10. Install the wheel and tire assembly. See **Group 40** for instructions.
11. Adjust the front axle brakes. See **Group 42** in the Sterling *L-Line and A-Line Maintenance Manual*.
12. Remove the safety stands from under the axle; lower the vehicle.
13. Remove the chocks from the rear tires.

Outboard-Mounted Drum Removal and Installation

WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

For an exploded view of a typical wheel and axle assembly, including the brake drum, see **Fig. 1**.

Removal

1. Chock the rear tires to prevent vehicle movement. Apply the parking brakes.

WARNING

Use safety stands to securely support all axle and frame weight during axle procedures. Unsecured components may drop when fasteners are loosened or removed, which could cause serious personal injury and component damage.

2. Raise the front of the vehicle until the tires clear the ground. Then place safety stands under the axle.
3. Back off the slack adjuster to release the front axle brake shoes.

WARNING

Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH. Wear a respirator at all times when servicing the brakes, starting with removal of the wheels and continuing through assembly.

4. Remove the wheel and tire assembly. See **Group 40** for instructions.

   To minimize the possibility of creating airborne brake lining dust, clean the dust from the brake drum, brake backing plate, and brake assembly, using an industrial-type vacuum cleaner equipped with a high-efficiency filter system. Using a rag soaked in water and wrung until nearly dry, remove any remaining dust. Do not use compressed air or dry brushing to clean the brake assembly.
5. Remove the brake drum.
6. Inspect the drum. See **Subject 120** for instructions.

Installation

1. When replacing a brake drum, verify that the replacement drum has the same drum pilot diameter as the hub. Also, check the stud length to verify that the stud standout will be correct for the new drum.

   Remove all foreign material to ensure that the drum fits the drum pilot properly and can fully seat against the hub mounting face.

   In environments where a corrosion inhibitor is beneficial, ConMet recommends the use of Corrosion Block, a product of Lear Chemical Research. In severely corrosive environments, a light coat of Corrosion Block on the drum and wheel pilots has proven beneficial.

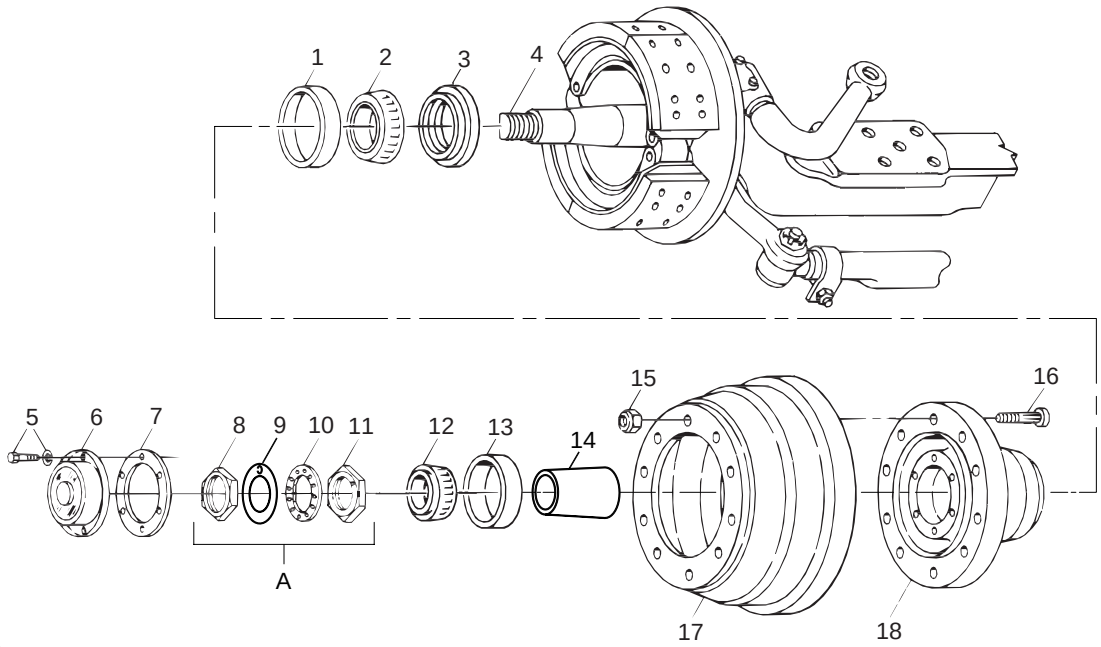
   Before installation of brake drums and wheels that use the hub piloted system, rotate the hub so one of the wheel pilot bosses is at the top. See **Fig. 2**.

   Position the brake drum over the hub so it seats on the drum pilot and against the hub face.
2. Install the brake drum on the wheel hub.

   2.1 On hub-piloted drums, position the brake drum on the top step of the pilot pad. One of the hub's pilot pads should be at the 12 o'clock (top center) position. See **Fig. 2**.

   IMPORTANT: If the drum is not positioned correctly, the pilot pad could be damaged when the wheel nuts are torqued.

Outboard-Mounted Drum Removal and Installation



02/22/2000 f330127a

NOTE: On some Meritor axles, the hub, wheel bearings, studs, and oil seal are assembled at Meritor and installed as an assembly.

12. Outer Wheel Bearing
13. Outer Bearing Cup
14. Bearing Spacer (ConMet PreSet® hubs only)
15. Wheel Nut
16. Wheel Stud
17. Brake Drum
18. Hub

Fig. 1, Typical Wheel and Axle Assembly

2.2 Make sure that the pilot pads securely center the drum (space between drum and hub is equal all around the hub).

IMPORTANT: If damage to the pads prevents the drum from centering, replace the hub. If necessary to hold the drum in position, adjust the brakes before installing the wheels.

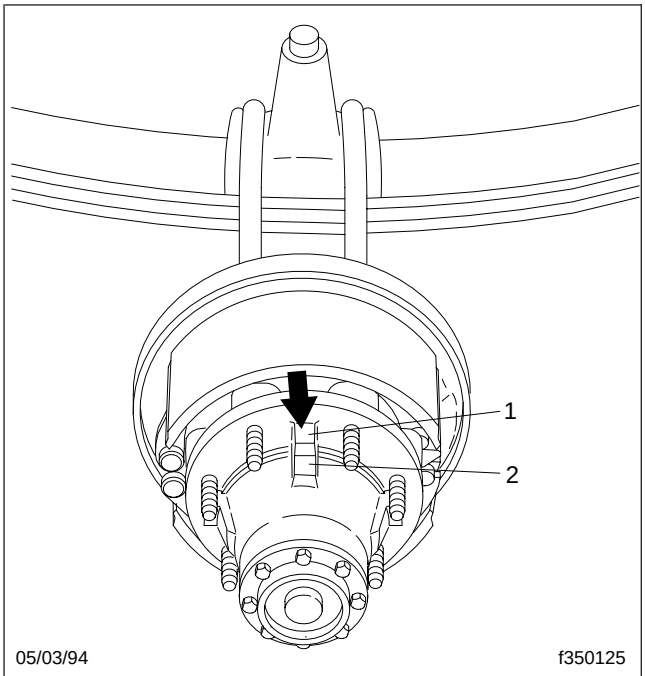
3. Install the wheel and tire assembly. To ensure that the drum does not slip off the pilot pad, follow the proper nut tightening sequence. For instructions, see **Group 40**.

⚠ WARNING

If the wheel nuts cannot be tightened to minimum torque values, the wheel studs have lost their locking ability, and the hub flange is probably damaged. In this case, replace it with a new wheel hub assembly. Failure to replace the wheel hub assembly when the conditions described above exist, could result in the loss of a wheel or loss of vehicle control, and possible personal injury.

4. Adjust the front axle brakes. See Group 42 in the vehicle maintenance manual.

5. Remove the safety stands from under the axle; lower the vehicle.
6. Remove the chocks from the rear tires.



NOTE: The pilot pad should be at the 12 o'clock position.

1. Drum Pilot
2. Wheel Pilot

Fig. 2, Hub Pilot Pads

Wheel Hub Assembly Inspection

1. Inspect the wheel hub mounting flange. A loose wheel assembly will cause the flange to be worn, jagged, or warped. See **Fig. 1**. Replace the wheel hub if any of these conditions exist.

   Inspect the flange surface around the wheel studs. Improperly torqued wheel nuts will cause worn or cracked stud grooves on the hub. See **Fig. 2**. If wear spots or cracks appear anywhere on the hub, or if the hub is otherwise damaged, replace it with a new one.

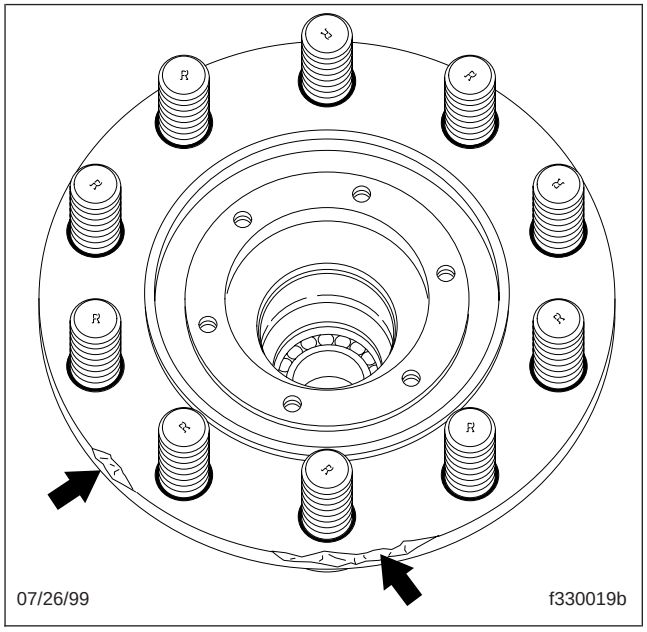


Fig. 1, Wear Spots

2. Remove all the old oil from the wheel hub cavity. Inspect the inner surface of the hub for cracks, dents, wear, or other damage. Replace the wheel hub if damage exists.

3. Remove all the old grease or oil from the surfaces of the wheel bearing cups. Inspect the wheel bearing cups for cracks, wear, spalling, or flaking. See **Fig. 3**. Replace the cups if damaged in any way. See **Subject 130** or **Subject 140**.

4. Inspect the wheel nuts on disc wheel installations, or the rim nuts on spoke-wheel installations. Damaged nuts (**Fig. 4**), usually caused by inadequate tightening, must be replaced with new ones.

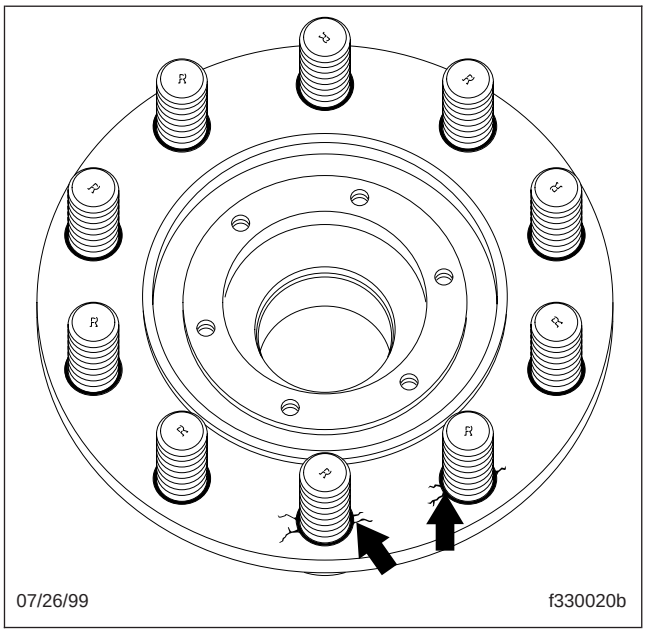

Fig. 2, Cracked Stud Grooves

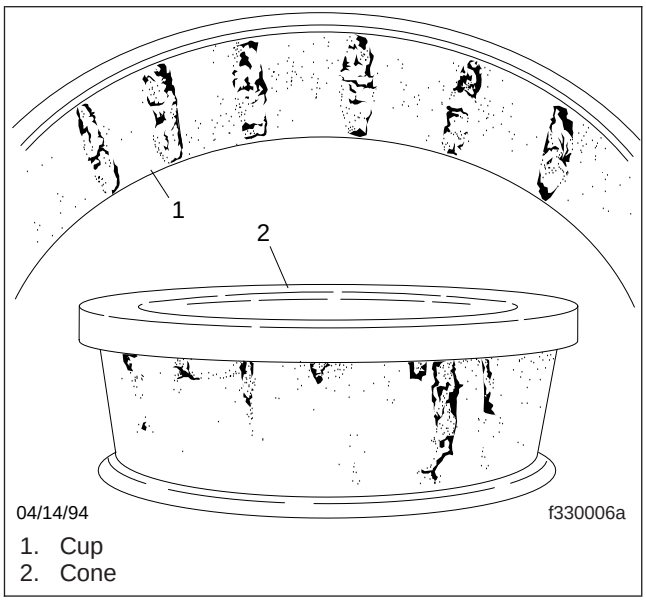

Fig. 3, Spalling (Flaking) of Wheel Bearing Assembly

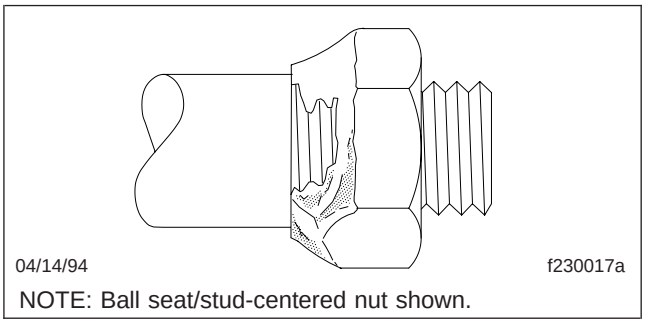
5. Inspect the wheel or rim studs. Replace studs that are stripped, broken, bent, or otherwise damaged. See **Subject 150**.

Axle Components Cleaning and Inspection



NOTE: Ball seat/stud-centered nut shown.

Fig. 4, Damaged Wheel Stud Nut

Wheel Bearing Inspection

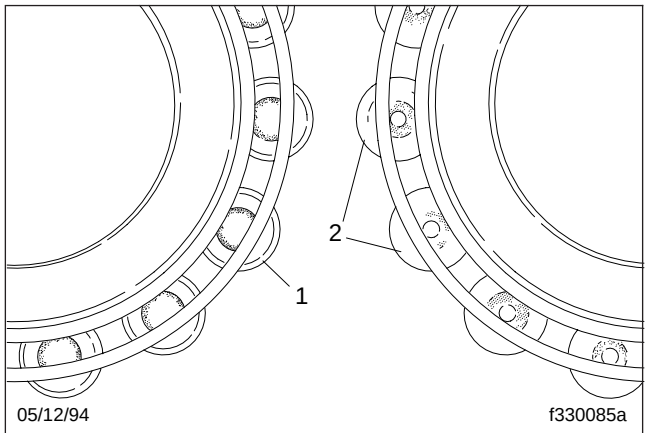
IMPORTANT: Wheel bearings should be very closely inspected at the time of disassembly. Optimal inspection conditions are possible only after the bearings have been thoroughly cleaned using kerosene or diesel fuel oil and a stiff brush.

1. Remove the wheel hub and bearing cones. See **Subject 100**.
2. Clean all old oil from the bearings and hub cavity with kerosene or diesel fuel and a stiff brush. Do not use gasoline or heated solvent.
3. Allow the cleaned parts to dry, or dry them with a clean absorbent cloth or paper. Clean and dry your hands and all tools used in the maintenance operation. Oil will not stick to a surface which is wet with kerosene or diesel fuel, and the kerosene or diesel fuel may dilute the lubricant.

CAUTION

Do not spin the bearing rollers at any time. Dirt or grit can scratch the roller surface and cause premature wear of the bearing assembly. Treat a used bearing as carefully as a new one.

4. After the bearings are cleaned, inspect the assemblies, which include the rollers, cones, cups, and cages. If any of the following conditions exist, replace the bearing assemblies:
   - large ends of rollers worn flush to the recess, or radii at the large ends of the rollers worn sharp (see **Fig. 5**)
   - visible step wear, particularly at the small end of the roller track; deep indentations,



1. New Bearing
2. Worn Bearing Rollers

Fig. 5, Wheel Bearing Roller Wear

cracks, or breaks in the cone surfaces (see **Fig. 6**)

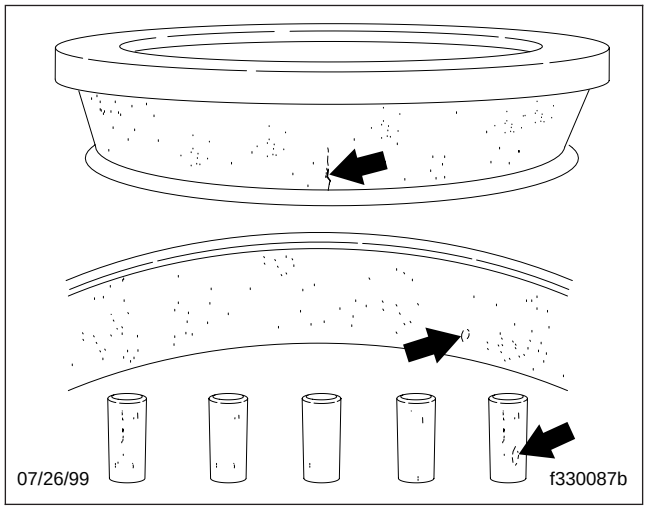


Fig. 6, Indentations, Cracks, or Breaks in Bearing Surfaces

- bright rubbing marks on the dark phosphate surfaces of the bearing cage (see **Fig. 7**)
- water etch on any bearing surface; water etch appears as gray or black stains on the steel surface and it greatly weakens the affected area
- etching or pitting on functioning surfaces (see **Fig. 8**)

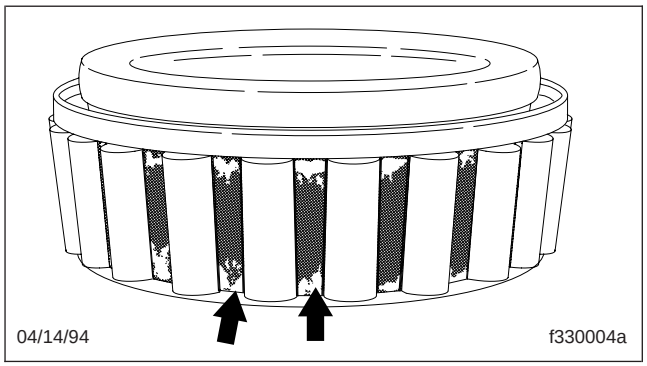

Fig. 7, Rubbing Marks on Bearing Cage

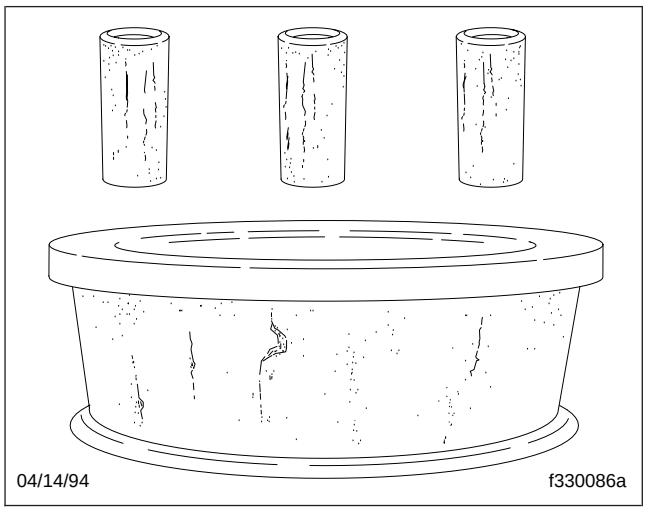

Fig. 8, Etching (Pitting) on Bearing Surfaces

- spalling (flaking) of the bearing cup, roller, or cone surfaces (see **Fig. 3**)

5. After inspection, brush the bearings with fresh axle lubricant.

Brake Drum Inspection

New brake drums are purposely undersized to allow for turning (remachining). Prior to new drum installation, the protective coating on the inner friction surface must be removed with a solvent and then rinsed with a hot water wash. Use a clean rag to remove any oily residue or metal chips from the friction surface.

If a drum must be turned or replaced, the other drum on the axle also must be turned or replaced to provide the same braking power on both wheels. Turned drums should not exceed the maximum allowable diameter stamped on the outside surface of the drum. See **Fig. 9** for a typical location of this stamp.

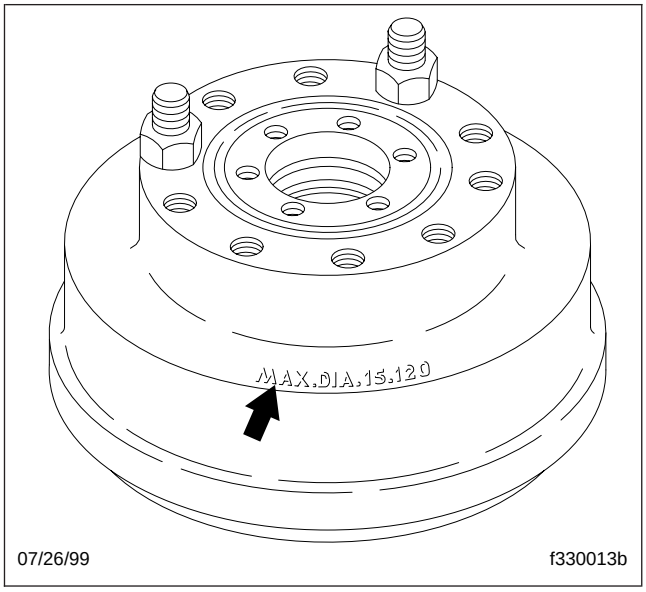

Fig. 9, Maximum Diameter Stamp

NOTE: Turned drums should be cleaned using a fine emery cloth and then rinsed with a hot water wash.

CAUTION

Failure to replace drums when worn or turned to limits exceeding the maximum allowable diameter will cause drum weakness and reduced braking capacity, which can lead to distortion, higher drum temperatures, and ultimate drum breakage.

If the drums are turned or replaced, replace the brake linings. See **Group 42** in this manual for instructions.

1. Inspect the inner friction surface. If a veneered (highly glossed) or glazed surface exists, renew the drum by using 80–grit emery cloth or by turning the drums.
2. Inspect for heat checking, which is a form of buckling (cracking) resulting from a temperature differential in the drum wall between a relatively cool exterior and a hot friction surface. Heat checking is normal on all drums and may not impair performance and lining life if the network

Axle Components Cleaning and Inspection

of fine hairline cracks remains small. Examine heat checks of drums frequently to be certain the checks have not widened into drum weakening cracks (substantial cracks extending to the open edge of the drum). Replace the same-axle drums if substantial cracks are present, or if widening of the fine hairline cracks occurs.

NOTE: If normal heat checking as described above is present, inspect the drums at least every 12,000 miles (19 300 km) thereafter. Inspect the drums (using a flashlight from the inboard side of the wheels) every 6000 miles (9700 km). Inspect more often under adverse operating conditions.

3. Check for a contaminated inner friction surface. If fluids are present, such as oil or grease, remove the contaminants. Locate and correct the source of the contamination. If the brake drums are contaminated with fluids, the brake linings will also be affected. Since oil or grease saturated linings cannot be salvaged, they must be replaced. For brake lining replacement procedures, see **Group 42** in this manual.

⚠ WARNING

If the brake drums are contaminated with fluids, replace the brake linings. Failure to replace fluid contaminated brake linings could result in a partial loss of braking capacity, which could lead to personal injury or property damage.

4. Measure the inside diameter of the drum. If the measured diameter is greater than the maximum allowable diameter, replace the same-axle drums and linings.
5. Check for a variation in gauge readings at different points on the radius of the drum's working surface. If the variation is more than 0.010 inch (0.25 mm) at any point, the drum is out-of-round to unacceptable limits. Remachine or replace the same-axle drums.
6. Inspect the outside surface of the drum. Remove any accumulation of mud, dirt, or rust; foreign matter acts as an insulator, trapping heat within the drum.
7. Check for hard, slightly raised dark-colored spots on the inner friction surface or for a bluish cast on the brake parts, both of which are caused by high temperatures. If the drums' maximum allowable diameters have not been exceeded, remachine both same-axle drums. If the spots or discoloration cannot be removed, or if remachining is not possible, replace the drums. Also replace the brake shoe return springs.

Wheel Bearing Cup Removal and Installation, Aluminum Hubs

Removal (See Fig. 1)

To insure a tight fit, wheel bearing cups are purposely larger than the wheel hub bores they occupy. To remove the bearing cups, aluminum hub bores must be temporarily expanded by heating the hub in an oven (the bearing cups will also expand, but to a considerably lesser extent). If adequate heating facilities are not available, replace the hub, wheel stud, and bearing cup assembly.

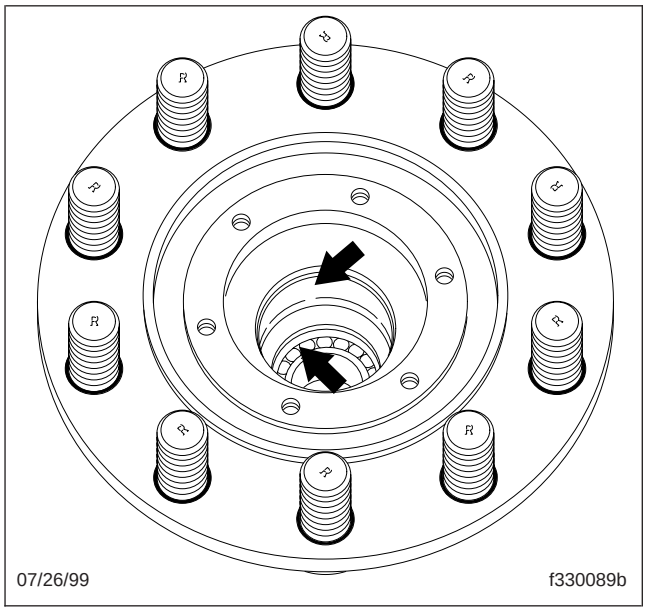

Fig. 1, Wheel Bearing Cup Locations

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Oven-heat the hub to a temperature range of 240° to 280°F (116° to 138°C). Make sure the oven thermostat is accurately set; if unsure, use an oven thermometer to check the temperature of the oven before placing the hub inside.

   If adequate heating facilities are not available, replace the hub, wheel stud, and bearing cup assembly.

⚠ WARNING

Do not use oxyacetylene equipment or similar equipment to heat the hub. Oxyacetylene equipment or similar equipment will cause cracks in the hub which could cause loss of a wheel and loss of vehicle control, leading to personal injury or property damage.

3. Wearing heavy protective gloves, remove the hub from the oven. Place the hub on a suitable press so that the base is fully supported. Quickly press out the bearing cups.

Installation

To install the bearing cups, aluminum hubs must again be temporarily expanded using oven heating. When the hub is properly heated, the bearing cup and hub can be press-fit together, using a suitable press.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Oven-heat the hub to a temperature range of 240° to 280°F (116° to 138°C). Make sure the oven thermostat is accurately set; if unsure, use an oven thermometer to check the temperature of the oven before placing the hub inside.

⚠ WARNING

Do not use oxyacetylene equipment or similar equipment to heat the hub. Oxyacetylene equipment or similar equipment will cause cracks in the hub which could cause loss of a wheel and loss of vehicle control, leading to personal injury or property damage.

4. Coat the replacement bearing cup hub contact surface with a film of grease.
5. Wearing heavy protective gloves, remove the hub from the oven.
6. Place the hub on a suitable press so that the base is fully supported. Quickly press-fit the bearing cup into the wheel hub until it is completely and evenly seated. Be careful not to shave the sides of the bearing cup bore as the bearing cup is seated. The accumulation of debris will prevent the cup from being seated and

Wheel Bearing Cup Removal and Installation, Aluminum Hubs

will also cause permanent damage to the wheel hub. If the sides of the bearing cup bore are damaged during installation, replace the wheel hub assembly.

7. Allow the wheel hub to cool before handling. Using a 0.0015-inch feeler gauge, check at several places for the seating of the bearing cup in the bearing cup bore. The gauge should not enter beneath the cup. If it does, there is probably dirt or debris preventing the cup from seating. Using the instructions above, remove the cup, then remove the foreign matter. Reinstall the cup.
8. Wipe off the accumulation of grease left after the bearing cup has been seated. Using a clean, lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Wheel Bearing Cup Removal and Installation, Ferrous Hubs

Removal

Wheel bearing cups on ferrous hubs are removed and installed by driving them out and pressing them in without heating the hub.

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly.
2. Using a mild-steel rod through the opposite end of the hub, drive against the inner edge of the bearing cup. Alternately drive on opposite sides of the cup to avoid cocking the cup and damaging the inside of the hub.

Installation

1. Using a solvent, completely remove all grease, oil, and other debris from the outer and inner surfaces of the wheel hub assembly, including the bearing cup bores.
2. Inspect the bearing cup bores of the hub for warpage or uneven surfaces. If a bearing cup bore is damaged, replace the wheel hub assembly.
3. Coat the replacement bearing cup hub contact surface with a film of grease.
4. Position the cup in the hub and press it into place, using a suitable driving tool. Cups must seat against the shoulder in the hub.
5. Wipe off the accumulation of grease left after the bearing cup has been seated. Then, using a clean lint-free cloth dampened with kerosene or diesel fuel oil, clean the inner surface of the bearing cup. Wipe the surface dry using a clean, absorbent, and lint-free cloth or paper.

Replacement

⚠ WARNING

If a wheel stud breaks, the remaining studs are subjected to undue strain and could fail due to fatigue. When a broken stud is replaced, replace the stud on each side of it. If more than one stud is broken, replace all of the studs. Failure to replace the studs could result in the loss of a wheel or loss of vehicle control, possibly resulting in personal injury.

1. Remove the wheel hub from the axle. For instructions, see **Subject 100**.
2. If a bent portion of a wheel stud will have to pass through the wheel stud bore, cut off the bent portion before removing the wheel stud.
3. Place the wheel hub on a suitable press; make sure the hub flange is supported evenly around and next to the stud being removed. With steady movement, press the damaged stud out of the hub.

⚠ CAUTION

Do not use a drift and hammer or concentrated heat for removing and installing the wheel studs. Constant, smooth movement of the wheel stud is necessary to ensure the least amount of metal removal from the wheel stud bore. Concentrated heat will damage the hub. If the hub is damaged during wheel stud removal or installation, replace it.

4. Apply a coating of clean axle grease to the entire shaft on headed studs.
5. With the hub on a suitable press, make sure the hub flange is supported evenly around and next to the stud being installed.
6. Position the stud in its hole. *Be sure the flat edge of the head flange on clipped studs is in line with the shoulder on the hub.*

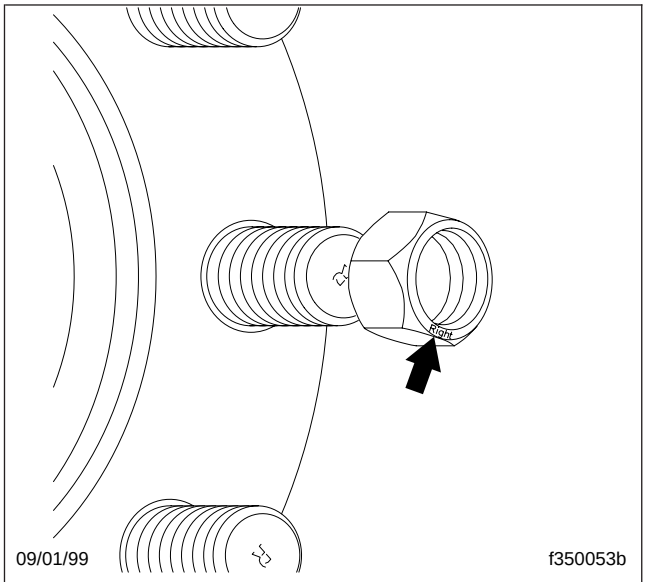
⚠ CAUTION

If headed studs with serrations are being installed, position the teeth of the serrated portion in the notches carved by the original wheel studs during factory installation. If additional metal is scraped from the wheel stud bores, the locking action provided by the serrations will be greatly weakened. Loss of locking action will prevent achieving final torque of the wheel nuts during wheel installation. If final wheel nut torques during wheel installation cannot be achieved, replace the wheel hub assembly.

NOTE: If the left side of the vehicle is being serviced, the replacement wheel stud must be stamped with an "L" (left-hand threaded), and the nut's face must be stamped "Left". If the right side of the vehicle is being serviced, the replacement stud must be stamped with an "R" (right-hand threaded), and the nut's face must be stamped "Right" (**Fig. 1**).

For 8-hole and 10-hole hub piloted disc wheel mountings, both sides have right-hand metric threads.

7. With steady movement, press the new stud all the way into the hub.



NOTE: Ball seat/stud-centered disc wheel mounting shown.

Fig. 1, Right Thread Stamp Location

8. Make sure the stud is fully seated and that its head (flange) is not embedded into the hub. If the head of the stud is embedded into the hub, replace the hub.

Wheel Stud Replacement

WARNING

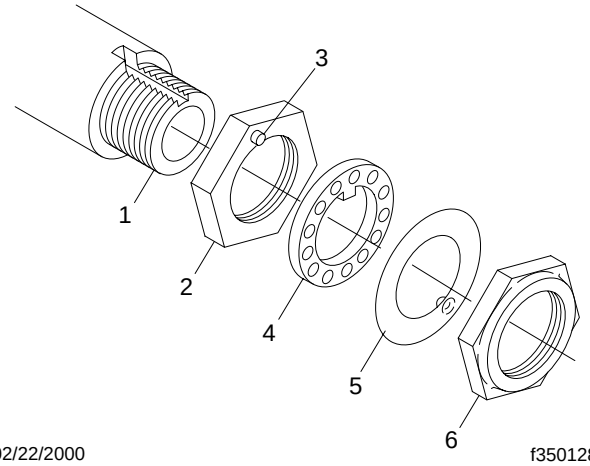
Do not embed the wheel stud heads in the wheel hub. Wheel studs with heads embedded in the wheel hub will weaken the wheel hub flange. Weakness in the wheel hub can result in the loss of a wheel or loss of steering control, possibly resulting in personal injury.

9. Wipe off any grease on the wheel studs and wheel hub. Install wheel nuts on dry wheel studs only.
10. Install the wheel hub on the axle. For instructions, see **Subject 100**.

Four-Piece Wheel Bearing System Installation and Adjustment

Installation and Adjustment

1. Carefully mount the hub and inner wheel bearing assembly on the axle spindle. See **Fig. 1**. Be careful not to unseat the inner wheel bearing or seal.



1. Axle Spindle
2. Adjusting Nut
3. Dowel
4. Lockring
5. Nut-Lock
6. Jam Nut

Fig. 1, Four-Piece Wheel Bearing Assembly

2. Fill the hub cavity with oil. Install the outer wheel bearing; handle the bearings with clean, dry hands. Use care not to damage the bearings as they are seated in the bearing cups.

3. Install the wheel bearing adjusting nut.

   3.1 After the wheel hub and bearings are assembled on the spindle, tighten the inner adjusting nut finger-tight.

   3.2 While rotating the wheel hub assembly, tighten the adjusting nut 100 lbf·ft (136 N·m).

   3.3 Back off the adjusting nut completely.

   3.4 Tighten the adjusting nut 20 lbf·ft (27 N·m) while rotating the wheel hub assembly.

   3.5 Back off the adjusting nut one-third turn.

   NOTE: If any holes in the lockring do not align with the dowel on the adjusting nut, remove the lockring, turn it over and install it again. If a hole still does not align with the dowel, loosen the adjusting nut, but only enough to align the dowel with a hole in the lockring.

4. Install the locking device and jam nut.

   4.1 Install the lockring and nut-lock.

   4.2 Then install the jam nut, and tighten it to the applicable torque in **Table 1**.

Dual-Nut Wheel Bearing Lock Torque Values		
Application	**Size**	**Torque: lbf·ft (N·m)**
Adjusting Nut	—	Stage 1: Tighten to 100 (135)
		Stage 2: Back Off Completely
		Stage 3: Tighten to 20 (25) While Rotating Hub
		Stage 4: Back Off 1/3 Turn
Jam Nut (with Wheel Bearing Nut, Pierced Lockwasher, and Bendable Lockwasher)	1-1/8	Target: 175 (235) Permissible Range: 150–225 (205–305)
	1-1/2 to 2-1/2	Target: 250 (340) Permissible Range: 200–300 (270–405)
	2-5/8 or Larger	Target: 325 (440) Permissible Range: 250–400 (340–540)

Table 1, Dual-Nut Wheel Bearing Lock Torque Values

Four-Piece Wheel Bearing System Installation and Adjustment

5. With the jam nut installed and tightened, adjust the wheel bearings.

   IMPORTANT: Do not adjust the wheel bearings with the wheel mounted on the hub. You cannot accurately adjust or measure the bearing end play with the wheel mounted on the hub.

   5.1 Attach a dial indicator to the hub and set the point of the indicator in line with the end of the axle spindle.

   If using aluminum hubs, you may have to install the brake drum on the hub to provide a steel base for the magnet of the dial indicator. Mount the drum on the hub's drum pilot. Adjust the brake or have someone apply the brakes to hold the drum securely while you secure the drum using the stud at the 12 o'clock position, then the studs at about the 4 o'clock and 8 o'clock positions.

   NOTE: If using a stud-piloted hub and a steel drum, install 1-1/4 inch washers between the nuts and the drum.

   5.2 Release the brakes if you used them to hold the drum while installing it.

   5.3 Grip the sides of the hub at the three o'clock and nine o'clock positions. Push in on the hub (and drum, if applicable), to seat the inboard bearing set. Zero the dial indicator.

   5.4 Once more, grip the sides of the hub at the three o'clock and nine o'clock positions. Pull out on the hub (and drum, if applicable). Read the dial indicator, and note the end play.

   5.5 Push the hub back in to confirm that the needle of the dial indicator returns to zero.

6. The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). If the end play is not within this range, adjust the end play.

   6.1 Remove the jam nut and locking device. Back off or tighten the inner adjusting nut.

   6.2 Install the locking device and jam nut as described earlier, and measure the end play. If the end play is not between 0.001 and 0.005 inch (0.03 and 0.13 mm), turn the adjusting nut again.

   6.3 Once the end play is correct, bend two tabs of the nut-lock over opposing flats on the jam nut. This will lock the jam nut in place.

   6.4 Rotate the wheel in both directions. It should turn freely with no dragging or binding.

ConMet PreSet® Hub Installation and Adjustment

General Information

ConMet PreSet® steer axle hubs are equipped with a special tubular spacer inside the hub, between the inner and outer bearings. See **Fig. 1**.

Wheel bearing adjustment is unnecessary when installing these hubs, because the spacer, together with specially toleranced bearings, automatically sets the bearing end-play. Front axle PreSet hubs can be identified by the part number NP874005 stamped on the outer bearing cone. The outer bearing cone is visible when the retaining nut is removed. See **Fig. 2**.

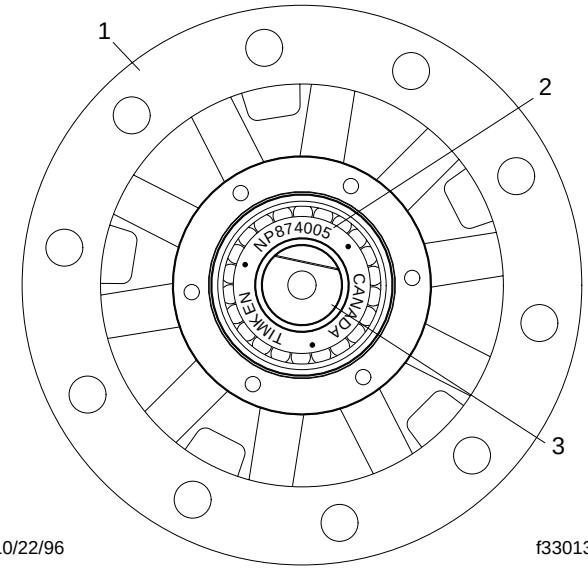
1. Hub
2. Inner Bearing
3. Bearing Spacer
4. Outer Bearing
5. Axilok® Retaining Nut
6. Axle Spindle

Fig. 1, ConMet PreSet Hub, Cut-Away View

NOTE: If you are replacing the bearings for a PreSet hub, and the required bearings are not available, use standard wheel bearings. Remove the bearing spacer and adjust the bearings manually. See the installation instructions for standard bearings under "Installation" in this subject.



10/22/96 f330138

1. Front Axle Hub
2. Outer Bearing Cone and Part Number
3. Axle Spindle

Fig. 2, Identifying a ConMet PreSet Hub

⚠ CAUTION

Do not use the bearing spacer with standard wheel bearings. To do so may result in too much bearing end-play, which could damage the wheel bearings, oil seals, the axle spindle, and the hub.

ConMet PreSet hubs use Axilok® retaining nuts. See **Fig. 3** and **Fig. 4**. Axilok retaining nuts can be damaged if they are not removed or installed correctly. Use the following guidelines when removing and installing Axilok retaining nuts:

- Use only the correct size, *six-point* socket to remove or install Axilok retaining nuts. Do not use a worn or loose-fitting socket. *Do not use a 12-point socket.*
- Do not use hammers, chisels, pliers, wrenches, or power tools to remove or install Axilok nuts.
- Do not use an Axilok nut if the locking clips are damaged or missing, or if the retainer cage tab or D-flat is damaged or missing.
- Never try to repair a damaged Axilok nut; always replace it with a new one.
- Always start an Axilok installation by hand. A good-fitting six-point socket will completely dis-

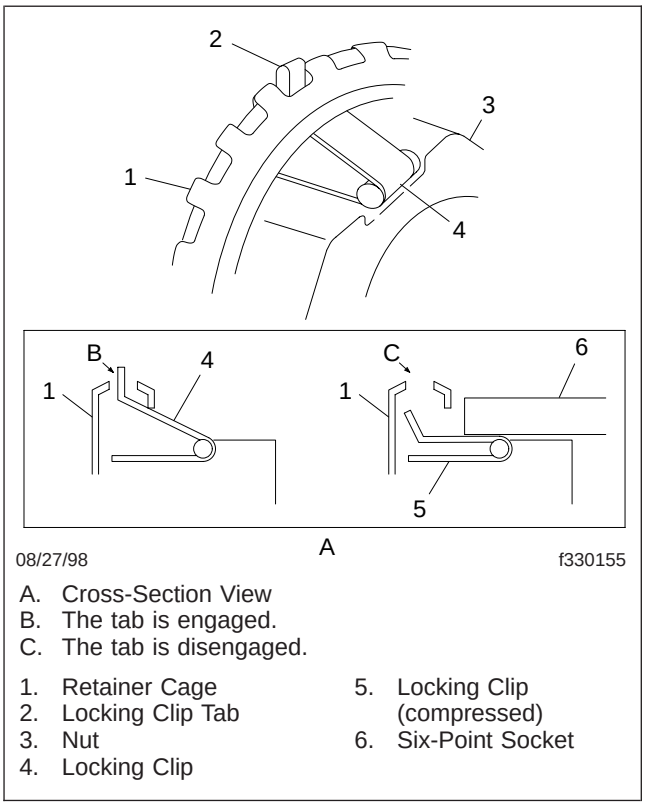
engage the nut's locking clips, allowing it to spin freely by hand. See **Fig. 5**. Use an accurately calibrated torque wrench to tighten the nut to its final torque value.

- After the nut is installed, always make sure that both locking clips are present and engaged in the retainer cage. See **Fig. 5**. If the locking clips are not engaged, the nut is not locked in position and can rotate freely.

Installation

Using PreSet Bearings

1. Wipe a film of axle oil on the axle spindle to prevent rust from forming behind the inner wheel bearing.
2. If present, remove the temporary plastic bearing cover from the front of the hub.
3. Install the PreSet hub assembly all the way onto the axle spindle. A temporary plastic alignment



A. Cross-Section View
B. The tab is engaged.
C. The tab is disengaged.

1. Retainer Cage
2. Locking Clip Tab
3. Nut
4. Locking Clip
5. Locking Clip (compressed)
6. Six-Point Socket

Fig. 5, Axilok Nut, Checking the Position of the Locking Clip

sleeve may be installed in the center of a new hub. It will be pushed out when the hub is installed on the axle spindle. If it is present, remove and discard this sleeve.

4. To prevent damage to the oil seal, do not pull the hub back after beginning the hub installation.

CAUTION

Do not remove the outer wheel bearing once the hub is installed on the axle. Removing the outer bearing could cause the oil seal to become misaligned, which could cause damage to the wheel bearings, the hub, and the axle spindle.

WARNING

Follow the guidelines at the beginning of this subject when installing an Axilok nut. Axilok retaining nuts secure the hub assemblies on the axle. If the Axilok nut is not correctly installed, the hub could separate from the axle, resulting in severe personal injury or death.

5. Install the Axilok retaining nut (see **Fig. 3** or **Fig. 4**) onto the axle spindle.
6. Tighten the retaining nut 250 lbf·ft (339 N·m). Do not back off the retaining nut. The nut should lock in place when you remove the wrench. If it does not, advance it until it does.
7. Install the hub cap, using a new gasket. Tighten the capscrews 15 lbf·ft (20 N·m).

WARNING

Failure to add oil to the wheel hub after the hub has been serviced will cause the wheel bearings to overheat and seize during vehicle operation. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury.

8. Fill the hub with fresh oil to the level shown on the hub cap. Do not overfill.

Using Standard Bearings

NOTE: Save the spacer for use when converting the hub back to the PreSet system.

CAUTION

Do not use the spacer with standard wheel bearings. To do so may result in too much bearing end-play, which could damage the wheel bearings, oil seals, the axle spindle, and the hub.

1. If not already done, remove the tubular spacer from inside the hub. Save it for future use to convert the hub back to the PreSet system.
2. Wipe a film of axle oil on the axle spindle to prevent rust from forming behind the inner wheel bearing.
3. Coat both bearing assemblies with fresh oil. Install the inner wheel bearing and oil seal in the hub. See **Section 33.02** for instructions on installing the various types of oil seals.
4. Install the hub with the inner bearing and oil seal onto the axle spindle. Be careful not to unseat the inner bearing or oil seal.
5. Fill the hub cavity with oil, and install the outer wheel bearing.

ConMet PreSet® Hub Installation and Adjustment

CAUTION

Do not remove the outer wheel bearing once the hub is installed on the axle. Removing the outer bearing could cause the oil seal to become misaligned, which could cause damage to the wheel bearings, the hub, and the axle spindle.

6. Adjust the wheel bearings as follows.

WARNING

Follow the guidelines at the beginning of this subject when installing an Axilok nut. Axilok retaining nuts secure the hub assemblies on the axle. If the Axilok nut is not correctly installed, the hub could separate from the axle, resulting in severe personal injury or death.

CAUTION

To prevent damage to the locking clips, use the correct socket size. See Fig. 5. The socket is used to compress the locking clips, which allows the nut to rotate.

6.1 Install the Axilok nut (see **Fig. 3** or **Fig. 4**) and turn it against the bearing while spinning the hub.

6.2 Tighten the nut 90 to 110 lbf·ft (122 to 149 N·m) while spinning the hub in both directions.

6.3 Loosen the nut to zero torque and spin the hub a few turns.

6.4 Tighten the nut 50 lbf·ft (68 N·m) while spinning the hub in both directions. Back off the nut one-eighth to one-sixth turn.

6.5 Remove the wrench from the nut. The Axilok nut should automatically lock in place. If it does not, advance it until it does.

7. Using a dial indicator, measure the end play as follows.

IMPORTANT: Do not measure the wheel bearings with the wheel mounted on the hub. You cannot accurately measure or adjust bearing end play with the wheel mounted on the hub.

7.1 Attach a dial indicator to the hub and set the point of the indicator in line with the end of the axle spindle. The point of the indicator should be parallel to the spindle axis.

If equipped with aluminum hubs and air brakes, it may be necessary to install the brake drum onto the hub to provide a steel base for the magnet of the dial indicator. Mount the drum on the hub's drum pilot. Adjust the brake or have someone apply the brakes to hold the drum secure. Secure the drum using the stud at the 12 o'clock position. Then secure the studs at about the 4 o'clock and 8 o'clock positions.

If using a stud-piloted hub and a steel drum, install 1-1/4-inch washers between the nuts and the drum.

7.2 Grip the sides of the hub at the 3 o'clock and 9 o'clock positions. Push in on the hub (and drum, if applicable), to seat the inboard bearing set. Zero the dial indicator.

7.3 Again, grip the sides of the hub at the 3 o'clock and 9 o'clock positions. This time, pull out on the hub (and drum, if applicable). Read the dial indicator, and note the end play.

7.4 Push the hub back in to confirm that the needle of the dial indicator returns to zero.

WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use the dial indicator to measure the end play.

8. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm)**. If it is not within this range, remove the Axilok nut, and repeat the tightening sequence as described earlier in this procedure. Once the end play is correct, go to the next step.

9. Install the hub cap, using a new gasket. Tighten the capscrews 15 lbf·ft (20 N·m).

⚠ WARNING

Failure to add oil to the wheel hub after the hub has been serviced will cause the wheel bearings to overheat and seize during vehicle operation. Seized bearing rollers can cause sudden damage to the tire or axle, possibly resulting in personal injury.

10. Fill the hub with fresh oil to the level shown on the hub cap. Do not overfill.

Meritor Easy Steer Plus Hub Installation and Adjustment

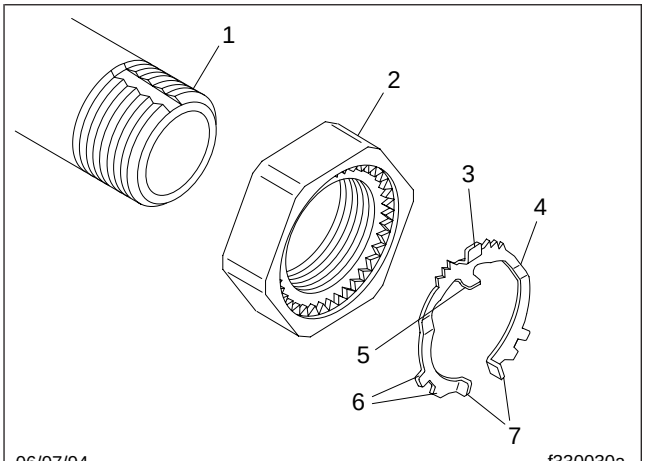
Installation and Adjustment

1. Apply Loctite® RTV 5699 sealant to the threads.
2. With the hub mounted on the axle spindle, install the inner (adjusting) nut and tighten it 600 lbf·ft (813 N·m).
3. Install the locking device (nut-lock, lockwasher, or both).
4. Install the jam nut and tighten it 350 lbf·ft (475 N·m).
5. Bend two opposing tangs of the nut-lock as needed to lock the jam nut and adjusting nut.

Pro-Torq® Nut Wheel Bearing-Lock System Installation and Adjustment

Installation and Adjustment

1. Carefully mount the hub and inner wheel bearing assembly on the axle spindle. See **Fig. 1**. Be careful not to unseat the inner wheel bearing or seal.



1. Axle Spindle
2. Pro-Torq Nut
3. Keeper Tab
4. Lockring
5. Keyway Tab
6. Keeper Arms
7. Keeper Projections

Fig. 1, Pro-Torq Nut Wheel Bearing-Lock Assembly, Eaton Front Axle Shown

2. Fill the hub cavity with oil. Install the outer wheel bearing; handle the bearings with clean, dry hands. Use care not to damage the bearings as they are seated in the bearing cups.
3. Install the Pro-Torq® nut, and turn it against the bearing while spinning the hub.
4. Tighten the adjusting nut 200 lbf·ft (270 N·m) while spinning the hub in both directions.

   Loosen the nut to zero torque and spin the hub a few turns.
5. *For Meritor and Sterling axles:* Tighten the nut 100 lbf·ft (136 N·m). Back off the nut one quarter-turn.

   For Eaton axles: Tighten the nut 75 lbf·ft (102 N·m). Back off the nut one third-turn.
6. Using a dial indicator, measure the end play as follows.

IMPORTANT: Do not measure the wheel bearings with the wheel mounted on the hub. You cannot accurately measure or adjust bearing end play with the wheel mounted on the hub.

6.1 Attach a dial indicator to the hub and set the point of the indicator in line with the end of the axle spindle. The point of the indicator should be parallel to the spindle axis.

If equipped with aluminum hubs and air brakes, it may be necessary to install the brake drum onto the hub to provide a steel base for the magnet of the dial indicator. Mount the drum on the hub's drum pilot. Adjust the brake or have someone apply the brakes to hold the drum secure. Secure the drum using the stud at the 12 o'clock position. Then secure the studs at about the 4 o'clock and 8 o'clock positions.

If using a stud-piloted hub and a steel drum, install 1-1/4-inch washers between the nuts and the drum.

6.2 Grip the sides of the hub at the three o'clock and nine o'clock positions. Push in on the hub (and drum, if applicable), to seat the inboard bearing set. Zero the dial indicator.

6.3 Again, grip the sides of the hub at the three o'clock and nine o'clock positions. This time, pull out on the hub (and drum, if applicable). Read the dial indicator, and note the end play.

6.4 Push the hub back in to confirm that the needle of the dial indicator returns to zero.

⚠ WARNING

The wheel-bearing end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm). Correct end play is crucial: if the wheel-bearing end play is not correct, the wheel bearings could fail. This could cause the loss of the wheel and hub assembly, resulting in an accident causing serious injury or property damage. Use the dial indicator to measure the end play.

Pro-Torq® Nut Wheel Bearing-Lock System Installation and Adjustment

7. **The end play must be between 0.001 and 0.005 inch (0.03 and 0.13 mm)**. If it is not within this range, remove the Pro-Torq nut, and repeat the tightening sequence as described in previous steps. Once the end play is correct, go to the next step.
8. Hold the lockring with the keeper projections facing outboard. See **Fig. 2**.

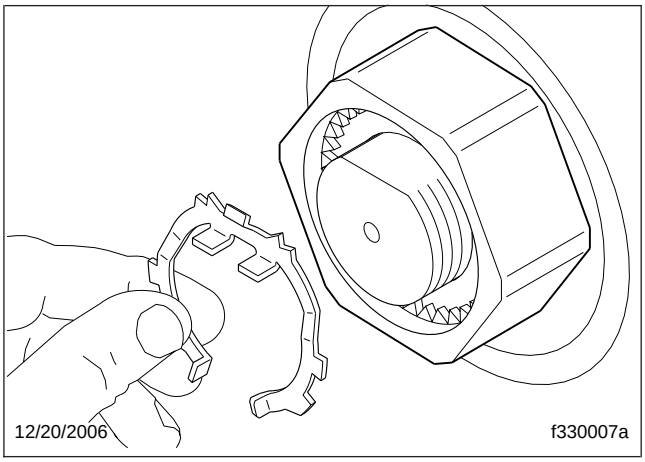


Fig. 2, Lockring Position, Meritor Front Axle Shown

WARNING

The keeper must be installed. If the keeper is not installed, the nut will back off, causing wheel loss. Wheel loss could cause an accident, possibly resulting in personal injury or property damage.

9. *For Meritor and Sterling axles:* Insert the keeper tab in the undercut groove of the Pro-Torq nut, while pressing the keyway tabs on the flat surface of the axle spindle, engaging the mating teeth.

   For Eaton axles: Insert the keeper tab in the undercut groove of the Pro-Torq nut, while pressing the keyway tab into the keyway of the axle spindle, engaging the mating teeth.
10. Insert a screwdriver, or similar tool, in the undercut groove of the nut, between the keeper arms. See **Fig. 3**. Using the tool, compress the lockring to lock it in place.

    Using the screwdriver, press around the edges of the lockring to be sure it is locked in place. See **Fig. 4**.

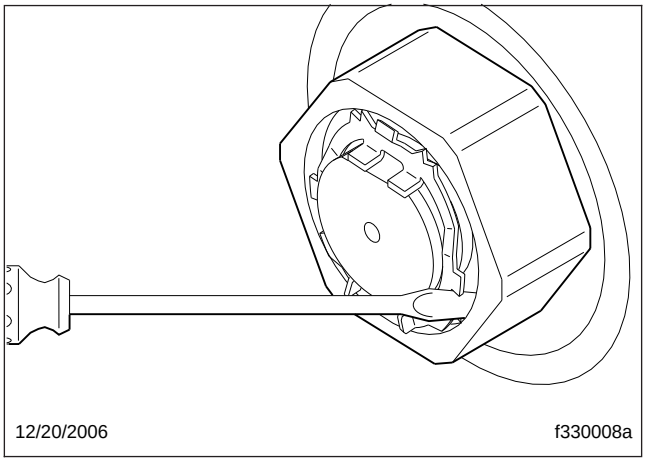

Fig. 3, Compressing the Lockring, Meritor Front Axle Shown

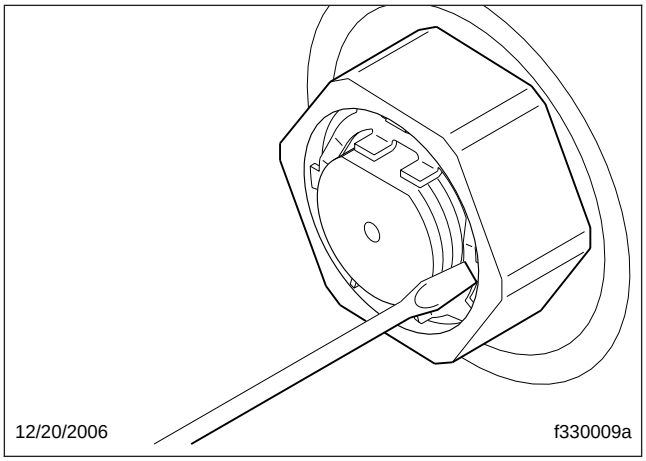

Fig. 4, Making Sure the Lockring is Locked, Meritor Axle Shown

CAUTION

Do not use pliers or similar devices on the keeper projections to compress the lockring. This could result in damage or breakage of the lockring.

Troubleshooting Tables

Problem—Noisy Bearings or Excessive Bearing Replacement Intervals

Problem—Noisy Bearings or Excessive Bearing Replacement Intervals	
Possible Cause	**Remedy**
Not enough, or wrong type of oil on bearings	Clean, then inspect the bearings for wear. Replace worn seals. Coat the bearing assemblies with fresh oil. Fill the hub to the level indicated on the hub cap. Check the hub cap for cracks or a damaged plug.
Foreign matter or corrosive agents entered bearing assembly; dirt or metallic debris not removed from bearings	Clean, then inspect the bearings for wear. Replace worn seals. Also clean the wheel hub, the axle spindle, and any other component in contact with the bearing lubricant. Fill the hub to the level indicated on the hub cap. Check the hub cap for cracks or a damaged plug.
Noise and wear caused by incorrect adjustment of wheel bearings	Adjust the wheel bearings following the applicable instructions in this section.
Flat spots or dents on roller surface caused by skidding of roller, or improper handling of wheel bearing during installation	Clean, then inspect the bearing rollers. Replace the bearing, if damaged. Coat the replacement bearings with fresh oil. For lubricant specifications, see **Specifications, 400**. Fill the hub to the level indicated on the hub cap. Check the hub cap for cracks or a damaged plug.

Problem—Broken Wheel or Rim Studs

Problem—Broken Wheel or Rim Studs	
Possible Cause	**Remedy**
Under-torqued wheel nuts	Replace the studs. Inspect the disc wheel and replace it if the mounting hole shows wear. Install the disc wheel using the proper torque and torque sequence.
Overtightened wheel or rim nuts	Replace the wheel or rim studs. See **Group 40** for the wheel or rim nut tightening sequence.
Incorrect nut tightening sequence used	
Mismatched wheels (hub-piloted wheels mixed with stud-piloted wheels)	Install properly matched wheels.
Overloaded vehicle	Do not exceed the maximum load-carrying capacity of the vehicle.

Problem—Damaged Hub

Problem—Damaged Hub	
Possible Cause	**Remedy**
Cracked hub; local surface of an aluminum hub was heated higher than 350°F (177°C) during bearing cup removal	Replace the hub assembly. When removing the bearing cup, oven-heat the hub.
Bent flange; incorrect installation of wheel studs, such as using a hammer and drift, or hub flange not fully supported on press during wheel stud replacement	Replace the hub assembly. Replace the wheel studs.
Wrong brake drums installed	Install new brake drums.
Insufficient tightening of wheel nuts to wheel hub	Replace the hub assembly and tighten the wheel nuts to the values in the torque table in **Specifications, 400**.

Troubleshooting

Problem—Damaged Hub	
Possible Cause	**Remedy**
Overloaded vehicle	Do not exceed the maximum load-carrying capacity of the vehicle.
Brake drum not seated properly before disc wheel installed and nuts torqued	Make sure brake drum is seated properly on hub before disc wheel is installed.

Problem—Loss of Lubricant from the Wheel Hubs

Problem—Loss of Lubricant from the Wheel Hubs	
Possible Cause	**Remedy**
Loose capscrew on hub cap	Tighten capscrews.
Cracked or damaged hub or missing or loose plug	Replace hub or plug.
Worn or damaged seals or gaskets	Replace worn or damaged parts.
Cracked hub barrel	Replace the hub.

Problem—Vehicle does not Slow Down Quickly Enough When Brakes are Applied

Problem—Vehicle does not Slow Down Quickly Enough When Brakes are Applied	
Possible Cause	**Remedy**
Dirt or grease has built up on brake linings (glazing), or brake linings have worn excessively	Install new brake linings on both sets of axle brake shoes. Clean, turn, or replace the drums. Inspect the hub and seals for oil or grease leaks. Replace as required.
Heat-checked or cracked brake drums	Install new brake drums.
Air system failure	Make sure both front and rear brakes are working properly.

Problem—Service Brakes Grab or Pull

Problem—Service Brakes Grab or Pull	
Possible Cause	**Remedy**
For detailed information, see **Group 42**.	

Problem—Poor Lining-to-Drum Contact

Problem—Poor Lining-to-Drum Contact	
Possible Cause	**Remedy**
Scored or grooved inside surface of the brake drum	Install new brake linings on both sets of axle brake shoes. Install new brake drums or turn the drums.
Stretched or bent brake shoes	Replace the brake shoes.
Undersized linings installed	Install new brake linings on both sets of axle brake shoes.
Incorrect grind was used on the brake linings	
Wrong brake drums were installed	Install new brake drums.

Problem—Poor Lining-to-Drum Contact	
Possible Cause	**Remedy**
Incorrect adjustment of the wheel bearings is causing wheel instability	Adjust the wheel bearings following the applicable instructions in this section.

Problem—Brake Linings are Tapered Across the Width

Problem—Brake Linings are Tapered Across the Width	
Possible Cause	**Remedy**
Inside surface of the brake drum is scored or grooved	Install new brake linings on both sets of axle brake shoes. Turn or replace the drums.
Bent brake shoes	Replace the brake shoes.
Incorrect adjustment of the wheel bearings is causing wheel instability	Adjust the wheel bearings following the applicable instructions in this section.

Problem—Brake Shoes on the Same Brake are Wearing Unequally

Problem—Brake Shoes on the Same Brake are Wearing Unequally	
Possible Cause	**Remedy**
Brake linings are not a matched set; different friction codes or different brands of brake linings are installed	Install a new matched set of brake linings on both sets of axle brake shoes. Clean, turn, or replace the drums.
Stretched brake shoes	Replace the brake shoes.

Problem—Shoes on Each Side of the Axle (Side-to-Side Brakes) are Wearing Unequally

Problem—Shoes on Each Side of the Axle (Side-to-Side Brakes) are Wearing Unequally	
Possible Cause	**Remedy**
Brake linings are not a matched set; different friction codes or different brands of brake linings are installed	Install a new matched set of brake linings on both sets of axle brake shoes. Clean, turn, or replace the drums.
Inside surface of the brake drum is in poor condition	Turn or replace the drums.
Out of adjustment wheel bearings	Adjust the wheel bearings following the applicable instructions in this section.

Problem—Edge of the Lining is Showing Wear

Problem—Edge of the Lining is Showing Wear	
Possible Cause	**Remedy**
Brake lining too wide	Install new brake linings on both sets of axle brake shoes.
Brake linings are misaligned because of incorrectly drilled brake lining holes	
Undersized brake drums installed	Install new brake drums.
Out of adjustment wheel bearings	Adjust the wheel bearings following the applicable instructions in this section.

Troubleshooting

Problem—Edge of the Lining is Showing Wear	
Possible Cause	**Remedy**
Incorrect fit of the hub onto the spindle due to the wrong wheel bearings	Install new wheel bearings and adjust them following the applicable instructions in this section.
Bent brake shoes	Replace the brake shoes.

Problem—Brake Linings are Scored or Grooved

Problem—Brake Linings are Scored or Grooved	
Possible Cause	**Remedy**
Worn or scored brake drums have been causing poor contact with the brake linings	Install new brake linings on both sets of axle brake shoes. Turn or replace the brake drums.
Abrasive material between the lining and drum	

Problem—Brake Linings are Loose

Problem—Brake Linings are Loose	
Possible Cause	**Remedy**
Rivet holes in brake shoes are too large	Replace the brake shoes.
Incorrectly crimped rivets are working loose and allowing the linings to move	Replace the rivets.
Rust has built up on the shoe table	Clean the brake shoe table of all rust, dirt, scale, and paint.

Problem—Brake Lining is Cracked at the Rivet Holes or Bolt Holes

Problem—Brake Lining is Cracked at the Rivet Holes or Bolt Holes	
Possible Cause	**Remedy**
Overtightening of the lining bolts is causing cracks	Install new brake linings. Replace the rivets or bolts with the correct size.
Wrong size counter bore for the rivet holes was made	
Wrong rivets or bolts were used	Replace the rivets or bolts with the correct size.
Incorrectly crimped rivets are working loose and allowing the linings to move	Replace the rivets.
Rust has built up on shoe table	Clean the brake shoe table of all rust, dirt, scale, and paint.

Problem—Out-of-Round Rivet Holes or Bolt Holes

Problem—Out-of-Round Rivet Holes or Bolt Holes	
Possible Cause	**Remedy**
Loose rivets or bolts	Replace the brake shoes or linings.

Problem—Brake Drums are Heat-Checked

Problem—Brake Drums are Heat-Checked	
Possible Cause	**Remedy**
Out-of-round brake drums	Turn or replace the brake drums.
Wrong brake drums installed	Install new brake drums.
Out of adjustment wheel bearings	Adjust the wheel bearings following the applicable instructions in this section.
Brake linings glazed (dirt or grease build-up) or worn unevenly	Install new brake linings on both sets of axle brake shoes. Clean, turn, or replace the drums.
Incorrect lining friction material for operation of vehicle	
Brake imbalance between tractor and trailer	Do a brake balance test (tractor versus trailer). Contact the District Service Manager if help is needed.
Drum not seated properly before disc wheel installed and nuts torqued	Make sure brake drum is properly seated on the hub before the disc wheel is installed.

Problem—Brake Drums are Heavily Scored

Problem—Brake Drums are Heavily Scored	
Possible Cause	**Remedy**
Damaged brake linings	Install new brake linings on both sets of axle brake shoes. Clean, turn, or replace the drums.
Excessive wear on linings	
On the last brake reline, the drums were not turned	Turn the brake drums.

Problem—Excessive Brake Lining Wear

Problem—Excessive Brake Lining Wear	
Possible Cause	**Remedy**
Brake imbalance between tractor and trailer	Do a brake balance test (tractor versus trailer). Contact the District Service Manager if help is needed.

Problem—Hard Steering

Problem—Hard Steering	
Possible Cause	**Remedy**
Low tire pressure in one or both front tires	Inflate tires to the correct pressure.
Binding in steering gear due to lack of lubrication	Test the steering system for binding with the front tires off the ground. For instructions, see **Group 46**.
Too much caster angle in front wheels	Check the caster angle and adjust as needed.
Sagging front suspension due to damaged spring	Repair or replace the spring as needed. For instructions, see **Group 32**.
Bent axle spindle	Replace the spindle.
Misaligned frame	Check the frame alignment; correct, as needed.

Troubleshooting

Problem—Erratic Steering When the Brakes are Applied

Problem—Erratic Steering When the Brakes are Applied	
Possible Cause	**Remedy**
Low tire pressure in one or both front tires	Inflate the tires to the correct pressure.
One or more loose front axle spring U-bolt nuts	Check the U-bolt nuts for looseness. If loose, check the U-bolt for damage. Replace damaged parts; tighten loose nuts.
Brakes not adjusted evenly	Adjust the brakes on all axles. Also, check the operation of the slack adjusters.
Grease or oil contamination of brake linings reducing brake effectiveness	Replace the brake linings and clean the drums. Find and correct the cause of grease or oil contamination.
Wrong caster angle	Check, and adjust as needed.
Bent axle spindle	Replace the axle spindle.
Worn or incorrectly adjusted front axle wheel bearings	Check the bearings for wear or damage; replace as needed.

Problem—Vehicle Pulls to One Side During Operation

Problem—Vehicle Pulls to One Side During Operation	
Possible Cause	**Remedy**
Low tire pressure in one or both front tires	Inflate the tires to the correct pressure.
One or more incorrect alignment measurements	Check all the alignment measurements. Correct as needed.
Out-of-round wheels or tires	Inspect the wheels and tires. Replace out-of-round parts.
Too tightly adjusted front axle wheel bearings	Check the bearings for wear or other damage. Replace the bearings if needed.
Sagging front suspension due to damaged spring	Repair or replace the spring as needed. For instructions, see **Group 32**.
Bent axle spindle	Replace the spindle.
Misaligned frame	Check the frame alignment; correct as needed.
Out of alignment rear axle(s)	Check, and if needed, adjust the rear axle alignment.

Problem—Front Wheel Wander

Problem—Front Wheel Wander	
Possible Cause	**Remedy**
One or more out-of-balance wheels or brake drums	Balance the wheels. Check for out-of-round brake drums; correct as needed.
One weak or broken front springs	Repair or replace the spring as needed. For instructions, see **Group 32**.

Problem—Front Wheel Shimmy

Problem—Front Wheel Shimmy	
Possible Cause	**Remedy**
Low tire pressure in one or both front tires	Inflate the tires to the correct pressure.

Troubleshooting

Problem—Front Wheel Shimmy	
Possible Cause	**Remedy**
One or more out-of-balance wheels or brake drums	Balance the wheels. Check for out-of-round brake drums, correct or replace as needed. Check hub and drum for proper installation.
One or more out-of-round or bulged tires	Replace the tire.
Worn or incorrectly adjusted front axle wheel bearings	Check the bearings for wear or other damage. Replace the bearings if needed.
Worn parts of steering gear or linkage	Test for play in the steering gear and linkage with the front tires off the ground. Replace parts as needed.
Bent axle spindle	Replace the spindle.
One or more incorrect alignment measurements	Check all alignment measurements and correct as needed.
Loose knuckle pin due to worn bushings	Inspect the knuckle pin and bushings for damage. Replace worn or damaged parts as needed.
Worn or damaged shock absorbers	Check the shock absorbers and replace if needed.

Problem—Vehicle Wanders

Problem—Vehicle Wanders	
Possible Cause	**Remedy**
Low tire pressure in one or both front tires	Inflate the tires to the correct pressure.
One or more incorrect alignment measurements	Check all of the alignment measurements; correct as needed.
Out of alignment rear axle(s)	Check the rear axle alignment and adjust as needed.
Worn parts of steering gear or linkage	Test for play in the steering gear and linkage with the front tires off the ground. Replace parts as needed.
Loose knuckle pin due to worn bushings	Inspect the knuckle pin and bushings for damage. Replace worn or damaged parts.
Bent axle spindle	Replace the spindle.

Problem—Cupped Tires

Problem—Cupped Tires	
Possible Cause	**Remedy**
Too low or too high tire pressure in one or both front tires	Inflate or deflate the tires to the correct pressure.
One or more out-of-balance wheels or brake drums	Balance the wheels. Check for eccentric brake drums; correct or replace as needed. Check hub and drum for proper installation.
Incorrect wheel toe-in	Adjust the wheel toe-in.
Brakes not adjusted evenly	Adjust the brakes on all axles. Also, check the operation of the slack adjusters.
Worn or incorrectly adjusted front axle wheel bearings	Check the bearings for wear or other damage; replace them if needed.

Troubleshooting

Problem—Cupped Tires	
Possible Cause	**Remedy**
Camber angle not within specifications	Check the front wheel camber angle. If not correct, find and replace the damaged axle component.

Problem—Steering Wheel Spokes do not Point at the 4 and 8 o'Clock Positions

Problem—Steering Wheel Spokes do not Point at the 4 and 8 o'Clock Positions	
Possible Cause	**Remedy**
Steering gear not centered	Center the steering gear.
If adjustable, out of adjustment drag link	Adjust the drag link.
Steering wheel not installed (positioned) correctly on steering column	Reposition the steering wheel on the steering column.
Pitman arm not correctly aligned with timing mark on steering gear output shaft	Reposition the pitman arm on the steering gear output shaft. For instructions, see **Group 46**.

Specifications

Dual-Nut Wheel Bearing Lock Torque Values		
Application	**Size**	**Torque: lbf·ft (N·m)**
Adjusting Nut	—	Stage 1: Tighten to 100 (135)
		Stage 2: Back Off Completely
		Stage 3: Tighten to 20 (25) While Rotating Hub
		Stage 4: Back Off 1/3 Turn
Jam Nut (with Wheel Bearing Nut, Pierced Lockwasher, and Bendable Lockwasher)	1-1/8	Target: 175 (235) Permissible Range: 150–225 (205–305)
	1-1/2 to 2-1/2	Target: 250 (340) Permissible Range: 200–300 (270–405)
	2-5/8 or Larger	Target: 325 (440) Permissible Range: 250–400 (340–540)

Table 1, Dual-Nut Wheel Bearing Lock Torque Values

Dana Spicer® Axle Recommended Lubricant		
Lubricant Type	**Condition**	**SAE Viscosity Grade**
Eaton Roadranger® Synthetic Axle Lubricants, or Equivalent with Military Specification MIL–L–2105D	Over-the-Road Service	75W–90
	Off-Highway Equipment, or Under Extra Heavy Loads	80W–140

Table 2, Dana Spicer Axle Recommended Lubricant

Meritor Axle Recommended Lubricant			
Lubricant Type	**Ambient Temperature**	**SAE Viscosity Grade**	**Meritor Specification**
Hypoid Gear Oil API Service Classification GL–5	+10°F (–12.2°C) and up*	85W–140	0–76–A
	–15°F (–26.1°C) and up*	80W–140	0–76–B
	–15°F (–26.1°C) and up*	80W–90	0–76–D
	–40°F (–40°C) and up*	75W–90	0–76–E
	–40°F (–40°C) to +35°F (+2°C)	75W	0–76–J
	–40°F (–40°C) and up*	75W–140	0–76–L
Synthetic Gear Oil	–40°F (–40°C) and up*	75W–90	0–76–N
	–40°F (–40°C) and up*	75W–140	0–76–M

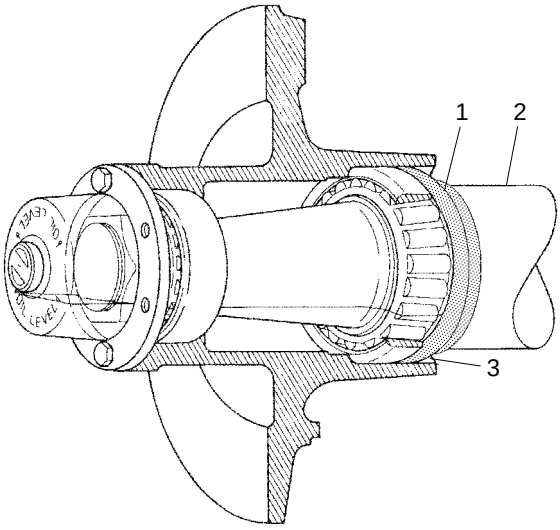
* There is no upper limit on these ambient temperatures, but axle sump temperature must never exceed 250°F (121°C).

Table 3, Meritor Axle Recommended Lubricant

General Information

Wheel oil seals (also called "oil bath seals" or "hub seals") work as a dam to keep oil in the hub cavity so that it constantly "bathes" the wheel bearings. The seals also protect the wheel bearings by keeping dirt, dust, and water out of the hub.

The oil seal fits between the hub bore and the axle spindle (see **Fig. 1**). The sealing element either turns with the wheel and seals against the axle spindle (*hub-mounted seals*), or the sealing element stays stationary with the axle spindle and seals against the turning hub (*spindle-mounted seals*).



05/19/95 f330100a

1. Wheel Oil Seal
2. Axle Spindle
3. Wheel Hub Bore

Fig. 1, Stemco Spindle-Mounted Wheel Oil Seal

Most wheel oil seals consist of four basic parts:

- the outside edge (also called the outer "cup" or "case")
- the inside edge (also called the inner "cup" or "case")
- the sealing element
- the garter spring

The outside edge is usually metal coated with rubber or another sealing agent so that it grips the hub bore tightly enough to prevent oil escaping between the outer edge of the seal and the hub bore.

The inside edge is usually metal or rubber with a metal ring within it to prevent the sealing element from wearing a groove in the axle spindle.

The sealing element is usually molded rubber, leather, or a synthetic such as nitrile or silicone. The element is molded into lips which will seal against the axle spindle or against the outside or inside edge described above. The innermost lip, called the "primary lip," keeps the oil inside the hub cavity. The outermost lip, called the "secondary lip," keeps dirt out of the hub cavity.

The garter spring is a coiled wire spring with its ends connected to make a loop. On hub-mounted seals, the spring runs around the outside of the sealing element to press the element inwards against the sealing surface. On spindle-mounted seals, the spring runs around the inside of the sealing element to press the element outward against the sealing surface.

Sterling uses two brands of axle oil seals:

- Chicago Rawhide (Scotseal® and Scotseal Plus®)
- Stemco (Guardian® and SS4®)

Chicago Rawhide (See Fig. 2)

The Chicago Rawhide Scotseal® is a unitized, one-piece design consisting of a sealing element (packing) that is assembled between metal outer and inner cups. The sealing element consists of three sealing lips; a spring-loaded primary sealing lip that is factory pre-lubed and two dirt exclusion lips. The seal is press fit into the hub bore using Scotseal® service installation tools. *Do not install the Scotseal® directly onto the axle spindle.*

Although you install the Scotseal® into the hub bore, the seal's element grips the axle spindle tightly enough that the sealing element stays stationary with the spindle and seals against the outer cup which turns with the hub.

The Chicago Rawhide Scotseal® maintains a metal-to-metal contact between the outer cup and the hub bore surface as well as a metal-to-metal contact between the sealing element inside edge and the axle spindle.

Fig. 2, Chicago Rawhide Scotseal®

Stemco (See Fig. 3 and Fig. 4)

The Stemco wheel oil seals are spindle-mounted, with a rubber-coated outside edge that grips inside the hub bore and also holds the sealing element.

Although you install the Stemco seal onto the axle spindle, the outside edge grips the hub bore tight enough that the sealing element turns with the hub and seals against the inside edge which grips the axle spindle and acts as a wear sleeve.

Seal Replacement, Chicago Rawhide

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

NOTE: This procedure applies to the Chicago Rawhide Scotseal®.

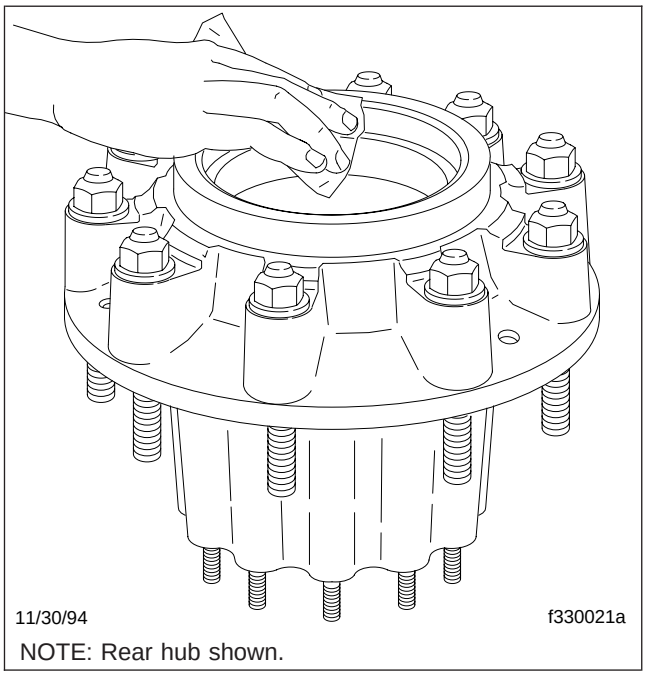
1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 33.01**.
2. Remove the inner wheel bearing assembly from the axle. Handling the bearings with clean dry hands, wrap the bearings in clean oil-proof paper or lint-free cloths. Occasionally, the inner wheel bearing cone assembly will remain in the hub after the hub is removed from the axle. In those cases, place a protective cushion to catch the bearing assembly. Using a hardwood drift and a light hammer, gently tap the bearing and seal out of the inner wheel bearing cup.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity. See **Fig. 1** and **Fig. 2**.
4. Remove all burrs from the shoulder and the seal bore with an emery cloth or a file. Clean any metal filings from the components.

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

IMPORTANT: Use extreme care in cleaning the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause premature wear of the bearing assembly.

5. Inspect the bearings and hub components for wear or damage. Replace any worn or damaged components as necessary.
6. Coat the wheel bearing cones with oil.
7. Install the inner wheel bearing cone in the inner wheel bearing cup.



NOTE: Rear hub shown.

Fig. 1, Clean the Hub

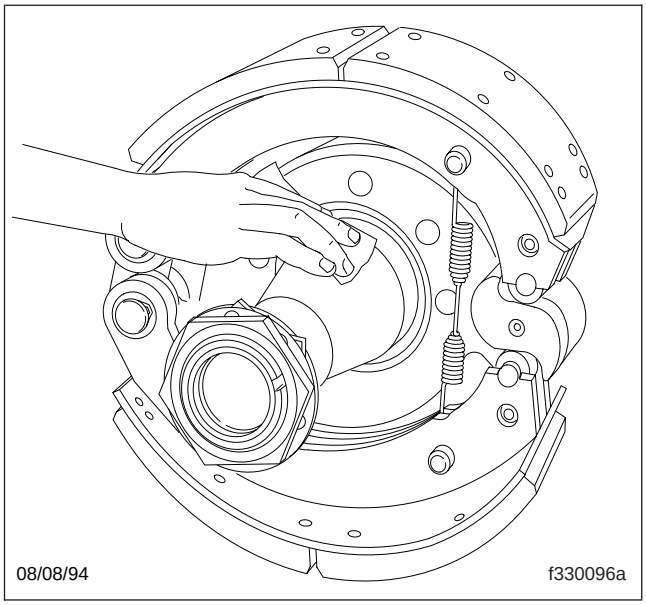


Fig. 2, Clean the Spindle

8. Seat the small outside edge of the seal in the recess of the tool adapter. See **Fig. 3**. The correct adapter is identified on the box.

Seal Replacement, Chicago Rawhide

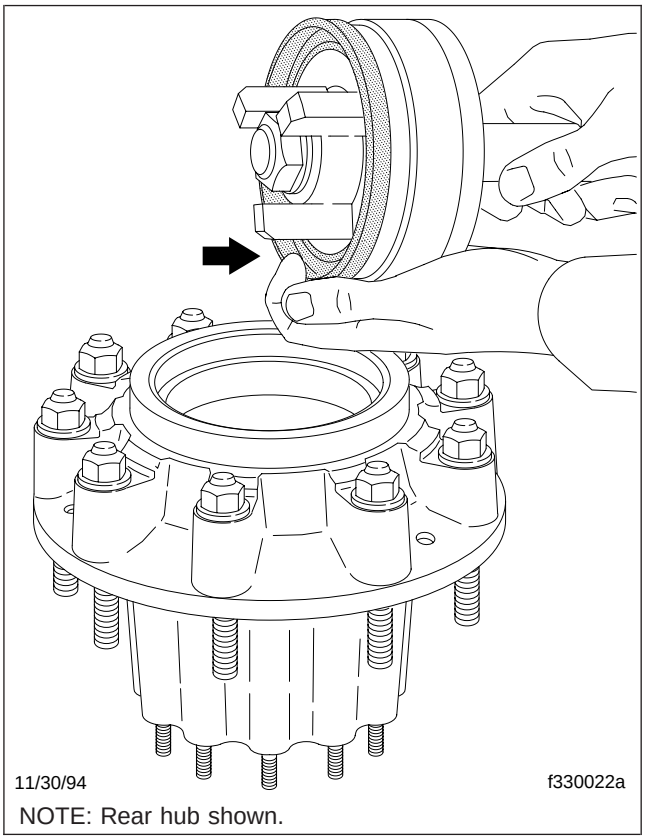

Fig. 3, Place the Seal on the Installation Tool

9. Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 4**. The plug prevents cocking of the seal in the bore.
10. Hold the tool handle firmly, and strike it until the sound of the impact changes as the seal bottoms out. See **Fig. 5**. Hold the tool firmly to avoid bounce or unseating of the seal from the adapter.
11. After the seal is bottomed in the bore, check for freedom of movement by manually moving the interior rubber part of the seal back and forth. A slight movement indicates a damage-free installation.
12. Install the wheel hub on the axle, and adjust the wheel bearings. For instructions, see **Section 33.01**.

IMPORTANT: When starting the wheel on the spindle, center the hub carefully to avoid seal damage from the leading edge of the spindle.

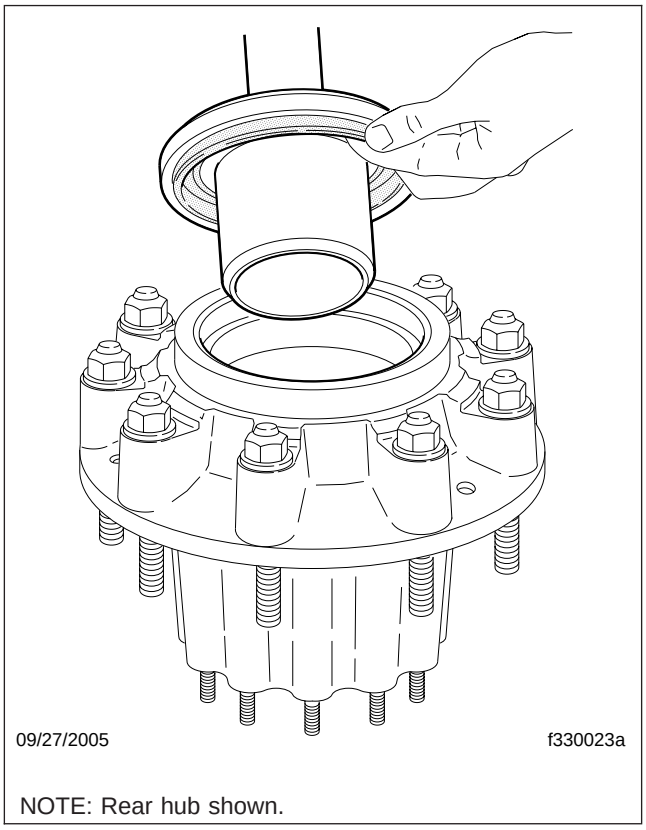

Fig. 4, Insert the Tool in the Hub Bore

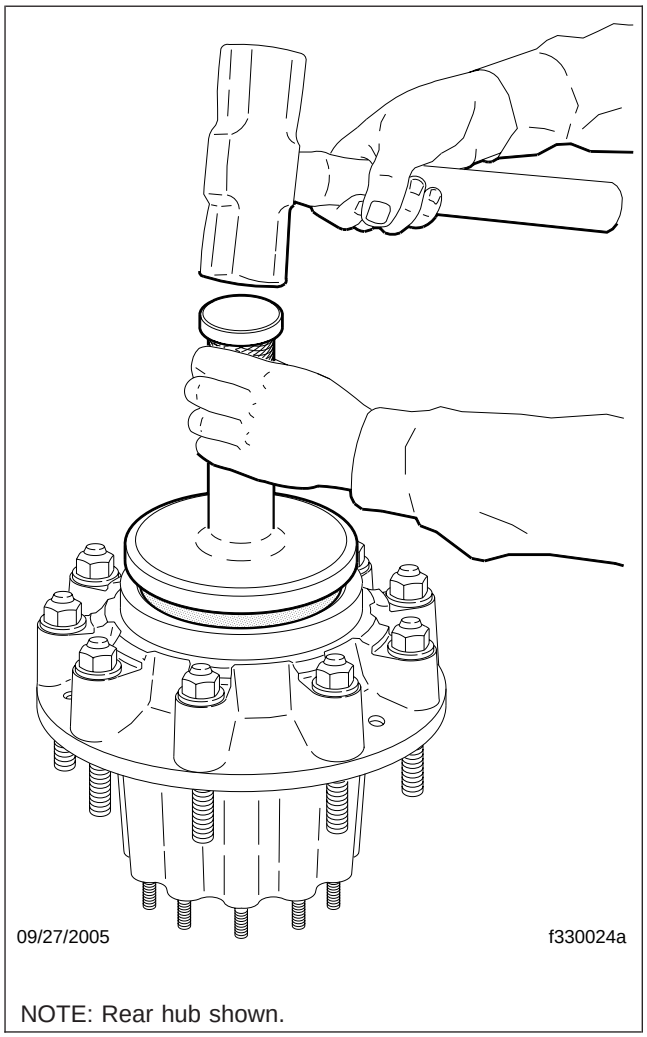
13. Place the hubcap and a new gasket in position. Install the capscrews. Tighten the capscrews 15 lbf·in (20 N·m).
14. Fill the hub with oil to the level shown on the hubcap. See **Fig. 6**. Do not overfill.
15. Spin the wheel and check the oil level.
16. Adjust the brake shoe-to-drum clearance. For instructions, see **Group 42**.

Seal Replacement, Chicago Rawhide



NOTE: Rear hub shown.

Fig. 5, Strike the Tool

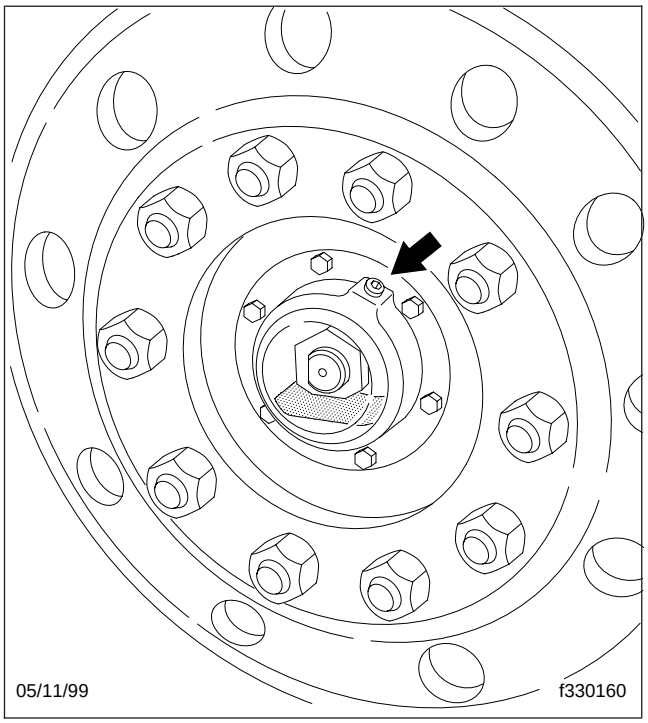


Fig. 6, Hub Filler Plug

Seal Replacement, Stemco®

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Replacement

1. Remove the wheel, drum, and hub from the axle. For instructions, see **Section 33.01**.
2. Remove the old oil seal from the hub or spindle.
3. Clean the spindle, spindle threads, seal bore, and the hub cavity.

⚠ CAUTION

Never use a sharp chisel to cut through an axle ring. A sharp chisel could damage the spindle or shoulder.

4. Remove the steel axle ring by striking the ring surface several times with a ball-peen hammer. See **Fig. 1**. Remove the stretched axle ring from the spindle.

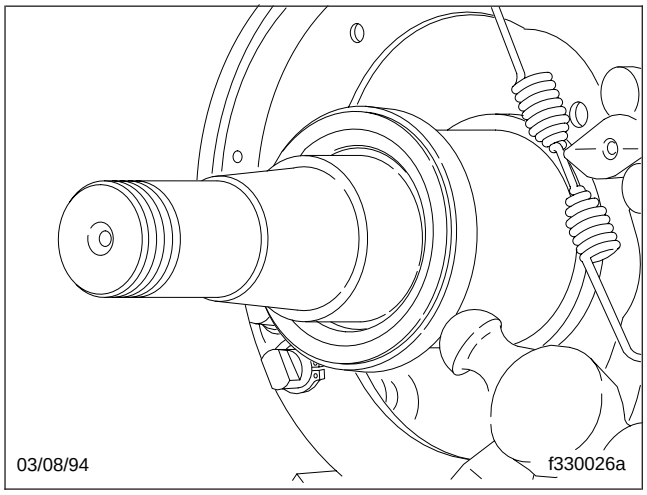

Fig. 1, Remove the Axle Ring

5. Using a wire brush, remove any old sealant and corrosion from the axle spindle and shoulder. Remove any burrs with an emery cloth. See **Fig. 2**. Wipe the spindle and shoulder clean with safety solvent.

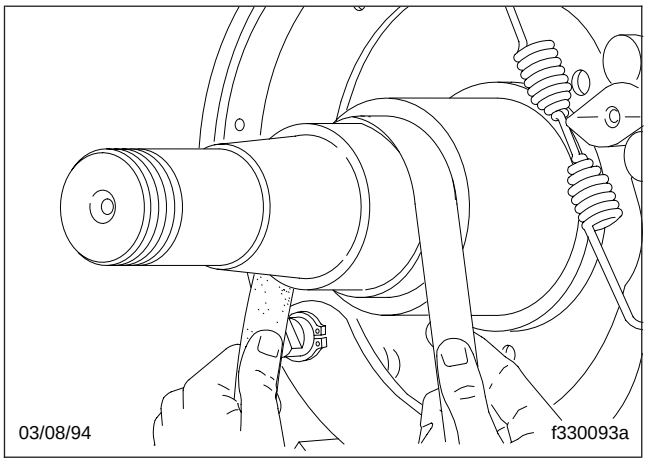

Fig. 2, Clean the Axle Spindle

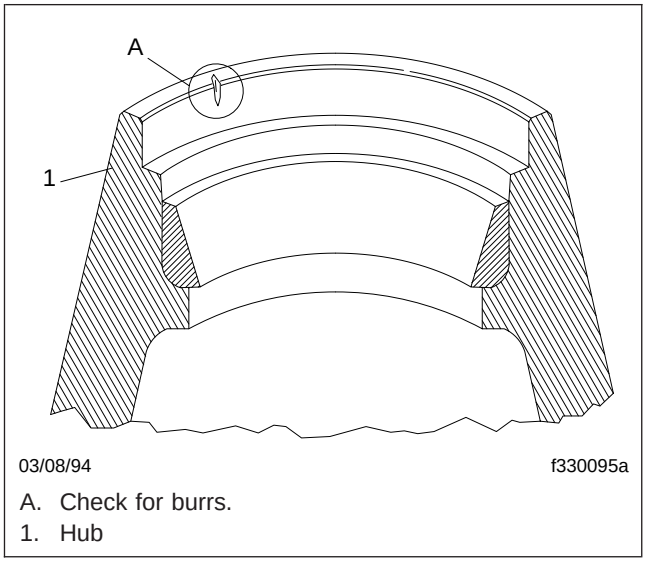
6. Remove any burrs from the inside of the hub bore. See **Fig. 3**. The hub bore must be free of burrs that will scratch the outer surface of the seal and allow oil to escape from the hub. Remove any spacer rings or washers, if so equipped.



A. Check for burrs.
1. Hub

Fig. 3, Inspect the Hub Bore

IMPORTANT: Clean the wheel hub cavity and axle spindle. Dirt, metal filings, or other contaminants can scratch the bearing roller surfaces, and cause rapid wear of the bearing assembly.

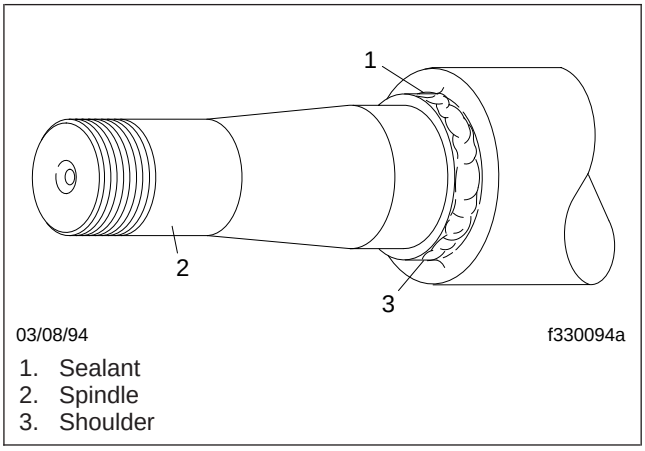
Seal Replacement, Stemco®

7. Inspect the bearings and hub components for wear or damage. Replace any worn or damaged parts as necessary.

⚠ CAUTION

Do not spin bearing rollers at any time. Dirt or grit can scratch the roller surface and cause rapid wear of the bearing assembly. Treat used bearings as carefully as new ones.

8. If burrs were removed from the spindle shoulder, apply a thin layer of non-hardening sealant to the spindle shoulder. See **Fig. 4**.



1. Sealant
2. Spindle
3. Shoulder

Fig. 4, Apply Sealant to the Spindle Shoulder

NOTE: Use a non-hardening sealant such as Permatex® Number-2 or Loctite® 515.

9. Place the oil seal on the spindle so the words "oil-bearing side" are exposed to the oil. A slight step on the inside circumference of the seal ring will allow it to be placed by hand about 1/8 inch (3 mm) onto the shoulder. See **Fig. 5**.

⚠ CAUTION

Do not install the oil seal in the hub bore. Incorrect seal installation will damage the seal and lead to possible spindle, hub, and bearing damage.

10. Position the Stemco installation tool over the spindle. See **Fig. 6**. Using a 3 to 5 lb (1 to 2 kg) hammer, drive the seal on the spindle until the tool bottoms against the shoulder. After the tool bottoms, turn it while applying several light taps with the hammer to ensure the seal ring is flush with the face of the shoulder. Wipe off all excess sealant.

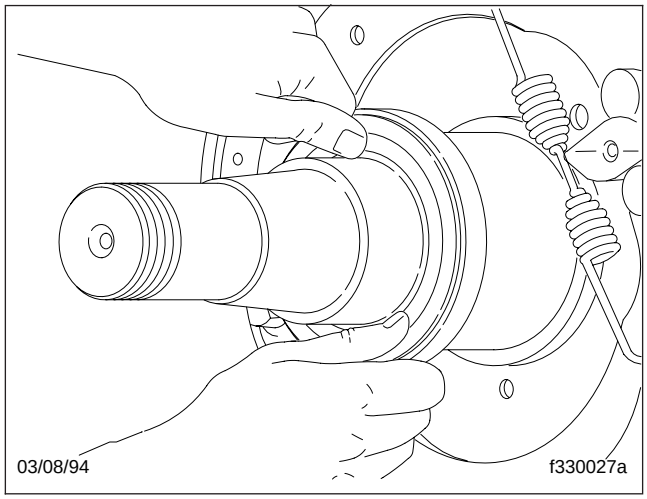


Fig. 5, Place the Seal on the Spindle

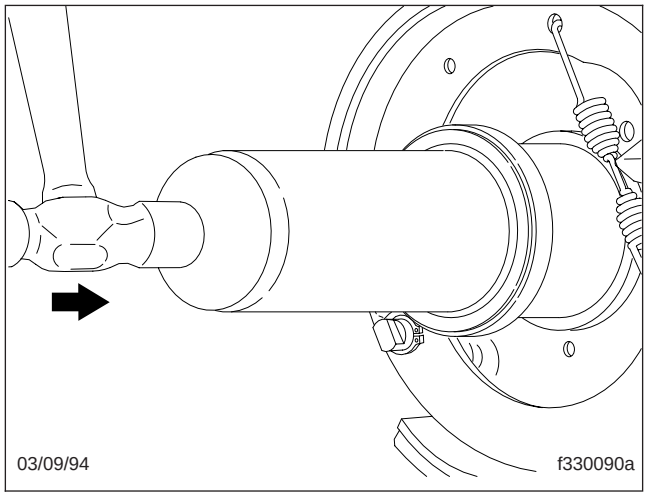

Fig. 6, Drive the Seal onto the Spindle

IMPORTANT: Use only the tool specified by Stemco for the vehicle's axle. In order for the Stemco warranty to apply, the product must be correctly installed using the correct tool made by Stemco or a tool approved by Stemco.

11. Make sure there are not any gaps between the ring and shoulder. See **Fig. 7**.

12. Coat the inner wheel bearing with oil and install it on the spindle. See **Fig. 8**. No additional oil is

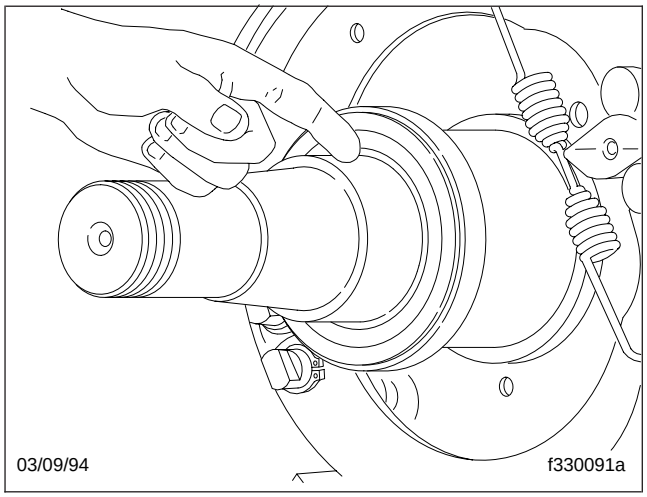

Fig. 7, Check the Ring for Gaps

needed on the outside of the seal. The seals are lubed at the factory.

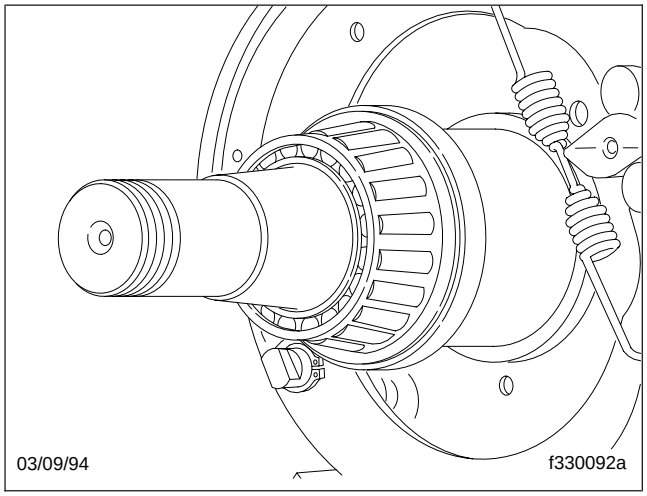

Fig. 8, Install the Inner Bearings

13. Install the hub and wheel bearings. For instructions, see **Section 33.01**.

IMPORTANT: Do not force the wheel onto the seal. The wheel will seat on the seal when the adjustment nut is tightened.

14. Adjust the wheel bearings. For instructions, see **Section 33.01**.
15. Install the hub cap with a new gasket. Tighten the hub cap nuts 15 lbf·ft (20 N·m). Add oil to the level shown on the window. See **Fig. 9**. Turn the hub and allow the oil to settle. Recheck the hub and fill to a level between the oil line and about 1/4 inch (6 mm) above the oil line. Do not overfill the hub. Install the vent plug or threaded filler plug.

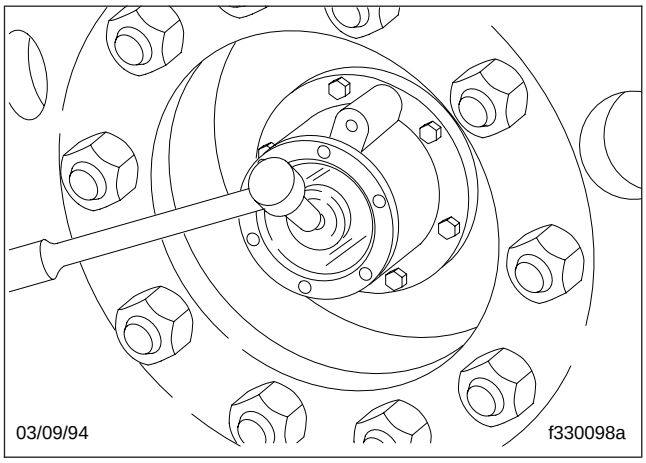

Fig. 9, Fill the Hub with Oil

16. Spin the wheel and check the oil level.
17. Adjust the brake shoe-to-drum clearance. For instructions, see **Group 42**.

General Information

Detroit front axles have a unique steering knuckle design that reduces vibration and wear. Low-friction, high-strength needle bearings roll on a large-diameter kingpin, replacing the conventional bushings. They are compatible with all standard industry model brakes, hubs, and wheel bearings.

The basic model is indicated by the numbers on the axle's identification tag. The following explains a typical model number.

Typical Model Number: AF-12-3.

- *AF* = front axle
- *12* = Weight Rating (times 1000 lbs.)
- *3* = Model Number

NOTE: Detroit axles are a proprietary product, though in some applications they may be referred to as "Sterling" or "Axle Alliance" axles or "MB components."

Removal

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the rear tires. Put the transmission in neutral.
2. At both ends of the front axle, loosen all the wheel nuts.

⚠ WARNING

Never work around or under a vehicle that is supported only by a jack. Always support the vehicle with safety stands. Jacks can slip, causing the vehicle to fall, which could result in serious injury or death.

3. Raise the front of the vehicle and support it with safety stands.
4. Drain the air system.
5. Remove the front wheel and tire assemblies. For instructions, see **Group 40**.
6. Remove the brake drums and front hubs from the axle. For instructions, see **Section 33.01, Subject 100**.
7. Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
8. Remove the ABS sensors and wiring from the brake spiders (anchor plates) and secure them and their wiring out of the way.
9. Remove the brake air chambers and the slack adjusters. For instructions, see the applicable sections in **Group 42**.
10. Remove the brake spiders from the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
11. Disconnect the drag link from the axle steering arm.
12. If so equipped, disconnect the sway bar from the axle brackets.
13. Using a suitable jack, support the front axle.
14. Remove the U-bolt nuts or remove the nuts that hold the axle beam to the leaf springs and the air bag brackets, as applicable.
15. Remove the U-bolts, if applicable.
16. Remove the axle from the vehicle.
17. If you are replacing the steering knuckles, put the axle on a suitable stand and secure it to prevent it from moving.

Installation

1. With the axle on a suitable jack, position it under the vehicle.
2. For vehicles with front air suspension, raise the axle so that the holes in the axle beam line up with the bolts that hold the air bags to the leaf springs. Install the nuts and washers and tighten the nuts 220 lbf·ft (298 N·m).

   For vehicles with a leaf-spring front suspension, install the U-bolts and nuts. For instructions on tightening U-bolt nuts, see the applicable section in **Group 32**.
3. If so equipped, connect the sway bar to the axle brackets. Tighten the sway bar fasteners 100 lbf·ft (136 N·m).
4. Connect the drag link to the steering arm. For instructions, see the applicable section in **Group 46**.
5. Install the brake spiders on the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
6. Install the brake air chambers and slack adjusters on the axle. For instructions, see the applicable sections in **Group 42**.
7. Install the ABS sensors.
8. Install the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
9. Install the hubs and adjust the wheel bearings. For instructions, see **Section 33.01, Subject 100**.
10. Install the brake drums.
11. Adjust the slack adjusters. For instructions, see the applicable section in **Group 42**.
12. Install the tire and wheel assemblies. For instructions, see **Group 40**.
13. Raise the vehicle, remove the safety stands, and lower the vehicle.
14. Start the engine and build the air pressure.

Axle Removal and Installation

15. If equipped with a front air suspension, check that the suspension air bags are inflating correctly.
16. Remove the chocks from the rear tires.

Disassembly

NOTE: The following procedures can be done with the axle installed on the vehicle or with the axle removed from the vehicle.

1. If the axle has been removed, make sure it is securely mounted on a suitable stand. Go to the step for removing the tie rod from the tie-rod arm.

   If the axle is on the vehicle, park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the rear tires. Drain the air system.

2. If the axle is on the vehicle, do the following substeps to gain access to the steering knuckle.

   2.1 Remove the wheel and tire assembly from the applicable side of the vehicle.

   2.2 Remove the brake drum and hub. For instructions, see **Section 33.01, Subject 100**.

   2.3 Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.

   2.4 If so equipped, remove the ABS sensor and wiring from the brake spider (anchor plate) and secure the sensor and the wiring out of the way.

   2.5 Disconnect the air line from the brake air chamber, then remove the air chamber and the slack adjusters. For instructions, see the applicable sections in **Group 42**.

   2.6 Remove the brake spider from the axle flange. For instructions, see the applicable service brake section in **Group 42**.

   2.7 Disconnect the drag link from the steering arm, if present.

   NOTE: On the driver's side of the vehicle, the steering arm connects to the steering knuckle. On the passenger's side, no steering arm is present.

3. If not already done, disconnect the tie rod from the tie-rod arm.

4. Remove the tie-rod arm from the steering knuckle. See **Fig. 1**.

5. If applicable, remove the steering arm. See **Fig. 1**.

6. Remove the steering knuckle and spindle assembly from the axle beam. See **Fig. 1**.

   6.1 Remove the upper and lower snap rings that hold the cover plates in place.

   6.2 Remove the upper and lower cover plates from the steering knuckle.

   6.3 Remove and discard the O-ring from the edges of each cover plate.

   6.4 Note the orientation of the draw keys and the kingpin, then remove the draw keys and nuts that hold the kingpin in place.

   6.5 Using a brass drift, remove the kingpin by driving it downward. Make a note of where the needle bearings were installed.

   6.6 Remove the spacer(s) and shim(s) from the upper surface of the axle beam bore.

   6.7 On the side with a steering arm, push down on the steering knuckle and spindle assembly to clear the lip on the thrust friction bearing and remove the assembly from the axle beam bore.

NOTE: The steering knuckle on the passenger's side (side without a steering arm) has a thrust roller bearing instead of a thrust friction bearing. Unlike the thrust friction bearing, the thrust roller bearing has no protruding lip at the top. When removing the thrust roller bearing from the axle beam bore, it is not necessary to push down on the steering knuckle.

7. Remove the grease seal from the upper steering-knuckle bore.

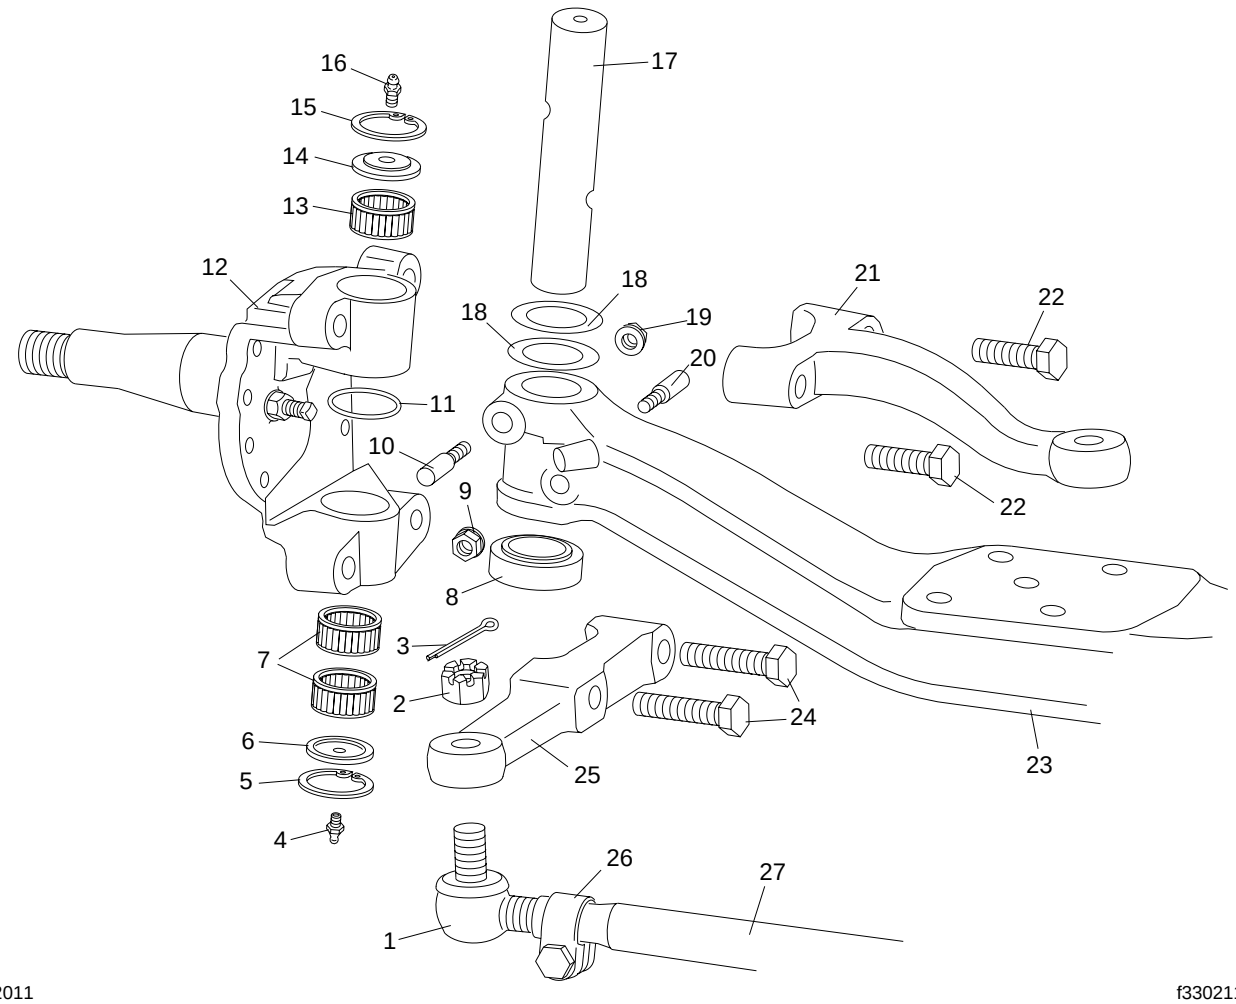
8. Remove the thrust friction bearing (driver's side) or the thrust roller bearing (passenger's side) from the top of the lower steering knuckle bore.

NOTE: If removing the thrust friction bearing (driver's side), note the orientation of the bearing for future reference.

9. Using a brass drift, drive out the needle bearings from the steering knuckle bores.

10. If needed, repeat the entire procedure for the other side of the axle assembly.

Steering Knuckle Disassembly and Assembly



06/08/2011 f330211a

NOTE: The number of upper and lower needle bearing sets may vary, depending on the axle model.

1. Tie-Rod Ball Joint
2. Castle Nut
3. Cotter Pin
4. Lower Grease Fitting
5. Lower Snap Ring
6. Lower Cover Plate
7. Lower Needle Bearings (may be one or two sets)
8. Thrust Friction Bearing (thrust roller bearing on the passenger side)
9. Lower Draw Key Nut
10. Upper Draw Key
11. Grease Seal
12. Steering Knuckle
13. Upper Needle Bearing (may be one or two sets)
14. Upper Cover Plate
15. Upper Snap Ring
16. Upper Grease Fitting

23. Axle Beam
24. Tie-Rod Arm Capscrews
25. Tie-Rod Arm
26. Tie-Rod Clamp
27. Tie-Rod Tube

Fig. 1, Front Axle Components (driver side shown)

Assembly

IMPORTANT: If replacing the kingpin, use a complete rebuild kit with all new components.

1. Clean the steering knuckle bores and the axle beam bores. Check for damage such as grooves, scratches, and pitting.

   If any bores show significant damage, replace the component.

2. Install the grease seal — with the grooved side down (toward the road) — into the top of the upper steering knuckle bore. Carefully drive the seal down into the bore until the outer edge of the seal is flush with the bottom edge of the bore. Make sure the seal is not cocked.

3. Install new needle bearings into the bores of one of the steering knuckles. Install the same number of bearings as was removed.

NOTE: Install the needle bearings just far enough into the bores so that the cover plates can be installed.

4. Install a new thrust friction bearing (driver's side) or thrust roller bearing (passenger's side) into the top of the lower steering knuckle bore. Install the thrust friction bearing (or thrust roller bearing) with the sealed side up.

NOTE: The thrust friction bearing has a protruding lip at the top. The thrust roller bearing has no such protruding lip.

5. Partially install the steering knuckle on the axle beam.

   5.1 Making sure the flats on the kingpin are aligned with the draw-key holes in the axle beam, put the new kingpin into the top bore of the steering knuckle. Note that the top of the new kingpin is clearly marked. Push the kingpin through the axle beam bore until the upper end of the kingpin is flush with the upper surface of the axle beam bore.

   5.2 Align the steering knuckle with the axle beam, then check the clearance between the axle beam bore and the upper steering knuckle bore. Clearance is to be a maximum of 0.003 inch (0.08 mm).

   IMPORTANT: To correctly check the clearance, the thrust friction or thrust roller bearing must be installed correctly, and upward pressure must be applied to the steering knuckle.

   5.3 If needed, install sufficient spacers to reduce the clearance to 0.002 to 0.003 inch (0.05 to 0.08 mm).

6. Install the kingpin fully into the steering knuckle bores, making sure the flats on the kingpin are still aligned with the draw-key holes in the axle beam.

7. Install new upper and lower draw keys and nuts. See **Fig. 1**.

   7.1 Install the upper draw key from the back of the axle, and the lower one from the front of the axle.

   IMPORTANT: Make sure the new draw keys are the same length as those removed. On some axle models the lower draw key is longer than the upper one.

   7.2 Tighten the draw-key nuts 30 to 55 lbf·ft (40 to 75 N·m).

8. Install new grease fittings and cover plates.

   8.1 Install the new upper cover plate (with a new O-ring) and the snap ring. Install the new grease fitting into the cover plate.

   8.2 Install the new lower cover plate (with a new O-ring) and the snap ring. Install the new grease fitting into the cover plate.

9. Install the steering arm. Apply Loctite® 277 to the threads and tighten the steering arm capscrews: if M20 capscrews are used, tighten them 425 lbf·ft (575 N·m); if M24 capscrews are used, tighten them 664 lbf·ft (900 N·m).

10. Attach the tie-rod arm to the steering knuckle. Apply Loctite® 277 to the threads and tighten the tie-rod arm capscrews: if M20 capscrews are used, tighten them 425 lbf·ft (575 N·m); if M24 capscrews are used, tighten them 664 lbf·ft (900 N·m).

11. Attach the tie-rod arm to the tie rod. Tighten the castle nut 120 to 170 lbf·ft (163 to 230 N·m) plus a maximum of one-sixth of a turn to align a slot in the castle nut with the cotter pin hole in the tie

rod stud. Insert the cotter pin and bend the tangs to secure it.

12. If removed, install the axle.
13. If removed, connect the drag link to the steering arm.
14. Install the brake spider on the axle flange. For instructions, see the applicable service brake section in **Group 42**.
15. Install the brake air chambers and slack adjusters on the axle. For instructions, see the applicable sections in **Group 42**.
16. Install the ABS sensor.
17. Install the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
18. Install the hub and adjust the wheel bearings. For instructions, see **Section 33.01**.
19. Install the brake drum.
20. Install the tire and wheel assembly. For instructions, see **Group 40**.
21. If necessary, repeat the entire procedure for the other side of the vehicle.
22. Raise the vehicle, remove the safety stand, then lower the vehicle.
23. Remove the chocks from the tires.

Sway Bar Fasteners	—	—	100 (136)

Table 1, Torque Values

General Information

WHEEL HUBS AND BEARINGS

(See Fig. 1)

A unitized wheel bearing seal is a standard item on all rear axles. The unitized wheel seal combines the functions of a wear sleeve and seal in one self-contained unit, with the seal and sleeve surface inside. The unitized design provides maximum protection for the sealing surface during installation and operation. The tools required for unitized seal installation are only available from C.R. Industries.

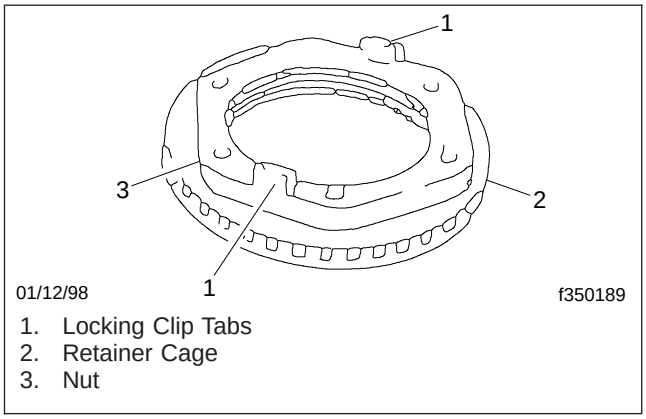
A two-piece seal is available as a regular production option. The seal consists of a lip-type oil seal and a wiper sleeve. The seal is installed in the wheel hub and the wiper sleeve is installed on the axle tube housing. When the hub is installed, a seal is formed between the wear sleeve and seal lip. The tools required for seal installation are only available from the Stemco warehouse.

New hub seals must be installed whenever the hub is removed. A damaged or worn seal can permit bearing lubricant to reach the brake linings, resulting in ineffective brake operation and necessitating premature replacement of linings.

AXILOK WHEEL BEARING ADJUSTING NUT **(See Fig. 2)**

A new wheel bearing adjustment nut is available for both front and rear axles on L-Line and A-Line vehicles.

The Axilok wheel bearing adjusting nut is self-locking, eliminating any other retainers (such as cotter keys). It allows precise wheel bearing adjustment to within 0.002 to 0.003 inch (0.0500 to 0.0762 mm), is easy to install and service following the proper procedure, replaces a three part adjusting nut system, and is reusable.



1. Locking Clip Tabs
2. Retainer Cage
3. Nut

6. Gasket
7. Axilok Wheel Bearing Adjusting Nut
8. Outer Cone and Roller Assembly
9. Outer Bearing Cup
10. Inner Bearing Cup
11. Inner Cone and Roller Assembly

Fig. 2, Typical Rear Wheel Hub

Removal

1. Chock the front tires.
2. Raise the rear wheels off the floor and place safety stands under the rear axle housing so the axle is parallel with the floor. See **Fig. 1**.

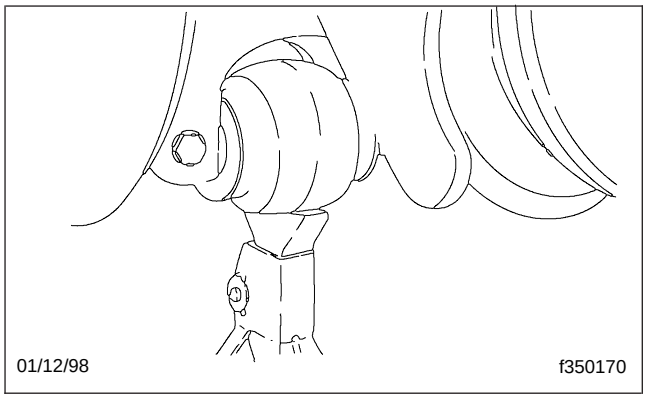

Fig. 1, Safety Stand Under Rear Axle

3. Back off the rear brake adjustment.
4. Remove the drive axle stud nuts and lockwashers. See **Fig. 2**.

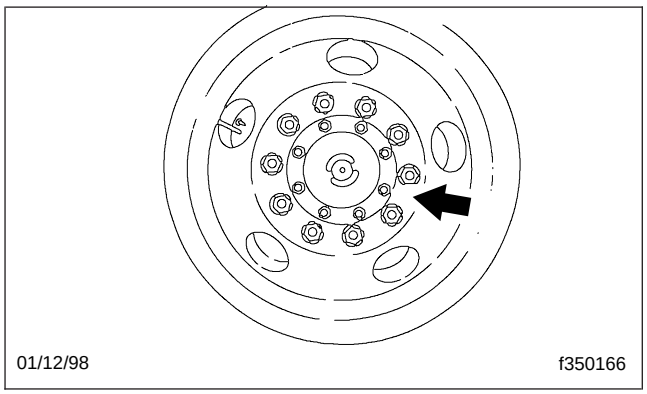

Fig. 2, Drive Axle Stud Nuts

5. If tapered dowels are installed in the axle shaft flange, place a drift in the center of the flange and strike it sharply to loosen the dowels. See **Fig. 3**.
6. Remove the axle shaft. See **Fig. 4**.

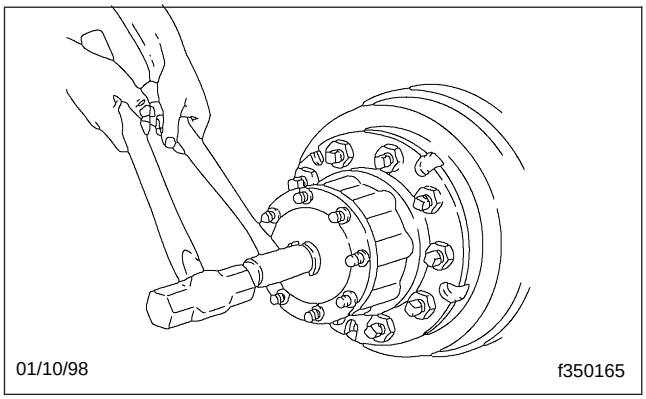

Fig. 3, Loosening Tapered Dowels With a Drift and Hammer

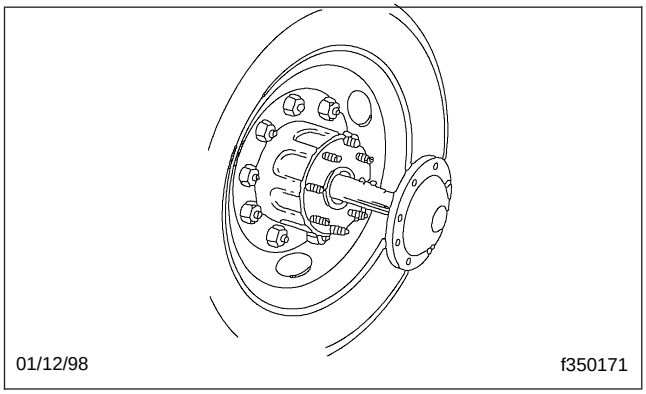

Fig. 4, Axle Shaft

CAUTION

Do not chisel, hammer, or use an impact tool to remove the Axilok wheel bearing adjusting nut. Use only the proper size 6-point socket as stamped on the nut to remove or install it. Do not use a 12-point socket. Failure to follow this precaution can cause damage to the nut.

7. Remove the Axilok wheel bearing adjusting nut. See **Fig. 5**.

   7.1 Apply a small amount of torque in the removal direction, but not over 50 lbf·ft (68 N·m).

   7.2 If the Axilok nut rotates freely, remove it from the spindle.

   If the Axilok nut does not rotate freely, check the socket size and make sure the

Wheel Hubs Removal and Installation

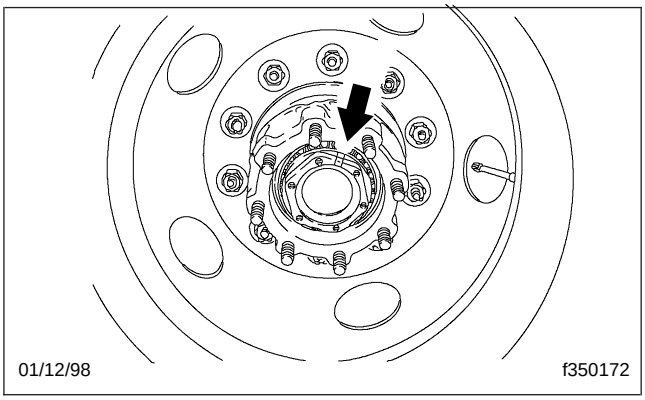

Fig. 5, Axilok Wheel Bearing Adjusting Nut

locking clip tabs are fully disengaged from the retainer cage holes.

8. Using a wheel dolly, raise the wheel so that all the wheel weight is removed from the wheel bearings. See **Fig. 6**.

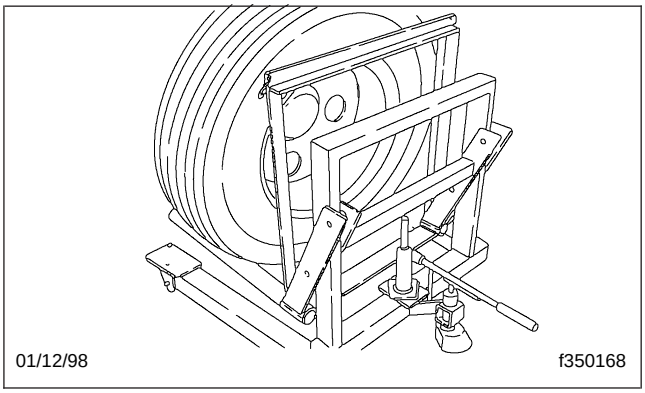

Fig. 6, Wheel Dolly

9. Remove the outer bearing cone. See **Fig. 7**.

NOTE: This step will remove the wheel, tire, and brake drum housing simultaneously.

10. Pull the wheel straight out and away from the axle.
11. Thoroughly clean the spindle of the axle housing. See **Fig. 8**.
12. Inspect the bearing cups and bearings for pitting, galling, and erratic wear patterns. See **Fig. 9**.

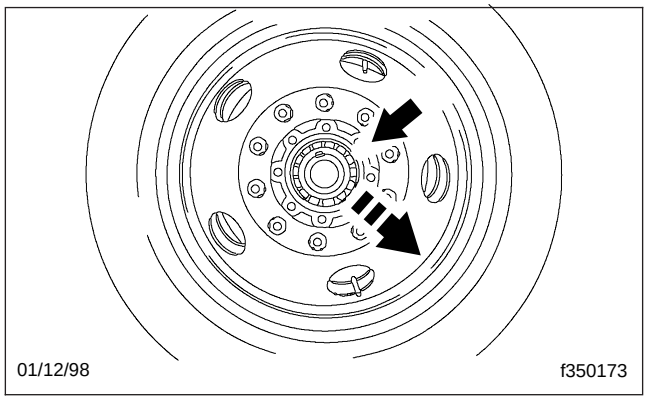

Fig. 7, Outer Bearing Cone

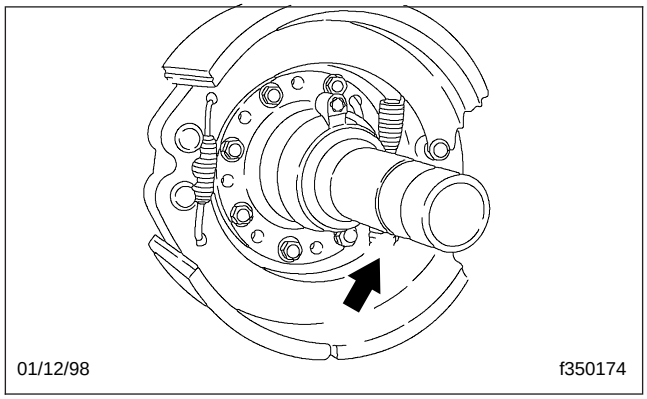

Fig. 8, Clean Axle Housing Spindle

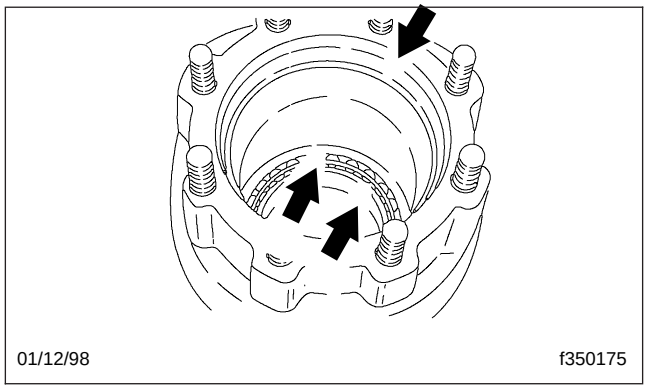

Fig. 9, Inspect Bearing Cups for Wear

Installation

1. Apply a light film of lithium-base grease to the axle spindle, and position a seal protector tool over the axle spindle threads.

NOTE: Use Premium Long-Life Grease XG–1–C or XG–1–K (or equivalent meeting Sterling specification ESA–M1C75–B).

2. With the hub centered on the axle spindle, carefully slide the hub, wheel, and brake drum assembly straight (to avoid seal damage or bumping the antilock brake sensor out of adjustment) onto the axle housing spindle. See **Fig. 10**. After performing this step, remove the seal protector from the axle spindle.

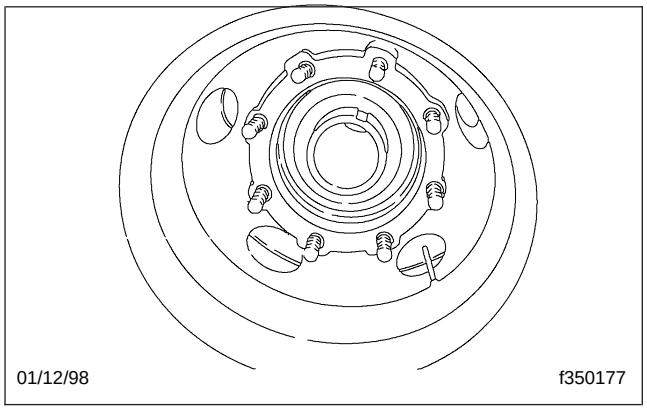

Fig. 10, Hub, Wheel, and Brake Drum Assembly

3. Fill the wheel cavity with rear axle lubricant before installing the outer bearing. See **Fig. 11**.

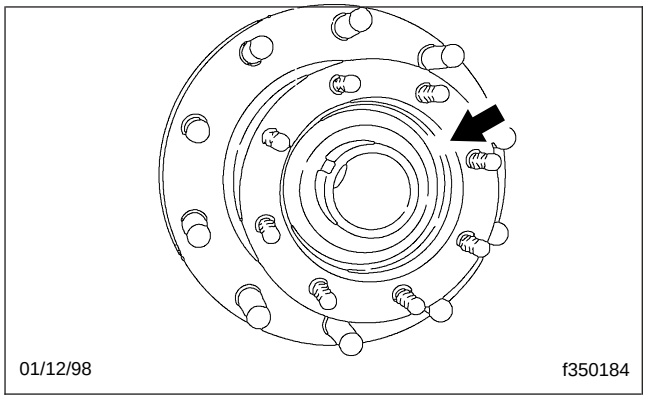

Fig. 11, Lubricating Wheel Cavity

⚠ CAUTION

Use only the proper size 6-point socket as stamped on the nut to install it. Do not use a 12-point socket. Failure to follow this precaution can cause damage to the nut.

4. Install the outer wheel bearing and start the Axilok wheel bearing adjusting nut. See **Fig. 5**.

   IMPORTANT: Do not install the Axilok wheel bearing adjusting nut if it is damaged in any way.

   4.1 Inspect the spindle threads and slot for damage. Do not install the Axilok wheel bearing adjusting nut on a damaged spindle.

   4.2 Inspect the locking clips, retainer cage, and threads. The components must not be damaged. If the nut assembly is damaged, use a new one.

5. Remove the wheel dolly.
6. Adjust the wheel bearings.
7. Install the axle shaft and a new gasket. See **Fig. 4**.
8. Install the tapered dowels, lockwashers, and drive axle stud nuts. See **Fig. 12**. Tighten the drive axle stud nuts to the torque values given in the table in **Specifications, 400**.

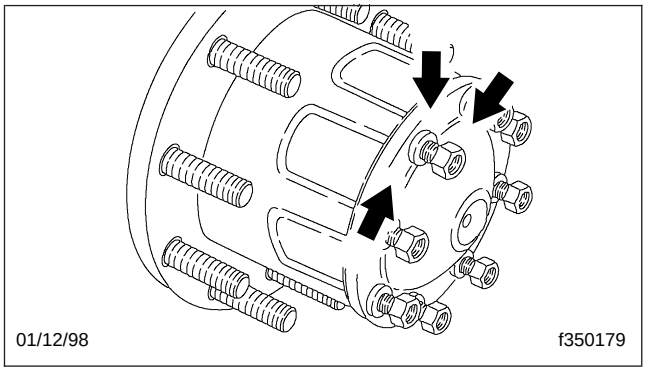

Fig. 12, Tapered Dowels, Lockwashers, and Drive Axle Stud Nuts

9. Adjust the brakes. See **Group 42** for instructions.
10. Check the rear axle oil level and fill with the recommended lubricant as required. For recommended lubricants and capacities, see **Group 35** of the Sterling *L-Line and A-Line Maintenance Manual*.
11. Remove the safety stands and lower the vehicle.
12. Remove the chocks from the front tires.

IMPORTANT: Make sure the required tools are available before beginning the service procedures described here. See the "Bearing Centering Tool Interchange" and "Adapter Plates" tables in **Specifications, 400**.

Unitized Rear Hub Seal

Removal

1. Remove and discard the old oil seal. See **Fig. 1**.

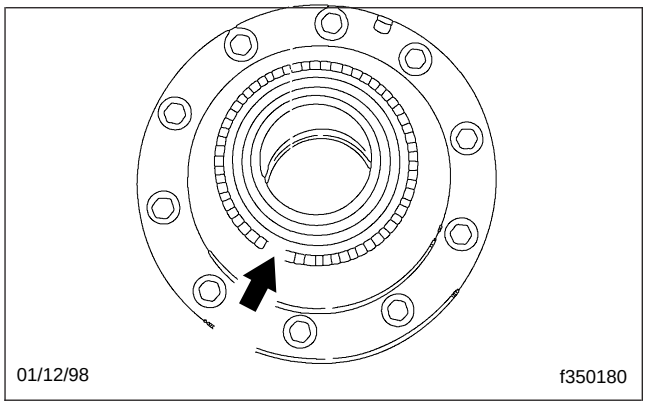

Fig. 1, Oil Seal

2. Thoroughly clean all grease and dirt from the spindle and threads. See **Fig. 2**.

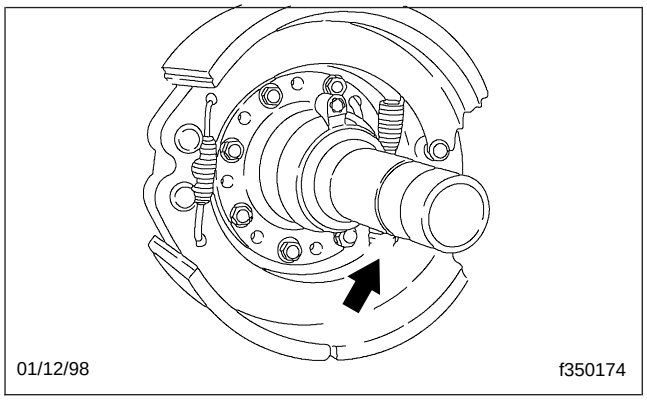

Fig. 2, Cleaning Axle Spindle

NOTE: Scratches in the hub seal bore may be too deep to be dressed out by light polishing with an emery cloth. In this case, apply a thin layer of non-hardening sealer such as Silicone Rubber D6AZ-19562-AA or -BA or equivalent sealer meeting Sterling specification ESB-M4G92-A or ESE-M4G195-A to the colored outside diameter of the new seal prior to installation.

3. Remove all burrs, nicks and scratches from the shoulder of the spindle and seal bore in the hub with emery cloth.

Installation

1. Seat the smaller outside diameter of the seal in the recess of the tool adapter. See **Fig. 3**.
   - Use the green tool with green seal E1HT-1175-AA
   - Use the red tool with red seal E1HT-1175-B

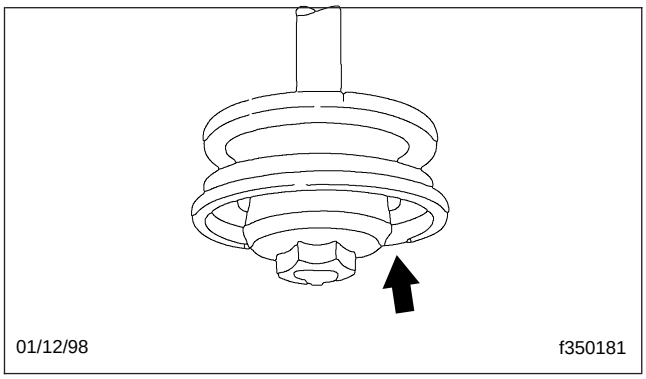

Fig. 3, Seal Installing Tool

NOTE: The plug prevents cocking of the seal in the bore.

2. Insert the centering plug of the tool in the bore of the inner bearing cone. See **Fig. 4**.
3. Using a 4- or 5-lb hammer, hold the tool handle firmly and strike until the sound of the impact changes to a ringing as the seal bottoms out.
4. Check for freedom of movement by manually moving the interior rubber component of the seal backward and forward. A slight movement indicates damage-free installation.

Two-Piece Rear Hub Seal

Removal

1. Remove and discard the old oil seal. See **Fig. 1**.

Rear Hub Seal Replacement

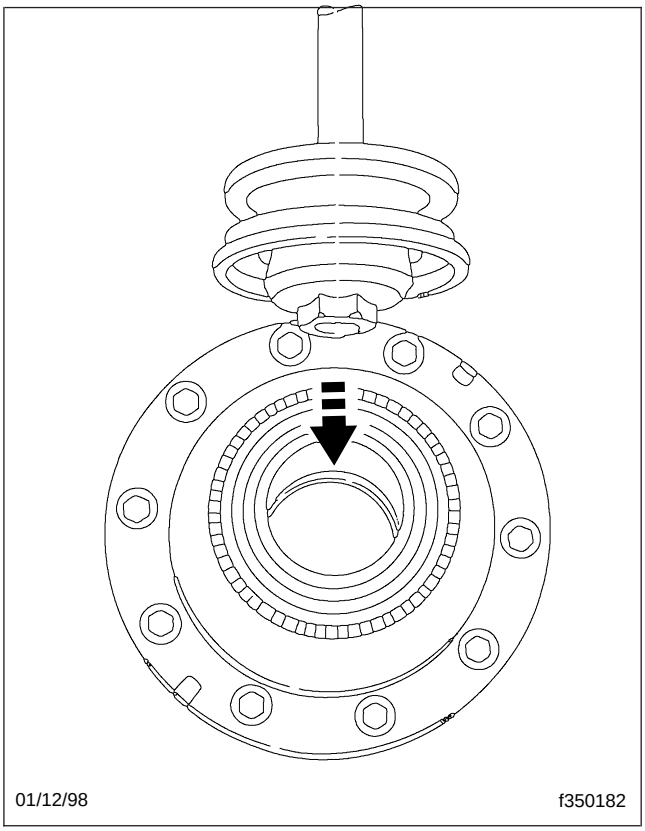

Fig. 4, Positioning the Seal Installing Tool

⚠ CAUTION

Do not use a chisel to cut through the wear sleeve. Damage to the spindle can occur.

2. Remove the old wear sleeve by striking the ring surface several times with a ball peen hammer. See **Fig. 5**.

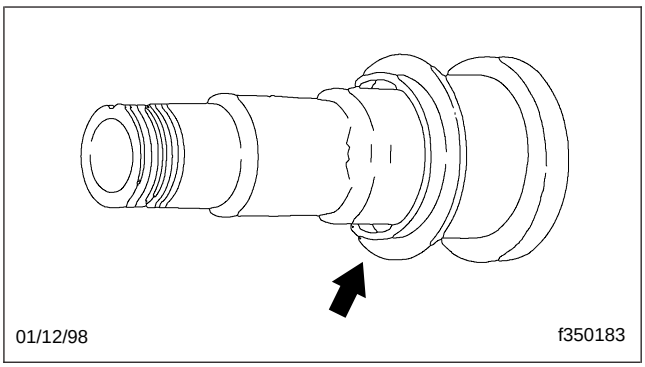

Fig. 5, Removing Old Wear Sleeve

Installation

1. Thoroughly clean the axle spindle. Remove all burrs with an emery cloth. See **Fig. 2**.
2. If the spindle shoulder is scored or pitted, apply a thin coat of non-hardening sealant such as Silicone Rubber D6AZ-19562-AA or -BA or equivalent meeting Sterling specification ESB-M4G92-A or ESE-M4G195-A.

NOTE: After bottoming, rotate the tool while applying several light hammer blows to make sure the seal ring is flush and square with the face of the shoulder.

3. Install the wear sleeve on the axle housing. See **Fig. 6**.

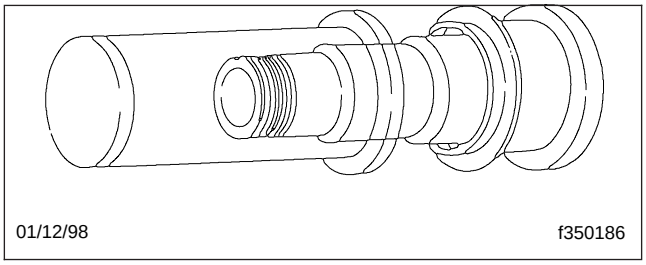

Fig. 6, Installing Wear Sleeve

4. Remove all burrs and protrusions from the oil seal area of the wheel hub.
5. Pack grease such as Premium Long-Life Grease XG-1-C or -K or equivalent meeting Sterling specification ESA-M1C75-B between the spring and seal lip to prevent the spring from dislocating when the seal is installed.
6. Position the oil seal in the hub bore and drive it squarely into position. See **Fig. 1**.

Bearing Cup Replacement (Aluminum Hubs)

Replacement

WARNING

Do not use oxyacetylene or similar equipment to heat the hub. This can cause overheating in localized areas, which will result in loss of strength that can cause failure of the hub assembly and, ultimately, loss of vehicle control.

1. Remove the brake drums and wheel bearings.
2. Thoroughly clean and degrease the hub with a nonflammable solvent.
3. Heat the hub evenly throughout in an oven to 175 to 205°F (79 to 96°C).

WARNING

You must replace damaged hubs. Using a damaged hub on a vehicle can result in hub failure and, ultimately, loss of vehicle control.

NOTE: Variations in tolerances of materials and oven temperatures may allow the bearing cup to drop in and out easily.

4. Remove the hub from the oven, and quickly press out the bearing cup.

   Use care to avoid damage to the bearing cup bore and shoulder.
5. Heat the hub evenly, as done previously.

NOTE: Make sure the cup is aligned properly and seated fully.

NOTE: Use care to avoid damage to the bearing cup and shoulder.

6. Remove the hub from the oven, and quickly press in the new bearing cup. See **Fig. 1**.
7. Check for proper seating of the new bearing cups by trying to insert a 0.0015-inch (0.038-mm) feeler gauge between the bottom of the cup and the wheel hub seat. You should not be able to insert the feeler gauge. See **Fig. 2**.
8. Install the wheel bearings. See **Fig. 3**.

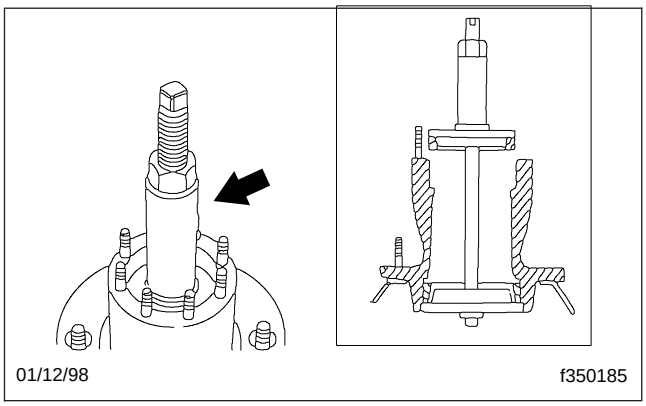

Fig. 1, Pressing Bearing Cup into Hub

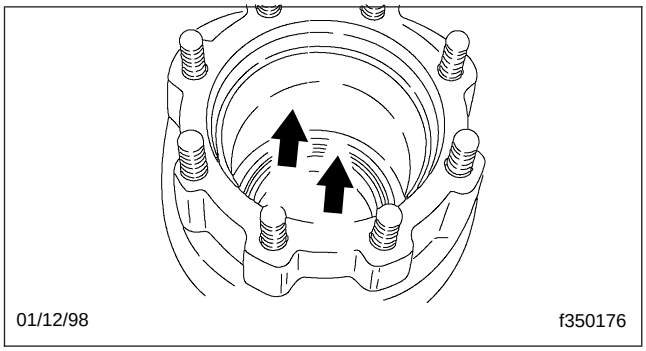

Fig. 2, Checking Installation of Bearing Cup

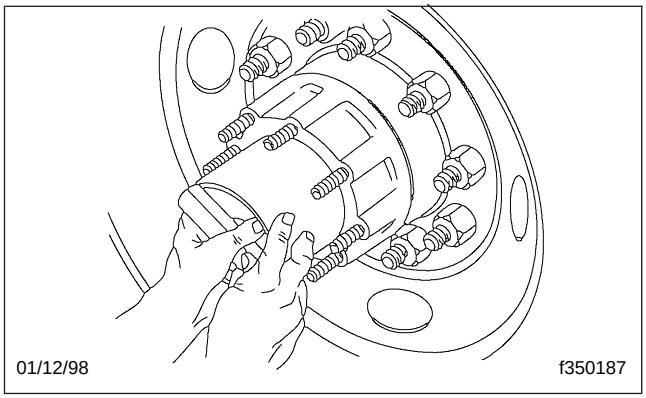

Fig. 3, Wheel Bearings

Replacement

1. Inspect Axilok nut to locate wrench size stamped into the nut.

   Using the appropriate, 6-point socket, push the socket onto the wheel bearing nut to "unlock" the nut.

   If the retainer cage does not spin freely about the nut by hand, the socket is not properly engaged. See **Fig. 1**.

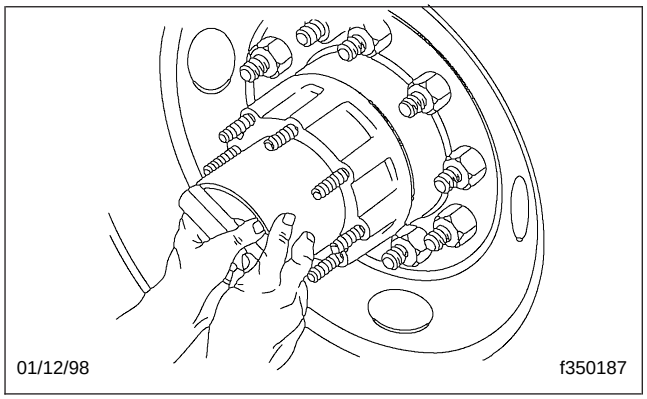

Fig. 1, Checking Socket Engagement

2. Using the socket, hand-start the wheel bearing nut onto the spindle.
3. Rotate the wheel assembly.

⚠ CAUTION

Always use a properly calibrated torque wrench to install each Axilok nut. Do not exceed the equipment manufacturer's recommended installation torque to prevent creating an unsafe condition.

4. With the wheel assembly rotating, tighten the nut. Refer to **Table 3** and **Fig. 2**.
5. Back the nut off one full turn (360 degrees).
6. Tighten the nut to the final adjusting torque according to **Table 1**.
7. Back the nut off as specified in **Table 2**.
8. The wheel assembly must rotate freely with an end play of 0.001 to 0.005 inch (0.025 mm to 0.127 mm).
9. Verify the nut assembly will lock and that the locking clips are not damaged. If damaged, replace the nut assembly.

   If the Axilok nut is not locked (the locking clips are not engaged with the retainer cage holes), then rotate the nut to advance the locking clips until they engage with the next set of holes in the retainer cage.

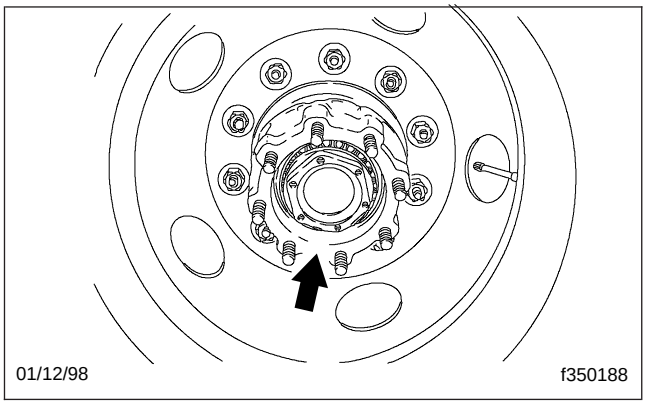

Fig. 2, Wheel Bearing Nut

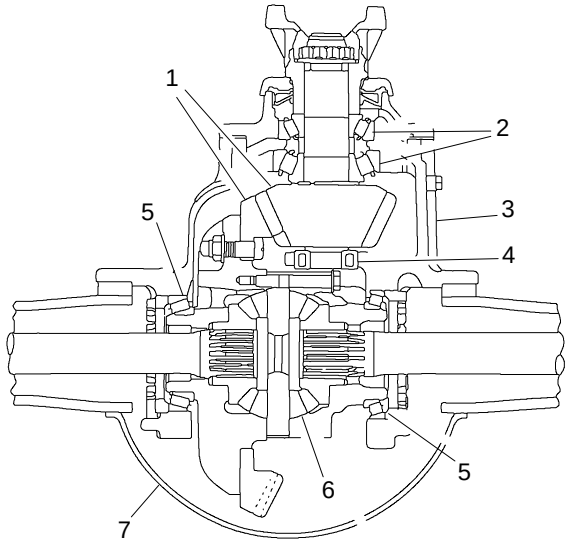
Table 5, Adapter Plates

Standard Single Reduction Carriers

The single reduction carriers are front-mounted into the axle housing. These carriers have a hypoid drive pinion and ring gearset and bevel gears in the differential assembly. See **Fig. 1** and **Fig. 2**.

A straight roller bearing (pilot) is mounted on the head of the drive pinion. All other bearings in the carrier are tapered roller bearings.

When the carrier operates, there is normal differential action between the wheels all the time.



09/18/98 f350262

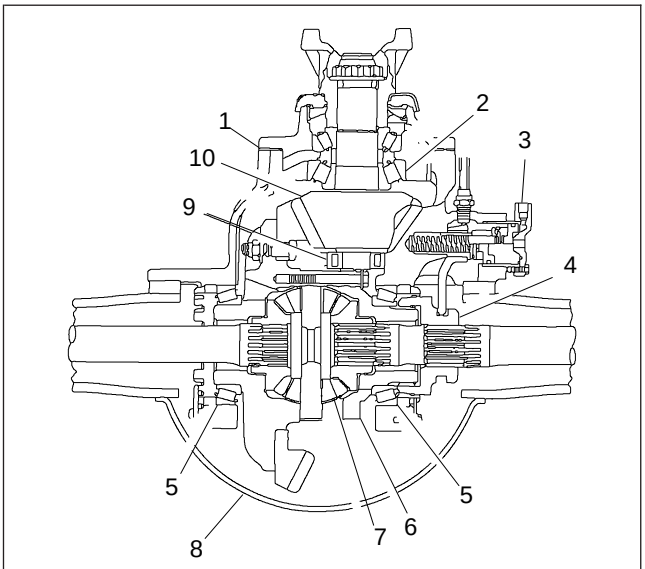
7. Rear Axle Housing

Fig. 1, Standard Carrier

Axle Speed Sensor

Speed sensors are multi-point, variable reluctance devices that provide individual wheel speed data at a 100 pulse-per-wheel revolution, resulting in high-quality output signals.



09/18/98 f350209

1. Rear Axle Differential Carrier

7. Differential Pinion Gears
8. Rear Axle Housing
9. Drive Pinion Pilot Bearing
10. Drive Pinion and Ring Gear

Fig. 2, Carrier With Differential Lock

The sensor is used in the antilock brake system (ABS) to monitor and report individual wheel speeds to the ABS electronic controller.

There are two sensor assemblies in each differential carrier. The speed sensors are mounted in each differential bearing adjusting ring.

Removal

NOTE: If the rear tandem axle is being repaired and if it is equipped with a driver-controlled main differential lock, refer to **Section 35.03** in this manual before performing any repair procedures.

1. Chock the front tires. See **Fig. 1**.

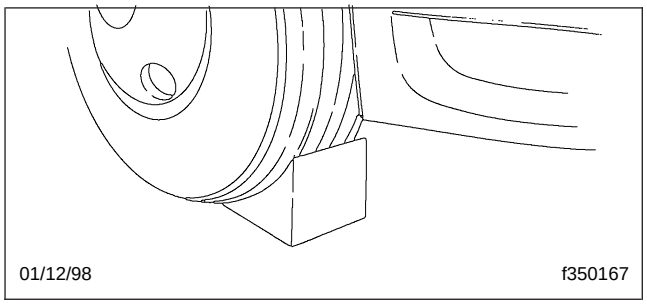

Fig. 1, Chock the Tires

NOTE: If the brake drums are to be removed, the brakes should be manually released before disconnecting the air brake hoses. Refer to **Group 42** in this manual.

2. Disconnect the air brake hoses. See **Fig. 2**.

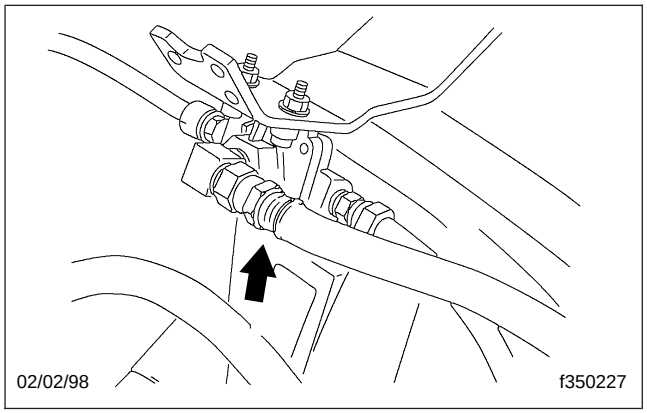

Fig. 2, Air Brake Hoses

3. For a single rear axle, disconnect the shock absorbers at the axle. See **Fig. 3**.
4. For a rear tandem axle, remove the torque rod bolts from the axle housing and loosen the torque rod. See **Fig. 4**.

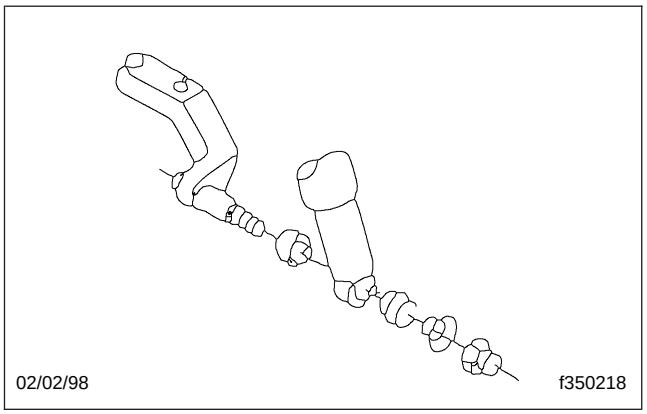

Fig. 3, Shock Absorber

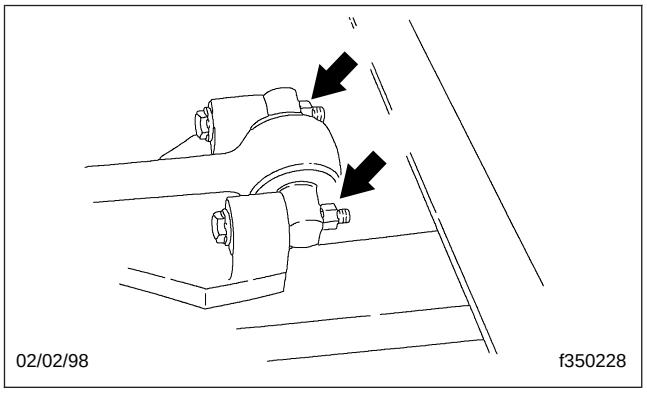

Fig. 4, Torque Rod Bolts at Rear Axle

5. Disconnect the driveshaft from the rear axle input flange or yoke and wire it out of the way. See **Fig. 5**.

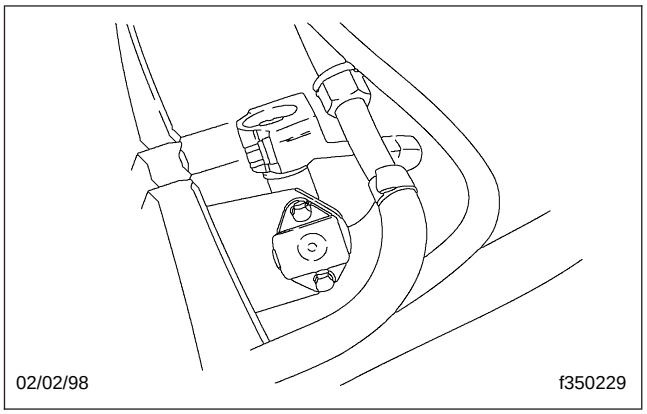

Fig. 5, Driveshaft

Removal and Installation

6. Raise the rear of the vehicle with a suitable jack high enough to clear the axle when it is to be removed, and insert jack stands.

NOTE: On a rear tandem axle or a single rear axle, the tires do not have to be removed.

7. If necessary, remove the tires. See **Fig. 6**.

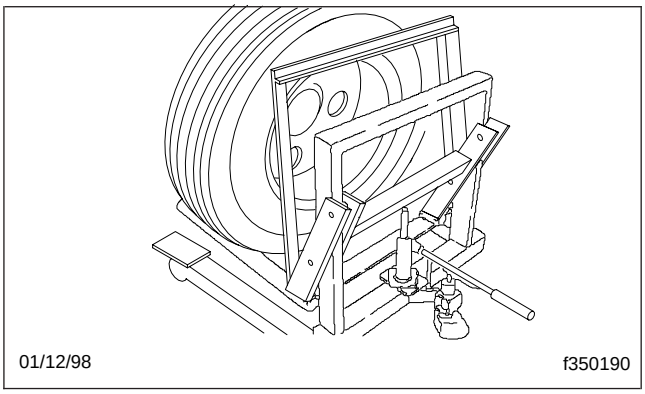

Fig. 6, Removing the Tire With Wheel Jack

8. Support the carrier housing with a floor jack.

NOTE: U-bolts and U-bolt nuts cannot be reused.

9. Remove the U-bolts and the U-bolt nuts and discard them. See **Fig. 7**.

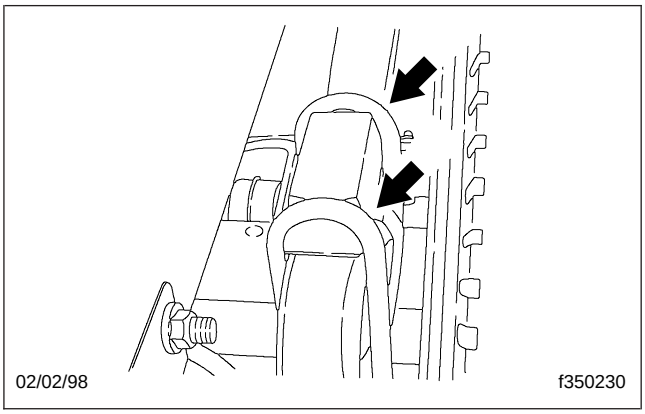

Fig. 7, U-Bolts and U-Bolt Nuts

IMPORTANT: While lowering the axle, watch for obstructions.

10. Carefully lower the axle with the floor jack and slide the axle out from under the vehicle.

Installation

NOTE: When tightening the air fittings, a minimum of two turns past finger-tight is required. Directional fittings are to be oriented in a tightening direction only.

1. Carefully raise the axle with the floor jack and slide the axle under the vehicle.

NOTE: U-bolts and U-bolt nuts cannot be reused.

2. Position the axle and install the U-bolts and the U-bolt nuts. Tighten the nuts to 260 to 320 lbf·ft (353 to 433 N·m). See **Fig. 7**.
3. Support the carrier housing with a floor jack.
4. If necessary, install the tires and tighten the nuts to 450 to 500 lbf·ft (611 to 677 N·m). See **Fig. 6**.
5. Raise the rear of the vehicle with a suitable floor jack. Remove the jack stands and lower the vehicle.
6. Connect the driveshaft at the rear axle input flange or yoke. Tighten the nuts and bolts 5/16-24: 35 to 41 lbf·ft (47 to 56 N·m) and 3/8-24: 45 to 60 lbf·ft (61 to 81 N·m). See **Fig. 5**.
7. For a rear tandem axle, install the torque rod bolts to the axle housing. Tighten the bolts 150 to 205 lbf·ft (204 to 277 N·m). See **Fig. 4**.
8. For a single rear axle, connect the shock absorbers at the axle, tighten nuts until firm. See **Fig. 3**.
9. Connect the air brake hoses. See **Fig. 2**.
10. Remove the chocks from the front tires. See **Fig. 1**.

Adjustment

NOTE: If the rear tandem axle is being repaired and if it is equipped with a driver-controlled main differential lock, refer to **Section 35.03** in this manual before performing any repair procedures.

NOTE: Some Meritor axles are not equipped with a thrust screw.

NOTE: If the carrier does not have a thrust block, skip the first three steps.

1. Rotate the carrier in the repair stand until the back surface of the ring gear is up. See **Fig. 1**.

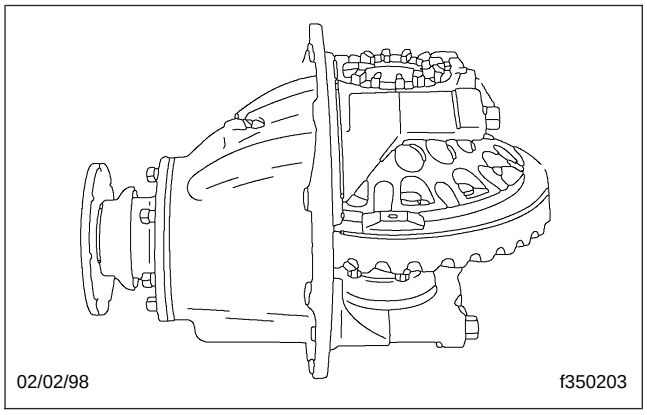

Fig. 1, Rotate the Carrier So the Ring Gear is Up

2. Put the thrust block on the back surface of the ring gear. The thrust block must be in the center between the outer diameter of gear and differential case.
3. Rotate the ring gear until the thrust block and the hole for the drive gear thrust screw in the carrier are aligned.
4. Install the jam nut in the middle of the drive gear thrust screw. See **Fig. 2**.
5. Install the drive gear thrust screw into the carrier until the screw stops against the ring gear or thrust block. See **Fig. 3**.
6. Loosen the drive gear thrust screw one-half turn, 180 degrees. See **Fig. 4**.
7. Tighten the jam nut to the correct torque value. Refer to **Specifications, 400**. See **Fig. 5**.

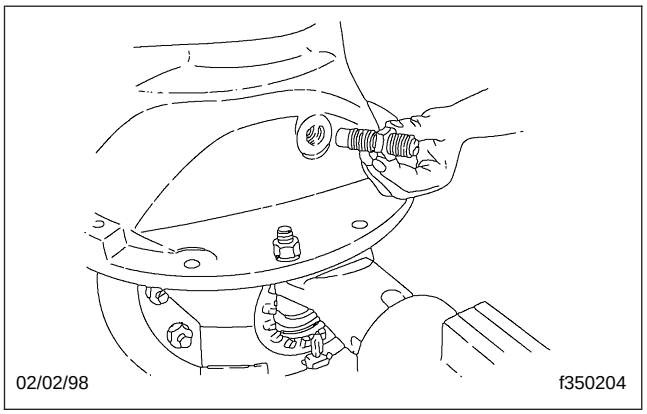

Fig. 2, Jam Nut Installation

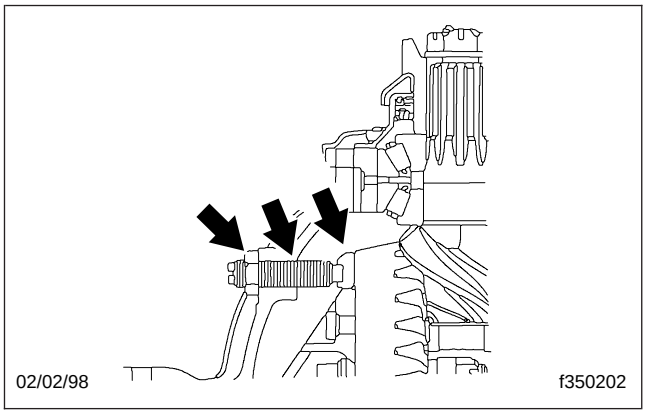

Fig. 3, Drive Gear Thrust Screw Installation

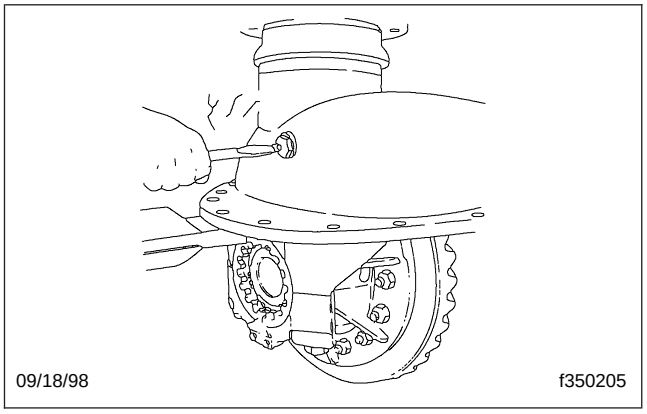

Fig. 4, Loosening the Drive Gear Thrust Screw 180 Degrees

Thrust Screw Adjustment

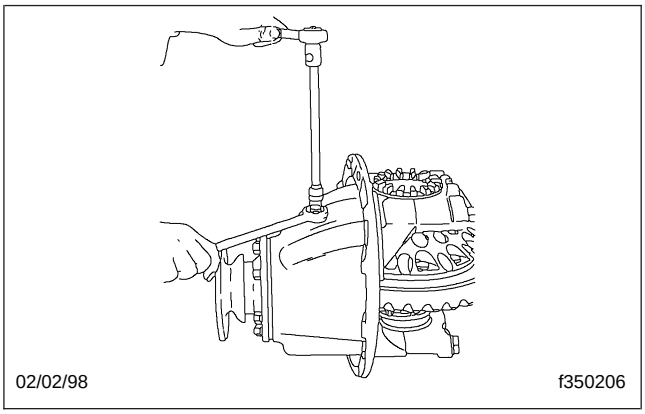

Fig. 5, Tightening the Jam Nut

Speed Sensor Removal and Installation

Removal

1. Disconnect the battery ground cable. On vehicles equipped with dual batteries, refer to **Group 54** in this manual.

CAUTION

Do not disconnect the sensor plug from the receptacle by pulling the wiring harness. Damage to the plug will occur and cause an open circuit. Always disconnect the sensor by pulling the plug housing.

2. Disconnect the left-hand and right-hand sensor plugs from the receptacles. Grasp the plug, press the lock tab on the top of the plug housing and pull the plug from the receptacle.
3. Remove the rear axle differential carrier. For instructions, refer to **Subject 130**.
4. With snap ring pliers, remove the snap ring that holds the speed sensor in the adjusting ring of the differential bearing.

CAUTION

When prying the speed sensor from the bearing adjusting ring, always position the screwdrivers under the two metal tabs. Do not pry the sensor from the plastic coil housing. Damage to the coil will occur.

5. Pry the speed sensor loose, but do not completely remove it from the bearing adjusting ring. Use two screwdrivers to pry the sensor at the two opposite tabs.

NOTE: Both sensor receptacles are mounted through bores in the flange of the carrier.

6. Using two screwdrivers, pry the snap ring out of the groove in both the left-hand and right-hand sensor receptacles.

NOTE: If the receptacle cannot be removed using this procedure, position a small block of wood against the receptacle and tap the block with a leather or plastic mallet until the receptacle is removed from the carrier flange.

7. Remove the receptacle from the differential carrier flange by pushing the receptacle from the outside surface of the flange toward the inside surface of the carrier.

CAUTION

When removing the speed sensor assembly from the bearing adjusting ring, do not drop the assembly. Damage to the components can occur.

8. Completely remove the speed sensor assembly by pulling it out from the bearing adjusting ring.
9. Remove the wave washer from inside the bore of the bearing adjusting ring.

NOTE: Removal of the drive tubes from the differential case halves is not a requirement to remove the speed sensors. Remove the drive tubes from the case halves only if required due to damaged parts.

10. Remove and disassemble the differential and ring gear assembly. For instructions, refer to the axle manufacturer's service literature.
11. Using a screwdriver, remove the snap ring that holds the drive tube in position inside the differential case half.
12. Lift out the backup washer that is behind the snap ring, inside the differential case half.
13. Pull the drive tube out from the bearing side of the differential case half.

Installation

CAUTION

Do not use cleaning solvents to clean the speed sensor assembly. Damage to components can occur. Clean the speed sensor assembly only with a clean dry rag or paper towel.

NOTE: If the drive tube was not removed, omit the next two steps.

1. Install the drive tube into the differential case half from the bearing side.
2. While holding the drive tube in position, place the backup washer over the drive tube and against the inside of the differential case half.
3. Install the snap ring into the groove in the drive tube, using a screwdriver, if necessary.

Speed Sensor Removal and Installation

4. Assemble and install the differential and ring gear assembly. For instructions, refer to the axle manufacturer's service literature.

CAUTION

Before installing the speed sensor assembly and components into the bearing adjusting ring, check the position of the roll pin that locks the adjusting ring in place. The speed sensor cannot be correctly installed if the roll pin extends beyond the snap ring groove in the lugs of the adjusting ring.

5. Adjust the position of the roll pin, if necessary, by using a drift and hammer.

NOTE: Check the outside of the speed sensor receptacle. There must be an O-ring positioned in the first groove.

6. Install an O-ring, if necessary.
7. Install the speed sensor by pushing the receptacle through the large hole in the carrier flange. Push from the inside of the flange toward the outside surface.
8. Apply and hold pressure against the back of the receptacle and install the snap ring into the first full groove that appears past the outside surface of the carrier flange.
   - 8.1 Using needle nose pliers, install the snap ring.
   - 8.2 Temporarily rest the sensor on the inside flange of the carrier.
9. Install the wave washer inside the bore of the bearing adjusting ring.
10. Apply axle lubricant to the outer surface of the drive tube and on the drive seal of the speed sensor.
11. Install the speed sensors in the bearing adjusting rings. The wire outlet area of the coil of each sensor must face out and align with the correct slot in the bearing adjusting ring.
12. Place the speed sensor over the bearing adjusting ring with the wire outlet area of the coil in the correct position. Turn the rotor in the sensor until the tabs align with the slots in the drive tube.

CAUTION

The speed sensor must be installed carefully and evenly into the bore of the bearing adjusting ring or damage to the sensor can occur.

NOTE: If the drive seal slips off the rotor of the speed sensor, remove the speed sensor from the bearing adjusting ring. Place the drive seal in position on the rotor.

13. Press the speed sensor evenly into the bore of the bearing adjusting ring manually, while carefully sliding the drive seal over the drive tube.
    - 13.1 Make sure the wire outlet area of the coil freely enters the selected slot in the bearing adjusting ring.
    - 13.2 Use even pressure around the sensor, near the outer diameter, until the sensor is seated against the wave washer.
14. Press the speed sensor down into the bearing adjusting ring so that the top of the sensor is past the snap ring grooves in the lugs. Hold the sensor in this position.

NOTE: The sensor should be positioned firmly and evenly against the snap ring. If it is not, apply hand pressure to the sensor, depressing it against the wave washer until sensor alignment is obtained.

NOTE: After the sensor is installed, make sure the outlet wires of the sensor are as close to the carrier leg as possible to make sure the wires are not pinched when the carrier is installed in the axle housing.

15. Place the snap ring over the speed sensor with the opening aligned with the wire outlet area of the coil housing.
16. Install the differential carrier into the axle housing. Refer to **Subject 130**.
17. Reconnect the electrical connectors.
18. Reconnect the battery ground cable. On vehicles equipped with dual batteries, refer to **Group 54** in this manual.
19. Refer to **Group 42** in this manual for diagnostic and repair procedures for the antilock brake system.

Differential Carrier Removal and Installation

Removal

WARNING

Do not work under the vehicle if it is supported by jacks or lifting tools. Jacks and lifting tools can slip and cause injury.

NOTE: If the rear tandem axle is being repaired and if it is equipped with a driver-controlled main differential lock, refer to **Group 35** in this manual before performing any repair procedures.

1. Raise the vehicle. Put jack stands under each spring seat of the axle to hold the vehicle in the raised position. See **Fig. 1**.

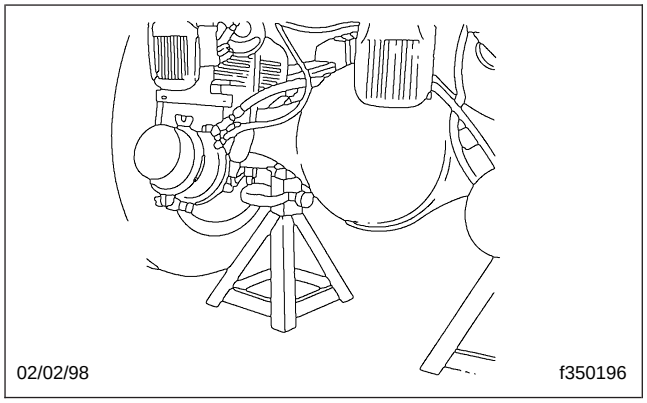

Fig. 1, Supporting Axle With Jackstands

2. Remove the plug from the bottom of the axle housing and drain the lubricant from the assembly.
3. Disconnect the driveline universal joint from the pinion input yoke or flange on the carrier. See **Fig. 2**.
4. Remove the capscrews and washers, or stud nuts and washers from the flanges of both axle shafts. See **Fig. 3**.

WARNING

Wear safe eye protection. Do not hit the round driving lugs on the head of the axle shafts. Lugs can break and cause injury.

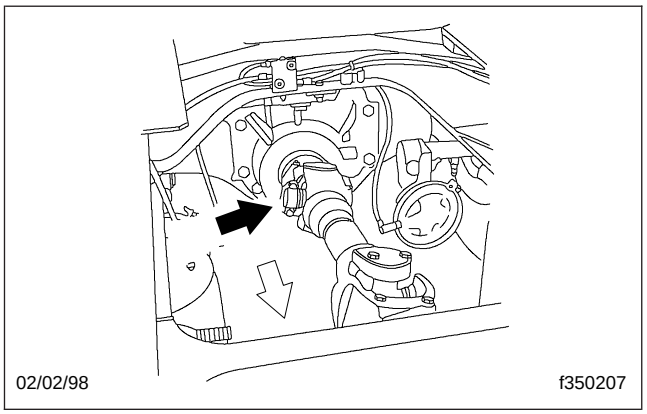

Fig. 2, Disconnecting the Universal Joint from the Pinion Input Yoke

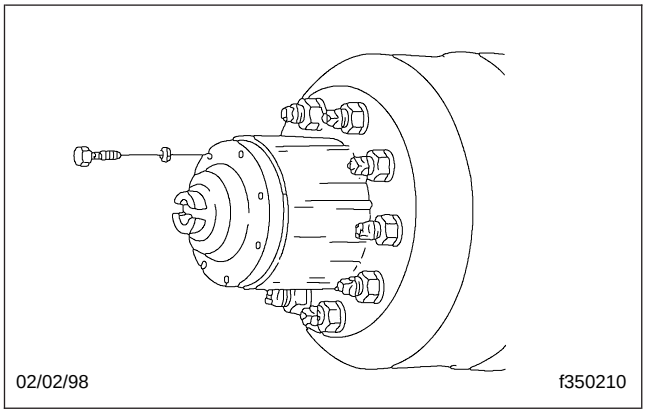

Fig. 3, Axle Shaft Flange Retainers

CAUTION

Do not use a chisel or wedge to loosen the axle shafts and dowels. The chisel or wedge can damage the hub, axle shafts and, if used, oil seals.

5. Loosen the tapered dowels in the flanges, if so equipped, of both axle shafts by holding a 1-1/2-inch diameter brass drift against the center of the axle shaft, inside the circular driving lugs (a 1-1/2-inch diameter brass hammer can be used as a drift). Hit the end of the drift with a large hammer (five to six pounds), and the axle shaft and the tapered dowels will loosen. See **Fig. 4**.
6. Remove the tapered dowels and both axle shafts from the axle assembly. See **Fig. 5**.
7. Place a suitable floor jack under the differential carrier to support the assembly. See **Fig. 6**.

Differential Carrier Removal and Installation

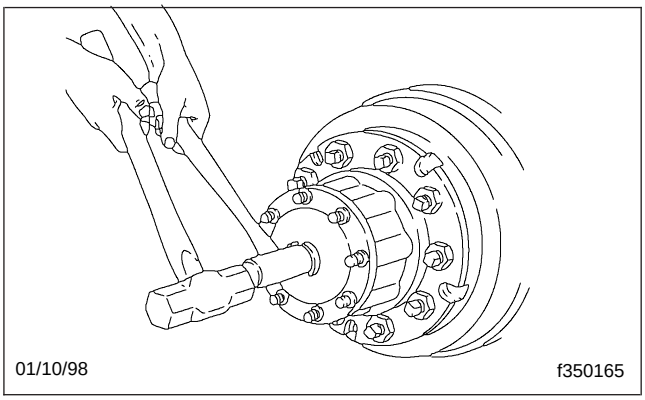

Fig. 4, Loosening Tapered Dowels

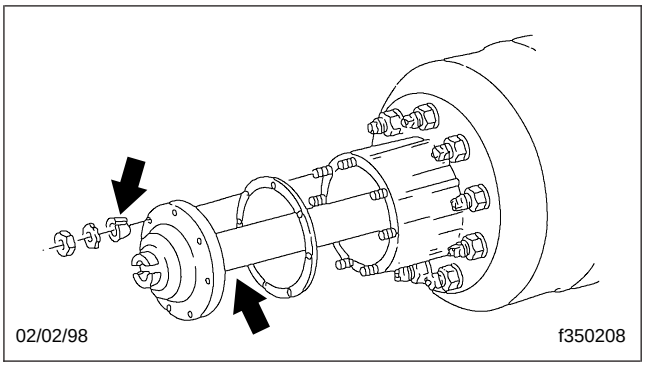

Fig. 5, Removing Tapered Dowels and Axle Shaft

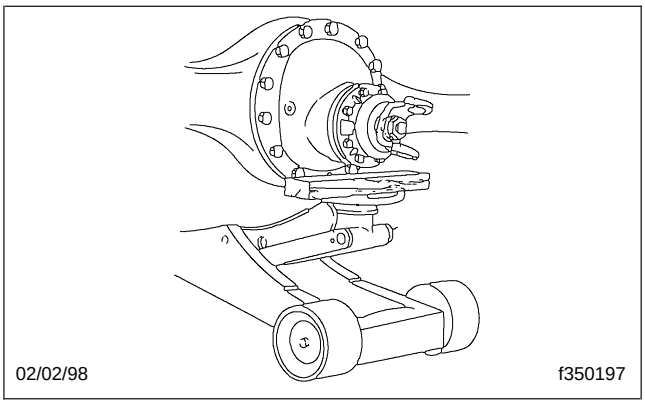

Fig. 6, Supporting Axle Carrier

NOTE: Loosen the top two differential carrier-to-housing fasteners and leave attached to the assembly. The fasteners will hold the differential carrier in the housing.

8. Remove all but the top two carrier-to-housing capscrews or stud nuts and washers. See **Fig. 7**.

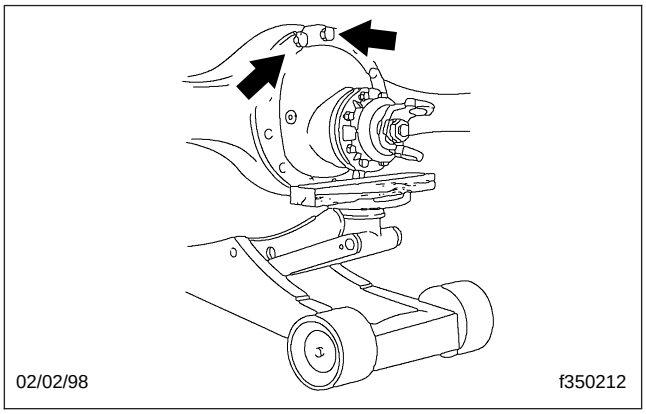

Fig. 7, Carrier-to-Housing Capscrews

9. Loosen the differential carrier in the axle housing. Use a leather mallet to hit the mounting flange of the carrier at several points.

NOTE: Some differential carrier models have threaded puller screw holes in the mounting flange. Puller screws can be used to loosen and pull the carrier from the axle housing. If puller screws are used, clean the threaded holes before the puller screws are installed.

10. Remove the top two fasteners after the differential carrier is loosened. See **Fig. 7**.

⚠ CAUTION

When using a pry bar, be careful not to damage the differential carrier or housing flange. Damage to these surfaces will cause oil leaks.

11. Remove the carrier from the axle housing carefully, using the floor jack.

⚠ WARNING

Use a lifting tool for this procedure. Do not lift by hand. Failure to observe this warning can result in damage to the unit and possible person injury.

12. Lift the differential carrier by the input yoke or flange and put the assembly in a suitable repair stand. See **Fig. 8**.

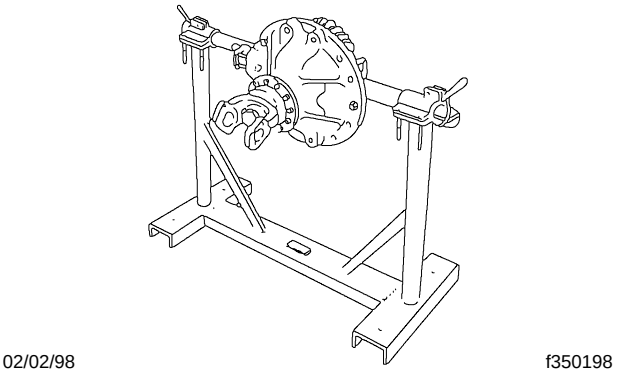

Fig. 8, Differential Carrier Mounted On a Repair Stand

Installation

1. Clean the inside of the rear axle housing and the mounting surface where the differential carrier fastens.
   - 1.1 Use a cleaning solvent and rags to remove dirt.
   - 1.2 Blow dry the cleaned areas with air.
2. Inspect the axle housing for damage.

   Repair or replace the axle housing.
3. Check for loose studs in the mounting surface of the housing where the differential carrier fastens. Remove and clean the studs that are loose (some Meritor axles are equipped with capscrews and some are equipped with stud nuts).
4. Apply liquid adhesive to the threaded holes and install the studs into the rear axle housing.
5. Apply silicone gasket material to the mounting surface of the rear axle housing where the carrier fastens. See **Fig. 9**.

CAUTION

Do not install the differential carriers using a hammer or mallet. A hammer or mallet will damage the mounting flange of the carrier and cause oil leaks.

6. Install the differential carrier into the rear axle housing, using a suitable floor jack.
7. Install the nuts and washers or capscrews and washers in the four corner locations around the differential carrier and rear axle housing. Tighten the fasteners hand-tight at this time. See **Fig. 10**.

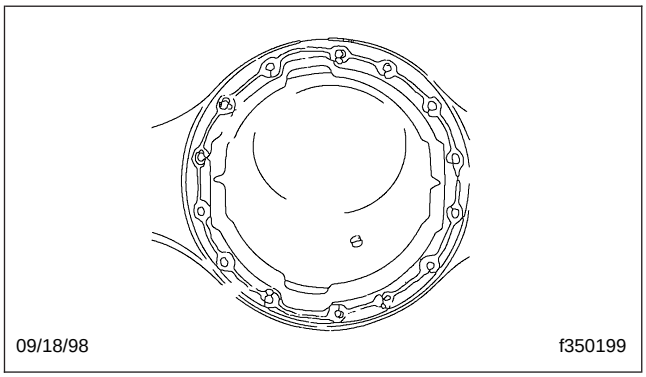

Fig. 9, Applying Silicone to the Mounting Surface

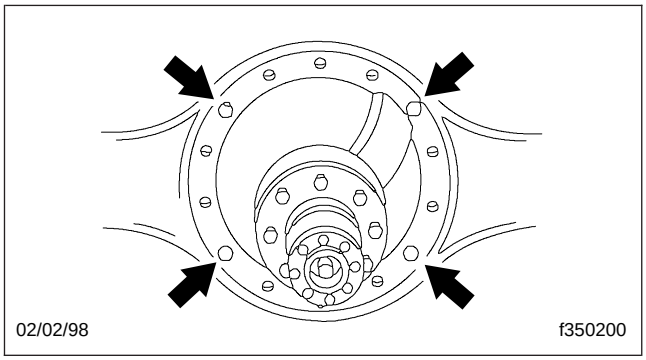

Fig. 10, Install the Bolts In Four Corners of Carrier

8. Push the differential carrier into position.
   - 8.1 Tighten the four fasteners, two or three turns each, in a pattern opposite each other.
   - 8.2 Repeat until the four fasteners are tightened to the correct torque value. Refer to **Specifications, 400**.
9. Install the other fasteners and washers that hold the carrier in the rear axle housing and tighten to the correct torque value. Refer to **Specifications, 400**. See **Fig. 11**.
10. Connect the driveline universal joint to the pinion input yoke or flange on the carrier. See **Fig. 4**.

CAUTION

The gasket and flange of the axle shafts must fit flat against the wheel hub to prevent fluid leakage and component damage.

Differential Carrier Removal and Installation

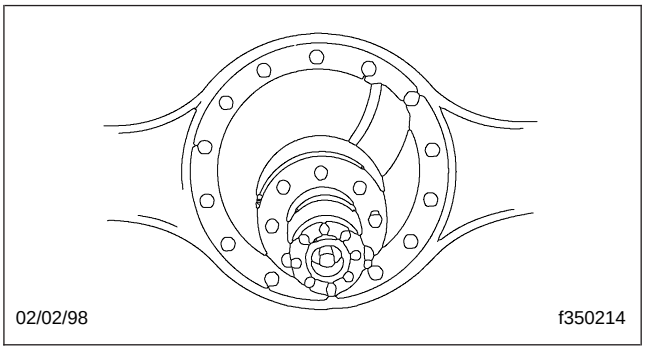

Fig. 11, Install the Carrier Bolts

11. Install the gaskets and axle shafts into the rear axle housing and carrier. See **Fig. 12**.

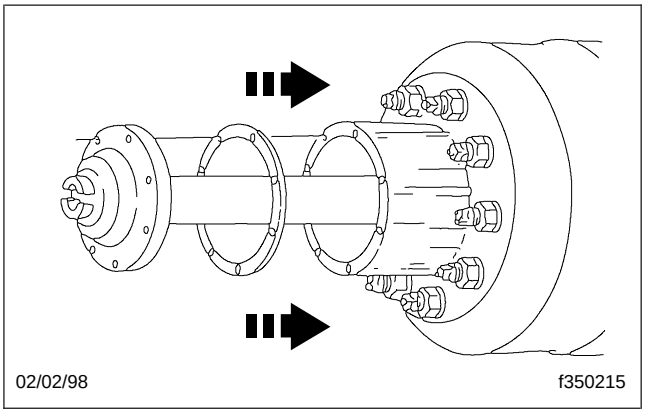

Fig. 12, Installing the Gaskets and Axle Shafts

12. Install the capscrews and washers that hold the axle shaft to the wheel hub and tighten the capscrews. See **Fig. 13**.

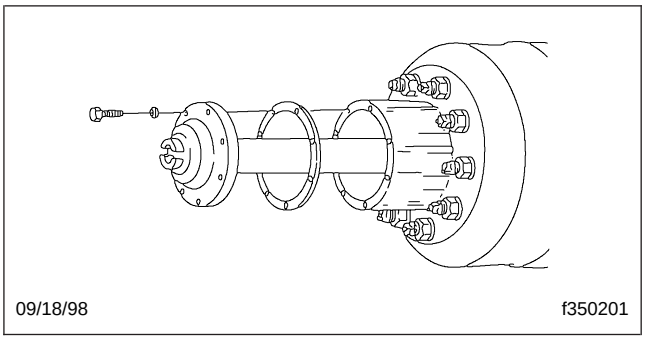

Fig. 13, Installing the Axle Shaft Bolts

13. Install the tapered dowels at each stud, if so equipped, and into the flange of the axle shaft. Use a punch or a drift and hammer, if needed. See **Fig. 7**.
14. Install the nuts and washers on the studs, and tighten the nuts to the correct torque value. Refer to **Specifications, 400**. See **Fig. 14**.

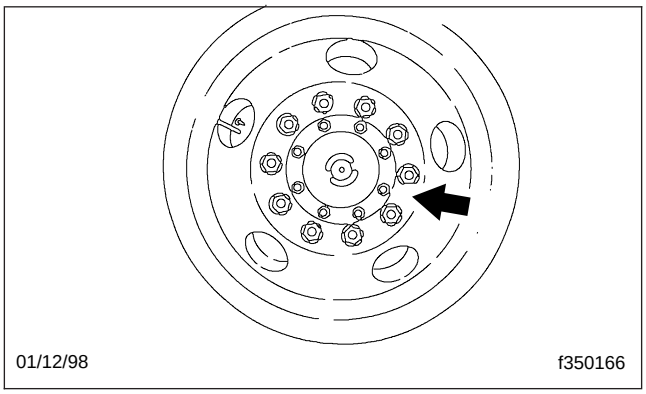

Fig. 14, Install the Nuts and Washers On the Studs

15. Install the drain plug and tighten.
16. Fill the rear axle with the specified lubricant. Refer to **Group 41** in this manual.
17. Remove the jack stands and lower the vehicle.

Table 2, Torque Specifications

Rear Drive Axle and Differential

MERITOR TWO-SPEED AXLE

The Meritor two-speed rear axle (see **Fig. 1**) has a first reduction differential ring gear and pinion set and a second reduction planetary gearset.

The differential pinion is supported by two differential pinion bearings mounted on the pinion shaft in front of the gear head.

A rear axle drive pinion pilot bearing supports the pinion in the rear axle differential carrier.

The main differential and the planetary gearset are mounted in the differential case halves that are contained in the planetary support case. See **Fig. 2**.

The planetary support case is mounted in the rear axle differential carrier on two tapered differential bearings (see **Fig. 3**). An electric shift unit is mounted on the carrier and is actuated by a switch in the cab of the vehicle. The driver can actuate the switch to shift the drive unit into high or low gear range.

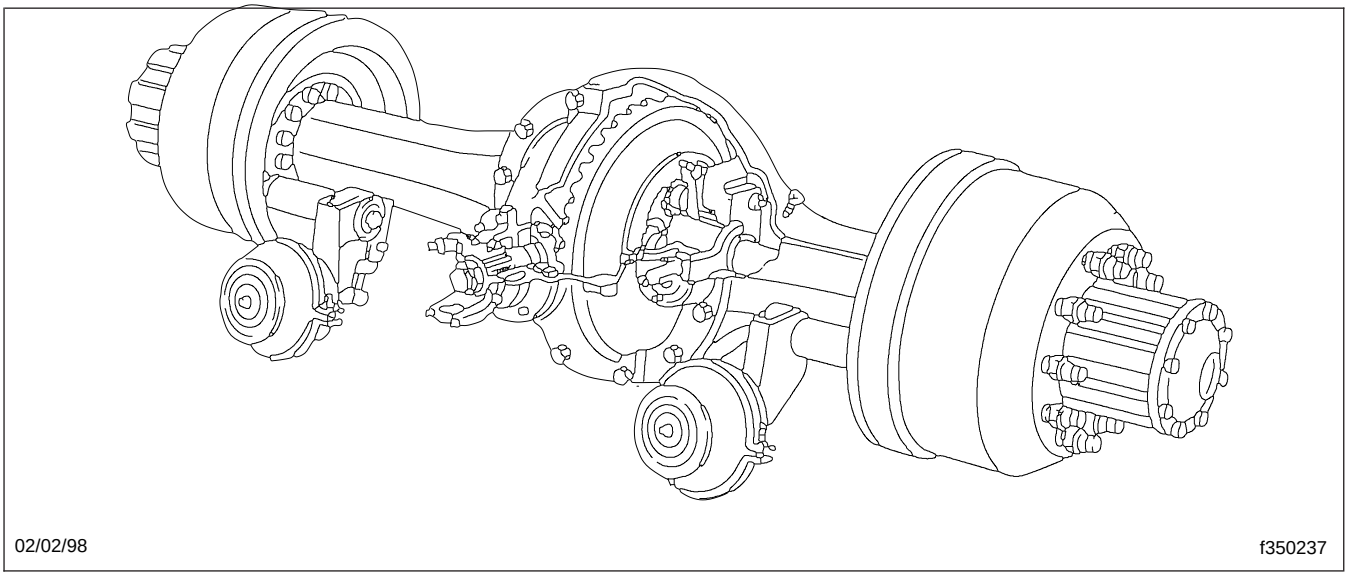

Fig. 1, Meritor Two-Speed Axle

In low gear range, the sun gear is shifted to engage with the clutch plate. The four planetary pinions are then free to rotate and become the second reduction gearset. See **Fig. 4**. The hypoid gearset ratio is now multiplied by the planetary gearset ratio. This gives the drive unit a higher numerical ratio for increased pulling power, but decreases the top speed. See **Fig. 5**.

In high gear range, the sun gear is engaged with the support case and the planetary pinions are locked in place. When the planetary pinions are locked, there is no second reduction and the power is sent directly from the hypoid gearset to the main differential (see **Fig. 6**). This hypoid single-reduction drive gives a lower numerical ratio for higher road speeds, but less pulling power.

SHIFT CONTROL, ELECTRIC

A slider block-type, electric shift control is used in conjunction with the two-speed axles.

The electric shift control system is composed of the control switch, the speedometer adapter, the electric shift unit, the relay, and the wiring harness.

The control switch, mounted on the gearshift lever, has two positions: up for high range and down for low range. See **Fig. 7**.

For vehicles with automatic transmission, the two-speed rear axle switch is located in the instrument panel. Push the top of the rocker switch for high range and push the bottom of the rocker switch for low range. When the switch is in either of these posi-

General Information

tions, the switch contacts complete the circuit between the battery and the motor in the axle shift unit (see **Fig. 8**).

A fuse (standard) or circuit breaker (optional) protects the two-speed axle system against a short circuit.

Relays are used in the circuit to connect the shift motor to battery power. The rear axle shift control switch connects the high gear or low gear relay coil to battery power. The contacts in the relays complete the circuit to the motor.

Removal

1. Chock the front tires. See **Fig. 1**.

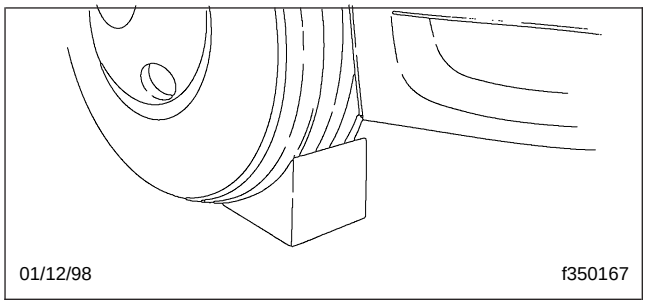

Fig. 1, Chock the Tires

2. Disconnect the electrical connectors. See **Fig. 2**.

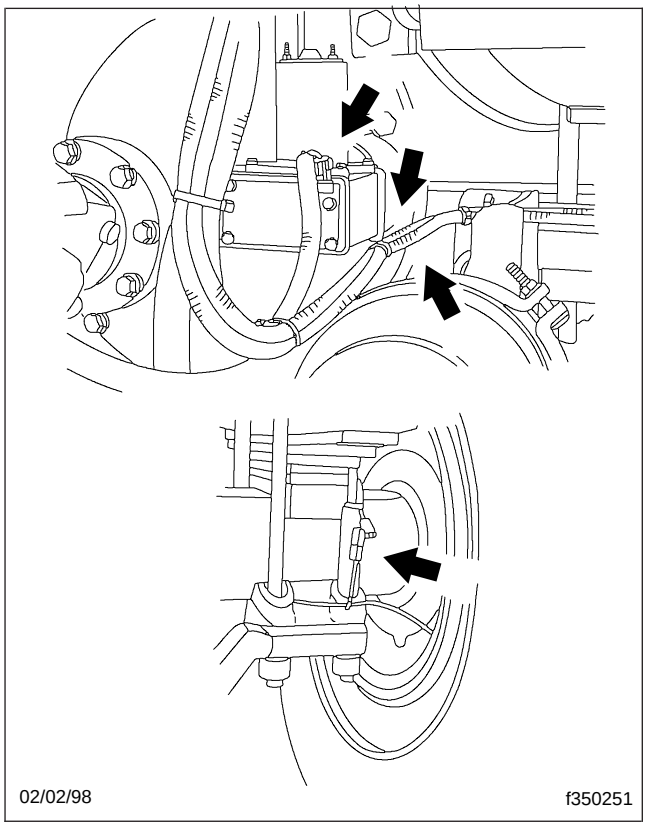

Fig. 2, Electrical Connectors

NOTE: If the brake drums are to be removed, the brakes should be caged before disconnecting the air brake hoses. Refer to **Group 42** for the caging procedure.

3. Release the brakes and bleed the air from the brake system. See **Fig. 3**.

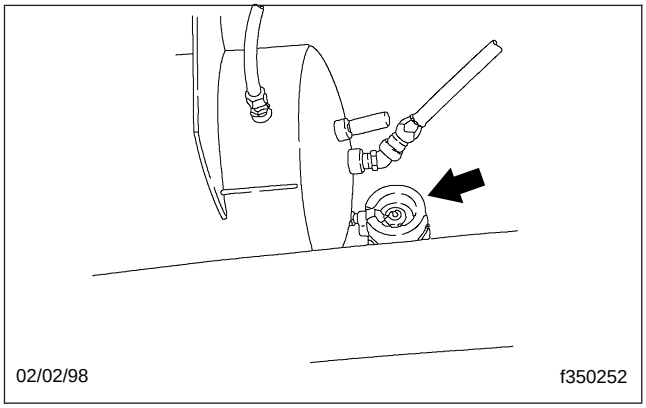

Fig. 3, Bleeding Air from Air Compressor

4. Disconnect the air brake hoses. See **Fig. 4**.

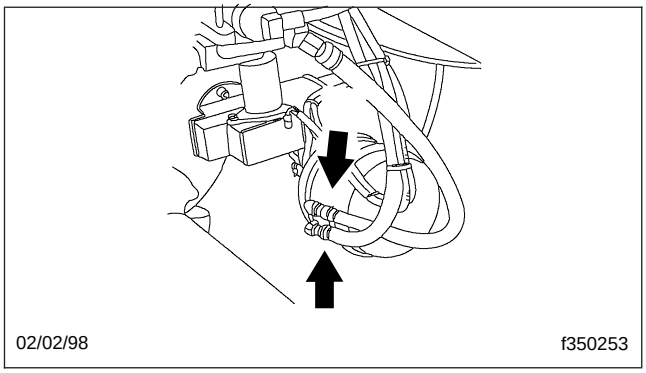

Fig. 4, Air Compressor Hoses

5. Disconnect the driveshaft at the axle and wire the driveshaft out of the way. See **Fig. 5**.

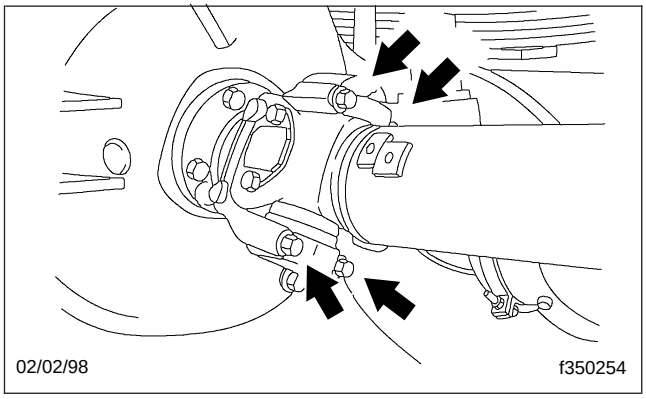

Fig. 5, Driveshaft at Axle

Removal and Installation

6. Disconnect the shock absorbers at the axle. See **Fig. 6**.

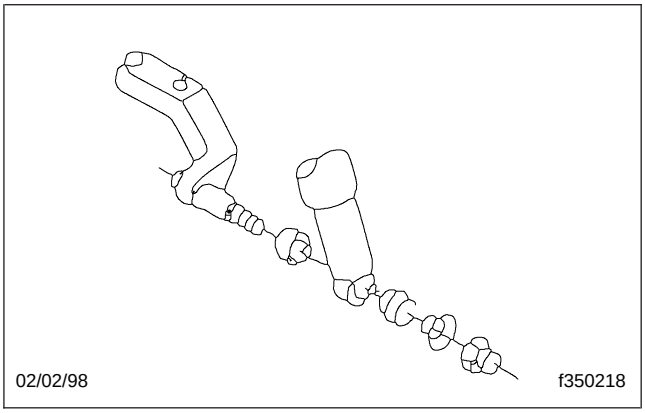

Fig. 6, Shock Absorbers at Axle

7. Raise the rear of the vehicle high enough to clear the axle so it can be removed and insert jack stands.
8. If necessary, remove the wheels and tires. See **Fig. 7**.

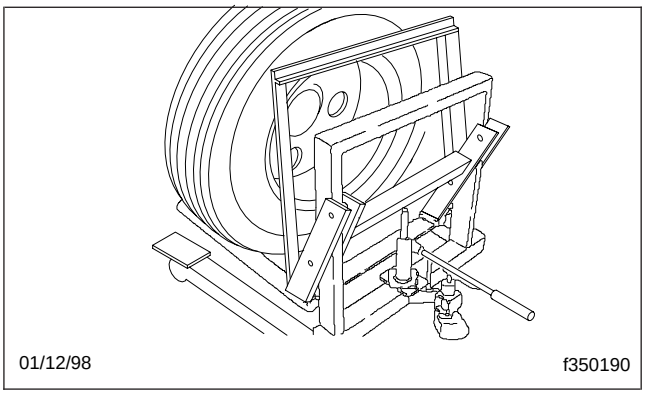

Fig. 7, Remove Wheels and Tires

9. Support the carrier housing with a floor jack.

NOTE: The U-bolts and U-bolt nuts cannot be reused.

10. Remove the U-bolts and U-bolt nuts and discard them. See **Fig. 8**.
11. Carefully lower the axle with the floor jack.

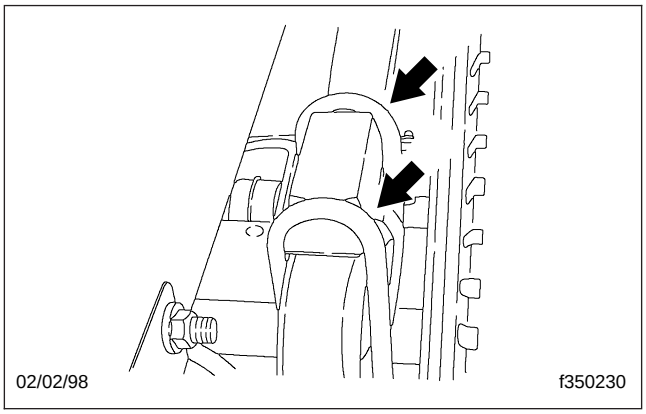

Fig. 8, U-Bolts and Nuts

Installation

NOTE: When tightening the air fittings, a minimum of two turns past finger-tight is required. Directional fittings are to be oriented in a tightening direction only.

1. Carefully raise the axle with the floor jack and slide the axle under the vehicle.

NOTE: U-bolts and U-bolt nuts cannot be reused.

2. Position the axle and install the U-bolts and the U-bolt nuts, tighten nuts to 260 to 320 lbf·ft (353 to 433 N·m). See **Fig. 8**.
3. Support the carrier housing with a floor jack.
4. If necessary, install the tires and tighten nuts to 450 to 500 lbf·ft (611 to 677 N·m). See **Fig. 7**.
5. Raise the rear of the vehicle with a suitable floor jack, remove the jack stands, and lower the vehicle.
6. Connect the driveshaft at the rear axle input flange or yoke, tighten nuts 5/16-24: 35 to 41 lbf·ft (47 to 56 N·m) and 3/8-24: 45 to 60 lbf·ft (61 to 81 N·m). See **Fig. 5**.
7. Connect the shock absorbers at the axle, tighten nuts until firm. See **Fig. 6**.
8. Connect the air brake hoses. See **Fig. 4**.
9. Connect the electrical connectors. See **Fig. 2**.
10. Remove the chocks from the front tires. See **Fig. 1**.

Removal

NOTE: All parts for models RS–17–220, RS–19–220, RS–21–230 and RS–23–240, except the shift unit to carrier studs and carrier to housing capscrews, are manufactured in metric dimensions. When the carriers are repaired, use the correct size tools.

NOTE: Before starting any repair or maintenance work on the differential carrier assembly, make sure the drive unit is shifted into the LOW range position. This will eliminate interference between the sun gear and the carrier mounting ring of the axle housing to allow differential carrier removal. To ensure a complete shift and positive gear engagement, drive the vehicle a short distance while shifting the drive unit into the low range position.

1. Remove the plug from the bottom of the axle housing and drain the lubricant.
2. Disconnect the driveline universal joint from the pinion input yoke or flange on the differential carrier. See **Fig. 1**.

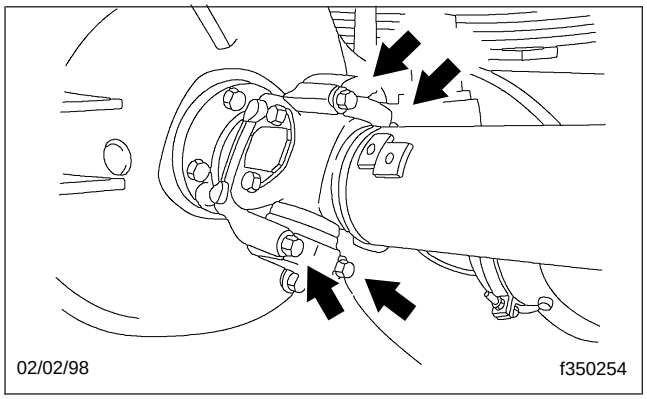

Fig. 1, Driveshaft

3. Remove the stud nuts and washers from the flanges of both axle shafts. See **Fig. 2**.

⚠ WARNING

Wear safe eye protection. Do not hit the round driving lugs on the head of the axle shaft. Lugs can break and cause injury.

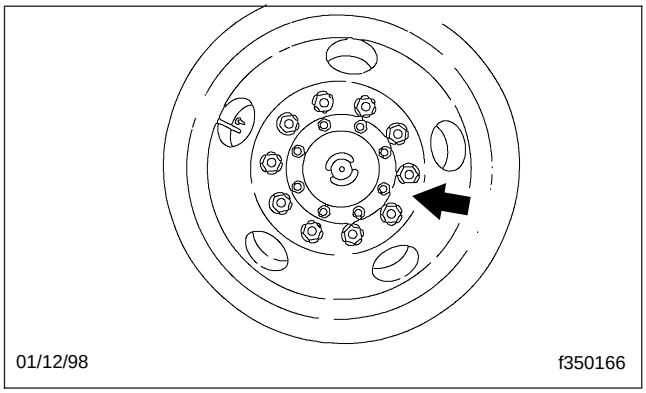

Fig. 2, Stud Nuts and Washers

⚠ CAUTION

Do not hit the circular driving lugs on the shaft head. This can cause the lugs to shatter and splinter. Do not use chisels or wedges to loosen the shaft or dowels. This will damage the hub, shaft and oil seal.

NOTE: A 1.5-inch (38-mm) diameter brass hammer can be used as a drift.

4. Loosen the tapered dowels in the flanges of both axle shafts by holding a 1.5-inch (38-mm) diameter brass drift against the center of the axle shaft head, inside the circular driving lugs and striking the drift with a 5- to 6-lb (2.7-kg) hammer or sledge. See **Fig. 3**.

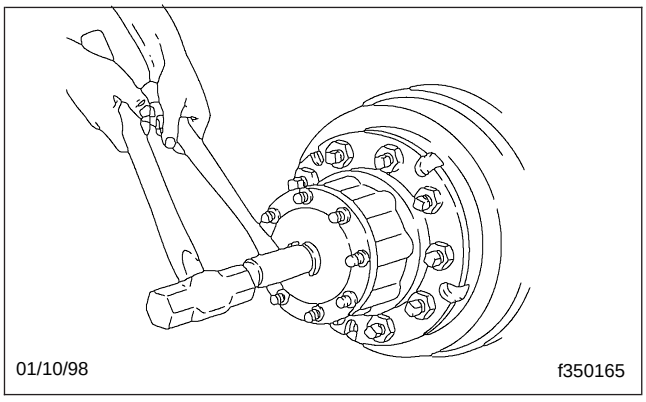

Fig. 3, Loosening Tapered Dowels

5. Remove the tapered dowels and axle shafts from the axle assembly. See **Fig. 4**.

Differential Carrier Removal and Installation

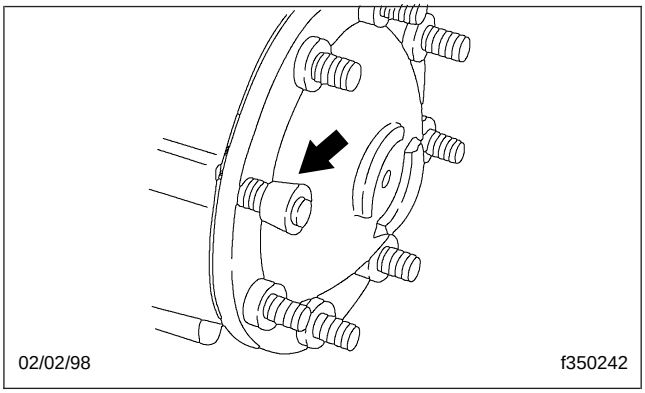

Fig. 4, Removing Tapered Dowels

NOTE: The shift motor can be removed altogether to facilitate carrier removal and to avoid inadvertent damage to the shift unit.

6. Disconnect the electric lines from the shift unit. See **Fig. 5**.

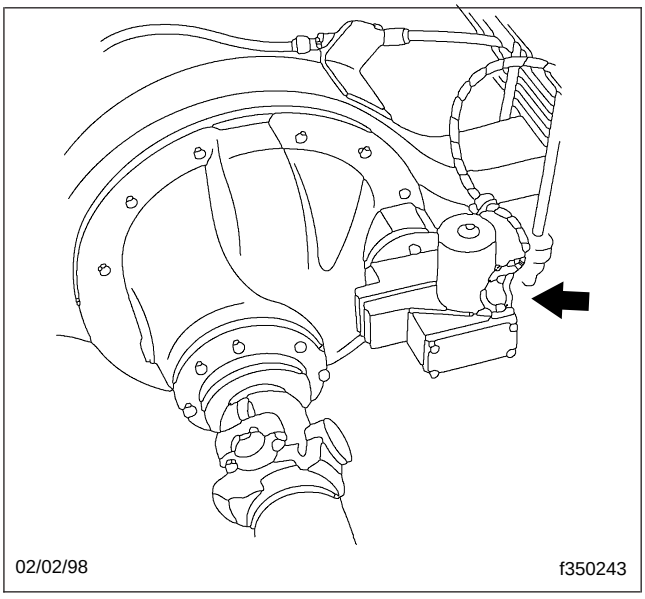

Fig. 5, Electrical Lines at Shift Unit

7. Remove all but the top two differential carrier-to-housing capscrews and washers. See **Fig. 6**.
8. Loosen the top two differential carrier-to-housing fasteners but leave them attached to the assembly. The fasteners will hold the carrier in the housing.

NOTE: If it is necessary to use puller bolts, there are two threaded holes in the differential carrier flange. Use the carrier-to-housing bolts.

9. Loosen the differential carrier in the axle housing. Use a soft mallet to hit the mounting flange of the carrier in several places. See **Fig. 7**.
10. Place the Rotunda Heavy Duty Truck Transmission Jack under the differential carrier to support the assembly. See **Fig. 8**.

CAUTION

Take care not to damage the differential carrier or housing flange as damage to these surfaces will cause oil leaks.

NOTE: Use a pry bar with a round end to help remove the differential carrier from the housing.

11. Remove the top two differential carrier-to-housing fasteners and carefully remove the differential carrier from the housing with the roller jack. See **Fig. 9**.
12. Place the differential carrier in a suitable repair stand. See **Fig. 10**.

Installation

1. Clean the inside of the axle housing and the mounting surface where the carrier fastens.
2. Inspect the axle housing for damage.
3. Apply silicone gasket material to the mounting surface of the housing where the carrier fastens. See **Fig. 11**.

CAUTION

Do not install the differential carrier using a hammer or mallet. A hammer or mallet can damage the mounting flange of the carrier and cause oil leaks.

Make sure the differential carrier is shifted into the low speed gear range. This will permit clearance between the sun gear and the differential carrier mounting ring on the housing.

4. Install the carrier into the axle housing using the Rotunda Heavy Duty Truck Transmission Jack.

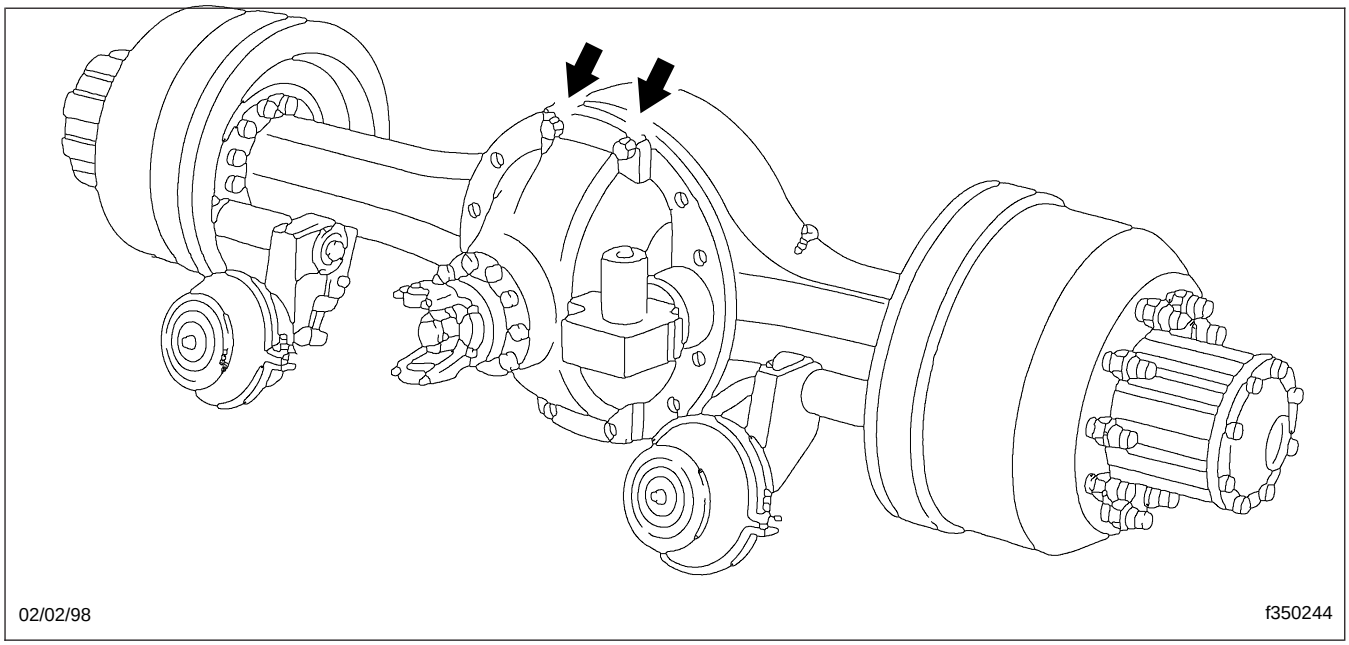

Fig. 6, Top Two Differential Carrier-to-Housing Bolts

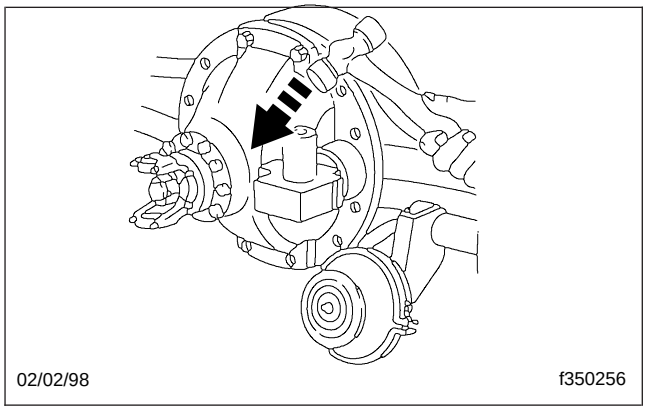

Fig. 7, Loosen the Differential from the Housing Using a Soft Mallet

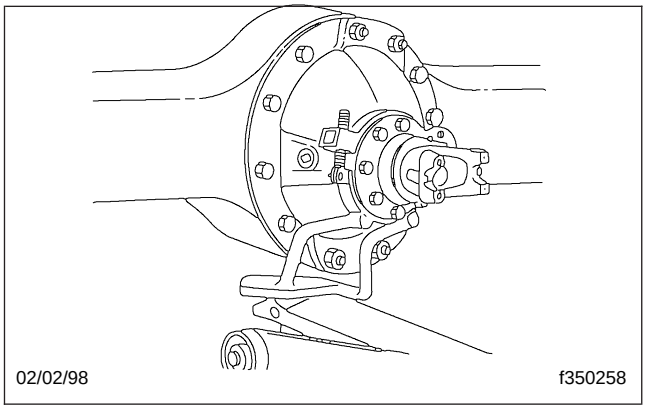

Fig. 8, Heavy Duty Truck Transmission Jack Supporting Carrier During Removal

NOTE: Apply four or five drops of Stud and Bearing Mount EOAZ–19554–BA or equivalent meeting Sterling specification WSK–M2G349–A1 on the capscrew threads.

5. Install the capscrews and washers in the four corner locations around the carrier and axle housing. Tighten the capscrews hand-tight at this time. Push the carrier into position. Tighten the four capscrews two or three turns each in a pattern opposite each other until you reach 199 to 243 lbf·ft (270 to 330 N·m). See **Fig. 12**.

6. Install the remaining capscrews that hold the carrier in the axle housing. Tighten to 199 to 243 lbf·ft (270 to 330 N·m).

   6.1 Tighten the fasteners to the specified torque.

   6.2 Remove the Rotunda Heavy Duty Truck Transmission Jack.

7. Connect the driveline universal joint to the pinion input yoke or flange on the carrier. See **Fig. 13**.

Differential Carrier Removal and Installation

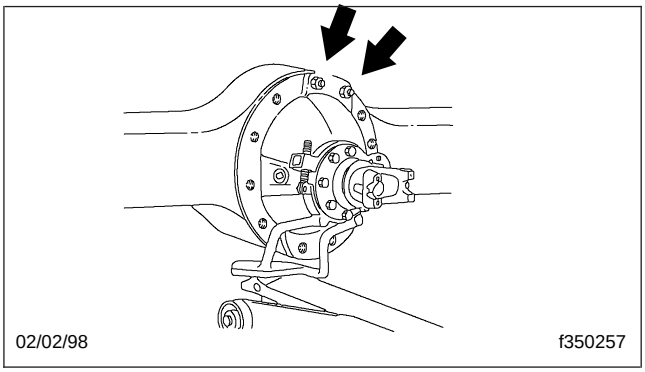

Fig. 9, Two Carrier-to-Housing Bolts, Removal

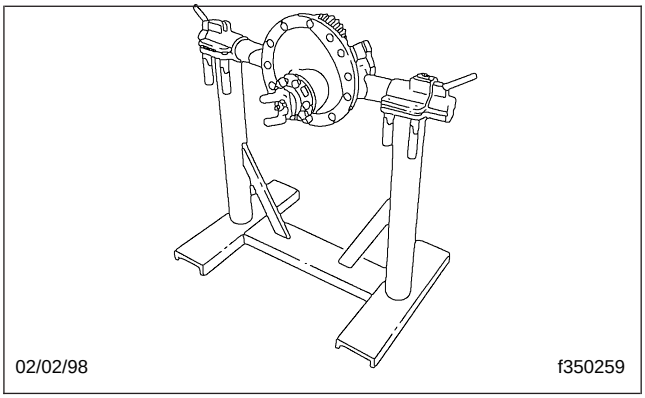

Fig. 10, Carrier Repair Stand

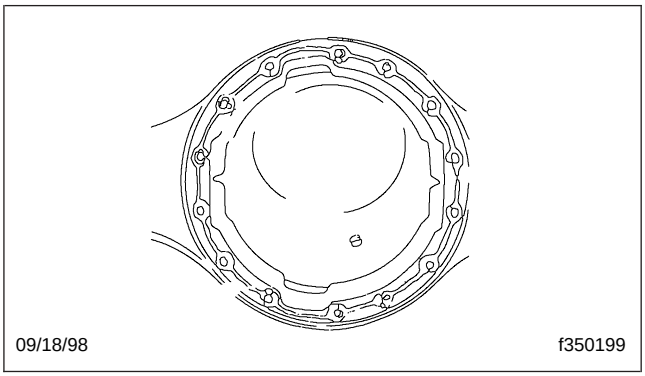

Fig. 11, Silicone Gasket Material Application

8. Install the gaskets and axle shafts into the axle housing. The gasket and flange of the axle shaft must fit flat against the wheel hub. See **Fig. 14**.
9. Install the tapered dowels over each stud and into the flange of the axle shaft, if used. Use a punch or drift and hammer, if necessary. See **Fig. 4**.

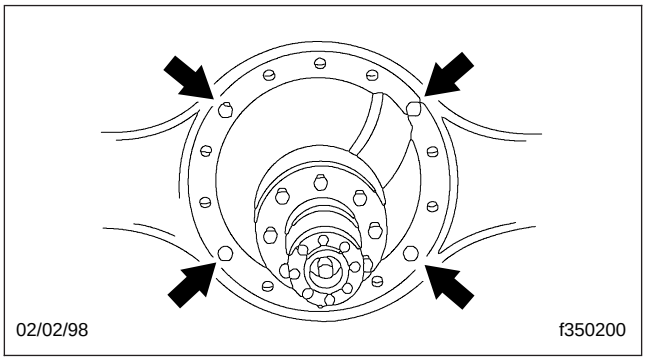

Fig. 12, Capscrews and Washers in Four Corners Around Carrier

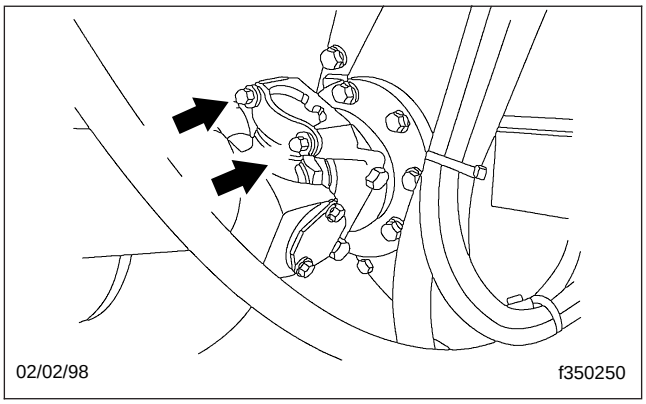

Fig. 13, Connect the Driveline Universal Joint to the Pinion Input Yoke

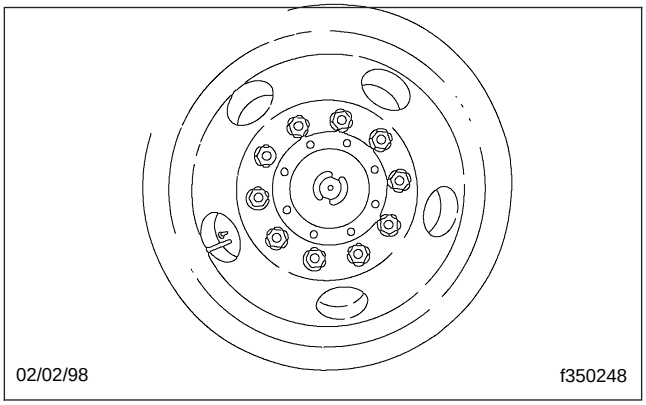

Fig. 14, Gasket and Axle Shaft Installation

10. Install Grade 8 nuts and lockwashers on the studs and tighten the stud nuts to the specified torque. Refer to **Specifications, 400**. See **Fig. 2**.
11. Connect the electric lines to the shift unit. See **Fig. 5**.

NOTE: For additional lubrication information, refer to **Specifications, 400**.

12. Fill the rear axle with the specified lubricant according to the following procedure.
    - 12.1 Make sure the vehicle is parked on a level surface.

      When the angle of the drive pinion changes, the lubricant capacity of the rear axle assembly will change.
    - 12.2 Remove the fill plug from the axle housing.
    - 12.3 Fill the rear axle with lubricant until the lubricant level is to the bottom of the filler plug hole.
13. Install the fill plug and tighten to 35 lbf·ft (47 N·m). When correctly installed, one complete thread of the fill plug is visible. See **Fig. 15**

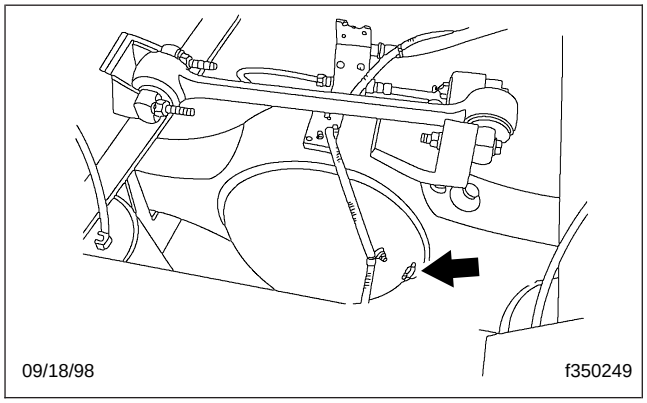

Fig. 15, Install the Fill Plug

14. Drive the vehicle in an unloaded condition for 1 to 2 miles (1.6 to 3.2 km) at speeds not more than 25 mph (40 km/h). Operating the vehicle ensures that the lubricant flows through the complete rear axle assembly.

Troubleshooting

Axle shafts, wheel hubs, wheel hub bearings, wheel hub grease seals, the electric shift unit and the differential drive pinion oil seal can be replaced without removing the differential carrier assembly from the axle housing or the rear axle assembly from the vehicle.

The axle shafts, wheel hub, bearings, and grease seal can be replaced, lubricated or adjusted.

For axle alignment, refer to **Section 35.04** in this manual.

INSPECTION AND VERIFICATION

Visually inspect the wiring harness for broken or frayed wires. Replace as necessary. Check harness connectors for corrosion and contact. Clean, if necessary. Verify that the connectors are properly mated (wiring into connector matches designated color out of connector).

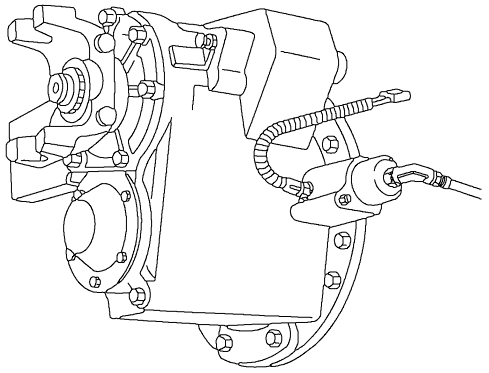
General Information

DRIVE UNIT

The 145-Series and 160-Series forward axle drive units of these tandem axles have a single-reduction, through-drive carrier. See **Fig. 1**.



02/04/98 f350339

Fig. 1, Forward Axle Drive Unit

The drive gearing consists of a two-helical geartrain and a hypoid ring gear and pinion. Bevel gears are used in the main differential and the inter-axle differential.

The inter-axle differential is located behind the helical drive gear on the input shaft. The forward side gear of the inter-axle differential is part of the upper helical gear hub and the through-shaft is splined to the rear side gear of the inter-axle differential. See **Fig. 2**.

The 160-Series axle is different from the 145-Series axle in the following components: The 160-Series axle has a wider helical driven gear. There are two notches on the inter-axle differential case of the 160-Series axle. The notches permit the differential case to clear the helical driven gear when the input shaft assembly is removed from the carrier. See **Fig. 3**.

PRESSURIZED LUBRICATION SYSTEM

The forward axle can be equipped with an optional pressurized lubrication system. This filtered system has an oil pump that is driven by the input shaft and circulates lubricant to the journals in the forward and rear input shaft bearings and through the inter-axle differential.

Fig. 3, Notches for Clearance When Removing Input Shaft Assembly from Carrier

DRIVER-CONTROLLED MAIN DIFFERENTIAL LOCK

Both the forward and rear axles can be equipped with an optional driver-controlled main differential lock. This differential lock is operated by an air-actuated shift unit that is mounted on the carrier. When the differential lock is activated, the shift collar is moved along the splines of the axle shaft toward the differential case. When the splines on the collar are engaged with the splines on the differential case, the axle shaft and the differential assembly are locked together.

General Information

When the carrier operates in the locked position, there is no differential action between the wheels of the axle. When the carrier is operated in the unlocked position, there is normal differential action between the wheels at all times.

IDENTIFICATION TAG

An identification tag is riveted on the axle housing or on the differential carrier (see **Fig. 4**). Use the model number and the ratio number marked on the identification tag and the number on the carrier to order replacement parts.

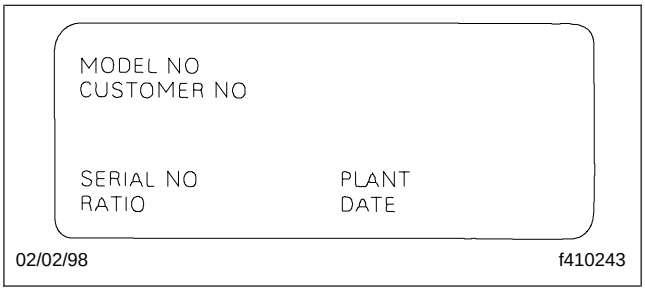

Fig. 4, Identification Tag

The illustration shows the location of the identification tag (or stamp number) for the axles (see **Fig. 5**). Location is determined from the left (driver) side looking toward the front of the vehicle. On front engine drive vehicles, the tag is located on the right rear of the axle, next to the cover. On rear drive vehicles, the tag is located on the left or right rear of the axle, next to the drive unit.

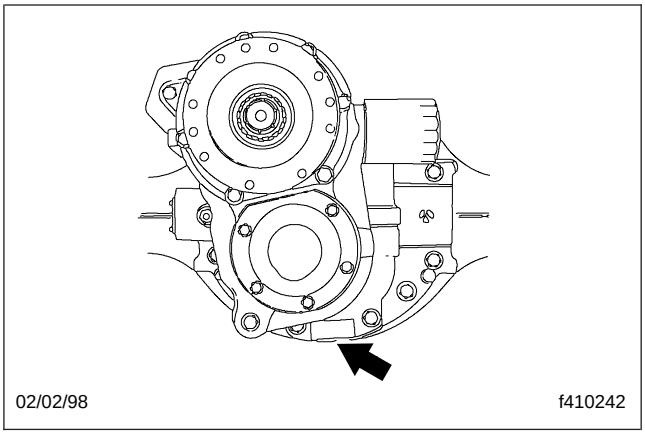

Fig. 5, Location of Identification Tag

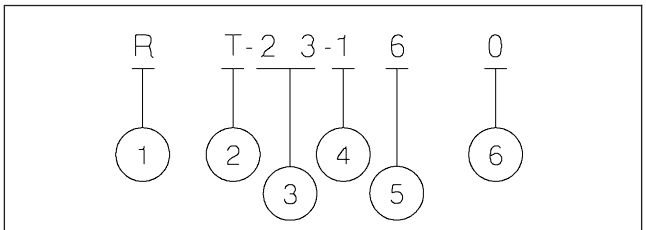
Refer to the model number information chart for the meaning of the model number. Individual forward and rear axles of a tandem set (D, N, P, R) are rated as single axles. A tandem set (T) is rated as the combination of two axles. See **Fig. 6**.



1. Meritor
2. **Axle Type** D = Tandem Forward/Rear Axle with Inter-Axle Differential. N = Tandem Forward/Rear Axle Less Inter-Axle Differential. P = Tandem Forward/Rear Axle with Inter-Axle Differential and Pump. T = Tandem Set (2 Axle Assemblies)
3. **Nominal Axle Load Rating (GAWR) (Two Digits)** Thousands of pounds to the nearest thousand pounds for axles made in U.S.A., Mexico and Brazil. All others in metric tonnes.
4. **Gearing Type** 1= Single Speed. 2 = Two Speed. 3 = Helical Double Reduction.
5. **Carrier Series** Identified by ring gear size (dimension). Larger number means bigger ring gear (more capacity and rating).
6. **Carrier Design Series or Variation** 0 = Original Design. 1- 2 = Variation Sequence. 3 = from original design. 4 = etc.

Fig. 6, Model Number Information Chart

Meritor Tandem Axle With Hendrickson HAS Suspension Removal and Installation

Removal

NOTE: The use of assistants to balance the axle as it is being lowered, raised or moved with the floor jack is highly recommended.

1. Chock the front tires.
2. Release the brakes and bleed the air from the brake system. See **Fig. 1**.

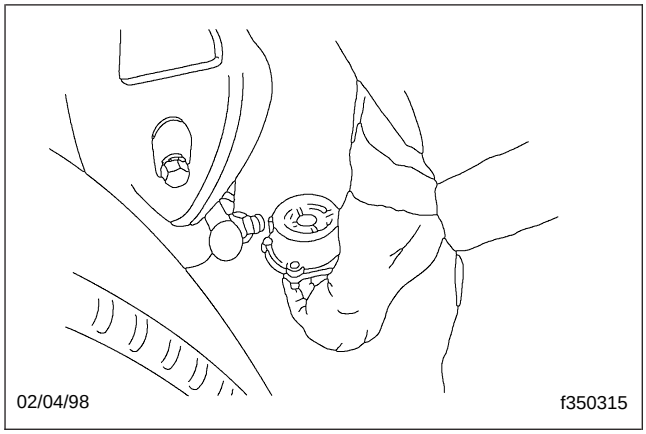


Fig. 1, Bleed the Air from the Brake System

NOTE: If the brake drums are to be removed, cage the brakes before disconnecting the air brake hoses. Refer to **Group 42** for the caging procedure.

3. Disconnect the air hoses to the brakes. See **Fig. 2**.

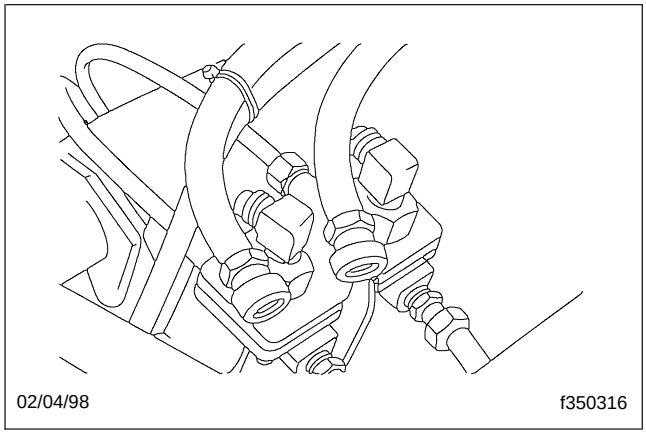

Fig. 2, Disconnect Brake Air Hoses

4. For forward tandem axles, disconnect the wiring harness connectors.
5. For forward tandem axles, disconnect the driveshaft and wire it out of the way. See **Fig. 3**.

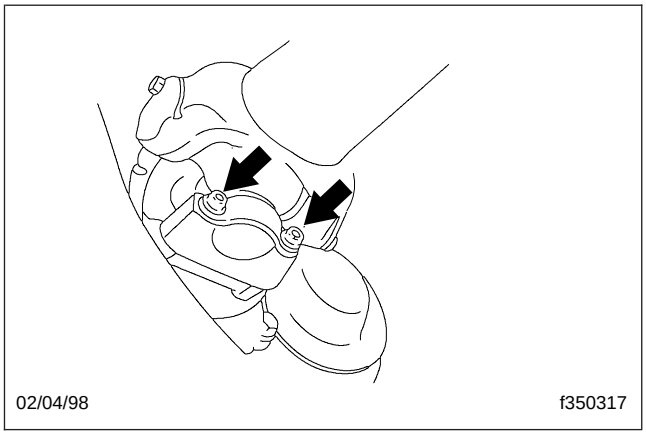

Fig. 3, Disconnect the Driveshaft

6. For forward tandem axles, disconnect the inter-axle driveshaft at the forward axle output flange or yoke and allow it to rest on the air shock support plate. See **Fig. 4**.

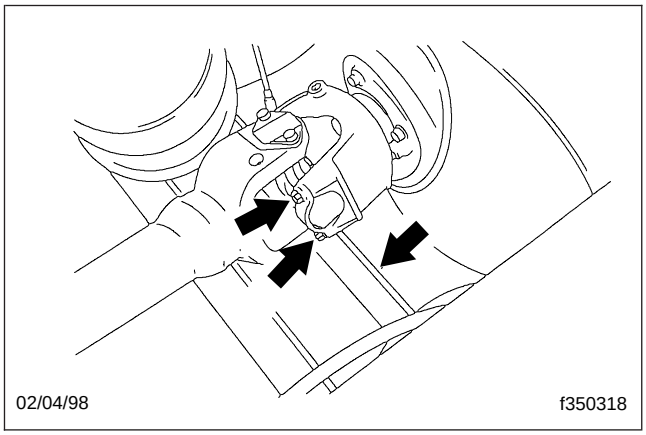

Fig. 4, Disconnect the Inter-Axle Driveshaft

7. For rear tandem axles, disconnect the inter-axle driveshaft at the rear axle input flange or yoke and wire it out of the way.
8. Disconnect the torque rod at the axle housing. See **Fig. 5**.

NOTE: Make sure to raise the vehicle high enough to clear the axle when it is ready to be lowered with the wheels and tires removed.

Meritor Tandem Axle With Hendrickson HAS Suspension Removal and Installation

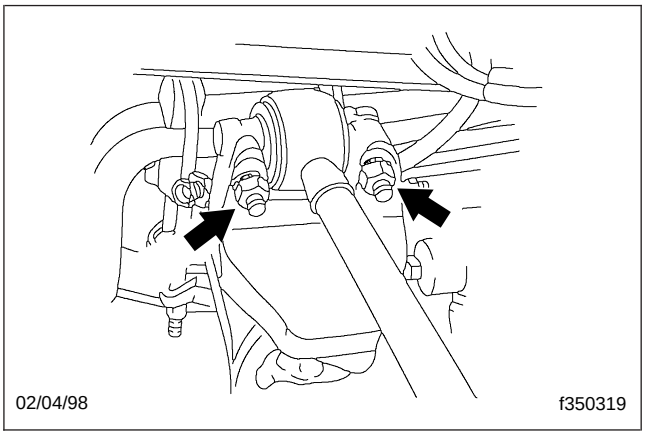

Fig. 5, Disconnect the Torque Rod

9. Raise the rear of the vehicle and insert jack stands under the axle not being removed.
10. Remove the wheels and tires from the axle to be removed.

NOTE: Supporting the drive unit on the forward axle is not necessary. The axle will not tip forward.

11. Support the housing of the axle to be removed with a floor jack. See **Fig. 6**.

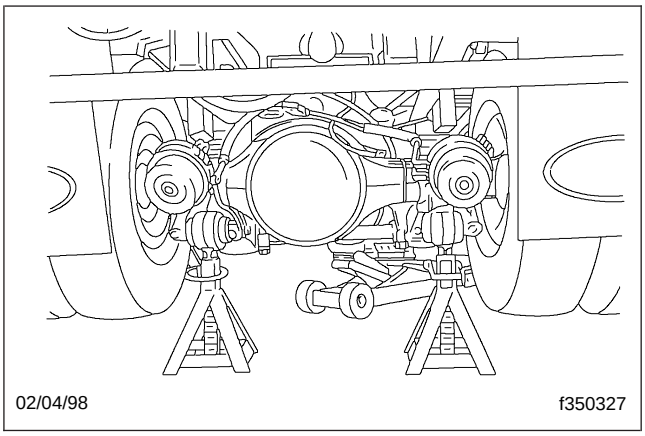

Fig. 6, Support the Axle to Be Removed With a Floorjack

12. Remove the U-bolts and nuts and discard them. See **Fig. 7**.

IMPORTANT: Watch for the axle hanging up on obstructions as it is being lowered.

