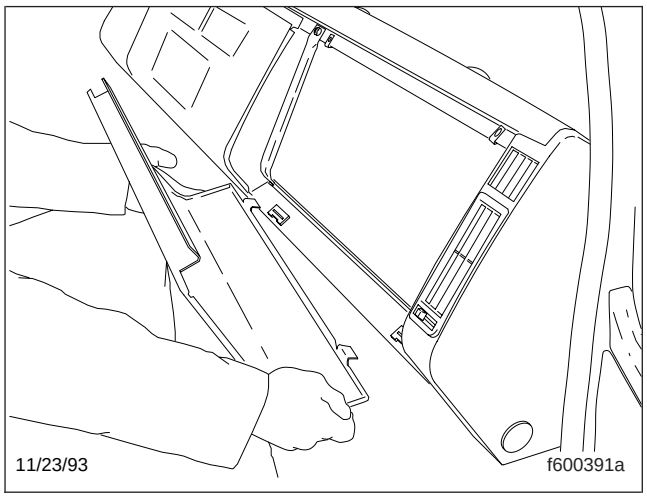

Fig. 2, Dash Panel Removal

NOTE: The TTM mounting location varies slightly depending on installed equipment. On vehicles equipped with an engine warning system, but without an engine shutdown system, the TTM is fastened to the top of the electrical accessories mounting bracket. On vehicles equipped with both engine warning and engine shutdown systems, the TTM is mounted to the underside of the accessories mounting bracket.

3. If equipped with an electronically-controlled automatic transmission, remove the transmission control module fasteners and reposition the module to allow TTM access. See **Fig. 3**.

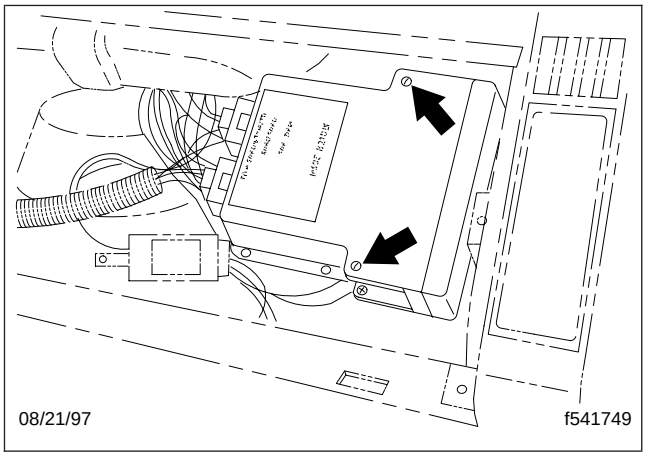

Fig. 3, Transmission Control Module Fastener Access Holes

4. If necessary, reposition or remove the right-hand dash outlet air duct. See **Fig. 4**.
5. Remove the torx fasteners securing the TTM to the electrical accessories mounting bracket (**Fig. 5**). Reposition the TTM to access its electrical connectors, disconnect the connectors, and remove the TTM.

Installation

1. Place the TTM on the electrical accessories mounting bracket and connect the wiring harness connectors to the TTM.
2. Reposition the TTM as necessary to install its mounting screws and tighten the screws. See **Fig. 5**.
3. If necessary, install or reposition the right-hand dash outlet air duct. Keep the duct as straight and kink-free as possible, to prevent reduced air flow from the dash outlet.

Kysor Temperature Transducer Module (TTM) Removal and Installation

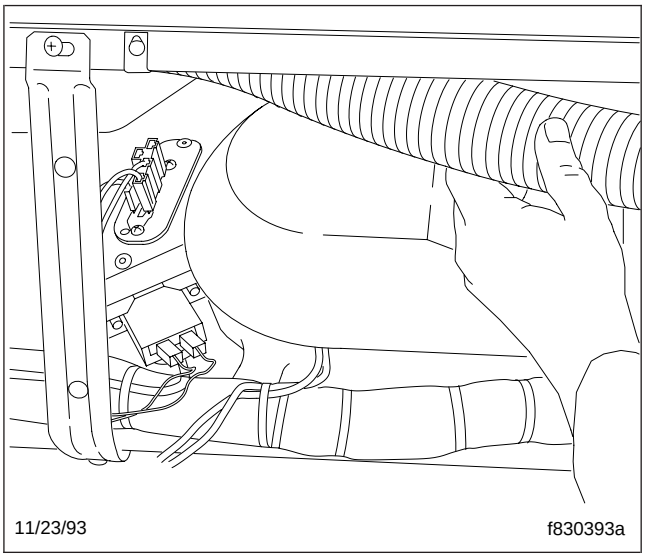

Fig. 4, Defroster Duct Repositioning

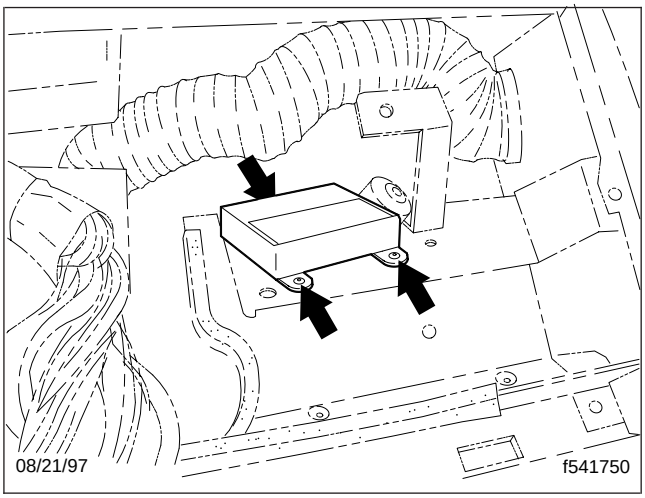

Fig. 5, Kysor TTM Fasteners

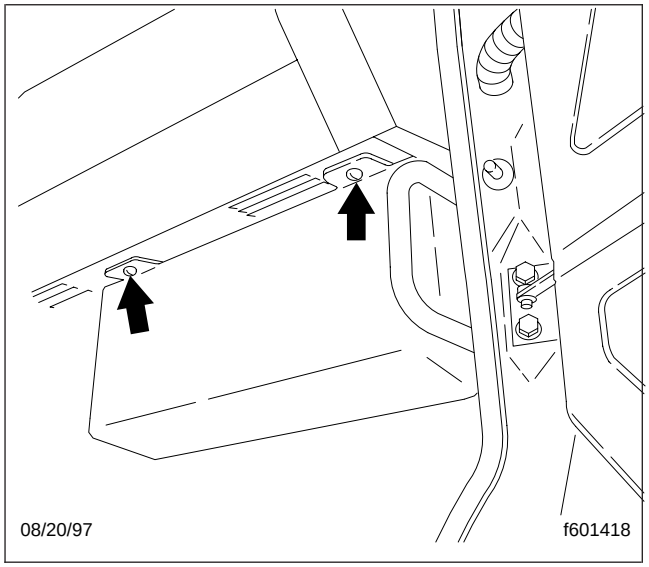
4. If equipped with an electronically-controlled automatic transmission, move the module back into position on the electrical accessories mounting bracket. Install the module mounting screws and tighten them. See **Fig. 3**.
5. Install the right-hand dash panel.
   5.1 Insert the two tabs on the lower edge of the dash panel into the slots in the dashboard. Then, pivot the top of the panel forward until it contacts the dashboard. See **Fig. 2**.
   5.2 Install the two torx screws at the top of the dash panel and tighten them.
6. Install the extruded rubber strip into the slot at the top of the dashboard. See **Fig. 1**.

Replacement

1. Remove the quarter-turn fasteners securing the fuse/relay/circuit breaker panel cover to the instrument panel and remove the cover. See **Fig. 1**.



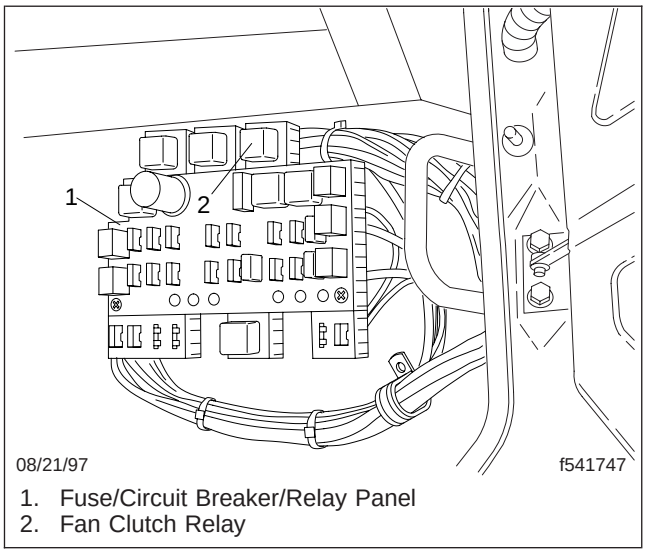


Fig. 1, Fuse/Relay/Circuit Breaker Panel Cover Fasteners

2. Locate the fan clutch relay, which is attached to the upper edge of the fuse/circuit breaker/relay panel. See **Fig. 2**. The exact mounting location varies depending upon the number and type of electrical accessories present on the vehicle, but the fan clutch relay can be positively identified by the four circuits connected to the relay: circuits 234 (2), 234A, and 234B.
3. Unplug the old relay, and install the new one.
4. Install the fuse/relay/circuit breaker panel panel.

Troubleshooting Tables

WITHOUT ENGINE PROTECTION OR SHUTDOWN SYSTEM

Problem—The Fan Clutch Does Not Engage

Problem—The Fan Clutch Does Not Engage	
Possible Cause	**Remedy**
Power is not reaching the coolant temperature switch (or the A/C override switch, if equipped).	Check for a blown fuse; replace the fuse, if necessary. Check for battery voltage at the coolant temperature switch (and A/C override switch, if equipped). If voltage is not present, repair or replace wiring as required.
The coolant temperature switch is faulty or an incorrect switch has been installed.	Check the switch temperature rating and verify that the switch closes when the rated temperature is reached. This can be done by connecting a voltmeters positive lead to the switches output terminal, and the voltmeters negative lead to a good ground. Then, start the engine and monitor engine coolant temperature as the engine heats up (to monitor the temperature use the instrument panel temperature gauge, a scan tool on electronic engines, or remove the radiator cap and install a thermometer before starting the engine). When the engine reaches the switches rated temperature, the voltmeter should show battery voltage.
The A/C override switch is faulty or an incorrect switch has been installed.	Install an A/C manifold gauge set on the vehicle and check the override switch closing and opening points. If the switch contacts do not close, replace the switch.
Power is not reaching the fan clutch coil.	Use an ohmmeter to check the continuity of circuit 234A between the coolant temperature switch and the fan clutch coil connector. Repair or replace the wiring, as necessary. Use an ohmmeter to check the continuity of circuits 234E and 234A between the A/C override switch and the fan clutch coil connector. Repair or replace the wiring, as necessary.
The fan clutch coil ground circuit is faulty.	Use an ohmmeter to check the continuity of the GND circuit between the ground terminal on the engine block and the fan clutch coil connector. Clean/tighten the ground terminal, or repair/replace the wiring, as necessary.
The fan clutch coil is faulty.	Unplug the fan clutch coil connector and use an ohmmeter to measure clutch coil resistance. Infinite resistance indicates an open coil; replace the fan clutch. Resistance above 5 ohms indicates a damaged coil; replace the fan clutch.

Troubleshooting

Problem—The Fan Clutch Does Not Disengage

Problem—The Fan Clutch Does Not Disengage	
Possible Cause	**Remedy**
The coolant temperature switch is faulty or an incorrect switch has been installed.	Make sure that the coolant temperature switch is a normally open switch, not a normally closed switch. Replace the switch if it is the wrong type. Use an ohmmeter to verify that the switch is open (infinite resistance) when the engine is cold. If the ohmmeter indicates low (or no) resistance when the engine is cold, replace the coolant temperature switch.
The A/C override switch is faulty or an incorrect switch has been installed.	Make sure that the override switch is a normally open switch, not a normally closed switch. Replace the switch if it is the wrong type. Install an A/C manifold gauge set on the vehicle and check the override switch closing and opening points. If the switching points are incorrect, replace the switch.
The fan clutch is seized due to damage (overheating, improper service, etc.)	Replace the fan clutch assembly.

Problem—The Fan Clutch Cycles Frequently

Problem—The Fan Clutch Cycles Frequently	
Possible Cause	**Remedy**
The fan clutch control circuit has a loose connection or is poorly grounded.	Check all wiring and connections; repair the circuit as needed.
An incorrect coolant temperature switch (wrong temperature rating) has been installed.	Determine the correct fan clutch switch-on temperature for the engine installed in the vehicle. Compare the specified switch-on temperature to that of the switch that is installed on the vehicle. Replace the temperature switch with one having the correct switch-on temperature, if necessary.

When the engine reaches the switches rated temperature, the voltmeter should show battery voltage. The switch should remain closed until coolant temperature drops to about 7 degrees below the switches rated temperature. Replace the switch if it does not perform as described.
The A/C override switch switches too soon.	Install an A/C manifold gauge set on the vehicle and check the A/C override switch closing and opening points. If the switching points are incorrect, replace the A/C override switch

Problem—The Fan Clutch Does Not Engage

Problem—The Fan Clutch Does Not Engage	
Possible Cause	**Remedy**
Power is not reaching the fan clutch relay and/or Temperature Transducer Module (TTM). NOTE: If power is not reaching the TTM, the coolant temperature gauge, the high temperature warning lamp, and the fan clutch will be affected. If any one of these three devices is operating normally, power to the TTM is not the problem.	Check for a blown fuse; replace the fuse, if necessary. Check for battery voltage at the fan clutch relay and the Temperture Transducer Module (TTM). If voltage is not present, repair or replace wiring as required.
The fan clutch relay is faulty.	Access the TTM and the electrical mounting panel behind the right hand side of the instrument panel. With the ignition turned off, disconnect the 6 cavity connector from the TTM. Then, turn the ignition switch to run and check for battery voltage at relay terminal 87a. If battery voltage isn't present, replace the relay.
The coolant temperature transducer is faulty or the wrong type of transducer has been installed. NOTE: A faulty or incorrect temperature tranducer will affect the coolant temperature gauge, the high temperature warning lamp, and the fan clutch. If any one of these three devices is operating normally, the temperature transducer is not the problem.	Make sure that the coolant temperature transducer is a KYSOR positive temperature coefficient (PTC) transducer. A negative temperature coefficient (NTC) sensor, like the type normally used to drive the coolant temperature gauge, will not work. Replace the transducer if it is the wrong type. Check transducer resistance when the engine is at room temperature and compare to specifications. If the transducer is questionable, remove it from the engine, and place it in a water bath with a thermometer. Connect an ohmmeter to the transducer terminals and measure resistance as the water bath is heated. Resistance will increase with increasing temperature. If resistances are not within specifications, replace the transducer.
Power is not reaching the fan clutch coil.	Use an ohmmeter to check the continuity of circuits 234B and 234C between the fan clutch relay and the fan clutch coil connector. Repair or replace the wiring, as necessary.
The fan clutch coil ground circuit is faulty.	Use an ohmmeter to check the continuity of the GND circuit between the ground terminal on the engine block and the fan clutch coil connector. Clean/tighten the ground terminal, or repair/replace the wiring, as necessary.

The coolant temperature transducer is disconnected, faulty, or an incorrect sensor has been installed.	Make sure that the coolant temperature transducer connector is connected to, and firmly seated on the transducer. Use an ohmmeter to verify that the transducer is not open (infinite resistance) at any temperature. If the ohmmeter indicates infinite resistance at any temperature, replace the transducer.
The A/C override switch is disconnected, faulty or and incorrect switch has been installed. NOTE: The TTM is programmed to keep the fan clutch engaged for 36 seconds following override switch closing. Do not mistake this for a system fault. Also, the module is programmed to respond to an override switch or circuit problem by running the fan for 5 minutes.	Make sure that the override switch is a normally closed switch, not a normally open switch. Replace the switch if it is the wrong type. Use an ohmmeter to verify that the transducer is not open (infinite resistance) when the A/C system is turned off. If the ohmmeter indicates low (or no) resistance when the system is off, replace the override switch. Install an A/C manifold gauge set on the vehicle and observe the override switch opening and closing points. If the switching points are incorrect, replace the switch.
The fan clutch relay is faulty.	Access the electrical mounting panel behind the right hand side of the instrument panel. With the ignition switch in run, connect one end of a jumper wire to the relay signal circuit (234A) and touch the other end of the jumper to a good ground. The relay should energize, disengaging the fan. If the relay does not energize, replace it.

General Information and Principles of Operation

The fan drive is a temperature-controlled, air-operated clutch for the engine cooling fan. It controls engine temperature by engaging or disengaging the fan. Internal spring pressure disengages the fan clutch when the coolant temperature is below the specified temperature range; internal air pressure engages the fan clutch when the coolant temperature rises above that range. Freightliner uses two models of Horton Advantage fan clutches: S Type and HT/S Type. See **Fig. 1**.

03/30/95 f200262a

A. The S Type fan clutch has a 7.5 inch (187.5 mm) wide piston friction disc.
B. The HT/S Type fan clutch has a 9.5 inch (237.5 mm) wide piston friction disc.

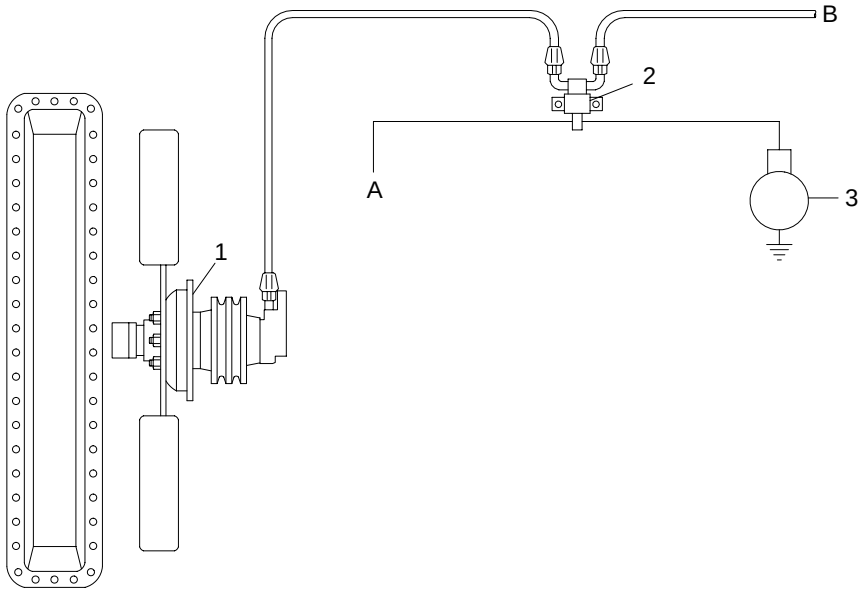
Fig. 1, Horton Advantage Fan Clutches

Air pressure to the fan clutch is controlled by a solenoid valve; the solenoid valve is controlled by a temperature switch that is installed in the thermostat housing. See **Fig. 2** and **Fig. 3**.

When you start a cold engine, the solenoid valve restricts air pressure to the cylinder, and the fan clutch remains disengaged.

When the coolant temperature rises to the temperature switch setting, the switch provides power to the solenoid valve, and the valve releases compressed air to engage the fan clutch.

When the coolant temperature drops to the temperature switch cutoff setting, the solenoid stops the compressed air, and the clutch disengages.



On vehicles with air conditioning, the fan clutch solenoid valve is connected to a fan cycling switch at the receiver-dryer. If the refrigerant pressure exceeds the setting of the fan cycling switch, the switch supplies power to the solenoid valve, which supplies air to engage the fan clutch.

Most Horton Advantage fan clutches include System Sentry™ fuses that protect the fan clutch from overheating. See **Fig. 4**. The System Sentry fuse is a brass fitting in the piston friction disc; the fitting uses lead alloy solder to hold a brass plug. If anything causes the fan clutch to slip excessively, heat from the slippage will melt the solder and release the plug. Air pressure inside the clutch will escape, and the clutch will release before heat build-up can damage the clutch bearings. The fuse is balanced by two counterweights.

If the fan clutch includes the System Sentry fuse, and the clutch will not engage, check to see if the fuse is melted, and check to see what might be making the fan clutch slip excessively.

For the fan clutch model number and serial number, refer to the side of the air chamber. See **Fig. 5**.

NOTE: The following procedure pertains to vehicles equipped with all engines except Detroit Diesel Series 55 engines. For vehicles equipped with that engine, see **Subject 105.**

1. Apply the parking brakes, and chock the tires.

⚠ WARNING

Drain the coolant only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

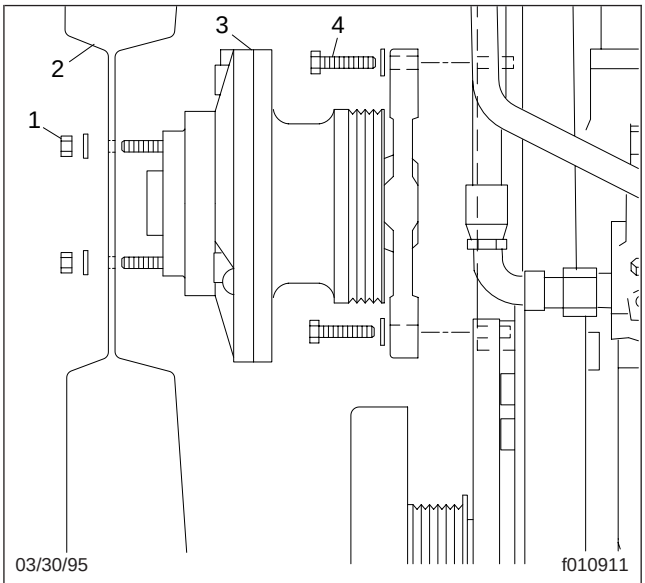
2. Remove the drain plug from the right side of the radiator bottom tank, and drain about seven liters (two gallons) of coolant. Install the drain plug and tighten it firmly.
3. Disconnect the radiator inlet hose and the radiator vent hose from the radiator, and move both hoses away from the radiator and fan shroud.
4. Disconnect the air intake hoses from the aftercooler, and move both hoses away from the aftercooler and fan shroud.
5. Remove the six 3/8–inch capscrews that hold the fan shroud to the radiator.
6. Loosen the fan belt. For instructions, refer to the applicable section in this manual.

⚠ WARNING

Use care when loosening the air line fitting. The line could be under pressure and may have dirt or sludge in the air stream. If quickly disconnected, the line may whip, possibly causing eye injury or other bodily injury.

7. Find the air line that runs between the fan clutch and the clutch solenoid, and disconnect the line from the solenoid. Cut any tie straps that secure the line to the engine.

⚠ WARNING



The fan clutch is heavy, and lifting it from, or installing it in, the center of a crowded engine compartment can be awkward. To avoid injury, a hoist should be used or two people should work together, to remove and install the fan clutch.

8. Remove the fan and fan clutch from the engine. **See Fig. 2.**

   NOTE: Four M8 x 35 mm capscrews hold the fan clutch to the engine. Two capscrews go through holes in the upper end of the fan clutch mounting plate, and two capscrews go through *notches* in the bottom of the mounting plate. If you loosen the lower capscrews, slightly, you can remove the two top capscrews, and the fan clutch will remain on the engine until you lift it straight up.

   8.1 Loosen the two lower capscrews that hold the fan clutch to the front of the engine.

8.2 Remove the two upper capscrews that hold the fan clutch to the engine.

8.3 With a helper, lift the fan clutch and fan up and out of the engine compartment. Move the fan shroud as needed.

8.4 Place the fan clutch on a work bench, and remove the six nuts that hold the fan to the fan clutch. Remove the fan from the fan clutch.

Installation

⚠ WARNING

The fan clutch is heavy and placing it in the center of a crowded engine compartment can be awkward. To avoid injury, two people should work together to place the fan clutch on the engine.

1. Install the fan and fan clutch on the engine.

   1.1 Place the fan on the fan clutch, and secure the fan with six nuts. Tighten the nuts 15 lbf·ft (20 N·m).

   NOTE: Four M8 x 35 mm capscrews hold the fan clutch to the engine. Two capscrews go through holes in the upper end of the fan clutch mounting plate, and two capscrews go through *notches* in the bottom of the mounting plate. If you install the lower capscrews in the engine, you can position the fan clutch on the lower capscrews and the fan clutch will remain on the engine as you install the upper capscrews.

   1.2 Install the lower capscrews in the front of the engine, but don't tighten them completely.

   1.3 With a helper, position the fan and fan clutch on the two lower mounting capscrews. The notches in the bottom of the fan clutch mounting plate should slide down over the capscrews. Move the fan shroud as needed.

   1.4 Install the two upper capscrews and tighten all four capscrews 13 lbf·ft (18 N·m).

   1.5 Route the air line up, behind the alternator mount and across the front of the engine to the solenoid. Connect the air line to the solenoid, and secure the line to the engine with tie straps.

2. Work the belt over the fan, and route and adjust the belt. For instructions, refer to **Group 01** in this manual.
3. Install the fan shroud on the radiator.
4. Connect the coolant hoses to the radiator, and the air hoses to the aftercooler.
5. Take the coolant drained from the radiator, and pour it back into the surge tank.
6. Check the fan clutch for proper operation. For instructions, refer to **Group 20** in this manual.

Removal and Installation, Equipped with Detroit Diesel Series 55 Engine

Fan Clutch Removal

1. Park the vehicle, set the parking brake, then chock the tires.
2. Disconnect the batteries.
3. Drain the air tanks.
4. Tilt the hood and support it on a stand.
5. Remove the four fasteners holding the fan shroud in place.
6. Remove the fan blade, then put it inside the radiator shroud.
7. Remove the fasteners attaching the radiator struts to the sides of the radiator. Swing the struts outboard.
8. Tilt the radiator forward, then lift the fan and shroud out of the engine compartment.
9. Remove the drive belts from their pulleys.
   - 9.1 Using a wrench, loosen one belt tensioner, then rotate it back until the drive belt slips off.
   - 9.2 Repeat the procedure for the other belt tensioner.

⚠ WARNING

Use care when loosening the air line fitting. The line could be under pressure and may have dirt or sludge in the air stream. If quickly disconnected, the line may whip, possibly causing eye injury or other bodily injury.

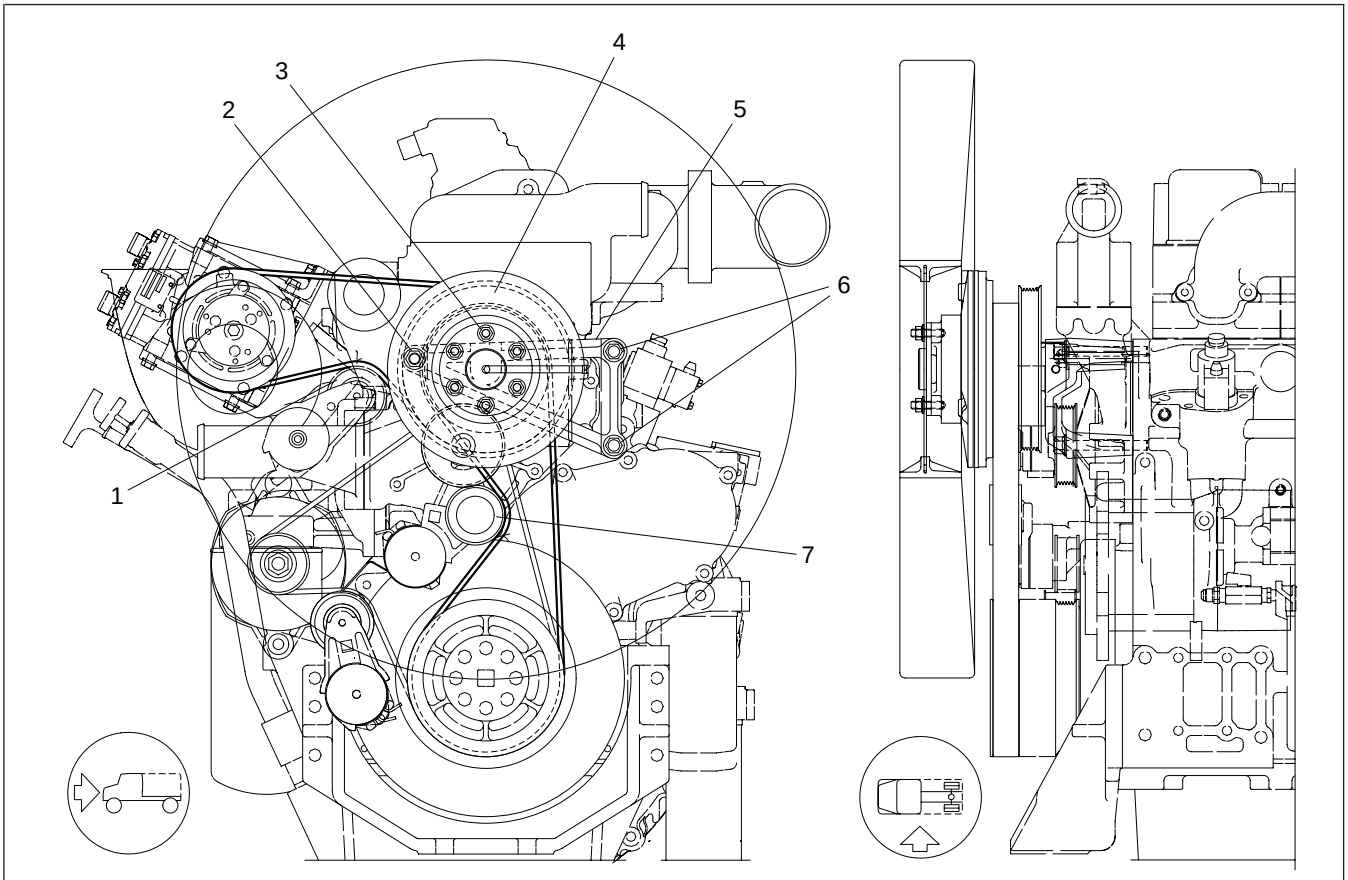
10. Disconnect the air line from the fan clutch.

⚠ WARNING

The fan clutch is heavy, and lifting it from the center of a crowded engine compartment can be awkward. To avoid injury, two people should work together to lift the fan clutch from the engine.

11. Remove the two hexbolts and the one nut and washer holding the fan clutch to the engine. See **Fig. 1.**
12. Remove the fan clutch from the engine, along with the two drive belts.

Fan Clutch Installation



1. Install the drive belts onto the fan clutch pulleys.

⚠ WARNING

The fan clutch is heavy, and installing it in the center of a crowded engine compartment can be awkward. To avoid injury, two people should work together to install the fan clutch onto the engine.

2. Install the fan clutch with the drive belts onto the engine.
   - 2.1 Position the fan clutch on the engine, aligning the one hole with the stud on the engine, and the other two holes with holes in the engine.
   - 2.2 Install the two bolts and the one nut and washer. Tighten them 60 lbf·ft (81 N·m).
3. Install the drive belts.
   - 3.1 Install the rearward drive belt first, by putting a wrench on the upper belt tensioner, then rotating it inward. Slide the belt over the tensioner, then release the tension on it.
   - 3.2 Repeat the procedure for the other drive belt.
4. Install the fan blade. Tighten the fasteners 28 lbf·ft (38 N·m).
5. Install the fan shroud. Tighten the four fasteners loosely.
6. Install the radiator struts onto the radiator. Tighten the fasteners 90 lbf·ft (122 N·m).
7. Align the fan shroud so that the fan blade will clear it, then tighten the fan shroud fasteners 108 lbf·in (1220 N·cm).
8. Connect the air line to the fan clutch.
9. Connect the batteries.
10. Close the hood.
11. Remove the chocks from the tires.

2. Clamp the fan clutch in a vise. See **Fig. 2**.
3. On some vehicles, the fan clutch has threaded studs on the air chamber and the fan is attached with nuts. On other vehicles, the fan is attached to the air chamber with hexbolts.

   If hexbolts were used to attach the fan, install two of the removed hexbolts in the air chamber so that a screwdriver can be used to keep the air chamber from rotating. See **Fig. 3**.

   Remove the socket-head capscrews from the air chamber.
4. If applicable, remove the two hexbolts previously installed.

⚠ WARNING

Apply air pressure slowly to the fan clutch. A sudden blast of air might blow the air chamber off the clutch, resulting in possible injury.

4. Install a new friction facing onto the sheave. Following a star pattern, tighten the socket-head capscrews 60 lbf·in (680 N·cm).

CAUTION

Never fill more than one-third of the bearing void with grease. Too much grease can cause overheating and possible bearing damage.

5. Install the journal spacer, and the disc and piston assembly. Make sure that the lip on the journal spacer is facing up. See **Fig. 11**.
6. Install the adjusting nut. Tighten 150 lbf·ft (203 N·m).
7. Remove any dust and debris from the air chamber.
8. Coat the new O-rings with an approved lubricant and install them. See **Fig. 12**.

12. Slide the air chamber assembly onto the clutch. If applicable, install two of the hexbolts that hold the fan in place.
13. Using a screwdriver to keep the air chamber from rotating, install the socket-head capscrews. Following a star pattern, tighten 15 lbf·ft (20 N·m).
14. If applicable, remove the two hexbolts previously installed.
15. Install the fan and clutch assembly on the engine. For instructions, refer to **Subject 100**.

Disassembly

NOTE: This procedure involves replacing only the air cartridge, System Sentry® fuse, the face seal, and the O-rings, using parts from the manufacturer's Seal Kit. If doing a major rebuild, go to **Subject 120**.

1. Remove the fan and clutch assembly from the vehicle. For instructions, refer to **Subject 100**.
2. Clamp the fan clutch in a vise. See **Fig. 1**.

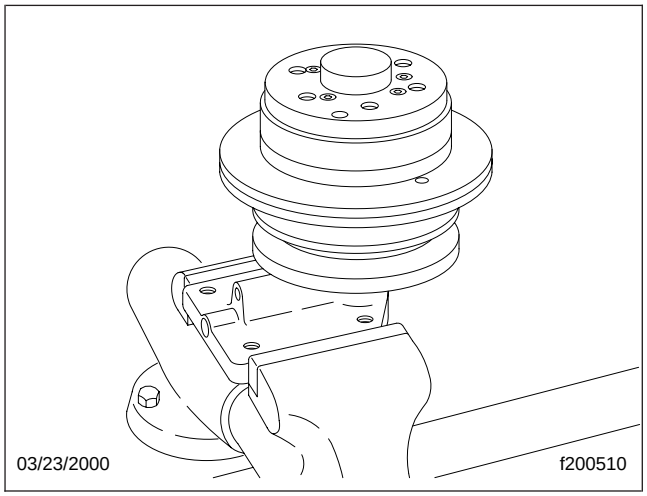

Fig. 1, Fan Clutch Placed in a Vise

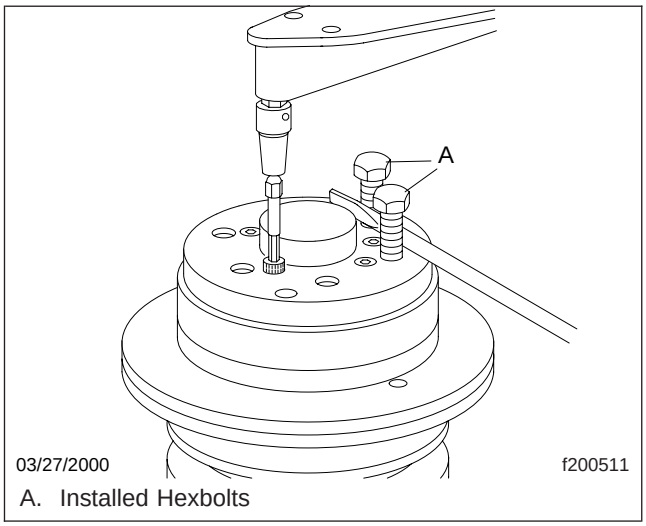
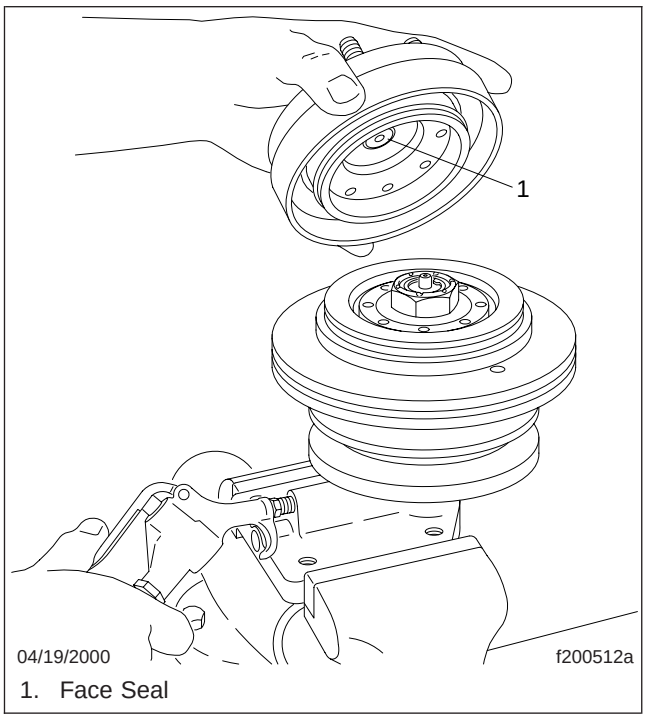


3. On some vehicles, the fan clutch has threaded studs on the air chamber and the fan is attached with nuts. On other vehicles, the fan is attached with hexbolts.

   If hexbolts were used to attach the fan, install two of the removed hexbolts in the air chamber so a screwdriver can be used to keep the air chamber from rotating. See **Fig. 2**.

   Remove the socket-head capscrews from the air chamber.
4. If applicable, remove the two hexbolts previously installed.

⚠ WARNING



Apply air pressure slowly to the fan clutch. A sudden blast of air might blow the air chamber off the clutch, resulting in possible injury.

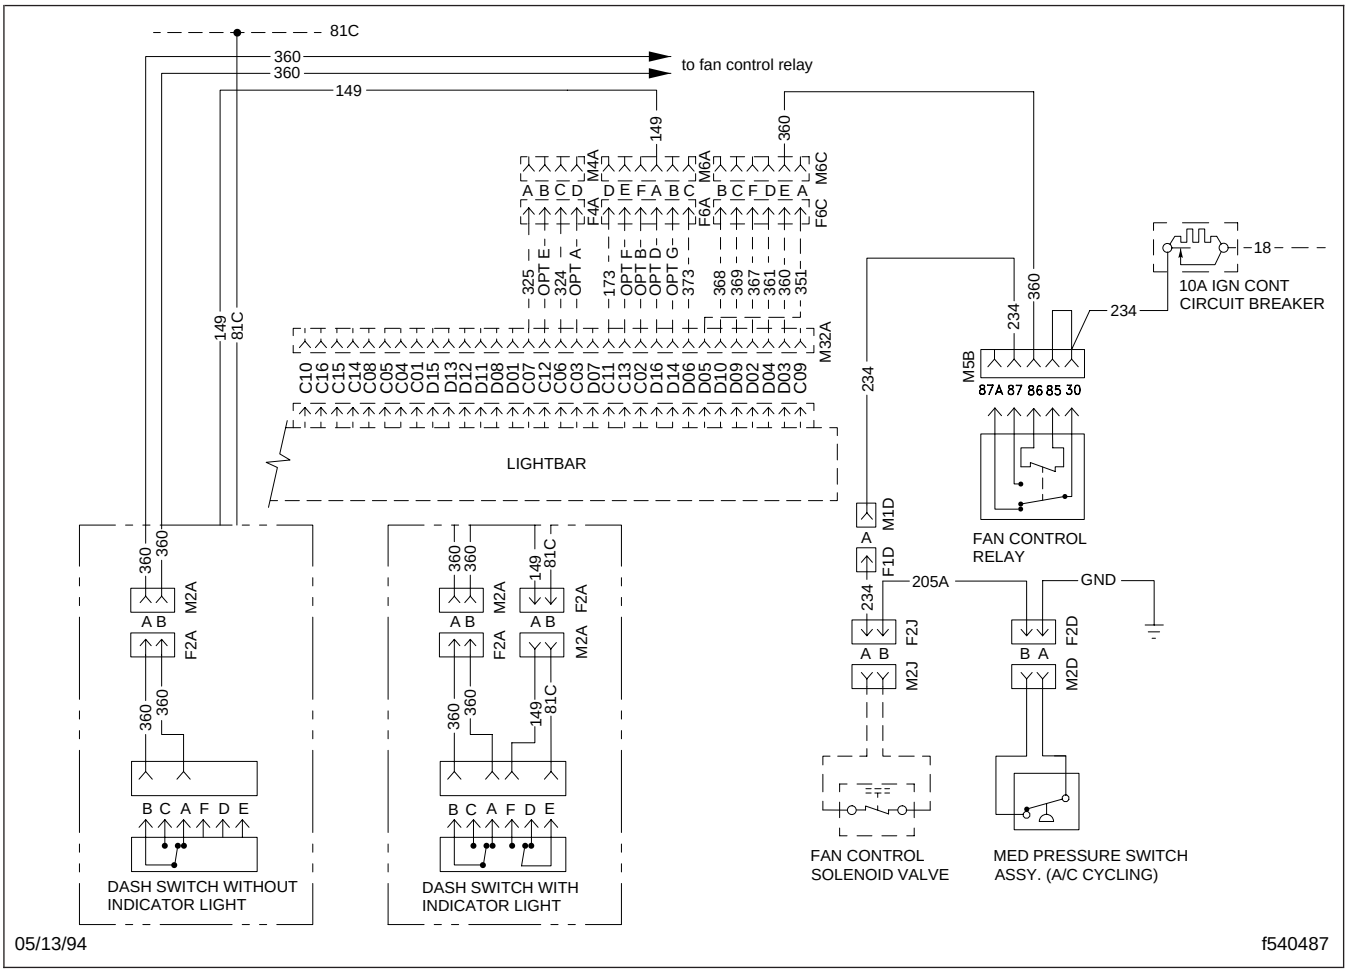

Fig. 1, Fan Clutch Wiring Diagram

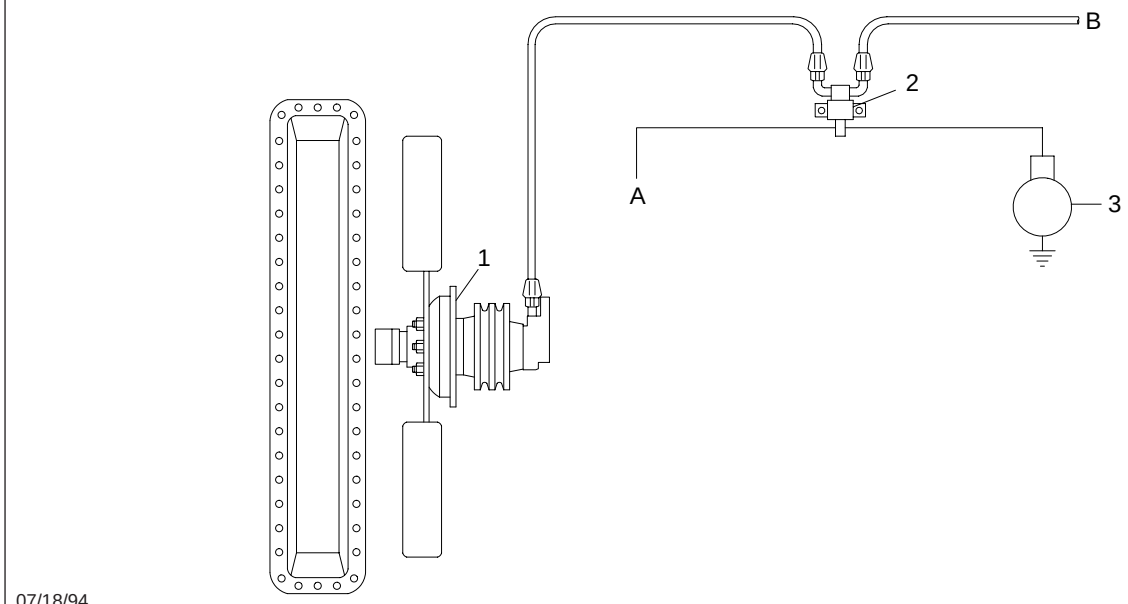
General Information

The K22RA fan drive unit is an air-operated, temperature-controlled clutch for the engine cooling fan. It is installed only on Caterpillar 3126 and Detroit Diesel Series 50 engines. Its purpose is to maintain engine temperature by engaging or disengaging the fan. The fan clutch is disengaged when the coolant temperature is at or below the specified temperature range. The fan clutch engages when the coolant temperature rises above the range.



Air pressure to the fan clutch is controlled by a solenoid valve; the solenoid valve is controlled by a temperature switch that is installed in the thermostat housing. See **Fig. 1**.

lenoid is controlled by a temperature switch that is immersed in the engine coolant.

When a cold engine is started, the temperature switch is open, which activates the solenoid. The solenoid valve allows compressed air to enter the cylinder, and the fan clutch remains disengaged. The fan does not turn.

When the coolant temperature rises to the temperature switch setting, the switch closes. The solenoid valve releases the compressed air from the cylinder. The fan clutch spring engages the clutch and the fan turns.

When the coolant temperature drops to the temperature switch cutoff setting, the switch opens, activating

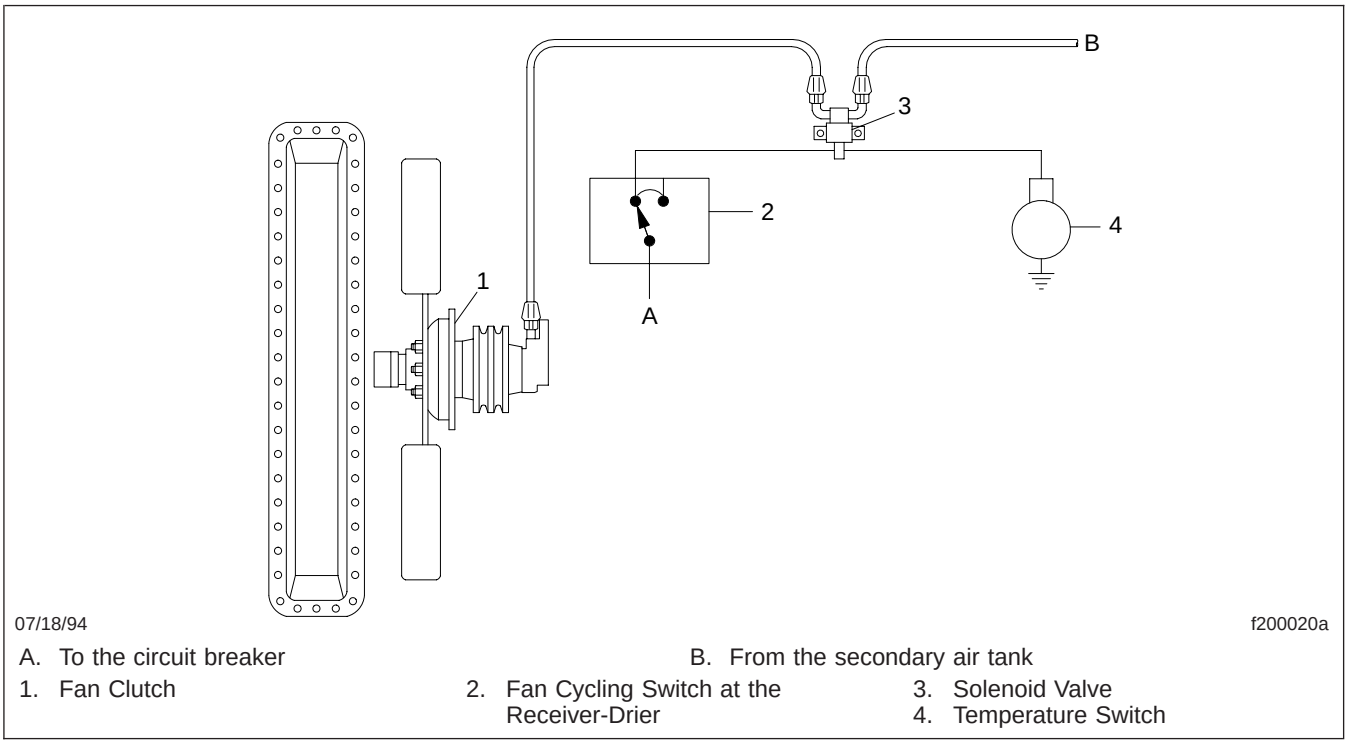

Fig. 1, Fan Clutch Piping and Wiring, Vehicle Without Air Conditioning

On vehicles with air conditioning, the fan clutch solenoid valve is connected to a fan cycling switch at the receiver-drier. If the refrigerant pressure exceeds the setting of the fan cycling switch, the switch supplies power to the solenoid valve. See **Fig. 2**.

The fan clutch is spring-loaded in the engaged position. It is disengaged when air pressure is applied to the cylinder on the front of the unit. Air pressure to the cylinder is controlled by a solenoid valve: the solenoid. Compressed air passes to the cylinder disengaging the clutch.

On vehicles with air conditioning, the fan clutch solenoid valve is connected to a fan cycling switch at the receiver-drier. If the refrigerant pressure exceeds the setting of the fan cycling switch, the switch supplies power to the solenoid valve, which stops air flow and allows the internal spring to engage the fan clutch.

NOTE: When disengaged, it is normal for the housing and fan to spin at about 300 rpm. When the compressed air is released and the clutch engages, the bearing housing and fan move forward approximately 1/10th-inch (2.5 mm).

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Tilt the hood.

WARNING

Use care when loosening the air line fitting. The line could be under pressure and may have dirt or sludge in the air stream. If quickly disconnected, the line may whip, possibly causing eye injury or other bodily injury.

3. Disconnect the air line from the fan clutch.
4. If necessary to tilt the radiator forward to gain sufficient clearance, remove the support struts from the top of the radiator.

   With one person holding each side of the radiator, tilt the top of the radiator forward.
5. With the radiator tilted forward, remove the fasteners attaching the fan to the fan clutch.

WARNING

If the fan clutch engages during the next step, it could cause personal injury. Keep the fan clutch disengaged throughout this procedure by maintaining between 90 and 120 psi (620 and 830 kPa) of air pressure.

6. Align the access holes in the fan clutch with the allen screws on the fan hub. See **Fig. 2**.

   6.1 Using shop air and a suitable nozzle attachment, apply between 90 and 120 psi (620 and 827 kPa) of air pressure to the fan clutch to disengage the clutch.

8. Remove the allen screws holding the fan clutch to the fan hub.
9. Remove the fan clutch from the fan clutch hub. It may be necessary to gently pry the clutch from the hub.

Installation

IMPORTANT: A new coupler must be used when installing the clutch onto the hub.

1. Install the fan clutch onto the fan clutch hub.
   - 1.1 Install a new coupler onto the fan hub.
   - 1.2 Position the fan clutch onto the fan hub, then push it toward the rear of the vehicle and rotate the clutch until the flats of the coupler engage the fan clutch.
   - 1.3 Line up the access holes in the clutch with the holes for the allen screws in the clutch hub.
   - 1.4 Install the allen screws, and tighten them 44 lbf·ft (60 N·m).
2. Install the fan. Tighten the fasteners firmly.
3. If the radiator was moved forward, position the radiator flat on its mounts, and connect the support struts to the top of the radiator.
4. Connect the air line to the fan clutch.
5. Lower the hood.
6. Remove the chocks from the tires.

2. Compressor

Fig. 1, Special Tools

1. Park the vehicle, apply the parking brakes, and chock the tires.
2. Remove the fan clutch from the vehicle. For instructions, refer to **Subject 110**.

CAUTION

When caging and compressing the engagement spring of the fan clutch, depress the clutch shaft only enough to relieve the pressure on the retaining plates (about 1/16-inch, or 1.5 mm). Applying additional force after the clutch shaft bottoms in the housing will damage the housing and render it unserviceable.

NOTE: There are two methods of caging the engagement spring. One uses the special tools and a press. The other uses carriage bolts, washers, and wingnuts. Either method is effective.

3. Cage the engagement spring.

   If using the special support and compressor tools, place the fan clutch in a press to cage the engagement spring. See **Fig. 2**.

   If using the optional method of caging the engagement spring, do the following:

   3.1 With the access holes in the housing assembly aligned with those in the shaft assembly, install two 3-1/2-inch (89-mm) long carriage bolts and suitable washers on opposite sides of the clutch assembly.

   3.2 On the shaft assembly side, install about a 1/2-inch (13-mm) thickness of washers onto each carriage bolt.

   3.3 Install a wingnut on the end of each carriage bolt and tighten the wingnuts evenly until the engagement spring is caged.

4. Remove the lining retaining plates and the lining. See **Fig. 2** and **Fig. 3**.

1. Compressor Tool
2. Support Tool

Fig. 2, Caging the Engagement Spring and Removing the Lining Retaining Plates

CAUTION

Do not press on the cylinder during this step, or the cylinder will be damaged. Use a 5/8-inch wrench as shown in Fig. 4 on the piston rod flats.

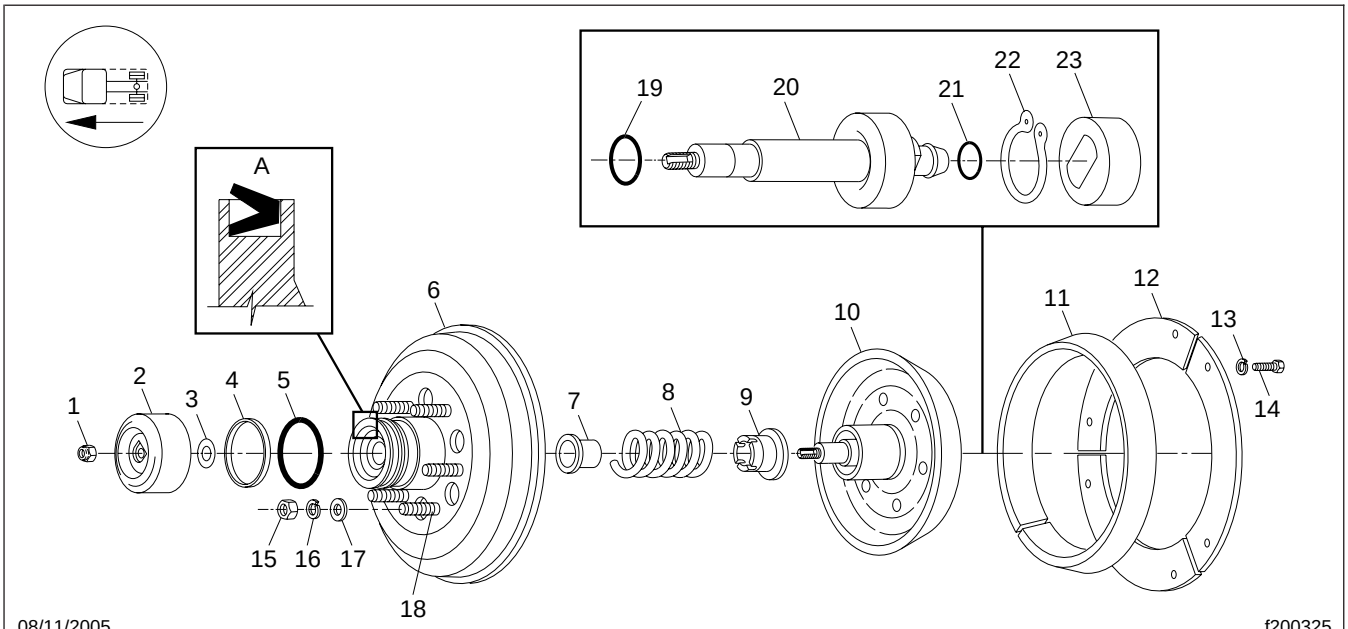
5. If applicable, turn the clutch over in the press, and use the special compressor tool to cage the engagement spring while removing the cylinder nut and cylinder. See **Fig. 4**.
6. Inspect the fan clutch. See **Fig. 3**
   - 6.1 Inspect the two surfaces where the lining rides.
   - 6.2 Inspect the needle bearing race on the shaft.
   - 6.3 Inspect the needle bearings inside the clutch housing.
   - 6.4 Inspect the piston bearing by rotating the piston.
7. If you find cracking or scoring on any surface, or if the bearings are rough, loose, or missing, replace the fan clutch.

NOTE: If you find metal particles in the existing grease, replace the fan clutch or contact Kysor for the training needed to perform a major fan clutch rebuild. Kysor will not provide parts for a major rebuild until the technician has completed rebuild training provided by Kysor.

IMPORTANT: Do not wash the clutch parts in solvent.

8. Using **Fig. 3** as a reference, lubricate the following rebuild parts with lubricant supplied with the rebuild kit (if the lubricant is unavailable, use one of the approved lubricants listed in **Specifications, 400)** :
   - The piston seal (pack the seal groove also)
   - The dust seal (pack the seal groove also)
   - The needle bearings inside the housing
   - The inside of the engagement spring
   - The outside of the piston rod assembly
   - The inside of the piston rod assembly
   - The inside of the cylinder assembly
   - Pack the lip of the grease seal

CAUTION



When caging the engagement spring, make sure the bottom edges of the housing assembly and the shaft assembly are flush and aligned all the way around. Failure to do so will cause the engagement spring pressure to affect the torque of the cylinder nut. This could result in the cylinder nut not being tight enough to effectively compress the piston seal washer, which could cause leakage and eventual fan clutch failure.

IMPORTANT: When caging the engagement spring, compress the clutch shaft only 1/16-inch (1.5 mm).

9. Assemble the fan clutch parts according to **Fig. 3**. Using either the special tools and a press, or carriage bolts, washers, and wingnuts, cage the engagement spring when installing the cylinder and lining. Be careful to depress the clutch shaft only 1/16-inch (1.5 mm).

   The piston rod seal washer is the last item to install before the cylinder goes on. See **Fig. 5**.
10. Tighten the cylinder nut 84 lbf·in (940 N·cm).
11. Tighten the lining screws 30 lbf·in (340 N·cm).

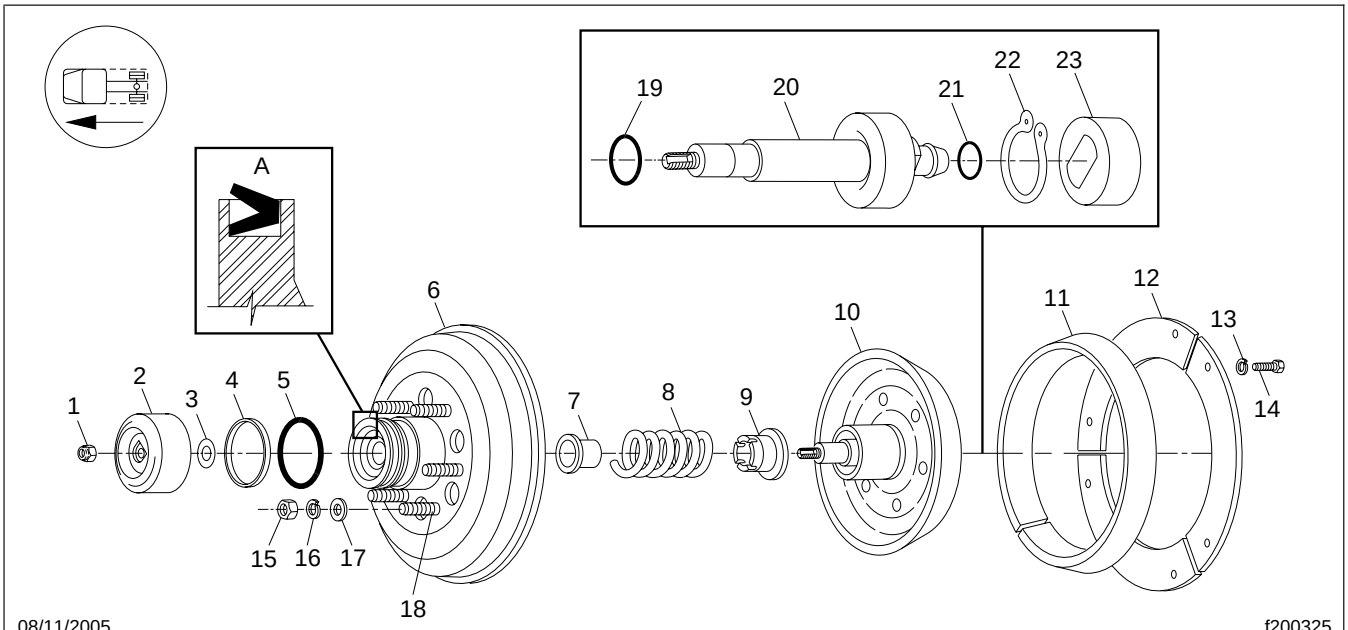
15. Close the hood and remove the chocks from the tires.

Fan Clutch Relining, Kysor K22RA

Relining (See Fig. 1)

IMPORTANT: Premature wearing of the fan clutch lining is due to either insufficient air pressure necessary to fully engage the clutch or a problem in the control circuit for the fan.



Before putting the fan clutch back in service, check the fan control and air supply systems and make any necessary repairs.

1. Park the vehicle, apply the parking brakes, and chock the tires.

WARNING

If the fan clutch engages during the next step, it could cause personal injury. Keep the fan clutch disengaged throughout this procedure by maintaining between 90 and 120 psi (620 and 830 kPa) of air pressure.

2. Remove the six lining plate screws, and remove the three lining plates. See **Fig. 2**.
3. Replace the lining.
4. Install the new lining plates, and tighten the screws 30 lbf·in (340 N·cm).
5. Remove the air pressure from the fan clutch, and allow the fan to engage.

Problem—Fan Clutch Fails to Engage

Problem—Fan Clutch Fails to Engage	
Possible Cause	**Remedy**
There is no power to the fan clutch control circuit.	Check all electrical connections, and repair or replace wiring as needed.
The engine temperature switch is damaged or an incorrect sensor has been installed.	Make sure the switch is normally closed, not normally open. Replace the switch if it is damaged or if the switch is the wrong type.
The solenoid valve is malfunctioning.	Replace the solenoid valve.
The fan clutch is leaking.	Install a new seal kit.
The air supply to the fan clutch is restricted.	Make sure the fan clutch air lines are not leaking or pinched. Repair the lines as needed.

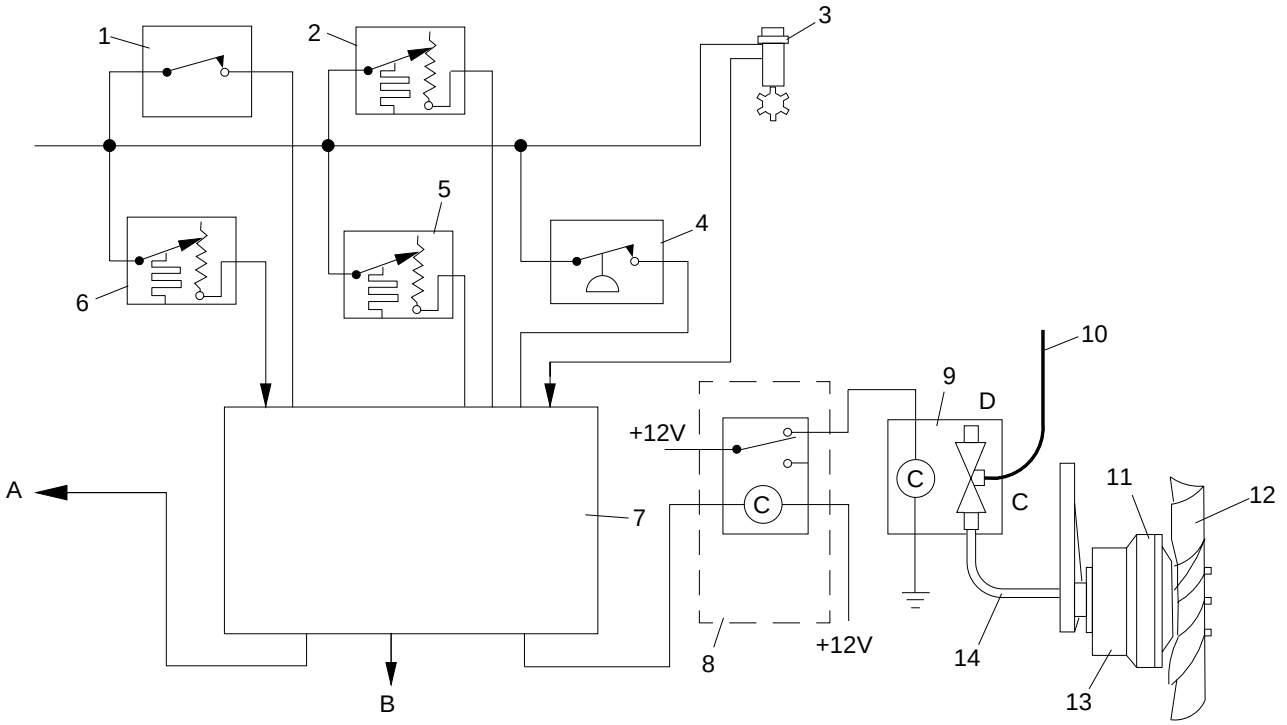
General Information



The Horton DriveMaster® fan clutch is a temperature-controlled, air-operated clutch for the engine cooling fan. It is spring engaged, and controls the engine temperature by engaging or disengaging the fan.

When the coolant temperature is below a specified range, air pressure keeps the fan disengaged to save engine power. When the coolant temperature rises above the specified range, air pressure to the fan clutch is cut off and internal spring pressure engages the fan.

Air pressure to the fan clutch is controlled by a solenoid valve; the solenoid valve is controlled by a temperature switch installed in the thermostat housing. The temperature switch is connected to the engine ECM, which controls the solenoid valve. See **Fig. 1**. When you start a cold engine, the solenoid valve allows air pressure to the fan clutch and the clutch remains disengaged. When the coolant temperature rises to the temperature switch setting, the switch provides power to the solenoid valve and the valve cuts off compressed air to engage the fan.

On vehicles with air conditioning, the fan clutch solenoid valve is connected to a fan cycling switch at the receiver-dryer. If the refrigerant pressure exceeds the setting of the fan cycling switch, the switch supplies power to the solenoid valve, which cuts off air to the fan clutch, engaging the fan.

Removal

1. Park the vehicle on a level surface, shut down the engine, set the parking brakes, and chock the tires.

⚠ WARNING

Wear safety goggles when draining the air system or disconnecting an air line, because dirt and sludge could fly out at high speeds. Do not direct the airstreams at anyone. Do not disconnect pressurized air lines, as they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

2. Drain the air tanks.
3. Tilt the hood.
4. Disconnect the left-side hose from the charge air cooler.
5. Remove the drive belts from the engine.
6. Disconnect the air line from the fan hub.
7. Remove the fan.

8.1 If equipped with a metal fan ring, remove the two top fasteners holding the upper mounting bracket for the fan ring.

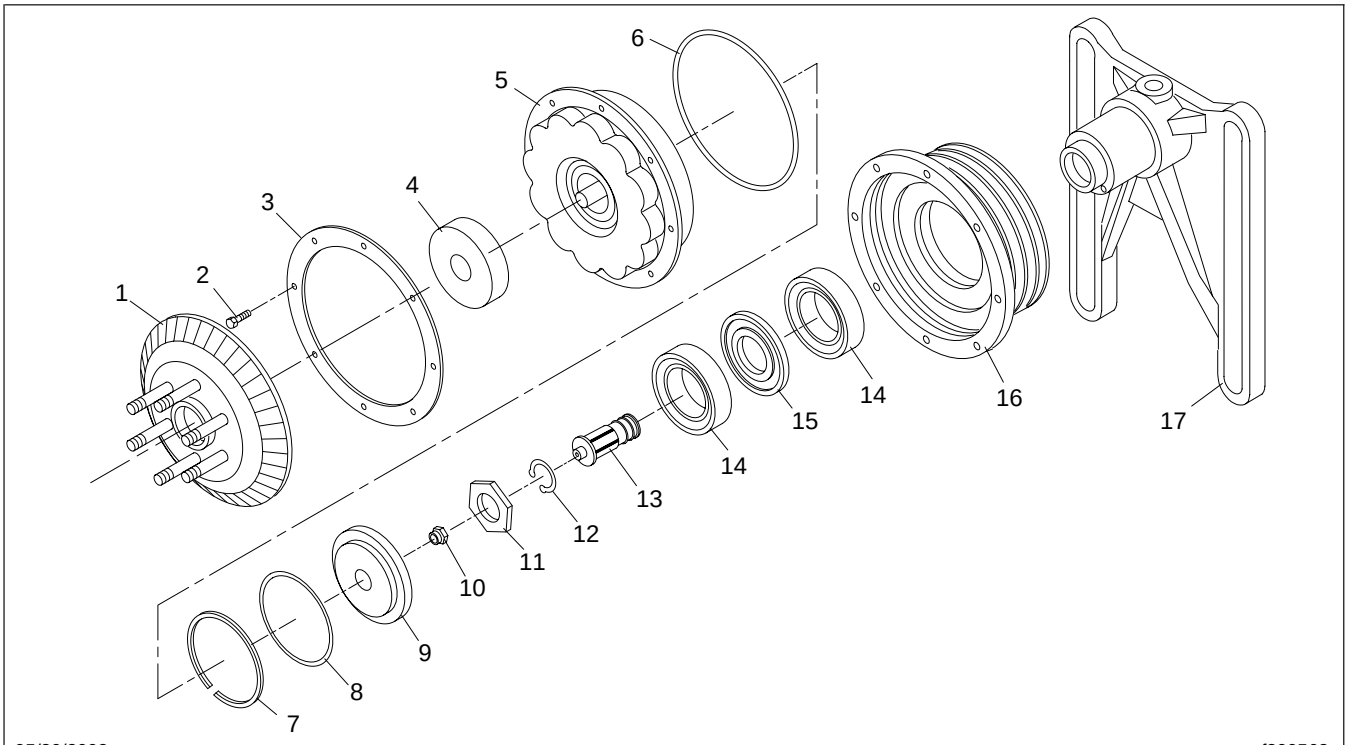
8.2 Remove the fasteners holding the fan clutch mounting bracket to the front of the engine.

⚠ WARNING

The fan clutch assembly may weigh up to 55 lb (25 kg). Be careful when lifting it. Use a helper or a hoist, if necessary. Failure to use care when lifting the fan clutch could result in injury or component damage.

8.3 Remove the fan clutch assembly from the vehicle. If equipped with a metal fan ring, carefully push the ring forward to allow removal of the fan clutch assembly.

Installation



1. Using either a helper or a hoist, position the fan clutch assembly in place on the front of the engine, aligning the holes in the mounting bracket with those in the front of the engine.
2. Install the fasteners.

   If equipped with a metal fan ring, don't tighten the upper fan clutch fasteners completely.
3. Install the drive belts.
4. Connect the air line to the fan clutch.
5. Install the fan. Tighten the fan mounting nuts firmly.
6. Tighten the M8 fan-clutch mounting fasteners 15 lbf·ft (20 N·m).
7. Connect the left-side hose to the charge air cooler.
8. Lower the hood.
9. Remove the chocks from the tires.

Disassembly

NOTE: This procedure involves a major rebuild of the Horton DriveMaster® fan clutch, using parts from the manufacturer's Super Kit. If you are replacing just the seals or the air cartridge, see **Subject 120** for the minor rebuild procedure.

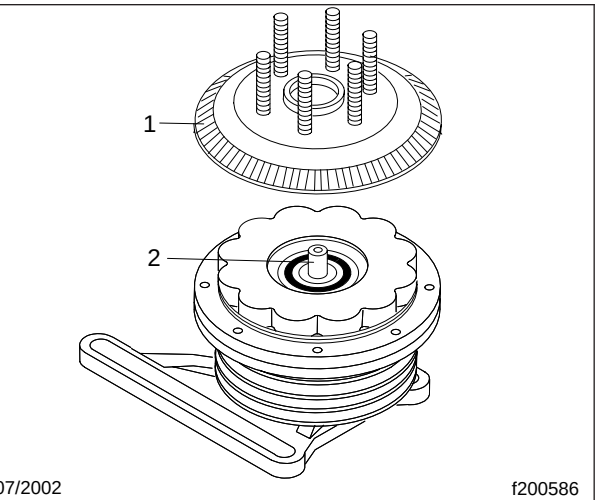
3. Connect a shop air hose to the fan clutch air inlet.
4. Apply 80 to 120 psi (552 to 827 kPa) to the fan clutch to lift the fan mounting disc off the spring housing/piston assembly.

CAUTION

Use care when placing the pry bar onto the fan mounting disc. Make sure it is secure and flat on the surface. Failure to do so make cause the pry bar to slip, which could result in damage to studs or the fan mounting disc.



5. Using a pry bar, wrench, and a T55 Torx® bit, loosen the jack bolt (left-hand thread) by turning it counterclockwise. See **Fig. 2**.

⚠ WARNING

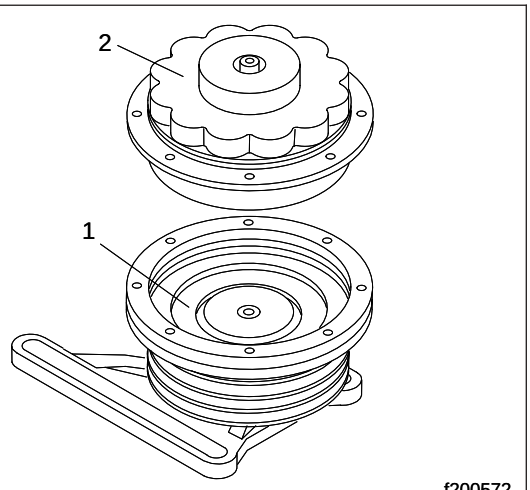
Do not disassemble the spring housing from the piston. The interior springs are very strong, and if released could eject the housing with considerable force, possibly resulting in serious injury. Always use the cage nut to hold the spring housing and the piston together.

8. Using a wrench and a T55 Torx bit to hold the jack bolt, install the cage nut from the kit onto the jack bolt (left-hand thread). Hand tighten it onto the spring housing.

   The cage nut will keep the spring housing and piston together as an assembly. It will also maintain pressure on the internal springs after the Torx-head screws holding the friction lining in place are removed.

9. Release the air pressure from the fan clutch.

⚠ WARNING



Release the air pressure from the fan clutch before removing the friction lining Torx-head screws. Failure to release the air pressure could result in the spring housing/piston assembly being ejected with force, which could result in personal injury.

10. Using a T27 Torx bit, remove the eight Torx-head screws holding the friction lining in place.
11. Remove the friction lining. See **Fig. 4**.
12. *Keeping the cage nut installed and tightened,* remove the spring housing/piston assembly. See **Fig. 5** .

IMPORTANT: If the fan clutch uses spacers, be sure to install them between the bearings.

2.2 Supporting the sheave, press the new sheave bearings — and spacers, if applicable — into place. Note the position of the lip inside the sheave.

2.3 Slide the sheave onto the mounting bracket. See **Fig. 8** .

2.4 Making sure that the bearing nut hex is facing up, install the bearing nut. See **Fig. 12** . Tighten 130 lbf·ft (176 N·m). See **Fig. 7** .

WARNING

The new spring housing/piston assembly from the kit has a cage nut installed on it. Do not remove the cage nut. This will cause the spring housing to be forcibly ejected from the piston assembly, which could result in serious injury.

14. Carefully set the new spring housing/piston assembly into position. See **Fig. 6** . Note that the new assembly has a cage nut installed on it.
15. Rotate the new spring housing/piston assembly to align the mounting holes with those of the sheave.

IMPORTANT: Handle the new friction liner by the edges to avoid contamination.

16. Set the new friction liner from the kit into place, being careful to touch only the edges.
17. Using a T27 Torx bit, install the eight Torx-head screws. See **Fig. 4** . Tighten alternately 80 lbf·in (900 N·cm).
18. Apply a minimum of 80 psi (552 kPa) of clean air to the air inlet.
19. Remove the cage nut from the spring housing/piston assembly.
20. Install the new fan mounting disc from kit.

CAUTION

Use care when placing the pry bar onto the fan mounting disc. Make sure it is secure and flat on the surface. Failure to do so make cause the pry bar to slip, which could result in damage to studs or the fan mounting disc.

21. Using a suitable wrench, a T55 Torx bit, and a pry bar, tighten the jack bolt (left-hand thread) 100 lbf·ft (136 N·m). Turn the wrench clockwise and push the pry bar counterclockwise.
22. Using shop air, actuate the fan clutch and check for correct engagement and disengagement of the fan mounting disc. If there is a problem, it must be corrected before installing the fan clutch onto the engine.
23. Check for air leaks at the bleed hole and around the spring housing/piston assembly.
24. Install the fan clutch assembly onto the engine. See **Subject 100** for instructions.

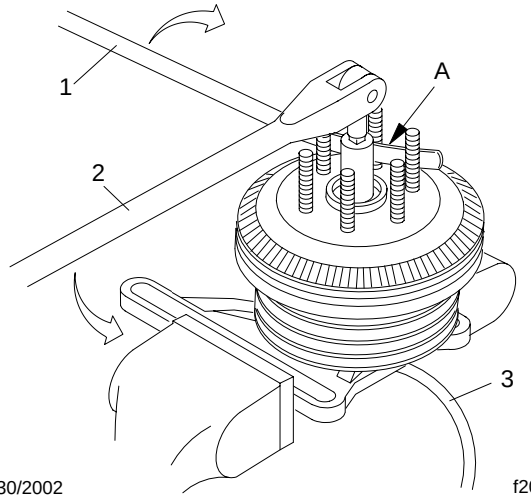
Disassembly

NOTE: This procedure involves a minor rebuild of the Horton DriveMaster® fan clutch, using parts from the manufacturer's Seal Kit. If a major rebuild of the fan clutch is needed, see **Subject 110**.

1. Remove the fan clutch assembly from the vehicle. For instructions, see **Subject 100**.
2. Put the fan clutch assembly in a vise.
3. Connect a shop air hose to the fan clutch air inlet.
4. Apply 80 to 120 psi (552 to 827 kPa) to the fan clutch to lift the fan mounting disc off the spring housing/piston assembly.

⚠ CAUTION

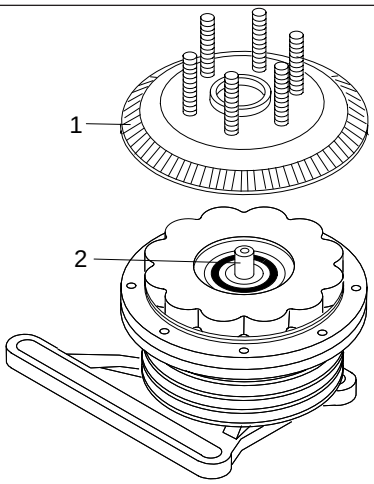
Use care when placing the pry bar onto the fan mounting disc. Make sure it is secure and flat on the surface. Failure to do so make cause the pry bar to slip, which could result in damage to studs or the fan mounting disc.



5. Using a pry bar, wrench, and a T55 Torx® bit, loosen the jack bolt (left-hand thread) by turning it counterclockwise. See **Fig. 1**.
6. Unscrew the fan mounting disc from the jack bolt. See **Fig. 2**.
7. Inspect the fan mounting disc for wear or damage.

⚠ WARNING

Do not disassemble the spring housing from the piston. The interior springs are very strong, and if released could eject the housing with considerable force, possibly resulting in serious injury. Always use the cage nut to hold the spring housing and the piston together.



8. Using a wrench and T55 Torx bit to hold the jack bolt, install the cage nut from the kit onto the jack bolt (left-hand thread). Hand tighten it onto the spring housing.

   The cage nut will keep the spring housing and piston together as an assembly. It will also maintain pressure on the internal springs after the Torx-head screws holding the friction lining in place are removed.

A. Place the pry bar here.

2. Torx Bit and Wrench (turn counterclockwise)
3. Shop Air Hose (connected to the inlet port)

⚠ WARNING

Release the air pressure from the fan clutch before removing the friction lining Torx-head screws. Failure to release the air pressure could result in the spring housing/piston assembly being ejected with force, which could result in personal injury.

10. Using a T27 Torx bit, remove the eight Torx-head screws holding the friction lining in place.

⚠ WARNING

The new spring housing/piston assembly from the kit has a cage nut installed on it. Do not remove the cage nut. This will cause the spring housing to be forcibly ejected from the piston assembly, which could result in serious injury.

13. Carefully set the new spring housing/piston assembly into position. See **Fig. 4** . Note that the new assembly has a cage nut installed on it.
14. Rotate the new spring housing/piston assembly to align the mounting holes with those of the sheave.

The face seal or air cartridge is damaged or worn.	Install a new seal kit.
The O-ring seals are damaged or worn.	Install a new seal kit.

Problem — The Fan Clutch Fails to Engage

Problem — The Fan Clutch Fails to Engage	
Possible Cause	**Remedy**
There's no power to the fan clutch control circuit.	Check all electrical connections, and repair or replace wiring as needed. Check the circuit breaker for the engine fan and repair or replace as needed.
The engine temperature switch is damaged or an incorrect sensor has been installed.	Make sure the switch is normally open, not normally closed. Replace the switch if it is damaged or if the switch is the wrong type.
The solenoid valve is malfunctioning.	Replace the solenoid valve.
The solenoid is not exhausting.	Make sure the solenoid exhaust port is not plugged.

Problem—The Fan Clutch Does Not Disengage

Problem — The Fan Clutch Does Not Disengage	
Possible Cause	**Remedy**
The engine temperature switch is damaged or an incorrect sensor has been installed.	Make sure the switch is normally open, not normally closed. Replace the switch if it is damaged or if the switch is the wrong type.
A restricted air line doesn't allow air supply to the clutch.	Make sure the air lines are not pinched or plugged. Repair the air lines as needed.
The fan clutch is leaking.	Install a new seal kit.
The air supply to the fan clutch is restricted.	Make sure the fan clutch air lines are not leaking or pinched. Repair the lines as needed.
The piston is seized due to contamination or dry seals.	Clean the air supply. Do a major rebuild.

Problem—The Fan Clutch Cycles Frequently

Problem — The Fan Clutch Cycles Frequently	
Possible Cause	**Remedy**
The fan clutch control circuit has a loose connection or is poorly grounded.	Check all wiring connections, and repair the circuit as needed. Check the circuit breaker for the engine fan and repair or replace as needed.
The temperature control settings are incorrect.	Check the fan clutch control setting of the temperature switch, according to the engine installed in the vehicle. Repair or replace the temperature switch as needed.

Troubleshooting

Problem — The Fan Clutch Cycles Frequently	
Possible Cause	**Remedy**
The fan cycling switch at the receiver-dryer is set too low.	Check the switch at the receiver-dryer, and if needed, replace the switch with a switch with a higher setting. Check the ACPU switch and unit.
There is an air restriction in front of the fan clutch.	Check for incorrect radiator shutter operation, winterfronts, or any other air restrictions.
The engine temperature is too high.	Check the programmable engine control parameters, and reprogram as needed.
The temperature switch is malfunctioning.	Replace the temperature switch.

General Description and Principles of Operation

Spicer Angle-Ring 310 mm and 350 mm clutches are a single-plate dry-disc design. There are no internal adjustments.

The clutch-cover assembly is bolted directly to the flywheel with twelve capscrews. The clutch-cover assembly drives the pressure plate through three drive straps. The driven disc uses ceramic friction material and has a spring-loaded center section for dampening.

The Angle-Ring clutch is a push-type release design. Depressing the clutch pedal moves the release (throw-out) bearing toward the engine flywheel. As the clutch is depressed, the pressure plate retracts from contact with the driven disc assembly, and the clutch is disengaged. As the clutch pedal is released, the release bearing and clutch levers move away from the engine flywheel. The belleville spring exerts pressure through the levers onto the pressure plate causing the driven disc to be locked up between the friction surfaces of the pressure plate and the engine flywheel. The clutch is then engaged.

Removal

1. Park the vehicle. Apply the parking brake and chock the tires.
2. Remove the transmission. See the applicable section in **Group 26**.

NOTE: The release bearing will drop to the bottom of the bell housing when the transmission is removed.

3. Remove the bell housing.
   - 3.1 On vehicles with Mercedes-Benz engines remove the twelve capscrews.

     On vehicles with Cummins B Series engines, loosen the nuts on the U-bolt holding the exhaust pipe to the bell housing. See **Fig. 1**. Remove the two capscrews (**Fig. 2**) holding the U-bolt bracket to the housing, and rotate the U-bolt bracket out of the way.

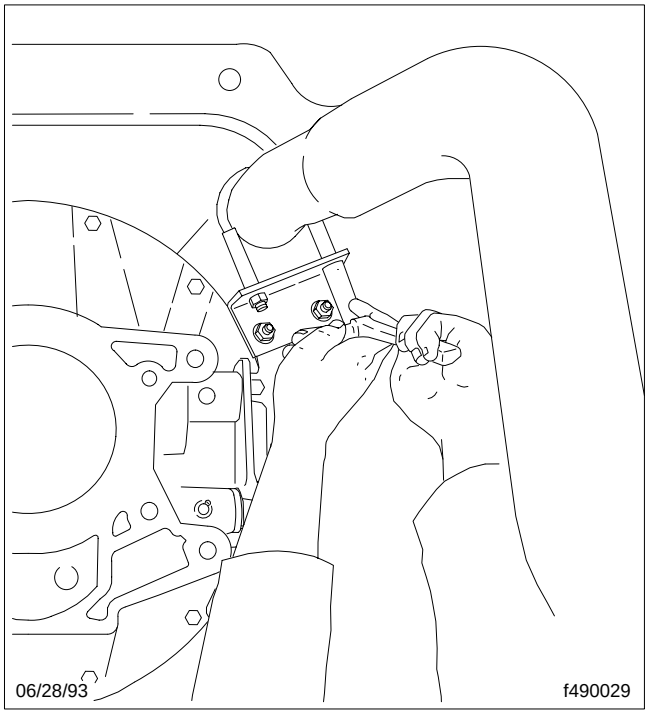

Fig. 1

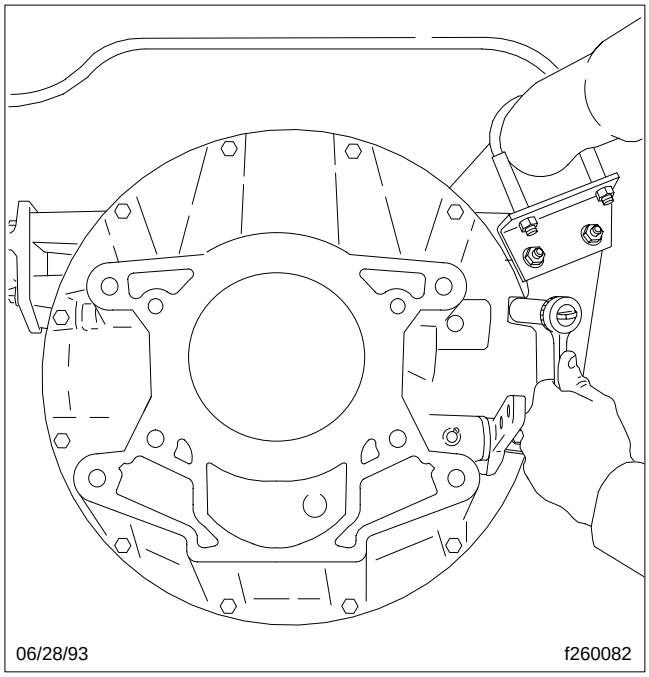

Fig. 2

   - 3.2 On vehicles with Cummins B Series engines, remove the remaining ten capscrews around the bell housing. See **Fig. 3**.
   - 3.3 On all vehicles, lift off the housing. See **Fig. 4**.
4. Remove the clutch assembly.
   - 4.1 Insert the pilot tool. See **Fig. 5**.
   - 4.2 Remove two capscrews from the top of the clutch and install dowels to support the pressure plate and cover assembly. See **Fig. 6**. Remove the remaining capscrews.
   - 4.3 Remove the clutch disc, pressure plate, and cover assembly along with the pilot tool. See **Fig. 7**.
5. Using a puller, remove the pilot bearing. See **Fig. 8**.

Inspection

1. Clean the clutch assembly thoroughly to inspect the parts. If there is excessive wear or damage

Clutch Removal, Inspection, and Installation

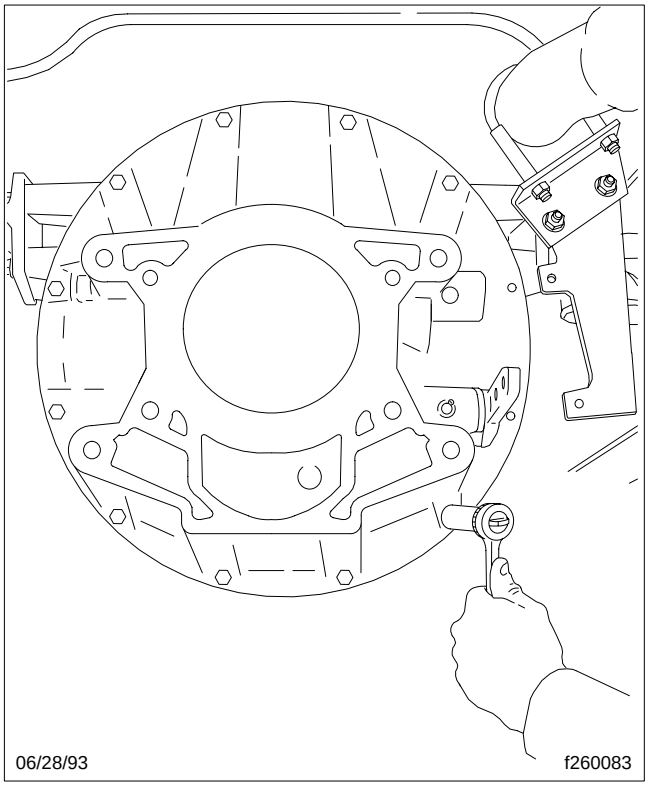

Fig. 3

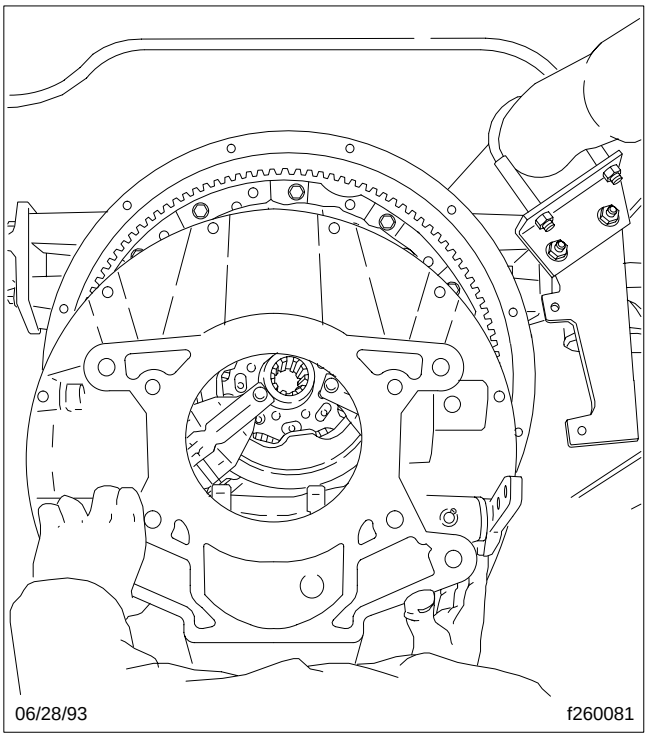

Fig. 4

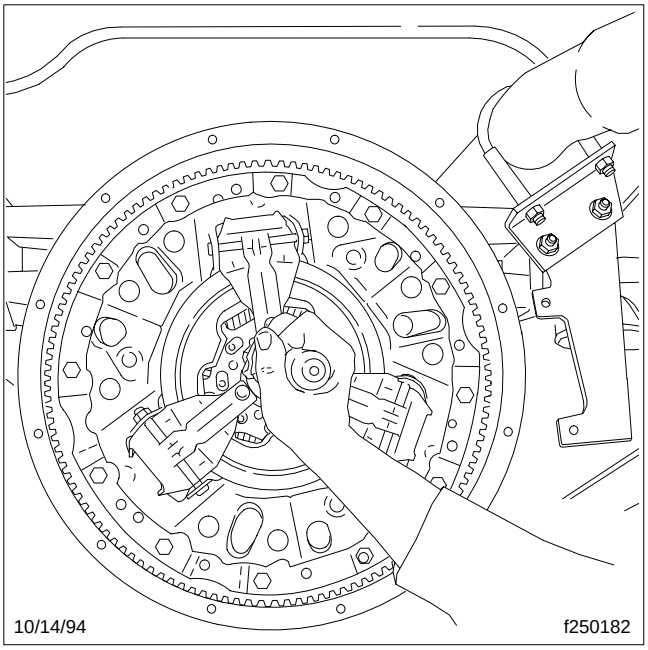

Fig. 5

or if parts are in questionable condition, replace them with a new clutch and driven disc assembly.

IMPORTANT: When taking the following readings, rotate the engine by hand; do not crank the engine with the starter. The engine may be rotated by the flywheel-mounting bolts or the starter ring-gear on the flywheel.

NOTE: Due to the design of the clutch assembly, do not rebuild it.

2. Clean the surfaces being measured to ensure accurate measurements.

NOTE: Before measuring the flywheel or flywheel housing, check the end-play of the crankshaft. Mount the dial indicator on the flywheel housing, with the indicator's finger against the flywheel. Force the crankshaft back and forth with a pry bar. If end-play exceeds the maxi-

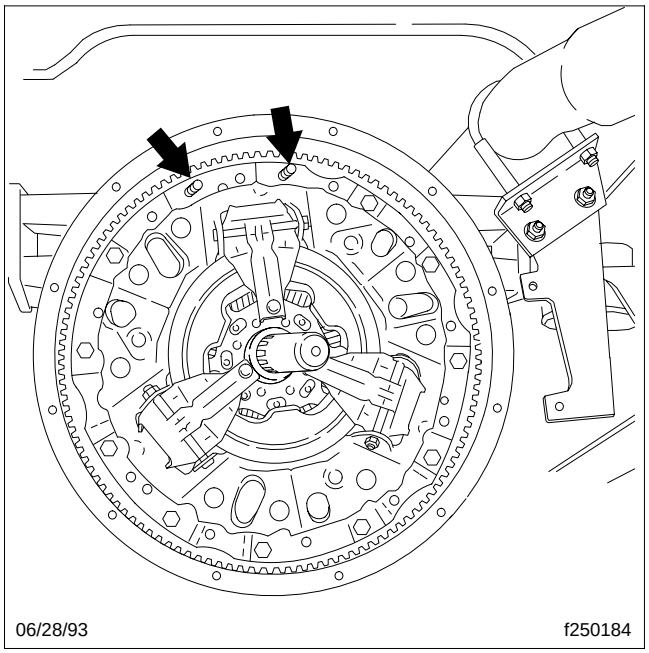

Fig. 6

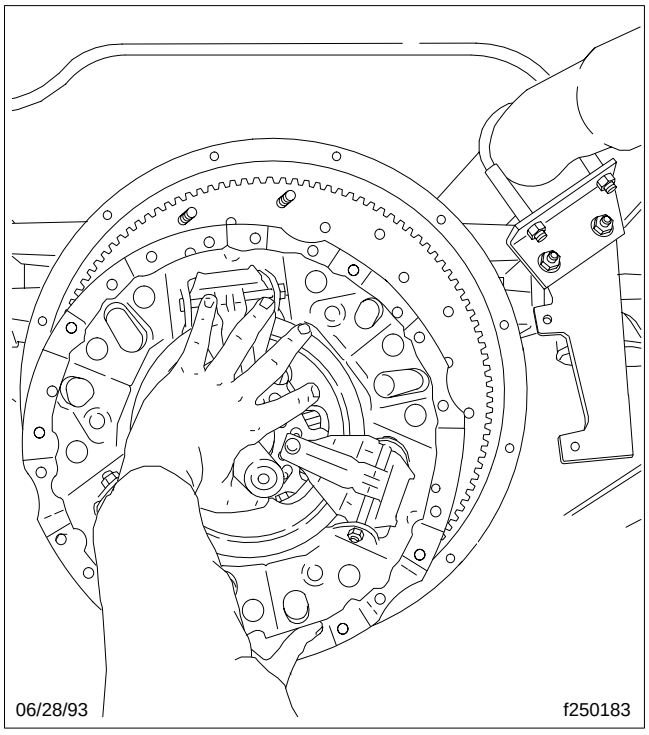

Fig. 7

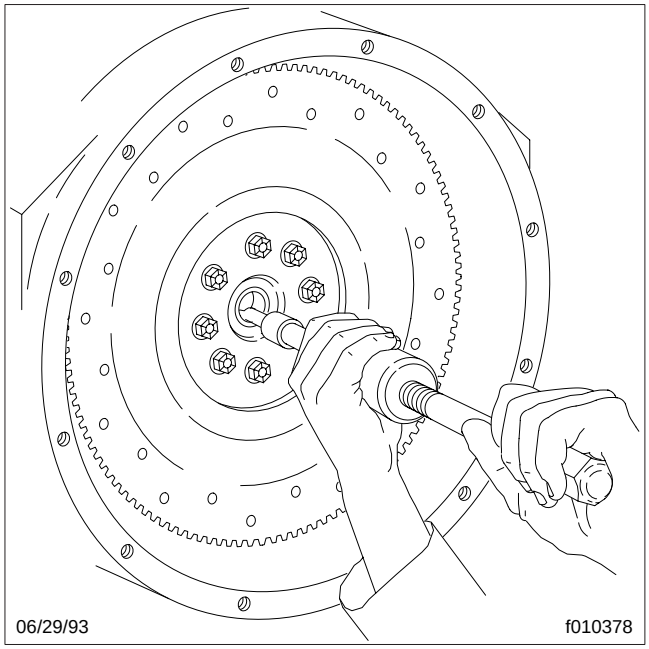

Fig. 8

mum, correct it. For specifications and instructions, see the engine manufacturer's service manual.

3. Inspect for a worn or corroded pilot (**Fig. 9**) on both the bell housing, and the flywheel housing. The pilot lip of the clutch housing can wear into the flywheel housing. This can be caused by the transmission loosening up, or by road and engine vibration after high mileage. Any measurable wear on either part will cause misalignment; replace the part. Wear may first appear between the 3 o'clock and 8 o'clock positions. See **Fig. 10**.

   3.1 Measure the runout of the pilot (bore) of the flywheel housing. Secure the dial indicator to the flywheel (or crankshaft), with the gauge finger against the housing pilot. See **Fig. 11**. With chalk or soapstone, mark the high and low points on the flywheel housing flange, while rotating the flywheel (or crankshaft) by hand. The total runout will be the difference between the highest plus and minus readings. See **Fig. 12**.

   The SAE maximum total runout for the flywheel housing pilot is 0.2 mm (0.008

Clutch Removal, Inspection, and Installation

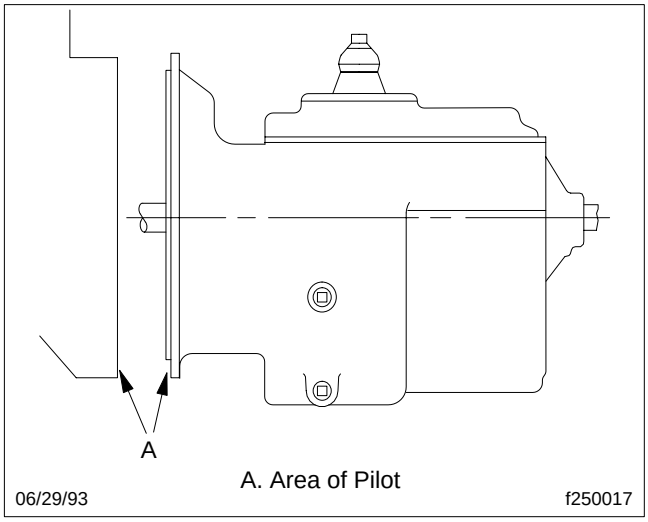

Fig. 9

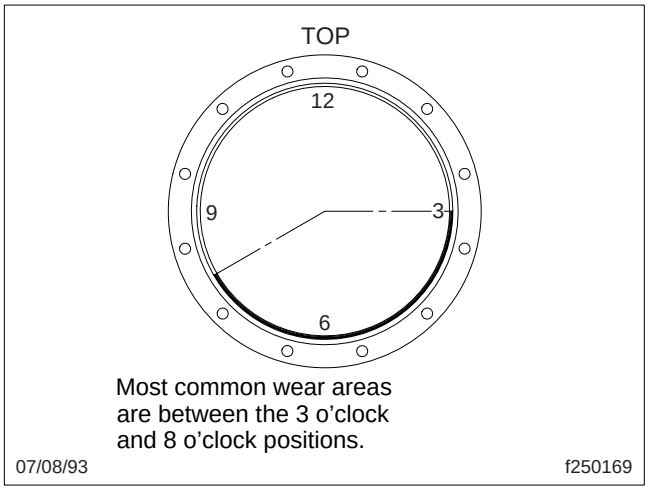

Fig. 10

inch). If the readings are higher, replace the housing. For instructions, see the engine manufacturer's service manual.

3.2 Measure the runout of the face of the flywheel housing. With the dial indicator secured to the flywheel (or crankshaft), move the finger to contact the face of the housing. See **Fig 13**. Mark the high and low points.

The SAE maximum total runout for the flywheel housing face is 0.2 mm (0.008 inch). If the readings are higher, replace the housing. For instructions, see the engine manufacturer's service manual.

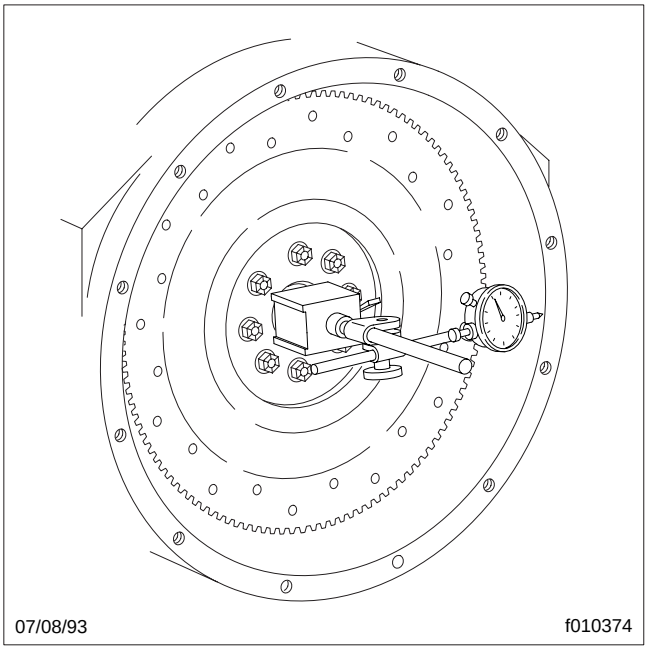

Fig. 11

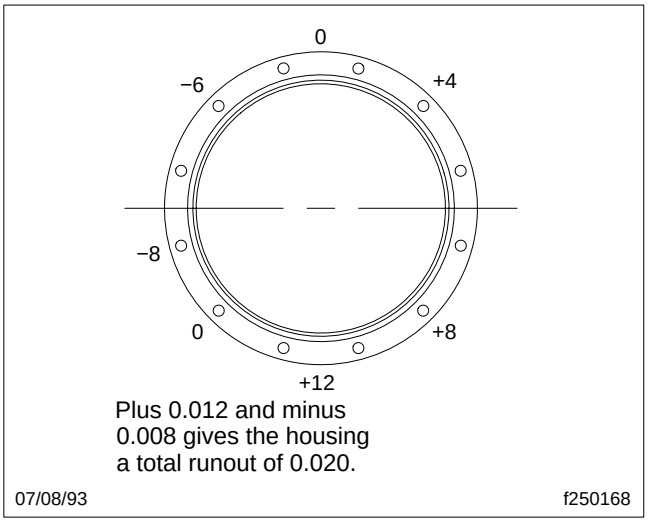

Fig. 12

NOTE: It is necessary to mark the high and low runout readings in clock positions only if you have to reposition the flywheel housing.

4. Measure the runout of the flywheel face. Secure the dial indicator to the flywheel housing, with the

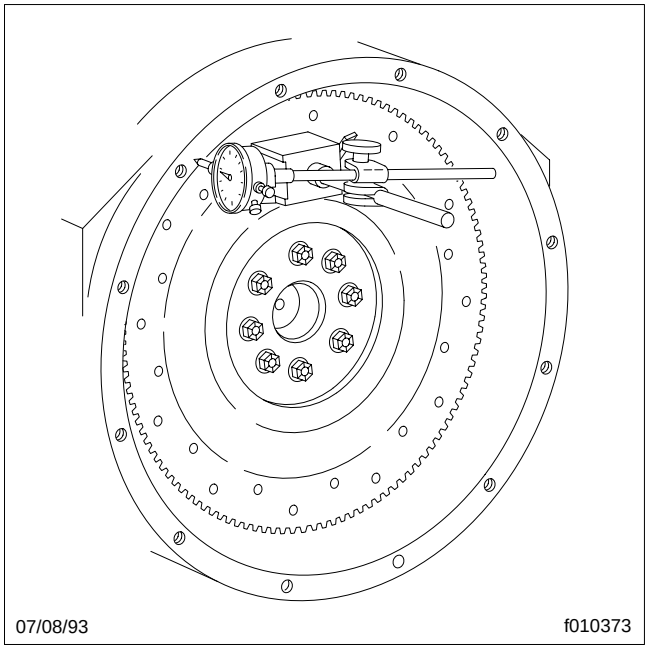

Fig. 13

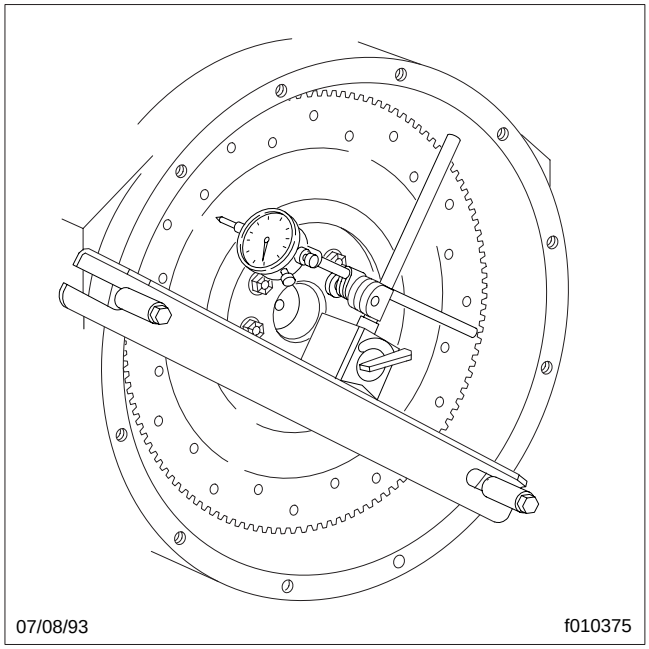

Fig. 14

gauge finger against the face of the flywheel near the outer edge. See **Fig. 14**. Turn the flywheel to obtain readings. With readings taken just outside the outer edge of the clutch disc wear pattern, the maximum tolerance is 0.18 mm (0.007 inch) for the 350-mm (14-inch) clutch and 0.17 mm (0.006 inch) for the 310-mm (13-inch) clutch. If the readings are higher, repair or replace the flywheel. See the engine manufacturer's service manual for instructions.

5. Measure the runout of the pilot-bearing bore of the flywheel. With the indicator secured to the flywheel housing, move the gauge finger to contact the pilot-bearing bore surface. See **Fig. 15**. Turn the flywheel to obtain the readings.

   The SAE maximum total runout for the pilot-bearing bore is 0.13 mm (0.005 inch). If the readings are higher, see the engine manufacturer's service manual for instructions.

6. Measure the runout of the transmission clutch-housing face and pilot.

   The SAE maximum runout for the clutch-housing face and pilot is 0.20 mm (0.008 inch). If the readings are higher, replace the clutch housing; see the transmission manufacturer's service manual.

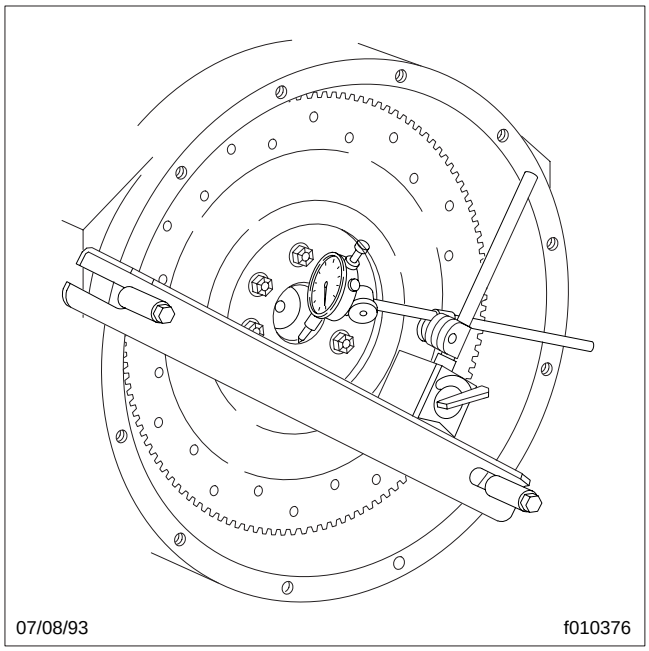

Fig. 15

Clutch Removal, Inspection, and Installation

⚠ CAUTION

CAUTION: The engine and transmission must line up. Misalignment of any parts will cause premature wear of drivetrain components.

NOTE: The clutch-housing face and pilot cannot be checked accurately unless you have a set of case-bore plugs and shaft. This set consists of plugs to be tapped into the front and rear bores of the transmission case. They have a very close fit in the bores. A shaft runs through the center of the plugs, and extends to the front far enough to secure a dial indicator and obtain a reading on the clutch housing.

7. Inspect the friction surface of the flywheel for unevenness, heat checks, scoring, and wear on the contact surface. Inspection for heat checks and scoring must be visual, and based on experience; however, measure the friction surface wear with a straightedge and feelers.

   Replace or repair the flywheel if the wear is extreme. For instructions, see the engine manufacturer's recommendations concerning flywheel replacement or rebuilding.

   If the flywheel has been replaced, measure the runout of the face and pilot diameters to make sure the measurements are within the engine manufacturer's specifications.

8. Check the fit of the splined hub of the clutch disc by sliding it on the transmission input shaft splines. The hub must slide freely so the clutch will release cleanly. If necessary, use a hand stone to dull the sharp edges of the splines. If the input shaft splines are badly worn or notched, replace the input shaft; for instructions, see the transmission manufacturer's service manual.

9. Check for wear on the fingers of the clutch release yoke, release shaft, and the release shaft bushings. Replace any worn parts.

10. Check the pilot bearing and release bearing. Replace parts as needed. Excessive wear can cause poor clutch performance and shortened clutch life.

11. Remove any oil or grease from the flywheel and bell housing area.

Installation

1. Using a driver, install a new pilot bearing. See **Fig. 16**.

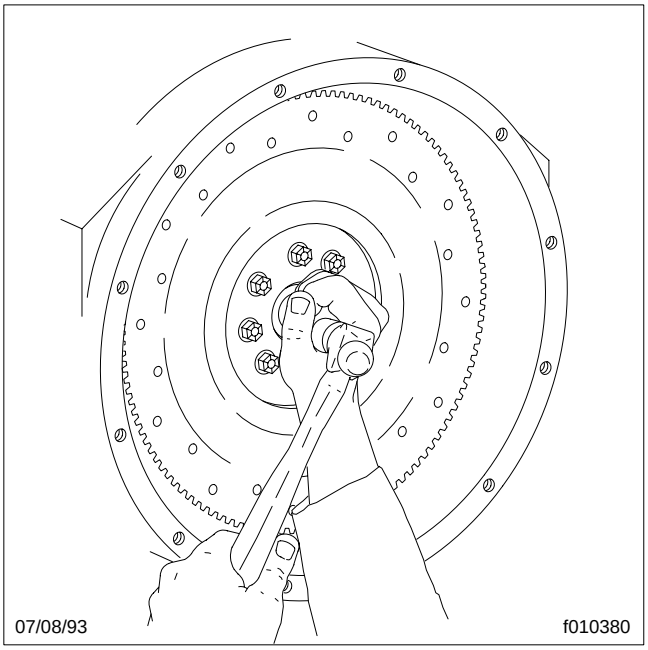

Fig. 16

2. Install the clutch assembly.

   2.1 Assemble the clutch disc and pressure plate on the pilot tool making sure the correct side of the disc will face the flywheel. See **Fig. 17**.

   2.2 If they were removed, install the dowels in the two upper holes in the flywheel.

   2.3 Lift the clutch disc, pressure plate, and pilot tool into position and hang them on the dowels. See **Fig. 7**.

   2.4 Install capscrews in the holes without dowels. Remove the dowels and install the remaining capscrews. Tighten them 45 N·m (33 lbf·ft) in the sequence shown in **Fig. 18**.

   2.5 Remove the pilot tool.

3. Lift the bell housing into position (**Fig. 4**) and install the twelve capscrews around the housing. Tighten the capscrews 54 N·m (40 lbf·ft).

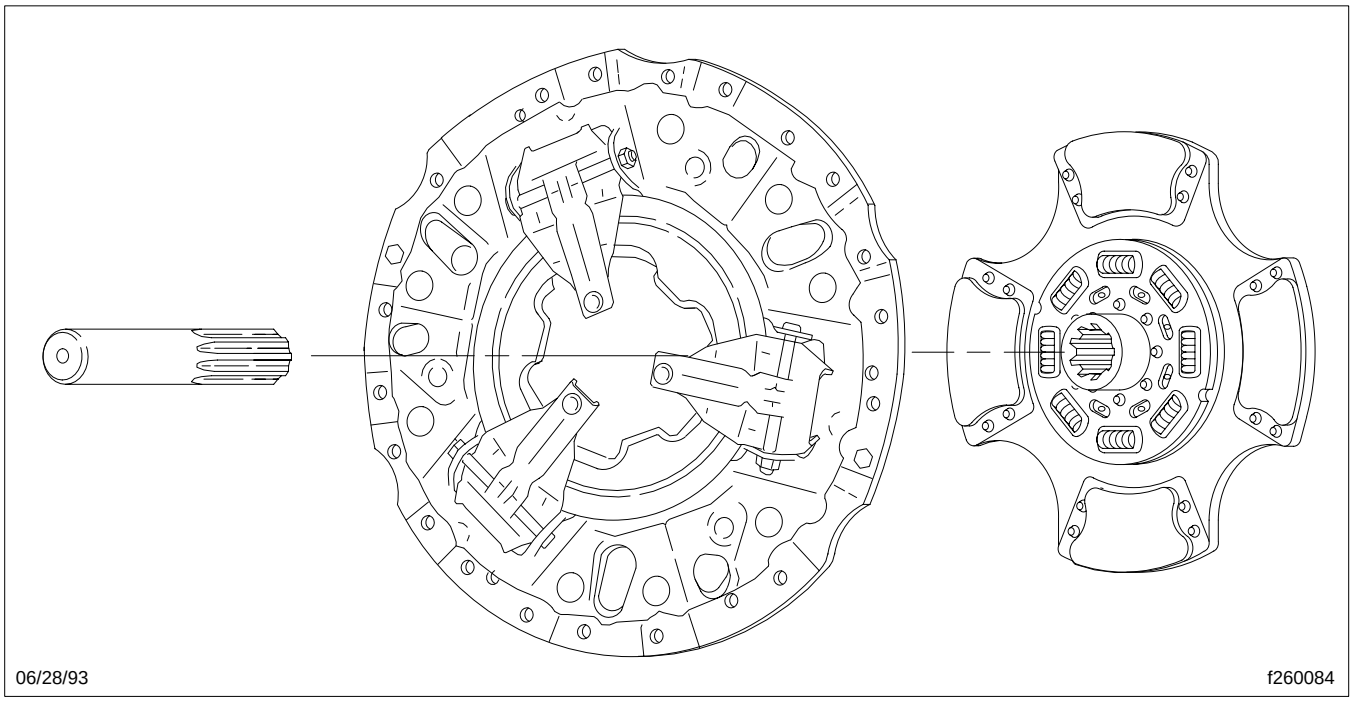

Fig. 17

NOTE: On vehicles with Cummins B Series engines some of the capscrews also hold brackets for the exhaust and various lines and cables (**Fig. 1** and **Fig. 2**).

4. Pull the clutch release fork back (**Fig. 19**); then, slide the release bearing into position.
5. Install the transmission. See the applicable section in **Group 26**.
6. Remove the chocks from the tires.
7. Test drive the vehicle to check for correct clutch operation.

Troubleshooting

This subject contains the following troubleshooting tables:

- Clutch Drags and Doesn't Release Completely
- Clutch Slips

Problem—Clutch Drags and Doesn't Release Completely

Possible Cause	Remedy
Slave cylinder is leaking or not working correctly.	Repair or replace the slave cylinder as needed.
Master cylinder is leaking or not working correctly.	Repair or replace the master cylinder as needed.
The clutch driven disc is bent or warped.	Replace the driven disc.

Problem—Clutch Slips

Possible Cause	Remedy
The shipping blocks were not removed.	Remove the shipping blocks and install the clutch correctly.
There is grease or oil on the clutch driven disk, the pressure plate, or the flywheel.	Clean the clutch components with isopropyl alcohol as needed. If the problem is due to a leaking rear crankshaft seal or transmission seal, replace seals as needed.
The driver is riding the clutch pedal.	Instruct the driver in the correct driving techniques. Slipping the clutch will cause clutch and flywheel damage.

General Description

Eaton® Fuller® Stamped Angle-Spring® (SAS), Easy-Pedal™, and Solo™ clutches are pull-type clutches of a dry-disc design.

Angle-Spring Clutches

Eaton® Fuller® Stamped Angle-Spring® (SAS) clutches are used in medium-duty applications and offered in two 14-inch (350-mm) versions:

- SAS 1401, with one driven disc, is standard on FL80 and optional on other medium-duty models. It is not available with non-synchronized transmissions.
- SAS 1402, with two driven discs, is optional on all medium-duty models.

All SAS clutches are adjustable using a lockstrap or the Kwik-Adjust™ mechanism. Both versions are mounted to a flat flywheel. See **Fig. 1**.

In the dual-disc version, the intermediate plate separating the driven discs is mounted directly to the flywheel. The flywheel ring carries four drivestraps to retract the pressure plate when the clutch is disengaged.

Clutch capacity for Angle-Spring clutches is indicated by the color code of the damper springs in the cover assembly. See the appropriate Angle-Spring clutch table in **Specifications, 400** for color codes.

Easy-Pedal Clutches

Easy-Pedal clutches are available in 14-inch (350-mm) dual-disc assemblies used in medium-duty applications and 15.5-inch (394-mm) dual-disc assemblies used in heavy-duty applications (FL112). All Easy-Pedal clutches are adjustable using a lockstrap or the Kwik-Adjust™ mechanism. See **Fig. 2**.

Clutch capacity for Easy-Pedal clutches is indicated by the color code of the damper springs in the cover assemblies. See the appropriate Easy-Pedal clutch table in **Specifications, 400** for color codes.

Easy-Pedal 14-Inch Clutches

14-inch Easy-Pedal Plus® dual-disc clutches are used in medium-duty applications. On these clutches, the intermediate plate separating the driven discs is carried on six pins mounted in the flange of a "pot-type" flywheel. Four return springs attached to the cover assembly retract the pressure plate when the clutch is disengaged.

Medium-duty Easy-Pedal clutch discs are offered in the following configurations:

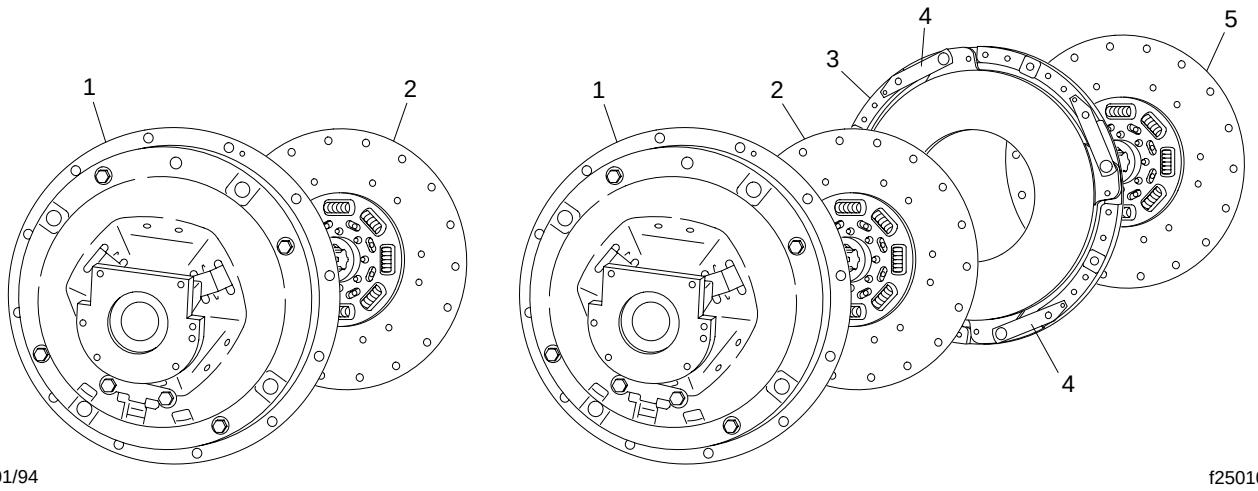
- Eight spring dampers with three ceramic facings;
- Eight spring dampers with four ceramic facings.

Super-duty clutches have thicker intermediate plates, and ceramic facings on each side of each disc. Do not mix standard-duty and super-duty discs.

- Standard-duty clutches use a thin intermediate plate of approximately 0.58 to 0.63 inches (15 to 16 mm) and thicker discs of approximately 0.45 inches (11 mm).
- Super-duty clutches use a thicker intermediate plate of approximately 0.75 to 0.81 inches (19 to 21 mm) and thin discs of approximately 0.36 inches (9 mm).

Easy-Pedal 15.5-Inch Clutches

15.5-inch Easy-Pedal 2000 clutches are available on FL112 models only. On these clutches, the intermediate (center) plate separating the driven discs is carried on four lugs within the cover assembly. The cover assembly is mounted on a flat flywheel. Four return springs attached to the cover assembly retract the pressure plate when the clutch is disengaged.



Heavy-duty Easy-Pedal clutch discs are offered in a standard configuration (see **Fig. 3**) and one optional configuration (see **Fig. 4**):

- Seven spring dampers with four ceramic facings are standard on FL112.
- Seven spring dampers with six ceramic facings and vibration control technology (VCT™plus) are optional on FL112.

NOTE: An earlier version of vibration control technology (VCT™) had a disc with six spring dampers and six ceramic facings. This disc has now been replaced by VCT™plus.

On older vehicles, clutch discs with eight-, nine-, or ten-spring dampers may be installed. In heavy-duty applications, these older types of dampers are not adequate for modern high-horsepower engines that operate at lower peak torques.

CAUTION

If your vehicle was originally equipped with six- or seven-spring discs, do not substitute eight- or ten-spring discs. This could cause excessive torsional vibration and component damage.

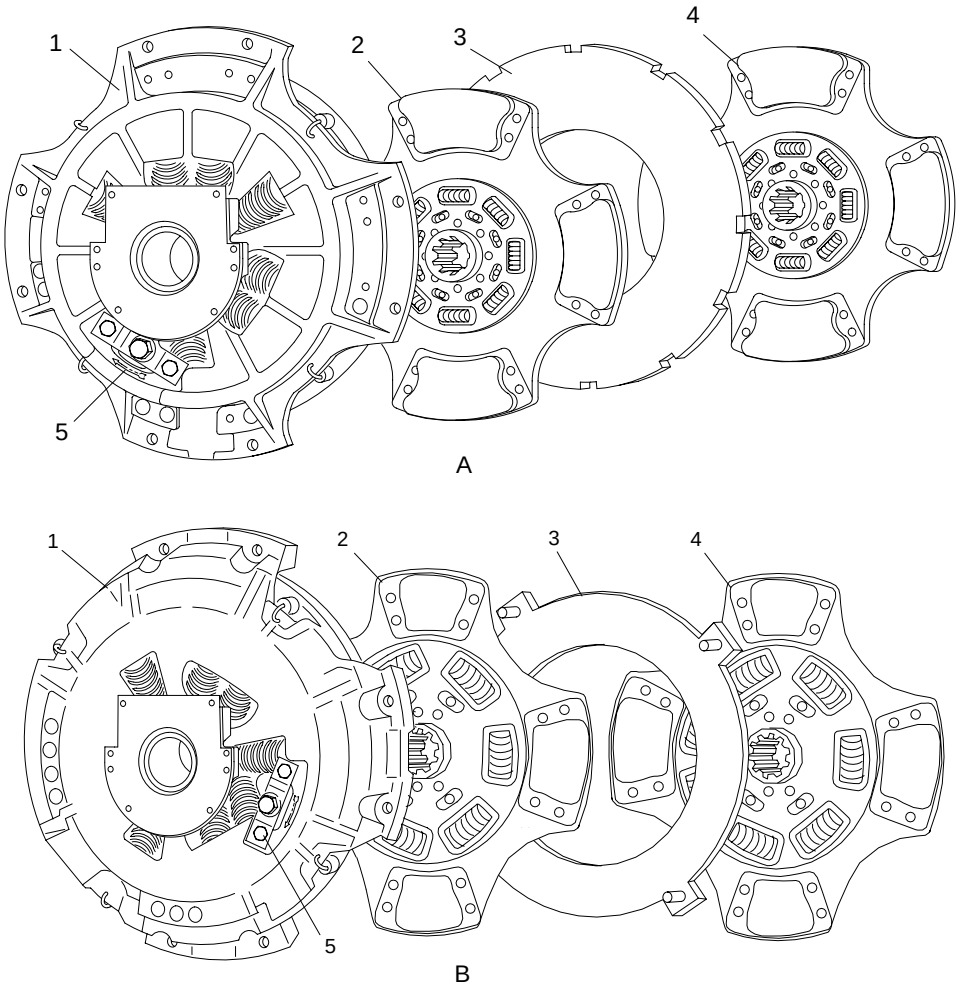
Solo Clutches

Eaton Fuller Solo™ clutches are 14-inch (350-mm) single- or dual-disc assemblies used in medium-duty applications and 15.5-inch (394-mm) dual-disc assemblies used in heavy-duty applications. See **Fig. 5**. Both versions are mounted to a flat flywheel.

Solo clutches are totally adjustment-free. As the clutch wears, its innovative wear-adjusting technology monitors clutch components and makes any necessary adjustments. The wear-adjusting technology comes from two sliding cams, which rotate to maintain the proper adjustment. Atop the upper cam, a wear indicating tab mirrors the cam's movement to let you know when it's time to replace the clutch. See **Fig. 6**. This tab cannot be used as a mechanism for adjusting the clutch.

Solo Medium-Duty 14-Inch Clutches

14-Inch Solo 1401 and 1402 clutches are optional on all medium-duty models. They are available in two 14-inch (350-mm) versions:



- Solo 1401, with one driven disc
- Solo 1402, with two driven discs

In the dual-disc version, the intermediate plate separating the driven discs is mounted directly to the flywheel. The flywheel ring carries four drivestraps (see **Fig. 5**) to retract the pressure plate when the clutch is disengaged. Four positive separator pins™ (roll pins) ensure an equal gap on all sides of the intermediate plate and increase the life of the clutch.

Medium-duty Solo clutch discs are available in two optional configurations:

- eight-spring dampers with three ceramic facings;
- eight-spring dampers with four ceramic facings.

For clutch capacities, see the appropriate Solo medium-duty clutch table in **Specifications, 400**.

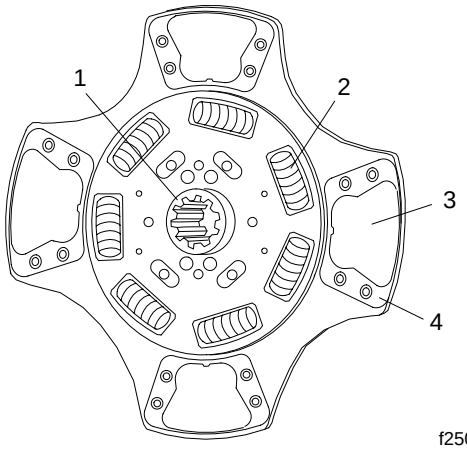
Solo Heavy-Duty 15.5-Inch Clutches



Solo Heavy-Duty clutches are available on FL112 models only. See **Fig. 7**.

Heavy-duty Solo clutch discs are offered in the following configurations:

- seven spring dampers with six ceramic facings and improved vibration control technology (VCTplus™);
- seven spring dampers with four ceramic facings.

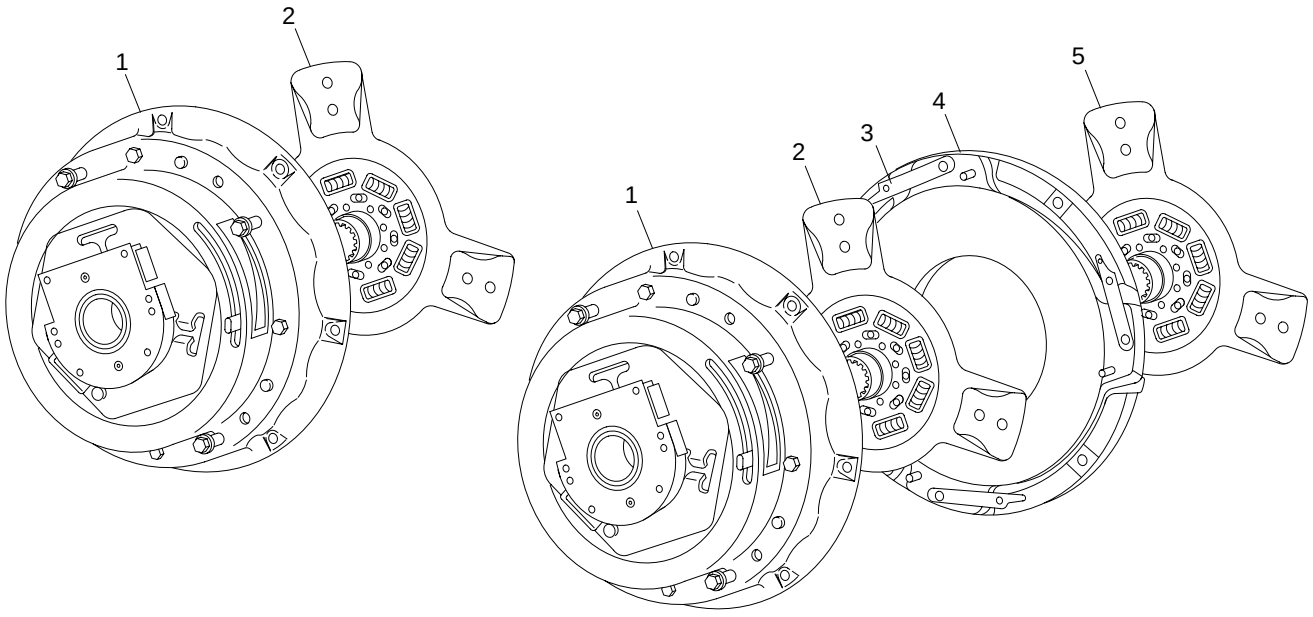
Principles of Operation

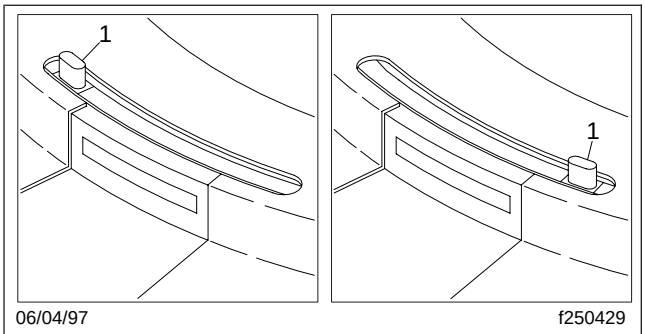
The primary purpose of the clutch is to transfer the power of the engine from the engine flywheel to the transmission. At the point where clutch engagement begins (clutch pedal partially released), the transmission input shaft may be stationary, as when the vehicle is not moving, or it may be rotating at a different speed than the flywheel, as in the case of upshifting or downshifting. Once the clutch is fully engaged (clutch pedal fully released), both the engine flywheel and the transmission input shaft will be rotating at the same speed.



The secondary purpose of the clutch is to damp unwanted vibrations that normally exist in the driveline system. The springs within each driven disc provide a flexible link between the friction surfaces and the disc hubs. Damped clutch discs are specifically designed to prolong the life of drivetrain components by reducing vibrations from the engine, non-uniform U-joint angles, and road dips and bumps.

When the clutch pedal is first pressed down, the first 1/2-inch to 1-inch (12.7 to 25.4 mm) of pedal movement (clutch free-pedal) causes the release yoke fingers to move into contact with the wear pads of the release bearing (release yoke free-travel). See **Fig. 8**. The release yoke pulls the release bearing away from the pressure plate inside the clutch cover. This compresses the pressure springs, allowing the driven discs to slip freely, and at a different speed from the drive discs.

Further downward movement of the clutch pedal (clutch release-pedal), causes the release bearing to move into contact with the clutch brake (release bearing travel). As the clutch begins to release, the pressure springs force the pressure plate toward the engine flywheel, applying friction to the driven discs. Slippage occurs between the drive and driven discs because of the difference in their speeds.



In the last 1 inch to 1-1/4 inches (25 to 33 mm) of downward pedal movement, the clutch brake and the release bearing are pressed together (clutch brake squeeze). The friction applied to the discs increases, and the slippage and difference in speeds decreases. When the pedal is fully released, pressure and friction are sufficient to stop the discs from slipping. With no slippage, the driving and driven members turn at the same speed.

When the vehicle is stationary, the clutch brake permits shifting into first gear or reverse gear without

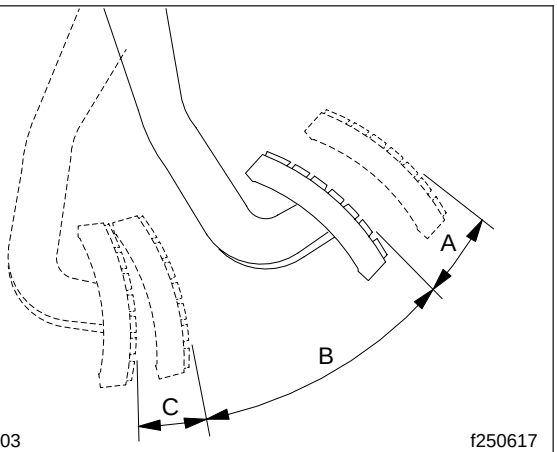
severe gear clash. The clutch brake is between the release bearing housing and the transmission bearing cap, and is engaged by tangs to the transmission input shaft. When the pedal is fully depressed, the clutch brake is squeezed between the release bearing housing and the transmission bearing cap, stopping the rotation of the main drive gear.



The clutch brake may be a disc type or a torque-limiting type. To prevent overloads to it, the torque-limiting clutch brake is designed to slip when loads of 20 to 25 lbf·ft (27 to 34 N·m) are reached. Clutch brakes are not designed for upshifting.

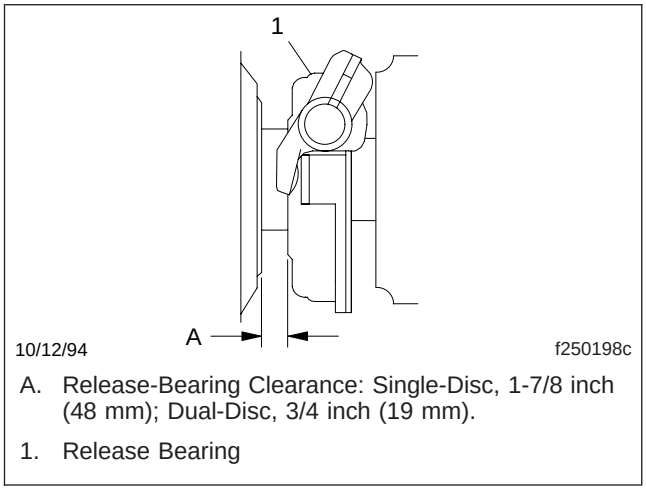
NOTE: The following procedures apply only to Eaton® Fuller® Easy-Pedal® and Stamped Angle Spring clutches. Solo™ clutches are adjustment-free.

Release Bearing Travel (synchronized transmissions)

Measurement

IMPORTANT: Do not skip steps in the adjustment operations. Internal adjustments must be correct before making any linkage adjustments for pedal free play. Incorrect adjustments can cause transmission gear clash, and slipping and burning of clutch components.

1. Apply the parking brakes, and chock the front tires.
2. Remove the clutch inspection cover from the bottom of the transmission clutch housing. See **Fig. 1**.



1. Clutch Inspection Cover

Fig. 1, Remove the Clutch Inspection Cover

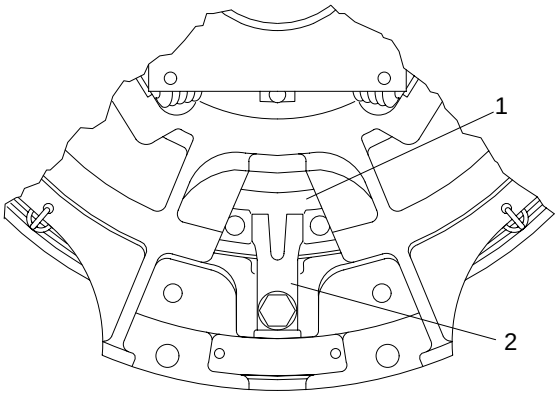
NOTE: When checking release bearing clearance, remove the free travel by *lightly* pulling the release fork against the clutch release bearing. This eliminates any bearing movement.

3. Measure the clearance between the release bearing and the clutch cover. For a single-disc clutch, this clearance must be 1-7/8 inch (48 mm) in order for the release-bearing to release properly. For a dual-disc clutch, this clearance must be 3/4 inch (19 mm) in order for the release-bearing to release properly. See **Fig. 2**. If the release bearing clearance is not within the specifications, then an adjustment is needed. Go to "Adjustment" in this section.

A. Release-Bearing Clearance: Single-Disc, 1-7/8 inch (48 mm); Dual-Disc, 3/4 inch (19 mm).
1. Release Bearing

Fig. 2, Release Bearing Clearance

4. If the release bearing clearance measurement is okay, check and adjust the clutch linkage. For instructions, see **Section 25.02**.



Adjustment

Angle-Spring and Easy-Pedal clutches are adjusted with either a lockstrap (**Fig. 3**), or with the Kwik-Adjust® mechanism (**Fig. 4**).

Clutches with a Lockstrap

1. Turn the engine flywheel until the lockstrap is aligned with the clutch inspection-cover opening. See **Fig. 1** and **Fig. 3**.
2. Remove the lockstrap. See **Fig. 3**.
3. Release the clutch by depressing the pedal. Block the pedal in the released position, or have someone assist you by holding the pedal down during the adjustment procedure.
4. Using a clutch adjusting tool, turn the adjusting ring clockwise to move the release bearing toward the transmission, or counterclockwise to move the release bearing toward the engine.

Clutch Adjustments

1. Adjusting Ring
2. Lockstrap

Fig. 3, Clutch Equipped with a Lockstrap

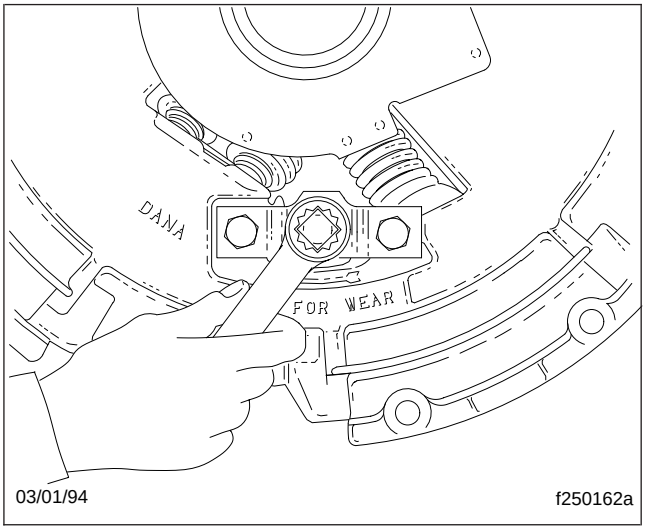


Fig. 4, Clutch Equipped with Kwik-Adjust

NOTE: Each notch in the adjusting ring represents about 0.020-inch (0.5-mm) release-bearing travel. Thus, three notches moved means 0.060 inch (1.5 mm) or about 1/16-inch release-bearing travel.

5. After adjusting, release the pedal, and check the clearance between the release-bearing housing and the clutch cover. For a single-disc clutch, when the clearance is 1-7/8 inch (48 mm), the internal adjustment is complete. For a dual-disc clutch, when the clearance is 3/4 inch (19 mm), the internal adjustment is complete.
6. Install the lockstrap, and tighten the bolt 35 to 40 lbf·ft (47 to 54 N·m).

IMPORTANT: Use the same length bolt when installing the lockstrap. A longer bolt will lock-up the clutch assembly.

NOTE: If the lockstrap will not engage the notches of the adjusting ring, check the clutch assembly for worn parts. For instructions, see **Subject 120**.

7. If the release bearing clearance measurement is okay, check and adjust the clutch linkage. For instructions, see **Section 25.02**.

Clutches with Kwik-Adjust

1. Turn the engine flywheel until the lockstrap is aligned with the clutch inspection-cover opening. See **Fig. 1** and **Fig. 4**.
2. Release the clutch by depressing the pedal. Block the pedal in the released position, or have someone assist you by holding the pedal down during the adjustment procedure.

NOTE: An open-end wrench is not recommended for the following step.

3. Insert a 12 point 3/4-inch socket or box-end wrench through the inspection cover opening. Depress the square bolt to adjust the release-bearing clearance.

   Rotate the adjusting ring counterclockwise to move the release-bearing toward the engine. Rotate the adjusting ring clockwise to move the release-bearing toward the transmission.

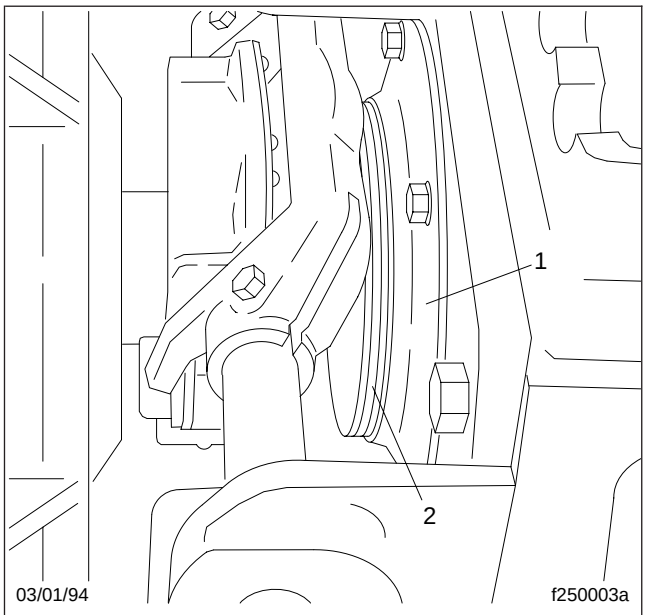
   Be sure the adjustment bolt is locked when you have completed the adjustment.

NOTE: Each quarter of a turn of the adjustment bolt represents about 0.017-inch (0.4-mm) release-bearing movement.

4. After adjusting, release the pedal, and check the internal clearance between the release-bearing housing and the clutch cover. For a single-disc clutch, when the internal clearance is 1-7/8 inch (48 mm), the adjustment is complete. For a dual-disc clutch, when the internal clearance is 3/4 inch (19 mm), the adjustment is complete.

5. If the release bearing clearance measurement is okay, check and adjust the clutch linkage. For instructions, see **Section 25.02**.

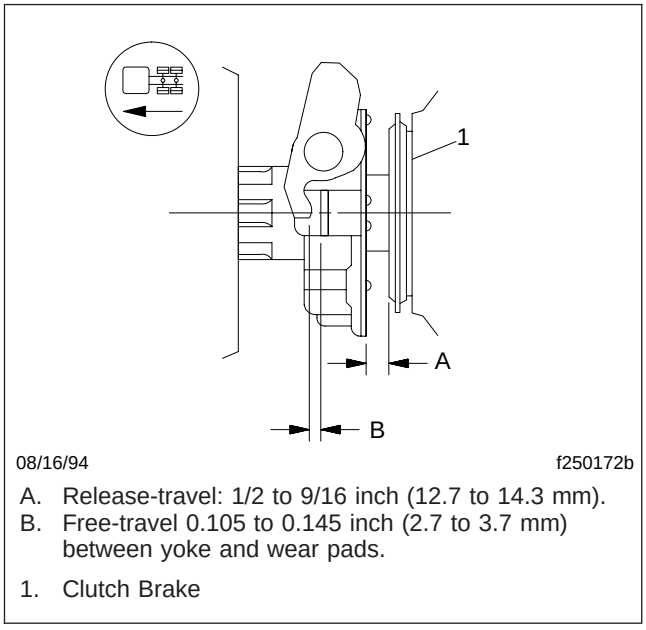
Release Bearing Travel (nonsynchronized transmissions)



Measurement

IMPORTANT: Do not skip steps in the adjustment operations. Internal adjustments must be correct before making any linkage adjustments for pedal free-travel. Incorrect adjustments can cause transmission gear clash, and slipping and burning of clutch components.

1. Apply the parking brakes, and chock the front tires.
2. Remove the clutch inspection cover from the bottom of the transmission clutch housing. See **Fig. 1**.
3. Slide the clutch-brake discs and washer, or torque-limiting clutch brake, tight against the transmission input shaft bearing cap. See **Fig. 5**. Also, slide the release-bearing as far as possible towards the transmission.
4. Measure the internal clearance between the aft face of the release-bearing and the forward face of the clutch brake disc, or torque-limiting clutch brake. This internal clearance must be 1/2 inch to 9/16 inch (12.7 mm to 14.3 mm) in order for the release-bearing to release properly. See **Fig. 6**.



IMPORTANT: An inspection tool A02–12419 (available through the PDCs) can be used to check the distance between the release-bearing and the clutch brake. See **Fig. 7**. One end of the tool has green tape on it and is 0.50 inch (12.7 mm) in diameter; the other end has blue tape on it and is 0.56 inch (14.3 mm) in diameter.

5. If using tool A02–12419 to check the distance between the release-bearing and the clutch brake, position the tool so that the legs straddle the transmission input shaft. Check the gap with both ends of the tool as follows:

1. Transmission Input Shaft Bearing Cap
2. Clutch Brake Discs and Washer

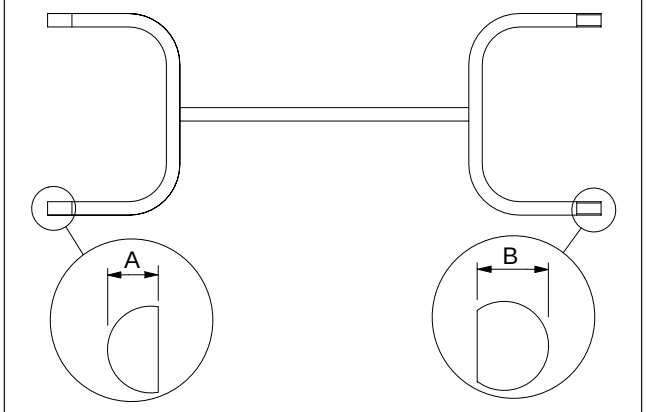
justment is needed. Go to "Adjustment" in this section.

5.2 If the blue 0.56-inch (14.3-mm) end can't be inserted in the gap, then try to insert the green 0.50-inch (12.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.



5.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Go to "Adjustment" in this section.

IMPORTANT: An inspection tool A02–12254 (available through the PDCs) can be used to check the distance between the release-bearing and the release yoke (free travel). See **Fig. 6** and **Fig. 8**. The legs on one end of the tool have green tape on them and are 0.105 inch (2.7 mm) thick; the legs on the other end have blue tape on them and are 0.145 inch (3.7 mm) thick.

6. If using tool A02–12254 to check the distance between the release-bearing and the release yoke, position the tool so it straddles the yoke to ensure that there won't be any misalignment. Check the distance with both ends of the tool as follows:

6.1 Insert the blue 0.145-inch (3.7-mm) end. If it fits loosely, the gap is too wide and linkage adjustment is needed. For instructions, see **Section 25.02**.

6.2 If the blue 0.145-inch (3.7-mm) end can't be inserted in the gap, then try to insert the green 0.105-inch (2.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

Adjustment

Angle-Spring and Easy-Pedal clutches are adjusted with either a lockstrap (**Fig. 9**), or with the Kwik-Adjust® mechanism (**Fig. 10**).

Clutches with a Lockstrap

1. Turn the engine flywheel until the lockstrap is aligned with the clutch inspection-cover opening. See **Fig. 1** and **Fig. 9**.
2. Remove the lockstrap. See **Fig. 9**.
3. Release the clutch by depressing the pedal. Block the pedal in the released position, or have someone assist you by holding the pedal down during the adjustment procedure.
4. Using a clutch adjusting tool, turn the adjusting ring to adjust release travel (the clearance between the release-bearing housing and the forward clutch brake disc).

   If clearance between the release-bearing housing and the clutch brake is *less than* 1/2 inch (12.7 mm), rotate the adjusting ring counterclockwise to move the release-bearing toward the engine.

   If clearance between the release-bearing housing and the clutch brake is *more than* 9/16 inch (14.3 mm), rotate the adjusting ring clockwise to move the release-bearing toward the transmission.

   The lockstrap bolt may be installed and used as a fulcrum in turning the adjusting ring.

NOTE: Each notch in the adjusting ring represents about 0.020-inch (0.5-mm) release-bearing travel. Thus, three notches moved means 0.060-inch (1.5-mm) or about 1/16-inch release-bearing travel.

5. After adjusting, release the pedal, and check the clearance between the release-bearing housing and the forward clutch brake disc, or torque-limiting clutch brake. When the clearance is 1/2 inch to 9/16 inch (12.7 mm to 14.3 mm), the adjustment is complete.
6. Install the lockstrap, and tighten the bolt 35 to 40 lbf·ft (47 to 54 N·m).

IMPORTANT: Use the same length bolt when installing the lockstrap. A longer bolt will lock-up the clutch assembly.

NOTE: If the lockstrap will not engage the notches of the adjusting ring, check the clutch assembly for worn parts. For instructions, see **Subject 120**.

7. Check and adjust the clutch linkage. For instructions, see **Section 25.02**.

Clutches with Kwik-Adjust

1. Turn the engine flywheel until the lockstrap is aligned with the clutch inspection-cover opening. See **Fig. 1** and **Fig. 10**.
2. Release the clutch by depressing the pedal. Block the pedal in the released position, or have someone assist you by holding the pedal down during the adjustment procedure.

NOTE: An open-end wrench is not recommended for the following step.

3. Insert a 12 point 3/4-inch socket or box-end wrench through the inspection cover opening. Depress the square bolt to adjust the release-bearing clearance.

   If clearance between the release-bearing housing and the clutch brake is *less than* 1/2 inch (12.7 mm), rotate the adjusting ring counterclockwise to move the release-bearing toward the engine.

   If clearance between the release-bearing housing and the clutch brake is *more than* 9/16 inch (14.3 mm), rotate the adjusting ring clockwise to move the release-bearing toward the transmission.

   Be sure the adjustment bolt is locked when you have completed the adjustment.

NOTE: Each quarter of a turn of the adjustment bolt represents about 0.017-inch (0.4-mm) release-bearing movement.

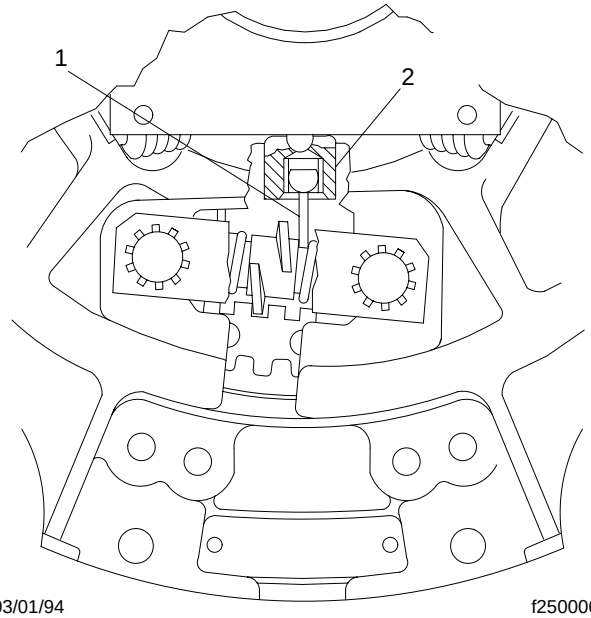
4. After adjusting, release the pedal, and check the clearance between the release-bearing housing and the forward clutch brake disc, or torque-limiting clutch brake. When the clearance is 1/2 inch to 9/16 inch (12.7 mm to 14.3 mm), the adjustment is complete.
5. Check and adjust the clutch linkage. For instructions, see **Section 25.02**.

Self-Adjusting Clutch

IMPORTANT: The self-adjusting clutch normally compensates for wear, and should only need adjustment when it is first installed. If the release-bearing clearance check shows the self-adjusting clutch to be out of adjustment, be sure that:

A. the actuator arm is correctly inserted into the release-bearing sleeve retainer (see **Fig. 11**);

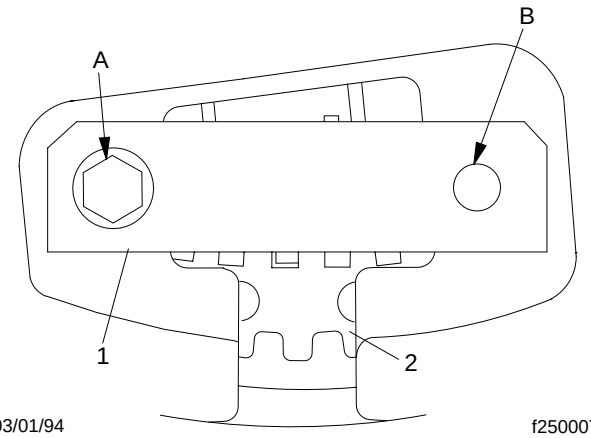
B. the adjuster arm is not bent;



C. the release-bearing has a 1/2 inch to 9/16 inch (12.7 mm to 14.3 mm) travel;

D. other clutch parts (such as the adjusting ring) aren't frozen or damaged.

If the clutch is damaged, replace it.



If adjustment is needed, do the following:

1. Turn the engine flywheel until the adjuster assembly is in line with the clutch inspection-cover opening. See **Fig. 1** and **Fig. 11**.
2. Remove the right-side bolt from the adjuster assembly, and loosen the left-side bolt one turn. See **Fig. 12**.
3. To allow manual adjustment, rotate the adjuster assembly upward. See **Fig. 13**. This will disengage the adjuster worm gear from the adjusting ring. Hold the adjuster assembly disengaged, and tighten the left-side bolt.
4. Release the clutch by depressing the pedal; block it in this position.
5. Using a clutch adjusting tool in the lower teeth, turn the adjusting ring clockwise to move the release-bearing toward the transmission, or counterclockwise to move the release-bearing toward the engine. See **Fig. 11**.

1. Adjuster Assembly

Fig. 13, Rotate the Adjuster Assembly

CAUTION

Do not pry on the innermost gear teeth of the adjusting ring. See Fig. 13. Doing so could damage the teeth, and prevent the clutch from self-adjusting.

NOTE: Each lower gear tooth of the adjusting ring represents about 0.010-inch (0.25-mm) release-bearing movement. Thus, six notches moved means 0.060-inch (1.5-mm) or about 1/16-inch release-bearing movement.

6. After adjusting, release the clutch pedal, and check the clearance between the release-bearing housing and the forward clutch brake disc, or torque-limiting clutch brake. When the clearance is 1/2 inch to 9/16 inch (12.7 mm to 14.3 mm), the adjustment is complete.

IMPORTANT: The clutch will not self-adjust if release-bearing travel is less than 1/2 inch (12.7 mm).

7. Loosen the left-side adjuster bolt, and rotate the adjuster assembly down, meshing the adjuster worm gear with the adjusting ring teeth. The ring may have to be moved slightly, to allow the worm to mesh. Install the right-side bolt, and tighten both bolts 30 to 35 lbf·ft (41 to 47 N·m).
8. Visually check that the actuator arm is inserted in the release-bearing sleeve retainer. See **Fig. 9**. If the adjuster assembly is installed correctly, the adjuster assembly spring will move back and forth as the clutch pedal is depressed and released.

IMPORTANT: The clutch will not self-adjust if the actuator arm is not correctly inserted in the release-bearing sleeve retainer.

After making release-bearing adjustments, check and adjust the clutch linkage. For instructions, see **Section 25.02**.

Removal

Stamped Angle-Spring™ Clutch

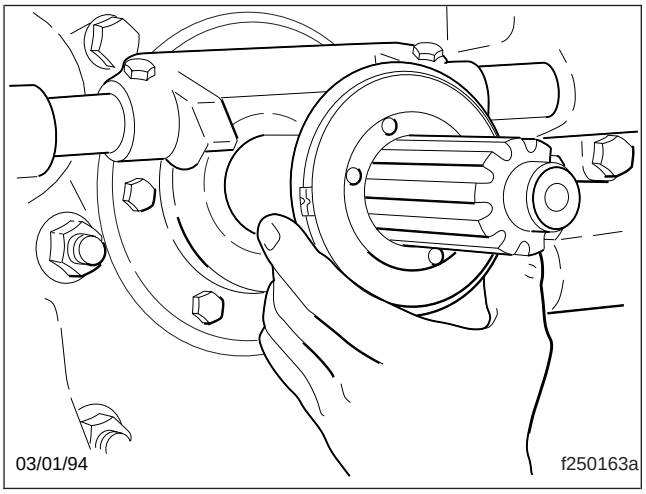
NOTE: Before pulling the transmission from the bell housing, disconnect the external clutch linkage and rotate the release yoke so the yoke will clear the release bearing when it is removed.

1. Remove the transmission. See **Section 26.00**.

⚠ CAUTION

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

2. If installed, remove the clutch brake from the transmission input shaft. See **Fig. 1**.



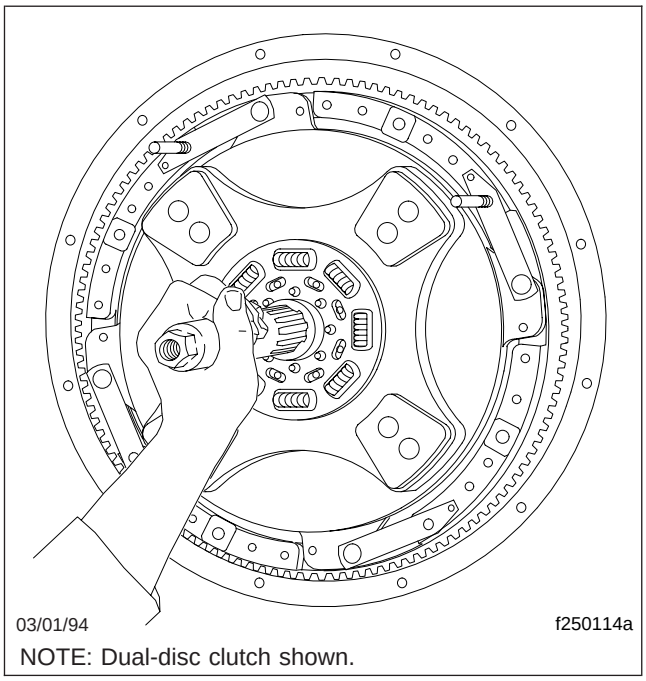


Fig. 1, Clutch Brake Removal

3. Install a spline aligning tool into the release bearing assembly, and through the driven discs. See **Fig. 2**. An old transmission input shaft may be used for this purpose.
4. Use a release tool and two 1- to 1.5-inch (25 to 37 mm) spacer blocks to pull the bearing back.
5. Remove the two top mounting capscrews from the cover assembly. Install two 3/8–16 x 3 guide studs in the open holes to help support the clutch assembly during removal. See **Fig. 3**.

NOTE: Dual-disc clutch shown.