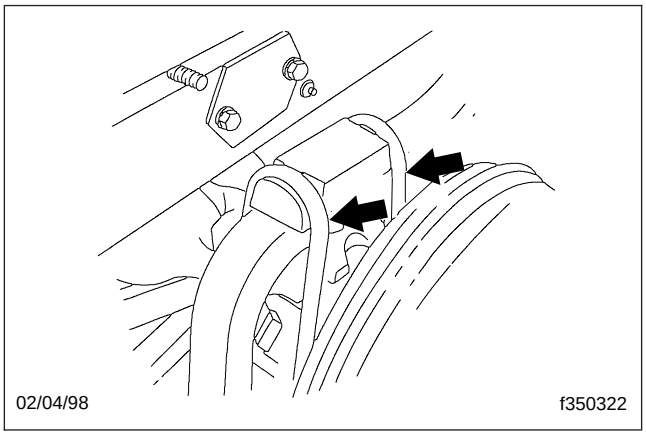

Fig. 7, U-Bolts and Nuts

13. Carefully lower the axle with the floor jack and slide it out from under the vehicle. See **Fig. 8**.

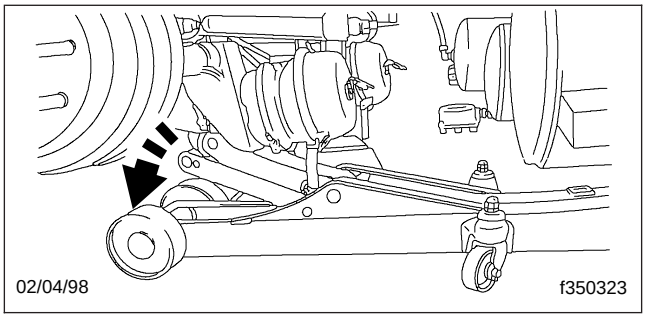

Fig. 8, Lower the Axle

Installation

NOTE: The use of assistants to balance the axle as it is being positioned or moved with the floor jack is highly recommended.

IMPORTANT: Use new U-bolts and U-bolt nuts for installation.

NOTE: When tightening the air fittings, a minimum of two turns past finger-tight is required. Directional fittings are to be oriented in a tightening direction only.

1. Position the axle with the floor jack under the vehicle. See **Fig. 8**.
2. Install the new U-bolts and nuts tighten nuts 260 to 320 lbf·ft (353 to 433 N·m). See **Fig. 7**.
3. Install the wheels and tires tighten nuts to 450 to 500 lbf·ft (611 to 677 N·m).

Meritor Tandem Axle With Hendrickson HAS Suspension Removal and Installation

4. Raise the rear of the vehicle and remove the jack stands.
5. Lower the rear of the vehicle and remove floor jack.
6. Connect the torque rod at the axle housing tighten to 150 to 250 lbf·ft (204 to 277 N·m). See **Fig. 5**.
7. For rear tandem axles, connect the inter-axle driveshaft at the rear axle input flange or yoke tighten 5/16-24: 35 to 41 lbf·ft (47 to 56 N·m) and 3/8-24: 45 to 60 lbf·ft (61 to 81 N·m).
8. For forward tandem axles, connect the inter-axle driveshaft at the forward axle output flange or yoke tighten 5/16-24: 35 to 41 lbf·ft (47 to 56 N·m) and 3/8-24: 45 to 60 lbf·ft (61 to 81 N·m). See **Fig. 4**.
9. For forward tandem axles, connect the drive-shaft. See **Fig. 3**.
10. For forward tandem axles, connect the wiring harness connectors.
11. Connect the air hoses to the brakes. See **Fig. 2**.
12. Remove the tire chocks.

Meritor Tandem Axle With Hendrickson RT2, UE2 and U2 Suspensions Removal and Installation

Removal

1. Chock the front tires.
2. Jack up the rear of the vehicle under the axle not being removed and insert jack stands under the ends of the walking beam attached to that axle. See **Fig. 1**.

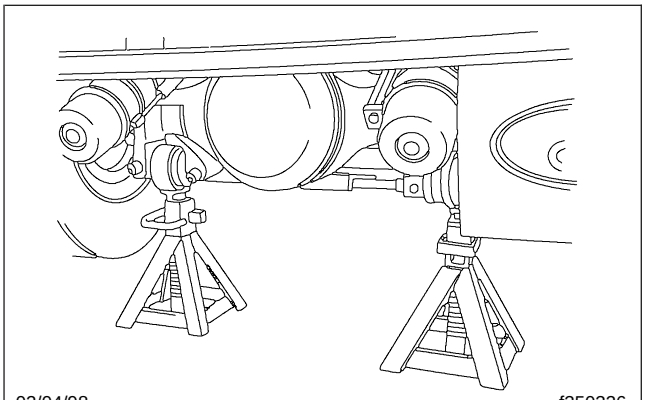

Fig. 1, Jack Up the Rear of the Vehicle

3. Support the axle to be removed with a floor jack. See **Fig. 2**.

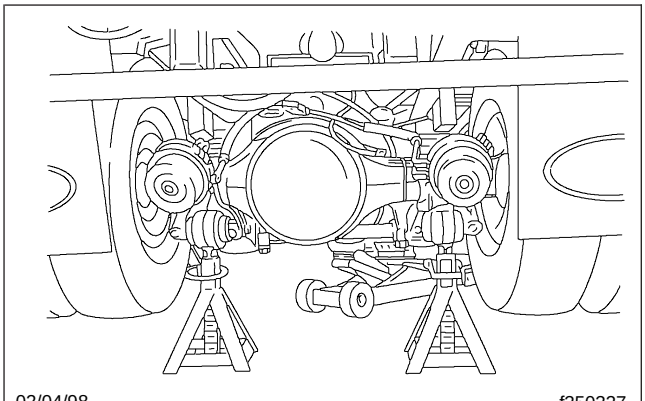

Fig. 2, Support the Axle to Be Removed With a Floor Jack

4. Remove the wheels and tires from the axle to be removed.
5. Disconnect the electrical connectors.
6. Release the brakes and bleed the air from the brake system. See **Fig. 3**.

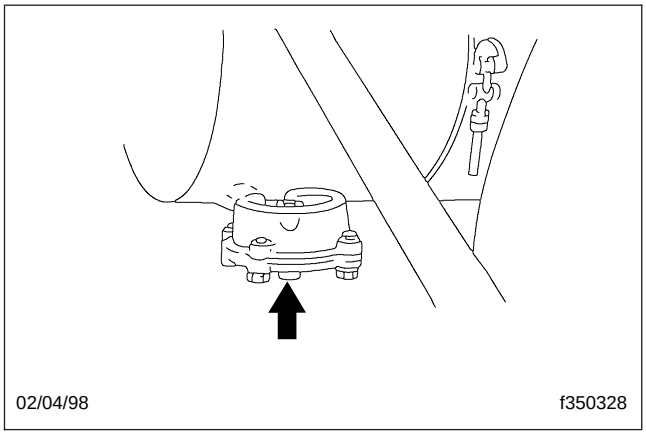

Fig. 3, Release the Brakes and Bleed the Air from the Brake System

NOTE: If the brake drums are to be removed, cage the brakes before disconnecting the air brake hoses. Refer to **Group 42**.

7. Disconnect the brake air hoses. See **Fig. 4**.

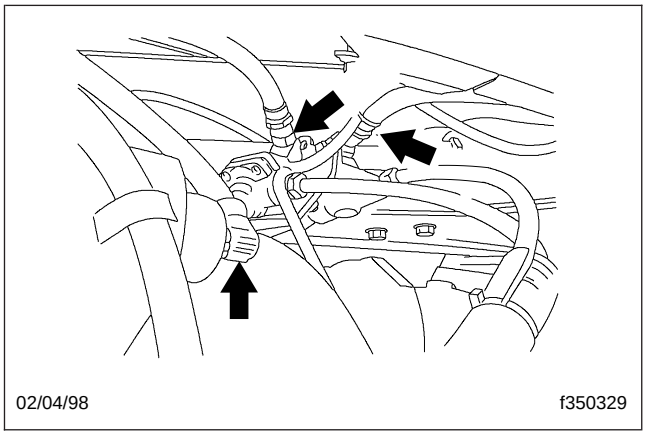

Fig. 4, Disconnect the Brake Air Hoses

8. Remove the torque rod nuts and bolts from the rear axle. See **Fig. 5**.
9. Disconnect the driveshaft(s) and wire it out of the way.
10. Remove the nuts from the bolts that retain the axle to the walking beam, but do not remove the bolts.

NOTE: Do not let the ends of the walking beams touch the floor, as they will be difficult to raise.

Meritor Tandem Axle With Hendrickson RT2, UE2 and U2 Suspensions Removal and Installation

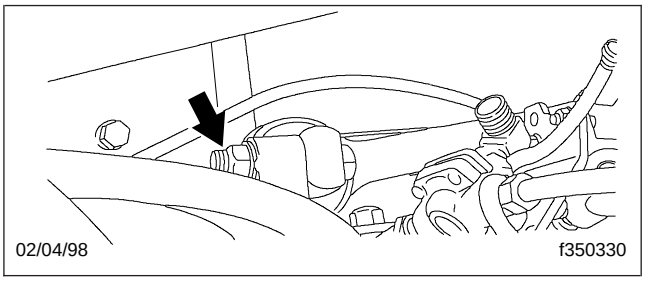

Fig. 5, Remove the Torque Rod Nuts and Bolts from the Rear Axle

11. Place short jack stands under the walking beam of the axle being removed, and carefully lower the axle.
12. Remove the bolts that retain the axle to the walking beam.

NOTE: The end of the walking beam should sit on the short jack stand.

13. Carefully jack up the axle high enough to clear the walking beam, making sure that the walking beam does not rise with the axle. See **Fig. 6**.

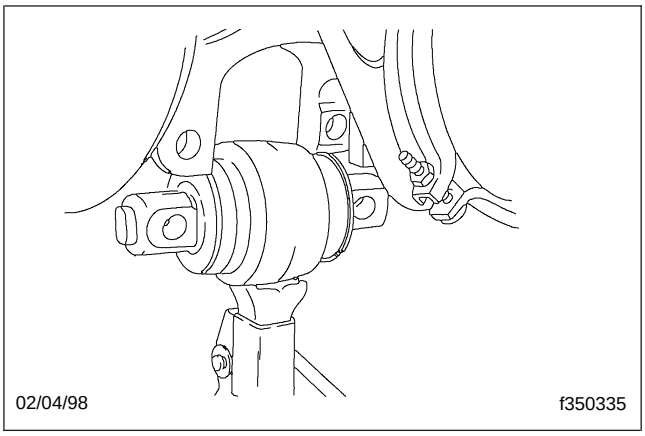

Fig. 6, Raise Axle High Enough to Clear Walking Beam

14. Remove the axle from under the vehicle.

Installation

NOTE: When tightening the air fittings, a minimum of two turns past finger-tight is required. Directional fittings are to be oriented in a tightening direction only.

1. Position the axle under the vehicle.
2. Install the nuts and bolts that retain the axle to the walking beam tighten 450 to 600 lbf·ft (610 to 813 N·m). See **Fig. 7**.

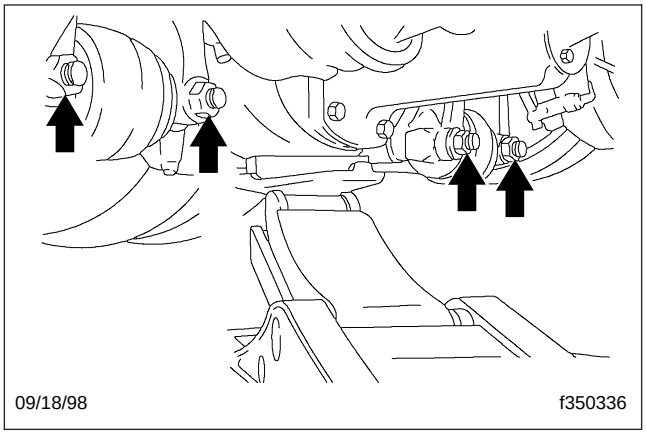

Fig. 7, Install Axle to Walking Beam Bolts and Nuts

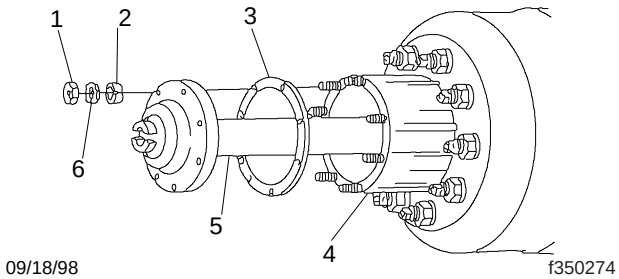
3. Connect the driveshaft(s) tighten 5/16-24: 35 to 41 lbf·ft (47 to 56 N·m) and 3/8-24: 45 to 60 lbf·ft (61 to 81 N·m).
4. Install the rear axle torque rod nuts and bolts tighten 150 to 250 lbf·ft (204 to 277 N·m). See **Fig. 5**.
5. Connect the brake air hoses. See **Fig. 4**.
6. Connect the electrical connectors.
7. Install the wheels and tires tighten nuts 450 to 500 lbf·ft (611 to 677 N·m).
8. Remove the jack stands and floor jack.
9. Remove the tire chocks.

Removal (See Fig. 1 and Fig. 2)



1. Nut
2. Tapered Dowels
3. Rear Axle Gasket
4. Rear Hub
5. Rear Axle Shaft
6. Washer

8. Shift Shaft
9. Sensor Switch

Fig. 2, Differential Carrier

REMOVAL

1. Remove the oil drain plug from the bottom of the axle housing and drain the lubricant from the assembly. See **Fig. 3**.
2. Remove the oil filter shield from the input bearing retainer. See **Fig. 4**.

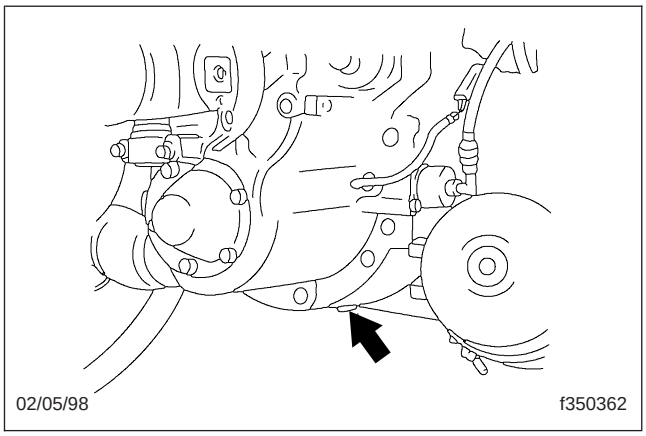

Fig. 3, Remove Oil Drain Plug

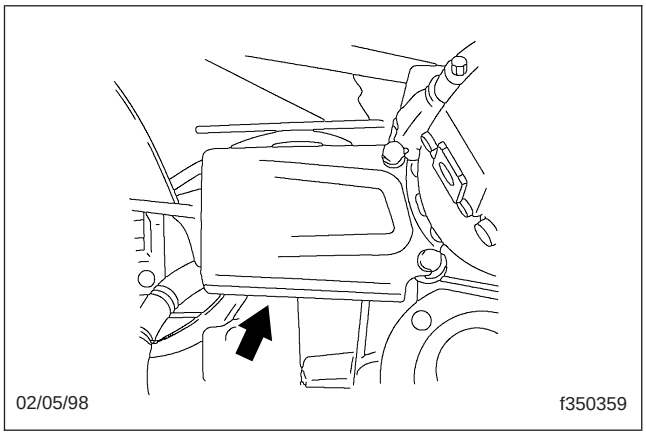

Fig. 4, Remove the Oil Filter Shield

IMPORTANT: There can be approximately 1 pint (0.47 liter) of lubricant remaining in the filter. Be careful that the oil does not spill when removing the filter.

NOTE: Replace the oil filter with a new filter at assembly.

3. Use a filter strap wrench to remove the oil filter. See **Fig. 5**.
4. Remove the oil filter adapter, if necessary. See **Fig. 6**.
5. For axles so equipped, shift the differential lock into the locked (engaged) position. Refer to "Driver-Controlled Differential Lock Engagement Procedures" in **Subject 130** or **Subject 140**.
6. Remove the stud nuts or capscrews and the washers from the flanges of both axle shafts.

Differential Carrier Removal and Installation

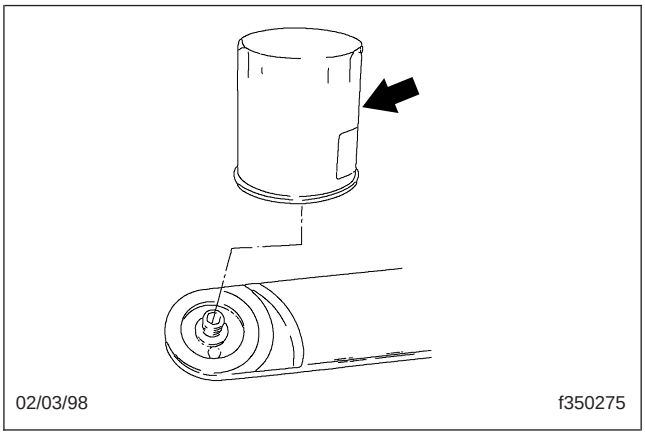

Fig. 5, Remove the Oil Filter

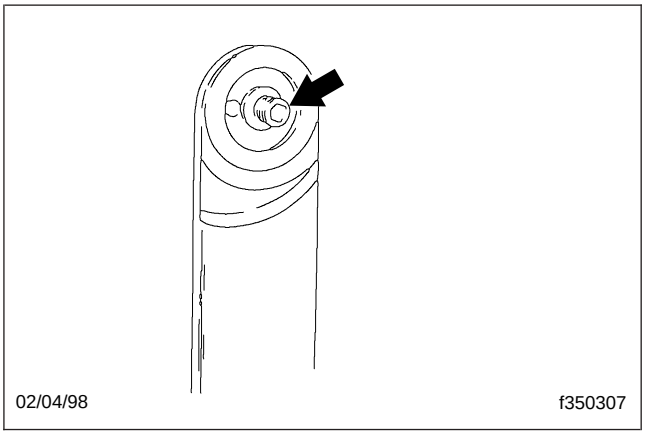

Fig. 6, Remove the Oil Filter Adapter

⚠ WARNING

Wear safe eye protection. Do not hit the round driving lugs on the flanges of the axle shafts. The lugs can break and cause injury.

NOTE: A 1-1/2-inch diameter brass hammer can be used for a drift.

7. Hold a 1-1/2-inch diameter brass drift against the center of the axle shaft, inside the round driving lugs, and hit the end of the drift with a large hammer (5-6 pounds) to loosen the axle shaft and tapered dowels.

⚠ CAUTION

Do not use a chisel or wedge to loosen the axle shafts and dowels. The chisel or wedge can damage the hub, axle shafts and, if used, the oil seals.

8. Remove the tapered dowels, if used, and remove both axle shafts from the axle assembly.
9. Disconnect the forward and rear driveshafts.
10. If not done previously, disconnect the air lines at the inter-axle differential and the main differential lock shift unit.

⚠ CAUTION

Do not use a hammer to loosen or remove the output yoke or flange. A hammer can damage the parts and cause difficulty with alignment.

NOTE: Use a suitable yoke puller to remove the output yoke or flange from the shaft.

11. Remove the output shaft nut, washer and output yoke or flange. See **Fig. 7** and **Fig. 8**.

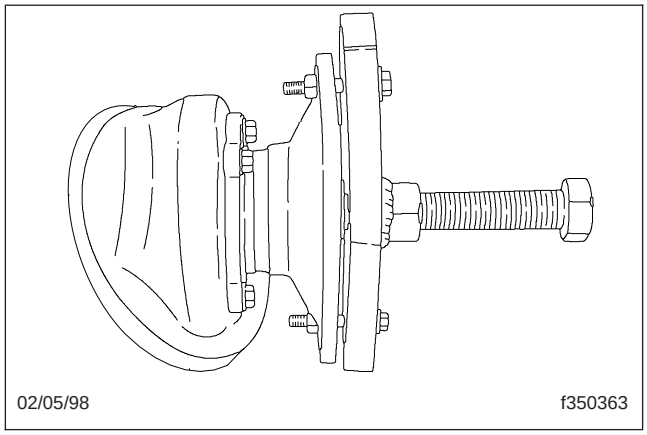

Fig. 7, Output Flange Removal

12. Position a hydraulic roller jack under the differential carrier to support the assembly. Secure the axle to the jack.

NOTE: If necessary, loosen the retainer from the housing with a soft mallet. Be careful that the oil seal is not damaged.

13. Remove the bearing retainer capscrews and washers, and pull the bearing retainer, gasket

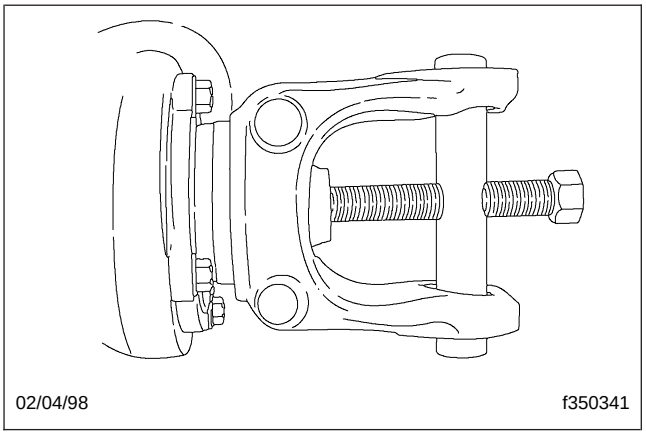

Fig. 8, Remove the Output Yoke

and bearings, and through-shaft assembly from the axle housing.

NOTE: Loosen, but do not remove, the top two fasteners. The fasteners will hold the carrier in the housing.

14. Remove all but the top two capscrews or stud nuts and washers. See **Fig. 9**.

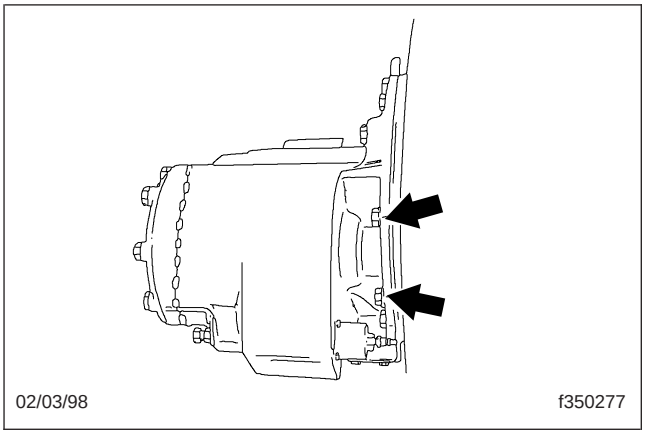

Fig. 9, Top Two Capscrews or Stud Nuts

15. Use a leather mallet to loosen the differential carrier in the axle housing. See **Fig. 10**.
16. Remove the top two capscrews or stud nuts and washers. See **Fig. 9**.

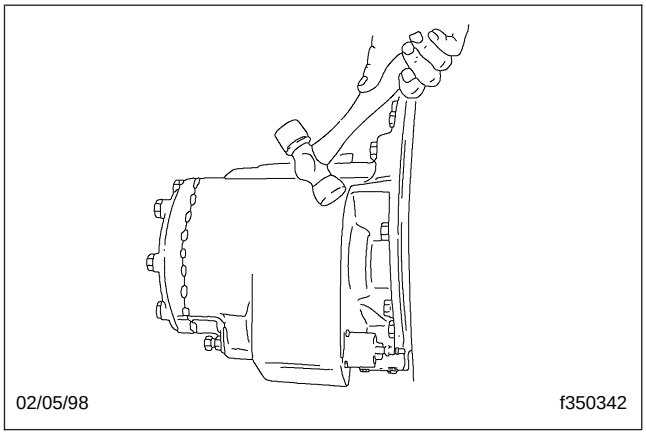

Fig. 10, Loosen the Differential Carrier With a Leather Mallet

CAUTION

When using a pry bar, be careful not to damage the carrier or housing flange. Damage to these surfaces will cause oil leaks.

NOTE: Use a pry bar that has a round end to help remove the carrier from the housing.

17. Remove the carrier from the axle housing, using the hydraulic roller jack.
18. For axles equipped with main differential lock, release the air pressure used to shift the differential into the locked (engaged) position and disconnect the air hose and electrical connector of the sensor unit from the shift unit.

WARNING

Use the endless lifting sling to lift the carrier. Do not lift by hand. Use care when handling it to prevent injury.

19. Lift the differential carrier by the input yoke or flange and put the assembly in a suitable stand. See **Fig. 11**.

Installation

NOTE: Use a cleaning solvent and clean rags to remove dirt.

NOTE: Blow dry the cleaned areas with air.

Differential Carrier Removal and Installation

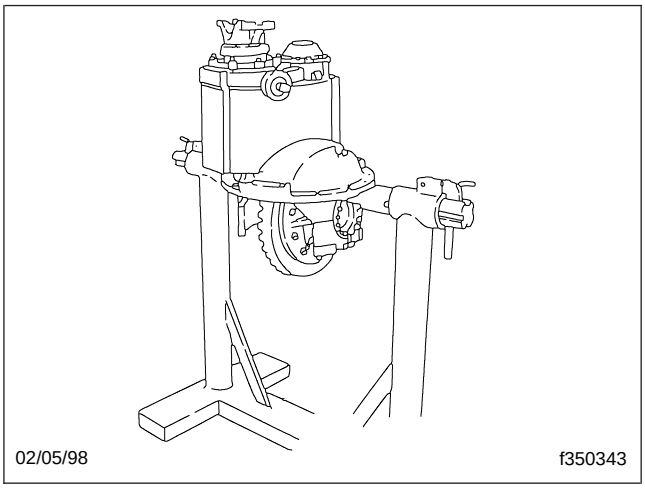

Fig. 11, Differential Carrier in a Suitable Stand

1. Clean the inside of the axle housing and the mounting surface where the carrier fastens.
2. Inspect the axle housing for damage and repair or replace the axle housing as necessary.
3. Check for loose studs, if used, in the mounting surface of the housing where the carrier fastens. See **Fig. 12**.

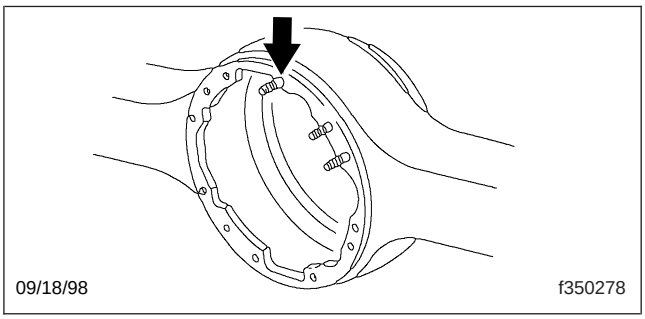

Fig. 12, Check for Loose Studs

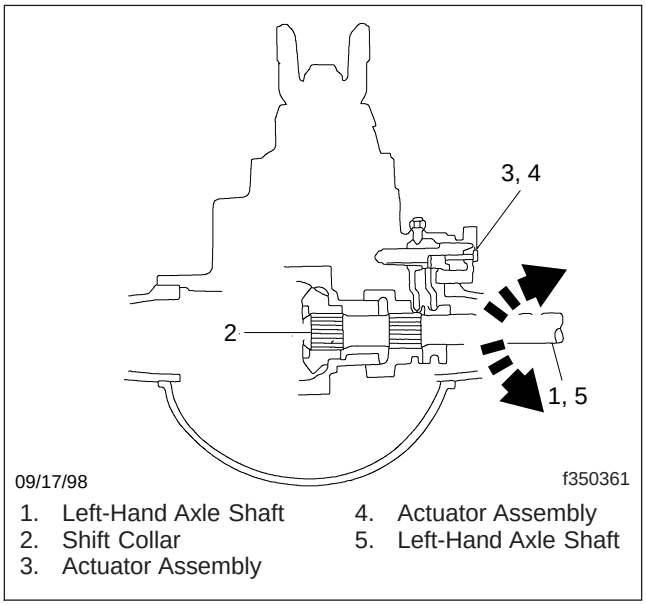
3.1 Remove and clean the loose studs.

3.2 Apply liquid adhesive to the threaded holes and install the studs in the axle housing. Tighten the studs.

IMPORTANT: On axles that use a main differential lock, the lock must be shifted into and held in the locked (engaged) position. The locked position gives enough clearance between the shift collar and the axle housing to permit the installation of the carrier.

NOTE: When the differential carrier is to be installed into the axle housing, the shift collar must be held in the engaged position. This can be done by keeping the air pressure applied to the shift cylinder or by using the manual engaging bolt. Failure to keep the differential in the locked (engaged) position will make it impossible to install the carrier assembly into the axle housing. After the differential carrier is installed into the axle housing, shift the differential into the unlocked (disengaged) position to permit the installation of the left-hand axle shaft.

4. Use the following procedure to install the shift cylinder if an auxiliary air supply is available. See **Fig. 13**.



1. Left-Hand Axle Shaft
2. Shift Collar
3. Actuator Assembly
4. Actuator Assembly
5. Left-Hand Axle Shaft

Fig. 13, Shift Cylinder, Installation

NOTE: A spline alignment tool can be made from a damaged left-hand axle shaft by cutting off approximately 24 inches (610 mm) from the spline end.

4.1 Before the differential carrier is installed into the housing, install the left-hand axle shaft through the shift collar and into the side gear.

⚠ WARNING

Do not use your hands to hold the collar in position. Injury can result when air pressure is applied to the actuator.

4.2 Align the splines of the shift collar and the differential case half by rotating the axle shaft tool or drive pinion.

4.3 Connect an auxiliary air supply to the actuator assembly.

NOTE: The air pressure will move the shift collar to engage the differential case half and lock the assembly.

4.4 Apply and hold pressure to the actuator assembly.

4.5 Rotate the axle shaft tool or the drive pinion one complete rotation to the right or left if the shift collar has not moved the full distance on the splines of the differential case half.

NOTE: Continue to hold the main differential in the locked (engaged) position with air pressure until the differential carrier is completely installed in the axle housing.

5. Remove the axle shaft tool from the carrier.
6. Use the following procedure to install the shift cylinder if an auxiliary air supply is not available. See **Fig. 14**.

6.1 Install the manual engaging capscrew into the threaded hole in the center of the shift unit.

IMPORTANT: Do not turn the capscrew beyond its normal stop.

NOTE: Lift the shift collar as required and rotate to align the splines of the collar and the case half while turning in the manual engaging capscrew.

6.2 Turn the manual engaging capscrew until it stops turning.

7. Apply silicone gasket material to the mounting surface of the housing where the carrier fastens.

⚠ CAUTION

Do not use a hammer or a mallet to install the differential carrier. A hammer or a mallet will damage the mounting flange of the carrier and cause oil leaks.

8. Install the differential carrier into the axle housing, using a hydraulic roller jack or a lifting tool.

NOTE: Do not tighten the fasteners to the specified torque.

9. Install the nuts and the washers or the capscrews and the washers in the four corner locations around the differential carrier and the axle housing, and tighten the fasteners by hand. See **Fig. 9** and **Fig. 15**.

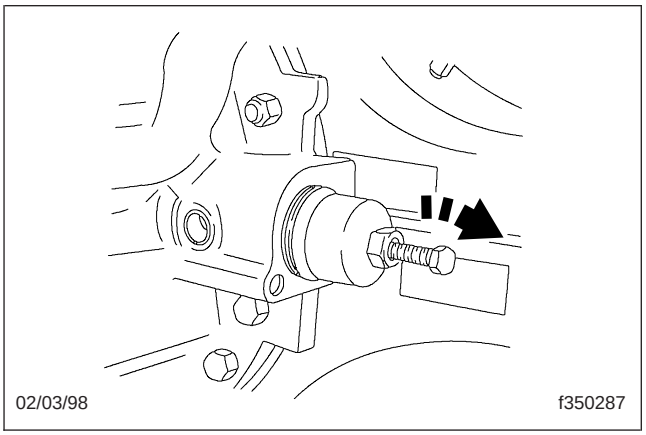


Fig. 14, Manual Procedure for Installing Shift Cylinder

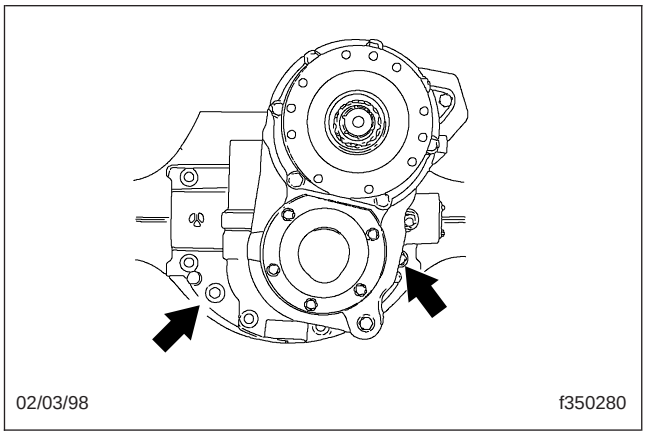

Fig. 15, Differential Carrier Installation

Differential Carrier Removal and Installation

10. Push the differential carrier into position and tighten the four fasteners two or three turns each in a pattern opposite each other.
11. Continue tightening in a pattern opposite each other until the four fasteners are tightened to specification. See **Fig. 9** and **Fig. 15**.
12. Install the remaining fasteners and washers that retain the carrier in the axle housing and tighten the fasteners. See **Fig. 16**.

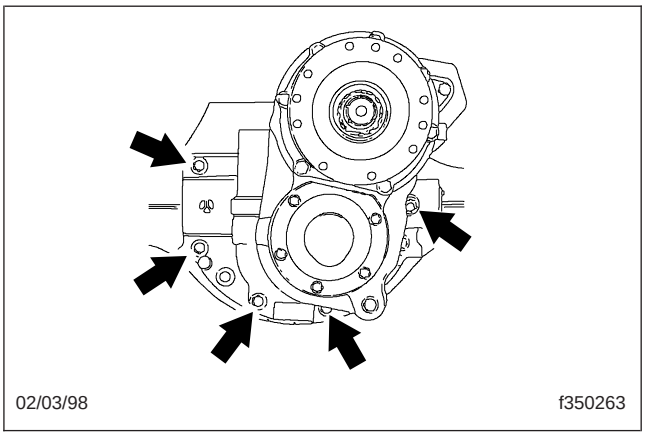

Fig. 16, Install Remaining Fasteners

13. If air pressure was used to engage the differential, release the air pressure from the differential lock and disconnect the auxiliary air supply.

NOTE: When the manual engaging capscrew is removed from the service position in the actuator, the main differential lock becomes disengaged.

14. Remove the manual engaging capscrew from its service position. See **Fig. 17**.
15. Clean the cylinder cover and threaded hole in the center of the cylinder cover. See **Fig. 18**.
16. Install the manual engaging capscrew into its storage position. See **Fig. 19**.

NOTE: The gasket and the flange of the axle shaft must fit flat against the wheel hub.

17. Install the gaskets and the axle shafts into the axle housing and the carrier. See **Fig. 20**.

NOTE: If necessary, use a hammer and a punch or a drift to install the dowels.

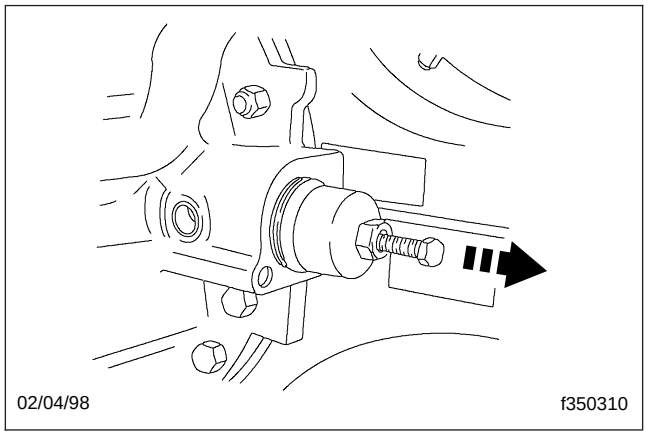

Fig. 17, Manual Engaging Capscrew Removal

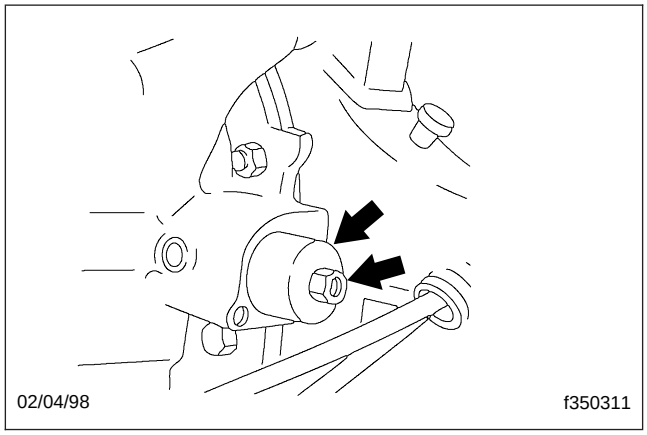

Fig. 18, Cleaning Cylinder Cover

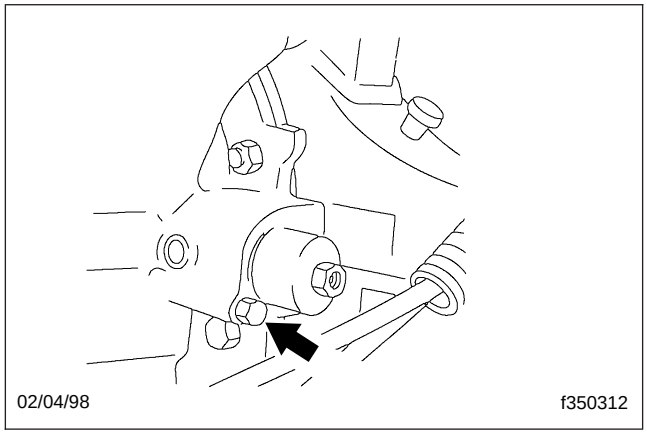

Fig. 19, Manual Engaging Capscrew Installation

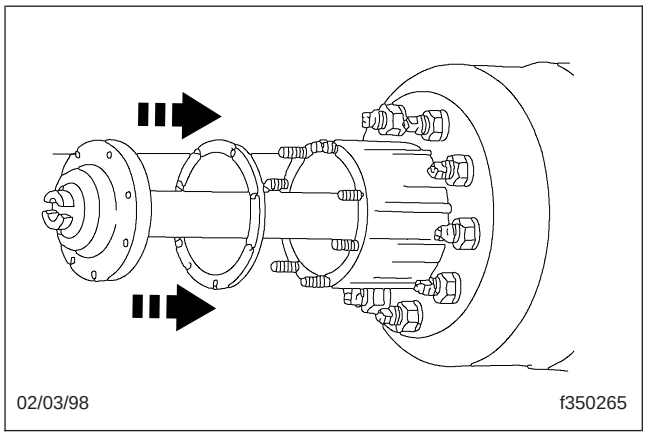

Fig. 20, Gaskets and Axle Shafts Installation

18. Install the tapered dowels, if so equipped, at each stud and on the flange of the axle shaft. See **Fig. 21**.

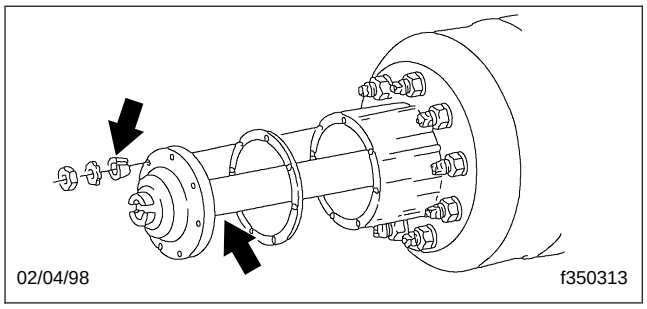

Fig. 21, Tapered Dowels Installation

19. Install the nuts or capscrews and the washers, as equipped, and tighten the nuts to specification. Refer to **Specifications, 400**. See **Fig. 22**.

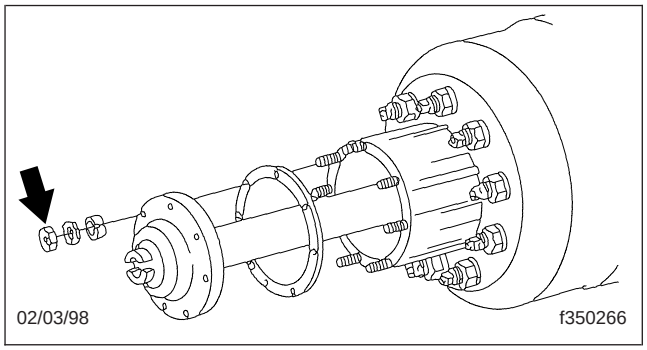

Fig. 22, Nuts or Capscrews Installation

20. Install the gasket between the through-shaft bearing retainer and the axle housing.
21. Position the through-shaft and bearing retainer assembly in the axle housing and rotate the through-shaft to align the splines of the through-shaft with the splines of the rear side gear.
22. Install the washers and the capscrews that fasten the output bearing retainer to the axle housing, and tighten the capscrews 35 to 50 lbf·ft (47 to 68 N·m). See **Fig. 23**.

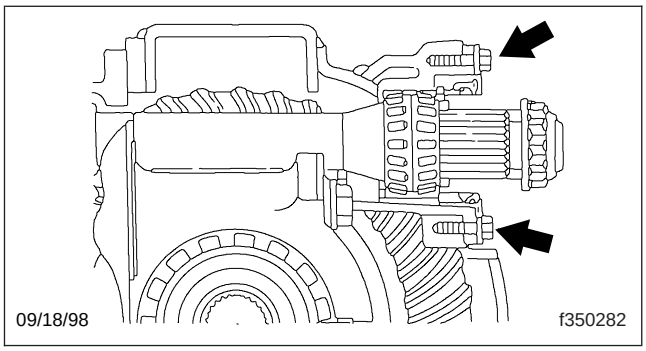

Fig. 23, Output Bearing Retainer Installation

23. Install the output shaft nut, washer, and yoke and tighten the nut 450 to 600 lbf·ft (610 to 813 N·m). See **Fig. 24**.

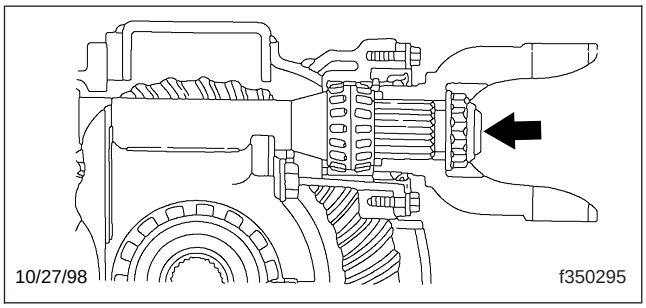

Fig. 24, Output Shaft Yoke Installation

NOTE: The movement of the shift fork is controlled by the adjusting screw for the air shift cylinder.

24. Loosen the jam nut on the adjusting screw and loosen the adjusting screw so that the screw does not touch the shift shaft when the shift collar engages the inter-axle differential case. See **Fig. 25**.
25. Apply and hold the specified air pressure to the shift cylinder so that the shift collar engages the splines in the inter-axle differential case.

Differential Carrier Removal and Installation

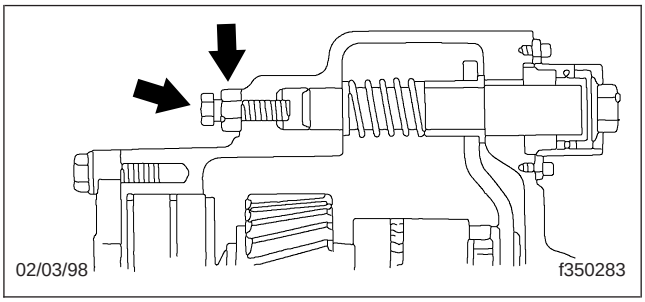

Fig. 25, Adjusting Screw Jam Nut

Air pressure must be held until after the jam nut is tightened. See **Fig. 26**.

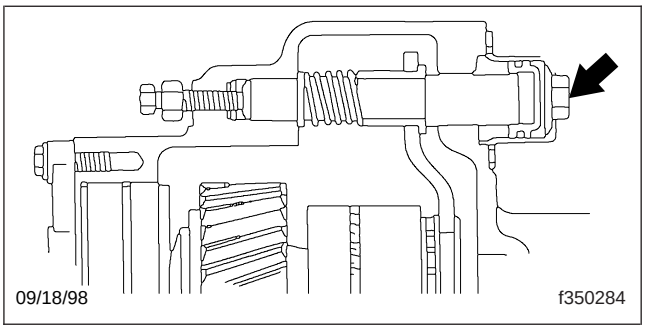

Fig. 26, Apply Air Pressure Here

26. Tighten the adjusting screw until the tip of the screw touches the end of the shift shaft.

    When the screw touches the shaft, tighten the adjusting screw an additional 1/4-1/2 turn. See **Fig. 27**.

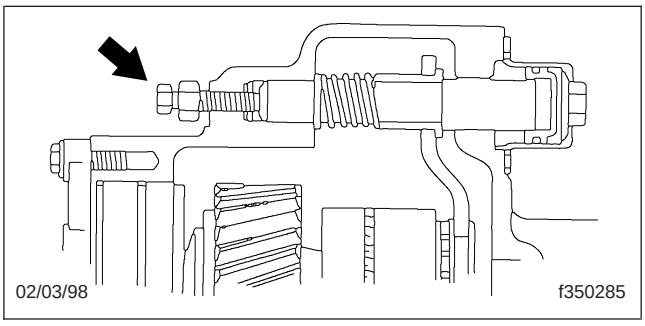

Fig. 27, Adjusting Screw

27. Release the air pressure.
28. Check that the inter-axle differential is disengaged by holding the input yoke or flange and rotating the output yoke or flange, which must rotate freely.
29. Apply and hold the specified air pressure to the shift collar to make sure the shift collar engages the splines in the inter-axle differential case.

    29.1 When the input yoke or flange is rotated, the output yoke or flange must rotate.

    29.2 Release the air pressure.
30. Apply a rust prevention oil such as Meritor Part Number 1199–U–1113 or equivalent to the inlet of the air cylinder.
31. Connect the driveshafts to the input and the output yokes or flanges.
32. Connect the air hoses to the air cylinder for the inter-axle differential lock and (if used) the main differential lock shift unit.
33. Connect the electrical connector of the sensor unit for axles equipped with a main differential lock.

NOTE: Apply Stud and Bearing Mount EOAZ–19554–BA or equivalent meeting Sterling specification WSK–M2G349–A1 to the bore in the carrier for the adapter.

34. Install the adapter for the oil filter on the differential carrier, if removed and tighten the adapter to specification.

IMPORTANT: If the oil filter is tightened more than 3/4 turn after it touches the carrier, the oil filter will be damaged and will leak fluid.

NOTE: Lubricate the gasket of the new oil filter with the lubricant that is used in the axle housing.

NOTE: If necessary, use an oil filter wrench to tighten the filter.

35. Install the oil filter on the adapter and tighten the oil filter 3/4 turn after the gasket on the filter touches the differential carrier.
36. Install the oil filter shield to the input bearing retainer, if so equipped. See **Fig. 28**.
37. Install the axle drain plug and tighten. See **Fig. 29**.
38. Fill the axle with the specified lubricant.
39. Check the operation of the main differential lock, if used.

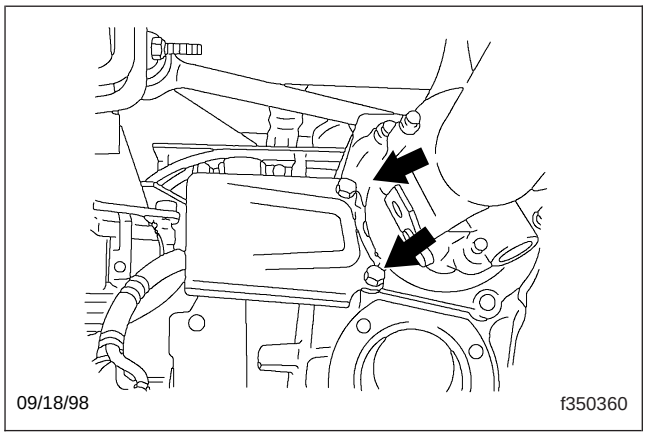

Fig. 28, Install the Oil Filter Shield to the Input Bearing Retainer

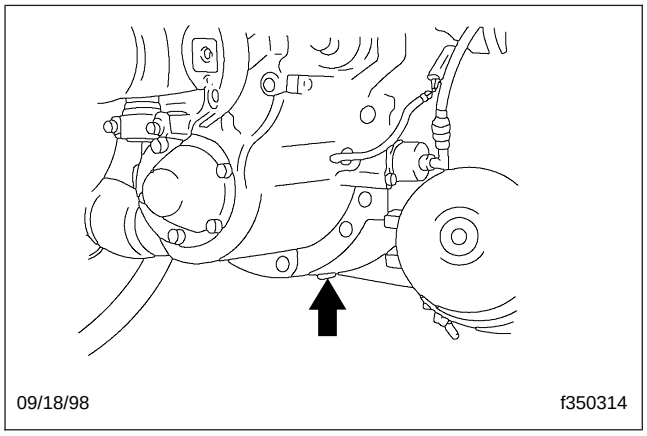

Fig. 29, Install Axle Drain Plug

Driver-Controlled Differential Lock Air Pressure Engagement Procedure

Engagement Procedure

NOTE: The Meritor carrier models with driver-controlled differential lock equipment are manufactured in metric dimensions and sizes. When these carriers are repaired, it is important to use the correct metric size tools on the fasteners.

NOTE: If the axle shafts were removed for towing with the differential in the unlocked (disengaged) position, install the right-hand axle shaft into the housing before continuing.

NOTE: Before the differential carrier can be removed or installed, the differential lock must be shifted into and held in the locked (engaged) position. The locked position gives enough clearance between the shift collar and the axle housing to permit the removal or installation of the carrier.

NOTE: To shift into the locked position, use either the following air pressure method or the manual engaging method.

1. Remove the drain plug from the bottom of the housing and drain the lubricant. See **Fig. 1**.

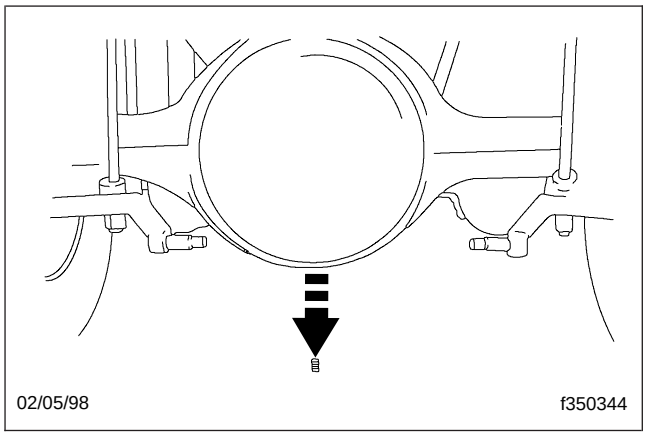

Fig. 1, Drainplug Removal

⚠ WARNING

Do not start the vehicle engine and engage the transmission with one wheel raised from the floor. When the differential is in the locked (engaged) position, power will go to the wheel on the floor and cause the vehicle to move, possibly causing personal injury and property damage.

2. Raise the right-hand wheel of the drive axle off the floor with a hoist or jack.

⚠ WARNING

Do not work under a vehicle supported only by jacks. Jacks can slip or tip over and cause personal injury and property damage.

3. Put a jack stand under the right-hand spring seat to hold the vehicle in the raised position.
4. Disconnect the driveshaft from the pinion input yoke. See **Fig. 2**.

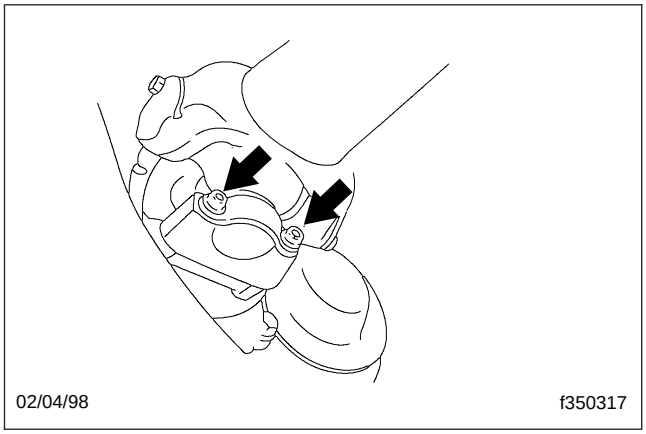

Fig. 2, Disconnect the Driveshaft

5. Disconnect the vehicle air line from the differential lock actuator assembly. See **Fig. 3**.

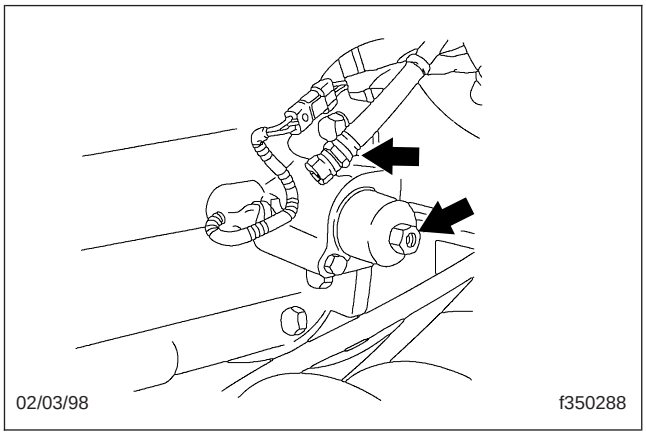

Fig. 3, Disconnect Vehicle Air Line from Differential Lock Actuator Assembly

Driver-Controlled Differential Lock Air Pressure Engagement Procedure

6. Remove the sensor switch.

NOTE: If an auxiliary air supply is not available, refer to **Subject 140**.

7. Connect an auxiliary air supply to the differential lock actuator assembly.

NOTE: The air pressure will move the shift collar to engage with the splines on the differential case half and lock the assembly.

8. Apply and hold air pressure to the actuator assembly.
9. Make sure that the shift collar has moved the full distance on the splines of the differential case half.
    - 9.1 Rotate the drive pinion or the right-hand wheel until the right-hand wheel makes one complete rotation (forward or backward).
    - 9.2 Continue to hold the main differential in the locked position with air pressure until the carrier assembly is completely removed from the axle housing.

Engagement Procedure

NOTE: If an auxiliary air supply is not available or if the differential carrier is to be stored for later use, use this manual engaging method.

1. Remove the manual engaging capscrew from the storage hole in the cylinder cover.

⚠ CAUTION

Do not turn the capscrew beyond its normal stop as damage to cylinder cover may occur.

2. Install the manual engaging capscrew into the threaded hole in the center of the cylinder cover and turn the manual engaging capscrew to the right until it stops turning. See **Fig. 1**.

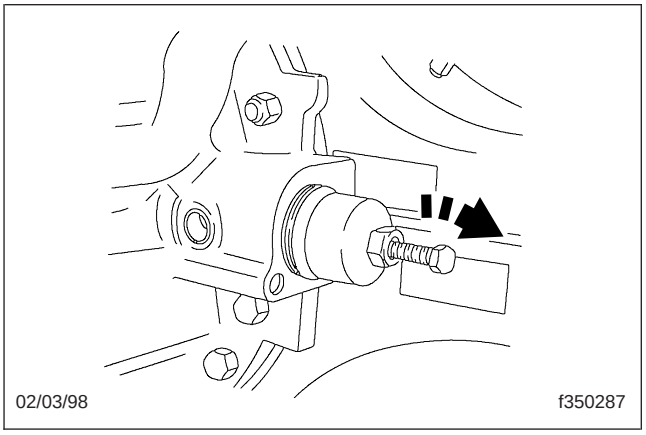

Fig. 1, Turning the Capscrew

NOTE: A high resistance on the capscrew indicates that the splines of the shift collar and the differential case half are not aligned or engaged.

3. Rotate the drive pinion or left-hand wheel to align the splines of the shift collar and case half while turning in the manual engaging capscrew.

Differential Shift Assembly Removal and Installation

Removal

NOTE: Install the differential shift assembly after the differential carrier is assembled and the gear and bearing adjustments are made. Parts of the shift assembly are shown.

NOTE: Release the differential lock if it is manually engaged.

1. Remove the differential lock sliding shift collar by tapping out the two retainer roll pins until they are level with the inner face of the shift fork.
2. Remove the sensor switch. See **Fig. 1**.

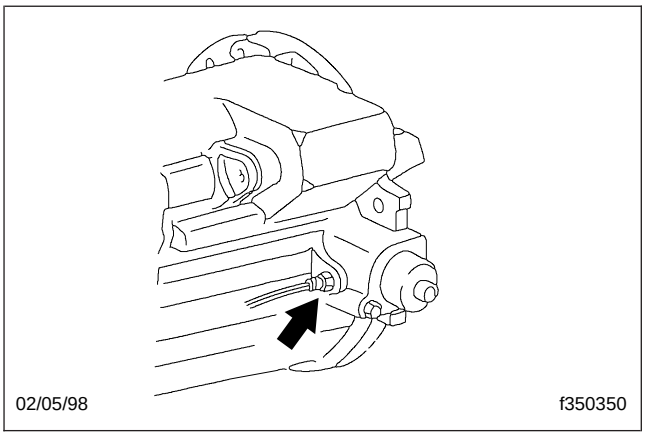

Fig. 1, Sensor Switch

NOTE: The piston will come off with the shift unit cover.

3. Remove the shift unit cover and the piston. See **Fig. 2**.
4. Remove the shift shaft. See **Fig. 3**.
5. Remove the O-ring from the piston.
6. Remove the shift fork. See **Fig. 4**.

Installation

1. Install the two roll pins into the ends of the shift fork.

   Tap the pins into position until they are level with the inner yoke faces.
2. Position the shift fork in the carrier case. See **Fig. 4**.

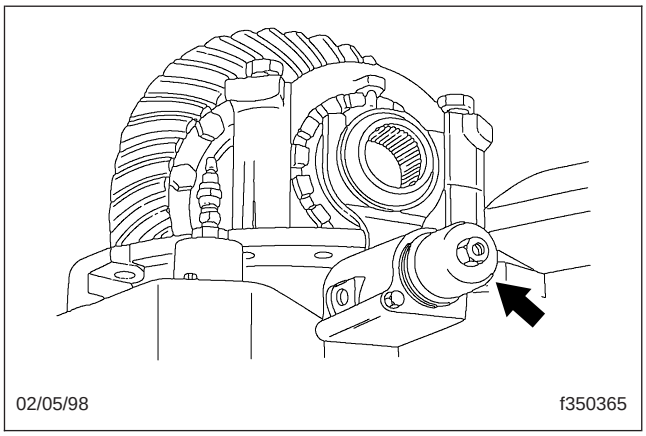

Fig. 2, Shift Unit and Cover

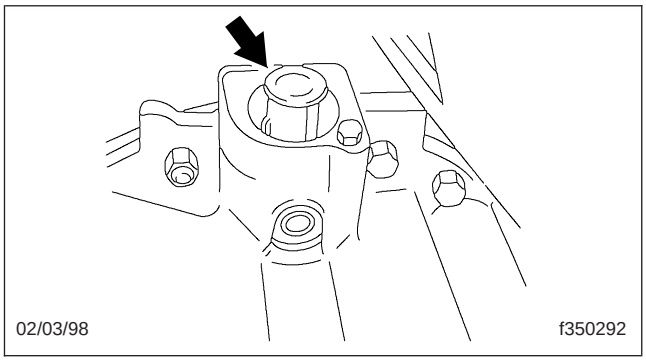

Fig. 3, Shift Shaft

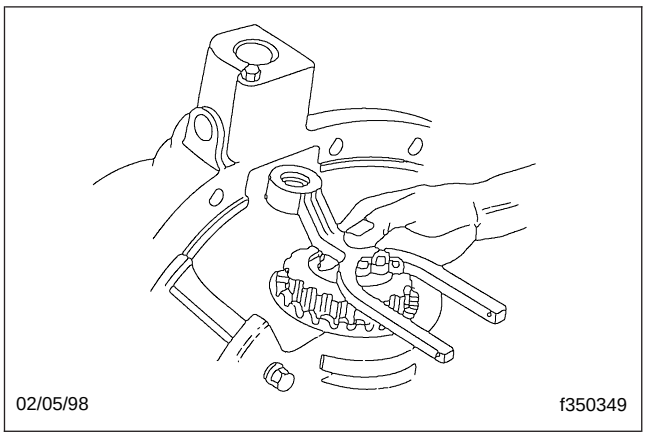

Fig. 4, Shift Fork

3. Install the shift shaft into the shift fork. See **Fig. 3**.

NOTE: Lubricate the O-ring with axle lubricant.

4. Install the O-ring into its groove on the piston.

Differential Shift Assembly Removal and Installation

5. Install the piston into the shift cover. See **Fig. 5**.

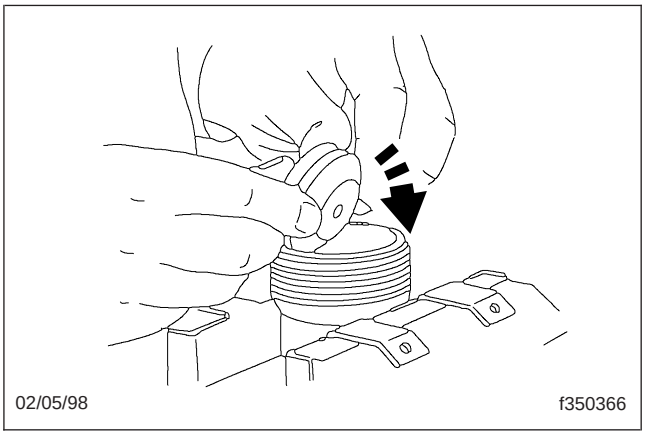

Fig. 5, Piston into Shift Cover Installation

NOTE: Make sure the pilot journal on the piston is against its bore on the shift shaft.

6. Install the shift cover into the housing bore. See **Fig. 6**.

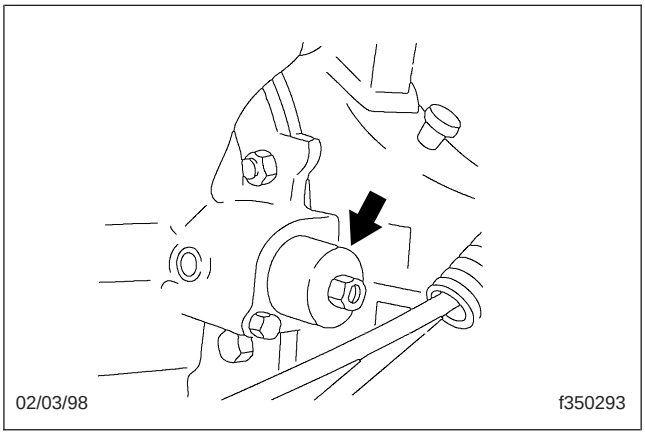

Fig. 6, Shift Cover into the Housing Bore Installation

NOTE: Use the manual engaging capscrew to move the shift collar splines into the differential case splines. Refer to **Subject 140**.

7. Slide the shift collar into the fork and engage the shift collar splines with the splines of the differential case.
8. Hold the shift collar in the locked (engaged) position and tap in the two roll pins in the shift fork ends until they are level with the outer yoke faces.
9. While the shift collar is still in the locked position, put the sensor switch into its hole. See **Fig. 1**.
10. For carriers without the differential lock (Less Air Shift), install the washer and plug into the hole for the sensor switch and tighten the plug.

Main Differential Case and Ring Gear Assembly Removal and Installation

Removal

1. Move the carrier so the ring gear is toward you.
2. Use a punch and a hammer to mark the position of the bearing caps on the legs of the differential carrier. See **Fig. 1**.

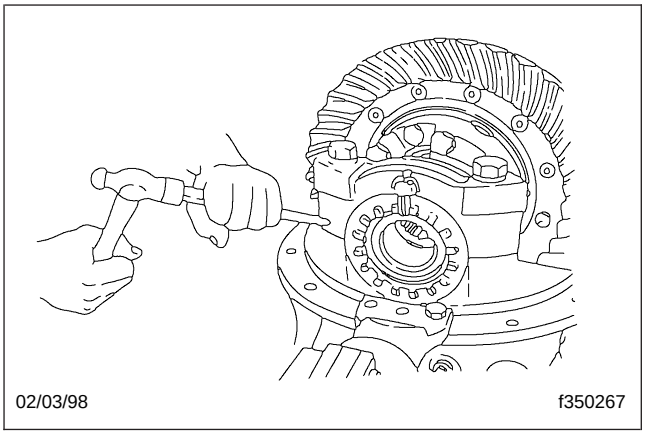

Fig. 1, Marking Position of Bearing Caps

3. Use a hammer and a drift to remove the adjusting ring lock pins on the bearing caps. See **Fig. 2**.

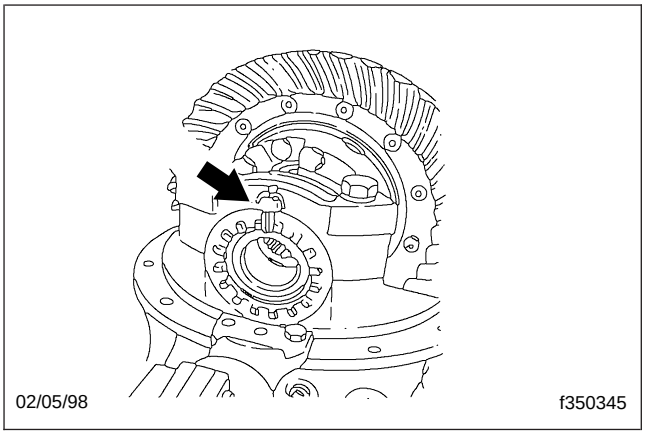

Fig. 2, Removing Adjusting Ring Lock Pins

CAUTION

Do not hit the adjusting ring with a hammer. Do not use a hammer and a drift to loosen the adjusting rings. These methods damage the adjusting rings.

4. Use a T-bar wrench tool to loosen the adjusting rings, but do not remove the adjusting rings.
5. Remove the capscrews and the washers retaining the bearing caps to the legs of the differential carrier.

IMPORTANT: Each bearing cap must be installed on the carrier leg from which it was removed. The cap is matched to the carrier leg before removal. Do not mix bearing caps on carrier legs.

6. Remove the bearing caps, the adjusting rings and the bearing cups from the differential carrier. See **Fig. 3**.

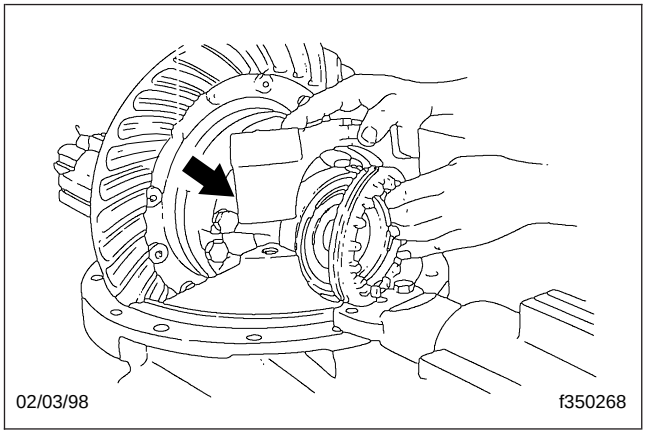

Fig. 3, Remove Bearing Caps, Adjusting Rings and Bearing Cups

7. Use the endless lifting sling to remove the main differential case and ring gear assembly from the differential carrier. See **Fig. 4**.

NOTE: If either the bearing cup or the cone needs to be replaced, both parts must be replaced in a set from the same manufacturer.

The bearing cones are not interchangeable.

8. Use a suitable bearing puller to remove the cones if the bearing cones on the main differential case need to be replaced.

Installation

NOTE: Use a press and a sleeve to install the cones on the case. Press on the inner race of the bearing.

Main Differential Case and Ring Gear Assembly Removal and Installation

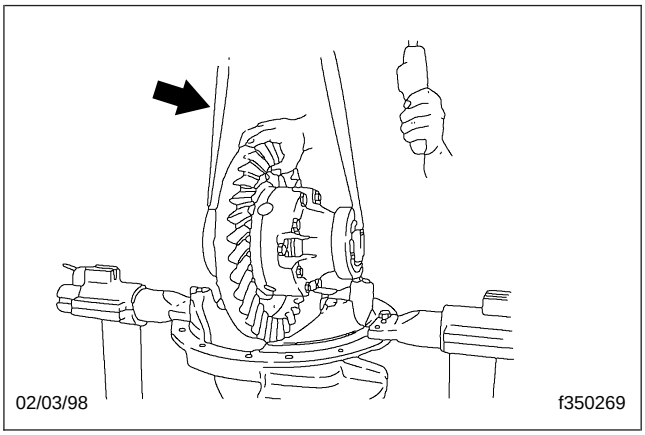

Fig. 4, Main Differential Case and Ring Gear Removal

1. Install a new cone and cup in a set from the same manufacturer if the bearing cones on the main differential case were removed. See **Fig. 5**.

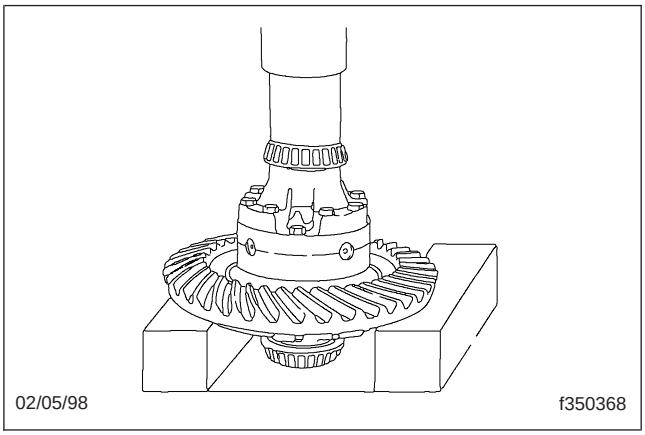

Fig. 5, New Cone and Cup Installation

2. Clean and dry the bearing cups and bores of the carrier legs and bearing caps.
3. Lubricate the bearing cups and cones with the lubricant used in the axle housing.
4. Apply Stud and Bearing Mount EOAZ–19554–BA or equivalent meeting Sterling specification WSK–M2G349–A1 in the bearing bores of the carrier legs and bearing caps.
5. Install the cups over the bearing cones. See **Fig. 6**.

NOTE: The bearing cups must be flat against the bores between the carrier legs.

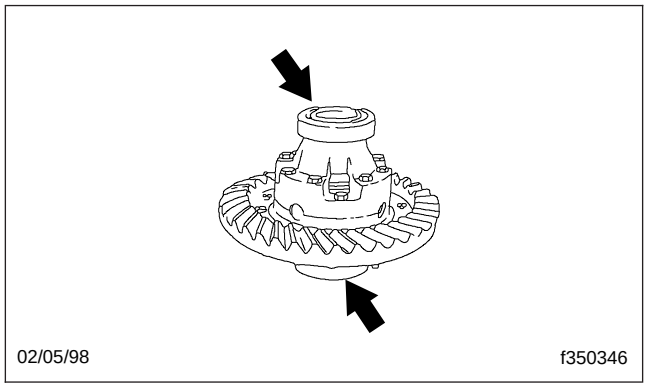

Fig. 6, Bearing Cone Installation

6. Using endless lifting sling, lift the main differential case and ring gear assembly, and install in the carrier.
7. Install both of the bearing adjusting rings into position between the carrier legs and turn each adjusting ring hand-tight against the bearing cup. See **Fig. 7**.

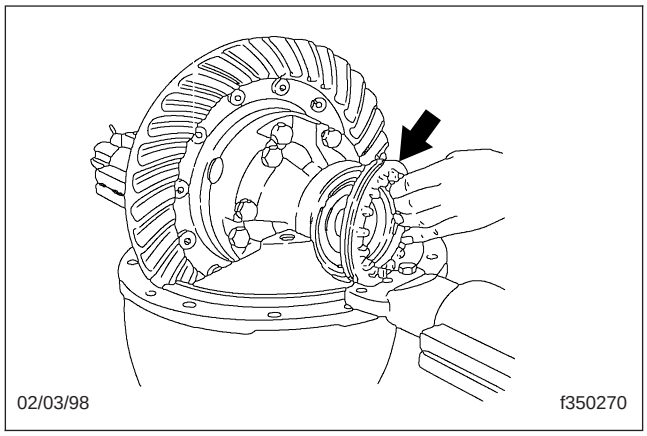

Fig. 7, Bearing Adjusting Rings Installation

8. Install the bearing caps over the bearings and adjusting rings in the correct locations as marked before removal. See **Fig. 8**.

⚠ WARNING

Wear eye protection. Do not hit steel parts with a steel hammer. Parts or tools can break and cause injury.

Main Differential Case and Ring Gear Assembly Removal and Installation

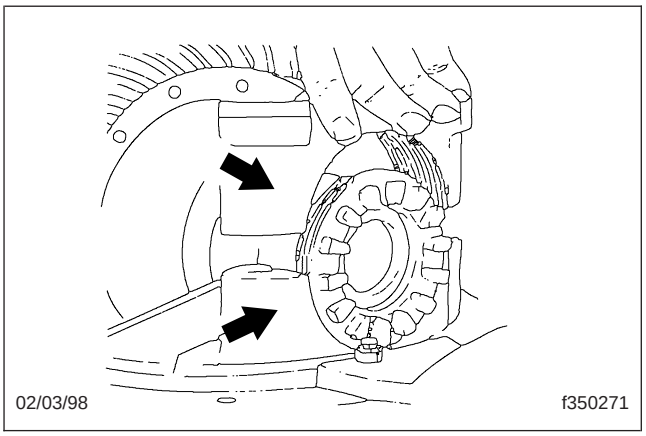

Fig. 8, Install Bearing Caps Over Bearings and Adjusting Rings as Marked at Removal

⚠ CAUTION

The bearing caps must be correctly installed and fit easily against the bearings, adjusting rings and carrier, or the adjusting rings will be damaged by cross-threading. Forcing the caps into position damages the caps and the carrier housing.

9. Hit each bearing cap into position with a light leather, plastic or rubber mallet. See **Fig. 9**.

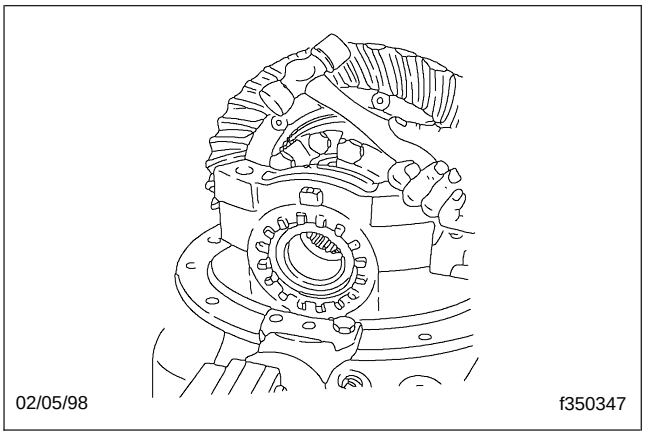

Fig. 9, Bearing Cap Installation

10. Install the capscrews and washers that retain the bearing caps to the carrier.

NOTE: The lock pins for the adjusting rings are installed after the tooth contact pattern is checked.

11. Tighten the capscrews by hand four to six turns and then, tighten the capscrews to the specification shown in the illustration for the appropriate axle model. See **Fig. 10**.

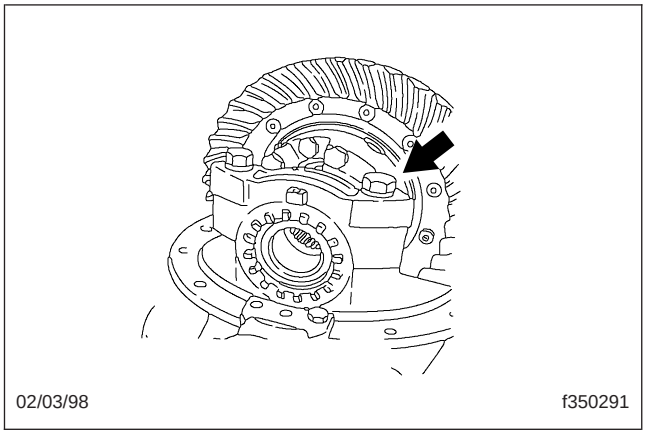

Fig. 10, Tighten the Capscrews

12. Adjust preload on the differential side gear bearings.
13. Check the ring gear runout.
14. Adjust the ring gear backlash.

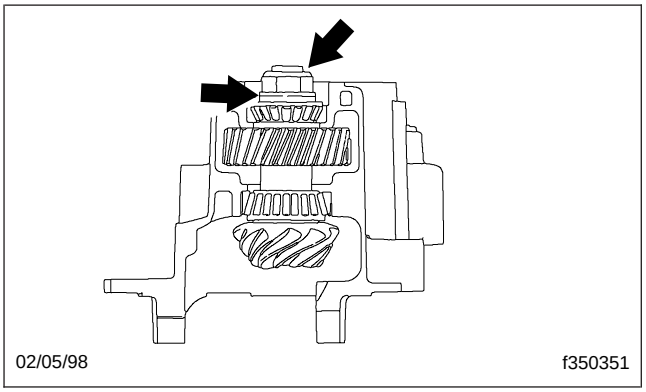
Adjustment

NOTE: If the depth of the drive pinion was changed, then the amount of the change must be added or subtracted to the size of the spacer between the outer bearing cup and the helical driven gear.

NOTE: After the correct gear tooth contact pattern is obtained and the correct thickness of the shim pack behind the pinion inner bearing cup is installed, the bearing preload on the drive pinion is adjusted.

NOTE: The preload on the inner and outer bearings of the drive pinion is controlled by a spacer between the helical driven gear and the outer bearing. Preload is adjusted by replacing the spacer between the helical driven gear and the outer bearing. The spacer between the helical driven gear and the outer bearing is available in different sizes. The spacer between the inner bearing and the helical driven gear is available in only one size.

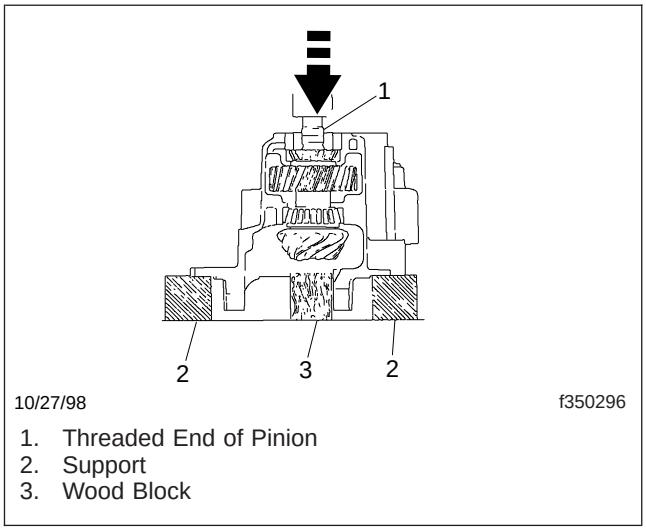
1. Check and record the backlash of the ring gear.
2. Remove the main differential case and ring gear assembly from the differential carrier.
3. Remove the nut and the washer from the drive pinion. See **Fig. 1**.



02/05/98 f350351

Fig. 1, Remove the Drive Pinion Nut and Washer

4. Put the drive pinion in a press. Press the drive pinion out of the outer bearing cone and remove the cone. See **Fig. 2**.



10/27/98 f350296

1. Threaded End of Pinion
2. Support
3. Wood Block

Fig. 2, Pressing Drive Pinion Out of the Outer Bearing Cone

4.1 Position the carrier in a press so that the threaded end of the pinion is toward the top of the press.

4.2 Position supports under the flange of the carrier so that the carrier is level.

4.3 Place a wood block under the head of the pinion.

5. Turn the carrier over so that the legs of the carrier are toward the top of the press. Position supports under the carrier so that the carrier is level.

NOTE: Make sure to position the helical driven gear in the pinion bore.

NOTE: Make sure the splines inside the gear are toward the front of the carrier.

6. Place the large spacer on top of the helical driven gear so that the spacer is toward the rear bearing cup. See **Fig. 3**.

NOTE: Make sure the splines on the pinion engage the splines inside the gear.

7. Install the drive pinion in the helical driven gear. See **Fig. 4**.

Bearing Preload Adjustment on Drive Pinion

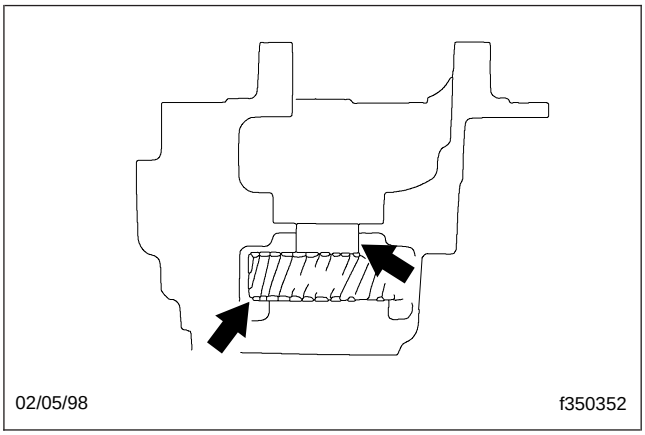


Fig. 3, Large Spacer on Top of the Helical Driven Gear

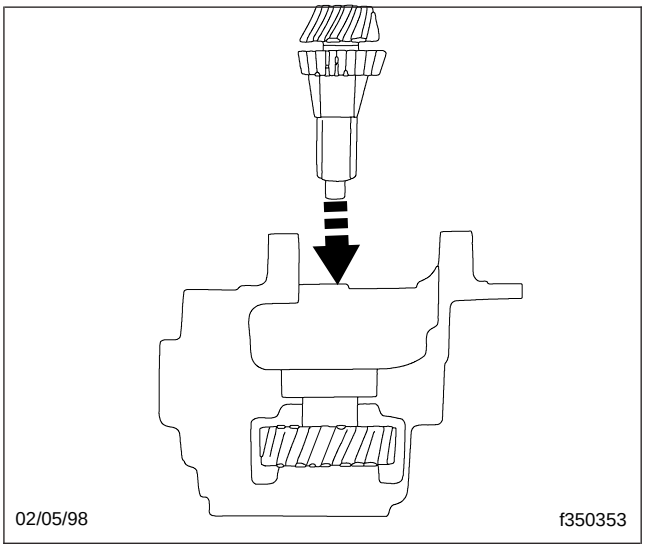

Fig. 4, Drive Pinion in the Helical Driven Gear Installation

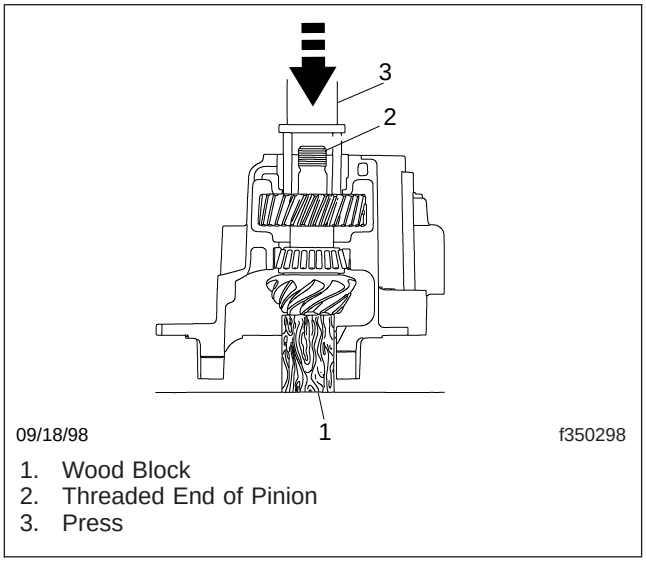
⚠ CAUTION

Do not apply pressure after the inner bearing cone touches the inner bearing cup. If pressure is applied, the cup, cone and drive pinion will be damaged.

NOTE: At this time, the helical driven gear will not be completely installed on the drive pinion.

NOTE: The inner bearing cone on the drive pinion must touch the inner bearing cup in the carrier when the helical driven gear is being installed.

8. Install the drive pinion into the carrier. See **Fig. 5**.



1. Wood Block
2. Threaded End of Pinion
3. Press

Fig. 5, Install the Drive Pinion into the Carrier

8.1 Place a wood block under the head of the drive pinion.

8.2 Position the carrier in a press so that the threaded end of the pinion is toward the top of the press.

8.3 Use the press to install the pinion into the carrier so that the inner bearing cone touches the bearing cup.

⚠ CAUTION

Do not apply pressure after the helical driven gear touches the spacer in front of the inner bearing on the drive pinion. If pressure is applied after the parts touch each other, the gear will damage the spacer.

9. Use a press and a sleeve to completely install the helical driven gear on the drive pinion.

   9.1 Use a sleeve on the hub of the gear that fits inside the pinion bore in the carrier.

   9.2 Press the gear on the drive pinion until the gear touches the spacer.

10. Cut two pieces of lead or solder approximately 9/16 inch (14 mm) long and 5/8 inch (16 mm) wide. Use the two pieces of solder or lead as

gauge blocks to determine the correct thickness of the spacer between the helical driven gear and the outer bearing.

11. Position the two pieces of lead or solder so that the pieces are opposite each other on top of the helical driven gear. See **Fig. 6**.

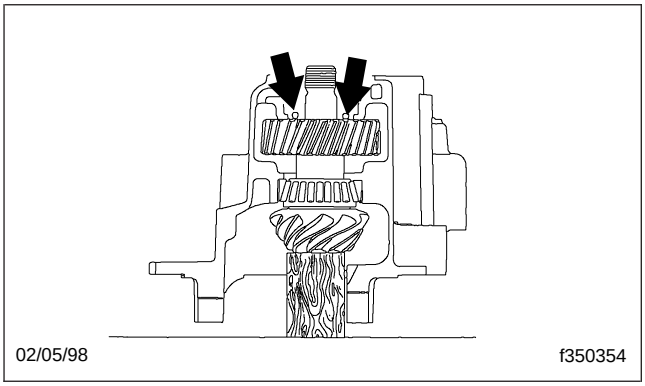


Fig. 6, Two Pieces of Lead or Solder Opposite Each Other On Top of the Helical Driven Gear

12. Place the outer bearing cone in the cup over the two pieces of lead or solder on top of the helical driven gear. See **Fig. 7**.

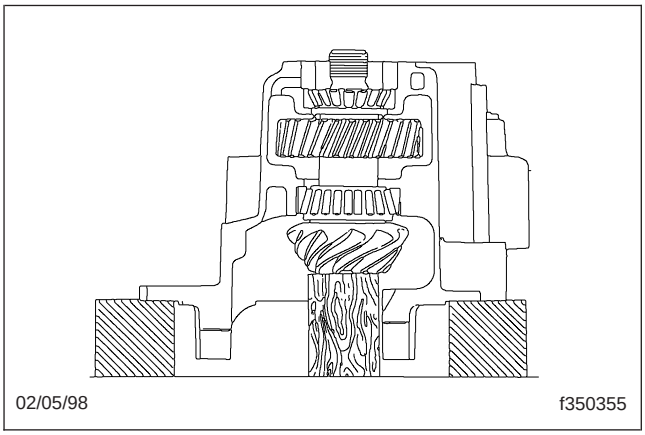

Fig. 7, Outer Bearing Cone In the Cup Over the Helical Driven Gear

⚠ WARNING

Do not apply more than the specified pressure with the press. Excessive pressure may cause damage to components.

13. Place a sleeve on top of the outer bearing cone, and use a press to apply the specified pressure to the outer bearing cone. The pressure of the press compresses the lead or solder pieces to the correct size. See **Fig. 8**.

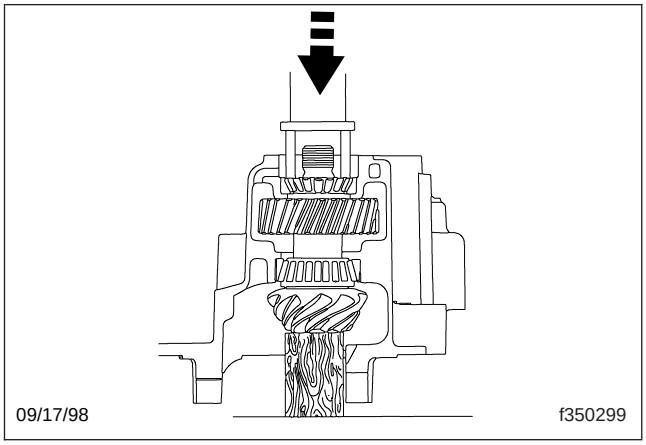

Fig. 8, Compressing the Lead or Solder

14. Release the pressure on the outer bearing cone. Remove the wood block from under the head of the drive pinion.
15. Use a press and a sleeve to press the shaft of the drive pinion out of the outer bearing cone. Do not press the shaft of the drive pinion out of the helical driven gear.
16. Remove the outer bearing cone and the two pieces of lead or solder from the outer bearing cone.

NOTE: If the depth of the drive pinion was changed, the thickness of the spacer that controls the preload of the pinion bearings must be changed by the same amount. If shims were added to increase the depth of the drive pinion, then the total amount of added shims must be added to the size of the spacer. If shims were removed to decrease the depth of the drive pinion, then the same amount of removed shims must be removed from the size of the spacer.

17. EXAMPLE:

    Determined size of the spacer for bearing preload: 0.509 inch (12.926 mm).

    Amount of shims added to increase the depth of the pinion: 0.003 inch (0.076 mm).

    Final size of the spacer for bearing preload: 0.512 inch (12.902 mm).

Bearing Preload Adjustment on Drive Pinion

Determined size of the spacer for bearing preload: 0.509 inch (12.926 mm).

Amount of shims removed to decrease the depth of the pinion: 0.003 inch (0.076 mm).

Final size of the spacer for bearing preload: 0.506 inch (12.850 mm).

Use a micrometer to measure the thicknesses of the compressed pieces of lead or solder. Add the measurements of the two pieces and divide by two to determine the average size of the pieces. Add 0.004 inch (0.100 mm) to the average size. Use this dimension to determine the size of the spacer to install between the helical drive gear and the outer bearing.

Determining Pinion Bearing Preload Spacer Thickness		
Description	**Inch**	**mm**
Thickness of Piece No. 1	0.504	12.800
Thickness of Piece No. 2	0.506	12.852
Total Thickness	1.010	25.652
Divided By 2 to Get the Average Thickness	0.505	12.826
Add 0.004 inch (0.100 mm) to Get the Thickness of the Spacer	0.509	12.926

Table 1, Pinion Bearing Preload Spacer Thickness

NOTE: The inner bearing cone on the drive pinion must touch the inner bearing cup in the carrier when the helical driven gear is being installed.

18. Place a wood block under the head of the drive pinion so that the inner bearing cone on the pinion touches the inner bearing cup in the carrier.

⚠ CAUTION

Do not apply pressure after the helical driven gear touches the spacer in front of the inner bearing on the drive pinion. If pressure is applied after the parts touch each other, the gear will damage the spacer.

19. Use a press and a sleeve to completely install the helical driven gear on the drive pinion. See **Fig. 9**.

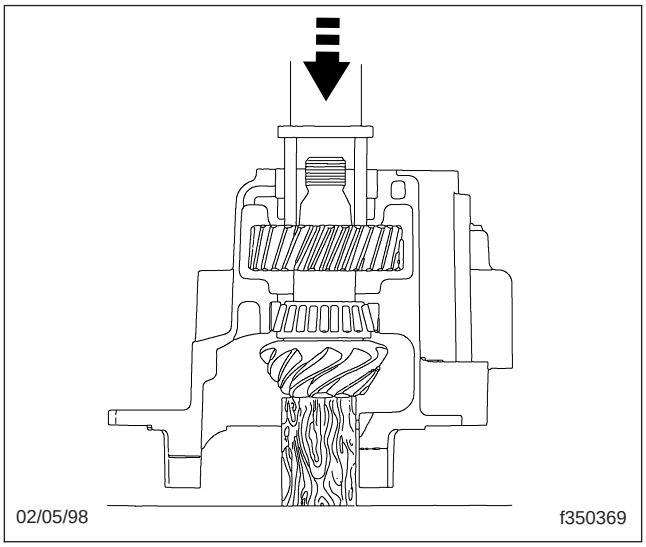

Fig. 9, Helical Driven Gear On the Drive Pinion Installation

19.1 Use a sleeve on the hub of the gear that fits inside the pinion bore in the carrier.

19.2 Press the gear on the drive pinion until the gear touches the spacer.

19.3 Do not remove the wood block at this time.

20. Install the correct size spacer on the shaft on the pinion in front of the helical driven gear. See **Fig. 10**.

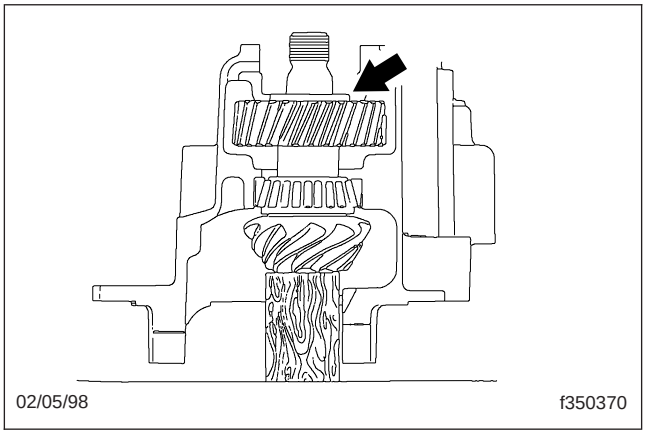

Fig. 10, Install the Correct Size Spacer

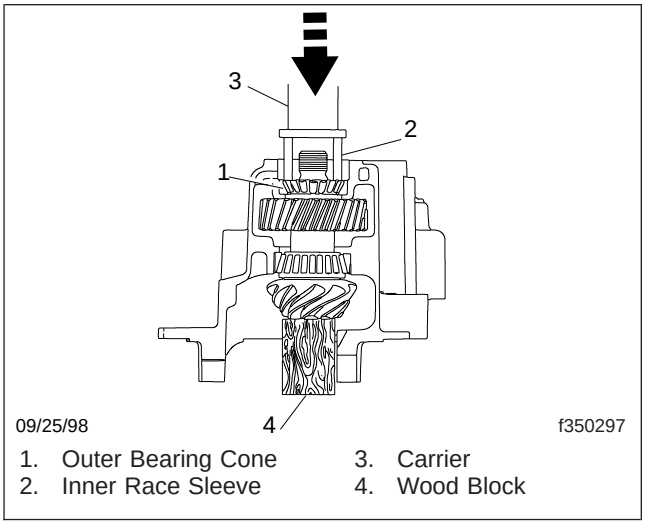
NOTE: Make sure the wood block is still under the head of the drive pinion. The inner bearing cone on the pinion must touch the cup in the carrier.

21. Use the following procedure to install the outer bearing cone on the shaft of the drive pinion. See **Fig. 11**.



1. Outer Bearing Cone
2. Inner Race Sleeve
3. Carrier
4. Wood Block

Fig. 11, Outer Bearing Cone Installation

21.1 Place the outer bearing cone on the shaft of the drive pinion.

21.2 Place a sleeve on the inner race of the outer bearing cone.

21.3 Use a press to apply pressure on the bearing cone to install the cone on the shaft of the drive pinion.

Move the carrier in both directions (so that the carrier pivots on the drive pinion) while the cone is being installed to make sure that the bearing cone is correctly installed.

21.4 Release the pressure on the bearing cone and remove the wood block from under the head of the drive pinion.

22. Remove the carrier from the press, and place the carrier in a suitable stand.

23. Install the washer and the nut on the drive pinion, preventing the drive pinion assembly from rotating by using a fixture to hold the teeth of the helical driven gear or putting wood blocks between the head of the pinion and the carrier wall.

Tighten the nut to 1200 to 1500 lbf·ft (1627 to 2034 N·m), and remove the holding fixture or the wood blocks. See **Fig. 12**.

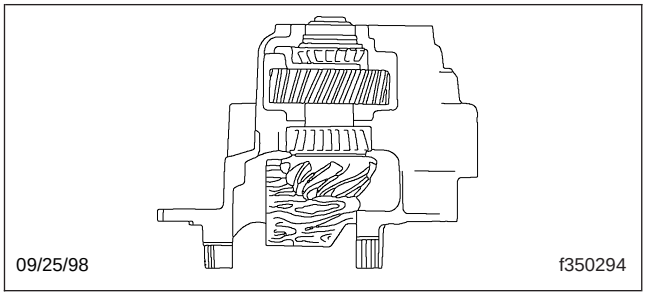


Fig. 12, Tighten the Drive Pinion Nut

NOTE: Use a lbf·in (N·cm) torque wrench or a spring scale to check the preload of the bearings on the drive pinion. If a spring scale is used, go to next step.

24. Place a lbf·in (N·cm) torque wrench and the correct socket on the nut of the drive pinion, and use the torque wrench to rotate the drive pinion assembly. Look at the reading on the torque wrench. See **Fig. 13**.

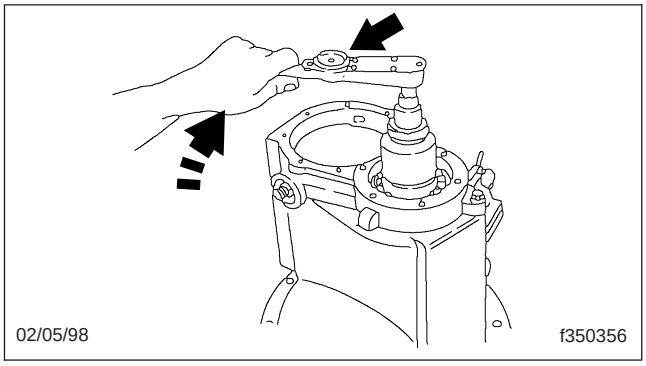

Fig. 13, Turning Torque Check

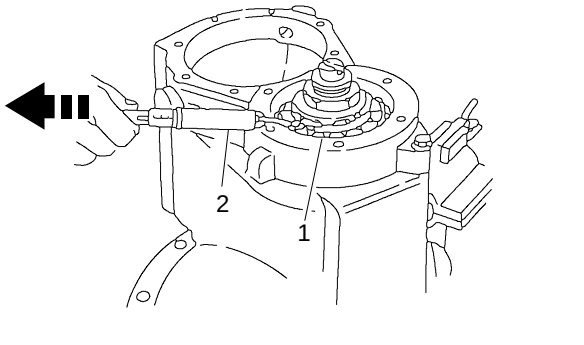
24.1 Record the torque required to rotate the assembly.

24.2 Do not use the torque required to start the rotation.

25. Use the following procedure to check the drive pinion bearing preload with the spring scale. See **Fig. 14**.

25.1 Wind a cord around the washer under the nut f the drive pinion.

Bearing Preload Adjustment on Drive Pinion



1. Cord
2. Spring Scale

Fig. 14, Drive Pinion Bearing Preload Procedure

25.2 Attach the Spring Scale to the end of the cord.

25.3 Pull the spring scale and cord in a horizontal direction while looking at the reading on the spring scale.

26. Calculate the bearing preload (torque) as follows: Pounds pulled x radius (inches) = lbf·in preload, x 0.113 = N·m preload, or kilograms pulled x radius (millimeters) = kg·mm preload, x 0.098 = N·m preload. EXAMPLE: Outer diameter of washer = 3.00 inches (76.20 mm). Spring scale reading = 9 lb (4 kg).

Drive Pinion Bearing Preload Calculation		
Description	**Inch**	**mm**
Outer Diameter of Washer	3.00	76.20
Divide the Outer Diameter By 2 to Get the Radius of the Washer	1.50	38.10
Multiply the Radius of the Washer By the Spring Scale Reading	13.5 lbf·in	152.4 kg·mm
Multiply the Lbf·In Reading By 0.113. Multiply the kg·mm Reading By 0.098 to Get N·m Preload	1.52	14.9

Table 2, Drive Pinion Bearing Preload Calculation

27. The preload of the drive pinion bearings must be within the specified limits. If the preload is not within the specified limits, remove and replace the spacer between the outer bearing assembly and the helical drive gear. See **Fig. 15**.

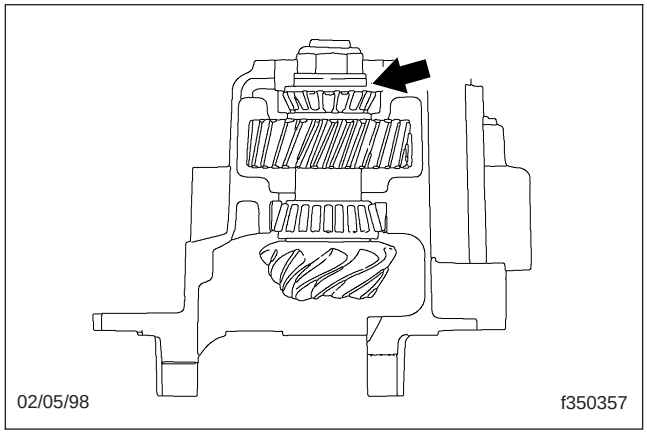


Fig. 15, Outer Bearing Assembly Spacer

27.1 New pinion bearings: 5 to 45 lbf·in (0.56 to 5.08 N·m) rotational torque.

27.2 Used pinion bearings: 10 to 30 lbf·in (1.13 to 3.39 N·m) rotational torque.

27.3 Install a thicker spacer to decrease the preload.

27.4 Install a thinner spacer to increase the preload.

NOTE: Prevent the drive pinion assembly from rotating by using a fixture to hold the teeth of the helical driven gear or by putting wood blocks between the head of the pinion and the carrier wall.

28. Remove the nut and the washer from the shaft of the drive pinion. See **Fig. 16**.

NOTE: Position supports under the flange of the carrier so that the carrier is level. Place a wood block under the head of the pinion. Make sure the wood block does not touch the head of the drive pinion.

29. Position the carrier in a press so that the threaded end of the pinion is toward the top of the press. Press the drive pinion out of the bearing cone and remove the inner bearing cone from the differential carrier. See **Fig. 17**.

30. Install the correct size spacer on the shaft of the pinion over the helical driven gear.

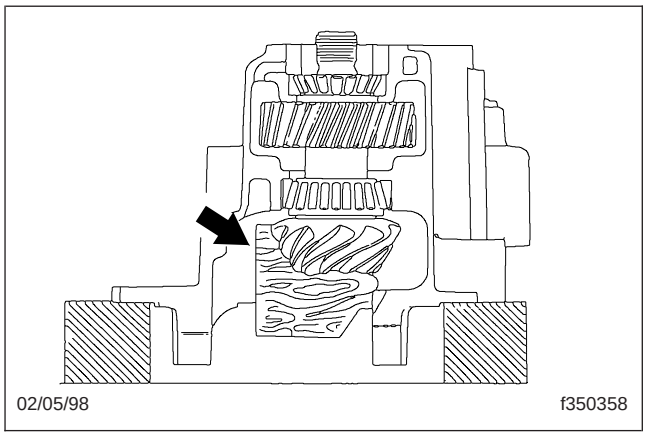

Fig. 16, Drive Pinion Nut and Washer Removal

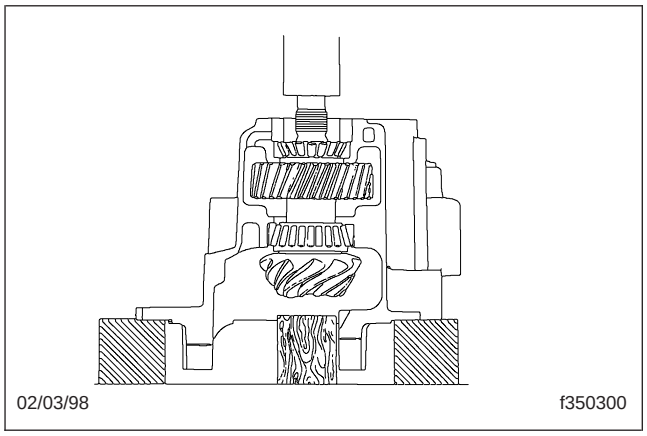

Fig. 17, Removing Drive Pinion from Bearing Cone

31. When the preload is within the specified range, install the main differential case and ring gear assembly in the carrier. Adjust the preload on the main differential bearings and the backlash of the ring gear, and check the contact pattern on the teeth of the ring gear.

Output Bearing End Play

1. Place the through-shaft and the bearing retainer assembly in a vise with soft metal covers on the jaws of the vise. See **Fig. 1**.

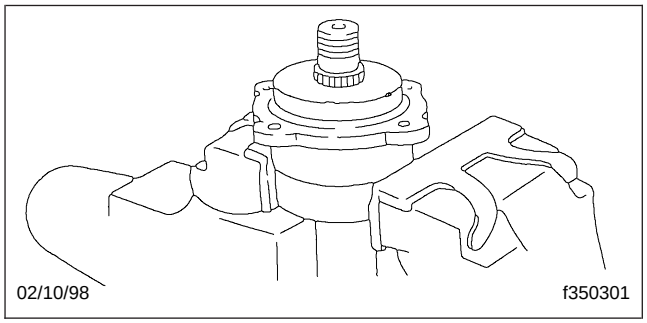

Fig. 1, Through-Shaft and Bearing Assembly

NOTE: Do not install the oil seal at this time.

2. Use a suitable installation tool to install the yoke or flange on the through-shaft. See **Fig. 2**.

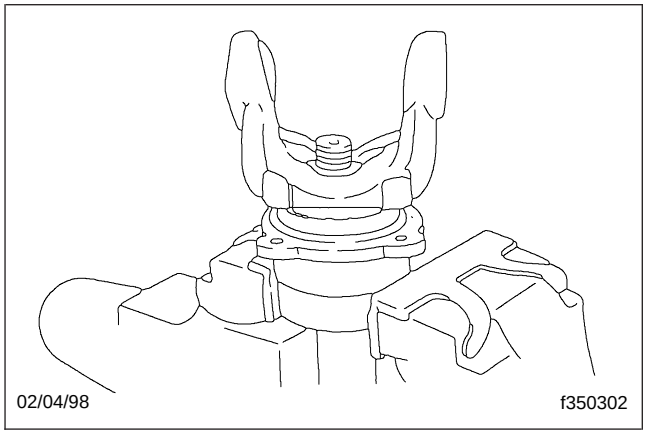

Fig. 2, Yoke or Flange Installation

3. Install the nut that fastens the yoke or flange to the through-shaft. Using a holding tool such as the companion flange holding tool to hold the yoke or flange in a stationary position, tighten the nut. See **Fig. 3**.
4. Push the yoke or flange toward the retainer and rotate the shaft in each direction to make sure that the bearings are correctly installed.
5. Install the dial indicator with bracketry so the base of the indicator is on the mounting flange of the retainer and the pointer of the indicator is touching the yoke or flange end of the through-shaft.

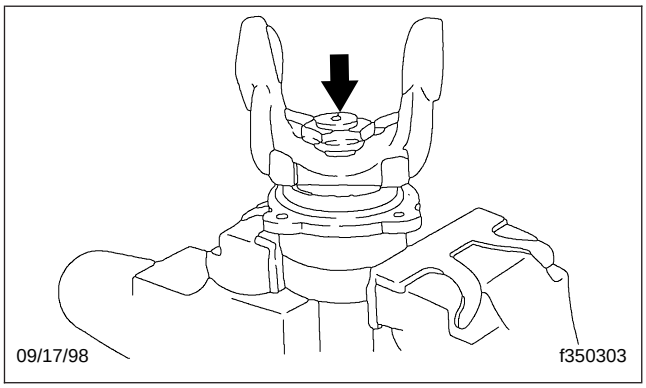

Fig. 3, Yoke or Flange Installation

Adjust the dial indicator to the zero (0) setting. See **Fig. 4**.

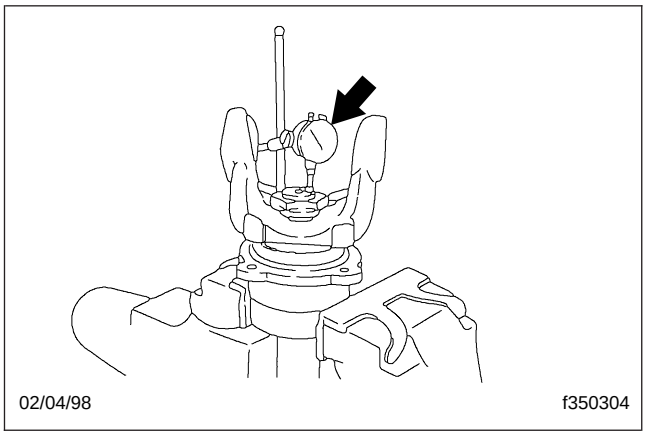

Fig. 4, End Play Check Setup

6. Position pry bars under the yoke or flange and push the yoke or flange away from the retainer. Record the reading on the dial indicator. The reading must be as specified. See **Fig. 5**.
7. Remove the nut that fastens the yoke or flange to the through-shaft.
8. Use a suit able puller tool to remove the yoke. See **Fig. 6**.
9. Remove and replace the snap ring that fastens the bearings in the retainer if the end play reading is not within specification (0.001 to 0.004 inch [0.025 to 0.102 mm]).

Output Bearing End Play

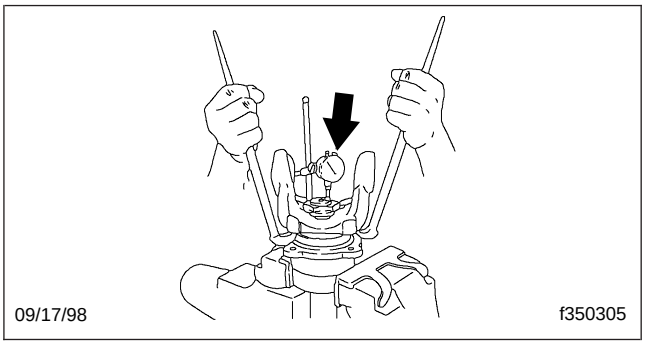

Fig. 5, End Play Specification Check

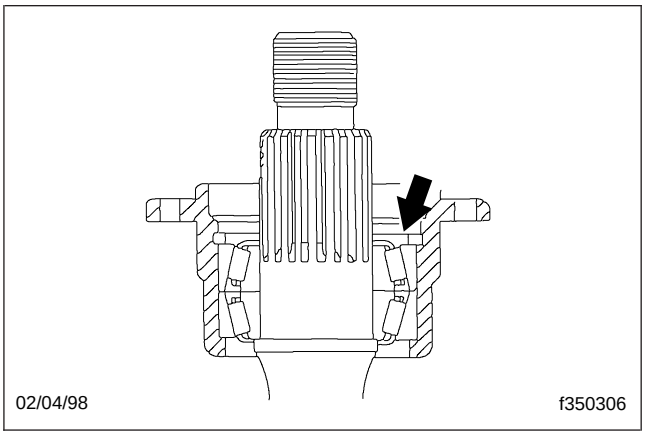

Fig. 6, Bearing Snap Ring

9.1 Install a thinner snap ring to increase end play.

9.2 Install a thicker snap ring to decrease end play.

Ring Gear Backlash

Check the backlash at three places on the ring gear. Record the reading found on the dial indicator. For instructions, refer to **Group 41** in this manual.

Check Rolling Resistance of Side Gears on Main Differential Case

For instructions, refer to **Group 41** in this manual.

Table 3, Torque Specifications

General Information

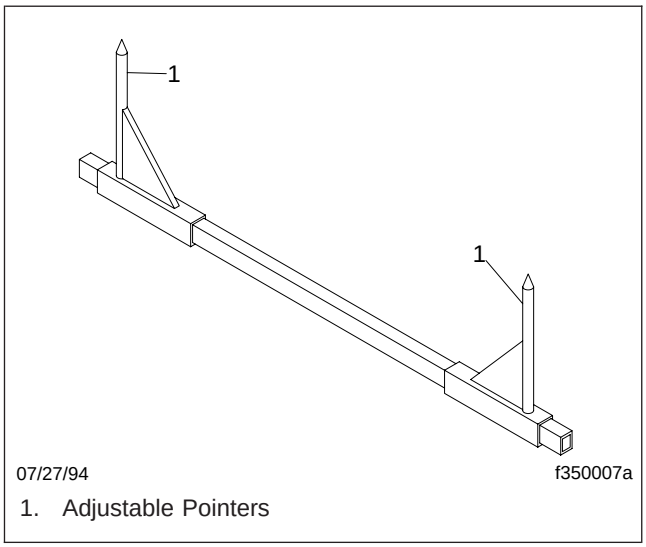
Rear axle alignment should be checked whenever rear axle or suspension components are replaced. It should also be checked when there is excessive front and rear tire wear or hard or erratic steering.

Manufacturers of axle alignment equipment offer a variety of systems to precisely measure and correct rear axle alignment. If this type of equipment is not available, the basic tools needed for checking rear axle alignment on tandem axles are a straightedge (which is nonflexible and at least as long as the axle), a steel tape rule and a center point bar. On single axle vehicles, a straightedge, trammel bar and a steel tape rule are needed.

The straightedge is used to see if a single axle, or a forward-rear axle of a tandem axle installation, is in alignment with the frame. The distance from the straightedge to the center of the wheel hub is measured on each side of the vehicle; any difference in the measurements means that the axle is out of alignment.

The center point bar (see **Fig. 1**) is used to see if the forward-rear axle and rearmost axle of a tandem installation are aligned with each other (parallel). The center point bar has adjustable pointers at each end that are inserted into the axle cap holes of each axle. It can be determined if the axles are parallel by comparing the distance between the two axles on one side to the distance on the other side.

Refer to **Subject 120** for instructions and a list of materials for making the center point bar.



1. Adjustable Pointers

Fig. 1, Center Point Bar

Checking

NOTE: Before checking the axle alignment, make sure the wheel bearings are adjusted. For instructions, refer to **Section 35.00** in this manual. Make sure that no wheel rims are bent and that all rims are correctly seated. Refer to **Group 31** in this manual for instructions on checking the frame rail alignment. Correct the frame rail alignment if necessary.

IMPORTANT: For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Sterling dealers must have proof of this calibration history.

1. Park the vehicle on a level surface. Relieve internal stresses in the suspension by driving the vehicle back and forth in a straight line, or by jacking the axle up and letting it down.
2. Chock the front tires and place the transmission in neutral. Release the parking brakes.

⚠ CAUTION

Do not use scribe lines for marking on frame rails. Scribe lines, which cut or scratch the metal, can develop into starting points for structural damage to the frame.

3. Select a point on the frame rail forward of the rear axle. Using a pencil or soapstone, mark two other points, exactly 4 inches (102 mm) forward and to the rear of the original point. Make sure that all three marks are aligned and of equal distance from the outside edge of the frame rail. Using a trammel bar, place one trammel pointer on the forwardmost point, and make an arc with a pencil or soapstone on the opposite frame rail. Then place the trammel pointer on the rearmost point and make an arc on the opposite frame rail intersecting the first arc. See **Fig. 1**. The point where the two arcs intersect and the original (or middle) point on the opposite frame rail have matching locations.
4. Line up the straightedge with the two matching points. Check that the straightedge extends out about the same distance on each side of the frame rail. Using C-clamps, clamp the straightedge to the frame. See **Fig. 2**. The straightedge must line up exactly with the points.
5. Measuring from the outside edge of each frame rail, mark the straightedge on both sides of the

4. Tape Measure
5. Wheel Hub

Fig. 2, Straightedge to Wheel Hub Measurement

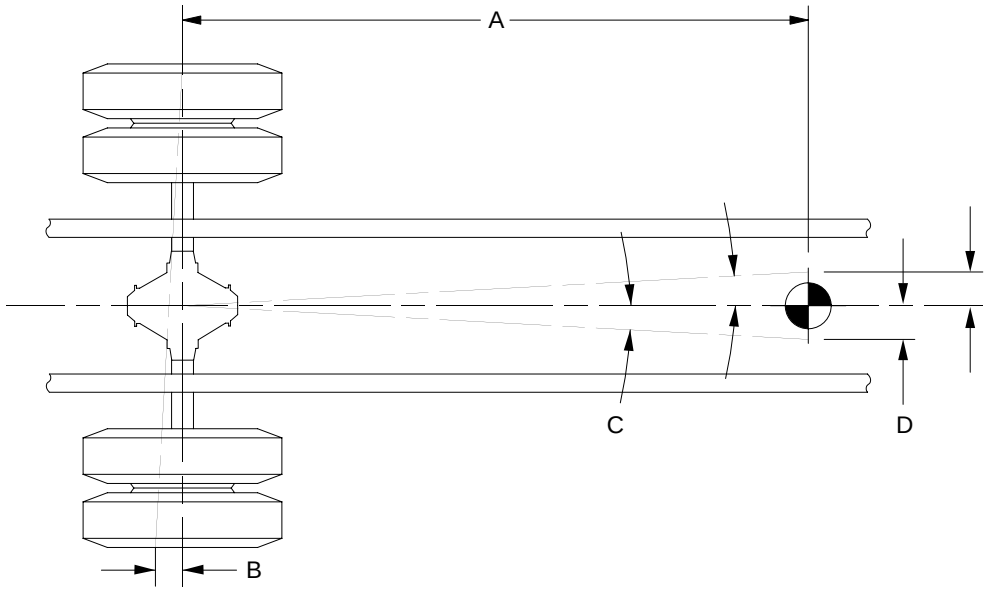
Manual Alignment Checking, Single Axle

frame. Reference "A" (see **Fig. 2**) must be of equal distance from the frame and as far from the frame rail as the tires are at their farthest point from the frame.

IMPORTANT: The distance between the mark on the straightedge and the frame rail must be equal on both sides of the vehicle.

6. On each side of the vehicle, measure the distance from the mark on the straightedge to the center of the wheel hub. See **Fig. 2**.

   The difference between these measurements should be 1/4 inch (6 mm) or less. See **Fig. 3**. If the difference is more than 1/4 inch (6 mm), adjust the axle alignment. For instructions, refer to the applicable suspension section in this manual, or to the suspension manufacturer's service literature.



A. Distance from Rear Axle to Target (using Bee Line alignment tools)
B. Maximum Allowable Difference if Aligned Manually = ±1/4 inch (6 mm)
C. Maximum Allowable Tolerance if Aligned With Hunter Tools = ±0.18 degrees
D. Maximum Allowable Tolerance if Aligned With Bee Line Tools

Fig. 3, Alignment Measurements

Manual Alignment Checking, Tandem Axle

Checking

A straightedge and a center point bar are needed to align a tandem axle. First, a straightedge and trammel bar are used to check and, if needed, align the rearmost axle. Then, the center point bar is used to check and, if needed, align the forward-rear axle.

Refer to **Subject 100** to check and align the rearmost axle. Then, check the alignment of the forward-rear axle as follows:

IMPORTANT: Align the rearmost axle before checking the forward-rear axle.

For vehicle alignment to be accurate, the shop floor must be level in every direction. The turn plates for the front wheels must rotate freely without friction, and the alignment equipment must be calibrated every three months by a qualified technician from the equipment manufacturer. Sterling dealers must have proof of this calibration history.

1. Using the center point bar, set the two points into the axle cap holes. See **Fig. 1**. Lock them in place by tightening the setscrews.
2. With the points still locked in place, move the center point bar to the other side of the vehicle, set the two points into the axle cap holes, and compare the axle spacing. If there is a difference of 1/8 inch (3 mm) or less between the spacing on one side of the vehicle compared to the other, no further action is necessary.

   If the difference is more than 1/8 inch (3 mm), adjust the forward-rear axle alignment. See **Fig. 2**. For instructions, refer to **Group 32** in this manual, or to the suspension manufacturer's service literature.

Center Point Bar Construction

Materials Required

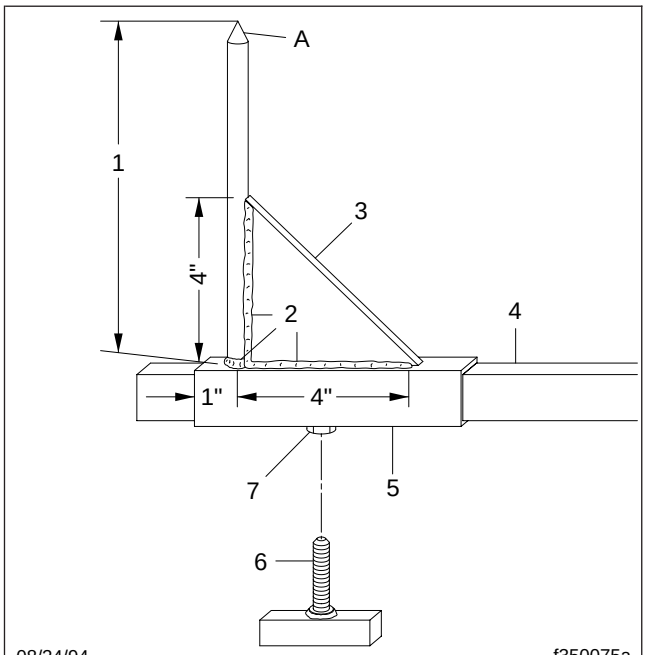
NOTE: To obtain metric conversions (millimeters), multiply the number of inches by 25.4.

Required materials are listed below:

- 62 inches of square steel tube (1-inch o.d.)
- 12 inches of square steel tube (1-1/8-inch i.d.)
- 20 inches of 3/8-inch steel rod
- two 1/2-inch x 3-inch pieces of steel square-bar stock
- one 4-inch x 4-inch steel plate, 1/8-inch thick
- two 3/8–16 capscrews (grade 5), 2 inches long
- two 3/8–16 hexnuts (equivalent to grade 5)

Construction Procedures

1. Cut the 1-1/8-inch i.d. square steel tube in half to obtain two pieces 6 inches long. These will be the sliding members (slides) of the center point bar.
2. Cut the 4-inch x 4-inch steel plate diagonally into two pieces (gussets). Weld one gusset to each slide. See **Fig. 1**.
3. Cut the steel rod in half to obtain two 10-inch rods. Grind one end of each to form a point.
4. Weld the pointed steel rods to the slides and gussets, as shown in **Fig. 1**.
5. Drill a 1/2-inch (12.7 mm) hole in the center of each slide, on the side opposite where the pointer was welded. Drill through only one side of the tube.
6. Directly over each hole drilled in the step above, weld a 3/8–16 nut (equivalent to grade 5).
7. Weld a piece of steel stock, about 1/2-inch wide x 3-inch long, over the head of each of two 3/8–16 x 2-inch long capscrews.
8. Place a slide over each end of the 60-inch piece of steel tube, with the pointed rods to the outside. Screw the handscrews (made in the step above) into the slides until they are clamped tightly to the cross tube.



A. Grind to a point.

1. 3/8-inch Diameter Rod
2. Weld
3. Gusset
4. 1-inch Square Steel Tube
5. 1–1/8-inch Square Steel Tube
6. 3/8–16 Bolt
7. 3/8–16 Nut

Fig. 1, Center Point Bar Construction

Method	Maximum Tolerance ± from Perpendicular
Manual	1/4-inch (6 mm)

Table 1, Maximum Tolerance from Perpendicular, Manual Method

Method	Maximum Tolerance ± from Perpendicular
Hunter *	0.18 degrees

* To use Hunter alignment equipment, refer to the applicable Hunter service literature.

Table 2, Maximum Tolerance from Perpendicular, Hunter Equipment

Distance from the Forward or Rear Drive Axle to Target inches (mm)	Maximum Tolerance ± from Perpendicular * inches (mm)
100 (2540)	5/16 (8)
120 (3048)	3/8 (10)
140 (3556)	7/16 (11)
160 (4064)	1/2 (13)
180 (4572)	9/16 (14)
200 (5080)	5/8 (16)
220 (5588)	11/16 (17)
240 (6096)	3/4 (19)
260 (6604)	13/16 (21)

* To use Bee Line alignment equipment, refer to the applicable Bee Line service literature.

Table 3, Maximum Tolerance from Perpendicular at Target, Bee Line Equipment

Method	Maximum Tolerance
Hunter	±0.08 degrees maximum axle-to-axle difference; reference "C", see **Fig. 1**.
Bee Line or Manual	±1/8-inch maximum difference in axle end-spacing; reference "B" minus "A", see **Fig. 1**.

Table 4, Rear Axle Parallelism Specifications

Specifications

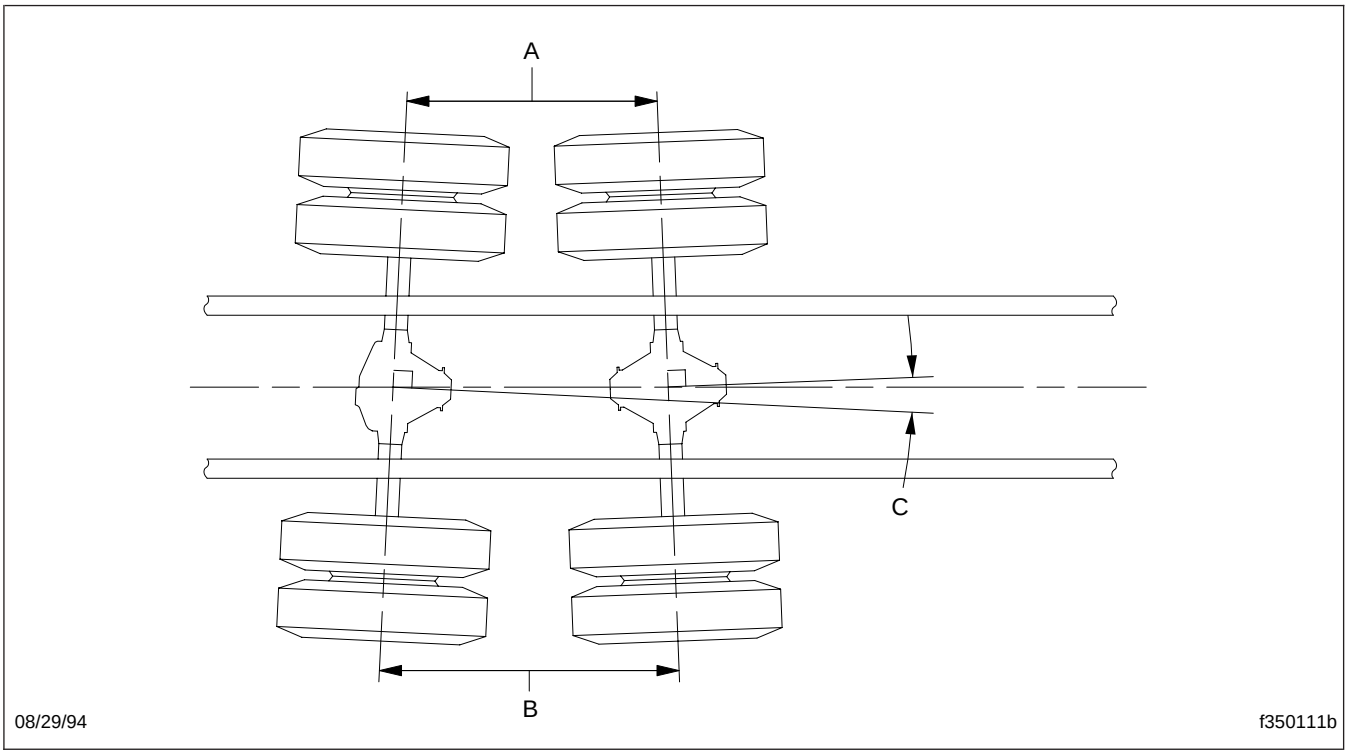


Fig. 1, Tandem Axle Measurements

General Information

Detroit rear axles are compatible with industry-standard brakes, hubs, and wheel bearings.

The following explains an example of the number found on a Detroit rear axle identification tag, which is located on the carrier. See **Fig. 1**.

Typical Model Number: ART-40.0-4

- *ART* = tandem rear axle
- *40.0* = weight rating (times 1000 lb)
- *4* = basic model number

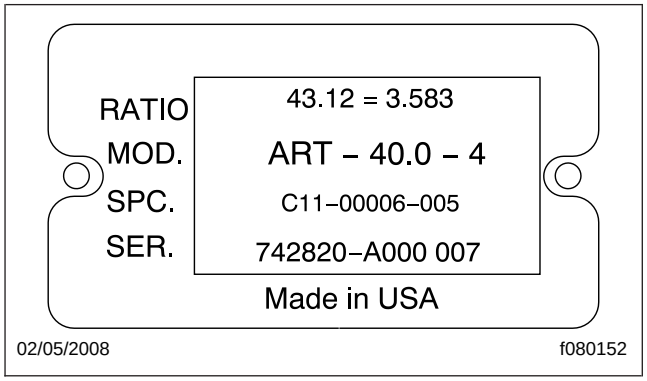

Fig. 1, Rear Axle ID Tag

Detroit rear axles may have a main differential lock, which is commonly known as the "DCDL" (Driver-Controlled Differential Lock). The DCDL is an optional feature that can lock the differential assembly to improve traction on icy road conditions. When the differential lock is engaged, the clutch collar completely locks the differential case, gearing, and axle shafts together to maximize traction of both wheels and protect against spinout. Each part of the DCDL is replaceable; see **Subject 180**.

On tandem axles there are three possible differential lock options: forward-rear carrier only, rear-rear carrier only, or both rear carriers.

NOTE: Detroit axles are a proprietary product, though in some applications they may be referred to as "Sterling" or "Axle Alliance" axles or "MB components."

Warranty

To assist in the determination of warrantable and non-warrantable failures for these axles, warranty evaluation guides are available through WarrantyLit on **www.accessfreightliner.com**. These guides help determine whether or not pre-approval is needed for a repair. The following evaluation guides are available:

- **Warranty Evaluation Guide**
- **Submission Guidelines - Differential Cross Failure**
- **Submission Guidelines - Pinion Bearing Cage Damage**
- **Submission Guidelines - Pinion Nut Failure**
- **Submission Guidelines - Thrust Bearing Failure**
- **Submission Guidelines - Yoke (Pinion) End Play**

Single Axle or Rearmost Tandem Axle Removal and Installation

Removal

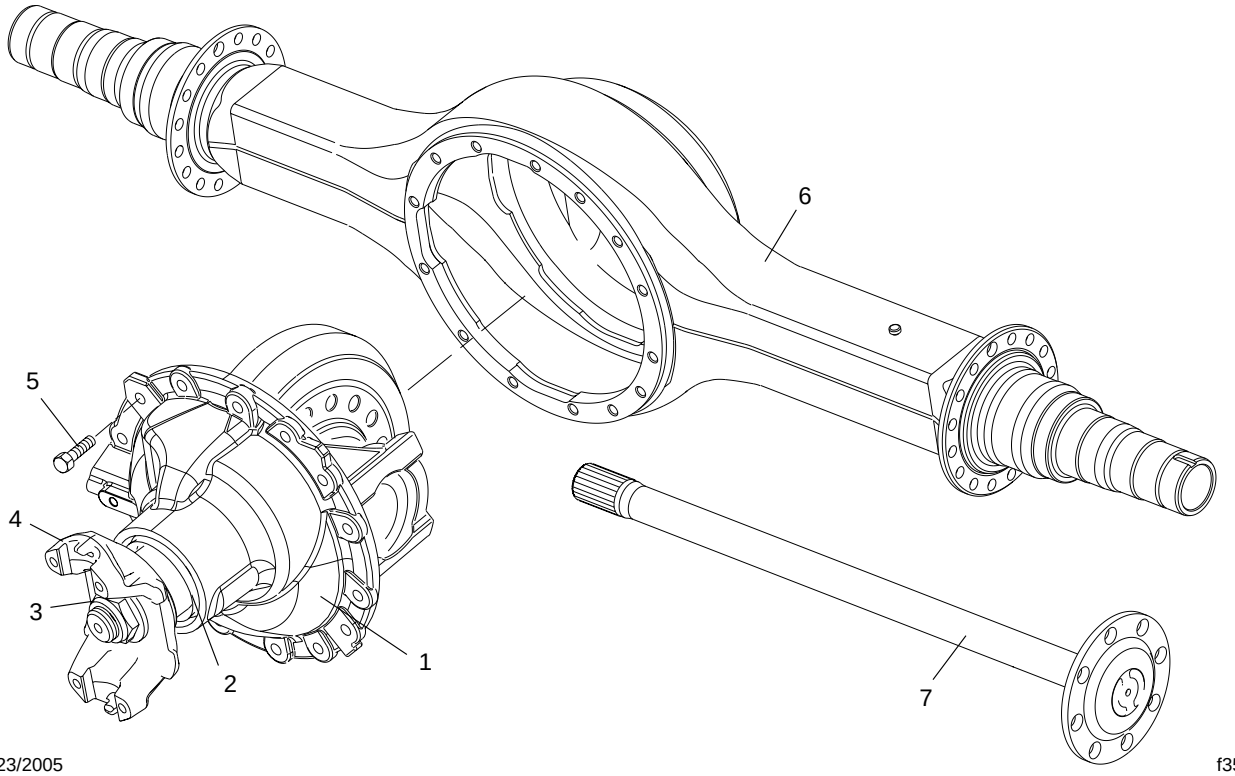
For rear axle components, see **Fig. 1**.

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires. Put the transmission in neutral.
2. Using a suitable jack, raise the vehicle enough to take the weight off the axles, but not enough to raise the tires off the ground.
3. At both ends of the axle, loosen all the wheel nuts.
4. Continue to raise the vehicle evenly until there is room to fit a jack underneath the axle housing.

⚠ WARNING

Never work around or under a vehicle that is supported only by a jack. Always support the vehicle with safety stands. Jacks can slip, allowing the vehicle to fall, which could result in serious injury or death.

5. Support the vehicle with safety stands.
6. Remove the tire and wheel assemblies.
7. Drain the oil from the differential housing. Install the drain plug.
8. Disconnect the driveshaft from the differential carrier. For instructions, see **Section 41.00, Subject 120**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.



1. Differential Carrier
2. Radial Shaft Seal
3. Yoke Nut
4. Carrier Yoke
5. Carrier Capscrew
6. Rear Axle Housing
7. Axle Shaft

Fig. 1, Rear Axle Components

Single Axle or Rearmost Tandem Axle Removal and Installation

9. Release the parking brakes.
10. Cage the parking brake springs to prevent the parking brakes from engaging. For instructions, see **Group 42**.
11. If DCDL is installed on the vehicle, use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged. Turn the appropriate hubs to ensure the lock is fully engaged.
12. Place a basin under the axle shaft flanges to catch any oil, then remove the axle shafts. For instructions, see **Subject 120**.
13. Drain the air system.
14. Disconnect the DCDL air line from the carrier housing.
15. If necessary, back off the slack adjusters, then remove the brake drums.
16. Remove the hubs from the axle spindles. For instructions, see **Section 35.00, Subject 100**.
17. Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
18. If applicable, disconnect the leveling valve rod(s) from the suspension.
19. Disconnect the air lines from the rear brake chambers. Then remove the brake air chambers and the slack adjusters from the axle housing. For instructions, see **Group 42**.
20. Remove the brake spiders from the axle flanges, as follows.
    - 20.1 At the frame rail or crossmember, disconnect the wiring for the ABS sensors. Remove any tie straps that hold the wires to the frame rails.
    - 20.2 Remove the ABS sensors and wiring.
    - 20.3 Remove the fasteners that hold the brake spiders to the axle flanges. Remove the spiders from the axle.
21. Using a suitable jack, support the axle housing.
22. If applicable, remove the hexnuts that hold the bottom of each suspension air bag to its suspension bracket.
23. Remove the suspension components that attach the axle to the vehicle. If applicable, remove the U-bolt nuts from the U-bolts. Discard the U-bolt nuts and U-bolts.
24. Lower the axle enough to clear the suspension components.
25. Remove the axle from the vehicle.
26. If you are going to replace the differential carrier, place the axle on a secure axle stand.

Installation

1. Position the axle underneath the vehicle.
2. Install the suspension components that attach the axle to the vehicle, as follows.

   NOTE: U-bolts and U-bolt nuts cannot be reused.

   - 2.1 On vehicles with conventional suspensions, install the upper U-bolt brackets, new U-bolts, lower U-bolt brackets, and new U-bolt nuts.

     On vehicles with air suspensions, in addition to the U-bolts, install the hexnuts that attach the air springs to the suspension brackets. For torque values, see **Group 32**.

     On vehicles without U-bolts, install the walking beams.
   - 2.2 If applicable, tighten the new U-bolt nuts in a diagonal pattern. For torque values, see **Group 32**.
3. Connect the driveshaft to the differential carrier yoke. For instructions, see **Section 41.00, Subject 100**.
4. Install the brake spiders on the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
5. Install the ABS sensors and connect the wiring at the frame rail. Secure the wiring with tie straps as needed.
6. Install the brake air chambers and slack adjusters on the axle housing brackets. For instructions, see **Group 42**.
7. Connect the air lines to the brake air chambers.

8. Install the brake shoes, as removed. For instructions, see the applicable service brake section in **Group 42**.
9. Fill each hub with enough 80W/90 gear oil until you can see a little amount of oil trickling out of the back of the hub (fill with about 0.8 quart, or 0.75 liter). Install the hubs on the axle spindles, and adjust the wheel bearings. For instructions, see **Section 35.00, Subject 100**.
10. If DCDL is installed on the vehicle, connect the DCDL air line, fill the air system, and use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged.
11. Using new gaskets, install the axle shafts. For instructions, see **Subject 120**.
12. Install the brake drums on the hubs.
13. Install the wheels and tires. For instructions, see **Group 40**.
14. Adjust the brakes. For instructions, see the applicable service brake section in **Group 42**.
15. Uncage the parking brake springs.
16. Using approved axle oil, fill the axle housing to the bottom of the fill hole, or until filled to capacity as shown in **Table 1**.

Approved Single Rear Axle Oil Type and Capacity				
Model	Oil Type		Capacity: quarts (liters)	
	Mineral	Synthetic	Hubs Full	Hubs Dry
2	80W-90	75W-90	5.8 (5.5)	7.4 (7.0)
4			10.6 (10.0)	12.2 (11.5)

Table 1, Approved Single Rear Axle Oil Type and Capacity

17. If the hubs are dry, raise one side of the vehicle about 8 inches (20 cm) to let the oil flow into the hub on the opposite side, then raise the other side in the same manner. On each side, hold the tilted position for three minutes to allow oil to run into the wheel end.

NOTICE

Make sure the hubs are filled. Driving with the hubs dry will cause bearing damage.

18. Turn the wheels, wait one minute, and check the lubricant level.
19. Raise the vehicle, remove the safety stands, then lower the vehicle.
20. If applicable, connect the suspension leveling valve(s). Start the engine, build the air pressure, and make sure the suspension air bags inflate correctly. Make sure the ride height is correct. For instructions, see **Group 32**.
21. Check the oil level in the axle housing. The level should be up to the bottom of the fill hole. Add approved axle oil, if needed.
22. Set the parking brake, then remove the chocks from the tires.

Single Axle or Rearmost Tandem Axle Differential Carrier Removal and Installation

When the wheel lock is removed, inspect the carrier for damage and replace it if damage is found. If no damage is found, install the carrier again.

Removal

NOTE: The differential carrier can be removed either with the rear axle installed on the vehicle or with the rear axle removed from the vehicle.

Axle Installed on Vehicle

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires.
2. Put the transmission in neutral.
3. If applicable, release the suspension air pressure.
4. Using suitable jacks, raise the vehicle evenly until there is room to fit a jack underneath the axle housing.
5. Remove the tire and wheel assemblies.
6. Drain the oil from the axle housing.
7. Disconnect the driveshaft from the carrier yoke. For instructions, see **Section 41.00, Subject 100**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
8. If DCDL is installed on the vehicle, use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged. Turn the appropriate hubs to ensure the lock is fully engaged.
9. Place a basin under the axle shaft flanges, then remove the axle shafts. For instructions, see **Subject 120**.
10. Do the steps under the heading, "Axle Removed from Vehicle."

Axle Removed from Vehicle

1. Using a suitable jack, support the differential carrier. Chain the differential carrier to the jack.
2. If DCDL is installed on the vehicle, ensure the lock is engaged. Turn the appropriate hubs to verify it is fully engaged.
3. Remove the carrier capscrews that hold the differential carrier to the axle housing. See **Fig. 1**.

⚠ WARNING

The differential carrier is heavy. Do not try to move it without a suitable support. To do so could result in the carrier falling, which could cause serious personal injury and component damage. Support the carrier with a suitable jack and chain it to the jack, or use a hoist if the axle has been removed from the vehicle.

4. With the differential carrier securely supported, remove it from the axle housing.

Installation

IMPORTANT: If you replace the yoke on the differential carrier, use a *new* nut when installing the new yoke.

NOTE: Use a cleaning solvent and clean rags to remove dirt. Blow dry the cleaned areas with air.

1. Remove any old sealant material from the mating surfaces of the axle housing. Clean the inside of the rear axle housing and the forward carrier mating surface.
2. Inspect the axle housing for damage. Repair or replace the axle housing as necessary.
3. Apply a thin bead of Loctite® 5900 sealant all the way around the mating surface of the axle housing, and around each bolt hole.

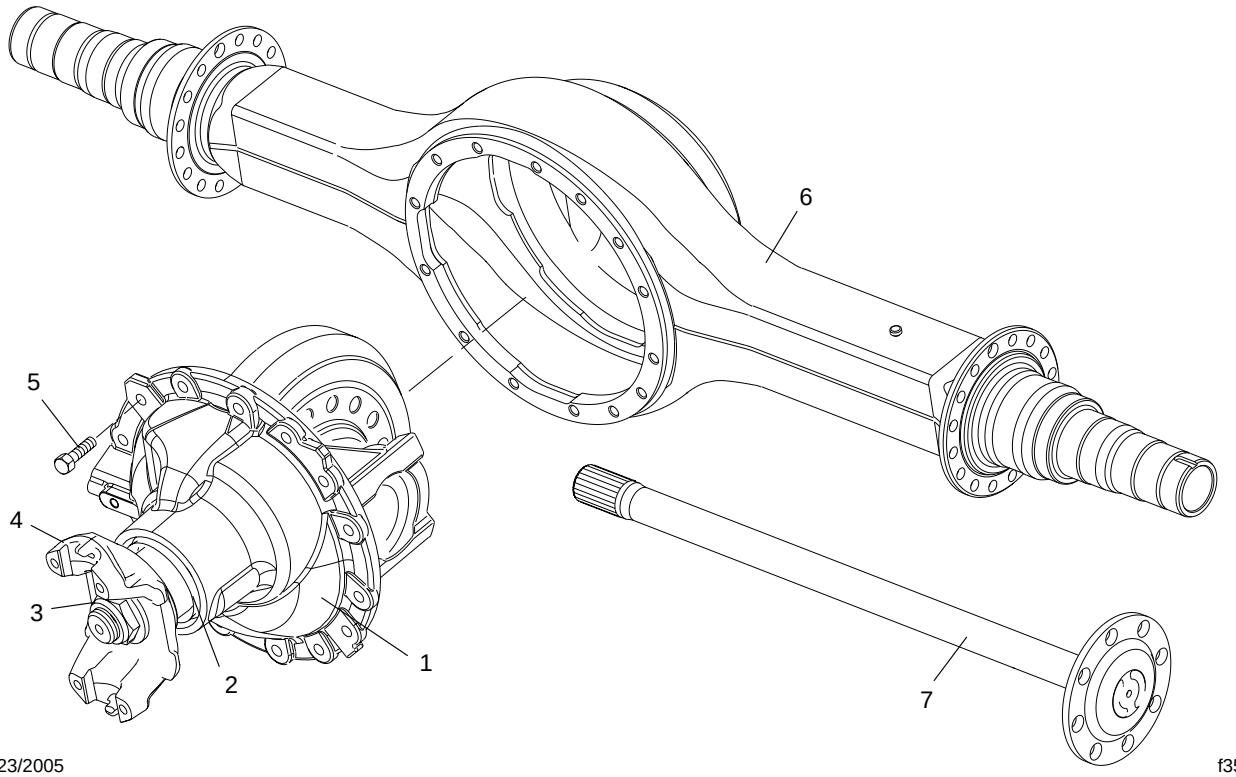
NOTE: Alignment dowels for installing the differential carrier can be made by sawing off the heads of two M12 x 1.5 x 100 mm bolts (for Model 2 axles) or M16 x 1.5 x 100 mm bolts (for Model 4 axles).

4. Install alignment dowels 180 degrees apart at the 3 o'clock and 9 o'clock positions on the axle housing flange.
5. If DCDL is installed on the vehicle, ensure it is engaged.

NOTICE

Make sure the differential carrier is centered and straight on the axle housing before you install the mounting capscrews. Attempting to install the carrier when it is not centered or straight may cause damage to the carrier.

Single Axle or Rearmost Tandem Axle Differential Carrier Removal and Installation



1. Differential Carrier
2. Radial Shaft Seal
3. Yoke Nut
4. Carrier Yoke
5. Carrier Capscrew
6. Rear Axle Housing
7. Axle Shaft

Fig. 1, Rear Axle Components

6. Using a hoist (if the axle is removed from the vehicle) or a suitable transmission jack, install the differential carrier into the axle housing. Use the alignment dowels to center the carrier on the axle housing.
7. Install the end caps at the sides of the carrier into the corresponding slots in the axle housing, as follows. See **Fig. 2**.

   7.1 For the last 3/4 inch (19 mm) or so of travel, walk the carrier slowly into the housing.

   IMPORTANT: The end caps fit tightly into the axle housing. Be very careful not to cock the carrier.

   7.2 Install the carrier capscrews finger-tight. Make sure the carrier capscrews turn easily in the axle housing.

   7.3 In a star pattern, gradually tighten the carrier capscrews to the values given.

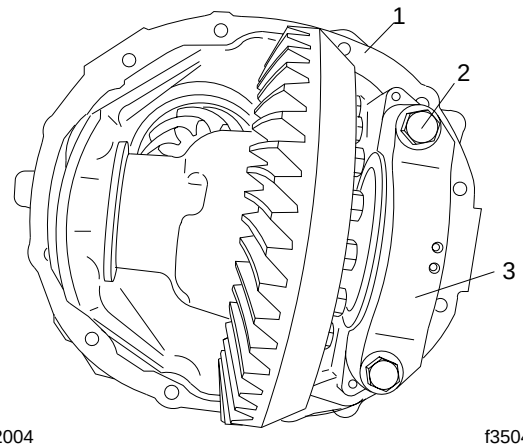
   - M12 capscrews: 115 lbf·ft (156 N·m)
   - M16 capscrews: 200 lbf·ft (270 N·m)

8. If removed, install the axle on the vehicle. For instructions, see **Subject 100**.

   If the axle is already on the vehicle, go to the next step.

9. Connect the driveshaft to the carrier yoke. For instructions, see **Section 41.00, Subject 100**.
10. Using new gaskets, install the axle shafts. For instructions, see **Subject 120**.
11. Install the wheels and tires. For instructions, see **Group 40**.
12. Using 80W/90 gear oil, fill the axle housing to the bottom of the fill hole, or until a small amount of

Single Axle or Rearmost Tandem Axle Differential Carrier Removal and Installation



1. Differential Carrier
2. End Cap Bolt
3. End Cap

oil trickles out of the fill hole. See **Table 1** for the oil capacities of axle models.

Approved Single Rear Axle Oil Type and Capacity				
Model	Oil Type		Capacity: quarts (liters)	
	Mineral	Synthetic	Hubs Full	Hubs Dry
2	80W-90	75W-90	5.8 (5.5)	7.4 (7.0)
4			10.6 (10.0)	12.2 (11.5)

Table 1, Approved Single Rear Axle Oil Type and Capacity

13. Raise one side of the vehicle about 8 inches (20 cm) to let the oil flow into the hub on the opposite side, then raise the other side in the same manner. On each side, hold the tilted position for three minutes to allow oil to run into the wheel end.

NOTICE

Make sure the hubs are filled. Driving with the hubs dry will cause bearing damage.

14. Raise the vehicle, remove the safety stands, then lower the vehicle.
15. Start the engine, build the air pressure, and check that the suspension air bags inflate evenly and correctly. Make sure the ride height is correct.
16. Check the oil level in the axle housing. The level should be up to the bottom of the fill hole. Add approved axle oil, if needed.
17. Remove the chocks from the tires.

Removal

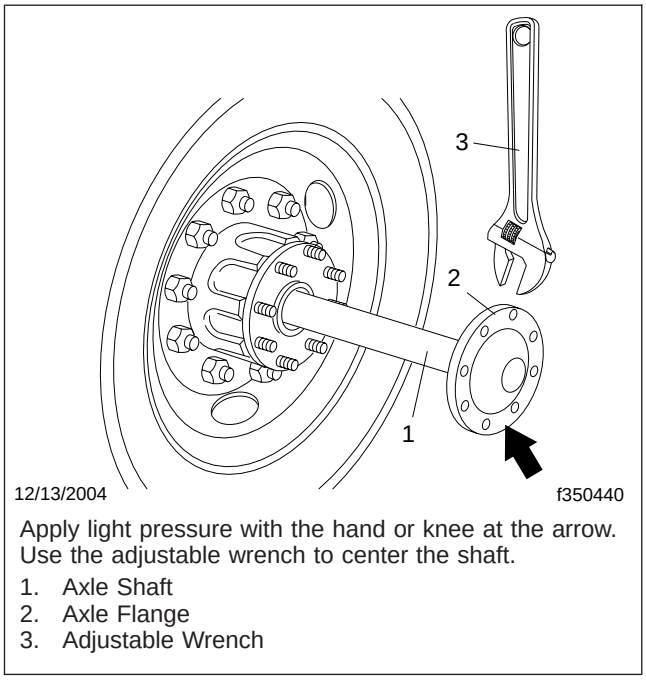
1. Chock the front tires.
2. Raise the rear of the vehicle with a suitable jack high enough to clear the axle. Support the axle with jack stands.
3. If DCDL is installed on the vehicle, use the DCDL switch in the cab to engage the lock. An indicator light comes on when the differential lock is engaged. Turn the appropriate wheels to ensure the lock is fully engaged.
4. Place a basin under the axle shaft flanges to catch any oil. Dispose of used oil properly.
5. If necessary, remove the tires. For procedures, see **Group 40**.

NOTE: This procedure can be done with the wheels and tires installed or with the wheels and tires removed.

6. Remove the drive axle stud nuts that attach the axle shaft to the wheel hub.
7. Tap the axle shaft flange if necessary to loosen it, then slide the axle shaft out of the axle. Remove and discard the gasket.

Installation

1. Position a new gasket on the axle shaft flange.
2. If DCDL is installed on the vehicle, ensure it is engaged.
3. Install the axle shaft, as follows. See **Fig. 1**.
   - 3.1 Carefully raise the axle with a floor jack, and support the axle with jack stands. Slide the axle shaft into the axle.
   - 3.2 Apply light pressure with the hand or knee to the axle flange.
   - 3.3 Use an adjustable wrench to center the shaft. Turn the shaft with a slight rotating motion.
   - 3.4 Install the drive axle stud nuts and tighten them to the values given.
     - 1/2–20 nuts: 75 to 115 lbf·ft (102 to 156 N·m)
     - 5/8–18 nuts: 150 to 170 lbf·ft (203 to 230 N·m)



Apply light pressure with the hand or knee at the arrow. Use the adjustable wrench to center the shaft.

1. Axle Shaft
2. Axle Flange
3. Adjustable Wrench

Fig. 1, Installing the Axle Shaft

4. If removed, install the tires and tighten the wheel nuts according to the procedures in **Group 40**.
5. Remove the supports and lower the vehicle.
6. As needed, replace any oil that was drained from the hub when the axle shaft was removed.
7. Remove the chocks.

Forward-Rear Tandem Axle Removal and Installation

Removal

For forward-rear axle components of a tandem installation, see **Fig. 1**.

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the front tires. Put the transmission in neutral.
2. Using a suitable jack, raise the vehicle enough to take the weight off the axles, but not enough to raise the tires off the ground.
3. At both ends of the axle, loosen all the wheel nuts.
4. Using a suitable jack, continue to raise the vehicle evenly until there is room to fit a stand underneath the axle housing.

Fig. 1, Forward-Rear Axle Components

Forward-Rear Tandem Axle Removal and Installation

⚠ WARNING

Never work around or under a vehicle that is supported only by a jack. Always support the vehicle with safety stands. Jacks can slip, allowing the vehicle to fall, which could result in serious injury or death.

5. Support the vehicle with safety stands.
6. Remove the oil drain plug from the bottom of the axle housing and drain the oil. Install the drain plug after emptying.
7. Remove the wheels and tires. For instructions, see **Group 40**.
8. Release the parking brakes.
9. If necessary, back off the slack adjusters, then remove the brake drums.
10. If installed, make sure the optional DCDL (main differential lock) has been shifted into the engaged (locked) position.
11. Disconnect the air lines at the interaxle lock and (if installed) the wheel lock. Drain the air system.
12. Disconnect the main driveshaft from the forward differential carrier. For instructions, see **Section 41.00, Subject 100**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
13. Disconnect the interaxle driveshaft from the output yoke of the forward tandem axle and the input yoke of the rear tandem axle. For instructions, see **Section 41.00, Subject 100**.
14. Cage the parking brake springs to prevent the parking brakes from engaging. For instructions, see **Group 42**.
15. Place a basin under the axle shaft flanges to catch any oil; then remove the axle shafts. For instructions, see **Subject 120**.
16. Remove the hubs from the axle spindles. For instructions, see **Section 35.01, Subject 100**.
17. Remove the brake shoes. For instructions, see the applicable service brake section in **Group 42**.
18. Remove the brake spiders from the axle flanges, as follows.
    - 18.1 At the frame rail or crossmember, disconnect the wiring for the ABS sensors. Remove any tie straps that hold the wires to the frame rails.
    - 18.2 Remove the ABS sensors and wiring.
    - 18.3 Remove the fasteners that hold the brake spiders to the axle flanges. Remove the spiders from the axle.
19. If applicable, disconnect the leveling valve rod(s) from the suspension.
20. Disconnect the air lines from the rear brake chambers.
21. Remove the brake air chambers and the slack adjusters from the axle housing. For instructions, see **Group 42**.
22. Using a suitable jack, support the axle housing.
23. If applicable, remove the hexnuts that hold the bottom of each suspension air bag to its suspension bracket.
24. Remove the suspension components that attach the axle to the vehicle. If applicable, remove the U-bolt nuts from the U-bolts. Discard the U-bolt nuts and U-bolts.
25. Lower the axle enough to clear the suspension components.
26. Remove the axle from the vehicle.
27. If you are going to replace the differential carrier, place the axle on a secure axle stand.

Installation

1. Position the axle underneath the vehicle.
2. Install the suspension components that attach the axle to the vehicle, as follows.

   NOTE: U-bolts and U-bolt nuts cannot be reused.

   - 2.1 On vehicles with conventional suspensions, install the upper U-bolt brackets, new U-bolts, lower U-bolt brackets, and new U-bolt nuts.

     On vehicles with air suspensions, in addition to the U-bolts, install the hexnuts that attach the air springs to the suspension brackets. For torque values, see **Group 32**.

Forward-Rear Tandem Axle Removal and Installation

On vehicles without U-bolts, install the walking beams.

2.2 If applicable, tighten the new U-bolt nuts in a diagonal pattern. For torque values, see **Group 32**.

3. Connect the interaxle driveshaft to the output yoke of the forward carrier and the input yoke of the rear carrier. For instructions, see **Section 41.00, Subject 100**.
4. Install the brake spiders on the axle flanges. For instructions, see the applicable service brake section in **Group 42**.
5. Install the ABS sensors and connect the wiring at the frame rail. Secure the wiring with tie straps as needed.
6. Install the brake air chambers and slack adjusters on the axle housing brackets.
7. Connect the air lines to the brake air chambers. For instructions, see **Group 42**.
8. Install the brake shoes, as removed. For instructions, see the applicable service brake section in **Group 42**.
9. If installed, disengage the wheel lock (main differential lock).
10. Install the hubs on the axle spindles, and adjust the wheel bearings. For instructions, see the applicable subject in **Section 35.00**.
11. Using new gaskets, install the axle shafts. For instructions, see **Subject 120**.
12. Connect the main driveshaft to the forward input yoke. For instructions, see **Section 41.00, Subject 100**.
13. Connect the air hoses to the air cylinder for the interaxle lock and (if installed) the wheel lock.
14. Connect the electrical connector of the sensor unit for axles equipped with a wheel lock.
15. Fill each hub with approved axle oil until you can see a little amount of oil trickling out of the back of the hub (use about 0.8 quart, or 0.75 liter).
16. Install the brake drums on the hubs.
17. Install the wheels and tires. For instructions, see **Group 40**.
18. Adjust the brakes. For instructions, see the applicable service brake section in **Group 42**.
19. Uncage the parking brake springs.
20. Using approved axle oil, fill the forward-rear axle housing to the bottom of the fill hole, or until filled to capacity as shown in **Table 1**.

Forward-Rear Axle Oil Type and Capacity		
Approved Oil Type	**Capacity: quarts (liters)**	
	Hubs Full	**Hubs Dry**
80W-90 Gear Oil	14.3 (13.5)	15.9 (15.0)
75W-90 Synthetic Gear Oil		

Table 1, Forward-Rear Axle Oil Type and Capacity

21. Raise one side of the vehicle about 8 inches (20 cm) to let the oil flow into the hub on the opposite side, then raise the other side in the same manner. On each side, hold the tilted position for three minutes to allow oil to run into the wheel end.

NOTICE

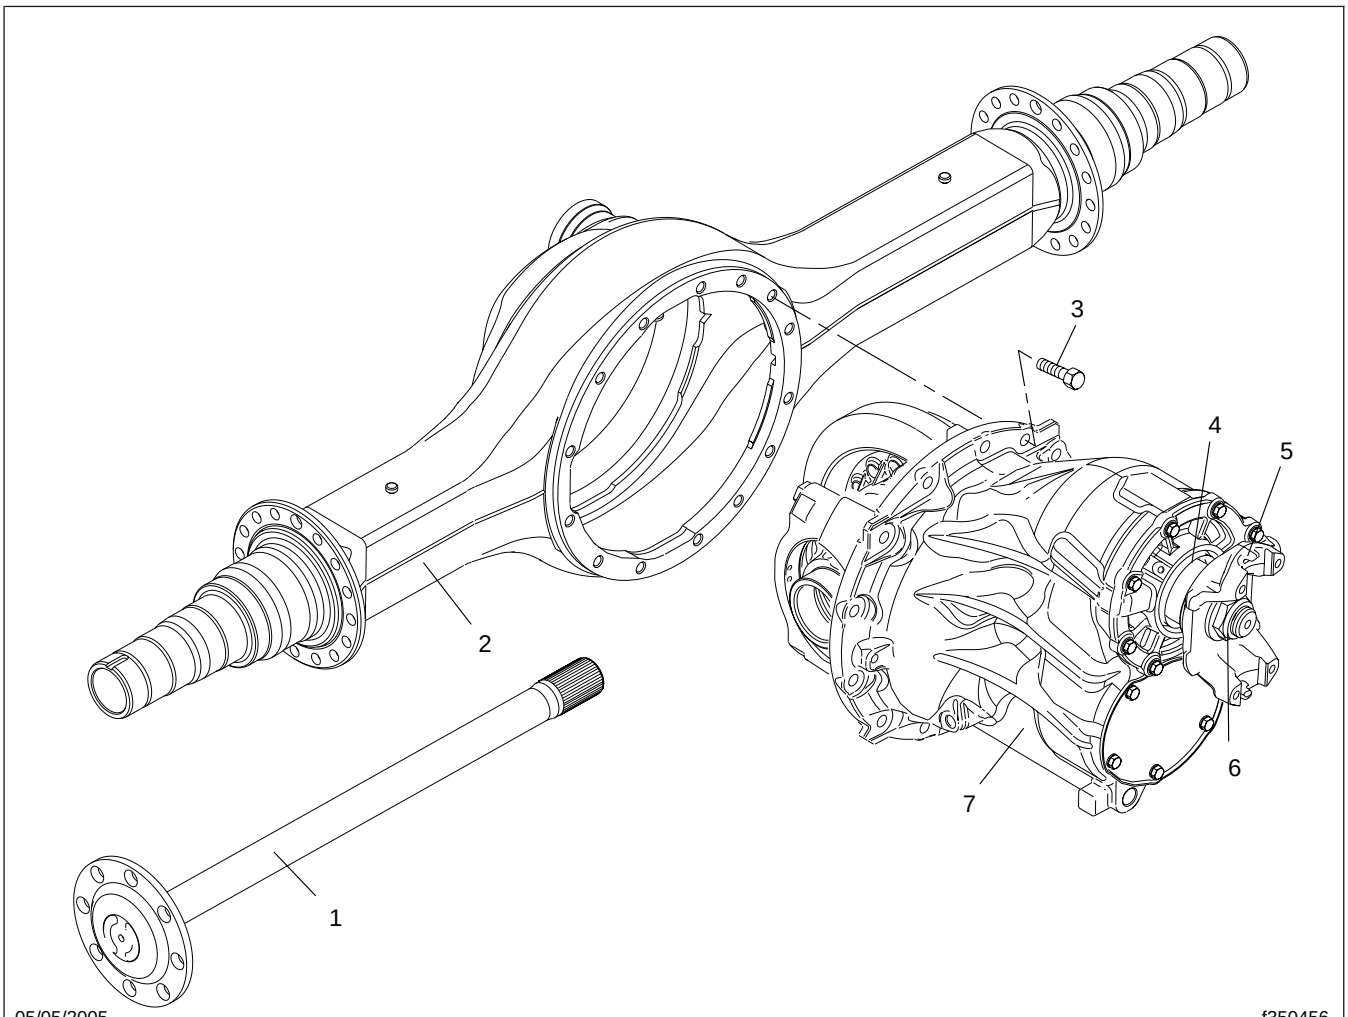
Make sure the hubs are filled. Driving with the hubs dry will cause bearing damage.

22. Turn the wheels, wait one minute, and check the lubricant level.
23. Raise the vehicle, remove the safety stands, then lower the vehicle.
24. If applicable, connect the suspension leveling valve(s). Start the engine, build the air pressure, and make sure the suspension air bags inflate correctly. Make sure the ride height is correct. For instructions, see **Group 32**.
25. Check the operation of the wheel lock, if installed.
26. Check the oil level in the axle housing. The level should be up to the bottom of the fill hole. Add approved axle oil, if needed.
27. Set the parking brake, then remove the chocks.

Forward-Rear Axle Differential Carrier Removal and installation

For forward-rear axle components of a tandem installation, see **Fig. 1**.

Forward-Rear Axle Differential Carrier



1. Axle Shaft
2. Forward-Rear Axle Housing
3. Carrier Capscrew
4. Input Seal
5. Carrier Yoke
6. Input Yoke Nut
7. Forward Differential Carrier

Fig. 1, Forward-Rear Axle Components

Removal

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the front tires. Put the transmission in neutral.
2. If applicable, release the suspension air pressure.

Forward-Rear Axle Differential Carrier Removal and installation

3. Using suitable jacks, raise the vehicle evenly until there is room to fit a jack underneath the axle housing.
4. Remove the tires and wheels. For instructions, see **Group 40**.
5. Remove the oil drain plug from the bottom of the axle housing and drain the oil. Install the drain plug after emptying.
6. Disconnect the driveshaft from the carrier yoke. For instructions, see **Section 41.00, Subject 120**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
7. Place a basin under the axle shaft flanges to catch any oil; then remove the axle shafts. For instructions, see **Subject 120**.

⚠ WARNING

The differential carrier is heavy. Do not try to move it without a suitable support. To do so could result in the carrier falling, which could cause serious personal injury and component damage. Support the carrier with a suitable jack and chain it to the jack, or use a hoist if the axle has been removed from the vehicle.

8. Using a suitable jack, support the differential carrier. Chain the differential carrier to the jack.

NOTICE

When using a pry bar, be careful not to damage the carrier or housing flange. Damage to these surfaces will cause oil leaks.

9. Remove the differential carrier from the axle housing, as follows.
   - 9.1 If equipped with a wheel lock, engage the lock with air. This will help separate the carrier assembly from the axle housing.
   - 9.2 Remove all but the top two forward carrier capscrews.
   - 9.3 Loosen and back off, but do not remove, the top two carrier capscrews. The capscrews will hold the carrier in the housing.
   - 9.4 Using a pry bar, separate the mating surfaces of the forward differential carrier and axle housing.

     NOTE: Use a pry bar that has a round end to help separate the carrier from the housing.
   - 9.5 When the surfaces are separated, remove the top two capscrews.
   - 9.6 With the carrier on the jack, slide the carrier away from the rear axle housing.
   - 9.7 Lift the carrier assembly onto a suitable stand.

Installation

NOTE: Use a cleaning solvent and clean rags to remove dirt. Blow dry the cleaned areas with air.

1. Remove any old sealant material from the mating surfaces of the axle housing. Clean the inside of the rear axle housing and the forward carrier mating surface.
2. Inspect the axle housing for damage. Repair or replace the axle housing as necessary.
3. Apply a thin bead of Loctite® 5900 sealant all the way around the mating surface of the axle housing, and around each bolt hole.

NOTE: Alignment dowels for installing the differential carrier can be made by sawing off the heads of two M16 x 1.5 x 100 mm bolts.

4. Install alignment dowels 180 degrees apart at the 3 o'clock and 9 o'clock positions on the axle housing flange.

⚠ WARNING

The differential carrier is heavy. Do not try to move it without a suitable support. To do so could result in the carrier falling, which could cause serious personal injury and component damage. Support the carrier with a suitable jack and chain it to the jack, or use a hoist if the axle has been removed from the vehicle.

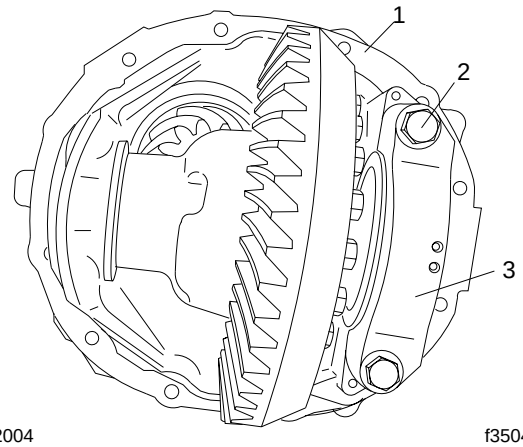
5. Position the forward differential carrier in front of the axle housing, using an axle jack or other suitable lifting tool.
6. If equipped with a wheel lock, engage the lock with air. This will help the carrier assembly join the axle housing.

Forward-Rear Axle Differential Carrier Removal and installation

NOTICE

Do not use a hammer or a mallet to install the differential carrier. A hammer or a mallet will damage the mounting flange of the carrier and cause oil leaks.

7. Install the end caps at the sides of the forward differential carrier into the corresponding slots in the axle housing. See **Fig. 2**.



1. Differential Carrier
2. End Cap Bolt
3. End Cap

Fig. 2, Carrier End Caps

7.1 For the last 3/4 inch (19 mm) or so of travel, walk the carrier slowly into the housing.

IMPORTANT: The end caps fit tightly into the axle housing. Be very careful not to cock the carrier.

7.2 Install the forward carrier capscrews finger-tight. Make sure the carrier capscrews turn easily in the axle housing.

7.3 In a star pattern, gradually tighten the M16 capscrews 200 lbf·ft (270 N·m).

8. Connect the driveshaft to the carrier yoke. For instructions, see **Section 41.00, Subject 120**.
9. Using new gaskets, install the axle shafts. For instructions, see **Subject 120**.
10. Install the wheels and tires. For instructions, see **Group 40**.
11. Using approved axle oil, fill the axle housing to the bottom of the fill hole, or until filled to capacity as shown in **Table 1**.

Forward-Rear Axle Oil Type and Capacity		
Approved Oil Type	Capacity: quarts (liters)	
	Hubs Full	Hubs Dry
80W-90 Gear Oil	14.3 (13.5)	15.9 (15.0)
75W-90 Synthetic Gear Oil		

Table 1, Forward-Rear Axle Oil Type and Capacity

12. If the hubs are dry, raise one side of the vehicle about 8 inches (20 cm) to let the oil flow into the hub on the opposite side, then raise the other side in the same manner. On each side, hold the tilted position for three minutes to allow oil to run into the wheel end.

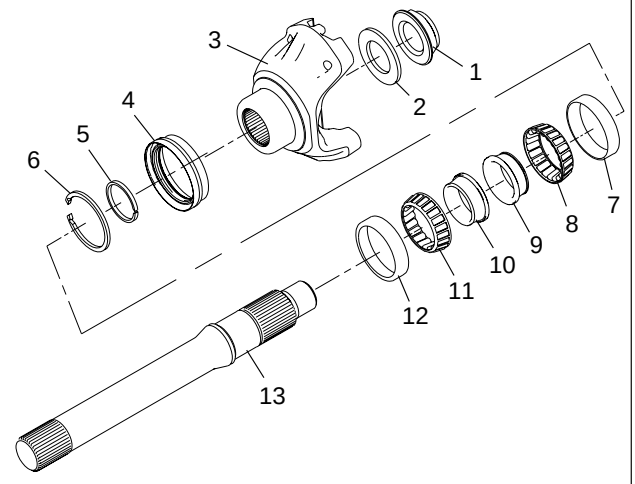
NOTICE

Make sure the hubs are filled. Driving with the hubs dry will cause bearing damage.

13. Turn the wheels, wait one minute, and check the lubricant level.
14. Raise the vehicle, remove the safety stands, then lower the vehicle.
15. Start the engine, build the air pressure, and check that the suspension air bags inflate evenly and correctly. Make sure the ride height is correct.
16. Check the oil level in the axle housing. The level should be up to the bottom of the fill hole. Add approved axle oil, if needed.
17. Remove the chocks from the front tires.

Repair

1. Remove the output yoke nut, washer, and output yoke. Then remove the output oil seal from the thru-shaft bore. See **Subject 170**.
2. Remove the snap ring and spacer from the thru-shaft. See **Fig. 1**.



05/04/2005 f350451

1. Output Yoke Nut
2. Washer
3. Output Yoke
4. Output Oil Seal
5. Spacer
6. Snap Ring
7. Outer Bearing Race
8. Outer Bearing
9. Outer Bearing Cup
10. Inner Bearing Cup
11. Inner Bearing
12. Inner Bearing Race
13. Thru-Shaft

Fig. 1, Thru-Shaft Components

3. Using a suitable shaft puller, draw the thru-shaft out of the bore.
4. Using a suitable bearing puller on the outer races, remove both the inner and outer bearings from the thru-shaft.
5. Inspect the bearings for wear and damage. Replace both bearings if any damage is found.
6. Install the bearings, as follows.
   - 6.1 Install the inner bearing race in the thru-shaft bore.
   - 6.2 Using an arbor press or other suitable pressing tool, press the bearings and bearing cups onto the thru-shaft.
   - 6.3 Insert the thru-shaft into its bore.
   - 6.4 Install the outer bearing race onto the thru-shaft and bore.
7. Install the snap ring and spacer. Use the next thicker snap ring from the snap ring pack supplied with the bearings.
8. Install a new output oil seal. See **Subject 170**.
9. Install the output yoke, and the new nut and washer. See **Subject 170**. Make sure the output yoke nut is firmly tightened, but do not tighten the nut to specifications at this time.
10. Attach a dial indicator to the flat surface of the output yoke.
11. Using a pry bar or other lever, apply force to the base of the output yoke. If the dial indicator shows a deflection of 0.0012 to 0.0024 inch (0.03 to 0.06 mm), the end play is correct.

    If the deflection is too large, use a thicker snap ring. If the deflection is too small, use a thinner snap ring.
12. Remove the yoke nut, and coat its threads with Loctite® 577. Install the nut, and tighten it 516 lbf·ft (700 N·m).

Single Axle or Rearmost Tandem Axle Yoke and Seal Replacement

Special Tools

Special tools are required for this procedure. See **Table 1**.

Special Tools			
Tool	**Description**	**Manufacturer**	**Part Number**
 f580400	Universal Handle*	Kent-Moore	J-8092
 f580406	Rear Pinion Seal Installer*	Kent-Moore	J-47354
 f580450	Yoke Nut Socket†	Daimler	MBA 742589020700

* To order Kent-Moore tools call 1-800-328-6657.

† The yoke nut socket is needed to remove the round, slotted yoke nut installed on some vehicles. It can be ordered through Paragon.

Table 1, Special Tools

Replacement

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires.
2. Disconnect the driveshaft from the input yoke. For instructions, see **Section 41.00, Subject 120**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
3. Remove the yoke nut from the center of the carrier yoke. If the yoke nut is round and slotted, use the yoke nut socket shown in **Table 1**. See **Fig. 1**. Be careful not to damage the seal bore.

NOTE: Older models may not require the special socket for yoke nut removal.

4. Remove the carrier yoke from the input shaft. Be careful not to damage the seal bore.
5. Pry up the seal, using a prybar or large screwdriver. Clean any old sealant from the axle housing. Do not allow dirt or grease to contaminate the seal bore or shaft bearings. See **Fig. 2**.
6. Install a new rear pinion seal on the input shaft, as follows. See **Fig. 3**.
   - 6.1 Inspect the area around the seal for damage. Use emery paper to remove scratches, nicks, or burrs on the seal bore.
   - 6.2 Assemble the rear pinion seal installer onto the threaded end of the universal handle. See **Table 1**.

Single Axle or Rearmost Tandem Axle Yoke and Seal Replacement

IMPORTANT: Be careful not to cock the seal during installation.

6.3 Using the rear pinion seal installer assembly, press the seal into the bore until the seal surface is flush with the bottom surface of the counterbore.

7. Install the carrier yoke on the input shaft. If the yoke is damaged or worn, install a new yoke.

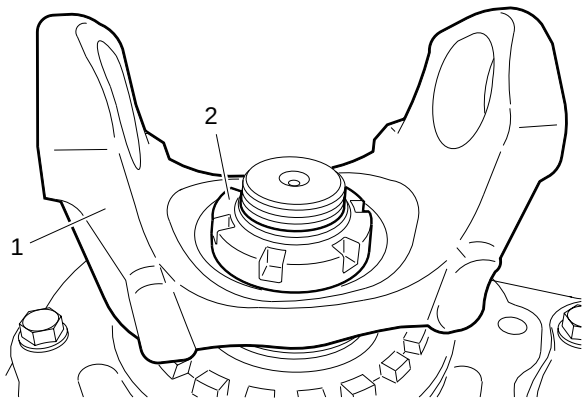
NOTE: It is not necessary to replace the yoke when replacing the seal.

8. Install a new M45 x 1.5 pinion nut on the carrier yoke, and tighten the nut 627 lbf·ft (850 N·m).

9. Punch in the cylindrical area at the pinion groove to lock the nut in place.

IMPORTANT: The bent area has to reach the bottom of the pinion groove.

10. Connect the driveshaft. For instructions, see **Section 41.00, Subject 120**.



04/01/2008 f350496

NOTE: The yoke nut may be a hexnut rather than the round, slotted nut shown here.

Forward-Rear Tandem Axle Yoke and Seal Replacement

Special Tools

Special tools are required for this procedure. See **Table 1**.

Special Tools for Forward-Rear Axle Yoke and Seal Replacement			
Tool	**Description**	**Manufacturer**	**Part Number**
 f580400	Universal Handle*	Kent-Moore	J-8092
 f580410	Input Seal Installer*	Kent-Moore	J-47369
 f580408	Output Seal Installer*	Kent-Moore	J-47368
 f580450	Yoke Nut Socket†	Daimler	MBA 742589020700

* To order Kent-Moore tools call 1-800-328-6657.

† The yoke nut socket is needed to remove the round, slotted yoke nut installed on some vehicles. It can be ordered through Paragon.

Table 1, Special Tools for Forward-Rear Axle Yoke and Seal Replacement

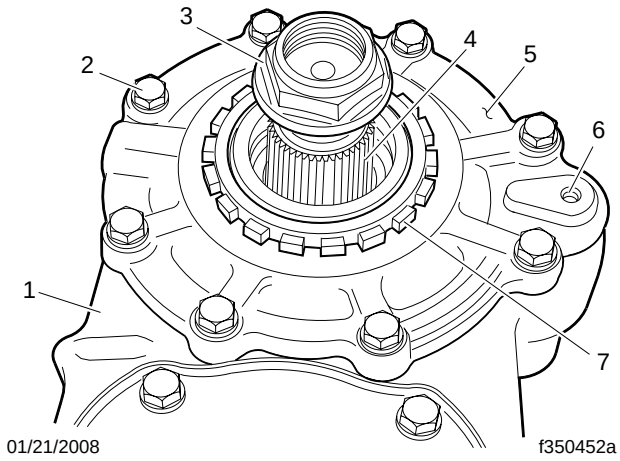
Replacement

Forward Carrier Input Yoke and Seal

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires.
2. Disconnect the main driveshaft from the forward carrier input yoke. For instructions, see **Section 41.00, Subject 100**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
3. Remove the input yoke nut and washer.
4. Remove the forward carrier input yoke from the forward input shaft.

Forward-Rear Tandem Axle Yoke and Seal Replacement

5. If there is an oil leak at the threaded ring, repair it; for instructions, see **Subject 200**.
6. If there is a leak between the bearing cage and the carrier housing, remove the bearing cage from the forward differential carrier, as follows. See **Fig. 1**.



1. Forward Carrier Housing
2. Bearing Cage Mounting Capscrew
3. Input Yoke Nut
4. Input Shaft
5. Bearing Cage
6. Interaxle Lock Bore
7. Threaded Ring

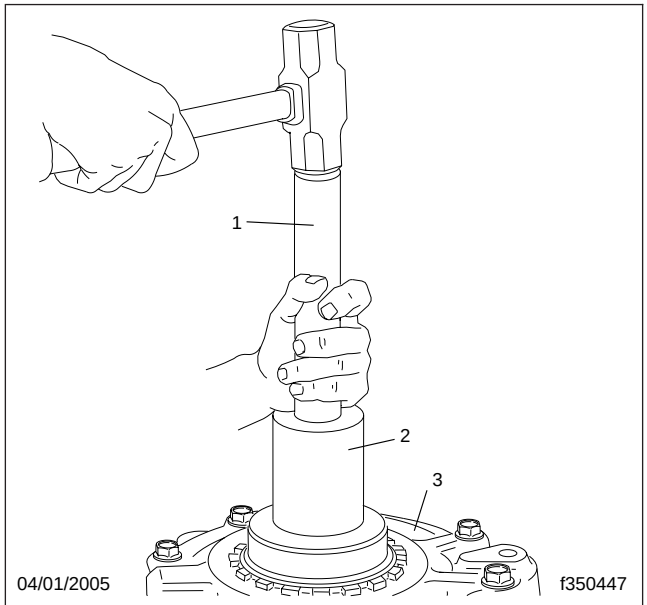
Fig. 1, Bearing Cage

6.1 Remove the bearing cage capscrews.

6.2 Pry the bearing cage from the forward carrier housing. Clean any remnants of sealant clinging to the mating surfaces of the carrier housing and the bearing cage.

7. Pry up the input seal, using a prybar or large screwdriver. Clean any old sealant from the axle housing. Do not allow dirt or grease to contaminate the seal bore or shaft bearings.
8. Install a new seal in the input shaft bore, as follows. See **Fig. 2**.

8.1 Inspect the area around the seal for damage. Use emery paper to remove scratches, nicks, or burrs on the seal bore.



1. Universal Handle
2. Input Seal Installer
3. Carrier Housing

Fig. 2, Installing the Forward Carrier Input Seal

8.2 Assemble the input shaft seal installer onto the threaded end of the universal handle. See **Table 1**.

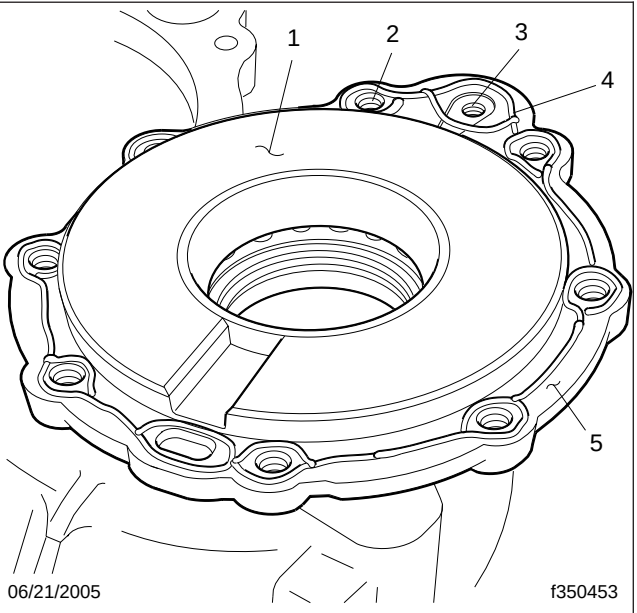
8.3 Using the input shaft seal installer assembly, press the seal into the bore until the seal surface is flush with the threaded ring.

9. On the mating surface of the bearing cage, lay down a bead of Loctite® 5900 sealant, or equivalent. Go around all of the bolt holes and other openings in the inside cover of the bearing cage. See **Fig. 3**.

IMPORTANT: Do not allow sealant to get into the interaxle lock bore. See **Fig. 4**. Do not attempt to repair the interaxle lock (IAD). No repairs to this component are possible.

10. Install the bearing cage onto the forward carrier housing. Tighten the M12 bearing cage capscrews 107 lbf·ft (145 N·m).
11. Install the forward carrier input yoke on the forward input shaft. If the yoke is damaged or worn, install a new yoke.

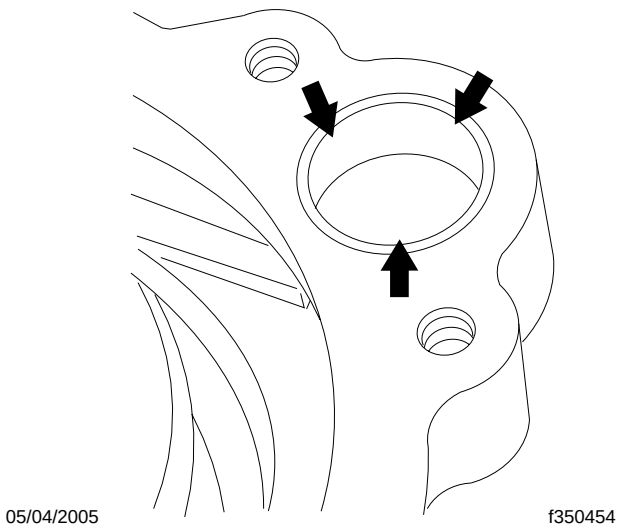
NOTE: It is not necessary to replace the yoke when replacing the seal.



Apply a bead of sealant to the inner mating surface as shown.

1. Inside Cover
2. Mounting Capscrew Hole
3. Interaxle Lock Bore
4. Sealant
5. Mating Surface

Fig. 3, Sealant Application



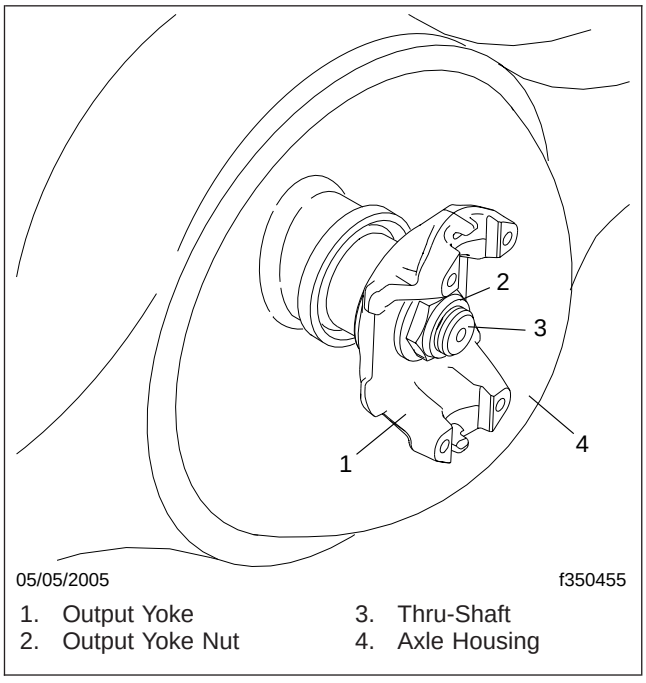
Keep sealant away from this bore.

Fig. 4, Interaxle Lock Bore

12. Coat the threads of a new M45 x 1.5 input yoke nut with Loctite® 277. Install the new washer and input yoke nut on the forward carrier input yoke. Tighten the nut 627 lbf·ft (850 N·m).
13. Connect the main driveshaft. For instructions, see **Section 41.00, Subject 100**.

Output Yoke and Seal

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires.
2. Disconnect the interaxle driveshaft from the output yoke. For instructions, see **Section 41.00, Subject 100**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
3. Remove the output yoke nut and washer from the center of the output yoke.
4. Remove the output yoke from the thru-shaft. See **Fig. 5**.



1. Output Yoke
2. Output Yoke Nut
3. Thru-Shaft
4. Axle Housing

Fig. 5, Output Yoke

5. Pry up the output oil seal, using a prybar or large screwdriver. Clean any old sealant from the axle housing. Do not allow dirt or grease to contaminate the seal bore or thru-shaft bearings.
6. Install a new seal on the thru-shaft, as follows.

Forward-Rear Tandem Axle Yoke and Seal Replacement

6.1 Inspect the area around the output oil seal for damage. Use emery paper to remove scratches, nicks, or burrs on the seal bore.

6.2 Assemble the output seal installer onto the threaded end of the universal handle. See **Table 1**.

6.3 Using the output seal installer assembly, press the seal into the bore until the seal surface is flush with the thru-shaft receptacle.

7. Install the output yoke on the thru-shaft. If the yoke is damaged or worn, install a new yoke.

NOTE: It is not necessary to replace the yoke when replacing the seal.

8. Coat the threads of a new M39 x 1.5 output yoke nut with Loctite® 577. Install the new washer and output yoke nut on the yoke. Tighten the nut 516 lbf·ft (700 N·m).
9. Connect the interaxle driveshaft. For instructions, see **Section 41.00, Subject 100**.

Main Differential Lock Disassembly and Assembly

Special Tool

A special tool is required for this procedure. See **Table 1**.

Special Tool for Main Differential Lock Disassembly and Assembly			
Tool	**Description**	**Manufacturer**	**Part Number**
 f580448	Spring Compression Tool	Axle Alliance Special Tool	W742 589 00 16 00

Table 1, Special Tool for Main Differential Lock Disassembly and Assembly

General Information

Commonly known as DCDL (Driver-Controlled Differential Lock), a main differential lock is available on single and tandem rear axles. On tandem rear axles DCDL is available for the forward, rear, or both axles. The following procedures only apply to Model 4 rear axles with optional DCDL.

Each part of the main differential lock is replaceable. See **Fig. 1**.

Disassembly

1. Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the front tires.
2. Remove the differential carrier, and place it on a work stand.

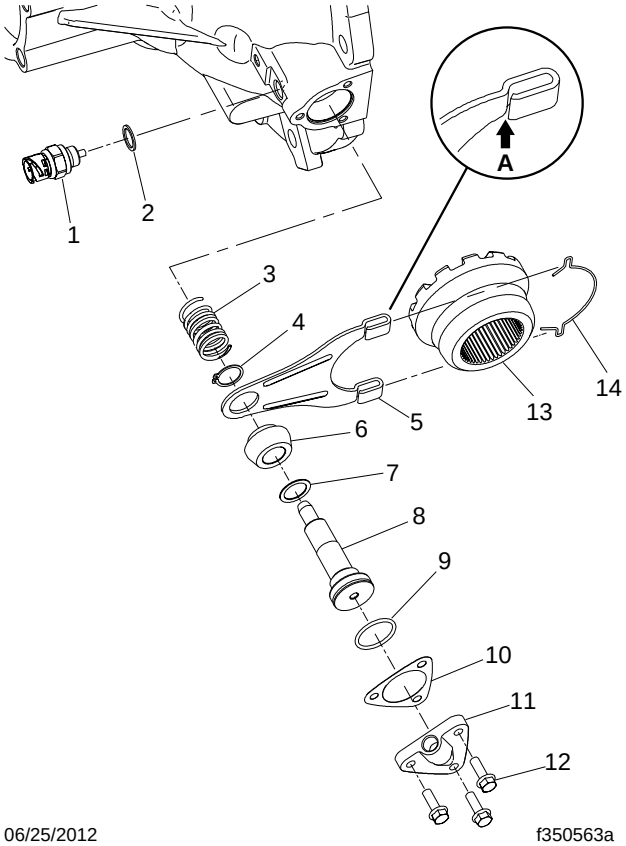
   To remove a single or rearmost axle differential carrier, see **Subject 110**.

   To remove a forward-rear differential carrier, see **Subject 140**.
3. Unlatch the retaining clip, and remove it. See **Fig. 1**.
4. Remove the clutch collar.
5. Remove the DCDL sending unit from the carrier housing.
6. Remove the three bolts that attach the air interface to the carrier housing.
7. Remove the air interface and gasket.
8. Remove the shift shaft piston from the bore in the carrier housing, and note the number of shims found on the piston. There should be at least one shim, and a maximum of three.
9. Using the spring compression tool (see **Table 1**), compress the spring and pull the shift fork from the carrier housing.
10. Remove the spring from the carrier housing.

Assembly

1. Install the spring in the carrier housing, and, using the spring compression tool, compress it to install the shift fork in the housing. Ensure that the spring is centered in the bore.
2. Ensure the O-ring on the shift shaft piston is properly installed and lubricated. Then install the piston, being careful to properly align it in the bore. Do not force the piston into the bore.
3. Place the air interface and gasket over the air interface bore, and insert the three capscrews that attach the air interface to the carrier housing. Tighten the capscrews in a regular sequence that ensures it seats evenly. Tighten the capscrews 19 lbf·ft (25 N·m).
4. Install the clutch collar.

Main Differential Lock Disassembly and Assembly



A. Opening in fork loop faces away from the clutch collar as shown.

1. Sending Unit
2. Sending Unit Seal
3. Spring
4. Snap Ring
5. Shift Fork
6. Alignment Boss
7. Shim(s)
8. Shift Shaft Piston
9. O-Ring
10. Air Interface Gasket
11. Air Interface
12. Capscrew
13. Clutch Collar
14. Retaining Clip

Fig. 1, DCDL Components

5. Install the retaining clip on the shift fork.
6. Install the DCDL sending unit in the carrier housing, as removed.
7. Connect the DCDL air line, and engage the DCDL. Ensure the teeth of the lock fully engage the teeth of the gear inside the carrier housing.
8. The clearance between the clutch collar and ring gear must be between 0.4 and 1.4 mm. Engage the DCDL, and use a feeler gauge to measure the gap.

   If the gap between the clutch collar and ring gear measured between 0.4 and 1.4 mm, ensure the same number of shims are on the shift shaft piston (as when it was removed).

   If the gap between the clutch collar and ring gear was not between 0.4 and 1.4 mm, add or remove shims to vary the gap until it measures within the acceptable range. The acceptable maximum number of shims is three, and the minimum is one.
9. Install the differential carrier.

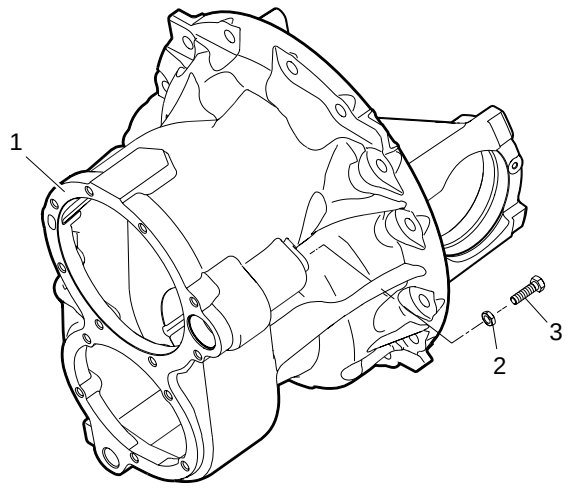
   For instructions on installing a single or rearmost axle differential carrier, see **Subject 110**.

   For instructions on installing a forward-rear axle differential carrier, see **Subject 140**.
10. Remove the chocks.

Adjustment

The Interaxle Differential (IAD) has an adjustment screw that can become loose or even fall out, causing an oil leak, and malfunction of the IAD. To ensure the adjustment screw is properly tightened and secured, follow the steps below. The IAD is sometimes called the power divider. See **Fig. 1**.

1. Chock the front tires.
2. Use the IAD switch in the cab to engage the lock.
3. At the forward-rear axle, rotate one of the wheels to ensure the teeth of the lock fully engage the teeth of the gear inside the carrier housing.
4. Remove the adjustment screw, and using a suitable solvent (such as brake cleaner), clean the threads of the screw and bore. Dry the surfaces completely, making sure no cleaning solvent remains.
5. Coat the threads of the adjustment screw with Loctite® 577, install it, and hand-tighten it until it hits the shaft.
6. Disengage the IAD to relieve the air pressure exerted on the adjustment screw.
7. Hand-tighten the adjustment screw one quarter turn, then tighten the locknut 30 lbf·ft (41 N·m).
8. Remove the chocks.



1. Carrier Housing
2. Locknut
3. Adjustment Screw

Fig. 1, Interaxle Differential and Adjustment Screw

Special Tools

Special tools are required for this procedure. See **Table 1**.

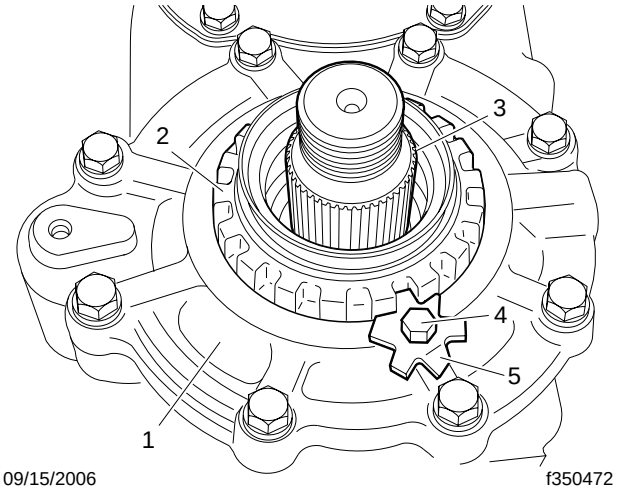
Special Tools for Threaded Ring Repair			
Tool	**Description**	**Manufacturer**	**Part Number**
 f580400	Universal Handle*	Kent-Moore	J-8092
 f580410	Input Seal Installer*	Kent-Moore	J-47369

* To order Kent-Moore tools call 1-800-328-6657.

Table 1, Special Tools for Threaded Ring Repair

Repair

1. Apply the parking brakes, shut down the engine, and chock the tires.
2. Disconnect the main driveshaft from the forward carrier input yoke. For instructions, see **Section 41.00, Subject 100**. Using suitable straps, support the end of the driveshaft by attaching it to the frame rail.
3. Remove the yoke nut and washer from the input shaft of the forward differential carrier, then remove the yoke.
4. Remove the capscrew and the locking plate from the bearing cage on the front of the differential carrier. See **Fig. 1**.
5. Using a spanner wrench, remove the threaded ring to expose the bearing cavity. See **Fig. 2**.
6. Using a suitable solvent, such as brake cleaner, clean the surface of the bearing cavity. See **Fig. 2**. Dry the surface, making sure no cleaning solvent remains.
7. Coat the threads of the threaded ring with Loctite® 577 sealant. Apply a 1/8-inch (3-mm) diameter bead all the way around the bottom thread, then spread the sealant evenly over the threads, so that all threads are thoroughly covered with the sealant.

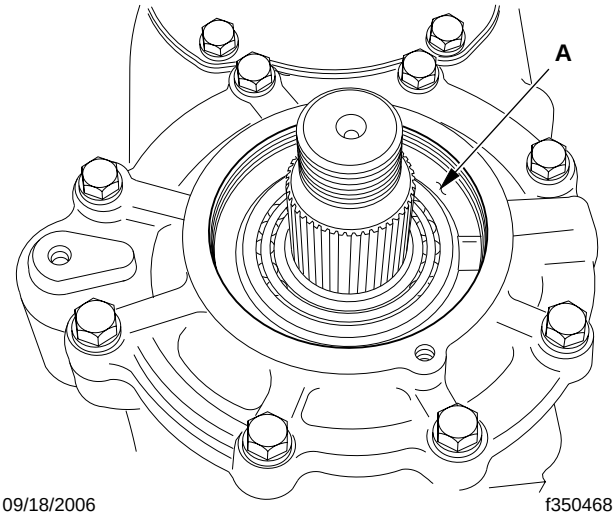


09/15/2006 f350472

1. Bearing Cage
2. Threaded Ring
3. Input Shaft (yoke removed)
4. Capscrew
5. Locking Plate

Fig. 1, Forward-Rear Axle Differential Housing

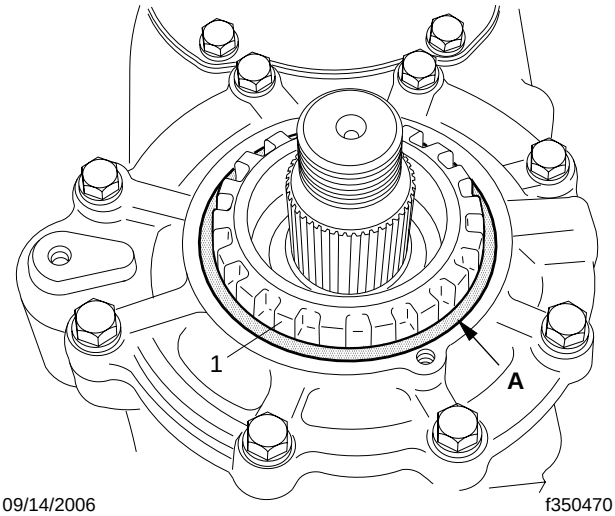
Threaded Ring Repair



A. Clean and dry this entire surface.

Fig. 2, Bearing Cavity Exposed

8. Install the threaded ring (without the new input-shaft seal) and turn it clockwise (tighten it) enough to form a uniform bead of sealant all the way around the threaded ring. See **Fig. 3**.

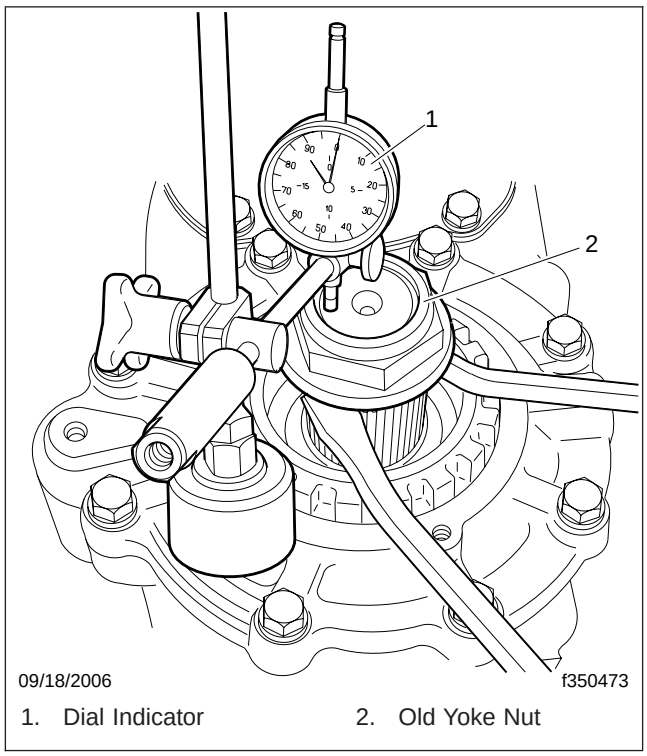


A. Loctite Bead from the Threads

1. Threaded Ring

Fig. 3, Preliminary Installation of the New Threaded Ring

9. Install the old yoke nut on the input shaft to protect the threads, then strike the nut sharply with a brass mallet to unseat the bearing.
10. Adjust the initial bearing preload to 0.002 inch (0.05 mm), as follows:
    10.1 Install a dial indicator on the bearing cage, and using two pry bars, pry up evenly on the yoke nut (and the input shaft) to determine the bearing preload. See **Fig. 4**.



1. Dial Indicator
2. Old Yoke Nut

Fig. 4, Measuring Bearing Preload

    10.2 Tighten the threaded ring until the dial indicator reads 0.002 inch (0.05 mm).
11. Using a suitable marker or paint, mark the center of one of the teeth on the threaded ring and the surface of the bearing cage. See **Fig. 5**.

IMPORTANT: The next step is critical. Tightening the threaded ring by advancing it one tooth will set the bearing preload to 0.00 to 0.0012 inch (0.00 to 0.03 mm). If you tighten the threaded ring beyond this tolerance, you cannot back it off; you will need to remove the threaded ring and repeat the entire installation procedure.

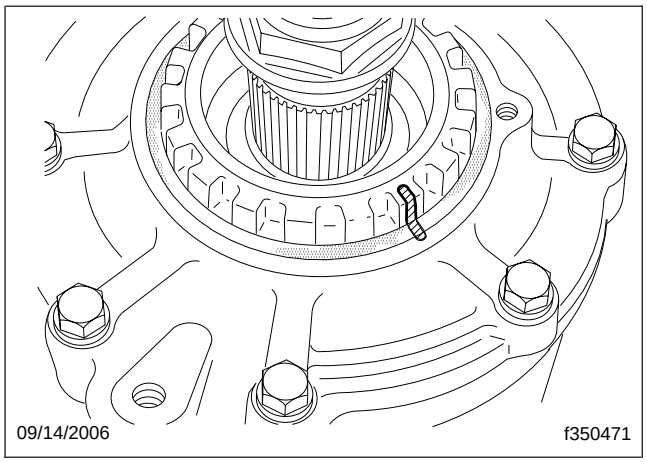


Fig. 5, Marking the Tooth and Bearing Cage

12. Very carefully advance the threaded ring one tooth while checking the paint mark. Stay close to a one-tooth advancement when making the final adjustment. Bear in mind that the new locking plate must fit into place once the correct tightness is achieved. The locking tab should fit in place either slightly before or slightly past a one-tooth advancement of the threaded ring. *You cannot back off the threaded ring once it is tightened.*

    Try fitting the new locking plate in place by turning and flipping it over as you slowly tighten the threaded ring. Tighten the threaded ring so the bearing preload is 0.00 to 0.0012 inch (0.00 to 0.03 mm). When the correct tolerance is reached, the mark on the surface of the bearing cage should line up with the center of the next tooth. See **Fig. 6**. Do not tighten the threaded ring any further.

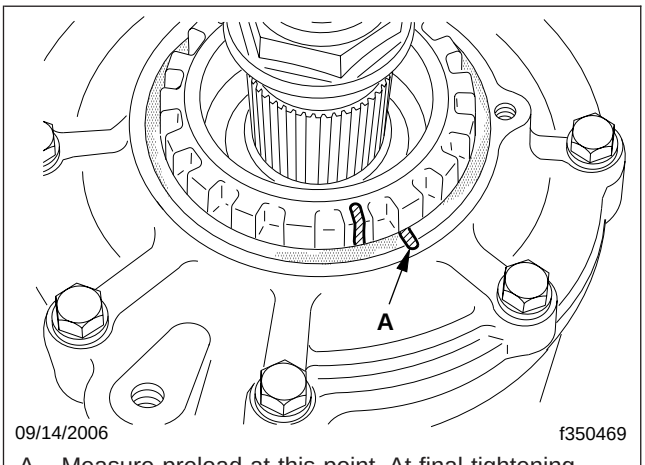
13. When the bearing preload is correct, install the new locking plate and capscrew. Tighten the capscrew 18 lbf·ft (24 N·m).

14. Install the new input-shaft seal as follows (see **Fig. 7**):

    14.1 Inspect the area around the seal for damage. Use emery paper to remove scratches, nicks, or burrs on the seal bore.

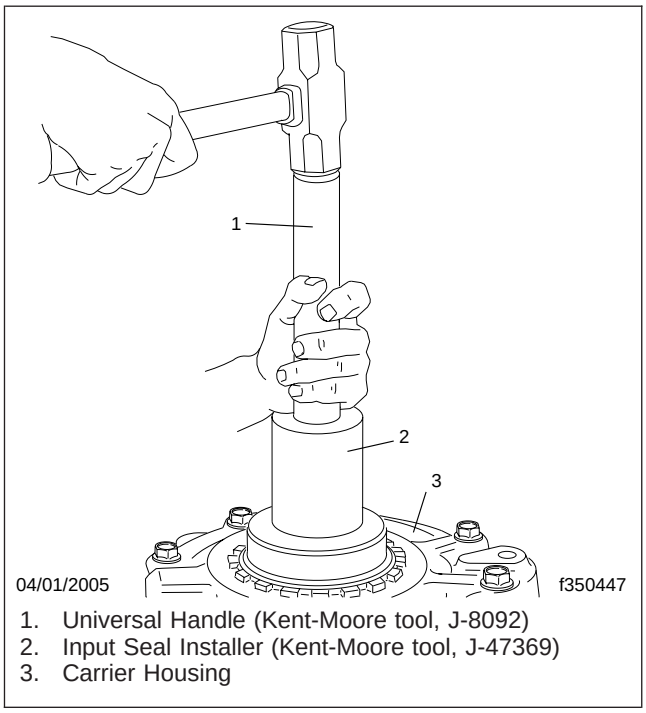
    14.2 Apply a light coating of axle oil to the seal bore.

    14.3 Coat the mating surfaces of the new seal with Loctite® 5900 sealant, or equivalent.



A. Measure preload at this point. At final tightening, this mark should be opposite the center of the next tooth, but no further.

Fig. 6, Advancing the Threaded Ring



1. Universal Handle (Kent-Moore tool, J-8092)
2. Input Seal Installer (Kent-Moore tool, J-47369)
3. Carrier Housing

Fig. 7, Installing the Forward Carrier Input Seal

14.4 Assemble the input shaft seal installer onto the threaded end of the universal handle. See **Fig. 7**.

Threaded Ring Repair

14.5 Using the input shaft seal installer assembly, press the seal into the bore until the seal surface is flush with the threaded ring.

15. Apply Loctite 242 to the threads of the new yoke nut, then using it and a new washer, install the existing yoke on the input shaft. Tighten the yoke nut 628 lbf·ft (850 N·m).
16. Connect the main driveshaft to the input shaft. For instructions, see **Section 41.00, Subject 100**.
17. Remove the chocks.

Specifications

Table 3, Special Tools for Detroit Rear Axles

General Information

Radial ply tubeless tires are standard on all L-Line and A-Line vehicles. Tubeless tires are mounted on 15-degree drop-center wheels.

NOTE: Do not mix 10-hole two-piece flange nut hub mount disc wheels with 10-hole ball seat lug nut stud mount disc wheels.

Heavy-duty 10-hole two-piece flange nut disc wheels have an 11.25-inch (285.75-mm) bolt circle with M22 x 1.5 wheel mounting studs.

CAST SPOKE WHEELS

Cast spoke wheels consist of a cast spider and a brake drum and a separate demountable one-piece rim. See **Fig. 1** and **Fig. 2**. Clamps and hold-down nuts on the 3/4-inch studs secure the rim to the wheel. On dual rear wheels, a ring-shaped spacer holds the inner and outer rims apart.

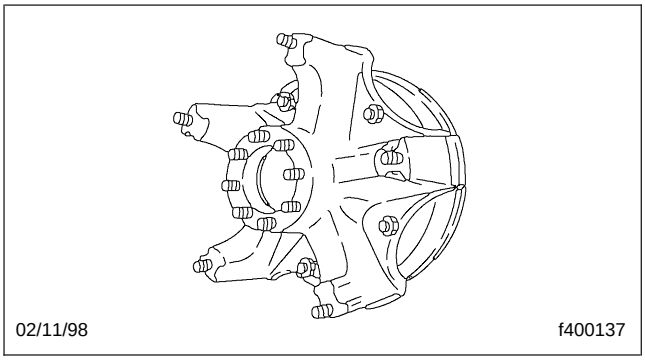

Fig. 1, Cast Spoke Wheel Cast Spider and Brake Drum

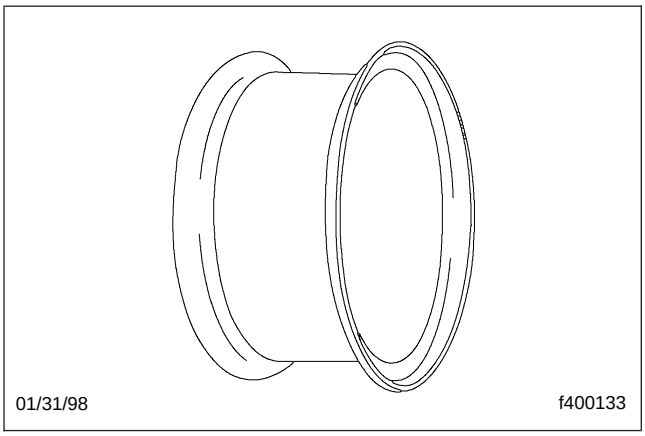

Fig. 2, Cast Spoke Wheel Demountable One-Piece Rim

Rear cast spoke wheels have five spokes on the 17,500- and 19,000-pound 2-speed axles, and six spokes on the 17,500- and 19,000-pound single-speed, and 21,000-, 23,000-, 34,000-, 40,000- and 46,000-pound rear axles.

The cast spoke wheel uses a one-piece steel, demountable rim. The demountable rim is mounted onto the cast wheel by clamps and stud nuts. See **Fig. 3**.

DISC WHEELS

The disc wheel is a one-piece wheel assembly and mounts onto the wheel hub using 22-mm wheel studs and two-piece wheel nuts. See **Fig. 4** and **Fig. 5**.

On dual rear wheel applications, the inner wheel mounts in the reverse direction of the outer wheel. See **Fig. 5** and **Fig. 6**.

WHEEL ORNAMENT SYSTEM

(See Fig. 7 and Fig. 8)

The wheel ornament system is designed for use on 22.5-inch and 24.5-inch hub-piloted wheels with a 10-hole 11.25-inch (285.75-mm) bolt circle. This system requires a minimum of four threads on the stud to extend through the top of the two-piece wheel nut.

The ornament system uses 10 screw-on Hug-a-Lug® nut covers to attach the center hub cover to the wheel. The lug nut covers screw on over the lug nuts.

TIRE MATCHING AND MIXING

IMPORTANT: Review and follow these requirements for matching and mixing tires, before installing any tire and wheel or rim assembly on a vehicle.

Before changing wheels and tires, consider the effect that the change may have on the Gross Vehicle Weight Rating (GVWR) of the vehicle. At the time of vehicle certification, the GVWR is calculated by adding the vehicle's Gross Axle Weight Ratings (GAWR). The GVWR and each of the GAWRs are shown on a certification label (U.S.-purchased tractors) or "Statement of Compliance" label (Canadian-purchased tractors) attached to the driver's side rear door post. See **Fig. 9**.

General Information

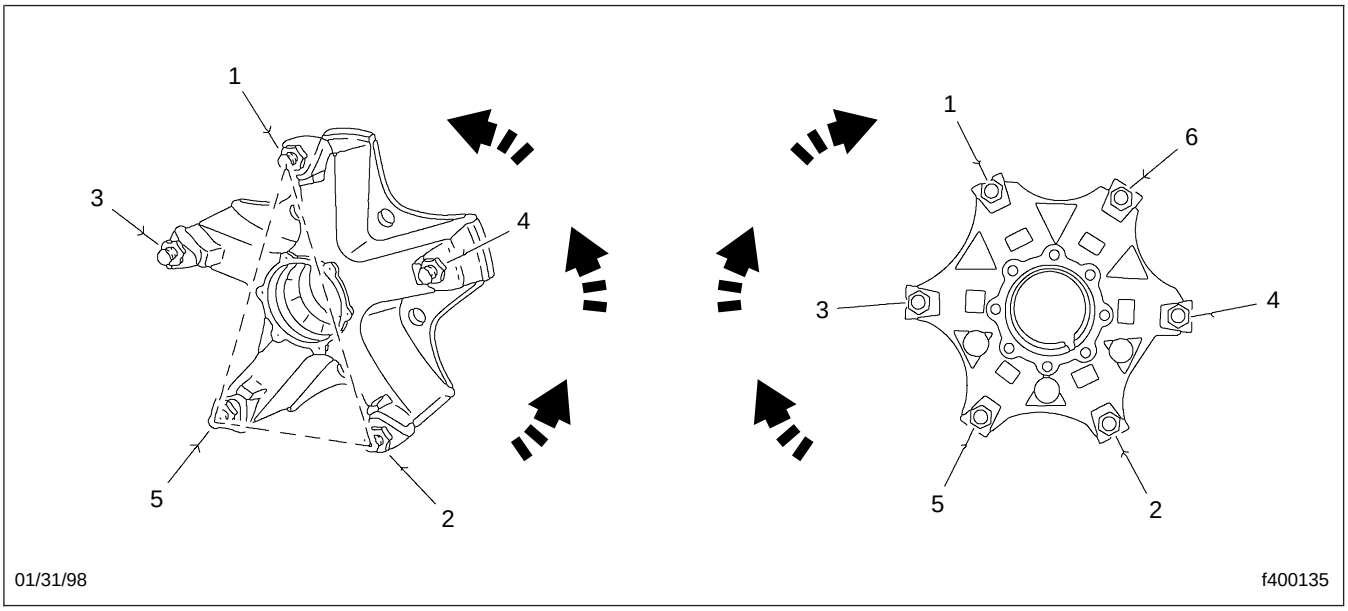

Fig. 3, Demountable Rim Tightening Sequence

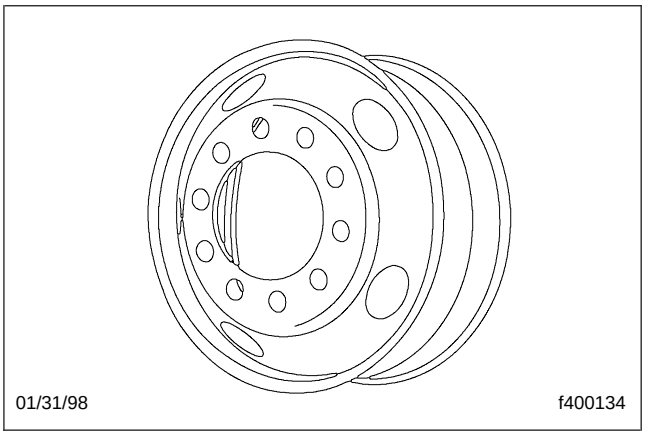

Fig. 4, Front Axle Disc Wheel

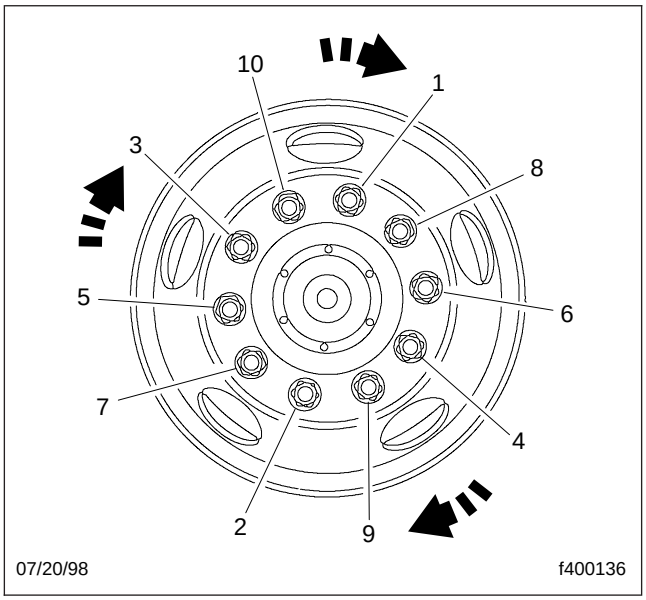

Fig. 5, Disc Wheel Tightening Sequence

Tire and rim labels (**Fig. 9** and **Fig. 10**) certify the minimum tire and rim combinations that can be installed on the vehicle for the given GAWRs. Each GAWR is determined by considering each component of the axle system, including suspension, axle, wheels, and tires. The lowest component's capacity is the value used for the system. Therefore, the tires and rims installed on the vehicle at the time of vehicle manufacture may have a higher load capacity than that certified by the tire and rim label. Tires and rims of the minimum capacity can be installed without changing the load limitations. If tires and rims are installed that have a lower load capacity than that shown on the tire and rim label, then the tires and rims determine the load limitations (the GAWRs and GVWR will be lower).

When pairing tires in a dual assembly, the tire diameters must not differ by more than 1/4 inch (6.4 mm), or the tire circumference by more than 3/4 inch (19 mm). The total tire circumference of one driving rear

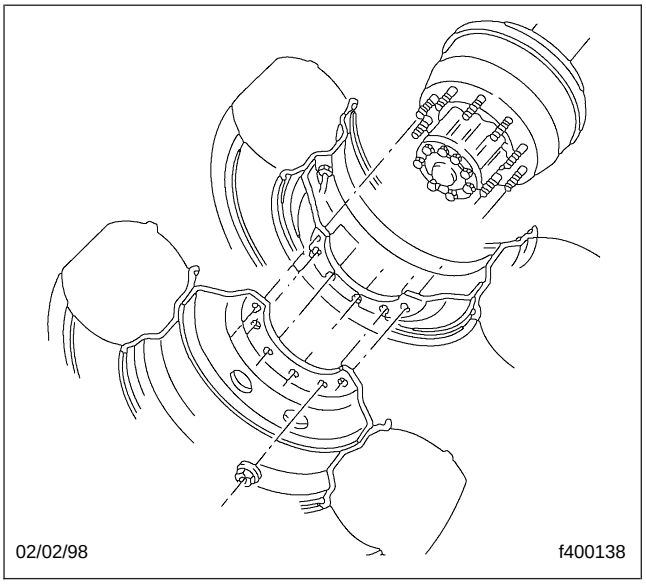

Fig. 6, Rear Axle Disc Wheel

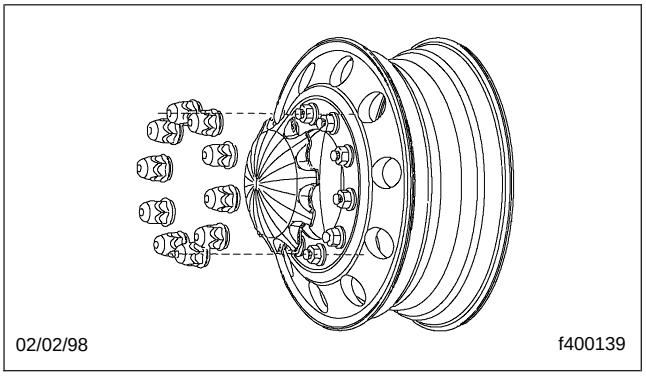

Fig. 7, Front Wheel Ornament System

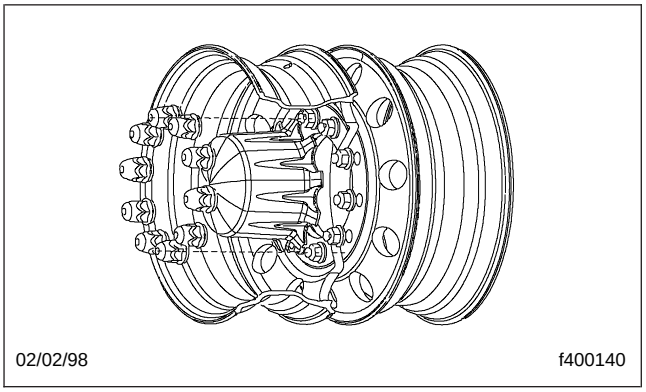

Fig. 8, Rear Wheel Ornament System

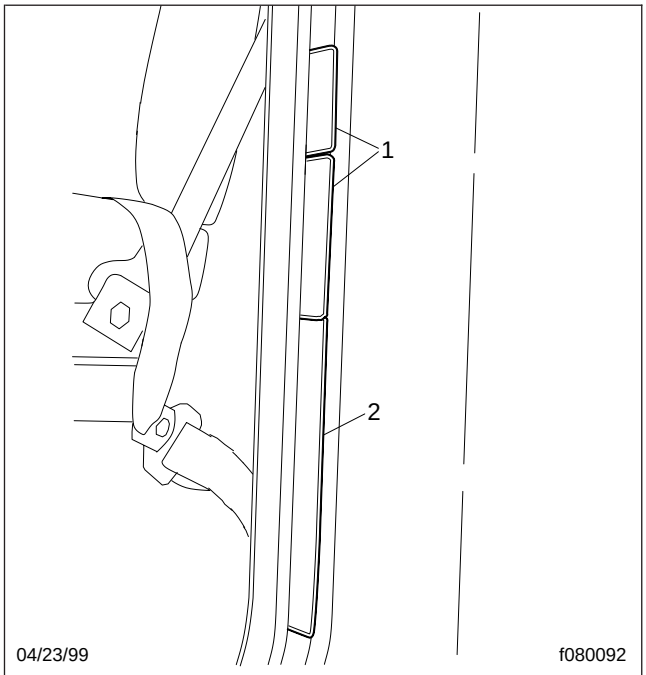
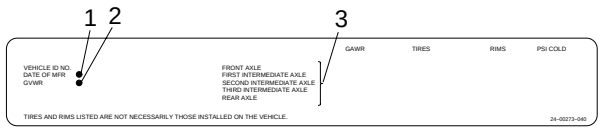


1. Tire and Rim Labels
2. Certification Label

Fig. 9, Labels Location



NOTE: Example only. Actual specifications may vary from vehicle to vehicle.

1. Date of manufacture by month and year.
2. Gross vehicle weight rating; developed by taking the sum of all the vehicle's gross axle ratings.
3. Gross axle weight ratings; developed by considering each component in an axle system, including suspension, axle, wheels, and tires. The lowest component capacity is the value for the system.

Fig. 10, Tire and Rim Label

axle must match, as nearly as possible, the total tire circumference of the other driving rear axle.

⚠ CAUTION

Mismatching dual tires overloads the larger diameter tire, causing it to overdeflect and overheat.

General Information

The smaller diameter tire, lacking proper road contact, wears faster and unevenly. Tread or ply separation, tire body breaks, and blowouts can occur from mismatched duals.

With an endless pi tape (see **Fig. 11**) or square (see **Fig. 12**), measure the diameter of the tires 24 hours after inflation. A matching stick (see **Fig. 13**), string gauge (see **Fig. 14**), or tire straight edge (see **Fig. 15**) can also be used to determine the difference in tire radius, which is then doubled to calculate the diameter difference.

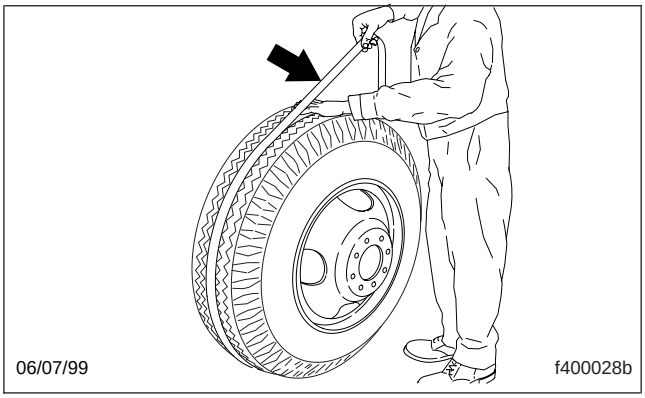


Fig. 11, Endless Pi Tape

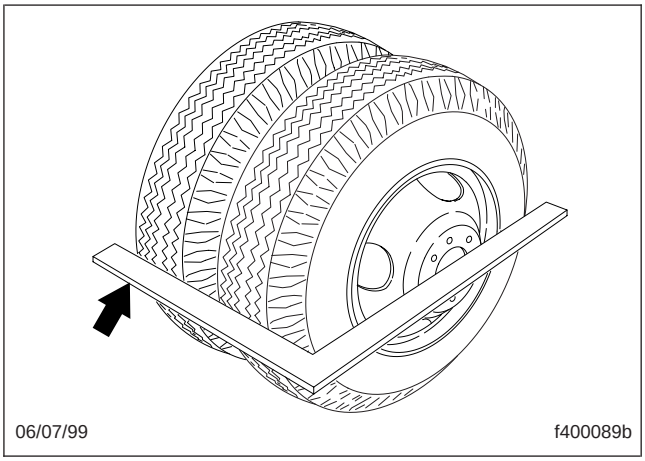

Fig. 12, Square

When pairing tires of unequal diameters (but within the above limits), mount the larger tire on the outside.

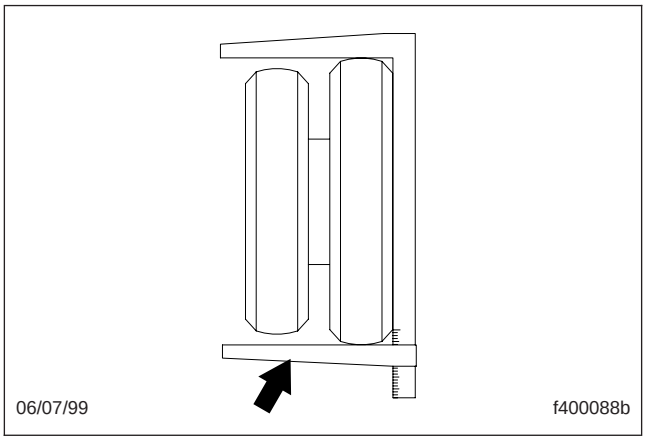

Fig. 13, Matching Stick

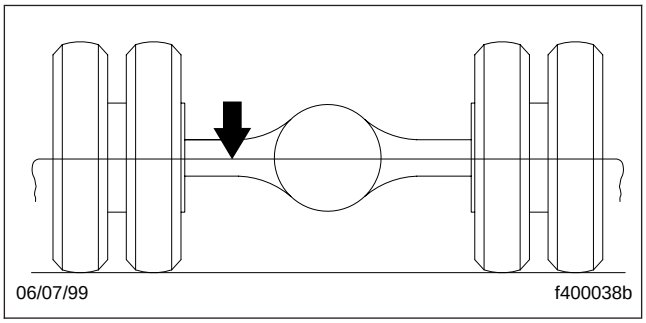

Fig. 14, String Gauge

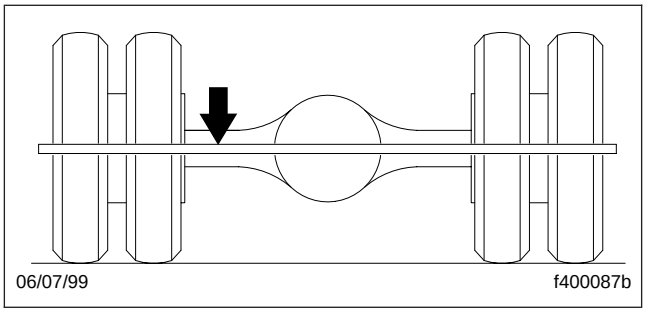

Fig. 15, Tire Straight Edge

⚠ WARNING

Both tires of a dual assembly must be used when driving a vehicle. Driving with only one tire of a dual assembly dangerously exceeds the carrying capacity of the single tire and wheel. Operating in this manner can cause damage to the tire and wheel. This may also result in loss of vehicle

control, which could cause personal injury and property damage.

Inflate all tires on an axle, or on both axles of a tandem unit, to within 5 psi (35 kPa) of one another. For tire inflation specifications, refer to **Specifications, 400**.

There must be sufficient space between dual tires for air to flow and cool the tires, and to prevent them from rubbing against one another. Rims and wheels of the same size, but of different makes and types, can have different offsets, which would affect dual spacing. If there is sidewall contact between tires, or between the inside tire and the chassis, refer to the tire manufacturer's catalog to determine the minimum dual spacing. Refer to the rim or wheel manufacturer's catalog to determine the correct offset.

Federal Motor Carrier Safety regulations require the removal of all tires with less than 4/32-inch (3-mm) remaining groove depth on a front axle, and tires with less than 2/32-inch (1.5-mm) remaining groove depth on a rear axle. However, tires with the word "Regroovable" on the sidewall, may be regrooved.

Better tire and vehicle performance is usually obtained by using tires of the same size and construction. Using tires of different construction is permitted if the following rules are observed:

- Do not mix radial and bias ply tires on the same axle.
- If both radial and bias ply tires are used, better handling is usually obtained by using the bias ply tires on the front axle.
- Use either all radial or all bias ply tires on the non-driving rear axles of a vehicle. However, all radial or all bias ply tires must be used on vehicles with tandem drive-axles.

CAUTION

Mixing radial and bias ply tires should be done as an emergency measure only. Some loss of steering control and premature tire wear could occur when driving under such conditions.

If installing radial tires on a vehicle formerly equipped with bias ply tires, refer to **Specifications, 400** concerning the inflation needs and load limits of the bias ply tires being removed, and of the radial ply tires being installed. Radial ply tires permit greater loads per tire, but also require higher inflation. They can also cause higher stresses on rims and wheels than bias ply tires. Contact the rim or wheel manufacturer about the compatibility of the rim or wheel with radial ply tires. Also, refer to the front axle section in this manual for information on the possible differences in toe-in setting between radial and bias ply tires.

Tire Demounting and Mounting Service Precautions

Service Precautions

⚠ WARNING

Failure to follow the safety precautions before and during tire demounting and mounting could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

IMPORTANT: Do not mount or demount tires without proper training as required in "Servicing Multi-Piece and Single Piece Rim Wheels", *Occupational Safety and Health Administration (OSHA) Rules and Regulations 1910.177*. Service information containing mounting and demounting instructions are available through your rim supplier. Charts detailing service procedures are available through OSHA area offices. The address and telephone number of the nearest OSHA area office can be obtained by looking in the local telephone directory under U.S. Government, Labor Department of Occupational Safety and Health Administration.

Use the information from the above sources with the following precautions before and during the demounting and mounting of tires:

- Examine all wheel and tire parts as explained in **Subject 110** and **Subject 120**. Replace damaged, rusted, or worn parts.
- Since wheels and rims are under stress, and are dangerous if improperly assembled, be sure all parts of an assembly match in size, manufacturer, and classification within a manufacturer's line. Before assembling the wheel or rim, check the catalog issued by the wheel or rim manufacturer for the correct part numbers and sizes of approved parts. Never use a part that does not bear clear, legible, and correct numbers and manufacturer's identification, even if that part appears to fit.
- Make sure that tires are stored indoors, or outdoors under cover, to prevent water collecting inside the tire.
- Use special tools, as recommended by tire suppliers, for mounting and demounting tires. These tools must be smooth, and used with care, to avoid gouging the rim.
- Loosening tire beads may be difficult, since considerable force may be needed. The use of a machine designed for loosening tire beads is recommended.
- Handle the wheels and rims on a wooden floor or rubber mat to prevent nicking or gouging the wheel or rim.
- Do not use a duck-bill hammer, or any steel hammer on wheel or rim parts. Use rubber, leather-faced, or plastic mallets to tap parts together, if necessary.
- Lubricate the tire with an approved tire-mounting lubricant. Never use antifreeze, silicones, petroleum-based lubricants, or any flammable material (ether/starting aid).
- When lubricating a tire prior to mounting, make sure excess lubricant does not run into the tire.
- Michelin Tire Corporation recommends applying lubricant to the valley of the tire, formed by the tire and rim, before using tools to break the bead.
- Michelin also recommends applying a sufficient but sparing amount of lubricant to the entire rim face when mounting a tire on a rim, to ensure correct bead seating and ease of mounting.
- Do not reinflate a tire that has been run flat or has been run at 80 per cent or less of its recommended operating pressure. Use your spare. Before removing the low tire from the vehicle, make sure it is completely deflated. Later, have the assembly taken apart and all the parts checked for damage, including the side or lockrings.
- The air pressure contained in a tire is dangerous. When servicing a tire, stay out of any potential path or route that a rim wheel component may travel during an explosive separation.

Inspection

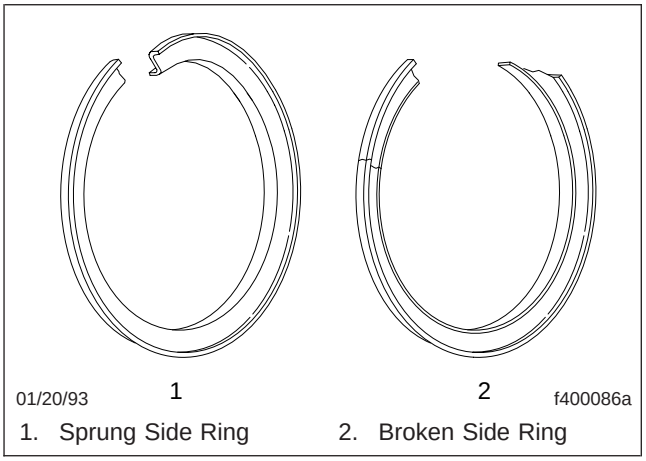
⚠ WARNING

Inspect the tires and wheels, and correct any problems. Failure to do so could cause tire or rim damage while servicing or while in use. An incorrectly mounted tire can burst causing equipment damage and personal injury.

Examine the wheel or rim, and all parts. Remove any grease, dirt, or rust. Using a wire brush, remove any rubber from the bead seat. Use special care when cleaning the rim gutter. Rust or other foreign matter can prevent the correct fitting of side rings. Replace corroded parts. Paint the rim to prevent corrosion.

NOTE: Do not paint Alcoa aluminum disc wheels. If the wheels are corroded, contact the manufacturer for instructions.

Sprung or broken rings (**Fig. 1**), a cracked rim, wheel (**Fig. 2**), or brake drum, damaged inner or outer wheel nuts (**Fig. 3**), or an out-of-round wheel or rim, requires the replacement of the damaged part. Replace the wheel if it has out-of-round stud holes.



1. Sprung Side Ring
2. Broken Side Ring

Fig. 1, Sprung and Broke Side Rings

NOTE: Refer to the front and rear axle sections in this manual for inspection and service procedures for the hub, wheel studs, wheel, and brake drum assemblies. When replacing the spoke wheel or the brake drum, contact the wheel manufacturer for the correct torque value for the brake drum nut that attaches the spoke wheel to the brake drum.

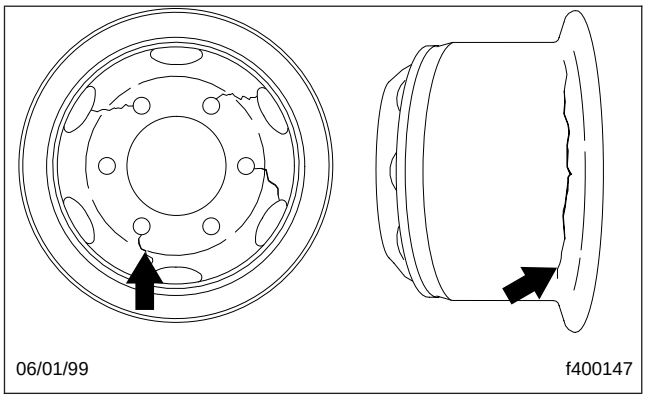


Fig. 2, Cracked Wheel and Rim

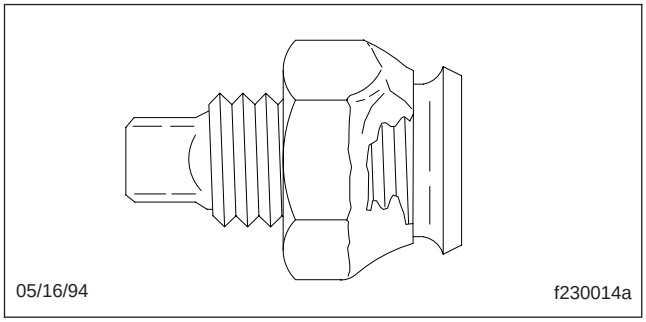

Fig. 3, Damaged Outer Wheel Nut

Inspect valve cores for cracks, bends, and air retention. Replace damaged or leaky cores.

The most critical area of a spoke wheel is the 28-degree tapered rim mounting surface (**Fig. 4**). Clean the surface and examine it for damage or excessive wear. Replace the wheel if the mounting surface is damaged or worn below the 28-degree taper.

Check the clamps, rim spacer, rim studs, and spoke-wheel nuts for damage or wear. The clamps must not be excessively worn. The end of the wedge portion must be at least 1/16-inch thick (1.5-mm). See **Fig. 5**. The rim spacer must not be bent, distorted, or crushed. Replace all damaged or broken parts.

Do not attempt to rework, weld, heat, or braze any rim or wheel parts that are cracked, broken, or damaged. Use new parts or parts that are not cracked, broken, or otherwise damaged, and that are of the same size and type.

Wheel and Components Inspection

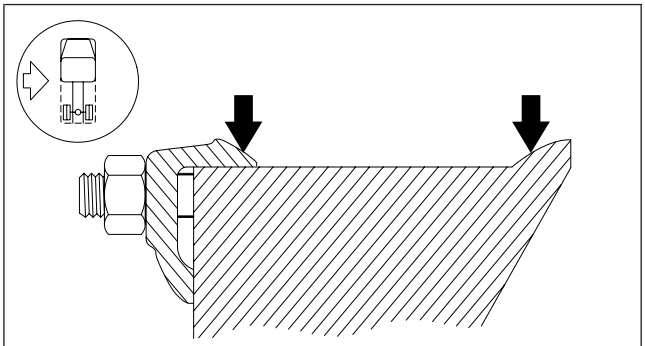

Fig. 4, 28 Degree Tapered Rim Mounting Surface

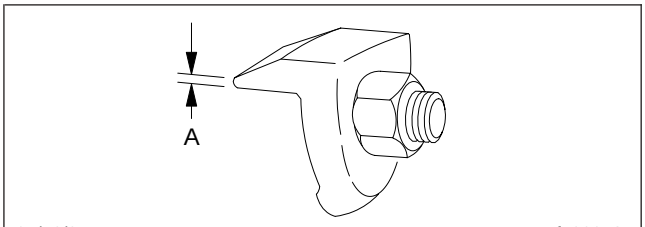

A. End of wedge must be at least 1/16-inch (1.5-mm) thick.

Fig. 5, Rim Clamp

Remove all foreign matter, such as grease and dirt, from the wheel mounting surface. Smooth any projections on the mounting surface to ensure even pressure when tightening the wheel nuts.

Inspection

WARNING

Inspect the tires and wheels, and correct any problems. Failure to do so could cause tire or rim damage while servicing or while in use. An incorrectly mounted tire can burst causing equipment damage and personal injury.

Inspect the inside and outside of the tire for out-of-roundness, loose cords, cuts, foreign objects, and other damage. Repair as needed. Contact the tire manufacturer for repair procedures.

Do not repair tires with the following problems:

- cuts in the tread that are wire or breaker fiber deep
- tread worn to the wire or breaker fibers
- tread that is scalloped or otherwise worn unevenly
- visible, broken, deformed, or otherwise damaged bead wires
- deteriorated rubber
- rubber cracked to the wire or cord
- separations in the casing
- exposed cord (for example, due to weather checking or sidewall scuffing)

Inspect the tread for abnormal or excessive wear. Refer to **Troubleshooting, 300** for possible causes of abnormal wear. If the tires are wearing irregularly, they should be rotated. If the front axle tires become irregularly worn, they should be moved to the drive axle(s) or trailer axles. The front-end alignment should be checked. In a dual assembly, if one tire wears faster than its mate, the position of the two tires should be reversed. Refer to the vehicle maintenance manual for tire rotation procedures.

Government regulations require the removal of any tire with less than 2/32-inch (1.5-mm) tread remaining. Retread the tire (if possible), regroove it (only if marked "Regroovable" on the sidewall), or discard it.

Clean and inspect the tube and flap of tube-type tires. Discard tubes or flaps that are buckled or creased. Do not use an old tube in a new tire, and always mount a used flap in the same size tire and on the same size rim as the one from which it was removed. Michelin Tire Corporation recommends using only new tubes, flaps, valve cores, caps, and O-rings in a new mounting.

Tire Inflation

1. Check all parts to make sure they are correctly seated prior to inflation.

NOTE: Inflate tires in a safety cage (see **Fig. 1**) or an approved portable restraining device. Always use a clip-on chuck with an inline valve and gauge. Make sure the inflation hose is long enough to permit standing to the side of the tire during inflation. Never sit on, or stand in front of, an assembly that is being inflated.

⚠ WARNING

During initial tire inflation, there is the possibility of an explosion of the assembly. Observe the following safety rules to reduce the possibility of serious physical injury in the event of an explosion.

IMPORTANT: Inflate tires immediately after mounting, before the tire lubricant dries. Once the lubricant dries, bead positioning is not possible, even with increased inflation pressure.

Water in the tire can cause ply separation. During tire inflation, air tank reservoirs and lines must be dry. Use well-maintained air line moisture traps, and service them regularly.

2. After placing the tire in a safety cage, or an approved portable restraining device, inflate the tire to 10 psi (69 kPa). Check the parts for correct seating. If the seating is not correct, completely deflate the tire and correct the problem. Never attempt to seat rings or other parts by hammering on an inflated or partially inflated tire.

IMPORTANT: Due to the different flex characteristics of radial sidewalls, it may be necessary to use an inflation aid to help seat tubeless tire beads, such as:

- Metal rings, which use a blast of compressed air to seat the beads;
- Rubber rings, which seal between the tire bead and rim, allowing the bead to move out and seat correctly. A well-lubricated, heavy-duty bicycle tube can be used to help seal between the tire bead and rim.

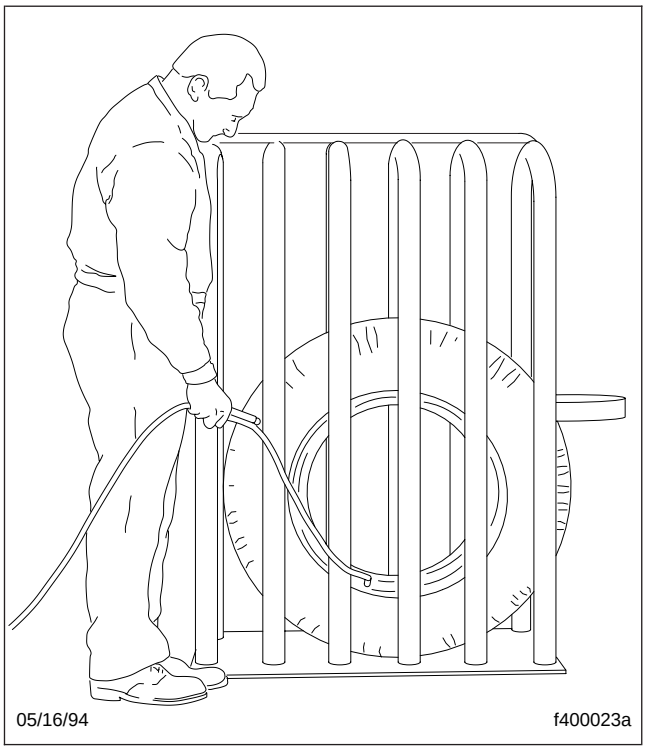

Fig. 1, Safety Cage

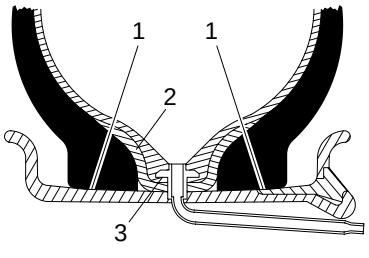
3. If there are no problems with the assembly at 10 psi (69 kPa), continue to inflate the tire to the recommended pressure. Refer to **Specifications, 400** for correct cold inflation pressures. Michelin Tire Corporation recommends an initial inflation pressure of 90 to 100 psi (620 to 690 kPa) to correctly seat the tire beads.

NOTE: The position of the beads, flap, and tube with 4 to 5 psi (28 to 35 kPa) pressure is shown in **Fig. 2**. The tube is fully rounded-out within the tire, but there is not enough pressure to move the beads on wide-base rims. Depending on the tire size and rim condition, from 20 to 40 psi (140 to 275 kPa) pressure is needed to push the beads onto the bead seat. See **Fig. 3**.

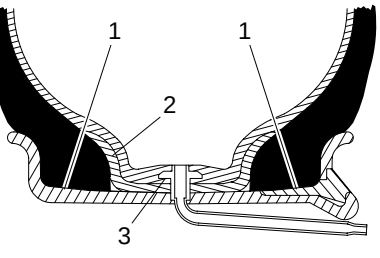
4. After the initial inflation, completely deflate the tire by removing the valve core. This ensures correct bead seating, and prevents buckling or overstretching the tube in tube-type tires. Then inflate the tire to the recommended cold inflation pressure listed in **Specifications, 400**. Install valve caps and finger-tighten them.

Tire Inflation



1. Tapered Bead Seat
2. Flap
3. Valve Base

Fig. 2, Position of Beads, Flap, and Tube at 4 to 5 psi (28 to 35 kPa)



1. Tapered Bead Seat
2. Flap
3. Valve Base

Fig. 3, Beads Pressured Onto the Bead Seat

⚠ CAUTION

Improperly inflating tube-type tires can crack or tear the edge or inside of the valve base. Once seated, the tube can stretch only in the rim area. Because resistance to stretch is greatest at the valve base, there is often enough tension to break the tube at the edge of the valve base or in the valve base.

IMPORTANT: Use tires of the same size, type, and capacity to carry the load at the recommended cold pressure. Attempting to increase the load capacity of a tire by overinflation will damage the tire assembly.

NOTE: Inflate the tires to the recommended pressure. Driving on overinflated tires will weaken the cords by reducing their ability to absorb road shocks, and will increase the danger of cuts, snags, and punctures. Overinflation will overstress and damage the rims. Driving on underinflated tires will generate excessive heat. This weakens the tire body, and reduces tire strength.

⚠ WARNING

Inflate tires to the specified pressure. Tire underinflation or overinflation will damage wheels and tires, and could result in a blowout, causing possible personal injury and property damage.

5. Check the inflation pressure 24 hours after mounting new tires.

NOTE: When testing a vehicle on a dynamometer, severe tire damage can occur. Because the manufacturers differ in their recommendations for preventing tire damage, refer to the manufacturer's instructions for testing a vehicle on a dynamometer.

10-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock all tires that will not be serviced to prevent vehicle movement.
2. If working on the front axle wheels, raise the front of the vehicle until the tires clear the floor. Place safety stands under the front axle.

   If working on the rear axle wheels, raise the rear of the vehicle until the tires clear the floor. Place safety stands under the axle being serviced.
3. If the tire or wheel is damaged or if there is suspected damage, deflate the tire (or tires, on a dual assembly) being serviced by removing the valve core.
4. Turn the wheel until one hub-pilot pad is in the top-center position.
5. Leaving the top and bottom nuts until last, remove the other eight two-piece flange nuts.
6. Place a jack or wheel-and-tire dolly under the wheel assembly being serviced. Remove the top and bottom nuts.

⚠ CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during removal and damage the stud threads or hub-pilot pads. Keep the wheel square to the hub during removal.

IMPORTANT: On both sides of the vehicle, the two-piece flange nuts have right-hand metric threads.

7. Remove the wheel. Do not let it drop on or drag across the stud threads.

Installation

IMPORTANT: Before installing the wheels, it is recommended that an anti-seize compound be applied on the 360 degree wheel pilot hubs of Meritor FF-981 "Easy Steer Plus" front axles. After time in service, a small amount of rust or corrosion may make the wheel difficult to remove because of the extended wheel-to-hub contact. Applying an anti-seize compound on the wheel pilot of the hub will ensure easy wheel removal at a later date. Compounds such as the following may be used:

- Armite Led-Plate No. 250
- Loctite® Anti-Seize No. 767
- Never-Seez
- Permabond Anti-Seize No. 82-9839

Compounds are available for purchase locally.

IMPORTANT: "Turbo" wheel assemblies require directional mounting, as shown in **Fig. 1**.

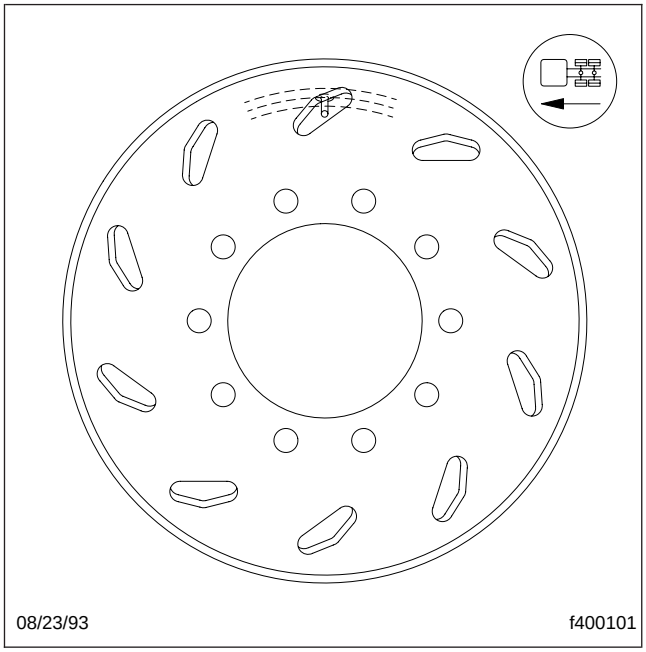


Fig. 1, Side View

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 110**. Also, follow the tire matching and mixing requirements in **Subject 050**.

1. Clean the hub and wheel mounting surfaces, and all disc faces of dual wheels. Make sure the tire is correctly inflated. For instructions, see **Subject 130.**
2. Apply a few drops of light engine oil to the wheel studs and the area between the body and the flange of each two-piece flange nut. Wipe off any excess oil.

10-Hole Disc Wheel With Two-Piece Flange Nuts Removal and Installation

CAUTION

The wheel center hole and hub pilot have close tolerances. If the wheel is not kept square to the hub, it could bind during installation and damage the stud threads or hub-pilot pads. Keep the wheel square to the hub during installation.

IMPORTANT: Before installing the wheels, make sure the drum is positioned on the raised step of the pilot pad. One of the hub's pilot pads must be at the top location. To help keep the drum in place, it may be necessary to adjust the brakes before installing the wheels.

3. If installing a rear wheel assembly, go to the next step. Install the front wheel assembly.
   - 3.1 Locate one hub-pilot pad in the top-center position. Using a jack or wheel-and-tire dolly, position the wheel assembly on the hub. Make sure the wheel is square to the hub so that the stud threads or hub-pilot pads are not damaged by contact with the wheel during installation.
   - 3.2 Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheel is 180 degrees opposite the balance weight(s) on the brake drum.

4. Install the rear wheel assembly.
   - 4.1 Locate one hub-pilot pad in the top-center position. Using a jack or wheel-and-tire dolly, position the inner wheel assembly on the hub. Make sure the wheel is square to the hub so that the stud threads or hub-pilot pads are not damaged by contact with the wheel during installation.
   - 4.2 Using the same procedure, mount the outer wheel against the inner wheel. Make sure the hub-pilot pad is still centered at the top.

IMPORTANT: Install the wheel assembly so that the balance weight(s) on the wheel is 180 degrees opposite the balance weight(s) on the brake drum. If this causes the valve stems to be in the same wheel hole on rear wheel assemblies, mount the outer wheel so that the outer wheel balance weight(s) is on the same side as the brake drum balance weight(s).

5. Install and hand-tighten a two-piece flange nut on the top and bottom studs.

CAUTION

The two-piece flange nuts have right-hand metric threads. Do not try to install a similar size SAE nut on a stud, or the stud and nut will be damaged.

6. Install and hand-tighten the remaining two-piece flange nuts. Tighten the nuts 50 lbf·ft (68 N·m) following the sequence in **Fig. 2**.

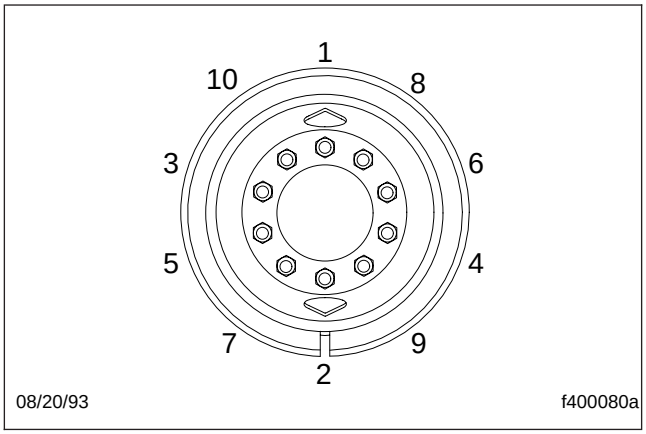

Fig. 2, 10-Stud Disc Wheel Tightening Sequence

7. Check that the wheel is correctly seated against the hub and on the hub-pilot pads.
8. Following the sequence in **Fig. 2**, tighten the two-piece flange nuts 450 to 500 lbf·ft (610 to 678 N·m).

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their

locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

9. Remove the safety stands, lower the vehicle, and remove the chocks.

CAUTION

Too little wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and extreme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 2.

IMPORTANT: The two-piece flange nuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts to the specified torque. Tighten the two-piece flange nuts to the specified torque 50 to 100 miles (80 to 160 km) after service work, and check the torque every 10,000 miles (16 000 km) thereafter.

10. After operating the vehicle for 50 to 100 miles (80 to 160 km), retighten the wheel nuts 450 to 500 lbf·ft (610 to 678 N·m). Follow the sequence in Fig. 2.

10-Hole Disc Wheel With Inner and Outer Nuts Removal and Installation

Removal

1. Chock all tires that will not be serviced to prevent vehicle movement.
2. If removing wheels and tires from a rear axle, go to the next step. Remove the wheels and tires from the front axle.
   - 2.1 Apply the parking brakes.
   - 2.2 Raise the front of the vehicle until the tires clear the floor. Place safety stands under the front axle.
   - 2.3 Deflate the tire being serviced by removing the valve core.
   - 2.4 Place a jack or wheel-and-tire dolly under the front wheel assembly being serviced. Remove the wheel nuts, then raise and remove the wheel assembly. Be careful not to damage the threads of the wheel studs as the wheel is pulled away.
3. Remove the wheels and tires from a rear axle.
   - 3.1 Raise the rear of the vehicle until the tires clear the floor. Place safety stands under the axle being serviced.
   - 3.2 Deflate both tires of the dual assembly being serviced by removing the valve cores.
   - 3.3 Place a jack or wheel-and-tire dolly under the outer wheel assembly. Remove the outer wheel nuts, then raise and remove the outer wheel. Be careful not to damage the threads of the inner wheel nuts as the outer wheel is pulled away.
   - 3.4 Place a jack or wheel-and-tire dolly under the inner wheel assembly. Remove the inner wheel nuts, then raise and remove the inner wheel. Be careful not to damage the threads of the wheel studs as the inner wheel is pulled away.

Installation

IMPORTANT: Before installing the wheels, it is recommended that an anti-seize compound be applied on the 360 degree wheel pilot hubs of Meritor FF–981 "Easy Steer Plus" front axles.

After time in service, a small amount of rust or corrosion may make the wheel difficult to remove because of the extended wheel-to-hub contact. Applying an anti-seize compound on the wheel pilot of the hub will ensure easy wheel removal at a later date. Compounds such as the following may be used:

- Armite Led-Plate No. 250
- Loctite® Anti-Seize No. 767
- Never-Seez
- Permabond Anti-Seize No. 82–9839

Compounds are available for purchase locally.

IMPORTANT: "Turbo" wheel assemblies require directional mounting, as shown in **Fig. 1**.

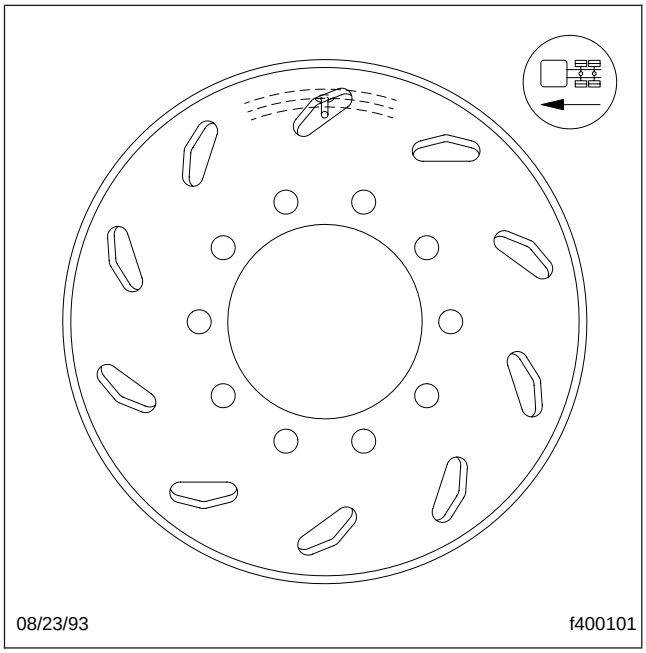

Fig. 1, Side View

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 110**. Also, follow the tire matching and mixing requirements in **Subject 050**.

1. Clean the hub and wheel mounting surfaces, and between the rims of dual wheels. Make sure the tire is inflated using the procedures in **Subject 130**.

10-Hole Disc Wheel With Inner and Outer Nuts Removal and Installation

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

2. If installing a rear wheel assembly, go to the next step. Install the front wheel assembly.

   2.1 Use a jack or wheel-and-tire dolly to mount the wheel assembly on the wheel studs. Be careful not to damage the threads of the wheel studs when installing the wheel assembly.

   2.2 Install a wheel nut on each wheel stud, and run them up until each nut is flush with the face or the chamfer of the wheel. Rotate the wheel a half turn to seat the parts.

   2.3 Tighten the wheel nuts 50 lbf·ft (68 N·m), following the sequence in **Fig. 2**.

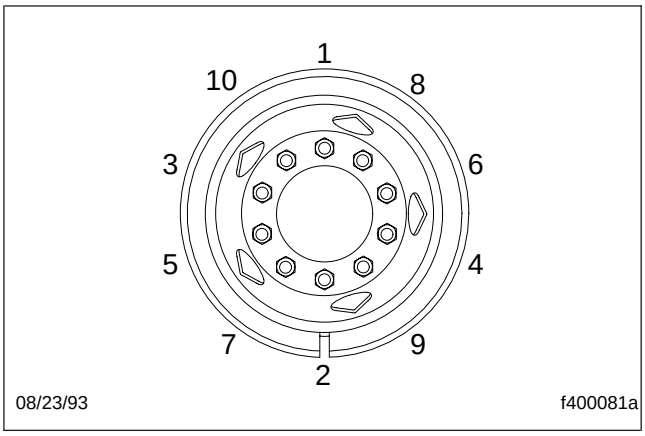

Fig. 2, 10-Stud Disc Wheel Tightening Sequence

   2.4 Using the same sequence, tighten the wheel nuts again to the torque in the disc-type wheel fastener torque table in **Specifications, 400**.

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

3. Install a rear wheel assembly.

   3.1 Use a jack or wheel-and-tire dolly to mount the inner wheel assembly on the wheel studs. Be careful not to damage the threads of the wheel studs when installing the wheel assembly.

   IMPORTANT: Mount the wheel assembly so that the balance weight(s) on the wheel is 180 degrees opposite the balance weight(s) on the brake drum (**Fig. 3**).

   If, on two-handhole wheels, this causes the valve stems to be in the same wheel hole, mount the outer wheel so that the outer wheel balance weight(s) is on the same side of the assembly as the brake drum balance weight(s). See **Fig. 4**.

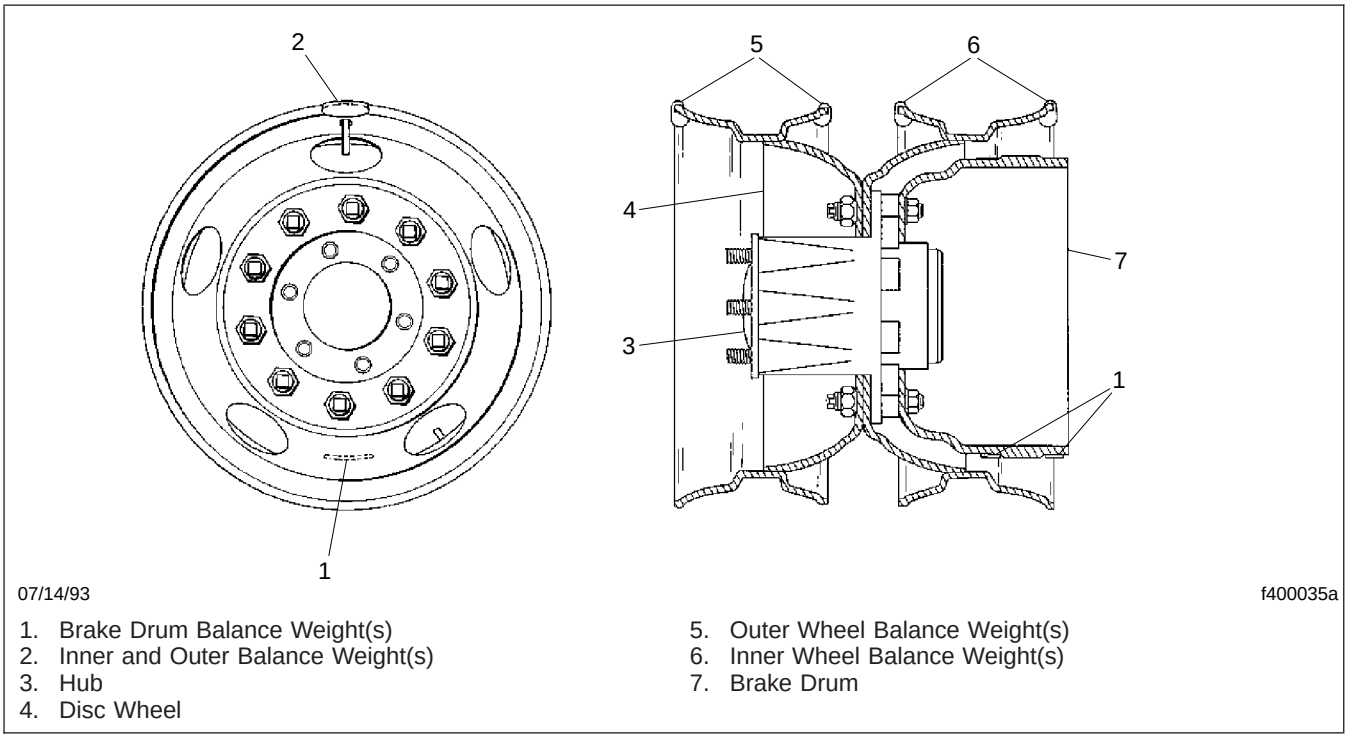
   If, on five-handhole or aluminum wheels, the valve stems are in the same handhole, separate the valve stems by one hole. If balancing the wheels, install the wheel weights evenly and as close to 180 degrees opposite the brake drum balance weight(s) as possible. See **Fig. 5**.

   3.2 Install the inner wheel nuts on each wheel stud, and run them up until each

10-Hole Disc Wheel With Inner and Outer Nuts Removal and Installation

nut is flush with the face or the chamfer of the wheel. Rotate the wheel a half turn to seat the parts.

3.3 Tighten the inner wheel nuts 50 lbf·ft (68 N·m), following the sequence in **Fig. 2**.



1. Brake Drum Balance Weight(s)
2. Inner and Outer Balance Weight(s)
3. Hub
4. Disc Wheel
5. Outer Wheel Balance Weight(s)
6. Inner Wheel Balance Weight(s)
7. Brake Drum

Fig. 3, Recommended Location of Wheel and Brake Drum Balance Weights

3.4 Using the same sequence, tighten the inner wheel nuts again to the torque in the disc-type wheel fastener torque table in **Specifications, 400**.

3.5 Use a jack or wheel-and-tire dolly to mount the outer dual wheel on the inner wheel nuts. Be careful not to damage the threads of the inner wheel nuts when installing the wheel assembly.

3.6 Install the outer wheel nuts following the procedures above.

4. Remove the safety stands, lower the vehicle, and remove the chocks.

CAUTION

Locknuts seat during vehicle operation. It is necessary to periodically tighten the wheel nuts to the specified torque. Not enough wheel nut torque can cause wheel shimmy, wheel damage, stud breakage, and extreme tire tread wear. Too much wheel nut torque can break studs, damage threads, and crack discs in the stud hole area. Use the specified torque values, and follow the tightening sequence in Fig. 2.

5. After operating the vehicle for 50 to 100 miles (80 to 160 km), retighten the wheel nuts to the torque in the disc-type wheel fastener torque table in **Specifications, 400**. Follow the sequence in **Fig. 2**.

NOTE: When retightening the inner wheel nuts, loosen the outer wheel nuts several turns, retighten the inner wheel nuts, then the outer wheel nuts.

Spoke Wheel Tire and Rim Assembly Removal and Installation

Removal

1. Chock all tires that will not be serviced to prevent vehicle movement.
2. If removing tire and rim assemblies from a rear axle, go to the next step. Remove the tire and rim assembly from the front axle.
   - 2.1 Apply the parking brakes.
   - 2.2 Raise the front of the vehicle until the tires clear the floor. Place safety stands under the front axle.
   - 2.3 Deflate the tire being serviced by removing the valve core.
   - 2.4 Place a jack or wheel-and-tire dolly under the front tire and rim assembly being serviced. Remove the rim nuts and rim clamps. Slide the tire and rim assembly off.
3. Remove a tire and rim assembly from a rear axle.
   - 3.1 Raise the rear of the vehicle until the tires clear the floor. Place safety stands under the axle being serviced.
   - 3.2 Deflate the tire(s) being serviced by removing the valve core(s).
   - 3.3 Place a jack or wheel-and-tire dolly under the outer tire and rim assembly being serviced. Remove the rim nuts and clamps. Slide the outer tire and rim assembly off.
   - 3.4 Remove the rim spacer. Place a jack or wheel-and-tire dolly under the inner tire and rim assembly. Slide the inner tire and rim assembly off.

Installation

NOTE: Before installing a wheel and tire assembly, inspect it using the instructions in **Subject 110**. Also, follow the tire matching and mixing requirements in **Subject 050**.

1. Clean the wheel, rim spacer, and rim mounting surfaces. The mounting surface of the wheel is the 28-degree taper on the inboard side of each spoke. See **Fig. 1**.

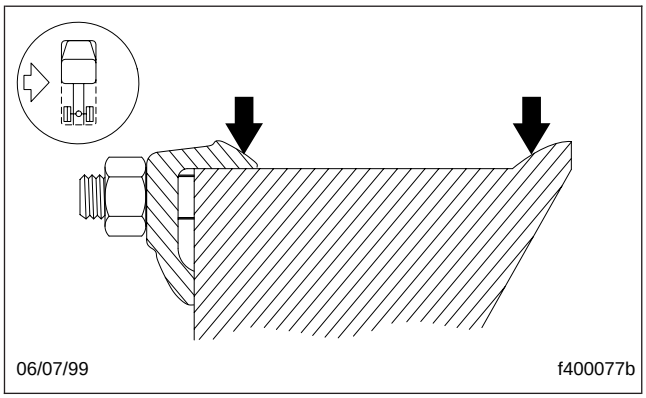

Fig. 1, 28 Degree Tapered Rim Mounting Surfaces

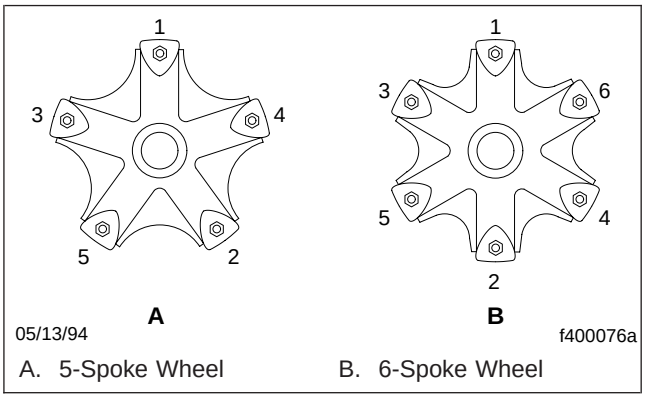
2. Make sure the tire and rim assembly is inflated using the procedures in **Subject 130**.
3. If installing a rear tire and rim assembly, go to the next step. Install a front tire and rim assembly.
   - 3.1 Slide the assembly over the wheel and push it into place against the tapered mounting surface. It should fit snugly against all the tapers. Be sure that the valve stem faces out and is centered between two spokes.
   - 3.2 Install the rim clamps and nuts. Run the nuts up until the end of each wheel stud is flush with the face of its nut. Rotate the wheel a half turn to seat the parts.

CAUTION

Failure to tighten the nuts in the sequence shown, and to the correct torque, could cause misalignment of the tire and chording of the rim (see Fig. 3). This would result in excessive vehicle vibration and permanent damage to the rim and wheel.

   - 3.3 Tighten the rim nuts a quarter turn at a time, following the star pattern shown in **Fig. 2**. Continue until all the rim nuts are tightened to the torque shown in the applicable torque table in **Specifications, 400**.

Spoke Wheel Tire and Rim Assembly Removal and Installation



A. 5-Spoke Wheel B. 6-Spoke Wheel

Fig. 2, Spoke Wheel Tightening Sequence

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

NOTE: When replacing a spoke wheel, contact the wheel manufacturer for the correct torque value for the brake drum nuts attaching the spoke wheel to the brake drum.

4. Install a rear tire and rim assembly.

   4.1 Slide the inner tire and rim over the wheel hub. Push it into position against the tapered mounting surface. Make sure the valve stem faces out and is centered between two spokes.

   4.2 Slide the rim spacer over the wheel hub.

   4.3 Slide the outer tire and rim over the wheel hub. Make sure the valve stem faces inward, and is in the same position as the inner valve stem.

   4.4 Push the whole assembly in place, so that the inner rim fits snugly against the tapers. The spacer is seated against the inner rim, and the outer rim is seated against the spacer.

   4.5 Install the rim clamps and nuts. Run the nuts up until the end of each stud is flush with the face of its nut. Rotate the wheel a half turn to allow the parts to seat.

CAUTION

Failure to tighten the nuts in the sequence shown, and to the correct torque, could cause misalignment of the tire and chording of the rim (see Fig. 3). This would result in excessive vehicle vibration and permanent damage to the rim and wheel.

   4.6 Tighten the rim nuts a quarter turn at a time, following the star pattern shown in **Fig. 2**. Continue until all the rim nuts are tightened to the torque shown in the applicable torque table in **Specifications, 400**.

   4.7 The clamps must not bottom out until at least 80 percent of the recommended torque is reached. If the clamps do bottom out, make sure the correct clamps and rim spacers are being used. Make sure the rim edges contact the spacer edges.

WARNING

Failure to replace damaged parts could result in the loss of a wheel or loss of vehicle control, causing personal injury or property damage. Always replace damaged parts with new parts.

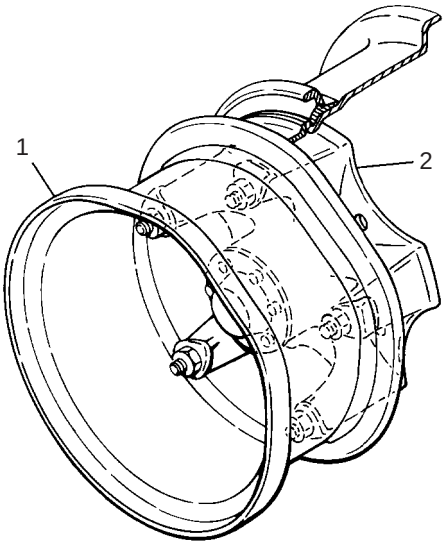
IMPORTANT: If the wheel nuts cannot be tightened to minimum torque values, the studs could be turning in the hub flange, having lost their locking ability. In this situation, the wheel hub assembly is damaged and must be replaced with a new assembly. Failure to reach minimum torque values could also be caused by stripped threads on the wheel studs or wheel nuts. Again, damaged parts must be replaced with new parts.

Spoke Wheel Tire and Rim Assembly Removal and Installation

NOTE: When replacing a spoke wheel, contact the wheel manufacturer for the correct torque value for the brake drum nuts attaching the spoke wheel to the brake drum.

5. Check the wheel alignment by placing a block of wood or any other point of reference on the floor next to the tire. Rotate the tire and note any variations in the space between the tire and the block. If the variation exceeds 1/16-inch (1.5-mm) for front rims, or 1/8-inch (3-mm) for rear duals, the rim is not correctly mounted.

   To correct any misalignment, loosen the rim nuts where the largest gap occurs, and tighten the nuts on the opposite side. Recheck and correct until the variation is corrected. Make sure the rim nuts are tightened to the correct torque shown in the applicable torque table in **Specifications, 400**.



1. Rim
2. Spoke Wheel

Fig. 3, Out-of-Round Rim (rim chording)

6. Remove the safety stands, lower the vehicle, and remove the chocks.
7. After driving the vehicle for 50 to 100 miles (80 to 160 km), retighten the rim nuts to the torque specified in the applicable torque table in **Specifications, 400**. Follow the sequence shown in **Fig. 2**.

Demounting and Mounting Tubeless Tires on One-Piece Drop Center Wheels or Rims

Five Degree Full Drop Center

WARNING

Read the information in Subject 100. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

To demount or mount tubeless tires on 5 degree full drop center rims, regular or safety type, follow the same procedures used to demount or mount tubeless automobile tires.

Fifteen Degree Tapered Drop Center

WARNING

Read the information in Subject 100. Failure to follow the precautions, before and during tire demounting and mounting, could cause tire or rim damage while servicing or in use. An incorrectly mounted tire can burst causing personal injury and equipment damage.

DEMOUNTING

1. Deflate the tire being serviced by removing the valve core. Check the valve stem by running a piece of wire through the stem to make sure it is not plugged.
2. Loosen both beads from the rim by driving the flat end of the tire tool between the tire bead and the rim flange. Holding the tool upright, hammer on the neck to free the tire bead from the rim (see **Fig. 1**). Repeat at 8-inch (20-cm) intervals around the flanges, until both beads are free from the rim.
3. Place the wide side of the rim down. Lubricate the tire bead and the rim. Insert the curved end of two tire tools between the bead and the rim, and just to one side of the tire valve. Step on the side of the tire, opposite from the valve, to force the first bead into the rim well (see **Fig. 2**). Hold one of the tools in place with your foot and pry with the second tool, forcing the bead over the rim flange. Continue to work the first bead off of the rim.

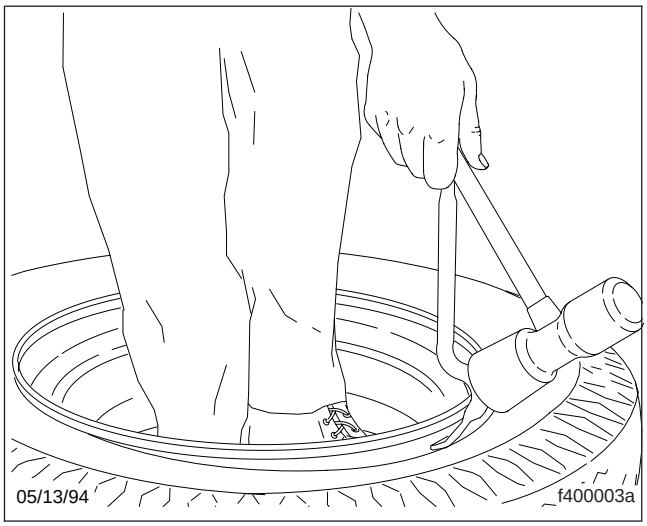


Fig. 1, Loosening the Beads

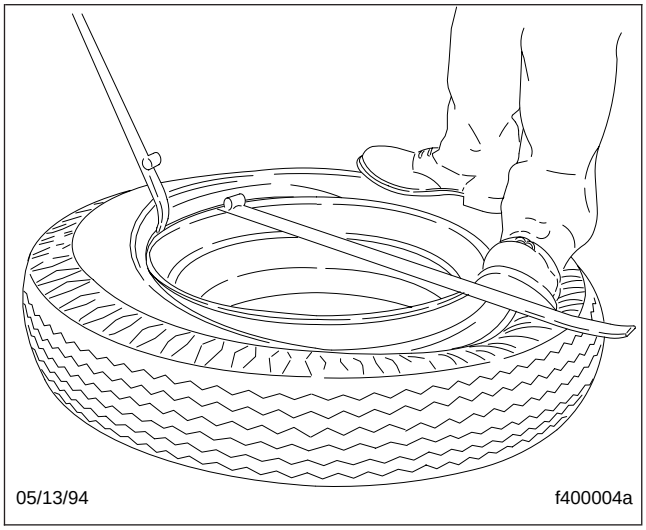

Fig. 2, Forcing the Bead into the Rim Well

4. When the first bead is off the rim, and the second bead is in the rim well, stand the assembly upright with the valve stem near the top. Lubricate the second bead and rim. Insert the straight end of the tool between the tire bead and the back rim flange, hooking the tool over the second flange. Lean the tire assembly toward the tool and use a rocking or bouncing action to pry the rim out of the tire. See **Fig. 3**.

Demounting and Mounting Tubeless Tires on One-Piece Drop Center Wheels or Rims

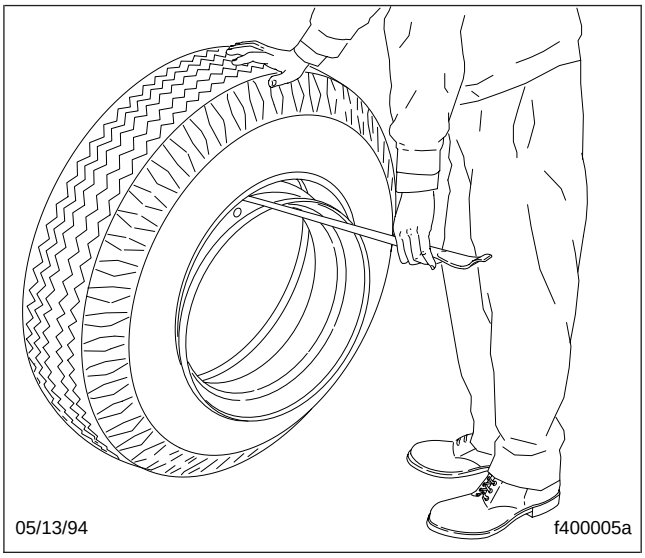

Fig. 3, Prying the Rim Out of the Tire

5. Clean and inspect all parts. Refer to **Subject 110** and **Subject 120** for procedures.

MOUNTING

1. Place the valve stem, with a rubber washer, through the valve hole from the tire side of the rim. Screw on the valve nut from the opposite side. Make sure the rubber bushing and metal collar or nut are centered and fit snugly in the valve hole (see **Fig. 4**). Tighten the nut securely.

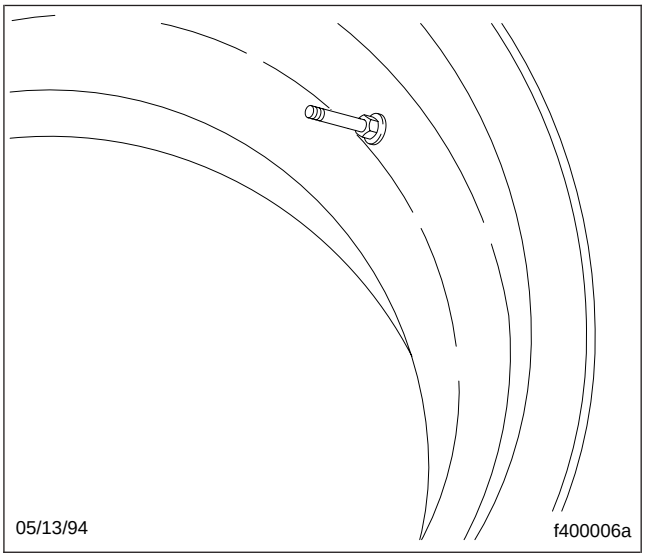

Fig. 4, Valve Stem Installation

2. Place the rim on the floor with the wide side down. Using a brush or swab, lubricate both bead seats (flanges) of the rim, and both tire beads, with an approved lubricant. Apply enough lubricant to enable correct bead seating, and to make mounting easier. Do not let excess lubricant run inside the tire.
3. Lay the tire on the rim. If there is a balance mark on the tire, line up this mark with the valve stem. Push the lower bead over the flange and into the rim well. Using the straight end of the tire tool (with the stop resting on the rim flange), take small bites to work the remaining section of the bead into the rim. See **Fig. 5**.

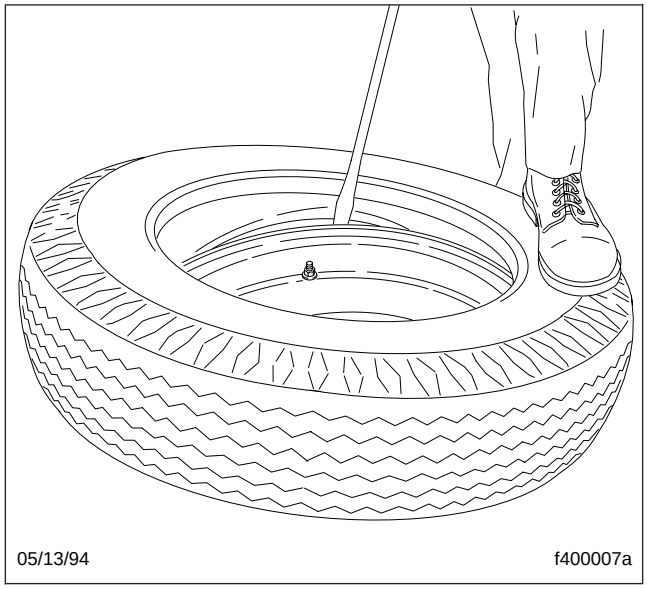

Fig. 5, Working the Lower Bead into the Rim

4. Start the upper bead over the rim flange and into the rim well by standing on the tire. If necessary, push a section of the bead into the rim well, and anchor it by attaching Vise-Grip® pliers to the rim flange (snub side toward the tire). Using the spoon end of the tire iron, with the stop toward the rim, work around the bead (see **Fig. 6**). Use small bites until the bead slips over the flange and into the rim well. If necessary, insert a second tire iron and relubricate the last 8 inches (20 cm) of bead.
5. Inflate the tire. Refer to **Subject 130** for procedures.

Demounting and Mounting Tubeless Tires on One-Piece Drop Center Wheels or Rims

Fig. 6, Working the Upper Bead into the Rim

General Information

Runout is side-to-side (lateral) or up-and-down (radial) movement when the tire/wheel assembly is rotated. Runout can be measured with a dial indicator, a tire runout gauge, or another instrument capable of measuring small movements of the tire/wheel assembly.

Lateral runout, shown in **Fig. 1**, is side-to-side movement of the rotating tire/wheel assembly. This may cause a perceived "shimmy" or "wobble".

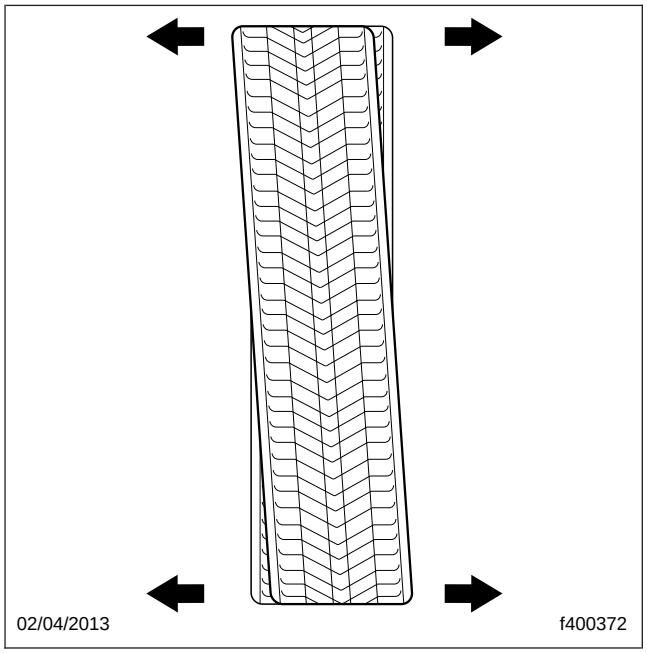

Fig. 1, Lateral Runout

Radial runout, shown in **Fig. 2**, is a changing radius of the rotating tire/wheel assembly. For a tire or wheel, its effect is to raise and lower the vehicle as it rolls along, giving the perception of a vertical "hop" or "bounce".

If a tire and wheel assembly shows visible up-and-down or side-to-side movement, it may have excessive runout. Use the inspection procedure that follows to measure runout.

Inspection

IMPORTANT: Before checking wheel runout, check the tires for proper:

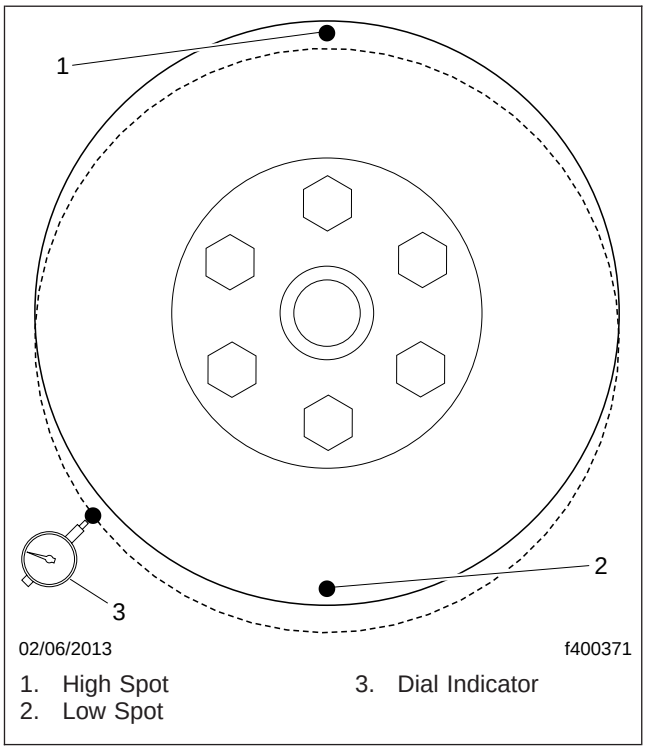

Fig. 2, Radial Runout

- inflation;
- wheel nut torque;
- bead seating on the rim.

Use a tire runout gauge, as shown in **Fig. 3**, to check lateral and radial runouts of the entire wheel end assembly.

Check radial runout on a smooth rib in the center of the tread. Check lateral runout on a smooth surface along the tire's mid-sidewall. If the wheel end assembly radial runout exceeds 0.060 inch (0.2 cm), or the lateral runout exceeds 0.150 inch (0.4 cm), the tire/wheel assembly should be removed to check the brake drum and hub runouts. Brake drum and hub runout tolerances are as follows:

- brake drum lateral runout—0.045 inch (0.11 cm)
- brake drum radial runout measured inside of the drum—0.020 inch (0.050 cm)
- hub lateral runout measured at the face of the hub—0.015 inch (0.38 cm)

Wheel and Tire Runout Measurements

- hub radial runout measured near the hub pilots—0.015 inch (0.38 cm)

If hub and brake drum runouts are within specification, then the wheel runout will need to be checked. Demount the tire from the wheel and check lateral and radial runouts for the wheel as shown in **Fig. 4**. For tire demounting instructions, see **Section 40.00, Subject 170**. Make certain the wheel is properly fixed in a wheel balancer or remounted on the hub. See **Table 1** for wheel runout specifications.

Wheel Runout Specifications		
Wheel Type	**Lateral Runout: inches (cm)**	**Radial Runout: inches (cm)**
Aluminum	0.030 (0.08)	0.030 (0.08)
Steel	0.060 (0.15)	0.060 (0.15)

Troubleshooting

Inspection and Verification

1. Verify the operator's original concern regarding the tires by duplicating the condition.

NOTE: Tires that show irregularities and definite roughness must be replaced.

2. Refer to the visual inspection list below and inspect for any of the conditions:
    - incorrect mounting
    - misalignment
    - loose wheel bearings
    - bent wheels
    - cupping or scalping of tires from imbalance
    - possible loose or worn steering connecting rod, drag link
    - underinflation and mechanical irregularities such as out-of-balance condition of wheel or tire and bent or damaged wheel
    - loose, damaged or worn front suspension parts
3. Determine if the tires and wheels have been subjected to road hazards that possibly contributed to the concern.
4. Check the vehicle for excessive or uneven loading. Correct as necessary.
5. Check the following:
    - wheels and tires installed properly
    - wheel clamps and lug nuts are tight
    - correct tire and wheel usage for vehicle specification

Problem—Tires Show Excess Wear on Edges of Tread

Problem—Tires Show Excess Wear on Edges of Tread	
Possible Cause	**Remedy**
Underinflated tires	Adjust air pressure in the tires.
Vehicle overloaded	Correct as required.
High speed cornering	Correct as required.
Incorrect toe setting	Set the toe to specifications.

Problem—Tires Show Excess Wear in Center of Tread

Problem—Tires Show Excess Wear in Center of Tread	
Possible Cause	**Remedy**
Tires overinflated	Adjust air pressure in the tires.

Problem—Excessive Tire Wear Concerns

Problem—Excessive Tire Wear Concerns	
Possible Cause	**Remedy**
Improper tire pressure	Adjust air pressure in the tires.
Incorrect tire/wheel usage	Install the correct tire and wheel combination.
Loose or leaking shock absorbers	Tighten or replace as necessary.
Front wheels out of alignment	Align the front wheels.
Front wheel bearings out of adjustment	Adjust the front wheel bearings.

Troubleshooting

Problem—Excessive Tire Wear Concerns	
Possible Cause	**Remedy**
Loose, worn or damaged steering linkage or joints	Inspect, repair or replace as required.
Loose, worn or damaged suspension components, bushings and spindle pin bushings	Inspect, repair or replace as required.
Wheels and tires out of balance	Balance the wheels and the tires.
Excessive lateral/radial runout of wheels and tires	Check, realign or reindex the tire rim or rim/wheel to hub or spider.

Problem—Wheel Hop (Excessive Vehicle Vibration, Rough Steering and Excessive Fatigue)

Problem—Wheel Hop (Excessive Vehicle Vibration, Rough Steering and Excessive Fatigue)	
Possible Cause	**Remedy**
Demountable rims—improper procedures in mounting the rim to the cast wheel; failure to follow proper tightening sequence and recommended torque results in "rim chording" where the rim clamps exert pressure as they are tightened which forces the rim out of round forming flat sides on the rim	Replace the chorded rims. Check shop practices and tools to be sure manufacturer's recommended torque and procedures are followed.
Out-of-balance rim or cast wheel, tire or hub and drum assembly	Determine the out-of-balance component and balance or replace.
Out-of-round rim (excessive radial runout) more than 0.060 inch (1.5 mm)	Check for: • Proper handling of the rim prior to use; • Overloading and unbalanced loads; • Road hazards and rugged operating conditions; • Proper rim specifications; • Proper mounting; • Tightening sequencing and alignment.
Disc wheels—dirt and rocks wedged between disc and rim	Clean.
Out-of-balance wheel/tire or hub and drum assembly	Determine the out-of-balance component and balance.
Out-of-round wheel (excessive radial runout) more than 0.060 inch (1.5 mm)	Check for: • Road hazards and rugged operating conditions; • Proper wheel specifications. Reindex the tire on the rim/wheel.
Vehicle—loose or worn driveline or suspension parts	Identify the location of the vibration carefully as it can be transmitted through the frame, making a rear end vibration appear to come from the front. Then repair or replace loose and worn parts.

Problem—Wobble (Excessive Vehicle Vibrations, Rough Steering, Excessive Fatigue, Severe Tire Wear and Wheel Shimmy)

Problem—Wobble (Excessive Vehicle Vibrations, Rough Steering, Excessive Fatigue, Severe Tire Wear and Wheel Shimmy)	
Possible Cause	**Remedy**
Demountable rims—excessive lateral runout	Check the mounting. Realign and retighten the wheels. Lateral runout must not exceed: • 0.090 inch (2.3 mm) for the front; • 0.125 inch (3.2 mm) dual rear.
Loose or improper attaching parts	Tighten or replace.
Worn or distorted spacers	Replace.
Overloading or unbalanced loads	Check the rim specifications against work load requirements. Recommend the correct tire and rim. Check on loading procedures.
Road hazards (curb and rock impacts, etc.)	Check operating conditions for possible change to heavier duty tire and rim.
Improperly installed rim	Recommend that the clamp nuts be retightened after a 50 to 100 mile (80 to 160 kilometer) seating-in period of the rim assembly to the wheel. Five and six spoke: 240 to 260 lbf·ft (325 to 352 N·m).
Disc wheels—excessive lateral runout	Replace the wheel if rim runout is more than 0.060 inch (1.5 mm).
Cracked, bent or distorted disc from overloading, road impact hazards or improper handling	Replace the wheel. Attempts to straighten the wheel can result in fractures in the steel and weakening of the disc or the weld between the disc and rim. Check loading and operating conditions and shop practices.
Loose mountings, damaged studs or wheel nuts, enlarged stud holes, worn or broken hub face, or foreign material on mounting surfaces	Tighten or replace worn or damaged parts. Clean mounting surfaces. Tighten the wheel nuts 450 to 500 lbf·ft (610 to 678 N·m).
Vehicle—improper alignment	Align the vehicle.
Loose, worn or broken suspension parts	Repair or replace.

Problem—Cracked Or Broken Wheel Rims (Cracks Develop in Rim Base, Back Flange or the Gutter Area)

Problem—Cracked Or Broken Wheel Rims (Cracks Develop in Rim Base, Back Flange or the Gutter Area)	
Possible Cause	**Remedy**
Demountable rims or disc wheel rims—overloading or road hazards	Replace the rim or wheel. Check loading and operating conditions. Avoid overinflation of the tires. Check the specifications for rim load capacity, working loads, tire size, ply rating and tire construction.
Improper use of tools	Check mounting, demounting and maintenance procedures.

Troubleshooting

Problem—Cracked Or Broken Wheel Discs (Cracks Develop in the Wheel Disc from Hand Hole to Hand Hole, from Hand Hole to Rim, or from Hand Hole to Stud)

Problem—Cracked Or Broken Wheel Discs (Cracks Develop in the Wheel Disc from Hand Hole to Hand Hole, from Hand Hole to Rim, or from Hand Hole to Stud)	
Possible Cause	**Remedy**
Metal fatigue resulting from overloading/road hazards	Replace the wheel. Check position of the wheel on the vehicle for working load specifications.
Loose wheel nuts	Tighten 450 to 500 lbf·ft (610 to 678 N·m).
Damaged holes	Replace the wheel.

Problem—Damaged Stud Holes (Stud Holes Become Worn, Elongated or Deformed, Metal Builds Up Around Stud Hole Edges, Cracks Develop from Stud Hole to Stud Hole)

Problem—Damaged Stud Holes (Stud Holes Become Worn, Elongated or Deformed, Metal Builds Up Around Stud Hole Edges, Cracks Develop from Stud Hole to Stud Hole)	
Possible Cause	**Remedy**
Truck operated with loose wheel mounting	Replace the wheel and check for: • Installation of correct studs and nuts; • Cracked or broken studs. Replace the stud. Also, replace the studs on each side of the damaged stud; • Worn hub face. Repair if not excessive, or replace if severe; • Broken or cracked hub barrel. Replace; • Worn stud grooves. Replace or install the recommended serrated bolts; • Rust streaks fanning out from the stud holes (an indication that the wheel nuts are, or have been, loose). Clean the mounting surfaces. Tighten the wheel nuts 450 to 500 lbf·ft (610 to 678 N·m).

Problem—Corrosion (Decreased Strength Because of Excessive Rust or Corrosion, Bead Seating Problems, or Loss of Pressure with Tubeless Tires)

Problem—Corrosion (Decreased Strength Because of Excessive Rust or Corrosion, Bead Seating Problems, or Loss of Pressure with Tubeless Tires)	
Possible Cause	**Remedy**
Demountable rims or disc wheel rims — adverse storage or operating conditions	Correct as required.
Poor maintenance practices	Follow the recommended cleaning and protective procedures.
Wheel disc—poor maintenance	Clean and protect with paint. Do not exceed 1.5 mil thickness of paint.

Problem—Severe Tire Damage (Related Maintenance Complaints on Tire Damage Including Erratic or Spotty Wear, Tire Slippage, Ply Separation, Excessive Flexing, Bead Chafing, Valve Stem Tear-Outs)

Problem—Severe Tire Damage (Related Maintenance Complaints on Tire Damage Including Erratic or Spotty Wear, Tire Slippage, Ply Separation, Excessive Flexing, Bead Chafing, Valve Stem Tear-Outs)	
Possible Cause	**Remedy**
Demountable rims or disc wheel rims — wrong rim selection	Match the rims and tires to the working loads and operating conditions.
Rims of different size in dual mountings	Match the rim size before mounting duals.
Improper inflation	Follow the specifications.
Severe hop and wobble	Follow the recommendations under "Problem—Wheel Hop (Excessive...)."
Wheel disc—bent or distorted disc.	Refer to "Disc wheels—excessive lateral runout" under "Problem—Wobble (Excessive...)."
Other conditions	Refer to tire mounting difficulties, rim mounting difficulties, and wheel mounting in the tire manufacturer's literature.

Problem—Tire Mounting Difficulties

Problem—Tire Mounting Difficulties	
Possible Cause	**Remedy**
Demountable rims or disc wheel rims—mismatched tire and rim sizes	Follow the specifications.
Tire mounting lubricant not used	Remount the tires using lubricant.
Overinflation of tires	Follow the recommended tire pressures.
Corrosion and dirt	Refer to "Problem—Corrosion (Decreased...)."

Problem—Rim Mounting Difficulties

Problem—Rim Mounting Difficulties	
Possible Cause	**Remedy**
Demountable rims—improper application or mismatched parts, including spacer and clamps	Follow the manufacturer's specifications. Check the specifications when chains, or special load tires are involved.
Corroded or worn parts	Clean or replace.

Problem—Wheel Mounting Difficulties

Problem—Wheel Mounting Difficulties	
Possible Cause	**Remedy**
Disc wheels—improper application or mismatched parts, including studs and nuts	Follow the manufacturer's specifications. Check the specifications for disc and spacing when chains, or special load tires are involved.
Corroded or worn parts	Clean or replace.

Troubleshooting

Problem—Dual Tires Rubbing

Problem—Dual Tires Rubbing	
Possible Cause	**Remedy**
Insufficient wheel spacing	Check the tire and wheel sizes. Make certain the proper size tire, rim and spacer/ wheel offsets are used.

Problem—Damaged Stud Threads

Problem—Damaged Stud Threads	
Possible Cause	**Remedy**
Sliding wheel across studs during assembly	Replace the studs. Follow the proper wheel installation procedures.

Problem—Loose Drum

Problem—Loose Drum	
Possible Cause	**Remedy**
Stud too long	Replace the stud with proper length stud.

Problem—Loose Inner Wheel

Problem—Loose Inner Wheel	
Possible Cause	**Remedy**
Excessive stud standout from mounting face of hub permitting wheel nut to bottom out	Replace the stud with a proper length stud.

Problem—Broken Studs

Problem—Broken Studs	
Possible Cause	**Remedy**
Loose wheel nuts	Replace the studs. Follow the proper tightening procedure. Replace all studs with OEM replacement components.
Overloading	Replace the studs. Compare the actual load against the wheel load ratings.

Problem—Stripped Threads

Problem—Stripped Threads	
Possible Cause	**Remedy**
Excessive torque	Replace the studs. Follow the proper tightening procedure.

Problem—Rust Streaks from Stud Holes

Problem—Rust Streaks from Stud Holes	
Possible Cause	**Remedy**
Loose wheel nuts	Check the complete assembly. Replace the damaged parts. Follow the proper tightening procedure.

Problem—Damaged Wheel Nuts

Problem—Damaged Wheel Nuts	
Possible Cause	**Remedy**
Loose wheel assembly	Replace the wheel nuts. Check for proper stud nut standout. Follow the proper tightening procedure.

Problem—Frozen Wheel Nuts

Problem—Frozen Wheel Nuts	
Possible Cause	**Remedy**
Corrosion or galling	If corrosion is slight, remove with a wire brush. If corrosion is excessive, replace the studs and nuts. If the condition persists, lubricate the first three threads of each stud with a graphite-based lubricant.

Tire Pressure

Do not reduce the pressure of a hot tire if it exceeds the specified pressure. In normal driving, tire temperature and inflation pressure increase. Increases of 10 to 15 psi (70 to 105 kPa) are common. Higher pressures may be signs of overloading, underinflation, excessive speed, improper tire size, or any combination of these factors, and must be checked when the tire is cool.

IMPORTANT: The load and cold inflation pressure must not exceed the rim or wheel manufacturer's recommendations, even though the tire may be approved for a higher load or inflation. Some rims and wheels are stamped with a maximum load and maximum cold inflation rating. If they are not stamped, consult the rim or wheel manufacturer for the correct tire inflation pressure for the vehicle load. If the load exceeds the maximum rim or wheel capacity, the load must be adjusted or reduced.

For further information on rims and tires (other than Michelin), and for inflation and load limits, refer to the "Tire and Rim Association Yearbook." Contact the Michelin Tire Corporation for further information on their tires.

Wheel Fastener Torque Values

Wheel Fastener Torque	
Description	**lbf·ft (N·m)**
5 and 6 Spoke Wheel Nut	240–260 (325–352)
Cast Wheel Rim Nut	240–260 (325–352)
Disc Wheel 2-Piece Flange Nut, 10-Hole, M22 x 1.5	450–500 (610–678)

Table 1, Wheel Fastener Torque

General Information

DRIVELINE

The driveline is composed of the universal joints (U-joints), connecting shafts and the attaching yokes.

All the vehicle U-joint spiders and sliding splines are equipped with lubrication fittings. They must be lubricated periodically with high-temperature 4x4 front axle and wheel bearing grease meeting specification ESA–M1C198–A.

The vehicles are equipped with center support bearings that are prelubricated and sealed for the life of the bearing.

NOTE: All driveline shafts are balanced. If a vehicle is to be undercoated, cover all shafts to prevent getting undercoating material on the shafts.

DRIVESHAFT

The driveshaft, coupling shaft and inter-axle shaft are composed of universal joints (U-joints), connecting shaft(s) and the attaching yokes.

Vehicles have the following types of driveshafts:

- Primary driveshaft: the shaft that accommodates the change in length (slip) in the driveline system and connects to the input shaft of the rear single axle or the forward tandem axle. See **Fig. 1**.

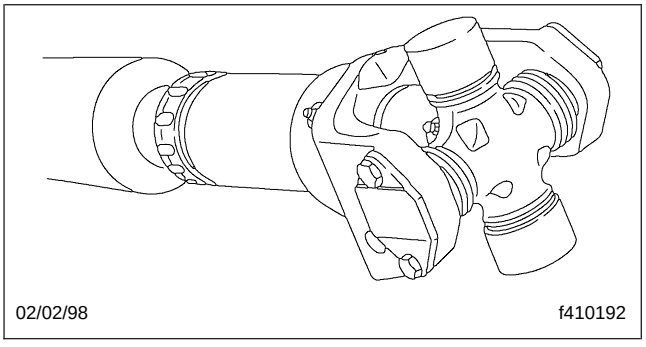

Fig. 1, Primary Driveshaft

- Coupling shaft: the front shaft in a two-piece driveline system. Coupling shafts are attached to a support plate via a shaft support bearing. See **Fig. 2**.

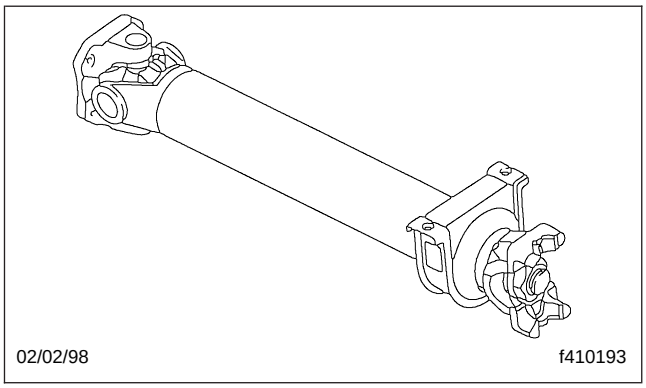

Fig. 2, Coupling Shaft

- Inter-axle shaft: the shaft that connects the forward axle of a tandem drive unit to the rear axle. See **Fig. 3**.

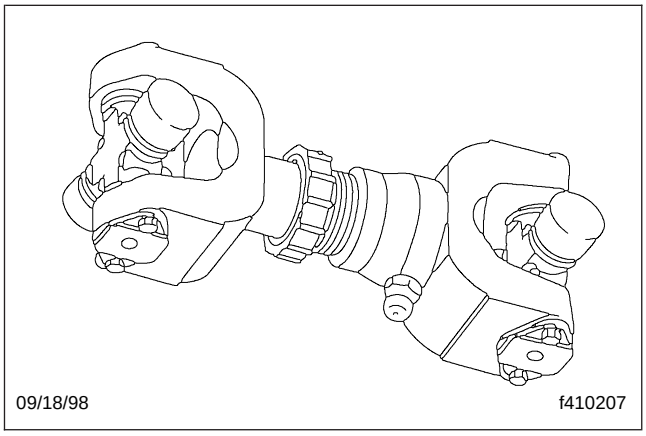

Fig. 3, Inter-Axle Shaft

UNIVERSAL JOINTS (U-JOINTS)

All U-joints are needle bearing type and are defined by the shape of the bearing caps (plate or bearing strap type). The U-joints are held in the yoke by bearing straps and bolts or snap rings. See **Fig. 4** and **Fig. 5**.

One-Piece Driveshaft

REMOVAL

NOTE: Index mark the slip-yoke and slip tube shafts as well as the yokes before removing the shaft to maintain the proper phase.

1. Set the parking brake and chock the tires.

NOTE: Support the driveshaft so that it does not hang from the opposite U-joint and yoke.

2. Remove the retaining bolts and disconnect the driveshaft at the axle. See **Fig. 1**.

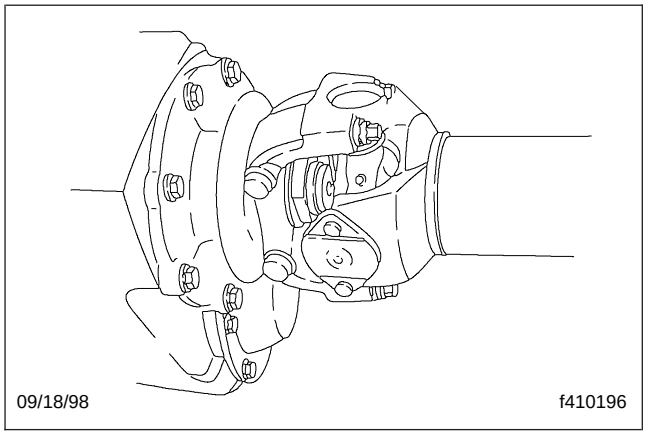

Fig. 1, Driveshaft Connection at the Axle

3. Unscrew the grease seal on the slip-yoke and remove the driveshaft from the slip-yoke. See **Fig. 2**.

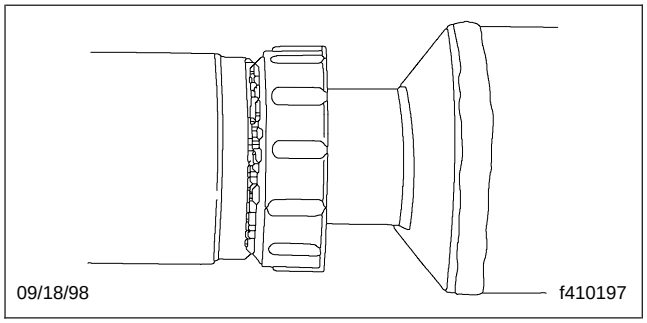

Fig. 2, Driveshaft Slip-Yoke and Grease Seal

4. Remove the retaining bolts and disconnect the slip-yoke at the transmission. See **Fig. 3**.

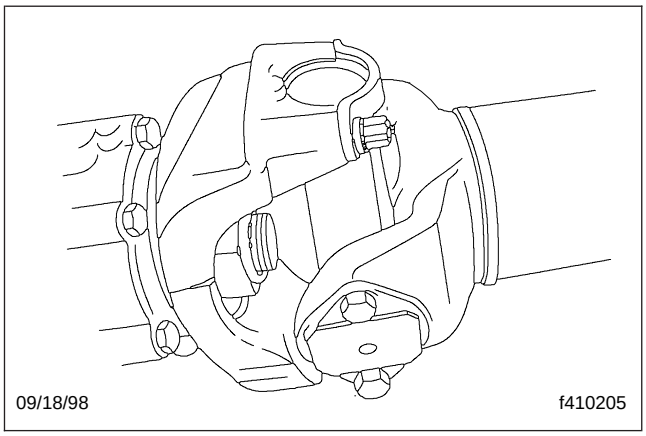

Fig. 3, Slip-Yoke Connection at the Transmission

INSTALLATION

NOTE: Make sure that the shaft is installed with the index marks aligned to maintain proper phasing of the yokes.

1. Connect the slip yoke to the transmission yoke and install the yoke retaining bolts. Tighten the yoke retaining bolts to the applicable torque value in **Specifications, 400**.
2. Install the driveshaft into the slip-yoke and hand-tighten the grease seal firmly on the slip-yoke.
3. Connect the driveshaft to the axle and install the yoke retaining bolts. Tighten the yoke retaining bolts to the applicable torque value in **Specifications, 400**.

Interaxle Driveshaft

REMOVAL

NOTE: Index mark the slip-yoke and slip tube shafts as well as the yokes before removing the shaft to maintain the proper phase.

1. Set the parking brake and chock the tires.
2. Remove the retaining bolts and disconnect the shaft at the axle. See **Fig. 1**.
3. Unscrew the grease seal on the slip-yoke and separate the shaft and slip-yoke. See **Fig. 2**.
4. Remove the retaining bolts from the yoke at the opposite axle and remove the shaft.

Driveshaft Removal and Installation

INSTALLATION

NOTE: Make sure that the shaft is installed with the index marks aligned to maintain proper phasing of the yokes.

1. Connect the shaft at the axle and install the yoke retaining bolts. Tighten the yoke retaining bolts to the applicable torque value in **Specifications, 400**.
2. Install the driveshaft into the slip-yoke and hand-tighten the grease seal firmly on the slip-yoke.
3. Connect the shaft to the axle and install the yoke retaining bolts. Tighten the yoke retaining bolts to the applicable torque value in **Specifications, 400**.

Coupling Driveshaft

REMOVAL

NOTE: Index mark the yokes before removing the shaft to maintain the proper phase.

1. Set the parking brake and chock the tires.
2. Remove the slip-yoke and position it aside. See **Fig. 4** and **Fig. 5**.

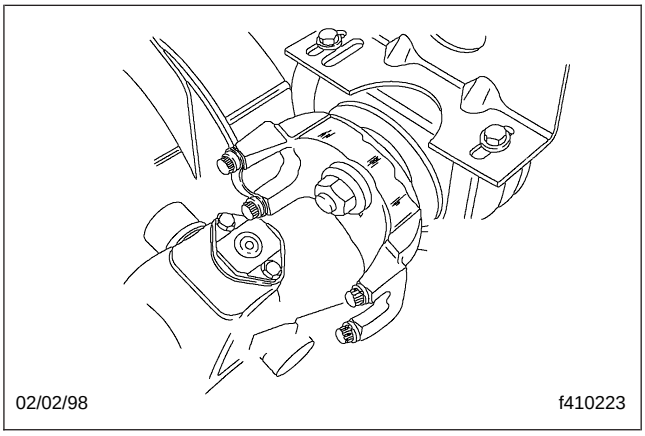

Fig. 4, Disconnecting the Slip-Yoke

NOTE: Support the coupling shaft so that is does not hang from the U-joint and yoke at the opposite end of the shaft.

3. Remove the retaining bolts at the coupling shaft. See **Fig. 6**.

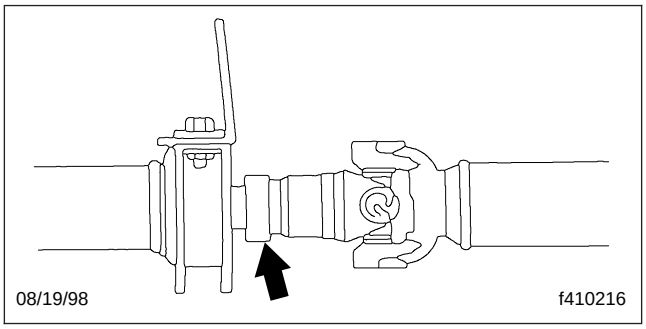

Fig. 5, Removing Slip-Yoke

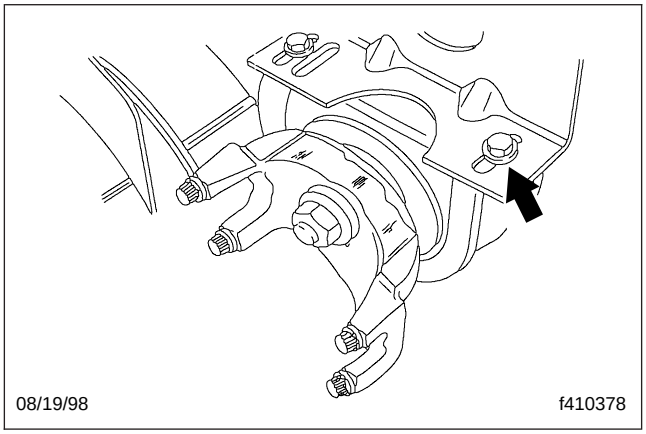

Fig. 6, Coupling Shaft

4. Remove the retaining bolts and disconnect the coupling shaft at the transmission. See **Fig. 3**.
5. Remove the yoke retaining nut. See **Fig. 7**.

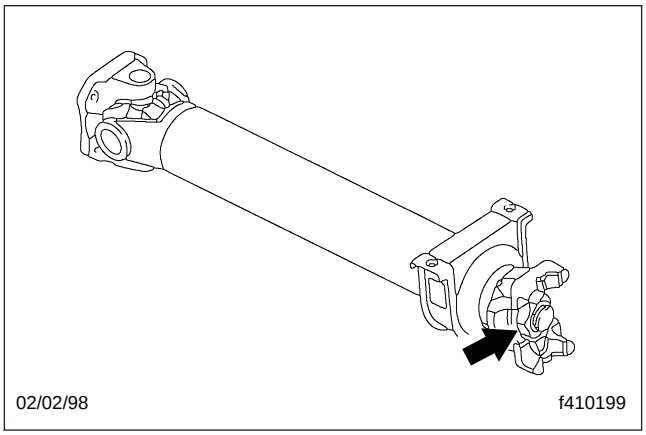

Fig. 7, Yoke Retaining Nut

NOTE: For the reverse slip type coupling shaft, proceed to Steps 9 through 11 of this procedure for bearing removal.

6. Remove the yoke. See **Fig. 8**.

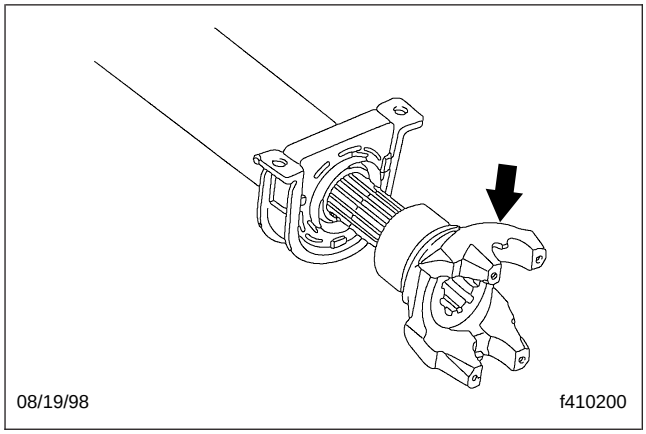

Fig. 8, Yoke

7. Slide the center bearing off the splined shaft. See **Fig. 9**.

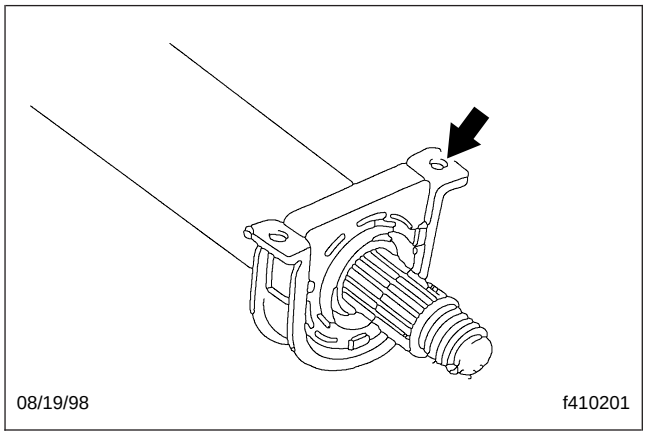

Fig. 9, Center Bearing

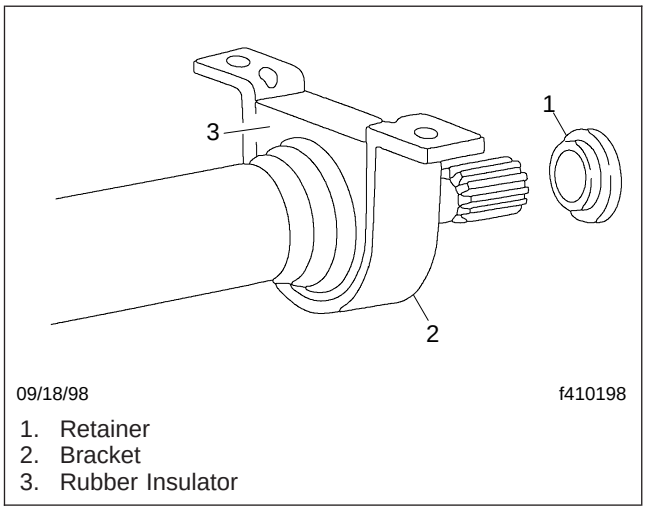
8. For reverse slip type couplingshaft, remove the rubber insulator. See **Fig. 10**.
   - 8.1 Remove the retainer.
   - 8.2 Remove the bracket.
   - 8.3 Remove the rubber insulator.
9. Use a suitable press to press the bearing and the retainer off the coupling shaft. See **Fig. 11**.



1. Retainer
2. Bracket
3. Rubber Insulator

Fig. 10, Rubber Insulator

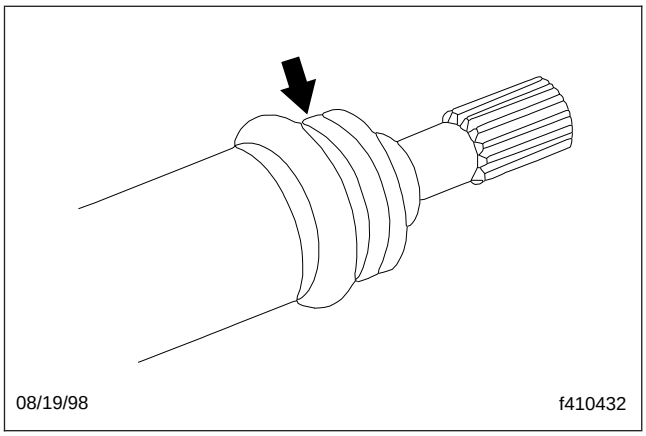


Fig. 11, Bearing and Retainer

10. Remove the dust slinger from the coupling shaft. See **Fig. 12**.

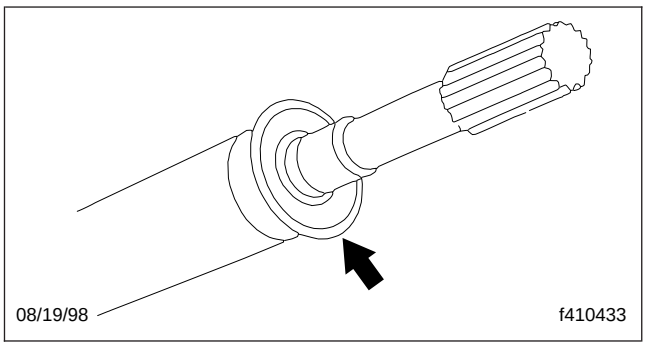

Fig. 12, Dust Slinger

Driveshaft Removal and Installation

11. Clean the splines.
    - 11.1 Use a suitable cleaning fluid.
    - 11.2 Clean all the dirt and old grease from the slip-yoke, slip-yoke splines and shaft splines.
12. Check the splines for wear, warpage and cracks. If the shaft is worn, warped or cracked, replace the shaft.
13. Carefully inspect the slip-yoke splines for wear or evidence of twisting. Check the clearance between the slip-yoke splines and shaft splines. See **Fig. 13**.

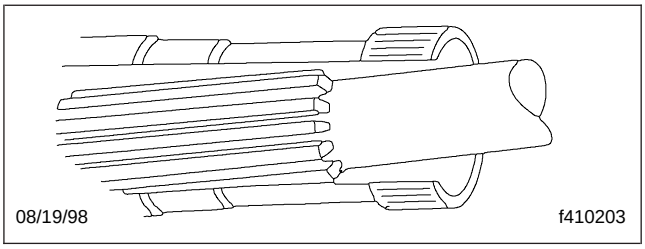

Fig. 13, Slip-Yoke Spline Inspection

14. Wipe the bearing and cushion clean with a cloth dampened with cleaning fluid.

NOTE: Do not immerse the sealed bearing in cleaning fluid.

15. Examine the rubber cushion for evidence of hardening, cracking or deterioration. Replace the cushion if damaged in any way.

NOTE: The retainers and slingers are serviced only as part of the bearing assembly.

16. Check the bearing for wear or rough action by rotating the inner race while holding the outer race. If wear or roughness is evident, replace the bearing. See **Fig. 14**.
17. Clean and inspect the yoke.
    - 17.1 Inspect the crosshole surfaces for damage and raised metal.

      Remove raised metal with a file or emery cloth.
    - 17.2 Check the crossholes for wear and misalignment.

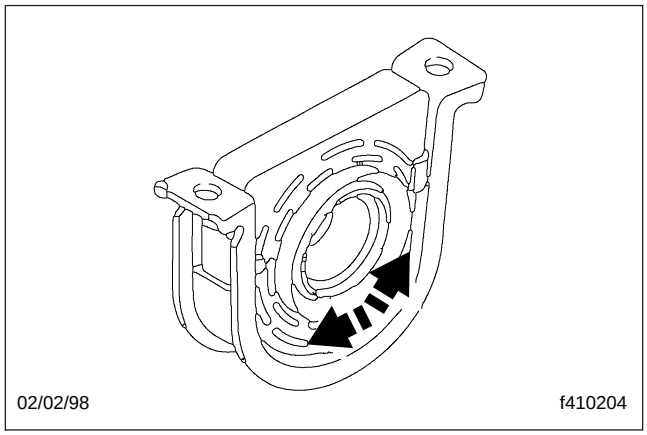

Fig. 14, Checking Bearing for Wear

INSTALLATION

NOTE: Make sure that the shaft is installed with the index marks aligned to maintain proper phasing of the yokes.

1. Fill the entire cavity around the bearing to the extreme edge of the surrounding slinger with a suitable waterproof grease. See **Fig. 15**.

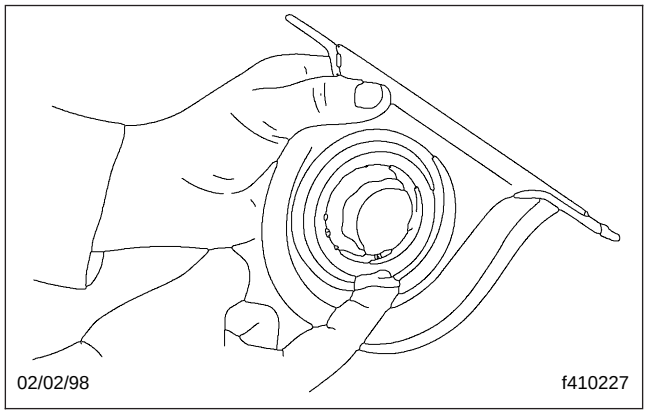

Fig. 15, Applying Waterproof Grease to Bearing Cavity

2. For reverse slip type couplingshaft, install the dust slinger on the coupling shaft. See **Fig. 12**.
3. Using a suitable press, press the bearing and the retainer onto the coupling shaft. See **Fig. 11**.
4. Install the rubber insulator. See **Fig. 10**.
    - 4.1 Install the rubber insulator.
    - 4.2 Install the bracket.

4.3 Install the retainer.

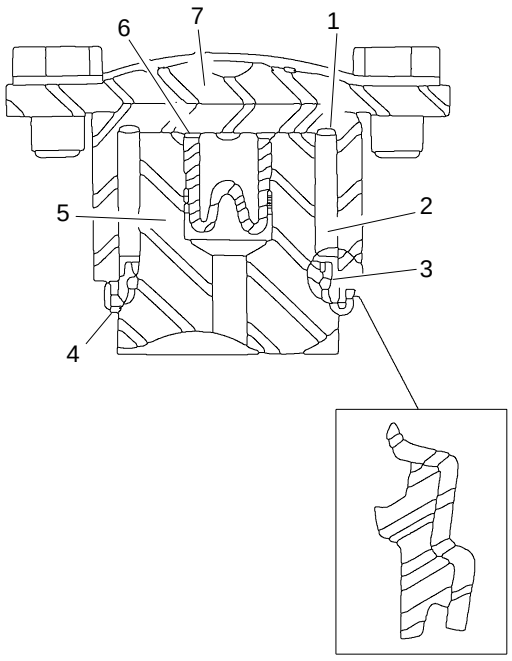
5. Slide the center bearing onto the splined shaft. See **Fig. 9**.
6. Install the yoke. See **Fig. 8**.
7. Install the yoke retaining nut. Tighten the yoke retaining bolt to the applicable torque value in **Specifications, 400**. See **Fig. 7**.
8. Connect the coupling shaft at the transmission and install the retaining bolts. Tighten the coupling shaft retaining bolts to the applicable torque value in **Specifications, 400**. See **Fig. 3**.

NOTE: Make sure the center bearing is not twisted in the support plate.

9. Install the retaining bolts at the coupling shaft. Tighten center bearing support retaining bolts to the applicable torque value in **Specifications, 400**. See **Fig. 6**.
10. Install the slip-yoke. Tighten the U-joint retaining bolts to the applicable torque value in **Specifications, 400**. See **Fig. 4** and **Fig. 5**.

Plate-Type Universal Joint

DISASSEMBLY (See Fig. 1)



09/18/98 f410209

1. Plate-Type Bearing Cap
2. Needle Bearings
3. Grease Seal
4. Oil Slinger
5. Spider
6. Lube Check Valve
7. Bearing Plate

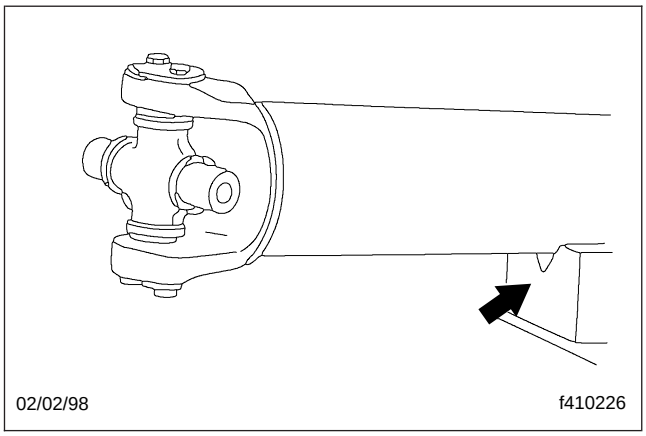
Fig. 1, Plate-Type Universal Joint

1. Place the driveshaft in V-blocks to remove the cross and bearing assembly. See **Fig. 2**.

⚠ CAUTION

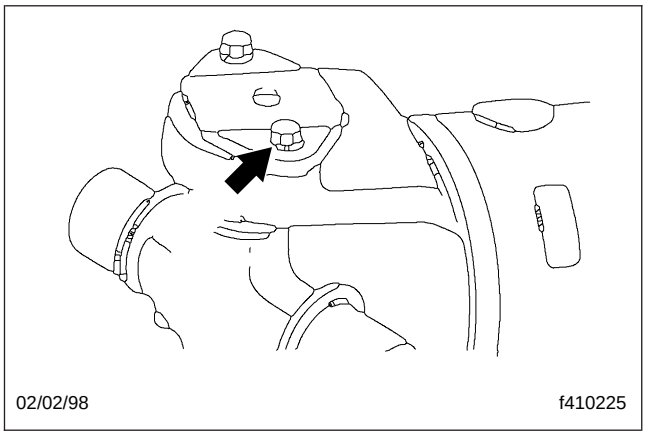
Do not distort the tube with excessive grip or damage to the driveshaft may result.

2. Remove the serrated retaining bolts. See **Fig. 3**.
3. Lightly tap the bearing cap clockwise. See **Fig. 4**.
4. Pry evenly on the bearing cap ends until removed from the yoke. See **Fig. 5**.
5. Repeat the previous steps as needed for the bearing cap on the opposite side.



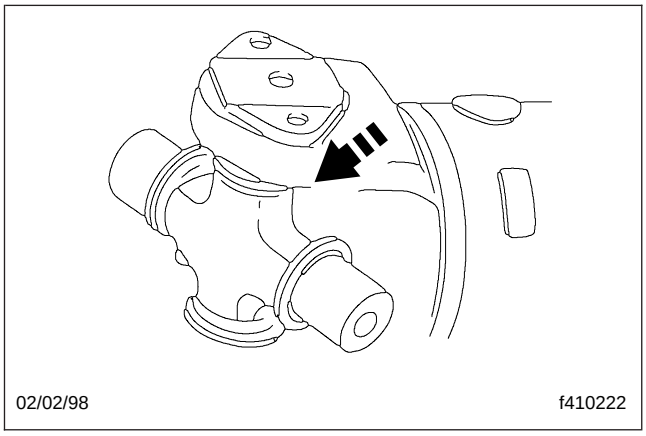
02/02/98 f410226

Fig. 2, Driveshaft in V-Blocks



02/02/98 f410225

Fig. 3, Serrated Retaining Bolts



02/02/98 f410222

Fig. 4, Tapping Bearing Cap

6. Remove the spider. See **Fig. 6**.
7. Clean and inspect the yokes. See **Fig. 7**.

Universal Joint Disassembly and Assembly

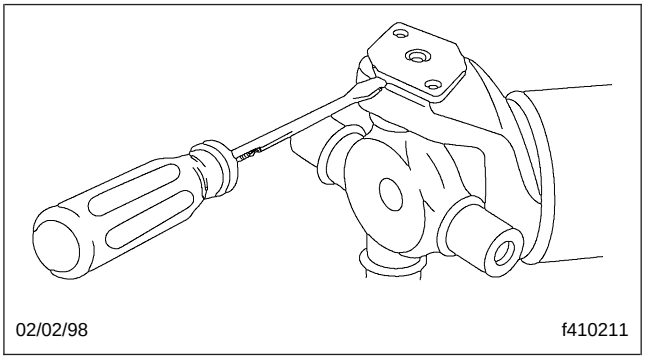


Fig. 5, Prying Bearing Cap

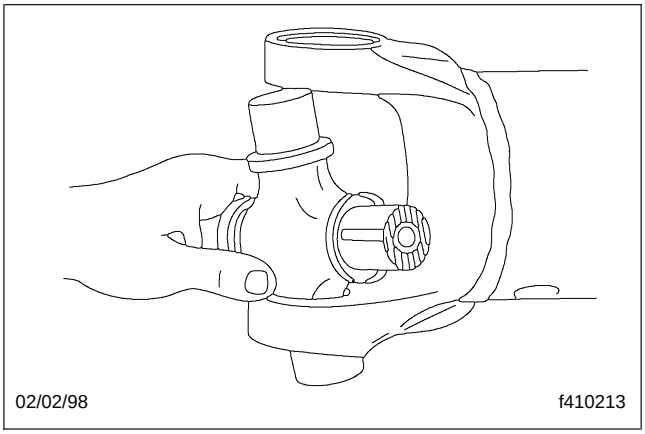

Fig. 6, Removing Spider

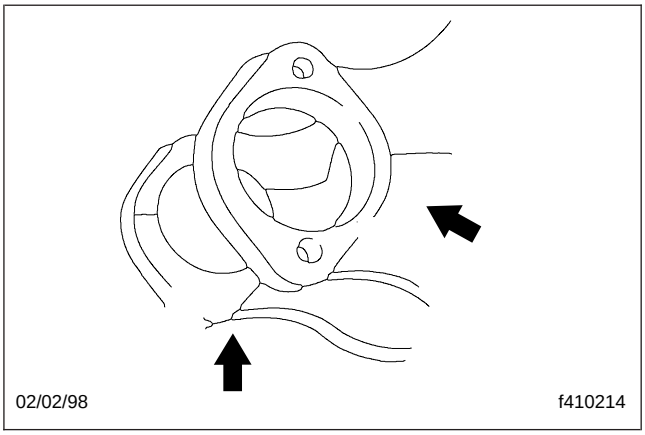

Fig. 7, Yoke Inspection

7.1 Inspect the crosshole surfaces for damage and raised metal.

Remove raised metal with a file or emery cloth.

7.2 Check the crossholes for wear and misalignment.

ASSEMBLY

1. Fill the journal passages with high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A. See **Fig. 8**.

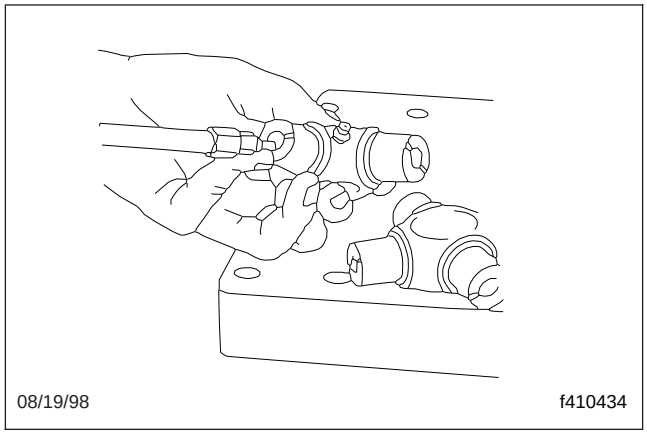

Fig. 8, Lubricating Universal Joints

2. Fill the bearing caps approximately one-third full with the same lubricant.
3. Lightly lubricate the seal lips with a lightweight oil to prevent seal damage during installation.
4. Apply anti-seize compound to the outside diameter of the four bearing assemblies.

NOTE: The lubrication fitting must point toward the driveshaft (inboard side). For slip-yoke installation, the fitting must also be in close orientation to the slip-yoke lubrication fitting.

5. Position the spider in the yoke, and install the bearing caps. Press or tap directly in the center of the cap with a soft drift. See **Fig. 9**.

⚠ CAUTION

Do not tap on the outer edges of the bearing cap or damage to the universal joint may result.

6. Install new serrated bolts. See **Fig. 3**.

NOTE: Lubricate with high-temperature 4x4 front axle and wheel bearing grease or equiva-

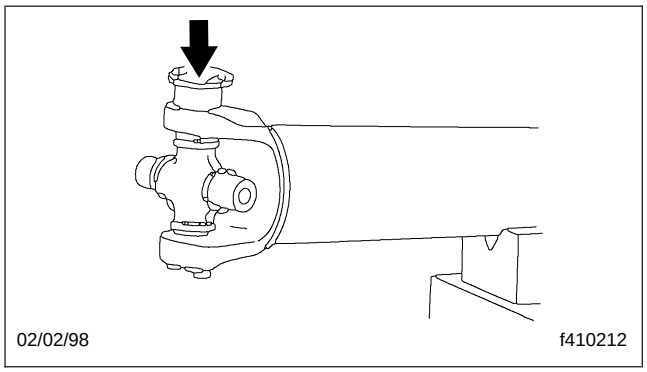

Fig. 9, Installing Bearing Caps

lent meeting specification ESA–M1C198–A through the zerk fittings.

7. Lubricate the U-joints, applying lubricant through the zerk fitting until fresh grease purges at each of the four seals. See **Fig. 10**.

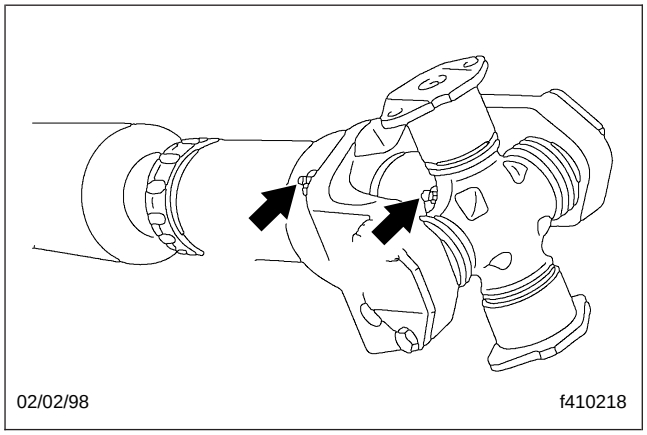

Fig. 10, Universal Joint Lubrication Points

8. Lubricate the slip-yoke, applying lubricant through the zerk fitting until it purges at the vent hole in the welch plug. Place a finger over the hole in the welch plug and apply the lubricant until it purges at the seal at the rear of the slip-yoke.

Outside Snap Ring Type Universal Joint

DISASSEMBLY (See Fig. 11)

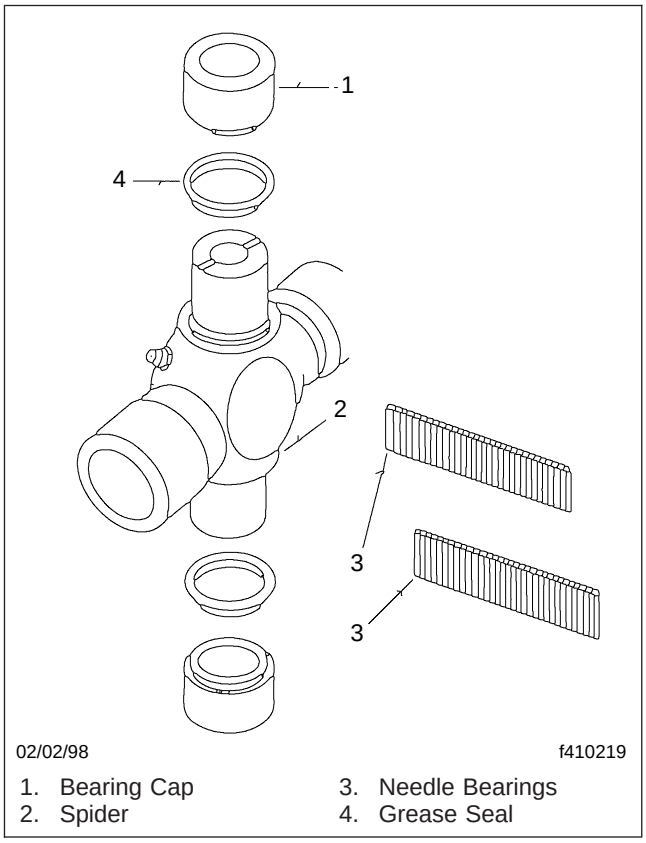

Fig. 11, Outside Snap Ring Type Universal Joint

CAUTION

Do not clamp the driveshaft in the jaws of a vise or similar holding fixture or damage to the driveshaft may result.

1. Place the driveshaft on a suitable workbench, being careful not to damage the tube.

NOTE: If components are not marked and therefore installed incorrectly, driveline imbalance may occur.

2. Index the driveshaft components. See **Fig. 12**.
3. Clamp U-joint tool in a vise. See **Fig. 13**.

Universal Joint Disassembly and Assembly

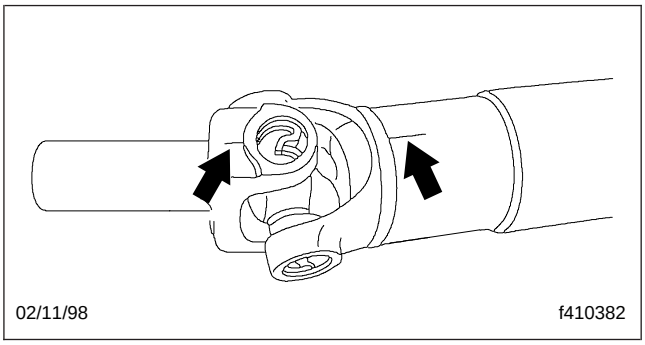

Fig. 12, Index Driveshaft Components

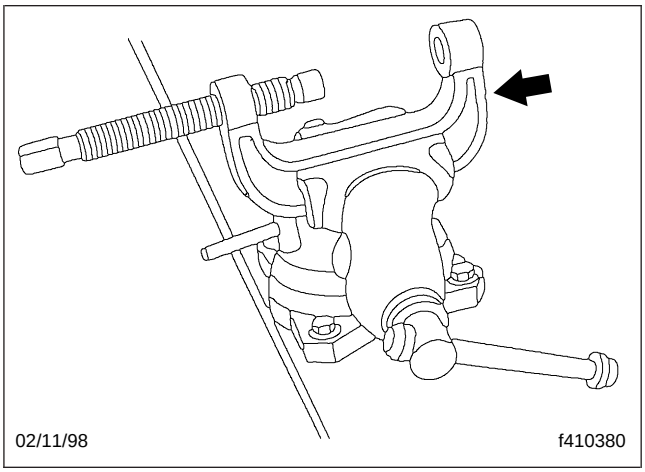

Fig. 13, U-Joint Tool

4. Remove the snap rings. See **Fig. 14**.

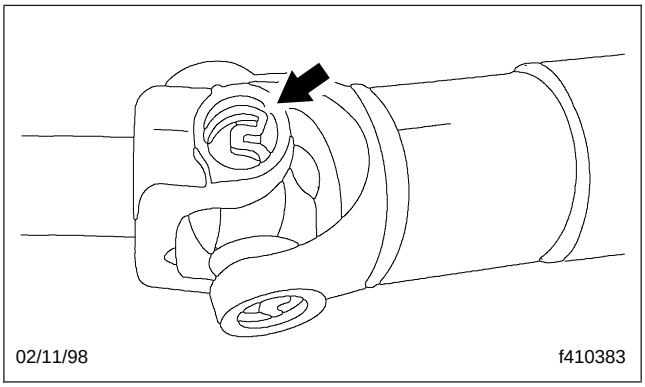

Fig. 14, Snap Ring

NOTE: If necessary, use a pair of pliers to remove the bearing cup if it cannot be pressed out all the way.

5. Remove the driveshaft slip-yoke. See **Fig. 15**.

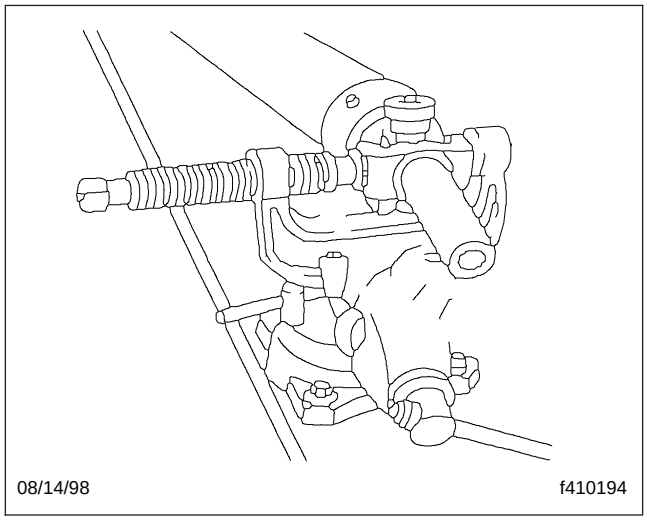

Fig. 15, Driveshaft Slip-Yoke Removal

5.1 Position the driveshaft slip-yoke in U-joint tool.

5.2 Press out the bearing cup.

5.3 Rotate the driveshaft slip-yoke.

5.4 Press on the spider to remove the remaining bearing cup.

5.5 Remove the driveshaft slip-yoke.

6. Repeat the previous step as needed to remove the remaining bearing cups, spiders and yoke from the driveshaft.

7. Clean the yoke area at each end of the driveshaft.

ASSEMBLY

NOTE: Universal joint service kits are to be installed as complete assemblies only. Do not use components from other universal joints.

1. Fill the journal passages with high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A. See **Fig. 8**.

2. Fill the bearing caps approximately one-third full with the same lubricant.

NOTE: The lubrication fitting must point toward the driveshaft (inboard side).

3. Install the bearing cup. See **Fig. 16**.

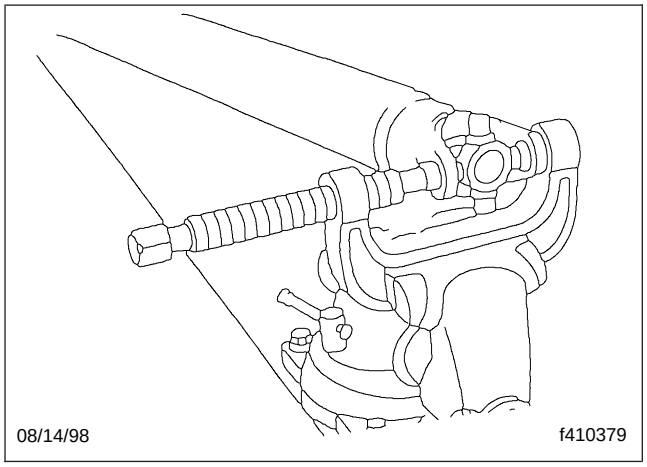

Fig. 16, Bearing Cup Installation

3.1 Start a new bearing cup into the driveshaft yoke.

3.2 Position the new spider in the driveshaft yoke.

3.3 Position the driveshaft in the U-joint tool.

3.4 Press the bearing cup just below the snap ring groove.

4. Remove the driveshaft from the U-joint tool and install the snap ring. See **Fig. 17**.

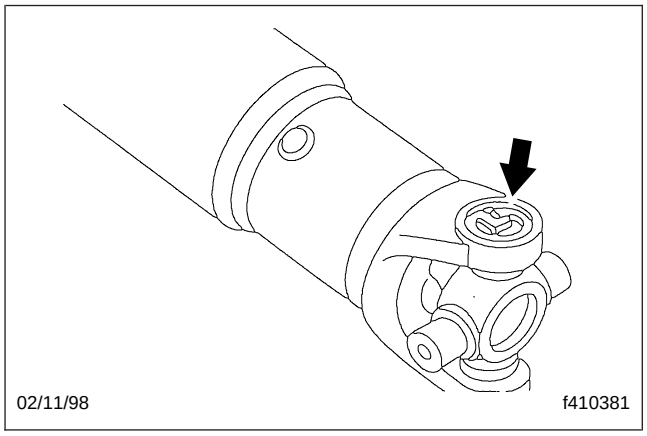

Fig. 17, Snap Ring Installation

5. Repeat the previous steps as needed for the opposite side of the driveshaft yoke.

NOTE: Re-index the slip-yoke and flange yoke.

6. Repeat the previous steps as needed to install the remaining new bearing cups, spider, and snap rings.

NOTE: Do not strike the bearings.

7. Check the U-joints for freedom of movement. If binding, strike the yoke with a brass or plastic hammer.

Driveline Cleaning and Inspection

SLIP-YOKE SPLINE

NOTE: Vehicle noise and vibration can be caused by a seized driveshaft slip-yoke spline resulting in the rubber isolator being pulled out of the driveshaft center bearing bracket.

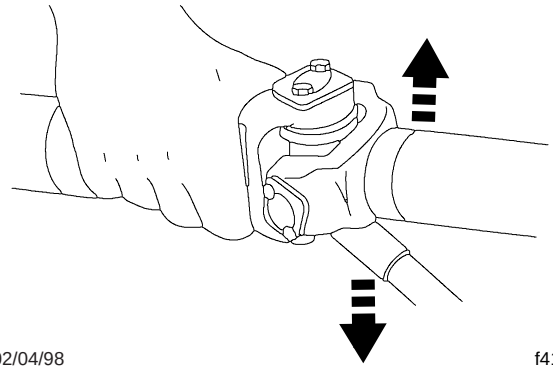
NOTE: The repair procedure to minimize driveshaft slip-yoke spline contamination and ultimate seizure is as follows:

1. Disconnect the driveshaft from the rear axle yoke and remove it from the vehicle.
2. Clean the male splines of the coupling shaft, using care not to damage the plastic coating. Fine abrasive cloth may be required to dress and polish the male spline. Remove all hardened grease deposits, dirt or rust. Inspect for worn or galled splines. The plastic coating on the stub spline must not be removed. Replace the coupling shaft if necessary.
3. Clean and inspect the female splines of the driveshaft slip-yoke, removing any hardened grease deposits, dirt or rust. Inspect the splines for worn or galled conditions; replace the driveshaft slip-yoke if necessary.
4. Apply a coating of high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A to the entire splined stub end of the coupling shaft prior to the assembling of the driveshaft to the coupling shaft.
5. Using a clean, long-handle (stencil-type) brush, apply high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A, spread evenly on all the female splines of the slip-yoke. The spline joint must slide freely by hand.
6. Assemble the driveshaft to the coupling shaft with the yokes phased properly. Attach the driveshaft to the rear axle yoke.
7. Using a hand-type grease gun, lubricate the driveshaft slip-yoke through the zerk fitting with high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A.

Driveline Lubrication

U-JOINTS

1. Apply high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A through the zerk fitting until fresh lubricant purges at each of the four seals. This flushes abrasive contaminants from each bearing and ensures all four bearings are filled properly.
2. Move the driveshaft from side to side while applying gun pressure if any seal fails to purge. This allows greater clearance on the thrust end of the bearing that is not purging. See **Fig. 1**.



02/04/98 f410322

Fig. 1, Moving Driveshaft from Side-to-Side

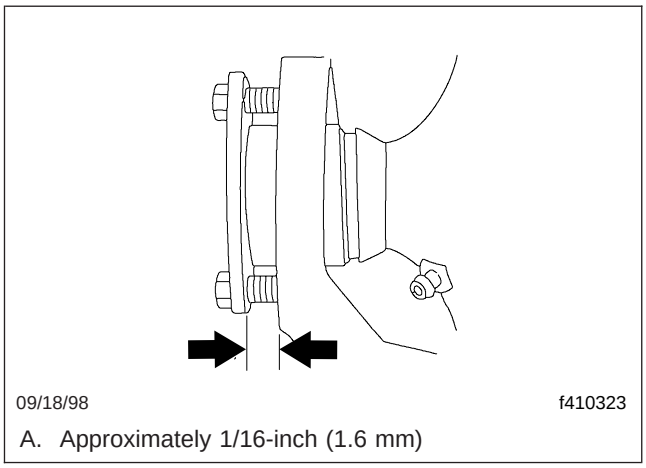
CAUTION

After lubricating, make sure that the bearing caps are firmly in place and that the retaining bolts are tightened per specifications.

3. If the seal still will not purge, release the seal tension by removing the bearing straps or loosening the bearing cap bolts and backing off the bearing cap assembly approximately 1/16 inch (1.6 mm). See **Fig. 2**.

SLIP-YOKE

1. Apply high-temperature 4x4 front axle and wheel bearing grease or equivalent meeting specification ESA–M1C198–A through the zerk fitting until the lubricant appears at the pressure relief hole

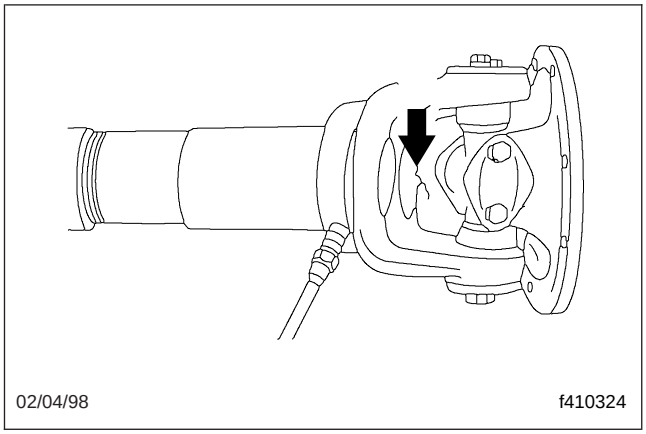


09/18/98 f410323

A. Approximately 1/16-inch (1.6 mm)

Fig. 2, Backing Off Bearing Cap Assembly

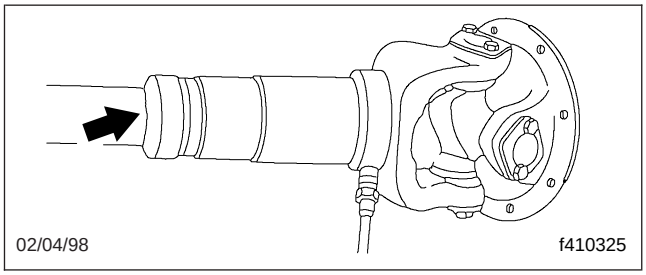
in the welch plug at the slip-yoke end of the spline. See **Fig. 3**.



02/04/98 f410324

Fig. 3, Welch Plug Pressure Relief Hole

2. After the lubricant appears at the pressure relief hole, cover the hole with a finger and continue to apply grease gun pressure until grease appears at the slip-yoke seal. See **Fig. 4**.



02/04/98 f410325

Fig. 4, Slip-Yoke Seal

Troubleshooting

INSPECTION AND VERIFICATION

Certain driveline concern symptoms are also common to the engine, transmission, rear wheel bearing, tires and other parts of the vehicle. For this reason, be sure that the cause of the concern is in the driveline before adjusting, repairing or replacing any of the parts. Refer to **Group 00** in this manual.

U-Joint Inspection

Perform a visual inspection of the driveshaft and U-joints. Inspect for any buildup of foreign material, such as mud or undercoating, on the driveshaft or in the U-joints. Check the shaft for damaged or bent tubing or missing balance weights.

Lubricate the U-joints and road test the vehicle to see if the condition improves. Refer to "U-Joints" in **Subject 130**.

If the condition does not improve, perform the following steps:

1. Remove the driveshaft.
2. Manipulate the rear axle shaft universal joint in each direction of rotation. If the U-joint feels stiff or has a "lumpy," "gritty" feel in any direction, replace the rear axle shaft universal joint.

Specifications

Torque Specifications		
Description	**Size**	**lbf·ft (N·m)**
Bearing Cap Bolt	5/16–24	35–41 (47–56)
	3/8–24	45–60 (61–81)
Bearing Strap Bolt to U-Joint Yoke	3/8–16	35–42 (47–57)
	3/8–24	45–60 (61–81)
	1/2–20	115–135 (156–183)
Bolt, Yoke (1480 and 1550 Series) Attaching Parts per Joint 2 Straps 4 Bolts (Gr. 8) 4 Nuts (Gr. 8)	3/8–16 x 1.75	35–41 (47–56)
Bolt, Yoke (1610 Series) Attaching Parts per Joint 2 Straps 4 Bolts (Gr. 8)	3/8–24 x 0.75	45–60 (61–81)
Bolt, Yoke (1710, 1760 and 1810) Attaching Parts per Joint 2 Straps 4 Bolts (Gr. 8)	1/2–20 x 1.00	115–135 (156–183)
Center Bearing to Support	1/2–13	75–105 (102–142)

High-Temperature 4x4 Front Axle and Wheel Bearing Grease	ESA–M1C198–A
Premium Long-Life Grease	ESA–M1C75–B
Adhesives	
Stud and Bearing Mount	WSK–M2G349–A1
Black Non-Acid Cure Silicone Rubber Sealant	ESL–M4G273–A

Table 2, General Specifications

Driveshaft Alignment

CAUTION

Perform this procedure before adjusting components for correct driveshaft alignment.

1. Inflate all tires to the pressure at which they are normally operated.
2. Park the empty vehicle on a surface which is as nearly level as possible both from front-to-rear and side-to-side.
3. The tractor must be in its normal operating position. Do not attempt to level the truck by jacking up the front or rear axles to obtain a level condition.

NOTE: All angles must be read within one-quarter degree and they must be measured with the protractor held plumb on a clean, flat surface.

4. Determine driveshaft angles, using a suitable digital inclinometer or spirit level protractor. When angles are read from the 0-degree mark (horizontally on the driveshaft), record and use the angle shown on the protractor. See **Fig. 1**.

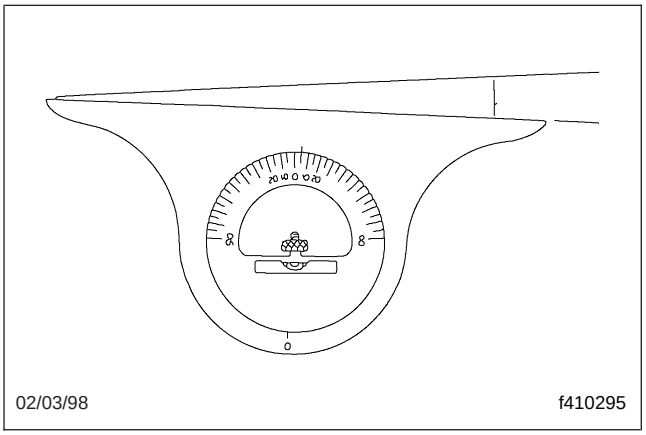

Fig. 1, Spirit Level Protractor

5. When angles are read from either of the 90-degree marks (vertically — on the flange), such as when measuring yoke angles, do not record the angle shown on the protractor since the 90-degree marks must be understood to be the same as 0 degrees on a horizontal plane. Thus, if a vertical reading is 85 degrees, the angle being measured is 5 degrees (90 degrees – 85 degrees = 5 degrees). See **Fig. 2**.

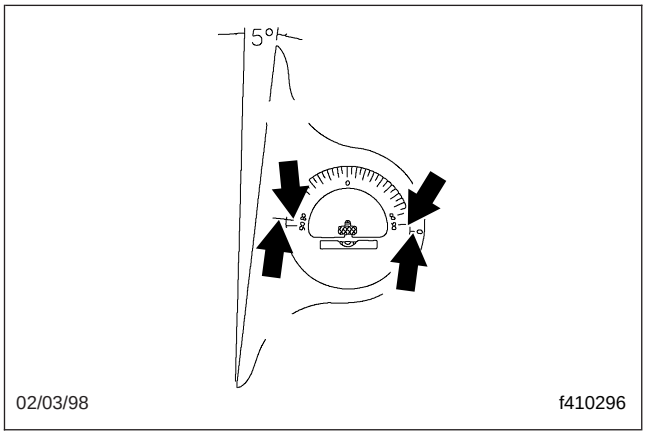

Fig. 2, Spirit Level Protractor Vertical Reading

Driveshaft Runout and Balance

DRIVESHAFT AND YOKE RUNOUT CHECK

NOTE: With the transmission in neutral, turn the rear wheel/drum to rotate the coupling shaft and driveshaft when checking runouts.

1. Check the coupling shaft for proper phasing. Check all U-joint to yoke installations for improperly seated U-joint bearing caps.

⚠ CAUTION

Measurements are to be made on the tube near the end welds, but not on them.

2. Check the runouts at the front and rear of the coupling shaft and the front, center and rear of the driveshaft. The runout check at the rear of the driveshaft is to be made on the tube, as close to the universal joint as possible. See **Fig. 1**.

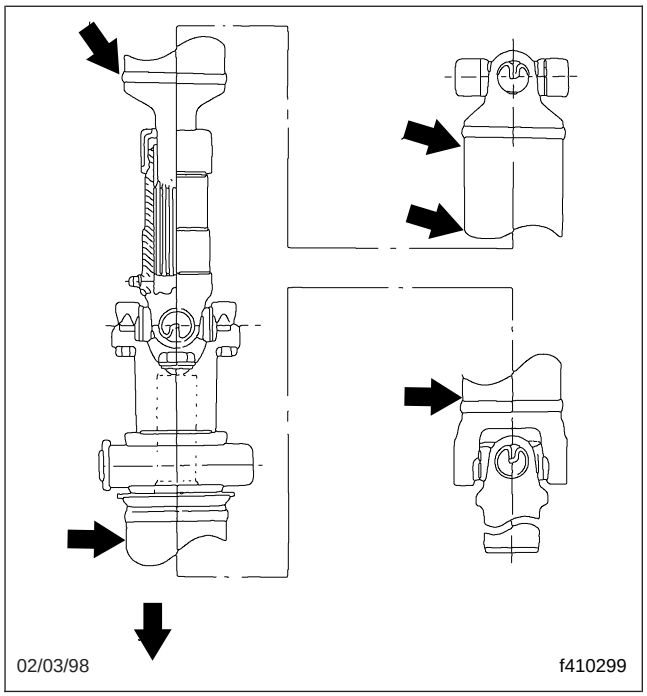

Fig. 1, Driveshaft Runout Check

NOTE: The runout at the rear of the driveshaft can be caused by either the driveshaft or the rear axle yoke.

3. Mark the points of the greatest runouts on the coupling shaft and driveshaft.
   - 3.1 If the runout on the coupling shaft or at the front or center of the driveshaft is equal to or greater than the specification given, replace the shaft.
   - 3.2 If the runout at the rear of the driveshaft is less than the specification given and the front and center runouts are also less than the specification given, proceed to driveshaft balancing.
   - 3.3 If the runout at the rear is more than the specification given and the front and center runouts are less than the specification given, mark the point of greatest runout on the shaft.
4. To determine the cause of the runout at the rear of the driveshaft, mark the U-joint and yoke, remove and rotate the driveshaft 180 degrees to the rear axle yoke, and check and mark the greatest runout at the rear of the driveshaft. If the runout is less than the specification given, evaluate on the hoist. Road test if the vibration is not present. Proceed to driveshaft balance if vibration is present. If the runout is more than the specification given, proceed to the following step.
5. Compare the first and second marks at the rear of the driveshaft to determine the cause of the runout. If the marks are within approximately 25.4 mm (1 inch), replace the driveshaft. If the marks are approximately on opposite sides of the shaft, replace the yoke.
6. After replacing either the driveshaft or rear axle yoke, recheck the runouts. If excessive runout is still evident after replacement of the rear axle yoke, it will be necessary to replace the ring gear and pinion and repeat the above checks until runout is within specifications.
7. Evaluate on a hoist. If the vibration is still present, proceed to "Driveshaft Balancing."

Driveshaft Runout and Balance

DRIVESHAFT BALANCING

Standard Procedure

WARNING

Self-locking bearing-cup-plate capscrews must not be reused; replace the capscrews with new ones. Also, do not undertighten or overtighten any bearing-cup-plate capscrews. A loose or broken fastener at any point in the driveline weakens the driveline connection, which could cause serious vehicle damage, or could result in the driveshaft separating from the vehicle, possibly causing loss of vehicle control that could result in serious personal injury or death.

NOTE: Vibration or shudder that is noticeable either on fast acceleration, when coasting, or when using the engine for braking can be caused by the rear axle housing being loose on the rear springs, improper tire balance, improper driveline installation or driveline imbalance.

NOTE: If detailed parts of the driveshaft are replaced and shaft vibration is encountered after installation, disconnect the shaft at the slip-spline. Rotate the slip-spline 180 degrees. Reconnect the shaft to the slip-spline. If the vibration persists, disconnect the shaft at the rear axle yoke. Rotate the rear axle yoke 180 degrees and reconnect the shaft to the yoke.

NOTE: If rotating the driveshaft 180 degrees does not eliminate vibration, the driveshaft may need to be balanced, using the following procedure. Two people are required to perform this operation: one in the vehicle, and one under the vehicle to make adjustments.

1. Raise the vehicle on a twin-post hoist so that both the front and rear axles are safely supported, with all wheels free to rotate.
2. With the transmission in gear, increase the vehicle speed to the maximum vibration level. Note and record the speedometer speed at this vibration level as a baseline speed.
3. Check the attachments of all U-joint bearing caps of the driveshaft or coupling shaft to the transmission yoke, front or rear axle pinion yokes and all transfer unit drive yokes for improper installation or damaged U-joint bearing cap locating lugs. All yokes with worn, shaved or damaged locating lugs must be replaced.
4. Check the driveshaft and coupling shaft for correct phasing.

WARNING

Do not wear loose clothing that could get caught on the rotating shaft.

Use caution when checking the driveshaft near the balance weights, to prevent injury to the hands.

5. With the transmission (and transfer unit) in gear, run the vehicle with the driveshaft and coupling shaft rotating at a speedometer speed of 40 to 50 mph (65 to 80 km/h). Carefully bring a crayon, piece of chalk, or colored pencil up until it just barely contacts the rear end, center and front end of the driveshaft. The chalk marks will indicate the heavy side of the driveshaft. See **Fig. 2**.

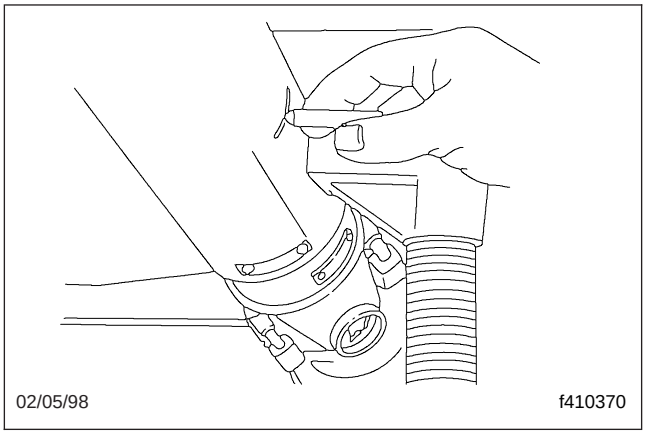

Fig. 2, Marking the Driveshaft

6. Install two screw-type hose clamps on the driveshaft so that their heads are located 180 degrees from the chalk mark, starting at the pinion yoke end of the driveshaft. Tighten the clamps and cut off the excess band from the clamps. See **Fig. 3**.
7. Run the vehicle up to the baseline speed. If vibration is still evident, rotate the clamps approximately 90 degrees away from each other and test for correction of vibration. See **Fig. 4**.

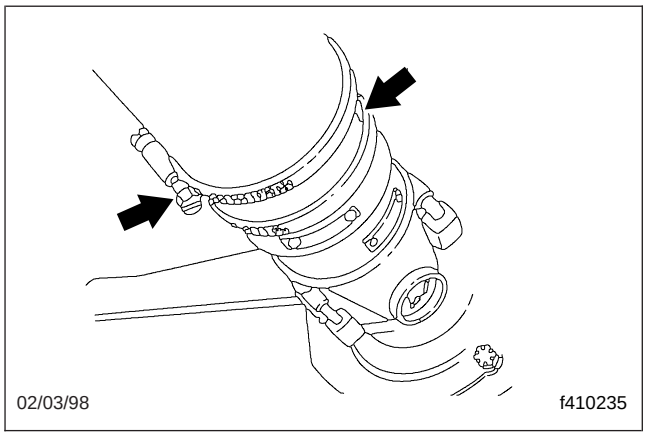

Fig. 3, Installing Screw-Type Hose Clamps

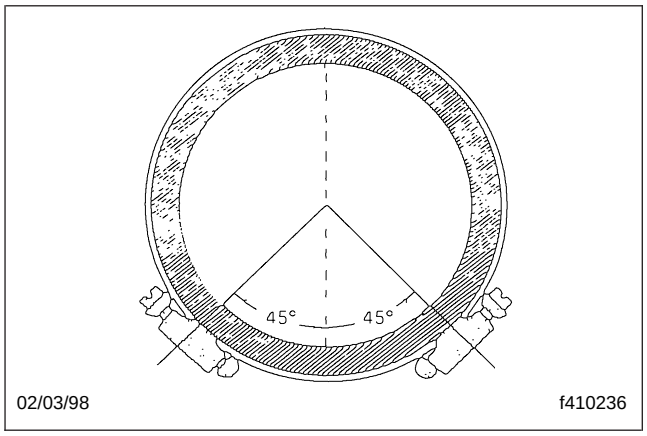

Fig. 4, Rotating Clamps 90 Degrees

8. If necessary, continue to rotate the clamps apart in smaller increments until the vibration is eliminated or begins to be reduced.
9. If the vibration is not completely eliminated, repeat this procedure and balance the front end of the driveshaft, checking for elimination or reduction in the vibration level.

⚠ CAUTION

To prevent overheating, do not run the vehicle on the hoist for an extended period.

10. To completely eliminate the driveline vibration, it may be necessary to balance the coupling shaft, following the same procedure as for the driveshaft.
11. Remove the vehicle from the hoist and road test.

Alternate Procedure

1. Road test. Evaluate and record the road speed at which the vibration occurs.
2. Raise the vehicle on a twin-post hoist or jack stands and re-evaluate by starting the engine, engaging the transmission and accelerating to the indicated speeds at which the vibration was most severe during the road test.
3. Disconnect the driveshaft from the axle yoke. Rotate the driveshaft 180 degrees from its original position and reinstall. Repeat the previous step. In some cases, rotating the driveshaft 180 degrees may decrease the vibration to an acceptable level. However, if the vibration level is increased, install the driveshaft in its original position and proceed to the following step.
4. A vehicle is more sensitive to excessive imbalance and runout at the rearward end of the driveshaft; therefore, locate the heavy side of the driveshaft by the use of a strobe light, such as the electronic strobe balancer and transducer.
5. Remove the rear wheels and tires, and reinstall all the wheel lug nuts in reverse, flat side of the nuts toward the drum or disc to avoid lug nut imbalance and to prevent the drum or disc from dislodging.
6. Scribe an axial chalk line (at any radial location) approximately 4 inches (101 mm) long at the rear of the driveshaft.
7. Locate the transducer so it is contacting the bottom side of the differential carrier and secure it in place. See **Fig. 5**.
8. Run the engine and driveline at the worst vibration speed noted and visually note the position of the chalk line by use of the strobe light. This provides a starting point for the initial location of the hose clamps.
9. Stop the engine and rotate the driveshaft so that the chalk line is in the same position as was noted under the strobe light. See **Fig. 6**.
10. Install two screw-type (stainless steel) hose clamps on the driveshaft. Position the clamp heads 180 degrees from the transducer and tighten the clamps. See **Fig. 7**.

Driveshaft Runout and Balance

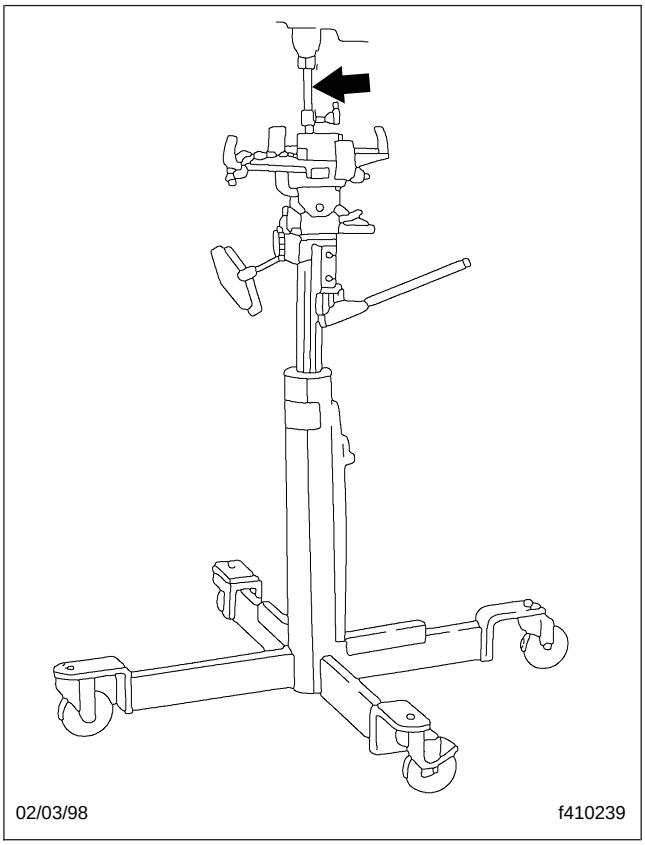

Fig. 5, Locating the Transducer

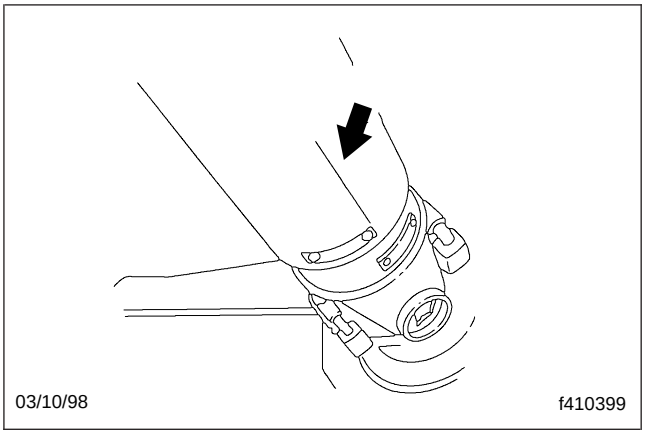

Fig. 6, Positioning the Chalk Line

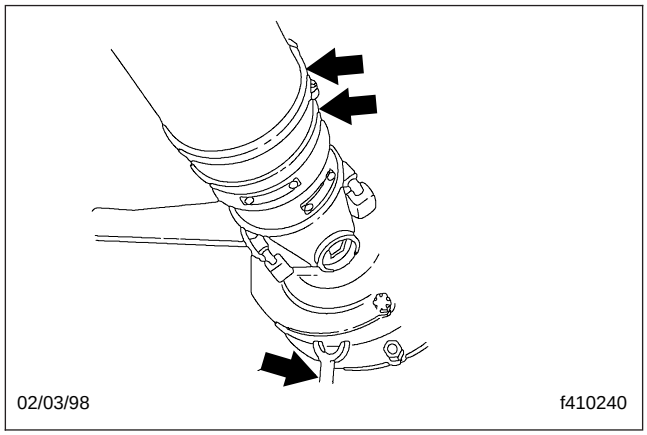

Fig. 7, Positioning the Hose Clamps 180 Degrees from the Transducer

⚠ CAUTION

Do not run the engine with the transmission engaged on the hoist for extended periods due to the danger of overheating the engine and transmission.

11. Run the engine and driveline through the speed range. If no vibration is felt, remove the lug nuts, install the wheels and tires, reinstall the lug nuts in the correct position and proceed to the last step in this procedure. However, if any vibration still exists, the combined weight of the two hose clamp heads may be excessive. To reduce this excess weight, rotate the clamp heads away from each other approximately 15 degrees (one each way from the original position). Run the engine and driveline and note if the vibration has been reduced.
12. Continue to rotate the clamp heads apart in smaller angular increments until the feel of balance is best. At this point, install the wheels and tires as described in the previous step and road test the vehicle to determine the actual degree of improvement. If satisfactory improvement has been obtained, proceed to the following step. If no improvement has been obtained, the clamps must be removed and diagnosis redirected to other areas, such as wheels, tires, driveline angle and yoke runout.
13. When the vehicle has been corrected to a satisfactory level, as determined by a road test evaluation, tighten the clamps securely. Clean thor-

oughly with lacquer thinner, and spray the clamps with a commercially available black paint for a finished appearance.

Universal Joint Phasing

NOTE: When universal joint yokes are assembled to their shafts in the same plane, they are in phase. When they are assembled to the shafts in different planes, they are out of phase.

NOTE: On vehicles with a slip-spline on the last coupling shaft, the yoke, which is part of the slip-yoke assembly, should be considered part of the coupling shaft. See **Fig. 1**.

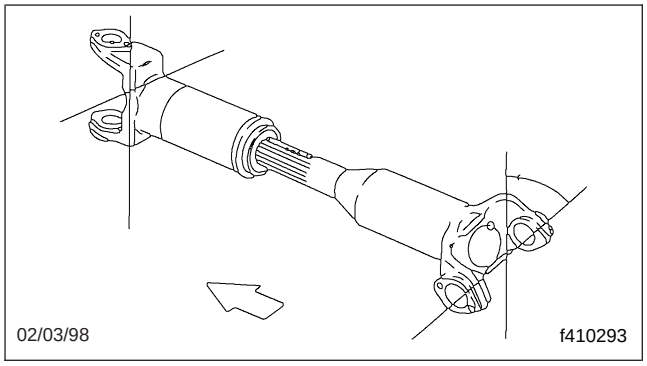

Fig. 1, Slip-Yoke Assembly

CAUTION

Do not revise universal joint phasing unless approved by engineering.

1. Check and correct universal joint phasing, as necessary, according to the following specifications (see **Fig. 2**):
   - 1.1 The universal joints between the rear axle and transmission must be in phase.
   - 1.2 The universal joints between tandem rear axles must be in phase (parallel).
   - 1.3 Tandem axle models will often require 90° phasing on one shaft of a 2-piece driveline.
2. Mark splined main driveline components prior to disassembly, to ensure reassembly in the same relative orientation.

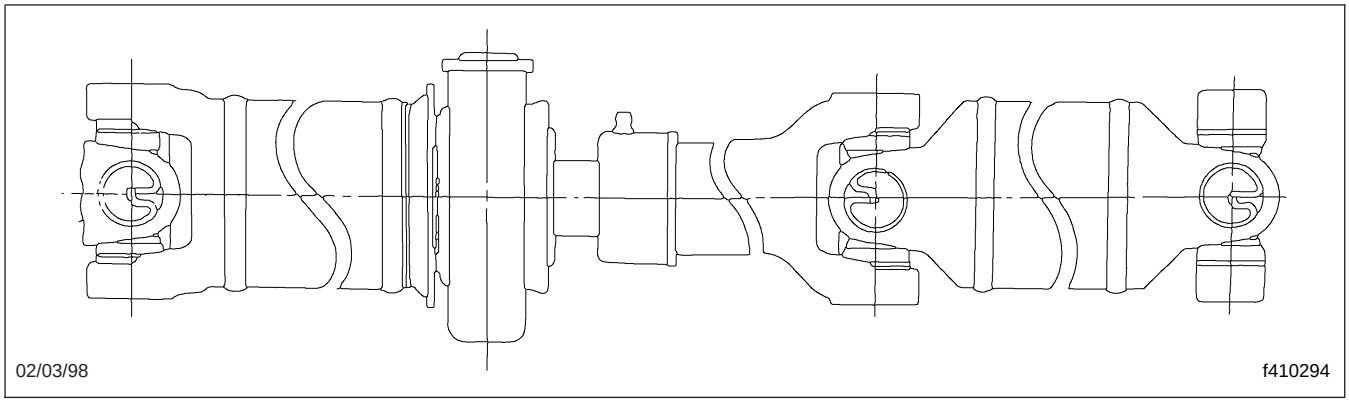

Fig. 2, U-Joint Phase

Driveshaft Angle Checking and Adjustment

SINGLE REAR AXLES

1. Check and record the angle of the engine and main transmission. This reading can be taken at the rear of the main transmission on the output yoke or flange. Record this reading. See **Fig. 1**.

   EXAMPLE: 1 degree (down from horizontal)

2. Check the angle of the driveshaft. Record this reading.

   EXAMPLE: 4 degrees 30 min. (down from horizontal)

3. Check the axle yoke angle. Record this reading.

   EXAMPLE: 2 degrees (down from horizontal)

4. Subtract the engine and main transmission angle from the driveshaft angle.

   4° 30 min. (driveshaft angle down from horizontal) -1° (engine and main transmission angle down from horizontal) = 3° 30 min. (transmission output shaft U-joint operating angle down from horizontal)

5. Use the axle yoke angle, and subtract it from the driveshaft angle.

   4° 30 min. (driveshaft angle down from horizontal) -2° (axle yoke angle down from horizontal) = 2° 30 min. (axle yoke U-joint operating angle down from horizontal)

6. Now, subtract the sum of the engine and main transmission angle minus the driveshaft angle from the sum of the axle yoke angle minus the driveshaft angle.

   3° 30 min. (transmission output shaft U-joint operating angle down from horizontal) -2° 30 min. (axle yoke U-joint operating angle down from horizontal) = 1° (U-joint operating angle difference)

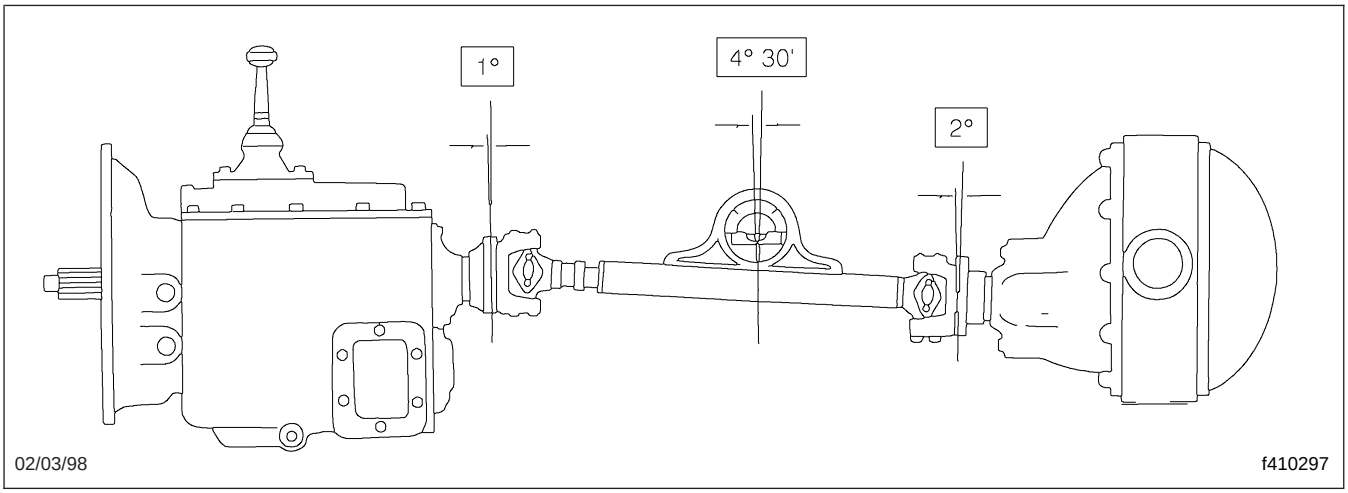

Fig. 1, Single Rear Axle Driveshaft Angles

TANDEM AXLES

CAUTION

This procedure must be performed for all tandem axle suspensions in which both axle pinion angles are set by longitudinal torque rod lengths and adjusted by varying the number of shims under the torque rod mounting brackets at the frame crossmember.

CAUTION

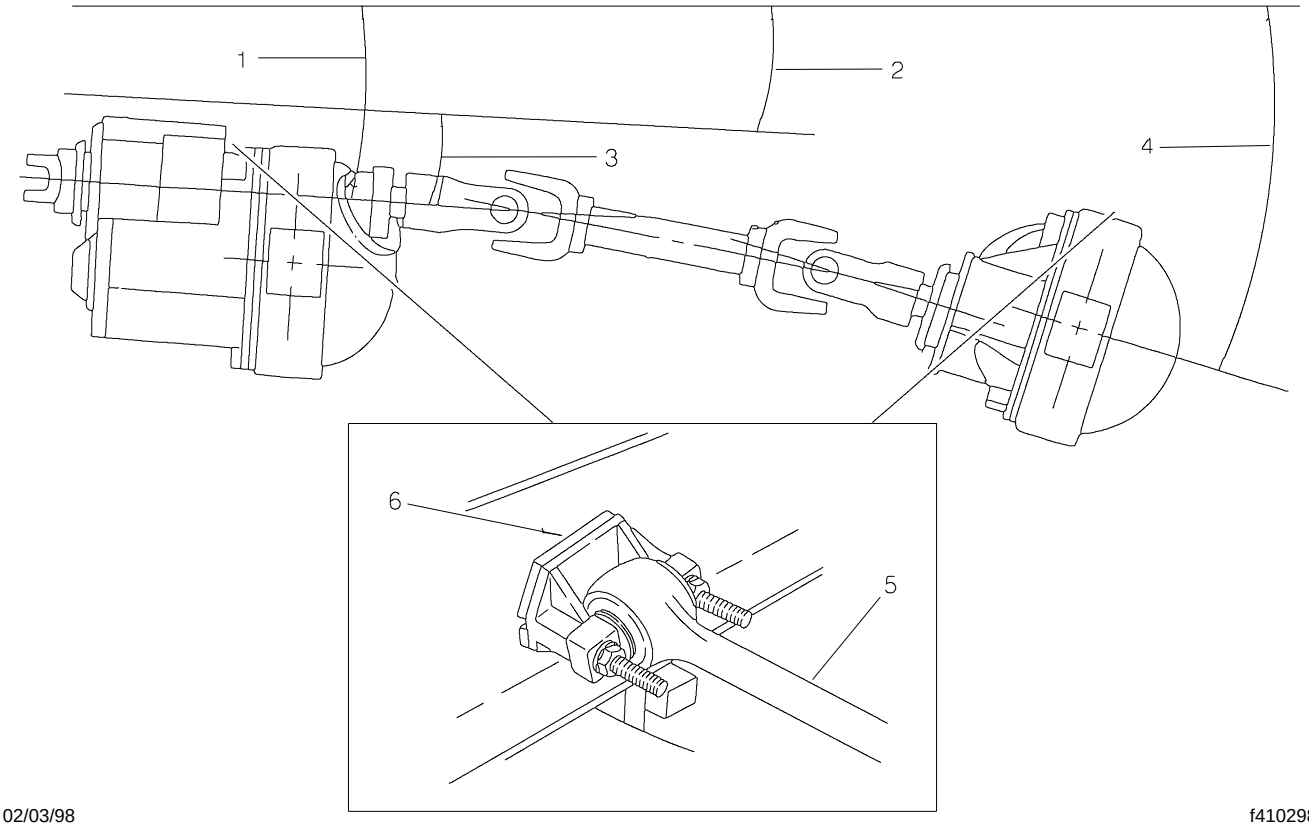
Before measurements are made, make sure the vehicle is in cab-chassis condition and tires are inflated to normal pressure ±69 kPa (10 psi).

Before any angles are measured, the vehicle must be standing on a level surface.

Driveshaft Angle Checking and Adjustment

1. With the forward torque arm installed, measure the forward axle pinion angle vs. the horizontal to the nearest 5 minutes, using a vernier inclinometer or electronic level gauge. The measuring instrument must be calibrated to provide repeated readings within ± 5 minutes of 0 degrees when placed on the level surface. See **Fig. 2**.

NOTE: Compare the calculated difference of the angles to the range shown for the suspension. Refer to the "Tandem Axle Angle Settings" table in **Subject 400**. If the measurement is within the specified range, the forward pinion angle is correct.



1. Forward Axle Pinion Angle vs. Horizontal
2. Engine/Transmission Angle vs. Horizontal
3. Difference Angle
4. Rear Axle Pinion Angle vs. Horizontal
5. Torque Rod
6. Shims

Fig. 2, Tandem Axle Driveshaft Angles

2. Measure the slope of the engine and transmission vs. the horizontal with the same inclinometer resting against a machined surface known to be parallel to the crankshaft (the manufacturing pads on some transmission cases are a suitable surface).
3. Subtract this angle from the forward axle pinion angle to obtain the difference in the angles.
4. Add or remove shims from the forward torque rod bracket to bring the measured forward axle pinion angle within the range specified for the suspension in the chart. Each thick shim (Part No. E4HT–4N002–CA or equivalent, 0.12-in. thick) will subtract approximately 22 minutes from the forward axle pinion angle (reverse for Neway air suspensions). Each thin shim (Part No. E4HT–4N002–BA or equivalent, 0.06-in. thick) will subtract approximately 11 minutes from the

forward pinion angle. Repeat the procedure following any change in the number of shims under the forward torque rod bracket.

5. With the rear torque arm installed, measure the rear axle pinion angle vs. the horizontal to the nearest five minutes, using the same gauge as for the forward axle.

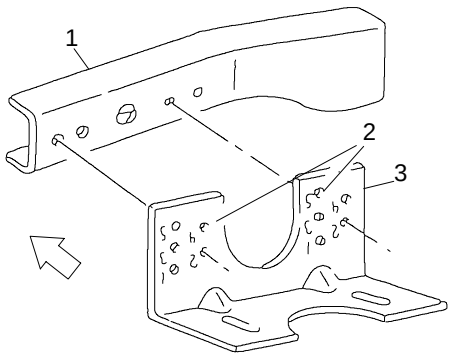
NOTE: Compare the measured rear pinion angle to the range shown for the suspension Refer to the "Tandem Axle Angle Settings" table in **Subject 400**. If the measurement is within the specified range, the rear pinion angle is correct.

6. Add or remove shims from the rear torque rod bracket to bring the measured rear axle pinion angle within the range specified for the suspension in the chart. Each thick (0.12-in.) shim will add approximately 22 minutes to the rear axle pinion angle. Each thin (0.06-in.) shim will add approximately 11 minutes to the rear pinion angle. Repeat the procedure following any change in the number of shims under the rear torque rod bracket.

Adjustable Driveline Support Plate Position Adjustment

Adjustment

NOTE: An adjustable driveline support plate is used on some applications. Although it can be mounted in any one of several positions, only one position is correct for a specific application. See **Fig. 1**.



09/18/98 f410366

1. Crossmember
2. Hole Set Numbers
3. Support Plate

Fig. 1, Adjustable Driveline Support Plate

1. Determine the correct position of the support plate part number shown on the Truck Specification List attached to each vehicle.

   1.1 The numerical digit in the adjustable support plate part number suffix indicates the hole set to be used. For example, FGHT–CA1 requires that the FGHT–4831–CA support plate be bolted to the crossmember (or 4691 bracket — some installations) through support plate hole set number 1.

   1.2 The hole sets are identified by the numbers 1 through 4 or 5 stamped into the support plate.

NOTE: The leg of the support plate must always face the rear of the vehicle.

2. Assemble the support plate to the crossmember through the hole set identified in the support plate part number suffix.

Table 2, Tandem Axle Angle Settings

General Information

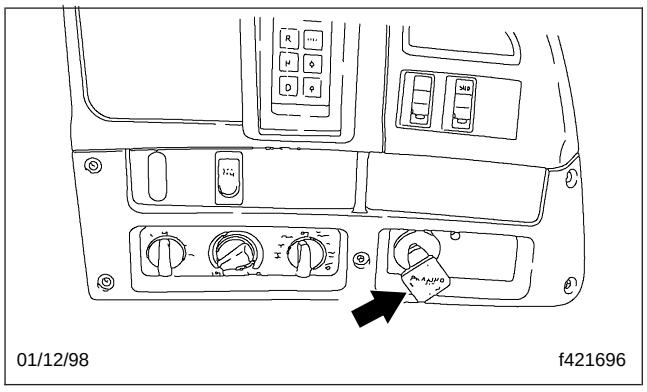
PARKING BRAKE CONTROL VALVE

(See Fig. 1)

The parking brake control valve is a push-pull operated valve with a square, yellow knob mounted on the instrument panel.

The parking brake control valve:

- Can be pulled out to exhaust air from the spring brake portion of the brake air chambers to apply the spring brakes when parking the vehicle;
- Can be pushed in to supply air to the spring brake chambers to release the spring brakes;
- Will automatically pop out from the release (in) position to the apply (out) position when the primary and secondary air reservoirs are reduced below 25 to 45 psi (241 to 310 kPa).



01/12/98 f421696

Fig. 1, Parking Brake Control Valve

TRAILER AIR SUPPLY CONTROL VALVE (See Fig. 2)

The trailer air supply control valve has two push-pull knobs, a square yellow parking brake control and an octagonal, red trailer air supply. The trailer air supply control valve is mounted on the instrument panel.

During initial charge, with the system completely discharged, both knobs are out. When system pressure reaches 65 psi (450 kPa), the red knob (trailer supply) can be pushed in and should stay in, charging the trailer system and releasing the trailer spring

2. Parking Brake Control
3. Trailer Air Supply
4. Trailer Brake Hand Control Valve

Fig. 2, Trailer Air Supply Control Valve

brakes. The yellow knob can now be pushed in, which will supply air to release the tractor spring brakes.

With both knobs pushed in, air is supplied to the trailer and to the tractor spring brakes; all brakes are released. See **Fig. 3**.

To apply only the trailer brakes, the red knob is pulled out, exhausting the trailer supply line. The trailer spring brakes are now applied. This mode is used to uncouple from the trailer and during bobtail operation. See **Fig. 4**.

With both knobs pushed in for normal run modes, the parking brakes on both the tractor and trailer can be applied by pulling the yellow (parking brake control) knob out, which exhausts the air from the tractor spring brakes and simultaneously causes the red (trailer supply) knob to pop out, applying the trailer spring brakes. See **Fig. 5**. This complies with the federal regulation that one control must apply all the parking brakes on the vehicle.

If both knobs are out when parking the combination vehicle and it is desired to recharge the trailer (leaving the tractor spring brakes applied), the red knob can be pushed in, repressurizing the trailer supply line. See **Fig. 6**. This mode can also be used to park a combination vehicle with air-actuated parking brakes on the trailer to provide demonstrated parking capability with tractor spring brakes only.

With both knobs pushed in, in the normal run configuration, if the supply pressure to the trailer air supply control valve is reduced to approximately 35 to

General Information

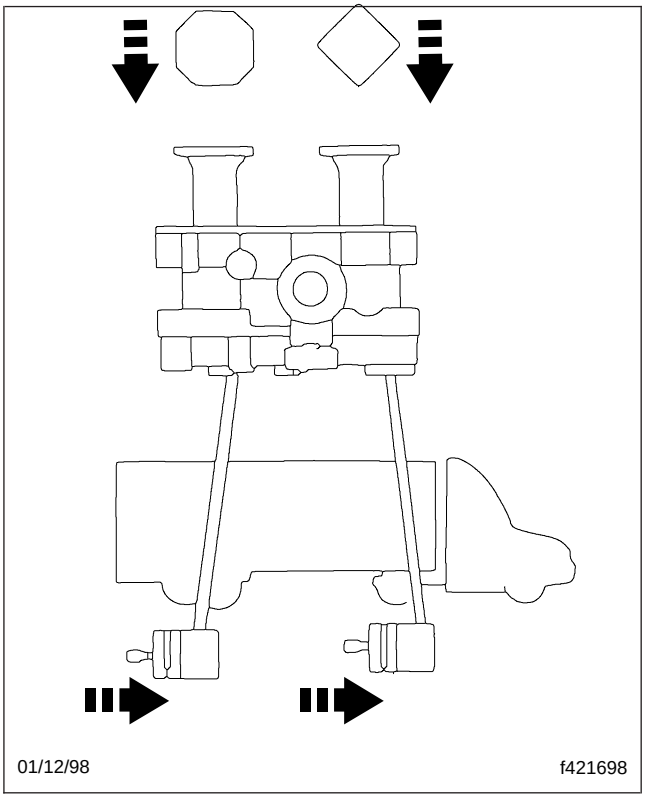

Fig. 3, Normal Operating Position, All Brakes Released

45 psi (241 to 310 kPa), the red knob (trailer supply valve) must pop out, applying the spring brakes on the trailer. If the red knob is held in manually and the pressure decreases to approximately 25 to 35 psi (172 to 241 kPa), a tripper piston within the trailer air supply control valve will move upward, exhausting the trailer supply, effecting the required non-override feature. The yellow (parking brake control) knob will pop out at approximately 20 to 30 psi (138 to 207 kPa).

The No. 1 service reservoir will at all times be selected as the primary supply source for the trailer air supply control valve. This is accomplished automatically by the function of the dual circuit supply valve contained in the body of the trailer air supply control valve. Only in the event of a pressure drop of more than 30 psi (207 kPa) below that of the No. 2 service reservoir will the dual circuit supply valve shuttle and establish the No. 2 service reservoir as the supply.

The spring brake chambers are part of the brake air chambers. See **Fig. 7**. The spring brake chambers contain a powerful spring used instead of air pressure to apply the vehicle brakes. See **Fig. 8**. The spring is kept compressed by air pressure, which is controlled by the parking brake control or the trailer air supply control valve.

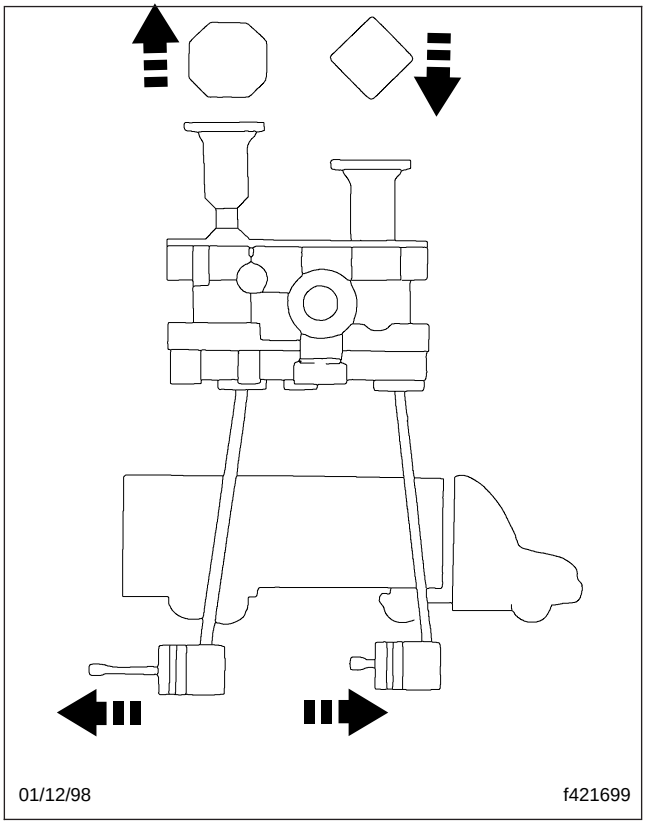

Fig. 4, Trailer Brakes Applied, Tractor Brakes Released

The quick release valve (see **Fig. 9**) controls the exhaust of air from the spring brake chambers. The valve is located near the brake air chambers. The nearer the exhaust port where the air pressure can be released, the more quickly the spring brakes can be applied.

Trailer Air Supply Control Valve Removal and Installation

Removal

NOTE: Match-mark the knobs to aid installation.

1. Remove the parking brake control, the trailer air supply and the trailer brake hand control valve knobs. See **Fig. 1**.

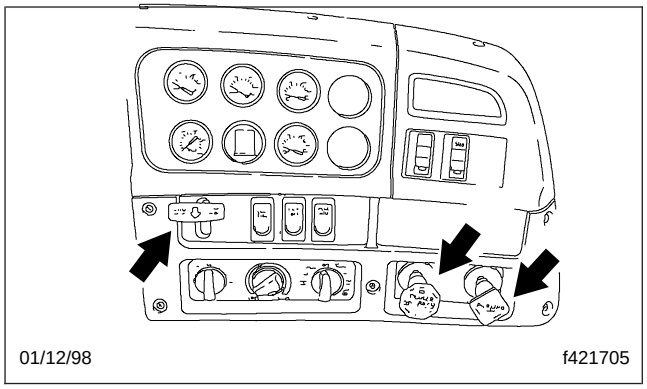

Fig. 1, Parking Brake Control, Trailer Air Supply and Trailer Brake Hand Control

2. Remove the eight screws from the instrument panel finish panel. See **Fig. 2**.

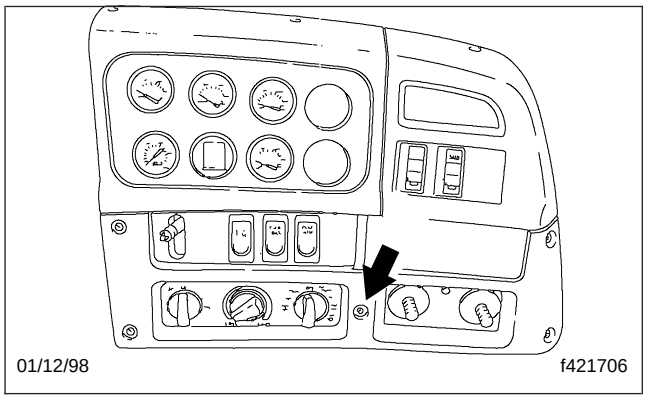

Fig. 2, Instrument Panel Finish Panel Screw

3. Position the instrument panel finish panel out of the way.

NOTE: Match-mark the air lines 1 through 4 to aid installation.

4. Disconnect the air lines from the trailer air supply control valve. See **Fig. 3**.

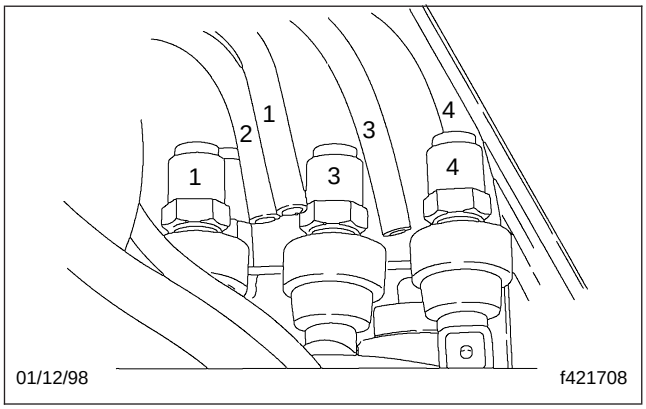

Fig. 3, Numbered Air Lines

5. Remove the two screws retaining the trailer air supply control valve to the finish panel center bracket. See **Fig. 4**.

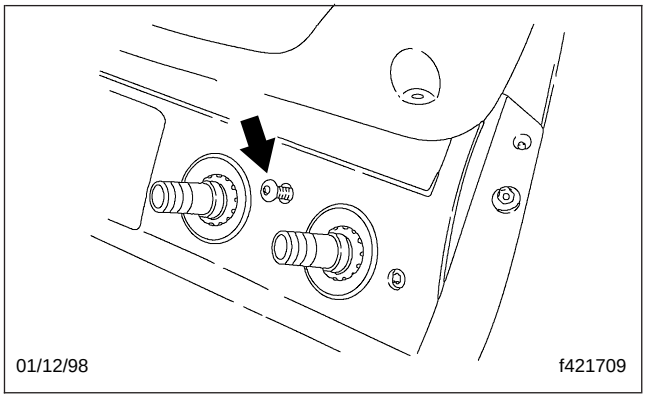

Fig. 4, Trailer Air Supply Control Valve Retaining Screws

6. Make room for valve removal. See **Fig. 5**.
   - 6.1 Remove the two screws retaining the finish panel center bracket to the instrument panel.
   - 6.2 Tilt the finish panel center bracket outward.
7. Remove the trailer air supply control valve. See **Fig. 6**.

Installation

1. Make room for valve installation by tilting the finish panel center bracket inward.

3. Install the eight screws from the instrument panel finish panel. See **Fig. 2**.
4. Connect the air lines to the trailer air supply control valve.
5. Install the two screws retaining the trailer air supply control valve to the finish panel center bracket. See **Fig. 4**.
6. Install the parking brake control, the trailer air supply and the trailer brake hand control valve knobs. See **Fig. 1**.

Specifications

System Pressures	
Item	**System Pressures psi (kPa)**
Trailer Supply (Red Knob) Will Hold the Release (In) Position	65 (450)
Trailer Supply (Red Knob) Will Pop Out Automatically	35–45 (241–310)
Trailer Air Supply Control Valve Will Automatically Exhaust Spring Brake Chambers if Trailer Supply (Red Knob) Is Held in Manually	25–35 (172–241)
Tractor/Trailer Configuration Parking Brake Control Valve (Yellow Knob) Will Pop Out	20–30 (138–207)
Truck Configuration Parking Brake Control Valve (Yellow Knob) Will Pop Out	35–45 (241–310)

Table 1, System Pressures

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

Brake System

INSPECTION AND VERIFICATION

With the engine stopped and the air reservoirs charged to governor pressure (130 psi [897 kPa] maximum), the rate of pressure drop shall not exceed 1 psi (7 kPa) per minute with the service brakes released and spring brakes applied.

For air pressure loss concerns, coat the fittings and exhaust ports of the suspected components with a soap solution and check for air bubble formation. Compare bubble formation to allowable leakage specifications. Tighten, repair or replace as required.

Inspect air lines for kinks, abrasions and correct routing. Repair or reroute as necessary.

For vibration concerns, check the brake drum and foundation brake components at the applicable axle location. Check the brake drum for out-of-round condition. Refinish or replace as necessary. Inspect the foundation brake components for loose mounting, wear, damage and correct installation. Repair or replace as necessary.

Problem—Brakes Pull or Drift

Problem—Brakes Pull or Drift	
Possible Cause	**Remedy**
Vehicle loading	Balance vehicle load.
Base brake components	Check air chamber stroke. Measure the air chamber stroke at all wheels when the brakes are applied. Refer to "DOT Adjusted Air Chamber Stroke Limits" in this section. If the air chamber stroke is not equal and within specification at all wheels, Adjust air chamber stroke. Refer to "Manual Slack Adjuster, Adjustment" in this section. Retest the system. If the air chamber stroke is equal and within specification at all wheels, check for air leaks at the valves, lines and brake air chambers when the brakes are applied. If leaks were found, repair or replace as necessary. Retest the brakes. If leaks were not found, check air chamber pressure. Measure the air pressure at the brake air chambers when the brakes are applied. If the pressure is not equal at all brake air chambers, repair or replace the associated relay valve. Retest the brakes. If the pressure is equal at all brake air chambers, check the brake drums for correct installation, out-of-round condition, cracks or other damage. Repair or replace as necessary. Test the system for normal operation.
Valves or line restriction	Perform "Inspection and Verification" in this section.

Problem—Brakes Do Not Release or Release Too Slowly

Problem—Brakes Do Not Release or Release Too Slowly	
Possible Cause	**Remedy**
Base brake components	Check the base brake components for binding, weak springs and incorrect installation. If the components are OK, repair or replace the associated quick release valve. Retest the brakes. If the components are defective, repair or replace as necessary. Test the system for normal operation.
Valves	Check the foot control valve. Operate and release the foot control valve. Observe the movement of the foot control valve. If the foot control valve does not return to the fully released position when it is released, remove the obstruction. Repair or replace as necessary. Retest the brakes.

Troubleshooting

Problem—Brakes Do Not Release or Release Too Slowly	
Possible Cause	**Remedy**
Line restriction	Check for restrictions. Inspect the air lines and check for a kinked or pinched condition. Correct the kinked or pinched condition. Retest the brakes. If no restrictions are found, check air brake chambers. Check for leaks at the spring brake portion of the brake air chambers. Repair or replace as necessary. Retest the brakes.

Problem—Brakes Insufficient, Do Not Apply or Apply Too Slowly

Problem—Brakes Insufficient, Do Not Apply or Apply Too Slowly	
Possible Cause	**Remedy**
Air chamber free stroke adjustment	Refer to "Air Chamber Free Stroke" under "Inspection and Verification" in this section. Perform slack adjuster manual adjustment.
Water or oil in air supply	Perform air dryer test. Refer to "Component Tests" in this section.
Valves, line restriction or base brake components	Check for vehicle overloading. If the vehicle is overloaded, correct as necessary. Retest the brakes. If the vehicle is not overloaded, check foot control valve. Operate the foot control valve. Check whether the foot control valve can move to the fully operated position. If the foot control valve does not operate OK, remove the obstruction. Repair or replace as necessary. If the foot control valve operates OK, check air brake stroke. Check the air chamber stroke. Refer to "DOT Adjusted Air Chamber Stroke Limits" in this section. If the air chamber stroke is not within specification, perform "Slack Adjuster, Manual Adjustment" in this section. If the air chamber stroke is within specification, check system air pressure. Check air delivery pressure to the brake air chambers. If delivery pressure is not at least 621 kPa (90 psi), perform the "Compressor—Operation and Leakage Tests" and the "Governor" test. Refer to "Component Tests" in this section. Repair or replace as necessary. If the delivery pressure is at least 621 kPa (90 psi), check the base brake components. Check the components for wear, damage or incorrect installation. If the components are OK, inspect the system for air line kinks, restrictions and components leaks. Correct as necessary. Retest brakes. If the components are defective, repair or replace as necessary. Test the system for normal operation.

Problem—Excessive Oil or Water in Brake System

Problem—Excessive Oil or Water in Brake System	
Possible Cause	**Remedy**
Air dryer	Perform the "Air Dryer" test. Refer to "Component Tests" in this section.
Contaminated air source	Drain and repressurize the system with clean, dry air.
Compressor	Perform "Compressor—Operation and Leakage Tests". Refer to "Component Tests" in this section.

Problem—Air Pressure Rises Above Normal

Problem—Air Pressure Rises Above Normal	
Possible Cause	**Remedy**
Governor	Perform the "Governor" test. Refer to "Component Tests" in this section.

Problem—Air Pressure Will Not Rise to Normal or Rises too Slowly

Problem—Air Pressure Will Not Rise to Normal or Rises too Slowly	
Possible Cause	**Remedy**
Compressor	Perform the "Compressor—Operation and Leakage Tests". Refer to "Component Tests" in this section.
Leaks	Perform the "Leakage" tests. Refer to "Component Tests" in this section.

Problem—Low Air Pressure Buzzer Sounding, Air Pressure Gauge Reads OK

Problem—Low Air Pressure Buzzer Sounding, Air Pressure Gauge Reads OK	
Possible Cause	**Remedy**
Low air pressure switch	Check low air pressure switch. Disconnect the electrical connector at the low air pressure switch. If the low air pressure buzzer continues, repair or replace the worn or damaged low air pressure buzzer or circuit. Refer to **Group 54** in this manual. Retest the system.
Air gauge	Check the air gauge. Compare the air gauge to a known good gauge. The original air gauge must be within 48 kPa (7 psi) of the known good gauge. If the air gauge is OK, replace the low air pressure switch. Retest the system. If the air gauge is defective, replace the air gauge, then test the system for normal operation.

Problem—Parking Brake Will Not Apply or Applies too Slowly

Problem—Parking Brake Will Not Apply or Applies too Slowly	
Possible Cause	**Remedy**
Valve	Check the release bolt. Check the brake air chamber to determine if the spring brake is caged with the release bolt. If the spring brake is caged, release the caged spring brake. Retest the system. If the spring brake is not caged, check parking brake control valve. Disconnect the output line at the parking brake control valve. If the parking brake operates, repair or replace the parking brake control valve. Retest the system. If the parking brake does not operate, check the quick release valve. Loosen the input line at the quick release valve.
Brake air chamber	If the quick release valve does not operate, repair or replace the quick release valve. Retest the system. If the quick release valve operates, check the brake air chamber. Disconnect the slack adjuster from the air chamber push rod. Operate the parking brake. If the air chamber push rod fully extends, inspect the base brake components. Repair or replace as necessary. Retest the system. If the air chamber push rod does not fully extend, repair or replace the brake air chamber. Retest the system.

Troubleshooting

Problem—Parking Brake Will Not Release or Releases too Slowly

Problem—Parking Brake Will Not Release or Releases too Slowly	
Possible Cause	**Remedy**
Valve	Check parking brake control. With the parking brake released, loosen the output line fitting at the parking brake control valve and check for air pressure at the fitting. If air pressure is not present at the output line fitting, repair or replace the parking brake control valve. Retest the system. If air pressure is present at the output line fitting, check the air pressure. With the parking brake released, loosen the input fitting at the air chamber spring brake chamber. Check for air pressure at the fitting. If air pressure is not present, correct the obstruction in the air supply path from the parking brake control valve to the brake air chamber. Retest the system. If air pressure is present, check brake air chamber. With the parking brake released, disconnect the slack adjuster from the brake air chamber. If the parking brake releases, repair or replace the brake air chamber. If the parking brake does not release, repair worn or damaged components in the base brake system causing the binding condition. Retest the system for normal operation.
Air supply	

COMPONENT TESTS

Valve—Modulator

1. Chock the wheels. Charge the air brake system to governor cutout pressure.
2. Place the parking brake control valve in the "Park" position. Observe that the spring brakes apply promptly. Remove one line or plug from the delivery port of the valve and install a test gauge known to be accurate. Place the parking brake control valve in the "Release" position. Observe that the spring brakes release fully.
3. With the parking brake control valve in the "Release" position, note the gauge pressure reading. The correct spring brake hold-off pressure setting is 95 to 105 psi (655 to 724 kPa). If the pressure reading is incorrect, replace the modulator valve.
4. Place the parking brake control valve in the "Park" position. The gauge reading should drop to zero promptly. A lag of more than one second in drop of pressure indicates incorrect operation of the single check valve (within the modulator valve).
5. With the parking brake control valve in the park position, fully apply the service brakes with the foot control valve several times and note that a pressure reading increase occurs on the gauge each time the foot control valve is applied. If a pressure reading does not occur, the modulator valve requires repair or replacement.
6. Place the parking brake control valve in the release position. Determine the reservoir which supplies the balance port and drain completely.
7. Apply the foot control valve several times and note that the pressure reading on the gauge decreases each time the foot control valve is applied. After the foot control valve has been applied several times, pressure on the gauge will drop to the point where release of the spring brakes will no longer occur.

LEAKAGE TEST

Place the parking brake control valve in the "Release" position. Using a soap solution, coat the modulator valve exhaust and vent hole in the proximity of the adjusting screw. Slight bubble leakage is permitted.

If the modulator valve does not function as described, or if the leakage is excessive, repair or replace as required.

Valve—Quick Release

1. With the air brake system fully charged, apply the brakes. Observe the brake action on the wheels controlled by the quick release valve or relay valve in question. The brakes should apply promptly.

2. Release the brakes and inspect to make sure the air pressure is exhausted rapidly from the exhaust port. Make sure the exhaust port is not restricted.
3. Disassemble and clean the quick release valve (if required) and retest. If the valve does not seat or operates improperly, replace the quick release valve.
4. With the brakes applied, coat the exhaust port with a soap solution and inspect for leaks. Leakage is not permissible.
5. Disassemble and clean the quick release valve, if required. If the valve does not seat or operates improperly, replace the quick release valve.

Valve—Parking Brake Control

1. Connect a 120 psi (827 kPa) air source to the supply port. An accurate test gauge should be placed in line with the supply line (use a T-fitting to do this). This provides a means of controlling the supply pressure. A small valve with a gauge should be connected to the delivery port.
2. With 120 psi (827 kPa) supply pressure and the button pulled out ("Applied" position), check that leakage at the exhaust port and at the plunger stem does not exceed a 1-inch (25.4 mm) bubble in five seconds. There should be no leakage between the upper and lower body.
3. Push the button in ("Released" position). Leakage at the exhaust port and at the plunger should not exceed a 1-inch (25.4 mm) bubble in three seconds.
4. Reduce the supply pressure. At a pressure of 35 to 45 psi (241 to 310 kPa), the button should pop out automatically, exhausting the delivery volume.

Compressor—Operation and Leakage Tests

NOTE: The tractor must be disconnected from the trailer to run this test.

Bleed both the primary and secondary reservoirs down to 85 psi (586 kPa) as measured with a test gauge.

Run the engine at full governed rpm until the air pressure in the reservoirs reaches 100 psi (689 kPa). If the pressure buildup time exceeds 40 seconds, the compressor is not operating properly and one or more of the following conditions may exist:

- The engine air cleaner or compressor inlet hose, the source of fresh air for the compressor, is clogged;
- Excessive air system leakage;
- The compressor drive gear is slipping;
- Restricted discharge cavity in the compressor or restricted discharge line;
- The discharge valve is stuck or broken;
- The unloader piston inside the compressor is stuck;
- Excessively worn compressor piston rings or cylinder walls;
- Governor out of adjustment or fouled.

The air compressor has three possible sources of leakage: engine coolant, lubricating oil and air. Coolant leakage can be checked by pressurizing the cylinder head water cavity to 60 psi (414 kPa) for five minutes. Make sure there are no leaking fittings by using the soap suds test. If the pressure drops in the system, this leakage is unacceptable and the compressor must be replaced.

Oil leakage can be checked visually at the compressor end caps, crankshaft seal and the base plate. If the leakage cannot be corrected by proper tightening of the end cap and base plate retainer bolts, the compressor or the gasket must be replaced.

The compressor can be checked for air leakage at the discharge and air inlet valves. With the engine stopped and air system pressure at 125 to 135 psi (862 to 931 kPa), discharge valve leakage can be detected by listening at the compressor intake for the sound of escaping air. With 120 psi (827 kPa) of air pressure applied to the unloader cavity and with the air inlet housing removed, check for leaks by squirting oil around the unloader plunger and stem. If leaks are found, replace the compressor or the unloader mechanism through the air inlet cavity.

Governor

The governor for all air compressors used on current Sterling vehicles is mounted on the compressor.

Install a test gauge in the air lines, in the supply or service reservoir. Run the engine to build up air pressure. Note the reading on the test gauge at which

the pressure stops rising. This is the point that the governor shuttles the compressor unloader piston and stops the compression cycle of the compressor. This is the compressor cutout pressure. The compressor cutout pressure must be between 135 psi (931 kPa) maximum. If the instrument panel air gauge is used, the pressure must range between 109 to 131 psi (752 to 903 kPa), allowing for gauge accuracy.

With the engine running, slowly reduce the amount of air pressure in the system by applying and releasing the brakes. Note on the gauge the level at which the pressure starts to build up again. This is the point that the governor releases the compressor unloader piston and starts the compression cycle of the compressor. This is the compressor cut-in pressure. The compressor cut-in pressure must be between 105 psi (724 kPa) minimum.

If the governor does not control the compressor to the above specifications, it must be replaced. Before replacing the governor, check the accuracy of the instrument panel air gauge with a test gauge. With the governor in its unloaded position and approximately 90 to 115 psi (621 to 793 kPa) reservoir pressure, check for leaks at the base of the governor where it mounts to the compressor and repair as required.

All current Sterling governors are nonadjustable and must be replaced if they do not operate as specified.

Air Dryer

NOTE: A small amount of oil in the system is normal and should not, in itself, be considered a reason to replace the desiccant cartridge.

The air dryer must be inspected every 900 operating hours or 25,000 miles (40,000 km), or every three months.

1. Check for moisture in the air brake system by opening reservoir drain cocks, or valves and checking for water. If moisture is found, the air dryer desiccant may need to be replaced; however, consider the following conditions before replacing the desiccant cartridge.
    - 1.1 An outside air source has been used to charge the system. This air did not pass through the air dryer.
    - 1.2 Air use is exceptionally high and not normal for a highway vehicle. This can be due to accessory air demands or some unusual air requirement that does not allow the compressor to load and unload in the usual way. Check for excessive air system leaks.
    - 1.3 The air dryer has been installed in a system that has been previously used without an air dryer. This type of system will be saturated with moisture and it can take several weeks of operation for the system to dry out.
    - 1.4 Location of the air dryer is too close to the air compressor. There must be a minimum of 6 ft (1.8 m) of metal tubing between the compressor discharge port and air dryer supply port.
    - 1.5 Vehicles operating in areas where more than a 30°F (17°C) range of temperature occurs in one day can have small amounts of water accumulating in the air brake system. Under these conditions, small amounts of water should not be considered an indication that the air dryer is not working.
2. Check the retaining bolt torque. Tighten loose bolts to specified torque.
3. Check the operation of the end cover check valve.
    - 3.1 Install an air pressure test gauge in the supply reservoir.
    - 3.2 While observing the test air gauge, start the engine and allow the system air pressure to reach governor cutout. The purge valve will be open when the governor cutout pressure is reached.
    - 3.3 Allow two minutes for completion of the purge cycle before testing the check valve.
    - 3.4 A quick loss of pressure can indicate a worn or damaged check valve. Check the purge valve exhaust to confirm a worn or damaged check valve. Use a soap solution to check air leakage. Air leakage must not exceed a 1-inch (2.5 cm) bubble in 5 seconds. Replace as necessary.

4. While the compressor is loaded, coat the exhaust with soap solution and check for air leaks at the purge valve.
5. Check the operation of the safety valve. While the compressor is loaded, pull the exposed stem. While the stem is held, there must be an exhaust of air. The valve must be re-seated when the stem is released.
6. Check the operation of the end cover heater and thermostat assembly during cold weather operation.

    6.1 With the ignition or engine control on, check for power at the dryer electrical terminal with a voltmeter or test light. On a single terminal air dryer, check between the electrical terminal in the vehicle wiring harness connector and the metal end cover. For dual terminal air dryers, check between the two electrical terminals in the vehicle wiring harness connector. If there is no voltage, look for a blown fuse, broken wires or corrosion in the vehicle wiring harness.

    6.2 Turn off the ignition switch and cool the end cover assembly to below 40°F (4°C).

    6.3 Using an ohmmeter, check resistance of the heater element between the electrical terminal and the metal end cover.

    6.4 On the dual terminal end cover, check the resistance of the heater element between the two terminals. The resistance should be 2.0 to 4.0 ohms for a 12-volt, 60-watt end cover and 4.0 to 7.0 ohms for a 24-volt, 120-watt end cover. These resistance values apply to either single or dual terminal air dryer end covers.

⚠ CAUTION

Do not remove the heater and thermostat assembly unless a replacement is available as it will be damaged during removal.

    6.5 Warm the end cover to over 90°F (32°C) and recheck the resistance of the heater element. The resistance must exceed 1,000 ohms for both single and dual terminal air dryers. If the resistance values are within the given limits, the thermostat and heater are operating properly. If the resistance values are outside the limits, replace the heater and thermostat assembly.

CUMMINS HOLSET E-TYPE COMPRESSOR

Test the Holset E-Compressor unloader system with feedback line and check the valve for proper operation. Make certain Holset ECON is not in use with the AD-IP air dryer; if so, remove and retest.

When the compressor is unloaded, use a soap solution to check for leaks from the turbo cutoff valve. Replace a leaking turbo cutoff valve.

Low Air Pressure Switch

1. Exhaust the brake system pressure and note the pressure at which the warning buzzer sounds. The contacts in the low air pressure switch should close the circuit to the buzzer as the reservoir air pressure approaches 60 psi (414 kPa).
2. If the buzzer does not sound during discharge, or if a sounding buzzer does not stop during buildup when this range is reached, the electrical connections are loose or the low air pressure switch is not operating properly. Check and tighten the electrical connections or replace the low air pressure switch. Retest the system.

Relay Valve

1. Fully charge the air brake system and adjust the brakes.
2. Make several brake applications and check for prompt application and release at all appropriate wheels. If a brake is slow to apply or release, make sure the brake camshaft is properly lubricated and any excessively worn brake parts are replaced before proceeding.
3. With the foot control valve in the released position, coat the relay valve exhaust port with soap solution and check for inlet valve and valve guide O-ring leakage. A 1-inch (25.4 mm) bubble in five seconds leakage is permitted.
4. Make and hold a foot control valve application. Coat the relay valve exhaust port with soap solution and check for leakage. A 1-inch (25.4 mm) bubble in three seconds leakage is permitted.

Troubleshooting

NOTE: If leakage is detected, replacing the inlet/exhaust valve may correct the problem. If leakage still occurs, leakage may be caused by the relay piston O-ring or exhaust valve seat.

5. Make and hold a foot control valve application. Coat the outside of the relay valve body in the area where the cover joins the body to check for cover O-ring leakage. No leakage is permitted. If the relay valve does not function as described above, or if leakage is excessive, it is recommended that the relay valve be repaired or replaced.

Safety Valve

The safety valves are located on the reservoirs and on the air dryer.

With air pressure in the system, pull the exposed end of the safety valve stem which removes the spring load from the ball check valve. Air should exhaust from the valve's exhaust port. Release the stem; the airflow should stop. Repair or replace a safety valve that does not operate as described.

Automatic Moisture Ejector Valve

With the system charged to 100 psi (689 kPa), make several brake applications and note each time an application is made whether or not an exhaust of air occurs at the manual release port of the automatic moisture ejector valve. If no air comes out, push the wire stem. If air still does not come out, the valve is plugged. Remove, disassemble and clean the valve.

The automatic moisture ejector valve functions as reservoir pressure is reduced. Excessive leakage in the air system will cause constant exhausting of the valve. Repair of the air brake system should restore the automatic moisture ejector valve to normal operation.

Foot Control Valve

Check the delivery pressure of both the primary and secondary circuits using test gauges known to be accurate in the appropriate delivery ports of the foot control valve. Depress the treadle to several positions between the fully released and fully applied positions. Then, check the delivered pressure on the test gauges to see that it varies proportionately with the movement of the treadle.

When the treadle is fully depressed, the reading on the test gauge should fall off to zero promptly when the treadle is released. Note that the primary (green) circuit delivery pressure will be about 2 psi (13.7 kPa) greater than the secondary circuit (red) delivery pressure with primary and secondary circuit supply reservoirs at the same pressure. This is normal for the foot control valve.

Any increase in normal stopping distance is a cause for concern and should be investigated. Although the vehicle air brake system may continue to function, the vehicle should not be operated until the necessary repair has been completed and both braking circuits are operating normally.

LEAKAGE TEST

Check leakage as follows:

- Make and hold full brake application.
- Coat the exhaust port and body of the foot control valve with soap solution.
- Leakage must not exceed a 1-inch (25.4 mm) bubble in three seconds in both the applied and released positions.

Trailer Air Supply Control Valve

To perform the following test, an accurate air test gauge is required. The vehicle dash air gauge(s), if used, must be checked for accuracy against the test gauge prior to making these tests.

1. Chock the wheels.
2. Charge the air brake system to 120 psi (827 kPa).
3. Check for leakage between the body of the trailer air supply control valve and the cover plate. Leakage at the exhaust port must not exceed a 1-inch (25.4 mm) bubble in five seconds.
4. With supply pressure still at 120 psi (827 kPa), push the red button in. The button must remain in. Leakage at the exhaust port must not exceed a 1-inch (25.4-mm) bubble in five seconds.

NOTE: The yellow button must not pop out before the red button.

5. Slowly reduce pressure in both service reservoirs. The red button must pop when supply pressure drops to 35 to 45 psi (241 to 310 kPa).

6. Hold the red button in and continue to reduce pressure in all service reservoirs. Air must start to escape from the exhaust port when the trailer supply line pressure reaches 20 to 35 psi (138 to 241 kPa).
7. Release the red button and rebuild the supply pressure to at least 120 psi (827 kPa). Push in the yellow button. The yellow button must remain in. Leakage at the exhaust port must not exceed a 1-inch (25.4 mm) bubble in five seconds.
8. With the red button out, slowly reduce pressure in all service reservoirs. The yellow button must pop at 20 to 30 psi (138 to 207 kPa).
9. Charge the system to 120 psi (827 kPa) and push both buttons in. Pull the red button out. The yellow button must remain in.
10. Push the red button in and pull the yellow button out. The red button must pop out almost instantaneously.
11. Install a gauge to monitor the tractor spring brake delivery pressure. Apply 120 psi (827 kPa) to all service reservoirs (No. 1 and No. 2). Push in the yellow button. Delivery pressure should equal the pressure in the reservoir No. 1. Reduce the pressure in the No. 1 reservoir. Delivery pressure and No. 1 reservoir pressure should descend together to 105 to 90 psi (724 to 620 kPa), at which point the dual circuit supply valve shuttle should switch to the No. 2 reservoir and delivery pressure should increase to No. 2 reservoir pressure. After the No. 1 reservoir pressure is reduced to zero, there should not be audible leakage at the No. 1 reservoir opening. Close the leak created in the No. 1 reservoir.
12. Leaving the yellow button in, recharge the No. 2 reservoir to 120 psi (827 kPa). The delivery pressure should also read 120 psi (827 kPa). Recharge the No. 1 reservoir to 100 psi (689 kPa). Slowly vent the No. 2 reservoir. As the No. 2 reservoir pressure and the delivery line pressure descend, pressure should stabilize at approximately 100 psi (689 kPa).
13. Close all reservoir drain cocks and charge both reservoirs to 120 psi (827 kPa). Position the red button out and the yellow button in. Cause a leak in the spring brake delivery line and hold the yellow button in. The No. 1 reservoir pressure must reduce to zero and No. 2 reservoir pressure to 20 to 30 psi (138 to 207 kPa). The dual circuit supply valve shuttle should cycle several times during this leak-down period.
14. If the trailer air supply control valve fails to operate as described or leakage exceeds the limits stated, repair or replace as required.
15. Close all reservoir drain cocks and deliberately caused leakage points before placing the vehicle in service.

Tractor Protection Valve

1. Charge air brake system to governor cut-out, chock the wheels and place the trailer air supply control valve in the emergency position.
2. Disconnect the trailer service line hose coupling. Make a trailer brake hand control valve application. Hold a finger over the 1/16-inch (1.6 mm) vent hole in the service line shut-off valve area of the tractor protection valve casting. Check for leakage at the hose coupling and at the exhaust port at the tractor protection valve. Excessive leakage at either port indicates a faulty inlet valve.
3. With the trailer brake hand control valve still applied and the key to run, check for stoplight function.
4. Release the trailer brake hand control valve application and place the trailer air supply control valve in normal position.
5. Connect the tractor service hose coupling to a test gauge, reapply the trailer brake hand control valve and note that there is pressure at the service hose coupling.
6. Check for leakage at the service line quick release valve. Excessive leakage indicates a worn or damaged diaphragm.
7. With service line pressure still applied through the trailer brake hand control valve, check for leakage at the foot control valve exhaust. Excessive leakage indicates a worn or damaged double check valve shuttle.
8. Check for leakage at the 1/16-inch (1.60 mm) vent hole. Leakage indicates that one of the two O-rings is worn or damaged.
9. Release the trailer brake hand control valve application and recheck for leakage at the vent

hole. If the leakage continues, it is the large O-ring which is leaking. If the leakage stops, it was the smaller O-ring that was leaking.

10. Make and hold a foot control valve application. Check for leakage at the exhaust of the trailer brake hand control valve. Excessive leakage indicates a worn or damaged double check valve shuttle.
11. Release the foot control valve application, disconnect the line from the primary (green) service brake circuit at the tractor protection valve delivery port and block off the end of the line from the foot control valve. Make a foot control valve application and check for leakage at the protection valve delivery port.
12. Reconnect the primary (green) circuit line and repeat the procedure with the secondary circuit line. Excessive leakage indicates a worn or damaged double check valve shuttle. Restore the secondary (orange) circuit connection to the tractor protection valve.
13. If the tractor protection valve does not function as described above or if leakage is excessive, the tractor protection valve must be replaced.

Trailer Brake Hand Control Valve

Connect an accurate test gauge to the trailer service line hose and leave the trailer emergency or supply hose connected to the trailer. If a trailer is not available, connect the trailer supply hose to an unvented dummy coupling or to a plugged hose fitting. The trailer air supply control valve must be in the normal position.

When the operating lever is moved to the fully applied position, the gauge should register full reservoir pressure. Intermediate positions should deliver proportional intermediate pressures. Upon release, the gauge should immediately register zero.

Locate the open end of the exhaust line from the trailer brake hand control valve in the engine compartment.

With the trailer brake hand control valve in the release position, no pressure should register on the test gauge. Leakage at the end of the exhaust line should not be greater than a 1-inch (25.4 mm) bubble in five seconds. With the trailer brake hand control valve fully applied, leakage at the exhaust line should not be greater than a 1-inch (25.4 mm) bubble in three seconds.

Repair or replace a trailer brake hand control valve that does not function as described.

Bobtail Proportioning Relay Valve

To properly test the function of the bobtail proportioning relay valve, a pair of test gauges or gauges of known accuracy must be used.

1. Park the vehicle on a level surface and chock the wheels.
2. Exhaust the system air pressure.
3. Install a tee at the proportioning valve service port and at one of the delivery ports, then install a gauge in each leg of the tee.
4. Connect the tractor service and emergency "glad hands" (hose couplings) to hose couplings that have been plugged, or alternatively, to a trailer. Build the system air pressure to governor cutout and make four to five full brake applications. Check the air fittings at the bobtail proportioning relay valve for leakage. Tighten as needed.
5. With the trailer air supply control valve (dash control with red octagonal button) and parking brake control valve (dash control with yellow diamond button) activated for tractor trailer operation, apply, hold, then release the brakes several times varying the application pressures while watching the reaction of the gauges installed on the bobtail proportioning relay valve. Note that a prompt application occurs and that it can be held and then promptly released.

NOTE: When performing the following procedure, the measured differential should be approximately 4 psi (28 kPa).

6. Check the proportioning valve differential pressure by applying 10 psi (69 kPa) to the service port and noting the pressure registered at the delivery port. Subtract delivery port pressure from the 10 psi (69 kPa) service pressure to obtain the differential. Compare the measured differential with the pressure specified for the proportioning valve part number.
7. Make and hold a full 100 psi (689 kPa or greater) brake application and note that full pressure is delivered to the brake air chambers.

8. Activate the dash-mounted trailer air supply control valve for bobtail tractor operation. Then make a slow brake application, increasing the pressure at the proportioning valve service port to 20 psi (138 kPa) while watching the reaction at the delivery port gauge. Note that delivery pressure rises to approximately 5 to 10 psi (34 to 69 kPa) and remains constant while service pressure continues to rise to 20 psi (138 kPa). Release the application.
9. Make another brake application and slowly increase the pressure at the proportioning valve service port to between 60 to 70 psi (413 to 482 kPa) while observing the gauge installed at the delivery port. Note that when service port pressure rises to between 20 to 30 psi (138 to 207 kPa), delivery pressure begins to rise above the initial pressure noted previously. The rise of delivery pressure should be at a proportioned rate of approximately 3:1 @70 psi (482 kPa) service pressure, delivered pressure should be 15 to 25 psi (103 to 172 kPa).
10. Make a full brake application and note that both test gauges register the same pressure.
11. Remove the test gauges from the bobtail proportioning relay valve.
12. Build the air system pressure to governor cutout. With the dash-mounted trailer air supply control valve activated for tractor trailer operation, apply a soap solution to all three exhaust ports (two in the cover and one in the body). The leakage noted should not exceed a 1-inch (25.4 mm) bubble in three seconds at any exhaust port.
13. Make and hold a full brake application and apply a soap solution to all three exhaust ports and around the cover where it joins the body. The leakage noted should not exceed a 1-inch (25.4 mm) bubble in three seconds at any exhaust port.

Slack Adjuster

NOTE: A loud clicking sound will be heard when turning the hex extension counterclockwise.

1. Turn the hex extension one-half turn counterclockwise. See **Fig. 1**.

NOTE: Place a box wrench on the hex extension to make rotation easier to verify.

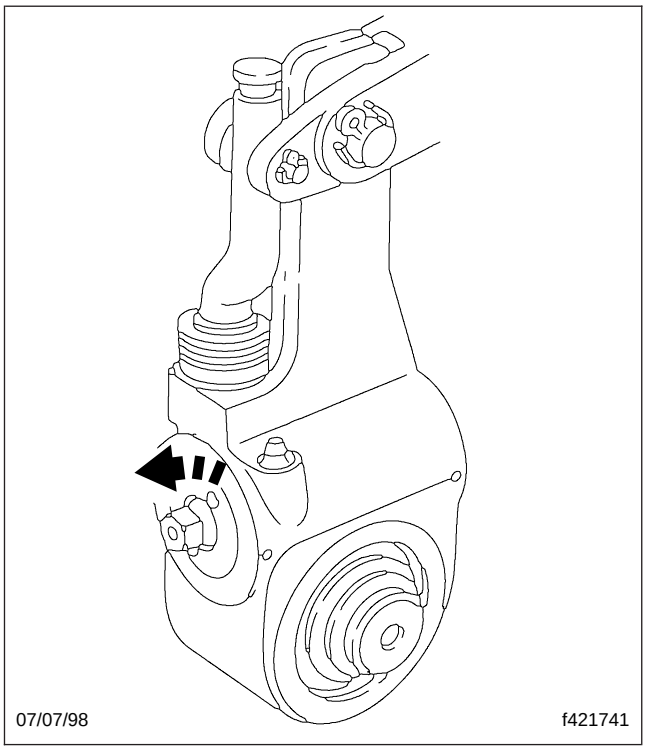

Fig. 1, Turn the Hex Extension Counterclockwise

2. While an assistant makes several service brake applications, check that the hex extension rotates clockwise. See **Fig. 2**. If the slack adjuster arm is rotated by the brake air chamber and there is no hex extension rotation, replace the slack adjuster.

NOTE: To obtain the adjusted air chamber stroke, measure the distance the clevis pin moves from the at-rest position to the brakes-applied position. See **Fig. 3**.

3. Continue to apply the brakes until the brake air chamber is brought within the "DOT Adjusted Air Chamber Stroke Limits". See **Table 1**.

Troubleshooting

DOT Adjusted Air Chamber Stroke Limits	
80 to 90 psi (550 to 620 kPa) Pressure in Air Chamber Clamp-Type Air Chamber	
Chamber Type (Size)	**Adjust the stroke as short as possible without the brakes dragging. The vehicle may be put out of service if the stroke is not:**
9	less than 1.5 ± 0.125 inches (38.1 ± 3.2 mm)
12	less than 1.5 ± 0.125 inches (38.1 ± 3.2 mm)
16	less than 1.5 ± 0.125 inches (38.1 ± 3.2 mm)
20	less than 1.5 ± 0.125 inches (38.1 ± 3.2 mm)
24	less than 1.625 ± 0.125 inches (41.3 ± 3.2 mm)
24 long stroke	less than 1.625 ± 0.125 inches (41.3 ± 3.2 mm)
30	less than 1.625 ± 0.125 inches (41.3 ± 3.2 mm)
36	less than 1.625 ± 0.125 inches (41.3 ± 3.2 mm)

Table 1, DOT Adjusted Air Chamber Stroke Limits

4. Measure the counterclockwise torque of the hex extension. If the counterclockwise torque is less than 15 lbf·ft (20 N·m), the slack adjuster must be replaced. If the slack adjuster cannot be replaced immediately, the brakes must be manually adjusted. See **Fig. 3**.

General Information (See Fig. 1)

The trailer brake hand control valve is a hand-operated, lever-type graduating control valve. The most common use of the trailer control valve is for independent control of trailer service brakes, however, the valve can be used for any application where graduated application pressure is required.

The trailer brake hand control valve is standard with all tractor packages. It can employ a cam, a cam follower, and a graduation spring to control air delivery pressure. Trailer control valves are most often used to snub the trailer brakes when descending grades or on slippery road conditions. They are also often used to hold the vehicle while the vehicle's clutch and accelerator are coordinated. The trailer brake hand control valve should never be used for parking.

Safety Precautions

Air Brake System Warnings

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

Trailer Brake Hand Control Valve Removal and Installation

⚠ CAUTION

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100.

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.

NOTE: Mark the knobs to aid installation.

2. Remove the knobs. See **Fig. 1**.

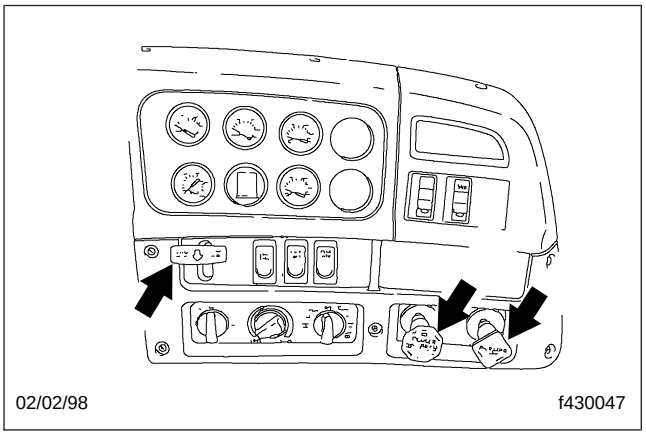

Fig. 1, Brake Control Knobs

3. Remove the eight screws. See **Fig. 2**.

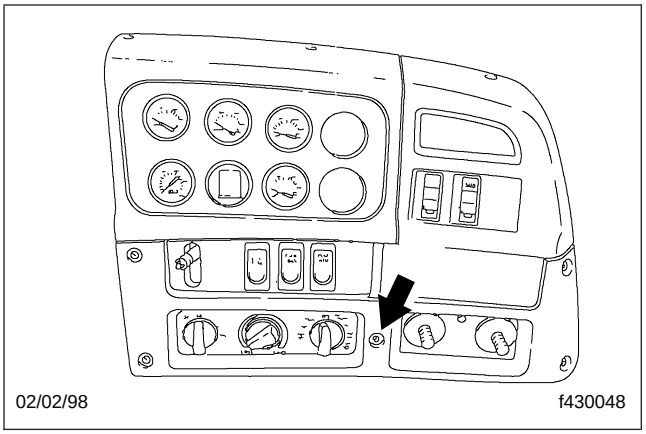

Fig. 2, Instrument Panel Finish Panel Screws

4. Position the instrument panel finish panel out of the way. See **Fig. 3**.

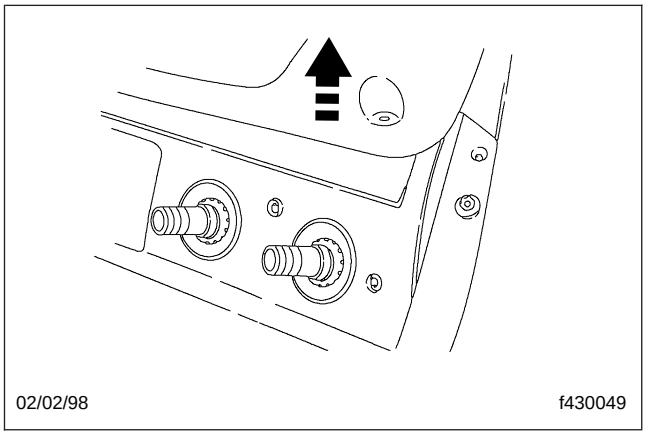

Fig. 3, Positioning the Instrument Panel for Access

5. Remove the three screws. See **Fig. 4**.

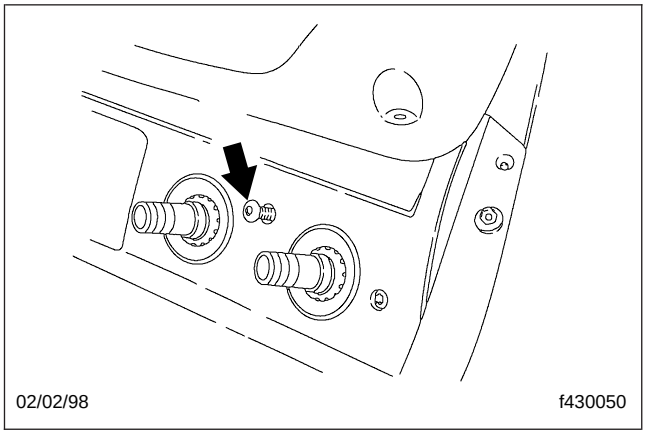

Fig. 4, Three Panel Screws

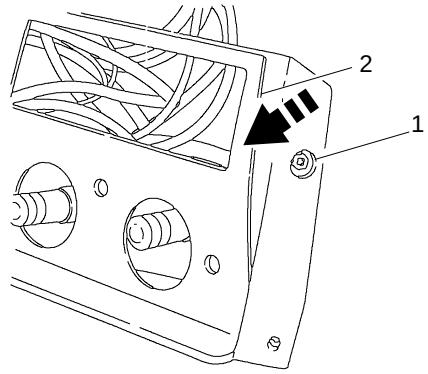
6. Make room for valve access. See **Fig. 5**.
   - 6.1 Remove the two screws.
   - 6.2 Tilt the finish panel center bracket outward.
7. Tag and disconnect the air lines. See **Fig. 6**.
8. Remove the trailer brake hand control valve retaining screws. See **Fig. 7**.
9. Remove the trailer brake hand control valve. See **Fig. 8**.

Trailer Brake Hand Control Valve Removal and Installation



1. Screw
2. Finish Panel

Fig. 5, Control Valve Access

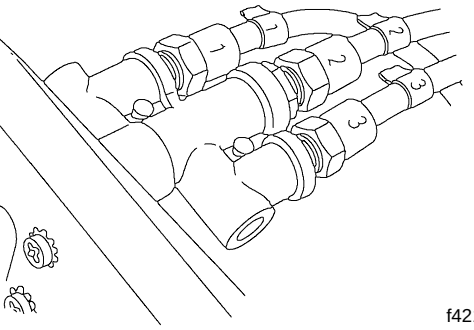


Fig. 6, Tagged Air Lines

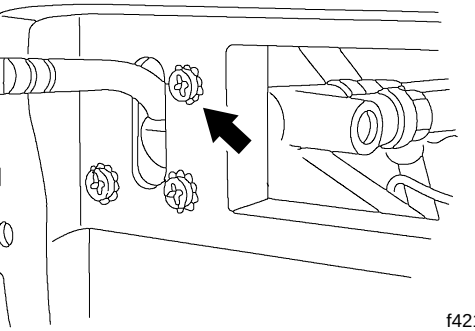

Fig. 7, Trailer Brake Hand Control Valve Retaining Screws

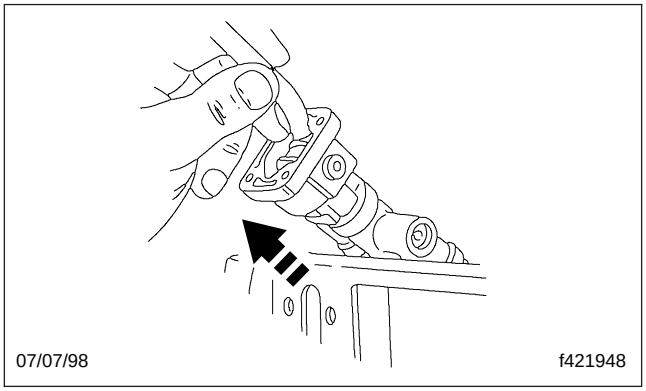

Fig. 8, Trailer Brake Hand Control Valve

Installation

1. Make room for valve access. See **Fig. 5**.
   - 1.1 Install the two screws.
   - 1.2 Tilt the finish panel center bracket outward.
2. Connect the air lines.
3. Install the four screws.
4. Install the trailer brake hand control valve.
5. Install the three screws. See **Fig. 4**.
6. Position the instrument panel finish panel into position. See **Fig. 3**.
7. Install the eight screws. See **Fig. 2**.
8. Install the knobs. See **Fig. 1**.
9. Remove the chocks from the tires.

General Information

The EC–16 is an electronic antilock controller. It is the base component in a family of full-vehicle wheel control antilock systems. See **Fig. 1**. In addition to the antilock function, the control module can be assembled and programmed to provide an optional traction control feature. Refer to **Table 1** for EC–16 mounting configurations.

Mounting Configuration			
Antilock Valve	**Added Function Provided**	**Vehicle Application**	**Designation (Valve+ EC–16)**
AR–1	None	All	CR–17 Controller Relay
AR–2	Bobtail Brake Proportioning	Tractors Only	CR–18 Controller Relay
ATR–1	Traction	All	AT–1 Antilock Traction
ATR–2	Traction and Bobtail Brake Proportioning	Tractors Only	AT–2 Antilock Traction

Table 1, Mounting Configuration

Designed to minimize the potential of brake lock-up on all wheels during aggressive braking, the four channel antilock system provides the vehicle with a high degree of stability and steerability during braking. In most cases, vehicle stopping distance is also reduced. The antilock portion of the four channel system minimizes wheel skid during hard or aggressive braking. By controlling wheel skid at all wheels on the vehicle, optimum steering control and stopping distance is obtained.

Traction control, an optional feature in the full-vehicle wheel control antilock systems, helps improve vehicle traction during acceleration in adverse road conditions. Integrated with antilock logic, the traction control monitors wheel speed information from the sensors during acceleration, as well as braking. The system helps maintain vehicle stability on slippery road surfaces and improves driveability and safety.

In order to provide full-vehicle wheel control antilock, the control module is used in combination with the following components:

- four wheel speed sensors
- two air pressure modulator valves
- one dash-mounted antilock warning lamp
- one service brake modulator relay valve
- two quick release valves (tandem axle only)
- one front modulator assembly (consists of two modulators and one quick release valve)

When programmed to provide traction control in addition to antilock, the following components are added:

- one traction solenoid (incorporated into the relay valve)
- two additional wheel speed sensors (on tandem drive vehicles only)
- one dash-mounted traction condition lamp
- serial connection to engine control module
- traction disable wiring and switch

INPUTS/OUTPUTS

All components in the ABS system either send a signal to or receive a signal from the control module. Components that send signals to the control module are module inputs and components that receive signals are module outputs.

Inputs

Wheel speed sensor information is provided to the control module by a wiring harness from individual wheel speed sensors at or in the vehicle wheels. Working with an indicator ring or wheel speed sensor ring, wheel speed sensors provide information to the control module in the form of an AC signal which varies in voltage and frequency as the speed of the wheel increases or decreases.

The control module is designed to receive wheel speed information, from various wheel speed sensor models. The control module is able to simultaneously receive, and individually interpret, speed signals from six wheel speed sensors. Vehicle drive configuration and whether the traction control feature is in use determines the number of speed sensors that must be used. A vehicle with a single rear axle drive requires four speed sensors for both antilock and traction operation. A vehicle with two rear drive axles (6 x 4) requires four speed sensors for antilock only opera-

Fig. 1, Component Location

tion, but have the option to use six speed sensors for enhanced performance of both antilock and traction operation.

Electrical power is supplied to the control module from the ignition switch through a fuse or a circuit breaker. The electrical ground for the control module is the vehicle chassis.

Outputs

Modulators like the M–22 are the means by which the control module modifies the driver applied air pressure to the service brakes. The modulator is an electrically controlled air valve located near the service actuator(s) it controls. A wiring harness connects the modulator to the control module. Solenoid valves contained in the modulator provide the electrical interface between the control module electronics and the air brake system. The control module is able to simultaneously and independently control four individual modulator assemblies.

An antilock dash lamp and its electrical relay or circuit are connected to, and controlled by, the control module and serve as a means of advising the driver of the condition of the antilock system.

A connection to the engine or transmission retarder and its relay is provided on the control module, which allows the control module to temporarily disable the retarder during certain modes of operation. While the control module is capable of this function, and connections are provided, it is not always used. The use of the retarder disable function is not essential but highly recommended for vehicles equipped with a retarder.

NOTE: The control module can also disable the retarder using the same protocol it uses to control the traction control, engine torque limiting feature. For this redundant retarder disable to function, the control module must be connected to the engine control module (as would be the case if the control module is programmed for the traction control, torque limiting feature).

The data link enables the control module to report its operating condition to a specialized, external computer in response to certain commands it receives. There are two connections to the control module devoted to the data link. While connections are provided for this function, it is not always used. The data link is not essential for the control module to be functional.

If the control module is programmed for traction control, it contains the following outputs:

- a connection to the engine control module allows the control module to reduce engine torque under certain circumstances
- a traction control dash lamp is connected to and controlled by the control module and serves as a means of advising the driver of the condition of the traction control system
- a connection to the traction solenoid (located in the upper portion of the antilock traction relay valve)
- a traction enable switch is provided, but not always used. The switch allows the traction control to be turned on or off manually

ANTILOCK OPERATION

The four-channel antilock system uses individual sensors, modulators and an electronic controller to control the four vehicle wheel ends. By monitoring the deceleration rate during braking, and subsequently adjusting the brake application pressure at each wheel, the control module is able to improve braking between the vehicle tire and the road surface it is on, while maintaining stability.

The rear axle brakes are controlled independently; therefore brake application pressure at an individual wheel is adjusted solely on the basis of its behavior on the road surface on which it is traveling.

While each steering axle brake is under the control of an individual modulator, the control module does not treat these brakes totally independently. The control module uses a modified individual control philosophy for the steering axle brakes. This is done in order to minimize steering wheel pull in the event each wheel is traveling on a different road surface (for example, ice close to the curb and a dry crown). Essentially the control module controls the braking force differences between the two brakes. The wheel on the dry pavement is initially given less braking force and is brought up to optimum during the stop, while the wheel on the ice attempts to maintain optimum braking during the entire stop.

In cases of vehicles equipped with tandem rear axles (6 x 2, 6 x 4), the wheel speed sensors are installed at the wheels on the axle that is most likely to lock first. A single modulator controls both curb side brakes on the tandem, and another modulator con-

trols both brakes on the driver's side of the tandem. With this arrangement of speed sensors and modulators, both brakes on one side of the tandem are treated as one since they will most likely be on the same type of road surface.

Non-Antilock Brake Application

During normal braking, air pressure from the brake valve enters the control port of the service relay valve. The service relay delivers air to, and through, the antilock modulator located near the braked wheel, and into the brake actuator. The service brakes are thus applied. If the wheel speed sensors do not detect an impending wheel lockup, the control module does not initiate any corrective action and the vehicle comes to a stop in a normal fashion.

Antilock Brake Application

If a service brake application is made and the wheel speed sensors detect an impending wheel lockup, the control module will immediately begin modification of the brake application using the antilock modulator(s) at the affected wheel(s). Solenoid valves contained in the modulator are energized and de-energized by the control module in order to modify the brake application.

When a solenoid coil is energized, its shuttle moves. Depending upon the function of the specific solenoid, it either opens or closes, thereby causing the exhaust or re-application of air pressure to the brake actuator. The solenoids in each modulator are controlled independently by the control module. By opening and closing the solenoid valves in the appropriate modulator, the control module is actually simulating what drivers do when they pump the brakes. It must be remembered, however, that unlike the driver, the control module is able to pump each brake on the vehicle independently and with far greater speed and accuracy.

TRACTION CONTROL OPERATION

Traction control is a natural extension of antilock. Just as antilock helps vehicle control and stability during braking, traction control helps during vehicle acceleration. The wheel speed sensors not only detect rapid decreases in wheel speed for antilock but also detect unreasonably high increases for traction control. With traction control, a spinning wheel is instantly detected and compared with the other wheels on the vehicle, both front and rear. Two different methods are used to control wheel spin: "Torque Limiting" and "Differential Braking". Depending upon the vehicle type, speed and road (surface) condition, each method provides a unique and desirable type of wheel spin control. Ideally both methods are used to control vehicle traction. While all new version control modules are capable of providing wheel control antilock and traction control (utilizing both methods of control), not all systems will be configured for both methods. Depending upon the vehicle, either or both traction control methods will be activated during the "Self Configuration Procedure" in this subject.

Torque Limiting

In order for the torque limiting control feature to be used, the vehicle must be equipped with an electronically controlled engine throttle. The torque limiting feature allows the control module to reduce engine torque to a suitable level for the available traction. Torque limiting helps to minimize the amount (or speed) of wheel spin. It is especially useful in helping to minimize a power jackknife when all drive wheels are on an equally slippery surface.

Differential Braking

In order for the differential braking control feature to be used, the vehicle must be equipped with an antilock traction relay valve such as the ATR–1 or 2. The ATR–1 and 2 contain a solenoid assembly which provides this feature. The differential braking feature allows the control module to gently pump the brake on the spinning wheel. Since the vehicle's differential tends to drive the wheel that presents the least resistance (the wheel on the most slippery surface), a slight brake application to this wheel only, forces the differential to drive the stationary or slowly spinning wheel. While a vehicle must be equipped with an electronic throttle to utilize the torque limiting feature of traction control, differential braking can be used on all vehicles. Differential braking can be activated only when the vehicle speed is under 25 mph and one drive wheel is spinning faster than the other(s).

Traction Control at Vehicle Speeds of 0 to 25 Mph (0 to 40 Km/h)

When wheel spin is detected and the vehicle is stopped, or moving at any speed up to 25 mph (40 km/h), the control module simultaneously executes the following operations:

- it instantly blinks the traction dash lamp to advise the driver that a wheel spin is occurring
- if the torque limiting feature is active, the control module uses its link to the engine control module and sends a signal to reduce engine torque to a level suitable for the available traction

If the differential braking feature is configured into the system, the control module energizes the solenoid in the ATR valve which then applies air to each of the rear axle modulators. Because the modulators are controlled by the control module, the solenoid valves in the appropriate modulator are opened and closed to gently pump the brake on the spinning wheel only. This gentle brake application forces the differential to drive the stationary or slowly spinning wheel

Once wheel spin is eliminated, the dash lamp goes out and the traction system disengages control.

Traction Control at Vehicle Speeds Above 25 Mph (40 Km/h)

If wheel spin occurs at any speed above 25 mph (40 km/h), the control module will instantly blink the traction dash lamp to advise the driver that a wheel spin is occurring.

NOTE: The control module will not signal the ATR valve to apply the brakes, even slightly, at any speed above 25 mph (40 km/h).

If the torque limiting feature is programmed in, the control module uses its link to the engine control module and sends a signal to reduce engine torque to a level suitable for the available traction.

COMPONENT FAILURE

Depending upon the type of failure and its position of occurrence, the control module disables all or only a portion of the antilock and traction system. A power or controller failure, however, will result in complete disabling of both systems and reversion to standard braking on all wheels.

Single Failure

The following descriptions and **Table 2** describe how the antilock and traction systems respond to a specific component failure.

NOTE: The right and left, front, mid and rear are determined from the driver seat. Left front is therefore the corner closest to the driver.

For example, if the right mid sensor (RM Sensor on the chart) fails, front and rear antilock will still be operative. Traction will be disabled, and, as always, the system has standard air braking.

Front Modulator

If a front modulator fails, antilock on that wheel is disabled. Antilock and traction on all other wheels remains active.

Rear Modulator

A rear modulator failure disables the traction system. Antilock on that wheel will also be disabled, but antilock on all other wheels remains active.

Front Sensor

The wheel is still modulated using input from the opposite sensor. The traction system is disabled.

Mid or Rear Sensor

Antilock on that wheel is disabled, but antilock on all other wheels remains active. Traction control is disabled.

Control Module

Antilock and traction are disabled. The system reverts to standard air braking.

Traction Solenoid

Traction control is disabled. Antilock remains active.

Engine Control Module

If the engine control module (ECM) or the wiring from the control module to the ECM fails, traction control is disabled. Antilock remains active.

Voltage

If system voltage is out of range, antilock and traction are disabled, and the system reverts to standard air braking.

General Information

Failure Location	System Still Operating (Yes/No)					
	ABS Front		ABS Rear		Traction	Standard Braking
	Left	Right	Left	Right		
RF Sensor	Yes	Yes	Yes	Yes	No	Yes
LF Sensor	Yes	Yes	Yes	Yes	No	Yes
RM Sensor	Yes	Yes	Yes	Yes	No	Yes
LM Sensor	Yes	Yes	Yes	Yes	No	Yes

LR Sensor	Yes	Yes	No	Yes	No	Yes
RF Modulator	Yes	No	Yes	Yes	Yes	Yes
LF Modulator	No	Yes	Yes	Yes	Yes	Yes
RR Modulator	Yes	Yes	Yes	No	No	Yes
LR Modulator	Yes	Yes	No	Yes	No	Yes
Controller	No	No	No	No	No	Yes
Traction Solenoid	Yes	Yes	Yes	Yes	No	Yes
Engine Control Module NOTE: When ECM wiring or voltage corrects itself, the system is restored.	Yes	Yes	Yes	Yes	No	Yes
Voltage	No	No	No	No	No	Yes

Table 2, Failure Location

Multiple Failures

In the event that multiple failures occur, the dash lamp will react as it normally would during a single failure, and the LEDs will show one failure at a time, see **Table 3**. When the first problem is fixed and the system is reset, the next problem area will appear at the LEDs. This way, the driver or mechanic does not lose track of problem areas, and the system is not restored until each and every error is corrected and the control module is reset.

Dash Lamp Conditions					
Antilock Lamp	Lamp On 1st Time	Lamp Off 1st Time	Lamp On 2nd Time	Lamp Off 2nd Time	Lamp On Stays On
Traction Lamp (control module with torque limiting & differential braking)	On	Off	On	Off	Stays Off
Traction Lamp (control module with torque limiting only)	Off	Off	On	Off	Stays Off
Traction Lamp (control module with differential braking only)	On	Off	Off	Off	Stays Off

Table 3, Dash Lamp Conditions

CONTROL MODULE CONFIGURATION

General

All control modules manufactured on or after August 1, 1995 incorporate the self configuring feature. New, replacement control modules will be provided factory preprogrammed for 6 speed sensor inputs and both the differential braking and torque limiting features for traction control.

Identifying the Self Configuring Control Module

The self configuring control module can most easily be identified while installed on the vehicle. Identification can be made by observing the reaction of the diagnostic display when the ignition is switched ON and power is applied to the control module. The current configuration of the control module is displayed via the troubleshooting LEDs and occurs during the normal self test sequence. This configuration review is repeated each time the ignition is turned on. The sequence and manner of LED illumination is described in "Control Module Configuration Display". That section should also be used to confirm that the system is configured as desired.

The diagnostic LEDs on older versions of the control module will only react as described in items 2 and 6 under "Control Module Configuration Display".

Control Module Configuration Display

1. Turn the ignition on.
2. All LEDs will illuminate then go out.
3. The number of active sensors will be displayed by the momentary illumination of the red SEN (sensor) LED and two or more of the red locating LEDs. No other LEDs will be on.
   - 3.1 SEN + FRT (front) + RER (rear) = A four sensor configuration (all systems must have at least a 4 sensor configuration).
   - 3.2 SEN + FRT + MID (middle) + RER = A six sensor configuration.
4. The red TRC LED will momentarily illuminate by itself if traction control torque limiting is active. If not, then the display will go to the condition described previously.
5. The red TRC and MOD LEDs will momentarily illuminate if traction control differential braking is active. If not, then the display will go to the condition described previously. No other LEDs will be on.
6. The diagnostic display will return to its normal operational status. Assuming no problems exist in the antilock or traction system, all red LEDs will be off and the single, green, VLT LED is illuminated.

Control Module Self Configuring Process

1. Three aspects of the antilock and traction system are influenced by the self configuring feature of the control module.
   - 1.1 Speed Sensors—The number of speed sensors connected to the control module will be detected during the self configuration process. The control module will check the MID SEN (mid axle speed sensor) locations on its connector to determine if a sensor is connected to it and will default to a six sensor configuration if it detects even one sensor connected. If no mid axle speed sensor is detected, the control module will default to a four sensor configuration.
   - 1.2 Electronic Engine Control—If the control module is connected to the control module of an electronic engine, the torque limiting feature of traction control will be activated during the self configuring process.
   - 1.3 Antilock Traction Relay Valve—If the solenoid assembly in the ATR valve is connected to the control module, the differential braking feature of traction control will be activated during the self configuring process.
2. No method is available to disable the self-configuration feature.
3. Due to the extended period of time the magnet must be held on "Reset" to initiate the self configuration process (between 10 and 20 seconds),

it is unlikely that a self-configuration would occur accidentally.

4. Basic, four speed sensor, antilock operation can not be removed during the self configuration process. This is a minimum configuration for all control modules.
5. If a speed sensor is connected to either wheel on the mid axle, the control module will configure for six sensors. If no mid axle speed sensor is detected, the control module will configure for four sensors. Any disconnected speed sensor(s) will register as a failure on the diagnostic display at the end of the control module self test.
6. All or part of traction control can be lost during self configuration by:
   - 6.1 Not connecting one of the wire harnesses (engine control module for torque limiting and ATR valve solenoid for differential braking).
   - 6.2 A missing or inoperative traction dash lamp (bulb missing or burned out).
   - 6.3 A missing or inoperative traction control enable/disable switch.
   - 6.4 Not placing the traction control enable/disable switch in the disabled position. The operator can tell that the traction features are lost by noting the absence of the traction lamp flash upon power-up. The operator should note the flashing of the antilock condition lamp, and the traction lamp if traction equipped, upon every power-up. Observing the dash lamps is the only method the operator has to verify the system operation.
7. The control module can be reprogrammed up to 10,000 times.
8. When a replacement control module is installed on a vehicle that does not have one or more of the preprogrammed features, a failure will be registered on the dash lamp(s) and on the control module diagnostic display. For this reason it is necessary to perform the self configuring procedure.
9. Some configuration information is available by observing the reaction of the dash condition lamps on vehicles configured with traction control and equipped with the self configuring control module. When the ignition is switched on, the control module self test is begun. During the self test the dash lamps will flash on and off together as indicated in the chart, depending upon the type and amount of traction control configured into the control module.

Self Configuration Process

In order to successfully complete the self-configuring process follow the steps below.

1. Connect all antilock and traction control wire harnesses. Make certain that all the speed sensors present on the vehicle are connected (H2, H3, J1, J2 on the 30 pin connector and E2, E3, F2, F3, B2, B3, C2, C3 on the 18 pin connector). If the vehicle has an electronic engine and traction control torque limiting is desired the engine control module must be connected (B2 and B3 on the 30 pin connector). If the vehicle is equipped with either an ATR–1 or ATR–2 valve, the solenoid connection must be made to the control module (D2 and D3 on the 18 pin connector) in order to obtain traction control differential braking.
2. If the vehicle is to be configured with traction control, it must have a traction control dash lamp and a traction control enable/disable switch. Both the lamp and switch must be functional. Place the traction control enable/disable switch in the traction control disabled position (traction control inoperative).

NOTE: If the control module is being configured with traction control (either torque limiting, differential braking or both), the traction control condition dash lamp will be illuminated as well as the appropriate LEDs on the control module diagnostic display.

3. Turn the ignition on and hold a magnet on the "Reset" position of the control module diagnostic display until the LEDs begin to randomly flash then remove the magnet. If the magnet is not removed during the random LED flashing, a second self configuration may be initiated. The magnet may have to be held on "Reset" for as long as 20 seconds. When the self-configuration process is complete, the control module will automatically go through a self test. During the self test, the diagnostic display will indicate the new configuration as described under "Control Module

Configuration Display". The traction control dash lamp will be illuminated until the traction control enable/disable switch is placed in the traction control enabled position (traction control operative).

4. Place the traction control enable/disable switch in the traction control enabled position (traction control operative), the traction control dash lamp should be off.
5. Before placing the vehicle in service, verify the configuration and the system condition by turning the ignition off then on while observing the control module diagnostic display. The diagnostic display should indicate the desired configuration as described under "Control Module Configuration Display" in this section and no red LEDs should be illuminated at the end of the self test.
6. If the configuration appears correct but the diagnostic LEDs indicate a failure somewhere in the system, refer to "Inspection and Verification" in **Troubleshooting, 300** to locate and repair the problem.

NOTE: The traction switch must be in the disable position to configure traction, but must be placed in the enable position to allow the traction lamp to flash.

7. If the configuration is incorrect, the process can be repeated as required. One common error is performing the self-configuration with the traction enable/disable switch in the wrong position. This will prevent any traction features from being activated.

Safety Precautions

⚠ WARNING

Where circumstances require that the engine be in operation, extreme caution must be used to prevent personal injury resulting from contact with moving, rotating, leaking, heated, or electrically charged components.

⚠ WARNING

If the vehicle is equipped with traction control, disable the traction system before performing any dynamic driveline maintenance.

1. Park the vehicle on a level surface, apply the parking brakes, and always block the wheels. Stop the engine when working around the vehicle.
2. Exhaust the air pressure from all reservoirs before beginning any work on the vehicle.
3. Shut the engine off when working in the engine compartment.
4. Never connect or disconnect a hose or line containing pressure; it may whip. Never remove a component or plug unless you are certain all system pressure has been exhausted.
5. Never exceed recommended pressures and always wear safety glasses.
6. Do not attempt to install, remove, disassemble or assemble a component without reading and thoroughly understanding the recommended procedures. Use only the proper tools and observe all precautions.
7. Replacement hardware, tubing, hose fittings, etc. must be of equivalent size, type and strength as original equipment, and be designed specifically for such applications and systems.
8. Components with stripped threads or damaged parts must be replaced rather than repaired. Repairs requiring machining or welding must not be attempted.
9. Prior to returning the vehicle to service, make sure all components and systems are restored to their proper operating condition. Repeat the initial check-out procedure.

Modulator Relay Valve Removal and Installation

Removal

WARNING

Make sure all the air pressure has been exhausted from the brake system to prevent personal injury or property damage; pressurized hoses may whip out of control.

1. Open the drain valve to exhaust the air pressure. See **Fig. 1**.

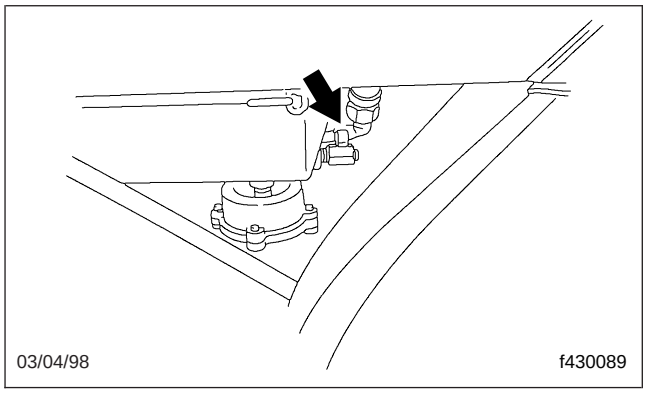

Fig. 1, Air Drain Valve

2. Remove the control module bolts and position the control module aside. See **Fig. 2**.

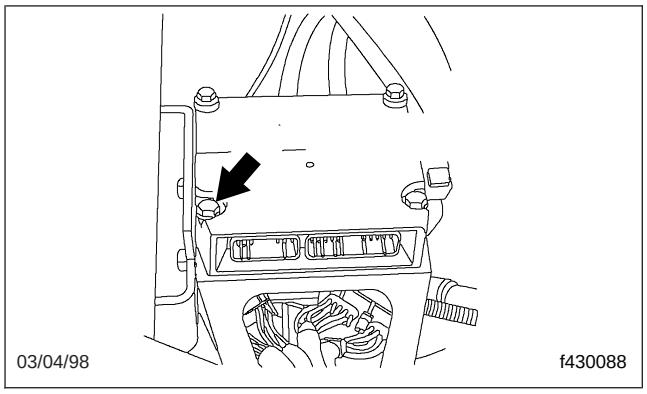

Fig. 2, Control Module Bolts

3. Disconnect the traction control electrical connector. See **Fig. 3**.
4. Cut the wire ties. See **Fig. 4**.
5. Mark and disconnect the air lines from the modulator relay valve. See **Fig. 5**.

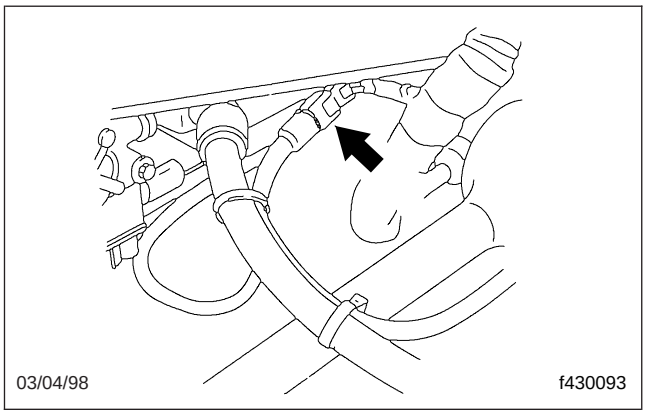

Fig. 3, Traction Control Electrical Connector

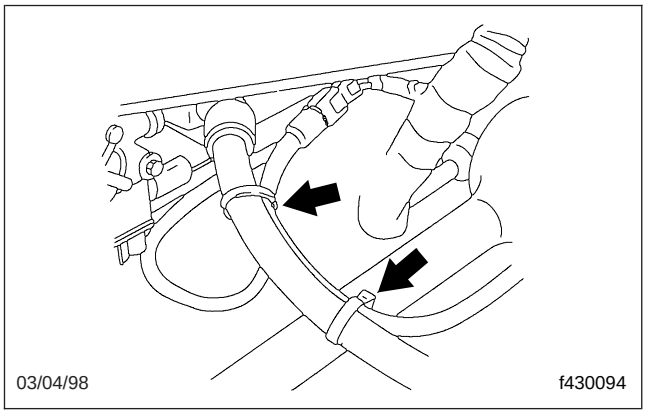

Fig. 4, Wire Ties

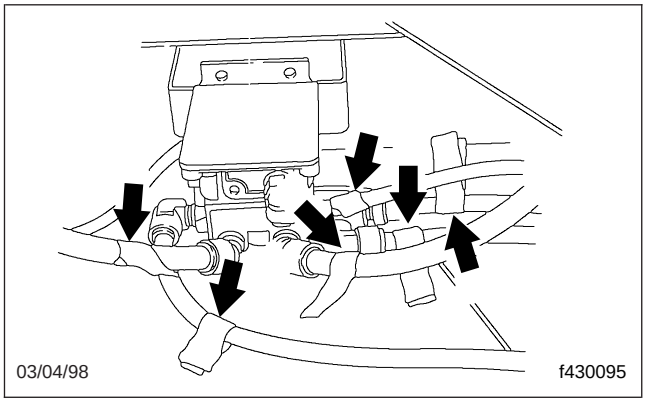

Fig. 5, Modulator Relay Valve Air Line

6. Remove the modulator relay valve bracket nuts.. See **Fig. 6**.
7. Remove the modulator relay valve air line fittings. See **Fig. 7**.

Modulator Relay Valve Removal and Installation

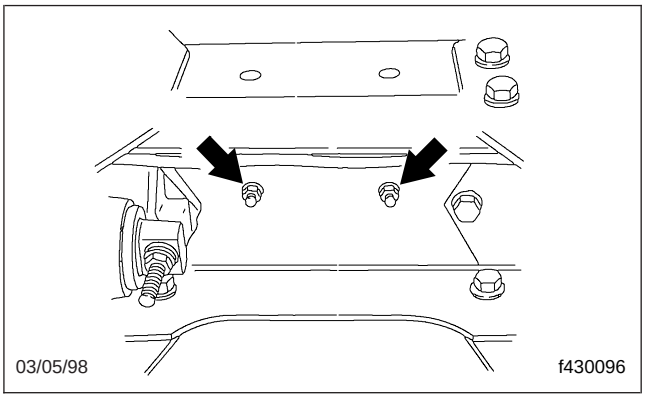

Fig. 6, Modulator Relay Valve Bracket Nuts

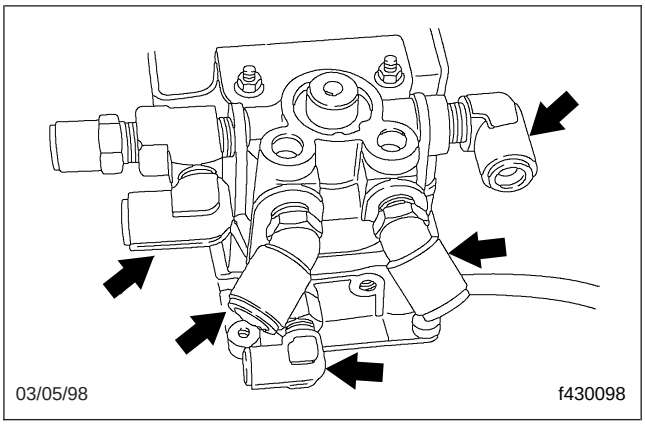

Fig. 7, Modulator Relay Valve Air Line Fittings

8. Remove the modulator relay valve bracket nuts and bolts. See **Fig. 8**.

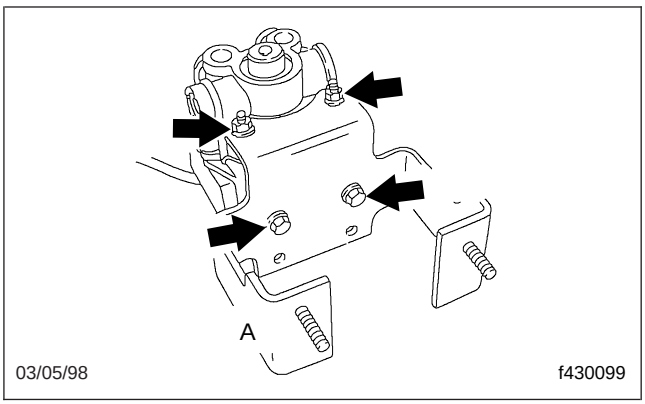

Fig. 8, Modulator Relay Valve Bracket Nuts

Installation

1. Install the modulator relay valve bracket nuts and bolts. Tighten the bolts 15 to 17 lbf·ft (20 to 23 N·m). See **Fig. 8**.
2. Install the modulator relay valve air line fittings. See **Fig. 7**.
3. Install the modulator relay valve bracket nuts. Tighten the nuts 28 to 31 lbf·ft (38 to 42 N·m). See **Fig. 6**.
4. Connect the air lines to the modulator relay valve. See **Fig. 5**.
5. Connect the traction control electrical connector. See **Fig. 3**.
6. Use wire ties to secure the traction control wiring. See **Fig. 4**.
7. Position the control module and Install the control module bolts. Tighten the bolts 50 to 80 lbf·in (56 to 90 N·cm). See **Fig. 2**.

Front Modulator Valve Removal and Installation

Removal

WARNING

Make sure all the air pressure has been exhausted from the brake system to prevent personal injury or property damage; pressurized hoses may whip out of control.

1. Open the drain valve to exhaust the air pressure. See **Fig. 1**.

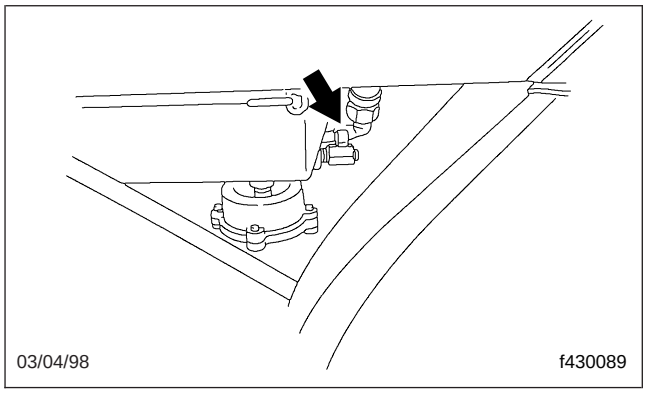

Fig. 1, Air Drain Valve

2. Disconnect the modulator electrical connectors. See **Fig. 2**.

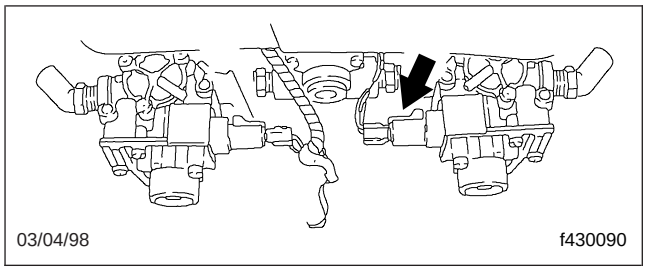

Fig. 2, Modulator Electrical Connectors

3. Disconnect the modulator air lines. See **Fig. 3**.
4. Remove the modulator valve nuts. See **Fig. 4**.
5. Separate the defective modulator valve. Then, remove the modulator valve. See **Fig. 5**.

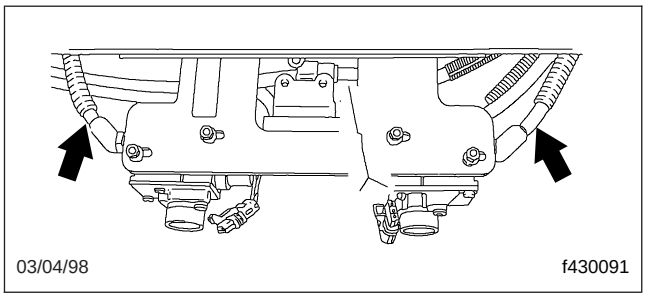

Fig. 3, Modulator Air Lines

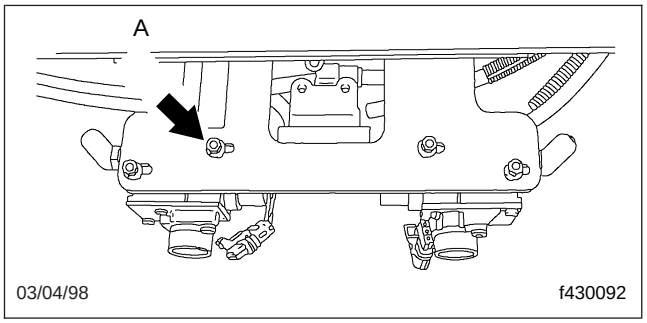

Fig. 4, Modulator Valve Nuts

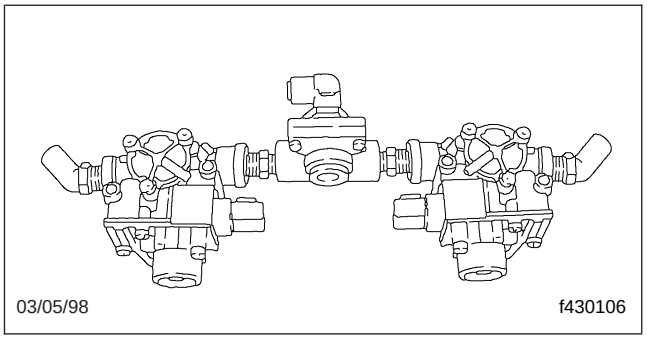

Fig. 5, Modulator Valve

Installation

1. Install the modulator valve and valve nuts. Tighten the modulator valve nuts 15 to 17 lbf·ft (20 to 23 N·m). See **Fig. 4**.
2. Connect the modulator air lines. See **Fig. 3**.
3. Connect the modulator electrical connectors. See **Fig. 2**.

Rear Modulator Valve Removal and Installation

Removal

WARNING

Make sure all the air pressure has been exhausted from the brake system to prevent personal injury or property damage; pressurized hoses may whip out of control.

1. Open the drain valve to exhaust the air pressure. See **Fig. 1**.

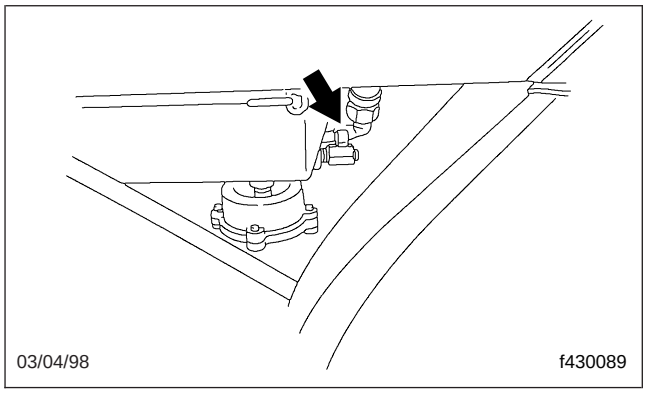

Fig. 1, Air Drain Valve

2. Disconnect the modulator electrical connector. See **Fig. 2**.

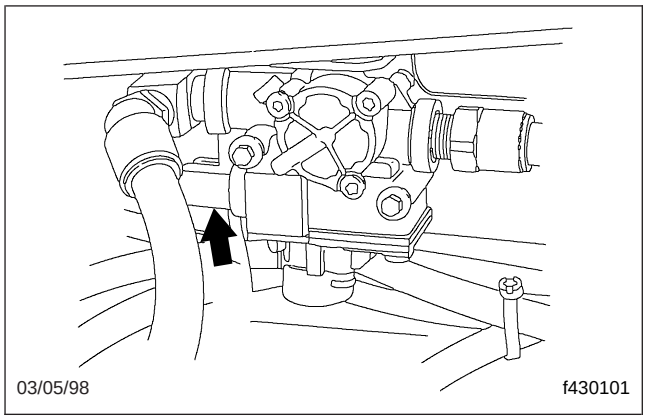

Fig. 2, Modulator Electrical Connector

3. Disconnect the modulator air line. See **Fig. 3**.
4. Remove the modulator valve bolts. See **Fig. 4**.
5. Disconnect the air line and remove the modulator valve. See **Fig. 5**.

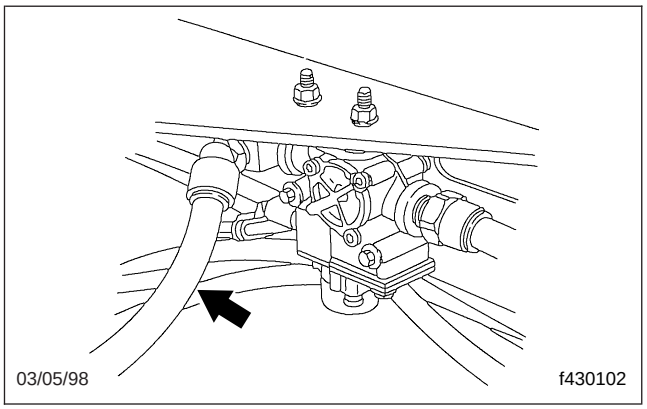

Fig. 3, Modulator Air Line

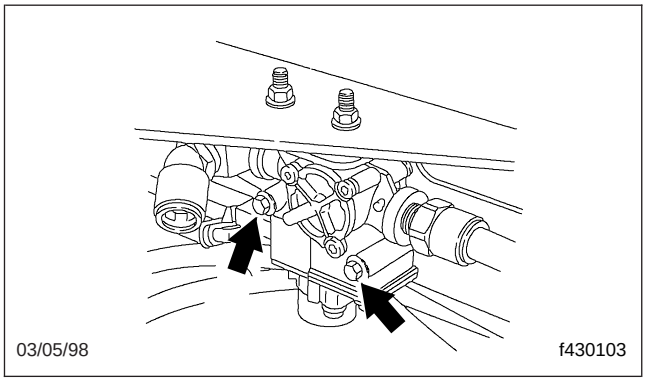

Fig. 4, Modulator Valve Bolts

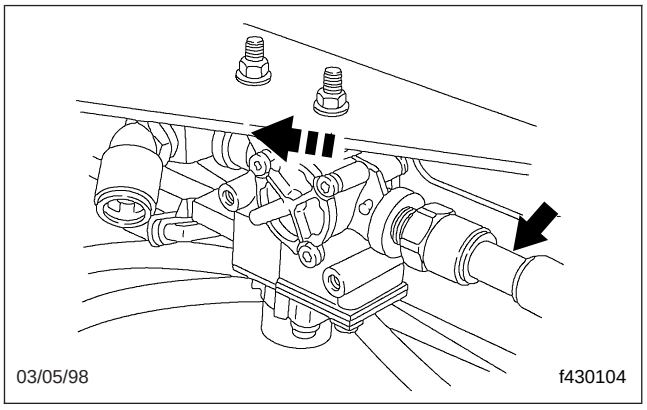

Fig. 5, Modulator Valve Air Line

Installation

1. Install the modulator valve and valve bolts. Tighten the modulator valve bolts 15 to 17 lbf·ft (20 to 23 N·m). See **Fig. 4**.

Rear Modulator Valve Removal and Installation

2. Connect the modulator air line. See **Fig. 3**.
3. Connect the modulator electrical connector. See **Fig. 2**.

Antilock Control Module Removal and Installation

Removal

1. Disconnect the battery ground cable. Refer to **Group 54**.
2. Remove the screws and disconnect the control module electrical connectors. See **Fig. 1**.

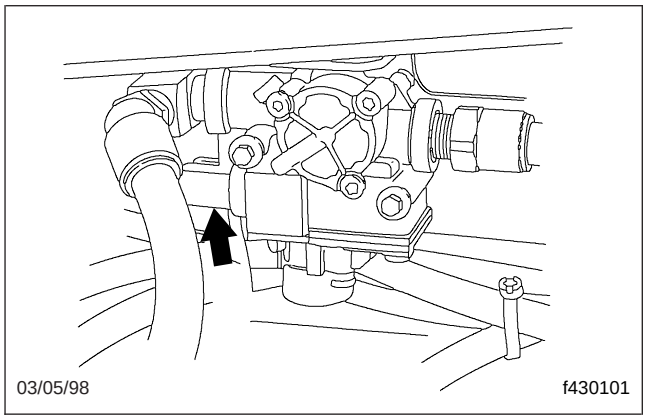

Fig. 1, Antilock Control Module Electrical Connectors

3. Remove the control module bolts and remove the control module. See **Fig. 2**.

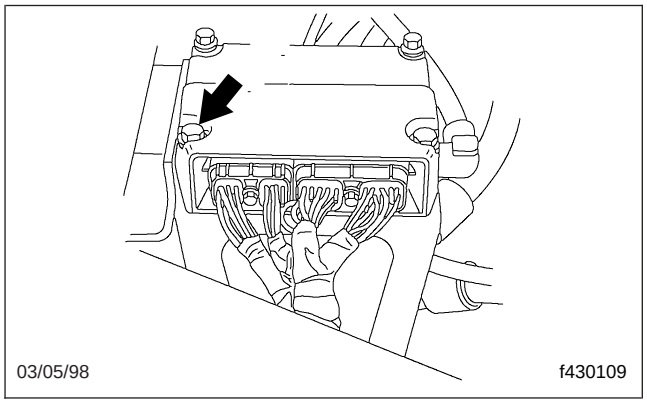

Fig. 2, Control Module Bolts

Installation

1. Install the control module and control module bolts. Tighten the bolts 50 to 80 lbf·in (56 to 90 N·cm). See **Fig. 3**.
2. Connect the control module electrical connectors and install the retaining screws. Tighten the screws 17 to 26 lbf·in (20 to 30 N·cm). See **Fig. 4**.

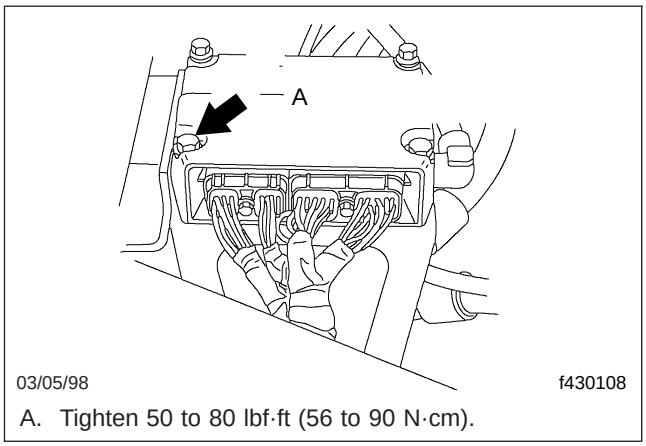

Fig. 3, Antilock Control Module Bolts

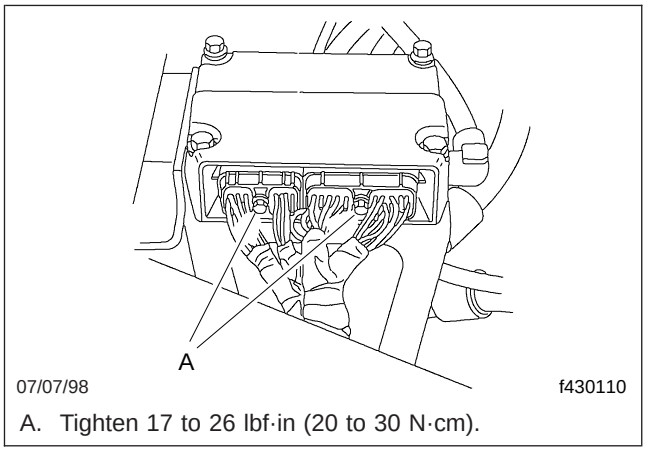

Fig. 4, Antilock Control Module Electrical Connector Screws

Front Wheel Speed Sensor Removal and Installation

Removal

IMPORTANT: Grasp the wheel speed sensor at the base to prevent damage to the component during removal.

1. Open the hood to gain access to the steering knuckle.
2. Remove the wheel speed sensor from the steering knuckle, using a twisting motion. See **Fig. 1**.