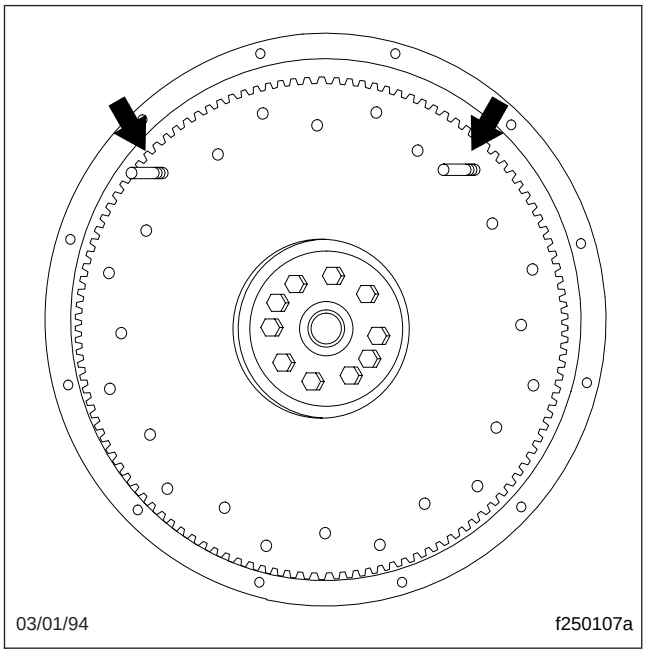

Fig. 3, Install the Guide Studs, SAS

6. Progressively loosen each of the mounting capscrews. See **Fig. 4**. This will prevent warping or

bending within the clutch, and will ease removal of the clutch mounting capscrews.

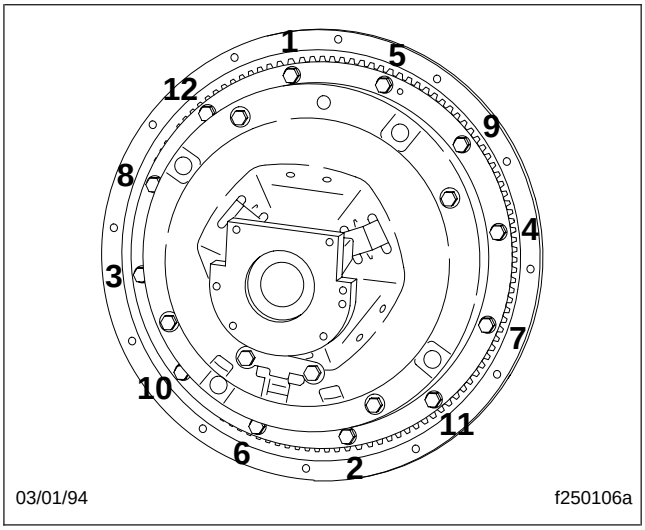

Fig. 4, Loosening Sequence, SAS

⚠ WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

7. Remove the mounting capscrews, and carefully remove the clutch assembly together with the spline aligning tool.
8. Use an appropriate puller to remove the pilot bearing. Inspect the old pilot bearing for any unusual wear or damage. Discard the pilot bearing.

Easy-Pedal™ Clutch

NOTE: Before pulling the transmission from the bell housing, disconnect the external clutch linkage and rotate the release yoke so the yoke will clear the release bearing when it is removed.

1. Remove the transmission. See **Section 26.00**.

⚠ CAUTION

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

2. Remove the clutch brake from the transmission input shaft. See **Fig. 1**.
3. Install a spline aligning tool into the release bearing assembly, and through the driven discs. See **Fig. 5**. An old transmission input shaft may be used for this purpose.

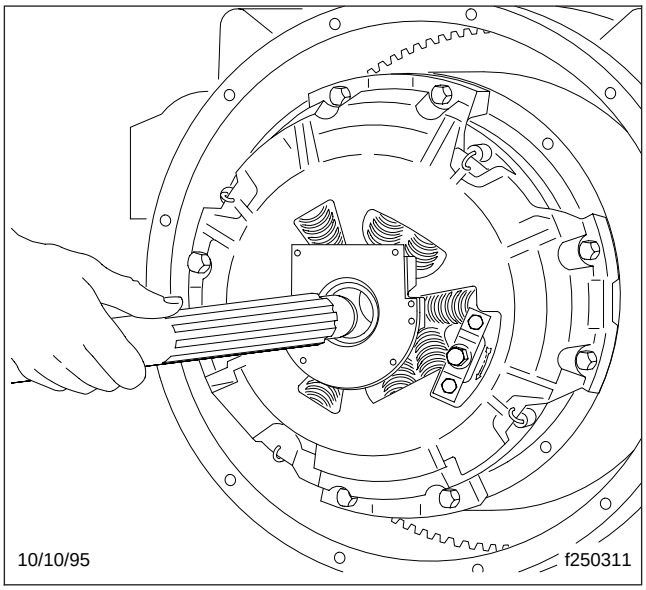

Fig. 5, Installing a Spline Aligning Tool, Easy-Pedal

4. Use a release tool and two 5/8-inch (16 mm) spacer blocks to pull the bearing back. See **Fig. 6**. The spacer blocks relieve the internal spring load in the clutch assembly, and facilitate clutch removal.
5. Remove the two top mounting bolts from the cover assembly. Install guide studs in the open holes to help support the clutch assembly during removal. See **Fig. 7**.

NOTE: Use 3/8–16 x 3 guide studs on 14-inch Easy-Pedal clutches and 7/16–14 x 5 guide studs on 15.5-inch clutches (installed on FL112 only).

6. Progressively loosen each of the mounting bolts in the pattern shown in **Fig. 8**. This will prevent warping or bending within the clutch, and will ease removal of the clutch mounting bolts.

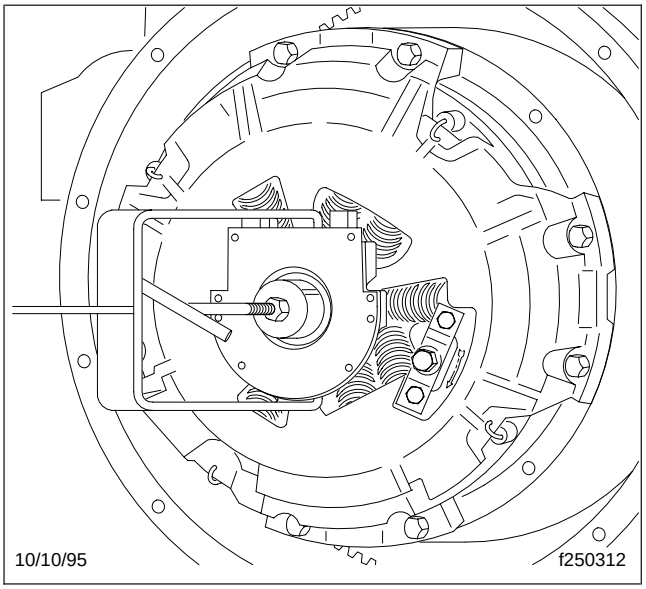

Fig. 6, Pulling the Bearing

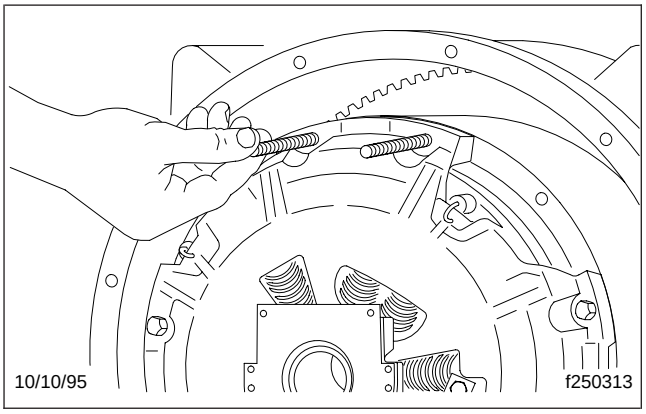

Fig. 7, Install the Guide Studs, Easy-Pedal

⚠ WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

7. Remove the mounting bolts, and carefully remove the clutch assembly.

   Be careful to keep the spline aligning tool in place to retain the discs and intermediate plate. Remove the spline aligning tool, the rear driven disc, the intermediate plate, and the front driven disc.

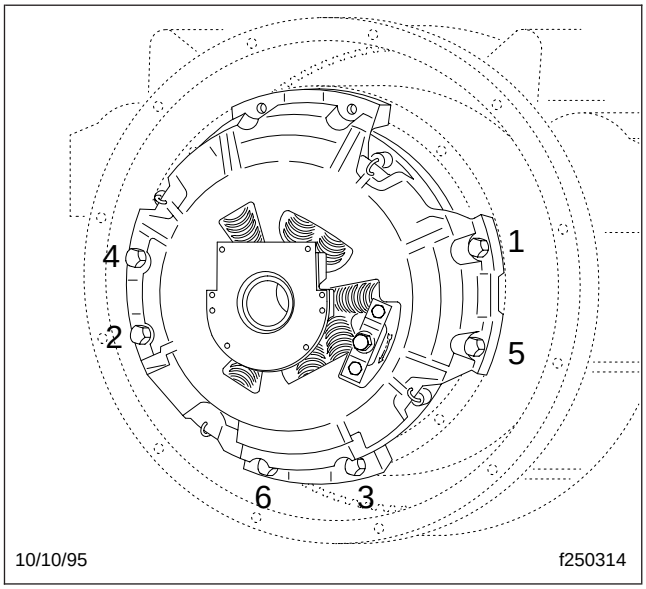

Fig. 8, Loosening Sequence, Easy-Pedal

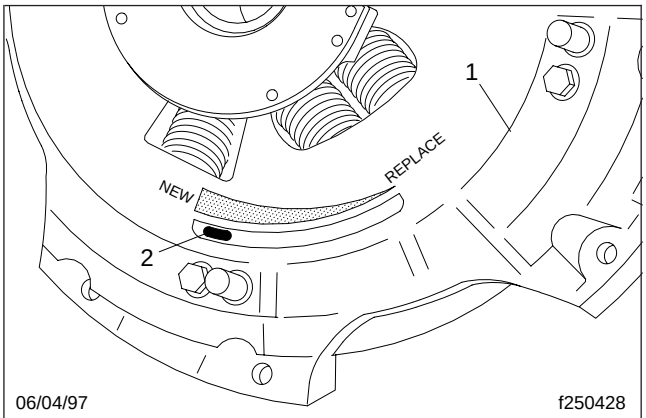
8. Use an appropriate puller to remove the pilot bearing. Inspect the old pilot bearing. Correct the cause of any unusual wear or damage. Discard the bearing.

Solo™ Clutch

⚠ CAUTION

For proper installation of the Solo clutch, the wear indicating tab must be reset. Resetting the wear indicating tab allows the clutch to release and prevents possible clutch damage.



NOTE: This procedure requires two persons: one under the vehicle with access to the wear indicating tab, and the other in the vehicle to press the clutch pedal.

1. Reset the wear indicating tab with the clutch in the vehicle.

   1.1 From inside the cab, press the clutch pedal all the way down. Hold the clutch pedal down until the wear indicating tab is reset.

   1.2 Through the clutch inspection cover, slide the wear indicating tab to the left until it is at the "NEW" position on the indicator. See **Fig. 9**.

Clutch Removal

With the clutch pedal down, set the tab to the "NEW" position on the indicator.

1. Clutch Cover
2. Wear Indicating Tab

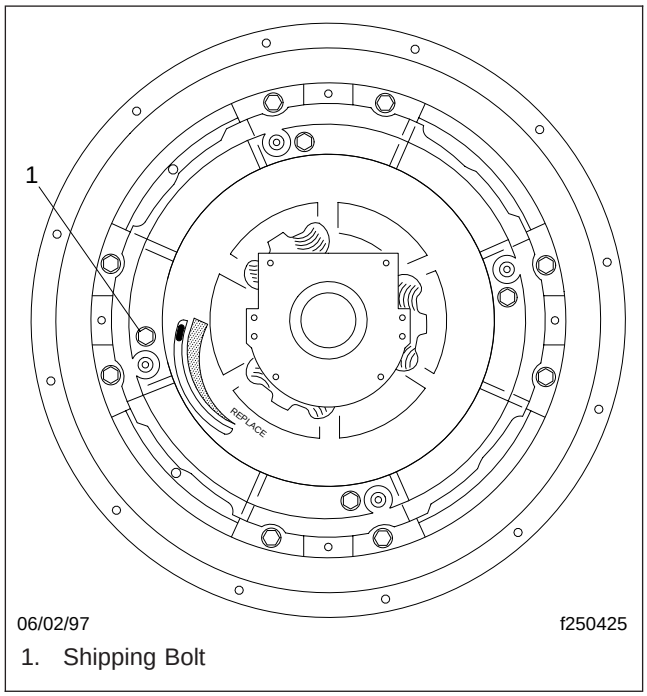
Fig. 9, Resetting the Wear Indicating Tab

IMPORTANT: Take note of the position of the wear indicating tab on the clutch cover. If the wear indicating tab is near the "REPLACE" position on the indicator, it is time to replace the clutch.

1.3 From inside the cab, release the clutch pedal. Check to be sure the wear indicating tab stays at the "NEW" position on the indicator.

NOTE: Before pulling the transmission from the bell housing, disconnect the external clutch linkage and rotate the release yoke so the yoke will clear the release bearing when it is removed.

2. Remove the transmission. See **Section 26.00**.



⚠ CAUTION

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

3. Remove the clutch brake from the transmission input shaft. See **Fig. 1**.
4. Install a spline aligning tool into the release bearing assembly, and through the driven discs. An old transmission input shaft may be used for this purpose.
5. Locate the four shipping bolts (hexhead machine screws). These shipping bolts were installed on the clutch cover prior to installation.

NOTE: Use 3/8–16 x 1-1/4 bolts on medium duty Solo 1401 or 1402 clutches and 7/16–14 x 1-3/4 bolts on heavy-duty 15.5-inch clutches (installed on FL112 only).

6. Install the four shipping bolts into the four clutch cover holes and fasten them finger-tight. See **Fig. 10**.

1. Shipping Bolt

Fig. 10, Install the Shipping Bolts

7. Remove the two top mounting capscrews from the cover assembly. Install two guide studs in the open holes to help support the clutch assembly during removal.

NOTE: Use 3/8–16 x 3 guide studs on medium-duty 14-inch clutches and 7/16–14 x 5 guide studs on heavy-duty 15.5-inch clutches (installed on FL112 only).

8. Progressively loosen each of the mounting capscrews in the pattern shown in **Fig. 11**. This will prevent warping or bending within the clutch, and will ease removal of the clutch mounting capscrews.

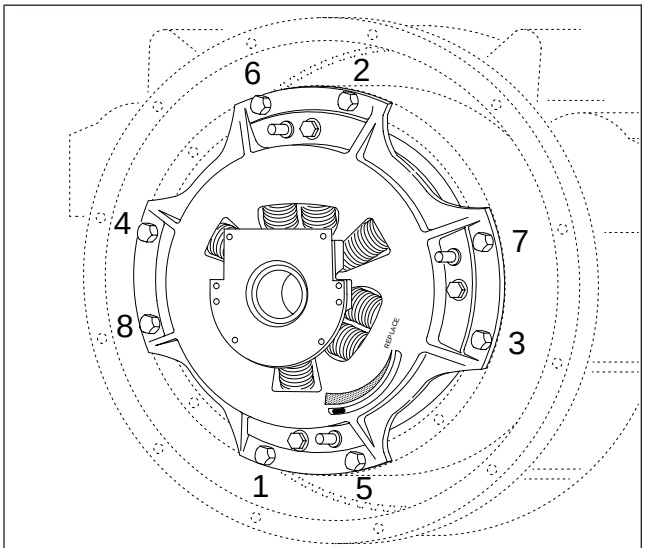


Fig. 11, Loosening Sequence, Solo

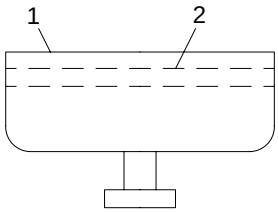
WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

9. Remove the mounting capscrews, and carefully remove the clutch assembly together with the spline aligning tool.



NOTE: For installation, mark the proper position of the discs and intermediate plate adaptor ring.

10. Reset the pressure plate wear pins. See **Fig. 12**.

    10.1 Progressively tighten the four shipping bolts in a crisscross pattern.

    10.2 Measure the depth of the pressure plate. On 14-inch clutches, the wear pins are reset when the pressure plate is 0.50 inches (12.7 mm) below the mounting surface. On 15.5-inch clutches (FL112 only), the wear pins are reset when the pressure plate is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface.

NOTE: Resetting the pressure plate wear pins will allow the clutch to release after installation.

NOTE: On 14-inch clutches, the wear pins reset when the pressure plate is 0.50 inches (12.7 mm) below the mounting surface. On 15.5-inch clutches (FL112 only), the wear pins reset when the pressure plate is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface.

1. Mounting Surface
2. Pressure Plate

Fig. 12, Reset Wear Pins

11. Use an appropriate puller to remove the pilot bearing. Inspect the old pilot bearing for any unusual wear or damage. Discard the pilot bearing.

Resetting the Wear Indicating Tab (clutch out of vehicle)

CAUTION

For proper installation of the Solo clutch, the wear indicating tab must be reset. Resetting the wear indicating tab allows the clutch to release and prevents possible clutch damage.

NOTE: Use this procedure if the transmission and clutch were removed without resetting the wear indicating tab.

1. Remove the four shipping bolts (if installed).
2. Support the clutch cover in an arbor press with the release bearing facing down. When setting up the arbor press, allow at least 1 inch (25 mm) clearance for both movement of the release bearing and access to install shipping bolts. See **Fig. 13**.
3. Center the ram and press downward on the retainer until it comes to a stop. Lock the ram in position.
4. Slide the wear indicating tab to the left until it is at the new position of the indicator (**Fig. 9**) and hold it in position with a magnet.
5. Locate the four shipping bolts.

Clutch Removal

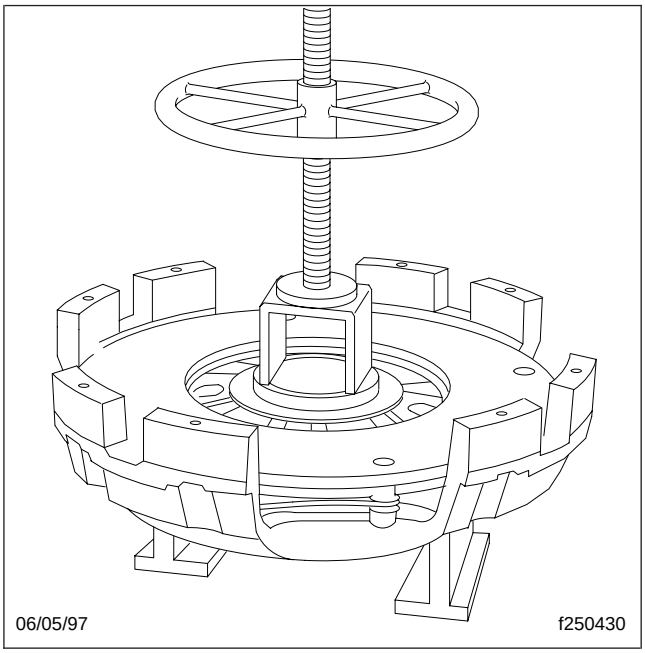


Fig. 13, Arbor Press Setup

NOTE: Use 3/8–16 x 1-1/4 bolts on medium duty Solo 1401 or 1402 clutches and 7/16–14 x 1-3/4 bolts on heavy-duty 15.5-inch clutches (installed on FL112 only).

6. Install the four 7/16–14 x 1-3/4 shipping bolts into the four clutch cover holes and fasten them finger-tight. See **Fig. 10**.

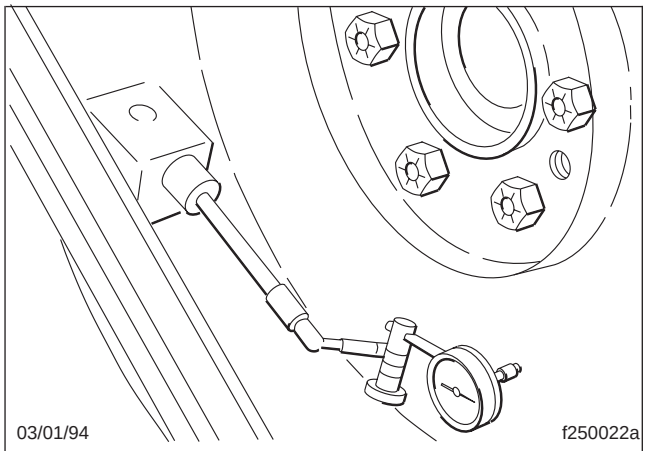
NOTE: You may need to temporarily install slightly longer bolts to allow engagement of the shipping bolts.

7. Reset the pressure plate wear pins. See **Fig. 12**.

   7.1 Progressively tighten the four shipping bolts in a crisscross pattern.

   7.2 Measure the depth of the pressure plate. On 14-inch clutches, the wear pins are reset when the pressure plate is 0.50 inches (12.7 mm) below the mounting surface. On 15.5-inch clutches (FL112 only), the wear pins are reset when the pressure plate is 1.75 to 1.78 inches (44.4 to 45.2 mm) below the mounting surface.

NOTE: Resetting the pressure plate wear pins will allow the clutch to release after installation.



Clutch Inspection

CAUTION

Misalignment of any parts described in these procedures will cause premature wear of drivetrain components.

IMPORTANT: When taking the following readings, rotate the engine by hand; do not crank the engine with the starter. The engine may be rotated by the pulley nut at the front of the crankshaft, the flywheel mounting bolts, or the starter ring-gear on the flywheel.

1. Clean the surfaces being measured to ensure accurate measurements.
2. Measure the runout of the flywheel face (friction surface). See **Fig. 1** for the correct set-up.

Secure the dial indicator to the flywheel housing, with the gauge finger against the flywheel face, and near the outer edge.

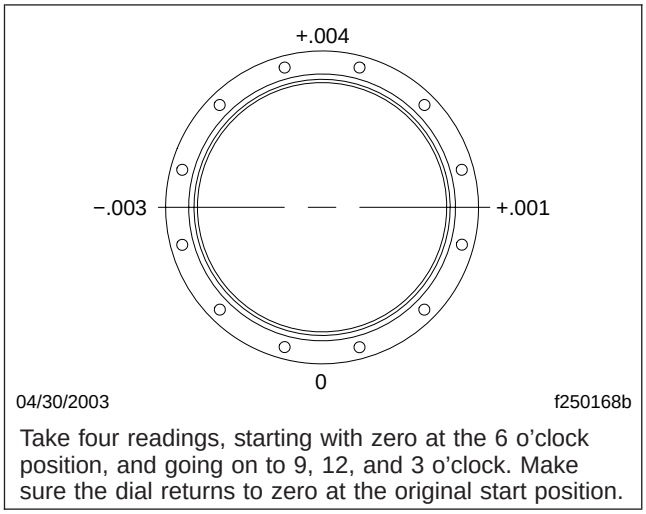


Fig. 1, Measure the Flywheel Face

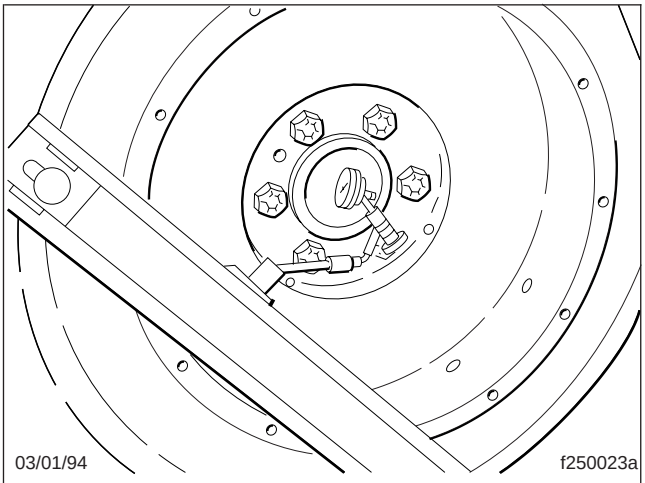
2.1 Secure the dial indicator to the flywheel housing, with the gauge finger against the face of the flywheel near the outer edge.

2.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the flywheel face.

2.3 The total runout will be the difference between the highest plus and minus readings. To calculate the runout, see **Fig. 2**.

Example: The highest reading is +0.004 at 12 o'clock. The lowest reading is –0.003 at 9 o'clock. Therefore the total runout is 0.007 inch.



Take four readings, starting with zero at the 6 o'clock position, and going on to 9, 12, and 3 o'clock. Make sure the dial returns to zero at the original start position.

Fig. 2, Calculate the Runout

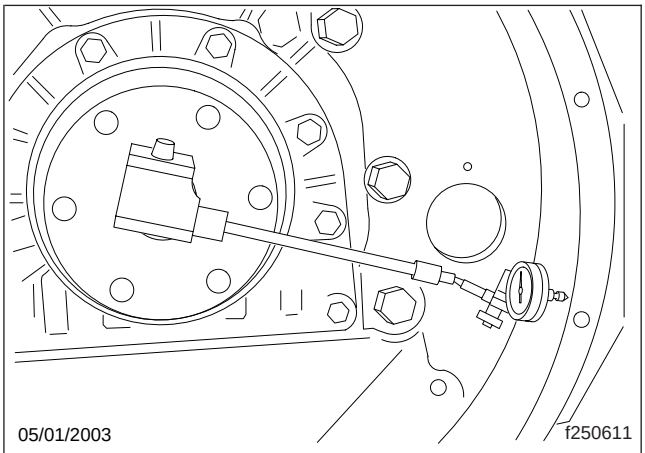
2.4 The SAE maximum total runout for the flywheel face is 0.008 inch (0.20 mm). If the readings are higher, see the engine manufacturer's manual for instructions.

3. Measure the runout of the pilot-bearing bore in the flywheel. See **Fig. 3** for the correct set-up.

Secure the dial indicator to the flywheel housing, with the gauge finger on the surface of the pilot-bearing bore.

Fig. 3, Measure the Pilot-Bearing Bore

Clutch Inspection



3.1 With the indicator still secured to the flywheel housing, move the gauge finger to contact the surface of the pilot-bearing bore.

3.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the bore of the pilot bearing.

3.3 Calculate the runout as before.

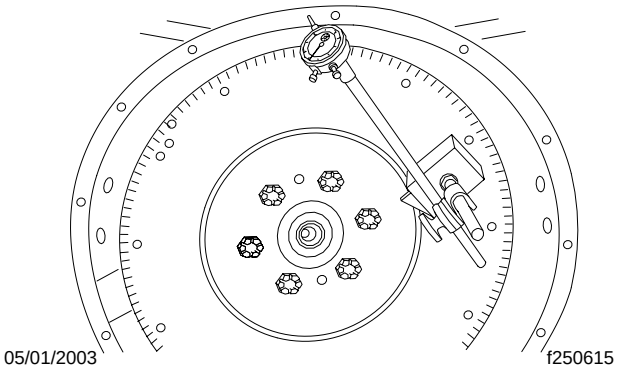
3.4 The SAE maximum total runout for the pilot-bearing bore is 0.005 inch (0.13 mm). If the readings are higher, see the engine manufacturer's manual for instructions.

4. Measure the runout of the flywheel housing bore. See **Fig. 4** for the correct set-up.

Secure the dial indicator to the crankshaft, with the gauge finger against the side of the flywheel housing.

Fig. 4, Measure the Flywheel Housing Bore

4.1 Secure the dial indicator to the crankshaft, with the gauge finger against the side of the flywheel housing.



4.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the side of the flywheel housing.

4.3 Calculate the runout as before.

NOTE: Only if you have to reposition the flywheel housing is it necessary to mark the high and low runout readings in clock positions.

4.4 The SAE maximum total runout for the flywheel-housing bore is 0.008 inch (0.20 mm). If readings are higher, replace the flywheel housing. For instructions, see the engine manufacturer's manual.

5. Measure the runout of the face of the flywheel housing. See **Fig. 5** for the correct set-up.

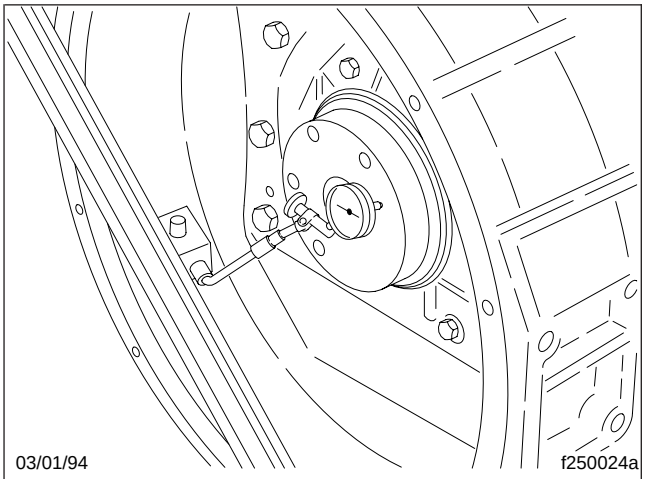
Secure the dial indicator to the outer diameter of the flywheel, with the gauge finger against the face of the flywheel housing.

Fig. 5, Measure the Flywheel Housing Face

5.1 With the dial indicator secured to the outer diameter of the flywheel, move the gauge finger to contact the face of the flywheel housing.

5.2 Turn the flywheel through one complete revolution. With chalk or soapstone, mark the high and low points on the face of the flywheel housing.

5.3 Calculate the runout as before.



NOTE: Only if you have to reposition the flywheel housing is it necessary to mark the high and low runout readings in clock positions.

5.4 The SAE maximum total runout for the flywheel-housing face is 0.008 inch (0.20 mm). If the readings are higher, replace the housing. For instructions, see the engine manufacturer's manual.

NOTE: Use a case-bore plug and shaft set to measure the bell-housing face and pilot. Case-bore plugs are tapped into the front and rear bores of the transmission case, and have very

close tolerances. The shaft runs through the center of the plugs, and extends to the front far enough to secure a dial indicator and obtain a reading on the bell housing.

6. Measure the runout of the bell housing face and pilot.
   - 6.1 Secure the dial indicator to the case-bore shaft, with the gauge finger against the face of the bell housing.
   - 6.2 Turn the case-bore shaft through one complete revolution. With chalk or soapstone, mark the high and low points on the face of the bell housing.
   - 6.3 Calculate the runout as before.
   - 6.4 The SAE maximum total runout for the bell-housing face is 0.008 inch (0.20 mm). If the readings are higher, replace the bell housing. See the transmission manufacturer's service manual for instructions.
7. Remove the flywheel (see the engine manufacturer's manual), and measure the runout of the flywheel crankshaft face. See **Fig. 6**.

Secure the dial indicator to the flywheel housing, with the gauge finger against the crankshaft face, and near the outer edge.

Fig. 6, Measure the Crankshaft Face Runout

   - 7.1 Secure the dial indicator to the flywheel housing, with the gauge finger against the crankshaft face, and near the outer edge.
   - 7.2 Turn the crankshaft through one complete revolution. With chalk or soapstone, mark the high and low points on the face of the crankshaft.
   - 7.3 Calculate the runout as before.
   - 7.4 See the engine manufacturer's manual for maximum runout, corrective measures, and flywheel installation instructions.

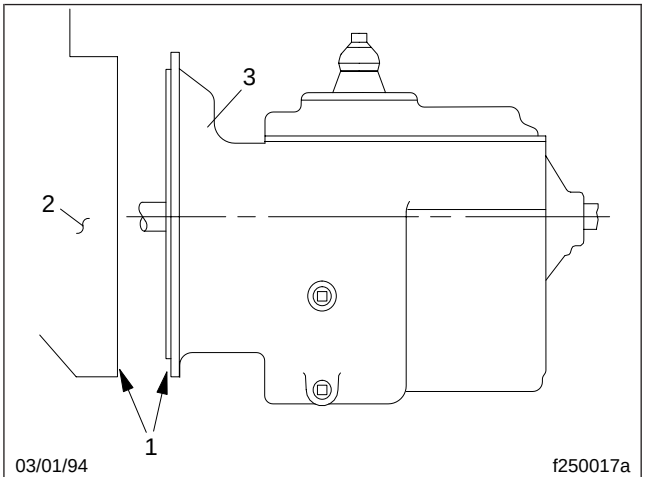
Pre-Installation Procedures

Before installing a new, rebuilt, or used clutch, do the following procedures:

1. Install a new pilot bearing. Be sure that the pilot bearing has a press-fit in the flywheel.

⚠ CAUTION

Tap on the outer race only. Tapping on the inner race could damage the pilot bearing.



NOTE: To discourage warranty claims for drag or clutch noise, use a premium grade C3/C4 pilot bearing. Due to increased operating temperatures and longer clutch life, the standard pilot bearings and grease are no longer acceptable.

2. Check for wear on the mating surfaces of the flywheel housing and the transmission bell housing. Any noticeable wear on either part causes misalignment. If worn, replace the part. See **Fig. 7**.
3. Check the flywheel for wear caused by the bell housing pilot (projecting lip of the bell housing). The correct dimension is 1/8-inch (3.2-mm). Wear is most likely to appear between the 3 o'clock and 8 o'clock positions. See **Fig. 8**.

NOTE: The pilot (lip) of the bell housing can wear into the flywheel housing. This can be caused by the transmission loosening up, or by road and engine vibration after high mileage.

4. Inspect the flywheel. Replace or repair the flywheel if the wear is extreme.
   - 4.1 Visually inspect the friction surface of the flywheel for heat checks and scoring.

4.2 Measure the friction surface wear with a straightedge and feeler gauge. For instructions, see the engine manufacturer's manual.

5. Inspect the input shaft, both the splined and the smooth area. See **Fig. 9**.

5.1 Check the fit of the splined hubs of the driven discs by sliding them along the splines of the input shaft. The hubs must slide freely so the clutch will release

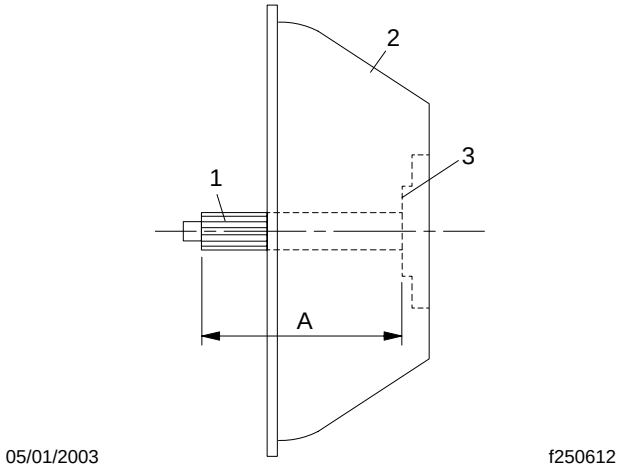
cleanly. If necessary, use a hand stone to dull the sharp edges of the splines.

5.2 If the input shaft splines are worn or notched, or if the hubs still do not slide freely, replace the input shaft. For instructions, see the transmission manufacturer's service manual.

5.3 Inspect the smooth area of the input shaft for wear and/or rough spots. Replace the input shaft if necessary.



6. To prevent side-loading, inspect all pivot points of the clutch linkage for excessive wear and replace them if necessary. See **Fig. 9**. Pay special attention to the following points:

6.1 Check for excessive wear at the fingers of the release yoke where they contact release bearing wear pads.

6.2 Check the clutch cross-shaft and sleeve bushings for excessive wear. Check the sleeve bushings for walk-out.

7. To prevent clutch brake wear, check the input-shaft bearing cap and measure it as shown in **Fig. 10**.

7.1 Visually check the bearing cap for excessive wear.

A. Length of Input Shaft, from the Splined End to the Bearing Cap

1. Input Shaft
2. Bell Housing
3. Bearing Cap

Fig. 10, Measure the Input Shaft

7.2 Measure the distance between the splined end of the input shaft and the bearing cap (dimension A). If dimension A is greater than 8.71 inches (221.5 mm), replace the bearing cap.

NOTE: Torque-limiting clutch brakes are a one-piece assembly with a large and a small face. When installing a torque-limiting clutch brake on an Eaton® Fuller® or Meritor™ transmission, install the smaller face toward the transmission.

8. On unsynchronized transmissions,install a new clutch brake on the transmission input shaft, as shown in **Fig. 11**. Slide it tight against the input-shaft bearing cap.
9. Check the diameter of the flywheel bore opening (this is the recessed area for the flywheel bolt circle). See **Table 1** for minimum flywheel bore diameters for each disc type.

IMPORTANT: For 15.5-inch clutches, see the installation procedures in **Subject 140**.

Stamped Angle-Spring® Single-Disc Clutch

NOTE: Do the clutch inspection and pre-installation procedures in **Subject 120** before installing the clutch.

1. If the clutch is new, remove any protective coating applied to the pressure plate.
2. If not already in place, install two 3/8–16 x 3 guide studs in two upper mounting holes of the flywheel. See **Fig. 1**.

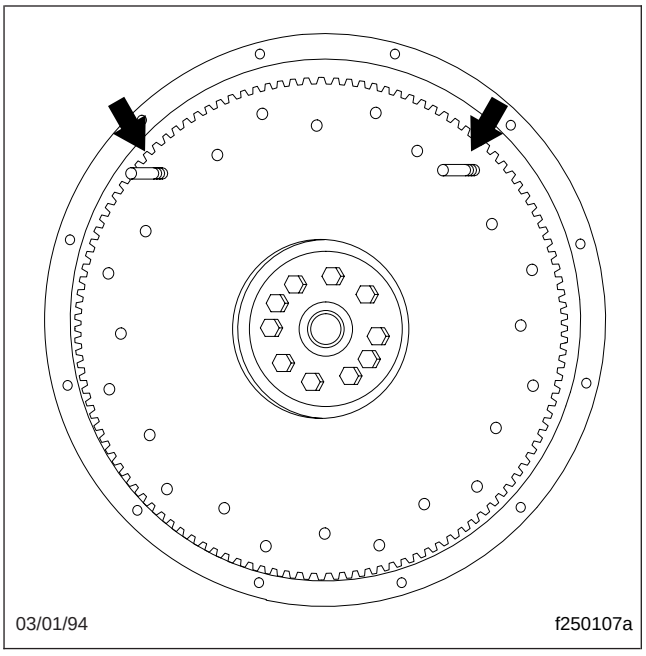

Fig. 1, Install the Guide Studs, SAS Single-Disc

3. Install the single driven disc on the flywheel.
   - 3.1 Insert an aligning tool through the splines of the driven disc and then, with the driven disc attached, into the pilot bearing. See **Fig. 2**.
   - 3.2 Be sure the side marked *PRESSURE PLATE SIDE* faces the pressure plate.

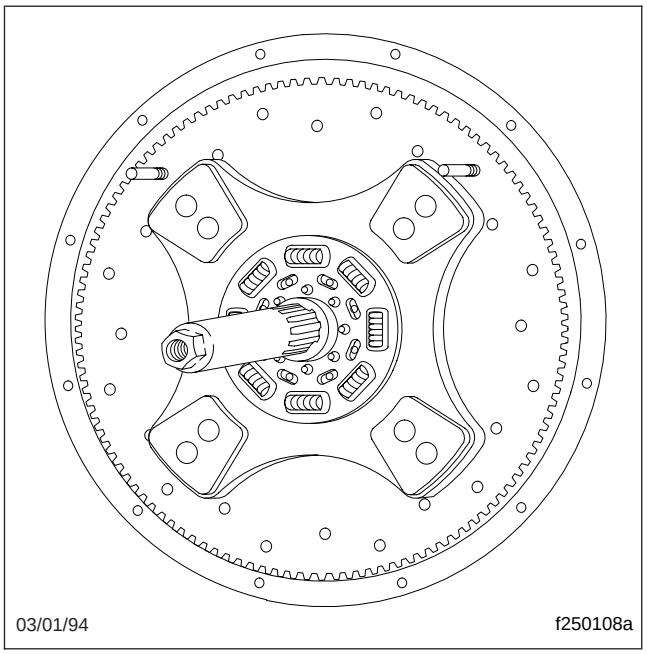

Fig. 2, Insert an Aligning Tool, SAS Single-Disc

See **Fig. 3** for the position of the driven disc when installed.

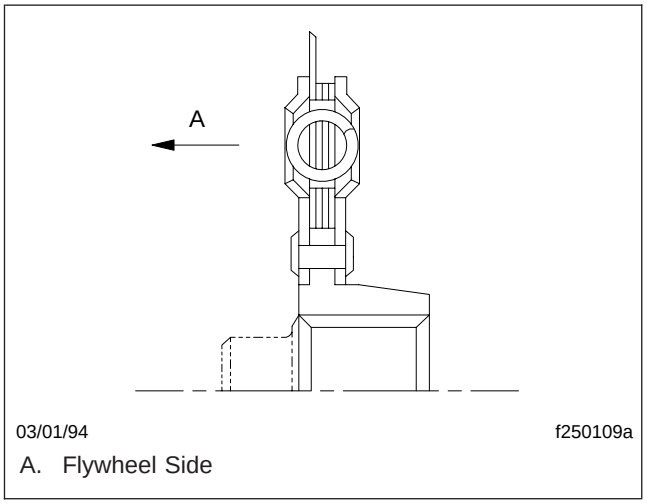

Fig. 3, Single Driven Disc Installed, SAS

WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

14-Inch Clutch Installation

4. Install the cover assembly. See **Fig. 4**.

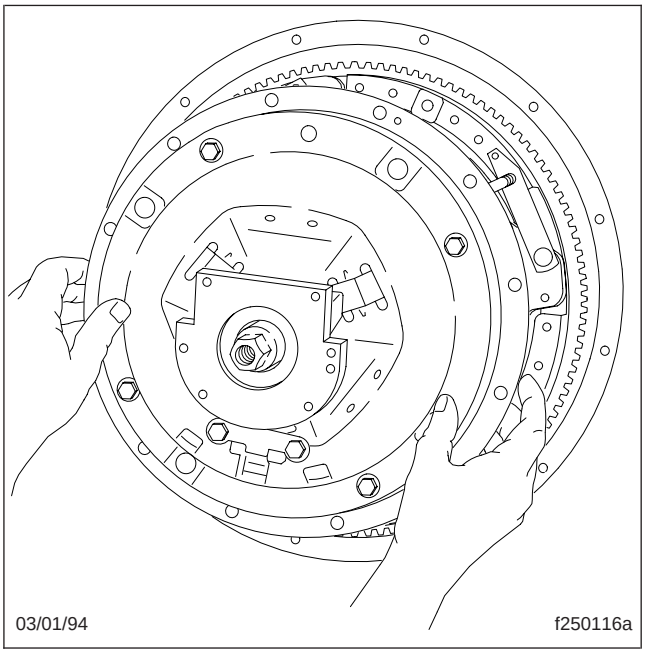

Fig. 4, Positioning the Clutch Cover, SAS

4.1 With the aligning tool still in place, slide the cover assembly over the aligning tool.

4.2 Align the lockstrap or adjustment bolt to be visible through the clutch inspection cover in the bell housing.

CAUTION

If the capscrews are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

5. Install the clutch mounting capscrews. See **Fig. 5** for the tightening sequence.

5.1 In the cover plate, start six (grade 5 or better) 3/8–16 capscrews with lockwashers. Fasten them finger-tight.

5.2 Remove the guide studs and replace them with two more mounting capscrews, as above.

5.3 Tighten the eight capscrews progressively. The final torque is 30 to 35 lbf·ft (40 to 47 N·m).

5.4 Remove the aligning tool.

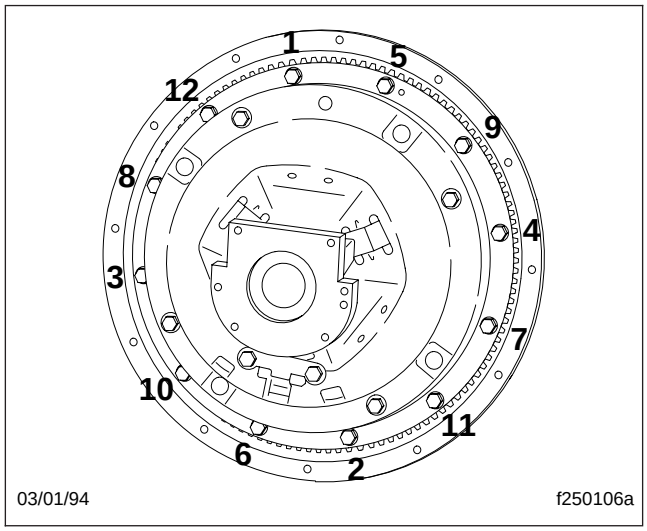

Fig. 5, Tightening Sequence, SAS

6. Remove the wooden spacer blocks installed at the time of removal.

7. Shift the transmission into gear so that during assembly the transmission input shaft can be rotated into line with the clutch driven-disc hub splines.

8. Install the transmission and attach the clutch linkage. For instructions, see **Group 26**.

CAUTION

Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

IMPORTANT: Be sure the release-bearing yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 20**. Align the splines by turning the transmission output shaft.

9. Adjust the clutch according to the procedures in **Subject 100**.

Stamped Angle-Spring® Dual-Disc Clutch

NOTE: Do the clutch inspection and pre-installation procedures in **Subject 120** before installing the clutch.

1. If the clutch is new, remove any protective coating applied to the pressure plate and the intermediate plate.
2. If not already in place, install two 3/8–16 x 3 guide studs in two upper mounting holes of the flywheel (at the 11 and 1 o'clock positions). See **Fig. 6**.

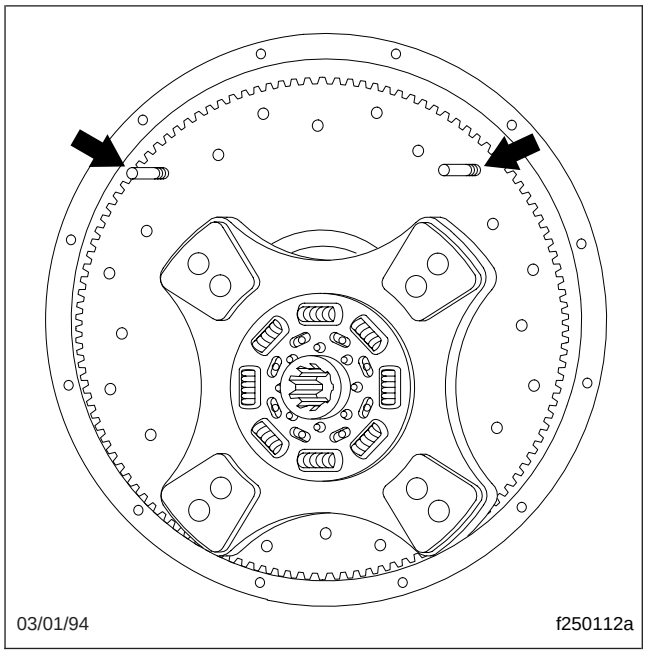

Fig. 6, Install the Guide Studs, SAS Dual-Disc

3. Place the front driven disc in the bell housing with the side marked *FLYWHEEL SIDE* facing the flywheel. See **Fig. 7**.
4. Install the drivestrap intermediate plate over the guide studs. Make sure the side marked *FLYWHEEL SIDE* faces the flywheel. See **Fig 8**.

IMPORTANT: The drivestraps of the intermediate plate must face the pressure plate.

NOTE: The four holes through the drivestraps are the pilot holes for the adapter ring.

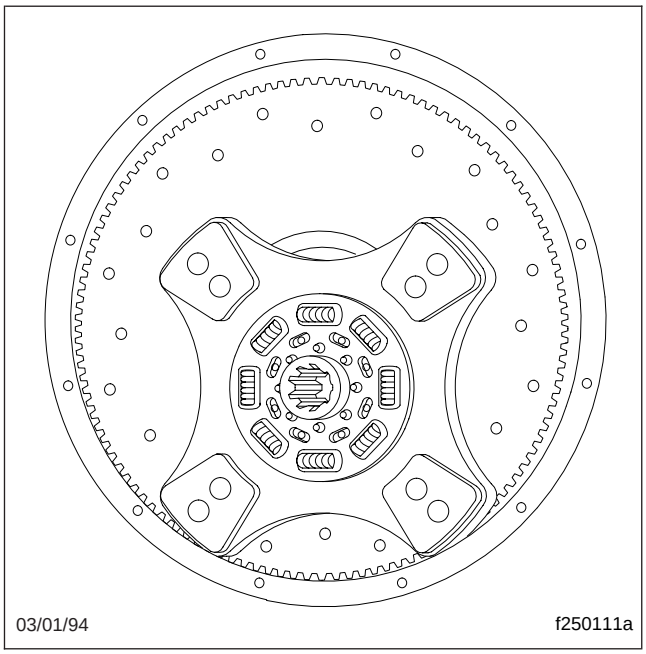

Fig. 7, Position the Front Disc, SAS

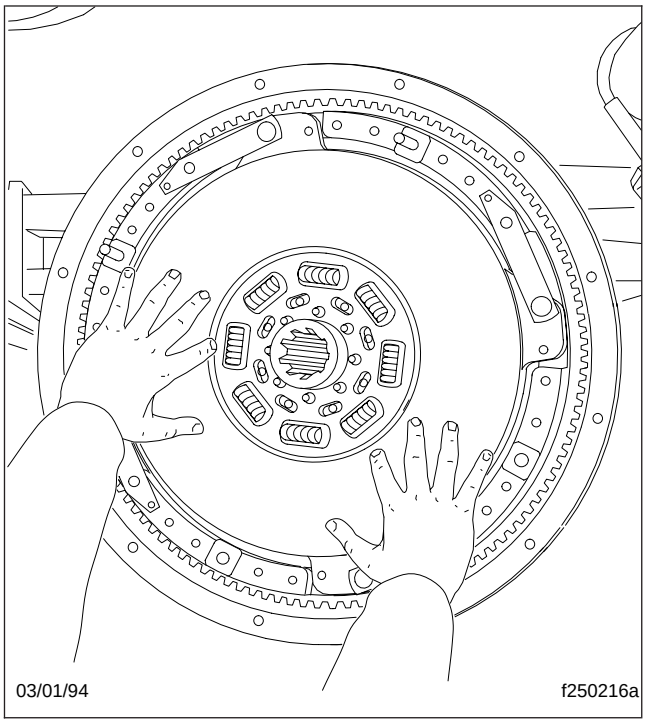

Fig. 8, Install the Intermediate Plate, SAS and Solo

5. Raise the front driven disc to fit into the intermediate plate opening.

14-Inch Clutch Installation

6. Install the rear driven disc.

   6.1 Insert an aligning tool through the splines of the rear disc and then, with the rear disc attached, into the pilot bearing. See **Fig. 9**.

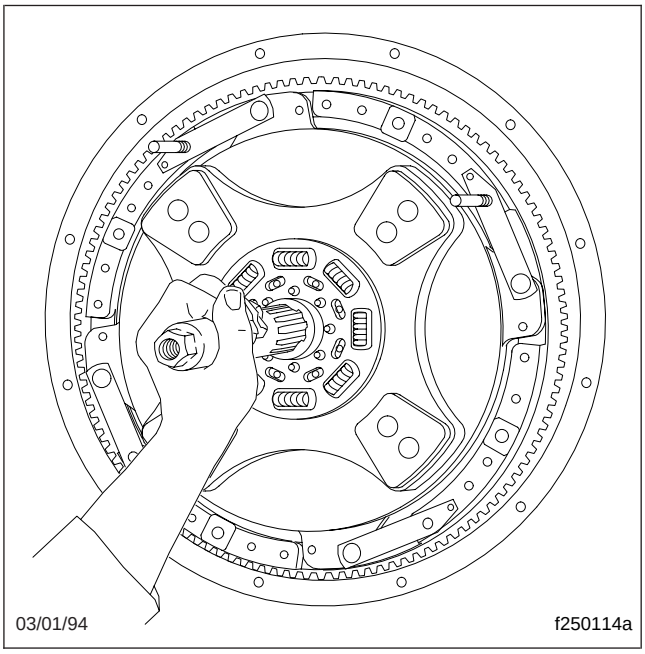

Fig. 9, Insert an Aligning Tool, SAS Dual-Disc

   6.2 Be sure the side marked *PRESSURE PLATE SIDE* faces the pressure plate. See **Fig. 10** for the position of the driven disc when installed.

⚠ WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

7. Install the cover assembly. See **Fig. 4**.

   7.1 With the aligning tool still in place, carefully slide the cover assembly over the aligning tool.

   7.2 Align the lockstrap or self-adjuster with the access hole in the bell housing.

   7.3 Slide the clutch assembly over the guide studs and against the spacer ring.

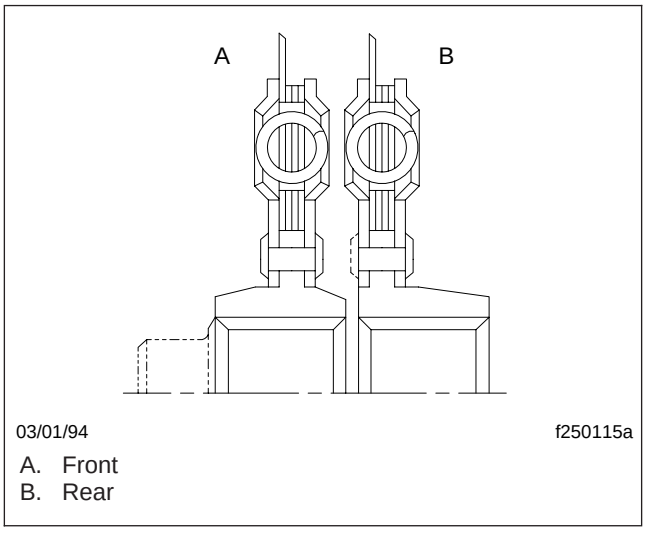

Fig. 10, Dual Driven Discs Installed, SAS

⚠ CAUTION

If the capscrews are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

8. Install the clutch mounting capscrews. See **Fig. 5** for the tightening sequence.

   8.1 In the cover plate, start six (grade 5 or better) 3/8–16 capscrews with lockwashers. Fasten them finger-tight.

   8.2 Remove the guide studs and replace them with two more mounting capscrews, as above.

   8.3 Tighten the eight capscrews progressively. The final torque is 30 to 35 lbf·ft (40 to 47 N·m).

   8.4 Remove the aligning tool.

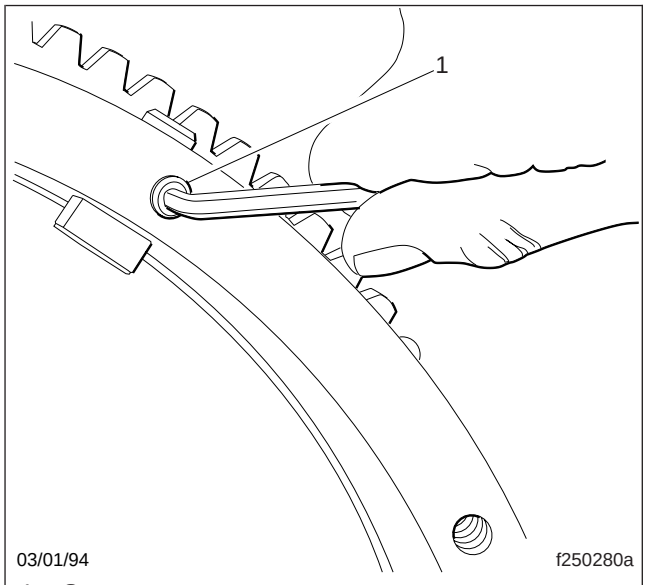
9. Remove the wooden spacer blocks installed at the time of removal.

10. Shift the transmission into gear so that during assembly the transmission input shaft can be rotated into line with the clutch driven-disc hub splines.

11. Install the transmission and attach the clutch linkage. For instructions, see **Group 26**.

⚠ CAUTION

Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.



IMPORTANT: Be sure the release-bearing yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 20**. Align the splines by turning the transmission output shaft.

12. Adjust the clutch according to the procedures in **Subject 100**.

Easy-Pedal Plus® Clutch

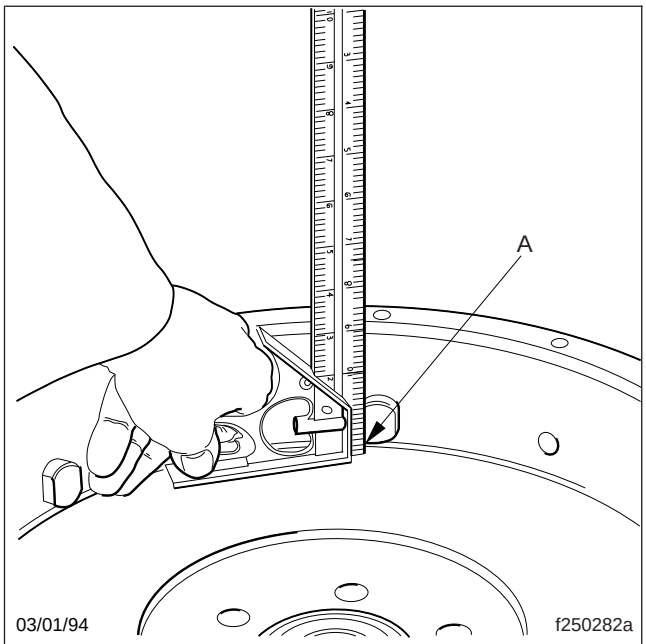
NOTE: Do the clutch inspection and preinstallation procedures in **Subject 120** before installing the clutch.

1. Remove the old drive pins from the flywheel. See **Fig. 11**.

1. Setscrew

Fig. 11, Remove the Setscrews

1.1 Remove the flywheel from the engine. For instructions, see the engine manufacturer's service manual.



⚠ WARNING

The drive pins are made of hardened steel. Wear eye protection when removing the old drive pins. Do not hit steel parts with a steel hammer. Parts can break or chip and cause injury.

1.2 Remove the setscrews from each of the drive pins.

1.3 Using a hammer and drift, remove the drive pins.

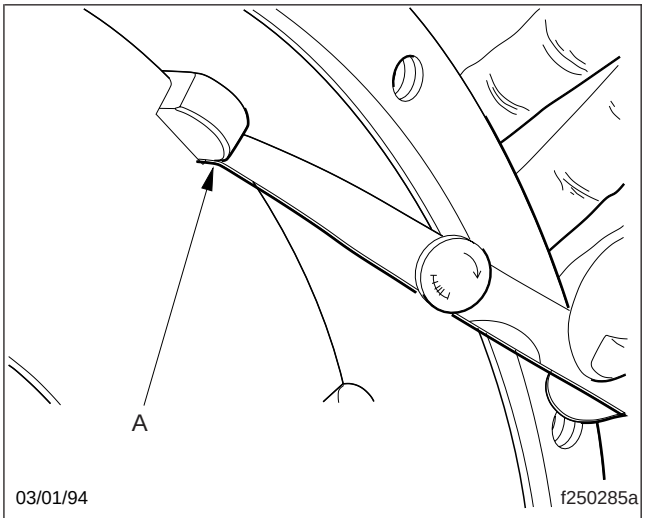
2. Install new drive pins in the flywheel. See **Fig. 12**.

A. Drive pin must be square to flywheel.

Fig. 12, Install the Drive Pins

2.1 Install six new drive pins in the flywheel, equally spaced. Make sure that the shanks of the drive pins are press-fit in the flywheel rim, and that the heads are square with the friction face.

NOTE: Before doing the next step, place two small spacers on the friction surface of the flywheel. This will prevent the intermediate plate from pinching your fingers, and will also allow an easy fingerhold when removing the plate.



14-Inch Clutch Installation

2.2 Carefully position the intermediate plate over the drive pins. Turn the intermediate plate in one direction as far as it will go.

⚠ CAUTION

Don't file the intermediate-plate slots to obtain the correct clearance. Doing so will cause an unequal load on the pins. This is a frequent cause of poor- or no-release complaints in newly installed clutches, and can result in broken drive pins.

2.3 Check the clearance between each drive pin and drive slot. Check each pin on the same side. See **Fig. 13**.

A. Drive Pin-to-Intermediate Plate Minimum Clearance: 0.006 inch (0.152 mm)

Fig. 13, Measure the Clearance

The minimum clearance between the drive pins and the drive slots is 0.006 inch (0.152 mm).

2.4 If the clearance is correct, remove the intermediate plate, and check the squareness alignment of the drive-pin heads to the friction face.

2.5 If the alignment and clearance are okay, remove the intermediate plate, and lock each of the pins in place with a new locking-type 3/8 by 3/8-inch setscrew. If only non-locking setscrews are available, tighten them 25 lbf·ft (35 N·m).

2.6 Install the flywheel. For instructions, see the engine manufacturer's service manual.

3. If the clutch is new, remove any protective coating applied to the pressure plate and the intermediate plate.

4. Place the front driven-disc assembly in the flywheel, with the side stamped *FLYWHEEL SIDE* facing the engine. See **Fig. 14**.

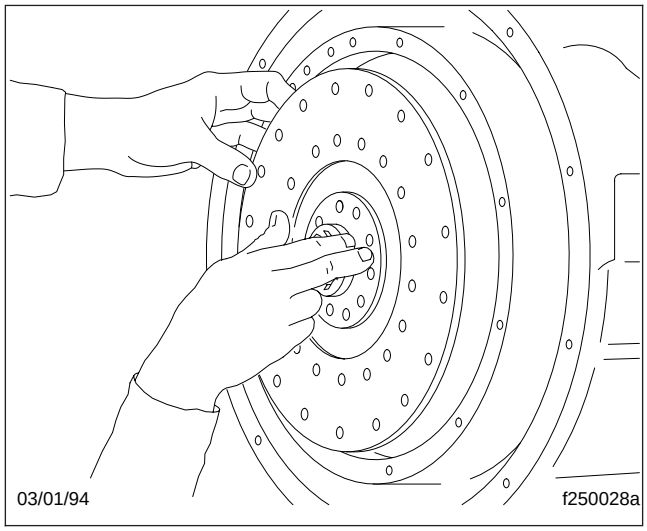


Fig. 14, Position the Front Disc, Easy-Pedal

5. Install the intermediate plate in the flywheel, locating the drive slots on the drive pins. See **Fig. 15**.

⚠ WARNING

Wear heavy gloves when installing the anti-rattle springs. Otherwise, the sharp edges can cut your hands.

6. On super-duty clutches only, install three anti-rattle springs equally spaced between the drive pins. See **Fig. 16**.

6.1 Wearing heavy gloves, install the springs with the rounded sections toward the flywheel face.

6.2 Push the springs toward the engine until they bottom against the face of the flywheel.

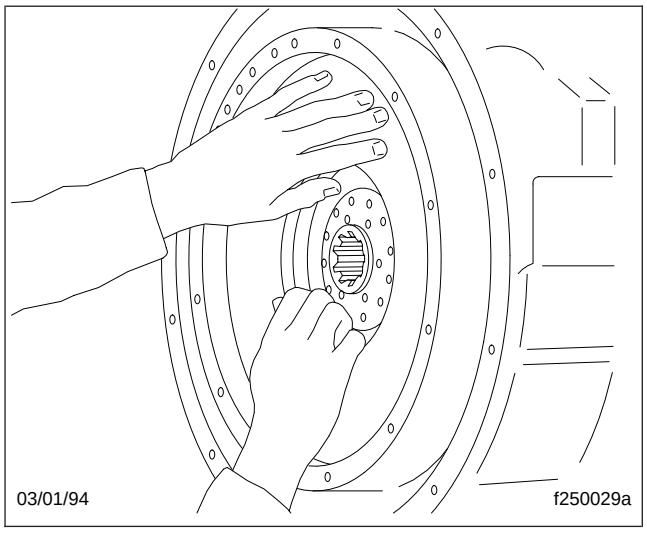

Fig. 15, Install the Intermediate Plate, Easy-Pedal

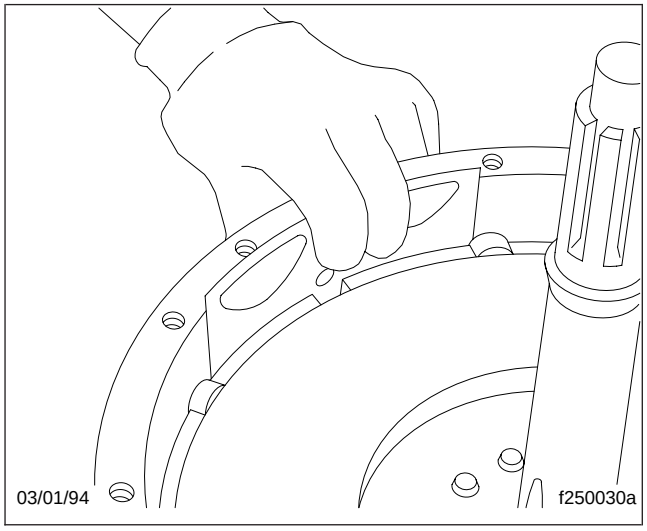

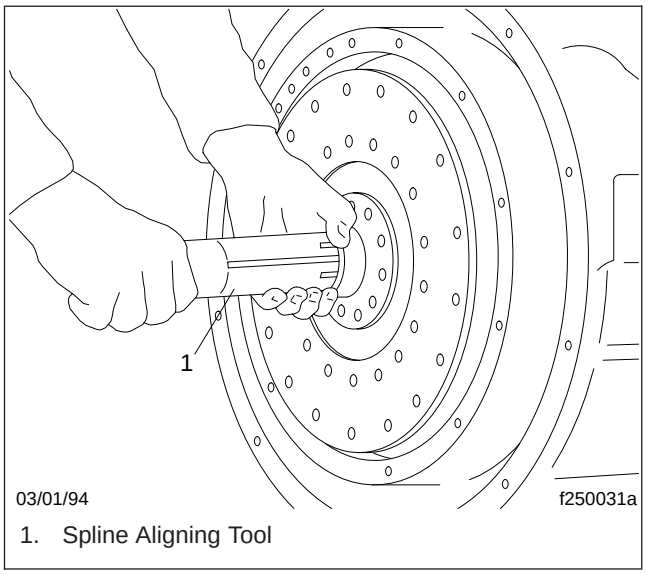

Fig. 16, Install the Anti-Rattle Springs

NOTE: Super-duty clutch discs have thicker intermediate plates. Do not mix standard and super-duty discs.

7. Install the rear driven disc. See **Fig. 17**.

   7.1 Insert an aligning tool through the hub of the rear driven disc. Make sure the side stamped *PRESSURE PLATE SIDE* is facing the transmission.

1. Spline Aligning Tool

Fig. 17, Install the Rear Disc, Easy-Pedal

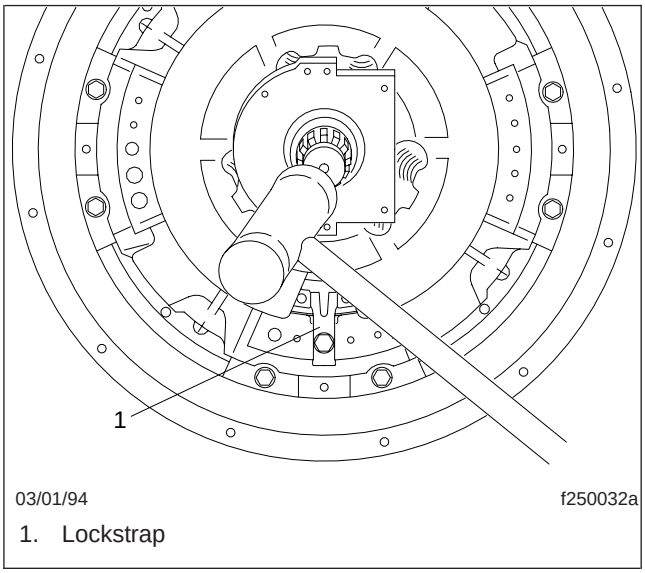
   7.2 Install two 3/8–16 x 2-1/2 guide studs in two upper mounting holes of the flywheel (at the 11 and 1 o'clock positions).

   7.3 Insert the aligning tool through the hub of the front driven disc, and into the pilot bearing.

   7.4 Install the rear driven disc behind the intermediate plate.

8. Position the cover assembly on the flywheel, with the lockstrap aligned with the opening in the transmission clutch housing. See **Fig. 18**.

CAUTION



If the capscrews are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

9. Install the clutch mounting capscrews. See **Fig. 19** for the tightening sequence.

   9.1 Start six 3/8–16 x 1-1/4 clutch mounting capscrews with lockwashers. Fasten them finger-tight.

   9.2 Tap the aligning tool to make sure it is centered and seated in the pilot bearing, then remove the two guide studs and replace them with 3/8–16 x 1-1/4 clutch mounting capscrews with lockwashers.

14-Inch Clutch Installation

1. Lockstrap

Fig. 18, Position the Clutch Cover, Easy-Pedal

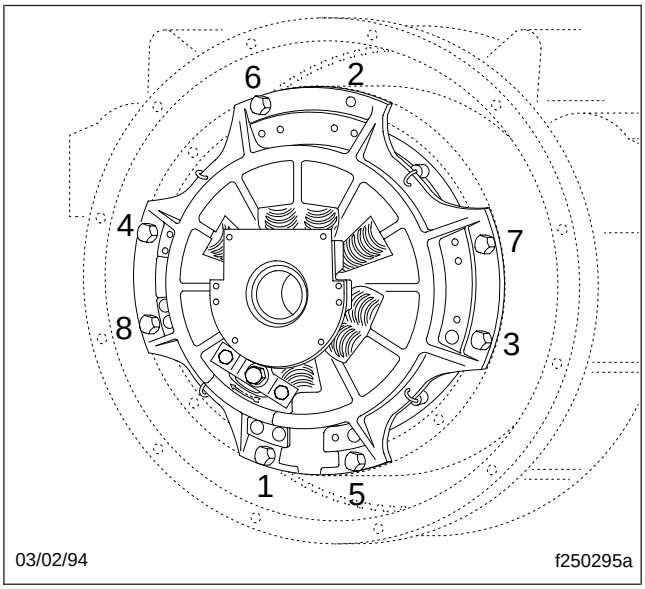


Fig. 19, Tightening Sequence, Easy-Pedal

9.3 Tighten the eight capscrews progressively. The final torque is 25 to 35 lbf·ft (34 to 47 N·m).

9.4 As the capscrews are tightened, the release-bearing spacers should fall free. If they don't, remove them. This may require light taps with a mallet on the end of the aligning tool. See **Fig. 18**.

9.5 Remove the aligning tool.

10. Shift the transmission into gear, so the transmission input shaft can be rotated into line with the clutch driven-disc hub splines during assembly.

11. Install the transmission and attach the clutch linkage. For instructions, See **Group 26**.

CAUTION

Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

IMPORTANT: Be sure the release-bearing yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 20**. Align the splines by turning the transmission output shaft.

12. Grease the release bearing and release shafts. For instructions and recommended lubricants, see **Group 25** of the *Business Class Trucks Maintenance Manual*.

13. Adjust the clutch according to the procedures in **Subject 100**.

Solo 1401 Single-Disc Clutch

NOTE: Do the clutch inspection and preinstallation procedures in **Subject 120** before installing the clutch.

1. If the clutch is new, remove any protective coating applied to the pressure plate.

2. If not already in place, install two 3/8–16 x 3 guide studs in the two upper mounting holes of the flywheel (at the 11 and 1 o'clock positions). See **Fig. 21**.

3. Install the single driven disc on the flywheel. See **Fig. 22**.

3.1 Insert an aligning tool through the splines of the driven disc and then, with the driven disc attached, into the pilot bearing.

3.2 Be sure the side marked *PRESSURE PLATE SIDE* faces the pressure plate.

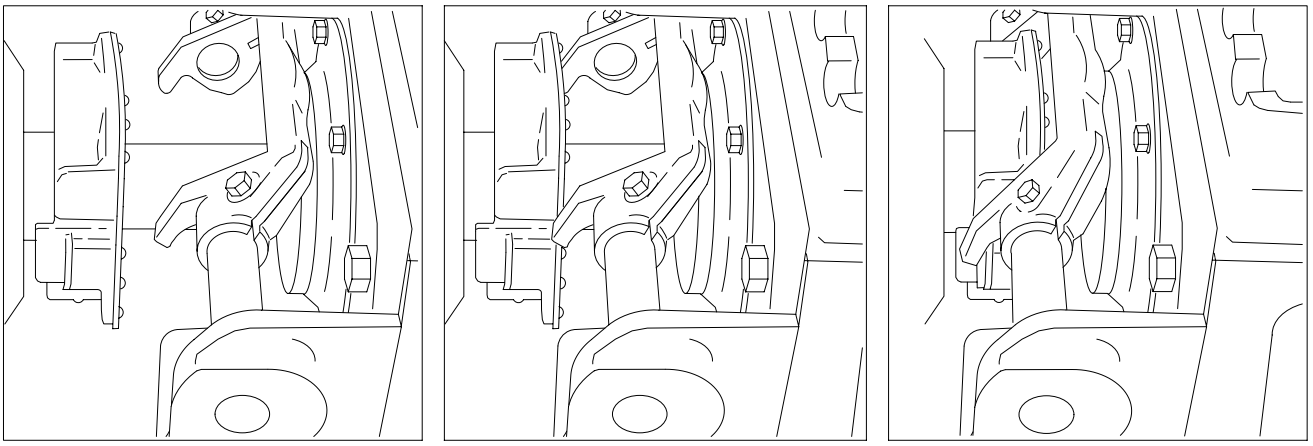

Fig. 20, Make Sure the Release Yoke Clears the Bearing

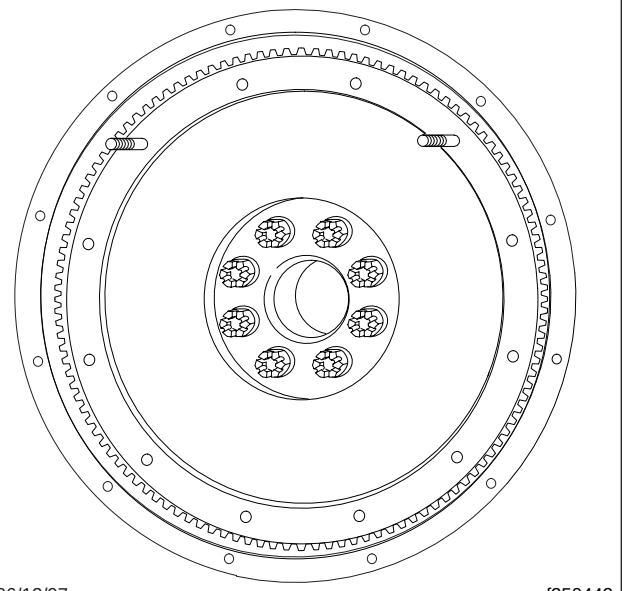

Fig. 21, Install the Guide Studs, Solo

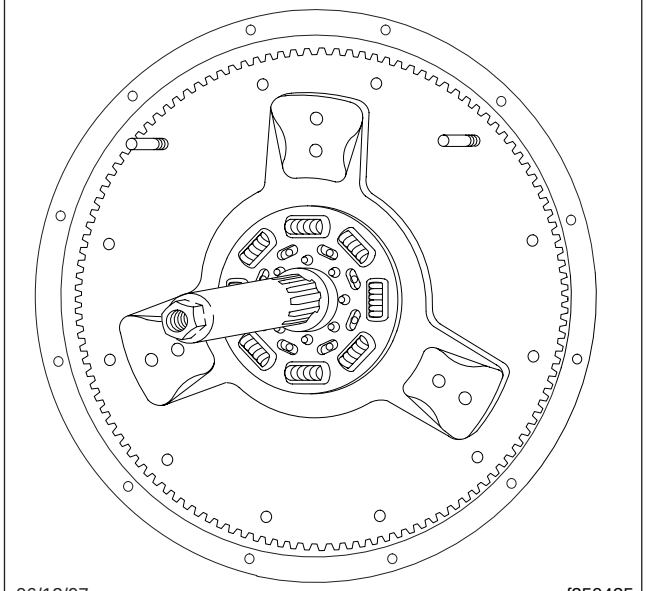

Fig. 22, Position the Driven Disc, Solo

⚠ WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

4. With the aligning tool still in place, slide the cover assembly over the aligning tool and the two guide studs. See **Fig. 23**.

14-Inch Clutch Installation

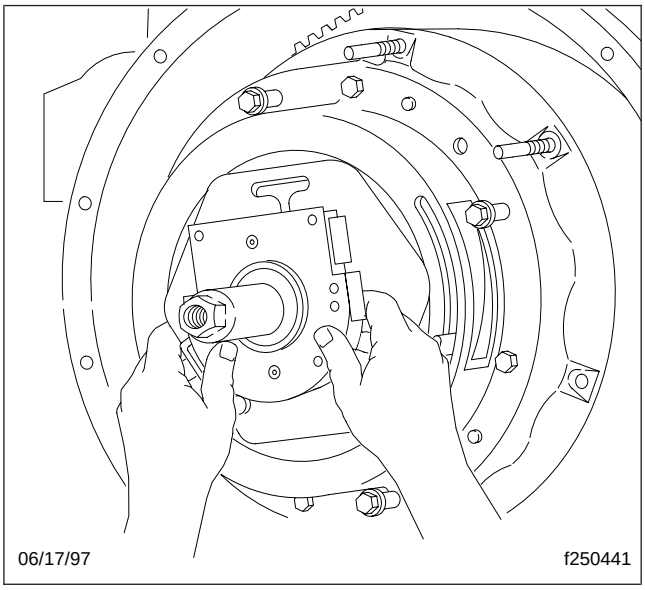

Fig. 23, Position the Clutch Cover, Solo

CAUTION

If the capscrews are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

5. Install the clutch mounting capscrews. See **Fig. 24** for the tightening sequence.

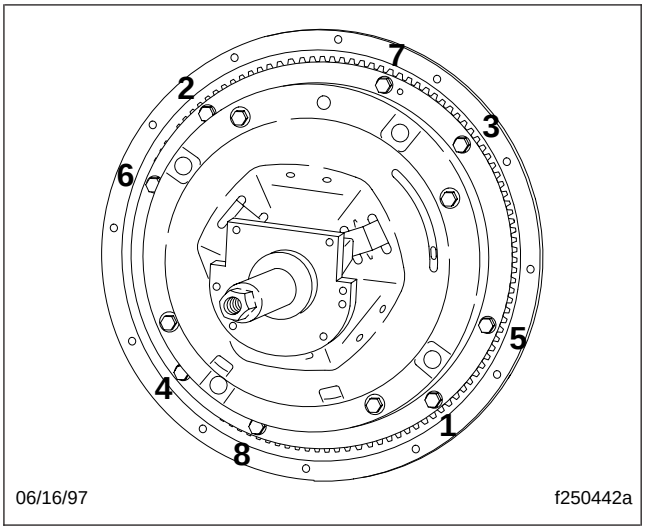

Fig. 24, Tightening Sequence, Solo

   5.1 In the cover plate, start six (grade 5 or better) 3/8–16 capscrews with lockwashers. Fasten them finger-tight.

   5.2 Remove the guide studs and replace them with two more mounting capscrews, as above.

   5.3 Tighten the eight capscrews progressively. The final torque is 30 to 35 lbf·ft (40 to 47 N·m).

   5.4 Remove the aligning tool.

6. Using a 9/16-inch socket and following a criss-cross pattern, remove the four yellow-colored shipping bolts from the clutch cover. See **Fig. 25**.

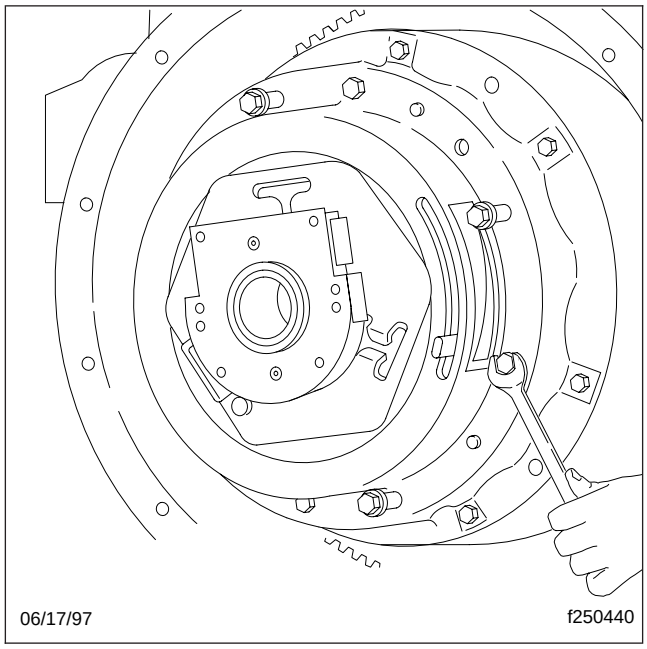

Fig. 25, Remove the Shipping Bolts

NOTE: Retain these four shipping bolts. These bolts will be needed in the future to secure the clutch assembly during removal and installation.

7. Using a clean cloth, remove all grease from the input shaft.
8. Shift the transmission into gear so that during assembly the transmission input shaft can be rotated into line with the clutch driven-disc hub splines.
9. Install the transmission and attach the clutch linkage. For instructions, see **Group 26**.

⚠ CAUTION

Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

IMPORTANT: Be sure the release-bearing yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 20**. Align the splines by turning the transmission output shaft.

10. Position a pipe, or similar tool, over the cross-shaft release lever and rotate it until the release bearing comes to a complete stop. Repeat this procedure a total of five times.
11. Lubricate the release bearing and the cross-shaft bushings. For instructions and recommended lubricants, see **Group 25** of the *Business Class Trucks Maintenance Manual*.

Solo 1402 Dual-Disc Clutch

NOTE: Do the clutch inspection and pre-installation procedures in **Subject 120** before installing the clutch.

1. If the clutch is new, remove any protective coating applied to the pressure plate and the intermediate plate.
2. If not already in place, install two 3/8–16 x 3 guide studs in the two upper mounting holes of the flywheel (at the 11 and 1 o'clock positions). See **Fig. 21**.
3. Install the front driven disc on the flywheel. See **Fig. 22**.
   - 3.1 Insert an aligning tool through the splines of the front disc and then, with the front disc attached, into the pilot bearing.
   - 3.2 Be sure the side marked *FLYWHEEL SIDE* faces the flywheel.
4. Install the intermediate plate assembly over the two guide studs and slide it forward until it touches the flywheel. See **Fig. 8**.

IMPORTANT: The drivestraps of the intermediate plate must face the pressure plate.

5. Install the rear driven disc. See **Fig. 26**.

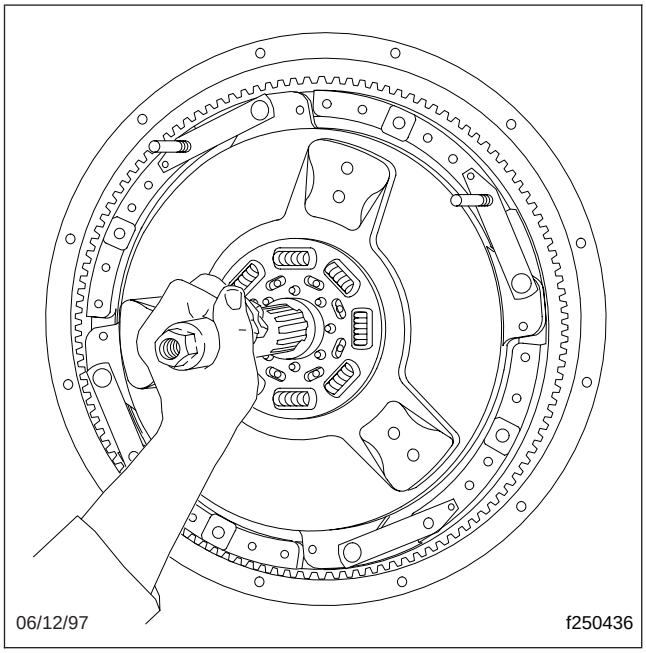

Fig. 26, Position the Rear Disc, Solo

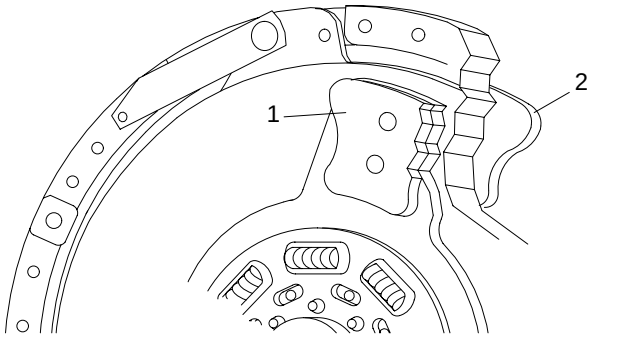
   - 5.1 Remove the aligning tool from the pilot bearing.
   - 5.2 Insert the aligning tool through the splines of the rear driven disc, and then, with the rear disc attached, into the pilot bearing.
   - 5.3 Be sure the side of the rear disc marked *PRESSURE PLATE SIDE* faces the pressure plate.
6. Make sure that the ceramic buttons on each disc are as closely aligned as possible. See **Fig. 27**.



NOTE: Aligning the discs in this way aids the function of the positive separator pins.

7. With the aligning tool still in place, slide the cover assembly over the aligning tool and the two guide studs until it rests against the intermediate plate assembly. See **Fig. 23**.

⚠ CAUTION

If the capscrews are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

8. Install the clutch mounting capscrews. See **Fig. 24** for the tightening sequence.
   - 8.1 Start six 3/8–16 (grade 5 or better) mounting capscrews in the cover plate. Fasten them finger-tight.
   - 8.2 Remove the guide studs and replace them with the two remaining mounting capscrews, as above.
   - 8.3 Tighten the eight capscrews progressively. The final torque is 30 to 35 lbf·ft (41 to 47 N·m).
   - 8.4 Remove the aligning tool.
9. Using a 9/16-inch socket and following a criss-cross pattern, remove the four yellow-colored shipping bolts from the clutch cover. See **Fig. 25**.

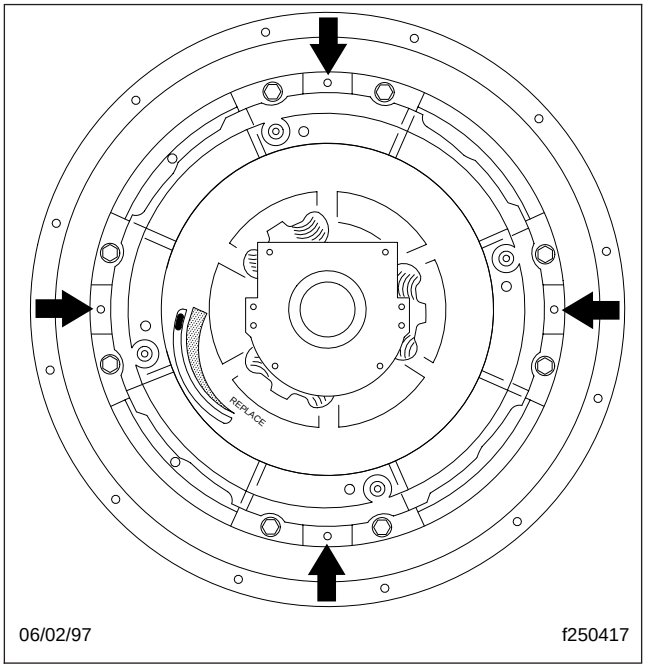
NOTE: Retain these four shipping bolts. These bolts will be needed in the future to secure the clutch assembly during removal and installation.

⚠ WARNING

Wear safety goggles when tapping the pins. If any of the metal parts were to chip, flying pieces of metal could possibly cause eye injury.

10. Set the positive separator pins™.
    - 10.1 Locate the positive separator pin access holes. See **Fig. 28**.

    NOTE: Only a small portion of the pin is visible through the access hole. See **Fig. 29**.



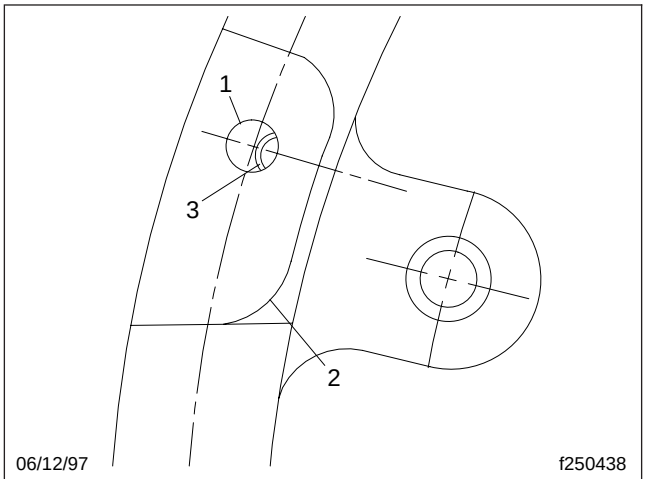


Fig. 28, Positive Separator Pin Access Holes

- 10.2 Using a 1/4-inch (6-mm) flat nose punch, *lightly* tap the four positive separator pins (roll pins) through the access holes of the clutch cover. See **Fig. 30**.

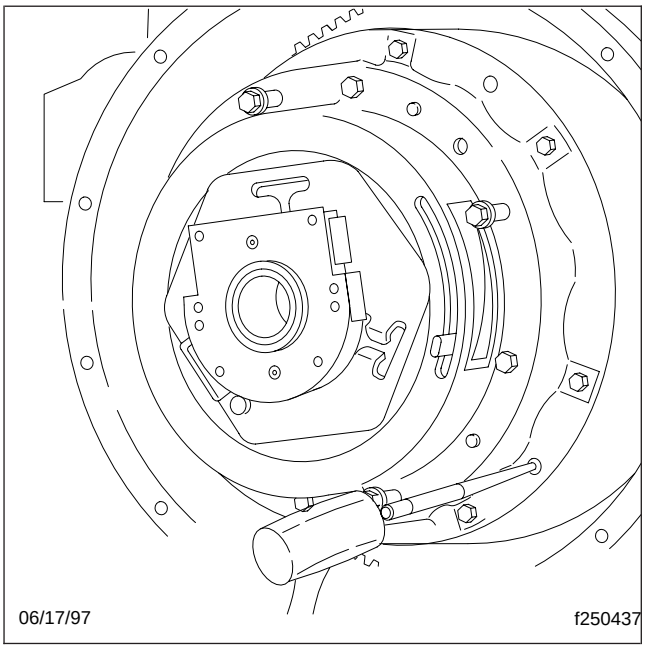

Fig. 30, Setting the Positive Separator Pins

NOTE: Do this step to ensure that all four pins are flush against the flywheel. This allows an equal gap on all sides of the intermediate plate during clutch disengagement.

11. Using a clean cloth, remove all grease from the input shaft.
12. Shift the transmission into gear so that during assembly the transmission input shaft can be rotated into line with the clutch driven-disc hub splines.
13. Install the transmission and attach the clutch linkage. For instructions, see **Group 26**.

⚠ CAUTION

Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

IMPORTANT: Be sure the release-bearing yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 20**. Align the splines by turning the transmission output shaft.

14. Position a pipe, or similar tool, over the cross-shaft release lever and rotate it until the release bearing comes to a complete stop. Repeat this procedure a total of five times.
15. Lubricate the release bearing and the cross-shaft bushings. For instructions and recommended lubricants, see **Group 25** of the *Business Class Trucks Maintenance Manual*.

Installation

IMPORTANT: For 14-inch clutches, see the installation procedures in **Subject 130**.

Easy-Pedal 2000™ Clutch

NOTE: Do the clutch inspection and preinstallation procedures in **Subject 120** before installing the clutch.

1. If the clutch is new, remove any protective coating applied to the pressure plate and the intermediate plate.
2. If not already installed, insert two 7/16–14 x 5 guide studs in the upper mounting holes of the flywheel. See **Fig. 1**. Rotate the flywheel to level the guide studs.

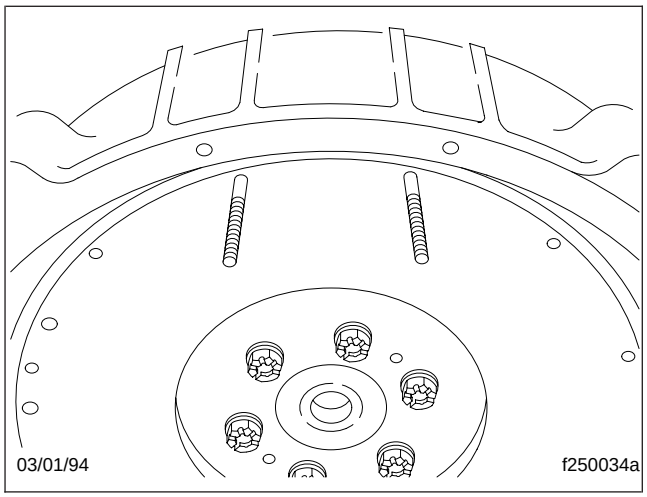

Fig. 1, Install the Guide Studs

3. Set the clutch cover upright, and insert a spline aligning tool through the release bearing sleeve. See **Fig. 2**.

NOTE: Six-spring driven discs are identical, front and rear. Either disc can be installed first on the aligning tool.

4. Install the rear driven disc and intermediate plate.
   - 4.1 Install the rear driven disc on the aligning tool, with the side stamped *INTERMEDIATE PLATE SIDE* facing away from the clutch cover. See **Fig. 3**.

5. Install the front driven disc on the aligning tool, with the side stamped *INTERMEDIATE PLATE SIDE* facing the intermediate plate. See **Fig. 5**.

   Be sure that both driven discs are aligned as shown in **Fig. 6**.

NOTE: On 8-, 9-, and 10-spring discs, this side is stamped *FLYWHEEL SIDE*.

WARNING

The clutch assembly is heavy. It should be removed and installed only with a lifting device. If the assembly is lifted incorrectly or dropped, it could cause serious personal injury.

6. Position the clutch over the two guide studs, and slide the assembly forward until it starts in the flywheel pilot. See **Fig. 7**.

CAUTION

If the capscrews are not tightened in sequence, it may cause permanent damage to the clutch cover and create an out-of-balance condition.

7. Install the clutch mounting capscrews. See **Fig. 8** for the tightening sequence.

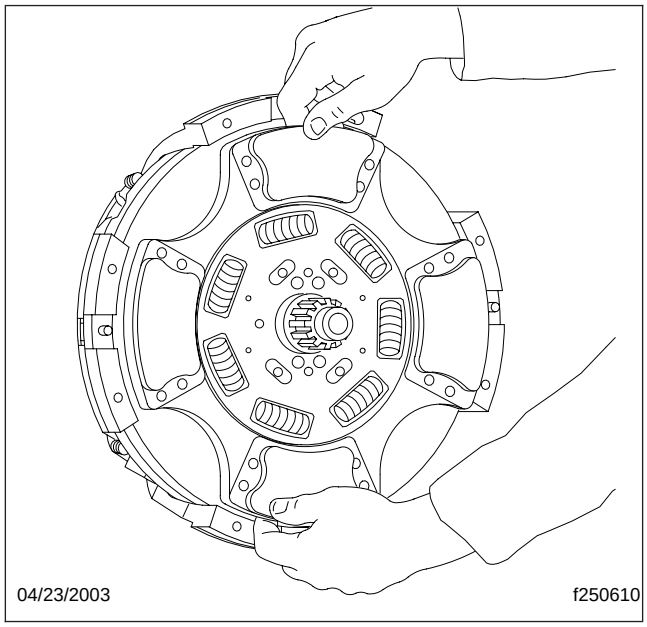

Fig. 5, Installing the Front Driven Disc

   7.1 Start six (grade 5 or better) 7/16–14 x 2-1/4 mounting capscrews with lockwashers. Fasten them finger-tight.

   7.2 Tap the aligning tool to make sure it is centered and seated in the pilot bearing. Remove the two guide studs and replace them with 7/16–14 x 2-1/4 capscrews and lockwashers.

   7.3 Tighten the eight clutch mounting capscrews progressively. The final torque is 40 to 50 lbf·ft (54 to 68 N·m).

   7.4 As the capscrews are tightened, the release bearing spacers should fall free. If they don't, remove them. This may require light taps with a mallet on the end of the aligning tool.

   7.5 Remove the aligning tool.

8. Set the positive separator pins.

   8.1 Locate the pin access holes. See **Fig. 9**.

WARNING

Wear safety goggles when tapping the pins. If any of the metal parts were to chip, flying pieces of metal could possibly cause eye injury.

8.2 Using a 1/4-inch (6-mm) diameter flat nose punch, *lightly* tap each of the four positive separator pins toward the flywheel through the access holes. This step verifies that all the four pins are flush against the flywheel. See **Fig. 10**.

NOTE: Failure to perform this step properly may cause the clutch to drag (clutch does not release). If necessary, after the transmission has been installed, the four pins can be set through the inspection opening of the transmission bell housing.

9. Using a clean cloth, remove all grease from the input shaft.

11. Install the transmission and attach the clutch linkage. See **Group 26** for instructions.

IMPORTANT: Be sure the release yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 11**. Align the splines by turning the transmission output shaft.

12. Grease the release bearing and release shafts. For instructions and recommended lubricants, See **Group 25** of the *Business Class Trucks Maintenance Manual*.
13. Adjust the clutch according to the procedures in **Subject 100**.

Solo™ Heavy-Duty Clutch

NOTE: Do the clutch inspection and pre-installation procedures in **Subject 120** before installing the clutch.

1. If the clutch is new, remove any protective coatings applied to the pressure plate and the intermediate plate.
2. If not already in place, insert two 7/16–14 x 5 guide studs in the upper mounting holes of the flywheel. See **Fig. 1**. Rotate the flywheel to level the guide studs.
3. Set the clutch cover upright, and insert a spline aligning tool through the release bearing sleeve. See **Fig. 12**.

NOTE: Six-spring driven discs are identical, front and rear. Either disc can be installed first on the aligning tool.

4. Install the rear driven disc and intermediate plate.
   - 4.1 Install the rear driven disc on the aligning tool, with the side stamped *INTERMEDIATE PLATE SIDE* facing away from the clutch cover. See **Fig. 3**.

7.3 Remove the two guide studs and replace them with the two remaining mounting capscrews and lockwashers.

7.4 Tighten the eight mounting capscrews progressively, in a crisscross pattern. The final torque is 40 to 50 lbf·ft (54 to 68 N·m).

7.5 Remove the aligning tool.

8. Following a crisscross pattern, remove and retain the four yellow shipping bolts from the clutch cover. See **Fig. 16**.

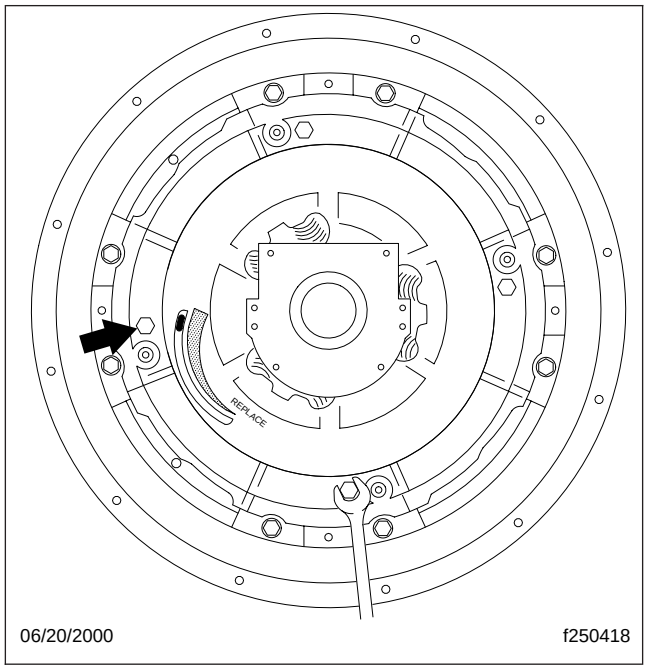

Fig. 16, Remove the Shipping Bolts

NOTE: Retain these four shipping bolts. These bolts will be needed in the future to secure the clutch assembly during removal and installation.

9. On maintenance-free clutches only, remove the input shaft sleeve.

NOTE: Do not be concerned if the release bearing housing touches the clutch cover.

⚠ WARNING

Wear safety goggles when tapping the pins. If any of the metal parts were to chip, flying pieces of metal could possibly cause eye injury.

10. Set the positive separator pins.

    10.1 Locate the pin access holes. See **Fig. 17**.

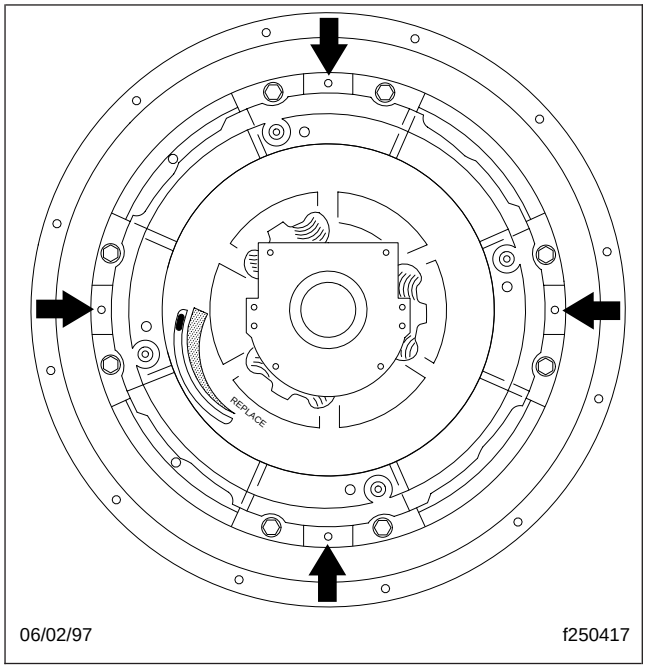

Fig. 17, Pin Access Holes, Solo

    10.2 Using a 1/4-inch (6-mm) diameter flat nose punch, *lightly* tap each of the four positive separator pins toward the flywheel through the access holes. This step verifies that all the four pins are flush against the flywheel. See **Fig.18**.

NOTE: Failure to perform this step properly may cause the clutch to drag (clutch does not release). If necessary, after the transmission has been installed, the four pins can be set through the inspection opening of the transmission bell housing.

11. Using a clean cloth, remove all grease from the input shaft.

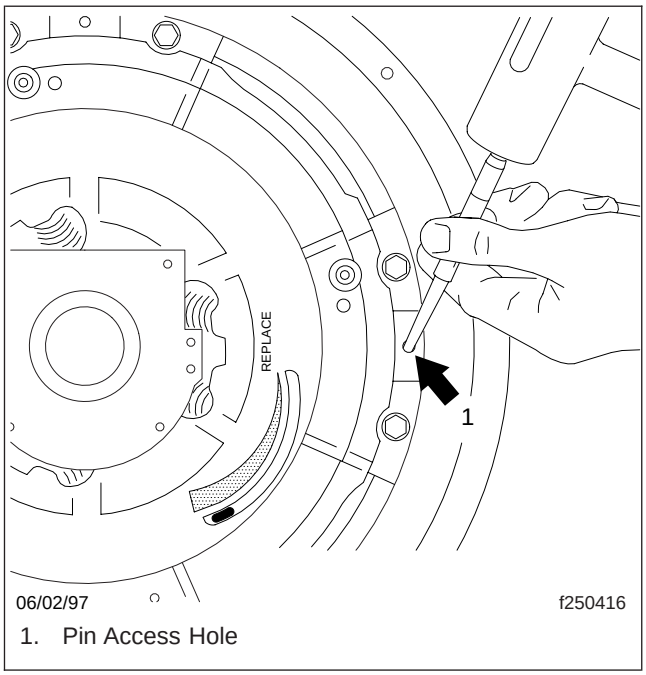

Fig. 18, Tapping the Pin, Solo

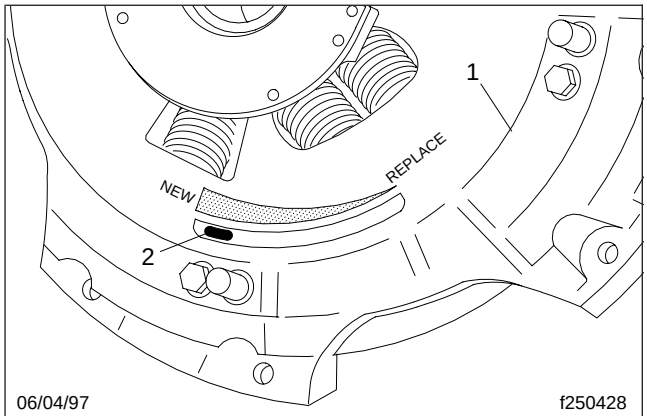
12. Shift the transmission into gear so that during assembly the transmission input shaft can be rotated into line with the clutch driven-disc hub splines.

13. Install the transmission and attach the clutch linkage. See **Group 26** for instructions.

⚠ CAUTION

Avoid springing the driven discs when the transmission is being installed. Don't force the transmission into the clutch or flywheel housing if it doesn't enter freely. Don't let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.



IMPORTANT: Be sure the release yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 11**. Align the splines by turning the transmission output shaft.

14. Lubricate the release bearing and cross-shaft bushings. For instructions and recommended lubricants, see **Group 25** of the *Business Class Trucks Maintenance Manual*.

Resetting

NOTE: This procedure requires two persons; one under the vehicle with access to the wear indicating tab, and the other in the vehicle to operate the clutch pedal.

1. Park the vehicle on a level surface. Shut down the engine, set the parking brake, and chock the tires.
2. Inside the cab, press the clutch pedal all the way down, and hold it there until instructed to release it later in this procedure.
3. Through the clutch cover, use moderate force to slide the wear indicating tab leftward until it is at the "NEW" position on the indicator. See **Fig. 1**. If the tab does not move, follow the instructions under the heading "Releasing a Seized Cam".

With the clutch pedal down, set the tab to the "NEW" position on the indicator.
1. Clutch Cover 2. Wear Indicating Tab

Fig. 1, Resetting the Wear Indicating Tab

4. Release the clutch pedal.
5. To remove the gap between the sleeve and the pin, install four 7/16–14 x 1-3/4 bolts (shipping bolts may be used when available), and use a hand tool to tighten them until the gap is removed and the bolts are snug. See **Fig. 2**.
6. Remove the bolts.
7. Press the clutch pedal all the way down, and squeeze the clutch brake five times to reposition the bearing.

Releasing a Seized Cam

A seized cam may be caused by grease, dust, or other debris accumulated around the outer perimeter of the cam. The cam must operate freely for the clutch to work properly. The Eaton Seized Cam Adjustment Tool is designed specifically for releasing a seized cam. See **Table 1**.

1. While an assistant holds down the clutch pedal, insert the tip of the Seized Cam Adjustment Tool through the access panel and position it under the bearing. See **Fig. 3**.
2. Align the tool so that the threaded bolt extends into the slot in the cam. See **Fig. 3**.

IMPORTANT: Use the Seized Cam Adjustment Tool carefully. Do not use heavy force on it; heavy force can break the cam.

3. Using the tool, carefully try to move the cam toward the right or "Replace" position.

   If the cam moves easily, move it back to the left to verify that spring tension will pull it back to the right. If it returns to the right, then the cam has been released and you can continue with the resetting procedure. If it will not return to the right, the cam spring may be broken.

   If the cam does not move easily, continue to the next step.

IMPORTANT: Use WD-40® only. Do not substitute another penetrant for WD-40.

4. Use sideways pressure to the right and lightly pull the tool away from the engine to separate the top cam from the bottom cam. If the cam moves slightly to the right, let up on the clutch pedal. If the cam is still seized, spray WD-40 into the cam slot and three spring perches. To access all three perches, rotate the engine as needed.

   If the cam is still seized, do the following.

   4.1 Again spray WD-40 into the cam slot and all three spring perches.

   4.2 Inside the cab, release the clutch pedal, then press it all the way down. Next, with the clutch pedal pressed down, jiggle the tool in the cam slots to apply pressure in all directions.

5. Remove the tool.

Troubleshooting Tables

Problem—The Clutch Does Not Release Completely

Problem—The Clutch Does Not Release Completely	
Possible Cause	**Remedy**
The clutch pedal height is incorrect.	Adjust the clutch to obtain the following settings: • 1/2 to 9/16 inch (12.7 to 14.3 mm) release bearing travel; • 0.105 to 0.145 inch (2.7 to 3.7 mm) release yoke free-travel; and • 1/2 to 1 inch (12.7 to 25.4 mm) clutch brake squeeze.
The bushing in the release bearing sleeve assembly is damaged.	Replace the clutch cover.
The clutch cover assembly is not properly seated into the flywheel.	Re-seat the clutch cover assembly into the flywheel. Use a crisscross pattern when tightening the mounting bolts.
The intermediate plate and/or pressure plate is cracked or broken.	Replace any damaged parts.
The cross shafts protrude through the release yoke (a side-loading condition exists).	Check for protruding cross shafts. Repair or replace as necessary.
The release yoke fingers are bent or worn (a side-loading condition exists).	Install a new release yoke.
The engine housing and bell housing are misaligned (a side-loading condition exists).	Check for loose transmission mounting bolts. Tighten the transmission mounting bolts to the proper torque.
The clutch linkage is set up improperly (a side-loading condition exists).	Thoroughly examine the clutch linkage and adjust as necessary.
The driven discs are distorted or warped.	Replace any distorted or warped driven discs. If the transmission is allowed to hang unsupported during clutch installation, the driven discs may become distorted.
The driven discs are installed backwards, or the front and rear driven discs were switched with each other.	Install new driven discs. Also, check the clutch cover for any damage. Replace the clutch cover if damaged.
The input shaft spline is worn.	Replace the input shaft. Also, check the driven disc hubs for wear. Replace the driven discs if worn.
The input shaft spline is coated with grease, anti-seize compound, etc.	Clean and dry the input shaft spline before installation.
The input shaft splines are twisted.	Select a new driven disc and slide it along the full length of the splines. If the disc does not slide freely, replace the input shaft.
The input-shaft bearing cap is worn.	Replace the input-shaft bearing.
The flywheel pilot bearing fits either too tight or too loose in the flywheel and/or end of input shaft.	Check the pilot bearing for proper fit and replace it if worn.
The pilot bearing is dry or damaged.	Replace the pilot bearing.
The positive separator pins are bent, damaged or incorrectly set.	Be sure to use the proper tool when setting the positive separator pins. Also, take great care when handling the intermediate plate. For procedures, see **Subject 130**.

Troubleshooting

Problem—The Clutch Does Not Release Completely	
Possible Cause	**Remedy**
The clutch brake is damaged and/or not functioning.	Install a new clutch brake.
The driven disc faces are coated with oil or grease.	Replace the driven disc assemblies. Cleaning the old driven discs is not recommended.
There is foreign material (dirt, chaff, salt, etc.) inside the clutch cover.	Remove the foreign material and make sure the clutch inspection cover is installed.
The drive pins are cocked, causing the intermediate plate to stick on the drive lugs (Easy-Pedal only).	The drive pins must be ninety degrees square to the flywheel surface with a 0.006-inch (0.15-mm) minimum clearance between drive pins and intermediate plate slots. Repair or replace as necessary.
The pressure plate is not fully retracting (Easy-Pedal only).	Check the pressure plate return springs through the clutch inspection cover. If any are bent, stretched, or broken, replace them as necessary.
The release bearing travel is excessive and is causing the lever to contact the pressure plate (Easy-Pedal only).	Adjust the release bearing travel from 1/2 to 9/16 inch (12.7 to 14.3 mm).
The three anti-rattle springs were installed backwards (Easy-Pedal only).	Install the anti-rattle springs so the rounded sections are pointed toward the flywheel/engine.

Problem—The Clutch Rattles or Is Noisy

Problem—The Clutch Rattles or Is Noisy	
Possible Cause	**Remedy**
There is excessive flywheel runout.	Repair or replace the flywheel. For procedures, see the engine manufacturer's manual.
There is corrosion between the input shaft spline and the driven disc hubs.	Clean the mating parts between the input shaft and driven discs to ensure that the discs slide freely over the input shaft spline.
The engine idle is too fast.	Readjust engine idle to proper idling speed.
The clutch release bearing is dry or damaged.	Lubricate the clutch release bearing. If the noise persists, install a new clutch cover.
The flywheel pilot bearing is dry or damaged.	Replace the flywheel pilot bearing.
The bridge of the release yoke is hitting the clutch cover (an over-stroking condition exists).	Check for a worn, broken or missing clutch brake. Also, check the release yoke and input-shaft bearing cap for wear. Replace any worn parts.
The release yoke fingers are hitting the clutch cover.	Check if the release bearing, clutch cover, or release yoke fingers are worn or broken. Replace worn parts.
The clutch inspection cover is not installed.	Re-install the clutch inspection cover.
The sleeve bushings are worn.	Investigate for any side-loading conditions on the release bearing housing. If there is a side-loading condition, determine its cause. Also, before installing the new clutch, make sure that the side-loading condition has been corrected.
The clutch linkage is rattling excessively.	Clean, lubricate and reassemble or replace missing/worn parts.
An idle gear rattle is coming from the transmission.	Specify low-vibration driven discs. Check the engine for correct idle speed. For procedures, consult the engine manufacturer's manual.

Problem—The Clutch Rattles or Is Noisy	
Possible Cause	**Remedy**
The damper spring cover of the driven disc assembly is interfering with the flywheel.	Install the correct clutch assembly.
The rivets of the rear driven disc are interfering with the retainer assembly (Easy-Pedal only).	Adjust the clutch internally (via the adjustment bolt). For procedures, see **Subject 100**.

Problem—The Clutch Vibrates

Problem—The Clutch Vibrates	
Possible Cause	**Remedy**
The flywheel is loose.	Retighten the flywheel mounting bolts to the proper specifications.
The universal joints are worn.	Replace the worn parts.
The driveshaft is not properly phased.	Investigate and correct the phasing of the driveshaft.
The driveshaft is not balanced.	Balance and straighten the driveshaft.
The driveline angles are incorrect.	Shim the drivetrain components to equalize universal joint angles.
The flywheel is not balanced.	Balance the flywheel.
The pilot area of the clutch is not completely seated into the flywheel.	Ensure that no dirt, burrs, etc., are preventing the clutch cover from completely seating into the flywheel mounting surface.
The engine mounts are loose, damaged, or worn out.	Replace any worn or damaged parts. Retighten all bolts to proper specifications.
The engine is misfiring.	The engine is not in tune. To correct the problem, see the engine manufacturer's manual.
There is excessive flywheel runout.	Repair or replace the flywheel. For procedures, see the engine manufacturer's manual.
The rivets of the rear driven disc are interfering with the retainer assembly (Easy-Pedal only).	Adjust the clutch internally (via the adjustment bolt). For procedures, see **Subject 100**.

Problem—The Clutch Needs Frequent Adjustments

Problem—The Clutch Needs Frequent Adjustments	
Possible Cause	**Remedy**
The release yoke free-travel is insufficient.	After first adjusting the clutch for 1/2 to 9/16 inch (12.7 to 14.3 mm) release bearing travel, adjust the clutch linkage to obtain release yoke free-travel of 0.105 to 0.145 inch (2.7 to 3.7 mm).
The clutch specification is incorrect.	Check the clutch specifications in **Subject 400**. Install a new clutch with the proper specifications, if necessary.
The cross shafts and/or clutch linkage system is worn.	Investigate the entire clutch linkage system to determine if it is binding or operating sporadically and/or worn excessively.
The clutch driven discs are worn down to the rivets.	Install a new clutch. For procedures, see **Subject 130**.

Troubleshooting

Problem—The Clutch Needs Frequent Adjustments	
Possible Cause	**Remedy**
The crankshaft has excessive end play.	Repair or replace the crankshaft. Consult the engine manufacturer's manual for procedures.

Problem—The Clutch Slips

Problem—The Clutch Slips	
Possible Cause	**Remedy**
The clutch pedal has no free travel.	Readjust the clutch.
The clutch is overloaded.	Verify that the proper clutch has been specified for the particular vehicle application.
The release mechanism is binding.	Free up the release mechanism and linkage. Also, check the clutch linkage adjustment.
The driven disc faces are coated with oil or grease.	Replace the driven disc assembly.
The driver is riding the clutch pedal.	Use correct driving procedures.
The input shaft spline is worn.	Replace the input shaft.

Problem—The Clutch Grabs or Chatters

Problem—The Clutch Grabs or Chatters	
Possible Cause	**Remedy**
The clutch is worn out.	Replace the clutch and all worn components.
The linkage system is not operating freely.	Check the clutch linkage for binding or excessive wear. Replace all worn parts.
The driven disc faces are coated with oil or grease.	Replace the driven disc assembly.
The engine mounts are loose.	Retighten the engine mounts to manufacturer's specifications.
The release yoke fingers and/or the release bearing wear pads are worn excessively.	Replace all the worn parts.

Table 15, Solo Heavy-Duty Clutch Capacity

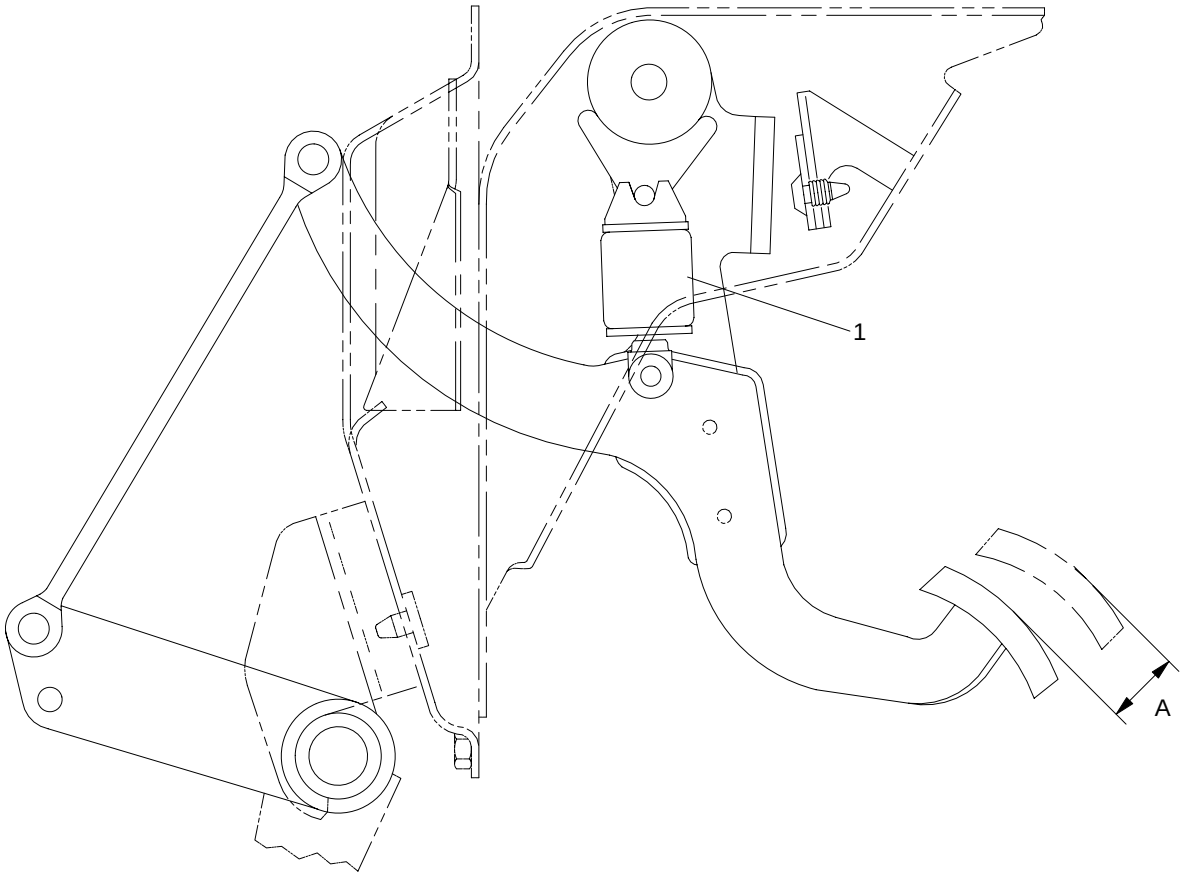
General Information

The clutch linkage transfers the motion of the clutch pedal to the clutch release bearing.

Free-play in the clutch pedal is required to ensure that the fingers of the release bearing do not run against the release bearing. There should not be any play or looseness in the connections and joints of the clutch linkage.

Two types of clutches may be installed on the vehicle: pull or push.

- On push-type clutches, depressing the clutch pedal moves the release bearing toward the engine flywheel. As the clutch is depressed, the pressure plate moves away from the driven disc assembly, and the clutch is disengaged. As the clutch pedal is released, the release bearing and clutch levers move away from the engine flywheel causing the driven disc to be locked up between the friction surfaces of the pressure plate and the engine flywheel. The clutch is then engaged.
- On pull-type clutches depressing the clutch pedal pulls the release bearing away from the pressure plate, disengaging the clutch. As the clutch pedal is released, the pressure plate is forced toward the engine flywheel until the driving and driven discs turn at the same speeds, engaging the clutch.



IMPORTANT: On pull-type clutches, release bearing and release fork clearance are internal clutch adjustments, and *can not be adjusted* by adjusting the clutch linkage. For internal clutch adjustments, see either the applicable clutch section in this group, or the clutch manufacturer's service literature.

On vehicles with right-hand drive, the clutch pedal is installed with the brake pedal inside a special pedal box assembly. Both pedals must be removed as a unit. Clutch adjustment procedures are not affected by this change.

Clutch Linkage Adjustment

IMPORTANT: Vehicles equipped with Rockwell clutches use clutch pedals with an over-center spring. See **Fig. 1**. Clutch pedals without an over-center spring are used on all vehicles except those equipped with Rockwell clutches. See **Fig. 2**.

- If the clutch free pedal is less than 19 mm (3/4 inch), adjust the clutch internally, not at the linkage. See **Fig. 1**, Ref. A.
- Be sure internal clutch adjustments are correct before making adjustments to the clutch linkage. For instructions, refer to the applicable clutch section in this group.
- Adjust the clutch linkage only after repair or replacement of the clutch or clutch linkage components.
- If equipped with cab air-suspension, be sure the air bags are properly inflated. If

the air bags are not inflated, the clutch linkage can't be adjusted correctly.

2. Tilt the hood.
3. Remove the clutch inspection cover from the bottom of the bell housing.
4. Be sure the clutch pedal is all the way up, against the upper stop.
5. Check the internal clutch adjustment. Refer to the applicable clutch section in this group for instructions, and adjust if needed.
6. Measure the distance between the release yoke and the release bearing. See **Fig. 3**. If this measurement is 2.7 to 3.7 mm (0.105 to 0.145 inch), no further work is needed. If the measurement is incorrect, do all of the remaining steps.
7. Remove the nut that attaches the lower clutch rod to the relay lever. Disconnect the lower clutch rod from the relay lever. Loosen the jam nut (**Fig. 4**, Ref. 6) on the lower clutch rod.

IMPORTANT: On vehicles built before January 1996, and if the clutch pedal has an over-center spring, adjust the clutch linkage using a special tool, part number 02–12448–000. See **Fig. 5**. If the clutch pedal doesn't have an over-center spring, adjust the clutch linkage using a different

8. Place the special tool between the clutch pedal and the plastic pedal stop. See **Fig. 5**, **Fig. 6**, or **Fig. 7.**

IMPORTANT: Don't apply excessive force when pulling the lower clutch rod forward as this could partially disengage the clutch.

9. Pull the lower clutch rod forward until resistance is felt. The release yoke is now touching the release bearing.
10. Hold the rod in the same position. Adjust the rod length (in or out) until the rod end lines up with the hole in the relay lever. Install the rod end in the relay lever. Tighten the nut 35 to 45 N·m (26 to 33 lbf·ft).

Installation

1. Install the cross-through shaft in the pedal box. Make sure the spacers, plastic sleeve, and washers are installed in the correct order, as removed. See **Fig. 4**.
   - 1.1 Install the plastic sleeve onto the brake pedal.
   - 1.2 Insert the brake pedal, plastic sleeve, spacers, and clutch pedal onto the cross-through shaft.
   - 1.3 Spread the pedal box slightly and insert the cross-through shaft into the space between the two ends of the box.
2. Insert the cross-through bolt, with washers, and attach the nut. Tighten the nut 135 lbf·ft (183 N·m).
3. Install the brake pedal return spring.
4. Seat the pedal box assembly in the cab. The assembly is seated properly when the bolt holes line up with the holes in the frontwall and the clutch pedal extends through the slot provided. See **Fig. 3**.

CAUTION

When installing the pedal box assembly, be careful not to damage the plastic HVAC tubing.

   - 4.1 From inside the cab, install the six M10 bolts to hold the box in place.
   - 4.2 From outside the cab, install the two 1/4–20 foot valve mounting capscrews and tighten them 84 lbf·in (940 N·cm).
   - 4.3 Install the M10 nuts on the M10 capscrews and tighten the nuts 30 lbf·ft (41 N·m).
5. Install the overcenter spring. See **Fig. 1**.
   - 5.1 Pull the clutch pedal out as far as it will go.
   - 5.2 Slip the washer, spring and plastic retainer onto the stop bolt.
   - 5.3 Push the clutch pedal in.
6. Install the clutch stop. Tighten the stop bolt 84 lbf·in (940 N·cm).
7. From outside the cab, connect the clutch linkage. See **Fig. 2**.
8. Attach the clutch switch electrical connector.
9. If removed, install the steering column. See **Section 46.02, Subject 110** for procedures.

General Information

The clutch linkage uses a hydraulic system consisting of a fluid reservoir, a master cylinder, and a slave cylinder. **See Fig. 1.**

Principles of Operation

When the clutch pedal is depressed, the fluid in the master cylinder is forced through a hydraulic line to the slave cylinder. The fluid pressure moves the slave cylinder piston, pushing the plunger rod and clutch release lever, which disengages the clutch. The system is self-adjusting. No "linkage" adjustment is required. Some clutch models have an internal adjustment, however.

Removal

WARNING

WARNING: Hydraulic brake fluid is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling hydraulic brake fluid or bleeding hydraulic lines. If you get hydraulic brake fluid on your skin, wash it off as soon as possible.

CAUTION

CAUTION: Do not spill hydraulic fluid on the cab paint. Clean it off immediately if any is spilled. Hydraulic brake fluid can damage paint.

1. On vehicles built since December 1992, go to the next step.

   On vehicles built before December 1992, remove the capscrews (**Fig. 1**) holding the reservoir mounting bracket to the master cylinder mounting bracket.

   1.1 Pour the hydraulic fluid out of the reservoir and safely discard it.

   1.2 Disconnect the hydraulic line from the reservoir and remove the reservoir. **See Fig. 2.**

   1.3 Unscrew the fitting (**Fig. 3**) at the bottom end of the master cylinder and disconnect the hydraulic line.

   1.4 Remove the two capscrews (**Fig. 4**) that hold the master cylinder mounting bracket to the firewall.

   1.5 From the backside of the mounting bracket remove the two capscrews (**Fig. 5**) that mount the master cylinder to the bracket.

2. On vehicles built from December 1992, remove the fasteners that attach the master cylinder and the hydraulic fluid reservoir mounting bracket to the firewall.

   2.1 Remove the cap from the hydraulic fluid reservoir and empty the reservoir into a container. Safely discard the fluid.

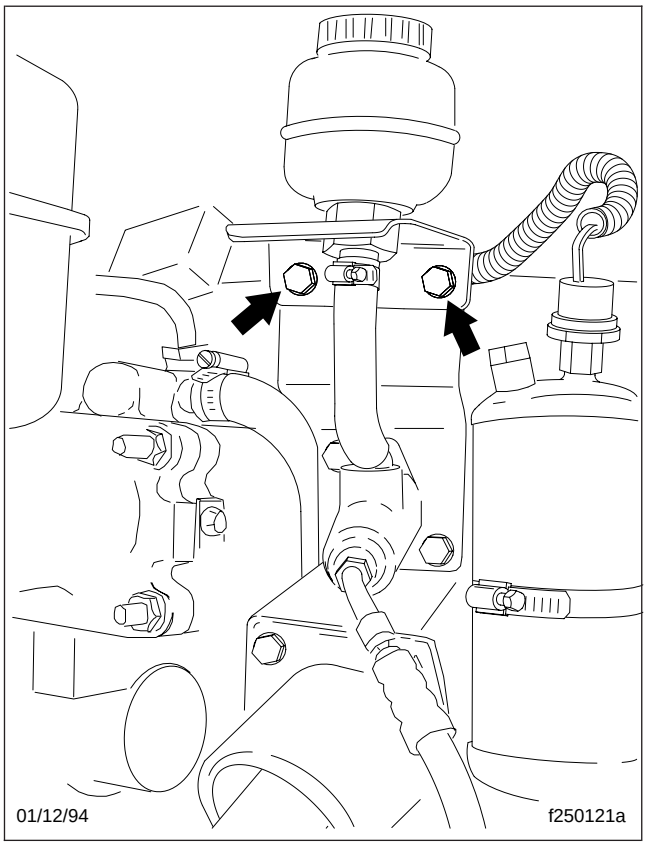

Fig. 1

   2.2 Unscrew the fitting at the bottom end of the master cylinder and disconnect the hydraulic line.

   2.3 Disconnect the hydraulic line from the reservoir and remove the master cylinder.

Installation

1. Adjust the master cylinder plunger rod.

   1.1 Before attaching the master cylinder, loosen the plunger rod jam nut.

CAUTION

CAUTION: Adjust the plunger rod to extend 38.5 mm (about 1-1/2 inches) beyond the outside surface of the firewall. If the rod extends too far, the piston seals will be damaged when the piston travels too far in the master cylinder bore. In addition, the clutch will not self-adjust because the

Master Cylinder Removal and Installation

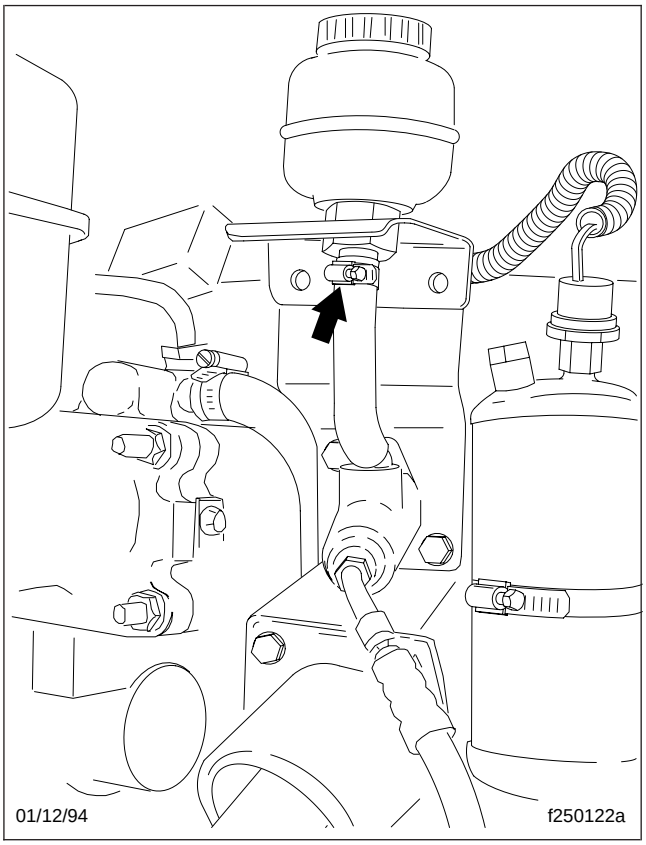

Fig. 2

opening to the clutch fluid reservoir will be blocked. If the rod doesn't extend far enough, there will be play at the clutch pedal.

NOTE: There is normally no play with a hydraulic clutch linkage.

1.2 Adjust the plunger rod by turning it in or out of the clevis yoke until it extends 38.5 mm (1-1/2 inches) beyond the firewall outside surface. **See Fig. 6.**

1.3 Tighten the jam nut.

2. On vehicles built since December 1992, go to the next step. On vehicles built before December 1992, install the master cylinder.

2.1 Position the master cylinder on the master cylinder mounting bracket. Install the two capscrews (**Fig. 5**). Tighten them 880 N·cm (78 lbf·in).

2.3 Install the mounting capscrews (**Fig. 4**) and tighten them 20 N·m (15 lbf·ft).

2.4 Install and fill the hydraulic fluid reservoir.

2.5 Connect the hydraulic line to the master cylinder. Tighten the fitting (**Fig. 3**) 18 to 24 N·m (13 to 18 lbf·ft).

2.6 Mount the reservoir and its bracket onto the master cylinder mounting bracket. Tighten the two capscrews (**Fig. 1**) 1080 N·cm (96 lbf·in).

2.7 Connect the hydraulic fluid line from the master cylinder to the reservoir. Tighten the hose clamp (**Fig. 2**).

2.8 Fill the reservoir with D.O.T. #3 hydraulic brake fluid.

3. On vehicles built since December 1992, install the master cylinder.

3.1 Connect the hydraulic line to the master cylinder. Tighten the fitting 18 to 24 N·m (13 to 18 lbf·ft).

3.2 Connect the hydraulic fluid line from the master cylinder to the reservoir. Tighten the hose clamp.

3.3 Position the master cylinder and hydraulic fluid reservoir mounting bracket on the firewall. Install and tighten the two capscrews 20 N·m (15 lbf·ft).

3.4 Fill the reservoir with D.O.T. #3 hydraulic brake fluid.

4. Bleed the clutch hydraulic system. For instructions, **refer to Subject 140.**

Slave Cylinder Removal and Installation

Removal

⚠ WARNING

WARNING: Hydraulic brake fluid is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling hydraulic brake fluid or bleeding hydraulic lines. If you get hydraulic brake fluid on your skin, wash it off as soon as possible.

1. Disconnect the hydraulic line from the slave cylinder and drain the fluid into a container.
2. Remove the rubber boot from the plunger rod. Remove the slave cylinder mounting capscrews (**Fig. 1**) and nuts; then, remove the slave cylinder.

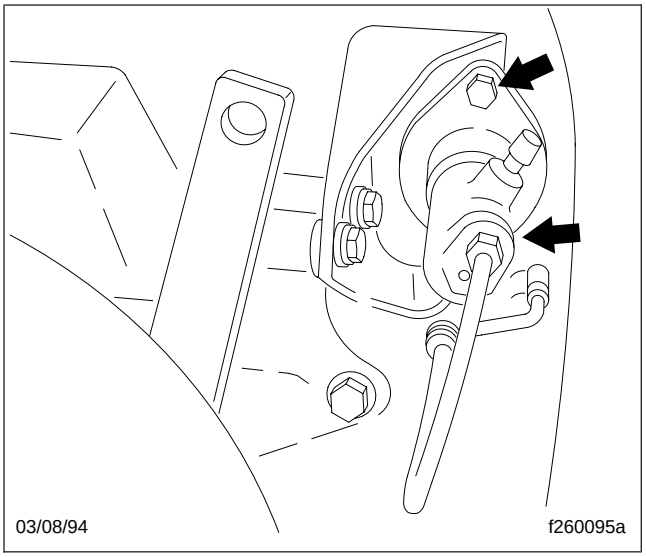

Fig. 1

Installation

1. Make sure that the index marks on the clutch release lever and the release shaft are aligned. **See Fig. 2.**
2. Install the slave cylinder.
   - 2.1 Place a new rubber boot on the plunger rod. Position the clutch slave cylinder on its bracket, making sure that the slave cylinder bleeding valve is pointing up.

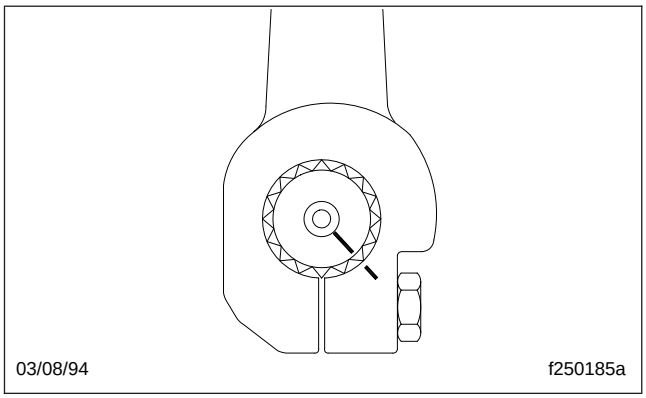

Fig. 2, Index Marks Aligned

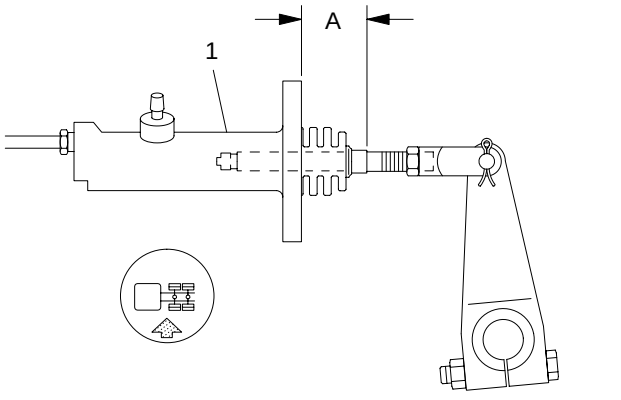
   - 2.2 Install the mounting capscrews and nuts. Tighten them 41 N·m (30 lbf·ft).

⚠ CAUTION

CAUTION: Do not push the slave cylinder piston more than 65 mm (2-1/2 inches) into the cylinder, or the piston seal will be damaged by the bleed hole.

   - 2.3 Connect the hydraulic line to the slave cylinder. Tighten the hydraulic line fitting 18 to 24 N·m (13 to 18 lbf·ft).



3. Adjust the slave cylinder plunger rod.

   NOTE: The dimensions below apply only to new push-type clutches and correctly adjusted pull-type clutches.

   - 3.1 Turn the plunger rod, moving it in or out of the clevis yoke, to obtain the correct distance between the cylinder mounting surface and the step on the plunger rod shaft. **See Fig. 3** and **Fig. 4**.
     - On a push-type clutch for vehicles built before May 1, 1992, that distance is 44 mm (about 1-3/4 inches): On vehicles built from May 1, 1992, that distance is 62 mm (about 2-1/2 inches).
     - On a pull-type clutch for vehicles with a synchronized transmission, that distance is 44 mm (about 1-3/4 inches): On vehicles with a nonsynchronized transmission, the dis-

tance is 82 mm (about 3-7/32 inches).

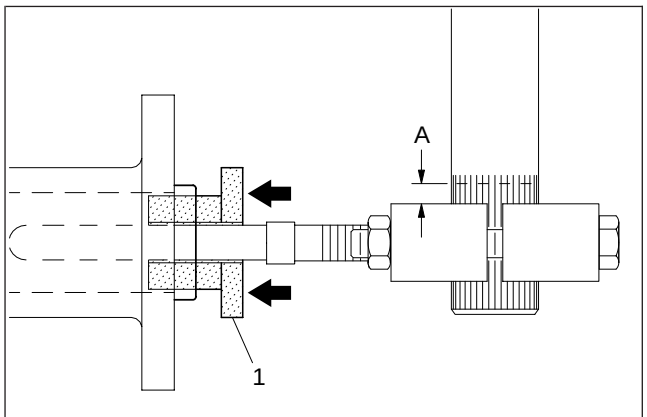
3.2 Tighten the jam nut.

4. Check the alignment of the slave cylinder.

4.1 Carefully detach the rubber boot from the slave cylinder, and push it forward to allow a clear view of the plunger rod where it enters the cylinder bore.

4.2 Place the slave cylinder alignment tool (part number 02-12245-000) over the plunger rod with the flange end of the tool away from the cylinder. Gently slide the tool towards the open end of the cylinder bore, and if possible, insert it into the cylinder bore until the flange of the tool is firmly seated against the end of the cylinder. If there is resistance, lightly press and rotate the tool until it slides into the cylinder. **See Fig. 5.** If the tool can be rotated 360 degrees around the plunger rod, the cylinder and rod are aligned as well as is possible. No other alignment is needed. Remove the tool. Install the rubber boot and make sure that the small end of the boot is located in the groove of the plunger rod and that the other end is seated properly on the slave cylinder flange. Fill and bleed the clutch hydraulic system. **See Subject 140** for instructions.

Otherwise, if the tool can't be rotated 360 degrees around the plunger rod, the cylinder and rod require further alignment. With the tool seated, it can be seen in which direction the rod and or cylinder need to be adjusted. Center the rod horizontally if required. Vehicles with synchronized transmissions (slave cylinder on the right) and non-synchronized transmissions (slave cylinder on the left) can be adjusted for horizontal alignment.



03/08/94 f250097a

A. Adjust here.
1. Slave Cylinder Alignment Tool

Fig. 5

4.3 Scribe or paint a line on the clutch release shaft at the edge of the clutch release lever opposite the direction the lever must be moved. This is in order to mark the original location of the lever on the shaft for later reference.

A. Measure adjustment.
1. Slave Cylinder Alignment Tool

Fig. 6

4.4 Loosen the pinch bolt securing the lever to the shaft, and slide the lever until the plunger rod is centered in the cylinder bore. When the rod is centered, the tool will seat against the end of the cylinder with the slot vertical. Tighten the pinch bolt 34 to 42 N·m (25 to 31 lbf·ft), being careful not to move the lever. Check to ensure that the plunger rod is still approximately centered in the cylinder.

4.5 Using the mark on the shaft as reference, measure the distance the lever was moved to align the plunger rod. **See Fig. 6.** If the lever was moved 5 mm (0.2 inch) or more, the rod was probably cocking the piston, and future cylinder leakage is likely. Replace the cylinder.

5. This step applies only to vehicles with synchronized transmissions (slave cylinder on the right). Center the rod vertically, if required.

5.1 Loosen the two fasteners that mount the slave cylinder bracket to the transmission. **See Fig. 5.**

5.2 Move the mounting bracket up or down until the plunger rod is centered vertically in the cylinder, and the tool will rotate 360 degrees around the plunger rod while pressed against the end of the cylinder; then tighten the two mounting fasteners 34 to 42 N·m (25 to 31 lbf·ft). Check alignment with the alignment tool. Readjust if necessary.

NOTE: The slave cylinder alignment tool is designed to be used during production, or in cases of realignment such as this. The need for readjustment does not necessarily mean that the previous setting was out of specification.

6. When the plunger rod is correctly aligned, and the slave cylinder has been replaced if necessary, carefully install the rubber boot on the cylinder. Ensure that the small end of the boot is located in the groove of the plunger rod and that the other end is seated properly on the slave cylinder flange.

7. Fill and bleed the clutch hydraulic system. **See Subject 140** for instructions.

Clutch Hydraulic System Filling and Bleeding

Filling and Bleeding Using a Pressurized Bleeding Unit

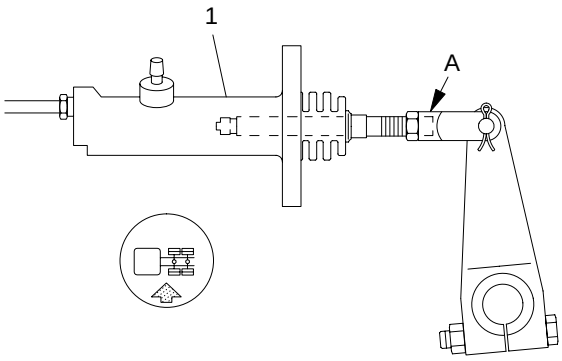
IMPORTANT: If a clutch with internal adjustments is installed on the vehicle, make sure those adjustments are correct before adjusting the plunger rod. Refer to the applicable clutch section in this group for instructions. Also, make sure the slave cylinder plunger rod is properly adjusted. For instructions, refer to **Subject 120**.

⚠ WARNING

WARNING: Hydraulic brake fluid is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling hydraulic fluid or bleeding hydraulic lines. If you get hydraulic fluid on your skin, wash it off as soon as possible.

⚠ CAUTION

CAUTION: Do not spill hydraulic brake fluid on the cab paint. Clean it off immediately if any is spilled. Hydraulic brake fluid can damage paint.



1. Apply the parking brake and chock the tires.
2. Remove the cap from the clutch hydraulic fluid reservoir. Make sure that the reservoir is at least two-thirds full.

NOTE: A pressure bleeding unit (J29532) and a bleeder adaptor (J35798) for the fluid reservoir are available through Kent-Moore Tools and may be used to complete the following procedure. To order these parts, call Kent-Moore at 1-800-328-6657.

3. Prepare the pressure bleeding unit for use according to the manufacturer's instructions. Use DOT #3 hydraulic brake fluid. Also, allow some fluid to run through the pressure unit hose to remove air from the hose. Pressurize the unit to 207 kPa (30 psi).
4. Connect the pressure bleeding unit to the reservoir.
5. Connect a clear drain line to the slave cylinder bleed valve.

IMPORTANT: The slave cylinder may not be mounted in a horizontal position. If it isn't, remove the slave cylinder and hold it in a horizontal position to completely purge all air from the cylinder.

6. Fully depress the clutch pedal and block it in this position.
7. Open the slave cylinder bleed valve; then, open the valve on the bleeder unit. Observe the flow of hydraulic fluid through the slave cylinder drain line. When no bubbles appear in the fluid, close the valve on the slave cylinder. Then, close the valve at the bleeding unit.
8. Move the slave cylinder plunger rod 13 mm (1/2 inch) in and out several times until a firm resistance is felt, or until no bubbles appear in the reservoir. **See Fig. 1.**

06/22/94 f250201b

A. Move the plunger rod in and out about 13 mm (1/2 inch).
1. Slave Cylinder

Fig. 1

9. Disconnect the bleeding unit, and install the cap on the slave cylinder bleeder valve.
10. Check the fluid level in the reservoir. If necessary, add or remove hydraulic fluid to bring the fluid level to the MAX line. Install the reservoir cap.
11. Depress the clutch pedal a few times. There should be resistance over the full pedal stroke.
12. Check the clutch function.
    - 12.1 Make sure that the parking brake is still set.

Clutch Hydraulic System Filling and Bleeding

12.2 Fully depress the clutch and hold it in this position.

12.3 With the transmission in neutral, start the engine.

12.4 Shift the transmission through the gears. All gears must engage easily.

12.5 Keep the clutch pedal fully depressed, the engine running, and the transmission in gear.

12.6 If the clutch begins to engage within approximately three minutes, the system is not working properly. Shut down the engine. Repeat the filling/bleeding procedure.

NOTE: If the clutch system still is not working properly, check the master and slave cylinder operation.

13. Check the entire system for leaks. Tighten connections if necessary. Check the fluid level in the reservoir again.

14. Remove the chocks from the tires.

Clutch Linkage Adjustment

NOTE: Clutch linkage adjustment may be necessary if the master cylinder or slave cylinder is being replaced. It is not necessary after replacing the clutch. Also, there is no linkage adjustment on used push-type clutches. On push-type clutches, the adjustment procedure below applies only to the original installation.

Adjustment

NOTE: If a clutch with internal adjustments is installed on the vehicle, make sure those adjustments are correct before checking the clutch linkage. If internal adjustment is needed, refer to the applicable clutch section in this group.

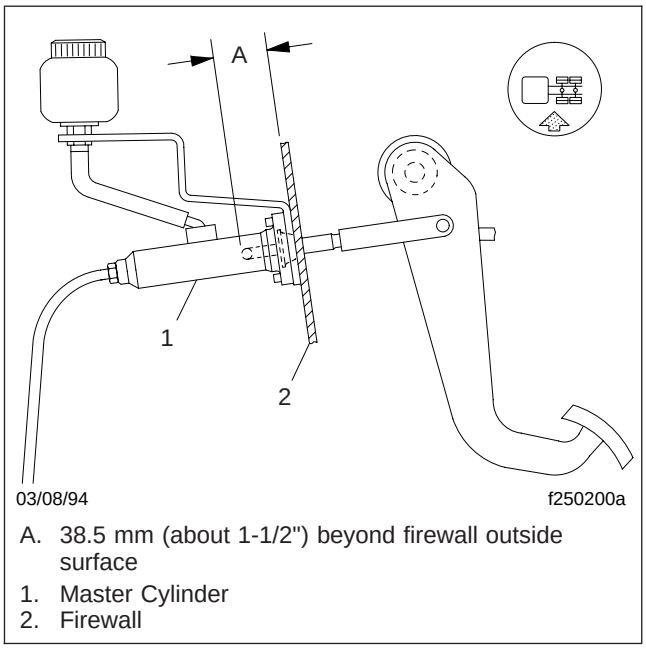
1. If the master cylinder is being replaced, check the master cylinder plunger rod adjustment.

   1.1 If adjustment is needed, and before attaching the master cylinder, loosen the plunger rod jam nut.

CAUTION

CAUTION: Adjust the plunger rod to extend 38.5 mm (about 1-1/2 inches) beyond the outside surface of the firewall. If the rod extends too far, the piston seals will be damaged when the piston travels too far in the master cylinder bore. In addition, the clutch will not self-adjust because the opening to the clutch fluid reservoir will be blocked. If the rod doesn't extend far enough, there will be play at the clutch pedal.

NOTE: There is normally no play with a hydraulic clutch.



1.2 Adjust the plunger rod by turning it in or out of the clevis yoke until it extends 38.5 mm (about 1-1/2 inches) beyond the outside surface of the firewall. **See Fig. 1.**

1.3 Tighten the jam nut.

1.4 Install the master cylinder. For instructions, **refer to Subject 100**.

2. If the slave cylinder is being replaced, check the slave cylinder plunger rod adjustment.

   2.1 Make sure that the index marks on the clutch release lever and the release shaft are aligned. **See Fig. 2.**

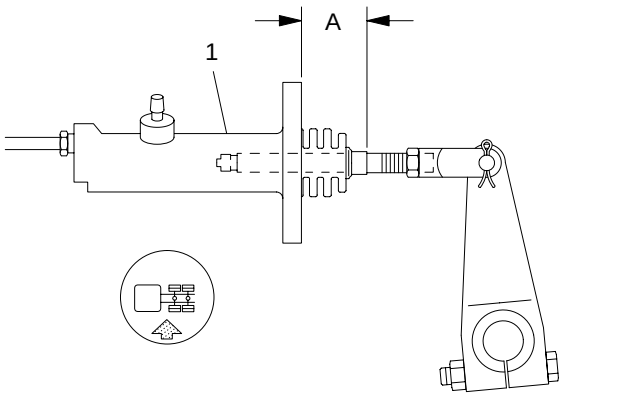
2.2 Install the slave cylinder. **Refer to Subject 120** for instructions.

CAUTION



CAUTION: Do not push the slave cylinder piston more than 65 mm (2-1/2 inches) into the cylinder, orthe piston seal will be damaged by the bleed hole.

2.3 If adjustment is needed, adjust the slave cylinder plunger rod by turning it in or out of the clevis yoke to obtain the correct

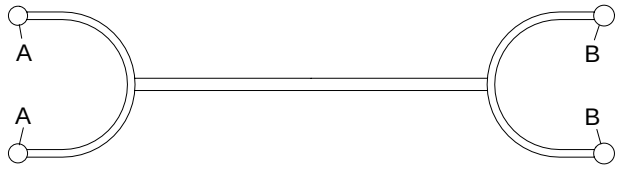
HYDRAULIC CLUTCH CONTROL SYSTEM

1. Using Kent-Moore tool J4749, loosen the locknut ring (**Fig. 1**). Then, rotate the sleeve with the adjuster ring to the specified release bearing clearance.

   With non-synchronized transmissions equipped with a clutch brake, release bearing clearance is 1/2 to 9/16 inch (12.7 to 14.3 mm). See **Fig. 1**.

   With non-synchronized transmissions and no clutch brake, release bearing clearance is 3/4 inch (19 mm).



2. Using Kent-Moore tool J4749, tighten the locknut ring against the release bearing coupler. Tighten the locknut 35 to 40 lbf·ft (47 to 61 N·m).

MECHANICAL LINKAGE CLUTCH CONTROL SYSTEM

IMPORTANT: An inspection tool A02–12419 (available through the PDCs) can be used to check the distance between the release bearing and the clutch brake. See **Fig. 2**. One end of the tool has green tape on it and is 0.50 inch (12.7 mm) in diameter; the other end has blue tape on it and is 0.56 inch (14.3 mm) in diameter.

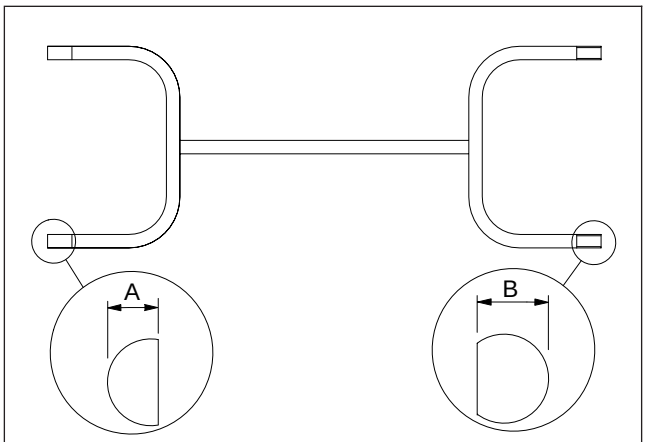
1. If using tool A02–12419 to check the distance between the release bearing and the clutch brake, position the tool so that the legs straddle the transmission input shaft. Check the gap with both ends of the tool as follows:

Clutch Adjustments

A. 0.50 inch (12.7 mm)
B. 0.56 inch (14.3 mm)

Fig. 2, Inspection Tool A02-12419

1.1 Insert the blue 0.56-inch (14.3-mm) end. If it fits loosely the gap is too wide and adjustment is needed. Go to the next step.



1.2 If the blue 0.56-inch (14.3-mm) end can't be inserted in the gap, then try to insert the green 0.50-inch (12.7-mm) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

1.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Go to the next step.

2. Disconnect the external linkage to allow free movement of the release yoke.
3. Using two spanner wrenches (Kent-Moore J4749), loosen the release bearing locknut. Thread the locknut back toward the transmission a small distance to ensure that it will not interfere with the adjustment procedure.
4. Rotate the sleeve with the adjuster ring to the specified release bearing clearance.
5. Using the two spanner wrenches, place one on the notches of the release bearing coupler and the other on the release bearing locknut. Use the first wrench to prevent the coupler from rotating while using the second wrench to tighten the locknut against the coupler as a jamnut.
6. Tighten the locknut ring against the release bearing coupler by placing the two wrenches in notches that will result in the two wrench handles diverging slightly from one another. Then both handles can be grasped with one hand and squeezed closely together.

IMPORTANT: An inspection tool A02–12254 (available through the PDCs) can be used to check the distance between the release bearing and the release fork (free travel). See **Fig. 3**. The legs on one end of the tool have green tape on them and are 0.105 inch (2.7 mm) thick; the legs on the other end have blue tape on them and are 0.145 inch (3.7 mm) thick.

7. If using tool A02–12254 to check the distance between the release bearing and the release fork, position the tool so it straddles the fork to ensure that there won't be any misalignment. Check the distance with both ends of the tool as follows:

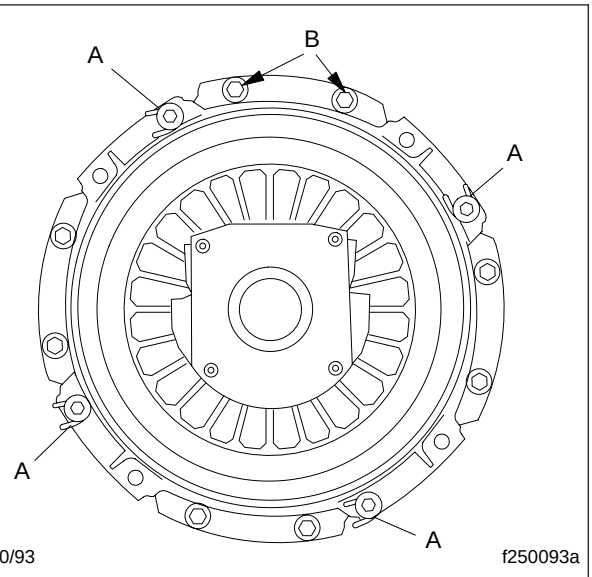
A. 2.7 mm (0.105 inch)
B. 3.7 mm (0.145 inch)

Fig. 3, Inspection Tool A02-12254

7.1 Insert the blue 3.7-mm (0.145-inch) end. If it fits loosely the gap is too wide and adjustment is needed. Connect the external linkage, then go to the section on clutch linkage adjustment in this group.

7.2 If the blue 3.7-mm (0.145-inch) end can't be inserted in the gap, then try to insert the green 2.7-mm (0.105-inch) end. If the green end of the tool fits, snug or loose, then no adjustment is needed.

7.3 If the green end of the tool can't be inserted in the gap, adjustment is needed. Connect the external linkage, then perform a clutch linkage adjustment. For instructions, see **Section 25.02**.



Removal

1. Remove the transmission. Follow the procedures in **Group 26** of this manual.

CAUTION

CAUTION: Do not let the transmission drop, and do not let the transmission hang unsupported by the input shaft in the pilot bearing. Taking these precautions will prevent damage to the clutch assembly and the pilot bearing.

2. Remove the clutch brake (if equipped) from the transmission input shaft.
3. To facilitate clutch removal and installation, Valeo clutches employ four U-clips to hold the pressure plate toward the clutch. Install the four U-clips. See **Fig. 1**.

A. Install U-clips here.
B. Install guide pins here.

Fig. 1, 14-Inch and 16-Inch Clutches

4. Install a clutch alignment tool through the clutch and into the flywheel pilot bearing to support the clutch assembly during removal.

NOTE: If an alignment tool is not available, use an input shaft from a manual transmission. Remove the gear from the end of the input shaft.

5. Remove the top two capscrews from the pressure plate assembly as indicated in **Fig. 1**. Install guide pins in the two holes. If guide pins are not available, they may be made by removing the heads from two capscrews.
6. Remove the remaining capscrews which secure the cover assembly to the flywheel.

WARNING

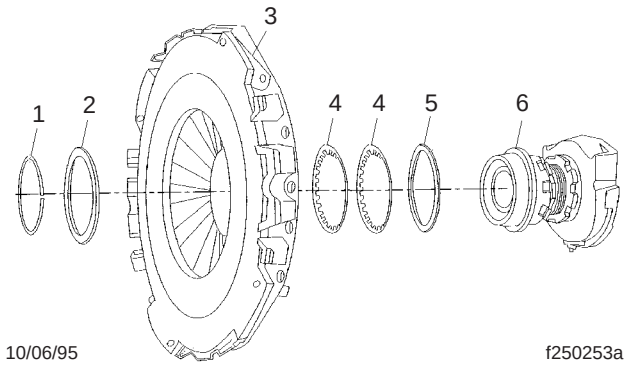
WARNING: The cover assembly is heavy and should be removed only with a lifting device. If the assembly is lifted improperly or dropped, it could cause serious personal injury.

7. Lift the pressure plate, release bearing, and clutch assembly over the alignment tool and guide pins.
8. Whenever the clutch assembly is serviced or the engine is removed, the pilot bearing in the flywheel should be removed and replaced. Use an appropriate internal puller and a slide hammer to remove the pilot bearing. Install the new pilot bearing with an appropriate driver.

Inspection

1. Inspect the release fork, the cross shaft, and the shaft bushings. Inspect the transmission input shaft splines. Minor scratches may be removed with emery cloth. Replace any damaged or excessively worn parts.
2. Inspect the flywheel for heat spots, warpage, scoring, or cracks around the bolt holes. If necessary, machine or replace the flywheel.
3. Inspect the pressure plate friction surface for wear or damage. If the plate is cracked, replace it. Heat marks are normally found on a pressure plate after operation. These marks can usually be removed with emery cloth. If you cannot remove heat marks with emery cloth, replace the pressure plate.
4. Inspect the pilot bearing. Although the pilot bearing should be replaced whenever the clutch is removed, any excessive wear or damage to the pilot bearing could indicate other problems which should be remedied.

Clutch Removal, Inspection, and Installation



5. Inspect the clutch release linkage, the shafts, and the yoke for wear or binding. Make any necessary repairs.
6. If a clutch brake is installed, inspect the clutch brake wear surface on the transmission. Replace the transmission front bearing cover if necessary.

Installation

NOTE: If you are installing components which have been in operation, do the inspection procedure in this subject before installing the clutch.

1. Lubricate the bore in the crankshaft for the pilot bearing with the specified lubricant. Do not overlubricate. Excess lubricant can contaminate the disc and cause the clutch to slip.

   Using an appropriate driver, install the pilot bearing. Refer to the engine manufacturer's service manual for instructions.
2. Install guide pins in the top two bolt holes of the flywheel. If guide pins are not available, make them by removing the heads from two capscrews.
3. If necessary, install the release bearing assembly on the pressure plate. See **Fig. 2** for assembly.

4. Position the clutch alignment tool in the clutch disc so the flat side of the disc marked *FLYWHEEL SIDE* will face the flywheel. Insert the alignment tool into the pilot bearing.

⚠ WARNING

WARNING: The cover assembly is heavy and should be installed only with a lifting device. If the assembly is lifted improperly or dropped, it could cause serious personal injury.

5. Install the pressure plate assembly over the alignment tool and the guide pins. See **Fig. 4**.
6. Install the mounting capscrews finger-tight in the cover assembly.

For 16-inch clutches, be sure the pressure plate cover fits inside the raised step of the flywheel. Refer to the detail in **Fig. 4**.

Remove the two guide pins, and install the remaining two capscrews.

IMPORTANT: Use hardened washers and grade 8 capscrews. Be sure the capscrews are the correct length. Capscrews which are too short will strip; capscrews which are too long will damage the flywheel and may break off under engine torque.

7. Tighten the capscrews one turn at a time until they are snug. Then, tighten the capscrews as specified below. Follow the tightening sequence in **Fig. 5**.
   - 14-Inch Clutches: 47 to 54 N·m (35 to 40 lbf·ft).
   - 16-Inch Clutches: 54 to 61 N·m (40 to 45 lbf·ft).