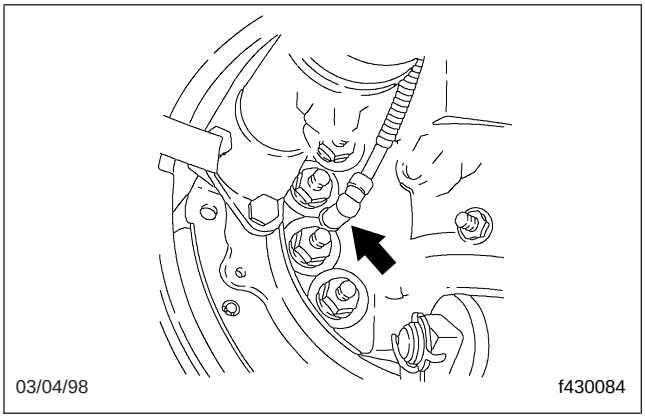

Fig. 1, Wheel Speed Sensor

3. Disconnect the wheel speed sensor electrical connector and remove the sensor. See **Fig. 2**.

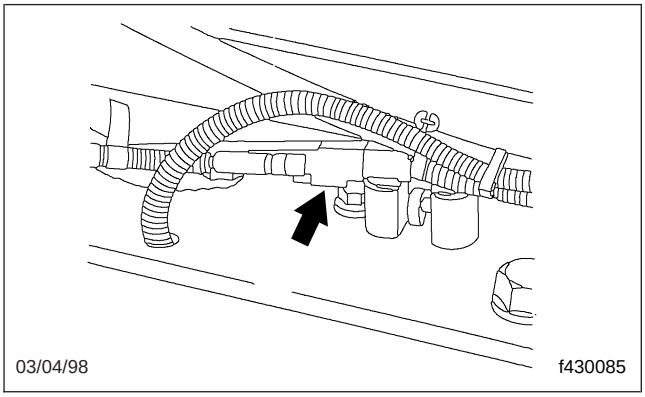

Fig. 2, Wheel Speed Sensor Electrical Connector

Installation

1. Open the hood to gain access to the steering knuckle.
2. Install the wheel speed sensor into the bushing in the steering knuckle until it comes to a stop.
3. Connect the wheel speed sensor electrical connector. See **Fig. 2**.

Rear Wheel Speed Sensor Removal and Installation

Removal

IMPORTANT:Grasp the wheel speed sensor at the base to prevent damage to the component during removal.

1. Remove the wheel and tire assembly; refer to **Group 40**.
2. Manually release the brake air chamber.
3. Remove the brake drum. See **Fig. 1**.

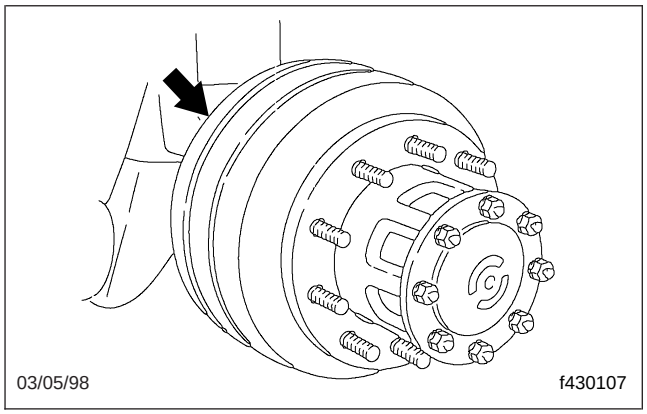

Fig. 1, Brake Drum

4. Remove the wheel speed sensor from the mounting block, using a twisting motion. See **Fig. 2** and **Fig. 3**.

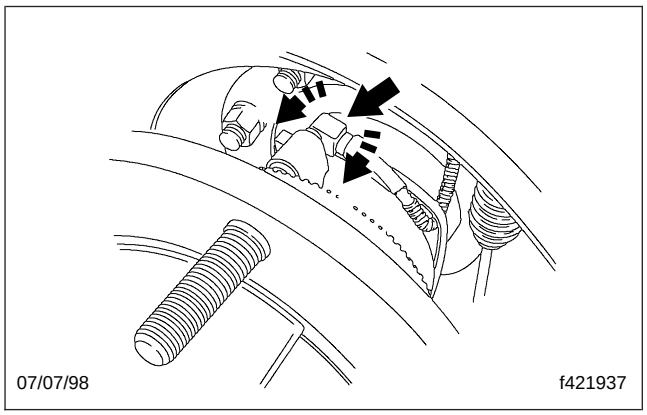

Fig. 2, Twisting the Rear Wheel Speed Sensor

5. Disconnect any fasteners that hold the wheel speed sensor harness, and disconnect the wheel speed sensor connector.

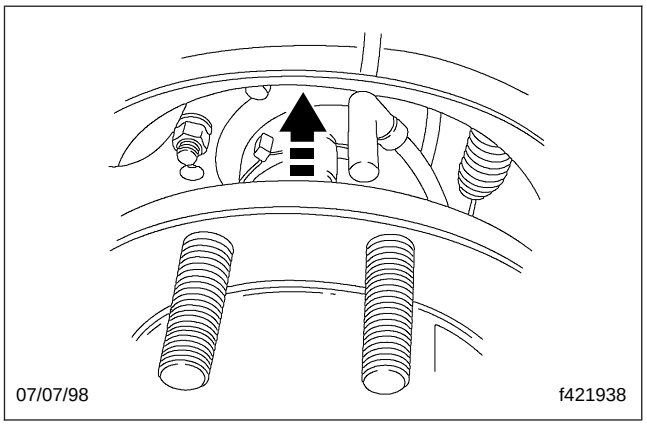

Fig. 3, Rear Wheel Speed Sensor, Removed

6. Pull the harness through the access hole to remove the wheel speed sensor harness.

Installation

1. Install the wheel speed sensor into the bushing until it comes to a stop.
2. Install any fasteners that hold the wheel speed sensor harness.
3. Connect the wheel speed sensor electrical connector.
4. Install the brake drum. See **Fig. 1**.
5. Install the wheel and tire assembly; refer to **Group 40**.

Wheel Speed Sensor Ring/ Sensor Indicator

The wheel speed sensor rings on the front and rear hubs are not serviceable. The hubs must be replaced.

Refer to **Group 35** for removal and installation procedures.

Troubleshooting

Inspection and Verification

General

While the diagnostic display locates a specific area, it is still needed to confirm whether the concern resides in the component itself or the wiring. The following troubleshooting procedure is devoted to narrowing the problem to either the wiring or a specific antilock or traction control component. It should be noted that all troubleshooting begins by observing the antilock and traction control lamps on the dash.

To assist the troubleshooting technician in keeping track of the procedure and also to provide a record of the repairs performed, use a troubleshooting record sheet. See **Fig. 1**. Refer to "Troubleshooting Tips" in this section.

Troubleshooting Tips

1. Determine if the vehicle is equipped with traction control. The presence of a traction control lamp on the dash can be used.
2. Some vehicles are equipped with a traction control disable switch. If so equipped, enable the traction system before beginning the troubleshooting.
3. If the vehicle is equipped with traction control and is a tandem axle unit, note the number of drive axles. The MID diagnostic LED is used only on 6 x 4 vehicles equipped with traction control.
4. It is generally advisable to replace a wire harness rather than repair individual wires in the harness. If a splice repair must be made, it is important that the splice be properly soldered with a rosin flux (not acid based) and made waterproof.
5. While the retarder disable, serial link, and traction on/off connections (4 total) are present on all control modules, they are not always used.

⚠ CAUTION

Use caution when probing the wire harness terminals. Excessive force can cause the terminal to spread, thereby causing a loss of contact with the mating terminal. Record all findings and the actions taken while troubleshooting on a troubleshooting record sheet. The troubleshooting record sheet should be filed in the vehicle maintenance folder for further reference and comparison. See Fig. 1.

No voltage or resistance tests are performed on the control module. All voltage and resistance tests are performed by beginning at the wire harness half of the connector and moving away from the control module toward an antilock traction system component (modulator, wheel speed sensor, etc.).

NOTE: If a failure occurs in a wheel speed sensor, both the antilock and traction control lamps will illuminate. Always begin diagnosis of the antilock lamp first.

Pin Test

When performing checks at the control module connector pins, be careful not to damage the pins. Also, check the pins for corrosion and damage. Make sure the terminals and pins make proper contact.

Ground Tests

Make sure all ground connections are tight and that all ground voltage measurements are zero volts.

Resistance Tests

Make sure the wiring harnesses are tight and in good condition without any damaged insulation or frayed wires. Measure the resistance or continuity at the control module connector to verify the condition of the wiring harness or component.

Component Resistance

If the resistance or continuity tests are not within specifications, measure the resistance of each component at the connector. If the resistance is not correct, check the component and repair or replace the parts as needed.

Checking Continuity, Power and Ground

When checking for continuity, do not pierce the wire insulation. Check for power, ground or continuity by disconnecting the connector and testing the individual pins or sockets in the connector.

Fig. 1, Troubleshooting Record

Exhaust Brake Disable, Data Link, and Traction "On/Off" Connections

The exhaust disable, data link, and traction on/off connections are on all control modules but are not always used.

Use Rotunda 73 Digital Multimeter or equivalent to perform troubleshooting procedures.

Problem—Initial Start-Up Procedure

Problem—Initial Start-Up Procedure	
Possible Cause	**Remedy**
System is functioning abnormally	Check the vehicle for traction control. Turn the ignition switch to the "On" position. If the vehicle is not equipped with traction control, check the antilock dash lamp. If the antilock dash lamp did not illuminate, blink twice then turn off, refer to "Problem—Antilock Warning Lamp" If the antilock dash lamp illuminated, blinked twice then turned off, check the antilock dash lamp status. Drive the vehicle. Increase vehicle speed to above 10 mph for 20 seconds and observe the antilock dash lamp. If the antilock dash lamp does not illuminate, the system is functioning normally. Note the parts replaced or repaired and the steps taken on the troubleshooting sheet. Test the system for normal operation. If the antilock dash lamp does illuminate, check the SEN LED. If the SEN LED is lit, refer to "Problem—Wheel Speed Sensor Failure" and test the appropriate wheel speed sensor. If the vehicle is equipped with traction control, check the dash lamps. Observe the antilock and traction control dash lamps. If the traction control lamp did not blink twice then turn off, check the traction control enable switch. Make sure the traction control enable switch is turned on. If the traction control dash lamp is illuminated, refer to "Problem—Traction Control Dash Lamp". If the traction control dash lamp is not illuminated, check the antilock dash lamp. If the antilock dash lamp did not illuminate, blink twice then turn off, refer to "Problem—Antilock Warning Lamp". If the antilock dash lamp illuminated, blinked twice then turned off, check the antilock dash lamp status. Drive the vehicle. Increase vehicle speed to above 10 mph for 20 seconds and observe the antilock dash lamp. If the antilock dash lamp does not illuminate, the system is functioning normally. Note the parts replaced or repaired and the steps taken on the troubleshooting sheet. Test the system for normal operation. If the antilock dash lamp does illuminate, check the SEN LED. If the SEN LED is lit, refer to "Problem—Wheel Speed Sensor Failure" and test the appropriate wheel speed sensor.

Problem—Antilock Warning Lamp

Problem—Antilock Warning Lamp	
Possible Cause	**Remedy**
Harness and relay shorts	Check the lamp with the control module disconnected. Turn the ignition switch to the "Off" position. Disconnect control module (30-Pin) electrical connector C409. Turn the ignition switch to the "On" position. Observe the amber antilock warning lamp on the dash. If the antilock dash lamp is lit, check the antilock wiring harness and relay for shorts to ground. Test the system for normal operation. If the antilock dash lamp is off, check the antilock wiring harness and the antilock dash lamp bulb for an open. Test the system for normal operation
Faulty warning lamp components	

Troubleshooting

Problem—Green LED Lit but Not Flashing

Problem—Green LED Lit but Not Flashing (See Fig. 2 and Fig. 3)	
Possible Cause	**Remedy**
Damaged control module	Check the red LEDs. If any red LEDs are lit, note and record the condition of all the red LEDs, then refer to "Problem—Red LED Lit". If no red LEDs are lit, reset the control module. Turn the ignition switch to the "On" position. Place the magnet over the reset portion of the control module and hold the magnet in place. If all the LEDs are not illuminated, replace the control module. Test the system for normal operation. If all the LEDs are illuminated, check the supply voltage to the control module. Turn the ignition switch to the "Off" position. Disconnect the control module 30-Pin connector C409. Measure the voltage between the control module 30-Pin connector C409 Pin E3 and ground. If the voltage is greater than 10 volts, repair or replace the antilock wiring harness, the circuitry to the warning lamp bulb or the bulb. Test the system for normal operation. If the voltage is less than 10 volts, repair or replace the antilock wiring harness or the ABS relays. Test the system for normal operation.
Harness and relay shorts	
False failure codes	

Problem—Green LED Flashing

Problem—Green LED Flashing (See Fig. 2)	
Possible Cause	**Remedy**
Damaged control module	Check the voltage supply to the control module. Turn the ignition switch to the "Off" position. Disconnect the control module 30-Pin electrical connector C409. Turn the ignition switch to the "On" position. Measure the voltage between the control module 30-Pin connector, Pins B1 to A1 and A3. If the voltage is not between 11 and 17 volts, repair the affected circuit(s). Test the system for normal operation. If the voltage is between 11 and 17 volts, check the supply voltage to the control module. Measure the voltage between the control module 30-Pin connector C409, Pins K2 to A1, A2 and A3. If the voltage is not between 11 and 17 volts, repair the affected circuit(s). Test the system for normal operation. If the voltage is between 11 and 17 volts, check the supply voltage.
Harness and relay shorts	
False failure codes	Measure the voltage between the control module 30-Pin connector C409, Pins K3 to A1, A2 and A3. If the voltage is between 11 and 17 volts, replace the control module. Repeat the "Problem—Initial Start-Up Procedure". Test the system for normal operation. If the voltage is not between 11 and 17 volts, repair the affected circuit(s). Test the system for normal operation.

Problem—Red LED Lit

Problem—Red LED Lit (See Fig. 2)	
Possible Cause	**Remedy**
Damaged control module	Check the red ECU LED. If the red ECU LED is lit, check the voltage supply to the control module. Turn the ignition switch to the "Off" position. Disconnect the control module 30-Pin electrical connector C409. Turn the ignition switch to the "On" position. Measure the voltage between the control module 30-Pin connector Pins B1 to A1 and A3. If the voltage is not between 11 and 17 volts, repair the affected circuit(s). Test the system for normal operation. If the voltage is between 11 and 17 volts, check the supply voltage tot the control module.
Harness and relay shorts	Measure the voltage between the control module 30-Pin connector C409, Pins K2 to A1, A2 and A3. If the voltage is not between 11 and 17 volts, repair the affected circuit(s). Test the system for normal operation. If the voltage is between 11 and 17 volts, check the supply voltage. Measure the voltage between the control module 30-Pin connector C409 Pins K3 to A1, A2 and A3. If the voltage is between 11 and 17 volts, replace the control module. Repeat the "Problem—Initial Start-Up Procedure". Test the system for normal operation. If the voltage is not between 11 and 17 volts, repair the affected circuit(s). Test the system for normal operation.
False failure codes	If the red ECU LED is not lit, check the combination of the red LEDs. There should be a minimum of three red LEDs illuminated and, of these three, there must be a RHT, LFT, FRT, RER and a MOD or SEN LED. If this condition does not exist, replace the control module. Test the system for normal operation. If this condition exists, note the illuminated LEDs. If the MOD LED is lit using the two positioning LEDs (RHT/LFT and FRT/RER), refer to "Problem—Modulator Valve" and test the appropriate modulator. If the MOD LED is not lit, and the SEN LED is lit, and the SEN LED is not lit, refer to "Problem—Initial Start-Up Procedure". If the SEN LED is lit using the two positioning LEDs (RHT/LFT and FRT/RER), refer to "Problem—Wheel Speed Sensor Failure", and test the appropriate wheel speed sensor.

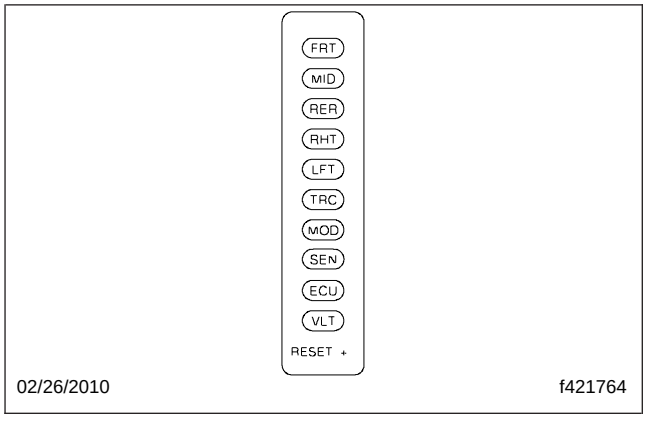

Fig. 2, Diagnostic LEDs

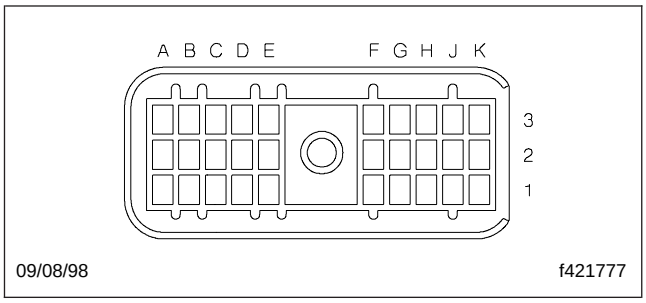

Fig. 3, Control Module 30-Pin Connector

Troubleshooting

Problem—Wheel Speed Sensor Failure

Problem—Wheel Speed Sensor Failure (See Fig. 2 and Fig. 4)	
Possible Cause	**Remedy**
Improper wheel speed sensor resistance	Turn the ignition switch to the "On" position. Reset the control module. Place the magnet over the reset portion of the control module, then remove the magnet. If any red LEDs are illuminated, observe the LEDs on the control diagnostic window. If the same red LEDs are not illuminated, refer to "Problem—Red LED Lit". If the same red LEDs are illuminated, check the wheel speed sensor circuitry. Turn the ignition switch to the "Off" position. Disconnect the control module 18-Pin and 30-Pin connectors C409 and C429. The 30-Pin connector C409 is for the front sensors and the 18-Pin connector C429 is for the rear and middle (tandem axle) sensors. Perform the component test for the appropriate wheel speed sensor at the control module connector. If the resistance values are within the specifications indicated in the component test, replace the control module. Test the system for normal operation. If the resistance values are not within the specifications indicated in the component test, check the wheel speed sensor resistance at the sensor. Disconnect the inoperative wheel speed sensor. Measure the resistance between the inoperative wheel speed sensor terminals (component side). If the resistance is not between 1500 and 2500 ohms, replace the wheel speed sensor. Repeat the "Problem—Initial Start-Up Procedure". Test the system for normal operation. If the resistance is between 1500 and 2500 ohms, connect the control module 18-Pin and 30-Pin connectors C409 and C429. Connect the wheel speed sensor wiring connector. Turn the ignition switch to the "On" position. Reset the control module. Place the magnet over the reset portion of the control module, then remove the magnet. If no red LEDs are illuminated, repeat "Problem—Initial Start-Up Procedure". If any red LEDs are illuminated, check the status of the red LEDs. Observe the LEDs on the control module diagnostic window. If the same red LEDs are illuminated as before, repair and replace the wheel sensor wiring harness. Test the system for normal operation. If the same red LEDs are not illuminated as before, refer to "Problem—Red LED Lit". If no red LEDs are illuminated, check the gap between the wheel speed sensor and the wheel speed sensor ring. Turn the ignition switch to the "Off" position. Check the gap between the inoperative wheel speed sensor and the wheel speed sensor ring. If the wheel speed sensor gap is between 0 and 0.015 inch, check the wheel bearing for proper free play. Adjust as necessary. Refer to **Group 32** for the front and **Group 35** for the rear. Check the wheel speed sensor ring. Visually inspect the wheel speed sensor ring for missing or damaged teeth and that the ring runs true and perpendicular to the sensor face. If the wheel speed sensor ring is not in proper condition, repair or replace as necessary. If the wheel speed sensor ring is in proper condition, check the wheel speed sensor harness. Visually inspect the wheel speed sensor harness and connector for damage. Check the harness for continuity. If the wheel speed sensor harness is not in proper condition, repair or replace as necessary. If the wheel speed sensor harness is in proper condition, check the brakes.
Damaged wheel speed sensor ring	
Circuitry open or shorted	
Damaged control module	
Improper wheel speed sensor resistance	

Problem—Wheel Speed Sensor Failure

Problem—Wheel Speed Sensor Failure (See Fig. 2 and Fig. 4)	
Possible Cause	**Remedy**
Damaged wheel speed sensor ring	Check the dragging brakes (overadjusted, trapped air in actuator, out of round drums, damaged return springs, parking brake system concerns, etc.). If the brakes are not within specification and operating properly, repair as necessary. If the brakes are within specification and operating properly, check the wheel speed sensor mounting tightness. If the wheel speed sensor is not securely mounted, tighten the sensor by replacing the spring sleeve that holds the sensor in the mounting block bore. Test the system for normal operation. If the wheel speed sensor is securely mounted, Inspect the wheel speed sensor for any cracks or physical damage. If the wheel speed sensor does not check OK, replace the wheel speed sensor. Test the system for normal operation. If the wheel speed sensor checks OK, turn the ignition switch to the "On" position. If the wheel speed sensor is OK, reset the control module. Place the magnet over the reset portion of the control module, then remove the magnet. If any red LEDs are illuminated, refer to "Problem—Red LED Lit". If no red LEDs are illuminated, repeat "Problem—Initial Start-Up Procedure". Test the system for normal operation. If the wheel speed sensor gap is not 0 to 0.015 inch, check for loose or worn wheel bearings before regapping the sensor. Refer to **Group 32** for the front and **Group 35** for the rear. Turn the ignition switch to the "On" position. If the wheel speed sensor checks OK, reset the control module. Place the magnet over the reset portion of the control module, then remove the magnet. If any red LEDs are illuminated, refer to "Problem—Red LED Lit". If no red LEDs are illuminated, repeat "Problem—Initial Start-Up Procedure". Test the system for normal operation.
Circuitry open or shorted	
Damaged control module	

Troubleshooting

Problem—Modulator Valve

Problem—Modulator Valve (See Fig. 2 and Fig. 5)	
Possible Cause	**Remedy**
Improper modulator valve resistance	Check the modulator valve circuits. Disconnect the control module 30-Pin and 18-Pin connectors C409 and C429. NOTE: The 30-Pin connector C409 is for the front modulators and the 18-Pin connector C429 is for the rear modulators. Perform the component test for the appropriate modulator valve at the control module connector. If the resistance values are within the specification indicated in the component test, connect the inoperative modulator connector. Connect the control module 30-Pin and 18-Pin connectors C409 and C429. Reset the control module. Place the magnet over the reset portion of the control module, then remove the magnet. If any red LEDs are illuminated, repair or replace the inoperative modulator valve wiring harness. Test the system for normal operation. If no red LEDs are illuminated, repeat "Problem—Initial Start-Up Procedure". If testing returns to this point two consecutive times, replace the control module. Test the system for normal operation. If the resistance values are not within the specification indicated in the component test, check the inoperative modulator valve. Disconnect the modulator valve connector. Measure the resistance between the inoperative modulator valve hold terminal and common terminal (component side). If the resistance is not between 3.5 and 5.0 ohms, replace the inoperative modulator valve. Test the system for normal operation. If the resistance is between 3.5 and 5.0 ohms, check the inoperative modulator valve resistance. Measure the resistance between the inoperative modulator valve exhaust terminal and common terminal (component side). If the resistance is not between 3.5 and 5.0 ohms, replace the inoperative modulator valve. Test the system for normal operation. If the resistance is between 3.5 and 5.0 ohms, check the modulator valve. Measure the resistance between the inoperative modulator valve exhaust terminal and hold terminal (component side). If the resistance is not between 7 and 10 ohms, replace the inoperative modulator valve. Test the system for normal operation. If the resistance is between 7 and 10 ohms, connect the inoperative modulator connector. Connect the control module 30-Pin and 18-Pin connectors C409 and C429. Reset the control module. Place the magnet over the reset portion of the control module, then remove the magnet. If any red LEDs are illuminated, repair or replace the inoperative modulator valve wiring harness. Test the system for normal operation. If no red LEDs are illuminated, repeat "Problem—Initial Start-Up Procedure". If testing returns to this point two consecutive times, replace the control module. Test the system for normal operation.
Circuitry open or shorted	
Damaged control module	

Problem—False Indication Caused By Wheel Speed Components

Problem—False Indication Caused By Wheel Speed Components (See Fig. 2)	
Possible Cause	**Remedy**
Harness and relay shorts	Turn the ignition switch to the "On" position. Place the magnet over the reset portion of the control module and hold the magnet in place. If all the LEDs are not illuminated, replace the control module. Test the system for normal operation. If all the LEDs are illuminated, remove the magnet, then check the wheel speed sensors and indicator rings. Turn the ignition switch to the "Off" position. Inspect the axle(s) for the presence of, and for proper installation of, the wheel speed sensors and indicator rings. Inspect the wheel speed sensor gap and the bearing end play. If all the components check OK, drive the vehicle at 10 mph for at least 20 seconds. Repeat the "Problem—Initial Start-Up Procedure". If all the components do not check OK, repair or replace as necessary. Drive the vehicle at 10 mph for at least 20 seconds. Repeat the "Problem—Initial Start-Up Procedure".
Damaged control module	
Faulty wheel speed sensor components	

Problem—Traction Control Dash Lamp

Problem—Traction Control Dash Lamp (See Fig. 3)	
Possible Cause	**Remedy**
Harness and relay shorts	Check the voltage to the control module. Turn the ignition switch to the "Off" position. Disconnect the control module 30-Pin connector C409. Turn the ignition switch to the "On" position. Measure the voltage between the control module 30-Pin connector C409, Pin C2 and ground. If the voltage is greater than 10 volts, replace the dash lamp. If OK, replace the control module. Test the system for normal operation. If the voltage is less than 10 volts, repair or replace the wiring harness. Repeat the "Problem—Initial Start-Up Procedure".
Damaged control module

Fig. 5, Modulator Valve Connector

Problem—Traction Control Solenoid

Problem—Traction Control Solenoid (See Fig. 2, Fig. 3, Fig. 6 and Fig. 7)	
Possible Cause	**Remedy**
Circuitry open or shorted	Check the LEDs on the control module. Turn the ignition switch to the "Off" position. Observe the LEDs on the control module. If only the TRC LED is illuminated, refer to "Problem—Engine Control Module Wiring Harness". If the TRC LED is not the only LED illuminated, check the status of the LEDs on the control module. Observe the LEDs on the control module. If the TRC and MOD LEDs are not illuminated, refer to "Problem—Initial Start-Up Procedure". If the TRC and MOD LEDs are illuminated, check the resistance at the control module. Turn the ignition switch to the "Off" position. Disconnect the control module 18-Pin and 30-Pin connector C429 Pin D2 and Pin D3. If the resistance is not between 10 and 12 ohms, check the resistance of the solenoid. Disconnect the solenoid 2-Pin connector. Measure the resistance between the solenoid 2-Pin connector terminals (component side). If the resistance is not between 10 and 12 ohms, replace the modulator relay valve. Test the system for normal operation. If the resistance is between 10 and 12 ohms, check the solenoid for a short to ground. Measure the resistance between the solenoid 2-Pin connector terminals and ground (component side). If continuity is indicated for each test, replace the modulator relay valve. Test the system for normal operation. If continuity is not indicated for each test, repair or replace the wiring harness. Test the system for normal operation. If the resistance is between 10 and 12 ohms, check for a short to ground.
Improper solenoid resistance	Measure the resistance between the 18-Pin control module connector C429, Pin D2 and the 30-Pin control module connector C409, Pins A1, A2 and A3. If continuity is not indicated on each test, check for a short. Measure the resistance between the 18-Pin control module connector C429, Pin D3 and the 30-Pin control module connector C409, Pins A1, A2 and A3. If continuity is not indicated on each test, check for a poor connection at the control module. Reset the control module. Repeat the "Problem—Initial Start-Up Procedure". If continuity is indicated on each test, check the resistance of the solenoid. Disconnect the solenoid 2-Pin connector. Measure the resistance between the solenoid 2-Pin connector terminals (component side). If the resistance is not between 10 and 12 ohms, replace the modulator relay valve. Test the system for normal operation. If the resistance is between 10 and 12 ohms, check the solenoid for a short to ground. Measure the resistance between the solenoid 2-Pin connector terminals and ground (component side). If continuity is indicated for each test, replace the modulator relay valve. Test the system for normal operation. If continuity is not indicated for each test, repair or replace the wiring harness. Test the system for normal operation.

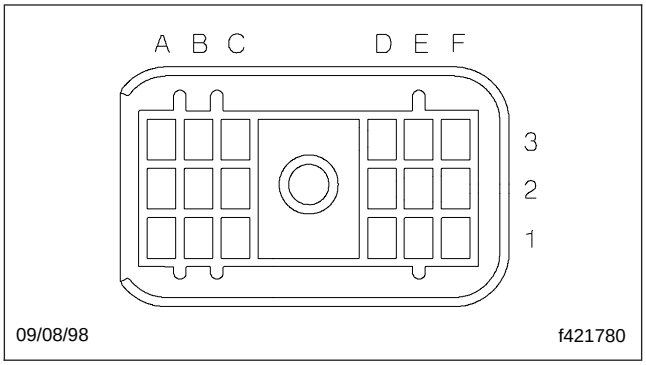

Fig. 6, Control Module 18-Pin Connector

Problem—Engine Control Module Wire Harness

Problem—Engine Control Module Wire Harness (See Fig. 2)	
Possible Cause	**Remedy**
Circuitry open or shorted	Check the control module. Turn the ignition switch to the "On" position. Observe the LEDs on the control module. If the TRC LED is not the only LED illuminated, reset the control module. Repeat the "Problem—Initial Start-Up Procedure". If the only LED illuminated is the TRC LED, check the wiring harness. Turn the ignition switch to the "Off" position. Disconnect the control module 30-Pin connector C409 and ECM connector. Measure the resistance between the control module 30-Pin connector C409, Pin B2 and the corresponding ECM connector pin. If the resistance is more than 5.0 ohms, repair or replace the wiring harness. Repeat the "Problem—Initial Start-Up Procedure". If the resistance is less than 5.0 ohms, check the wiring harness for continuity. Measure the resistance between the control module 30-Pin connector C429, Pin B3 and the corresponding ECM connector pin. If the resistance is less than 5.0 ohms, check the ECM. If the resistance is more than 5.0 ohms, repair or replace the wiring harness. Repeat the "Problem—Initial Start-Up Procedure".
Damaged control module	

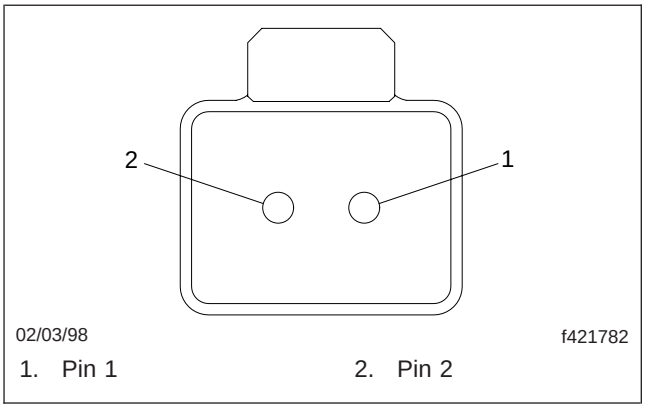

Fig. 7, Traction Control Solenoid Connector

LED Diagnosis

NOTE: Refer to **Table 1** for specific LED descriptions.

FRT (Front) LED

This red LED lights and latches on in order to show the location of the worn or damaged component or its wiring. It will illuminate in conjunction with either the right or left LED and the MOD or SEN LED.

MID (Mid Axle) LED

This red LED is not used in all installations. On those vehicles that have six wheel speed sensors installed, this red LED lights and latches on to show the location of the worn wheel speed sensor or its wiring. The MID LED should not illuminate with the MOD LED.

RER (Rear) LED

This red LED lights and latches on in order to show the location of the worn or damaged component or its wiring. It will illuminate in conjunction with either the right or left LED and the MOD or SEN LED.

LED Description	
LED	**Description**
FRT	Red LED
MID	Red LED (see "NOTE")
RER	Red LED
RHT	Red LED
LFT	Red LED
TRC	Red LED
MOD	Red LED
SEN	Red LED
ECU	Red LED
VLT	Green LED
Reset	No LED

Table 1, LED Description

RHT (Right) LED

This red LED lights and latches on in order to show the location of the worn or damaged component or its wiring. It will illuminate in conjunction with either the front or rear LED and the MOD or SEN LED.

LFT (Left) LED

This red LED lights and latches on in order to show the location of the worn or damaged component or its wiring. It will illuminate in conjunction with either the front or rear LED and the MOD or SEN LED.

TRC (Traction Control) LED

NOTE: If an intermittent concern exists with the wiring to the engine control module, this LED will illuminate. However, it will not latch on. It will go out when the concern corrects itself.

This red LED lights and latches on to show a permanent problem in the traction control system. It may be lit with the MOD LED or it may be lit by itself.

MOD (Modulator) LED

NOTE: The MID positioning LED should not be lit with this LED. This LED is also used to show a concern with a traction control solenoid. When lit for a traction control system concern, the TRC LED will also be lit.

This red LED lights and latches on to show a permanent or intermittent open or short circuit in the solenoids of one of the four modulators or the wiring. When indicating a concern with a modulator, this LED will be lit with two positioning LEDs (RHT/LFT + FRT/RER).

SEN (Wheel Speed Sensor) LED

This red LED lights and latches on to show a permanent or intermittent failure. The failures indicated are open or shorted wheel speed sensor, open or shorted wheel speed sensor wiring, wheel speed signal not present or not to specification. The SEN LED will be lit with two positioning LEDs (RHT/LFT + FRT/MID/RER).

ECU (Electronic Control Unit) LED

This red LED, when lit, shows that the control module itself has failed. It is latched on for all control module failures except low voltage. Before the control module is replaced, always check for battery voltage at the control module connector.

VLT LED

This green LED lights and remains lit during vehicle operation to show that the battery voltage is reaching the control module. If the battery voltage is out of range (below 11 volts or above 17 volts) this LED will flash until the battery voltage is brought into range.

Reset

Beneath the "Reset" area of the display is a magnetically sensitive switch that is used to reset the diagnostic system. The device will respond to a magnet which has the strength sufficient to lift a three ounce weight. Momentarily holding a magnet against the "Reset" will cause all LEDs to illuminate during the time the magnet is held against it. Holding the magnet against "Reset" longer than 10 seconds will cause the newer version of the control module to initiate the self-configuration feature.

Modulator Valve Test

NOTE: Refer to **Table 2** for test information.

Modulator Valve Test			
Modulator	**Pin**	**Control Module Connector**	**Resistance Value**
Left Rear Modulator	E1 to F1	18-Pin C429	3.5–5.0 Ohms
Left Rear Modulator	D1 to F1	18-Pin C429	3.5–5.0 Ohms
Left Rear Modulator	D1 to E1	18-Pin C429	7–10 Ohms
Left Rear Modulator	F1 to Ground	18-Pin C429	No Continuity

Table 1, Torque Specifications

General Information

The Gunite automatic slack adjuster has two main functions:

- As a lever it converts the straight-line force of the brake chamber pushrod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the drum.
- As an automatic slack adjuster, it maintains the lining-to-drum clearance needed for proper brake chamber pushrod stroke.

The slack adjuster is installed between the brake chamber pushrod and the brake camshaft. See **Fig. 1**. A clevis connects the brake chamber pushrod to the top of the slack adjuster. The bottom of the slack adjuster is splined to the brake camshaft. The splines hold the slack adjuster internal gear to the camshaft, so the camshaft turns when the slack adjuster moves. When the brakes are applied, the brake chamber pushrod moves outward forcing the slack adjuster and camshaft to rotate. This movement forces the brake shoes against the drum.

The brakes are adjusted when the slack adjuster senses an increase in the lining-to-drum clearance. The slack adjuster's internal worm shaft and ratchet shorten excessive lining-to-drum clearance. This provides maximum leverage for the brake chamber pushrod. The automatic slack adjuster adjusts the brakes at the beginning of the brake application.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Slack Adjuster Removal and Installation

WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

IMPORTANT: This automatic slack adjuster cannot be rebuilt. If it is damaged or inoperative, replace the unit.

Each factory-installed brake chamber has a clevis welded onto the pushrod. See **Fig. 1**. On a replacement brake chamber, the clevis is threaded onto the pushrod, and has a jam nut installed. See **Fig. 2**.

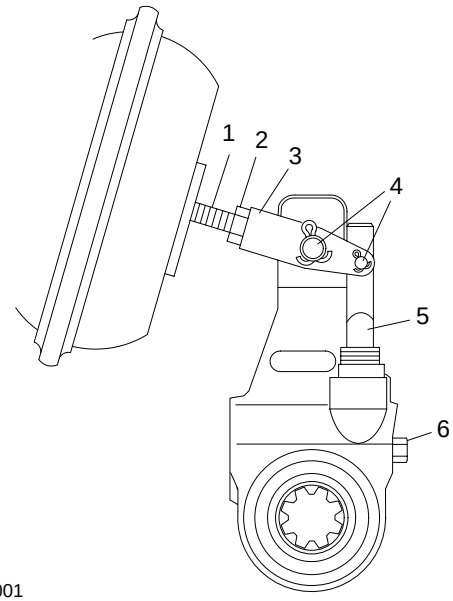
1. Brake Chamber Pushrod and Clevis Assembly
2. Cotter Pins and Clevis Pins
3. Link
4. Adjusting Hexnut

Fig. 1, Slack Adjuster (attached to welded clevis)

Removal

1. With the vehicle parked on a level surface, chock the tires. If you are removing a rear slack adjuster, cage the parking brake power spring. For instructions, refer to the applicable brake chamber section in this group.
2. Remove the cotter pins and clevis pins.



09/14/2001 f430274

1. Brake Chamber Pushrod (threaded)
2. Jam Nut
3. Threaded Clevis
4. Cotter Pins and Clevis Pins
5. Link
6. Adjusting Hexnut

Fig. 2, Slack Adjuster (attached to threaded clevis)

3. Rotate the adjusting hexnut counterclockwise until the slack adjuster clears the clevis.
4. Remove the snap ring from the brake camshaft, then slide the slack adjuster off the camshaft.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

1. Coat the camshaft splines, and the splines of the slack adjuster gear with an anticorrosion grease.

Slack Adjuster Removal and Installation

2. Using the old snap ring, install the automatic slack adjuster on the brake camshaft.
3. Turn the adjusting hexnut clockwise to rotate the slack adjuster toward the brake chamber until the holes line up.
4. Install the clevis pins and cotter pins.

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

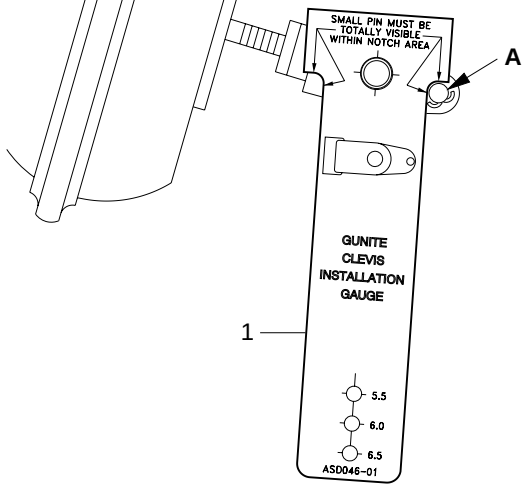
⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

5. If the pushrod has a threaded clevis, use the gauge supplied with a new slack adjuster to check the adjustment of the clevis, as follows. See **Fig. 3**.
   - 5.1 Position the 1/2-inch hole in the gauge over the end of the 1/2-inch clevis pin.
   - 5.2 Align the applicable 1/4-inch hole in the bottom of the gauge over the center of the camshaft.
   - 5.3 Check that the 1/4-inch pin is visible in the notched area of the gauge. If the pin is not in the right location, back off the slack adjuster and readjust the pushrod length, then repeat this step.

NOTE: Make sure there is clearance between the slack adjuster and other vehicle components when the brakes are applied and the pushrod travels its maximum stroke.

6. Set the initial free-stroke, as follows.
   - 6.1 Turn the adjusting hexnut clockwise until the brake linings contact the drum.
   - 6.2 Turn the adjusting hexnut counterclockwise one-half turn. There should be about 30 lbf·ft (41 N·m) resistance, and a ratcheting sound will be heard.



05/15/2008 f420654a

A. Adjust the clevis in or out to position the 1/4-inch clevis pin within the notched area of the gauge.

1. Installation Gauge

Fig. 3, Checking the Clevis Adjustment

7. Measure the brake chamber applied stroke, as follows.
   - 7.1 With the brakes fully released, use a ruler to measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 4**.
   - 7.2 Build air pressure to at least 85 psi (586 kPa). Apply the brakes, then measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 4**. The difference between the measurements is the brake chamber stroke.
   - 7.3 The brake chamber stroke must be within the range shown in **Table 1**. If it is not, check the foundation brakes for problems such as worn cams, bushings, pins and rollers, or broken springs. Repair or replace as needed. For instructions, refer to the applicable brake section in this group. Then, repeat the two previous steps.

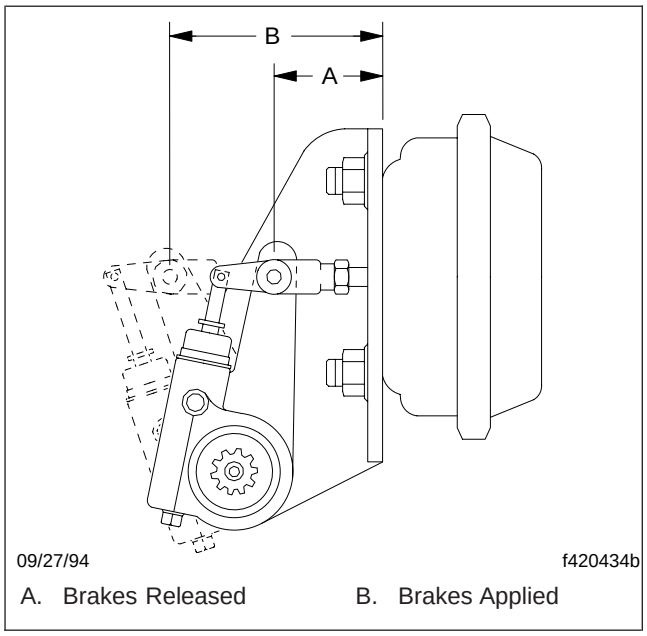


Fig. 4, Brake Stroke Measurements

8. If a rear axle slack adjuster was installed, manually uncage the parking brake. Refer to the applicable brake chamber section in this group for instructions.
9. Apply the parking brakes.
10. Remove the chocks from the tires.
11. In a safe area, check for proper brake operation, as follows.
    - 11.1 Apply and release the brakes several times to check for correct operation of the slack adjusters.
    - 11.2 Perform six low-speed stops to ensure correct parts replacement and full vehicle control.
    - 11.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others show a lack of braking effort on those wheels.

Brake Chamber Stroke Specifications			
Chamber Type (Size)	**Maximum Applied Stroke*: inch (mm)**	**Free-Stroke: inch (mm)**	
		New Brake Installation	**In-Service Brake**
Long Stroke†			
16 and 20	2-1/2 (64)	5/8–3/4 (16–19)	1/2–5/8 (13–16)
24 and 30	3 (76)		

* Specifications are relative to a brake application with 80–90 psi (550–620 kPa) air pressure in the brake chambers.

† Long stroke design is indicated by a tag, or embossing, on the brake chamber.

Table 1, Brake Chamber Stroke Specifications

Specifications

Approved Lubricants

24	1-3/4 (44)	2 (51) — *2-1/2-Inch rated stroke*
		2-1/4 (63) — *3-Inch rated stroke*
30	2 (51)	2-1/2 (57)

Table 2, Maximum Adjusted Brake Chamber Stroke

Safety Precautions

Before attempting to work on the air brake system, observe the following precautions:

- Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.
- When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.
- Air lines will whip dangerously if disconnected under pressure. Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.
- As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber pushrods and spring actuators that apply automatically with the loss of pressure. This also applies when checking the service brake system.
- Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.
- Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.
- The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.
- Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.
- To avoid injury, keep clear of the air chamber pushrod when brakes are applied or when air is exhausted from the system.

⚠ WARNING

Make sure the air system has been reduced to 0 psi before attempting to remove an air line. Do not disconnect pressurized air lines as they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Replacement

⚠ CAUTION

Before working on or around air brake systems and components, see Safety Precautions 100.

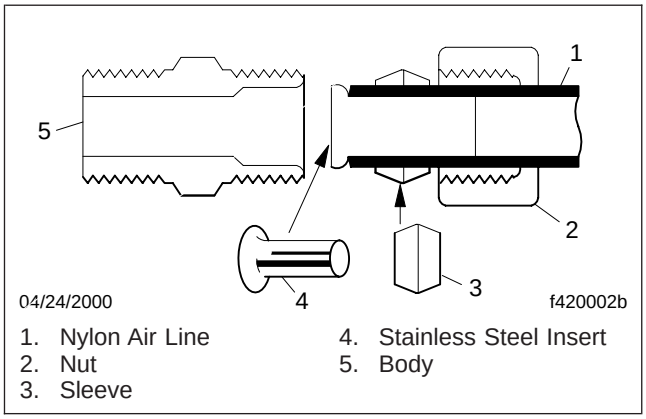
⚠ CAUTION

If the air line is bent to a radius smaller than the specified minimum bend radius, it may kink and shut off normal airflow to the component.

NOTE: When installing a nylon or a wire braid air line, be careful not to bend it past its minimum bend radius. For minimum bend radius values, see **Specifications 400**.

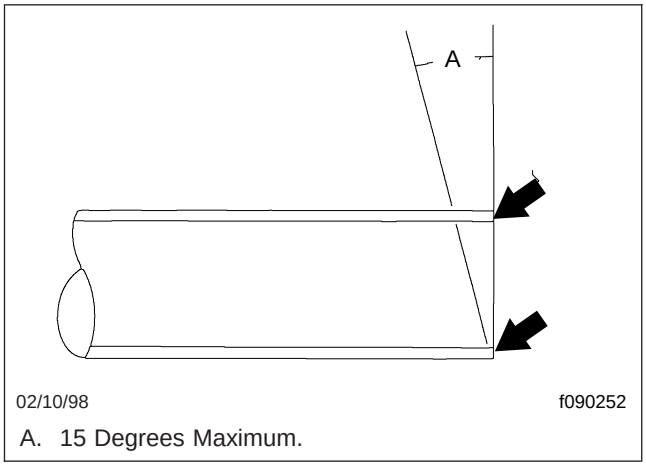
Nylon Air Lines and Compression Fittings

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line. See **Fig. 1**.
   - 3.1 Loosen the fitting nut.
   - 3.2 Pull the air line out of the fitting.
4. Use pliers to remove the stainless steel insert from the fitting. Discard the insert.
5. Clean all of the fitting components.
6. Place a new stainless steel insert into the fitting body. Use thumb pressure to press it into position.
7. Check the air line end for a square cut-off that does not exceed a 15-degree angle. Check that the air line is not distorted or damaged. See **Fig. 2**.



1. Nylon Air Line
2. Nut
3. Sleeve
4. Stainless Steel Insert
5. Body

Fig. 1, Nylon Air Line and Compression Fitting



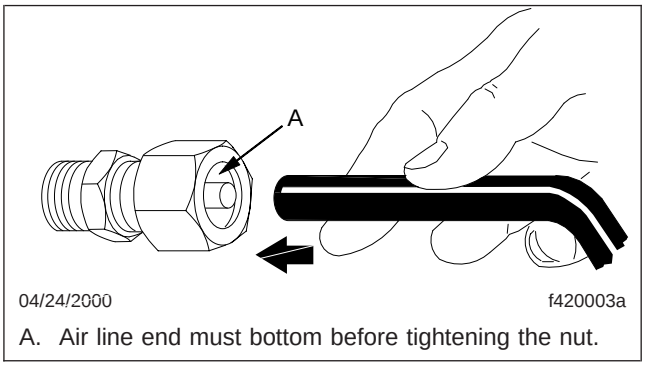
A. 15 Degrees Maximum.

Fig. 2, Check Air Line End Angle

- 7.1 If the angle exceeds the specification, recut the air line.
- 7.2 Use a sharp blade to prevent collapsing the air line or leaving burrs.

8. Make sure the nylon air line ends and fittings are free of grease and debris. If the air line is crimped or otherwise damaged, replace it with a new air line.
9. Install a new sleeve in the nut. Start the threads of the nut on the fitting body.
10. Insert the squared end of the air line in the fitting until it bottoms in the body of the fitting. See **Fig. 3**.
11. Tighten the nut until one thread remains visible.

Air Lines Replacement



A. Air line end must bottom before tightening the nut.

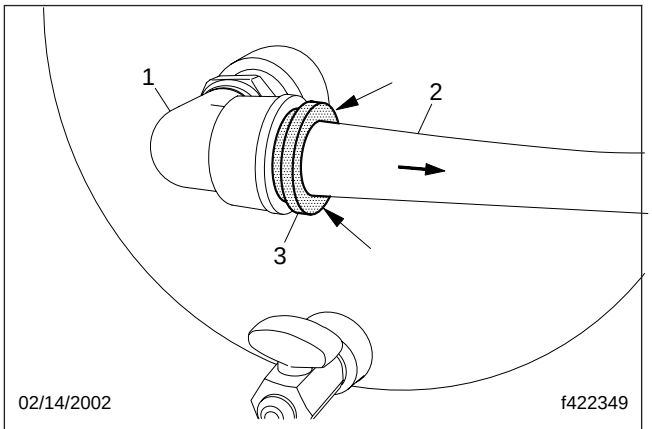
Fig. 3, Installing Nylon Air Line into Compression Fitting

12. Pull back on the air line to make sure it is fully seated.
13. Pressurize the air system. Check the air system for leaks.
14. Remove the chocks from the tires.

Nylon Air Lines and KV2 One-Touch Fittings

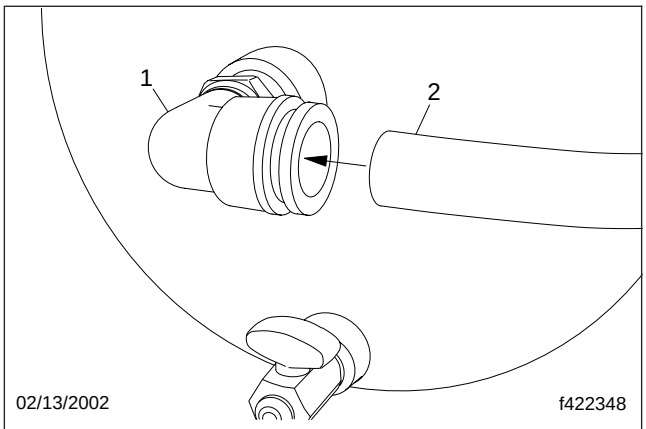
IMPORTANT: The use of a sharp air line cutter is highly recommended. This tool will insure a clean, perpendicular cut of the air line.

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Push the air line into the fitting.
4. Press and hold the release button against the body of the fitting and remove the air line. See **Fig. 4**.
5. Remove the air line.
6. Clean any dirt or contamination from the leading edge of the air line.
7. Lubricate the leading end of the air line with light oil, petroleum jelly or silicone lubricant.
8. Insert the end of the air line into the fitting until it bottoms. See **Fig. 5**.
9. Pull on the air line to verify it is properly retained.
10. Pressurize the air system. Check the air system for leaks.



1. Push-to-Connect Fitting
2. Air Line
3. Release Button

Fig. 4, Push on Release Button and Remove Air Line



1. Push-to-Connect Fitting
2. Air Line

Fig. 5, Insert Air Line

11. Remove the chocks from the tires.

Wire Braid Air Lines

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line.
   - 3.1 Unthread the swivel fitting nut.
   - 3.2 Remove the air line assembly from the mating fitting.

4. Make sure the wire braid air line assembly is free of grease and dirt. Replace the assembly if the air line or fitting is crimped or otherwise damaged.
5. Install the air line and finger-tighten the nut.
6. Using two wrenches to prevent twisting of the air line, tighten the nut until it seats solidly. Tighten the nut one-sixth turn more.
7. Pressurize the air system. Check the air system for leaks.
8. Remove the chocks from the tires.

WARNING

Make sure the air system has been reduced to 0 psi before attempting to remove an air line. Do not disconnect pressurized air lines as they may whip as air escapes. Failure to take all necessary precautions could result in personal injury.

Replacement

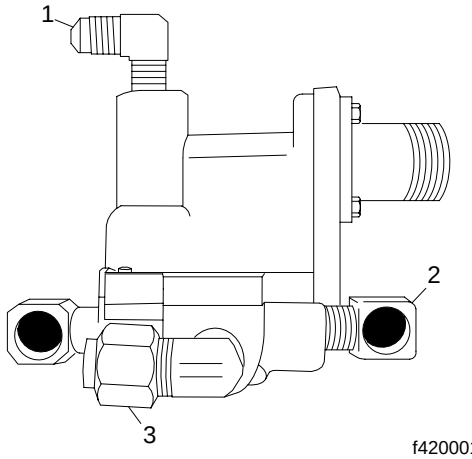
CAUTION

Before working on or around air brake systems and components, see Safety Precautions 100.

CAUTION

Never use diagonal pliers, a razor knife, saw or dull cutting tool to cut nylon air lines. The use of such tools leaves the air line with a sharp edge, burr or out-of-round condition which can damage the seal when the air line is inserted into the fitting. This reduces the sealing ability of the fitting. The use of a sharp air line cutter is highly recommended. This tool will insure a clean, perpendicular cut of the air line.

Brass or Steel Pipe Fittings



1. Wire Braid Hose Fitting
2. Brass or Steel Pipe Fitting
3. Nylon Tube Compression Fitting

Fig. 1, Screw-On Fittings

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see **Subject 110**.
4. Using an open-end wrench or similar tool, rotate the fitting counterclockwise until it is completely disengaged from the fitting port. See **Fig. 1**.
5. Make sure the fitting is free of grease, dirt, and old sealant. Apply liquid thread sealant (white) to the threads and finger-tighten securely.

NOTE: Always apply the sealant to the external thread, so that any excess will be scraped off externally rather than internally to the joint.

6. Install the fitting:
   - *For a fitting that must be positioned*, tighten one additional turn from finger-tight using a wrench. Continue to tighten the fitting clockwise until it is correctly positioned. Never turn the fitting counterclockwise to position it.

Fittings Replacement

- *For a fitting that does not require positioning*, tighten 1-1/2 additional turns from finger-tight.

7. Install the air line in the fitting. For instructions, see **Subject 110**.
8. Pressurize the air system. Check the air system for leaks.
9. Remove the chocks from the tires.

Brass or Steel Pipe Fittings on Plastic Components

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see **Subject 110**.
4. Remove the fitting.
5. Install the fitting. For tightening specifications, see the applicable table in **Specifications, 400**.
6. Install the air line in the fitting. For instructions, see **Subject 110**.
7. Pressurize the air system. Check the air system for leaks.
8. Remove the chocks from the tires.

Copper Fittings

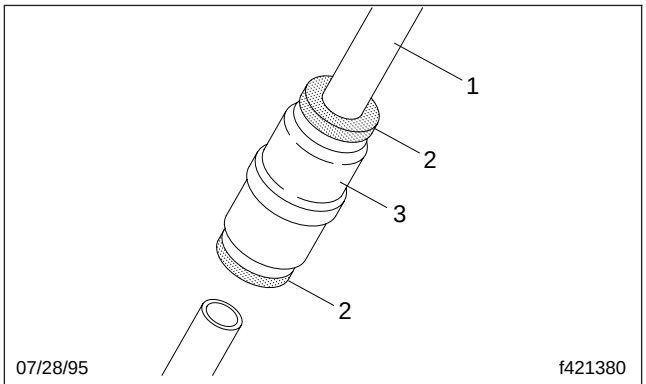
1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see **Subject 110**.
4. Loosen the nut and remove the fitting.
5. Position the fitting.
6. Finger-tighten the nut.
7. Using two wrenches to prevent twisting of the air line, tighten the nut the number of turns shown in the applicable table in **Specifications 400**.
8. Install the air line in the fitting. For instructions, see **Subject 110**.
9. Pressurize the air system. Check the air system for leaks.
10. Remove the chocks from the tires.

Quick-Connect Fittings

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.

NOTE: If damaged, quick-connect fittings must be replaced as an assembly.

3. Push in on the fitting collar to release the air line.
4. Pull the air line out of the fitting. See **Fig. 2**.



1. Air Line
2. Collar
3. Fitting

Fig. 2, Nylon Air Line and Quick-Connect Fitting

5. Push the air line into the fitting.
6. Pull the collar away from the fitting to secure the air line.
7. Check and make sure that the air line is seated in the fitting.
8. Pressurize the air system. Check the air system for leaks.
9. Remove the chocks from the tires.

KV2 One-Touch Fittings

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.

2. Drain the air system.
3. Remove the air line from the fitting. For instructions, see **Subject 110**.
4. Using an open-end wrench or similar tool, rotate the fitting's hexstud end counterclockwise until it is hand-loose.
5. Continue to rotate the fitting by hand until it is completely disengaged from the fitting port.
6. Clean any dirt or thread sealant from the fitting and fitting port.
7. If required, apply liquid thread sealant (white) to the threads.
8. Insert the fitting into the port and rotate it clockwise until it is hand-tight.
9. Using an open-end wrench or similar tool, tighten the fitting to the manufacturer's recommended torque. For torque specifications, see the applicable table in **Specifications 400**.
10. Rotate the fitting body by hand to the correct position.
11. Install the air line in the fitting. For instructions, see **Subject 110**.
12. Pressurize the air system. Check the air system for leaks.
13. Remove the chocks from the tires.

Brake Chamber Removal and Installation

Removal

1. Chock the tires.
2. Release the spring brake.
3. Exhaust the system air pressure.
4. Disconnect the air lines from the brake air chamber. See **Fig. 1**.

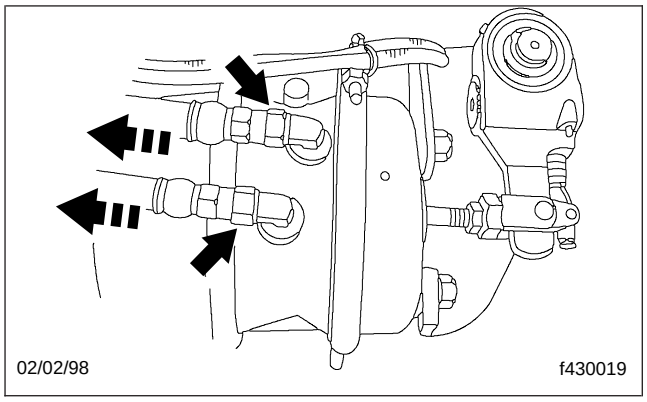

Fig. 1, Air Lines at the Brake Air Chamber

5. Remove and discard the cotter pins from the clevis pin and the adjusting link pin. See **Fig. 2**.

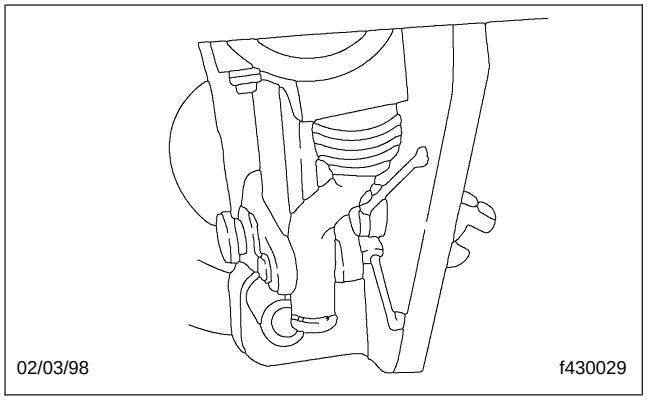

Fig. 2, Cotter Pins

6. Remove the clevis pin and adjusting link pin. See **Fig. 3**.

NOTE: Support the brake air chamber while removing the nuts.

7. Remove the nuts and the brake air chamber. See **Fig. 4**.

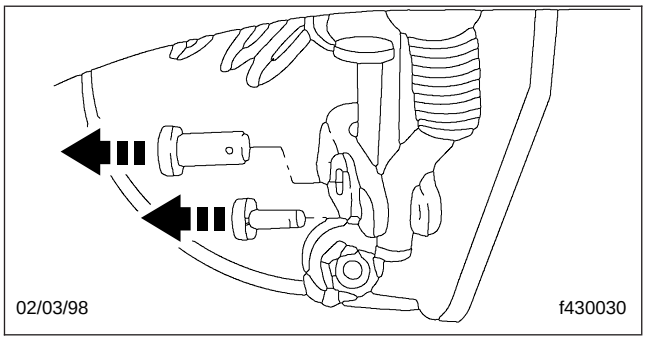

Fig. 3, Clevis Pin and Adjusting Link Pin

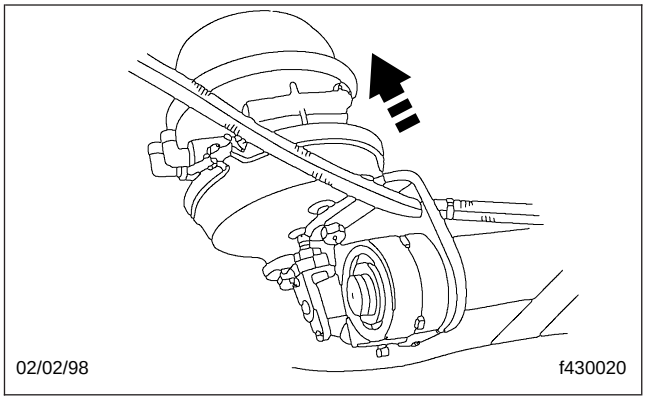

Fig. 4, Brake Air Chamber

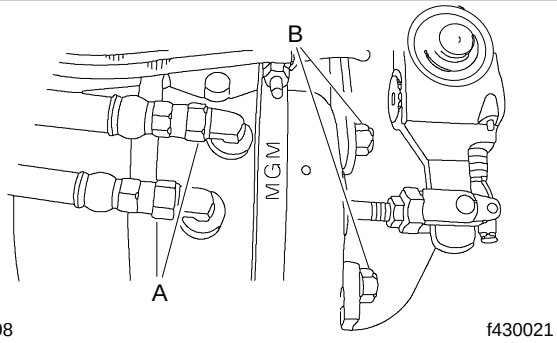
Installation

NOTE: If installing a new brake air chamber, cut the air chamber push rod to the correct length. Refer to "Brake Chamber Push Rod Cutting" in **Subject 120**.

NOTE: Support the brake air chamber while installing the nuts.

1. Install the nuts and the brake air chamber. See **Fig. 4**.
2. Connect the air lines to the brake air chamber. Tighten "A" to: MGM: 24 lbf·ft (33 N·m) and "B" to: MAXI-BRAKE: 12 lbf·ft (16 N·m). See **Fig. 5**.
3. Install the clevis pin and adjusting link pin. See **Fig. 3**.
4. Install new cotter pins to the clevis pin and the adjusting link pin. See **Fig. 2**.
5. Engage the spring brake.
6. Unchock the tires.

Brake Chamber Removal and Installation



A. Tighten 24 lbf·ft (33 N·m).
B. Tighten 12 lbf·ft (16 N·m).

Fig. 5, Tighten the Air Line Fittings

Disassembly

DANGER

Do not attempt to repair the spring brake portion of the brake chamber for any reason. If the power spring were to break loose, it could result in property damage, severe personal injury, or death.

1. Match-mark the service brake end cap, then clamp ring and the bulkhead. See **Fig. 1**.

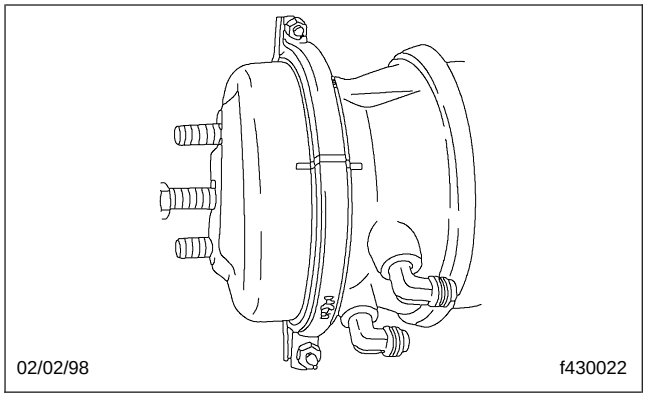


Fig. 1, Service Brake End Cap, Clamp, Ring and Bulkhead

DANGER

The internal return spring can separate parts unexpectedly. Severe personal injury or death can result.

2. Remove the nuts and separate the two-part service chamber clamp ring. See **Fig. 2**.

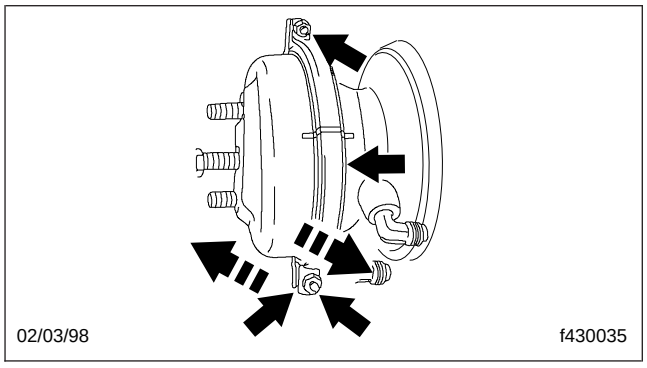

Fig. 2, Two-Part Service Chamber Nuts

3. Separate the service brake chamber end cap assembly from the bulkhead assembly. See **Fig. 3**.

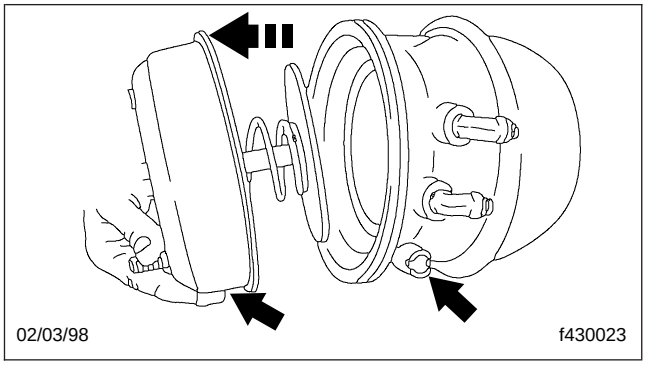

Fig. 3, Service Brake Chamber End Cap/Bulkhead Assembly

4. Remove the service brake diaphragm. See **Fig. 4**.

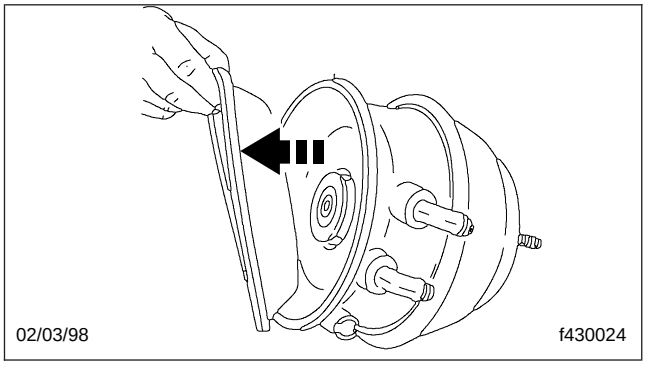

Fig. 4, Brake Diaphragm

Assembly

1. Install a new service brake diaphragm.

DANGER

The internal return spring can separate parts unexpectedly. Severe personal injury or death can result.

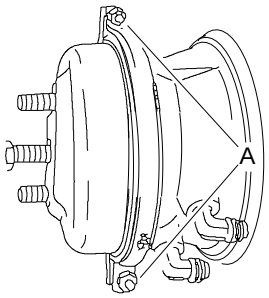
2. Connect the two-part service chamber clamp ring. See **Fig. 2**.
3. Connect the service brake chamber end cap assembly to the bulkhead assembly. See **Fig. 3**.

Brake Chamber Disassembly and Assembly

DANGER

To avoid the risk of injury, do not attempt to repair the spring brake portion of the brake chamber. The spring brake portion is not intended to be serviced. Serious injury or death may result from the sudden release of the spring.

4. Clamp the ring to the bulkhead. See **Fig. 1**.
5. Tighten the diaphragm ring bolts: MGM: 30 to 35 lbf·ft (41 to 47 N·m); MAXI-BRAKE: 16 to 19 lbf·ft (22 to 26 N·m). See **Fig. 5**.



02/03/98 f430036

A. Tighten 16 to 19 lbf·ft (22 to 26 N·m).

Fig. 5, Tighten the Nuts

Brake Chamber, Manual Release

1. Park the vehicle on a level surface and chock the tires.
2. Pull the rubber plug from the hole on the spring brake end cap. See **Fig. 1**.

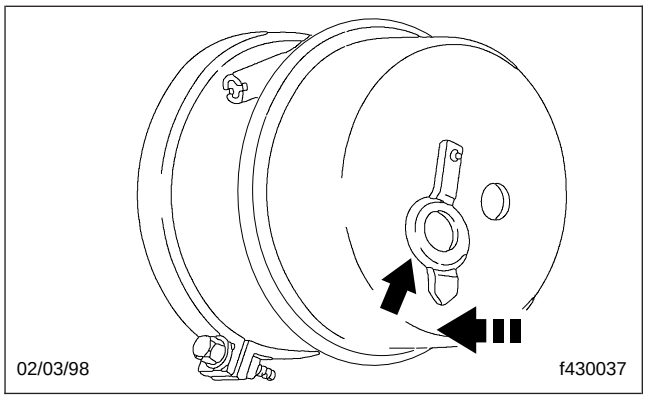


Fig. 1, Spring Brake End Cap Rubber Plug

3. Remove the release bolt, nut and washer from the side of the brake air chamber. See **Fig. 2**.

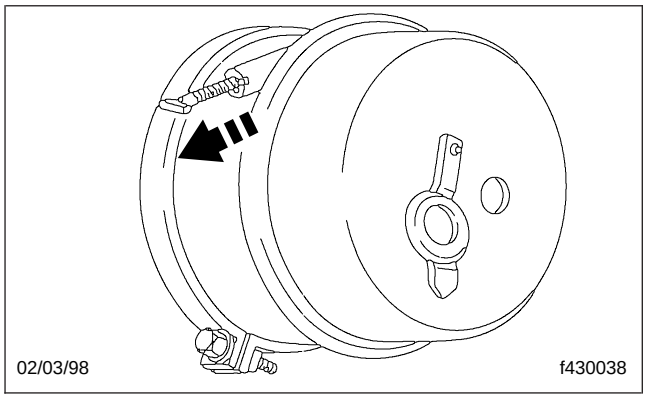

Fig. 2, Bolt, Nut and Washer on the Side of the Air Brake Chamber

4. Insert the release bolt into the spring brake chamber and into the internal T-slot. Turn the release bolt 90 degrees, until it locks and cannot be pulled out. See **Fig. 3**.

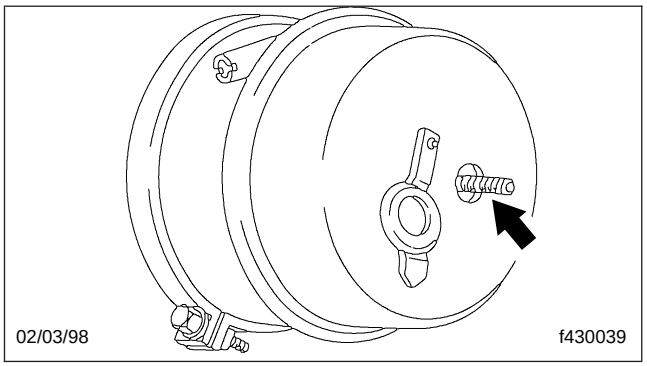

Fig. 3, Brake Chamber Release Bolt

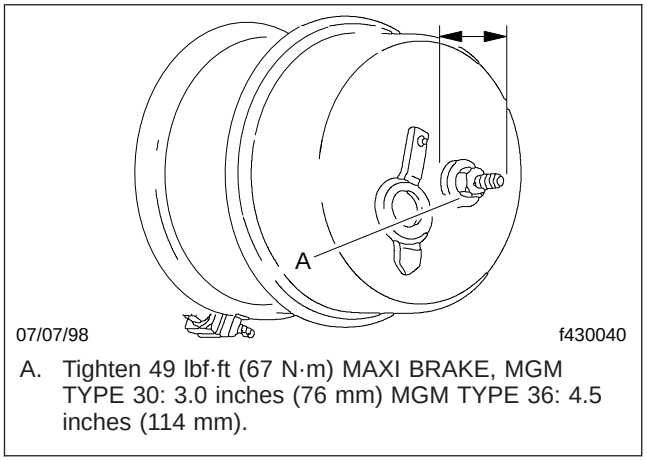
CAUTION

To avoid damage to the spring brake chamber, do not use air-driven tools to tighten the release bolt nut. Do not exceed the torque specification.

NOTE: Charging the brake system with normal air pressure will ease the tightening process.

5. Install the washer and nut on the release bolt and tighten to: 49 lbf·ft (67 N·m) MAXI BRAKE, MGM TYPE 30: 3.0 inches (76 mm), MGM TYPE 36: 4.5 inches (114 mm). See **Fig. 4**.



A. Tighten 49 lbf·ft (67 N·m) MAXI BRAKE, MGM TYPE 30: 3.0 inches (76 mm) MGM TYPE 36: 4.5 inches (114 mm).

Fig. 4, Tighten the Release Bolt and Nut

6. Unchock the tires.

Brake Chamber Push Rod Cutting

1. Park the vehicle on a level surface and chock the tires.

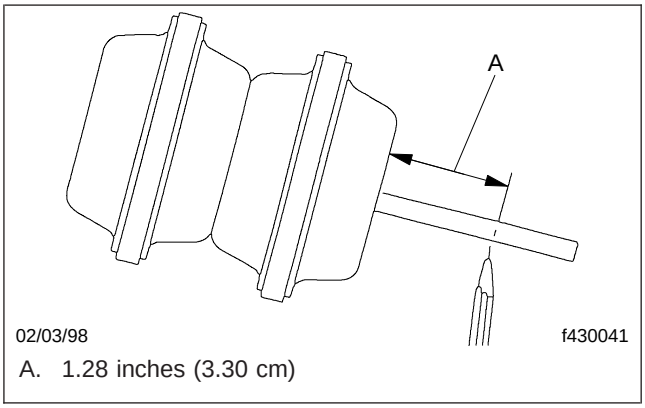
⚠ CAUTION

If the spring brake is not fully released, the air chamber push rod can be cut too short.

2. Release the spring brake. Make sure the air chamber push rod is fully retracted in the brake air chamber.

NOTE: Make sure, when marking the air chamber push rod, that it is centered in the air chamber hole.

3. Measure and mark the specified distance from the face of the brake air chamber. It should be 1¼ inches (3.30 cm). See **Fig. 5**.



A. 1.28 inches (3.30 cm)

Fig. 5, Brake Chamber Face Distance

4. Position the jam nut, clevis nut and collar nut, in that order, above the mark made in the previous step. See **Fig. 6**.
5. Cut the air chamber push rod at the mark made previously. See **Fig. 7**.

⚠ CAUTION

Failure to position the nuts as specified will diminish braking function.

6. Position the nuts for attachment to the slack adjuster. See **Fig. 8**.
   - 6.1 Position the collar nut at the end of the push rod.
   - 6.2 Position the clevis nut against the collar nut.
   - 6.3 Position the jam nut close to the clevis nut.
7. Unchock the tires.

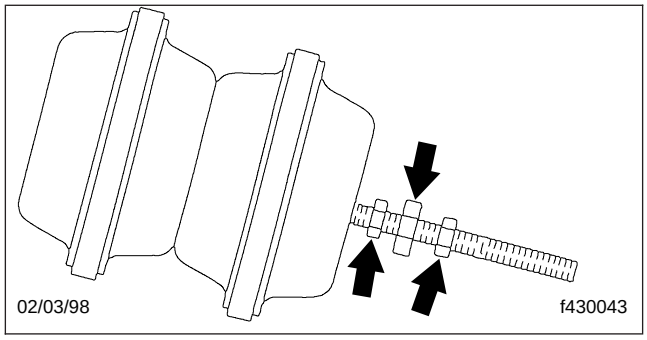


Fig. 6, Jam Nut, Clevis Nut and Collar Nut

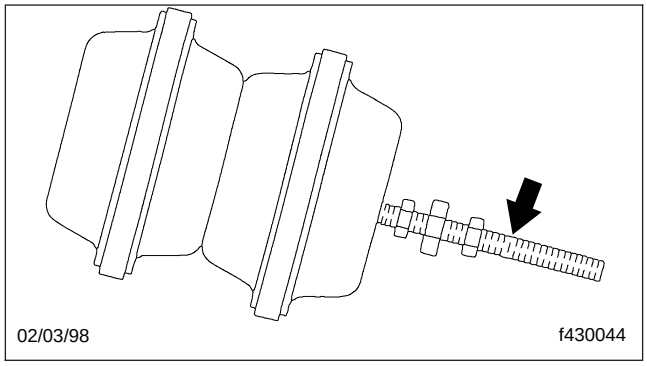

Fig. 7, Brake Chamber Push Rod Cut-off Position

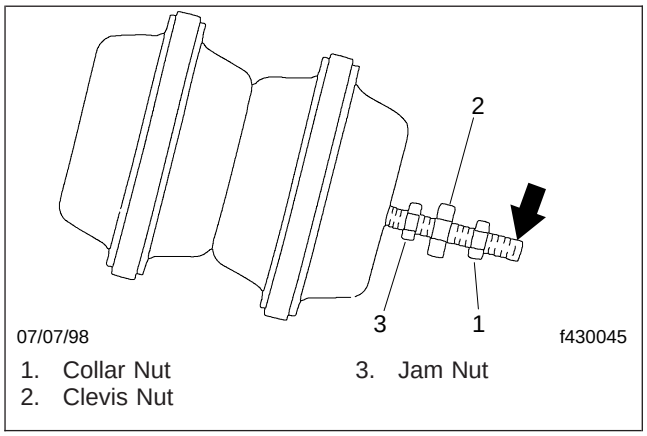

1. Collar Nut
2. Clevis Nut
3. Jam Nut

Fig. 8, Position of Nuts on the Slack Adjuster

Brake Chamber Free Stroke Checking

Free stroke is the amount of slack adjuster movement required to bring the brake shoes and linings into contact with the brake drum. Check the brake chamber free stroke as follows:

1. With the brakes released, measure and record the distance from the brake chamber face to the center of the large clevis pin. See **Fig. 1**.

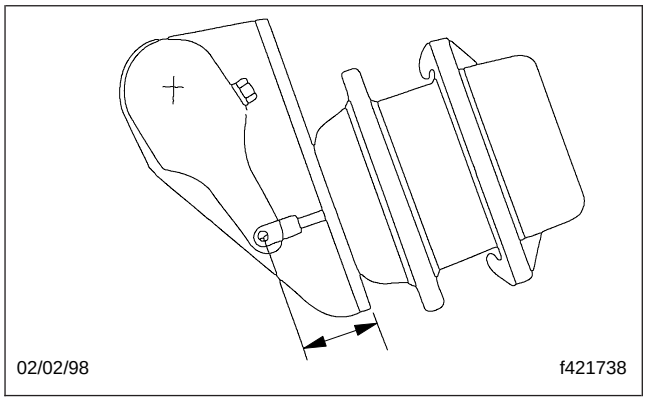

Fig. 1, Brake Chamber Face to Center of Large Clevis Pin Distance

2. Using a lever, extend and hold the brake chamber push rod at the point at which the brake shoe and lining is felt to come into contact with the brake drum.
3. Make the same measurement as in the previous step. See **Fig. 2**.

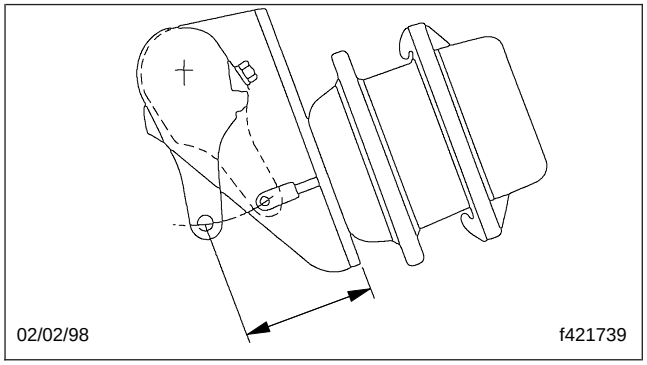

Fig. 2, Measurement with Brake Application

4. Subtract the measurement from the previous step to obtain the free stroke measurement.
5. For a properly installed slack adjuster and properly adjusted brakes, the free stroke must be 3/8 to 5/8 inch (10 to 16 mm). A free stroke that is longer than specified is caused by a worn or damaged slack adjuster. If the slack adjuster is OK, inspect the foundation brakes for proper installation, missing, worn or damaged parts. Correct as necessary. Recheck the brake chamber free stroke.

Specifications

Torque Specifications	
Description	**lbf·ft (N·m)**
Slack Adjuster Hex Extension (Counterclockwise, Maximum)	15 (20)

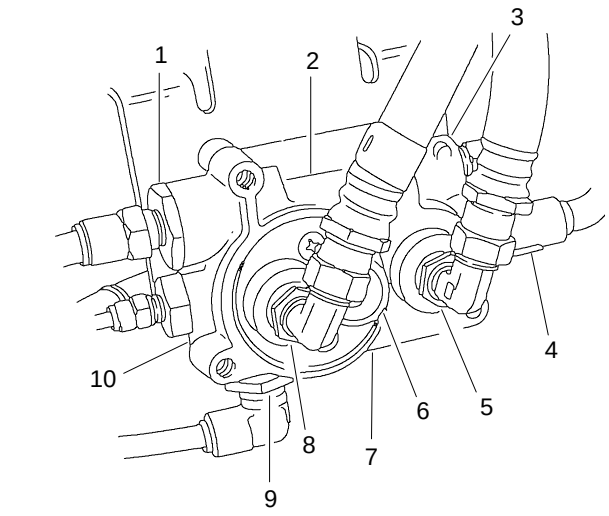
General Information (See Fig. 1)



07/07/98 f430061

1. Primary Circuit Delivery Port
2. Tractor Protection Valve
3. Secondary Delivery Port
4. Trailer Parking Control Port (from trailer air supply control valve)
5. Trailer Parking Supply Port (to trailer parking brakes)
6. Exhaust Port
7. Vent (not shown)
8. Trailer Service Supply Port (to trailer service brakes)
9. Trailer Control Port (from trailer brake hand control valve)
10. Service Line Shut-Off Control Port

Fig. 1, Tractor Protection Valve

The tractor protection valve (TPV), as required by United States Federal law, protects the tractor brakes in the event of trailer breakaway or a severe air system leak. When used with a dash-mounted trailer supply control valve, the trailer protection valve can be used to shut off the trailer control line before the trailer is disconnected.

The TPV also includes an integral single check valve which prevents air from getting trapped in the trailer control line. Trapped air in this line could cause service/spring brake compounding and, if the trailer is parked with air applied, a trailer roll-away situation can occur. See **Fig. 2** for the tractor protection valve and related plumbing.

Initial Charge

Pushing in the red trailer air supply knob on the instrument panel causes air to flow into the tractor protection valve at the tractor supply port. Air flows through the valve housing, exiting via the auxiliary supply port (if used) and the trailer supply port, to pressurize the trailer brake system and release the trailer parking brakes.

As air pressure builds in the trailer supply circuit, the single check valve seats, and the valve plunger begins to move (against spring pressure) toward the guide. When pressure reaches about 45 psi (310 kPa), the plunger bottoms against the guide and the inlet valve is open.

The tractor protection valve is in the "Run" mode, and ready to receive and deliver a service brake application from either the foot brake control valve or the hand valve.

Service Brake Application

When the foot brake control valve is pressed, air flows to the tractor protection valve tractor control primary and secondary ports. If the trailer control valve is also used, the external double check delivers the higher pressure (trailer control or foot control valve secondary) to the TPV tractor control secondary port.

Inside the tractor protection valve, the higher pressure (primary or secondary) moves the diaphragm to seal off the port at the lower pressure.

With the plunger bottomed against the guide and the inlet valve open (as described earlier), the higher pressure air flows through the valve to the trailer control port and the stop lamp switch, applying the brakes and activating the stop lamps.

NOTE: While air pressure also reaches the single check valve, the valve stays closed because supply pressure is acting on the other side.

Service Brake Release

When the foot pedal is released, air stops flowing into the tractor protection valve at the tractor control primary or secondary port. At the same time, air in

4. Stop Lamp Switch
5. Pass-Thru Grommet
6. Tractor Protection Valve
7. Relay Valve

Fig. 2, Tractor Protection Valve Plumbing Diagram

the trailer control line returns to the valve, flowing back through the open inlet valve.

The air forces the diaphragm to seat, sealing off the tractor control primary port. The air then exits the valve at the tractor control (secondary) port and flows to the foot brake control valve or hand valve where it is exhausted.

Tractor Protection

If the red trailer air supply knob on the instrument panel is pulled out (or if a large leak develops in the trailer supply circuit), pressure in the trailer supply circuit (and the auxiliary supply circuit, if used) is vented. When pressure drops to about 20 to 30 psi (138 to 207 kPa), the pressure can no longer overcome the spring force inside the tractor protection valve and the inlet valve closes.

With the inlet valve closed, air pressure from the brake foot or hand control valves will not reach the trailer control circuit when the brakes are applied.

Anti-Compounding

If the red trailer air supply knob on the instrument panel is pulled out while the service brakes are applied, the single check valve in the tractor protection prevents simultaneous spring and service brake application. As pressure in the trailer supply circuit drops, the spring in the tractor protection valve forces the inlet valve closed (as described above in "Tractor Protection"). Any pressure in the trailer control circuit is relieved by passing first through the single check valve and then exhausting at the trailer supply valve.

If the service brakes (hand or foot) are released and applied again, the closed inlet valve prevents air pressure from reaching the trailer control circuit.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

10. Double Check Valve
11. Trailer Control Valve
12. Parking Brake Valve
13. To Tractor Spring Brakes

Fig. 1, Tractor Protection Valve Plumbing

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the batteries.
3. Drain the air system.
4. Remove the trailer hose assemblies from the TPV. Disconnect the tractor service and supply lines. Mark the lines for later assembly reference. Cap the air lines tightly to keep out contaminants.
5. Remove the fasteners attaching the TPV to the vehicle, then remove the valve.

Installation

1. Install the tractor protection valve on the vehicle, and install the attaching bolts, washers, and nuts. Tighten the fasteners 11 to 15 lbf·ft (15 to 20 N·m).
2. Remove the caps from the air lines, connect the air hoses to the correct valve ports, and tighten the nuts finger-tight. Use a wrench to tighten the nuts at least two turns, or until no threads show on the fitting.
3. Close the drain cocks to the air reservoirs and pressurize the air system.
4. Leak test the valve following the instructions in Subject 120.
5. Connect the batteries.
6. Remove the chocks from the tires.

Leakage Test

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Chock the tires, start the engine, and run it until the air system is fully charged.
2. Shut down the engine and place the trailer air supply valve in the emergency position.
3. Disconnect the trailer control line hose coupling and apply a soap-water solution to the coupling.
4. With tractor reservoirs charged to at least 100 psi (689 kPa) make and hold a full service brake application using either the foot valve or the trailer control valve. Leakage at the hose coupling should not exceed a 1-inch (2.5-cm) bubble in five seconds.
5. Release the service brake application and place the trailer supply valve in the "Run" position. Connect the trailer control valve to a test gauge.
6. Make a service brake application and note that service air pressure is present at the trailer control line hose coupling.
7. Disconnect the air line at the TPV tractor control port (primary), plug the line, and apply a soap-water solution to the valve.
8. Make a service brake application and check for leakage at the open tractor control port. Leakage should not exceed a 1-inch (2.5-cm) bubble in five seconds.
9. Reconnect the air line to the tractor control port (primary) and disconnect the air line at the tractor control port (secondary). Then, plug the disconnected line and apply a soap-water solution to the valve.
10. Make and service brake application and check for leakage at the open tractor control port. Leakage should not exceed a 1-inch (2.5-cm) bubble in five seconds.

IMPORTANT: If the valve does not function as described, or if leakage is excessive, repair or replace the valve.

Disassembly, Cleaning and Inspection, and Assembly

11. Collar
12. O-Ring
13. Plunger O-Ring
14. Plunger O-Ring
15. Valve Body

Fig. 1, Tractor Protection Valve

⚠ CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Remove the valve from the vehicle, retaining the mounting hardware. For instructions, see Subject 120.
2. Scribe a line across the valve cover and valve body to ensure proper alignment during assembly.

Disassembly, Cleaning and Inspection, and Assembly

3. Remove the two 1/4-inch screws that secure the valve cover to the valve body and allow the valve spring to expand until the valve cover can be removed.
4. Remove the cover O-ring and discard it.
5. Remove the diaphragm from the valve body and discard it.
6. Remove the guide from the valve body.
7. Remove the O-rings from the guide and discard them.
8. Remove the valve spring from the plunger, then the plunger from the valve body.
9. Remove the O-rings from the plunger and discard them.
10. Remove the collar and the O-ring from the plunger. Discard the O-ring, but keep the collar.

Cleaning and Inspection

⚠ WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the valve in cleaning solvent, then dry them using compressed air.
2. Examine the cover, body, guide, and plunger for corrosion, excessive wear, cracks, or other damage. If any of these conditions are found on a part, replace the part with a new one.
3. Check the spring for distortion and corrosion. If the spring is distorted or corroded, replace it.
4. Check the valve body bores for deep scratches or gouging.

Assembly

1. Lubricate the O-rings, O-ring grooves, body bores, and all sliding parts with the lubricant provided in the overhaul kit (Bendix silicone lubricant #291126 or equivalent).
2. Install the O-rings on the plunger.
3. Install the O-ring on the plunger and then the collar over the O-ring. Make sure that the collar is fully seated and firmly in place over the O-ring.
4. Install the plunger into the valve body and the spring into the plunger.
5. Install the O-rings in their grooves on the guide.
6. Align the indexing tab on the guide with the notch in the valve body and install the guide in the valve body.
7. Place the diaphragm in its recess on the guide.
8. Place the O-ring on the cover.
9. Place the cover on the guide and press them down, against spring pressure, until the cover is seated against the valve body.
10. Install the two 1/4-inch screws and tighten them 30 to 60 lbf·in (340 to 675 N·cm).
11. Install the valve on the vehicle following the instructions in **Subject 120**.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

Removal and Installation, Left-Hand-Drive Vehicle

Removal

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drive out and remove the foot control valve pin. See **Fig. 1**.

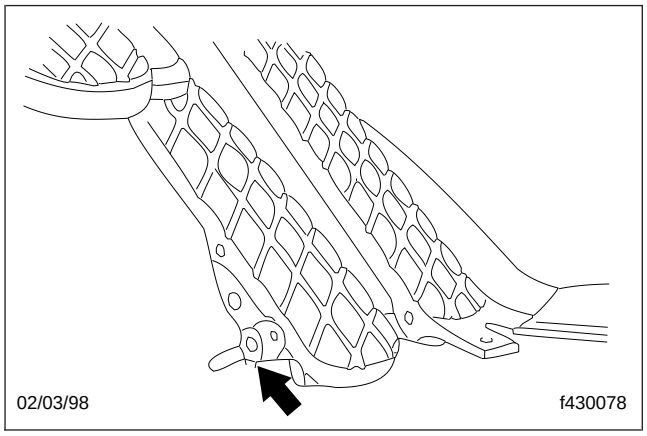

Fig. 1, Foot Control Valve Pin

3. Remove the fulcrum shaft and the brake pedal. See **Fig. 2**.

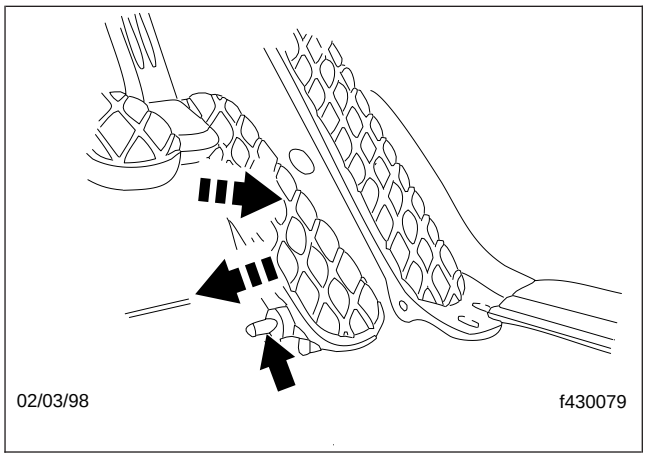

Fig. 2, Fulcrum Shaft and Brake Pedal

4. Remove the screws. See **Fig. 3**.

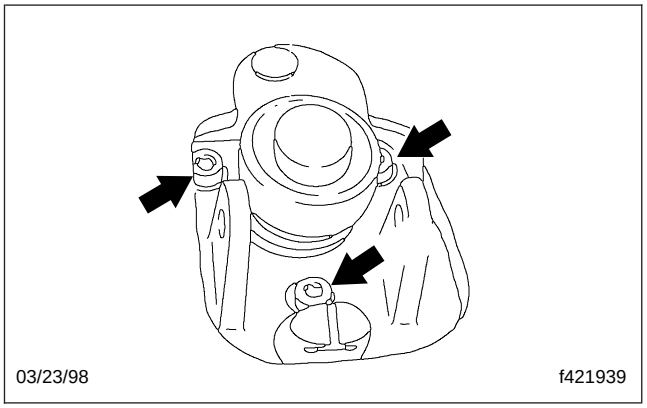

Fig. 3, Foot Valve Footwell

NOTE: Removing the left-side fender well eases access to the foot control valve air lines.

5. Remove the five fender well capscrews. See **Fig. 4**.

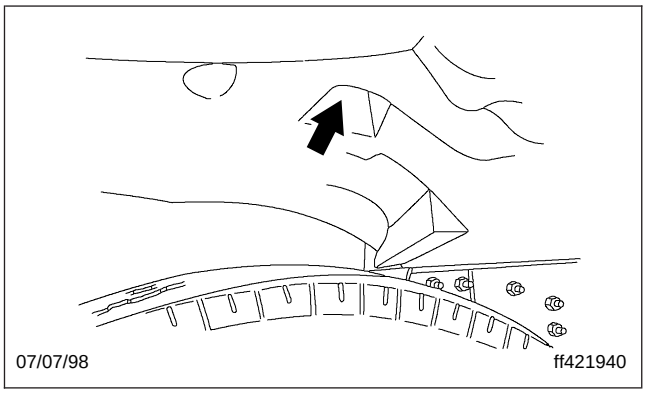

Fig. 4, Fender Well Access

6. Remove the left-side fender well. See **Fig. 5**.

NOTE: The air line fittings are all of the quick-disconnect type.

7. Remove the foot control valve.
   - 7.1 Tag and disconnect the air lines. See **Fig. 6**.
   - 7.2 Remove the foot control valve.
8. Beneath the floor, remove the five nuts. See **Fig. 7**.
9. Remove the reinforcement plate. See **Fig. 8**.

Removal and Installation, Left-Hand-Drive Vehicle

10. Remove the pedal bracket. See **Fig. 9**.

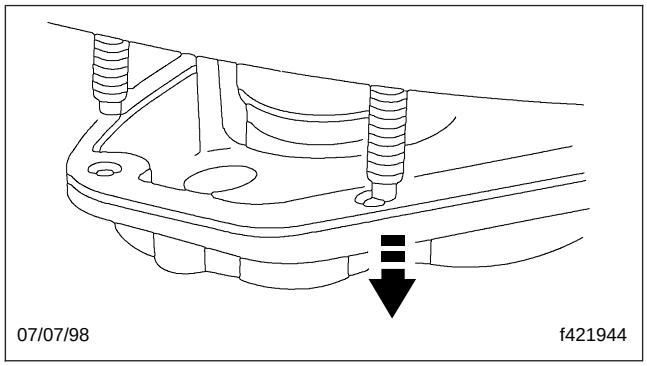

Fig. 8, Reinforcement Plate

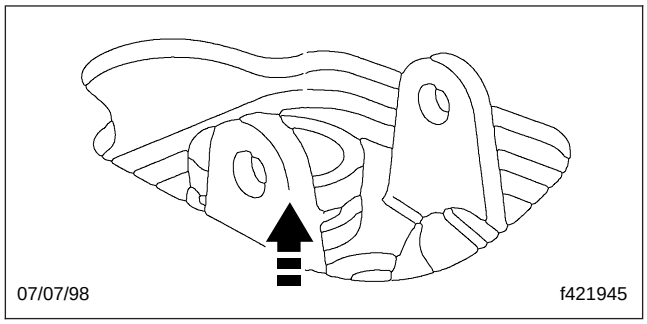

Fig. 9, Pedal Bracket

Installation

NOTE: An assistant is necessary to position the foot control valve while the capscrews are installed from inside the cab.

1. Install the fulcrum shaft and the brake pedal. See **Fig. 2**.
2. Install the left side fender well.
3. Install the five fender well capscrews.
4. Install the foot control valve.
   - 4.1 Connect the air lines.
   - 4.2 Install the foot control valve.
5. Beneath the floor, install the five nuts. See **Fig. 7**.
6. Install the reinforcement plate.
7. Install the pedal bracket.
8. Install the foot control valve pin. See **Fig. 1**.
9. Remove the chocks from the tires.

Removal and Installation, Right-Hand-Drive Vehicle

Removal (See Fig. 1)

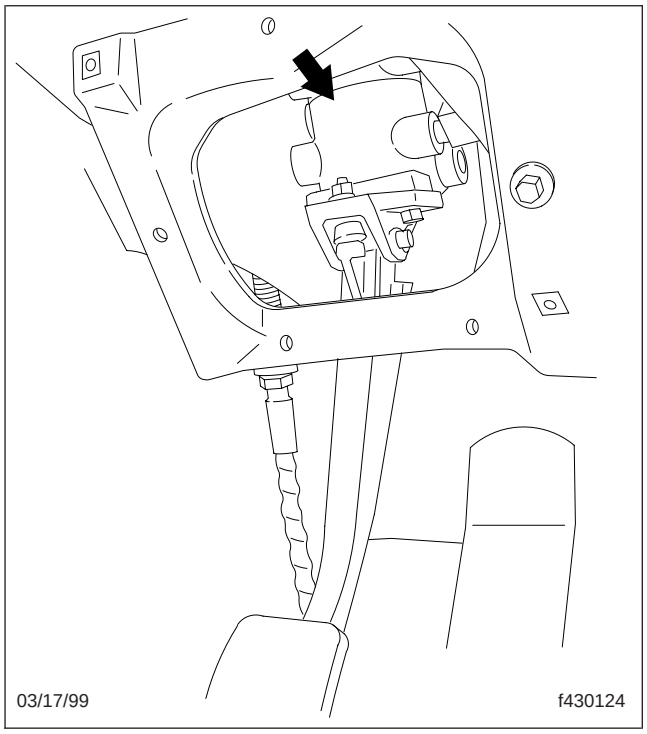

Fig. 1, Foot Brake Control Valve

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the battery.
3. Drain the air system.
4. Remove the under steering panel.
5. Disconnect the electrical connectors.
6. Disconnect and mark the air lines.
7. Remove the foot brake control valve assembly retaining bolts. See Fig. 2.
8. Remove the foot brake control valve assembly.

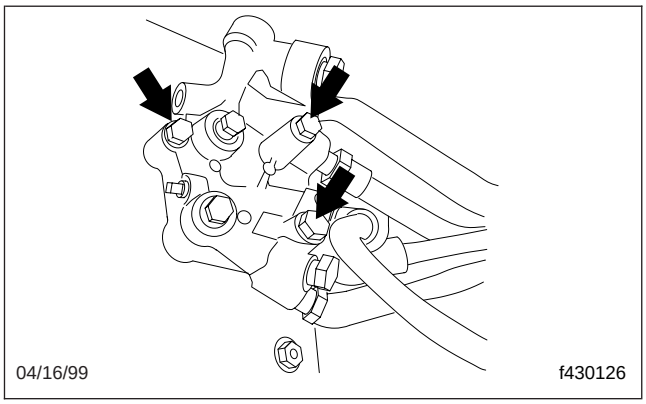

Fig. 2, Brake Control Treadle Valve and Assembly Bolts

Installation

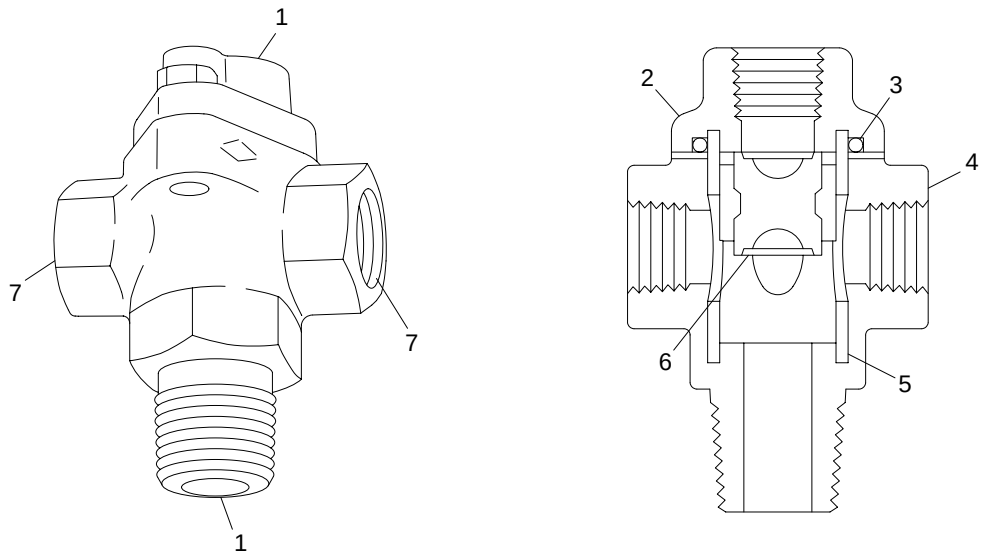
NOTE: An assistant is necessary to position the foot control valve assembly on the three bolts that are installed through the brake control treadle valve and assembly under the hood.

1. Position the foot brake control valve assembly.
2. Install the retaining bolts.
3. Connect the air lines.
4. Connect the electrical connectors.
5. Install the under steering panel.
6. Connect the battery.
7. Remove the chocks from the tires.

General Information (See Fig. 1)

Sterling vehicles use one or two shuttle type double check valves. If a vehicle is equipped with a trailer control valve it has two double check valves. Otherwise, most other vehicles will only have one. A shuttle type valve has a movable shuttle to seal off the lower pressure source. The valves are screwed into the forward side of the foot brake valve.

Double check valves are used in the air brake system to direct a flow of air into a common line from either of two sources, whichever is at the higher pressure.



1. Supply Port
2. End Cap
3. O-Ring
4. Valve Body
5. Shuttle Guide
6. Shuttle Valve
7. Delivery Port

Fig. 1, Double Check Valve

Principles of Operation

As pressurized air enters either end of the double check valve inlet port, the moving shuttle responds to the greater pressure source and seals the opposite port. The air flow continues out the delivery port of the valve. The position of the shuttle will reverse if the pressure levels are reversed. Double check valves are designed so the shuttle cannot interfere with the backflow of air in the exhaust mode.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

Removal

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air tanks.
3. Tilt the hood.
4. Remove the ziptie holding the air lines together.

NOTE: To disconnect the air lines, push the hose in, push the retaining ring in and pull out the hose in a swift motion.

5. Mark the air lines and disconnect them.
6. Remove the bolt and remove the valve. See Fig. 1.

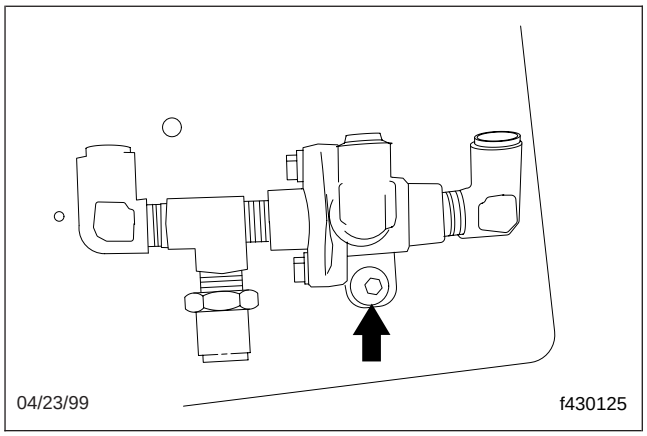


Fig. 1, Double Check Valve Bolt

Installation

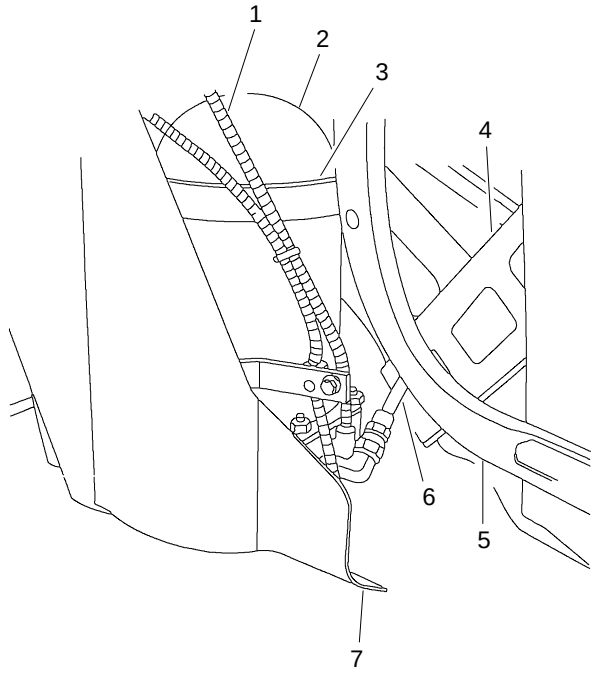
1. Install the double check valve. Tighten the bolt.
2. Connect the air lines.
3. Close the hood.
4. Remove the chocks from the tires.

General Information

The air dryer receives the compressed air from the air compressor and removes excess moisture and contaminants.

Two types of air dryers are available: the Bendix AD–9 and the Bendix AD–IP. The AD–9 air dryer must be removed from the vehicle to change the desiccant cartridge. The AD–IP air dryer desiccant cartridge can be changed on-vehicle. To determine which type is in use, note whether the air dryer is equipped with a clamp around the upper end of the desiccant canister. The AD–9 has a clamp around the upper end of the desiccant canister and the AD–IP does not. See **Fig. 1**.

Follow the manufacturer's instructions when replacing the desiccant cartridge.



07/07/98 f430056

1. Tubing (to governor)
2. Air Dryer
3. Clamp
4. Battery Support Brace
5. Fender Brace (left-side)
6. Braided Shield Tubing (from compressor)
7. Splash Shield

Fig. 1, AD-9 Air Dryer

Removal

WARNING

Before working on, or around, air brake systems and components, read "Safety Precautions" in Section 42.01. Failure to do so can result in personal injury.

NOTE: Air dryer removal is easier with the wheels turned all the way to the right.

This procedure covers the Bendix AD–9 and AD–IP air dryers.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Relieve system air pressure.
3. Release the wiring harness and shield bracket by removing the nut and bolt. See Fig. 1.

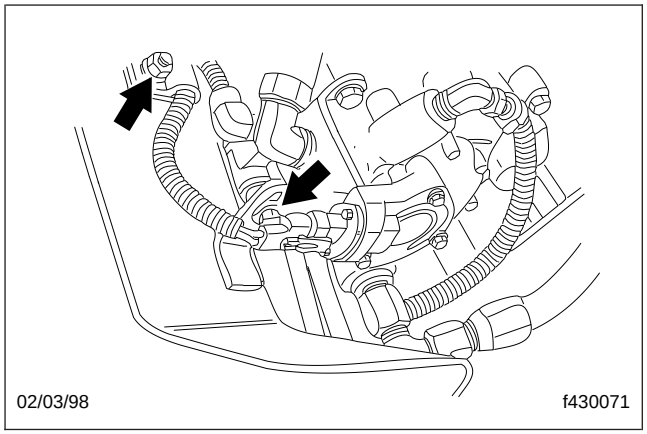


Fig. 1, Wiring Harness and Bracket Nuts

IMPORTANT: A-Line models are equipped with an inner fender splash guard. The splash guard and mounting bracket must be removed to access the air dryer.

4. Remove the nuts and bolts. Remove the air dryer shield. See Fig. 2.

NOTE: The 1/4-inch (6.4-mm) governor signal line is the quick-disconnect type.

Tag the air lines to aid installation, noting their orientation.

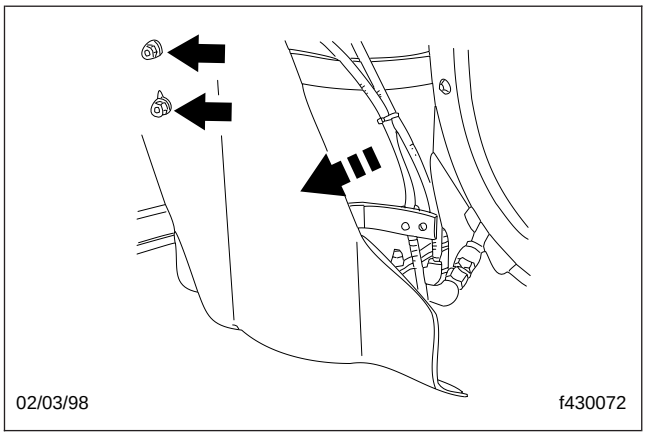

Fig. 2, Air Dryer Shield Nuts and Bolts

Note the orientation of the air dryer ports relative to the vehicle.

5. Disconnect the following (see Fig. 3):

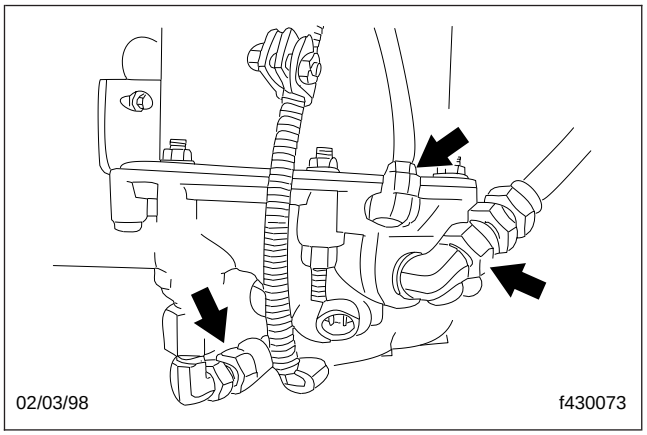

Fig. 3, Electrical Connector and Air Lines

- electrical connector
- governor signal air line
- supply air line from the air compressor
- delivery air line to the reservoir

CAUTION

To avoid breaking the canister-to-base seal, do not remove the canister-to-base nuts.

IMPORTANT: Support the air dryer while removing the bolts.

Air Dryer Removal and Installation

6. Remove the air dryer support bracket nuts and bolts.
7. Remove the clamp bracket nuts and bolts and remove the air dryer.

Installation

NOTE: Air dryer installation is easier with the wheels turned all the way to the right.

Support the air dryer while installing the mounting bolts.

1. Install the air dryer.
2. Tighten the air dryer support bracket nuts and bolts 23 to 29 lbf·ft (31 to 40 N·m). See **Fig. 4**.

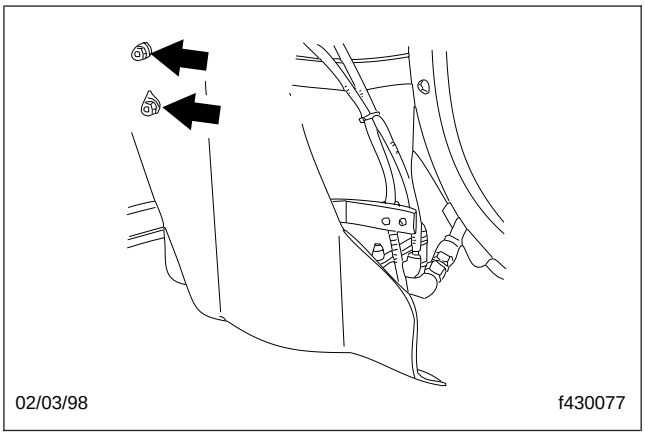

Fig. 4, Air Dryer Shield Nuts and Bolts

3. Install the air dryer clamp bracket nuts and bolts. Tighten them 26 to 33 lbf·in (36 to 45 N·m).
4. Install the air dryer shield, nuts and bolts. See **Fig. 2**.

NOTE: The 1/4-inch (6.4-mm) governor air line is the quick-disconnect type.

5. Connect the following (see **Fig. 3**):
   - electrical connector
   - governor air line
   - supply air line from the air compressor
   - delivery air line to the reservoir
6. Position the wiring harness and install the shield bracket. See **Fig. 1**.
7. Remove the chocks from the tires.
8. Start the vehicle and check for air leaks and proper operation.

Bendix AD–9 Disassembly, Cleaning, Inspection, and Assembly

Disassembly (See Fig. 1)

⚠ WARNING

Before working on, or around, air brake systems and components, read "Safety Precautions" in Section 42.01. Failure to do so could result in personal injury.

⚠ CAUTION

While servicing the air dryer, do not use a clamping device (vise, C-clamp, etc.) to hold any die cast aluminum part, as damage may result. To hold the end cover, install a pipe nipple in the supply port, and clamp the nipple in a vise.

NOTE: As a convenience when rebuilding the air dryer, several replacement parts and maintenance kits are available that do not require full disassembly. Use the instructions provided with these parts or kits.

1. Remove the air dryer from the vehicle. Refer to Subject 100.
2. Remove the check valve assembly and O-ring. Remove the O-ring from the check valve assembly.
3. Remove the purge valve housing assembly.
   - 3.1 Remove the three self-tapping screws that secure the purge valve housing assembly to the end cover assembly.
   - 3.2 Pull the purge valve housing assembly out of the end cover assembly.
   - 3.3 Remove and discard the three O-rings from the exterior of the purge valve housing assembly.

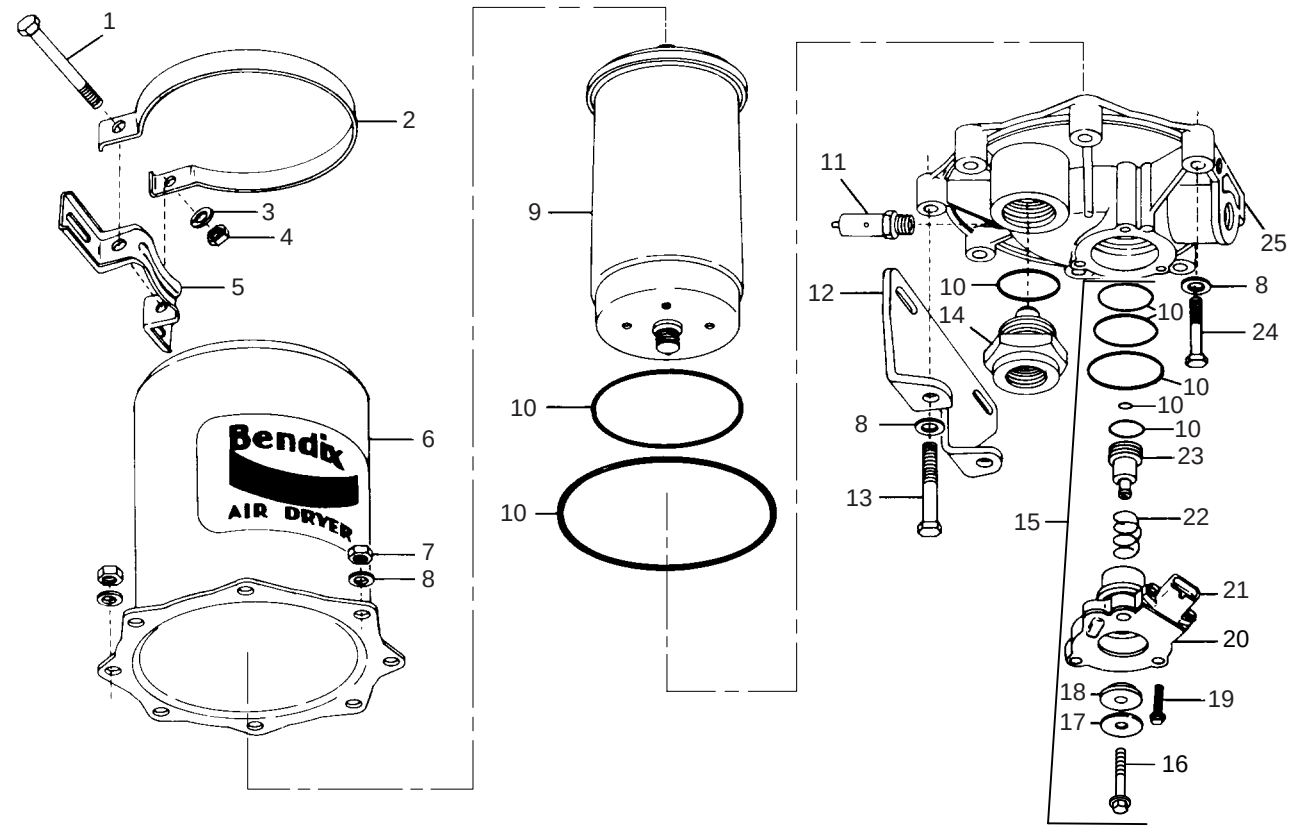
   NOTE: These O-rings may lodge in and have to be removed from the end cover bores.
4. Remove the heater and thermostat assembly.
   - 4.1 Remove and discard the two screws that attach the heater and thermostat assembly to the purge valve housing.
   - 4.2 Gently rotate the electrical connector to the left until the thermostat clears the purge valve housing. Slide the heater element out to the right and up. Discard the assembly.
5. Disassemble the purge valve housing assembly.
   - 5.1 If a flat non-extended exhaust cover is used, leave it intact while servicing the purge valve housing assembly.

     If an extended type exhaust cover is used for the attachment of an exhaust hose, *carefully* separate the exhaust cover from the purge valve housing. *Use a thin flat blade to pry the exhaust cover off, taking care not to damage the potting material (RTV sealant) under the cover.*
   - 5.2 Remove the bolt from the bottom of the purge valve housing assembly. Remove the diaphragm and the purge valve from the purge valve housing.
   - 5.3 Remove the purge piston, the return spring and two O-rings (one on the outside and the other in the inside of the purge piston).
6. Remove the remaining six capscrews, locknuts, and 12 special washers that secure the end cover to the housing. Separate the end cover and desiccant cartridge from the housing.
7. Remove the end-cover-to-outer-housing O-ring.
8. Do not remove the safety valve from the end cover unless it is known to be inoperative. If replacement is needed, apply thread sealant or Teflon® tape on the threads of the replacement valve and tighten 120 to 400 lbf·in (1360 to 4520 N·m). Make sure the drain hole (slot) is facing down.

NOTE: It may be necessary to apply up to 50 lbf·ft (68 N·m) of torque to separate the desiccant cartridge from the end cover.

9. Place a strap or chain wrench around the desiccant cartridge so that it is about 2 to 3 inches (5 to 8 cm) away from the end cover. Rotate the cartridge counterclockwise until it completely separates from the end cover.
10. Remove the desiccant cartridge O-ring from the end cover.

Bendix AD–9 Disassembly, Cleaning, Inspection, and Assembly



08/09/95 f421383

1. 5/16-Inch x 4-1/2-Inch Upper Bracket Capscrew
2. Upper Bracket Strap

24. 3/8-Inch Capscrew
25. End Cover

Fig. 1, AD-9 Air Dryer (exploded view)

Cleaning and Inspection

1. Wash all metal parts thoroughly, using a quality commercial solvent, such as mineral spirits.
2. Check for severe corrosion, pitting, and cracks on the inside and outside of all metal parts that will be reused. Superficial corrosion and pitting on the outside of the upper and lower body halves is acceptable.
3. Inspect the bores of both the end cover and the purge valve housing for deep scuffing or gouges.

4. Make sure that all purge valve housing and end cover passages are open and free of blockages.
5. Inspect the pipe threads in the end cover. Make sure they are clean and free of thread sealant.
6. Inspect the purge valve housing bore and seats for excessive wear and scuffing.
7. Inspect the purge valve piston seat for excessive wear.
8. Inspect all air line fittings for corrosion. Clean all old thread sealant from the pipe threads.
9. Replace all removed O-rings with new ones that are provided in the kits.
10. Replace parts that show any of the conditions described in the previous steps.

Assembly (See Fig. 1)

WARNING

Before working on, or around, air brake systems and components, read "Safety Precautions" in Section 42.01. Failure to do so could result in personal injury.

1. Before and during assembly, coat all O-rings, O-ring grooves, and bores with a generous amount of barium-based lubricant unless otherwise advised.

IMPORTANT: When installing the heater and thermostat assembly, make sure that the seal ring under the electrical connector is not twisted.

2. Install the heater and thermostat assembly.
   - 2.1 Insert the heater element into the slot in the purge valve housing until the connector contacts the housing.
   - 2.2 Gently push the connector and the thermostat to the left until the thermostat clears the cavity in the housing. Turn the connector to the right while pushing the thermostat all the way down into the cavity.

     Make sure that the connector is seated evenly against the housing.
   - 2.3 Install the two mounting screws. Tighten the screws 10 to 20 lbf·in (113 to 226 N·cm).
3. Assemble the purge valve housing.
   - 3.1 Install the O-ring on the purge piston. Place the return spring in the purge valve housing. Place the O-ring in the bore of the purge piston. Insert the purge piston into the spring. Push the piston into the purge valve housing until it bottoms.
   - 3.2 While holding the purge piston in, install the purge valve with its rubber side first, followed by the diaphragm and the bolt. Torque the purge valve bolt 60 to 80 lbf·in (680 to 900 N·cm).
   - 3.3 Install the three O-rings in their correct locations on the purge valve housing.
   - 3.4 If an extended type exhaust cover was removed, install it on the purge valve housing assembly, making sure the "bubble" portion is positioned over the thermostat.
   - 3.5 Install the assembled purge valve housing in the end cover; make sure you orient both parts so that the connector is about 10 degrees clockwise from the supply port. Also, make sure the purge valve housing is fully seated against the end cover.
   - 3.6 Secure the purge valve housing to the end cover using the three self-tapping screws. Start all three screws by hand, then torque them 85 to 125 lbf·in (960 to 1400 N·cm).
4. Install an O-ring on the check-valve assembly. Install the assembly in the end cover using a socket. Tighten it 200 to 250 lbf·in (2260 to 2820 N·cm).
5. Install the desiccant cartridge in the end cover.
   - 5.1 Install the smaller desiccant cartridge O-ring in its groove in the end cover. Using a light coat of barium grease, lubricate the bottom of the desiccant cartridge in the area that will contact the O-ring and end cover.

Bendix AD–9 Disassembly, Cleaning, Inspection, and Assembly

5.2 Screw the desiccant cartridge into the end cover until the cartridge contacts the O-ring. Using a strap or chain wrench positioned 2 to 3 inches (5 to 8 cm) from the bottom of the cartridge, turn the desiccant cartridge clockwise 180 to 225 degrees beyond the position where initial contact was made with the O-ring. Torque should not exceed 50 lbf·ft (68 N·m).

6. Install the housing over the desiccant cartridge.

6.1 Install the large O-ring on the shoulder in the end cover. Place the housing over the desiccant cartridge and align the holes.

6.2 Install the 6 capscrews, locknuts, and the 12 special washers, making sure they are positioned as referenced earlier. The 2 longer capscrews will be used to secure the air dryer to its mounting bracket.

6.3 Tighten the six capscrews and nuts in a star pattern (depending on lower bracket location) 270 to 385 lbf·in (3060 to 4340 N·cm). See **Fig. 2**.

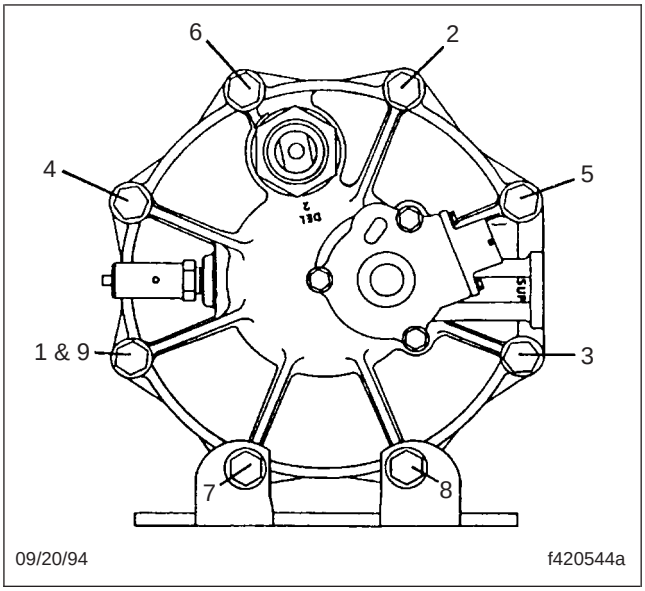

Fig. 2, End Cover-to-Housing Torque Pattern

NOTE: The two remaining bolt holes in the end cover and two 3/8-inch capscrews must be the ones marked during removal to ensure correct orientation of the ports and adequate length of the capscrews.

7. Connect the electrical connector to the heater and thermostat assembly.

Bendix AD–IP Disassembly, Cleaning, Inspection, and Assembly

Disassembly (See Fig. 1)

⚠ WARNING

Before working on, or around, air brake systems and components, read "Safety Precautions" in Section 42.01. Failure to do so could result in personal injury.

⚠ CAUTION

While servicing the air dryer, don't use a clamping device (vise, C-clamp, etc.) to hold any die cast aluminum part, as damage may result. To hold the end cover, install a pipe nipple in the supply port, and clamp the nipple in a vise.

NOTE: As a convenience when rebuilding the air dryer, several replacement parts and maintenance kits are available that do not require full disassembly. Use the instructions provided with these parts or kits.

1. Remove the air dryer from the vehicle. Refer to Subject 100.
2. Loosen the cartridge bolt and remove the desiccant cartridge and the cartridge bolt from the end cover.
3. Remove the two O-rings from the cartridge bolt.
4. Remove the purge valve retaining ring.
5. Remove the purge valve assembly from the end cover.

NOTE: The exhaust diaphragm and the purge valve may come out when the purge piston bolt is removed.

6. Hold the purge piston with a large screwdriver and remove the purge piston bolt with a wrench.
7. Remove the exhaust diaphragm and the purge valve from the purge valve assembly.
8. Remove the O-rings from the purge valve assembly.
9. Remove the purge piston and the return spring.
10. Remove the O-ring from the purge piston.
11. Remove the delivery check valve retaining ring.
12. Remove and separate the perforated plate, check valve spring, check valve and O-ring from the end cover.
13. Remove the heater/thermostat retaining ring.
14. Carefully pull the heater and thermostat assembly and the O-ring from the end cover.
15. Remove the safety valve from the end cover.

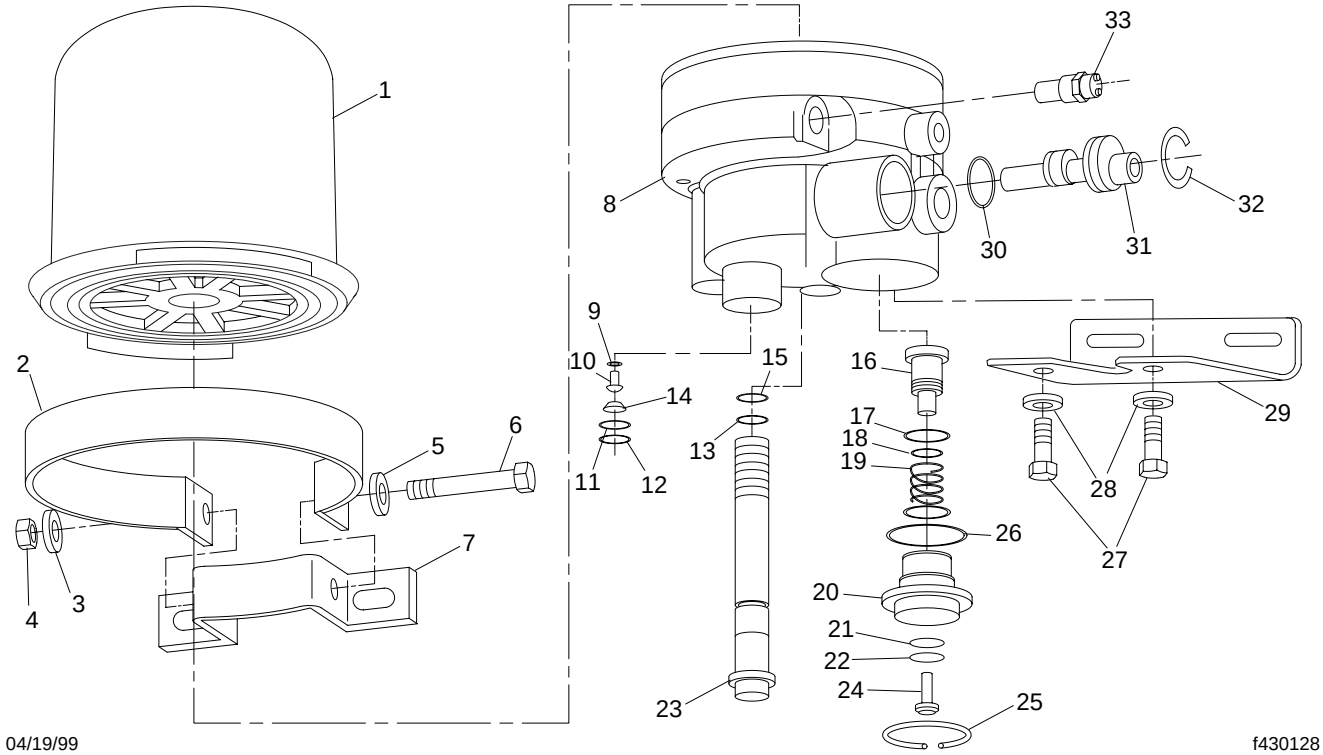
Cleaning and Inspection

1. Wash all metal parts thoroughly, using quality mineral spirits or an equivalent solvent.
2. Check for severe corrosion, pitting, and cracks on the inside and outside of all metal parts that will be reused. Superficial corrosion and pitting on the outside of the upper and lower body halves is acceptable.
3. Inspect the bores of both the end cover and the purge valve assembly for deep scuffing or gouges.
4. Make sure that all purge valve assembly and end cover passages are open and free of blockages.
5. Inspect the pipe threads in the end cover. Make sure they are clean and free of thread sealant.
6. Inspect the purge valve assembly bore and seats for excessive wear and scuffing.
7. Inspect the purge valve piston seat for excessive wear.
8. Inspect all air line fittings for corrosion. Clean all old thread sealant from the pipe threads.
9. Make certain that the purge orifice in the cartridge bolt is open and free of obstructions.
10. Replace all removed O-rings with new ones that are provided in the kits.
11. Replace parts that show any of the conditions described in the previous steps.

Assembly (See Fig. 1)

NOTE: Before assembly, coat all O-rings, O-ring grooves, and bores with a generous amount of silicone grease during assembly unless otherwise advised.

Bendix AD–IP Disassembly, Cleaning, Inspection, and Assembly



1. Desiccant Cartridge

29. Mounting Bracket
30. O-Ring
31. Heater and Thermostat Assembly
32. Heater/Thermostat Retaining Ring
33. Safety Valve

Fig. 1, AD-IP Air Dryer (exploded view)

1. Position the O-ring in its groove on the O.D. of the purge piston.
2. Position the return spring in the bore of the purge valve assembly.
3. Position the purge piston into the I.D. of the return spring.

NOTE: Make sure the exhaust diaphragm is over the shoulder of the purge piston bolt.

4. Position the exhaust diaphragm on the purge piston bolt.
5. With the metal support side against the exhaust diaphragm, position the purge valve on the purge piston bolt.

Bendix AD–IP Disassembly, Cleaning, Inspection, and Assembly

6. Holding the purge piston with a large screwdriver, position the purge piston bolt assembly into the purge valve assembly. Tighten the purge piston bolt to 60 to 80 lbf·in (70 to 90 N·cm).
7. Position the two O-rings on the purge valve assembly.

NOTE: Make certain that the purge valve retaining ring is fully seated in its groove.

8. Install the purge valve assembly in the end cover and secure with the purge valve retaining ring.
9. Install the safety valve.

IMPORTANT: Install with the vent hole pointing down. Tighten pipe threaded fittings a minimum of two turns past finger-tight. Position directional fittings in the tightening direction only.

10. Position the O-ring on the check valve body and push it down past the three guide lands until it seats in the O-ring groove.
11. Position the check valve spring on the check valve body so that the small coils of the spring slip over the check valve body.
12. Position the check valve assembly in the end cover so that the O-ring is seated and the check valve spring is visible.
13. Position the perforated plate over the check valve and secure with the check valve retaining ring. Make certain that the check valve retaining ring is fully seated.
14. Install the O-ring on the heated thermostat assembly and gently push the heater and thermostat assembly into the end cover.
15. Install the heater/thermostat assembly retaining ring.
16. Position the O-rings on the cartridge bolt.

NOTE: Make certain that the desiccant cartridge is fully seated and flush on the end cover.

17. Align the locking lugs and position the desiccant cartridge on the end cover.

⚠ CAUTION

Overtightening the cartridge bolt can cause it to shear.

18. Tighten the cartridge bolt to 50 lbf·ft (67 N·m).
19. Install the clamp ring, nut and bolt. Tighten the nut 60 to 190 lbf·in (70 to 110 N·cm).

Testing

During cold-weather operation, check the operation of the end cover heater and thermostat assembly.

1. With the ignition on, check for voltage to the heater and thermostat assembly. Unplug the electrical connector at the air dryer, and place the test leads on each of the pins of the male connector. If there is no voltage, look for a blown fuse, broken wires, or corrosion in the vehicle wiring harness. Check that a good ground path exists.
2. Check the thermostat and heater operation. Turn off the ignition switch and cool the end cover assembly to below 40°F (4°C). Using an ohmmeter, check the resistance between the electrical pins in the female connector. The resistance should be 1.5 to 3.0 ohms for the 12-volt heater assembly, and 6.8 to 9.0 ohms for the 24-volt heater assembly.

NOTE: Some early models of the AD–9 will have resistance readings of 1.0 to 2.5 ohms for the 12-volt heater assembly, and 4.8 to 7.2 ohms for the 24-volt heater assembly. If the resistance is higher than this, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

3. Warm the end cover assembly to over 90°F (32°C) and again check the resistance. It should exceed 1000 ohms. If it does, the thermostat and heater assembly is operating properly. If it doesn't, replace the purge-valve housing assembly, which includes the heater and thermostat assembly.

Problem—Air Dryer is Constantly Cycling or Purging

Problem—Air Dryer is Constantly Cycling or Purging	
Possible Cause	**Remedy**
Excessive system leakage	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is as follows: • Single Vehicle—1 psi/min (7 kPa/min) per service reservoir • Tractor/Trailer—3 psi/min (21 kPa/min) per service reservoir
There is excessive leakage in the fittings, hoses, and tubing connected to the compressor, air dryer, and wet tank	Using a soap solution, test for leakage at the fittings, drain valve, and safety valve in the wet tank. Repair or replace as needed.
The check valve assembly in the air dryer end cover is not working	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at the opposite end, and check for leakage. Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.
Governor is inoperative	Test the governor for proper cutin or cutout pressures and excessive leakage in both positions.
Leaking purge valve housing assembly or O-rings in the air dryer end cover	With the supply port open to atmosphere, apply 120 psi (830 kPa) at the control port. Apply a soap solution to the supply port and exhaust port (purge valve seat area). Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. Repair or replace as needed.
Compressor unloader mechanism is leaking excessively	Remove the air strainer or fitting from the compressor inlet cavity. With the compressor unloaded, check for unloader piston leakage. Slight leakage is allowed.
Holset "E" type compressor	Test the air dryer system. For instructions, refer to *Bendix Product Bulletin PRO-08-19* entitled "Troubleshooting the Holset "E" Compressor System with Bendix Air Dryer."
Lack of air at the governor RES port (rapid cycling of the governor)	Test the governor for proper pressure at the RES port. Pressure should not drop below cutin pressure when the compressor begins the unloaded cycle. If the pressure does drop, check for kinks or restrictions in the line connected to the RES port. The line connected to the RES port on the governor must be the same diameter, or larger than the lines connected to the UNL ports on the governor.

Problem—Water in the Vehicle Reservoirs

Problem—Water in the Vehicle Reservoirs	
Possible Cause	**Remedy**
Desiccant cartridge assembly contains excessive contaminants	Replace the desiccant cartridge.
Discharge line is of improper length or material	Discharge line must consist of at least 6 ft (1.8 m) of wire braid Teflon® hose, copper tubing, or a combination of both between the discharge port of the compressor and the air dryer supply port. Discharge line lengths and inside diameter requirements are dependent on the vehicle application. Contact your local Bendix representative for further information.
Air system was charged from an outside air source that did not pass through an air dryer	If the system must have an outside air fill provision, the outside air should pass through an air dryer. This practice should be minimized.
Air dryer is not purging	Refer to "Problem—Air Dryer Does Not Purge or Exhaust Air."

Troubleshooting

Problem—Water in the Vehicle Reservoirs	
Possible Cause	**Remedy**
Purge (air exhaust) is insufficient due to excessive system leakage	Refer to "Problem—Air Dryer is Constantly Cycling or Purging."
Air bypasses the desiccant cartridge assembly	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed.
Purge (air exhaust) time is significantly less than the minimum allowable	Replace the desiccant cartridge/end cover O-ring. Make sure the desiccant cartridge assembly is properly installed. Replace the desiccant cartridge assembly.
Excessive air usage; air dryer not compatible with vehicle air system	Install an accessory bypass system. Consult your Bendix representative for additional information.

Problem—Safety Valve on Air Dryer is Popping Off or Exhausting Air

Problem—Safety Valve on Air Dryer is Popping Off or Exhausting Air	
Possible Cause	**Remedy**
Desiccant cartridge is plugged or saturated	Check the compressor for excessive oil passing, or incorrect installation. Repair or replace as needed.
The check valve in the air dryer end cover is inoperative	Test to determine if air is passing through the check valve. Repair or replace as needed.
There is a problem in the fittings, hose, or tubing between the air dryer and the wet tank	See if air is reaching the first reservoir. Inspect for kinked tubing or hose. Check for undrilled or restricted hose or tubing fittings.
Safety valve setting is lower than the maximum system pressure	Reduce the system pressure, or install a safety valve with a higher pressure setting.

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure	
Possible Cause	**Remedy**
Air dryer purge valve is leaking excessively	With the compressor loaded, apply a soap solution on the purge valve exhaust to test for excessive leakage. Repair the purge valve as needed.
The governor is inoperative	Check the governor for proper cutin and cutout pressures, and excessive leakage in both positions. Repair or replace as needed.
Purge control line is connected to the reservoir or exhaust port of the governor	Connect the purge control line to the unloader port of the governor.
Purge valve is frozen open due to an inoperative heater or thermostat, bad wiring, or a blown fuse	Test the heater and thermostat, following instructions in this manual.
Inlet and outlet air connections are reversed; unable to build system pressure	Reconnect the lines properly.
Discharge line is kinked or blocked	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line; water is collecting and freezing	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.

Problem—Constant Exhaust of Air at the Air Dryer Purge Valve Exhaust; Unable to Build System Pressure	
Possible Cause	**Remedy**
System is leaking excessively	Test for excessive leakage. Eliminate leaks, as needed. Allowable leakage is as follows: • Single Vehicle—1 psi/min (7 kPa/min) per service reservoir • Tractor/Trailer—3 psi/min (21 kPa/min) per service reservoir
Purge valve stays open; supply air leaks to control side	Replace the purge valve assembly O-rings.

Problem—Air Dryer Does Not Purge or Exhaust Air

Problem—Air Dryer Does Not Purge or Exhaust Air	
Possible Cause	**Remedy**
Purge control line is broken, kinked, frozen, plugged, or disconnected	See if air flows through the purge control line when the compressor is unloaded. The purge control line must be connected to the unloader port of the governor.
Air dryer purge valve is not working	See if air reaches the purge valve. If it does, repair the purge valve.
The governor is inoperative	Check the governor for proper cutin and cutout pressures, and excessive leakage in both positions. Repair or replace as needed.
Inlet and outlet air connections are reversed; unable to build system pressure	Reconnect the lines properly.
Discharge line is kinked or blocked	See if air passes through the discharge line. Check for kinks, bends, or excessive carbon deposits.
There are excessive bends in the discharge line; water is collecting and freezing	Discharge line should be constantly sloping from the compressor to the air dryer with as few bends as possible.

Problem—Desiccant is Being Expelled from the Air Dryer Purge Valve Exhaust (May Look Like Whitish Liquid, Paste, or Small Beads); or, Unsatisfactory Desiccant Life

Problem—Desiccant is Being Expelled from the Air Dryer Purge Valve Exhaust (May Look Like Whitish Liquid, Paste, or Small Beads); or, Unsatisfactory Desiccant Life	
Possible Cause	**Remedy**
This problem usually occurs with one or more of the previous problems	Refer to the appropriate corrections listed previously.
Air dryer is not securely mounted; there is excessive vibration	Vibration should be held to a minimum. Tighten the mounting fasteners.
Cloth-covered perforated plate in the air dryer desiccant cartridge is damaged, or the cartridge was rebuilt incorrectly	Replace the plate or cartridge as needed. High operating temperatures may cause deterioration of filter cloth. Check the installation.
Compressor is passing excessive oil	Check for proper compressor installation; if symptoms persist, replace the compressor.
Heater and thermostat, wiring, or a fuse is at fault, and is not allowing the air dryer to purge during cold weather	Test the heater and thermostat, following instructions in this manual.

Troubleshooting

Problem—Desiccant is Being Expelled from the Air Dryer Purge Valve Exhaust (May Look Like Whitish Liquid, Paste, or Small Beads); or, Unsatisfactory Desiccant Life	
Possible Cause	**Remedy**
Desiccant cartridge not attached properly to the end cover	Check the torque and tighten if necessary. Refer to **Specifications, 400**.

Problem—Pinging Noise is Excessive During Compressor Loaded Cycle

Problem—Pinging Noise is Excessive During Compressor Loaded Cycle	
Possible Cause	**Remedy**
Pinging noise is due to a single cylinder compressor with high pulse cycles	A slight pinging sound may be heard during system build-up when a single cylinder compressor is used. If this sound is deemed objectionable, it can be reduced substantially by increasing the discharge line volume. This is done by adding a 90 in ^{3} (1475 cm ^{3}) reservoir between the compressor and the air dryer.

Problem—Constant Air Seepage at the Purge Valve (Non-Charging Mode)

Problem—Constant Air Seepage at the Purge Valve (Non-Charging Mode)	
Possible Cause	**Remedy**
Air compressor inlet is pressurized by the engine turbocharger	Some pressure leakage past the metal seat of the turbocharger cutoff feature of the AD–9 air dryer is normal, and may be heard. This slight loss of air will not affect the engine or turbocharger performance.
Check valve assembly in the air dryer end cover is not working	Remove the check valve assembly from the end cover. Apply compressed air to the delivery side of the valve. Apply a soap solution at the opposite end, and check for leakage. Permissible leakage is a 1-inch (2.5-cm) bubble in 5 seconds. If there is excessive leakage, replace the check valve assembly.

Problem—Air Dryer Purge Piston Cycles Rapidly in the Unloaded Mode

Problem—Air Dryer Purge Piston Cycles Rapidly in the Unloaded Mode	
Possible Cause	**Remedy**
Compressor does not "unload"	Check the governor installation. If there is no air line from the governor to the compressor, or the line is restricted, repair or replace as needed.

Specifications

General Information

Each vehicle is equipped with two or more air reservoirs, depending on the number of rear axles. On all vehicles, each reservoir is identified as one of three types: supply, primary, and secondary.

A supply reservoir receives compressed air directly from the compressor. Also referred to as the wet air tank, its functions are to collect most of the water and oil condensate from the air, and to supply air to the primary and secondary reservoirs. At the outlet port of the supply reservoir (the port leading to the primary reservoir) is a safety valve, which protects the air system against excessive air pressure build-up.

The primary air reservoir is the air source for the rear brakes. The front brakes are supplied by the secondary air reservoir. The combined volumes of all supply reservoirs are at least 12 times the combined volumes of all service brake chambers at maximum travel of the diaphragms.

The reservoirs are made from steel or aluminum and each reservoir is internally coated for corrosion resistance. Each reservoir is tested at 300 psi (2068 kPa) hydrostatic pressure.

Some reservoirs are of dual chamber configuration, and include an integral check valve between chambers. Dual chamber reservoirs must have a drain valve in each chamber.

The integral-type check valve used in the dual chamber reservoir is a means of providing a one-way passage of air from one chamber of the reservoir to the other chamber. This is to protect against the loss of the whole air supply in the event of a failure in part of the system.

Service involving welding should never be performed on reservoirs. If a reservoir has been damaged so as to be unfit for use, it should be replaced with a new one.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

Replacement

WARNING

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Mark all of the air lines, couplers, and valves for later assembly, then disconnect the components.
4. Cap the exposed ports tightly to keep out contaminants. If access is limited, remove the air reservoir components after removal.
5. Remove the air reservoir strap fasteners, then remove the air reservoir. See Fig. 1.

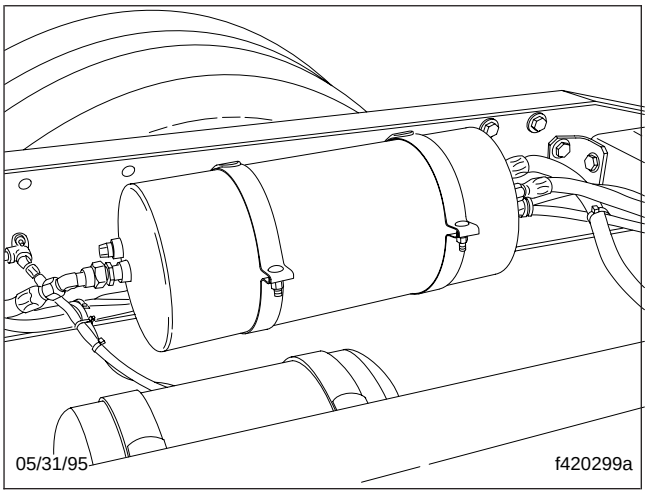

Fig. 1, Frame-Rail-Mounted Air Reservoir with Two-Piece Strap

6. If access is limited, connect the air lines, couplers, and valves first. If not, place a new reservoir in the mount, install the strap fasteners, then connect the components (air lines, couplers, and valves). Tighten the straps 20 to 25 lbf·ft (27 to 34 N·m).
7. Charge the air system and inspect for leaks. Repair as needed.
8. Remove the chocks from the tires.

Wet Air Tank Removal and Installation

Removal

WARNING

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air tanks.
3. Disconnect the air lines.
4. Loosen and disconnect the two clamps by removing the nuts.
5. Remove the wet air tank.

Installation

1. Place the wet air tank into the clamps. Support the tank.
2. Connect the clamps by tightening the nuts.
3. Connect the air lines.
4. Charge the air system and inspect for leaks. Repair as needed.
5. Remove the chocks from the tires.

Internal Check Valve Replacement

WARNING

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

Replacement

Contamination in the two-chamber, wet/secondary, reservoir may cause the inline check valve to become clogged or stuck closed. This can result in insufficient air buildup. Sterling vehicles were built with an internal check valve that is not serviceable. If insufficient air buildup is noted, install an external bypass line. Contact the PDC for the appropriate bypass kit for your vehicle.

1. Park the vehicle on a level surface, shut down the engine, and set the parking brake. Chock the tires.
2. Drain the secondary air reservoir.
3. At the top ports of the reservoir, remove the pressure-protection valve and the 90-degree elbow from the wet reservoir side, and the existing fittings from the secondary side.
4. Install a T-fitting on each side of the reservoir. See **Fig. 1**.
5. On the secondary reservoir side, install the existing plumbing on the top port of the T-fitting. On the side port of the T-fitting, install a check valve, then a 45-degree elbow.
6. On the wet reservoir side, install the existing plumbing onto the top port of the T-fitting. Install a brass fitting on the side port of the T-fitting.
7. Install a 1/2-inch air line between the 45-degree elbow on the secondary side, and the brass fitting on the wet side.
8. Charge the air system and inspect for leaks. Repair as needed.
9. Remove the chocks from the tires.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

Removal

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the batteries.
3. Release the system air pressure.
4. Remove the left-side outboard seat belt. For instructions, see **Group 91**.
5. Disconnect the left-side seat from the cab floor and move it forward to access the brake tube manifold. For instructions, see **Group 91**.
6. Remove the brake tube manifold cover retaining screws and remove the cover. See **Fig. 1**.
7. From beneath the cab, mark and disconnect the air lines. See **Fig. 2**.
8. Mark and disconnect the brake tube manifold electrical connectors. See **Fig. 1**.
9. Fold back the cab floor covering to access the brake tube manifold retaining bolts.
10. Remove the retaining bolts, then remove the brake tube manifold.

Installation

1. Position the brake tube manifold in the cab.
2. Install the retaining bolts. Tighten the bolts 5 to 7 lbf·ft (7 to 9 N·m).
3. From beneath the cab connect the air lines. See **Fig. 2**.
4. Connect the brake tube manifold electrical connectors. See **Fig. 1**.
5. Install the brake tube manifold cover and the four retaining screws. See **Fig. 1**.
6. Replace the cab floor covering to its original location.
7. Install the left-side seat. For instructions, see **Group 91**.
8. Install the left-side outboard seat belt. For instructions, see **Group 91**.
9. Connect the batteries.
10. Remove the chocks from the tires.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

Observe these warnings while investigating all applicable brake system concerns.

⚠ CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air tanks.
3. Tilt the hood.
4. Remove the ziptie holding the air lines together.

NOTE: To disconnect the air lines, push the hose in; push the retaining ring in and pull out the hose in a swift motion.

5. Mark and disconnect the air lines.
6. Loosen and remove the three bolts on the treadle valve and assembly. See **Fig. 1**.

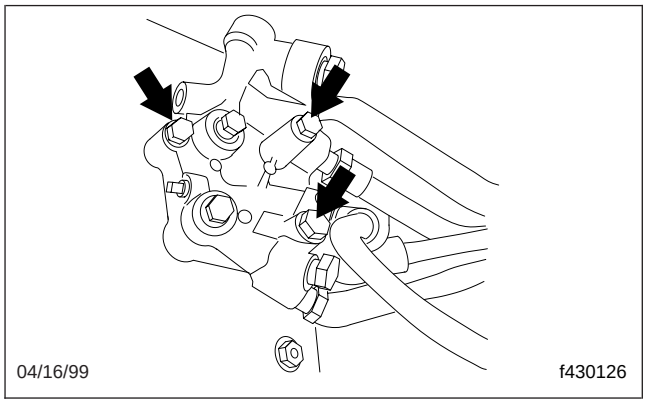

Fig. 1, Brake Control Treadle Valve and Assembly Bolts

7. Remove the treadle valve and assembly.

Installation

1. Remove the under steering panel from inside of the cab by removing the five screws.

NOTE: This is a two-person operation.

2. Install the treadle valve and assembly.

2.1 With one person holding the three brake control treadle valve and assembly bolts in place and the other, from inside of the cab, aligning the foot brake control assembly onto the bolts, install the foot brake control assembly. See **Fig. 2**.

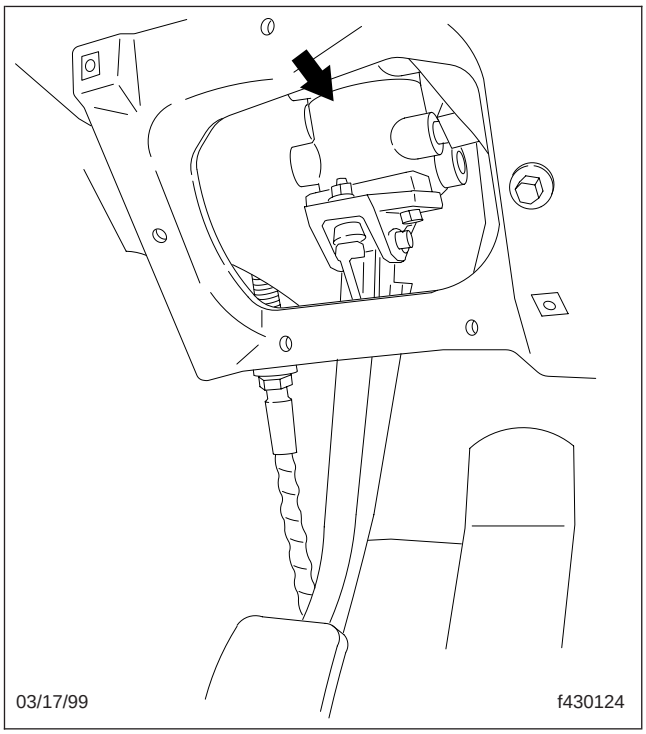

Fig. 2, Foot Brake Control Valve

2.2 Tighten the bolts.

3. Install the under steering panel. Tighten the five capscrews.
4. Connect the air lines.
5. Replace the ziptie.
6. Close the hood.
7. Remove the chocks from the tires.

General Information

The function of the QR–1 quick release valve is to speed up the release of air pressure from the brake chambers. If the front brake chambers are equipped with a QR–1 valve and a foot brake application is released, the exhaust port of the quick release valve opens and air from the front brake chambers is exhausted through the quick release valve. See **Fig. 1**. This accelerates the release of the front brakes. When a vehicle is equipped with a tractor protection valve, a quick release valve is fitted on the rear of the cab. See **Fig. 2**. A delivery line from the tractor protection valve is connected to the port on top of the quick release valve; the two side ports are for trailer glad hand connections.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

The wheels must be chocked to prevent vehicle movement while servicing any component in the brake system.

Observe these warnings while investigating all applicable brake system concerns.

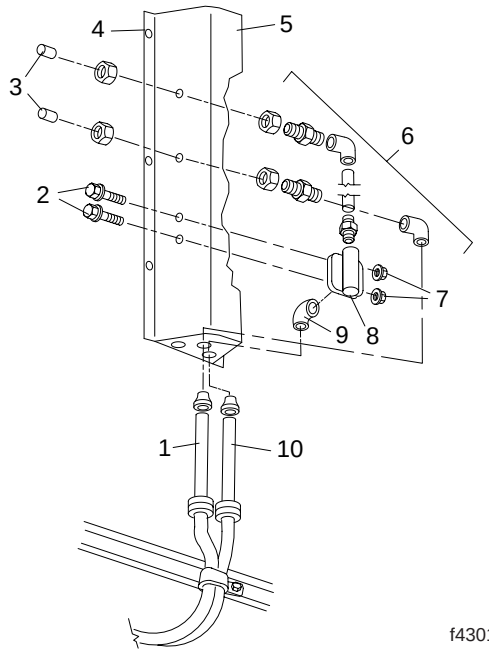
Quick Release Valve Removal and Installation

Removal

CAUTION

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. If equipped, remove the cover stud nuts and remove the cover. See **Fig. 1**.



1. Supply Air Line

10. Control Air Line

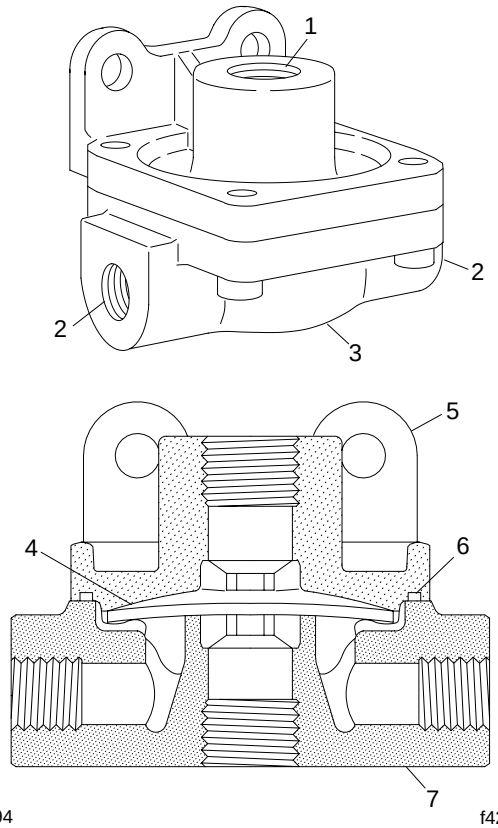
Fig. 1, Trailer Air and Electrical Connections Cover and Components

4. If equipped, disconnect the trailer electrical supply socket. For instructions, see **Section 54.13**.
5. Mark and disconnect the air lines to the quick release valve.
6. Remove the valve mounting fasteners and remove the valve.

Installation

1. Position the valve with the exhaust port facing down. Install and securely tighten the mounting fasteners.
2. Connect the air lines to the valve.
3. If equipped, install the trailer electrical supply socket. For instructions, see **Section 54.13** in this manual.
4. If equipped, position the cover and install cover stud nuts. See **Fig. 1**.
5. Perform the operation and leakage test in **Subject 120**.

Test (See Fig. 1 and Fig. 2)



1. Brake Valve Port
2. Brake Chamber Port
3. Exhaust Port
4. Diaphragm
5. Cover
6. O-Ring
7. Valve Body

8. Body
9. Quick Release Diaphragm
10. Cover

Fig. 2, QR-1C Quick Release Valve

CAUTION

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100.

The following test should be performed after repairing or replacing the quick release valve to ensure that it is functioning properly.

1. Chock the tires.
2. Apply the parking brakes.
3. Drain the air system.
4. Remove the air line from the valve balance port. Build system air pressure to 120 psi (827 kPa). Release the parking brakes. Coat the exhaust and balance ports with a soap solution; leakage of a 1-inch (2.5 cm) bubble in 5 seconds at either port is allowable. Install the air line at the balance port.

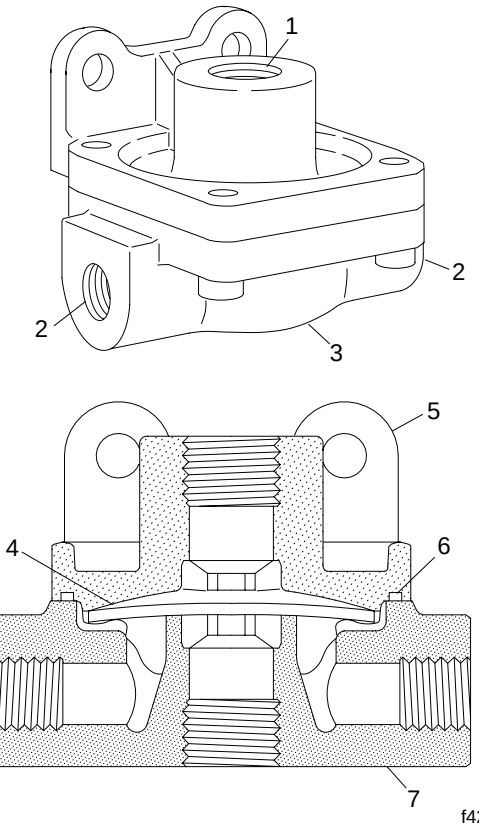
Quick Release Valve Operation and Leakage Test

5. Apply the parking brakes. Step on the foot brake; the quick release valve should exhaust air at the exhaust port.
6. Drain the air system.
7. Remove the air line from the valve supply port. Build system air pressure to 120 psi (827 kPa). With the foot valve depressed, coat the supply port and the seam between the body and cover with a soap solution; leakage of a 1-inch (2.5 cm) bubble in 5 seconds at the supply port is allowable. No leakage between the body and cover is permitted. Install the air line at the supply port.
8. If the valve does not function properly, or if leakage is excessive, repair or replace it following the instructions in this section.
9. Apply the parking brakes.
10. Remove the chocks from the tires.

QR–1 Disassembly, Cleaning and Inspection, and Assembly

Disassembly

1. Remove the quick release valve from the vehicle following the instructions in **Subject 110**.
2. Remove the four screws holding the valve cover on the valve body. See **Fig. 1**.



1. Brake Valve Port
2. Brake Chamber Port
3. Exhaust Port
4. Diaphragm
5. Cover
6. O-Ring
7. Valve Body

Fig. 1, QR-1 Quick Release Valve

3. If equipped, remove the spring and spring seat.
4. Remove the diaphragm.
5. Remove the cover O-ring.

Cleaning and Inspection

1. Clean all metal parts in mineral spirits. Wipe all rubber parts clean.
2. It is recommended that all rubber parts and any other part showing signs of wear or deterioration be replaced with genuine Bendix parts.

Assembly

1. If the quick release valve is not equipped with a spring, install the diaphragm into the valve body. See **Fig. 1**.

   If the quick release valve is equipped with a spring, position the spring in the valve body. Position the diaphragm over the spring seat.
2. Install the O-ring in the valve cover groove and install the valve cover. Tighten the screws 30 to 60 lbf·in (340 to 680 N·cm) evenly and securely.
3. Install the quick release valve, following the instructions in **Subject 110**.
4. Perform the operation and leakage test as instructed in **Subject 120**.

QR–1C Disassembly, Cleaning and Inspection, and Assembly

Disassembly (See Fig. 1)

Fig. 1, QR-1C Quick Release Valve

1. Remove the quick release valve from the vehicle following the instructions in Subject 110.
2. Mark the valve body and cover for ease of installation.
3. Remove the cap nut at the supply port. Remove the sealing ring from the cap nut.
4. Remove the double check diaphragm.
5. Remove the four screws holding the valve cover on the valve body.
6. Separate the cover from the body and remove the sealing ring and the quick release diaphragm.

Cleaning and Inspection

1. Clean all metal parts in mineral spirits. Wipe all rubber parts clean.
2. It is recommended that all rubber parts and any other part showing signs of wear or deterioration be replaced with genuine Bendix parts.

Assembly

1. Install the sealing ring on the cap nut.
2. Install the double check diaphragm in the valve body.
3. Install the cap nut. Tighten 12 to 33 lbf·ft (17 to 45 N·m).
4. Install the quick release diaphragm in the cover.
5. Install the valve cover on the body. Tighten the screws 30 to 60 lbf·in (340 to 680 N·cm) evenly and securely.
6. Install the quick release valve as instructed in Subject 110.
7. Perform the operation and leakage test as instructed in Subject 120.

Specifications

Torque Specifications		
Description	**Torque lbf·in (N·cm)**	**Torque lbf·ft (N·m)**
Cover Capscrews	30–60 (340–675)	—
Quick Release Valve Mounting Capscrews	—	11–15 (15–20)

Table 1, Torque Specifications

General Information (See Fig. 1)

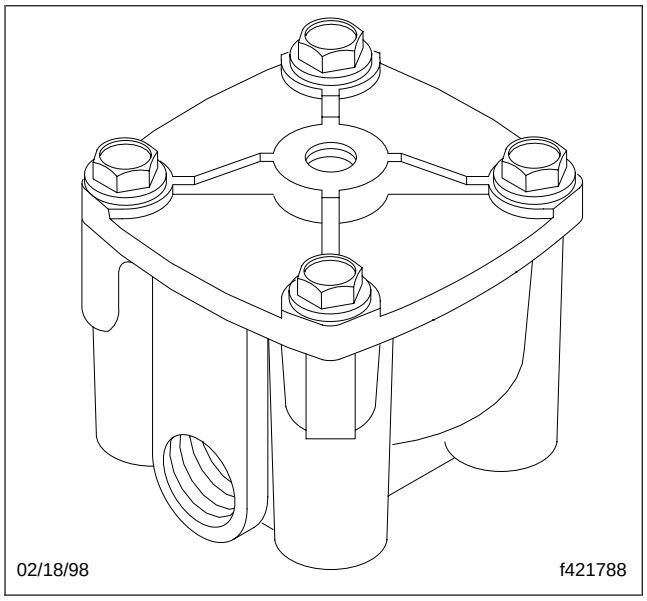

Fig. 1, R–12 Valve

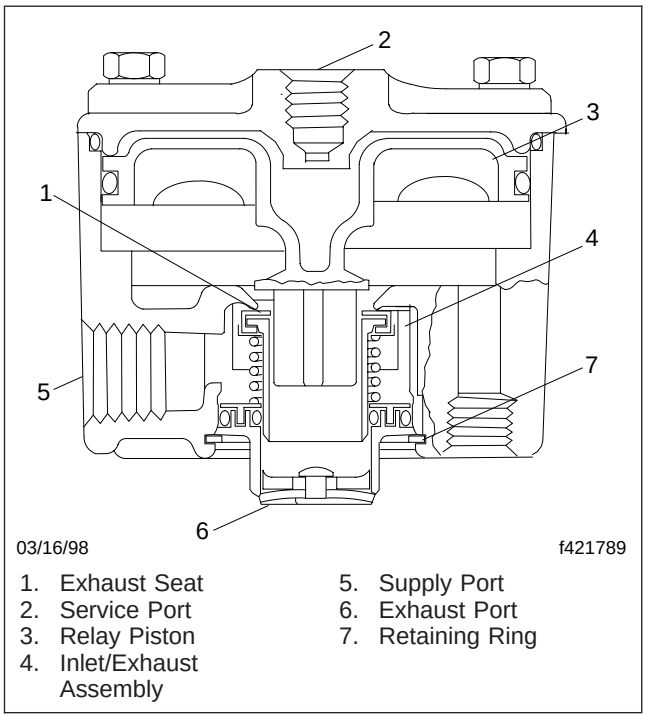
The relay valve is a control relay station in the air brake system used to speed the application and release of the brakes. Mounted at the rear of the vehicle, it is operated by remote control and gives about the same amount of air pressure to the brake chambers as it receives from the service brake foot valve or other source. The valve is piston operated and has an insert-type inlet and exhaust valve that is serviceable.

Application (See Fig. 2)

Air pressure delivered to the service port enters the small cavity above the piston and moves the piston down. The exhaust seat moves down with the piston and seats on the inner or exhaust portion of the inlet/exhaust valve, sealing off the exhaust passage. At the same time, the outer or inlet portion of the inlet/exhaust valve moves off its seat, permitting supply air to flow from the reservoir, past the open inlet valve and into the brake chambers.

Balance (See Fig. 2)

The air pressure being delivered by the open inlet valve also is effective on the bottom area of the relay piston. When air pressure beneath the piston equals



1. Exhaust Seat
2. Service Port
3. Relay Piston
4. Inlet/Exhaust Assembly
5. Supply Port
6. Exhaust Port
7. Retaining Ring

Fig. 2, R-12 Valve (sectional view)

the service air pressure above, the piston lifts slightly and the inlet spring returns the inlet valve to its closed position. The exhaust remains closed as the service line pressure balances the delivery pressure. As delivered air pressure is changed, the valve reacts to the change, holding the brake application at the level.

Exhaust or Release (See Fig. 2)

When air pressure is released from the service port and air pressure in the cavity above the relay piston is exhausted, air pressure beneath the piston lifts the relay piston and the exhaust seat moves away from the exhaust valve, opening the exhaust passage. With the exhaust passage open, the air pressure in the brake chambers is then permitted to exhaust through the exhaust port, releasing the brakes.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

The wheels must be chocked to prevent vehicle movement while servicing any component in the brake system.

Observe these warnings while investigating all applicable brake system concerns.

Removal

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove all air hoses from the valve. Cap the hoses and mark them for reassembly.
4. Remove the relay valve mounting bolts.
5. Remove the valve.

Installation

1. Attach the valve to the vehicle, using the bolts, washers, and nuts. Tighten the nuts 11 to 15 lbf·ft (15 to 20 N·m).
2. Remove the caps from the air lines and connect the air lines to the valve.
   - 2.1 For nylon tubing, connect the air line fittings to the valve ports, and tighten the nuts finger-tight. Using a wrench, tighten the nuts at least two turns, or until one thread shows on the fittings.
   - 2.2 For wire braid hoses, connect the hose fittings to the valve ports, and hand-tighten the nuts. Using a wrench, tighten the nuts until resistance is felt. Tighten one-sixth turn more. Do not overtighten.
3. Close the air reservoir drain cocks. Start the engine to pressurize the air system.
4. Test the valve following the instructions in **Subject 120**.
5. Remove the chocks from the tires.

⚠ CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

Operation Test

1. Start the vehicle and build the brake system to cut-out pressure, about 130 psi (827 kPa).
2. Using a soap-and-water solution, check all air line fittings on the valve for leakage. If the fittings or air lines are leaking, replace the fittings.
3. Make several service brake applications and check for prompt application and release of the brakes.
4. If brake response is slow, troubleshoot the brake system. For instructions, see **Section 42.01**. If the valve is malfunctioning, repair or replace it.

Leakage Test

1. Start the vehicle and build the brake system to cut-out pressure, about 130 psi (827 kPa).
2. Using a soap-and-water solution, check for inlet valve and O-ring leakage.
   - 2.1 Make this check with the service brakes released when the R–12 or R–14 is used to control the service brakes.
   - 2.2 Make the check with the spring brakes (parking brakes) applied when the R–14 is used to control the spring brakes.
3. While holding a full service brake application, apply a soap-and-water solution to the exhaust port. Leakage at the exhaust port should not exceed a 1-inch (2.5-cm) bubble in 3 seconds.

NOTE: If the anti-compound feature is in use, the line attached to the balance port must be disconnected to perform this test.

4. Coat the outside of the valve where the cover joins the body to check for O-ring leakage; no leakage is permitted.
5. If the R–14 relay valve is used to control the spring brakes, release the parking brake, apply a soap solution to the balance port. Leakage at the balance port should not exceed a 1-inch (2.5-cm) bubble in 3 seconds.

IMPORTANT: If the valves do not function as described in the above test, or if leakage is excessive, replace it. For instructions, see **Subject 110**.

Disassembly, Cleaning and Inspection, and Assembly

Disassembly

CAUTION

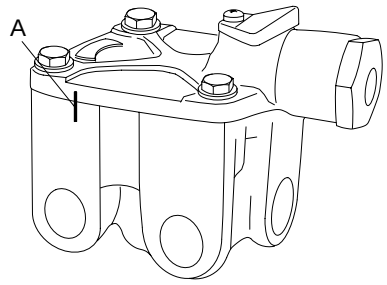
Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Remove the valve from the vehicle. For instructions, see **Subject 110**.

NOTE: Prior to disassembly, draw an alignment mark across the valve cover and body, for reassembly alignment. See **Fig. 1**.

2. Disassemble the valve.

   2.1 Referring to **Fig. 2**, remove the four cover capscrews and integral lockwashers.



A. Mark the valve housing for reassembly alignment.

Fig. 1, R-14 Valve Marked for Reassembly

   2.2 Remove the valve cover and O-ring.

   2.3 Remove the relay piston, and the O-ring.

   2.4 While depressing the exhaust cover, remove the retainer ring; slowly remove the exhaust cover and the valve spring. Remove the O-rings from the exhaust cover.

   2.5 Remove the inlet/exhaust valve. Remove the valve retainer from the inlet/exhaust valve.

3. On the R–14 valves, remove the Phillips-head screw and the exhaust cover. Then, remove the service port cap nut, the O-ring, and the diaphragm located inside the service port.

Cleaning and Inspection

WARNING

Wear goggles when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the valve in cleaning solvent. Dry the metal parts of the disassembled valve with compressed air.
2. Wipe all rubber parts clean with a clean cloth. Examine all rubber parts for cracks, tears, or other deterioration. If any rubber parts are worn, cracked, torn or otherwise damaged, replace them with new parts.
3. Examine all metal parts for wear, cracks, or other damage. If any metal parts are worn, cracked or otherwise damaged, replace them with new parts.
4. Check the springs for distortion and corrosion. If the springs are distorted or corroded, replace them.
5. Inspect the exhaust seat of the quick release diaphragm in the R–14 cover and make sure all internal air passages in the area are open and clean and free of nicks and scratches.

Assembly

1. Lubricate the O-rings and all sliding parts with Dow Corning 55-M pneumatic grease or equivalent. Assemble the valve. Refer to **Fig. 2**.

   1.1 Install the O-ring on the relay piston.

   1.2 Install the inner and outer O-rings on the exhaust cover.

   1.3 Install the O-ring on the valve cover.

   1.4 Install the relay piston in the body, taking care not to damage the piston O-ring.

   1.5 Noting the reference mark made during disassembly, secure the valve cover with four capscrews and lockwashers. Torque the capscrews 7 to 10 lbf·ft (9 to 14 N·m).

1.6 Install the valve retainer and spring on the inlet/exhaust valve assembly. Install the inlet/exhaust valve assembly in the body.

1.7 Install the exhaust cover. While depressing the exhaust cover, install the retaining ring, making sure the retaining ring is completely seated in the groove.

1.8 On R–14 valves, place the diaphragm in the service port making sure it is positioned between the guide ribs. Install the

service port cap nut and O-ring and tighten to 13 lbf·ft (17 N·m).

1.9 Position the exhaust cover, then install the Phillips-head screw. Tighten the screw 25 lbf·in (280 N·cm).

2. Install the relay valve on the vehicle following the instructions in **Subject 110**.

3. Test the valve following the instructions in **Subject 120**.

6. Exhaust

Fig. 1, BP–R1 Bobtail Proportioning Valve Port Locations

During tractor-trailer operation, the trailer supply valve knob is pushed in to deliver compressed air to the trailer and the bobtail proportioning valve control port.

Upon brake application, air pressure supplied to the control port holds the blend-back piston against the valve cover, and the initial delivery spring forces the proportioning piston to seat in the valve body. This opens the inlet valve, closes the exhaust valve, and allows air pressure to enter the supply port and flow to the front brake chambers. Air pressure delivered to the front brake chambers is also present beneath the proportioning piston. Since the area on the delivery side (brake chamber side) of the proportioning piston is larger than the area on the supply side (brake foot valve side), the delivery side needs less air pressure to apply the same force. After initial brake application, the bobtail proportioning valve delivers less air pressure to the front brake chambers than it receives from the brake foot valve.

During bobtail operation, the trailer supply valve knob is pulled out. Air in the valve flows back to the trailer supply valve and is exhausted to atmosphere. With no pressure at the valve control port, the blendback piston contacts the proportioning piston. The inlet/exhaust valve is held by its spring and seals the exhaust passage. In this position, the bobtail proportioning valve delivers full service brake air pressure to the front brake chambers. When the brakes are released, delivery air pressure flows back through the valve and exhausts at the foot valve. Air from the front brake chambers exhausts through the quick release valve.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

The wheels must be chocked to prevent vehicle movement while servicing any component in the brake system.

Observe these warnings while investigating all applicable brake system concerns.

Removal

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Disconnect the air lines from the valve. Cap the lines and mark them for reassembly.
4. Remove the valve mounting bolts.
5. Remove the valve.

Installation

1. Attach the valve to the vehicle, using the bolts, washers, and nuts. Tighten the nuts 11 to 15 lbf·ft (15 to 20 N·m).
2. Remove the caps from the air lines and connect the air lines to the valve.
   - 2.1 For nylon tubing, connect the air line fittings to the valve ports, and finger-tighten the nuts. Using a wrench, tighten the nuts at least two turns, or until one thread shows on the fittings.
   - 2.2 For wire braid hoses, connect the hose fittings to the valve ports, and finger-tighten the nuts. Using a wrench, tighten the nuts until resistance is felt. Tighten one-sixth turn more. Do not overtighten.
3. Close the air reservoir drain cocks. Start the vehicle engine to pressurize the air system.
4. Check for leaks and proper valve function. For instructions, see Subject 120.
5. Remove the chocks from the tires.

Operation Test

1. Park the vehicle on a level surface and chock the tires.
2. Before testing the air brake proportioning system, do the following.
   - 2.1 Check the operation of the air compressor. For instructions, see **Group 13**.
   - 2.2 Check the pressure levels of the air reservoirs.
   - 2.3 Check the operation of the brake chambers. For instructions, see **Section 42.07**.
   - 2.4 Inspect all hoses and tubing for kinks, dents, and other damage. Replace damaged tubing. For instructions, see **Section 42.06**.
   - 2.5 Inspect all air line fittings. Tighten loose connections; replace fittings that are damaged. For instructions, see **Section 42.06**.
3. Drain all air tanks.
4. Install a tee at the service port and at one of the delivery ports, then install an air pressure gauge in each.
5. Connect the tractor service and emergency gladhands to hose couplings that have been plugged or connect them to a trailer. Build the tractor system air pressure to the governor cut-out point.
6. With the dashboard trailer supply valve and system park control valve activated for tractor/trailer operation, apply, hold, and then release the brakes several times, varying the application pressures while watching the reaction of the gauges installed on the valve ports. Note that a prompt application occurs and that it can be held, then promptly released.
7. Check the proportioning valve differential pressure by applying 10 psi (69 kPa) to the service port and noting the pressure registered at the delivery port. Subtract delivery port pressure from the 10 psi (69 kPa) service pressure to obtain the differential.

NOTE: For valves without a relay piston spring (**Fig. 1**), the measured differential should be about 4 psi (28 kPa). When a relay piston spring is used, the differential will be higher.

8. Make and hold a full brake application of 100 psi (689 kPa) or greater, and note that full pressure is delivered to the chambers.
9. Activate the dash-mounted trailer supply valve for bobtail tractor operation. Make a slow brake application and watch the gauges installed previously. Both gauge readings should rise until the delivery pressure is 5 to 10 psi (34 to 69 kPa). Then the service supply pressure should continue rising while delivery pressure remains constant. Hold the brake application at 20 psi (138 kPa) and check that the delivery pressure is 5 to 10 psi (34 to 69 kPa). Release the application.
10. Make another brake application and slowly increase the pressure at the bobtail proportioning valve service port to between 60 to 70 psi (414 to 483 kPa) while observing the gauge installed at the delivery port. Note that when service port pressure rises between 20 and 30 psi (138 to 207 kPa), delivery pressure begins to rise above the initial pressure noted in the previous step. The rise of delivery pressure should be at a proportioned rate of about three-to-one. At 70 psi (483 kPa) service pressure, delivered pressure should be 15 to 25 psi (103 to 172 kPa).
11. Make a full brake application, and note that both test gauges register the same pressure.
12. Remove the test gauges from the valve ports.
13. Remove the chocks from the tires. Test drive the vehicle (without a trailer) in a safe area at slow speed with the trailer supply valve pulled out (bobtail position). Make several brake applications to become familiar with the feel of the system before returning the vehicle back to service.

Leakage Tests

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

NOTE: The following checks should be made with two test gauges or two gauges known to be accurate.

Operation and Leakage Tests

Fig. 1, BP-R1 Bobtail Proportioning Valve (exploded view)

Depending upon installation, it may be easier or necessary to completely remove the valve to test it properly.

1. Install a test gauge in a control and supply line. Install the other test gauge in the delivery port. Gradually apply pressure to the supply and control line.

   Slowly decrease pressure in the control cavity and note at which pressure delivery is made and

compare this value with the air system requirements in **Section 13.01**.

2. As the pressure rises, note at what pressure exhaust occurs and compare this value with the air system requirements in **Section 13.01**.
3. With air pressure present in the supply and control ports, apply a soap-and-water solution around the supply port cap nut. No leakage is permitted.
4. Apply soap-and-water solution to the delivery and exhaust ports. A slight bubble leakage is permissible. Excessive leakage indicates a faulty O-ring or inlet valve.

Disassembly, Cleaning and Inspecting, and Assembly

Disassembly (See Fig. 1)

CAUTION

The bobtail proportioning valve may be lightly clamped in a bench vise during disassembly, however, over-clamping will cause damage to the valve and result in leakage or malfunction.

If a vise is to be used, position the valve so that the jaws bear on the supply ports on opposing sides of the valve's body.

1. Remove all air fittings and plugs from the valve.
2. Mark the relationship of the valve cover to the body, and if the valve is equipped with a mounting bracket, mark the relationship of the bracket to the cover.
3. While holding the exhaust cover, remove and discard the retaining ring that secures it to the body.
4. Remove and discard the exhaust cover along with both O-rings.
5. Remove and discard the valve spring, valve retainer, and the valve assembly from the body.
6. Remove and retain the four capscrews and washers that secure the cover to the body.
7. Separate the cover from the body. Remove and discard the sealing ring and O-ring.
8. Remove and retain the relay piston and, if present, the relay piston spring from the body.

NOTE: The relay piston spring is not used in all valves.

9. Remove and discard the O-ring from the relay piston.
10. Remove and discard the dust shield and the retaining ring from the valve cover. Remove and save the exhaust piston.
11. Remove and discard the exhaust piston O-ring and the exhaust diaphragm.
12. Remove and save the service piston from the valve cover. Remove and discard the service piston O-ring.
13. Remove the spring and spring cage from the valve cover. Discard the spring and retain the spring cage.
14. Remove and retain the blend-back piston from the valve cover. Remove and discard both O-rings.
15. Remove and save the proportioning piston from the valve cover. Remove and discard both O-rings.
16. While holding the inlet valve seat in place, remove and discard the retaining ring from the proportioning piston.
17. Remove the inlet valve seat, the inlet valve, and the valve spring from the proportioning piston. Remove and discard the O-ring from the valve seat. Discard the valve and spring also.
18. Remove and discard the exhaust cover screw and exhaust cover.

Cleaning and Inspection

1. Using mineral spirits or an equivalent solvent, clean and thoroughly dry all metal parts. Do not damage any bores with metal tools.
2. Wash all non-metallic parts in a soap-and-water solution, making certain to rinse and dry thoroughly.
3. Inspect the interior and exterior of all metal parts that will be re-used. Check for severe corrosion, pitting, gouges and cracks. Superficial corrosion or pitting of the exterior portion of the body and cover is acceptable. Replace the entire valve if the interior of the body or cover show signs of corrosion or pitting.
4. Inspect each non-metallic part for cracks, wear or distortion. Replace the entire valve if these conditions exist.
5. Replace all rubber parts.
6. Make certain the air channel running between the top surface of the body and its supply port is clear and free of blockages.
7. Make certain all air channels and exhaust passages in the valve cover are clear and free of blockages.

8. Inspect the pipe threads in the body and valve cover. Make certain they are clean and free of thread sealant.
9. If the valve was equipped with a relay piston spring, check it for signs of corrosion, pitting, and cracks. Replace as needed.
10. Inspect all air line fittings for corrosion; replace as needed. Be sure to remove all old thread sealant before re-use.

Assembly (See Fig. 1)

1. Prior to assembly, lubricate all O-rings, seals, and pistons, as well as body and cover bores, using the lubricant provided in the Bendix maintenance kit. Use all of the lubricant, and spread it evenly on the rubbing surfaces.
2. Install the O-ring on the inlet valve seat.
3. Install the small end of the valve spring over the rubber portion of the inlet valve, making sure the spring coils rest on the valve's four tabs.
4. Insert the spring and valve into the valve seat, making sure the four tabs are inside the seat's bore.
5. Insert the valve, seat, and spring assembly into the proportioning piston, large end of the spring first.
6. While holding the seat in place, install the retaining ring to secure it in the piston. Make certain the retaining ring is fully seated in its groove. Make sure the valve is straight against the exhaust seat and free to move.
7. Install both the large and small diameter O-rings on the proportioning piston.
8. Install both the large and small diameter O-rings on the blend-back piston. Insert the small diameter of the proportioning piston into the small diameter end of the blend-back piston.
9. Carefully insert the assembled proportioning and blend-back pistons to the edge of the bore in the cover. Do not cut or pinch the O-rings.
10. With the bore of the cover facing up, install the spring cage in the blend-back piston so that its flat side rests against the blend-back piston (its depressed side out towards spring).
11. Install the O-ring on the service piston. Install the spring in the cage so that its coils are inside the diameter of the cage.
12. Install the O-ring on the exhaust piston, and place the exhaust diaphragm between the six posts of the service piston.
13. Place the exhaust piston on the service piston with its six-ribbed side facing the service piston. Then install both pistons while pushing the proportioning and blend-back pistons all the way into the cover.
14. Install the dust shield in the cover.
15. While holding the dust shield in the cover, install the retaining ring, making certain it is fully seated in its groove.
16. Install the exhaust cover using the screw to retain it. Torque the screw 8 to 15 lbf·in (100 to 160 N·cm).
17. Install the valve retainer on the valve assembly so that the flange of the retainer surrounds the rubber portion of the valve. Install the valve assembly in the body.
18. Install the valve spring in the body.
19. Install the large and small diameter O-rings in the exhaust cover. Install the exhaust cover in the body, taking care not to damage the O-rings. Hold the exhaust cover in place.
20. While depressing the exhaust cover, install the retaining ring in the body. Make sure this ring is fully seated in its groove in the body.
21. If the bobtail proportioning valve was equipped with a relay piston spring, install the spring in the body, large diameter first.
22. Using lubricant to hold them in place, install the large O-ring and small sealing ring on the cover.
23. Install the O-ring on the relay piston. Install the piston in the body.
24. After noting the relationship marks made prior to disassembly, install the mounting bracket (not shown) on the cover. Secure the cover and mounting bracket on the body using the four capscrews and washers. Torque the capscrews 10 to 13 lbf·ft (14 to 17 N·m).

Fig. 1, TR-3 Inversion Valve (sectional view)

The inversion valve is an on/off, two-way valve. With normal operating pressure at both supply and control ports, the delivery port will be exhausted to the atmosphere. As control pressure is reduced to the point that the piston return spring overcomes the force on the control piston, the valve will deliver full supply pressure at the delivery port.

During brake application, air pressure delivered to the service port enters the small cavity above the piston and moves the piston down. The exhaust seat moves down with the piston and seats on the inner or exhaust portion of the inlet/exhaust valve, sealing off the exhaust passage. At the same time, the outer or inlet portion of the inlet/exhaust valve moves off its seat, permitting supply air to flow from the reservoir, past the open inlet valve and into the brake chambers.

The inversion valve balances when air pressure beneath the piston equals the service air pressure above. The piston lifts slightly and the inlet spring returns the inlet valve to its closed position. The exhaust remains closed as the service line pressure balances the delivery pressure. As delivered air pressure is changed, the valve reacts to the change, holding the brake application at the level.

When air pressure is released from the service port and air pressure in the cavity above the relay piston is exhausted, air pressure beneath the piston lifts the relay piston and the exhaust seat moves away from the exhaust valve, opening the exhaust passage. With the exhaust passage open, the air pressure in the brake chambers is then permitted to exhaust through the exhaust port, releasing the brakes.

Safety Precautions

AIR BRAKE SYSTEM WARNINGS

⚠ WARNING

Before attempting to work on the air brake system, certain precautions must be observed. Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized.

When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.

Hoses will whip dangerously if disconnected under pressure.

Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.

As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber push rods and spring actuators which apply automatically with the loss of pressure. This also applies when checking the service brake system.

Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.

Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.

The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.

Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.

To avoid injury, keep clear of the air chamber push rod when brakes are applied or when air is exhausted from the system.

The wheels must be chocked to prevent vehicle movement while servicing any component in the brake system.

Observe these warnings while investigating all applicable brake system concerns.

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Drain the air system.

NOTE: To disconnect the air lines, push the hose in; push the retaining ring in and pull out the hose in a swift motion.

3. Mark and disconnect the air lines.
4. Loosen the retaining bolts and remove the inversion valve.

Installation

1. Attach the valve to the vehicle, using the bolts, washers, and nuts. Tighten the nuts 11 to 15 lbf·ft (15 to 20 N·m).
2. Connect the air lines to the valve.
3. Close the air reservoir drain cocks. Start the engine to pressurize the air system.
4. Check for leaks and proper valve function. For instructions, see **Subject 120**.
5. Remove the chocks from the tires.

CAUTION

Before working on or around air brake systems and components, review "Safety Precautions" in Subject 100.

NOTE: The following checks should be made with two test gauges or two gauges known to be accurate.

Depending upon installation, it may be easier or necessary to completely remove the valve to test it properly. For instructions, see **Subject 110**.

Operation and Leakage Tests

(See Fig. 1)

1. Install one test gauge in a common control and supply line; install the other gauge in the delivery port. Gradually apply pressure to the common supply and control line.

   Slowly decrease pressure in the control cavity and note at which pressure delivery is made and compare this value with the air system requirements in **Section 13.01**.

2. As the pressure rises, note at what pressure exhaust occurs and compare this value with the air system requirements in **Section 13.01**.

3. With air pressure present in the supply and control ports, apply a soap solution around the supply port cap nut. No leakage is permitted.

4. Apply soap solution to the delivery and exhaust ports. A slight bubble leakage is permissible. Excessive leakage indicates a faulty O-ring or inlet valve.

5. Operate the manual control of the inverting relay valve and check to insure that delivery and exhaust occurs promptly.

NOTE: If the inversion valve does not function properly or leakage is excessive, replace the valve with a new or remanufactured unit is. If the valve is repaired, use genuine valve manufacturer parts.

General Description

CAUTION

The size of the tires installed at the factory is programmed into the electronic control unit (ECU). Installing different size tires could result in a reduced braking force, leading to longer stopping distances and possibly resulting in personal injury or property damage.

The Meritor WABCO Antilock Braking System (ABS) is an electronic wheel speed monitoring and control system that works with the standard air brake system. It passively monitors vehicle wheel speed at all times, then controls wheel speed during emergency stops. As a result, the driver has full control of braking until the electronic control unit senses that a lockup is about to occur.

The ABS includes signal-generating sensors activated by tone (tooth) wheels located on the hubs of the monitored wheels. See **Fig. 1**. The sensors transmit vehicle wheel speed information to the electronic control unit (ECU).

According to programmed specifications, the ECU signals the appropriate modulator valve to increase, reduce, or maintain air pressure in the brake chamber. This prevents front and rear wheel lockup, and enhances steering control during emergency braking situations.

Sterling vehicles with a 4 x 2, 6 x 2, or 6 x 4 wheel configuration normally have the standard four-channel ABS with four wheel speed sensors and four modulator valves (4S/4M). Vehicles with tandem rear axles may be optionally equipped with a 6S/4M or 6S/6M ABS.

During normal braking conditions, the standard air brake system is in effect. If the vehicle is equipped with Automatic Traction Control (ATC), wheel spin is controlled during reduced-traction startup and acceleration.

Principles of Operation

The ABS has an electronic control unit that serves as the information processing and command center for the antilock braking system. The ECU is a digital microcomputer that receives and processes vehicle wheel speed information from the sensors. During emergency brake applications, the control unit regulates the braking force applied to each wheel by sending control signals to the modulator valves.

The major components of the Meritor WABCO pneumatic ABS system include the following:

- Wheel speed sensors
- An electronic control unit (ECU)
- Modulator valves (solenoid control valves)
- Automatic Traction Control (ATC) valve (optional)
- ABS warning and wheel-spin indicator lights
- Retarder relay

CAUTION

Before performing any electric welding on a vehicle, disconnect the battery power, ground cables, and the electrical harness connectors at the ABS electronic control unit (ECU). Electric currents produced during electric welding can damage various electronic components on the vehicle.

WHEEL SPEED SENSORS

The wheel speed sensor assembly is a signal-generating device. The assembly includes a sensor (coil wrapped around a magnet), a tone wheel, and a sensor clip that holds the sensor in position near the tone wheel. See **Fig. 2**.

Each ABS-controlled wheel has a wheel speed sensor assembly with a tone wheel mounted on the hub. When the vehicle is moving, the teeth on the tone wheel cause interruptions in the magnetic field created by the sensor. The interruptions create electrical pulses that are sent to the electronic control unit where they are used to determine the wheel speed.

ELECTRONIC CONTROL UNIT (ECU)

Sterling L-Line and A-Line vehicles that are equipped with a Meritor WABCO ABS have a frame-mounted D-version ECU.

The ECU contains microcomputers to monitor the front and rear control channels. See **Fig. 3**. It is mounted on the right-hand frame rail.

General Information

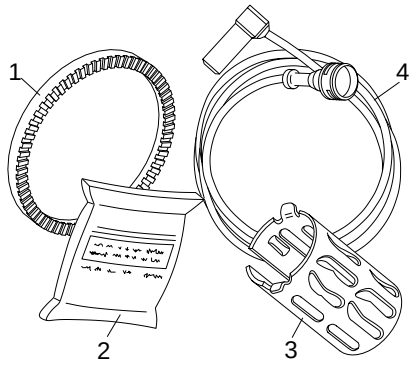
9. Sensor Mounting Block (weld on)
10. Sensor Bushing (weld on)

Fig. 1, ABS Component Location (4-channel, 4S/4M system shown)

The ECU receives signals from the wheel speed sensors and uses them to calculate wheel speed and a vehicle reference speed. The unit is programmed to determine whether the wheels are slowing at a nor-



1. Tone Wheel
2. Lubricant
3. Sensor Spring Clip
4. Sensor

Fig. 2, Wheel Speed Sensor Components

mal braking rate or at a higher rate, requiring ABS braking control. If the ECU senses wheel slip or lockup, the appropriate control circuit signals the modulator valve(s) to release, hold, or reapply braking pressure.

The ECU also shuts down the engine brake and the exhaust brake, if equipped, when a wheel approaches a slip or lockup condition. When the wheels return to a normal rate of speed, the engine and exhaust brakes are reactivated automatically.

B. ECU connector pin locations.
1. X1 Connector (gray)
2. X2 Connector (black)
3. X3 Connector (green)
4. X4 Connector (brown—6S/4M, 6S/6M only)

Fig. 3, Frame-Mounted ECU and Pin Locations

The ECU constantly monitors the wheel sensors, modulator valves, Automatic Traction Control valve (if equipped), and the electrical circuitry. After the ignition switch is turned on, the ABS warning light (ABS, TRACTOR ABS, or ANTI LOCK) and the ATC wheel spin indicator light (TRAC) on the dash light for about 3 seconds. See **Fig. 4** for a typical instrument cluster for a vehicle without ATC.

During the self-test, the modulator valves and the ATC valve cycle on and off, creating clicking noises that may be heard inside the cab. These clicking noises are normal and do not indicate an ABS problem. After about 3 seconds, the lights go off only if all of the ABS and ATC components are functioning correctly.

On vehicles with Automatic Traction Control, after the self-test the ATC indicator light comes on if a drive wheel spins during startup or acceleration.

IMPORTANT: If the ABS warning light and the ATC indicator light do not work as described above, repair the ABS/ATC system. See **Troubleshooting, 300** for fault diagnosis.

If, during vehicle operation, the safety circuit senses a failure in any part of the ABS system (such as a sensor, modulator valve, wiring connection, or short circuit), the ABS warning light comes on, a fault code is stored in ECU memory, and the control circuit where the failure occurred is switched to normal braking action. The remaining control circuit retains the ABS effect.

Even if the ABS system is completely inoperative, normal braking is maintained. An exception would be if a modulator valve or valve assembly is damaged and inoperative. These components are an integral part of the air brake system so normal braking may be impaired or inoperative.

For troubleshooting purposes, the ECU can communicate with the Meritor WABCO PC Diagnostics (recommended), ServiceLink, or a hand-held Pro-Link electronic diagnostic tool through the J1587 diagnostic datalink connector. The connector is located below the dash on the driver's side. See **Fig. 5**. Fault codes can be retrieved through the datalink connection, when necessary.

IMPORTANT: Do not open the ECU. Opening the ECU to gain access to the internal components will void the warranty.

MODULATOR VALVES

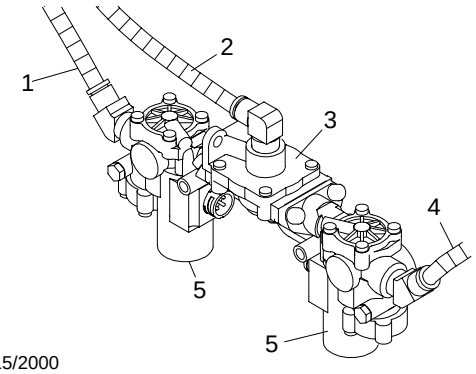
Modulator valves control the air pressure in each affected brake chamber during an ABS operation. Depending on the signal received from the ECU, modulator valves prevent wheel lockup by reducing, maintaining, or increasing brake pressure. During normal braking applications, the ABS system is inactive and compressed air flows freely through the modulator valves to the brake chambers.

Each ABS-monitored wheel has its own modulator valve. The front modulator valve assembly, mounted on the front crossmember, includes two modulator valves connected to a quick-release valve. See **Fig. 6**.

The rear modulator valve assembly is mounted on a crossmember near the rear brake chambers. See **Fig. 1**. The assembly includes two modulator valves, one mounted on each side of a service relay valve. If the vehicle has an ATC system, the ATC valve is mounted on the control port of the service relay valve.

Vehicles with tandem rear axles and a 4S/4M ABS share modulator valves. One wheel is sensed but the modulator valve controls both wheels.

Each modulator valve includes two solenoid control valves (one supply and one exhaust) and two diaphragms. See **Fig. 7**.



05/15/2000 f430159

1. Air Line to RH Brake Chamber
2. Supply Air Line
3. Quick-Release Valve
4. Air Line to LH Brake Chamber
5. Modulator Valve

Fig. 6, Front Modulator Valve Assembly

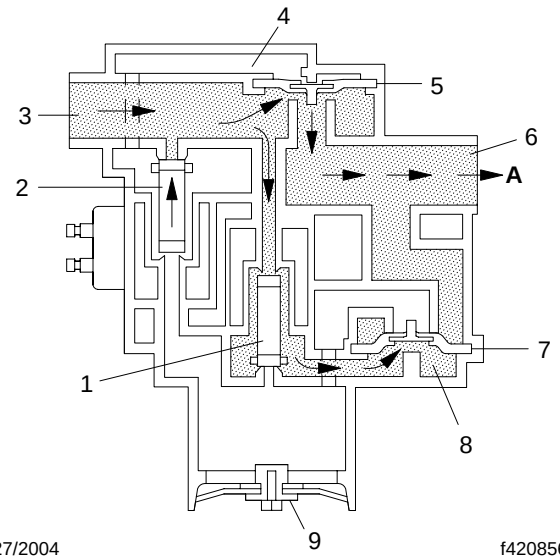
- The supply diaphragm opens and closes an air passage between the supply port and delivery port. It is controlled by the supply solenoid valve.
- The exhaust diaphragm opens and closes an air passage between the exhaust port and the delivery port. It is controlled by the exhaust solenoid valve.

The ECU energizes different combinations of these solenoid valves to perform four functions: normal braking (without ABS control), ABS brake release (exhaust), ABS brake hold, and normal brake reapply.

Normal Brake Control

The normal brake function (without ABS control) operates as follows:

- Before braking, the supply pilot chamber is open to the atmosphere through the exhaust port.
- When the brakes are applied, both solenoid valves in the ABS modulator valve are closed (de-energized). See **Fig. 7**.
- Increased air pressure entering the supply port unseats the supply diaphragm by increasing the pressure under the diaphragm. This opens the passage to the delivery port and allows air to flow directly through the valve and into the brake chamber.



02/27/2004 f420856b

NOTE: Both solenoid valves are closed. The modulator valve is shown in the braking configuration with increased air pressure at the supply port (supply diaphragm unseated, exhaust diaphragm seated).

A. Air to brake chamber.

1. Exhaust Valve (closed)
2. Supply Valve (closed)
3. Supply Port
4. Supply Diaphragm (unseated)
5. Delivery Port
6. Exhaust Diaphragm (seated)
7. Exhaust Port

Fig. 7, Modulator Valve, Normal Brake Control (brake applied)

- Air also flows through the exhaust valve. The increased pressure under the exhaust diaphragm seats the diaphragm, which closes the passage between the exhaust port and the delivery port.
- When the brake pedal is released, air pressure at the supply port decreases and the higher pressure in the brake chamber reverses the flow of air in the modulator valve. Air now flows from the delivery port to the supply port until the pressure is balanced. This releases the supply diaphragm and closes the passage between the two ports.
- The reduced pressure unseats the exhaust diaphragm and air is vented through the exhaust port to the atmosphere.

Brake Release (ABS Active)

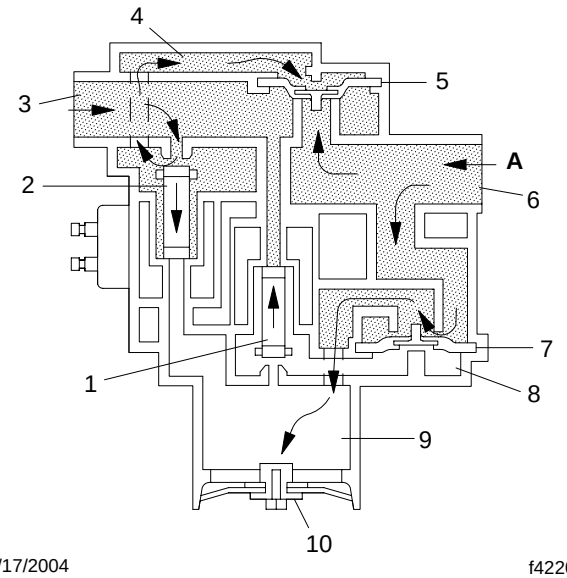
The ABS brake release (exhaust) function is triggered when the ECU determines that the brakes are about to lock.

- When a wheel is going to lock, the ECU opens (energizes) both solenoid valves in the ABS modulator valve. See **Fig. 8**.
- The open supply valve allows compressed air to enter the supply pilot chamber above the supply diaphragm. The increased pressure seats the diaphragm and stops air from entering the brake chamber.
- The open exhaust valve shuts off the supply of air entering the exhaust pilot chamber. It also creates an opening between the pilot and exhaust chambers.
- Air from the brake chamber enters through the delivery port. The pressure unseats the exhaust diaphragm, creating an opening between the delivery and exhaust chambers. Brake-chamber air is then released through the exhaust port.

Brake Hold Control (ABS Active)

The ABS brake hold function takes control during an emergency stop when the pedal control valve delivers more air than the brakes can handle without locking. The hold function occurs after the ABS has started to control the pressure in the brake chamber by releasing some of the air.

- When enough air is released through the exhaust port to stop the wheel from locking (ABS brake release), the exhaust valve is closed and air pressure is allowed to flow into the exhaust pilot chamber. See **Fig. 9**.
- The increased pressure under the exhaust diaphragm seats the diaphragm, which closes the passage between the exhaust port and the delivery port. This stops the flow of air from the brake chamber to the exhaust port.
- The supply valve stays open to maintain pressure in the supply pilot chamber and keep the supply diaphragm seated. This prevents further buildup of pressure in the brake chamber.
- The remaining air pressure in the brake chamber is held and remains constant for stopping the vehicle in the minimum distance.



NOTE: Both solenoid valves are open.

A. Air from brake chamber.

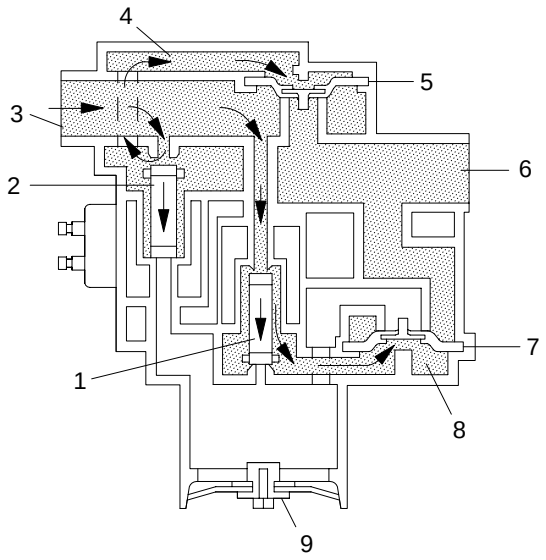
2. Supply Valve (open)
3. Supply Port
4. Supply Pilot Chamber
5. Supply Diaphragm (seated)
6. Delivery Port
7. Exhaust Diaphragm (unseated)
8. Exhaust Pilot Chamber
9. Exhaust Chamber
10. Exhaust Port

Fig. 8, Modulator Valve, Brake Release (exhaust)

Reapply Brake Control (ABS Active)

The last ABS function is the reapply brake control. To achieve maximum braking, the ECU determines when to reapply the air pressure that the pedal control valve is delivering. When appropriate, both ABS solenoid valves are closed, which returns the system to the normal brake control state shown in **Fig. 7**.

During an ABS event, the ECU cycles the modulator valve(s) through the sequence of ABS valve states (brake release, hold, and reapply) very rapidly in order to control wheel speed. The effect is similar to manually pumping the brakes on a vehicle without an ABS.



NOTE: The supply valve is open; the exhaust valve is closed.

1. Exhaust Valve (closed)
2. Supply Valve (open)
3. Supply Port
4. Supply Pilot Chamber
5. Supply Diaphragm (seated)
6. Delivery Port
7. Exhaust Diaphragm (seated)
8. Exhaust Port

Fig. 9, Modulator Valve, Brake Hold Control

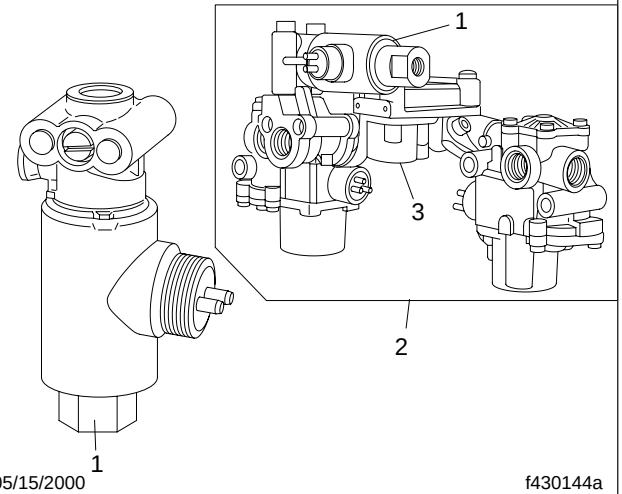
NOTE: The driver always controls the maximum amount of pressure applied to the brakes. Pressure to the brake chamber can never be more than the driver applies with the foot pedal. The ABS can override the pedal pressure to provide less brake pressure but not more.

AUTOMATIC TRACTION CONTROL

If the vehicle is equipped with Automatic Traction Control (ATC), the ABS/ATC system automatically reduces wheel spin during low-traction startup or acceleration.

If a drive wheel starts to spin faster than the steer-axle wheels, the ATC system applies air pressure to brake that drive wheel. This transfers engine torque to the wheel or wheels that have better traction (differential braking). If two or more drive wheels spin, the ATC reduces the engine torque to provide improved traction, overriding the throttle pressure from the driver.

The ATC valve controls only the brake chambers for the drive wheels. It is mounted on the service relay valve (rear modulator valve assembly). See **Fig. 10**. The solenoid in the ATC valve controls an on/off air valve, which allows or prevents air flow to the control side of the service relay valve.



1. ATC Valve
2. Rear Modulator Valve Assembly
3. Service Relay Valve

Fig. 10, ATC Valve

If a wheel spin from one side of the vehicle is detected, the ECU signals the ATC valve to open. This allows compressed air to enter the service relay valve and the normal ABS control system determines which brake to apply.

An ATC function switch on the dash allows the driver to select from two levels of drive-axle traction control (see **Fig. 11**):

- In the default position, the ATC reduces drive-axle wheel spin on icy, wet, or sand-covered roads.
- Pressing the TRAC MUD/SNOW switch increases the available traction on extra soft surfaces like snow, mud, or gravel by slightly increasing the permissible wheel spin. The

General Information

greater wheel spin may also be used to help burn through a thin layer of ice.

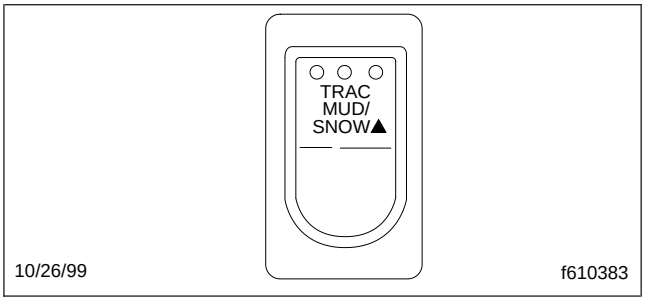


Fig. 11, ATC Switch for Soft Surfaces

The ATC function turns on and off automatically; drivers do not have to select this feature. If a drive wheel spins during startup or acceleration, the ATC indicator lamp comes on, indicating the ATC is active. It goes out when the drive wheel stops spinning.

The TRAC MUD/SNOW mode overrides the ATC function. It must be manually selected by pressing the TRAC MUD/SNOW spring-loaded switch briefly after the vehicle is started. The ECU indicates the activation by a constant flashing of the TRAC lamp. This mode is disengaged by pressing TRAC MUD/SNOW on the switch again or turning the ignition switch off.

ABS WARNING AND ATC INDICATOR LIGHTS

The ABS warning light (ABS, TRACTOR ABS, or ANTI-LOCK) receives power whenever the ignition switch is turned on. The ground paths for this indicator are through the ABS ECU and the blink-code switch. During the self-test, and whenever a malfunction occurs, the ECU completes the ground path and the ABS indicator on the dash comes on. See **Fig. 4**. The light is also used to display blink code diagnostics.

The warning light alerts the driver that the self-test is working or that an ABS system malfunction exists. After a wheel-sensor-related fault has been repaired, if the stored faults are cleared, the ABS warning light remains on until the vehicle is driven above a speed of 4 mph (6 km/h).

The ATC indicator light also receives power whenever the ignition switch is on. If the drive-axle wheels spin, the ATC indicator light turns on.

On vehicles equipped with Automatic Traction Control, if the TRAC MUD/SNOW switch (**Fig. 11**) is activated, the ABS ECU allows more wheel spin than normal and the ATC indicator blinks continuously until the switch is deactivated.

If the ATC wheel-spin indicator light stays on during normal vehicle operation, there is a malfunction in the ATC system.

TIRE SIZE

For proper ABS/ATC operation with the standard ECU, the front and rear tire sizes must be within 14 percent of each other. When the tire-size range is exceeded, system performance can be affected and the warning lamp may come on.

Call Meritor WABCO at 1-800-535-5560 if you plan a tire-size difference greater than 14 percent.

Calculate the percentage difference of the tire sizes with the following equation:

Percentage Difference = {(steer-axle tire RPM ÷ drive-axle tire RPM) – 1} x 100, where RPM equals tire revolutions per mile.

Safety Precautions

When working on or around air brake systems and components, observe the following precautions:

- Park the vehicle on a level surface, shut down the engine, set the parking brake, and chock the tires before working under the vehicle. Releasing air from the system can cause the vehicle to roll.
- Keep hands away from brake chamber push rods and slack adjusters; they will apply as the air pressure drops.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes.
- Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed the recommended air pressure.
- Always wear safety glasses when working with compressed air. Never look into air jets or direct them toward anyone.
- Never attempt to disassemble a component until you have read and understood the recommended procedures. Some components contain powerful springs and injury can result if they are not correctly disassembled. Use only the correct tools and observe all precautions regarding use of those tools.

Wheel Speed Sensor Replacement

IMPORTANT: Do not attempt to repair the wheel sensor wire (the wire that comes with the sensor). If the wire is damaged, replace the sensor assembly.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. Refer to **Section 54.13** for information on special terminals and connectors, and on ordering tools for them.

FRONT AXLE

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires to prevent vehicle movement.
2. Twist and pull the sensor to remove it from the steering knuckle. See **Fig. 1**.

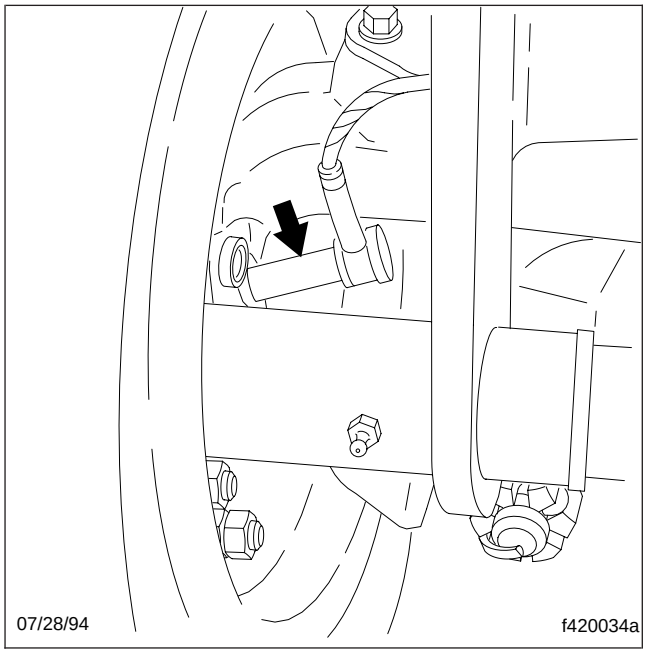

Fig. 1, Front Wheel Speed Sensor Removal

3. Remove the sensor cable from the steering knuckle top cap.
4. Disconnect the sensor cable from the chassis harness.
5. Remove the clamping bushing from the steering knuckle.
6. Connect the new sensor cable to the chassis harness.
7. Attach the sensor cable to the steering knuckle top cap.
8. Press the clamping bushing into the brake spider hole until it stops.
9. Coat the sensor with Mobil HP, Valvoline EP 633, Pennzoil 707L, or an equivalent. Press the sensor into the clamping bushing until it is stopped by the tone wheel.
10. Remove the chocks from the rear tires.

REAR AXLE

1. Park the vehicle on a flat surface, set the parking brake, and shut down the engine. Chock the front tires to prevent vehicle movement.
2. Raise the rear of the vehicle until the tires clear the ground. Place safety stands under the axle.
3. Back off the slack adjuster to release the rear axle brake shoes.
4. Remove the wheel and tire assembly from the rear axle. For instructions, see **Group 40**.
5. Remove the brake drum. For instructions, refer to **Group 35**.
6. Twist and pull the sensor to remove it from the mounting block in the axle housing.
7. Remove the clamping bushing.
8. Remove the capscrew that attaches the sensor cable and the hose clamp to the axle tube.
9. Disconnect the sensor cable from the chassis harness.
10. Connect the new sensor cable to the chassis harness.
11. Attach the hose clamp and sensor cable to the axle tube located between the backing plate and the spring plate.
12. Press the clamping bushing into the mounting block until it stops.
13. Coat the sensor with Mobil HP, Valvoline EP633, Pennzoil 707L, or an equivalent. Using your

Wheel Speed Sensor Replacement

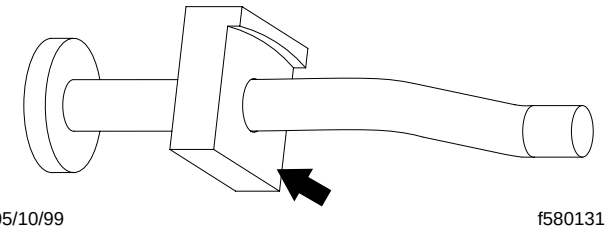
hand, push the sensor into the clamping bushing until it is stopped by the tone wheel.

14. Install the brake drum on the wheel hub. For instructions, refer to **Group 35**.
15. Adjust the rear axle brakes. For instructions, refer to the applicable brake section in this manual.
16. Install the wheel and tire assembly, and tighten the wheel nuts. Use the tightening sequence and torque values listed in **Group 40**.
17. Remove the safety stands, lower the vehicle, and remove the chocks from the front tires.

Adjustment

NOTE: The following adjustment procedure requires the use of special tool T11-17556-000. Use of this tool, available through the PDCs, eliminates the time-consuming task of removing the wheel and tire assembly, and the brake drum. See **Fig. 1**.

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the front tires.



05/10/99 f580131

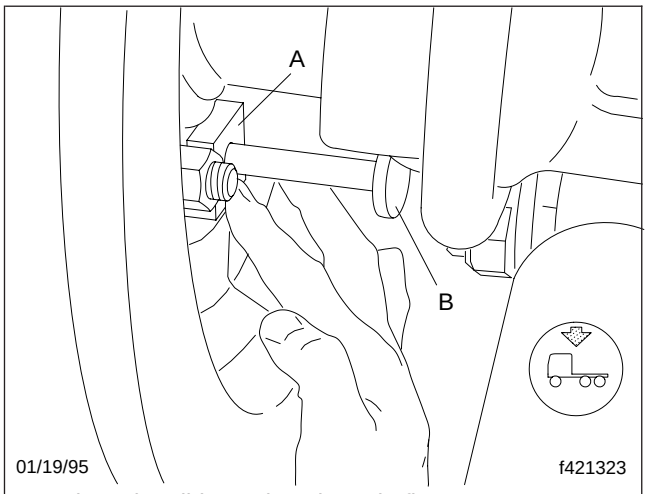
1. Adjustment Tool Slide

Fig. 1, ABS Sensor Adjustment Tool

2. Find the sensor access hole in the rear-axle flange.
   - 2.1 View the inboard side of the brake drum and axle from the rear. The ABS sensor wiring harness should be visible through a hole in the 12 o'clock position.
   - 2.2 Find the S-cam at either the 3 or 9 o'clock position.
   - 2.3 The sensor access hole is opposite the S-cam. The hole is approximately 3/4 inch (19 mm) in diameter.

IMPORTANT: Do not pry or push the sensor with sharp objects.

3. Insert service tool T11-17556-000 in the sensor access hole.
4. Place the slide of the tool on the axle flange to align the tool. See **Fig. 2**.
5. Tap the tool handle lightly with the palm of your hand. This ensures that the sensor is touching the tone wheel.
6. Remove the tool from the wheel and repeat the procedure on the other rear-axle speed sensor.



01/19/95 f421323

A. Place the slide against the axle flange.
B. Tap the handle with your hand.

Fig. 2, Position the Tool

7. Remove the chocks from the tires.

Modulator Valve Removal and Installation

Removal

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. See **Section 54.13** for information on special terminals and connectors, and on ordering tools for them.

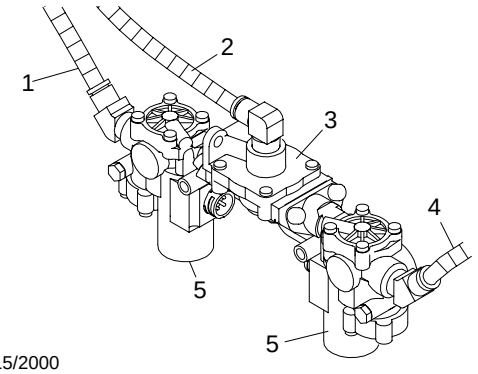
1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the front and rear tires.

⚠ WARNING

Release all the compressed air from the air reservoirs before disconnecting any air hose. Disconnecting air hoses from the modulator valves without first releasing the pressure in the air reservoirs can cause the hoses to swing uncontrollably, possibly resulting in personal injury or property damage. Before starting work on the brake system, read Safety Precautions, 100 in this section.

2. Release the pressure from the air reservoirs.
3. Mark the electrical connectors for ease of installation. Disconnect the wiring from the applicable front or rear modulator valve assembly.
   - The modulator valves for the front-axle brakes are mounted as an assembly on a bracket on the front crossmember (behind the front bumper). See **Fig. 1**. The assembly includes two modulator valves and a quick-release valve.
   - The rear modulator valve assembly is mounted on a bracket on a crossmember near the rear brake chambers. See **Fig. 2**. The assembly includes two modulator valves and a service relay valve.
4. Mark the air lines for ease of installation. Disconnect the air lines.
5. Remove the fasteners attaching the modulator valve assembly to the mounting bracket. Remove the valve assembly.

NOTE: The modulator valve assemblies can be disassembled if replacement of the quick-release valve, service relay valve, automatic traction control valve (if equipped), or one of the modulator valves is needed. For disassembly and assembly instructions, see **Subject 140**.



05/15/2000 f430159

5. Control Air Line (green, from foot pedal valve)
6. Modulator Valve Electrical Connection
7. Supply Air Line (green, from primary air reservoir)

Fig. 2, Rear Modulator Valve Assembly

Installation

1. Install the new modulator valve assembly on the bracket on the crossmember. Tighten the fasteners 18 lbf·ft (24 N·m).

Modulator Valve Removal and Installation

2. Connect the air lines to the valves, as marked during removal.
3. Connect the electrical cable connectors to the modulator valves. Tighten only hand-tight.

Installation Checkout

1. Apply the brakes, turn the ignition switch on, and wait for the ABS indicator light to come on.
2. Listen to the modulator valves cycle one by one, then together diagonally as follows:
    - 4-Channel valve cycle: 1, 2, 3, 4; then 1 and 2 together followed by 3 and 4.
    - 6-Channel valve cycle: 1, 2, 3, 4, 5, 6; then 1, 2, and 3 together followed by 4, 5, and 6.
3. If a valve fails to cycle, turn the ignition switch off and make sure the electrical connections are tight. Then, turn the ignition switch on and listen to the valve cycle again.

   If a valve still fails to cycle, check for fault codes. See **Troubleshooting, 300** for fault-code identification.
4. Apply the brakes and check the modulator valve fittings for leaks. No air leakage is permitted.
5. Remove the chocks from the tires.
6. Test drive the vehicle to verify that the ABS warning light is functioning correctly.

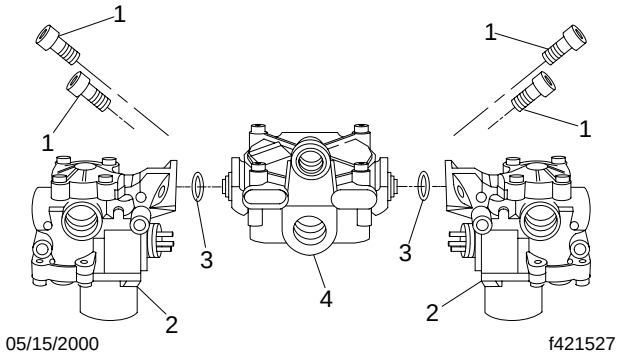
Modulator Valve Assembly, Disassembly and Assembly

Disassembly

NOTE: On vehicles equipped with Automatic Traction Control (ATC), the ATC valve can be replaced without removing the rear modular valve assembly if there is enough room to work.

1. Remove the modulator valve assembly from the crossmember. See **Subject 130** for instructions.
2. Remove the modulator valves from the quick-release or service relay valve.

   2.1 Using a 6-mm Allen wrench, remove two Allen-head capscrews that attach each modulator valve to the quick-release or service relay valve. See **Fig. 1**.



05/15/2000 f421527

NOTE: The fasteners are the same for both the front and rear modulator valve assemblies.

1. Capscrew, Allen-Head, M8
2. Modulator Valve
3. O-Ring
4. Service Relay Valve

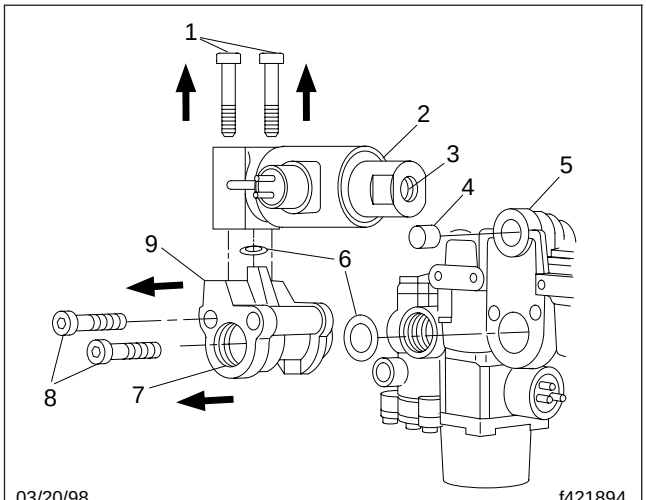
Fig. 1, Rear Modulator Valve Assembly

   2.2 Carefully separate the modulator valves from the quick-release or service relay valve.

   2.3 Remove and discard the O-rings.

3. If the vehicle is equipped with Automatic Traction Control (ATC), remove the ATC valve from the service relay valve. See **Fig. 2**.

   3.1 Using a 5-mm Allen wrench, remove two Allen-head capscrews that attach the adaptor to the service relay valve. Remove the adapter/ATC valve assembly.



03/20/98 f421894

1. Capscrew, Allen-head, M8
2. ATC Valve
3. Control Port
4. Seal
5. Service Relay Valve
6. O-Ring
7. Supply Port
8. Capscrew, Allen-head, M6
9. Adaptor

Fig. 2, ATC Valve Mounting

   3.2 Using a 6-mm Allen wrench, remove two Allen-head capscrews that attach the ATC valve to the adaptor. Separate the valve from the adaptor.

   3.3 Remove and discard the seal and two O-rings.

Assembly

1. If the vehicle is equipped with Automatic Traction Control (ATC), install the ATC valve on the service relay valve.

   1.1 Clean the O-ring grooves on the adaptor. Lubricate the small replacement O-ring and install it in the top port in the adaptor.

   1.2 Using two new M8 Allen-head capscrews, install the ATC valve on the adaptor. Tighten the capscrews 12 to 13 lbf·ft (18 to 20 N·m).

Modulator Valve Assembly, Disassembly and Assembly

1.3 Lubricate the replacement seal and install it in the control port (upper port) of the service relay valve.

1.4 Lubricate the large replacement O-ring and install it in the groove in the supply port (lower port) of the service relay valve.

1.5 Using two new M6 Allen-head capscrews, install the adaptor on the service relay valve. Tighten the capscrews 48 to 60 lbf·in (542 to 678 N·cm).

2. Install the modulator valves on the quick-release or service relay valve.

2.1 Plug any unused ports on the replacement modulator valves.

2.2 Clean the O-ring surfaces on the modulator and quick-release or service relay valves. Lubricate the replacement O-rings and place them in the applicable grooves in the valves.

2.3 Install each modulator valve on the quick-release or service relay valve with two M8 Allen-head capscrews. Tighten the capscrews 13 to 15 lbf·ft (18 to 20 N·m).

3. Install the modulator valve assembly on the bracket on the crossmember. For instructions, see **Subject 130**.

ABS Tone Ring Installation on Service Hubs

Installation

IMPORTANT: Some ABS service hubs do not have a tone (tooth) ring installed on the hub. The tone ring must be ordered separately and installed on the hub before installation of the hub onto the axle. Tone rings are made of a special material and require a specific installation procedure for proper installation.

⚠ WARNING

When installing an ABS system, special ABS hubs must be ordered. Machining older hubs to accommodate the installation of tone rings can cause problems due to insufficient hub bore wall thickness. Machining an older hub with insufficient hub bore wall thickness could result in cracking, causing bearing damage and wheel loss. This could cause an accident resulting in personal injury and property damage.

1. Submerge the tone ring in boiling water or place it in an oven at 250°F (121°C) for approximately 15 minutes.

⚠ CAUTION

Do not attempt to heat the tone ring with a torch as this can damage the ring.

2. Using pliers, remove the tone ring from the boiling water or oven and center it on the machined area of the hub bore. See **Fig. 1**.
3. While the tone ring is still hot, make sure it is properly centered on the machined surface. Using a rubber mallet, tap the tone ring until it bottoms out around the machined surface on the hub. See **Fig. 2**.
4. Install the hub on the axle. Place a dial indicator with a magnetic base so the dial indicator is against the tone-ring teeth. See **Fig. 3**.
5. Rotate the hub and check the ring for runout. The runout should be less than 0.005 inch (0.13 mm). See **Fig. 4**.
6. Install the wheel. For instructions, see **Group 40**.

Dynamometer Testing Vehicles with ATC

⚠ WARNING

Do not test a vehicle equipped with Automatic Traction Control (ATC) on a dynamometer unless the ATC system is disabled. Activation of the ATC on a dynamometer will cause unequal drive-wheel torque that can result in loss of vehicle control and personal injury or death.

Vehicles with ATC must have the ATC disabled before testing the vehicle on a dynamometer. Use one of the following methods to disable the ATC:

- Use the Meritor PC Diagnostics or the Pro-Link electronic diagnostic tool to disable the ATC.
- Press and hold the blink code switch for a least three seconds. Once the system identification code begins, the ATC system has been disabled. See **Table 1** for system ID codes.
- Removing the ABS circuit breaker or fuse, or removing the ECU power connector will disable both the ABS and ATC.

The ATC light on the dash comes on and stays on when the ATC is disabled.

System Identification Blink Codes *		
Blink Code	**Sensors/ Modulators**	**Wheel Positions**
1 Blink	6S/6M	6 x 2
2 Blinks	4S/4M	4 x 4
4 Blinks	6S/4M	6 x 4
5 Blinks	6S/6M	6 x 4

* The system identification blink code, followed by a 4-second pause, repeats until the ignition switch is turned off.

Table 1, System Identification Blink Codes

General Information

⚠ WARNING

Before testing a vehicle equipped with Automatic Traction Control (ATC) on a dynamometer, the ATC system must be disabled. See Subject 160 for instructions. Activation of the vehicle ATC on a dynamometer will cause unequal drive-wheel torque that can result in loss of vehicle control and personal injury or death.

Before testing a wheel speed sensor, modulator valve, or ATC valve, make sure the supply voltage to the antilock braking system (ABS) electronic control unit (ECU) is sufficient (see "ECU Supply Voltage Test") and check for leaks in the ABS pneumatic system.

The sensor and valve resistance tests are given in two steps. First, disconnect the applicable cable from the ECU and measure the resistance across the terminals in the cable connector. If the resistance is within the specified range, both the cable and the sensor or valve are good.

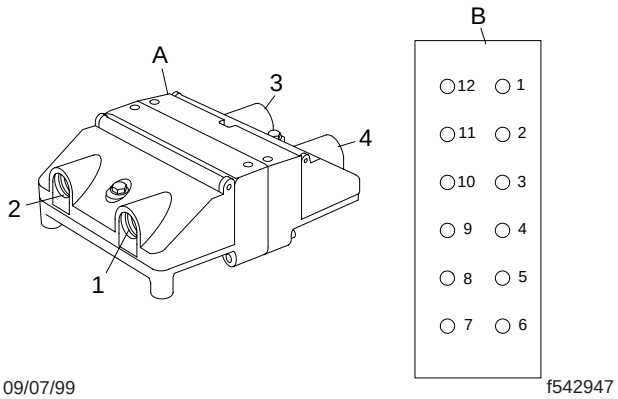
Next, if the resistance reading is not acceptable, disconnect the cable from the sensor or valve and measure the resistance across the sensor or valve terminals. This two-step procedure quickly determines whether the problem is in the cable or the component.

Wire Numbers and Connector Pin Locations

⚠ CAUTION

The ignition switch must be off when connecting or disconnecting connectors from the ECU. Power applied to the ECU during connector installation or removal could damage the pins.

The WABCO D-Version, frame-mounted ECU has several multi-pin connectors that must be disconnected to test the wheel speed sensors, modulator valves, or ATC valve. To disconnect the electrical connectors from the ABS ECU, remove the capscrews and lift the covers. See **Fig. 1** to identify the pin locations on the ECU connector. **Table 1** provides the wire numbers and circuit descriptions for testing the ABS/ATC components.



A. Frame-mounted ECU.
B. ECU connector pin locations.

2. X2 Connector (black)
3. X3 Connector (green)
4. X4 Connector (brown—6S/4M, 6S/6M only)

Fig. 1, Frame-Mounted ECU and Pin Locations

ECU Supply Voltage Test

Use Meritor WABCO PC Diagnostics system to check the supply voltage to the ABS ECU. If the PC Diagnostics is not available, use the following procedure to check the voltage.

1. Park the vehicle on a level surface, set the parking brake, shut down the engine, and chock the rear tires.
2. Disconnect the X1 (gray) connector at the ABS ECU.
3. Turn the ignition switch on.
4. Connect a voltmeter between pin 1 and a good chassis ground. The voltmeter must indicate 9.5 to 14 volts.
5. Connect a voltmeter between pin 2 and a good chassis ground. The voltmeter must indicate 9.5 to 14 volts.
6. Turn the ignition switch off.
7. If the voltage at the ECU is not within the specified range, check the battery voltage and test the wiring to the ECU and to ground.

Testing

8. Connect the X1 connector to the ECU and remove the chocks from the tires.

ABS/ATC Circuit Pin and Wire Numbers				
Pin Connector	**Pin Number**	**Color**	**Wire Number**	**Circuit Description**

Table 1, ABS/ATC Circuit Pin and Wire Numbers

ABS Pneumatic System Test

To check for air leaks in the ABS pneumatic system, listen for the sound of escaping air at each valve. To confirm a slow air leak, apply a soap-and-water solution to air line fittings and watch for bubbles.

Wheel Speed Sensor Tests

WHEEL SPEED SENSOR AND CIRCUIT RESISTANCE

To check the resistance in a wheel speed sensor circuit, perform the following test:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Disconnect the sensor cable connector from the ABS ECU. See **Table 1**.

3. Connect ohmmeter probes to the sensor connector terminals and read the resistance.
    - If the resistance is 500 to 2000 ohms, the cable and the sensor circuit are good. Proceed to the "Wheel Speed Sensor Voltage" test.
    - If the resistance is less than 500 ohms or greater than 2000 ohms, perform the next test, "Wheel Speed Sensor Resistance."

WHEEL SPEED SENSOR RESISTANCE

To check the resistance in a wheel speed sensor, perform the following test:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Disconnect the wheel sensor cable from the chassis harness.
3. Connect ohmmeter probes to the pins on the sensor and read the resistance.
    - If the resistance reading is 500 to 2000 ohms but the resistance noted in the previous test, "Wheel Speed Sensor and Cable Resistance" was not, repair or replace the chassis harness wiring.
    - If the resistance is less than 500 ohms or greater than 2000 ohms, clean the terminals and check the resistance again.
    - If the resistance reading is still not correct, replace the sensor. See **Subject 110** for instructions.
4. Install the connectors and remove the chocks from the tires.

WHEEL SPEED SENSOR VOLTAGE

To check the voltage output of a wheel speed sensor:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine.
2. Chock the tires of the axle not being tested. Raise the vehicle and put jack stands under the axle so the wheels can rotate.
3. Disconnect the applicable connector from the ABS ECU for the sensor being tested. See **Table 1**.
4. Set a digital multimeter to the AC voltmeter mode. Connect the probes to the cable connector terminals for the sensor being tested.
5. Rotate the wheel by hand at a speed of 30 rpm (one-half revolution per second) and read the voltage output. The wheel speed sensor must generate a minimum of 0.2 volt AC.
    - If the voltage is at least 0.2 volt AC, skip to the next step.
    - If the voltage reading is less than 0.2 volt AC, push the sensor in its holder until the sensor touches the tooth wheel. See **Subject 120** for instructions. Repeat the voltage test.
    - If the sensor output is still less than 0.2 volt AC, replace the sensor.
6. Install the connector on the ECU. Remove the jack stands, lower the vehicle, and remove the chocks from the tires.

Modulator Valve Tests

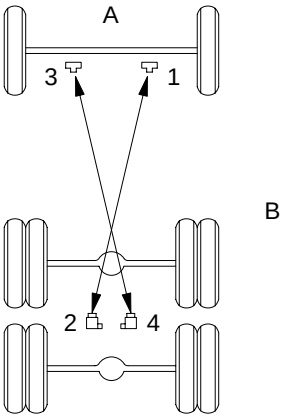
MODULATOR VALVE FUNCTION CHECK

NOTE: Valves can be tested using the Meritor WABCO PC Diagnostics software or the following procedure.

Modulator valves control the air pressure to each affected brake during an ABS function. To make sure the modulator valves are working, listen to them cycle during the ABS self-test.

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Turn the ignition switch on.
3. When the ABS warning light comes on, listen for the modulator valves to cycle one by one, then together diagonally. See **Fig. 2**.
    - 4-Channel valve cycle: 1, 2, 3, 4; then 1 and 2 together followed by 3 and 4.

- 6-Channel valve cycle: 1, 2, 3, 4, 5, 6; then 1, 2, and 3 together followed by 4, 5, and 6.



NOTE: During the self-test, the valves cycle one by one in order (1–2–3–4), then in pairs diagonally (1/2 and 3/4). A 4-channel valve cycle is shown.

A. Cab
B. Curbside
1. Right Front Modulator Valve
2. Left Rear Modulator Valve
3. Left Front Modulator Valve
4. Right Rear Modulator Valve

Fig. 2, Modulator Valve Self-Test Sequence

4. If the valves do not all cycle correctly, turn the ignition off and check the connectors for tightness. Repeat the self-test.
5. If the valves still do not cycle correctly, start the engine and check the air line connections to the valves for leaks. Shut down the engine and tighten the air line fittings. Repeat the self-test.
6. If the valves still do not cycle correctly, perform the next test, "Modulator Valve and Cable Resistance."

MODULATOR VALVE AND CABLE RESISTANCE

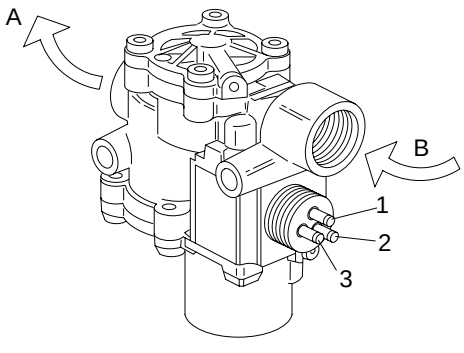
To check the resistance in a modulator valve and cable circuit, perform the following test:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Disconnect the modulator valve connector from the ABS ECU. See **Table 1**.
3. Connect ohmmeter probes to the cable connector pins for the modulator valve "In" solenoid and "Ground." Read the resistance. Then, move the probes to the "Out" and "Ground" pins and read the resistance.
4. The resistance in each solenoid coil and cable circuit must be 4 to 8 ohms.
   - If the resistance in each solenoid circuit is 4 to 8 ohms, the cable and modulator valve are good. Install the connector on the ECU and remove the chocks from the tires.
   - If the resistance in either solenoid circuit is less than 4 ohms or greater than 8 ohms, go to the next test, "Modulator Valve Resistance."

MODULATOR VALVE RESISTANCE

To check the resistance in the solenoid coils in an ABS modulator valve, perform the following test:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Disconnect the cable connector from the modulator valve being tested. See **Table 1**.
3. Connect ohmmeter probes to the modulator valve "In" solenoid and "Ground" terminals and read the resistance. Then, move the probes to the "Out" and "Ground" terminals and read the resistance. See **Fig. 3** for the modulator terminal locations.
4. The resistance in each solenoid coil must be 4 to 8 ohms.
   - If the resistance in each solenoid coil is 4 to 8 ohms but the resistance noted in the previous test, "Modulator Valve and Cable Resistance" was not, repair or replace the chassis harness.
   - If the resistance is less than 4 ohms or greater than 8 ohms, clean the terminals on the modulator valve and check the resistance again.



A. Delivery Port B. Supply Port
1. Ground (Common), green-yellow wire
2. Exhaust Solenoid (Out), blue wire
3. Supply Solenoid (In), brown wire

Fig. 3, Modulator Valve Terminals

- If the resistance is still not correct, replace the valve. See **Subject 130** for instructions.

5. Install the cable connectors and remove the chocks from the tires.

ATC Valve Tests

ATC VALVE AND CABLE RESISTANCE

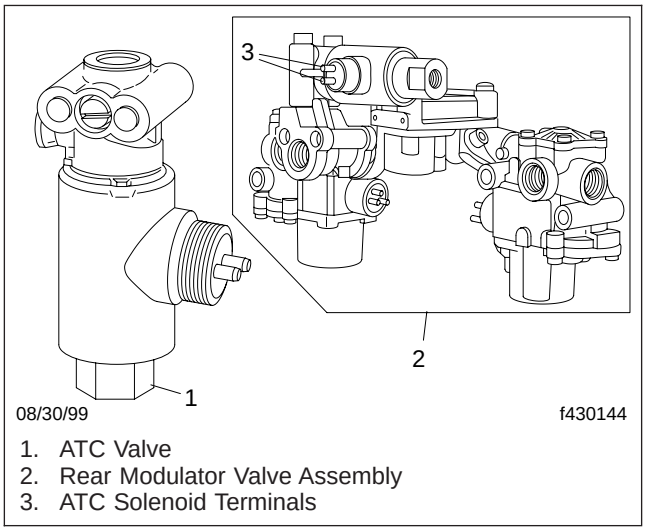
To check the resistance in the ATC valve and cable circuit, perform the following test:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Disconnect the ATC valve connector from the ABS ECU. See **Table 1**.
3. Connect ohmmeter probes to the cable connector pins for the ATC valve and read the resistance.
4. The resistance in the ATC solenoid coil and cable circuit must be 6.4 to 12 ohms.
   - If the resistance is 6.4 to 12 ohms, the ATC valve and cable are good. Install the cable connector on the ECU and remove the chocks from the tires.
   - If the resistance is less than 6.4 ohms or greater than 12 ohms go to the next test, "ATC Valve Resistance."

ATC VALVE RESISTANCE

To check the resistance in the solenoid coil in the ATC valve, perform the following test:

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the rear tires.
2. Disconnect the cable connector from the ATC valve. See **Table 1**.
3. Connect ohmmeter probes to the ATC valve terminals and read the resistance. See **Fig. 4**.



1. ATC Valve
2. Rear Modulator Valve Assembly
3. ATC Solenoid Terminals

Fig. 4, ATC Valve Terminals

4. The resistance of the ATC solenoid coil and its wiring must be 6.4 to 12 ohms.
   - If the resistance is 6.4 to 12 ohms but the resistance noted in the previous test, "ATC Valve and Cable Resistance" was not, repair or replace the electrical cable.
   - If the resistance is less than 6.4 ohms or greater than 12 ohms, clean the terminals on the ATC valve and check the resistance again.
   - If the resistance is still not correct, replace the valve. See **Subject 140** for instructions.

5. Install the connectors and remove the chocks from the tires.

Troubleshooting

⚠ WARNING

Before testing a vehicle equipped with Automatic Traction Control (ATC) on a dynamometer, the ATC system must be disabled. See Subject 160 for instructions. Activation of the vehicle ATC on a dynamometer will cause unequal drive-wheel torque that can result in loss of vehicle control and personal injury or death.

This subject includes troubleshooting procedures for diagnosing problems indicated by the ABS warning light(s) or the ATC wheel spin indicator light (if equipped) on the instrument panel. If any of these lights come on after the initial self-test, use one of the following methods to identify the problem:

- Troubleshoot using the Meritor WABCO PC Diagnostics software.
- Troubleshoot using J1587 codes viewed on a computer with Freightliner's ServiceLink installed.
- Troubleshoot using the instrument panel blink codes (with or without Pro-Link 9000®).

The J1587-code method provides more information about the specific problem than can be obtained from the blink codes.

The ABS (and ATC, if equipped) system has built-in diagnostics to ensure that all components are operating correctly. The first step is an automatic self-test. Under normal conditions, the ABS warning light(s) (ABS, TRAILER ABS, or ANTI LOCK) and ATC wheel spin indicator light (TRAC) light up on the instrument cluster when the ignition is turned on. After about 3 seconds, these lights should go out if all of the vehicle's ABS/ATC components are working.

If any of the lights stay on, or come back on later, a problem within the ABS/ATC system has occurred. The driver can continue to drive the vehicle, but the ABS system could be partially or completely inoperative.

NOTE: The TRAC indicator stays lit when the ATC is controlling wheel spin and blinks continuously if the ATC switch (TRAC MUD/SNOW) is activated. These are normal conditions and do not indicate a fault.

To check the type of fault code recorded, stop the vehicle and turn off the engine. Then, turn on the ignition switch, but don't start the engine. If the light stays on after the 3-second self-test, there is an active system fault that must be repaired to ensure proper system operation.

If the light does not stay on, a stored or intermittent fault (indicating a loose connector or broken wire) has been recorded in the ABS electronic control unit (ECU) memory.

If either light does not come on during the self-test, check the bulb, all related circuit breakers in the electrical panel, or the batteries (the ABS/ATC system requires at least 9.5 volts to function correctly).

If a fault has been corrected since the ABS warning light originally came on, the system must be calibrated by driving the vehicle a short distance at 4 mph (6 km/h) or more before the light will go out.

Using Meritor WABCO PC Diagnostics

Follow the instructions in the Meritor WABCO PC Diagnostics manual for troubleshooting the ABS/ATC system.

Using J1587 Fault Codes

Use Freightliner's ServiceLink to diagnose the ABS/ATC system if detailed fault codes are needed or if the diagnosis must be done remotely. Connect a computer, with ServiceLink installed, to the J1587 datalink connector located under the left-hand dash. Follow the instructions found in the ServiceLink manual.

The J1587 fault codes are eight-digit numbers.

- The first three digits refer to the message identifier (MID) that indicates the ECU reporting the fault. The MID is 136 for the ABS/ATC ECU.
- The next three digits (preceded by a lowercase "s") represents the subsystem identifier (SID), which indicates the component at fault.
- The last two digits, the Failure Mode Identifier (FMI), represent the specific problem with the component.

The tables provided in "Troubleshooting Tables" all have an MID code of 136. Each table lists all the FMI codes for a specific component (SID). See **Table 1**

Troubleshooting for D-Version ABS

for a list of the first six digits of the fault codes with their corresponding components and troubleshooting table references.

Active faults cannot be cleared until they are repaired. A wheel sensor fault that has been repaired will not be cleared from memory until the vehicle has been driven at least 4 mph (6 km/h) to calibrate the system.

To erase all the stored fault codes from the ECU memory, refer to the ServiceLink manual. Make sure to make a note of all the stored fault codes before clearing them. Stored faults cannot be cleared if active faults exist.

J1587 Fault Code Cross-Reference

***** The left or right third wheel sensor is located at the wheel end of the rearmost axle on a 6S/4M or 6S/6M configuration.

† The left or right third modulator valve is located on the chassis near the rearmost axle on a 6S/6M configuration.

Table 1, J1587 Fault Code Cross-Reference

Using The Instrumentation Panel Blink Codes

NOTE: If troubleshooting the system with the Pro-Link 9000, use the instruction booklet that is supplied with the WABCO D-Version ABS cartridge.

Use the ABS CHECK switch and the ABS warning light to:

- Display any active or stored faults (press the ABS CHECK switch 1 second for the Diagnostic mode).
- Erase stored faults from the ECU memory or display the system identification code (press the ABS CHECK switch 3 seconds for the Clear All mode).

NOTE: For simplicity, the ABS warning light will be referred to as the ABS light in this procedure. The warning light(s) on your vehicle may indicate ABS, TRAILER ABS, or ANTI LOCK.

Displaying Fault Codes

Fault codes are displayed as follows:

- With the ignition switch on, press the ABS CHECK switch for about 1 second (Diagnostic mode), then release. The ABS light should go out during the 1-1/2 second pause. See **Fig. 1**.
- The ABS light will blink (flash) a number equal to the first digit of the two-digit fault code. The first digit is a number from one to eight.
- After a 1-1/2 second pause, the light will blink the second digit. The number of blinks for the second digit is from one to six.
- After a 4-second pause, the cycle repeats an active fault code until it is repaired.
- If there are no active faults but one or more stored faults are in the ECU memory, the system will display all recorded faults in sequence starting with the most recent, with a 4-second pause between codes.

For example, after the ABS CHECK switch is pressed 1 second and released, fault code 2–3 is indicated by two blinks, a pause of 1-1/2 seconds, followed by three blinks and a 4-second pause.

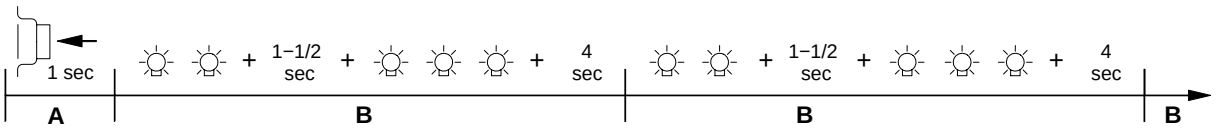
- If it is an active fault, the same fault code will repeat until the ignition switch is turned off. See **Fig. 1**.
- If it is a stored fault, the next fault in the ECU memory will be displayed after the 4-second pause. See **Fig. 2**. The last fault stored in memory is displayed first; each stored fault is displayed only once.
- If there are no fault codes in the ECU memory, blink code 1–1 is displayed, meaning the system is clear. See **Fig. 3**.

Identifying Blink Codes

The first digit in a blink code identifies the type of fault; the second digit indicates the specific location of the fault. See **Table 2** to identify the blink codes.

CAUTION

The ignition switch must be off when connecting or disconnecting connectors from the ECU. Power applied to the ECU during connector installation or removal could damage the pins.



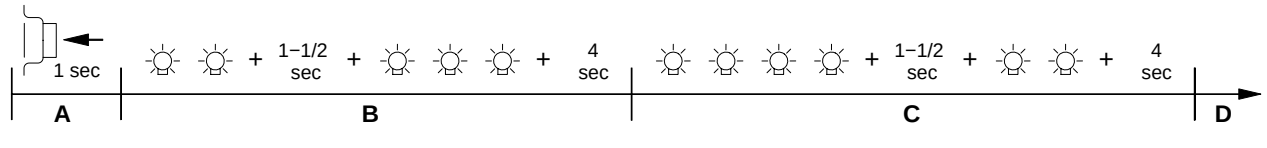
05/18/2000 f151013

NOTE: An active fault code repeats until the ignition switch is turned off.

A. Press the ABS CHECK switch 1 second. The ABS light goes out during a 1-1/2 second pause.
B. Blink code 2–3: two blinks, a 1-1/2 second pause, three blinks, and a 4-second pause.

Fig. 1, Active Fault Codes Repeat (blink code 2-3 shown)

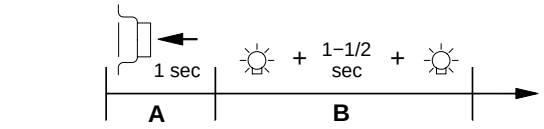
Troubleshooting for D-Version ABS



NOTE: The last fault stored is displayed first; each stored fault is displayed only once.

A. Press the ABS CHECK switch 1 second. The ABS light goes out during a 1-1/2 second pause.
B. The newest stored fault is displayed (blink code 2–3 is shown).
C. The second newest stored fault is displayed if one exists (blink code 3–2 is shown).
D. The third newest stored fault is displayed if one exists.

Fig. 2, Stored Fault Codes Display in Sequence



A. Press the ABS CHECK switch 1 second. The ABS light goes out during a 1-1/2 second pause.
B. Blink code 1–1: one blink, a 1-1/2 second pause, and 1 blink.

Fig. 3, No Faults, System OK

Once a fault code has been identified, use a multimeter to check the electrical harness at the ABS ECU connectors. See **Testing, 200** for wire numbers and connector pin locations on the frame-mounted ECU.

Refer to the applicable table in "Troubleshooting Tables" for fault codes, pins to be tested, and the correct multimeter readings. Repair or replace the components and/or wiring if the readings are not correct.

NOTE: Wire repairs may require the use of special tools for certain connectors and terminals. Refer to **Group 54** for information on special terminals and connectors, and ordering tools for them.

Refer to the wiring diagrams in **Specifications, 400** when troubleshooting the ABS system.

After the repair is complete, drive the vehicle at least 4 mph (6km/h) to calibrate the ABS/ATC system. Then, shut down the engine and turn the ignition switch on to verify the fault is no longer active. After pressing the ABS CHECK switch 1 second, a 1–1 "no fault" blink code should be displayed if there are no stored faults in the ECU memory.

Erasing Stored Faults

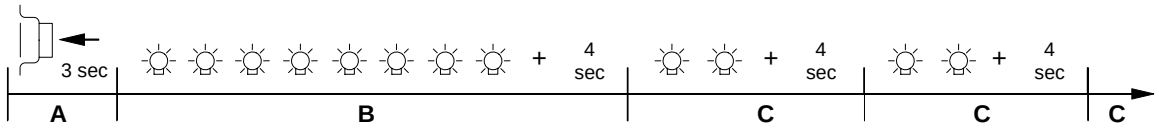
An active fault code cannot be erased from ECU memory but stored faults can be erased all at once without being repaired. Make sure that all stored fault codes are recorded before they are erased because they should be repaired as soon as possible.

Stored faults can be erased from the ECU memory as follows:

- Press the ABS CHECK switch for 3 to 6 seconds (Clear All mode).
- After releasing the switch, the ABS light will go out during the 1-1/2 second pause.
- If there were stored faults but no active faults, the ABS light will blink eight times meaning all stored faults have been cleared. See **Fig. 4**. (If there are active faults, only the system identification code will be displayed. See **Fig. 5**).
- After a 4-second pause, the ABS light will display the system identification code followed by another 4-second pause repeatedly until the ignition switch is turned off.

If there are active faults, only the system identification code will be displayed. See **Fig. 5**.

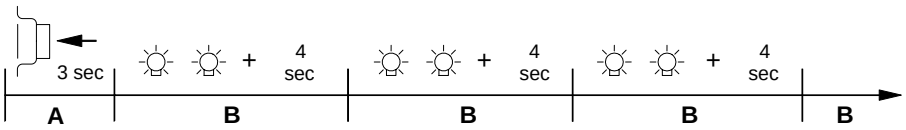
The system identification code indicates the number of ABS wheel speed sensors (S) and modulator valves (M) installed on the vehicle. See **Table 3** for a list of system identification codes.



05/18/2000 f151015

A. Press the ABS CHECK switch 3 seconds. The ABS light goes out during a 1-1/2 second pause.
B. Eight quick blinks followed by a 4-second pause. (Faults cleared.)
C. The system ID code followed by a 4-second pause repeats until the ignition switch is turned off. (The system ID code for a 4 x 4 vehicle is two quick blinks.)

Fig. 4, Stored Faults Cleared



05/18/2000 f151016

A. Press the ABS CHECK switch 3 seconds. The ABS light goes out during a 1-1/2 second pause.
B. The system ID code followed by a 4-second pause repeats until the ignition switch is turned off.

Fig. 5, Faults Not Cleared (active faults still exist)

ABS Blink Codes			
1st Digit (blinks)	**Type of Fault**	**2nd Digit (blinks)**	**Specific Location of Fault**
1	No Faults	1	—
2	ABS Modulator Valve	1	Right Front Steer Axle
		2	Left Front Steer Axle
		3	Right Rear Drive Axle
		4	Left Rear Drive Axle
		5	Right Rear Additional Axle
		6	Left Rear Additional Axle
3	Sensor Gap Too Large	See 2nd digit and fault-location list above.	
4	Short or Open Sensor Circuit		
5	Erratic Sensor Signal		
6	Tone Wheel		

Troubleshooting for D-Version ABS

ABS Blink Codes			
1st Digit (blinks)	**Type of Fault**	**2nd Digit (blinks)**	**Specific Location of Fault**
7	System Function *	1	J1922 or J1939 Datalink
		2	ATC Valve
		3	Retarder Relay † (third brake)
		4	ABS Warning Light
		5	ATC Configuration
		6	Reserved for future use
8	ECU	1	Low Power Supply
		2	High Power Supply
		3	Internal Fault
		4	System Configuration
		5	Ground

* Reconfigure the ECU if fault messages appear for components not installed on the vehicle.

† The ECU detects only fault code 136 S013 03, indicating the retarder relay is shorted to power. See "Troubleshooting Tables," **Table 16**. If the retarder relay circuit is open or if it is shorted to ground, the system will not indicate a fault.

Table 2, ABS Blink Codes

System Identification Blink Codes		
Blink Code	**Sensors/ Modulators**	**Vehicle Wheel Positions**
1 Blink	6S/6M	6 x 2
2 Blinks	4S/4M	4 x 4
4 Blinks	6S/4M	6 x 4
5 Blinks	6S/6M	6 x 4

Table 3, System Identification Blink Codes

If a fault cannot be repaired or erased from ECU memory, contact your Meritor district service manager or call Meritor WABCO at 1-800-535-5560.

Troubleshooting Tables

Left Front Wheel Sensor Troubleshooting (SID = s001)					
J1587 Fault Code			**Problem**	**Diagnostic Procedure**	**Blink Code**
MID	**SID**	**FMI**			
136	001	01	Excessive air gap	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 7 and 8 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. Check for loose wheel bearings and/or excessive hub runout.	3–2
136	001	02	Incorrect tire	Check for correct tire size. Check for correct number of teeth on the tone wheel.	5–2

Left Front Wheel Sensor Troubleshooting (SID = s001)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	001	03	Shorted to power	Measure the voltage across pin 7 of the X2 (black) connector and ground, and pin 8 of the X2 connector and ground. If the measurement indicates a voltage, the sensor is shorted to power.	4–2
136	001	04	Shorted to ground	Check the continuity between pin 7 of the X2 (black) connector and ground, and pin 8 of the X2 connector and ground. If continuity exists in either pin, the sensor is shorted to ground.	
136	001	05	Open circuit	Check the continuity between pins 7 and 8 of the X2 (black) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	001	06	Short circuit	Check the continuity between pins 7 and 8 of the X2 (black) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	001	07	Damaged tone wheel	Check the tone wheel for damage such as missing teeth.	6–2
136	001	08	Wheel slip	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 7 and 8 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. A fault is triggered if the wheel slips longer than 16 seconds.	3–2
136	001	09	Wires mismatched	Check for a mismatch fault of another sensor and correct the problem in the wiring harness.	5–2
136	001	10	Intermittent signal loss	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 7 and 8 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	3–2
136	001	11	Erratic signal	Check the sensor wiring and connectors for intermittent contact. Check the tone wheel for damage. Verify the signal by measuring the voltage across pins 7 and 8 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	5–2
136	001	12	Frequency incorrect	Check the sensor wiring and connectors for intermittent contact. The ECU may be at fault if the problem persists.	

* Use Meritor WABCO PC Diagnostics software to view the wheel speed signals. If there is an intermittent loss of the signal, check the connections.

Table 4, Left Front Wheel Sensor Troubleshooting (SID = s001)

Right Front Wheel Sensor Troubleshooting (SID = s002)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	002	01	Excessive air gap	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 5 and 6 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. Check for loose wheel bearings and/or excessive hub runout.	3–1

Troubleshooting for D-Version ABS

Right Front Wheel Sensor Troubleshooting (SID = s002)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	002	02	Incorrect tire	Check for correct tire size. Check for correct number of teeth on the tone wheel.	5–1
136	002	03	Shorted to power	Measure the voltage across pin 4 of the X2 (black) connector and ground, and pin 6 of the X2 connector and ground. If the measurement indicates a voltage, the sensor is shorted to power.	4–1
136	002	04	Shorted to ground	Check the continuity between pin 4 of the X2 (black) connector and ground, and pin 6 of the X2 connector and ground. If continuity exists in either pin, the sensor is shorted to ground.	
136	002	05	Open circuit	Check the continuity between pins 5 and 6 of the X2 (black) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	002	06	Short circuit	Check the continuity between pins 5 and 6 of the X2 (black) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	002	07	Damaged tone wheel	Check the tone wheel for damage such as missing teeth.	6–1
136	002	08	Wheel slip	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 5 and 6 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. A fault is triggered if the wheel slips longer than 16 seconds.	3–1
136	002	09	Wires mismatched	Check for a mismatch fault of another sensor and correct the problem in the wiring harness.	5–1
136	002	10	Intermittent signal loss	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 5 and 6 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	3–1
136	002	11	Erratic signal	Check the sensor wiring and connectors for intermittent contact. Check the tone wheel for damage. Verify the signal by measuring the voltage across pins 5 and 6 of the X2 (black) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	5–1
136	002	12	Frequency incorrect	Check the sensor wiring and connectors for intermittent contact. The ECU may be at fault if the problem persists.	

* Use Meritor WABCO PC Diagnostics software to view the wheel speed signals. If there is an intermittent loss of the signal, check the connections.

Table 5, Right Front Wheel Sensor Troubleshooting (SID = s002)

Left Rear Wheel Sensor Troubleshooting (SID = s003)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	003	01	Excessive air gap	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 1 and 2 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. Check for loose wheel bearings and/or excessive hub runout.	3–4
136	003	02	Incorrect tire	Check for correct tire size. Check for correct number of teeth on the tone wheel.	5–4
136	003	03	Shorted to power	Measure the voltage across pin 1 of the X3 (green) connector and ground, and pin 2 of the X3 connector and ground. If the measurement indicates a voltage, the sensor is shorted to power.	4–4
136	003	04	Shorted to ground	Check the resistance between pin 11 and 14 of the X3 (green) connector and ground, and pin 2 of the X3 connector and ground. If continuity exists in either pin, the sensor is shorted to ground.	
136	003	05	Open circuit	Check the continuity between pins 1 and 2 of the X3 (green) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	003	06	Short circuit	Check the continuity between pins 1 and 2 of the X3 (green) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	003	07	Damaged tone wheel	Check the tone wheel for damage such as missing teeth.	6–4
136	003	08	Wheel slip	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 1 and 2 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. A fault is triggered if the wheel slips longer than 16 seconds.	3–4
136	003	09	Wires mismatched	Check for a mismatch fault of another sensor and correct the problem in the wiring harness.	5–4
136	003	10	Intermittent signal loss	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 1 and 2 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	3–4
136	003	11	Erratic signal	Check the sensor wiring and connectors for intermittent contact. Check the tone wheel for damage. Verify the signal by measuring the voltage across pins 1 and 2 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	5–4
136	003	12	Frequency incorrect	Check the sensor wiring and connectors for intermittent contact. The ECU may be at fault if the problem persists.	

* Use Meritor WABCO PC Diagnostics software to view the wheel speed signals. If there is an intermittent loss of the signal, check the connections.

Table 6, Left Rear Wheel Sensor Troubleshooting (SID = s003)

Troubleshooting for D-Version ABS

Right Rear Wheel Sensor Troubleshooting (SID = s004)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	004	01	Excessive air gap	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 3 and 4 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. Check for loose wheel bearings and/or excessive hub runout.	3–3
136	004	02	Incorrect tire	Check for correct tire size. Check for correct number of teeth on the tone wheel.	5–3
136	004	03	Shorted to power	Measure the voltage across pin 3 of the X3 (green) connector and ground, and pin 4 of the X3 connector and ground. If the measurement indicates a voltage, the sensor is shorted to power.	4–3
136	004	04	Shorted to ground	Check the continuity between pin 3 of the X3 (green) connector and ground, and pin 4 of the X3 connector and ground. If continuity exists in either pin, the sensor is shorted to ground.	
136	004	05	Open circuit	Check the continuity between pins 3 and 4 of the X3 (green) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	004	06	Short circuit	Check the continuity between pins 3 and 4 of the X3 (green) connector. A good resistance measurement will be between 500 and 2000 ohms. If the resistance is not within this range, check the sensor and the chassis wiring.	
136	004	07	Damaged tone wheel	Check the tone wheel for damage such as missing teeth.	6–3
136	004	08	Wheel slip	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 3 and 4 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. A fault is triggered if the wheel slips longer than 16 seconds.	3–3
136	004	09	Wires mismatched	Check for a mismatch fault of another sensor and correct the problem in the wiring harness.	5–3
136	004	10	Intermittent signal loss	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 3 and 4 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	3–3
136	004	11	Erratic signal	Check the sensor wiring and connectors for intermittent contact. Check the tone wheel for damage. Verify the signal by measuring the voltage across pins 3 and 4 of the X3 (green) connector. A good measurement should be above 0.2 volt AC when the tire is rotated 30 rpm. *	5–3
136	004	12	Frequency incorrect	Check the sensor wiring and connectors for intermittent contact. The ECU may be at fault if the problem persists.	

* Use Meritor WABCO PC Diagnostics software to view the wheel speed signals. If there is an intermittent loss of the signal, check the connections.

Table 7, Right Rear Wheel Sensor Troubleshooting (SID = s004)

Left Third Wheel Sensor Troubleshooting (SID = s005)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	005	01	Excessive air gap	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 3 and 4 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. Check for loose wheel bearings and/or excessive hub runout.	3–6
136	005	02	Incorrect tire	Check for correct tire size. Check for correct number of teeth on the tone wheel.	5–6
136	005	03	Shorted to power	Measure the voltage across pin 3 of the X4 (brown) connector and ground, and pin 4 of the X4 connector and ground. If the measurement indicates a voltage, the sensor is shorted to power.	4–6
136	005	04	Shorted to ground	Check the continuity between pin 3 of the X4 (brown) connector and ground, and pin 4 of the X4 connector and ground. If continuity exists in either pin, the sensor is shorted to ground.	4–6
136	005	05	Open circuit	Check the continuity between pins 3 and 4 of the X4 (brown) connector. A good resistance measurement will be between 700 and 3000 ohms.	4–6
136	005	06	Short circuit	Check the continuity between pins 3 and 4 of the X4 (brown) connector. A good resistance measurement will be between 700 and 3000 ohms.	4–6
136	005	07	Damaged tone wheel	Check the tone wheel for damage such as missing teeth.	6–6
136	005	08	Wheel slip	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 3 and 4 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. A fault is triggered if the wheel slips longer than 16 seconds.	3–6
136	005	09	Wires mismatched	Check for a mismatch fault of another sensor and correct the problem in the wiring harness.	5–6
136	005	10	Intermittent signal loss	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 3 and 4 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. *	3–6
136	005	11	Erratic signal	Check the sensor wiring and connectors for intermittent contact. Check the tone wheel for damage. Verify the signal by measuring the voltage across pins 3 and 4 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. *	5–6
136	005	12	Frequency incorrect	Check the sensor wiring and connectors for intermittent contact. The ECU may be at fault if the problem persists.	5–6

* Use Meritor WABCO PC Diagnostics software to view the wheel speed signals. If there is an intermittent loss of the signal, check the connections.

Table 8, Left Third Wheel Sensor Troubleshooting (SID = s005)

Troubleshooting for D-Version ABS

Right Third Wheel Sensor Troubleshooting (SID = s006)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	006	01	Excessive air gap	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 5 and 6 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. Check for loose wheel bearings and/or excessive hub runout.	3–5
136	006	02	Incorrect tire	Check for correct tire size. Check for correct number of teeth on the tone wheel.	5–5
136	006	03	Shorted to power	Measure the voltage across pin 5 of the X4 (brown) connector and ground, and pin 6 of the X4 connector and ground. If the measurement indicates a voltage, the sensor is shorted to power.	4–5
136	006	04	Shorted to ground	Check the continuity between pin 5 of the X4 (brown) connector and ground, and pin 6 of the X4 connector and ground. If continuity exists in either pin, the sensor is shorted to ground.	4–5
136	006	05	Open circuit	Check the continuity between pins 5 and 6 of the X4 (brown) connector. A good resistance measurement will be between 700 and 3000 ohms.	4–5
136	006	06	Short circuit	Check the continuity between pins 5 and 6 of the of the X4 (brown) connector. A good resistance measurement will be between 700 and 3000 ohms.	4–5
136	006	07	Damaged tone wheel	Check the tone wheel for damage such as missing teeth.	6–5
136	006	08	Wheel slip	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 5 and 6 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. A fault is triggered if the wheel slips longer than 16 seconds.	3–5
136	006	09	Wires mismatched	Check for a mismatch fault of another sensor and correct the problem in the wiring harness.	5–5
136	006	10	Intermittent signal loss	Adjust the sensor. Verify the adjustment by measuring the voltage across pins 5 and 6 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. *	3–5
136	006	11	Erratic signal	Check the sensor wiring and connectors for intermittent contact. Check the tone wheel for damage. Verify the signal by measuring the voltage across pins 5 and 6 of the X4 (brown) connector. A good measurement should be above 0.2 volt AC when the tire is rotated at 30 rpm. *	5–5
136	006	12	Frequency incorrect	Check the sensor wiring and connectors for intermittent contact. The ECU may be at fault if the problem persists.	5–5

* Use Meritor WABCO PC Diagnostics software to view the wheel speed signals. If there is an intermittent loss of the signal, check the connections.

Table 9, Right Third Wheel Sensor Troubleshooting (SID = s006)

Left Front Modulator Valve Troubleshooting (SID = s007)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	007	01	Open circuit in the inlet and/or outlet solenoid circuits	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 10 and 11 of the X2 (black) connector, and between pins 2 and 11. A good measurement should be between 4 and 8 ohms.	2–2
136	007	03	Shorted to power	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Measure the voltage across pins 2, 10, and 11 of the X2 (black) connector and ground. If any of the measurements indicate a voltage, the valve is shorted to power.	
136	007	05	Open circuit	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 10 and 11 of the X2 (black) connector, and between pins 2 and 11 of the X2 connector. A good measurement should be between 4 and 8 ohms.	
136	007	06	Shorted to ground	Check continuity between pin 2 of the X2 (black) connector and ground, and pin 10 of the X2 connector and ground. If continuity exists in either pin, the valve is shorted to ground.	

Table 10, Left Front Modulator Valve Troubleshooting (SID = s007)

Right Front Modulator Valve Troubleshooting (SID = s008)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	008	01	Open circuit in the inlet and/or outlet solenoid circuits	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 3 and 9 of the X2 (black) connector, and between pins 4 and 9. A good measurement should be between 4 and 8 ohms.	2–1
136	008	03	Shorted to power	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Measure the voltage across pins 3, 4, and 9 of the X2 (black) connector and ground. If any of the measurements indicate a voltage, the valve is shorted to power.	
136	008	05	Open circuit	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 3 and 9 of the X2 (black) connector, and between pins 4 and 9 of the X2 connector. A good measurement should be between 4 and 8 ohms.	
136	008	06	Shorted to ground	Check continuity between pin 3 of the X2 (black) connector and ground, and pin 4 of the X2 connector and ground. If continuity exists in either pin, the valve is shorted to ground.	

Table 11, Right Front Modulator Valve Troubleshooting (SID = s008)

Troubleshooting for D-Version ABS

Left Rear Modulator Valve Troubleshooting (SID = s009)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	009	01	Open circuit in the inlet and/or outlet solenoid circuits	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 10 and 11 of the X3 (green) connector, and between pins 12 and 11. A good measurement should be between 4 and 8 ohms.	2–4
136	009	03	Shorted to power	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Measure the voltage across pins 10, 11, and 12 of the X3 (green) connector and ground. If any of the measurements indicate a voltage, the valve is shorted to power.	
136	009	05	Open circuit	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 10 and 11 of the X3 (green) connector, and between pins 12 and 11 of the X3 connector. A good measurement should be between 4 and 8 ohms.	
136	009	06	Shorted to ground	Check continuity between pin 10 of the X3 (green) connector and ground, and pin 12 of the X3 connector and ground. If continuity exists in either pin, the valve is shorted to ground.	

Table 12, Left Rear Modulator Valve Troubleshooting (SID = s009)

Right Rear Modulator Valve Troubleshooting (SID = s010)					
J1587 Fault Code			Problem	Diagnostic Procedure	Blink Code
MID	SID	FMI			
136	010	01	Open circuit in the inlet and/or outlet solenoid circuits	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 7 and 8 of the X3 (green) connector, and between pins 9 and 8. A good measurement should be between 4 and 8 ohms.	2–3
136	010	03	Shorted to power	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Measure the voltage across pins 7, 8, and 9 of the X3 (green) connector and ground. If any of the measurements indicate a voltage, the valve is shorted to power.	
136	010	05	Open circuit	Check the modulator valve wiring. Check for damaged wiring in the inlet, outlet and ground circuits. Check the resistance between pins 7 and 8 of the X3 (green) connector, and between pins 9 and 8 of the X3 connector. A good measurement should be between 4 and 8 ohms.	
136	010	06	Shorted to ground	Check continuity between pin 7 of the X3 (green) connector and ground, and pin 9 of the X3 connector and ground. If continuity exists in either pin, the valve is shorted to ground.	

Table 13, Right Rear Modulator Valve Troubleshooting (SID = s010)

Wiring Diagrams

Use the following wiring diagrams when troubleshooting the Meritor WABCO D-Version ABS/ATC system with a frame-mounted ECU:

- For systems with the J1922 datalink, see **Fig. 1** for a full view of wiring diagram D06-31049.

  See **Fig. 2** or **Fig. 3** for enlarged partial views.

- For systems with the J1939 datalink, see **Fig. 4** for a full view of wiring diagram D06-31861.

  See **Fig. 5** or **Fig. 6** for enlarged partial views.

General Information

The Haldex automatic slack adjuster serves two main functions:

- As a lever, it converts the straight-line force of the air brake chamber pushrod to torque on the brake camshaft. Rotation of the camshaft spreads the brake shoes out against the brake drum, applying the brakes.
- As an adjuster, it maintains cam brake chamber pushrod stroke and lining-to-drum clearance automatically during normal use.

When the brakes are applied, the slack adjuster rotates and moves the shoes into contact with the drum. The clearance notch corresponds to the normal lining-to-drum clearance. See **Fig. 1**. Different notches are available to meet the requirements of various vehicles and brake duty cycles. As the brake application continues, the rack moves upward and rotates the one-way clutch which slips in this direction.

As the brake torque increases, the coil-spring load is overcome and the wormshaft is displaced axially, releasing the cone clutch.

When the brake begins its return stroke, the coil spring load returns to normal and the cone clutch is again engaged. The rack is pulled back to its original position in the notch. Any additional travel brought about by brake lining wear causes the rack to turn the locked one-way clutch and rotates the wormshaft through the locked cone clutch. The wormshaft then rotates the worm wheel and camshaft, adjusting the brakes.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

⚠ WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

Removal

1. With the vehicle parked on a level surface, set the parking brakes, and shut down the engine. Chock the tires.
2. If a rear-axle slack adjuster will be removed, release the parking brakes and cage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this group.
3. Remove the anchor bracket fasteners and the anchor bracket. See **Fig. 1**.

1. Clevis Pin
2. Clevis
3. Anchor Bracket
4. Control Arm
5. Adjusting Hexnut

Fig. 1, Anchor Bracket Removal/Installation

4. Remove the cotter pin from the clevis pin. Remove the clevis pin.
5. Remove the snap ring that secures the slack adjuster on the camshaft.

⚠ CAUTION

Do not use an impact wrench on the adjusting hexnut. To do so may damage the slack adjuster or camshaft.

6. Using a 7/16-inch box wrench, turn the adjusting hexnut counterclockwise to move the adjuster arm out of the clevis. A minimum of 13 lbf·ft (18 N·m) is required to overcome the internal clutch. You will hear a ratcheting sound.
7. Remove the slack adjuster from the camshaft.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

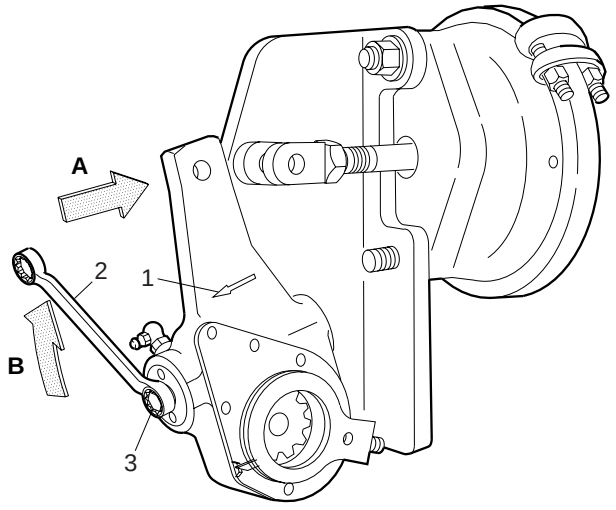
1. Check that the brake-chamber pushrod is fully retracted.
2. Apply antiseize compound to the camshaft splines.

IMPORTANT: When correctly installed, the brake-chamber pushrod pushes in the direction of the arrow on the slack adjuster housing.

3. Install the slack adjuster on the camshaft, with the adjusting hexnut pointing away from the brake chamber. See **Fig. 2**.
4. Using a snap ring, secure the slack adjuster on the camshaft. Use at least one inner washer and enough outer washers to allow no more than 0.060-inch (1.52-mm) movement on the shaft.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting hexnut for positioning.

Slack Adjuster Removal and Installation



05/01/2000 f420472b

A. Use only the adjusting hexnut to align the slack adjuster with the pushrod clevis.
B. Turn the adjusting hexnut clockwise.

1. Direction of Applied Stroke
2. Box Wrench, 7/16 inch
3. Adjusting Hexnut

Fig. 2, Slack Adjuster Installation

5. Using a 7/16-inch box wrench, turn the adjusting hexnut clockwise until the slack adjuster hole is aligned with the pushrod clevis hole. See **Fig. 2**.
6. Apply antiseize compound to the clevis pin, and insert the pin in the clevis hole. Do not install the cotter pin at this time.

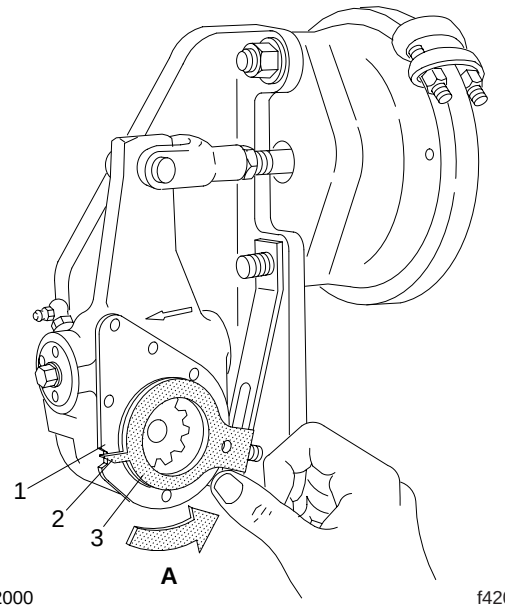
CAUTION

Never hammer the control arm. Hammering may damage the slack adjuster or camshaft splines.

7. Rotate the control arm away from the adjusting hexnut toward the brake chamber until it comes to a definite internal stop. Make sure the installation indicator is in the center of the indicator notch on the slack adjuster. See **Fig. 3**.

IMPORTANT: If the installation indicator is not aligned with the indicator notch, the brakes will be too tight.

NOTE: The anchor bracket and slack adjuster housing design will vary, depending on the axle.



05/01/2000 f420473b

NOTE: The installation indicator must be aligned with the indicator notch.

A. Rotate the control arm counterclockwise until it stops.

1. Indicator Notch
2. Installation Indicator
3. Control Arm

Fig. 3, Aligning the Control Arm

The anchor bracket mounting location is determined by the length of the control arm.

8. Install the control-arm anchor bracket, as follows. See **Fig. 1**.
   - 8.1 Tighten the anchor bracket fastener at the control arm 10 to 15 lbf·ft (14 to 20 N·m), making sure the control arm does not move from its position.
   - 8.2 Tighten the fastener at the brake chamber mounting stud according to the brake chamber manufacturer's specifications.
9. Adjust the brakes. See "Brake Adjustment".

Brake Adjustment

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

1. Adjust the brake lining clearance by manually turning the adjusting hexnut clockwise until the brake lining contacts the brake drum, then back off the hexnut counterclockwise 1/2 turn. You will hear a ratcheting sound.

IMPORTANT: Incorrect installation can cause dragging brakes.

2. Make sure the brakes are still fully released, then check the position of the installation indicator on the control arm. It must be within the indicator notch on the slack adjuster.

   If the indicator is out of position, loosen the control arm fasteners and repeat the control-arm adjustment procedure. Then, tighten the bracket fasteners.

⚠ WARNING

Install and lock a new cotter pin in the clevis pin. Failure to do so could allow the pushrod to disengage from the slack adjuster, causing a loss of braking ability that could result in personal injury and property damage.

3. Install and lock a new cotter pin in the clevis pin.

IMPORTANT: Ensure that the air system has at least 100 psi prior to uncaging the brake chamber. This will aid in the uncaging of the parking brake since the parking brake should be fully released.

4. If a rear-axle slack adjuster was installed, manually uncage the parking brake. For instructions, refer to the applicable brake chamber section in this group.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

IMPORTANT: To check the brake adjustment, measure both the applied and free strokes.

NOTE: The location of the measurements is the same for both strokes but the applied stroke is measured with the brakes applied, while a lever is used to manually move the slack adjuster to measure the free stroke.

5. Measure the free stroke, as follows. The free stroke is the distance the slack adjuster has to travel to move the brake shoes against the drum.

   5.1 With the brakes released, measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement A.

   5.2 Using a lever, move the slack adjuster until the brake shoes contact the drum. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement B.

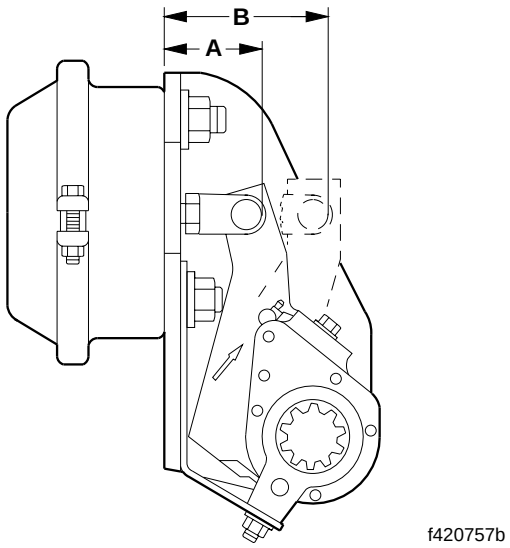
   5.3 Subtract measurement A from measurement B to determine the free stroke. For new brake installations, the free stroke should be 5/8 to 3/4 inch (16 to 19 mm). For in-service brakes, the free stroke should be 1/2 to 5/8 inch (13 to 16 mm). If it is not in this range, refer to **Troubleshooting 300**.

6. Measure the applied stroke, as follows.

   6.1 With the brakes released (pushrod fully retracted), measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. See **Fig. 4**. Record the exact distance as measurement A.

   6.2 Apply and hold an 80 psi (551 kPa) brake application. Measure the distance from the bottom of the brake chamber to the far

Slack Adjuster Removal and Installation



NOTE: Measurements are from the bottom of the brake chamber to the far side of the clevis-pin hole.

A. Measurement with brakes released.
B. Measurement with brakes applied at 80 psi (551 kPa).

Fig. 4, Brake Applied Stroke Check

side of the clevis-pin hole. Record the exact distance as measurement B.

6.3 Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 1**.

6.4 If the stroke varies or is greater than the maximum allowed length, refer to **Troubleshooting 300**.

7. Apply the parking brakes.
8. Remove the chocks from the tires.
9. In a safe area, check for proper brake operation, as follows.

9.1 Apply and release the brakes several times to check for correct operation of the slack adjusters.

9.2 Perform six low-speed stops to ensure correct parts replacement and full vehicle control.

9.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others show a lack of braking effort on those wheels.

Chamber Size	Maximum Applied Stroke: inch (mm)	Free Stroke: inch (mm)	
		New Brake Installation	In-Service Brake Installation
16	1-3/4 (44)	5/8–3/4 (16–19)	1/2–5/8 (13–16)
20			
24	1-7/8 (48)		
30	2 (51)		

Table 1, Brake Chamber Stroke Specifications

Troubleshooting Tables

Problem—Tight or Dragging Brakes

Problem—Tight or Dragging Brakes	
Possible Cause	**Remedy**
Improperly positioned control arm anchor bracket	See instructions in **Subject 110**.
System air pressure too low to fully release spring brake	Check that the air governor cuts out at the recommended setting.
Ruptured spring brake diaphragm or leaking piston seal	Replace the diaphragm or spring brake piston seal.
Broken return spring in brake chamber	Replace the spring brake return spring.
Pushrod binds on chamber housing	Check for correct alignment and correct chamber mounting bracket. Adjust or replace parts as needed.
Air supply does not exhaust completely	Test the air system valves for leakage and correct operation.
Out-of-round brake drums	Turn the brake drums, if possible. If the maximum allowable diameter of any brake drum has been exceeded, replace the drum. Also, turn or replace the other drum on the axle. For turning the drums, see the brake manufacturer's service manual.
Extreme differences in lining-to-drum clearances between shoes on same wheel	Check for proper operation of the brake mechanism. Lubricate or overhaul as needed.
Out-of-adjustment wheel bearings	Adjust the wheel bearings, or replace them if damaged. For instructions see **Section 33.01** for front axles and **Section 35.00** for rear axles.
Broken brake shoe return spring	Replace the brake shoe return spring.

Problem— Brake Chamber Pushrod Travel Is Excessive

Problem— Brake Chamber Pushrod Travel Is Excessive	
Possible Cause	**Remedy**
Loose, broken, or bent control arm anchor bracket	Tighten or replace the anchor bracket as required.
Excessive wear between anchor bracket bolt and control arm slot	Replace the worn parts.
Damaged or worn control arm assembly, resulting in lateral movement between control arm and cover plate	Replace the slack adjuster.
Worn camshaft bushings	Replace the worn camshaft bushings.
Camshaft binds	Lubricate the camshaft or overhaul the brake mechanism as needed.
Loose brake chamber mounting	Tighten the brake chamber mounting fasteners.
Slack adjuster bound against camshaft housing, no end play	Check that the correct camshaft and camshaft tube have been used and that they are assembled correctly. Overhaul the brake mechanism as needed.
Worn slack adjuster clutch assembly	Replace the slack adjuster.

Specifications

Maximum Applied Stroke	
Chamber Size	**Inch (mm)**
16	1-3/4 (44)
20	1-3/4 (44)
24	1-7/8 (48)
30	2 (51)

Table 1, Maximum Applied Stroke

General Information (See Fig. 1)

The Meritor automatic slack adjuster has two main functions:

- As a lever, it converts the straight-line force of the brake chamber pushrod to torque on the brake camshaft. Rotation of the camshaft forces the brake shoes against the brake drum.
- As an automatic adjuster, it automatically maintains brake chamber pushrod stroke, which controls lining-to-drum clearance during operation.

Meritor's automatic slack adjuster automatically adjusts the clearance between the brake lining and the brake drum (rotor). When linings wear, this clearance increases and causes the chamber pushrod to move a greater distance to apply the brakes.

During operation, if the chamber stroke exceeds the design limit, the automatic slack adjuster will automatically adjust the pushrod's return stroke to control clearance between the lining and the drum (rotor) and reset the stroke to the correct length.

A pressed-in, sealed actuator boot is standard equipment on Meritor slack adjusters. The boot features a metal retaining ring with additional material that extends beyond the base of the retainer. The boot forms a seal once it is pressed into the slack adjuster body.

Meritor's automatic slack adjusters, including the factory-installed slack adjusters on the Q Plus cam brakes, have a one-piece threaded clevis. See **Fig. 2**.

The one-piece threaded clevis:

- Has a threaded hole for the pushrod;
- Can be straight or offset;
- Is used on all service replacement automatic slack adjusters.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

Removal

1. With the vehicle parked on a level surface, set the parking brakes, and shut down the engine. Chock the tires.

WARNING

Manually cage each parking brake chamber power spring in the release (no application) position before continuing. Loss of brake chamber air pressure will cause sudden application of the parking brakes, which could result in personal injury.

2. If the rear slack adjusters will be removed, release the parking brakes, then cage the power spring of the parking brake chamber.
3. Remove the retainer clips from the large and small clevis pins. Remove the clevis pins. See Fig. 1.

CAUTION

Disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

4. Using a screwdriver or an equivalent tool, pry the pawl button out about 1/32 inch (0.8 mm). See Fig. 2.

   Wedge the tool in place. Pull-pawls are spring-loaded; when the tool is removed, the pull-pawl will engage the teeth automatically.
5. Using a wrench, manually turn the square adjusting nut clockwise to move the slack adjuster away from the clevis. See Fig. 3.
6. Remove the snap ring, washer(s), and seal (if equipped) that secure the slack adjuster in place on the brake camshaft; save them for later installation.
7. Remove the slack adjuster from the camshaft.
8. Note the location and number of any remaining spacing washers on the camshaft. Remove the spacers and seal (LX500 and MX500 series only), and save them for later installation.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

1. Inspect the parts and prepare the slack adjuster for installation.
2. Check the brake camshaft splines for wear or corrosion.

IMPORTANT: The following lubricants provide corrosion protection. Do not mix them with other types of lubricants.

3. Coat the camshaft splines and the splines of the slack adjuster gear with Meritor 0-637, Meritor 0-695 (LX500 and MX500 only), Southwest SA 8249496, or an equivalent.
4. Apply the service brake several times. Make sure the return spring retracts the pushrod quickly and completely. Replace the return spring or brake chamber, if needed.
5. Slide the spacing washer(s) on the camshaft.

   On LX500 and MX500, install the slack adjuster seal with the lip facing the brake spider.
6. If reinstalling the same slack adjuster:

   6.1 Slide the slack adjuster on the camshaft, with the actuator rod on the side opposite the brake chamber.

   6.2 On LX500 and MX500, install the orange slack adjuster seal on the camshaft. The lip on the seal must face the snap ring.

   6.3 Install the outer washer(s) and snap ring on the camshaft.

Slack Adjuster Removal and Installation

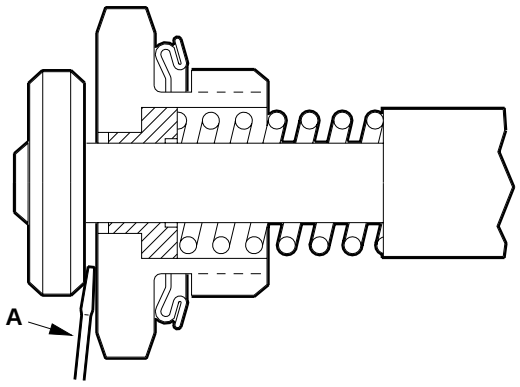
29. Slack Adjuster Housing

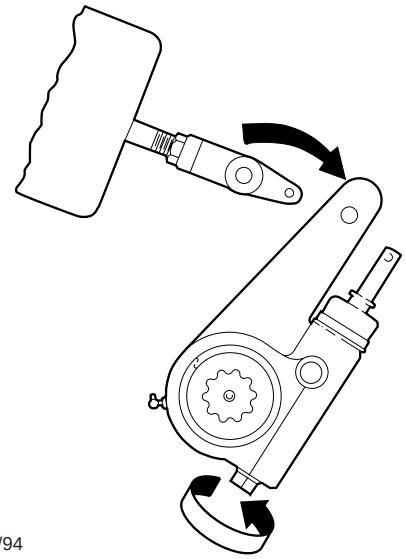
Fig. 1, Meritor Automatic Slack Adjuster



06/19/2007 f422462

A. Insert a screwdriver here to pry the pull-pawl button out about 1/32 inch (0.8 mm).

Fig. 2, Pull-Pawl Assembly



09/26/94 f420183a

Turn the manual adjusting nut clockwise.

Fig. 3, Slack Adjuster Removal

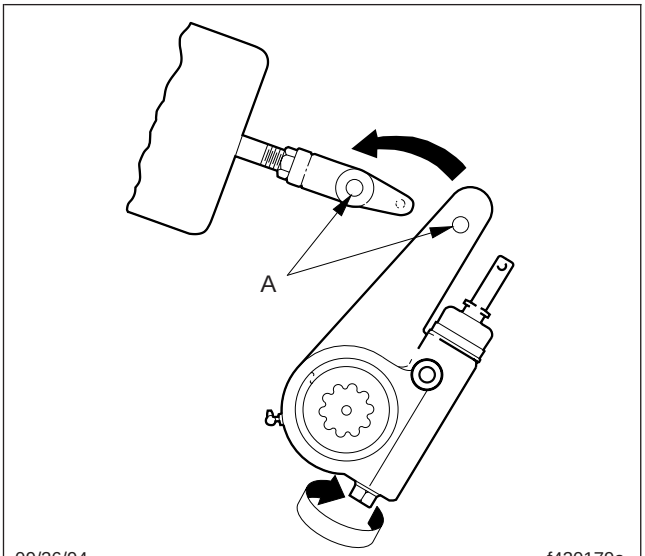
CAUTION

Disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

6.4 Using a screwdriver or an equivalent tool, pry the pawl button out at least 1/32 inch (0.8 mm). See **Fig. 2**. Wedge the tool in place.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting nut for positioning.

6.5 Using a wrench, turn the manual adjusting nut counterclockwise to align the hole in the slack adjuster housing with the large hole in the clevis. See **Fig. 4**.



09/26/94 f420179a

A. Turning the adjusting nut counterclockwise, align the large holes in the slack adjuster and clevis.

Fig. 4, Slack Adjuster Installation

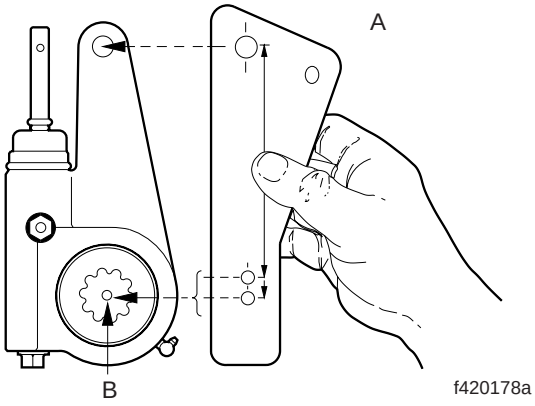
7. If installing a new slack adjuster:

7.1 Using an installation template, measure the old and new slack adjusters. Measure from the center of the large clevis-pin hole to the center of the camshaft opening. See **Fig. 5**.

Make sure the old and new slack adjusters are the same length.

7.2 Slide the slack adjuster on the camshaft, with the actuator rod on the side opposite the brake chamber.

Slack Adjuster Removal and Installation



A. Using a template, measure the slack adjuster arm length.
B. Camshaft Center

Fig. 5, Slack Adjuster Measurement

7.3 On LX500 and MX500 series, install the orange slack adjuster seal on the camshaft. The lip on the seal must face the snap ring.

7.4 Install the outer washer(s) and snap ring on the camshaft.

7.5 Using a dial indicator, measure the in-and-out (axial) end play of the camshaft. If necessary, add the appropriate number of spacing washers to achieve the correct axial end play.

- For all Cam-Master brakes, except LX500 and MX500 series, there should be no more than 0.060 inch (1.52 mm) movement.
- For LX500 and MX500, the axial end play should be no more than 0.020 inch (0.51 mm).

⚠ CAUTION

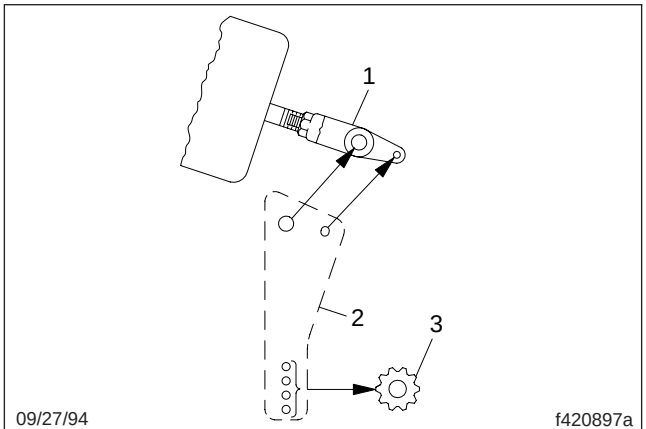
Disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

7.6 Using a screwdriver or an equivalent tool, pry the pawl button out about 1/32 inch (0.8 mm). See **Fig. 2**. Wedge the tool in place.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting nut for positioning.

7.7 Using a wrench, turn the manual adjusting nut counterclockwise to align the hole in the slack adjuster housing with the large hole in the clevis. See **Fig. 4**.

7.8 With the brakes fully released, place the installation template over the clevis and camshaft end. See **Fig. 6**.



Place the template over the clevis and camshaft end.
1. Clevis
2. Template
3. Camshaft End

Fig. 6, Template Placement

7.9 Temporarily insert the large clevis pin through the large holes in the template and the clevis.

7.10 Select the hole in the lower part of the template that matches the length of the slack adjuster. Hold the template in place on the center of the camshaft with a pencil.

7.11 Make sure the small hole in the clevis is completely visible through the 1/8-inch hole at the top of the template.

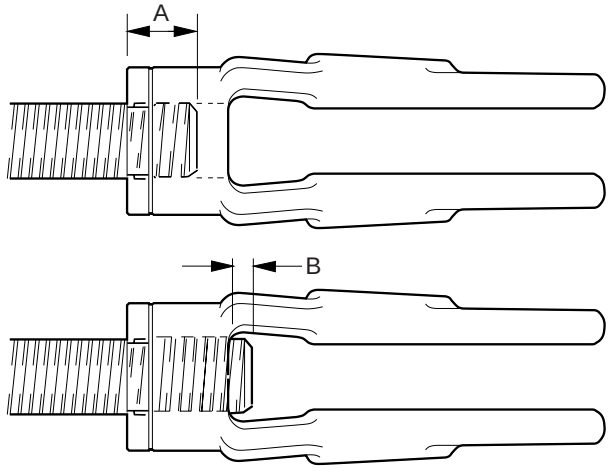
If it is not, loosen the clevis jam nut, and turn the clevis adjusting nut to adjust the position of the clevis on the pushrod until the small clevis hole is completely visible.

IMPORTANT: The pushrod must be installed in the clevis at least 1/2 inch (13 mm) and not extend beyond it more than 1/8-inch (3-mm).

7.12 Make sure there is at least 1/2 inch (13 mm) of thread engagement between the clevis and the pushrod. Also, check that the pushrod does not extend through the clevis more than 1/8-inch (3-mm). See **Fig. 7**.

If necessary, cut the pushrod, install a new pushrod, or install a new brake chamber.

7.13 Temporarily insert the small clevis pin through the template, clevis, and actuator rod to make sure the alignment is correct. Repeat the adjustment, if necessary. When the alignment is correct, remove both clevis pins and the template.



A. Minimum 1/2 inch (13 mm).
B. Maximum 1/8 inch (3 mm).

Fig. 7, Check Pushrod Engagement

8. Apply antiseize compound to the two clevis pins.
9. Insert both clevis pins with their pinheads on the inboard side of the slack adjuster. Be sure the small clevis pin is inserted through the hole in the actuator rod. Install new retaining clips to secure the clevis pins.
10. If it was loosened, tighten the clevis jam nut to the following values.
    - For 1/2–20 threads, tighten the clevis jam nut 20 to 30 lbf·ft (27 to 41 N·m).
    - For 5/8–18 threads, tighten the jam nut 25 to 50 lbf·ft (34 to 68 N·m).
11. Lube the slack adjuster through the grease fitting until the lubricant is forced out through the pawl slot or through the gear splines around the inboard snap ring.
12. Adjust the brakes. See "Brake Adjustment" below.

Brake Adjustment

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

1. If a rear axle slack adjuster was installed, manually uncage the parking brake.
2. Fully release the brakes (the air chamber pushrod must be fully retracted).

⚠ CAUTION

Before turning the manual adjusting nut on the slack adjuster, disengage the pull-pawl. Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

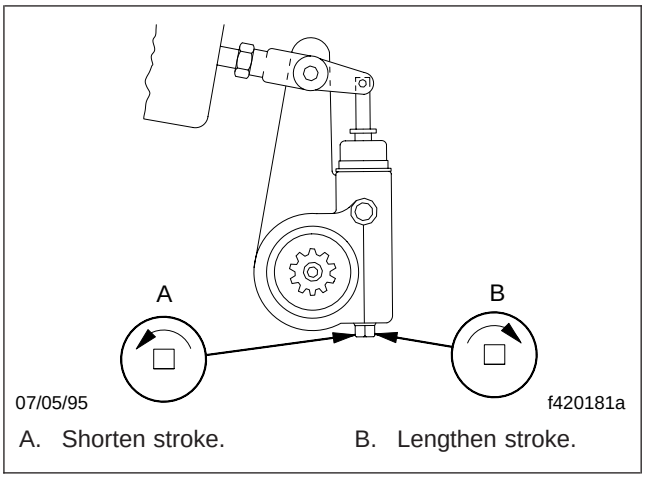
3. Using a screwdriver, pry the pull-pawl button out at least 1/32 inch (0.8 mm) to disengage the pull-pawl teeth from the slack adjuster actuator. See **Fig. 2**. Wedge the screwdriver in place. The pull-pawl will need to be disengaged until the brake adjustment is complete.

Slack Adjuster Removal and Installation

NOTE: When the screwdriver is removed, the pull-pawl will engage automatically.

4. Using the manual adjusting nut on the slack adjuster, adjust the brake chamber stroke (coarse adjustment), as follows. See **Fig. 8**.

   4.1 Turn the adjusting nut counterclockwise until the brake linings touch the brake drum.



A. Shorten stroke. B. Lengthen stroke.

Fig. 8, Adjusting the Stroke

   4.2 Then, turn the adjusting nut clockwise 1/2 turn.

5. Measure and adjust the free-stroke, as follows.

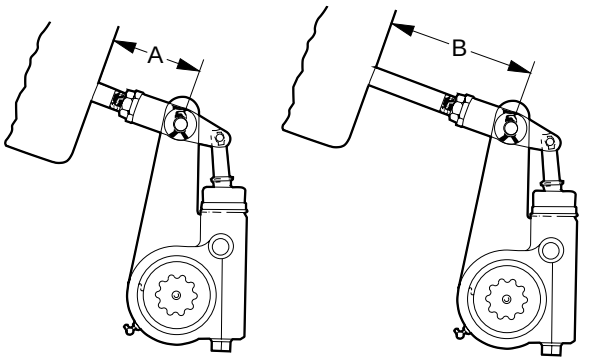
   5.1 With the brakes released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension A. See **Fig. 9**.

   5.2 Using a lever, move the slack adjuster until the brake linings contact the brake drum.

   Measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension B. See **Fig. 9**.

   5.3 Subtract dimension A from dimension B. The difference between these measurements is the free-stroke.

   5.4 The free-stroke for a new brake installation should be 5/8 to 3/4 inch (16 to 19 mm). For a brake that is in service, the free-stroke should be 1/2 to 5/8 inch (13 to 16 mm). If it is not, turn the adjusting nut 1/8 turn, as shown in **Fig. 8**. Then, measure the free-stroke again; readjust it until it is correct.



NOTE: For either free-stroke or applied chamber stroke, subtract measurement A from B.

A. Measurement with the brakes released.
B. Measurement with the brakes applied by manual lever (free-stroke) or pressurized brake application (applied chamber stroke).

Fig. 9, Measuring the Stroke

6. Measure and adjust the applied chamber stroke (fine adjustment), as follows.

   6.1 If system pressure is not already at 100 psi (689 kPa), start the engine and build air pressure, then shut down the engine.

   6.2 With the brakes released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension A. See **Fig. 9**.

   6.3 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 9**, Ref. B. Record this measurement as dimension B.

   6.4 Subtract dimension A from dimension B. The difference between these measurements is the true applied chamber stroke.

CAUTION

The adjusted applied chamber stroke should be as short as possible but not so short that the free-stroke is too short and the linings drag. If the linings drag, the brakes could be damaged.

6.5 The applied chamber stroke must not exceed the maximum value specified in **Table 1**.

If the applied chamber stroke is incorrect, turn the adjusting nut 1/8-turn counterclockwise to shorten the stroke, or 1/8-turn clockwise to lengthen it. See **Fig. 8**. Measure the applied stroke again and readjust it until it is correct.

6.6 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes. See **Section 42.29, Subject 150**.

7. Remove the screwdriver from the pull-pawl assembly. This will engage the pull-pawl with the actuator.

WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

8. In a safe area, check for proper brake operation before you put the vehicle in service, as follows.

8.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.

8.2 Perform six low-speed stops to ensure proper parts replacement and full vehicle control.

8.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than others show a lack of braking effort on those wheels.

Brake Chamber Stroke Specifications			
Chamber Type (Size)	Maximum Applied Stroke*: inch (mm)	Free-Stroke: inch (mm)	
		New Brake Installation	In-Service Brake
Long Stroke†			
16 and 20	2-1/2 (64)	5/8–3/4 (16–19)	1/2–5/8 (13–16)
24 and 30	3 (76)		

* Specifications are relative to a brake application with 80–90 psi (550–620 kPa) air pressure in the brake chambers.

† Long stroke design is indicated by a tag, or embossing, on the brake chamber.

General Information

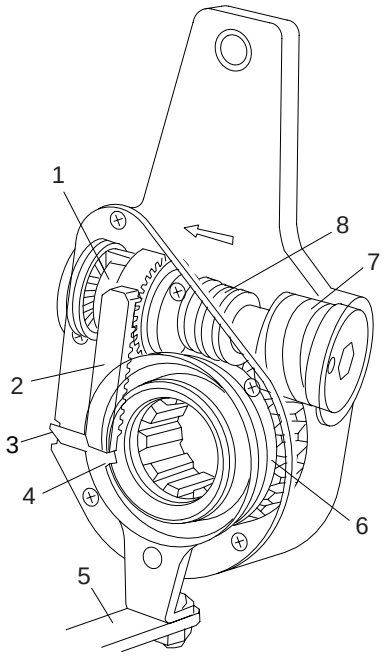
The Dana® Spicer® automatic slack adjuster serves two main functions:

- As a lever, it converts the straight-line force of the air brake chamber pushrod to torque on the brake camshaft. Rotation of the camshaft spreads the brake shoes out against the brake drum, applying the brakes.
- As an adjuster, it maintains cam brake chamber pushrod stroke and lining-to-drum clearance automatically during normal use.

When the brakes are applied, the slack adjuster rotates and moves the shoes into contact with the drum. The clearance notch corresponds to the normal lining-to-drum clearance. See **Fig. 1**. Different notches are available to meet the requirements of various vehicles and brake duty cycles. As the brake application continues, the rack moves upward and rotates the one-way clutch which slips in this direction.

As the brake torque increases, the coil-spring load is overcome and the wormshaft is displaced axially, releasing the cone clutch.

When the brake begins its return stroke, the coil spring load returns to normal and the cone clutch is again engaged. The rack is pulled back to its original position in the notch. Any additional travel brought about by brake lining wear causes the rack to turn the locked one-way clutch and rotates the wormshaft through the locked cone clutch. The wormshaft then rotates the worm wheel and camshaft, adjusting the brakes.



02/13/2001 f420074c

NOTE: Older slack adjusters may not have an installation indicator.

Safety Precautions

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices with stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

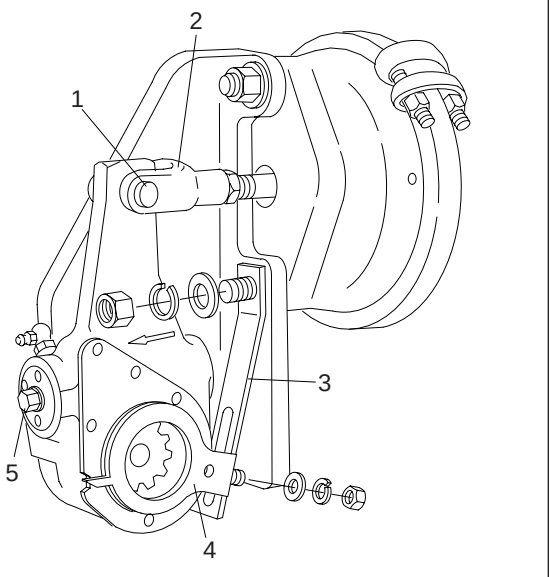
Slack Adjuster Removal and Installation

⚠ WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

Removal

1. With the vehicle parked on a level surface, set the parking brakes, and shut down the engine. Chock the tires.
2. If a rear-axle slack adjuster will be removed, release the parking brakes and cage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this group.
3. Remove the anchor bracket fasteners and the anchor bracket. See **Fig. 1**.



05/01/2000 f420471b

1. Clevis Pin
2. Clevis
3. Anchor Bracket
4. Control Arm
5. Adjusting Hexnut

Fig. 1, Anchor Bracket Removal/Installation

4. Remove the cotter pin from the clevis pin. Remove the clevis pin.
5. Remove the snap ring that secures the slack adjuster on the camshaft.

⚠ CAUTION

Do not use an impact wrench on the adjusting hexnut. To do so may damage the slack adjuster or camshaft.

6. Using a 7/16-inch box wrench, turn the adjusting hexnut counterclockwise to move the adjuster arm out of the clevis. A minimum of 13 lbf·ft (18 N·m) is required to overcome the internal clutch. You will hear a ratcheting sound.
7. Remove the slack adjuster from the camshaft.

Installation

NOTE: For brake chambers that have pushrods with threaded clevises, measure the pushrod length before installing the new slack adjuster. With the brakes fully released, and no air pressure to the chamber, check the dimension between the chamber face and the centerline of the 1/2 inch clevis pin hole. It should be 2.25 inches (57 mm) for long stroke chambers, and 2.75 inches (70 mm) for standard stroke chambers.

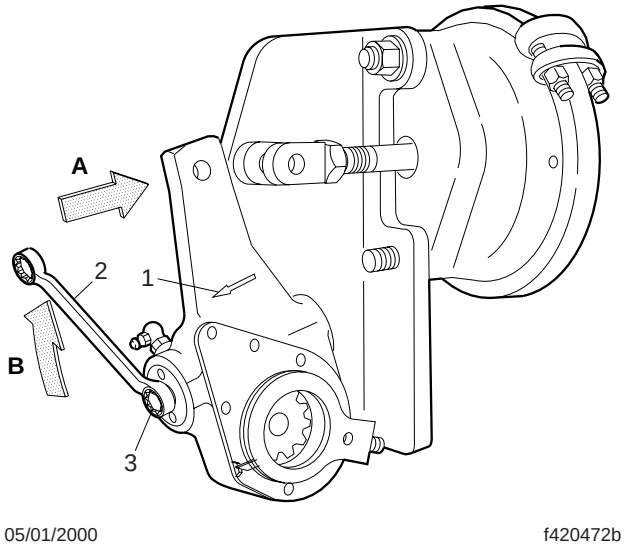
1. Check that the brake-chamber pushrod is fully retracted.
2. Apply antiseize compound to the camshaft splines.

IMPORTANT: When correctly installed, the brake-chamber pushrod pushes in the direction of the arrow on the slack adjuster housing.

3. Install the slack adjuster on the camshaft, with the adjusting hexnut pointing away from the brake chamber. See **Fig. 2**.
4. Using a snap ring, secure the slack adjuster on the camshaft. Use at least one inner washer and enough outer washers to allow no more than 0.060-inch (1.52-mm) movement on the shaft.

IMPORTANT: Never pull the pushrod out to meet the slack adjuster or push the slack adjuster into position. Always turn the adjusting hexnut for positioning.

Slack Adjuster Removal and Installation



05/01/2000 f420472b

A. Use only the adjusting hexnut to align the slack adjuster with the pushrod clevis.
B. Turn the adjusting hexnut clockwise.

1. Direction of Applied Stroke
2. Box Wrench, 7/16 inch
3. Adjusting Hexnut

Fig. 2, Slack Adjuster Installation

5. Using a 7/16-inch box wrench, turn the adjusting hexnut clockwise until the slack adjuster hole is aligned with the pushrod clevis hole. See **Fig. 2**.
6. Apply antiseize compound to the clevis pin, and insert the pin in the clevis hole. Do not install the cotter pin at this time.

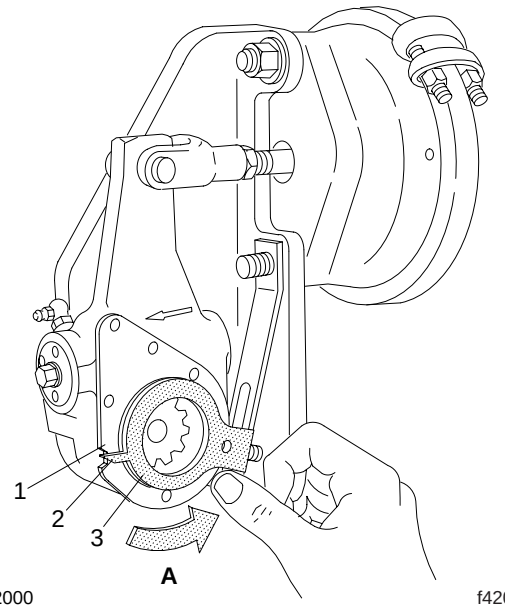
⚠ CAUTION

Never hammer the control arm. Hammering may damage the slack adjuster or camshaft splines.

7. Rotate the control arm away from the adjusting hexnut toward the brake chamber until it comes to a definite internal stop. Make sure the installation indicator is in the center of the indicator notch on the slack adjuster. See **Fig. 3**.

IMPORTANT: If the installation indicator is not aligned with the indicator notch, the brakes will be too tight.

NOTE: The anchor bracket and slack adjuster housing design will vary, depending on the axle.



05/01/2000 f420473b

NOTE: The installation indicator must be aligned with the indicator notch.

A. Rotate the control arm counterclockwise until it stops.

1. Indicator Notch
2. Installation Indicator
3. Control Arm

Fig. 3, Aligning the Control Arm

The anchor bracket mounting location is determined by the length of the control arm.

8. Install the control-arm anchor bracket, as follows. See **Fig. 1**.
   - 8.1 Tighten the anchor bracket fastener at the control arm 10 to 15 lbf·ft (14 to 20 N·m), making sure the control arm does not move from its position.
   - 8.2 Tighten the fastener at the brake chamber mounting stud according to the brake chamber manufacturer's specifications.
9. Adjust the brakes. See "Brake Adjustment".

Brake Adjustment

NOTE: A properly working self-adjusting slack adjuster does not require manual adjustment while in service.

Slack Adjuster Removal and Installation

⚠ WARNING

Manually adjusting an automatic slack adjuster to bring the pushrod stroke within legal limits is likely masking a mechanical problem. Adjustment is not repairing. Before adjusting an automatic slack adjuster, troubleshoot the foundation brake system and inspect it for worn or damaged components. Improperly maintaining the vehicle braking system may lead to brake failure, resulting in property damage, personal injury, or death.

1. Adjust the brake lining clearance by manually turning the adjusting hexnut clockwise until the brake lining contacts the brake drum, then back off the hexnut counterclockwise 1/2 turn. You will hear a ratcheting sound.

IMPORTANT: Incorrect installation can cause dragging brakes.

2. Make sure the brakes are still fully released, then check the position of the installation indicator on the control arm. It must be within the indicator notch on the slack adjuster.

   If the indicator is out of position, loosen the control arm fasteners and repeat the control-arm adjustment procedure. Then, tighten the bracket fasteners.

⚠ WARNING

Install and lock a new cotter pin in the clevis pin. Failure to do so could allow the pushrod to disengage from the slack adjuster, causing a loss of braking ability that could result in personal injury and property damage.

3. Install and lock a new cotter pin in the clevis pin.

IMPORTANT: Ensure that the air system has at least 100 psi prior to uncaging the brake chamber. This will aid in the uncaging of the parking brake since the parking brake should be fully released.

4. If a rear-axle slack adjuster was installed, manually uncage the parking brake. For instructions, refer to the applicable brake chamber section in this group.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

IMPORTANT: To check the brake adjustment, measure both the applied and free strokes.

NOTE: The location of the measurements is the same for both strokes but the applied stroke is measured with the brakes applied, while a lever is used to manually move the slack adjuster to measure the free stroke.

5. Measure the free stroke, as follows. The free stroke is the distance the slack adjuster has to travel to move the brake shoes against the drum.

   5.1 With the brakes released, measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement A.

   5.2 Using a lever, move the slack adjuster until the brake shoes contact the drum. Measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. Record the exact distance as measurement B.

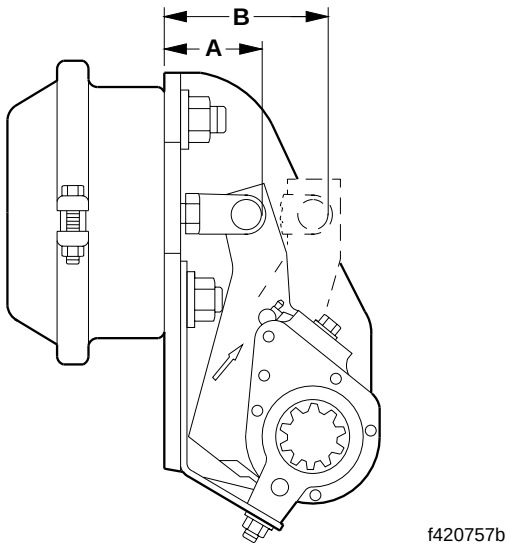
   5.3 Subtract measurement A from measurement B to determine the free stroke. For new brake installations, the free stroke should be 5/8 to 3/4 inch (16 to 19 mm). For in-service brakes, the free stroke should be 1/2 to 5/8 inch (13 to 16 mm). If it is not in this range, refer to **Troubleshooting 300**.

6. Measure the applied stroke, as follows.

   6.1 With the brakes released (pushrod fully retracted), measure the distance from the bottom of the brake chamber to the far side of the clevis-pin hole. See **Fig. 4**. Record the exact distance as measurement A.

   6.2 Apply and hold an 80 psi (551 kPa) brake application. Measure the distance from the bottom of the brake chamber to the far

Slack Adjuster Removal and Installation



01/22/2008 f420757b

NOTE: Measurements are from the bottom of the brake chamber to the far side of the clevis-pin hole.

A. Measurement with brakes released.
B. Measurement with brakes applied at 80 psi (551 kPa).

Fig. 4, Brake Applied Stroke Check

side of the clevis-pin hole. Record the exact distance as measurement B.

6.3 Subtract measurement A from measurement B to determine the applied stroke. Compare this value to the value in **Table 1**.

6.4 If the stroke varies or is greater than the maximum allowed length, refer to **Troubleshooting 300**.

7. Apply the parking brakes.
8. Remove the chocks from the tires.
9. In a safe area, check for proper brake operation, as follows.

9.1 Apply and release the brakes several times to check for correct operation of the slack adjusters.

9.2 Perform six low-speed stops to ensure correct parts replacement and full vehicle control.

9.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others show a lack of braking effort on those wheels.

Chamber Size	Maximum Applied Stroke: inch (mm)	Free Stroke: inch (mm)

Table 1, Brake Chamber Stroke Specifications

Troubleshooting Tables

Problem—Tight or Dragging Brakes

Problem—Tight or Dragging Brakes	
Possible Cause	**Remedy**
Improperly positioned control arm anchor bracket	See instructions in **Subject 110**.
System air pressure too low to fully release spring brake	Check that the air governor cuts out at the recommended setting.
Loose brake linings	Repair or replace the linings as required.
Pushrod binds on chamber housing	Check for correct alignment and correct chamber mounting bracket. Adjust or replace parts as needed.
Air supply does not exhaust completely	Test the air system valves for leakage and correct operation.
Out-of-round brake drums	Turn the brake drums, if possible. If the maximum allowable diameter of any brake drum has been exceeded, replace the drum. Also, turn or replace the other drum on the axle. For turning the drums, see the brake manufacturer's service manual.
Extreme differences in lining-to-drum clearances between shoes on same wheel	Check for proper operation of the brake mechanism. Lubricate or overhaul as needed.
Out-of-adjustment wheel bearings	Adjust the wheel bearings, or replace them if damaged. For instructions see **Section 33.01** for front axles and **Section 35.00** for rear axles.
Broken brake shoe return spring	Replace the brake shoe return spring.

Problem— Brake Chamber Pushrod Travel Is Excessive

Problem— Brake Chamber Pushrod Travel Is Excessive	
Possible Cause	**Remedy**
Loose, broken, or bent control arm anchor bracket	Tighten or replace the anchor bracket as required.
Worn camshaft bushings	Replace the worn camshaft bushings.
Camshaft binds	Lubricate the camshaft or overhaul the brake mechanism as needed.
Loose brake chamber mounting	Tighten the brake chamber mounting fasteners.
Worn slack adjuster clutch assembly	Replace the slack adjuster.

	2.5 (64) — Long Stroke	

* Without drag.

Table 2, Stroke Specifications

Brake Pedal Removal and Installation

Removal

See **Fig. 1** for a complete exploded view of the clutch- and brake-pedal assembly.

1. Park the vehicle on a level surface, shut down the engine, apply the parking brakes, and chock the tires.
2. Remove the clutch pedal. For instructions on removal See **Section 25.03**, Subject 100.
3. Remove the clutch stop and neutral safety switch. See **Fig. 2**.
4. Remove the flanged hexnut, washer, and bolt securing the brake plunger to the air brake lever. See **Fig. 3**. Discard the hexnut.
5. Remove the bearing from the air brake lever. The bearing sits horizontally in a U-shaped cutout near the cab end of the brake plunger. See **Fig. 4**.
   - 5.1 Lift the brake pedal up and push the brake plunger in slightly.
   - 5.2 Reach behind the brake lever and remove the bearing from the plunger.
6. Remove the wedge, belleville washers, and capscrew from each end of the brake cross-shaft.
   - 6.1 Remove the capscrews and belleville washers from the wedge at each end of the brake cross-shaft.
   - 6.2 Pry the wedges out from end.
   - 6.3 Discard the wedges, washers, and capscrews. DO NOT REUSE!
7. Remove the two 5/16–18 machine screws and washers securing the rubber seal assembly (rubber boot) to the mounting bracket. See **Fig. 5**. Remove the seal.
8. Slide the brake plunger out of the bore in the center of the mounting bracket. Wipe off the old grease from the plunger, rubber seal, and bracket.
9. Wipe out the old lubricant from the bore, and any bearing dust and using clean shop air.
10. Inspect the brake plunger bearing (in the center bore) and the sliding surface of the plunger. If there is any wear or damage (cracks or chips), replace the part.
11. Inspect the guide bearing and rubber seal assembly; replace the assembly if it is damaged.

NOTE: Removing the brake lever allows the cross-shaft to move far enough to the right for the brake pedal to be removed.

12. Slide the cross-shaft to the left and remove the brake lever.
13. Slide the cross-shaft to the right and remove the brake pedal.

Installation

1. Slide the brake cross-shaft to the right and slide the brake pedal onto the shaft.
2. Slide the cross-shaft to the left and install the brake lever.
3. Lightly Lubricate the sliding surface on the brake plunger and the bearing bore with a silicone-based grease such as Dow Corning 55 O-Ring Lubricant or Loctite V-755 O-Ring Lubricant.
4. Carefully slide the brake plunger into the bearing in the mounting bracket. Make sure the plunger is positioned correctly with the U-shaped cutout facing up. See **Fig. 5**.
5. Install the guide bearing and rubber seal assembly on the mounting bracket with the arrow pointing up. Secure the seal with two washers and 5/16–18 machine screws. Tighten the screws 15 lbf·ft (20 N·m).
6. Inside the cab, place the lever bearing in the U-shaped cutout near the end of the brake plunger. See **Fig. 3**.
7. Align the lever bearing with the holes in the brake lever.

IMPORTANT: The shoulder bolt may be reused but the hexnut must be replaced after it is removed for any reason. For part numbers, see **Specifications 400**.

8. Insert a washer and M8 x 1.25-50 shoulder bolt through the holes in the brake lever and bearing. Secure in place with a new M8, class 10 flanged hexnut. Tighten the nut 17 lbf·ft (23 N·m).

IMPORTANT: The wedge, belleville washers and capscrews must be replaced after they are re-

2. Nuetral Safety Switch
3. Clutch Pedal

Fig. 2, Clutch Pedal Removed

IMPORTANT: The belleville washers are concave and must be installed facing each other as shown in **Fig. 6**.

9.1 Install the capscrews and belleville washers at each end of the brake cross-shaft. The belleville washers are concave and must be installed opening away from each other as shown in **Fig. 6**.

9.2 Tighten the capscrews 8 lbf·ft (10.8 N·m).

10. Install the clutch stop and neutral safety switch. See **Fig. 2**.
11. Install the Clutch Pedal. For instructions, see **Section 25.03**, Subject 100.
12. Remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

13. Test drive the vehicle in a safe area at low speed. Make several brake applications to be sure the vehicle comes to a stop.

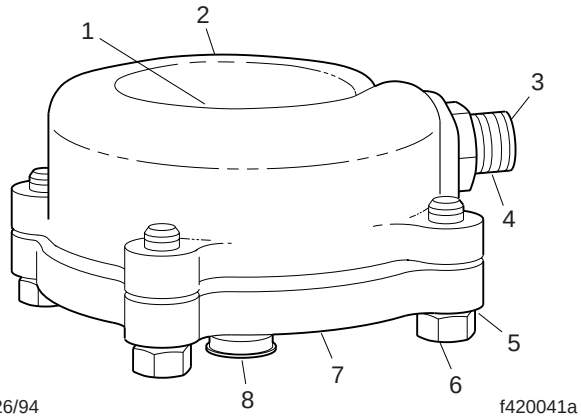
M8 Class 10 Flanged Hexnut	MBT N210100008000

Table 1, Brake Pedal Replacement Parts

General Information

The DV–2 automatic reservoir drain valve automatically removes contaminants and water from the wet air tank each time the brakes are applied. See **Fig. 1**. The drain valve is attached to a drain cock located on the bottom of either end of the wet air tank. Since the brake application valve is protected by a check valve between the wet and dry air tanks, any leak or failure will not reduce the supply of air that is in the dry part of the system. If the leak is severe, it could prevent the continued resupply of air as it is used when applying the brakes. A failed drain valve will allow moisture to build up in the wet tank which in turn could reach the dry tank, and then travel into the air brake system where it could cause brake failure. A leaking drain valve allows wet tank leakdown which in turn can cause premature wear on the air compressor during vehicle operation as the air compressor continues to run to maintain wet tank air pressure.



1. Top Reservoir Port
2. Valve Body
3. Hexhead Nipple
4. Side Reservoir Port
5. Lockwasher (4 qty.)
6. Capscrew (4 qty.)
7. Valve Cover
8. Exhaust Port

Fig. 1, DV-2 Valve

With no pressure in the system, the drain valve's inlet and exhaust valves are closed. See **Fig. 2**. Upon charging the system, a slight pressure opens the inlet valve which permits air and contaminants to collect in the sump. See **Fig. 3**. The inlet valve remains open when pressure is rising in the system until the air compressor cuts off, allowing the spring action of the valve guide in the sump cavity to close the inlet valve. The inlet valve and the exhaust valve are now both closed. See **Fig. 4**. When the wet tank pressure drops approximately 2 psi (14 kPa), the air pressure in the sump cavity opens the exhaust valve and allows moisture and contaminants to be ejected from the sump cavity until pressure in the sump cavity drops sufficiently to close the exhaust valve. See **Fig. 5**.

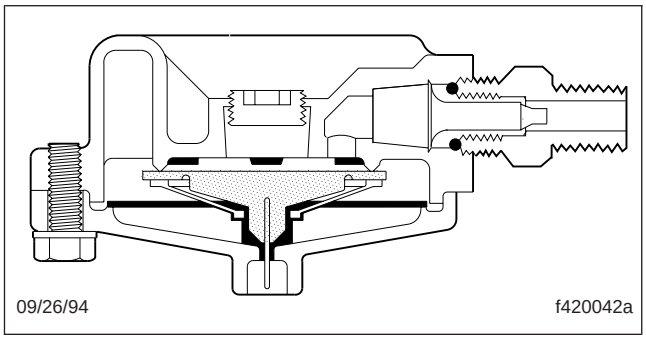


Fig. 2, No System Pressure

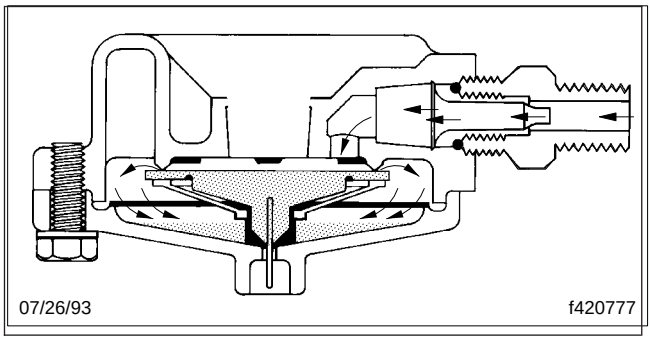

Fig. 3, Start of System Pressure Charging

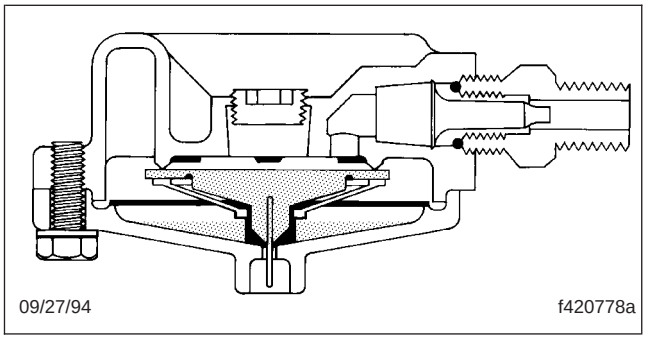

Fig. 4, System Pressure Rising

The length of time the exhaust valve remains open and the amount of moisture and contaminants ejected depends upon the sump pressure and the

General Information

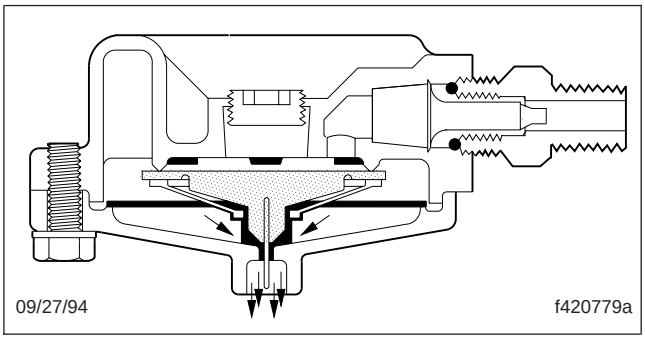

Fig. 5, Exhaust Cycle

wet tank pressure drop that occurs each time air is used from the system.

Safety Precautions

Before attempting to work on the air brake system, observe the following precautions:

- Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.
- When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.
- Hoses will whip dangerously if disconnected under pressure. Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.
- As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber pushrods and spring actuators that apply automatically with the loss of pressure. This also applies when checking the service brake system.
- Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.
- Used reservoirs must not be used as replacements in order to eliminate the possibility of component failure.
- The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured in order to prevent valve failure.
- Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.
- To avoid injury, keep clear of the air chamber pushrod when brakes are applied or when air is exhausted from the system.

⚠ WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

Operating Test

Perform the following test after repairing or replacing the DV–2 valve to ensure that the valve is functioning properly.

With the system charged, apply the brakes several times. Each time the brakes are applied, an exhaust of air should occur from the exhaust port of the drain valve. If no air comes out, push the wire stem located inside the exhaust port. If no air comes out after pushing the wire stem, there may be a plugged filter in the adapter which should be replaced.

If the drain valve does not function properly, repair or replace it following the instructions in this section.

Leakage Test

Perform the following test after repairing or replacing the DV–2 valve to ensure that the valve is functioning properly.

With the system charged and pressure stabilized in the system, there should be no leaks at the drain valve exhaust port. A constant slight exhaust of air at the drain valve exhaust port could be caused by excessive leakage in the air brake system.

If the drain valve is leaking excessively, repair or replace it following the instructions in this section.

⚠ WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

Removal

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the tires.
2. Drain the air system.
3. Remove the drain valve assembly from the end of the wet tank air reservoir.

Installation

1. Using a cleaning solvent, thoroughly flush and clean the wet tank reservoir to avoid early fouling at the drain valve. Aerate the wet tank thoroughly if solvents were used during cleaning.
2. Install the drain valve assembly on the wet tank by tightening the hexagonal nipple until the drain valve is positioned so that the valve body is parallel to the bottom of the wet tank with the exhaust port facing straight down. Make sure that the exhaust port is clear of any air, electric, or fuel lines. Make sure the drain valve is attached tight enough to prevent leakage.
3. Close the drain cocks to the wet and dry air reservoirs. Start the vehicle engine to pressurize the air system.
4. Leak test the drain valve following the instructions in **Subject 110**.
5. Remove the chocks from the tires.

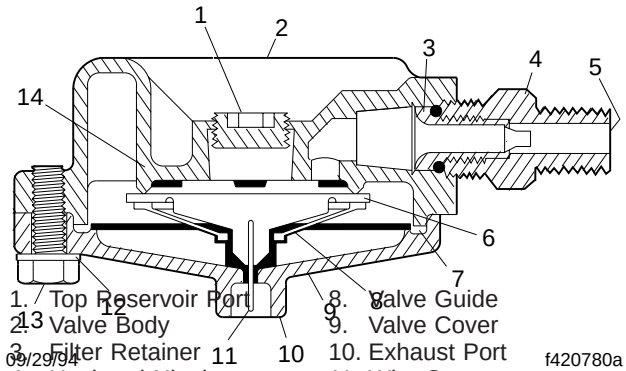
Disassembly, Cleaning and Inspection, and Assembly

⚠ WARNING

Before working on or around air brake systems and components, see "Safety Precautions" in Subject 100. Failure to do so may result in personal injury.

NOTE: For a cutaway view of the DV–2 valve, see **Fig. 1**.

Disassembly



1. Top Reservoir Port
2. Valve Body

4. Hexhead Nipple
5. Side Reservoir Port
6. Inlet and Exhaust Valve
7. Valve Sealing Ring
8. Valve Guide
9. Valve Cover
10. Exhaust Port
11. Wire Stem
12. Lockwasher (4 qty.)
13. Capscrew (4 qty.)
14. Inlet Valve Seat

Fig. 1, DV-2 Valve (cutaway view)

1. Remove the drain valve following the instructions in **Subject 120**.
2. Remove the four capscrews that hold the valve cover to the valve body.
3. Remove the valve cover and sealing ring.
4. Remove the valve guide, and the inlet and exhaust valve from the valve body.
5. Remove the hexhead nipple from the valve body.

Cleaning and Inspection

⚠ WARNING

Use eye protection when using compressed air to clean or dry parts, as permanent harm to eyes could result from flying debris.

1. Wash all metal parts of the drain valve in an approved cleaning solvent. Dry the metal parts of the disassembled moisture ejection valve with compressed air.
2. Wipe all rubber parts with a clean cloth. Examine all rubber parts for wear, cracks, tears, or other deterioration. If any rubber parts are worn, cracked, torn or otherwise deteriorated, replace them with new parts.
3. Examine all metal parts for wear, cracks, or other damage. If any metal parts are worn, cracked, or otherwise damaged, replace them with new parts.
4. Clean and examine the filter. If it will not clean completely, or is torn or damaged, replace it with a new filter.

⚠ CAUTION

Do not reassemble the drain valve with a dirty filter; to do so could result in failure of the drain valve in service.

Assembly

Before assembling the drain valve, apply a light film of grease on the inlet valve seat.

⚠ CAUTION

Do not apply oil to the inlet and exhaust valve.

1. Install the valve sealing ring into its groove in the valve cover.
2. Install the valve guide over the inlet and exhaust valve.
3. Install the valve guide, and the inlet and exhaust valve as an assembly into the valve cover. The wire stem will project through the exhaust port.

Disassembly, Cleaning and Inspection, and Assembly

4. Install the valve body on the valve cover and install the lockwashers and capscrews. Tighten the capscrews 72 to 96 lbf·in (820 to 1080 N·cm).
5. Install the hexhead nipple onto the valve body, and tighten it 48 to 72 lbf·in (540 to 820 N·cm).
6. Install the drain valve on the wet tank following the instructions in **Subject 120**.

Specifications

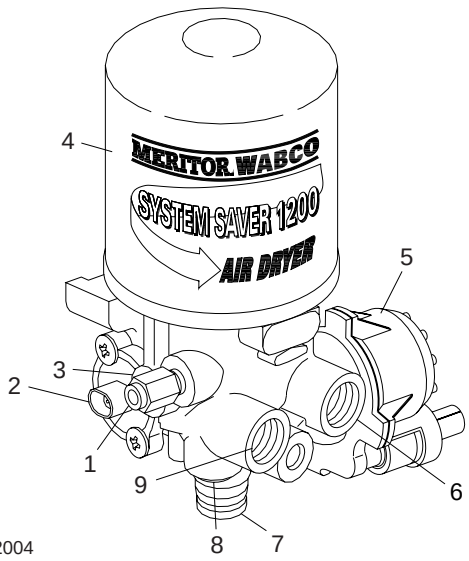
Valve Cover Capscrews	72–96 (820–1080)
Hexhead Nipple	48–72 (540–820)

Table 1, Torque Values

General Information

The System Saver 1200 air dryer (see **Fig. 1**) is a desiccant air dryer, mounted vertically between the air compressor and the supply reservoir. The air dryer receives hot compressed air, which it cools and filters before sending it to the supply reservoir, reducing the build-up of dirt and moisture in the vehicle air system.



1. Pressure Relief Valve
2. Heater/Thermostat Assembly
3. Governor Port (to air governor)
4. Desiccant Canister
5. Regeneration Valve Assembly
6. Outlet Port (to air supply reservoir)
7. Exhaust Port (Purge Valve Assembly)
8. Turbocharger Cutoff Valve
9. Inlet Port (from air compressor)

Fig. 1, WABCO System Saver 1200

The air dryer consists of a light-weight aluminum and steel body. The desiccant cartridge is contained in a spinoff canister at the top of the air dryer.

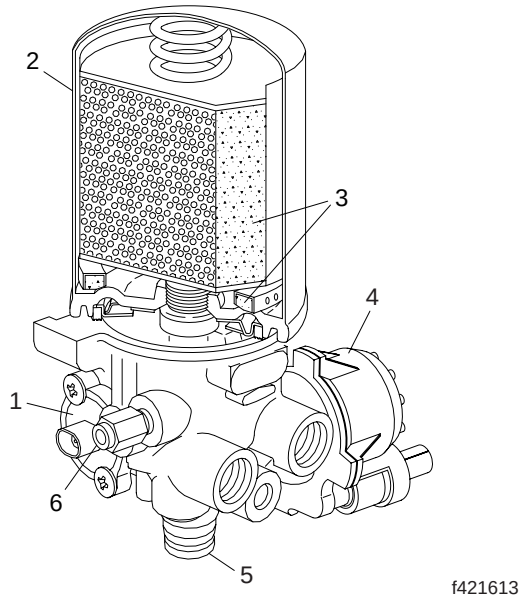
The following components attach to the body of the air dryer:

- Pressure Relief Valve—this valve protects the air dryer from over pressurization. The valve is attached directly to the air dryer.
- Desiccant Canister—a cylindrical steel housing that contains the filter elements and the desiccant needed to filter and dry the air that passes through it.
- Heater/Thermostat Assembly—located in the air dryer base, this assembly is designed to prevent the collected moisture from freezing.
- Outlet Check Valve—this valve prevents air in the system from flowing back through the air dryer and escaping out the purge valve during the compressor unload cycle.
- Pressure-Controlled Check Valve—this valve is separate from the air dryer and is installed on the system air tank. The valve allows air to back flow from the system tank to the supply tank as long as air system pressure remains between the normal cut-in and cut-out range of the air governor.
- Purge Valve—this valve allows the collected moisture and contaminants to be expelled from the air dryer during the purge cycle.
- Regeneration Valve—this valve allows air from the supply and system tanks to bypass the outlet check valve and flow into the regeneration valve. Air then flows through an orifice where the air expands and back flushes moisture off of the desiccant. The air is then exhausted through the purge valve.
- Silencer (Muffler)—an optional component that is attached to the purge valve and used to eliminate most of the noise during the air dryer purge cycle.
- Turbocharger Cut-Off Valve—this valve closes the path between the air compressor and the air dryer purge valve to help maintain boost pressure for maximum engine horsepower during the compressor unload cycle.

Principles of Operation

Hot, compressed air enters the air dryer through the inlet port. As the hot air is forced into the desiccant cartridge, the temperature of the compressed air falls to nearly ambient. Oil and water vapor condense and initially settle into the base of the dryer. The moisture-laden air also passes through the desiccant bed, where any remaining moisture is retained by the desiccant. The clean air then passes through the air dryer outlet port to the supply reservoir. See **Fig. 2 .**

General Information and Principles of Operation



1. Heater/Thermostat Assembly
2. Desiccant Canister
3. Filter
4. Regeneration Valve Assembly
5. Exhaust Port (Purge Valve Assembly)
6. Pressure Relief Valve

Fig. 2, Sectional View

When the compressor reaches about 125 psi (862 kPa), the purge valve opens, allowing the initial decompression of the dryer, and expelling the water and contaminants collected in the base of the dryer. The regeneration valve, along with the pressure-controlled check valve, allows the system air to flow back through the dryer. This back flow dries the desiccant for the next cycle.

Safety Precautions

⚠ WARNING

When draining the air system, do not look into the air jets or direct them toward another person, as dirt or sludge particles may be in the air-stream. Do not disconnect pressurized hoses because they may whip as air escapes from the line. Failure to take all necessary precautions during service operations of the air brake system can cause personal injury.

When working on or around air brake systems and components, observe the following precautions.

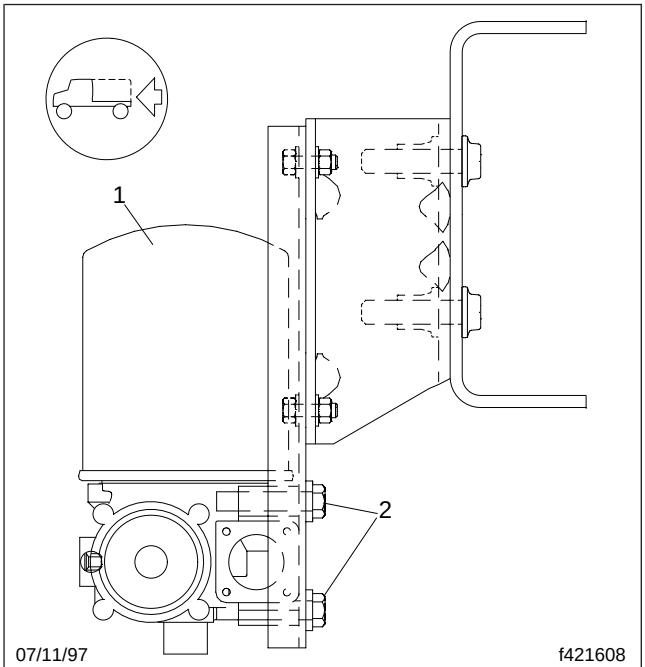
1. Apply the parking brake, chock the tires, and stop the engine when working under the vehicle. Draining the air system may cause the vehicle to roll. Keep hands away from the brake chamber push rods and slack adjusters, which may apply as air system pressure drops.
2. Wear safety goggles.
3. Never connect or disconnect a hose or line containing air under pressure; it may whip as air escapes. Never remove a component or pipe plug unless you are sure all system pressure has been depleted.
4. Don’t disassemble a component before reading and understanding recommended procedures. Use only the correct tools and follow basic tool safety.
5. Replacement hardware, tubing, hose, fittings, etc. should be the same size, type, length, and strength as the original equipment. When replacing tubing or hose, be sure that all of the original supports, clamps, or suspending devices are installed or replaced.
6. Replace any components that have stripped threads or damaged parts. Don’t attempt to repair parts by machining.
7. Never exceed recommended air pressure.

WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

Removal

1. Drain the air system.
2. Disconnect the wiring harness from the air dryer.
3. Mark the air lines for later reference, then disconnect them from the air dryer.
4. Remove the capscrews, washers, and spacers that attach the air dryer to the mounting bracket.
5. Remove the air dryer. See **Fig. 1**.



1. Desiccant Canister
2. 1/2" Capscrew, Washer, and Spacer

Fig. 1, Air Dryer Installation (outboard rail mounting shown)

Installation

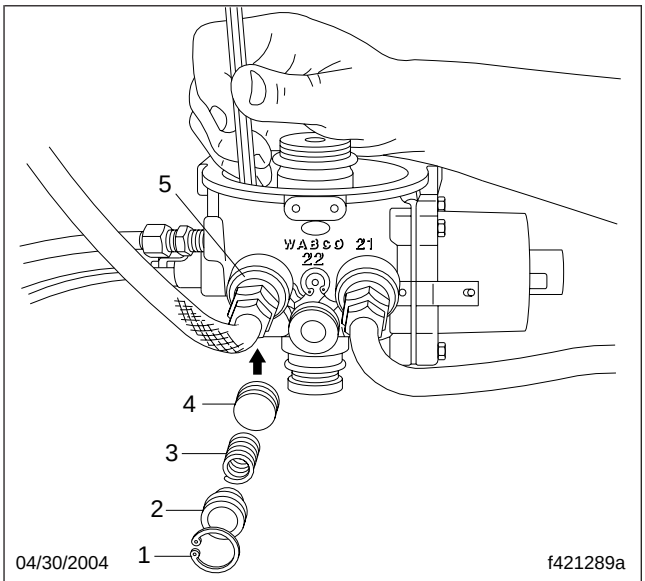
1. Position the air dryer on the mounting bracket. Install the spacers, washers, and capscrews. Tighten them 22 to 30 lbf·ft (30 to 41 N·m). See **Fig. 1** .
2. Make sure the air lines are clean. Replace any line or fitting that is crimped or damaged.
3. Connect the remaining air lines to the air dryer as previously marked. Tighten the nut on each fitting finger-tight. Then, using two wrenches to prevent twisting the hose, further tighten the nut until there is firm resistance.
4. Connect the air dryer wiring harness.
5. Pressurize the air system and check for leaks. Repair as necessary.

Replacement

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Remove the snap ring at the bottom of the valve assembly. The valve cover and spring may fall out of the cavity when the snap ring is removed. See **Fig. 1**.



1. Snap Ring
2. Cover
3. Spring
4. Piston
5. Inlet Port

Fig. 1, Push the Piston, Spring, and Cover out of the Valve Cavity

3. Using a strap wrench, turn the desiccant cartridge counterclockwise and remove it.
4. Using a wooden stick, push the piston, spring, and the cover out of the valve cavity.
5. Clean the valve cavity with a commercial cleaning solvent.
6. Install new O-rings on the piston and the cover.
7. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-rings and the valve cavity.
8. Install the new piston with its hollow side facing out.

IMPORTANT: If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

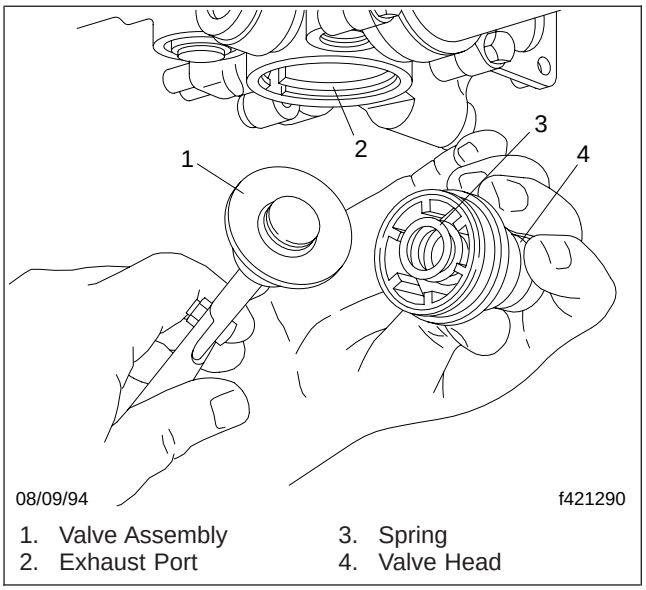
9. Install the new spring, cover, and snap ring to hold the components in place.
10. Thread the desiccant cartridge onto the dryer base (turn clockwise). When the seal contacts the base, tighten the cartridge one complete turn more. Do not over-tighten.

Replacement

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Remove the snap ring, valve head, and the spring from the exhaust port. See **Fig. 1**.



1. Valve Assembly
2. Exhaust Port
3. Spring
4. Valve Head

Fig. 1, Remove the Valve Assembly

3. Pull the valve assembly out of the exhaust port.
4. Remove the O-ring from the base of the exhaust port.
5. Clean the purge valve cavity area with a commercial cleaning solvent.
6. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the O-rings and the valve cavity. Install the O-rings in the base of the exhaust port and on the valve head.
7. Position the new valve assembly in the valve cavity.

IMPORTANT: If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

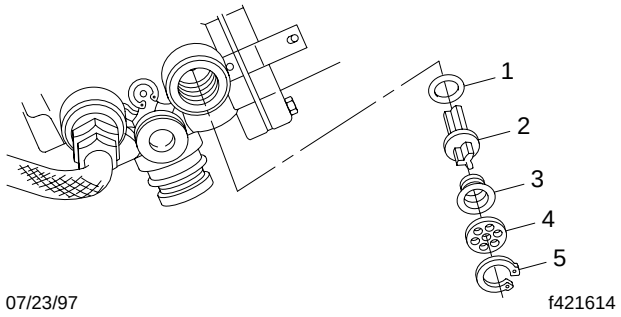
8. Install the spring in the valve head, and position them in the valve cavity.
9. Install the snap ring to secure the valve head in position.

Replacement

WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Disconnect the air line from the outlet port. See **Fig. 1**.



1. O-Ring
2. Valve Body
3. Spring
4. Washer
5. Snap Ring

Fig. 1, Outlet Check Valve Assembly

3. Remove the snap ring, washer, valve body, and the O-ring.
4. Clean the cavity area with a commercial cleaning solvent.
5. Install a new O-ring on the valve body.
6. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-ring and the valve cavity.
7. Install the new valve body. Make sure that the long end of the body is inserted first into the valve cavity.
8. Install the new spring with its small end around the "Y" shaped fins on the valve body.

IMPORTANT: If the valve cavity is damaged, preventing a tight seal, replace the air dryer.

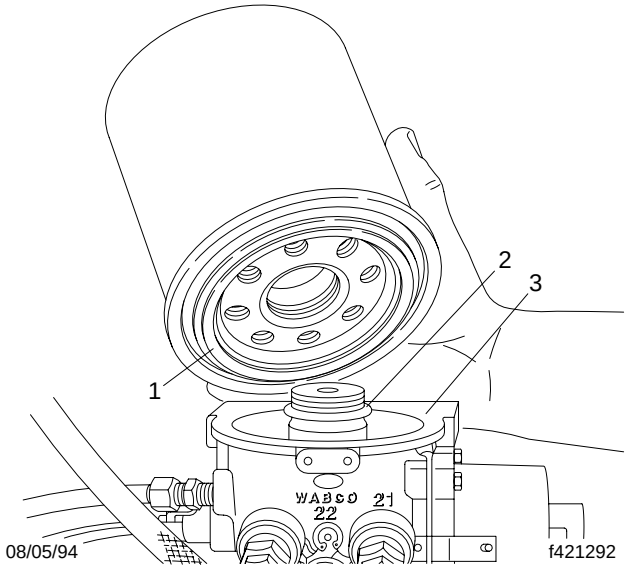
9. Install a new washer and snap ring to secure the assembly in the valve cavity.
10. Connect the air line to the outlet port. Tighten the nut on the fitting finger-tight. Then, using two wrenches to prevent twisting the hose, further tighten the nut until there is firm resistance. Tighten the nut one-sixth turn more.

Replacement

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Using a strap wrench, turn the desiccant cartridge counterclockwise and remove it. See **Fig. 1**.



1. Seal
2. O-Ring
3. Air Dryer Base

Fig. 1, Desicant Cartridge Replacement

3. Remove and discard the O-ring.
4. Clean the top surface of the dryer base with a commercial cleaning solvent.
5. Using a multipurpose, high-temperature grease that resists water, steam, and alkali, lightly coat the surfaces of the new O-ring and the dryer base. Install the O-ring.
6. Thread the desiccant cartridge onto the dryer base (turn clockwise). When the seal contacts the base, tighten the cartridge one complete turn more. Do not over-tighten.

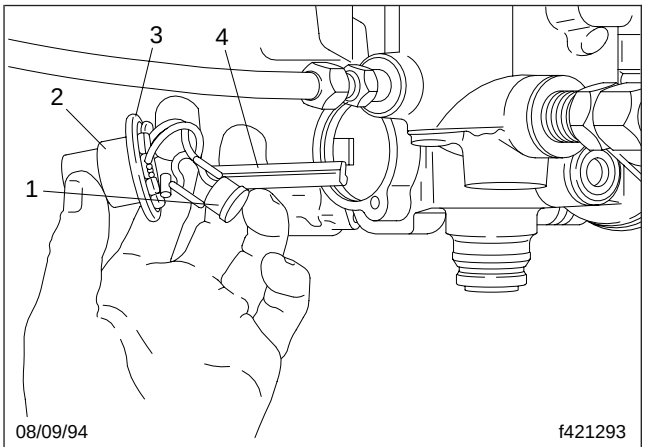
IMPORTANT: If the air dryer base is damaged, preventing a tight seal, replace the air dryer.

Replacement

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Disconnect the wiring harness.
3. Remove the screws that attach the heater/thermostat receptacle. Remove the receptacle and the O-ring.
4. Remove the retaining screw that holds the assembly in place. Remove and discard the heater/thermostat assembly. See **Fig. 1**.



1. Thermostat
2. Receptacle
3. O-Ring
4. Heater Element

Fig. 1, Heater/Thermostat Replacement

5. Clean the heater/thermostat assembly area with a commercial cleaning solvent.
6. Position the new heater/thermostat assembly in the cavity. Install the retaining screw.
7. Position the new receptacle and O-ring, and install the screws. Tighten the screws securely.
8. Connect the wiring harness.

Replacement

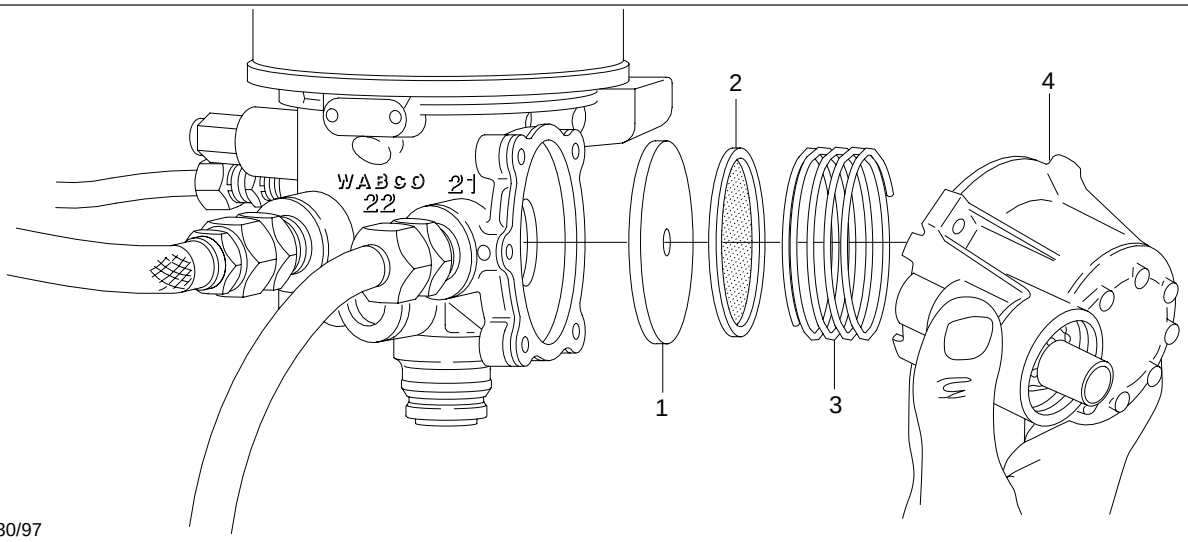
WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.

NOTE: When the valve housing is removed, the spring and the retainer will fall out of the housing. See **Fig. 1**.

2. Remove the four mounting bolts and remove the valve housing assembly.



1. Diaphragm
2. Retainer
3. Spring
4. Valve Housing Assembly

Fig. 1, Regeneration Valve Assembly

3. Remove the rubber diaphragm.
4. Using a commercial cleaning solvent, clean the groove where the diaphragm lip fits.
5. Install a new diaphragm with its lip in the groove.

IMPORTANT: If the groove is damaged, preventing a tight seal, replace the air dryer.

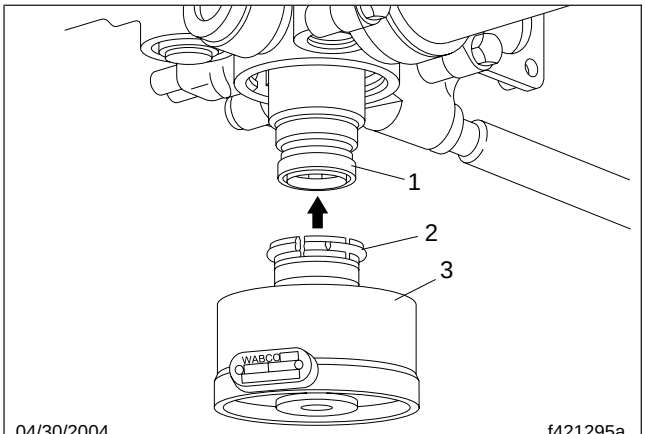
6. Install the new spring and retainer (with the retainer lip facing out).
7. Position the valve housing on the air dryer. Install the bolts and tighten them to 53 lbf·in (600 N·cm).

Replacement

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Using snap ring pliers, expand the snap ring and pull the silencer off of the purge valve head. See **Fig. 1**.



1. Purge Valve Head
2. Snap Ring
3. Silencer

Fig. 1, Silencer Replacement

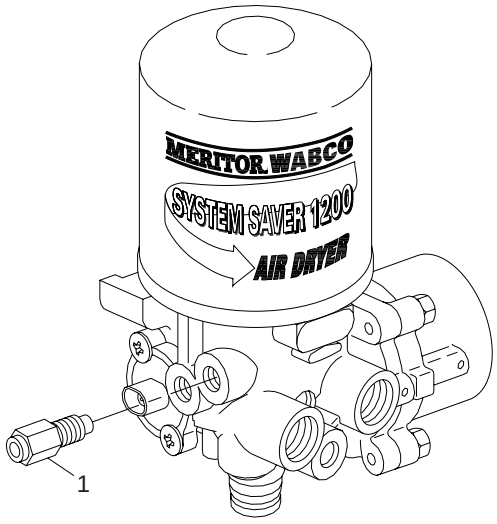
2. Push the new silencer onto the purge valve head until the silencer snaps into place.

Replacement

⚠ WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Unscrew and remove the old valve from the dryer. See **Fig. 1**.



06/18/2004 f422406

1. Pressure Relief Valve

Fig. 1, Pressure Relief Valve Replacement

3. Screw the replacement valve into the dryer base. Do not exceed a torque of 30 lbf·ft (41 N·m) for a 3/8-inch thread, or 65 lbf·ft (88 N·m) for a 1/2-inch thread.

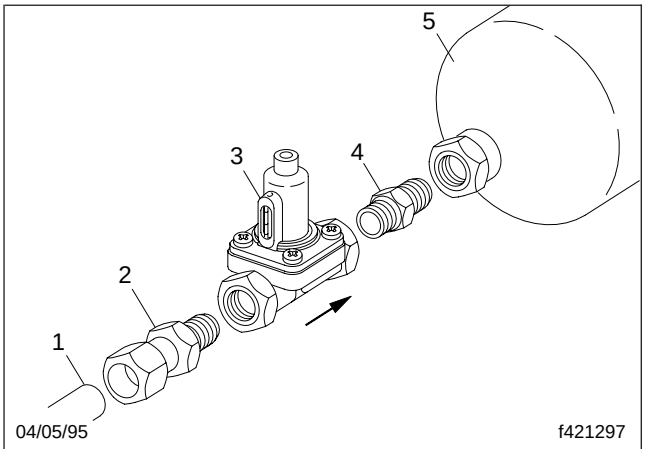
NOTE: The threads on the replacement pressure relief valve provided by Meritor WABCO are coated with sealant. They do not require any additional sealant.

Replacement

WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Drain the air system.
2. Disconnect the air line from the fitting on the valve. See **Fig. 1**.



1. Air Line
2. Nylon Tube Connector
3. Pressure-Controlled Check Valve
4. Hex Nipple Pipe Fitting
5. Air Tank

Fig. 1, Check Valve Assembly Replacement

3. Remove the air-line fitting firm the valve.
4. Remove the valve and the hex nipple fitting from the air tank. Then remove the nipple from the valve.

NOTE: Apply liquid Loctite® Hydraulic Sealant (brown), or an equivalent, to the threads of all fittings before installing them. Always apply sealant to the external threads so that any excess will be scraped off externally rather than internally to the joint.

5. Install the pipe fittings on the new valve. Make sure that the arrow on the valve will be pointing towards the tank when installed.
6. Install the new valve on the air tank.
7. Connect the air line to the air-line fitting on the valve. Tighten the air line securely.

Operating Tests

WARNING

Before starting the procedures below, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

Air Dryer Operating Check

1. Drain the air system.
2. Start the engine and build the air pressure to as close to cutout pressure as possible (about 125 psi [862 kPa]).
3. When the compressor reaches the unload cycle, the air dryer purges, beginning regeneration of the air dryer.
4. During the purge cycle, which lasts about 10 to 15 seconds, the wet tank and secondary system tank with pressure-controlled check valve will drop about 10 psi (69 kPa). Check the secondary system air gauge in the cab dash panel.
5. If the secondary gauge needle does not show a pressure drop of about 10 psi (69 kPa), one of the following problems may exist.
    - A pressure-controlled check valve is not installed.
    - The pressure-controlled check valve is installed in the wrong air tank.
    - The pressure-controlled check valve is installed on a one-way check valve, instead of in place of a one-way check valve.
    - There is an extra check valve located somewhere between the air dryer and the secondary air tank (usually at the wet tank).
    - The secondary air gauge is not plumbed to the secondary air system.
6. If system secondary air pressure drops 25 psi (172 kPa) or more during the purge cycle, and there are no other air-operated components in use, then there are air leaks or other system problems. Refer to **Troubleshooting, 300** for other possible causes.

Pressure-Control Check Valve Operating Check

1. Start the engine and build the air pressure to cutout pressure (about 125 psi [862 kPa]).
2. Stop the engine after the air compressor has unloaded.
3. Drain the supply system air tank down to about 80 psi (552 kPa) or lower.
4. Check the secondary air gauge. It should read 95 ±5 psi (655 ±34 kPa).

    If the gauge reading is less that 90 psi (621 kPa), either the pressure-control check valve is installed backwards, it is damaged, or there are air leaks in the secondary air system.

    If the secondary gauge reading does not change, or the reading does not fall below 100 psi (689 kPa):

    - There is no pressure-controlled check valve installed, or it is installed in the wrong tank.
    - The pressure-controlled check valve is installed into a one-way check valve, rather than in place of a one-way check valve.
    - There is another check valve located between the air dryer and the secondary air tank.
    - The secondary air gauge is not plumbed to the secondary air system.

Troubleshooting Table

Meritor WABCO System Saver 1200 Troubleshooting

Meritor WABCO System Saver 1200 Troubleshooting		
Condition	**Possible Cause**	**Solution**
Dryer leaks from purge valve during compressor-loaded cycle. The leak may cause excessive compressor cycling or prevent the system from building air pressure.	Purge valve frozen open (cold weather operation).	Check heater. Repair/replace if necessary. Make sure governor to dryer port 4 line is free of water/oil.
		Remove and inspect purge valve and clean water/oil from top of piston.
	Debris under purge valve seat, such as particles from fittings or air inlet line.	Disassemble and clean purge valve.
	Purge valve washer installed upside-down.	Remove cartridge and clean dryer sump area. Ensure lip on aluminum washer faces DOWN, away from dryer.
	Wrong air-line connected to dryer port 4 (unloader port).	Verify correct air-line installation and correct as needed.
	Purge valve snap-ring not fully seated in groove.	Seat snap-ring fully into groove.
Slight leak from purge valve. After several hours, the supply tank may be empty.	Outlet check valve not seating or regeneration valve not shutting off regeneration airflow.	Remove, inspect, and clean outlet check valve and regeneration valve diaphragms. Replace if worn or damaged.
Regeneration cycle too long (more than 30 seconds), accompanied by loss of pressure in the supply tank.	Outlet check valve not seating.	Inspect and replace outlet check valve as needed.
	Regeneration valve not shutting off regeneration airflow.	Replace regeneration valve.
Regeneration cycle too short (less than 10 seconds).	High air system demands during compressor unloaded cycle.	Increase air system capacity or reduce air demands.
	Pressure-controlled check valve not installed in system or not working properly.	Check and replace pressur-econtrolled check valve as needed.
	One-way check valve installed in system reservoir instead of, or with, pressure-controlled check valve.	Remove one-way check valve. Make sure pressure-controlled check valve is installed correctly.
	Regeneration valve not working.	Remove regeneration valve and clean oil from diaphragm.
		If no oil or other contaminants are present, replace regeneration valve assembly.
	Air governor not working properly.	Inspect per manufacturer's instructions and repair/replace as needed.

Troubleshooting

Meritor WABCO System Saver 1200 Troubleshooting		
Condition	**Possible Cause**	**Solution**
No regeneration cycle. No airflow from purge valve after initial purge blast (dryer decompression).	Air dryer not connected to supply tank or connections reversed at dryer.	Verify proper dryer installation per system diagram.
	Regeneration valve not working.	Replace regeneration valve.
	One-way check valve installed in supply tank.	Remove one-way check valve.
	Alcohol evaporator installed between dryer and supply tank.	Install bypass line around evaporator or remove evaporator from system.
Air dryer does not purge when compressor unloads (no blast of air from purge valve).	Air line between governor and air dryer port 4 kinked or plugged.	Repair air line.
	Purge valve stuck closed.	Replace purge valve.
	Air governor not working properly.	Inspect air governor. Repair/replace per manufacturer's instructions.
	Cut-out pressure never achieved by air compressor.	Check for air leaks in system and repair as needed. If no leaks in system, check compressor output. Repair/replace per manufacturer's instructions.
Air dryer purges too often, perhaps as frequently as every 15 seconds, accompanied by excessive cycling of the compressor.	Leak in line between governor and dryer port 4.	Repair air line.
	Leak in line between supply tank and governor.	Repair air line.
	Excessive air system leaks.	Repair leaks.
	Excessive air system demands.	Increase air system capacity or reduce air demand.
	Outlet check valve not seating.	Inspect and replace outlet check valve as needed.
	Regeneration valve not shutting off properly.	Replace regeneration valve.
	Air governor has less than 16 psi range.	Replace air governor.
	Leaking air compressor unloader(s).	Inspect compressor. Repair/replace per manufacturer's instructions.
Air flows out of purge valve entire time compressor is unloaded.	Turbo cut-off valve not sealing. NOTE: With U Series air dryers the compressor unloads through the dryer, so a steady flow of air is normal.	Replace turbo cut-off valve.
Rapid "spitting" of air from purge valve in small amounts. Frequency varies with engine speed.	Holset E-type compressor used, but no Econ valve installed.	Install Econ valve to provide make-up air to compressor.
	Compressor not completely unloading when cut-out pressure is reached.	Inspect compressor. Repair/replace per manufacturer's instructions.

Meritor WABCO System Saver 1200 Troubleshooting		
Condition	**Possible Cause**	**Solution**
Air leak at turbo cut-off valve vent. Hole burned in piston.	Temperature of air coming into dryer is too high—not enough cooling takes place before dryer inlet.	Move dryer farther from compressor. Add additional compressor discharge line before air dryer. Add cooling coil or heat exchanger before air dryer. NOTE: Inlet air temperature must not exceed 175°F (80°C).
Air leak at turbo cut-off valve vent.	Lip seal installed upside-down on piston. Lip must face UP (towards dryer).	Install lip seal correctly.
	Valve bore worn excessively.	Inspect valve bore for wear. If a new turbo cut-off valve does not seal in a clean, lubricated bore, replace the air dryer.
Air dryer frozen (water collecting in base of dryer is freezing).	No electrical power to heater connector.	Check for a blown fuse. Repair heater circuit. NOTE: There must be power to the heater connector the entire time the vehicle's ignition is ON.
	Low voltage to heater connector.	Repair cause of low voltage, such as poor electrical ground, bad connections, corroded wire splices, etc.
	Heater assembly not working.	Replace heater assembly.
	Wrong voltage air dryer used; i.e., 12-volt air dryer used in a 24-volt system.	Replace with correct voltage air dryer.
No air pressure build-up in system.	Air dryer not plumbed correctly (connections reversed).	Ensure compressor discharge line is plumbed to air dryer port 1, and air dryer port 21 is connected to vehicle's supply tank.
	Wrong air line connected to dryer port 4.	Ensure dryer port 4 line is connected to the "UNL" port of the air governor.
	Air governor not working properly.	Inspect governor per manufacturer's instructions. Repair or replace as needed.
	Air system leaks, such as compressor discharge line, air dryer, reservoirs, brake or suspension valves, etc.	Locate leak(s) and repair.
	Air dryer leaks from purge valve.	Refer to purge valve conditions listed in this chart.
Water in tanks; often following aftermarket installation or when dryer is a replacement for a competitive brand.	Pressure-controlled check valve not installed in correct tank or not installed at all.	Install pressure-controlled check valve in secondary tank.
	Pressure-controlled check valve properly installed, but one-way check valve not removed.	Remove one-way check valve so that only the pressure-controlled check valve is installed between the secondary tank and supply tank.

Troubleshooting

Meritor WABCO System Saver 1200 Troubleshooting		
Condition	**Possible Cause**	**Solution**
Water, oil, or sludge in air system tanks.	Desiccant contaminated with oil.	Replace desiccant. Inspect compressor per manufacturer's instructions.
Water in system tanks, everything else checks out okay.	Dryer not suitable for application.	Review application guidelines. For assistance, call Arvin Meritor's Customer Service Center at 800-535-5560.

General Description

Dana Spicer extended service (ES) brakes can be installed on both the front and rear axles. See **Table 1** for brake model identification.

The brakes are actuated by an S-type cam head that is forged integrally with the camshaft and supported with nylon bushings. Cam pressure is applied through the cam rollers. **Figure 1** shows a Dana Spicer front axle brake.

Dana Spicer Brake Model Identification Sample Model Number: ES-150-8D			
Code	**Definition**		
Service			
ES	Extended Service Brake		
Drum Diameter	(inch)	(mm)	
150	15	381	
165	16-1/2	419	
180	18	457	
Shoe Size	(inch)	(mm)	
4	4	102	
7	7	178	
8	8-5/8	219	
Configuration	(Shoe)	(Spider)	(Anchor Pin)
L	Fabricated	Fabricated	Single
D	Fabricated	Cast	Single

Table 1, Dana Spicer Brake Model Identification

Steer axles have seven holes for attaching the spider to the axle flange. An eighth hole is left open on the brake spider, on both left and right sides of the steer axle. See **Fig. 2**.

The seven holes used for attaching the spider to the axle flange are 0.656 inch in diameter. The eighth hole is oversized at 0.687 inch in diameter and is used for the antilock braking system (ABS) speed sensor bushing.

The front- and rear-axle brakes may have significant differences, as shown in **Table 2**.

Fig. 2, Brake Spider Oversize Hole

General Information

Principles of Operation

When the brake pedal is depressed, compressed air enters the brake chamber, causing the diaphragm to move a pushrod assembly.

The pushrod turns the slack adjuster and brake camshaft. As the camshaft turns, the S-head forces the brake shoes against the brake drum and braking occurs.

When the brakes are released and air is exhausted from the brake chamber, the actuator return spring (within the brake chamber) and the brake shoe return spring return the camshaft, brake shoes, slack adjuster, and pushrod to their released positions.

Dana Spicer ES Brake Characteristics		
Item	**Front Brakes**	**Rear Brakes**
Brake drums	15 or 16-1/2 in	15 or 16-1/2 in
Brake Shoe Lining	4, 5, or 6 in 1- or 2-piece	7 or 8-5/8 in 2-piece
Brake Shoe Web	Single or Double	Double
Cam Roller	Center groove or Bushing-type	Bushing-type roller with protruding center pin and retainer clip
Hold-down Spring (clip)	Some models	No
Retaining Spring	1	2
Return Spring	1	1

Table 2, Dana Spicer ES Brake Characteristics

General Safety Precautions

⚠ WARNING

When replacing brake pads, shoes, rotors, or drums, always replace components as an axle set.

- Always reline both sets of brakes on an axle at the same time.
- Always replace both rotors/drums on an axle at the same time.
- Always install the same type of linings/pads or drums/rotors on both axle ends of a single axle, and all four axle ends of a tandem axle, at the same time. Do not mix component types.

Failure to do so could cause uneven braking and loss of vehicle control, resulting in property damage, personal injury, or death.

When working on or around a vehicle, observe the following precautions:

- Park the vehicle on a level surface and apply the parking brakes. Shut down the engine and chock the tires.
- If the vehicle is equipped with air brakes, make certain to drain the air pressure from all reservoirs before beginning any work on the vehicle. Depleting air system pressure may cause the vehicle to roll. Keep hands away from brake chamber pushrods and slack adjusters, which may apply as air pressure drops.
- Disconnect the batteries.
- Never connect or disconnect a hose or line containing compressed air. It may whip as air escapes. Never remove a component or pipe plug unless you are certain all system pressure has been released.
- Never exceed recommended air pressure. Always wear safety glasses when working with compressed air. Never look into air jets or direct them at anyone.
- Do not remove, disassemble, assemble, or install a component until you have read and understand the service procedures. Some components contain powerful springs, and injury can result if not properly disassembled. Use the correct tools and observe all precautions pertaining to use of those tools.
- Replacement hardware, tubing, hose, fittings, etc. should be the equivalent size, type, length, and strength of the original equipment.
- Make sure when replacing tubes or hoses that all of the original supports, clamps, or suspending devices are installed or replaced.
- Replace devices that have stripped threads or damaged parts. Repairs requiring machining should not be attempted.
- Prior to returning the vehicle to service, make certain all components and systems are restored to their proper operating condition.

Asbestos and Non-Asbestos Safety

⚠ WARNING

Wear a respirator at all times when servicing the brakes, starting with the removal of the wheels and continuing through assembly. Breathing brake lining dust (asbestos or non-asbestos) could cause lung cancer or lung disease. OSHA has set maximum levels of exposure and requires workers to wear an air purifying respirator approved by MSHA or NIOSH.

Because some brake linings contain asbestos, you should know the potential hazards of asbestos and the precautions to be taken. Exposure to airborne asbestos brake lining dust can cause serious and possibly fatal diseases such as asbestosis (a chronic lung disease) and cancer.

Because medical experts believe that long-term exposure to some *non-asbestos* fibers could also be a health hazard, the following precautions should also be observed if servicing non-asbestos brake linings.

Areas where brake work is done should be separate from other operations, if possible. As required by OHSA regulations, the entrance to the areas should have a sign displayed indicating the health hazard.

During brake servicing, an air purifying respirator with high-efficiency filters must be worn. The respirator and filter must be approved by MSHA or NIOSH, and worn during all procedures.

Safety Precautions

OSHA recommends that enclosed cylinders equipped with vacuums and high-efficiency particulate air (HEPA) filters be used during brake repairs. Under this system, the entire brake assembly is placed within the cylinder and the mechanic works on the brake through sleeves attached to the cylinder. Compressed air is blown into the cylinder to clean the assembly, and the dirty air is then removed from the cylinder by the vacuum.

If such an enclosed system is not available, the brake assembly must be cleaned in the open air. During disassembly, carefully place all parts on the floor to minimize creating airborne dust. Using an industrial vacuum cleaner with a HEPA filter system, remove dust from the brake drums, brake backing plates, and brake parts. After vacuuming, any remaining dust should be removed using a rag soaked in water and wrung until nearly dry. Do not use compressed air or dry brushing to clean the brake assembly.

If grinding or other machining of the brake linings is necessary, other precautions must be taken because exposure to asbestos dust is highest during such operations. In addition to the use of an approved respirator, there must be local exhaust ventilation such that worker exposure is kept as low as possible.

Work areas should be cleaned by industrial vacuums with HEPA filters or by wet wiping. Compressed air or dry sweeping should never be used for cleaning. Asbestos-containing waste, such as dirty rags, should be sealed, labeled, and disposed of as required by EPA and OSHA regulations. Respirators should be used when emptying vacuum cleaners and handling asbestos waste products.

Workers should wash before eating, drinking, or smoking, should shower after work, and should not wear work clothes home. Work clothes should be vacuumed after use and then laundered, without shaking, to prevent the release of asbestos fibers into the air.

Removal

WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires on the axle that is not being repaired.
2. Raise the front or rear axle, then place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.

WARNING

When work is being done on the spring chamber, carefully follow the service instructions of the chamber manufacturer. The sudden release of a compressed spring can cause serious personal injury or death.

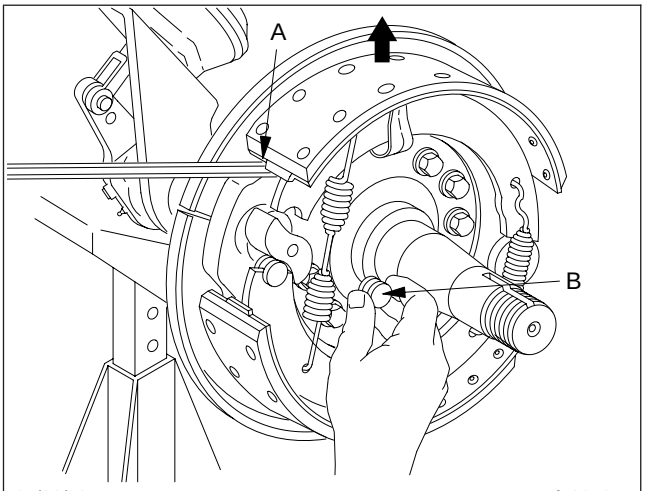
3. If the brake has spring chambers, carefully cage and lock the springs so that the springs cannot actuate during disassembly.
4. Remove the wheels. For instructions, see Section 40.00.
5. Remove the brake drums. For instructions, see Section 33.01, Subject 100, for front axles or Section 35.01, Subject 100, for rear axles.

CAUTION

Before you back off the automatic slack adjuster, refer to the applicable slack adjuster section in this manual or to the manufacturer's service information for instructions. Failure to do so could damage the slack adjusters.

6. Back off the slack adjuster. For instructions, refer to the applicable slack adjuster section in this manual.
7. To remove the front brake shoes (4-inch shoes with single webs):

   7.1 Using a large screwdriver or lever, raise the upper shoe and remove the upper cam roller. See Fig. 1.

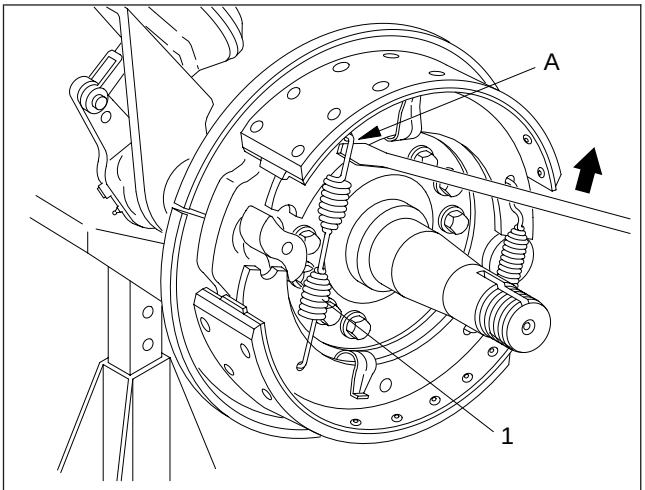


A. Lift the upper shoe to stretch the spring.
B. Remove the cam roller.

Fig. 1, Remove the Upper Cam Roller

   7.2 Reposition the tool and pry the lower shoe downward. Remove the lower cam roller.

   7.3 Using a large screwdriver or lever, stretch the shoe return spring and unhook it from the upper shoe web. See Fig. 2. Remove the spring from the lower web.

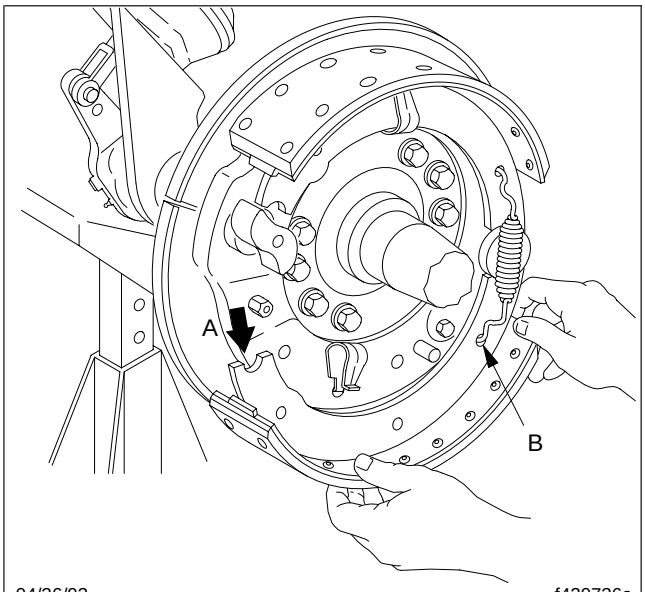


A. Stretch the return spring and unhook it from the shoe web.
1. Shoe Return Spring

Fig. 2, Stretch the Shoe Return Spring

Brake Shoe Removal and Installation

7.4 Rotate the lower shoe downward around the anchor pin to remove the tension on the shoe retaining spring. See **Fig. 3**. Remove the retaining spring from the lower shoe. Remove the lower shoe from the spider.



A. Rotate the lower shoe around the anchor pin.
B. Unhook the retaining spring.

Fig. 3, Rotate the Lower Shoe Downward

7.5 Remove the upper shoe from the spider.

7.6 Discard the cam rollers, shoe return spring, and shoe retaining spring.

8. To remove the rear brake shoes (7- or 8-5/8-inch shoes with dual webs):

8.1 Pry the roller retainer loops out of both shoe web holes. See **Fig. 4**. Pivot the roller retainer to swing the loops clear of the shoe webs.

8.2 Using a large screwdriver or lever, raise the upper shoe, stretching the return spring. See **Fig. 5**. Remove the cam roller and retainer as a unit.

Pry the the lower shoe downward and remove the lower cam roller and retainer.

8.3 Position a suitable lever to engage the return-spring rod. See **Fig. 6**. Force the lever down to release the tension on the upper part of the spring. Remove the upper spring hook.

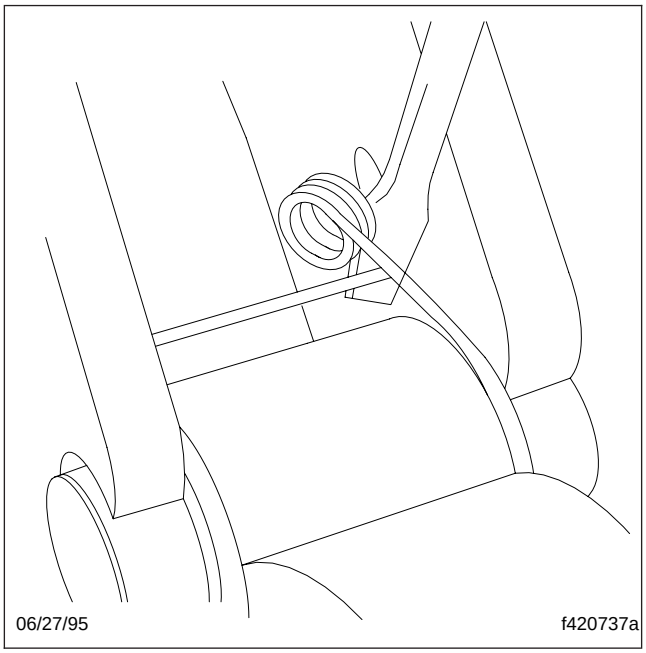


Fig. 4, Pry out the Roller Retainer Loops

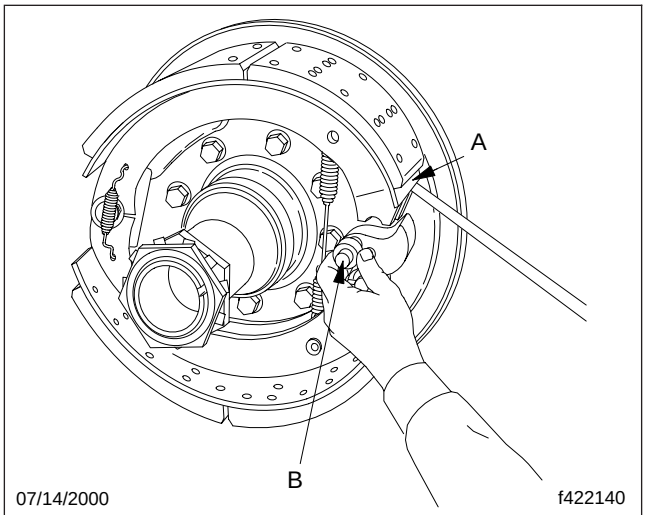
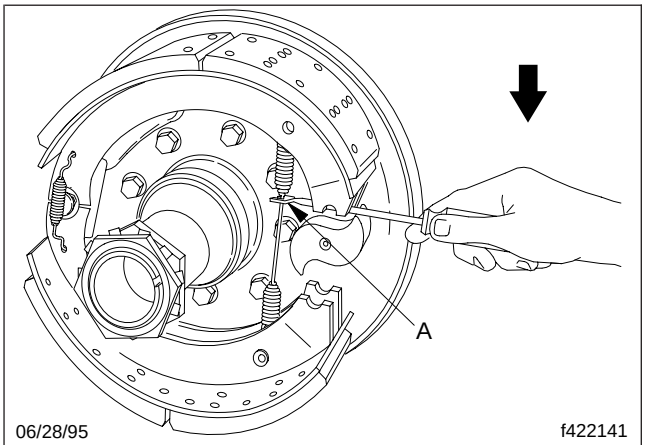


A. Lift upper shoe to stretch the return spring.
B. Remove the roller and retainer.

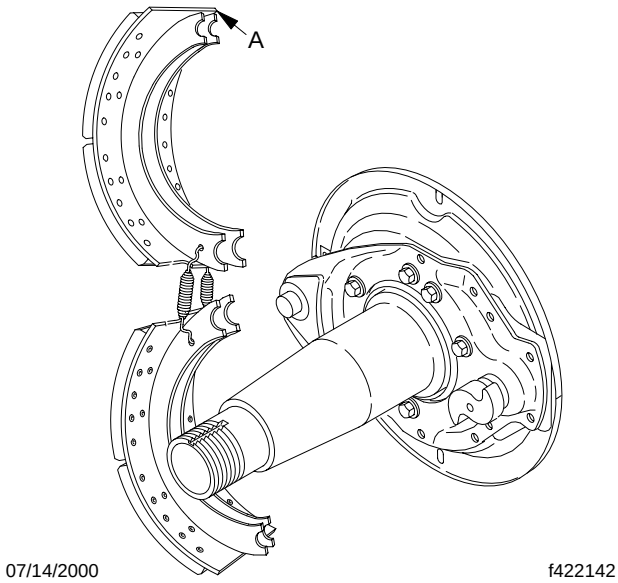
Fig. 5, Remove the Cam Roller



A. Pry up on the return spring for easy removal of the upper hook.

Fig. 6, Remove the Return Spring

8.4 Rotate both shoes around the anchor pin and remove the shoes from the spider. See **Fig. 7**.



A. Rotate both shoes around the anchor pin and remove the brake shoes from the spider.

Fig. 7, Remove the Brake Shoes

8.5 Discard the cam rollers and retainers, and the shoe return spring.

9. Inspect the brake shoes and linings for wear or damage. For instructions, see **Subject 120**.

Installation

IMPORTANT: For best brake performance, do not mix Extended Service brakes with other Dana Spicer series brakes. Use the same brake series on the entire vehicle.

1. Make sure the spider, camshaft, air chamber bracket, and slack adjuster are serviceable and properly installed.

IMPORTANT: Do not lubricate the cam-head surface or the corresponding surface on the cam rollers. For efficient operation, the cam interface must remain free of oil, grease, and other contaminants.

2. Apply a thin film of NLGI grade 1, high-temperature, waterproof grease (Kendall M-621, or an equivalent) to the recesses on the end of each shoe web where the web contacts the cam roller and anchor pin.
3. To install a single-web brake shoe assembly on a 15-inch front brake:

   3.1 Place the upper brake shoe web on the anchor pin and rotate the shoe assembly downward until the web is secured in the shoe hold-down spring (clamp).

   NOTE: The shoe hold-down spring is mounted on the spider between the anchor pin and the S-cam.

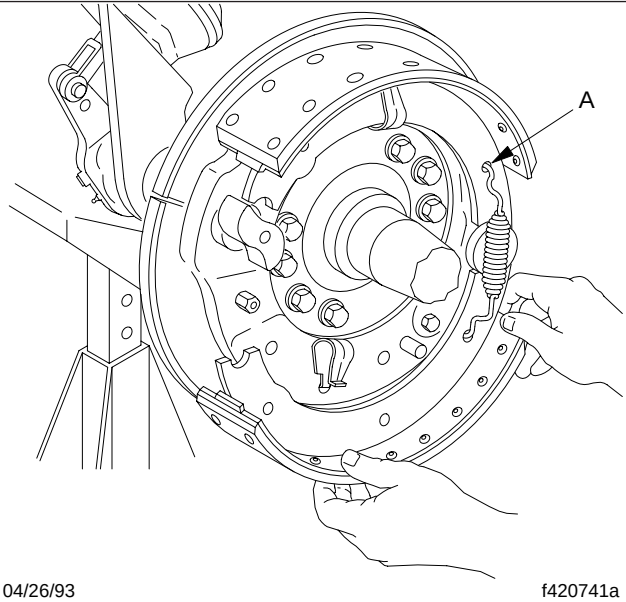
   3.2 Hook one end of a new shoe retaining spring in the hole in the upper shoe web so that the coil lays across the anchor pin. See **Fig. 8**.

   3.3 Hook the lower end of the retaining spring in the hole on the lower shoe web.

   3.4 Place the lower shoe web against the anchor pin and stretch the retaining spring enough to rotate the shoe assembly into place on the spider.

   3.5 Hook one end of a new shoe return spring in the hole in the lower shoe web. Using a large screwdriver, stretch the shoe return spring to hook it in the upper shoe web hole. See **Fig. 2**.

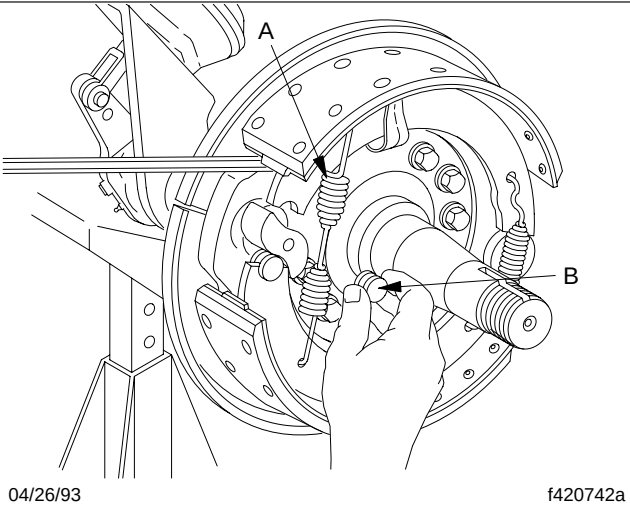
Brake Shoe Removal and Installation



A. Hook the retaining spring in the shoe web hole.

Fig. 8, Install a New Shoe Retaining Spring

3.6 Using a large screwdriver or lever, pry the upper shoe upward and install a new cam roller between the upper shoe web and the S-cam. See **Fig. 9**.



A. Install a new return spring.
B. Install the upper and lower cam rollers.

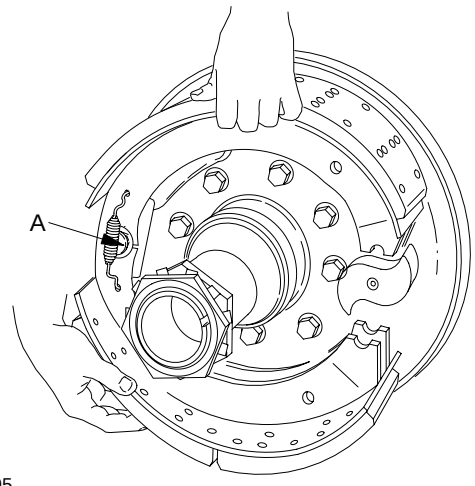
Fig. 9, Install the Cam Rollers

3.7 Pry the lower shoe downward and install a new cam roller between the lower shoe web and the S-cam.

4. To install a dual-web brake shoe assembly on a 15- or 16-1/2-inch rear brake:

4.1 Hook the ends of a new retainer spring in the holes on the upper and lower webs. Install a second retainer spring on the webs on the back side of the brake shoe assembly.

4.2 Place the upper and lower shoes around the anchor pin. See **Fig. 10**.



A. With both retainer springs installed, place the upper and lower shoes around anchor pin.

Fig. 10, Position the Upper and Lower Shoes

4.3 Place a new return spring between the webs and hook the bottom of the spring in the hole in the lower shoe web.

4.4 With a suitable tool placed against the return spring rod, force the tool handle down to stretch the lower half of the spring. See **Fig. 6**. Hook the top of the return spring in the hole in the upper shoe web.

4.5 Assemble the roller retainer on the ends of the roller. See **Fig. 11**.

4.6 Lift the upper shoe assembly and insert the new roller and retainer assembly between the shoe webs and the S-cam. See **Fig. 12**.

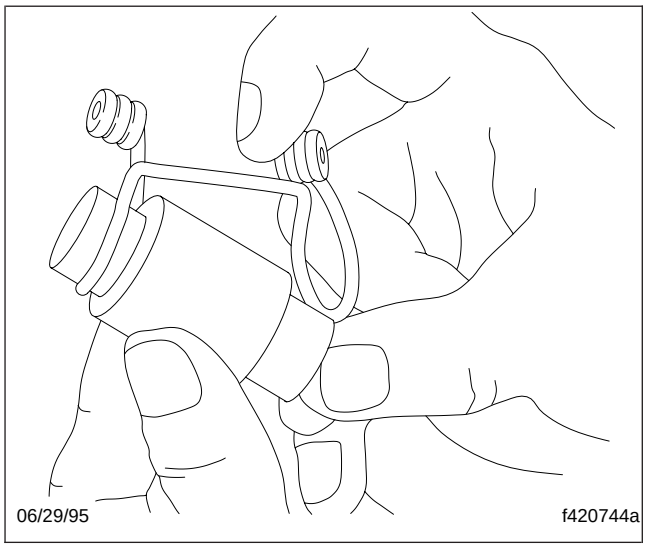


Fig. 11, Assemble the Roller Retainer

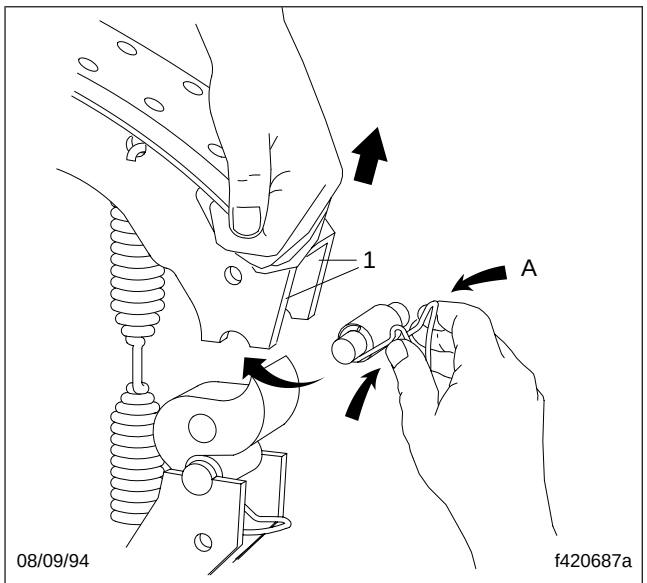
Squeeze the retainer loops and swing the retainer assembly into position (see **Fig. 13**), then snap the loops into the web holes. Make sure that both retainer loops are engaged in the web holes.

Repeat on the lower shoe.



A. Squeeze the ears of the retainer together.

1. Brake Shoe Web

Fig. 12, Install the Cam Rollers

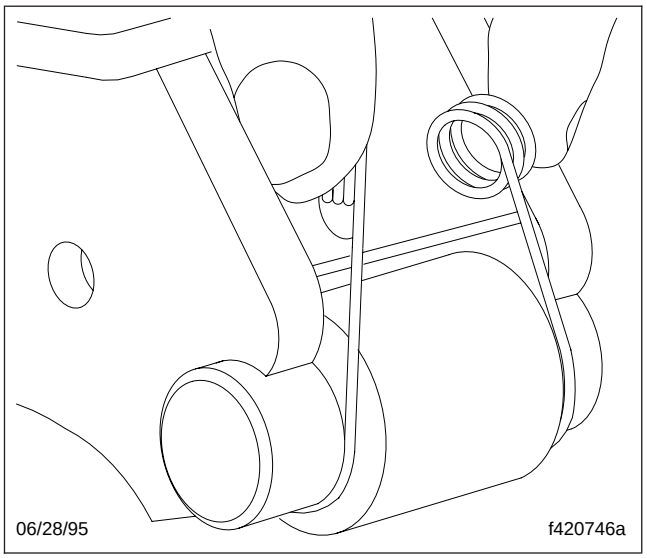


Fig. 13, Position the Retainer Assembly

5. Install the brake drums. For instructions, see **Section 33.01**, Subject 100, for front axles or **Section 35.01**, Subject 100, for rear axles.
6. Install the wheels. For instructions, see **Section 40.00**.
7. If working on the rear axle, manually uncage the power spring of the parking brake chamber. For instructions, refer to the applicable brake chamber section in this manual.
8. Adjust the brakes at the slack adjusters. For instructions, see **Subject 150.**
9. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

10. In a safe area, check for proper brake operation before you put the vehicle in service.

    10.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.

Brake Shoe Removal and Installation

10.2 Perform six low-speed stops to ensure proper parts replacement and full vehicle control.

10.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than the others indicate a lack of braking effort on those wheels.

Inspection

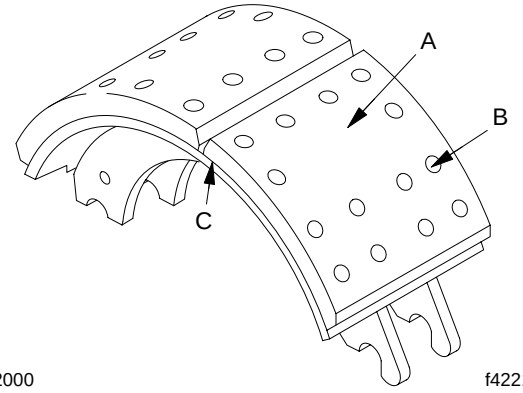
WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

1. Remove the brake shoes. Refer to **Subject 110** for instructions.
2. Inspect the brake shoe linings.

   On front-axle brakes, if the linings are grease- or oil-soaked, cracked, or worn to less than 3/16 inch (4.5 mm) thickness at any point, replace them. See **Fig. 1**. The lining surface should be no closer than 1/16 inch (1.5 mm) to any rivet head.

   On rear-axle brakes, if the linings are grease- or oil-soaked, cracked, or worn to less than 1/4-inch (6.4-mm) thickness at any point, replace them.

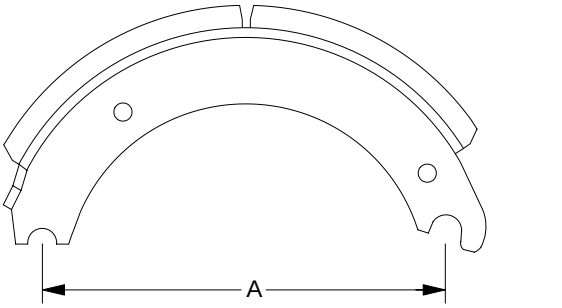


07/14/2000 f422145

A. Check for cracks or contamination.
B. The lining surface must not be closer than 1/16 inch (1.5 mm) to any rivet head.
C. The minimum lining thickness is 3/16 inch (4.5 mm).

Fig. 1, Inspect the Brake Shoe (15-inch series shown)

3. Check the shoes for bent or cracked webs or tables, broken welds, loose rivets, or out-of-round rivet holes. Replace the shoes if any of these conditions exist.
4. Check the anchor pin for looseness and camshaft roller recesses in the shoe webs for visible wear. Replace the shoe if needed.
5. Check the shoe span. Measure the distance between the centerlines of the anchor pin and cam roller recesses in the shoe web. See **Fig. 2**.
   - On 15-inch series brakes, if the measurement is more than 11-3/4 inches (298 mm), replace the shoe.
   - On 16-1/2-inch series brakes, if the measurement is more than 12-9/16 inches (319 mm), replace the shoe.



08/09/94 f420068a

A. Measure the distance between recess centers.

Fig. 2, Shoe Span Measurement

Replacement

WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

IMPORTANT: Vehicle brake systems require the correct lining material to perform as originally designed. The type of lining material that is specified for the vehicle is based on several technical considerations and Department of Transportation (DOT) braking performance regulations. To ensure fewer relines and greater compatibility with the vehicle's brake system, use the same quality of friction lining material that was installed at the factory.

Always reline both wheels of a single axle and all wheels of a tandem axle at the same time.

Always install the same linings and drums on both wheels of a single axle and all four wheels of a tandem axle. It is not necessary for the steering axle brakes to have the same linings as the rear drive axle brakes.

When the minimum thickness is reached for any of the brake linings on an axle, reline both brakes on that axle at the same time.

NOTE: Replace the springs each time the brakes are relined. Dana Spicer recommends replacement of the cam rollers at each reline.

1. Remove the brake shoes. For instructions, see **Subject 110**.

CAUTION

Drilling out rivets or cutting off rivet heads with a chisel can cause the rivet hole to become out-of-round. This could damage the brake shoe.

2. Using a suitable riveting mandrel, push out (do not drill out) the old rivets.
3. Clean the shoe table. For instructions, see **Subject 140**, "Cleaning."

CAUTION

Make sure that the replacement lining material conforms to FMSI 1308, a standard for lining size and shape only. Use of an improper FMSI lining specification or friction material type may cause brake dragging or grabbing, or improper brake performance.

4. Align the brake shoe and lining rivet holes. Using a C-clamp, clamp the lining to the brake shoe.

IMPORTANT: Use rivets that have the correct material, shank diameter, length, head size, and shape. Use tubular rivets that are:

- 1/4-inch (6-mm) diameter by 1/2-inch (13-mm) long,
- SAE no. 10-8, and
- made of zinc- or brass-plated steel.

5. Insert the correct size rivets into all the holes in the new block. Temporarily hold them in place with masking tape.
6. Secure the rivets in the correct sequence.
   - For front brake shoes with one-piece, 4-inch linings, start with the two middle holes and work toward the ends in a criss-cross pattern.
   - For rear brake shoes, follow the sequence shown in **Fig. 1**.
7. Check for a close fit between the lining and shoe table.

   Try to insert a 0.006-inch (0.15-mm) feeler gauge between the lining and shoe table along the edges. See **Fig. 2**. It should not be possible to insert the gauge anywhere along the edge, except at each end beyond the last row of rivets. A larger clearance may exist in these areas.
8. Remove the C-clamp and masking tape.

IMPORTANT: Always adjust the brakes at the slack adjusters after replacing the linings. For instructions, see **Subject 150.**

Brake Shoe and Lining Replacement

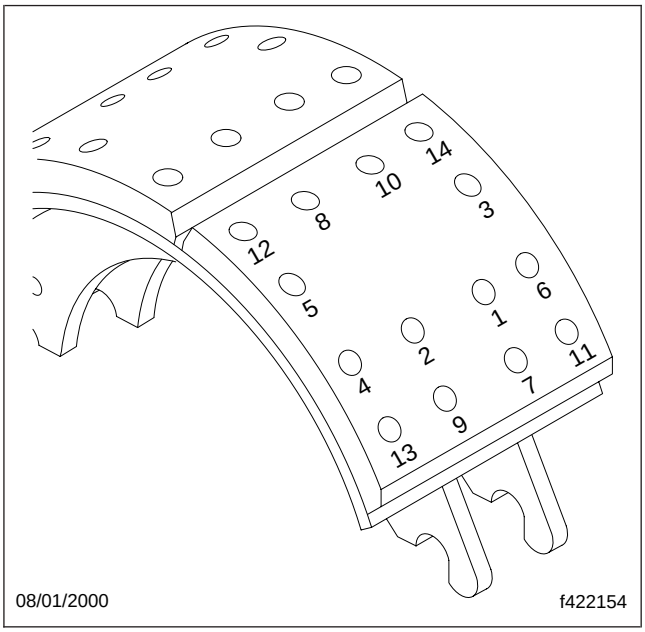


Fig. 1, Rear Lining Rivet Sequence

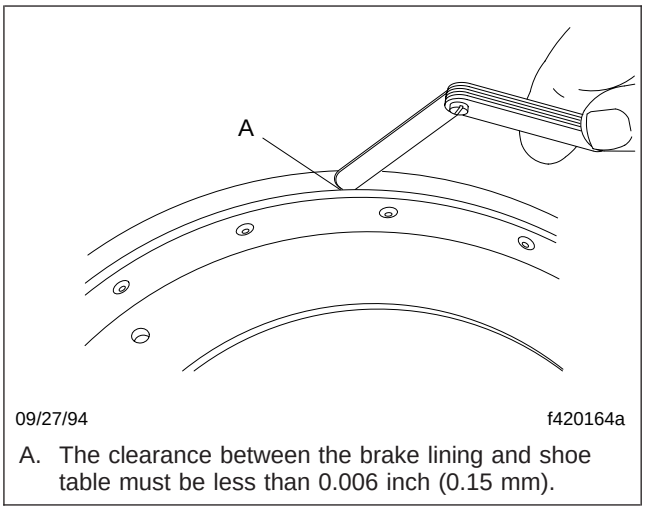

A. The clearance between the brake lining and shoe table must be less than 0.006 inch (0.15 mm).

Fig. 2, Check Fit Between Lining and Shoe Table

Brake Components Disassembly and Inspection, Cleaning, and Assembly

WARNING

Before doing this procedure, read the information in Safety Precautions, 100. Failure to follow the safety precautions during service operations on the air brake system can cause personal injury.

Disassembly and Inspection

On front-axle brakes, the upper and lower brake shoe assemblies have single webs, one-piece brake shoe linings, and a single retaining spring. See **Fig. 1**.

On rear-axle brakes, the brake shoe assemblies have dual webs, two-piece brake shoe linings, and two retaining springs. **Figure 2** is an exploded view of a typical rear-axle brake assembly.

1. Remove the brake shoes. For instructions, see **Subject 110**.
2. Inspect the drum.
   - 2.1 Check the drum for cracks. Replace any cracked drum.
   - 2.2 Using a drum caliper or other measuring device, measure the inside diameter of the drum in several places. Replace the drum if it exceeds the maximum diameter stamped on it.
   - 2.3 Check the drum for heat checks, glazing, grooving, run-out, and out-of-round. See **Fig. 3**. Some drums that are glazed, grooved, or out-of-round can be repaired. For detailed instructions, see **Section 33.01** or **Section 35.01**.

IMPORTANT: Never pull the slack adjuster out of the pushrod clevis. Always turn the adjusting nut for positioning.

3. Disconnect the slack adjuster from the pushrod clevis. For detailed instructions, see the appropriate section in this manual for the automatic slack adjusters installed on the vehicle.
   - 3.1 Remove the cotter pin from the clevis pin; remove the clevis pin. See **Fig. 4**.

CAUTION

For a Meritor automatic slack adjuster, disengage the pull-pawl before turning the manual adjusting nut. Failure to do so could damage the pull-pawl teeth. The brake clearance will not automatically adjust if the pull-pawl is damaged.

   - 3.2 For a Meritor automatic slack adjuster, disengage the pull-pawl on the side of the adjuster. Using a screwdriver or an equivalent tool, pry the pawl button out about 1/32 inch (0.8 mm) and wedge the tool in place. See **Fig. 5**. Pull-pawls are spring loaded. When the tool is removed, the pull-pawl will engage the teeth automatically.

IMPORTANT: Never pull the slack adjuster out of the pushrod clevis. Always turn the adjusting nut for positioning.

   - 3.3 Using a wrench, turn the manual adjusting nut to back the slack adjuster out of the clevis.
     - On Meritor adjustors, turn the square adjusting nut clockwise.
     - On Haldex or Gunite adjusters, turn the adjusting hexnut counterclockwise. You will hear a ratcheting sound.
4. Using a dial indicator, measure the up-and-down and side-to-side end-play of the camshaft. Replace the bushings if there is more than 0.020-inch (0.5 mm) of movement.

CAUTION

Do not hammer on the slack adjuster to remove it. Damage to the adjuster or camshaft spline may result.

5. Remove the slack adjuster.
   - 5.1 From the slack adjuster side of the camshaft support bracket, remove the snap ring and any washers, spacers, and seals from the camshaft. See **Fig. 1** or **Fig. 2**.
   - 5.2 Remove the slack adjuster from the camshaft.

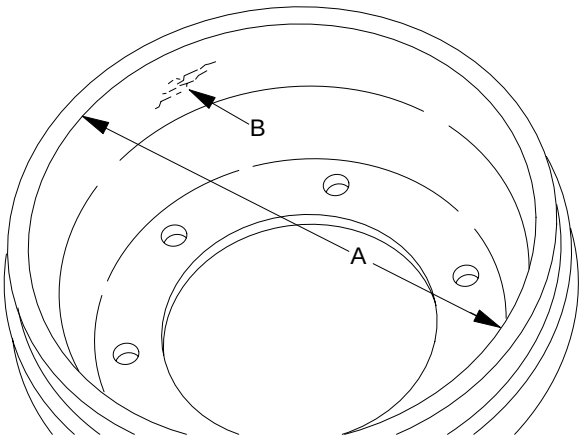
NOTE: For a Haldex or a Gunite automatic slack adjuster, there is an internal clutch that resists the manual adjusting nut from being turned in the counterclockwise direction. When checking these slack adjusters for

Brake Components Disassembly and Inspection, Cleaning, and Assembly



06/23/94 f420690a

A. Measure the diameter and check for out-of-round.
B. Check for cracks, heat checks, glazing, and grooves.

Fig. 3, Check the Drum

binding, only rotate the manual adjusting nut in the clockwise direction.

6.2 Using a torque wrench that measures lbf·in (or N·cm), turn the manual adjusting nut clockwise so that the worm gear rotates a full 360 degrees (typically 22 turns of the wrench).

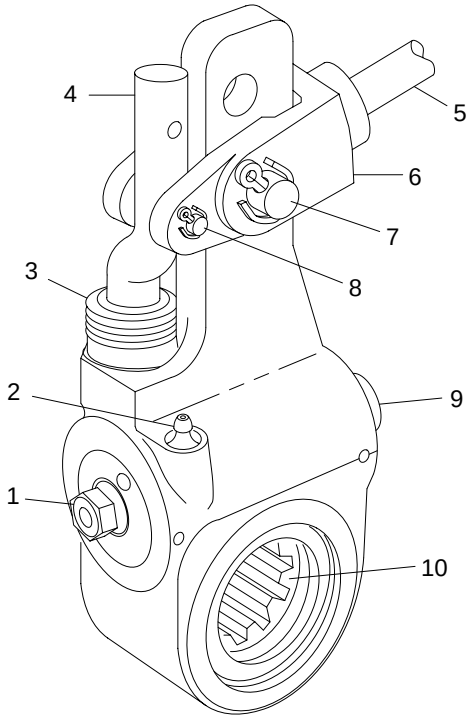
If there is binding, or if more than 25 lbf·in (280 N·cm) is needed to turn the slack adjuster, replace it. For instructions, see the applicable slack adjuster section in this group.

IMPORTANT: If any slack adjuster problem is found, repair or replace the unit, depending on the manufacturer's recommendations.

7. Check to see if a camhead thrustwasher is installed between the S-cam and the spider. If so, note the orientation for later installation. The orientation depends on the brake assembly model.

8. Remove the camshaft by grasping its head and pulling the camshaft outboard from the brake spider and camshaft support bracket.

   Remove the camhead thrustwasher from the camshaft, if one is installed.



10/27/93 f420653a

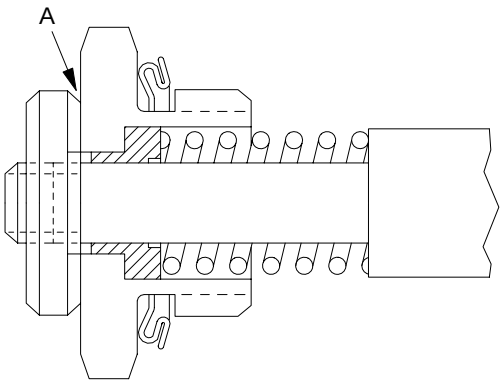
Fig. 4, Disconnect Slack Adjuster from Clevis

9. Check the camshaft spline end for cracks, or worn or deformed splines. Replace the camshaft if damaged.

10. Check the camshaft bushing journals for wear or corrosion. Replace the camshaft if it is worn or if roughness is felt in the journal area.

11. Inspect the camshaft head for brinelling, cracking, or flat spots. Replace the camshaft if a ridge can be felt between the worn area and the camhead surface.

12. Remove the brake chamber stud nuts and lockwashers that attach the brake chamber to the camshaft support bracket. Check the chamber and parts for problems.



A. Insert a screwdriver here and pry the pull-pall out about 1/32 inch (0.8 mm).

Fig. 5, Disengage the Pull-Pall on Meritor Automatic Slack Adjusters

Check the brake chamber for a cracked housing, bent pushrod, loose clamp ring, loose air fitting, air leaks, or clogged vent holes. Repair or replace parts as needed.

13. Remove and inspect the camshaft support bracket. Remove and discard the gasket. Check the bracket for a bent, broken, or cracked arm, and for cracked welds. Replace the bracket if any of these conditions exist.

⚠ WARNING

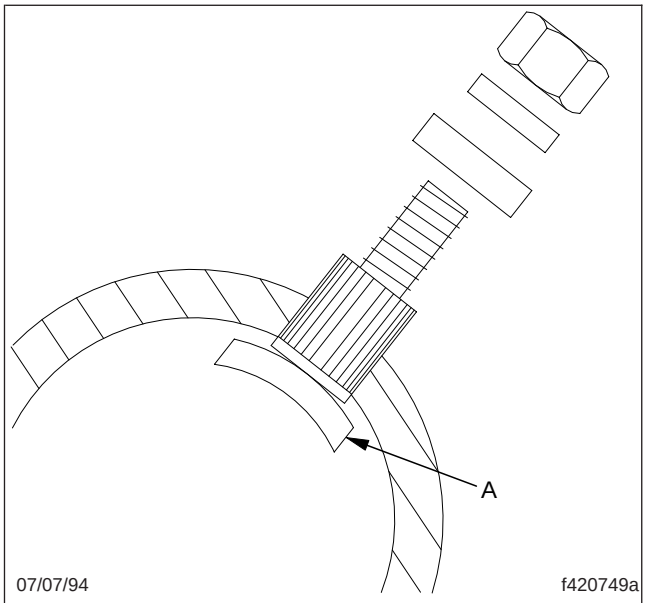
When removing bushings with a driver, wear eye protection. Do not hit steel parts with a steel hammer. To do so could cause steel pieces to break off, which could cause serious eye injury.

14. Remove and inspect the old bushing and the grease seal.
    - 14.1 Check the camshaft bushing for wear. The inner surface must be smooth; if rough or abrasive, replace the bushing.
    - 14.2 Inspect the seal. Replace it if the lip is nicked, cut, or distorted.
15. On front brakes, check the stabilizing screw for bends, looseness, or damaged threads.
16. If necessary, replace the stabilizing screw.

⚠ WARNING

Wear eye protection when driving the screw into the camshaft bracket tube with a pin punch and hammer. Failure to wear eye protection could result in personal injury due to flying metal debris.

- 16.1 Remove the damaged screw by driving it into the camshaft bracket tube with a pin punch and hammer.
- 16.2 Aligning the curvature of the screw head with the curvature of the bracket tube, install the new screw. See **Fig. 6**.



A. Align the curvature of the head with the curvature of the camshaft bracket tube.

Fig. 6, Align the Screw Head

- 16.3 Install the spacer, lockwasher, and nut. Tighten the nut 23 to 27 lbf·ft (31 to 37 N·m) to draw the screw serrations uniformly through the camshaft bracket tube wall.
- 16.4 Remove the nut and washer before assembling the bracket on the spider.

17. Using a suitable piloted driver, install the new bushing or seal.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

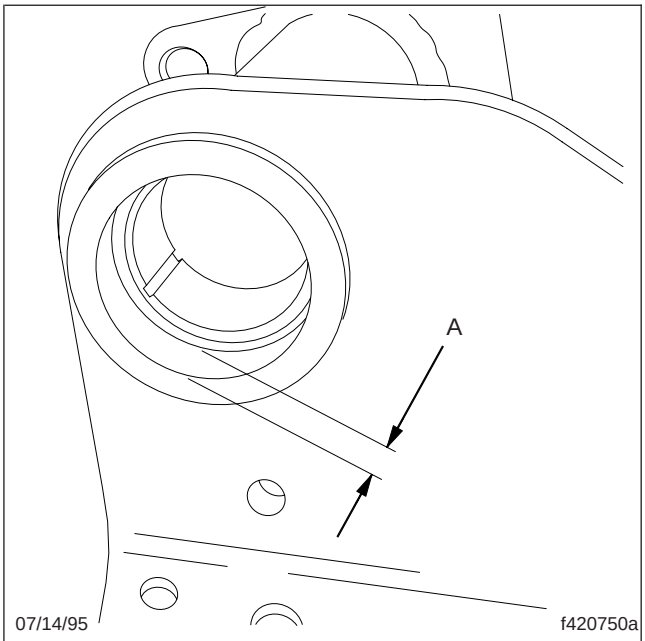
On front brakes, install the new bushing to a depth of 3/8 inch (9.5 mm) from each end of the bracket tube. See **Fig. 7**.

On rear brakes, install the new bushing to a depth of 22/32 inch (17.5 mm) at the slack adjuster end of the bracket tube and to a depth of 9/32 inch (7.1 mm) at the cam head end of the bracket tube.

Install the grease seal flush with the end of the air chamber bracket tube.

IMPORTANT: Grease seals are installed in both the bracket and the brake spider so that the seal lip is facing toward the slack-adjuster end of the bracket tube. See **Fig. 8**.

18. Remove the spider-to-axle attaching nuts, hardened washers, and bolts; remove the spider from the axle flange.

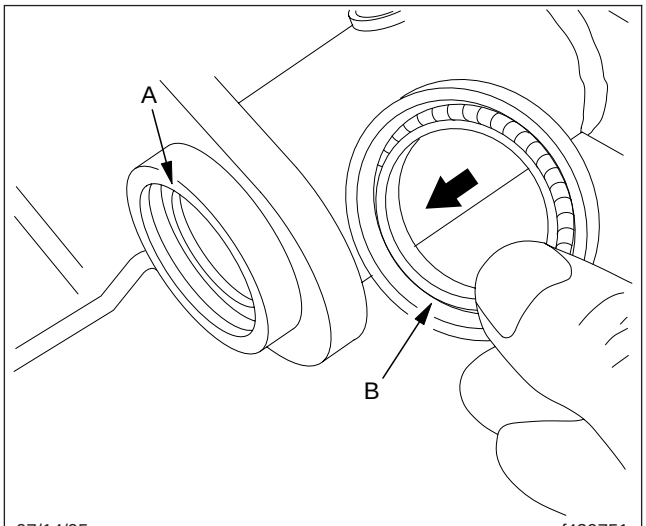


A. Recess the bushing (see text for specifications).

Fig. 7, Install the New Bushing

19. If equipped, remove the capscrews that attach the dust shield to the spider; remove the dust shield.

20. Inspect the spider and parts for damage; replace as needed.



A. Install seals flush with end of tube.
B. Lip side of both seals must face toward slack-adjuster end of the bracket.

Fig. 8, Install the Grease Seals

20.1 Check for cracks at the bolt holes, cam area, and around the anchor pin. Replace if damaged.

20.2 Check the anchor pin. See **Fig. 9**. If the pin is loose, or grooved more than 0.03 inch (0.8 mm) below the original surface, replace the spider assembly.

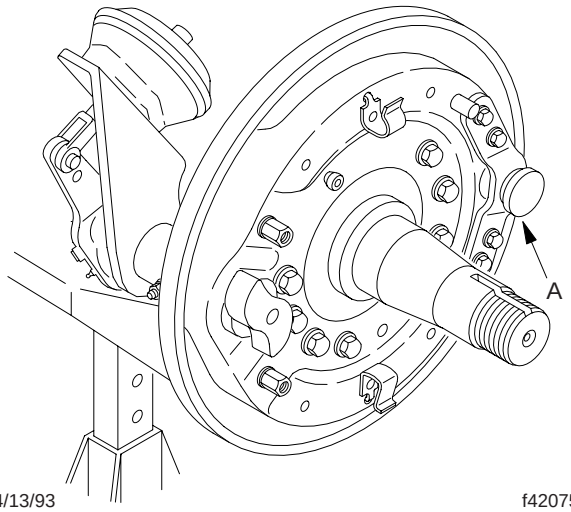
20.3 Check the anchor pin and brake spider bushings for deterioration. The inner surfaces must be smooth. If any surface is rough or abrasive, replace the part.

20.4 On front brakes, check the anchor pin reinforcement plate attaching nuts (see **Fig. 10**) for tightness. If needed, tighten the nuts 35 to 40 lbf·ft (47 to 54 N·m).

Check the anchor pin retaining nut for tightness. See **Fig. 10**. If needed, tighten the nut 475 to 525 lbf·ft (644 to 712 N·m).

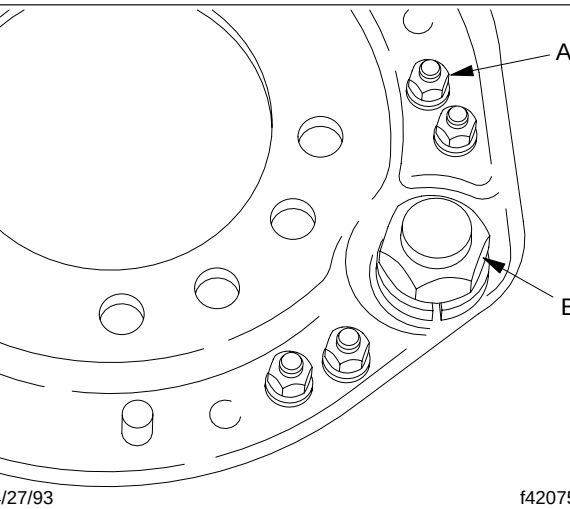
IMPORTANT: If the anchor pin turns while checking the retaining nut torque, replace the spider assembly. Dana Spicer recommends replacing the complete spider and pin assembly. Do not try to repair the spider assembly.

Brake Components Disassembly and Inspection, Cleaning, and Assembly



A. Check for grooving and looseness.

Fig. 9, Check the Anchor Pin



A. Reinforcement Plate Nut
B. Anchor Pin Retaining Nut

Fig. 10, Check the Anchor Pin Nuts

Cleaning

CAUTION

Do not clean ground or polished metal parts in a hot solution tank or with water, steam, or alkaline solutions. These solutions will cause parts to corrode.

IMPORTANT: Do not apply brake grease or corrosion-preventive materials to the brake linings or the brake drum.

After removing the brake parts being serviced, do the following:

1. Clean the camshaft journals with an emery cloth.
2. Wire brush all parts that have been exposed to mud, road dirt, and salt, including the exterior of the drum, spider, brake chamber bracket, and dust shields (if equipped).

   If relining the shoes, thoroughly wire-brush the shoe tables and paint them with a rust-inhibitive coating.

CAUTION

A thick layer of oxidation and dirt on the outside of a brake drum acts as an insulator and may hinder normal heat dissipation. Make sure oxidation and dirt are removed by wire brushing, or damage to brake components could occur.

3. Using an industrial vacuum cleaner with a HEPA filter system, remove any dust accumulation from the brake parts.
4. Wipe the inside of the drums with a damp rag to remove lining dust.
5. Prepare the brake parts for assembly.

   5.1 Thoroughly clean all the brake parts.

   For ground or polished metal parts, use a cleaning solvent to clean the parts and surfaces that are ground or polished.

   For rough metal parts, use a cleaning solvent or a weak alkaline solution in a hot solution tank to clean the parts. If a hot solution tank is used, leave the rough parts in the hot solution tank until they are completely cleaned and heated. Remove the rough parts from the hot solution tank and wash them with water until the alkaline solution is removed.

   5.2 Thoroughly dry all the brake parts with a clean, lint-free cloth or paper towel, or use low-pressure filtered and compressed air.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

WARNING

All worn or damaged brake parts must be replaced. If the brakes are assembled with worn or damaged parts, they may not perform to their capacity and a brake failure could occur, which could cause personal injury and property damage.

5.3 Thoroughly inspect all the brake parts for wear or damage. It is very important that all the parts be carefully inspected before they are assembled. Repair or replace any worn or damaged parts.

5.4 For parts that will be assembled, apply a thin layer of brake grease to the parts after they have been cleaned, dried, and inspected to protect them from corrosion.

If the parts will be stored, apply a special material that prevents corrosion and rust on all surfaces. The parts should be stored in special paper (or other material) that prevents corrosion and rust.

Assembly

1. Install the dust shield (if equipped). See **Fig. 1** or **Fig. 2.**

   If installing a one-piece dust shield, place it against the spider and install the capscrews. Tighten the capscrews to the specifications in **Table 1**.

   If installing a two-piece dust shield, place both halves against the spider and tighten the attaching screws finger-tight. Reposition the dust shield halves to allow a uniform space of 1/8 inch (3 mm) along the mating edges. See **Fig. 11**. Tighten the screws to the specifications in **Table 1**.

NOTE: Because of the interference fit in the upper dust shield-to-brake chamber bracket area (see **Fig. 12**) you may need to deform the upper dust shield slightly by hand to correctly align the upper half with the lower half.

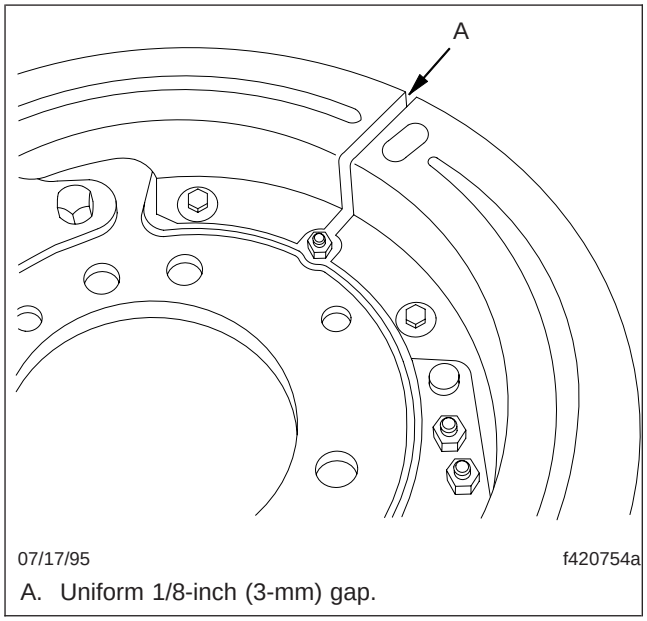
2. Install the spider.

   Place the spider on the axle flange. Using a hardened washer under the bolt head and the nut, install the mounting fasteners. Tighten the bolts to the specifications in **Table 1** in a cross pattern.

Brake Assembly Torque Specifications		
Description	**lbf·ft**	**N·m**
Dust Shield Fasteners		
One- and Two-Piece Dust Shield	11 to 16	15 to 22
Brake Spider Fasteners		
1/2–13	60 to 80	81 to 108
5/8–11 (hexhead capscrew)	130 to 160	176 to 217
5/8–11 (flanged hexhead capscrew)	160 to 200	217 to 271
Brake Chamber		
Midland 12, 16	30	41
Midland 20, 24, 30, 36	100	136
MGM 24, 30, 36	100 to 115	136 to 156
Camshaft Support Bracket Fasteners, 1/2–13	55 to 65	75 to 88
Stabilizing Screw (front brake)	23 to 27	31 to 37

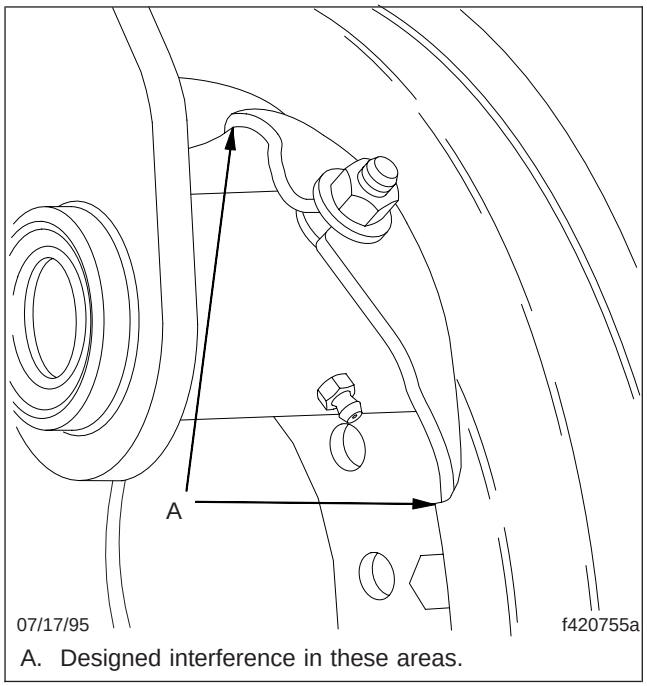
Table 1, Brake Assembly Torque Specifications

3. Install the brake chamber and bracket.



A. Uniform 1/8-inch (3-mm) gap.

Fig. 11, Two-Piece Dust Shield Installation



A. Designed interference in these areas.

Fig. 12, Check the Fit at the Upper Dust Shield-to-Brake Chamber Bracket

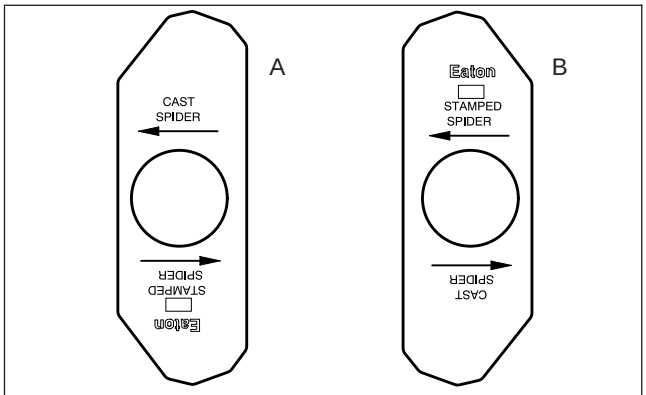
3.1 Place the brake chamber on the mounting bracket with the chamber mounting studs through the bracket holes. Install the lockwashers and stud nuts. Tighten the nuts to the specifications in **Table 1**.

3.2 Place the bracket against the spider, and install the lockwashers and barrel nuts. Tighten the nuts to the specifications in **Table 1**.

3.3 Install the washer, lockwasher, and nut on the stabilizing screw (if equipped). Tighten the nut to the specification in **Table 1**.

4. Install the camshaft in the spider.

4.1 If a camhead thrustwasher was removed during disassembly, reinstall it in the same orientation between the S-cam and the spider. See **Fig. 13**.



A. Cast Spider: Place the camhead thrustwasher under the camhead with the CAST SPIDER arrow pointing toward the center of the spider. Exception: for model ES-150-8D, the arrow points away from the center of the spider.
B. Stamped Spider: Place the camhead thrustwasher under the camhead with the STAMPED SPIDER arrow pointing toward the center of the spider.

Fig. 13, Install Thrustwasher

4.2 Apply a thin film of chassis grease on the inside of the camshaft bushings and journals. Do not grease the camshaft head area.

4.3 Apply a thin film of rust preventive grease (Meritor 0-637 or an equivalent) on the camshaft splines.

Brake Components Disassembly and Inspection, Cleaning, and Assembly

4.4 Carefully slip the camshaft into the spider and the mounting bracket tube.

4.5 Install the thick camshaft washer on the camshaft.

5. Install the slack adjuster on the camshaft, with the adjuster nut on the side opposite the brake chamber.
6. Install the thin outer washer(s) and snap ring.
7. Using a dial indicator, measure the end play of the camshaft.

   7.1 With the slack adjuster centered between the brake chamber bracket and the snap ring groove, pull inboard on the slack-adjuster end of the camshaft to take up the end play.

   7.2 Set the dial indicator to zero.

   7.3 Push outboard on the slack-adjuster end of the camshaft and note the maximum reading.

   7.4 There should be 0.005 to 0.045 inch (0.1 to 1.1 mm) of movement. Add or remove outer washers as needed to adjust the end play.

⚠ WARNING

When lubricating the camshaft bracket bushings, if grease leaks out under the cam head, the camshaft grease seal is worn or damaged. If the seal is not replaced, the brake linings could be contaminated by grease and the vehicles stopping distance could be reduced, which could result in personal injury or property damage.

NOTE: Use meter-type fittings, having a maximum 40 psi (276 kPa) pressure relief at the shutoff.

8. Pressure lube the camshaft bracket bushings.

   Pump multipurpose chassis grease (NLGI grade 1 or 2) into the chamber bracket until it appears at the slack-adjuster end of the bracket. Use care that no grease enters the drum cavity.

   If grease leaks out under the cam head, the camshaft grease seal is worn or damaged, or is installed backwards. Replace the seal.

9. Adjust the brakes at the slack adjusters. For instructions, refer to **Subject 150**.
10. Install the brake shoes. For instructions, see **Subject 110**.

⚠ WARNING

Do not operate the vehicle until the brakes have been adjusted and checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

Pre-Adjustment Checks and General Adjustment Information

Before adjusting the brakes, check and adjust the following:

- Adjust the wheel bearings. For instructions, see **Section 33.01** or **Section 35.01** in this manual.
- Check the slack adjuster and the brake chamber for loose fasteners and tighten as necessary. For torque specifications, see **Specifications, 400**.

  For slack adjuster installation instructions, see the appropriate section in this manual for the type of adjuster installed on the vehicle.

Brakes with automatic slack adjusters should never have to be manually adjusted while in service. The only time automatic slack adjusters should be manually adjusted is during installation or after the brakes have been relined.

For cam brakes, there are two brake chamber stroke measurement specifications: applied chamber stroke and free-stroke.

IMPORTANT: The U.S. Department of Transportation (DOT) Federal Highway Administration has issued the applied chamber stroke specifications for cam brakes. When the applied chamber stroke is checked and adjusted, it must not be greater than the DOT specification. See **Table 1**.

The specific procedure for adjusting the brake chamber stroke at the slack adjuster's manual adjusting nut may vary, depending on which slack adjuster is installed, but there are three basic steps in completing a manual brake chamber stroke adjustment:

1. Adjusting the approximate brake chamber stroke using the manual adjusting nut on the slack adjuster (coarse adjustment).
2. Measuring and adjusting the free-stroke.
3. Measuring and adjusting the applied chamber stroke (fine adjustment).

The stroke (free or applied chamber) is the distance that the large clevis pin moves when the brakes are applied. The type of force used to move the slack adjuster from its released position to its applied position (where the brake linings contact the brake drum) distinguishes the free-stroke from the applied chamber stroke.

- The free-stroke is measured using a lever to move the slack adjuster. The length of the free-stroke equals the clearance between the brake linings and the drum when the brakes are not applied.

Brake Chamber Stroke Specifications		
Chamber Type (Size)	**Maximum Applied Stroke*: inch (mm)**	**Free-Stroke: inch (mm)**
Standard Stroke		5/8 to 3/4 (16 to 19)
16, 20, and 24	1-3/4 (44)	
30	2 (51)	
36	2-1/4 (57)	
Long Stroke†		
16, 20, and 24	2 (51)	
30	2-1/2 (64)	

* Specifications are relative to a brake application with 80 to 90 psi (550 to 620 kPa) air pressure in the brake chambers.

† Long stroke design is indicated by a tag, or embossing, on the brake chamber.

Table 1, Brake Chamber Stroke Specifications

Brake Adjustment

- The applied chamber stroke is measured using an 80 to 90 psi (550 to 620 kPa) brake application to move the slack adjuster.

With the engine off, 100 psi (689 kPa) of air tank pressure will apply the required 80 to 90 psi (550 to 620 kPa) brake application for measuring the applied chamber stroke.

The applied chamber stroke measurement can be used for diagnostic purposes. A stroke that is too long or too short may indicate excessive wear in the cam, cam bushings, return springs, or air chamber.

The applied chamber stroke should always be adjusted (minimized) to within the specified limit, but it should not be reduced to the point where the free-stroke is too short and the brakes drag. To check for brake drag, spin the wheel end, tap the rim lightly with a hammer, and listen for a drag noise (a sharp ringing sound).

Adjustment

Meritor Automatic Slack Adjuster

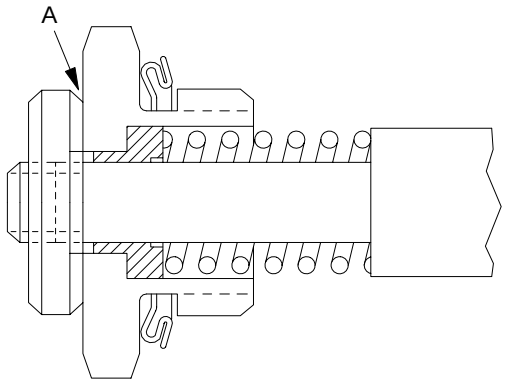
IMPORTANT: Before adjusting the brakes, see the pre-adjustment checks and general adjustment information at the beginning of this subject.

1. Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires on the axle that is not being repaired.
2. Raise the front or rear axle and place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
3. Fully release the brakes (the air chamber push-rod must be fully retracted).
4. Check the condition of the boot on the slack adjuster. It should be held in the correct position with a retaining clip. If the boot is torn or cracked, see the slack adjuster disassembly and inspection procedures for information.

⚠ CAUTION

Before turning the manual adjusting nut on the slack adjuster, disengage the pull-pawl. Failure to do so could damage the pull-pawl teeth. A damaged pull-pawl will not allow the slack adjuster to automatically adjust the brake clearance.

5. Using a screwdriver, pry the pull-pawl button out at least 1/32 inch (0.8 mm) to disengage the pull-pawl teeth from the slack adjuster actuator. See **Fig. 1**. Wedge the screwdriver in place. The pull-pawl will need to be disengaged until the brake adjustment is complete.



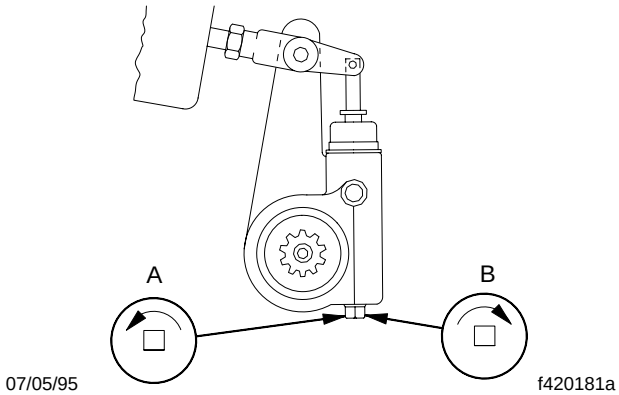
09/27/94 f420693a

A. Insert screwdriver here.

Fig. 1, Disengage the Pull-Pawl

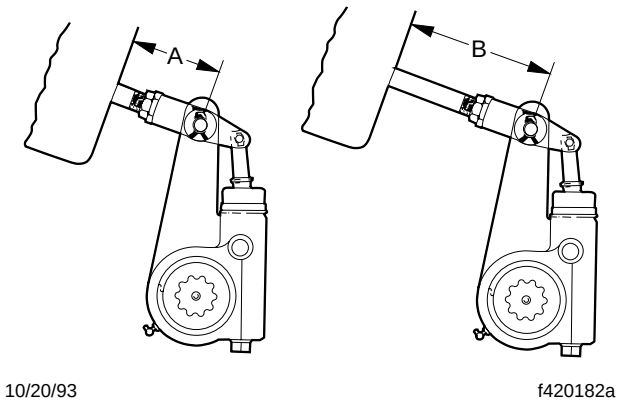
NOTE: When the screwdriver is removed, the pull-pawl will engage automatically.

6. Using the manual adjusting nut on the slack adjuster, adjust the brake chamber stroke (coarse adjustment). See **Fig. 2**.
   - 6.1 Turn the adjusting nut counterclockwise until the brake linings touch the brake drum.
   - 6.2 Then, turn the adjusting nut clockwise one-half turn.
7. Measure and adjust the free-stroke.
   - 7.1 With the brakes released, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension A. See **Fig. 3**.
   - 7.2 Using a lever, move the slack adjuster until the brake linings contact the brake drum.



A. Shorten stroke. B. Lengthen stroke.

Fig. 2, Turn the Adjusting Nut



NOTE: For either free-stroke or applied chamber stroke, subtract measurement A from B.

A. Measurement with the brakes released.
B. Measurement with the brakes applied by manual lever (free-stroke) or pressurized brake application (applied chamber stroke).

Fig. 3, Measuring the Stroke

7.3 Measure the distance from the bottom of the brake chamber to the center of the large clevis pin. Record this measurement as dimension B. See **Fig. 3**.

7.4 Subtract dimension A from dimension B. The difference between these measurements is the free-stroke.

7.5 The free-stroke should be 5/8 to 3/4 inch (16 to 19 mm). If it is not, turn the adjusting nut one-eighth turn, as shown in **Fig. 2**. Then, measure the free-stroke again, and readjust it until it is correct.

8. Measure and adjust the applied chamber stroke (fine adjustment).

8.1 Start the engine and build the air pressure to 100 psi (689 kPa). Shut down the engine.

8.2 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 3**, Ref. B. Record this measurement as dimension C.

8.3 Subtract dimension A from dimension C. The difference between these measurements is the true applied chamber stroke.

8.4 The applied chamber stroke must not exceed the maximum value specified in **Table 1**.

⚠ CAUTION

The adjusted applied chamber stroke should be as short as possible but not so short that the free-stroke is too short and the linings drag. If the linings drag, the brakes could be damaged.

8.5 If the applied chamber stroke is incorrect, turn the adjusting nut one-eighth turn counterclockwise to shorten the stroke, or one-eighth turn clockwise to lengthen it. See **Fig. 2**. Measure the applied stroke again and readjust it until it is correct.

8.6 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes. See **Subject 150**. If necessary, replace the slack adjuster.

9. Remove the screwdriver from the pull-pawl assembly. This will engage the pull-pawl with the actuator.

10. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability,

Brake Adjustment

which could cause personal injury or death, and property damage.

11. Check for proper brake operation. For instructions, see **Subject 110**.

Haldex Automatic Slack Adjusters

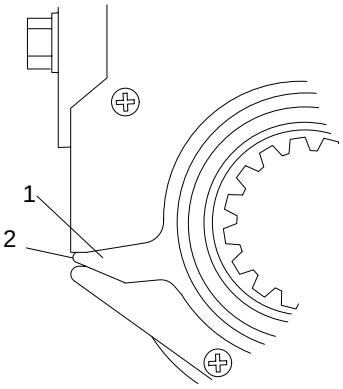
IMPORTANT: Before adjusting the brakes, see the pre-adjustment checks and general adjustment information at the beginning of this subject.

1. Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires on the axle that is not being repaired.
2. Raise the front or rear axle. Then, place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
3. Fully release the brakes (the air chamber pushrod must be fully retracted).

⚠ CAUTION

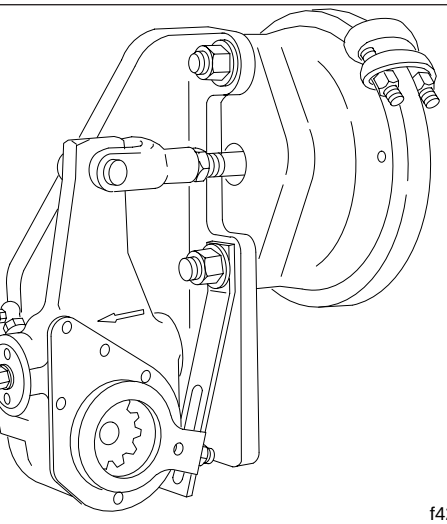
The installation indicator must be aligned with the indicator notch on the slack adjuster. If the indicator is not within the notched area, the control arm is installed in the wrong position. This may result in tight brakes, excessive lining wear, and possible brake damage.

4. Make sure the installation indicator is aligned with the indicator notch on the slack adjuster. See **Fig. 4**. If the indicator is not within the notched area, the control arm is not installed correctly.
5. Measure how much torque is required to overcome the resistance of the internal clutch (internal clutch slippage).
   - 5.1 Using a 7/16-inch torque wrench, turn the adjusting nut counterclockwise. See **Fig. 5**. You will hear a ratcheting sound.
   - 5.2 If the clutch slips with a torque less than 13 lbf·ft (18 N·m), the slack adjuster must be replaced.
6. Using the manual adjusting nut on the slack adjuster, adjust the brake chamber stroke (coarse adjustment).



1. Installation Indicator 2. Indicator Notch

Fig. 4, Installation Indicator



1. Adjusting Hexnut

Fig. 5, Adjusting Hexnut

   - 6.1 Turn the adjusting nut clockwise until the brake linings contact the brake drum.
   - 6.2 Then, turn the adjusting nut counterclockwise one-half turn. You will hear a ratcheting sound.
7. Measure and adjust the free-stroke.
   - 7.1 Measure the distance from the bottom of the brake chamber to the far side of the clevis pin. See **Fig. 6**. Record this measurement as dimension A.

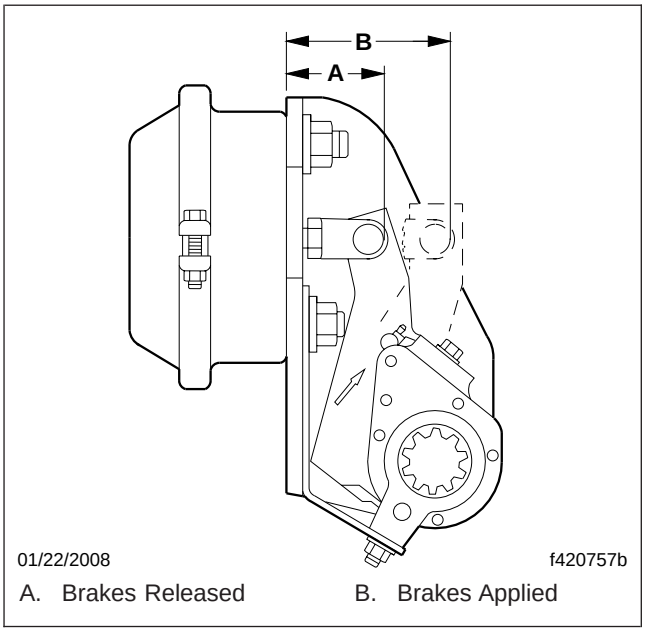


Fig. 6, Measure the Stroke

7.2 Using a lever, move the slack adjuster until the brake linings contact the brake drum. Then, measure the distance from the bottom of the brake chamber to the far side of the clevis pin. See **Fig. 6**. Record this measurement as dimension B.

7.3 Subtract dimension A from dimension B. The difference between these measurements is the free-stroke.

7.4 The free-stroke should be 5/8 to 3/4 inch (16 to 19 mm). If it is not, turn the adjusting nut in the required direction. Then, measure the free-stroke again and readjust it until it is correct.

8. Measure and adjust the applied chamber stroke (fine adjustment).

8.1 Start the engine and build the air pressure to 100 psi (689 kPa). Shut down the engine.

8.2 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the far side of the clevis pin hole. See **Fig. 6**, Ref. B. Record this measurement as dimension C.

8.3 Subtract dimension A from dimension C. The difference between these measurements is the applied chamber stroke.

8.4 The applied chamber stroke must not exceed the maximum value specified in **Table 1**. If the stroke is not correct, turn the adjusting nut in the required direction. Then, measure the applied chamber stroke again and readjust it until it is correct.

8.5 If the slack adjuster does not maintain the correct applied chamber stroke, check the condition of the foundation brakes. See **Subject 150**. If necessary, replace the slack adjuster.

9. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

10. Check for proper brake operation. For instructions, see **Subject 110**.

Gunite Automatic Slack Adjusters

IMPORTANT: Before adjusting the brakes, see the pre-adjustment checks and general adjustment information at the beginning of this subject.

1. Park the vehicle on a level surface, apply the parking brakes, and shut down the engine. Chock the tires on the axle that is not being repaired.
2. Raise the front or rear axle. Then, place safety stands under the frame or axle. Be sure the stands will support the weight of the vehicle.
3. Fully release the brakes (the air chamber pushrod must be fully retracted).
4. Measure how much torque is required to overcome the resistance of the internal clutch (internal clutch slippage).

Brake Adjustment

4.1 Using a 7/16-inch torque wrench, turn the adjusting nut counterclockwise. See **Fig. 7**. You will hear a ratcheting sound.

4.2 If the clutch slips with a torque less than 15 lbf·ft (20 N·m), the slack adjuster must be replaced.

Fig. 7, Gunite Slack Adjuster

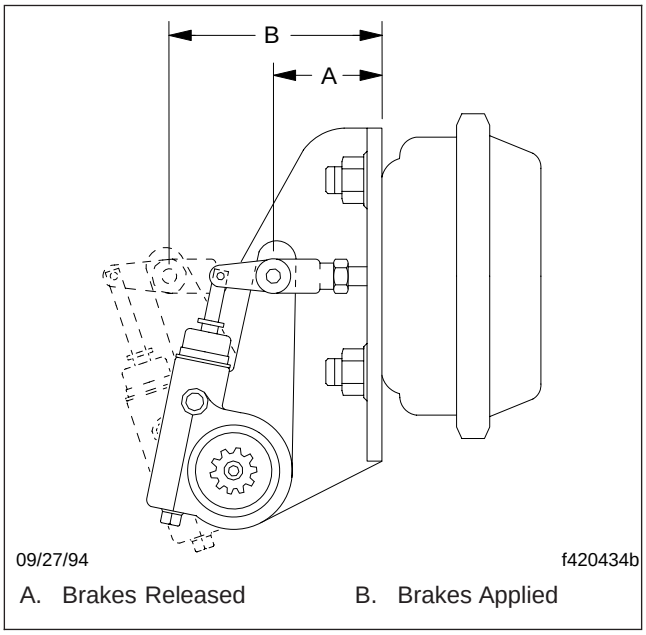
5. Using the manual adjusting nut on the slack adjuster, adjust the brake chamber stroke (coarse adjustment).

5.1 Turn the adjusting nut clockwise until the brake linings contact the brake drum.

5.2 Turn the adjusting nut counterclockwise one-half turn. There should be about 30 lbf·ft (41 N·m) resistance. You will hear a ratcheting sound.

6. Measure and adjust the free-stroke.

6.1 Measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 8**. Record this measurement as dimension A.



A. Brakes Released B. Brakes Applied

Fig. 8, Measure the Stroke

6.2 Using a lever, move the slack adjuster until the brake linings contact the brake drum.

6.3 Measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 8**. Record this measurement as dimension B.

6.4 Subtract dimension A from dimension B. The difference between these measurements is the free-stroke.

6.5 The free-stroke should be 5/8 to 3/4 inch (16 to 19 mm). If it is not, turn the adjusting nut in the required direction. Then, measure the free-stroke again and readjust it until it is correct.

7. Measure and adjust the applied chamber stroke (fine adjustment).

7.1 Start the engine and build air pressure to 100 psi (689 kPa). Shut down the engine.

7.2 Fully apply the brakes. Then, measure the distance from the bottom of the brake chamber to the center of the large clevis pin. See **Fig. 8**, Ref. B. Record this measurement as dimension C.

7.3 Subtract dimension A from dimension C. The difference between these measurements is the applied chamber stroke.

7.4 The applied chamber stroke must not exceed the maximum value specified in **Table 1**. If the stroke is not correct, turn the adjusting nut in the required direction. Then, measure the applied stroke again and readjust it until it is correct.

7.5 If the slack adjuster is not maintaining the correct applied chamber stroke, check the condition of the foundation brakes. See **Subject 150**. If necessary, replace the slack adjuster.

8. Remove the safety stands, lower the vehicle, and remove the chocks from the tires.

⚠ WARNING

Do not operate the vehicle until the brakes have been checked for proper operation. To do so could result in inadequate or no braking ability, which could cause personal injury or death, and property damage.

9. In a safe area, check for proper brake operation before you put the vehicle in service.

9.1 Apply and release the brakes several times to check for air leaks and proper operation of the slack adjusters.

9.2 Perform six low-speed stops to ensure proper parts replacement and full vehicle control.

9.3 Immediately after doing the above stops, check the drum temperatures. Any drums that are significantly cooler than others shows a lack of braking effort on those wheels.

Description

The Bendix SR-7™ spring brake modulating valve (see **Fig. 1** and **Fig. 2**) is used in conjunction with a dual air brake system and spring brake actuator, and performs the following functions:

- Provides a rapid application of the spring brake actuator when parking.
- Modulates the spring brake actuator application using the dual brake valve should a primary failure occur in the service brake system.
- Prevents compounding of service and spring brake forces.

The SR-7 valve has one park control, one service control, one supply, one balance, four delivery NPT ports, and an exhaust port protected by an exhaust diaphragm. The valve incorporates two mounting studs for mounting the valve to the frame rail or crossmember.

⚠ CAUTION

Do not attempt to disassemble the SR-7 valve. The valve contains high spring forces that could result in personal injury if disassembly is attempted.

Operation

The operation guidelines in this subject represent the relay-valve-based SR-7. A quick-release-based valve functions similarly to the relay-valve-based version with the exception that all air delivered to the spring brakes passes through the park control port through the inline single check valve. The SR-7 quick release style can be easily identified by the pipe plug in the supply port of the valve. See **Fig. 1**. For vehicle-specific plumbing diagrams, go to **EZWiring**.

Charging the Spring Brake Actuators Below 107 psi (737 kPa)

With the air brake system charged and the parking brakes released (by pushing in the dash valve button), air enters the park control port. This opens the SR-7 valve, to supply air pressure to the spring brake chambers. As illustrated, air pressure in the chambers is below 107 psi (737 kPa) (nominal). See **Fig. 3**.

Charging the Spring Brake Actuators Above 107 psi (737 kPa)

Once the SR-7 valve delivery pressure reaches 107 psi (nominal), the inlet and exhaust are closed (valve lap position). This maintains the spring brake hold-off pressure at 107 psi (nominal). See **Fig. 4**.

Normal Service Application

During a service brake application, the valve remains in the lap position. The SR-7 valve monitors the presence of air pressure in both primary and secondary delivery circuits. See **Fig. 5**.

Parking

Actuating the park brakes (by pulling out the dash valve button) exhausts spring brake air pressure through the SR-7 valve exhaust port. See **Fig. 6**.

Service Application with Loss of Air in Primary Circuit

With the parking brakes released (dash valve button in) and the absence of air in the primary circuit delivery, a service brake application from the secondary circuit causes the pressure in the spring brakes to be exhausted proportionally to this application. This is known as spring brake modulation. A 30 psi (207 kPa) service brake application will exhaust the spring brake pressure to approximately 60 psi (414 kPa). See **Fig. 7**.

Service Application with Loss of Air in Secondary Circuit

With the parking brakes released (dash valve button in) and the absence of air in the secondary circuit reservoir, the external single check valve in the supply port seals to prevent air leakage to atmosphere from the SR-7 valve. The dash valve delivery air flows through the inline single check valve and becomes SR-7 valve supply air. This air is delivered to maintain at least 107 psi (737 kPa) (nominal) in the spring brake chambers. See **Fig. 8**.

Anticompounding

The SR-7 valve provides anticompounding of the service and spring brake forces. When the park brakes are actuated (by pulling out the dash valve button), a service brake application will cause the SR-7 valve to deliver air pressure to the spring brake chambers. Thus the vehicle is held stationary using a service brake application. When the service brake application is released, the delivery pressure is exhausted from the spring brake chambers and the vehicle remains parked using the spring brake actuators. See **Fig. 9**.

Safety Precautions

Before attempting to work on the air brake system, observe the following precautions:

- Since the compression and storage of air can be compared to energy in a coiled spring, when released, it can present a hazard if not properly recognized. The wheels of the vehicle must always be chocked so that depletion of air will not permit the vehicle to roll.
- When draining the system, do not look into the air jets or direct them toward a person, as dirt or sludge particles can be carried in the air stream.
- Hoses will whip dangerously if disconnected under pressure. Follow the manufacturer's recommended procedures when working on any air devices so as to avoid injury or damage from parts which, when released, are subject to mechanical (spring) or pneumatic propulsion.
- As system pressure is drained and the emergency brakes apply, hands must be away from the air chamber pushrods and spring actuators that apply automatically with the loss of pressure. This also applies when checking the service brake system.
- Reservoirs that are closest to the sources of compressed air (compressors or auxiliary sources) must contain a safety valve in known working order and sufficient capacity to limit the reservoir pressure to a safe maximum level.
- Used reservoirs must not be used as replacements, in order to eliminate the possibility of component failure.
- The safety valves must not be reset higher than specified by the reservoir manufacturer, vehicle manufacturer, or code to which the reservoir had been manufactured, in order to prevent valve failure.
- Various actuators contain powerful internal springs that require special handling procedures. Note and be guided by the warning tags on such units to avoid personal injury or property damage.
- To avoid injury, keep clear of the air chamber pushrod when brakes are applied or when air is exhausted from the system.

Removal

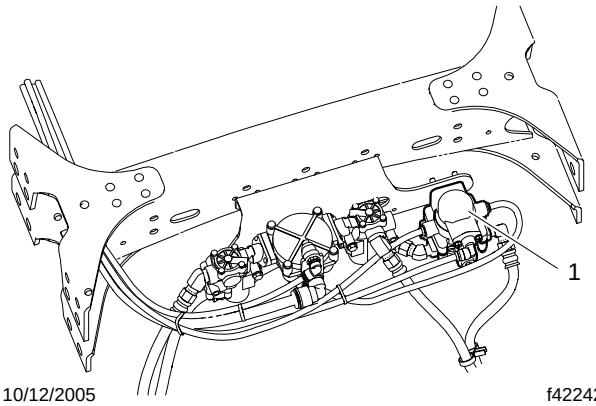
WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so could result in personal injury.

CAUTION

Do not attempt to disassemble the SR-7 valve. The valve contains high spring forces that could result in personal injury if disassembly is attempted.

1. Park the vehicle on a level surface, set the parking brake, and shut down the engine. Chock the tires.
2. Drain the air system.
3. Identify all the air lines attached to the valve, for reinstallation. See **Fig. 1** for a view of a typical installation, or access EZWiring for vehicle-specific plumbing diagrams.



1. SR-7 Valve

Fig. 1, SR-7 Spring Brake Modulating Valve Installation (typical)

4. Disconnect all the air lines from the valve.
5. Remove the two mounting nuts that secure the valve to the crossmember bracket, and remove the valve.
6. If the valve is being replaced, note the orientation of all fittings, then remove the fittings for use on the new valve.

Installation

1. If a new valve is being installed, install the fittings removed from the old valve.
2. Position the valve on the crossmember bracket and install the mounting nuts. Tighten to 15 to 18 lbf·ft (20 to 24 N·m).
3. Attach all the air lines as noted during removal.
4. Before returning the vehicle to service, perform the operating and leakage tests in **Subject 120**, *Tests*.

Operating Test

⚠ WARNING

Before working on or around air brake systems and components, see Safety Precautions 100. Failure to do so could result in personal injury.

⚠ CAUTION

Do not attempt to disassemble the SR-7 valve. The valve contains high spring forces that could result in personal injury if disassembly is attempted.

1. Chock the tires.
2. Charge the air brake system to governor cut-out pressure.
3. Place the parking control valve in the PARK position. Observe that the spring brake actuators apply promptly.
4. Remove one line from a delivery port of the SR-7 valve and install a test gauge that is known to be accurate. See **Fig. 1** for the port locations.
5. Place the parking control valve in the RELEASE position. Observe that the spring brake actuators fully release.
6. With the parking control valve still in the RELEASE position, note the gauge pressure reading. Correct spring brake actuator hold-off pressure is 107 psi (737 kPa) nominal.
7. Place the parking control valve in the PARK position. The gauge reading should drop to zero promptly. A lag (more than 3 seconds) in the drop of pressure would indicate faulty operation.
8. With the parking control valve still in the PARK position, gradually apply the foot brake valve and note a pressure reading increase on the gauge installed in the SR-7 valve delivery port.
9. Place the parking control valve in the RELEASE position.
10. Drain the reservoir that supplies the rear service brake circuit; apply the foot brake valve several times and note that the pressure reading on the gauge decreases each time the foot brake valve is applied (spring brake modulation). After the foot brake valve has been applied several times, the pressure reading on the gauge will drop to the point where release of the spring brake actuators will no longer occur.

NOTE: The SR-7 valve is not serviceable. If the valve does not function as described, replace it.

Leakage Test

Place the park control valve in the RELEASE position; using a soap solution, coat all ports including the exhaust port. A 1-inch (25-mm) bubble in three seconds is permitted.

NOTE: The SR-7 valve is not serviceable. If the valve does not function as described, or if leakage is excessive, replace it.

General Information

The steering linkage on L-Line and A-Line vehicles consists of left-side and right-side spindle assemblies attached to an I-beam front axle. Separate steering and spindle arms attach to the spindles. A tie rod, adjustable for toe-in, is connected between the left-side and right-side spindle arms. The drag link is connected between the steering arm on the left-side spindle assembly and the pitman arm on the steering gear. See **Fig. 1**.

DUAL-GEAR STEERING LINKAGE

18,000- to 20,000-lb front axles utilize steering gears on both the left- and right-sides to reduce steering efforts normally associated with heavy axles. This is known as a dual-gear system. In a dual-gear system, the steering linkage on the right-side is the mirror image of the linkage on the left-side. See **Fig. 2**.

Tie Rod End Removal and Installation

NOTE: All figures show left-hand drive configurations. Right-hand drive configurations are similar.

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the cotter pin and nut from the tie rod end. Discard the cotter pin. See **Fig. 1**.

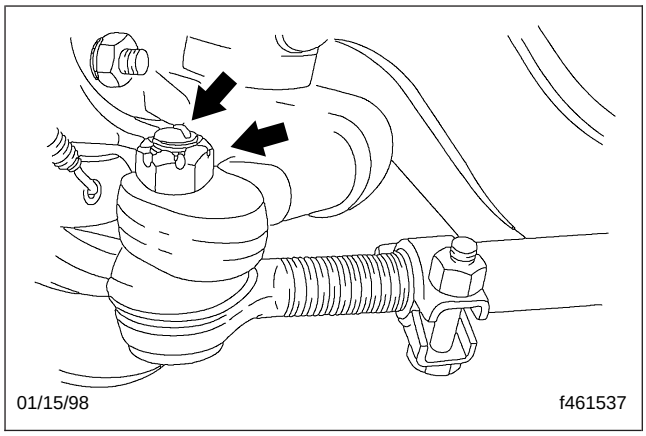

Fig. 1, Remove the Cotter Pin and Nut

3. Remove the tie rod end ball stud from the steering arm using the pitman arm puller. See **Fig. 2**.

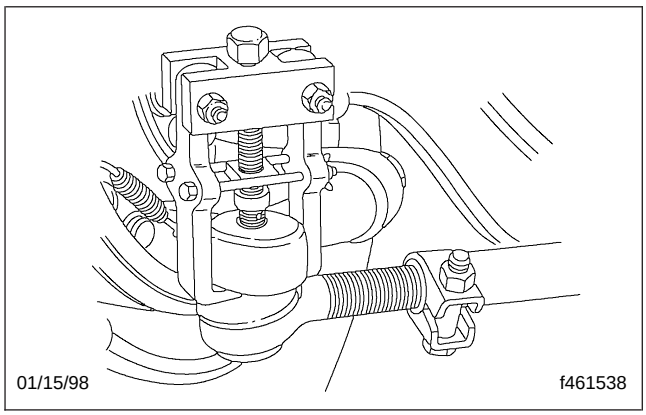

Fig. 2, Remove the Tie Rod End Ball Stud

4. Remove and discard the grease seal from the tie rod end. See **Fig. 3**.

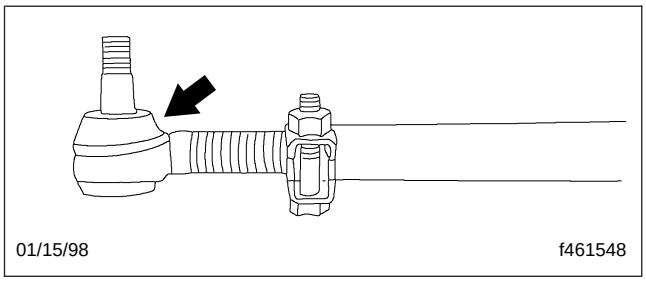

Fig. 3, Grease Seal

5. Loosen the tie rod end clamp bolt, and count the number of turns required to remove the tie rod end. See **Fig. 4**.

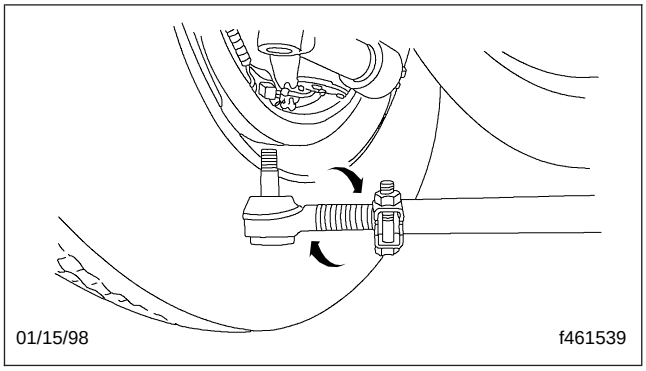

Fig. 4, Unscrew the Tie Rod (Count the Number of Turns)

Installation

1. Install the tie rod end. Turn the tie rod end the same number of turns used to remove the old tie rod end. See **Fig. 5**.
2. Install a new grease seal on the tie rod end. See **Fig. 3**.
3. Install the tie rod end to the steering arm. For 9,000-lb front axles, tighten the nut 75 to 105 lbf·ft (102 to 142 N·m). For 10,000- to 20,000-lb front axles, tighten the nut 110 to 150 lbf·ft (149 to 203 N·m). Advance to the next castlelation, if necessary, to install the cotter pin. See **Fig. 6**.
4. Install a new cotter pin.
5. Tighten the tie rod end clamp bolt 50 to 70 lbf·ft (68 to 95 N·m). See **Fig. 7**.
6. Check the vehicle alignment.
7. Remove the chocks from the tires.

Tie Rod End Removal and Installation

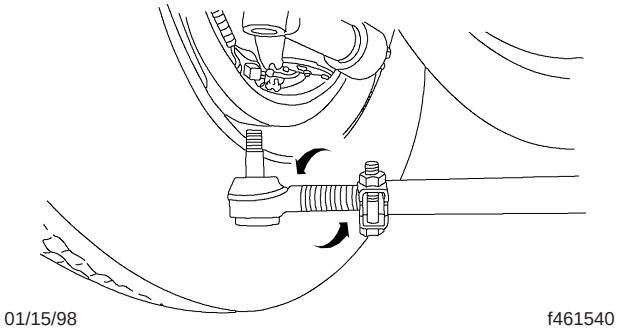

Fig. 5, Screw in the Tie Rod

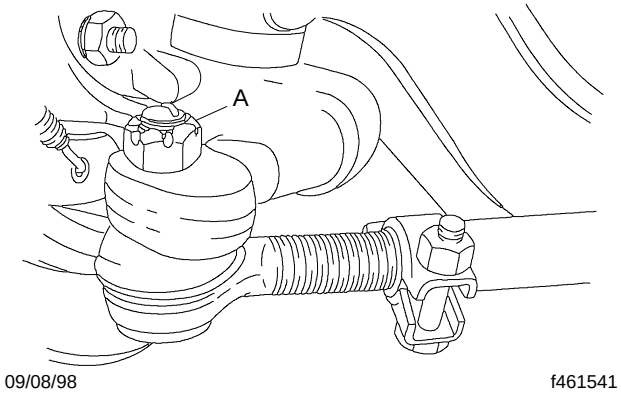

A. On 9,000-lb front axles, tighten 75 to 105 lbf·ft (102 to 142 N·m). On 10,000- to 20,000-lb front axles, tighten 110 to 150 lbf·ft (149 to 203 N·m).

Fig. 6, Tie Rod End Nut

Drag Link Removal and Installation

Removal

WARNING

All steering mechanisms are essential to the safe operation of the vehicle. Follow the instructions in this subject exactly. Failure to do so may result in loss of steering, which could cause personal injury and property damage.

NOTE: All figures show left-hand drive configurations. Right-hand drive configurations are similar.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the cotter pin and nut from the drag link ball stud to the steering arm. Discard the cotter pin. See **Fig. 1**.

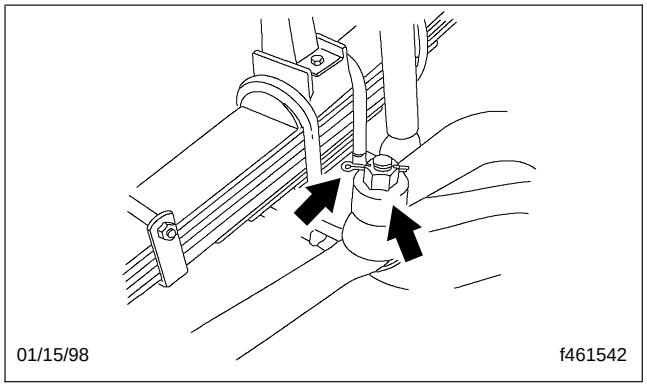

Fig. 1, Remove the Cotter Pin and Nut

3. Using the pitman arm puller, remove the ball stud. See **Fig. 2**.
4. Remove the cotter pin and nut from the drag link ball stud to the pitman arm. Discard the cotter pin. See **Fig. 3**.
5. Using the pitman arm puller, remove the drag link from the pitman arm. See **Fig. 4**.

Installation

1. Attach the drag link to the pitman arm. Tighten the castle nut to the appropriate torque spec:
   - 3/4–16: 90 to 170 lbf·ft (122 to 230 N·m)
   - 7/8–14: 160 to 300 lbf·ft (217 to 407 N·m)
2. Install a new cotter pin.
3. Install the drag link on the steering arm. Tighten the castle nut to the appropriate torque spec:
   - 5/8–18: 60 to 115 lbf·ft (81 to 156 N·m)
   - 3/4–16: 90 to 170 lbf·ft (122 to 230 N·m)
   - 7/8–14: 160 to 300 lbf·ft (217 to 407 N·m)

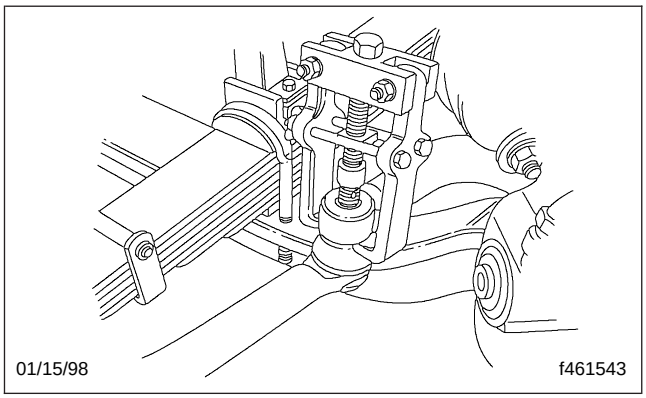

Fig. 2, Remove the Ball Stud

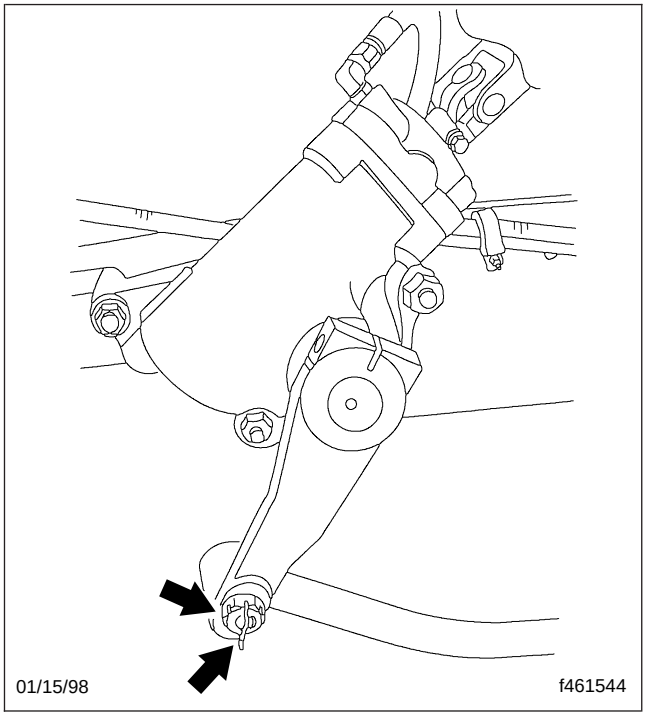

Fig. 3, Remove the Cotter Pin and Nut

Drag Link Removal and Installation

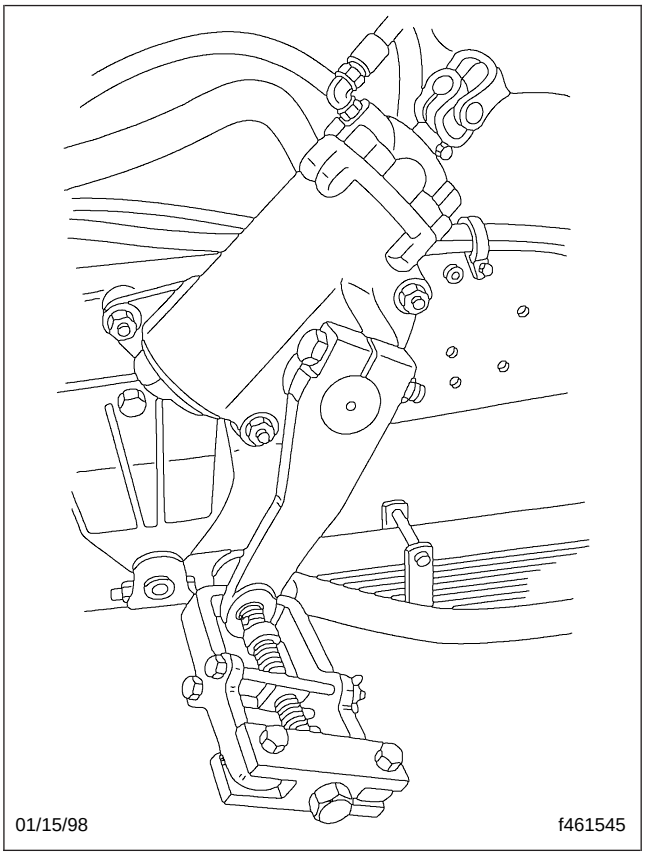

Fig. 4, Remove the Drag Link from the Pitman Arm

4. Install a new cotter pin.

⚠ WARNING

Install and lock new cotter pins in the ball studs and nuts. Failure to do so could result in disengagement of the components, causing loss of steering control, which could result in personal injury and property damage.

5. Check vehicle alignment. See **Group 32** for instructions.
6. Remove the chocks from the tires.

Pitman Arm Removal and Installation

NOTE: All figures show left-hand drive configurations. Right-hand drive configurations are similar.

Removal

NOTE: When parking the vehicle, make sure the tires are in the straight ahead position.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Open the hood.
3. Remove the cotter pin and nut from the drag link ball stud to the pitman arm. Discard the cotter pin. See **Fig. 1**.

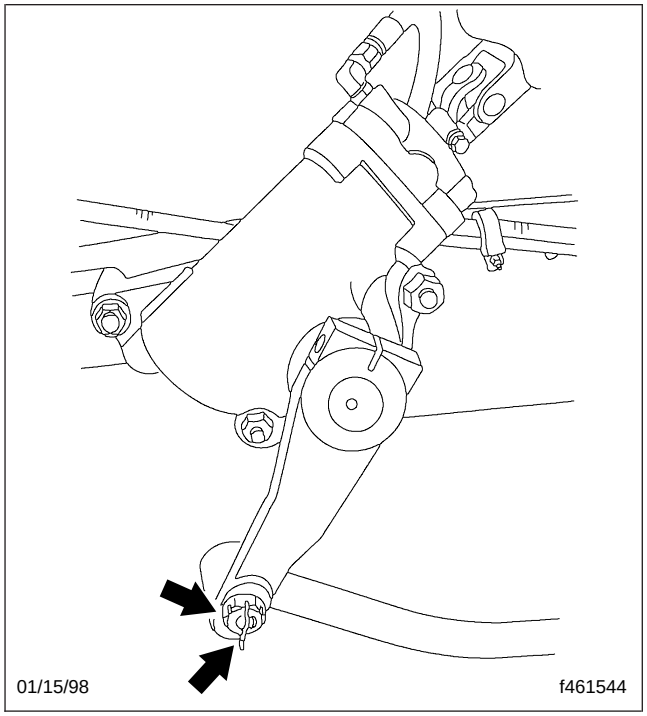

Fig. 1, Remove the Cotter Pin and Nut

4. Remove the drag link ball stud to the pitman arm using the pitman arm puller. See **Fig. 2**.
5. Remove and discard the nut and bolt. See **Fig. 3**.
6. Remove the pitman arm from the steering gear using the pitman arm puller. See **Fig. 4**.

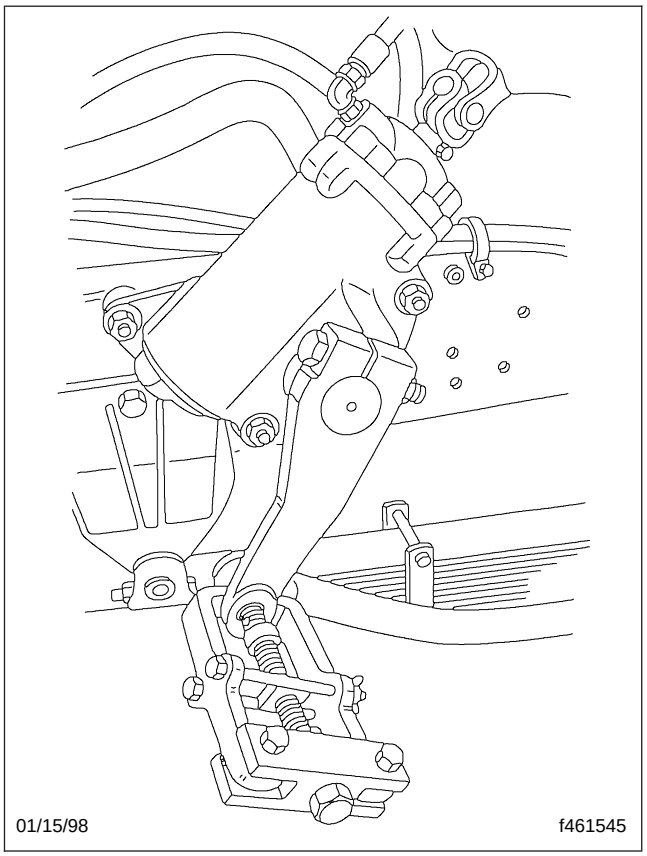

Fig. 2, Remove the Drag Link Ball Stud

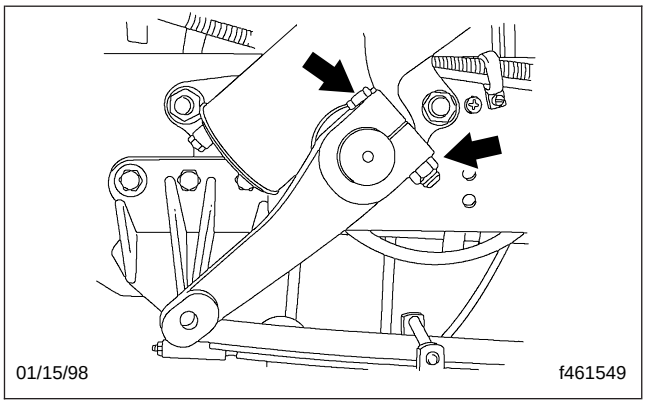

Fig. 3, Remove the Nut and Bolt

Installation

1. Install a new pitman arm on the sector shaft. Be careful to align the index mark on the steering

Pitman Arm Removal and Installation

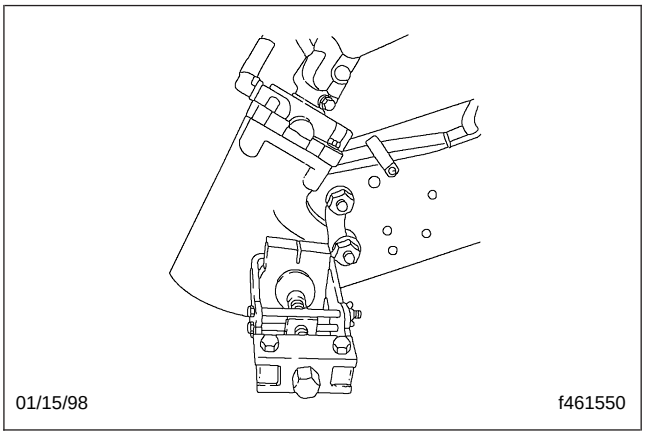

Fig. 4, Remove the Pitman Arm

gear sector shaft with the index mark on the pitman arm. See **Fig. 5**.

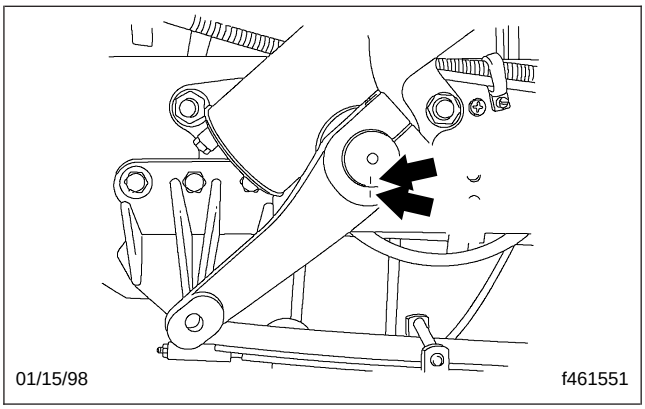

Fig. 5, Align the Index Marks

2. Using a new nut and bolt, install the pitman arm on the steering gear. Tighten the nut to the appropriate torque spec:
    - 5/8–18: 130 to 155 lbf·ft (177 to 211 N·m)
    - 3/4–16: 200 to 230 lbf·ft (272 to 313 N·m)
3. Attach the drag link to the pitman arm. Tighten the nut to the appropriate torque spec:
    - 3/4–16: 90 to 170 lbf·ft (122 to 230 N·m)
    - 7/8–14: 160 to 300 lbf·ft (217 to 407 N·m)
4. Install a new cotter pin. Advance to the next castlellation, if necessary, to install the cotter pin.
5. Close the hood.
6. Remove the chocks from the tires.

Spindle/Upper Steering Arm Removal and Installation

Removal

1. Raise and support the vehicle. Refer to **Group 00** in this manual for instructions.
2. Remove the cotter pin and castle nut from the drag link. Discard the cotter pin. See **Fig. 1**.

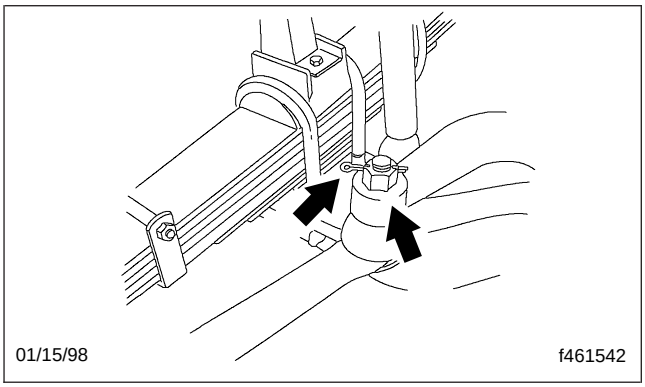

Fig. 1, Remove the Cotter Pin and Nut

3. Remove the brake camshaft. Refer to **Group 42**.
4. Remove the brake air chamber. Refer to **Group 42**.
5. Remove the bolts. See **Fig. 2**.

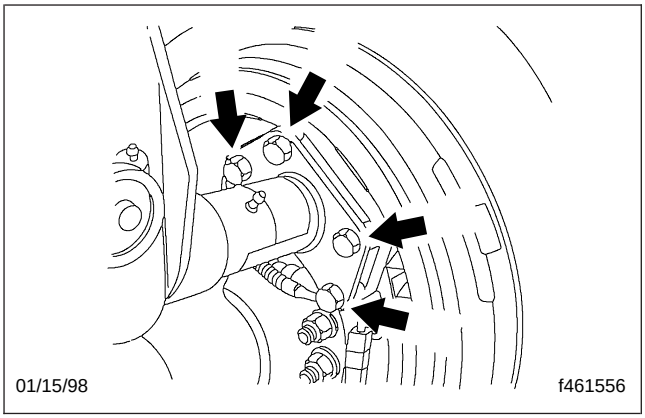

Fig. 2, Remove the Bolts

6. Remove the cotter pin and castle nut from the steering arm. Discard the cotter pin. See **Fig. 3**.
7. Drive the steering arm out of the spindle.

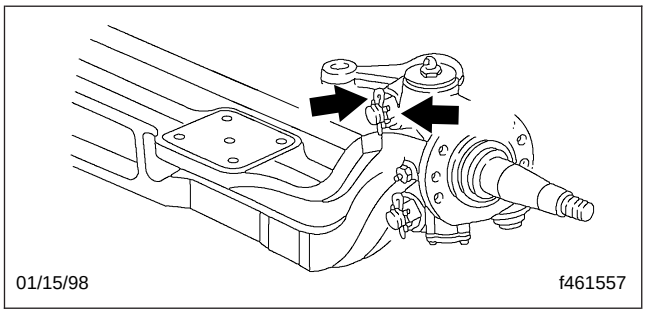

Fig. 3, Remove and Discard the Cotter Pin

Installation

NOTE: The spindle hole is slotted to align the arm with a key.

1. Install a new arm in the spindle.
   - 1.1 Insert the key in the slot from the nut side of the spindle.
   - 1.2 Be sure the key is flush with the slot face of the spindle. See **Fig. 4**.

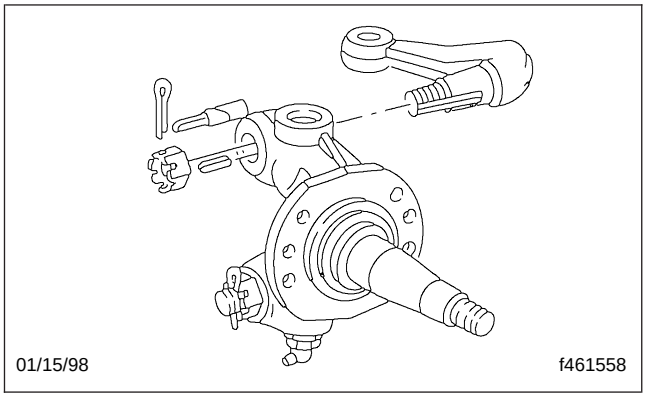

Fig. 4, Align the Key With the Slot Face

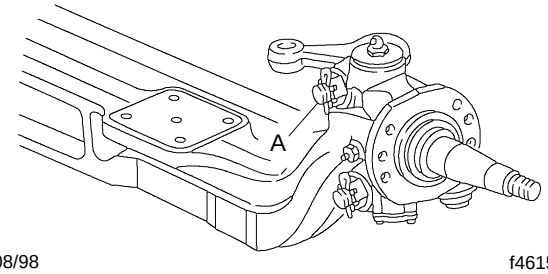
2. Install the nut. For 9,000-lb front axles, tighten the nut 360 to 480 lbf·ft (489 to 650 N·m). For 10,000- to 20,000-lb front axles, tighten the nut 540 to 730 lbf·ft (733 to 989 N·m). Advance to the next castellation, if necessary, to install the cotter pin. See **Fig. 5**.
3. Install a new cotter pin. Advance to the next castellation, if necessary, to install the cotter pin.
4. Install the bolts. Tighten the bolts 75 to 105 lbf·ft (102 to 142 N·m). See **Fig. 6**.

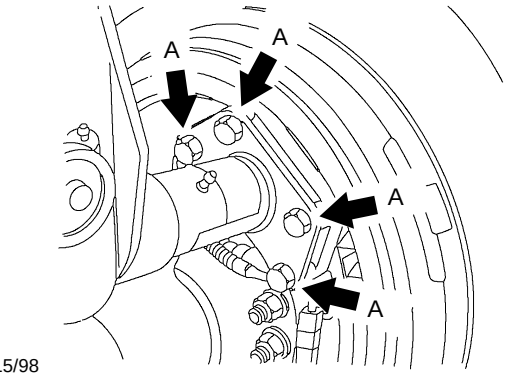
Spindle/Upper Steering Arm Removal and Installation



09/08/98 f461559

A. On 9,000-lb Front Axles, tighten 360 to 480 lbf·ft (489 to 650 N·m). On 10,000- to 20,000-lb Front Axles, tighten 540 to 730 lbf·ft (733 to 989 N·m).

Fig. 5, Install the Nut

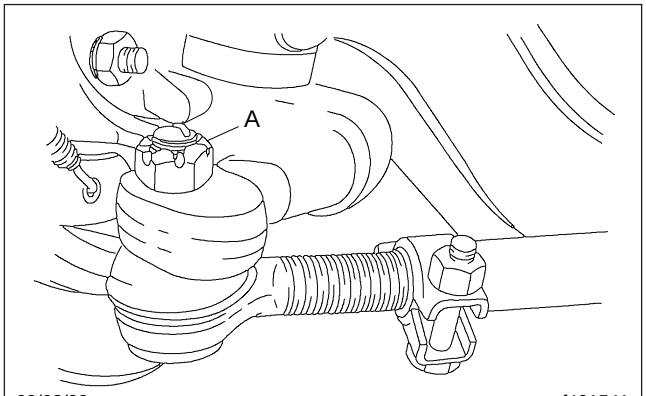


01/15/98 f461559

A. Tighten 75 to 105 lbf·ft (102 to 142 N·m).

Fig. 6, Install the Bolts

5. Install the brake air chamber. Refer to **Group 42** in this manual for instructions.
6. Install the brake camshaft. Refer to **Group 42**.
7. Install the drag link to the steering arm. For 9,000-lb front axles, tighten the nut 75 to 105 lbf·ft (102 to 142 N·m). For 10,000- to 20,000-lb front axles, tighten the nut 110 to 150 lbf·ft (149 to 203 N·m). See **Fig. 7**.
8. Install a new cotter pin. Advance to the next castellation, if necessary, to install the cotter pin.
9. Lower the vehicle. Refer to **Group 00** in this manual for instructions.
10. Check vehicle alignment. Refer to **Group 32** in this manual for instructions.



09/08/98 f461541

A. On 9,000-lb Front Axles, tighten 75 to 105 lbf·ft (102 to 142 N·m). On 10,000- to 20,000-lb Front Axles, tighten 110 to 150 lbf·ft (149 to 203 N·m).

Fig. 7, Install the Nut and a New Cotter Pin

Spindle/Lower Steering Arm Removal and Installation

Removal

1. Raise and support the vehicle. Refer to **Group 00** in this manual for instructions.
2. Remove the cotter pin and nut from the tie rod end. Discard the cotter pin. See **Fig. 1**.