8. Remove the four wire U-clips (**Fig. 5**). Remove the clutch alignment tool.
9. Install the transmission. Follow the procedures in **Group 26** of this manual.

CAUTION

CAUTION: Do not let the transmission drop, and do not let the transmission hang unsupported by the input shaft in the pilot bearing bore in the flywheel. Taking these precautions will prevent damage to the clutch assembly and the pilot bearing. If excessive force is required to install the transmission into the flywheel housing, investigate the cause and make necessary corrections.

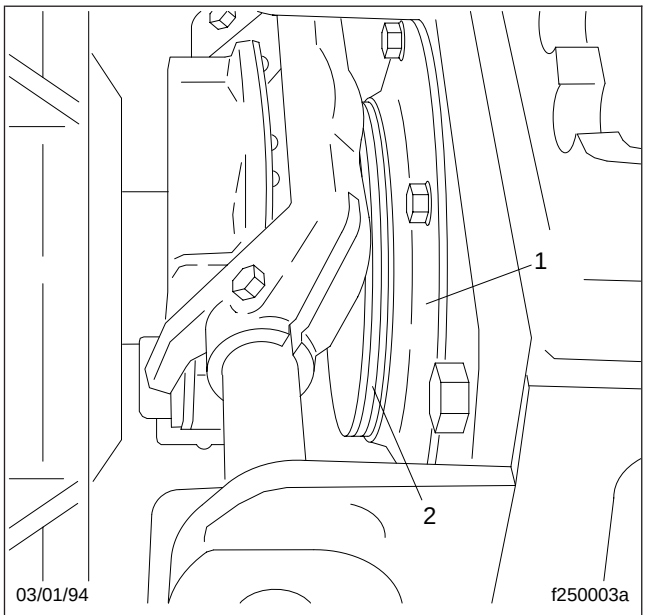
General Description

When the vehicle is stationary, a clutch brake permits shifting into first gear or reverse gear without severe gear clash.



Clutch brake engagement occurs approximately during the last 1 to 1-1/4 inches (25 to 33 mm) of downward pedal travel. The clutch brake is between the release-bearing housing (see **Fig. 1**) and the transmission bearing cap, and is engaged by tangs to the transmission input shaft. When the pedal is fully depressed, the clutch brake is squeezed between the release-bearing housing and the transmission bearing cap (see **Fig. 2**), stopping the rotation of the main drive gear.

The clutch brake may be a disc-type or a torque-limiting type. In addition, the clutch brake may be either a one-piece or two-piece design. To prevent overloads to it, the torque-limiting clutch brake is designed to slip when loads of 20 to 25 lbf·ft (27 to 34 N·m) are reached. Clutch brakes are not designed for upshifting.

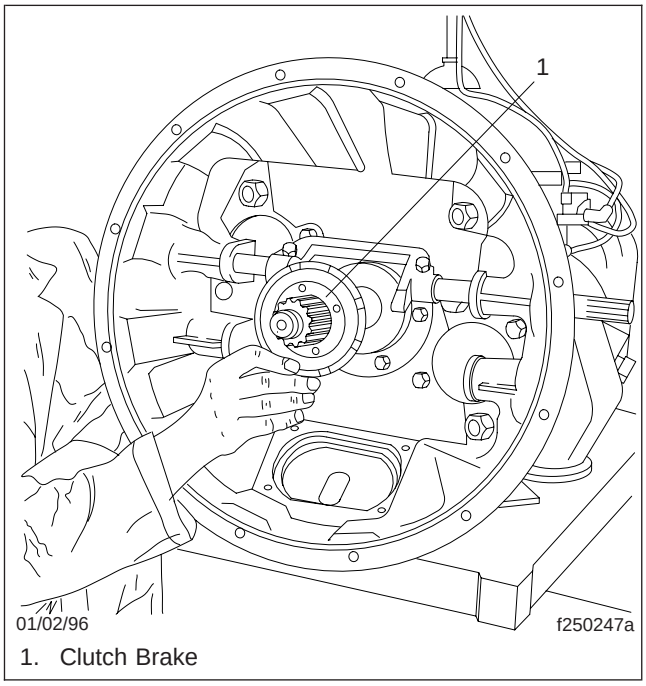
1. Shut down the engine, set the parking brake, and chock the tires.
2. Tilt the hood.
3. Drain the air tanks.
4. Disconnect the batteries.
5. Place the transmission in gear.
6. Remove the shift tower from the top of the transmission. See **Group 26** in this manual for instructions.
7. Disconnect the driveline from the rear of the transmission. See **Group 41** in this manual for instructions.
8. Disconnect the midship bearing. See **Group 41** in this manual for instructions. Pull the driveshaft aside and position it out of the way.
9. Remove the fuel tank compression brace. See **Group 47** in this manual for instructions.
10. Disconnect the clutch rod from the clutch release lever. See **Section 25.02** in this group for instructions.
11. Disconnect the transmission wiring.
12. Disconnect the transmission air lines.
13. Remove the auxiliary air tank, if so equipped.
14. Remove the transmission oil cooler and set it aside, out of the way.



IMPORTANT: Do not disconnect the oil cooler lines.

15. Place a transmission jack in position below the transmission. Adjust the jack to support the transmission.
16. Secure the transmission to the jack.
17. Remove the flywheel housing-to-clutch housing bolts. See **Group 26** in this manual for instructions.

CAUTION

Do not let the rear of the transmission drop, and do not let the transmission hang unsupported in the splined hubs of the clutch discs. Taking these precautions will prevent bending and distortion of the clutch discs.

18. Pull the transmission back until the input shaft clears the flywheel.
19. Remove the old clutch brake from the transmission input shaft. See **Fig. 1**.

1. Clutch Brake

Fig. 1, Clutch Brake Removal

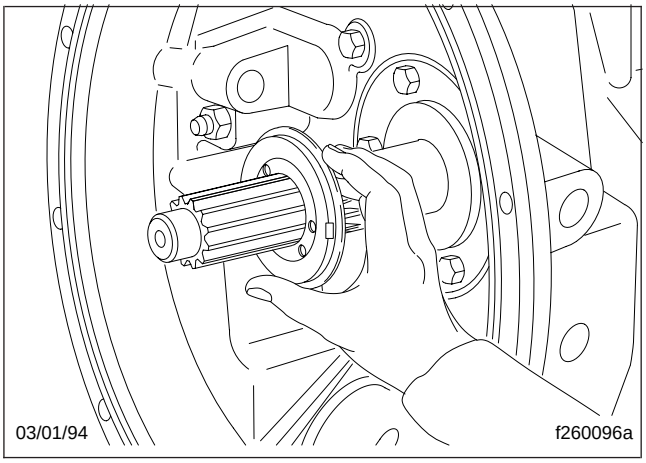
20. Align the tangs of the new clutch brake with the grooves on the input shaft and slide the clutch brake into position. See **Fig. 2**.

CAUTION

Use care to avoid springing the drive discs when the transmission is being installed. Do not force the transmission into the clutch or flywheel housing if it does not enter freely. Do not let the transmission drop or hang unsupported in the driven discs. These practices can damage the clutch assembly.

21. Install the transmission. See **Group 26** in this manual for instructions.
22. Remove the transmission jack.
23. Connect the air lines and the transmission wiring.

One-Piece Clutch Brake Replacement



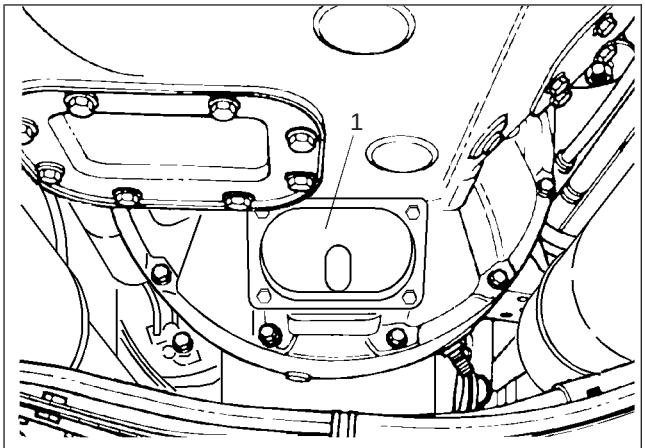


Fig. 2, Clutch Brake Installation

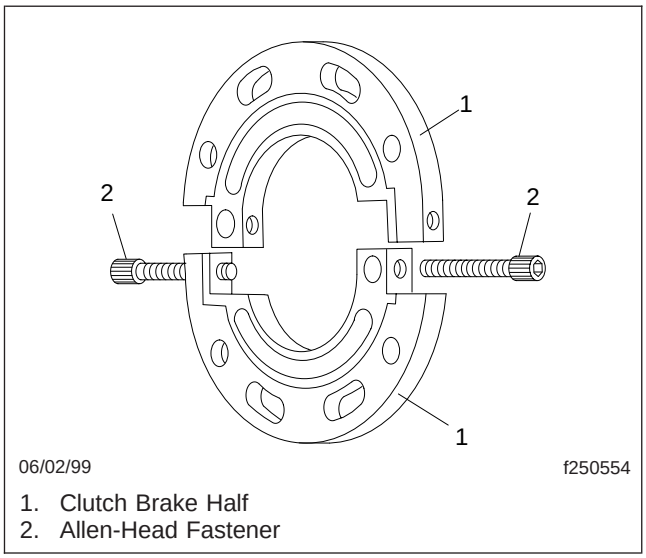
24. Install the fuel tank compression brace. See **Group 47** in this manual for instructions.
25. Install the auxiliary air tank, if so equipped.
26. Install the transmission oil cooler.
27. Install the shift tower on the top of the transmission. See **Group 26** in this manual for instructions.
28. Connect the clutch rod to the clutch release lever. See **Section 25.02** in this group for instructions.
29. Connect the driveline at the rear of the transmission. See **Group 41** in this manual for instructions.
30. Connect the midship bearing. See **Group 41** in this manual for instructions.
31. Ensure that the transmission is out of gear and adjust the clutch. See **Group 25** in this manual for instructions.
32. Connect the batteries.
33. Lower the hood and remove the chocks from the tires.
34. Test drive the vehicle and ensure that the clutch brake and clutch operate properly.

Replacement of a One-Piece Clutch Brake with a Two-Piece Clutch Brake

Replacement

1. Shut down the engine, set the parking brake, and chock the tires.
2. Tilt the hood.
3. Remove the four fasteners and the clutch inspection cover. See **Fig. 1**.



1. Inspection Cover

Fig. 1, Clutch Inspection Cover

⚠ WARNING

Wear safety goggles when cutting off the old clutch brake. If any of the metal parts were to chip, flying pieces of metal could cause eye injury.

4. Using an air chisel, carefully cut off the old clutch brake.
5. Check the orientation and fit of the new two-piece clutch brake halves.
6. Place one half of the new two-piece clutch brake onto the input shaft and rotate it to the top side of the shaft. See **Fig. 2**.
7. Align the lower half with the upper half at the connecting points.
8. Hold both halves together and start the fasteners on both sides.
9. Align the fasteners with the grooves on the input shaft.

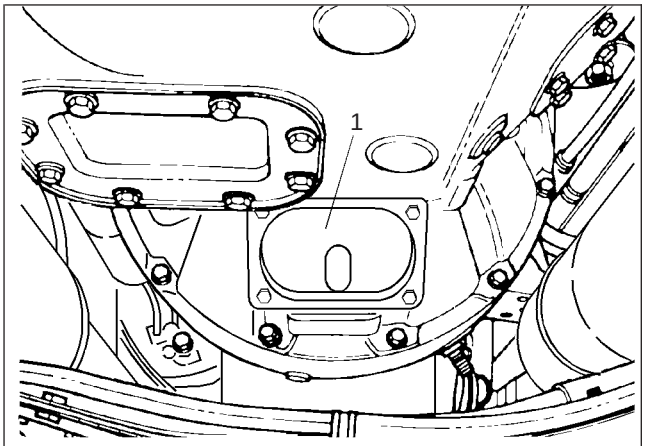
NOTE: Other types of two-piece clutch brakes use roll pins for fasteners.

⚠ WARNING



Wear safety goggles when driving in roll pins. If any of the metal parts were to chip, flying pieces of metal could cause eye injury.

11. If the replacement clutch brake uses roll pins, carefully drive in the roll pins equally with a punch and mallet, securing the halves to each other.
12. Install the clutch inspection cover and the four fasteners. Tighten the fasteners securely.
13. Adjust the clutch. See **Group 25** in this manual for instructions.
14. Lower the hood and remove the chocks from the tires.
15. Test drive the vehicle and ensure that the clutch brake and clutch operate properly.

NOTE: Some types of two-piece clutch brakes use roll pins for fasteners.

4. Rotate the input shaft until the Allen-head fasteners or roll pins securing the two clutch brake halves are visible.
5. If the old clutch brake uses Allen-head fasteners, remove the fasteners and remove the two brake halves from the input shaft.

⚠ WARNING

Wear safety goggles when driving out roll pins. If any of the metal parts were to chip, flying pieces of metal could cause eye injury.

6. If the old clutch brake uses roll pins, carefully drive out the pins with a punch and mallet and remove the two brake halves from the input shaft.
7. Check the orientation and fit of the new two-piece clutch brake halves.
8. Place one half of the new two-piece clutch brake onto the input shaft and rotate it to the top side of the shaft. See **Fig. 2**.

General Information

The Sachs hydraulic clutch is a 14.5-inch (365 mm) push-type clutch that is used with the MBT520 and MBT660 medium-duty transmissions. All Mercedes-Benz transmission models require a hydraulic clutch system. For more information on the Mercedes-Benz transmissions, see **Section 26.00**.

The hydraulic clutch control system consists of a fluid reservoir, a master cylinder, various connectors and hoses, and a slave cylinder. See **Fig. 1**.

2. Reservoir Cap
3. Reservoir Bracket
4. Clutch Support Plate
5. Master Cylinder
6. Hydraulic Hose
7. Slave Cylinder
8. Elbow Connector
9. Reservoir Hose
10. Jam Nut

Fig. 1, Clutch Components

Principles of Operation

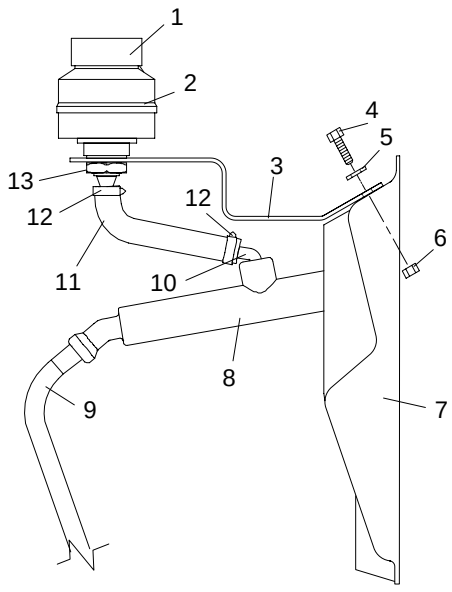
When the clutch pedal is pressed, the fluid in the master cylinder is forced through a hydraulic line to the slave cylinder. The fluid pressure moves the slave cylinder piston, pushing the plunger rod and clutch release lever, which disengages the clutch.

The hydraulic system is self-adjusting. To bleed the system, see **Subject 140**.

Reservoir Removal and Installation

Removal

⚠ WARNING



Clutch hydraulic fluid (DOT 3 brake fluid) is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling clutch hydraulic fluid or bleeding hydraulic lines. If you get clutch hydraulic fluid on your skin, wash it off as soon as possible.

1. Shut down the engine.
2. Apply the parking brakes, chock the front and rear tires, and open the hood.
3. Using a flat-head screwdriver, remove the quick-disconnect clamp that attaches the hydraulic hose to the slave cylinder. Retain the clamp for later installation.

⚠ CAUTION

Do not spill clutch hydraulic fluid (DOT 3 brake fluid) on the cab paint. Clean it off immediately if any is spilled. DOT 3 brake fluid can damage paint.

4. Drain the hydraulic fluid from the entire system.
   - 4.1 Using a drain pan or other suitable container, collect the fluid that drains from the reservoir, not more than 0.3 quarts (0.3 liters).
   - 4.2 Allow the open end of the drain hose to remain over the drain pan.
   - 4.3 Press down on the pedal several times, until no more fluid drains from the reservoir.
   - 4.4 Cover the hose to avoid contamination of the hydraulic fluid.
5. Using a flat-head screwdriver, remove the hose clamp that attaches the reservoir hose to the master cylinder. Retain the clamp for later installation.
6. Remove the two 5/16–24 mounting bolts, washers, and locknuts with nylon inserts attaching the reservoir bracket to the clutch support plate (pie pan). See **Fig. 1**.

7. Remove the reservoir and reservoir bracket from the vehicle.
8. Clamp the reservoir bracket in a vise.
9. Loosen the M18 jam nut attaching the reservoir to the reservoir bracket. Remove the reservoir from the bracket.

Installation

1. Position the reservoir on the bracket, with the bracket still in the vise. Tighten the jam nut 147 lbf·ft (199 N·m).

Reservoir Removal and Installation

2. Mount the reservoir bracket on the flange of the clutch support plate, as removed.
3. With the bracket mounted on the vehicle, remove the vise holding the reservoir and bracket.
4. Install the two bracket mounting bolts and tighten them 13 lbf·ft (18 N·m).
5. Connect the reservoir hose to the master cylinder. Install the clamp, as removed.

⚠ WARNING

Use only approved clutch hydraulic fluid (DOT 3 brake fluid). Do not mix different types of brake fluid. The wrong fluid will damage the rubber parts of the system, causing loss of clutch function and the risk of serious personal injury.

6. Fill the reservoir with approved DOT 3 hydraulic brake fluid. Flush and bleed the system according to the procedures in **Subject 140**.

NOTE: Make sure clean fluid comes out while bleeding.

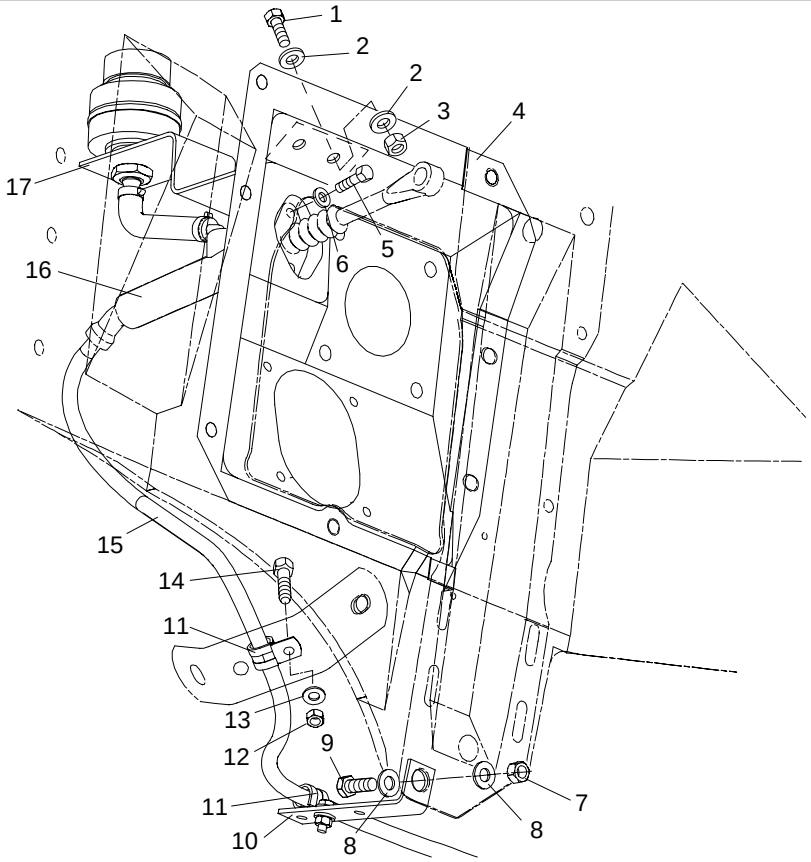
7. Check the function of the clutch actuation system according to the procedures under the heading "Clutch Actuation System Check" in **Troubleshooting, 300**.

Replacement

WARNING

Clutch hydraulic fluid (DOT 3 brake fluid) is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling clutch hydraulic fluid or bleeding hydraulic lines. If you get clutch hydraulic fluid on your skin, wash it off as soon as possible.

1. Drain the hydraulic fluid from the entire system. For detailed procedures, see **Subject 100**.
2. Remove the reservoir, following the procedures in **Subject 100**.



CAUTION

Do not spill clutch hydraulic fluid (DOT 3 brake fluid) on the cab paint. Clean it off immediately if any is spilled. DOT 3 brake fluid can damage paint.

3. Using a flat-head screwdriver, remove the quick-disconnect clamp that attaches the hydraulic hose to the hose connector on the master cylinder. Retain the clamp for later installation. Remove the hose connector from the opening in the end of the master cylinder. See **Fig. 1**.
4. Remove the two M6 master cylinder capscrews and washers from the holes in the clutch support plate.
5. Slide the clevis on the master cylinder off the clevis pin on the clutch pedal.
6. Remove the old master cylinder from the clutch support plate.
7. Attach the clevis on the new master cylinder to the clevis pin on the clutch pedal.
8. Fasten the new master cylinder to the clutch support plate. Tighten the capscrews 60 lbf·in (680 N·cm).
9. Attach the hose connector and hydraulic hose to the opening in the end of the master cylinder.
10. Moisten the tip of the elbow connector in DOT 3 brake fluid. Insert the moistened tip of the elbow into the opening in the top of the master cylinder.
11. Install the reservoir hose.
12. Install the reservoir, following the procedures in **Subject 100**.

NOTE: Make sure clean fluid comes out while bleeding.

WARNING

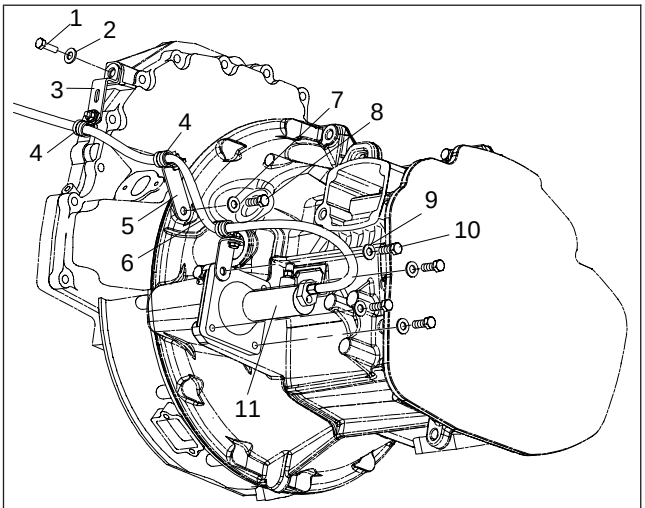
Clutch hydraulic fluid (DOT 3 brake fluid) is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling clutch hydraulic fluid or bleeding hydraulic lines. If you get clutch hydraulic fluid on your skin, wash it off as soon as possible.

1. Shut down the engine.
2. Apply the parking brakes, chock the front and rear tires, and open the hood.
3. Using a flat-tip screwdriver, remove the quick-disconnect clamp that attaches the hydraulic hose to the slave cylinder. Retain the clamp for later installation.

WARNING

Never take the slave cylinder apart while it is connected to the hydraulic hose. If the slave cylinder is removed from the bell housing, the metal pushrod inside the cylinder can be released at high speed, causing component damage and serious personal injury.

4. Drain the hydraulic fluid from the entire system. See **Fig. 1**. For detailed procedures, see **Subject 100**.
5. Loosen the four M8 slave cylinder mounting capscrews attaching the slave cylinder to the bell housing.
6. After bracing the slave cylinder so that it does not fall, remove the four slave cylinder mounting capscrews. Retain the capscrews for later installation.



IMPORTANT: Be sure to mount the slave cylinder with the bleed valve on top, as shown in **Fig. 1**.

7. Mount the slave cylinder on the bell housing, as removed.
   - 7.1 Make sure that the pushrod is attached to the clutch fork and inserted into the pushrod bore in the slave cylinder.
   - 7.2 Push the slave cylinder against the bell housing to compress the internal spring.
8. Install the four slave cylinder mounting capscrews and tighten them 13 lbf·ft (18 N·m).
9. Connect the hydraulic hose to the slave cylinder. Install the clamp, as removed.

WARNING

Use only approved clutch hydraulic fluid (DOT 3 brake fluid). Do not mix different types of brake fluid. The wrong fluid will damage the rubber parts of the system, causing loss of clutch function and the risk of serious personal injury.

10. Fill the reservoir with approved DOT 3 hydraulic brake fluid. Flush and bleed the system according to the procedures in **Subject 140**.

Tool	**Description**	**Manufacturer**	**Part Number**
 f580335	Clutch Centering Pin	Kent-Moore	J-45719

Table 1, Special Tool

NOTE: To check tool availability, and to order tools, call SPX Kent-Moore at 1-800-328-6657.

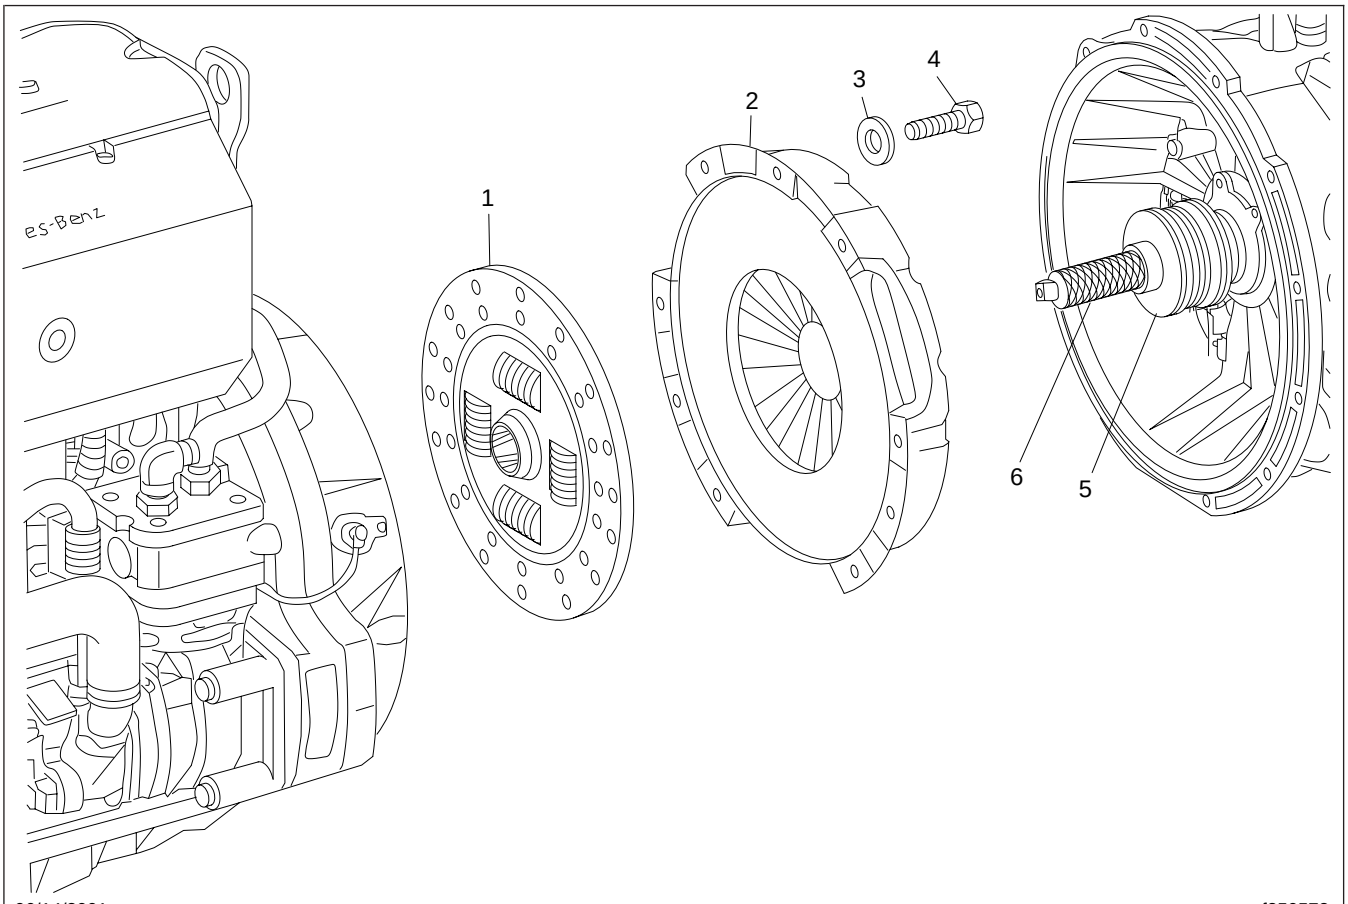
Removal

1. Remove the transmission from the engine. For instructions, see **Section 26.00**, Subject 110.
2. Remove the cover assembly. See **Fig. 1**. Loosen the capscrews in a star pattern, taking care not to loosen any one capscrew too much before loosening the next one.

IMPORTANT: The clutch disc is under tension. If one capscrew is loosened too much, it places too much tension on the cover assembly.

3. Remove the clutch disc assembly.

Installation



1. Grease the splines of the input shaft and the hub of the disc assembly. Remove any excess grease.

NOTE: Do not grease the guide of the release bearing. The release bearing is made of plastic with an embedded grease.

IMPORTANT: Don't remove the centering pin until the clutch is completely installed.

2. Using the centering pin (**Table 1**), center the disc assembly on the input shaft. See **Fig. 2**.
3. Install the cover assembly.
   - 3.1 Tighten the capscrews progressively in a star pattern. Do not put more tension on one side of the clutch than on the other.
   - 3.2 Tighten the eight clutch capscrews to a final torque of 37 lbf·ft (50 N·m).
4. When all bolts have been tightened, remove the centering pin.
5. Install the transmission on the engine. For instructions, see **Section 26.00**, Subject 110.

NOTE: Use pressurized bleeding to flush a unit for service. Use manual bleeding if a problem arises during the pressurized bleeding process.

Filling and Bleeding Using a Pressurized Bleeding Unit

1. Apply the parking brake and chock the tires.

⚠ WARNING

Clutch hydraulic fluid (DOT 3 brake fluid) is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling clutch hydraulic fluid or bleeding hydraulic lines. If you get clutch hydraulic fluid on your skin, wash it off as soon as possible.

2. Prepare the pressure bleeding equipment according to the manufacturer's instructions. Use DOT 3 brake fluid. Pressurize the bleeder unit to 15 psi (103 kPa).

⚠ WARNING

Use only approved clutch hydraulic fluid (DOT 3 brake fluid). Do not mix different types of brake fluid. The wrong fluid will damage the rubber parts of the system, causing loss of clutch function and the risk of serious personal injury.

3. Remove the reservoir lid and install the pressure bleed adaptor on the reservoir. See **Fig. 1**.
4. Remove the cap from the bleed valve. Install a transparent drain hose on the bleed valve of the slave cylinder. See **Fig. 2**.

IMPORTANT: The slave cylinder may not be mounted in a horizontal position. If it isn't, remove the slave cylinder and hold it in a horizontal position to completely purge all air from the cylinder.

5. Pressurize the reservoir, filling the system. Open the bleed valve on the bleed tank.

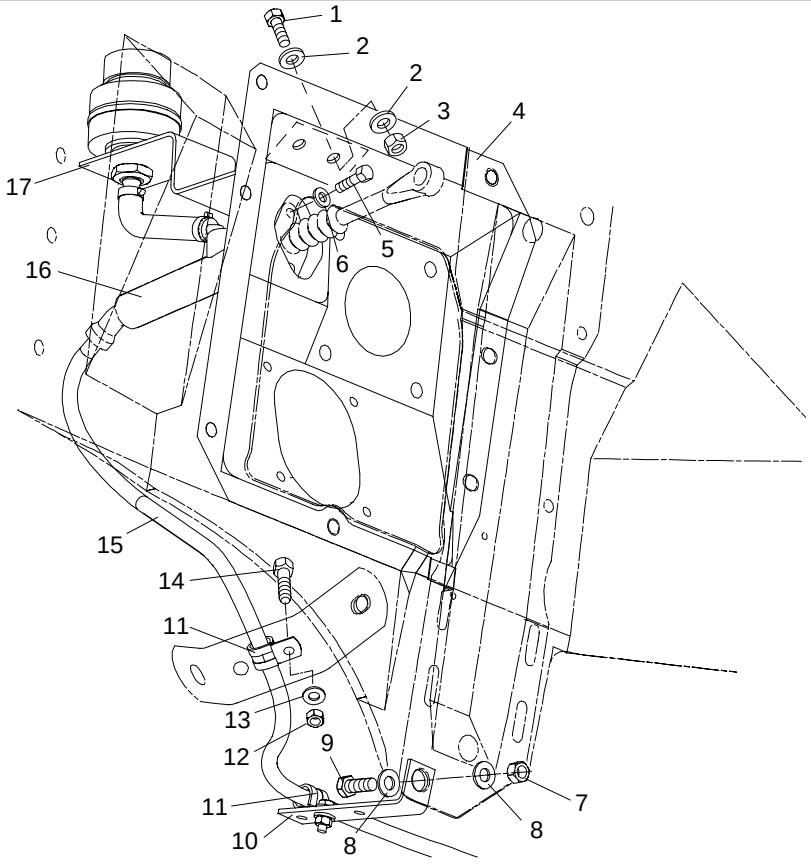
NOTE: A pressure bleeder hose (J-29532) and a bleeder adaptor (J-35798) for the fluid reservoir are available through SPX Kent-Moore Tools and may be used to complete the following procedure. To order these parts, call Kent-Moore at 1-800-328-6657.

6. Press the clutch pedal all the way down and keep it down.
7. Open the slave cylinder bleed valve. Observe the flow of clutch hydraulic fluid through the drain hose. When no bubbles appear in the fluid, close the valve on the slave cylinder. Release the clutch pedal and then close the valve at the bleeder unit.

NOTE: Make sure clean fluid comes out while bleeding.

8. Disconnect the bleeder unit, and install the cap on the slave cylinder bleed valve. Tighten the bleed screw 65 lbf·in (740 N·cm).
9. Check the fluid level in the reservoir. If necessary, add or remove DOT 3 brake fluid to bring the fluid level to the MAX line. Install the reservoir cap.
10. Depress the clutch pedal a few times. There should be resistance over the full pedal stroke.
11. Check the entire system for leaks. Tighten connections if necessary. Check the fluid level in the reservoir again.
12. Remove the chocks from the tires.

Manual Filling and Bleeding



1. Apply the parking brake and chock the tires.
2. Raise the hood.

⚠ WARNING

Clutch hydraulic fluid (DOT 3 brake fluid) is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling clutch hydraulic fluid or bleeding hydraulic lines. If you get clutch hydraulic fluid on your skin, wash it off as soon as possible.

3. Fill the reservoir with DOT 3 brake fluid. Check periodically throughout the bleed process to make sure that the reservoir remains full.

NOTE: The following procedure requires two persons, one to operate the bleed valve and the other to press on the clutch pedal.

8. Bleed the air from the hydraulic clutch system.
   - 8.1 Press the clutch pedal down by hand, using a slow stroke. Stop before the pedal reaches the floor.
   - 8.2 Open the bleed valve while the other person is pressing down on the pedal.
   - 8.3 Close the bleed valve quickly, before the pedal stroke has ended.
   - 8.4 Slowly return the pedal to the top of its travel.
   - 8.5 With the bleed valve closed, pump the pedal several times slowly.
   - 8.6 Observe the clean fluid in the drain hose for air bubbles. Repeat this procedure as often as necessary, until no bubbles appear in the fluid.

   NOTE: Make sure clean fluid comes out while bleeding.
9. Check the function of the clutch actuation system according to the procedures under the heading "Clutch Actuation System Check" in **Troubleshooting, 300**.
10. If the pedal still feels soft or spongy, there may be air in the system.
    - 10.1 Press the pedal halfway down, then quickly jerk the pedal back to the top of its travel. Repeat a few times.
    - 10.2 Repeat the bleed procedure above until the pedal feels firm and responsive.
11. Check the fluid level in the reservoir and add fluid if necessary.
12. Tighten the bleed screw 65 lbf·in (740 N·cm).
13. Remove the chocks from the tires.

Replacement

IMPORTANT: Position the release bearing with the stop pin located at either the top or the bottom.

5. Install the bearing onto the release yoke.

NOTE: Do not grease the guide of the release bearing. The release bearing is made of plastic with an embedded grease.

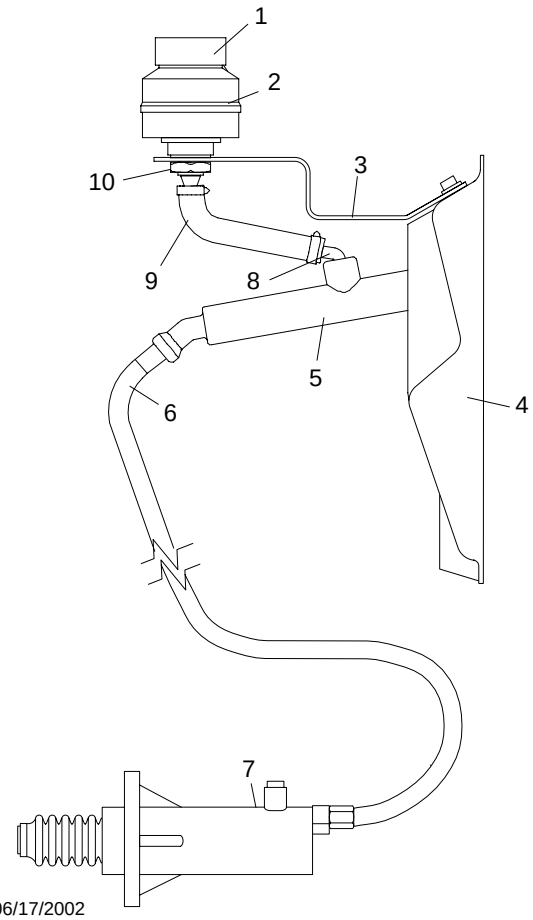
6. Install the transmission on the engine. For instructions, see **Section 26.00**, Subject 110.

Hydraulic Hose Replacement

Replacement

1. Shut down the engine.
2. Apply the parking brakes, chock the front and rear tires, and open the hood.

⚠ WARNING



Clutch hydraulic fluid (DOT 3 brake fluid) is hazardous. It may be a skin irritant and can cause blindness if it gets in your eyes. Always wear safety glasses when handling clutch hydraulic fluid or bleeding hydraulic lines. If you get clutch hydraulic fluid on your skin, wash it off as soon as possible.

3. Using a flat-head screwdriver, remove the quick-disconnect clamp that attaches the hydraulic hose to the slave cylinder. Retain the clamp for later installation. See **Fig. 1**.
4. Drain the hydraulic fluid from the entire system. For detailed procedures, see **Subject 100**.
5. Using a flat-tip screwdriver, remove the quick-disconnect clamp that attaches the old hydraulic hose to the hose connector on the master cylinder. Retain the clamp for later installation.
6. Connect the new hydraulic hose to the slave cylinder and the hose connector. Install the clamps, as removed.

⚠ WARNING

Use only approved clutch hydraulic fluid (DOT 3 brake fluid). Do not mix different types of brake fluid. The wrong fluid will damage the rubber parts of the system, causing loss of clutch function and the risk of serious personal injury.

7. Fill the reservoir with approved DOT 3 hydraulic brake fluid and bleed the system according to the procedures in **Subject 140**.
8. Check the function of the clutch actuation system according to the procedures under the heading "Clutch Actuation System Check" in **Trouble-shooting, 300**.

3. Remove the switch assembly from the pedal stop bracket.
4. Mount the new switch assembly on the pedal stop bracket and tighten the 15/32–32 hexnuts.
5. Connect the clutch control electrical connector, and check the function of the clutch actuation system according to the procedures under the heading "Clutch Switch Check" in **Troubleshooting, 300**.

IMPORTANT: If any problems are noticed during these diagnostic checks, take corrective action using the information under the heading "Troubleshooting Tables."

When repairing any components of the hydraulic clutch system, bleed the clutch before restoring the vehicle to service. This will prevent air from remaining in the system.

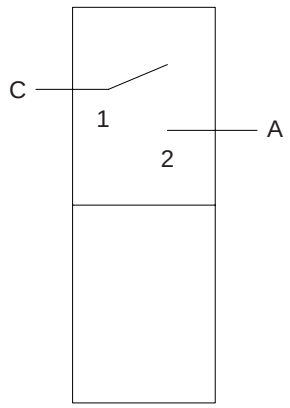
Clutch Leak Check

⚠ WARNING

Air in the clutch hydraulic system can prevent the gears from engaging properly, and cause a serious accident resulting in personal injury.

1. Shut down the engine.
2. Apply the parking brakes, chock the front and rear tires, and open the hood.

NOTE: This step requires two persons.



3. Have one person press down on the clutch pedal while the other person checks the clutch hydraulic system for signs of leakage.

Clutch Actuation System Check

1. Shut down the engine.
2. Apply the parking brakes, chock the front and rear tires, and open the hood.
3. Do the "Clutch Leak Check."
4. Press the pedal all the way to the floor several times and check the action of the pedal. The pedal should be easy to operate and return without difficulty to its original position. It should feel firm and responsive, not soft or spongy.
5. With both the brake and the clutch pedals pressed down, start the engine.
   - 5.1 If the engine does not start, take corrective action using the information under the heading "Troubleshooting Tables."
   - 5.2 If the clutch does not disengage properly, the engine will start and then stall. Take corrective action using the information under the heading "Troubleshooting Tables."
6. Remove the chocks from the front and rear tires.
7. Test drive the vehicle.
   - 7.1 Check for proper clutch functioning while shifting gears.
   - 7.2 With cruise control on, press the clutch pedal down. If cruise control does not deactivate, take corrective action using the information under the heading "Troubleshooting Tables."

Clutch Switch Check

1. Shut down the engine.
2. Apply the parking brakes, chock the front and rear tires, and open the hood.
3. Disconnect the clutch control switch connector located under the dash just above the clutch pedal.
4. Do a continuity check between pin A and pin C of the connector. See **Fig. 1**.

03/24/2003 f250590a

The switch is normally open, but held closed.

NOTE: Pin "B" is not used.

1. Open Position 2. Closed Position

Fig. 1, Clutch Switch Positions

Troubleshooting

4.1 With the pedal not pressed, the circuit should be closed and resistance should be measured.

4.2 With the pedal pressed down about 4 inches (10 cm), the switch should open and no resistance should be measured.

Troubleshooting Tables

Problem–The Clutch Pedal Feels Soft or Spongy

Problem–The Clutch Pedal Feels Soft or Spongy	
Possible Cause	**Remedy**
There is air in the hydraulic system.	Bleed the hydraulic system. See **Subject 140** for instructions.
There is a hydraulic fluid leak.	Check the fluid level. Check for leakage and replace any components found to be leaking. Fill and bleed the hydraulic system.

Problem–The Clutch Pedal Is Unusually Hard To Operate

Problem–The Clutch Pedal Is Unusually Hard To Operate	
Possible Cause	**Remedy**
The clutch is damaged.	Check clutch function and make any necessary repairs. See the instructions under the heading "Clutch Actuation System Check."
The assist spring is broken.	Replace the clutch pedal.
The pedal assembly is worn or jammed.	Replace the clutch pedal.
The master cylinder has components that are jammed or broken.	Replace the master cylinder. See **Subject 110** for instructions.

Problem–The Clutch Does Not Completely Disengage; Shifting Is Difficult

Problem–The Clutch Does Not Completely Disengage; Shifting Is Difficult	
Possible Cause	**Remedy**
The clutch is worn.	Replace the clutch. See **Subject 130** for instructions.
There is air in the hydraulic system.	Bleed the hydraulic system. See **Subject 140** for instructions.
There is a hydraulic fluid leak.	Check the fluid level. Check for leakage and replace any components found to be leaking. Fill and bleed the hydraulic system.
The slave cylinder is defective.	Replace the slave cylinder. See **Subject 120** for instructions.
The slave cylinder is loose.	Tighten the M8 slave cylinder mounting capscrews 12 lbf·ft (16 N·m).
The wrong type of brake fluid was used.	Replace the complete system. Fill only with approved DOT 3 brake fluid.

Problem–The Clutch Switch Does Not Activate

Problem–The Clutch Switch Does Not Activate	
Possible Cause	**Remedy**
The switch contacts are damaged or worn.	Replace the clutch switch assembly. See **Subject 170** for instructions.
The switch cam is damaged.	Replace the clutch pedal.

WARNING

Do not attempt to disassemble the preloaded assist spring. Sudden release of the assist spring could cause property damage and serious personal injury.

Problem–The Clutch Pedal Does Not Return

Problem–The Clutch Pedal Does Not Return	
Possible Cause	**Remedy**
The assist spring is broken.	Replace the clutch pedal.

Problem–Cruise Control or Engine Brake Does Not Deactivate When the Clutch Pedal Is Pressed Down

Problem–Cruise Control or Engine Brake Does Not Deactivate When the Clutch Pedal Is Pressed Down	
Possible Cause	**Remedy**
The clutch switch is damaged.	Check switch function and make any necessary repairs. See the instructions under the heading "Clutch Switch Check."
There has been an external electrical failure.	See **Section 54.01** for instructions.

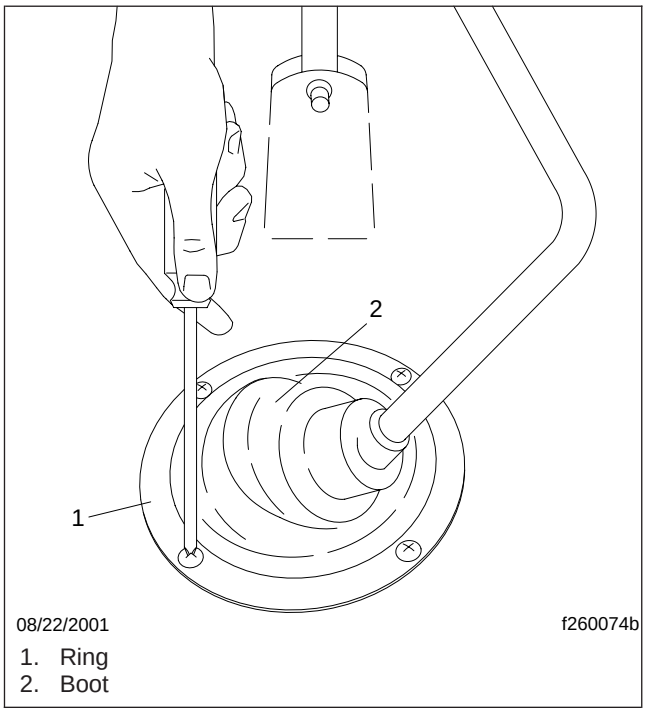
Eaton® Fuller® and Meritor™ Transmission Removal and Installation

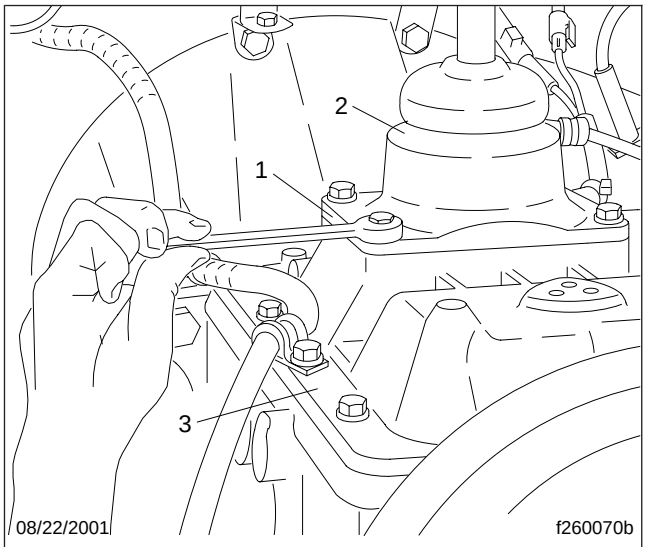
Removal



1. Park the vehicle on a level surface. Shut down the engine, set the parking brake, and chock the tires.

⚠ WARNING

Wear safety goggles when draining the air system or loosening an air line because dirt or sludge could fly out at high speeds. Don't direct the airstreams at anyone. Don't disconnect pressurized hoses, since they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.



2. If applicable, drain the vehicle system at the air reservoirs.
3. If applicable, disconnect the transmission air supply and signal lines. Label the lines for reconnection.
4. Remove the shift lever from the transmission.
   - 4.1 Place the transmission in high gear.
   - 4.2 Remove the four screws from the retaining ring around the shift lever boot. See **Fig. 1**. Remove the ring and the boot.
   - 4.3 Remove the four capscrews from the plate holding the shift tower to the top cover. See **Fig. 2**.
   - 4.4 Lift up on the shift lever assembly and remove it and the air signal lines (if applicable). See **Fig. 3**.
   - 4.5 Cover the opening in the shift tower to prevent entry of dirt.
5. Disconnect the driveshaft from the transmission.
   - 5.1 If the vehicle is equipped with a driveline parking brake, remove the nuts on the brake flange. See **Fig. 4**.

     If the vehicle is not equipped with a driveline parking brake, remove the transmission yoke U-joint end caps.
   - 5.2 Loosen the bolts holding the midship bearing bracket so that the driveshaft can slide to the rear. See **Fig. 5**.

5.3 Slide the front of the driveshaft off of the driveline brake flange or out of the transmission output yoke.

NOTE: It may be necessary to remove the bolts from the midship bearing bracket so that the driveshaft can be moved far enough back.

5.4 Support the disconnected driveshaft or tie it out of the way.

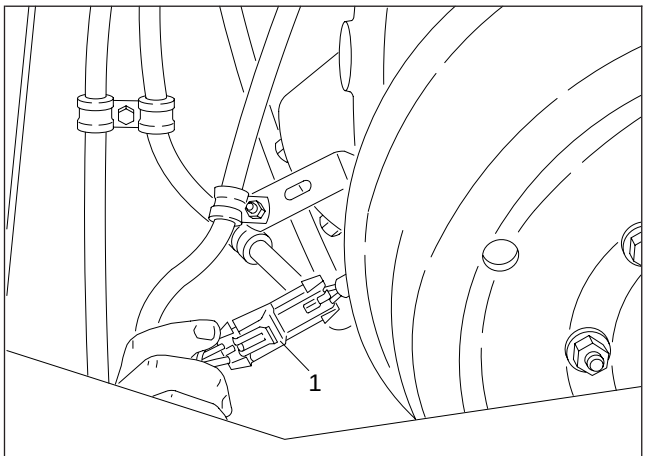
6.3 Loosen the capscrews holding the speedometer sensor wiring harness to the transmission. See **Fig. 8**. Move the harness out of the way.

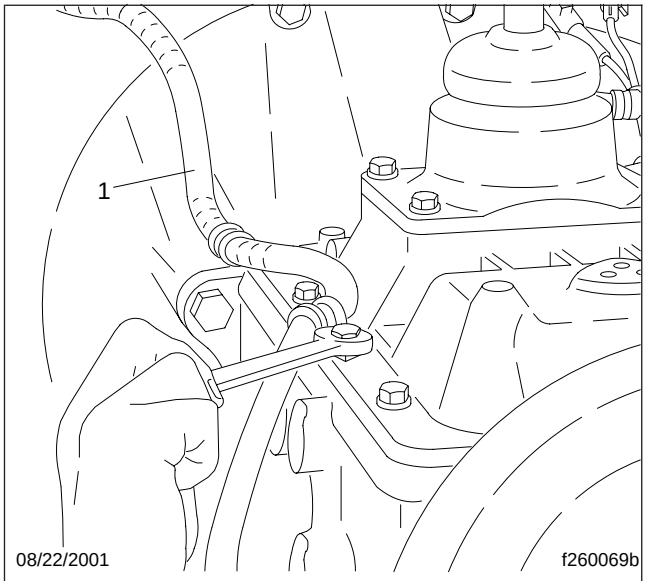
7. If the vehicle is equipped with a driveline parking brake, remove the cotter pin holding the clevis to the driveline brake lever. See **Fig. 9**. Remove the two bolts holding the driveline brake cable bracket to the transmission, then remove the bracket.



8. On vehicles with a manual clutch, disconnect the clutch linkage rod from the clutch release lever. Rotate the clutch release yoke so it will clear the clutch release bearing.

9. On vehicles with a hydraulic clutch, disconnect and move the clutch slave cylinder.

9.1 Remove the cotter pin holding the slave cylinder clevis to the clutch release lever. See **Fig. 10**.



9.2 Remove the two capscrews holding the clutch slave cylinder bracket to the transmission. See **Fig. 11**. Remove the slave cylinder, and support it.

10. If the vehicle is equipped with optional dual fuel tanks, remove the fuel crossover line and the support between the tanks.

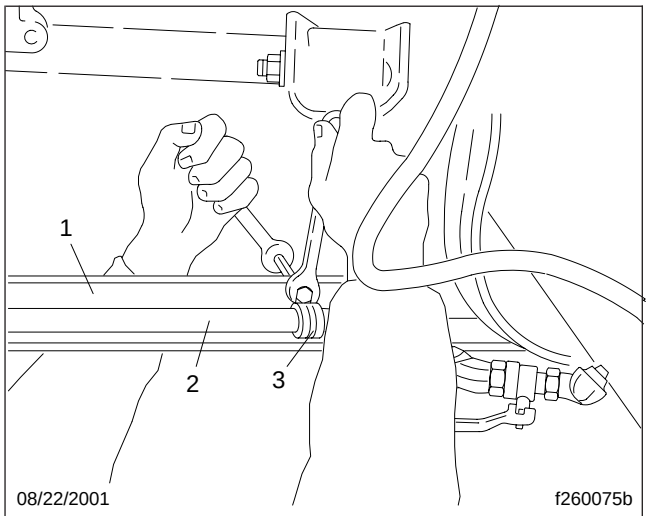
11.2 Adjust the support plates to cradle the transmission.

11.3 Using a chain, secure the transmission to the jack.

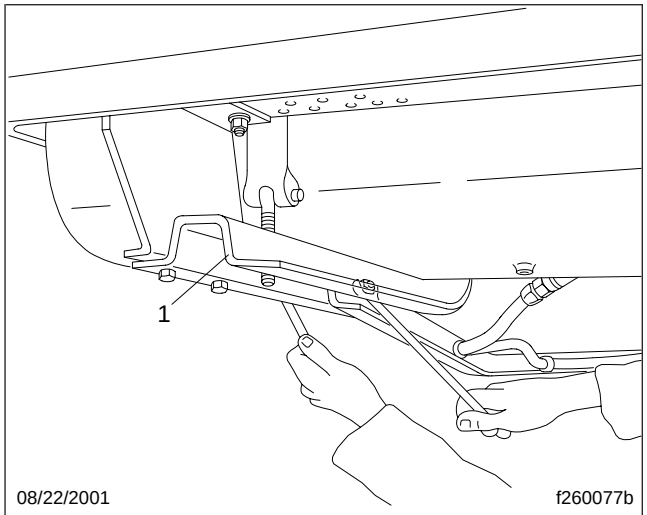
12. Remove the transmission.



12.1 Remove the capscrews that hold the bell housing to the flywheel housing, and remove the bell housing with the transmission.

12.2 Pull the transmission and jack straight back, until the transmission input shaft is clear of the clutch.

12.3 If required, lower the jack supporting the transmission. Raise the front of the vehicle and slide the transmission and jack out from under the vehicle.



⚠ CAUTION

Do not allow the rear of the transmission to drop, and do not let the transmission hang unsupported in the splined hubs of the clutch disc(s). Keep the flange of the bell housing parallel (all

Installation

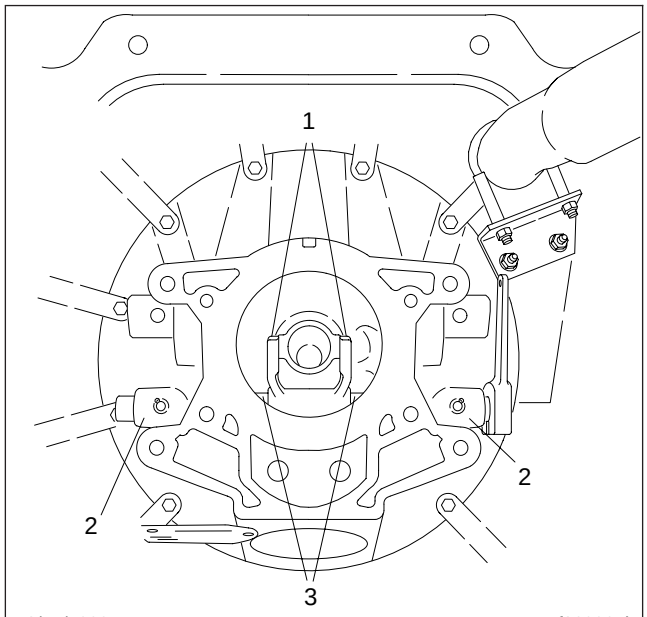
IMPORTANT: Before installing the transmission, ensure that the rear tires are securely chocked and that the transmission is securely chained to the transmission jack support plates.

Eaton® Fuller® and Meritor™ Transmission Removal and Installation

1. Driver-Side Fuel Tank
2. Crossover Line

Fig. 16, Fuel Crossover Line (at driver-side fuel tank)

1. If the vehicle is equipped with a clutch brake, install it on the transmission input shaft. Slide it tightly against the input shaft bearing cap.



NOTE: When installing a torque-limiting clutch brake on an Eaton Fuller transmission, install the smaller face toward the transmission.

2. Check for wear on the fingers of the clutch release yoke, release shaft, and the release shaft bushings. Replace any worn parts, as needed. See **Fig. 17**.

3. Install the transmission.

   3.1 Shift the transmission into gear, so that the transmission input shaft can be rotated during assembly to align it with the clutch driven-disc hub splines.

   3.2 Align the jack and the transmission behind the engine. Raise the transmission, and adjust the angle of the jack until the bell housing and the transmission input flange (single-countershaft transmissions) or the flywheel housing flange and the bell housing flange (twin-countershaft transmissions) are parallel.

1. Release Shaft Bushing
2. Clutch Release Yoke Finger
3. Clutch Release Shaft

Fig. 17, Clutch Release Mechanism

   3.3 Push the transmission and jack straight forward making sure that the flanges remain parallel.

   NOTE: On twin-countershaft transmissions, be sure that the release-bearing yoke clears the bearing, and is rotated over the wear pads as the transmission is moved forward. See **Fig. 18**. Align the splines by turning the transmission output shaft.

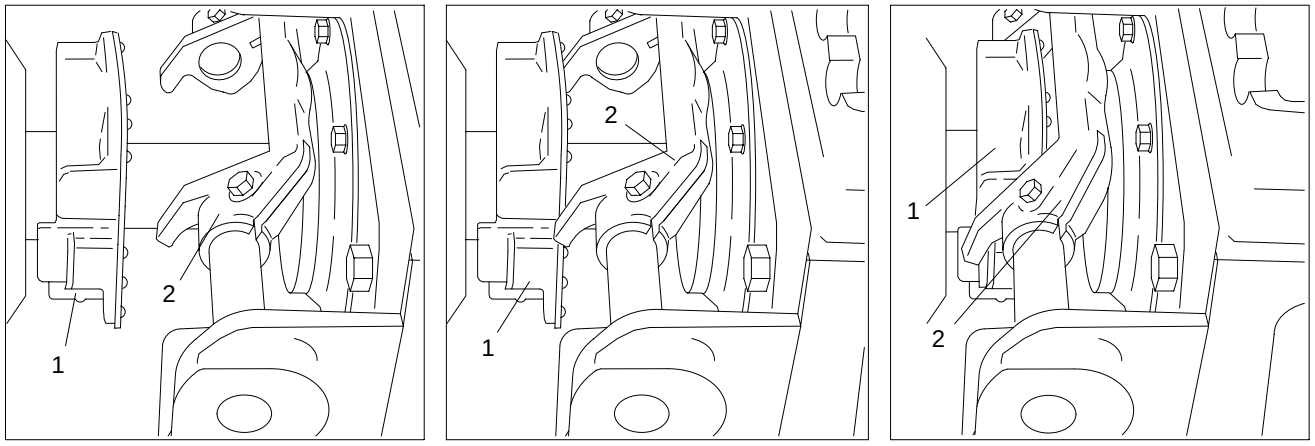
   3.4 Reach through the access hole in the bottom of the bell housing and hold the release bearing in place by hand. See **Fig. 19**.

   3.5 Slide the splined input shaft into the clutch driven disc.

⚠ CAUTION

Use care to avoid springing the driven disc(s) when the transmission is being installed. Do not force the transmission into the bell housing if it does not enter freely. Do not let the transmission

drop or hang unsupported in the driven disc(s). These practices can damage the clutch assembly.



3.6 Install the capscrews holding the bell housing to the flywheel housing and tighten 34 lbf·ft (46 N·m).

3.7 Remove the chain securing the transmission to the jack, then remove the jack.

5. On vehicles with a manual clutch, connect the clutch rod to the clutch release lever, as removed.

6. On vehicles with a hydraulic clutch, install and connect the clutch slave cylinder.

6.1 Install the two capscrews holding the clutch slave cylinder bracket to the transmission and tighten 40 lbf·ft (54 N·m). See **Fig. 11**.

1. Release Bearing
2. Yoke

Fig. 18, Release Bearing and Yoke

4. If the vehicle is equipped with the optional dual fuel tanks, install the fuel crossover line and the support between the tanks.

4.1 Install the allen-head drain plug in the driver-side fuel tank. See **Fig. 15**. Tighten it finger tight; then, tighten it 1-1/2 turns more.

4.2 Install the fuel crossover line support and the mounting bolts and tighten 95 lbf·ft (129 N·m). See **Fig. 13**.

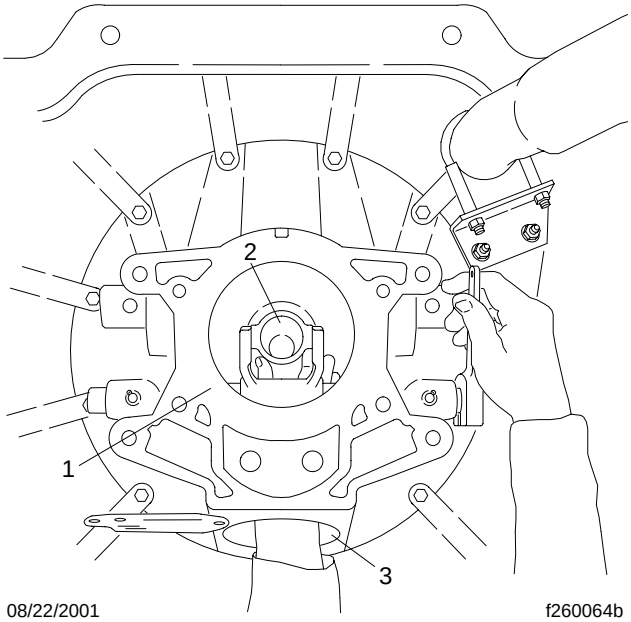
4.3 Connect the fuel crossover line to the driver-side fuel tank. See **Fig. 16**.

4.4 Open the fuel crossover line shutoff valve at the bottom of the passenger-side fuel tank. See **Fig. 14**.

4.5 Install the mounting clamps holding the fuel crossover line onto the support and tighten 40 lbf·ft (54 N·m). See **Fig. 12**.

6.2 Attach the slave cylinder clevis to the clutch release lever; then, insert and lock the cotter pin. See **Fig. 10**.

7. If the vehicle is equipped with a driveline parking brake, mount the driveline brake cable bracket to the transmission. Install the two bolts and tighten 100 lbf·ft (136 N·m). Attach the clevis to the brake lever; then, insert and lock the cotter pin. See **Fig. 9**.



8. Connect all electrical lines to the transmission.

8.1 Connect the back-up light harness connectors. See **Fig. 6**.

8.2 Connect the electrical harness to the speedometer sensor. See **Fig. 7**.

8.3 Install the speedometer sensor wiring harness. Install the capscrews attaching it to

the transmission and tighten 40 lbf·ft (54 N·m). See **Fig. 8**.

9. Connect the driveshaft.
   - 9.1 Slide the front of the driveshaft into the transmission output yoke or onto the driveline parking brake flange, if so equipped.
   - 9.2 On vehicles without a driveline parking brake, install the transmission yoke U-joint end caps and tighten 45 lbf·ft (61 N·m).

     On vehicles with a driveline parking brake, slide the driveshaft flange onto the studs in the parking brake.

     Install the nuts and tighten 40 lbf·ft (54 N·m).
   - 9.3 Install the capscrews and the nuts on the midship bearing bracket and tighten 95 lbf·ft (129 N·m).
10. Install the shift lever.
    - 10.1 Remove the covering from the opening in the shift tower.
    - 10.2 Install the shift lever and the plate. See **Fig. 3**.
    - 10.3 Install the four capscrews in the plate and tighten 40 lbf·ft (54 N·m). See **Fig. 2**.
    - 10.4 Install the rubber boot and the retaining ring. Install the four screws and tighten them 28 lbf·ft (38 N·m). See **Fig. 1**.
11. If applicable, connect the air signal and supply lines to the transmission.

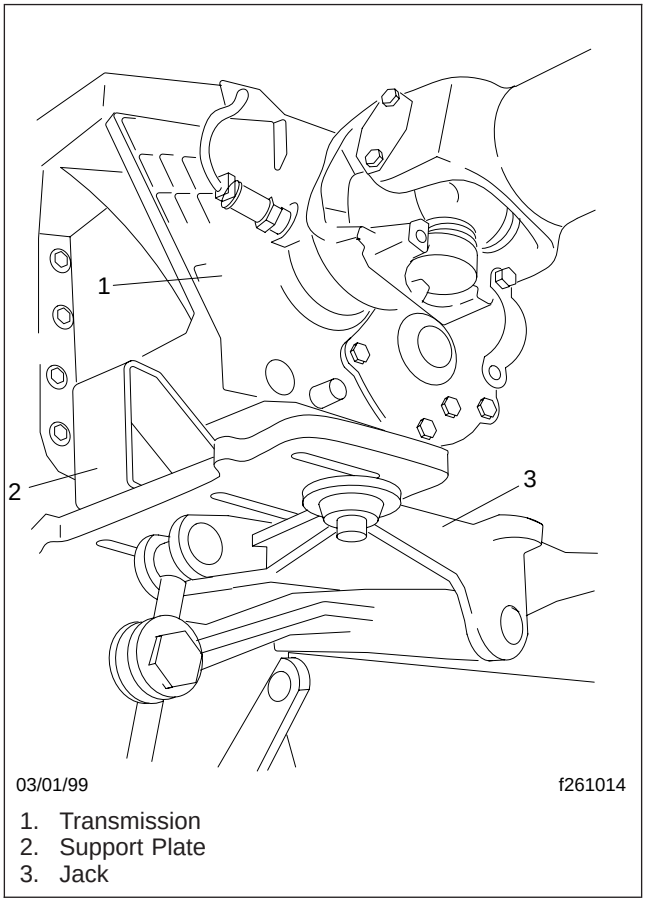
13.1 Position a transmission jack under the transmission and raise its support plates against the base of the transmission.

13.2 Adjust the support plates to cradle the transmission.

13.3 Using a chain, secure the transmission to the jack.

14. Remove the 16-mm capscrews attaching the timing case to the bell housing. See **Fig. 13**.

14.1 Remove each of the eleven capscrews.



14.2 After removing the transmission, insert the capscrews into the holes in the timing case for safekeeping.

⚠ CAUTION

Do not allow the rear of the transmission to drop, and do not allow the transmission to hang unsupported. Keep the flange of the bell housing parallel (all the way around) to the flange of the timing case, until the input shaft is clear of the flywheel. Taking these precautions will prevent damage to the input shaft, flywheel, and clutch.

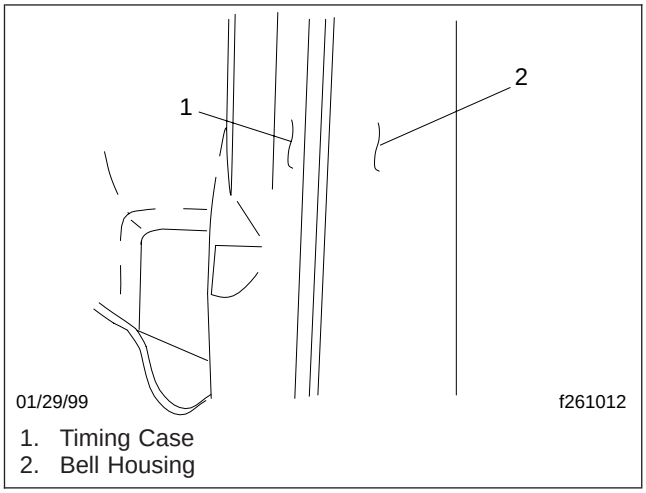
transmission. It might also be necessary to jack up the truck to get enough clearance to allow the transmission to pass.

IMPORTANT: Watch closely the clearance between the bell housing and the leaf spring.

15.3 Pull the transmission out through the space behind the front wheel.

Installation



IMPORTANT: Before installing the transmission, make sure that the rear tires are chocked and that the transmission is securely chained to the support plates on the transmission jack.

1. Install the transmission.

   1.1 Align the jack and the transmission behind the engine.

   1.2 Raise the transmission and adjust the angle of the jack until the bell housing and the timing case flange are parallel.

   1.3 Push the transmission and jack straight forward, making sure the flanges remain parallel and the mating seals align with each other without overlap as shown in **Fig. 15**.

1. Timing Case
2. Bell Housing

Fig. 15, Correct Seal Alignment

   1.4 Install the eleven M10 capscrews holding the bell housing to the timing case. Use a crossover pattern. Do a final tightening of the capscrews to 33 lbf·ft (45 N·m). See **Fig. 16**.

   1.5 While installing the bell housing-to-timing case capscrews, also install the battery cable bracket(s), as removed.

   1.6 Remove the chain securing the transmission to the jack; then remove the jack.

2. Install the exhaust clamp at the exhaust elbow, as removed.
3. If the vehicle is equipped with the optional dual fuel tanks, install the fuel cross-over line and its support between the tanks. Tighten the clamps 40 lbf·ft (54 N·m) and the mounting bolts 95 lbf·ft (129 N·m).
4. Install the PTO cover on the transmission. Tighten the M10 hardened mounting capscrews 43 lbf·ft (58 N·m). Bend back the tabs on the nut retainers.

5. Connect the driveshaft.
   - 5.1 Slide the front of the driveshaft into the transmission output yoke.
   - 5.2 Install the U-joint end caps on the output yoke. Tighten the nuts 50 lbf·ft (68 N·m) for 3/8-inch end cap bolts and 110 lbf·ft (149 N·m) for 1/2-inch end cap bolts.
   - 5.3 Install the bolts and nuts on the midship bearing bracket. Tighten the nuts 95 lbf·ft (129 N·m).
6. Install the fuel line standoff bracket and connect the fuel lines to the bracket.
7. Connect the electrical connectors. Connect the electrical cable to the speedometer sensor. Connect the electrical connector(s) on the shift lever.
8. Install the shift lever.
   - 8.1 Fit the shift lever over the cone of the transmission tower.
   - 8.2 Insert the hardened M10 x 20 shift lever mounting bolt and a thick washer into the hole in the shift lever. See **Fig. 6**.

   IMPORTANT: Don't forget to install the washer. Without the washer, the shift lever may loosen. The driver could lose control of the vehicle.
   - 8.3 Tighten the M10 bolt 50 lbf·ft (68 N·m).
   - 8.4 Install the rubber boot and the metal retaining ring. Install the four screws and tighten against the cab floor 28 lbf·ft (38 N·m). See **Fig. 5**.
9. Fasten the clutch slave cylinder to the mounting bracket and tighten the four M8 mounting bolts 15 lbf·ft (20 N·m).
10. Bleed the hydraulic clutch system. For detailed instructions, see **Section 25.03**, Subject 140, in this manual.
11. Clean the transmission drain plug and install it on the transmission, along with a new aluminum gasket. Tighten the drain plug 42 lbf·ft (57 N·m).
12. Add transmission fluid until it is level with the lower edge of the fill opening. See **Fig. 1** for the location of the fill plug and **Fig. 17** for the correct level. See Chapter 26 of the *Business Class® Trucks Maintenance Manual* for approved transmission lubricants and lubricant capacities.

Mercedes-Benz Transmission Input Shaft Radial Seal Replacement

Replacement

1. Remove the transmission from the engine. For procedures, see **Subject 110**.
2. Remove the release fork and release bearing.
3. Remove the guide tube from the transmission case. Discard the mounting bolts. See **Fig. 1**.
6. Install the guide tube on the transmission case. Use new mounting capscrews (p/n N000000000761). Tighten the capscrews 17 lbf·ft (23 N·m).
7. Install the release fork and release bearing.
8. Install the transmission on the engine. For procedures, see **Subject 110**.

To prevent damage, make sure that the new radial seal is not installed on the race of the old seal.

5. Install a new radial seal (p/n A 021 997 25 47) on the input shaft.

Mercedes-Benz Transmission Output Shaft Radial Seal Replacement

Replacement

1. Secure the output yoke so that it cannot turn on the output shaft.
2. Remove the pressure plate mounting capscrew. Remove the pressure plate. See **Fig. 1**.

3. Remove the output yoke. Use a suitable extractor tool.
4. Remove the radial seal from the output shaft. Discard the old radial seal.

CAUTION

To prevent damage, make sure that the new radial seal is not installed on the race of the old seal.

5. Install a new radial seal (p/n A 024 997 04 47) on the output shaft. Use a rubber hammer or a piece of wood to prevent damage to the bearings.
6. If the radial seal cannot be pressed on cold, preheat the output yoke to 176°F (80°C) and try again.
7. Position the pressure plate on the output shaft. Secure it to the shaft using the pressure plate mounting capscrew. Tighten the M16 capscrew 190 lbf·ft (258 N·m).

Removal

1. Apply the parking brake, chock the tires, and disconnect the batteries.
2. Remove the transmission drain plug and drain the automatic transmission fluid. **See Fig. 1.** Install the drain plug and tighten it 25 to 32 N·m (18 to 24 lbf·ft).

1. Drain Plug

Fig. 1

NOTE: The ATF drained from the transmission can be used again if it is clean and if the container into which it was drained contained no ethylene glycol.

3. Support the driveline with a jack stand between the transmission output yoke and the midship bearing.
4. Disconnect the driveline from the transmission.
   - 4.1 Loosen the bolts holding the midship bearing bracket so the driveshaft can slide to the rear. **See Fig. 2.**
   - 4.2 If the vehicle is equipped with a driveline parking brake, remove the nuts on the brake flange. **See Fig. 3.**

     If the vehicle is not equipped with a driveline parking brake, remove the transmission yoke U-joint end caps or lock straps.
   - 4.3 Slide the front of the driveshaft off the driveline brake flange or out of the transmission output yoke.

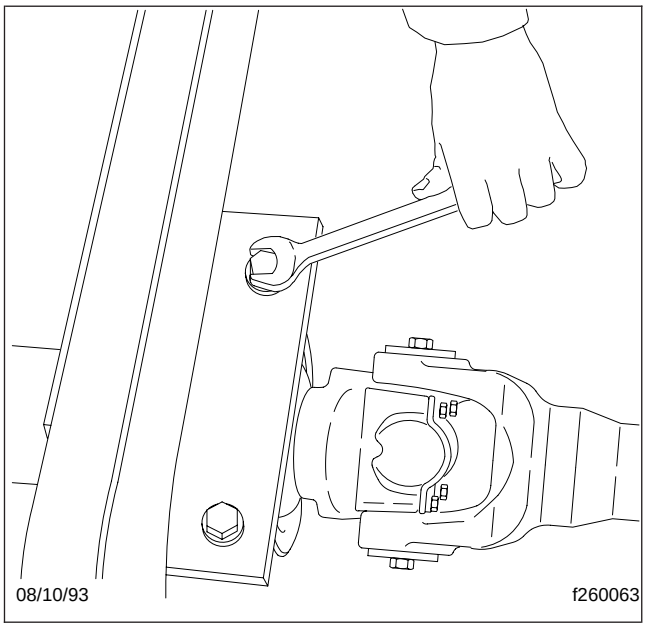

Fig. 2

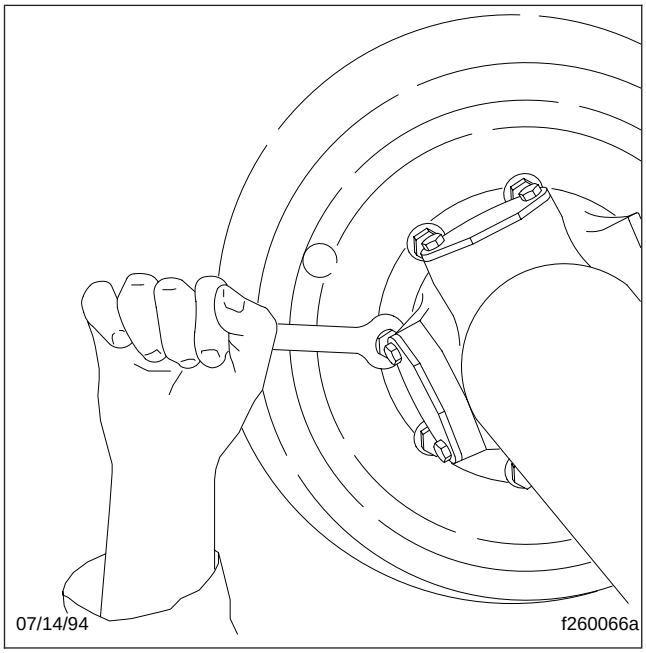

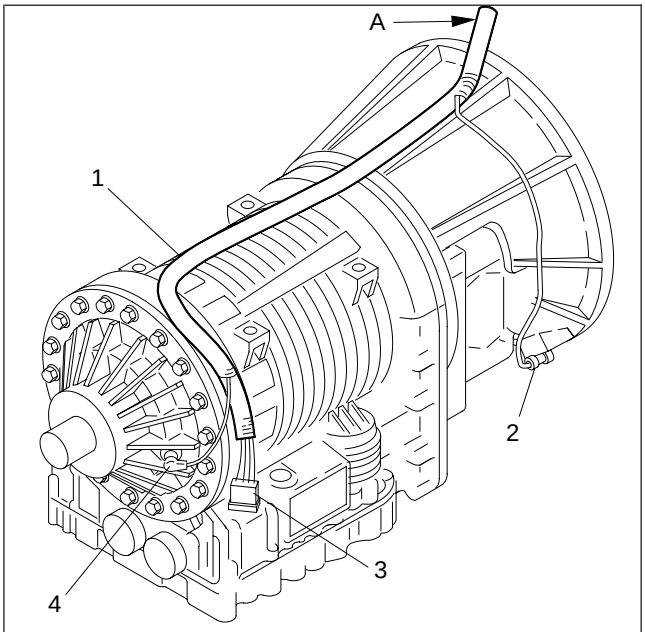

Fig. 3

NOTE: It may be necessary to remove the mounting bolts from the midship bearing bracket so the driveshaft can be moved far enough back.

Removal and Installation

4.4 Support the disconnected driveshaft and tie it to the frame rail.

5. Disconnect the three electrical connections to the transmission. **See Fig. 4.**

6. If the vehicle is equipped with a driveline parking brake, release the parking brake, and remove the cotter pin holding the clevis to the driveline brake lever. **See Fig. 5.** Remove the flanged bolt and flanged nut holding the driveline brake cable bracket to the transmission; then, remove the bracket.

7. Remove the ATF fill/dipstick tube. **See Fig. 6.**

   7.1 Remove the U-bolt holding the fill/dipstick tube to its support bracket.

   7.2 Remove the bolt and metal strap holding the fill/dipstick tube.

   7.3 Pull the fill/dipstick tube out of the transmission case.

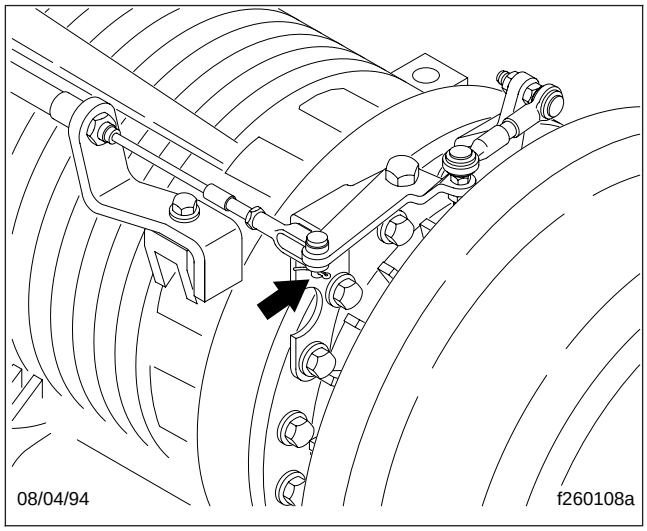

Fig. 5

   7.4 Plug the hole with a clean rag to prevent entry of foreign material.

8. Disconnect the flexplate from the transmission.

   8.1 Remove the capscrews holding the ring gear access cover. Then, remove the cover. **See Fig. 7.**

   NOTE: For easier access on Mercedes-Benz engines, first remove the three bolts holding the exhaust pipe to the turbocharger exhaust elbow. Then, lower the exhaust pipe.

   8.2 Using a screwdriver, turn the ring gear until one of the capscrews holding the flexplate adapter to the torque converter can be removed. Continue turning the ring gear and removing the capscrews through the access hole until all twelve are removed.

9. Remove the wiring harness and the air line from the standoff bracket (**Fig. 8**) on the right side of the transmission. Remove the standoff bracket.

10. Disconnect the transmission fluid cooler lines (**Fig. 9**) from the transmission and drain the remaining ATF.

11. Place a piece of plywood on a transmission jack to support the transmission.

12. Slide the jack into place under the transmission. Secure the transmission with a chain. Anchor the

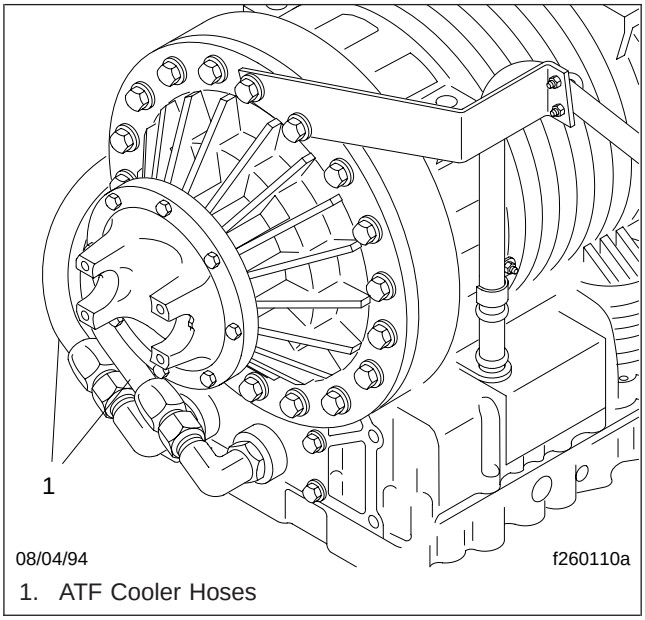
chain with bolts at the front lifting bosses on the top of the transmission. **See Fig. 10.**

13. Remove the two bolts holding the transmission to the rear overslung transverse support spring. **See Fig. 11.**
14. Remove the twelve transmission flange bolts. **See Fig. 12.**
15. Move the transmission jack to the rear. Lower the jack and lift the front of the truck, as needed, so the transmission clears the frame rail and any attached components.
16. Place jack stands under the raised front of the vehicle.
17. Roll the transmission jack back, and remove the transmission.

Installation



IMPORTANT: Before installing the transmission, make sure the rear tires are chocked and the

transmission is securely chained to the transmission jack.

1. Raise the front of the vehicle frame with a hydraulic jack to obtain adequate clearance for installing the transmission. Place jack stands under the front of the vehicle.

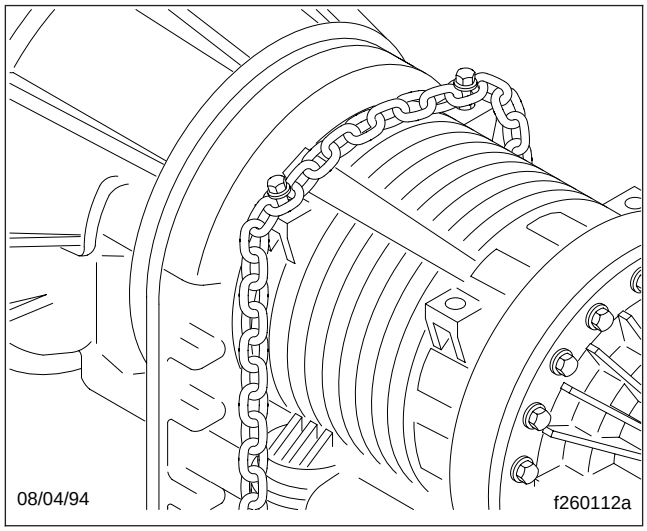

Fig. 10

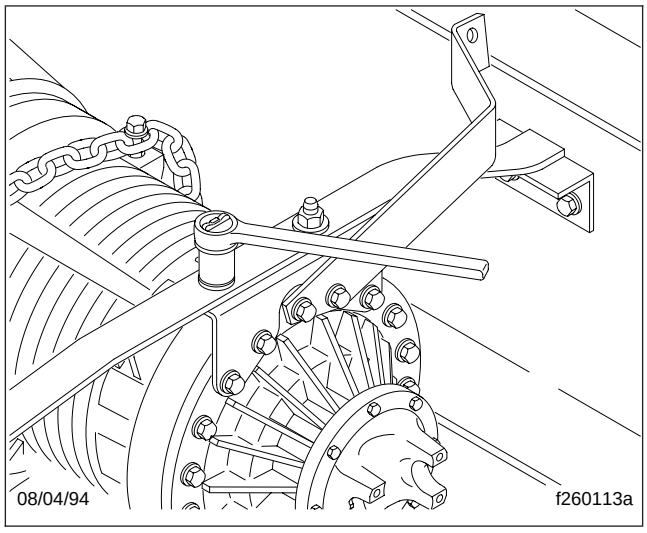

Fig. 11

2. With the transmission on a jack, roll the transmission into place behind the flexplate. Remove the jack stands, and lower the front of the vehicle frame.
3. Raise the jack until the transmission lines up with the flexplate.
4. Push the transmission toward the engine until it seats squarely against the engine flywheel hous-

ing with the bolt holes in the transmission housing aligned with those in the flywheel housing.

NOTE: No force is required. If interference is encountered, move the transmission away from the engine and correct the problem.

5. Install the transmission flange bolts finger-tight.
6. Install the transverse support spring at the rear of the transmission. Install the two bolts and washers. Tighten the bolts 184 N·m (136 lbf·ft). **See Fig. 11.**
7. Remove the chain holding the transmission to the transmission jack.
8. Lower the transmission jack and remove it.
9. Connect the transmission fluid cooler hoses to the transmission. Tighten the fittings 54 to 68 N·m (40 to 50 lbf·ft). **See Fig. 9.**
10. Install the twelve flexplate adapter capscrews.
    - 10.1 Turning the ring gear for access, install all the capscrews through the access hole. Don't tighten them now.

      Be careful not to drop the capscrews inside the torque converter cover. The transmission must be removed to get them out.

    IMPORTANT: Install all the capscrews before tightening any of them to prevent cocking of the flexplate adapter.

    - 10.2 Tighten the capscrews 24 to 29 N·m (18 to 21 lbf·ft) in a star pattern.
    - 10.3 Install the access cover and its capscrews. There are three capscrews on Mercedes-Benz engines, two on Cummins and Detroit Diesel engines.
11. Tighten the twelve M10 transmission flange bolts (**Fig. 12**) 51 to 61 N·m (38 to 45 lbf·ft) in a star pattern.
12. If the vehicle is equipped with a driveline parking brake, mount the driveline brake cable bracket to the transmission. Install the two flanged bolts and flanged nuts, and tighten them 31 N·m (23 lbf·ft). Attach the clevis to the brake lever; then, insert and lock the cotter pin. **See Fig. 5.**
13. Connect the driveshaft.
    - 13.1 Slide the front of the driveshaft into the transmission output yoke or onto the driveline parking brake flange if so equipped.
    - 13.2 On vehicles without a driveline parking brake, install the transmission yoke U-joint end caps or lock straps.

      On vehicles with a driveline parking brake, slide the driveshaft flange onto the studs in the parking brake. Install the nuts, and tighten them 54 N·m (40 lbf·ft).
    - 13.3 If the midship bearing bracket bolts and nuts were removed, install them. Tighten the nuts 129 N·m (95 lbf·ft).
14. On Mercedes-Benz engines, if the exhaust pipe was disconnected from the turbocharger exhaust elbow, connect the pipe and tighten the bolts 81 N·m (60 lbf·ft).
15. Install the ATF fill/dipstick tube.
    - 15.1 Install the fill/dipstick tube support bracket. Tighten the two capscrews 108 N·m (80 lbf·ft).
    - 15.2 Inspect the fill/dipstick tube seal. Replace it if damaged.
    - 15.3 Install the fill/dipstick tube and clamp. Tighten the capscrew 16 N·m (12 lbf·ft).
    - 15.4 Install the U-bolt and nuts holding the fill/dipstick tube to the bracket. Tighten the U-bolt nuts 11 N·m (8 lbf·ft).

Removal and Installation

16. Install the standoff bracket on the right side of the transmission.

    Make sure the air line and the wiring harness are securely attached to the standoff bracket.

17. Fill the transmission with ATF.

18. Connect all electrical lines to the transmission.

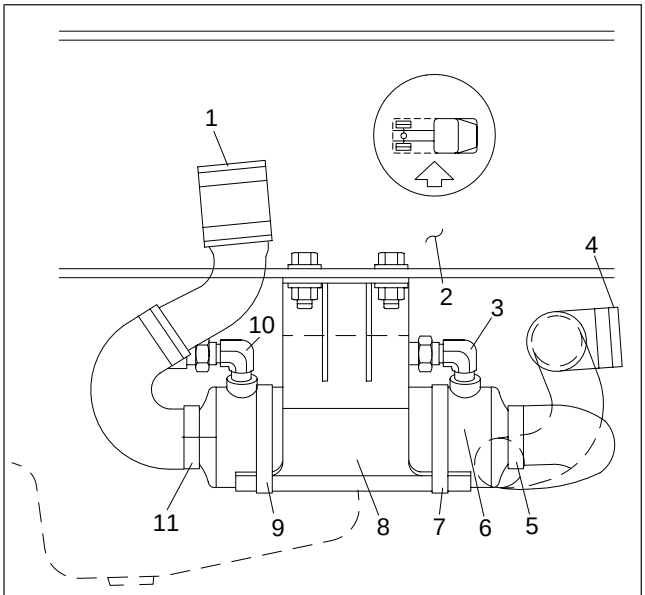
    18.1 Connect the transmission control connector.

    18.2 Connect the electrical cable to the output speed sensor.

    18.3 Connect the cable to the engine speed sensor.

    18.4 Using tie straps, secure the cables where necessary.

19. Connect the batteries and remove the chocks from the tires.



20. Start the engine, and check for any leaks. Repair leaks as needed.

21. Check the ATF level. Add fluid as needed.

22. Road test the vehicle, and check for correct transmission operation.

1. Apply the parking brakes and chock the tires.

⚠ WARNING

Drain the coolant system only when the coolant and engine are cool. Draining it when these are hot could cause severe personal injury due to scalding.

2. With the engine cool, loosen the surge tank cap to release cooling system pressure.
3. Place a suitable container under the radiator. Open the drain petcock at the bottom of the radiator and drain the cooling system. Close the drain petcock.
4. Disconnect the coolant hoses from the fittings at both sides of the automatic transmission fluid (ATF) cooler. When the coolant stops draining, secure the ends of the hoses to prevent leakage.

5. Disconnect the ATF hoses from the fittings at both sides of the ATF cooler. Catch the ATF by directing the disconnected end of each hose into a drain pan. When the ATF stops draining, plug the hoses and cap the fittings.
6. Remove the two hexnuts and washers that attach the ATF cooler to the T-bolt mounting bracket assembly, and remove the ATF cooler. Drain the ATF cooler into a drain pan.

Installation

1. Hold the ATF cooler in place; then install the hexnuts and washers on the T-bolt mounting bracket assembly. Tighten them 28 lbf·ft (38 N·m).
2. Attach the coolant hoses to the fittings at both sides of the ATF cooler, as removed.
3. Remove the plugs from the ATF hoses and the caps from the fittings. Attach the ATF hoses to the fittings at both sides of the ATF cooler. Tighten the fittings 40 to 50 lbf·ft (54 to 68 N·m).
4. Fill the coolant system and install the surge tank cap.
5. Start the engine and operate the transmission for one or two minutes, then add the correct ATF to

the transmission as needed. For instructions and lubricant specifications, see Group 26 of the *Business Class Trucks Maintenance Manual*.

6. Run the engine until operating temperature is reached and check for leaks in the coolant system or ATF cooler. Repair leaks as needed.
7. Check the coolant level and add as needed.
8. Remove the tire chocks.

Removal

CAUTION

To avoid component damage, be sure to remove the transmission and torque converter as an assembly. The converter drive plate, pump bushing, and oil seal can be damaged if the converter is left attached to the drive plate during removal.

1. Apply the parking brake, chock the tires, and disconnect the batteries.
2. Drain the automatic transmission fluid (ATF). If equipped, remove the transmission drain plug. Otherwise, remove the transmission oil pan. When removing the drain plug, use one wrench to hold the nut and another to turn the drain plug.

   After draining the ATF, install the oil pan (or drain plug, if equipped). Tighten all oil pan bolts 17 N·m (13 lbf·ft). Tighten the drain plug nut (if equipped) 17 N·m (13 lbf·ft) also.
3. Remove the exhaust system components. See **Fig. 1**.

   IMPORTANT: Mark both oxygen sensors, left-hand and right-hand. Be careful not to mix them up during assembly.

   3.1 Remove both oxygen sensors, one from each exhaust pipe.

   3.2 Disconnect the exhaust manifold saddle brackets.

   3.3 Disconnect the clamps attaching each pipe to the catalytic converter.

   3.4 Remove the rubber isolators from the exhaust support. Push the exhaust pipes back until the exhaust hangers clear the brackets. Remove both exhaust pipes from the vehicle.
4. Disconnect the driveline from the transmission. See **Fig. 2**.

   4.1 Support the driveline with a jack stand between the transmission output yoke and the midship bearing.

   4.2 Make one reference mark on the driveline and another on the transmission output yoke, for use during assembly.

   4.3 Remove the midship bracket and end bracket.

   4.4 Pull the driveline straight back until it comes free of the splined shaft on the transmission output yoke.

   4.5 Support the disconnected driveline and tie it to the frame rail.
5. Disconnect the transmission fluid cooler lines (see **Fig. 3**) from the transmission. Disconnect the standoff bracket.
6. Remove the two engine-to-transmission struts. See **Fig. 4**.

   6.1 Remove the transmission-to-strut bolt.

   6.2 Remove the engine-to-strut bolt. After removing the strut, install the bolt; this bolt is part of the engine mount.

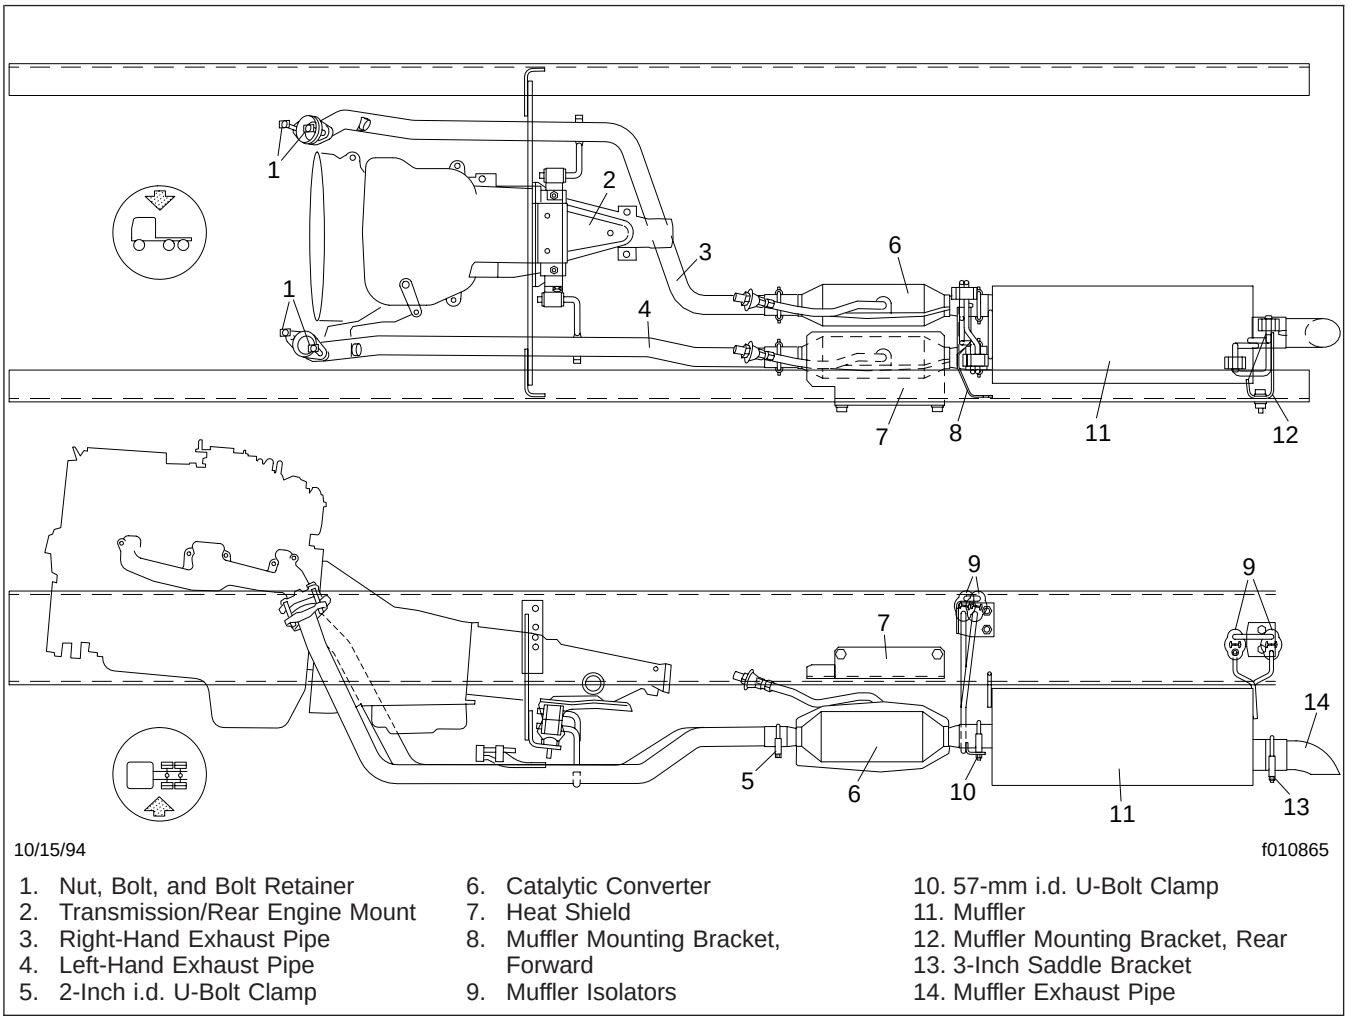
   6.3 Remove the strap for the ATF cooler lines from the left-hand strut.
7. Remove the ATF fill/dipstick tube. See **Fig. 5**.

   7.1 Remove the bolt attaching the fill/dipstick tube bracket to the engine.

   7.2 Pull the fill/dipstick tube out of the transmission case.

   7.3 Plug the hole with a clean rag to prevent entry of foreign material.

CAUTION



The crankshaft position sensor will be damaged if the transmission is removed (or installed) while the sensor is still bolted to the engine block. To avoid damage, be sure to remove the sensor before removing the transmission.

8. Disconnect the five electrical connections to the transmission.

   8.1 Remove the crankshaft position sensor (bolted to the engine at the bell housing). See **Fig. 6**.

   8.2 Disconnect the transmission temperature sensor attached to the forward ATF cooler

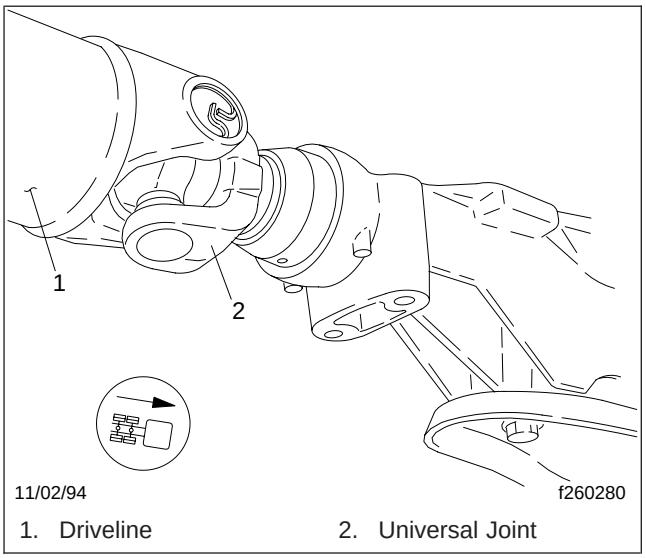
8.3 Disconnect the park-neutral position switch located on the transmission case just aft of the inner shift lever. See **Fig. 7**.

8.4 Disconnect the transmission overdrive solenoid located on the transmission case behind the throttle valve cable. See **Fig. 7**.

8.5 Disconnect the vehicle speed sensor from the speedometer adapter located on the overdrive unit just forward of the U-joint. See **Fig. 7**.

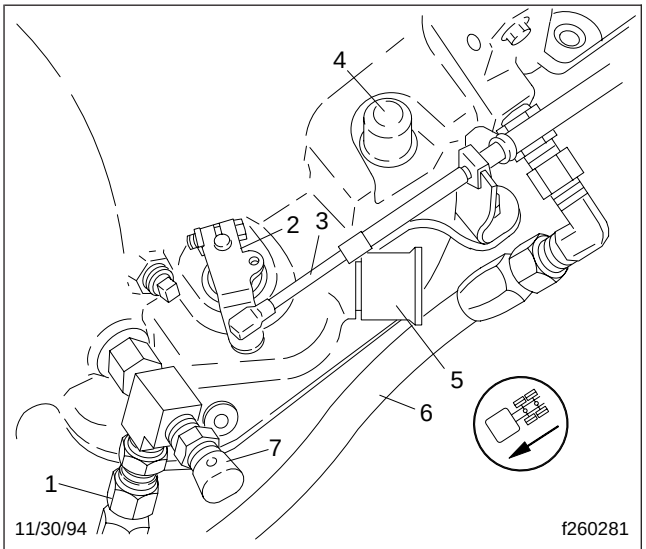
9. Remove the shift linkage from the transmission.



9.1 Remove the U-bolt holding the shift cable to the shift cable support bracket. See **Fig. 8** .

9.2 Remove the clip attaching the shift cable to the inner shift lever. See **Fig. 9** .

10. Remove the throttle valve linkage from the transmission. See **Fig. 10**.



10.1 Disconnect the spring attaching the throttle lever to the spring bracket.

10.2 Using a screwdriver blade, remove the quick-disconnect fitting at the clamp on the throttle valve cable. Then snap off the

11. Remove the starter from the bell housing.

    11.1 Remove the battery cable standoff brackets. Remove the battery cable bolt and bracket. Do not remove the clamp from the battery cable.

    11.2 Mark and disconnect the battery and solenoid cable leads. Remove the two starter mounting bolts.

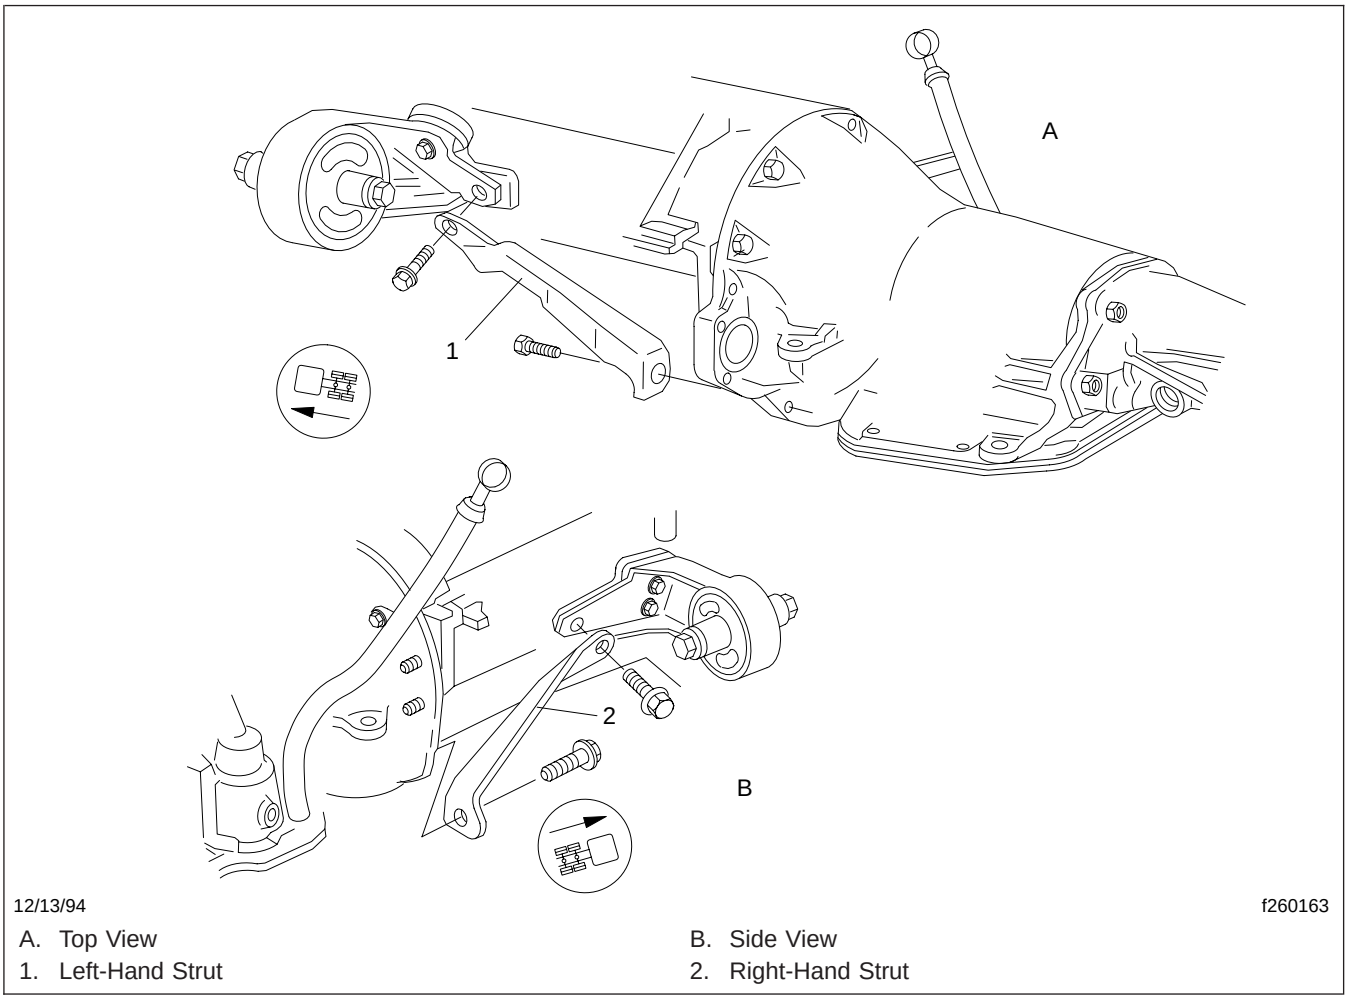
    11.3 Move the starter forward until the nose of the starter gear housing clears the lower mounting stud. See **Fig. 11**.

12. Remove the two bolts attaching the fuel line support bracket to the transmission case. Remove it from the fuel lines and set it aside for assembly. See **Fig. 12**. Remove the standoff bracket from the air pump hose going to the catalytic converter.

13. Remove the torque converter from the drive plate.

    13.1 Remove the three bolts on the torque converter access cover. Make alignment marks on the torque converter and drive plate for reference. See **Fig. 13**.

    13.2 Using a socket wrench, turn the crankshaft vibration damper clockwise until converter bolts are accessible. Then remove the bolts one at a time.



14. Remove the main support crossmember. See **Fig. 14**.

    14.1 Lift the front or the rear of the vehicle, as needed, to allow the transmission to clear the frame rail and any attached components. Support the rear of the engine with a safety stand or jack. Place other safety stands under the vehicle as needed.

    14.2 Secure the transmission jack to the transmission. Using the jack, raise the transmission slightly to relieve the load on the crossmember.

    IMPORTANT: Make sure the chain or cable securing the transmission to the jack is not interfering with the shift and throttle valve linkage levers on the right-hand side of the transmission.

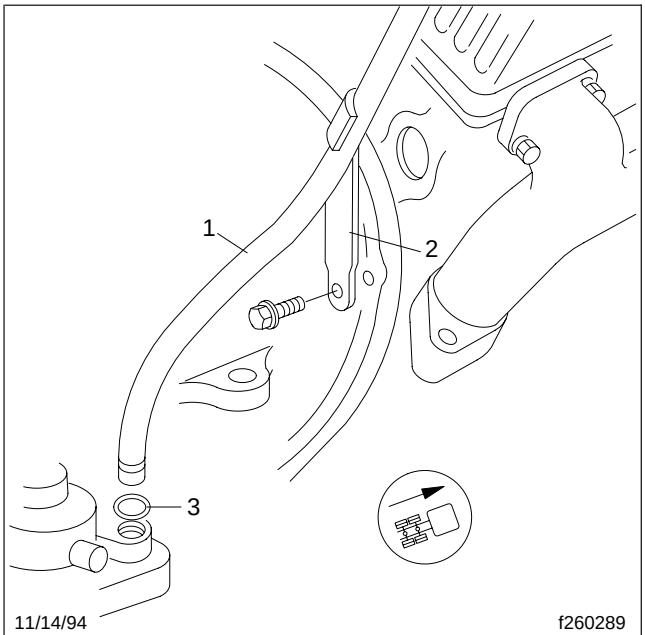
14.3 Remove the three bolts holding the transmission to the triangular rear support bracket connected to the crossmember. Remove the bolts attaching the crossmember to each frame rail bracket.

NOTE: The crossmember is not symmetrical. To save installation time, mark the front of the crossmember before removal.

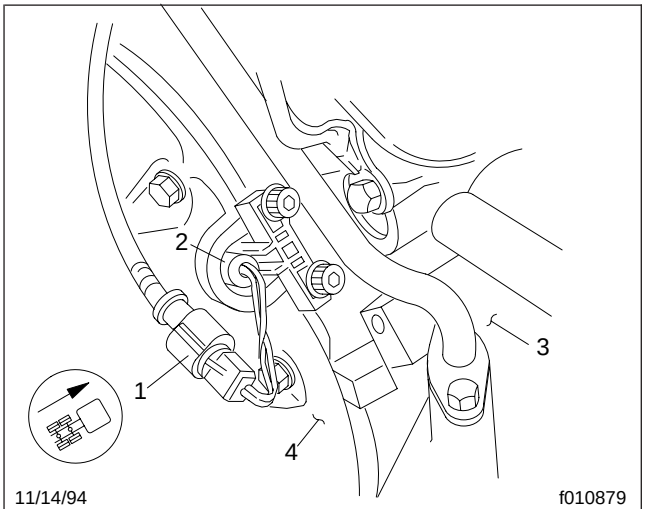
14.4 Remove the crossmember and rear support bracket as a unit. Carefully lower them, taking care to clear the battery cable and any other lines or hoses.



15. Remove the transmission flange bolts attaching the engine block to the bell housing.

15.1 Remove the five out-facing offset bolts on the bell housing.

15.2 Remove the last, in-facing bolt by pushing the transmission forward, loosening the bolt, pushing the transmission backward to gain more room, and repeating this process until the bolt is out. See **Fig. 15**.



16. Use a C-clamp or wedge tool to hold the torque converter in position while the transmission is being removed. See **Fig. 16**.

17. Remove the transmission from the vehicle. Make sure clearance is adequate and safety stands are properly placed. Adjust vehicle height and placement of supports, if necessary.

Installation

IMPORTANT: Before installing the transmission, make sure the rear tires are chocked, the engine is supported, and the transmission is securely chained to the transmission jack.

1. Install the transmission on the vehicle.

   1.1 Raise the front of the vehicle frame with a hydraulic jack to obtain adequate clearance for installing the transmission. Place safety stands under the front of the vehicle.

   1.2 Check converter seating with steel scale and straightedge (see **Fig. 17**). The surface of the converter lugs should be 13 mm (1/2 inch) to the rear of the straightedge when fully seated.

   1.3 With the transmission on a jack, roll the transmission into place behind the drive

plate. Remove the C-clamp from the torque converter.

IMPORTANT: If reinstalling the old transmission, check drive plate for cracks, distortion, and damage. Be sure the transmission dowel pins are seated in the engine block and that they stick out far enough to hold the transmission in alignment.

plate, and the bolt holes in the transmission housing align with those in the engine block.

NOTE: No force is required. If interference is encountered, move the transmission away from the engine and correct the problem.

1.6 Install the transmission flange bolts. First, tighten the in-facing bolt (bolt head toward front of vehicle) located directly behind the oil filter. Then, tighten the five out-facing bolts. Tighten all six bolts 41 N·m (30 lbf·ft).

2. Install the main support crossmember and triangular rear support bracket.

   2.1 Line up the crossmember using the reference mark made on removal. The crossmember is in front of the frame brackets when correctly installed. See **Fig. 14**.

   2.2 Install the standoff bracket for the battery cable to the lower frame rail.

   NOTE: Be sure the battery cable is above the crossmember before tightening the bolts.

   2.3 Install the crossmember to the frame rail brackets on each side of the vehicle. Tighten all six bolts 68 N·m (50 lbf·ft).

   2.4 Adjust the transmission again, if necessary.

   2.5 Install the transmission mount onto the transmission using the three bolts on the bottom of the support bracket. Tighten all bolts 68 N·m (50 lbf·ft).

3. Remove the safety stands under the engine. Remove the chain holding the transmission to the jack. Lower the jack and remove it.

4. Align the engine with the transmission.

   4.1 Turn the engine until the alignment mark made on removal becomes visible. Use a socket wrench to turn the crankshaft vibration damper clockwise to install the bolts.

   NOTE: Be careful not to drop the bolts inside the torque converter. The transmission must be removed to get them out.

   4.2 Tighten each torque converter bolt 31 N·m (23 lbf·ft).

   4.3 Install the torque converter access cover.

5. Install the ATF fill/dipstick tube.

   5.1 Replace the fill/dipstick tube seal.

   5.2 Insert the fill/dipstick tube into the hole in the transmission housing.

5.3 Fasten the fill/dipstick tube bracket to the engine.

6. Install the two engine-to-transmission struts. Tighten each transmission-to-strut bolt 102 N·m (75 lbf·ft). Tighten each engine-to-strut bolt 47 N·m (35 lbf·ft).

NOTE: Be sure to install the strap for the transmission fluid cooler lines onto the standoff bracket attached to the left-hand strut.

7. Connect all electrical lines and sensors to the transmission (see **Fig. 6** and **Fig. 7**).

7.1 Install the crankshaft position sensor. Install the bolts and connect the receptacle.

7.2 Connect the coolant temperature sensor to the three-pin plug on the forward transmission cooler line fitting.

7.3 Connect the park-neutral position switch to the three-pin plug on the side of the transmission case just aft of the inner shift lever.

7.4 Connect the transmission solenoid to the three-pin plug on top of the transmission case above the throttle lever.

7.5 Connect the vehicle speed sensor to the three-pin receptacle on the speedometer adapter just before the U-joint.

7.6 Using tie straps, secure all lines and cables as needed.

8. Connect the shift linkage to the transmission.

⚠ CAUTION

Do not overtighten the small U-bolt to the shift cable. If this bolt is too tight, it could squeeze the cable housing and prevent the transmission from shifting.

8.1 Attach the small U-bolt to the shift cable. Tighten the nuts.

8.2 Install the clip attaching the shift cable to the shift lever. See **Fig. 9**.

9. Connect the throttle valve linkage to the transmission.

9.1 Attach the battery cable standoff bracket to the flange on the right-hand side of the transmission case. Using the same bolt, attach the spring bracket to the standoff bracket and fasten the nuts finger-tight.

9.2 Attach the throttle valve cable to the cable bracket and the ball stud on the throttle valve lever.

9.3 Attach the spring on the throttle valve lever to the spring bracket.

9.4 Tighten the nuts on the standoff bracket.

10. Connect the ATF cooler lines to the transmission. Tighten the fittings 18 N·m (13 lbf·ft).

11. Install the starter.

11.1 Attach the battery cable connectors to the starter, as previously marked. Tighten the connector on the battery lead 800 to 1240 N·cm (70 to 110 lbf·in). Tighten the connector on the solenoid lead 500 to 740 N·cm (45 to 65 lbf·in)

11.2 Insert the starter gear housing into the hole in the torque converter access cover. Slip the starter into place over the starter mounting stud.

11.3 Install the two starter mounting bolts and tighten them 68 N·m (50 lbf·ft). Install the starter mounting nut on the stud and tighten it 27 N·m (20 lbf·ft).

11.4 Install the battery cable standoff brackets.

12. Tighten up the wiring harness lines and cables.

12.1 Install the fuel line support bracket on the transmission case and attach the fuel lines to it. See **Fig. 12**.

12.2 Attach the standoff bracket to the air pump hose going to the catalytic converter.

12.3 Attach the standoff bracket to the electrical lines.

12.4 Secure all lines and wires with tie straps as needed.

13. Connect the driveline to the transmission.

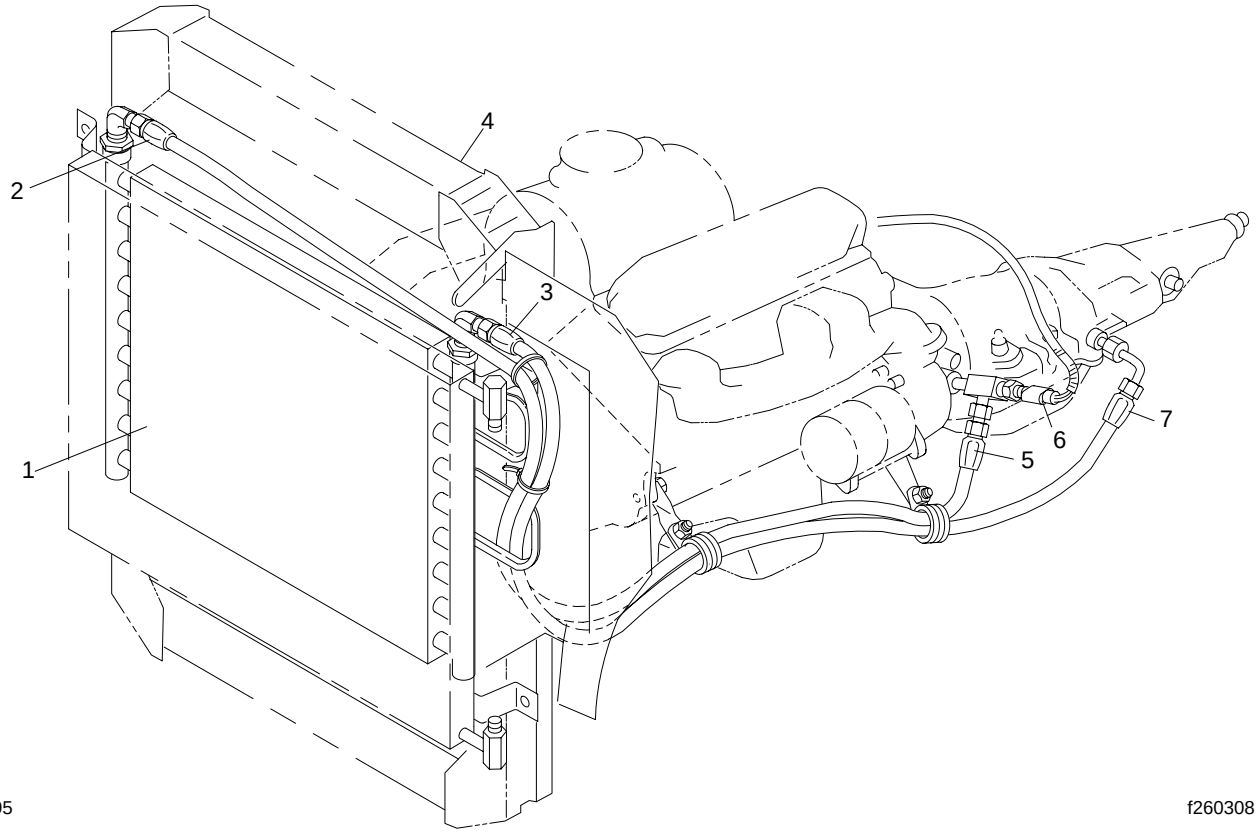
13.1 Slide the front of the driveshaft into the splined end of the transmission output yoke. Use the reference marks made on removal to align the driveshaft and output yoke.

Removal and Installation

13.2 Install the midship bracket and end bracket bolts and nuts. Tighten the nuts 68 N·m (50 lbf·ft).

14. Install the exhaust pipes. Attach the saddle brackets to the exhaust manifold and the clamps to the catalytic converter. Tighten the saddle brackets 34 N·m (25 lbf·ft) and the clamps 43 N·m (32 lbf·ft). Install the rubber isolators (if removed). Attach the left-hand and right-hand oxygen sensors, using the markings made on removal.
15. Fill the transmission with Mopar ATF Plus, Type 7176. If the torque converter was drained and/or replaced, add 5.7 liters (6 quarts). If the torque converter was not drained or replaced, add 1.9 liters (2 quarts). Lower the vehicle and remove the safety stands.
16. Connect the batteries and remove the chocks from the tires.
17. Start the engine, and check for any leaks. Repair leaks as needed.
18. With the engine running, check the ATF level. Follow the procedure for checking the fluid level in Group 26 of the *Business Class Trucks Maintenance Manual*. Add fluid or drain excess as needed.
19. Road test the vehicle, and check the transmission for correct operation.

ATF Cooler Removal and Installation



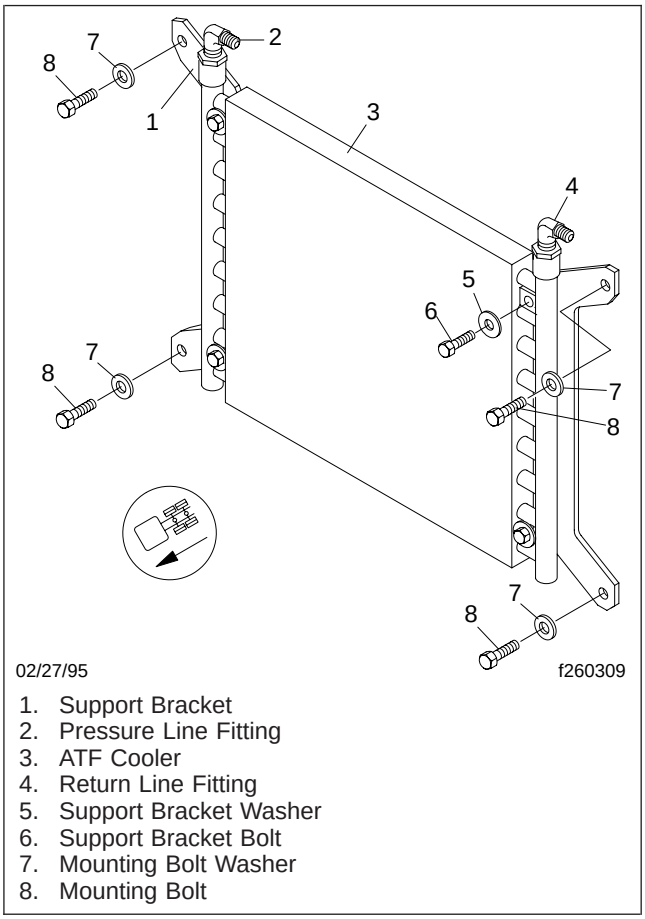
Removal (See Fig. 1)

CAUTION

If a leak should occur inside the internal radiator-mounted transmission ATF cooler, engine coolant may become mixed with automatic transmission fluid (ATF). To prevent damage to the cooling system and the transmission, drain and inspect both systems.

1. Apply the parking brake, chock the tires, and disconnect the batteries.
2. If equipped, remove the air conditioning condenser. For procedures, refer to **Group 83** in this manual.
3. Remove the transmission oil pan and drain the ATF.
4. Disconnect both ATF cooler lines from the cooler. See **Fig. 2**.
5. Remove the four ATF cooler mounting bolts. Remove the ATF cooler from the vehicle.

Installation



NOTE: On models with air conditioning, the air conditioning condenser is installed in front of the ATF cooler.

1.1 Tighten the support bracket bolts 20 N·m (15 lbf·ft), if needed.

1.2 Install the upper mounting bolts but do not tighten them yet.

1.3 Position the oil cooler on the radiator so that the lower mounting bolts line up with the bolt holes on the radiator flange.

1.4 Install the lower mounting bolts. Tighten both the upper and lower mounting bolts 1100 N·cm (95 lbf·in).

2. Connect the ATF cooler lines to the oil cooler.

2.1 If a fitting requires replacement, apply Loctite® 242 to the fitting threads.

2.2 Wipe the cooler line and fitting with a clean, dry cloth.

2.3 Connect the ATF cooler lines and tighten the fittings 18 N·m (13 lbf·ft).

3. Fill the transmission with Mopar ATF Plus, Type 7176. Add 1.9 liters (2 quarts).

4. If equipped, install the air conditioning condenser. For instructions, see **Group 83** in this manual.

5. Connect the batteries and remove the chocks from the tires.

6. Start the engine, and check for leaks. Repair any leaks as needed.

7. With the engine running, check the ATF level. Follow the procedure for checking the fluid level in Group 26 of the *Business Class Trucks Maintenance Manual*. Add fluid or drain excess as needed.

8. Road test the vehicle, and check the transmission for correct operation.

IMPORTANT: Before replacing the transmission you must call Aisin for approval and a Return Material Authorization (RMA) number. Call (734) 453-5551 to speak with an Aisin representative.

Transmission Replacement

1. Apply the parking brake, chock the tires, and disconnect the batteries.
2. Remove the transmission drain plug and drain the automatic transmission fluid. See **Fig. 1**. Install the drain plug and tighten it 27 to 36 lbf·ft (37 to 49 N·m).

A. Remove Drain Plug

Fig. 1, Draining the Transmission Fluid

NOTE: The ATF drained from the transmission can be used again if it is clean and if the container into which it was drained contained no ethylene glycol.

3. Support the driveline with a jack stand at the midship bearing.
4. Remove the bolts that hold the midship bearing bracket so the driveshaft can slide to the rear. See **Fig. 2**.
5. If the vehicle is equipped with a driveline parking brake, remove the nuts on the brake flange. See **Fig. 3**.

   If the vehicle is not equipped with a driveline parking brake, remove the transmission yoke U-joint bearing caps or bearing straps.

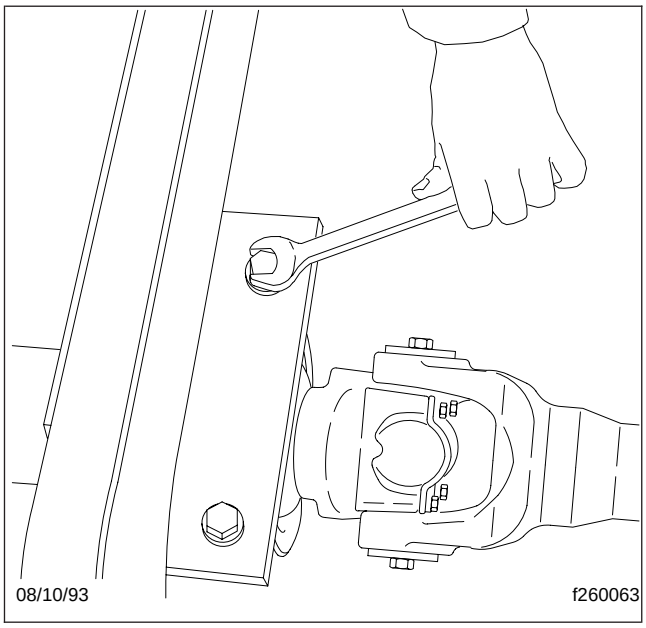

Fig. 2, Removing the Midship Bearing Bolts

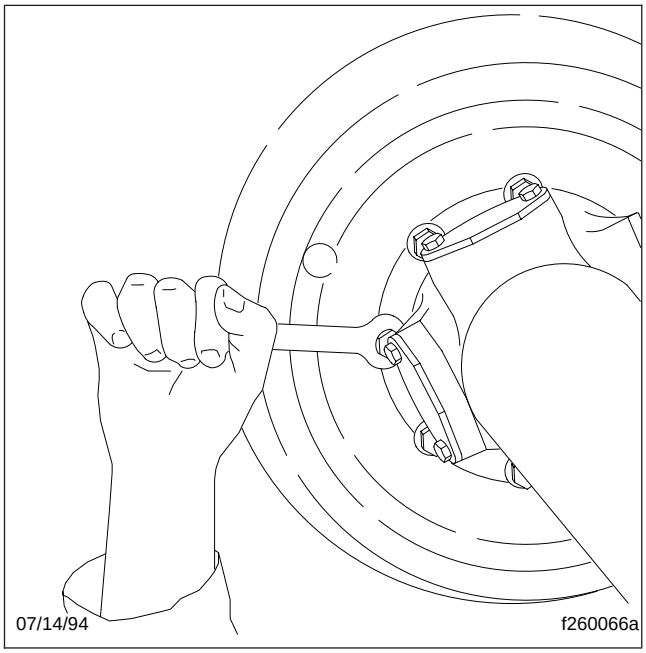

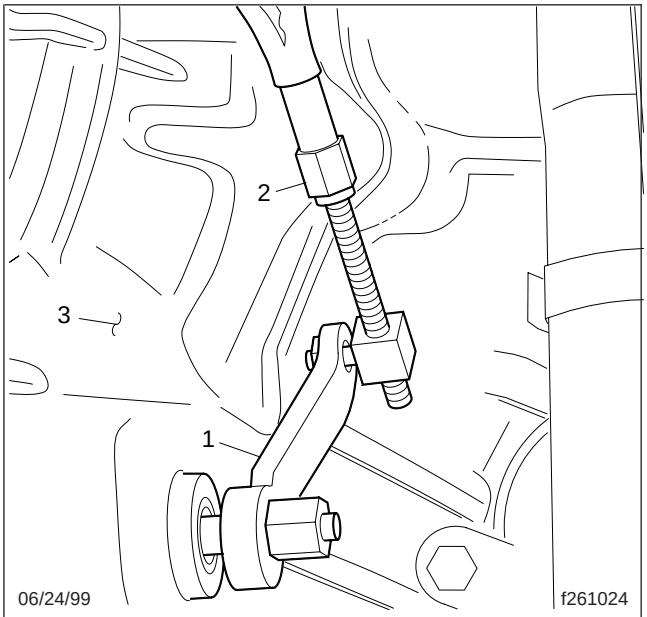

Fig. 3, Removing the Brake Flange Nuts

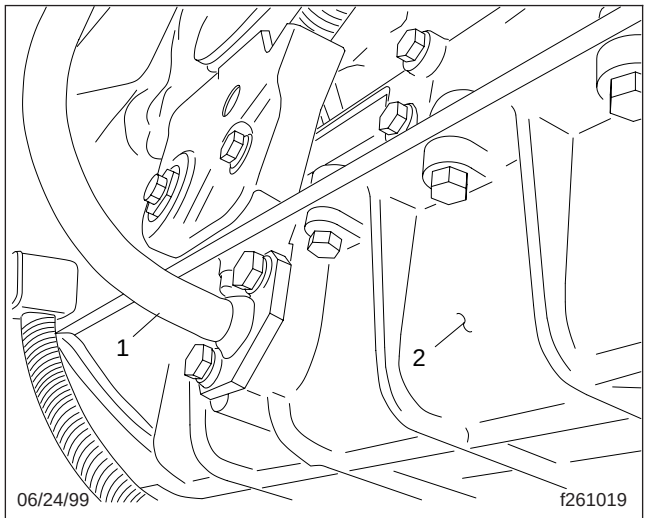
6. Slide the front of the driveshaft off the driveline brake flange or out of the transmission output yoke.

Transmission Replacement



7. Support the disconnected driveshaft and tie it to the frame rail.
8. Remove the shift cable by pulling the cotter pin from the end of the shift assembly and disconnecting the shift lever. See **Fig. 4**.

1. Transmission Shift Arm
2. Shift Cable
3. Transmission

Fig. 4, Transmission Shift Lever

9. Disconnect the transmission cooler lines.
10. Remove the ATF fill/dipstick tube, as follows. See **Fig. 5**.
    - 10.1 Remove the U-bolt that holds the fill/dipstick tube to its support bracket.
    - 10.2 Remove the two bolts that secure the fill/dipstick tube to the transmission.
    - 10.3 Pull the fill/dipstick tube and O-ring from the transmission case.
    - 10.4 Plug the hole with a clean rag to prevent entry of foreign material.
11. Disconnect the flexplate from the transmission, as follows.
    - 11.1 Remove the capscrews that hold the ring gear access cover. Then, remove the cover.

1. Fill/Dipstick Tube
2. Transmission Oil Pan

Fig. 5, Fill/Dipstick Tube

    - 11.2 Using a screwdriver, turn the ring gear until one of the capscrews that hold the flexplate adapter to the torque converter can be removed.
    - 11.3 Continue turning the ring gear and removing the capscrews through the access hole until all six are removed.
12. Tilt the hood.
13. Under the hood, disconnect the five electrical harnesses for the transmission. They are bundled together and should be fed down to the transmission to be removed easily.
14. If necessary, place a piece of plywood on a transmission jack to support the transmission.
15. Remove all but the top two mounting bolts.
16. Slide the jack into place under the transmission. Secure the transmission with a chain. Anchor the chain with bolts at the front lifting bosses on the top of the transmission.
17. Remove the remaining transmission flange bolts.
18. Move the transmission jack to the rear. Lower the jack and lift the front of the vehicle, as needed, so the transmission clears the frame rail and any attached components.
19. If necessary, place jack stands under the raised front of the vehicle.

20. Roll the transmission jack backward and remove the transmission.

IMPORTANT: Before installing the new transmission, make sure the rear tires are chocked and the transmission is securely chained to the transmission jack.

21. If necessary, raise the front of the vehicle frame with a hydraulic jack to obtain adequate clearance for installing the new transmission. Place jack stands under the front of the vehicle.
22. With the transmission on a jack, roll the transmission into place behind the flexplate. Remove the jack stands and lower the front of the vehicle frame.
23. Raise the jack until the transmission lines up with the engine bell housing.
24. Push the transmission toward the engine until it seats squarely against the engine bell housing with the bolt holes in the transmission housing aligned with those in the flywheel housing.

NOTE: No force is required. If interference is encountered, move the transmission away from the engine and correct the problem.

25. Install all the transmission flange bolts finger tight. Once all bolts are in place tighten the bolts in a criss-cross pattern to 45 lbf·ft (61 N·m).
26. Remove the chain that was used to secure the transmission to the transmission jack.
27. Lower the transmission jack and remove it.
28. Connect the flexplate to the transmission, as follows.
    - 28.1 Remove the capscrews that hold the ring gear access cover. Then remove the cover.
    - 28.2 Using a screwdriver, turn the ring gear until a hole in the flexplate adaptor aligns with a hole in the torque converter. Install a capscrew. Continue turning the ring gear and installing the capscrews through the access hole until all six are installed.
    - 28.3 Tighten the six fasteners 32 to 43 lbf·ft (44 to 58 N·m).
    - 28.4 Install the ring gear access cover and capscrews.
29. Install the fill/dipstick tube. Tighten the two capscrews 11 lbf·ft (15 N·m).
30. Install the shift cable.
31. Feed the bundle of electrical cables up to the hood area and connect them where the old bundle was disconnected under the hood.
32. Install tie straps on all electric lines, at all locations where tie straps were previously installed.
33. If previously removed, connect the exhaust bracket.
34. Connect the driveshaft, as follows.
    - 34.1 Slide the front of the driveshaft into the transmission output yoke or onto the driveline parking brake flange, as equipped.
    - 34.2 On vehicles without a driveline parking brake, install the transmission yoke U-joint bearing caps or bearing straps, and tighten per **Table 1** or **Table 2**.

      On vehicles with a driveline parking brake, slide the driveshaft flange onto the studs in the parking brake. Install and tighten the nuts 40 lbf·ft (54 N·m).

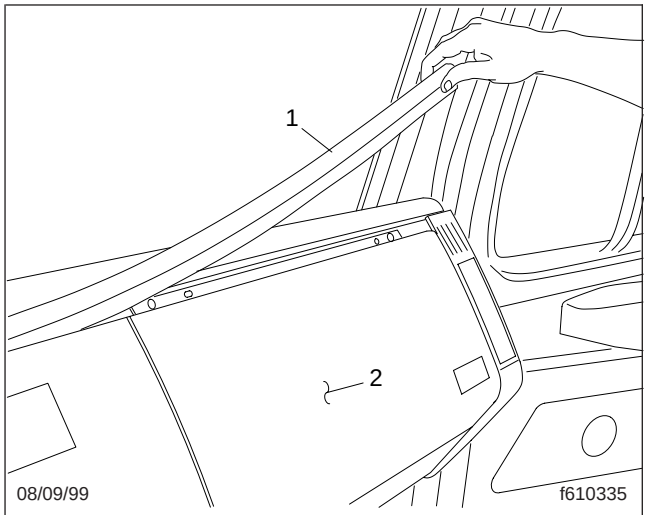
    - 34.3 If the midship bearing bracket bolts and nuts were removed, install them.

      Whether removed, or just loosened, tighten the nuts 95 lbf·ft (129 N·m).
35. Connect the batteries and remove the chocks from the tires.
36. Check the ATF level. Add fluid as needed.
37. Start the engine and check for any leaks. Repair leaks as needed.

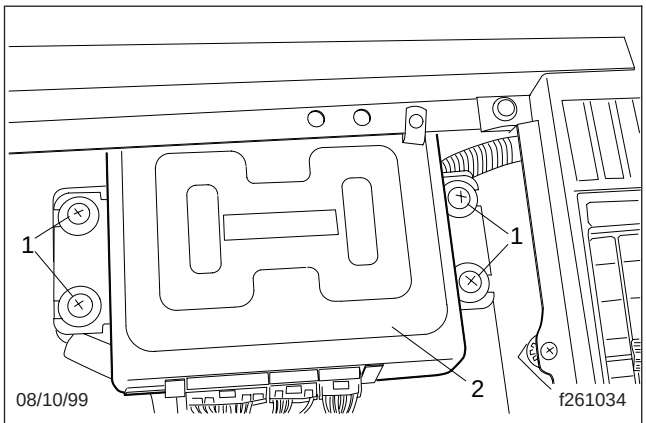


Transmission Replacement

38. Road test the vehicle and check for correct transmission operation.

ECU Replacement

The ECU is located inside the cab, behind the passenger-side upper dash panel. Follow the steps to replace the ECU.



1. Remove the molding strip on the top end of the dash panel. See **Fig. 1**.

1. Molding Strip
2. Passenger-Side Dash Panel

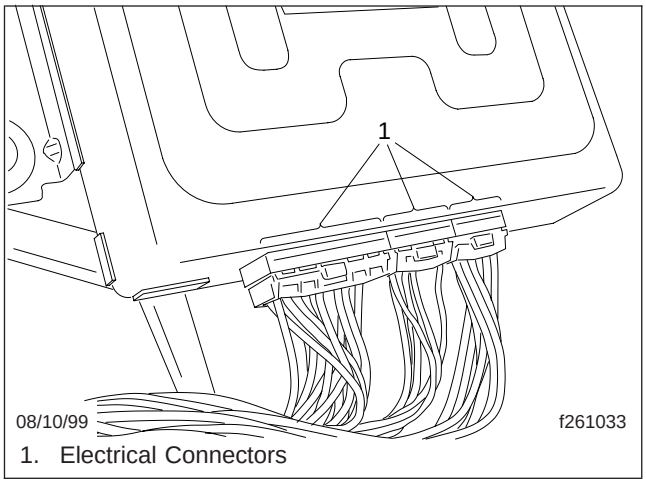


Fig. 1, Molding Strip on Dash

2. Under the molding strip are two screws securing the dash panel. Remove the two screws.
3. Remove the panel.
4. Remove the four screws securing the ECU to the mounting bracket. See **Fig. 2**.
5. Pull the ECU away from the mounting bracket.
6. Disconnect all three electrical connectors from the ECU. See **Fig. 3**.
7. Connect the electrical connectors to the new ECU.
8. Install the new ECU onto the bracket, and fasten it with the screws.
9. Install the dash panel.
10. Install the molding strip.

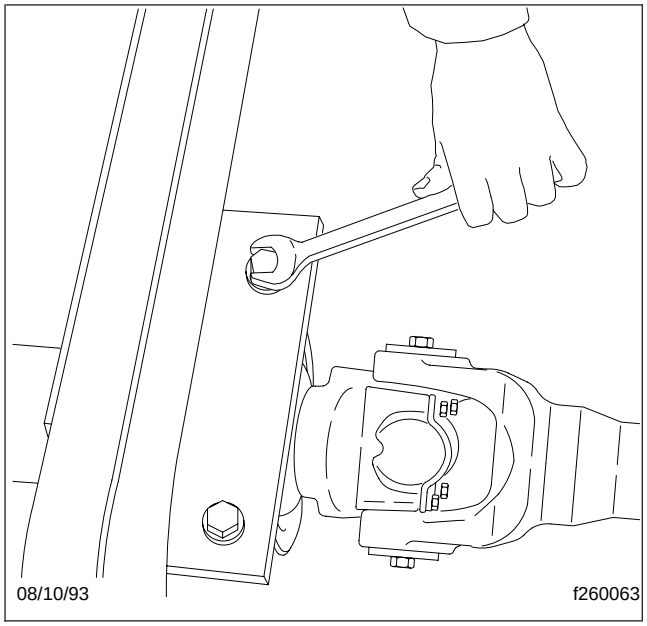
Replacement

1. Apply the parking brake, chock the tires, and disconnect the batteries.
2. Support the driveline with a jack stand at the midship bearing.
   - 2.1 Loosen the bolts holding the midship bearing bracket so the driveshaft can slide to the rear. See **Fig. 1**.



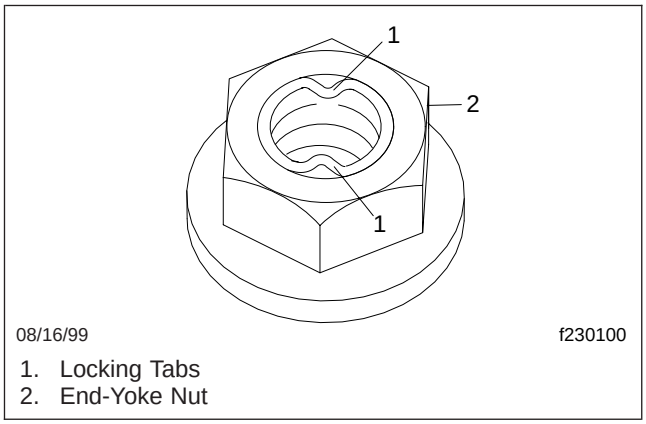


Fig. 1, Loosen the Midship Bearing Bolts

   - 2.2 Remove the transmission yoke U-joint end caps or lock straps
   - 2.3 Slide the front of the driveshaft off the driveline brake flange or out of the transmission output yoke.

NOTE: It may be necessary to remove the mounting bolts from the midship bearing bracket so the driveshaft can be moved far enough back.

   - 2.4 Support the disconnected driveshaft and tie it to the frame rail.
3. Pry open the locking tabs on the nut. See **Fig. 2**.

1. Locking Tabs
2. End-Yoke Nut

Fig. 2, End-Yoke Nut

4. Secure the end-yoke so it will not rotate and remove the end-yoke nut.

NOTE: Transmission fluid (ATF) may partially drain after removing the end yoke.

5. Slide the end yoke off the end of the output shaft. Discard the O-ring.
6. Remove the oil seal. See **Fig. 3**.

End-Yoke and End-Yoke Seal Replacement

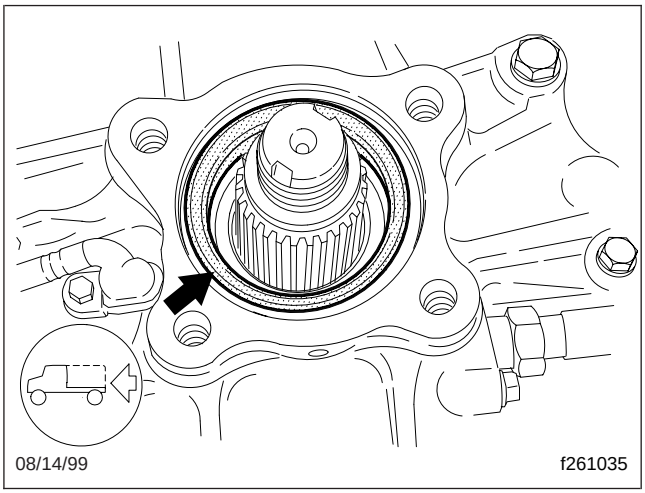

Fig. 3, End-Yoke Seal

7. Using the special oil seal installation tool (Kent Moore p/n J-44434), install the new oil seal. The tool will set the seal in the transmission. See **Fig. 4**.

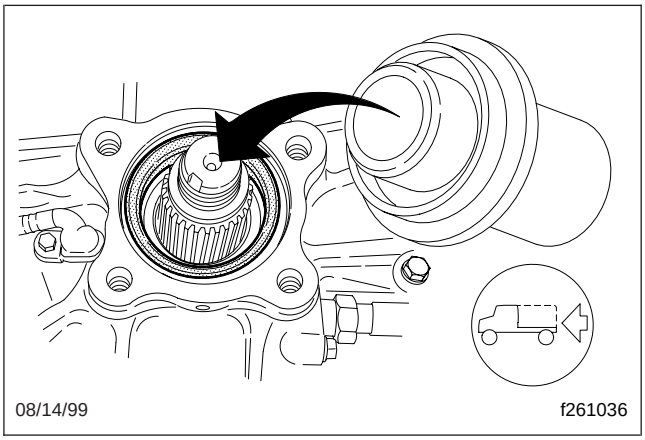

Fig. 4, Install the Seal with the Tool

8. Wipe away any loose particles at the opening point of the end yoke and lubricate it with grease or ATF.
9. Install the new end yoke (if replacing end-yoke, otherwise use the existing yoke) onto the output shaft slowly. Be careful not to damage the oil seal when installing.

IMPORTANT: The O-ring must be replaced each time the end yoke is removed.

10. Apply ATF to the new O-ring and install it into the groove between the end yoke and the output shaft.
11. Install the end yoke nut and tighten by hand.

⚠ CAUTION

Do not over tighten the end-yoke nut. Over torquing the nut could result in severe damage to the O-ring. O-ring damage can cause transmission fluid to leak.

12. Tighten the end yoke nut 181 to 214 lbf·ft (245 to 290 N·m).
13. Connect the driveshaft.
    - 13.1 Slide the front of the driveshaft into the transmission output yoke.
    - 13.2 Install the transmission yoke U-joint end caps or lock straps.
    - 13.3 If the midship bearing bracket bolts and nuts were removed, install them. Tighten the nuts 95 lbf·ft (129 N·m).
14. Remove the chocks from the tires.
15. Check the ATF level. Add fluid as needed.
16. Road test the vehicle, and check for correct transmission operation.

Troubleshooting

The oil temperature light on the instrument panel is the primary diagnostic tool for the Aisin automatic transmission. The light should remain off during normal operation but will either illuminate or flash to indicate a problem. See **Table 1** for troubleshooting symptoms, potential causes, and solutions.

IMPORTANT: If the vehicle is experiencing symptoms similar to those described in one of the diagnostic codes but the oil temperature light is not flashing, confirm that a light bulb was installed in the IL14 port of the instrument cluster. See **Fig. 1**. Vehicles built prior to April 2000 may be missing this bulb (reference Field Service Campaign SF206A/SC206A). If this bulb was installed, confirm that it is seated properly and that the circuit is complete.

If the oil temperature light is flashing:

1. The oil temperature light will flash in the generic pattern (1.2 seconds ON, 0.5 seconds OFF, 1.2 seconds ON, etc.).
2. Disconnect the diagnostic code connector at the ECU, as follows. See **Fig. 2**. The specific diagnostic codes will only flash when this diagnostic-code connector is disconnected.
   - 2.1 Open the lower dash panel on the passenger side.
   - 2.2 Follow the wiring from the bulkhead connector 14 inches (355 mm), or from the transmission ECU 36 inches (914 mm) to the looped diagnostic code connector.

   NOTE: Vehicles built prior to July 1, 1999, have a looped, 8-pin, combined options/diagnostic code connector. Vehicles built after July 1, 1999, have a looped, 4-pin diagnostic code connector and a separate 8-pin options connector.
3. Identify the specific diagnostic code. The specific codes will be displayed every 2.4 seconds.
   - The first digit will be illuminated for 0.3 seconds each, separated by 0.5 second off intervals.
   - The second digit (if any) will be illuminated for 1.3 seconds each, separated by 0.5 second off intervals.
   - The third digit (if any) will be illuminated for 0.3 seconds each, separated by 0.5 second off intervals.

   NOTE: If there is more than one diagnostic code to be displayed, the lowest number of the codes will be displayed first and then the higher number.

   See **Fig. 3** for a sample diagnostic code.
4. Locate the specific diagnostic codes in **Table 2**. Then, locate the troubleshooting guide for that particular diagnostic code in this subject (e.g. *Troubleshooting Diagnostic Code 143*).

IMPORTANT: The vehicle ignition must be left on to clear the fault codes. If the ignition is turned off prior to reconnecting the connector, the diagnosis will be stored within the memory and may reappear and cause confusion if a new problem arises.

5. Clear the diagnostic fault codes by reconnecting the diagnostic code connector at the ECU while the vehicle ignition is left on. See **Fig. 2**.

Oil Temperature Light Troubleshooting		
Condition	**Cause**	**Solution**
oil temperature light is off	normal operation	No fix needed.
oil temperature light is on	sharp rise in transmission oil temperature	Stop driving the vehicle and continue idling until the oil temperature drops to the normal level and the lamp goes out.
	short circuit of oil temperature lamp or the transmission system wiring	Inspect the wiring of the transmission oil temperature warning lamp. If a short circuit is found, repair the circuit.
	transmission oil temperature switch failure	Inspect the oil temperature switch. If defects are found, replace the switch.

Troubleshooting

Oil Temperature Light Troubleshooting		
Condition	**Cause**	**Solution**
oil temperature light is flashing	problem with the transmission system	Disconnect the diagnostic code terminal and identify the flash pattern, then begin troubleshooting to detect causes and locate defective parts. For diagnostic code troubleshooting, see **Table 2**.

Table 1, Oil Temperature Light Troubleshooting

Diagnostic Code Definition			
Diagnostic Code	**Problem**	**Potential Causes**	**Vehicle Status**
25	Speed Sensor	• open or short circuit in speed sensor system • speed sensor failure	• Ordinary running is possible. However, when the turbine revolution sensor is not functioning, the automatic speed change function does not work.
2	Turbine Revolution Sensor	• open or short circuit in turbine revolution sensor system • turbine revolution sensor failure	• Ordinary running is possible. However, when both the speed sensor and the turbine revolution sensor are out of order, the automatic speed change function does not work.
143	Neutral Start Switch	• open or short circuit in neutral switch system • the control of the shift lever does not conform with operation of the neutral start switch. • misplacement of switch • neutral start switch failure	• When the shift lever is set to the range 3, 2, and L by manual shift operation, automatic speed change is not performed. The shift to the range N and R indicates no problem.
24	Pulse Width Modulation Sensor	• throttle sensor failure • engine ECU failure • open or short circuit in throttle signal harness • transmission ECU failure • throttle sensor output does not conform to the throttle opening rate due to adjustment error.	• Severe shock during speed change. • During acceleration, forward shifting occurs too early (resulting in insufficient acceleration) or too late.
341	Solenoid #1	• open or short circuit in solenoid No. 1 system • solenoid No. 1 failure	• Abnormal speed shift (except when in drive range, 2nd gear shift is skipped).
342	Solenoid #2	• open or short circuit in solenoid No. 2 system • solenoid No. 2 failure	• Abnormal speed shift (except when in drive range, speed is shifted directly to fourth gear).

Diagnostic Code Definition			
Diagnostic Code	**Problem**	**Potential Causes**	**Vehicle Status**
343	Solenoid #3	• open or short circuit in solenoid No. 3 system • solenoid No. 3 failure	• Abnormal speed shift (except when in drive range, speed is shifted directly to the 3rd gear).
335	Lock-up Solenoid	• open or short circuit in lock-up solenoid system • lock-up solenoid failure	• No lock-up occurs, or, during low-speed driving, lock-up occurs immediately after the shift to 2nd gear; hence vibration occurs from T/C.
21	Oil Temperature Sensor	• open or short circuit in oil temperature sensor system • oil temperature sensor failure	• Despite A/T being sufficiently warmed up, gear change shock is severe for a while after driving.
347	Linear Solenoid Problem	• open or short circuit in linear solenoid system • linear solenoid failure	• Speed change caused shock is extremely severe during low throttle opening rate.

Table 2, Diagnostic Code Definition

Troubleshooting Diagnostic Codes 341, 342, 343, 335

1. Confirm that all transmission ECU connectors are properly connected, and conduct a visual inspection of the circuits.
2. Check item voltage or resistance, as follows. See **Table 3**.

Table 3, ECU Connector Check Item List

3. Check the automatic transmission harness.
4. If steps 1 through 3 are all good, replace the transmission ECU. For instructions, see **Subject 150**.

   If the problem is not solved, go to the next step.

   If the problem is solved, skip to the last step under this heading.
5. Check the connectors, as follows.

   5.1 Remove all connectors and check for wire disconnection at the terminals caused by excessive harness tension, rust on the terminals, and contact failure on the terminals caused by foreign matter.

   5.2 Pull each wire to confirm that the terminals are securely connected. If the connector terminal stopper breaks, the terminal may slip off the connector even when the connector body is engaged with the harness.

   5.3 Remove corrosion and dust from the terminals.

   IMPORTANT: Do not use chlorine, petroleum detergent, or conductive detergent to clean terminals. Use a cleaning solvent that easily evaporates to prevent condensation inside connectors. Before attaching connectors to their counterparts or hardware, blow or shake off excess solvent to prevent deterioration of the connector seals.
6. Test drive the vehicle.

   If the problem is still present, continue on to the next step.

   If the problem is solved, skip to the last step under this heading.
7. Examine the wire harness for defects, as follows.

   7.1 Remove the connectors.

   7.2 At one side of the harness, connect the wire to be inspected to the appropriate terminal using a jumper, forming a circuit.

   7.3 At the other side of the harness, check the conductivity of the wire connected by the jumper.

   7.4 Measure the resistance. If the resistance is 0 or close to 0 ohms, there is no wire disconnection. If the resistance is infinite, there is a wire disconnection. Locate and repair the breakage.

   If the problem is still present, continue to the next step.

   If the problem is solved, skip to the last step under this heading.
8. Test for wire harness short circuits, as follows.

   8.1 Place one probe of the tester on one terminal of the circuit to be inspected. With the other test probe, make contact with each terminal of the connectors and chassis ground.

   8.2 Measure the resistance. If the resistance is close to 0 ohms, there is a short circuit. Locate and repair the short.

9. Test drive the vehicle.
10. If the problem is not resolved, replace the harness assembly and test drive the vehicle again. If the problem is not solved, contact Aisin for approval to remove and replace the transmission.
11. Clear the diagnostic codes.

Troubleshooting Diagnostic Codes 2, 21, 25, 347

1. Confirm that all transmission ECU connectors are properly connected, and conduct a visual inspection of the circuits.
2. Check item voltage or resistance, as follows. See **Table 3**.
   - 2 Diagnostic Code — Check item 16 (Turbine Revolution Sensor Ground)
   - 21 Diagnostic Code — Check item 20 (Oil Temperature Sensor Ground)
   - 25 Diagnostic Code — Check item 18 (Speed Sensor Ground)
   - 347 Diagnostic Code — Check item 30 (Linear Ground)
3. If the above steps indicate no problems, go to the next step.

   If any of the previous steps show problems, replace the ECU. For instructions, see **Subject 110**.

   If the problem still exists after ECU replacement, go to the next step.

   If the problem is solved, skip to the last step under this heading.
4. Check item voltage or resistance, as follows. See **Table 3**.
   - 2 Diagnostic Code — Check item 15 (Turbine Revolution Sensor)
   - 21 Diagnostic Code — Check item 19 (Oil Temperature Sensor)
   - 25 Diagnostic Code — Check item 17 (Speed Sensor)
   - 347 Diagnostic Code — Check item 29 (Linear Solenoid)
5. If the voltage or resistance is acceptable, replace the ECU. For instructions, see **Subject 110**.

   If, after replacing the ECU, the problem is not solved continue to the next step.

   If, after replacing the ECU, the problem was solved, skip to the last step under this heading.
6. Check the connectors, as follows.

   6.1 Remove all connectors and check for: wire disconnection at the terminals caused by excessive harness tension; rust on the terminals; and contact failure on the terminals caused by foreign matter.

   6.2 Pull each wire to confirm that the terminals are securely connected. If the connector terminal stopper breaks, the terminal may slip off the connector even when the connector body is engaged with the harness.

   6.3 Remove corrosion and dust from the terminals.

   IMPORTANT: Do not use chlorine, petroleum detergent, or conductive detergent to clean terminals. Use a cleaning solvent that easily evaporates to prevent condensation inside connectors. Before attaching connectors to their counterparts or hardware, blow or shake off excess solvent to prevent deterioration of the connector seals.
7. Test drive the vehicle.

   If the problem was not solved, continue to the next step.

   If the problem was solved, skip to the last step under this heading.
8. Test for wire harness short circuits, as follows.

   8.1 Place one probe of the tester on one terminal of the circuit to be inspected. With the other test probe, make contact with each terminal of the connectors and chassis ground.

   8.2 Measure the resistance. If the resistance is close to 0 ohms, there is a short circuit. Locate and repair the short.
9. Test drive the vehicle.
10. If the problem is not solved, replace the harness assembly and test drive the vehicle again.

    If the problem was not solved, continue to the next step.

If the problem was resolved after replacing the harness, skip to the last step under this heading.

11. Complete the following.
    - 2 Diagnostic Code – Contact Aisin for approval to remove and replace the transmission.
    - 21 Diagnostic Code — Contact Aisin for approval to remove and replace the transmission.
    - 25 Diagnostic Code — Replace the speed sensor (part number located in service parts list).
    - 347 Diagnostic Code — Replace the linear solenoid (part number located in service parts list).
12. Clear the diagnostic codes.

Troubleshooting Diagnostic Code 143

1. Confirm that all transmission ECU connectors are properly connected, and conduct a visual inspection of the circuits.
2. Check items 7 through 12 in **Table 3**.
3. If the above procedures show no problems, replace the transmission ECU. For instructions, see **Subject 110**.

   If the problem is not solved, continue to the next step.

   If the problem was corrected, go to the last step under this heading.
4. Check the connectors, as follows.

   4.1 Remove all connectors and check for: wire disconnection at the terminals caused by excessive harness tension, rust on the terminals, and contact failure on the terminals caused by foreign matter.

   4.2 Pull each wire to confirm that the terminals are securely connected. If the connector terminal stopper breaks, the terminal may slip off the connector even when the connector body is engaged with the harness.

   4.3 Remove corrosion and dust from the terminals.

   IMPORTANT: Do not use chlorine, petroleum detergent, or conductive detergent to clean terminals. Use a cleaning solvent that easily evaporates to prevent condensation inside connectors. Before attaching connectors to their counterparts or hardware, blow or shake off excess solvent to prevent deterioration of the connector seals.
5. Test drive the vehicle.

   If the problem is still present, go to the next step.

   If the problem is solved, skip to the last step under this heading.
6. Examine the wire harness for defects, as follows.

   6.1 Remove the connectors.

   6.2 At one side of the harness, connect the wire to be inspected to the appropriate terminal using a jumper, forming a circuit.