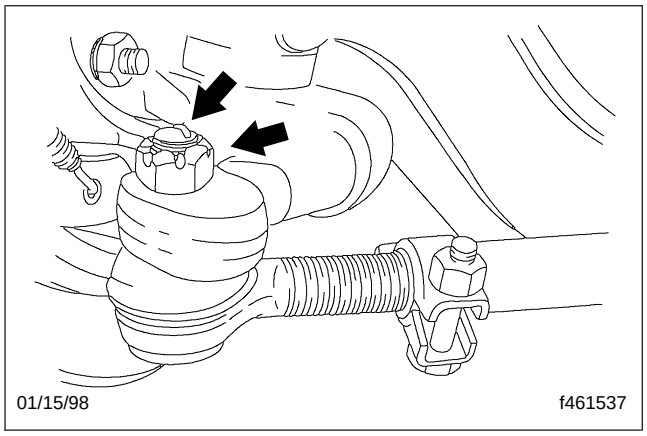


Fig. 1, Remove the Cotter Pin and Nut

3. Using the pitman arm puller, remove the tie rod end ball stud from the steering arm. See **Fig. 2**.

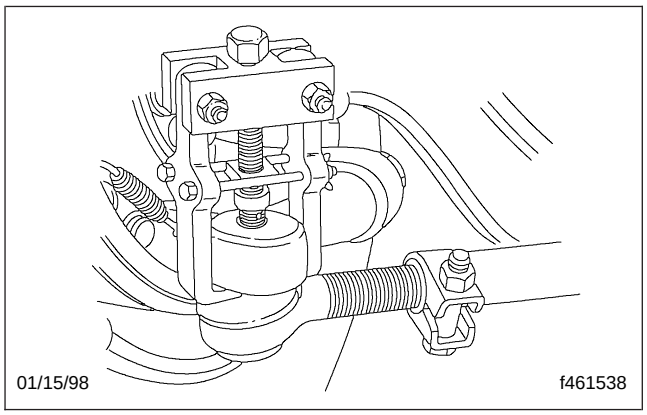

Fig. 2, Remove the Tie Rod End Ball Stud

4. Remove the cotter pin and nut from the steering arm. Discard the cotter pin. See **Fig. 3**.

⚠ CAUTION

Do not use a steel hammer to drive arm out of the spindle. Damage to the arm or threads can result. A brass hammer is recommended for removal.

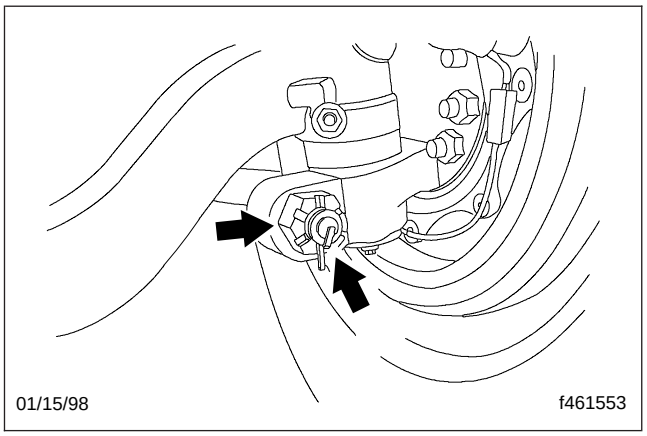

Fig. 3, Remove the Cotter Pin and Nut

5. Drive the arm out of the spindle.

Installation

NOTE: The spindle hole is slotted to align the arm with a key.

1. Install a new arm in the spindle.
   - 1.1 Insert the key in the slot from the nut side of the spindle.
   - 1.2 Be sure the key is flush with the slot face of the spindle. See **Fig. 4**.

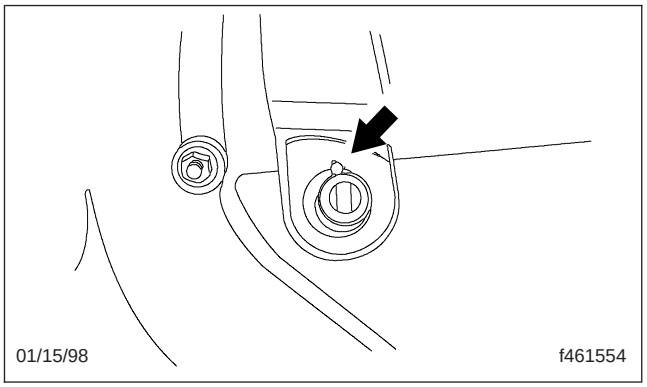

Fig. 4, Check the Key Position

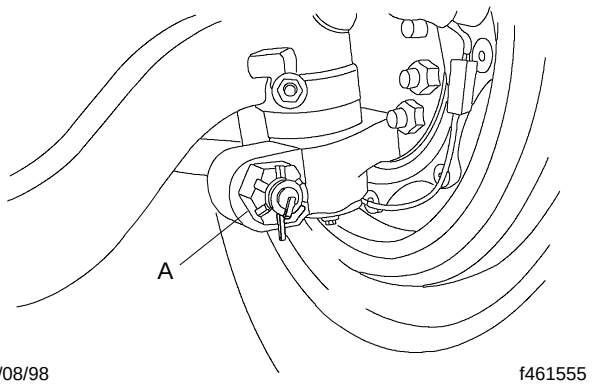
2. Install the nut. For 9,000-lb front axles, tighten the nut 360 to 480 lbf·ft (489 to 650 N·m). For 14,600- to 20,000-lb axles, tighten the nut 540 to 730 lbf·ft (733 to 989 N·m). See **Fig. 5**.
3. Install a new cotter pin. Advance to the next castellation, if necessary, to install the cotter pin.

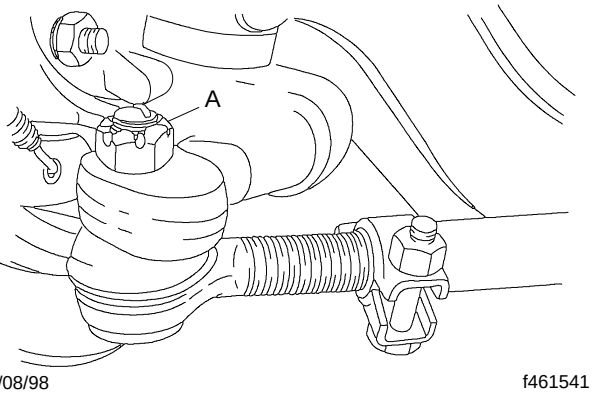
Spindle/Lower Steering Arm Removal and Installation



A. On 9,000-lb Front Axles, tighten 360 to 480 lbf·ft (489 to 650 N·m). On 14,600- to 20,000-lb Front Axles, tighten 540 to 730 lbf·ft (733 to 989 N·m).

Fig. 5, Install the Nut

4. Install the tie rod end to the steering arm. For 9,000-lb front axles, tighten the nut 75 to 105 lbf·ft (102 to 142 N·m). For 10,000- to 20,000-lb front axles, tighten the nut 110 to 150 lbf·ft (149 to 203 N·m). See **Fig. 6**.



A. On 9,000-lb Front Axles, tighten 75 to 105 lbf·ft (102 to 142 N·m). On 10,000- to 20,000-lb Front Axles, tighten 110 to 150 lbf·ft (149 to 203 N·m).

Fig. 6, Install the Nut

5. Install a new cotter pin. Advance to the next castellation, if necessary, to install the cotter pin.
6. Lower the vehicle. Refer to **Group 00** in this manual for instructions.
7. Check vehicle alignment. Refer to **Group 32** in this manual for instructions.

Specifications

Torque Specifications		
Description	**Bolt Size**	**lbf·ft (N·m)**
Drag Link Ball Stud to Pitman Arm Retaining Nut	3/4–16 7/8–14	90–170 (122–230) 160–300 (217–407)
Tie Rod End to Steering Arm Retaining Nut, 9000-lb Front Axles	—	75–105 (102–42)
Tie Rod End to Steering Arm Retaining Nut, 10,000- to 20,000-lb Front Axles	—	110–150 (149–203)
Drag Link Ball Stud to Upper Steering Arm Retaining Nut	—	110–150 (149–203)
Tie Rod End Clamp Bolt	—	50–70 (68–95)
Pitman Arm Pinch Bolt Retaining Nut	5/8–18 3/4–16	130–155 (177–211) 200–130 (272–313)
Steering Arm to Spindle Retaining Nut, 9000- to 13,000-lb Front Axles	—	360–480 (489–650)
Steering Arm to Spindle Retaining Nut, 14,600- to 20,000-lb Front Axles	—	540–730 (733–989)
Brake Camshaft Bracket Retaining Bolt	—	75–105 (102–142)

Table 1, Torque Specifications

System Flushing

To perform system flushing, follow the instructions provided with the Power Steering Analyzer.

System Bleeding

1. If bubbles are visible in the power steering fluid, bleed air from the system.
2. Check the power steering reservoir fluid level and add fluid if necessary.

⚠ CAUTION

Do not hold the steering wheel in the far-left or far-right position for more than five seconds. Doing so causes high steering system temperatures and can cause damage to components.

3. Run the engine until the fluid reaches normal operating temperature.
4. Turn the steering wheel all the way to the left and right several times and return to center.
5. Recheck the fluid level and add Motorcraft Mercon® ATF XT–2–QDX or Mercon® equivalent, if necessary.

Final Fill

NOTE: The fluid level must show between the ADD and FULL markings on the dipstick. If the fluid is below the ADD mark, add Motorcraft Mercon® ATF XT–2–QDX or Mercon® equivalent.

NOTE: After any major power steering system or component overhaul, the system must be purged of old fluid and the oil filter discarded, and new fluid and a new filter installed.

1. Check the fluid level in the power steering reservoir with the engine off. Use the HOT or COLD markings on the dipstick, depending upon the fluid temperature.
   - 1.1 Use COLD for checking at room temperature, 70°F (20°C).
   - 1.2 Use HOT for normal operating temperatures, 175° F (80°C).

IMPORTANT: Do not turn the steering wheel during the initial fill procedure. Place the front wheels in a straight-ahead position and engage the parking brake.

2. Fill the reservoir with fluid and allow the fluid to gravity feed the system.
   - 2.1 Crack the pressure line fittings at the pump and steering gear.
   - 2.2 Tighten the fittings when fluid is visible.
   - 2.3 Keep adding fluid to the reservoir as required.
3. When the fluid level in the reservoir no longer goes down, start the engine. Continue to add fluid to the reservoir as required. Do not exceed the FULL mark.
4. After the fluid level in the reservoir no longer goes down, rotate the steering wheel to full-right and full-left turns, stop to stop. Add fluid as required.
5. Continue the process until the fluid level no longer changes. Fluid level is correct when it is in the FULL range on the dipstick.
6. Place the front wheels in a straight-ahead position and engage the parking brake.

NOTE: Whenever a minor leak is corrected, follow the next four steps.

7. Fill the reservoir to the FULL mark on the dipstick.
   - 7.1 Start the engine and let idle for several minutes.
   - 7.2 Check fluid level and add as required.
8. Rotate the steering wheel to full-right and full-left turns, stop to stop, several times.
9. Stop the engine and check fluid level. Fill the reservoir to FULL range indicated on the dipstick.

Sector Shaft Adjusting Screw Jam Nut	43 (58)

Table 2, Torque Specifications

General Information

L-Line and A-Line vehicles can be equipped with one of three types of steering column assemblies. The fixed column (see **Fig. 1**) is standard equipment. The tilt (**Fig. 2**) and tilt/telescopic (**Fig. 3**) steering columns are optional.

Steering Wheel Removal and Installation

Removal

1. Make sure that the vehicle road wheels are in the straight-ahead position. Mark the steering wheel and column with a grease pencil for alignment reference.
2. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
3. Disconnect the battery ground cable(s).
4. Remove two horn pad retaining screws. See **Fig. 1**.

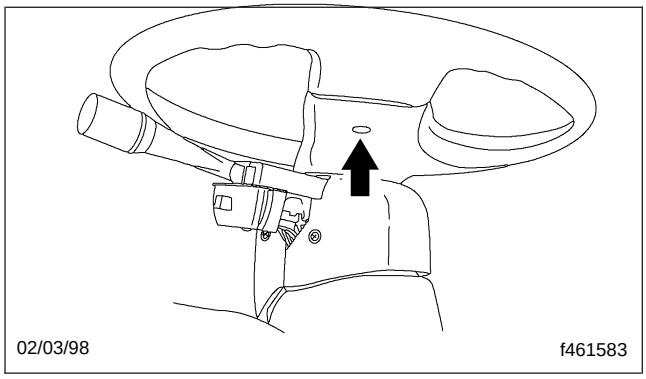

Fig. 1, Horn Pad Retaining Screw

5. Tilt the horn pad upward and disconnect the horn pad/speed control connector (if so equipped). See **Fig. 2**.

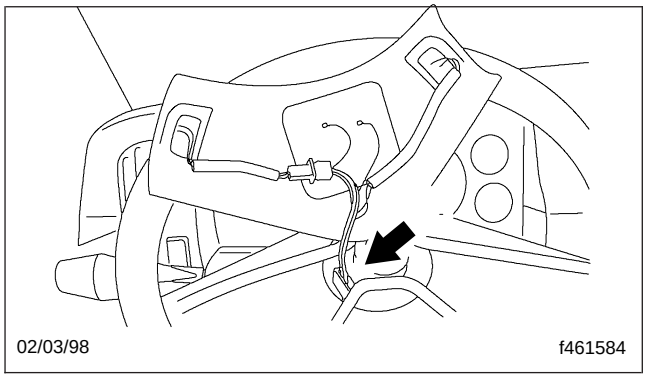

Fig. 2, Horn Pad/Speed Control Connector

6. Remove the steering wheel retaining nut. See **Fig. 3**.
7. Install the steering wheel puller and remove the steering wheel. See **Fig. 4**.

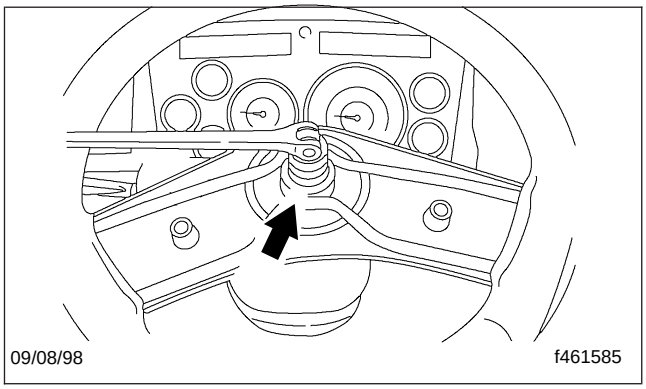

Fig. 3, Remove the Steering Wheel Retaining Nut

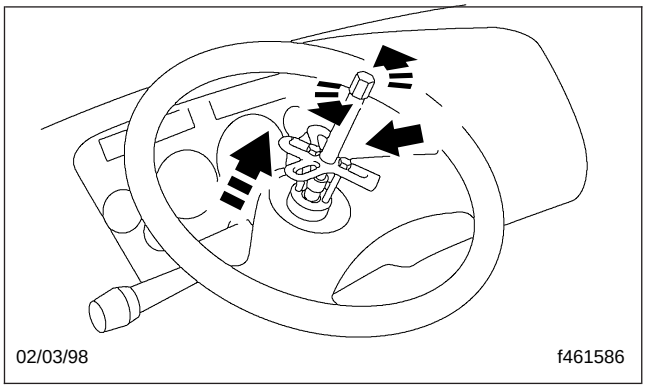

Fig. 4, Install the Steering Wheel Puller

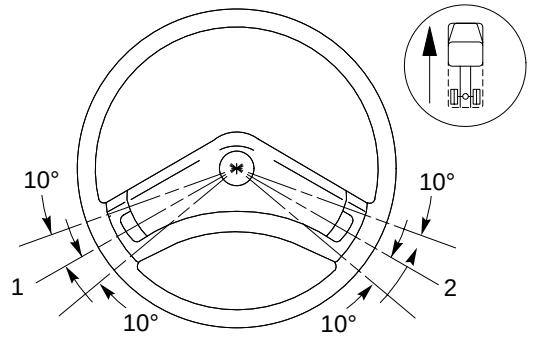
Installation

1. Remove the steering wheel puller and replace the steering wheel.
2. Check the steering wheel spoke position. With the front tires pointing straight ahead, check the position of the steering wheel spokes. They must be pointing within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 5**. If not, remove the steering wheel and install it in the correct position.
3. Tighten the steering wheel nut 45 to 65 lbf·ft (61 to 88 N·m). See **Fig. 6**.
4. Apply torque seal OGP F900WHITE to the exposed thread and to the locknut.
5. Connect the horn pad/speed control connector (if so equipped).
6. Install two horn pad retaining screws.
7. Connect the battery ground cable(s).

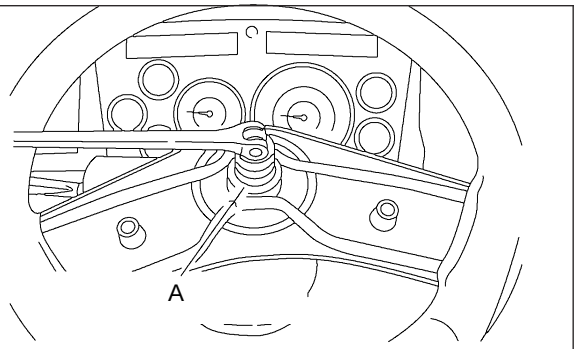
Steering Wheel Removal and Installation



01/04/2000 f461750

1. 8 o'Clock 2. 4 o'Clock

Fig. 5, Steering Wheel Centered



02/03/98 f461587

A. Tighten 45 to 65 lbf·ft (61 to 88 N·m).

Fig. 6, Tighten the Steering Wheel Nut

8. Remove the chocks from the rear tires.
9. Test drive the vehicle, or take a ride with the driver.

Steering Column Removal and Installation

Removal

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service work will be done. Do not move the tires from the straight-ahead position during removal or at any time while the steering column is removed.
2. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
3. Disconnect the batteries at the negative terminals or at the battery shutoff switch.
4. Remove the steering wheel. For instructions, see **Subject 100**.
5. Remove the clockspring. For instructions, see **Subject 130**.
6. Remove the under steering panel. For instructions, see **Section 60.01**.
7. Remove the SmartShift™ transmission shift control, if equipped. For instructions, see **Section 26.12**.
8. Disconnect the multifunction switch electrical connectors. See **Fig. 1**.
9. Remove the screws that secure the multifunction switch, then remove the switch. See **Fig. 2**.

NOTE: Before disconnecting the steering driveline from the steering column yoke, mark the steering driveline so that it can be installed in the same orientation it was in when removed.

10. Mark the steering driveline/steering column yoke orientation. Remove and discard the steering column pinch bolt and nut. Slide the steering driveline out of the way. See **Fig. 3**.
11. Remove the four bolts that attach the steering column to the support bracket. See **Fig. 4**.
12. Remove the steering column.

Installation

1. Position the steering column on the steering column mounting bracket.
2. Install the four bolts that attach the steering column to the support bracket. Tighten the bolts 32 to 41 lbf·ft (43 to 55 N·m).

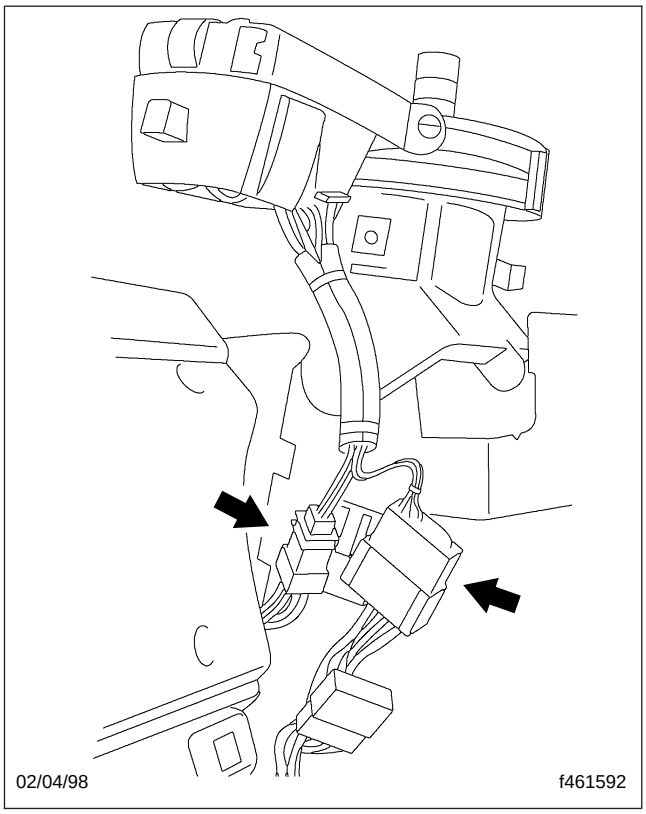


Fig. 1, Multifunction Switch Electrical Connectors

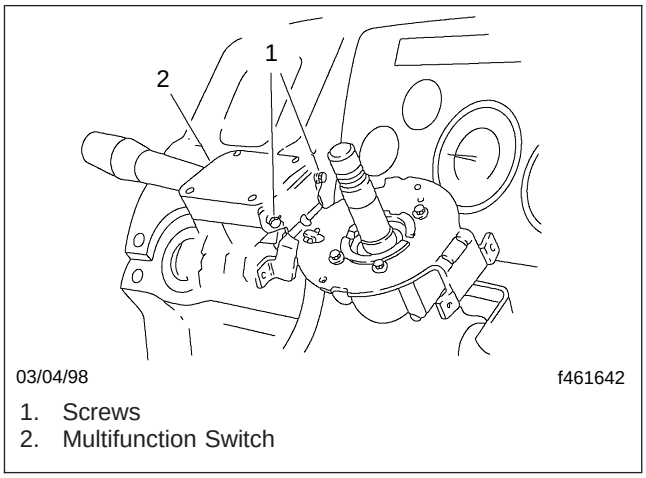

1. Screws
2. Multifunction Switch

Fig. 2, Remove the Multifunction Switch

NOTE: The steering column yoke must be installed in the same orientation it was in when removed.

Steering Column Removal and Installation

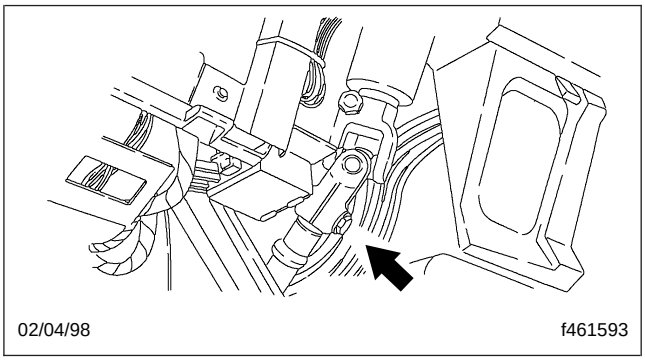

Fig. 3, Steering Column Yoke Pinch Bolt

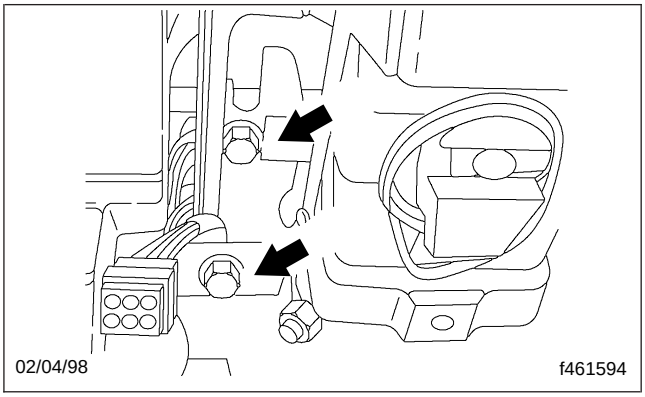

Fig. 4, Support Bracket Bolts

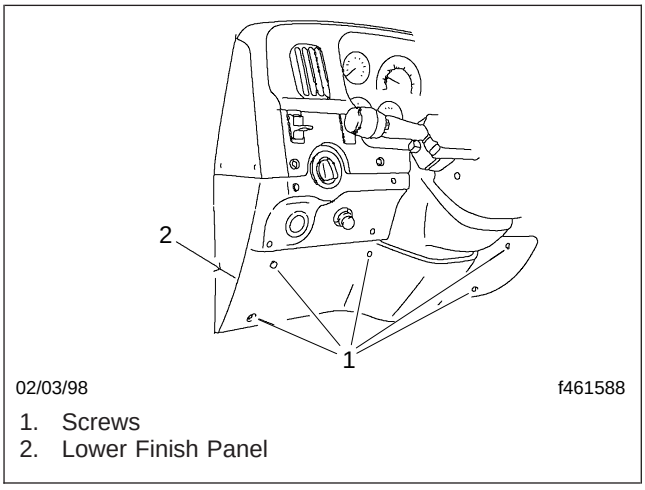
3. Slide the upper end of the steering driveline into the steering column yoke. Install the new pinch bolt. Before installing the nut, make sure the pinch bolt is centered in the steering column shaft notch. The pinch bolt is centered if it can slip in and out of the end yoke with ease. Install a new nut and tighten the nut to one of the following torque specs:
   - 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
   - 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut
4. Apply torque seal, OGP F900WHITE, to the exposed bolt thread and to the nut.
5. Install the multifunction switch.
6. Connect the multifunction switch electrical connectors.
7. Install the SmartShift™ transmission shift control, if equipped. For instructions, see **Section 26.12**.
8. Install the under steering panel. For instructions, see **Section 60.01**.
9. Install the clockspring. For instructions, see **Subject 130**.
10. Install the steering wheel. For instructions, see **Subject 100**.
11. Check the position of the steering wheel when the front tires are pointing forward. The steering wheel should be within ±10 degrees of center.
12. Connect the batteries.
13. Remove the chocks from the tires.

U-Joint Removal and Installation

Removal

NOTE: Make sure the front wheels are in the straight-ahead position.

1. Remove the instrument panel lower finish panel. See **Fig. 1**.



1. Screws
2. Lower Finish Panel

Fig. 1, Instrument Panel

1.1 Remove the screws.

1.2 Remove the instrument panel lower finish panel.

NOTE: Before removing the U-joint, mark it in a manner that will allow it to be installed in the same orientation as when removed. The short yoke must be installed on the output shaft of the column.

2. Mark the U-joint/shaft orientation. Remove the coupling shaft-to-steering column pinch bolt, washer and nut and slide the coupling shaft out of the way. See **Fig. 2**.
3. Mark the U-joint/shaft orientation. Remove the pinch bolt, two washers and nut holding the U-joint in place. See **Fig. 3**.
4. Remove the U-joint, then inspect the U-joint and pinch bolts for damage. Replace if necessary. See **Fig. 4**.

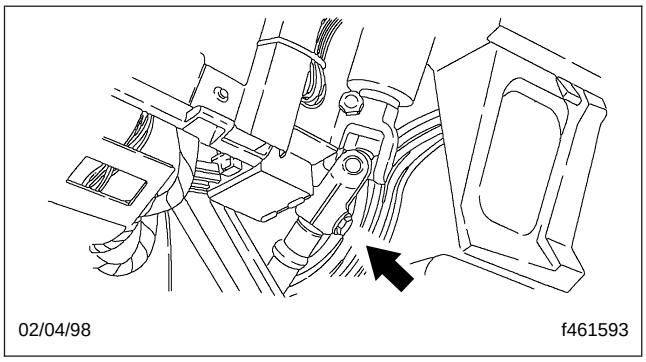


Fig. 2, Coupling Shaft Pinch Bolt

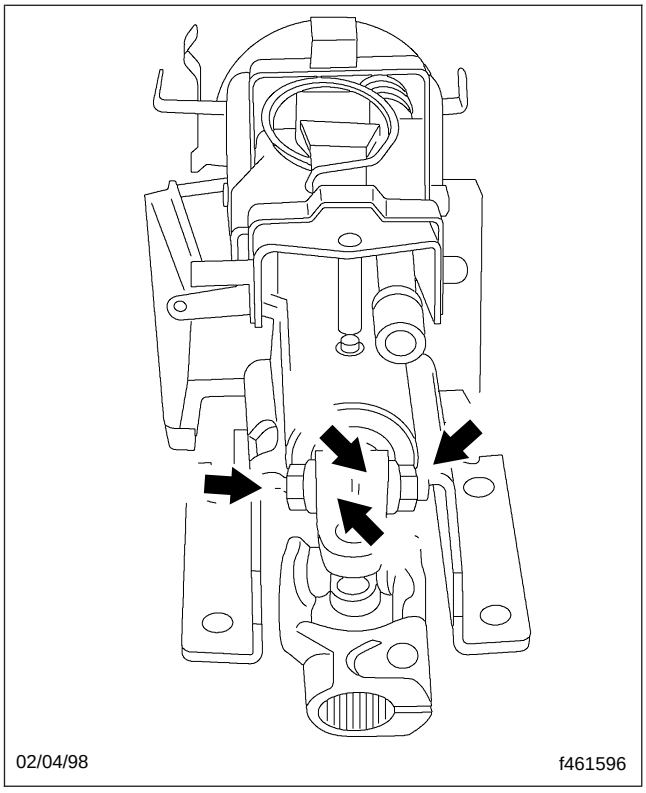

Fig. 3, U-Joint Retaining Points

Installation

NOTE: The U-joint must be installed in the same orientation as when removed. The short yoke must be installed on the output shaft of the column.

1. Position the U-joint and install the pinch bolt, two washers and nut holding the U-joint in place.

U-Joint Removal and Installation

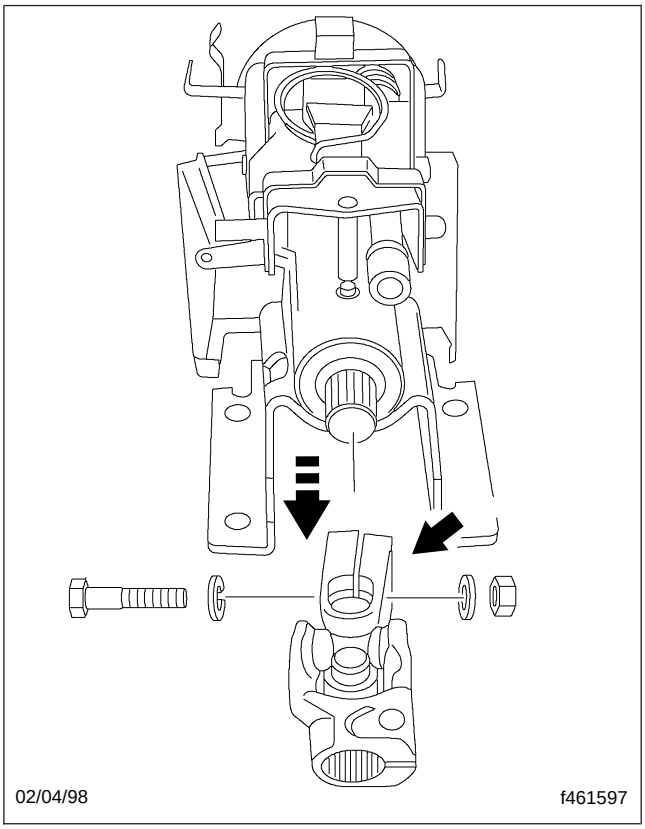

Fig. 4, Remove the U-Joint from the Steering Shaft

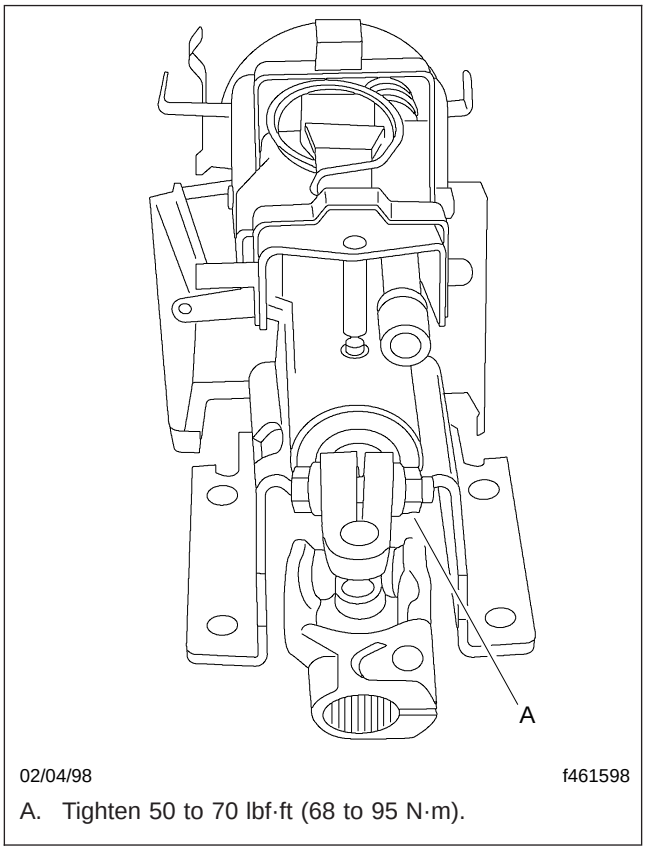
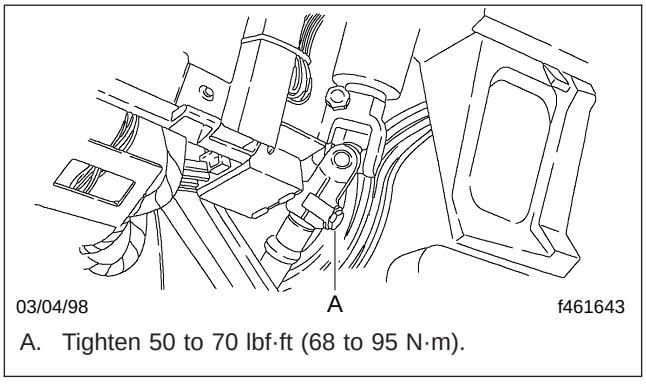
Tighten the nut 50 to 70 lbf·ft (68 to 95 N·m). See **Fig. 5**.

2. Position the coupling shaft and install the coupling shaft-to-steering column pinch bolt, washer and nut. Tighten the nut 50 to 70 lbf·ft (68 to 95 N·m). See **Fig. 6**.
3. Install the instrument panel lower finish panel. See **Fig. 1**.



A. Tighten 50 to 70 lbf·ft (68 to 95 N·m).

Fig. 5, U-Joint Clamp Bolt



A. Tighten 50 to 70 lbf·ft (68 to 95 N·m).

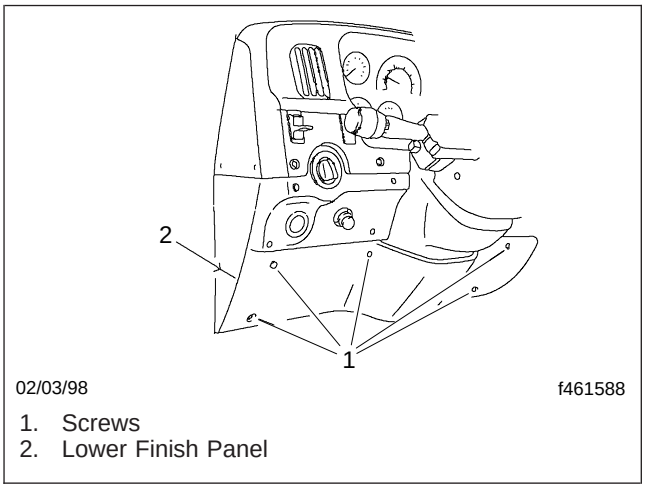
Fig. 6, Tighten the Coupling Shaft Pinch Bolt

Clockspring Removal and Installation

Removal

NOTE: Make sure the front wheels are in the straight-ahead position.

1. Remove the steering wheel; see **Subject 100**.
2. Remove the upper steering column shrouds.
3. Remove the instrument panel lower finish panel. See **Fig. 1**.



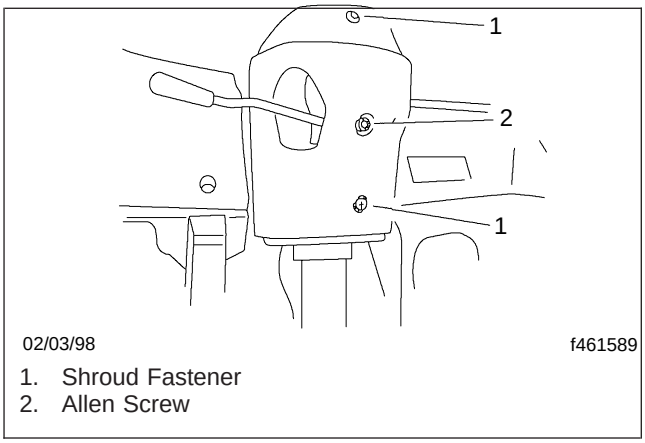
1. Screws
2. Lower Finish Panel

Fig. 1, Instrument Panel

3.1 Remove the screws.

3.2 Remove the instrument panel lower finish panel.

4. Remove the lower shroud. See **Fig. 2**.



1. Shroud Fastener
2. Allen Screw

Fig. 2, Lower Steering Column Cover

4.1 Remove the screws.

4.2 Remove the Allen screw.

5. Disconnect the clockspring electrical connector. See **Fig. 3**.

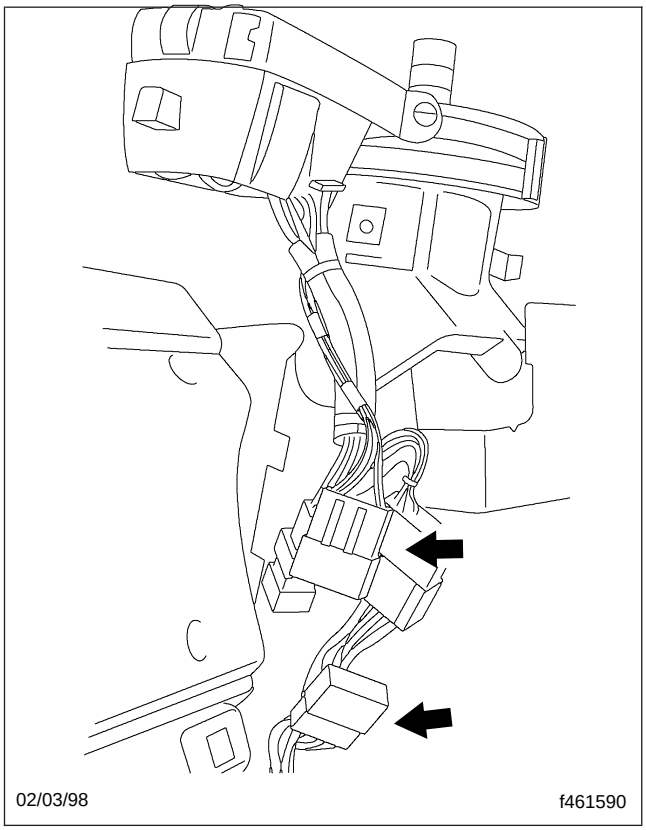


Fig. 3, Clockspring Electrical Connector

NOTE: The clockspring retaining tabs are located at the 12 o'clock, 6 o'clock and the 9 o'clock positions.

6. Depress the three clockspring retaining tabs (located at the bottom of the clockspring adapter plate) while slightly lifting the clockspring off the steering column shaft. See **Fig. 4**.

Installation

NOTE: The clockspring retaining tabs are located at the 12 o'clock, 6 o'clock and the 9 o'clock positions.

Clockspring Removal and Installation

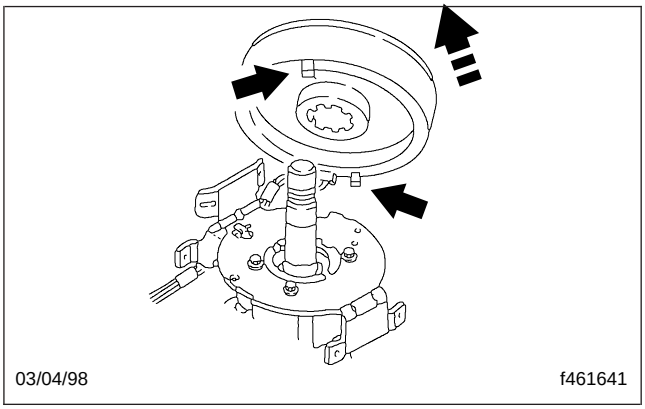

Fig. 4, Clockspring Retaining Tabs

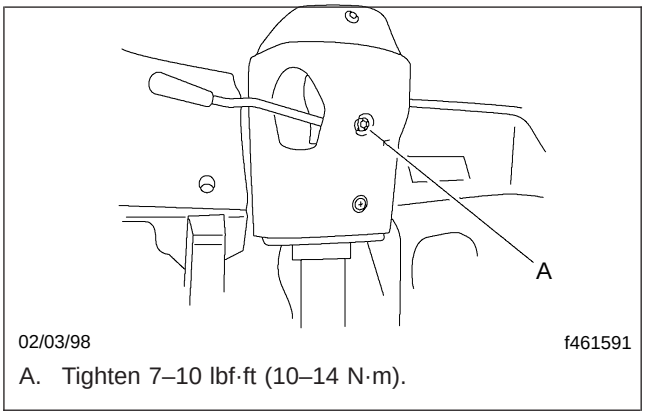
1. Depress the three clockspring retaining tabs (located at the bottom of the clockspring adapter plate) while pushing the clockspring back on the steering column shaft.
2. Connect the clockspring electrical connector.
3. Install the lower shroud.
   - 3.1 Install the Allen screw.

     Tighten the lower shroud Allen screw 7 to 10 lbf·ft (10 to 14 N·m). See **Fig. 5**.



A. Tighten 7–10 lbf·ft (10–14 N·m).

Fig. 5, Tightening the Allen Screw

   - 3.2 Install the screws.
4. Install the instrument panel lower finish panel.
   - 4.1 Position the instrument panel lower finish panel.
   - 4.2 Install the screws.
5. Install the upper steering column shrouds.
6. Install the steering wheel; see **Subject 100**.

Tilt Steering Column Disassembly and Assembly

Disassembly

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Disconnect the battery ground cable(s).
3. Remove the steering wheel. For instructions, see **Subject 100**.
4. Remove the clockspring. For instructions, see **Subject 130**.
5. Remove the steering column. For instructions, see **Subject 110**.
6. Remove the under steering panel brackets.
7. Place the column in a soft-jawed vise, clamping on the mounting bracket flange. See **Fig. 1**.

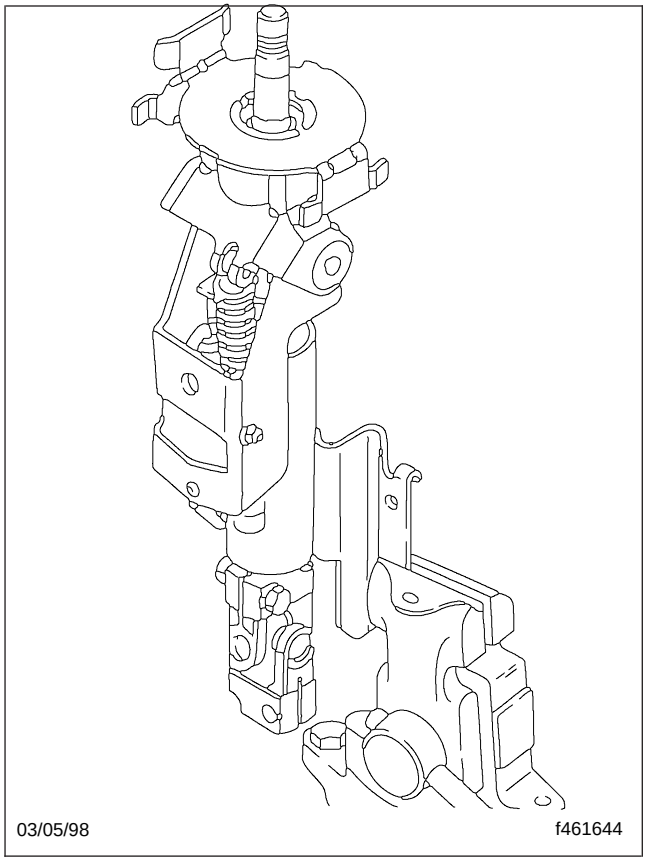


Fig. 1, Soft-Jawed Vise Holding Column

8. Remove the clockspring adaptor plate. See **Fig. 2**.

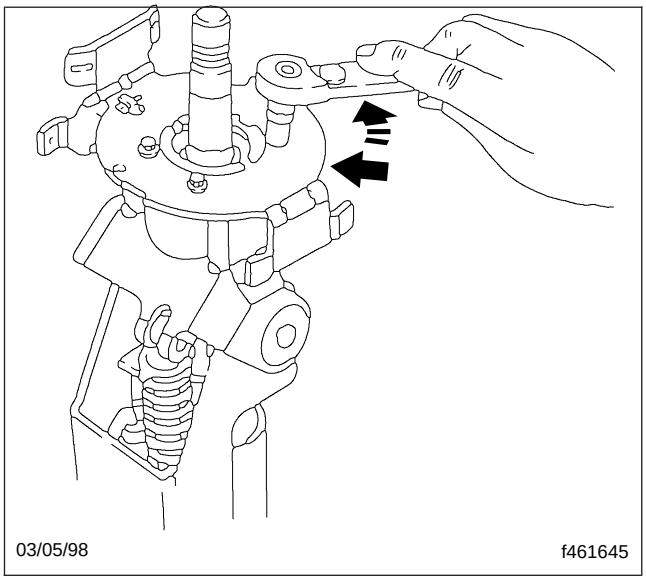

Fig. 2, Clockspring Adaptor Plate

9. Remove four bolts from the steering column and bearing cap. See **Fig. 3**.

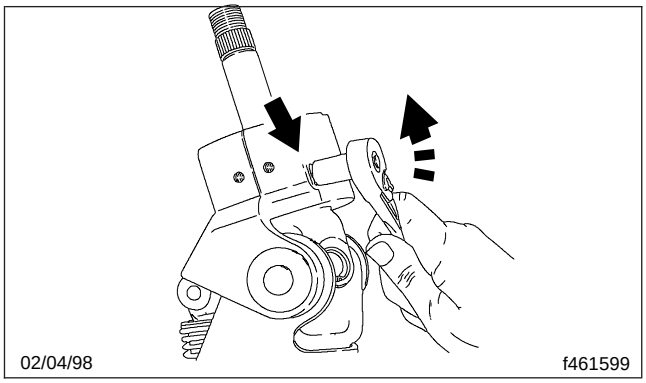

Fig. 3, Remove the Bolts from the Steering Column and Bearing Cap

10. Remove the bearing cap. See **Fig. 4**.

NOTE: Before removing the U-joint, mark it in a manner that will allow it to be reinstalled in the same orientation as when removed. The short yoke must be installed on the output shaft of the column.

11. Mark the U-joint/shaft orientation. Remove the U-joint from the lower end of the rotating shaft. See **Fig. 5**.

Tilt Steering Column Disassembly and Assembly

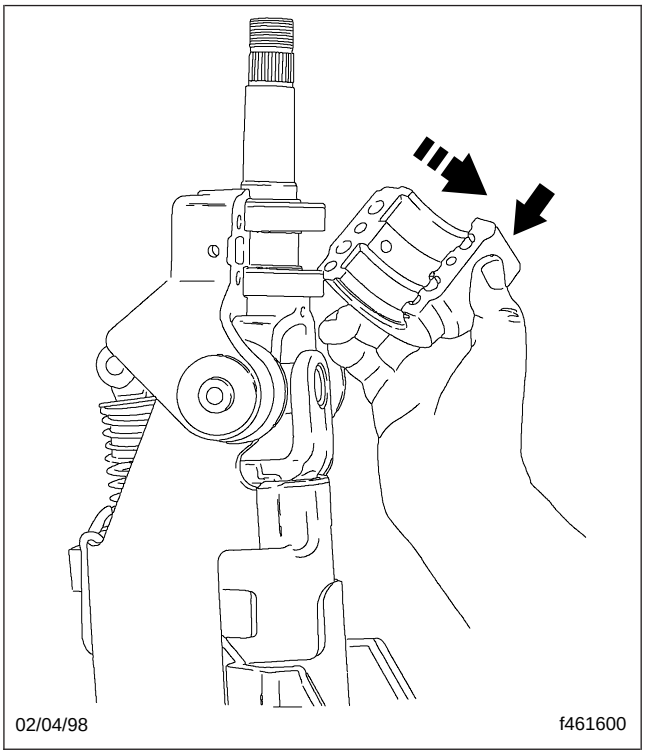

Fig. 4, Remove the Bearing Cap

12. Remove the retaining ring from the lower end of the steering column shaft.
13. Unseat the bearings from their seat in the housing. Tilt the unit rearward, and remove the steering column shaft. Lightly tap with a rubber mallet to start the process, if necessary. See **Fig. 6**.

    13.1 Check for lash in the U-joint. Inspect for twisted or otherwise damaged serrations. If either condition exists, replace the rotating assembly.

    13.2 Inspect the housing thread. Make sure the threads are not stripped. If the housing threads are stripped, the entire unit must be replaced.

    13.3 Remove the bearing gaskets from each bearing and discard.
14. Tilt the steering column forward to relieve spring tension. Remove the socket head capscrew and actuator handle. See **Fig. 7**.
15. Remove the retaining ring, actuator cam and washer.

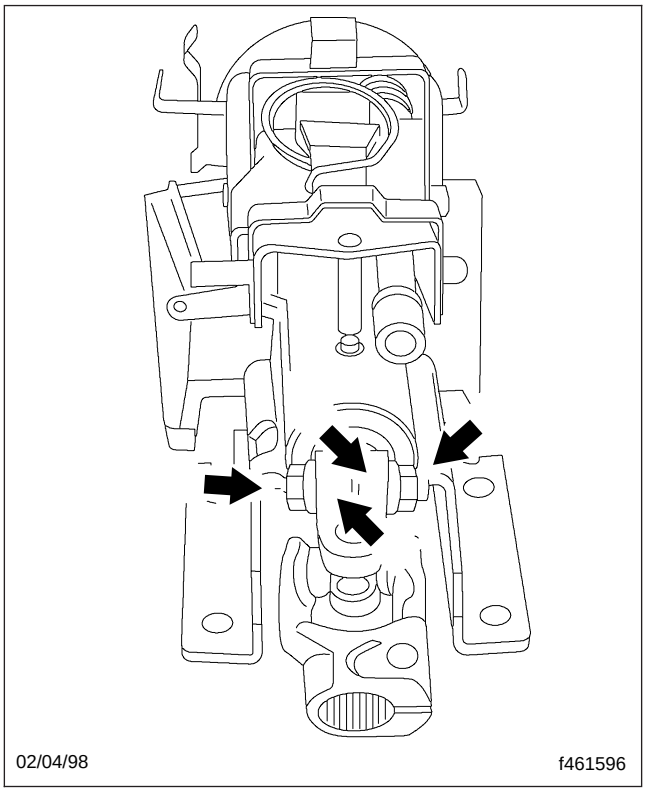

Fig. 5, Mark the U-Joint/Shaft Orientation

Inspect the actuator cam for cracks or breaks. Replace if necessary.

16. Remove the prevailing torque locknut and washer, then use a rubber mallet to lightly tap out the shoulder screw. See **Fig. 8**.

⚠ CAUTION

Handle the tilt lock mechanism carefully. The spring may be loaded.

17. Drive the tilt pivot pin on the other end of the tilt lock mechanism, from the smaller hole toward the larger, with a punch. Remove the tilt lock mechanism. See **Fig. 9**.

    If the tilt function no longer locks, replace the tilt lock mechanism, tilt pivot pin, shoulder screw, washer and locknut.

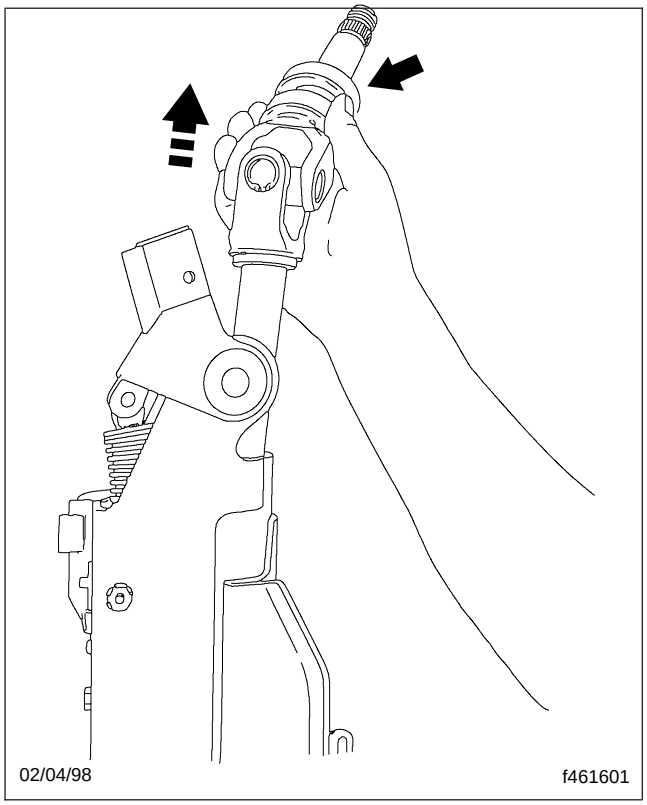

Fig. 6, Remove the Steering Column Shaft

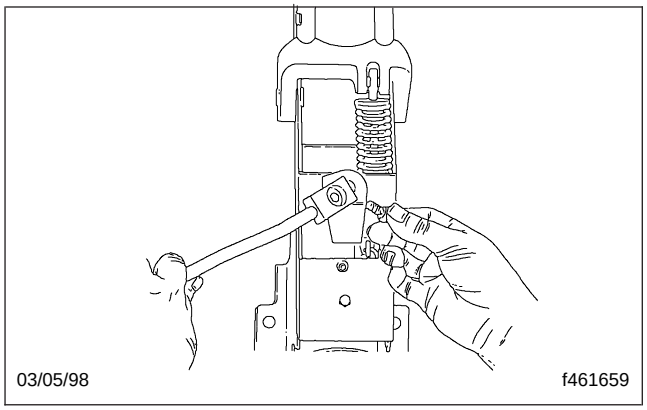

Fig. 7, Actuator Handle

Assembly

1. Position the tilt lock mechanism in the steering column with the spring toward the tilt housing, so the lever is exposed through the window on the steering column.

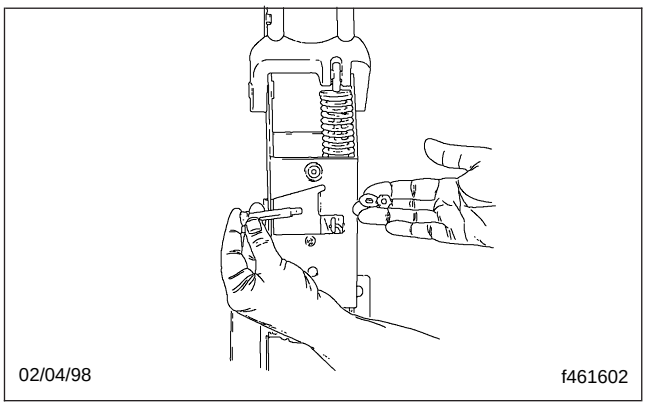

Fig. 8, Remove the Shoulder Screw

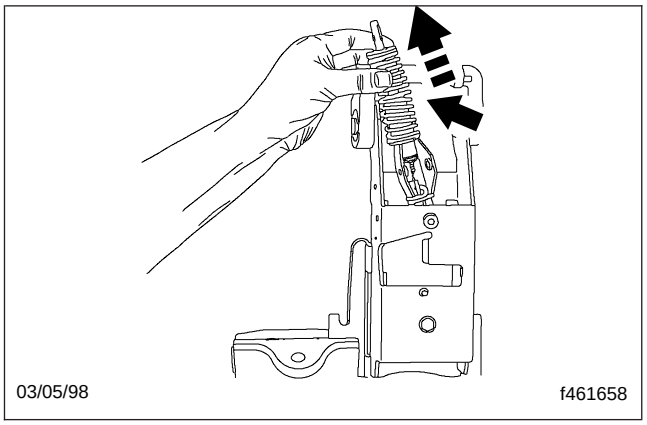

Fig. 9, Tilt Lock Mechanism

2. Align the tilt lock mechanism holes with the hole in the steering column, and replace the shoulder screw with the threads on the outside of the steering column. Replace the washer and the prevailing torque nut. Tighten the nut 72 to 88 lbf·in (813 to 994 N·cm).

⚠ CAUTION

The pin must be fully seated, not just pressed flush with the boss. If the tilt pivot pin is not seated properly, the tilt function can cease to operate.

3. Install the tilt pivot pin through the other end of the tilt mechanism. Carefully line up the tilt pivot pin with the holes, and use a punch to tap the tilt pivot into place until it stops. See **Fig. 10**.
4. Install the actuator cam and washer on the base unit, with the tail end under the bracket and posi-

Tilt Steering Column Disassembly and Assembly

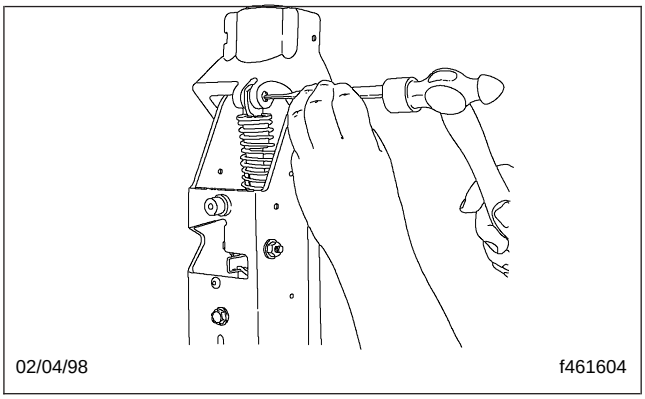

Fig. 10, Tap the Tilt Pivot into Place

tioned between the travel stop and the tilt mechanism lever. See **Fig. 11**.

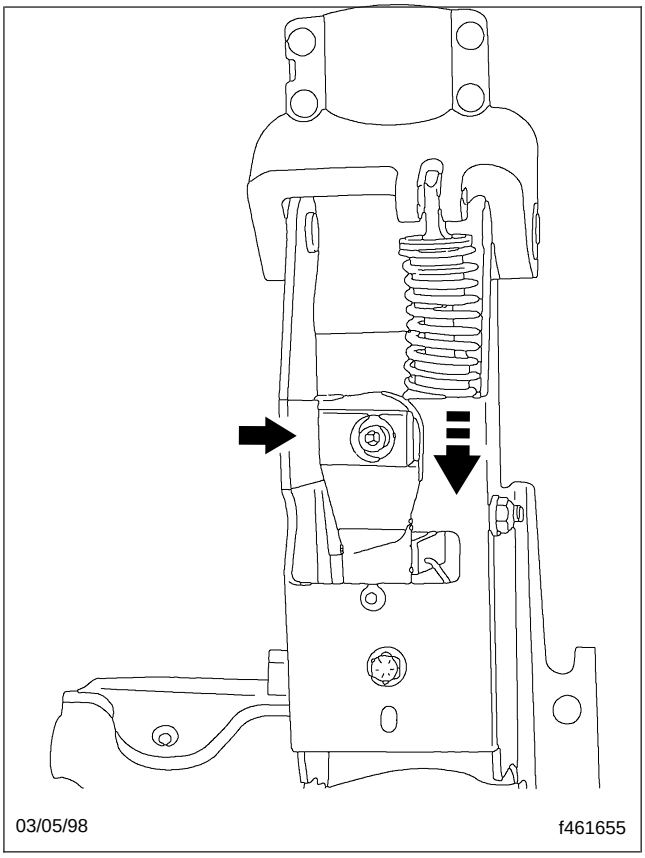

Fig. 11, Actuator Cam and Washer

5. Install the retaining ring, rounded edge toward the actuator cam, making sure it is properly seated in its groove. Install the actuator handle and socket head screw. Tighten to 7 to 10 lbf·ft (10 to 14 N·m). See **Fig. 12**.

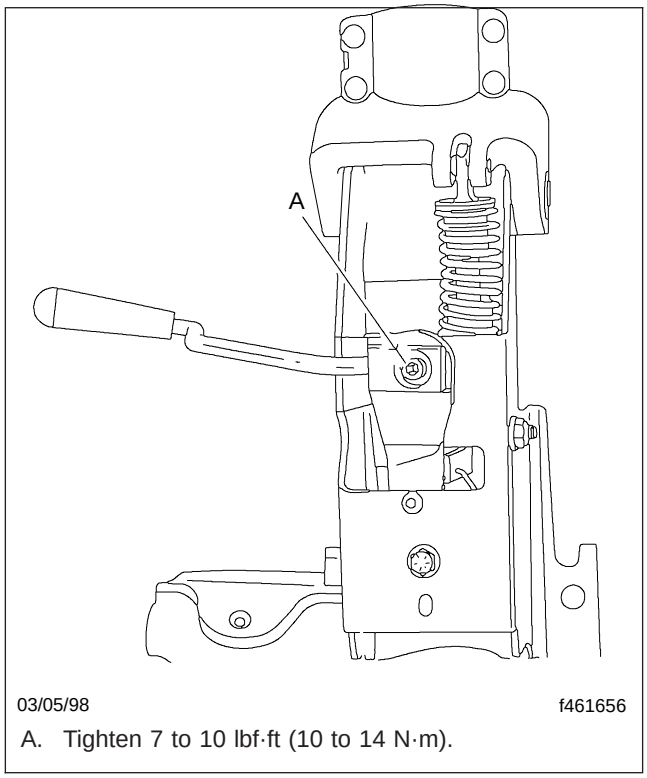

Fig. 12, Actuator Handle

6. Install a new bearing gasket on each bearing. See **Fig. 13**.

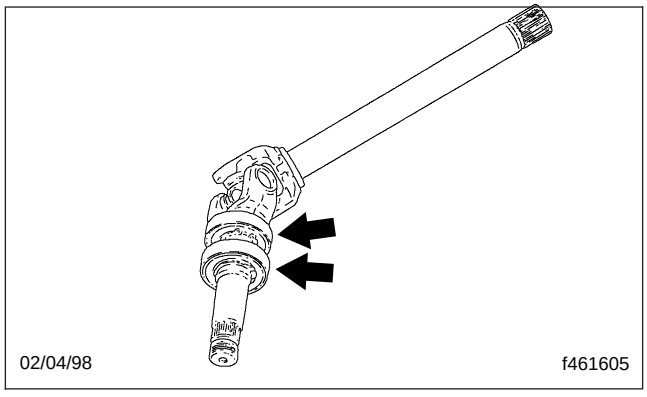

Fig. 13, Location of Bearing Gasket Installation

7. Tilt the unit rearward and insert the steering column shaft into the jacket tube. See **Fig. 14**.

Tilt Steering Column Disassembly and Assembly

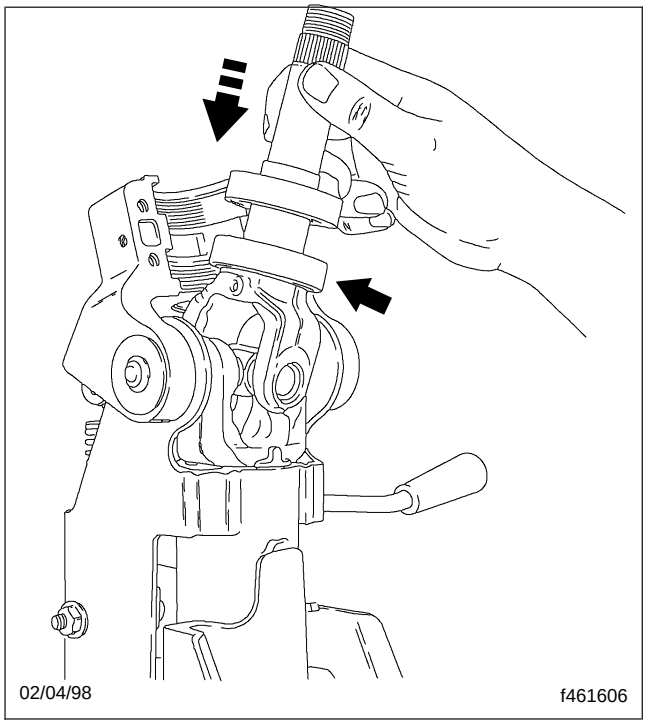

Fig. 14, Insert the Steering Column Shaft into the Jacket Tube

NOTE: Install the U-joint so that the shorter yoke is attached to the column output shaft aligning the marks previously made during disassembly for proper orientation of the U-joint/shaft.

8. Install the U-joint to the column output shaft. Tighten the U-joint bolt 50 to 70 lbf·ft (68 to 95 N·m).
9. Seat the bearings in the tilt housing grooves. Make sure the four gaskets are straight and seated properly. See **Fig. 15**.
10. Install the bearing cap with the pilot lip up, so it matches up with the pilot lip on the housing. Install the four bolts and tighten 75 to 80 lbf·in (840 to 900 N·cm). See **Fig. 16**.
11. Test the tilt lock mechanism. The actuator handle should self-return to a neutral position. See **Fig. 17**.
12. Reinstall the clockspring adaptor plate. Tighten the screws 80 to 115 lbf·in (900 to 1300 N·cm).
13. Install the under steering panel brackets.

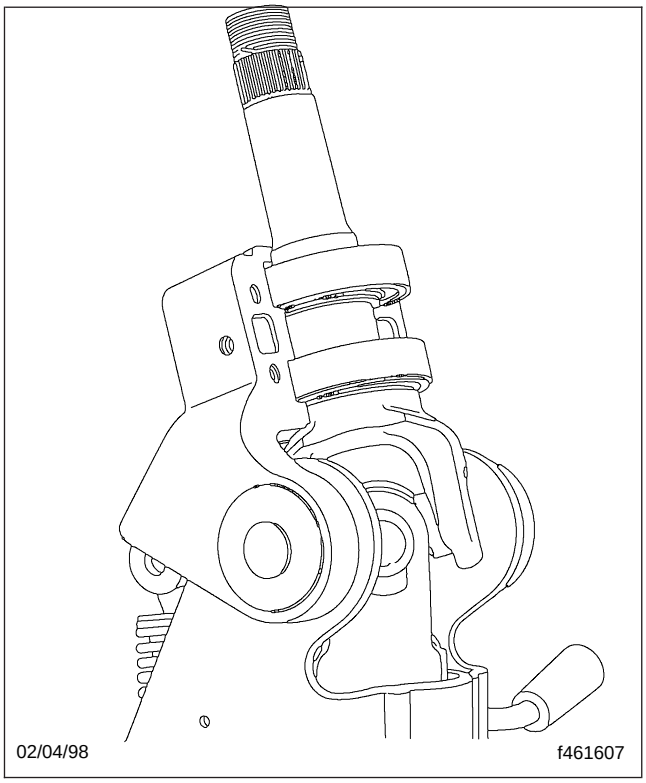

Fig. 15, Seat the Bearings in the Tilt Housing

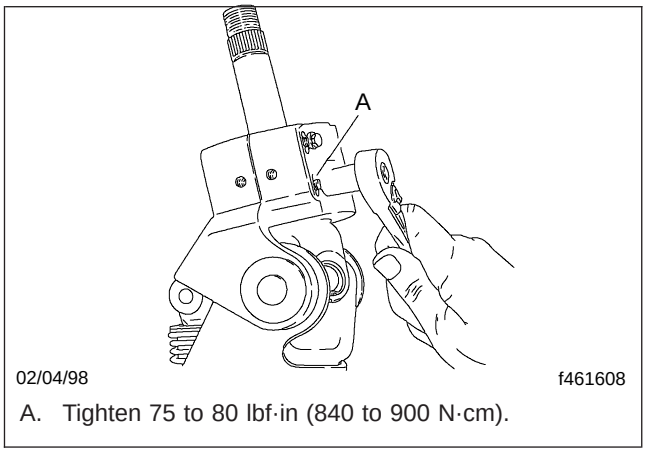

A. Tighten 75 to 80 lbf·in (840 to 900 N·cm).

Fig. 16, Install the Four Bearing Cap Bolts

14. Install the steering column. For instructions, see **Subject 110**.
15. Install the clockspring. For instructions, see **Subject 130**.
16. Install the steering wheel and check if it is centered (within ±10 degrees). See **Subject 100**.

Tilt Steering Column Disassembly and Assembly

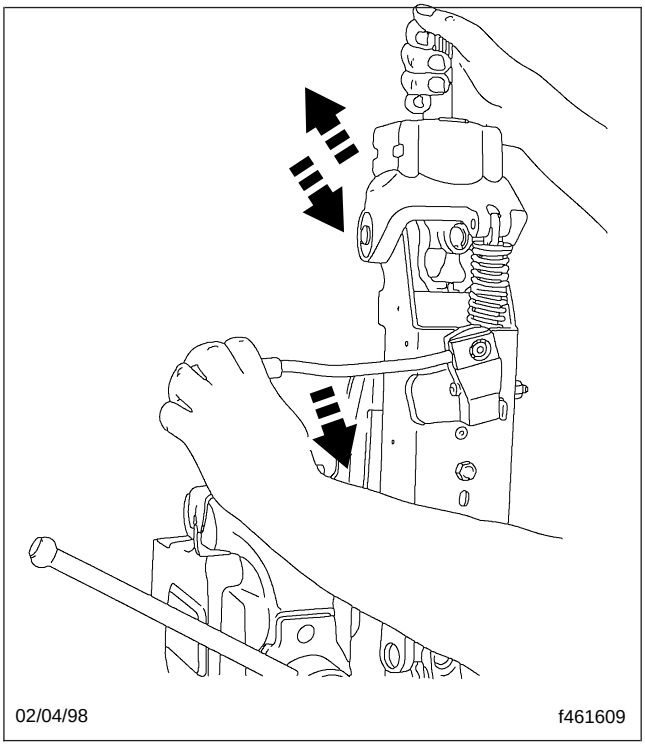

Fig. 17, Test the Tilt Lock Mechanism

17. Connect the battery ground cable(s).
18. Remove the chocks from the rear tires.

Tilt/Telescopic Steering Column Disassembly and Assembly

Disassembly

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Disconnect the battery ground cable(s).
3. Remove the steering wheel. For instructions, see **Subject 100**.
4. Remove the clockspring. For instructions, see **Subject 130**.
5. Remove the steering column. For instructions, see **Subject 110**.
6. Remove the under steering panel brackets.
7. Place the column in a soft-jawed vise, clamping on the mounting bracket flange. See **Fig. 1**.

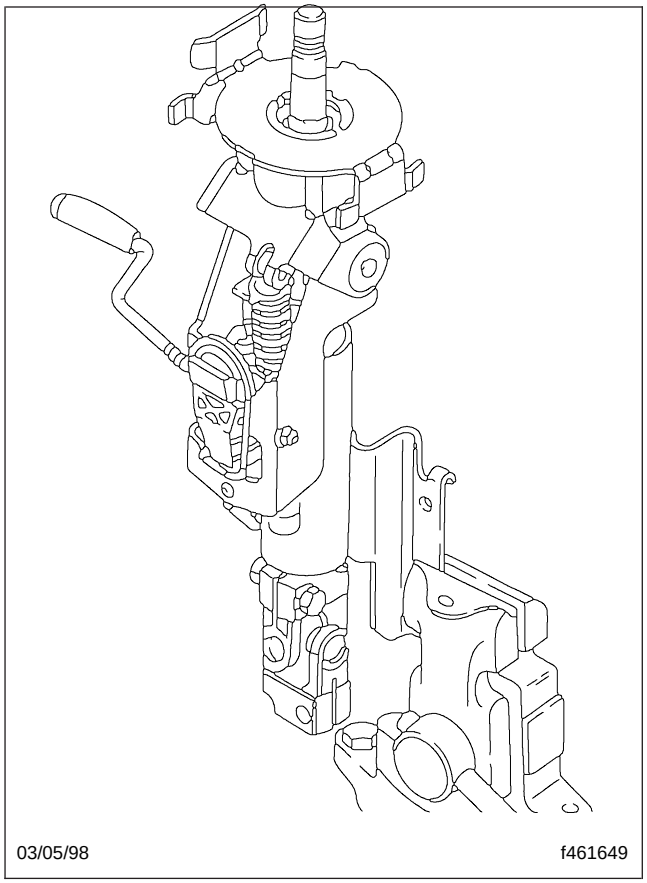

Fig. 1, Soft-Jawed Vise Holding Column

8. Telescope the steering column up to fully unload the telescope spring.
9. Remove the clockspring adaptor plate. See **Fig. 2**.

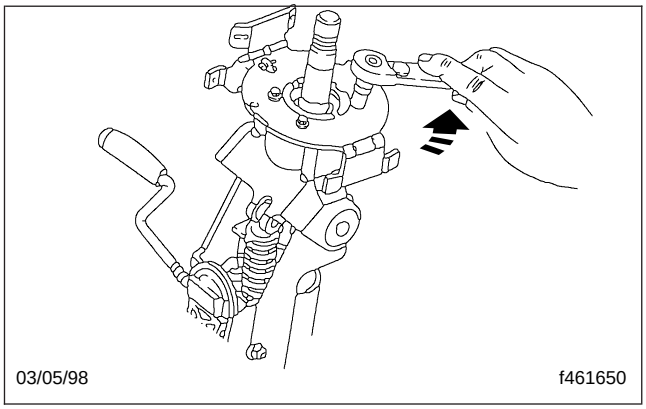

Fig. 2, Clockspring Adaptor Plate

10. Remove four bolts from the steering column and bearing cap. See **Fig. 3**.

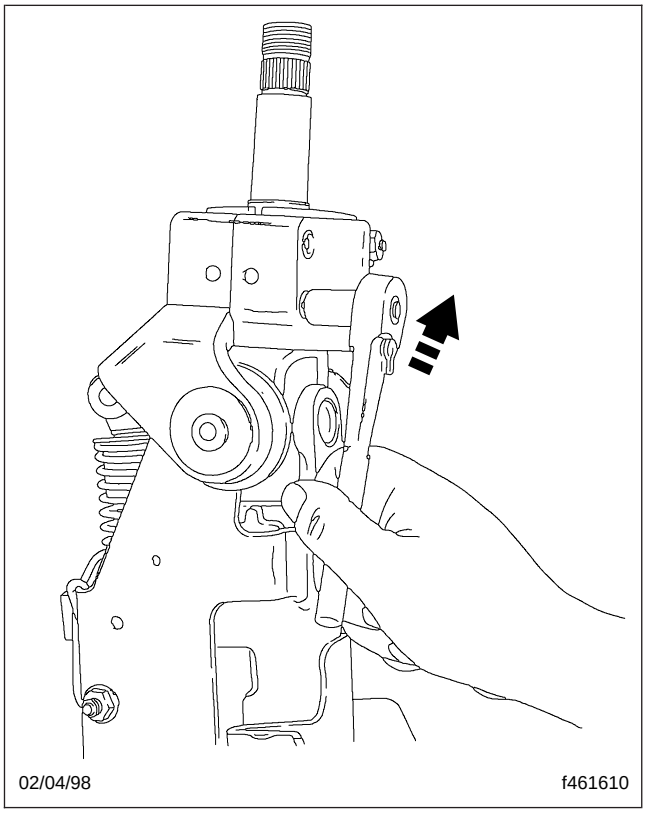

Fig. 3, Remove the Bearing Cap Bolts

Tilt/Telescopic Steering Column Disassembly and Assembly

⚠ WARNING

Wear eye protection during this step. The upper rotating tube is under spring tension. If the column has not been telescoped fully, this assembly will spring upward causing possible eye injury.

11. Remove the bearing cap. See **Fig. 4**.

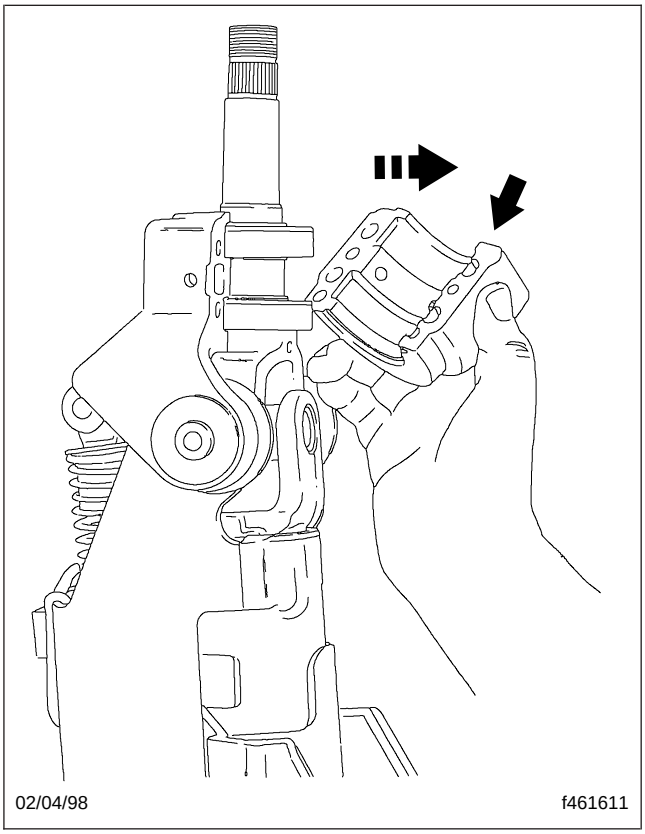

Fig. 4, Remove the Bearing Cap

12. Tilt the unit away from the mounting bracket and remove the upper rotating tube by lifting the bearings out of their seats, rotating the shaft if necessary for U-joint clearance, and pulling on the input shaft. See **Fig. 5**.

    12.1 Inspect the rotating bearings for looseness.

    12.2 Check for lash in the U-joint. Inspect for twisted or otherwise damaged serrations. If either condition exists, replace the rotating assembly.

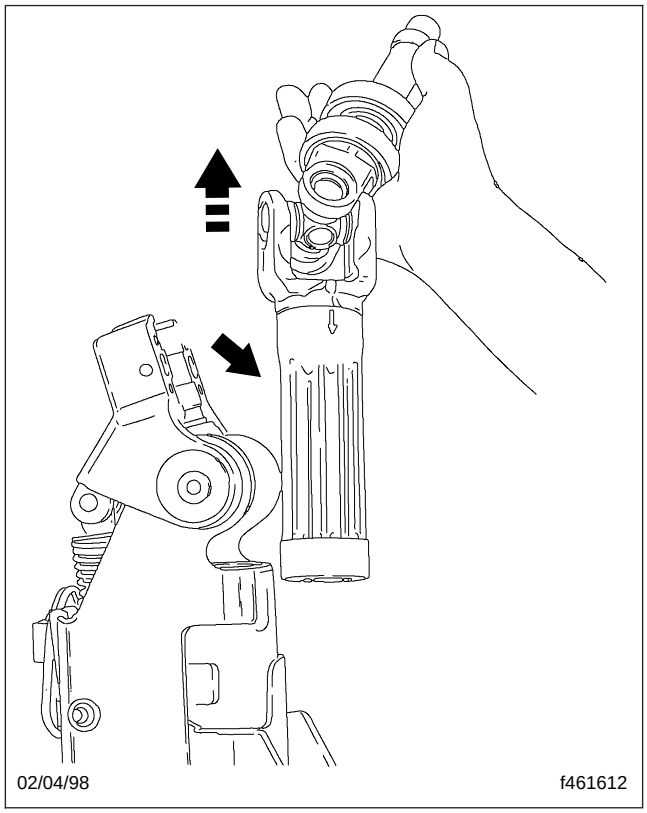

Fig. 5, Remove the Input Shaft and Bearing Assembly

    12.3 Remove the bearing gaskets from both bearings and discard.

NOTE: Before removing the U-joint, mark it in a manner that will allow it to be installed in the same orientation as when removed. The short yoke must be installed on the output shaft of the column.

13. Mark the U-joint/shaft orientation. Remove the pinch bolt, two washers and nut holding the U-joint in place. See **Fig. 6**.
14. Inspect the housing threads; make sure the threads are not stripped. If housing threads are stripped, the entire unit must be replaced. See **Fig. 7**.
15. Remove the retaining ring holding the lower rotating tube.
16. Remove the lower rotating tube and the telescope spring from jacket tube.

Tilt/Telescopic Steering Column Disassembly and Assembly

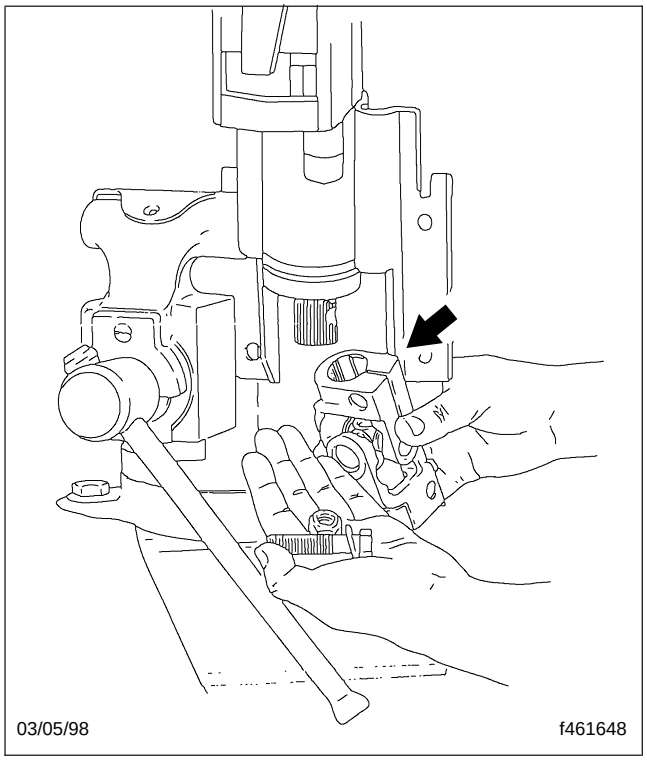

Fig. 6, Remove the U-Joint

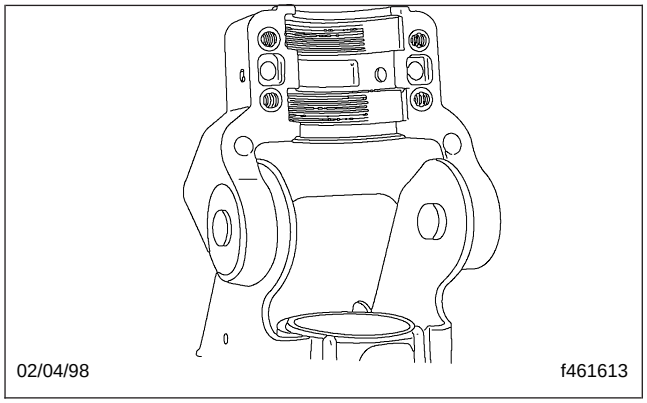

Fig. 7, Inspect the Housing Threads

17. Turn the unit upside down and allow the dust cover to fall out of the unit. See **Fig. 8**.

Assembly

1. Install the dust cover and the telescope spring. See **Fig. 9**.

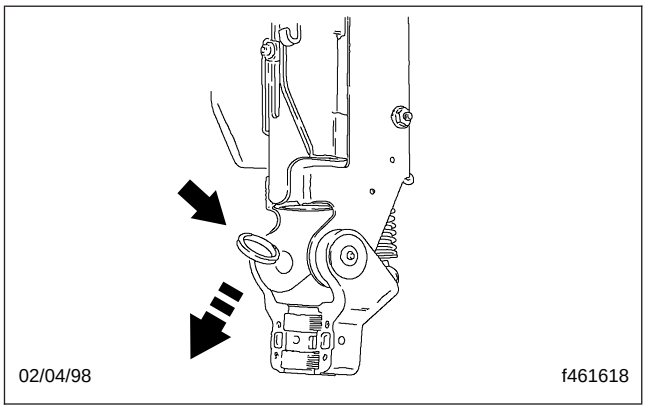

Fig. 8, Release the Dust Cover from the Unit

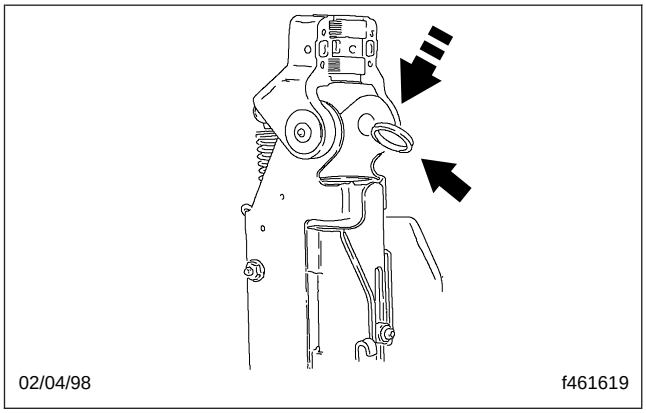

Fig. 9, Install the Dust Cover

NOTE: Note the position of the alignment arrows on the rotating tubes. Alignment arrows must line up for the tubes to fit together and function properly. Mark if necessary to align parts during installation, but not on the formed surfaces.

NOTE: Telescoping the column down may make this procedure easier.

2. Separate the upper and lower rotating tubes, and insert the new lower rotating tube in the jacket tube, inside the spring. See **Fig. 10**.

   2.1 Tap the lower tube with a wooden hammer handle if all components are properly aligned, and if it does not seat easily.

   2.2 If the lower tube still will not seat, clean the I.D. of the lower bearing with a fine grade of emery cloth and retry.

Tilt/Telescopic Steering Column Disassembly and Assembly

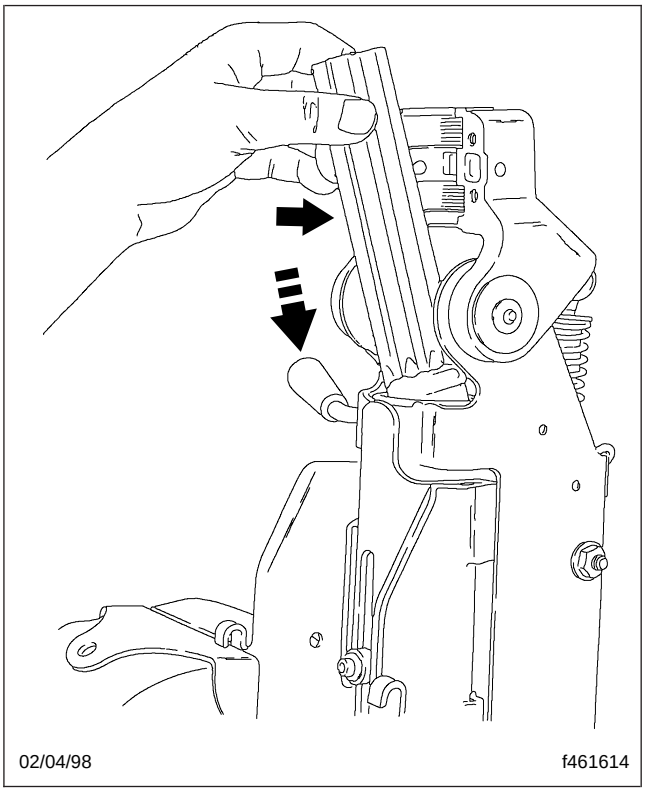

Fig. 10, Insert the Lower Rotating Tube

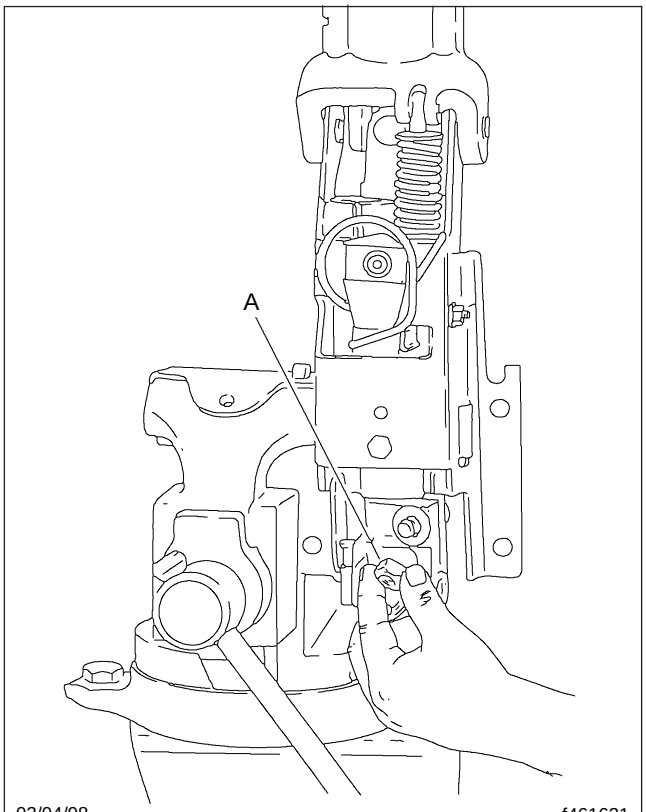
3. Install new gaskets on both bearings.

NOTE: Install the U-joint so that the shorter yoke is attached to the column output shaft aligning the marks previously made during disassembly for proper orientation of the U-joint/shaft.

4. Install the U-joint to the column output shaft. Tighten 50 to 70 lbf·ft (68 to 95 N·m). See **Fig. 11**.
5. Align the arrows or marks on the upper and lower rotating tubes, and install the upper rotating tube onto the lower rotating tube.
6. Seat the bearings in the tilt housing grooves. Make sure the gaskets are straight and seated properly. See **Fig. 12**.
7. Install the bearing cap with the pilot lip up, so it matches up with the pilot lip on the housing. Install the four bolts and tighten 75 to 80 lbf·in (840 to 900 N·cm). See **Fig. 13**.



A. Tighten 50 to 70 lbf·ft (68 to 95 N·m).

Fig. 11, Install the U-Joint

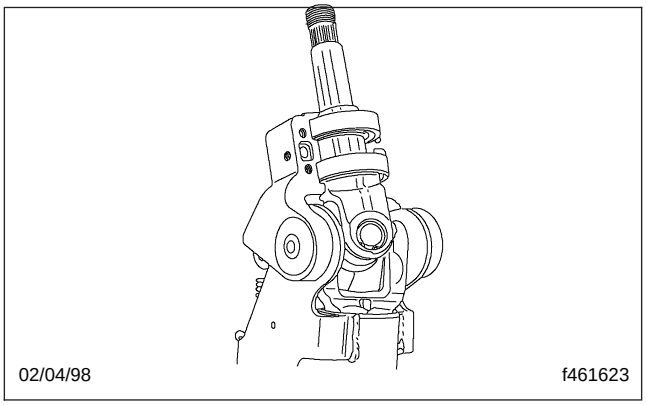


Fig. 12, Bearings Seated in Tilt Housing Grooves

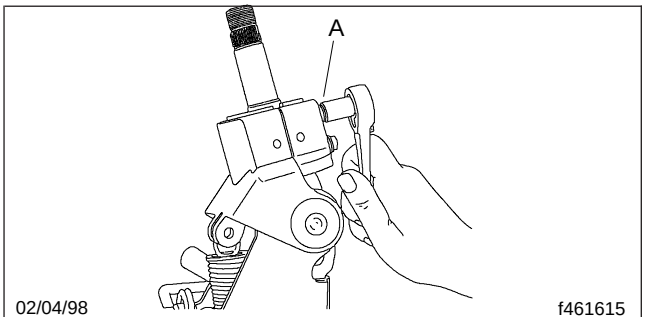
8. Test the tilt and telescope mechanisms. The actuator handle should self-return to a neutral position. See **Fig. 14**.

Tilt/Telescopic Steering Column Disassembly and Assembly



A. Tighten 75 to 80 lbf·in (840 to 900 N·cm).

Fig. 13, Install Bearing Cap Retaining Bolts

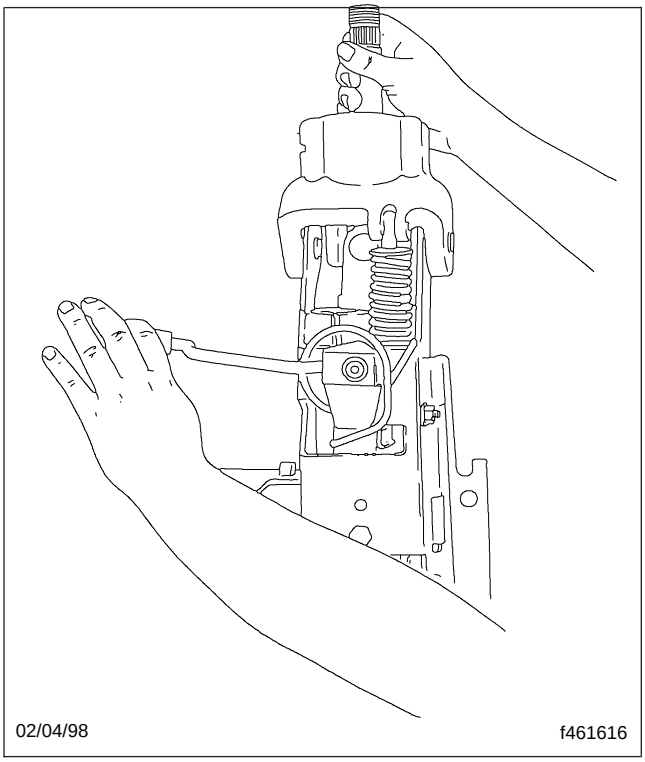


Fig. 14, Test the Tilt and Telescoping Mechanisms

9. Install the clockspring adaptor plate. Tighten the screws 80 to 115 lbf·in (900 to 1300 N·cm).
10. Install the under steering panel brackets.
11. Install the steering column. For instructions, see **Subject 110**.
12. Install the clockspring. For instructions, see **Subject 130**.
13. Install the steering wheel and check if it is centered (within ±10 degrees). See **Subject 100**.
14. Connect the battery ground cable(s).
15. Remove the chocks from the rear tires.

Steering Column Cam Kit Replacement

Replacement

1. Disconnect the battery ground cable(s).
2. Remove the steering wheel. Refer to **Subject 100**.
3. Remove the clockspring. Refer to **Subject 130**.
4. Remove the steering column. Refer to **Subject 110**.
5. Remove the steering column shrouds.

CAUTION

Wear eye protection when working with springs and spring-loaded devices.

6. Remove the steering column shroud brackets.
7. Place the column in a soft-jawed vise, clamping on the mounting bracket flange.

NOTE: The capscrew has a nylon patch.

8. Use a 5/32-inch Allen socket to remove the socket head capscrew and actuator handle.
9. Remove the winged O-ring. See **Fig. 1**.

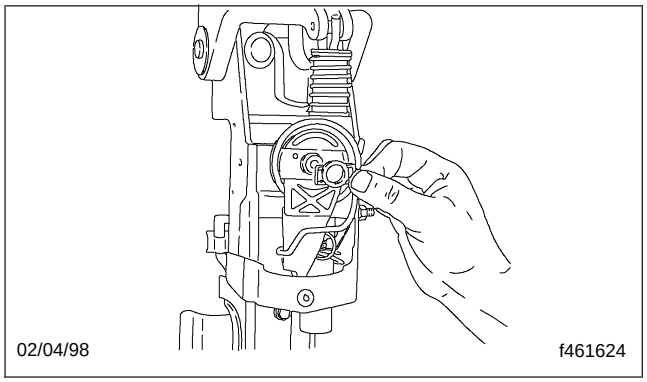

Fig. 1, Remove the Winged O-Ring

10. Use vise grips to release the lower end of the torsion spring from its position over the wire form. Guide the spring end until the spring rests in a non-tension position. See **Fig. 2**.
11. Remove the retaining ring. See **Fig. 3**.
12. Remove the cam and torsion spring.

    Inspect the actuator cam for cracks or breaks. Replace if necessary. See **Fig. 4**.
13. Wipe off the grease from around the pivot pin.

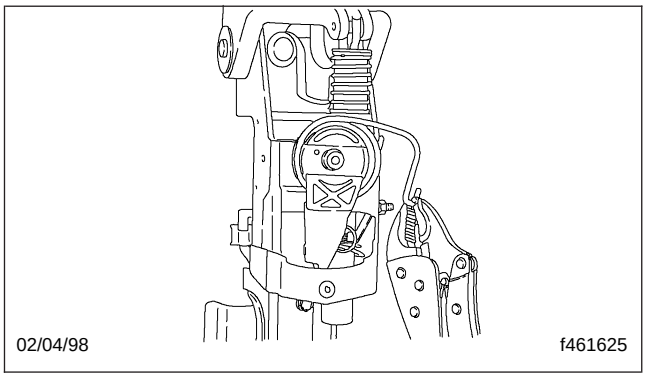

Fig. 2, Guide the Spring to a Rest Position

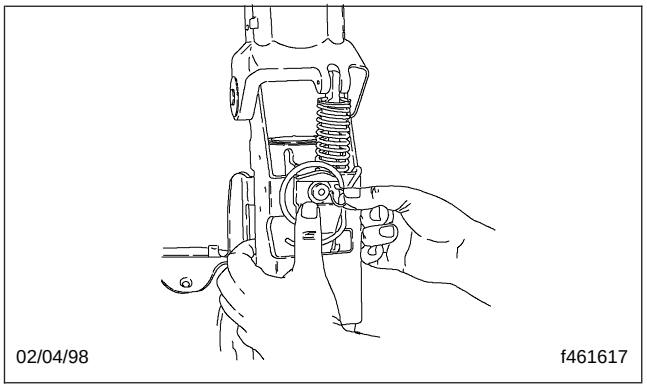

Fig. 3, Remove the Retaining Ring

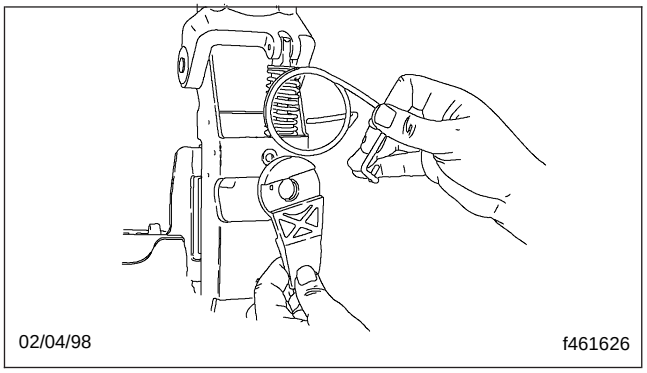

Fig. 4, Remove the Cam and Torsion Spring

14. Grease the area around the pivot pin, and the back of the cam.
15. Install the torsion spring.
16. Position the cam on the pivot pin, and install the retaining ring. Make sure the retaining ring is seated properly. See **Fig. 5**.

Steering Column Cam Kit Replacement

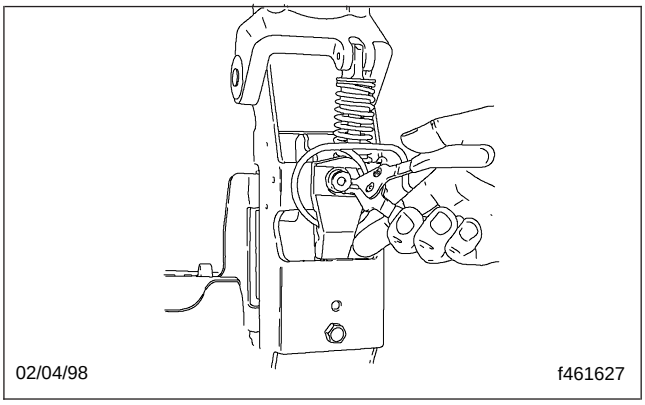

Fig. 5, Install the Retaining Ring

17. Use vise grips to pull the lower end of the torsion spring into place over the wire form. See **Fig. 6**.

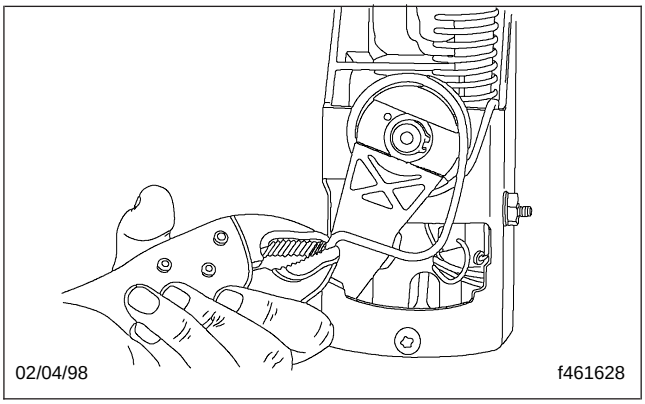

Fig. 6, Pull the Torsion Spring into Place

18. Install the winged O-ring. See **Fig. 7**.

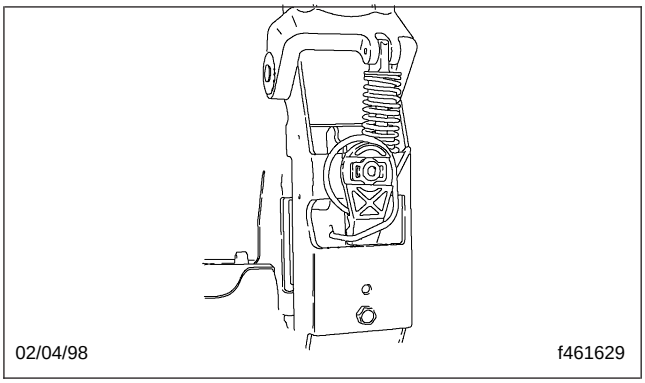

Fig. 7, Install a Winged O-Ring

19. Install the actuator handle on the actuator pivot pin. Test the function of the tilt and telescopic mechanism. See **Fig. 8**.

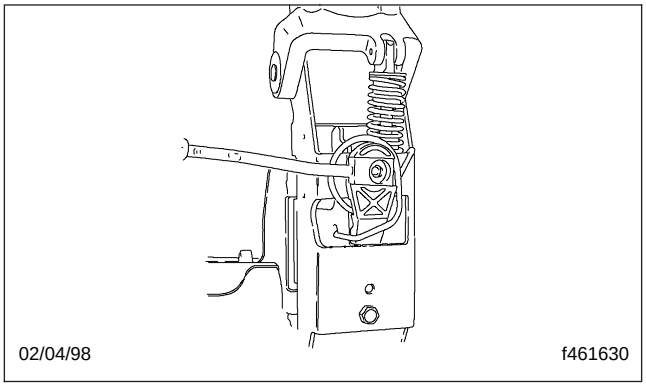

Fig. 8, Test the Tilt/Telescopic Function

20. Install the steering column shroud brackets.
21. Install the steering column. Refer to **Subject 110**.
22. Install the clockspring. Refer to **Subject 130**.
23. Install the steering wheel. Refer to **Subject 100**.
24. Connect the battery ground cable(s).

General Information

Two different multi-function switches are used on the L-Line and A-Line vehicles:

- a UTA self-canceling switch (see **Fig. 1**)
- a Signal-Stat manual cancel switch (see **Fig. 2**)

The multi-function switch combines the following features:

- integral wiper/washer controls
- windshield wiper interval control
- headlamp dimmer (UTA)
- flash-to-pass control
- turn signal "On/Off" switch
- hazard lamp "On/Off" switch

The UTA self-canceling multi-function switch automatically returns the turn signal lever to the "Off" position, upon completion of a turn, by means of a cancel cam located on the steering column shaft.

For more information on exterior lights, refer to **Group 54**.

8. Steering Column Lower Back Shroud

Fig. 1, UTA Turn Signal and Windshield Wiper Switch Assembly

⚠ CAUTION

Do not drop the screw or the cancel cam down the steering column housing.

1. Remove the screws and the panels from the steering column. See **Fig. 2**.
2. Remove the multi-function switch.
3. Remove the screw and the cancel cam. See **Fig. 3**.
4. Position the cancel cam and install the screw. Tighten the screw 25 to 35 lbf·in (280 to 390 N·cm). See **Fig. 2**.
5. Install the multi-function switch.

Cancel Cam Replacement

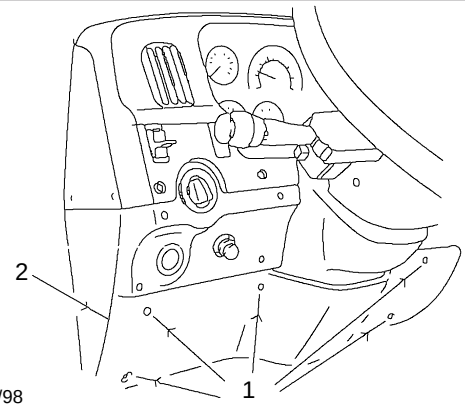
2. Remove the screws and the steering column upper front and upper back shrouds. See **Fig. 3**.
3. Remove the steering column lower front shroud. See **Fig. 4**.
   - 3.1 Remove the steering column lock actuator lever screw.
   - 3.2 Remove the two screws.
   - 3.3 Remove the steering column lower front shroud with the lock actuator lever.
4. Disconnect the turn signal switch assembly electrical connectors.

Signal-Stat Multi-Function Switch Replacement



1. Screws
2. Lower Finish Panel

Fig. 2, Instrument Panel

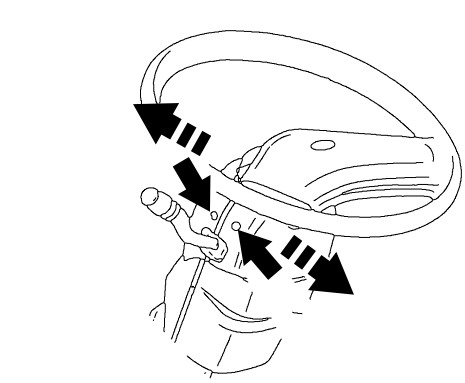


Fig. 3, Remove the Upper Shrouds

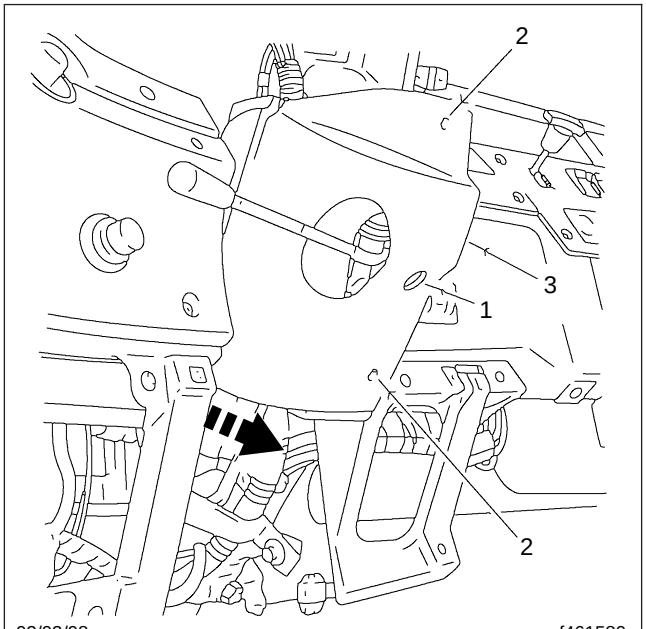
5. Remove the screws and the turn signal switch assembly from the steering column. See **Fig. 5**.
6. Position the turn signal switch on the steering column and install the retaining screws.
7. Connect the turn signal switch assembly electrical connectors.
8. Install the steering column lower front shroud.
   - 8.1 Position the steering column lower front shroud with the lock actuator lever.
   - 8.2 Install the two screws.
   - 8.3 Install the steering column lock actuator lever screw.



1. Lock Actuator Lever Screw
2. Shroud Screws
3. Lower Front Shroud

Fig. 4, Removing the Lower Front Shroud

9. Install the screws and the steering column upper front and upper back shrouds.
10. Install the instrument panel lower finish panel.
    - 10.1 Position the instrument panel lower finish panel.
    - 10.2 Install the screws.

Troubleshooting

INSPECTION AND VERIFICATION

Inspect the installation of the steering column shroud parts to make sure there is no interference with the operation of the turn signal control or hazard warning switch.

- Remove the steering column shroud to gain access to the multi-function switch mounting screws. Make sure the screws are secure.
- With the steering column shroud and the multi-function switch removed, inspect the cancel cam, if so equipped. Check for wear or damage. Replace as necessary.
- Inspect the multi-function switch connectors. Make sure the connections are tight.
- Operate the multi-function switch controls through all function positions. Check for binding or looseness. Make sure the multi-function switch controls hold in each detent position. Repair or replace as necessary.

Problem—Multi-Function Switch/Controlled Component Will Not Function Properly

Problem—Multi-Function Switch/Controlled Component Will Not Function Properly	
Possible Cause	**Remedy**
Multi-function switch	Refer to **Group 54** in this manual for instructions.
Circuit/controlled component	For exterior lighting concerns, refer to **Group 54** in this manual for instructions. For wiper and washer circuit concerns, refer to **Group 82** in this manual for instructions.
Damaged or missing cancel cam (UTA)	Replace cancel cam.

Specifications

Torque Specifications	
Description	**lbf·in (N·cm)**
Cancel Cam Retaining Screw	25–35 (280–390)
Steering Column Lock Actuator Lever Screw	120 (1400)

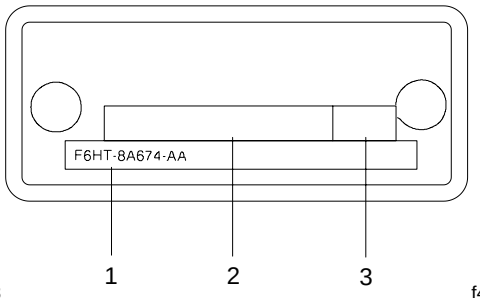
Table 1, Torque Specifications

General Information

The ZF power steering pump has been specially designed to supply pressurized oil to power steering units.

The ZF power steering pump is directly driven by the engine. As the driven shaft rotates the rotor, the slipper vanes inside the power steering pump also move. The centrifugal force and pressurized oil force the slipper vanes against the track of the cam ring. The oil passes from the two pressure chambers to the area between the rear cover and faceplate, thus pressing this plate against the cam ring at operating pressure. The oil then passes through a flow-limiting valve to the pressure line.

ZF power steering pumps are identified by a tag riveted on the pump body. The tag provides the Sterling part number, pump serial number, and date code. See **Fig. 1**.



1. Part Number
2. Pump Serial Number
3. Date Code

Fig. 1, Steering Pump Identification Tag

Cast Iron Power Steering Pump Disassembly and Assembly

Disassembly

1. Remove the helical drive gear. See **Fig. 1**.

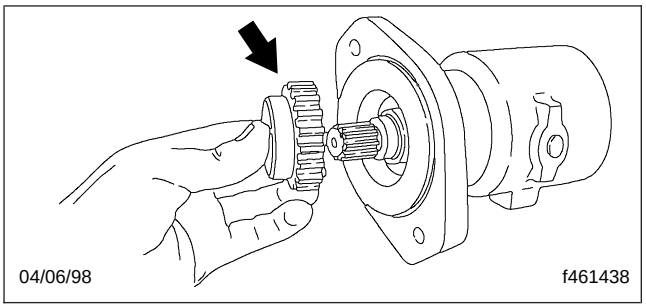


Fig. 1, Helical Drive Gear

2. Remove the hook spring ring from the radial groove in the housing, using pliers. See **Fig. 2**.

NOTE: The O-ring is inboard of the backup ring.

3. Remove the cover and the pressure spring then remove the internal O-ring and backup ring from the rear cover. See **Fig. 3**.
4. Remove the circlip from the groove. See **Fig. 4**.

NOTE: This O-ring is outboard of the backup ring.

NOTE: Check and record the direction of rotation (arrow on the cam ring) and the location of the set pins. The power steering pump cannot be reassembled properly without this information.

5. Turn the housing over and remove the rear faceplate, rotor assembly (rotor, cam ring, vanes and set pin) and front faceplate from the housing.

   Remove the O-ring and backup ring from the rear faceplate. See **Fig. 5**.
6. Clamp the driveshaft in a vise (use soft jaws) and with a soft mallet, tap on the housing to remove the driveshaft from the housing. See **Fig. 6**.
7. If the ball bearing is to be replaced, remove the retaining ring and press the bearing from the driveshaft. See **Fig. 7**.
8. If the shaft seal or the needle bearing needs repair, remove the seal or the bearing from the housing. Discard the seal. See **Fig. 8**.

Assembly

1. If removed, press in a new needle bearing.
2. If removed, install a new shaft seal in the housing.
3. If removed, press a new bearing onto the driveshaft and install the retaining ring in the driveshaft groove. See **Fig. 9**.
4. Install the driveshaft and bearing assembly into the housing.
5. Install the bearing circlip in the groove.
6. Install the O-ring and backup ring on the rear faceplate.

NOTE: The cam ring of the rotor assembly must be installed with the arrow pointed in the direction of rotation (DDC 60 counterclockwise, all others clockwise). The set pin is installed in the location recorded during disassembly.

7. Install the set pin, front faceplate and rotor assembly into the housing.
8. Install the rear pressure spring and rear cover.
   - 8.1 Install the O-ring and backup ring in the rear cover housing. See **Fig. 2**.
   - 8.2 Place the rear pressure spring in the rear faceplate.
   - 8.3 Position the rear cover in the housing.
9. Press down on the rear cover plate and install the hook spring ring in the groove in the housing.
10. Install the helical drive gear.

Aluminum Power Steering Pump Disassembly and Assembly

Disassembly

1. Clamp the power steering pump in a soft-jawed vise.
2. Mark the position of the cover and housing, then remove four power steering pump cover retaining bolts. See **Fig. 1**.
3. Remove the protecting screw and O-ring. See **Fig. 2**.
4. Remove the valve spool together with the compression spring. See **Fig. 3**.
5. Lift the pressure plate from the housing. See **Fig. 4**.
6. Remove the sealing ring and the backup ring from the pressure plate. See **Fig. 5**.
7. Remove the rotor set together with the needle rollers. See **Fig. 6**.
8. Remove the needle rollers and the vanes from the rotor.
9. Remove the pressure plate. See **Fig. 7**.
10. Remove the retaining ring. See **Fig. 8**.
11. Press the power steering shaft out of the power steering pump housing together with the ball bearing and snap ring. See **Fig. 9**.

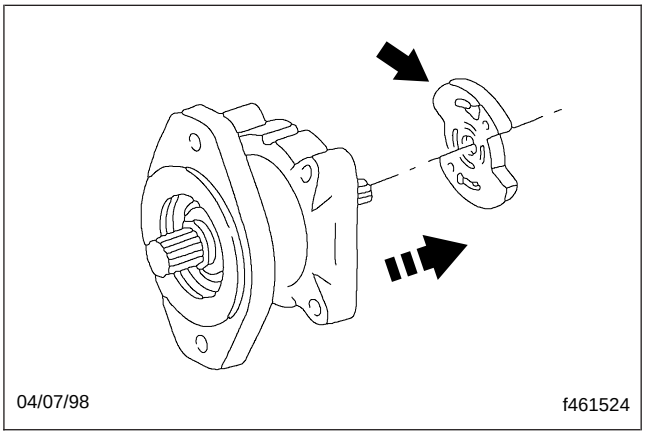

Fig. 4, Lift the Pressure Plate from the Housing

NOTE: Press the ball bearing from the shaft only if it is damaged. Release the bearing from the shaft by removing the snap ring/retaining ring.

12. Press the bearing from the shaft.

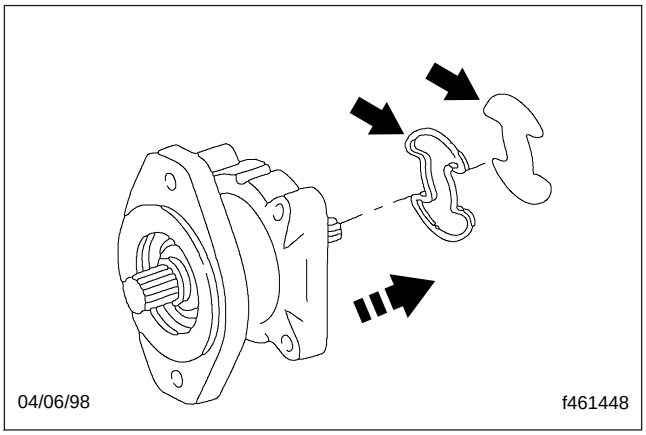

Fig. 5, Remove the Sealing Ring and Back-Up Ring

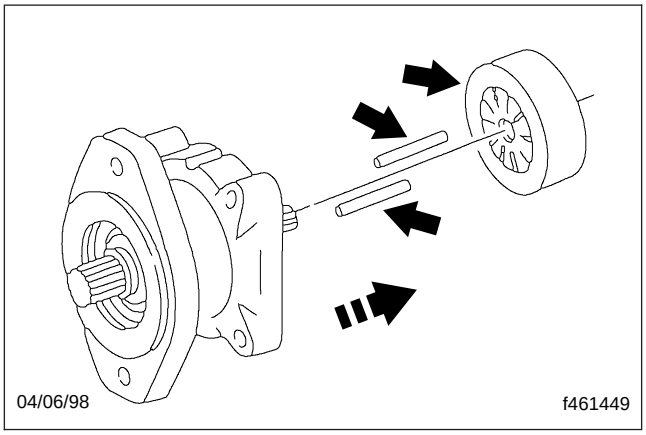

Fig. 6, Remove the Rotor Set and Rollers

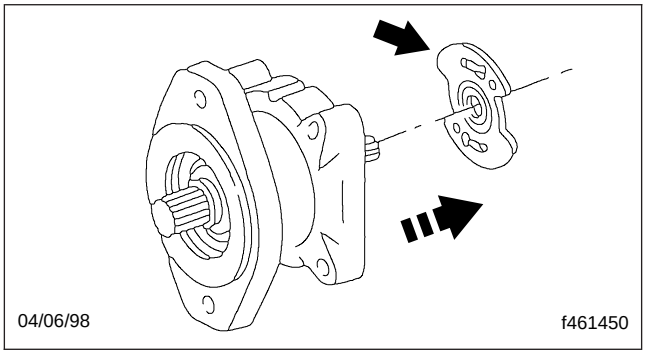

Fig. 7, Remove the Pressure Plate

13. Remove the shaft seal using a seal extractor. See **Fig. 10**.
14. Remove the O-ring from the pump housing. See **Fig. 11**.

Aluminum Power Steering Pump Disassembly and Assembly

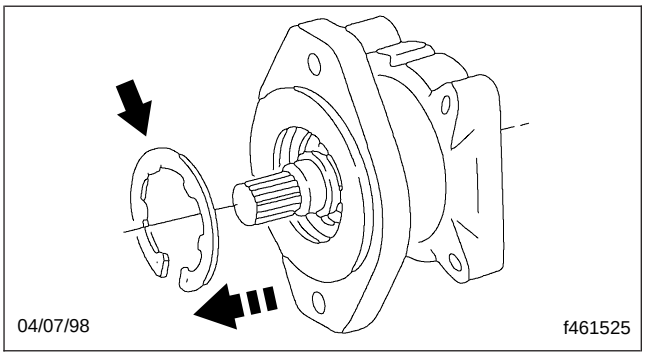

Fig. 8, Remove the Retaining Ring

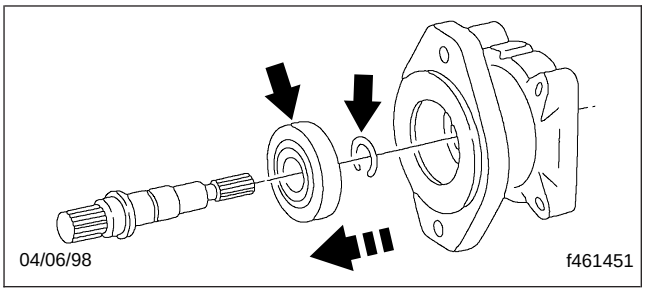

Fig. 9, Shaft, Bearing and Snap Ring

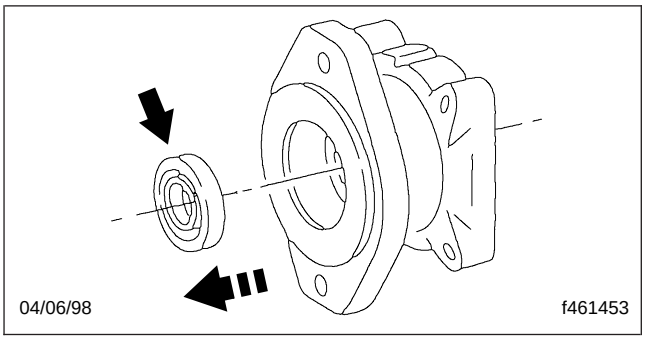

Fig. 10, Remove the Shaft Seal

15. If the shaft is damaged in the area of the needle sleeve bearing surface, remove the needle sleeve using the shaft seal extractor and counter support for shaft seal extractor or equivalents. See **Fig. 12**.

Assembly

1. If removed, press the needle sleeve onto the power steering pump shaft using the mandril tool. See **Fig. 13**.
2. Install the O-ring. See **Fig. 14**.

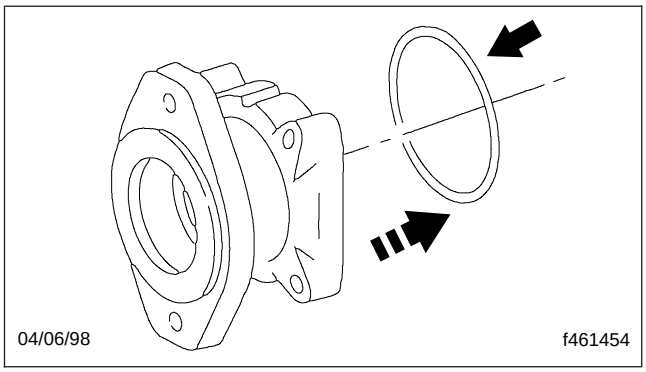

Fig. 11, Remove the O-Ring

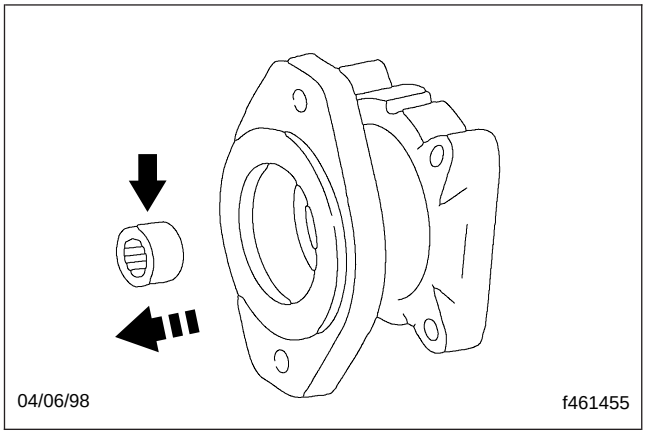

Fig. 12, Remove the Needle Sleeve

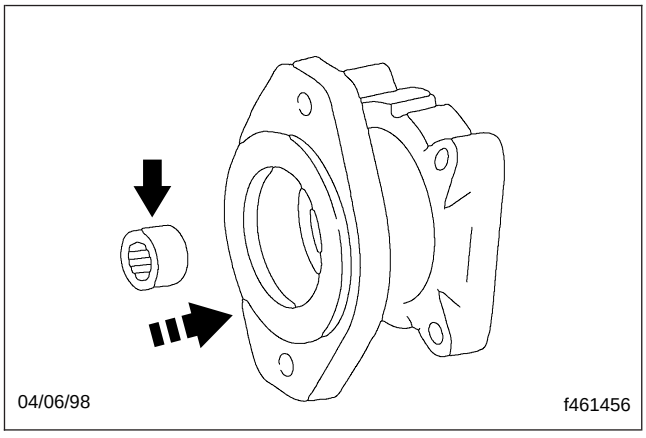

Fig. 13, Press the Needle Sleeve onto the Shaft

3. Install the shaft seal using the mandril tool. See **Fig. 15**.

Aluminum Power Steering Pump Disassembly and Assembly

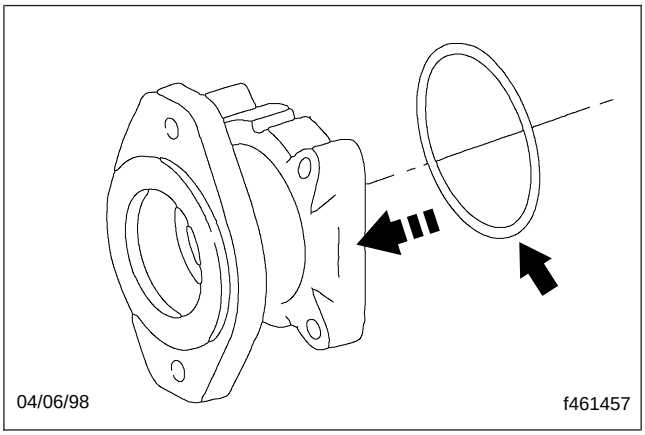

Fig. 14, Install the O-Ring

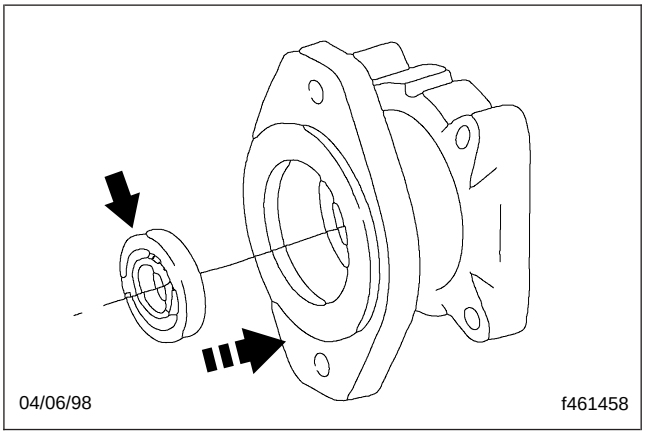

Fig. 15, Install the Seal into the Housing

4. Press the ball bearing onto the power steering pump shaft and secure with the bearing snap ring. See **Fig. 16**.

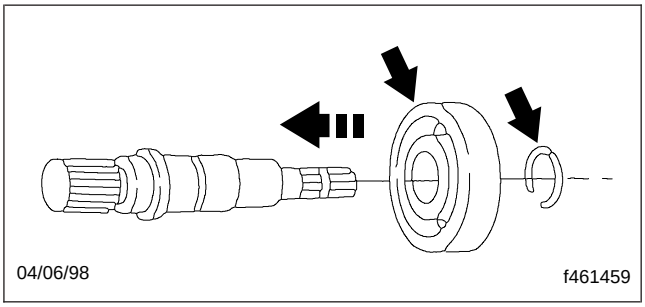

Fig. 16, Press the Bearing onto the Shaft

5. Press the shaft into the housing up to the stop and secure with the retaining ring. See **Fig. 17**.

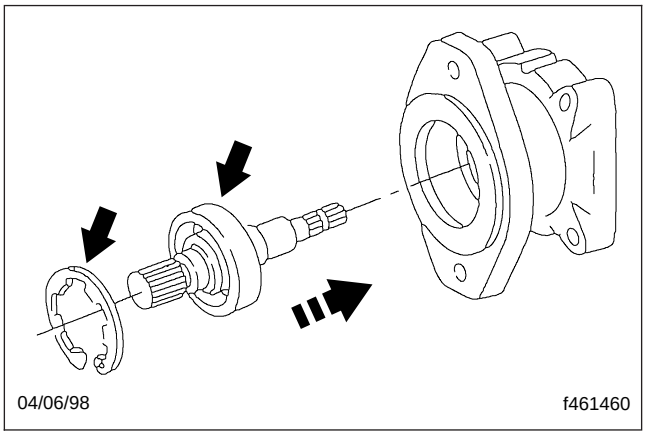

Fig. 17, Press the Shaft into the Pump Housing

6. Install the pressure plate onto the shaft. See **Fig. 18**.

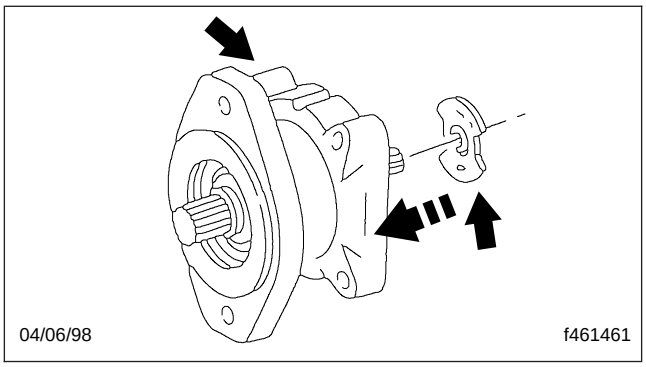

Fig. 18, Install the Pressure Plate

7. Install the 10 vanes into the rotor with the rounded, polished sides aligned to the curved ring.
8. Install the rotor onto the shaft with the internal chamfer toward the housing. See **Fig. 19**.

NOTE: Fit the curved ring so that the direction of the rotation arrows and the assembly markings are aligned.

9. Install the needle rollers in the curved ring, pressure plate and housing. See **Fig. 20**.
10. Install the compression spring and the spool valve into the cover. See **Fig. 21**.
11. Install the protecting screw and the O-ring. Tighten the screw 52 lbf·ft (70 N·m). See **Fig. 22**.

Aluminum Power Steering Pump Disassembly and Assembly

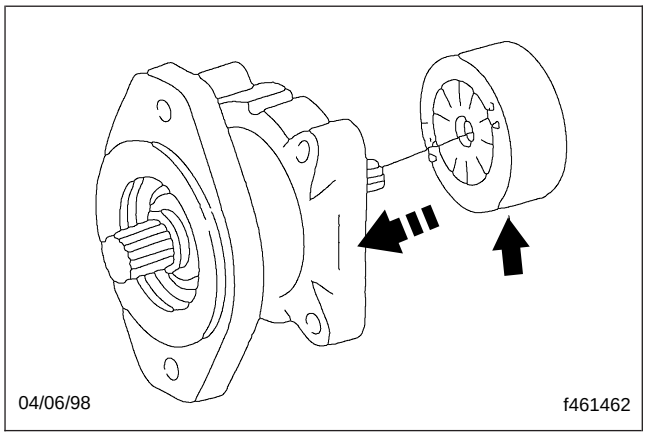

Fig. 19, Install the Rotor

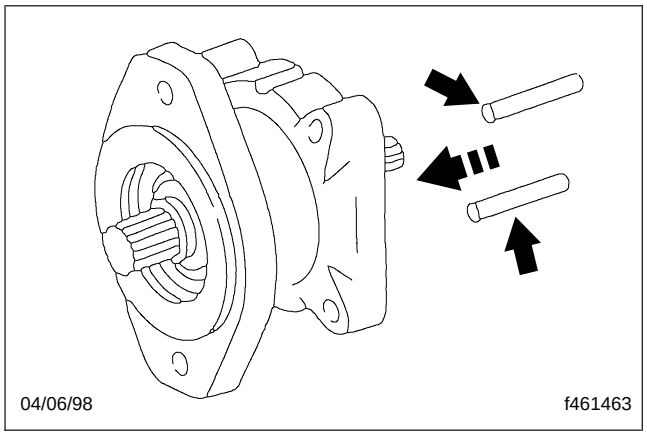

Fig. 20, Install the Needle Rollers

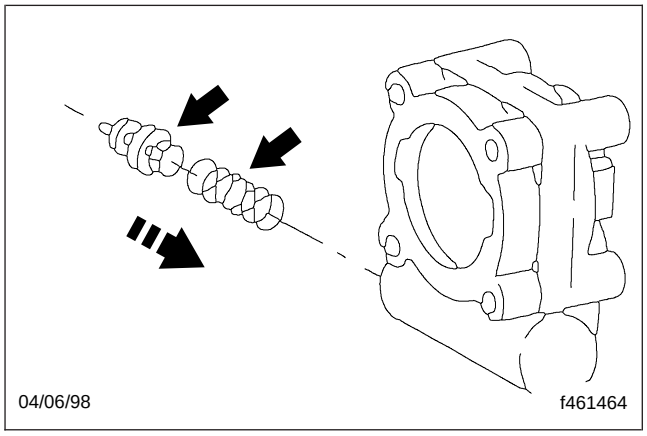

Fig. 21, Install the Compression Ring and Spool Valve

12. Install the power steering pump cover as marked and install the four power steering pump cover retaining bolts. Tighten the bolts 17 to 20 lbf·ft (23 to 27 N·m).

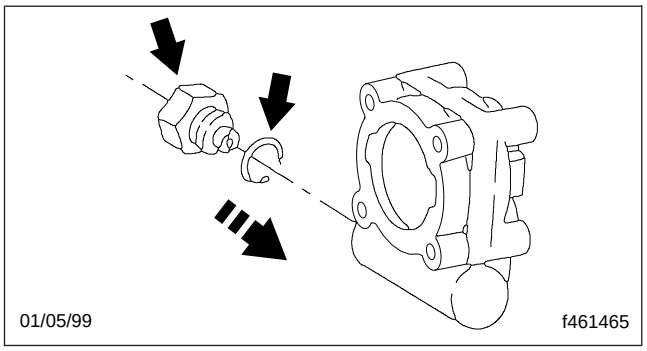

Fig. 22, Install the Protecting Screw

Power Steering Pump Removal and Installation

Removal

1. Turn off the engine, apply the parking brakes, and chock the rear tires.
2. Drain the power steering reservoir using a suction pump.
3. Place a drain pan under the power steering pump, and remove the hoses from the pump.
4. If necessary, remove the starter to access the power steering pump. For instructions, see **Group 15**.
5. Remove the capscrews that attach the power steering pump to the engine, and remove the pump and gasket.
6. If replacing the power steering pump, remove the fittings from the pump.

Installation

1. If necessary, install the fittings on the power steering pump. Torque the fittings 31 to 41 lbf·ft (42 to 56 N·m).
2. Using capscrews, install the gasket and pump on the engine. Torque the capscrews 27 to 32 lbf·ft (37 to 43 N·m).
3. Attach the power steering hoses to the pump, and torque the lines 31 to 42 lbf·ft (42 to 57 N·m).
4. Fill the power steering reservoir with Dexron® III automatic transmission fluid.
5. Bleed the air from the power steering system. For instructions, see **Section 46.02, Subject 100**.
6. Remove the chocks from the tires.

Power Steering Plumbing Components Removal and Installation

Power Steering Reservoir

Removal

1. Remove the filler cap and, using a suction gun, remove power steering fluid from the filler opening.
2. With the container nearby, disconnect the return hoses from the power steering reservoir and drain the reservoir into the container.
3. Loosen fasteners and remove the power steering reservoir from the bracket.

Installation

1. Position the power steering reservoir into the bracket. See **Fig. 1**.

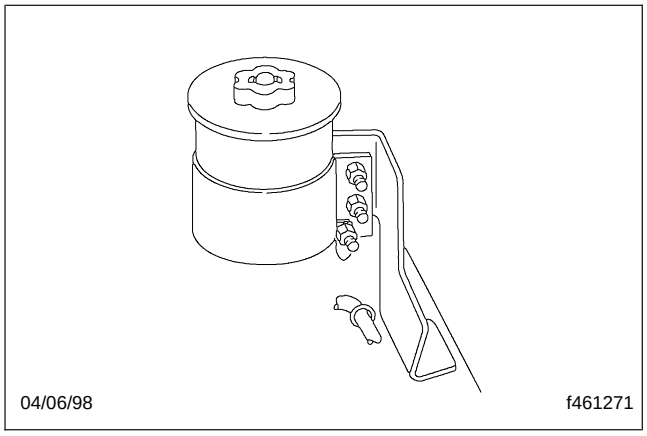

Fig. 1, Power Steering Fluid Reservoir

2. Fill the system with the recommended hydraulic oil. Then, bleed the air from the power steering hydraulic system.
3. Tighten the bolts.

Power Steering Fluid Filter Element

Removal

1. Drain the power steering reservoir using a suction pump.
2. Loosen the worm screw of the band clamp, then remove the cover and spring from the reservoir. See **Fig. 2**.

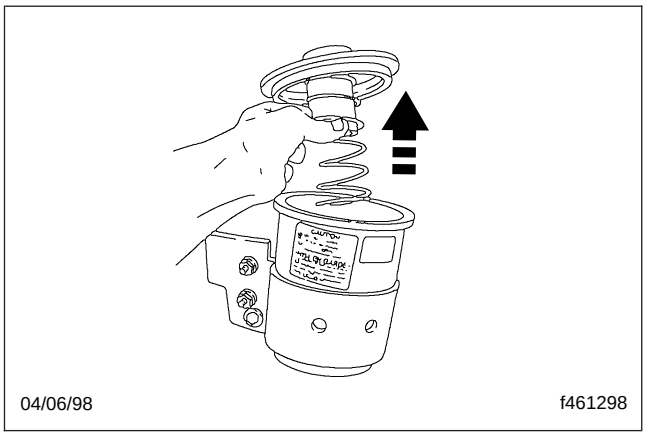

Fig. 2, Removing the Cover and Spring from the Reservoir

3. Remove the filter from the power steering reservoir. See **Fig. 3**.

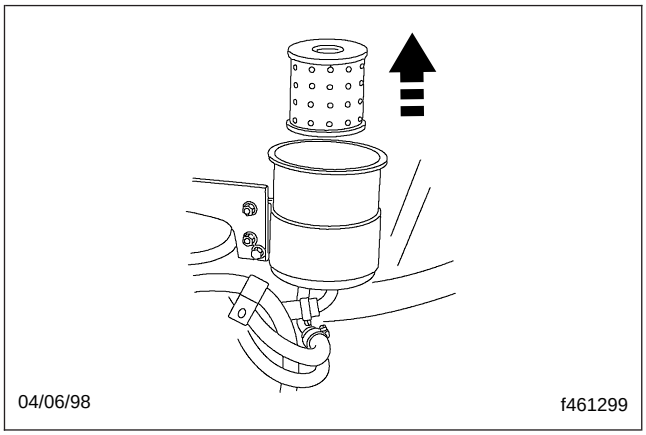

Fig. 3, Removing the Filter from the Reservoir

Installation

1. Install the new filter into the power steering reservoir.
2. Install the worm screw of the band clamp. Then install the cover and spring into the reservoir.
3. Fill the system with the recommended hydraulic oil. Then bleed the air from the power steering hydraulic system.

Power Steering Plumbing Components Removal and Installation

Power Steering Cooler

Removal

1. Position a suitable container below the power steering cooler connections.
2. Loosen the worm screw of the band clamps and disconnect the hoses.
3. Remove the two bolts and the power steering cooler assembly. See **Fig. 4**.

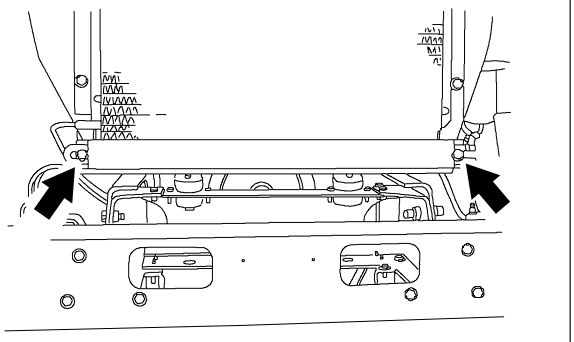

Fig. 4, Power Steering Cooler Bolts

Installation

1. Install the two power steering cooler assembly bolts. Tighten bolts to 31 lbf·ft (42 N·m). See **Fig. 4**.
2. Connect the hoses and install the worm clamps.
3. Fill the system with the recommended hydraulic oil. Then bleed the air from the power steering hydraulic system.

System Flushing

To flush the power steering system, follow the instructions provided with the Power Steering Analyzer.

System Bleeding

1. If bubbles are visible in the power steering fluid, bleed the air from the system.
2. Check the power steering reservoir fluid level and add Dexron® III automatic transmission fluid (ATF) if necessary.

⚠ WARNING

Do not hold the steering wheel in the far-left or far-right position for more than five seconds to avoid high temperature and possible damage to components.

3. Run the engine until the fluid reaches normal operating temperature.
4. Turn the steering wheel to the left and right completely (but not lock to lock), several times and return to center.
5. Check the fluid level and add Dexron® III ATF if necessary.

Final Fill

NOTE: The fluid level must show between the ADD and FULL mark on the dipstick or reservoir. If the fluid is below the ADD mark, add Dexron® III ATF.

NOTE: After any major power steering system or component overhaul, the system must be purged of hydraulic fluid and the oil filter discarded. Add clean ATF and install a new filter.

1. Check the fluid level in the power steering reservoir with the engine off. Use the HOT or COLD marks on the dipstick or reservoir, depending upon the fluid temperature.
   - 1.1 Use COLD for checking at 70°F (21°C).
   - 1.2 Use HOT for normal operating temperatures of 175°F (80°C).

⚠ CAUTION

Do not turn the steering wheel during the initial fill procedure.

Place the front wheels in a straight-ahead position and engage the parking brake.

2. Fill the reservoir with fluid and allow the fluid to gravity feed the system.
   - 2.1 Crack the pressure line fittings at the pump and steering gear.
   - 2.2 Tighten the fittings when fluid is visible.
   - 2.3 Keep adding fluid to the reservoir as required.
3. When the fluid level in the reservoir no longer goes down, start the engine. Continue to add fluid to the reservoir as required.

IMPORTANT: Do not exceed the FULL mark on the dipstick or reservoir.

4. After the fluid level in the reservoir no longer goes down, rotate the steering wheel to full-right and full-left turns, stop to stop. Add fluid as required.
5. Continue the process until the fluid level no longer changes. Fluid level is correct when it is in the FULL range on the dipstick or reservoir.
6. Place the front wheels in a straight-ahead position and set the parking brake.

NOTE: When a minor leak is corrected, follow the next steps.

7. Fill the reservoir to the FULL mark on the dipstick or reservoir.
   - 7.1 Start the engine and let idle for several minutes.
   - 7.2 Check fluid level and add as required.
8. Rotate the steering wheel to full-right and full-left turns, stop to stop, several times.
9. Stop the engine and check fluid level. Fill the reservoir to FULL range indicated on the dipstick or reservoir.

General Information

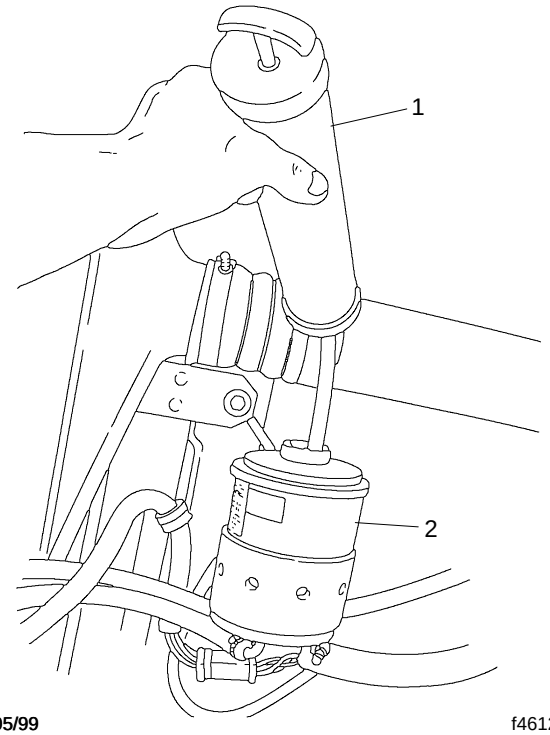
Some heavy-truck power steering systems are equipped with a rotary assist cylinder to increase power steering forces. The rotary assist cylinder is similar in design to the power steering gear but without the worm gear and valve components that attach to the steering wheel.

The rotary assist cylinder consists of a combined cylinder and gear box that contains a piston with an integral rack. The rack meshes with a gear sector that connects to a pitman arm and steering linkage similar to the integral power steering gear.

The piston operates from pressure supplied from and controlled by the integral power steering gear. When the integral gear supplies pressure to the top of its own piston, it supplies pressure to the top of the auxiliary cylinder piston. When it supplies pressure to the bottom of its own piston, it supplies pressure to the bottom of the auxiliary cylinder piston.

Removal

1. Drain the power steering system using a suction pump. See **Fig. 1**.



1. Suction Pump 2. Reservoir

Fig. 1, Drain the Power Steering Fluid Reservoir

NOTE: Plug all port holes immediately after removing the hoses and before removing the gear from the vehicle to prevent foreign matter from entering.

2. Disconnect the hydraulic fluid lines at the rotary assist cylinder. Plug all port and line openings. See **Fig. 2**.
3. Remove the pitman arm. For instructions, see **Section 46.01, Subject 120**.
4. If replacing the rotary assist cylinder, remove the power steering hose fittings from the rotary assist cylinder. See **Fig. 3**.
5. Remove the four nuts and bolts, then remove the cylinder. See **Fig. 4**.

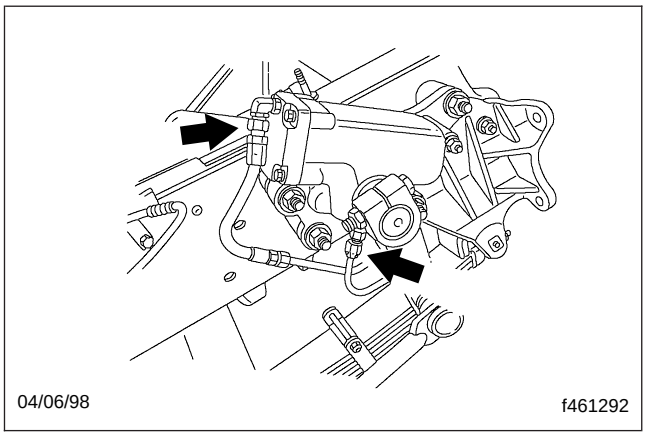


Fig. 2, Hydraulic Fluid Lines

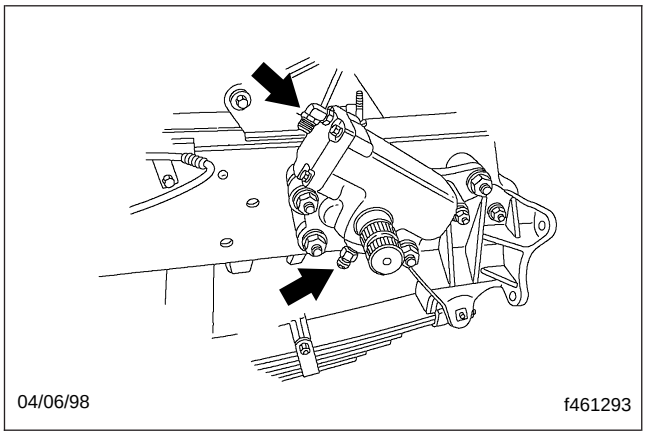

Fig. 3, Hose Fittings

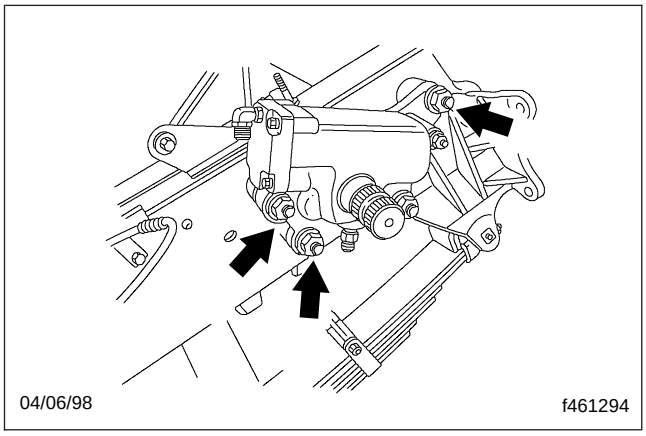

Fig. 4, Nuts and Bolts

Removal and Installation

Installation

1. Position the rotary assist cylinder and install the four retaining nuts and bolts. Tighten 360 to 480 lbf·ft (488 to 650 N·m). See **Fig. 4**.
2. Install the pitman arm. For instructions, see **Section 46.01, Subject 120**.
3. Install the power steering hose fittings and tighten 31 to 42 lbf·ft (42 to 57 N·m). See **Fig. 3**.
4. Connect the hydraulic fluid lines to the rotary assist cylinder. Tighten 31 to 42 lbf·ft (42 to 57 N·m). See **Fig. 2**.
5. Fill the system with the recommended hydraulic oil. See **Specifications 400** for approved power steering fluids. Bleed the air from the power steering hydraulic system.

Disassembly

⚠ WARNING

Wear eye protection and be sure to comply with OSHA or other maximum air pressure requirements.

⚠ CAUTION

Never steam clean or high-pressure wash hydraulic steering components. Do not force or abuse closely fitted parts, or component damage can result.

NOTE: The special tools used in this procedure are available from SPX Kent-Moore, Warren, MI 48092, 800-328-6657.

NOTE: Thoroughly clean and dry the rotary assist cylinder before disassembly. During disassembly of the rotary assist cylinder, clean all parts in fresh, petroleum base solvent, and blow dry. Keep each part separate to avoid nicks and burrs.

See **Fig. 1** for an exploded view of the rotary assist cylinder gear.

1. Put the cylinder in a vise, clamping firmly against the housing mounting flange or boss.

   The piston bore should be horizontal and the side cover and end cover are accessible for disassembly. See **Fig. 2**.

2. Place a suitable container under the gear, then unplug the hydraulic ports. See **Fig. 3**.
3. Rotate the sector shaft until the timing mark on the end of the sector shaft is in line with the timing mark on the end of the housing.

   This will position the sector shaft for removal (rotary cylinder is now in its center of travel). See **Fig. 4**.

4. Remove and discard the dirt and water seal from the housing trunnion. See **Fig. 5**.
5. Remove any paint or corrosion from the exposed area of the sector shaft, using a fine grade emery cloth. See **Fig. 6**.
6. Tape the serrations and bolt groove of the sector shaft with one layer of masking tape.

   The tape should not extend onto the sector shaft bearing diameter. See **Fig. 7**.

7. Remove the sector shaft adjusting screw jam nut. See **Fig. 8**.
8. Remove the six special bolts from the side cover. See **Fig. 9**.
9. Remove the side cover and sector shaft assembly from the cylinder.

   Start the shaft and cover assembly removal by tapping the end of the shaft lightly with a soft mallet or wooden hammer handle. See **Fig. 10**.

10. Remove and discard the side cover gasket. See **Fig. 11**.
11. Remove and discard the vent plug. See **Fig. 12** .
12. Turn the sector shaft adjusting screw clockwise through the side cover and pull the sector shaft out of the side cover. See **Fig. 13**.

IMPORTANT: Do not damage the bore or DU bushing when removing the seal.

13. Remove the seal.

    13.1 Clamp the side cover in a vise.

    13.2 Place a standard 5/8-inch or 11/16-inch, 3/8-inch drive socket in the center of the side cover.

    13.3 Pry the seal out with a rolling head pry bar, using the socket for support.

    13.4 Discard the seal and remove the socket.

NOTE: The retainer must be securely staked in place. The adjusting screw must rotate by hand with no perceptible end play (lash).

14. Inspect the sector shaft assembly for damaged adjusting screw threads. See **Fig. 14**.

NOTE: Mark the orientation of the end cover to the housing prior to removal of the end cover.

15. Remove the four Torx® head end cover bolts and the end cover. See **Fig. 15**.

IMPORTANT: The set position of poppet seat and sleeve assemblies must not be disturbed if the poppets are not going to be replaced or reset during disassembly.

16. Remove the piston subassembly and place it on a clean cloth. See **Fig. 16**.

23. Backup Piston O-Ring
24. Retaining Ring
25. Roller Bearing
26. Dirt Seal
27. Trunnion Dirt and Water Seal

Fig. 1, Rotary Assist Cylinder Gear

17. Remove and discard the end cover seal ring. See **Fig. 17**.
18. Cut and remove the Teflon® seal ring and O-ring from the piston. See **Fig. 18**.

NOTE: TRW recommends that the poppet adjuster seat and sleeve assemblies not be removed unless replacement of the poppet components is required.

19. Push the poppet stems and the poppet seat. The poppet stems should spring back and the poppet seats should not move by hand. See **Fig. 19**.

NOTE: If components are bent or broken, the poppet stems do not spring back, or the poppet seat moves by hand, proceed to the next step. If poppet component replacement is not necessary, skip the next nine steps.

20. Place the piston in a soft-jawed vise. See **Fig. 20**.

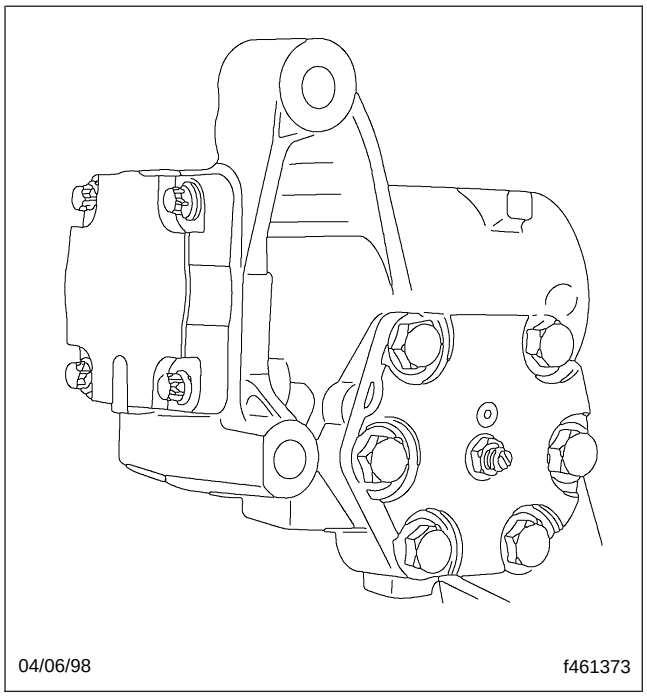

Fig. 2, Correct Position of the Steering Gear

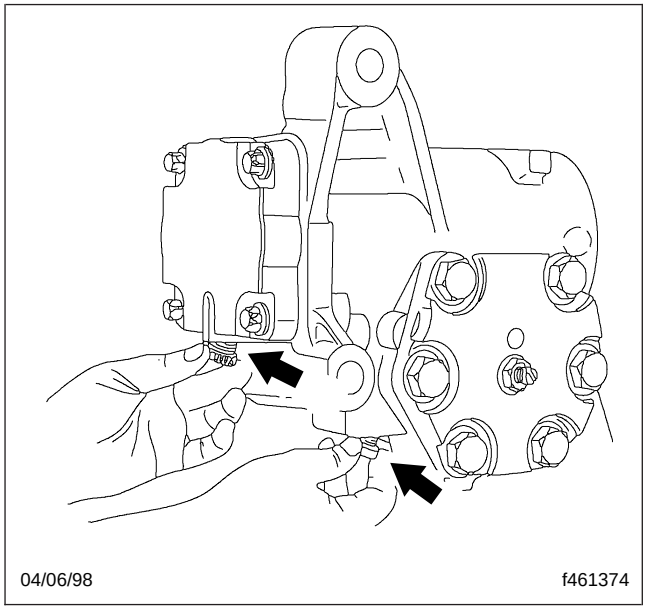

Fig. 3, Unplug the Hydraulic Ports

NOTE: Poppet adjuster seat and sleeve assemblies are retained by Loctite® applied to the threads, which makes the assemblies difficult to remove.

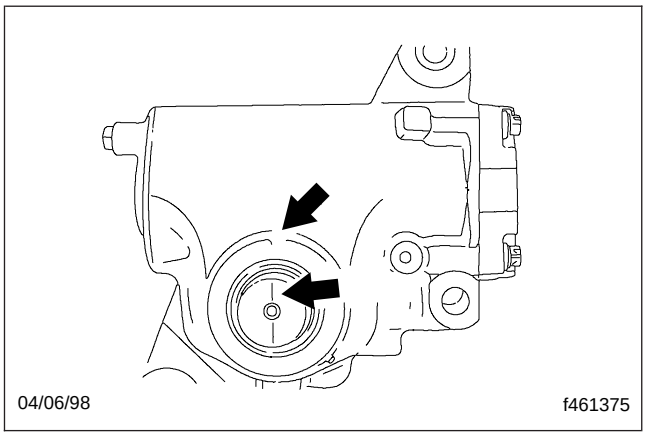

Fig. 4, Line Up the Timing Marks

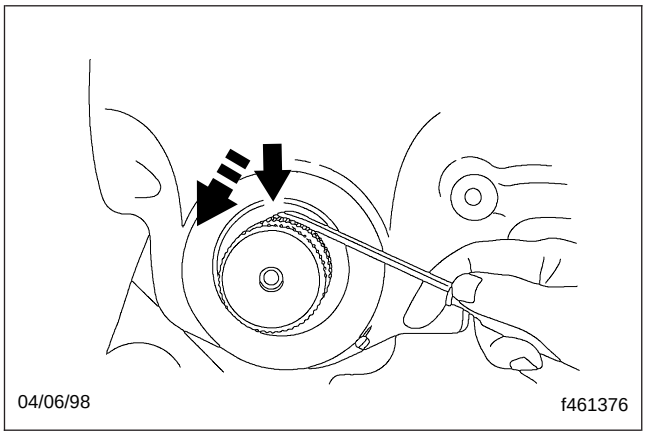

Fig. 5, Remove the Dirt and Water Seal

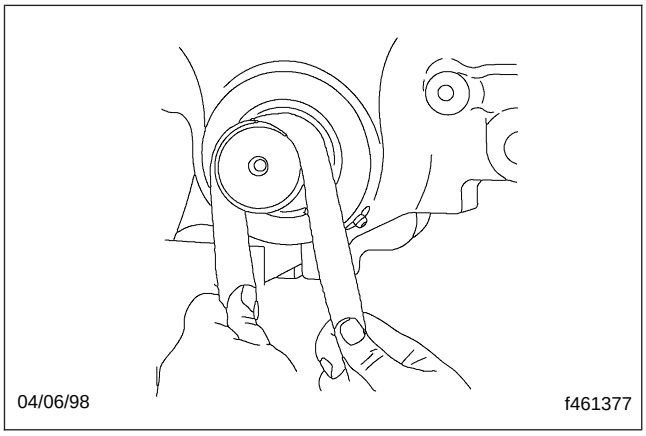

Fig. 6, Remove the Paint and Corrosion

Disassembly and Assembly

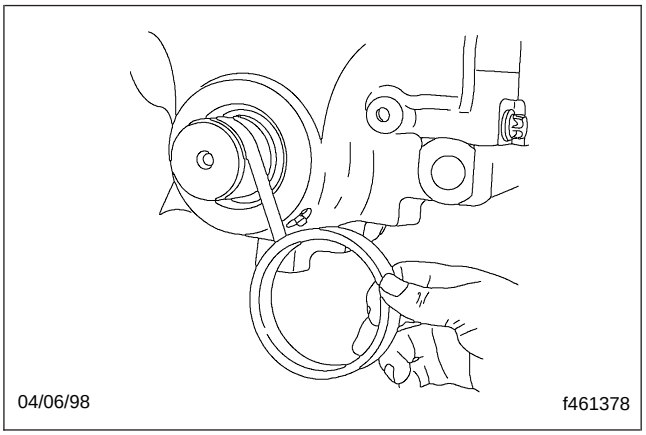

Fig. 7, Tape the Sector Shaft

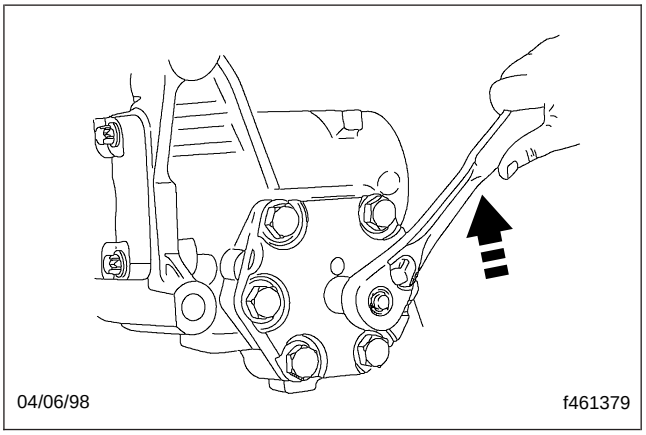

Fig. 8, Remove the Sector Shaft Screw Jam Nut

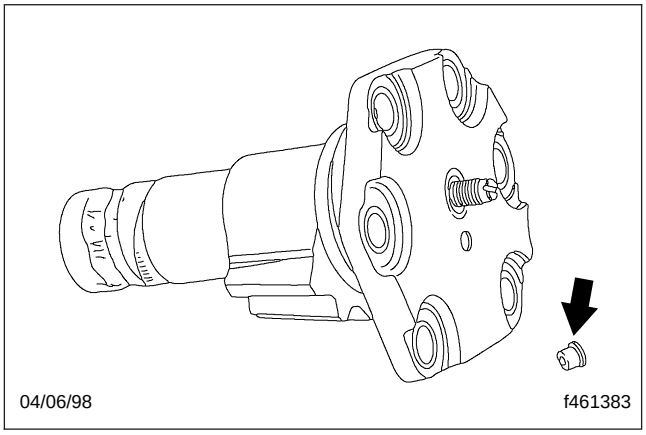

Fig. 12, Remove the Vent Plug

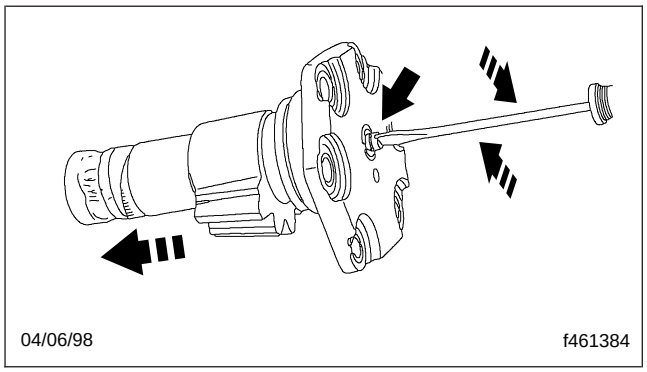

Fig. 13, Remove the Sector Shaft

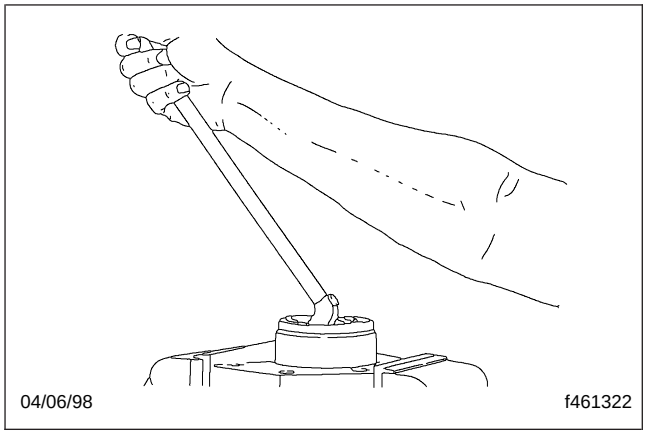

Fig. 14, Inspect the Sector Shaft Assembly

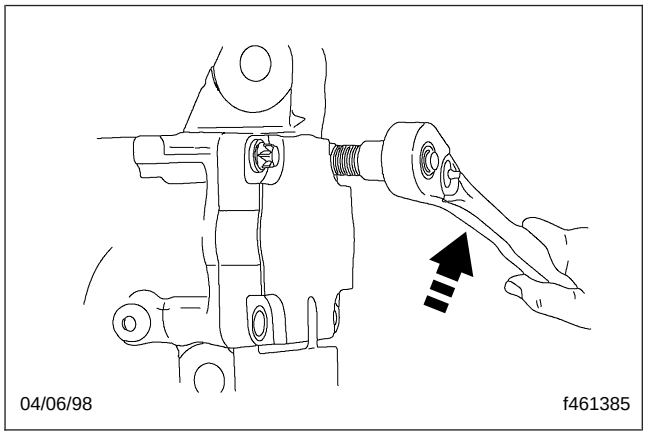

Fig. 15, Remove the End Cover

21. Slide the poppet adjusting seat tool over the seat of the poppet adjuster seat and sleeve assembly and engage the tool in the slots in the threaded sleeve.

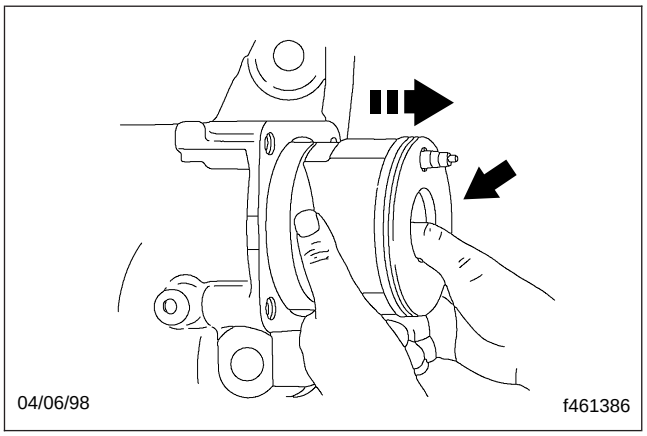

Fig. 16, Remove the Piston Subassembly

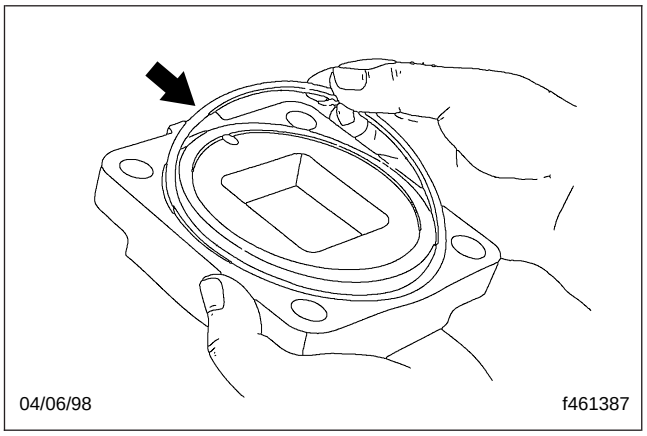

Fig. 17, Remove the End Cover Seal Ring

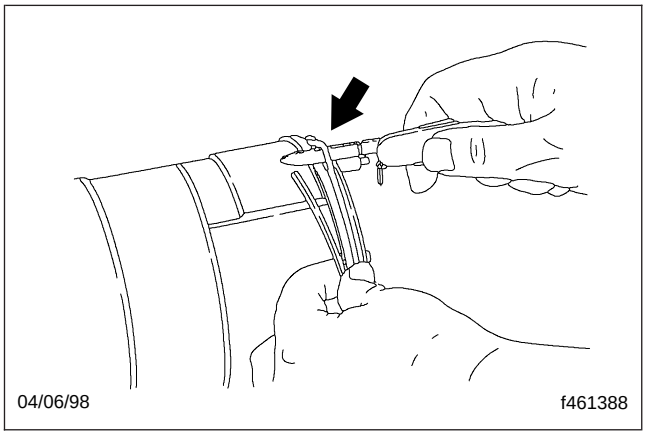

Fig. 18, Remove the O-Ring

Disassembly and Assembly

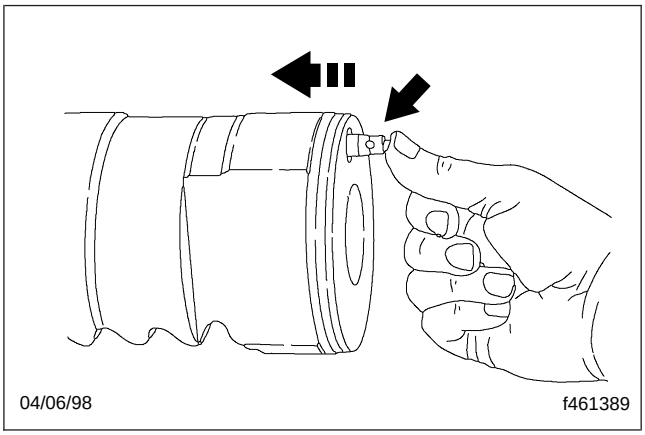

Fig. 19, Push the Poppet Stems and Seat

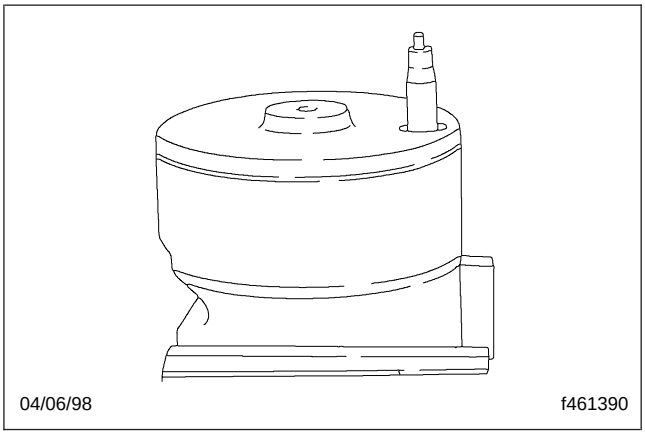

Fig. 20, Piston in a Soft-Jawed Vice

Hit the end of the tool firmly, four or five times with a 2-pound sledge hammer, to loosen the Loctite®. See **Fig. 21**.

22. With a ratchet applied to the tool, turn one adjuster seat and sleeve assembly out of the piston. See **Fig. 22**.

    22.1 If the ratchet does not turn easily, strike the adjuster removal tool again with a hammer.

    22.2 If the engaging tangs will not stay in place while loosening, it might be necessary to hold in place with an arbor press while applying loosening torque.

    22.3 Discard the poppet seat and sleeve assembly.

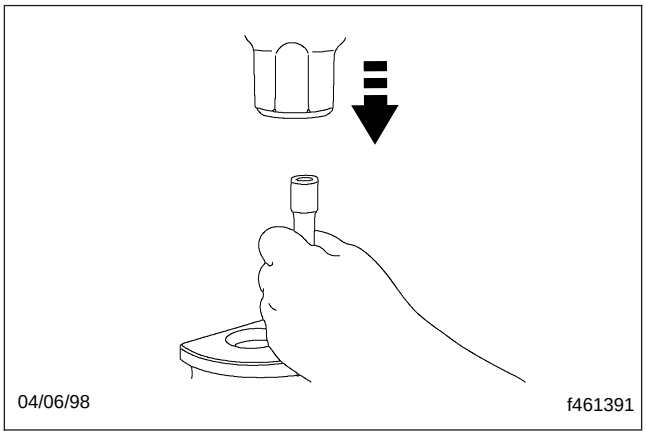

Fig. 21, Loosen the Poppet Adjuster Seat and Sleeve Assembly

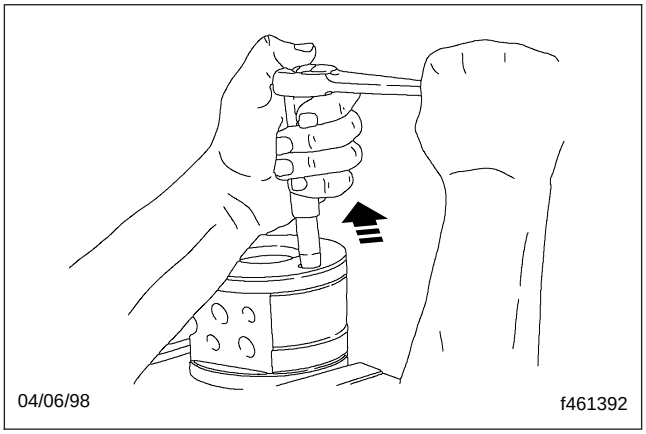

Fig. 22, Remove Seat and Sleeve Assembly from Piston

23. Remove the two poppets, spring, spacer rod, and push tube. See **Fig. 23**.

NOTE: It is possible to reset one poppet adjuster seat and sleeve assembly for automatic poppet adjustment while it is in the piston, if one adjuster seat and sleeve assembly and poppets, spring, spacer rod, and push tube are removed.

24. Remove and discard the remaining poppet seat and sleeve assembly only if required. See **Fig. 24**.

25. If one poppet seat and sleeve assembly was left in the piston, it can be reset for automatic poppet adjustment by inserting a 3/8-inch diameter x 6-inch (9.52 x 152.4 mm) drill rod down through the poppet seat hole at the opposite end of the

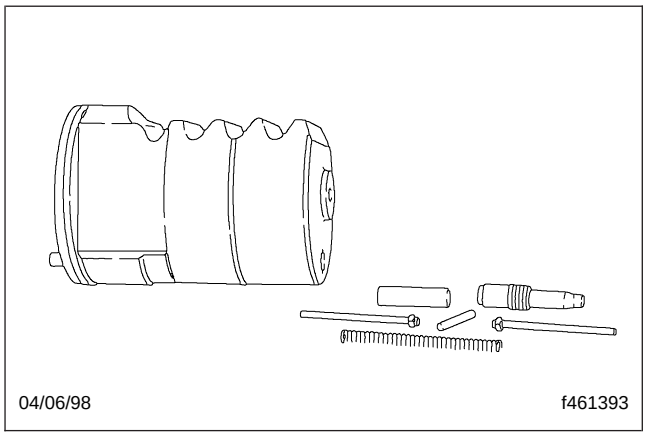

Fig. 23, Poppet Assembly Removed

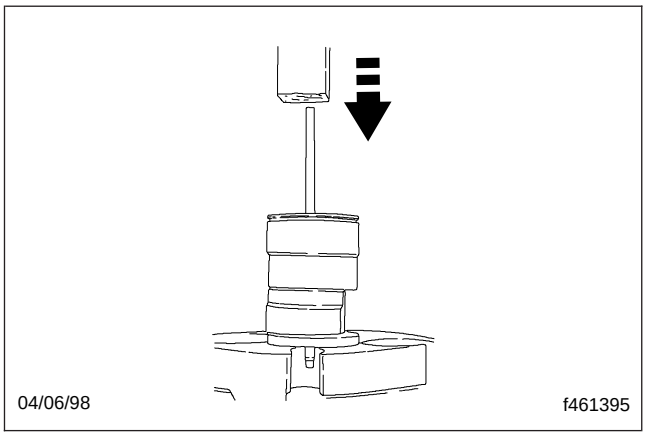

Fig. 25, Reset Poppet Assembly

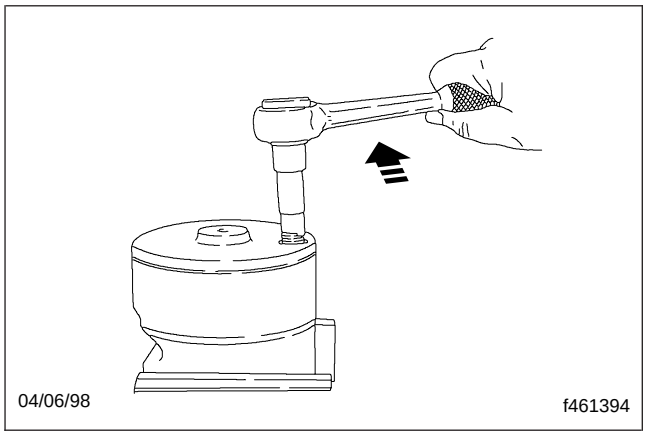

Fig. 24, Remove Remaining Poppet Assembly

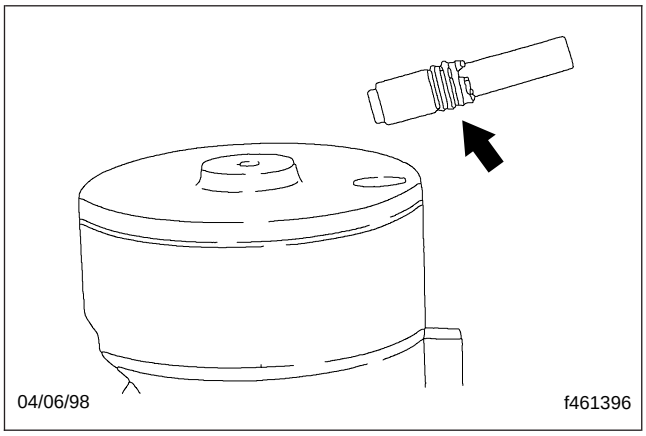

Fig. 26, Poppet Threads

piston and against the adjuster seat, to press the seat in until it bottoms against the adjuster sleeve. See **Fig. 25**.

CAUTION

Do not allow Loctite® or Locquic® to get on the adjuster seat and sleeve assembly. The poppets will not function properly.

26. Carefully apply Locquic® T primer or equivalent to the threads in poppet holes and threads on the new seat and sleeve assemblies. Allow to dry for 10 minutes, then carefully apply Loctite® RC680 or equivalent to same threads. See **Fig. 26**.

WARNING

Wear eye protection while assembling poppets. Spring-loaded poppets could eject and cause eye injury.

27. Place the piston in a soft-jawed vise and turn one new poppet adjuster seat and sleeve assembly, with slotted end out, into the poppet hole in one end of the piston. See **Fig. 27**.
28. From the other end of the poppet hole in the piston, install one poppet, poppet spring, nylon spacer rod, push tube, the other poppet, and the other new poppet adjuster seat and sleeve assembly.

Disassembly and Assembly

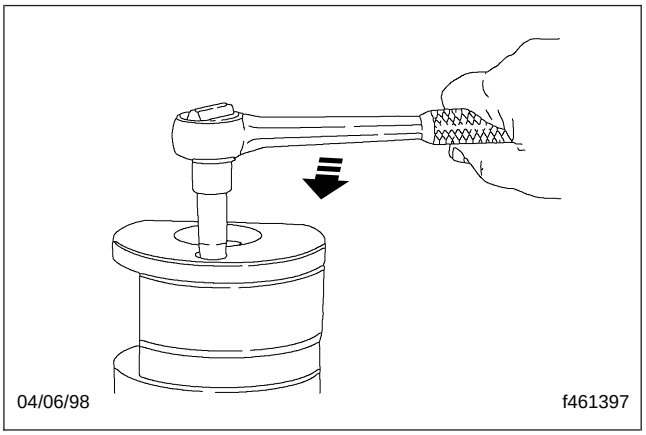

Fig. 27, Install the Poppet Assembly

Using the poppet adjusting seat tool and a torque wrench, tighten both the poppet adjuster seat and the sleeve assemblies to 18 lbf·ft (25 N·m).

29. Remove the retaining ring that is closest to the output end of the housing trunnion. See **Fig. 28**.

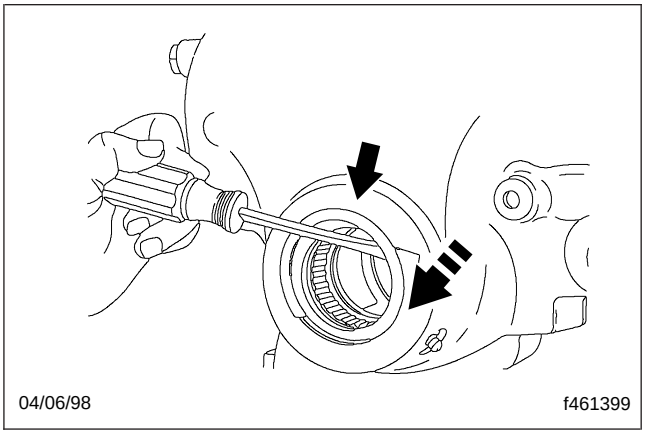

Fig. 28, Remove the Retaining Ring

30. Remove and discard the dirt seal. See **Fig. 29**.

NOTE: Be careful not to damage the sealing area of the bore or the spacer washer when performing this step.

31. Insert a screwdriver into the housing bearing bore from the trunnion end and carefully push the seal and spacer washer out of the other end of the bearing bore. Discard the seal. See **Fig. 30**.

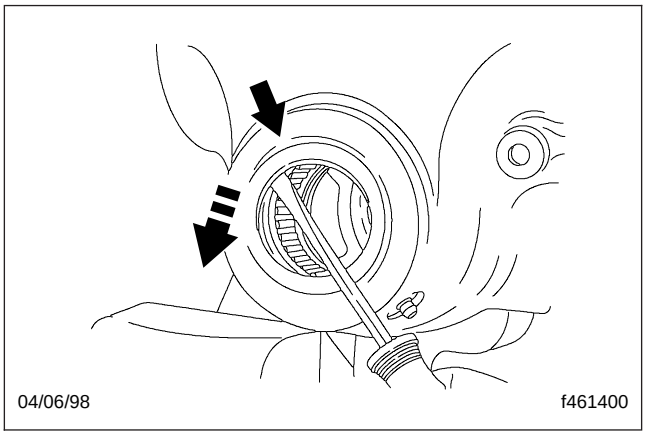

Fig. 29, Remove the Dirt Seal

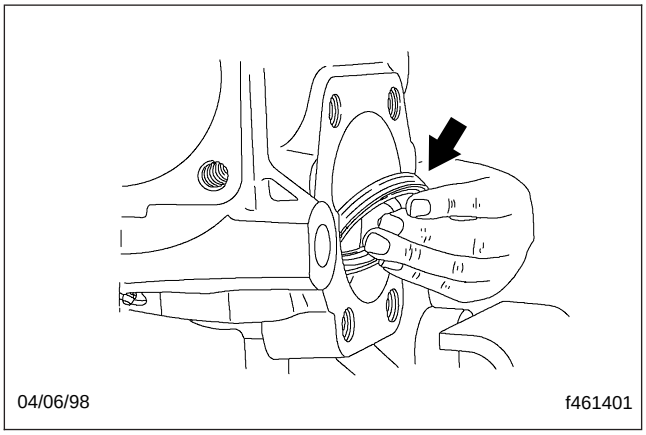

Fig. 30, Remove the Seal and Spacer Washer

32. Inspect the roller bearing in the housing for brinelling or spalling and the retaining ring for damage.

⚠ CAUTION

The bearing must be pressed out from the side cover side to protect the seal counterbore. Be sure to use a bearing removal tool that will clear the retaining ring.

33. If the roller bearing in the housing needs to be replaced, place the bearing removal end of the bearing and seal tool against the side cover end of the bearing and press it out of the trunnion end of the bearing bore. Discard the bearing. See **Fig. 31**.

34. If the retaining ring that is still in the housing bore needs to be replaced, remove it through the

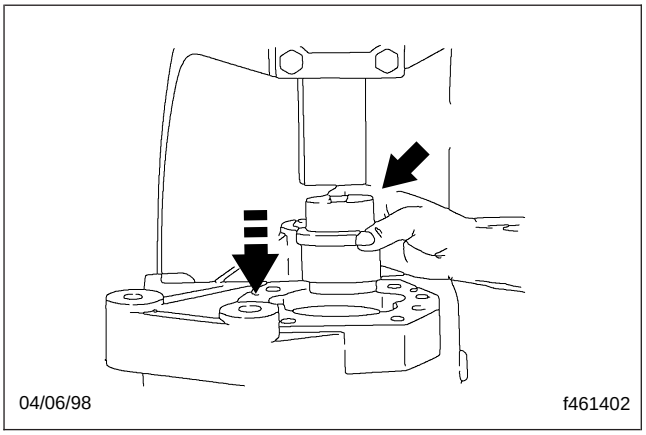

Fig. 31, Remove the Roller Bearing

trunnion end of the bearing bore, to protect the pressure seal bore area from being damaged. See **Fig. 32**.

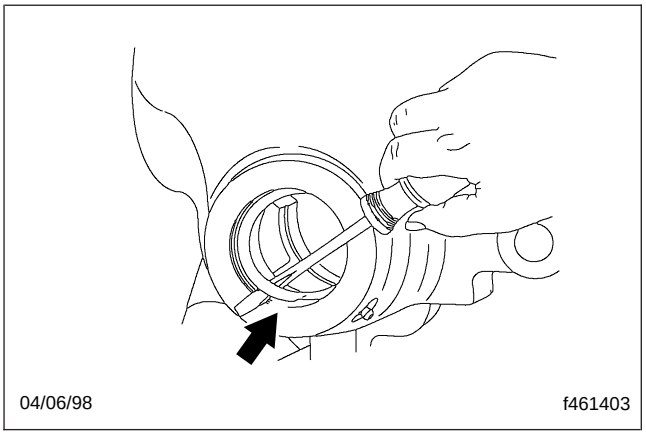

Fig. 32, Remove the Retaining Ring

Assembly

1. Insert the retaining ring, if it was removed, into the housing bore from the trunnion end, to protect the sealing area.

   Verify that the retaining ring is seated in the retaining ring groove closest to the side cover end of the bearing bore.

   Lubricate the bearing bore. See **Fig. 33**.

⚠ CAUTION

Use the bearing installation end of the tool. If the bearing removal end of the bearing and seal tool

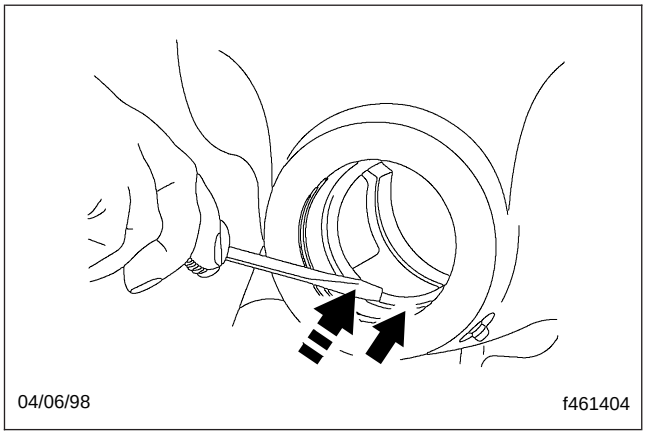

Fig. 33, Install the Retaining Ring

is used to press in the bearing, the cage on the new bearing can be damaged.

2. Press the roller bearing into the housing from the trunnion end of bearing bore, using the installation end of the bearing and seal tool, until it is seated against the retaining ring.

   Verify the housing is square with the press base and the bearing is not cocked. See **Fig. 34**.

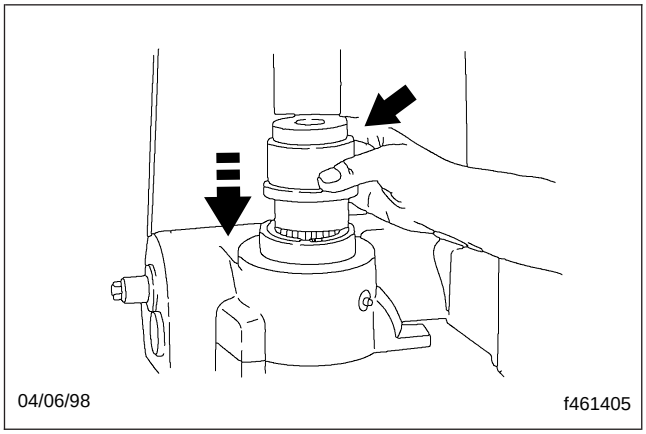

Fig. 34, Install the Roller Bearing

NOTE: Perform an inspection of the components prior to assembling the rotary steering gear.

3. Inspect the poppet fixed stop screw or poppet adjusting screw for damage.

NOTE: If damaged, remove the fixed poppet stop screw and sealing nut without allowing the nut to change its position on the screw.

Disassembly and Assembly

4. Assemble the new nut onto the adjusting screw, matching its position to the nut and screw removed. Tighten the sealing nut to 35 lbf·ft (47 N·m).
5. Install a new dirt seal into the trunnion end of the housing sector shaft bore and against the bearing, with the seal lip out. See **Fig. 35**.

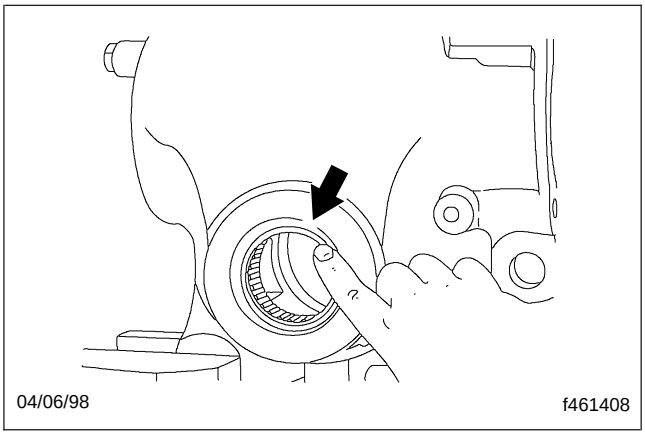

Fig. 35, Install the Dirt Seal

6. Install the second retaining ring, seating it firmly in the housing retaining ring groove. See **Fig. 36**.

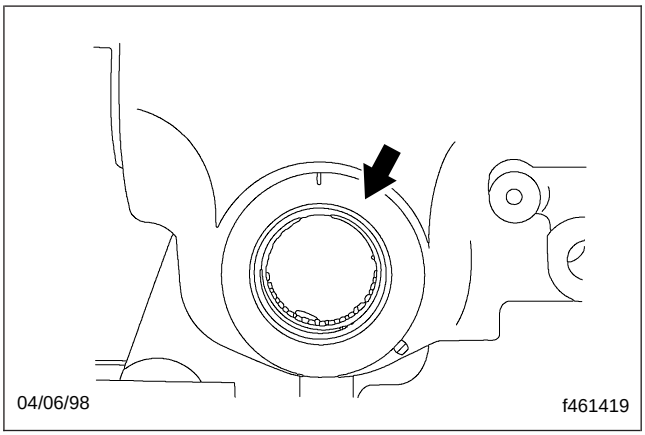

Fig. 36, Install the Second Retaining Ring

7. Install the washer into the side cover side of the housing seal bore, with the small diameter piloted into the retaining ring. See **Fig. 37**.
8. Liberally pack the area between the dirt seal and the pressure seal, including the roller bearing, with clean high temperature front axle and wheel bearing grease E8TZ–19590–A or equivalent meeting specification ESA–M1C198–A. See **Fig. 38**.

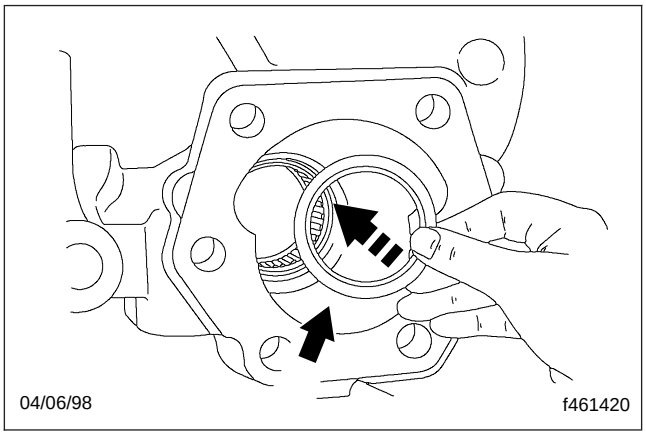

Fig. 37, Install the Washer

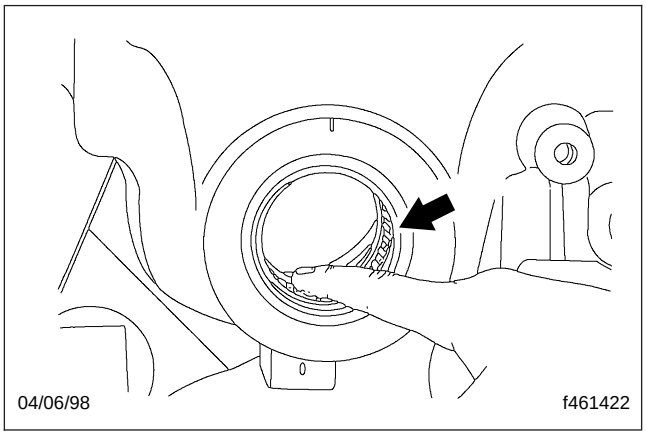

Fig. 38, Grease the Dirt Seal and the Pressure Seal

9. Oil a new seal ring and assemble in the end cover mounting face groove. See **Fig. 39**.

NOTE: Do not overstretch these rings as you install them. Do not allow the Teflon® seal ring to become twisted.

10. Install a new backup O-ring and then a new Teflon® seal ring on the piston. See **Fig. 40**.

NOTE: Do not damage the seal ring while installing the piston into the housing.

NOTE: The poppet seat and sleeve assemblies must not bottom out against the internal poppet stops in the steering gear until the gear is in-

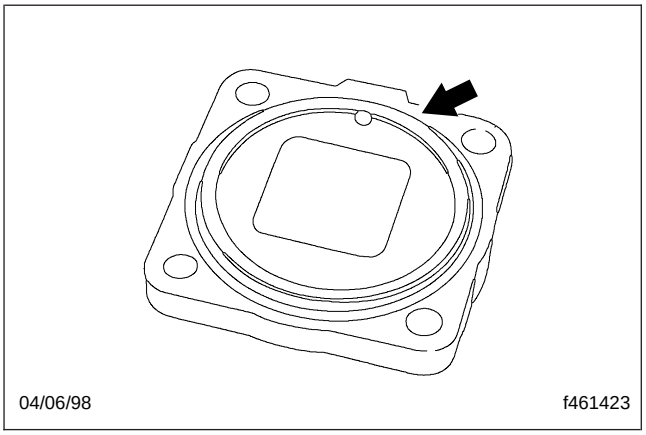

Fig. 39, Seal Ring

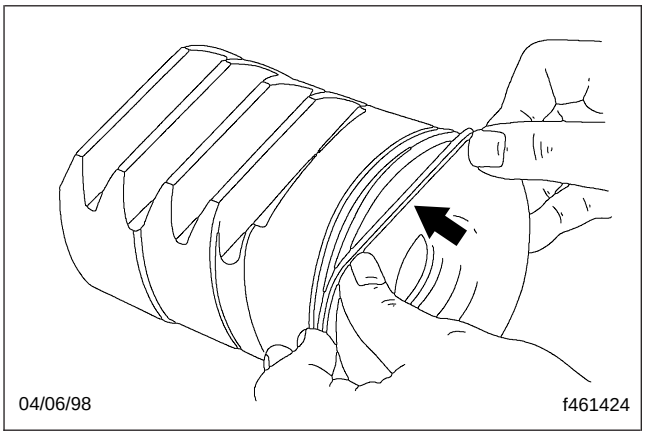

Fig. 40, Install the New Rings

stalled on the vehicle and the poppet adjustment procedures are performed.

11. Apply clean oil to the housing cylinder bore and Teflon® seal ring on the piston. Place the piston in the housing piston bore with piston teeth toward the sector shaft opening. See **Fig. 41**.
12. Lubricate and install the four end cover bolts in the housing. Tighten the bolts to 80 lbf·ft (108 N·m). See **Fig. 42**.

NOTE: Do not use grease.

13. Lightly oil the DU bushing. See **Fig. 43**.

NOTE: Assemble a new seal on the bearing and seal tool so that the lip with the garter spring is toward the shoulder of the tool.

14. Working from the side cover side of the housing, pilot the seal tool into the washer and bearing

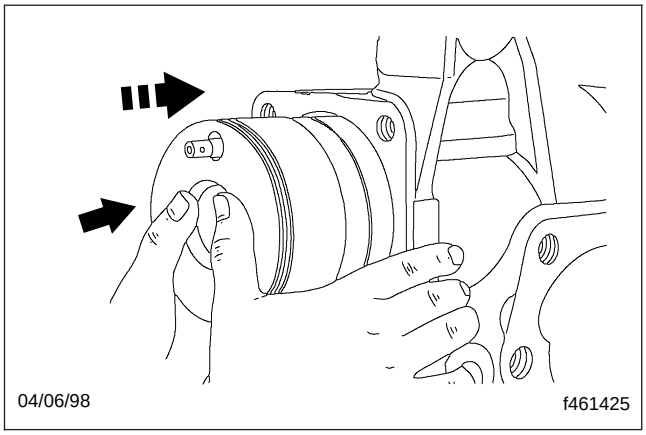

Fig. 41, Install the Piston

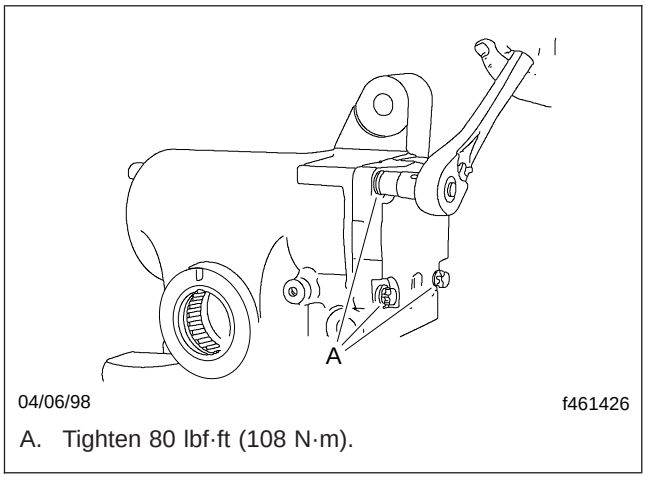

A. Tighten 80 lbf·ft (108 N·m).

Fig. 42, Install the End Cover Bolts

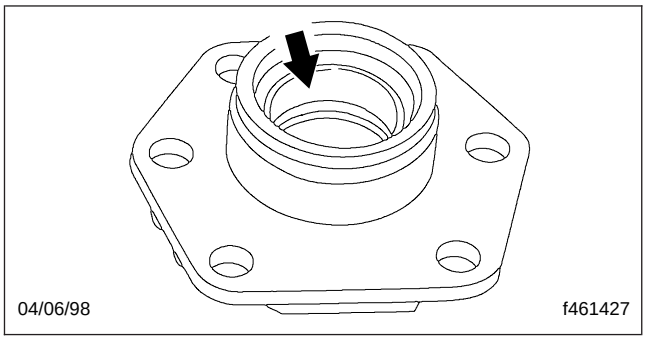

Fig. 43, DU Bushing

and press with a force of 100 to 800 lbf (445 to 3500 N) until seated against the washer. See **Fig. 44**.

Disassembly and Assembly

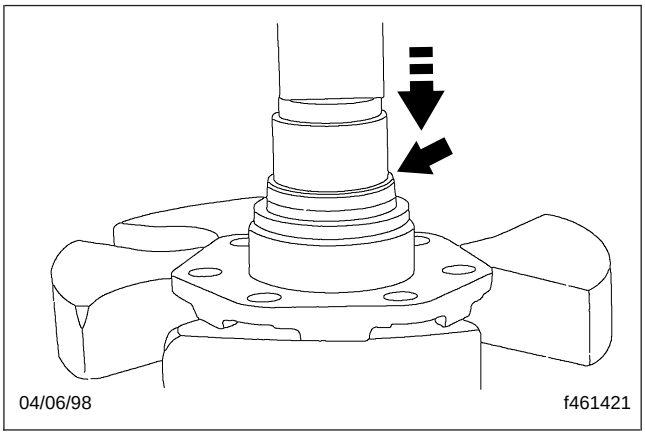

Fig. 44, Press the Seal Tool into the Washer and Bearing

15. Lightly oil the short bearing area of the sector shaft. See **Fig. 45**.

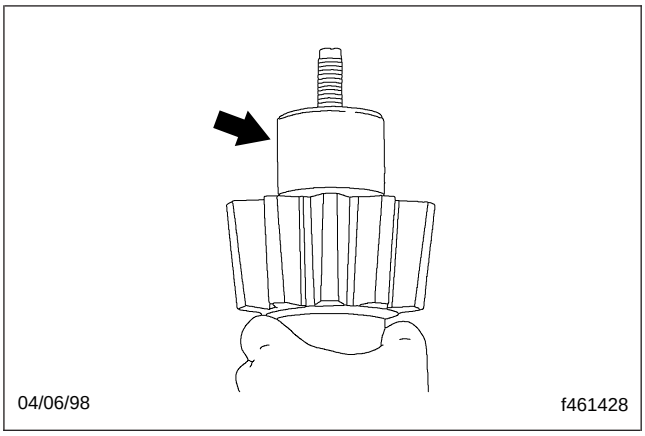

Fig. 45, Short Bearing Area of the Sector Shaft

16. Insert the sector shaft into the side cover subassembly and screw the sector shaft adjusting screw counterclockwise into the side cover, until the screw reaches solid height. See **Fig. 46**.
17. Install the sector shaft adjusting screw jam nut onto the sector shaft adjusting screw a few threads. The final adjustment will be made later. See **Fig. 47**.

⚠ WARNING

Do not weld or otherwise plug the vent in any permanent manner. This is a safety vent which functions only if the side cover fails. If the seal

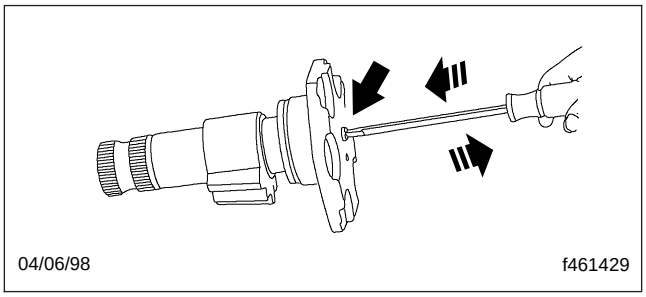

Fig. 46, Insert the Sector Shaft

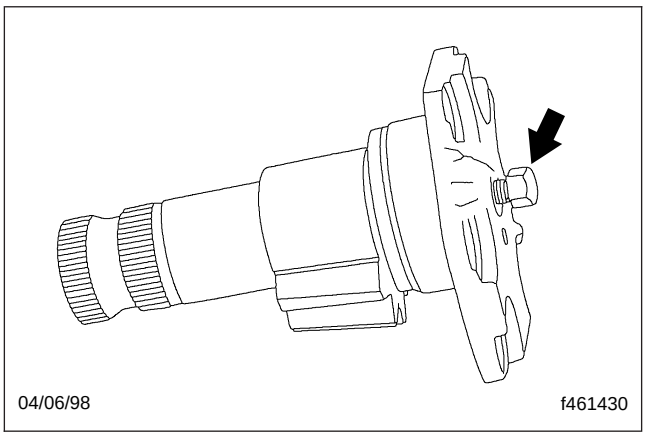

Fig. 47, Sector Shaft Adjusting Screw Jam Nut

fails and the plug cannot vent, the cylinder may lock up or otherwise function improperly.

18. Press the new vent plug into the hole provided in the side cover until the plug is bottomed. See **Fig. 48**.

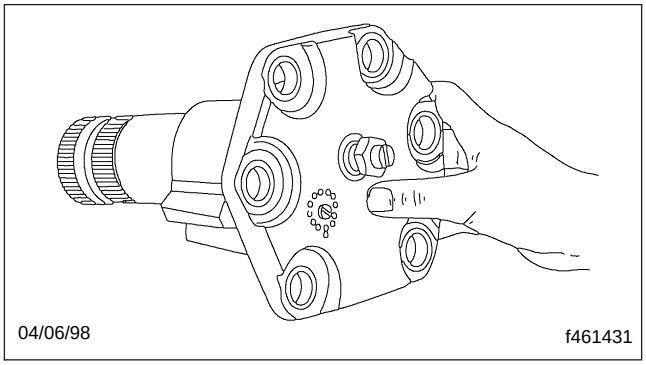

Fig. 48, Install the New Vent Plug

19. Apply clean grease to the new side cover gasket to hold it in place and assemble it onto the side cover. See **Fig. 49**.

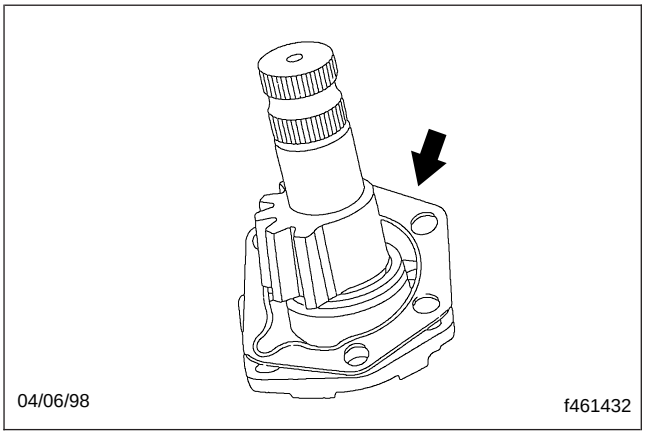

Fig. 49, New Side Cover Gasket

WARNING

If the piston is not centered when the sector shaft is installed, gear travel will be severely limited in one direction, which could result in an accident.

NOTE: There are four teeth on the piston.

20. Position the piston so the space between the second and third teeth is in the center of the sector shaft opening.

    This will center the piston for assembly of the sector shaft. See **Fig. 50**.

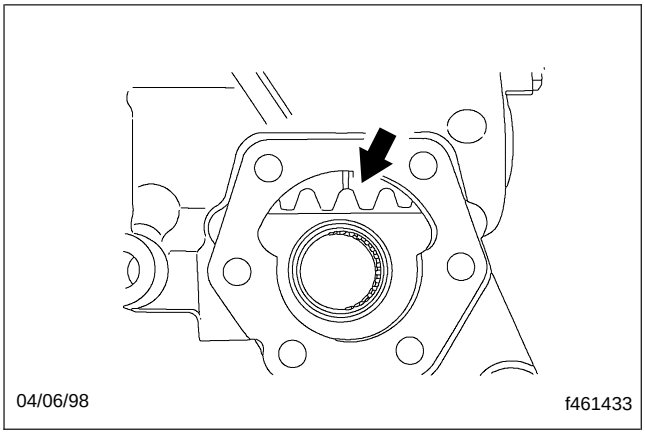

Fig. 50, Position the Piston

CAUTION

If the serrations are not properly taped, they will damage the output seal in the housing, causing the seal to leak.

NOTE: The center tooth of the sector shaft must engage the center space between the second and third teeth of the piston, with the side cover gasket in place.

21. Install the sector shaft assembly into the housing.

    Clean off any old tape on the serrations and reapply one layer of masking tape.

    Rock the sector shaft for ease of assembly, if necessary. See **Fig. 51**.

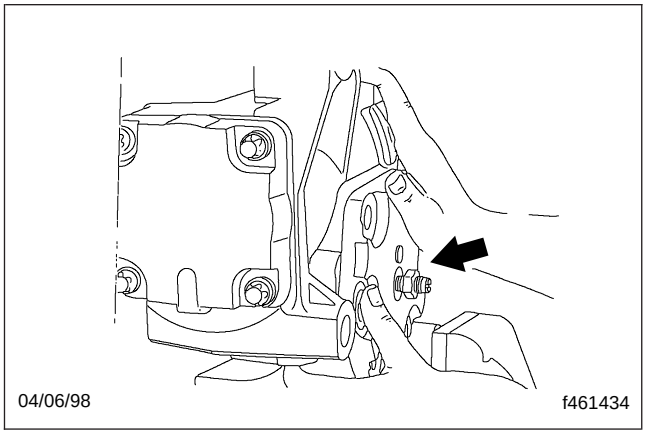

Fig. 51, Install the Sector Shaft Assembly

NOTE: If bolts must be replaced, use bolts of the same design, type and length as those removed. Do not use a substitute.

22. Lubricate and install the special side cover bolts into the side cover and tighten them in sequence, as shown. Tighten bolts to 170 lbf·ft (230 N·m). See **Fig. 52**.

NOTE: Remove tape from the sector shaft and pack the end of the housing trunnion area at the sector shaft with clean, high-temperature industrial grease, Mobil® Temp 1 or 2 or equivalent.

23. Apply the grease to the inside of the new trunnion dirt seal and assemble it over the sector shaft and into the trunnion. See **Fig. 53**.

Disassembly and Assembly

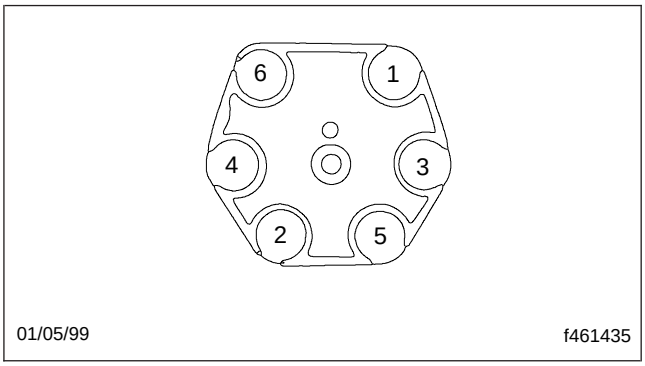

Fig. 52, Tightening Sequence

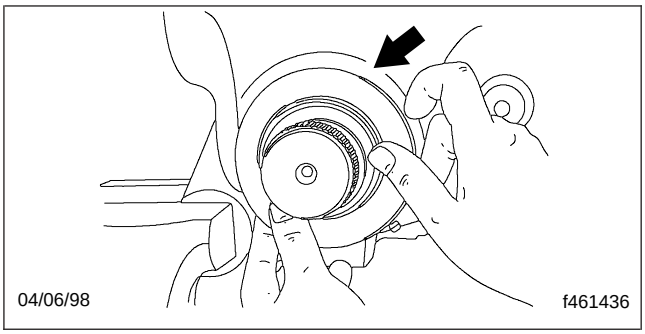

Fig. 53, Install the New Trunnion Dirt Seal

Adjustments

1. To center the steering gear, rotate the sector shaft until the timing mark on the end of the sector shaft is in line with the timing mark on the end of the housing trunnion. See **Fig. 1**.

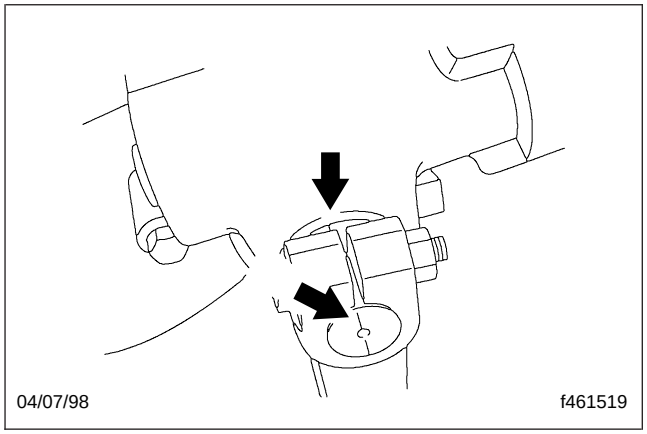

Fig. 1, Center the Steering Gear

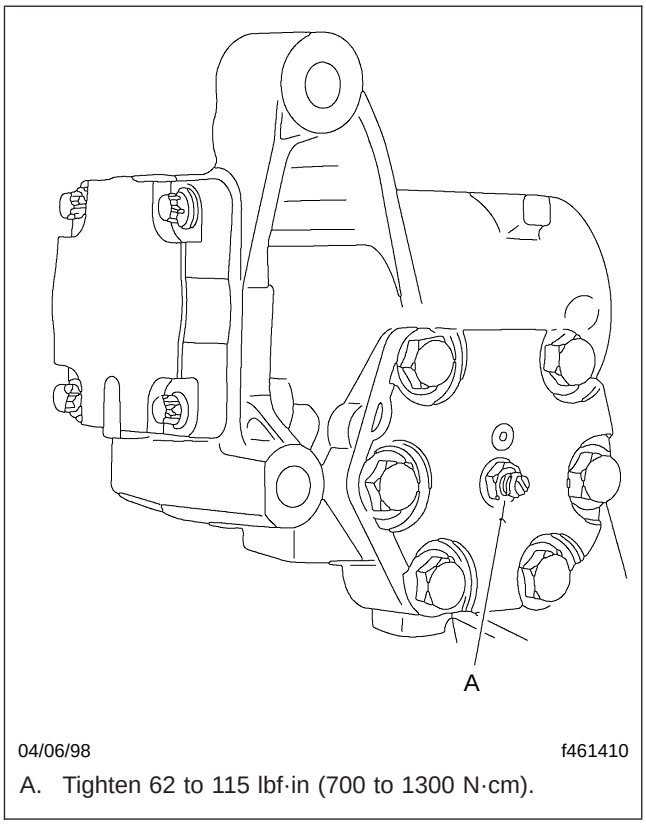
2. Tighten the side cover adjusting screw to 62 to 115 lbf·in (700 to 1300 N·cm), then back the screw out one-half turn. See **Fig. 2**.
3. Check the torque to rotate sector shaft through approximately 20 degrees each side of center.
4. Screw in the adjusting screw to provide a torque as specified over the previously established torque as the sector shaft passes through center. See **Fig. 3**.
5. Tighten the jam nut to 40 to 80 lbf·in (450 to 900 N·cm). See **Fig. 4**.

NOTE: The torque to rotate the sector shaft must not exceed 30 lbf·ft (41 N·m) at any point during travel of the cylinder.

6. Using a suitable spring scale, measure the sector shaft travel.

Poppet Valve Manual Adjustment, 9000-lb (4082-kg) Front Axles Only

NOTE: The adjuster tool (J37070) and the adjuster locknut tool (J37464) are available from SPX Kent-Moore, Warren, MI, 48092 800-328-6657.



A. Tighten 62 to 115 lbf·in (700 to 1300 N·cm).

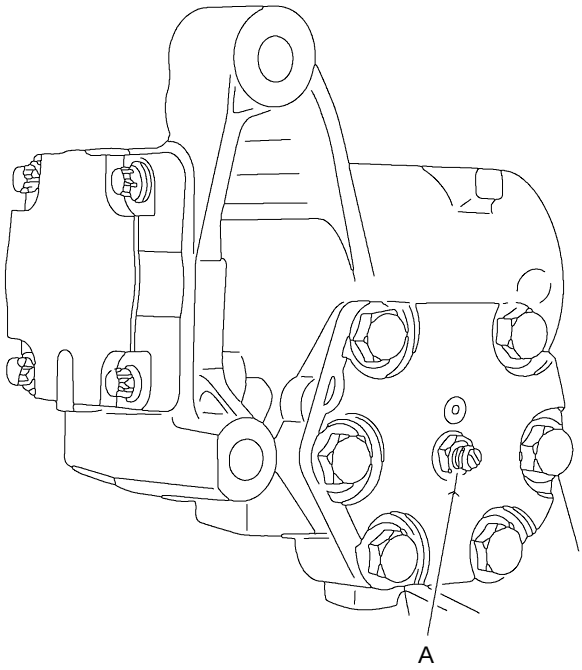
Fig. 2, Adjusting Screw

NOTE: This resetting procedure will work in most cases with at least 1-3/4 hand wheel turns from side to side of center. If making a large reduction in wheel cut and this procedure does not work, the poppets may need to be internally reset.

NOTE: The steering gear is equipped with two hydraulic pressure-relieving poppet valves that were automatically set to trip, relieving pressure just before reaching the axle stops. This was achieved after initial installation into the vehicle at the first full right and left turns. The pressure-relieving poppet valves will automatically reset themselves within the poppet adjustment limits if the axle stops are reset for increased steering gear travel based on acceptable equipment revisions from original factory installations.

1. To determine if the poppets require readjustment or if they are performing properly, install a Power Steering System Analyzer (PSSA) between the

Adjustments



04/06/98 f461411

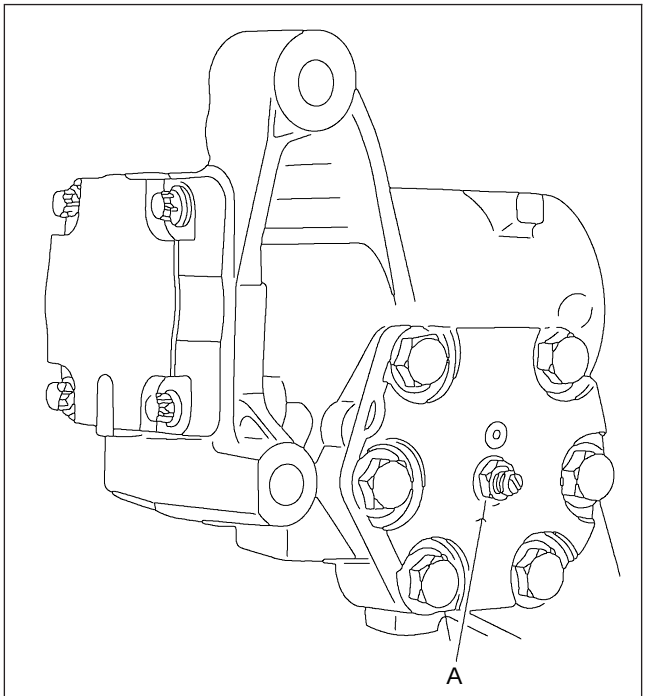
A. Tighten 62 to 115 lbf·in (700 to 1300 N·cm).

Fig. 3, Screw In the Adjusting Screw

power steering pump and the steering gear. If poppet readjustment is necessary, you can leave the PSSA in the system to verify that the following procedure is completed properly.

2. Poppets might need to be readjusted if the following conditions exist:
   - changing to larger tires
   - reduced vehicle wheelcut
   - pitman arm mistimed, condition corrected
   - steering gear being installed on a different truck
   - steer axle stop bolt(s) were bent or broken
   - steer axle U-bolt(s) were bent or broken

NOTE: The steering gear will have either a fixed stop screw or an adjusting screw. If the adjusting screw is already part of the steering gear,



04/06/98 f461412

A. Tighten 40 to 80 lbf·in (450 to 900 N·cm).

Fig. 4, Jam Nut

back the nut off the adjusting screw until it is flush with the end of the adjusting screw. See **Fig. 5**.

NOTE: Only perform the following step with the wheels in the straight-ahead position, the steering gear in its center position and only when the timing marks on the end of the sector shaft and the housing trunnion are aligned.

NOTE: An alternate method of manually resetting the poppet valves with the steering gear installed in the vehicle is done by using TRW special service tools, poppet adjuster tool and adjuster locknut tool.

3. Check the maximum turn angle of the front wheels. Refer to **Group 32** in this manual for the correct specifications.
4. Turn adjusting tool into the nonsealing end of adjuster locknut tool until the drive end of the screw is flush with the nut. See **Fig. 6**.

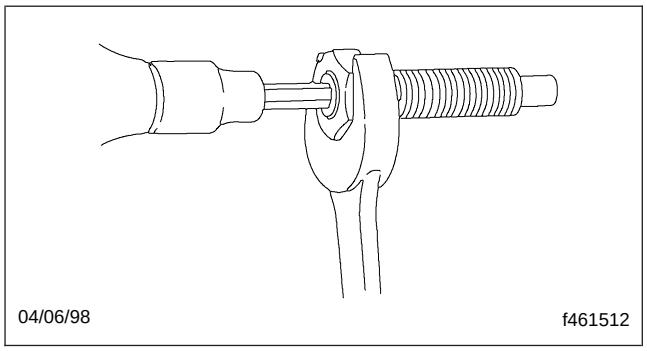


Fig. 5, Back the Nut Off of the Adjusting Screw

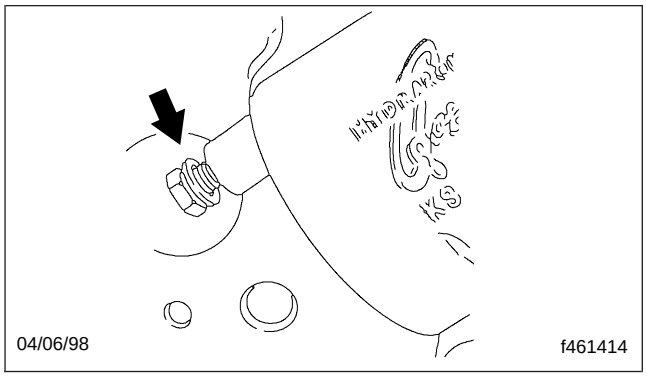

Fig. 6, Turn the Adjuster Locknut

NOTE: If the unit has a poppet adjusting screw and sealing nut that need to be replaced, remove and discard them.

5. With the vehicle unloaded, the engine off and the wheels in the straight-ahead position, remove and discard the fixed stop screw, if so equipped, and the washer from the lower end of the housing.
6. Install the adjusting screw and the sealing nut assembly (without moving the nut on the screw) into the housing until the nut is firmly against the housing. Tighten the sealing nut against the housing. See **Fig. 7**.

⚠ CAUTION

Do not mix fluid types. Mixing transmission fluid, motor oil, or other hydraulic fluids will cause seals to deteriorate faster.

7. Fill the power steering reservoir with the specified fluid, Motorcraft Mercon® ATF XT–2–QDX or Mercon® equivalent.

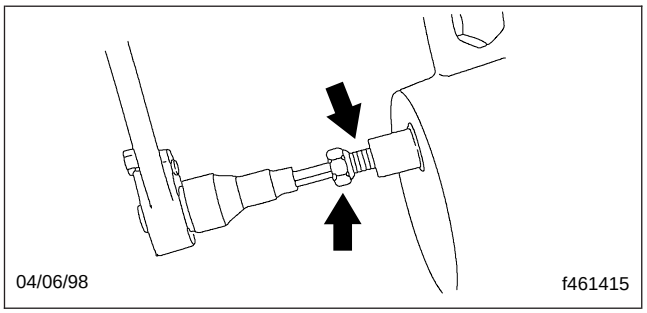

Fig. 7, Tighten the Sealing Nut Against the Housing

8. Place a jack under the center of the front axle and jack up the front end of the vehicle so the steering axle tires are off the ground.
9. Start the engine and let it run at idle speed.
10. Note which output shaft timing mark is nearest the housing piston bore.
11. Turn the steering wheel to make right-hand turn (which makes the pitman arm turn in a counterclockwise direction toward the poppet adjusting screw). Turn in this direction until axle stop contact is made.
12. Pull hard on the steering wheel (put 30 pounds of rim pull on a 20-inch diameter steering wheel) after the axle stop is contacted.
13. Turn the steering wheel in the opposite direction (end of timing mark away from the adjusting screw) until the other axle stop is contacted.
14. Pull hard on the steering wheel. Put 44 pounds of rim pull on an 18-inch diameter steering wheel.
15. Release the steering wheel and shut off the engine. Do not steer again until instructed to do so.
16. Loosen the sealing nut and back out the adjusting screw until it is past the nut. Tighten the sealing nut against the housing.
17. Start the engine and let it idle.

⚠ CAUTION

Do not hold the steering wheel in this position for more than 10 seconds at a time. Excessive heat buildup can damage components.

18. Turn the steering wheel in the original direction (end of timing mark toward adjusting screw), until axle stop contact is made.

Adjustments

19. Hold the steering wheel in this position (with 30 pounds rim pull) for 10 seconds, then release. Repeat this hold and release process as many times as necessary.
20. With the steering wheel held at full-lock position, loosen the jam nut and hold it in place with a wrench.

NOTE: Do not attempt to turn further.

NOTE: Pause the turning of the adjusting screw each time the driver releases the steering wheel. Continue turning only while the wheel is held at full turn.

21. Turn the adjusting screw clockwise using finger pressure only until the Allen wrench comes to a stop. Do not use a ratchet. See **Fig. 8**.

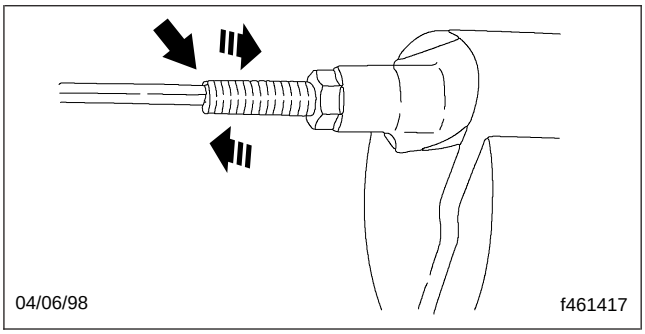

Fig. 8, Turn the Adjusting Screw Clockwise

22. Back off the adjusting screw 1-1/2 turns and tighten the sealing nut. Tighten the sealing nut 30 to 37 lbf·ft (40 to 50 N·m). See **Fig. 9**.

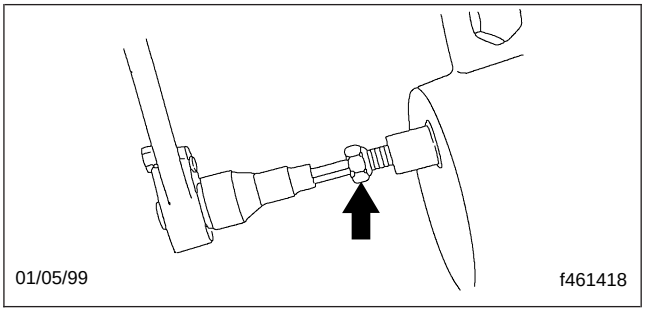

Fig. 9, Sealing Nut

23. Check the reservoir and fill if required.

IMPORTANT: The length of the adjusting screw beyond the nut must be on more than 1-1/16 inch for proper thread engagement.

NOTE: The length of the adjusting screw beyond the sealing nut may be different for each vehicle.

24. For vehicles equipped with a dual system, use the following procedure to set the poppets.

    TAS gear with slave gear—back out the poppet screws on the slave gear (RCS slave) so that 1 to 1-1/16 inch of poppet adjusting screw is protruding beyond the nut.
25. Set the main TAS gear using the procedures described above. Leave the adjusting screws on the rotary cylinders in place as described above after the poppets on the main gear have been reset.
26. Lower the vehicle.

General Information[1]

NOTE: Procedures contained in this section have been slightly modified from the original component manufacturer's service manual. If you are not clear on how to perform an operation, consult the component manufacturer's service literature before continuing a specific procedure.

The TRW THP60 power steering gear is an integral hydraulic power steering gear. An integral hydraulic power steering gear contains a manual steering mechanism, a hydraulic control valve, and a hydraulic power cylinder.

The rotary control valve controls the flow of hydraulic fluid through the steering gear. The speed at which the driver can turn the steering wheel with power assist is dependent on the pump flow directed to a cylinder cavity.

The pressure required for the steering gear to steer the vehicle is created by the power steering pump to overcome resistance at the steered wheels. The control valve senses these requirements and directs fluid to the appropriate cylinder cavity in the steering gear (and in the auxiliary cylinder if it is a dual steering system) at the proper flow rate and pressure.

The higher the pressure a steering gear can withstand, the more work it can perform. The maximum operating pressure for the THP60 gear is 2685 psi (18 512 kPa). The maximum flow rate is 8 gpm (30.3 L/min).

The THP60 power steering gear can steer a vehicle within its front axle weight rating through a turn at low speed and engine idle. As the steering wheel is turned faster or slower, more or less fluid will be required by the gear. The recommended minimum flow at 1.5 steering wheel turns per second is 2.6 gpm (9.8 L/min). The THP60 power steering gear is used for front axle capacities up to 13,300 pounds (6032 kg).

If the rotary control valve is controlling an auxiliary cylinder, increased minimum flow is required (generally at least 75 percent) based on the size of the auxiliary cylinder and the steering geometry of the vehicle.

Maximum internal leakage for the THP60 gear is 1.2 gpm (4.5 L/min).

Principles of Operation

When the steering wheel is turned, force is transmitted from the steering wheel to the steering gear input shaft. A torsion bar, pinned at one end to the input shaft and at the other end to the worm shaft, turns with the input shaft and exerts a rotational force on the worm shaft. In response, the worm shaft, acting through the recirculating ball mechanism, tries to move the rack piston on or along the axis through the gear housing cylinder bore.

The axial movement of the rack piston is resisted by its engagement to the sector shaft, which is connected by linkage to the steered wheels. Because of this resistance, the torsion bar is twisted by the input shaft, thereby actuating the control valve. Pressurized fluid, directed by the control valve, assists in moving the rack piston on or along the axis through the cylinder bore. The rack piston then turns the sector shaft to steer the vehicle.

If the steered wheels receive a shock load, the shock forces are transmitted through the sector shaft to the rack piston and on to the worm shaft. The internal construction of the steering gear causes the control valve to send high-pressure fluid to the correct cylinder cavity to resist the shock forces. By absorbing the shock forces hydraulically, the steering gear prevents kickback at the steering wheel.

Most THP steering gears are equipped with two poppet (unloading) valves, one at each end of the rack piston. One valve or the other, depending on the direction of the turn, will trip as the steered wheels approach the axle stops, which must be set to the manufacturer's specifications. The tripped valve reduces pressure in the gear and helps to reduce heat generated by the pump. At the same time, the valves also reduce forces on the steering linkage. These valves are automatically set to axle stops after installation in the vehicle at first full-right and first full-left turns.

Some THP steering gears with or without poppets are supplied with a relief valve. The relief valve limits maximum supply pressure to protect the power steering gear, but it does not reduce pressure as the steered wheels approach the axle stops.

[1] The illustrations in this section are provided by TRW Commercial Steering Systems and are used with permission.

General Information

Some THP steering gears that are mounted with the output shaft above the rack piston bore are equipped with either an automatic bleed system or a manual bleed screw. Most L-Line and A-Line vehicles have an automatic bleed system.

See **Fig. 1** for an exploded view of the THP steering gear.

Replacement

1. Verify that the axle stops are adjusted to the specifications in **Section 33.00**, Subject 110. Ensuring correct axle stop adjustment now will eliminate the possibility of resetting the steering gear poppets after the steering gear is replaced.
2. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance stopping at the spot where the work is to be done.
3. Turn off the engine, apply the parking brakes, chock the tires, and open the hood.
4. Disconnect the batteries at the negative terminals or at the battery shutoff switch.
5. Clean all the fittings and hose connections on the steering gear until they are free of dirt.
6. Drain the hydraulic fluid from the power steering system. Disconnect the hydraulic lines from the steering gear, marking the lines for later reference. Plug the lines and the fittings to keep out dirt.
7. Remove the bolts, nuts, and washers that attach the power steering reservoir to the mounting bracket. Remove the power steering reservoir.

CAUTION

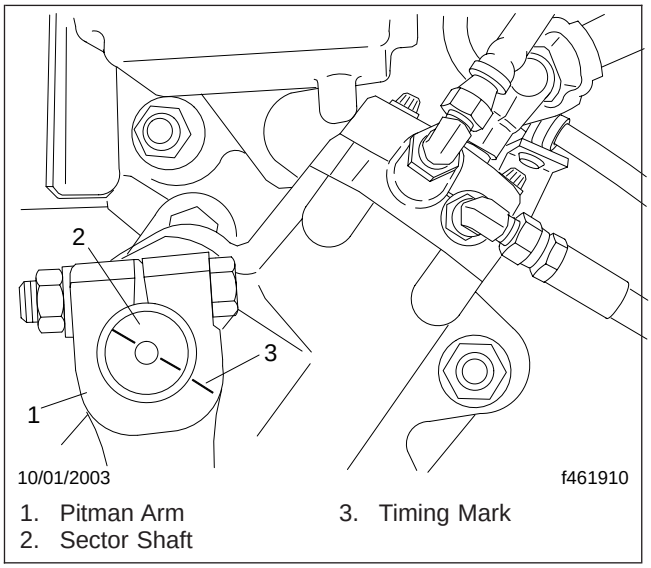
Do not pound the U-joint or lower end yoke on or off the steering gear input shaft. Internal damage to the steering gear can result.

8. Remove and discard the pinch bolt and nut that attach the steering driveline to the steering gear. Remove the lower end yoke from the steering gear.
9. Remove and discard the pinch bolt and nut that attach the pitman arm to the steering gear. Remove the pitman arm from the steering gear.

WARNING

The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

10. Remove the bolts, nuts, and washers that attach the steering gear to the frame rail. Remove the steering gear.
11. Using bolts, nuts, and washers, attach the steering gear to the frame rail. Torque the nuts 342 to 434 lbf·ft (464 to 588 N·m).
12. Match the mark on the pitman arm to the timing mark on the steering gear sector shaft and attach the pitman arm to the steering gear. See **Fig. 1**. Using a new pinch bolt and nut, secure the pitman arm to the steering gear.
    - For a 5/8–18 pinch bolt, torque the nut 130 to 155 lbf·ft (176 to 210 N·m).
    - For a 3/4–16 pinch bolt, torque the nut 200 to 230 lbf·ft (271 to 312 N·m).



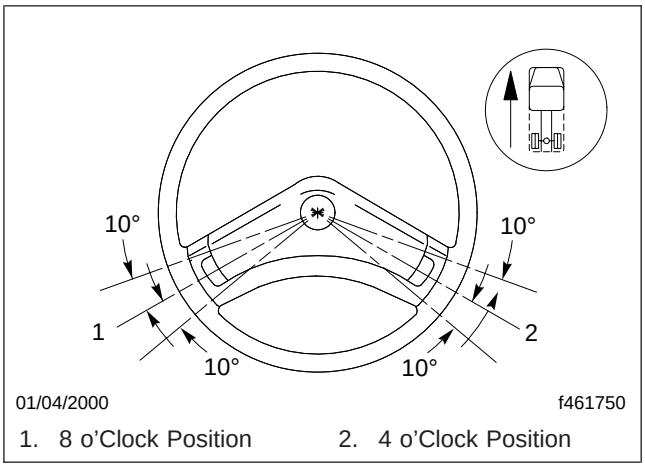
1. Pitman Arm
2. Sector Shaft
3. Timing Mark

Fig. 1, Pitman Arm Timing Mark

13. Match the mark made on the lower end yoke to the mark made on the input shaft and attach the lower end yoke to the steering gear. Using a new pinch bolt and nut, secure the lower end yoke to the input shaft. Tighten the nut to one of the following torque specs:
    - 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
    - 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut
14. Unplug the hydraulic lines and fittings and connect the lines to the power steering reservoir.

Power Steering Gear Replacement

15. Using bolts, nuts, and washers, attach the power steering reservoir to the mounting bracket.
16. Connect the batteries at the negative terminals or at the battery switch.
17. Fill the power steering reservoir to the full line on the reservoir or dipstick. For approved power steering fluids, see **Specifications 400**.
18. Start the engine and turn the steering wheel from full right to full left two or three times to remove air from the lines.
19. Check the power steering reservoir again and add fluid if needed.
20. Check the hydraulic lines for leaks.
21. Remove the chocks from the tires and close the hood.
22. Test drive the vehicle.
    - 22.1 With the front tires pointing straight ahead, check the position of the steering wheel spokes. The spokes on the steering wheel should be within ±10 degrees of the 4 o'clock and 8 o'clock positions. See **Fig. 2**.
    - 22.2 If the steering wheel is not in the correct position, remove the steering wheel and install it in the correct position. For instructions, see **Group 46**.



1. 8 o'Clock Position 2. 4 o'Clock Position

Fig. 2, Steering Wheel Centered

Filling and Air Bleeding the System

IMPORTANT: Make sure the poppets are set correctly before beginning this procedure. If the poppets are not set correctly, see **Subject 160**.

1. Fill the power steering reservoir nearly full. Do not steer.
2. Start the engine and run it for 10 seconds, then shut it off. Check and fill the reservoir. Repeat this step at least three times checking the fluid level in the reservoir each time.

IMPORTANT: Do not let the fluid level drop significantly or allow the reservoir to empty. Doing so may introduce air into the system.

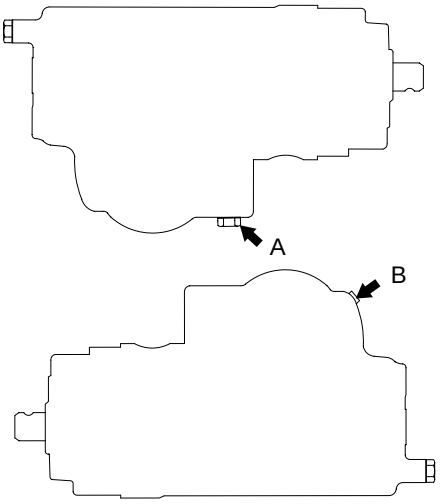
3. Start the engine and let it idle for two minutes. Do not steer. Shut off the engine and check the fluid level in the reservoir. If needed, add more fluid.
4. Start the engine again. Turn the steering wheel from full left to full right several times. If needed, add fluid to the reservoir.

   Automatic bleed systems should now be free of trapped air. If the vehicle has a manual bleed system, proceed to the next step. See **Fig. 1**.

IMPORTANT: Do not turn the steering wheel while the bleed screw is loosened.

5. With the engine idling, turn the steering wheel from full left to full right several times. Stop steering and loosen the manual bleed screw about one turn. Allow air and aerated fluid to bleed out until only clear fluid is seen. Close the bleed screw and add fluid to the reservoir if needed.

   Repeat this step until all the air is out of the system. Torque the bleed screw 40 to 50 lbf·in (452 to 565 N·cm).



12/07/2001 f461929

A. Steering gear with automatic bleed plug. Do not remove the bleed plug.
B. Steering gear with manual bleed plug.

Fig. 1, Steering Gears With Bleed Systems

Replacement

The power steering pump is used in this procedure to force out the input shaft seal. To use this procedure, the power steering pump should have a minimum of 1500 psi (10 342 kPa) available.

1. Turn off the engine, apply the parking brakes, and chock the tires.
2. Disconnect the return line from the steering gear and plug the line. Cap the return port of the steering gear with a high pressure fitting.
3. Remove the steering driveline from the steering gear input shaft.
4. Remove the dirt and water seal, item 2 in **Fig. 1**, from the steering gear. Save this seal to determine the correct size of the new seal.
5. Using a clean cloth, remove the grease from around the input shaft.
6. Using a screwdriver inserted into the notch formed in the end of the retaining ring, item 3 in **Fig. 1**, remove the retaining ring. Be careful not to scratch the bore with the screwdriver.
7. Using a pinch bolt and nut, attach the steering driveline to the input shaft but do not tighten the nut.
8. Tie or wrap a shop towel around the input shaft and place a drain pan under the steering gear to catch the oil.

⚠ WARNING

Do not mix hydraulic fluid types or use unapproved fluids. Doing so could cause seal deterioration, leaks, and a loss of steering assist, which could result in serious personal injury or death.

9. If needed, add hydraulic fluid to the power steering reservoir to the full line on the reservoir dipstick. Do not mix fluid types. See **Specifications 400** for a list of approved hydraulic fluids.
10. With the vehicle in neutral, momentarily turn the starter. If the engine starts, quickly turn it off. This should force out the input shaft seal.
11. Remove the shop towel. Disconnect the steering driveline from the steering gear and remove the input shaft seal, item 4 in **Fig. 1**.
12. Inspect the seal area of the valve housing for seal fragments. Remove all seal fragments.
13. Check the input shaft seal for heat damage. If the seal is stiff and brittle, it is probably heat damaged. Determine and fix the cause of excessive heat in the vehicle.

⚠ WARNING

Do not use a socket to install the input shaft seal. You will not be able to control the seal installation depth with a socket and this could lead to leaks. Leaks could result in loss of steering assist which could result in serious personal injury or death.

14. Install a new input shaft seal.
    - 14.1 Using Exxon Polyrex® EP2 grease (045422), lubricate the inside diameter of the new input shaft seal and install it on the input shaft.
    - 14.2 Using a hammer and seal driver (J37073), tap the driver until the shoulder of the driver is square against the valve housing. Remove any seal material that may have sheared off in the seal bore or retaining ring groove.
15. Install a new retaining ring in the groove.
16. Using Exxon Polyrex EP2 grease (045422), pack the end of the valve housing bore.
17. Install a new dirt and water seal.
    - 17.1 Choose the correct size dirt and water seal by comparing the replacement seals to the old seal, or by measuring the major diameter of the input shaft serrations. See **Table 1** for the major serration diameter and the corresponding seal part number.
    - 17.2 Apply Exxon Polyrex EP2 grease (045422) to the new dirt and water seal and install it on the input shaft. Seat it in the groove behind the serrations and against the valve housing.
18. Using a new pinch bolt and nut, attach the steering driveline to the input shaft. Tighten the nut 30 to 35 lbf·ft (41 to 47 N·m).
19. Attach the return line to the steering gear return port.

Major Serration Diameters and Corresponding Seal Part Numbers		
Major Serration Diameter inch (mm)	**Serration Size**	**Part Number**
0.807/0.799 (20)	13/16 inch (21 mm) x 36	478044
0.866/0.857 (22)	7/8 inch (22 mm) x 36	478060
0.987/0.977 (25)	1 inch (25 mm) x 36	478050
1.008/1.000 (25)	1 inch (25 mm) x 79	478050

Table 1, Major Serration Diameters and Corresponding Seal Part Numbers

20. Bleed the air from the system. For instructions, see **Subject 110**.
21. Remove the chocks from the tires.

Sector Shaft Adjustment

The sector shaft adjustment can only be completed if the adjusting screw jam nut is accessible when the steering gear is attached to the frame rail. The jam nut is located on the side cover. If the jam nut is not accessible, the adjustment can be made by removing the steering gear and placing it in a vise. See **Subject 100** for removal instructions.

1. Apply the parking brakes and chock the rear tires.
2. With the engine on, turn the steering wheel until the timing mark on the sector shaft lines up with the timing mark on the housing. The line on the sector shaft should be at a 90-degree angle from the input shaft. The sector shaft is now on its center of travel. Turn the engine off.
3. Remove the cotter pin and castle nut that attach the drag link to the pitman arm. Remove the drag link from the pitman arm.

IMPORTANT: To avoid resetting the poppets, do not turn the input shaft more than 1-1/2 turns from the center-of-travel position while the drag link is disconnected.

4. From the center-of-travel position, grasp the pitman arm at the lower end of the arm and gently try to move the arm back and forth. If the pitman arm is loose or lash (free play) is detected, the sector shaft is out of adjustment.
5. Loosen the adjusting screw jam nut.

NOTE: If the steering gear is removed from the frame rail to correct the lash, leave the pitman arm attached to the steering gear and follow the instructions under the "Final Adjustments" heading in **Subject 150**.

6. If no lash is detected, use a screwdriver to turn the shaft adjusting screw counterclockwise until you feel lash at the sector shaft.
7. Slowly turn the shaft adjusting screw clockwise until you feel no lash at the sector shaft without using more than 10 lbf·ft (14 N·m) of torque. See **Fig. 1**. From this position, turn the screw clockwise 1/8 to 3/16 of a turn more. Hold the adjusting screw in place and tighten the jam nut 43 lbf·ft (58 N·m).

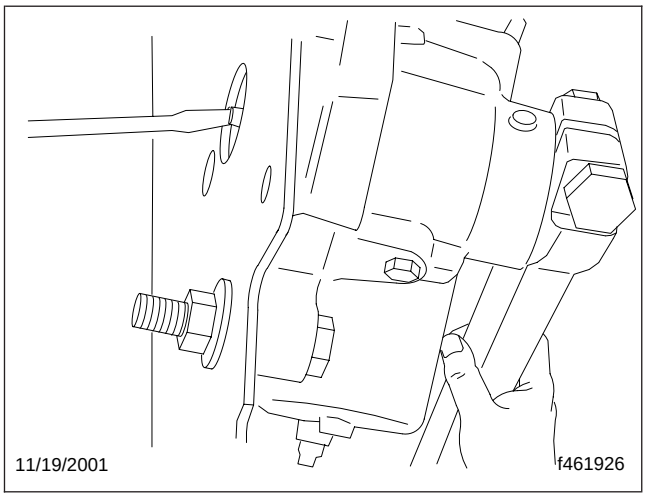

Fig. 1, Adjusting the Sector Shaft

8. Turn the steering wheel one-quarter turn each side of center then back to center and check the pitman arm for lash. There should be no lash. If lash is detected, loosen the jam nut and repeat the previous step as well as this step.
9. If the steering gear was removed from the frame rail, install the steering gear on the frame rail. For instructions, see **Subject 100**.
10. Using a castle nut, attach the drag link to the pitman arm. Torque the castle nut using the appropriate torque value.
    - 3/4–16: 90 to 170 lbf·ft (122 to 230 N·m)
    - 7/8–14: 160 to 300 lbf·ft (217 to 407 N·m)
11. If required, continue to tighten the castle nut until a slot on the nut aligns with the hole in the ball stud. Do **not** reverse the tightening direction of the nut when locating the cotter pin hole. Install a new cotter pin in the ball stud and nut, then lock the cotter pin in place.

⚠ WARNING

Failure to install and lock a new cotter pin in the ball stud and nut could result in disengagement of the parts and loss of steering control.

⚠ CAUTION

Do not use a power grease gun to add grease to the sector shaft bearing. Doing so could damage

Sector Shaft Adjustment

the high pressure seal and contaminate the hydraulic fluid.

12. Using only a hand-operated grease gun, add grease to the sector shaft bearing through the grease fitting in the housing until grease begins to extrude past the dirt and water seal.
13. Remove the chocks from the tires.

Poppet Adjustment

Poppet adjustment will work in most cases with at least 1-3/4 turns of the steering wheel from each side of center. If a large reduction in wheel cut is being made and this procedure does not work, you may have to replace or reset the poppets, using the "Poppet Component Replacement" procedure in **Subject 160**.

1. Check that the axle stops are adjusted to the specifications in **Section 33.00, Subject 110**.
2. Start the engine, and allow it to idle for 5 to 10 minutes to warm the hydraulic fluid.
3. Shut down the engine, apply the parking brakes, and chock the rear tires.
4. If a new poppet adjusting screw and nut (**Fig. 1**, Items 38 and 39) are being used, turn the screw into the nonsealing end of the nut until the drive end of the screw is flush with the nut.

NOTE: The steering gear will have either a poppet fixed stop screw or a poppet adjusting screw. See **Fig. 1**. If the adjusting screw is already part of the steering gear, back the nut off of the adjusting screw until it is flush with the end of the adjusting screw.

5. Make sure that the engine is off and the wheels are in the straight-ahead position.
6. If equipped with a poppet fixed stop screw and washer, remove and discard both items from the lower end of the housing.

   If equipped with a poppet adjusting screw and nut that need to be replaced, remove and discard both items.
7. Using a wrench, turn the adjusting screw and nut assembly (without turning the nut on the screw) into the housing until the nut is firmly against the housing. Tighten the nut against the housing.

CAUTION

Make sure the drive end of the adjusting screw is not below the face of the nut. If the drive end of the adjusting screw is below the face of the nut, the poppet seat flange will break when the upper poppet is prepared for setting.

WARNING

Fill the power steering reservoir with approved, clean fluid only. Do not mix automatic transmission fluid types. If you are changing fluid types, completely flush the steering system with the fluid type being added. Any mixture or any unapproved fluid could lead to seal deterioration and leaks. Any fluid leak could eventually cause loss of power steering assist, which could cause personal injury and property damage.

8. Fill the power steering reservoir to the full line on the reservoir dipstick. For approved hydraulic fluids, see **Specifications 400**.
9. Place a jack under the center of the front axle and jack up the front of the vehicle so the steer axle tires are off the ground.

CAUTION

Do not hold the steering wheel at full turn for more than 10 seconds at a time. The heat buildup at pump relief pressure may damage components.