   6.3 At the other side of the harness, check the conductivity of the wire connected by the jumper.

   6.4 Measure the resistance. If the resistance is 0 or close to 0 ohms, there is no wire disconnection. If the resistance is infinite, there is a wire disconnection. Locate and repair the breakage.
7. Test drive the vehicle.

   If the problem is not solved, continue to the next step.

   If the problem is solved, skip to the last step under this heading.
8. Test for wire harness short circuits, as follows.

   8.1 Place one probe of the tester on one terminal of the circuit to be inspected. With the other test probe, make contact with each terminal of the connectors and chassis ground.

   8.2 Measure the resistance. If the resistance is close to 0 ohms, there is a short circuit. Locate and repair the short.
9. Test drive the vehicle.

   If the problem was not solved, replace the harness assembly and test drive the vehicle again.

   If the problem is not solved, go to the next step.

If the problem is solved, go to the last step under this heading.

10. Adjust the neutral start switch, as follows. See **Fig. 6**.

1. Manual Valve Shaft Nut
2. Manual Valve Shaft
3. Neutral Start Switch
4. Fixing Bolt

Fig. 6, Neutral Start Switch

10.1 Set the manual valve shaft to position N using the manual lever.

10.2 Loosen the fixing bolt to allow the neutral start switch to rotate in the rotating direction of the manual valve shaft.

10.3 Rotate the neutral start switch and visually align the baseline N with the centerline passing through the flats of the manual valve shaft.

10.4 Torque the fixing bolts to 8 to 11 lbf·ft (10 to 16 N·m).

10.5 Recheck by eye that the baseline N is aligned with the centerline passing though the flats of the manual valve shaft.

10.6 Repeat step 2. Check items 7 through 12 in **Table 3**.

11. Test drive the vehicle.

    If the problem is still present, contact Aisin for approval to remove and replace the transmission.

12. Clear the diagnostic codes.

Troubleshooting Diagnostic Code 24

1. Confirm that all transmission ECU connectors are properly connected, and conduct a visual inspection of the circuits.
2. Check item 21 in **Table 3**.
3. Confirm that the transmission ECU connector VA pin voltage is constant and at 9.5 to 15.5 volts.

   If the VA pin voltage is constant and correct, skip to the last step under this heading.

   If the VA pin voltage is constant but incorrect, go to the next step.

   If the VA pin voltage varies, replace the transmission ECU and drive test the vehicle. For instructions on ECU replacement, see **Subject 110**.

   If the problem is not solved, continue to the next step.

   If the problem is solved, skip to the last step under this heading.
4. Check the connectors, as follows.

   4.1 Remove all connectors and check for: wire disconnection at the terminals caused by excessive harness tension, rust on the terminals, and contact failure on the terminals caused by foreign matter.

   4.2 Pull each wire to confirm that the terminals are securely connected. If the connector terminal stopper breaks, the terminal may slip off the connector even when the connector body is engaged with the harness.

   4.3 Remove corrosion and dust from the terminals.

   IMPORTANT: Do not use chlorine, petroleum detergent, or conductive detergent to clean

terminals. Use a cleaning solvent that easily evaporates to prevent condensation inside connectors. Before attaching connectors to their counterparts or hardware, blow or shake off excess solvent to prevent deterioration of the connector seals.

5. Test drive the vehicle.

   If the problem is not solved, go to the next step.

   If the problem is solved, skip to the last step under this heading.

6. Examine the wire harness for defects, as follows.

   6.1 Remove the connectors.

   6.2 At one side of the harness connect the wire to be inspected to the appropriate terminal using a jumper, forming a circuit.

   6.3 At the other side of the harness, check the conductivity of the wire connected by the jumper.

   6.4 Measure the resistance. If the resistance is close to 0 ohms, there is no wire disconnection. If the resistance is anything but 0 ohms, there is a wire disconnection. Locate and repair the breakage.

7. Test drive the vehicle.

   If the problem did not go away, continue to the next step.

   If the problem is solved, skip to the last step under this heading.

8. Test for wire harness short circuits, as follows.

   8.1 Place one probe of the tester on one terminal of the circuit to be inspected. Make contact with each terminal of the connectors and chassis ground with the other test probe.

   8.2 Measure the resistance. If the resistance is close to 0 ohms, there is a short circuit. Locate and repair the short.

9. Test drive the vehicle.

   If the problem did not go away, replace the harness assembly and test drive the vehicle again.

   If the problem is not solved, continue to the next step.

   If the problem is solved, skip to the last step under this heading.

10. Check the engine ECU for fault codes.

    If the engine is not registering a TPS fault code, troubleshoot the engine ECU. See **Group 01**.

11. Test drive the vehicle.

12. Clear the diagnostic codes.

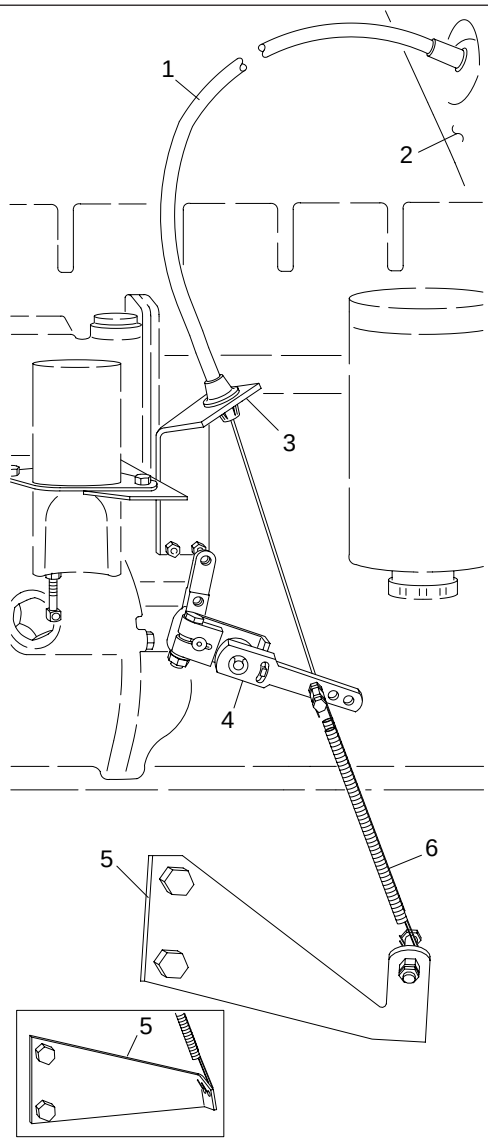
Table 2, Aisin Parts List

General Description

Cummins B and C Series engines use a cable to connect the throttle pedal to the throttle lever on the engine. Vehicles built before June 1993 are equipped with a nonadjustable cable. From June 1993, the throttle cable can be adjusted at the throttle cable bracket. For examples see **Fig. 1**, **Fig. 2**, or **Fig. 3**. The cable runs from the pedal, through the frontwall, and directly to the engine throttle lever. Return springs return the throttle lever to the idle position when pressure on the throttle pedal is released.

Right-hand-drive vehicles with B-series engines use a deck-mounted throttle pedal with mechanical linkage. See **Fig. 4**. The cable runs across the top of the frontwall, and then down to the engine. See **Fig. 5**.



When depressed, the throttle pedal pulls the cable, and the cable pulls the engine throttle lever up to increase fuel delivery to the engine. The cable length enables the throttle pedal to operate the throttle lever through its full range, from idle to full throttle. The cable conduit prevents any interference with, or wear on, the throttle cable.

The throttle lever consists of two parts held in alignment by a breakover spring. See **Fig. 6** and **Fig. 7**. The rear half of the lever connects to the throttle cable. The forward half connects to a shaft which controls the fuel injection pump rack. As the throttle cable pulls the lever upward or releases it downward, the lever rotates the shaft to increase or decrease fuel delivery to the fuel injectors.

When the throttle cable pulls the rear half of the throttle lever as far upward as the injection pump shaft will rotate, additional force applied at the throttle pedal overcomes the breakover spring in the throttle lever. See **Fig. 8**. This allows the rear portion of the throttle lever to continue rotating upward as the throttle cable pulls, but the injection pump shaft is not forced to rotate beyond its rotation limit.

A throttle pedal stop prevents the cable from pulling the throttle lever beyond the breakover range.

Vehicles equipped with automatic transmissions have a throttle position sensor which is connected to the throttle lever by a cable. See **Fig. 9**, **Fig. 10**, **Fig. 11**, or **Fig. 12**.

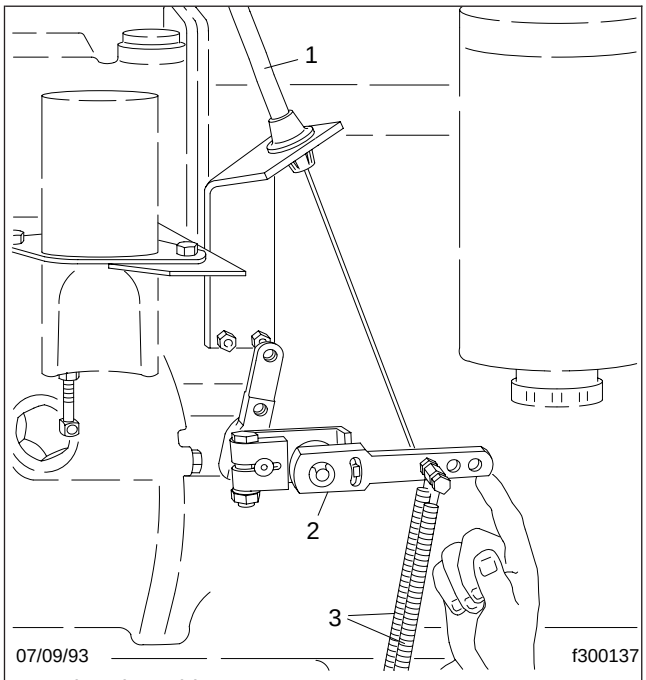
Nonadjustable Throttle Control Cable Operation Checking

Operation Checking

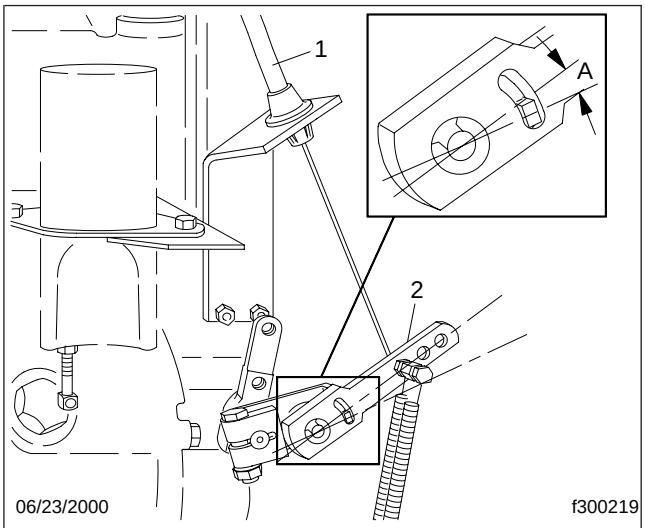


1. Shut down the engine, set the parking brake, and chock the tires. Tilt the hood.
2. Check the linkage attachment fasteners for tightness; tighten any that are loose.
3. Operate the throttle lever by hand, from idle to full throttle, while checking that nothing interferes with movement of the throttle lever or of the throttle pedal. Reposition any parts that interfere.
4. Operate the throttle lever by hand, from idle to full throttle, while checking that the return springs pull the throttle lever back to idle when the lever is released. See **Fig. 1** and **Fig. 2**.

1. Throttle Cable
2. Throttle Lever
3. Return Springs

Fig. 1, Idle Position

5. Inspect the return springs, as follows:
   - 5.1 Disconnect the anchor hook of each spring from the throttle lever, then disconnect each spring from the spring bracket.



1. Throttle Cable
2. Throttle Lever
3. Return Springs

Fig. 2, Partial Throttle

   - 5.2 Inspect the springs, especially in the area of the anchor loops, for wear, nicks, or other damage that might cause breakage.
   - 5.3 Measure the springs for stretching. The relaxed spring should be no longer than 9.4 inches (238 mm), from the outside of one anchor loop to the outside of the opposite anchor loop.
   - 5.4 If the springs are worn, damaged, or stretched, install new springs.
   - 5.5 Install the springs by inserting one end of each spring into the holes, or around the bolt in the spring bracket. Then hook the opposite ends of the springs on the throttle lever.
6. Operate the pedal, from idle to the pedal stop, while checking that the throttle cable pulls the throttle lever into the breakover range. See **Fig. 3**.
7. Lower the hood. Remove the chocks from the tires.

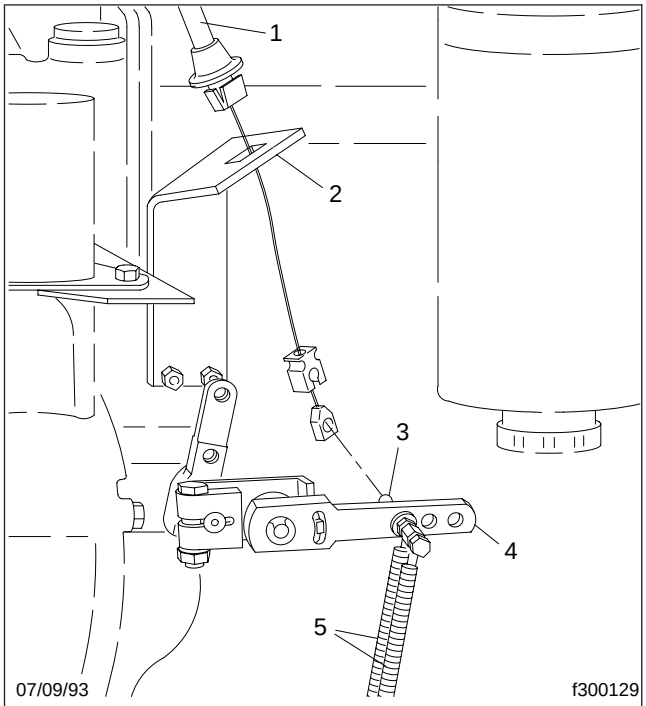
8. Test drive the vehicle and ensure that the throttle system operates properly.

Removal

1. Shut down the engine, set the parking brake, and chock the tires. Tilt the hood.
2. Lift the throttle pedal to get some slack in the throttle cable as it comes through the frontwall. See **Fig. 1**.

   For Right-Hand-Drive Vehicles: Remove the cable from the mounting bracket on the frontwall.



Note: Lift the pedal to get slack in the throttle cable.

3. Pry out the plastic bushing that holds the cable end in the throttle pedal lever. See **Fig. 1**. Take the bushing off of the cable, and remove the cable from the pedal lever.
4. Remove the cable clamp nut and toothed lock washer from the cable conduit at the frontwall, inside the cab. See **Fig. 1**.

   For Right-Hand-Drive Vehicles: Disconnect the yoke from the throttle pedal assembly, under the deck.
5. Pass the cable out through the frontwall.
6. Pull the plastic cover up, off of the cast-metal cable end, and remove the cable end from the ball stud in the throttle lever. See **Fig. 2** or **Fig. 3**.

1. Throttle Cable
2. Throttle Cable Bracket
3. Ball Stud
4. Throttle Lever
5. Return Springs

Fig. 2, Throttle Cable Connection to Throttle Lever

7. For nonadjustable throttle cables, slide the cable up through the hole in the throttle cable bracket.

Installation

1. Connect the throttle cable to the throttle pedal.
   - 1.1 Pass the cable through the frontwall into the cab. Make sure that the bulkhead seal washer is in place against the engine side of the frontwall.
   - 1.2 Secure the cable conduit at the frontwall with the toothed lock washer and the cable clamp nut. See **Fig. 1**. Tighten the nut 10 lbf·ft (13 N·m).

Throttle Cable Removal and Installation

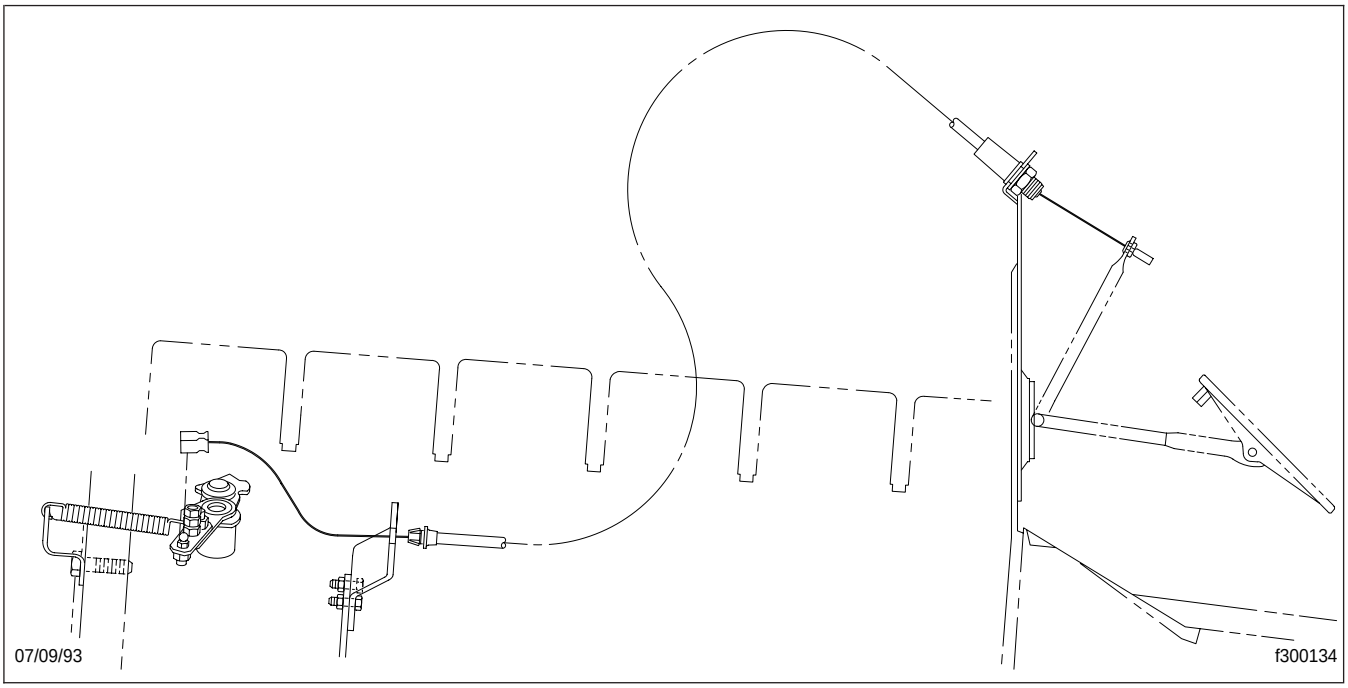

Fig. 3, Throttle Cable Connection to Throttle Lever

1.3 Thread the cable through the throttle pedal lever, and slip a new plastic bushing onto the cable (with the open slot of the bushing facing down) so that the cable end can't pass back through the lever. See **Fig. 1**.

1.4 Snap the bushing into the hole at the upper end of the throttle pedal lever.

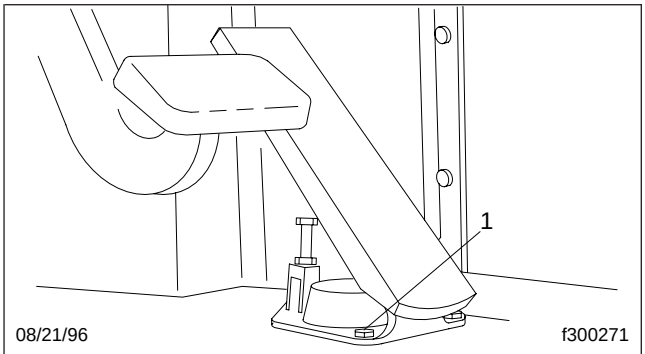
For Right-Hand-Drive Vehicles: Connect the yoke to the throttle pedal assembly, then install the rubber boot.

Attach the cable to the standoff bracket on the frontwall.

2. Inspect the ball stud in the throttle lever for wear. Replace it if necessary. If replacing the ball stud, apply Perma-Lock® MM 115 sealant or the equivalent to the ball stud threads, and secure the stud to the throttle lever with the nut (a locknut on C Series and 160 horsepower B Series engines, or a grooved nut on any other B Series engine). Tighten the nut 10 lbf·ft (13 N·m).

3. For a nonadjustable cable, thread the cable through the cable bracket hole, and assemble the cast-metal cable end onto the ball stud. Secure the joint by sliding the plastic cover down onto it.

4. Position the cable in the throttle bracket. For nonadjustable cables, secure the cable with the push-snap fitting.

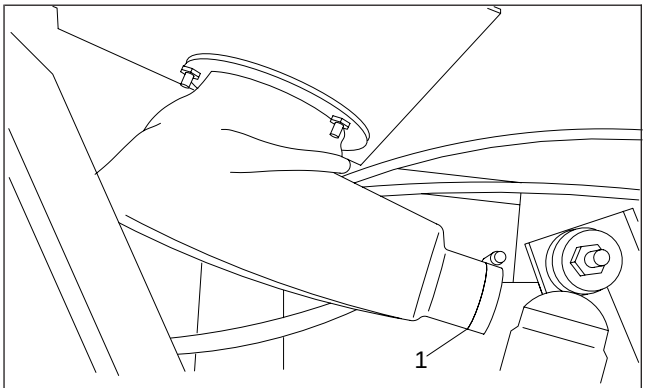


5. Lower the hood. Remove the chocks from the tires.

6. Test drive the vehicle and ensure that the throttle system operates properly.

Throttle Pedal Removal and Installation, Right-Hand Drive

Removal



1. Shut down the engine, set the parking brake, and chock the tires.
2. Remove the three pedal assembly-to-floorboard capscrews, washers, and nuts. See **Fig. 1**.

1. Pedal Assembly-to-Floorboard Capscrew

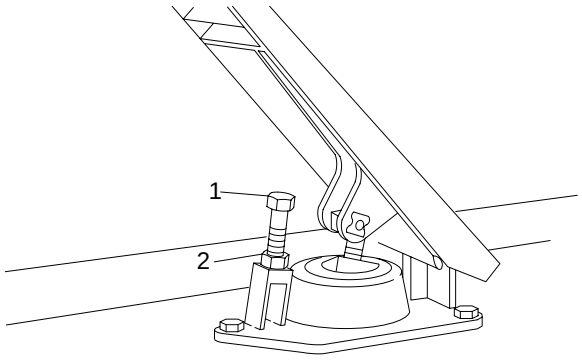
Fig. 1, Pedal Mounting

3. Remove the clamp and slide the boot off of the pedal assembly. See **Fig. 2**.

1. Boot Clamp

Fig. 2, Pedal Boot

4. Disconnect the throttle cable clevis from the pedal assembly.
5. Remove the cable clamp.
6. Remove the pedal assembly from the interior of the vehicle.



Installation

1. Position the pedal assembly on the deck, then install the three pedal assembly-to-floorboard capscrews, washers, and nuts. Tighten them securely.
2. From underneath the vehicle, connect the throttle cable clevis to the pedal assembly.
3. Install the boot and clamp onto the pedal assembly linkage.
4. Remove the chocks from the tires.
5. Test drive the vehicle and ensure that the throttle pedal operates properly.

Throttle Pedal Adjustments, Right-Hand Drive

Pedal Limit Stop Adjustment

1. Shut down the engine, set the parking brake, and chock the tires.
2. On the throttle pedal assembly, loosen the jam nut, and lower the limit stop screw. See **Fig. 1**.

Throttle Pedal Adjustments, Right-Hand Drive

4. Loosen the jam nut, and lower the limit stop screw.
5. Lightly depress the pedal to the wide open throttle position. Raise the limit stop screw until it touches the foot pedal. See **Fig. 2**.
6. Tighten the jam nut securely.
7. Remove the chocks from the tires.
8. Test drive the vehicle and ensure that the throttle pedal assembly operates properly.

General Description

A non-adjustable cable connects the Mercedes-Benz OM 366LA engine to the throttle pedal. **See Fig. 1.** The cable runs from the pedal, through the firewall, and directly to the engine throttle lever. The throttle lever is spring-loaded to return to the idle position.

Principles of Operation

When depressed, the throttle pedal pulls the cable, and the cable pulls the engine throttle lever up to increase fuel delivery to the engine. The cable length enables the throttle pedal to operate the throttle lever through its full range, from idle to full throttle. The cable conduit prevents any interference with or wear on the throttle cable.

The Bosch throttle lever consists of two parts held in alignment by a breakover spring. **See Fig. 2 and Fig. 3.** The rear half of the lever connects to the throttle cable. The forward half connects to a shaft which controls the fuel injection pump rack. As the throttle cable pulls the lever up or releases it down, it rotates the shaft to increase or decrease fuel delivery to the fuel injectors.

When the throttle cable pulls the rear half of the throttle lever as far up as the injection pump shaft will rotate, additional force applied at the throttle pedal overcomes the breakover spring in the throttle lever. **See Fig. 4.** This allows the rear portion of the throttle lever to continue rotating upward as the throttle cable pulls, but the injection pump shaft is not forced to rotate beyond its rotation limit.

A throttle pedal stop prevents the cable pulling the throttle lever beyond the breakover spring range.

Checking

1. Check the linkage attachment fasteners (cap-screws, locknuts, and hexnuts) for tightness; tighten any that are loose.
2. Operate the throttle by hand, from idle to full throttle, while checking that nothing interferes with movement of the throttle lever or the throttle pedal. Reposition any parts that interfere.
3. Operate the throttle by hand, from idle to full throttle, while checking that the throttle lever returns to idle when released, and that the throttle lever pulls the throttle pedal back up. **Refer to Fig. 1 and Fig. 2.**
4. Operate the throttle pedal by hand, from idle to the pedal stop, while checking that the throttle cable pulls the throttle lever into the breakover range. **Refer to Fig. 3.**

Throttle Cable Removal and Installation

Removal

1. Lift the throttle pedal to get some slack in the throttle cable as it comes through the firewall. **Refer to Fig. 1.**
2. Pry out the plastic bushing which holds the cable end in the throttle pedal lever. **Refer to Fig. 1.** Take the bushing off the cable, and remove the cable from the pedal lever.
3. Remove the cable clamp nut and toothed lockwasher from the cable conduit at the inside of the firewall. **See Fig. 1.**
4. Pass the cable out through the firewall.
5. Pull the plastic cover up, off the cast-metal cable end, and remove the cable end from the ball stud in the throttle lever. **Refer to Fig. 2.**
6. Remove the push-snap fitting from the throttle cable bracket. **Refer to Fig. 2.**
7. Slide the cable up through the hole in the cable bracket.

Installation

1. Pass the cable through the firewall into the cab. Make sure the bulkhead seal washer is in place against the engine side of the firewall.
2. Secure the cable conduit at the firewall with the toothed lockwasher and the cable clamp nut. **Refer to Fig. 1.** Tighten the clamp nut 14 N·m (10 lbf·ft).
3. Thread the cable through the throttle pedal lever, and slip a new plastic bushing onto the cable (with the open slot of the bushing facing up) so it can't pass back through the lever. **See Fig. 1.**
4. Snap the bushing into the hole at the upper end of the throttle pedal lever.
5. Inspect the ball stud in the throttle lever for wear, and replace if needed. If replacing the ball stud, apply Perma-Lock® MM 115 sealant or equivalent to the ball stud threads, and secure the stud to the throttle lever with the nut. Tighten the nut 13 N·m (10 lbf·ft).
6. Thread the cable through the cable bracket hole, and assemble the cast-metal cable end on the ball stud. Secure the joint by sliding the plastic cover down onto it.

Throttle Pedal Assembly

A Williams brand suspended, electronic throttle pedal is used in vehicles with Caterpillar, Cummins, and Detroit Diesel engines. See **Fig. 1**, **Fig. 2**, **Fig. 3**, and **Fig. 4**. The pedal is mounted to the inside of the frontwall and is connected by wiring to the engine control module.

NOTE: On vehicles with Detroit Diesel Series 50 engines, the pedal arm pulls an accelerator cable attached to the spring loaded spool assembly. The cable pulls the spool assembly and the assembly rotates. See **Fig. 4**.

The sensor, attached to the inboard side of the assembly, monitors how far the pinion gear (spool assembly on DDE Series 50 engines) rotates. Depending on how much the driver presses on the pedal, and the pedal rotates the pinion gear (or the cable rotates the spool assembly), the sensor signals the

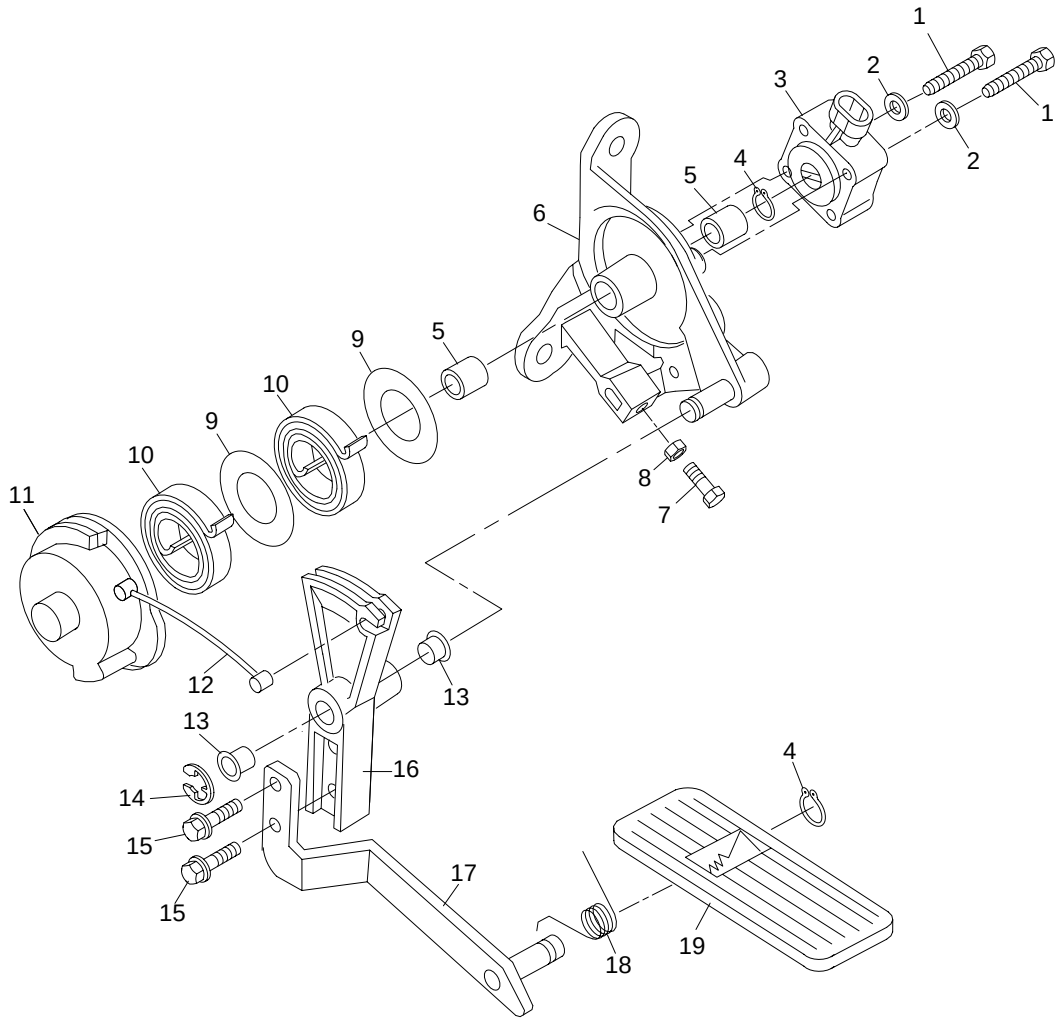
electronic engine control how much fuel to deliver to the engine.

When the driver stops pressing on the pedal, return springs within the pedal (or spool) assembly return the pedal to the original idle position. Only the pedal sensor is serviceable. If any other part of the pedal malfunctions, replace the entire pedal assembly.

Throttle Position Sensor

The throttle position sensor (TPS) is an electro-mechanical device that converts the mechanical input from the throttle pedal assembly into an electrical signal proportional to the input of the pedal. This electrical signal is fed to the engine ECU, which uses the signal to manage engine and engine accessory operations.

Two types of throttle position sensors are used on electronic engines:



- The first type is a ratiometric sensor that produces a linear voltage output in proportion to pedal input. The engine ECU uses a converter circuit to turn the analog voltage into a digital "count."
- The second type is a pulse-width modulated (PWM) sensor that generates a series of discrete voltage pulses. The width of the pulses is proportional to the pedal position. A narrower pulse width indicates a smaller throttle pedal request and a wider pulse width indicates a larger pedal request. The pulse width is termed the "duty cycle" of the TPS.

The linear-type sensor is used on Cummins and Detroit Diesel engines. The PWM sensor is used on Caterpillar engines.

The TPS can also provide an idle validation signal (IVS). At present, an IVS is only available on vehicles equipped with Cummins electronic engines. The IVS is a single-pole, dual-throw switch integral with the TPS. When the throttle pedal returns to idle, the IVS moves to the "idle" position to tell the engine ECU that the pedal has returned to idle. When the throttle pedal is moved off of idle, the IVS moves to an "off idle" position to tell the engine ECU that the pedal is no longer in the idle position. Unlike a switch, there is a transition point on the TPS where a high resistance between the IVS common lead and either of the output leads may appear.

When properly installed, the TPS does not operate in either the lower or the upper 10 to 15 percent of the full range of travel. The output signal from the TPS can never be zero volts or equal the supply voltage from the engine. If such a condition should occur, the engine ECU will report a TPS problem.

The input signal from the TPS to the engine ECU is converted to binary data for engine management re-

quirements. Detroit Diesel engines report the input voltage as "counts," one "count" being equal to about 0.005 volt. Caterpillar and Cummins engines convert the actual TPS position to a percentage TPS value. The percentage TPS value is scaled so that the values represent the sensor position in the allowed range of travel. A 0 percent value (3 percent for Caterpillar engines) corresponds to idle. A 100 percent value corresponds to full throttle. Raw data may be available for diagnosis, but percentage TPS values are displayed by the diagnostic tools and appear in troubleshooting manuals.

⚠ WARNING

To prevent personal injury, always wear eye protection and use caution when servicing pedal assemblies. Springs under tension could release suddenly and cause personal injury.

3. Disconnect the wiring harness from the throttle pedal. See **Fig. 1** and **Fig. 2**.
4. Remove the throttle pedal assembly from the vehicle.
   - 4.1 Remove the two locknuts and washers that secure the mounting plate to the two studs on the cab frontwall.
   - 4.2 Lift the pedal assembly off of the studs.

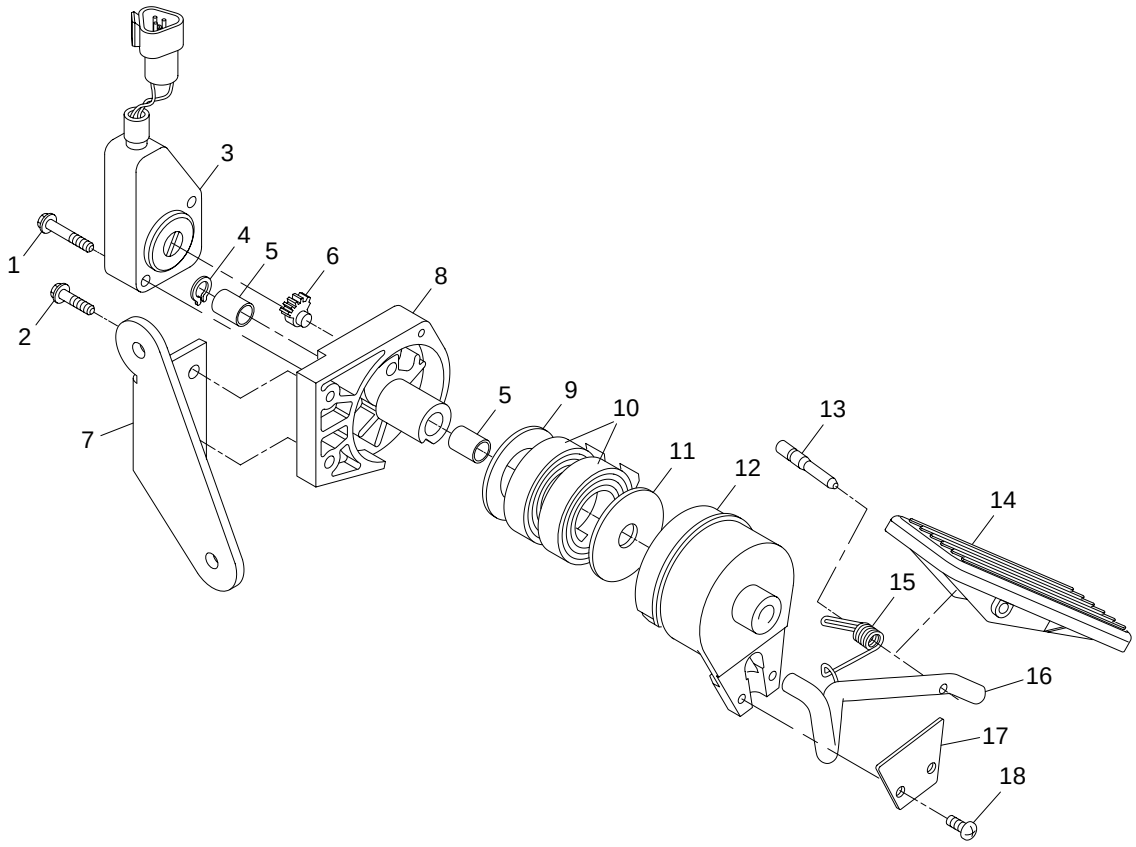
Installation



1. Install the throttle pedal assembly. See **Fig. 1** and **Fig. 2**.
   - 1.1 If applicable, make sure that the spacer is in place on the lower mounting stud, then position the mounting plate on the two studs on the inside of the cab frontwall.
   - 1.2 Secure the plate on the studs with two 5/16–18 locknuts, and tighten the locknuts securely.
2. Connect the wiring harness to the throttle pedal.
3. Connect the batteries.
4. Remove the chocks from the tires.
5. Test drive the vehicle and ensure that the throttle pedal operates properly.

Replacement

1. Shut down the engine, set the parking brakes, and chock the tires.
2. Disconnect the batteries.

NOTE: The sensor is not a serviceable part. If the sensor is malfunctioning, replace it.

3. Remove the sensor. See **Fig. 1**.
   - 3.1 Remove the two screws that hold the sensor to the throttle base.
   - 3.2 Disconnect the wiring harness from the throttle pedal sensor.
4. Install the sensor.
   - 4.1 Align the sensor with the pinion gear.
   - 4.2 Rotate the sensor so that the mounting holes line up, then secure the sensor with the mounting screws, and tighten the screws 15 to 20 lbf·in (160 to 220 N·cm).
   - 4.3 Connect the wiring harness to the sensor.
5. Connect the batteries and remove the chocks from the tires.

Throttle Pedal Sensor Timing (Caterpillar CFE Engine)

Sensor Timing

1. Shut down the engine, set the parking brake, and chock the tires.
2. Loosen the two screws that hold the sensor to the throttle base.
3. Connect the Caterpillar Digital Diagnostic Tool to the vehicle's electronic data link. With the pedal in the idle position, adjust the sensor by rotating the housing until the reader displays the correct output of 10 to 22 percent of duty cycle.

CAUTION

Do not overtighten the sensor screws. Overtightening the screws can damage the sensor.

4. After the sensor is adjusted to the correct specifications, tighten the two sensor screws 15 to 20 lbf·in (169 to 226 N·cm).
5. Tighten the wiring harness clamps.
6. Remove the chocks from the tires.

Troubleshooting Procedures

CAUTION

The throttle pedal assembly is designed so that the throttle position sensor (TPS) will not reach the internal stop points when it is mounted to the pedal assembly. Very little sensor rotational adjustment is available once the TPS is installed. Attempting to modify the TPS, in an effort to gain adjustment range, or forcing the TPS shaft beyond the internal stop points will result in severe damage to the TPS.

The TPS used with Caterpillar engines is a pulse-width modulated (PWM) sensor. It cannot be properly diagnosed with a digital multimeter set to measure voltage, resistance, or continuity. A multimeter capable of measuring "duty cycle" can be used to view the TPS output. Caterpillar engine diagnostic tools are recommended for viewing the percentage TPS reported by the engine ECU. Attempting to diagnose a PWM sensor assembly without the proper tools will result in damage to the TPS.

Common Problems and Indications

A number of symptoms may be reported which can indicate a problem with the throttle pedal, TPS, or wiring to the electronic engine, including:

- low power or poor acceleration
- the vehicle will not reach programmed top speed
- the engine is stuck at idle
- the engine brake or engine retarder does not function
- slow deceleration
- the check engine light comes on
- an engine fault code indicating a TPS problem appears

These symptoms do not always indicate a throttle pedal, TPS, or wiring problem. Symptoms can disappear when the TPS is replaced, however, the TPS may not be faulty. A thorough diagnosis of the entire TPS system must be performed to ensure that a TPS is faulty.

Preliminary Checks

1. Verify, by testing with the particular engine manufacturer's diagnostic software and tools, that the TPS is operating properly. For Cummins engines, also verify idle validation signal (IVS) inputs. See **Table 1**.

IMPORTANT: **Table 1** is a guide for common engine installations. It is necessary to verify the correct information for the specific engine installed in the vehicle.

2. If the engine manufacturer's diagnostic software and tools produce the readings shown in **Table 1**, the TPS is not at fault. If you are unable to produce the readings shown in **Table 1**, go to the next step.
3. Verify that the TPS is wired properly. See **Table 2**.

IMPORTANT: Reversing the TPS signal line and the ground line can result in a percentage TPS reading that does not change, and may also produce a fault code at the engine ECU. Reversing the TPS signal line and the +v supply line can prevent the TPS signal from reaching 100 percent. Reversing the +v supply line and the common line will result in the TPS providing "inverted" pedal information, or not working at all. Verify circuit positions and circuit designations in the engine ECU connector using the engine manufacturer's troubleshooting documentation.

NOTE: On Caterpillar engines, swapping any circuits may cause the TPS not to operate.

4. Check the voltage to the TPS. See **Table 3** for TPS connector pin locations.

IMPORTANT: The ignition key must be in the ON position. For Cummins and Detroit Diesel engines, disconnect the TPS connector at the TPS. For Caterpillar and Mercedes-Benz engines, use or fabricate a breakout harness. After diagnosis, clear any historical TPS fault codes to prevent misdiagnosis in the future.

NOTE: It is normal for the engine to report fault codes when the TPS connector is disconnected.

Troubleshooting

CAUTION

Do not perform the tests in steps 5, 6, and 7 on the PWM sensor used with Caterpillar engines. Doing so may result in serious damage to the TPS.

5. If you do not read the voltages shown in **Table 3**, test resistance on the +v supply and common circuits between the TPS and the engine connectors. Disconnect the OEM harness connector at the engine ECU.

IMPORTANT: For Caterpillar engines, also disconnect the TPS connector from the TPS. Ensure that the ignition key is in the OFF position before making any tests.

6. If a resistance greater than 10 ohms is read, there is a potential wiring problem. Correct any wiring problem before attempting further tests. If a wiring problem is discovered and repaired, go back and repeat step 1 to determine if this was the only problem.

NOTE: If circuit resistance is 10 ohms or less but the voltage is below that listed in **Table 3**, the engine ECU is probably faulty. If both voltage and circuit resistance are within spec, go to the next step.

7. For Cummins and Detroit Diesel TPS, check the resistance of the TPS at the OEM harness connector with a digital multimeter. Before making measurements, reconnect the TPS connector to the TPS. Leave the OEM harness connector disconnected. See **Table 4** for acceptable readings.

8. Inspect and ensure that all connector pins at the TPS sensor, frontwall, and engine ECU are free of corrosion and are not bent or damaged. Inspect and ensure that the connections between the pins and the wires are secure and also free of corrosion.

NOTE: If the TPS does not return to idle, one of two conditions exists. Either the IVS is faulty or the TPS signal voltage or PWM duty cycle, recorded by the engine ECU, is dropping significantly after the engine has calibrated the idle position.

9. On Cummins engines only, check and ensure that the IVS is working properly. If a problem is found with the IVS, replace the TPS with a new unit or one known to be good and continue testing. If no problem is found, go to the next step.

10. Remove the pedal assembly from the floor. Loosen (but do not remove) the TPS mounting screws. By hand, rotate the TPS sensor assembly as far as possible. Then, tighten the mounting screws securely. Check the operation of the TPS again.

NOTE: In some cases, it may be necessary to exchange the existing TPS with another because the TPS and pedal assembly tolerances result in an idle position too close to the edge of acceptable operation. In this situation, the TPS is probably not faulty and may perform acceptably in another pedal.

11. If the engine will not reach rated speed or recognize full throttle, the cause is something other than the TPS. Check the engine ECU parameters and reset them if necessary. Check and ensure that the TPS is wired correctly. Remove the TPS from the pedal assembly and move the pedal through the full range of operation. Watch the operation of the TPS actuator tab. Ensure that no parts are binding or broken.

12. If the TPS does not leave idle, check IVS operation (if so equipped) and ensure that the switch transitions from the idle to the off-idle state. Also, check for a signal on the appropriate wires at the engine ECU for both idle and off-idle states. On vehicles not equipped with an IVS, check and ensure that the TPS is connected correctly to the engine.

13. If the problem has still not been resolved, the problem is not with the TPS. See the engine manufacturer's service literature for further guidance.

General Description

An adjustable cable connects the throttle pedal to the throttle body on the Dodge Magnum V-8 and V-10 engines. **See Fig. 1** and **Fig. 2**. The cable runs from the pedal, through the firewall, and directly to the engine throttle body. Return springs on the throttle body shaft will return the throttle lever to the idle position when pressure on the throttle pedal is released. Engines equipped with manual transmissions have an additional pedal return spring. **See Fig. 3.**

When depressed, the throttle pedal pulls the cable, and the cable pulls the engine throttle lever to increase fuel delivery to the engine. The cable length enables the throttle pedal to operate the throttle lever through its full range, from idle to full throttle. To adjust the cable length, reposition the threaded cable end in the throttle body mounting bracket, and secure the cable with the cable clamp nuts. The cable housing prevents any interference with, or wear on, the throttle cable.

⚠ WARNING

WARNING: Be careful not to kink or damage the cable core wire (within the cable housing) while servicing the throttle pedal or cables. A damaged cable could cause loss of throttle control, possibly resulting in a vehicle crash and personal injury or property damage.

3. Lift the throttle pedal to get some slack in the throttle cable as it comes through the firewall. **See Fig. 2.**
4. Pry out the plastic bushing which holds the cable end in the throttle pedal lever. Take the bushing off the cable, and remove the cable from the pedal lever.

the cable adjustment is correct. If the transmission lever moves ahead of or lags behind the throttle body cam, adjust the cable. If the throttle body cam prevents the transmission lever from returning to the closed position, adjust the cable. Refer to the cable adjustment procedure that follows.

8. If the alignment is correct and the transmission lever and throttle cam move simultaneously, connect the engine end of the cable to the stud on the throttle body cam. Go to the last three steps in the Adjustment procedure.

Adjustment

1. If not already done, park the vehicle, shut down the engine, and set the parking brakes. Tilt the hood.
2. To access the throttle body, remove the air cleaner housing. **See Fig. 1.** For complete removal instructions, refer to **Group 09**.
3. Disconnect the cable end from the stud on the throttle body cam.
4. Make sure the transmission throttle control valve lever is in the fully closed position. Then, make sure the throttle body cam is in the idle position.
5. Find the cable lock button. **See Fig. 4.** The button is part of the cable retainer at the engine end of the cable.
6. Press the cable lock button to release the cable. The button only has to move about 2 mm to release the cable.

   Center the cable end on the attachment stud to within 1 mm and release the cable lock button.
7. Attach the cable end to the throttle body cam, and check that the transmission throttle control valve lever and the throttle body cam move simultaneously as described in the checking procedure, above.
8. Make sure all cable routing clamps are tight, and that the cable is securely connected to the transmission throttle control valve lever and the throttle body cam.
9. Install the air cleaner housing and tighten the mounting band 400 N·cm (35 lbf·in). For complete installation instructions, refer to **Group 09**.
10. Lower the hood, and test drive the vehicle.

General Information

IMPORTANT: This service manual *does not cover* the procedures and calculations necessary to perform frame modifications. For basic information, see the *Freightliner Body Builder's Manual*; for more extensive frame modifications, be sure to consult with the Freightliner Engineering Department.

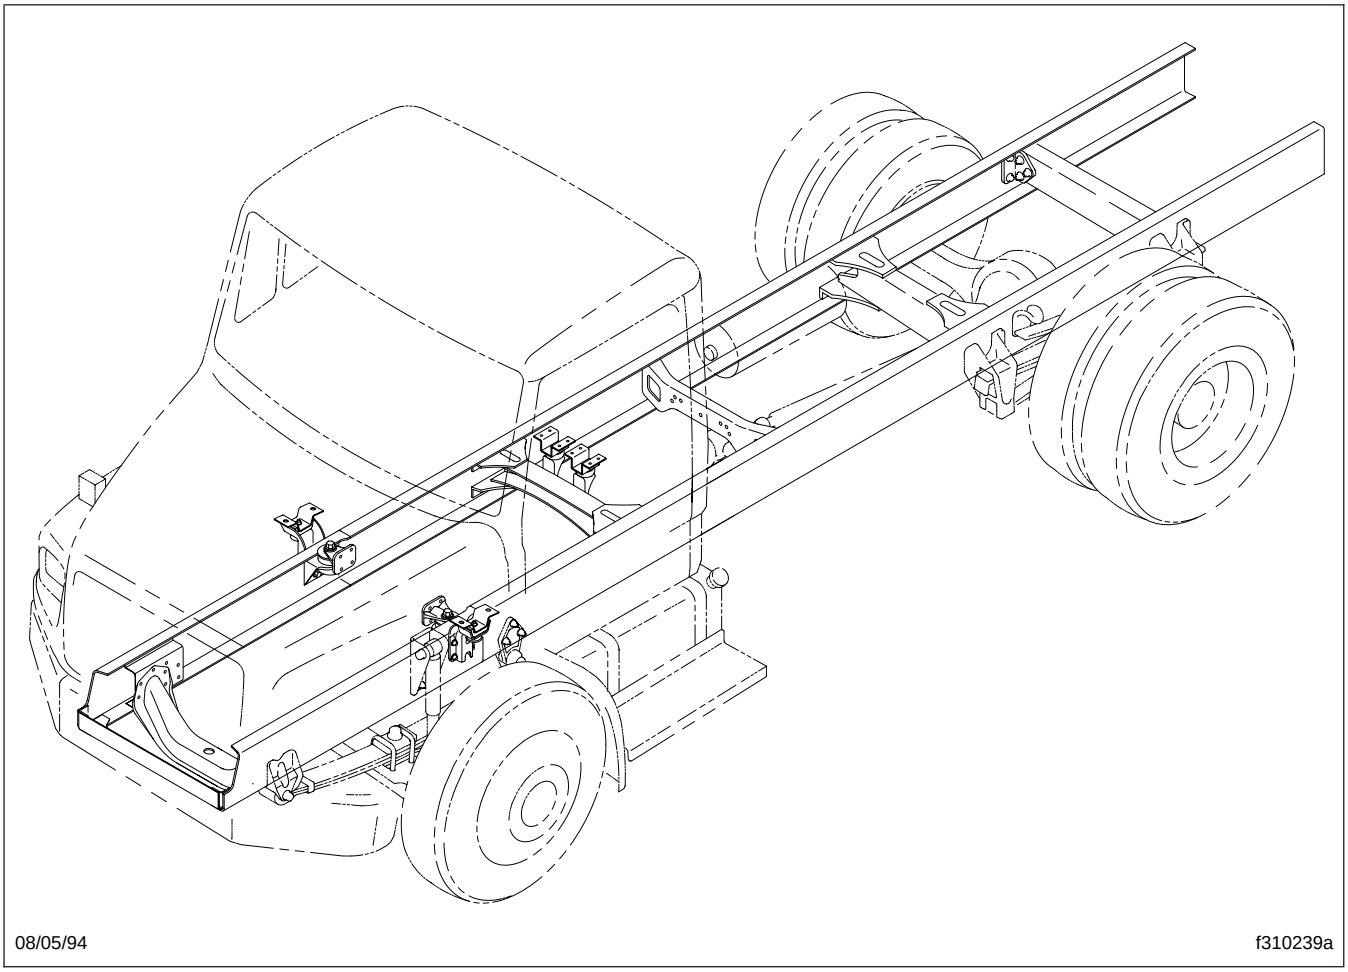
The main body of the frame is two non-heat-treated steel frame rails secured together by crossmembers. See **Fig. 1**. The frame assembly is supported on the front and rear axles, and supports the rest of the chassis and body.

Both frame rails have identical specifications. Each has an upper flange, lower flange, and web (the surface area between the flanges). The inside area of the frame rail is called the channel. See **Fig. 2**.

Crossmembers control axial rotation and longitudinal motion of the rails, and reduce torsional stress transmitted from one rail to the other. Crossmembers are also used for vehicle component mounting, and for protection of the wires and tubing that are routed from one side of the vehicle to the other.

FRAME STATIONS

A frame station is a reference point along each frame rail from which the location of each component



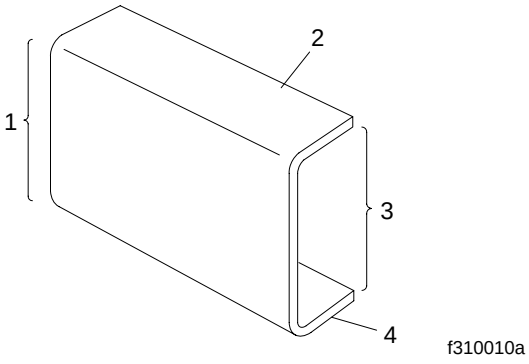


Fig. 1, Frame Assembly

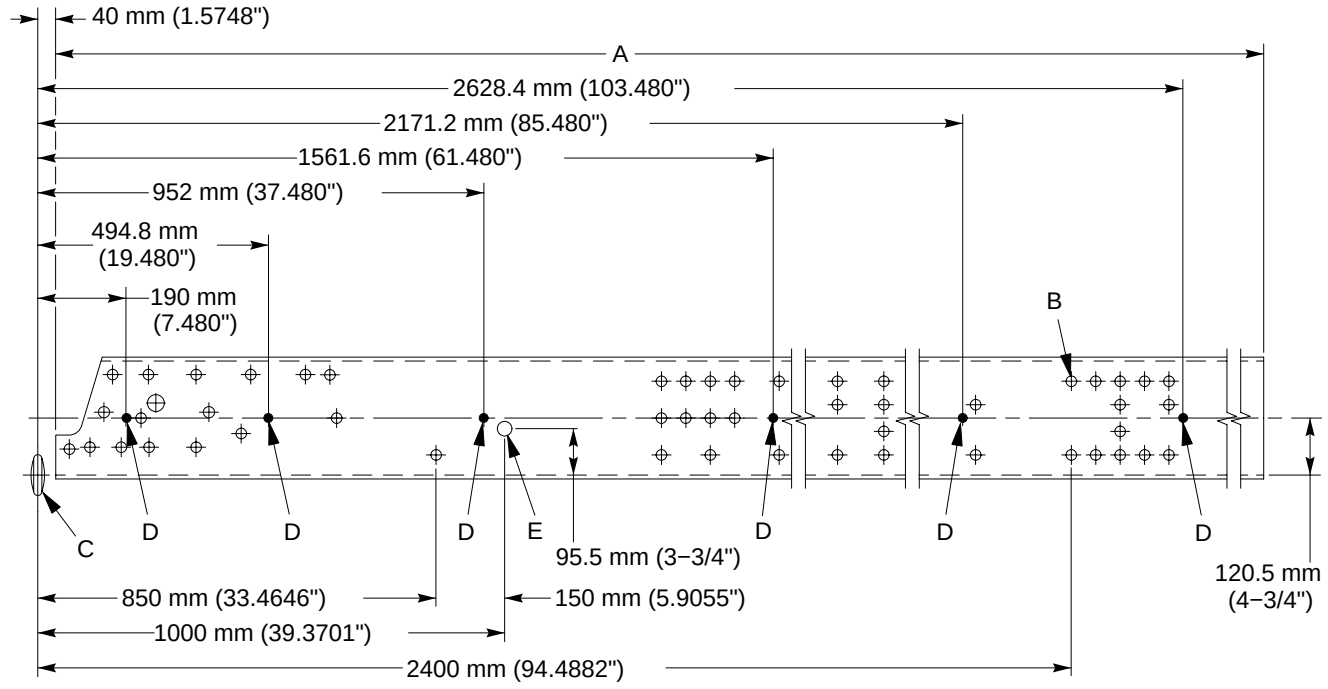
(mounted on that frame rail) is measured. There are

General Information

1. Web
2. Upper Flange
3. Channel
4. Lower Flange

Fig. 2, Frame Terminology



two frame stations along the frame rails: station zero and station 1000. See **Fig. 3**.

There is no identifying mark for station zero; it is located 40 mm (about 1.6 inches) forward of the forward end of the frame rail, and 290 mm (about 11.4 inches) forward of the centerline of the front suspension's forward spring pin. Station 1000 is located 1000 mm (about 39.4 inches) to the rear of station zero, and is directly above the centerline of the front axle.

Station 1000 is used when station zero is not accessible because of vehicle assembly. Station 1000 is identified by a 27 mm (1-1/16 inch) diameter hole near the bottom third of the frame rail web. A bulkhead fitting for the air or hydraulic brake lines is installed in the hole.

The vehicle's frame drilling chart lists the location of each frame rail component. For example: if a component is given a location of 850, then that component is installed on the frame rail 850 mm (33-15/32 inches) aft of station zero, or 150 mm (5-29/32 inches) forward of station 1000.

In addition to frame stations zero and 1000, each frame rail has six manufacturing holes along the centerline of the frame rail web. All six holes are 16-mm (5/8-inch) diameter. See **Fig. 3**. These holes can be used for location and measurement in the same manner as the hole at frame station 1000.

General Handling

Whenever the frame rails are lifted or moved, take care to avoid anything that may scratch, cut, or damage the exposed frame assembly. Cushion all chain hoists or cable slings with a section of heavy hose. If the frame rail is raised with a jack, place a block of wood between the jack and the frame rail.

Never heat the frame rails for straightening purposes; such work should be done cold.

⚠ CAUTION

CAUTION: Heating the frame rail for straightening purposes will reduce the strength of the rail in localized areas, which can result in structural failure of the frame rail.

Use pencil lines or soapstone marking for any work that requires marking of the frame rail. High visibility can be obtained by first chalking the surface of the frame rail, then making the pencil marks.

⚠ CAUTION

CAUTION: Before performing any electric welding on a vehicle, disconnect the battery power and ground cables and any electronic control units (ECUs) installed on the vehicle. Electric currents produced during electric welding can damage various electrical components on the vehicle, such as alternator diodes and ECUs.

Freightliner vehicle components that typically use ECUs include electronic engine, electronic automatic transmission, and ABS (antilock braking system).

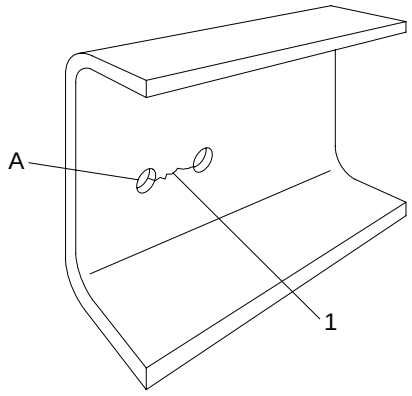
For any ECU with a battery power harness, disconnect its ground terminal from the chassis ground, and disconnect its power terminal from the battery positive post. Or else disconnect the main connection at the ECU.

Apply Alumilastic® Compound or a paintable, air-cured synthetic rubber or moisture-cured polyurethane, flexible weather-sealant between any dissimilar metal surfaces that contact each other (except nuts, bolts, and zinc or cadmium plated washers), regardless of whether the surfaces are primed or painted.

Repairing Cracks, Filling Unused Holes, and Drilling Holes

Repairing Cracks

IMPORTANT: In most cases cracked or damaged frame rails should be replaced. In some cases it may be necessary to repair minor damage; before attempting any repairs, contact your regional service representative for approval.



CAUTION

Before performing any electric welding on a vehicle, disconnect the battery power and ground cables and any electronic control units (ECUs) installed on the vehicle. Electric currents produced during electric welding can damage various electrical components on the vehicle, such as alternator diodes and ECUs.

Vehicle components that typically use ECUs include electronic engine, electronic automatic transmission, and ABS (antilock braking system).

For any ECU with a battery power harness, disconnect its ground terminal from the chassis ground, and disconnect its power terminal from the battery positive post, or disconnect the main connection at the ECU.

Fig. 2, Cross-Section View

NOTE: If it will not be possible to grind both sides of the frame rail, then grind the vee groove on one side to the full depth of the stock thickness. See **Fig. 3**.

3. Clamp a copper or aluminum bar on the opposite side of the groove. The bar will act as a "chill" strip, keeping the heat from spreading to the surrounding area of the frame rail. See **Fig. 4**. Deposit the weld material using the applicable welding method described in this section.
4. Grind the weld flush with the frame rail. See **Fig. 5**.
5. Cut a deep enough vee groove on the opposite side of the frame rail to reach the weld metal. See **Fig. 6**.
6. Clamp the "chill" strip on the opposite side of the groove. See **Fig. 7**. Weld the vee groove, as instructed above. Make full penetration of the weld.
7. Grind the weld flush with the frame rail. See **Fig. 8**.

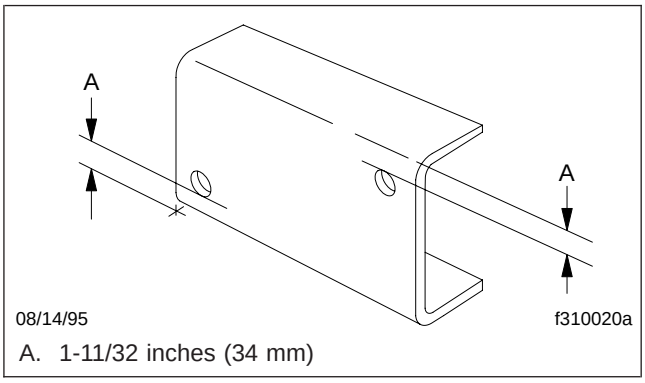
Filling Unused Holes

1. Fill all unused holes in the frame assembly with the applicable nut, washer, and bolt combination.
2. If the diameter of a hole is less than 3/8 inch (9.5 mm), enlarge it to 3/8 inch (9.5 mm), and fill it with the applicable nut, washer, and bolt combination.
3. Tighten the fasteners to the applicable torque value. For proper frame fastening instructions, refer elsewhere in this group.



Drilling Holes

During vehicle manufacture, holes are drilled or punched in the frame rail only as specified on the vehicle frame drilling chart. If any additional holes need to be drilled, contact your regional service representative for approval.

A single exception to this rule is that holes may be drilled for tubing clips and the like through the web portion of the channel only, with the following restrictions:

- The *edge* (not the center) of the hole must be no closer than 1-11/32 inches (34 mm) from the outer face of the flange. See **Fig. 9** for the minimum distance to the flanges that holes can be placed on the web.
- Material between the centerline of the hole and the outside of the upper or lower flange must be at least 2-13/32 inches (60 mm).
- Minimum material between hole centerlines must be 2 inches (50 mm).
- All attaching fasteners must be Grade 8. Flat washers must be made with high strength steel.
- The minimum material between the rear suspension bracket and the end of the frame must be at least 2 inches (50 mm).
- Holes between the front axle centerline and the rear axle centerline cannot exceed 3/4 inches (19 mm).

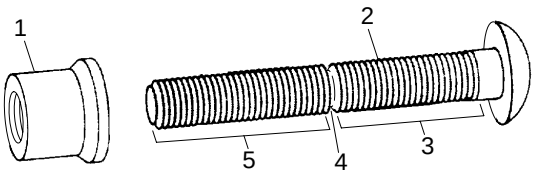
Frame Fasteners

Either Huckbolts® or grade 8 hexhead bolts and grade C prevailing torque locknuts are used for frame attachments. **See Fig. 1 and Fig. 2**. For attachments where clearance is minimal, low-profile hexhead bolts and grade C prevailing torque locknuts are used. For some components, grade 8.2 flanged hexhead bolts and grade G prevailing torque locknuts are used for frame attachments. **See Fig. 3** . Prevailing torque locknuts of all three bolt types have distorted sections of threads to provide torque retention.

When nonflanged hexhead bolts and locknuts are used on an attached aluminum part, a hardened flatwasher is required to prevent the bolt head or nut from embedding in the part. In general, hardened washers are used to distribute the load, and to prevent localized overstressing of the frame rails, brackets, and other parts. They are placed directly against the part, under the nut or bolt head. These special hardened washers are used on frame rails, and for the engine rear supports, rear suspension brackets, and fifth wheel mountings. They are cadmium-or zinc-plated, and have a hardness rating of 38 to 45 HRC.

Flanged hexhead bolts and locknuts have integral flanges which eliminate the need for washers on steel and aluminum surfaces. The fasteners are placed directly against the frame where the part is attached.

HEXHEAD BOLT REPLACEMENT



Replace hexhead bolts and locknuts with identical fasteners. Refer to the Freightliner *Parts Book* for fastener specifications.

Apply Alumilastic® compound, or an equivalent, to all bolts, nuts, and washers that contact aluminum parts.

CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the frame or parts.

Never hammer or screw bolts into place. Align the holes of the frame and the part being attached to it, so that the nut and bolt surfaces are flush against the frame and the part. For bolts 4 inches (102 mm) or less in length, make sure that at least 1-1/2 threads and no more than 5/8-inch (16 mm) bolt length extend through the self-locking nut after it has been tightened. For bolts longer than four inches (102 mm), allow a minimum of 3 threads and a maximum of 3/4-inch (19 mm) bolt length.

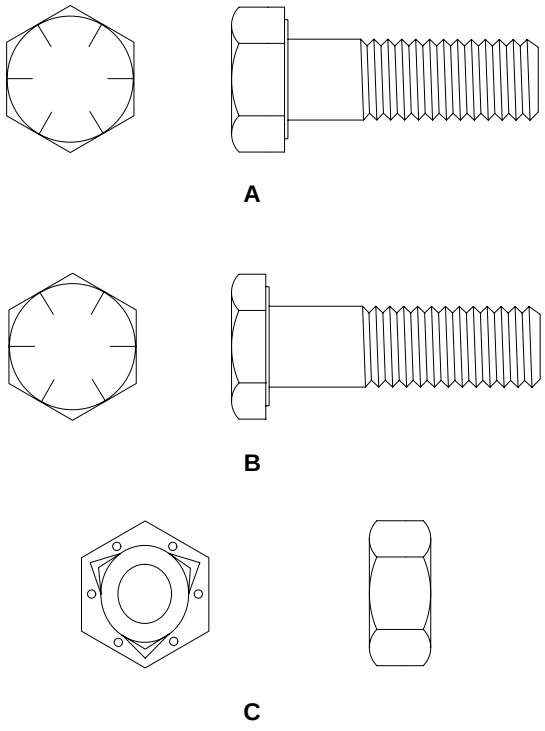
HUCKBOLT REMOVAL



Huckbolt HP 8® frame fasteners **(see Fig. 1)**have parallel locking grooves on the lockbolt pintail. The swaged collar cannot be unscrewed. Use the Huck Collar Cutter to remove HP8 fasteners. If the Collar Cutter isn't available, split the collar with an air chisel while supporting the opposite side of the collar with an anvil. **Refer to Fig. 4**. Then, drive out the lockbolt with a punch. Discard the fastener after removing it.

HUCK-FIT® frame fasteners have locking threads instead of grooves; the collar can be removed using a standard impact wrench and sockets. Discard the fastener after removing it.

CAUTION

CAUTION: Never attempt to reuse any Huck fastener that has been removed. Even though HUCK-FIT fasteners can be removed with a socket wrench, they cannot be correctly installed again. Reusing any Huck frame fastener can result in damage to the vehicle frame or components attached to the frame.

HUCKBOLT INSTALLATION

NOTE: Huckbolts cannot be installed without the proper Huckbolt installation equipment.

1. Insert the pintail through the prepared hole in the frame or other component. **Refer to Fig. 5**.
2. Place the collar over the pintail.
3. Place the Huck installation tool nose assembly over the pintail. **Refer to Fig. 6**. The pintail pulling grooves ratchet into the chuck jaws, which securely grip the pintail.
4. As the installation tool trigger is pulled, the tool piston and chuck jaws move rearward, pulling on the pintail, seating the bolt head, and closing the gap between the work surfaces. As pulling on the pintail continues, the collar is swaged into the locking grooves on the pintail; and the collar is lengthened, developing clamping force. **Refer to Fig. 7**.
5. The pintail breaks (**see Fig. 8**), freeing the nose assembly anvil from the swaged collar.

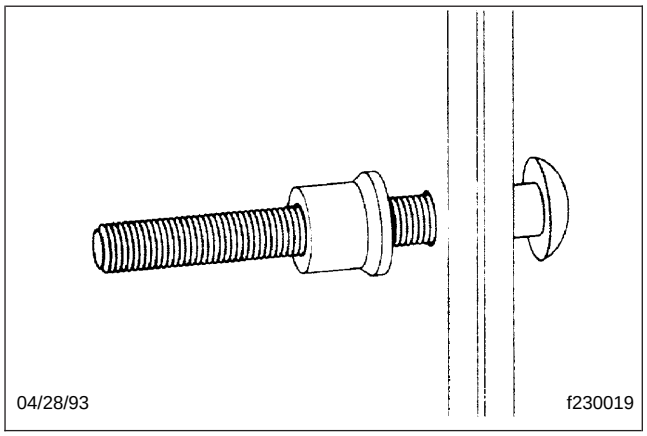

Fig. 5

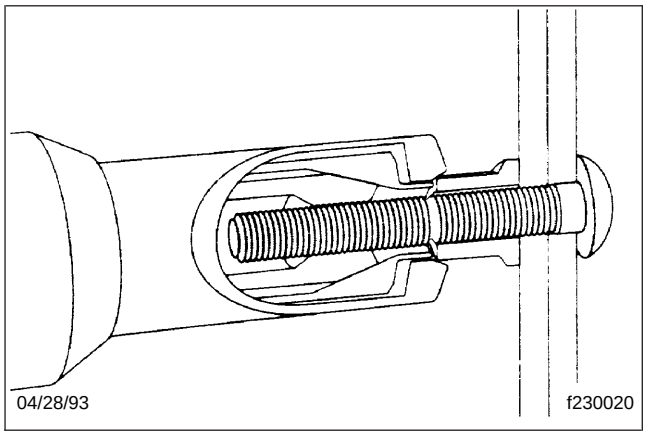

Fig. 6

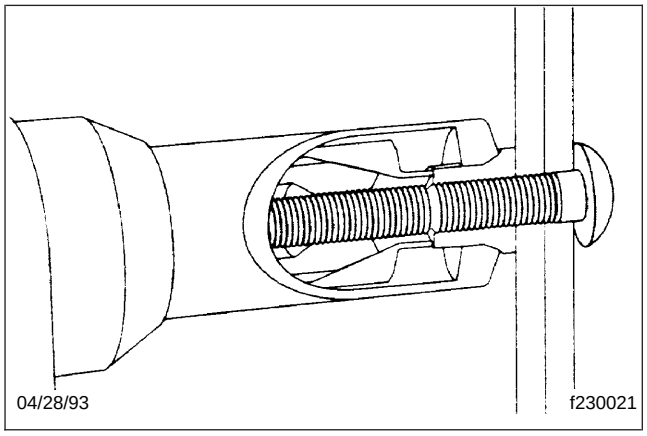

Fig. 7

NOTE: Most Huck fasteners have a constriction, the breakneck (Fig. 1), which determines the point where the pintail breaks free. MAGNA-GRIP® fasteners do not have this breakneck; the pintail should break flush with the top of the collar. No more than two grooves should be visible on the collar after installation. **Refer to Fig. 9** for examples of acceptable and unacceptable MAGNA-GRIP pintail breaks.

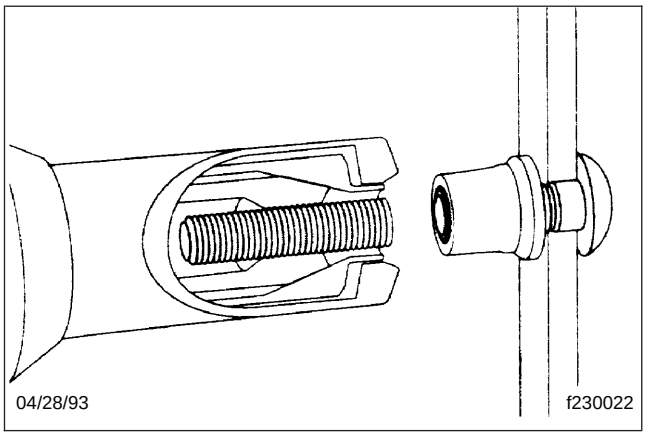

Fig. 8

FRAME FASTENER TIGHTENING

⚠ CAUTION

CAUTION: Continued vehicle operation with loose fasteners could result in component, bracket, and frame damage.

Tighten hexhead bolts and locknuts periodically to offset the effects of "bedding in" (seating). Refer to the Maintenance Schedule and the frame section in the vehicle maintenance manual for intervals.

When tightening the fasteners, tighten the nut, not the bolt head. This will give a true torque reading by eliminating bolt body friction. For torque specifications, refer to the general information section in the vehicle maintenance manual.

NOTE: Huck fasteners do not require periodic tightening.

Crossmember Removal and Installation

Removal

The placement of crossmembers affects the overall stability of the frame. If a crossmember is being eliminated, added, or relocated, Freightliner dealers must contact their Regional Service Office for instructions and approval. All others must contact a Freightliner dealership, which will contact the Regional Service Office for approval.

IMPORTANT: Before removing any crossmember, note the direction, size, and type, of all fasteners that attach the crossmember to the frame rail, and that attach other parts to the crossmember. Also note which direction the open channel of the crossmember is facing, for installation reference.

NOTE: If a 5-piece (welded) crossmember (**Fig. 1**) must be removed, it must be cut in two, removed, then replaced with a 5-piece crossmember having upper and lower gussets that bolt in place (**Fig. 2**).

5-PIECE (WELDED) CROSSMEMBER (Removal for replacement with a 5-piece bolted crossmember) **(See Fig. 1)**

1. Apply the parking brakes, then chock the tires on both the front and rear axles.
2. If any air brake valve is attached to the crossmember, drain the air reservoirs, then remove the valve(s) from the crossmember.

   Remove any clamps that attach air lines or wiring to the crossmember. Secure the lines or wires away from the crossmember.
3. If the back-of-cab crossmember is being removed, support the cab (at its normal ride height), the fuel tank(s), and the cab-access steps, as applicable. Remove the fasteners that attach the rear cab support brackets to the crossmember. See **Fig. 3**.
4. If rear suspension brackets are attached to the frame rails with the same fasteners that attach the crossmember, support the rear of the frame at its normal ride height, using safety stands.
5. Using a cutting torch, cut the crossmember channel in two. A 76 mm (3-inch) cut will make removal easier.
6. Remove the fasteners that attach the crossmember halves to the frame rails, and remove the crossmember.

REAR-CLOSING CROSSMEMBER **(See Fig. 4)**

1. Apply the parking brakes, then chock the tires on both the front and rear axles.
2. If so equipped, remove the backup alarm from the crossmember.

   If any air brake valve is attached to the crossmember, drain the air reservoirs, then remove the valve(s) from the crossmember.

   Remove any clamps that attach air lines or wiring to the crossmember.

   If the leveling valve for an AirLiner suspension is attached to the crossmember, remove the valve. For instructions, refer to **Group 32** in this manual.
3. Remove the fasteners that attach the crossmember to the front angle brackets.
4. If rear suspension brackets are attached to the frame rails with the same fasteners that attach the angle brackets, support the rear of the frame at its normal ride height, using safety stands.
5. Remove the fasteners that attach the rear angle brackets to each frame rail; then remove, as an assembly, the rear brackets and the crossmember.
6. If needed, remove the front angle brackets and their fasteners. If applicable, after removing the fasteners, remove the rear suspension brackets from the springs.

SPLAYED CROSSMEMBER **(See Fig. 5)**

1. Apply the parking brakes, then chock the tires.
2. If removing a midship bearing crossmember, support the driveline on a safety stand, then remove the fasteners that attach the midship bearing bracket to the crossmember.
3. Unbolt the crossmember from both frame rails.

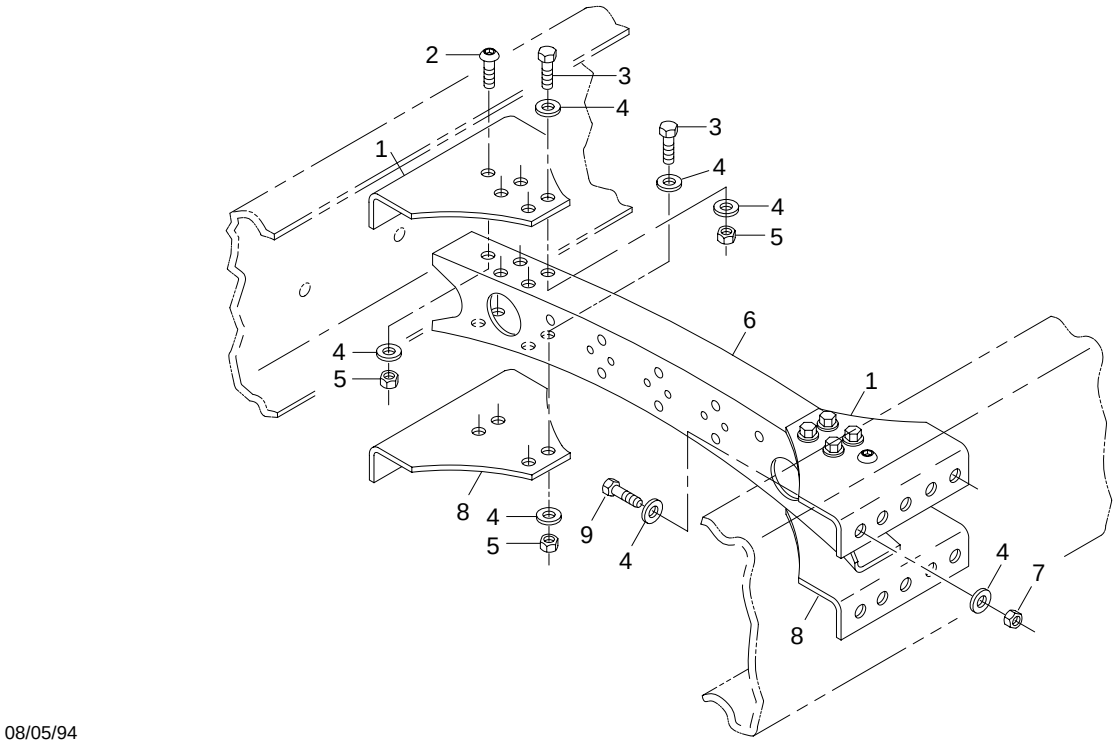
4. At one end of the crossmember, use a deadblow hammer to tap against its curved side (the closed side of the channel), until the crossmember is no longer wedged in the frame. Remove the crossmember.

Overslung Crossmember (See Fig. 6)

1. Apply the parking brakes, then chock the tires on both the front and rear axles.
2. Remove the half-fender from the left side of the vehicle.
3. Provide support underneath both fuel tanks.
4. From underneath the chassis, remove the two 5/8–11 fasteners that attach each side of the crossmember to its mounting brackets.
5. Remove the overslung crossmember by rotating it down and outward on the left side of the vehicle.



Installation

5-PIECE (BOLTED) CROSSMEMBER (Installation for replacement of a 5-piece welded crossmember)

(See Fig. 2)

1. Attach one upper gusset to the crossmember channel; tighten the fasteners snug, but not to their final torque value.
2. Install the crossmember channel and gusset in the frame rails with its open channel facing the same direction that was noted during removal.

Position the crossmember so its channel is supported on the lower flanges of both frame rails.

3. Attach the other upper gusset to the crossmember channel; tighten the fasteners snug, but not to their final torque value.
4. Tighten the locknuts on the button-head capscrews at the outboard end of both upper gussets 92 N·m (68 lbf·ft).
5. Using a deadblow hammer, tap the crossmember up into place. Align the mounting holes of the upper gussets with the holes in the frame rails. Install the fasteners, but don't tighten them.
6. Install the lower gussets on the crossmember channel, but don't tighten the fasteners at this time. Install the fasteners that attach the lower gussets to the frame rails.
7. Tighten the fasteners that attach the gussets to the frame rails 184 N·m (136 lbf·ft). Then, tighten the fasteners that attach the gussets to the crossmember channel 92 N·m (68 lbf·ft).
8. If any air brake valve was attached to the crossmember, install the valve(s) on the crossmember.

   Install any clamps that attach air lines or wiring to the crossmember.
9. If the back-of-cab crossmember was replaced, install the fasteners that attach the rear cab support brackets to the crossmember. See **Fig. 3**. Tighten the cab support bracket fasteners 92 N·m (68 lbf·ft). Remove the supports from under the cab, fuel tanks, and cab-access steps.

REAR-CLOSING CROSSMEMBER

(See Fig. 4)

1. If they were removed, install the front angle brackets and their fasteners, but don't tighten the fasteners at this time. If applicable, install the rear suspension brackets on the springs.
2. Slide the crossmember into the opening at the rear of the frame rails, then turn it upright, to position it against the front angle brackets.
3. Attach the rear angle brackets to the frame rails, but don't tighten the fasteners at this time.
4. Install but do not tighten the fasteners that attach the crossmember to the front angle brackets.
5. If they were removed from the rear-closing crossmember, install any air brake valves, and securely tighten the fasteners.

   If so equipped, install the backup alarm.

   Install any clamps that attach air lines or wiring to the crossmember.

   If the leveling valve for an AirLiner suspension was removed from the crossmember, install the leveling valve. For instructions, refer to **Group 32** in this manual.
6. Tighten the fasteners that attach the angle brackets to the frame rails, then tighten the fasteners that attach the crossmember to the angle brackets. Tighten all fasteners 184 N·m (136 lbf·ft).
7. Remove the chocks.

SPLAYED CROSSMEMBER **(See Fig. 5)**

1. Install the crossmember in the frame rails with its open channel facing the same direction that was noted during removal. Align the mounting holes at one end of the crossmember with the holes in the frame rail.

NOTE: With the crossmember not straight across in the frame rails, and the holes not aligned on the opposite end, the holes at that end will be in approximate alignment.

2. Install the fasteners in that end of the crossmember and frame rail, but tighten the locknuts finger-tight only.
3. At the other end of the crossmember, use a deadblow hammer to tap against its straight side, until the crossmember is straight across in the frame rails, and the mounting holes at both ends are in alignment with the holes in the frame rails.
4. If a midship bearing crossmember is being installed, install the fasteners that attach the midship bearing bracket to the crossmember. Remove the safety stands that supported the driveline.
5. Tighten all of the fasteners to their applicable torque values; refer to **Section 00.04.**
6. Remove the chocks.

Overslung Crossmember **(See Fig. 6)**

1. Rotate the new crossmember into place from the left side.
2. Place the crossmember on the rear surface of the mounting brackets.
3. Install the 5/8–11 mounting fasteners (bolt heads facing forward). Tighten the fasteners 184 N·m (136 lbf·ft).
4. Install the half-fender on the left side of the vehicle. Tighten the fasteners 16 N·m (12 lbf·ft).

Alignment

Frame rail alignment is checked by measuring the distances from two sets of points on the upper (or lower) flanges of the frame rails. See **Fig. 1**. The rear set of points must be as far back as possible from the forward set of points. There must be no interference, along or between the frame rails, that would prevent measuring from any one of the four points to the other three points. If the upper flanges are being used for the measurements, the fifth wheel and deck plate (as equipped) must be removed.

There are no marks or bolt holes in the upper or lower flanges of the frame rails. Therefore, the points must be projected from the frame station marks, manufacturing holes, or component attachment holes in the frame rail webs. See **Fig. 2**.

B. Right Rear Point

2. Left Frame Rail

Fig. 1, Alignment Points

IMPORTANT: Use a pencil or soapstone to make all lines, points, or other marks. Do not use any marker or tool that will scratch the surface of the frame rail. Use a machinist's square to project all points from the webs to the upper (or lower) flanges, and to measure inboard from the outside face of the frame rails.

1. Apply the parking brakes and chock all the tires.
2. For each frame rail, project the exact vertical centerline of the 5/8-inch (16-mm) manufacturing hole at frame station 2628.4, from the frame web to the upper (or lower) flange, and mark it with a line across the flange.

   If, because of interference, the manufacturing hole at frame station 2628.4 cannot be used, choose and mark another matched set of points.

   2.1 Determine how far forward that the upper (or lower) flanges of both frame rails are clear.

   2.2 Find a matched set of bolt holes on the frame rail webs, that are aligned with, or just rearward of, the front of the clear area on the flanges. The bolt holes must be in exactly the same location in each frame rail.

   2.3 Project the exact vertical centerline of each bolt hole, and mark a line across the upper (or lower) flange of its respective frame rail.
3. Find the exact center of the width of each flange, and mark the point on each projected line. This will be the forward set of points. The forward points must be in identical locations on both frame rails.
4. If needed and as equipped, remove the fifth wheel and deck plate; refer to the applicable section in this Group for instructions.
5. Measure along each frame rail, to find a set of holes *at least* 72 inches (180 cm) rearward from the forward set of points. The holes must be in exactly the same location in each frame rail.

IMPORTANT: If, because of interference, the distance must be less than 72 inches (180 cm), the distance must be the maximum that is possible.

6. Project the exact vertical centerline of each bolt hole, and mark a line across the upper (or lower) flange of its respective frame rail.
7. Along each line, measure and mark a point 2 inches (5 cm) inboard from the outside face of its respective frame rail. The rear points must be in identical locations on both frame rails.
8. Measure the distance from the forward point on one frame rail to the rear point on the opposite frame rail. See **Fig. 1**. Then measure the distance from the other forward point to the rear point on its opposite frame rail. Compare the two measurements.

Fig. 2, Critical Dimensions, Frame Rails

If the values differ by more than 1/8 inch (3 mm), proceed with the next step.

If the measurements are within 1/8 inch (3 mm) of each other, the frame rails do not need to be aligned; go to the step for fifth wheel and deck installation.

9. Loosen *all* of the frame fasteners enough to allow movement of the parts when force is applied.

IMPORTANT: To align the frame rails, the frame must have all of the crossmembers in place, but the attachment fasteners should *not* be tightened.

10. Using a large hammer and a large wooden block, place the block against the rear end of the frame rail that had its rear point the greater distance from its opposite rail's front point. Tap the block until the measurements are within 1/8 inch (3 mm) of each other.
11. Tighten all of the frame fasteners, starting at the middle of the frame and working alternately toward both ends. Tighten all fasteners to their applicable torque values; refer to the Specifications in **Section 00.04**.
12. Again, check the frame rail alignment.
13. When the measurements are within specifications, install the fifth wheel and deck plate (as

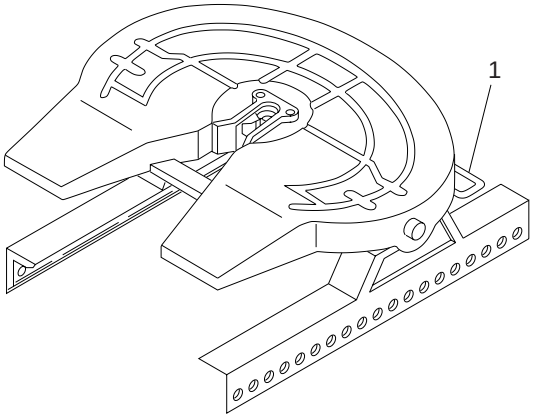
equipped); refer to the applicable section in this Group for instructions.

14. If the frame rails needed aligning, check the axle alignment; refer to the appropriate suspension section in **Group 32** for instructions.
15. Remove the chocks from the tires.

General Information

NOTE: The Holland 3500 series XA–3501 model fifth wheel top plate has been replaced by the XA–351 model. All 3500 series fifth wheel top plates which are marked with a manufactured date after June 1, 1996 are XA–351 models.

NOTE: Service operations for the Holland 3500 series slide mounts (FW2535/FW35) are covered in **Section 31.05** in this group.



MODEL XA–3501 TOP PLATE

NOTE: The part number prefix for the stationary fifth wheel is FW3500 and the part number prefix for the sliding fifth wheel is FW2535.

Holland 3500 series XA–3501 fifth wheels are used for pulling trailers having the standard SAE kingpin. When installed as stationary fifth wheels, they are bracket-mounted to the trailer frame in a position that best distributes the trailer load over the tractor axles. When installed as sliding fifth wheels, they are mounted on the Holland 3500 series sliding mount. These fifth wheels have a capacity of 150,000 lbf (667 000 N) maximum drawbar pull and 40,000 to 50,000 lbf (178 000 to 222 000 N) maximum vertical load. The fifth wheel (**Fig. 1**) has a cast steel top plate, and is equipped with a split type "B" mechanical spring lock. This steel kingpin lock system requires a 300 lbf (1330 N) push (force) to couple, and also includes a slack adjustment and the Holland lockguard (which prevents high kingpin coupling).

The two spring-loaded lock halves separate as the kingpin enters the lock mechanism. See **Fig. 2**. The final forward motion of the kingpin forces the lock to close in a 360 degree grip around the shoulder and neck of the kingpin, and moves the yoke between the lock halves and the tapered rib members of the fifth wheel understructure. The kingpin can be released only by manually operating the kingpin lock control handle. See **Fig. 1**. An adjustment nut compensates for wear on the lock or kingpin, if necessary.

See Chapter 10 of the *Business Class Trucks Driver's Manual* for complete operating instructions.

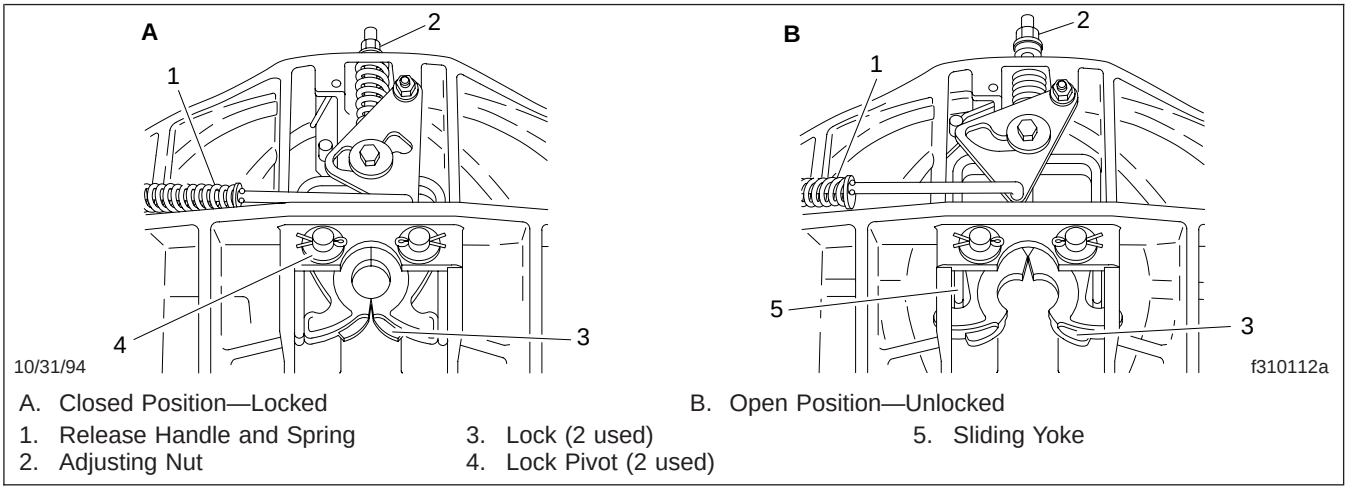
Fig. 1, XA-3501 Fifth Wheel

MODEL XA–351 TOP PLATE

NOTE: The part number prefix for the stationary fifth wheel and the sliding fifth wheel is FW35.

The Holland 3500 series XA–351 fifth wheels are applicable for general over-the-road use. They are designed to pull trailers having a 2 inch (5 cm) SAE J700b kingpin. They have a capacity of 150,000 lbf (667 000 N) maximum drawbar pull and 55,000 lbf (244 652 N) maximum vertical load. These fifth wheels are available in three different mounting assemblies: the Kompensator®; the slide mount; and the stationary mount.



The stationary mount fifth wheels are available with four different mounting bracket styles, which include:

- a bracket with a mounting base for over-the-frame mounting;
- a bracket with a mounting angle for over-the-frame mounting;
- a bracket for angle mounting (designed to be welded to the angle) for over-the-frame mounting;
- and, a bracket for outboard angle mounting.

The mounting brackets use nylon-lined "up-shock" bushings. These fifth wheels come in a variety of heights to accommodate many applications.

The sliding fifth wheels are available with either an over-the-frame mounting bracket or an outboard angle mounting bracket. These mounting brackets

are either equipped with a manual slide release or an air slide release mechanism. These sliding mounts have a position adjustment that gives the fifth wheel top plate the ability to be released, incrementally moved (by 1.5 inch [3.8 cm] displacements) and locked in alternate positions. The position adjustment feature allows the fifth wheel position to vary combination length and tractor axle load distribution for maximum equipment utilization. The mounting brackets use nylon-lined "up-shock" bushings. The sliding fifth wheels are available in a variety of heights and slide travel lengths.

The Kompensator® fifth wheel is equipped with either a stationary or sliding mounting bracket. This fifth wheel is designed for rigid trailers that don't flex during torsional loading. It provides torsional stress relief and promotes vehicle stability with trailers that have an unusually high center of gravity (where the center of gravity is up to 44 inches [111 cm] above the top plate surface). This fifth wheels unique cradle design provides side-to-side movement to help relieve the torque and twist of the trailer. Spring cushions act as a restoring force to provide stability after absorbing the strain and pressure of the load. Additionally, it keeps the center of compensation above the fifth wheel bearing surface and centered between the frame rails. All models are available with an optional "lock-out" feature to restrict compensation for applications that do not require compensation. See **Fig. 3**.

The 3500 series top plate consists of:

- the cast steel top plate;
- the bracket pin mount;

4. Kompensator® Cradle Design Mounting Bracket

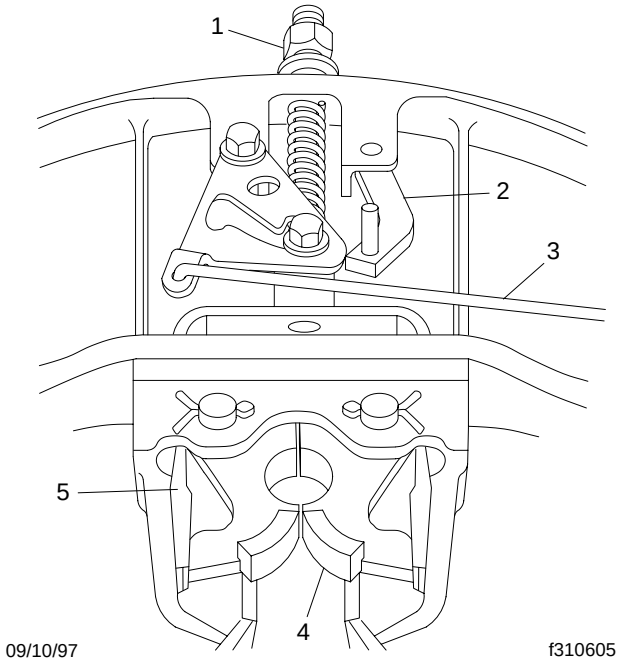
- the release handle;
- the infinite lock adjustment nut;
- and the kingpin lock mechanism.

See **Fig. 4**.

The kingpin lock mechanism consists of:



- the infinite lock adjustment nut;
- the secondary lock;
- the release handle;
- the type "B" forged steel split lock;
- and, the yoke.

See **Fig. 5**.

5. Yoke

Fig. 5, Kingpin Lock Mechanism (bottom view)

When the yoke is retracted, the two spring-loaded lock halves separate as the kingpin enters the lock mechanism. When the yoke engages, the final forward motion of the kingpin forces the lock to close in a 360 degree grip around the shoulder and neck of the kingpin. After the yoke is engaged (positioned between the lock halves and the tapered rib members of the top plate casting), the secondary lock moves behind the yoke. For fifth wheels with an automatic secondary lock, the kingpin is released by manually operating the release handle. For fifth wheels with a manual secondary lock, the fifth wheel is released by pulling the secondary release handle, then hooking the secondary release handle to the top plate casting, and finally manually operating the primary release handle. For high coupling protection, a one step rear lock is incorporated into the split lock. For increased durability of the kingpin lock mechanism, the infinite lock adjustment positions are available to compensate for wear of both the kingpin and the lock jaws.

See Chapter 10 of the *Business Class Trucks Driver's Manual* for complete operating instructions.

Model XA–3501 Top Plate Removal and Disassembly

Removal and Disassembly

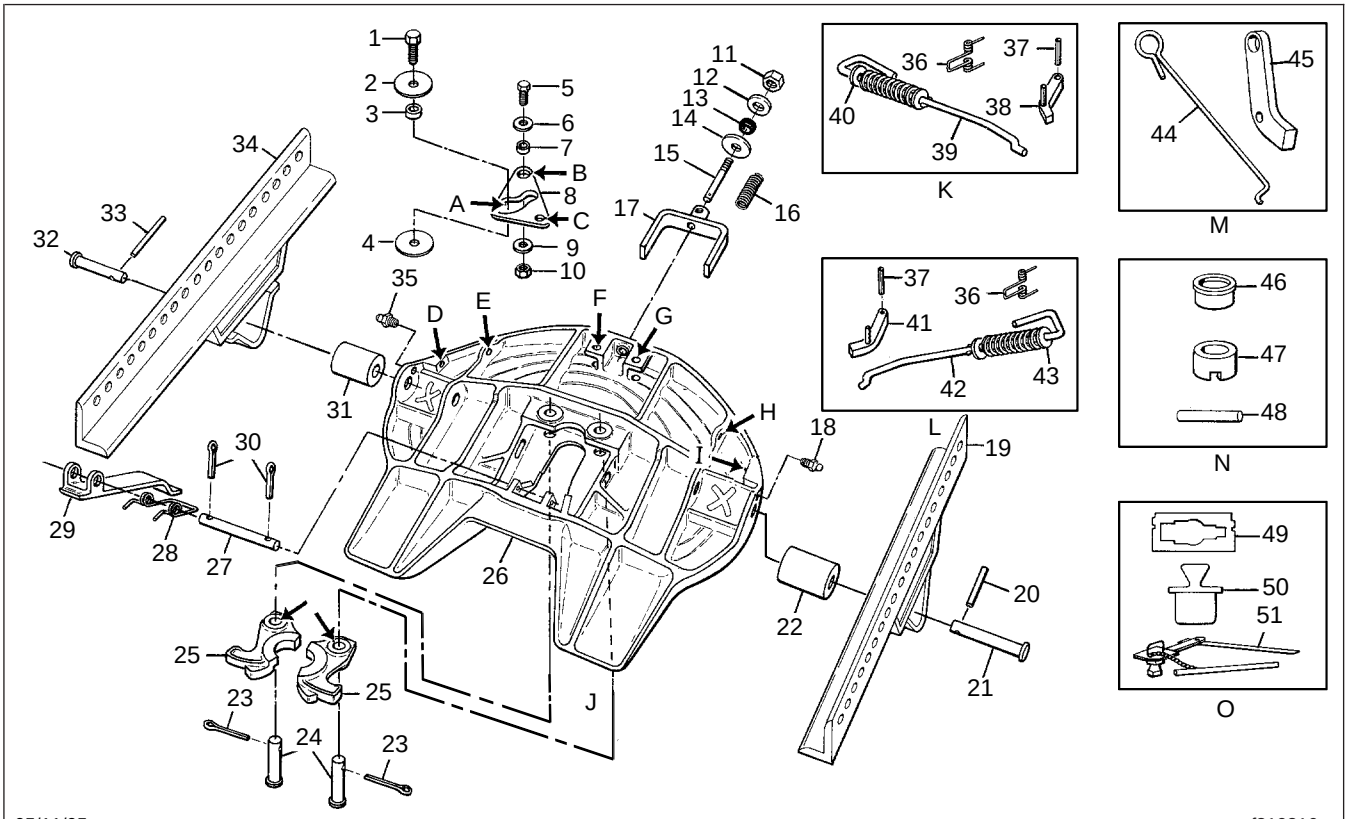
(See Fig. 1)

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

A fifth wheel rebuild kit is available for servicing the 3500 series XA–3501 fifth wheel (part number RK–63501 [left release] and RK–63500 [right release]). The kit contains all replacement parts for the fifth wheel, except the fifth wheel plate, slide mount assembly, rubber bushings, bushing pins, and roll pins.

Review the troubleshooting section before rebuilding the fifth wheel. Rebuilding may be unnecessary.



1. Steam clean the top plate. Remove it from the slide mounts (**Fig. 1**) by removing the roll pins from the bushing pins; then, remove the bushing pins from the mounting brackets. Use an overhead hoist to lift the fifth wheel from the mounting brackets and tractor frame.
2. Turn the fifth wheel upside down with the locks open.
3. While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.
   - 3.1 Remove the lockguard, the lockguard torsion spring, the lockguard pin, and the lockguard cotter pins.
   - 3.2 On fifth wheels with a right-hand release, remove the secondary lock roll pin from hole F. Then, remove the right-hand secondary lock from under hole F.

     On fifth wheels with a left-hand release, remove the secondary lock roll pin from hole G. Then, remove the left-hand secondary lock with the secondary lock spring from under hole G.
   - 3.3 Remove the attaching release arm capscrew, capscrew washer, and roller from hole A of the release arm and yoke subassembly.
   - 3.4 Remove the release arm capscrew, release arm capscrew washer, and release arm roller from hole G for models with right-hand release or from hole F for models with left-hand release.
   - 3.5 Remove the release handle from the fifth wheel top plate. Remove the washer, release handle spring, and release handle washer from the release handle.
   - 3.6 Remove the yoke shaft locknut, yoke shaft washer, and rubber block from the yoke shank. Then, remove the yoke shank and the yoke shank spring from the yoke subassembly.
   - 3.7 Remove the yoke from the fifth wheel top plate.
   - 3.8 Remove the lock cotter pins, lockpins, and the lock jaws from the fifth wheel top plate.
   - 3.9 If the top plate is cracked, discard it. If the lockpin hole is worn, the top plate can be returned for a factory rebuild.

⚠ WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or if the lockpin does not fit tightly. The top plate could fail or the locks could malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Assembly and Installation

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

A fifth wheel rebuild kit is available for servicing the 3500 series XA–3501 fifth wheel (part numbers RK–63501 [left release] and RK–63500 [right release]). The kit contains all replacement parts for the fifth wheel, except the fifth wheel plate, slide mount assembly, rubber bushings, bushing pins, and roll pins.

Review the troubleshooting section before rebuilding the fifth wheel. Rebuilding may be unnecessary.

IMPORTANT: Use only Holland rebuilding kits. Replace all roll pins, cotter pins, springs, capscrews, nuts, and washers.

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Before installing the lock jaws (**Fig. 1**), lubricate the lockpin holes (Ref. J) with Never-Seez®.

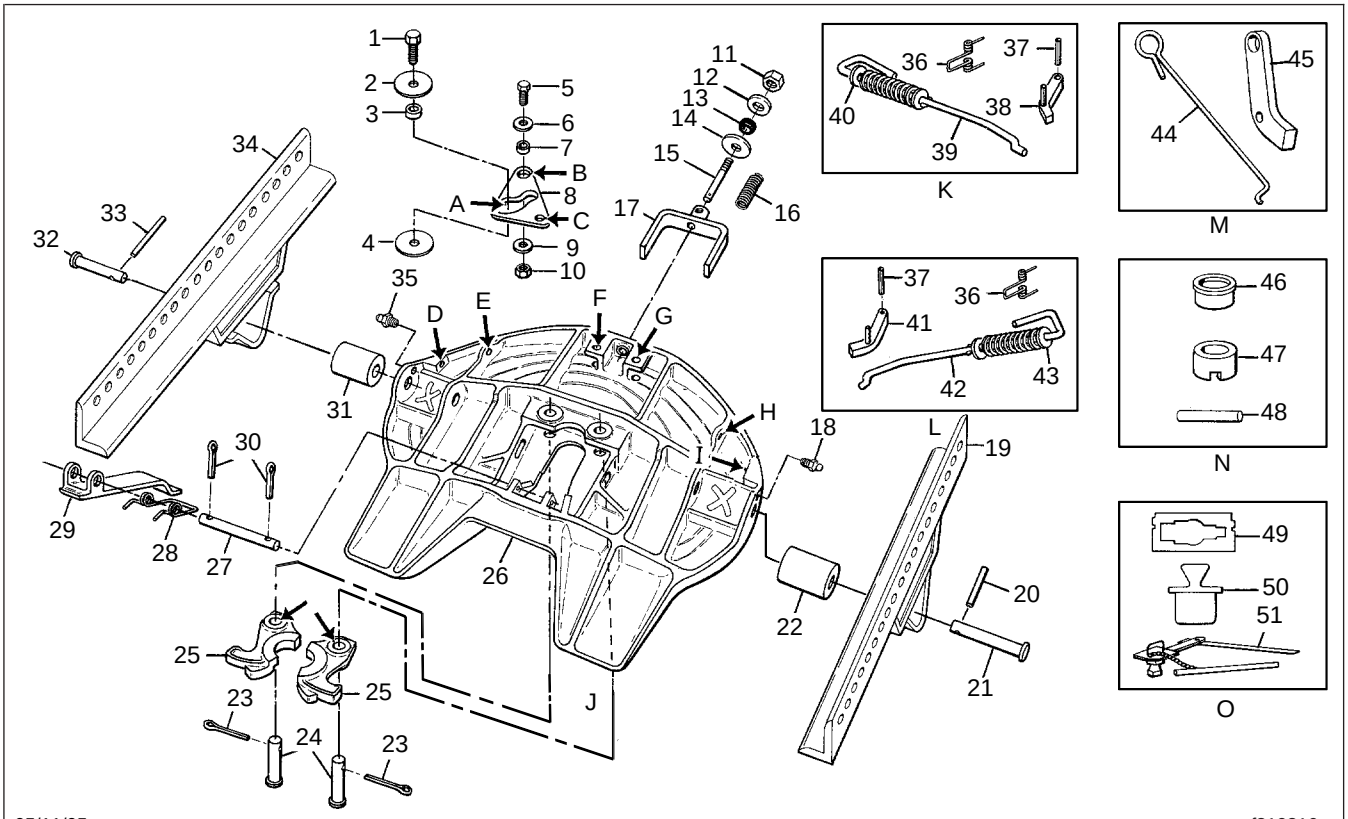
⚠ CAUTION

Use only Never-Seez®. Other lubricants can damage the lockpin holes.

3. Place the lock jaws in the top plate with the 2-7/8 inch bore toward the face of the top plate. See **Fig. 2**.
4. Drive the lockpins (**Fig. 1**) through the top plate and lockpin holes (Ref. J) in the lock jaws until the head of the pins are flush with the top plate.
5. If the top plate is equipped with lockpin bushings, use roll pins instead of cotter pins. See **Fig. 3**.
6. Check that the lock jaws move freely.

⚠ WARNING

Use only Holland part number TF–0237 or a precision plug machined to 2.000 ± 0.005 inch (5.08 ± 0.0127 cm) to adjust the locking mechanism. Failure to do so may cause locking mechanism malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.



7. Install a 2-inch (5.08 cm) diameter plug (Holland part number TF–0237) in the lock jaws. See **Fig. 4**.
8. Strike the yoke with a mallet to bend the yoke tips outward slightly. See **Fig. 5**.
9. Slide the yoke into the top plate with the threaded hole facing up, and tap the yoke into position.

⚠ WARNING

Never grind on the inside of the yoke or on the locks. This can weaken the yoke structure, possibly causing the kingpin to fit loosely. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

10. Inspect the yoke tips. The tips must be flush with the ends of the locks, or extend no more than 1/32 inch (0.8 mm) beyond. See **Fig. 6**.
    - 10.1 If the yoke tips fall short (**Fig. 7**), use a belt sander or disk grinder to grind the outside surfaces of the yoke until it fits precisely into place. See **Fig. 8**.
    - 10.2 If the yoke tips extend beyond the ends of the locks, build up the outer surfaces of the yoke using a low hydrogen E70XX welding rod. See **Fig. 9**. After welding, grind the beads smooth.
11. The outside of each yoke tip has two contact areas. Check that all four surfaces have full area contact with the top plate ribs (**Fig. 10**) after welding and grinding.
12. Continue welding, grinding, and fitting until the yoke has full contact and the yoke tips are flush with the ends of the locks.
13. Apply a coat of light grease to both the inside and outside friction surfaces of the yoke, then slide the yoke into the top plate with the threaded hole facing up.
14. Install the spring (**Fig. 1**) between the yoke and the top plate. Insert the yoke shank through the top plate and spring, then into the yoke. Make

sure that the predrilled recess in the yoke shank aligns with the threaded hole in the yoke.

15. Install the lock adjustment tag, the rubber block, a 13/16-inch i.d. steel washer, and the 3/4-inch locknut in the order stated.
16. Install the 9/16-inch i.d. washer on the release handle as shown in **Fig. 1**.
17. Pass the open end of the release handle through the guide hole (Ref. D for models with right-hand release, Ref. I for models with left-hand release) toward the outside of the top plate.
18. Inspect the release arm (cam plate) for burrs or rough edges in the cam profile (Ref. A). Remove any burrs or rough edges.

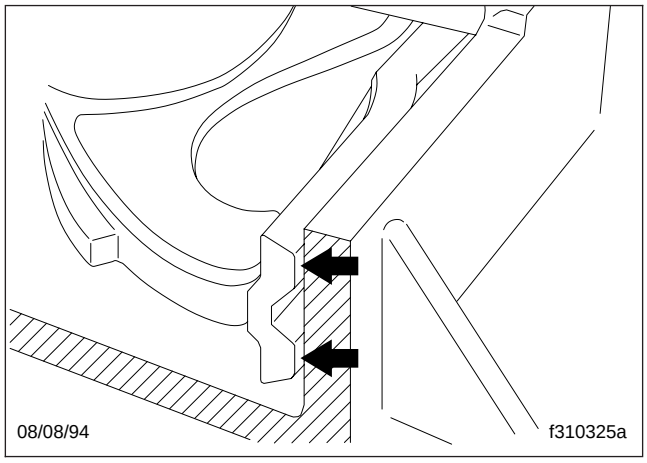

Fig. 10, Contact with Top Plate

19. Apply a light coat of grease to the cam profile and pivot holes.
20. Insert the "S" end of the release handle through the small hole in the release arm (cam plate).
21. Place the release arm (cam plate) on the top plate so that the cam profile (**Fig. 11**, Ref. A) is over the hole in the yoke and the large hole (Ref. B) is over the lug in the top plate opposite the release handle.

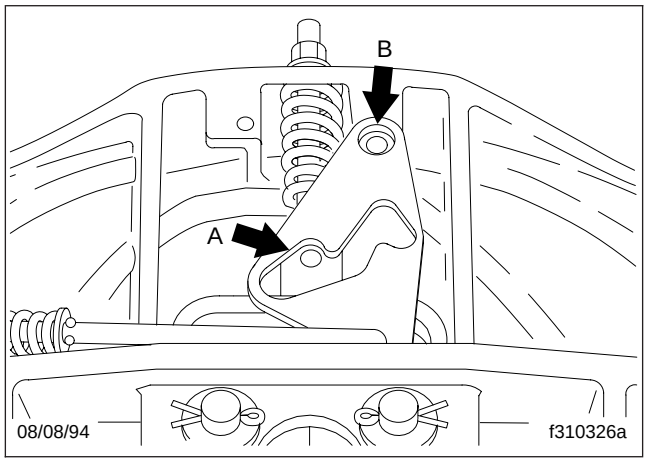

Fig. 11, Place the Release Arm

22. Slide a 9/16-inch i.d. flatwasher between the plate lug and the release arm with the rounded edge towards the cam. See **Fig. 12**.
23. Install the 1/2-inch i.d. roller (**Fig. 1**) in the large hole of the release arm.

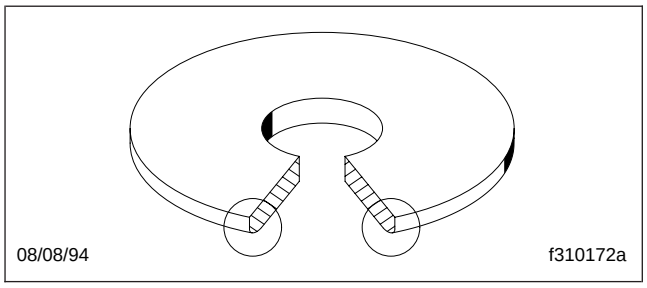

Fig. 12, Rounded Edge

24. Place a second 9/16-inch i.d. flatwasher over the release arm. Make sure the rounded edge of the washer faces the cam.
25. Install the 1/2-inch diameter capscrew through the washers, roller, and hole in the top plate lug (Ref. G for right-hand release models, Ref. F for left-hand release models).
26. Secure the capscrew with a 1/2-inch locknut. Tighten the locknut; then, check that the release arm moves freely.
27. Place a 5/8-inch i.d. washer between the yoke and the release arm. Make sure that the rounded edge of the washer faces the release arm.
28. Insert the 5/8-inch i.d. roller in the release arm opening.
29. Install the second 5/8-inch i.d. washer on top of the release arm.
30. Pass the 5/8-inch diameter capscrew through the assembly. Be certain that the bolt passes through the yoke and into the recess in the yoke shank.
31. Tighten the capscrew securely, but make sure the top washer turns freely.
32. Turn the nut on the yoke shank clockwise until the yoke just begins to move.
33. Check the plug (Holland part number TF–0237). It should fit snugly in the locks, but you should be able to turn it with some force.
34. On models with an automatic secondary lock assembly, Install the secondary lock.
    - 34.1 Start the roll pin into the hole in the top plate lug opposite the release arm anchor capscrew.
    - 34.2 Install the torsion spring on the secondary lock, and position them on the lug. Be sure the open end of the spring faces toward the rib of the lug. See **Fig. 13**.

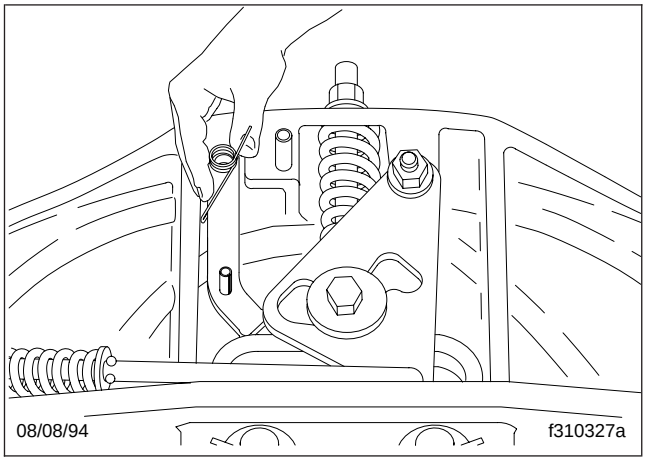

Fig. 13, Torsion Spring Installation

    - 34.3 While holding the parts in place, drive the roll pin until it is flush with the lug.
    - 34.4 Check the spring tension on the secondary lock. Check that the lock moves freely.
35. On models with a manual secondary lock assembly, install the manual secondary lock.
    - 35.1 Pass the end of the manual secondary lock handle (**Fig. 1**) through the hole (Ref. E for right-hand release, Ref. H for left-hand release).
    - 35.2 Attach the handle to the secondary lock.
    - 35.3 Start the roll pin into the hole in the top plate lug opposite the release arm anchor capscrew.
    - 35.4 Install the torsion spring on the secondary lock, and place them in position on the lug. Be sure the open end of the spring faces toward the rib of the lug. See **Fig. 13**.
    - 35.5 While holding the parts in place, drive the roll pin until it is flush with the lug.
    - 35.6 Check the spring tension on the secondary lock. Check that the lock moves freely.

Model XA–3501 Top Plate Assembly and Installation

36. Pull the release handle, remove the plug, and pry open the lock jaws.
37. Assemble the lockguard and the torsion spring.
38. Mount the lockguard using the lockguard pin and cotter pins. See **Fig. 14**.

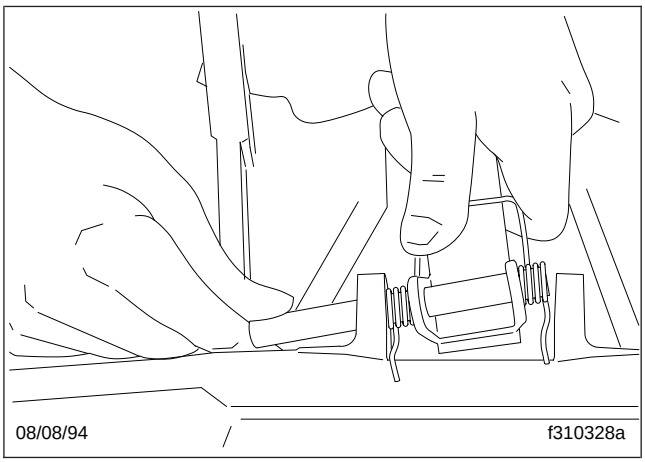

Fig. 14, Mount the Lockguard

39. Check the spring tension on the lockguard. Check that the lockguard moves freely.
40. Check the adjustment. The tip of the guard should be even with the edge of the 2-inch bore in the lock jaw. See **Fig. 15**.

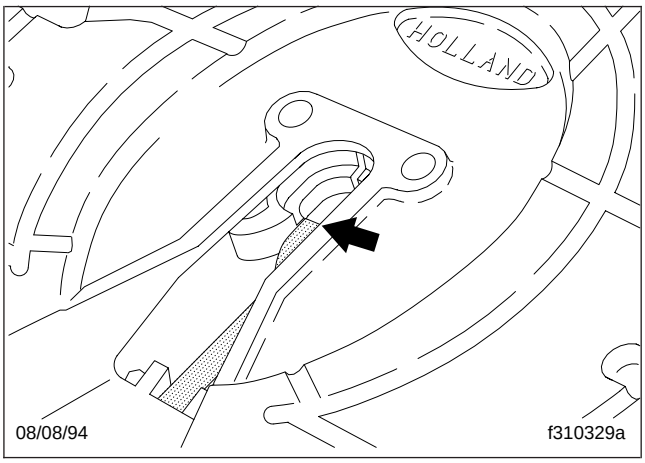

Fig. 15, Check the Guard

41. Adjust the lockguard position by supporting the end of the guard with a short piece of steel placed between the locks and the lock-guard. Tap the center of the guard to adjust it. See **Fig. 16**.

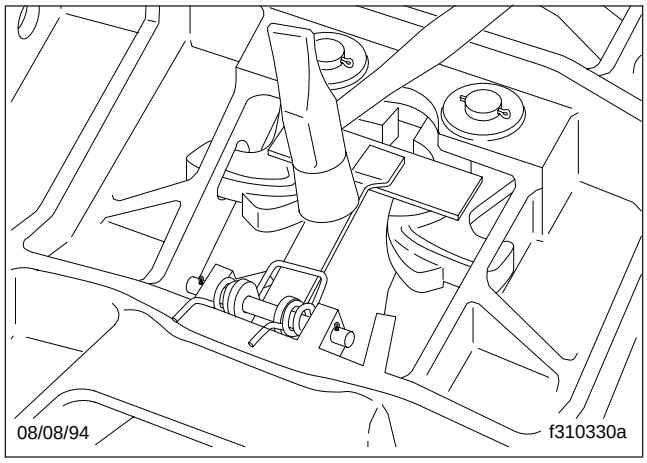

Fig. 16, Adjust the Guard

42. Using a Holland Lock Tester, close the locks. For instructions, refer to Holland Publication FW 130. Make sure that the locking mechanism functions properly. See **Fig. 17**. If the fifth wheel does not operate properly, repeat the above procedures or contact your local Holland representative for assistance.

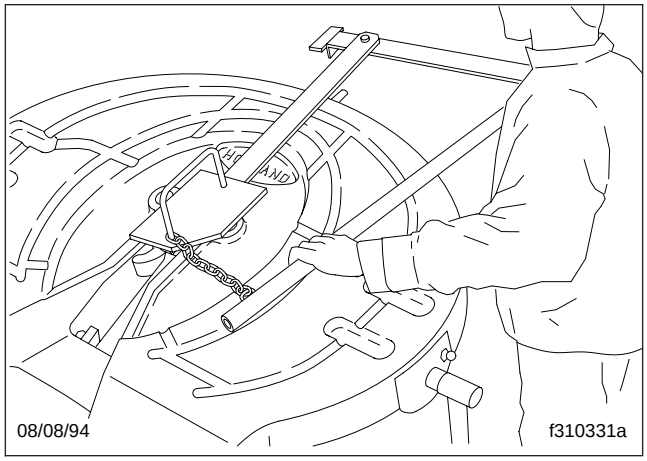

Fig. 17, Using the Lock Tester

IMPORTANT: The fifth wheel must be well lubricated to operate correctly. See Group 31 of the *Business Class Trucks Maintenance Manual*, for complete maintenance and lubrication instructions of the fifth wheel assembly.

Model XA–3501 Top Plate Assembly and Installation

⚠ WARNING

If the fifth wheel does not operate properly, do not use it. The fifth wheel could malfunction, resulting in bodily injury or property damage due to possible separation of the trailer from the tractor.

43. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Then install the roll pins.

Model XA–351 Top Plate Removal and Disassembly

⚠ WARNING

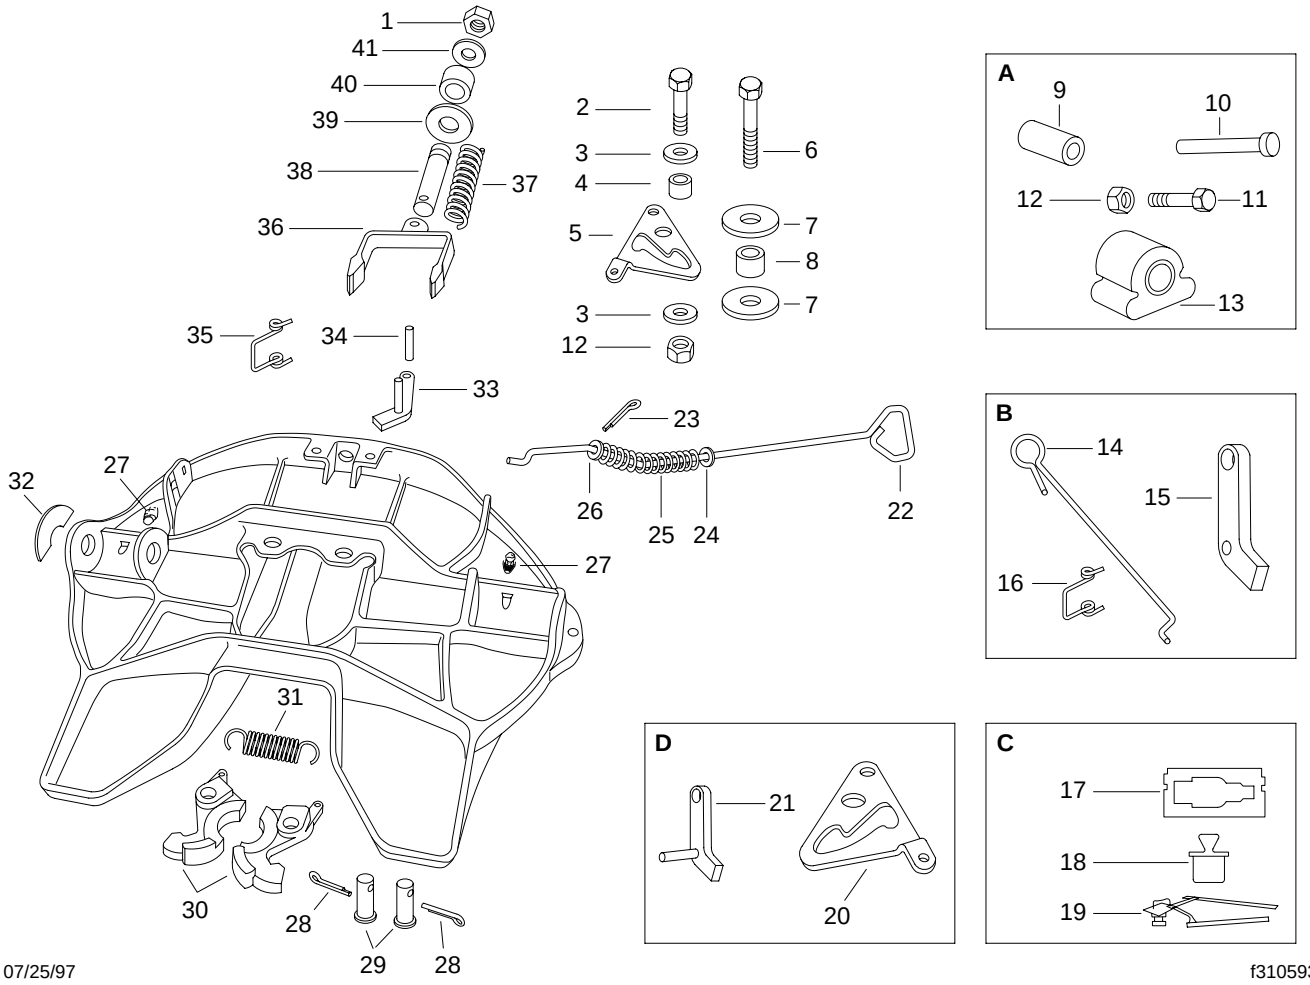
All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Fifth wheel rebuild kits are available for servicing the 3500 series XA–351 fifth wheels. For the rebuild kits, the part numbers include:

- RK–351AL (left release with automatic secondary lock);
- RK–351A02L (left release with manual secondary lock);
- RK–351A (right release with automatic secondary lock);
- RK–351A02 (right release with manual secondary lock).

These fifth wheel rebuild kits contain all the replacement parts, except: the fifth wheel top plate; the bracket assembly rubber bushings; the bracket assembly bushing pins; and the bracket assembly bushing pin capscrews and locknuts.

Rebuilding the fifth wheel may be unnecessary. Review the troubleshooting section before rebuilding the fifth wheel. If the troubleshooting section does not correct the problem, then the fifth wheel may need rebuilding.



While disassembling the fifth wheel, Check it for cracks and for missing or damaged parts. Discard all used components.

Removal and Disassembly

(See Fig. 1)

1. Steam clean the top plate.
2. Remove the top plate from the bracket assembly.
   - 2.1 Loosen and remove the 1/2–20 bushing pin capscrews and locknuts from the top plate.
   - 2.2 Remove the bushing pins from the bracket assembly. See **Fig. 2**.
   - 2.3 Using an overhead hoist, lift the fifth wheel from the bracket assembly and tractor frame.
3. Disassemble the secondary lock.
   - 3.1 Turn the fifth wheel upside down with the locks open.
   - 3.2 Using a suitable driver and hammer, drive the 1/2-inch by 2-3/4 inch roll pin from the top plate and the secondary lock. See **Fig. 3**.
   - 3.3 If the fifth wheel has an automatic secondary lock, proceed to the next substep, otherwise, remove the manual secondary release handle by passing the "S" bend of the release handle through the large hole in the secondary lock and then through the guide hole. See **Fig. 4**.
   - 3.4 Remove the secondary lock.
4. Disassemble the cam plate.
   - 4.1 Loosen and remove the 5/8-inch capscrew from the threaded hole in the yoke. Remove the washers, and the roller from the cam plate. See **Fig. 5**.
   - 4.2 Loosen and remove the 1/2-inch capscrew and nut from the top plate lug. Remove the washers, and the roller from the cam plate. See **Fig. 6**.
   - 4.3 Remove the release handle by passing the "S" bend of the release handle through the large hole in the raised tab of the cam plate and through the top plate casting hole. See **Fig. 6**.
5. Disassemble the yoke.
   - 5.1 Slide the yoke shaft assembly away from the yoke, through the compression spring, and out of the top plate casting. See **Fig. 7**.
   - 5.2 Remove the compression spring and remove the yoke.
6. Disassemble the lock.
   - 6.1 Remove the cotter pins from the lockpins.

Do not attempt to repair or rebuild the top plate if it is cracked or if the lockpin does not fit tightly. The top plate could fail or the locks could malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Fifth wheel rebuild kits are available for servicing the 3500 series XA–351 fifth wheels. For the rebuild kits, the part numbers include:

- RK–351AL (left release with automatic secondary lock);
- RK–351A (right release with automatic secondary lock);
- RK–351A02L (left release with manual secondary lock);
- RK–351A02 (right release with manual secondary lock).

These fifth wheel rebuild kits contain all the replacement parts, except: the fifth wheel top plate; the bracket assembly rubber bushings; the bracket assembly bushing pins; and the bracket assembly bushing pin capscrews and locknuts.

Review the troubleshooting section before rebuilding the fifth wheel. Rebuilding may be unnecessary.

IMPORTANT: Use only Holland rebuilding kits. Replace all roll pins, springs, capscrews, nuts, and washers that are included in the kit. Do not reuse all parts.

WARNING

Use only genuine Holland parts and do not modify, change or add to the product. Any alterations to the fifth wheel assembly could compromise its performance. This could result in the loss of the trailer connection during vehicle travel, possibly causing bodily injury and property damage.

Assembly and Installation

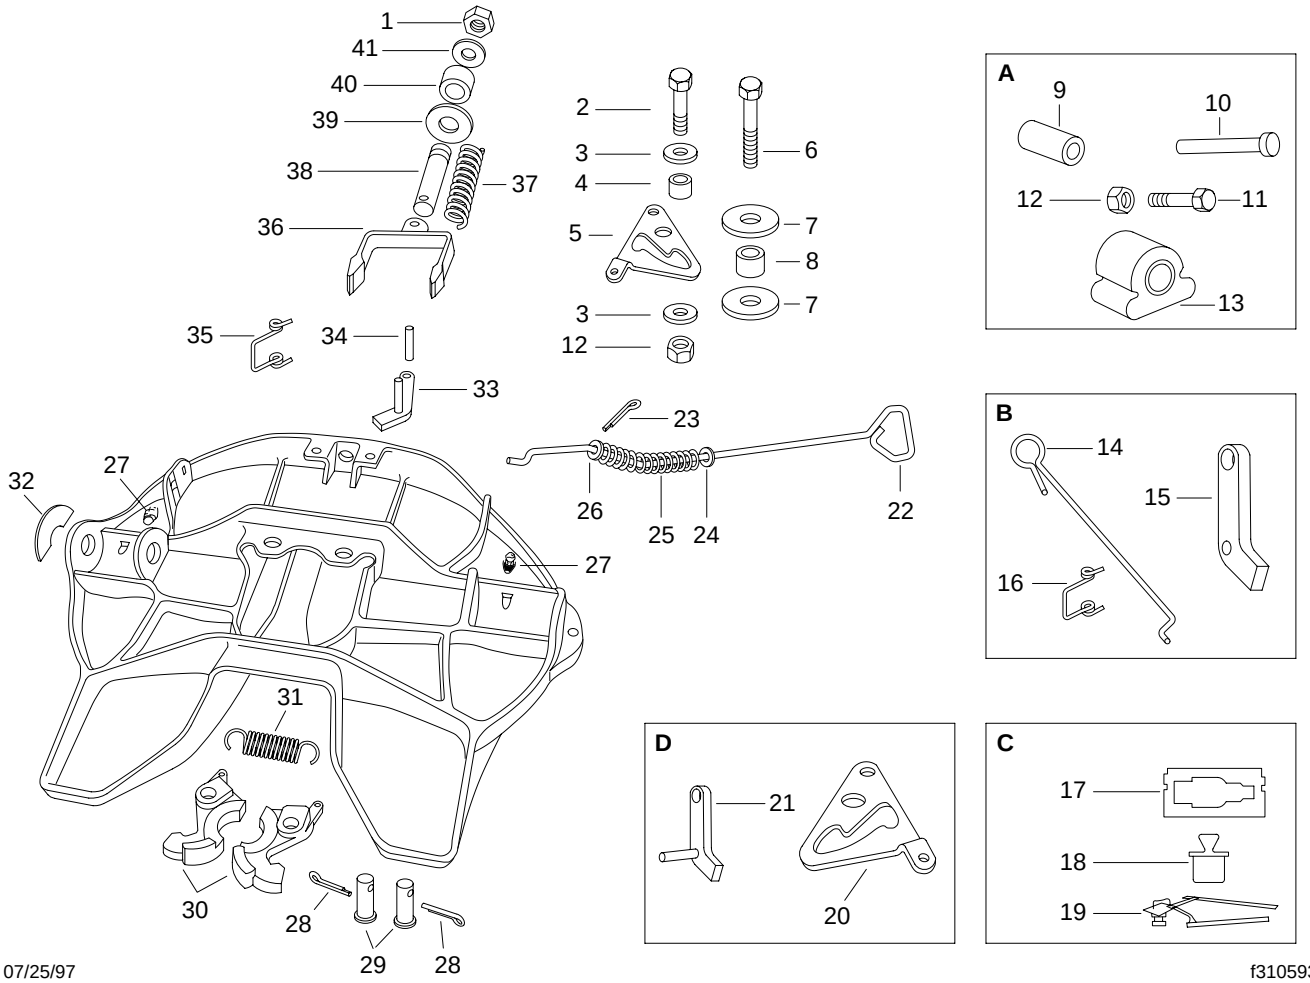
(See Fig. 1)

WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or distorted or if the lockpin does not fit tightly. The top plate could fail or the locks could malfunction. This could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

1. Inspect the top plate.
   - 1.1 If necessary, turn the fifth wheel upside down.
   - 1.2 Inspect the front lock surface for burrs or cracks. See **Fig. 2**. The front lock surface must be free of any burrs or cracks.
2. Install the lock.
   - 2.1 Lubricate the lockpin holes of the lock jaws with Never-Seez (provided in the kit). See **Fig. 3**.

CAUTION



Use only Never-Seez. Other lubricants can damage the lockpin holes.

   - 2.2 Align the lock jaws in the casting and position the lock jaws so that the raised edge of the kingpin guides are facing up. See **Fig. 4**.
   - 2.3 Align the holes in the lockpins so that the cotter pins can be inserted. Insert the lockpins into the casting and through the lock jaws. Using a suitable hammer, drive the lockpins into the casting until the heads are flush with the casting. See **Fig. 5**.
   - 2.4 Insert the cotter pins and spread.
   - 2.5 Check that the lock jaws move freely.

WARNING

You must use a Holland lock gauge (TF–0237) or a precision plug that is 2.000 ± 0.005 inch (5.08 ± 0.0127 cm) for proper installation of the locking

6. Install the secondary lock.

6.1 If equipped with the automatic version, start the roll pin into the hole in the top plate opposite the cam attachment capscrew. Then, assemble and install the secondary lock and torsion spring. Make sure the flats of the torsion spring are resting against the casting. See **Fig. 15**.

With a suitable hammer, drive the roll pin through the torsion spring and secondary

lock until the roll pin is flush with the casting. See **Fig. 15**.

7.1 If equipped, pull the secondary release handle and hook it on the casting. Next, pull the primary release handle to open the locks. Now, remove the 2-inch plug.

7.2 Turn the fifth wheel right side up and close the locks using a Holland Lock tester (see Holland publication FW130 for operating instructions for the lock tester).

7.3 Verify that the locks are completely closed around the kingpin. The lock halves should be seated against each other.

7.4 Alternate tightening the adjustment nut and attempting to turn the lock tester back and forth. Continue tightening the adjustment nut until there is some resistance felt in the lock tester (as it is turned back and forth).

The fifth wheel is properly adjusted when there is resistance between locks and the lock tester, but the lock tester can still be turned by hand.

7.5 Pull the release handle and remove the lock tester.

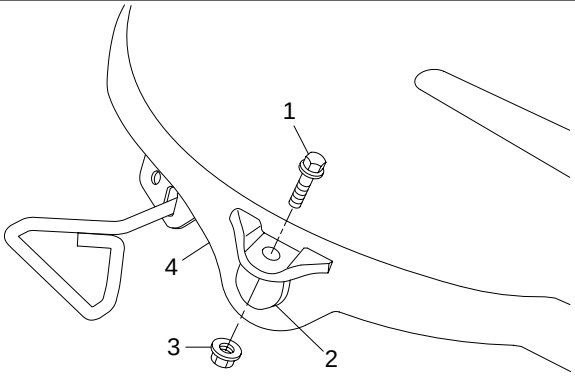
8. Check the fifth wheel for proper operation.

8.1 Using the Holland lock tester, open and close the fifth wheel at least three times.

Each time you close the locks, verify that the locks have closed completely around the kingpin and that the adjustment nut and rubber bushing are seated snug against the casting.

8.2 Check for resistance between the locks and the lock tester one final time, and adjust as needed.

⚠ WARNING



If the fifth wheel does not operate properly, do not use it. Either disassemble it and repeat the rebuilding procedure or contact your nearest Holland representative for assistance. Never use a fifth wheel that does not operate properly. The fifth wheel could malfunction, resulting in bodily injury or property damage due to a possible separation of the trailer from the tractor.

8.3 The fifth wheel is now ready for operation.

9. Install the top plate.

9.1 Using an overhead hoist, lift and position the fifth wheel over the bracket assembly.

9.2 Install the bushing pins through the fifth wheel and into the bracket assembly. Then, install and tighten securely the 1/2–20 bushing pin capscrews and locknuts. See **Fig. 18**. Remove the overhead hoist.

Troubleshooting Tables

Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer

Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer	
Possible Cause	**Remedy**
The trailer may be too high; the kingpin is not entering the locks properly.	Lower the trailer landing gear until the bolster plate contacts the fifth wheel
The locks are closed.	Pull the release handle and pry open the locks.
Rust or grime is interfering with the lock operation.	Spray a light lubricant or diesel fuel on all moving parts including the release handle. Operate the release mechanism several times.
The fifth wheel locks are too tight.	Check the lock adjustment. Correct as needed.
A bent release handle, bent kingpin, or damaged bolster plate is interfering with the lock movement.	Check the release handle, kingpin, and bolster plate. Replace parts as required.
The locks are damaged.	Inspect the locks and replace parts as required.
The fifth wheel needs rebuilding.	Rebuild the fifth wheel, using the parts in the appropriate rebuilding kit.

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer	
Possible Cause	**Remedy**
The secondary lock is not released.	If equipped with a manual secondary lock, pull the release handle and lock it open by resting it against the top plate. If equipped with an automatic secondary lock, inspect the lock for missing or broken parts, and repair or replace as required.
The tractor is putting pressure against the locks.	Set trailer brakes. Back the tractor into the trailer to relieve pressure and lock the tractor brakes before pulling the release handle.
There is rust or grime on the locking mechanism.	Spray a light lubricant or diesel fuel on all moving parts including the release handle. Operate the release mechanism several times.
The kingpin is bent or the bolster plate is damaged.	Check the kingpin, using a Holland TF–0110 Kingpin Gauge. Check the bolster plate, using a 48-inch (122 cm) straight edge. Repair or replace parts as required.
The fifth wheel locks are too tight.	Check the lock adjustment. Correct as needed.
The release handle will not stay out or must be held out when unlocking.	Replace the cam or release arm and the release handle spring.

General Description

Fontaine 5000 series fifth wheels are used for pulling trailers having a standard kingpin. When installed as a stationary fifth wheel, it is bracket-mounted to the tractor frame in a position that best distributes the trailer load over the tractor axles **(Fig. 1).**

The Fontaine fifth wheel lock mechanism for the trailer kingpin consists of a spring-loaded jaw and a sliding wedge. Kingpin release is accomplished by activating a manual lock control handle located on the left side (roadside) of the fifth wheel. Kingpin lockup occurs when the kingpin is forced into the jaws and the lock control handle moves to the locked position.

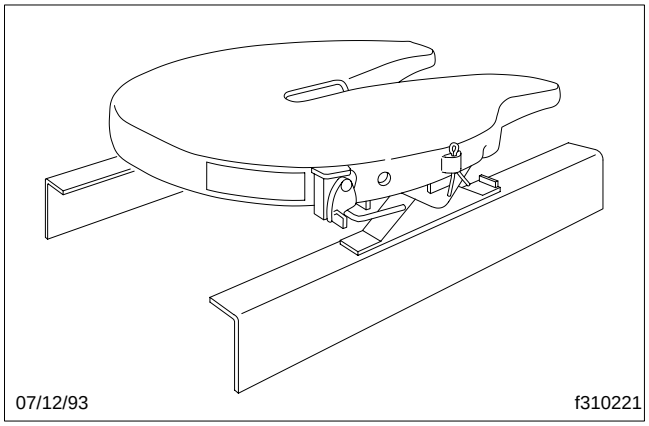

Fig. 1, Fontaine 5000 Series Fifth Wheel and Angle Mount

Principles of Operation

As the kingpin enters the lock mechanism, the jaw is moved first with the spring-loaded wedge sliding in place against the jaw. **See Fig. 2.** The jaw will move behind the kingpin, followed by the wedge. The wedge reinforces the jaw and takes up slack around the kingpin.

Placing the lock control handle in the unlocked position moves the wedge and jaw out from behind the kingpin. This action unlocks the fifth wheel, allowing freedom of movement underneath the trailer when the tractor is moved.

Refer to the vehicle driver's manual for complete operating instructions.

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in a hazardous operating condition due to a possible disengagement of the trailer from the tractor.

Parts are under spring compression. Wear safety goggles during disassembly and assembly. Failure to do so can result in personal injury, due to parts ejecting with force.

1. Steam clean the top plate. Remove it from the sliding mount by removing the cotter pins (Ref. 6) from the retaining pins (Ref. 7). Remove the retaining pins and bushing pins (Ref. 9) from both sides of the top plate.

Removal and Disassembly

2. Using an overhead hoist, lift the fifth wheel off the angle mount and tractor frame.
3. Turn the fifth wheel upside down.

⚠ WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or if parts are damaged. The top plate or parts could malfunction. This could result in disengagement of the trailer during vehicle travel, possibly causing personal injury and property damage.

NOTE: While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.

4. Unhook the bumper spring (Ref. 17) from its clasp. See **Fig. 2**.
5. Remove the two hexhead capscrews (Refs. 14 and 16) from the operating handle (Ref. 12). See **Fig. 3**.
6. Remove the bumper (Ref. 15). See **Fig. 4**.
7. Remove the cotter pin (Ref. 6) and flatwasher (Ref. 13) that attach the release handle (Ref. 18) to the operating handle.

   Slide the release handle out through the side of the fifth wheel. See **Fig. 5**.
8. Slide the operating handle over to the side of the fifth wheel. See **Fig. 6**.

NOTE: Slide the bottom part of the operating handle first. This will allow the handle to clear the studs under the handle.

9. Lift the timer (Ref. 3) off the studs. See **Fig. 7**.
10. Slide the operating handle out through the slot at the top or bottom of the fifth wheel. See **Fig. 8**.
11. Using pliers or a screwdriver, pry the wedge and jaw springs (Refs. 2 and 5) over the studs. See **Fig. 9**.
12. Remove the jaw and wedge (Ref. 4). See **Fig. 10**.
13. Remove the jaw and wedge springs as follows:

    13.1 Remove the cotter pin **(Fig. 11)**.

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in a hazardous operating condition due to a possible disengagement of the trailer from the tractor.

Parts are under spring compression. Wear safety goggles during disassembly and assembly. Failure to do so can result in personal injury, due to parts ejecting with force.

IMPORTANT: Replace any parts that show signs of wear, damage, or deterioration.

Assembly and Installation

⚠ WARNING

When cleaning parts with no. 2 diesel fuel, do not smoke or use an open flame near the area. To do so could result in a possible fire.

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Insert the wedge spring through the slot and lay the spring coil over the spring bracket. See **Fig. 2**.

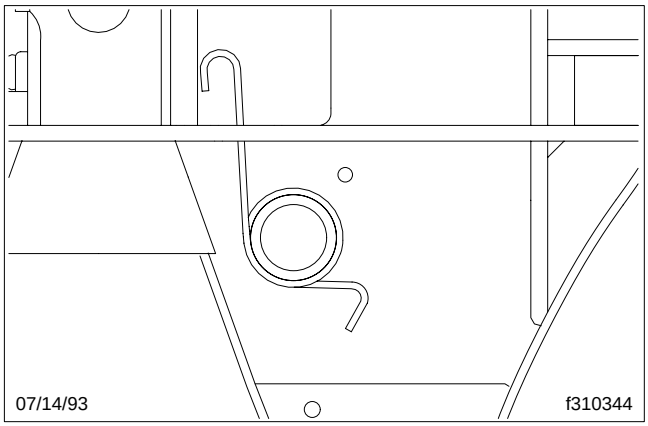

Fig. 2

3. Insert the spring tool part number 710 into the spring bracket (**Fig. 3**). Engage the small hooked tail and wind it around until it is directly over the small stud at the back of the bracket.

   Using a hammer, tap down on the spring until it catches on the stud. Install the cotter pin (**Fig. 4**).

NOTE: Order the spring tool part number 710 from: Fontaine Fifth Wheel Company 125 Cleage Drive Birmingham, Alabama 35217

4. The jaw spring has very little tension; install it by hand.
5. Install a 2-inch diameter shaft where the kingpin will engage in the fifth wheel.
6. Apply a moderate amount of a multipurpose chassis grease to the sides and serrated edges of the jaw and wedge (**Fig. 1**, Ref. 4), and also the stationary jaw in the throat of the fifth wheel.
7. Install the wedge and jaw.
8. Using pliers or a screwdriver, pry the jaw and wedge springs over the studs. See **Fig. 5**.
9. Insert the operating handle (Ref. 12) and move it over to the side of the wheel. Apply a moderate amount of multipurpose chassis grease to the grooved middle section of the operating handle.

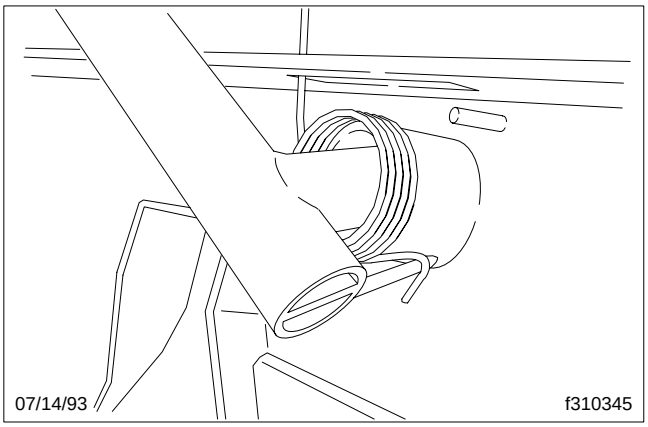

Fig. 3

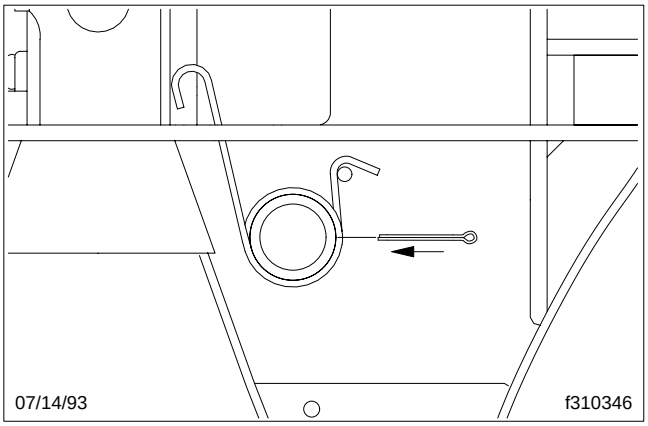

Fig. 4

10. Install the timer (Ref. 3) over the studs.

NOTE: The small hole on the timer fits over the top stud. Make sure the small bent arm of the timer is facing down.

11. Slide the operating handle (top part first) over to the side. Make sure that the handle is in a vertical position once it goes over the studs. See **Fig. 6**.
12. Slide the release handle (Ref. 18) in through the safety lock. Using a flatwasher (Ref. 13) and cot-

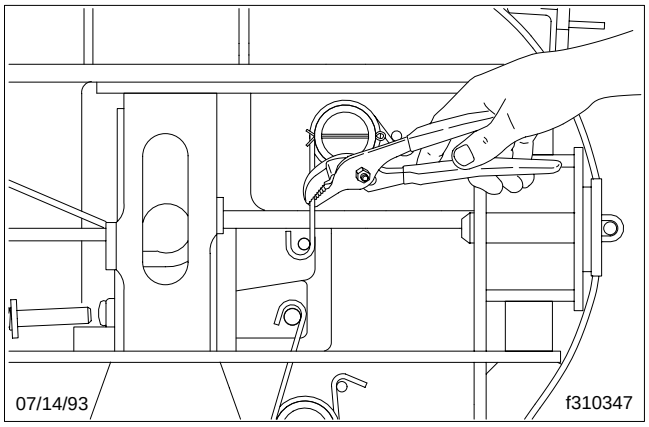

Fig. 5

ter pin (Ref. 6), attach the release handle to the second hole from the top on the operating handle.

13. Position the bumper (Ref. 15), then attach it to the operating handle with a new 1/2–13 x 1-1/2 inch capscrew (Ref. 16), bushing, washer, and locknut.
14. On the other end of the operating handle, install a new 1/2–13 x 2-inch capscrew (Ref. 14), washer, bushing, and locknut.
15. Apply multipurpose chassis grease to the operating handle, and to other fifth wheel parts that may come into contact with the handle during operation.
16. Connect the bumper spring.
17. Using multipurpose chassis grease, grease the top plate and the zerk fittings on the side of the fifth wheel.

    On heavy-duty oscillating fifth wheels, grease the top of the rocker bearing bushing.
18. Measure the distance from the wedge to the end of the wedge stoprod (**Fig. 7**). The correct measurement should be 3 mm (3/8 inch). Turn the wedge stoprod clockwise if the measurement is more than 3 mm (3/8 inch), or turn it counterclockwise if the measurement is less than 3 mm (3/8 inch).

⚠ WARNING

If the fifth wheel does not operate properly, do not use it. The fifth wheel could malfunction, resulting in personal injury or property damage due to possible disengagement of the trailer from the tractor.

IMPORTANT: The fifth wheel must be well lubricated to operate correctly. Refer to the frame and fifth wheel section of the vehicle maintenance manual for complete maintenance and lubrication instructions of the fifth wheel assembly.

19. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Install the retaining pins and the 1-inch long cotter pins.

Fig. 7

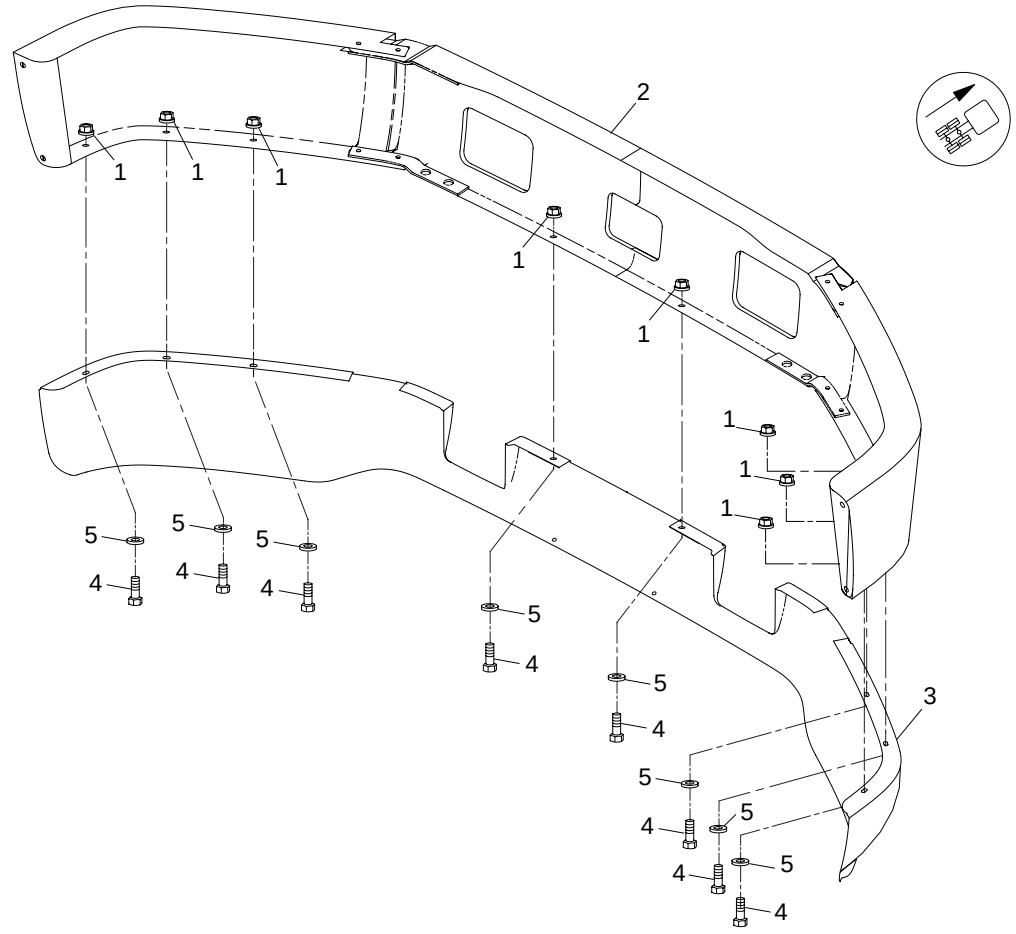
Problem—The Fifth Wheel Is Hard to Hook Up to the Trailer

Possible Cause	Remedy
The trailer may be too high; the kingpin is not entering the locks correctly.	Lower the trailer landing gear until the trailer plate contacts the fifth wheel.
Bent kingpin, or damaged trailer plate is interfering with the lock movement.	Check the kingpin and trailer plate. Replace parts as needed.

Problem—The Fifth Wheel Is Hard to Unhook from the Trailer

Possible Cause	Remedy
The tractor is putting pressure against the locks.	Back the tractor into the trailer; set the tractor brakes. Strike the wedge stoprod to release pressure.
Too much slack in the fifth wheel locks.	Check that the wedge stoprod is 3 mm (3/8 inch) from the end of the wedge. Adjust as needed.
	Check the kingpin diameter; it should not be worn more than 3 mm (3/8 inch). Replace if needed.
	Check the jaw and wedge for excessive wear. Replace if needed.

Bumper and Air Dam Removal and Installation



Removal

1. Park the vehicle on a level surface; then apply the parking brakes. Chock the tires.
2. If equipped with road lights, remove them from the bottom of the bumper.
   - 2.1 Disconnect the wiring from each road light.
   - 2.2 Remove the fasteners that attach the road light mounting bracket to the bottom of the bumper; then remove the road light and its mounting bracket.
3. Remove the air dam from the bumper.
   - 3.1 Remove the 1/4–20 fasteners that attach the air dam to the bottom of the bumper. **See Fig. 1.**
   - 3.2 Remove the air dam from the bumper. Set it aside.
4. Remove the bumper.
   - 4.1 On each side of the vehicle, remove the upper and lower outboard fasteners holding the bumper extension to the bumper. **See Fig. 2.**
   - 4.2 Loosen the upper and lower inboard bumper extension fasteners enough so you can swing the bumper extension out of the way. This will provide easier access to the upper bumper fasteners.
   - 4.3 Support the bumper. On one side of the vehicle, remove first the lower, then the upper 1/2–13 fasteners that attach the bumper to the frame rail bracket. **See Fig. 2.**
   - 4.4 Repeat the procedure on the other side of the vehicle.
   - 4.5 Remove the bumper assembly from the vehicle.

Installation

1. Support the bumper on the frame rail brackets.
2. Install the 1/2–13 fasteners.
   - 2.1 Install the 1-1/4 inch-long bolts in the upper edge of the bumper and through the upper part of the bracket. Install the washers and nuts.
   - 2.2 Install the 1-1/2 inch-long bolts in the lower edge of the bumper and through the lower part of the bracket. Install the washers and nuts.
   - 2.3 Tighten the nuts 68 lbf·ft (92 N·m).
3. On one side of the vehicle, swing the bumper extension back into place; then install the outboard fasteners. Tighten both the inboard and outboard fasteners 68 lbf·ft (92 N·m).
4. Repeat the above procedure on the other side of the vehicle.
5. Install the road lights onto the bumper.
   - 5.1 Line up the hole in the road light mounting bracket with that in the bottom edge of the bumper.
   - 5.2 Install the fasteners; then tighten them finger tight.
   - 5.3 Turn the light to correctly align it; then tighten the mounting bracket fasteners firmly.
   - 5.4 Connect the wiring.
   - 5.5 Repeat the procedure on the other side of the vehicle.
6. Install the air dam.
   - 6.1 Put the air dam in position under the bumper, aligning the holes in the bumper with those in the air dam.
   - 6.2 Install the 1/4–20 fasteners. Tighten them 8 lbf·ft (11 N·m).
7. Remove the chocks from the tires.

General Description (See Fig. 1)

The Holland Fleetmaster fifth wheel is used for pulling trailers having the standard 2-inch diameter kingpin. When installed as a stationary fifth wheel, it is bracket-mounted to the tractor frame in a position that best distributes the trailer load over the tractor axles. When used as a sliding fifth wheel, it is mounted to a slide bracket and plate assembly (air-operated or manual release).

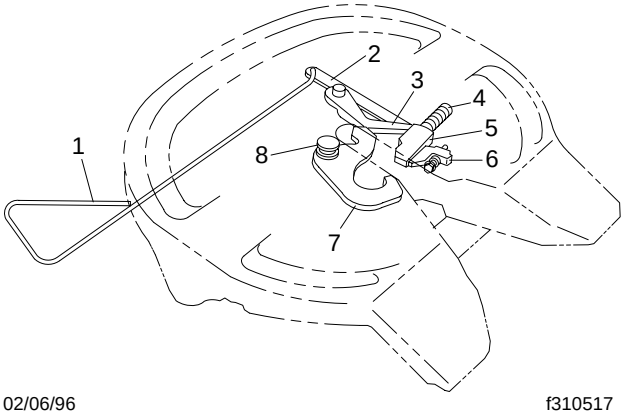
Principles of Operation

The fifth wheel lock mechanism for the trailer kingpin consists of a hinged lock, locking plunger, plunger spring, cam arm, release arm, and operating rod. The lock rotates on a lock pin during coupling and uncoupling operations. During coupling the hinged lock and cam arm pivot against the kingpin and are secured by the locking plunger (See **Fig. 2**).



Uncoupling is accomplished by pulling the release handle using 60–70 lbs. (27–32 kg) of force. The release arm pivots and forces the locking plunger against the plunger spring. The hinged lock is released and the trailer kingpin can be removed (See **Fig. 3**).

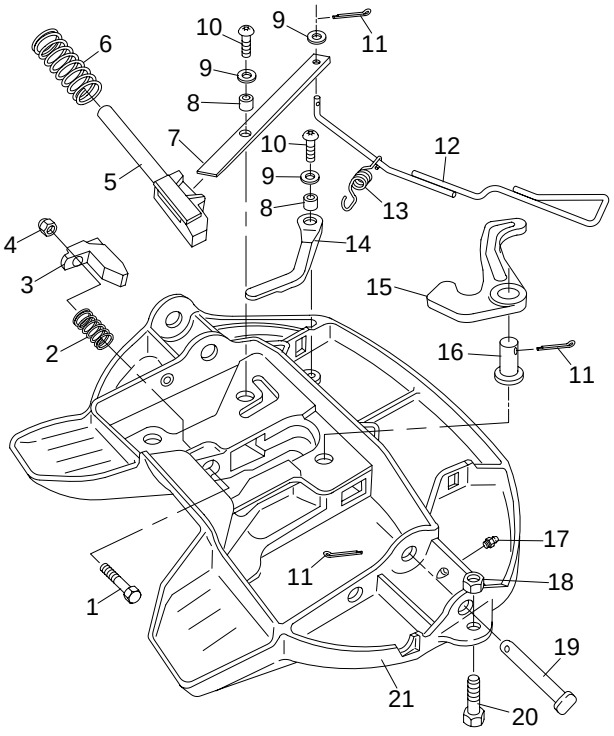
⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in a hazardous operating condition due to possible disengagement of the trailer from the tractor.

Parts are under spring compression. Wear safety goggles during disassembly and assembly. Failure to do so can result in personal injury, due to parts ejecting with force.

1. Steam clean the top plate. Remove the cotter pins from the bracket pins. Remove the bracket pins. Discard the cotter pins and remove the top plate.
2. Using an overhead hoist, lift the fifth wheel off the mount and tractor frame.

Disassembly (See Fig. 1)



1. Turn the fifth wheel upside down.

⚠ WARNING

Do not attempt repair or rebuilding if the top plate is cracked or distorted or if the lock pin is sloppy in the top plate. These conditions could result in top plate failure or malfunction of the locks.

NOTE: While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.

2. Pull the release handle out, slide it forward and hook the handle to the unlock notch of the casting.
3. With the plunger in the unlocked position, remove and discard the cotter pin. Remove the lock pin.
4. Slide the hinged lock away from the locking plunger and remove it from the top plate.

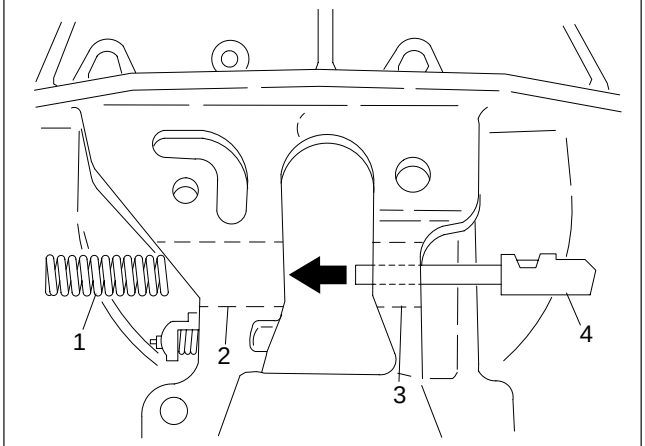
⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in a hazardous operating condition due to possible disengagement of the trailer from the tractor.



Parts are under spring compression. Wear safety goggles during disassembly and assembly. Failure to do so can result in personal injury, due to parts ejecting with force.

IMPORTANT: When rebuilding use only Holland rebuilding kits. Replace all roll pins, cotter pins, springs, bolts, nuts, and washers. Inspect the rebuild kit to verify that all parts are present.

IMPORTANT: Check the lock pin holes. If the holes are elongated the top plate must be replaced. Replace any parts that show signs of wear, damage, or deterioration. Brackets, bracket bushings, bracket pins, and bracket shoes should be replaced in pairs.

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Replace the grease fittings.
3. Apply a thin film of multipurpose chassis grease to the release arm, release arm roller, hinged lock, lock pin, cam arm and roller, adjusting wedge, and locking plunger.
4. Install a 5/8-inch capscrew through the hole in the right side of the throat of the fifth wheel.
5. Slide the wedge spring, and wedge over the capscrew. Thread a 5/8-inch locknut onto the capscrew. Hand tighten the locknut.
6. Install the plunger through the opening in the right throat of the fifth wheel, through the left throat into the plunger spring, and through the hole in the rib of the casting. See **Fig. 2**.
7. Compress the plunger spring by inserting the fabricated block into the throat until the plunger is flush with the throat of the casting. See **Fig. 3**.
8. Insert the cam arm tail into the pocket in the plunger. Align the cam arm hole with the bolt hole in the casting. See **Fig. 4**.
9. Install the roller, washer (rounded edge towards roller), and torx bolt. Tighten the torx bolt 85 to 120 lbf·ft (115 to 163 N·m).
10. Insert the tapered end of the release arm through the main rib of the casting into the

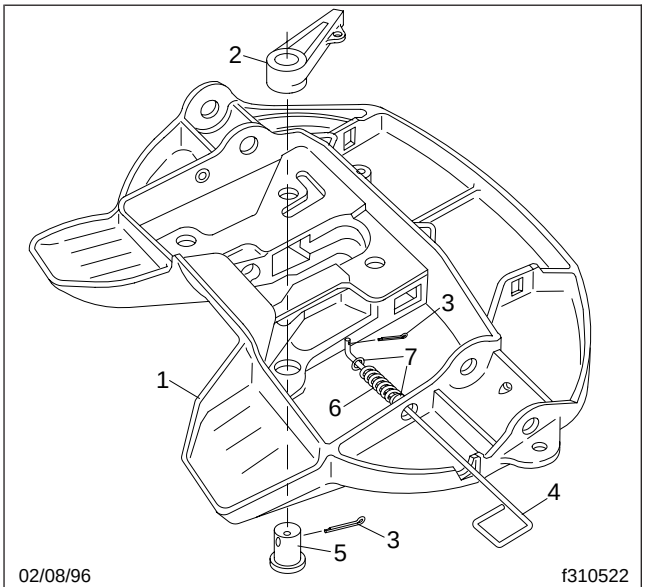
14. Lubricate the release handle spring contact areas with a light grease. Attach the release handle spring to the casting ear.
15. Pull the release handle and hook it on the unlock notch of the casting.
16. Remove the fabricated block. Keep hands and fingers clear.
17. Grease the lock pin hole and lock contact areas. Slide the hinged lock through the opening in the right-hand side of the throat of the fifth wheel. Align the lock pin hole with the hole in the casting.
18. Slide the lock pin through the casting from the face of the top plate through the lock, then through the bottom of the casting. Install the cotter pin.
19. Unhook the release handle from the notch in the casting.

Installation

NOTE: Before remounting the top plate, inspect the rubber bushings and bracket pins for wear. Replace as necessary. If bushing replacement is required, be sure to use the correct diameter bushing.

1. Using an overhead hoist, position the fifth wheel on the sliding or stationary mount brackets. Clamp the fifth wheel in place to compress the bracket rubbers.
2. Insert the bracket pins and new cotter pins. Lock the cotter pins.

Lock Adjustment



1. Open the hinged lock by pulling the release handle and putting pressure against the hinged lock, moving it towards the open position.
2. Close the fifth wheel using a Holland lock tester. Tighten the adjustment bolt while attempting to rotate the lock tester back and forth.
3. Slowly tighten the bolt until the lock tester just stops rotating. Loosen the adjustment bolt two full turns.
4. Verify proper operation by locking and unlocking the fifth wheel several times using the tester.

⚠ WARNING

If the fifth wheel top plate does not operate properly, do not use it. An improperly functioning fifth wheel could cause loss of vehicle or trailer control, resulting in personal injury. Repeat the above procedure or call your local Holland representative for assistance.

4. Align the pin holes of the secondary lock arm and the casting. Drive the lock pin through the casting from the top plate, through the secondary lock. Install the cotter pin through the secondary lock.
5. Install a 45-degree lube fitting into the secondary lock pin.
6. Grasp the secondary lock handle handhold, and slide the other end of the handle through the rib of the casting, through the 7/16-inch washer, through the handle spring, through another 7/16-inch washer, and up through the bottom of the loop on the secondary lock arm.
7. Compress the release handle spring and secure the release handle using a cotter pin. Lock the cotter pin.
8. Check the secondary release handle for proper operation.

Troubleshooting

Problem—Hard to Hook Up the Fifth Wheel to the Trailer

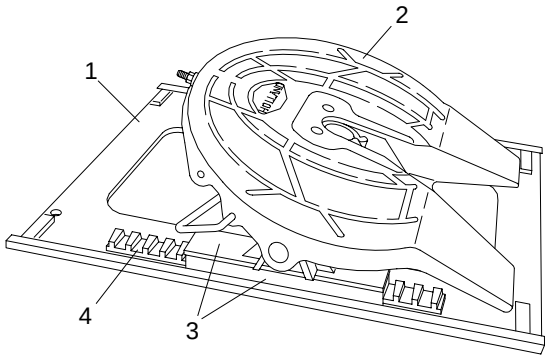
Problem—Hard to Hook Up the Fifth Wheel to the Trailer	
Possible Cause	**Remedy**
The trailer may be too high; the kingpin is not entering the lock correctly.	Lower the trailer landing gear until the trailer plate contacts the fifth wheel.
A bent kingpin or damaged trailer plate is interfering with the hinged lock movement.	Check the kingpin and trailer plate. Replace parts as needed.
The hinged lock has not been adjusted correctly.	Check the clearance between the lock and the kingpin. Adjust as described in this section.
Attempting to couple too quickly.	Pick up the trailer with the fifth wheel. Stop. Continue backing up until the fifth wheel locks firmly to the kingpin. Stopping helps prevent hitting the kingpin too hard.
The locks are closed.	Pull the release handle. Hook the handle on the notch in the casting and pry the hinged lock open.
Accumulated rust or grime is interfering with lock operation.	Spray a light lubricant or diesel fuel on all moving parts, including the release handle. Operate the unit several times.
The locks are damaged.	Inspect and replace components as described in this section.
The fifth wheel requires rebuilding	Follow the procedures contained in this section using the appropriate rebuilding kit.
Using a lube plate with the wrong kingpin length.	See Holland Service Bulletins 4 and 4A.

Problem—Hard to Unhook the Fifth Wheel from the Trailer

Problem—Hard to Unhook the Fifth Wheel from the Trailer	
Possible Cause	**Remedy**
The tractor is putting pressure against the locks.	Back the tractor up a little to relieve kingpin load against the fifth wheel lock. Lock the tractor brakes before pulling the release handle and hooking it on the notch in the top of the plate casting.
The optional secondary lock (if equipped) is not released.	Pull out the secondary release handle and move it forward to secure it on the top plate casting.
The release handle will not stay out or must be held out when unlocking.	Follow the procedures contained in this section using the appropriate rebuilding kit.
The primary release handle is not pulled out completely and locked on the notch in the casting.	Slide the primary release handle out and pull it forward. Slide the handle forward, hooking it on the notch on the top plate casting.
Rust or grime is on the locking mechanism.	Spray a light lubricant or diesel fuel on all moving parts including the release handle. Operate the unit several times.
Bent kingpin or damaged bolster plate.	Check the kingpin with a Holland TF–0110 Kingpin Gage and bolster plate with a 48 inch straightedge. Repair or replace as required.
Fifth wheel locks are adjusted too tight.	Check the clearance between the lock and the kingpin. Adjust as described in this section.

Troubleshooting

NOTE: After the fifth wheel is unlocked and moves freely from the kingpin, it is normal for the release handle to disengage from the notch in the casting to return to a position between locked and unlocked.



General Information

NOTE: For Holland 3500 series fifth wheel service operations, see **Section 31.01**.

NOTE: Prior to June 1, 1996, the Holland sliding fifth wheel mount carried a part number prefix FW2535. Since June 1,1996, the Holland sliding fifth wheel mount part number prefix has been replaced by FW35.

The Holland sliding fifth wheel mount is designed to provide maximum tractor use for different lengths and types of trailers. The FW2535/FW35 sliding fifth wheel mount is used with the Holland 3500 series fifth wheel, and is equipped with either a manually operated or an air-operated release slider.

Sliding fifth wheel assemblies are mounted on a baseplate with notched rails. See **Fig. 1**. Plungers are meshed into teeth on the baseplate to lock the fifth wheel. This assembly allows forward or rearward movement of the fifth wheel along the notched rails for optimum weight distribution over the tractor axles. The mounting baseplate is bolted to the tractor frame.

Disassembly

⚠ WARNING

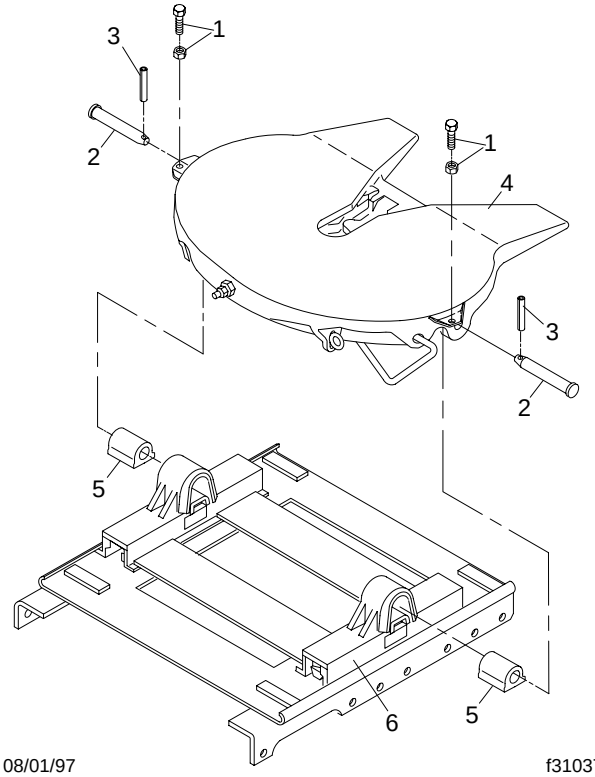
Fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Incorrect or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

1. Remove the top plate.
   - 1.1 If equipped with model XA–3501 top plate, remove the roll pins (**Fig. 1**) from both the right and left side of the top plate. Then, remove the bushing pins.

     Using an overhead hoist, lift the fifth wheel off the slide mount assembly.
   - 1.2 If equipped with model XA–351 top plate, loosen and remove the 1/2–20 bushing pin capscrews and locknuts from both the left and right sides of the top plate. Then, remove the bushing pins (**Fig. 1**) from the bracket assembly.

     Using an overhead hoist, lift the fifth wheel off the slide mount assembly.

⚠ WARNING

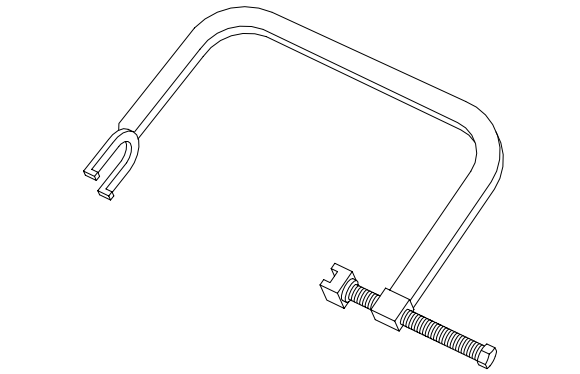


When draining the air reservoir, do not look into the air jets, or direct them toward anyone. Dirt or sludge particles may be in the airstream, and could cause injury if ejected.

2. If the fifth wheel has a manual release sliding mount, then go to the next step. Otherwise, drain the air reservoir; then disconnect and plug the air line from the air cylinder.

⚠ WARNING

Parts are under spring compression. Wear safety goggles during disassembly and assembly, and keep fingers away from possible pinch points at the ends of springs. Failure to do so can result in bodily injury, due to parts ejecting with force.



3. Using a Holland TF–TN 2500 spring compressor (**Fig. 2**), compress one of the plunger return springs (**Fig. 3**).

   If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), remove the plunger retaining pin from the release lever, then remove the plunger.

5. Carefully remove the spring compressor; then remove the plunger return spring, the spring compression stop, and the spring retainer (**Fig. 3**).

   Repeat the procedure for the other plunger.

6. Remove the air-release cylinder or the manual release lever.

   If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), remove the air-release cylinder or the manual release lever along with the right and left release levers (**Fig. 3**). Disconnect the release levers from the air-release cylinder or manual release lever.

⚠ WARNING

Wear protective eye and facial gear when grinding to remove the rear stops. Failure to do so could result in personal injury due to flying metal debris from the grinding.

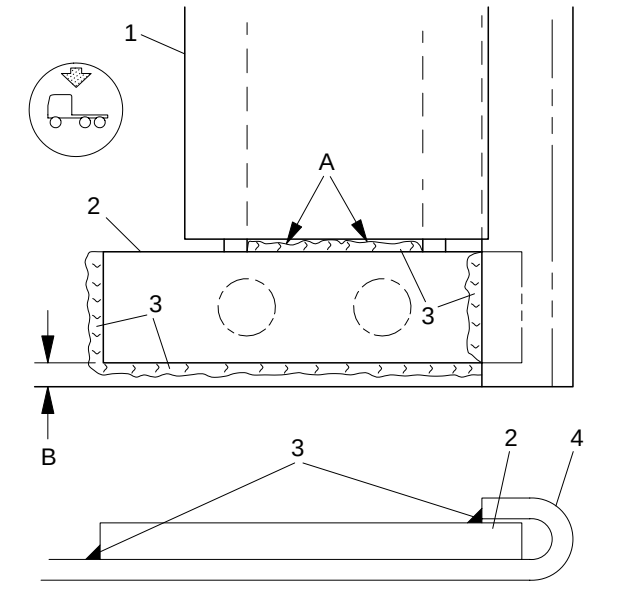
7. If the slide mount assembly (**Fig. 3**) is damaged, dismantle it from the baseplate (Ref. 9).

   7.1 Grind down the welded area to remove the rear stops.

   7.2 Remove the slide mount assembly from the baseplate by sliding it off the rear of the tracks.

8. Remove all dirt and grease from the parts. Replace any parts that show signs of wear or damage.

NOTE: If the rubber bushings (**Fig. 1**) are damaged, or if they allow movement of more than 1/8 inch (3 mm), replace them.



Assembly

⚠ WARNING

Fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Incorrect or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

1. Using a rubber lubricant or a waterless hand cleaner, lubricate the outer surfaces of the new rubber bushings.
2. Install the rubber bushings (**Fig. 1**) into the slide mount assembly until they are flush with the outboard ends of the assembly.
3. Using a multipurpose chassis grease, lubricate the flanges on the slide mount assembly. Then slide the assembly onto the tracks of the baseplate.
4. Move the slide mount assembly to the rearmost position. Install the plungers into the outboard ends of the slide mount. Engage the plungers in the rail teeth.
5. Install the rear stops under the curled edge of the baseplate. Allow a clearance of about 1/8 inch (3 mm) from the rear stops to the slide mount (when it's in the full rear position). The stops should be about 1/4 to 1/2 inch (6 to 13 mm) from the rear edge of the baseplate. See **Fig. 4**.
6. Clamp the rear stops in place, then move the slide mount assembly forward and out of the way.
7. Weld the stops in place. The welds should be 1/4-inch (6-mm) fillet. On the forward edge, weld only the center area; not the area where the slide mount assembly contacts the stop. See **Fig. 4**.
8. Move the slide mount assembly to the rearmost position and check for clearance. Make sure the plungers seat into the rail with all teeth engaged.
9. If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), and if new release levers are being installed, attach the right and left release levers to the tie bar (**Fig. 3**). Install

3/8–16 capscrews and locknuts and tighten them firmly, but make sure the parts are not binding.

Using the 1/2–20 capscrews and locknuts, attach the air-release cylinder or the manual release lever to the ends of the release levers, tighten the nuts firmly, but make sure the parts are not binding.

10. Install the spring compression stops and the plunger return springs on the inboard ends of the plungers. Then install the spring retainers.

⚠ WARNING

Parts are under spring compression. Wear safety goggles during disassembly and assembly, and keep fingers away from possible pinch points at the ends of springs. Failure to do so can result in bodily injury, due to parts ejecting with force.

11. Using a Holland TF–TN 2500 spring compressor, compress one of the plunger return springs and its spring retainer enough to access the hole through the end of the plunger shaft.

12. If equipped with a standard fifth wheel, position the air-release cylinder or the manual release lever so that the holes in its clevis line up with the hole through the end of the plunger shaft. Install the retaining pin.

    If equipped with a fifth wheel height of 6.62 or 8.12 inches (16.8 or 20.6 cm), line up the holes in the clevis of one of the release levers (**Fig. 3**) with the hole in the end of the plunger shaft. Install the retaining pin.

13. Carefully remove the spring compressor.

14. Repeat the procedure on the other side of the vehicle.

15. If the fifth wheel has a manual release sliding mount, then go to the next step, otherwise connect the air lines.

    15.1 Remove the plugs from the air line.

    15.2 Connect the air line to the inlet on the air-release cylinder.

    15.3 Start the engine to build air pressure, then check the operation of the slide mechanism.

16. Adjust the plungers, following the procedure in **Subject 110**.

17. Install the top plate.

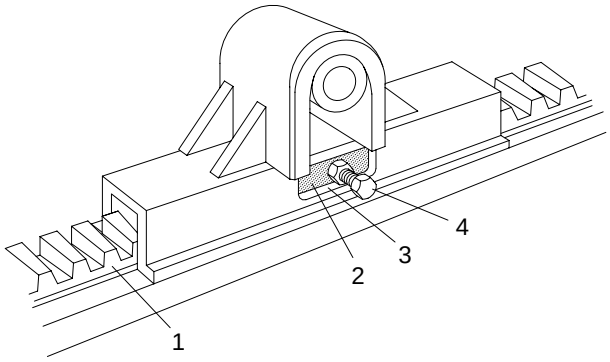
    17.1 If equipped with model XA–3501 top plate, using an overhead hoist, lift the fifth wheel onto the slide mount assembly.

    From both the right and left side of the top plate, install the bushing pins and the roll pins (**Fig. 1**).

    17.2 If equipped with model XA–351 top plate, using an overhead hoist, lift the fifth wheel onto the slide mount assembly.

    From both the right and left side of the top plate, Install the bushing pins. Then, install and tighten snugly the 1/2–20 bushing pin capscrews and locknuts (**Fig. 1**).

Adjustment



⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Incorrect or incomplete procedures could result in loss of trailer connection during vehicle travel, possibly causing bodily injury and property damage.

NOTE: The locking plungers are adjusted at installation and again after one month of operation. Make additional adjustments as needed.

1. The plungers should seat in the pocket with a small amount of play when locked (engaged). See **Fig. 1**. If they wedge or bind, turn the adjusting bolt clockwise or counterclockwise as needed.

   Turning the adjusting bolt clockwise moves the plunger out of the pocket; turning it counterclockwise moves the plunger further into the pocket.

2. If the plungers don't unlock (release), check the air-release cylinder or the manual release lever for correct operation. Replace it if needed. See **Subject 100** for removal and installation instructions.

3. If the adjusted plunger binds on the bottom of the pocket, remove it; then grind the plunger top edges 1/16 inch (2 mm). See **Fig. 2**. Install the plunger. See **Subject 100** for plunger removal and installation instructions.

   Adjust the plunger, following the instructions above.

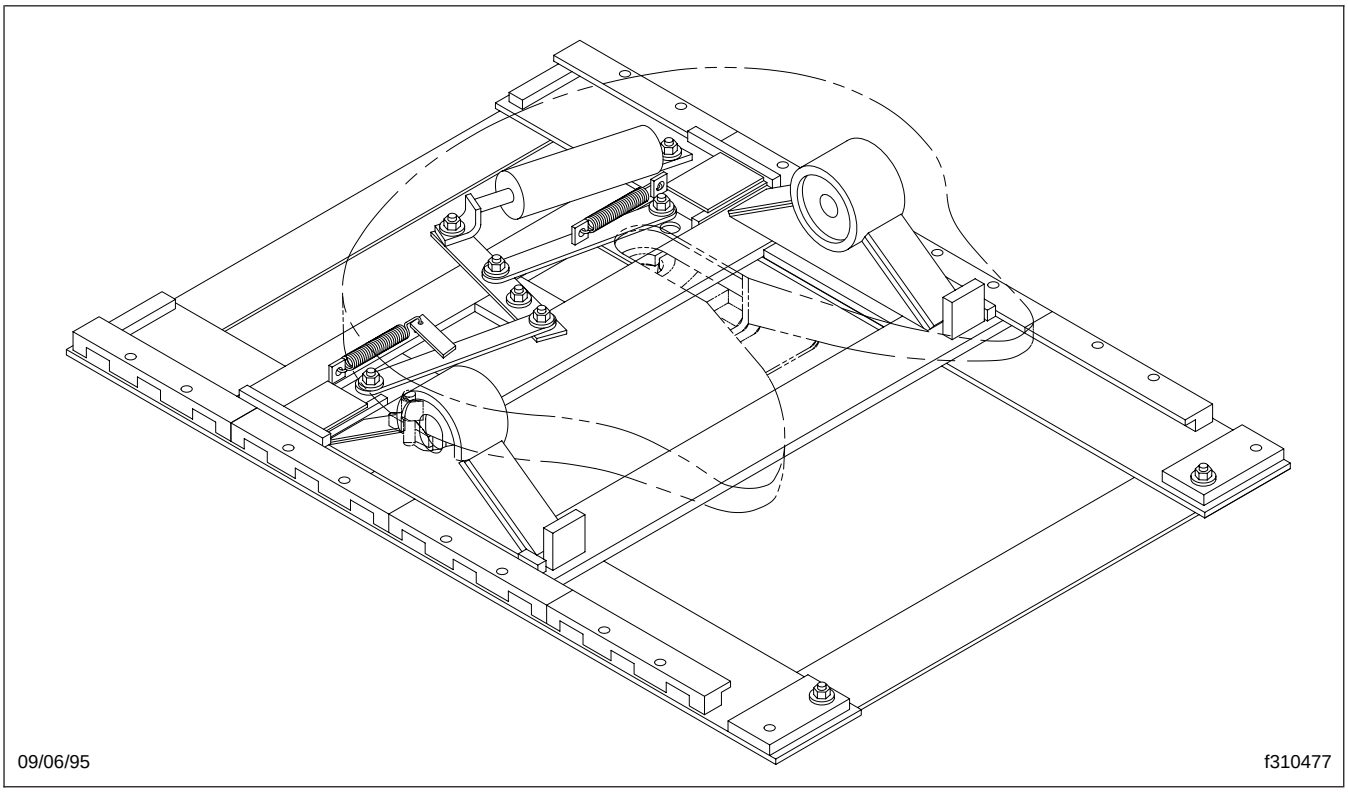
4. If the plungers are too loose, check the tension of the plunger return springs. If the springs are damaged or worn, replace them, following the instructions in **Subject 100**.

   If the plungers are still too loose, replace the plungers, following the instructions in **Subject 100**.

General Information

Fontaine H5092 series fifth wheels couple to trailers having a standard 2-inch kingpin. When installed as a stationary mount, the fifth wheel is bracket-mounted to the tractor frame in a position that best distributes the trailer load over the tractor axles. Sliding fifth wheels (**Fig. 1**), are mounted on the Fontaine HAWB or HMWS (previously called 5AWB and 5MWS) model slide mounts.



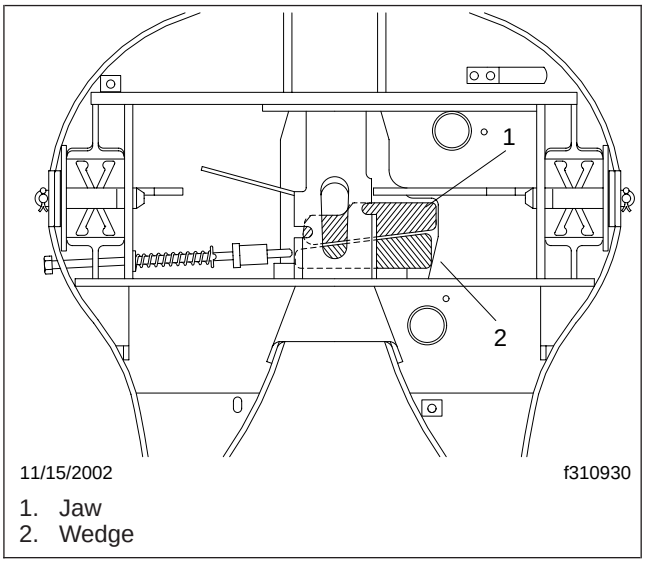


Fig. 1, Fontaine H5092 Series Air Slide Fifth Wheel

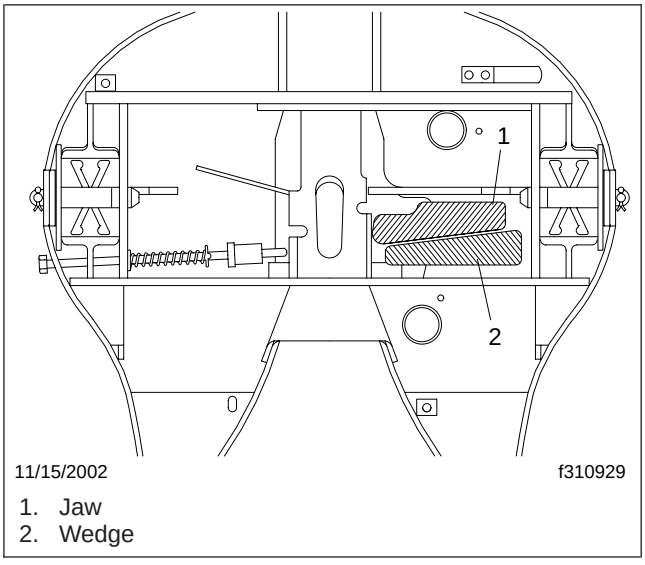
The Fontaine fifth wheel lock mechanism for the trailer kingpin consists of a spring-loaded jaw and sliding wedge. Kingpin release is accomplished by pulling a manual lock control handle located on either the right side (curbside) or left side (roadside) of the fifth wheel. Kingpin coupling occurs when the kingpin enters the throat of the fifth wheel, triggers the jaw and wedge to slide into place behind the kingpin, and moves the lock control handle into the locked position.

As the kingpin enters the lock mechanism, the jaw is moved first with the spring-loaded wedge sliding in place against the jaw. The jaw will move behind the kingpin, followed by the wedge. The wedge reinforces the jaw and automatically adjusts for slack around the kingpin. See **Fig. 2** for an illustration of the jaw and wedge in the locked position.



Placing the lock control handle in the unlocked position moves the wedge and jaw out from behind the kingpin and unlocks the fifth wheel. See **Fig. 3** for an illustration of the jaw and wedge in the unlocked position.

2. Using an overhead hoist, lift the fifth wheel off the sliding mount and tractor frame.
3. Turn the fifth wheel upside down.

NOTE: While disassembling the fifth wheel, check it for cracks and for missing or damaged parts.

⚠ WARNING

Do not attempt to repair or rebuild the top plate if it is cracked or if parts are damaged. The top plate or parts could malfunction. This could result in disengagement of the trailer during vehicle travel, possibly causing personal injury and property damage.

4. Set the fifth wheel in a locked position, then unhook the bumper spring from the bumper tang and the tab on the side of the fifth wheel substructure. See **Fig. 2**. Remove the bumper spring.

⚠ WARNING

All fifth wheel maintenance, adjustment, and rebuilding must be done only by a qualified mechanic. Improper or incomplete procedures could result in possible disengagement of the trailer

IMPORTANT: Replace any parts that show signs of wear, damage, or deterioration.

Fifth Wheel Assembly and Installation

1. Clean all moving parts with no. 2 diesel fuel before assembly.
2. Always assemble the parts around a 2-inch kingpin or a shaft with a 2-inch diameter. Insert the jaw first and then the new wedge below it. Apply a moderate amount of grease having EP (extra pressure) additives to the sides and serrated edges of the jaw and wedge. Also apply grease to the stationary jaw in the throat of the fifth wheel. See **Fig. 2**.

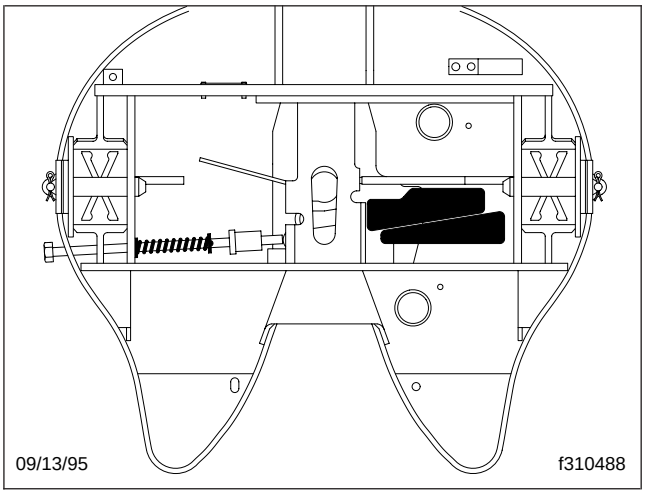

Fig. 2, Wedge and Jaw Installation

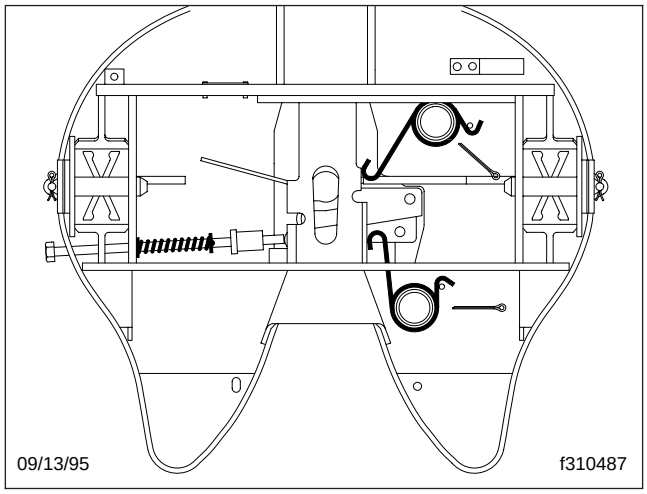
3. Insert the new wedge spring through the slot in the rear crossmember and lay the coil over the spring boss. Using a spring tool, engage the small hooked tail of the wedge spring and wind it around until it is directly over the small stud at the back of the bracket. Using a hammer, nudge the spring downward allowing it to catch on the stud. Insert a new cotter pin. See **Fig. 3**.

   Repeat these steps to replace the jaw spring.

NOTE: The jaw spring has minimal tension and can be replaced by hand.

4. Place the bumper back in position, sliding the bumper tang through the operating handle guide slot and toward the tab on the side of the fifth wheel substructure. See **Fig. 4**.
5. Apply a liberal amount of grease to the grooved middle section of the operating handle, then insert the operating handle and move it over to the side of the wheel. See **Fig. 5**.



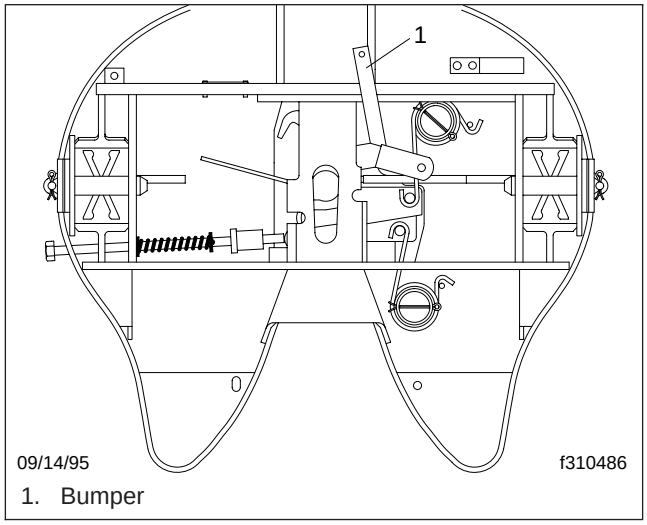


Fig. 3, Spring Installation

1. Bumper

Fig. 4, Bumper Installation

6. Insert the timer over the jaw and wedge studs. the small hole on the timer fits over the jaw stud and the slotted hole fits over the wedge stud. Be certain the small bent arm of the timer is facing downward. See **Fig. 6**.
7. Slide the operating handle toward the center of the wheel to engage the handle with the studs on the jaw and wedge. Slide the top part first. This will ensure that the grooves on the operating handle are aligned with the studs. A correctly aligned operating handle should be in a vertical position once it goes over the studs. See **Fig. 7**.

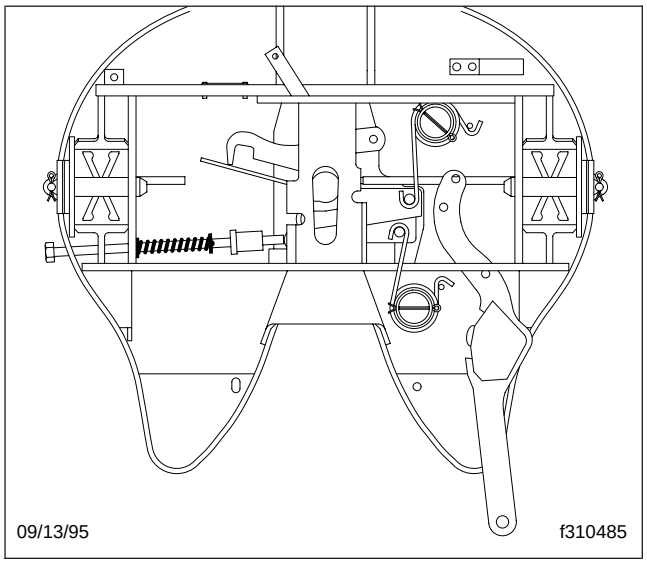

Fig. 5, Operating Handle Installation

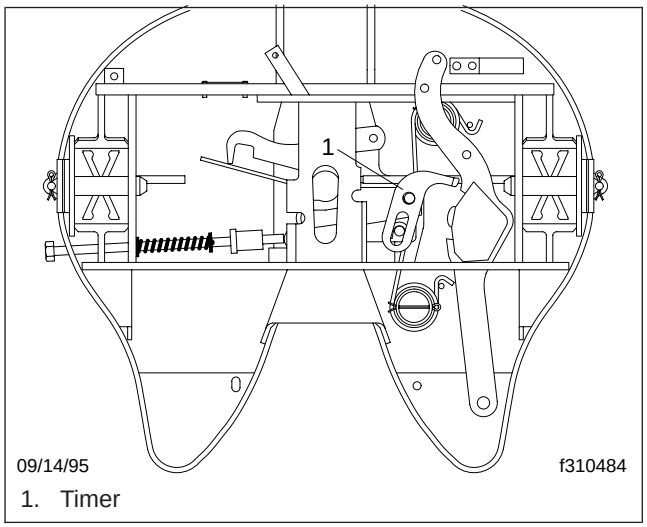

Fig. 6, Timer Installation

8. Slide the pull handle in through the safety lock and using the cotter pin and washer, fasten it in the top hole of the operating handle. See **Fig. 8**.
9. Align the bumper hole with the hole in the operating handle. Replace the bolts on the operating handle. The bolt which fastens the operating handle to the bumper must be inserted with the threads facing toward you to prevent interference with the jaw springs. The other bolt should be positioned with the threads facing downward. Each bolt has a nut, washer, and new bushings.

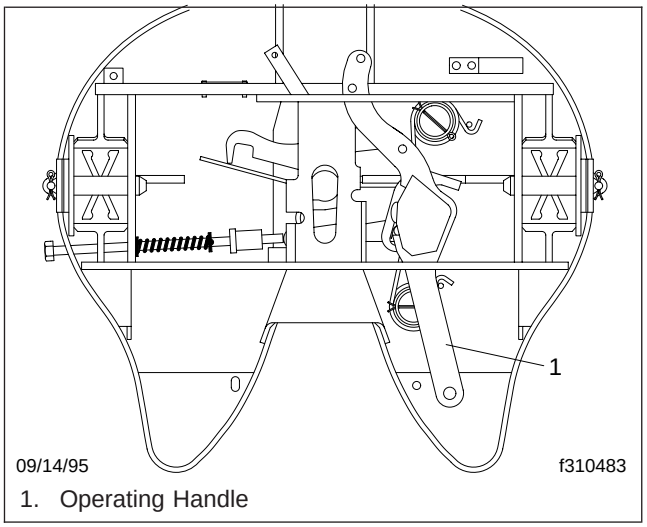

Fig. 7, Operating Handle Positioning

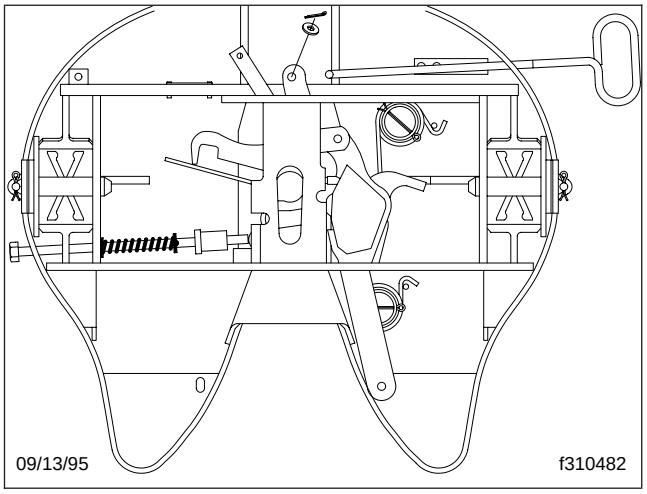

Fig. 8, Pull Handle Installation

Apply grease to the bolt parts and where there is metal to metal contact with the operating handle. See **Fig. 9**. Do not overtighten the bolts. Lubricate all pivot points.

IMPORTANT: The fifth wheel must be well lubricated to operate correctly. Refer to Group 31 of the *Business Class®: Maintenance Manual* for complete maintenance and lubrication instructions for the fifth wheel assembly.

10. Connect the bumper spring to its clasp. Apply grease to the bracket pockets and to the grease fittings on the side of the fifth wheel until grease

flows into the upper brackets. Also apply a liberal amount of grease to the top plate. See **Fig. 10**.

1. Bumper Spring

Fig. 10, Spring Installation

WARNING

If the fifth wheel does not operate properly, do not use it. The fifth wheel could malfunction, resulting in personal injury or property damage due to possible disengagement of the trailer from the tractor.

11. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Install the retaining pins and the 1-inch-long cotter pins.

Troubleshooting Tables

Problem—Difficulty Coupling

Possible Cause	Remedy
The kingpin is too high to trip the latch	Lower the landing gear.
The trailer plate or kingpin is damaged.	Check the trailer plate for flatness. Check the kingpin for squareness with the trailer plate.

Problem—Excessive Wear on the Fifth Wheel Top Plate

Possible Cause	Remedy
Damaged trailer plate	If the trailer plate is not flat, replace it.

Problem—Difficulty Uncoupling

Possible Cause	Remedy
Pressure on the locking mechanism caused by truck drifting apart from the trailer putting excess pressure on the lock	Back up the trailer and set the brakes. Strike the wedge stop rod which protrudes through the side of the fifth wheel. This spring-loaded rod will release the pressure on the locking mechanism.
Oval-shaped kingpin	Lower the landing gear.

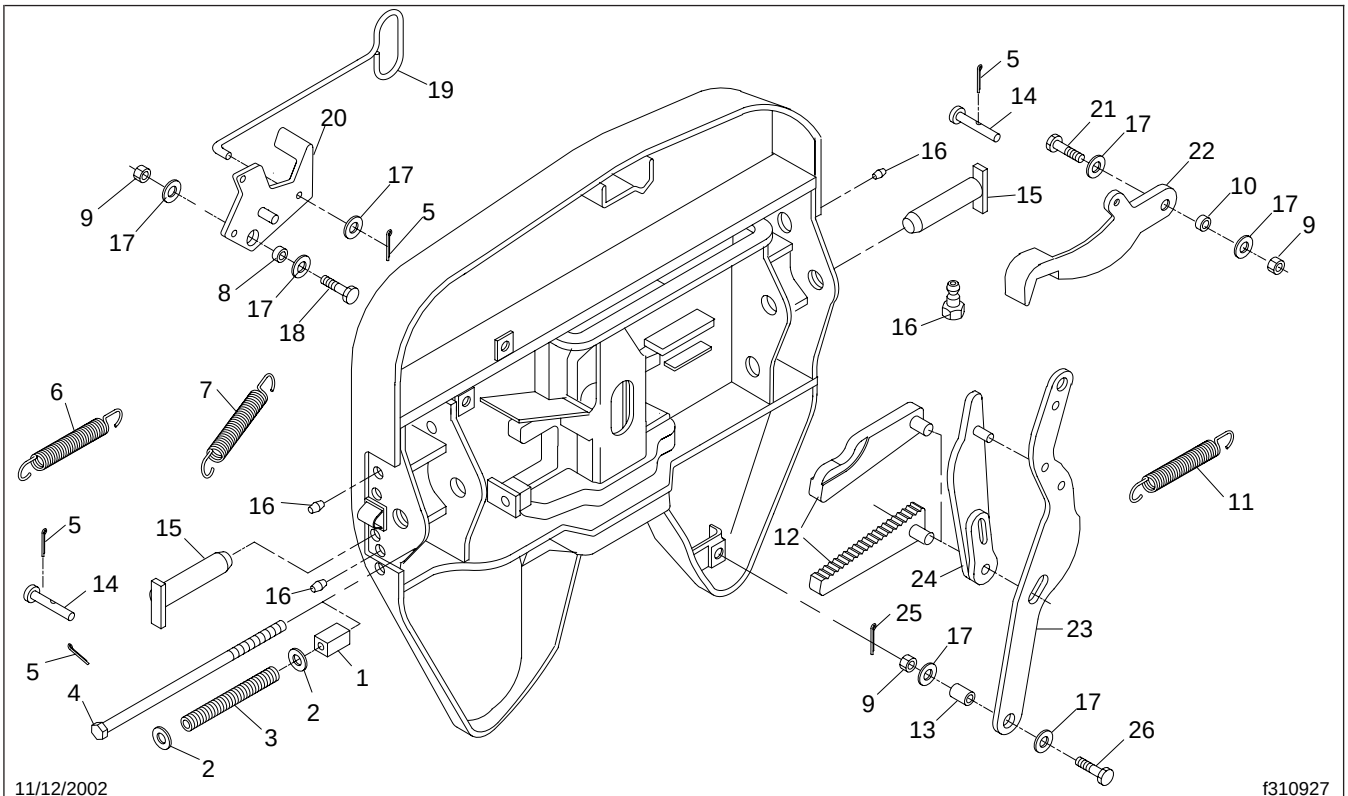
Assembly and Installation

⚠ WARNING

Before rebuilding the assembly, check to make sure that there are no cracks in the crossmembers or other components. Also check the bracket pin holes to ensure they are not worn oversize (pins should fit snugly). Under no circumstances should a fifth wheel be repaired or used if any component (crossmember, saddle bearing, etc.) is cracked. Operating a fifth wheel with damaged components could result in disengagement of the trailer from the tractor, leading to personal injury or property damage.

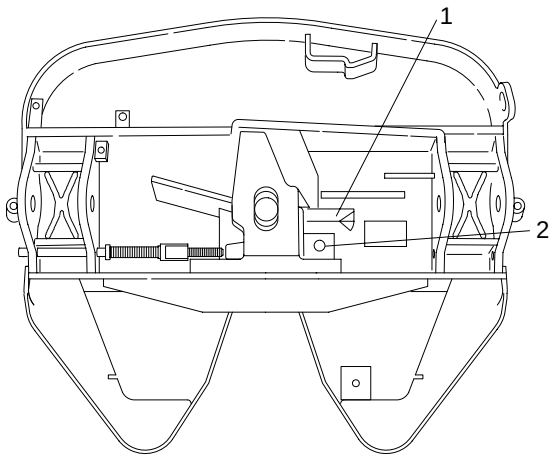
Use a Moly-based lubricant such as Mobil grease Moly 50 or equivalent when applying lubricant to the locking jaw and wedge. Lightly oil other moving parts in the fifth wheel.



See **Fig. 1** for an exploded view of a Fontaine® 6000 or 7000 No-Slack II series fifth wheel.

1. Always assemble parts around a 2-inch kingpin or a 2-inch-diameter shaft. Insert the jaw first, then the wedge below it. See **Fig. 2**. Grease the jaw and wedge on the top and bottom.
2. Install the timer and the timer spring. See **Fig. 3**.
3. Install the operating handle and bolt to the pivot mount. See **Fig. 4**. Use the existing bolt, washer, hairpin cotter pin and bushing. Inspect the bushing for wear before using it and replace it if necessary. Use the new locknut that is supplied in the repair kit. Note the orientation of the bolt (**Fig. 1**).
4. Install the bumper and bolt it to the operating handle. See **Fig. 5**. Use the existing bolt and washers (inspect for wear before using and replace if necessary). Use the new locknut and bushing that is supplied in the repair kit. Note the orientation of the bolt (**Fig. 1**). After installing the bumper, check to make sure that it can pivot freely.
5. Insert the secondary lock and bolt it to the operating handle. See **Fig. 6**. Use the existing bolt and washers (inspect for wear before using and replace if necessary). Use the new locknut and bushing that is supplied in the repair kit. Note the orientation of the bolt (**Fig. 1**).
6. Install the pull handle. See **Fig. 7**. Use the existing washer and cotter pin (inspect for wear before using and replace if necessary). Attach the new secondary lock/bumper spring that is supplied in the repair kit. Open and close the fifth wheel to ensure that it works properly. The fifth wheel must be properly lubricated before opening and closing the wheel.

Use a Moly-based lubricant such as Mobil grease Moly 50 or equivalent when applying lubricant to the locking jaw and wedge. Lightly oil other moving parts in the fifth wheel.



7. Close the fifth wheel several times with a standard 2-inch kingpin tool. With the lock closed, adjust the wedge stop rod so that the end is 1/4-inch (6 mm) from the wedge. See **Fig. 8**.
8. Using an overhead hoist, position the fifth wheel on the sliding mount assembly. Insert the bushing pins. Install the retaining pins and the 1-inch-long cotter pins.

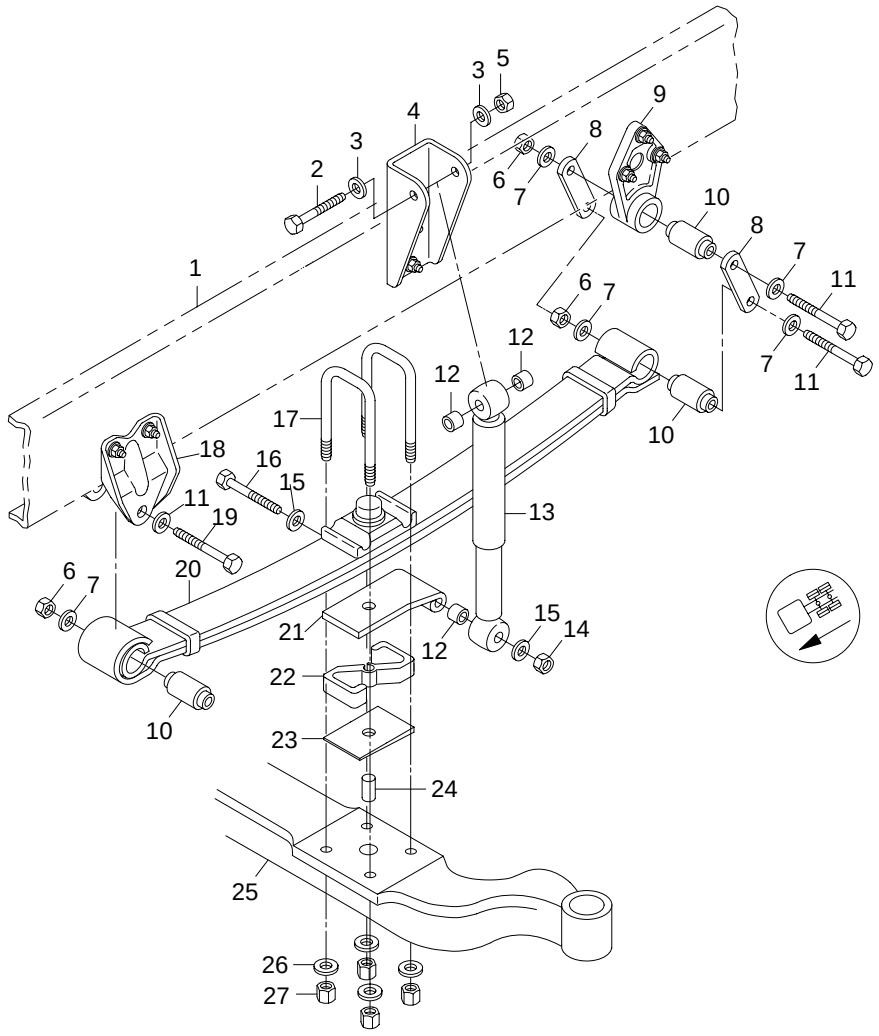
General Description

Freightliner front suspensions use either a taperleaf or a flatleaf assembly. The taperleaf suspensions are available in varying capacities from 6,000-pound (2 722 kg) to 14,000-pound (6 350 kg). Shock absorbers are standard. The flatleaf suspensions are available in varying capacities from 12,000-pound (5 543 kg) to 18,000-pound (8 165 kg), and shock absorbers are optional.



The spring assemblies are attached to the axle with U-bolts, hardened washers, and high nuts. See **Fig. 1**, **Fig. 2**, **Fig. 3**, and **Fig. 4**. The forward end of each spring mounts to a stationary front spring bracket. The rear of each spring mounts to a spring shackle suspended from a frame-mounted bracket. The shackle allows for variations in spring length as the spring flexes.

The leaf spring assembly absorbs and stores energy over bumps, releasing it at a controlled rate to smooth the ride. Individual spring leaves are held together by a center bolt. Alignment clips limit the sideways spread and vertical separation of the individual leaves.

A design change implemented in March 1999 combines the axle pad and the shock absorber lower mounting bracket into one part. See **Fig. 5**.

The all-wheel-drive front suspension (see **Fig. 6**) is nearly identical to the standard front suspension, except the U-bolts are longer and there is a thicker steel spacer between the leaf springs and the top of the front axle. See **Subject 130** for information about the all-wheel-drive front suspension.

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Open the hood.
3. Remove the front bumper. For instructions, see **Group 31**.
4. Remove the wheel and tire for access to the leaf spring. For instructions, see **Group 40**.
5. Remove the half-fender. For instructions, see **Group 88**.

⚠ WARNING

Use safety stands to securely support all axle and frame weight during suspension repairs. Unsecured components may drop when fasteners are loosened or removed, causing component damage and serious personal injury.

IMPORTANT: Make sure the frame rails are level and an equal distance off the ground.

6. Raise the front of the vehicle until both wheels are off the ground and the frame and axle are supported with safety stands. The axle and leaf springs can then be manipulated with the floor jack.
7. Remove the leaf spring assembly.

   NOTE: Leaf spring assemblies on vehicles with suspensions manufactured at 14,000-pound (6 350 kg) and 18,000-pound (8 165 kg) weight ratings have multiple leaf springs, heavy duty brackets, U-bolts, and other components.

   7.1 Remove the U-bolt high nuts and washers. Remove the U-bolts. See **Fig. 1**.

   7.2 Loosen the shock absorber upper mounting bolt. Swing the shock absorber and attached lower mounting bracket out of the way. See **Fig. 2** or **Fig. 3**.

   7.3 Remove the spring shackle lower bolt. See **Fig. 4**.

   7.4 Remove the front spring mounting eye bolt. See **Fig. 5**.

axle enough to allow removal of the spring. Note the location of the spring spacer and any caster adjustment shims.

WARNING

The spring assembly is heavy. To prevent bodily injury, always use two people to remove it.

7.6 Remove the spring by sliding it toward the front of the vehicle. See **Fig. 6**.

8. Remove the shackle upper bolt and nut. See **Fig. 7**. Press out the bushing. Remove the fasteners that hold the shackle bracket to the frame and remove the bracket. See **Fig. 8**.

Cleaning and Inspection

1. Using a wire brush and solvent or steam cleaning equipment, wash all parts to remove dirt, grease, and scale.
2. Inspect all components for damage.

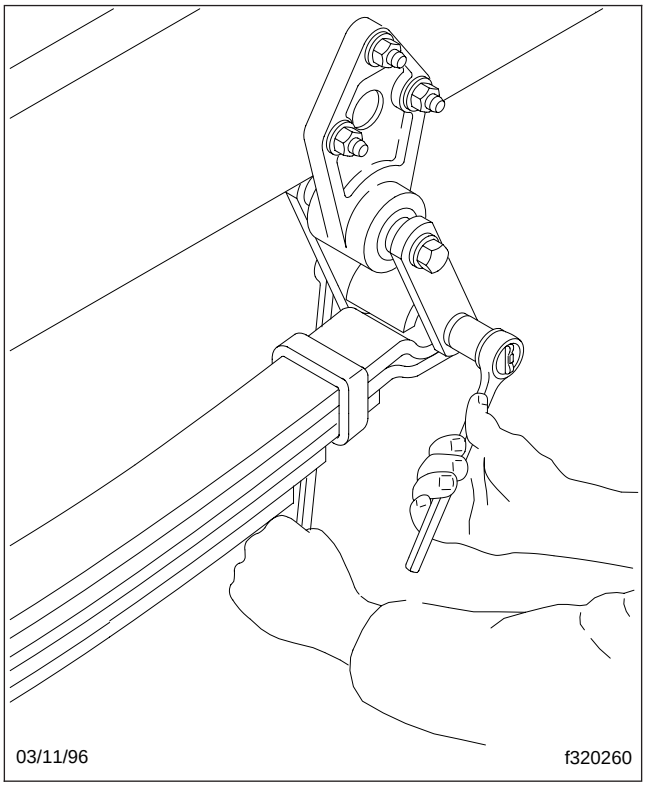

Fig. 4, Spring Shackle Lower Bolt Removal/Installation

2.1 Inspect the spring shackles and the shackle bracket for cracks, wear, and other damage. Replace any damaged parts.

2.2 Inspect the leaf spring assembly for cracks or corrosion. If any leaves are cracked or broken, replace the *entire spring assembly.*

WARNING

Do not replace individual leaves of a leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. On front spring assemblies, if cracks or breaks exist in the two top leaves, a loss of vehicle control could occur. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

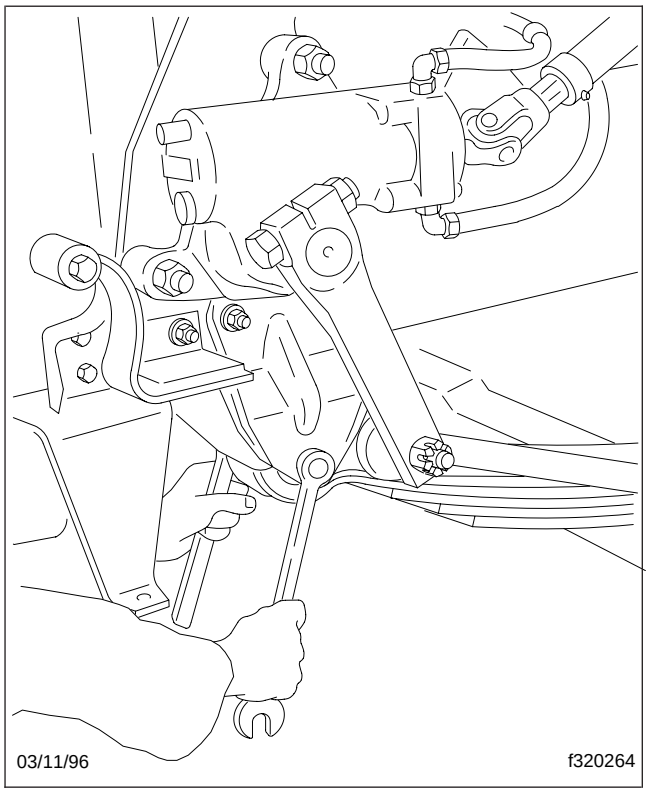

Fig. 5, Spring Eye Bolt Removal/Installation

2.3 If the protective coating is gone from some areas of the spring, the cleaned areas can be painted with a rust-inhibiting paint. If rusting or corrosion is severe, replace the spring assembly.

Installation

IMPORTANT: For normal highway operation do not install springs of two different designs or load capacities on the front axle. In order to maintain a balanced front suspension system, install identical spring assemblies.

1. If the shackle bracket was removed, install it. See **Fig. 8**. Tighten the mounting bolts 135 lbf·ft (183 N·m).

NOTE: All suspension bracket (frame) fasteners require periodic retightening. See Group 00 of the *Business Class® Trucks Maintenance Manual* for the recommended intervals.

2. If the spring shackle was removed, install it. Do not tighten the upper bolt in the shackle at this time. See **Fig. 7**.

⚠ WARNING

The spring assembly is heavy. To prevent bodily injury, always use two people to install it.

3. Install the spring assembly.

   NOTE: Leaf spring assemblies on vehicles with suspensions manufactured at 14,000-pound (6 350 kg) and 18,000-pound (8 165 kg) weight ratings have multiple leaf springs, heavy duty brackets, U-bolts, and other components.

   3.1 Lift the spring into position. See **Fig. 6**. Install the spring eye bolt at the front of the spring (see **Fig. 5**) and the lower bolt in the shackle at the rear of the spring (see **Fig. 4**).

   3.2 Tighten the spring eye bolt and the bolts at the top and bottom of the shackle 240 lbf·ft (325 N·m).

   3.3 Apply Alumilastic® or a similar compound to the top and bottom of the spring spacer and any caster adjustment shims.

⚠ CAUTION

Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to suspension parts.

   3.4 Place the caster adjustment shim and spring spacer on the axle. See **Fig. 9** or **Fig. 10**.

   3.5 Place the U-bolt pad (and shock absorber lower mounting bracket, if equipped, for vehicles built after March 1999) in position on the leaf spring.

   3.6 Using a jack, lift the axle into position.

   3.7 For vehicles so equipped (and built before March 1999), position the shock absorber lower mounting bracket between

Leaf Spring and Components Removal, Cleaning and Inspection, and Installation

the spring spacer and the caster adjustment shims.

3.8 Install the U-bolts over the spring leaves, spring spacer, shock absorber lower mounting bracket, caster adjustment shims, and through the front axle.

3.9 Install the high nuts on the U-bolts and tighten them as described in **Specifications 400**.

4. Remove the floor jack and safety stands.
5. Install the half-fender. See **Group 88** for instructions.
6. Install the wheel and tire. See **Group 40** for instructions.
7. Install the front bumper. For instructions, see **Group 31**.
8. Close and latch the hood.
9. Remove the chocks from the tires.

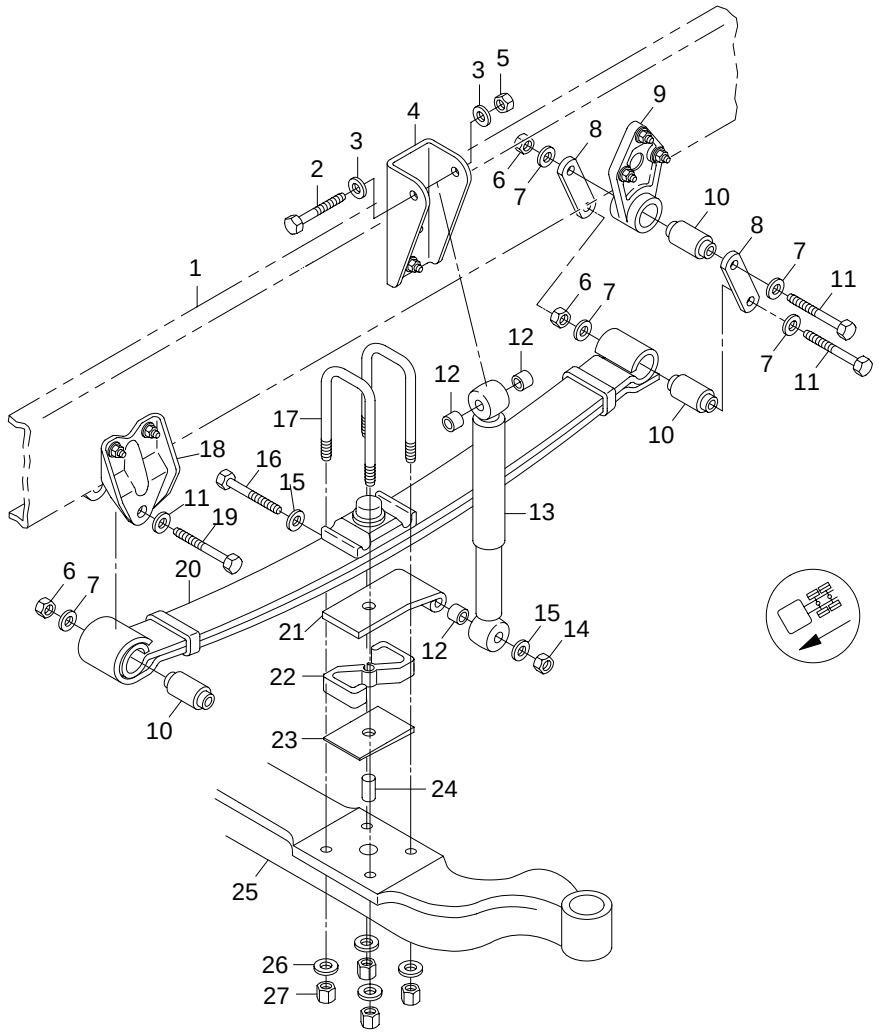
Shackle Bracket Bushing Replacement

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Open the hood.
3. Remove the front bumper. For instructions, see **Group 31**.
4. Remove the wheel and tire for access to the leaf spring. For instructions, see **Group 40**.
5. Remove the half-fender. For instructions, see **Group 88**.
6. Remove the shackle bracket from the vehicle. See **Fig. 1** or **Fig. 2**.
   - 6.1 Jack up the frame until the shackle lower bolt can be removed. Remove the bolt.
   - 6.2 Remove the shackle upper bolt and the spring shackle.
   - 6.3 Remove the shackle bracket from the frame.
7. Using a press, remove the bushing from the shackle bracket.
8. Inspect the shackle bracket and new bushing.
   - 8.1 With an inside micrometer or bore gauge, check whether the bracket bore is out-of-round. Replace the bracket if the bushing bore is out-of-round.
   - 8.2 Before installing the new bushing, check the shackle bracket bolt for ease of fit in the bushing. There should be an easy slip fit without wobble between the bolt and the bushing.
9. Using a press, insert the new bushing into the bracket until the bushing is centered in the bracket.

IMPORTANT: Do not press in the bushing by the center sleeve. This could damage the bushing.

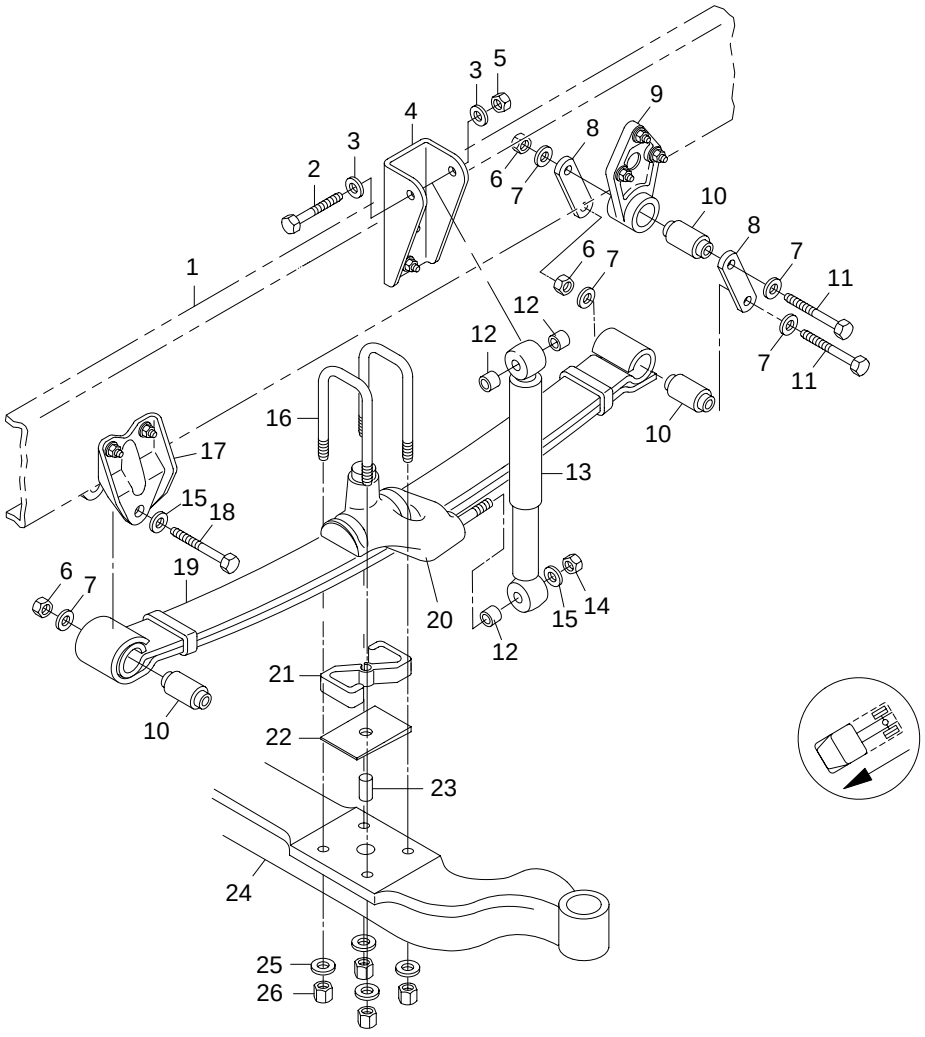
10. Check the shackle bracket bolt again for ease of fit in the bushing. It should still fit easily without wobble between the bolt and the bushing. If it binds, the bushing may have been distorted during installation. Replace the bushing and check again for proper fit.
11. Install the shackle bracket. Install the fasteners and tighten them 183 N·m (135 lbf·ft).
12. Connect the leaf spring.
    - 12.1 Install the spring shackle and the shackle upper bolt.
    - 12.2 Adjust the height of the jack supporting the frame until the bushing at the rear of the leaf spring lines up with the hole for the shackle lower bolt.
    - 12.3 Install the shackle lower bolt. Tighten it 325 N·m (240 lbf·ft).
13. Install the half-fender. For instructions, see **Group 88**.
14. Install the wheel and tire. For instructions, see **Group 40**.
15. Install the front bumper. For instructions, see **Group 31**.
16. Close and latch the hood.
17. Remove the chocks from the tires.



Spring Bushing Replacement

1. Remove the leaf spring from the vehicle. For instructions, see **Subject 100**.
2. Using a press, remove the worn or damaged bushing.
3. Using a press, insert the new bushing into the spring eye until the bushing is flush with the edges of the spring eye.

IMPORTANT: Do not press in the bushing by the center sleeve. This could damage the bushing.



4. Install the leaf spring. For instructions, see **Subject 100**.

Shock Absorber Replacement

Replacement

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Open the hood.
3. Remove the shock absorber.
   - 3.1 Remove the locknut from the shock absorber upper mount. Remove the capscrew, washers, and spacers.
   - 3.2 Remove the locknut from the shock absorber lower mount. Remove the capscrew, washers, and spacers.
   - 3.3 Remove the shock absorber.
4. Install the new shock absorber. Make sure the washer is on the lower shock absorber mounting bushing and toward the outside. Tighten the locknuts 149 N·m (110 lbf·ft). See **Fig. 1** or **Fig. 2**.
5. Close and latch the hood.

All-Wheel-Drive Components Removal, Cleaning and Inspection, and Installation

Removal

1. Apply the parking brakes, chock the rear tires, and tilt the hood.
2. Remove the front bumper. Remove the wheel and tire for access to the leaf spring. For instructions, see **Group 40**.
3. Remove the half-fender. For instructions, see **Group 88**.
4. Using a floor jack, lift the front of the vehicle by the frame until all weight is off the spring being removed.
5. Support the frame and axle with safety stands.

⚠ WARNING

Use safety stands to securely support all axle and frame weight during suspension repairs. Unsecured components may drop when fasteners are loosened or removed, causing serious personal injury and component damage.

6. Remove the leaf spring assembly.
   - 6.1 Remove the U-bolt high nuts and washers; then, remove the U-bolts. See **Fig. 1**.
   - 6.2 Loosen the shock absorber upper mounting bolt. Swing the shock absorber and attached lower mounting bracket out of the way. See **Fig. 2**.
   - 6.3 Remove the lower spring shackle bolt.

   NOTE: All-wheel-drive suspensions use either spring pins or bolts in the leaf spring assembly to attach the leaf spring to the shackle and front spring bracket.

   - 6.4 Remove the spring front eye bolt or spring pin. See **Fig. 3**.

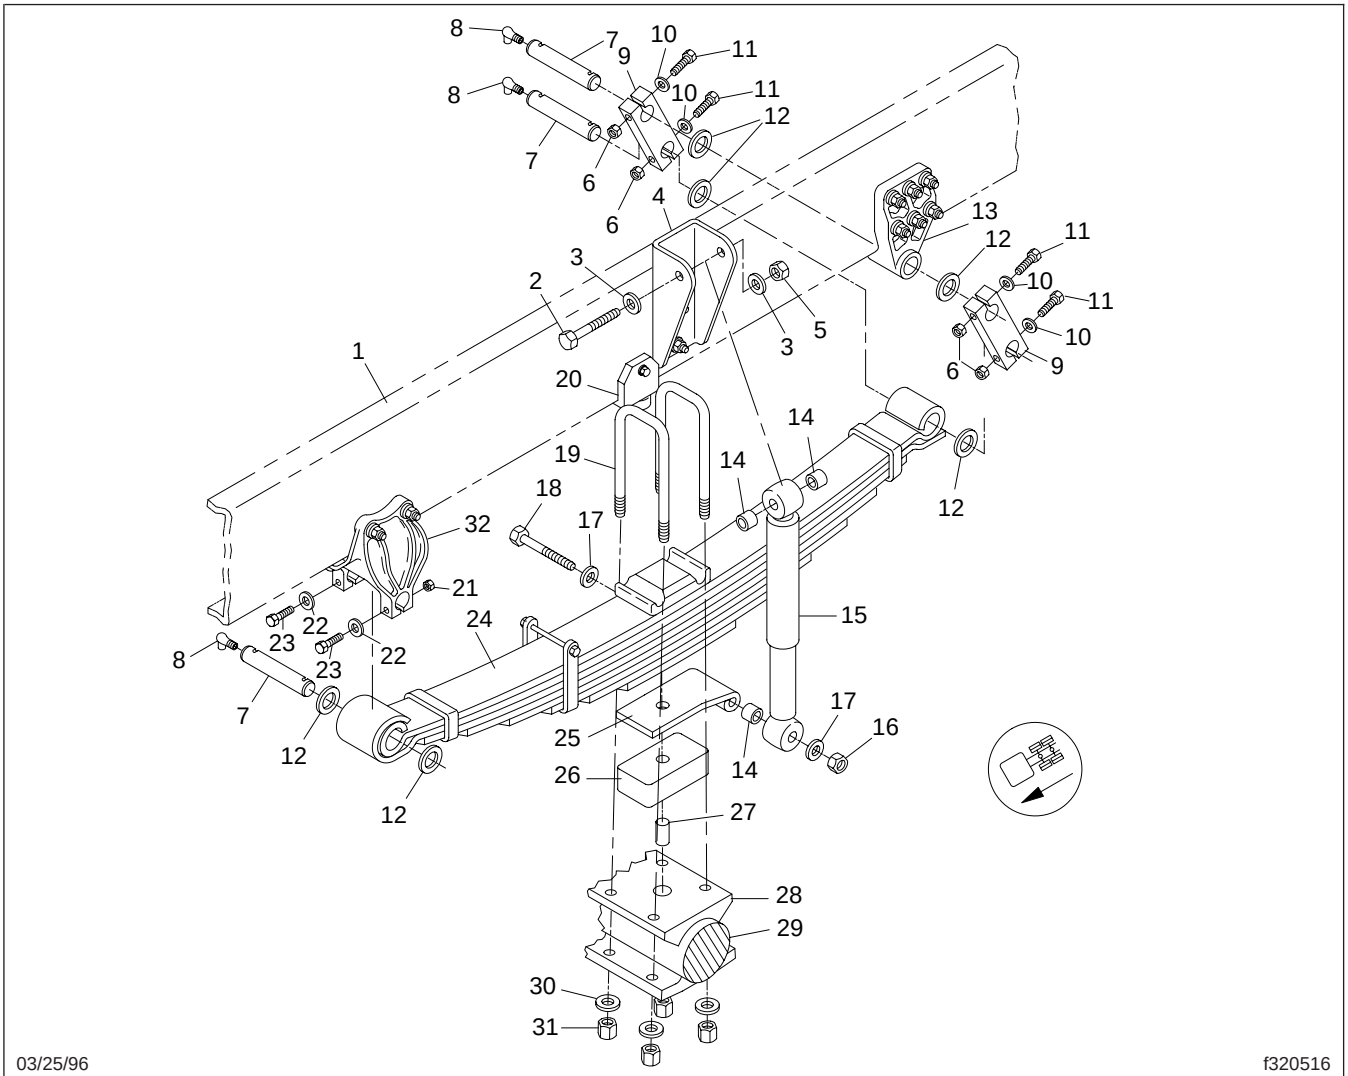
   NOTE: If removing the driver's side spring, the steering must be at right full-lock so the bolt or spring pin can clear the drag link.

   - 6.5 Support the front axle with a jack. Remove the safety stand; then, lower the front axle enough to allow removal of the spring. Note the location of the spring spacer.
   - 6.6 Remove the spring by sliding it toward the front of the vehicle. See **Fig. 4**.
7. Remove the upper shackle. If necessary, press out the spring pin. Remove the fasteners that hold the shackle bracket to the frame. Then, remove the bracket.

Cleaning and Inspection

1. Using a wire brush and solvent or steam cleaning equipment, wash all parts to remove dirt, grease, and scale.
2. Inspect all components for damage.
   - 2.1 Inspect the spring shackles and the shackle bracket for cracks, wear, and other damage. Replace any damaged parts.
   - 2.2 Inspect the leaf spring assembly for cracks or corrosion. If any leaves are cracked or broken, replace the *entire spring assembly.*

⚠ WARNING



Do not replace individual leaves of a leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. On front spring assemblies, if cracks or breaks exist in the two top leaves, a loss of vehicle control could occur. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

   - 2.3 If the protective coating is gone from some areas of the spring, the cleaned areas can be painted with a rust-inhibiting paint. If rusting or corrosion is severe, replace the spring assembly.

Installation

IMPORTANT: For normal highway operation do not install springs of two different designs or load capacities on the front axle. In order to maintain a balanced front suspension system, install identical spring assemblies.

Troubleshooting

This subject contains the following troubleshooting tables:

- Vehicle Leans to One Side
- Vehicle Wanders
- Vehicle Bottoms Out
- Frequent Spring Breakage
- Noisy Spring
- Rough Ride

Problem—Vehicle Leans to One Side

Possible Cause	Remedy
One or more spring leaves are broken.	Replace the spring assembly.
The spring assembly is weak or fatigued.	Replace the spring assembly.
Unmatched spring-design/load-capacity spring assemblies are installed.	Install the correct spring assemblies as originally specified for the vehicle.
A frame rail is bent or twisted.	Check the frame rails for bends and twists. Correct as needed.

Problem—Vehicle Wanders

Possible Cause	Remedy
One or more spring leaves are broken.	Replace the spring assembly.
The wheels are out of alignment.	Adjust the wheel alignment using the instructions in the **front axle group.**
Caster is incorrect.	Install correct caster shims. Refer to the **front axle group** for specifications.
Steering gear is not centered.	Adjust steering using the instructions in the **steering group.**
Drive axle is out of alignment.	Align the drive axle using the instructions in the **rear axle group.**

Problem—Vehicle Bottoms Out

Possible Cause	Remedy
Excessive weight on the vehicle is causing an overload.	Reduce the loaded vehicle weight to the maximum spring capacities.
One or more spring leaves are broken.	Replace the spring assembly.
The spring assembly is weak or fatigued.	Replace the spring assembly.

Problem—Frequent Spring Breakage

Possible Cause	Remedy
The vehicle is overloaded or operated under severe conditions.	Reduce the loaded vehicle weight to the maximum spring capacities. Caution the driver on improper vehicle handling.
There is insufficient torque on the U-bolt high nuts.	Torque the U-bolt high nuts to the value listed in the torque table in **"Specifications, 400."**
A loose center bolt is allowing the spring leaves to slip.	Check the spring leaves for damage. If damaged, replace the spring assembly. If not, tighten the center-bolt nut to the value listed in the torque table in **"Specifications, 400."**
Worn or damaged spring bushings are allowing spring end-play.	Replace the spring bolt and bushing.

Troubleshooting

Possible Cause	Remedy
A loose spring bolt is allowing spring end-play.	Replace the spring bolt and bushing.

Problem—Noisy Spring

Possible Cause	Remedy
A loose U-bolt nut or center bolt is allowing spring leaf slippage.	Inspect the components for damage. Replace damaged components as necessary. Torque all fasteners to the values listed in the torque table in **"Specifications, 400."**
A loose, bent, or broken spring shackle or front suspension bracket is impairing the spring flex.	Inspect the shackles and brackets for damage. Replace damaged components as necessary. Torque the fasteners to the values listed in the torque table in **"Specifications, 400."**
Worn or damaged spring bolts are allowing spring end-play.	Replace any worn or damaged spring bolts.
Worn or damaged spring bushings are allowing spring end-play.	Replace the spring bolt and bushing.

General Description

The rear leaf spring suspension **(Fig. 1)** uses a slip spring design with varying capacities. Optional helper leaves provide a progressive spring rate and additional roll stability. The spring ends ride in cast iron brackets mounted on the frame rails. Each spring bracket holds a replaceable wear pad. The spring assemblies are attached to the axle with U-bolt assemblies. A radius leaf attaches each spring assembly to its forward spring bracket and holds the axle in alignment.

Shock absorbers are optional with all suspension capacities.

Replacement

1. Lift the rear axle and support it with safety stands. Lift the vehicle frame to take weight off the rear springs.
2. Remove the U-bolt high nuts; then, remove the U-bolts. See **Fig. 1**.

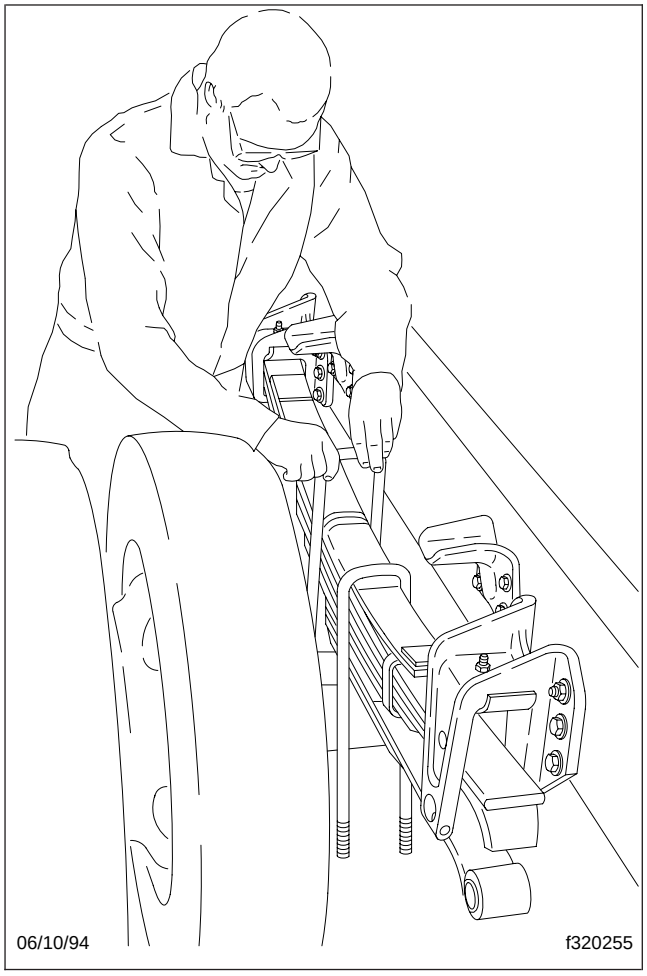

Fig. 1, Removing the U-bolts

3. Remove the spring eye pin that attaches the radius leaf to the front spring bracket.
   - 3.1 Using a C-clamp, take the load off the radius leaf. See **Fig. 2**.

WARNING

Failure to use a C-clamp may cause components to be forcibly ejected, possibly causing serious personal injury.

   - 3.2 Remove the pinch bolts. See **Fig. 3**.
   - 3.3 Using a brass hammer and drift, tap the eye pin out. See **Fig. 4**.

4. Remove the clip (**Fig. 5**) and the spring retainer pin (**Fig. 6**).

WARNING

The leaf spring assembly is heavy. Always use two people when moving it, to avoid personal injury.

5. Remove the spring assembly.

6. Inspect the wear pads for wear. Replace them if needed. For instructions, see **Subject 130**.

7. Install the new spring assembly.

7.1 Position the new spring on the axle seat.

NOTE: It may be necessary to raise the frame slightly.

7.2 Lower the frame until the spring is properly located between the spring brackets.

7.3 If equipped with the optional auxiliary spring, place it on the main spring.

8. Install the U-bolts and the U-bolt retainer. The taller end of the retainer must be towards the front of the vehicle. See **Fig. 9**.
9. Install the U-bolt high nuts (**Fig. 10**), but don't tighten them now.
10. Lift the spring above the hole for the spring retainer pin in the front spring bracket; then, insert the retainer pin. See **Fig. 11**.
11. Install the clip on the pin. See **Fig. 5**.
12. Install the spring eye pin.
    - 12.1 Using a C-clamp, compress the spring until the front spring eye pin can be installed. See **Fig. 12**.
    - 12.2 Inspect the pin for wear or damage. Replace it with a new pin if necessary.
    - 12.3 Using a brass hammer, tap the pin into position. See **Fig. 12**.
    - 12.4 Install the pinch bolts and nuts. See **Fig. 3**. Tighten the nuts to 32 lbf·ft (43 N·m).
    - 12.5 Remove the C-clamp.
13. Tighten the U-bolt high nuts as described in **Specifications 400**.
14. Remove the jack or safety stands from the rear axle and the frame.

1. Park the vehicle and chock the front tires.
2. Jack up the frame rail at the rear of the vehicle until the leaf spring is floating free in the rear spring bracket.
3. Remove the fasteners holding the rear spring bracket to the frame rail. See **Fig. 1**.
4. Slide the spring bracket off the end of the leaf spring assembly. See **Fig. 2**.
5. Check the wear pad for wear. Replace it if needed. For instructions, refer to **Wear Pad Replacement, 130**.
6. Slide the new spring bracket into position.
7. Install the fasteners and tighten them 184 N·m (135 lbf·ft).
8. Lower the frame rail and remove the chocks from the tires.

Forward Spring Bracket Replacement

1. Park the vehicle and chock the front tires.
2. Jack up the frame rail at the rear of the vehicle until the weight is removed from the leaf spring.
3. Remove the spring bracket.
   - 3.1 Using a C-clamp, take the load off the radius leaf. See **Fig. 3**.
   - 3.2 Remove the pinch bolts holding the spring eye pin. See **Fig. 4**.
   - 3.3 Using a brass hammer, tap out the spring eye pin. See **Fig. 5**.
   - 3.4 Remove the clip (see **Fig. 6**) and the spring retainer pin (see **Fig. 7**).
   - 3.5 Remove the fasteners holding the front spring bracket to the frame rail.
   - 3.6 Slide the spring bracket off the front of the leaf spring assembly.
4. Install a new spring bracket.
   - 4.1 Slide a new spring bracket into position.
   - 4.2 Install the fasteners and tighten them 325 N·m (240 lbf·ft).
   - 4.3 While lifting the spring, install the spring retainer pin and clip. See **Fig. 7**.

Replacement

NOTE: Wear pads can be replaced without removing the leaf spring assemblies.

1. Park the vehicle and chock the front tires.
2. For front wear pad replacement, remove the clip **(Fig. 1)** and the spring retainer pin **(Fig. 2).**
3. Using a floor jack or a crane, take the weight off the frame rail so there is no contact between the spring and the wear pad.
4. Remove the allen-head screws attaching the wear pad to the spring bracket. **See Fig. 3** for the front wear pad, **Fig. 4** for the rear wear pad. Remove and discard the wear pad.
5. Install the new wear pad so that the thicker portion of the pad is toward the axle. **See Fig. 5** for the front wear pad. While holding it in place, install and tighten the allen-head screws until snug.
6. If removed, install the spring retainer pin and its clip.

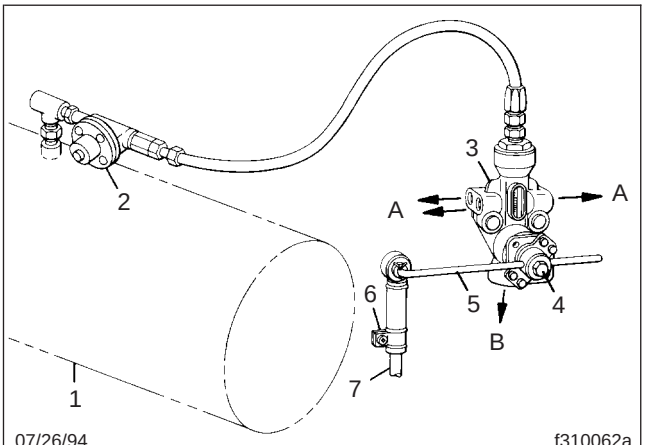
General Information

The Freightliner AirLiner Suspension is a single axle or tandem axle suspension that uses a combination of air and leaf springs. The suspension is manufactured at numerous weight ratings up to 46,000 pounds (20 865 kg). The top of the air spring is bolted to a bracket on the frame rail or through the bottom flange of the frame rail; the bottom is bolted to the rear end of the tapered leaf spring assembly or, for the 23,000-pound (10 433 kg) and 46,000-pound suspensions, to a cross bar. The axle housing is fastened to the leaf spring assembly by U-bolts. A control rod, mounted between the axle housing and the frame rail, can be used to help locate the assembly laterally.

The air springs compensate for changes in road conditions and vehicle load, maintaining constant vehicle height. The air springs also absorb road shock.

A height control valve regulates the air flow into or out of the air springs. **See Fig. 1.** Changes in the clearance between the vehicle frame and the differential housing activate the height control valve. Then, the height control valve adjusts the frame height by compression or expansion of the air springs.



The pressure holding valve (**Fig. 1**, Ref. 2), located in the air line to the height control valve, is preset to maintain a minimum pressure of 448 kPa (65 psi) in the vehicle secondary air system if a leak should occur in the air suspension system.

Principles of Operation

The height control valve controls the air suspension system. All of the air in the system is admitted through or exhausted from this valve.

The height control valve is mounted on a frame crossmember. An overtravel lever extends horizontally from the end of the height control valve control shaft to a linkage arm that connects to the height control valve linkage bracket welded to the differential housing. **See Fig. 2.**

When the load changes, the overtravel lever turns the height control valve control shaft, activating either the intake or exhaust valve section of the height control valve. This adjusts the volume of air in the air springs, until the frame returns to the normal ride height, and the overtravel lever returns to the (horizontal) neutral position.

A 9-second time delay is built into the height control valve to prevent rapid suspension height changes due to bumps. This also reduces the air consumption of the suspension.

A side-to-side restriction valve inside the height control valve maintains vehicle roll stability by preventing inflation of the air spring on one side and deflation on the other side during curves.

General Guidelines

1. To keep the air suspension system operating reliably, the air system must be kept free of any oil, moisture, or foreign material. Inspect and maintain the air system components regularly. Refer to the applicable group of the vehicle maintenance manual for maintenance operations.

⚠ CAUTION

CAUTION: Failure to take precautions against the entry of moisture, oil, or other foreign material into the air suspension system could eventually lead to sludge forming in the air system. Sludge could adversely affect the operation of the air suspension system and other air system components.

2. Use only SAE grade 8 bolts, grade C prevailing torque locknuts, and hardened washers to attach spring hangers and brackets to the frame.
3. For suspension component inspecting, lubricating, and fastener torque checking intervals and instructions, refer to the maintenance schedule and the suspension group in the vehicle maintenance manual.

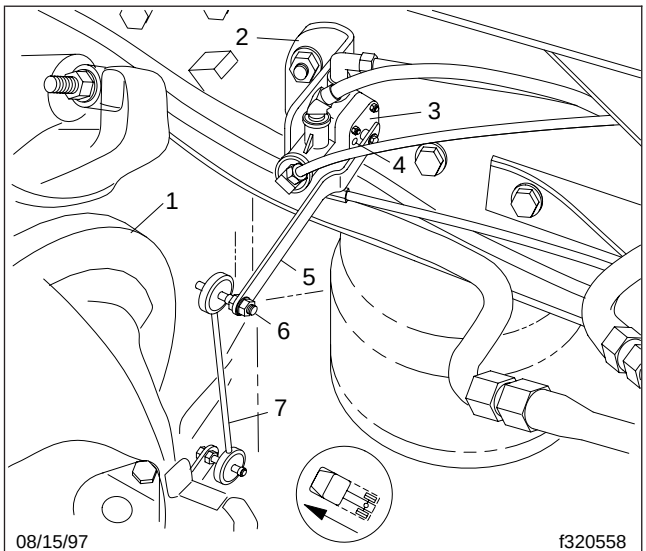
General Information

CAUTION

Failure to adjust the suspension ride height could adversely affect driveline angles. Also, if the air springs are set too high, the driver may have difficulty (or be prevented from) backing the vehicle under a trailer. If the air springs are set too low, rapid wear of suspension parts will result.

Use the applicable procedure to adjust the suspension height.

- Ride Height Adjustment, Vehicle with a Meritor WABCO Valve Adjustable Installation
- Ride Height Adjustment, Vehicle with a Meritor WABCO Valve Fixed Installation
- Ride Height Adjustment, Vehicle with a Barksdale Valve



The Barksdale height-control valve replaced the Meritor WABCO valve after July 25, 1997. On vehicles with tandem-axle AirLiner rear suspensions, the Barksdale valve linkage rod is attached to the forward drive axle instead of the rearmost drive axle, and the valve is mounted on the frame rail. See **Fig. 1**.

There are two types of WABCO height-control valve installations: adjustable and fixed. See **Fig. 2**. On adjustable installations, the suspension height is changed by tilting the height-control valve up or down. On fixed installations, the suspension height is changed by adjusting the length of the vertical linkage rod.

Ride Height Adjustment, Vehicle with a Meritor WABCO Valve Adjustable Installation

IMPORTANT: Before checking the AirLiner suspension height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty.

1. Park the vehicle on a level surface, using a light application of the brakes. Do not apply the parking brakes. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.

2. Mark the location of the front and rear tires on the floor, then chock the tires on one axle only.
3. Check the length of the over-travel lever between its pivot points. See **Fig. 3**. The length should be 8 inches (203 mm). If needed, adjust the length of the over-travel lever.
   - 3.1 Loosen the adjustment locknut on the control shaft.
   - 3.2 Move the over-travel lever fore or aft until the length between the pivot points is 8 inches (203 mm).
   - 3.3 Tighten the adjustment locknut 62 lbf·in (700 N·cm).
4. AirLiner suspensions may have one of three types of axle seats. See **Fig. 4**.

   The three styles are:

   - a one-piece, cast axle seat, that is *not* welded to the axle housing;
   - a one-piece, cast axle seat, that *is* welded to the axle housing;

IMPORTANT If the axle seat is a two-piece welded type, subtract 1/4 inch (6 mm) from the minimum, target, and maximum heights when adjusting the suspension height.

5. Measure the distance from the bottom of the left forwardmost axle stop to the top of the axle U-bolt. See *Suspension Ride Height Measurement*, **Table 3**, **Table 4**, **Table 5**, **Table 6**, and **Table 7** for an acceptable range of heights for each suspension.
6. If the distance is within the acceptable range, apply the parking brakes, then remove the chocks from the tires.

   If the distance is not within the acceptable range, go to the next step.
7. Loosen the two fasteners that attach the height-control valve to the mounting bracket.

9. Rotate the height-control valve counterclockwise, and raise the suspension height to the target height (previously noted from the appropriate table). Stop the air flow to the air bag by rotating the height-control valve clockwise.

10. Center the height-control valve.

    10.1 Rotate the valve very slightly clockwise and counterclockwise until you can insert a 4-mm pin, or drill bit, into the valve centering hole. Don't rotate the valve too much, or you will change the suspension height.

    Park the vehicle using a light brake application. Chock the tires on one axle only, and put the transmission in neutral. Do not apply the parking brakes.

12. Check the adjusted distance between the bottom of the left forwardmost axle stop and the top of the axle U-bolt. It should be within the acceptable range for the applicable suspension previously noted.

13. If the distance is not within the acceptable range, repeat the adjustment procedure.

    If the distance is within the acceptable range, apply the parking brakes, then remove the chocks from the tires.

Ride Height Adjustment, Vehicle With a Meritor WABCO Valve Fixed Installation

IMPORTANT: Before checking the AirLiner suspension height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty. In order to adjust the suspension height, you must change the length of the linkage rod using the following procedure.

1. Park the vehicle on a level surface, using a light application of the brakes. Do not apply the parking brakes. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.

2. Mark the location of the front and rear tires on the floor, then chock the tires on one axle only.

3. Check the length of the height-control valve over-travel lever. See **Fig. 3**. See **Table 1** for the correct length.

   If the length is acceptable, go to the next step.

   If the length is not acceptable, adjust the length of the over-travel lever as follows.

3.2 Move the over-travel lever fore or aft until it is the correct length.

3.3 Tighten the adjustment locknut 62 lbf·in (700 N·cm).

4. Measure the distance from the bottom of the left forwardmost axle stop to the top of the axle U-bolt. See *Suspension Ride Height Measurement*, **Table 3**, **Table 4**, **Table 5**, **Table 6**, and **Table 7** for an acceptable range of heights for each suspension.

   If the distance is within the acceptable range, apply the parking brakes, then remove the chocks from the tires.

   If the distance is not within the acceptable range, go to the next step.

5. Determine how much the suspension height needs to be adjusted so the distance matches the target height in the applicable table. Then, using **Table 2**, find the amount the length of the linkage rod needs to be changed. See **Fig. 3**.

Table 2, Vertical Linkage Lengths

6. Adjust the length of the linkage rod as needed, adding or subtracting the amount shown in **Table 2**.

   NOTE: If the linkage rod is too short, replace it with a new rod, part number 16–13485–000. The linkage rod should be long enough so that at least 1/2 inch (13 mm) of it fits into both flexible end-sections of the linkage.

   6.1 Mark the existing length of the linkage rod between the upper and lower flexible end-sections of the linkage. See **Fig. 3**.

   6.2 Loosen both linkage adjustment clamps.

   6.3 Slide the flexible end-sections of the linkage over the linkage rod until the rod is the correct length.

   To increase the suspension height, lengthen the linkage rod; to decrease the suspension height, shorten the rod.

   6.4 Tighten the adjustment clamps.

7. Drive the vehicle unloaded for about 1/4 mile (1/2 km), then stop the vehicle in the exact location (as previously marked) of the original measurement.

   Park the vehicle using a light brake application. Chock the tires on one axle only, and put the transmission in neutral. Don't apply the parking brakes.

8. Check the distance between the bottom of the left forwardmost axle stop and the top of the axle U-bolt.

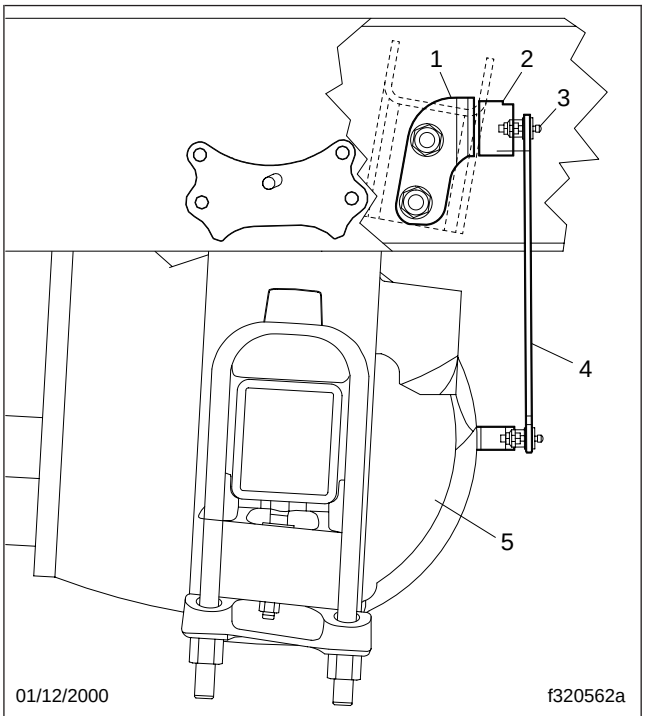
9. If the distance is within the acceptable range, apply the parking brakes, then remove the chocks from the tires.

   If the distance is not within the acceptable range, repeat the adjustment procedure.

Ride Height Adjustment, Vehicle with a Barksdale Valve

IMPORTANT: Before checking the suspension height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty.

1. Park the vehicle on a level surface, using a light application of the brakes. Do not apply the parking brakes. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.



2. Mark the location of the front and rear tires on the floor, then chock the tires on one axle only.

NOTE: The stud bolt that fastens the lever arm to the linkage rod is oriented correctly when the linkage rod is vertical as viewed from the side of the vehicle. See **Fig. 5**.

3. Measure the distance between the left forward most axle stop and the suspension as indicated; see **Table 3**, **Table 4**, **Table 5**, **Table 6**, and **Table 7** for an acceptable range of heights for each suspension.

IMPORTANT: **Suspensions with Dual-Leaf Springs, and all Vehicles built before August 24, 2001:** Measure between the top of the U-bolt and the bottom of the axle stop (distance A).

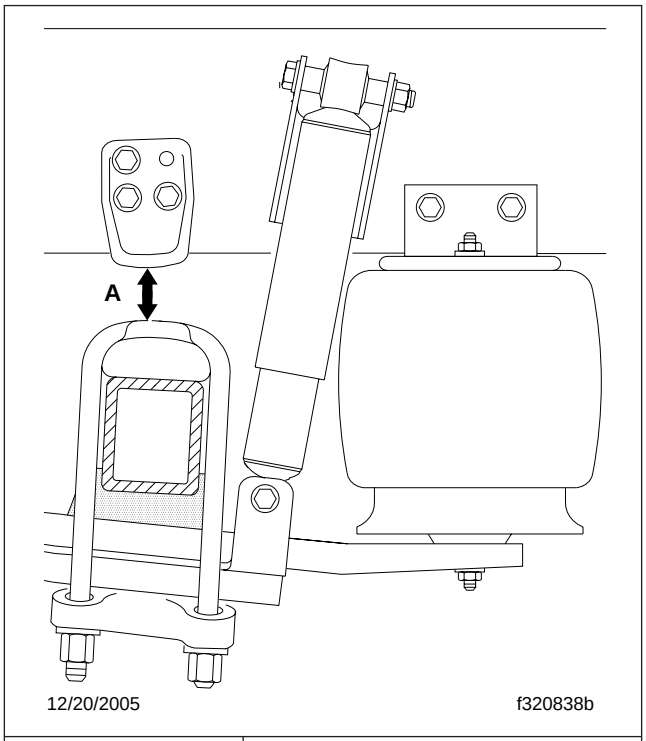
Fig. 5, Barksdale Height-Control Valve Installation (side view)

Suspensions with Single-Leaf Springs, built after August 24, 2001: Measure between the top of the U-bolt **pad** and the bottom of the axle stop (distance B).



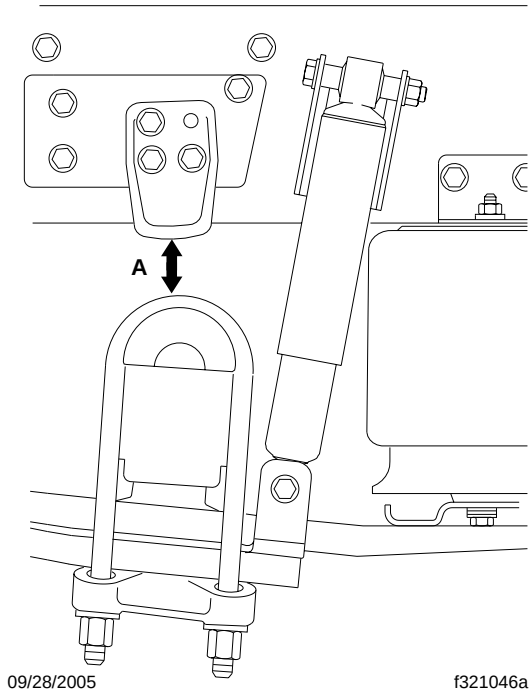
4. If the distance is within the acceptable range, apply the parking brakes, then remove the chocks from the tires.

   If the measurement is not within the acceptable range, go to the next step.

5. Adjust the suspension height.

   5.1 Loosen the two fasteners that attach the valve to the valve mounting bracket.

   5.2 Adjust the position of the valve body, until the distance from the bottom of the left axle stop to the top of the U-bolt or U-bolt pad is the target measurement from the applicable *Suspension Ride Height Measurement* table.



Measure Point	Suspension Height Measurement (A)		
	Min	Target	Max
A = Measure Here	2-3/8 inch (60 mm)	2-5/8 inch (67 mm)	2-7/8 inch (73 mm)

   5.3 Center the lever arm on the valve by inserting a 4-mm pin, or drill bit, into the hole in the lever arm and aligning the pilot hole with the valve body.

   5.4 Tighten the two fasteners that attach the valve to the mounting bracket.

   5.5 Remove the pin from the hole in the lever arm.

Measure Point	Suspension Height Measurement (A)		
	Min	Target	Max

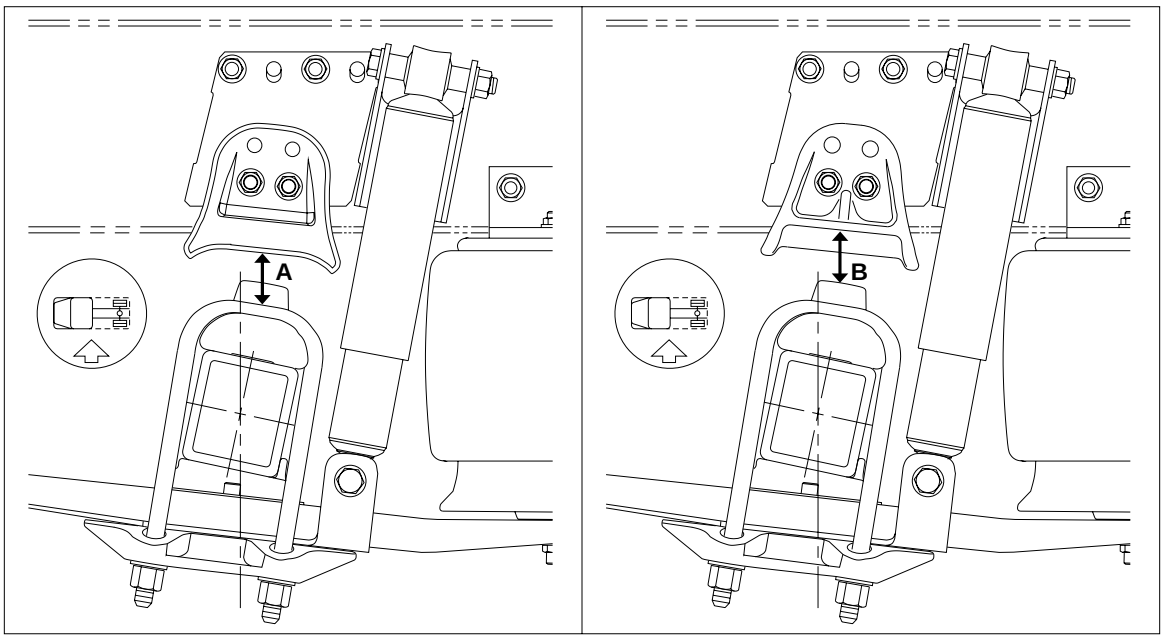
6. Drive the vehicle unloaded for about 1/4 mile (1/2 km), then stop the vehicle in the exact location (as previously marked) of the original measurement.

   Park the vehicle using a light brake application. Chock the tires on one axle only, and put the transmission in neutral. Do not apply the parking brakes.

7. Check the distance between the bottom of the left axle stop and the top of the axle U-bolt or U-bolt pad.



IMPORTANT: **Suspensions with Dual-Leaf Springs, and all Vehicles built before August 24, 2001:** Measure between the top of the U-bolt and the bottom of the axle stop (distance A).

Suspensions with Single-Leaf Springs, built after August 24, 2001: Measure between the top of the U-bolt *pad* and the bottom of the axle stop (distance B).

8. If the distance is within the acceptable range, apply the parking brakes, then remove the chocks from the tires.

   If the distance is not within the acceptable range, repeat the adjustment procedure.

Checking

The leveling valve is the control center of any air suspension system and responds to changes in height. When correctly adjusted, it maintains the correct suspension ride height.

Carefully check the valve before replacing it. Do the following steps to see if a valve is working correctly.

1. Disconnect the leveling valve linkage from the overtravel lever. **Refer to Fig. 1.**
2. Pull the overtravel lever up about 45 degrees. **See Fig. 2**, Ref. A. If air passes through the valve, that section of the valve is working.
3. Return the valve to the neutral position. **See Fig. 2**, Ref. B. Air should stop flowing. If so, that section of the valve is working.
4. Push the overtravel lever down about 45 degrees. **See Fig. 2**, Ref. C. If air exhausts from the valve, that section of the valve is working.
5. Return the valve to the neutral position. If the air stops again in the neutral position, the valve is working correctly.
6. If the valve works as stated in all of the above steps, then no further checking is necessary. Connect the leveling valve linkage to the overtravel lever. Secure the linkage with a cotter pin.

   If the valve needs adjusting, refer to **"Leveling Valve Adjustment, 110."** If the valve needs replacing, refer to **"Leveling Valve Replacement, 130."**

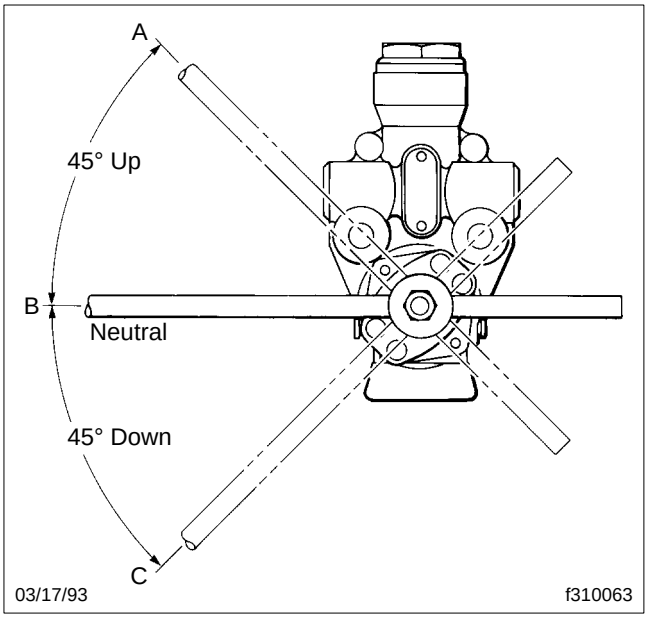

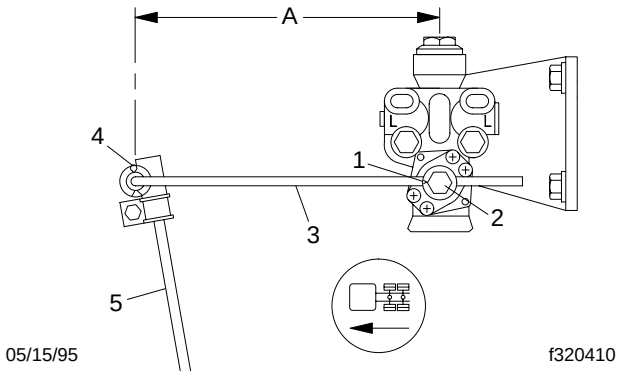

Fig. 2

Replacement

NOTE: A new type of height control valve (manufactured by Barksdale Inc.) replaced the Meritor WABCO valve. On vehicles with tandem-axle AirLiner rear suspensions, the Barksdale valve linkage rod is attached to the forward drive axle instead of the rearmost drive axle, and the valve is mounted on the frame rail. The Barksdale valves are installed on Business Class vehicles built after July 25, 1997.

Meritor WABCO

1. Park the vehicle on a level surface. Shut down the engine and apply the parking brake. Chock the front tires.
2. Drain the air reservoirs.
3. Disconnect the linkage from the overtravel lever. See **Fig. 1**. Exhaust all air from the air springs by moving the overtravel lever down.

4. Disconnect the air lines at the height control valve, and mark the lines for later reference. Using tape, cover the open ends of the air lines and fittings to prevent dirt or foreign material from entering.
5. Remove the height control valve mounting bolts and nuts, and remove the height control valve from the bracket.
6. Remove the overtravel lever from the height control valve.
7. Attach the new height control valve to the bracket. Tighten the valve mounting bolt nuts 14 lbf·ft (19 N·m).
8. Remove the tape from the air lines and fittings, and connect the air lines to the height control valve as marked earlier. Tighten nylon tube air fittings until only two threads show on the fitting. On wire-braid hose fittings, tighten the nut with a wrench until there is firm resistance, then tighten one-sixth turn more.
9. Connect the height control valve linkage to the overtravel lever. Secure the linkage with a cotter pin.
10. Connect the overtravel lever to the height control valve. Insert the overtravel lever into the valve at the hole with the V-shaped mark. See **Fig. 1**. Be sure the length between pivot points is 8 inches (20.3 cm). See **Fig. 1**, Ref. A.
11. Close the drain cocks on all reservoirs.
12. Build up normal operating pressure in the air system. Check all air lines and connections for leaks. Eliminate all leaks.
13. Remove the chocks from the tires.
14. Adjust the height control valve. For instructions, see **Subject 110**.

Barksdale Inc.

1. Park the vehicle on a level surface. Shut down the engine and apply the parking brake. Chock the front tires.
2. Drain the air reservoirs.
3. Disconnect the linkage from the overtravel lever. See **Fig. 2**. Exhaust all air from the air springs by moving the overtravel lever down.
4. Disconnect the air lines at the height control valve, and mark the lines for later reference. Using tape, cover the open ends of the air lines and fittings to prevent dirt or foreign material from entering.

Replacement (See Fig. 1)

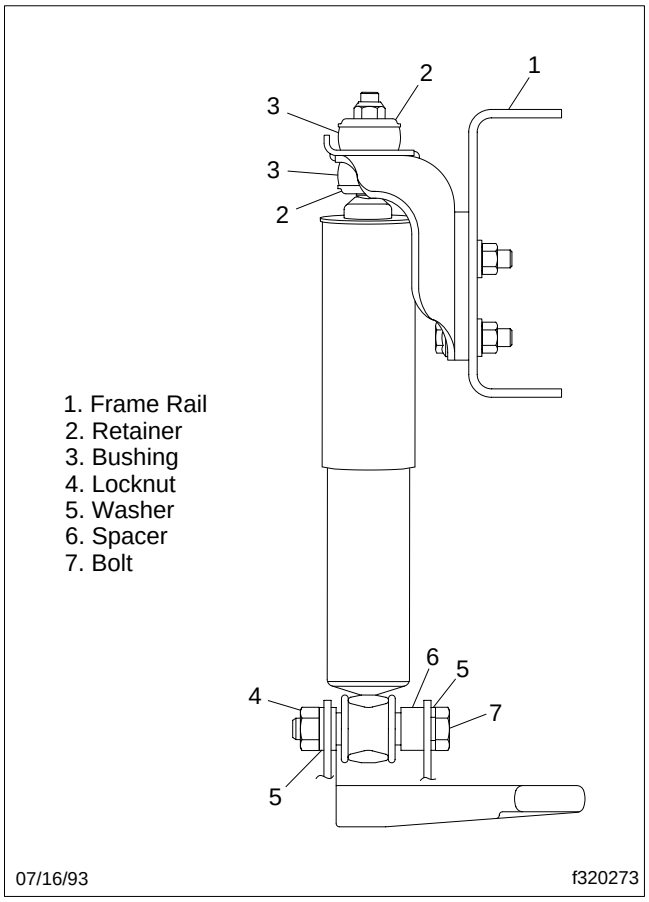

Fig. 1, Shock Absorber Mounting

1. Chock the tires.
2. Remove the locknut, bolt, washers, and spacer from the shock absorber lower mounting bracket.
3. Remove the nut, upper retainer, and upper bushing from the top of the shock absorber.
4. Pull the shock absorber out of the upper mounting bracket, and remove the retainer and bushing.
5. Install the replacement shock absorber, making sure the new bushings and retainers are positioned as shown in **Fig. 2**.

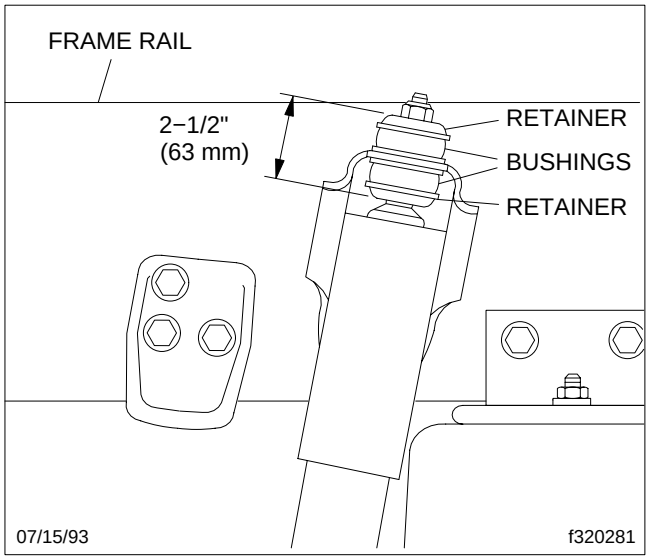

Fig. 2

WARNING

WARNING: Use only the retainers included with the replacement shock absorber. Do not use washers. They can be pushed over the nut and be ejected violently, possibly causing personal injury and property damage.

6. Tighten the shock absorber lower mounting locknut 230 N·m (170 lbf·ft).
7. Tighten the shock absorber upper mounting nut to compress the bushings to the dimension shown in **Fig. 2**.

Air Spring Bag Replacement

Replacement

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front tires. Raise the vehicle frame and support it with safety stands to remove all weight from the air springs.
2. Disconnect the leveling valve and exhaust all air from the air springs.
3. Using a dull instrument, pry the air spring bead off the piston lip. Be careful not to damage the piston.
4. Disconnect the air supply line, including the brass tee, from the air spring. Using tape, cover the ends of the air supply line and the fitting to prevent dirt or foreign material from entering.
5. Remove the locknuts and washers that connect the air spring bag to the upper mounting bracket.
6. Remove the air spring bag.
7. Check the piston for residue, and remove any, if found.

NOTE: When space is limited (such as at the forward axle of tandem axles), it may be easier to remove the piston from the leaf spring and assemble the bag and piston on a workbench. Secure the air spring mounting bracket, which is attached to the bag, in a vise. Fully extend the air bag and plug the air supply port. Apply a soap-and-water solution to the piston lip and air bag bead, and, using a twisting motion, push the piston onto the airbag until the piston is fully seated. Inspect the circumference of the bag-to-piston connection to make sure there is less than 1/8 inch (3.2 mm) of clearance between the air bag and the piston shoulder. The gap should be uniform around the assembly. After inspecting, remove the plug in the air supply port and push the piston into the air bag so that it rolls over the piston. Then, install on the vehicle.

⚠ WARNING

Do not add air pressure to the air spring assembly when it is not mounted on a vehicle.Doing so could cause components to eject from the assembly, which could cause serious personal injury or property damage.

8. Attach the new air spring bag to the upper mounting bracket, using the 1/2–13 locknut on the outsideof the frame rail and the 3/4–16 locknut on the inside. Tighten 3/4–16 locknuts 61 N·m (45 lbf·ft);tighten 1/2–13 locknuts 31 N·m (23 lbf·ft).
9. Remove the tape from the ends of the air supply line, the fitting, and the brass tee. Connect the air supply line to the air spring. Tighten nylon tube air fittings until only two threads show on the fitting. Onwire-braid hose fittings, tighten the nut with a wrench until there is firm resistance, then tighten one-sixth turnmore.
10. Make sure the air spring bag is fully extended alongside the piston so there are no folds in thebag near the bead. See **Fig. 1.**
11. Fold the air spring bag so the bead is fully parallel with the piston lip. See **Fig. 2.**
12. Apply a soap-and-water solution to the bead and piston lip.
13. Pull the rear of the air spring bag over the piston lip making sure the bead is the lowest part of thebag— none of the bag should droop over the piston. Then, work the front of the bag over the piston lip like a button in a button hole. See **Fig. 3.**
14. Feeling the bead through the folds of the air spring bag, snap the bead over the piston lip so itseats fully. A snapping sound confirms correct seating of the bead.
15. Inspect the circumference of the bag-to-piston connection to make sure there is less than 1/8 inch (3.2 mm) of clearance between the air bag and the piston shoulder. The gap should be uniform around the assembly.
16. Connect the leveling valve and inflate the air spring bag. As it's inflating, the bag shouldroll into position over the piston. See **Fig. 4.**
17. Remove the safety stands, and lower the vehicle. Remove the chocks from the tires.

Air Spring Replacement

1. Chock the front tires. Raise the vehicle frame and support it with safety stands to remove all weight from the air springs. The leveling valve automatically releases air from the air springs when all weight is removed from the suspension.
2. Disconnect the air supply line,including the brass tee, from the air spring. Using tape, cover the ends of the air supply line and the fitting to prevent dirt or foreign material from entering.
3. Remove the locknuts and washers that connect the air spring to the upper mounting bracket, or to the frame rail flange. See **Fig. 1** and **Fig. 2.**

4. Remove the capscrews and lockwashers that connect the air spring to the rear of the leaf spring. Remove the air spring. **See Fig. 3.**

NOTE: Suspensions manufactured to a 46,000-pound (20 865 kg) or 23,000-pound (10 433 kg) weight rating have a different leaf spring, and an additional cross bar attached between the air spring and rear of the leaf spring. **See Fig. 4.**

5. Place the new air spring on the rear of the leaf spring (or the cross bar on the 23,000- and 46,000-pound suspensions), and install the washer and locknut that hold the air spring (and cross bar) in place. **See Fig. 3.** Tighten the locknut 55 lbf·ft (75 N·m).
6. *For bracket-mounted air springs:* Attach the air spring to the upper mounting bracket, using the 1/2–13 locknut on the outside of the frame rail and the 3/4–16 locknut on the inside. **See Fig. 1.** Tighten the 3/4–16 locknut 45 lbf·ft (61 N·m); tighten the 1/2–13 locknut 23 lbf·ft (31 N·m).

   For flange-mounted air springs: Attach the air spring to the frame rail flange, using the 3/4–16 locknut on the forward stud of the air spring, and the 1/2–13 locknut on the rear stud. **See Fig. 2.** Tighten the 3/4–16 locknut 45 lbf·ft (61 N·m); tighten the 1/2–13 locknut 23 lbf·ft (31 N·m).
7. Remove the tape from the ends of the air supply line, the fitting, and the brass tee. Connect the air supply line to the air spring. Tighten nylon tube air fittings until only two threads show on the fitting. On wire-braid hose fittings, tighten the nut with a wrench until there is firm resistance, then tighten one-sixth turn more.
8. Remove the safety stands, and lower the vehicle. Remove the chocks from the tires.

Fig. 4, Leaf Spring and Air Spring Assembly (23,000- and 46,000-pound suspensions)

Leaf Spring Replacement

(See Fig. 1)

WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Chock the front tires.
2. Raise the rear of the vehicle, and support the rear axle(s) with safety stands. Raise the vehicle so that all weight is removed from the leaf springs, then securely support the frame with safety stands. Remove the wheel and tire assembly to easily access the suspension. Refer to the wheels and tires section in this manual for instructions.
3. Remove the nut, bolt, and washers from the shock absorber lower mounting bracket. Remove the high nuts, flatwashers, and axle clamp from each U-bolt. Support the leaf spring assembly with a jack.
4. If the air spring mounts to the leaf spring, disconnect the bottom of the air spring from the leaf spring.

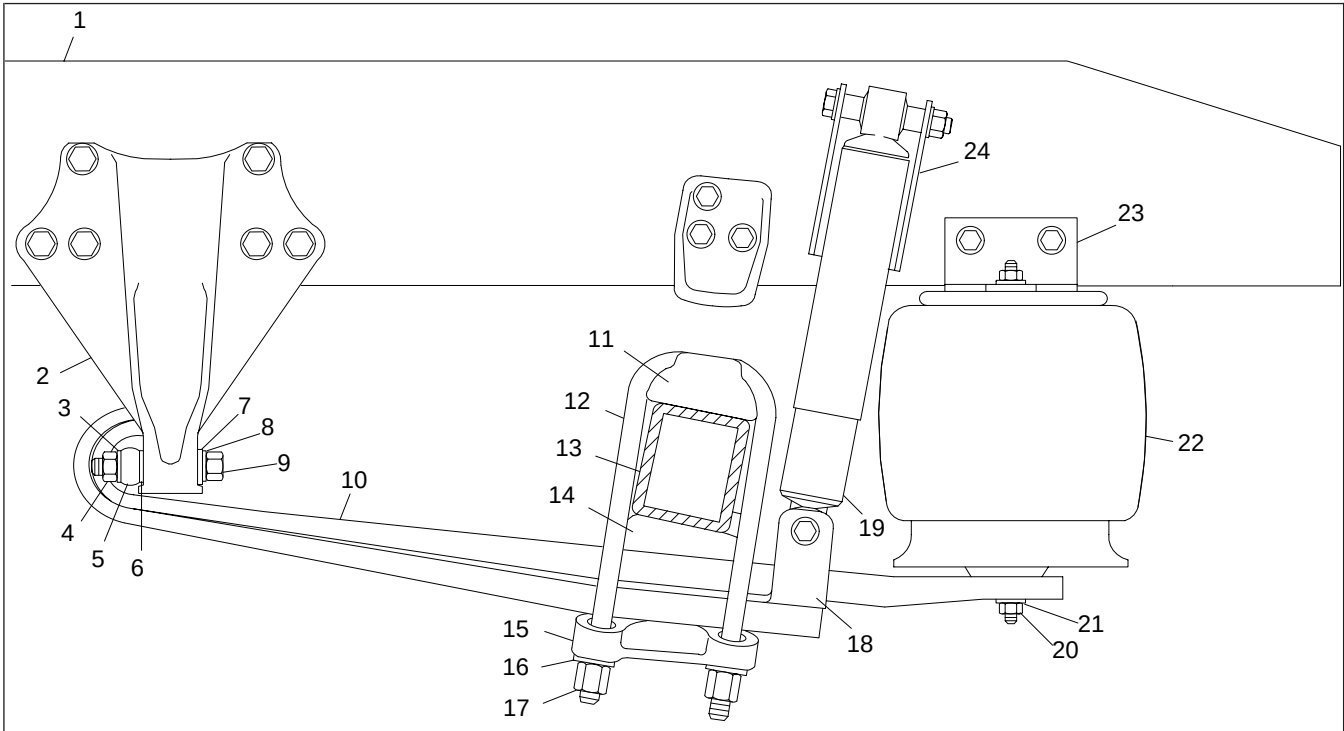
   If the air spring mounts to a cross bar, disconnect the cross bar from the leaf spring by removing the capscrews, nuts, and washers. See Fig. 2.
5. Note the number and position of the alignment shims (See Fig. 1) on the spring mounting bolt.
6. Remove the hexnut, washers, alignment shim(s), spring mounting bolt, and wear shoe clip from the spring hanger. See Fig. 1.

WARNING

The leaf spring assembly is heavy. Use care when handling it to prevent injury.

7. Remove and discard the leaf spring assembly.
8. While supporting a new leaf spring assembly with a jack, position the assembly on the spring hanger. Install the bolts, wear shoe clips, washers, alignment shims, and hexnuts. Tighten the bolts just enough to hold the leaf spring assembly in place.
9. If the air spring mounts to the leaf spring, attach the air spring to the leaf spring assembly. Install the washer and locknut. Tighten the locknut 55 lbf·ft (75 N·m).

   If the air spring mounts to a cross bar, attach the cross bar to the leaf spring assembly. The longer capscrews attach in the forwardmost holes; the shorter capscrews attach in the aft holes.
10. Making sure that the U-bolt pads are in place on the top of the axle, fasten the leaf spring assembly to the axle using the U-bolts, axle clamp, washers, and high nuts making sure the U-bolt pads and axle clamps are positioned correctly.



NOTE: On single-drive axles angled 5 degrees, the arrow on the U-bolt pads must point to the front of the axle housing. See Fig. 3. On single-drive axles angled 3 degrees, there is no arrow. Make sure that the axle bump stop on the U-bolt pad is positioned toward the vehicle centerline. See Fig. 4 .

With both 5- and 3-degree single-drive axle angles, the arrow on the bottom of the axle clamp (see Fig. 1) must point toward the rear of the vehicle.

On tandem axle suspensions, refer to Table 1 for U-bolt pad orientation. The arrow on the bottom of the axle clamp must point toward the rear of the vehicle on the forward rear axle and toward the front of the vehicle on the rearmost axle.

11. Tighten the U-bolt high nuts as described in Specifications 400.
12. Install the bolt, washers, and hexnut to connect the shock absorber to its lower mounting bracket. Tighten the hexnut 170 lbf·ft (230 N·m).
13. Tighten the locknut on the bottom of the air spring 55 lbf·ft (75 N·m).

Replacement

WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Park the vehicle on a level surface. Shut down the engine. Set the parking brake and chock the front tires.
2. Raise the rear of the vehicle, and support the rear axle(s) with safety stands. Raise the vehicle so that all weight is removed from the leaf springs, then securely support the frame with safety stands.
3. Remove the wheel and tire assembly to easily access the suspension. For instructions, see the information in **Group 40**.
4. Remove the leaf spring assembly. See removal information in **Subject 170**.

WARNING

The leaf spring assembly is heavy. Use care when handling it to prevent injury.

5. Remove the bushing from the leaf spring eye.

WARNING

Do not use a cutting torch to remove the outer metal of the bushing from the spring eye. Welding, torching or cutting the leaf spring assembly can damage the leaf spring material, which may result in the failure of the components and cause serious personal injury, death, or property damage.

   5.1 Using a shop press with a capacity of at least 10 tons (9 072 kg), place the spring assembly in the shop press with the spring assembly squarely supported on the press bed for safety and to avoid bending the spring assembly.

   5.2 Center the bushing tool on the outer metal of the bushing and push the bushing from the spring eye.

   5.3 Remove any burrs or material left behind by the old bushing.

6. Install the new bushing in the leaf spring eye.

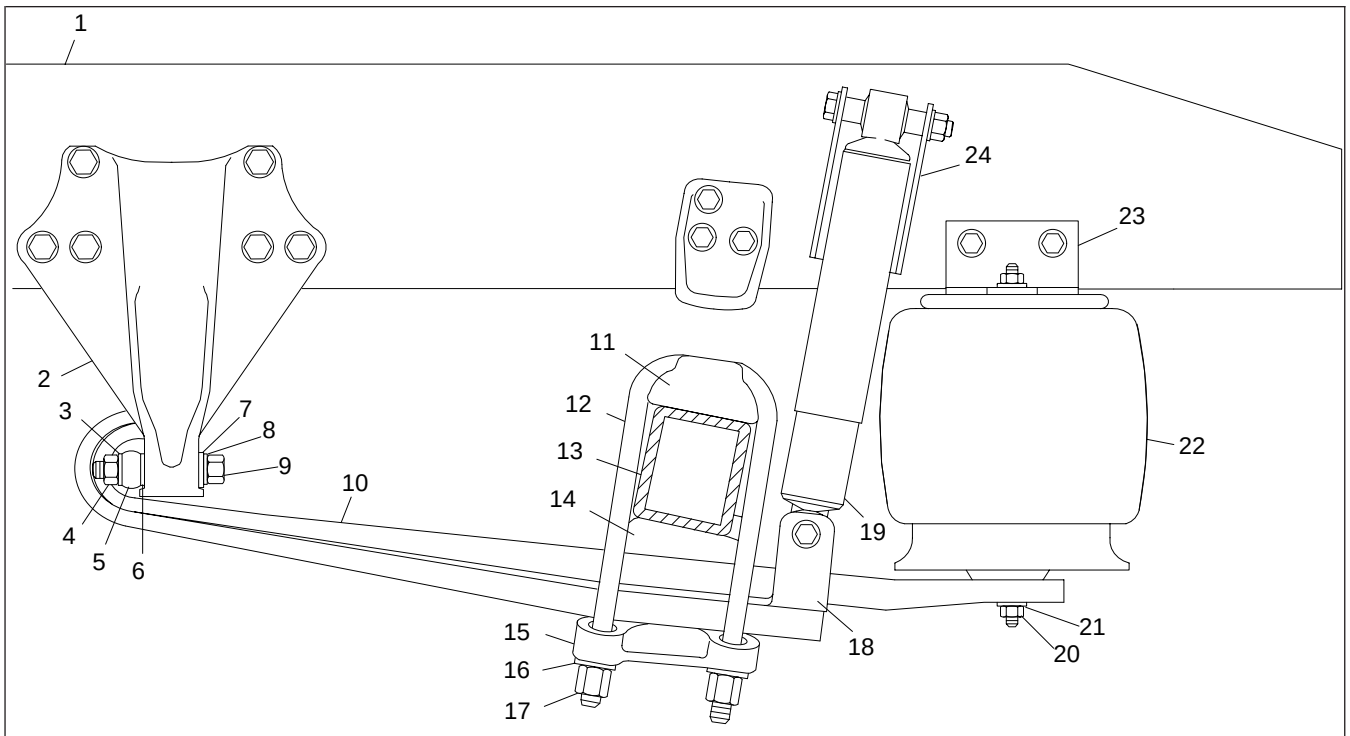
   6.1 Position the bushing on the shop press.

   6.2 Apply a bonding agent, either Permabond HM–160 or Loctite RC–609 or 680, liberally around the outside surface of the bushing.

   6.3 Press the bushing into place.

   6.4 Allow the bonding agent to cure for 24 hours.

   NOTE: After the curing time, the bushing must resist a minimum 7,700 lb (3 490 kg) pushout force.



7. Install the leaf spring assembly. See the information in **Subject 170**.
8. Install the wheel and tire assembly. For instructions, see **Group 40**. Remove the safety stands, and lower the vehicle.
9. Check the rear axle alignment. For instructions, refer to **Group 35** in this manual. If necessary, adjust the rear axle alignment using the instructions in **Group 35**.
10. Remove the chocks from the tires.

Adjusting

See **Fig. 1**.

Follow the instructions in the rear axle alignment checking section of this manual to see if rear axle alignment adjustment is needed. If it is needed, proceed as follows:

2. Move the axle forward or backward until it is aligned within the tolerances in the rear axle section of this manual.
3. When the axle is in alignment, install alignment shim(s) to take up the slack between the spring hanger and the spring mounting eye pin.

1. Loosen the spring mounting eye bolts so that the forward end of the leaf spring can slide fore and aft in the spring hanger.

IMPORTANT: Make sure the same number of shims is installed on both ends of the spring mounting eye pin.

4. Tighten the spring mounting eye bolts 230 N·m (170 lbf·ft).

Rear Axle Alignment Adjusting

5. Check the axle alignment again. If necessary, repeat the above procedure until the alignment is within tolerances.

Rear Axle Tracking Adjustment

Single Axle

1. At the forward edge of the right rear tire, measure the distance from the inner side of the tire to the outer side of the right frame rail. See **Fig. 2**.

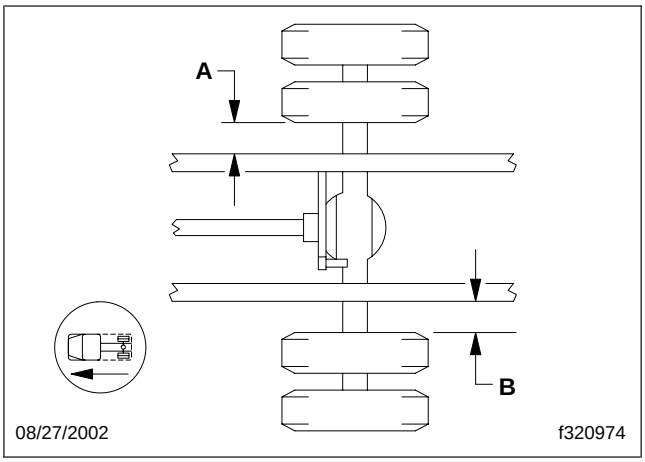

Fig. 2, Rear Axle Tracking Measurements (single axle)

2. At the rear edge of the left rear tire, measure the distance from the inner side of the tire to the outer side of the left frame rail. See **Fig. 2**.

IMPORTANT: Measurement "A" should not vary by more than 1/4-inch (6 mm) from measurement "B."

3. If measurements "A" and "B" vary by more than 1/4-inch (6 mm), loosen the fasteners holding the lateral torque rod to the frame rail. Add or remove torque-rod shims as needed.
4. For bar-pin style torque rods, tighten the fasteners 136 lbf·ft.

   For taper-pin style torque rods, tighten the fasteners 165 lbf·ft (224 N·m). See **Fig. 3**.

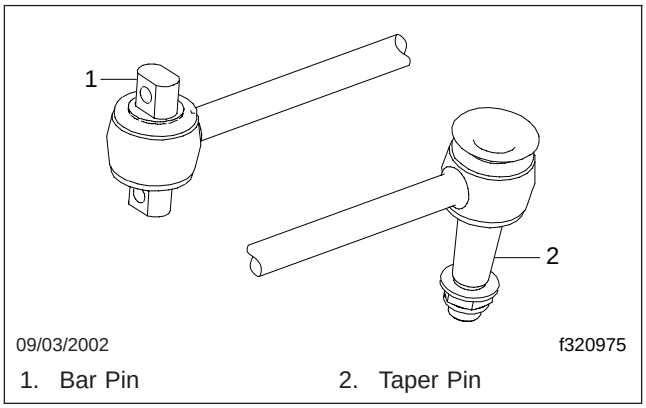

Fig. 3, Torque Rod Types

Tandem Axles

1. Check the tracking of the forward-rear axle. For instructions, see "Single Axle" in this subject. Adjust the tracking if needed.
2. At the forward-rear drive axle, measure the distance from the inner side of the right rear tire to the outer side of the right frame rail. Measure at the forward edge of the tire. See **Fig. 4**.

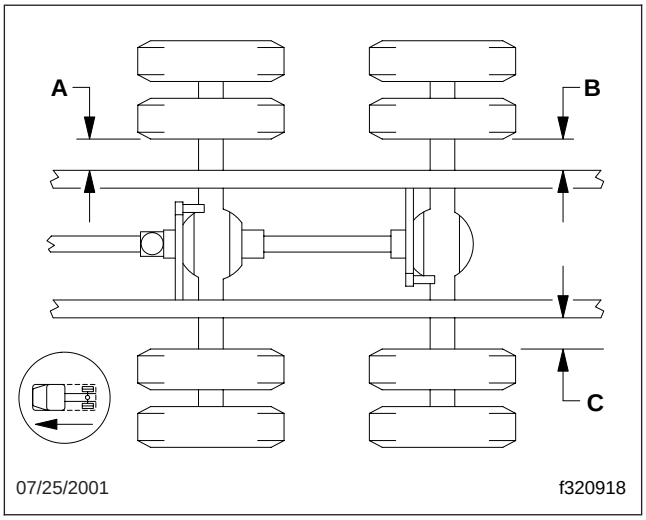

Fig. 4, Rear Axle Tracking Measurements (tandem axles)

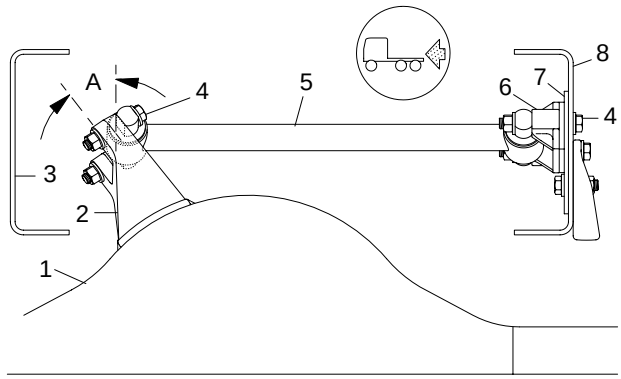
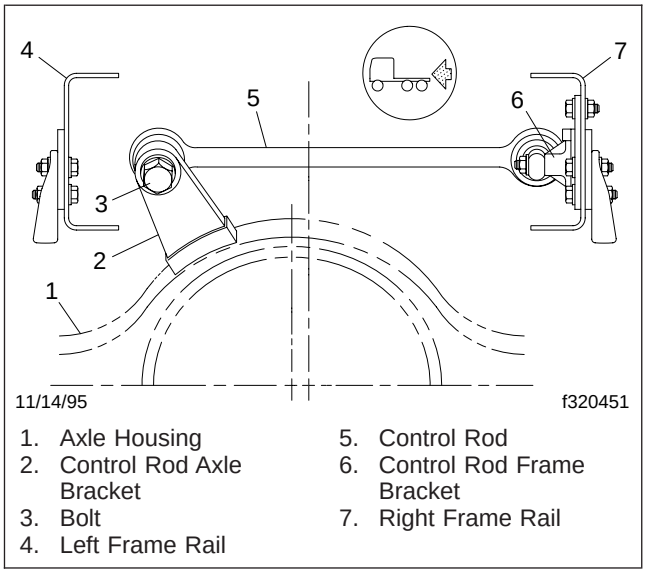


3. At both sides of the rear-rear drive axle, measure the distance from the inner side of the rear tires to the outer side of each frame rail. Measure at the rear edge of each tire. See **Fig. 4**.

IMPORTANT: Measurements "B" and "C" should not vary by more than 1/4-inch (6 mm) from measurement "A."

4. If measurements "B" and "C" vary by more than 1/4-inch (6 mm) from measurement "A," loosen the fasteners holding the axle lateral torque rod at the rear-rear drive axle to the frame rail. Add or remove torque-rod shims as needed.
5. For bar-pin style torque rods, tighten the fasteners 136 lbf·ft. For taper-pin style torque rods, tighten the fasteners 165 lbf·ft (224 N·m). See **Fig. 3**.

Replacement



1. Park the vehicle. Shut down the engine, and apply the brakes.
2. Chock the tires. Raise the vehicle. Support the frame rails with jack stands.
3. Remove the fasteners holding the control rod to the frame rail bracket. Remove the shims, and set the shims aside.
4. Remove the control rod.
5. Position the new control rod so that the end with the fasteners angled up at 35 degrees is installed in the axle housing bracket. **See Fig. 1.**

General Description

Ride quality is determined by a complex interaction of several factors including the vehicle specifications, installed equipment, vehicle speed, suspension loading, and the roughness of the road. An unusual combination of these factors may result in a rough ride.

There are two terms used to describe rough ride conditions: harmonic and harsh. Harmonic ride problems are those in which the once-per-revolution energy input from such things as bent or imbalanced wheels matches the natural frequency of the frame flexing. This produces a fore-and-aft motion in the cab, which continues as long as the critical road speed is maintained. Harmonic ride problems can occur on smooth roads.

Harsh ride problems are those in which the suspension transfers, rather than absorbs, the momentary energy inputs produced when the tires hit bumps or holes in the road. Wavy asphalt, or a series of bumps, may cause repetition of the harsh, jarring motion in the cab, but the motion stops after the tires pass over the bumps. Harsh ride problems occur on rough roads.

This section is designed for use as an aid in locating and correcting rough ride problems. It is not intended for use as a replacement for the detailed service information located in the applicable sections in this manual, or in the component manufacturer's service manuals.

Harmonic Ride Checks

1. Visually check the vehicle for signs of damaged or missing suspension components. Repair or replace the components using the instructions **in the suspension group, the front axle group, or the rear axle group .**
2. Test drive the vehicle.

NOTE: When test driving the vehicle, duplicate as closely as possible the conditions under which the problem occurs. Note the area of the vehicle where the problem seems to be coming from. Pay special attention to this area during the service operations.

3. Chock the tires and apply the parking brakes.
4. Raise the vehicle until the tires are off the ground, and all of the weight is removed from the leaf springs. Block the axle and frame with safety stands. Perform the remedies **under "Troubleshooting, 300: Harmonic Ride, Tires Off the Ground."**

⚠ WARNING

WARNING: Serious personal injury, property damage, or component damage may occur when fasteners are loosened or removed causing unsecured components to drop.

5. Remove the safety stands from under the frame and axle, then lower the vehicle. Perform the remedies **under "Troubleshooting, 300: Harmonic Ride, Tires On the Ground."**

Harsh Ride Checks

1. Visually check the vehicle for signs of damaged or missing suspension components. Repair or replace the components using the instructions **in the suspension group, the front axle group, or the rear axle group .**
2. Test drive the vehicle.

NOTE: When test driving the vehicle, duplicate as closely as possible the conditions under which the problem occurs. Note the area of the vehicle where the problem seems to be coming from. Pay special attention to this area during the service operations.

3. Perform the corrections under **"Troubleshooting, 300: Harsh Ride, Tires On the Ground."**
4. If the problem persists, perform the harmonic ride checks in this subject. Occasionally, ride problems associated with rough roads are harmonic ride problems masked by the road conditions.

Problem—Harmonic Ride, Tires Off the Ground

Possible Cause	Remedy
Bent, distorted, or out-of-round wheels or rims are causing a rough ride.	Inspect and repair the assemblies using the instructions in the **wheels and tires group.**
Bent, distorted, or out-of-round brake drums or hubs are causing a rough ride.	Replace damaged components using the instructions in the **front axle group** or the **rear axle group.**
An improperly seated tire-to-rim bead is causing an out-of-round assembly.	Inspect the tires and rims for proper bead seating. Correct the problem using the instructions in the **wheels and tires group.**
A tire and rim assembly on spoke wheels is improperly installed, causing an out-of-round assembly.	Remove and install the tire and rim assembly using the instructions in the **wheels and tires group.**
Worn or distorted rim spacers are causing an out-of-round assembly.	Replace damaged spacers using the instructions in the **wheels and tires group.**
The wheels, brake drums, or hub assemblies are out of balance.	Inspect the components for missing balance weights. Balance, as necessary.
Radial force variations in the tires are causing a rough ride.	Exchange the tires and wheels with a set that is known to cause no ride problems. If this corrects the problem, discard the old tires. For instructions, **refer to the wheels and tires group.**

Problem—Harmonic Ride, Tires On the Ground

Possible Cause	Remedy
Worn or loose cab mounts allow the cab to bounce.	With a long bar, lever the cab legs up and down. If there is looseness, replace or tighten the mounts, as necessary.
Forces from the trailer suspension are pushing on the tractor fifth wheel.	Review the ride problems in this subject that apply to the trailer suspension. Perform the corrections, as necessary.

Problem—Harsh Ride, Tires Off the Ground

Possible Cause	Remedy
Seized front spring shackle pins are not allowing the springs to flex.	Replace the seized shackle pins. For instructions, refer to the applicable front suspension section in this service manual group.

Problem—Harsh Ride, Tires On the Ground

Possible Cause	Remedy
The tires are improperly inflated.	Adjust the tire pressure using the instructions in the wheels and tires group of the maintenance manual.
The frame is bottoming out against the suspension.	Check the suspension for weak or damaged springs or components. Inspect the springs for "gull-winging" when the vehicle is loaded. Replace the spring assembly, as necessary, using the instructions in the **suspension group.**
	Reduce the overall loaded weight on each axle to conform with the maximum spring load capacities on the vehicle specification sheet. Do not exceed the maximum spring load capacities.
	Adjust the air spring height using the instructions in the **suspension group.**

Troubleshooting

Possible Cause	Remedy
The vehicle normal loaded weight is markedly below the spring load capacity.	Customers should contact a Freightliner dealer for the correct application of a lower rated spring. Replace the spring assembly using the instructions in the **suspension group.**
When the vehicle is loaded, the front axle spring shackle angle is not within the rearward 3 to 18 degree angle.	Customers should contact a Freightliner dealer for shackle angle corrective measures. **Refer to the suspension group** for service instructions.
The weight on the tractor fifth wheel is causing overloading on the front axle springs.	Change the loading pattern on the trailer.
Forces from the trailer suspension are pushing on the tractor fifth wheel causing a rough ride condition.	Review the ride problems in this subject that apply to the trailer suspension. Perform the corrections, as necessary.

General Description

Hendrickson RT and U series suspensions **(Fig. 1 and Fig. 2)** use leaf springs to absorb road shock. The forward and rear ends of each spring assembly ride in hangers attached to the frame rails, and the spring assembly rests on a saddle connected to an equalizing beam. Each end of the beam is secured to beam hangers welded on the vehicle axles.

NOTE: No alignment adjustments are needed for RT and U suspensions; alignment is determined by the placement of the spring hangers on the frame rails, and the beam hangers on the axle housings.

To allow for spring length change caused by spring deflection, the forward end of each spring assembly is secured to the number one hanger by a pin that runs through the legs of the hanger and through the spring eye. The spring eye contains a bronze bushing, and the pin that runs through the eye and the spring hanger legs is hardened steel with lubrication channels. The pin is also notched to allow two bolts to pass through the spring hanger legs and lock the pin in place.

The rear end of the spring assembly isn't fastened to the number two spring hanger; instead, the spring rests against the rounded underside (or cam) of the hanger and is free to rub against the hanger as the spring assembly changes length due to deflection caused by vehicle weight and road shock.

A spacer runs between the legs of the number two spring hanger to prevent the spring assembly from moving out of position against the hanger.

U series suspensions are light-weight versions of the RT suspensions, and use U-bolts to hold the spring assembly on the saddle. RT suspensions use four bolts that run down through the spring top pad to hold the spring assembly on the saddle.

Hendrickson RT suspensions also feature a "pilot cup" (similar to a raised disk), forged upward in the main spring leaf around the center bolt. This cup fits into the spring top pad to ensure the spring assembly is positioned correctly in the saddle. U suspensions feature similar pilot cups **(see Fig. 3),** but the U pilot cups are forged downward, around the center bolt to ensure the spring assembly is positioned correctly in the saddle.

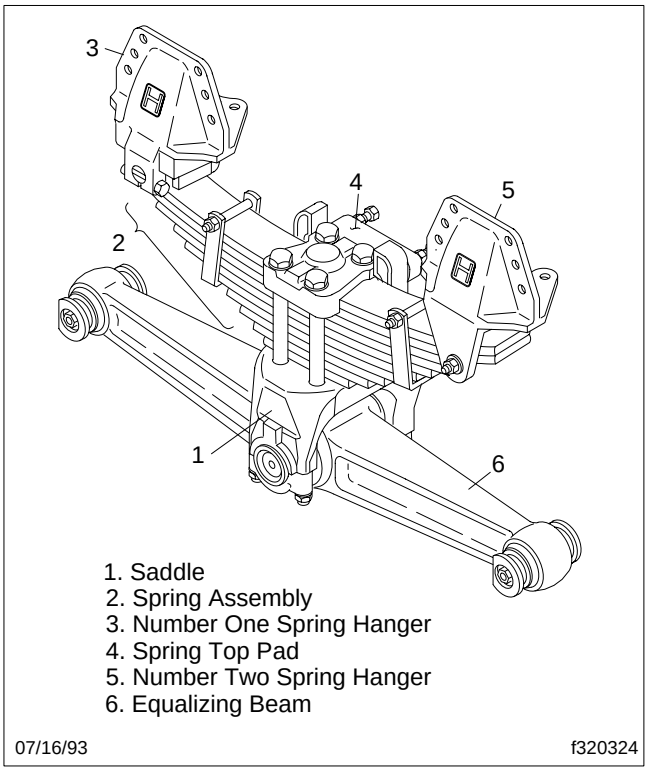

Fig. 1, RT Suspension

Because of this difference in pilot cups, springs for the two types of suspensions are not interchangeable.

RTE and UE series suspensions **(Fig. 4 and Fig. 5)** are basically the same as the RT and U suspensions, but feature longer spring assemblies that require a third spring hanger. This design provides a two-stage spring rate, depending on the vehicle load. When the vehicle is unloaded, there should be a 3/8-inch gap between the top spring and the number two spring hanger, and the rear end of the spring assembly should rest against the number three spring hanger.

Loaded **(see Fig. 5),** the springs deflect until the spring assembly rests against all three spring hangers.

On all models of RT and U suspensions, torque rods— mounted between the axle housings and the frame rails— prevent the axles from twisting or shifting side-to-side as the vehicle accelerates, stops, or corners.

General Description

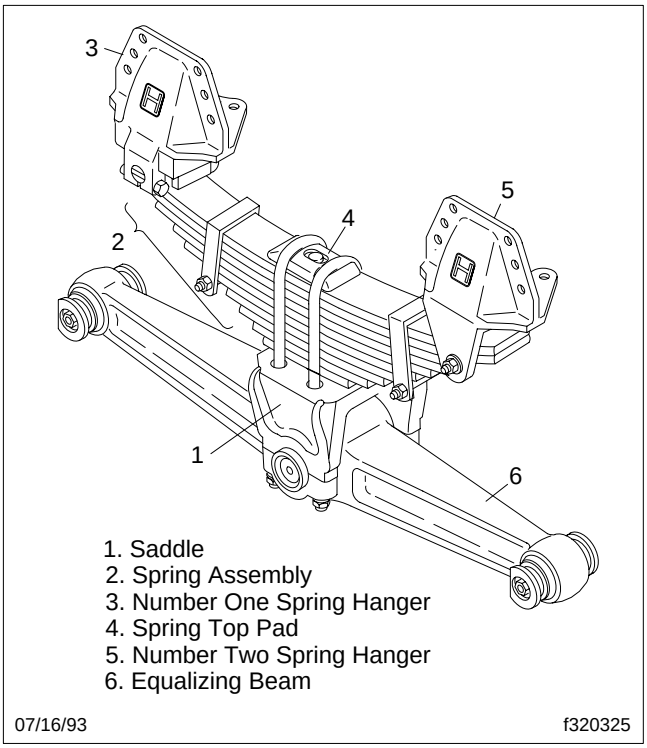

Fig. 2, U Suspension

All suspension fasteners require periodic tightening. For suspension inspecting, lubricating, and fastener torque checking instructions, refer to the suspension section in the vehicle maintenance manual.

⚠ WARNING

WARNING: Failure to periodically torque the suspension fasteners could result in damage to the frame hangers or separation of components. This could cause a loss of vehicle control, resulting in injury or property damage.

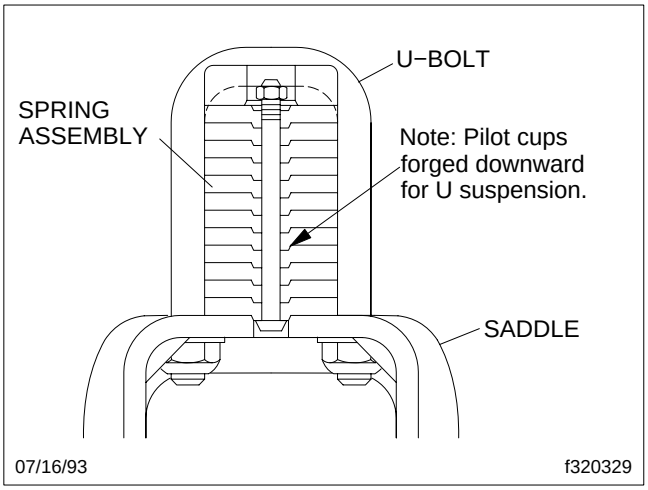

Fig. 3, Pilot Cups (cross-section view of springs)

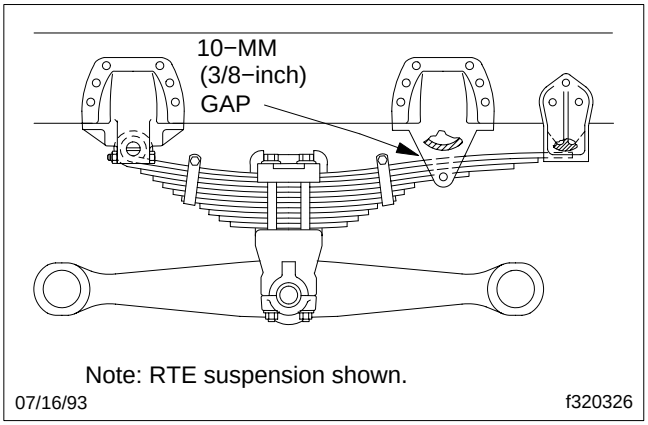

Fig. 4, Unloaded Suspension

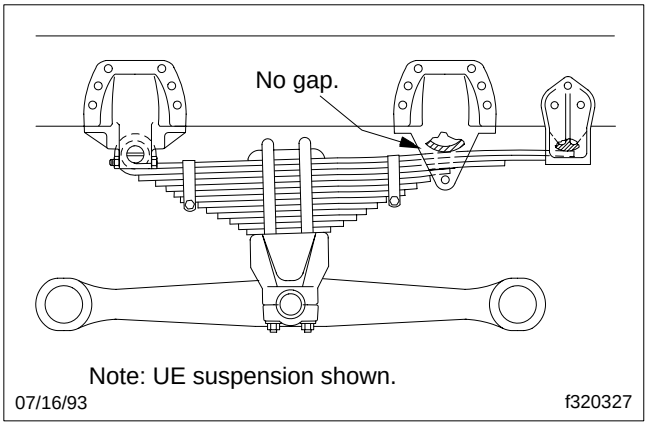

Fig. 5, Loaded Suspension

Removal (Refer to Fig.1or Fig.2)

1. Chock the front tires.
2. Drain the vehicle air system.
3. Disconnect all air lines leading to the rear axles, marking the lines for later assembly reference. Plug or cap all lines and fittings to prevent dirt from entering the system.
4. Disconnect the driveline rear universal joint from the forward-rear axle.
5. Manually release the spring brake chambers. For instructions, **refer to the brakes group.**

⚠ WARNING

WARNING: When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

6. Remove the torque rods. For instructions, **refer to Subject 170.**

   To prevent the axles from pivoting, secure chains between the crosstube and each fore and aft torque rod axle mounting bracket.
7. Raise the rear of the vehicle so that all weight is removed from the suspension. Then, block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

8. Remove the saddle cap nuts and washers from each side of the vehicle, and remove the saddle caps.

NOTE: If the saddle cap studs are damaged, replace them.

9. Raise the rear of the vehicle frame until there is enough clearance to roll the axles out from under the vehicle. Install safety stands under the frame, then roll the axles— with the equalizer beams attached— out from under the vehicle.

Installation (Refer to Fig.1or Fig.2)

1. Roll the axles under the vehicle frame. Align the center bushing of each equalizer beam with the center of the saddle legs.
2. Raise the vehicle frame off the safety stands, then remove the safety stands.
3. Lower the frame, centering the saddles on the beam center bushings.
4. Lubricate the saddle cap studs with SAE 20 oil. Install the saddle caps, washers and new self-locking nuts. Do not tighten.
5. Install the torque rods. For instructions, **refer to Subject 170.**

   Remove the chains between the crosstube and each fore and aft torque rod axle mounting bracket.
6. Tighten the saddle cap locknuts to the applicable torque in the torque table in **"Specifications, 400."**

NOTE: Maintain an even gap between the saddle cap and the saddle when tightening the self-locking nuts **(see Fig.3).**

7. Remove the safety stands from under the frame and axle, and lower the vehicle.
8. Manually reset the spring brake chambers. For instructions, **refer to the brakes section.**
9. Connect the driveline rear universal joint to the forward-rear axle. For instructions, **refer to the driveline components section.**
10. Uncap all air lines and fittings, then connect the lines leading to the rear axles.

Spring and Saddle Removal and Installation

Removal

1. Remove the suspension. For instructions, **refer to Subject 100.**
2. Support the spring and saddle assembly with a floor jack.
3. Remove the locknuts from the spring pin lockbolts; then remove the lockbolts and washers from the number one spring hanger.
4. Using a suitable drift, drive the spring pin through the no. 1 spring hanger and out the inboard side of the spring hanger **(see Fig. 1).**
5. Remove the locknut and lockwasher from the rebound spacer bolt in the no. 2 spring hanger. Remove the rebound spacer bolt and the spacer.

⚠ WARNING

WARNING: The leaf spring assembly is heavy. Use care when handling it to prevent injury.

6. Lower the spring and saddle assembly from the spring hangers.
7. Remove the spring assembly from the saddle.

   7.1 *On RT series suspensions ,* loosen the spring alignment setscrews on the top pad, and remove the top pad locknuts, washers, bolts, and top pad.

   On U series suspensions , remove the U-bolt locknuts, washers, U-bolts, and U-bolt top pad.

   7.2 Lift the spring assembly from the saddle.

Installation

1. Seat the leaf spring assembly on the saddle.
2. Install the spring assembly on the saddle.

   2.1 Position the top pad on the spring assembly, and check that the pad is seated on the spring center-bolt.

   IMPORTANT: The pilot cups on U springs are forged downward around the spring center-bolt and fit in a pilot hole in the saddle; therefore, springs for RT and U suspensions are not interchangeable.

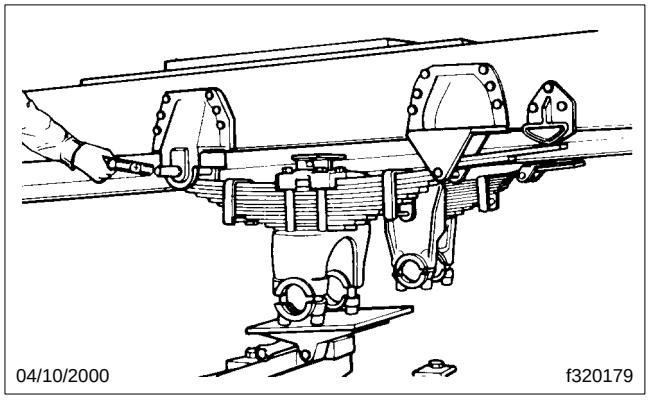

Fig. 1

NOTE: On RT series suspensions, the main leaf has a pilot cup forged upward around the center-bolt. This cup serves as a pilot when installing the top pad, and ensures correct alignment of the spring assembly.

2.2 Lubricate the threads of the top pad bolts or U-bolts with SAE 20 oil.

On RT series suspensions , install washers on the top pad bolts, and install the bolts through the top pad and saddle. Secure the bolts with new washers and nuts, and tighten the nuts finger-tight.