10. Push the upper poppet out to prepare it for setting, as follows.
    - 10.1 Start the engine and let it run at idle speed.
    - 10.2 Note which sector shaft timing mark is nearest the housing piston bore.
    - 10.3 Turn the steering wheel in the direction that makes this timing mark move toward the adjusting screw just installed. Turn the steering wheel in this direction until axle stop contact is made.
    - 10.4 Pull hard on the steering wheel. Put up to 40-lbf (178-N) pull on a 20-inch diameter steering wheel after the axle stop is contacted.
11. Set the upper poppet, as follows.
    - 11.1 Turn the steering wheel in the opposite direction (the end of the timing mark away from the adjusting screw) until the other axle stop is contacted.
    - 11.2 Pull hard on the steering wheel. Put up to 40-lbf (178-N) pull on a 20-inch diameter steering wheel.

Fig. 1, THP Steering Gear

11.3 Release the steering wheel and shut off the engine.

12. Loosen the nut and back out the adjusting screw until the adjusting screw is 1 inch (2.5 cm) past the nut. Tighten the nut against the housing.
13. Set the lower poppet, as follows.

    13.1 Start the engine and let it idle.

    13.2 Turn the steering wheel in the original direction (the end of the timing mark is toward the adjusting screw) until axle stop contact is made.

    13.3 Hold the steering wheel in this position with up to 40-lbf (178-N) pull for 10 seconds, then release. Repeat this hold-and-release process as many times as necessary while completing the next step.

14. Position the adjusting screw, as follows.

    14.1 With the steering wheel held tightly at full turn, loosen the nut and hold it in place with a wrench.

    14.2 Using a wrench and finger pressure only, turn the adjusting screw clockwise until the wrench stops. Do not attempt to turn the adjusting screw any farther. Pause the turning-in process each time the driver releases the steering wheel. Continue turning only while the steering wheel is held at full turn.

    14.3 Back off the adjusting screw 3-1/4 turns and tighten the nut 35 lbf·ft (47 N·m).

⚠ WARNING

If the adjusting screw protrudes more than 1-1/16 inches (27 mm) from the sealing nut, the screw could fall out of the steering gear, resulting in loss of power steering. This could cause an accident resulting in serious personal injury or property damage.

IMPORTANT: Once the poppet adjusting screw and sealing nut are in place and the poppet valves have been manually adjusted, the adjustment procedures must be repeated if steering travel is increased or decreased in the future.

NOTE: The length of the adjusting screw beyond the nut may be different for each vehicle, but must not exceed 1-1/16 inches (27 mm).

15. The poppets have now been completely reset. Check the power steering reservoir and fill it if necessary.
16. Lower the vehicle and remove the chocks.

Disassembly, Inspection, Assembly, and Final Adjustments

Disassembly

NOTE: Replace all seals, seal rings, and gaskets each time the gear is disassembled.

1. Place the front tires in the straight ahead position. If possible, drive the vehicle in a straight line for a short distance stopping at the spot where the work is to be done. Apply the parking brakes, chock the tires, disconnect the batteries, and open the hood.
2. Remove all dirt from around the fittings and hose connections before removing the steering gear.

IMPORTANT: To avoid resetting the poppets, do not turn the input shaft more than 1-1/2 turns from the center-of-travel position while the drag link is disconnected.

3. Remove the power steering gear. For instructions, see **Subject 100**.

⚠ CAUTION

Never steam clean or high-pressure wash hydraulic steering components. Do not force or abuse closely fitted parts. Use care that the bearing and sealing surfaces are not damaged by the disassembly and assembly procedures. Failure to follow these precautions could result in damage to the components.

4. Clean and dry the steering gear before beginning to disassemble it.
5. As you disassemble the gear, clean all parts in clean, OSHA-approved solvent and use only air to blow dry the parts.
6. With the input shaft horizontal and the side cover and valve housing accessible, put the steering gear in a vise with the clamps firmly against the housing mounting flange or boss.

IMPORTANT: Do not clamp against the body of the housing. If the mounting boss or flange is not accessible, fabricate and attach a mounting plate to the housing mounting bosses.

7. Place a drain pan under the gear and remove the plugs from the hydraulic ports.
8. Rotate the input shaft until the timing mark on the end of the sector shaft is in line with the timing mark on the end of the housing. The sector shaft is now positioned for removal.
9. Remove any paint or corrosion from the exposed area of the sector shaft.
10. Tape the serrations and bolt groove of the sector shaft with one layer of masking tape. The tape should not extend on to the sector shaft bearing diameter.
11. Remove the adjusting screw jam nut, item 50 in **Fig. 1**.
12. Remove the capscrews that attach the side cover to the housing.
13. Remove the side cover and sector shaft assembly from the gear. Start the cover and sector shaft assembly removal by lightly tapping the end of the shaft with a soft mallet.
14. Remove and discard the vent plug, item 49 in **Fig. 1**.
15. Remove and discard the side cover O-ring, item 47 in **Fig. 1**.
16. Turn the sector shaft adjusting screw, item 44 in **Fig. 1**, clockwise through the side cover and pull the sector shaft out of the side cover.

IMPORTANT: Take care not to damage the bore or bearing when removing the output seal.

17. Clamp the side cover in a vise. Place a 3/8-inch drive socket in the center of the side cover. Using the socket for support, pry out the output seal with a rolling head pry bar. Discard the seal and remove the socket. Remove the washer.
18. Inspect the sector shaft assembly for damaged adjusting screw threads. The retainer must be securely staked in place. The adjusting screw must rotate by hand with no perceptible end play.
19. If equipped with a relief valve, remove the relief valve cap, the O-ring, and the relief valve from the valve housing. Discard the O-ring.
20. Remove the dirt and water seal, item 2 in **Fig. 1**, from the input shaft assembly. Save this seal to determine the correct size of the new seal.
21. Clean any paint or corrosion from the exposed area of the input shaft

Fig. 1, THP Steering Gear

22. Remove the four valve housing capscrews and remove the rack piston. Place the rack piston on a clean cloth.

IMPORTANT: The set position of the poppet seat and sleeve assembly must not be disturbed if the poppets are not going to be replaced or reset during disassembly.

23. Remove and discard the O-ring and the valve housing O-ring, items 13 and 11 in **Fig. 1**.

CAUTION

Do not remove the input shaft assembly or the balls from the rack piston until the ball return guides are removed. If this precaution is not followed, the ball return guides will be damaged.

24. Remove and discard the two Torx® capscrews, item 33 in **Fig. 1**. Remove the ball return guide cap and the cap seal. Discard the cap seal.

25. Remove the ball return guide by carefully inserting a screwdriver between the rack piston and guide.

NOTE: Left-hand ball return guide halves are plated with copper or zinc chromate for identification. Right-hand guide halves are not plated.

26. Remove the balls from the rack piston by rotating the input shaft assembly until the balls fall out. Place the balls and return guide in a container. Count the balls and make sure all have been removed. There are 31 balls in the THP60 steering gear.

IMPORTANT: The balls are a matched set. If any are lost, the set must be replaced.

27. Remove the valve housing and input shaft assembly from the rack piston.

28. Cut and remove the seal ring and O-ring, items 23 and 22 in **Fig. 1**, from the rack piston.

29. Inspect the poppet seat and sleeve assembly.

    29.1 Push on the poppet stem; it should spring back.

    29.2 Push on the poppet seat; it should not move by hand.

    29.3 If the components are bent or broken, if the poppet stems don't spring back, or if the poppet seat moves by hand, replace the poppet seat and sleeve assembly. For instructions, see **Subject 160**.

NOTE: TRW recommends that the poppet seat and sleeve assemblies not be removed unless replacement of the poppet is required.

30. Inspect the valve housing and input shaft assembly for heat damage or bearing roughness. If these conditions are present, if there is excessive internal leakage, or if preload adjustment is required, see the instructions in **Subject 170**.

31. Remove and discard the dirt and water seal, item 35 in **Fig. 1**.

32. Insert a screwdriver through the trunnion opening and carefully push the output seal out without damaging the sealing area of the bore. Discard the output seal.

NOTE: A special hook groove has been machined into the bore to hold the seal in position. Clean out the rubber from the groove prior to installing a new seal.

33. Inspect the roller bearing for brinelling or spalling. If the roller bearing needs to be replaced, see the instructions in **Subject 180**.

34. Inspect the following components for damage. If they are damaged, see the instructions in **Subject 190**.
    - poppet fixed stop screw
    - poppet adjusting screw and nut
    - automatic bleed plug
    - manual bleed screw
    - auxiliary port plug and O-ring

Inspection

WARNING

If one of the conditions in Table 1 is found in one component of the steering gear, inspect all components carefully for signs of impact damage. Replace the components if you suspect impact damage. Failure to replace all damaged components could result in a serious vehicle accident.

Disassembly, Inspection, Assembly, and Final Adjustments

Conditions in the Steering Gear That Indicate Impact Damage	
Condition	**Area**
Brinelling	Ball track grooves of rack piston
	Ball track grooves of worm screw
	Bearing area of sector shaft
	Thrust washer and bearing in valve housing
	Ball cup and bearing in valve housing
Cracks or Breaks	Bearing area of sector shaft
	Sector shaft teeth
	Rack piston teeth
	Housing
	Thrust washer and bearing in valve housing
	Worm screw
	Ball cup and bearing in valve housing
Twisted Serrations	Output shaft serrations

Table 1, Conditions in the Steering Gear That Indicate Impact Damage

1. Make sure all sealing surfaces and seal cavities are free of nicks and corrosion. Any nicked or corroded surface requires part replacement to ensure proper sealing.
2. Inspect the rack piston teeth for cracks or damage. If teeth are damaged, replace the rack piston, the sector shaft, and the set of balls.
3. Inspect the rack piston ball track grooves for brinelling or spalling. If either condition exists, replace the input shaft assembly, the valve housing, the rack piston, and the balls.
4. Inspect the sealing area of the input shaft assembly for nicks and damage. Inspect for discoloration from excess heat. Inspect the input shaft ball track grooves for brinelling or spalling. If any of these conditions exist, replace the:
   - input shaft
   - worm/valve assembly
   - valve housing
   - balls
   - rack piston
5. Inspect the gear housing cylinder bore. Some scoring marks are normal. If there was internal leakage greater than 1.2 gpm (4.5 L/min), make sure there are no damaged seals before replacing the housing.
6. Inspect the valve housing mating surface for nicks that would prevent proper sealing. Replace the gear housing if these nicks are present and cannot be easily removed with a fine-tooth flat file without changing the dimensional characteristics.
7. Inspect the roller bearing in the side cover assembly for brinelling or spalling. If either condition exists, replace the side cover assembly.
8. Inspect the sector shaft bearing and sealing areas and sector teeth contact surfaces for brinelling, spalling, or cracks. Run the end of your fingernail across these areas to detect steps. Remove the masking tape from the shaft and inspect the shaft for twisted or damaged serrations. If any of these conditions exist, replace the sector shaft.

NOTE: A replacement sector shaft comes with the adjusting screw and retainer.

Assembly

NOTE: Use the bearing and seal tool, J37071, in the following two steps.

1. Install a new output seal on the short end of the bearing and seal tool so that the lip with the garter spring is toward the shoulder of the tool. Working from the side cover side of the housing, pilot the bearing and seal tool into the washer and bearing, then press with 100 to 800 lbf (445 to 3560 N) until the seal is seated firmly.
2. Using the long end of the bearing and seal tool, install the dirt and water seal, item 35 in **Fig. 1**, making sure it is not distorted or twisted.

IMPORTANT: Press the seal only until it seats against the bearing; do not press it in farther.

3. Pack the roller bearing seal, the output seal, and the dirt and water seal liberally with clean, high-temperature industrial grease, Exxon Polyrex® EP2 grease (045422).

4. Lightly oil the valve housing O-ring, item 11 in **Fig. 1**, and install the O-ring in the mounting face groove of the valve housing.
5. Lightly oil a new seal ring, item 14 in **Fig. 1**, and install the seal ring in the valve housing mounting face groove.
6. Install a new O-ring, item 22 in **Fig. 1**, and then a seal ring, item 23, on the rack piston. Do not overstretch the rings as they are being installed. Do not allow the seal ring to become twisted.
7. Apply clean oil to the gear housing cylinder bore. Place the rack piston in the housing with the ball return guide holes up.
8. Install the input shaft assembly in the rack piston close to maximum depth without the valve housing making contact with the poppet stem. Insert two 14 mm x 2.0 mm All Threads through the lower valve housing mounting holes and tighten them to support the worm and valve assembly. Line up the rack piston ball guide holes with the worm ball track grooves by rotating the input shaft.
9. Install the ball return guide in the rack piston until seated. Rotate the input shaft slightly if necessary.

⚠ WARNING

Do not seat the ball return guide with a hammer. Damage to the guide can result in subsequent lockup or loss of steering, resulting in personal injury or property damage.

IMPORTANT: If a new rack piston, input shaft, or input shaft assembly is being installed, the balls must be replaced. The balls in a service ball kit are sized to function in the ball track guide path as altered by component replacement.

When using a service ball kit, use the correct quantity of balls. There are 31 balls in the THP60 steering gear.

NOTE: Hold the ball return guide firmly in place while performing the following step.

10. Insert as many balls as you can through the hole in the top of the ball return guide. Rotate the input shaft to pull the balls down and around the ball track guide path. Continue until the correct number of balls is in the ball track guide path.

    If the ball guide becomes unseated (raised) at any time, start the procedure again beginning with the previous step.

⚠ WARNING

Hold down the ball return guide until the ball return guide cap is installed. Failure to hold the guide will result in a trapped ball or balls, which could cause a vehicle accident resulting in personal injury or property damage.

⚠ CAUTION

Do not allow the valve housing to contact the poppet stem or move more than 2.5 inches (64 mm) from the upper end of the rack piston during these procedures. This could incorrectly reset the poppet or back out the input shaft assembly beyond the closed ball loop, trapping the balls.

⚠ CAUTION

Remove any fluid present in the two screw holes. Fluid in these holes could cause improper clamp load when torquing the ball return guide cap.

11. Install a new cap seal in the groove of the ball return guide cap. Make sure the seal makes full contact with the rack piston surface. Install two new Torx capscrews and torque each capscrew alternately until a final torque of 18 lbf·ft (24 N·m) is reached.

IMPORTANT: The cap seal is greased to hold the seal in the groove while it is assembled. Be sure not to trap the seal outside of the groove during assembly.

12. Rotate the input shaft from one end of travel to the other without contacting the poppet stem to the valve housing and without moving the valve housing face more than 2.5 inches (64 mm) from the input end (upper end) of the rack piston. If you cannot rotate the input shaft, remove the balls and install them again.

Disassembly, Inspection, Assembly, and Final Adjustments

WARNING

If a gear is installed on a vehicle when the input shaft is not able to be rotated, the gear will not function correctly. Steering and gear failure may result, possibly causing personal injury or property damage.

13. Apply clean oil to the seal ring, item 23 in **Fig. 1**, on the rack piston. Make sure there is a space of 3/8 to 1/2 inch (10 to 13 mm) between the valve housing and the poppet stem to prevent poppet contact at either end. Remove the All Threads and push the rack piston into the housing with the rack piston teeth toward the sector shaft cavity. Line up the valve housing cylinder feed hole with the gear housing feed hole. Make sure both O-rings in the valve housing remain in position.

IMPORTANT: Do not damage the seal ring while installing the rack piston in the housing.

IMPORTANT: The poppet seat and sleeve assembly must not bottom against the internal poppet stops in the steering gear until the gear is installed on the vehicle and the poppet adjustment procedures are performed.

14. Lubricate and install the four valve housing capscrews in the housing. Torque the capscrews 118 to 138 lbf·ft (160 to 187 N·m).

15. If the gear is equipped with a relief valve, install a new O-ring on the relief valve cap. Install the small end of the tapered spring on the pin on the relief valve cartridge and install the relief valve with the large end of the tapered spring end first in the relief valve cap cavity. Turn the relief valve cap into the valve housing and torque 30 lbf·ft (41 N·m).

CAUTION

The caged bearing assembly is sealed and will not receive lubrication from the hydraulic fluid in the gear. Failure to use the proper grease could result in premature bearing wear.

16. Apply a generous amount of Exxon Polyrex EP2 grease (045422), and **only** this type of grease, to the caged bearing assembly in the side cover. Then install the washer, item 45 in **Fig. 1**, on top of the bearing.

NOTE: Use bearing and seal tool, J37071, on the THP60 steering gear.

17. Grease and install a new output seal on the installation tool so that the side with the garter spring is against the shoulder of the tool. Pilot the tool into the side cover with a force of 100 to 800 lbf (445 to 3560 N) until it is seated against the bearing or bushing.

IMPORTANT: Make sure the outside diameter of the seal and the inside diameter of the bore are free from grease and dust for proper engagement of the seal.

18. Apply a generous amount of Exxon Polyrex EP2 grease (045422) to the short bearing area of the sector shaft.

19. Install the sector shaft in the side cover and turn the sector shaft adjusting screw counterclockwise until the screw reaches solid height.

    Rotate the adjusting screw clockwise one-half turn so that the side cover will rotate freely on the sector shaft.

20. Install the sector shaft adjusting screw jam nut, item 50 in **Fig. 1**, on the sector shaft adjusting screw a few threads. Final adjustment will be made later.

21. Press the new vent plug into the hole provided in the side cover until the plug has bottomed.

WARNING

Hold down the ball return guide until the ball return guide cap is installed. Failure to hold the guide will result in a trapped ball or balls, which could cause a vehicle accident resulting in personal injury or property damage.

22. Apply clean oil to the new side cover O-ring, item 47 in **Fig. 1**, and install it on the side cover.

WARNING

If the rack piston is not centered when the sector shaft is installed, gear travel will be severely limited in one direction. This could cause an accident possibly resulting in personal injury or property damage.

23. There are four teeth on the rack piston. Rotate the input shaft to position the rack piston so that the space between the second and third tooth is in the center of the sector shaft opening. This will center the rack piston for installation of the sector shaft.

⚠ CAUTION

If the serrations are not properly taped, they will damage the output seal in the housing and cause the seal to leak.

24. Remove all tape on the serrations. Apply one layer of masking tape on the serrations and bolt groove of the sector shaft. Install the sector shaft in the housing. The center tooth of the sector shaft must engage the center space (between the second and third tooth) of the rack piston. Lightly tap on the side cover with a rubber mallet to seat the cover against the housing face.
25. Install the capscrews in positions 3 and 4 on the side cover by hand. Then install the remaining capscrews in the side cover and tighten them in the sequence shown in **Fig. 2**. Lubricate the capscrews and torque 180 to 220 lbf·ft (244 to 298 N·m).

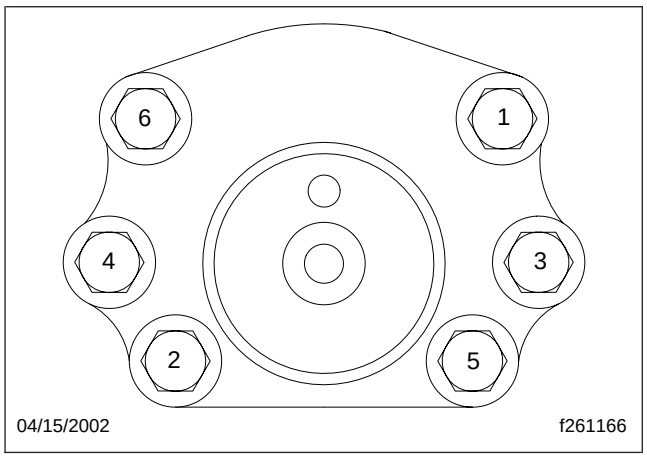

Fig. 2, Capscrew Tightening Sequence

IMPORTANT: If the capscrews must be replaced, use capscrews of the same design, type, and length as those removed.

26. Remove the tape from the sector shaft.
27. Pack the end of the valve housing bore with Exxon Polyrex EP2 grease (045422). Apply more grease to the inside of a new dirt and water seal, and install it on the input shaft. Seat the seal in the groove behind the serrations and against the valve housing.

NOTE: This step may have already been completed if the valve housing and input shaft assembly were disassembled for repair.

Final Adjustments

Before installing the steering gear on the vehicle, make the following adjustments.

NOTE: Worm shaft preload adjustment was done when the input shaft was installed in the valve housing during the assembly procedure.

IMPORTANT: When the steering gear is not connected to the steering system, don't turn the input shaft more than 1-1/2 turns from the center position or the automatic poppets could become inoperative when the steering gear is installed on the vehicle. This would require disassembling the gear to position the poppet seat and sleeve assemblies.

1. Using a 3/4- or 11/16-inch socket or box end wrench, center the steering gear by rotating the input shaft until the timing mark on the end of the sector shaft is in line with the timing mark on the end of the housing trunnion.

NOTE: If new or reset poppets are in the gear, they will be moved when the input shaft is turned less than one rotation in either direction from the center position. This will not affect the function of the poppets.

2. With the adjusting screw jam nut loose, turn the sector shaft adjusting screw clockwise to provide 45 to 50 lbf·in (508 to 565 N·cm) of torque to rotate the input shaft through one-half turn each side of center.

NOTE: This step will properly mesh and seat the rack piston and sector shaft for final adjustments.

3. Turn the sector shaft adjusting screw counterclockwise one-half turn and note the maximum

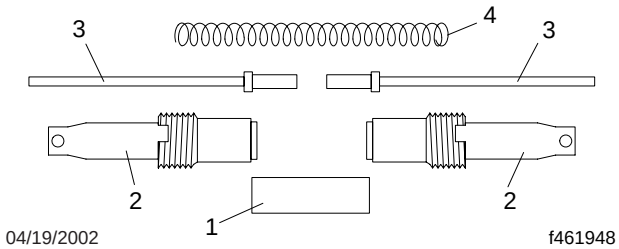
Disassembly, Inspection, Assembly, and Final Adjustments

torque required to rotate the input shaft through one-half turn each side of center.

4. Turn the sector shaft adjusting screw clockwise to increase the maximum torque noted in the previous step by 7 lbf·in (79 N·cm). Tighten the jam nut firmly against the side cover while holding the adjusting screw in position.
5. Torque the jam nut 43 lbf·ft (58 N·m) and check the input shaft torque again. Adjust the sector shaft adjusting screw if the input shaft torque exceeds 40 lbf·in (452 N·cm).
6. Install the steering gear on the vehicle. For instructions, see **Subject 100**.
7. Remove the chocks from the tires.

Replacement

1. Remove the rack piston from the steering gear. For instructions, see **Subject 150**.
2. Place the rack piston in a soft-jawed vise.
3. Place special tool, J36452-A, over the seat of the poppet seat and sleeve assembly and engage the special tool in the slots of the threaded sleeve. Hit the end of the tool firmly four or five times with a two-pound sledge hammer to loosen the Loctite®.
4. Place a ratchet on the special tool and remove the seat and sleeve assembly from the rack piston. If the ratchet does not turn easily, strike the special tool again with a hammer. If the engaging tangs won't stay in place while torquing, it may be necessary to hold the tool in place with an arbor press while applying loosening torque.
5. Discard the poppet seat and sleeve assembly. See **Fig. 1**.



1. Push Tube
2. Poppet Seat and Sleeve Assembly
3. Poppet
4. Spring

Fig. 1, Poppet Components

6. Remove the two poppets, the spring, and the push tube. See **Fig. 1**.
7. If necessary, remove and discard the second poppet seat and sleeve assembly.

NOTE: It is possible to reset one poppet seat and sleeve assembly for automatic poppet adjustment while it is in the rack piston if one poppet seat and sleeve assembly and the poppets, spring, spacer rod, and push tube are removed.

8. To reset the automatic poppet adjustment when one poppet seat and sleeve assembly has been left in the rack piston, insert a 3/8-inch (9.5-mm) diameter x 6-inch (152-mm) drill rod down through the poppet seat hole at the opposite end of the rack piston and against the adjuster seat to press the seat in until it bottoms against the adjuster sleeve.

CAUTION

Do not allow Loctite or Locquic to get on the adjuster seat component of the poppet seat and sleeve assembly. Failure to follow this precaution will prevent the poppets from functioning properly.

9. Carefully apply Locquic® T primer to the threads in the poppet holes and to the threads on the new seat and sleeve assemblies. Allow the primer to dry for 10 minutes, then carefully apply Loctite RC680 to the same threads.

WARNING

Wear eye protection when assembling the poppets since the spring-loaded poppets could eject and cause personal injury.

10. Place the rack piston in a soft-jawed vise. If the second poppet seat and valve assembly was removed, install a new poppet seat and sleeve assembly, with the slotted end out, into the poppet hole in one end of the rack piston.
11. From the other end of the poppet hole in the rack piston, install one poppet, the poppet spring, push tube, the other poppet, and a new poppet seat and sleeve assembly. The new components will fit together as shown in **Fig. 2**.

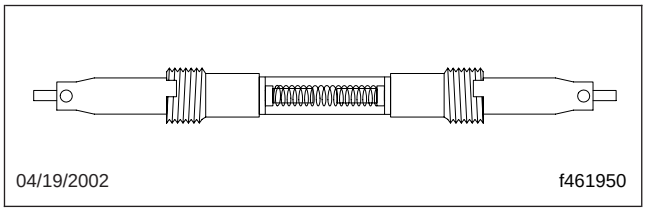


Fig. 2, Poppet Components Assembled

12. Torque the poppet seat and sleeve assemblies 18 lbf·ft (24 N·m).
13. Install the rack piston in the steering gear. For instructions, see **Subject 150**.

Valve Housing/Input Shaft Disassembly, Inspection, and Assembly

Disassembly

1. Remove the valve housing and the input shaft assembly from the steering gear. For instructions, see **Subject 150**.
2. Place the valve housing, with the input shaft in the upright position, in a soft-jawed vise.
3. Unstake the valve housing where the material was moved into the adjuster locknut slot.
4. Using a roll pin punch and hammer, unstake the adjuster locknut from the bearing adjuster. See **Fig. 1**.
5. Using the adjuster locknut tool (J37464), remove the adjuster locknut from the valve housing.
6. Using the bearing adjuster tool (J37070), remove the bearing adjuster from the valve housing.
7. Remove and discard the seal ring and O-ring, items 18 and 19 in **Fig. 1**, from the bearing adjuster.
8. Remove the input shaft from the valve housing.
9. Remove the thrust washer and thrust bearing, items 17 and 16 in **Fig. 1**, from the input shaft.

CAUTION

The input shaft assembly must not be disassembled any further. The components are a select fit at assembly and are available only as part of this subassembly. If disassembled further, the subassembly must be replaced.

10. Remove the bearing assembly, item 12 in **Fig. 1**, from the valve housing.

IMPORTANT: Do not remove the ball cup that the bearing assembly rides on. Do not remove the special spacer seal behind the ball cup.

11. Remove and discard the seal ring, item 14 in **Fig. 1**, from the valve housing.
12. Remove the valve housing from the vise. Turn the valve housing over and remove the retaining ring, item 3 in **Fig. 1**.

CAUTION

Be careful when removing the input shaft seal to prevent damage to the valve housing seal bore.

13. Using a 1-1/8-inch socket and hammer, remove the input shaft seal, item 4 in **Fig. 1**, from the valve housing. Discard the input shaft seal.

NOTE: The valve housing also utilizes a ball plug for manufacturing purposes that must not be removed.

Inspection

1. Inspect the sealing areas of the input shaft and valve housing for nicks. Run the edge of your fingernail over the sealing surfaces to detect steps. Inspect for discoloration from excess heat. Inspect the input shaft ball track grooves for brinelling or spalling. If any of these conditions exist, the input shaft assembly, valve housing, and balls must be replaced. Replace the rack piston if brinelling or spalling is found.
2. Inspect the rollers in the thrust bearing and the bearing assembly for deterioration. Inspect the thrust washer and ball bearing race in the valve housing for brinelling, spalling, or cracks. Replace all parts that exhibit these conditions.

Assembly

IMPORTANT: Do not clamp the valve housing against the threaded port hole or relief valve hole sealing faces when placing the valve in the vise.

1. Place the valve housing in a vise so the input shaft can be assembled with the worm screw up.
2. Lightly oil a new seal ring and install the seal ring in the large diameter groove in the valve housing. It may be necessary to bend and work the seal ring into the groove. Smooth out the seal ring.

IMPORTANT: The seal ring must be smoothed out to prevent it from damage when the worm screw is installed.

3. Install the bearing assembly in the valve housing. See **Fig. 2** for correct orientation of the bearing assembly.
4. Dip the input end of the input shaft assembly in oil up to the worm lead. Install the input shaft

Valve Housing/Input Shaft Disassembly, Inspection, and Assembly

1. Bearing Assembly 2. Valve Housing

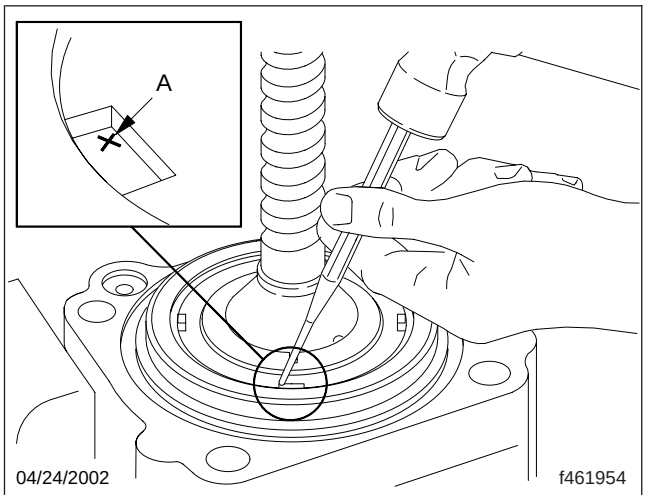
Fig. 2, Correct Orientation of Bearing Assembly

end of the assembly in the valve housing until it is firmly seated.

5. Apply oil to the thrust bearing and thrust washer, then install the bearing and washer over the ball groove end of the worm screw and seat them against the shoulder of the input shaft assembly.
6. Lightly oil a new O-ring and install it in the bearing adjuster seal groove. Lightly oil a new seal ring and install it in the same bearing adjuster seal groove. Smooth out the seal ring.

NOTE: Be sure the valve housing, the adjuster locknut, and the bearing adjuster threads are clean and free of any staking burrs that would impede the locknut from turning freely in the valve housing.

7. Lightly oil a new bearing adjuster and install it in the valve housing. Using a torque wrench inserted in the bearing adjuster tool (J37070), torque the bearing adjuster 13 lbf·ft (18 N·m). This will seat the components. Back off the adjuster one-quarter to one-half of a turn.
8. Lightly oil a new adjuster locknut and install it on the bearing adjuster with the slightly rounded side down. Tighten slightly to keep the bearing adjuster in place.
9. Reverse the valve housing in the vise so that the worm screw is down. With a pound-force-per-inch torque wrench on the input shaft, note the torque required to rotate the input shaft 360 degrees in each direction. Tighten the bearing adjuster to increase the maximum torque at the input shaft 5 to 10 lbf·in (56 to 113 N·cm) over that which was previously noted.
10. Reverse the valve housing in the vise so that the worm screw is up. Torque the adjuster locknut while holding the bearing adjuster in the position established in the previous step with the adjuster locknut tool (J37464). When using a torque wrench in the adjuster locknut tool, the torque wrench reading should be 112 lbf·ft (152 N·m).
11. Check the input shaft torque. It should match the torque measured previously. If the torque readings do not match, repeat the previous two steps.
12. Stake the valve housing in the clockwise-most corner of two opposing slots in the adjuster locknut. See **Fig. 3**. Stake the locknut into the bearing adjuster in two places, 180 degrees apart, at the threaded area. Choose areas that have not been previously staked.



A. Stake the valve housing in the clockwise-most corner of the slot in the adjuster locknut.

Fig. 3, Stake the Valve Housing

13. After staking, the torque required to rotate the input shaft must be between 5 to 10 lbf·in (56 to 113 N·cm) greater than the torque noted previously. The torque value must not exceed 22 lbf·in (249 N·cm). If necessary, unstake and readjust.
14. Place the valve housing/worm screw assembly in the vise so that the worm screw is down.

Valve Housing/Input Shaft Disassembly, Inspection, and Assembly

IMPORTANT: Remove any seal material that may have sheared off and is in the seal bore and retaining groove ring.

15. Apply Exxon Polyrex® EP2 grease (045422) to the outside and inside diameters (fill cavity between the lips) of the new input shaft seal and install it, garter spring side first, on the input shaft. Align the seal in the valve housing seal bore.

IMPORTANT: The input shaft seal must be square in the seal bore and installed to the correct depth.

16. Place the seal driver tool (J37073) with the smaller end first, on the input shaft and against the seal. Tap the seal installer tool until the tool shoulder is squarely against the valve housing. This will correctly position the seal in the housing bore just beyond the retaining ring groove.
17. Insert the new retaining ring, item 3 in **Fig. 1**, into the retaining ring groove in the valve housing.
18. Pack the end of the valve housing bore around the input shaft with Exxon Polyrex EP2 grease (045422). Apply more of the grease to the inside of a new dirt and water seal and install it on the input shaft. Seat the seal in the groove behind the serrations and against the valve housing.
19. Install the valve housing/input shaft assembly in the steering gear. For instructions, see **Subject 150**.

Replacement

1. Remove the side cover assembly in order to access the roller bearing, item 41 in **Fig. 1**. For instructions, see **Subject 150**.
2. Place the long end of the bearing and seal tool, J37071–A, against the trunnion end of the bearing and press it out of the side-cover end of the bearing bore. Discard the roller bearing.

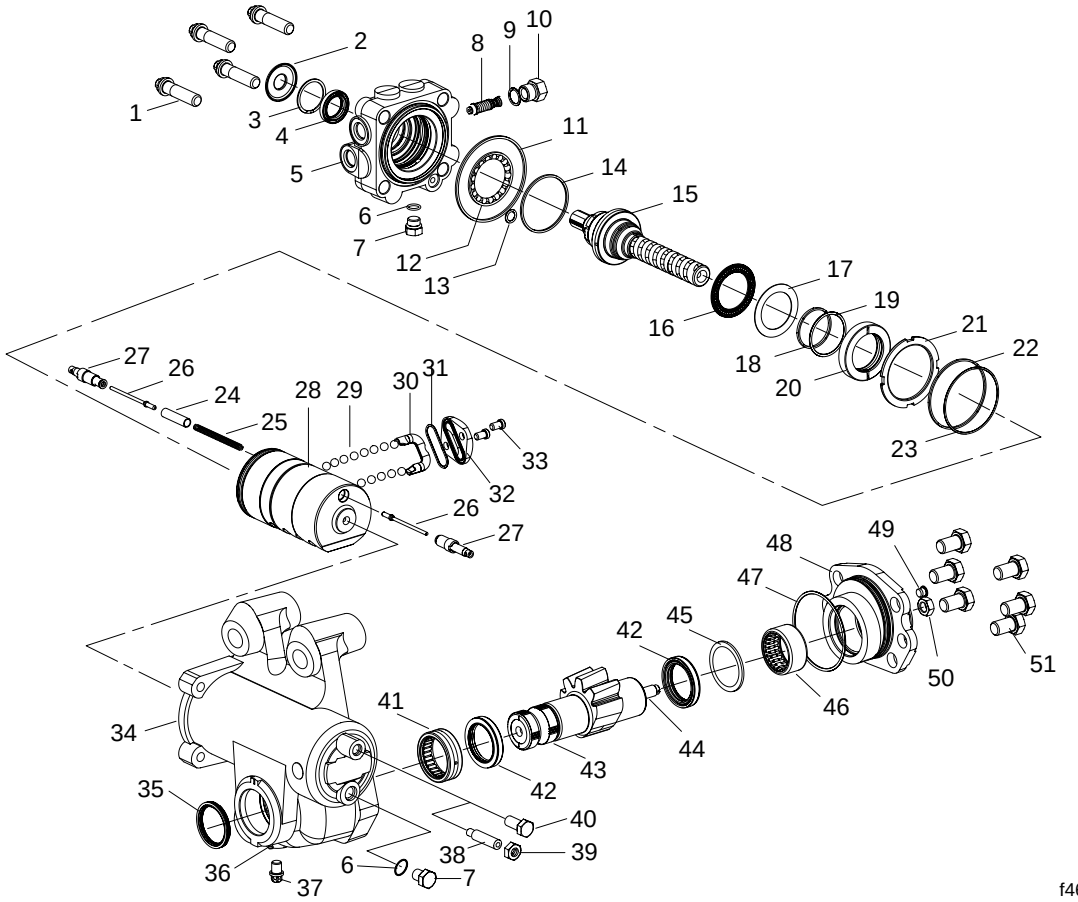
⚠ CAUTION

Use the short end of the bearing and seal tool to press in the roller bearing. If the long end of the bearing and seal tool is used to press in the bearing, the cage on the roller bearing may be damaged.

NOTE: If the unmachined trunnion face is not square, use shims to square it before pressing in the bearing.

3. Using the short end of the bearing and seal tool, press the new roller bearing into the gear housing from the side-cover end of the bearing bore until it is seated against the step bore. Be sure the housing is square with the press base and the bearing is not cocked.
4. Install the side cover on the gear housing. For instructions, see **Subject 150**.

Roller Bearing Replacement



10/21/2003 f461925

1. Valve Housing Capscrew

Housing Port Plugs, Screws, and Fittings Replacement

Poppet Fixed Stop Screw Replacement

1. If the poppet fixed stop screw is damaged, remove the stop screw, item 40 in **Fig. 1**, and the washer. Discard the washer.
2. Install a new poppet fixed stop screw and torque 48 lbf·ft (65 N·m).

Poppet Adjusting Screw Replacement

1. If the poppet adjusting screw and poppet adjusting screw nut are damaged, remove the adjusting screw and nut, items 38 and 39 in **Fig. 1**, without allowing the nut to change its position on the screw.
2. Install a new nut on the new poppet adjusting screw matching its position to the nut and screw removed. Torque the nut 35 lbf·ft (47 N·m).

Automatic Bleed Plug and Auxiliary Port Plug Replacement

1. If the automatic bleed plug is damaged, remove the plug, item 37 in **Fig. 1**.
2. Install a new automatic bleed plug and torque the plug 48 lbf·ft (65 N·m).
3. If the auxiliary port plug and the auxiliary port O-ring are damaged, remove the plug and the O-ring, items 7 and 6 in **Fig. 1**.
4. Install a new auxiliary port plug and auxiliary port O-ring in the gear housing or valve housing and torque the plug 30 lbf·ft (41 N·m).

Manual Bleed Screw Replacement

1. If the manual bleed screw is damaged, remove the bleed screw. For possible manual bleed screw locations, see **Fig. 2**.
2. Install a new manual bleed screw and torque the screw 45 lbf·in (508 N·cm).

Post-Service Checks |

After power steering components have been worked on and before the vehicle is placed into service, the following items must be checked.

⚠ WARNING

Failure to check the following items could result in damage to the power steering system. This could cause a loss of hydraulic assist, which could cause personal injury or property damage.

1. Operate the engine at low idle while turning the steering wheel through several full-left and full-right turns. With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level, a sign that air is trapped in the system. If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as necessary. Bleed the air from the system.
2. With the engine turned off and warm, check the power steering reservoir fluid level using the instructions in **Group 46** of the *L-Line and A-Line Maintenance Manual*.
3. At full-left and full-right wheel cuts, be sure the axle stops on the rear side of the spindle are set so there is at least 1/2-inch (13-mm) clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be 3/4 inch (19 mm). If clearance is less than the above, reset the axle stops.
4. Check that the poppets are set correctly. If needed, adjust them. For instructions, see **Subject 140**.
5. If there are still problems with the power steering system, see **Section 46.10, Subject 300** and perform the troubleshooting procedures; otherwise, go to the next step.
6. Test drive the vehicle. Check the steering wheel spoke position. If during straight-ahead driving on a level road the steering wheel spokes are not within ±10 degrees of the 8 o'clock and 4 o'clock positions, remove the steering wheel and reposition it. See **Fig. 1**.

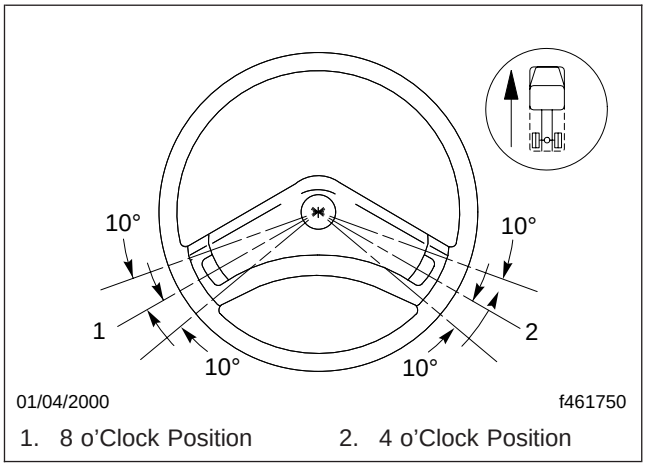

Fig. 1, Steering Wheel Centered

⚠ WARNING

Fill the power steering system only with approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. A fluid leak could eventually cause loss of power steering assist.

The following hydraulic fluids are approved for use in the steering system:

- Automatic Transmission Fluid (ATF), Dexron® II
- Automatic Transmission Fluid (ATF), Dexron® III

The following type of grease is approved for use on the steering gear components:

- Exxon Polyrex® EP2 (045422)

Table 1, SPX Kent-Moore Tools

General Information

The TRW TAS power steering gear uses pressurized hydraulic fluid to help the driver turn the front wheels. The steering gear incorporates a manual steering mechanism, hydraulic control valve, and a hydraulic power cylinder. The control valve is a rotary design that directs oil flow from the power steering pump to the upper or lower cylinder cavity. The TAS65 power steering gear is used for front axle capacities of up to 14,000 pounds (6350 kg). The TAS85 power steering gear is used for front axle capacities of up to 18,000 pounds (8164 kg).

⚠ CAUTION

Never steam clean or pressure wash the steering gear. Damage to the gear seals can result, ultimately causing internal damage to the steering gear.

Principles of Operation

When the steering wheel is turned, force is transmitted from the steering wheel to the steering gear input shaft. A torsion bar, pinned at one end to the input shaft, and at the other to the worm shaft, turns with the input shaft and exerts a rotational force on the worm shaft. In response, the worm shaft, acting through the recirculating ball mechanism, tries to move the rack piston up or down (as applicable) in the gear housing cylinder bore.

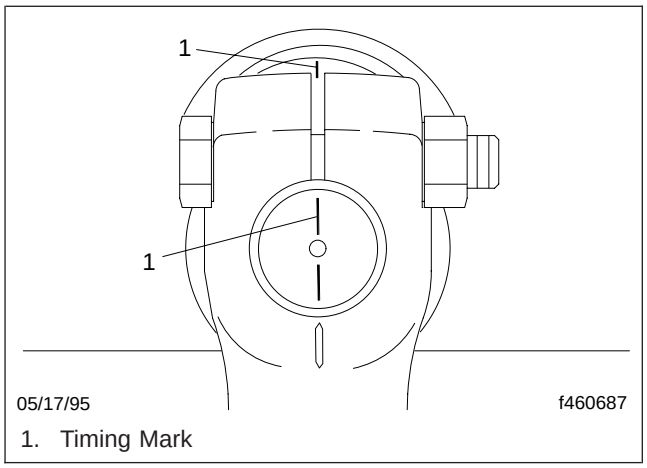
The movement of the rack piston is resisted by its engagement to the sector shaft, which is linked to the steered wheels. Because of this resistance, the torsion bar is twisted by the input shaft, thereby actuating the control valve. Pressurized fluid, directed by the control valve to the upper or lower cylinder cavity (depending on the direction of turn), assists in moving the rack piston up or down (as applicable) in the cylinder bore. The rack piston then turns the sector shaft to steer the vehicle.

If the steered wheels receive a shock load, the shock forces are transmitted through the sector shaft to the rack piston, and on to the worm shaft. The internal construction of the steering gear causes the control valve to send high-pressure fluid to the correct cylinder cavity to resist the shock forces. By absorbing the shock forces hydraulically, the steering gear prevents kickback at the steering wheel.

On each end of the rack piston is a poppet (unloading valve). The appropriate poppet will trip as the steered wheels approach the axle stop for that direction of turn. The tripped poppet reduces pressure in the gear, heat generated by the pump, and outside forces acting on the steering linkage.

Sector Shaft Adjustment

1. Position the sector (output) shaft at its center of travel by turning the steering wheel until the alignment mark on the sector shaft is at a right angle to the input shaft centerline, and in line with the timing mark on the end of the housing trunnion. See **Fig. 1**.



1. Timing Mark

Fig. 1, Position the Sector Shaft

2. Disconnect the drag link from the pitman arm.

   The input shaft/valve/worm assembly must not be turned more than 1-1/2 turns in either direction from its center of travel while the drag link is disconnected from the pitman arm. Turning the input shaft more than 1-1/2 turns from center will cause misadjustment of the automatic poppets. This may require the installation of a service poppet adjustment tool to manually reset the poppets.

3. With the sector shaft in the center position, grasp the pitman arm and gently try to move it back and forth. Fingertip force is adequate to detect lash (free play) of a loose sector shaft. See **Fig. 2**. There must be no movement of the input shaft or sector shaft. If no lash is detected, no adjustment is needed.

   If lash is detected, find the sector shaft adjusting screw, in the center of the sector shaft cover, on the inboard side of the gear housing. Loosen the adjusting screw jam nut, and move the adjusting screw clockwise until the sector shaft and rack piston are in contact. Use no more than 10 lbf·ft (14 N·m) of torque. Then turn the adjusting screw counterclockwise one turn. At this point, there should be lash at the pitman arm.

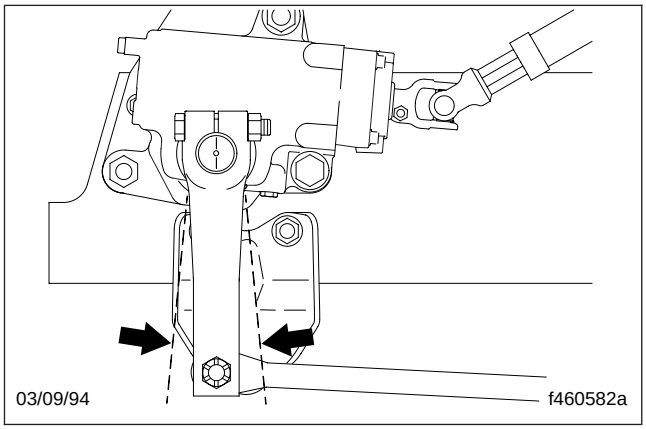


Fig. 2, Checking Sector Shaft Free Play

4. To adjust, slowly turn the adjusting screw clockwise until no lash is felt at the pitman arm, then turn it clockwise an additional one-eighth turn. Hold the adjusting screw in place and tighten the jam nut 40 to 45 lbf·ft (54 to 61 N·m).

5. Check the pitman arm for lash. Turn the steering wheel one-quarter turn each side of center. No lash should be felt. If lash exists, readjust the sector shaft.

6. Connect the drag link to the pitman arm. For instructions, see **Subject 110**.

Poppet Valves Adjustments

The TRW TAS power steering gear has automatic poppet valves that reset themselves if the axle stops are reset for increased steering travel. However, if the axle stops are reset for decreased steering travel, the poppet valves must be adjusted manually, through the use of a special service poppet adjusting screw and sealing jam nut kit, unless they were reset while the steering gear was disassembled.

Use the following procedure for manually resetting the poppet valves.

1. Verify correct axle stop adjustment. For instructions, refer to **Group 33**.

   If both axle stops were set for increased travel, the steering gear poppets have reset automatically and gear adjustments are complete. No further action is required.

In-Vehicle Adjustments

If either axle stop was set for decreased travel, the steering gear poppets must be set manually. Continue to the next step.

IMPORTANT: The axle stops must be set so that there are at least 1-3/4 steering wheel turns from a straight-ahead position to both a full-left turn and a full-right turn; otherwise the poppet valves will not work.

2. Install the steering gear manual poppet adjusting screw.

   2.1 Screw the special poppet adjusting screw (from TRW kit number 021407-X1) into the nonsealing end of the sealing jam nut, until the drive end of the screw is flush with the nut. See **Fig. 3**.

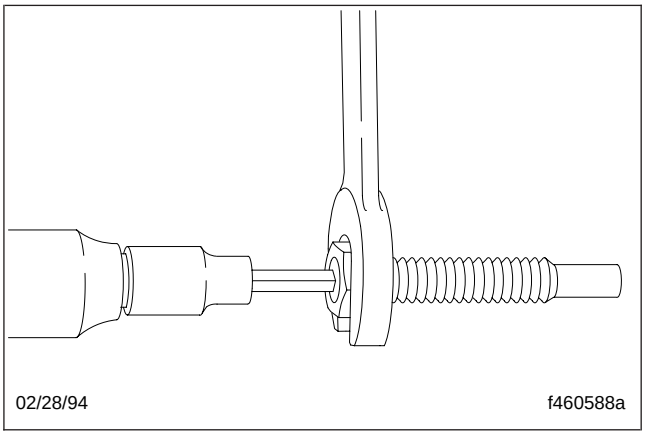

Fig. 3, Screw in the Poppet Adjusting Screw

   2.2 With the vehicle unloaded, the engine off, and the front wheels in the straight-ahead position, remove and discard the poppet fixed stopscrew and washer from the lower end of the steering gear housing. See **Fig. 4**.

   NOTE: With the wheels in the straight-ahead position and the timing marks on the sector shaft and gear housing aligned, the steering gear is centered. See **Fig. 1**.

   2.3 Using an Allen wrench, turn the adjusting screw and nut, without rotating the nut, into the steering gear housing until the nut is firmly against the housing. Tighten the nut 38 to 42 lbf·ft (52 to 57 N·m). See **Fig. 5**.

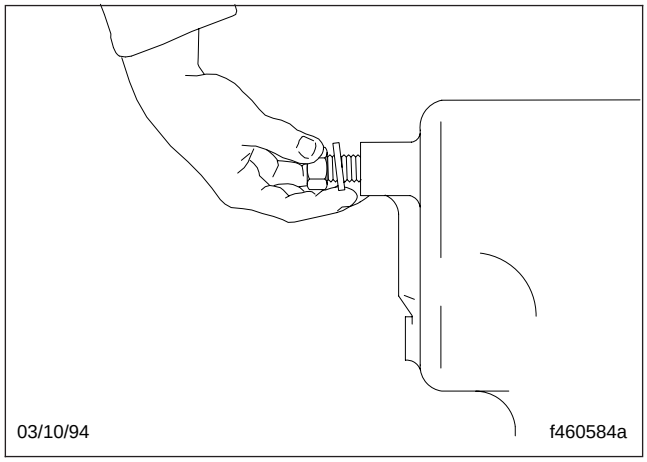

Fig. 4, Remove the Poppet Fixed Stopscrew and Washer

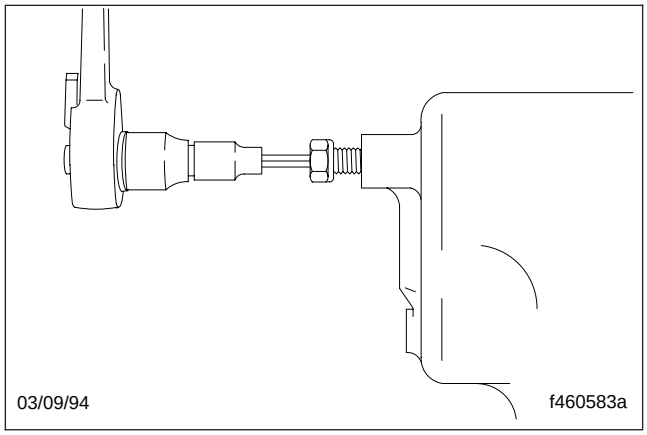

Fig. 5, Turn the Adjusting Screw

   NOTE: It may be necessary to move the sector shaft slightly from the straight-ahead position to assemble the service adjusting screw as instructed and then return it to the straight-ahead position.

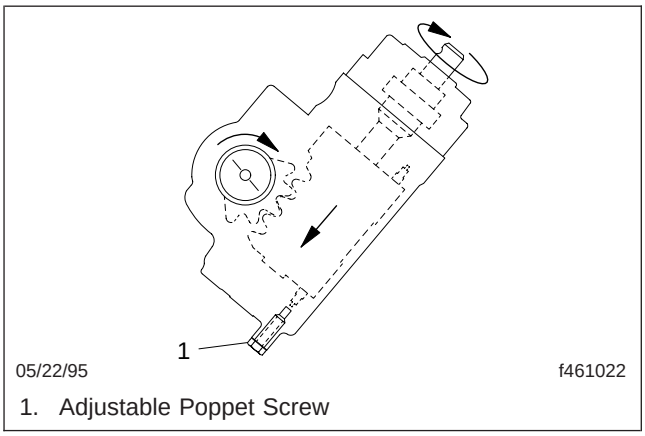
3. Adjust the poppets manually.

   3.1 Check the fluid level and fill the power steering reservoir with Dexron® II or Dexron® III automatic transmission fluid if required.

   3.2 Make sure the engine is off.

   3.3 Place a jack under the center of the front axle, and raise the steer tires off the ground.

3.4 Turn the steering wheel to the right until the axle stopscrew contacts the axle stop, or the end of the gear travel is reached. This pushes out the left-hand turn poppet to prepare it for setting. See **Fig. 6**.



1. Adjustable Poppet Screw

Fig. 6, Preparing the Poppet for Setting

3.5 Turn the steering wheel to the left until the left-hand stop makes contact. This sets the left-turn poppet. Release the steering wheel, and do not steer again until after the adjusting nut has been backed out and the sealing nut tightened.

3.6 Loosen the sealing nut on the gear housing, and back out the adjusting screw until it is 1 to 1-1/16 inches (25 to 27 mm) beyond the sealing nut. See **Fig. 7**. Tighten the sealing nut 38 to 42 lbf·ft (52 to 57 N·m).

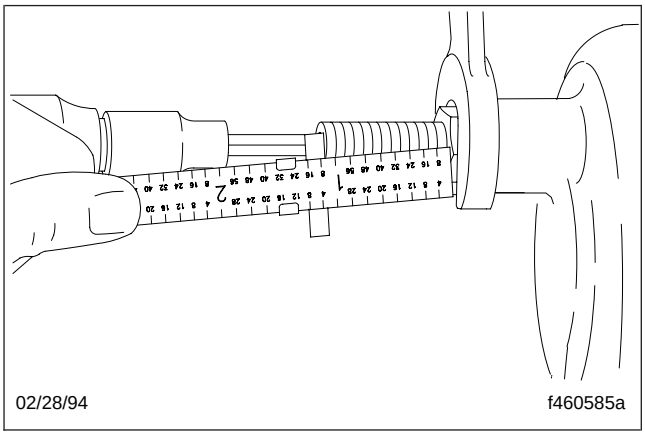


Fig. 7, Back Out the Adjusting Screw and Measure

IMPORTANT: Make sure the adjusting screw does not protrude more than 1-1/16 inches (27 mm) beyond the sealing nut.

3.7 Have someone turn the steering wheel all the way to the right, and hold it in place when the axle stops are contacted.

3.8 With the steering wheel held in place, loosen the sealing nut one turn, and while holding the sealing nut, turn the adjusting screw using an Allen wrench. Do not force the screw. Use one or two fingers and turn the Allen wrench until it comes to a stop. When this happens, contact has been made with the poppet seat. **Do not turn it any further.** Back out the screw four complete turns. Have the steering wheel released at this time.

3.9 While holding the adjusting screw in place, tighten the sealing nut firmly against the gear housing. See **Fig. 8**. Tighten it 38 to 42 lbf·ft (52 to 57 N·m).

Check the adjusting screw. If it extends more than 1-1/16 inches (27 mm) from the sealing nut, loosen the sealing nut, and turn the adjusting screw in as needed. Tighten the sealing nut 38 to 42 lbf·ft (52 to 57 N·m). See **Fig. 7** and **Fig. 8**.

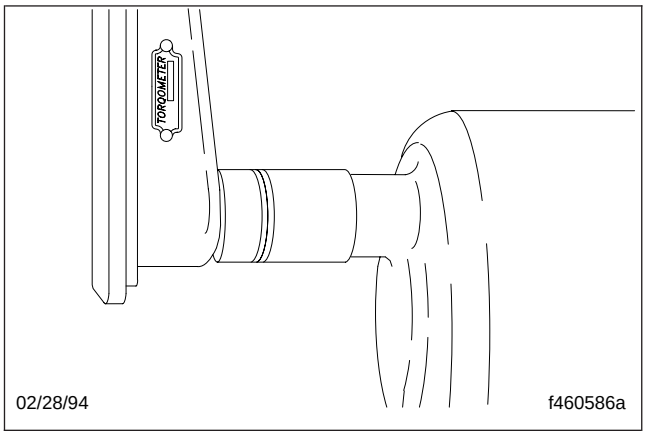

Fig. 8, Tightening the Sealing Nut

⚠ WARNING

If the adjusting screw protrudes more than 1-1/16 inches (27 mm) from the sealing nut, the screw could fall out of the steering gear, resulting in

In-Vehicle Adjustments

loss of power steering. This could cause an accident resulting in serious personal injury or property damage.

IMPORTANT: Once the poppet adjusting screw and sealing nut are in place and the poppet valves have been manually adjusted, the adjustment procedure must be repeated if steering travel is either increased or decreased in the future.

Removal

1. Verify correct axle stop adjustment. For instructions, see **Section 33.00**, Subject 110. Ensuring correct axle stop adjustment now will eliminate the possibility of resetting steering gear poppet valves after the gear is installed.
2. Place the front tires in the straight-ahead position. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where the work is to be done. Apply the parking brakes and chock the tires.

CAUTION

Do not turn the steering wheel or the steering shaft more than a half turn (except for alignment purposes) during the removal and installation procedures. Doing so may damage the clockspring in a vehicle equipped with an air bag.

3. Clean all outside dirt from around the fittings and hose connections.
4. Drain the power steering system. Disconnect all hydraulic lines from the gear, marking the lines for later assembly reference. Seal the lines and the fittings to keep out dirt.
5. Remove the drag link.
6. Disconnect the steering driveline from the steering gear input shaft as follows.

   6.1 Remove and discard the pinch bolt and nut from the steering driveline lower end yoke.

CAUTION

Do not pound the U-joint or lower end yoke on or off the input shaft. Internal damage to the steering gear can result.

   6.2 Remove the end yoke from the input shaft.

7. Clean the entire assembly before removing the gear.

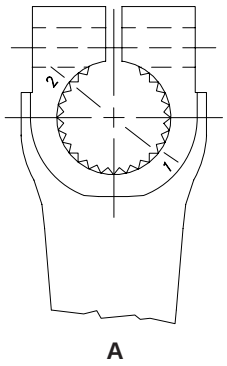
WARNING

The steering gear is heavy. Use caution when removing, lifting, or carrying the steering gear. Failure to do so could cause personal injury.

8. Remove the fasteners that attach the steering gear to the frame rail and frame rail extension. Remove the spacers and the steering gear.

Installation

1. Install the steering gear and mounting fasteners. Torque the fasteners 427 lbf·ft (579 N·m).
2. If not previously done, center the steering gear. The sector (output) shaft alignment mark must be at a right angle to the steering gear input shaft center line. Make sure the steering gear remains centralized as the service work continues.
3. If the pitman arm was removed, install the pitman arm on the steering gear, aligning the timing marks as shown in **Fig. 1**.



05/01/95 f461023

A. Timing Mark No. 2 Aligned

Fig. 1, Typical Pitman Arm and Timing

NOTE: The pitman arm may not fit over the splines on the sector shaft without spreading the slot in the arm. To wedge the slot open, clamp the pitman arm in a vise with the slot at the top. Use a ball-peen hammer to drive a chisel into the slot. Hold the chisel in place, remove the

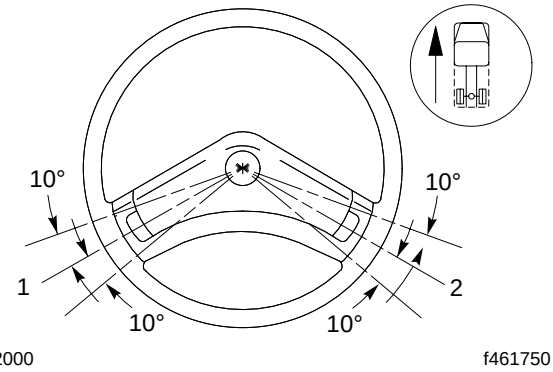
Steering Gear Removal and Installation

pitman arm from the vise, and install the pitman arm on the sector shaft. Remove the chisel from the slot.

⚠ WARNING

Never leave a chisel wedged in the pitman arm slot. When using a chisel to spread the slot in the pitman arm, maintain a firm grip on the chisel at all times. Otherwise the chisel may fly loose, which could cause an injury.

4. Install a new pitman arm pinch bolt, washer (if applicable), and a new nut. Tighten the nut 230 lbf·ft (312 N·m).
5. Connect the steering driveline to the steering gear input shaft.
   - 5.1 Clean the input shaft and the inside of the driveline yoke.
   - 5.2 Position the steering wheel so that it is within ±10 degrees of center as shown in **Fig. 2**.



1. 8 o'Clock Position 2. 4 o'Clock Position

Fig. 2, Steering Wheel Centered

   - 5.3 Slide the yoke on the input shaft, and install a new pinch bolt and nut. Tighten the nut to one of the following torque specs:
     - 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
     - 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut
6. Connect the drag link to the pitman arm.
   - 6.1 Connect the pitman arm end of the drag link to the pitman arm, and install the castle nut.
   - 6.2 Tighten the castle nut 160 to 300 lbf·ft (217 to 407 N·m). If necessary, continue tightening the castle nut until a slot on the nut aligns with a hole in the ball stud. **Do not back off the nut.**
   - 6.3 Install a new cotter pin through the ball stud and the castle nut, then lock the cotter pin in place.
   - 6.4 Wipe the grease fittings clean at both ball stud sockets, then fill the sockets with Exxon Polyrex® EP2 grease using a pressure gun.
7. If they were removed, attach the hydraulic line elbow fittings to the steering gear. Tighten the fittings 37 lbf·ft (50 N·m). Tighten the pressure-line fitting jam nut 41 lbf·ft (56 N·m) maximum.
8. Remove the plugs from the hydraulic lines. Connect the hydraulic lines to the steering gear as previously marked. Tighten the nut on each fitting finger-tight. Then use a wrench to tighten the nut until there is firm resistance. Tighten one-sixth turn more.
9. Fill and bleed the steering system.

   IMPORTANT: For the next two substeps, do not turn the steering wheel. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

   - 9.1 Fill the power steering reservoir nearly full. See **Specifications 400** for approved hydraulic fluids.

     Crank the engine for 10 seconds without allowing it to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed.

     Repeat this procedure three times, each time checking and filling the reservoir.
   - 9.2 Start the engine and let it idle for two minutes. Shut down the engine and check the fluid level in the reservoir.
   - 9.3 Start the engine again. Steer the vehicle from full left to full right several times. As

necessary, add fluid to the full line on the reservoir dipstick.

IMPORTANT: If the poppet adjuster seat and sleeve assemblies were not set for automatic adjustment during the assembly of the steering gear, **and** if the axle stops have been adjusted for decreased steering travel or the steering gear is installed on a different vehicle, the poppets must be set manually following the procedure under **Subject 100**.

10. Go to **Subject 140** and do the checks as instructed.
11. Test drive the vehicle or take a ride with the driver. Check the steering wheel spoke position. If during straight-ahead driving on a level road, the steering wheel spokes are not within ±10 degrees of the 8 o'clock and 4 o'clock positions, remove the steering wheel and reposition it.

Replacement

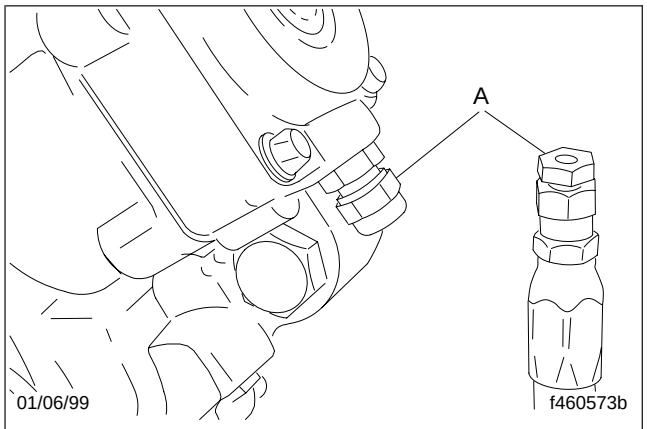
⚠ WARNING

All steering mechanisms are safety items. Because of this, follow the instructions in this subject exactly. Failure to do so may result in loss of steering, which could cause an accident resulting in personal injury or property damage.

Be sure that the required tools are available before beginning the service procedures described here. See the special tools table in **Specifications 400**. The special tool required for replacing the seal is available from SPX Kent-Moore or an affiliated dealer.

If the input shaft seal is causing an external leak, use the following procedure to replace it. This procedure does not require removing and disassembling the steering gear.

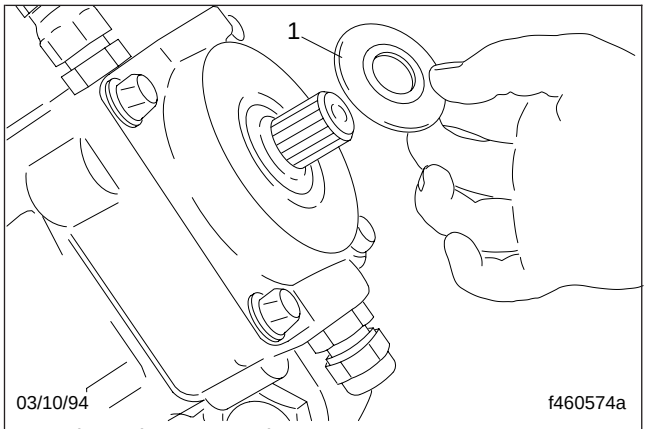
1. Apply the parking brakes, chock the tires, and tilt the hood.
2. Clean all dirt from the area around the return line fitting and input shaft.
3. Disconnect the return line from the steering gear, and cap the line. See **Fig. 1**. Cap the return port of the gear with a 3/4–16 O-ring-type high pressure fitting.



A. Cap the return line and the return port.

Fig. 1, Disconnect the Return Line

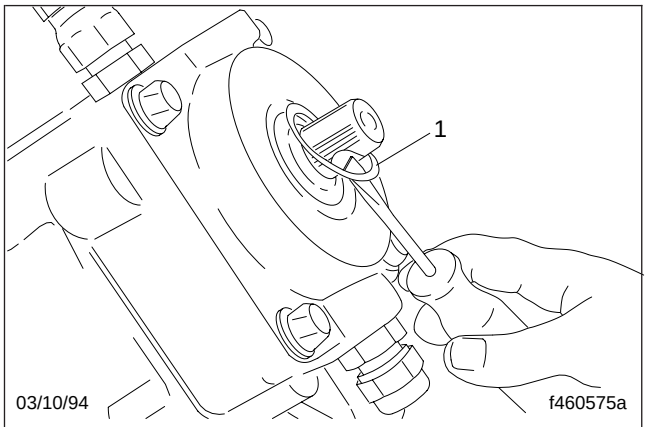
4. Disconnect the steering driveline from the steering gear input shaft. For instructions, refer to **Subject 110**.
5. Remove the dirt and water seal from the input shaft. See **Fig. 2**.



1. Dirt and Water Seal

Fig. 2, Remove the Dirt and Water Seal

6. Wipe off the grease from around the input shaft, then remove the spiral retaining ring by inserting a screwdriver into the notch in the end of the ring. See **Fig. 3**.

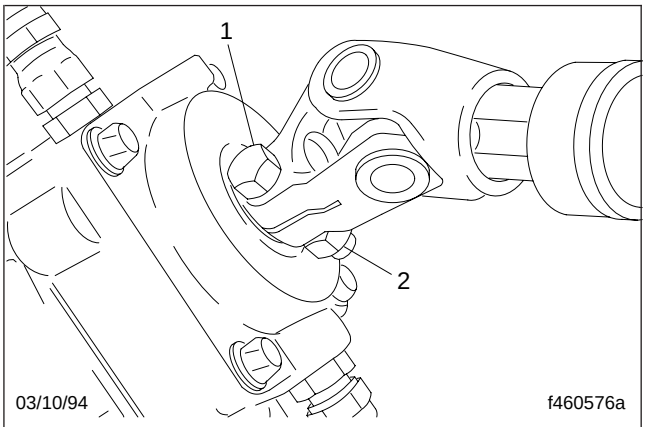


1. Retaining Ring

Fig. 3, Remove the Retaining Ring

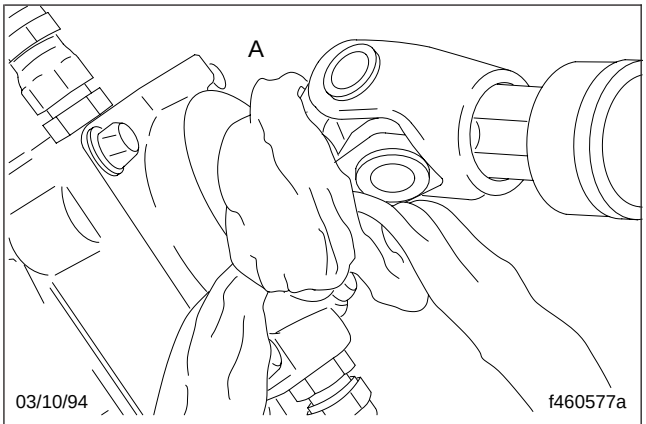
7. Slip the input yoke back onto the input shaft. Install the pinch bolt, but do not tighten it. See **Fig. 4**.
8. Tie or wrap a shop towel around the input shaft area, and place a drip pan under the gear to catch any spilled oil. See **Fig. 5**.
9. If needed, fill the power steering reservoir with Dexron® II or III automatic transmission fluid.

Input Shaft Seal Replacement



1. Pinch Bolt 2. Pinch Bolt Nut

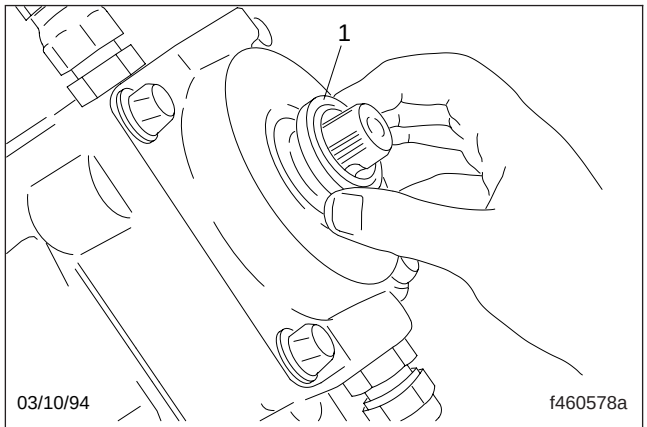
Fig. 4, Install the Pinch Bolt



A. Cover the input shaft area.

Fig. 5, Shop Towel Covering the Input Shaft

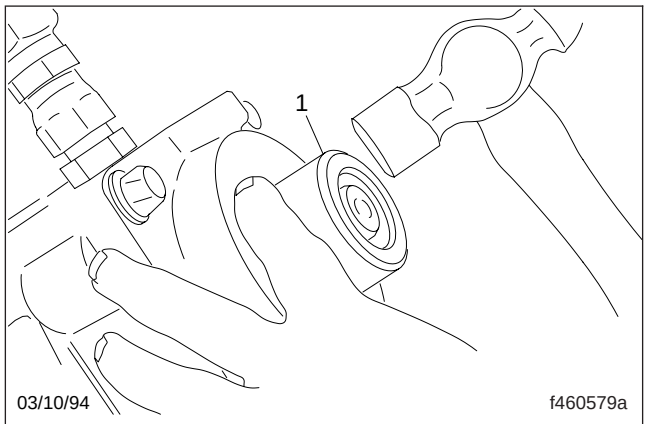
10. With the transmission in neutral, momentarily crank the starter. Quickly turn off the engine if it starts.
11. Remove the shop towel and disconnect the steering driveline from the input shaft.
12. Remove the input shaft seal. See **Fig. 6**.
13. Check the seal area of the valve housing for any seal fragments. Remove any that are found.
14. Check the seal for heat damage. If the seal is stiff and brittle, and not pliable like the new seal, it is probably heat damaged. Determine and fix the cause of excessive heat. For instructions, see **Troubleshooting 300**.



1. Input Shaft Seal

Fig. 6, Remove the Input Shaft Seal

15. Put clean grease on the new input shaft seal, and place it over the input shaft, garter spring side first. Place the input seal installer tool, J37073, over the input shaft and against the seal, small diameter end first. See **Fig. 7**. Tap the seal installer tool until the tool shoulder is square against the valve housing. Remove any seal material that may have sheared off in the seal bore or retaining ring groove.

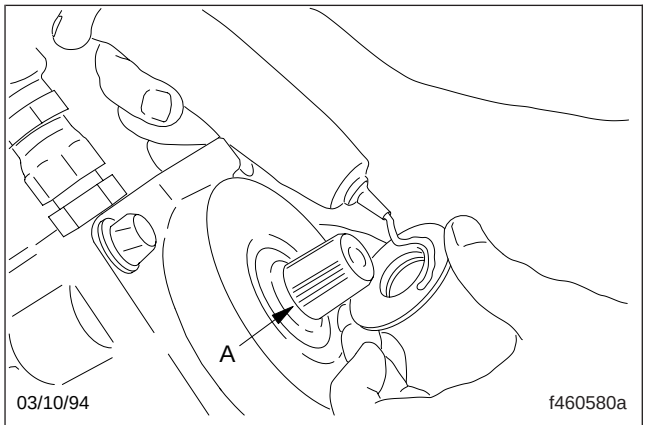


1. Seal Installer Tool

Fig. 7, Position the Seal Installer Tool

16. Insert the new retaining ring into the groove.
17. Pack the end of the valve housing bore around the input shaft with Exxon Polyrex® EP2 grease. Also apply grease to a new dirt and water seal. Install the seal over the input shaft, seating it in

the groove behind the serrations and against the valve housing. See **Fig. 8**.



A. Seat the seal here.

Fig. 8, Install the Dirt and Water Seal

18. Connect the steering driveline to the steering gear input shaft. For instructions, see **Subject 110**.
19. Connect the return line to the steering gear return port.
20. Fill and bleed the steering system.

    IMPORTANT: For the next two substeps, do not turn the steering wheel. Doing so can cause air to enter the system, which can make it more difficult and time-consuming to bleed air from the system.

    20.1 Crank the starter for 10 seconds without allowing the engine to start. If the engine does start, shut it down immediately. Check and fill the reservoir as needed.

    Repeat this procedure three times, each time checking and filling the reservoir.

    20.2 Start the engine and let it idle for two minutes. Shut down the engine, and check the fluid level in the reservoir.

    20.3 Start the engine again. Turn the steering wheel from full left to full right, several times. As needed, add fluid to the full line on the reservoir dipstick.

21. With the engine running, check for leaks in the steering system. Eliminate leaks as needed.
22. Lower the hood and remove the chocks from the tires.

Post-Service Checks |

After power steering components have been worked on, and before the vehicle is placed into service, the following items must be checked.

⚠ WARNING

Failure to check the following items could result in damage to the power steering system. This could cause a loss of hydraulic assist, which could cause personal injury or property damage.

1. Place a thermometer in the power steering reservoir, then warm the hydraulic system to normal operating temperature of 125 to 135°F (52 to 57°C) by operating the engine at low idle while turning the steering wheel through several full-left and full-right turns. With the engine running and the power steering system at operating temperature, turn the steering wheel slowly from stop to stop while checking the power steering reservoir for frothing or a change in the fluid level (a sign that air is trapped in the system). If air is present, inspect the system for leaking hoses or loose fittings. Replace the hoses or tighten the fittings as necessary. Bleed the air from the system.
2. With the engine turned off and warm, check the power steering reservoir fluid level. For instructions, see **Group 46** in the*L-Line and A-Line Maintenance Manual*.
3. At full-left and full-right wheel cuts, be sure the axle stops (on the rear-side of the spindle) are set so there is at least 1/2-inch (13-mm) clearance between the tires and any fixed components that are attached to the vehicle. Clearance between moving components should be 3/4 inch (19 mm). If clearance is less than the above, reset the axle stops.
4. Check that the poppet plungers are set correctly. If needed, adjust them. For instructions refer to **Subject 100**.
5. If there are still problems with the power steering system, go to **Section 46.10, Subject 300** and perform the troubleshooting procedures. Otherwise, go to the next step.
6. Test drive the vehicle. Check the steering wheel spoke position. If during straight-ahead driving on a level road, the steering wheel spokes are not within ±10 degrees of the 8 o'clock and 4 o'clock positions, remove the steering wheel and reposition it.

⚠ WARNING

Fill the power steering system only with approved, clean hydraulic fluid. Mixing hydraulic fluids and using unapproved hydraulic fluid could lead to seal deterioration and leaks. A fluid leak could eventually cause loss of power steering assist.

The following hydraulic fluids are approved for use in the steering system:

- Automatic Transmission Fluid (ATF), Dexron® II
- Automatic Transmission Fluid (ATF), Dexron® III

The following type of grease is approved for use on the steering gear components:

- Exxon Polyrex® EP2 (PN 045422)

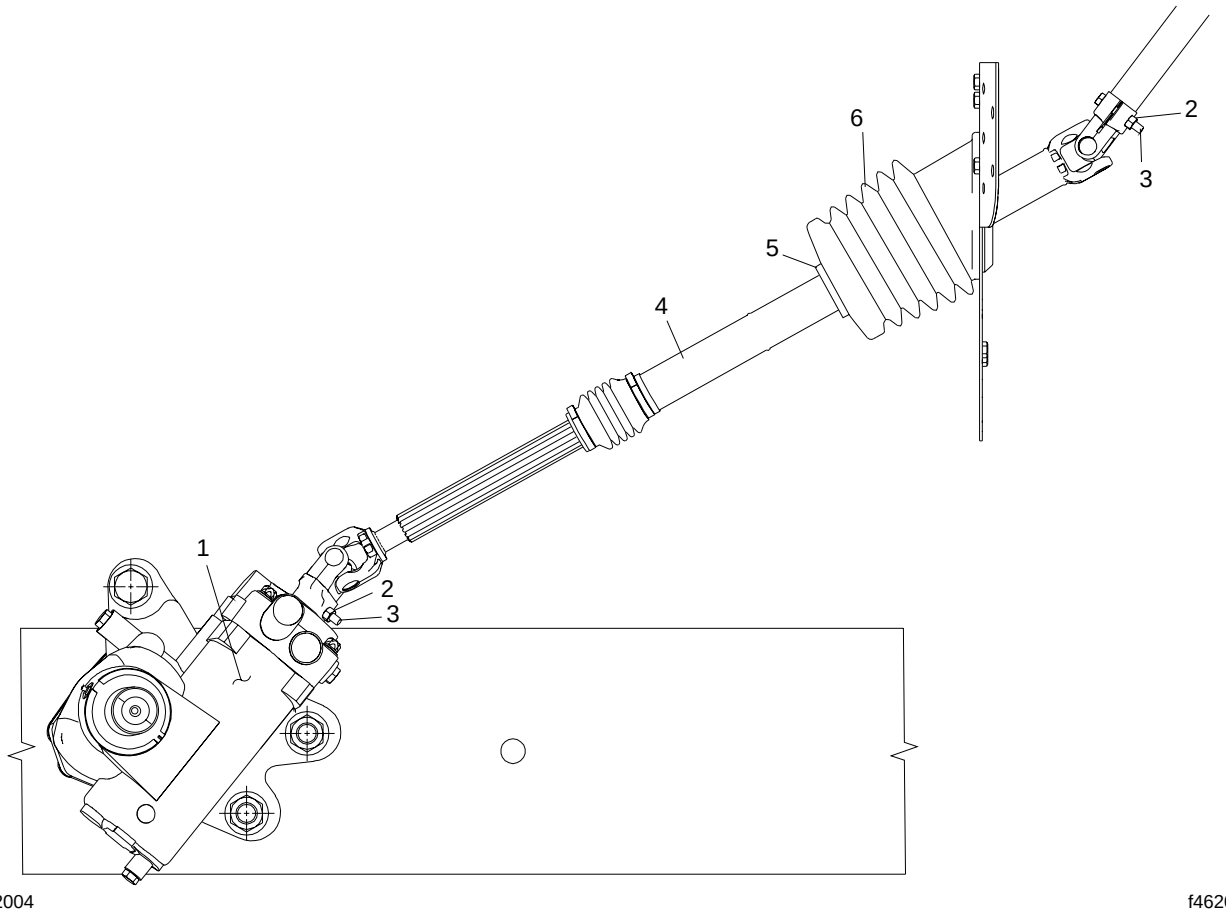
Steering Driveline Replacement

Replacement

1. Position the front tires straight ahead. If possible, drive the vehicle in a straight line for a short distance, stopping at the spot where service operations will be done.
2. Shut down the engine, apply the parking brakes, chock the tires, and open the hood.
3. Remove and discard the pinch bolt and nut that attach the steering column to the steering driveline, then remove the steering driveline from the steering column. See **Fig. 1**.
4. From inside the cab, push the steering driveline boot into the engine compartment.
5. Remove and discard the pinch bolt and nut that attach the steering driveline to the steering gear, then remove the steering driveline.
6. Remove the boot and boot bushing from the steering driveline.
7. Install the boot and boot bushing on the new steering driveline.
8. Install the steering driveline.

   8.1 Using a new pinch bolt and nut, attach the steering driveline to the steering gear.



1. Steering Gear
2. Nut
3. Pinch Bolt
4. Steering Driveline
5. Boot Bushing
6. Boot

Fig. 1, Steering Driveline Installation, TRW Model Shown

Steering Driveline Replacement

Tighten the nut to one of the following torque specs:

- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

8.2 Apply torque seal, OGP F900WHITE, to the exposed threads of the pinch bolt and to the nut.

8.3 Place the driveline through the frontwall.

8.4 Using a new pinch bolt and nut, attach the steering driveline to the steering column. Tighten the nut to one of the following torque specs:

- 55 to 65 lbf·ft (75 to 88 N·m) for a 7/16–20 pinch bolt and nut
- 30 to 35 lbf·ft (41 to 47 N·m) for an M10 x 1.25 pinch bolt and nut

9. Apply torque seal, OGP F900WHITE, to the exposed threads of the pinch bolt and to the nut.
10. Make sure the steering wheel is centered.
11. Put the boot in place on the frontwall.
12. Close the hood and remove the chocks from the tires.

General Information

A *Checklist for Troubleshooting Power Steering Problems*, form STI-492, has been developed to accompany the procedures below. Form STI-492 can be downloaded or printed **here** after logging into **www.AccessFreightliner.com**.

Each step and substep in these troubleshooting procedures corresponds to a step or substep on form STI-492. Use **Table 1** to determine which steps should be completed, based on the customer's complaint. It is very important that the information provided by the driver is communicated accurately to prevent wasting of diagnostic time. For example, if complaints include "Pulling to one side" and "Noisy steering," steps 1, 3, 4, 5, and 6 will be the tests for the most likely failure modes.

Start with the lowest test number and work up to the highest. For example, when completing steps 1, 3, and 6 to determine the cause of a vehicle pulling to one side, start with step 1 and finish with step 6.

Troubleshooting Steps

NOTE: Some of these inspections and procedures can be found in the Pretrip and Post-Trip Inspections and Maintenance chapter in the vehicle driver's/operator's manual.

Steps 1 through 4 may have been performed by the customer. Verify the vehicle service history with the customer to prevent redundant testing.

All measurements and readings must be recorded on STI-492.

Refer to the applicable section in this manual to repair or replace steering system components.

1. Check the tire pressure and load.

   1.1 Check the tires for damage.

   1.2 Check that the front tires are inflated to the correct pressure, and the tire pressure is equal on both sides. Correct the pressure if needed.

   Low pressure causes increased steering effort due to friction with the road surface. Unequal tire pressure causes unequal friction between the tire and the road. This can cause pulling to one side.

Steering Complaint and Troubleshooting Steps Checklist												
LH	RH	Both	Complaint	Troubleshooting Steps								
				1	2	3	4	5	6	7	8	9
			Hard or heavy steering	•	•		•	•	•	•	•	•
			Low assist									
			Binding									
			Locking									
			Occasional loss of assist									
			Reduced wheel cut								•	
			Pulling to one side*	•		•			•			
			Darting/oversteering	•	•	•	•		•			
			Wandering									
			Noisy steering				•	•	•			
			External seals leaking					•	•			•
			Excessive heat									

* If there is consistent pull to one side, a braking issue could feel like a steering assist problem. Refer to **Group 42** in this manual to ensure the brake system is functioning properly.

Table 1, Steering Complaint and Troubleshooting Steps Checklist

Troubleshooting Procedures

1.3 Check that the rear tires are inflated to the correct pressure, and the tire pressure is equal on both sides. Correct the pressure if needed.

1.4 Check that the tire sizes are correctly matched, and whether duplex or oversized tires (that were not originally specified for the vehicle) have been installed.

Extra tire width causes increased steering effort due to extra friction with the road surface. If the axle stops were turned out to reduce wheel cut due to a change in tires, the power steering gear poppets may need to be adjusted.

1.5 Communicate with the driver or operator to determine whether the vehicle is operated at or over the rated load.

Increased load causes greater steering effort. Make sure the vehicle is being operated within rated capacities.

2. Check fifth wheel lubrication and condition.

A dry fifth wheel plate makes it difficult to change direction. Check the plate surface for burrs, gouges, and irregularities.

3. Check vehicle alignment and wheel bearing adjustment.

3.1 Check the vehicle service history for the last known alignment, and inspect tire wear for indications that an alignment needs to be completed.

3.2 Check front axle caster and camber measurements.

3.3 Ensure wheel bearings and rear axle are in good condition, and that toe is set correctly.

3.4 Ensure the rear axle is properly aligned.

4. Check for loose and binding components. Check whether any steering components need maintenance or adjustment.

4.1 Check for proper lubrication of the drag link, tie rods, and knuckle pins. Apply lubrication as needed.

4.2 Check the COE steering column, if equipped. Chock the rearmost tires. With the engine shut down, turn the steering wheel and check for looseness or binding. Make sure all components are free to move, but are not excessively loose.

4.3 Check the steering driveline U-joints for looseness or binding. Lubricate them if needed.

4.4 Check the sector shaft adjustment.

- With the vehicle on the ground, the engine idling, and the front tires pointed straight ahead, turn the steering wheel until slight motion is observed at the front wheels.
- Align a reference mark on the steering wheel to a rule, then, with the engine running, slowly turn the steering wheel in the opposite direction until motion is again detected at the wheels.
- Measure the lash (free play) at the rim of the steering wheel.

Excessive lash exists if steering wheel movement exceeds 2-1/2 inches (64 mm) with a 20-inch (508-mm) steering wheel, or 2-1/4 inches (57 mm) with an 18-inch (457-mm) steering wheel.

4.5 Check that the front wheels self-return without binding.

- With the engine off, chock the rearmost tires and place the front tires on radius plates (turntables).
- Disconnect the drag link from the steering arm.
- By hand, pull one tire to the axle stop and release. The tire should self-return to almost straight ahead.
- Repeat with the opposite tire.

If a tire does not return to near straight ahead, check for binding or lack of lubrication in the steering axle kingpin bushings or tie rod linkage.

- Connect the drag link and tighten the castle nut, then install a new cotter pin.

4.6 Inspect all suspension fasteners and components for wear or looseness.

5. Check the steering system for leaks and restrictions, and test the system back pressure.

5.1 Inspect hoses, fittings, and seals for damage or leaks.

- With the engine idling, inspect for kinked or collapsed hoses. Repair or replace any collapsed or kinked hoses. If collapsed hoses are found, ensure the steering system is filled with the correct automatic transmission fluid.
- Inspect fittings for leaks. Repair leaking fittings; replace parts as needed.
- Inspect all external seals. Replace leaking seals.

  Inspect the seal bores and sealing surfaces for scrapes or burrs. Make sure the seals are installed correctly using the recommended tools.
- If you replaced the steering gear input shaft seal and found it to be excessively hard, test the system operating temperature in step 6.

5.2 Inspect the steering gear for external leakage.

- Clean the area around the input shaft and inspect the input shaft for signs of leakage after operating the vehicle under normal conditions through steering maneuvers.
- Inspect the sector shaft for signs of leakage. A well greased or heavily used steering gear may weep oil from the grease seal, but a confirmed leak will be evidenced by fluid collecting while the vehicle is being operated under normal conditions.
- Inspect the vent plug in the trunnion housing for signs of leakage. Any fluid in or around the rubber vent plug indicates leakage from an internal steering gear seal.

NOTICE

Do not turn the steering wheel or allow system pressure to exceed the rating of the gauge during the following test. Damage to the gauge could occur.

5.3 Check total steering system back pressure.

- Install a low pressure gauge—300 psi (2068 kPa) maximum—between the steering pump and the steering gear.
- Check for correct fluid level. If necessary, add fluid. If bubbles or foam appear in the reservoir, check hose fittings for looseness or leaks.
- With the engine idling, read the total system back pressure on the pressure gauge.
- If the total system back pressure is greater than 100 psi (689 kPa), or 140 psi (965 kPa) for a vehicle with hydraulic brakes, replace the steering fluid filter and re-test the system. If the system back pressure is still excessive, go to the next substep.

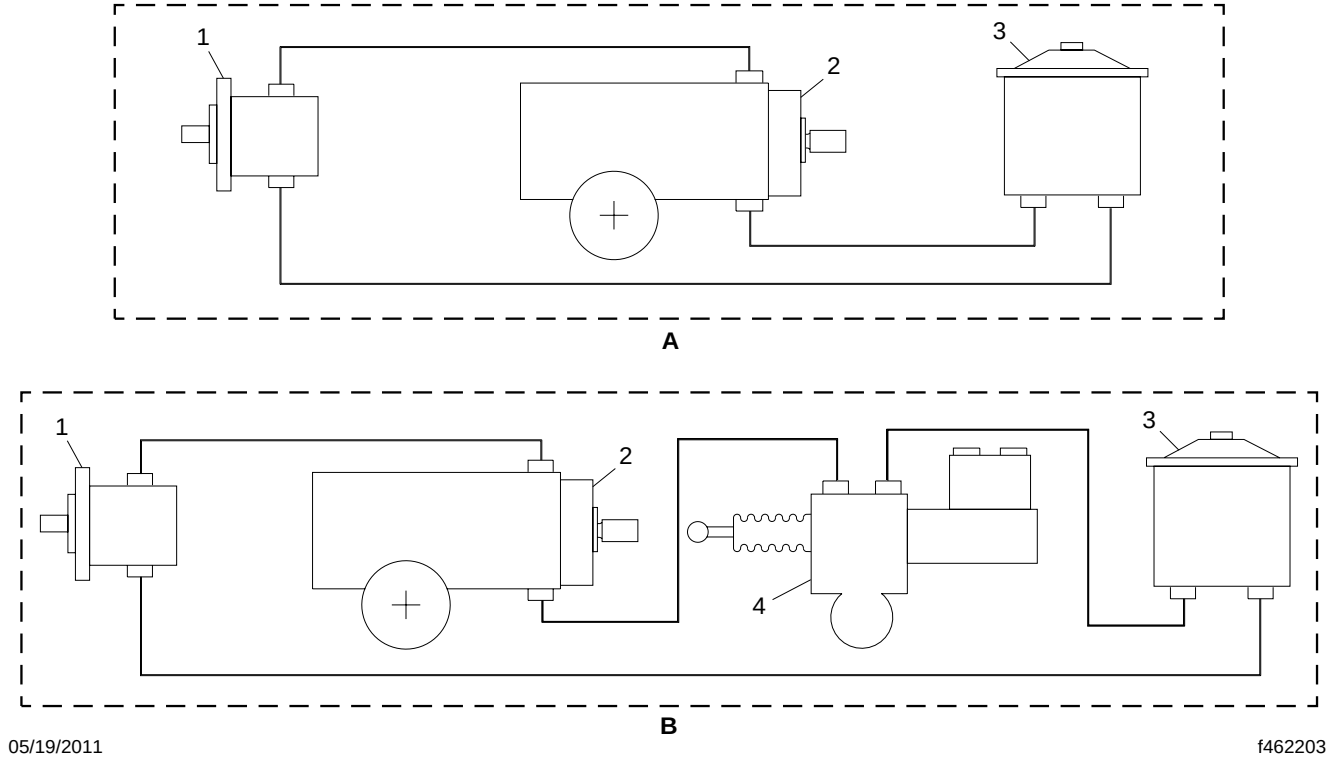
  If the total system back pressure is less than 100 psi (689 kPa), or 140 psi (965 kPa) for a vehicle with hydraulic brakes, restriction is not a problem—go to step 6.

5.4 Leave the low pressure gauge in place and check individual steering system components for excessive restriction. See **Fig. 1** for a plumbing diagram.

- Bypass the steering gear by disconnecting the steering gear input and output lines from the gear and coupling them together. See **Fig. 2** for an example.

  If the drop in system pressure from the value found in substep 5.3 is greater than 55 psi (379 kPa), the steering gear has excessive restriction. If the drop in pressure is less than 55 psi (379 kPa), reconnect the

Troubleshooting Procedures



A. Vehicles With Air Brakes
1. Steering Pump
2. Steering Gear

B. Vehicles With Hydraulic Brakes
3. Reservoir
4. Brake Booster

Fig. 1, Plumbing Diagrams

gear input and output lines to the gear and continue with this substep.

- If the vehicle is equipped with hydraulic brakes, bypass the brake booster by disconnecting the booster input and output lines and coupling them together.

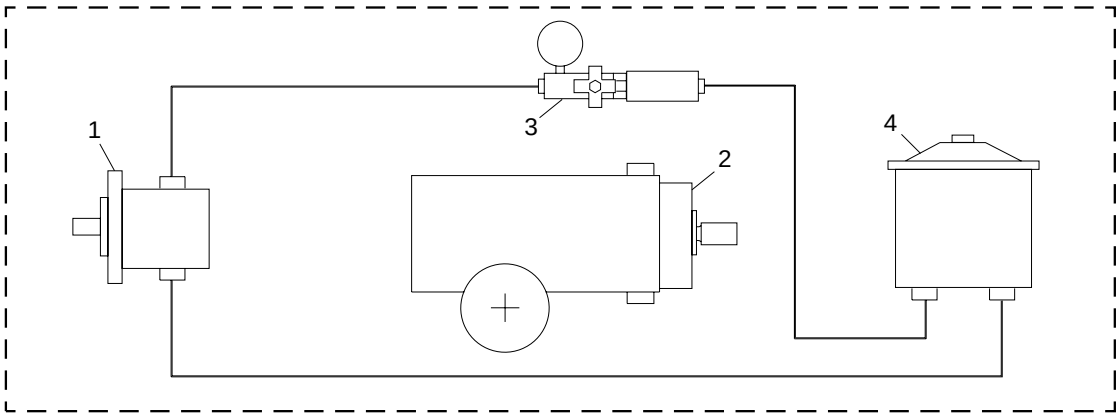
  If the drop in system pressure from the value found in substep 5.3 is greater than 40 psi (276 kPa), the brake booster has excessive restriction. If the drop in pressure is less than 40 psi (276 kPa), reconnect the booster input and output lines and continue with this substep.

- Test each hydraulic line in the power steering system individually by bypassing them one at a time, as was done with the steering gear and brake booster, if equipped.

  If the drop in system pressure from the value found in substep 5.3 is greater than 12 psi (83 kPa) for any one line, replace the line and test total system back pressure again.

6. Check steering pump performance. Power steering fluid temperature should be approximately 180°F (82°C) to best replicate fluid temperatures under normal driving conditions.

   If the system fails the tests in the following substeps, replace the pressure relief valve (PRV) and complete the tests in the substeps below again. If the system fails again, replace the pump.



1. Steering Pump
2. Steering Gear
3. Low Pressure Gauge
4. Reservoir

Fig. 2, Testing Steering Gear Restriction

Install the PSSA between the steering pump and the gear for the following substeps. See the following heading, **Power Steering System Analyzer Setup**, for instructions on PSSA installation.

NOTICE

Do not leave the load valve closed for longer than five seconds during the following test. Doing so could damage the power steering system.

6.1 Check for erratic pump response.

- Slowly close the load valve and watch the pressure and flow readings as the valve closes, then open the valve immediately.
- If the pressure rises rapidly or appears uncontrolled, open the load valve immediately.
- If the response was erratic, replace the PRV or pump, as required. If the response was smooth and controlled, go to the next substep.

6.2 Check the pump relief pressure.

- Slowly close the load valve. When the valve is completely closed, read the pressure gauge, then open the valve.
- If the pump relief pressure does not exceed the relief pressure in **Table 2** or **Table 3**, refer to the pump manufacturer's service literature to verify the exact relief pressure for the pump.
- If the pump relief pressure does not exceed the relief pressure in **Table 2**, **Table 3**, or the pump manufacturer's specifications, replace the PRV or pump, as required.
- If the pump relief pressure exceeds the relief pressure in **Table 2** or **Table 3**, it is acceptable. Go to the next substep.

6.3 Test the pump relief valve reaction at idle.

- Run the engine at idle and note the flow rate with the load valve open.

Troubleshooting Procedures

Minimum Measured Pump Flow and Relief Pressure at Engine Idle				
Power Steering Gear	**Flow at 1500 rpm, No Load: gpm (L/min)**	**Flow at 1000 psi (6900 kPa): gpm (L/min)**	**Flow at 1800 psi (12 400 kPa): gpm (L/min)**	**Typical Relief Pressure: psi (kPa)**
Sheppard M100	3.7 (14.0)	2.8 (10.6)	2.3 (8.7)	2175 ± 100 (15 000 ± 700)*

Table 3, Minimum Measured Pump Flow and Relief Pressure for High-Pressure Gears at Engine Idle

- Close the load valve until the pump relief pressure is reached. Smoothly and quickly open the load valve and note the flow rate. Repeat this action three times. The flow rate should return to the flow rate first noted with the load valve open.
- If the flow rate does not return smoothly and quickly, the pump relief valve is not working correctly. Replace the replace the PRV or pump, as required.
- If the flow rate returns smoothly and quickly, the pump relief valve is acceptable. Go to the next substep.

6.4 Test the pump relief valve reaction at 1500 rpm.

- Run the engine at 1500 rpm and note the flow rate with the load valve open.
- Close the load valve until the pump relief pressure is reached. Smoothly and quickly open the load valve and note the flow rate. Repeat this ac-

tion three times. The flow rate should return to the flow rate first noted with the load valve open.

- If the flow rate does not return smoothly and quickly, replace the PRV or pump, as required.
- If the flow rate returns smoothly and quickly, the pump relief valve is acceptable. Go to the next substep.

6.5 Test the flow of the pump at idle with a load applied.

For vehicles with low-pressure steering gears, run the engine at idle and slowly close the load valve until the pressure gauge reads 1000 psi (6900 kPa). Read the flow rate on the gauge, then set the pressure to 1800 psi (12 400 kPa). Read the flow gauge, then open the load valve. Compare the values to those in **Table 2**.

For vehicles with high-pressure steering gears, use 1000 psi (6900 kPa) and 2300 psi (15 860 kPa) as the test load pressures. See **Table 3** for minimum flow rate.

6.6 Test the maximum flow of the pump with no load applied.

- Run the engine at 1500 rpm, make sure the load valve is completely open, and read the flow gauge.
- If the flow rate is below the minimum indicated in **Table 2** or **Table 3**, replace the PRV or pump, as required.
- If the flow rate is above 5.5 gpm (20.8 L/min) on a vehicle with a single steering gear, or 7.7 gpm (28.8 L/min) on a vehicle with an assist cylinder installed, replace the pump.

7. Test the steering gear internal leakage.

Select TRW integral steering gears and all ThyssenKrupp rack and pinion steering gears are equipped with an internal PRV that significantly limits maximum supply pressure to protect the steering gear. These gears, unlike gears on vehicles fitted with hydraulic brake boosters, cannot be tested for internal leakage by plugging the internal PRV in the gear. The pump output must be limited to prevent excessive pressure from damaging the gear, and the internal PRV passage must be blocked to direct oil flow through the gear.

Use PartsPro® for the specific VIN to determine if the steering gear is equipped with an internal PRV, which will be listed as a serviceable part under module 536.

If a TRW steering gear has an internal PRV but no hydraulic brake booster, see the following heading, **Internal Leakage Test Setup, TRW Steering Gears With an Internal PRV**, for instructions on setting up the necessary test components before proceeding with the following substeps.

ThyssenKrupp rack and pinion steering gears are also equipped with an internal PRV, but cannot be tested for internal leakage.

IMPORTANT: Make sure the fluid temperature is approximately 180°F (82°C) and the vehicle is stationary with the front wheels pointing forward.

7.1 Run the engine at idle with the load valve open.

WARNING

Keep fingers clear of the stop bolt and spacer block during the following test. Make sure that the spacer block contacts the axle stop squarely. Contact that is not square could break the stop bolts or eject the spacer block, which could cause serious personal injury.

7.2 Place an unhardened steel spacer, 1-inch (25-mm) thick, between the axle and the stop bolt on one side of the axle.

The spacer should have an extension or handle long enough to keep fingers clear of the axle stop area. A brazing rod or welding rod works well for this purpose.

NOTICE

While running the following test, do not hold the steering wheel in the full-turn position for more than five seconds. Doing so could damage the pump.

Troubleshooting Procedures

7.3 Have someone turn the steering wheel, applying enough force to completely close the rotary valve.

Complete closure of the rotary valve requires approximately 20 lbf (27 N) pull on the steering wheel, and will be indicated by a pressure reading nearly equal to the system relief pressure (tested in substep 6.2).

7.4 Hold the steering wheel in the full-turn position. Note the steering gear internal leakage on the PSSA.

7.5 Repeat the previous substeps for the opposite turn.

The maximum permissible internal leakage for a single gear is 1.0 gpm (3.8 L/min). If leakage is greater in either turning direction, replace the steering gear components as needed.

For systems with two or more steering gears and/or linear cylinders, the total acceptable internal leakage is 1.0 gpm (3.8 L/min) for each steering gear/ram in the system. Maximum internal leakage on a dual-gear system is 2.0 gpm (7.6 L/min). If the leakage is more than 2.0 gpm (7.6 L/min) on a dual-gear system, isolate the auxiliary cylinder from the system using the substeps that follow.

7.6 Disconnect the auxiliary cylinder hydraulic lines at the main gear auxiliary ports.

7.7 Plug the main steering gear ports with suitable steel or high-pressure plugs or caps.

7.8 Repeat the internal leakage test.

If the internal leakage is less than 1 gpm (3.8 L/min), repair or replace the auxiliary gear or linear cylinder. If the internal leakage is greater than 1 gpm (3.8 L/min), repair or replace the main gear.

8. Check the steering gear poppet relief valve and stop bolt adjustment.

NOTE: Poppets limit the steering assist when the front wheels approach the stop bolts. Improper adjustment can apply excessive force to the steering linkage, or cause loss of assist, as the steering wheel approaches either full-left or full-right turn.

8.1 Check the steering system for stop bolt adjustment.

Make sure the stop bolt settings limit the steering travel so there is ½-inch (13-mm) clearance from all stationary components, and 3/4-inch (19-mm) clearance from all moving components.

8.2 Make sure the pitman arm is situated on the steering gear sector shaft correctly. Check that the pitman arm and sector shaft timing marks are aligned.

NOTICE

If power steering pump relief pressure is reached while the steering wheel is at full lock, release the steering wheel from this position. Do not allow the pump relief pressure to be maintained for longer than five seconds or damage to the pump may result.

8.3 Check the poppet relief pressure.

- Install the PSSA between the steering pump and the steering gear. See the following heading, **Power Steering System Analyzer Setup**, for instructions on PSSA installation.
- Run the engine at idle with the load valve open. Turn the steering wheel to either full-lock position. Note the pressure gauge reading, then repeat for the opposite turn.
- The pressure should drop slightly before the stop bolts are contacted. If the pressure increases (from contact with the stop bolts), the poppets must be manually reset.

  If the pressure is relieved and assist is lost when the wheel is too far from the axle stop bolts, refer to the applicable section in this manual for gear-specific information.
- After poppet replacement or adjustment, test again for correct poppet relief function and record the new pressure.

8.4 Check for normal hissing sound at full turn.

NOTE: Noise from the power steering system does not necessarily mean there is a problem. Some noises are normal and are the result of proper operation.

See **Table 4** for possible causes and remedies for common noises associated with the power steering system and power steering pump.

8.5 Check for abnormal power steering noise.

Listen for a hissing sound at less than full turn. If a hissing sound is heard, check the steering gear poppet and the axle stop adjustment.

NOTICE

If the temperature exceeds 250°F (121°C), damage to hoses, seals, and other components may result if the vehicle continues to operate at excessive steering system temperatures. If this temperature is exceeded, stop the test and record the last noted temperature on STI-492.

9. Test the system operating temperature.

- Run the engine at governed speed.
- Observe the power steering fluid temperature until it stabilizes.
- Record the power steering fluid temperature in 10-minute intervals until 40 minutes have passed.
- If the temperature does not exceed 250°F (121°C) during the test, excessive heat due to system components is probably not the cause of the complaint. The system may still experience overheating due to driving and load conditions.

  If the temperature exceeds 250°F (121°C), excessive steering system back pressure or excessive pump flow may be the cause of the high temperature problem. If system back pressure or restriction values found in substeps 5.3 and 5.4 above were close to the maximum allowable, complete step 5 again. If steering pump flow and relief pressures found in step 6 above were close to the maximum allowable, complete step 6 again.
- If excessive heat continues to be a problem, a cooler may need to be added to the system.

Power Steering System Noise	
Noise	**Remedy**
Growling or other abnormal steering noise	Check the fluid level. Check for air bubbles and foam. Check for hose and fitting leaks. If there is air in the fluid, check for inlet tube and hose leaks. Correct all leaks.
A change from the usual pump sound	Check the steering fluid reservoir for air bubbles and foam. If there is air in the fluid, check for inlet tube and hose leaks. Correct all leaks.
Clicking noise during a turn	Check for loose steering components. Tighten any loose steering components. Check the front suspension for insufficient spring pin shims. Add front spring pin shims if needed.
Hissing when the steering wheel is at or near full turn	This is normal; no action is needed.
Steering Pump intake line is plugged	Drain the system. Clear the intake line if needed. Fill the system.
Air leak at the pump or reservoir connections, fittings, or shaft seal	Check all the connections by pouring power steering fluid over them, and listening for a reduction in sound. Tighten all connections as needed.
Pump input shaft is misaligned	Replace the pump.

Table 4, Power Steering System Noise

Troubleshooting Procedures

Power Steering System Analyzer Setup

The hydraulic power steering system is tested with a Power Steering System Analyzer (PSSA), and with the hydraulic fluid at operating temperature. The PSSA and adaptor kit are available from SPX Kent-Moore.

A PSSA is a combination of a flow meter, a shutoff valve, and a high-pressure gauge. See **Fig. 3**. The PSSA will allow you to measure flow and pressure, and provide a load on the pump in the hydraulic lines of the steering system.

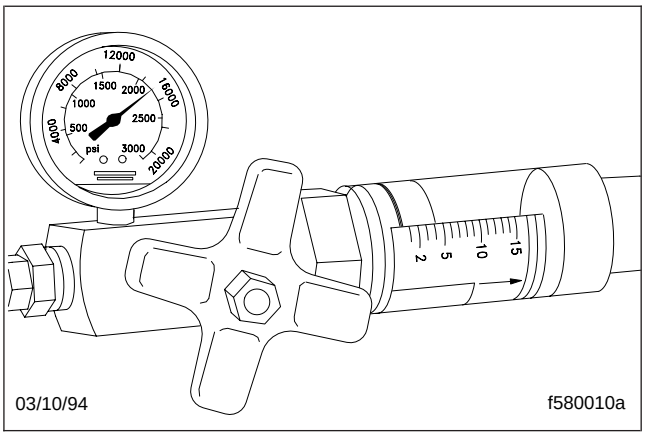

Fig. 3, Power Steering System Analyzer

1. Install a PSSA between the pump high-pressure line and the steering gear.
2. Fill and bleed the steering system as needed.

NOTICE

Do not leave the load valve fully closed for longer than five seconds. Doing so could damage the power steering system.

3. Run the engine at idle.
4. Partially close the load valve on the PSSA until the pressure gauge reads 1000 psi (6895 kPa).
5. Open the valve when the fluid temperature reaches about 180°F (82°C).

Internal Leakage Test Setup, TRW Steering Gears With an Internal PRV

Select TRW steering gears are equipped with an internal PRV that limits maximum supply pressure to protect the steering gear. These gears cannot be tested for internal leakage using the standard procedure. The pump output must be limited to prevent excessive pressure from damaging the gear, and the internal PRV passage must be blocked to direct oil flow through the gear.

Use PartsPro® to determine if a specific TRW steering gear is equipped with an internal PRV, which will be listed as a serviceable part under module 536.

If your TRW steering gear has an internal PRV, complete the following steps to set up the necessary internal leakage test components. See **Table 5** for a list of required leakage test components. The plumbing fittings and hose part numbers are recommended, but may be replaced with identical parts from other suppliers, if necessary.

The ThyssenKrupp rack and pinion steering gear is also equipped with an internal PRV, but cannot currently be tested for internal leakage.

IMPORTANT: The front wheels must be raised or on turnplates during this procedure.

1. Turn the engine off. Remove the relief valve cap, O-ring, and relief valve from the steering gear. See **Fig. 4**.
2. Install the relief valve plug, J-37130, in the internal PRV hole. Install the relief valve cap and O-ring over the plug.
3. Assemble the relief valve cartridge body, relief valve, and tee fittings as shown in **Fig. 4**.
4. Install the PSSA and other test components as shown in **Fig. 4**.
5. Open the external relief valve (**Fig. 4**, Item 15) on the relief valve cartridge. Ensure the PSSA shutoff valve is fully open.
6. Raise the front wheels off the ground and turn the steering wheel to the right and left full-lock positions five times to bleed air from the system.
7. Start the engine and bleed the remaining air out of the system by continuing to turn the wheel from side to side.

NOTICE

Do not leave the PSSA shutoff valve fully closed for longer than five seconds. Doing so could damage the power steering system.

8. With the engine on, close the shutoff valve on the PSSA.
9. Set the system relief pressure by closing the external relief valve (**Fig. 4**, Item 15) until the gauge on the PSSA reaches 2,000 psi (13 790 kPa), then fully open the shutoff valve on the PSSA.
10. Continue with the steering gear internal leakage test (step 9 of the **Troubleshooting Steps** heading above).

General Information

The system consists of the following:

- fuel tanks
- fuel lines
- fuel filter/water separator
- fuel cooler
- fuel flow splitter valve
- fuel level sensor
- fuel heater

Fuel drawn from the fuel tank under suction is routed to the pre-filter and then to the transfer pump (integral to the fuel injection pump). After leaving the transfer pump, fuel is pumped under pressure to the primary fuel filter/water separator. After leaving the fuel filter/water separator, clean fuel enters the fuel injection pump, then, under high pressure, is routed to the fuel injectors. Unused fuel is routed through a fuel cooler unit (if equipped) back into the fuel tank.

All heavy truck fuel tanks are of the outside frame-mounted type and are made of steel or aluminum. Some vehicles are equipped with dual fuel tanks.

A single draw/return system is simply a system that uses a single fuel pickup and return line. This system is found on single fuel tank applications.

Some vehicles are equipped with a dual draw/dual return fuel system. The dual draw/dual return fuel system is designed to provide accurate and reliable equalization of fuel levels in dual tanks without using a fuel crossover tube and to dissipate the heat added to the fuel by the electronic engines to both tanks. The supply tubes and fittings are designed to ensure right-hand and left-hand symmetry and smooth, upward flow paths throughout the fuel system.

A dual draw/return with crossover system is the same as the dual draw/dual return without crossover except that a crossover tube has been added to aid in balancing the levels between the dual fuel tanks.

Two fuel splitter valves are located in the fuel lines. See **Fig. 1**. The return splitter valve splits a single fuel return line into two lines providing balanced fuel return to each of the two fuel tanks. The supply splitter valve channels two fuel lines from the fuel tanks into one delivery fuel line.

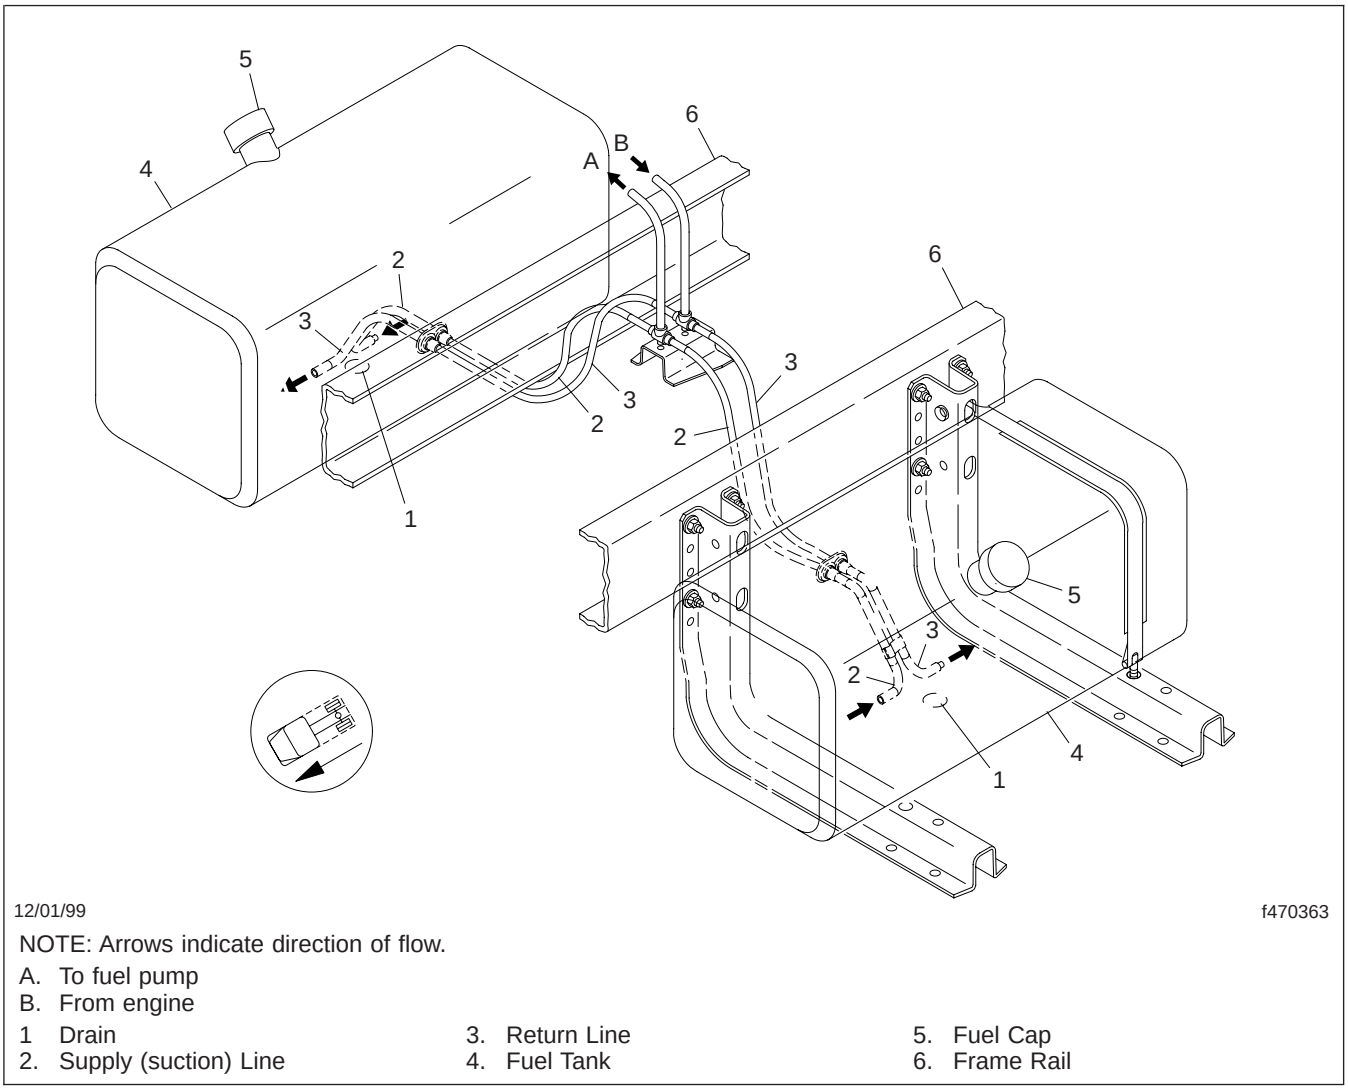
Fig. 1, Fuel Splitter Valve

The EquiFlo® inboard fuel system consists of inboard-routed fuel lines, with the suction and return lines installed in a common opening of the fuel tank(s), and a quarter-turn non-vented fuel cap. See **Fig. 2**. The fuel tank vent and line are located on the top of the tank.

Fuel is drawn equally from, and returned to, each tank, so that their levels stay equal. The suction and return fuel lines, although entering the fuel tank via the same opening, are designed to direct the fuel flow to the bottom of the tank. This ensures thorough mixing of the fuel before it is drawn up by the suction line, so that vapor can disperse, and (electronic engines only) warm fuel is not recirculated.

The fuel cooler is available only on vehicles with an electronic engine and a single fuel tank application. See **Fig. 3**. The fuel cooler is in-line on the return side of the fuel lines and cools the fuel before it is returned to the fuel tank.

General Information



NOTE: Arrows indicate direction of flow.

5. Fuel Cap
6. Frame Rail

Fig. 2, EquiFlo Inboard Fuel System

The fuel level sensor is located inside the fuel tank and consists of a variable resistor (potentiometer) attached to a float and varies according to fuel levels in the fuel tank. When the fuel level is low, resistance in the sensor unit is high and allows only a low current to flow through the indicator gauge windings, causing the indicator to move a short distance. When the fuel level is high, the resistance in the sensor unit is low and allows a higher current flow causing the indicator to move a greater distance.

4. Fuel Cooler

Fig. 3, Fuel Cooler

Fuel Tank Removal and Installation

Removal

NOTE: The following procedure is a typical fuel tank removal and installation procedure. See **Subject 050** for component locations.

1. Disconnect the battery negative cables.
2. Drain the fuel from the fuel tank.
3. Disconnect the fuel supply and return lines from the fuel tank.

NOTE: On dual tank systems, close the shutoff valves on the crossover tube.

4. Disconnect the crossover tube from the shutoff valve on the fuel tank to be removed.
5. Position a suitable jack under the fuel tank.
6. Remove the retaining nuts from the fuel tank support straps.
7. Remove the support straps from the fuel tanks.
8. Lower the jack, then slide the fuel tank away from the vehicle.

Installation

1. Position the fuel tank onto a suitable jack.
2. Position the fuel tank onto the fuel tank support brackets.
3. Position the fuel tank support straps over the fuel tank.
4. Install the nuts onto the fuel tank support straps.
5. Remove the jack.

NOTE: On dual tank systems, open the shutoff valves on the crossover tube.

6. Connect the crossover tube onto the shutoff valve on the fuel tank being installed.
7. Connect the fuel supply and return lines onto the fuel tank.
8. Fill the fuel tank.
9. Connect the battery negative cables.
10. Run the engine and check for leaks.

Fuel Level Sensor Removal and Installation

Removal

1. Disconnect the negative battery cables.
2. Disconnect the electrical connector. See **Fig. 1**.

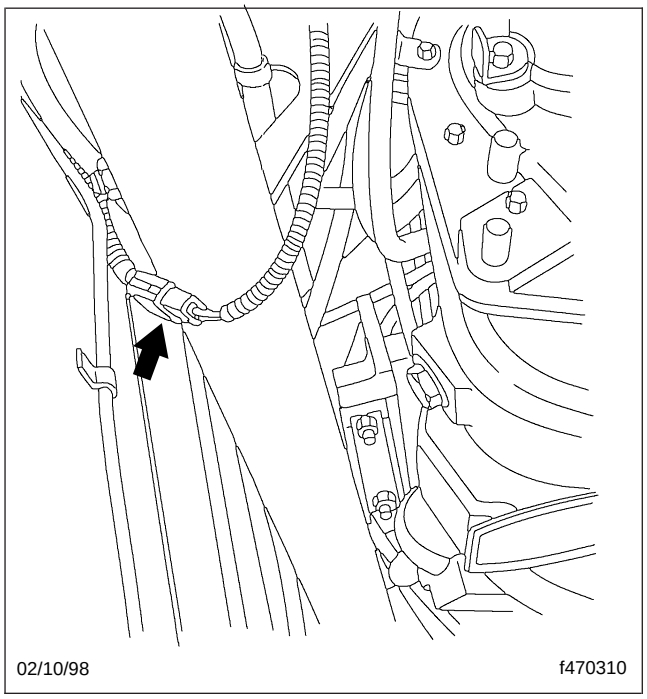

Fig. 1, Electrical Connector

3. Remove the retaining bolts. See **Fig. 2**.

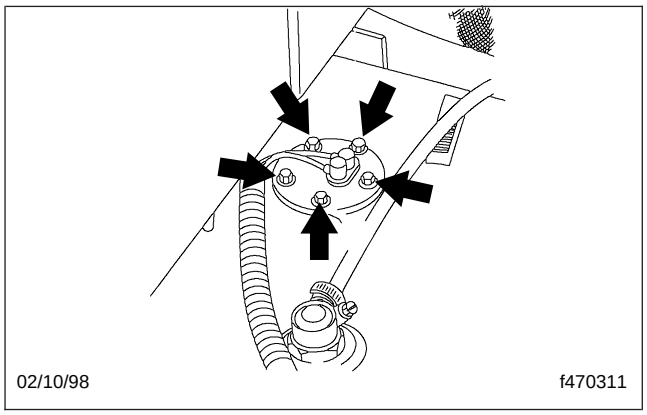

Fig. 2, Retaining Bolts

4. Remove the fuel level sensor and gasket. See **Fig. 3** .
5. Remove and discard the gasket.

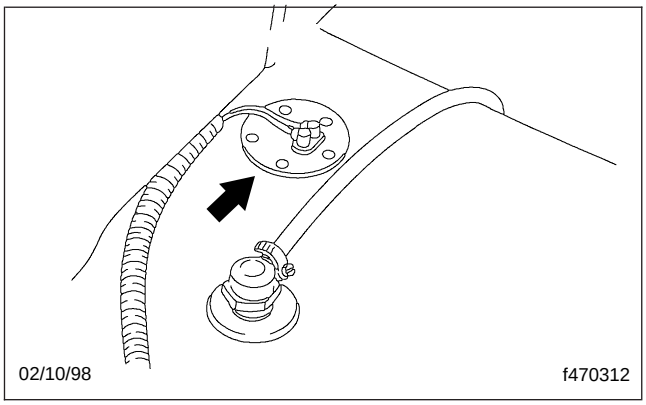

Fig. 3, Fuel Level Sensor

Installation

1. Position the new gasket on the fuel level sensor.
2. Position the fuel level sensor on the fuel tank and align the bolt holes with the holes in the fuel tank. See **Fig. 3**.
3. Install the fuel level sensor retaining bolts. See **Fig. 2**.
4. Connect the electrical connector. See **Fig. 1**.
5. Connect the negative battery cables.
6. Run the vehicle and check for leaks.

Behr Fuel Cooler Removal and Installation

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Place a drain pan under the fuel cooler.
3. Using a 1-1/4-inch box wrench, remove the drain plug from the fuel cooler and drain the fuel from the cooler. See **Fig. 1**.

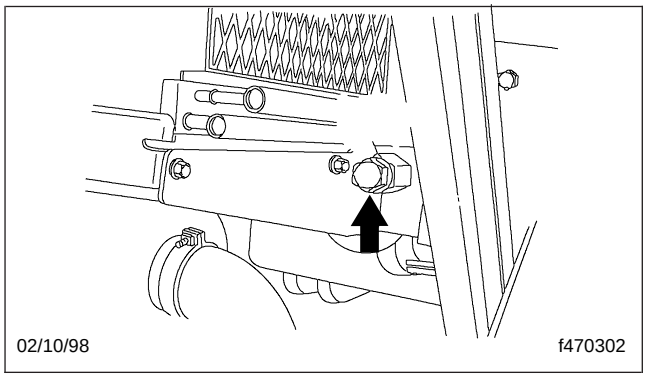

Fig. 1, Drain Plug

4. Install the drain plug into the fuel cooler. See **Fig. 1**.
5. Using a 15/16-inch wrench, disconnect the fuel lines. See **Fig. 2**.

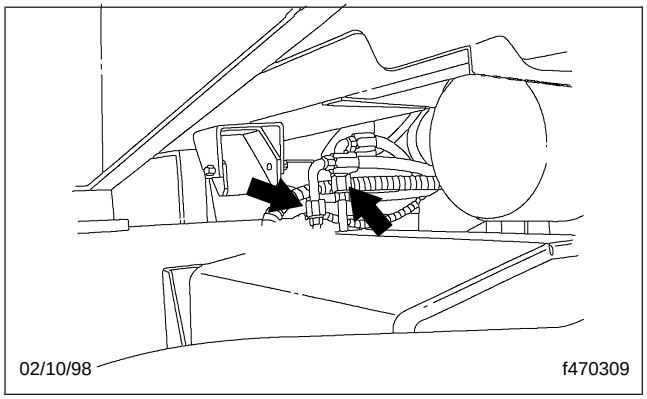

Fig. 2, Fuel Line Connections

6. Remove the four 1/2-inch hexhead mounting bolts from the fuel cooler assembly. See **Fig. 3** and **Fig. 4**.
7. Remove the fuel cooler from the vehicle.

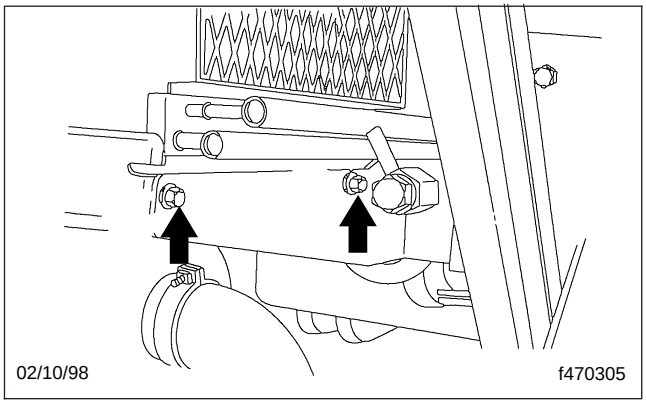

Fig. 3, Fuel Cooler Mounting Bolts

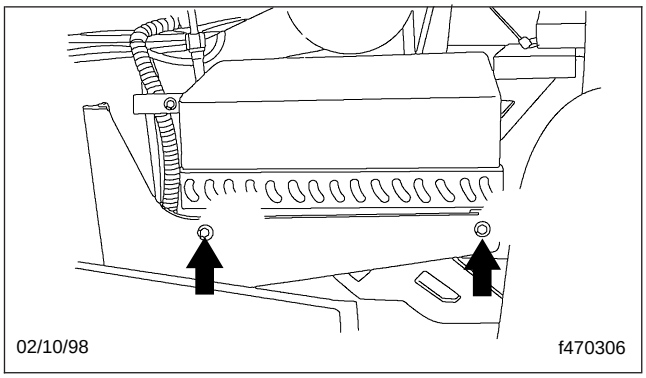

Fig. 4, Fuel Cooler Mounting Bolts

Installation

1. Position the fuel cooler on the mounting bracket.
2. Install the four 1/2-inch hexhead mounting bolts to the fuel cooler assembly. See **Fig. 3** and **Fig. 4**.
3. Connect the two fuel lines to the fuel cooler. See **Fig. 2**.
4. Run the engine and check for leaks.
5. Remove the chocks from the tires.

Specifications

Fuel Tubes		
Tube OD inch (mm)	**Minimum Bend Radius inch (mm)**	**Tube Nut Torque lbf·ft (N·m)**
1/4 (6.4)	1 (25.4)	7–10 (10–14)
3/8 (9.5)	1-1/4 (31.7)	12–17 (16–23)
1/2 (12.7)	2 (50.8)	12–17 (16–23)

Table 1, Fuel Tubes

Fuel/water separators are mounted between the fuel tank and the fuel pump. Fuel drawn to the engine travels through the fuel/water separator, which removes water and impurities.

At the fuel/water separator inlet port, a check valve (**Fig. 1**, Item 12) prevents the fuel from draining back to the fuel tank. Large pieces of dirt and water separate from the fuel in the lower housing, and collect in the bottom to be drained out when the drain valve (**Fig. 1**, Item 1) is opened. From the lower housing, the fuel level rises into the clear cover, which contains the replaceable filter. In the clear cover, the fuel passes through the filter element into the center of the filter, and to the outlet port.

When the filter is new, the fuel is able to pass through the lower part of the filter element. As the element's lower portion clogs, the fuel level rises in order to pass through the filter. This process continues until the filter element is clogged all the way to the top.

For efficiency, the filter should be changed only when the fuel level has reached the top of the filter element. There is no significant restriction to fuel flow until the element is completely clogged.

DAVCO fuel/water separators come in a number of different configurations. The lower housing may be screw-assembled or locking-collar-assembled. There may be an electric heating element installed in the lower housing or there may be fluid heating in the lower housing.

If there is fluid heat, the warming fluid may be fuel returning from the engine or engine coolant. **Fig. 2** shows the patterns that fuel and heating fluids follow in fluid-heated units.

NOTE: The Daimler Trucks North America Learning Center (accessible through **www.AccessFreightliner.com**) and DAVCO (**www.DavcoTec.com**) offer excellent online resources for understanding, testing, and diagnosing fuel/water separator problems.

Removal

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

Most service procedures are done with the fuel/water separator in place, but some procedures, such as pressure testing, require that the fuel/water separator be removed from the vehicle.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve (**Fig. 1**, Item 1) has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap (**Fig. 1**, Item 10) and open the drain valve to drain the fuel completely, then close the drain valve.
4. Unplug the electric heating element, if equipped, or disconnect the heating fluid lines.
5. Disconnect the fuel outlet line.
6. Disconnect the fuel inlet line. If the inlet line is difficult to reach, loosen the connection, then fully disconnect it after the fuel/water separator is removed from the frame rail.
7. Remove the fuel/water separator mounting fasteners and remove the fuel/water separator from the frame rail. If the fuel inlet line was not completely disconnected in the previous step, disconnect it.

Removal and Installation

Installation

IMPORTANT: All fittings, including the locking collars, must be very clean as they are installed. A piece of grit or a damaged surface on a sealing face or in threads can cause air leaks.

Use teflon pipe thread sealant to ensure that the tapered thread fuel line fittings will not leak. Do not use sealer on compression fittings and do not seal the fittings with tape, which may eventually leak.

1. If the inlet fuel line is inaccessible when the fuel/water separator is mounted on the vehicle, loosely connect the inlet fuel line before mounting the fuel/water separator on the frame rail.

   To minimize restrictions, keep fuel line routing as smooth as possible, with no low-hanging loops that could trap water. If the fuel line is being made to length on the job, be sure that the inner liner of the hose is not cut by the fitting. Be certain the interior of all fuel lines is clean and free of debris before connecting them, and confirm that all fittings are clean.

2. Mount the fuel/water separator on the frame rail and install the mounting fasteners.

NOTICE

The lower housings on DAVCO fuel/water separators are made of aluminum. To avoid damaging threads, be careful not to overtighten fasteners or fittings on the fuel/water separator.

3. If the fuel inlet line was loosely connected previously, tighten it. If it was not connected, connect and tighten it.
4. Connect the fuel outlet line.
5. Install the electric heating element, if equipped, and connect the wiring harness, or connect the fluid heater lines. It does not matter which direction the heating fluid flows through the housing; the lines can be reversed.
6. Prime the system
   - 6.1 Ensure that the drain valve is closed.
   - 6.2 Remove the vent cap from the cover, and fill the housing to the top with clean diesel fuel.
   - 6.3 Install and hand-tighten the vent cap.
   - 6.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 6.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.
   - 6.6 Check for leaks and shut down the engine.

Filter Replacement

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

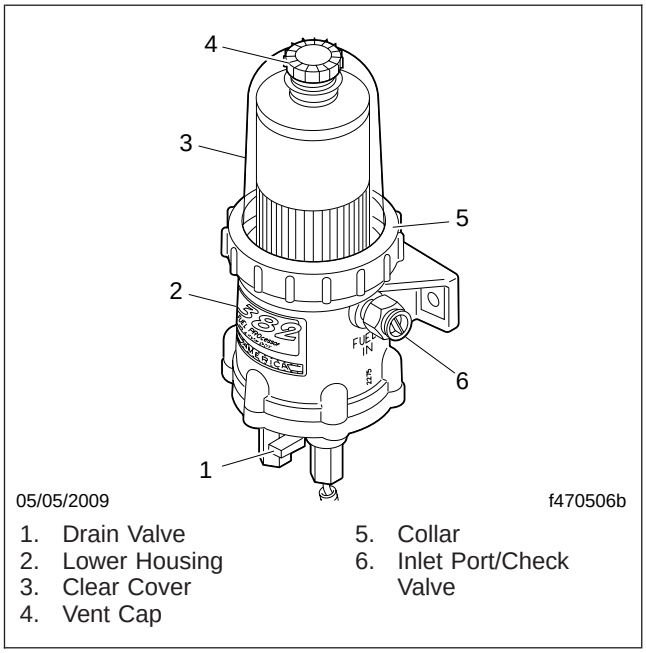
If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve (**Fig. 1**, Item 1) has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap (**Fig. 1**, Item 4) and open the drain valve to drain the fuel completely, then close the drain valve.
4. Using a DAVCO Collar Wrench (**Fig. 2**), remove the clear cover and collar.

NOTE: Broken vent cap and collar warranty claims will not be accepted if any tool other than a DAVCO Collar Wrench, part number 380134, is used for removal. During installation, the vent cap and collar are to be **hand-tightened only**, not tightened with a wrench.

5. Remove the filter, cover O-ring, and vent cap O-ring. Dispose of them in an environmentally acceptable manner.
6. Clean all threads and sealing surfaces very thoroughly. Even a small amount of dirt will prevent the fuel/water separator from sealing, and an air leak may result.
7. Install the grommet on the bottom of the new filter.



1. Drain Valve
2. Lower Housing
3. Clear Cover
4. Vent Cap
5. Collar
6. Inlet Port/Check Valve

Fig. 1, DAVCO Fuel/Water Separator

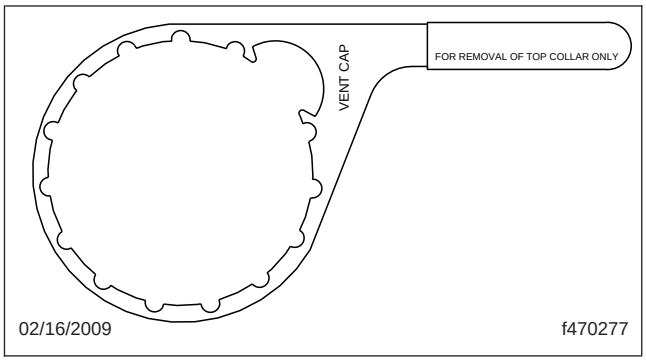


Fig. 2, DAVCO Collar Wrench

8. Install the new filter and grommet assembly and cover O-ring on the housing.
9. Install the clear cover and the collar. Hand-tighten the collar.
10. Prime the system

    10.1 Ensure that the drain valve is closed.

    10.2 Fill the housing to the top with clean diesel fuel.

    10.3 Install and hand-tighten the vent cap O-ring and vent cap.

Filter and Check Valve Replacement

10.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.

10.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.

10.6 Check for leaks and shut down the engine.

Emergency Temporary Filter Replacement

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap (**Fig. 1**, Item 4) and open the drain valve (**Fig. 1**, Item 1) to drain the fuel completely, then close the drain valve.
4. Using a DAVCO Collar Wrench (**Fig. 2**), remove the clear cover and collar.

NOTE: Broken vent cap and collar warranty claims will not be accepted if any tool other than a DAVCO Collar Wrench, part number 380134, is used for removal. During installation, the vent cap and collar are to be **hand-tightened only**, not tightened with a wrench.

5. Remove the filter and dispose of it in an environmentally acceptable manner.
6. Clean all threads and sealing surfaces very thoroughly. Even a small amount of dirt will prevent the fuel/water separator from sealing, and an air leak may result.
7. Ensure that the drain valve is closed.
8. Remove the filter grommet from the filter stud, if equipped.
9. Install a standard engine spin-on filter (part number FF105 or equivalent) on the filter stud.
10. Install the cover O-ring, clear cover, and the collar. Hand-tighten the collar.
11. Fill the housing to the top with clean diesel fuel.
12. Install and hand-tighten the vent cap O-ring and vent cap.
13. Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
14. Check for leaks and shut down the engine.

Check Valve Replacement

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

1. Shut down the engine, apply the parking brake, and chock the tires.

2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

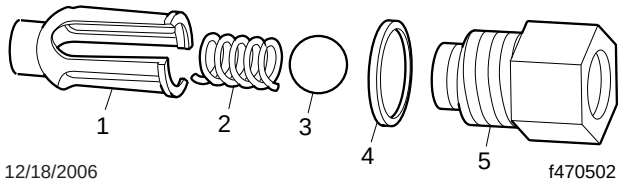
   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.

3. Remove the vent cap (**Fig. 1**, Item 4) and open the drain valve (**Fig. 1**, Item 1) to drain the fuel completely. Close the drain valve.

4. Place a shop towel under the fuel inlet fitting. Hold the check valve body in place with an open-end wrench and remove the fuel inlet hose from the fitting. Continue holding the check valve body in place and, using a flare-nut wrench, carefully remove the fuel inlet fitting. Drain any residual fuel into the container.

5. Remove the check valve assembly from the fuel/water separator housing.

6. Remove and discard the check ball, spring, and plastic retainer. See **Fig. 3**.



1. Plastic Spring Retainer
2. Retaining Spring
3. Check Ball
4. Seal (Diesel Pro® units only)
5. Check Valve Body

Fig. 3, Check Valve Assembly

7. Carefully clean the threads on the check valve body. Install the new check ball, spring, and plastic retainer on the check valve body.

   The plastic retainer snaps into a groove in the check valve body.

8. Clean the threads on the fuel inlet fitting and fuel/water separator housing. Apply a teflon pipe thread sealant to the check valve body threads.

9. Install the check valve body in the fuel/water separator housing. Do not use tape to seal the fuel fittings; it may eventually leak.

   Tighten the check valve body 44 to 60 lbf·ft (60 to 81 N·m).

10. Install the fuel inlet fitting and connect the fuel inlet line.

11. Prime the system

    11.1 Ensure that the drain valve is closed.

    11.2 Remove the vent cap from the clear cover, and fill the housing to the top with clean diesel fuel.

    11.3 Install and hand-tighten the vent cap.

    11.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.

    11.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.

    11.6 Check for leaks and shut down the engine.

Electric Pre-Heater, Thermoswitch, and Fluid Heat Tests

Any one of several types of pre-heaters and thermoswitches may be fitted to DAVCO fuel/water separators. They include 12 VDC pre-heaters, 120 VAC pre-heaters, combination pre-heater thermoswitches, and fluid heaters. The voltage and wattage ratings are stamped on the hex or the sheath of each component.

Test procedures under these headings apply to the following pre-heater types, as specified:

- Electric Pre-Heater
- 12 VDC Thermoswitch
- Combination Pre-Heater Thermoswitch
- Fluid Heat

The following equipment is recommended to test DAVCO pre-heaters and thermoswitches:

- A precision low-resistance ohmmeter capable of measuring 0.1 ohm or less
- A clamp-on DC current-flow meter
- A means of chilling a thermoswitch, such as ice, dry ice, or compressed carbon dioxide
- A flameless source of heat, such as an infrared heat lamp
- A vortex tube to heat and cool a thermoswitch

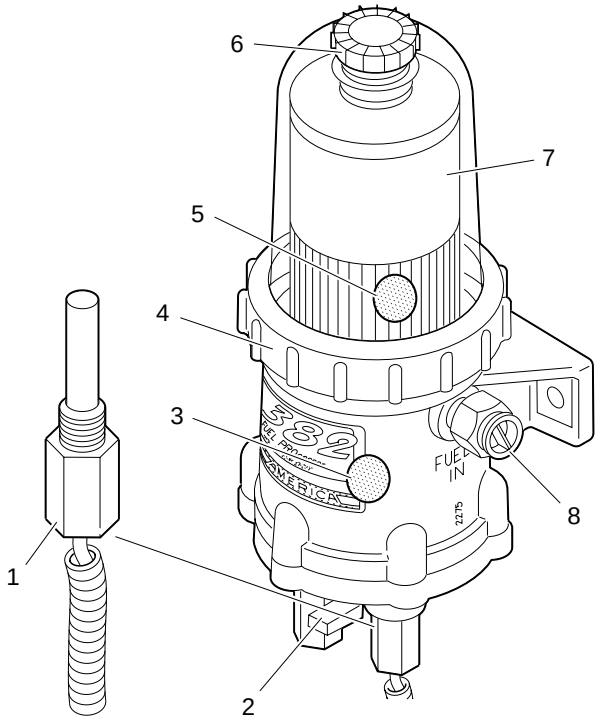
⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

Electric Pre-Heater

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Disconnect the pre-heater from the wiring harness, see **Fig. 1**.
3. Connect the ohmmeter leads to the pins of the pre-heater (for pre-heaters with one pin, connect to the pin and the bushing).
4. Read the resistance and use **Table 1** to determine whether the pre-heater is within the acceptable resistance range.
5. Connect the pre-heater wiring harness.



1. Electric Heating Element
2. Drain Valve
3. Housing
4. Collar
5. Filter Element
6. Vent Cap
7. Clear Cover
8. Inlet Port/Check Valve

Fig. 1, Fuel Pro 382 With Electric Heating Element

Electric Pre-Heater Test Paramaters		
Electric Pre-Heater	**Watts**	**Resistance Range: Ohms**
12 VDC (two pin)	250	0.6–0.8
12 VDC (single pin)	250	0.6–0.8

Electric Pre-Heater, Thermoswitch, and Fluid Heat Tests

Electric Pre-Heater Test Paramaters		
Electric Pre-Heater	**Watts**	**Resistance Range: Ohms**
12 VDC (single pin)	150	0.9–1.1
120 VAC	75	173–203
120 VAC	37	369–411

Table 1, Electric Pre-Heater Test Parameters

12 VDC Thermoswitch

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Disconnect the thermoswitch wiring harness, see **Fig. 2**. Remove the thermoswitch from the fuel/water separator.

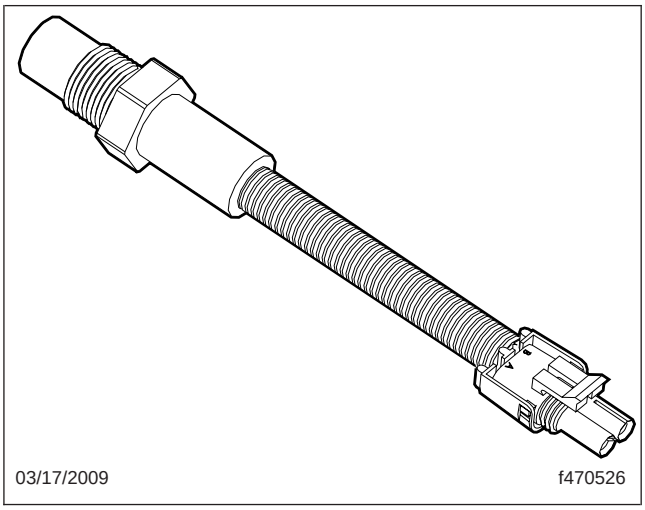


Fig. 2, 12 VDC Thermoswitch

5. Connect the ohmmeter leads to the pins of the thermoswitch.
6. Lower the thermoswitch temperature to below 40°F (4.4°C). The resistance shown on the ohmmeter should be less than or equal to 0.1 ohm.
7. Raise the thermoswitch temperature to above 60°F (15.5°C). The resistance should be more than 10 megohms.
8. Install the thermoswitch in the fuel/water separator. Connect the thermoswitch wiring harness.
9. Prime the system

   9.1 Ensure that the drain valve is closed.

   9.2 Remove the vent cap from the clear cover, and fill the housing to the top with clean diesel fuel.

   9.3 Install and hand-tighten the vent cap.

   9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.

   9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.

   9.6 Check for leaks and shut down the engine.

Combination Pre-Heater Thermoswitch

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Disconnect the pre-heater/thermoswitch unit from the wiring harness, see **Fig. 3**.

Electric Pre-Heater, Thermoswitch, and Fluid Heat Tests

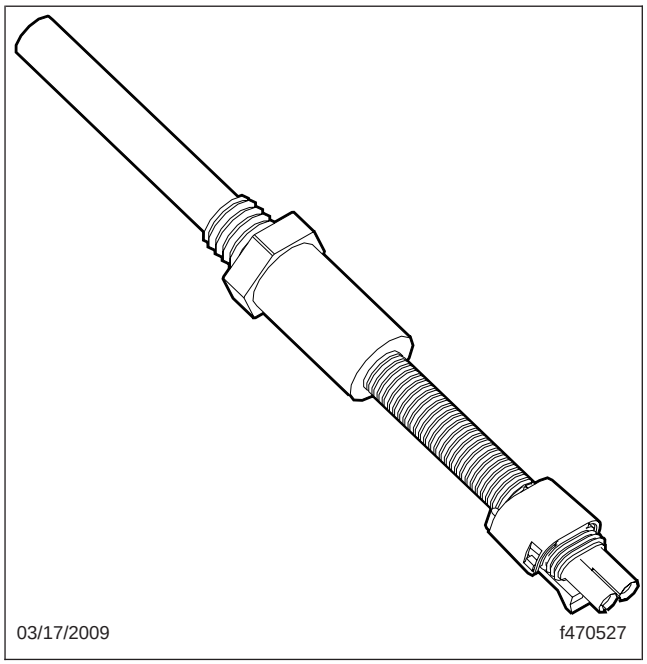

Fig. 3, Combination Pre-Heater Thermoswitch

5. Connect the ohmmeter leads to the pre-heater/thermoswitch pins.
6. Lower the pre-heater/thermoswitch unit temperature to below 40°F (4.4°C).

   The resistance shown on the ohmmeter should be:

   - 0.9 to 1.1 ohms for a 12 VDC 150 W unit
   - 0.6 to 0.8 ohms for a 12 VDC 250 W unit

7. Raise the pre-heater/thermoswitch unit temperature to above 70°F (21°C). The pre-heater/thermoswitch unit should show an open circuit.
8. Install the pre-heater/thermoswitch in the fuel/water separator. Connect the pre-heater/thermoswitch wiring harness.
9. Prime the system

   9.1 Ensure that the drain valve is closed.

   9.2 Remove the vent cap from the clear cover, and fill the housing to the top with clean diesel fuel.

   9.3 Install and hand-tighten the vent cap.

   9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.

   9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.

   9.6 Check for leaks and shut down the engine.

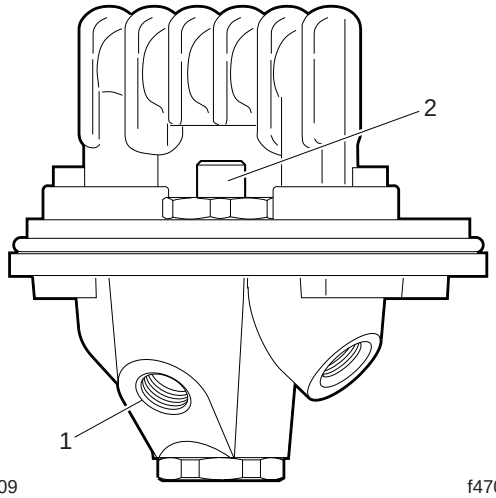
Fluid Heater

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Disconnect the heating fluid lines from the bottom plate. These will be either engine coolant lines or return fuel lines. Plug engine coolant lines after removing them from the bottom plate of the housing.
3. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe use a hose with a 1/2-inch pipe thread to fit correctly.
4. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
5. Remove the bottom plate and lower housing O-ring.
6. While looking into the fluid port of the bottom plate (**Fig. 4**), flow cold water over the thermovalve for 30 seconds, then run hot water over the thermovalve to determine whether the thermovalve spool is opening and closing.

   When the fuel entering the fuel/water separator is cold, the thermovalve moves up, allowing warming fluid to enter the heater loop in the heat exchanger. When the fuel is warm, the thermovalve moves down, causing the warming fluid to bypass the heater loop and return directly to the tank. See **Fig. 5**.
7. Replace the lower housing O-ring, and install the bottom plate on the fuel/water separator. There are two types of bottom plates: locking-collar-assembled and screw-assembled.

Electric Pre-Heater, Thermoswitch, and Fluid Heat Tests



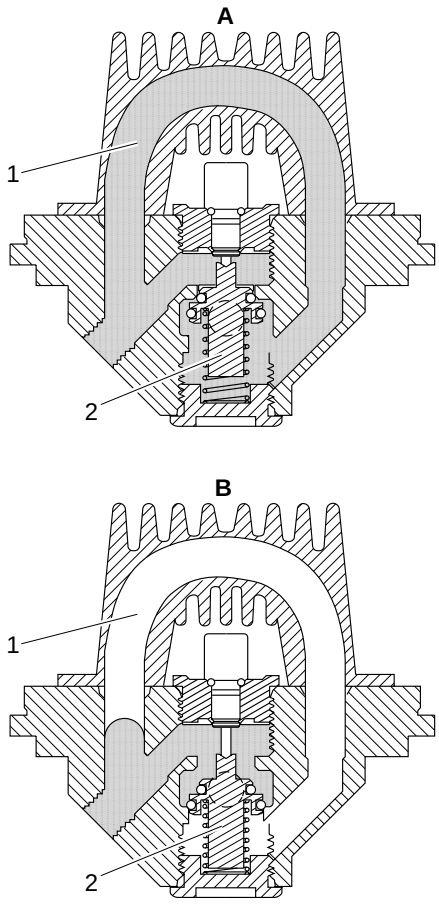
03/17/2009 f470528

1. Fluid Port
2. Top of Thermovalve Spool

Fig. 4, Fluid Pre-Heater Thermovalve Test

- Locking-collar-assembled: Apply 2 to 3 drops of Loctite 406 to the bottom collar threads, then tighten 50 to 60 lbf·ft (68 to 81 N·m).
- Screw-assembled: Install the screws on the bottom plate and tighten them 8 to 10 lbf·ft (11 to 14 N·m).

8. Connect the heating fluid lines.
9. Prime the system
   - 9.1 Ensure that the drain valve is closed.
   - 9.2 Remove the vent cap from the clear cover, and fill the housing to the top with clean diesel fuel.
   - 9.3 Install and hand-tighten the vent cap.
   - 9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.



04/08/2009 f470529

A. Fuel is Cold, Thermovalve Is Up
B. Fuel is Warm, Thermovalve is Down

Fig. 5, Heat Exchanger Fluid Flow

   - 9.6 Check for leaks and shut down the engine.

The Daimler Trucks North America Learning Center (accessible through **www.AccessFreightliner.com**) and DAVCO (**www.DavcoTec.com**) offer excellent online resources for understanding, testing, and diagnosing fuel/water separator problems.

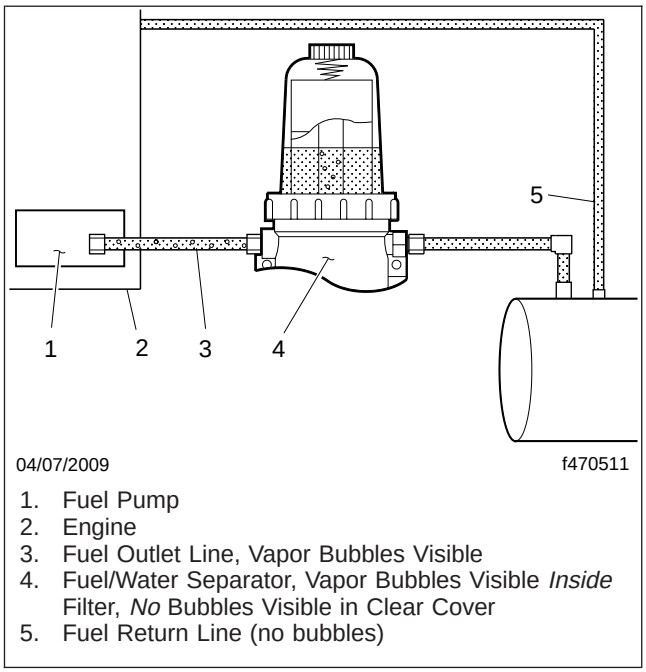
Identifying Bubble Types

Vapor Bubbles

Vapor bubbles are harmless and are present in all diesel fuel systems. Vapor bubbles are often mistaken for air bubbles, but *do not affect engine performance.*

Vapor bubbles (see **Fig. 1**) may be visible in a diagnostic sight tube installed between the fuel/water separator and the fuel pump. They consist of harmless fuel vapor and trapped air, may vary from champagne-size to 1/4-inch (6-mm) diameter, and may increase in volume or size as the engine rpm increases. The lower pressure inside a fuel/water separator filter, caused by the suction of the fuel pump pulling fuel through the fuel/water separator, creates vapor bubbles. These vapor bubbles are normal and harmless to engine operation. In the fuel pump, the fuel is pressurized and the vapor bubbles dissolve. Vapor bubbles do not appear on the fuel return side of the system.

There is no troubleshooting or repair procedure required for vapor bubbles. Vapor bubbles do not cause performance issues and will not be present downstream of the fuel pump.



1. Fuel Pump
2. Engine
3. Fuel Outlet Line, Vapor Bubbles Visible
4. Fuel/Water Separator, Vapor Bubbles Visible *Inside* Filter, *No* Bubbles Visible in Clear Cover
5. Fuel Return Line (no bubbles)

Fig. 1, Harmless Vapor Bubbles

Air and Gas Bubbles

Air or gas bubbles indicate harmful leaks, and can cause hard starting and impaired engine performance. All diesel fuel holds some trapped air, caused by the natural splashing that occurs in the fuel tank. But excessive air bubbles, severe enough to degrade engine performance, indicate an air leak on the suction side of the fuel system, from the fuel tank into the fuel pump.

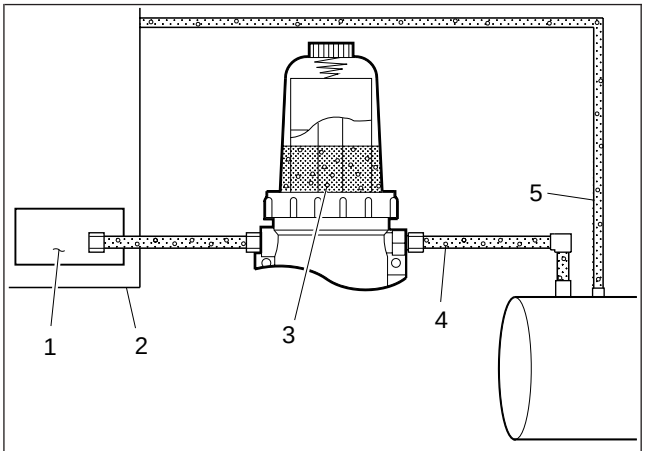
Air bubbles visible in the clear cover of a DAVCO fuel/water separator may indicate an air leak in the fuel system upstream of the bubbles, or in the fuel/water separator; see **Fig. 2**. If there are no bubbles visible in the clear cover but the engine runs rough, there may be an air leak at or between the fuel/water separator outlet port and the fuel pump inlet. These bubbles will be visible in a diagnostic sight tube installed between the fuel pump and the fuel/water separator, and in a diagnostic sight tube installed in the fuel return hose.

Exhaust gas bubbles may also be visible in the clear filter cover. They are the result of leaking fuel injector seals, which can allow combustion gases to enter the fuel system, pass through the fuel return line into the fuel tank, and be drawn into the fuel/water separator. They may be visible in a diagnostic sight tube installed in the fuel return line. To test for combustion gas in the fuel, disconnect the return line at the tank, submerge the end in a bucket of fuel, run the engine, and watch for bubbles. As they pop, these bubbles may smell like exhaust fumes.

In extreme cases, these combustion gas bubbles cause enough aeration in the fuel tank to create visible bubbles in the clear cover of the fuel/water separator and impair engine performance. See the engine manufacturer's documentation for diagnosis and repair of injector seal leakage.

Use the following procedures to determine which bubbles are present in the fuel system, and whether repair is necessary.

Troubleshooting



1. Fuel Pump
2. Engine
3. Fuel/Water Separator, Bubbles Visible in Clear Cover
4. Fuel Inlet Line, Bubbles Visible
5. Fuel Return Line, Bubbles Visible

Fig. 2, Air Bubbles Indicating a Leak

Initial Diagnostic Procedure

1. Apply the parking brake, chock the tires, and turn on the engine.
2. Check for air bubbles in the fuel/water separator clear cover.
3. If no bubbles are visible in the clear cover, but the engine continues to run rough, lopes, or has loss of power, there may be an air leak between the fuel/water separator outlet and the fuel pump inlet.

   If so, bubbles should be visible in a diagnostic sight tube installed at the fuel pump inlet. Air bubbles may also be visible in a diagnostic sight tube installed in the fuel return line to the fuel tank.
4. Replace fuel lines and tighten fittings as needed.
5. A DAVCO fuel/water separator, properly assembled with the rubber grommet in the bottom of the fuel filter, does not restrict fuel flow until the fuel level has risen to the top of the filter. If the fuel level has risen to the top of the filter, replace the filter.

Testing Procedures

Air Leak in the Fuel System

Air leaks are sometimes caused by:

- loose fittings;
- a faulty inlet check valve;
- faulty O-rings;
- leakage elsewhere in the fuel system;
- or dirt on threads and sealing surfaces.

Air leaks originating between the fuel tank and the fuel/water separator cause air bubbles visible in the clear cover, as shown in **Fig. 2**.

If there are symptoms of sucking air and there are no bubbles in the clear cover, look for the air leak at:

- the outlet fitting;
- the fuel pump inlet connection;
- the fuel hose connections;
- or at the vent cap O-ring.

1. Shut down the engine, apply the parking brake, and chock the tires.

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

2. Remove the fuel hose from the fuel pump inlet port.
3. Install a jumper hose from the inlet port into the fuel tank through the fill cap, or into a container of fuel.
4. Start the engine and look for bubbles in the clear filter cover. If the air bubbles are eliminated, the

air source (and the leak) is at either the fuel tank fittings, or the hose connections.

If air bubbles persist after the tank fittings and hose connections are secured, the leak may be in the fuel/water separator.

5. If the leak is suspected to be in the fuel/water separator, disconnect all fuel connections, coat the threads with teflon pipe thread sealant, and reconnect the fuel connections and tighten them securely.

Air Pressure Testing

⚠ WARNING

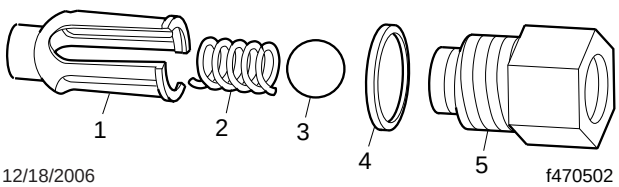
Wear goggles and skin protection when pressure-testing a fuel/water separator, and be careful not to perform this test near a source of possible ignition, such as an open flame. Never exceed the maximum pressure stipulated for the test, and do not perform this test if the clear cover appears to be damaged.

1. Shut down the engine, apply the parking brake, and chock the tires.
2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.
3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Remove the fuel/water separator from the chassis. For instructions, see **Subject 100**.
5. Plug the fuel outlet port. Do not remove the filter, filter cover, collar, vent cap, drain valve, or check valve. Do not remove the electric heating element (if equipped), and do not plug the fluid heat ports (if equipped).
6. Apply 15 psi (207 kPa) air pressure at the fuel inlet. Immerse the unit in a tank of water and look for air bubbles.
7. If a leak is found, repair the fuel/water separator as needed.
8. Install the fuel/water separator onto the chassis frame rail. For instructions, see **Subject 100**.
9. Prime the system
   - 9.1 Ensure that the drain valve is closed.
   - 9.2 Remove the vent cap from the cover, and fill the housing to the top with clean diesel fuel.
   - 9.3 Install and hand-tighten the vent cap.
   - 9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.
10. If no bubbles appear, the air leak is not in the fuel/water separator.

Check Valve Operation Test

When air is introduced into the fuel system, (e.g. when draining fluid or when replacing the fuel filter), the check valve (**Fig. 3**) works to keep the fuel system primed from the fuel tank to the fuel/water separator.



1. Plastic Spring Retainer
2. Retaining Spring
3. Check Ball
4. Seal (Diesel Pro units only)
5. Check Valve Body

Fig. 3, Check Valve Assembly

To test for proper check valve operation, remove the fuel inlet line, then open the vent cap. Fuel should not flow out of the check valve, although a slight seepage of fuel is normal. If fuel drains back out of the check valve, complete the following procedure.

1. Shut down the engine, apply the parking brake, and chock the tires.

Troubleshooting

⚠ WARNING

Fluid circulated through the fuel/water separator to heat the fuel may be diesel fuel returned from the engine, or engine coolant. Drain the fuel/water separator only when the engine and fluids have cooled. Draining it when the engine is hot could cause severe personal injury due to scalding.

If returning fuel is released into the atmosphere, its vapors can ignite in the presence of any ignition source. Do not expose the fuel to, or work with the fuel system near, open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

2. Put a clean receptacle under the fuel/water separator and attach a piece of hose to the drain valve, to direct fuel into the receptacle.

   The drain valve has a 1/2-inch (12.7-mm) pipe; use a hose with a 1/2-inch pipe thread to fit correctly.

3. Remove the vent cap and open the drain valve to drain the fuel completely, then close the drain valve.
4. Place a shop towel under the fuel inlet fitting. Hold the check valve body in place with an open-end wrench and, using a flare-nut wrench, carefully remove the fuel inlet fitting. Drain any residual fuel into the container.
5. Remove the check valve assembly from the fuel/water separator housing, see **Fig. 3**.
6. Clean and inspect the check valve body. If the valve body is damaged, or if the ball seat is not smooth, replace the valve. For instructions, see **Subject 110**.
7. If the valve body and ball seat are not damaged, clean the threads on the check valve body, fuel inlet fitting, and the water separator housing.
8. Apply a teflon pipe thread sealant to the check valve body threads. Install the check valve body in the fuel/water separator housing. Do not use tape to seal the fuel fittings; it may eventually leak.

   Tighten the check valve body 44 to 60 lbf·ft (60 to 81 N·m).

9. Prime the system
   - 9.1 Ensure that the drain valve is closed.
   - 9.2 Remove the vent cap from the clear cover, and fill the housing to the top with clean diesel fuel.
   - 9.3 Install and hand-tighten the vent cap O-ring and vent cap.
   - 9.4 Start the engine. When the lubricating oil reaches its normal operating pressure, increase engine speed to high idle for one to two minutes to purge air from the system.
   - 9.5 While the engine is running, and after the air is purged from the system, loosen the vent cap until the fuel level falls to just above the collar, then hand-tighten the vent cap.
   - 9.6 Check for leaks and shut down the engine.

Other Conditions Visible Inside the Cover

The clear filter covers fitted to DAVCO fuel/water separators provide the opportunity to monitor several aspects of fuel condition and engine status, as described in **Table 1**.

Conditions Visible Inside DAVCO Clear Filter Covers

If You See:	What to Do:	Comments:
Amber-colored fuel below the top of the filter element	Nothing, the filter is doing its job	Do not change the filter.
Amber-colored fuel with dark patches in places on the filter element	Dark patches indicate bacteria or algae may be present. Use Fleetguard Monitor Kit CC2650 to test for microbiological activity.	It may be necessary to use a microbicide, and suggest vehicle operator carry extra filters.

Conditions Visible Inside DAVCO Clear Filter Covers		
If You See:	**What to Do:**	**Comments:**
Extremely dark or cloudy fuel with thick black film or sludge collecting on the filter element	Black film or sludge on the filter media indicates the presence of asphaltenes. It may be necessary to use an asphaltene conditioner.	Do not assume this is oil from the engine. Monitor the vehicle for oil consumption. Refer to engine manufacturer's service literature for more information.
Bubbles inside the clear cover	Check for air leaks anywhere in the fuel system. Any leak in any fitting will cause bubbles to appear in the clear cover.	This problem will lead to power complaints; it must be remedied.
No bubbles in the cover, but the engine is running rough	Check for air leaks between the fuel/water separator outlet port and the fuel pump inlet. Check and tighten all fuel fittings in the area of the leak.	—
Coolant in the fluid drained from the fuel/water separator	Check for leaks in the engine, where fuel and coolant are near each other. The most common problem place is the injector cup.	Do not allow the equipment to be operated until the problem is found and repaired.
Anything not listed here	Call DAVCO at 1-800-328-2611, or email: customerservice@DavcoTec.com	—

Table 1, Torque Values

General Description

The fuel/water separator is mounted on the frame rail, between the fuel tank and the fuel pump. Fuel drawn to the engine travels through the fuel/water separator, which removes water and solid contaminants. The fuel/water separator includes a spin-on filter element and a sight bowl. See **Fig. 1**. The fuel/water separator may also be equipped with the following optional components:

- Ignition-controlled heater to melt ice and wax in the fuel
- Water sensor probe to alert the operator to drain the sight bowl
- Manual priming pump to easily prime the fuel/water separator

Principles of Operation

Diesel fuel enters at the top of the separator and flows down past the heater element, if equipped, to the top of the filter element. As the fuel flows down the sides of the element, the heavier contaminants fall directly to the collection bowl. The filter element itself contains a resin that repels water and forces it to bead and fall to the collection bowl.

Filtered fuel is drawn out through the top of the separator, and the water and solid contaminants remain in the collection bowl. As water collects, it completes the circuit between the two prongs of the water sensor probe, if equipped, and a warning light on the dash alerts the operator to drain the bowl.

The heater is operated by turning on the ignition switch for 5 minutes before starting the engine.

Fig. 1, Fuel/Water Separator Assembly

Removal

1. Shut down the engine, apply the parking brake, and chock the tires.

   Open the hood.

2. Place a suitable container under the fuel/water separator.

IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground.

3. Turn the drain plug counterclockwise to open it. If equipped, operate the priming pump. See **Fig. 1**.

9. Filter Element
10. Sight Bowl
11. Drain Plug

Fig. 1, Fuel/Water Separator Assembly and Installation

4. When the fuel/water separator is completely drained, turn the drain plug clockwise to close it.

⚠ WARNING

Do not expose the fuel to open fire. Do not work with the fuel system near open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

5. Disconnect the fuel lines from the fuel/water separator.
6. If equipped, disconnect the wiring harnesses from the water sensor probe and the heater element.
7. Remove the fuel/water separator mounting bolts, and remove the fuel/water separator from its mounting bracket.

Installation

1. Mount the fuel/water separator on the frame rail mounting bracket, and install the mounting bolts. Tighten the bolts 40 lbf·ft (55 N·m).
2. Remove the sight bowl and the filter element as a unit from the new fuel/water separator.
3. Using clean motor oil or diesel fuel, lubricate the gasket in the top of the filter element.
4. Make sure the drain in the sight bowl is closed, then fill the filter element and bowl assembly with clean fuel.
5. Install the element and bowl assembly on the mounting head and hand-tighten it until snug.
6. If equipped, connect the wiring harnesses to the water sensor probe and the heater.
7. Connect the fuel lines to the fuel/water separator. Tighten all fittings finger-tight plus 1/4 turn.
8. Prime the fuel/water separator.

   If equipped with a priming pump, loosen the drain plug and operate the priming pump until fuel comes out at the drain.

   If not equipped with a priming pump, fill the filter element and sight bowl with clean fuel and crank the engine until it starts.
9. Start the engine and check for leaks.
10. Shut down the engine and repair any leaks.

Replacement

1. Shut down the engine, apply the parking brakes, and chock the tires.

   Open the hood.

2. Place a suitable container under the fuel/water separator.

IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground.

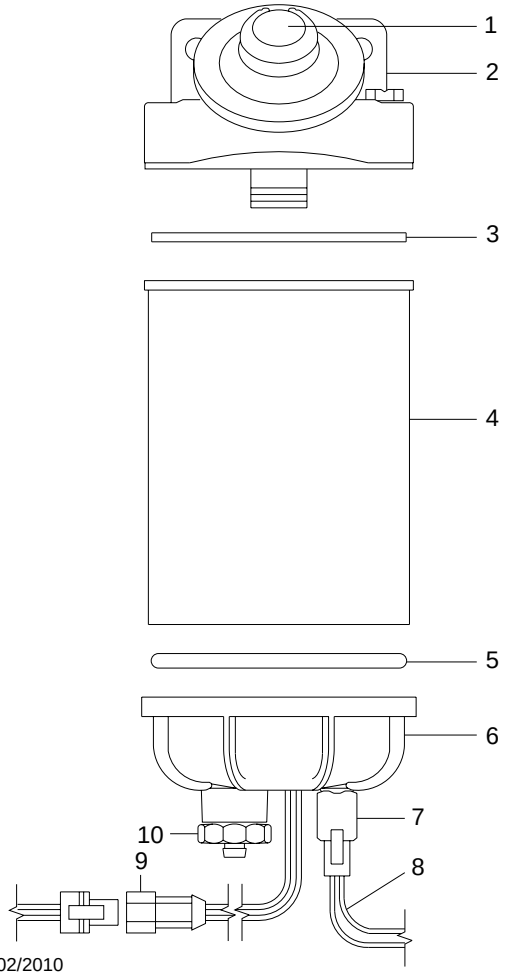
3. Turn the drain plug counterclockwise to open it. If equipped, operate the pump.
4. When the fuel/water separator is completely drained, turn the drain plug clockwise to close it.

⚠ WARNING

Do not expose the fuel to open fire. Do not work with the fuel system near open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

5. If equipped, disconnect the wiring harnesses from the water sensor probe and the heater. See **Fig. 1**.
6. Spin off the sight bowl and the filter element as a unit. Remove the gasket from the top of the filter element.
7. Remove the sight bowl from the filter element. Clean the O-ring seating surface.
8. Apply a thin coating of clean diesel fuel or engine oil to the O-ring and the new gasket.
9. Spin the sight bowl onto the new filter element and then fill the filter element and sight bowl assembly with clean diesel fuel.
10. Spin the entire assembly onto the mounting head and tighten by hand until snug.
11. Connect the heater and water sensor wiring harnesses, if equipped.
12. Prime the fuel/water separator.

    If equipped with a priming pump, loosen the drain plug and operate the priming pump until fuel comes out at the drain.



1. Priming Pump

   If not equipped with a priming pump, fill the filter element and sight bowl with clean fuel and crank the engine until it starts.

13. Start the engine and check for leaks.
14. Shut down the engine and repair any leaks.

Replacement

1. Shut down the engine, apply the parking brake, and chock the tires.

   Open the hood.

2. Place a suitable container under the fuel/water separator.

IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground.

3. Turn the drain plug counterclockwise to open it. If equipped, operate the priming pump.
4. When the fuel/water separator is completely drained, turn the drain plug clockwise to close it.

⚠ WARNING

Do not expose the fuel to open fire. Do not work with the fuel system near open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

5. If equipped, disconnect the wiring harness from the water sensor probe. See **Fig. 1**.

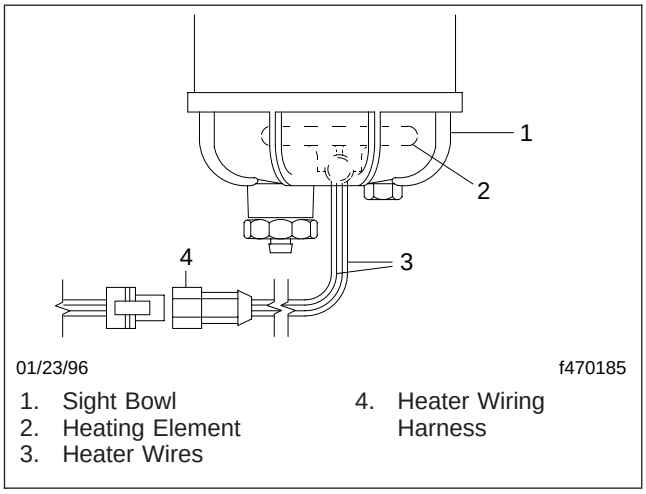
6. Disconnect the heater wiring harness. See **Fig. 2**.



1. Sight Bowl
2. Heating Element
3. Heater Wires
4. Heater Wiring Harness

Fig. 2, In-Bowl Heater

7. Spin off the sight bowl and the filter element as a unit.
8. Remove the sight bowl from the filter element.
9. Remove the O-ring from the lip of the new sight bowl. Lubricate the O-ring with a thin film of clean engine oil or diesel fuel and put it back in the sight bowl.
10. Install the sight bowl on the bottom of the filter element and hand-tighten until it is snug.
11. Make sure the drain in the sight bowl is closed, then fill the filter element and bowl assembly with clean fuel.
12. Install the element and bowl assembly on the mounting head and hand-tighten it until snug.
13. Connect the heater wiring harness.

    If equipped, connect the water sensor wiring harness to the water sensor probe.

14. Prime the fuel/water separator.

    If equipped with a priming pump, loosen the drain plug and operate the priming pump until fuel comes out at the drain.

    If not equipped with a priming pump, fill the filter element and sight bowl with clean fuel and crank the engine until it starts.

15. Start the engine and check for leaks.
16. Shut down the engine and repair any leaks.

Replacement

1. Apply the parking brakes, shut down the engine, and chock the tires.

   Open the hood.

2. Place a suitable container under the fuel/water separator.

IMPORTANT: When draining fluid from a fuel/water separator, drain the fluid into an appropriate container, and dispose of it properly. Many states now issue fines for draining fuel/water separators onto the ground.

3. Turn the drain plug counterclockwise to open it. If equipped, operate the priming pump.
4. When the fuel/water separator is completely drained, turn the drain plug clockwise to close it.

⚠ WARNING

Do not expose the fuel to open fire. Do not work with the fuel system near open flame or intense heat. To do so could cause fire, possibly resulting in serious personal injury or property damage.

5. Disconnect the water sensor wiring harness from the water sensor probe. See **Fig. 1**.

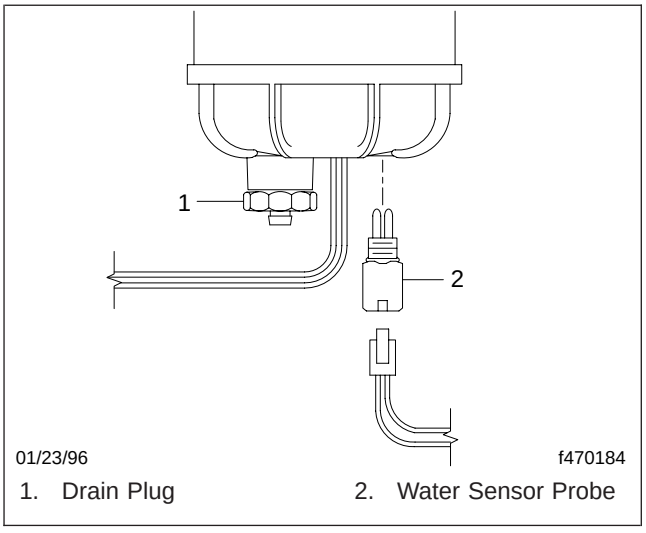


Fig. 1, Water Sensor Probe

6. Spin off the sight bowl and filter element as a unit.
7. Unscrew the water sensor probe from the base of the sight bowl.
8. Install a new water sensor probe in the base of the sight bowl.
9. Make sure the drain plug in the base of the sight bowl is closed snugly.
10. Fill the filter element and sight bowl assembly with clean diesel fuel.
11. Install the element and bowl assembly on the mounting head and hand-tighten it until snug.
12. Connect the water sensor wiring harness to the water sensor probe.
13. Prime the fuel/water separator.

    If equipped with a priming pump, loosen the drain plug and operate the priming pump until fuel comes out at the drain.

    If not equipped with a priming pump, fill the filter element and sight bowl with clean fuel and crank the engine until it starts.

14. Start the engine and check for leaks.
15. Shut down the engine and repair any leaks..

Troubleshooting

Problem—Air Leaking into the Fuel System

Problem—Air Leaking into the Fuel System	
Possible Cause	**Remedy**
The drain is not closed.	Tighten the drain valve.
The sight bowl or filter element is loose.	Hand-tighten the sight bowl or filter element until snug.
There are loose, broken, or clogged fuel fittings, valves, or filters.	Tighten, clean, or repair the fuel fittings, valves, or filters as needed.

Problem—High Water Light Does Not Illuminate For 2 to 5 Seconds When Ignition is Turned to ACCESSORY

Problem—High Water Light Does Not Illuminate For 2 to 5 Seconds When Ignition is Turned to ACCESSORY	
Possible Cause	**Remedy**
Wiring connections are loose.	Tighten connections as needed.
Fuel/water separator is not grounded.	Check that power is on, and the fuel/water separator is grounded.
Wiring is damaged.	Check for damaged wiring and replace as needed. See EZWiring for a diagram of the sensor circuit.
Water sensor probe is damaged.	Replace the water sensor probe. See **Subject 130** for instructions.

General Information

The exhaust system routes hot exhaust gas away from the cab and reduces engine exhaust noise. The exhaust system consists of the following:

- exhaust manifold (part of engine)
- turbocharger (part of engine)
- engine outlet exhaust pipe
- flex pipes
- clamps
- muffler
- inlet pipe
- outlet pipe
- exhaust stack (vertical exhaust systems only)
- exhaust brake

Mufflers can be either cab-mounted or frame-mounted. See **Fig. 1**.

Frame-mounted mufflers can be vertically-mounted or horizontally-mounted. See **Fig. 2** or **Fig. 3**.

Horizontally-mounted mufflers can be equipped with a cab-mounted exhaust stack or a frame-mounted exhaust stack. See **Fig. 4** or **Fig. 5**.

A transverse horizontally-mounted muffler is also available. See **Fig. 6**.

Fig. 1, Horizontal Frame-Mounted Muffler

REMOVAL

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Loosen the muffler inlet clamp.
3. Disconnect the muffler inlet pipe.
4. Loosen the muffler outlet clamp.
5. Disconnect the muffler outlet crossover pipe.
6. Remove the front and rear muffler support clamps.
7. Remove the muffler.

Muffler Removal and Installation

INSTALLATION

1. Position the muffler and insert the muffler inlet pipe. Tighten the clamp 45 to 60 lbf·ft (61 to 81 N·m).
2. Insert the muffler into the rear muffler support bracket and tighten 26 lbf·ft (35 N·m).
3. Insert the muffler into the front muffler support bracket and tighten 26 lbf·ft (35 N·m).
4. Install the crossover to the muffler outlet (including the muffler elbow). Tighten the clamp 108 to 144 lbf·in (1220 to 1620 N·cm).
5. Remove the chocks from the tires.

Vertical Frame-Mounted

(See Fig. 2)

REMOVAL

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Loosen the muffler outlet-to-tailpipe clamp. Remove the exhaust tailpipe.
3. Remove the two-piece elbow support clamps and loosen the muffler-to-elbow clamp. Remove the elbow from the muffler inlet.
4. Loosen the lower muffler-to-frame support clamp.
5. Loosen the upper muffler-to-frame support clamp.

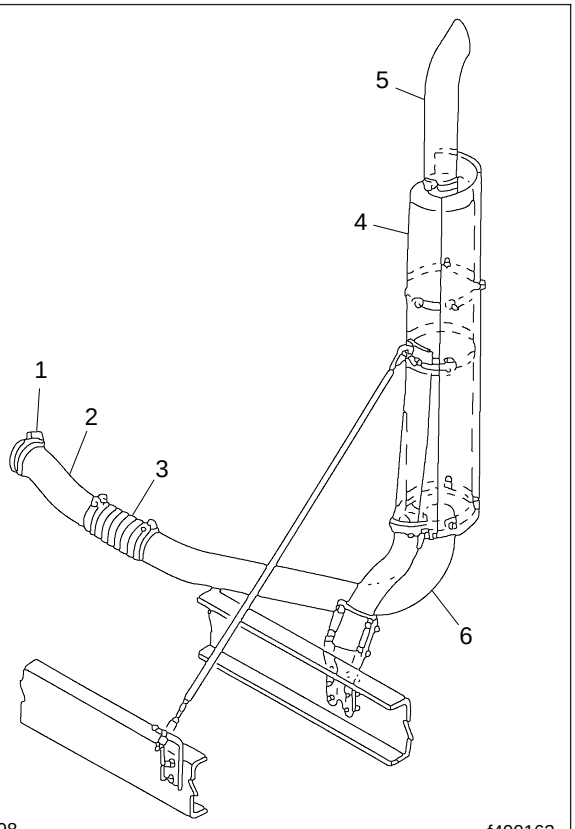
NOTE: The following step must be performed by two people.

6. With the help of an assistant, remove the muffler.

INSTALLATION

NOTE: The following step must be performed by two people.

1. With the help of an assistant, position the muffler and insert the elbow into the muffler inlet.
2. Install the muffler inlet-to-elbow clamp. Tighten the clamp 45 to 60 lbf·ft (61 to 81 N·m).
3. Install the upper muffler-to-frame support clamp and tighten 12 to 17 lbf·ft (17 to 23 N·m).



1. Clamp

15. Cab-to-Muffler Bracket

Fig. 3, Vertical Cab-Mounted Muffler

REMOVAL

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Loosen the muffler outlet-to-tailpipe clamp. Remove the exhaust tailpipe.
3. Remove the two-piece elbow support clamps and loosen the muffler-to-elbow clamp. Remove the elbow from the muffler inlet.

Muffler Removal and Installation

4. Loosen the lower muffler-to-cab bracket clamp.
5. Loosen the upper muffler-to-cab bracket clamp.

NOTE: The following step must be performed by two people.

6. With the help of an assistant, remove the muffler.

INSTALLATION

NOTE: The following step must be performed by two people.

1. With the help of an assistant, position the muffler and insert the elbow into the muffler inlet.
2. Install the muffler inlet-to-elbow clamp. Tighten the clamp 45 to 60 lbf·ft (61 to 81 N·m).
3. Install the upper muffler-to-cab bracket clamp and tighten 12 to 17 lbf·ft (17 to 23 N·m).
4. Install the lower muffler-to-cab bracket clamp and tighten 12 to 17 lbf·ft (17 to 23 N·m).
5. Insert the muffler tailpipe into the muffler outlet.
6. Install the muffler outlet-to-tailpipe clamp and tighten 12 to 17 lbf·ft (17 to 23 N·m).
7. Remove the chocks from the tires.

Transverse Frame-Mounted

(See Fig. 4)

REMOVAL

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the muffler heat shield.
3. Loosen the muffler outlet pipe exhaust clamps.
4. Remove the muffler outlet pipe.
5. Loosen the muffler inlet pipe exhaust clamps.
6. Remove the muffler inlet pipe.
7. Remove the spring bolts from the muffler support brackets.
8. Remove the muffler.

INSTALLATION

1. Position the muffler.
2. Install the spring bolts in the muffler support brackets. Tighten 26 lbf·ft (35 N·m).
3. Install the muffler inlet pipe.
4. Tighten the muffler inlet pipe exhaust clamps 45 to 60 lbf·ft (61 to 81 N·m).
5. Install the muffler outlet pipe.
6. Tighten the muffler outlet pipe exhaust clamps 45 to 60 lbf·ft (61 to 81 N·m).
7. Install the muffler heat shield. Tighten the fasteners 26 lbf·ft (35 N·m).
8. Remove the chocks from the tires.

10. Lower Exhaust Stack
11. Lower Exhaust Shield Clamp
12. Lower Grab Handle and Fasteners
13. Lower Exhaust Stack Bracket

Fig. 1, Cab-Mounted Exhaust Stack

NOTE: The exhaust stack has an upper and lower pipe. However, it is not necessary to separate them for this procedure.

2. Loosen the clamp between the flex pipe and the lower exhaust stack.
3. Disconnect the upper and lower clamps from the exhaust stack brackets.

Exhaust Stack and Heat Shield Removal and Installation

4. Remove the upper and lower cab-to-exhaust stack bracket nuts.

IMPORTANT: Be sure to support the exhaust stack while removing it from the cab.

5. With the help of an assistant, separate the exhaust stack from the flex pipe and remove the exhaust stack.
6. Remove the grab handle upper and lower retaining bolts and remove the grab handle.
7. Remove the heat shield retaining bolts and remove the heat shield.

INSTALLATION (See Fig. 1)

1. Install the heat shield and the retaining bolts. Tighten the bolts 12 to 17 lbf·ft (17 to 23 N·m).
2. Install the grab handle and the upper and lower retaining bolts. Tighten the bolts 12 to 17 lbf·ft (17 to 23 N·m).

IMPORTANT: Be sure to support the exhaust stack while installing it to the cab.

3. With the help of an assistant, connect the exhaust stack to the flex pipe.
4. Attach the upper and lower clamps to the exhaust stack brackets.
5. Install and tighten the upper and lower cab-to-exhaust stack bracket bolts 26 to 37 lbf·ft (35 to 50 N·m).
6. Tighten the flex pipe-to-exhaust stack clamp to 45 to 60 lbf·ft (61 to 81 N·m).
7. Remove the chocks from the tires.

Frame-Mounted

REMOVAL (See Fig. 2)

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Loosen the muffler lower outlet pipe band clamp.
3. Loosen the lower band clamp from the flex pipe.
4. Remove the muffler lower outlet pipe.
5. Loosen the upper band clamp from the flex pipe.
6. Remove the flex pipe.
7. Loosen the heat shield band clamps.

IMPORTANT: Be sure to support the exhaust stack while removing it from the support bracket.

8. With the help of an assistant, remove the exhaust stack.
9. If equipped, remove the grab handle upper and lower retaining bolts and remove the grab handle.
10. Remove the heat shield bolts.
11. Remove the heat shield from the exhaust stack.

INSTALLATION (See Fig. 2)

1. Position the heat shield on the exhaust stack.
2. Install the heat shield bolts. Tighten 12 to 17 lbf·ft (17 to 23 N·m).
3. If equipped, install the grab handle and the upper and lower retaining bolts. Tighten the bolts 12 to 17 lbf·ft (17 to 23 N·m).

IMPORTANT: Be sure to support the exhaust stack while installing it on the support bracket.

4. With the help of an assistant, position the exhaust stack.
5. Install the heat shield band clamps. Tighten 45 to 60 lbf·ft (61 to 81 N·m).
6. Position the flex pipe.
7. Install the flex pipe upper band clamp. Tighten 45 to 60 lbf·ft (61 to 81 N·m).
8. Position the lower muffler outlet pipe.
9. Install the flex pipe lower band clamp. Tighten 45 to 60 lbf·ft (61 to 81 N·m).
10. Install the lower muffler outlet pipe band clamp. Tighten 45 to 60 lbf·ft (61 to 81 N·m).
11. Remove the chocks from the tires.

Fig. 2, Frame-Mounted Exhaust Stack

Exhaust Support Brackets Removal and Installation

Vertical Frame-Mounted Exhaust Stack

REMOVAL (See Fig. 1)

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the tires.
2. Remove the exhaust stack. For instructions, see **Subject 110**.
3. Loosen the nut and bolt holding the support brace to the exhaust stack support.
4. Loosen the nuts surrounding the bushings on the support brace bracket and remove the support brace.
5. Remove the nut and bolt from the support brace at the exhaust stack support and remove the support brace.
6. Loosen the four nuts, washers and bolts holding the exhaust stack support bracket cap to the exhaust stack support bracket.
7. Remove the exhaust stack support from the bracket.
8. Remove the mounting brackets from the frame rail.

INSTALLATION (See Fig. 1)

1. Install the mounting brackets on the frame rail. Tighten 128 lbf·ft (173 N·m).
2. Install the exhaust stack support into the bracket.
3. Tighten the four nuts, washers and bolts holding the exhaust stack support bracket cap to the exhaust stack support bracket 26 lbf·ft (35 N·m).
4. Position the support brace and loosely install the nut and bolt in the support brace at the exhaust stack support.
5. Position the support brace in the support brace bracket and tighten the nuts surrounding the bushings on the support brace bracket 35 to 48 lbf·ft (47 to 65 lbf·ft).
6. Tighten the nut and bolt holding the support brace to the exhaust stack support 12 to 17 lbf·ft (17 to 23 N·m).
7. Install the exhaust stack. For instructions, see **Subject 110**.
8. Remove the chocks from the tires.

Vertical Cab-Mounted Muffler

REMOVAL (See Fig. 2)

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the tires.
2. Remove the muffler. For instructions, see **Subject 100**.
3. Remove the three mounting bolts and remove the lower bracket.
4. Remove the four mounting bolts and remove the upper bracket.

INSTALLATION (See Fig. 2)

1. Apply sealant around all bolt holes on the cab.
2. Position the upper bracket and install the four mounting bolts. Tighten 12 to 17 lbf·ft (17 to 23 N·m).
3. Position the lower bracket and install the three mounting bolts. Tighten 12 to 17 lbf·ft (17 to 23 N·m).
4. Install the muffler. For instructions, see **Subject 100**.
5. Remove the chocks from the tires.

Troubleshooting

INSPECTION AND VERIFICATION

Exhaust system performance complaints such as excessive back-pressure are usually noticeable by their effect on engine performance. Other worn or damaged components can have the same effect on engine performance and be characterized by the same symptoms or complaints. Refer to the applicable engine manufacturer's service literature when attempting to diagnose this type of problem.

Exhaust Leakage or Noise

Noise can be caused by exhaust leaks. Inspect the exhaust system for the following:

- holes, cracks or gaps
- loose or missing clamps
- black soot residue (indicates leakage) on the exhaust pipes or the muffler

COMPONENT TESTS

Exhaust Back-Pressure Test—Full Load

NOTE: The chassis dynamometer or "Full Load" test is the preferred method for testing exhaust back pressure. However, if a chassis dynamometer is not available, the "No Load" test is the only other authorized method for testing the exhaust back-pressure.

NOTE: Follow the setup procedures supplied by the chassis dynamometer manufacturer.

1. Install the pressure gauge in the test port. The test port is located on the muffler inlet pipe, either near the turbocharger or the muffler assembly.
2. Start and run the engine until the temperature gauge indicates normal operating temperature.
3. Select a transmission gear range where acceleration to full throttle can be accomplished safely.
4. Accelerate to full throttle and peak engine power.
5. When the engine reaches maximum rpm and load, record the maximum exhaust back-pressure reading.
6. The reading should be less than 6 inHg (20 kPa). If the reading is higher than this, replace the muffler assembly.

   If the reading is acceptable, then the muffler assembly is not plugged. Refer to the applicable engine manufacturer's service literature for engine related components.

Exhaust Back-Pressure Test—No Load

⚠ WARNING

Make sure the vehicle parking brake is set, the wheels are blocked, the transmission is in NEUTRAL, and the area around the vehicle is clear before performing this test. Failure to take all necessary precautions could result in personal injury due to unexpected vehicle movement.

1. Install the pressure gauge in the pressure test port.
2. Start and run the engine until the temperature gauge indicates normal operating temperature.

NOTE: Engine rpm will exceed the rated rpm range by 10 to 17 percent under full throttle, no-load conditions. This is normal and no cause for concern.

NOTE: If the engine is unable to reach maximum rpm rating plus 10 percent, it will be necessary to repair this problem before the back-pressure test can be performed.

3. Accelerate to full throttle. Record the maximum engine rpm and the maximum exhaust back-pressure reading.
4. The maximum back-pressure reading under a no load condition is 3 inHg (10.2 kPa). If the reading exceeds this, replace the muffler assembly.

   If the reading is acceptable, then the muffler assembly is not plugged. Refer to the applicable engine manufacturer's service literature for engine related components.

Troubleshooting

Problem—Exhaust Fumes in the Cab

Problem—Exhaust Fumes in the Cab	
Possible Cause	**Remedy**
Leaking gaskets.	Replace the gaskets.
Loose mounting bolts.	Tighten the mounting bolts. Check the gaskets for damage.
Leaking exhaust system.	Repair or replace worn or damaged exhaust components.

Problem—Insufficient Exhaust Back-Pressure

Problem—Insufficient Exhaust Back-Pressure	
Possible Cause	**Remedy**
Leaking exhaust system.	Repair or replace damaged exhaust components.
Insufficient air supply.	Check for air leaks or low system air pressure.
Damaged exhaust brake actuating cylinder.	Repair or replace the actuating cylinder or seal.
Leaking gasket.	Replace the gasket.

Problem—Excessive Exhaust Back-Pressure

Problem—Excessive Exhaust Back-Pressure	
Possible Cause	**Remedy**
Plugged catalyst converter/muffler.	Perform the exhaust back-pressure test. Refer to "Component Tests" in this subject.
Restricted exhaust system.	Check the exhaust system for damage or plugged pipes.

Specifications

Torque Specifications	
Description	**lbf·ft (N·m)**
Turbocharger Outlet Pipe Clamps	7–9 (9–12)
Exhaust Pipe Clamps	45–60 (61–81)
Heat Shield Clamps	12–17 (17–23)
Exhaust System-to-Frame Rail U-Bolt Nuts, 1/2–20	72 (98)
3/8–16 Hexnut	26 (35)
5/8–11 Hexnut	128 (173)
5/16 Fasteners	12–17 (17–23)

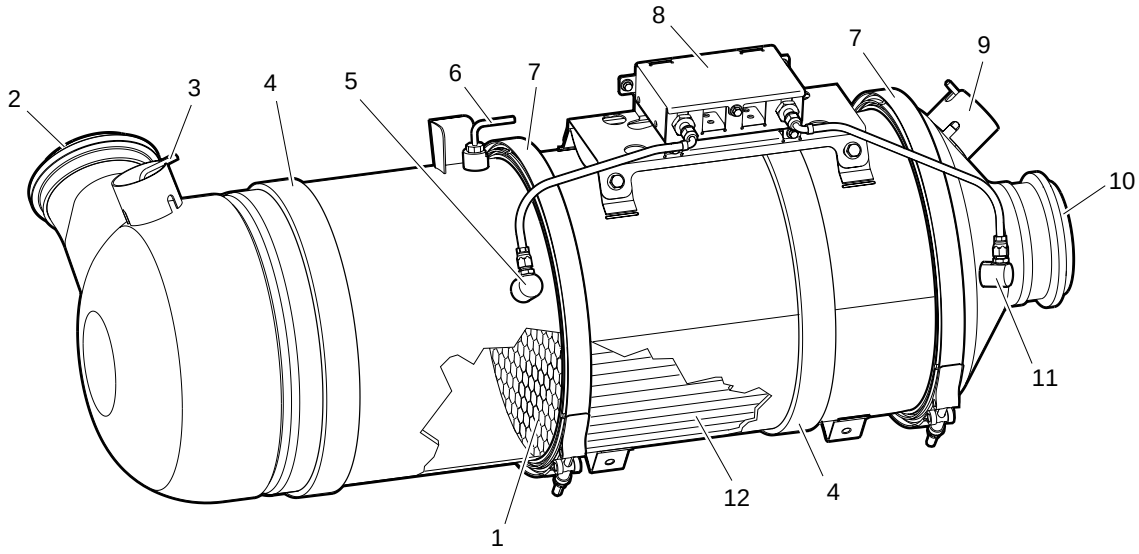
Table 1, Torque Specifications

General Information

The aftertreatment system (ATS), introduced to meet the requirements of the EPA07 emission control regulations, includes all the piping and equipment between the turbocharger outlet and the tip of the exhaust pipe. It resembles the exhaust system on pre-EPA07 vehicles, but includes an aftertreatment device (ATD) instead of a muffler (see **Fig. 1**), and other equipment. Monitoring and operation of the ATS is controlled by an electronic control module (ECM).

ways chassis-mounted, but can be mounted either vertically or horizontally. ATS exhaust piping is stainless steel.

Inside the ATD, the exhaust first passes through the diesel oxidation catalyst (DOC) where combustion gases are chemically broken down to water and carbon dioxide, then through the (DPF), where solid particles are trapped. The trapped particles are almost completely vaporized in the DPF in regeneration, sometimes shortened to the term, "regen." The soot from engine oil additives which cannot be vaporized is burned to ash and held in the DPF until it eventu-



1. Diesel Particulate Filter (DPF) Ceramic Honeycomb Substrate Openings

9. DPF Outlet Temperature Sensor (connection to sensor housing not shown)
10. Exhaust Outlet Marmon Fitting
11. DPF Outlet Pressure Sensor
12. DPF Substrate Tubes

Fig. 1, ATD Components (typical)

EPA07 emissions regulations limit NOx to just over 1 gram per brake horsepower hour (g/bhp-hr) and particulate matter cannot exceed 0.01 g/bhp-hr. EPA07 engines require ultralow sulphur diesel (ULSD) fuel, for low emissions and long life of the diesel particulate filter (DPF), a honeycomb soot filter inside the ATD.

Engine manufacturers use different methods and equipment to reduce emissions from their engines, but an ATD is used on all of them. The ATD is al-

ally builds up, and the DPF must be removed and physically cleaned.

IMPORTANT: To minimize soot buildup on the DPF, low-ash oil is necessary for maximum service between physical cleanings. Only low-ash oil should be used in EPA07 engines.

NOTE: Sterling documentation deals only with removal and installation of the components of the ATS. Refer to the engine manufacturer's ser-

vice literature for all testing, disassembly, cleaning, and repair of the ATD and other components.

IMPORTANT: The ATS is part of an integrated engine and emissions management system, controlled by the ECM. Follow the engine manufacturer's procedures, and use the correct equipment when diagnosing or working on any part of the ATS.

Regeneration

There are two types of regeneration; passive and active.

Passive regeneration happens whenever the ATD internal temperature is 572°F (300°C) or higher. This happens during normal loaded vehicle operation, and exhaust gas temperature is no higher than normal. Under load and at highway speeds, passive regeneration may be all that is necessary to keep the DPF clear. But running light loads, or at low speeds, does not generate enough heat in the ATD for passive regeneration, and soot builds up in the DPF.

As soot builds up in the DPF, it creates back pressure and decreases engine efficiency. So at intervals determined by the ECM, which keeps track of measurements such as engine hours, fuel consumed, and mileage, the ATS raises the temperature inside the ATD to burn the built-up soot to ash. This reduces the back pressure and allows the DPF to continue operating efficiently for tens of thousands of miles.

During active regeneration, engine rpm rise to fast-idle speed and extra fuel is injected into the ATD to raise its interior temperature very high, over 1112°F (600°C), and turn the trapped soot to harmless ash. There are two types of active regeneration; at-speed and parked.

- When conditions permit, the ECM automatically initiates at-speed regeneration. The exact conditions for regeneration vary, according to the engine manufacturer's design. Generally, it can happen only when the vehicle speed is above 7.5 mph, and active regeneration stops when the vehicle slows to 5 mph or below.
- Parked regeneration is initiated by a driver or technician when the vehicle is safely parked with the exhaust outlet well away from any flammable substance, a specific sequence of procedures is followed, and the driver pushes the regeneration button on the dashboard. The parked regeneration sequence varies according to engine and vehicle configuration, but it must be exactly followed or regeneration cannot happen. Follow the exact sequence prescribed for the vehicle, according to the engine manufacturer's literature.

EPA07 Aftertreatment Device Removal and Installation

Removal

These instructions are generalized, because vehicle configurations vary widely. The basic procedures apply to all aftertreatment systems. For service and repair beyond removal and installation, refer to the engine manufacturer's service literature.

NOTE: For test or service procedures on components of the ATS, consult the engine manufacturer's service literature.

NOTICE

The ATD assembly weighs from 125 to 150 pounds (57 to 68 kg) and must be protected from impact or sharp jolts. Dropping the ATD, or subjecting it to jarring impact can crack the diesel particulate filter (DPF) inside, which is built on a ceramic substrate. If that happens, the DPF is ruined and must be replaced.

A secure support is necessary to remove and install the ATD safely. The ATD must be held securely to protect it from falling, or hitting hard against something else.

The horizontal ATD lifting device (TLZ00785) is designed to handle a horizontal ATD. Vertical ATDs require a shop hoist secured to the lifting ears on top.

The aftertreatment device (ATD) is constructed so that its exterior operating temperature is comparable to that of a standard muffler, but during active regeneration, when a fuel mist is injected to raise its temperature and destroy soot deposits, its interior (see **Fig. 1**) and the outlet become hot enough to melt or ignite many common materials.

⚠ WARNING

Aftertreatment Device (ATD) internal temperatures can remain hot enough to cause personal injury, or ignite combustible materials, for hours after the engine is shut down.

To avoid potentially serious burns or material damage:

- Let the ATD cool before handling it; be especially careful when opening it to expose the DPF.
- Wear appropriate protective gear.
- Be careful not to place the ATD where flammable gases or other combustible materials may come into contact with hot interior parts.

1. Set the parking brake and chock the tires.

NOTE: Never attempt to start the vehicle with the ATD removed or with the ATD sensors disconnected, unless the engine manufacturer's documentation allows it for a diagnostic procedure.

2. Disconnect the connections at the sensor housing and the diesel oxidation catalyst (DOC) inlet temperature sensor. See **Fig. 1**.
3. Mark the Marmon fitting joints and mounting bracket orientation to the ATD, so that it can be installed exactly as it was removed. See **Fig. 2**.

NOTE: There are guide pins (see **Fig. 3**) to position the ATD during vehicle manufacture, but they are designed to break off if they are stressed. The most important thing about ATD mounting is that the other ATS components, particularly the bellows, must align correctly.

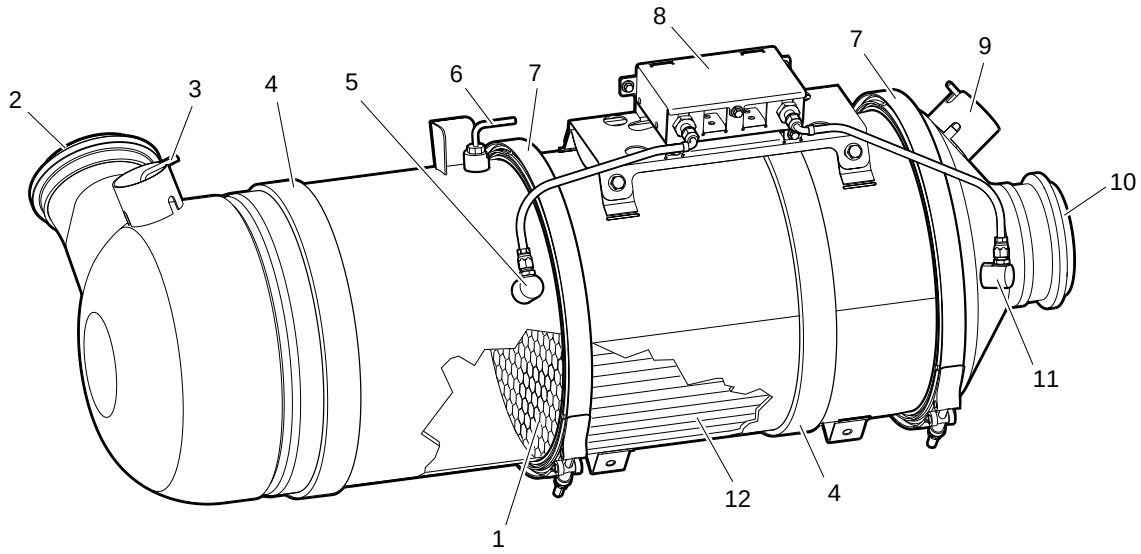
4. If the ATD is horizontally mounted, raise the ATD-handling device into place against it, so that the ATD is supported securely. If the ATD is vertically mounted, attach a shop crane or similar device to the lifting ears and take up the slack so that the lifting device is beginning to take the weight of the ATD.
5. The exhaust pipe may require support, such as a rope sling, to support it when the ATD is removed. If such support is required, install it now.

NOTICE

Be careful not to stress or twist the bellows as the ATD is manipulated. The bellows is not designed to support weight or withstand undue stress and can easily be damaged, requiring expensive replacement.

6. Remove the clamps from the Marmon fittings at the ATD inlet and outlet.
7. Remove the two mounting bands that hold the ATD to its mounting brackets, so that the ATD is held by the ATD handling device.

EPA07 Aftertreatment Device Removal and Installation



1. Diesel Particulate Filter (DPF) Front End Honeycomb
2. Marmon Fitting at Inlet from Turbocharger
3. Diesel Oxidation Catalyst (DOC) Intake Temperature Sensor
4. ATD Mounting Band
5. DPF Intake Pressure Sensor
6. DOC Outlet Temperature Sensor (connection to sensor housing not shown)
7. DPF V-Band Mounting Clamp
8. Sensor Housing
9. DPF Outlet Temperature Sensor (connection to sensor housing not shown)
10. Exhaust Outlet Marmon Fitting
11. DPF Outlet Pressure Sensor
12. DPF Ceramic Substrate

Fig. 1, Typical ATD

NOTE: It may be necessary to raise the vehicle, or remove heat shields or body panels, to remove the ATD.

8. Move the ATD handling device slightly, so that the ATD positioning pin (see **Fig. 4**) clears its hole in the mounting bracket. Carefully remove the ATD from the vehicle.

NOTE: ATD component service procedures, such as cleaning the DPF or servicing the sensors, are documented in the engine manufacturers' service literature.

Installation

1. Use the ATD handling device to move the ATD into position, so the inlet and exhaust align with the inlet and exhaust piping. Be sure the ATD positioning pin engages its hole in the ATD mounting bracket, or that the positioning marks align.
2. Install the ATD mounting bands, but do not tighten them yet.
3. Position the V-band clamps on the Marmon fittings and tighten them to the value shown in **Table 1**.
4. Tighten the ATD mounting bands to the value shown in **Table 1**.
5. Connect the harness to the sensor housing and the front temperature sensor.
6. Remove the ATD handling device.
7. If a support was fastened around the exhaust pipe, remove it.
8. Operate the vehicle and check for leaks.

6. Fuel Tank Mounting Bracket

Fig. 4, ATD Mounting Bracket

EPA07 Aftertreatment System Bellows Replacement

Replacement

1. Open the hood.
2. Open the tool box under the passenger-side door, and remove the cover.
3. Remove the right quarter fender and mud flap. For instructions, see **Group 88**.
4. Remove the V-clamp (**Fig. 1**, Item 5) that holds the turbo outlet pipe to the turbocharger.
5. Remove the U-clamp that holds the aftertreatment device (ATD) inlet pipe to the support bracket on the frame rail (**Fig. 1**, Item 2).
6. Remove the clamp that holds the exhaust pipe to the front of the ATD, then disconnect the exhaust pipe from the ATD.
7. Remove the bellows and exhaust pipes as a unit from under the vehicle. If the vehicle is equipped with side fairings, remove the parts from the rear of the vehicle.
8. Place the assembly on a work bench. Loosen and spread the seal clamps on the ends of the bellows. Pry the ends of the bellows off the exhaust pipes, being careful not to damage the exhaust pipe ends. If it is not possible to remove the bellows this way, proceed as follows:

⚠ WARNING

Always wear a face shield and other appropriate protection when using a cutting wheel.

The cut edges of the bellows are extremely sharp, and can cause serious injury. Wear appropriate protective gear, including heavy gloves and a face shield, when removing the bellows from the exhaust pipes.

9. If you cannot remove the bellows by prying, use a cutoff wheel to cut through each end of the bellows between the exhaust pipe ends. Be careful not to cut the exhaust pipes. Discard the center section of the bellows when it is cut loose.

2. U-Clamp
3. Seal Clamp
4. Bellows
5. V-Clamp
6. Bellows Support Bracket

Fig. 1, Bellows Installation

EPA07 Aftertreatment System Bellows Replacement

10. Carefully remove the bellows ends and clamps from the exhaust pipes, either by prying them off, or by driving them off with a soft drift. Be careful not to damage the exhaust pipes.

IMPORTANT: Take the following measurements *before* installing the bellows.

The main section of the ATD inlet pipe is a larger diameter than the turbo outlet pipe. Make sure you measure at the **end** of the pipe, where it inserts into the bellows. The two measurements should be identical. If they are not, loosen the U-clamp nuts that hold the ATD inlet pipe to the frame-rail support bracket, and move the pipe up or down as needed.

NOTICE

The ends of the ATD inlet pipe and the turbo outlet pipe must be in exact vertical and horizontal alignment before installing the new bellows. If they are not aligned the bellows will be twisted, and will fail after a short time.

11. Attach the turbo outlet pipe to the turbocharger, then to the bellows support bracket. Tighten the clamps enough to hold the pipe in place.
12. Attach the ATD inlet pipe to the ATD and the frame-rail support bracket. Tighten the clamps enough to hold the pipes in place.
13. Using a ruler or tape measure, measure the vertical distance between the end of the ATD inlet pipe and the frame rail. See **Fig. 2**. Do the same for the end of the turbo outlet pipe. The two measurements must be the same. If the measurements are different, loosen the U-clamp nuts on the frame-rail support bracket, and raise or lower the ATD inlet pipe as needed. Tighten the U-clamp nuts enough to hold the pipe in place.
14. Using a ruler (or a T-square) and a tape measure, measure the distance between each pipe end and the frame rail. See **Fig. 3**. If these two measurements are different, do one or more of the following adjustments (see **Fig. 4**):
    - Check that the U-clamp on the bellows support bracket is installed correctly, and is not crooked.
    - Rotate the turbo outlet pipe at the turbocharger.
    - Support the ATD with a suitable jack, then loosen the ATD straps and rotate the ATD.
    - Rotate the ATD inlet pipe at the Marmon flange on the ATD.
15. With the two pipe ends in horizontal and vertical alignment and the bellows not installed, measure the distance between them. See **Fig. 5**.

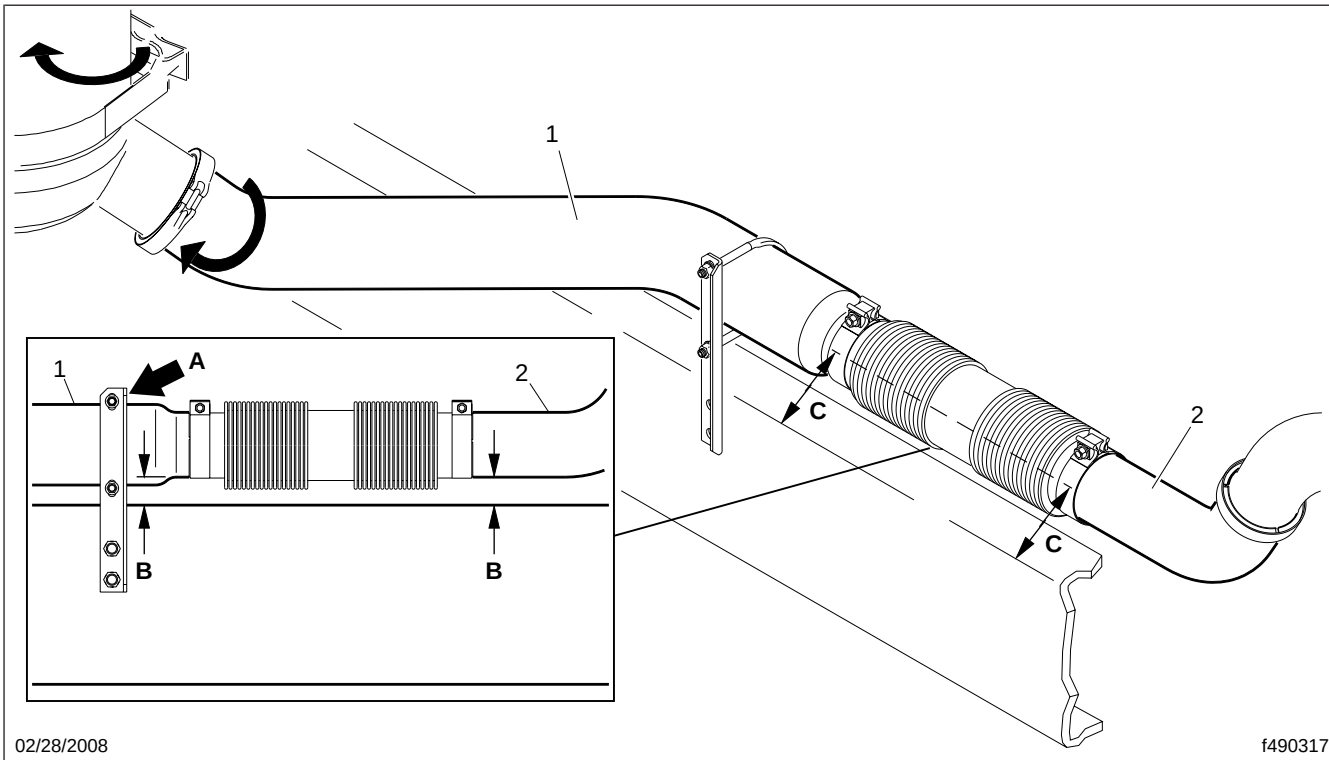
    The distance between the pipe ends is to be at least 14 inches (35.5 cm), but not more than 14-3/8 inches (36.5 cm).

    If the distance is less than the above, remove the turbo outlet pipe and the ATD inlet pipe, and cut off an equal amount from each pipe end, as needed; otherwise, go to the next step. Make sure you remove all burrs from the cut ends of the pipes.

IMPORTANT: If they were loosened, do not tighten the ATD mounting straps until the U-clamp nuts on the frame-rail support bracket are tightened to their final torque. To do otherwise will affect the alignment of the exhaust pipes.

16. When the horizontal and vertical alignment is the same for both exhaust pipes and the distances between the pipe ends is correct, tighten the U-clamp nuts on the frame-rail support bracket that holds the ATD inlet pipe in place. See **Subject 100** for torque values.
17. Tighten the V-clamp that holds the inlet pipe to the ATD. See **Subject 100** for torque values.
18. If applicable, tighten the mounting straps on the ATD, then remove the jack.
19. Remove the turbo outlet pipe from the turbocharger.
20. Remove any dirt or soot from the outer surface of the exhaust pipe ends to ease the installation of the new bellows.
21. Install the new bellows on the ATD inlet pipe, with the clamp nuts on top and facing outboard (**Fig. 2**).
22. Insert the end of the turbo outlet pipe into the bellows, then connect the pipe to the turbocharger and to the new bellows support bracket. See **Subject 100** for torque values.
23. Tighten the bellows seal clamps; see **Subject 100** for torque values.

EPA07 Aftertreatment System Bellows Replacement



A. Up-and-down adjustment to be done at this bracket.
B. Vertical measurements to be the same.
C. Horizontal (in-and-out) measurements to be the same.

1. ATD Inlet Pipe
2. Turbo Outlet Pipe (support bracket not shown)

Fig. 2, Rotation and Adjustment Areas for Exhaust Pipe alignment (vertical ATD installation shown)

24. Start the engine and check for leaks. Shut down the engine, and tighten any clamps as needed.

EPA07 Aftertreatment System Bellows Replacement

Fig. 5, Measuring the Distance Between Pipe Ends

General Information

WARNING

Do not use the cruise control in heavy traffic or when road conditions are wet or slippery. Improper use of cruise control can result in loss of vehicle control and possible property damage or personal injury.

The cruise control system consists of the following components:

- control switch (ON/OFF, see **Fig. 1**)
- speed control switch (SET/CST and RSM/ACCL, see **Fig. 2**)
- clutch pedal switch
- brake cutoff switch
- engine electronic control module (ECM)

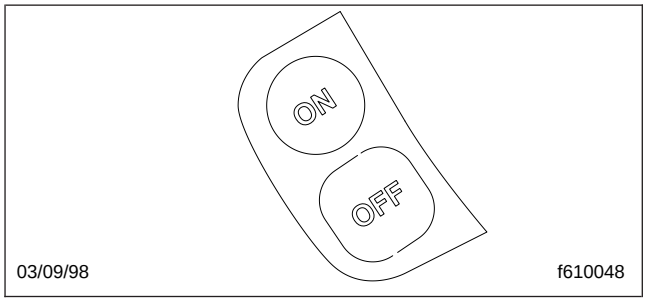

Fig. 1, Control Switch

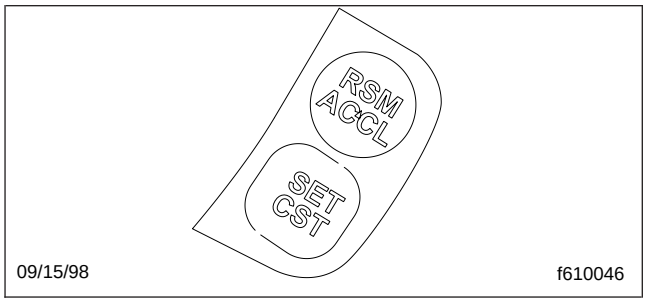

Fig. 2, Speed Control Switch

The ECM (see **Fig. 3** for Caterpillar, **Fig. 4** for Cummins, or **Fig. 5** for DDC) stores the last set speed until either the cruise control system is turned off or the engine is turned off. The ECM is also programmed with the minimum and maximum operational speeds. These settings do not erase when the system is turned off.

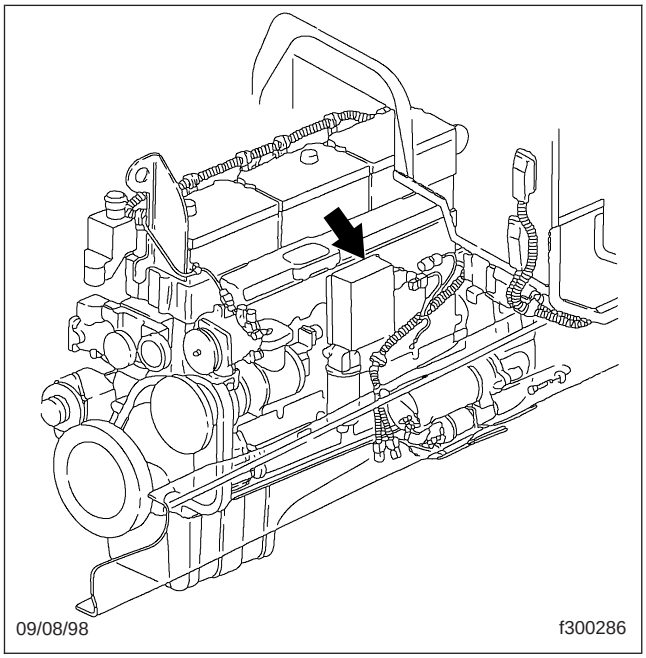

Fig. 3, Caterpillar Engine ECM

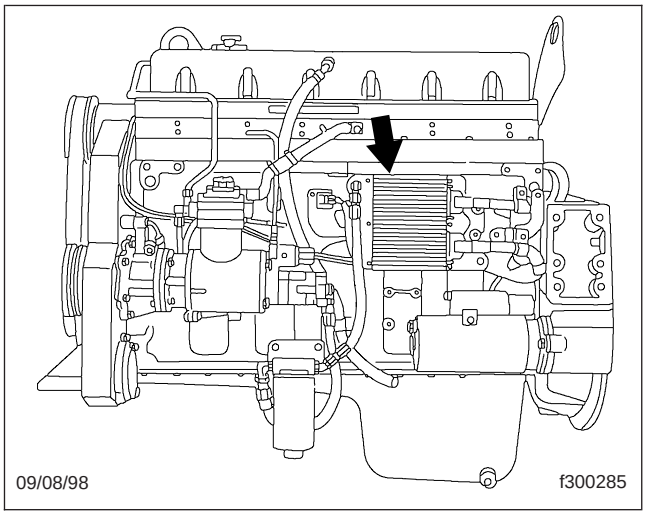

Fig. 4, Cummins Engine ECM

The accelerator pedal can be used to exceed the last set speed if the maximum engine governed speed is greater than the cruise control maximum speed. Releasing the accelerator pedal returns the vehicle to the cruise control set speed.

General Information

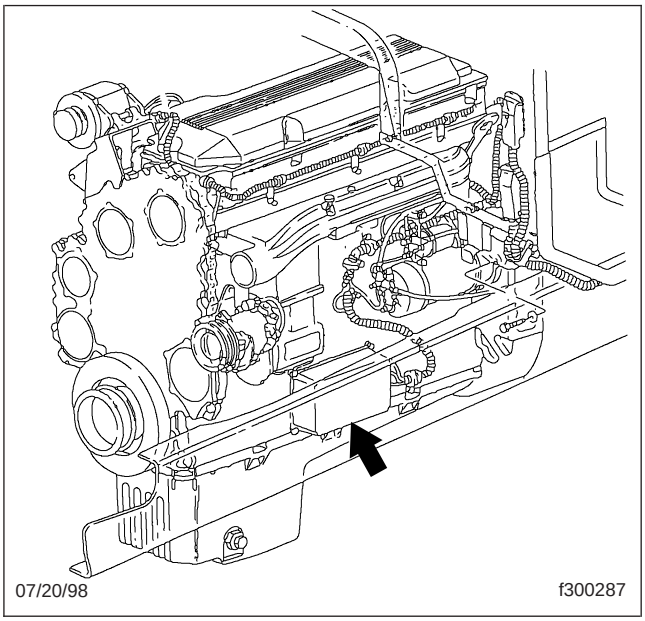

Fig. 5, DDC Engine ECM

When the vehicle has reached 30 mph (48 km/h) perform the following steps to activate the cruise control system:

1. Press the ON button on the control switch.
2. Accelerate to the desired road speed.
3. Press the SET/CST button on the speed control switch.

NOTE: If the SET/CST button is pressed for more than one second, the vehicle will continue to increase in speed until either the SET/CST switch is released or the vehicle reaches the maximum programmed speed.

To disengage the cruise control, perform one of the following steps:

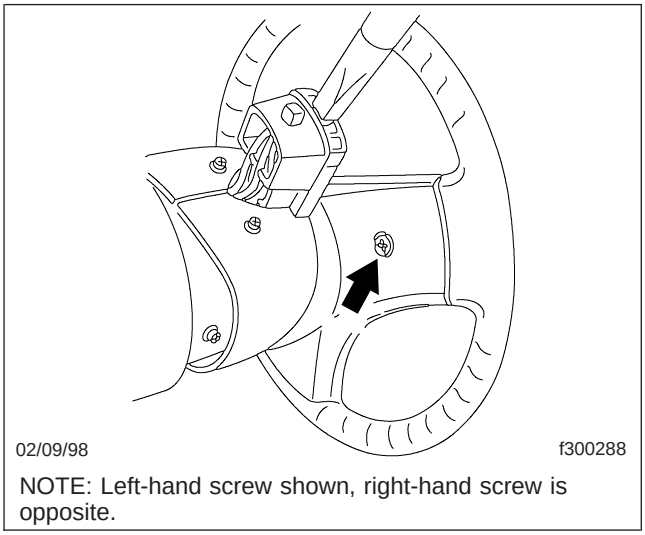
1. Press the OFF button on the control switch, or
2. Press the clutch pedal, or
3. Press the brake pedal.

Control Switches Removal and Installation

NOTE: The following procedures should be used to replace either the control switch (ON/OFF) or the speed control switch (RSM/ACCL and SET/CST).

Removal

1. Remove the horn pad. See **Fig. 1**.



NOTE: Left-hand screw shown, right-hand screw is opposite.

Fig. 1, Horn Pad Screw

1.1 Remove the two screws retaining the horn pad to the steering wheel.

1.2 Lift the horn pad away from the steering wheel.

2. Disconnect the horn pad wiring retainers. See **Fig. 2**.
3. Disconnect the wiring connector. See **Fig. 3**.
4. Disconnect the electrical connector. See **Fig. 4**.
5. Press the lock tabs, and remove the switch from the horn pad. See **Fig. 5**.

Installation

1. Install the switch into the horn pad. See **Fig. 5**.
2. Connect the electrical connector. See **Fig. 4**.
3. Connect the wiring connector. See **Fig. 3**.
4. Connect the wiring to the horn pad. See **Fig. 2**.

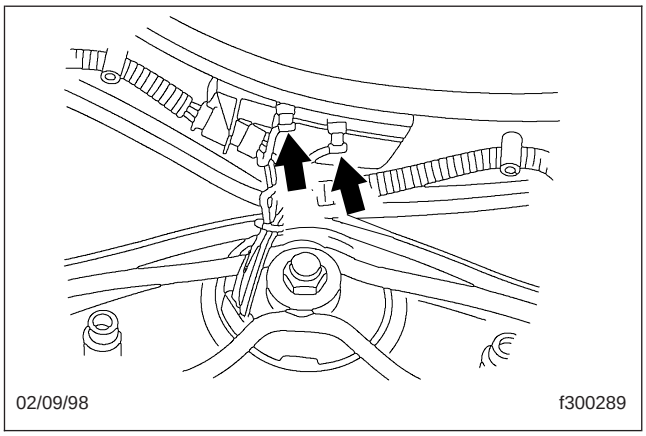


Fig. 2, Horn Pad Wiring Retainers

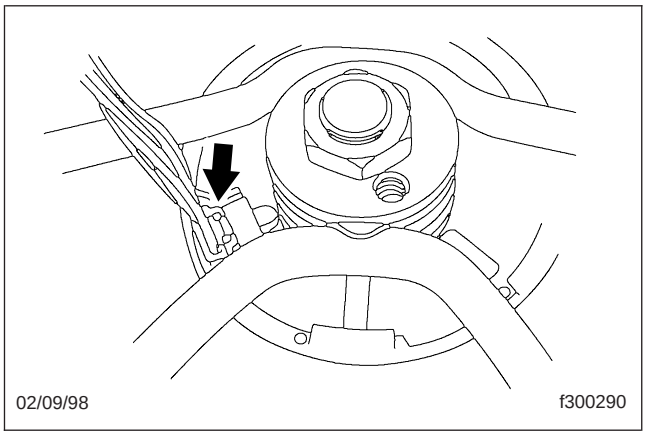

Fig. 3, Horn Pad Wiring Electrical Connector

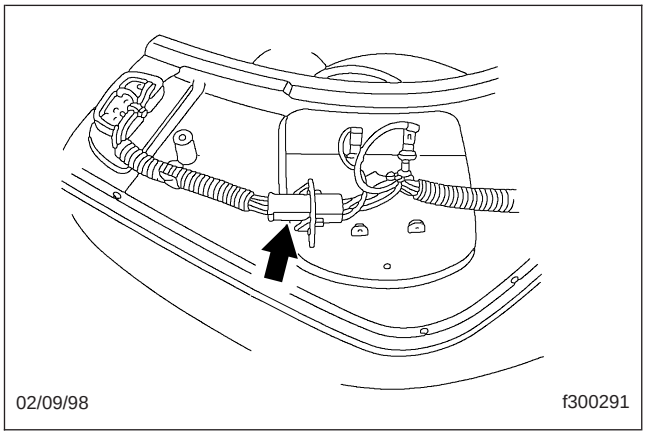

Fig. 4, Electrical Connector

5. Install the horn pad.

Control Switches Removal and Installation

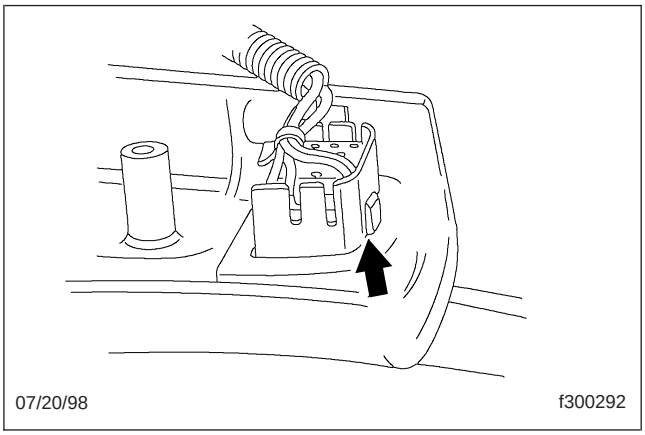

Fig. 5, Switch

5.1 Position the horn pad onto the steering wheel.

5.2 Install the two screws retaining the horn pad to the steering wheel. See **Fig. 1**.

Clutch Pedal Position Switch Removal and Installation

Removal

1. Remove the lower left-hand instrument panel finish panel. See **Fig. 1**.

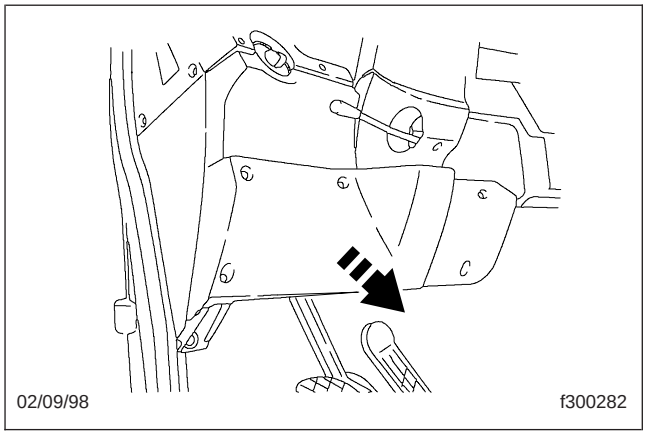

Fig. 1, Instrument Panel Finish Panel

NOTE: Slide the wiper module forward to disengage it from the mounting bracket.

2. Disconnect the wiring, and remove the windshield wiper control module. See **Fig. 2**.

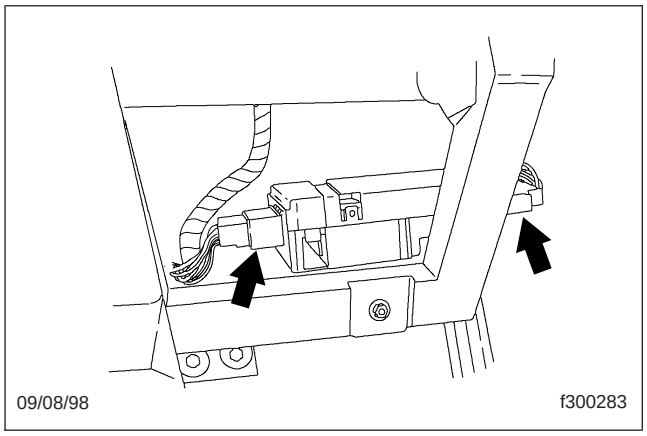

Fig. 2, Windshield Wiper Control Module Wiring

3. Remove the screw and the clutch pedal position switch. See **Fig. 3**.

Installation

1. Install the clutch pedal position switch and the screw. See **Fig. 3**.

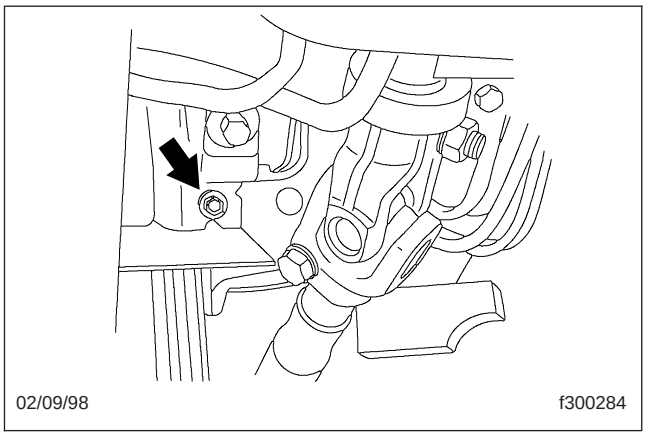

Fig. 3, Remove Clutch Pedal Position Switch Screw

2. Connect the windshield wiper control module wiring. See **Fig. 2**.
3. Slide the windshield wiper control module onto the mounting bracket until it locks in place.
4. Install the lower left-hand instrument panel finish panel. See **Fig. 1**.

Brake Cutoff Switch Removal and Installation

Removal

1. Set the parking brake and chock the wheels.
2. Exhaust air from the air brake system.
3. Remove the screws and the air manifold cover.
4. Disconnect the wiring at the brake switch.
5. Remove the brake switch. See **Fig. 1**.

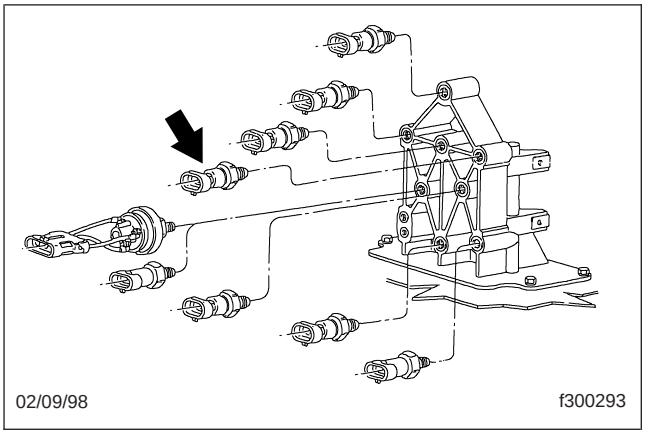

Fig. 1, Brake Switch

Installation

1. Install the brake switch. See **Fig. 1**.
2. Connect the wiring at the brake switch.
3. Install the air manifold cover and the screws.
4. Remove the wheel chocks.

Troubleshooting

Inspection and Verification

NOTE: Diagnosis and testing procedures for Sterling-installed components are covered in this section. For all other components, see the appropriate engine manufacturer's service literature.

1. Verify the customer's concern by operating the speed control system to duplicate the condition.
2. Inspect to determine if one of the following mechanical or electrical concerns apply (see **Table 1**):

Inspection and Verification Chart	
Mechanical	**Electrical**
Inspect and verify that system switches are not damaged.	Verify proper horn operation
	Verify stoplamp operation
	Check Fuse 22
	Inspect and verify that: • connections are complete with no loose wires or terminals • wiring is not broken, shorted or corroded • wiring is not misrouted

Table 1, Inspection and Verification Chart

3. If inspection reveals obvious concerns, correct the concerns before proceeding.

Troubleshooting

Problem—Cruise Control is Inoperative

Problem—Cruise Control is Inoperative	
Possible Cause	**Remedy**
Function switches	Check for battery feed to the clockspring connector. Disconnect the clockspring to harness connector. Turn the ignition switch to the "On" position. Measure the voltage at connector C250, pin 1, Circuit 976 (BK/GN). If the voltage is not greater than 10 volts, repair the open in Circuit 976 (BK/GN). Test the system for normal operation. If the voltage is greater than 10 volts, check "On/Off" switch function. Connect the clockspring-to-harness connector. Connect the positive lead of an ohmmeter to connector C250, pin 591 (BK/O). Connect the ohmmeter negative lead to a clean chassis ground. Press the speed control "On" switch. If the ohmmeter does not show continuity when the "On" switch is pressed, check continuity at the clutch switch. Connect the brake cutoff switch connector. Disconnect the clutch switch connector. Measure the resistance across the clutch switch terminals. If the resistance is less than 5 ohms, replace the switch. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of clockspring Circuit 591 (BK/O). Measure the resistance between connector C250, terminal 5, Circuit 591 (BK/O) and the seventh terminal in the clockspring connector. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of clockspring Circuit 937 (BK). Measure the resistance between connector C250, terminal 1, Circuit 937 (BK) and the seventh terminal in the clockspring connector. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of clockspring Circuit 57 (BK). Measure the resistance between connector C250, terminal 8, Circuit 860 (P/W) and the fifth terminal in the clockspring connector. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of clockspring Circuit 976 (BK/GN). Disconnect the clockspring-to-horn pad. Turn the steering wheel as necessary to position the wheels in the straight-ahead position. Remove the steering wheel. Measure the resistance between connector C250, terminal 1, Circuit 976 (BK/GN) and the sixth terminal in the clockspring connector. If the resistance is less than 5 ohms, replace the on/off switch. Test the system for normal operation. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the ohmmeter shows continuity when the "On" switch is pressed check Circuit 57 (BK) for continuity. Disconnect the clockspring-to-harness connector. Connect the positive lead of an ohmmeter to connector C250, pin 6, Circuit 57. Connect the ohmmeter negative lead to a clean chassis ground. If the ohmmeter does not show continuity, repair the open in Circuit 57 (BK). Test the system for normal operation.
Clutch switch	
Brake cutoff switch wiring	
Clockspring	

Problem—Cruise Control is Inoperative	
Possible Cause	**Remedy**
Function switches	If the ohmmeter does show continuity, check Circuit 591 (BK/O) for continuity. Disconnect the ECM connector. Measure the resistance between connector C250, pin 5, Circuit 591 (BK/O) and one of the following connectors: • Cummins electronic engine—ECM connector C170, pin 2 • Caterpillar electronic engine—ECM connector C110, pin 20 • Caterpillar 3126 engine—ECM connector C118, pin 59 • DDC engine—ECM connector C136, pin F2 • Cummins Encore engine—ECM connector C118, pin 14 If the resistance is more than 5 ohms repair the open in Circuit 591 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check sensor common at clockspring connector—Circuit 937 (BK). Measure the resistance between connector C250, pin 9, Circuit 937 (BK) and ground. If the resistance is more than 5 ohms, repair the open in Circuit 937 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check continuity of Circuit 937 (BK). Measure the resistance between connector C250, terminal 9, Circuit 937 (BK) and one of the following connectors: • Cummins electronic engine—ECM connector C170, pin 10 • Caterpillar electronic engine—ECM connector C110, pin 27 • Caterpillar 3126 engine—ECM connector C118, pin 10 • DDC engine—Ground • Cummins Encore engine—Ground If the resistance is more than 5 ohms, repair the open in Circuit 937 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check continuity at the brake cutoff switch. Disconnect the brake cutoff switch. Measure the resistance across the brake cutoff switch terminals. If the resistance is less than 5 ohms replace the switch. Test the system for normal operation.
Clutch switch	
Brake cutoff switch wiring	
Clockspring	

Troubleshooting

Problem—Cruise Control is Inoperative	
Possible Cause	**Remedy**
Function switches Clutch switch Brake cutoff switch wiring Clockspring	If the resistance is more than 5 ohms, check continuity at the clutch switch. Connect the brake cutoff switch connector. Disconnect the clutch switch connector. Measure the resistance across the clutch switch terminals. If the resistance is less than 5 ohms, replace the switch. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of clockspring Circuit 591 (BK/O). Measure the resistance between connector C250, terminal 5, Circuit 591 (BK/O) and the seventh terminal in the clockspring connector. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of clockspring Circuit 937 (BK). Measure the resistance between connector C250, terminal 1, Circuit 937 (BK) and the seventh terminal in the clockspring connector. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms check the continuity of clockspring Circuit 57 (BK). Measure the resistance between connector C250, terminal 8, Circuit 860 (P/W) and the fifth terminal in the clockspring connector. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of clockspring Circuit 976 (Y). Disconnect the clockspring-to-horn pad. Turn the steering wheel as necessary to position the wheels in the straight-ahead position. Remove the steering wheel. Measure the resistance between connector C250, terminal 1, Circuit 976 (BK/GN) and the sixth terminal in the clockspring connector. If the resistance is less than 5 ohms, replace the on/off switch. Test the system for normal operation. If the resistance is more than 5 ohms, replace the clockspring. Test the system for normal operation.

Problem—Resume/Accel is Inoperative

Problem—Resume/Accel is Inoperative	
Possible Cause	**Remedy**
Function switches	Check sensor common at clockspring connector—Circuit 937 (BK). Measure the resistance between connector C250, Pin 9, Circuit 937 (BK) and ground. If the resistance is more than 5 ohms, repair the open in Circuit 937 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check continuity of Circuit 937 (BK). Disconnect the ECM connector. Measure the resistance between connector C250, terminal 9, Circuit 937 (BK) and one of the following connectors: • Cummins electronic engine—ECM connector C170, pin 10 • Caterpillar electronic engine—ECM connector C110, pin 27 • Caterpillar 3126 engine—ECM connector C118, pin 10 • DDC engine—Ground • Cummins Encore engine—Ground If the resistance is more than 5 ohms, repair the open in Circuit 937 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of clockspring Circuit 862 (W/BL). Turn the steering wheel as necessary to position the wheels in the straight-ahead position. Remove the steering wheel. Measure the resistance between connector C250, terminal 7, Circuit 862 (W/BL) and the first terminal in the clockspring connector. If the resistance is more than 5 ohms, repair the clockspring. Test the system for normal operation. If the resistance is less than 5 ohms, check continuity of Circuit 862 (W/BL). Disconnect the ECM harness connector. Measure the resistance between connector C250, terminal 7, Circuit 862 (W/BL) and one of the following connectors: • Cummins electronic engine—ECM connector C170, pin 22 • Caterpillar electronic engine—ECM connector C110, pin 15 • Caterpillar 3126 engine—ECM connector C118, pin 44 • DDC engine—ECM connector C136, pin 63 • Cummins Encore engine—ECM connector C118, pin 17 If the resistance is less than 5 ohms, see the engine manufacturer's service literature for test procedures related to the ECM. If the resistance is more than 5 ohms, repair the open in Circuit 862 (W/BL). Test the system for normal operation.

General Information (See Fig. 1)

DAYTIME RUNNING LIGHTS (DRL), UNITED STATES

The daytime running light (DRL) system is designed to turn on the low beam headlights with a reduced light intensity output when the following conditions are met:

- the vehicle is running
- the parking brake is fully released
- the headlight switch is in the "Off" or "Park" position

When the necessary conditions are present, the daytime running light (DRL) system is engaged and the DAY LAMPS indicator in the instrument cluster will be illuminated.

NOTE: The low beam headlights and high beam headlights should be working properly.

NOTE: The daytime running lights control module is grounded through the high beam headlights. The pulsed voltage to the low beam headlights cannot be accurately measured.

If the headlight switch is turned to the "Head" position (DRL disabled) with the low beam filaments illuminated, there will be voltage present at Pin 1, Circuit 41 (BK/Y) allowing the illumination of the fog or road lights.

The system senses the manual actuation of the headlight high beams at Pin 6 of the DRL module, through Circuit 12 (GN/BK). Under this condition, the DRL module will be disabled and a pulsed voltage output on Pin 8, Circuit 13 (R/BK) will not be present. The high beam indicator will be illuminated by the high beam Circuit 12 (GN/BK).

Pin 8, Circuit 13 (R/BK) is used as an input to sense the manual actuation of the low beams and as an output to drive the low beams with a pulsed voltage.

The parking brake switch is a closed circuit when the parking brake is engaged. The system senses the parking brake release when the ground is no longer present at Pin 4, Circuit 162 (GN/R).

DAYTIME RUNNING LIGHTS (DRL), CANADA

The daytime running light (DRL) system is designed to turn on the high beam headlights with a reduced light intensity output without illuminating the high beam indicator light in the instrument cluster when the following conditions are met:

- the vehicle is running
- the parking brake is fully released
- the headlight switch is in the "Off" or "Park" position

When the necessary conditions are present, the daytime running lights (DRL) system is engaged and the DAY LAMPS indicator in the instrument cluster will be illuminated.

NOTE: The low beam headlights and high beam headlights should be working properly.

NOTE: The daytime running lights control module is grounded through the low beam headlights. The pulsed voltage to the high beam headlights cannot be accurately measured.

If the headlight switch is turned to the "Head" position (DRL disabled) with the high beam filaments illuminated, voltage will be present at Pin 1, Circuit 41 (BK/Y), illuminating the high beam indicator. The voltage at Pin 1, Circuit 41 (BK/Y) under any other condition will equal zero, disabling the high beam indicator.

The system senses the manual actuation of the headlight low beams at Pin 6 of the DRL module, through Circuit 13 (R/BK). Under this condition, the DRL module will be disabled and a pulsed voltage output on Pin 8, Circuit 12 (GN/BK) will not be present.

Pin 8, Circuit 12 (GN/BK) is used as an input to sense the manual actuation of the high beams and as an output to drive the high beams with a pulsed voltage.

The parking brake switch is a closed circuit when the parking brake is engaged. The system senses the parking brake release when the ground is no longer present at Pin 4, Circuit 162 (GN/R).

Troubleshooting

1. Before performing any lighting systems test, check that the battery is fully charged, battery connections are clean and tight, and burned-out fuses and bulbs have been replaced. See **Table 1** and **Table 2** for normal operating conditions.
2. See **Table 3** to inspect and determine if one of the electrical concerns applies.
3. If the concern(s) remains after the inspection, determine the symptoms and proceed to the problem charts. See **Table 4** and **Table 5**.

Normal Operating Conditions, DRL System, USA	
Condition	**Results In**
Headlight switch off. DRL operating.	Voltage at Pins 3 and 7 (DRL module power). Zero voltage at Pin 6 (high beams not turned on) (DRL ground). Pulsed voltage output at Pin 8 (cannot be accurately measured). No ground at Pin 4 (parking brake released). Voltage at Pin 2 (DRL indicator illuminated).
Headlight switch manually turned to the "Head" position and headlights in low beam.	Voltage at Pins 3 and 7 (DRL module power). No voltage at Pin 6 (high beams not turned on). Steady voltage input at Pin 8. Parking brake actuated. No voltage at Pin 2 (DRL indicator not illuminated). Voltage at Pin 1 (fog or road lights can be turned on).
Headlight switch manually turned to the "Head" position and headlights in high beam.	Voltage at Pins 3 and 7 (DRL module power). Voltage at Pin 6 (high beams turned on). No voltage at Pin 8. Parking brake actuated. No voltage at Pin 2 (DRL indicator not illuminated). No voltage at Pin 1 (fog or road lights cannot be turned on).