On U series suspensions , install the U-bolts over the top pad and spring assembly, and through the saddle. Secure the bolts with new washers and nuts, and tighten the nuts finger-tight.

2.3 *On RT series suspensions ,* lubricate the threads on the spring setscrews with SAE 20 oil. Hand-tighten the spring setscrews against the leaf springs, then tighten them 135 to 203 N·m (100 to 150 lbf·ft). Tighten the setscrew locknuts until the lockwashers are locked.

Tighten the top pad locknuts 373 to 542 N·m (275 to 400 lbf·ft). Use the tightening sequence shown in **Fig. 2**.

On U series suspensions , tighten the locknuts evenly 320 to 410 N·m (237 to 302 lbf·ft) Using a hammer, tap the tops of the U-bolts to settle the assembly, then tighten the locknuts 320 to 410 N·m (237 to 302 lbf·ft).

Spring and Saddle Removal and Installation

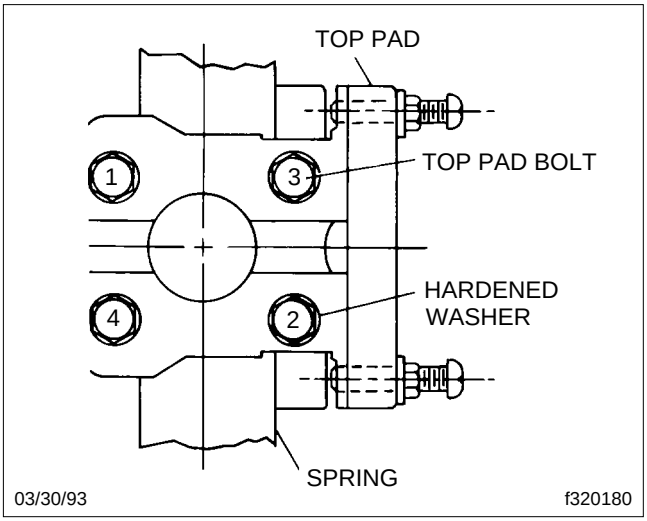

Fig. 2, Top Pad Bolt Tightening Sequence

CAUTION

CAUTION: Failure to tap the U-bolts and tighten the locknuts a second time could allow the assembly to loosen, damaging the pilot hole in the saddle seat.

3. Position the spring and saddle assembly into the no. 1 and no. 2 spring hangers.
4. Coat the spring pin and the inside diameter of the spring eye bushing with multipurpose chassis grease.
5. Align the spring pin with the spring eye bushing in the forward spring hanger.
6. From the outboard side of the spring hanger, tap the spring pin into the bushing with a soft hammer. If necessary, adjust the spring to assist spring pin entry.
7. Place washers on the spring pin lockbolts, and insert the lockbolts through the spring hanger. If necessary, use a screwdriver to turn the spring pin until the lockbolts can slide past it.
8. Lubricate the lockbolt threads with SAE 20 oil. Install the lockwashers and locknuts. Tighten the locknuts 61 to 85 N·m (45 to 63 lbf·ft).
9. Position the rebound spacer in the no. 2 spring hanger leg, then install the rebound spacer bolt, lockwasher, and locknut. Tighten the locknut 51 to 61 N·m (38 to 45 lbf·ft).
10. Install the grease fittings in both spring eye pins. Apply multipurpose chassis grease to the grease fittings until grease appears on both sides of the spring eye bushings.
11. Install the suspension. For instructions, **refer to Subject 100.**

Spring Leaf, Spring Pin, and Spring Eye Bushing Checking and Replacement

Checking

1. Shut down the engine, apply the parking brakes, and chock the tires.
2. Check for spring eye bushing or pin damage.
   - 2.1 Place a block of wood on the spring **(see Fig. 1),** and with a pry bar, try to lift the spring hanger and frame rail. Note how much movement occurs around the spring eye pin.
   - 2.2 With the vehicle unloaded, try to rock the chassis back and forth. Note how much movement occurs around the spring eye pin.
   - 2.3 In either case, if 3 mm (1/8 inch) or more movement occurs between the spring eye pin and the spring bushing, replace the bushing.

   NOTE: Movement around the spring eye pin can also indicate a broken spring eye. In this case, replace the main leaf or the spring assembly.
3. Remove the chocks from the tires.

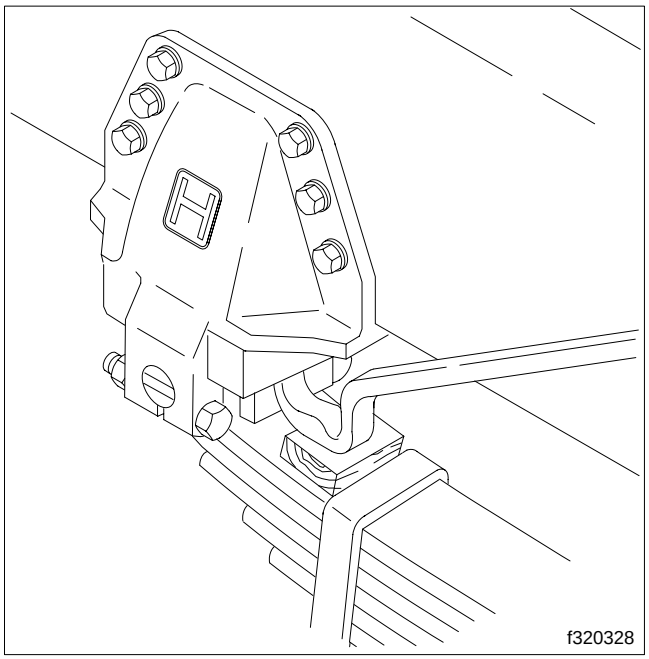

Fig. 1

Replacement

1. Remove the spring and saddle assembly. For instructions, **refer to Subject 110.**
2. Using a C-clamp to hold the spring leaves together, remove the center-bolt and nut, and the spring alignment clips. Remove the C-clamp and separate the leaves.

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

3. Using a wire brush and solvent, clean all grease, dirt, and rust from the spring leaves. Inspect the spring leaves for cracks, gouges, wear, or abnormal bends. The no. 1 main and no. 2 wrapper spring leaves (the top two spring leaves) may each be replaced; if equipped with the RTE or UE series suspension, the nos. 1, 2, and 3 spring leaves (the top three spring leaves) may each be replaced. If a spring leaf is damaged below these numbers in a pack, replace the spring assembly. Replace both spring assemblies to ensure even spring deflection.
4. Inspect the spring pin and spring eye bushing for wear or damage. If the pin diameter is less than 1.367 inch, replace it. If the inside diameter of the spring eye bushing is more than 1.395 inch, replace it.

NOTE: If necessary, press out the bushing with a hydraulic press. Install the new bushing with the split of the bushing positioned at the top (30 degrees) of the spring eye **(see Fig. 2).**

5. Position the spring leaves in order, then insert a drift through the center-bolt hole to align the leaves.
6. Compress the leaves with a C-clamp, then install the spring alignment clips on the spring leaves. Install the spring alignment clip nuts and bolts. Tighten the nuts 20 N·m (15 lbf·ft).
7. Remove the drift punch. At the bottom of the spring, insert a new center-bolt. Install a new

Spring Leaf, Spring Pin, and Spring Eye Bushing Checking and Replacement

center-bolt nut and tighten to the value in the torque table in **"Specifications, 400."**

8. Install the spring and saddle assembly. For instructions, **refer to Subject 110.**

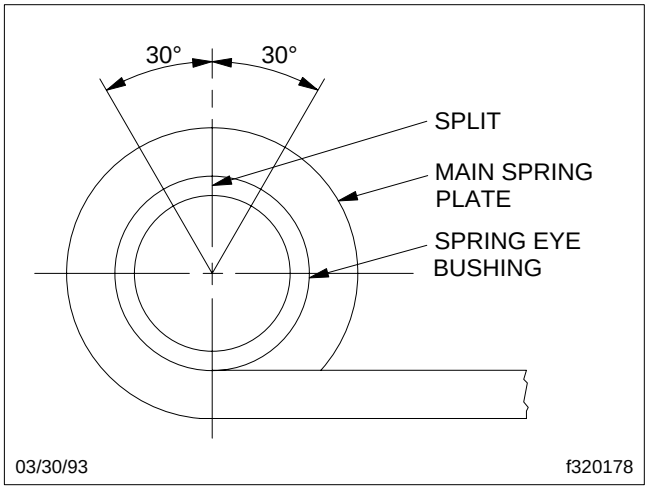

Fig. 2

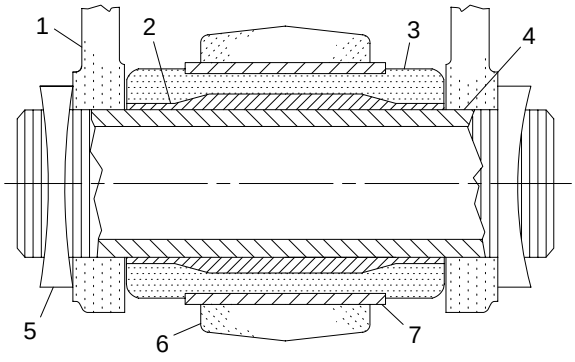
Equalizer Beam Adapter- and Tube-Type End Support Removal and Installation



Removal

IMPORTANT: To ensure that the required tools are available, see the table of special tools **"Specifications, 400,"** before beginning these procedures. Special tools are available from the Owatonna Tool Company, Owatonna, Minnesota, or an affiliated dealer. Although these tools are recommended, shop-made adapters can be used if a vertical hydraulic press with a 50-ton capacity is available. Dimensions for the shop-made adapters are provided in the table in **"Specifications, 400."**

1. Chock the front tires.
2. Remove the saddle cap nuts and washers, then remove the saddle cap. Support the equalizer beam with safety stands.
3. Raise the rear of the vehicle until the saddle studs clear the equalizer beam. Block the axles and frame with safety stands.
4. Remove the wheels and tires. For instructions, **refer to the wheels and tires group.**
5. Remove the brake shoes, brake spider, and brake backing plate (dust shield). **Refer to the rear axle group** for instructions.
6. Apply a penetrating oil to all beam end connections.
7. On a tube-type end support **(see Fig. 1),** remove the tube nuts from both sides of the beam end tube.

   On an adapter-type end support **(see Fig. 2),** remove the nut, washers, and the adapter bolt.
8. If using Owatonna tools, remove the tube-type end supports by positioning the receiving tube over the outboard end of the beam end tube. Position the hydraulic ram, pulling screw, speed nut, and the removing adapter **(see Fig. 3).** Connect a hydraulic pumping unit to the ram, and apply pressure to remove the beam end tube.
9. Remove the adapter-type end supports (if using Owatonna tools).

   9.1 Using either a 7/8-or 15/16-inch hand-tap **(see Fig. 4),** tap the adapter bolt hole (outboard side) to a depth of about 38 mm (1-1/2 inches).

passes through the adapter bolt hole, use a 15/16-inch tap; if it doesn't, use a 7/8-inch tap.

9.2 On the outboard side of the axle, thread the removing screw into the tapped hole. Position the receiving cup and hexnut on the removing screw **(see Fig. 5).** Turn the hexnut until the adapter plug breaks loose and bottoms on the inside of the receiving cup. If needed, add spacers to complete removal of the adapter plug. **See Fig. 6.**

9.3 On the inboard side of the axle, position the receiving cup over the adapter plug. On the outboard side of the axle, insert the removing screw through the receiving cup and secure it with the hexnut. **See Fig. 7.**

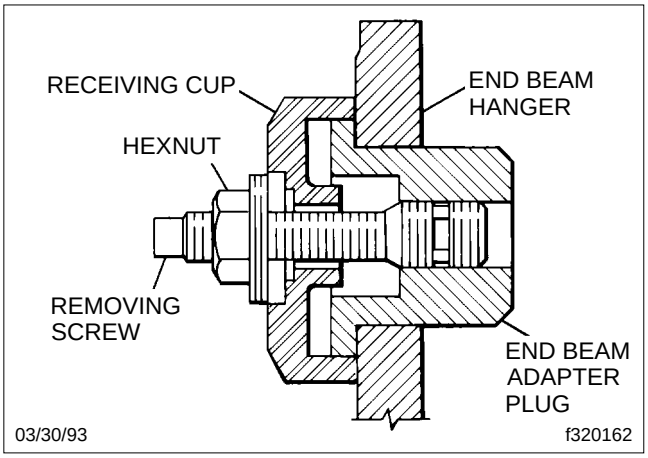

Fig. 5

9.4 Hold the removing screw and turn the nut with a 1-1/2 inch open-or box-end wrench. Turn the nut until the adapter plug bottoms on the inside of the receiving cup.

10. Remove the end supports (if not using Owatonna tools).

10.1 For tube-type end supports, install a spacer bushing between one end-tube nut and the beam hanger. Tighten the nut to pull the end tube out of the beam end bushing. If the tube doesn't come loose, use a hacksaw and saw the tube along the inside surface of both axle beam hanger legs.

Equalizer Beam Adapter- and Tube-Type End Support Removal and Installation

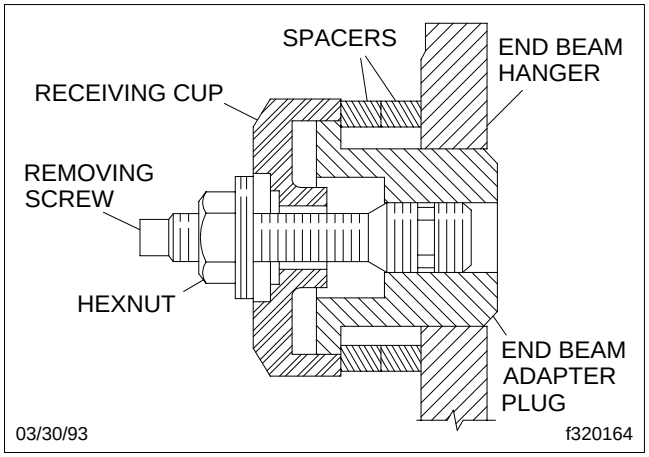

Fig. 6

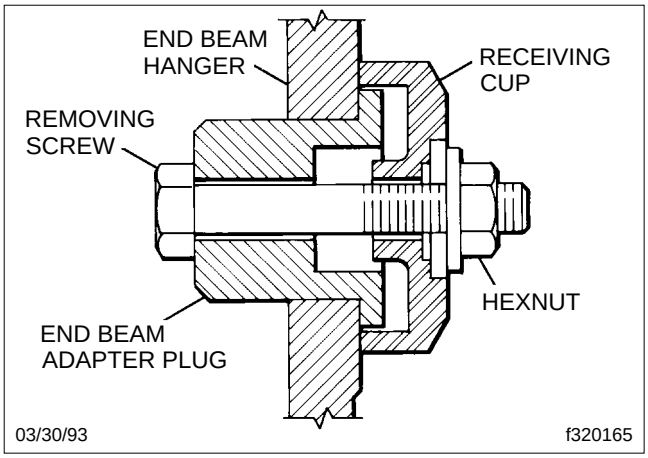

Fig. 7

⚠ WARNING

WARNING: Don't use a cutting torch to remove the equalizer beams from the beam hangers. The equalizer beams are heat treated, and using a cutting torch could weaken them. This could result in a loss of vehicle control and possible personal injury.

10.2 For adapter-type end supports, a relief is located on each side of the adapter **(see Fig. 8).** Turn the adapter with an air chisel, then insert a chisel into the relief on the inboard adapter. Drive the chisel in and wedge the adapter out of the beam hanger. Do the same on the outboard adapter.

If a split-ring adapter is used, drive a chisel between the two halves to remove the end support plug. Drive the plug into the equalizer beam end bushing until it is clear of the beam hanger. After the equalizer beam is removed, drive the adapter plug out of the bushing.

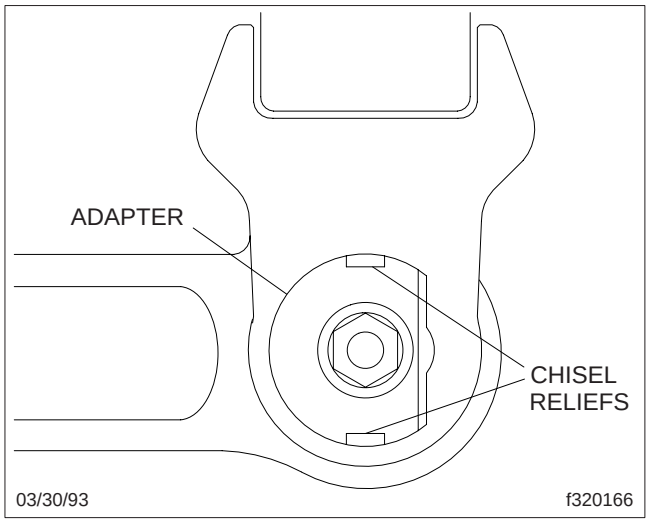

Fig. 8

11. Remove the ends of the equalizer beams from the axle beam hangers.
12. Lower the equalizer beams and the crosstube to the ground. Remove the thrustwashers and pull the beams from the crosstube.

Installation

1. On adapter-type end supports, apply Texaco Compound L, or an equivalent rust preventive lubricant, to the axle beam hanger eyes,

   beam end bushing inner sleeve, end support adapters, outside surface of the bushing intermediate tubes, and the ends of the crosstube.

   Install the crosstube and thrustwashers in both equalizer beam center bushings.

   On tube-type end supports, apply Texaco Compound L, or an equivalent rust preventive lubri-

Equalizer Beam Adapter- and Tube-Type End Support Removal and Installation

cant, to the axle beam hanger eyes, beam end bushing inner sleeve, outer surface of the beam end tubes, beam center bushing inner sleeves, and the ends of the crosstube.

Using SAE 20 oil, lubricate the threads of the beam end tube, then install the crosstube and thrustwashers in both equalizer beam center bushings.

2. Position the equalizer beam assembly under the axles, then raise the assembly and place the forward ends of each beam in the forward-rear axle beam hangers. Align the beam end bushings with the beam hangers.

   On adapter-type end supports, install the intermediate tubes, the adapters, the adapter bolt, washers, and nut in each beam end to hold the beam in the axle beam hangers. Do not tighten.

   On tube-type end supports, install the beam end tubes through the beam hangers and the beam end bushings. Hand-tighten both nuts on the beam end tubes.

3. Place the rear ends of each beam in the rearmost axle beam hangers. Align the beam end bushings with the beam hangers.

   On adapter-type end supports, install the intermediate tubes, the adapters, the adapter bolt, washers, and nut in each beam end to hold the beam in the axle beam hangers. Do not tighten.

   On tube-type end supports, install the beam end tubes through the beam hangers and the beam end bushings. Hand-tighten both nuts on the beam end tubes.

4. Position the saddle caps on the saddle cap studs, then install the washers and new self-locking nuts. Tighten the nuts to the applicable torque in the torque table in **"Specifications, 400."**

5. Tighten the adapter bolt nuts 285 to 325 N·m (210 to 240 lbf·ft). Make sure the flat section of the adapter flange is in the vertical position. **See Fig. 9.**

6. Tighten the end tube nuts 508 to 576 N·m (375 to 425 lbf·ft).

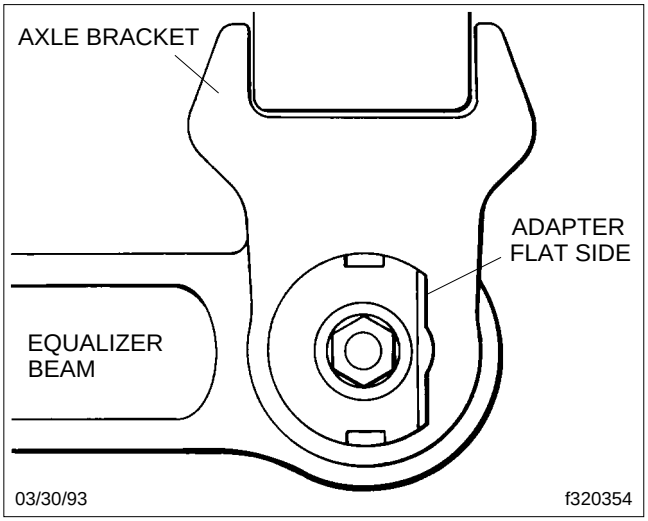

Fig. 9

WARNING

WARNING: The adapter bolt nuts and end tube nuts must be tightened to the specified values. If not, the metal surfaces of the end support assembly will rub, and excessive wear to the beam hanger legs and end bushing inner sleeves will occur. This could result in separation of suspension components, loss of vehicle control, and possible injury or property damage.

7. Install the brake backing plate (dust shield), brake spider, and brake shoes. **Refer to the rear axle group** for instructions.

8. Install the wheels and tires. For instructions, **refer to the wheels and tires group.**

Equalizer Beam End Bushing Removal and Installation

Removal

⚠ WARNING

WARNING: Don't use a cutting torch to remove the beam end bushing. Equalizer beams are heat treated by the manufacturer. Using a cutting torch could weaken the beams, and may result in a loss of vehicle control. This could cause personal injury or property damage.

1. Remove the equalizer beam ends from the axle beam hangers. For instructions, **refer to Subject 130.**
2. Cut off the protruding rubber from one side of each beam end bushing **(see Fig. 1).**
3. Remove the beam end bushings (if using Owatonna tools, refer to **Fig. 2**).
   - 3.1 Install the receiving adapter on the receiving tube.
   - 3.2 Position the hydraulic ram and slide the pulling screw through the end bushing.
   - 3.3 Install the end bushing removing adapter on the inboard side of the beam end bushing. Check that the cone-shaped surface of the adapter is facing the equalizer beam.

   IMPORTANT: Align the receiving tube so that the bushing will clear the edges of the tube when force is exerted against the beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

   - 3.4 Install the hexnut on the pulling screw. Full thread engagement is needed.
   - 3.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.
   - 3.6 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely remove the end bushing.

NOTE: If the pressure gauge on the hydraulic pumping unit reads 68 950 kPa (10,000 psi) and the bushing has not broken loose, stop and check the alignment of the receiving tool and removal adapter. If both tools are aligned correctly, attach a sledging adapter on the speed nut end of the pulling screw. Maintaining hydraulic pressure, strike the sledging adapter with a heavy hammer. A loud noise followed by a sudden drop of the pressure gauge reading indicates the bushing has broken loose.

Equalizer Beam End Bushing Removal and Installation

4.2 Position the equalizer beam on a 50-ton vertical hydraulic press.

4.3 Center the shop-made adapter (refer to the table of special tools in **"Specifications, 400"**) on the trimmed end of the equalizer beam bushing. Press the end bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.
2. Using emery cloth, clean the outer sleeves of the new equalizer beam end bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing.
3. Install the beam end bushings, (if using Owatonna tools, refer to **Fig. 3**):

   3.1 Fit the adapter clamp over the exposed rubber on the new bushing. Tighten the clamp nuts until the clamp is flush against the bushing outer sleeve.

   3.2 Install the receiving adapter on the receiving tube.

   3.3 Position the hydraulic ram and slide the pulling screw through the end bushing.

   3.4 Center the adapter clamp and bushing on the inboard side of the beam end.

   3.5 Install the adapter plate and secure it with the hexnut.

   IMPORTANT: Check that the new bushing and the installation tools are centered so that the bushing will clear the receiving tube when force is exerted against the beam.

   3.6 Tighten the speed nut and remove any slack in the assembly.

   3.7 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

   3.8 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely install the end bushing.

   NOTE: The pressure gauge on the pumping unit should read 27 580 to 37 920 kPa (4000 to 5500 psi) during installation. If the reading reaches the operating limit of 68 950 kPa (10,000 psi) and the bushing is not going into the beam end, check the alignment of the bushing, tooling, and hydraulic equipment. Installation is complete when the adapter clamp is flush against the beam.

   3.9 Install the equalizer beam ends on the axle beam hangers. For instructions, **refer to Subject 130.**

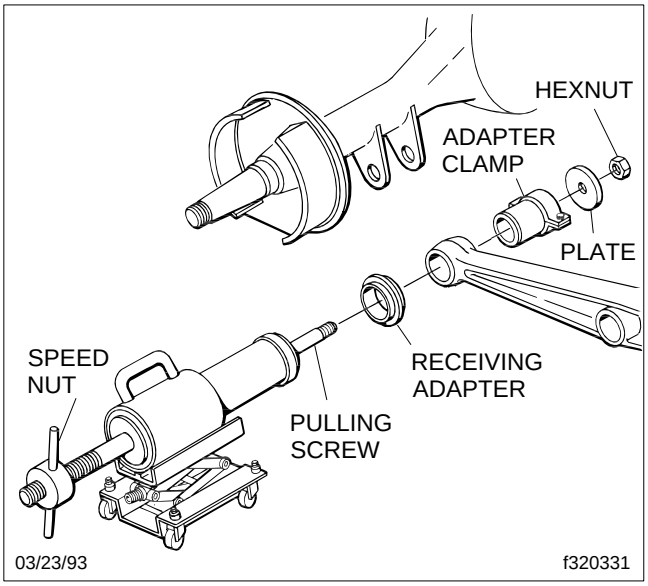

Fig. 3

4. Install the beam end bushings (if using shop-made adapters, see **Fig. 4**).

   4.1 Position the equalizer beam on a 50-ton hydraulic press.

   4.2 Using a sheave puller, compress the exposed rubber of the bushing until the puller jaws are flush against the end of the bushing outer sleeve.

   4.3 Position the shop-made adapter (refer to the table in **"Specifications, 400"**)

against the jaws of the sheave puller. Press the new bushing into the beam eye.

4.4 Install the equalizer beam. For instructions, **refer to Subject 130.**

Equalizer Beam Bar Pin/Bushing Assembly Removal, Installation, and Alignment

Removal

NOTE: From July 1995, most Hendrickson suspensions are manufactured with a bar pin-type bushing assembly that connects the equalizer beam to the axle. The bar pin/bushing assembly can be serviced without removing the brake assembly.

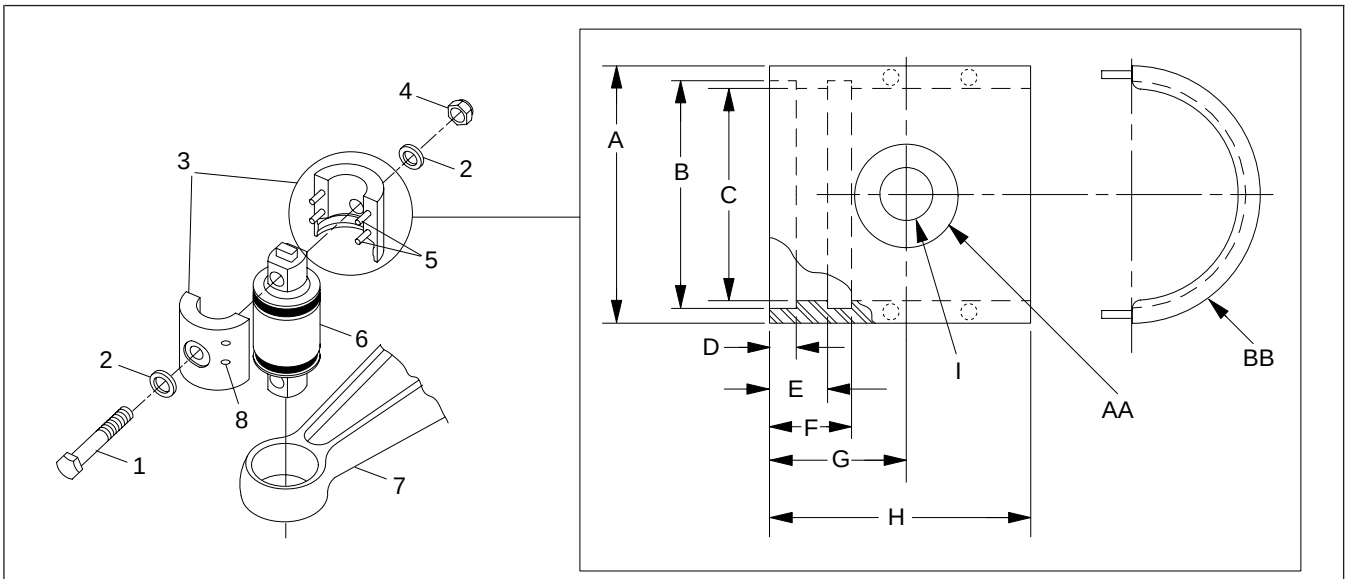
⚠ WARNING

Do not use a cutting torch to remove the equalizer beams from the beam hangers. The equalizer beams are heat-treated, and using a cutting torch could weaken them. This could result in a loss of vehicle control, possible personal injury, or property damage.

1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. Support the equalizer beams with jack stands.
4. Remove the four bolts attaching the equalizer beam to the saddle.
5. Apply a penetrating oil to the threads of the two 1-inch (25 mm) bolts and locknuts attaching each bar pin/bushing assembly to the axle brackets.
6. Remove the bolts. If the fasteners are rusted in place, an air hammer chisel may be used to loosen the bolts attaching the bar pin/bushing assembly to the axle brackets.

NOTE: The upper torque rods may have to be disconnected at the top of the axle, and the axle rotated to a more vertical position to assist in the removal of the equalizer beam from the axle bracket.

7. Remove the equalizer beam from the axle beam hangers.
8. The bar pin/bushing assemblies can be removed from the equalizer beams with Owatonna tools. To do so, follow Owatonna recommendations.
9. If shop-made tools are used, remove the bar pin/bushing assemblies from the beam ends as follows:
   - 9.1 Position the equalizer beam on a 50-ton vertical hydraulic press.
   - 9.2 Center the shop-made tool, and press the bar pin/bushing assembly from the beam end eye.



Installation

IMPORTANT: Do not reuse the old fasteners. Replace them during installation.

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.
2. The outer metals of some Hendrickson rubber bushings are covered with a phosphate coating that acts as a rust preventive. This coating must be removed with emery cloth before installation. Also apply a coating of grease to the cleaned outer metals of the bar pin/bushing assembly, and to the beam end eyes to help when pressing the bar pin/bushing assembly into the beam end eye.
3. If using Owatonna tools, install the bar pin/bushing assemblies using Owatonna recommendations.
4. If using shop-made tools, create the needed assembly tool from a 5-inch (127 mm) length of 5-inch (127 mm) O.D. steel tubing with 1/2-inch (13 mm) wall thickness. See **Fig. 1**. The assembly tool must be split in half, then clamped or bolted together to compress the rubber to allow contact with the bushing outer metal.
   - 4.1 Position the equalizer beam on a 50-ton hydraulic press with the beam end bore squarely supported on the bed for safety and to avoid bending the equalizer beam.
   - 4.2 Before pressing the bar pin/bushing assembly, align the holes in the end of the bar pin/bushing assembly with the center line of the equalizer beam. This will help assembly into the axle brackets. Care should be taken during the assembly process to ensure the orientation of the bar pin/bushing assembly in the beam eye.

   NOTE: After installation, verify that the bar pin/bushing assembly is centered in the end of the beam.

5. Install the equalizer beam on the axle hangers.
6. Attach the bar pin/bushing assembly to the axle brackets. Tighten the 1-inch (25 mm) bolts 450 to 600 lbf·ft (610 to 813 N·m).

NOTE: Bar pin/bushing assembly kits are available with or without alignment shims.

7. Install the four bolts attaching the equalizer beam to the saddle. Tighten 225 to 275 lbf·ft (305 to 375 N·m).
8. Remove the jack stands.
9. Remove the chocks from the tires.

Equalizer Beam Rubber Center Bushing Removal and Installation

Removal

NOTE: If using Owatonna tools, removal of the equalizer beam is not required for removal or installation of the rubber center bushing.

1. Chock the front tires.
2. Raise the rear of the vehicle so that all weight is removed from the suspension. Block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

3. Remove the saddle cap nuts and washers from each side of the vehicle, and remove the saddle caps.
4. Raise the rear of the truck frame until the saddle studs clear the equalizer beam. Install safety stands under the frame.
5. Using a 2-1/2 inch diameter hole saw **(see Fig. 1),** cut out the end plug from the center bushing on each side of the suspension, and remove the crosstube.

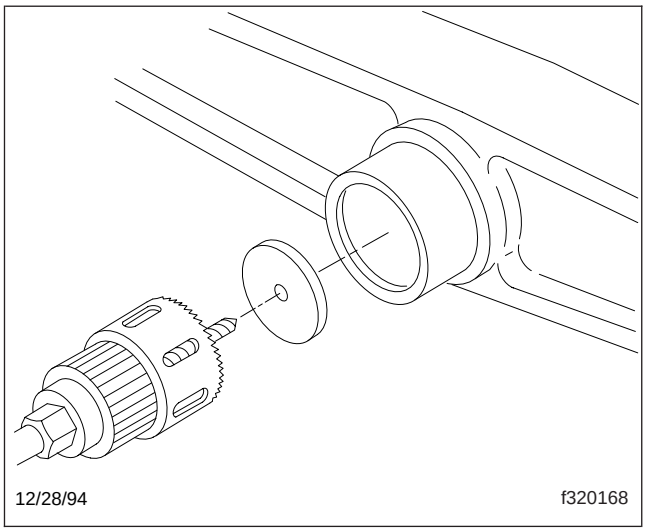

Fig. 1

⚠ CAUTION

CAUTION: Do not use a cutting torch to burn out the end plugs. The equalizer beams are heat treated, and the use of a cutting torch could weaken the beam.

6. On the inboard side of the equalizer beam, inspect the exposed edge of the bushing's outer sleeve.
7. Chisel or grind off any portion of the outer sleeve that has flared over the surface of the equalizer beam.
8. Remove the rubber center bushings (if using Owatonna tools, refer to **Fig. 2**).

   8.1 Position the hydraulic ram and slide the pulling screw through the center bushing.

   8.2 Install the center bushing removing adapter on the inboard side of the beam eye.

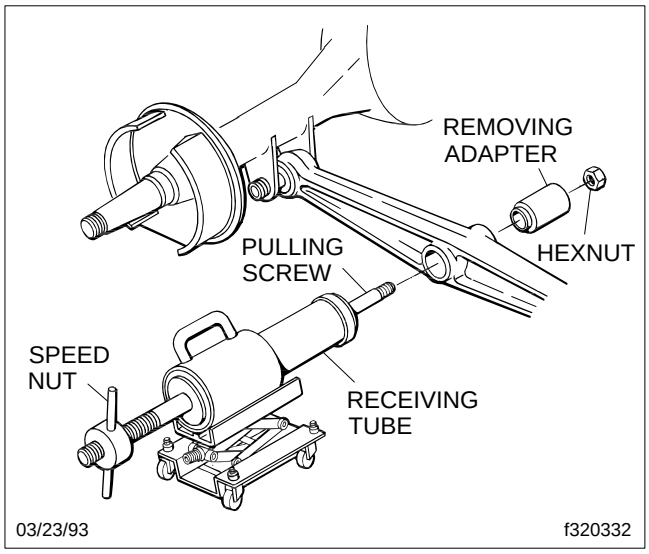

Fig. 2

IMPORTANT: Align the receiving tube so that the bushing will clear the edges of the tube when force is exerted against the beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

8.3 Install the hexnut on the pulling screw. Full thread engagement is needed.

Equalizer Beam Rubber Center Bushing Removal and Installation

8.4 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

8.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

8.6 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely remove the bushing.

NOTE: If the pressure gauge on the hydraulic pumping unit reads 68 950 kPa (10,000 psi) and the bushing has not broken loose, stop and check the alignment of the receiving tool and removal adapter. If both tools are aligned correctly, attach a sledging adapter on the speed nut end of the pulling screw. Maintaining hydraulic pressure, strike the sledging adapter with a heavy hammer. A loud noise followed by a sudden drop of the pressure gauge reading indicate that the bushing has broken loose.

9. If using shop-made adapters, remove the equalizer beams. For instructions, **refer to Subject 130.**

9.1 Position the equalizer beam on a 50-ton vertical hydraulic press.

9.2 Center the shop-made adapter (refer to the table in **"Specifications, 400"**) on the trimmed end of the equalizer beam bushing. Press the center bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.

2. Using emery cloth, clean the outer sleeves of the new equalizer beam center bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing.

3. Install the rubber center bushings (if using Owatonna tools, refer to **Fig. 3**).

3.1 Center the hydraulic ram and slide the pulling screw through the beam eye.

3.2 Position the bushing on the inboard side of the beam eye.

IMPORTANT: Center the new bushing to ensure a clean pull through the beam eye.

3.3 Fit the installing adapter over the inner sleeve and against the outer sleeve of the bushing.

3.4 Install the hexnut on the pulling screw. Full thread engagement is needed.

3.5 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

3.6 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

3.7 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely install the center bushing.

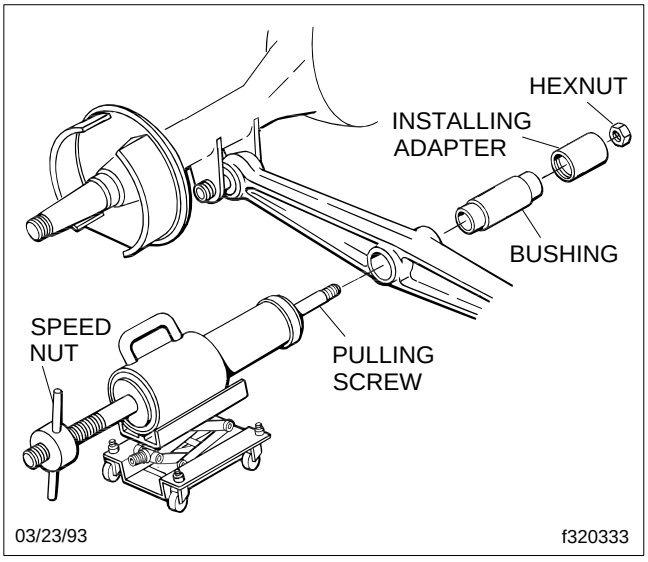

Fig. 3

NOTE: The pressure gauge on the pumping unit should read 27 580 to 37 920 kPa (4000 to 5500 psi) during installation. If the

reading reaches the operating limit of 68 950 kPa (10,000 psi) and the bushing is not going into the beam, check the alignment of the bushing, tooling, and hydraulic equipment. Installation is complete when the installing adapter is flush against the beam.

3.8 Position the crosstube in the center bushings.

⚠ WARNING

WARNING: Wear protective welding masks and gloves when welding. Failure to do so could result in personal injury due to the intensity of heat, sparks, and flying debris from the welding process.

3.9 Arc weld new end plugs to the tire side of each center bushing inner sleeve.

NOTE: Heat from welding the end plugs will not affect the beam or the new rubber bushings because of their distance from the point of welding.

4. Position the saddle caps on the saddle cap studs, then install the washers and new self-locking nuts. Tighten the nuts to the applicable torque in **"Specifications, 400."**

5. If using shop-made adapters, position the equalizer beam on a 50-ton hydraulic press.

5.1 Using standard center bushings with the end plugs welded in place, position the shop-made adapter (refer to the table in **"Specifications, 400"**) over the inner sleeve of the bushing. Check that the adapter bottoms against the bushing outer sleeve, then press the new bushing into the beam eye.

5.2 Install the equalizer beams. For instructions, **refer to Subject 130.**

Equalizer Beam Bronze Center Bushing Removal and Installation

Removal

NOTE: If using Owatonna tools, you can remove or install the bronze center bushing without removing the equalizer beam.

1. Chock the front tires.
2. Raise the rear of the vehicle so that all weight is removed from the suspension. Block the axles and the frame with safety stands. Make sure the stands will securely support the weight of the axles and the frame.

NOTE: Do not raise the vehicle to the point where the weight of the suspension and axles hangs from the vehicle.

3. Remove the saddle cap nut and washers from each side of the suspension, and remove the saddle caps.
4. Raise the rear of the truck frame until the saddle studs clear the equalizer beam. Install safety stands under the frame.
5. Using a 2-1/2 inch diameter hole saw, cut out the retaining disk from the center bushing on each side of the suspension, and remove the cross-tube.

⚠ CAUTION

CAUTION: Do not use a cutting torch to burn out the retaining disk. The equalizer beams are heat treated, and the use of a cutting torch could weaken the beam.

6. Remove the bronze center bushing (if using Owatonna tools, refer to **Fig. 1**).

   6.1 Position the hydraulic ram and slide the pulling screw through the center bushing.

   6.2 Install the center bushing removing adapter on the inboard side of the beam eye.

   IMPORTANT: Align the receiving tube so that the bushing will clear the edges of the tube when force is exerted against the beam. Align the removing adapter so that force is exerted only on the bushing to ensure a clean pull through the beam.

   6.3 Install the hexnut on the pulling screw. Full thread engagement is needed.

   6.4 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

   6.5 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

   6.6 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely remove the center bushing.

   NOTE: If the pressure gauge on the hydraulic pumping unit reads 68 950 kPa (10,000 psi) and the bushing has not broken loose, stop and check the alignment of the receiving tool and removal adapter. If both tools are aligned correctly, attach a sledging adapter on the speed nut end of the pulling screw. Maintaining hydraulic pressure, strike the sledging adapter with a heavy hammer. A loud noise followed by a sudden drop of the pressure gauge reading indicates that the bushing has broken loose.

7. If using shop-made adapters, remove the equalizer beams. For instructions, **refer to Subject 130.**

Equalizer Beam Bronze Center Bushing Removal and Installation

7.1 Position the equalizer beam on a 50-ton vertical hydraulic press.

7.2 Center the shop-made adapter (refer to the table in **"Specifications, 400"**) on the center bushing. Press the bushing from the beam eye.

Installation

1. Using emery cloth, remove all scale, rust, or corrosion from the beam eyes. Inspect the equalizer beam eyes for cracks, gouges, or damage. Replace the equalizer beam if any of these conditions exist.
2. Using emery cloth, clean the outer sleeves of the new equalizer beam center bushings. Apply a thin coating of Texaco Compound L, or an equivalent rust preventive lubricant, to the surface of the outer sleeves on the new bushing, and to the inside surface of the beam eye.
3. Position the bushing on the equalizer beam eye.
4. Install the bronze center bushings (if using Owatonna tools, refer to **Fig. 2**):

4.1 Center the hydraulic ram and slide the pulling screw through the beam eye.

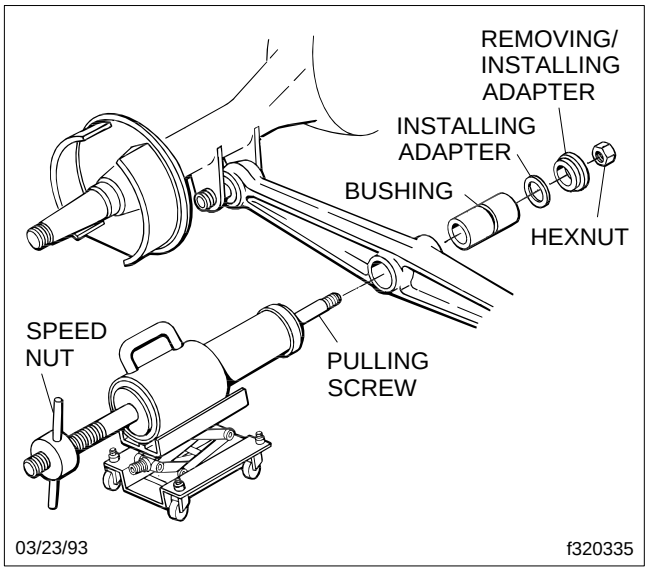

Fig. 2

4.2 Position the bushing on the inboard side of the beam eye. Check that the grooves of the bushing are aligned with the vertical centerline of the equalizer beam **(see Fig. 3).**

4.3 Fit the installing adapter and the removing/installing adapter against the outer sleeve of the bushing. Make sure the deep ridge on the installing adapter is positioned against the bronze bushing **(see Fig. 4).**

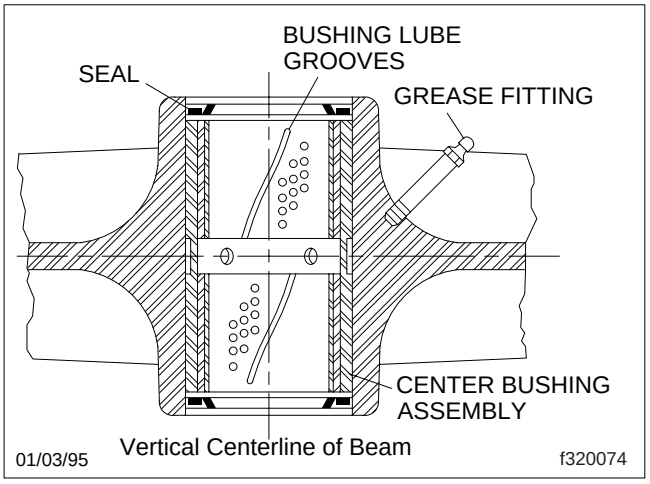

Fig. 3

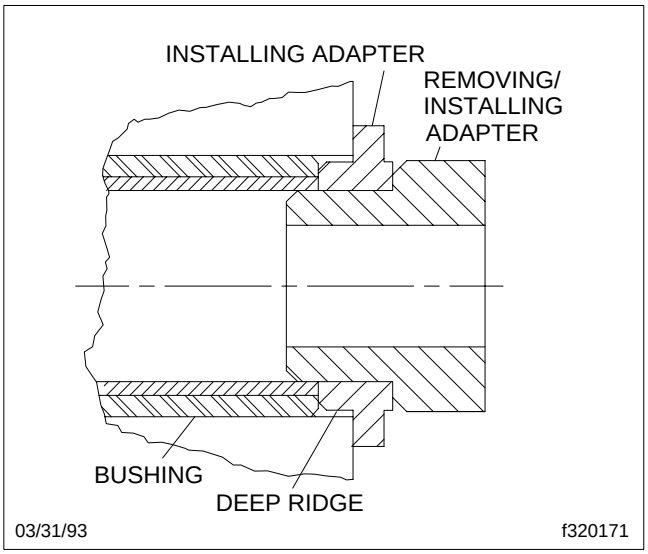

Fig. 4

4.4 Install the hexnut on the pulling screw. Full thread engagement is needed.

4.5 Install spacers between the ram cylinder and the speed nut. Tighten the speed nut and remove any slack in the assembly.

4.6 Connect a hydraulic pumping unit to the ram and apply force until the ram cylinder reaches its stroke limit.

4.7 Release the pressure, add spacers, and tighten the speed nut. About three adjustments are needed to completely install the center bushing.

NOTE: The pressure gauge on the pumping unit should read 27 580 to 37 920 kPa (4000 to 5500 psi) during installation. If the reading reaches the operating limit of 68 950 kPa (10,000 psi) and the bushing is not going into the beam, check the alignment of the bushing, tooling, and hydraulic equipment. Installation is complete when the installing adapter is flush against the beam.

4.8 On the inboard side of the beam, position a grease seal and installing adapter against the center bushing. Make sure the shallow end of the adapter is against the grease seal **(see Fig. 5).** Using a hammer, tap the installing adapter until it is flat against the beam. Using the same procedure, install a grease seal on the outboard side of the beam.

5. If using shop-made adapters, position the equalizer beam on a 50-ton hydraulic press.

5.1 Center the new bushing in the beam eye. Using a standard bushing driver, press the bushing in until there is equal spacing between both bushing ends and the sides of the beam eye.

5.2 Install the new grease seals (with the seal lips facing out).

NOTE: Check that the new seals are 1/6 inch (4 mm) inside the beam hub surface to ensure clearance and protection of the seals when the saddle cap is installed.

6. Apply a thin coating of multipurpose chassis grease to the inside surface of the center bushing. Slide the bushing center sleeve into the bushing.

7. Install the grease fitting into the beam hub. Rotate the center sleeve and apply multipurpose chassis grease in the grease fitting. Lubricate until clean grease appears at both ends of the grease seals.

8. Install the crosstube.

9. Install the saddle caps or the equalizer beam (if removed) on the axle beam hangers. For instructions, **refer to Subject 130.**

Torque Rod Removal, Bushing Replacement, and Installation

Removal

IMPORTANT: To ensure that the required tools are available, see the table of special tools in **"Specifications, 400,"** before beginning these procedures. Special tools are available from the Owatonna Tool Company, Owatonna, Minnesota, or an affiliated dealer.

⚠ WARNING

WARNING: When the torque rods are disconnected from the axle brackets, the axles become free to pivot on the equalizer beam end bushings. Keep clear of the beam hangers and beam ends to avoid possible injury.

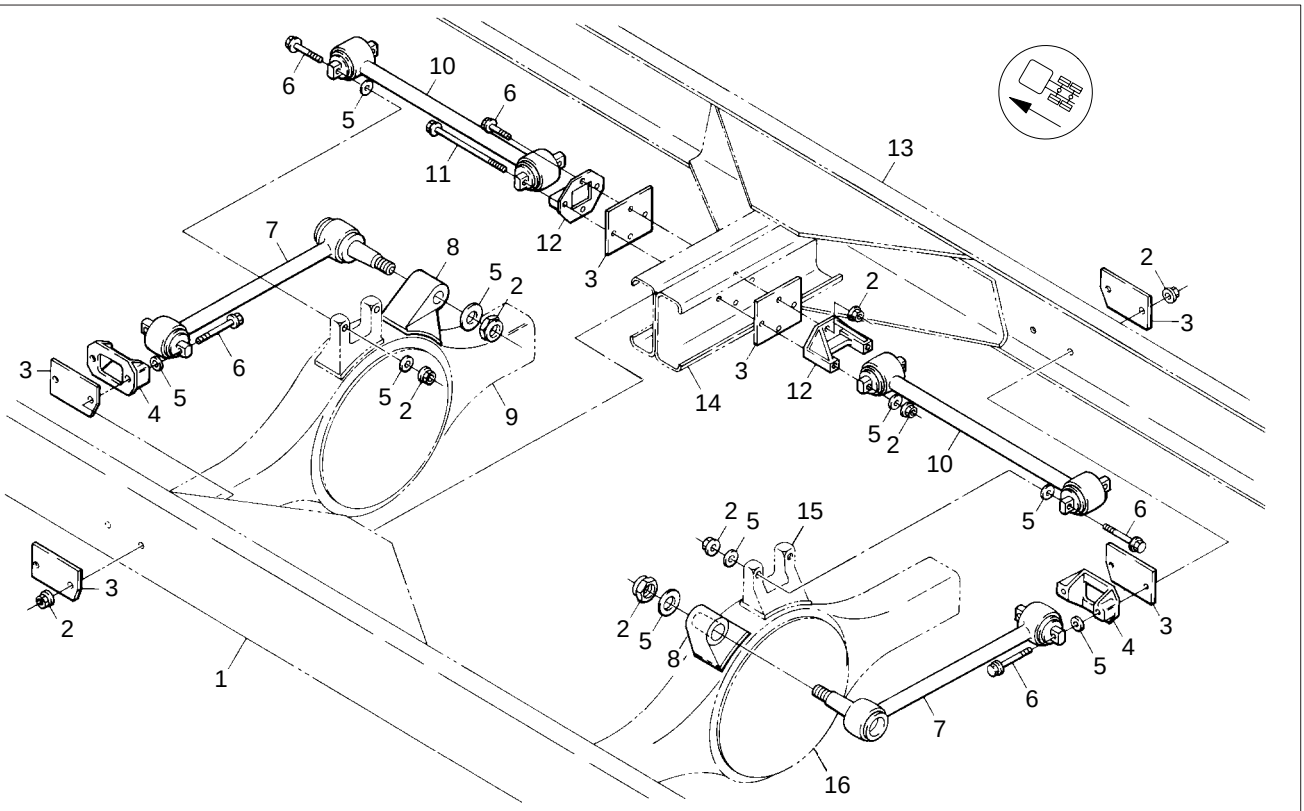
1. On fore-and-aft torque rods, remove the bolts and nuts from the torque rod axle brackets, and the crossmember mounting brackets **(see Fig.1).** Remove the torque rods.

   On transverse torque rods, remove the nuts and washers from the axle brackets, and remove the bolts and nuts from the frame rail mounting brackets **(see Fig.1).** Remove the torque rods.

NOTE: If necessary, use an impact hammer and tap the top of the axle bracket to disengage the rod stud from the axle bracket.

2. Inspect the torque rods. If bent or cracked, replace. Check the torque rod bushings. If one of the bushings is loose or damaged, replace both of the bushings.
3. Position the press plate on the hydraulic press. Check that the small counterbore of the plate hole is facing up.

NOTE: Some tapered stud torque rod bushings have a large non-removable washer on the stud that will not fit though the press plate hole. Loosen the press plate capscrews and separate the halves **(see Fig.2)** until the washer clears the counterbore, and the torque rod sets on the press plate. Tighten the capscrews until the press plate halves are closed.



4. Position the tapered stud removal tool (using the end with the larger inside diameter) on the torque rod stud. Apply lubricating oil **(see Fig.3),** then press the stud out of the bushing.
5. Position the bushing remover/replacer tool (using the end with the larger outside diameter) on the bushing. Install the cap, then apply lubricating oil to the torque rod bushing.
6. Press the rubber bushing out of the torque rod eye.
7. Position the straddle mount end of the torque rod into the hole of the press plate. Tighten the press plate capscrews.
8. Position the straddle mount pin remover on the straddle mount pin **(see Fig.4).**
9. Apply lubricating oil to the straddle mount pin. Press the straddle mount pin out of the bushing.
10. Position the end of the rubber bushing remover/replacer tool (using the end that has the larger outside diameter) on the bushing. Install the cap, then apply lubricating oil to the torque rod bushing.
11. Press the rubber bushing out of the torque rod eye.

Installation

1. Remove all dirt and grease from the torque rod ends. Apply lubricant on the new bushings and in the torque rod eyes.
2. Position the press plate on the hydraulic press. Check that the small counterbore of the plate hole is facing up.
3. Position the new bushing on the tapered stud of transverse torque rods. Position the clamp and tighten it to compress the rubber **(see Fig.5).**
4. Place the torque rod end, the bushing, and the clamp on the press plate.
5. Place the remover/replacer tool **(see Fig.6)** and cap on top of the clamping tool and press the bushing in the torque rod end. Check that the bushing sleeve protrudes equally on each side of the torque rod end.
6. On straddle mount end assemblies, align the clamping tool on the bushing **as shown in Fig.7.** Tighten the clamp to compress the rubber of the new straddle mount bushing.

NOTE: When tightening the clamp, make sure that the position of the bushing pin is at a right

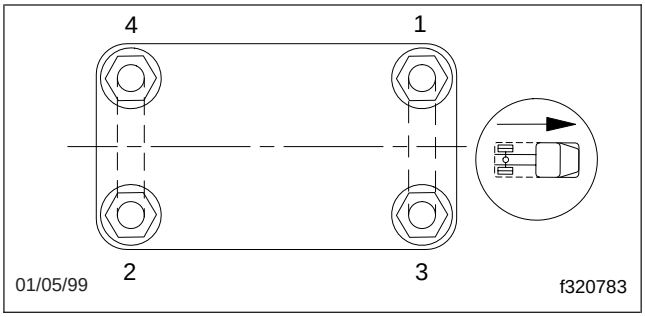

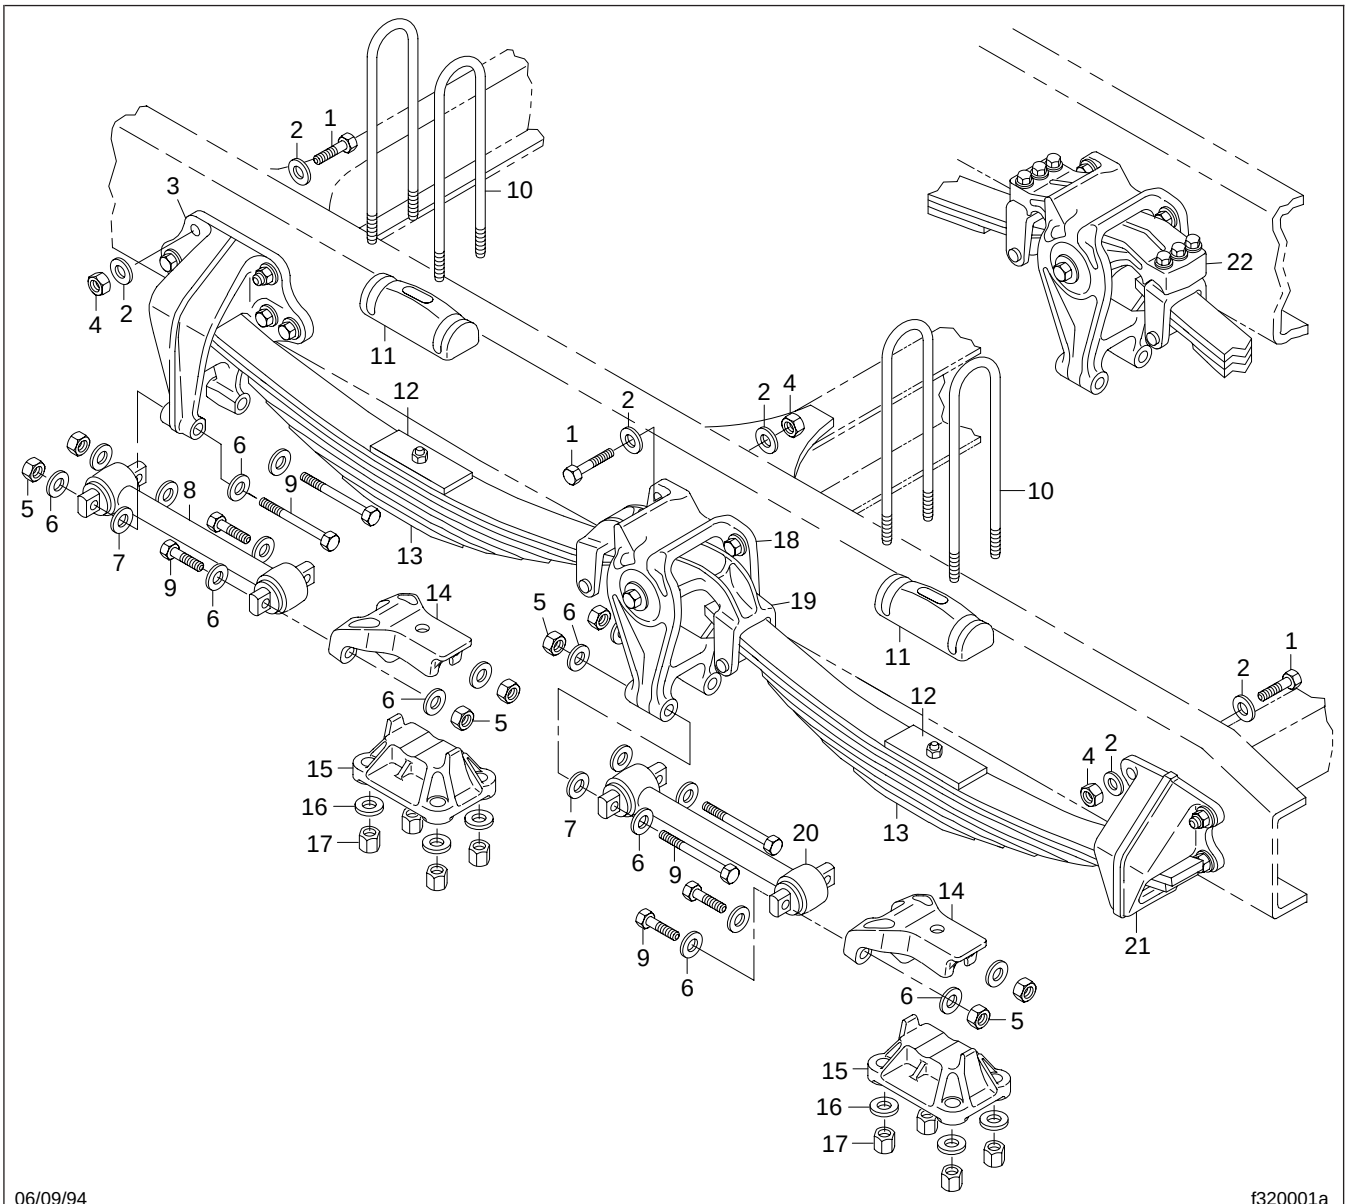

Fig. 1, Tightening Pattern for U-Bolt High Nuts

General Description

The tandem-axle rear spring suspension **(Fig. 1)** uses a six-point equalizing leaf spring design, which compensates for axle articulation, from side to side, and front to rear. Four semi-elliptical spring assemblies are attached to the axles with U-bolts. On both sides of the vehicle, the forward end of the forward spring and the rear end of the rear spring ride in aluminum brackets that are mounted on the frame rails. Steel wear shoes are cast into each bracket.

At the center, between the forward and rear springs, the springs ride on an equalizer, which pivots on a sleeve in the equalizer bracket. Equalizer travel is stopped when the top of the equalizer and the equalizer bracket make contact. Each axle is held in alignment by a pair of radius rods that extend forward from the axle seats to the forward spring brackets for the forward-rear axle, and to the equalizer brackets for the rearmost axle.

1. Apply the parking brakes, and chock the tires.
2. Note the number of axle alignment washers (Ref. 4) at the forward end of each radius rod that is being removed.
3. Remove the fasteners that attach the radius rod to the forward spring bracket or equalizer bracket, and to the axle seat.
4. Remove the radius rod and any axle alignment washers.

Installation (See Fig. 1)

IMPORTANT: At all points where steel parts (including bolts, washers, and nuts) contact aluminum brackets, apply Alumilastic compound, or an equivalent, on the mating surfaces.

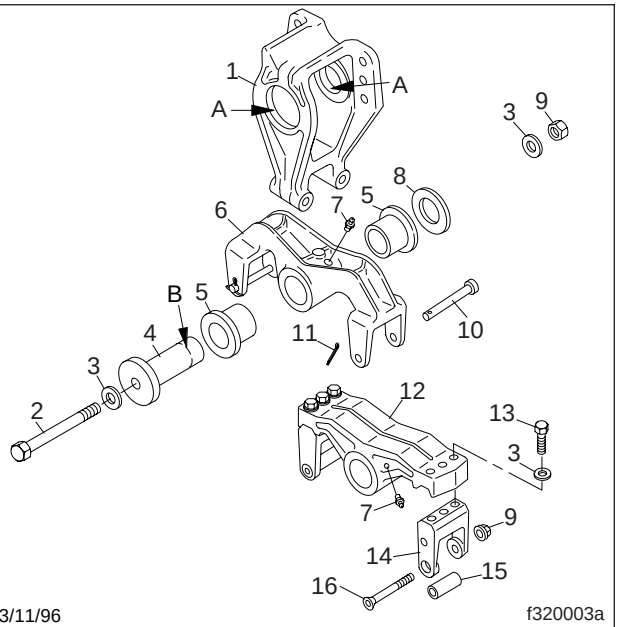
⚠ CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the suspension.

If installing forward and rear radius rods, install the forward radius rod before installing the rear radius rod.

1. If installing a forward radius rod, place the radius rod front pin on the front side of the forward spring bracket, and place the radius rod rear pin in front of the axle seat.

   If installing a rear radius rod, place the radius rod pins between the rear side of the equalizer bracket and the front side of the axle seat.



Radius Rod Removal and Installation

2. Install a hexhead bolt with a hardened washer through each end of the radius rod rear pin and the axle seat ears. Install the hardened washers and locknuts.
3. If installing a forward radius rod, install any previously removed axle alignment washers between the radius rod front pin and the forward spring bracket. Install the hexhead bolts, hardened washers, and locknuts.

   If installing a rear radius rod, install any previously removed axle alignment washers between the radius rod front pin and the equalizer bracket. Install the hexhead bolts, hardened washers, and locknuts.
4. Tighten the radius rod locknuts to the torque value in **Specifications, 400**.
5. After all of the radius rods are installed, check the rear axle alignment. For instructions, refer to **Group 35**. If necessary, adjust the axle alignment, using the instructions in **Subject 140**.

Fig. 1, Equalizer Assembly

1. Chock the front tires.
2. Raise the rear of the vehicle, and block the axles with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will securely support the weight of the axles and frame. To allow access to the equalizer, remove the wheel assemblies on that side, using the instructions found in **Group 40**.
3. If removing an equalizer from a vehicle with two drive axles, remove the cotter pin from the outboard end of each spring retainer pin, then remove the retainer pins.

   If removing an equalizer from a vehicle with a pusher or tag axle, remove the nuts from the flathead bolts in the wear-shoe side-restraints, on each end of the equalizer. Remove the flathead bolts and side-restraint sleeves. Remove the six capscrews and washers, and remove both wear-shoe side-restraints from the equalizer.
4. Remove the cap and tube assembly locknut, inboard bearing washer, bolt, and outboard bearing washer.
5. Insert a bar between the bottom of the equalizer and the equalizer bracket. Gently lever the weight of the equalizer off the cap and tube assembly. Insert a piece of barstock through the inboard cap and tube assembly bolt hole, and lightly tap the cap and tube assembly out of the equalizer.
6. Remove the equalizer from the equalizer bracket. Remove the wear washer(s) and equalizer bushings from the equalizer.

Inspection

1. Thoroughly clean the equalizer with steam or a hot soap solution. Inspect it for wear, cracks, or other damage. Replace the equalizer if any of these conditions are present.

⚠ WARNING

WARNING: Replace a worn or damaged equalizer. A broken equalizer could cause a loss of vehicle control, resulting in personal injury or property damage.

2. Inspect the equalizer bushings, cap and tube assembly, and the equalizer bracket. If wear, cracks, or other damage are present, replace the bushings, cap and tube assembly, or bracket.

Installation (See Fig. 1)

1. Apply a thin film of multipurpose chassis grease to the outside of the equalizer bushings, then install the bushings in the equalizer.

NOTE: The equalizer is *not* symmetrical. To ensure that the equalizer is installed in the proper direction, an arrow is cast into its top surface.

Equalizer Removal, Inspection, and Installation

2. Install the equalizer in the equalizer bracket. Make sure that the arrow cast into the top of the equalizer is pointing toward the frame rail. **See Fig. 2.**

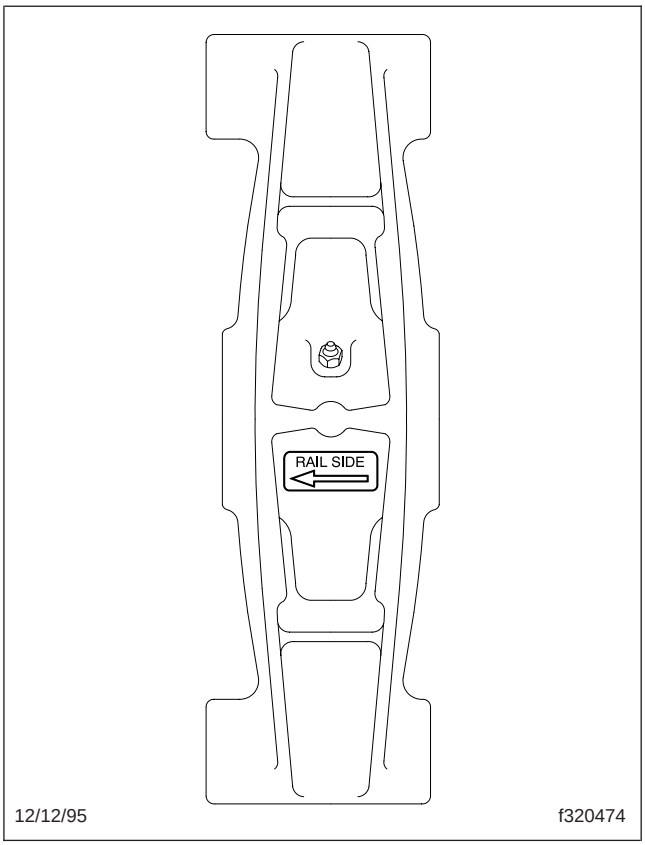

Fig. 2, Equalizer Marking

NOTE: The next four steps must be completed before the Loctite begins to cure (approximately 5 to 10 minutes).

IMPORTANT: Be careful to prevent grease from contacting the inboard surface of the cap and tube assembly, where the Loctite is applied.

3. Apply Loctite 680 to both interior surfaces of the equalizer bracket, where the cap and tube assembly is inserted. Apply multipurpose chassis grease to the cap and tube assembly, except the last inch which connects to the equalizer bracket. **See Fig. 1 ,** Ref. B. Start the cap and tube assembly into the equalizer, through the equalizer bracket.
4. Push the cap and tube assembly part way through the equalizer, then place the wear washer(s) between the inboard equalizer bushing and the equalizer bracket. Push the cap and tube assembly the rest of the way into the equalizer bracket.
5. Place the outboard bearing washer on the equalizer cap and tube assembly bolt, and install the bolt in the cap and tube assembly.
6. Install the inboard bearing washer and locknut on the cap and tube assembly bolt. Tighten the locknut to the torque value in **Specifications, 400**.
7. Lubricate the equalizer assembly by applying multipurpose chassis grease at the grease fitting. Lubricate with a hand gun or pressure gun until grease is forced past the bushing seals, or if equipped with a pressure-relief grease fitting, until grease is forced out from the base of the pressure relief fitting.
8. If installing an equalizer on a vehicle with two drive axles, apply Alumilastic compound, or an equivalent, to the spring retainer pins; then install them from the inboard side. Be sure the hooked ends of the spring leaves are above the retainer pins. Install a cotter pin in the outboard end of each retainer pin, and lock it in place.

   If installing an equalizer on a vehicle with a pusher or tag axle, apply Alumilastic compound, or an equivalent, to the surfaces where the wear-shoe side-restraints contact the equalizer. Attach the side-restraints to the equalizer, offsetting them toward the inboard side of the equalizer. Tighten the equalizer wear-shoe capscrews to the torque value in **Specifications, 400**. Install the side-restraint sleeves and flathead bolts in the wear-shoe side-restraints. Be sure the hooked ends of the spring leaves are above the side-restraint sleeves. Install the nuts, and tighten them to the applicable torque value in **Specifications, 400**.

⚠ CAUTION

CAUTION: Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel contact each other, could lead to corrosion of the metals, resulting in suspension damage.

9. Install the wheel assemblies, using the instructions found in **Group 40**. Remove the safety stands from under the frame and axle, and lower the vehicle.
10. If the radius rods have been loosened, or the equalizer bracket has been removed, check the rear axle alignment. For instructions, refer to **Group 35**. If necessary, adjust the axle alignment using the instructions in **Subject 140**.

Replacement (See Fig. 1)

⚠ WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

1. Chock the front tires.
2. Raise the frame so that all weight is removed from the leaf springs; then block the frame with safety stands. Raise the rear axle until the spring no longer contacts the spring bracket wear shoes and the spring retainer pin (or side-restraint sleeve); then block the axle. Make sure the stands will securely support the weight of the axles and frame. To access the spring assembly, remove the wheel assembly. See **Group 40** for instructions.
3. If equipped with two drive axles, remove the cotter pin from the spring retainer pin on the end of the equalizer where the spring is being replaced. Drive the spring retainer pin out of the equalizer.

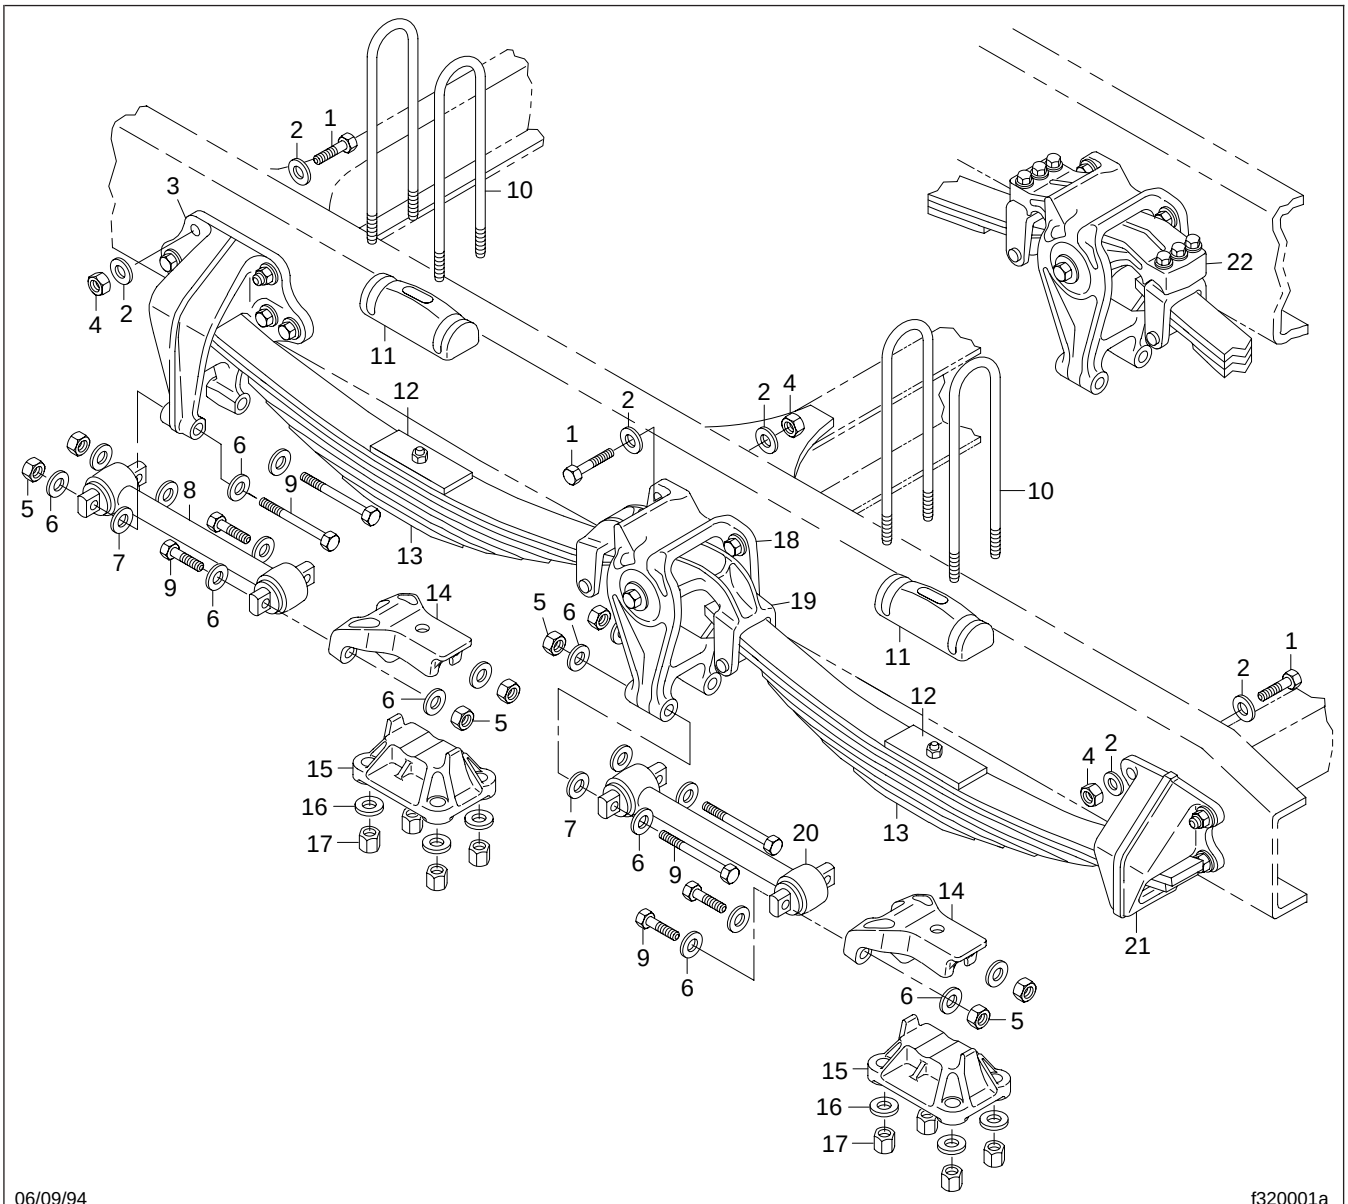
   If equipped with a pusher or tag axle, remove the nut from the flathead bolt on the end of the equalizer where the spring is being replaced. Remove the bolt and the side-restraint sleeve from the wear-shoe side-restraint.
4. Remove the U-bolt high nuts, hardened washers, U-bolt retainer, U-bolts, and upper U-bolt pad.
5. Remove the spring assembly by lifting it off the axle seat, then moving it toward the equalizer, out of the forward or rear spring bracket.
6. Using chassis grease, lubricate the new spring assembly where the ends will contact the stationary wear shoes in the spring bracket and equalizer.
7. Place the new spring assembly in the spring bracket and on the axle seat. Make sure the spring center-bolt head seats in the axle seat hole.
8. If the upper U-bolt pad is aluminum, apply Alumilastic compound, or an equivalent, to those areas of the pad that will come in contact with the U-bolts and with the upper spring leaf.

⚠ CAUTION

Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel contact each other, could lead to corrosion of the metals, resulting in suspension damage.

9. Place the upper U-bolt pad on the spring assembly. Place the U-bolts over the upper U-bolt pad and the spring assembly.
10. Install the U-bolt retainer, hardened washers, and U-bolt high nuts. Tighten the high nuts until snug.
11. If installing a spring assembly on a vehicle with two drive axles, apply Alumilastic compound, or an equivalent, to the spring retainer pins, then install them from the inboard side. Be sure the hooked ends of the spring leaves are above the retainer pins. Install a cotter pin in the outboard end of each retainer pin, and lock it in place.

    If installing a spring assembly on a vehicle with a pusher or tag axle, install the side-restraint sleeves and flathead bolts in the wear-shoe side-restraints. Be sure the hooked ends of the spring leaves are above the side-restraint sleeves. Install the nuts, and tighten them to the applicable torque value in **Specifications 400**.
12. Tighten the axle U-bolt high nuts as described in **Specifications 400**.



⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets,and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, refer to Group 32 of the *Business Class Trucks Maintenance Manual*.

13. Install the wheel assembly, using the instructions found in **Group 40**. Remove the safety stands from under the frame and axle, and lower the vehicle.

Spring Bracket and Equalizer Bracket Replacement

Replacement (See Fig. 1)

WARNING

Failure to replace worn, cracked, or damaged spring brackets or equalizer brackets could result in breakage of the bracket, which could cause a loss of vehicle control, resulting in personal injury or property damage.

IMPORTANT: At all points where steel parts (including bolts, washers, and nuts) contact the aluminum spring brackets, apply Alumilastic compound, or an equivalent, on the mating surfaces.

CAUTION

Failure to apply Alumilastic compound, or an equivalent, to areas where aluminum and steel parts contact each other, could lead to corrosion of the metals, resulting in damage to the suspension.

1. Chock the front tires.
2. Raise the rear of the vehicle, and block the axles with safety stands. Raise the vehicle frame so that all weight is removed from the leaf springs, then block the frame with safety stands. Make sure the stands will securely support the weight of the axles and frame.
3. If removing the forward spring bracket or the equalizer bracket, note the number of any axle alignment washers, then remove the fasteners that attach the radius rod to the forward spring bracket or equalizer bracket. Remove any axle alignment washers.
4. If removing an equalizer bracket, remove the equalizer. For instructions, refer to **Subject 110**.
5. Remove the fasteners that attach the forward or rear spring bracket, or equalizer bracket, to the frame rail. Remove the bracket.
6. Place the new spring bracket or equalizer bracket on the frame rail. Align the mounting holes, and install the bracket bolts, hardened washers, and locknuts.

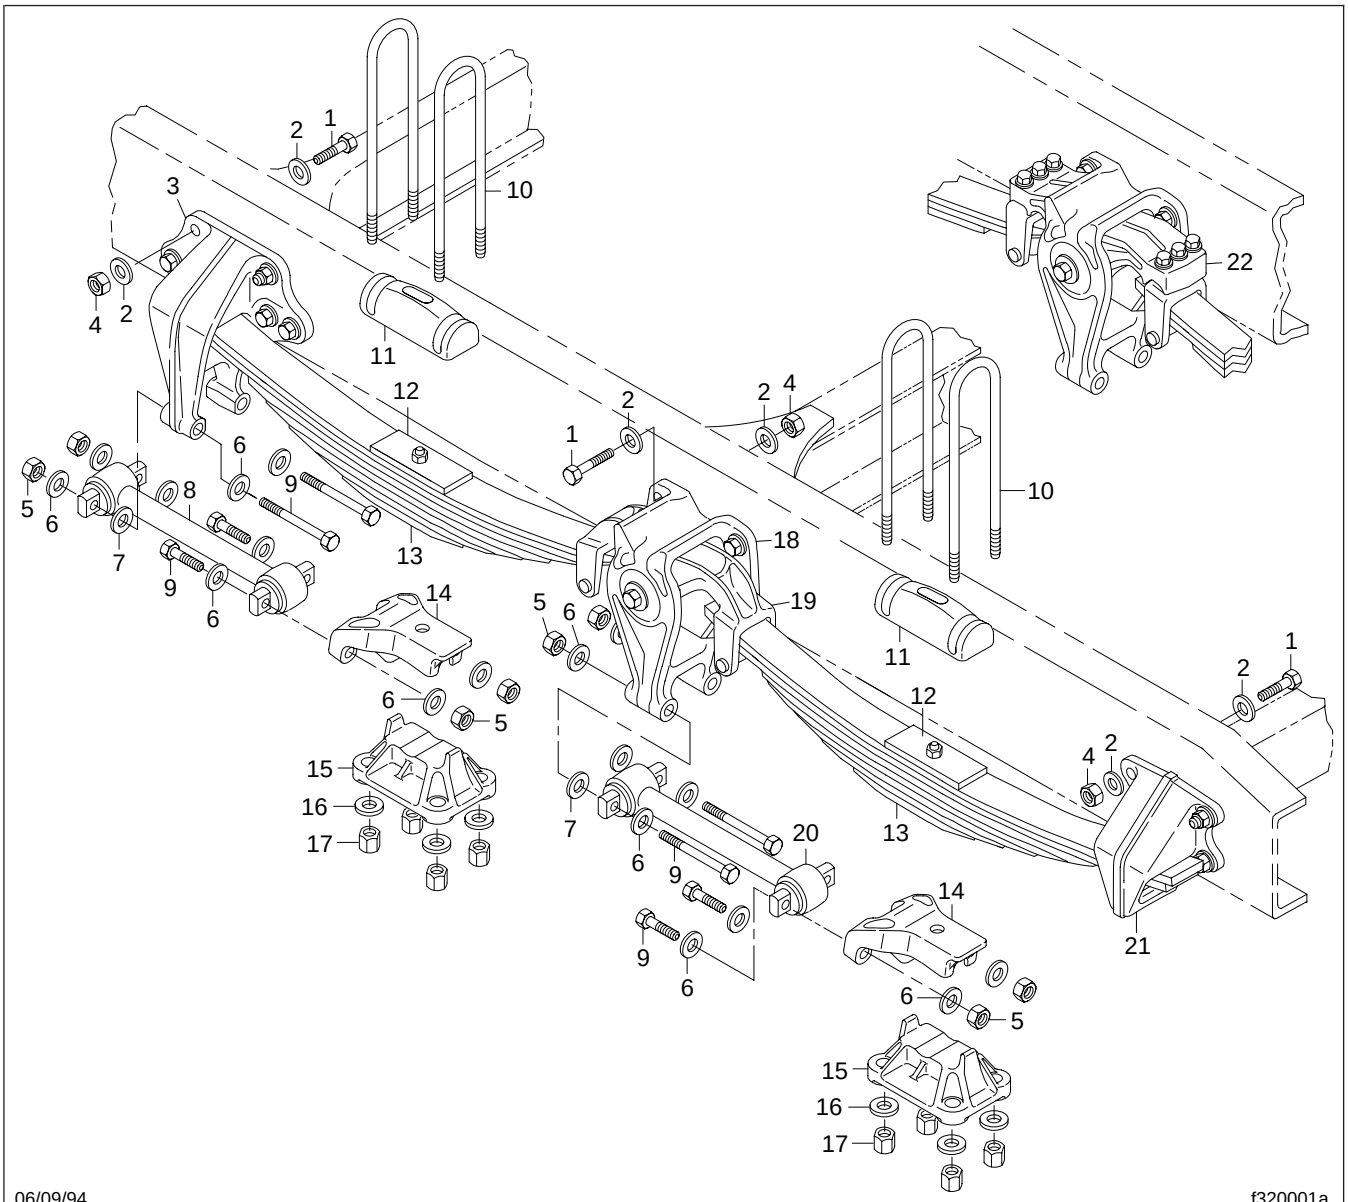
NOTE: If installing the forward spring bracket, install the nuts for the top two bolts on the outboard side of the frame rail, and install the nuts for the bottom four bolts on the inboard side of the frame rail. See **Fig. 2**.

If installing the equalizer bracket, for clearance, install all of the nuts on the inboard side of the frame rail. See **Fig. 2**.

If installing the rear spring bracket, install the nuts for the top two bolts on the outboard side of the frame rail, and install the nuts for the bottom two bolts on the inboard side of the frame rail. See **Fig. 2.**

7. Tighten the bracket mounting locknuts to the applicable torque value in **Specifications, 400**.

CAUTION



Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Business Class Trucks Maintenance Manual*.

8. When replacing the forward spring bracket or equalizer bracket, install any previously removed axle alignment washers between the forward radius rod front pin and the forward spring bracket, or between the rear radius rod front pin and the equalizer bracket, as applicable. See **Fig. 3**.

   Install bolts with hardened washers in the radius rod front pin, and the forward spring bracket or equalizer bracket. Install the hardened washers and locknuts, and tighten the locknuts to the torque value in **Specifications, 400**.
9. If replacing an equalizer bracket, install the equalizer. For instructions, see **Subject 110**.
10. Remove the safety stands from under the frame and axle, and lower the vehicle.
11. Check the rear axle alignment. For instructions, see **Group 35**. If necessary, adjust the axle alignment, using the instructions in **Subject 140**.

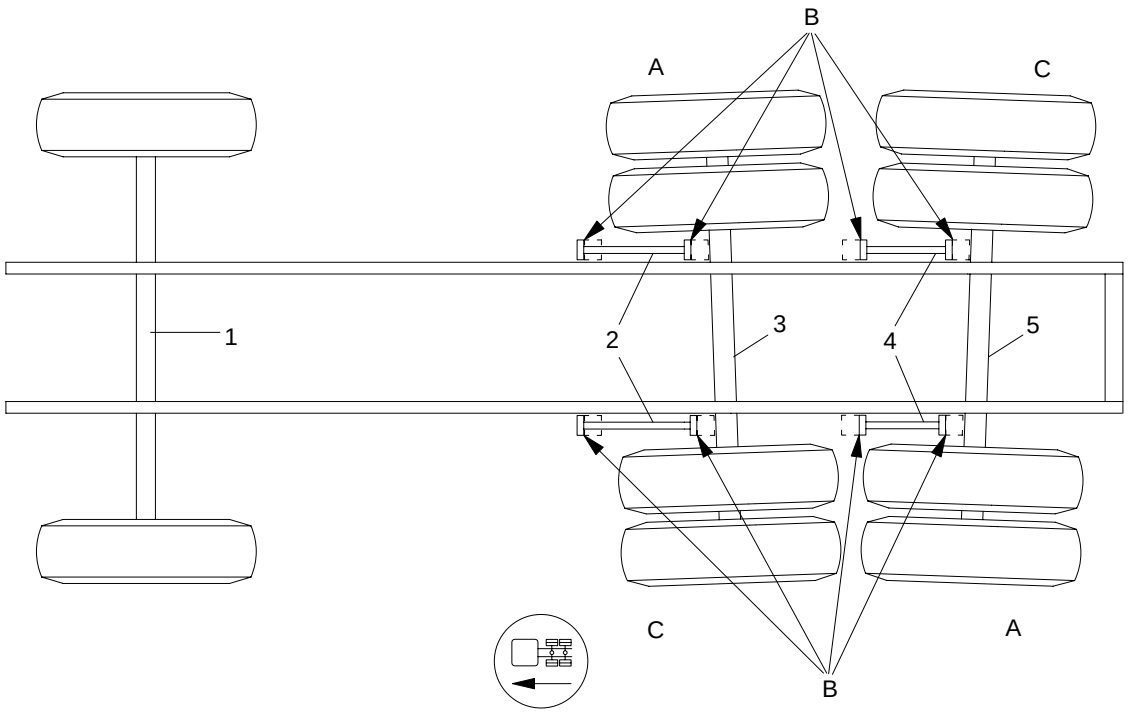
Rear Axle Alignment Adjustment



Adjustment

1. Using a straightedge and a tape measure, determine the amount of adjustment needed to align the forward-rear axle at a right angle to the frame. For instructions, see **Group 35**. The difference in measurements between the sides of the vehicle is the approximate amount that the trailing end of the forward-rear axle will have to be brought forward, or the leading end will have to be moved back to align it at a right angle to the frame. See **Fig. 1**.

   If the forward-rear axle alignment is within specifications, go to the step that begins "Using a center-point bar, determine...".

2. Chock the front tires. On both sides of the forward-rear axle, loosen the axle U-bolts enough to allow the springs to shift on the axle seats.
3. On the side of the vehicle that is to be adjusted, remove the fasteners that attach the forward radius rod to the forward spring bracket. Remove any axle alignment washers.

NOTE: To move the leading end of the forward-rear axle rearward, *remove* alignment washers from between the radius rod and the leading end of the forward spring bracket or *add* alignment washers between the radius rod and the forward-rear axle seat.

To move the trailing end of the forward-rear axle forward, *remove* alignment washers from be-

tween the radius rod and the forward-rear axle seat on the trailing end.

Whenever possible, alignment washers should be *removed* instead of added.

4. Raise the frame just enough to relieve the weight from the springs. Place safety stands under the frame. Make sure the stands will securely support the weight of the frame.
5. Move the loosened end of the axle forward or backward as needed, by rolling the wheels.
6. Insert or remove axle alignment washers at the appropriate location (front or rear of the left-hand or right-hand radius rod) to bring the forward-rear axle into alignment. Install the hexhead bolt, hardened washers, and locknut in the radius rod pin and forward spring bracket or axle seat.
7. Place an equal thickness of washers on the other end of the radius rod pin, and install the fasteners.
8. Tighten the radius rod locknuts to the torque value in **Specifications 400**.
9. Remove the safety stands, and lower the vehicle.
10. Check the forward-rear axle alignment with the straightedge and the tape measure. If alignment is within specifications, center the spring in the forward spring bracket, if needed, then tighten the axle U-bolt nuts to the torque value in **Specifications 400**.

    If not in alignment, repeat all of the steps above.

⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 in the vehicle maintenance manual.

11. Using a center-point bar, determine the difference between the forward-rear and the rearmost axles' center-to-center measurements on each side of the vehicle. For instructions, see **Group 35**. This difference is the approximate distance that the leading end of the rearmost axle will have to be adjusted rearward, or that the trailing end will have to be adjusted forward, to align it at a right angle to the frame, and to align it parallel to the forward-rear axle. See **Fig. 1**.
12. On both sides of the rearmost axle, loosen the axle U-bolts enough to allow the springs to shift on the axle seats.
13. On the side of the vehicle that is to be adjusted, remove the fasteners that attach the rear radius rod to the equalizer bracket. Remove any axle alignment washers.
14. Raise the frame just enough to relieve the weight from the springs. Place safety stands under the frame. Make sure the stands will securely support the weight of the frame.
15. Move the loosened end of the axle forward or backward, by rolling the wheels. Move the axle just enough to provide space to allow installation of alignment washers between the equalizer bracket and the radius rod pin.
16. Between one end of the radius rod pin and the equalizer bracket, insert the additional thickness of alignment washers needed to make up for the difference in center-point bar measurements.

    For example, if one end of the axle was equipped with a 4.5 mm (3/16-inch) thickness of washers, and the difference in the center-point bar measurements is 6 mm (1/4 inch) less on that side, add an additional 6 mm (1/4 inch) of washers — for a total of 10.5 mm (7/16 inch) — to correct the alignment.

    Or, if one end of the axle was equipped with a 6 mm (1/4-inch) thickness of washers, and the difference in center-point bar measurements is 4.5 mm (3/16 inch) more on that side, install a 1.6 mm (1/16-inch) thickness of washers in place of the 6 mm (1/4-inch) thickness.
17. Install the bolt, hardened washers, and locknut in the equalizer bracket and the radius rod pin. Place an equal thickness of alignment washers on the other end of the radius rod pin, and install the fasteners at that end.
18. Tighten the radius rod locknuts to the torque value in **Specifications 400**.

19. Remove the safety stands, and lower the vehicle. Remove the chocks from the front tires.
20. Using the center-point bar, check the rearmost axle alignment. If alignment is within specifications, center the spring in the rear spring bracket, if needed, then tighten the axle U-bolt nuts to the applicable torque value in **Specifications 400**.

    If not in alignment, repeat the applicable steps above.

CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 in the vehicle maintenance manual.

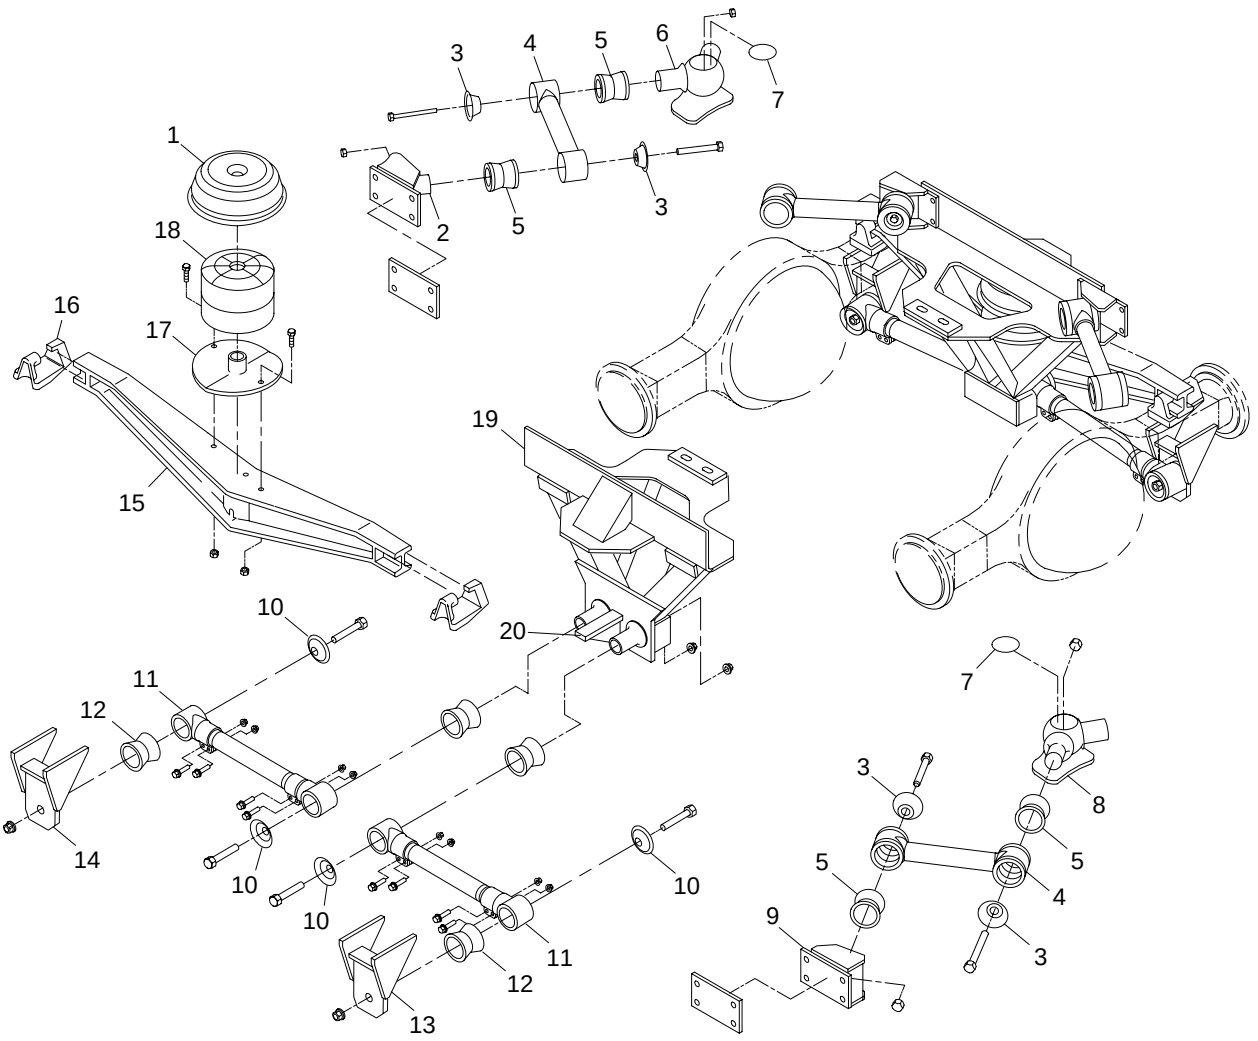
General Description

The Chalmers 800 Series Rear Suspension is a walking beam-type tandem axle suspension that uses hollow rubber springs instead of leaf springs or air bags. Each hollow rubber spring is mounted between a frame-rail plate and the center (front-to-rear) of the steel walking beam. A sawhorse bracket assembly is attached to the frame and provides mounting points for the lower torque rods that tie the axles to the frame. The upper torque rods are fastened to brackets that bolt to the frame side rails and to tower assemblies that are welded to the top of the differential housings. **See Fig. 1.**

The 800 Series Rear Suspension allows a high degree of both parallel and diagonal articulation, while maintaining wheel load equalization to within 3%.

The Chalmers suspension design separates the rear suspension's responsibility for supporting/cushioning the load from that of locating/guiding the axles. The suspension is very light, relative to its load carrying capacity, but requires very little maintenance. In fact, there are no lubrication fittings since grease and oil are never needed.

The 800 Series Rear Suspension is available in two different maximum load capacities: 18,000 kg (40,000 lb) and 21,000 kg (46,000 lb). The 18,000 kg version is easily distinguished from the 21,000 kg version since the upper torque rods do not cross over one another on the 18,000 kg version.



The 800 Series is also available in three different axle spacings: 54-inch, 60-inch, and 72-inch axle-to-axle. The axle-to-axle spacing dimension is often included as part of the suspension name, e.g. "Chalmers 854 Rear Suspension" or "Chalmers 860 Suspension."

Shock absorbers are optional on all versions of the suspension, and available in two styles—beam mounted and axle housing mounted.

Other variations depend on whether the suspension is installed on a truck (high-mount) or a tractor (low-mount) and whether high center-of-gravity or low center-of-gravity is desired.

The rear suspension may be precision-aligned by adjusting the length of the lower torque rods. These rods have both left and right hand threads cut on the same tube so rotating the tube changes the effective length of the tube.

Restrictor Can Removal, Inspection, and Installation

1. If necessary, power wash the spring restrictor can area to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Raise the rear of the vehicle just enough to remove all weight from the rear axles, and place safety stands under the frame to support the vehicle in its raised position.
4. Remove the two bolts and nuts that secure the walking beam spring plate (**see Fig. 1**, Ref. 17) to the walking beam assembly. Discard the fasteners.

NOTE: On 54-inch spread suspensions, it may be necessary to remove either the front or rear tires to allow spring assembly removal.

5. Pull the lower spring plate, rubber spring, and restrictor can as one assembly outward, off the beam assembly. **See Fig. 1**, Refs. 1, 17, 18.
6. Separate the restrictor can, spring, and spring plate.

Inspection

1. Carefully inspect the restrictor can for cracks or severe corrosion. Pay special attention to the top surface of the can and the can rim. **See Fig. 2 .**

NOTE: It is recommended that both restrictor cans be replaced at the same time to insure evenness of ride and handling characteristics.

2. Replace a cracked or severely corroded restrictor can.

Installation

1. Using a stiff wire brush or gasket scraper, clean rust and road dirt from the spring plate. Also, make sure that the center vent holes in the plate and in the walking beam are free of rust and debris. **See Fig. 3.**

4. Remove and discard the shock absorber.
5. On axle-mounted shock absorber installations, the compression sleeve (**see Fig. 2**, Ref. 3) may be rusted to the shock mounting pin and remain on the pin when the shock is removed. If this occurs, drive the sleeve off of the pin using a small, sharp chisel.
6. On axle-mounted shock absorber installations, clean the shock mounting pin threads using a stiff wire brush or, if necessary, a thread-chaser die.

   Lubricate the threads with a small amount of engine oil.

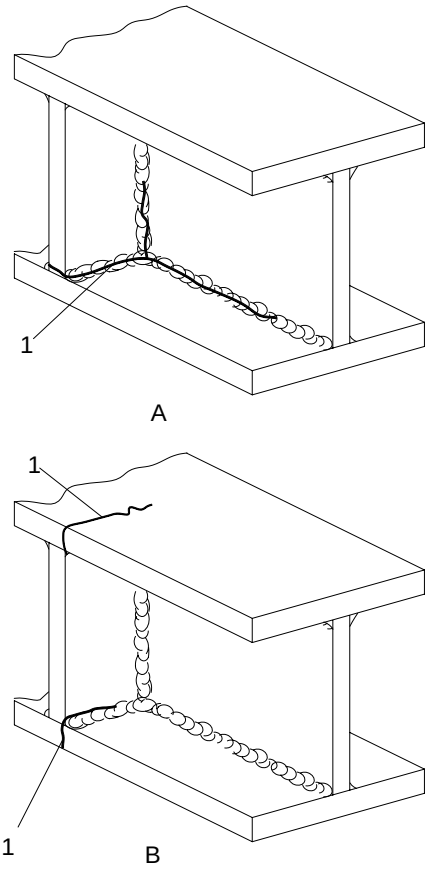
Walking Beam Removal, Inspection, and Installation

1. If necessary, power wash the walking beams and axle housing ends to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Relieve all drive axle brake or wind-up loads by placing the transmission in neutral and releasing the spring or driveline brakes.
4. Raise the rear of the vehicle to remove all weight from the rear axles, and place safety stands under the frame to secure the vehicle in its raised position.
5. If equipped, disconnect beam-mounted shock absorbers from the walking beam being replaced. Refer to **Subject 120**, if necessary.
6. Remove the two bolts and nuts that secure the walking beam spring plate (**see Fig. 1**, Ref. 17) to the walking beam assembly. Discard the fasteners.

NOTE: On 54-inch spread suspensions, it may be necessary to remove the front or rear tires to allow spring assembly removal.



7. Pull the lower spring plate, rubber spring, and restrictor can as one assembly outward, off the beam assembly. **See Fig. 1**, Refs. 1, 17, 18.

NOTE: Tag or otherwise mark each torque rod to ensure that it can be re-installed in the same position and orientation.

8. Disconnect the rearmost axle's upper torque rods from the rear axle tower and the lower torque rods from the rear axle housing brackets. **See Fig. 1**, Refs. 4, 8, 11, 13.
9. Roll the rear axle rearward just enough to disengage the axle saddles (Ref. 16) from the walking beam ends.
10. Lift up the free end of the walking beam and slide the beam rearward to disengage it from the front axle saddle; remove the walking beam.

Inspection

1. Inspect the beam ends carefully, looking for cracks. Cracks along weld lines may be repairable, while cracks in or across the beam flanges require walking beam replacement. **See Fig. 2.**

NOTE: Take flange thickness measurements at least 12 mm (1/2 inch) from the flange edges. Measurements taken at the flange edges are not an accurate indication of beam wear and may lead to unnecessary beam repair/replacement.

2. Check for excessive wear on the beam flanges, where they contact the axle housing saddle brackets.

If flange wear is significant, use a micrometer or vernier calipers to take measurements at both unworn and worn areas. The maximum allowable difference between unworn and worn areas is 1.5 mm (0.062 inch). **See Fig. 3.**

3. Beams showing excessive wear must be repaired or replaced. Refer to **Subject 140** for beam repair information.

Installation

1. Position the new or repaired walking beam over the rearmost rear axle, with the front end of the beam tilted downward.
2. Slide the beam forward and downward so the front end of the beam enters the axle housing saddle bracket. **See Fig. 4.** Let the middle of the beam rest on the sawhorse bracket beam stop.

1. Front Axle Housing, Beam Saddle Bracket
2. Walking Beam

Fig. 4, Beam/Saddle Bracket Alignment

NOTE: On 54-inch spread suspensions, it may be necessary to install the spring assembly before the rearmost axle is rolled into place.

3. Carefully roll the rearmost rear axle forward, while lifting the rear end of the walking beam enough so the beam end enters the axle housing saddle bracket.
4. Connect the rearmost axle's upper and lower torque rods to the axle housing brackets. Install and tighten the torque rod bushing through-bolts 183 N·m (135 lbf·ft).
5. Slide, as one assembly, the spring plate, rubber spring, and restrictor cap, into position on the walking beam.
6. Install and tighten the spring plate fasteners 47 N·m (35 lbf·ft).
7. If so equipped, connect the beam-mounted shock absorbers to the beam brackets and tighten the fasteners 230 N·m (170 lbf·ft).
8. Remove the safety stands from under the vehicle, then lower the vehicle.
9. Remove the chocks from the tires.

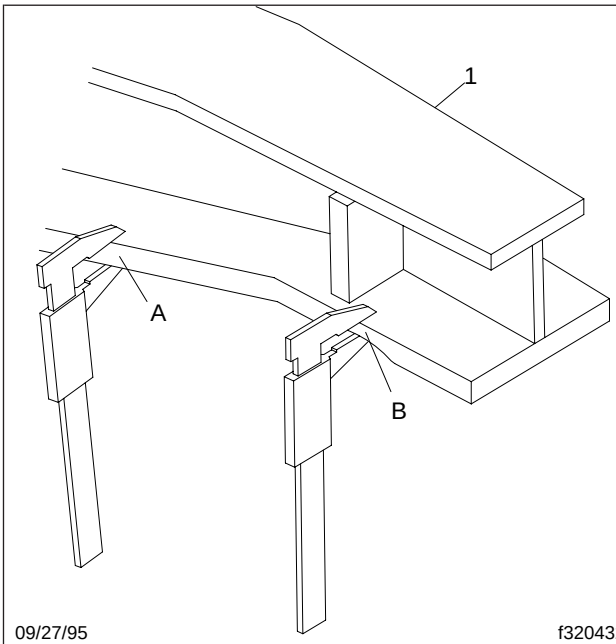
Repair

NOTE: This subject addresses only instances where excessive beam flange wear occurs, but cracks in the web or flange are not present.

Cracked webs and/or flanges require walking beam replacement.

Walking beams with excessive flange wear, however, can be repaired by welding a Chalmers Wear Plate over the worn areas as described below.

1. Remove the walking beam assembly. Refer to **Subject 130** for information.

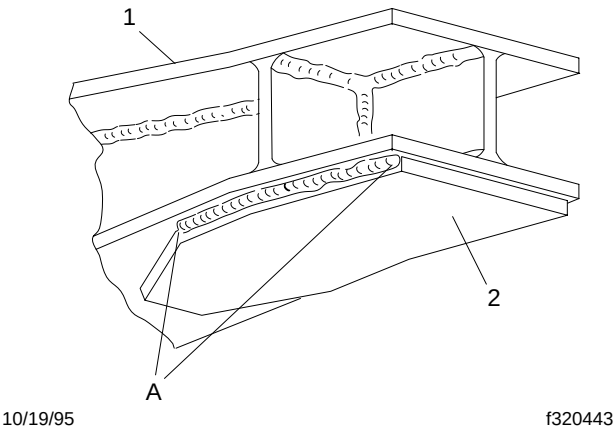


NOTE: Take flange thickness measurements at least 12 mm (1/2 inch) from the flange edges. Measurements taken at the flange edges are not an accurate indication of beam wear and may lead to unnecessary beam repair/ replacement.

2. Confirm that flange wear is severe enough to warrant repairs. Use a micrometer or vernier calipers to take flange thickness measurements at both unworn and worn areas. The maximum allowable difference between unworn and worn areas is 1.5 mm (0.062 inch). **See Fig. 1.**
3. If repair is required, clean the worn area of the beam thoroughly. Make sure that any oil or grease is removed, as well as rust or road dirt accumulation. If necessary, slight grinding of the beam is allowed to smooth raised areas.
4. Clamp Chalmers Wear Plate #700313 to the bottom flange of the beam. Make sure the plate is centered and has good surface-to-surface contact with the beam. Slight grinding is allowable to obtain good plate-to-beam contact.
5. Tack weld the plate to the beam, welding on the sides of the plate only.

CAUTION

CAUTION: Weld at sides of wear plate and beam only. Never weld at the ends of the wear plate.



6. Remove the clamps and weld the plate to the beam, welding on the sides of the plate only. **See Fig. 2.**

Torque Rod Removal and Installation

The torque rods hold the rear axles in place, maintaining both axle alignment and pinion nose angle. When servicing the torque rods, it is good practice to remove and install them one at a time to avoid the possibility of mixing them up and affecting the alignment or pinion nose angle.

Several different styles of torque rods and bushing spigots exist. On the 18,000 kg (40,000 lb) version of the 800 Series suspension, the torque rods have tubular steel bodies and the upper rods do not cross over one another. On the 21,000 kg (46,000 lb) version, the lower torque rods have tubular steel bodies, but the upper torque rods are made of "I-beam" shaped ductile iron. These upper torque rods do cross over one another. See **Fig. 1** and **Fig. 2.**

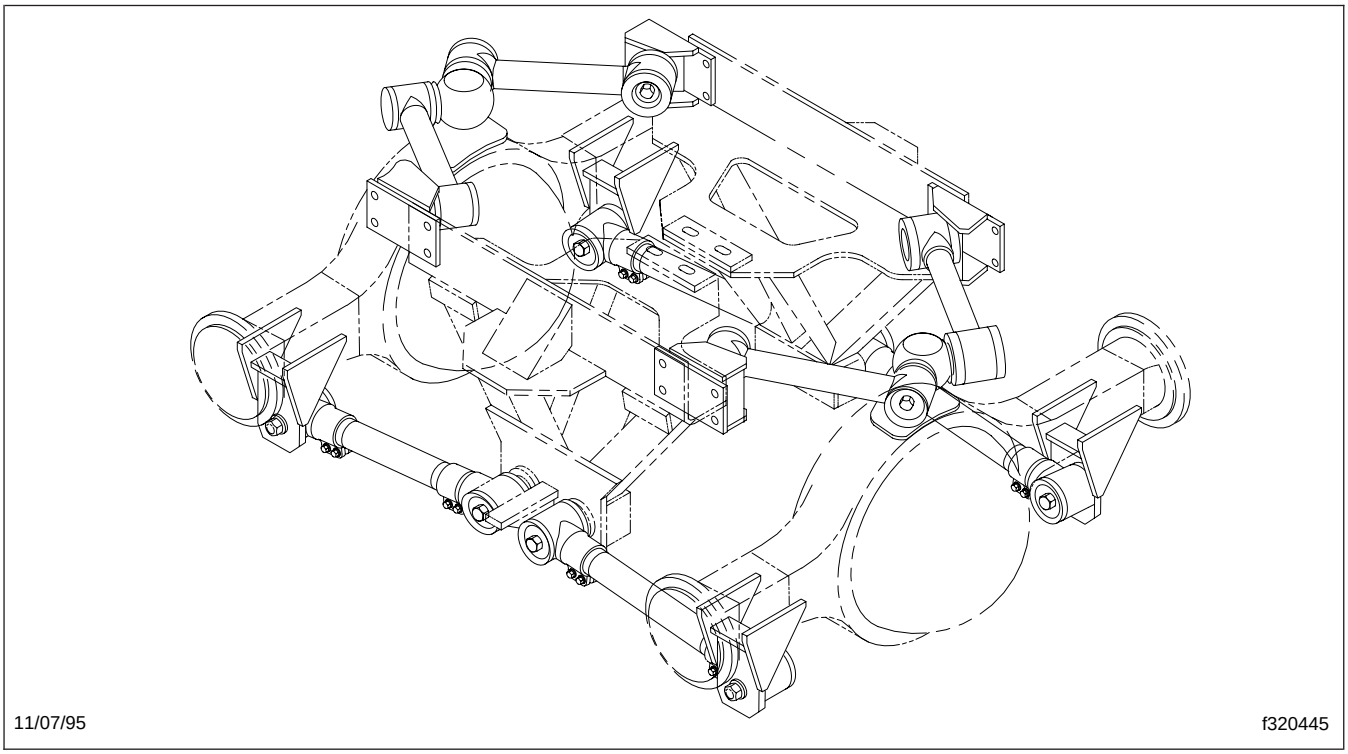

Fig. 1, Torque Rod Arrangement, 40,000 lb Capacity Suspension

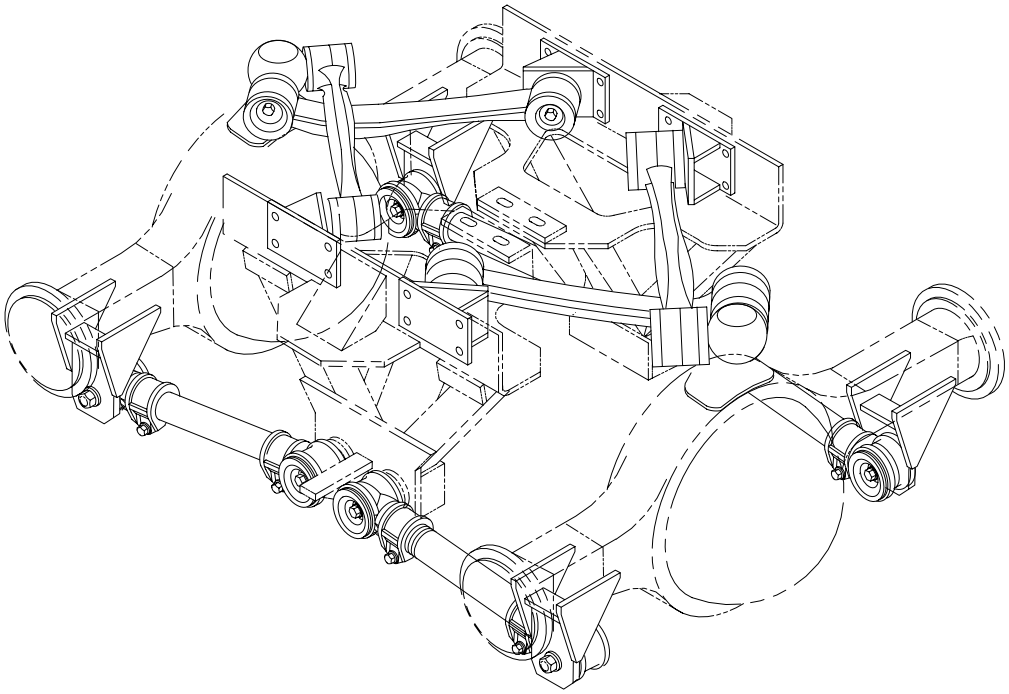
Removal



NOTE: Inspect torque rod bushings for free play before removing the torque rods. See **Subject 160** for torque rod bushing inspection information.

1. If necessary, power wash the rear suspension to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Relieve all drive axle brake or wind-up loads by placing the transmission in neutral and releasing the spring or driveline brakes.
4. Raise the rear of the vehicle to remove all weight from the rear axles, and place safety stands under the frame to secure the vehicle in its raised position.
5. Working on one torque rod at a time remove the torque rod bolts and spigot caps. Discard the bolts. Set the spigot caps aside for cleaning and inspection.

   Remove the torque rods by prying between the torque rod eye and the spigot base or frame bracket.

NOTE: At the axle housing towers, pry off the tower cap to access the torque rod fasteners.

Torque Rod Removal and Installation

6. Replace worn or damaged bushings following the instructions in **Subject 160**.
7. Inspect the spigots for damage, severe corrosion, or extensive wear. Replace damaged or severely corroded spigots. To determine whether or not a spigot is worn enough to warrant replacement, see **Fig. 3** and **Table 1**.

   The smaller of the two measurements should be used as the spigot diameter.
8. On vehicles equipped with Size #0 spigots, carefully inspect the spigot cap bolt head contact area for wear. A worn cap must be replaced to avoid fastener loosening. See **Fig. 4**.

IMPORTANT: Never use any mineral based oils, greases, jellies, or solvent soaps to aid in the assembly of rubber suspension parts. Use only lubricants specifically designed for use with rubber compounds.

2. Lubricate the outside of the spigots and the inside of the rubber bushings with a generous amount of rubber lubricant such as Rimslip® or equivalent.
3. Push the torque rod into position on its spigots. After the torque rod is partially installed, use a heavy soft-faced mallet to drive the torque rod into position until the bushing contacts the spigot bottom face.

Torque Rod Removal and Installation

NOTE: For easier installation, alternate mallet blows between ends of the torque rod to drive it onto the spigots evenly.

4. Install the spigot caps.
5. Install and tighten the torque rod bushing through-bolts 183 N·m (135 lbf·ft).
6. Remove the safety stands from under the vehicle, then lower the vehicle.
7. Remove the chocks from the tires.

Torque Rod Bushing Inspection and Replacement

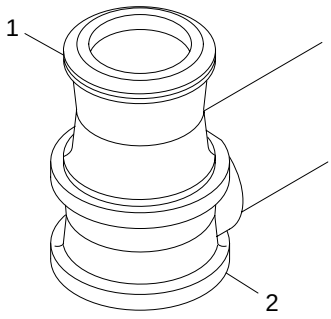
Inspection

1. If necessary, power wash the upper and lower torque rods to remove road dirt accumulation.
2. Chock the front tires to prevent vehicle movement.
3. Relieve all drive axle brake or wind-up loads by placing the transmission in neutral and releasing the spring or driveline brakes.
4. Using your hands only, attempt to move the torque rod ends, checking for free play. Some movement as the bushings "give" is normal, but only free play is cause for bushing replacement.

NOTE: Never use a lever or pry bar to check for torque rod bushing free play. To do so may result in unnecessary bushing replacement.

5. If free play is detected, replace the bushing as described below.

Replacement



1. Remove the torque rod containing the worn out bushing. Refer to **Subject 150**, if necessary.

NOTE: Remove only one torque rod at a time to avoid mixing-up torque rod positions.

2. Place the torque rod on the floor or a workbench with a bushing open end facing upward. Push the tip of a large screwdriver down between the torque rod eye and the bushing and pry out the bushing. Discard removed bushings.
3. Use a wire brush and/or scraper to clean the torque rod eyes, removing all rust, scale, and rubber accumulations.
4. Inspect the torque rod eyes looking for cracks, distortion, or severe corrosion. Replace torque rods with damaged bushing eyes.

IMPORTANT: Never use any mineral based oils, greases, jellies, or solvent soaps to aid in the assembly of rubber suspension parts. Use only lubricants specifically designed for use with rubber compounds.

5. Lubricate both the inside of the torque rod eye and the outside of the new bushing with a generous amount of rubber lubricant, such as Rimslip® or equivalent.
6. Place the torque rod on a solid level floor with an open end of the eye facing upward. Position a lubricated bushing on the eye, making sure that the tapered shoulder of the bushing is centered on the eye. **See Fig. 1.**

1. Torque Rod Bushing 2. Torque Rod Eye

7. Using a heavy, soft-faced mallet, strike the bushing squarely to drive it into the torque rod eye. Then, flip the torque rod over 180 degrees and tap on the torque rod shaft with the mallet while the bushing rests on the floor.

NOTE: If available, a small press may be used instead of a mallet for bushing installation.

8. The bushing is completely installed when it is centered within the torque rod eye. **See Fig. 2.**
9. Install the re-bushed torque rod. Refer to **Subject 150**, if necessary.

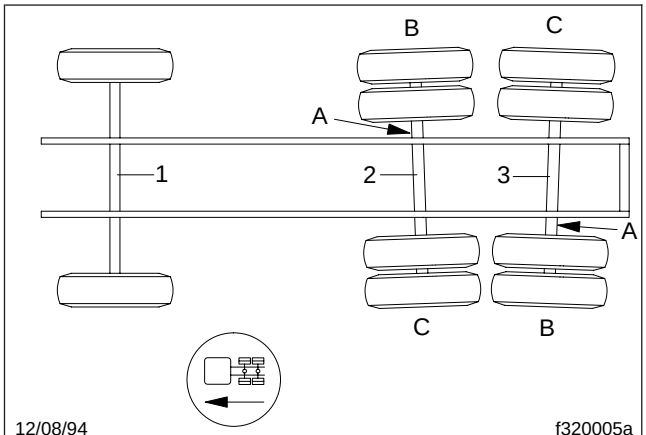
Rear Axle Alignment Adjustment

On the Chalmers 800 Series Rear Suspension, the lower torque rods provide the only means for adjusting rear axle alignment. The upper torque rods play no part in the axle alignment process.

The lower torque rod bodies consist of steel tubes, with fine threads cut into the ends of the tube. Left-hand threads are cut into one end of the tube, right-hand threads into the other end. Therefore, by simply twisting the tube body while restraining the ends, the effective length of the tube is changed.

Two different types of torque rod ends are used. On #0 and #1 sizes, two 1/2-inch clamp bolts secure the rod ends to the tube. On the #2 size, a single 5/8-inch bolt is used. See **Fig. 1.**



1. #0/#1 Joint
2. #2 Joint

Fig. 1, Adjustable Torque Rod Ends

Adjustment

1. Ensure that the torque rod bushings are in a fully relaxed, neutral state by slowly moving the vehicle back and forth a few times. Apply the service brakes, *not the parking brakes*.
2. Chock the front tires to prevent vehicle movement.
3. Relieve drive axle brake or wind-up loads by placing the transmission in neutral and releasing the brakes.
4. Using a straightedge and a tape measure, determine the amount of adjustment needed to align the forward-rear axle at right angles to the frame. For instructions, refer to **Group 35**. The difference in measurements between the sides of the vehicle is the approximate amount that the trailing end of the forward-rear axle will have to be brought forward, or the leading end will have to be moved back to align it at a right angle to the frame. See **Fig. 2**.

   If the forward-rear axle alignment is within specifications, go to the step that begins "Using a center-point bar, determine...".

5. On the side of the vehicle that is to be adjusted forward or rearward, loosen the torque rod end pinch bolts at both ends of the torque rod.

NOTE: If the pinch bolts are badly corroded or otherwise damaged, remove and discard them. Install new Chalmers fasteners.

6. Attach a pipe wrench to the tube body (chain type preferred) and rotate the tube to shorten or

Rear Axle Alignment Adjustment

lengthen the torque rod. Continue to rotate the tube until the forward-rear axle is square to the frame.

NOTE: If the torque rod tube is difficult to rotate, apply penetrating oil to the tube threads. If this does not help, remove the pinch bolts and drive wedges between the eye lugs to relieve the clamping effect.

7. When the forward-rear axle is square with the frame, tighten the pinch bolts.
   - 7.1 Tighten 1/2-inch UNC bolts on #0 and #1 joints 88 N·m (65 lbf·ft).
   - 7.2 Tighten 5/8-inch UNC bolts on #2 joints 183 N·m (135 lbf·ft).
8. Using a center-point bar, determine the difference between the forward-rear and the rearmost axles' center-to-center measurements on each side of the vehicle. For instructions, refer to **Group 35**. This difference is the approximate distance that the leading end of the rearmost axle will have to be adjusted rearward, or that the trailing end will have to be adjusted forward, to align it at a right angle to the frame, and to align it parallel to the forward-rear axle. See **Fig. 2**.
9. On the side of the vehicle that is to be adjusted forward or rearward, loosen the torque rod end pinch bolts at both ends of the torque rod.

NOTE: If the pinch bolts are badly corroded or otherwise damaged, remove and discard them. Install new Chalmers fasteners.

10. Attach a pipe wrench to the tube body (chain type preferred) and rotate the tube to shorten or lengthen the torque rod. Continue to rotate the tube until the rearmost axle is square to the frame.

NOTE: If the torque rod tube is difficult to rotate, apply penetrating oil to the tube threads. If this does not help, remove the pinch bolts and drive wedges between the eye lugs to relieve the clamping effect.

11. When the rearmost axle is square with the frame, tighten the pinch bolts.
    - 11.1 Tighten 1/2-inch UNC bolts on #0 and #1 joints 88 N·m (65 lbf·ft).
    - 11.2 Tighten 5/8-inch UNC bolts on #2 joints 183 N·m (135 lbf·ft).
12. Remove the safety stands, and lower the vehicle. Remove the chocks from the front tires.
13. Using the center-point bar, check the rearmost axle alignment. If alignment is not within specifications, repeat the applicable steps above.

⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the suspension.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Business Class Trucks Maintenance Manual*.

Table 1, Fastener Torques, 800 Series Suspension

General Description (See Fig. 1)

The Reyco 79KB suspension uses a full–floating spring design. Semi-elliptical spring assemblies, or optional parabolic springs, are attached to the axles with U–bolt assemblies. The spring ends ride in hangers that are mounted on the frame rails. Adjustable torque rods are attached to the forward spring hanger and axle seat to hold the axle in alignment.

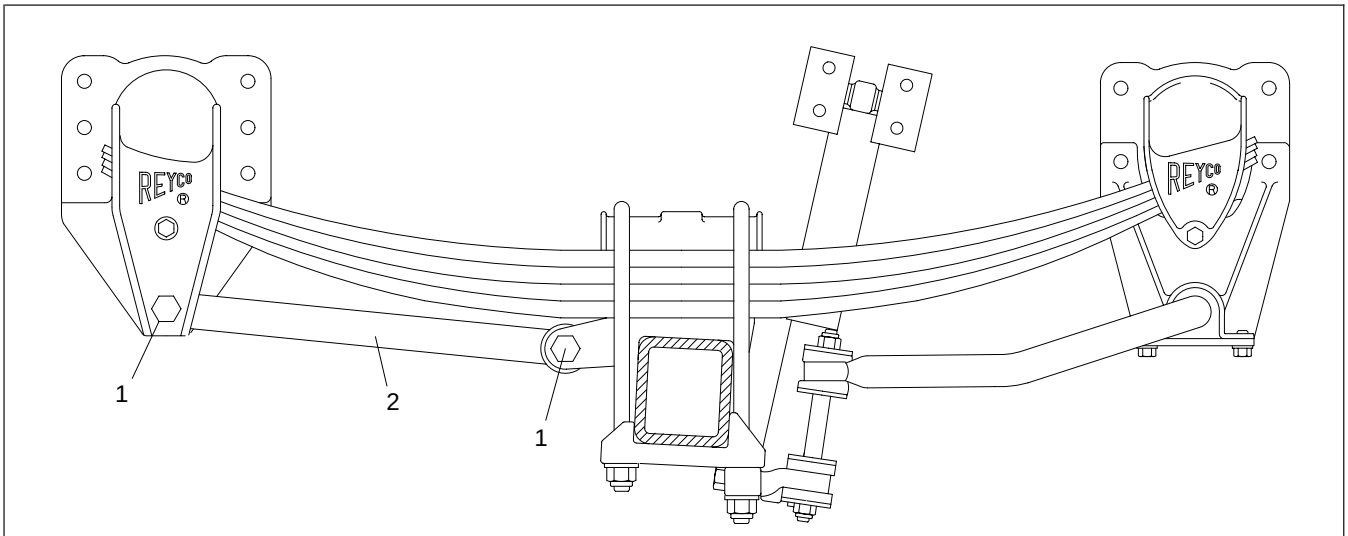

Fig. 1, Reyco 79KB Suspension

Torque Rod Removal and Installation

Removal (See Fig. 1)

There are two torque rods installed on the Reyco 79KB suspension. The curb (right) side torque rod is not adjustable (rigid). The left (driver's) side torque rod is adjustable to allow proper axle alignment.

1. Apply the spring, or driveline brakes and chock the front tires.
2. Use a lifting device and raise the rear of the tractor until the rear tires are elevated above the ground. Place jack stands under the frame rails to unload the suspension, and lower the lifting device until only the jack stands are supporting the vehicle weight.
3. Place the lifting device under the axle and raise the axle to unload the torque rod. Place jack stands under the axle.
4. Remove the two torque rod bolts and nuts, and remove the torque rod. See **Fig. 1**.
2. Raise the opposite end of the torque rod on the lower axle mounting plate.
3. Install a bolt on the torque rod
4. Tighten the torque rod locknuts 540 to 610 N·m (400 to 450 lbf·ft).
5. Raise the axle and remove the jack stands. Lower the axle to the ground.
6. Raise the rear of the vehicle and remove the jack stands. Lower the vehicle to the ground.
7. Check the axle alignment. For instructions, see **Group 35**. If necessary, adjust the rear axle alignment, using the instructions in **Subject 130**.

1. Place the torque rod on the forward frame hangar and install a torque rod bolt to hold it in place.

Spring Assembly Replacement

Removal (See Fig. 1)

⚠ WARNING

Do not replace individual leaves of a damaged leaf spring assembly; replace the complete spring assembly. Visible damage (cracks or breaks) to one leaf causes hidden damage to other leaves. Replacement of only the visibly damaged part(s) is no assurance that the spring is safe. Failure to replace a damaged spring assembly could cause an accident resulting in serious personal injury or property damage.

Leaf spring assemblies weigh approximately 100 to 190 lbs (45 to 86 kg). Do not attempt to remove a leaf spring assembly without assistance. Personal injury and property damage may result.

1. Park the vehicle on a level surface. Apply the spring, or driveline brakes and chock the front tires.
2. Raise the frame so that all weight is removed from the leaf springs, then support the frame with safety stands. Raise the rear axle until the spring no longer contacts the spring retainer rollers, then support the axle with safety stands. Make sure the stands will securely support the weight of the axles and frame. To gain easy access to the suspension system, remove the wheel assembly; see **Group 40** for instructions.
3. Remove the U-bolt locknuts and washers. Remove the U-bolt mounting plate. Remove the U-bolts, and the upper axle mounting plate.
4. Remove the spring retaining bolts, spring rollers, and nuts.
5. Use a pry tool to lift the leaf spring assembly off of the lower mounting plate.

NOTE: There is a projection at the center of the leaf spring assembly to locate the spring.

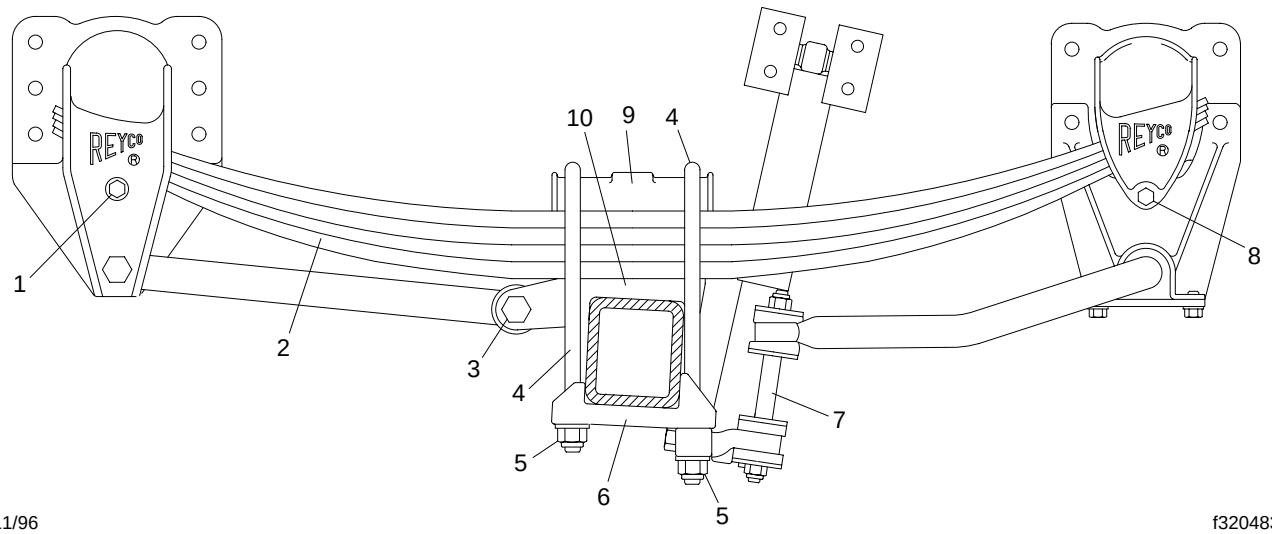
6. With assistance, carefully move the leaf spring assembly forward to clear the rear hanger. Raise the rear of the leaf spring assembly and move it rearward to clear the front hanger. Remove the leaf spring from the vehicle.

Installation

⚠ WARNING

Leaf spring assemblies weigh approximately 100 to 190 lbs (45 to 86 kg). Do not attempt to install a leaf spring assembly without assistance. Personal injury and property damage may result.

1. With assistance, position the leaf spring assembly on the axle.
2. Place the front of the leaf spring assembly through the hanger, then place the rear of the leaf spring assembly through the rear hanger.
3. Install the projection on the center of the leaf spring assembly on the spring seat.
4. Install the U-bolt pad on the leaf spring assembly.
5. Install the U-bolts over the U-bolt pad and axle tube. Insert the U-bolts through the axle clamp, then install the U-bolt washers and high nuts. Tighten the U-bolt high nuts as described in **Section 32.07, Specifications 400**.
6. Install the spring retainer bolts, rollers, and locknuts. Tighten the spring retaining bolt locknuts 60 to 80 lbf·ft (85 to 110 N·m).
7. Move the torque rod into position with the lower axle mounting plate.
8. Install the torque rod mounting bolt and locknut. Tighten the locknut 350 to 400 lbf·ft (475 to 545 N·m).
9. Install the wheel assembly. See **Group 40** for instructions.
10. Raise the axle assembly, remove the safety stands and lower the axle to the ground.
11. Raise the vehicle frame, remove the safety stands from under the frame and lower the vehicle.



⚠ CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

Spring Assembly Replacement

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, Group 32 of the *Business Class Trucks Maintenance Manual*.

12. Check the axle alignment. For instructions, see **Group 35** in this manual. If necessary, adjust the rear axle alignment, using the instructions in **Subject 130**.

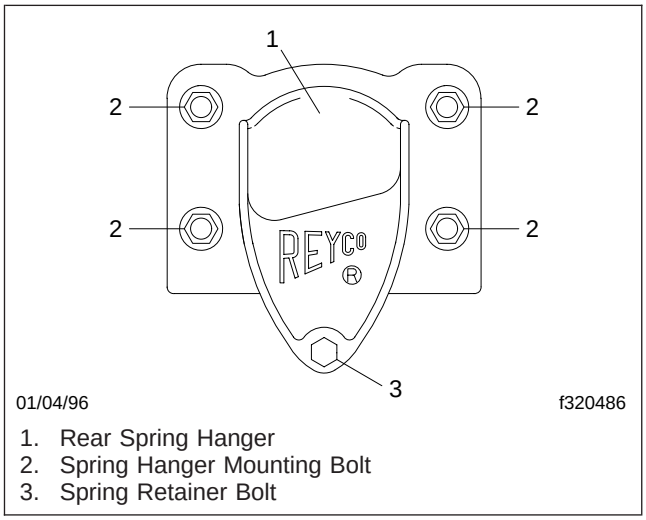
Removal

⚠ WARNING

Replace worn, cracked, or damaged spring hangers. Failure to do so could result in bracket breakage, possibly leading to loss of vehicle control and resulting in personal injury or property damage.



1. Park the vehicle on a level surface. Apply the spring or driveline brakes, and chock the front tires.
2. Place a lifting device under the vehicle frame. Lift the frame until the leaf spring assemblies are no longer in contact with the hangers, and support the frame with safety stands.
3. Remove the torque rod mounting bolt located on the forward hanger. See **Fig. 1**, Ref. 4.

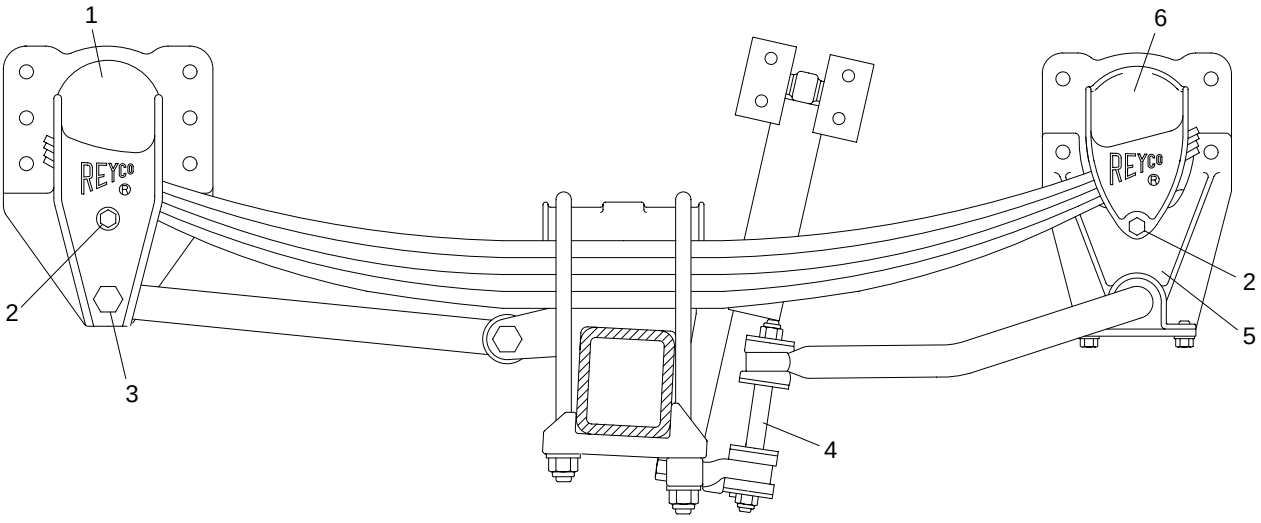
9. Remove the lower spring hanger mounting bolts (see **Fig. 2**, Ref. 2) and remove the anti-sway bar mounting bracket, if equipped. See **Fig. 3**, Ref. 5.
10. Remove the upper spring hanger mounting bolts (see **Fig. 2**, Ref. 2) and remove the rear hanger.

⚠ CAUTION



Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Business Class Trucks Maintenance Manual*.

Installation

1. Install the rear spring hanger on the frame rail, then install the two upper mounting bolts.

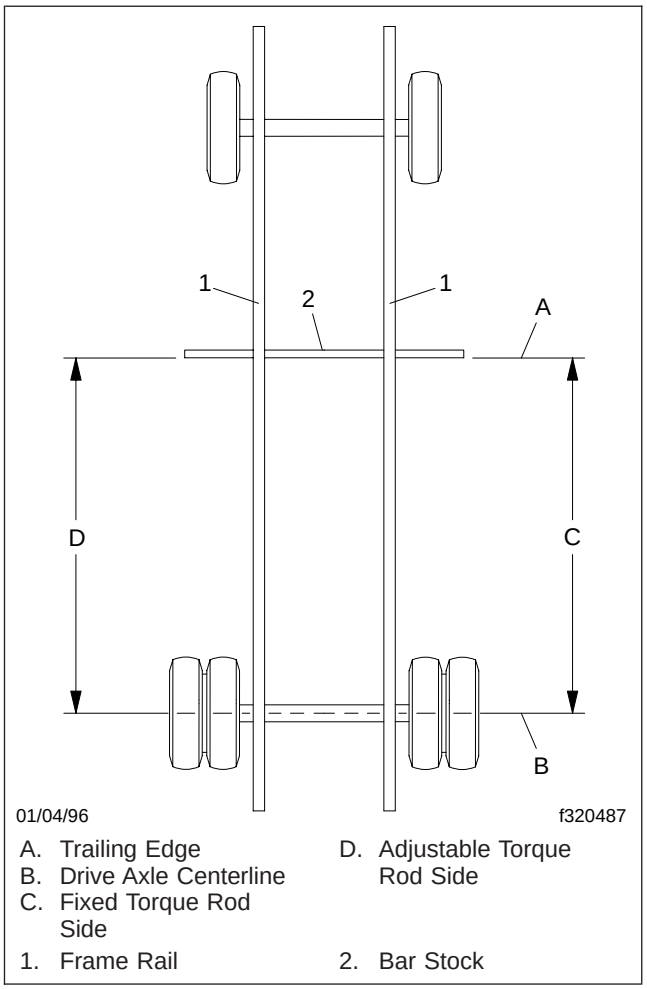
2. If equipped, position the anti-sway bar mounting bracket over the lower bolt holes on the rear hanger, and install the two lower mounting bolts.
3. Tighten the rear spring hanger mounting bolts 190 lbf·ft (258 N·m).
4. Install the anti-sway bar end link and bushings, if equipped. Tighten the end link capscrew. See **Group 00** for torque specifications.
5. Install the spring retainer bolt, roller, and nut. Tighten the spring retainer bolt 60 to 80 lbf·ft (85 to 110 N·m).
6. Install the forward spring hanger on the frame rail, then install the mounting bolts. Tighten the mounting bolts 190 lbf·ft (258 N·m).
7. Install the torque rod mounting bolt. Tighten the torque rod mounting bolt 350 to 400 lbf·ft (475 to 545 N·m).
8. Install the spring retainer bolt, roller, and nut. Tighten the spring retainer bolt 60 to 80 lbf·ft (85 to 110 N·m).
9. Raise the vehicle frame with a lifting device, and remove the safety stands. Lower the vehicle to the ground.
10. Remove the wheel chocks.

Adjustment

CAUTION

Failure to periodically torque the suspension fasteners can result in abnormal tire wear, and damage to the springs, spring brackets, and frame rail.

IMPORTANT: All suspension fasteners require periodic torquing. For suspension component inspecting and fastener torque checking intervals and instructions, see Group 32 of the *Business Class Trucks Maintenance Manual*.



1. Park the vehicle on a level surface. Move the vehicle slowly back and forth several times without using the brakes to free all of the suspension joints. Shut down the engine. Do not apply the spring, or driveline brakes.
2. Chock the front tires.

NOTE: Check that the leaf springs are not binding in the frame hangars. Make sure that the U-bolts and torque rod bolts are torqued to specification, and all of the bushings are in good condition.

3. Position an 2-1/2 meter (8 ft) length of bar stock, or angle iron across the frame. Square the bar across the frame using a carpenter's square, and clamp it in place on the frame rail. See **Fig. 1**, Ref. 2.

NOTE: Position the bar as far forward of the drive axle as possible.

4. Start on the fixed (right) torque rod side. Measure the distance from the bar stock to the centerline of the drive axle. Repeat the same procedure on the adjustable (left) torque rod side. See **Fig. 1**, Ref. C and D.
5. If the distance varies more than 1/8-inch, alignment is necessary.
6. Loosen the torque rod clamp bolts. See **Fig. 2**, Ref. 1.
7. Use a pipe wrench or other suitable tool and slowly turn the torque rod.

General Description

The Watson and Chalin SL series steerable axle lift suspension (**Fig. 1**) uses a full-floating air spring design. Two air springs are attached to a trailing arm assembly. One air spring controls the suspension riding height, depending on load requirements, and the other air spring is used to lift the axle assembly when not in use. The trailing arm and air springs are attached to the frame rail with an upper torque rod, and a fastener that rides on a rubber bushing. Weld collars locate the suspension on the frame and hold the axle in alignment.

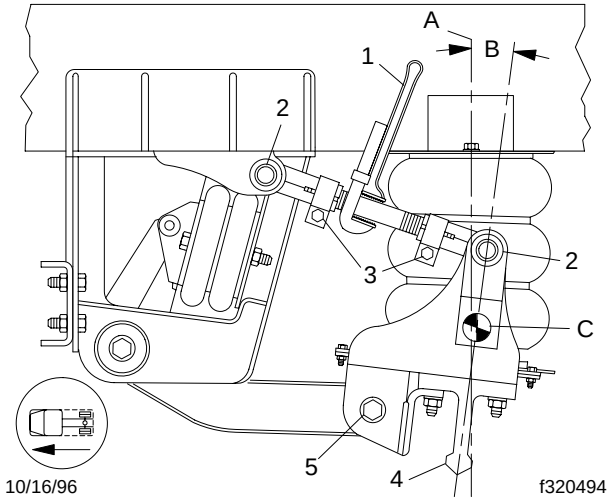
1. Park the vehicle on a level surface. Apply the parking brakes, and chock the tires.
2. Completely drain all of the air from the air system. The air pressure gauge should read 0 psi (0 kPa).

⚠ WARNING

WARNING: Failure to drain the air system could result in personal injury, or property damage.

NOTE: If the upper torque rod has been previously serviced, remove the two mounting capscrews, two nuts, and four washers that attach the upper torque rod to the frame rail and axle assembly.



3. Remove the two huck bolts, two huck collars, and four washers that attach the upper torque rod to the frame rail and axle assembly.
4. Remove the upper torque rod from the vehicle.

1. If you are replacing the upper torque rod, measure the length of the old upper torque rod.
2. Duplicate the measurement, as closely as possible, on the new upper torque rod.
3. Install the upper torque rod onto the frame rail and axle assembly using the two capscrews, four washers, and two locknuts. Do not tighten the upper torque rod clamps.

   Use a pipe wrench to align the upper torque rod to the frame hanger and the axle pad assembly.
4. Tighten the capscrew at the frame rail 600 lbf·ft (814 N·m).
5. Tighten the capscrew at the axle assembly 1000 lbf·ft (1356 N·m).
6. Connect a magnetic protractor to the steerable axle.
7. Position the protractor on the axle pad assembly, so it is even with the centerline of the axle and the axle spindle center. See **Fig. 2**, Ref. 2.

Upper Torque Rod Removal and Installation

8. Move the protractor to position the centerline of the axle with the centerline of the upper torque rod capscrew. See **Fig. 2**, Ref. 6.

NOTE: Check both wheels for proper caster settings.

Caster should be set at 5° to 6° positive. Caster cannot be less than 5° positive.

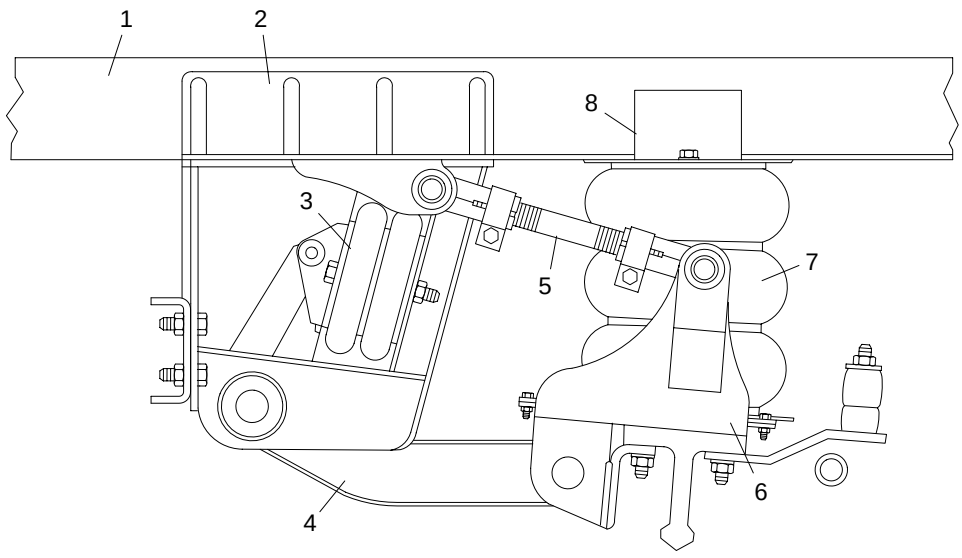
10. If the caster setting is incorrect, adjust by turning the upper torque rod clockwise, or counterclockwise to achieve the proper caster setting. See **Fig. 2**, Ref. 1.
11. Tighten the upper torque rod clamps 600 lbf·ft (814 N·m).
12. Check the toe-in of the axle, using instructions found in **Group 33**.

Air Spring Inspection and Replacement

Inspection (See Fig. 1)

Check the air springs periodically to ensure that there is no dry-rot, cracking, deformities, or other damage that could impede the performance of the vehicle. Refer to the driver's manual for additional information regarding daily, pre-trip inspections of the air springs.

1. Park the vehicle on a level surface. Apply the parking brakes, and chock the tires.
2. Check the air bags for cracks, deformities, dry-rotting, or other damage. Replace the air bags as needed.
3. Check for obstructions that could cause a breach of the air bag integrity. Reposition any component that is making contact with the air spring.
4. Check that the air system is fully charged, then check the operation of the axle lift air spring. If the axle lift air springs do not operate properly, refer to **Subject 300** for troubleshooting information.
5. Check the air lines for cracks, deformities, or leaking. Replace the air lines as needed.



Replacement (See Fig. 2)

⚠ WARNING

WARNING: Before attempting to remove the air springs, be sure that all of the air has been drained from the air system. The air spring will expand, suddenly, when removed from its mount if the air system is not fully drained and could result in personal injury, or property damage.

8. Remove the 3/4-inch hexnut and washer; then remove the axle lift air spring.
9. Remove the 1/2-inch hexnut and lockwasher from the lift plate; then separate the axle-lift air spring (Ref. 14).
10. Install the axle-lift air spring on the lift plate. Install the 1/2-inch hexnut and lockwasher on the lift plate. Tighten the hexnut 25 lbf·ft (34 N·m).
11. Install the new axle-lift air spring, lockwasher, and 3/4-inch hexnut on the frame hanger. Tighten the hexnut 200 lbf·ft (271 N·m).
12. Raise the trailing arm and insert the clevis pin through the lift plate; then insert and lock a new cotter pin into the clevis pin.
13. Start the capscrew (Ref. 26) through the frame hanger (Ref 1). Position the washers between the frame hanger and the lower trailing arm and the trailing arm. Install the capscrew through the frame hanger and the trailing arm. Install the locknut and tighten it 1000 lbf·ft (1356 N·m).
14. Install the air fittings and the air lines.
15. Remove the jack stands.
16. Start the engine and build up air pressure.
17. Check for air leaks, and check axle lift operation.
18. Remove the chocks from the tires.

Load Bearing Air Spring

⚠ WARNING

WARNING: Before attempting to remove the air springs, be sure that all of the air has been drained from the air system. The air spring will expand suddenly when removed from its mount if the air system is not fully drained. This could result in personal injury or property damage.

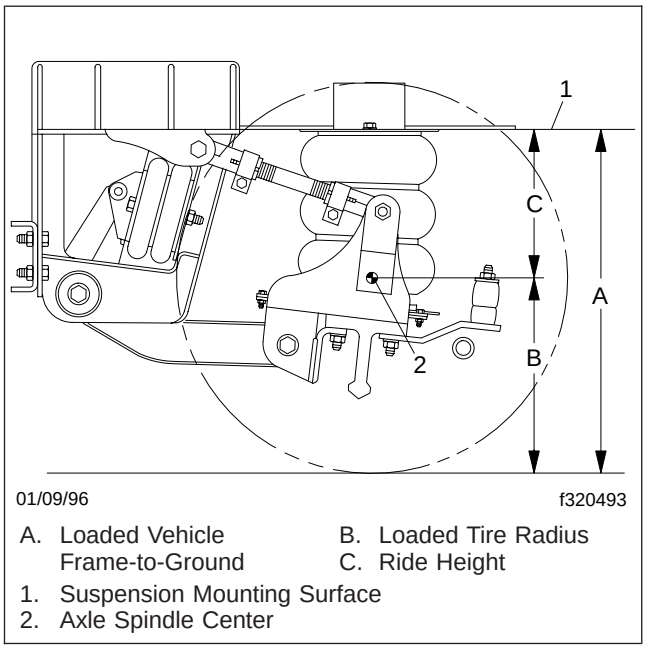
1. Park the vehicle on a level surface. Apply the parking brakes, and chock the tires.
2. Completely drain all of the air from the air system. The air pressure gauges should read 0 psi (0 kPa).
3. Remove the air line and fitting.
4. Remove the 3/4-Inch hexnut and lockwasher (Refs. 2 and 3) from the upper air-spring plate.
5. Remove the 3/8-inch capscrew and lockwasher (Refs. 4 and 5) from the upper air-spring plate.
6. Remove three 3/8-inch capscrews, hexnuts, and three lockwashers (Refs. 4, 5 and 10) from the rear of the axle pad assembly.
7. Place a pry tool between the upper air-spring plate and the load bearing air spring.
8. Pull down on the pry tool to separate the air spring from the mounting plate, and remove the air spring from the vehicle.
9. Remove two 3/8-inch capscrews and two lockwashers that secure the lower air-spring plate to the air spring. Separate the lower air-spring plate from the air spring.
10. Check the upper and lower air-spring plates for signs of corrosion, cracks, or other damage. Replace any air-spring plate that appears damaged, or excessively corroded.
11. Install the lower air-spring plate on the air spring.
12. Apply a light coating of Loctite® 242 to the threads of the capscrews. Install the capscrews on the air spring and tighten 15 lbf·ft (20 N·m).
13. Install the air spring on the upper air-spring plate and center the lower air-spring plate capscrew holes on the axle pad assembly.
14. Install the three 3/8-inch capscrews, three lockwashers, and three hexnuts on the lower air spring plate. Tighten the capscrews 15 lbf·ft (20 N·m).
15. Install the 3/8-inch x 1-1/8 inch capscrew and lockwasher on the upper air-spring plate. Tighten the capscrew 15 lbf·ft (20 N·m).
16. Install the 3/4-inch hexnut and lockwasher on the upper air-spring plate. Tighten the hexnut 200 lbf·ft (271 N·m).
17. Install the air fitting, then connect the air line to the air springs.
18. Start the engine and build up air pressure. Check for air leaks and repair as needed. See **Subject 300** for troubleshooting information.
19. Shut down the engine and remove the chocks from the tires.

Ride Height Measurement and Load Capacity Adjustment

IMPORTANT: It is the responsibility of the vehicle operator to weigh the vehicle to get accurate axle load capacity for the vehicle for legal operation. The amount of air pressure supplied to the lift axle load air spring will vary depending on vehicle load.

Ride Height Measurement

Suspension ride height is defined as the distance between the suspension mounting surface and the spindle center of the auxiliary liftable axle.Suspension ride height must be calculated with the vehicle in its loaded condition.

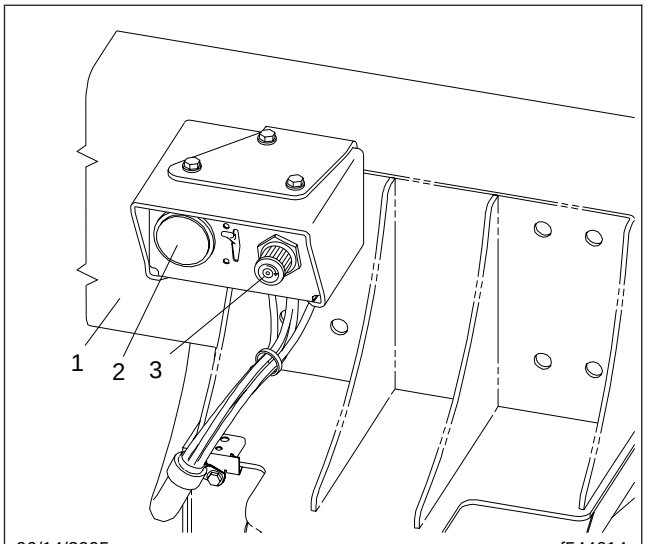


To check the ride height of the Watson & Chalin SL series suspension, use the following formula: A (loaded vehicle frame-to-ground) – B (loaded tire radius) = C (Ride Height). See **Fig. 1**.

1. Park the vehicle on a level surface. Apply the parking brakes and chock the front tires.
2. Run the engine until pressure in the air brake system exceeds 115 psi (792 kPa). Shut down the engine.
3. Measure the loaded frame-to-ground measurement; the distance from the bottom of the frame rail to the ground, with the vehicle in a loaded condition.
4. Measure the loaded tire radius; the distance from the axle spindle center to the ground, with the vehicle in a loaded condition.
5. Subtract the loaded tire radius from the loaded frame-to-ground measurement to determine ride height.

Load Capacity Adjustment

Load capacity can be adjusted by increasing or decreasing the air pressure to the lift air springs. The amount of air pressure varies depending on vehicle load. See **Specifications 400**, for load-to-pressure specifications.



The air pressure to the lift air springs, which is indicated on the gauge located on the frame rail or in the cab, is set by the pressure regulator. See **Fig. 2**. Pressure is increased by turning the knob clockwise, and it is reduced by turning the knob counterclockwise.

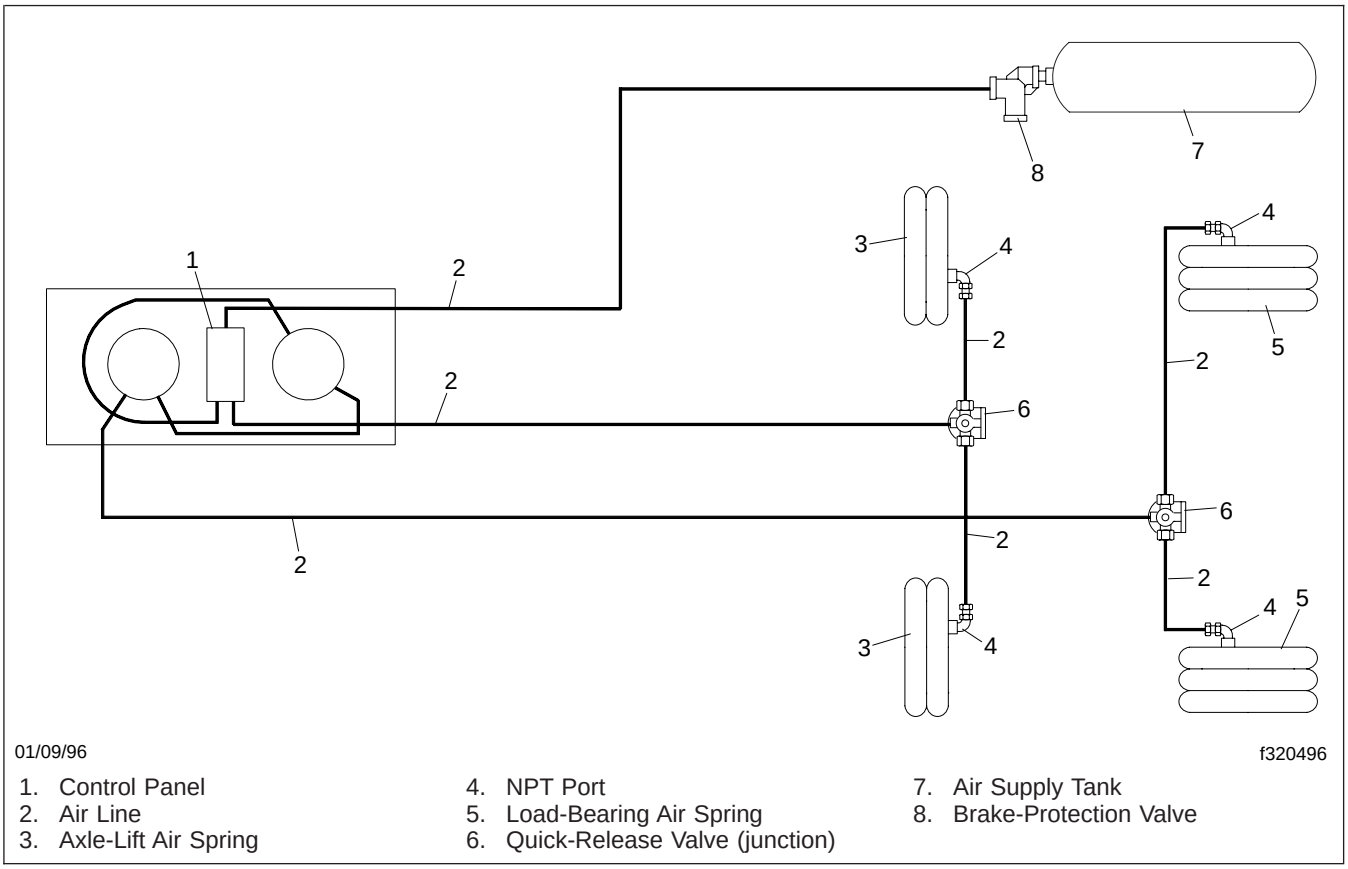
Inspection

The Watson & Chalin SL series steerable-axle lift suspension is operated from a control panel consisting of an air pressure gauge, pressure regulator, and a double-pull, double-throw air valve. See **Fig. 1**.

The control panel is designed so the driver can regulate the load pressure in the air springs for the proper, or desired load on the auxiliary axle. It is also designed to lift the auxiliary axle to the UP position when the vehicle load is empty, or the auxiliary axle is not required.

Optionally, an automatic reverse lift can be installed to automatically lift the suspension when the vehicle is shifted into reverse. An automatic reverse lockout will automatically lock the steerable axle to prevent it from turning when the vehicle is shifted to reverse. See **Fig. 2**.

1. Park the vehicle on a level surface. Apply the parking brakes, and chock the front tires.
2. Start the engine and build up air pressure in excess of 80 psi (552 kPa).



⚠ WARNING

Maintain air pressure of 80 psi (552 kPa). Failure to do so could result in brake failure if the suspension system suffered an air loss. This could result in personal injury or property damage.

3. Shut down the engine.
4. With a mixture of soap and water, coat the air fitting on the load bearing air springs, axle lift air springs, and at each air line junction.
5. If an air leak exists, air bubbles will form around the area where the leak originated. Repair or replace any leaking air line, fitting, or junction as needed.
6. Inspect the air supply tank for excessive corrosion, dents, or other damage that could weaken the tank. Replace any air supply tank that's damaged.
7. On vehicles equipped with an automatic reverse lift, check the solenoids for proper operation.
   - 7.1 Start the engine and lower the auxiliary axle suspension.
   - 7.2 Shift the transmission to reverse and check the position of the auxiliary axle.

   NOTE: When the shifter is placed in reverse, the steering will lock in a straight-ahead position, and the axle will lift off the ground.
8. If the axle does not lift, shut down the engine and use the following instructions.
   - 8.1 Turn the ignition key ON, but do not start the engine.
   - 8.2 Disconnect the harness connector from the reverse lock-out solenoids.
   - 8.3 With a voltmeter, probe the harness side of the connector. There should be no voltage with the shifter in neutral or any forward gear.
   - 8.4 Do not start the engine. Move the shifter into reverse, and recheck for voltage. When the shifter is in reverse gear there should be 11 to 13 volts at the solenoid. If no voltage is found, trace and correct a short to ground in circuit 120B.
9. Check the air springs for cuts, dry-rotting, deformities, or other damage. Replace the air springs as needed. Refer to **Subject 110**, for replacement instructions.

General Information

The AirLiner Plus suspension is used on vehicles with pusher or tag axles to improve traction performance.

The system maintains an accurate leveling of frame height through the use of the Rockwell WABCO ECAS (Electronically Controlled Air Suspension) system with sensors and an electronic control unit. A height sensor mounted between the frame and the drive axle housing provides the ECAS control unit with frame height information. Other sensors provide additional information, which the control unit uses to quickly lower or raise the frame height as necessary. The operation occurs while the vehicle is in motion or while parked.

The vehicle must be equipped with a rear axle air suspenion, and requires ABS with Automatic Traction Control to trigger the optional load transfer function automatically.

AirLiner Plus components include:

- A cab-mounted electronic control unit that uses information about the vehicle's rear frame height to adjust the air pressure of the air spring bags;
- A frame rail-mounted solenoid valve that adjusts the air pressure;
- An axle- and frame-mounted height sensor that provides the control unit with frame-height information;
- A brake light switch that informs the control unit when the brakes are applied;
- A dash-mounted warning light that indicates a system fault;
- A load transfer light that displays automatic load transfer status;
- A three-position dash switch that allows automatic load transfer, driver-activated load transfer, or no load transfer.
- An optional hand-held remote control unit that is used to alter the chassis height for loading and unloading.

System Operation

Indicator Lights

ECAS FAIL: Lights for approximately two seconds when the ignition key is turned on, then the light goes out and remains out during vehicle operation. If the ECAS FAIL light does not go out after two seconds, or if it comes on during vehicle operation, there is a failure in the ECAS system.

LOAD X-FER: Lights for approximately two seconds when the igition key is turned on, then the light goes out. Lights whenever there is a manual or an automatic load transfer.

Frame Height Control

ECAS will maintain the vehicle frame to a pre-set height within a 3/16-inch (5 mm) range. The optional remote control unit allows frame height adjustment within operating limits if the vehicle is parked or moving less than 7 mph.

Load Transfer Activation

If the load weight is transferred from the tag axle to the drive axle, it will remain shifted for 20 seconds and is then slowly transferred back to a normal condition. The complete load cycle takes approximately 45 seconds.

Slippage of the driving wheels (usually when starting out on a slick surface) will activate the automatic load transfer. The load transfer will activate after the Automatic Traction Control activates.

Pressing the MOM ON (momentary on) side of the LOAD X-FER dash switch will activate the load transfer system. Manual activation works, however, only at vehicle speeds less than 30 mph.

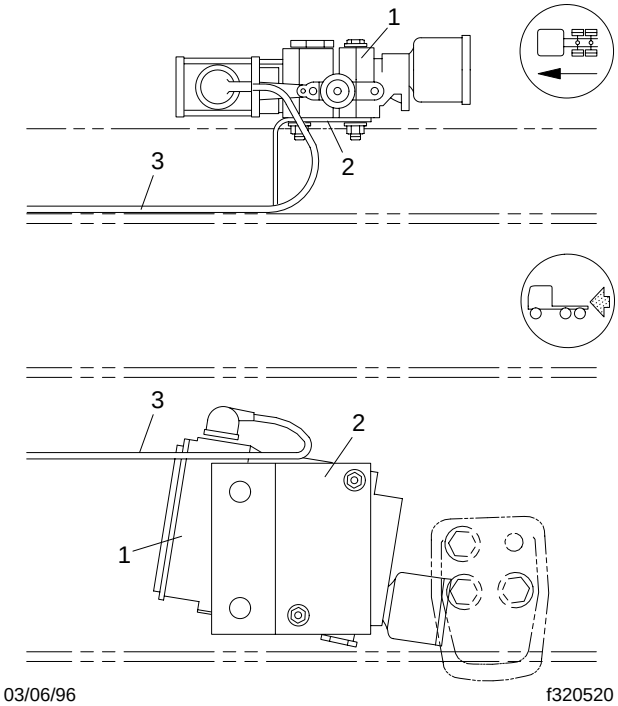
Load Transfer Termination

The load transfer cycle will immediately terminate if the service brakes are applied when the vehicle speed is more than 30 mph, when the STOP button on the remote control (if equipped) is pressed, or when the vehicle speed exceeds 75 mph.

The STOP button on the remote control will terminate the load transfer at any speed.

ECU Removal and Installation

Removal



1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. Remove the lower cover at the base of the left B-pillar.
4. Disconnect the electrical connections at the base of the B-pillar.
5. Remove the grab handle.
6. Remove the shoulder harness adjustable D-loop mechanism mounted to the B-pillar.
7. Detach the plastic channel that attaches the upholstery to the door frame. This will provide slack in the upholstery to allow access to the ECU mounted inside the B-pillar.
8. Remove the fasteners that attach the B-pillar upholstery to the cab wall.
9. Reach inside the B-pillar and remove the fasteners that attach the ECU.
10. Disconnect the electrical connections on the unit, and remove the ECU from the B-pillar.

Installation

1. Install the ECU inside the B-pillar. Connect the electrical connections.
2. Install the B-pillar upholstery.
3. Attach the plastic channel around the door frame and upholstery.
4. Install the shoulder harness adjustable D-loop mechanism.
5. Install the grab handle.
6. Connect the electrical connections at the base of the B-pillar.
7. Install the lower panel at the base of the B-pillar.
8. Remove the chocks from the tires.

Replacement

1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. Drain air from the suspension system.
4. At the ECAS solenoid valve (see **Fig. 1**), which is mounted to the frame rail, disconnect the electrical connector.

8. Remove the valve from the bracket.
9. Attach the new valve to the bracket. Install the bolts.
10. Connect the air lines to the valve as marked earlier.
11. Connect the electrical connector to the valve.
12. Remove chocks from tires.

Replacement

1. Shut down the engine and set the parking brake.
2. Chock the front tires.
3. At the ECAS height sensor (see **Fig. 1**), which is mounted between the frame rail and the drive axle housing, disconnect the electrical plug on the back of the sensor.

Troubleshooting Information

1. Indicator Lights:
    - ECAS FAIL lights up if there is a failure in the ECAS system.
    - Load XFER lights up whenever there is a manual or automatic load transfer.
2. Frame Height Control: ECAS will maintain the vehicle frame height to a preset value within 3/16-inch (4.7 mm) by adjusting the pressure in the rear suspension air bags. With the remote-control unit, the operator can adjust the frame height within the operating limits if the vehicle is parked or traveling less than 7 mph (15 km/h).
3. Load Transfer Activation: The weight is transferred from the tag axle to the drive axle by adjusting the pressure in the air bags. The load is shifted for 20 seconds, then is slowly equalized back to the normal condition. The complete load transfer cycle takes approximately 45 seconds. The load transfer occurs under the following conditions.
    - Automatic activation: The drive wheels slipping (usually when staring out on a slick surface) will activate the load transfer. If the vehicle is equipped with Automatic Traction Control, the load transfer will activate just after the ATC.
    - Manual activation: Pressing the MOM ON (Momentary On) side of the ECAS XFER dash switch will activate the load transfer. Manual activation works only at vehicle speeds less than 30 mph (50 km/h).
4. Load Transfer Termination: The load transfer cycle will terminate under the following conditions.
    - Applying the service brakes with a vehicle speed of more than 30 mph (50 km/h).
    - Vehicle speed exceeds 75 mph (120 km/h).
    - Pressing the STOP button on the remote control or disconnecting the remote control. This will terminate the load transfer at any speed.

Troubleshooting Tables

Before performing any diagnostics, make sure there are no ABS faults. Because of the interaction of the ABS and the ECAS systems, a fault in one system may cause a malfunction in the other system.

The following types of failures cause the "ECAS FAIL" indicator light to remain on:

- Grounded "ECAS FAIL" light wire;
- No power at ECAS electronic control unit (ECU) pin 1;
- Electrical fault in ECAS height sensor;
- Electrical fault in ECAS valve;
- Failure of J1587 data bus;
- Internal ECU fault;
- Faulty calibration of ECAS height control;
- Frame height cannot be adjusted within five minutes after ignition or within 30 seconds during normal service.

See **Table 1** for troubleshooting problems when the "ECAS FAIL" light remains on. This would include problems where the wrong action occurs, such as the air bags inflating rather than deflating, or the drive axle air bags deflating rather than the tag axle air bags. The causes may be crossed electrical wiring or air supply plumbing.

See **Table 2** for frame height problems.

See **Table 3** for incorrect ECAS functionality.

See **Table 4** for indicator lamp problems.

See **Table 5** for manual load transfer problems.

NOTE: All lamps are activated by the ECU for approximately two seconds after the ignition is switched on. The ignition must be switched off for at least 6.4 seconds before restarting to determine lamp condition.

General Description

The Hendrickson HAS suspension (see **Fig. 1**) uses air bags to support the sprung weight on vehicles with both single and tandem axles. The air bags (air springs) mount on a crossmember between the two main support beams that are fastened to the axle housing and pivot on forward-mounted hanger brackets on the frame. Torque rods, running from the hanger brackets to the axle seats, transfer vehicle motion to the frame. Lateral stability is provided by transverse torque rods from the inside of the frame rails to brackets on the axle housings. The shock absorbers help to dampen the oscillations of the air springs and control the torque reaction of the axle housings on acceleration.

height, even with varying loads. Although most vehicles with the HAS system use only one height control valve for the rear suspension, some vehicles with uneven loading may have a height control valve for each side of the vehicle. An optional suspension dump system permits the driver to temporarily lower the frame for trailer coupling or uncoupling without having to leave the cab. See **Subject 400** for a schematic of the air control system.

The suspension air control system uses air supplied from the secondary air brake system. The air supply line is connected to a secondary air manifold located behind the instrument panel. If a loss of air pressure occurs forward (upstream) of the protection valve, the air spring system will be isolated and maintain

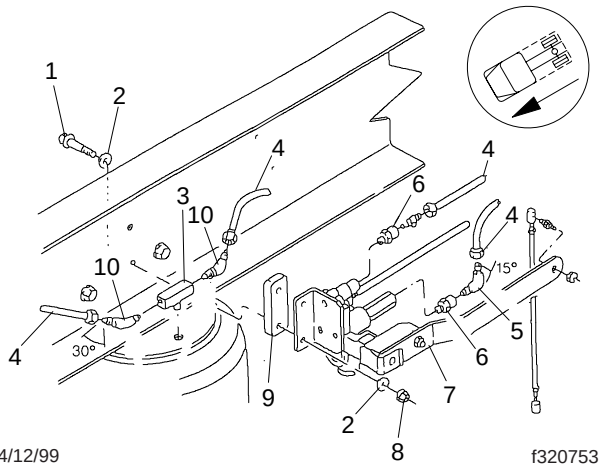
AIR CONTROL SYSTEM

The Hendrickson HAS air suspension system allows for a smooth ride while maintaining a constant ride

the air pressure within the suspension system until repairs can be made. However, if a loss of air occurs rearward (downstream) of the protection valve, the

General Information

air in the brake system will be protected, but the air pressure in the air springs will be lost.



The vehicle ride height is maintained by a height control valve mounted on the frame and linkage that connects the valve to the suspension crossmember. (See **Fig. 2**). As the frame-to-axle housing clearance changes due to a change in the vehicle load, the linkage moves the lever on the height control valve, causing air to move in or out of the air bags. A slight delay in the operation of the height control valve prevents the system from trying to adjust the ride height for each suspension movement.

The optional air suspension dump system is used to deflate the rear suspension air springs during trailer coupling and uncoupling operations. The dump control valve is located on the dash in the cab. When the dump control valve is toggled, supply air flows through the dump control valve delivery port and pressurizes the signal line to the relay valve. The pressurization of the signal line closes the relay valve supply port while opening the ports from the air bags to the atmosphere. Air from the air bags exhausts through the relay valve until the dump control valve is released or until the frame rests on the stops inside the air bags. A pressure switch in the signal line to the relay valve senses the signal pressure and switches on an optional red status light on the dash. To allow the air springs to inflate after being dumped, the dump control valve must be first toggled downward to exhaust the pressure in the signal line.

The pilot-operated relay valve is used for rapid deflation of the air bags for trailer coupling and uncoupling. When pilot pressure from the dump control valve is applied to the relay valve, the supply air from the height control valve is stopped from flowing through the relay valve and, simultaneously, the air spring pressure is exhausted directly to the atmosphere through passages in the relay valve.

REAR SUSPENSION COMPONENTS

The axle housing, the lower shock mounts and the lower air bag mounts are all solidly attached to the HAS main support arms. See **Fig. 3 and Fig. 4**. The main support arm hanger brackets, the upper shock mounts and the upper air bag mounts are all solidly mounted to the frame rails. The torque rods, with flexible bushings in each end, connect the hangers to the axle seats. When the vehicle travels over a bump, the axle housing suddenly rises and compresses the air bags. The pressure in the air bags increases immediately, which absorbs most of the energy of the upward-moving axle housing without transferring that movement to the frame. The shock absorbers then help absorb the release of that higher pressure by slowing the downward movement of the axle housing after the bump.

The front of each main support arm is allowed to pivot and slide on replaceable slipper pads in the hanger brackets. A torque rod is attached to each hanger bracket and to each axle seat bracket by rubber bushings with internal pins, installed in the torque rods at specified angles. Shims are used for adjustment at the front of each torque rod to make sure that the wheels run parallel to the frame rails.

The torque rods control the forward and aft movement of the unsprung pieces during suspension travel. The flexible rubber bushings in the torque rods allow vertical movement of the axle housing while limiting its forward and aft movement. The driveline angles are kept within the specified limits by the torque rods' control of the rotational forces on the axle housings during acceleration and deceleration. The torque rods transfer the forward motion of the axle housing to the frame rails on acceleration and pull back on the frame during braking.

The transverse rods, also with rubber bushings in each end, connect the brackets on the axle housings to the brackets on the frame rails. The transverse rods keep a constant lateral relationship of the frame to the axle housing, while still allowing vertical movement of the axle housings.

The Hendrickson HAS suspension is available in varying capacities and for limited off-highway use. The heavy-duty or off-highway suspensions have thicker main support arms, heavier crossmembers and torque rods, and heavy-duty air bags and shock absorbers. There are two HAS ride height specifications (measured from the bottom of the frame rail to the bottom of the main support arm at the axle seat) depending on which suspension is used. The HAS suspensions are available for single or tandem axle vehicles and can be ordered with or without the suspension dump feature.

REAR SUSPENSION SERVICE NOTES

⚠ WARNING

A main support member that has been subjected to heat, nicks or gouges can fail, causing loss of vehicle control and possible personal injury or property damage.

⚠ CAUTION

Do not use an arc welder on the suspension parts or use a cutting torch to remove any fasteners. The use of heat on suspension components will adversely affect the strength of these parts. Never reinstall used suspension fasteners. Always use the same part number or an exact equivalent part number when replacing any suspension fastener. All fasteners must be tightened

to their specified torque and the U-bolts must be tightened in stages as described in Specifications 400.

Check the axle alignment after replacing components that affect alignment, such as a main support beam, a torque rod or a hanger.

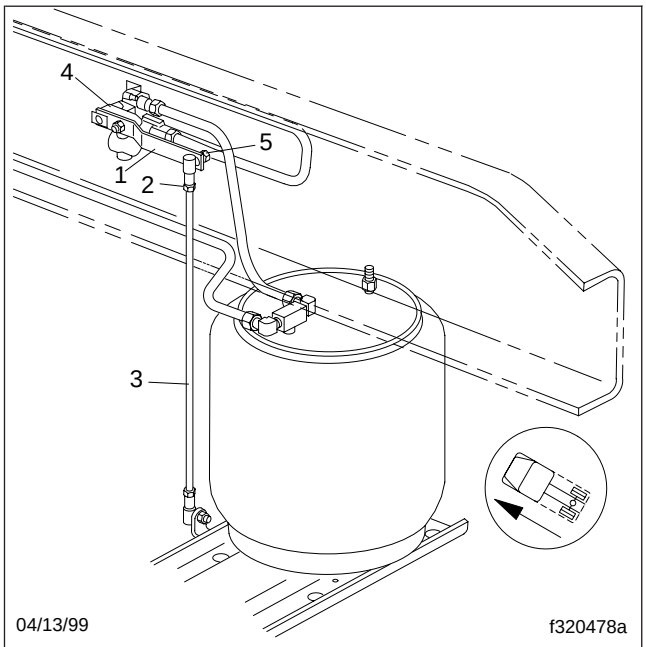
NOTE: During installation, apply Pipe Sealant with Teflon D8AZ–19554–A or equivalent meeting specification WSK–M2G350–A2 or ESR–M18P7–A to the air fitting threads.

NOTE: When replacing the torque rod bushings, lubricate the new bushings with a vegetable-based oil only. Make sure the new bushings are centered in the torque rod bores.

NOTE: A shim pack of three 0.11 inch (2.8 mm) thick spacers are used to adjust axle lateral tracking offset. Install the spacers as required to adjust tracking.

Main Support Member Removal and Installation

Removal



NOTE: Operation of the HAS suspension will result in wear between the main support member and the spring hanger slipper pad. In normal use, these components will function satisfactorily even though they show some wear. Premature wear may occur, however, and requires the replacement of one or both parts. A main support member should be replaced if it has 3/8 inch (9.5 mm) or more wear at the hanger cam contact area.

1. Stop the vehicle on a level surface, shut down the engine and apply the park brakes. Chock the front and rear tires.
2. Support the axle housing with a jack stand under the pinion nose to prevent the axle housing from rotating when the U-bolts are removed.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the frame about 3 inches (75 mm). Support the frame at that position with jack stands.
4. Remove the locknuts, washers and bolts that connect the cross channel and shock absorber brackets to both main support members. See **Fig. 2**. Remove the lower shock mount fasteners on the HAS–40LH models.
5. Use a floor jack to raise the cross channel about 3 inches (75 mm). Support the cross channel assembly with jack stands.
6. Remove the locknut, washers and bolt from the rebound roller assembly at the front hanger. See **Fig. 3**. Remove the rebound roller and spacer.
7. Remove the U-bolt high nuts and washers, then remove the bottom cap, U-bolts and the top pad and Delrin liner.

9. Inspect the main support member for wear. Replace the main support member if worn more than 3/8 inch (9.5 mm) at the hanger end where it contacts the slipper pad or if it has cracks, nicks or signs of the application of heat from a torch or welder.
10. Inspect the slipper pad for wear. Replace the slipper pad if worn. Remove the four bolts and washers that hold the slipper pad to the hanger. If rivets were installed instead of bolts to hold the slipper pad, use a grinder to remove the rivet heads.

⚠ WARNING

Always use new fasteners when installing suspension components. Reuse of fasteners can lead to component damage and loss of vehicle control, possibly resulting in personal injury or property damage.

1. Install the slipper pad, bolts and washers into the hanger. Tighten the bolts 25 lbf·ft (34 N·m). Install new rivets if so equipped.
2. Slide the main support member into the hanger assembly.
3. Position the main support member on the axle seat, or on the spacer plate if the vehicle is so equipped, with the main support member center dowel sliding into the hole in the axle seat or spacer plate.

4. The Delrin liner must be positioned on the top of the main support member. Install the U-bolt top pad on the Delrin liner. Install the U-bolts over the top pad and liner and around the main support member, the spacer (if so equipped), the axle seat assembly, the axle housing, and the bottom cap. Install the washers and high nuts and tighten with your fingers, but do not fully tighten the U-bolt high nuts at this time.
5. Lower the floor jack under the cross channel until the cross channel is against the main support members. Install the shock absorber bracket (if so equipped) and bolts into the cross channel and main support members. See **Fig. 2**. Install the washers and tighten the locknuts 280 lbf·ft (380 N·m). On the HAS–40LH models, install the

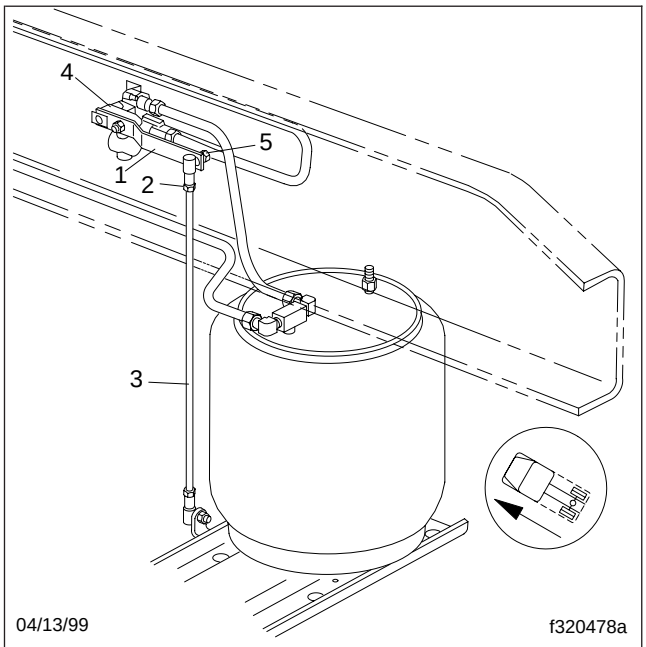
lower shock absorber mount bolts, washers and nuts. Tighten the shock absorber nut 60 lbf·ft (82 N·m).

6. Install the rebound roller into the hanger. Install the bolt, washer and locknut. Tighten the locknut 60 lbf·ft (82 N·m).
7. Center the main support member between the hanger legs. Move the lever for the height control valve up to lift the frame from its jack stands. Remove the jack stands from the frame.
8. Tighten the U-bolt locknuts in stages as described in **Specifications 400**. Rap the top of the U-bolts with a hammer and then retighten the high nuts 500 lbf·ft (680 N·m).

IMPORTANT: Do not exceed the specified torque on the U-bolt high nuts. Retighten the U-bolt high nuts after 1000 miles (1600 km).

9. Move the lever for the height control valve down to lower the frame until the upper ball joint stud in the vertical linkage exactly aligns with the hole in the lever when the lever is in the horizontal position. Install the height control valve ball joint stud, washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
10. Remove the jack stand from under the nose of the axle housing.
11. Check and adjust the ride height as described in **Subject 180**.
12. Check the alignment after new main support members are installed.

Axle Seat Removal and Installation



Removal

1. Stop the vehicle on a level surface, shut down the engine and apply the park brakes. Chock the front and rear tires.
2. Support the axle housing with a jack stand under the pinion nose to prevent the axle housing from rotating when the U-bolts are removed.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.
4. Remove the nuts, washers and bolts that hold the torque rod to the hanger legs.
5. Remove the nuts and washers that hold the torque rod to the axle seat. Remove the torque rod.
6. Remove the high nuts from the U-bolts and remove the bottom cap and top pad and Delrin liner.
7. Use a floor jack to raise the cross channel and main support member just enough to remove the axle seat.
8. Remove the axle seat. See **Fig. 2**.
9. If the axle seat studs need replacement, remove them with a hammer and brass drift.

Installation

⚠ WARNING

Always use new fasteners when installing suspension components. Reuse of fasteners can lead to component damage and loss of vehicle control, possibly resulting in personal injury or property damage.

1. Install the new studs with a stud driver. Insert the stud in the hole of the axle seat and tap into position with a hammer and brass drift.
2. Lift the main support member with a floor jack and install the axle seat on the top of the axle housing. Install the spacer (if so equipped) above the axle seat.
3. Position the main support member on the axle seat, or on the spacer plate if the vehicle is so equipped, with the main support member center dowel sliding into the hole in the axle seat or spacer plate.
4. The Delrin liner must be positioned on the top of the main support member. Install the U-bolt top pad on the Delrin liner. Install the U-bolts over the top pad and liner and around the main support member, the spacer (if so equipped), the axle seat assembly, the axle housing, and the bottom cap. Install the washers and high nuts

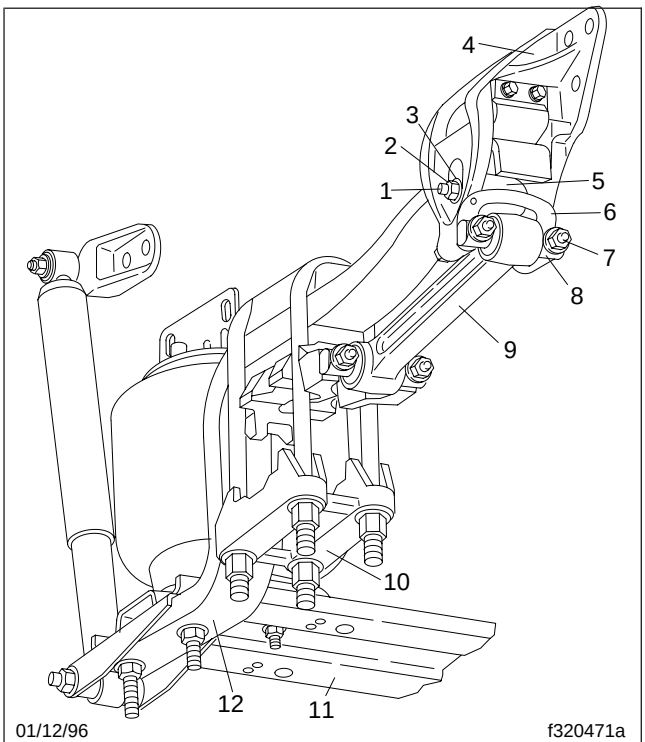
and tighten with your fingers, but do not fully tighten the U-bolt high nuts at this time.

5. Install the torque rod on the axle seat so that the holes in the bushing pin align with the axle seat studs. Install the washers and nuts, but do not tighten at this time.
6. Install the front end of the torque rod onto the hanger legs and install any shims that were removed. Install the bolts through the hanger legs, shims, and the front bushing pin.
7. Tighten the nuts on the front of the torque rod 175 lbf·ft (237 N·m).
8. Tighten the nuts for the torque rod pin at the axle seat 175 lbf·ft (237 N·m).
9. Move the lever for the height control valve up to lift the frame from its jack stands, Remove the jack stands from the frame.
10. Tighten the U-bolt locknuts in stages as described in **Specifications 400**. Rap the top of the U-bolts with a hammer and then retighten the high nuts 500 lbf·ft (680 N·m).

IMPORTANT: Do not exceed the specified torque on the U-bolt high nuts. Retighten the U-bolt high nuts after 1000 miles (1600 km).



11. Move the lever for the height control valve down to lower the frame until the upper ball joint stud in the vertical linkage exactly aligns with the hole in the lever when the lever is in the horizontal position. Install the height control valve ball joint stud, washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
12. Remove the jack stand from under the nose of the axle housing.
13. Check and adjust the ride height as described in **Subject 180**.
14. Check the alignment after new axle seats are installed.

Torque Rod Bushing Replacement

Replacement (See Fig. 1)

Use the following procedure to replace the torque rod bushing.

1. Chock the front tires, and the tires of the drive axles.
2. Remove the bushing pin locknuts and washers at the axle end of the torque rod. See **Fig. 1**.

3. Loosen the rebound bolt locknut in the hanger.
4. Remove the bushing pin locknuts, bolts and washers, and any alignment shims at the hanger end of the torque rod. Note the number of shims, as the same thickness shim pack must be reinstalled to avoid affecting the vehicle's alignment.
5. Push out the old bushings. Use a vertical shop press with a capacity of at least 10 tons. A 5-inch (127 mm) piece of 2-inch by 1/4-inch (50-mm by 6-mm) wall, steel-tubing receiving tool is required. The bushings are not cartridge-type bushings and do not have a metal outer sleeve.
6. Support the torque rod end on the receiving tool with the end tube of the torque rod centered on the tool.

⚠ WARNING

Do not use heat or a cutting torch to remove the bushings from the torque rod. The use of heat will weaken the torque rod, which could cause the rod to break. This could result in a loss of vehicle control, personal injury, or property damage.

7. Push directly on the bushing pin until the bushing is pushed out of the torque rod end tube.
8. Clean and inspect the torque rod ends. Remove any nicks with emery cloth.
9. Lubricate the torque rod ends and the new rubber bushings with a vegetable-based oil. Do not use a petroleum-based or soap-based lubricant.
10. Press in the new bushings while supporting the torque rod end on the receiving tool with the end tube of the torque rod centered on the receiving tool. The bushings must be installed with the mounting flats on the bar pin positioned 90 degrees to the shank of the torque rod. See **Fig. 2**.

1. Torque Rod
2. Bushing Bar Pin

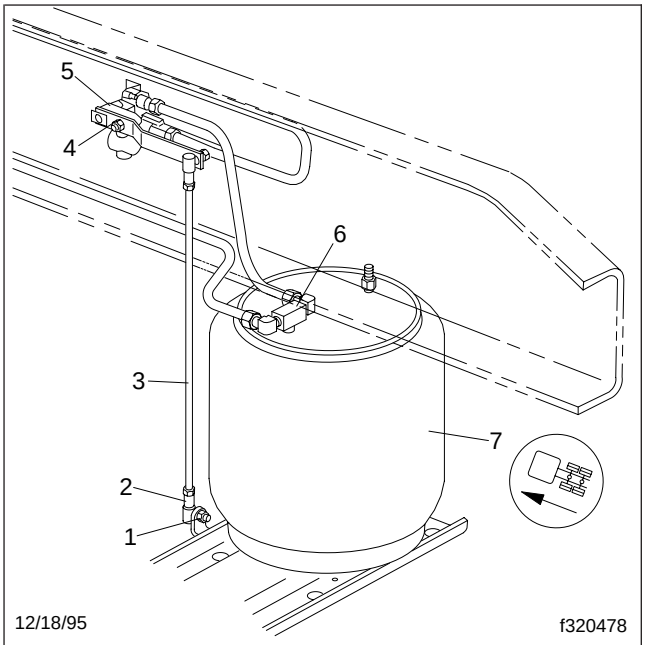
Fig. 2, Positioning the Bar Pin Mounting Flats

11. Press directly on the bar pin of the bushings, which must be centered within the torque rod end tubes. When pressing in the new bushings, overshoot the final position by approximately 3/16 inch (5 mm).
12. Press the bushing again from the opposite side to center the bushing within the torque rod end.

Torque Rod Bushing Replacement

13. Position the torque rod into the axle seat and attach it with the washers and locknuts. Handtighten the locknuts.
14. Position the torque rod onto the forward face of the hanger legs. Assemble the bolts, washers and locknuts, and any alignment shims. Tighten locknut 175 lbf·ft (237 N·m). See **Fig. 1**.
15. Tighten locknuts at the axle end of the torque rods 175 lbf·ft (237 N·m).
16. Tighten rebound bolt locknut 60 lbf·ft (81 N·m).

Height Control Valve Removal and Installation



Removal

1. Chock the front tires.
2. Drain the vehicle's air system.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Remove the height control valve vertical rod from the valve lever by removing the nut and lock washer. Push down on the lever of the height control valve to exhaust the air from the rear suspension air bags.
4. Remove the air lines attached to the height control valve. See **Fig. 1**.

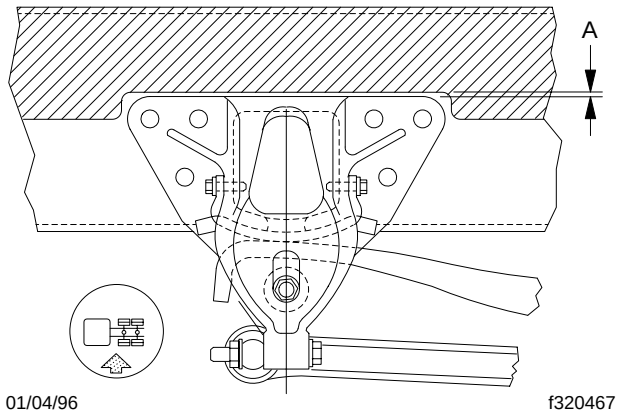
5. Remove the locknuts, washers, and bolts that attach the height control valve to the frame.
6. Remove the brass air fittings from the height control valve.



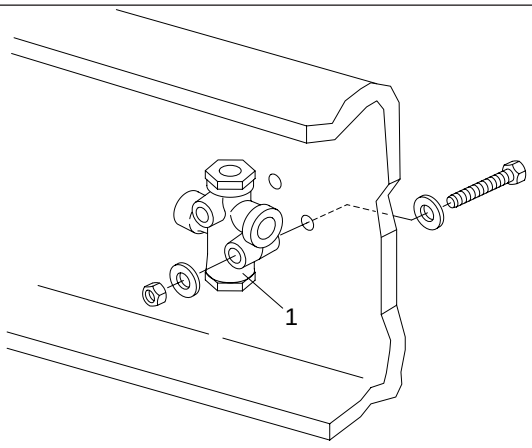
Installation

1. Install the brass air fittings into the height control valve ports.
2. Install the bolts, washers, and locknuts that attach the valve to the frame rail.
3. Attach the air lines to the height control valve.
4. Attach the height control valve vertical linkage rod to the height control valve lever, and install the lock washer and nut. See **Fig. 1**.
5. Return air to the system.
6. Adjust the height control valve for proper ride height as described in **Subject 180**.

Fifth Wheel/Hanger Clearance

Information

The HAS front hangers must have at least 1/4-inch (6 mm) clearance between the top of the hanger and the bottom of the fifth wheel mounting bracket on the sides of the frame rails. In some cases, the fifth wheel mounting bracket may have to be cut out to provide the correct clearance. See **Fig. 1** for an example of a fifth wheel mounting bracket that has been modified.



A. Clearance: 1/4 inch (6 mm)

Fig. 1, Fifth Wheel Mounting Angle Clearance

Replacement (See Fig. 1)

1. Chock the front tires.
2. Drain the vehicle's air system.
3. Disconnect the air lines from the quick release valve. Identify the air line at the top of the valve.
4. Remove the quick release valve from the frame or cross member.
5. Remove the brass air fittings from the valve.
6. Attach the brass air fittings to the replacement quick release valve.
7. Attach the valve to the frame or cross member.

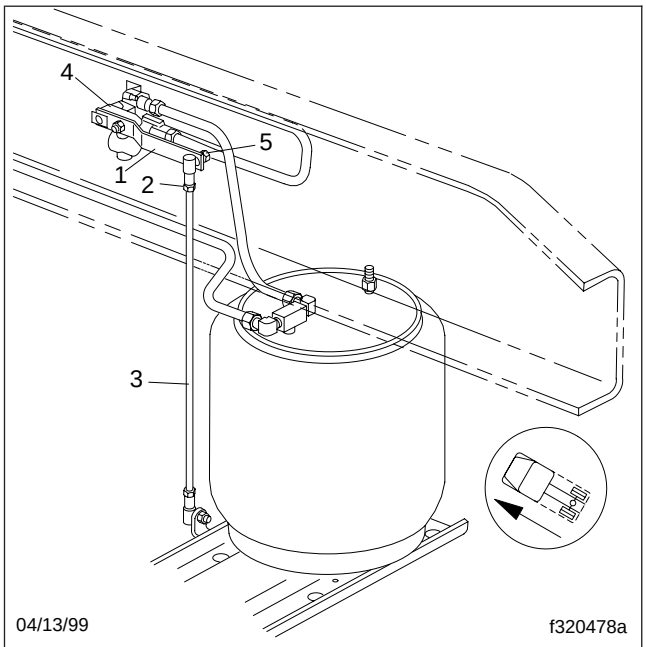
8. Connect the air lines to the valve, making sure to attach the identified line to the top of the valve.
9. Build up pressure in the air system.
10. Remove the chocks from the front tires.

Slipper Pad Removal and Installation

Removal

NOTE: Operation of the HAS suspension will result in wear between the main support member and the hanger slipper pad. In normal use, these components will function satisfactorily even though the components indicate some wear.

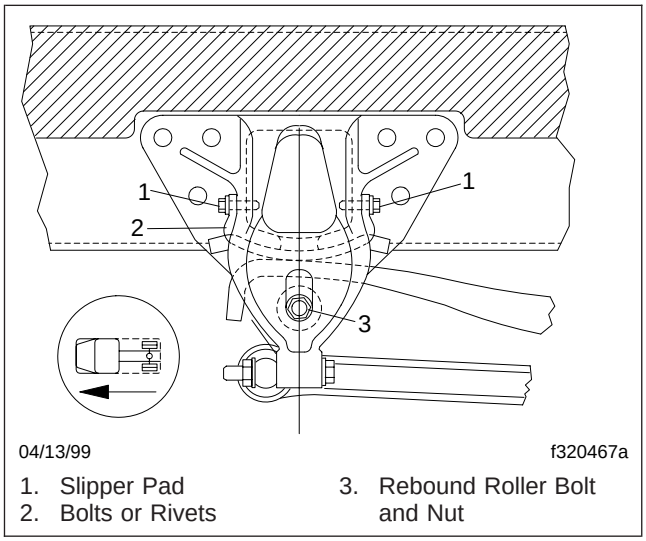
1. Chock the front tires.



⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage from the lever of the height control valve and lift the lever to raise the rear of the frame about 3 inches (75 mm). See **Fig. 1**.
3. Support the frame with jack stands.
4. Apply an upward force on the cross channel with a jack or, on single axles, by pushing down on the height control lever to lift the cross channel. This will cause the tips of the main support members to drop away from the slipper pad. See **Fig. 2**.



IMPORTANT: Do not nick or gouge the cross channel.

5. Remove the fasteners and the slipper pad. In some instances, the screws may have to be drilled out. See **Fig. 3**.
6. In some instances, remove the rebound roller to gain enough clearance to remove the slipper pad. Loosen the rebound bolt locknut, remove the washer, the bolt, and the rebound roller assembly.
7. For rivets, remove the four 1/4-inch (6-mm) rivets by grinding away the rivet heads. With a drift pin, punch the rivets through the holes and remove the slipper pad.

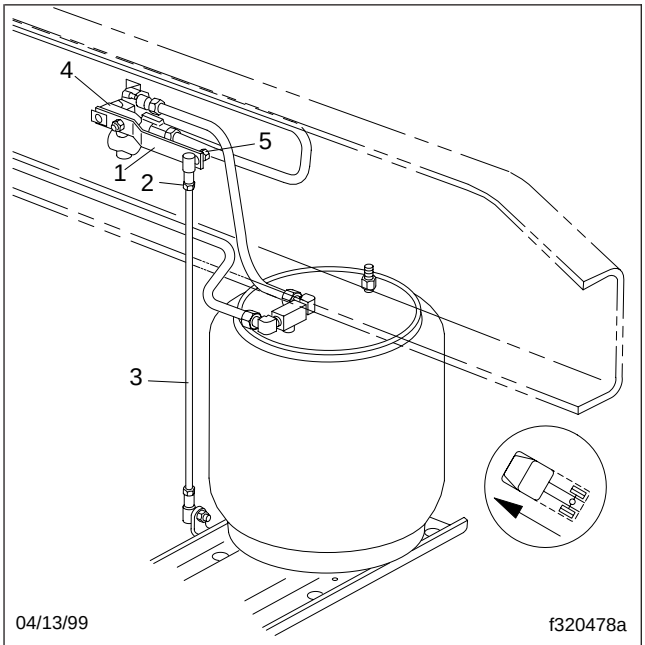
Installation

1. Position the slipper pad and retainer plate on the frame hanger.
2. Tighten the hexhead self-tapping screws 25 lbf·ft (34 N·m).
3. Or, install the rivets using a rivet gun.
4. Raise the frame off the jack stands by pulling up on the height control valve lever. Remove the jack stands.
5. Push down on the height control valve lever to lower the frame until the upper ball stud on the vertical linkage rod exactly aligns with the hole in the lever when the lever is horizontal.
6. Install the ball stud into the hole in the lever and install the washer and nut. Tighten the nut 10 lbf·ft (14 N·m).
7. Remove the chocks from the tires.

Cross Channel Removal and Installation

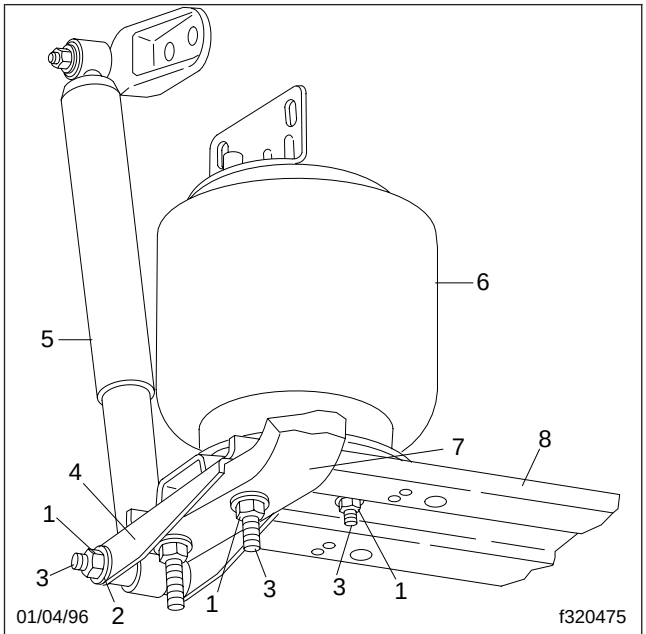


Removal

1. Stop the vehicle on a level surface and shutdown the engine. Chock the front and rear tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.



2. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.

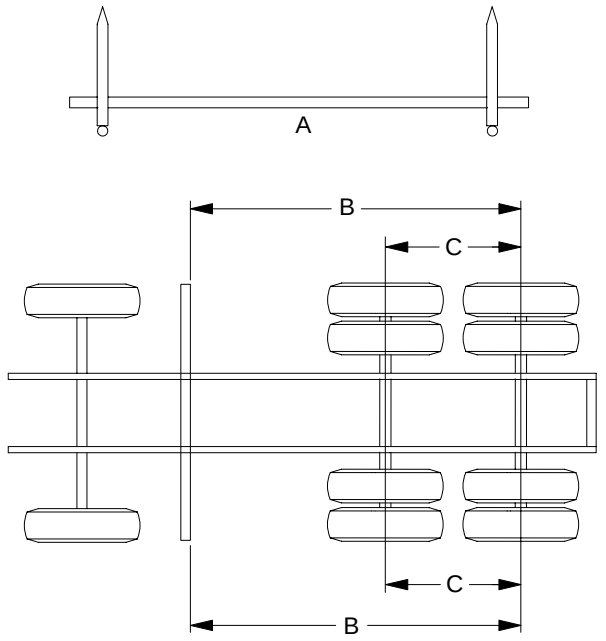
5. Raise the cross channel by pushing down on the height control lever to compress the air springs just enough to clear the studs on the bottom of the air springs. Remove the cross channel.

Installation

1. Position the cross channel so that the holes in the cross channel are aligned under the studs of the air springs. Install the washers and nuts. Tighten the nuts on the air spring studs 25 lbf·ft (34 N·m).

Cross Channel Removal and Installation

2. Lower the cross channel assembly onto the main support members by pushing down on the height control valve lever.
3. Install the bolts, washers and locknuts that connect the cross channel to the main support member and lower shock absorber mounts. Tighten the locknuts 290 lbf·ft (393 N·m).
4. Raise the frame by lifting the height control valve lever and remove the jack stands.
5. Attach the ball joint stud of the vertical linkage rod to the height control valve link, and tighten the locknut on the ball joint stud 10 lbf·ft (14 N·m).
6. Remove the chocks from the tires.



Checking and Adjustment

Use the following procedure after all repairs to the suspension:

1. Park vehicle on a level surface. Free and center all suspension joints by slowly moving the vehicle back and forth several times without applying the brakes.
2. Chock the front tires and the tires of drive axles.
3. C-clamp a nine-foot (2.74-m) piece of straight bar stock or angle iron across the frame. Select a location as far forward of the forward drive axle as possible where components will not interfere. The lower frame flange may be preferred on some vehicles, otherwise use the upper frame flange.
4. Align the straight bar stock or angle iron on the frame using a carpenter's square.
5. Check the rear drive axle first. See **Fig. 1** . Use a trammel bar or its equivalent to measure from the straight edge to the center line of the rear axle on both sides of the vehicle. If both sides measure within 3/16 inch (5 mm) of being the same, the alignment of the rear drive axle is acceptable. If the sides differ by more than 3/16-inch (5 mm), first loosen the rebound locknut, and then adjust the rear drive axle by loosening up the torque rod bar pin locknuts on the hangers. Add or remove drop-in shims as needed.

NOTE: The torque rod bar pin must be mounted to the forward face of the hanger legs. No more than four shims may be used (for a maximum thickness of 1/4 inch (6 mm).

6. Snug the torque rod bar pin locknuts but do not torque to specification.
7. With the rear drive axle properly aligned, the front drive axle alignment can be checked by measuring forward from the center of the axle shafts on the rear drive axle using a trammel bar. If the forward drive axle spacing measurements differ by more than 1/8 inch (3 mm), add or subtract shims at the forward hangers.
8. Following the adjustment of both axles, move the vehicle back and forth several times prior to removing the straight edge from the frame. Recheck the alignment.

A. Trammel Bar
B. Each side must be within 3/16 inch (5 mm) of each other.
C. Distances between axles must be within 1/8 inch (3 mm) of each other.

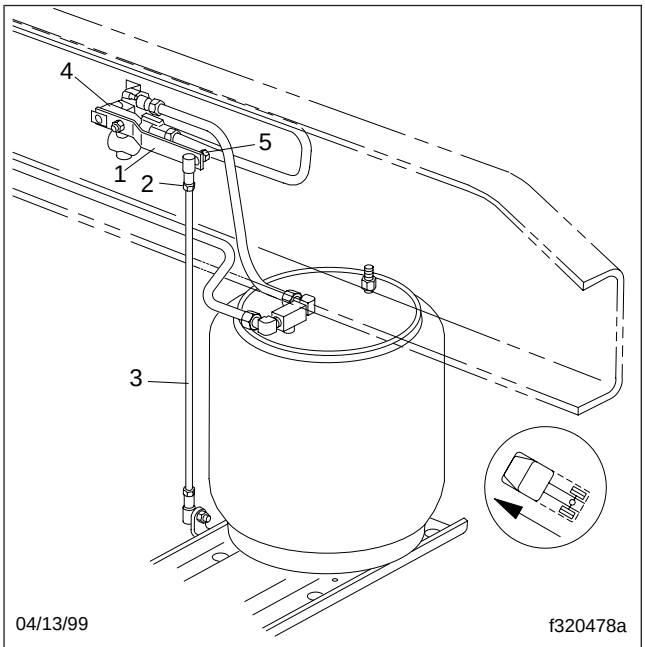
10. Remove the chocks from the tires.



Replacement

1. Chock the front tires.
2. Support the frame with jack stands.
3. Drain the vehicle's air system.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

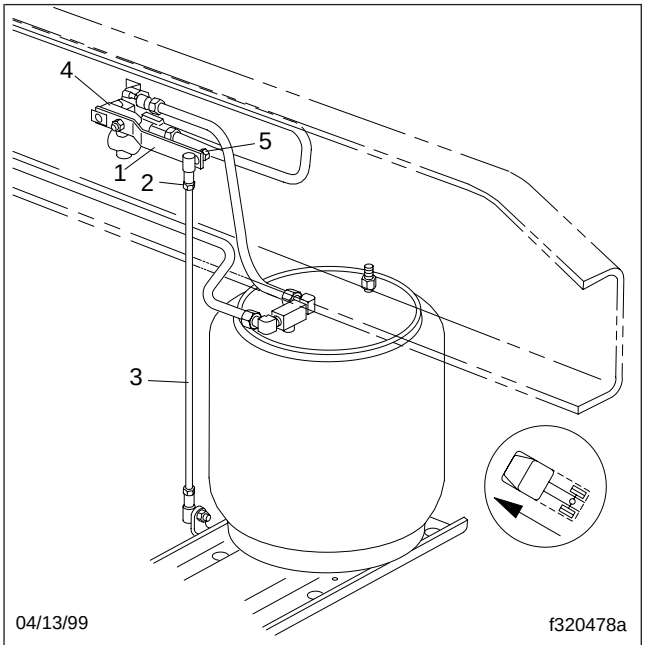
16. Remove the jack stands.
17. Build up pressure in the air system and check the ride height as described in **Subject 180**.
18. Remove the chocks from the tires.

Air Spring Frame Hanger Removal and Installation



Removal

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

2. Disconnect the vertical linkage for the height control valve at the end of the horizontal lever. See **Fig. 1**. Lift the lever on the height control valve so that the air bags raise the rear of the frame about 3 inches (75 mm). Support the frame at that position with jack stands.

5. Remove the brass air fittings from the air spring.
6. Remove the locknuts and washers that attach the air springs studs to the upper bracket on the frame rail. See **Fig. 2**.
7. Remove the nuts, washers and bolts that hold the upper air spring bracket to the frame rail. Remove the air spring bracket.

Installation

1. Position the air spring upper bracket on the frame rails. Install the bolts through the frame rail and upper bracket and install the washers, and locknuts. Tighten the locknuts 340 lbf·ft (461 N·m).
2. Attach the air spring to the air spring frame bracket. Tighten the outboard locknut 25 lbf·ft (34 N·m).

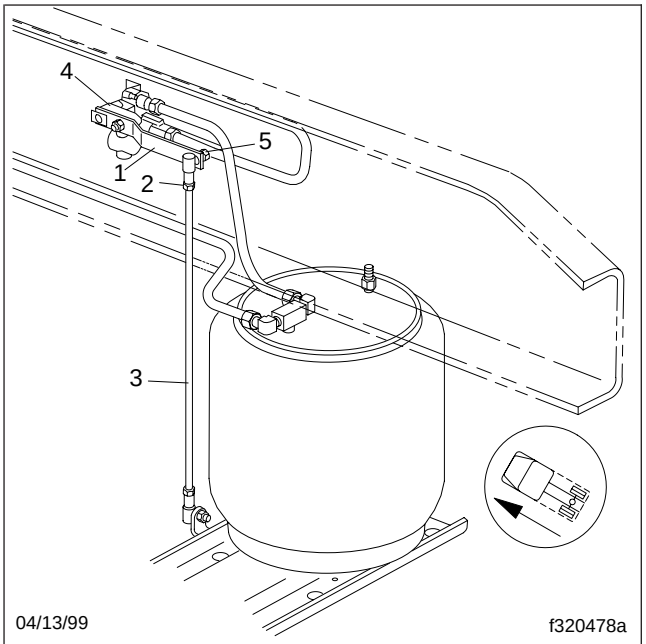
6. Align the ball joint stud in the vertical linkage rod with the hole in the height control lever. Install the ball joint stud, the washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
7. Remove the chocks from the tires.

Shock Absorber Bracket Removal and Installation



Removal

1. Chock the front tires.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

3. Lift the height control lever to raise the rear of the frame enough to remove the load from the suspension.

   NOTE: The front of the main support member will move downward as the load is removed. Support the frame in this position with jack stands.

4. Remove the shock absorber. Refer to **Subject 170**.

5. Remove nuts, washers and bolts from the shock absorber frame hanger bracket. See **Fig. 2**. Remove the top shock absorber bracket from the frame.

6. Remove the nuts, washers and bolts that attach the cross channel and lower shock absorber bracket to the rear of the main support member.

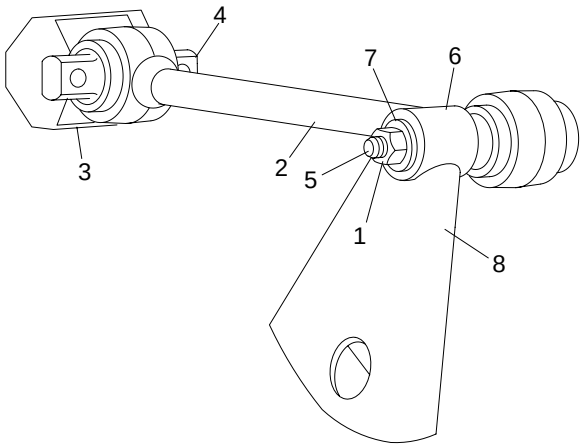
7. Remove the lower bracket by sliding the bracket to the rear.

Installation

1. Install the bolts and washers that attach the frame hanger bracket from the inboard side of the frame. Install the brackets, washers and locknuts. Tighten the nuts 340 lbf·ft (461 N·m).

2. Position the lower bracket between the cross channel and the main support member.

Shock Absorber Bracket Removal and Installation



3. Install the bolts and washers from the top of the cross channel, through the shock bracket and main support member. Install the washers and locknuts and tighten the locknuts attaching the cross channel to the main support member 290 lbf·ft (393 N·m).
4. Install the shock absorber. Install the washers at both sides of each shock bushing for a total of four washers per shock absorber.
5. Tighten shock absorber locknuts 60 lbf·ft (81 N·m).
6. Lift the lever of the height control valve to raise the rear of the frame off the jack stands. Remove the jack stands and lower the frame by pushing down on the height control valve lever.
7. Align the ball joint stud in the vertical linkage rod with the hole in the height control valve lever. Install the washer and locknut. Tighten the locknut 10 lbf·ft (14 N·m).
8. Remove the chocks from the tires.

Transverse Rod Removal and Installation

Removal (See Fig. 1)

NOTE: This procedure is for replacement of a transverse rod with a tapered stud at the axle connection and a straddle mount pin at the frame bracket end. Some installations have straddle mounts at both ends of the transverse rod.

1. Chock the front and rear tires.
2. Remove the nuts and washers from the bolts that fasten the pin in the transverse rod bushing to the frame bracket. Disconnect the transverse rod where it is attached to the frame bracket bracket.
3. Remove the nut from the tapered stud in the tube bracket on the axle housing. Hit the top of the axle bracket tube hard with a large hammer to momentarily distort the tube and loosen the tapered stud. Remove the stud and transverse rod from the bracket on the axle housing.

Installation

1. Clear the tapered hole in the axle bracket of all foreign matter.
2. Insert the tapered stud and torque rod bushing into the bracket.
3. Attach the washer and locknut to the stud. Tighten 200 lbf·ft (271 N·m).
4. After tightening, hit the top of the axle bracket tube with a hammer to seat the tapered stud. Retighten.
5. Position the straddle mount end of the transverse rod at the frame bracket, and tighten 200 lbf·ft (271 N·m).
6. Remove the chocks from the tires.

Replacement

NOTE: Shock absorbers are 1 3/8 inches (35 mm) in diameter with a compressed length of 18 1/3 inches (466 mm) and an extended length of 30 inches (762 mm).

1. Chock the front tires.
2. Remove the nut, washer and bolts that attach the shock absorber to the frame hanger bracket. See **Fig. 1**.

3. Remove the fasteners that attach the shock absorber to the lower bracket.
4. Remove the shock absorber.
5. Install the new shock absorber with the rod and shield tube at the top. Install the bolts, washers and nuts in the lower bracket and the frame hanger bracket. Install washers at both sides of each shock bushing, that is four washers per shock absorber.
6. Tighten the fasteners 60 lbf·ft (81 N·m).

General Information

NOTE: This subject applies only to Hendrickson series HAS 190/210/230/40LH/400/402/460 suspensions.

Adjust the vehicle ride height with the unloaded vehicle on a level surface. The frame slope, driveline angles, and axle mounting alignment should be checked after the ride height has been changed.

⚠ CAUTION

Failure to adjust the vehicle ride height could adversely affect driveline angles. Also, if the air springs are set too high, the driver may have difficulty (or be prevented from) backing the vehicle under a trailer. If the air springs are set too low, rapid wear of driveline parts will result.

Ride Height Adjustment

The vehicle ride height for Hendrickson HAS air suspension systems is changed by adjusting the length of the vertical linkage at the ride height control valve. Use the following procedure to adjust the ride height of the frame rails.

IMPORTANT: Before checking the ride height, make sure there is no load on the chassis. For tractors, unhitch the trailer. Trucks must be empty when checking the ride height.

1. Stop the vehicle on a level surface, using a light application of the brakes. Slowly move the vehicle forward and back several times without using the brakes to center the suspension joints. Do not apply the parking brakes.
2. Put the transmission in neutral. Build the secondary air pressure to at least 100 psi (690 kPa). Shut down the engine.

   NOTE: Allow several minutes for the air pressure to equalize in the system before checking the ride height.
3. Mark the location of the front and rear tires on the floor so that the vehicle can be checked in the same location after a test drive. Chock the front tires.

IMPORTANT: Any difference in height between the two sides of the vehicle must be corrected using spacers between the main support arm and the rear axle housing before setting the vehicle ride height. See the appropriate section in Group 32 in the vehicle's service manual for the alignment procedure.

4. Measure the distance from the bottom of the frame rail to the bottom of the main support arm at the rear axle U-bolts. See **Fig. 1**. The correct measurement for Hendrickson HAS suspension systems is 4-1/4±1/8 inches (108±3 mm) for vehicles with a specified ride height of 8-1/2 inches (215 mm) or greater. For vehicles with less than an 8-1/2-inch (215 mm) ride height, the distance between the bottom of the frame rail and the bottom of the main support arm must be 2-3/8 inches (60 mm).

   If the measurement is the same as the specification at each support arm, the ride height is correctly adjusted. If the distance measured is not the same at each rear axle mount on the vehicle, correct this alignment problem before attempting to adjust the ride height.

⚠ WARNING

The air suspension system will start moving the frame when the lever for the ride height control valve is moved from its center position. To avoid injury or property damage, make sure that your hands and all objects are away from any pinch points when the lever is moved.

5. Remove the nut and lockwasher from the ball joint stud at the end of the lever on the ride height control valve. See **Fig. 2**. Separate the vertical rod assembly from the lever, being careful to avoid moving the lever while disconnecting the ball joint.
6. Push the lever down to lower the frame by removing the air in the suspension air bags.
7. Slowly pull the lever up to raise the frame until the ride height measurement is exactly correct for the specified ride height.
8. Make sure that the centering hole in the lever near its pivot aligns with the centering hole in the height control valve body. Check the height control valve to make sure that no air flows through

the ride height control valve when the lever is in the centered position.

9. Loosen the jam nuts a few turns at the top and bottom ball joints on the vertical rod that attaches to the height control lever. Note that one of the ball joints and jam nuts has left-hand threads. Hold the top ball joint with your hand and turn the vertical rod with a wrench until the top ball joint stud exactly aligns with the hole in the end of the lever when the lever is centered horizontally on the control valve.
10. Install the ball joint stud in the lever and install the lockwasher and nut on the stud. Tighten the nut on the stud to 125 lbf·inch (11 N·cm).
11. Tighten the jam nut on each ball joint without changing the length of the vertical rod.
12. Apply the parking brakes; then remove the chocks from the tires. Drive the vehicle unloaded for about 1/4 mile (1/2 km); then stop the vehicle in the exact location (as previously marked) of the original measurement.
13. Park the vehicle using only a light brake application. Chock the tires on one axle only and put the transmission in neutral. Do not apply the parking brakes.
14. Check the adjusted distance between the bottom of the frame and the bottom of the main support arm at the U-bolts. See **Fig. 1**.
15. If the distance is still not correct, loosen the ball joint jam nuts on the vertical rod and turn the rod to adjust the ride height. Lengthen the vertical rod to raise the frame or shorten the rod to lower the frame to the correct ride height. Drive the vehicle and again check the ride height.
16. Apply the parking brakes; then remove the chocks from the tires.

Problem—All Air Bags Are Deflated

Problem—All Air Bags Are Deflated	
Possible Cause	**Remedy**
The vehicle air system pressure is too low.	Run the engine until the air gauge indicates 100 psi (690 kPa).
Air is leaking from the vehicle air system.	Listen for air leakage at the air fittings, tanks, and brake componenets. Repair or replace fittings as needed.
The linkage for the height control valve is disconnected or maladjusted.	Connect the linkage and adjust as described in **Subject 180**.
The suspension dump valve is activated.	Toggle the dump control valve to the normal position.
The relay valve is stuck open.	Check and repair the relay valve.
The air bags have a leak.	Listen for leaks at the air bags, tubes, and fittings.
The height control valve is not operating correctly.	Disconnect the linkage and raise and lower the lever to check the operation of the height control valve. Make sure that no air flows through the valve when the lever is in the center position. Replace the valve if it is bad.
There is a obstruction in the lines to the height control valve.	Check the air pressure at the height control valve supply port. Remove any obstruction or restriction to air flow to the valve.
The pressure protection valve is not allowing air to flow to the height control valve.	Check the operation of the pressure protection valve between the secondary air tank and the height control valve. Replace the valve if it is not operating correctly.

Problem—One Side of the Vehicle Is Higher Than the Other

Problem—One Side of the Vehicle Is Higher Than the Other	
Possible Cause	**Remedy**
The axle seat spacer thickness is not the same on each side.	Adjust the spacers so that the frame is level before adjusting the ride height.
The load on the vehicle is not distributed evenly.	Change the position of the load to ensure equal weight on each side.
There is an obstruction to air flow to the air bags on one side of the vehicle.	Disconnect the fittings and test the flow to the air bags on the lower side of the vehicle.
The height control valve or relay valve has an internal restriction.	Check for the same pressure at the ports on each side of the valve. Replace the valve if the pressure is not the same.
The air bags or fittings have a leak.	Listen for leaks at the air bags, tubes, and fittings. Tighten the fittings, if loose, or replace any bad parts.

Problem—The Ride Height Is Not Constant

Problem—The Ride Height Is Not Constant	
Possible Cause	**Remedy**
Air is leaking from the air bags or lines.	Listen or use soap bubbles to find air leaks. Tighten or replace leaking fittings or air bags.
The height control valve is not working correctly.	Make sure that no air is exhausted from the height control valve when the lever is in the horizontal position and that the air bags inflate when the lever is raised. The bags must deflate when the lever is pushed down. There must be a slight delay between the lever movement and the valve operation. Check for fluid leaks from the height control valve. Replace the valve if damaged.

Troubleshooting

Problem—The Ride Height Is Not Constant	
Possible Cause	**Remedy**
There is an obstruction to air flow to the air bags.	Disconnect the fittings and test the flow to the air bags.
The height control valve has a restriction at the exhaust port.	Check for air exhausting from the valve when the height control lever is pushed down.
The height control linkage is loose.	Make sure that all the jam nuts are tight and that the ball sockets are not worn.

Problem—The Ride Height Measurement Is Not Correct

Problem—The Ride Height Measurement Is Not Correct	
Possible Cause	**Remedy**
The vehicle is loaded.	The ride height of a loaded vehicle will be slightly lower than that of an unloaded vehicle. Adjust the ride only when the vehicle is unloaded.
The ride height adjustment is not correct.	Adjust the ride height as described in **Subject 180**.
Air is leaking from the air bags or lines.	Listen or use soap bubbles to find air leaks. Tighten or replace leaking fittings or air bags.
The height control valve is not working correctly.	Make sure that no air is exhausted from the height control valve when the lever is in the horizontal position and that the air bags inflate when the lever is raised. The height control linkage is loose.	Make sure that all the jam nuts are tight and that the ball sockets are not worn.

Problem—The Air Springs Have Cuts

Problem—The Air Springs Have Cuts	
Possible Cause	**Remedy**
The ride height is adjusted too high.	Adjust the ride height so that the air bags are not continually overinflated.
The tires are too wide and are rubbing the air bags.	Install the correct tires.
A shock absorber or mount is broken.	Replace any broken components.

Problem—The Vehicle Does Not Track Straight

Problem—The Vehicle Does Not Track Straight	
Possible Cause	**Remedy**
The axle alignment is not correct.	Adjust the alignment with shims at the front of the torque rods.
The bushings in the torque rods are worn.	Replace the worn bushings.

Problem—The Vehicle Does Not Track Straight	
Possible Cause	**Remedy**
The bushings in the transverse rods are worn.	Replace the worn bushings.
A shock absorber or mount is broken.	Replace any broken components.
The U-bolt high nuts are loose.	Periodically tighten the nuts as described in **Specifications 400**.
The suspension fasteners are loose or damaged.	Tighten or replace the fasteners.

Problem—The Vehicle Vibrates When Driven

Problem—The Vehicle Vibrates When Driven	
Possible Cause	**Remedy**
The ride height is not correct.	Adjust the ride height as described in **Subject 180**.
The axle housing rotational alignment is not correct.	Adjust the rotational alignment of the axle housing with wedge-shaped shims at the axle seats. The driveline U-joint angles must be with 1% of each other.
The shock absorbers are worn or disconnected.	Replace the shock absorbers, if worn, or tighten the mounting fasteners.
The bushings in the torque rods are worn.	Replace the worn bushings.
The U-bolt high nuts are loose.	Periodically tighten the nuts as described in **Specifications 400**.
The suspension fasteners are loose or damaged.	Tighten or replace the fasteners.
The frame is not level from front to rear.	Check and adjust the ride height at the front suspension and each rear axle. The frame should not slope more than 1/2 inch (13 mm). Correct the ride height if not at specifications.

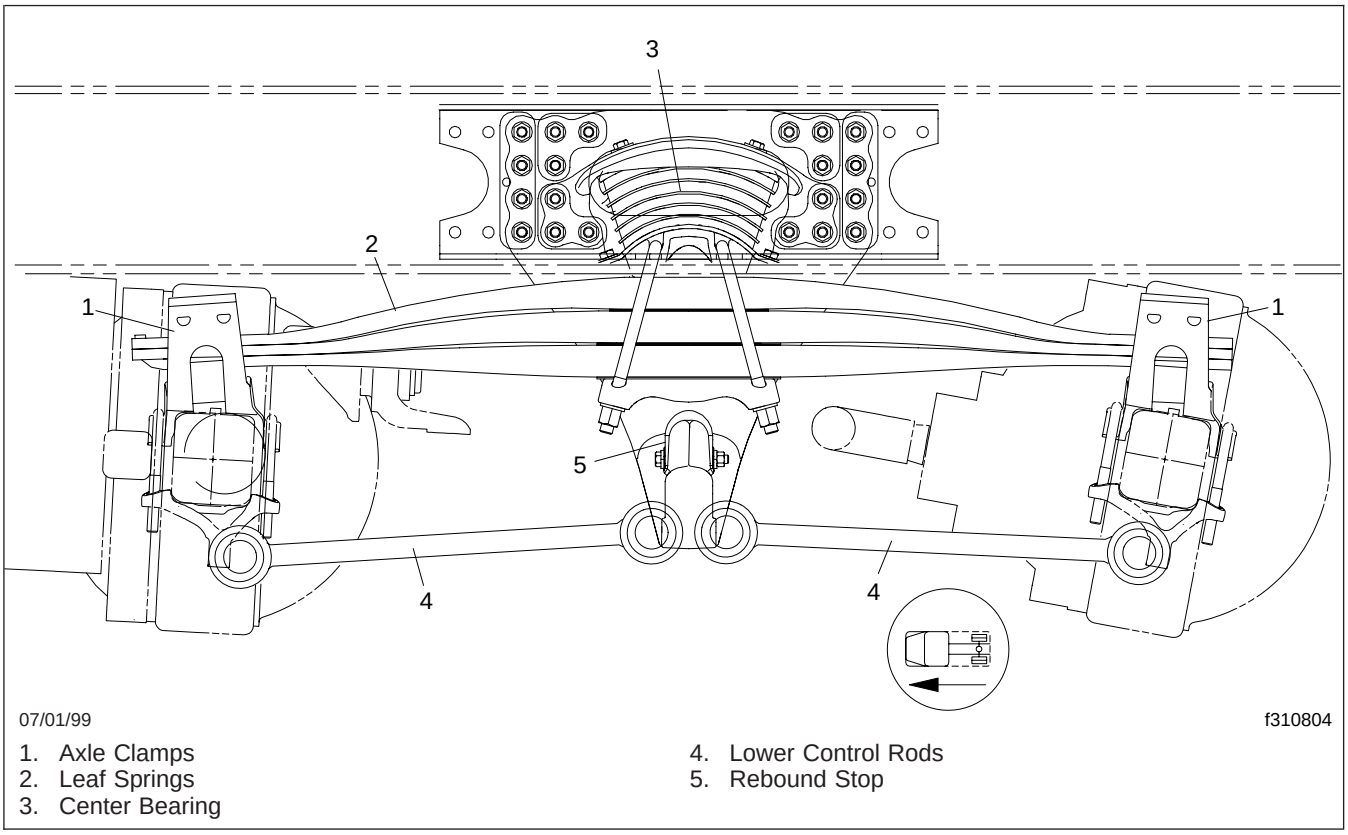
General Description



The TufTrac Suspension (**Fig. 1**) is heavy-duty "six rod" tandem-axle suspension option for trucks built for severe on/off highway work. The TufTrac design allows a truck to maneuver over bumps, ridges and washboard roads that typically generate high rates of axle articulation, without bottoming out the suspension or losing traction.

The TufTrac suspension is available in three weight ratings – 40,000-, 46,000- and 52,000-pound (18 144-, 20 865-, 23 586-kilogram) capacities. The 40,000-pound (18 144-kilogram) capacity suspension uses two taper leaf springs and has an axle spacing of 54 inches. The 46,000-pound (20 865-kilogram) capacity suspension has three leaf springs (shown in this section), while the 52,000-pound (23 586-kilogram) suspension features four leaf springs. Both the 46,000-pound (20 865-kilogram) and the 52,000-pound (23 586-kilogram) suspensions have a standard axle spacing of 56 inches.

Principles of Operation

Six functional links in the TufTrac suspension maintain the positions of the axles. Side-to-side axle movement is controlled by two v-rods from the frame to the axles at the top of the suspension. Four bar links from the frame to the axles at the bottom control the forces of driving and braking as well as fore-and-aft road shocks. Vertical loads are carried by the rubber-isolated parabolic taper leaf spring packs.

Replacement

1. Park the vehicle on a level surface, shut down the engine and apply the parking brakes. Chock the tires.
2. Remove the lower shock mounting nut and washer. See **Fig. 1**.
3. Remove the upper shock mounting nut and washer.
4. Remove the upper and lower mounting bolts and remove the shock absorber.
5. Position the new shock absorber in place and install the mounting bolts.
6. Loosely fasten the bolts with the nuts and washers removed from the old shock absorber.
7. Torque each mounting nut 241 lbf·ft (327 N·m).
8. Remove the chocks from the tires.

   2.2 Slide the rebound stop from the mounting bracket.

3. Remove the upper two fasteners on the center bearing.
4. Jack up the vehicle under the rear axle.
5. Support the rear frame rails with jack stands, then lower the jack. This will clear the center bearing from the top of the mounting bracket. See **Fig. 2**.
6. Remove the lower center bearing bolts attached to the spring assembly casting. Discard the bolts.
7. Remove the center bearing. See **Fig. 3**.
8. Position the new center bearing in the mounting bracket.
9. Install the upper mounting bolts and tighten 68 lbf·ft (92 N·m).
10. With the jack, raise the rear axle until bottom of the center bearing meets the mounting bracket on the leaf springs.

IMPORTANT: Be sure to use new bolts with loctite (p/n 23–12576–125) when attaching the center bearing to the leaf spring casting.

11. Install new lower mounting bracket bolts (p/n 23–12576–125). Tighten the bolts 155 lbf·ft (210 N·m).

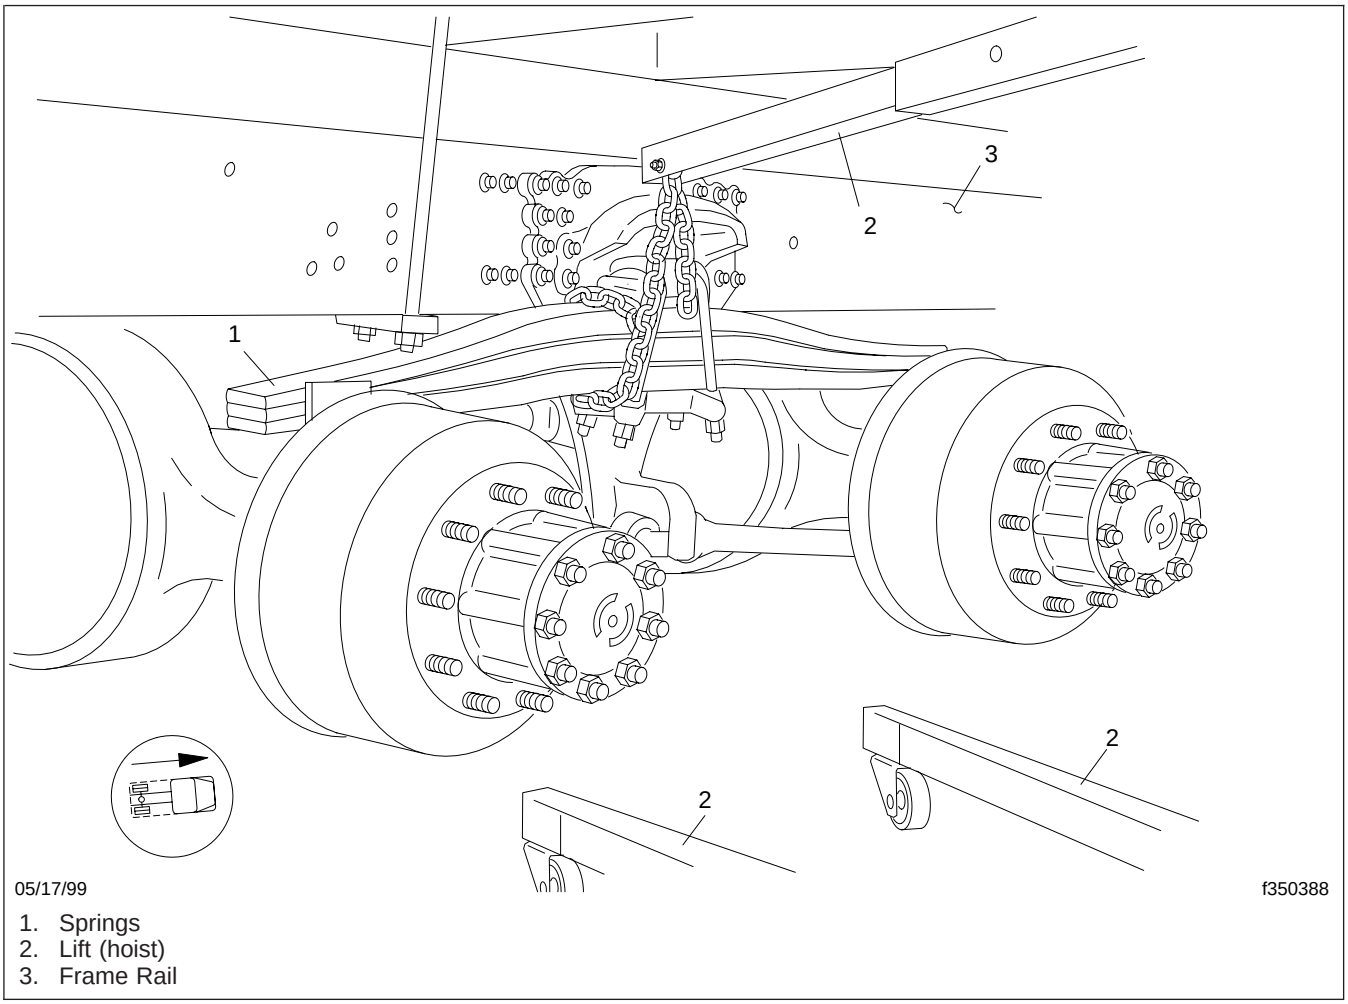
3. Remove the center bearing. See **Subject 110**.
4. With the vehicle still raised, remove the wheels on both rear axles on the side the spring assembly will be replaced. For instructions, see **Group 40**.

⚠ WARNING

Do not attempt to remove the spring assembly by hand. The assembly is very heavy and attempting to remove it could result in bodily injury.



5. Using a lift (i.e. engine hoist), remove the leaf spring assembly from the vehicle. See **Fig. 2**.

⚠ WARNING

Do not attempt to install the spring assembly by hand. The assembly is very heavy and attempting to remove it could result in bodily injury.

6. Place the new spring assembly on the vehicle.
   - 6.1 Attach the new assembly to the lift.
   - 6.2 Using the lift (hoist), lift the assembly into place on the axle clamps.
7. Install the center bearing. For instructions, see **Subject 110**.
8. Install the tip pad and bolts on each axle clamp. Tighten the bolts 37 lbf·ft (50 N·m). See **Fig. 1**.
9. If not already installed, install the rebound stop and mounting bolt. Tighten the nut 68 lbf·ft (92 N·m).
10. Install the wheels. For instructions, see **Group 40**.
11. Return the vehicle to its normal operating position.
12. Remove the chocks from the tires.

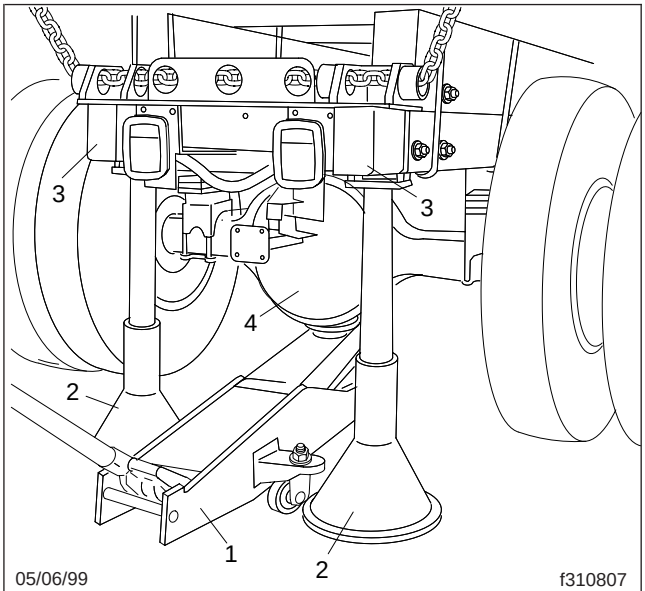
3. Lower the jack under the axle. See **Fig. 2**.
4. Remove the bolts holding both rods between the rear axles, below the rebound stop. See **Fig. 3**.
5. Remove the nut and bolt from the axle clamp.
6. Remove the control rod from the vehicle.



IMPORTANT: When installing the rods make sure the labels on the rods are facing upward. Forward axle rods are marked "FDA" and rear axle rods "RDA."

7. Fasten the new control rod to the axle clamp. Tighten the nut 136 lbf·ft (184 N·m).
8. Fasten the other end of the rod to the bracket below the rebound stop. Tighten the nut 136 lbf·ft (184 N·m).
9. Return the vehicle to the normal operating position.

V-Rod Replacement

1. Park the vehicle on a level surface, shut down the engine, and apply the parking brakes. Chock the tires.
2. Raise the rear axle and support the frame rails with jack stands.
3. Lower the jack under the axle. See **Fig. 2**.

3. Disconnect the shock absorbers from the lower axle retainer on the left suspension spring.
   - 3.1 Remove the lower shock mounting nuts and washers.
   - 3.2 Remove the lower shock absorber mounting bolts.
4. Disconnect the two lower torque control rods from the lower axle retainers on the left side of the vehicle.
5. Loosen and remove the U-bolt nuts and washers, and discard.
6. Remove the brake cam tube support bracket from the left rear axle.
7. Remove the lower axle retainers from the left forward and left rear drive axles, and discard.
8. Remove the axle U-bolts from the left forward drive axle and the left rear drive axle, and discard.
9. Jack up the center of the left suspension spring (at the center bearing, between the tandem) and support with the jack stands at the frame. See **Fig. 2**. Make sure that all of the weight has been relieved from the axle clamp group and that there is sufficient clearance to remove the upper axle clamp.
10. Remove the lower spring tip pads from the left forward and left rear drive axles.
11. Remove the upper axle clamps from the left forward and left rear drive axles. Discard the clamps.

Axle Clamp and Retainer Replacement

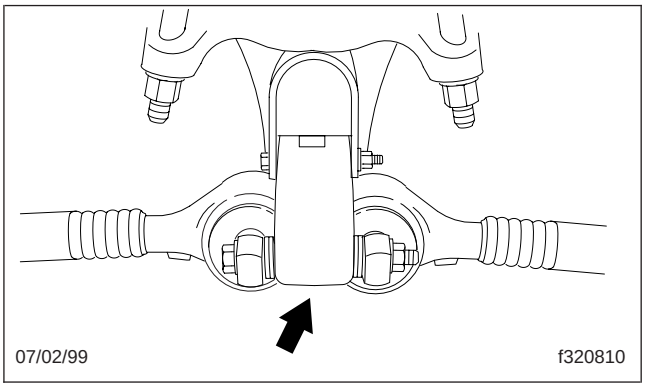

Fig. 2, Jack the Vehicle Here

12. Install the new upper axle clamps from the applicable warranty kit to the left forward and left rear drive axles. Locate the dowel pin through the hole in the bottom of each axle clamp to confirm proper alignment

NOTE: Confirm that you are installing the correct upper axle clamps before continuing. You are able to visually identify the new upper axle clamp because the step has been removed from the area directly above the U-bolt saddles. See **Fig. 3**.

13. Install the lower spring tip pads into the left front and rear axle clamps.
14. Jack up the left suspension spring, remove the jack stands, and lower the suspension spring. Ensure while the spring is being lowered that it is seated correctly onto the lower spring tip pads.
15. Install the new lower axle retainers onto the left forward and rear drive axles.
16. Install the brake cam tube support bracket onto the left rear axle.
17. Install the U-bolts on the left forward and rear drive axles.

    IMPORTANT: Install two washers for each U-bolt nut.

    17.1 Install each U-bolt over the U-bolt saddle in the upper axle clamp and through the holes in the lower axle retainer.

    17.2 Install the washers and finger-tighten the nuts in the order shown in **Fig. 4**.

    Make sure all brackets are snug against the axle housing before proceeding to the next step.

    IMPORTANT: U-bolt nuts must be tightened in the order shown in **Fig. 4**.

    17.3 Tighten the nuts 60 lbf·ft (81 N·m) and then to 200 lbf·ft (271 N·m) in two separate rotations following the order shown in **Fig. 4**.

18. Install the lower torque control rods to the lower axle retainers on the left side of the vehicle and tighten 136 lbf·ft (184 N·m).
19. Install the shock absorbers to the lower axle retainers.

    19.1 Install the lower shock mounting bolts.

    19.2 Install the lower shock absorber mounting washers and nuts and tighten by hand.

    19.3 Tighten the lower shock absorber mounting nuts to 241 lbf·ft (327 N·m).

20. Install the spring tip pads to the left suspension spring.

    20.1 Install the spring tip pads to the upper axle clamps.

    20.2 Install the bolts to secure each upper spring tip pad and tighten 37 lbf·ft (50 N·m).

21. Repeat the above steps for the right suspension spring.
22. Remove the chocks from the tires.

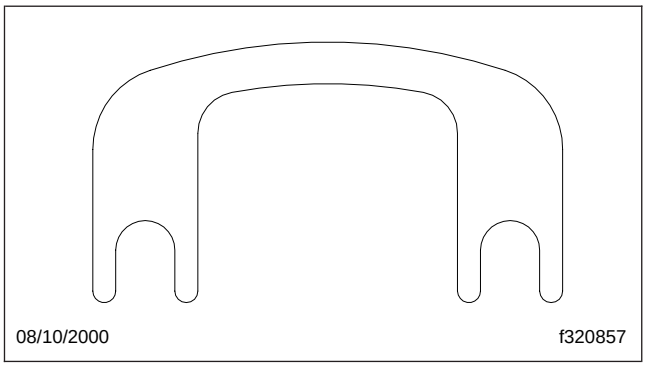
Adjustments

Rear axle positioning and alignment on a vehicle equipped with the TufTrac suspension is determined by the length of the lower control rods and the V-rods. See **Fig. 1**. The length of the control rods and V-rods can be controlled by the addition or removal of shims at the mounting points of the control rods and/or V-rods. The addition of shim(s) between the control rod or V-rod and its mounting will effectively lengthen the rod moving the axle relative to the frame. Conversely, the removal of shim(s) will shorten the length of the rod, moving the axle in the opposite direction.

The lower control rods use a horse-shoe style of shim (**Fig. 2**) while the V-rods use hardened washers for shims.



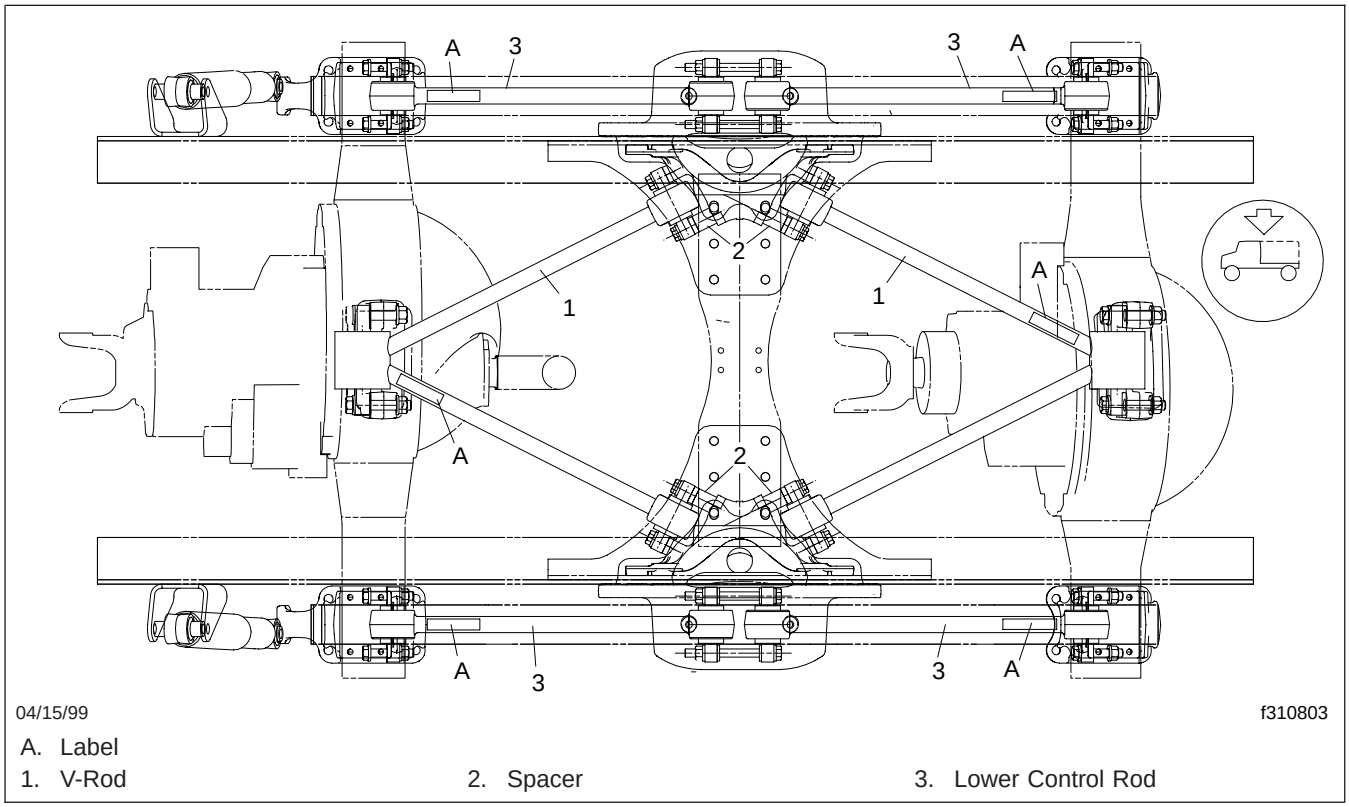


Fig. 2, Lower Control Rod Shim

Control rod shimming is performed at the center bracket. See **Fig. 3**. The purpose of this shim adjustment is to provide axle alignment and planing adjustment (angle of the axle from vertical in the side view).

Alignment Adjustments

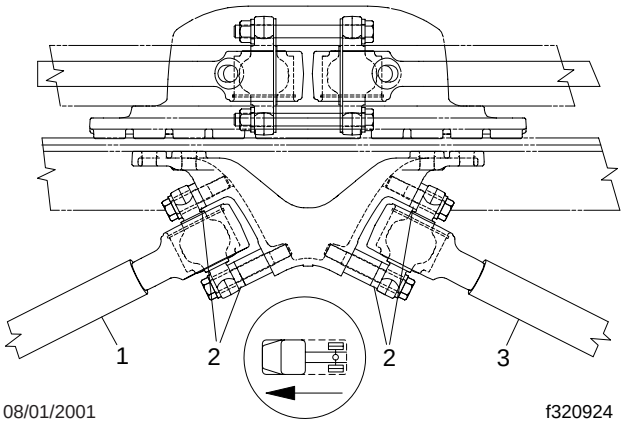
NOTE: Alignment refers to the squareness of the axles to each other and the frame rails viewed from the top of the vehicle.

Add or remove shims at the center bracket to achieve proper alignment. See **Fig. 3**. To minimize the effect on planing angles, if possible, add or remove shims from both sides of the vehicle.

When one 3mm thick shim is added and one removed (from the opposite side) the axle position is affected as follows:

- Angle of the axle in the plan view: 0.33 degrees
- Fore-aft movement of the wheel at the outside (assuming 97.6 in. (2480 mm) wheel to wheel distance): 0.283 in. (7.2 mm)

Planing Adjustments



NOTE: planing refers to the angle of the axle from vertical in the side view.

Add or remove shims at the center bracket to change the planing angle. See **Fig. 3**. Unless alignment is required, an equal number of shims should be used left and right for a given axle; example, when adding one shim to the left forward rod add one shim to right forward rod. A shim 0.12 inch thick changes the planing angle 0.3 degrees.

V-Rods

Axle Tracking Adjustments

The tracking adjustment of the forward and rear axles is done by adding and/or removing hardened washers between the V-rod bar pin and the frame-mounted bracket. See **Fig. 4**.

Preliminary Checks

Precision instruments and equipment are needed for accurately measuring and adjusting wheel alignment. Refer to the operating instructions provided by the wheel alignment equipment manufacturer.

Before checking or correcting wheel alignment, make sure the vehicle is at curb weight. Curb weight is the weight of the unloaded vehicle complete with accessories and full fuel tanks.

If a road test is necessary, the route should be one that allows full left and right turns and full stops. It should also include a length of straight, level road to check the steering wheel position during straight-ahead driving.

During the road test, note any steering effort and possible roughness. Check for looseness, too much wheel play, any tendency for the vehicle to lead in one direction, and for pull during stopping.

Note the position of the steering wheel while driving on a straight, level road. When the steering gear is centered, the steering wheel spokes should be within 10 degrees of the 4 and 8 o'clock positions. **See Fig. 1.**

NOTE: These steering wheel location specifications are for reference and apply only for the conditions of this road test. Variations outside of these specifications may occur later when the vehicle is placed in service.

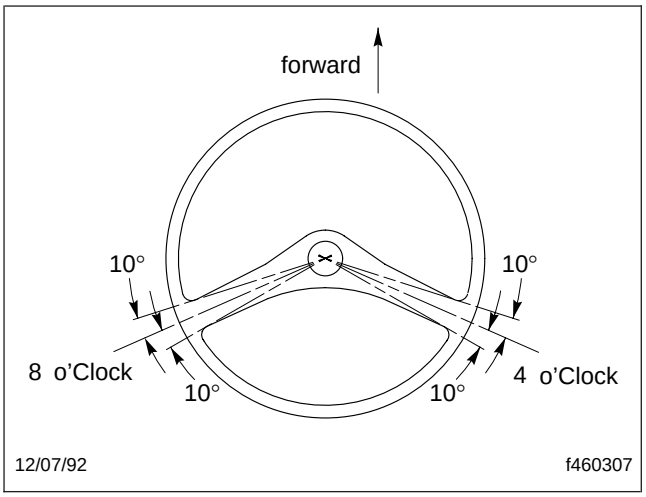

Fig. 1, Steering Wheel Position

If there are any problems, **refer to "Troubleshooting, 300."**

1. Steering axle wheel assemblies should be balanced, especially for vehicles that travel at sustained speeds of more than 80 km/h (50 mph). Off-balance wheel assemblies cause vibrations that result in severely shortened life for tires, and steering suspension parts.
2. Do not mix tires of different size, type, or weight. Tire wear should be even and not worn to limits exceeding government specifications. **Refer to the wheels and tires group** in this manual and the vehicle maintenance manual, for more information. Replace any tire that is excessively worn.
3. Check the inflation pressure of the tires. **Refer to the wheels and tires group** in this manual for recommended pressures. An underinflated tire causes tread wear completely around both tire shoulders. An overinflated tire causes tread wear in the center of the tire. **Refer to Fig. 2.**
4. Check for out-of-round wheels, rims, or wheel stud holes. Replace the wheel if any of these conditions exist.
5. On each side of the vehicle, check the height of the chassis above the ground. Sagging, fatigued, or broken suspension springs create a lopsided vehicle appearance. This causes an unbalanced weight distribution. Anything that changes the ratio of weight on the springs affects the alignment angles and also the tire tread contact area. Replace damaged springs as instructed **in the suspension group.**
6. Inspect the front axle beam (also called the axle center) for bends or twists. If the axle beam is bent or twisted over 1/2 degree, replace it before aligning the front axle wheels.
7. Check for damaged, worn, or bent steering gear or linkage parts. Make sure the steering gear is centered. Replace damaged components, and adjust the steering gear, using the instructions **in the steering group.**
8. Check the steering angle, and adjust the axle steering stops, as needed. **Refer to "Steering Angle Checking and Adjusting, 110."**

Preliminary Checks

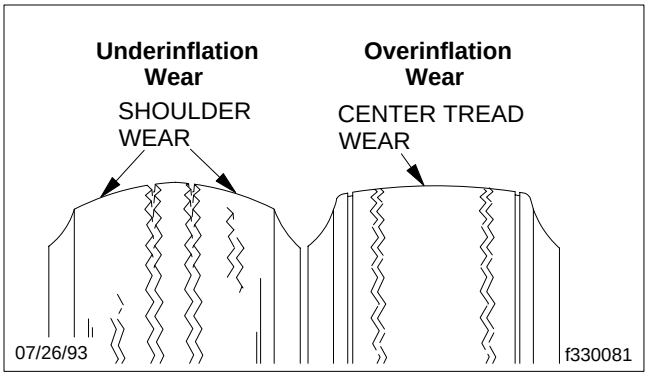

Fig. 2, Tire Damage Due to Underinflated or Overinflated Tires

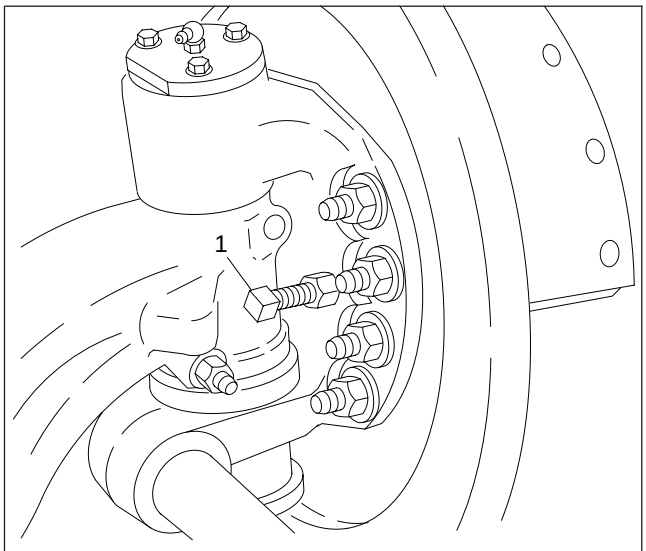


Checking and Adjusting

Steering (or turning) angle is the degree of front wheel movement from a straight-ahead position to either an extreme right or left position. Although front wheel movement can be limited by the amount of internal travel in the steering gear, it generally depends on how much clearance there is between chassis components and the tire and wheel assemblies. All axles have adjustable stopscrew-and locknut-type axle stops (**Fig. 1**), which are located on the rear side of each front axle spindle.

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Make sure the steering gear is in the center of travel when the wheels are in a straight-ahead position. Center the gear, using the instructions in the steering gear section in the **steering group**. Bottoming of the steering gear must not occur when making an extreme right or left turn.
2. If using stationary turn-plates or turntables (**Fig. 2**), drive the vehicle on the plates; the tires must be exactly straight ahead. Apply the parking brakes.

   If using portable gauges, apply the parking brakes, chock the rear tires, and raise the front of the vehicle. Place a turn-plate or turntable under each tire. With the tires exactly straight ahead, lower the vehicle so that the tires rest on the center of the gauges.
3. Remove the lockpins from the gauges, and adjust the dials so that the pointers on both gauges read zero.
4. With the brakes fully applied, turn the steering wheel clockwise to the end of travel. Have someone check both sides of the vehicle for interference at the tires and wheels. There must be at least 0.50 inch (13 mm) clearance from any fixed object, and 0.75 inch (19 mm) from any moving object.

1. Stopscrew and Locknut

Fig. 1

   If necessary, loosen the stopscrew locknut; adjust the stopscrew to contact the axle when the maximum turning angle of the wheels is determined.

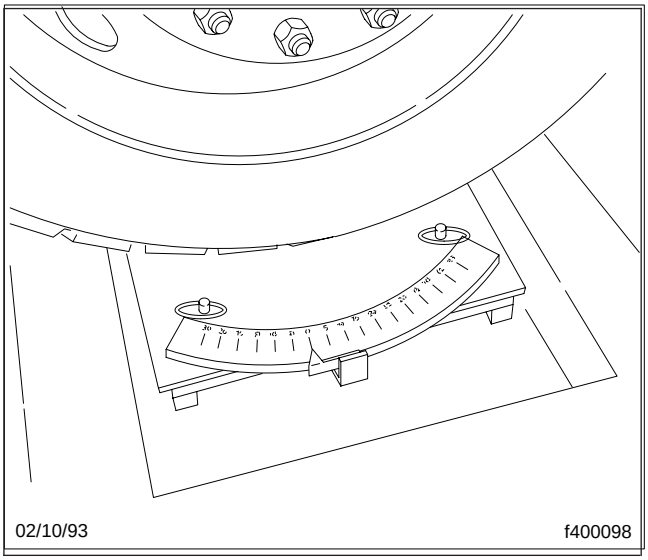
   Tighten the locknut to the value in the torque table in **Specifications, 400**.

   Repeat the step with the steering wheel turned counterclockwise. Adjust the axle stop, as needed.

NOTE: The turning angle may not be the same on both sides.

5. Adjust the steering gear so that pressure is released ahead of the axle stop. This will prevent possible damage to the steering or axle components. For poppet valve adjustment instructions, refer to the steering gear section in the **steering group**.
6. Drive the vehicle off the turn-plates or turntables, or remove them from under the tires and lower the vehicle.

Steering Angle Checking and Adjusting



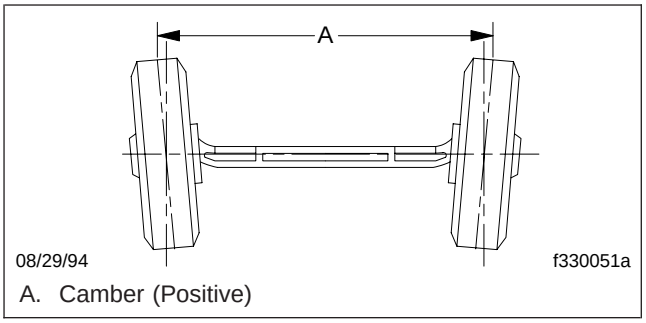


Fig. 2, Turn-Plate (Turntable), Stationary Type

Checking (See Fig. 1)

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Apply the parking brakes and chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground. Place safety stands under the axle; make sure the stands will support the weight of the cab, frame, and front axle.
3. Before measuring camber, check the front wheel bearings for wear and incorrect adjustment. Try moving the wheel on the axle spindle (steering knuckle) either by grasping the front tire on the top and bottom, or by using a bar for leverage. If movement between the brake drum and the backing plate or other axle-mounted reference point is 0.05 inch (1 mm) or more, the bearings may be worn or incorrectly adjusted. Inspect the wheel bearings for damage using the instructions in the front axle group of the vehicle maintenance manual. If needed, replace or adjust the bearings using the instructions in **Section 33.01** of this manual.
4. Remove the safety stands, and lower the vehicle to the ground.
5. Using the alignment equipment manufacturer's instructions, measure the front wheel camber.

A. Camber (Positive)

Fig. 1, Camber Angle

6. Compare the camber angles with those shown in the applicable table in **Specifications, 400**. Differences between the measurements taken in this subject and the angles in the applicable table in **Specifications, 400** are caused by damaged (bent) axle components.

   Incorrect camber angles could be caused by damage in one or more of the following front axle components: the knuckle pin, the knuckle pin bushings, the axle spindle, or the axle beam. Replace twisted or otherwise damaged components. Don't try to straighten twisted or bent components; replace them with new components. If a bent or twisted front axle knuckle pin, axle spindle, or axle beam has been straightened, the axle warranty will be voided.

WARNING

WARNING: Trying to straighten a twisted or bent front axle component can crack or weaken it. A cracked or weakened axle component could result in a collapsed front axle or the loss of a wheel, which could cause serious personal injury.

7. Remove the chocks from the tires.

Checking and Adjusting

(See Fig. 1)

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

Using the alignment equipment manufacturer's operating instructions, measure the front wheel caster.

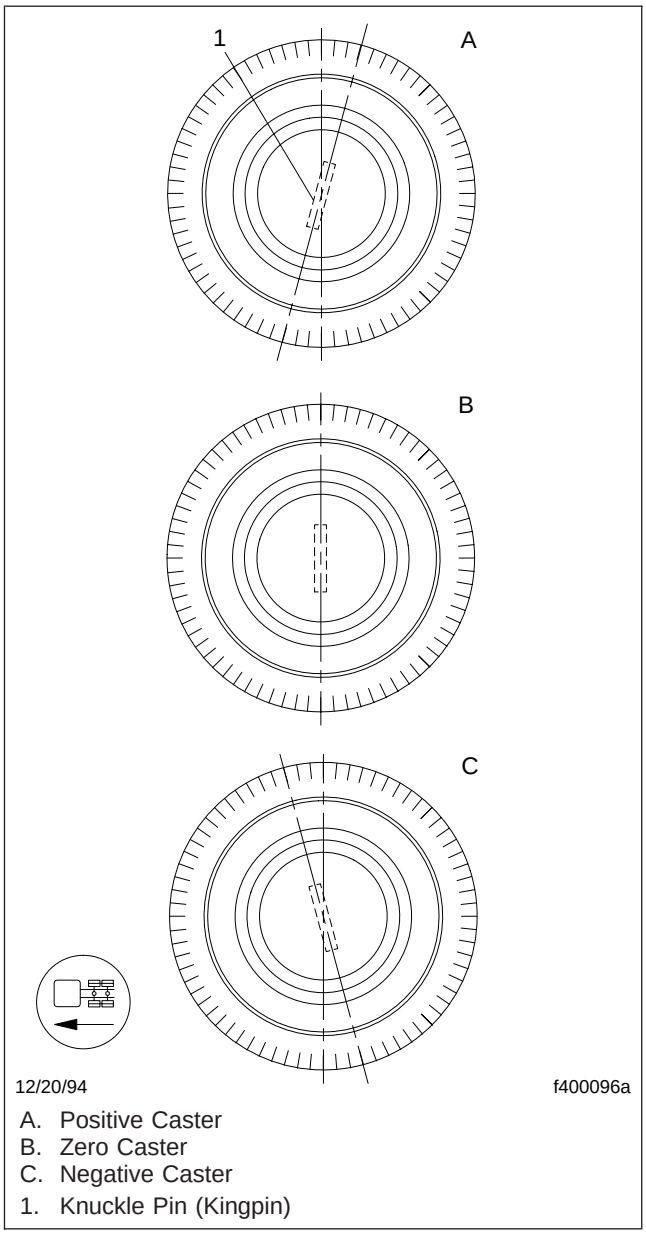
Compare the caster angles with those shown in the applicable table in **Specifications, 400**. If needed, adjust the caster angle by placing wedge-shaped shims between the axle spacer and the axle beam, as follows (**see Fig. 2**):

IMPORTANT: Extreme angle shims cannot be used to correct caster angles that vary by more than 2 degrees from the values in the table in **Specifications, 400**. Weak or broken leaf springs, or worn shackle bushings, can cause extreme deviations to caster angles. Replace damaged parts before doing caster adjustments.

1. Apply the parking brakes and chock the front and rear tires.
2. Back off the U-bolt high nuts from the U-bolts on one side of the front axle. **See Fig. 2.**
3. Raise the spring away from the axle enough to allow removal of the front caster shim.
4. Remove the shim, and install one that will provide the correct caster angle, as specified in the table in **Specifications, 400**. Install the dowel pin and check penetration.

IMPORTANT: Place front caster shims between the axle beam and the axle spacer. **See Fig. 2.**

5. Lower the vehicle onto the axle.
6. Coat the threaded ends of the U-bolts with chassis lube or an antiseize compound, such as Loctite® 242. Tighten the U-bolt nuts to the value in the torque table in **Specifications, 400**.



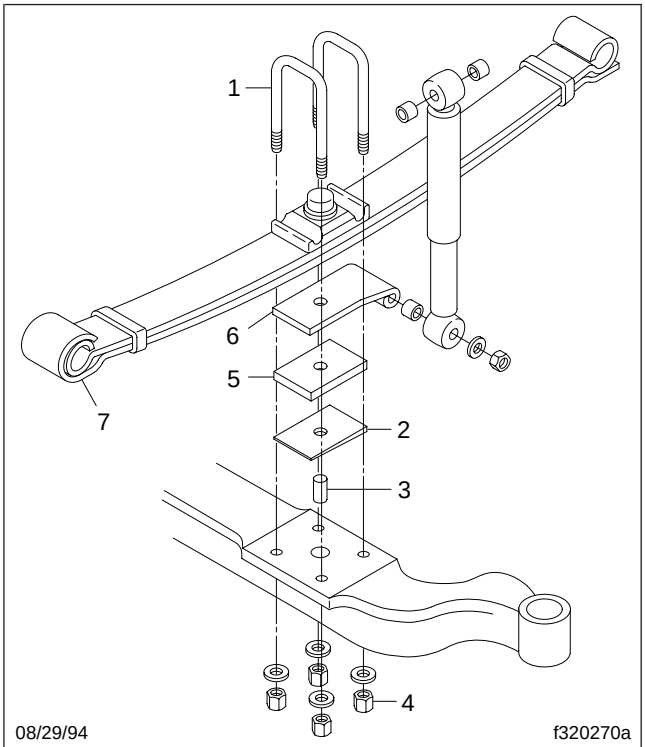


Fig. 1, Caster Angle

U-bolt high nuts need periodic retightening. Refer to the suspension group in the vehicle maintenance manual for recommended intervals.

Fig. 2

⚠ CAUTION

CAUTION: Failure to periodically retighten the U-bolt high nuts could result in spring breakage and abnormal tire wear.

7. Using the steps above, replace the shim on the other side of the axle.
8. Remove the chocks from the tires. Do a final caster angle check.

Checking and Adjusting

(See Fig. 1)

NOTE: If using electronic alignment equipment, measure the wheel toe-in following the manufacturer's operating instructions. Compare the measurement with that shown in the table in **Specifications, 400**. If corrections are needed, go to the step in this subject which describes loosening the tie rod clamp nuts, and proceed.

If electronic alignment equipment is not available, do all the steps.

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Apply the parking brakes and chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground. Place safety stands under the axle. Make sure the stands will support the weight of the cab, axle, and frame.
3. Using spray paint or a piece of chalk, mark the entire center rib of each front tire.
4. Place a scribe or pointed instrument against the marked center rib of each tire, and turn the tires. The scribes must be held firmly in place so that a single straight line is scribed all the way around each tire.
5. Place a turn-plate or turntable under each tire. Remove the safety stands from under the axle, then lower the vehicle. Remove the lockpins from the gauges; make sure the tires are exactly straight ahead.
6. Place the trammel bar at the rear of the front tires; locate the trammel pointers at spindle height, and adjust the pointers to line up with the scribe lines. Lock in place. Make sure that the scale is set on zero.

NOTE: If turn-plates or turntables are not available, lower the vehicle. Remove the chocks from the rear tires and release the parking brakes. Move the vehicle backward and then forward about two meters (six feet).

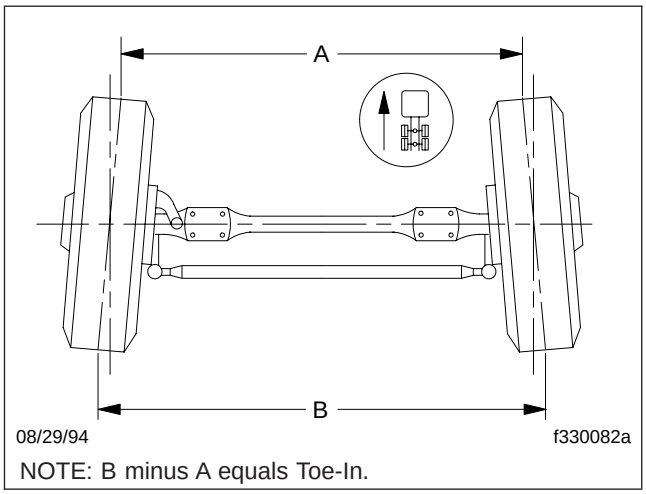

Fig. 1, Wheel Toe-In (Overhead View)

7. Place the trammel bar at the front of the tires as shown in **Fig. 2**. Adjust the scale end so that the pointers line up with the scribe lines. **See Fig. 3.**
8. Read the toe-in from the scale. Compare the toe-in with the value in the table in **Specifications, 400**. Make corrections if necessary.
9. Loosen the tie rod (cross tube) clamp nuts, and turn the tie rod as needed.

   If the vehicle is not on turn-plates or turntables, move the vehicle backward and then forward about two meters (six feet). This is important when setting the toe-in on vehicles equipped with radial tires.

   Do a final wheel toe-in check to make sure that it is correct.

   Tighten the clamp nuts to the values in the table in **Specifications, 400**.
10. If not already done, remove the chocks from the rear tires. Road test the vehicle.

Wheel Toe-In Checking and Adjusting

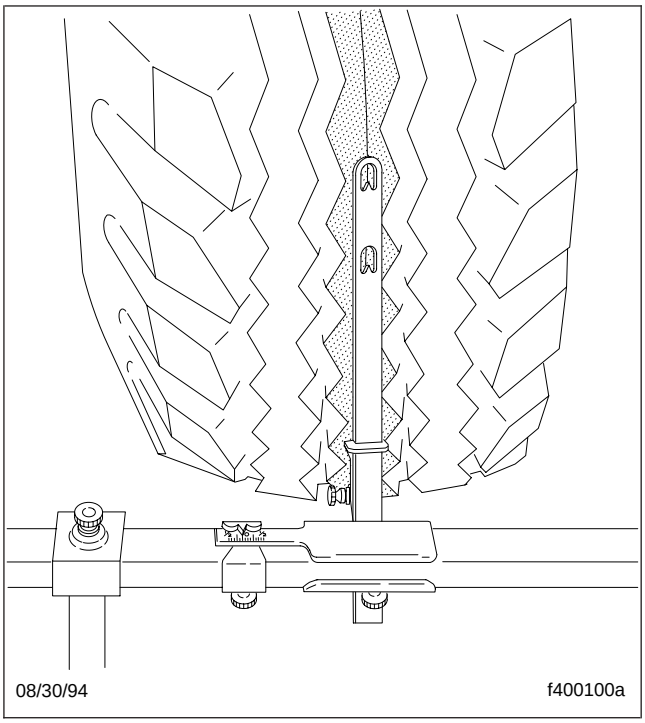

Fig. 3, Calculating Wheel Toe-In

General Information

Correct front axle wheel alignment is needed to ensure long tire life, ease of handling, and steering stability.

Three factors are involved in wheel alignment: camber angle, caster angle, and wheel toe-in.

Camber angle **(Fig. 1)** is the vertical tilt of the wheel as viewed from the front of the vehicle. Camber angle is measured in degrees, and is not adjustable. Positive camber is the outward tilt of the wheel at the top. Excessive positive camber in one wheel causes the vehicle to pull in the opposite direction, rapidly wearing the outboard side of the tire tread. Negative camber is the inward tilt of the wheel at the top. Excessive negative camber in one wheel causes the vehicle to pull in the same direction that the negative-camber wheel is on, wearing the inboard side of the tire tread. If camber angles are not correct, the tires will wear smooth around the edge on one side. **See Fig. 2.**

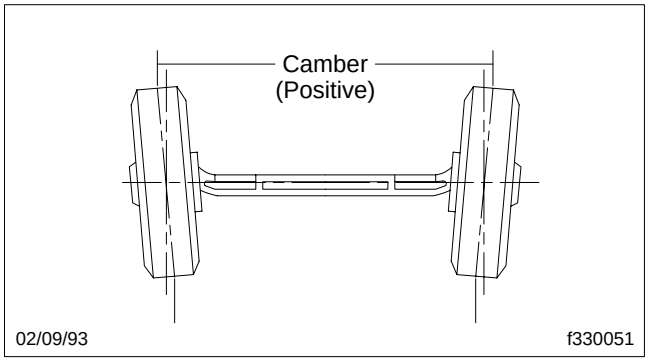

Fig. 1, Camber Angle

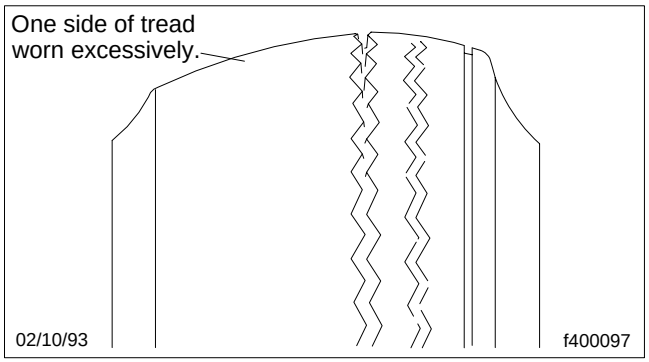

Fig. 2, Tire Damage Due to Excessive Camber

Caster angle **(Fig. 3)** is the tilt of the knuckle pin (or kingpin) as viewed from the side. Caster angle is measured in degrees and it is adjustable. A positive caster angle is the tilt of the top of the knuckle pin toward the rear of the vehicle. A negative caster angle is the tilt of the top of the knuckle pin toward the front of the vehicle. Caster angles are based on the design load of the vehicle. An incorrect caster angle does not cause tire wear. However, a positive caster angle that exceeds specifications could cause vehicle shimmy, road shock, and an increased steering effort. A negative caster angle that does not meet specifications could cause unstable steering. The vehicle may wander and weave, and extra steering effort may be necessary. After leaving a turn, the tendency to return to and maintain a straight-ahead position is reduced. Too much or too little caster in one wheel can cause erratic steering when the service brakes are applied to stop the vehicle.

Wheel toe-in **(Fig. 4)** is the distance in inches that the front of the wheels are closer together than the rear of the wheels, as viewed from the top. Wheel toe-in is adjustable. If it is not adjusted correctly, the vehicle could pull to one side while driving. Wheel shimmy and cupped tire treads (indentations on the road contact surface of the treads) could occur. Also, rapid or severe tire wear on the steering axle could occur, usually in a feather-edged pattern. **See Fig. 5.**

Advanced wear patterns can be seen, but less severe wear patterns are detected only by rubbing the palm of your hand flat across the tire tread.

Feather-edging more often affects the front tire on the passenger's side of the vehicle, and is usually more apparent on the outside grooves of the tire.

If any of the conditions listed above occur, the vehicle could need a front end wheel alignment, and possibly, drive axle alignment. However, in some cases these conditions are not wheel alignment related: **refer to "Troubleshooting, 300"** for other possible causes.

If excessive tire tread wear has resulted from incorrect wheel alignment, replace the damaged tires. For minimum tread wear specifications, refer to the wheels and tires group of the vehicle maintenance manual.

Troubleshooting

Service instructions for most of the remedies below are found by referring to the index in the back of this manual. For axles, refer to the service literature provided by either Rockwell or Eaton Corporation. For tire inflation pressures, refer to the wheels and tires section in this manual. For more steering system troubleshooting information, refer to the steering section in this manual.

Problem - Hard Steering

Problem - Hard Steering	
Possible Cause	**Remedy**
Tire pressure is low in one or both front tires.	Inflate tires to the correct pressure.
Binding in the steering gear due to a lack of lubrication.	Lubricate the steering gear. For instructions, refer to the vehicle maintenance manual.
Too much caster angle in the front wheels.	Check the caster angle and adjust as needed
The front suspension is sagging due to a damaged spring.	Repair or replace the spring as needed. For instructions, refer to the suspension section in this manual.
The axle spindle is bent.	Replace the spindle.
The frame is misaligned.	Check the frame alignment; correct, as needed.
Low pressure in the power steering system.	Repair the power steering system.
Steering gear is not assembled correctly.	Assemble the steering gear correctly.
King pins are binding.	Replace the king pins.
Steering arm geometry is incorrect.	Service the steering system as necessary.
Tie rod ends are hard to move.	Replace the tie rod ends.
Thrust bearing is worn.	Replace the thrust bearing.

Problem - Erratic Steering When the Brakes are Applied

Problem - Erratic Steering When the Brakes are Applied	
Possible Cause	**Remedy**
Tire pressure is low in one or both front tires.	Inflate the tires to the correct pressure.
One or more front axle spring U-bolt nuts are loose.	Check the U-bolt nuts for looseness. If loose, check the U-bolt for damage. Replace damaged parts; tighten loose nuts.
The brakes are not adjusted evenly.	Adjust the brakes on all axles. Also, check the operation of the slack adjusters.
Grease or oil contamination of the brake linings is reducing brake effectiveness.	Replace the brake linings and clean the drums. Find and correct the cause of grease or oil contamination.
The caster angle is wrong.	Check, and adjust as needed.
An axle spindle is bent.	Replace the axle spindle.
The front axle wheel bearings are worn or were incorrectly adjusted.	Check the bearings for wear or damage; replace as needed.

Troubleshooting

Problem - Vehicle Pulls to One Side During Operation

Problem - Vehicle Pulls to One Side During Operation	
Possible Cause	**Remedy**
Tire pressure is low in one or both front tires.	Inflate the tires to the correct pressure.
One or more of the alignment measurements are incorrect.	Check all the alignment measurements. Correct as needed.
The wheels or tires are out-of-round.	Inspect the wheels and tires. Replace out-of-round parts.
The front axle wheel bearings are too tightly adjusted.	Check the bearings for wear or other damage. Replace the bearings if needed.
The front suspension is sagging due to a damaged spring.	Repair or replace the spring as needed. For instructions, refer to the suspension section in this manual.
The axle spindle is bent.	Replace the spindle.
The frame is misaligned.	Check the frame alignment; correct as needed.
The rear axle(s) is out of alignment.	Check, and if needed, adjust the rear axle alignment.

Problem - Front Wheel Wander

Problem - Front Wheel Wander	
Possible Cause	**Remedy**
One or more wheels or brake drums are out-of-balance.	Balance the wheels. Check for out-of-round brake drums; correct as needed.
One of the front springs is weak or broken.	Repair or replace the spring as needed. For instructions, refer to the suspension section in this manual.

Problem - Front Wheel Shimmy

Problem - Front Wheel Shimmy	
Possible Cause	**Remedy**
Tire pressure is low in one or both front tires.	Inflate the tires to the correct pressure.
One or more wheels or brake drums are out-of-balance.	Balance the wheels. Check for out-of-round brake drums, correct or replace as needed.
One or more tires are out-of-round or bulged.	Replace the tire.
The front axle wheel bearings are worn or were incorrectly adjusted.	Check the bearings for wear or other damage. Replace the bearings if needed.
Parts of the steering gear or linkage are worn.	Test for play in the steering gear and linkage with the front tires off the ground. Replace parts as needed.
The axle spindle is bent.	Replace the spindle.
One or more of the alignment measurements are incorrect.	Check all alignment measurements and correct as needed.
The knuckle pin is loose due to worn bushings.	Inspect the knuckle pin and bushings for damage. Replace worn or damaged parts as needed.

Problem - Front Wheel Shimmy	
Possible Cause	**Remedy**
Shock absorbers are worn or damaged.	Check the shock absorbers and replace if needed.
Caster is out of adjustment.	Adjust the caster.

Problem - Vehicle Wanders

Problem - Vehicle Wanders	
Possible Cause	**Remedy**
Tire pressure is low in one or both front tires.	Inflate the tires to the correct pressure.
One or more of the alignment measurements are incorrect.	Check all of the alignment measurements; correct as needed.
The rear axle(s) is out of alignment.	Check the rear axle alignment and adjust as needed.
Parts of the steering gear or linkage are worn.	Test for play in the steering gear and linkage with the front tires off the ground. Replace parts as needed.
A knuckle pin is loose due to worn bushings.	Inspect the knuckle pin and bushings for damage. Replace worn or damaged parts.
The axle spindle is bent.	Replace the spindle.

Problem - Cupped Tires

Problem - Cupped Tires	
Possible Cause	**Remedy**
Tire pressure is too low or too high in one or both front tires.	Inflate or deflate the tires to the correct pressure.
One or more wheels or brake drums are out-of-balance.	Balance the wheels. Check for eccentric brake drums; correct or replace as needed.
The wheel toe-in is not correct.	Adjust the wheel toe-in.
The brakes are not adjusted evenly.	Adjust the brakes on all axles. Also, check the operation of the slack adjusters.
The front axle wheel bearings are worn or were not adjusted correctly.	Check the bearings for wear or other damage; replace them if needed.
The camber angle is not within specifications.	Check the front wheel camber angle. If not correct, find and replace the damaged axle component.

Problem - Steering Wheel Spokes Do Not Point at the 4 and 8 O'clock Positions

Problem - Steering Wheel Spokes Do Not Point at the 4 and 8 O'clock Positions	
Possible Cause	**Remedy**
The steering gear is not centered.	Center the steering gear.
If adjustable, the drag link is out of adjustment.	Adjust the drag link.

Troubleshooting

Problem - Steering Wheel Spokes Do Not Point at the 4 and 8 O'clock Positions	
Possible Cause	**Remedy**
The steering wheel was not installed (positioned) correctly on the steering column.	Reposition the steering wheel on the steering column.
The pitman arm is not correctly aligned with the timing mark on the steering gear output shaft.	Reposition the pitman arm on the steering gear output shaft. For instructions, refer to the steering section in this manual.

Problem - Tires Wear Out Quickly or Have Uneven Tire Tread Wear

Problem - Tires Wear Out Quickly or Have Uneven Tire Tread Wear	
Possible Cause	**Remedy**
Tires have incorrect air pressure.	Inflate or deflate the tires to the correct pressure.
Tires are out of balance.	Balance or replace the tires.
Tandem axle alignment is incorrect.	Align the tandem axles.
Toe-in setting is incorrect.	Adjust toe-in to the specified setting.
Steering arm geometry is incorrect.	Service the steering arm as necessary.

Problem - Ends of the Cross Tube are Worn

Problem - Ends of the Cross Tube are Worn	
Possible Cause	**Remedy**
Ends of the cross tube need lubrication.	Lubricate the ends of the cross tube. Make sure lubrication schedule is followed.
Vehicle is operated in severe conditions.	Operate the vehicle correctly.
Boot on end of cross tube is damaged.	Replace the boot.
Add-on type of power steering cylinders are not installed correctly.	Install the power steering cylinders correctly.

Problem - Bent or Broken Cross Tube, Ball Stud, Steering Arm or Cross Tube Arm

Problem - Bent or Broken Cross Tube, Ball Stud, Steering Arm or Cross Tube Arm	
Possible Cause	**Remedy**
Too much pressure in the power steering system.	Adjust the power steering system to the specified pressure.
Cut-off pressure in the power steering system is out of adjustment.	Adjust the power steering system to the specified pressure.
Vehicle is not operated correctly.	Make sure vehicle is operated correctly.
Add-on type power steering system is not installed correctly.	Install the add-on power steering system correctly.

Problem - Worn or Broken Steering Ball Stud

Problem - Worn or Broken Steering Ball Stud	
Possible Cause	**Remedy**
Drag link fasteners are tightened past specified torque.	Tighten the drag link fasteners to the specified torque.
Lack of lubrication, or lubricant is incorrect.	Lubricate the linkage with specified lubricant.
Power steering stops are out of adjustment.	Adjust the stops to specified dimension.

Problem - Worn King Pins and Knuckle Bushings

Problem - Worn King Pins and Knuckle Bushings	
Possible Cause	**Remedy**
Seals and gaskets are worn or missing.	Replace the seals and gaskets.
Lubricant is incorrect.	Lubricate the axle with specified lubricant.
Axle is not lubricated at scheduled frequency.	Lubricate the axle at scheduled frequency.
Lubrication procedures are incorrect.	Use the correct lubrication procedures.
Lubrication schedule does not match the operating conditions.	Change the lubrication schedule to match the operating conditions.

Specifications

IMPORTANT: When aligning the front axle, it is essential that the rear axle(s) be checked for correct alignment at the same time. Alignment of the rear axle(s) has a direct impact on how the vehicle tracks. See **Section 35.01**, Specifications.

General Information

The front axle full-floating wheel hub assembly is made up of four major components: tapered wheel bearings, the wheel hub, wheel studs, and the brake drum or rotor. **See Fig. 1.**

TAPERED WHEEL BEARINGS

A typical tapered wheel bearing assembly consists of a cone, tapered rollers, a roller cage, and a separate cup that is press-fit in the hub. **See Fig. 2.** All components carry the load, with the exception of the cage, which spaces the rollers around the cone.

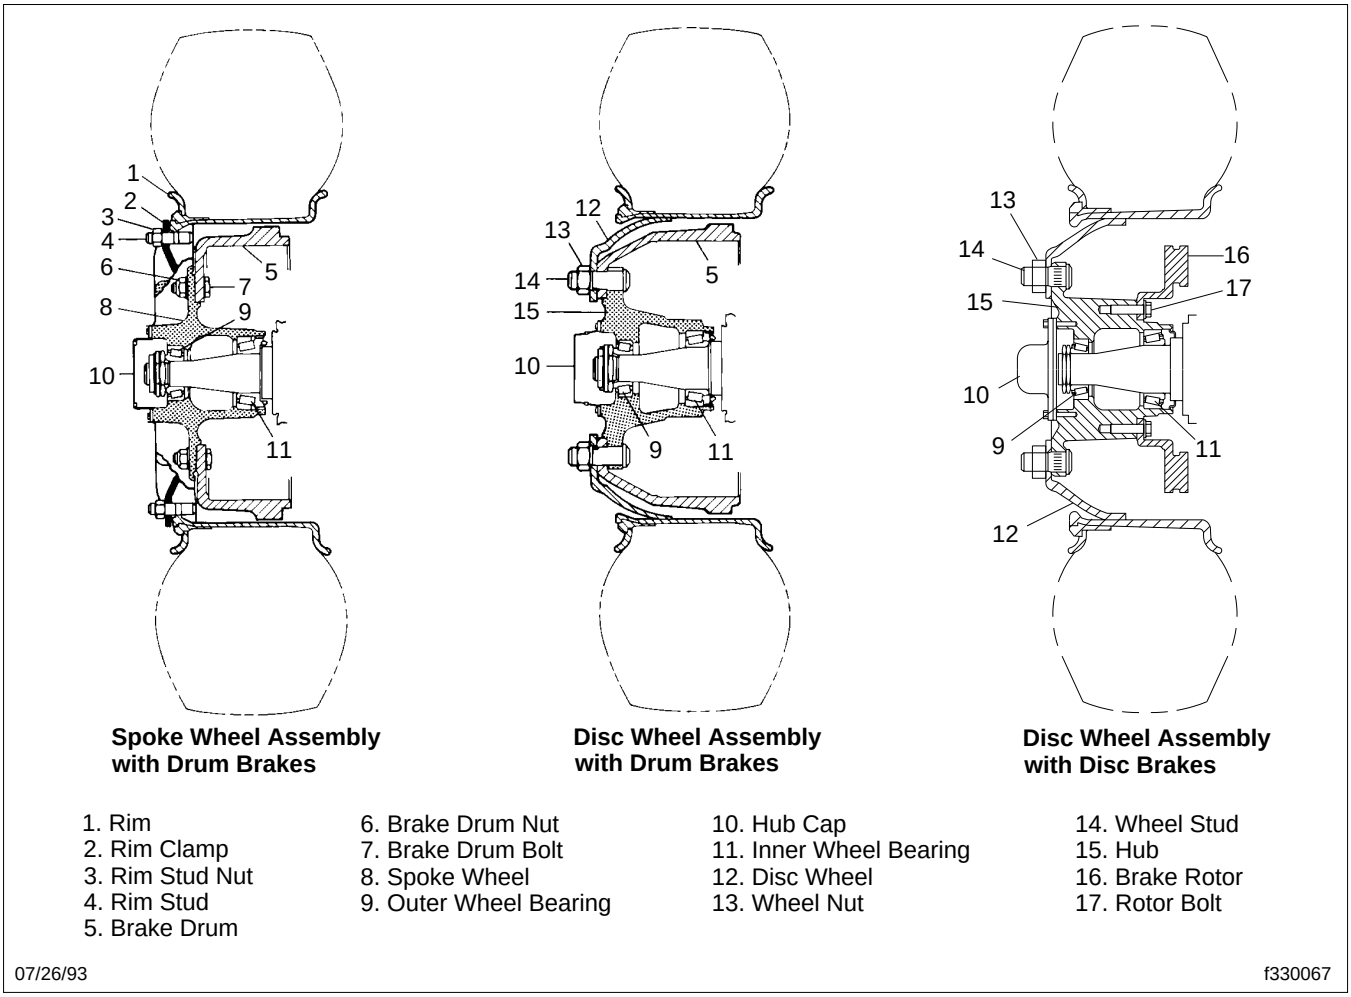
Each hub has a set of inner and outer tapered wheel bearing assemblies. The bearing setting is locked in place on the axle spindle (steering knuckle) by an adjusting nut and jam nut. **See Fig. 3.**

WHEEL HUB

The wheel and the brake drum or rotor are mounted on a steel or iron wheel hub **(Fig. 4).**

Both the inner and outer wheel bearing cups and the wheel studs are press-fit in the hub.

Spoke wheels combine the wheel and hub into a single unit.



WHEEL STUDS

A headed wheel stud **(Fig. 5)** is used on front axle disc wheel hub assemblies and has serrations on the stud body to prevent the stud from turning in the wheel hub.

The end of the stud that faces away from the vehicle is stamped with an "L" or "R," depending on which side of the vehicle the stud is installed. Studs stamped with an "L" are left-hand threaded and are installed on the driver's side of the vehicle. Studs stamped with an "R" are right-hand threaded and are installed on the passenger's side of the vehicle.

Spoke wheels have rim studs. Rim studs are threaded on both ends, with a nonthreaded section midway along the shaft of the stud. The studs are coated with an anaerobic locking compound.

Removal

WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer, or lung disease. OSHA has set maximum safe levels of exposure, and requires workers to wear an air-purifying respirator approved by MSHA or NIOSH. Always wear a respirator when servicing the brakes, from removal of the wheels through assembly.

Never use compressed air or dry brushing to remove brake dust. Both methods can spread hazardous particles beyond the work area.

1. Apply the parking brakes, and chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground. Place safety stands under the axle.
3. Remove the wheel and tire assembly. See **Group 40** for instructions.
4. Remove the brake drum or brake caliper. For instructions, see **Group 42**.

NOTE: On vehicles equipped with oil-lubricated bearings, oil will spill as the hub cap and wheel hub are removed. Place a suitable container under the axle spindle to catch any spilled oil. Dispose of the oil properly.

5. Remove the capscrews, washers, and hub cap. Remove and discard the hub cap gasket. See **Fig. 1**.
6. Remove the axle spindle jam nut, lockwasher, and cotter pin or lockring. See **Fig. 2** for the cotter pin, or **Fig. 3** for the lockring.
7. Back off the wheel bearing adjusting nut about two turns, enough to allow the weight of the hub to be lifted from the wheel bearings.
8. Lift the hub until all weight is removed from the wheel bearings. Remove the adjusting nut.

IMPORTANT: When moving the hub, be careful not to let the outer wheel bearing fall from the axle spindle. Dropping the bearing can warp the cage or damage the rollers, ruining the bearing.

9. Move the hub about 1/2 inch (13 mm) to jar loose the outer wheel bearing. Allow the hub-only assembly to rest on the axle spindle; be careful not to damage the axle spindle threads.
10. Carefully remove the outer wheel bearing. Handle the bearing assembly with clean, dry hands or gloves; wrap all bearing assembly parts in clean oil-proof paper or lint-free rags.

IMPORTANT: Do not spin the bearing rollers. Be careful to keep them clean. Dirt or grit can scratch their surfaces, and cause rapid wear of the bearing assembly. Treat good used bearings as carefully as new ones.

11. Remove the hub from the axle spindle. Be careful not to damage the axle spindle threads as the assembly is removed.
12. Remove the oil or grease seal from the hub with a seal removal tool.
13. Remove the inner wheel bearing from the hub. Handle the bearing assembly with clean, dry hands.

    If the bearing is difficult to remove, place a protective cushion to catch it. Then, use a hardwood drift and a light hammer to gently tap the bearing (and seal, if needed) out of the cup. Wrap all bearing assembly parts in clean, oil-proof paper or lint-free rags.

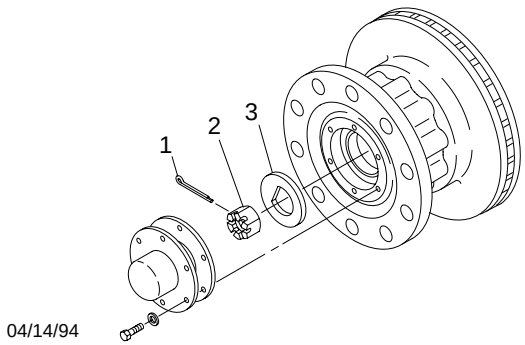
IMPORTANT: When cleaning the wheel hub cavity and axle spindle, be careful not to allow dirt or filings to get inside. They can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

14. Use an emery cloth or file to remove all burrs from the hub shoulder. See **Fig. 4** or **Fig. 5**.

    Clean any metal filings from the parts. For instructions, see **Subject 110**.

Installation

1. Use clean solvent to remove the old oil or grease from the axle spindle and the disassembled parts. Allow the parts to dry, or dry them with a clean, absorbent, and lint-free cloth or paper.
2. Wrap a protective layer of tape onto the axle spindle threads.



IMPORTANT: When coating the bearing assemblies with oil or grease, do not use old lubricant,

3. If the axle is equipped with oil-lubricated bearings, coat them with fresh oil. If it is equipped with greased bearings, pack them using a pressure packer, if one is available; otherwise, pack the bearings by hand. 5.1 Put a light coating of gear oil on the inner and outer surfaces of the new oil seal.

5.2 If using a press, put the hub onto a centering fixture, inboard side up.

If you are manually installing the oil seal, make sure the hub is on a firm, level surface (inboard side up).

5.3 Install the adapter plate and bearing pilot onto the steel handle using the hexnut and washers provided.

5.4 Put the oil seal onto the adapter plate, making sure the words "Air Side" on the oil seal are facing the adapter plate surface.

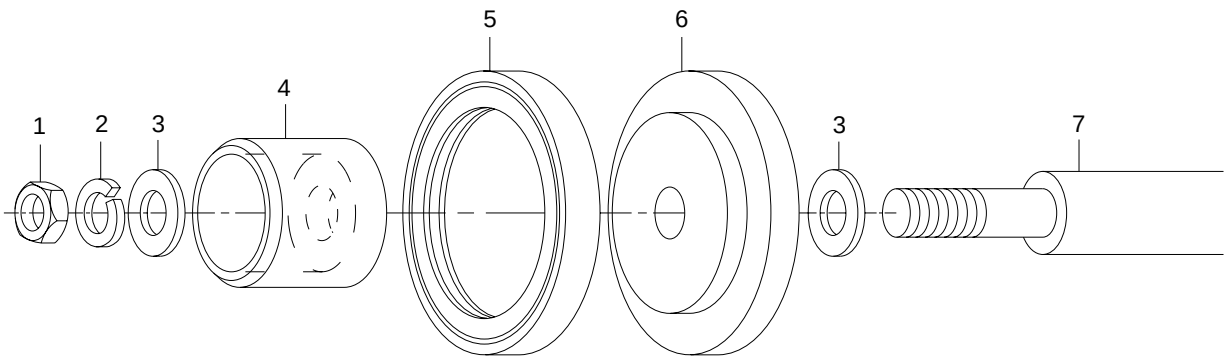
5.5 Making sure the oil seal is aligned straight with the hub bore, install it into the hub. See **Fig. 7**.

5.6 If using a press, press the oil seal into the hub with 3000 to 5000 psi (20 684 to 34 500 kPa) of pressure.

If manually installing the seal, strike the end of the installation tool with a heavy mallet. Continue striking until the sound changes, indicating the tool flange is against the hub, and the seal is flush with the face of the hub.

5.7 Wipe any excess oil from the face of the oil seal.

NOTE: When the oil seal is correctly installed in the hub bore, the face of the seal (the side with the words "Air Side") should be flush with the face of the hub.



6. Carefully mount the hub and inner wheel bearing assembly on the axle spindle. Be careful not to unseat the inner wheel bearing or seal.

7. If the axle is equipped with oil-lubricated bearings, fill the hub cavity with oil; if equipped with greased bearings, pack the hub between the bearing cups with lubricant to the level of the smallest diameter of the cups. See **Fig. 8**.

   Install the outer wheel bearing. Handle the bearing assembly with clean, dry hands. Use care not to damage the bearing while seating it in the cup. Remove the tape from the axle spindle threads.

8. Install the wheel bearing adjusting nut (see **Fig. 2** for single-nut assemblies, **Fig. 3** for dual-

nut assemblies with a plain lockring, or **Fig. 9** for dual-nut assemblies with a tanged nut-lock).

8.1 After the wheel hub and bearings are assembled on the spindle, tighten the inner adjusting nut finger-tight.

IMPORTANT: Be sure there is sufficient clearance between the brake shoe and the brake drum, so brake shoe drag will not interfere with bearing adjustment.

8.3 Back off the adjusting nut completely.

8.4 Rotate the wheel hub assembly, as you tighten the adjusting nut 20 lbf·ft (27 N·m).

8.5 Back off the adjusting nut one-third turn.

9. Install the locking device and jam nut.

On single-nut assemblies, install a new cotter pin (see **Fig. 2**).

On dual-nut assemblies, install the jam nut and locking device as follows (see substeps):

NOTE: If you are securing the wheel bearings with a pierced lockring, and no hole in the lockring aligns with the dowel on the adjusting nut, remove the lockring, turn it over and install it again. If still no hole aligns with the dowel, loosen the adjusting nut, but only enough to align the dowel with a hole in the lockring.

9.1 Install the locking device.

NOTE: The locking device can be any one of the following types:

- Tanged nut-lock
- Lockring
- Lockwasher *and* lockring
- Nut-lock *and* lockring

9.2 Install the jam nut, and tighten it to the applicable torque value in **Table 1**.

10. With the jam nut installed and tightened, adjust the wheel bearings.

IMPORTANT: Do not adjust the bearings with the wheel mounted on the hub. You cannot accurately adjust or measure the bearing end play with the wheel mounted on the hub.

10.1 Attach a dial indicator to the hub, and set the point of the indicator in line with the end of the axle spindle.

If the hub is aluminum, you may have to install the brake drum to provide a steel base for the magnet of the dial indicator. Mount the drum on the hub's drum pilot, then adjust the brake, or have someone apply the brakes to hold the drum securely. Secure the drum using the stud at the 12 o'clock position, then the studs at about the 4 o'clock and 8 o'clock positions.

NOTE: If using a stud-piloted hub and a steel drum, install 1-1/4 inch washers between the nuts and the drum.

10.2 Grip the sides of the hub at the three o'clock and nine o'clock positions. Push in on the hub (and drum, if applicable), to seat the inboard bearing set. Zero the dial indicator.

10.3 Grip the sides of the hub at the three o'clock and nine o'clock positions. Pull out on the hub (and drum, if applicable). Read the dial indicator, and note the end play.

10.4 Push the hub back in, and confirm that the needle of the dial indicator returns to zero.

11. The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). If the end play is not within this range, adjust the end play.

11.1 Remove the jam nut and locking device, and back off or tighten the inner adjusting nut.

IMPORTANT: *If the axle has a nut-lock,* turning the adjusting nut 1/4 turn will change the end play about 0.014 inch (0.36 mm).

Hub Assembly Removal and Installation, Disc Wheels

If the axle has a lockring, turning the inner nut one lockring hole will change the end play about 0.005 inch (0.13 mm). If you take the lockring off, reverse it, and then turn the adjusting nut to the next hole, this will change the end play about 0.0025 inch (0.064 mm).

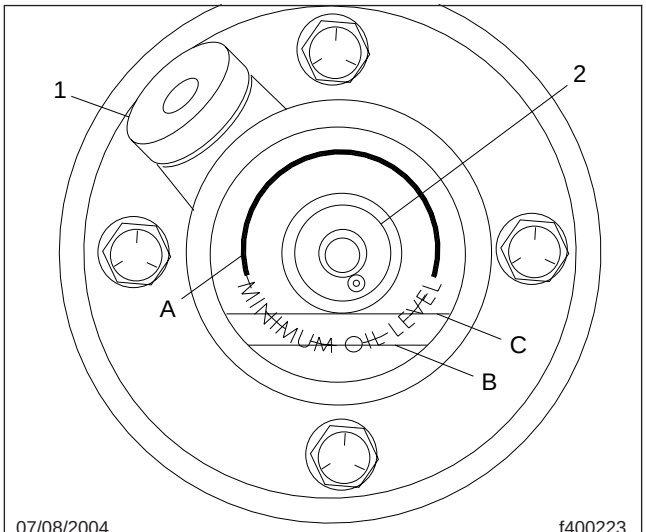
11.2 Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), turn the inner adjusting nut again.

11.3 Once the end play is correct, bend the nut-lock or lockwasher, as applicable. This will lock the jam nut and/or adjusting nut in place.

11.4 Rotate the hub in both directions. It should turn freely with no dragging or binding.

12. If the axle is equipped with grease-packed bearings, pack the hub between the bearing cups with lithium-based wheel bearing grease to the level of the smallest diameter of the cups (see **Fig. 8**).

13. Place the hub cap and a new gasket in position, then install the washers and capscrews. Tighten the capscrews to the value in the torque table in **Specifications, 400**.



14. If the axle is equipped with oil-lubricated bearings, add fresh oil to the wheel hub, to the level mark on the hub cap. See **Fig. 10**, and see **Specifications, 400**, for recommended axle lubricants.

14.1 Turn the hub until the drain/fill plug on the hub cap is at the top of the hub.

14.2 Remove the drain/fill plug and put a funnel into the hole.

⚠ WARNING

You must add oil to the wheel hub after the hub has been serviced, or the wheel bearings will overheat and seize during vehicle operation. See Fig. 11. Seized bearing rollers can cause sudden, severe damage to the tire or axle, possibly causing lost vehicle control and resulting in personal injury.

Fig. 10, Hub Oil Levels

14.3 Add enough oil (about 2 oz or 60 ml) to the hub, to bring the level up to the bottom of the vent cap.

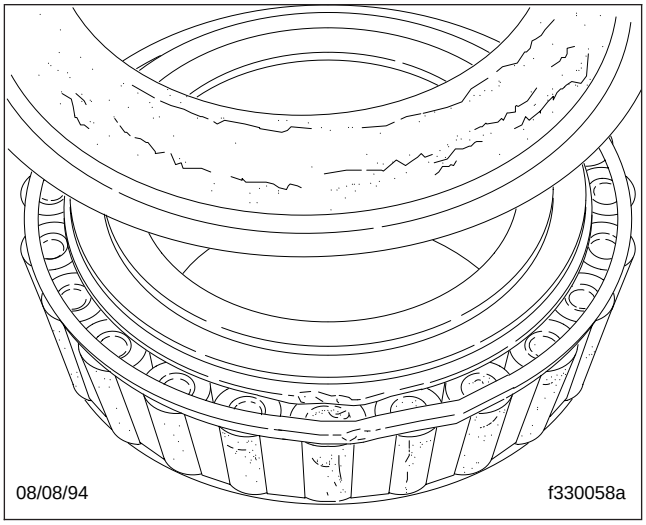

Fig. 11, Bearing Damage Resulting from Inadequate Lubrication

14.4 Install the drain/fill plug, and rotate the hub several times to distribute the oil.

14.5 Once the oil level has stabilized in the hub cap, check the level in the window and if needed, add enough oil to bring the level up to the bottom of the vent plug. See **Fig. 10**.

14.6 Let the hub sit for about 30 minutes, then check the oil level again. Add oil as needed.

15. Install the brake drum or caliper on the wheel hub. See **Group 42** for instructions.
16. Install the wheel and tire assembly. See **Group 40** for instructions.

⚠ WARNING

If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking action, and the wheel hub flange is probably damaged. In that case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when these conditions exist could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

17. Remove the safety stands from under the axle, and lower the vehicle.
18. Remove the chocks from the rear tires.

See **Fig. 1** for this procedure.

1. Apply the parking brake, and chock the rear tires.
2. Raise the front of the vehicle until the tires clear the ground, and place safety stands under the axle. Position a jack, or wheel-and-tire dolly under the tire.
3. Remove the rim and tire assembly. See **Group 40** for instructions.

NOTE: On axles equipped with oil-lubricated bearings, oil will spill as the hub cap is removed. Place a suitable container under the wheel to catch any spilled oil. Dispose of the oil properly.

4. Remove the capscrews, washers, and hub cap. Remove and discard the hub cap gasket and oil.
5. Remove the axle spindle jam nut, lockwasher, and lockring or cotter pin. See **Fig. 2** or **Fig. 3**.

wheel and drum assembly to be lifted from the wheel bearings.

7. Use an adjustable wheeled support to raise the wheel and drum assembly until all weight is removed from the bearings. Remove the adjusting nut.

8. Carefully remove the outer wheel bearing. Handle the bearing assembly with clean, dry hands. If the bearing hasn't loosened from the cup, move the wheel assembly about 1/2 inch (13 mm), to jar loose the outer wheel bearing. Be careful to not drop the bearing. Wrap all bearing assembly parts in clean oil-proof paper or lint-free rags.

CAUTION

Do not spin the bearing rollers, and be careful to keep them clean. Dirt or grit can scratch their surfaces and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

9. Use the wheeled support to pull the wheel assembly away from the vehicle. Be careful not to damage the axle spindle threads as the assembly is removed.

WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air-purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, from removal of the wheels through assembly.

Never use compressed air or dry brushing to clean brake dust away. Both methods can spread dangerous particles beyond the work area.

10. To minimize exposure to brake lining dust, clean the brake drum, brake backing plate and brake assembly, using OSHA-approved materials and methods. Do not use compressed air or dry brushing to clean the brake assembly.

11. Remove the brake drum nuts (see **Fig. 1**) and detach the brake drum from the wheel.

12. Remove the oil or grease seal using a seal removal tool.

13. Remove the inner wheel bearing from the hub. Handle the bearing assembly with clean, dry hands.

    If the bearing is difficult to remove, place a protective cushion to catch it. Then use a hardwood drift and a light hammer to tap the bearing (and seal if needed) gently out of the cup. Wrap all bearing assembly parts in clean oil-proof paper or lint-free rags.

IMPORTANT: Dirt, metal filings, or other debris can scratch the bearing roller surfaces, and

cause premature wear of the bearing assembly. Be very careful when cleaning the wheel hub cavity and axle spindle.

14. Use an emery cloth or file to remove all burrs from the hub shoulder. See **Fig. 4** or **Fig. 5**.

    Clean any metal filings from the parts. For instructions, see **Subject 110**.

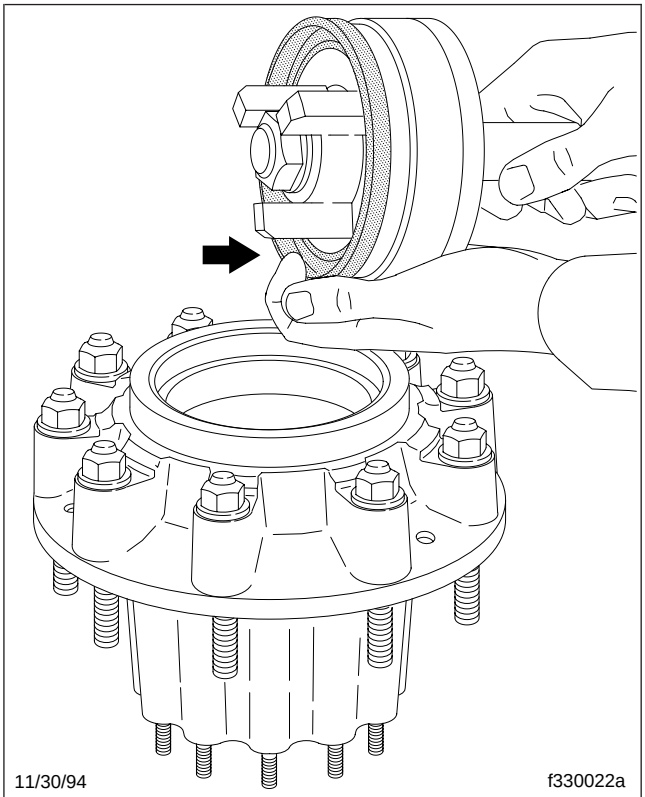
⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air-purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, from removal of the wheels through assembly.



Never use compressed air or dry brushing to clean brake dust away. Either method can spread dangerous particles beyond the work area.

1. Use clean solvent to remove the old oil or grease from the axle spindle (steering knuckle) and the disassembled parts. Inspect and clean the wheel hub cavity and the wheel bearings as detailed under **Subject 110**. Allow the parts to dry, or dry them with a clean, absorbent, and lint-free cloth or paper.
2. Wrap a protective layer of tape on the axle spindle threads.
3. If it was removed, attach the brake drum to the hub. Install the bolts and nuts, then tighten the nuts 240 lbf·ft (325 N·m).
4. If the axle is equipped with oil-lubricated bearings, coat them with fresh oil; If equipped with greased bearings, pack them using a pressure packer, if possible. If a packer is not available, pack the bearing by hand. Starting from the large end of the cone, force lithium-based wheel bearing grease into the cavities between the rollers and the cage. For lubricant specifications, see **Specifications, 400**.

   Install the inner wheel bearing. Handle the bearing assembly with clean, dry hands.
5. Install the new oil or grease seals.

   5.1 Seat the small outer diameter of the seal in the recess of the tool adaptor. See **Fig. 6**. The correct adaptor is identified on the box.

Hub Assembly Removal and Installation, Spoke Wheels

NOTE: Typical application.

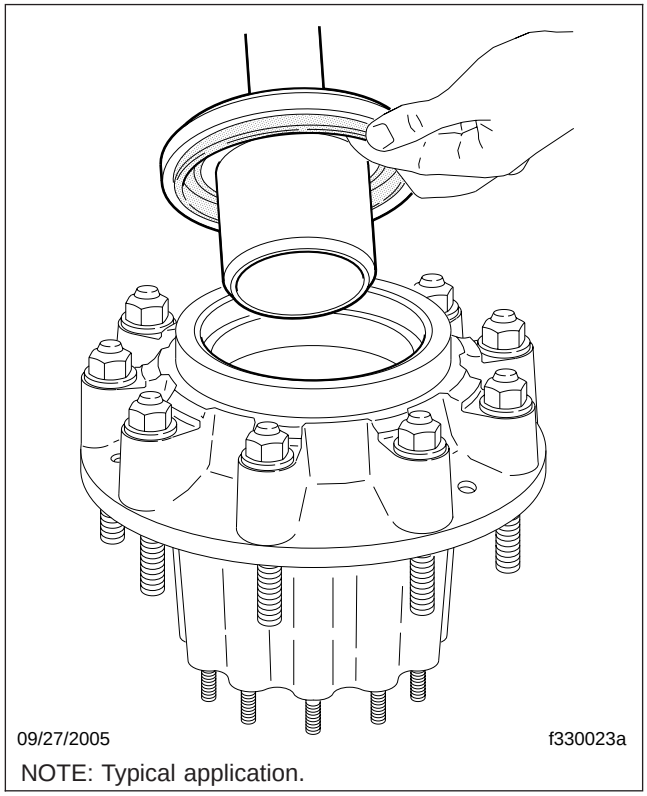


Fig. 6, Seating the Seal on the Tool

5.2 Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 7**. The plug prevents the seal from getting cocked and jamming in the bore.

5.3 Hold the tool handle firmly, and strike it until the sound of the impact changes as the tool flange bottoms out against the hub face. See **Fig. 8**. Hold the tool firmly to prevent bouncing, and unseating of the seal from the adaptor.

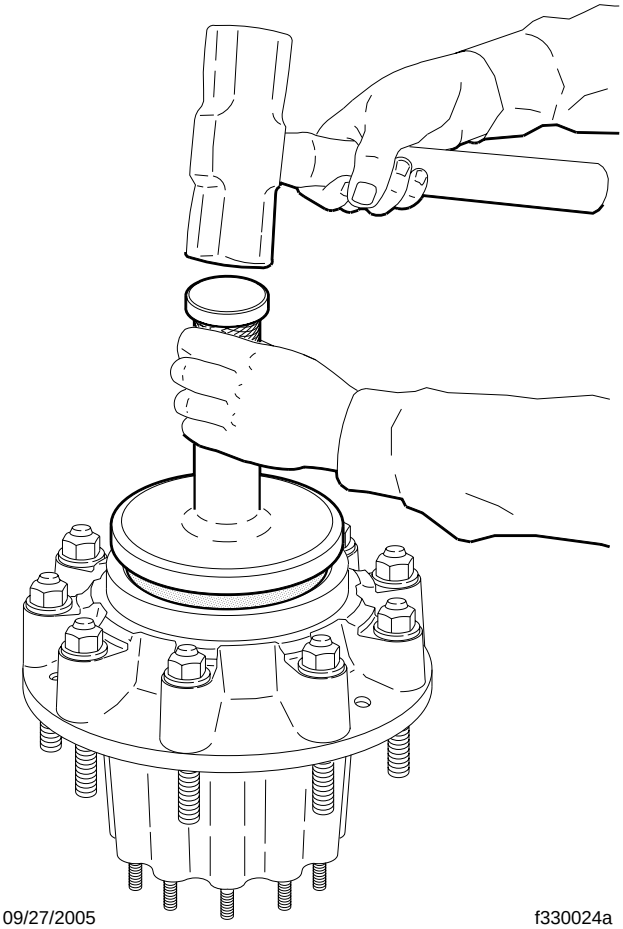
5.4 When the seal is flush with the hub face, check for freedom of movement by manually moving the interior rubber part of the seal back and forth. If it is not damaged, the seal should move slightly.

6. Depending on the type of bearing lubricant used on the axle, wipe a film of axle oil or grease on the axle spindle, to prevent rust from forming behind the inner wheel bearing.

NOTE: Typical application.

Fig. 7, Inserting the Tool into the Hub

7. Use a wheeled support to mount the wheel and drum assembly on the axle spindle; be careful not to unseat the bearing or seal.



⚠ WARNING

You must add oil to the wheel hub after the hub has been serviced, or the wheel bearings will overheat and seize during vehicle operation. See Fig. 10. Seized bearing rollers can cause sudden, severe damage to the tire or axle, possibly causing loss of vehicle control, and personal injury.

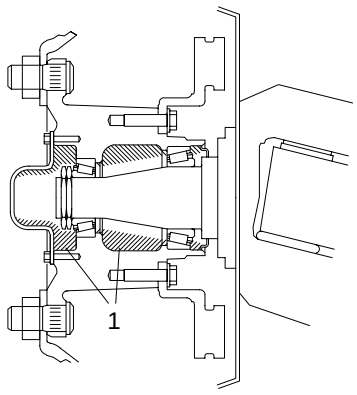
8. If the axle is equipped with oil-lubricated bearings, fill the hub cavity with oil; if equipped with greased bearings, pack the hub between the bearing cups with lubricant to the level of the smallest diameter of the cups. See **Fig. 9**.

   Install the outer wheel bearing. Handle the bearing assembly with clean, dry hands or gloves. Be careful not to damage the bearing as you seat it in the cup. Remove the friction tape from the axle spindle threads.

Hub Assembly Removal and Installation, Spoke Wheels

NOTE: Typical application.

Fig. 8, Striking the Tool



9. Install the wheel bearing adjusting nut. Tighten the nut finger-tight. Adjust the bearings (see **Fig. 2** or **Fig. 3**).

   IMPORTANT: Be sure there is sufficient clearance between the brake shoe and the brake drum, so brake shoe drag won't interfere with bearing adjustment.

   9.1 After the wheel hub and bearings are assembled on the spindle, tighten the inner (adjusting) nut 200 lbf·ft (271 N·m) while rotating the wheel hub assembly.

   9.2 Back off the inner nut one full turn.

   9.3 Tighten the inner nut 50 lbf·ft (68 N·m) while rotating the wheel hub assembly.

1. Lubricate here.

Fig. 9, Bearing Lubrication

   9.4 Back off the inner nut one quarter turn.

   9.5 Where one is used, install a new cotter pin (see **Fig. 3**), or install the jam nut and locking device as follows:

   NOTE: If you are securing the wheel bearings with a pierced lockring, but no hole in the lockring aligns with the dowel on the adjusting nut, remove the lockring, turn it over and install it again. If still no hole aligns with the dowel, loosen the adjusting nut just enough to align the dowel with a hole in the lockring.

   9.6 Install the locking device:

   - Tanged nut-lock
   - Lockring
   - Lockwasher *and* a lockring
   - Nut-lock *and* a lockring

   Install the jam nut, and tighten it to the proper torque from **Table 1**.

   IMPORTANT: Do not adjust the wheel bearings with the wheel mounted. You cannot accurately adjust or measure bearing end play with the wheel mounted.

   9.7 With the jam nut installed and tightened, attach a dial indicator to the hub and set the point of the indicator in line with the end of the axle spindle.

9.8 Release the brakes, if you used them to hold the drum while installing it.

Grip the sides of the hub at the three o'clock and nine o'clock positions then push the hub to seat the inboard bearing set. Zero the dial indicator.

Grip the sides of the hub at the three o'clock and nine o'clock positions, and pull outward. Read the dial indicator, and note the end play.

Push the hub back in to confirm that the needle of the dial indicator returns to zero.

The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm).

10. If the end play is not within this range, remove the jam nut and locking device, and back off or tighten the inner (adjusting) nut to adjust the end play. Keep the following in mind:

    If you are using a nut-lock: turning the inner nut 1/4 turn will change the end play about 0.014 inch (0.36 mm).

    If you are using a lockring: turning the inner nut one lockring hole will change the end play about 0.005 inch (0.13 mm). If you take the lockring off and reverse it, then turn the inner nut to the next hole, this will change the end play about 0.0025 inch (0.06 mm).

    Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), adjust the inner (adjusting) nut again.

11. Once the end play is correct, bend the nut-lock or lockwasher as needed to lock the jam nut and/or adjusting nut in place.
12. Rotate the wheel in both directions. It should turn freely with no dragging or binding.
13. If the axle is equipped with grease-packed bearings, pack the hub between the bearing cups with lithium-based wheel bearing grease to the level of the smallest diameter of the cups (see **Fig. 9**).
14. Place the hub cap and a new gasket in position, then install the washers and capscrews. Tighten the capscrews to the value from the torque table in **Specifications, 400**.
15. Install the rim and tire assembly. See **Group 40** for instructions.

⚠ WARNING

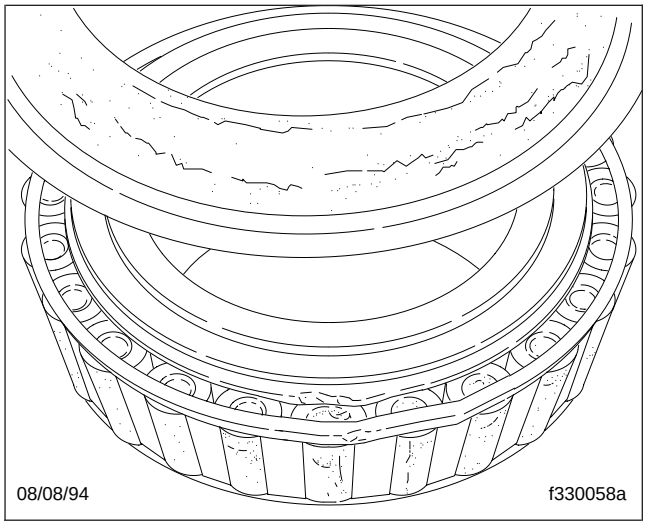
If the rim nuts cannot be tightened to minimum torque values, the rim studs have lost their locking ability, and the wheel hub flange is probably damaged. In this case, install a new wheel. Failure to replace the wheel when these conditions exist could result in loss of a wheel, loss of vehicle control, physical damage, and possible personal injury.

16. Lower and remove the jack or wheel-and-tire dolly from under the tires.
17. If the axle is equipped with oil-lubricated bearings, add fresh oil to the wheel hub to the level shown on the hub cap. See **Specifications, 400** for recommended axle lubricants.

⚠ WARNING

You must add oil to the wheel hub after the hub has been serviced, or the wheel bearings will overheat and seize during vehicle operation. See Fig. 10. Seized bearing rollers can cause sudden, severe damage to the tire or axle, possibly causing loss of vehicle control, and personal injury.

18. Adjust the front axle brakes. For instructions, see **Group 42**.



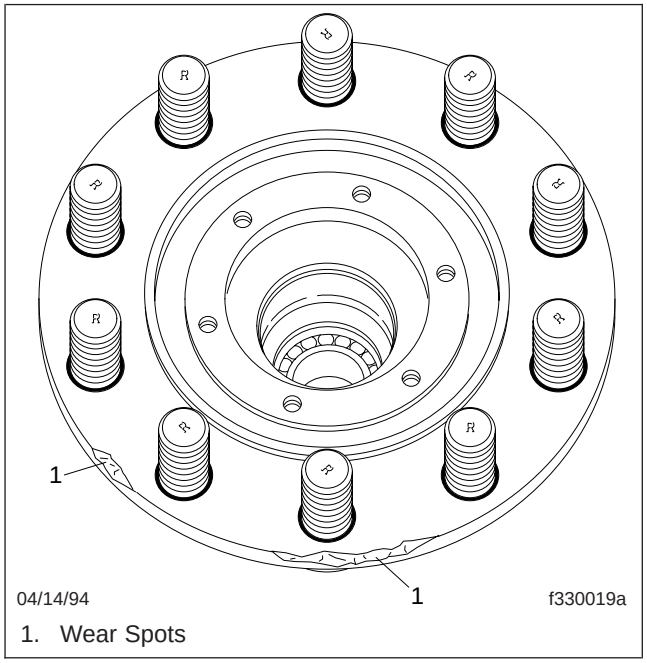


Fig. 10, Bearing Damage Resulting from Inadequate Lubrication

19. Remove the safety stands from under the axle; lower the vehicle.
20. Remove the chocks from the rear tires.

Wheel Hub Assembly Inspection

1. Inspect the wheel hub mounting flange. A loose wheel assembly will cause the flange to be worn, jagged, or warped. **See Fig. 1.** Replace the wheel hub if any of these conditions exist.

   Inspect the flange surface around the wheel studs. Improperly torqued wheel nuts will cause worn or cracked stud grooves on the hub. **See Fig. 2.** If wear spots or cracks appear anywhere on the hub, or if the hub is otherwise damaged, replace it with a new one.

1. Wear Spots

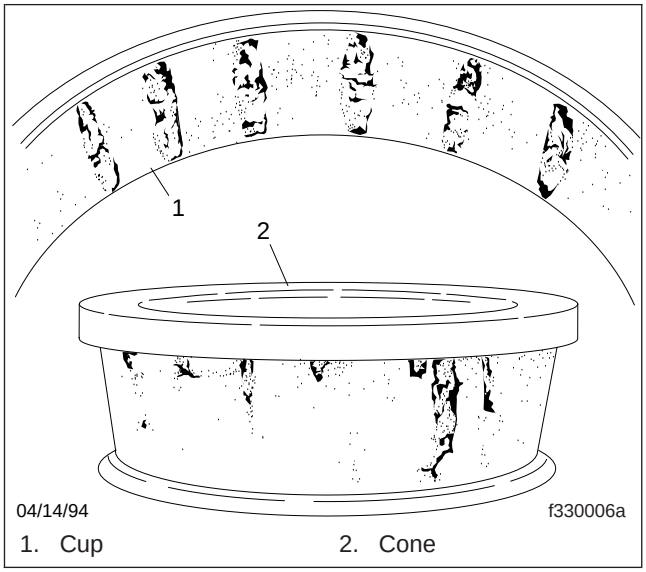

Fig. 1, Damaged Front Axle Wheel Hub

2. Remove all the old oil or grease from the spoke wheel or hub cavity. Inspect the inner surface of the wheel or hub for cracks, dents, wear, or other damage. Replace the wheel or hub if damaged.
3. Remove all the old grease or oil from the surfaces of the wheel bearing cups. Inspect the cups for cracks, wear, spalling, or flaking. **See Fig. 3.** Replace the cups if damaged in any way. Refer to **Subject 120**.
4. Inspect the wheel nuts on disc wheel installations, or the rim nuts on spoke-wheel installations. Damaged nuts (**Fig. 4**), usually caused by inadequate tightening, must be replaced with new ones.

Wheel Bearing Cleaning and Inspection

CLEANING

⚠ WARNING

WARNING: To prevent skin irritation, wear chemical resistant gloves when working with diesel fuel or kerosene. Also, don't expose these fluids to flames or heat exceeding 38°C (100°F); both are combustible, and could cause personal injury if ignited.

⚠ CAUTION

CAUTION: Don't spin the bearing rollers at any time. Dirt or grit can scratch the roller surface and cause premature wear of the bearing assembly. Treat a used bearing as carefully as a new one.

Wheel bearings should be very closely inspected at the time of disassembly. The best inspection conditions are possible only after the bearings have been thoroughly cleaned using kerosene or diesel fuel oil, and a stiff brush (**see Fig. 5**). Before inspecting, clean the bearings, as described below.

1. Clean all old oil or grease from the bearings and hub cavities, with kerosene or diesel fuel and a stiff brush. **See Fig. 5.** Don't use gasoline or heated solvent.

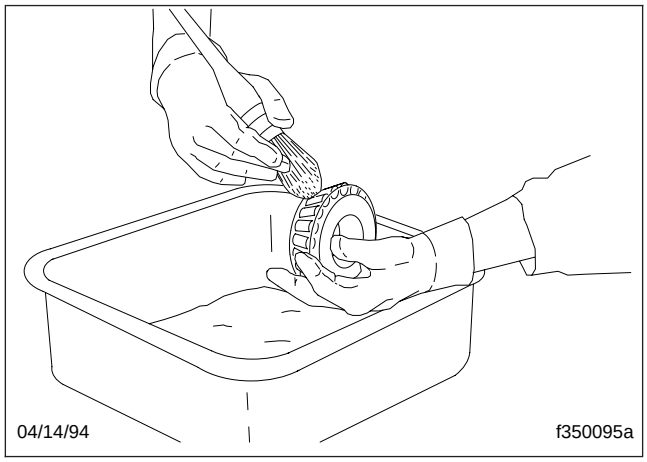

Fig. 5, Wheel Bearing Cleaning

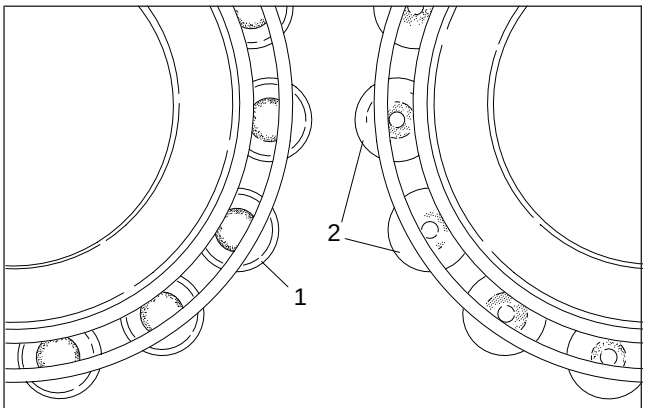
2. Allow the cleaned parts to dry, or dry them with a clean absorbent cloth or paper.

   Clean and dry your hands and all tools used in the maintenance operation. Oil will not stick to a surface that is wet with kerosene or diesel fuel, and the kerosene or diesel fuel may dilute the lubricant.

INSPECTION

After the bearings are cleaned, inspect the assemblies, which include the rollers, cones, cups, and cages. If any of the conditions below exist, replace the bearing assemblies.



A. The large ends of the rollers are worn flush to the recess; the radii at the large ends of the rollers are worn sharp. These are signs of advanced wear. **See Fig. 6.**

B. Visible step wear, especially at the small end of the roller track, or deep indentations, cracks, or breaks in the cone surfaces. **See Fig. 7.**

C. Bright rubbing marks on the dark phosphate surfaces of the bearing cage. **See Fig. 8.**

D. Water etch on any bearing surface. Water etch appears as gray or black stains on the steel surface, and it greatly weakens the affected area. If water etch is present, check the bearing seal sealing surfaces.

E. Etching or pitting on functioning surfaces. **See Fig. 9.**

1. New Bearing
2. Worn Bearing Rollers

Fig. 6, Wheel Bearing Roller Wear

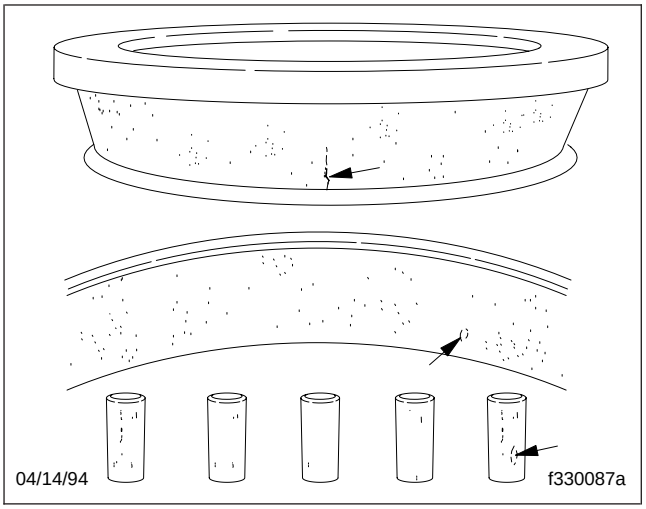


Fig. 7, Indentations, Cracks, or Breaks in Bearing Surfaces

F. Spalling (flaking) of the bearing cup, roller, or cone surfaces. **See Fig. 3.**

After inspection, pack the bearings with fresh axle lubricant. If a packer is not available, pack the bearing by hand. Starting from the large end of the cone, force lithium-based wheel bearing grease into the cavities between the rollers and the cage. For installation, refer to **Subject 100** or **Subject 102**.

Wheel Bearing Cup Removal and Installation, Ferrous Hubs

Removal

Wheel bearing cups in ferrous hubs are removed by driving them out; there is no need to first heat the hubs.

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Using a mild-steel rod through the opposite end of the hub, drive against the inner edge of the bearing cup. Alternately drive on opposite sides of the cup to avoid cocking the cup and damaging the inside of the hub.

Installation

Wheel bearing cups are installed in ferrous hubs by pressing them in; there is no need to first heat the hubs.

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Coat the hub-contact surface of the replacement bearing cup with a film of grease.
4. Position the cup in the hub and press it into place, using a suitable driving tool. Cups must seat against the shoulder in the hub.

⚠ WARNING

WARNING: To prevent skin irritation, wear chemical resistant gloves when working with diesel fuel or kerosene. Also, don't expose these fluids to flames or heat exceeding 38°C (100°F); both are combustible, and could cause personal injury if ignited.

5. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Replacement

WARNING

WARNING: If a wheel stud breaks, the remaining studs are subjected to undue strain and could fail due to fatigue. When a broken stud is replaced, replace the stud on each side of it. See Fig. 1. If more than one stud is broken, replace all of the studs. Failure to replace the studs could result in the loss of a wheel or loss of vehicle control, possibly resulting in personal injury.

1. Remove the wheel hub from the axle. For instructions, **refer to "Hub Assembly Removal and Installation, Disc Wheels, 100."**
2. If a bent portion of a wheel stud will have to pass through the wheel stud bore, cut off the bent portion before removing the wheel stud.
3. Place the wheel hub on a suitable press; make sure the hub flange is evenly supported around and next to the stud being removed. With steady movement, press the damaged stud out of the hub.

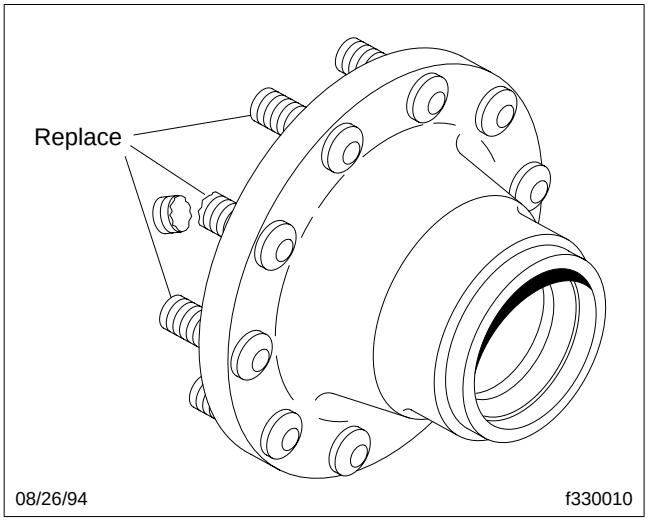

Fig. 1

CAUTION

CAUTION: Don't use a drift and hammer or concentrated heat for removing and installing the wheel studs. Constant, smooth movement of the wheel stud is needed to ensure the least amount of metal removal from the wheel stud bore. Concentrated heat will damage the hub. If the hub is damaged during wheel stud removal or installation, replace it.

4. Apply a coat of clean axle grease to the entire shaft on headed studs.
5. With the hub on a suitable press, make sure the hub flange is evenly supported around and next to the stud being installed.
6. Position the stud in its hole.

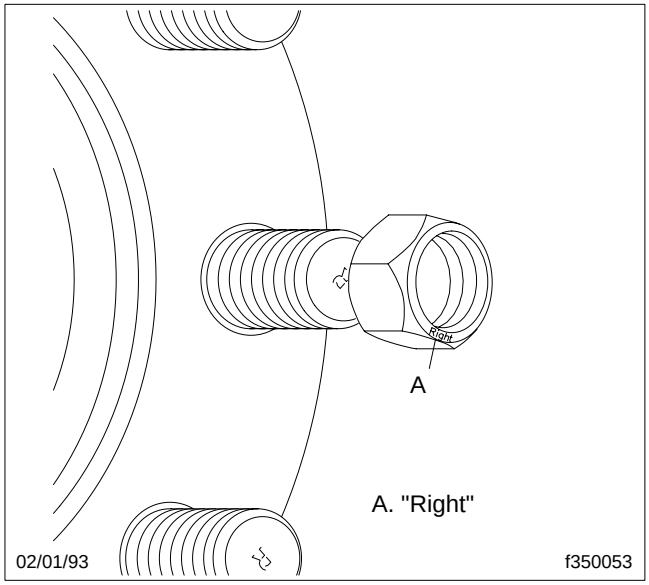

Fig. 2

CAUTION

CAUTION: Position the teeth of the serrated portion in the notches carved by the original wheel studs during factory installation. If additional metal is scraped from the wheel stud bores, the locking action provided by the serrations will be greatly weakened. Loss of locking action will prevent achieving final torque of the wheel nuts during wheel installation. If final wheel nut torques cannot be achieved, replace the wheel hub assembly.

IMPORTANT: If the driver's side of the vehicle is being serviced, the replacement wheel stud must be stamped with an "L" (left-hand

Wheel Stud Replacement, Disc Wheels

threaded), and the nut's face must be stamped "Left." If the passenger's side of the vehicle is being serviced, the replacement stud must be stamped with an "R" (right-hand threaded), and the nut's face must be stamped "Right" **(Fig. 2).**

7. With steady movement, press the new stud all the way into the hub.
8. Make sure the stud is fully seated and that its head (flange) is not embedded in the hub. If the head of the stud is embedded in the hub, replace the hub.
9. Wipe off any grease on the wheel studs and hub. Install wheel nuts on dry wheel studs only.
10. Install the wheel hub on the axle. For instructions, **refer to "Hub Assembly Removal and Installation, Disc Wheels, 100."**

Replacement

1. Remove the rim and tire assembly from the spoked wheel. For instructions, **refer to the wheels and tires group.**
2. If enough threads remain on the damaged stud, remove it by double-nutting the stud. Turn the inner nut with a wrench in order to remove the stud. Then, go to the step for tapping out the rim stud hole.

   If the rim stud is broken near the surface of the wheel, the stud should be center-drilled using a high-speed drill, and then removed with an easy-out tool. If needed, grind off a flat surface on the damaged stud, then centerpunch the surface as starting point for drilling. Remove the stud.

   2.1 Determine the correct drill diameter by referring to the easy-out tool manufacturer's guidelines. At no time should it be large enough to penetrate the threads of the stud; if the stud threads in the wheel are damaged, replace the wheel.

   2.2 Don't drill more than 32 mm (1-1/4 inches) into the broken stud, as measured at the stud's entrance into the wheel. Drilling through the bottom of the rim stud could damage the wheel. If the wheel is drilled into, replace it.

   2.3 While drilling, keep the cutting surfaces of the drill well lubricated with oil, which acts as a coolant. Allow the drill and drill bit to cool frequently.
3. After the damaged stud is removed, tap out the rim stud hole in the wheel to rid the threads of old stud-locking compound. Use an appropriate tap size, depending on the original rim stud installation size.
4. Be sure the threads of the new stud are clean and dry. Then, coat the insertion end of the rim stud with an anaerobic thread-lock compound.
5. Using double nuts on the fine thread portion of the stud, install the new stud. Seat the rim stud using the torques values in the torque table in **"Specifications, 400."**
6. Allow enough time for the thread-lock compound to set, as suggested by the manufacturer.
7. Install the rim and tire assembly. For instructions, **refer to the wheels and tires group.**

Troubleshooting

- Noisy Bearings or Excessive Bearing Replacement Intervals
- Broken Wheel or Rim Studs
- Damaged Hub
- Loss of Lubricant from the Wheel Hubs
- Vehicle Doesn't Slow Down Quickly Enough When the Brakes Are Applied

Problem—Noisy Bearings or Excessive Bearing Replacement Intervals

Possible Cause	Remedy
Not enough oil or grease was used on the bearings, or the wrong type of oil or grease was used.	Clean then inspect the bearings for wear. Replace worn seals. Coat the bearing assemblies with fresh oil or grease. For lubricant specification, **refer to "Specifications, 400."**
Foreign matter or corrosive agents entered the bearing assembly. Dirt or metallic debris from the bearings was not removed.	Clean then inspect the bearings for wear. Replace worn seals. Also clean the wheel hub, the axle spindle, and any other part in contact with the bearing lubricant.
An incorrect adjustment of the wheel bearings is causing noise and wear.	Adjust the wheel bearings following the instructions in **Subject 100** and **Subject 102** in this section.
Flat spots or dents on the roller surface were caused by skidding of the roller or improper handling of the wheel bearing during installation.	Clean then inspect the bearing rollers. Replace the bearing if damaged. Coat the replacement bearings with fresh oil. For lubricant specifications, **refer to "Specifications, 400."**

Problem—Broken Wheel or Rim Studs

Possible Cause	Remedy
The wheel or rim nuts were overtightened.	Replace the wheel or rim studs. **Refer to the wheels and tires group** for the wheel or rim nut tightening sequence.
An incorrect nut tightening sequence was used.	
The vehicle is being overloaded.	Don't exceed the maximum load-carrying capacity of the vehicle.

Problem—Damaged Hub

Possible Cause	Remedy
(Bent flange) Incorrect installation of the wheel studs, such as using a hammer and drift, or the hub flange was not fully supported on the press during wheel stud replacement.	Replace the hub assembly. Replace the wheel studs as instructed under **"Wheel Stud Replacement, Disc Wheels, 130."**
Insufficient tightening of the wheel nuts to the wheel hub.	Replace the hub assembly and tighten the wheel nuts to the values in the torque table in **"Specifications, 400."**

Problem—Loss of Lubricant from the Wheel Hubs

Possible Cause	Remedy
The seals or gaskets are worn or damaged.	Replace worn or damaged parts.

Troubleshooting

Problem—Vehicle Doesn't Slow Down Quickly Enough When the Brakes Are Applied

Possible Cause	Remedy
The brake drums are worn, heat-checked, or cracked.	Install new brake drums.

General Information

Rear axle alignment should be checked whenever rear axle or suspension components are replaced. It should also be checked when there is excessive front or rear tire wear, or hard or erratic steering.

Manufacturers of axle alignment equipment offer a variety of systems to precisely measure and correct rear axle alignment. Alignment specifications for Hunter and Bee Line alignment equipment, and for manual measurement, are in **"Specifications, 400."**

If alignment equipment is not available, the basic tools needed for checking rear axle alignment on tandem axles are a straightedge (which is nonflexible and at least as long as the axle), a steel tape rule, and a center point bar. On single axle vehicles, a straightedge, trammel bar, and steel tape rule are needed.

The straightedge is used to see if a single axle, or a forward rear axle of a tandem axle installation, is in alignment with the frame. The distance from the straightedge to the center of the wheel hub is measured on each side of the vehicle; any difference in the measurements means that the axle is out of alignment.

The center point bar **(Fig. 1)** is used to see if the forward rear axle and rearmost axle of a tandem installation are aligned with each other (parallel). The center point bar has adjustable pointers at each end, which are inserted into the axle cap holes of each axle. By comparing the distance between the two axles on one side to the distance on the other side, it can be determined if the axles are parallel.

Instructions and a list of materials for making the center point bar are in **"Specifications, 400."**

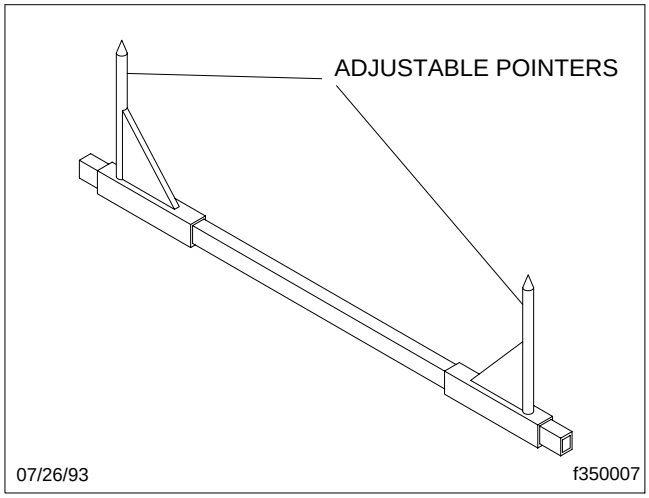

Fig. 1, Center Point Bar

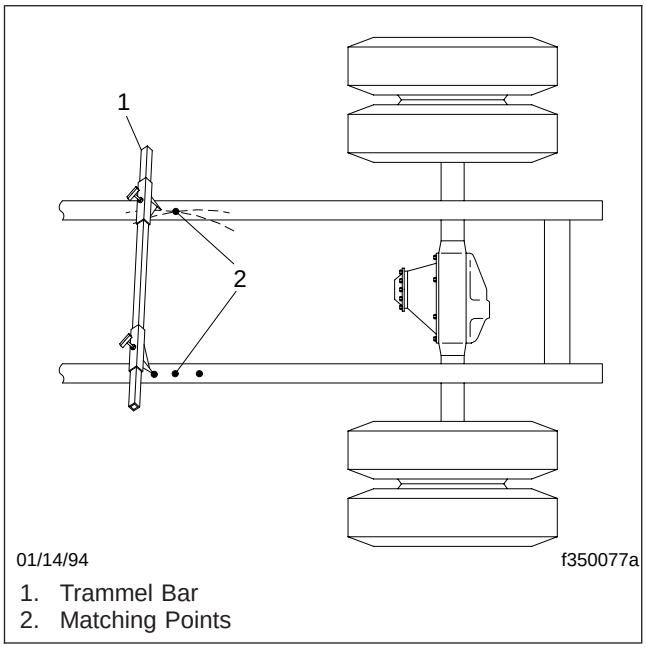
Checking Thrust Angle (Perpendicularity)

NOTE: Before checking the axle alignment, make sure the wheel bearings are adjusted. For instructions, refer to the appropriate subject in this group. Make sure that no wheel rims are bent and that all rims are correctly seated. Check the frame rail alignment following the instructions in the frame group in this manual. Correct the frame rail alignment if necessary.

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

1. Park the vehicle on a level surface. Relieve internal stresses in the suspension by driving the vehicle back and forth in a straight line, or by jacking the axle up and letting it down.
2. Chock the front tires and place the transmission in neutral. Release the parking brakes.



CAUTION

CAUTION: Do not use scribe lines for marking on frame rails. Scribe lines which cut or scratch the metal can develop into starting points for structural damage to the frame.

3. Select a point on the frame rail forward of the rear axle. Using a pencil or soapstone, mark two other points, about 102 mm (4 inches) forward and to the rear of the original point.

IMPORTANT: The distance from the original point to the forward and to the rear point does not have to be exactly 102 mm (4 inches), but the distance from the original point to the forward point *must* exactly equal the distance from the original point to the rear point.

4. Make sure that all three marks are aligned and of equal distance from the outside edge of the frame rail. Using a trammel bar, place one trammel pointer on the forwardmost point, and make an arc with a pencil or soapstone on the opposite frame rail. Then place the trammel pointer on the rearmost point and make an arc on the opposite frame rail intersecting the first arc. **See Fig. 1.** The point where the two arcs intersect and the original (or middle) point on the opposite frame rail have matching locations.

1. Trammel Bar
2. Matching Points

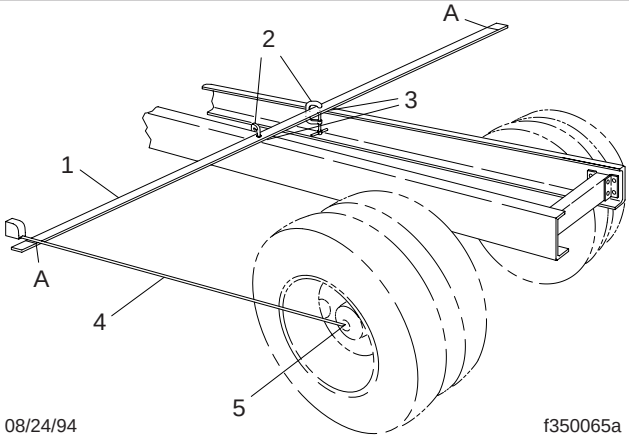


Fig. 1, Marking an Arc With the Trammel Bar

5. Line up the straightedge with the two matching points. Check that the straightedge extends out about the same distance on each side of the frame rail. Using C-clamps, clamp the straightedge to the frame. **See Fig. 2.** The straightedge must line up exactly with the points.
6. Measuring from the outside edge of each frame rail, mark the straightedge on both sides of the frame. The marks (**Fig. 2**, Ref. A) must be of equal distance from the frame and as far from the frame rail as the tires are at their farthest point from the frame.

IMPORTANT: The distance between the mark on the straightedge and the frame rail must be equal on both sides of the vehicle.

7. On each side of the vehicle, measure the distance from the mark on the straightedge to the center of the wheel hub. **See Fig. 2.** The difference between these measurements should be 9

mm (3/8 inch) or less. If the difference is more than 9 mm (3/8 inch), adjust the axle alignment. For instructions, refer to the suspension section in this manual, or to the suspension manufacturer's service literature.

Checking

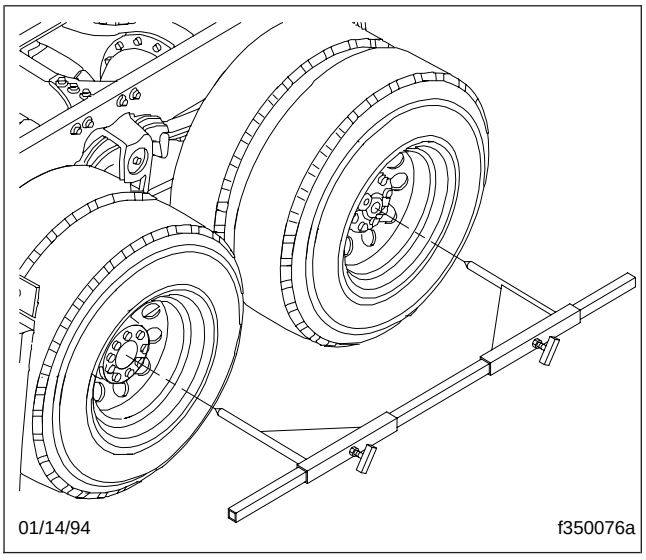
IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Freightliner dealers must have proof of this calibration history.

A straightedge and a center point bar are needed to align a tandem axle. First, a straightedge and trammel bar are used to check and, if needed, align the rearmost axle. Then, the center point bar is used to check and, if needed, align the forward-rear axle.

Use the instructions in **Subject 100** to check and align the rearmost axle. Then, check the alignment of the forward-rear axle as follows:

IMPORTANT: Align the rearmost axle before checking the forward-rear axle.

1. Using the center point bar, set the two points into the axle cap holes as shown in **Fig. 1**. Lock them in place by tightening the setscrews.



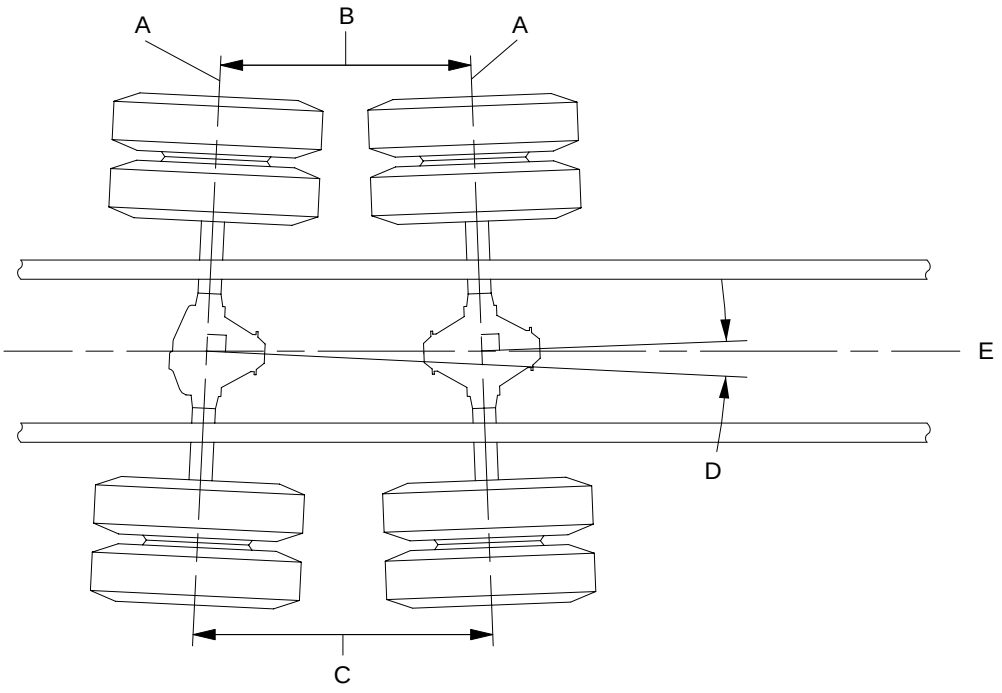


Fig. 1

2. With the points still locked in place, move the center point bar to the other side of the vehicle, set the two points into the axle cap holes, and compare the axle spacing. If there is a difference of 1/8 inch (3 mm) or less between the spacing on one side of the vehicle compared to the other, no further action is necessary.

   If the difference is more than 1/8 inch (3 mm), adjust the forward-rear axle alignment. **See Fig. 2.** For instructions, refer to the suspension section in this manual, or to the suspension manufacturer's service literature.

General Information

The rear axle full-floating wheel hub assembly is made up of five major components: inner and outer tapered wheel bearings, the drive axle spindle assembly, the wheel hub, the brake drum, and the wheel studs. **See Fig. 1.**

Each hub has a set of inner and outer tapered wheel bearing assemblies. The bearing setting is locked in place on the axle spindle by an adjusting nut, lockring, and jam nut. **See Fig. 3.**

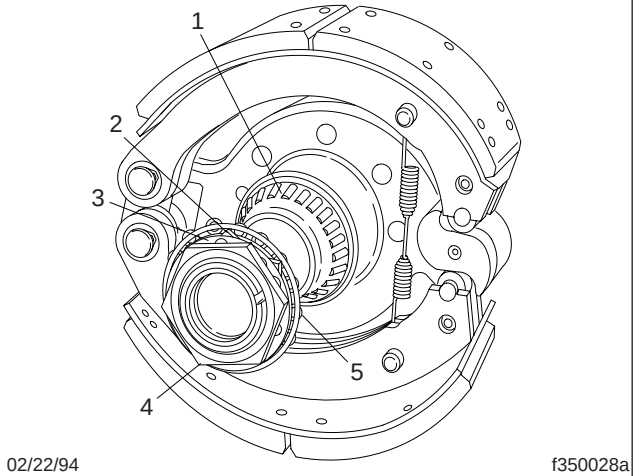
TAPERED WHEEL BEARINGS

A typical tapered wheel bearing assembly consists of a cone, tapered rollers, a roller cage, and a separate cup that is press-fit in the hub. **See Fig. 2.** All components carry the load, with the exception of the cage, which spaces the rollers around the cone.

The drive axle spindle assembly is made up of a drive axle flange and shaft, drive axle studs and stud nuts, a flange gasket, an axle spindle, an oil seal, and the nut/lockring assembly described above (**see Fig. 4**, Refs. 3 through 10, 13).



The surfaces of the spindle and the nut threads are machined. When these surfaces become damaged,

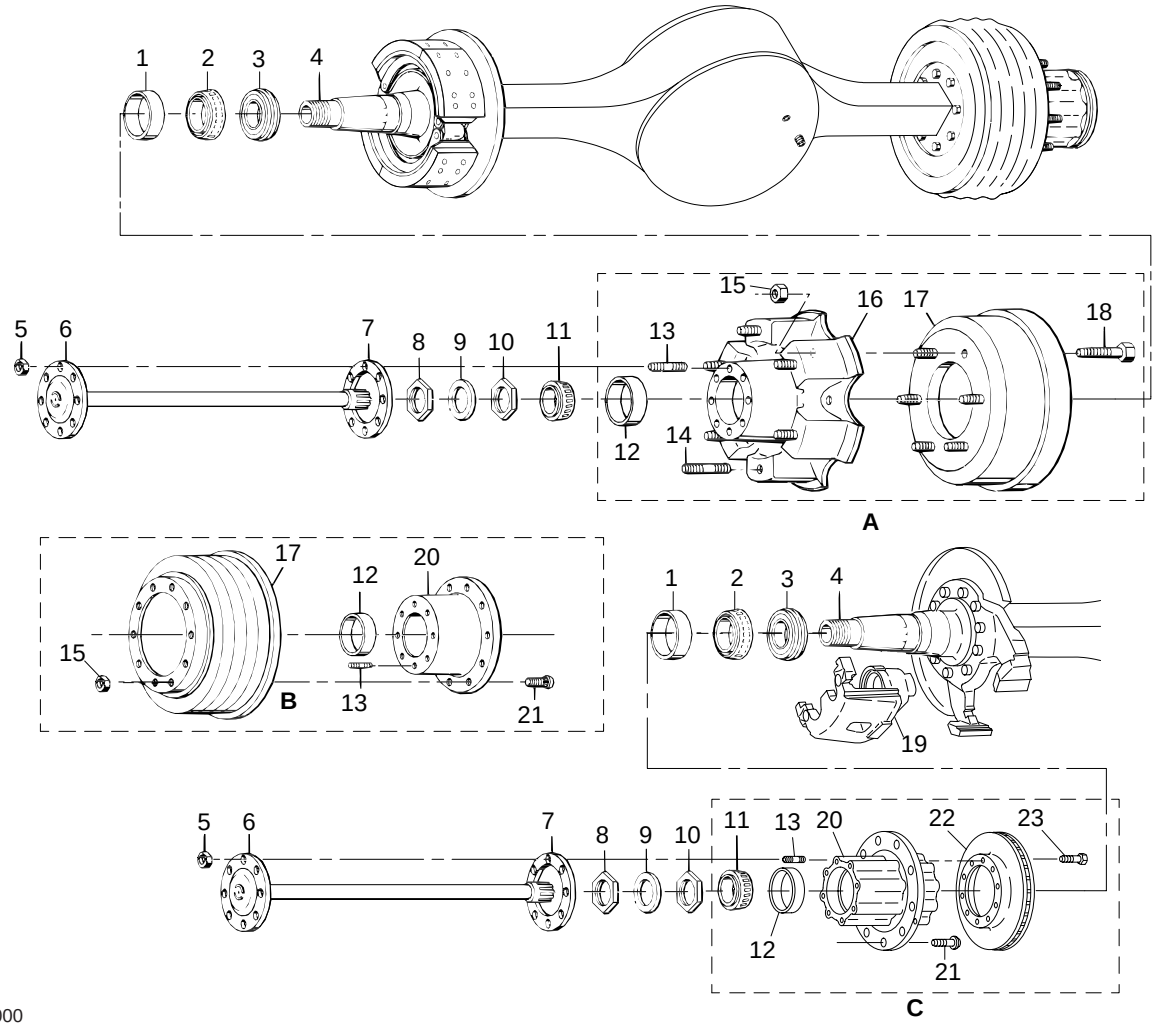
repairs are necessary. There are standard methods for performing those repairs that preserve the proper alignment of the axle spindle assembly. Refer to the axle manufacturer for instructions.

CAUTION

CAUTION: The National Highway Traffic Safety Administration (NHTSA) has warned against repairs that involve cutting off a portion of a damaged spindle and welding on a replacement part. The heat of welding can reduce the strength of spindles made with heat-treated materials and lead to spindle failure. After the cutting and welding operations, the replacement part may not be correctly aligned on the spindle. This can cause damage to the spindle nut.

WHEEL HUB

The inner disc wheel and/or brake drum is mounted on an aluminum or iron wheel hub (**Fig. 4**, Ref. 20). Both the inner and outer bearing cups and certain types of wheel studs are press-fit in the hub. The hub is also the interconnecting point for the drive axle shaft and wheels.



Each spoke wheel (**Fig. 4**, Ref. 16) combines both wheel and hub into a single unit.

WHEEL STUDS

A headed wheel stud (**Fig. 5**) is used on rear axle disc wheel hub assemblies and has either serrations on the stud body or a flat area on the stud's head to prevent the stud from turning in the wheel hub.

The end of the stud that faces away from the vehicle is stamped with an "L" or "R," depending on which side of the vehicle the stud is installed. Studs stamped with an "L" are left-hand threaded and are installed on the driver's side of the vehicle. Studs stamped with an "R" are right-hand threaded and are installed on the passenger's side of the vehicle.

Spoke wheels have rim studs. Rim studs are threaded on both ends, with a nonthreaded section midway along the shaft of the stud. The studs are coated with an anaerobic locking compound.

Hub Assembly Removal and Installation, Disc Wheels

Removal

See **Fig. 1** for this procedure.

1. Chock the front tires to prevent vehicle movement. Release the parking brakes.
2. Raise the rear of the vehicle until the tires clear the ground. Place safety stands under the axle.
3. On vehicles equipped with air brakes, back off the slack adjuster to release the rear axle brake shoes. For instructions, see the applicable slack adjuster section in **Group 42**.
4. Remove both wheel and tire assemblies. For instructions, see **Group 40**.

WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air-purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, from removal of the wheels through assembly.

Never use compressed air or dry brushing to clean brake dust away. Either method can spread dangerous particles beyond the work area.

5. To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.
6. On vehicles with outboard drum brakes, remove the brake drum. On vehicles with disc brakes, remove the brake caliper; for instructions, see **Group 42**.

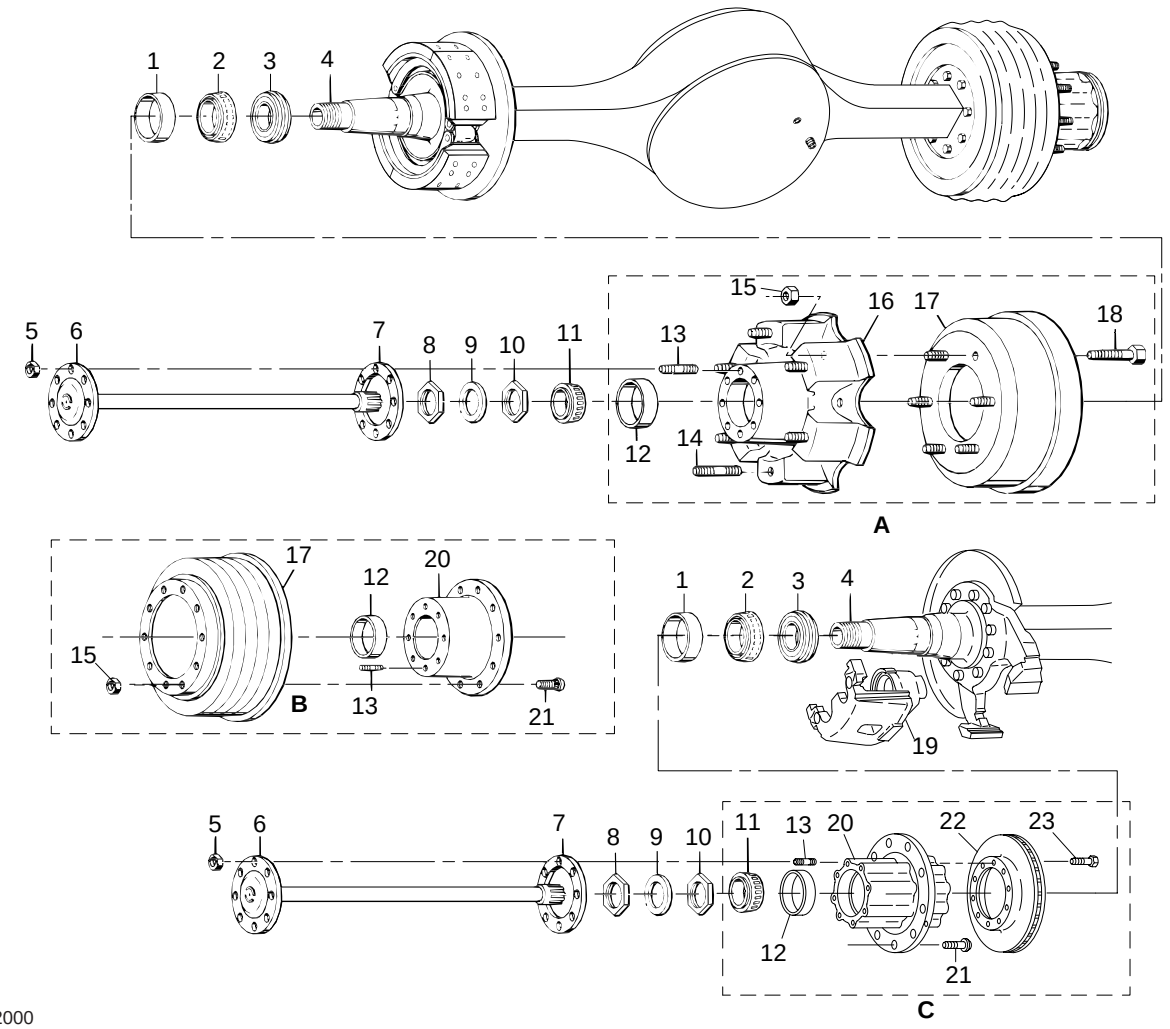
NOTE: Oil will spill as the drive axle shaft and the wheel hub are removed. Place a suitable container under the drive axle flange to catch any spilled oil. Dispose of the oil properly.

7. Remove the drive axle stud nuts and washers. See **Fig. 2**.
8. Using a hammer and a soft drift, such as one made of brass, sharply tap the center portion of the drive axle flange. See **Fig. 2**. The shaft will usually spring slightly outward after the seal has broken. Remove the drive axle shaft.

CAUTION

When tapping the drive axle flange, avoid striking the drive axle studs. If struck, the studs may bend or break, or the stud threads can be damaged. Replace damaged studs.

NOTE: Even if the drive axle shaft doesn't spring outward, the seal may have loosened enough to allow the shaft to be pulled from the axle spindle. If the seal has not broken, repeat this step.



9. If equipped, remove the tapered dowels and washers from the drive axle flange.
10. Remove and discard the gasket.
11. Remove the axle spindle jam nut and the lock-ring or nut-lock, as equipped. See **Fig. 3**.
12. Back off the wheel bearing inner adjusting nut about two turns, or enough to allow the weight of the hub to be lifted from the wheel bearings.
13. Lift the hub until all weight is removed from the wheel bearings; remove the wheel bearing inner adjusting nut.

CAUTION

When moving the hub, be careful not to let the outer wheel bearing drop from the axle spindle. Dropping the bearing can warp the cage or damage the rollers, ruining the bearing.

14. Move the hub about 1/2 inch (13 mm) to jar loose the outer wheel bearing (allow the hub-only assembly to rest on the axle spindle; be careful not to damage the axle spindle threads).
15. Carefully remove the outer wheel bearing; handle the bearings with clean, dry hands. Wrap them in either clean oil-proof paper or lint-free rags.

CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch their surfaces and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

16. Remove the hub. Be careful not to damage the axle spindle threads as the assembly is removed.
17. Using a seal removal tool, remove the oil seal from the hub, if not already removed.
18. Remove the inner wheel bearing from the hub. Handle all bearing assembly parts with clean, dry hands.

    If the bearings aren't easily removed, place a protective cushion where it will catch them. Then, use a hardwood drift and a light hammer to gently tap the bearings (and seal, if needed) out of the cup. Wrap all bearing assembly parts in clean oil-proof paper or lint-free rags.
19. Using an emery cloth or a file, remove all burrs from the hub shoulder and the seal bore. See **Fig. 4** and **Fig. 5**. Clean any metal filings from the parts. For instructions, see **Subject 110**.

NOTE: Typical application.

Fig. 4, Clean the Hub Shoulder

IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle. Dirt, metal filings, or other debris can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

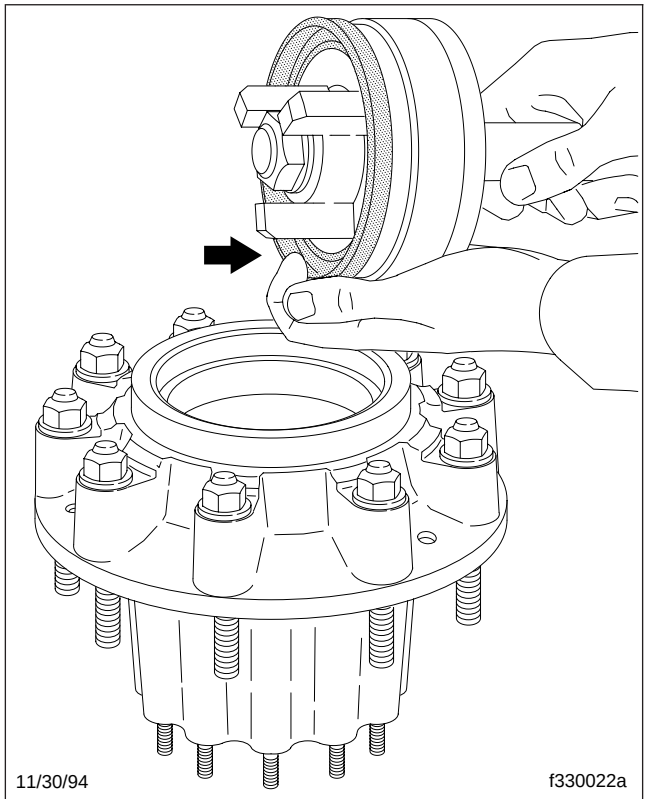
Installation

⚠ WARNING



Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, continuing through installation of the wheels.

1. Using clean solvent, remove the old oil from the axle spindle and the disassembled parts. Allow the parts to dry, or dry them with a clean, absorbent, and lint-free cloth or paper. Wrap a protective layer of friction tape on the axle housing threads.
2. Coat both bearing assemblies with fresh oil. Install the inner wheel bearing and oil seal. Handle the bearings with clean, dry hands. For lubricant specifications, see **Specifications, 400**.

⚠ CAUTION

Use only fresh oil on the bearing assemblies; old oil could be contaminated with dirt or water (both are corrosives) and could cause damage to both wheel bearing assemblies and the wheel hub.

2.1 Seat the small outer diameter of the seal in the recess of the tool adaptor. See **Fig. 6**. The correct adaptor is identified on the box.

NOTE: Typical application.

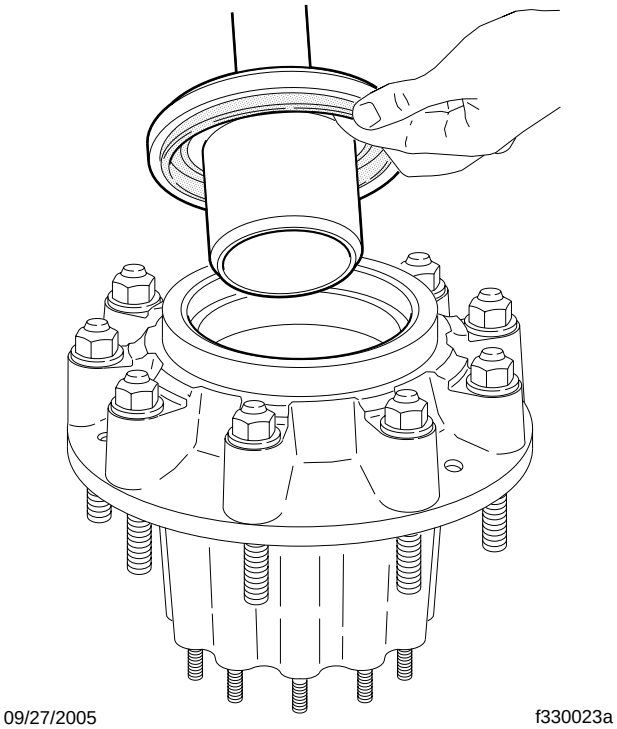


Fig. 6, Seat the Seal in the Tool

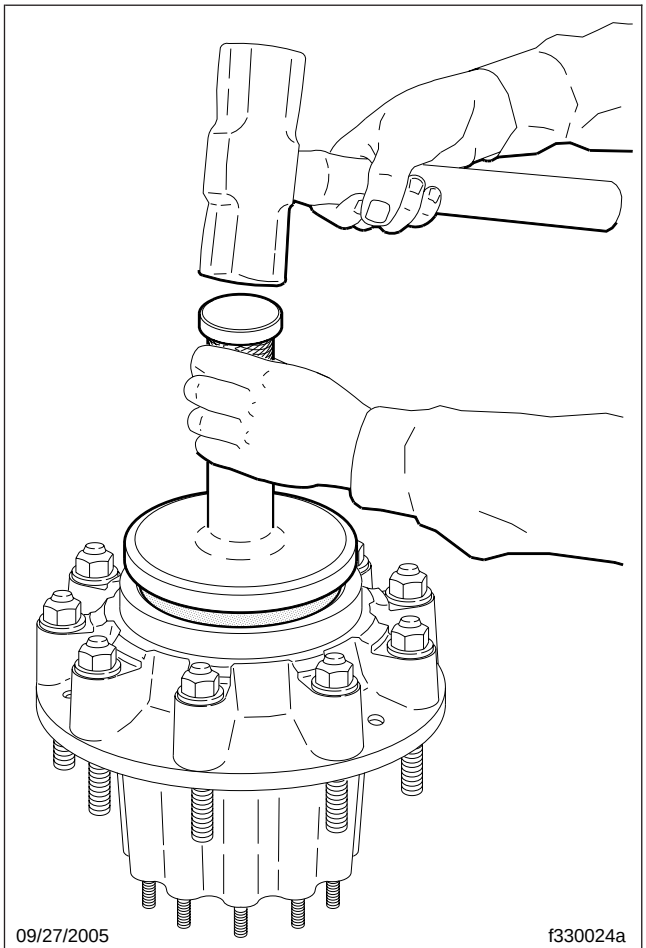
2.2 Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 7**. The plug prevents cocking of the seal in the bore.

2.3 Hold the tool handle firmly, and strike it until the sound of the impact changes as the seal bottoms out. See **Fig. 8**. Hold the tool firmly to avoid bounce or unseating of the seal from the adaptor.

2.4 After the seal is bottomed in the bore, check for freedom of movement by manually moving the interior rubber part of the

Hub Assembly Removal and Installation, Disc Wheels



NOTE: Typical application.

seal back and forth. A slight movement indicates a damage-free installation.

3. Wipe a film of axle oil on the axle spindle to prevent rust from forming behind the inner wheel bearing.
4. Carefully mount the hub and inner wheel bearing assembly on the axle spindle. Be careful not to unseat the inner wheel bearing or seal.
5. Fill the hub cavity with oil, and install the outer wheel bearing; handle the bearings with clean, dry hands. Use care not to damage the bearings as they are seated in the bearing cups. Then remove the friction tape from the axle spindle threads.
6. Install the wheel bearing adjustment nut (see **Fig. 3**):
   - 6.1 After the wheel hub and bearings are assembled on the spindle, tighten the inner adjusting nut finger-tight.

NOTE: Typical application.

Fig. 8, Strike the Tool

IMPORTANT: Be sure there is enough clearance between the brake shoes and the brake drum, so brake shoe drag won't interfere with bearing adjustment.

- 6.2 While rotating the wheel hub assembly, tighten the inner adjusting nut 100 lbf·ft (135 N·m).
- 6.3 Back off the adjusting nut completely.
- 6.4 Tighten the adjusting nut 20 lbf·ft (27 N·m) while rotating the wheel hub assembly.
- 6.5 Back off the adjusting nut one-third turn.

NOTE: If you're securing the wheel bearings with a pierced lockring, and no hole in the

Hub Assembly Removal and Installation, Disc Wheels

lockring aligns with the dowel on the adjusting nut, remove the lockring, turn it over and install it again. If a hole still doesn't align with the dowel, loosen the adjusting nut, but only enough to align the dowel with a hole in the lockring.

7. Install the locking device and jam nut.

   7.1 Install the locking device.

   NOTE: The locking device can be any one of the following types:

   - Tanged nut-lock
   - Lockring
   - Lockwasher *and* lockring
   - Nut-lock *and* lockring

   7.2 Install the jam nut, and tighten it to the applicable torque value in **Table 1**.

Dual-Nut Wheel Bearing Lock Torque Values		
Application	**Size**	**Torque: lbf·ft (N·m)**

		Stage 3: Tighten to 20 (25) While Rotating Hub
		Stage 4: Back Off 1/3 Turn
Jam Nut (with Wheel Bearing Nut, Pierced Lockwasher, and Bendable Lockwasher)	1-1/8	Target: 175 (235) Permissible Range: 150–225 (205–305)
	1-1/2 to 2-1/2	Target: 250 (340) Permissible Range: 200–300 (270–405)
	2-5/8 or Larger	Target: 325 (440) Permissible Range: 250–400 (340–540)

Table 1, Dual-Nut Wheel Bearing Lock Torque Values

8. With the jam nut installed and tightened, adjust the wheel bearings.

   8.1 Attach a dial indicator to the hub and set the point of the indicator in line with the end of the axle spindle.

   If using aluminum hubs, you may have to install the brake drum on the hub to provide a steel base for the magnet of the dial indicator. Mount the drum on the hub's drum pilot, then adjust the brake or have someone apply the brakes to hold the drum securely while you secure the drum using the stud at the 12 o'clock position, then the studs at about the 4 o'clock and 8 o'clock positions.

   NOTE: If using a stud-piloted hub and a steel drum, install 1–1/4 inch washers between the nuts and the drum.

   8.2 Release the brakes if you used them to hold the drum while installing it.

   8.3 Grip the sides of the hub at the three o'clock and nine o'clock positions, then push the hub (and drum, if applicable), to seat the inboard bearing set. Zero the dial indicator.

   8.4 Grip the sides of the hub at the three o'clock and nine o'clock positions, then pull the hub (and drum, if applicable). Read the dial indicator, and note the end play.

   8.5 Push the hub back in to confirm that the needle of the dial indicator returns to zero.

9. The end play must be between 0.001 and 0.005 inch (0.025 and 0.127 mm). If the end play is not within this range, adjust the end play.

Hub Assembly Removal and Installation, Disc Wheels

9.1 Remove the jam nut and locking device, and back off or tighten the inner adjusting nut to adjust the end play.

IMPORTANT: *If you're using a nut-lock,* turning the adjusting nut 1/4 turn will change the end play about 0.020 inch (0.51 mm).

If you're using a lockring, turning the adjusting nut one lockring hole will change the end play about 0.005 inch (0.13 mm). If you take the lockring off and reverse it, then turn the adjusting nut to the next hole, this will change the end play about 0.0025 inch (0.064 mm).

9.2 Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), turn the inner adjusting nut again.

9.3 Once the end play is correct, bend the nut-lock or lockwasher as applicable to lock the jam nut and/or adjusting nut in place.

9.4 Rotate the wheel in both directions. It should rotate freely with no dragging or binding.

10. Install a new gasket on the drive axle studs.
11. Install the drive axle shaft. The splined end of the axle shaft must seat before the drive axle flange will fit over the studs.
12. If equipped, install the dowels and washers on the drive axle studs. Install the drive axle stud nuts. Using the sequence shown in **Fig. 9**, tighten the nuts to the torque values in the torque table in **Specifications, 400**.
13. Install the brake drum on the wheel hub.
14. Install the inner and outer wheel and tire assemblies. For instructions, see **Group 40**.

⚠ WARNING

If the inner wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking action, and the hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist, could result in loss of a wheel or loss of vehicle control, and possible personal injury.

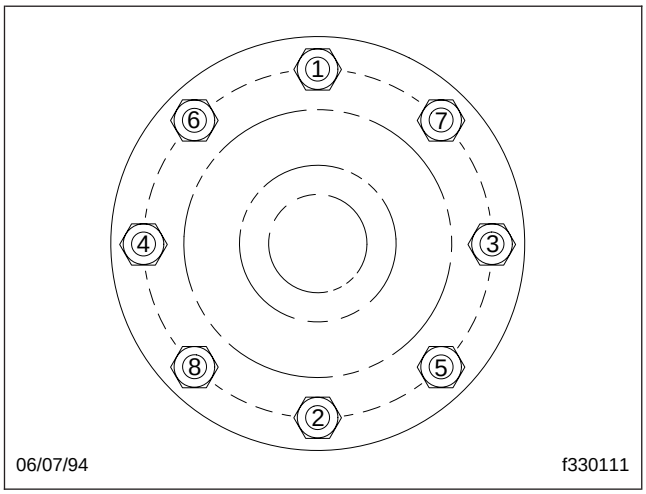

Fig. 9, Drive Axle Stud Nuts, Tightening Sequence

15. Fill the axle with lubricant. See **Specifications, 400** for the recommended axle lubricants.

⚠ WARNING

Failure to add oil to the axle housing bowl or the wheel hub after the drive axle shaft and wheel hub have been serviced will damage the wheel bearings and cause them to seize during vehicle operation. See Fig. 10. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury.

15.1 Add the recommended drive axle lubricant through the axle housing filler hole (see **Fig. 11**) or the carrier filler hole (see **Fig. 12**) until the lubricant is level with the bottom of the hole. See **Fig. 13**. Tighten the fill plug 35 lbf·ft (47 N·m).

15.2 Tilt the axle to the left and right, by jacking the opposite side. Hold the tilted position for one minute on each side, to allow oil to run into the wheel end.

15.3 Return the axle to a level position, and add oil through the axle housing fill hole. About one quart (0.9 liter) of lubricant will be needed to bring the oil level even with the base of the fill hole.

NOTE: Drive axle wheel bearings are lubricated by oil drawn from the axle housing bowl section. This method ensures good exchange of heat, prevents stagnation, and minimizes the maintenance required on bearings and hub assemblies.

16. Turn the wheels, and check the lubricant level.
17. Adjust the rear axle brakes at the slack adjuster. For instructions, see **Group 42** of the *Business Class Trucks Maintenance Manual*.

Hub Assembly Removal and Installation, Spoke Wheels

Spoke wheel assemblies with inboard drums don't need to be completely disassembled for brake component maintenance. The tires and rims can remain attached to the wheel, and the wheel to the brake drum. The assembly is then removed from the axle as a single unit to expose brake components. See **Group 42** for brake assembly service information.

1. Chock the front tires to prevent vehicle movement. Release the parking brakes.
2. Raise the rear of the vehicle until the tires clear the ground. Then place safety stands under the axle to be serviced. Position a jack or wheel-and-tire dolly under the tires.
3. Remove both rim and tire assemblies. For instructions, see **Group 40**.
4. If the vehicle is equipped with air brakes, back off the slack adjuster to release the rear axle brake shoes. For instructions, see the applicable slack adjuster section in **Group 42**. If the vehicle is equipped with hydraulic brakes, remove the brake caliper. For instruction, see **Group 42**.
5. Remove the drive axle flange nuts (**Fig. 2**) and washers.

06/09/94 f400090b

1. Drive Axle Studs and Nuts
2. Center Portion of Drive Axle Flange

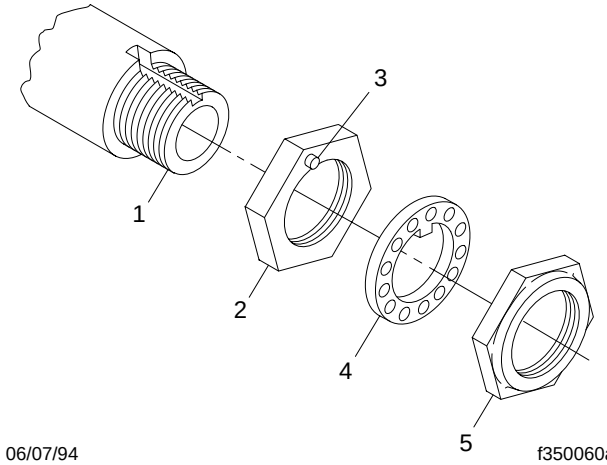
Fig. 2, Wheel Assembly and Hub

NOTE: Oil will spill as the drive axle shaft and wheel are removed. Place a suitable container under the wheel to catch any spilled oil. Safely discard the oil.

6. Using a hammer and a soft drift, such as one made of brass, sharply tap the center portion of the drive axle flange. See **Fig. 2**. The shaft will usually spring slightly outward after the seal has broken. Then remove the drive axle shaft.

CAUTION

When tapping the drive axle flange, avoid striking the drive axle studs. If struck, the studs may bend or break, or the stud threads can be damaged. Replace damaged studs.



NOTE: Even if the drive axle shaft doesn't spring outward, the seal may have loosened enough to allow the shaft to be pulled from the axle housing. If the seal has not broken, repeat the above step.

7. If so equipped, remove the tapered dowels and washers from the drive axle flange.
8. Remove and discard the gasket.
9. Remove both the axle spindle jam nut and the lockring. See **Fig. 3**. Then, back off the wheel bearing inner adjusting nut about two turns, or enough to allow the weight of the wheel and drum assembly to be lifted from the wheel bearings.
10. Using the wheel dolly or jack, raise the wheel and drum assembly until all weight is removed from the bearings. Then remove the wheel bearing inner adjusting nut.
11. Carefully remove the outer wheel bearing; handle the bearings with clean, dry hands. If the wheel bearings have not loosened from the cup, move the wheel assembly about 1/2 inch (13 mm) to jar loose the outer wheel bearing. Be careful to not drop the bearings. Wrap them in clean oil-proof paper or lint-free rags.

WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air-purifying respirator approved by MSHA or NIOSH. Wear a res-

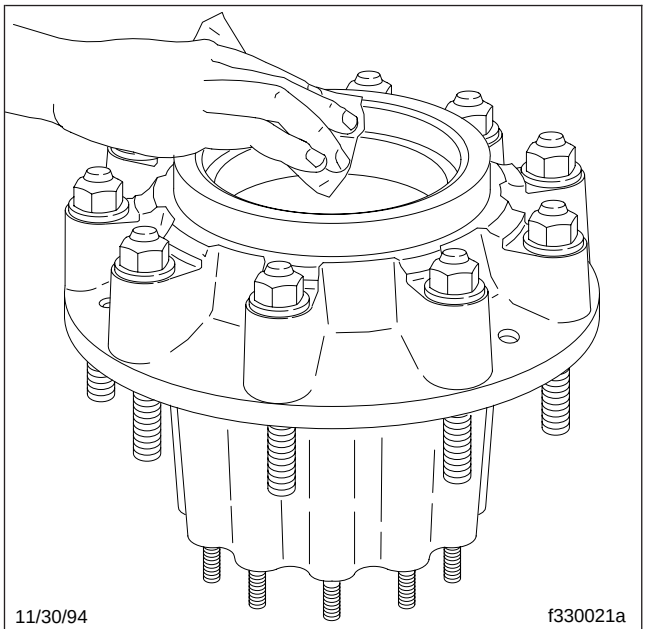
pirator at all times when servicing the brakes, from removal of the wheels through assembly.



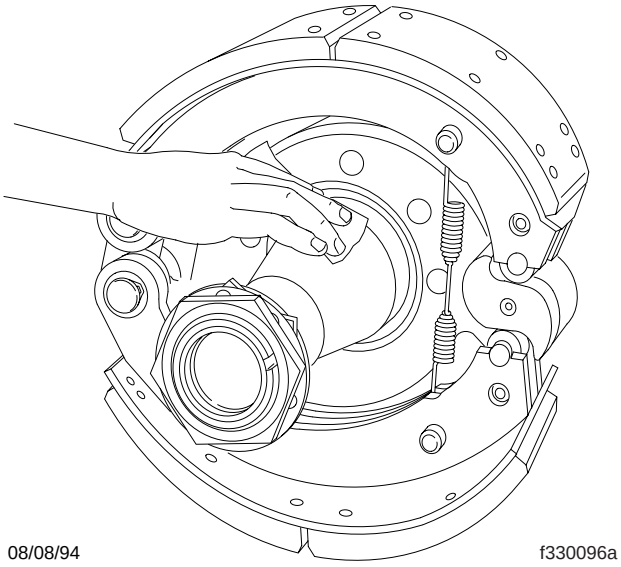
Never use compressed air or dry brushing to clean brake dust away. Either method can spread dangerous particles beyond the work area.

⚠ CAUTION

Don't spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

12. Using the wheeled support, pull the wheel assembly away from the vehicle. Be careful not to damage the axle spindle threads as the assembly is removed.
13. Remove the brake drum or rotor nuts (**Fig. 1**) and detach the brake drum or rotor from the wheel. For instructions, see **Group 42**.

    To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Then, using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Don't use compressed air or dry brushing to clean the brake assembly.
14. Remove the oil seal, using an oil seal removal tool.
15. Remove the inner wheel bearing from the hub. If the bearings aren't easily removed, place a protective cushion where it will catch the bearing. Then, use a hardwood drift and a light hammer to gently tap the bearing (and seal, if needed) out of the cup. Handle the bearings with clean, dry hands. Wrap them in clean oil-proof paper or lint-free rags.
16. Remove all burrs from the shoulder and the seal bore with an emery cloth or a file. See **Fig. 4** and **Fig. 5**. Clean any metal filings from the parts.



NOTE: Typical application.

Fig. 4, Clean the Hub Shoulder

IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

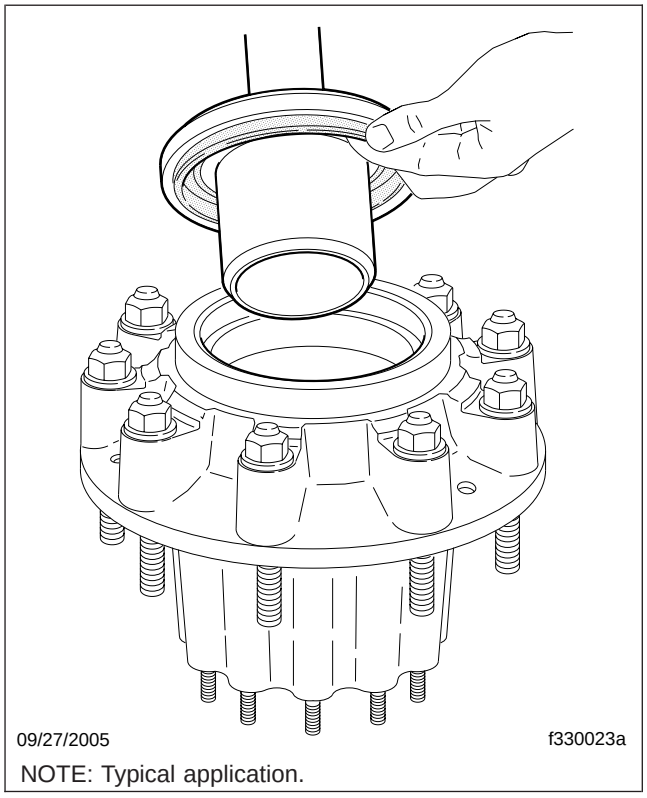
Installation (See Fig. 1)

⚠ WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, continuing through installation of the wheels.

1. Using clean solvent, remove the old oil from the axle spindle and also the disassembled parts. Inspect and clean the wheel hub cavity and the wheel bearings as instructed under **Subject 110**. Allow the parts to dry, or dry them with a clean, absorbent, and lint-free cloth or paper.
2. Wrap a protective layer of friction tape on the axle spindle threads.
3. If it was removed, attach the brake drum or rotor to the wheel. Install the brake drum or rotor bolts and nuts, then tighten the nuts to the torque values in the torque table in **Specifications, 400**. See **Group 42** for additional instructions.
4. Coat both bearing assemblies with fresh oil. Install the inner wheel bearing and oil seal. Handle the bearings with clean, dry hands.
   - 4.1 Seat the small outer diameter of the seal in the recess of the tool adaptor. See **Fig. 6**. The correct adaptor is identified on the box.
   - 4.2 Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 7**. The plug prevents cocking of the seal in the bore.



NOTE: Typical application.

Fig. 6, Seat the Seal in the Tool

   - 4.3 Hold the tool handle firmly, and strike it until the sound of the impact changes as the seal bottoms out. See **Fig. 8**. Hold the tool firmly to avoid bounce or unseating of the seal from the adaptor.

5. Wipe a film of axle oil on the axle spindle to prevent rust from forming behind the inner wheel bearing.
6. Using a wheeled support, mount the wheel and drum assembly on the axle spindle; be careful not to unseat the bearings or seal.
7. Fill the hub cavity with oil, and install the outer wheel bearing; handle the bearings with clean, dry hands. Then remove the friction tape from the axle spindle threads.
8. Adjust the wheel bearings as follows (see **Fig. 3**):

   IMPORTANT: Be sure there is enough clearance between the brake shoes and the brake drum, so brake shoe drag won't interfere with bearing adjustment.

   8.1 After the wheel hub and bearings are assembled on the spindle, tighten the inner (adjusting) nut 200 lbf·ft (271 N·m) while rotating the wheel hub assembly.

   8.2 Back off the inner nut one full turn.

   8.3 Tighten the inner nut 50 lbf·ft (68 N·m) while rotating the wheel hub assembly.

   8.4 Back off the inner nut one quarter turn.

   NOTE: If you're securing the wheel bearings with a pierced lockring, and no hole in the lockring aligns with the dowel on the adjusting nut, remove the lockring, turn it over and install it, again. If a hole still doesn't align with the dowel, loosen the adjusting nut, but only enough to align the dowel with a hole in the lockring.

NOTE: Typical application.

8.5 Install the locking device:

- Tanged nut-lock
- Lockring
- Lockwasher *and* a lockring
- Nut-lock *and* a lockring

Then install the jam nut, and tighten it to the applicable torque in **Table 1**.

	2-5/8 or Larger	Target: 325 (440) Permissible Range: 250–406 (340–540)

Table 1, Dual-Nut Wheel Bearing Lock Torque Values

8.6 With the jam nut installed and tightened, attach a dial indicator to the hub and set the point of the indicator in line with the end of the axle spindle.

If using aluminum hubs, you may have to install the brake drum on the hub to provide a steel base for the magnet of the dial indicator. Mount the drum on the hub's drum pilot, then adjust the brake or have someone apply the brakes to hold the drum securely while you secure the drum using the stud at the 12 o'clock position, then the studs at about the 4 o'clock and 8 o'clock positions.

NOTE: If using a stud-piloted hub and a steel drum, install 1–1/4 inch washers between the nuts and the drum.

8.7 Release the brakes if you used them to hold the drum while installing it.

Grip the sides of the hub at the three o'clock and nine o'clock positions, then push the hub (and drum, if applicable), to seat the inboard bearing set. Zero the dial indicator.

Grip the sides of the hub at the three o'clock and nine o'clock positions, then pull the hub (and drum, if applicable). Read the dial indicator, and note the end play.

Push the hub back in to confirm that the needle of the dial indicator returns to zero.

The end play must be between 0.001 and 0.005 inch (0.025 and 0.127 mm).

9. If the end play is not within this range, remove the jam nut and locking device, and back off or tighten the inner (adjusting) nut to adjust the end play. Keep the following in mind:

If you're using a nut-lock: turning the inner nut 1/4 turn will change the end play about 0.020 inch (0.508 mm).

If you're using a lockring: turning the inner nut one lockring hole will change the end play about 0.005 inch (0.127 mm). If you take the lockring off and reverse it, then turn the inner nut to the next hole, this will change the end play about 0.0025 inch (0.0635 mm).

Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.025 and 0.127 mm), adjust the inner (adjusting) nut, again.

10. Once the end play is correct, bend the nut-lock or lockwasher as applicable to lock the jam nut and/or adjusting nut in place.
11. Rotate the wheel in both directions. It should rotate freely with no dragging or binding.
12. Install a new gasket on the drive axle studs.
13. Install the drive axle shaft. The splined end of the axle shaft must seat before the drive axle flange will fit over the studs.
14. If equipped, install the dowels and washers on the drive axle studs. Install the drive axle nuts. Using the sequence shown in **Fig. 9**, tighten the nuts to the torque values in the torque table in **Specifications, 400**.

Hub Assembly Removal and Installation, Spoke Wheels

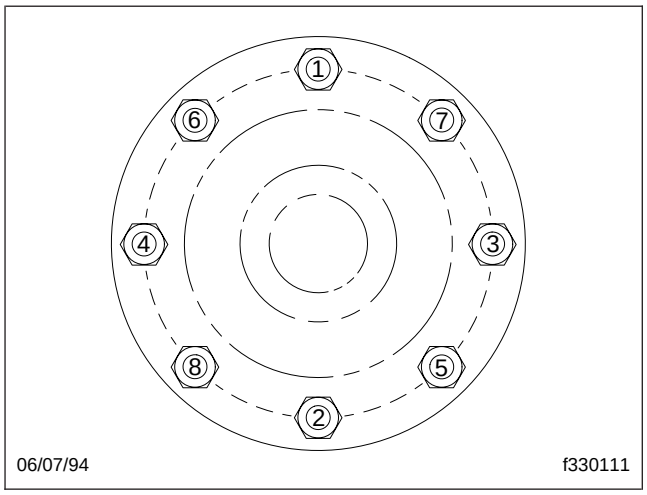

Fig. 9, Axle Shaft Flange Nut-Tightening Sequence

15. Install the brake caliper, if removed. See **Group 42** for instructions.
16. Install the rim and tire assemblies. For instructions, see **Group 40**.

⚠ WARNING

If the inner rim nuts cannot be tightened to minimum torque values, the rim studs have lost their locking action, and the wheel is probably damaged. In this case, replace it with a new wheel. Failure to replace the wheel when the conditions described above exist, could result in loss of a wheel or loss of vehicle control, and possible personal injury.

17. Fill the axle with lubricant.

⚠ WARNING

Failure to add oil to the axle housing bowl or the wheel hub after the drive axle shaft and wheel have been serviced will damage the wheel bearings and cause them to seize during vehicle operation. See Fig. 10. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury.

17.1 Pour the recommended drive axle lubricant through the axle housing filler hole (**Fig. 11** or **Fig. 12**) until the lubricant is level with the bottom of the hole. See **Fig. 13**. See **Specifications, 400** for the recommended axle lubricants. Tighten the plug 35 lbf·ft (47 N·m).

17.2 Tilt the axle to the left and right, by jacking the opposite side. Hold the tilted position for one minute on each side, to allow oil to run into the wheel end.

17.3 Return the axle to a level position, and add oil through the axle housing filler hole. About one extra liter (two pints) of lubricant will be needed, to bring the oil level even with the base of the filler hole.

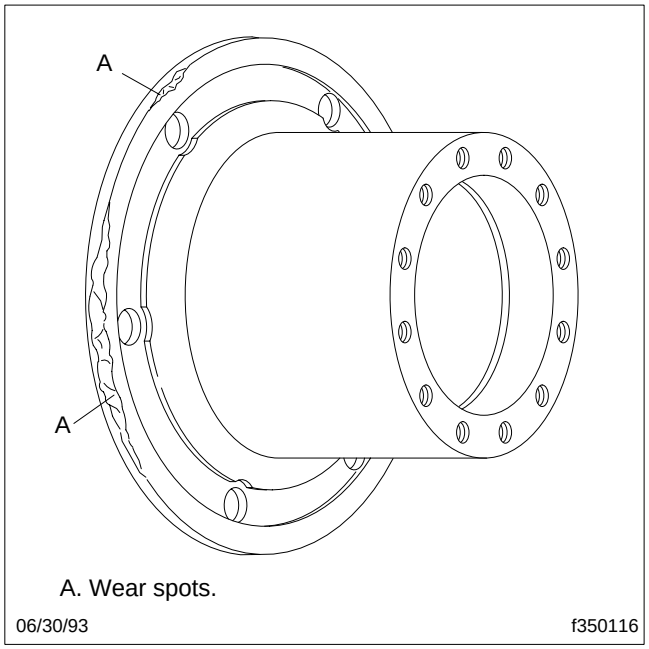
NOTE: Drive axle wheel bearings are lubricated by oil drawn from the axle housing bowl section. This method ensures good exchange of heat, prevents stagnation, and minimizes the maintenance required on bearings and hub assemblies.

18. Turn the wheels, and check the lubricant level.
19. If the vehicle is equipped with air brakes, adjust the rear axle brakes at the slack adjusters. For instructions, see Group 42 of the *Business Class Trucks Maintenance Manual*.
20. Remove the safety stands from under the axle, then lower the vehicle.
21. Apply the parking brakes, then remove the chocks from the front tires.



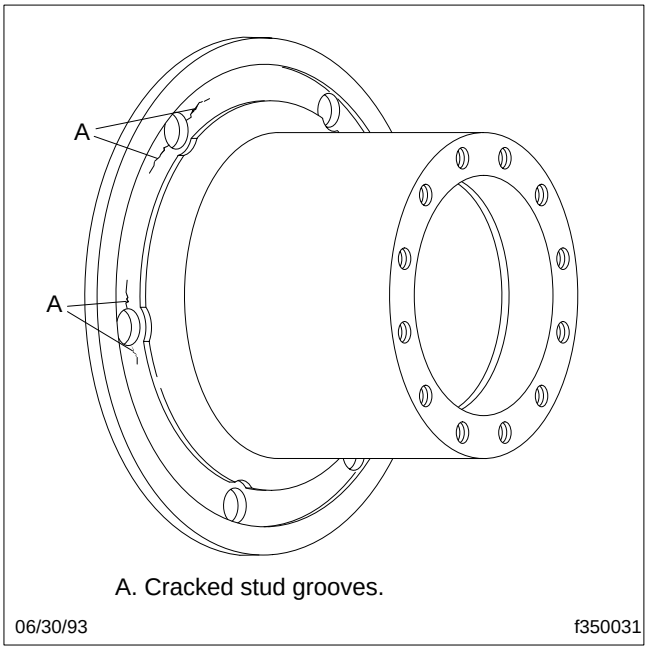
Wheel Hub Assembly and Drive Axle Inspection

1. Inspect the wheel hub flange. A loose wheel assembly will cause the flange to be worn, jagged, or warped. **See Fig. 1.** Replace the wheel hub if any of these conditions exist.

   Inspect the flange surface around the wheel studs. Improperly torqued wheel nuts will cause worn or cracked stud grooves on the hub. **See Fig. 2.** If wear spots or cracks appear anywhere on the hub, or if the hub is otherwise damaged, replace it with a new one.

2. Remove all the old oil from the spoke wheel or hub cavity. Inspect the inner surface of the wheel or hub for cracks, dents, wear, or other damage. Replace the wheel or hub if damaged.

3. Remove all the old grease or oil from the surfaces of the wheel bearing cups. Inspect the cups for cracks, wear, spalling, or flaking. **See Fig. 3.** Replace the cups if damaged in any way; for instructions, **refer to "Wheel Bearing Cup Removal and Installation, Ferrous Hubs, 120."**



A. Wear spots.

06/30/93 f350116

Fig. 1, Typical Wheel Hub, Damaged

4. Inspect the wheel nuts on disc wheel installations, or the rim nuts on spoke-wheel installations. Damaged nuts **(Fig. 4),** usually caused by inadequate tightening, must be replaced with new ones.

   Inspect the wheel studs or rim studs. Replace studs that are stripped, broken, bent, or otherwise damaged **(Fig. 5);** for instructions, **refer to "Wheel Stud Replacement, Disc Wheels, 130"** or **"Spoke Rim Stud Replacement, Spoke Wheels, 140."**

5. Inspect the drive axle studs. Replace the studs that have stripped threads or are broken. Also, replace bent or otherwise damaged studs; for instructions, **refer to "Drive Axle Stud Replacement, 150."**

6. Inspect the drive axle shaft. If the vehicle has been overloaded, or used under severe or improper operations, the drive axle shaft may be twisted, bent, or otherwise damaged. **See Fig. 6.** Replace the drive axle shaft and flange assembly if damaged.

Axle Components Cleaning and Inspection

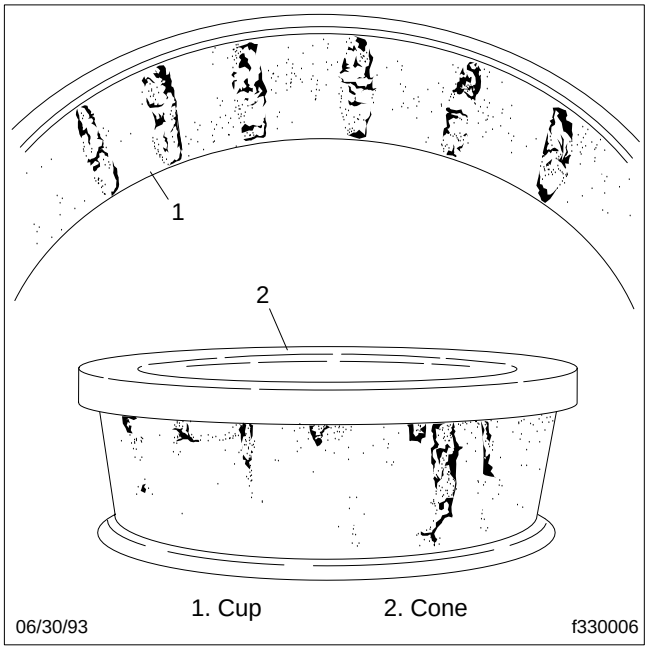

Fig. 3, Spalling (Flaking) of Wheel Bearing Assembly

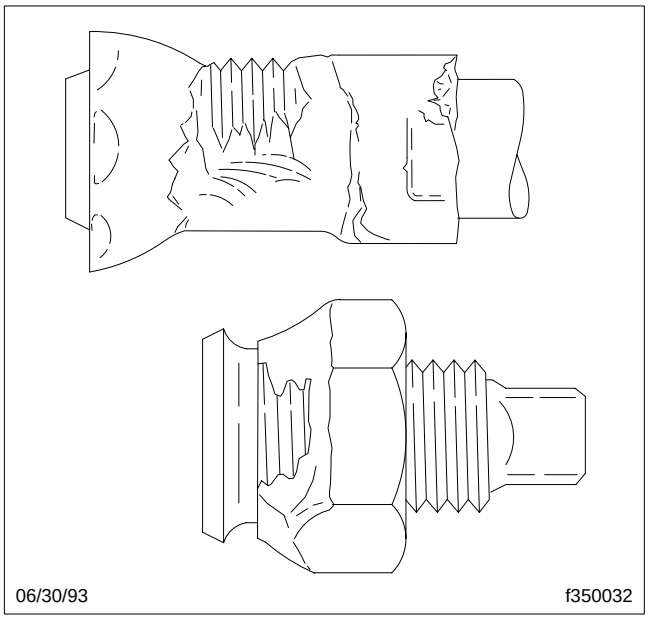

Fig. 4, Damaged Wheel Stud Nuts

⚠ CAUTION

CAUTION: If the drive axle shaft and flange assembly is not replaced once the shaft is twisted or otherwise damaged, it will continue to twist until fracture occurs. With complete fracture of the shaft, other axle parts may be damaged which will increase the cost of repairs. Whenever a drive axle assembly is damaged, the drive axle shaft and flange on the opposite side of the axle should also be carefully examined, and replaced if damaged.

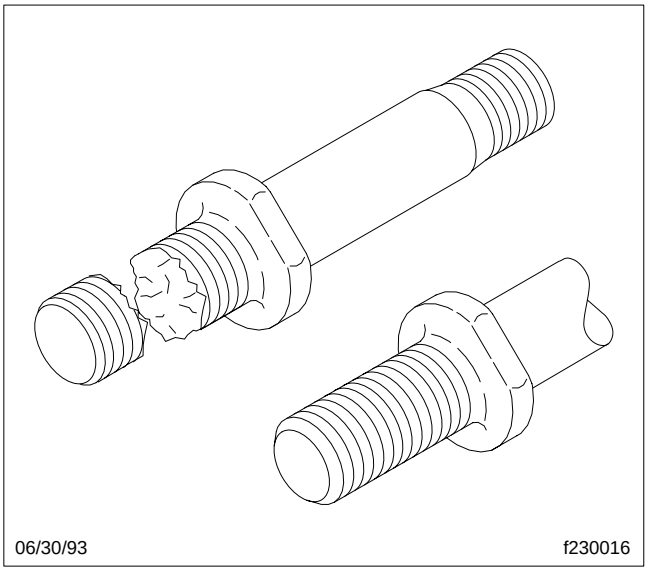

Fig. 5, Damaged Wheel Studs (shouldered type)

7. Inspect the drive axle shaft-to-flange surface. Loose wheel bearings can lead to progressive fatigue fractures where the shaft and flange meet. **See Fig. 7.** Replace the drive axle assembly if damaged.
8. Inspect the inboard portion of the drive axle flange. Minor burrs or rough spots can adversely affect the sealing action of the oil or grease seals. Remove the burrs or rough spots using fine-grit emery cloth. If they cannot be removed, replace the drive axle shaft.
9. Inspect the drive axle flange around the stud holes. Replace the drive axle shaft and flange assembly if any of the following conditions exist:
   - cracks on the flange surface;
   - metal build-up around the stud holes (a result of wear);
   - out-of-round stud holes.

Wheel Bearing Cleaning and Inspection

CLEANING

⚠ WARNING

WARNING: To prevent skin irritation, wear chemical resistant gloves when working with diesel fuel or kerosene. Also, don't expose these fluids to flames or heat exceeding 38°C (100°F); both are combustible, and could cause personal injury if ignited.

Don't spin the bearing rollers at any time. Dirt or grit can scratch the roller surface and cause premature wear of the bearing assembly. Treat a used bearing as carefully as a new one.

Wheel bearings should be very closely inspected at the time of disassembly. The best inspection conditions are possible only after the bearings have been thoroughly cleaned using kerosene or diesel fuel oil, and a stiff brush **(Fig. 8).** Before inspecting, clean the bearings as follows:

1. Clean all old oil from the bearings and hub cavities, with kerosene or diesel fuel and a stiff brush. **See Fig. 8.** Don't use gasoline or heated solvent.
2. Allow the cleaned parts to dry, or dry them with a clean absorbent cloth or paper. Clean and dry your hands and all tools used in the maintenance operation. Oil will not stick to a surface that is wet with kerosene or diesel fuel, and the kerosene or diesel fuel may dilute the lubricant.

INSPECTION

After the bearings are cleaned, inspect the assemblies, which include the rollers, cones, cups, and cages. If any of the following conditions exist, replace the bearing assemblies:

1. The large ends of the rollers are worn flush to the recess; the radii at the large ends of the rollers are worn sharp. These are signs of advanced wear. **See Fig. 9.**
2. Visible step wear, especially at the small end of the roller track, or deep indentations, cracks, or breaks in the cone surfaces. **See Fig. 10.**

Axle Components Cleaning and Inspection

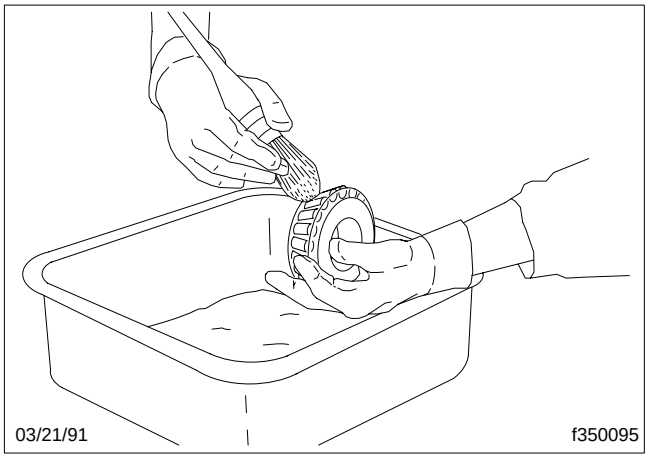

Fig. 8

3. Bright rubbing marks on the dark phosphate surfaces of the bearing cage. **See Fig. 11.**

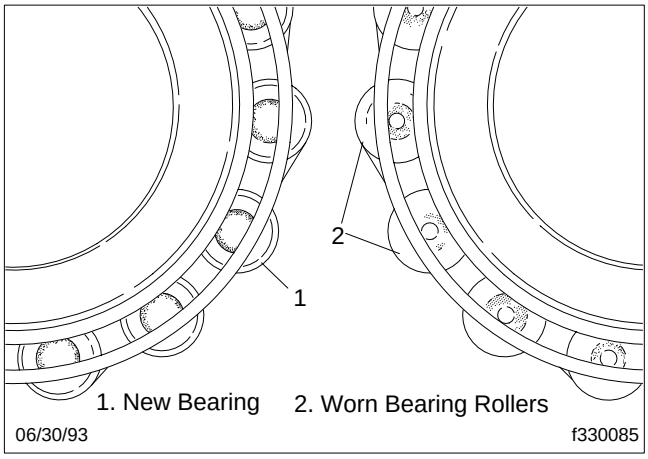

Fig. 9

4. Water etch on any bearing surface. Water etch appears as gray or black stains on the steel surface, and it greatly weakens the affected area. If water etch is present, check the oil seal sealing surfaces.

5. Etching or pitting on functioning surfaces. **See Fig. 12.**

6. Spalling (flaking) of the bearing cup, roller, or cone surfaces. **See Fig. 3.**

After inspection, brush the bearings with fresh axle lubricant.

Wheel Bearing Cup Removal and Installation, Ferrous Hubs

Removal

Wheel bearing cups are removed from ferrous hubs by driving them out; there is no need to first heat the hubs.

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Using a mild steel rod through the opposite end of the hub, drive against the inner edge of the bearing cup. Alternately drive on opposite sides of the cup to avoid cocking the cup and damaging the inside of the hub.

Installation

Wheel bearing cups are installed in ferrous hubs by pressing them in; there is no need to first heat the hubs.

⚠ WARNING

WARNING: Commercial cleaning solvents are toxic, can cause severe skin irritation, and may be fire hazards. When using solvents, follow the safety precautions recommended by the solvent manufacturer.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Coat the hub-contact surface of the replacement bearing cup with a film of grease.
4. Position the cup in the hub and press it into place, using a suitable tool against the outer edge of the cup. Cups must seat against the shoulder in the hub.

⚠ WARNING

WARNING: To prevent skin irritation, wear chemical resistant gloves when working with diesel fuel or kerosene. Also, don't expose these fluids to flames or heat exceeding 38°C (100°F); both are combustible, and could cause personal injury if ignited.

5. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Wheel Stud Replacement, Disc Wheels

Replacement

⚠ WARNING

WARNING: If a wheel stud breaks, the remaining studs are subjected to undue strain and could fail due to fatigue. When a broken stud is replaced, replace the stud on each side of it (Fig. 1). If more than one stud is broken, replace all of the studs. Failure to replace the studs could result in the loss of a wheel or loss of vehicle control, possibly resulting in personal injury.

1. Remove the wheel hub from the axle. For instructions, refer to **"Hub Assembly Removal and Installation, Disc Wheels, 100."**
2. If a bent portion of a wheel stud will have to pass through the wheel stud bore, cut off the bent portion before removing the wheel stud.
3. Place the wheel hub on a suitable press; make sure the hub flange is evenly supported around and next to the stud being removed. With steady movement, press the damaged stud out of the hub.

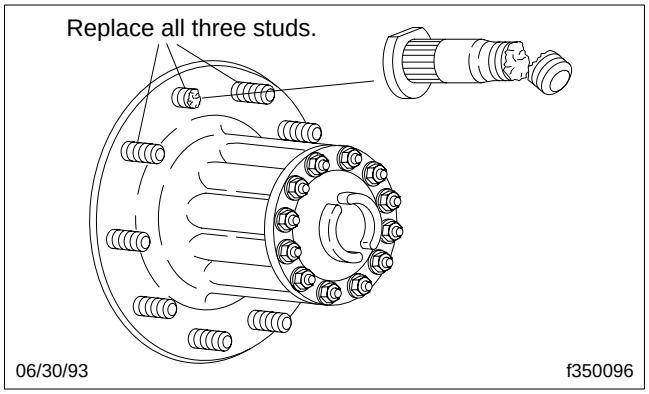

Fig. 1

⚠ CAUTION

CAUTION: Don't use a drift and hammer or concentrated heat to remove or install the wheel studs. Constant, smooth movement of the wheel stud is necessary to ensure the least amount of metal removal from the wheel stud bore. Concentrated heat will damage the hub. If the hub is damaged during wheel stud removal or installation, replace it.

4. Apply a coat of clean axle grease to the entire shaft on headed studs.
5. With the hub on a suitable press, make sure the hub flange is evenly supported around and next to the stud being installed.
6. Position the stud in its hole.

⚠ CAUTION

CAUTION: Position the teeth of the serrated portion in the notches carved by the original wheel studs during factory installation. If additional metal is scraped from the wheel stud bores, the locking action provided by the serrations will be greatly weakened. Loss of locking action will prevent achieving final torque of the wheel nuts during wheel installation. If final wheel nut torques during wheel installation cannot be achieved, replace the wheel hub assembly.

IMPORTANT: If the driver's side of the vehicle is being serviced, the replacement wheel stud and inner wheel nut must be stamped with an "L" (left-hand threaded), and the nut's face must be stamped "Left." **Refer to Fig. 2.** If the passenger's side of the vehicle is being serviced, the replacement stud and inner wheel nut must be stamped with an "R" (right-hand threaded), and the nut's face must be stamped "Right."

7. With steady movement, press the new stud all the way into the hub.
8. Make sure the stud is fully seated and that its head (flange) is not embedded in the hub. If the head of the stud is embedded in the hub, replace the hub.

⚠ WARNING

WARNING: Wheel studs with heads embedded in the wheel hub will weaken the wheel hub flange. Weakness in the wheel hub can result in the loss of a wheel or loss of steering control, possibly resulting in personal injury.

9. Wipe off any grease on the wheel studs and wheel hub. Install wheel nuts on dry wheel studs only.

Wheel Stud Replacement, Disc Wheels

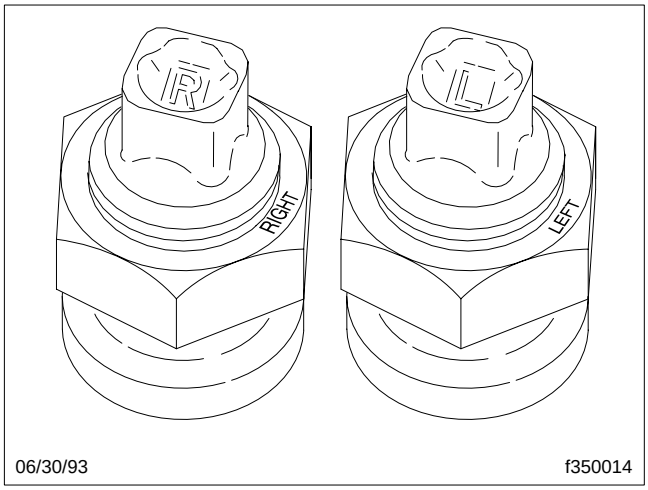

Fig. 2, Wheel Nuts

10. Install the wheel hub on the axle. For instructions, **refer to "Hub Assembly Removal and Installation, Disc Wheels, 100."**

Rim Stud Replacement, Spoke Wheels

Replacement

1. Remove the rim and tire assemblies from the spoke wheel. For instructions, **refer to the wheels and tires group.**
2. If enough threads remain on the damaged stud, remove it by double-nutting the stud. Turn the inner nut with a wrench in order to remove the stud. Then, go to the step for tapping out the rim stud hole.

   If the rim stud is broken near the surface of the wheel, the stud should be center-drilled using a high-speed drill, and then removed with an easy-out tool. If needed, grind off a flat surface on the damaged stud, then centerpunch the surface as a starting point for drilling. Remove the stud.

   2.1 Determine the correct drill diameter by referring to the easy-out tool manufacturer's guidelines. At no time should it be large enough to penetrate the threads of the stud; if the stud threads in the wheel are damaged, replace the wheel.

   2.2 Don't drill more than 32 mm (1-1/4 inches) into the broken stud, as measured at the stud's entrance into the wheel. Drilling through the bottom of the rim stud could damage the wheel. If the wheel is drilled into, replace it.

   2.3 While drilling, keep the cutting surfaces of the drill well lubricated with oil, which acts as a coolant. Allow the drill and drill bit to cool frequently.
3. After the damaged stud is removed, tap out the rim stud hole in the wheel to rid the threads of old stud-locking compound. Use an appropriate sized tap, depending on the original rim stud installation size.
4. Be sure the threads of the new stud are clean and dry. Then, coat the insertion end of the rim stud with an anaerobic thread-lock compound.
5. Using double nuts on the fine thread portion of the stud, install the new stud. Seat the rim stud using the torque values in the torque table in **"Specifications, 400."**
6. Allow enough time for the thread-lock compound to set, as suggested by the manufacturer.
7. Install the rim and tire assemblies. For instructions, **refer to the wheels and tires group.**

Replacement

NOTE: If the hub has been removed from the axle, go to the step for removing the stud.

1. Apply the parking brakes.
2. Oil will spill as the drive axle shaft is removed. Place a suitable container inside the wheel and under the drive axle flange. Safely discard the lubricant after removal.
3. Remove the drive axle shaft.
   - 3.1 Remove the drive axle stud nuts (**see Fig. 1**), and the washers.

1. Drive Axle Studs and Nuts
2. Center Portion of Drive Axle Flange

Fig. 1

   - 3.2 Using a hammer and a soft drift, such as one made of brass, sharply tap the center portion of the drive axle flange (**see Fig. 1**). The shaft will usually spring slightly outward after the seal has broken.

CAUTION

CAUTION: When tapping the drive axle flange, avoid striking the drive axle studs. If struck, the studs may bend or break, or the stud threads can be damaged. Replace damaged studs.

   - 3.3 If the drive axle shaft does not spring outward, the seal may have loosened enough to allow the shaft to be manually pulled from the axle housing. Try to manually remove the drive axle shaft from the housing. If the seal has not broken, repeat steps as required.
4. If equipped, remove the tapered dowels and washers from the drive axle flange.
5. Remove and discard the gasket.
6. If enough threads remain on the damaged stud, remove it by double-nutting the stud. Turn the inner nut with a wrench in order to remove the stud. Then, go to the step for tapping out the drive axle stud hole.

   If the drive axle stud is broken near the surface of the hub, the stud should be center-drilled using a high-speed drill, and then removed with an easy-out tool. If needed, grind off a flat surface on the damaged stud, then centerpunch the surface as a starting point for drilling.

   - 6.1 Determine the correct drill diameter by referring to the easy-out tool manufacturer's guidelines. At no time should it be large enough to penetrate the threads of the stud; if the stud threads in the wheel hub are damaged, replace the hub.
   - 6.2 Do not drill more than 32 mm (1-1/4 inches) into the broken stud, as measured at the stud's entrance into the wheel hub. Drilling through the bottom of the drive axle stud could damage the hub. If the wheel hub is drilled into, replace it.
   - 6.3 While drilling, keep the cutting surfaces of the drill well lubricated with oil, which acts as a coolant. Allow the drill and drill bit to cool frequently.
7. After the damaged stud is removed, tap out the drive axle stud hole in the wheel to rid the threads of old stud-locking compound. Use an appropriate sized tap, depending on the original drive axle stud installation size.
8. Be sure the threads of the new stud are clean and dry. Then, coat the insertion end of the drive axle stud (the coarse threads) with an anaerobic thread-lock compound.

Drive Axle Stud Replacement

9. Using double nuts on the fine-thread portion of the stud, install the new stud. Seat the drive axle stud using the torque values in the torque table in **Specifications, 400.**
10. Allow sufficient time for the thread-lock compound to set, as suggested by the manufacturer.
11. If the hub was removed from the axle, proceed to **Subject 100** or **Subject 102** for installation instructions. If the hub was not removed from the axle, install the drive axle shaft.
    - 11.1 Install a new axle flange gasket over the drive axle studs.
    - 11.2 Install the drive axle shaft in the axle housing. The splined end of the shaft must seat before the drive axle flange will fit over the drive axle studs.
    - 11.3 If equipped, install the dowels and washers on the drive axle studs. Install the drive axle nuts. Using the sequence shown in **Fig. 2**, tighten the nuts to the torque values in the torque table in **Specifications, 400**.

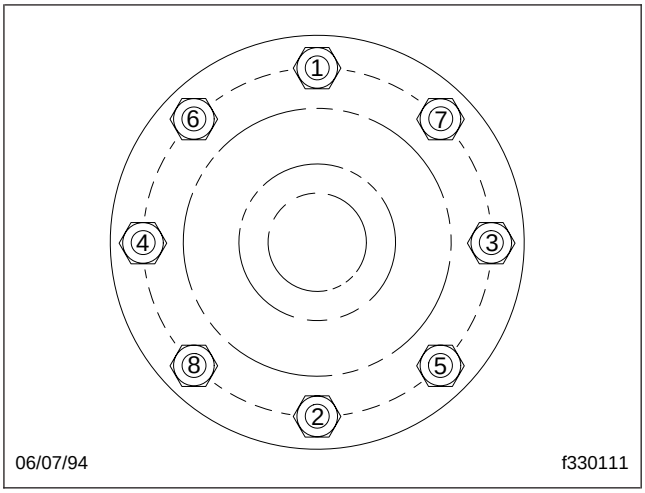

Fig. 2, Axle Shaft Flange Nut-Tightening Sequence

- 11.4 Add fresh oil to the wheel hub. For instructions, refer to **Subject 100** or **Subject 102**.

WARNING

WARNING: Failure to add oil to the wheel hub after the drive axle shaft has been serviced will damage the wheel bearings and cause them to seize during vehicle operation. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury.

Troubleshooting

This subject contains the following troubleshooting tables:

- Noisy Bearings or Excessive Bearing Replacement Intervals
- Broken Wheel or Rim Studs
- Damaged Hub
- Loss of Lubricant From the Wheel Hubs

Problem—Noisy Bearings or Excessive Bearing Replacement Intervals

Possible Cause	Remedy
Not enough oil was used on the bearings, or the wrong type of oil was used.	Clean then inspect the bearings for wear. Replace worn seals. Coat the bearing assemblies with fresh oil. For lubricant specifications, **refer to "Specifications, 400."**
Foreign matter or corrosive agents entered the bearing assembly. Dirt or metallic debris from the bearings was not removed.	Clean then inspect the bearings for wear. Replace worn seals. Also clean the wheel hub, the axle spindle, and any other part in contact with the bearing lubricant.
An incorrect adjustment of the wheel bearings is causing noise and wear.	Adjust the wheel bearings following the instructions in **Subject 100** and **Subject 102** in this section.
Flat spots or dents on the roller surface were caused by skidding of the roller or improper handling of the wheel bearing during the installation.	Clean then inspect the bearing rollers. Replace the bearing if damaged. Coat the replacement bearings with fresh oil. For lubricant specifications, **refer to "Specifications, 400."**

Problem—Broken Wheel or Rim Studs

Possible Cause	Remedy
The wheel or rim nuts were overtightened.	Replace the wheel or rim studs. **Refer to the wheels and tires group** for the wheel or rim tightening sequence.
The vehicle is being overloaded.	Don't exceed the maximum load-carrying capacity of the vehicle.

Problem—Damaged Hub

Possible Cause	Remedy
(Bent flange) Incorrect installation of the wheel studs, such as using a hammer and drift, or the hub flange wasn't fully supported on the press during wheel stud replacement.	Replace the hub assembly. Replace the wheel studs as instructed under **"Wheel Stud Replacement, Disc Wheels, 130."**
Insufficient tightening of the wheel nuts to the wheel hub.	Replace the hub assembly and tighten the wheel nuts to the values in the torque table in **"Specifications, 400."**

Problem—Loss of Lubricant From the Wheel Hubs

Possible Cause	Remedy
The drive axle studs are loose.	Tighten the nuts to the torque values in the torque table in **"Specifications, 400."** Add lubricant to the axle housing or to the wheel hub.
The seals or gaskets are worn or damaged.	Replace worn or damaged parts.
Minor burrs or rough spots are on the inboard portion of the drive axle flange.	Use fine-grit emery cloth to remove the burrs or rough spots. If they can't be removed, replace the drive axle shaft.

Table 5, Dual-Nut Wheel Bearing Lock Torque Values

General Information

WHEELS AND TIRES

The tires support the weight of the vehicle, and are integral parts of the drivetrain and braking systems. The wheels serve as load carrying members between the tires and the axle.

There are two types of wheels: spoke and disc.

Spoke wheels consist of a wheel and brake drum assembly installed on the axle **(Fig. 1),** and a tire and rim assembly that mounts on the wheel. Rim clamps and rim nuts hold the tire and rim assembly in place.

Disc wheels consist of a rim and disc. The rim, the portion of the wheel on which the tire is mounted and supported, is welded to the disc **(Fig. 2).** After the tire is mounted on the wheel, the assembly is held in place on the hub with wheel studs and nuts.

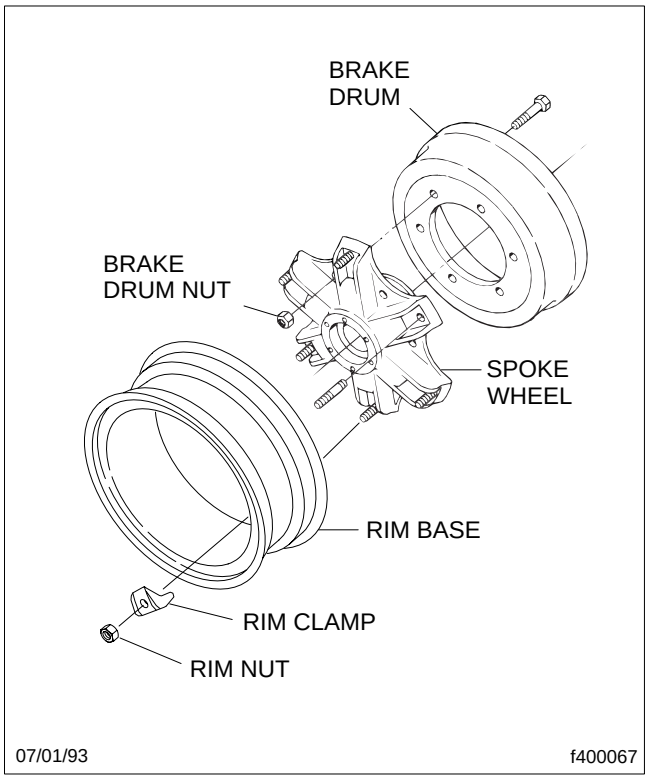

Fig. 1, Spoke Wheel and Brake Drum Assembly

Standard ten-hole dual disc wheels are held in place on the hub by self-centering inner and outer wheel nuts. Eight-hole and optional ten-hole (single and dual) disc wheels are centered by pilot pads and are held in place on the hub with cone locknuts.

Tires are constructed of either radial or bias plies:

Radial tires have ply cords that run from bead to bead, and at a right angle to the belt plies and tire tread **(Fig. 3).** The belt plies constrict the radial ply cords and give rigidity to the tread.

Bias ply tires have body ply cords that run diagonally from bead to bead **(Fig. 4).** The tires may also have narrow plies under the tread, called breakers, with cords that lie in about the same direction as the body ply cords.

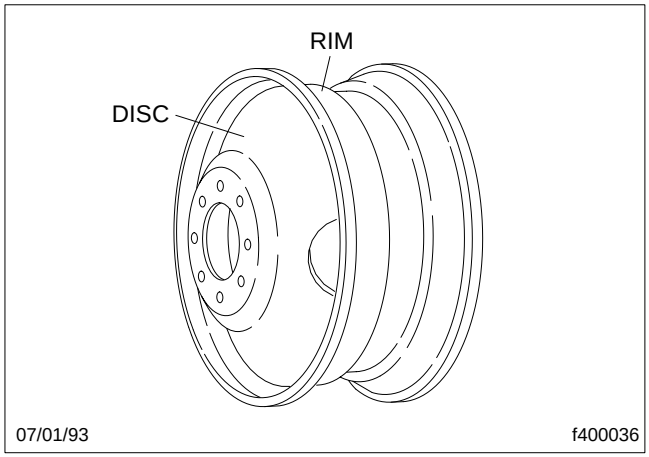

Fig. 2, Disc Wheel

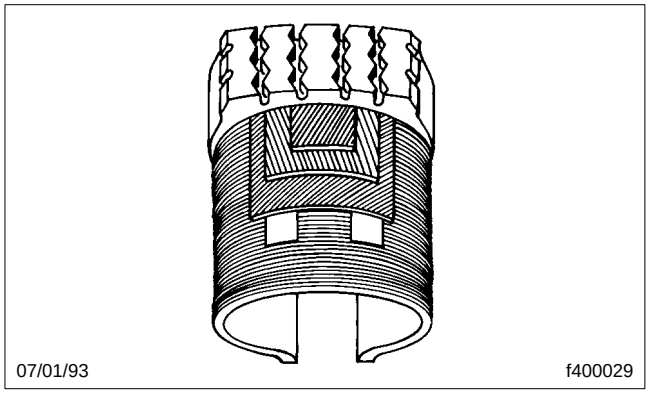

Fig. 3, Radial Ply Tire Construction

Tire body plies, breakers, and belts are made of polyester, rayon, nylon, fiberglass, steel, or aramids (fibrous reinforcements). In radial ply tires, these materials are used in various combinations, including

General Information

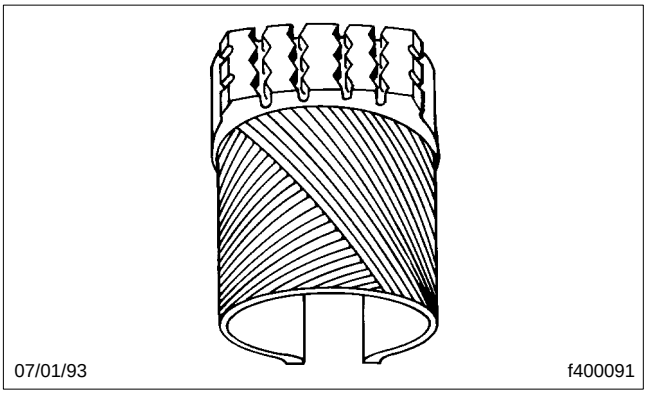

Fig. 4, Bias Ply Tire Construction

steel body/steel belt, polyester body/fiberglass belt, or nylon body/steel belt.

Wheels and tires operate either with or without tubes. Tube-type tires require a tube and flap for correct assembly on a two-or three-piece rim **(Fig. 1).** Tubeless tires require only the tire, and a one-piece drop-center wheel or rim. **See Fig. 2.**

TIRE MATCHING AND MIXING

IMPORTANT: Review and follow these requirements for matching and mixing tires, before installing any tire and wheel or rim assembly on a vehicle.

Before changing wheels and tires, consider the effect that the change may have on the Gross Vehicle Weight Rating (GVWR) of the vehicle. At the time of vehicle certification, the GVWR is calculated by adding the vehicle's Gross Axle Weight Ratings (GAWR). The GVWR and each of the GAWRs are shown on a certification label (U.S.-purchased vehicles) or "Statement of Compliance" label (Canadian-purchased vehicles) attached to the left rear door post. **See Fig. 5.**

Tire and rim labels **(Fig. 5 and Fig. 6)** certify the minimum tire and rim combinations that can be installed on the vehicle for the given GAWRs. Each GAWR is determined by considering each component of the axle system, including suspension, axle, wheels, and tires. The lowest component's capacity is the value used for the system. Therefore, the tires and rims installed on the vehicle at the time of vehicle manufacture may have a higher load capacity than that certified by the tire and rim label. Tires and rims of the minimum capacity can be installed without changing the load limitations. If tires and rims are installed that have a lower load capacity than that shown on the tire and rim label, then the tires and rims determine the load limitations (the GAWRs and GVWR will be lower).

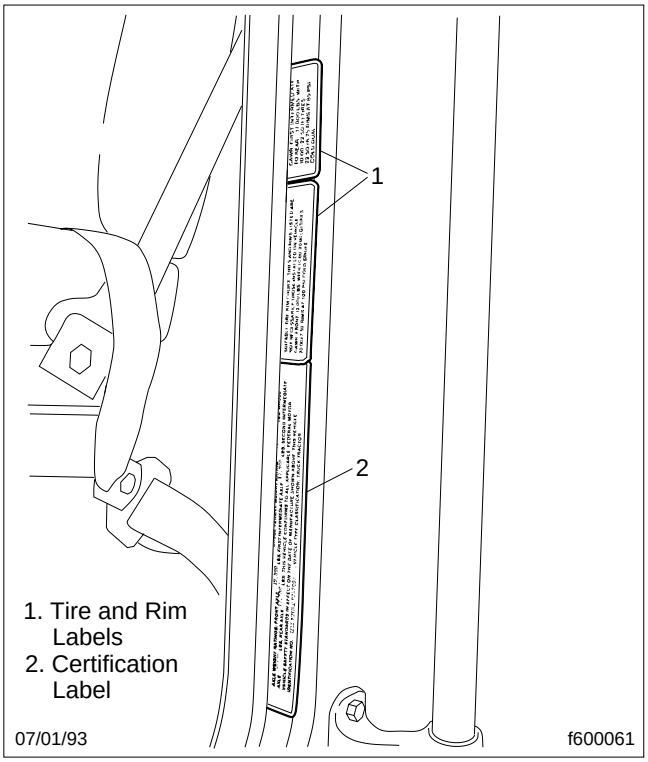

Fig. 5

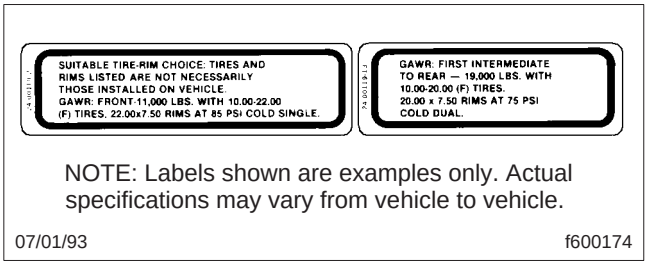

Fig. 6

When pairing tires in a dual assembly, the tire diameters must not differ by more than 1/4 inch (6.4 mm), or the tire circumference by more than 3/4 inch (19 mm).

CAUTION

CAUTION: Mismatching dual tires overloads the larger diameter tire, causing it to overdeflect and overheat. The smaller diameter tire, lacking proper road contact, wears faster and unevenly. Tread or ply separation, tire body breaks, and blowouts can occur from mismatched duals.

With an endless pi tape **(Fig. 7)** or square **(Fig. 8),** measure the diameter of the tires 24 hours after inflation. A matching stick **(Fig. 9),** string gauge **(Fig. 10),** or tire straight edge **(Fig. 11)** can also be used to determine the difference in tire radius, which is then doubled to calculate the diameter difference.

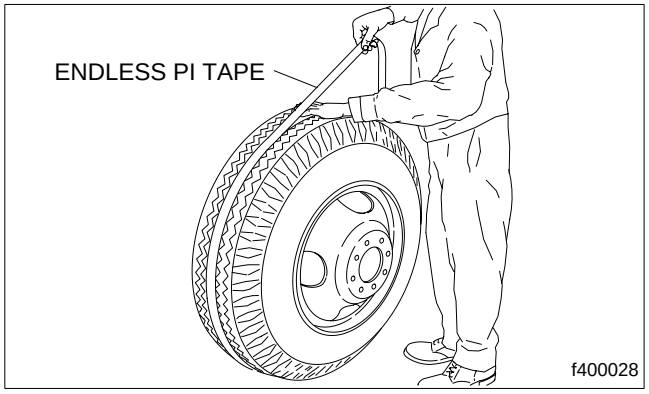

Fig. 7

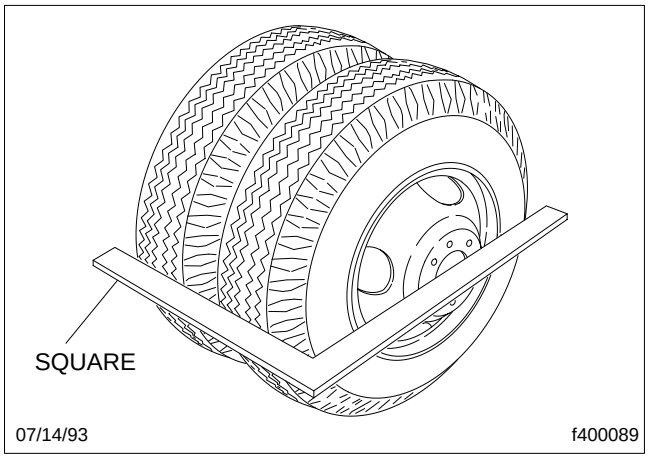

Fig. 8

When pairing tires of unequal diameters (but within the above limits), mount the larger tire on the outside.

CAUTION

CAUTION: Driving a vehicle on one tire of a dual assembly dangerously exceeds the carrying capacity of the single tire and wheel. Operating in this manner can cause damage to the wheel and tire.

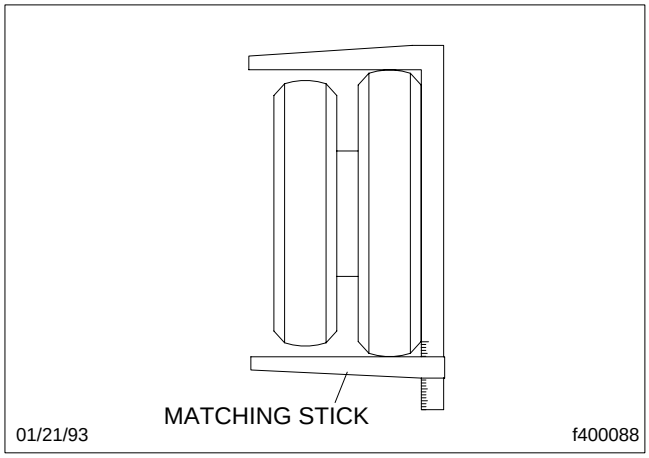

Fig. 9

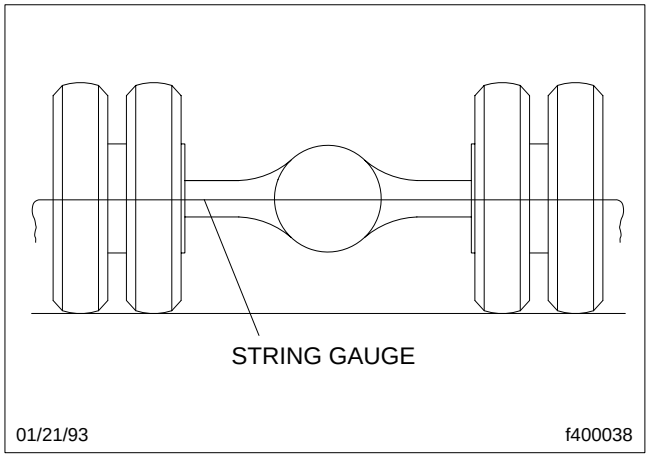

Fig. 10

Inflate all tires on an axle to within 35 kPa (5 psi) of one another. For tire inflation specifications, refer to the applicable tables in **"Specifications, 400."**

There must be sufficient space between dual tires for air to flow and cool the tires, and to prevent them from rubbing against one another. Rims and wheels of the same size, but of different makes and types, can have different offsets, which would affect dual

General Information

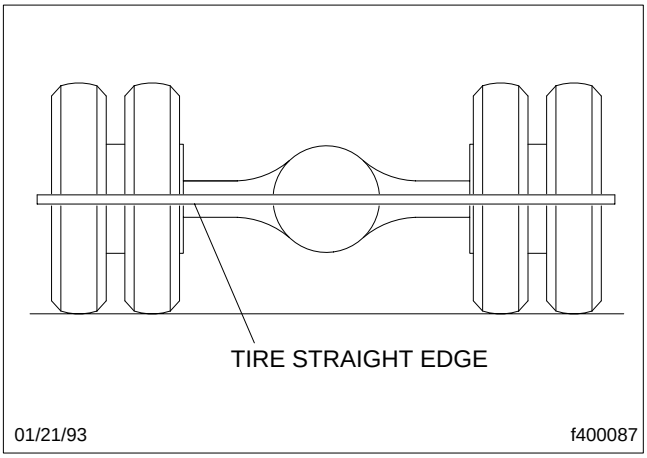

Fig. 11

spacing. If there is sidewall contact between tires, or between the inside tire and the chassis, refer to the tire manufacturer's catalog to determine the minimum dual spacing. Refer to the rim or wheel manufacturer's catalog to determine the correct offset.

Federal Motor Carrier Safety regulations require the removal of all tires with less than 3-mm (4/32-inch) remaining groove depth on a front axle, and tires with less than 1.5-mm (2/32-inch) remaining groove depth on a rear axle. However, tires with the word "Regroovable" on the sidewall, may be regrooved.

Better tire and vehicle performance is usually obtained by using tires of the same size and construction. Using tires of different construction is permitted if the following rules are observed:

- Do not mix radial and bias ply tires on the same axle.
- If both radial and bias ply tires are used, better handling is usually obtained by using the bias ply tires on the front axle.

⚠ CAUTION

CAUTION: Mixing radial and bias ply tires should be done as an emergency measure only. Some loss of steering control and premature tire wear could occur when driving under such conditions.

If installing radial tires on a vehicle formerly equipped with bias ply tires, refer to the applicable tables in **"Specifications, 400,"** concerning the inflation needs and load limits of the bias ply tires being removed, and of the radial ply tires being installed. Radial ply tires permit greater loads per tire, but also require higher inflation. They can also cause higher stresses on rims and wheels than bias ply tires. Contact the rim or wheel manufacturer about the compatibility of the rim or wheel with radial ply tires.

8-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

Removal

1. Chock all tires that will not be serviced, to prevent vehicle movement. If removing the wheels and tires from the front axle, apply the parking brake.
2. Raise the end of the vehicle being serviced until the tires clear the floor. Place safety stands under the axle being serviced.
3. If the tire or wheel is damaged (or if there is suspected damage), deflate the tire being serviced by removing the valve core. On rear axles deflate both tires of the dual assembly.
4. Place a jack or wheel-and-tire dolly under the wheel assembly being serviced. Turn the wheel until one hub-pilot pad is in the top-center position.
5. Leaving the top nut until last, remove all eight two-piece flange nuts.

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during removal and damage the stud threads or pilot pads. Keep the wheel square to the hub during removal.

IMPORTANT: On both sides of the vehicle, the two-piece flange nuts have right-hand threads.

6. Remove the wheel. Do not let it drop on or drag across the stud threads.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 160**. Also, follow the tire matching and mixing requirements in **Subject 050**.

1. Clean the hub and wheel mounting surfaces, and between the rims of dual wheels. Make sure the tire is correctly inflated. For instructions, see **Subject 180**.
2. Apply a few drops of light engine oil to the wheel studs and the area between the body and the flange of each two-piece flange nut. Wipe off any excess oil.

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during installation and damage the stud threads or pilot pads. Keep the wheel square to the hub during installation.

IMPORTANT: Before installing the wheels, make sure the drum is positioned on the raised step of the pilot pad. One of the hub's pilot pads must be at the top location. To help keep the drum in place, it may be necessary to adjust the brakes before installing the wheels.

3. Locate one hub-pilot pad in the top-center position. Using a jack or wheel-and-tire dolly, position the wheel assembly (inner wheel assembly of rear axles) on the hub. Make sure the wheel is square to the hub and that the threads or pilot pads are not damaged by contact with the wheel during installation. On rear axles, mount the outer wheel against the inner wheel using the same procedure.
4. Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum. If this causes the valve stems on rear wheel assemblies to be in the same wheel hole, mount the outer wheel so that the outer wheel balance weight(s) are on the same side as the brake drum balance weight(s).

5. Install and hand-tighten a two-piece flange nut on the top and bottom studs.

CAUTION

The two-piece flange nuts have right-hand metric threads. Do not try to install a similar size SAE nut on a stud, or the stud and nut will be damaged.

6. Install and hand-tighten the remaining two-piece flange nuts. Tighten the two-piece flange nuts 50 to 100 lbf·ft (68 to 135 N·m) following the sequence in **Fig. 1**.

8-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

7. Check that the wheel is correctly seated against the hub and on the hub-pilot pads.
8. Following the sequence in **Fig. 1**, tighten the two-piece flange nuts 450 to 500 lbf·ft (610 to 678 N·m).

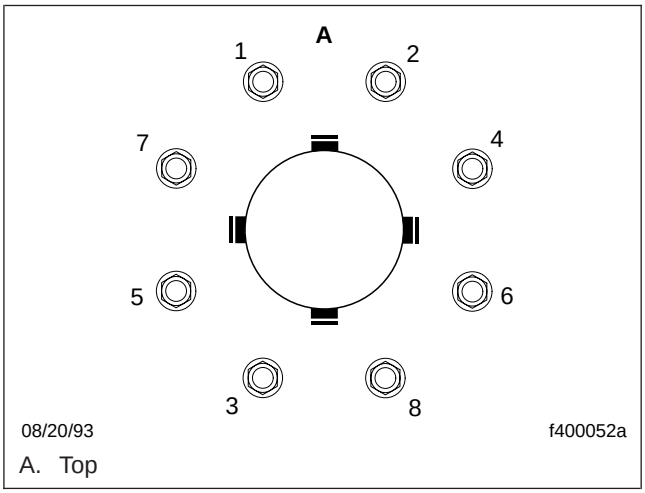

Fig. 1, 8-Stud Disc Wheel Tightening Sequence

WARNING

If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this case, the wheel hub assembly is damaged and must be replaced with a new assembly.

Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts. Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing property damage or personal injury.

NOTE: Replace damaged parts following the instructions in the front axle or rear axle group in this manual.

9. Remove the safety stands, lower the vehicle, and remove the chocks.
10. After operating the vehicle for 50 to 100 miles (80 to 160 km), retighten the wheel nuts 450 to 500 lbf·ft (610 to 678 N·m). Follow the sequence in **Fig. 1**.

CAUTION

Too little wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and extreme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 1.

IMPORTANT: The two-piece flange nuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts to the specified torque. Tighten the two-piece flange nuts to the specified torque 50 to 100 miles (80 to 160 km) after service work, and check the torque every 50,000 miles (80 000 km) thereafter.

10-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock all tires that will not be serviced to prevent vehicle movement.
2. Raise the end of the vehicle being serviced until the tires clear the floor. Place safety stands under the axle being serviced.
3. If the tire or wheel is damaged or if there is suspected damage, deflate the tire (or tires, on a dual assembly) being serviced by removing the valve core.
4. Turn the wheel until one hub-pilot pad is in the top-center position.
5. Leaving the top and bottom nuts until last, remove the other eight two-piece flange nuts.
6. Place a jack or wheel-and-tire dolly under the wheel assembly being serviced. Remove the top and bottom nuts.

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during removal and damage the stud threads or pilot pads. Keep the wheel square to the hub during removal.

IMPORTANT: On both sides of the vehicle, the two-piece flange nuts have right-hand metric threads.

7. Remove the wheel. Do not let it drop on or drag across the stud threads.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 160**. Also follow the tire matching and mixing requirements in **Subject 050**.

1. Clean the hub and wheel mounting surfaces, and all disc faces of dual wheels. Make sure the tire is correctly inflated. For instructions, see **Subject 180**.
2. Apply a few drops of light engine oil to the wheel studs and the area between the body and the flange of each two-piece flange nut. Wipe off any excess oil.

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during installation and damage the stud threads or pilot pads. Keep the wheel square to the hub during installation.

IMPORTANT: Before installing the wheels, make sure the drum is positioned on the raised step of the pilot pad. One of the hub's pilot pads must be at the top location. To help keep the drum in place, it may be necessary to adjust the brakes before installing the wheels.

3. Locate one hub-pilot pad in the top-center position. Using a jack or wheel-and-tire dolly, position the wheel assembly (inner wheel assembly of rear axles) on the hub. Make sure the wheel is square to the hub and that the threads are not damaged by contact with the wheel during installation. On rear axles, mount the outer wheel against the inner wheel using the same procedure.
4. Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum. If this causes the valve stems to be in the same wheel hole on the rear wheel assemblies, mount the outer wheel so that the outer wheel balance weight(s) is on the same side as the brake drum balance weight(s).

5. Install and hand-tighten a two-piece flange nut on the top and bottom studs.

CAUTION

The two-piece flange nuts have right-hand metric threads. Do not try to install a similar size SAE nut on a stud, or the stud and nut will be damaged.

6. Install and hand-tighten the remaining two-piece flange nuts. Tighten the nuts 50 lbf·ft (68 N·m) following the sequence in **Fig. 1**.

10-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

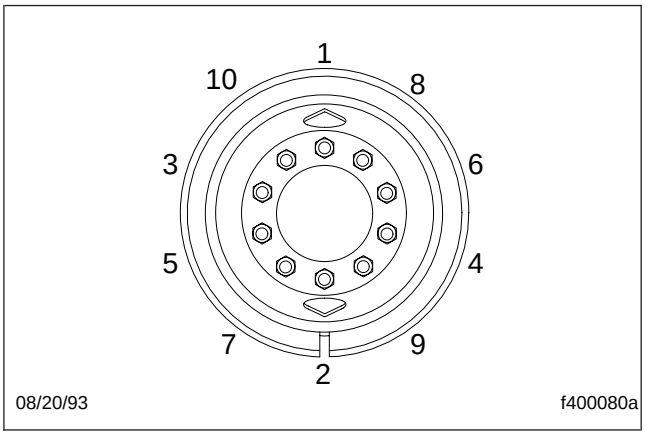

Fig. 1, 10-Stud Disc Wheel Tightening Sequence

7. Check that the wheel is correctly seated against the hub and on the hub-pilot pads.
8. Following the sequence in **Fig. 1**, tighten the two-piece flange nuts 450 to 500 lbf·ft (610 to 678 N·m).

⚠ WARNING

If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this case, the wheel hub assembly is damaged and must be replaced with a new assembly.

Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts. Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing property damage or personal injury.

IMPORTANT: Replace damaged parts following the instructions in the front axle or rear axle group in this manual.

9. Remove the safety stands, lower the vehicle, and remove the chocks.
10. After operating the vehicle for 50 to 100 miles (80 to 160 km), retighten the wheel nut 450 to 500 lbf·ft (610 to 678 N·m). Follow the sequence in **Fig. 1**.

⚠ CAUTION

Too little wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and extreme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 1.

IMPORTANT: The two-piece flange nuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts to the specified torque. Tighten the two-piece flange nuts to the specified torque 50 to 100 miles (80 to 160 km) after service work, and check the torque every 10,000 miles (16 000 km) thereafter.

10-Hole Disc Wheel With Inner and Outer Nuts; Removal and Installation

Removal

1. Chock all tires that will not be serviced, to prevent vehicle movement. If removing the wheels and tires from the front axle, apply the parking brake.
2. Raise the end of the vehicle being serviced until the tires clear the floor. Place safety stands under the axle being serviced.
3. If the tire or wheel is damaged (or if there is suspected damage), deflate the tire being serviced by removing the valve core. On rear axles deflate both tires of the dual assembly.
4. Place a jack or wheel-and-tire dolly under the wheel assembly being serviced. Remove the wheel nuts, then raise and remove the wheel assembly. Be careful not to damage the threads of the wheel studs as the wheel is pulled away. On rear wheel assemblies, remove the outer wheel first, being careful not to damage the threads of the inner wheel nuts.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions under **Subject 160**. Also, follow the tire matching and mixing requirements under **Subject 050**.

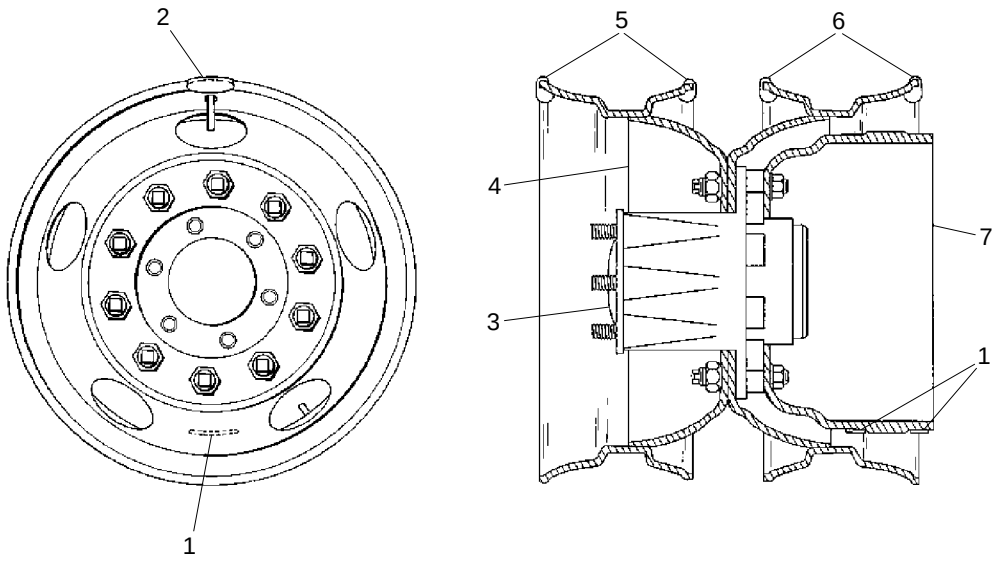
1. Clean the hub and wheel mounting surfaces, and between the rims of dual wheels. Make sure the tire is inflated using the procedures under **Subject 180**.
2. Use a jack or wheel-and-tire dolly to mount the wheel assembly (inner dual wheel of rear wheel assemblies) on the wheel studs. Be careful not to damage the threads of the wheel studs when installing the wheel assembly.

IMPORTANT: Mount the wheel assembly so that the balance weight(s) on the wheels are 180 degrees opposite the balance weight(s) on the brake drum (**Fig. 1**).

If, on two-handhole wheels, this causes the valve stems of rear wheel assemblies to be in the same wheel hole, mount the outer wheel so that the outer wheel balance weight(s) are on the same side of the assembly as the brake drum balance weight(s). **See Fig. 2**.

If, on five-handhole or aluminum wheels, the valve stems of rear wheel assemblies are in the same handhole, separate the valve stems by one hole. Install the wheel weights evenly and as close to 180 degrees opposite the brake drum balance weight(s) as possible. **See Fig. 3**.

3. Install a wheel nut (inner wheel nut of rear wheel assemblies) on each wheel stud, and run them up until each nut is flush with the face or the chamfer of the wheel. Rotate the wheel a half turn to seat the parts.
4. Tighten the wheel nuts 68 N·m (50 lbf·ft), following the sequence in **Fig. 4**.
5. Following the same sequence, tighten the wheel nuts again. Refer to the applicable table in **Specifications, 400**.



⚠ WARNING

WARNING: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this case, the wheel hub assembly is damaged and must be replaced with a new assembly.

Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts, as described in the front axle or rear axle group of this manual. Failure to replace damaged parts could result in the loss of a wheel and loss of vehicle control, causing property damage or personal injury.

6. For front wheel assemblies, go to the next step. For rear wheel assemblies, use a jack or wheel-and-tire dolly to mount the outer dual wheel on the inner wheel nuts. Be careful not to damage the threads of the inner wheel nuts when installing the wheel assembly. Install the outer wheel nuts following the procedures above.
7. Remove the safety stands, lower the vehicle, and remove the chocks.
8. After operating the vehicle for 80 to 160 km (50 to 100 miles), retighten the wheel nuts to the

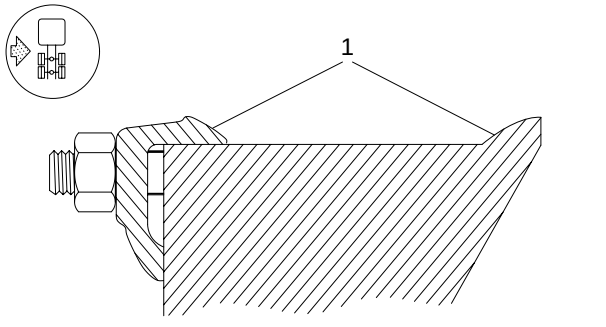
torque in the applicable table in **Specifications, 400**. Follow the sequence in **Fig. 4**.

CAUTION

CAUTION: Locknuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts to the specified torque. Too little wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and extreme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 4.

NOTE: When retightening the inner wheel nuts, loosen the outer wheel nuts several turns, retighten the inner wheel nuts, then the outer wheel nuts.

Spoke Wheel, Tire and Rim Assembly; Removal and Installation

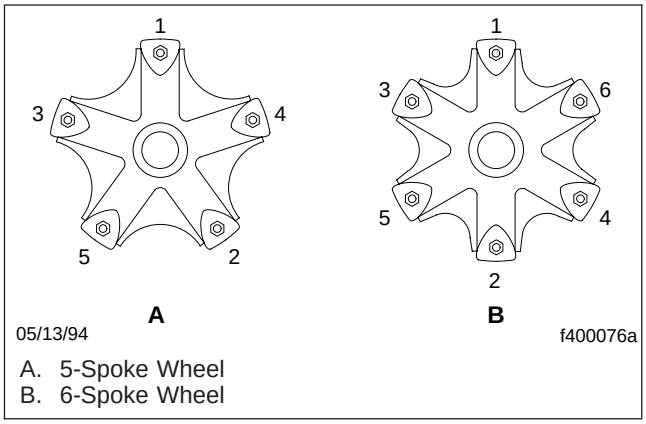


Removal

1. Chock all tires that will not be serviced, to prevent vehicle movement. If removing tire and rim assemblies from the front axle, apply the parking brake.
2. Raise the end of the vehicle being serviced until the tires clear the floor. Place safety stands under the axle being serviced.
3. Deflate the tire(s) being serviced by removing the valve core(s).
4. Place a jack or wheel-and-tire dolly under the tire and rim assembly being serviced (outer tire and rim assembly on rear axle). Remove the rim nuts and clamps; then, slide the tire and rim (outer tire and rim on rear axle) off the wheel.
5. On rear axles only, remove the rim spacer. Place a jack or wheel-and-tire dolly under the inner tire and rim assembly, and slide it off.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions under **Subject 160**. Also, follow the tire matching and mixing requirements under **Subject 050**.



1. Clean the wheel, rim spacer, and rim mounting surfaces. The mounting surface of the wheel is the 28-degree taper on the inboard side of each spoke. **See Fig. 1**.

1. 28-Degree Tapered Rim Mounting Surfaces

Fig. 1, Spoke Wheel Tapered Mounting Surface

2. Make sure the tire and rim assembly is inflated using the procedures under **Subject 180**.
3. Slide the assembly over the wheel and push it into place against the tapered mounting surface. It should fit snugly against all the tapers. Be sure that the valve stem faces out and is centered between two spokes.
4. Install the rim clamps and nuts. Run the nuts up until the end of each wheel stud is flush with the face of its nut. Rotate the wheel a half turn to seat the parts.
5. Tighten the rim nuts a quarter turn at a time, following the star pattern **shown in Fig. 2**. Continue until all the rim nuts are tightened to the required torque value. Refer to the applicable torque table in **Specifications, 400**.

A. 5-Spoke Wheel
B. 6-Spoke Wheel

Fig. 2, Spoke Wheel Tightening Sequence

WARNING

WARNING: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this case, the wheel hub assembly is damaged and must be replaced with a new assembly.

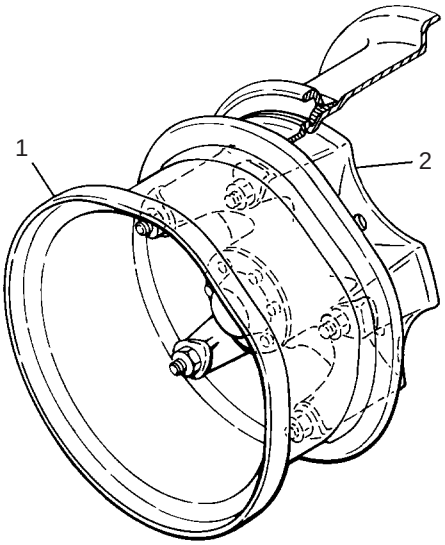
Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts, as described in the front axle or rear axle group in this manual. Failure to replace damaged parts could result in the loss of a wheel and loss of vehicle control, causing property damage or personal injury.

Spoke Wheel, Tire and Rim Assembly; Removal and Installation

CAUTION

CAUTION: Failure to tighten the nuts in the sequence shown, and to the correct torque, could cause misalignment of the tire and chording of the rim (Fig. 3). This would result in excessive vehicle vibration and permanent damage to the rim and wheel.

IMPORTANT: On rear tire and rim assemblies, the clamps must not bottom out until at least 80 percent of the recommended torque is reached. If the clamps do bottom out, make sure the correct clamps and rim spacers are being used. Make sure the rim edges contact the spacer edges.



NOTE: When replacing a spoke wheel, contact the wheel manufacturer for the correct torque value for the brake drum nuts attaching the spoke wheel to the brake drum.

6. Check the wheel alignment by placing a block of wood or any other point of reference on the floor next to the tire. Rotate the tire and note any variations in the space between the tire and the block. If the variation exceeds 1.5 mm (1/16 inch) for front rims, or 3 mm (1/8 inch) for rear duals, the rim is not correctly mounted.

   To correct any misalignment, loosen the rim nuts where the largest gap occurs, and tighten the nuts on the opposite side. Recheck and correct until the variation is corrected. Make sure the rim nuts are tightened to the correct. Refer to the applicable torque table in **Specifications, 400**.

7. Remove the safety stands, lower the vehicle, and remove the chocks.

8. After operating the vehicle for 80 to 160 km (50 to 100 miles), retighten the rim nuts to the torque specified in the applicable table in **Specifications, 400**. Follow the sequence **shown in Fig. 2**.

Tire Demounting and Mounting Service Precautions

Safety Precautions

IMPORTANT: Don't mount or demount tires without proper training as required in Occupational Safety and Health Administration (OSHA) Rules and Regulations 1910.177, *Servicing Multi-Piece and Single Piece Rim Wheels* . Service information containing mounting and demounting instructions are available through your rim supplier. Charts detailing service procedures are available through OSHA area offices. The address and telephone number of the nearest OSHA area office can be obtained by looking in the local telephone directory under U.S. Government, Labor Department of Occupational Safety and Health Administration.

Use the information from the above sources with the following precautions before and during the demounting and mounting of tires:

- Examine all wheel and tire parts as explained under the headings **Subject 160** and **Subject 170**. Replace damaged, rusted, or worn parts.
- Since wheels and rims are under stress, and are dangerous if improperly assembled, be sure all parts of an assembly match in size, manufacturer, and classification within a manufacturer's line. Before assembling the wheel or rim, check the catalog issued by the wheel or rim manufacturer for the correct part numbers and sizes of approved parts. Never use a part that does not bear clear, legible, and correct numbers and manufacturer's identification, even if that part appears to fit.
- Make sure that tires are stored indoors, or outdoors under cover, to prevent water collecting inside the tire.
- Use special tools, as recommended by tire suppliers, for mounting and demounting tires. These tools must be smooth, and used with care, to avoid gouging the rim.
- Loosening tire beads may be difficult, since considerable force may be needed. The use of a machine designed for loosening tire beads is recommended.
- Handle the wheels and rims on a wooden floor or rubber mat to prevent nicking or gouging the wheel or rim.
- Do not use a duck-bill hammer, or any steel hammer on wheel or rim parts. Use rubber, leather-faced, or plastic mallets to tap parts together, if necessary.
- Lubricate the tire with an approved tire-mounting lubricant. Never use antifreeze, silicones, petroleum-based lubricants, or any flammable material (ether/starting fluid).
- When lubricating a tire prior to mounting, make sure excess lubricant does not run into the tire.
- Michelin Tire Corporation recommends applying lubricant to the valley of the tire, formed by the tire and rim, before using tools to break the bead.
- Michelin also recommends applying a sufficient but sparing amount of lubricant to the entire rim face when mounting a tire on a rim, to ensure correct bead seating and ease of mounting.
- Balance the tire and wheel or rim assembly before installing the assembly on a vehicle.
- Don't reinflate a tire that has been run flat or has been run at 80 percent or less of its recommended operating pressure. Use your spare. Before removing the low tire from the vehicle, make sure it is completely deflated. Later, have the assembly taken apart and all the parts checked for damage, including the side or lockrings.
- The air pressure contained in a tire is dangerous. When servicing a tire, stay out of any potential path or route that a rim wheel component may travel during an explosive separation.

Fifteen Degree Tapered Drop Center

⚠ WARNING

WARNING: Read the information under Subject 140. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing equipment damage and personal injury.

DEMOUNTING

1. Deflate the tire being serviced by removing the valve core. Check the valve stem by running a piece of wire through the stem to make sure it is not plugged.
2. Loosen both beads from the rim by driving the flat end of the tire tool between the tire bead and the rim flange. Holding the tool upright, hammer on the neck to free the tire bead from the rim **(Fig. 1).** Repeat at 20-cm (8-inch) intervals around the flanges, until both beads are free from the rim.
3. Place the wide side of the rim down. Lubricate the tire bead and the rim. Insert the curved end of two tire tools between the bead and the rim, and just to one side of the tire valve. Step on the side of the tire, opposite from the valve, to force the first bead into the rim well **(Fig. 2).** Hold one of the tools in place with your foot and pry with the second tool, forcing the bead over the rim flange. Continue to work the first bead off of the rim.
4. When the first bead is off the rim, and the second bead is in the rim well, stand the assembly upright with the valve stem near the top. Lubricate the second bead and rim. Insert the straight end of the tool between the tire bead and the back rim flange, hooking the tool over the second flange. Lean the tire assembly toward the tool and use a rocking or bouncing action to pry the rim out of the tire. **See Fig. 3.**
5. Clean and inspect all parts. Refer to **Subject 160** and **Subject 170** for procedures.

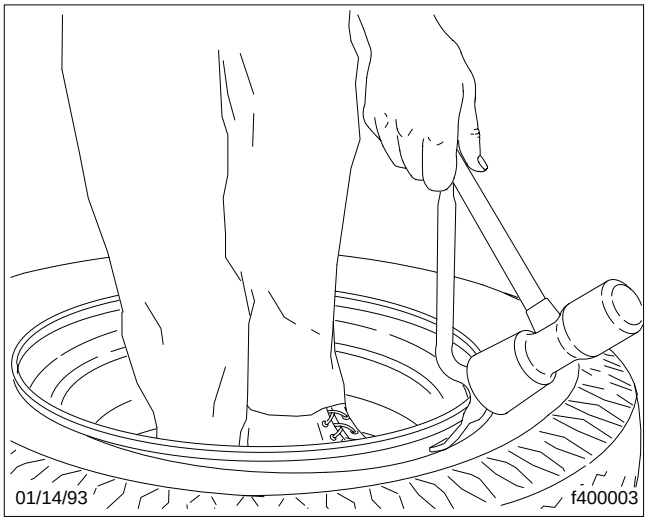

Fig. 1

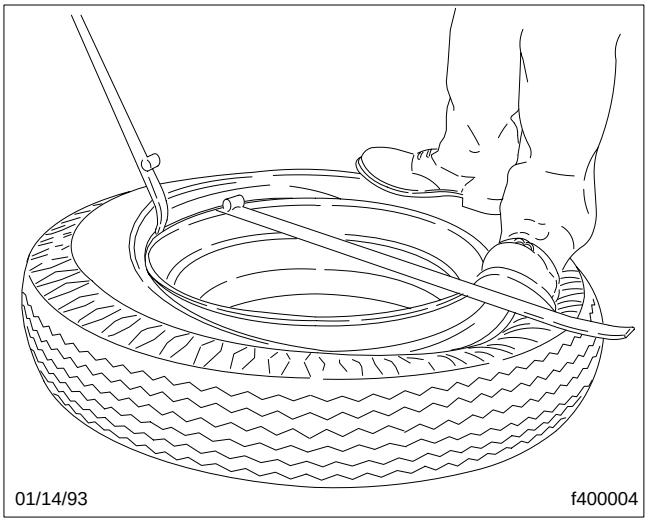

Fig. 2

MOUNTING

1. Place the valve stem, with a rubber washer, through the valve hole from the tire side of the rim. Screw on the valve nut from the opposite side. Make sure the rubber bushing and metal collar or nut are centered and fit snugly in the valve hole **(Fig. 4).** Tighten the nut securely.
2. Place the rim on the floor with the wide side down. Using a brush or swab, lubricate both bead seats (flanges) of the rim, and both tire beads, with an approved lubricant. Apply enough

lubricant to enable correct bead seating, and to make mounting easier. Don't let excess lubricant run inside the tire.

3. Lay the tire on the rim. If there is a balance mark on the tire, line up this mark with the valve stem. Push the lower bead over the flange and into the rim well. Using the straight end of the tire tool (with the stop resting on the rim flange), take small bites to work the remaining section of the bead into the rim. **See Fig. 5.**
4. Start the upper bead over the rim flange and into the rim well by standing on the tire. If necessary, push a section of the bead into the rim well, and anchor it by attaching Vise-Grip® pliers to the rim flange (snub side toward the tire). Using the spoon end of the tire iron, with the stop toward the rim, work around the bead **(Fig. 6).** Use small bites until the bead slips over the flange and into the rim well. If necessary, insert a second tire iron and relubricate the last 8 inches (20 cm) of bead.
5. Inflate the tire. Refer to **Subject 180** for procedures.

Inspection

WARNING

WARNING: Failure to inspect the tires and wheels and correct any problems, could cause tire or rim damage while servicing or while in use. An incorrectly mounted tire can burst causing equipment damage and personal injury.

Inspect the inside and outside of the tire for out-of-roundness, loose cords, cuts, foreign objects, and other damage. Repair as needed. Contact the tire manufacturer for repair procedures.

Do not repair tires with the following problems:

- Cuts in the tread that are wire or breaker fiber deep.
- Tread worn to the wire or breaker fibers.
- Tread that is scalloped or otherwise worn unevenly.
- Visible, broken, deformed, or otherwise damaged bead wires.
- Deteriorated rubber.
- Rubber cracked to the wire or cord.
- Separations in the casing.
- Exposed cord (for example, due to weather checking or sidewall scuffing).

Inspect the tread for abnormal or excessive wear. **Refer to "Troubleshooting, 300"** for possible causes of abnormal wear. If the tires are wearing irregularly, they should be rotated. If the front axle tires become irregularly worn, they should be moved to the drive axle. The front-end alignment should be checked. In a dual assembly, if one tire wears faster than its mate, the position of the two tires should be reversed. Refer to the vehicle maintenance manual for tire rotation procedures.

Government regulations require the removal of any tire with less than 1.5-mm (2/32-inch) tread remaining. Retread the tire (if possible), regroove it (only if marked " Regroovable " on the sidewall), or discard it.

Michelin Tire Corporation recommends using only new valve cores, caps, and O-rings in a new mounting.

Tire Inflation

⚠ WARNING

WARNING: During initial tire inflation, there is the possibility of an explosion of the assembly. Observe the following safety rules to reduce the possibility of serious physical injury in the event of an explosion.

NOTE: Inflate tires in a safety cage **(Fig. 1)** or an approved portable restraining device. Always use a clip-on chuck with an inline valve and gauge. Make sure the inflation hose is long enough to permit standing to the side of the tire during inflation. Never sit on or stand in front of an assembly that is being inflated.

1. Check all parts to make sure they are correctly seated prior to inflation.

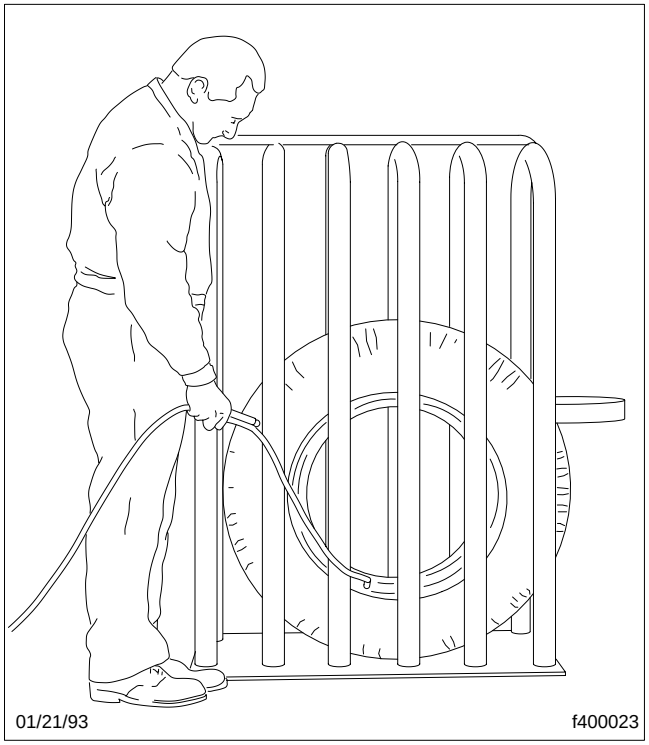

Fig. 1, Safety Cage

IMPORTANT: Inflate tires immediately after mounting, before the tire lubricant dries. Once the lubricant dries, bead positioning is not possible, even with increased inflation pressure.

2. Water in the tire can cause ply separation. During tire inflation, air tank reservoirs and lines must be dry. Use well-maintained air line moisture traps, and service them regularly.

   After placing the tire in a safety cage, or an approved portable restraining device, inflate the tire to 69 kPa (10 psi). Check the parts for correct seating. If the seating is not correct, completely deflate the tire and correct the problem. Never attempt to seat rings or other parts by hammering on an inflated or partially inflated tire.

3. If there are no problems with the assembly at 69 kPa (10 psi), continue to inflate the tire to the recommended pressure. Refer to the applicable tables under **"Specifications, 400"** for correct cold inflation pressures. Michelin Tire Corporation recommends an initial inflation pressure of 620 to 690 kPa (90 to 100 psi) to correctly seat the tire beads.

IMPORTANT: Due to the different flex characteristics of radial sidewalls, it may be necessary to use an inflation aid to help seat tubeless tire beads:

- Metal rings, which use a blast of compressed air to seat the beads.
- Rubber rings, which seal between the tire bead and rim, allowing the bead to move out and seat correctly. A well-lubricated, heavy-duty bicycle tube can be used to help seal between the tire bead and rim.

4. After the initial inflation, completely deflate the tire by removing the valve core. This ensures correct bead seating. Then inflate the tire to the applicable recommended cold inflation pressure listed in tables under **"Specifications, 400."** Install valve caps and tighten them finger-tight.

⚠ WARNING

WARNING: Tire underinflation or overinflation will damage wheels and tires, and could result in a blowout causing possible property damage and personal injury.

Tire Inflation

Use tires of the same size, type, and capacity to carry the load at the recommended cold pressure. Attempting to increase the load capacity of a tire by overinflation will damage the tire assembly.

NOTE: Inflate the tires to the recommended pressure. Driving on overinflated tires will weaken the cords by reducing their ability to absorb road shocks, and will increase the danger of cuts, snags, and punctures. Overinflation will overstress and damage the rims. Driving on underinflated tires will generate excessive heat. This weakens the tire body, and reduces tire strength.

5. Check the inflation pressure 24 hours after mounting new tires.

NOTE: When testing a vehicle on a dynamometer, severe tire damage can occur. Because the manufacturers differ in their recommendations for preventing tire damage, refer to the manufacturer's instructions for testing a vehicle on a dynamometer.

Troubleshooting

This subject contains the following troubleshooting tables:

- Abnormal Tire Wear
- Vehicle Vibration
- Excessive On-the-Road Tire Failures

Problem—Abnormal Tire Wear

Possible Cause	Remedy
Tires are not inflated to the correct pressure.	Operate the tires at the recommended inflation pressure and use the proper size tires, wheels, and rims for the load to be carried. Refer to the applicable tables in **"Specifications, 400"** for specifications.
Inflation pressures in a dual assembly are unequal.	Inflate all tires to a uniform pressure , within 35 kPa (5 psi). Refer to the applicable tables in **"Specifications, 400"** for the proper cold inflation pressures.
Dual tires are mismatched.	Examine all tires and match them according to the specifications in this section.
Vehicle is vibrating severely.	Follow the recommendations under "Vehicle Vibration" in this chart.
Brakes are grabbing.	Examine and adjust the brakes according to the instructions in the **brakes group.**
Axles are improperly aligned.	Align the axles. **Refer to the front axle group** and **the rear axle group** for instructions.
Wheel bearings are loose or damaged, or bushings are excessively worn.	Examine, and repair or replace according to the instructions in **the front axle group** and **the rear axle group.**
Wear is uneven among tire sets.	Rotate the tires according to the instructions in the wheels and tires group of the vehicle maintenance manual.
Driver is abusing equipment.	Caution the driver .

Problem—Vehicle Vibration

Possible Cause	Remedy
Axles are improperly aligned.	Align the axles. **Refer to the front axle group** and **the rear axle group** for instructions.
Wheels, rims, or tires are out-of-round, bent, or distorted.	Replace damaged components.
Tires, wheels, rims, or brake drums are out-of-balance.	Determine the out of balance component and balance.
Tire beads are not properly seated.	Demount and mount the tire. Make certain adequate lubrication is used and, if necessary, use an inflation aid to help seat tubeless tire beads.
Tire and rim assembly is improperly installed on a spoke wheel.	Remove the tire and rim assembly and inspect it for out-of-round or rim chording. Replace the rim if it is damaged. Follow closely the tightening sequence and torque values listed.
Rim spacers are worn or distorted.	Replace the rim spacers.
Driveline, suspensions, or steering components are loose or worn.	Determine the location of the vibration, then repair or replace the loose or worn components.

Troubleshooting

Problem—Excessive On-the-Road Tire Failures

Possible Cause	Remedy
Tires are not inflated to the correct pressure.	Operate the tires at the recommended inflation pressure and use the proper size tires, wheels, and rims for the load to be carried. Refer to the applicable tables in "Specifications, 400" for specifications.
Dual tires are mismatched.	Examine all tires and match them according to the specifications in this section.
Water or foreign material is inside the casing.	Clean and dry the tires prior to mounting. Make sure excess lubricant does not flow down into the tire. Store unmounted tires indoors, or under cover, to prevent moisture from collecting inside.
Tires are contaminated with oil.	Clean the tires and inspect the engine seals, transmission seals, axle-end and drive axle seals, oil filters and oil lines for leakage. Make sure the lubricant used in mounting does not contain a petroleum derivative.
Vehicle is vibrating severely.	Follow the recommendations under "Vehicle Vibration" in this chart.
Wheel or rim components are mismatched.	Check the catalog issued by the applicable wheel or rim manufacturer for the proper part numbers and sizes of approved components. Make sure that all parts of an assembly match in size, manufacturer, and classifications within a manufacturer's line. Never use a component which does not bear clear, legible, and proper numbers and manufacturer's identification, even if it appears to fit.
Parts are corroded, worn, or otherwise damaged.	Clean or replace parts as necessary.

IMPORTANT: Do not reduce the pressure of a hot tire if it exceeds the specified pressure. In normal driving, tire temperature and inflation pressure increase. Increases of 10 to 15 psi (70 to 105 kPa) are common. Higher pressures may be signs of overloading, underinflation, excessive speed, improper tire size, or any combination of these factors, and must be checked when the tire is cool.

The load and cold inflation pressure must not exceed the rim or wheel manufacturer's recommendations, even though the tire may be approved for a higher load or inflation. Some rims and wheels are stamped with a maximum load and maximum cold inflation rating. Consult the rim or wheel manufacturer if they are not stamped. If the load exceeds the maximum rim or wheel capacity, the load must be adjusted or reduced.

For further data on rims and tires, and for inflation and load limits not given here, see the "Tire and Rim Association Yearbook." Contact the tire manufacturer for further information on their tires.

NOTE: To obtain metric equivalents, use the following conversions:

- kg = lbs x 0.454
- kPa = psi x 6.890