Run power relay No. 1
Instrument panel fuse junction panel Fuse 5 (15 A)
Instrument panel fuse junction panel Fuse 38 (5 A)

Table 3, Visual Inspection Chart

Troubleshooting

Problem—The Daytime Running Lights are Inoperative (See Fig. 1)	
Possible Cause	**Remedy**
Daytime running light control module	Check the high (low USA) beam operation. Turn the ignition switch to the "On" position, fully release the parking brake and position the headlight switch in the "Off" or "Park" position. If the high beams (low beams USA) are on, check the high (low USA) beam intensity. If not, check the daytime running lights control module installation. Check the high (low USA) beam intensity. If the high (low USA) beams are on at reduced intensity, the system is functioning properly. No repair required. If not, replace the daytime running lights control module. Test the system for normal operation. Check the daytime running lights control module installation. Turn the ignition switch and headlight switch to the "Off" position. Check the installation of the daytime running lights control module connector C145. If the daytime running lights control module installed and the connector fully seated, check the daytime running lamps control module power. If not, reinstall the daytime running lights control module. Test the system for normal operation. Check the daytime running lights control module power. Disconnect the daytime running lights control module connector C145 harness connector. Turn the ignition switch to the "On" position. Fully release the parking brake. The headlight switch should be in the "Off" or in the "Park" position. The multi-function switch should be in the LO beam (HI beam USA) position. Measure the voltage between the daytime running lights control module connector C145 Pins 2 and 4, Circuit 34 (GN/BK) and ground. If the voltage is less than 10 volts, repair Circuit 34 (GN/BK) for an open circuit. Test the system for normal operation. If the voltage is more than 10 volts, check the daytime running lights control module Pin 8. Place the headlight switch in the "Head" position, and the multi-function switch in the HI beam (LO beam USA) position. Measure the voltage between the daytime running lights control module connector C145 Pin 8, Circuit 13 (R/BK) (USA) or Circuit 12 (GN/BK) (Canadian) and ground. If the voltage is less than 6 volts, repair the open on Circuit 13 (R/BK) (USA) or Circuit 12 (GN/BK) (Canadian) between the headlights and the daytime running lights control module connector C145. Test the system for normal operation. If the voltage is more than 6 volts, check the module ground. Measure the resistance between the daytime running lights control module connector C145 Pin 7, Circuit 12 (GN/BK) (USA) or Circuit 13 (R/BK) (Canadian) and ground. If the resistance is more than 5 ohms, repair the open on Circuit 12 (GN/BK) (USA) or Circuit 13 (R/BK) (Canadian) between the headlights and daytime running lights control module connector C145. Test the system for normal operation. If the resistance is less than 5 ohms, check the high beam indicator (Canadian). Place the multi-function switch in the HI beam position. Measure the voltage between the control module connector C145 Pin 1 and ground. If the voltage is less than 10 volts, replace the illumination bulb or repair Circuit 41 (BK/Y) feeding the bulb or Circuit 57 (BK) for an open. Test the system for normal operation. If the voltage is more than 10 volts, check the parking brake switch.

Troubleshooting

Problem—The Daytime Running Lights are Inoperative (See Fig. 1)	
Possible Cause	**Remedy**
Daytime running light control module	Turn the ignition switch to the "Off" position. Measure the resistance between the daytime running lights control module connector C145 Pin 6, Circuit 162 (GN/R) and ground. Apply and release the parking brake switch. If the resistance is less than 5 ohms with the parking brake applied and greater than 10,000 ohms with the parking brake released, replace the daytime running lights control module. Test the system for normal operation. If not, repair Circuit 57 (BK) between the parking brake switch and ground, or repair Circuit 162 (GN/R) for an open or a short, or replace the parking brake switch. Test the system for normal operation.

Table 4, Problem: The Daytime Running Lights are Inoperative

Problem—The Daytime Running Lights are On With Parking Brake Set (See Fig. 1)	
Possible Cause	**Remedy**
Parking brake switch	Measure the resistance between the daytime running lights control module connector C145 Pin 6, Circuit 162 (GN/R) and ground. If the resistance is less than 5 ohms with the parking brake applied and greater than 10,000 ohms with the parking brake released, replace the daytime running lights control module. Test the system for normal operation. If not, repair Circuit 57 (BK) between the parking brake switch and ground, or repair Circuit 162 (GN/R) for an open or a short, or replace the parking brake switch. Test the system for normal operation.

Table 5, Problem: The Daytime Running Lights are On With Parking Brake Set

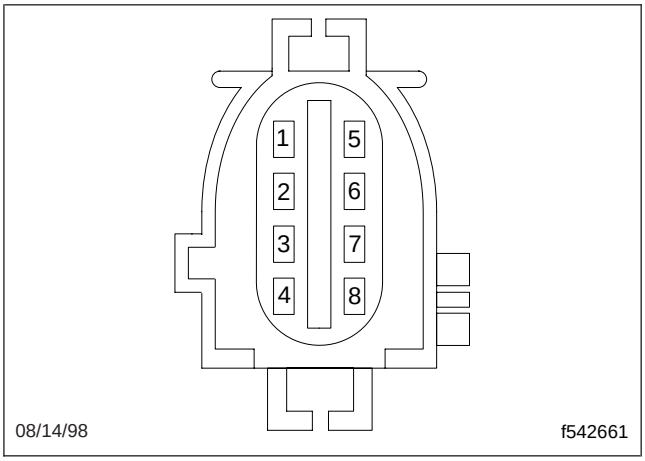

Fig. 1, Connector C145 Pin Identification

See **Fig. 1** for a full view of the daytime running lights wiring.

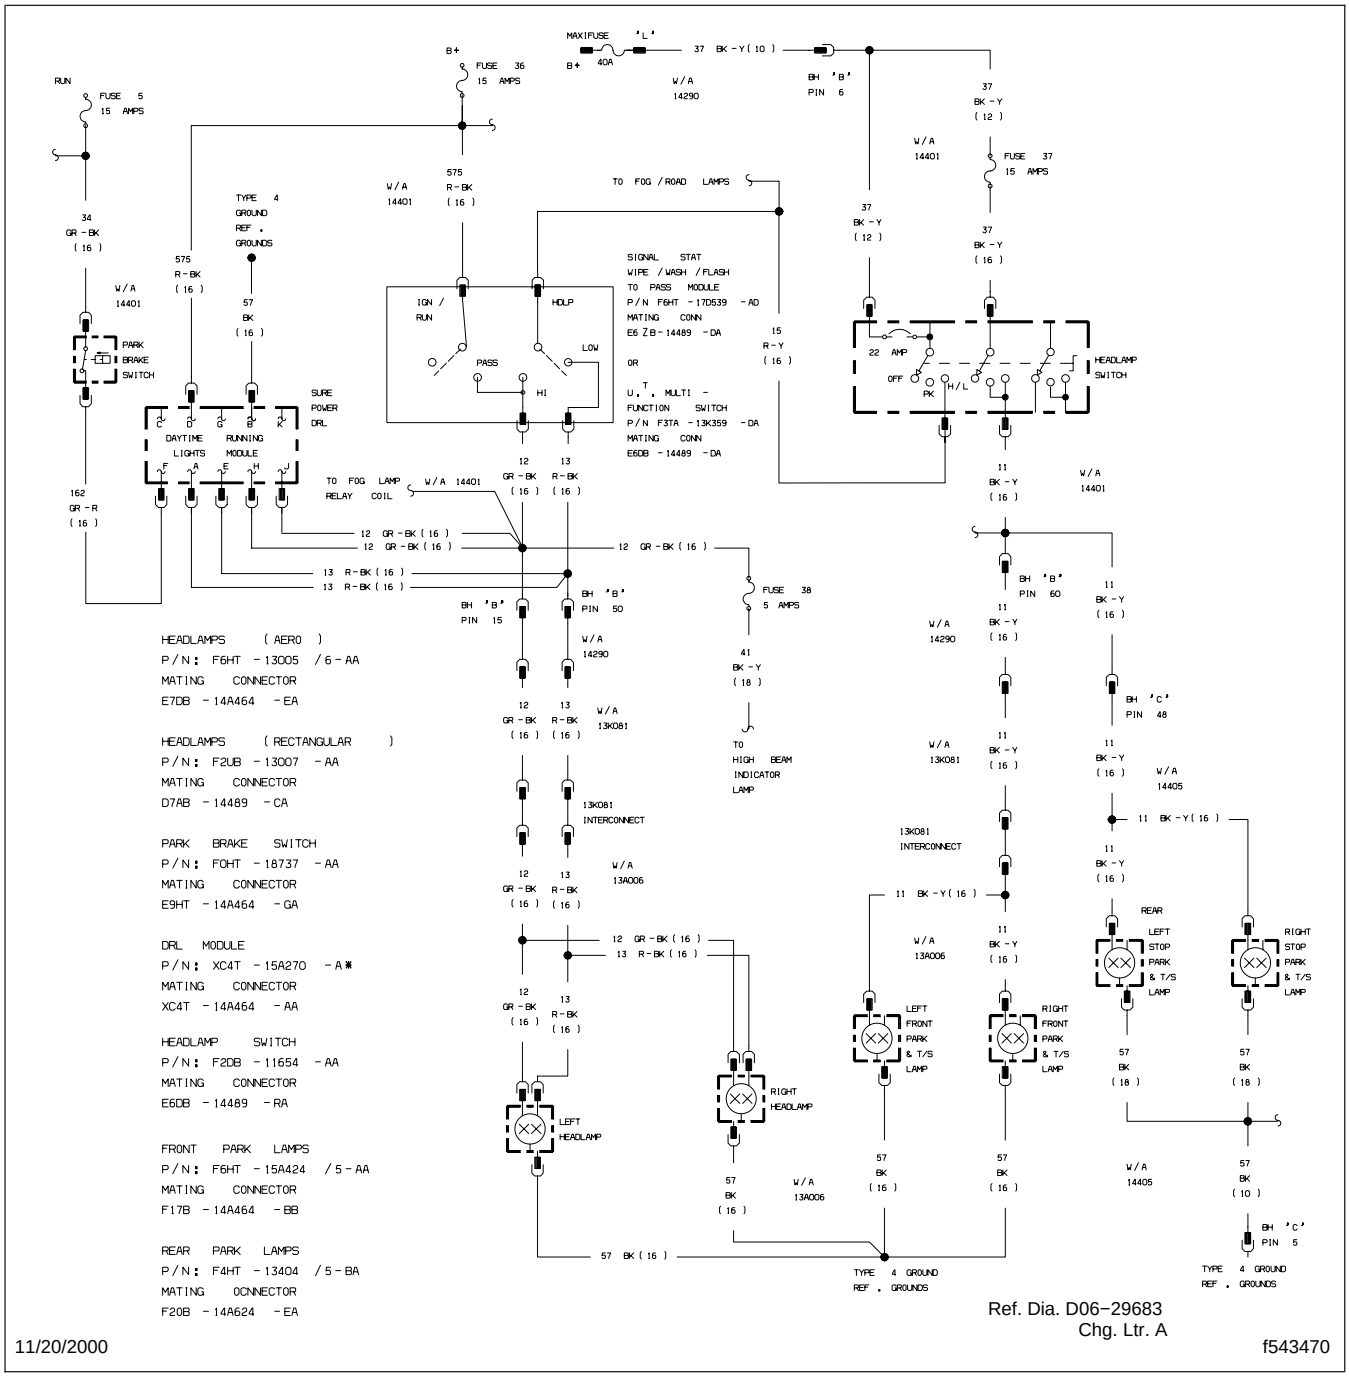

Fig. 1, Daytime Running Lights Wiring

Troubleshooting

Audio System

1. Verify the concern by operating the vehicle. Inspect to determine if one of the following electrical concerns applies:
   - instrument panel fuse junction panel fuses 15 and 16
   - SilverStar sleeper fuse panel fuse 3
   - damaged audio shields
2. Check for damaged components, open fuses, and loose or corroded connections. Check the wiring harness for obvious signs of shorts, opens, bad connections or damage. Verify the circuit operation. See **Table 1**, **Table 2** and **Table 3** for the SilverStar sleeper premium sound circuit types and functions.

Wiring Shields		
Name	**Shielded Circuits**	**Termination Points**
Radio Line Level Audio Output (to the amplifier and the rear radio control)	857 (W), 853 (R/GN), 855 (P), 854 (BR), 851 (GN), 850 (BL/W), 856 (O) and 857 (W)	Radio connector C216 and junction above and right of the dash air manifold
Line Level Audio to the Amplifier	857 (W), 853 (R/GN), 855 (P), 854 (BR), 851 (GN), 850 (BL/W), 856 (O) and 857 (W)	Junction above and right of the dash air manifold and the amplifier connector C208
Line Level Audio (to the rear radio control) and the Audio Control Protocol Lines (to the rear radio control and CD changer) to the Sleeper Accessory Harness	851 (GN), 850 (BL/W), 856 (O), 857 (W), 832 (Y/BK) and 833 (GN)	Junction above and right of the dash air manifold and the sleeper accessory harness connector C309
Line Level Audio to the Rear Radio Control	851 (GN), 850 (BL/W), 856 (O) and 857 (W)	Sleeper accessory harness connector C309 and the rear radio control connector C762
Radio Line Level Audio Input (from the CD changer) and the ACC-ON Conditioned Ignition Power Output (to the CD changer and the rear radio control)	876 (Y), 868 (R/BR), 865 (BK), 866 (BK) and 867 (R)	Radio connector C216 and the sleeper accessory harness connector C311
CD Changer Line Level Audio Output (to radio) and the ACC-ON Conditioned Ignition Power (to the CD changer and the rear radio control)	876 (Y), 868 (R/BR), 865 (BK), 866 (BK) and 867 (R)	Sleeper accessory harness connector C311 and the CD changer connector C764
Amplifier Line Level Audio Output and the Subwoofer Enable to the Sleeper Accessory Harness (to the subwoofer)	915 (BK/O), 916 (R) and 830 (GN/W)	Amplifier connector C207 and sleeper accessory harness connector C311
Amplifier Line Level Audio and the Subwoofer Enable to the Subwoofer	915 (BK/O), 916 (R) and 830 (GN/W)	Sleeper accessory harness connector C311 and the subwoofer connector C751

Table 1, Wiring Shields

Troubleshooting

Twisted Wires	
Name	**Twisted Circuits**
Radio Connector C216 to the Amplifier Connector C208, Twisted Pairs	857 (W) and 853 (R/GN) 855 (P) and 854 (BR) 851 (GN) and 850 (BL/W) 856 (O) and 857 (W)
Radio Connector C216 to the Rear Radio Control Connector C762, Twisted Pairs	832 (Y/BK) and 833 (GN) 851 (GN) and 850 (BL/W) 856 (O) and 857 (W)
Radio Connector C216 to the CD Changer Connector C764, Twisted Quad	876 (Y), 868 (R/BR), 865 (BK) and 866 (BK)
Amplifier Connector C207 to the Subwoofer Connector C751, Twisted Triplet	830 (GN/W), 915 (BK/O) and 916 (R)

Table 2, Twisted Wires

Logic Circuits			
Circuit	**State**	**Source**	**Function**
Circuit 689 (P) is triggered by the power button on the radio and by Circuit 690 (GN/W).	Ground	Radio	System "On" (amplifier and rear radio control "On").
	5 Volts		System "Off" (amplifier and rear radio control "Off").
Circuit 690 (GN/W) is used to trigger a mute on the audio system.	Open Circuit	Speaker Interrupt Module	No call is being received.
	Ground		A call is being received or is in progress.
Circuit 830 (GN/W) is triggered by Circuit 689 (P).	5 Volts	Amplifier	System "On" (rear radio control "On").
	Ground		System "Off" (rear radio control "Off").
Circuit 867 (R) is regulated ignition power through the radio.	2 Volts	Radio	Key in "Run" (ignition power present at CD changer and rear radio control).
	0 Volts		Key not in "Run" (ignition power not present at CD changer and rear radio control).

Table 3, Logic Circuits

3. If the fault is not visually evident, determine the symptom and proceed to the appropriate trouble-shooting table.

Problem—Radio Chassis Is Inoperative, Weatherband Radio

Problem—Radio Chassis is Inoperative, Weatherband Radio (See Fig. 1 and Fig. 2)	
Possible Cause	**Remedy**
Radio	Substitute a known good radio. If the symptom is not present have the radio serviced by an authorized service center. Test the system for normal operation.

Problem—Radio Chassis is Inoperative, Weatherband Radio (See Fig. 1 and Fig. 2)	
Possible Cause	**Remedy**
Missing power or ground	Turn the ignition switch to the "Off" position. Disconnect the radio harness connector C217. Measure the voltage between the radio connector C217 Pin 7, Circuit 54 (GN/Y) and ground. Turn the ignition switch to the ACC position. Measure the voltage between the radio connector C217 Pin 1, Circuit 137 (Y/BK) and ground. If the voltage is less than 10 volts, check for opens on the power feeds to the radio. Turn the ignition switch to the "Off" position. Disconnect the battery ground cable. Disconnect the instrument panel fuse junction panel Fuses 15 and 16. Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 15, Circuit 54 (GN/Y) and the radio connector C217 Pin 7, Circuit 54 (GN/Y). Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 16, Circuit 137 (Y/BK) and the radio connector C217 Pin 1, Circuit 137 (Y/BK). If the resistance is less than 5 ohms, repair Circuit 37 (BK/Y) feeding Fuse 15 or repair Circuit 297 (BK/R) feeding Fuse 16. Test the system for normal operation. If the resistance is greater than 5 ohms, repair the open in the affected circuit(s) between the instrument panel fuse junction panel and the radio. Test the system for normal operation. If the voltage is greater than 10 volts, check for opens on the ground to the radio. Turn the ignition switch to the "Off" position. Disconnect the battery ground cable. Measure the resistance between the radio connector C217 Pin 2, Circuit 18 (BK/BL) and ground. If the resistance is less than 5 ohms, have the radio serviced by an authorized service center. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 18 (BK/BL) for an open. Make sure that all ground connections are clean and tight. Test the system for normal operation.

Troubleshooting

Problem—Radio Chassis is Inoperative, Standard Radio

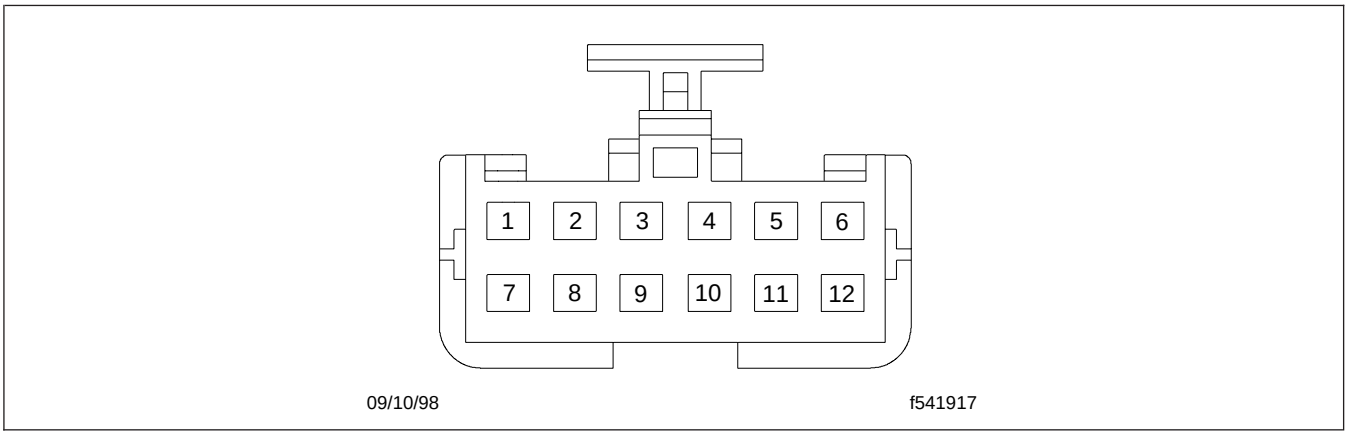

Fig. 1, C217 Radio Connector

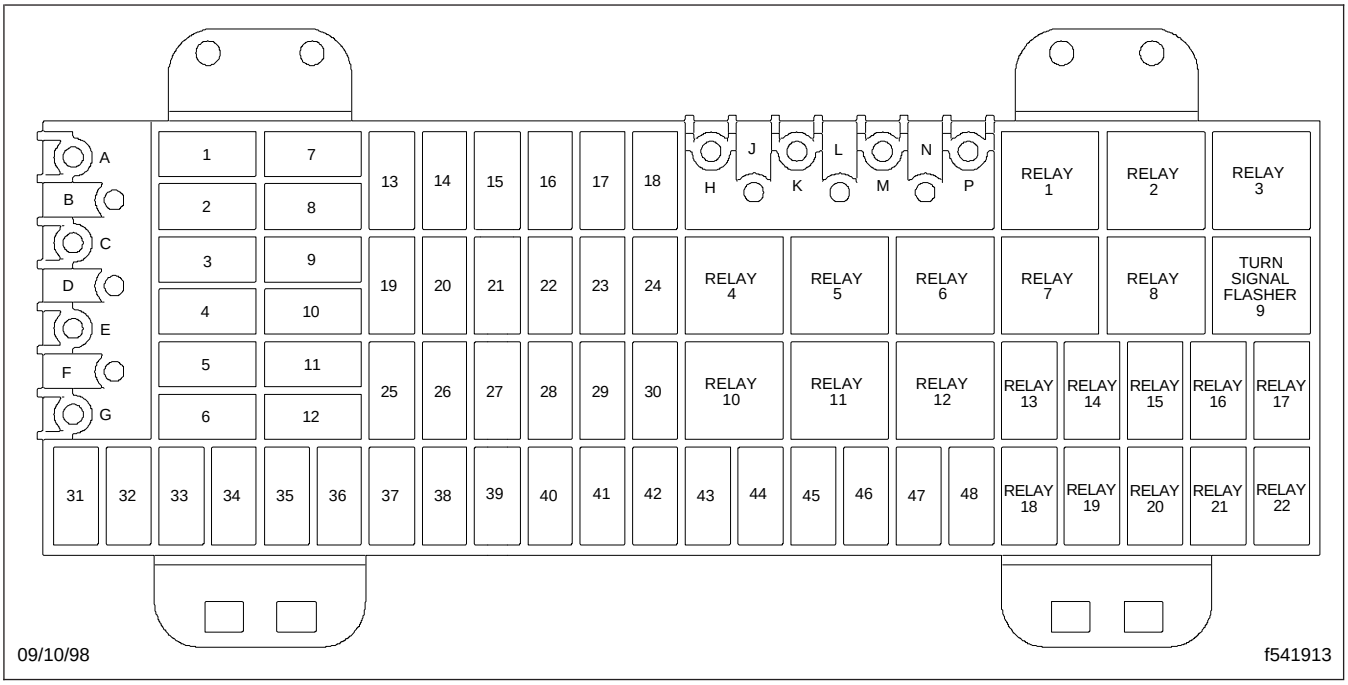

Fig. 2, Instrument Panel Fuse Junction Panel

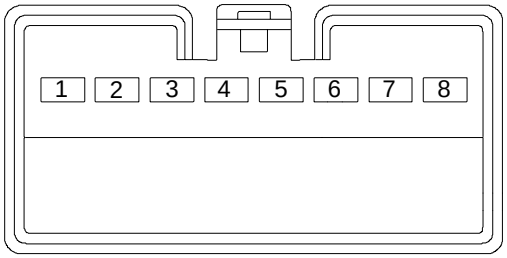
Problem—Radio Chassis is Inoperative, Standard Radio (See Fig. 2 and Fig. 3)	
Possible Cause	**Remedy**
Radio	Substitute a known good radio. If the symptom is not present have the radio serviced by an authorized service center. Test the system for normal operation.

Problem—Radio Chassis is Inoperative, Standard Radio (See Fig. 2 and Fig. 3)	
Possible Cause	**Remedy**
Missing power or ground	Check the power feeds to the radio. Turn the ignition switch to the "Off" position. Disconnect the radio connector C219. Measure the voltage between the radio connector C219 Pin 8, Circuit 54 (GN/Y) and ground. Turn the ignition to the ACC position. Measure the voltage between the radio connector C219 Pin 6, Circuit 137 (Y/BK) and ground. If the voltage is less than 10 volts, check opens on the power feeds to the radio. Disconnect the battery ground. Turn the ignition switch to the "Off" position. Disconnect the instrument panel fuse junction panel Fuses 15 and 16. Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 15, Circuit 54 (GN/Y) and the radio connector C219 Pin 8, Circuit 54 (GN/Y). Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 16, Circuit 137 (Y/BK) and the radio connector C219 Pin 6, Circuit 137 (Y/BK). If the resistance is less than 5 ohms, repair Circuit 37 (BK/Y) feeding Fuse 15 or repair Circuit 297 (BK/R) feeding Fuse 16. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s) between the instrument panel fuse junction panel and the radio. Test the system for normal operation. If the voltage is greater than 10 volts, check the grounds to the radio for opens. Turn the ignition switch to the "Off" position. Disconnect the battery ground cable(s). Measure the resistance between the radio connector C219 Pin 3, Circuit 18 (BK/BL) and ground. Measure the resistance between the radio connector C219 Pin 7, Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, have the radio serviced by an authorized service center. Test the system for normal operation. If the resistance is more than 5 ohms, repair the affected circuit(s). Make sure that all ground connections are clean and tight. Test the system for normal operation.

Troubleshooting

Problem—Radio Chassis is Inoperative, Premium Radio



09/10/98 f541911

Fig. 3, C219 Radio Connector

Problem—Radio Chassis is Inoperative, Premium Radio (See Fig. 2, Fig. 3 and Fig. 4)	
Possible Cause	**Remedy**
Radio	Substitute a known good radio. If the symptom is not present have the radio serviced by an authorized service center. Test the system for normal operation.

Problem—Radio Chassis is Inoperative, Premium Radio (See Fig. 2, Fig. 3 and Fig. 4)	
Possible Cause	**Remedy**
Missing power or ground	Check the power feeds to the radio. Turn the ignition switch to the "Off" position. Disconnect the radio connector C219. Measure the voltage between the radio connector C219 Pin 8, Circuit 54 (GN/Y) and ground. Measure the voltage between the amplifier connector C209 Pin 14, Circuit 54 (GN/Y) and ground. Turn the ignition to the ACC position. Measure the voltage between the radio connector C219 Pin 6, Circuit 137 (Y/BK) and ground. If the voltage in the circuits is less than 10 volts, check opens on the power feeds to the radio. Disconnect the battery ground. Turn the ignition switch to the "Off" position. Disconnect the instrument panel fuse junction panel Fuse 15. Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 15, Circuit 54 (GN/Y) and the radio connector C219 Pin 8, Circuit 54 (GN/Y). Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 15, Circuit 54 (GN/Y) and the amplifier connector C209 Pin 14, Circuit 54 (GN/Y). Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 16, Circuit 137 (Y/BK) and the radio connector C219 Pin 6, Circuit 137 (Y/BK). If the resistance is less than 5 ohms, repair Circuit 37 (BK/Y) feeding Fuse 15 or repair Circuit 297 (BK/R) feeding Fuse 16. Test the system for normal operation. If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Make sure all ground connections are clean and tight. Test the system for normal operation. If the voltage in the circuits is less than 10 volts, check for opens between the grounds to the radio and the amplifier. Turn the ignition switch to the "Off" position. Disconnect the battery ground cable(s). Measure the resistance between the radio connector C219 Pin 3, Circuit 18 (BK/BL) and ground. Measure the resistance between the radio connector C219 Pin 7, Circuit 57 (BK) and ground. Measure the resistance between the amplifier connector C209 Pin 13, Circuit 18 (BK/BL) and ground. If the resistance is less than 5 ohms, have the radio serviced by an authorized service center. Test the system for normal operation. If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Make sure all ground connections are clean and tight. Test the system for normal operation.

Troubleshooting

Problem—CD Changer is Inoperative

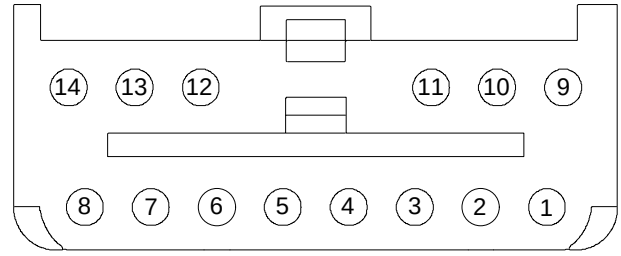


Fig. 4, C209 Radio Connector

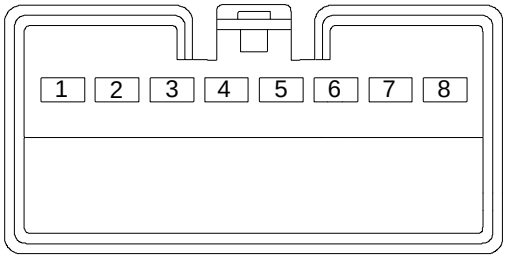
Problem—CD Changer is Inoperative (See Fig. 4, Fig. 5, Fig. 6, Fig. 7 and Fig. 8)	
Possible Cause	**Remedy**
CD changer	Substitute a known good radio. If the symptom is not present replace the CD changer. Test the system for normal operation

Problem—CD Changer is Inoperative (See Fig. 4, Fig. 5, Fig. 6, Fig. 7 and Fig. 8)	
Possible Cause	**Remedy**
Missing power or ground	Check the power feeds to the CD changer. Turn the ignition switch to the "Off" position. Disconnect the CD changer connector C764. Measure the voltage between the CD changer connector C764 Pin 10, Circuit 37 (BK/Y) and ground. If the voltage is less than 10 volts, check an open on the power feed. Turn the ignition switch to the "Off" position. Disconnect the battery ground cable(s). Disconnect the sleeper fuse panel Fuse 3 connector. Measure the resistance between the bottom of the sleeper fuse panel Fuse 3, Circuit 37 (BK/Y) and the CD changer connector C764 Pin 10, Circuit 37 (BK/Y). If the resistance is less than 5 ohms, repair Circuit 150 (R) feeding Fuse 3. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in Circuit 37 (BK/Y) between the sleeper fuse panel and the CD changer. Test the system for normal operation. If the voltage is greater than 10 volts, check the ACC-ON power feed. Turn the ignition switch to the ACC position. Turn the radio on. Measure the voltage between the CD changer connector C764 Pin 11, Circuit 867 (R) and ground. If the voltage is less than 10 volts, check the ACC-ON power. Turn the ignition switch to the "Off" position. Disconnect the sleeper accessory harness connector C311. Turn the ignition switch to the ACC position. Turn the radio on. Measure the voltage between the cab side of the sleeper accessory harness connector C311 Pin 7, Circuit 867 (R) and ground. If the voltage is greater than 10 volts repair the open circuit in the sleeper accessory harness, Circuit 867 (R). Test the system for normal operation. If the voltage is less than 10 volts check the radio ACC-ON power output. Turn the ignition switch to the "Off" position. Disconnect the radio connector C216. Remove the Circuit 867 (R) wire from the radio connector C216. Reconnect the radio connector C216. Turn the ignition switch to the ACC position. Turn the radio on. Measure the voltage between the open Terminal 16 and ground. If the voltage is greater than 10 volts, repair the open circuit in the sleeper accessory harness, Circuit 867 (R). Test the system for normal operation. If the voltage is less than 10 volts have the radio serviced by an authorized service center. Test the system for normal operation.
No audio system "On" power	If the voltage is greater than 10 volts, check the CD changer ground. Turn the ignition switch to the "Off" position. Disconnect the battery ground cable(s). Measure the resistance between the CD changer connector C764 Pin 4, Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, repair Circuit 57 (BK) open circuit between the CD changer and ground. Test the system for normal operation. If the resistance is greater than 5 ohms, check the power output to the radio. Turn the ignition switch to the "Off" position. Disconnect the radio connector C216 and CD changer connector C764. Measure the resistance between the radio connector C216 Pins 16, 15, 8 and 7, Circuits 868 (R/BR), 865 (BK) and 866 (BK), and the CD changer connector Pins 2, 8, 1 and 7 Circuits 876 (Y), 868 (R/BR), 865 (BK) and 866 (BK). If the resistance is greater than 5 ohms, see troubleshooting table "Problem—CD Changer Display is Blank, Does Not Operate Properly." If the resistance is less than 5 ohms, repair the open in the affected circuit(s) between the radio and CD changer. Test the system for normal operation.

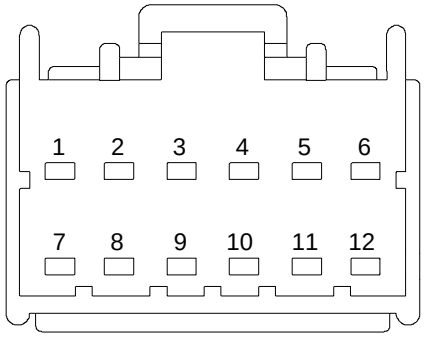
Troubleshooting

Problem—CD Changer Display is Blank, Does Not Operate Properly



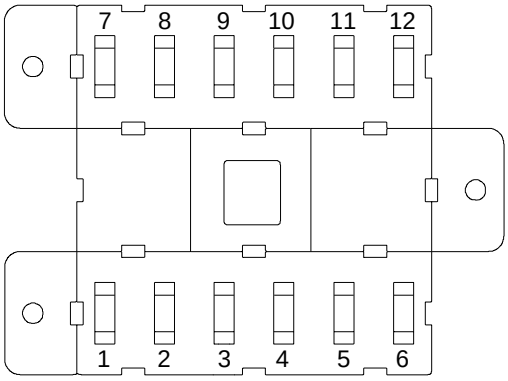
09/10/98 f541911

Fig. 5, C219 Radio Connector



09/10/98 f541931

Fig. 6, C764 CD Changer Connector



09/11/98 f541944

Fig. 7, Sleeper Fuse Panel

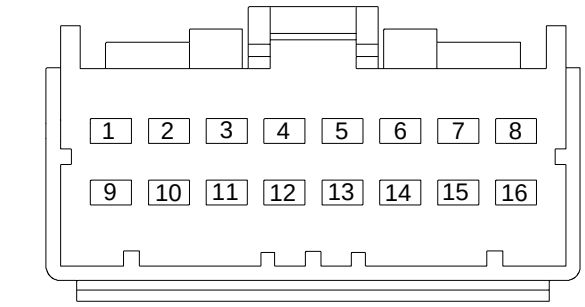


Fig. 8, C216 Radio Connector

Problem—CD Changer Display is Blank, Does Not Operate Properly (See Fig. 6, Fig. 8 and Fig. 9)	
Possible Cause	**Remedy**
NOTE: Circuits 832 (Y/BK) and 833 (GN) are the audio control protocol lines that allow the radio to control the CD changer. These circuits are a twisted pair at 7.3 turns per foot (24 turns per meter). If a repair is necessary, use 20 gauge wire and preserve the twisted pair specification.	
Audio control protocol lines	Check the audio control protocol lines. Disconnect the battery ground cable(s). Disconnect the radio connector C216 and the sleeper accessory harness connector C309. Measure the resistance between the radio connector C216 Pin 9, Circuit 832 (Y/BK) and the cab side of the sleeper accessory harness connector C309 Pin 15, Circuit 832 (Y/BK). Measure the resistance between the radio connector C216 Pin 1, Circuit 833 (GN) and the cab side of the sleeper accessory harness connector C309 Pin 14, Circuit 833 (GN). If the resistance is less than 5 ohms, substitute a known good system, one component at a time. If the known good system functions, have the radio serviced by an authorized service center and replace the CD changer if necessary. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s) in the sleeper accessory harness. Test the system for normal operation.
Audio control protocol to the CD changer	Check the audio control protocol to the CD changer. Measure the resistance between the sleeper side of the accessory harness connector C309 Pin 15, Circuit 832 (Y/BK) and the CD changer connector C764 Pin 6, Circuit 832 (Y/BK). Measure the resistance between the sleeper side of the sleeper accessory harness connector C309 Pin 14, Circuit 833 (GN) and the CD changer connector C764 Pin 12, Circuit 833 (GN). If the resistance is less than 5 ohms, substitute a known good system, one component at a time. If the known good system functions, have the radio serviced by an authorized service center and replace the CD changer if necessary. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s) in the sleeper accessory harness. Test the system for normal operation.

Troubleshooting

Problem—Noisy Reception

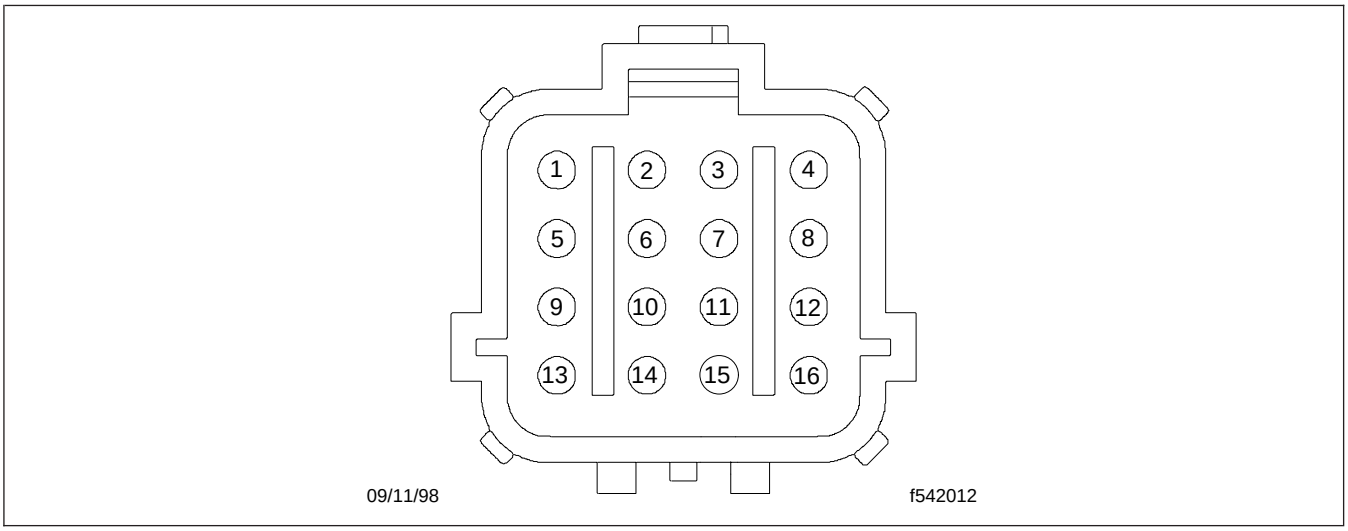

Fig. 9, C309 Sleeper Accessory Harness Connector

Problem—Noisy Reception	
Possible Cause	**Remedy**
Radio	Substitute a known good radio. If the symptom is not present have the radio serviced by an authorized service center. Test the system for normal operation.
Antenna system	If the symptom is present check the antenna. Remove the antenna mast. Check the mast connection to make sure the threads are clean. Tighten the mast. Remove the antenna base. Check the antenna lead-in-cable to make sure that the connection is tight. Then install the antenna base. Remove the radio. Check the antenna lead-in-cable connection to the radio. Reconnect the lead-in-cable. Tune the radio to the strongest signal in the region. If the noisy reception is not present, the system is repaired.
Generator	If the noisy reception is present, check for generator interference. Disconnect the battery ground cable(s). Disconnect the generator connectors. Cover any battery (hot) wires. Connect the battery ground cable(s). Turn the ignition switch to the ACC position. Tune the radio to the strongest signal in the region. If the noisy reception is not present, replace the generator voltage regulator.

Problem—Noisy Reception	
Possible Cause	**Remedy**
Antenna Connections	If the noisy reception is present, check the antenna lead-in cable at the radio. Measure the resistance between the antenna base outside the vehicle and the tip of the antenna lead-in cable at the radio. Measure the resistance between the antenna base outside the vehicle and the metal shield on the antenna lead-in cable at the radio. If the resistance is less than 5 ohms, check the antenna and the lead-in cable for a short. Disconnect the antenna base from the lead-in cable. Measure the resistance between the antenna lead-in cable shield and tip. If the resistance is greater than 10,000 ohms secure the antenna base to the vehicle. Test the system for normal operation. If the resistance is less than 10,000 ohms replace the antenna lead-in cable or the antenna base. Test the system for normal operation. If the resistance is greater than 5 ohms, check the antenna lead-in cable. Disconnect the antenna base from the lead-in cable. Measure the resistance between the antenna lead-in cable center terminals and between the antenna lead-in cable shield (outside) terminals. If the resistance is greater than 5 ohms, replace the antenna lead-in cable. Test the system for normal operation. If the resistance is less than 5 ohms, check the antenna base. Measure the resistance between the antenna mast and the antenna base center terminal. If the resistance is greater than 5 ohms, replace the antenna base. Test the system for normal operation. If the resistance is less than 5 ohms, check the antenna and the antenna lead-in cable for a short. Measure the resistance between the antenna lead-in cable shield and tip. If the resistance is greater than 10,000 ohms, secure the antenna base to the vehicle. Test the system for normal operation. If the resistance is less than 10,000 ohms replace the antenna lead-in cable or the antenna base. Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Weatherband Radio

Problem—Poor Quality/Distorted Sound from One or More Speakers, Weatherband Radio (See Fig. 1, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Speaker	Check the suspect speaker(s). Connect the suspect speaker(s) to a bench test audio amplifier. If the speaker is not functioning properly, replace the speaker(s). Test the system for normal operation.
Radio	Check the system with a known good radio. If the symptom is corrected have the radio serviced by an authorized service center. Test the system for normal operation.

Troubleshooting

Problem—Poor Quality/Distorted Sound from One or More Speakers, Weatherband Radio (See Fig. 1, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Intermittent connection	Check for a short to ground on the right front speaker feed. Turn the ignition switch to the "Off" position. Disconnect radio connector C217. Measure the resistance between the radio connector C217 Pin 12, Circuit 803 (R/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 803 (R/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the right front speaker feeds. Measure the resistance between the radio connector C217 Pins 12 and 11, Circuits 803 (R/Y) and 287 (BK) and the speaker feed connector C918, Circuits 803 (R/Y) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, the right front system is OK. If more speakers are distorted, check for a short to ground on the left front speaker feed. Measure the resistance between the radio connector C217 Pin 6, Circuits 802 (BL/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 802 (BL/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the left front speaker feeds. Disconnect the left front speaker connector C919. Measure the resistance between the radio connector C217 Pins 6 and 5, Circuits 802 (BL/Y) and 287 (BK) and the speaker feed connector C919, Circuits 802 (BL/Y) and 287 (BK). If the resistance is less than 5 ohms, the left front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Weatherband Radio (See Fig. 1, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Able Body sleeper speaker feeds (in-cab wiring)	If more speakers are distorted check for short to ground on the Able Body rear speaker feeds. Measure the resistance between the radio connector C217 Pins 4 and 10, Circuits 807 (O) and 806 (W) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the Able Body sleeper speaker feeds (in-cab wiring). Disconnect the sleeper accessory harness connector C310. Measure the resistance between the radio connector C217 Pins 4, 3, 10 and 9 Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK) and the cab side of the sleeper accessory harness connector C310 Pins 3, 4, 2 and 1 Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker ground feeds. Disconnect the left speaker connector C727 and right sleeper speaker connector C728. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 4 and 1, Circuits 410 (P) and 430 (P) and the speaker feed connectors C727 and C728, Circuits 410 (P) and 430 (P). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the rear radio control (in-sleeper wiring). Disconnect the rear radio control connector C729. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 3 and 2, Circuits 400 (O) and 420 (W) and the rear radio control connector C729, Circuits 400 (O) and 420 (W). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the speakers (in-sleeper wiring). Measure the resistance between the rear radio control connector C729, Circuits 400 (O) and 450 (W) and the speaker feed connectors C727 and C728, Circuits 400 (O) and 450 (W). If the resistance is less than 5 ohms, replace the rear radio control. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Standard Radio

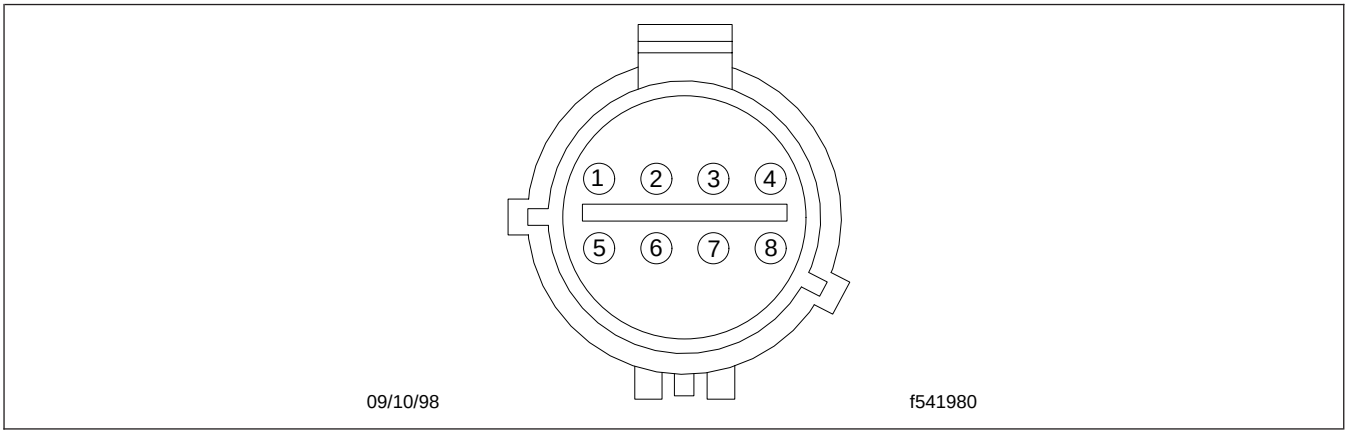

Fig. 10, C246 Interrupt Module Connector

Troubleshooting

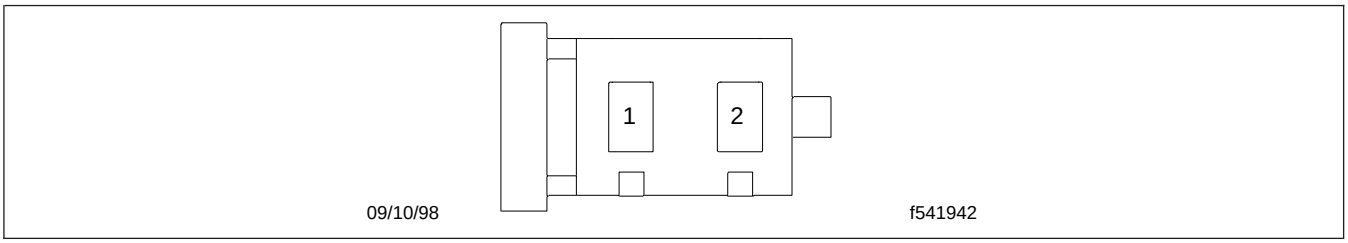

Fig. 11, C918 Speaker Feed Connector

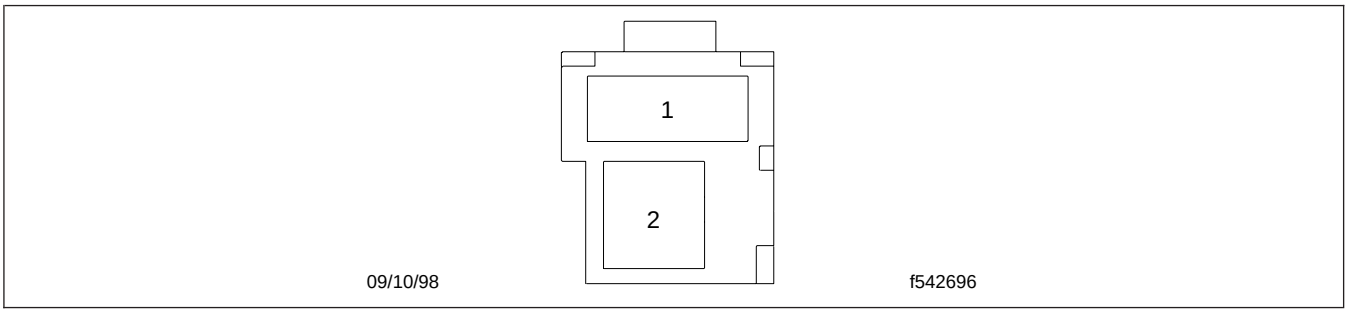

Fig. 12, C727 Speaker Feed Connector

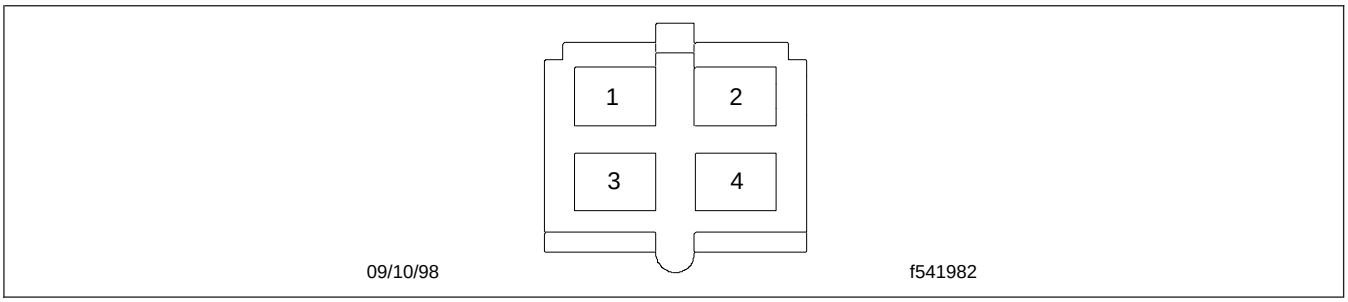

Fig. 13, C310 Sleeper Accessory Harness Connector

Problem—Poor Quality/Distorted Sound from One or More Speakers, Standard Radio (See Fig. 3, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Speaker	Check the suspect speaker(s). Connect the suspect speaker(s) to a bench test audio amplifier. If the speaker is not functioning properly replace the speaker(s). Test the system for normal operation.
Radio	Check the system with a known good radio. If the symptom is corrected have the radio serviced by an authorized service center. Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Standard Radio (See Fig. 3, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Short to Ground	Check for a short to ground on the right front speaker feed. Turn the ignition switch to the "Off" position. Disconnect radio connector C220. Measure the resistance between the radio connector C220 Pin 4, Circuit 803 (R/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 803 (R/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the right front speaker feeds. Measure the resistance between the radio connector C220 Pins 4 and 3, Circuits 803 (R/Y) and 287 (BK) and the speaker feed connector C918, Circuits 803 (R/Y) and 287 (BK). If the resistance is less than 5 ohms, the right front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are distorted, check for a short to ground on the left front speaker feed. Measure the resistance between the radio connector C220 Pin 8, Circuits 802 (BL/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 802 (BL/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the left front speaker feeds. Disconnect the left front speaker connector C919. Measure the resistance between the radio connector C220 Pins 8 and 7, Circuits 802 (BL/Y) and 287 (BK) and the speaker feed connector C919, Circuits 802 (BL/Y) and 287 (BK). If the resistance is less than 5 ohms, the left front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are distorted, check for short to ground on the Able Body rear speaker feeds. Measure the resistance between the radio connector C220 Pins 6 and 2, Circuits 807 (O) and 806 (W) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the Able Body sleeper speaker feeds (in-cab wiring). Disconnect the sleeper accessory harness connector C310. Measure the resistance between the radio connector C220 Pins 6, 5, 2 and 1 Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK) and the cab side of the sleeper accessory harness connector C310 Pins 3, 4, 2 and 1 Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker ground feeds. Disconnect the left speaker connector C727 and right sleeper speaker connector C728. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 4 and 1, Circuits 410 (P) and 430 (P) and the speaker feed connectors C727 and C728, Circuits 410 (P) and 430 (P). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Troubleshooting

Problem—Poor Quality/Distorted Sound from One or More Speakers, Standard Radio	
Possible Cause	**Remedy**
Short to Ground	If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the rear radio control (in-sleeper wiring), disconnect the rear radio control connector C729. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 3 and 2, Circuits 400 (O) and 420 (W) and the speaker feed connectors C727 and C728, Circuits 400 (O) and 420 (W). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the rear radio control (in-sleeper wiring). Measure the resistance between the rear radio control connector C729, Circuits 400 (O) and 450 (W) and the speaker feed connectors C727 and C728, Circuits 400 (O) and 450 (W). If the resistance is less than 5 ohms, replace the rear radio control. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Premium Radio

Problem—Poor Quality/Distorted Sound from One or More Speakers, Premium Radio (See Fig. 4, Fig. 8, Fig. 9, Fig. 10, Fig. 11 and Fig. 14)	
Possible Cause	**Remedy**
NOTE: Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. The shield is spirally wrapped aluminum with a 50% overlap per turn. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification. If the shield is damaged, it must be replaced and must conform to the above specification. Test only the suspect speaker circuits. Shake the wire harness while testing the circuit to expose an intermittent condition which may be causing the distorted sound.	
Speaker	Check the suspect speaker(s). Connect the suspect speaker(s) to a bench test audio amplifier.
Radio	Check the audio system with a known good radio. If the symptom is corrected have the radio serviced by an authorized service center. Test the system for normal operation. If the symptom is not corrected check the audio system with a known good amplifier. If the symptom is corrected replace the amplifier. Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Premium Radio (See Fig. 4, Fig. 8, Fig. 9, Fig. 10, Fig. 11 and Fig. 14)	
Possible Cause	**Remedy**
NOTE: Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. The shield is spirally wrapped aluminum with a 50% overlap per turn. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification. If the shield is damaged, it must be replaced and must conform to the above specification. Test only the suspect speaker circuits. Shake the wire harness while testing the circuit to expose an intermittent condition which may be causing the distorted sound.	
Intermittent connection	Check the shield wire ground feed from the radio. Turn the ignition to the "Off" position. Disconnect the radio connector C216. Remove the Circuit 57 (BK) wire from the radio connector C216. Re-connect the radio connector C216. Measure the resistance between the open terminal 14 and ground. If the resistance is more than 5 ohms, verify a good ground at the radio connector C219 Pin 7. Have the radio serviced by an authorized service center. Test the system for normal operation. If the resistance is less than 5 ohms, check the shields for a good ground. Install the Circuit 57 (BK) wire to the radio connector C216. Disconnect the radio connector C216. Measure the resistance between the shield terminating near the amplifier connector C208 and ground. Measure the resistance between the shield terminating near the radio connector C216 and ground. Measure the resistance between the shields terminating in the harness takeout/splice region above and to the right of the dash air manifold and ground. If the resistance is more than 5 ohms, replace the entire affected shield wire. Test the system for normal operation. If the resistance is less than 5 ohms, check for a short to ground on the amplifier input feeds. Disconnect the radio connector C216. Measure the resistance between the radio connector C216 Pins 13, 5, 11 and 3, Circuits 857 (W), 855 (P), 851 (GN) and 856 (O) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity between the radio and the amplifier. Disconnect the amplifier connector C208. Measure the resistance between the radio connector C216 Pins 13, 12, 5, 4, 11, 10, 3 and 2, Circuits 857 (W), 853 (R/GN), 855 (P), 854 (BR), 851 (GN), 850 (BL/W), 856 (O) and 857 (W) and the amplifier connector C208 Pins 8, 4, 6, 2, 7, 3, 5 and 1, Circuits 857 (W), 853 (R/GN), 855 (P), 854 (BR), 851 (GN), 850 (BL/W), 856 (O) and 857 (W). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check for a short to ground on the right front speaker feed. Disconnect the right speaker front speaker connector C918. Measure the resistance between the amplifier connector C209 Pin 4 Circuit 803 (R/Y) and ground.

Troubleshooting

Problem—Poor Quality/Distorted Sound from One or More Speakers, Premium Radio	
Possible Cause	**Remedy**
NOTE: Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. The shield is spirally wrapped aluminum with a 50% overlap per turn. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification. If the shield is damaged, it must be replaced and must conform to the above specification. Test only the suspect speaker circuits. Shake the wire harness while testing the circuit to expose an intermittent condition which may be causing the distorted sound.	
Intermittent connection	If the resistance is less than 5 ohms, repair Circuit 803 (R/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the right front speaker feeds. Disconnect the right front speaker connector C918. Measure the resistance between the amplifier connector C209 Pin 4 and 3, Circuits 803 (R/Y) and 287 (BK) and the speaker feed connector C918, Circuits 803 (R/Y) and 287 (BK). If the resistance is less than 5 ohms, the right front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are distorted, check for a short to ground on the left front speaker feed. Measure the resistance between the amplifier connector C209 Pin 8 Circuit 802 (BL/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 802 (BL/Y) for a short to ground. Test the system for normal operation.

Problem—Poor Quality/Distorted Sound from One or More Speakers, Premium Radio

Problem—Poor Quality/Distorted Sound from One or More Speakers, Premium Radio	
Possible Cause	**Remedy**
NOTE: Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. The shield is spirally wrapped aluminum with a 50% overlap per turn. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification. If the shield is damaged, it must be replaced and must conform to the above specification. Test only the suspect speaker circuits. Shake the wire harness while testing the circuit to expose an intermittent condition which may be causing the distorted sound.	
Intermittent connection	If the resistance is more than 5 ohms check the continuity of the left front speaker feeds Disconnect the left front speaker connector C919. Measure the resistance between the amplifier connector C209 Pins 8 and 7, Circuits 802 (BL/Y) and 287 (BK) and the speaker feed connector C919, Circuits 802 (BL/Y) and 287 (BK). If the resistance is less than 5 ohms, the right front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are distorted, check for a short to ground on the rear speaker feeds (in-cab wiring). NOTE: The short to ground may be present in the SilverStar sleeper wiring. Measure the resistance between the amplifier connector C209 Pins 6 and 2, Circuits 807 (O) and 806 (W) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the rear speaker feeds (in-cab wiring). Disconnect the left rear speaker connector C302 and the right rear speaker connector C306. Measure the resistance between the amplifier connector C209 Pins 6, 5, 2 and 1, Circuits 807 (O), 806 (W) and 287 (BK) and the speaker feed connectors C302, C306, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is less than 5 ohms, the rear system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are distorted, check the continuity of the SilverStar sleeper speaker feeds (in-cab wiring). Disconnect the sleeper accessory harness connector C309. Measure the resistance between the amplifier connector C209 Pins 6, 5, 2 and 1, Circuits 807 (O), 287 (BK), 806 (W), and 287 (BK) and cab side of the sleeper accessory harness connector C309 Pins 12, 4, 5, and 3, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are distorted, check the continuity of the SilverStar sleeper rear speaker feeds (in-cab Wiring). Disconnect the left and right rear speaker connectors C735 and C734. Measure the resistance between the sleeper side of the sleeper accessory harness connector C309 Pins 12, 4, 5 and 3, Circuits 807 (O), 287 (BK), 806 (W), and 287 (BK) and the speaker feed connectors C735 and C734, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is less than 5 ohms, the rear system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Troubleshooting

Problem—No Sound from One or More of the Speakers, Weatherband Radio

Problem—No Sound from One or More of the Speakers, Weatherband Radio (See Fig. 1, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Speaker	Check the suspect speaker(s). Connect the suspect speaker(s) to a bench test audio amplifier. If the speaker is not OK replace the speaker(s). Test the system for normal operation.
Radio	Check the audio system with a known good radio. If the symptom is corrected have the radio serviced by an authorized service center. Test the system for normal operation. If the symptom is not corrected, check for a short to ground on the right front speaker feed. Disconnect the radio connector C217. Measure the resistance between the radio connector C217 Pin 12, Circuit 803 (R/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 803 (R/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the right front speaker feeds. Disconnect the radio connector C918. Measure the resistance between the radio connector C217 Pins 12, and 11, Circuits 803 (R/Y), 287 (BK) and the speaker feed connector C918, Circuits 803 (R/Y) and 287 (BK). If the resistance is less than 5 ohms, the right front system is OK. If the resistance is less than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are inoperative, check for a short to ground on the left front speaker feed. Measure the resistance between the radio connector C217 Pin 6 Circuit 802 (BL/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 802 (BL/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the left front speaker feeds. Disconnect the left front speaker connector C919. Measure the resistance between the radio connector C217 Pins 6 and 5, Circuits 802 (BL/Y) and 287 (BK) and the speaker feed connector C919, Circuits 802 (BL/Y) and 287 (BK). If the resistance is less than 5 ohms, the left front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are inoperative, check for a short to ground on the Able Body rear speaker feeds. Measure the resistance between the radio connector C217 Pins 4 and 10, Circuits 807 (O) and 806 (W) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s). Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the Able Body sleeper feeds (in-cab wiring). Disconnect the sleeper accessory harness connector C310.

Problem—No Sound from One or More of the Speakers, Weatherband Radio	
Possible Cause	**Remedy**
Radio	Measure the resistance between the radio connector C217 Pins 4, 3, 10 and 9, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK) and the cab side of the sleeper accessory harness connector C310 Pins 3, 4, 2 and 1, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker ground feeds. Disconnect the left sleeper speaker connector C727 and the right sleeper speaker connector C728. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 4 and 1, Circuits 410 (P) and 430 (P) and the speaker feed connectors C727 and C728, Circuits 410 (P) and 430 (P). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the rear radio control (in-sleeper wiring). Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 3 and 2, Circuits 400 (O) and 420 (W) and the rear radio control connector C729 Pins 3 and 4, Circuits 400 (O) and 420 (W). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the speakers (in-sleeper wiring). Measure the resistance between the rear radio control connector C729 Pins 1 and 2, Circuits 400 (O) and 450 (W) and the speaker feed connectors C727 Pin 2 and C728 Pin 2, Circuits 400 (O) and 450 (W). If the resistance is less than 5 ohms, replace the rear radio control. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—No Sound from One or More of the Speakers, Standard Radio

Problem—No Sound from One or More of the Speakers, Standard Radio (See Fig. 1, Fig. 3, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
NOTE: Test only the suspect speaker circuits.	
Speaker	Check the suspect speaker(s). Connect the suspect speaker(s) to a bench test audio amplifier. If the speaker is not OK, replace the speaker(s). Test the system for normal operation.

Troubleshooting

Problem—No Sound from One or More of the Speakers, Standard Radio (See Fig. 1, Fig. 3, Fig. 10, Fig. 11, Fig. 12 and Fig. 13)	
Possible Cause	**Remedy**
Radio	Check the audio system with a known good radio. If the symptom is corrected have the radio serviced by an authorized service center. Test the system for normal operation. If the symptom is not corrected check for a short to ground on the right front speaker feed. Disconnect the radio connector C220. Measure the resistance between the radio connector C220 Pin 4, Circuit 803 (R/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 803 (R/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the right front speaker feeds. Disconnect the radio connector C918. Measure the resistance between the radio connector C220 Pins 4, and 3, Circuits 803 (R/Y), 287 (BK) and the speaker feed connector C918, Circuits 803 (R/Y) and 287 (BK). If the resistance is less than 5 ohms, the right front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are inoperative, check for a short to ground on the left front speaker feed. Measure the resistance between the radio connector C220 Pin 8 Circuit 802 (BL/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 802 (BL/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the left front speaker feeds. Disconnect the left front speaker connector C919. Measure the resistance between the radio connector C220 Pins 8 and 7, Circuits 802 (BL/Y) and 287 (BK) and the speaker feed connector C919, Circuits 802 (BL/Y) and 287 (BK). If the resistance is less than 5 ohms, the left front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are inoperative, check for a short to ground on the Able Body rear speaker feeds. Measure the resistance between the radio connector C220 Pins 6 and 2, Circuits 807 (O) and 806 (W) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s). If the resistance is more than 5 ohms, check the continuity of the Able Body sleeper feeds (in-cab wiring), disconnect the sleeper accessory harness connector C310. Measure the resistance between the radio connector C220 Pins 6, 5, 2 and 1, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK) and the cab side of the sleeper accessory harness connector C310 Pins 3, 4, 2 and 1, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—No Sound from One or More of the Speakers, Standard Radio	
Possible Cause	**Remedy**
NOTE: Test only the suspect speaker circuits.	

Problem—No Sound from One or More of the Speakers, Standard Radio	
Possible Cause	**Remedy**
Radio	If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker ground feeds. Disconnect the left sleeper speaker connector C727 and the right sleeper speaker connector C728. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 4 and 1, Circuits 410 (P) and 430 (P) and the speaker feed connectors C727 and C728, Circuits 410 (P) and 430 (P). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the rear radio control (in-sleeper wiring). Disconnect the rear radio connector C729. Measure the resistance between the sleeper side of the sleeper accessory harness connector C310 Pins 3 and 2, Circuits 400 (O) and 420 (W) and the rear radio control connector C729, Circuits 400 (O) and 420 (W). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the Able Body sleeper speaker positive feeds to the speakers (in-sleeper wiring). Measure the resistance between the rear radio control connector C729, Circuits 400 (O) and 450 (W) and the speaker feed connectors C727 and C728, Circuits 400 (O) and 450 (W). If the resistance is less than 5 ohms, replace the rear radio control. Test the system for normal operation. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—No Sound From One or More of the Speakers, Premium Radio

Problem—No Sound From One or More of the Speakers, Premium Radio (See Fig. 3, Fig. 4, Fig. 8, Fig. 9, Fig. 10 and Fig. 11)	
Possible Cause	**Remedy**
NOTE: Test only the suspect speaker circuits. Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification.	
Speaker	Check the suspect speaker(s). Connect the suspect speaker(s) to a bench test audio amplifier. If the speaker is not OK, replace the speaker(s). Test the system for normal operation.

Troubleshooting

Problem—No Sound From One or More of the Speakers, Premium Radio (See Fig. 3, Fig. 4, Fig. 8, Fig. 9, Fig. 10 and Fig. 11)	
Possible Cause	**Remedy**
NOTE: Test only the suspect speaker circuits. Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification.	
Radio	Check the audio system with a known good radio. If the symptom is corrected have the radio serviced by an authorized service center. Test the system for normal operation. If the symptom is not corrected check the audio system with a known good amplifier. If the symptom is corrected replace the amplifier. Test the system for normal operation. Check the radio output-to-amplifier and output-to-rear radio control for a normal ground condition. Disconnect the amplifier connector C209 and rear radio control connector C762. Remove the Circuit 689 (P) wires from the amplifier connector C209, Pin 12 and from the rear radio control module connector C762, Pin 8. Do not let the Circuit 689 (P) wires touch ground and cover the wire terminations until ready to probe. Disconnect the amplifier connector C209 and rear radio control connector C762. Turn the ignition to the ACC position. Turn the radio on and make sure that no calls on the cellular phone are received during this test step. Measure the voltage between the Circuit 689 (P) wire terminations at the amplifier connector and at the rear radio control connector and ground. If voltage is present, do not proceed. Repair Circuit 689 (P) for a short to power. Measure the resistance between the Circuit 689 (P) wire terminations at the amplifier connector and at the rear radio control connector and ground. If the resistance is more than 5 ohms, repair Circuit 689 (P) for an open circuit. Test the system for normal operation. If the resistance is less than 5 ohms, check for a short to ground on the amplifier input feeds. Disconnect the radio connector C216. Measure the resistance between the radio connector C216 Pins 13, 5, 11 and 3, Circuits 857 (W), 855 (P), 851 (GN) and 856 (O) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity between the radio and the amplifier. Measure the resistance between the radio connector C216 Pins 13, 12, 5, 4, 11, 10, 3 and 2, Circuits 857 (W), 853 (R/GN), 855 (P), 854 (BR), 851 (GN), 850 (BL/W), 856 (O), and 857 (W) and the amplifier connector C208 Pins 8, 4, 6, 2, 7, 3, 5 and 1, Circuits 857 (W), 853 (R/GN), 855 (P), 854 (BR), 851 (GN), 850 (BL/W), 856 (O), and 857 (W). If the resistance is less than 5 ohms, check for a short to ground in the right front speaker leads. Disconnect the amplifier connector C209. Measure the resistance between the amplifier connector C209 Pins 4, Circuit 803 (R/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 803 (R/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the right front speaker feeds. Disconnect the right front speaker connector C918. Measure the resistance between the amplifier connector C209 Pins 4 and 3, Circuits 803 (R/Y) and 287 (BK) and the speaker feed connector C918, Circuits 803 (R/Y) and 287 (BK). If the resistance is less than 5 ohms, the right front system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Problem—No Sound From One or More of the Speakers, Premium Radio	
Possible Cause	**Remedy**
NOTE: Test only the suspect speaker circuits. Circuits 857 (W) and 853 (R/GN), 855 (P) and 854 (BR), 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are twisted pairs at 24 turns/meter (7.3 turns/foot). These circuits are the radio output circuits to the premium amplifier. The twisted pairs are shielded by Pin 14 of the radio connector C216. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted pair specification.	
Radio	If more speakers are inoperative, check for a short to ground on the left front speaker feed. Measure the resistance between the amplifier connector C209 Pin 8, circuit 802 (BK/Y) and ground. If the resistance is less than 5 ohms, repair Circuit 802 (BL/Y) for a short to ground. Test the system for normal operation. If the resistance is more than 5 ohms, check the continuity of the left-front speaker feeds. Disconnect the left front speaker connector C919. Measure the resistance between the amplifier connector C209 Pin 8, Circuit 802 (BL/Y) and ground. If the resistance is less than 5 ohms, the front speaker system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). If more speakers are inoperative check for a short to ground on the rear speaker feeds (in-cab wiring). Disconnect the left front speaker connector C919. Measure the resistance between the amplifier connector C209 Pins 6 and 2, Circuits 807 (O) and 806 (W) and ground. If the resistance is less than 5 ohms, repair the affected circuit(s) for a short to ground. Test the system for normal operation. NOTE: The short to ground may be present in the SilverStar sleeper wiring. If the resistance is more than 5 ohms, check the continuity of the rear speaker feeds (in-cab wiring). Disconnect the left front speaker connector C919. Measure the resistance between the amplifier connector C209 Pins 6, 5, 2 and 1, Circuits 807 (O), 287 (BK), 806 (W), and 287 (BK) and the speaker feed connectors C302 and C306, Circuits 807 (O), 287 (BK), 806 (W), and 287 (BK). If the resistance is less than 5 ohms, the rear system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If more speakers are inoperative, check the continuity of the SilverStar sleeper feeds (in-cab wiring) disconnect the sleeper accessory harness connector C309. Measure the resistance between the sleeper side of the sleeper accessory harness connector C309 Pins 12, 4, 5 and 3, Circuits 807 (O), 287 (BK), 806 (W), and 287 (BK) and the speaker feed connectors C735 and C734, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation. If the resistance is less than 5 ohms, check the continuity of the SilverStar sleeper feeds (in-sleeper wiring). Disconnect the left and right rear speaker connectors C735 and C734. Measure the resistance between the sleeper side of the sleeper accessory harness connector C309 Pins 12, 4, 5 and 3, Circuits 807 (O), 287 (BK), 806 (W), and 287 (BK) and the speaker feed connectors C735 and C734, Circuits 807 (O), 287 (BK), 806 (W) and 287 (BK). If the resistance is less than 5 ohms, the rear speaker system is OK. If the resistance is more than 5 ohms, repair the open in the affected circuit(s). Test the system for normal operation.

Troubleshooting

Problem—Subwoofer Speaker Inoperative, SilverStar Sleeper

Problem—Subwoofer Speaker Inoperative, SilverStar Sleeper (See Fig. 8, Fig. 11, Fig. 14, Fig. 15 and Fig. 16)	
Possible Cause	**Remedy**
NOTE: Circuits 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are line level inputs to the rear radio control module and are twisted pairs at 24 turns/meter (7.3 turns/foot). The twisted pairs are shielded by Pin 14 of the radio connector C216. The shield is spirally wrapped aluminum with a 50% overlap per turn. If a repair of a signal line is necessary, use 20 gauge wire and preserve the twisted configuration specification. If the shield is damaged, it must be replaced and must conform to this specification.	
Subwoofer	Check the system with a known good subwoofer. If the symptom is corrected, replace the subwoofer. Test the system for normal operation. If the symptom is not corrected, check the subwoofer speaker. Connect the subwoofer speaker to a bench Test audio amplifier. If the speaker is not OK replace the subwoofer speaker. Test the system for normal operation.
Missing power	Check the power feeds to the subwoofer. Turn the ignition to the "Off" position. Disconnect the subwoofer connector C752. Measure the voltage between the subwoofer connector C752 Pins 4, 5 and 6, Circuit 37 (BK/Y) and ground. If the voltage is less than 10 volts, check for an open on the power feed. Disconnect the battery ground cable(s). Measure the resistance between the bottom pin of the sleeper fuse panel Fuse 3, Circuit 37 (BK/Y) and the subwoofer connector C752 Pins 4, 5 and 6, Circuit 37 (BK/Y). If the voltage is less than 10 volts, repair Circuit 150 (R) feeding Fuse 3. Test the system for normal operation. If the voltage is greater than 10 volts, check the subwoofer grounds.
Missing ground	Check the subwoofer grounds. Disconnect the battery ground cable(s). Measure the resistance between the subwoofer connector C752 Pins 1, 2 and 3, Circuit 57 (BK) and ground. If the resistance is more than 5 ohms, repair Circuit 57 (BK) for an open circuit. Test the system for normal operation. If the resistance is less than 5 ohms, check the subwoofer speaker wiring.
Subwoofer speaker wiring	Disconnect the subwoofer speaker connector C750. Measure the resistance between the subwoofer connector C752 Pins 7 and 8, Circuits 822 (BR) and 287 (BK) and the subwoofer speaker connector C750, Circuits 822 (BR) and 287 (BK). If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Test the system for normal operation. If the resistance is less than 5 ohms, check the subwoofer enable circuit for voltage.

Problem—Subwoofer Speaker Inoperative, SilverStar Sleeper (See Fig. 8, Fig. 11, Fig. 14, Fig. 15 and Fig. 16)	
Possible Cause	**Remedy**
Subwoofer enable circuit	Disconnect the subwoofer connector C751. Connect the battery ground cable(s). Turn the ignition key to the ACC position. Turn the radio on. Measure the voltage between the subwoofer connector C751 Pin 2, Circuit 830 (GN/W) and ground. If the voltage is not equal to 5 volts, check the subwoofer enable output at the amplifier. Turn the ignition to the "Off" position. Disconnect the amplifier connector C207. Remove the Circuit 830 (GN/W) wire from the amplifier connector C207. Reconnect the amplifier connector C207. Turn the ignition to the ACC position. Turn the radio on. Measure the voltage between the open terminal 10 and ground. If the voltage is equal to 5 volts, repair Circuit 830 (GN/W) for an open between the subwoofer and the amplifier. Test the system for normal operation. If the voltage is not equal to 5 volts, replace the amplifier. Test the system for normal operation. If the subwoofer enable circuit voltage was equal to 5 volts, check the continuity of the line level audio feeds. Turn the ignition to the "Off" position. Disconnect the amplifier connector C207. Measure the resistance between the amplifier connector C207 Pins 9 and 3, Circuits 915 (BK/O) and 916 (R) and the subwoofer connector C751 Pins 5 and 6, Circuits 915 (BK/O) and 916 (R). If the resistance is less than 5 ohms, replace the amplifier. Test the system for normal operation. If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Test the system for normal operation.

Troubleshooting

Problem—No Auxiliary Headphone Audio, SilverStar Sleeper

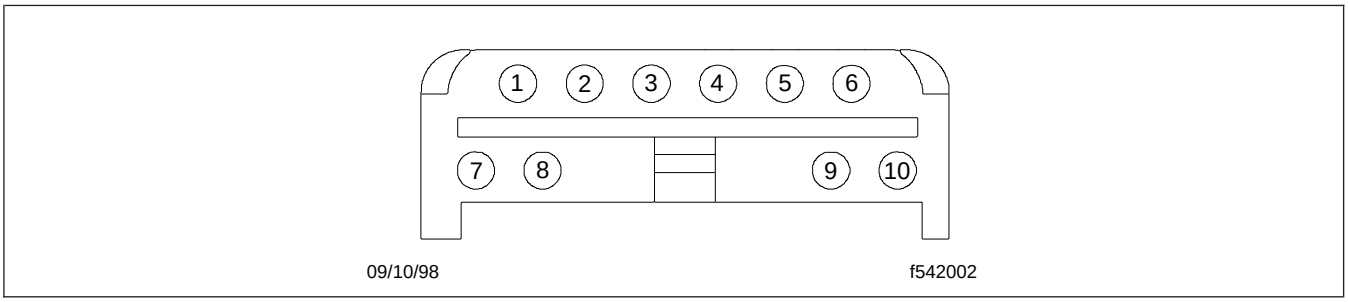

Fig. 15, C750 Subwoofer Speaker Connector

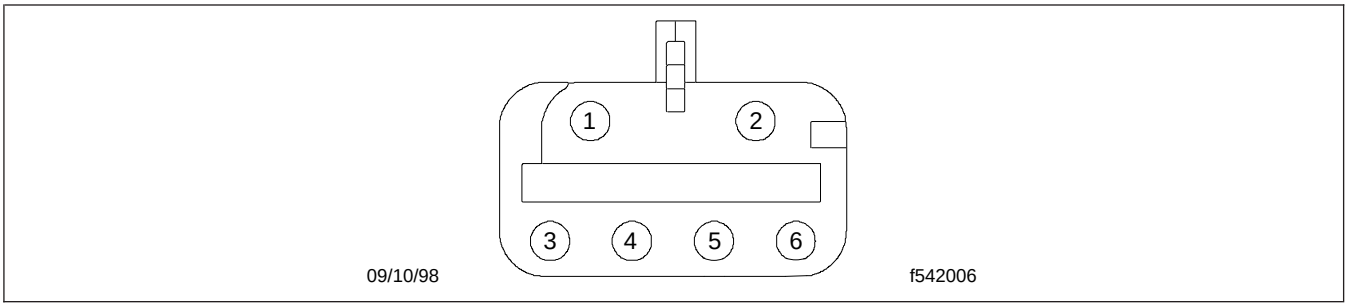

Fig. 16, C751 Subwoofer Connector

Problem—No Auxiliary Headphone Audio, SilverStar Sleeper (See Fig. 2, Fig. 8, Fig. 9, Fig. 11, Fig. 14, Fig. 15 and Fig. 17)	
Possible Cause	**Remedy**
NOTE: Circuits 851 (GN) and 850 (BL/W), 856 (O) and 857 (W) are line level inputs to the rear radio control module and are twisted pairs at 7.3 turns/foot (24 turns/meter). The twisted pairs are shielded by Pin 14 of the radio connector C216. The shield is spirally wrapped aluminum with a 50% overlap per turn. If a repair of a signal line is necessary, use a 20-gauge wire and preserve the twisted configuration specification. If the shield is damaged, it must be replaced and must conform to this specification.	

Problem—No Auxiliary Headphone Audio, SilverStar Sleeper (See Fig. 2, Fig. 8, Fig. 9, Fig. 11, Fig. 14, Fig. 15 and Fig. 17)	
Possible Cause	**Remedy**
Rear radio control	Check the system with a known good rear radio control. If the symptom is corrected replace the rear radio control. Test the system for normal operation. If the symptom is not corrected. Check Circuit 137 (Y/BK) at the rear radio control. Disconnect the rear radio control connector C762. Turn the ignition to the ACC position. Measure the voltage between the rear radio control connector C762 Pin 1, Circuit 137 (Y/BK) and ground. If the voltage is less than 10 volts, check Circuit 137 (Y/BK) at the cab side of the sleeper accessory harness. Turn the ignition to the "Off" position. Disconnect the sleeper accessory harness connector. Turn the ignition switch to the ACC position. Measure the voltage between the cab side of the sleeper accessory connector C309 Pin 7, Circuit 137 (Y/BK) and ground. If the voltage is greater than 10 volts repair the open circuit in the sleeper accessory harness, Circuit 137 (Y/BK) and ground. Test the system for normal operation. If the voltage is less than 10 volts, check the continuity between the instrument panel fuse junction panel Fuse 16 and the cab side of the sleeper accessory harness. Turn the ignition switch to the "Off" position. Disconnect the instrument panel fuse junction panel Fuse 16. Disconnect the battery ground cable(s). Measure the resistance between the bottom pin of the instrument panel fuse junction panel Fuse 16, Circuit 137 (Y/BK) and the cab side of the sleeper accessory harness connector C309 Pin 7, Circuit 137 (Y/BK). If the resistance is less than 5 ohms, repair Circuit 297 (BK/R) feeding Fuse 16. Test the system for normal operation. If the resistance is less than 5 ohms, repair Circuit 137 (Y/BK) for an open circuit. Test the system for normal operation.
Sleeper accessory harness voltage	
Sleeper accessory harness continuity	
Circuit 867 (R) at the rear radio control	If the voltage is more than 10 volts, check Circuit 867 (R) at the rear radio control. Turn the radio on. Measure the voltage between the rear radio control connector C762 Pin 2, Circuit 867 (R) and ground. If the voltage is less than 10 volts, check Circuit 867 (R) at the cab side of the sleeper accessory harness. Turn the ignition to the "Off" position. Disconnect the sleeper accessory harness connector C311. Turn the ignition to the ACC position. Turn the radio on. Measure the voltage between the cab side of the sleeper accessory connector C311 Pin 7, Circuit 867 (R) and ground. If the voltage is greater than 10 volts, repair the open circuit in the sleeper accessory harness, Circuit 867 (R). Test the system for normal operation. If the voltage is less than 10 volts check the Circuit 867 (R) output at the radio. Turn the ignition to the "Off" position. Disconnect the radio connector C216. Remove the Circuit 867 (R) wire from the radio connector C216. Re-connect the radio connector C216. Turn the ignition to the ACC position. Turn the radio on. Measure the voltage between the open terminal 16 and ground. If the voltage is greater than 10 volts, repair Circuit 867 (R) for an open circuit between the radio and the sleeper accessory harness. Test the system for normal operation. If the voltage is less than 10 volts, have the radio serviced by an authorized service center. Test the system for normal operation.

Troubleshooting

Problem—No Auxiliary Headphone Audio, SilverStar Sleeper (See Fig. 2, Fig. 8, Fig. 9, Fig. 11, Fig. 14, Fig. 15 and Fig. 17)	
Possible Cause	**Remedy**
Output-to-rear radio control ground	If the voltage is more than 10 volts, check the Circuit 689 (P) for output-to-rear radio control for a normal ground condition. Turn the ignition to the "Off" position. Remove the Circuit 689 (P) wire from the rear radio control connector C762, Pin 8. Do not let the Circuit 689 (P) touch ground and cover the wire termination until ready to probe. Re-connect the rear radio control connector C762. Turn the ignition to the ACC position. Turn the radio on. Measure the voltage between Circuit 689 (P) wire termination at the rear radio control connector and ground. If voltage is present, do not proceed, repair Circuit 689 (P) for a short to power. Measure the resistance between the Circuit 689 (P) wire termination at the rear radio control connector and ground. If the resistance is more than 5 ohms, repair Circuit 689 (P) for an open circuit if the radio is providing the correct output. Test the system for normal operation. If the resistance is less than 5 ohms, check the rear radio control ground.
Rear radio control ground	Turn the ignition to the "Off" position. Disconnect the rear radio control connector C762. Disconnect the battery ground cable(s). Measure the resistance between the rear radio control connector C762 Pin 11, Circuit 57 (BK) and ground. If the resistance is more than 5 ohms, repair the Circuit 57 (BK) for an open circuit. Test the system for normal operation. If the resistance is less than 5 ohms, check the rear radio control audio ground. Measure the resistance between the rear radio control connector C762 Pin 10, Circuit 18 (BK/BL) and ground. If the resistance is more than 5 ohms, check the rear radio control audio ground at the sleeper accessory harness. Measure the resistance between the cab side of the sleeper accessory harness connector C309 Pin 13, Circuit 18 (BK/BL) and ground. If the resistance is less than 5 ohms, repair Circuit 18 (BK/BL) for an open circuit in the sleeper accessory harness. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 18 (BK/BL) for an open circuit in the cab harness. Test the system for normal operation.
Audio control protocol lines	Check the audio control protocol lines. Disconnect the radio connector C216. Measure the resistance between the radio connector C216 Pin 9, Circuit 832 (Y/BK) and the cab side of the sleeper accessory harness connector C309 Pin 15, 832 (Y/BK). Measure the resistance between the radio connector C216 Pin 1, Circuit 833 (GN) and the cab side of the sleeper accessory harness connector C309 Pin 14, Circuit 833 (GN). If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Test the system for normal operation. If the resistance is less than 5 ohms, check the audio control protocol lines in the sleeper. Measure the resistance between the sleeper side of the sleeper accessory harness connector C309 Pin 15, Circuit 832 (Y/BK) and the rear radio control connector C762 Pin 5, Circuit 832 (Y/BK). Measure the resistance between the sleeper side of the sleeper accessory harness connector C309 Pin 14, Circuit 833 (GN and the rear radio control connector C762 Pin 4, Circuit 833 (GN). If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Test the system for normal operation.

Problem—No Auxiliary Headphone Audio, SilverStar Sleeper (See Fig. 2, Fig. 8, Fig. 9, Fig. 11, Fig. 14, Fig. 15 and Fig. 17)	
Possible Cause	**Remedy**
Line level audio input to the rear radio control	Check the continuity of the line level audio input to the rear radio control. Measure the resistance between the radio connector C216 Pins 11, 10, 3 and 2, Circuits 851 (GN), 850 BL/W), 856 (O) and 857 (W) and the rear radio control connector C762 Pins 15, 16, 13 and 14, Circuits 851 (GN), 850 (BL/W), 856 (O) and 857 (W). If the resistance is less than 5 ohms, rear radio control is OK. Check the radio line level outputs. Test the system for normal operation. If the resistance is more than 5 ohms, repair the affected circuit(s) for an open. Test the system for normal operation.

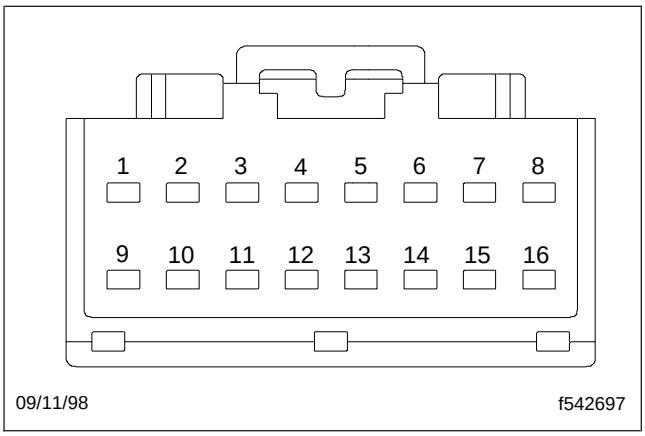

Fig. 17

Specifications

Specifications	
Item	**Specification**
Shields	Spirally Wrapped Aluminum With a 50% Overlap Per Turn
Twisted Wires	7.3 Turns/Foot (24 Turns/ Meter)

Table 1, Specifications

Audio System

Rear Radio Control, SilverStar Sleeper (See Fig. 1)

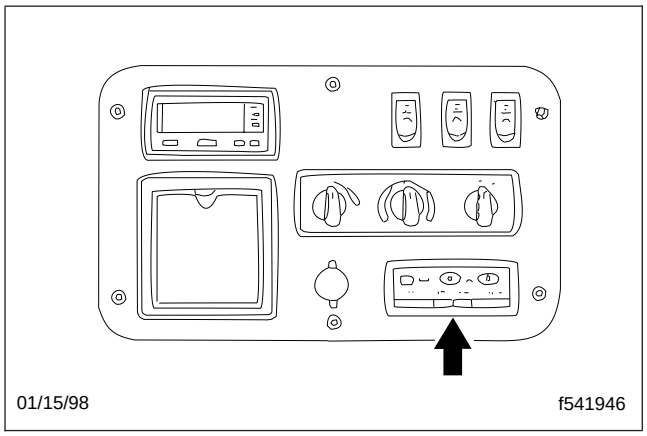

Fig. 1, Rear Radio Control, SilverStar Sleeper

The rear radio control is located on the back wall of the sleeper. The rear radio control includes volume, band selection, memory, seek, speaker toggle knobs and headphone jacks.

Rear Radio Control, Able Body Sleeper (See Fig. 2)

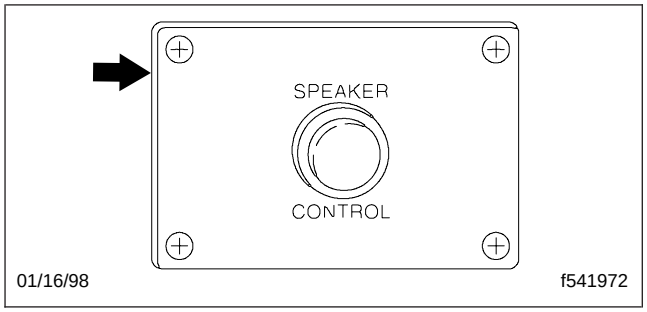

Fig. 2, Rear Radio Control, Able Body Sleeper

The rear radio control is located on the back wall of the sleeper. The rear radio control includes a volume and a balance control.

AM/FM Radio Removal and Installation

Removal

1. Disconnect the battery ground cable(s).
2. Insert the tools into the access holes provided in the bezel until a click is heard. See **Fig. 1**.

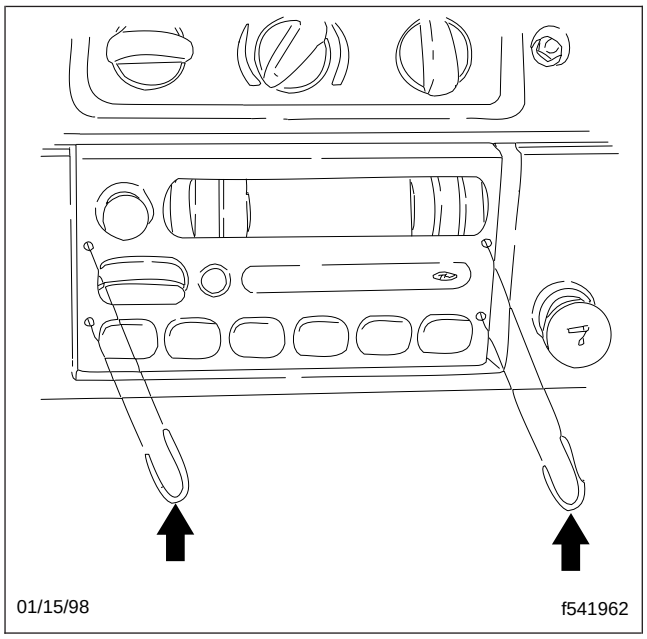

Fig. 1, Radio Chassis Removal Tools

3. Apply outward pressure on the radio chassis removal tools to release the locking tangs, then slide the radio out from the dash. See **Fig. 2**.

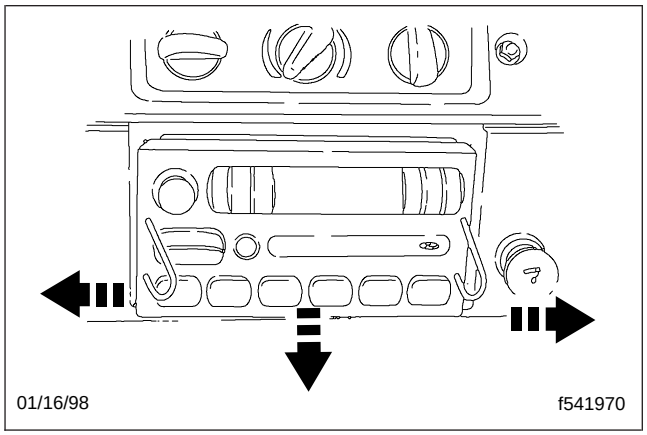

Fig. 2, Radio Chassis Movement

4. Disconnect the radio electrical connectors and the antenna lead-in cable. See **Fig. 3**.

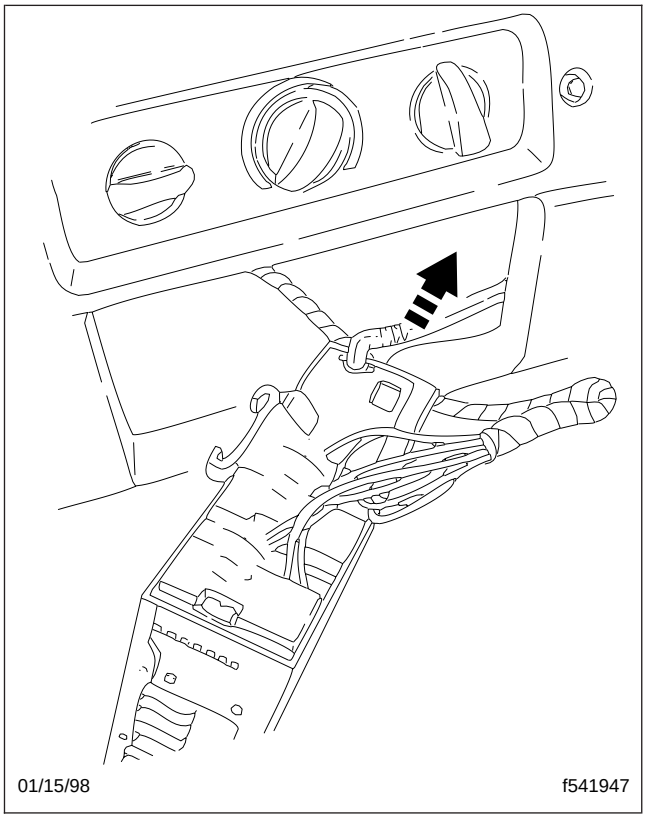

Fig. 3, Radio Electrical Connectors and Antenna Lead-In

5. Remove the radio chassis removal tools from the radio by pressing on the locking tangs on the side of the radio and pulling outward.

Installation

1. Connect the radio electrical connectors and the antenna lead-in cable (see **Fig. 4**). Push the air line harness located behind the instrument panel upward to provide space for the radio.
2. Slide the radio into the dash until the locking tangs engage. See **Fig. 5**.
3. Connect the battery ground cable(s).
4. Refer to the driver's manual to reset the station presets and the clock.

AM/FM Radio Removal and Installation

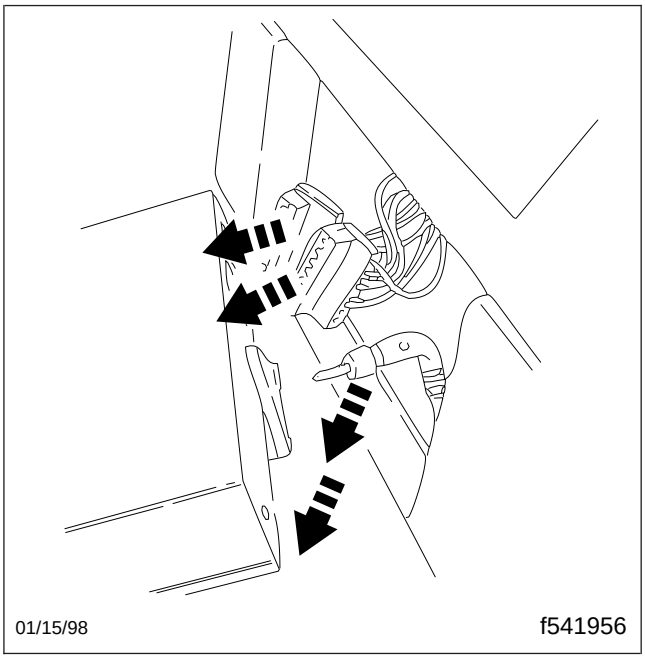

Fig. 4, Radio Electrical Connectors and Antenna Lead-In

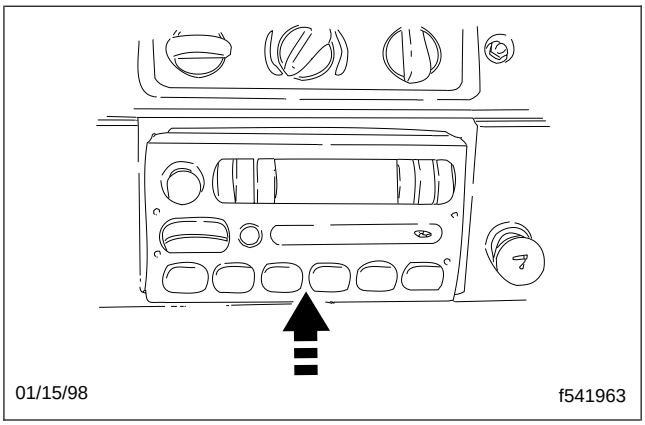

Fig. 5, Slide the Radio into Position

AM/FM Cassette Weather Band Electronic Stereo Radio Removal and Installation

Removal

1. Disconnect the battery ground cable(s).
2. Insert the tools into the access holes provided in the bezel until a click is heard. See **Fig. 1**.

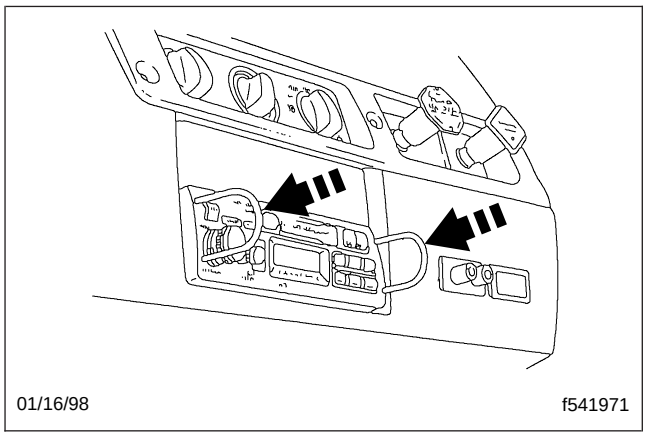

Fig. 1, Insert the Removal Tools

3. Apply outward pressure on the tools to release the locking tangs, then slide the radio partially out from the dash. See **Fig. 2**.

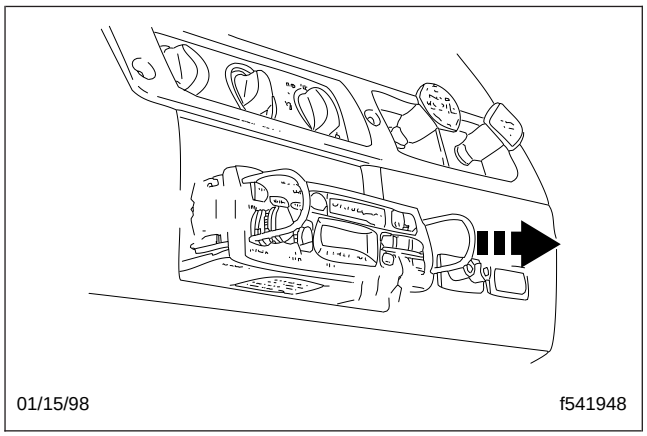

Fig. 2, Slide the Radio Partially Out of the Dash

4. Reach under the dash from the right side and turn the radio chassis support 90 degrees, then slide the radio from the dash. See **Fig. 3**.
5. Disconnect the radio electrical connector and the antenna lead-in cable, then remove the radio. See **Fig. 4**.

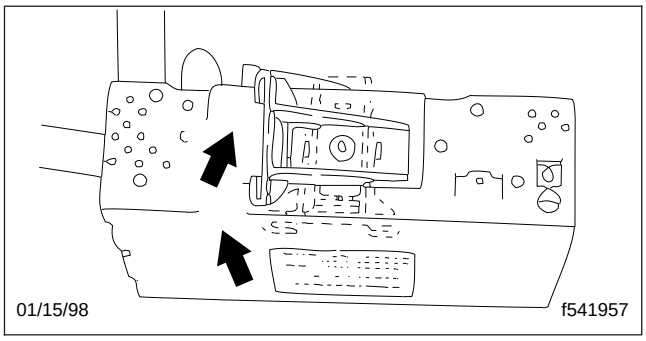

Fig. 3, Radio Chassis Support

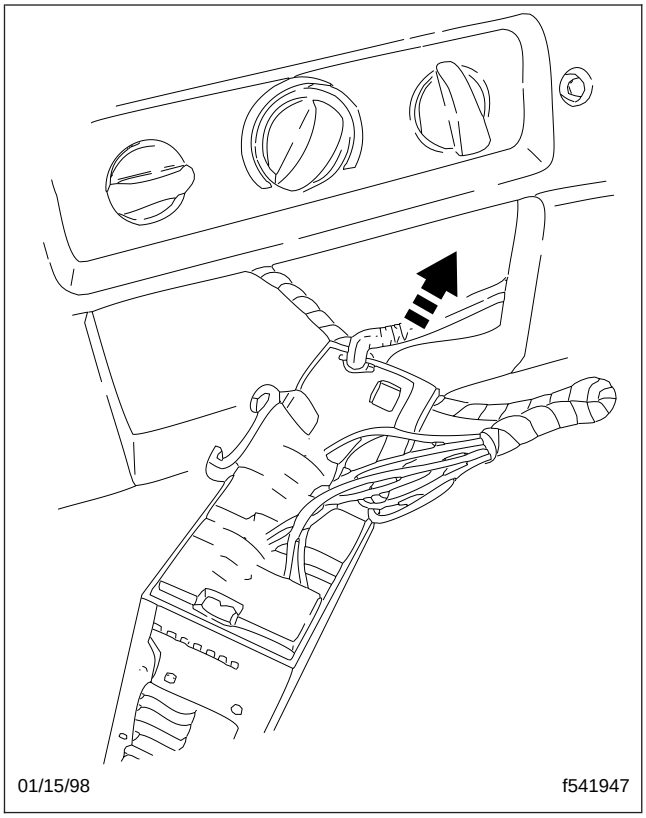

Fig. 4, Radio Electrical Connector and Antenna Lead-In Cable

6. Remove the tools from the radio by pressing on the locking tangs on the sides of the radio and pulling the tools out.

Installation

1. Connect the radio electrical connector and the antenna lead-in cable (see **Fig. 5**). Push the air

AM/FM Cassette Weather Band Electronic Stereo Radio Removal and Installation

line harness located behind the instrument panel upward to provide space for the radio.

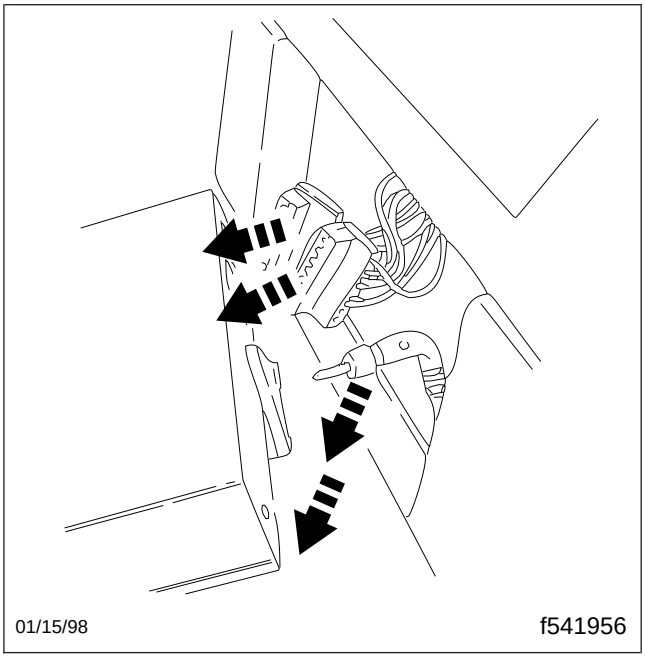

Fig. 5, Radio Electrical Connector and Antenna Lead-In Cable

2. Slide the radio partially into the dash, then reach below the dash from the right side and turn the radio chassis support 90 degrees. See **Fig. 6**.

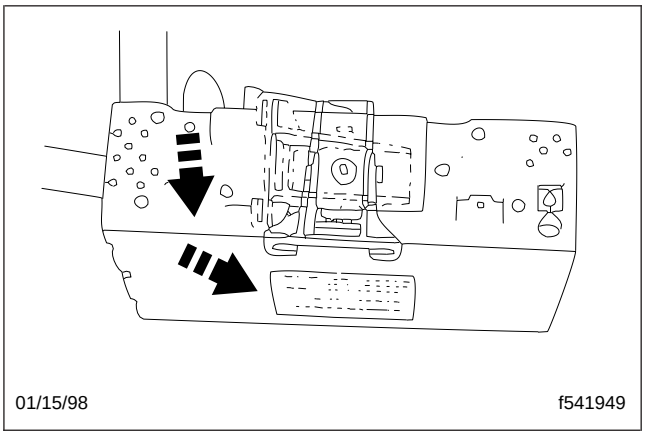

Fig. 6, Radio Chassis Support

3. Make sure that the chassis support is aligned on the metal bracket slide.
4. Slide the radio into the dash until the locking tangs engage. See **Fig. 7**.

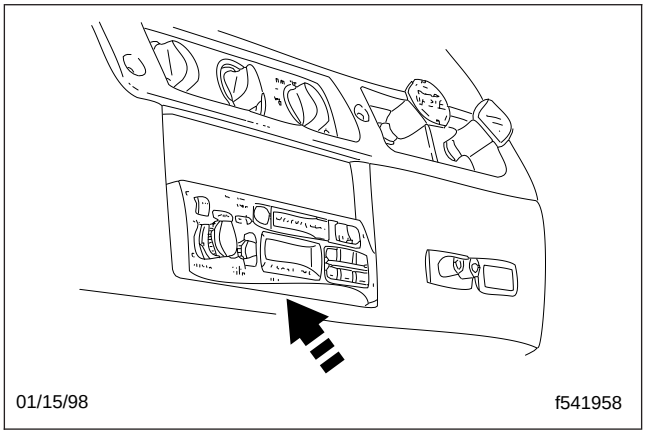

Fig. 7, Install the Radio into the Dash

5. Connect the battery ground cable(s).
6. Refer to the driver's manual to reset the station presets and the clock.

Replacement

1. Make sure the CD changer door is closed. See **Fig. 1**.

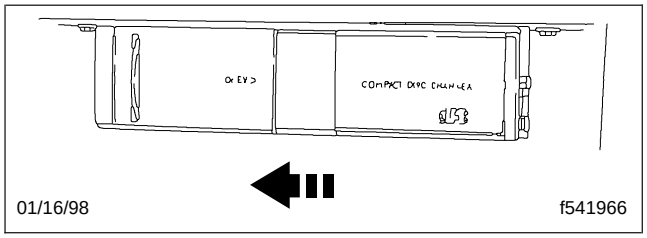

Fig. 1, CD Changer Door

2. Disconnect the battery ground cable(s).
3. Remove the right retaining screws, and support the CD changer. See **Fig. 2**.

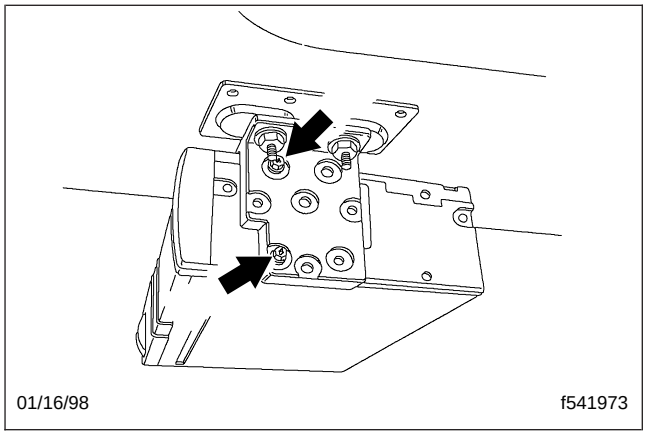

Fig. 2, CD Changer Right Retaining Screws

4. Remove the left retaining screws. See **Fig. 3**.
5. Disconnect the electrical connector. See **Fig. 4**.
6. Connect the electrical connector.
7. Hold the CD changer in the correct position. Then, install the left and right CD changer retaining screws.
8. Connect the battery ground cable(s).

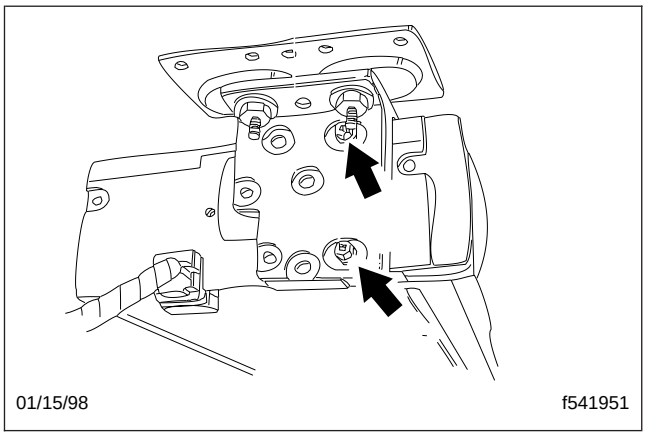

Fig. 3, CD Changer Left Retaining Screws

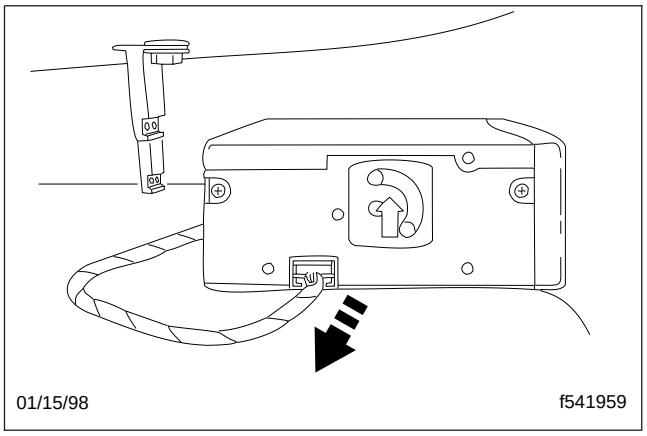

Fig. 4, CD Changer Electrical Connector

Replacement

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Disconnect the battery ground cable(s).
3. Disengage the quarter-turn fasteners and remove the PDM trim panel. See **Fig. 1**.

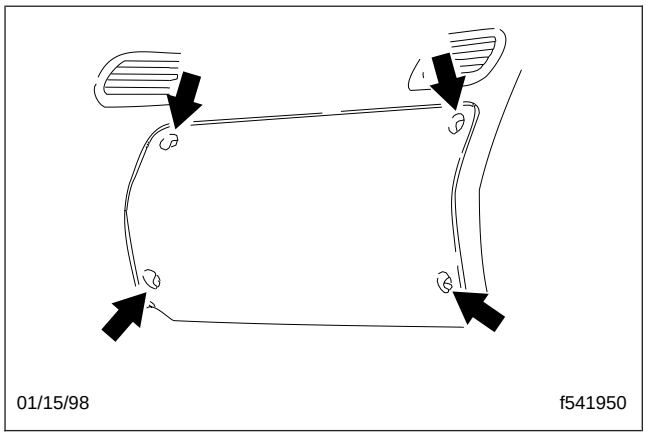

Fig. 1, PDM Trim Panel

4. Remove the lower panel screws and remove the panel. See **Fig. 2**.

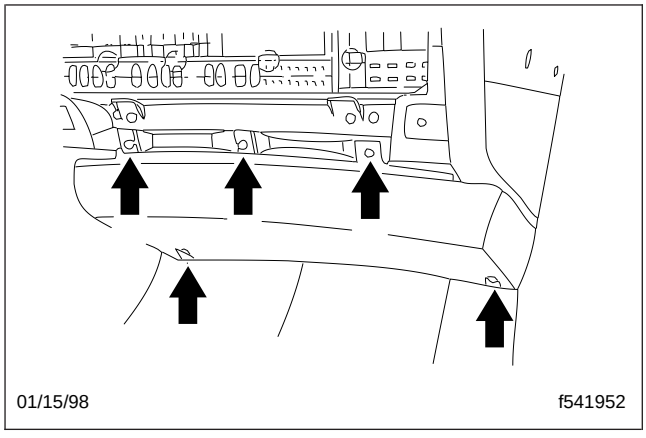

Fig. 2, Instrument Panel Lower Panel

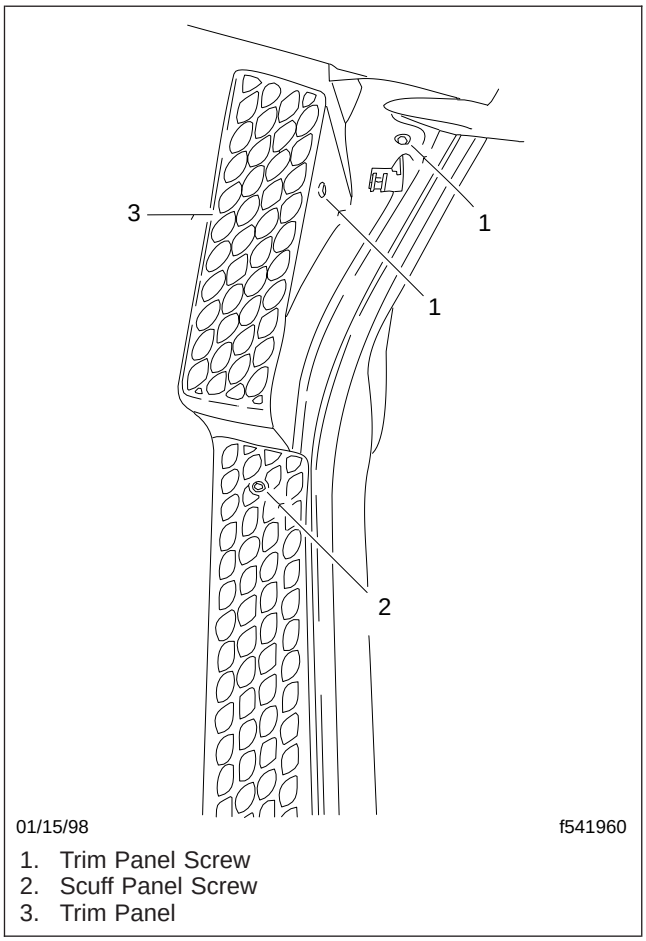
5. Remove the cowl side trim panel. See **Fig. 3**.
   - 5.1 Remove the cowl side trim panel screws.
   - 5.2 Remove the first scuff panel screw.
   - 5.3 Remove the cowl side trim panel.



1. Trim Panel Screw
2. Scuff Panel Screw
3. Trim Panel

Fig. 3, Cowl Side Trim Panel

6. Remove the heater outlet floor duct screws and remove the duct. See **Fig. 4**.

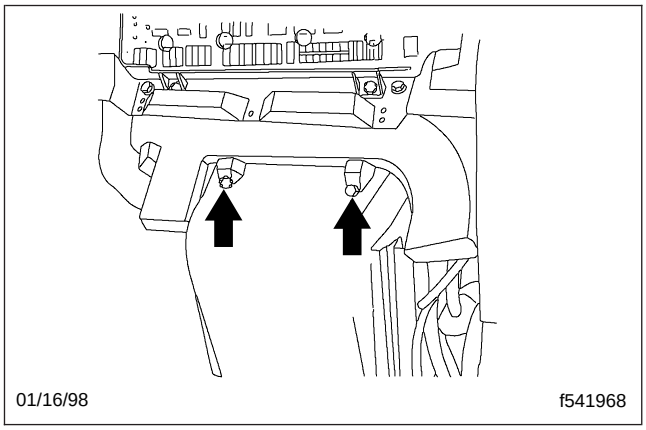


Fig. 4, Heater Outlet Floor Duct

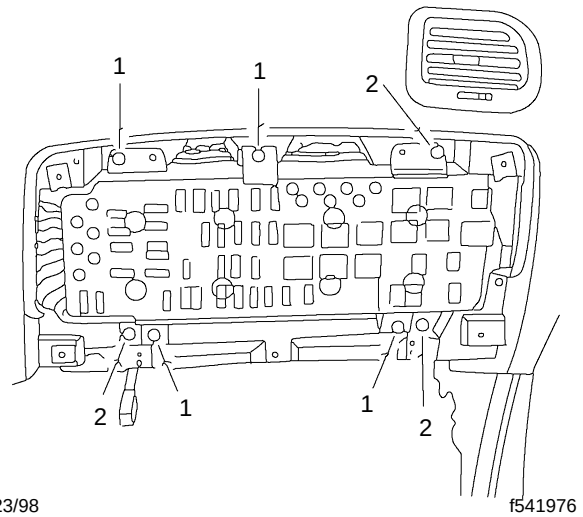
Radio Amplifier Replacement

7. Unfasten the PDM. See **Fig. 5**.



1. PDM Mask Screws
2. PDM Retaining Screws

Fig. 5, PDM

7.1 Remove the PDM mask screws and the mask.

7.2 Remove the PDM retaining screws.

8. Pull the PDM out of the seated position, and support the PDM. See **Fig. 6**.
9. Remove the wiring bracket screw and drop the bracket out of the way.
10. Disconnect the two radio amplifier electrical connectors. See **Fig. 7**.
11. Remove the lower two bolts retaining the radio amplifier. See **Fig. 8**.
12. Remove the radio amplifier. See **Fig. 9**.

12.1 Swing the lower edge of the radio amplifier upward.

12.2 Remove the last radio amplifier retaining bolt.

12.3 Remove the radio amplifier.

13. Install the radio amplifier.

13.1 Position the amplifier.

13.2 Install the radio amplifier retaining bolts.

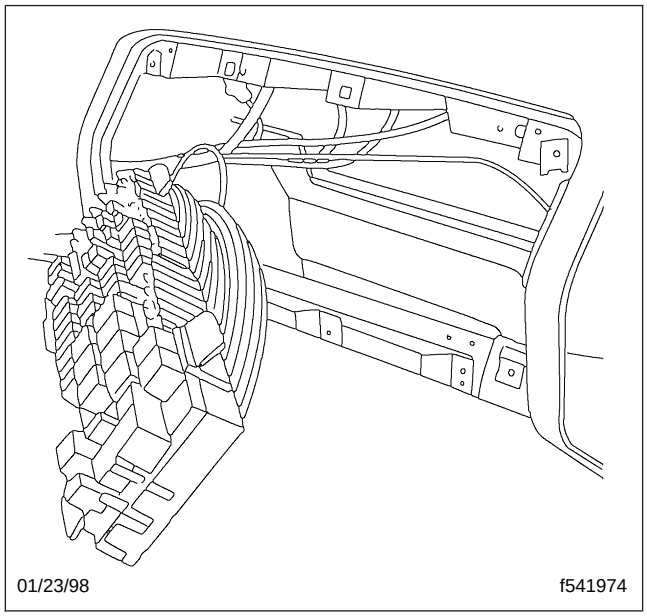


Fig. 6, Pull Out PDM

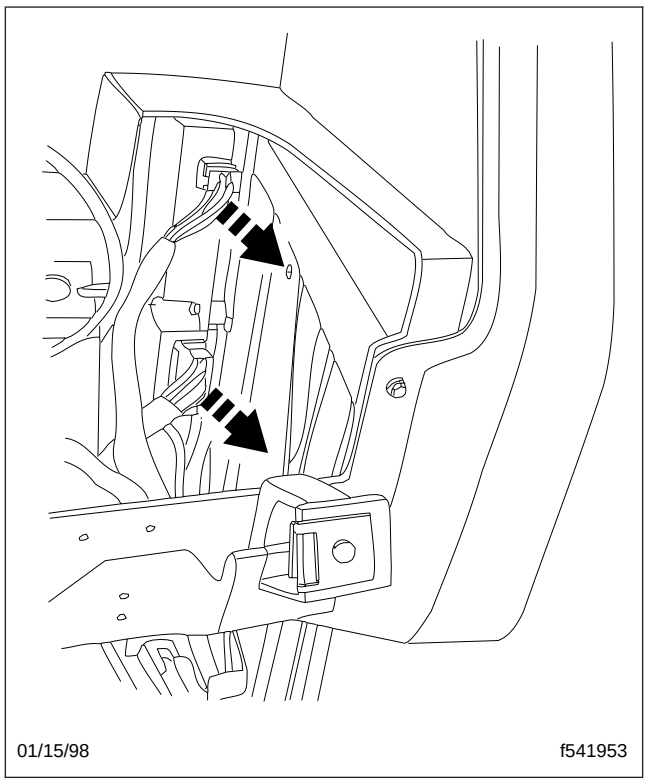

Fig. 7, Radio Amplifier Electrical Connectors

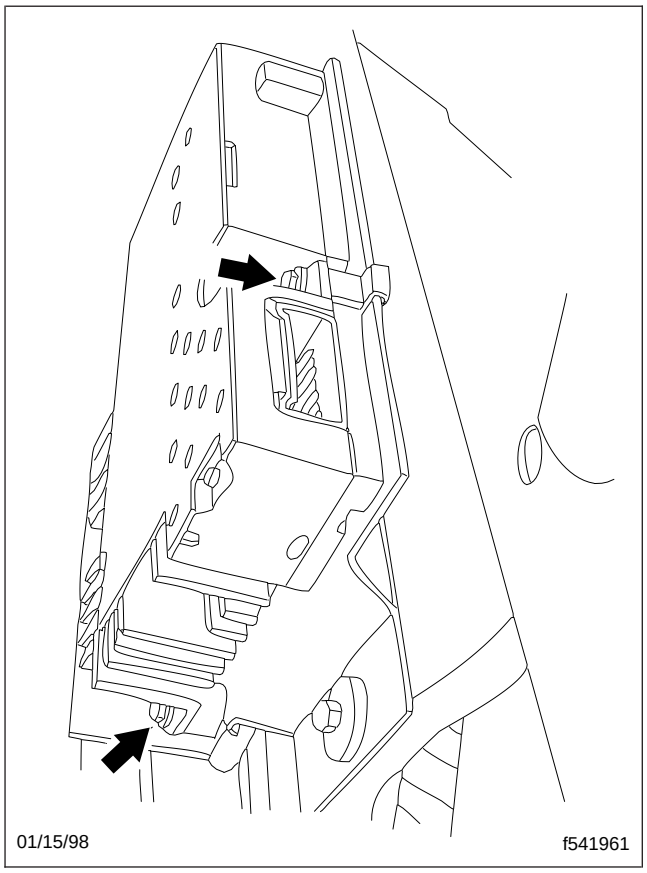

Fig. 8, Radio Amplifier Retaining Bolts

14. Connect the two radio amplifier electrical connectors.
15. Position the wiring bracket and install the wiring bracket screw.
16. Install the PDM.
    - 16.1 Position the PDM.
    - 16.2 Install the PDM mask and the screws.
    - 16.3 Install the PDM retaining screws.
17. Install the cowl side trim panel.
    - 17.1 Position the cowl side trim panel.
    - 17.2 Install the cowl side trim panel screws.
18. Position the lower panel and install the panel screws.
19. Position the PDM trim panel and engage the quarter-turn fasteners.

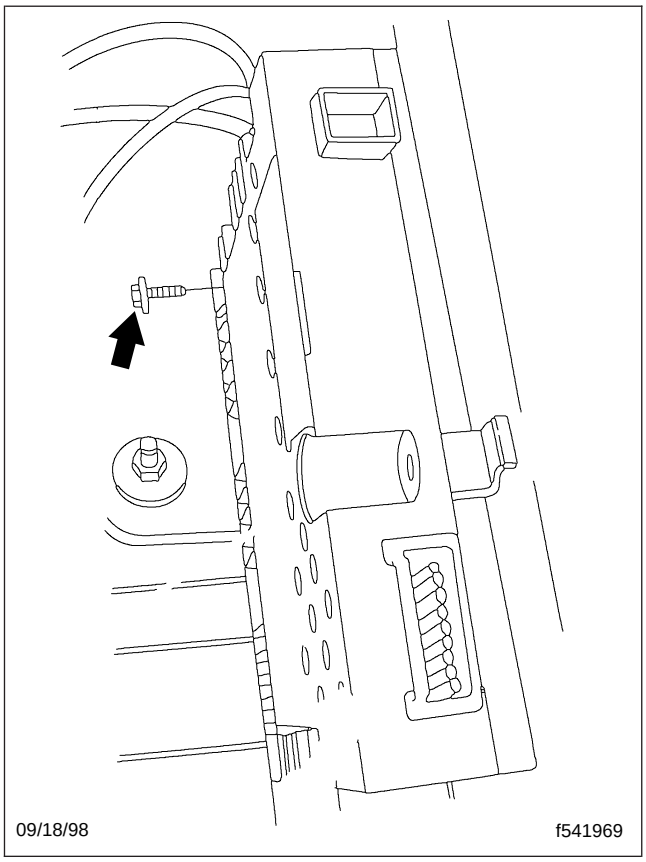

Fig. 9, Radio Amplifier Retaining Bolt

20. Connect the battery ground cable(s).
21. Remove the chocks from the tires.

Rear Radio Control Replacement, SilverStar Sleeper

Replacement

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Carefully pry outward at the top of the rear radio control panel with a small screwdriver. See **Fig. 1**.

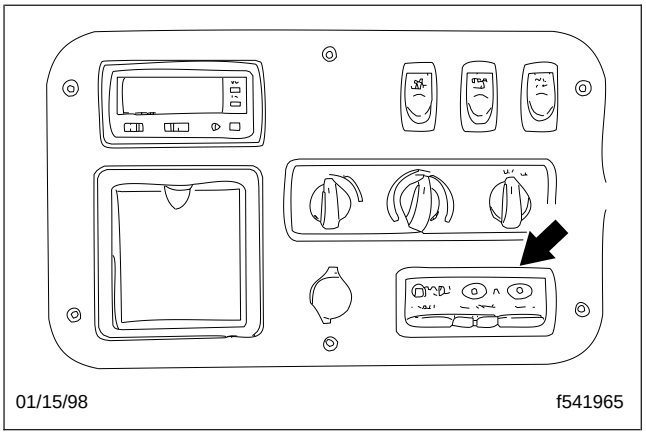

Fig. 1, Rear Radio Control

3. Pull the rear radio control from the control panel until the electrical connector is visible.
4. Disconnect the rear radio control electrical connector.
5. Remove the rear radio control.
6. Connect the rear radio control electrical connector.
7. Install the rear radio control into the control panel.
8. Remove the chocks from the tires.

Rear Radio Control Replacement, Able Body Sleeper

Replacement

1. Park the vehicle on a level surface and apply the parking brakes. Shut down the engine. Chock the rear tires.
2. Remove the rear radio control retaining screws. See **Fig. 1**.

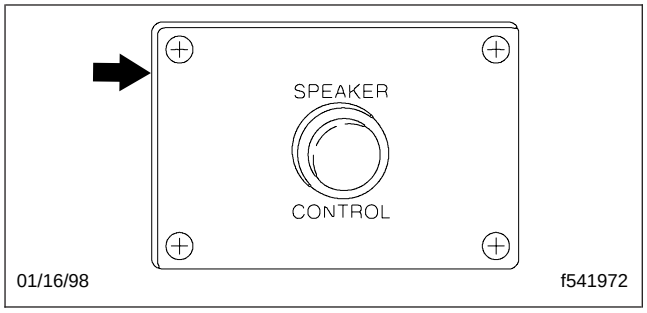

Fig. 1, Rear Radio Control Retaining Screws

3. Separate the rear radio control from the sleeper wall.
4. Disconnect the electrical connector and remove the rear radio control. See **Fig. 2**.

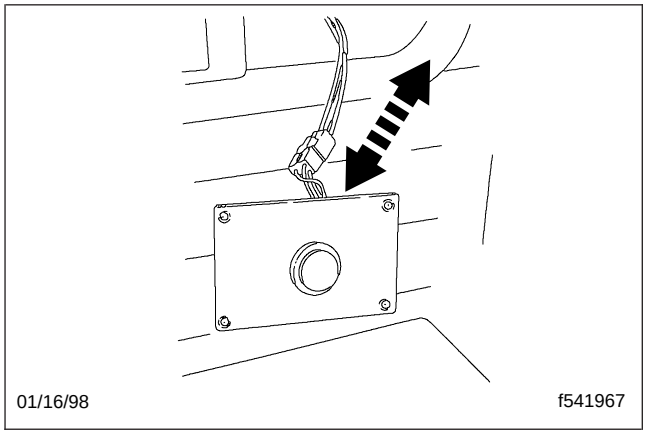

Fig. 2, Rear Radio Control Electrical Connector

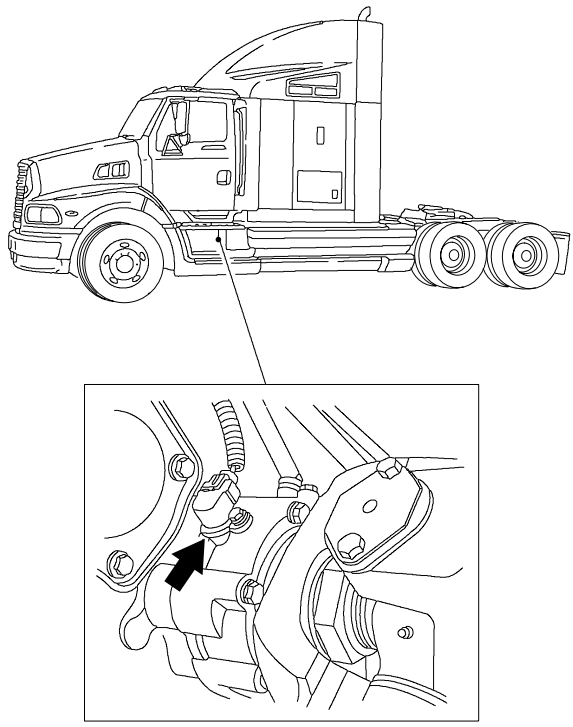
5. Connect the electrical connector and position the rear radio control.
6. Install the rear radio control retaining screws.
7. Remove the chocks from the tires.

General Information

Vehicle Speed Sensor (VSS)

The transmission-mounted vehicle speed sensor (VSS) (see **Fig. 1**) transmits a signal to the speedometer/odometer that is dependent on:

- Rear axle ratio;



07/18/98 f610175

NOTE: The sensor is located at the rear of the transmission, next to the driveshaft.

Fig. 1, Vehicle Speed Sensor (VSS) Location

- Tire revolutions per mile, which is based on tire height.

Two instrument clusters are available on these vehicles. The electronic instrument cluster uses push-in gauges, which can be removed after removing the instrument cluster lens and mask. The non-electronic instrument cluster uses round clamp-mount gauges. The non-electronic instrument cluster must be removed to replace these gauges. The instrument cluster has been designed to clearly indicate the most important vehicle information to the driver. All auxiliary vehicle information is located on the auxiliary instrument cluster. Refer to the driver's manual for both instrument cluster configurations.

Instrument Cluster Display Proveout

NOTE: The brake indicator and buzzer will remain on until enough pressure is built up in the tanks. If the engine is started with enough pressure in the tanks, the brake indicator will proveout normally.

When the ignition switch lock cylinder is turned to the "Run" position, the following warning lamps will proveout by momentarily lighting:

- brake (BRAKE)
- antilock brakes (ABS)
- engine warning (ENG WARN)

Electronic Instrument Cluster Printed Circuit

The instrument cluster printed circuit, which supplies current to the instrument cluster indicators and gauges on the electronic instrument cluster, is made of copper foil bonded to a polyester base film (usually referred to as Mylar®).

The instrument cluster printed circuit is mounted to the back of the cluster housing and, due to its location, cannot be easily inspected or tested in the vehicle. This makes the instrument cluster printed circuit vulnerable to damage when a probe is used for in-vehicle testing, as the probe can pierce the instrument cluster printed circuit or, in some cases, burn the copper conductor.

NOTE: A diode is a polarized electronic device that totally blocks current flow in one direction and passes current flow with a small voltage drop in the other direction.

When testing a printed circuit path when a diode is present, check the resistance across the diode terminals first. Attach the positive terminal of the ohmmeter to the anode and attach the negative terminal to the cathode. The resistance should be in the 1 kohm range. Reverse the ohmmeter terminals and a near infinite resistance should be measured.

Test the printed circuit path in the same manner as the diode was tested. If an infinite resistance is measured in both directions or if a very small resistance

General Information

is measured in both directions, the diode or printed circuit is bad and the printed circuit needs to be replaced.

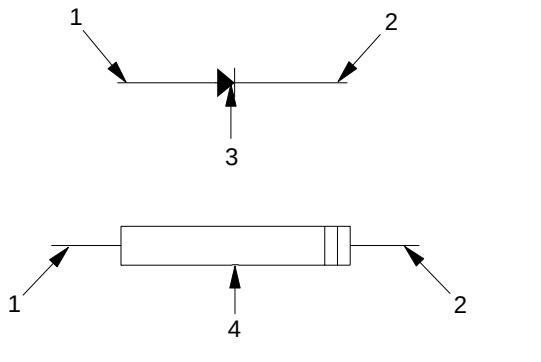
Since there is no approved procedure for in-vehicle testing of the instrument cluster printed circuit, it must be removed for visual inspection. If no visual damage is evident, test each circuit with an ohmmeter. If an open circuit or short between non-linked traces is detected, the instrument cluster printed circuit must be replaced.

Non-Electronic Instrument Cluster Printed Circuit

Two printed circuits supply current to the warning indicators on the non-electronic instrument cluster, and are made of copper foil bonded to a polyester base film.

The right-side and left-side warning lamp module printed circuits are mounted to the back of the cluster housing and, due to their location, cannot be easily inspected or tested in the vehicle. This makes the printed circuits vulnerable to damage when a probe is used for in-vehicle testing, as the probe can pierce the printed circuits or, in some cases, burn the copper conductors.

NOTE: A diode is a polarized electronic device that totally blocks current flow in one direction and passes current flow with a small voltage drop in the other direction. See **Fig. 2**.



1. (+) Anode
2. (-) Cathode
3. Circuit Representation
4. Physical Representation

Fig. 2, Diode

When testing a printed circuit path when a diode is present, check the resistance across the diode terminals first. Attach the positive terminal of the ohmmeter to the anode and attach the negative terminal to the cathode. The resistance should be in the 1000 ohm range. Reverse the ohmmeter terminals and a near infinite resistance should be measured.

Test the printed circuit path in the same manner as the diode was tested. If an infinite resistance is measured in both directions or if a very small resistance is measured in both directions, the diode or printed circuit is bad and the printed circuit needs to be replaced.

Since there is no approved procedure for in-vehicle testing of the instrument cluster printed circuit, it must be removed for visual inspection. If no visual damage is evident, test each circuit with an ohmmeter. If an open circuit or short between non-linked traces is detected, the instrument cluster printed circuit must be replaced.

Fuel Level Indication System

The fuel indicating system is an electromagnetic system and consists of a fuel indicator gauge mounted in the instrument cluster and a fuel level sensor located in the fuel tank. The system operates directly from battery voltage and indicates fuel level condition based on the variable resistance of the fuel level sensor. See the driver's manual for a description of the fuel gauge.

Fuel Level Sensor

The fuel level sensor consists of a variable-screened resistor made up of a ceramic substrate. It is controlled by the action of an attached float in the fuel tank.

The fuel level sensor should vary in resistance between 15 and 280 ohms. When the fuel level is low (empty), the resistance of the fuel level sensor will be high. When the fuel level is high (full), the resistance of the fuel level sensor will be low.

Coolant Temperature Indication System

The engine coolant temperature indication system is a magnetic gauge system. It consists of a magnetic engine coolant temperature gauge mounted in the instrument cluster and an engine coolant temperature

sensor. See the driver's manual for a description of the coolant temperature gauge.

High Coolant Temperature Warning Lamp

See the driver's manual for a description of the high coolant temperature warning lamp.

See **Group 20** of this manual for cooling system service.

Coolant Temperature Sensor

The coolant temperature sensor varies in resistance according to the engine coolant temperature. The coolant temperature sensor should vary in resistance between 1 and 1.5 kohms. When the engine coolant temperature is cold, the resistance of the engine coolant temperature sensor will be high. When the engine coolant temperature is hot, the resistance of the engine coolant temperature will be low.

Oil Pressure Indication System

The oil pressure indication system consists of the:

- Oil pressure gauge;
- Low oil pressure warning indicator;
- Oil pressure switch;
- Necessary circuitry.

Oil Pressure Sensor/Switch

The oil pressure sensor consists of a pressure tube connected to the engine.

The oil pressure switch will become a closed circuit when a low pressure exists.

Charge Indication System

The voltmeter is a gauge that measures the voltage potential at the battery to indicate the battery state of charge. The voltmeter is not adjustable and must be replaced if inoperative. See the driver's manual for a description of the voltmeter gauge.

Air Pressure Gauge

Refer to the driver's manual for a description of the air pressure gauge.

Speedometer/Odometer

The speedometer uses an air-core meter to indicate the speed at which the vehicle is moving. This air core meter receives input internally from the electronic buffer circuit, which receives its input from the vehicle speed sensor (VSS). The speedometer is equipped with dip switches necessary to calibrate the electronic buffer circuit to different tire sizes and axle ratios.

NOTE: The speedometer pointer will not return to zero with the ignition switch lock cylinder in the "Off" position. This should not be interpreted as an inoperative condition.

See the driver's manual for a description of the odometer.

Odometer Replacement

The mileage on replacement speedometer/odometers cannot be reset. If a replacement speedometer/odometer is installed, a label recording the vehicle's mileage and date at the time of the speedometer/odometer replacement must be attached to the driver door jam.

Tachometer

NOTE: The tachometer pointer will not return to zero with the ignition lock cylinder in the "Off" position. This should not be interpreted as an inoperative condition.

NOTE: The tachometer has a 1 to 1-1/2 second delay time in response with the engine rpm. This condition is considered normal.

The tachometer uses an air-core meter to indicate engine speed in revolutions per minute (rpm). This air core meter receives input internally from the electronic buffer circuit, which receives its input from the tachometer sensor. The tachometer is equipped with dip switches necessary to calibrate the electronic buffer circuit to electronic engines or mechanical engines that use a variable reluctance sensor.

Warning Indicators

Brake System

The brake system warning lamp should illuminate when the ignition switch lock cylinder is turned to the "Start" position. If the air pressure in the dual air

tanks is low, the brake lamp and buzzer will stay on until enough pressure is built up for normal application of the vehicle brakes. If air pressure is lost during normal operation of the vehicle, the brake lamp and buzzer will actuate to the "On" state.

Antilock Brakes

See the driver's manual for a description of the antilock lamp.

See **Group 42** of this manual for diagnosis and testing of the ABS system.

Engine Warning

The check engine warning indicator comes on when the engine control system is not working properly.

NOTE: If the vehicle is equipped with dual fuel tanks, the ENG WARN lamp may come on if fuel is restricted to the engine. This condition is normal and the ENG WARN lamp should turn off sometime after fuel flow is restored.

The check engine warning indicator comes on briefly when the ignition switch lock cylinder is turned to the "Start" position, and should turn off when the engine starts. If the check engine warning indicator does not come on when the ignition switch lock cylinder is turned to the "Run" position or if it comes on while the vehicle is moving, the system is malfunctioning.

Low Coolant

See the driver's manual for a description of the low coolant warning lamp.

See **Group 20** of this manual for cooling system service.

Instrument Cluster and Panel Lighting

The electronic instrument cluster and the non-electronic instrument cluster both contain the following gauges:

- speedometer
- tachometer
- voltmeter
- fuel
- coolant temperature
- oil pressure
- air pressure (brake pressure)

The driver side instrument panel contains the following switches:

- ignition switch
- engine start button
- headlamp switch
- marker lamp blink switch
- dome lamp and instrument panel dimmer switch
- two auxiliary rocker switches

The auxiliary instrument panel can have a maximum of eight gauges, nine rocker switches and three rocker-type air controls. Six of the eight gauges are factory equipped while the seventh and eighth gauges are a dealer-installed option.

The three rocker-type air controls are governed by the following in left to right order:

- axle lock valve (priority 1—leftmost valve)
- air dump suspension valve (priority 2)
- wheel lock valve (priority 3)
- fifth wheel slide valve, tractor (priority 4)

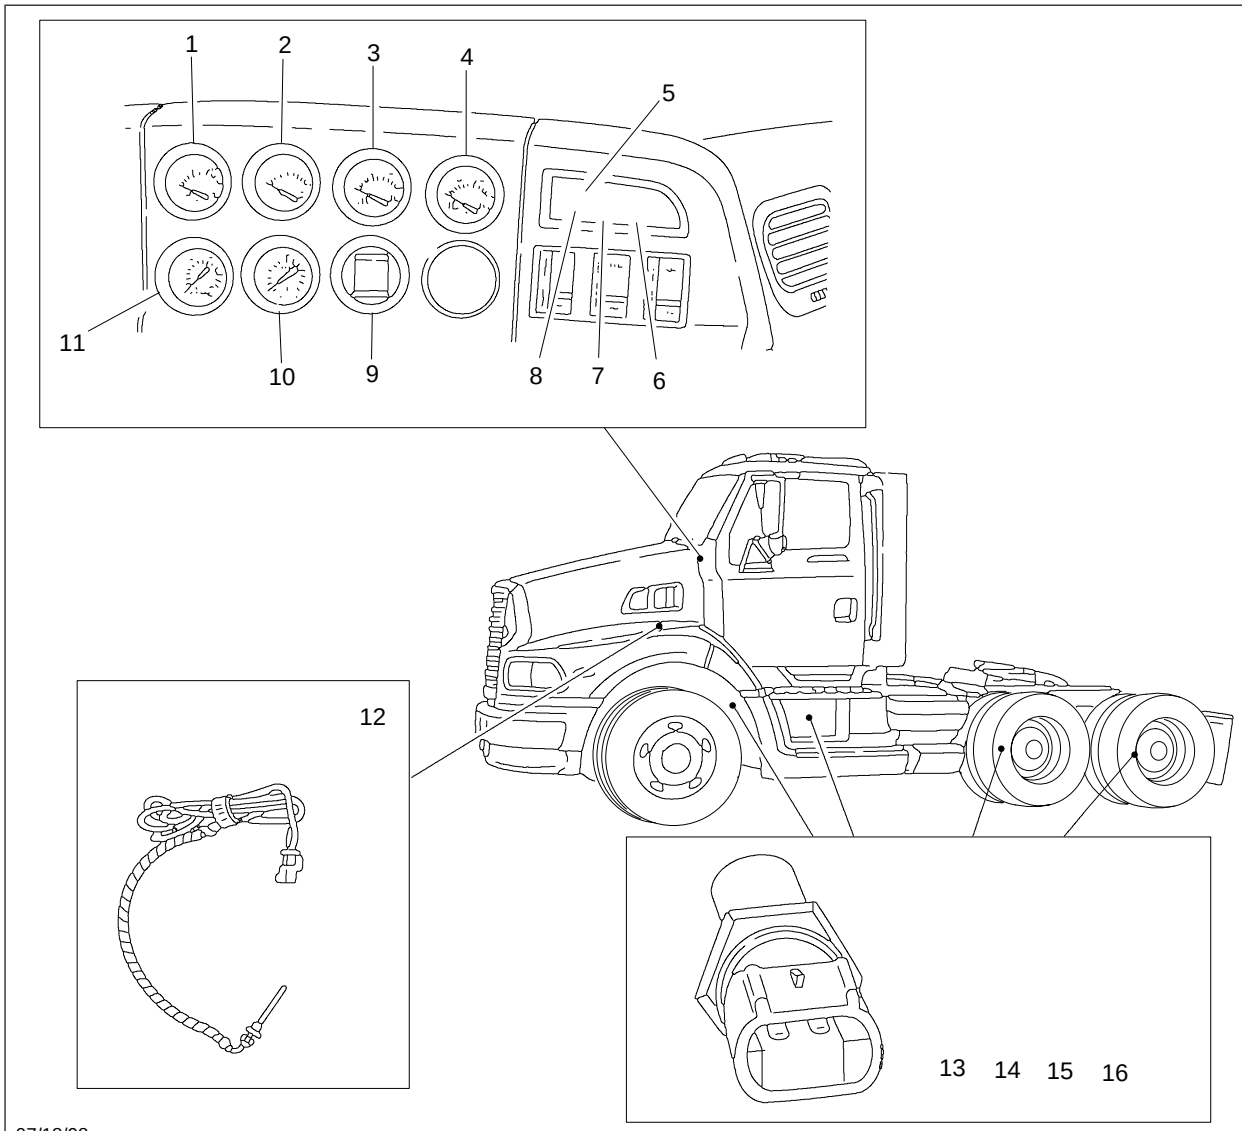
Gauges with priorities 3 and 4 are mutually exclusive (one or the other, not both).

The headlamp switch controls the instrument cluster and panel lighting. When the headlamp switch is in the PARK or HEAD position, the battery supplies voltage through the headlamp switch and through the dome lamp and instrument panel dimmer switch to the instrument cluster and panel illumination lamps. The lamps can be dimmed manually with the dome lamp and instrument panel dimmer switch. Actuating the dome lamp and instrument panel dimmer switch to its highest vertical position will illuminate the dome lamp. Circuit 19 (BL/R) feeds the instrument cluster and panel lighting.

Auxiliary Gauges and Warning Devices **(See Fig. 3)**

Air Restriction Gauge

The air restriction gauge allows the operator to monitor the ability of the engine to receive air through the air filter. As the filter retains more dirt and debris, the vacuum it creates will begin to register on the gauge.



1. Engine Oil Temperature Gauge
2. Transmission Oil Temperature Gauge
3. Forward Drive Axle Oil Temperature Gauge
4. Rear Drive Axle Oil Temperature Gauge
5. Traction Control Warning Lamp (TRAC)
6. Service Soon Warning Lamp (SERVICE SOON)
7. Air Suspension Dump Warning Lamp (SUSP DUMP)
8. Do Not Shift Warning Lamp (DO NOT SHIFT)
9. Air Restriction Gauge
10. Exhaust Gas Temperature Gauge
11. Brake Application Air Pressure Gauge
12. Engine Oil Temperature Gauge
13. Exhaust Gas Pyrometer
14. Transmission Oil Temperature Sensor
15. Forward Drive Axle Oil Temperature Sensor
16. Rear Drive Axle Oil Temperature Sensor

Fig. 3, Gauge and Warning Device Component Location (Left-Hand-Drive Shown, Right-Hand-Drive Similar)

When the gauge reading reaches a predetermined point, the air filter must be replaced and the gauge reset.

General Information

Brake Application Air Pressure Gauge

The brake application air pressure gauge allows the operator to monitor the amount of assist air pressure being applied to the brakes by the operator through the brake pedal. As brake pedal effort is increased, the indicator shows an increase in the amount of pressure being applied to the brakes.

Exhaust Gas Temperature Gauge

The exhaust gas temperature gauge uses a pyrometer sensor to generate the signal for the gauge. The sensor is located in the exhaust outlet pipe from the turbocharger. It allows the operator to monitor the temperature of the exhaust. It works in conjunction with the CAT CONV warning lamp, giving the operator the opportunity to prevent engine or turbocharger damage due to an overtemp condition.

Engine Oil Temperature Gauge

The engine oil temperature gauge uses a thermistor sensor located in the oil pan to provide a signal to the gauge. This allows the operator to monitor the temperature of the engine oil. It works in conjunction with the OIL TEMP warning lamp, giving the operator the opportunity to prevent engine damage due to an engine oil overtemp condition.

Forward Drive Axle Oil Temperature Gauge

The forward drive axle oil temperature gauge uses a thermistor sensor located in the back of the forward drive axle housing to provide a signal to the gauge. This allows the operator to monitor the temperature of the forward drive axle oil. It works in conjunction with the OIL TEMP warning lamp, giving the operator the opportunity to prevent damage to the forward drive axle due to an axle oil overtemp condition.

Rear Drive Axle Oil Temperature Gauge

The rear drive axle oil temperature gauge uses a thermistor sensor located in the back of the rear drive axle housing to provide a signal to the gauge. This allows the operator to monitor the temperature of the rear drive axle oil. It works in conjunction with the OIL TEMP warning lamp, giving the operator the opportunity to prevent damage to the rear drive axle due to an axle oil overtemp condition.

Transmission Oil Temperature Gauge

The transmission oil temperature gauge uses a thermistor sensor located in the transmission case to provide a signal to the gauge. This allows the operator to monitor the temperature of the transmission oil. It works in conjunction with the OIL TEMP warning lamp, giving the operator the opportunity to prevent transmission damage due to a transmission oil overtemp condition.

Air Suspension Dump Warning Lamp

The air suspension dump warning lamp illuminates whenever the dump control valve is in the UP (exhaust) position.

⚠ CAUTION

This control must not be operated during normal vehicle operation because damage to the system or vehicle can occur.

The SUSP DUMP warning lamp is used in conjunction with the red status light on the dump valve switch to alert the operator that the air suspension system is in the exhaust position.

DO NOT SHIFT Warning Lamp (Electronic Allison Transmissions Only)

The DO NOT SHIFT warning lamp will illuminate (accompanied by eight seconds of short beeps from the shifter selector) when the transmission control unit (TCU) has detected the transmission operating parameters have been exceeded and the upshifts and downshifts are being restricted.

SERVICE SOON Warning Lamp (DDC 60 Engine Only)

The SERVICE SOON warning lamp illuminates whenever there is an engine sensor problem. It is activated by the engine control module (ECM) and will stay illuminated until the key is turned to the "Off" position or the problem is no longer present.

Traction Control Warning Lamp

The traction control warning lamp illuminates whenever there is wheel spin and stays on until the wheel spin is eliminated. It will also illuminate whenever there is a problem with the traction control system. During the time a system problem is occurring, the TRAC lamp will illuminate and stay on until the problem is either corrected or the key is turned to the "Off" position. If the problem is there only temporarily, the lamp will be extinguished when the problem is no longer present.

Proveout

When the key is turned to "Run", the DO NOT SHIFT lamp illuminates and stays lit until the engine is started, the TRAC lamp illuminates and stays lit until the traction control system completes a self test, and the SERVICE SOON lamp, for Detroit Diesel engine applications, illuminates for approximately five seconds and extinguishes if no diagnostic trouble codes are set.

When the key is turned to "Start", the SUSP DUMP lamp illuminates for as long as the key stays in "Start".

Engine Protection System (See Fig. 4)

The engine protection system (or engine alarm/shutdown system) is designed to prevent engine damage resulting from operation of the engine during prolonged periods of low oil pressure, high engine oil temperature, high coolant temperature or low coolant level.

The system includes a visual indicator and an audible indicator to alert the operator of each condition. In vehicles equipped with the engine shutdown option, these indicators are accompanied by a delay of 30 to 40 seconds before the engine shuts down. This 30 to 40 second delay is provided to allow the operator to safely remove the vehicle from the road.

⚠ CAUTION

Any attempt to use the override feature to drive the vehicle very far will result in serious engine damage.

This delay feature can be overridden by pressing the engine shutdown override switch if more time is required to remove the vehicle from the road.

On vehicles with mechanical engines (Cummins ISB, ISC and Caterpillar 3306), the engine shutdown system uses a multi-function type module that incorporates the engine shutdown control, brake low air pressure warning and buzzer functions into one module. On electronic engines (Caterpillar 3176, 3406, Cummins M11, N14 and Detroit Diesel Series 60), the engine shutdown system is controlled by the electronic engine control module (ECM).

Engine Alarm/Shutdown Activation

When the engine alarm/shutdown control is grounded at any of the temperature related switches or opened through the coolant level switch, it immediately sounds the audible warning. After approximately 30 to 40 seconds, it opens the circuit that provides power to the fuel shutoff relay and the engine shuts down.

The fuel shutoff solenoid is used to allow the engine to run or be shutdown. This solenoid moves the fuel rack into the fuel "On" or fuel "Off" positions. Power for the solenoid is controlled by the ignition switch and fuel shutoff relay for Cummins ISB and ISC engines or the fuel shutoff relay only for the Caterpillar 3306 engine.

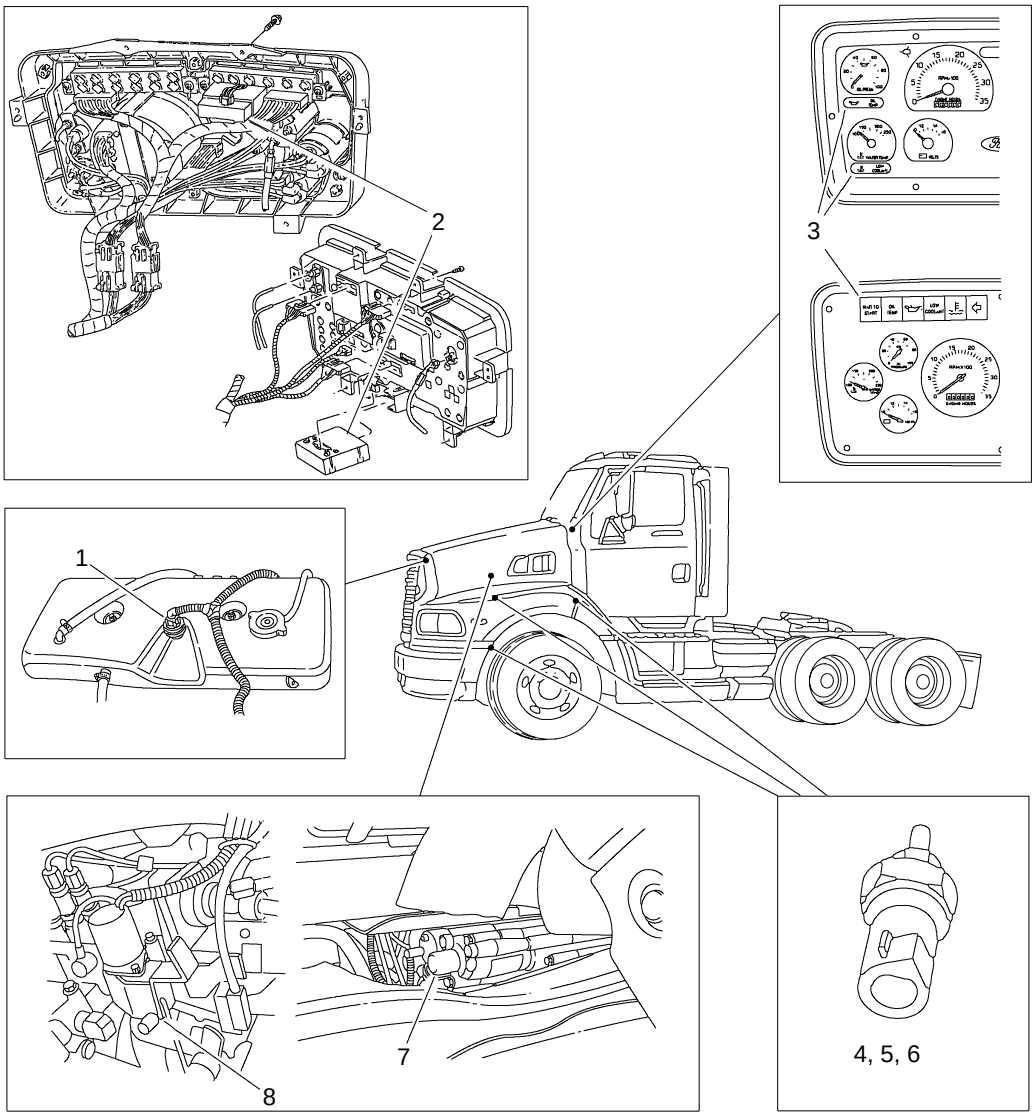
On the Cummins ISB and ISC engines, the fuel shutoff solenoid encompasses two coils within one housing. A powerful pull coil is used to pull the fuel shutoff lever to the open position, allowing fuel to flow. The pull coil is fed from the switched side of the starter motor relay, so it is energized only when the key is in the "Start" position. At the same time, a much less powerful hold coil is fed from the fuel shutoff relay output circuit. When the key is released to the "Run" position, the pull coil de-energizes and the hold coil remains energized to keep the fuel shutoff lever in the open position.

⚠ CAUTION

The pull coil draws a considerable amount of current while it is energized. Do not allow it to remain energized for longer than 30 seconds or it can cause damage to the solenoid.

On the Caterpillar 3306 engine, a single coil solenoid is used for both pull and hold functions of the fuel shutoff solenoid.

General Information



1. Low Coolant Level Sensor
2. Brake Low Air Pressure Buzzer, Engine Warning Chime, Engine Alarm/Shutdown Module
3. Indicator Warning Lamps
4. High Oil Temperature Switch
5. High Coolant Temperature Switch
6. Low Oil Pressure Switch
7. Fuel Shutoff Solenoid, Cummins 3306 (part of engine assembly)
8. Fuel Shutoff Solenoid, Cummins ISB and ISC (part of engine assembly)

Fig. 4, Engine Protection System Components (Left-Hand-Drive Shown, Right-Hand-Drive Similar)

Start

With the key in the "Start" position, the fuel shutoff solenoid is energized by circuit 669 (R/BL) from the starter relay on vehicles equipped with the Cummins ISB or ISC engines. On vehicles equipped with the Caterpillar 3306 engine, the fuel shutoff solenoid is energized by circuit 932 (BL) when the engine alarm/shutdown module activates the fuel shutoff relay coil through circuit 720 (BL), allowing circuit 932 (BL) to

close through the relay contacts to circuit 69 (R/GN). The solenoid pulls the shutoff lever to the open position and the engine receives fuel through the fuel distributor.

Run

When the key returns to the "Run" position, the starter relay and circuit 669 (R/BL) are de-energized on the Cummins ISB and ISC engines. The fuel shutoff solenoid remains energized through circuit 932 (BL) in the same manner that the Caterpillar 3306 engine is energized and held activated. The engine alarm/shutdown module activates the fuel shutoff relay by applying battery voltage to circuit 720 (BL). This activates the fuel shutoff relay, allowing battery voltage to be applied to circuit 932 (BL) through circuit 69 (R/GN) when the relay contacts close.

Shutoff

NOTE: Turning off power to the engine alarm/shutdown system (key off) resets the system, and the sequence of events can be repeated.

When the key is turned to the "Off" position, current to the fuel shutoff relay coil is cut off, the relay is de-energized and the relay contacts open. This de-energizes the fuel shutoff solenoid, the fuel shutoff lever returns to the "Off" position, fuel flow is cut off and the engine stops.

Automatic Shutoff With the Engine Shutdown System

If the engine alarm/shutdown module receives a low oil pressure, high oil temperature, high coolant temperature or low coolant level input, the module will immediately sound the audible warning and, after a 30 to 40 second delay, interrupt the voltage supply to circuit 720 (BL). This de-energizes the fuel shutoff relay, cutting off current to the fuel shutoff solenoid. The shutoff lever moves to the "Off" position and the engine stops running.

Prove-Out Mode

All four engine protection warning lamps will illuminate when the starter is engaged.

Low Oil Pressure Detection

NOTE: At extremely cold temperatures, with a high viscosity oil, the engine shutdown system can activate the engine alarm/shutdown module before the engine has a chance to start.

The oil pressure switch is normally closed. The presence of adequate oil pressure opens the switch, thereby turning off the oil pressure warning indicator lamp and the audible warning. When oil pressure is insufficient, the oil pressure switch remains closed, grounding the oil pressure warning indicator lamp circuit and the engine alarm/shutdown circuit. The indicator lamp illuminates and the audible warning sounds. If the circuit is grounded for 30 to 40 seconds, the engine alarm/shutdown module opens the power circuit for the fuel shutoff relay coil and the engine shuts down.

High Oil Temperature Detection

The oil temperature switch is normally open. If the oil temperature exceeds the design parameter, the switch closes, grounding the oil temperature warning indicator lamp circuit and the engine alarm/shutdown circuit. The indicator lamp illuminates and the engine alarm/shutdown module sounds the audible warning. If the circuit is activated (grounded) for 30 to 40 seconds, the engine alarm/shutdown module opens the power circuit for the fuel shutoff relay coil and the engine shuts down.

High Coolant Temperature Detection

The coolant temperature switch is normally open. If the coolant temperature exceeds the design parameter, the switch closes, grounding the coolant temperature warning indicator lamp circuit and the engine alarm/shutdown circuit. The indicator lamp illuminates and the engine alarm/shutdown module sounds the audible warning. If the circuit is activated (grounded) for 30 to 40 seconds, the engine alarm/shutdown module opens the power circuit for the fuel shutoff relay coil and the engine shuts down.

Low Coolant Level Detection

NOTE: The resistance value of pure antifreeze (without water mix) is high and the sensor can indicate a low level if it is submerged in pure antifreeze. During a system refill, mix the antifreeze with water in the proper ratio before adding it to the coolant reservoir. See **Group 20** of this manual for information on refilling the cool-

General Information

ing system and for information on antifreeze mixture ratios.

The engine alarm/shutdown module monitors the resistance between the tip of the low coolant sensor and the threaded base of the sensor. If the coolant level drops far enough so that the sensor is no longer submerged in coolant mixture, the engine alarm/shutdown module registers the increase in resistance (air has a much higher resistance than coolant). After a short delay of one to three seconds, the engine alarm/shutdown module grounds the coolant level warning indicator lamp circuit and the engine alarm/shutdown module circuit. The coolant level warning indicator lamp is illuminated and the engine alarm/shutdown module sounds the audible warning. If the low coolant level sensor circuit remains at a high resistance for 30 to 40 seconds, the engine alarm/shutdown module opens the power circuit to the fuel shutoff relay coil and the engine shuts down.

Electronic Instrument Cluster Removal and Installation

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the air system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the air system.
3. Remove the driver side finish panel. see **Section 60.01** for instructions.
4. Remove the screws from the instrument cluster. See **Fig. 1**.

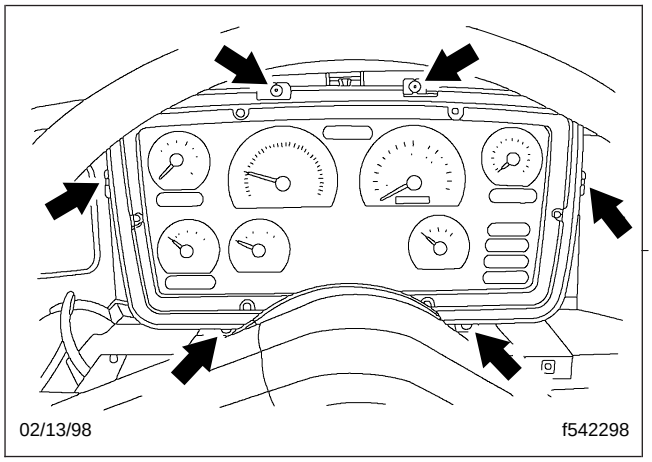


Fig. 1, Instrument Cluster Screws

NOTE: The pneumatic lines are of the quick-release type.

5. Tilt the cluster outward and disconnect the electrical connectors. See **Fig. 2**.
6. Disconnect the air pressure lines. See **Fig. 3**.
7. Remove the oil pressure line and remove the cluster. See **Fig. 4**.

Installation

1. Install the oil pressure line. See **Fig. 4**.

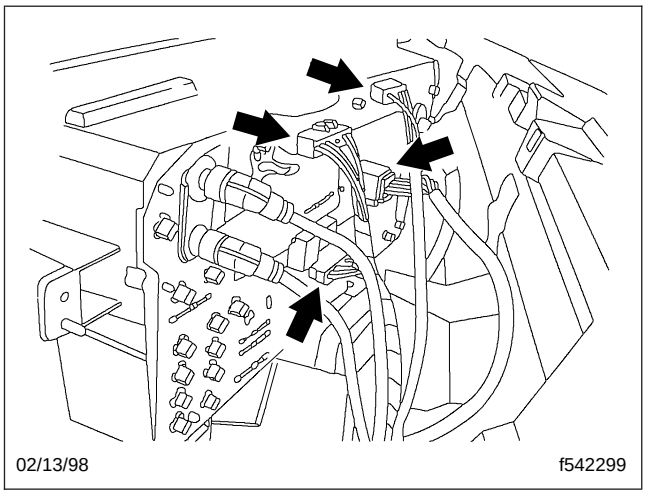

Fig. 2, Instrument Cluster Electrical Connectors

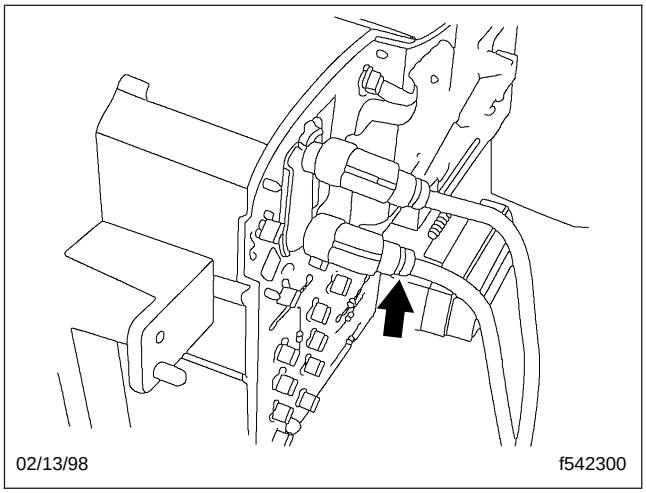

Fig. 3, Air Pressure Lines

2. Connect the air pressure lines. See **Fig. 3**.
3. Connect the electrical connectors. See **Fig. 2**.
4. Install the instrument cluster and tighten the screws. See **Fig. 1**.
5. Install the driver side finish panel. See **Section 60.01** for instructions.
6. Remove the chocks from the tires.

Electronic Instrument Cluster Removal and Installation

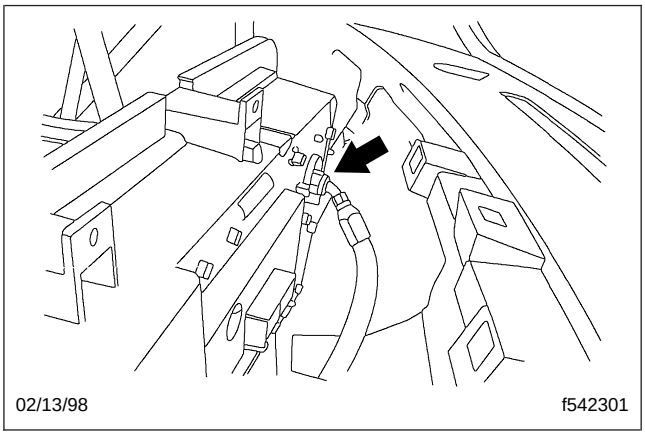

Fig. 4, Oil Pressure Line

Non-Electronic Instrument Cluster Removal and Installation

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the driver side finish panel. See **Section 60.01** for instructions.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the air system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

3. Drain the air system.
4. Remove the screws from the instrument cluster housing. See **Fig. 1**.

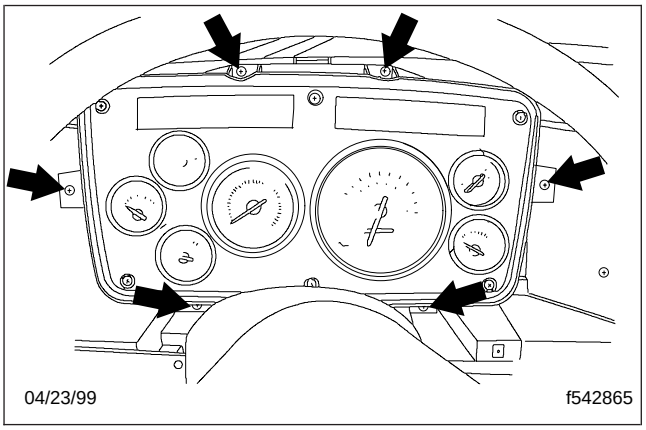

Fig. 1, Instrument Cluster Housing Screws

NOTE: The pneumatic lines are of the quick-release type.

5. Tilt the cluster outward and disconnect the electrical connectors. See **Fig. 2**.
6. Disconnect the air pressure lines. See **Fig. 3**.
7. Disconnect the oil pressure line and remove the cluster. See **Fig. 4**.

Installation

1. Connect the oil pressure line. See **Fig. 4**.
2. Connect the air pressure lines. See **Fig. 3**.

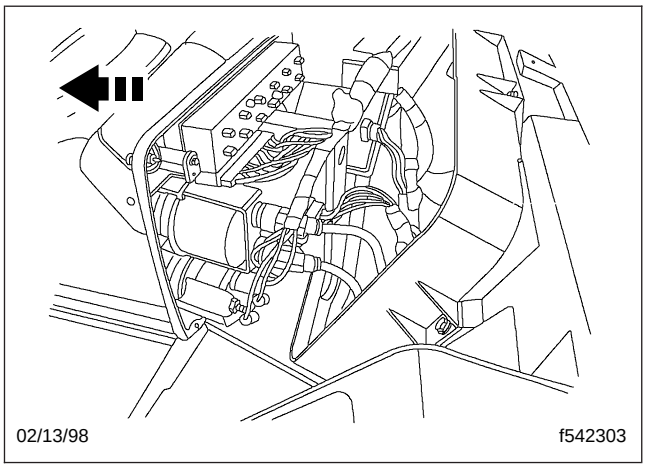

Fig. 2, Instrument Cluster Electrical Connectors

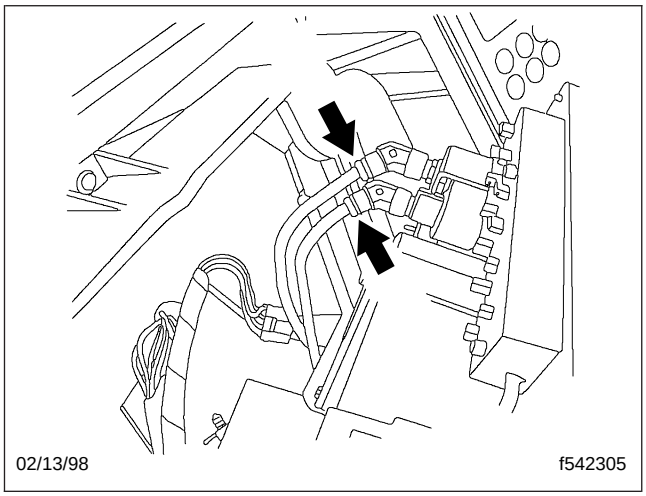

Fig. 3, Air Pressure Lines

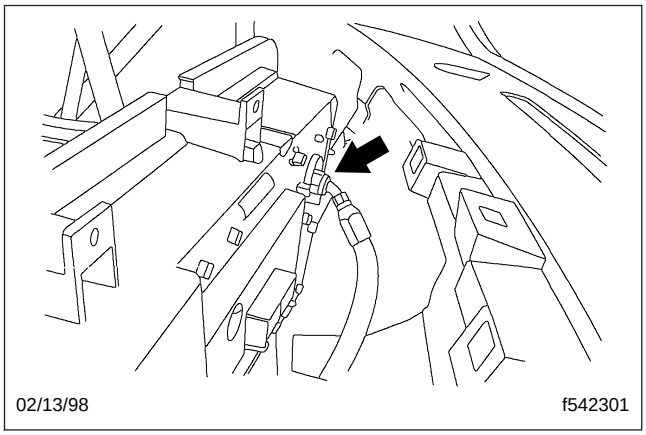

Fig. 4, Oil Pressure Line

Non-Electronic Instrument Cluster Removal and Installation

3. Connect the electrical connectors. See **Fig. 2**.
4. Install the instrument cluster and tighten the housing screws. See **Fig. 1**.
5. Install the driver side finish panel. See **Section 60.01** for instructions.
6. Remove the chocks from the tires.

Electronic Instrument Cluster Gauges Removal and Installation

Oil Pressure and Air Pressure Gauges

REMOVAL

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the batteries.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the air system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

3. Drain the air system.
4. Remove the instrument cluster. For instructions, see **Subject 100**.
5. Disconnect the oil and air lines.
6. Remove the instrument cluster lens and mask assembly.
7. Remove the gauge.

INSTALLATION

1. Connect the electrical connector.
2. Connect the air lines.
3. Install the gauge.

⚠ CAUTION

Before replacing the lens/mask assembly, carefully move the speedometer and tachometer pointers above zero to avoid pointer damage.

4. Install the instrument cluster, then install the instrument cluster lens and mask assembly. For instructions, see **Subject 100**.
5. Engage the quarter-turn fasteners. See **Fig. 1**.
6. Connect the batteries.
7. Remove the chocks from the tires.

Speedometer, Tachometer, Coolant Temperature, Voltmeter, and Fuel Gauges

REMOVAL

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the batteries.
3. Release the quarter-turn fasteners from the instrument cluster. See **Fig. 1**.

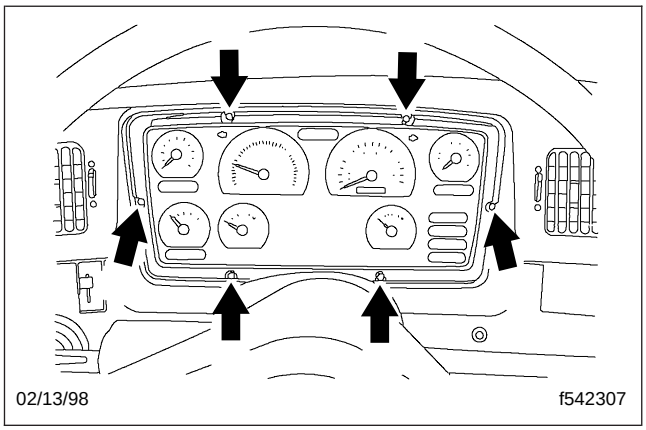

Fig. 1, Quarter-Turn Fasteners

4. Remove the instrument cluster lens and mask assembly. See **Fig. 2**.

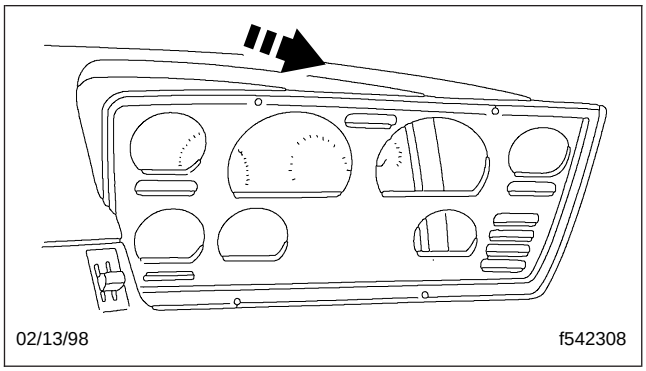

Fig. 2, Instrument Cluster Lens and Mask Assembly

5. Pull the gauge outward. See **Fig. 3**.

Electronic Instrument Cluster Gauges Removal and Installation

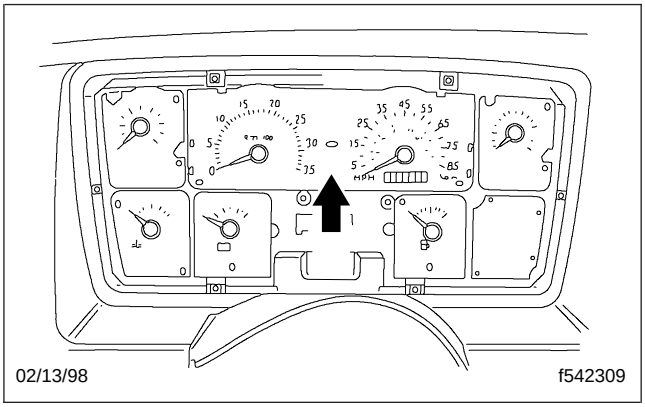

Fig. 3, Speedometer/Tachometer Assembly

6. Disconnect the electrical connector and remove the speedometer/tachometer assembly. See **Fig. 4**.

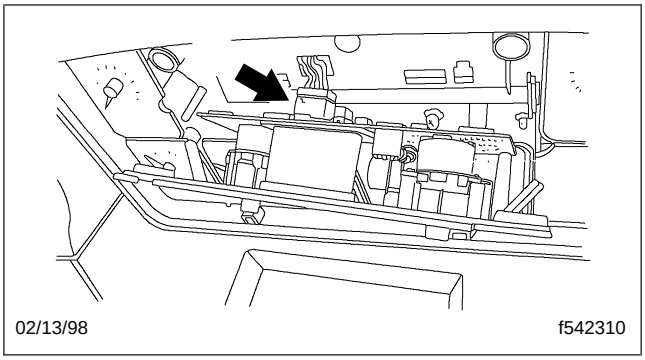

Fig. 4, Speedometer/Tachometer Electrical Connector

INSTALLATION

1. Connect the electrical connector and install the speedometer/tachometer assembly. See **Fig. 4**.

NOTE: Make sure the warning indicator lamp tubes are properly aligned when inserting the gauges.

⚠ CAUTION

Before replacing the lens/mask assembly, carefully move the speedometer and tachometer pointers above zero to avoid pointer damage.

2. Install the instrument cluster lens and mask assembly. See **Fig. 2**.
3. Engage the quarter-turn fasteners. See **Fig. 1**.
4. Connect the batteries.
5. Remove the chocks from the tires.

Non-Electronic Instrument Cluster Gauges Removal and Installation

Fuel Gauge

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the air system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the air system.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.

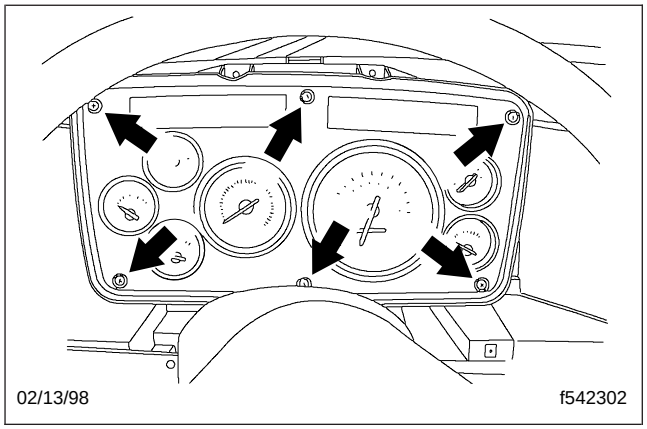

Fig. 1, Quarter-Turn Fasteners

5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the electrical to the fuel gauge.
7. Disconnect the bracket nuts and the fasteners. See **Fig. 3**.
8. Remove the fuel gauge through the front of the instrument cluster. See **Fig. 4**.

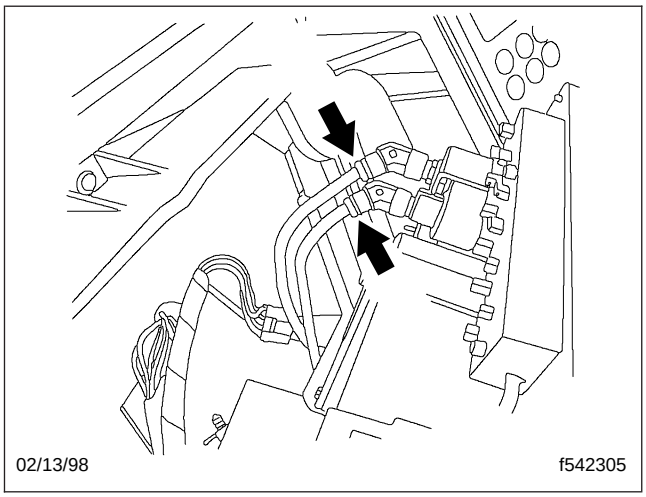

Fig. 2, Air Pressure Gauge Air Lines

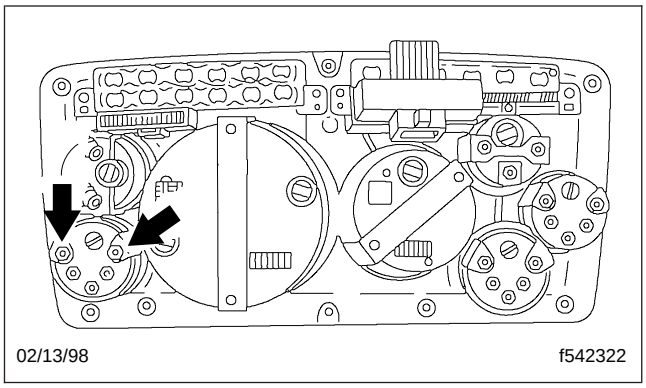

Fig. 3, Fuel Gauge Fasteners

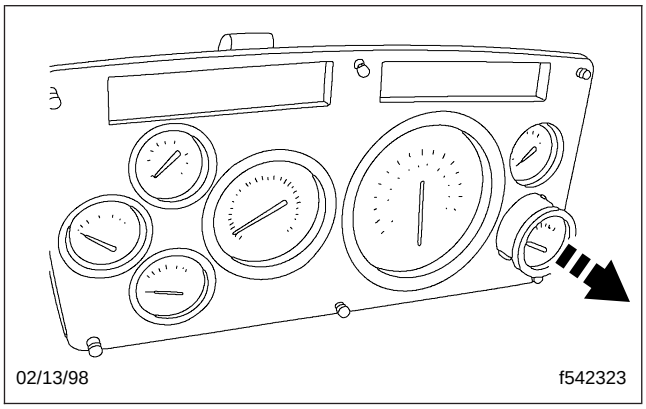

Fig. 4, Fuel Gauge

Non-Electronic Instrument Cluster Gauges Removal and Installation

INSTALLATION

NOTE: Align the fuel gauge locating key to the instrument cluster slot.

1. Install the fuel gauge through the front of the instrument cluster.
2. Install and tighten the bracket nuts.
3. Connect the electrical.
4. Connect the air lines.
5. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
6. Connect the battery.
7. Remove the chocks from the tires.

Voltmeter Gauge

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the seating system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the vehicle air reservoirs.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.
5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the electrical to the voltmeter gauge.
7. Disconnect the bracket nuts and remove the fasteners. See **Fig. 5**.
8. Remove the voltmeter gauge through the front of the instrument cluster. See **Fig. 6**.

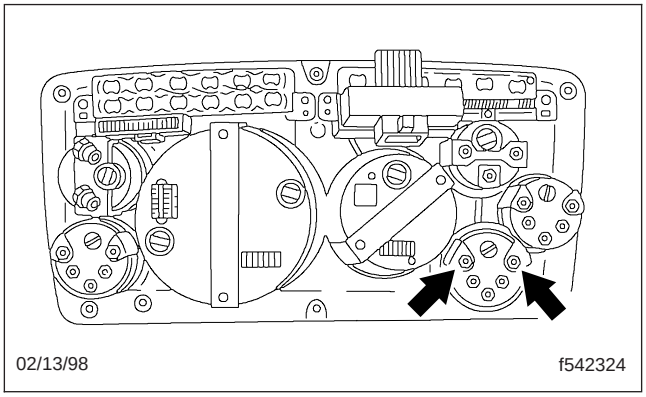

Fig. 5, Voltmeter Fasteners

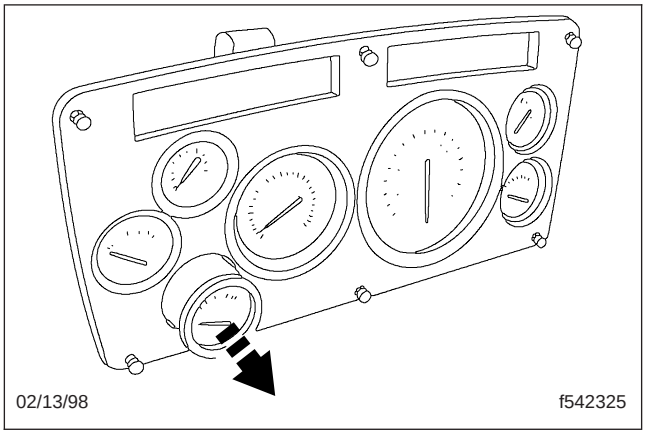

Fig. 6, Voltmeter Gauge

INSTALLATION

NOTE: Align the voltmeter gauge locating key to the instrument cluster slot.

1. Install the voltmeter gauge.
2. Install and tighten the bracket nuts.
3. Connect the electrical.
4. Connect the air lines.
5. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
6. Connect the battery.
7. Remove the chocks from the tires.

Non-Electronic Instrument Cluster Gauges Removal and Installation

Coolant Temperature Gauge

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the seating system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the vehicle air reservoirs.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.
5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the electrical to the coolant temperature gauge.
7. Disconnect the bracket nuts and fasteners. See **Fig. 7**.

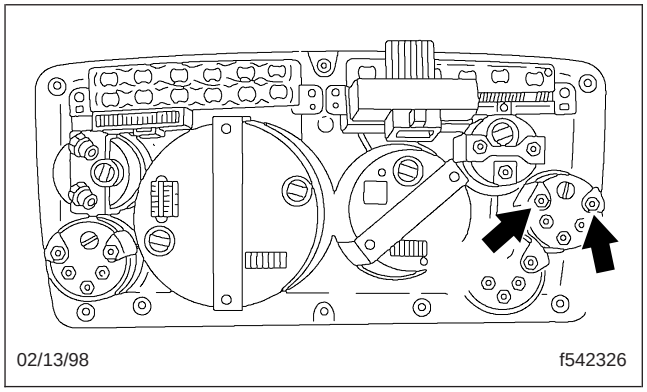

Fig. 7, Coolant Temperature Gauge Fasteners

8. Remove the coolant temperature gauge through the front of the instrument cluster. See **Fig. 8**.

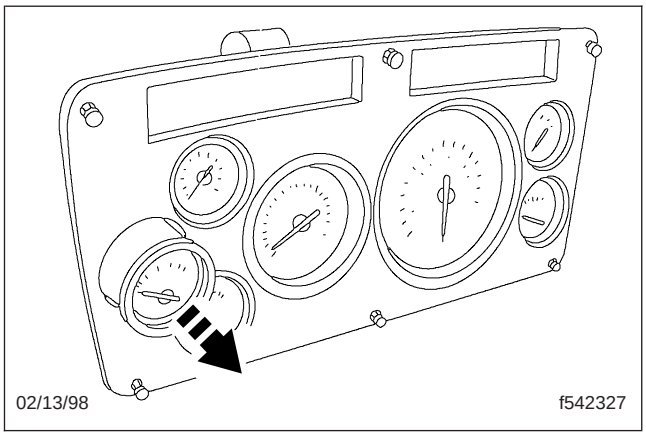

Fig. 8, Coolant Temperature Gauge

INSTALLATION

NOTE: Align the coolant temperature gauge locating key to the instrument cluster slot.

1. Install the coolant temperature gauge.
2. Install and tighten the bracket nuts.
3. Connect the electrical.
4. Connect the air lines.
5. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
6. Connect the battery.
7. Remove the chocks from the tires.

Oil Pressure Gauge

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the seating system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

Non-Electronic Instrument Cluster Gauges Removal and Installation

2. Drain the vehicle air reservoirs.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.
5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the electrical to the oil pressure gauge.
7. Disconnect the oil pressure line. See **Fig. 9**.

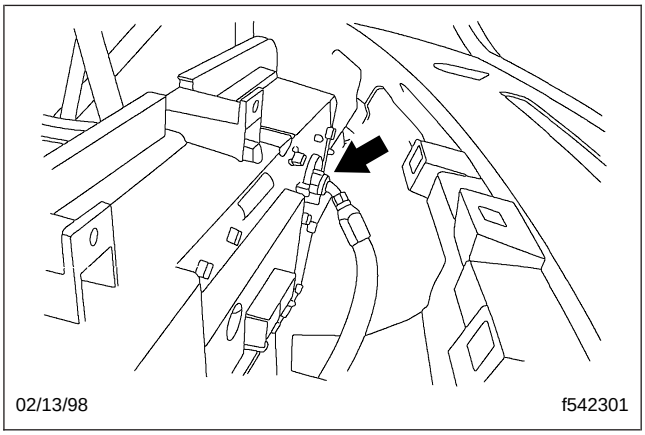

Fig. 9, Oil Pressure Line

8. Disconnect the bracket nuts and remove the fasteners. See **Fig. 10**.

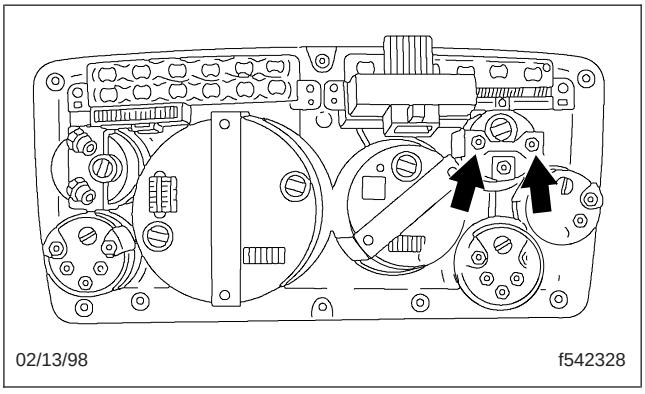

Fig. 10, Oil Pressure Gauge Fasteners

9. Remove the oil pressure gauge through the front of the instrument cluster. See **Fig. 11**.

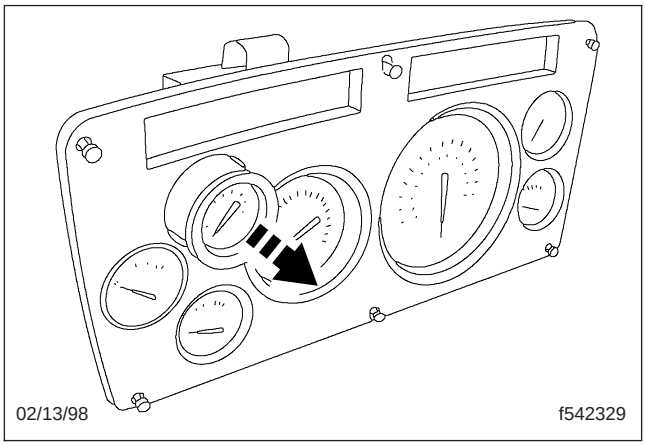

Fig. 11, Oil Pressure Gauge

INSTALLATION

NOTE: Align the oil pressure gauge locating key to the instrument cluster slot.

1. Install the oil pressure gauge.
2. Install and tighten the bracket nuts.
3. Connect the electrical.
4. Connect the air lines.
5. Connect the oil pressure line. See **Fig. 9**.
6. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
7. Connect the battery.
8. Remove the chocks from the tires.

Air Pressure Gauge

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the seating system. Failure to re-

Non-Electronic Instrument Cluster Gauges Removal and Installation

lieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the vehicle air reservoirs.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.
5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the air fittings from the air pressure gauge. See **Fig. 12**.

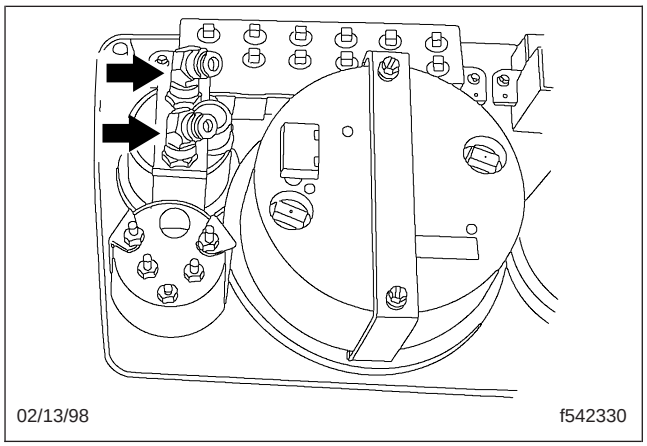

Fig. 12, Air Pressure Fittings

7. Disconnect the electrical to the air pressure gauge.
8. Remove the fasteners. See **Fig. 13**.

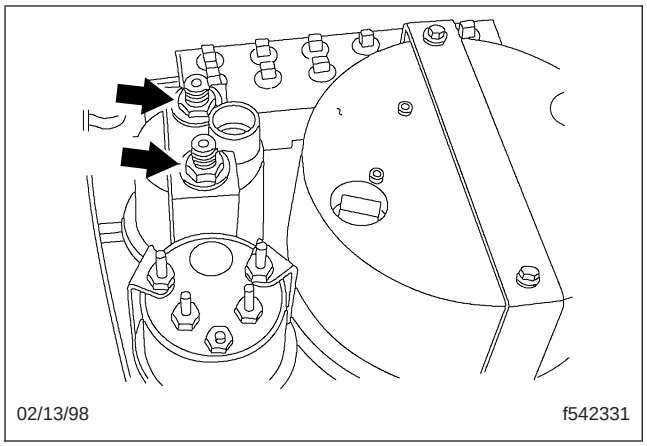

Fig. 13, Air Pressure Gauge Fasteners

9. Remove the air pressure gauge through the front of the instrument cluster. See **Fig. 14**.

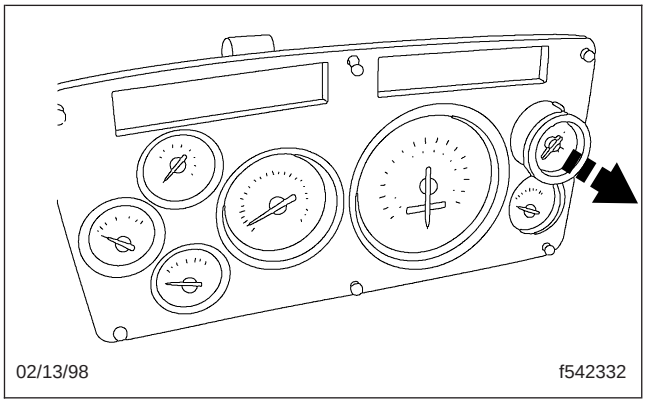

Fig. 14, Air Pressure Gauge

INSTALLATION

NOTE: Align the air pressure gauge locating key to the instrument cluster slot.

1. Install the air pressure gauge.
2. Slide the bracket over the bottom of the gauge.
3. Install the bracket nuts and fasteners. See **Fig. 13**.
4. Install the air pressure fittings. See **Fig. 12**.
5. Connect the electrical.
6. Connect the air lines.
7. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
8. Connect the battery.
9. Remove the chocks from the tires.

Speedometer

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

Non-Electronic Instrument Cluster Gauges Removal and Installation

WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the seating system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the vehicle air reservoirs.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.
5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the electrical to the speedometer.
7. Remove the two screws from the bracket and remove the bracket. See **Fig. 15**.

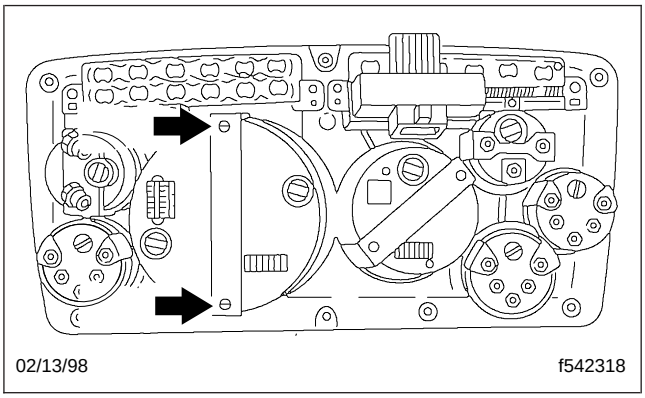

Fig. 15, Speedometer Fasteners

8. Remove the speedometer through the front of the instrument cluster. See **Fig. 16**.
9. Calibrate the speedometer. Refer to **Subject 170** for instructions.

INSTALLATION

NOTE: Align the speedometer locating key to the instrument cluster slot.

1. Install the speedometer through the front of the instrument cluster.
2. Install and tighten the bracket screws. See **Fig. 15**.
3. Connect the electrical.

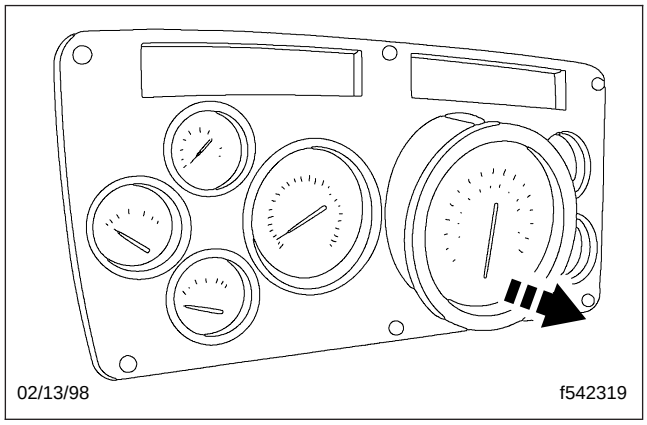

Fig. 16, Speedometer

4. Connect the air lines.
5. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
6. Connect the battery.
7. Remove the chocks from the tires.

Tachometer Gauge

REMOVAL

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.

WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the seating system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

2. Drain the vehicle air reservoirs.
3. Disconnect the battery.
4. Loosen the six quarter-turn screws and pull the instrument cluster forward. See **Fig. 1**.
5. Disconnect the air lines from the air pressure gauge. See **Fig. 2**.
6. Disconnect the electrical to the tachometer.

7. Remove the two screws from the bracket and remove the bracket. See **Fig. 17**.

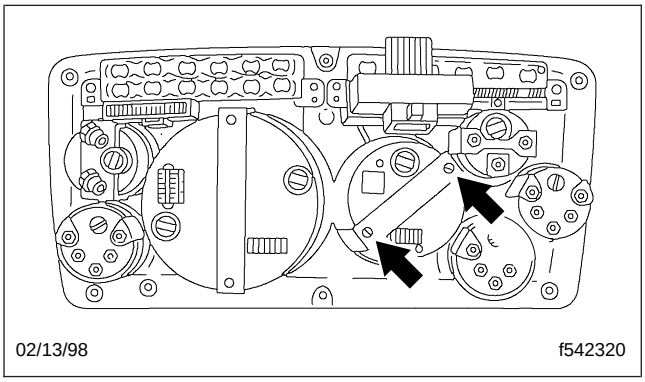

Fig. 17, Tachometer Fasteners

8. Remove the speedometer through the front of the instrument cluster. See **Fig. 18**.

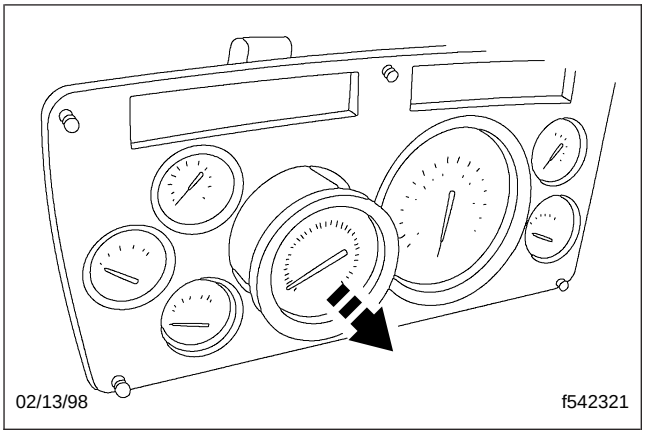

Fig. 18, Tachometer

9. Calibrate the tachometer. See **Subject 170** for instructions.

INSTALLATION

NOTE: Align the tachometer locating key to the instrument cluster slot.

1. Install the tachometer through the front of the instrument cluster.
2. Install and tighten the bracket screws. See **Fig. 17**.
3. Connect the electrical.
4. Connect the air lines.
5. Insert the instrument cluster and tighten the quarter-turn screws. See **Fig. 1**.
6. Connect the battery.
7. Remove the chocks from the tires.

Electronic Instrument Cluster Printed Circuit Removal and Installation

Removal

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the battery.

⚠ WARNING

All air pressure must be relieved from the air reservoirs before disconnecting any pneumatic lines or hoses from the air system. Failure to relieve air pressure could cause the lines to whip, resulting in personal injury.

3. Drain the air system.
4. Remove the instrument cluster. See **Subject 100** for instructions.
5. Remove the lens and mask assembly. See **Fig. 1**.

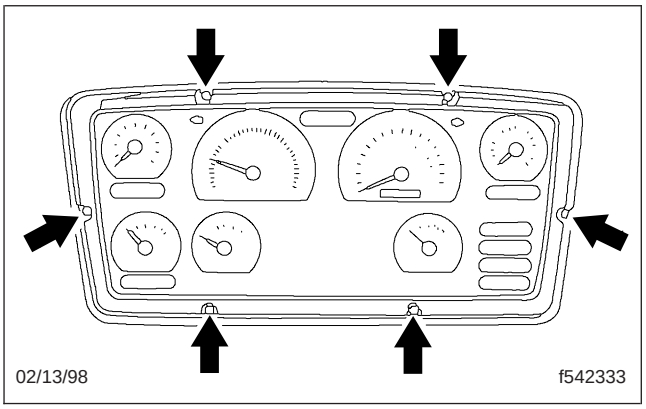

Fig. 1, Lens and Mask Assembly

6. Remove the coolant temperature gauge, the voltmeter gauge, the speedometer/tachometer assembly, and the fuel gauge by pulling the gauges outward. See **Subject 120** for instructions. See **Fig. 2**.
7. Remove the miniature bulbs (maximum of 27). See **Fig. 3**.
8. Disconnect the electrical connector. See **Fig. 4**.
9. Push the gauge terminals through the back of the cluster and remove the instrument cluster printed circuit. See **Fig. 5**.

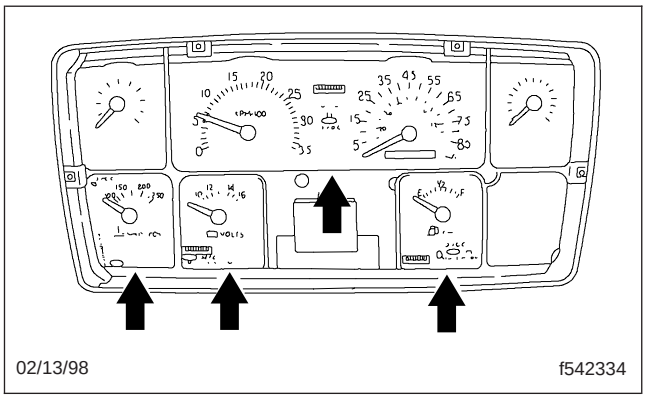

Fig. 2, Gauges

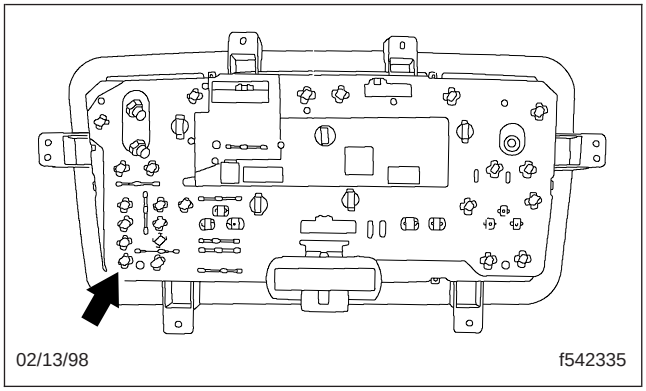

Fig. 3, Miniature Bulbs

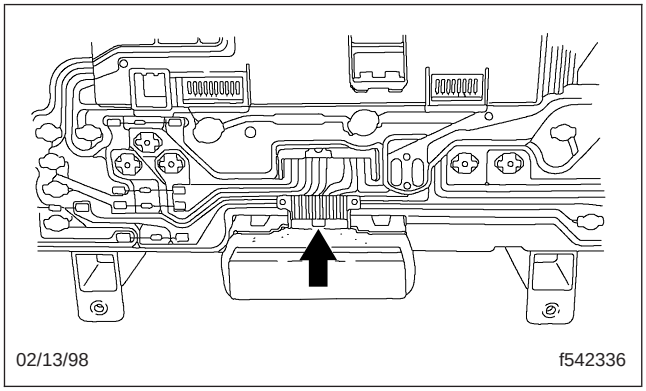

Fig. 4, Instrument Cluster Printed Circuit Electrical Connector

Installation

1. Install the instrument cluster printed circuit. See **Fig. 5**.

Electronic Instrument Cluster Printed Circuit Removal and Installation

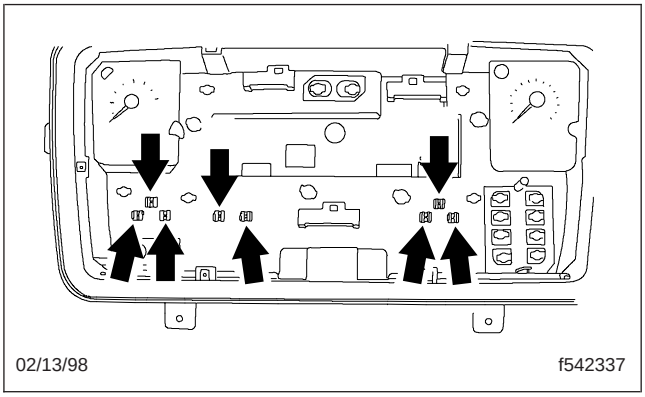

Fig. 5, Gauge Terminals

2. Connect the electrical connector. See **Fig. 4**.
3. Install the miniature bulbs. See **Fig. 3**.

NOTE: Make sure the warning indicator lamp tubes are properly aligned when inserting the gauges.

4. Install the speedometer/tachometer assembly, the fuel gauge, the voltmeter gauge and the coolant temperature gauge. See **Fig. 2**.

⚠ CAUTION

Before replacing the lens/mask assembly, carefully move the speedometer and tachometer pointers above zero to avoid pointer damage.

5. Install the lens and mask assembly. See **Fig. 1**.
6. Install the instrument cluster. See **Subject 100** for instructions.
7. Connect the battery.
8. Remove the chocks from the tires.

Warning Lamp Module Bulb Replacement

Electronic Instrument Cluster

REPLACEMENT

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the battery.
3. Loosen the quarter-turn fasteners.
4. Remove the instrument cluster lens and mask assembly.

NOTE: The warning indicator panel, in the lower right corner of the instrument cluster, is removed in a manner similar to the gauge removal.

NOTE: For replacement of the bulb socket, the instrument cluster must be removed.

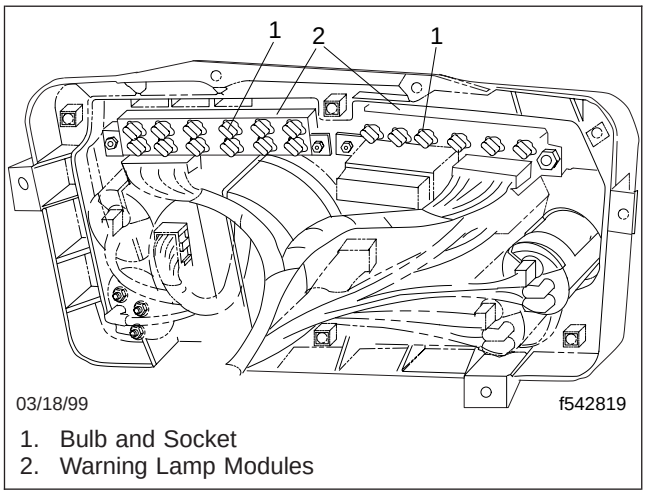
5. It may be necessary to remove more than one gauge to gain access to the desired bulb.

   Grasp the bulb(s) and pull it straight out of the socket.
6. Install the bulb.
7. Install the instrument cluster lens and mask assembly.
8. Tighten the quarter-turn fasteners.

Non-Electronic Instrument Cluster

REPLACEMENT **(See Fig. 1)**

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the battery.
3. Loosen the six quarter-turn screws and pull the instrument cluster forward to reveal the warning lamp modules.
4. Twist the socket counterclockwise approximately a quarter-turn. Pull the bulb out of the warning lamp module. See **Fig. 1**.
5. Twist the socket clockwise a quarter-turn. Insert the bulb into the warning lamp module.



1. Bulb and Socket
2. Warning Lamp Modules

Fig. 1, Bulb and Socket and Warning Lamp Modules

6. Install the instrument cluster and tighten the six quarter-turn screws.
7. Connect the battery.
8. Remove the chocks from the tires.

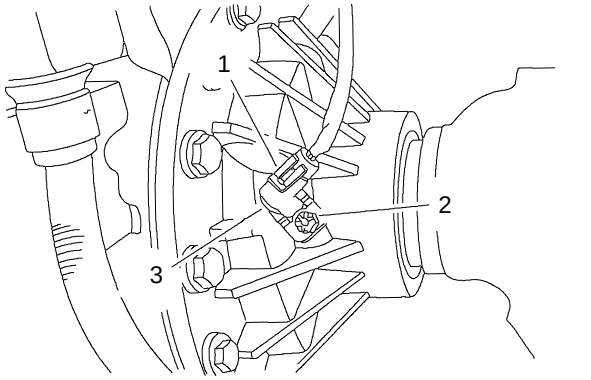
Speedometer Vehicle Speed Sensor (VSS) Replacement

Replacement

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the battery.

NOTE: The vehicle speed sensor (VSS) is located in the transmission housing. Its position in the housing varies depending on the transmission model.

3. Remove the VSS. See **Fig. 1**.



1. Electrical Connector
2. Bolt
3. Vehicle Speed Sensor (VSS)

Fig. 1, Vehicle Speed Sensor (VSS)

3.1 Disconnect the electrical connector.

3.2 Remove the bolt.

3.3 Remove the sensor.

4. Install the VSS.

4.1 Position the sensor.

4.2 Install the bolt.

4.3 Connect the electrical connector.

5. Connect the battery.
6. Remove the chocks from the tires.

Tachometer Calibration

NOTE: The tachometer is calibrated according to the engine type and the number of flywheel teeth. The tachometer can be calibrated by setting the eight dip switches on the back of the tachometer. See **Fig. 1** for the electronic instrument cluster, and **Fig. 2** for the individual gauge instrument cluster. Embossed on the switch are the numbers 1 through 8.

NOTE: A switch is in the "On" position when the switch is pressed towards the number on the top of the switch (settings are listed on the tachometer case label).

1. Determine the number of flywheel teeth from **Table 1**.

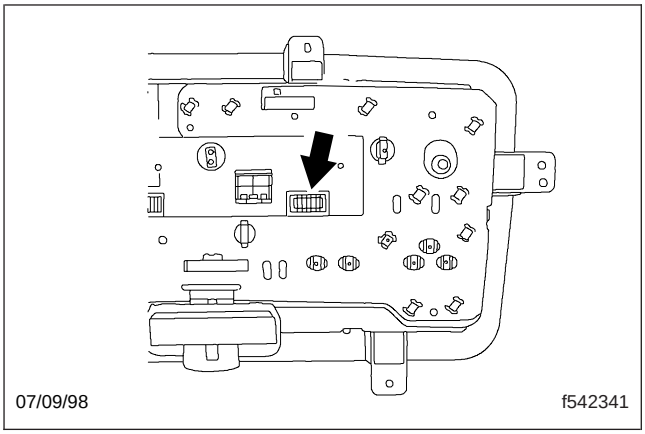


Fig. 1, Electronic Instrument Cluster Eight-Pin Tachometer Dip Switch

Flywheel Teeth	
Engine Type	**Flywheel Teeth**
Cummins M11, N14	103
Caterpillar 3306	156
Caterpillar C10, C12, 3406 (electronic speed output present)	113
Detroit Diesel	118

Table 1, Flywheel Teeth

2. Determine the test frequency required to produce any rpm by using the following equation:

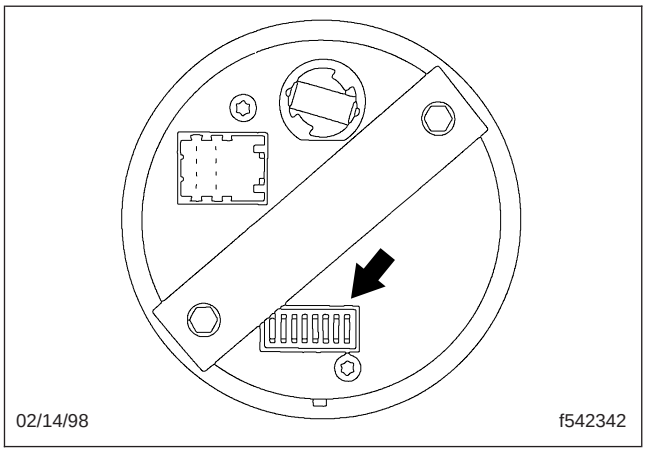

Fig. 2, Non-Electronic Instrument Cluster Eight-Pin Tachometer Dip Switch

Test Frequency = rpm x (Flywheel Teeth/60).

3. Place the switches in either the "On" or "Off" position, depending on the engine type.

NOTE: Electronic engines usually have a separate engine speed output. This output provides 12 pulses per revolution:

4. Refer to the following list for switch settings for the 12 pulse per revolution signal:
   - S1, Off
   - S2, Off
   - S3, Off
   - S4, Off
   - S5, On
   - S6, On
   - S7, Off
   - S8, Off
   - Frequency at 1/2 scale (Hz.), 300
5. Refer to the "Tachometer Dip Switch Setting Chart" in **Specifications, 400** for correct calibration given the number of flywheel teeth and the test frequency at half-scale in hertz.

Speedometer Calibration

NOTE: Periodic inspection of the vehicle speed sensor (VSS) is necessary to ensure the electronic speedometer system operates accurately. The intervals at which to check the speed sensor in mileage (kilometers) are: 500 (800), 12,500 (20 000), 25,000 (40 000), 37,500 (60 000), 50,000 (80 000). Scheduled maintenance beyond 50,000 miles (80 000 kilometers) is every 50,000 miles (80 000 kilometers).

1. Inspect the vehicle speed sensor (VSS) for metal filings accumulating on the sensor pole face.

   Metal filings that have developed on the sensor pole face must be removed.

NOTE: If the vehicle has a two-speed differential (e.g., 4.15/5.72:1), use the smaller number (4.15 in this case) in all calculations.

2. Determine the rear axle differential ratio by referring to the information delivered with the vehicle or finding the metal tag attached to the differential.

NOTE: Measure to the nearest 1/8 inch, then use **Table 1** to convert eighths to a decimal (if the measurement is done in centimeters, divide the tire height by 2.54 to convert to inches).

NOTE: Example: If the tire height is 36-1/8 inches, use 36.125 in the revolutions per mile calculation.

3. Calculate the revolutions per mile by first measuring the tire height (ground to the top of the tire) in inches with the vehicle on level ground, loaded, with the tires cold and inflated to the recommended pressure.

Eighths to Decimal Conversion	
Fraction	**Decimal**
1/8	0.125
1/4	0.25
3/8	0.375
1/2	0.5
5/8	0.625
3/4	0.75
7/8	0.875

Table 1, Eighths to Decimal Conversion

4. Divide 20,168 (constant) by the tire height to get the revolutions per mile.

   Example: 20,168/36.125 = 558.28

5. Calculate the calibration frequency by multiplying the axle ratio times the revolutions per mile times 0.267 (constant).

   Example: 4.15 x 558.28 x 0.267 = 611.14

6. Refer to the "Speedometer Dip Switch Setting Chart" in **Specifications, 400**, find the "Test Frequency" column and determine the switch settings.

   6.1 A number means the switch is to be placed in the On or closed position and a period (.) means that the switch is to be placed in the Off or open position.

   6.2 Example: If the test frequency is calculated at 358, the chart gives the switch settings as (..34..7.90). This means that switches 3, 4, 7, 9, 10 are On and switches 1, 2, 5, 6, 8 are Off.

7. Calibrate the electronic or individual gauge speedometer, using the dip switches located on the back of the speedometer. See **Fig. 1** for the electronic speedometer. See **Fig. 2** for the individual gauge speedometer.

Speedometer Calibration

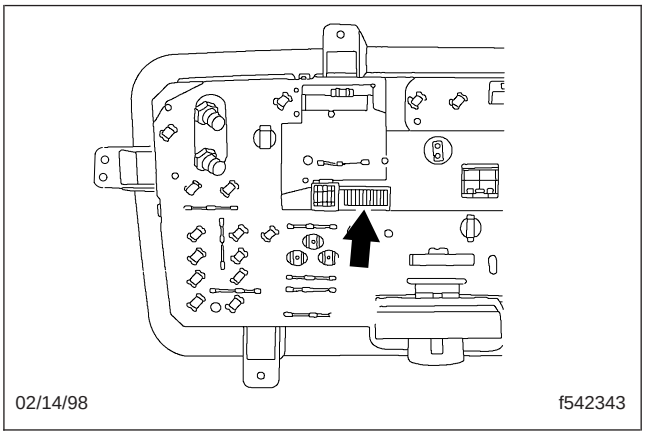

Fig. 1, Electronic Instrument Cluster Speedometer Dip Switch

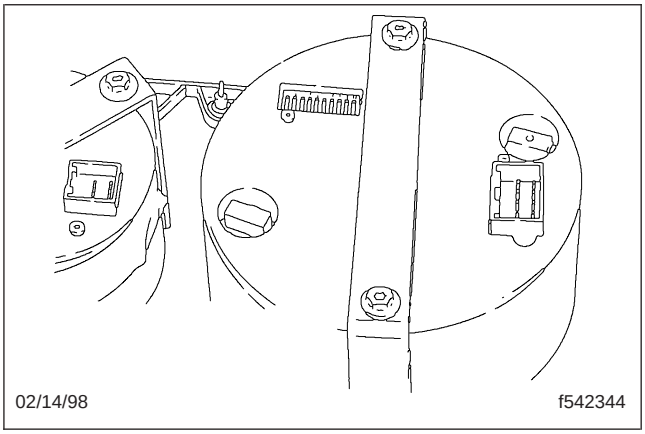

Fig. 2, Non-Electronic Instrument Cluster Speedometer Dip Switch

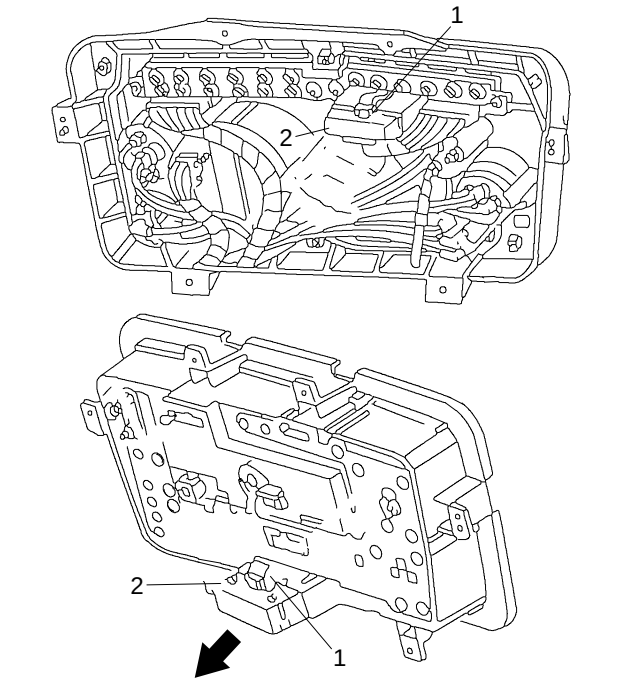
Brake Low Air Pressure Buzzer/Engine Warning Chime/Engine Alarm/Shutdown Module Replacement

Replacement

NOTE: All three types of warning modules are mounted in the same place in the instrument cluster and have the same replacement procedure.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the instrument cluster. For electronic instrument cluster removal instructions, see **Subject 100**. For non-electronic instrument cluster removal instructions, see **Subject 110**.
3. Disconnect the electrical.
4. Remove the module. See **Fig. 1**.



1. Connector
2. Module

Fig. 1, Warning Module

4.1 For the electronic instrument cluster, disconnect the printed circuit electrical connector.

4.2 Remove the module.

5. Install the module.
6. For the electronic instrument cluster, connect the printed circuit connector.
7. Connect the electrical.
8. Install the instrument cluster.
9. Connect the battery.
10. Remove the chocks from the tires.

Auxiliary Instrument Cluster Gauge Replacement

Replacement

NOTE: This procedure is typical and covers left-hand-drive and right-hand-drive vehicles.

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Disconnect the battery.
3. Remove the trailer brake control valve knob. See **Fig. 1**.

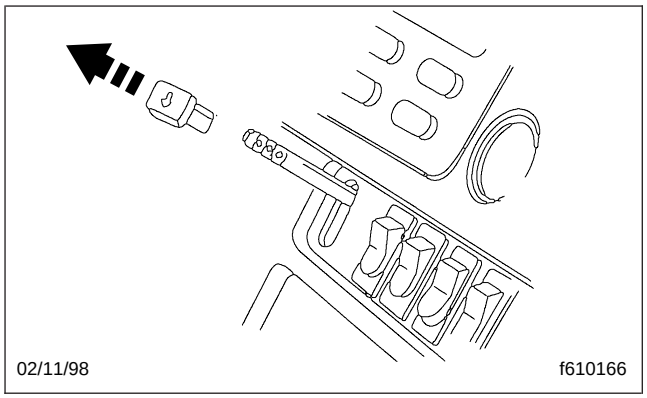


Fig. 1, Trailer Brake Control Valve Knob

4. Remove the screws. See **Fig. 2**.

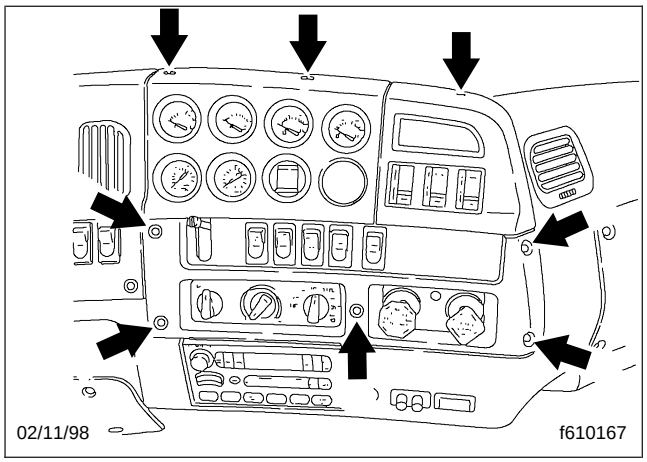

Fig. 2, Auxiliary Finish Panel Screws

5. Tilt the top of the auxiliary finish panel away from the instrument panel cluster to gain access to the gauge retaining bracket and nuts. See **Fig. 3**.
6. Remove the gauge. See **Fig. 4**.

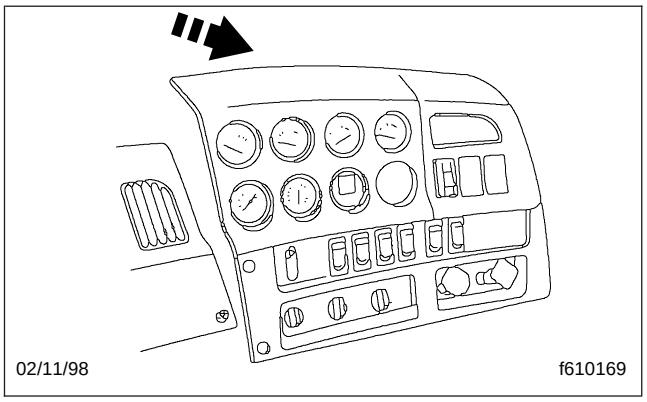

Fig. 3, Auxiliary Finish Panel

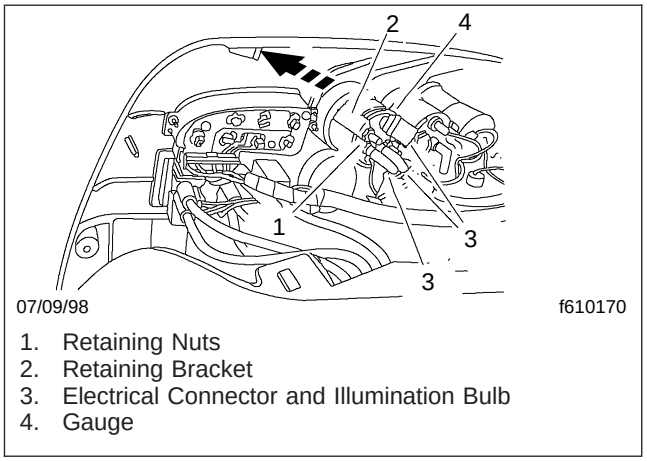

1. Retaining Nuts
2. Retaining Bracket
3. Electrical Connector and Illumination Bulb
4. Gauge

Fig. 4, Auxiliary Instrument Cluster Gauge

6.1 Remove the two retaining nuts.

6.2 Remove the gauge retaining bracket.

6.3 Disconnect the electrical connectors and illumination bulb.

6.4 Pull the gauge out of the auxiliary instrument cluster from the front.

7. Position the gauge.
8. Connect the electrical connector and illumination bulb.
9. Install the gauge retaining bracket and nuts.
10. Install the auxiliary finish panel screws.
11. Install the trailer brake control valve knob.
12. Connect the battery.
13. Remove the chocks from the tires.

Electronic and Non-Electronic Instrument Cluster Illumination Bulb Replacement

Electronic Gauge Instrument Cluster Illumination Bulb Replacement

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Release the quarter-turn fasteners. See **Fig. 1**.

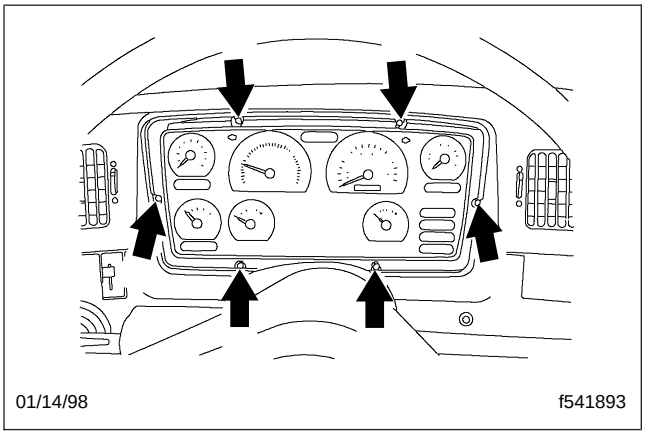

Fig. 1, Quarter-Turn Fasteners

3. Remove the instrument cluster lens and mask assembly. See **Fig. 2**.

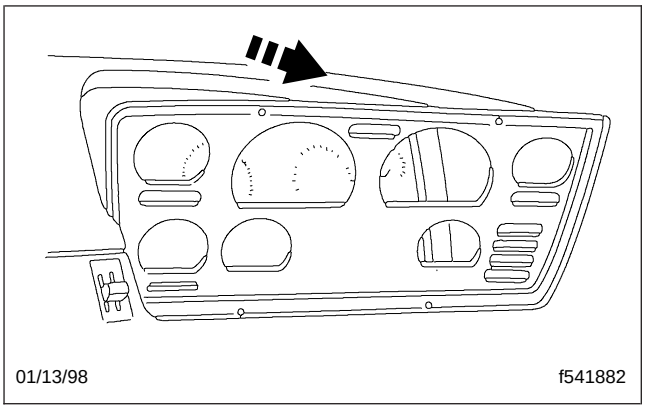

Fig. 2, Instrument Cluster Lens and Mask Assembly

NOTE: If the bulb socket is to be replaced, the instrument cluster must be removed.

4. Pull the gauge outward where the illumination bulb is located.
5. Remove the illumination bulb by twisting and pulling outward.
6. Install the new bulb.
7. Install the gauge.
8. Install the instrument cluster lens and mask assembly.
9. Engage the quarter-turn fasteners.
10. Remove the chocks from the tires.

Non-Electronic Instrument Cluster Illumination Bulb Replacement

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Release the quarter-turn fasteners. See **Fig. 3**.

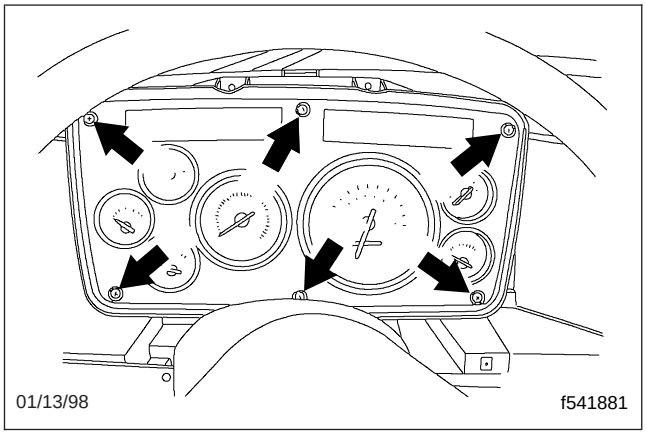

Fig. 3, Quarter-Turn Fasteners

NOTE: Each gauge has its own illumination bulb.

3. Tilt the instrument cluster outward to gain access to the bulb(s).
4. Remove the burned out bulb.
5. Install the new bulb.
6. Install the instrument cluster.
7. Engage the quarter-turn fasteners.
8. Remove the chocks from the tires.

Electronic and Non-Electronic Instrument Cluster Illumination Bulb Replacement

Auxiliary Instrument Cluster Illumination Bulb Replacement

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the trailer brake control valve knob by pulling it straight out. See **Fig. 4**.

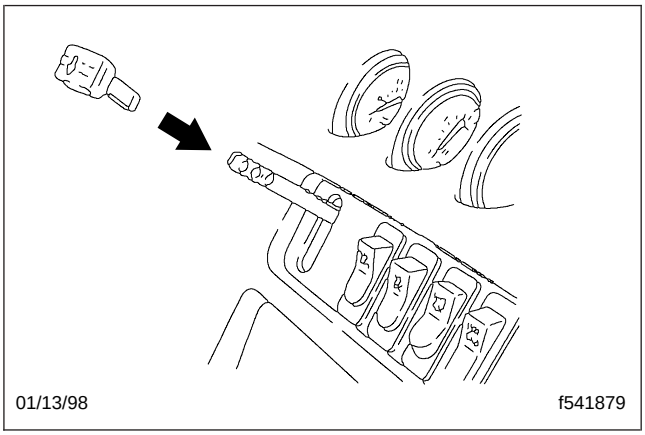

Fig. 4, Trailer Brake Control Valve Knob

3. Remove the screws. See **Fig. 5**.

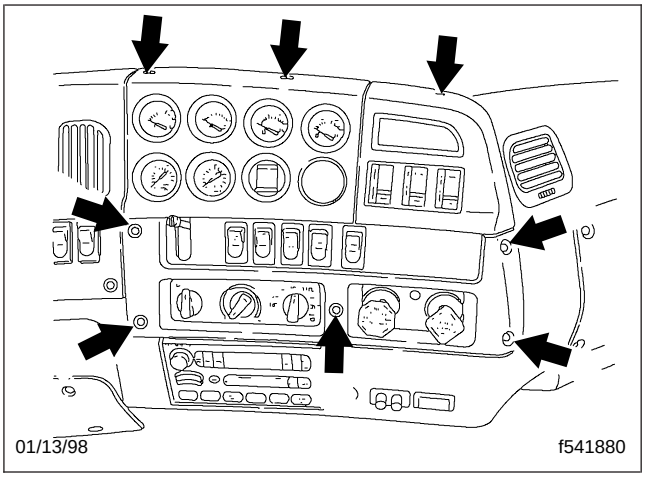

Fig. 5, Auxiliary Finish Panel Screws

NOTE: Each gauge has its own illumination bulb.

4. Tilt the auxiliary instrument cluster outward to gain access to the bulb(s).
5. Remove the burned out bulb.
6. Install the new bulb.
7. Install the auxiliary finish panel.
8. Install the trailer brake control valve knob.
9. Remove the chocks from the tires.

Troubleshooting

Inspection and Verification

1. Verify the vehicle owner's concern by duplicating the original concern. Verify speedometer/ odometer operation by road testing the vehicle.
2. Verify the components or systems related to the fuse for proper operation. If the components or systems are not operating properly, the fuse(s), fuse feed circuit(s) or fuse load side circuit(s) may be the cause.
3. If the concern(s) remains after the inspection, determine the possible causes and proceed to the following problem charts.

Troubleshooting

Problem—Incorrect Fuel Gauge Indication (Electronic Instrument Cluster)

Problem—Incorrect Fuel Gauge Indication (Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Fuse	See **Fig. 1, Fig. 2, Fig. 3, and Fig. 4**. Check Circuit 976 (BL/GN). Turn the ignition switch to the "Off" position and disconnect the electronic instrument cluster connector. Turn the ignition switch to the "On" position and measure the voltage between the electronic instrument cluster connector C231 Pin 12, Circuit 976 (BK/GN) and ground. If the voltage is not greater than 10 volts, repair Circuit 976 (BK/GN) between the splice and the electronic instrument cluster connector. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 25 (BK/O).
Circuitry open or shorted	Turn the ignition switch to the "Off" position. Measure the resistance between the electronic instrument cluster connector C231 Pin 9, Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 286 (O) for an open.
Fuel level sensor arm is damaged	Disconnect the fuel level sensor connector. Measure the resistance between the fuel level sensor connector C413 Circuit 286 (O) and the electronic instrument cluster connector C231 Pin 10, Circuit 286 (O). If the resistance is more than 5 ohms, repair Circuit 286 (O) between the electronic instrument cluster connector C231 and the fuel level sensor connector C413. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 286 (O) for a short to ground.
Damaged gauge	Measure the resistance between the fuel level sensor connector C413 Circuit 286 (O) and ground. If the resistance is less than 10,000 ohms, repair Circuit 286 (O) between the electronic instrument cluster connector C231 and the fuel level sensor connector C413. Test the system for normal operation. If the resistance is more than 10,000 ohms, check the ground for the fuel level sensor.
Resistor element worn or damaged	Measure the resistance between the fuel level sensor connector C413 Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the fuel level sensor connector C413 and ground. Test the system for normal operation. If the resistance is less than 5 ohms, check the instrument cluster printed circuit voltage supply.
Leaking fuel level sensor float	Connect the electronic instrument cluster connector C231. Remove the fuel gauge. See **Subject 130** for instructions. Turn the ignition switch to the "On" position. Measure the voltage between the voltage supply terminal to the fuel gauge (top terminal) and ground. If the voltage is less than 10 volts, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the voltage is more than 10 volts, check the instrument cluster printed circuit ground supply.
	Turn the ignition switch to the "Off" position. Measure the resistance between the fuel gauge ground terminal (right terminal) and ground. If the resistance is more than 5 ohms, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the resistance is less than 5 ohms, check the printed circuit.

Problem—Incorrect Fuel Gauge Indication (Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Fuse	Disconnect the electronic instrument cluster connector. Taking care not to damage the printed circuit, measure the resistance between the printed circuit connection to the electronic instrument cluster connector C231 Pin 10 and the fuel gauge signal return terminal (left terminal). If the resistance is more than 5 ohms, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the resistance is less than 5 ohms, install the fuel gauge and test the fuel gauge. Connect the electronic instrument cluster connector C231. Using the instrument gauge system tester, connect one lead of the tester to the fuel level sensor connector C413 Circuit 286 (O) and connect the other lead to ground. Set the tester to the 270-ohm scale and wait one minute. The fuel gauge should read E (empty). Set the tester to the 18-ohm scale and wait one minute. The fuel gauge should read F (full). If the fuel gauge does not perform as specified, replace the fuel gauge. Test the system for normal operation. If the fuel gauge performs as specified, inspect the fuel tank for any signs of distortion or damage. If the fuel tank is damaged, replace the fuel tank. See **Group 47**. If the fuel tank is not damaged, replace the fuel level sensor. See **Group 47**.
Circuitry open or shorted	
Fuel level sensor arm is damaged	
Damaged gauge	
Resistor element worn or damaged	
Leaking fuel level sensor float	

Problem—Incorrect Voltage Gauge Indication (Electronic Instrument Cluster)

Problem—Incorrect Voltage Gauge Indication (Electronic Instrument Cluster) **(See Fig. 5 and Fig. 6)**	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Turn the ignition switch to the "Off" position. Disconnect the electronic instrument cluster connector. Turn the ignition switch to the "On" position and measure the voltage between the electronic instrument cluster connector C232 Pin 7, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the electronic instrument cluster connector. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 25 (BK/O). Turn the ignition switch to the "Off" position. Measure the resistance between the electronic instrument cluster connector C232 Pin 8, Circuit (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check the voltage supply to the voltmeter. Connect the electronic instrument cluster connector C232. Remove the voltmeter gauge. See **Subject 130** for instructions. Turn the ignition switch to the "Off" position. Measure the voltage between the left voltmeter terminal (instrument cluster side) and ground. If the voltage is less than 10 volts, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the voltage is more than 10 volts, check the ground for the voltmeter gauge. Turn the ignition switch to the "Off" position. Measure the resistance between the right voltmeter terminal (instrument cluster side) and ground. If the resistance is less than 5 ohms, replace the voltmeter gauge. Test the system for normal operation. If the resistance is more than 5 ohms, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation.
Circuitry open or shorted	
Incorrect battery voltage	
Damaged gauge	

Troubleshooting

Problem—Incorrect Oil Pressure Gauge Indication (Electronic Instrument Cluster)

Problem—Incorrect Oil Pressure Gauge Indication (Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Plugged or kinked oil pressure line	Check the oil pressure line. Verify the oil pressure line is not plugged, broken or kinked. If the oil pressure line is OK, replace the oil pressure gauge. Test the system for normal operation. If the oil pressure line is not OK, replace the oil pressure line. Test the system for normal operation.
Damaged gauge	

Problem—Incorrect Coolant Temperature Gauge Indication (Electronic Instrument Cluster)

Problem—Incorrect Coolant Temperature Gauge Indication (Electronic Instrument Cluster) (See Fig. 5, Fig. 7, Fig. 8, and Fig. 9)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Turn the ignition switch to the "Off" position. Disconnect the electronic instrument cluster connector. Turn the ignition switch to the "On" position. Measure the voltage between the electronic instrument cluster connector C232 Pin 7, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the electronic instrument cluster connector. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 25 (BK/O). Turn the ignition switch to the "Off" position. Measure the resistance between the electronic instrument cluster connector C232 Pin 8, Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 39 (R/W) for an open. Disconnect the engine coolant temperature sensor connector. Measure the resistance between the engine coolant temperature sensor connector C126 Circuit 39 (R/W) and the electronic instrument cluster connector C232 Pin 6, Circuit 39 (R/W). If the resistance is more than 5 ohms, repair Circuit 39 (R/W) between the electronic instrument cluster connector C232 and the engine coolant temperature sensor connector C126. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 39 (R/W) for a short to ground. Measure the resistance between the engine coolant temperature sensor connector C126 Circuit 39 (R/W) and ground. If the resistance is less than 10,000 ohms, repair Circuit 39 (R/W) between the electronic instrument cluster connector C232 and the engine coolant temperature sensor connector C126. Test the system for normal operation. If the resistance is more than 10,000 ohms, check the ground circuit for the engine coolant temperature sensor. Measure the resistance between the engine coolant temperature sensor connector C126 Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the engine coolant temperature sensor connector C126 and ground. Test the system for normal operation. If the resistance is less than 5 ohms, check the instrument cluster printed circuit voltage supply. Connect the electronic instrument cluster connector C232. Remove the coolant temperature gauge. See **Subject 130** for instructions. Turn the ignition switch to the "On" position. Measure the voltage between the voltage supply terminal of the coolant temperature gauge (top terminal) and ground. If the voltage is less than 10 volts, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the voltage is more than 10 volts, check the instrument cluster printed circuit ground supply.
Circuitry open or shorted	
Worn or damaged coolant temperature sensor	
Damaged gauge	

Problem—Incorrect Coolant Temperature Gauge Indication (Electronic Instrument Cluster) (See Fig. 5, Fig. 7, Fig. 8, and Fig. 9)	
Possible Cause	**Remedy**
Fuse	Turn the ignition switch to the "Off" position. Measure the resistance between the coolant temperature gauge ground terminal (right terminal) and ground. If the resistance is more than 5 ohms, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the resistance is less than 5 ohms, check the printed circuit.
Circuitry open or shorted	Disconnect the electronic instrument cluster connector. Taking care not to damage the printed circuit, measure the resistance between the printed circuit connection to the electronic instrument cluster connector C232 Pin 6 and the coolant temperature gauge signal return terminal (left terminal). If the resistance is more than 5 ohms, replace the electronic instrument cluster printed circuit (flex circuit assembly). Test the system for normal operation. If the resistance is less than 5 ohms, Install the coolant temperature gauge and test.
Worn or damaged coolant temperature sensor	Test the coolant temperature gauge. Connect the electronic instrument cluster connector C232. Turn the ignition switch to the "Off" position. Using the instrument gauge system tester, connect one lead of the tester to the engine coolant temperature sensor connector C126 Circuit 39 (R/W) and connect the other lead to ground. Set the tester to the 1.35-kohm scale and wait one minute. Coolant temperature gauge should read C (cold). Set the tester to the 2-ohm scale and wait one minute. Coolant temperature gauge should read H (hot). If the coolant temperature gauge performs as specified, replace the engine coolant temperature sensor. Test the system for normal operation. If the coolant temperature gauge does not perform as specified, replace the coolant temperature gauge. Test the system for normal operation.
Damaged gauge	

Problem—Incorrect Tachometer Indication (Electronic Instrument Cluster)

Problem—Incorrect Tachometer Indication (Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Damaged gauge	Check the tachometer. NOTE: The tachometer has a 1 to 1-1/2 second delay time in response with the engine rpm. This condition is considered normal.
Worn or damaged tachometer sensor	Perform the "Tachometer Gauge Test". Refer to "Component Tests" in this subject. If the tachometer and the tachometer sensor do not check OK, replace the tachometer or tachometer sensor. Test the system for normal operation. If the tachometer and the tachometer sensor check OK, check the calibration of the tachometer. See **Subject 180** for instructions. If the tachometer is calibrated properly, check for an intermittent malfunction. Test the system for normal operation. If the tachometer is not calibrated properly, calibrate the tachometer. Test the system for normal operation.
Improperly calibrated gauge	

Troubleshooting

Problem—Inaccurate Speedometer Reading (Electronic Instrument Cluster)

Problem—Inaccurate Speedometer Reading (Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Damaged gauge	Check the speedometer. Perform the "Speedometer Gauge Test". Refer to "Component Tests" in this subject. If the speedometer and the vehicle speed sensor (VSS) do not check OK, replace the speedometer or the VSS. Test the system for normal operation. If the speedometer and the VSS check OK, check the speedometer calibration. See **Subject 190** for instructions. If the speedometer is calibrated properly, check for an intermittent malfunction. Test the system for normal operation. If the speedometer is not calibrated properly, calibrate the speedometer. Test the system for normal operation.
Worn or damaged vehicle speed sensor (VSS)	
Improperly calibrated gauge	

Problem—Tachometer Inoperative (Electronic Instrument Cluster) (Vehicles Equipped With ECM)

Problem—Tachometer Inoperative (Electronic Instrument Cluster) (Vehicles Equipped With ECM) **(See Fig. 10, Fig. 11, Fig. 12, and Fig. 13)**	
Possible Cause	**Remedy**
Fuse	Check the voltage supply to the tachometer. Disconnect the electronic instrument cluster connector. Turn the ignition switch to the "Off" position. Measure the voltage between the electronic instrument cluster connector C279 Pin 9, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the electronic instrument cluster connector. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 713 (W) for an open. Turn the ignition switch to the "Off" position. Disconnect the ECM connector. Measure the resistance between the electronic instrument cluster connector Pin 1, Circuit 713 (W) and the ECM connector Pin 17 (Caterpillar engine) or Pin K1 (Cummins and Detroit Diesel engines), Circuit 713 (W). If the resistance is more than 5 ohms, repair Circuit 713 (W). Test the system for normal operation. If the resistance is less than 5 ohms, perform the "Tachometer Gauge Test". Refer to "Component Tests" in this subject. If the tachometer checks OK, perform powertrain control diagnostics. If the tachometer does not check OK, replace the tachometer. Test the system for normal operation.
Circuitry open or shorted	
Damaged gauge	
Improperly calibrated gauge	
Worn or damaged tachometer sensor	

Problem—Tachometer Inoperative (Electronic Instrument Cluster) (Vehicles Without ECM)

Problem—Tachometer Inoperative (Electronic Instrument Cluster) (Vehicles Without ECM) (See Fig. 10, Fig. 11, Fig. 12, and Fig. 13)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Disconnect the electronic instrument cluster connector. Turn the ignition switch to the "On" position. Measure the voltage between the electronic instrument cluster connector C279 Pin 9, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the electronic instrument cluster connector. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 855 (P).
Circuitry open or shorted	Turn the ignition switch to the "Off" position. Measure the resistance between the electronic instrument cluster connector C279 Pin 8, Circuit 855 (P) and ground. If the resistance is more than 5 ohms, repair Circuit 855 (P). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 713 (W) for an open.
Damaged gauge	Disconnect the tachometer sensor connector. Measure the resistance between the electronic instrument cluster connector C279 Pin 1, Circuit 713 (W) and the tachometer sensor connector C172 Circuit 713 (W). If the resistance is more than 5 ohms, repair Circuit 713 (W). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 713 (W) for a short to ground.
Improperly calibrated gauge	Measure the resistance between the electronic instrument cluster connector C279 Pin 1, Circuit 713 (W) and ground. If the resistance is less than 10,000 ohms, repair Circuit 713 (W). Test the system for normal operation. If the resistance is more than 10,000 ohms, check Circuits 826 (W/PK) and 232 (GN/Y) for an open.
	Measure the resistance between the electronic instrument cluster connector C279 Pin 15, Circuit 826 (W/PK) and the tachometer sensor connector C172 Circuit 232 (GN/Y). If the resistance is more than 5 ohms, repair Circuit 826 (W/PK) or Circuit 232 (GN/Y). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuits 826 (W/PK) and 232 (GN/Y) for a short to ground.
Worn or damaged tachometer sensor	Measure the resistance between the electronic instrument cluster connector C279 Pin 15, Circuit 826 (W/PK) and ground. If the resistance is greater than 10,000 ohms, perform the "Tachometer Gauge Test". Refer to "Component Tests" in this subject. Replace as necessary. Test the system for normal operation. If the resistance is less than 10,000 ohms, repair Circuits 826 (W/PK) or Circuit 232 (GN/Y). Test the system for normal operation.

Troubleshooting

Problem—Speedometer/Odometer Inoperative (Electronic Instrument Cluster)

Problem—Speedometer/Odometer Inoperative (Electronic Instrument Cluster) (See Fig. 10 and Fig. 14)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Disconnect the electronic instrument cluster connector. Turn the ignition switch to the "On" position. Measure the voltage between the electronic instrument cluster connector C279 Pin 9, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the electronic instrument cluster connector. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 855 (P).
Circuitry open or shorted	Turn the ignition switch to the "Off" position. Measure the resistance between the electronic instrument cluster connector C279 Pin 8, Circuit 855 (P) and ground. If the resistance is more than 5 ohms, repair Circuit 855 (P). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 614 (GN) for an open. Disconnect the vehicle speed sensor (VSS) connector. Measure the resistance between the electronic instrument cluster connector C279 Pin 10, Circuit 614 (GN) and the VSS connector C115 or C122 Circuit 614 (GN). If the resistance is more than 5 ohms, repair Circuit 614 (GN). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 614 (GN) for a short to ground.
Damaged gauge	Measure the resistance between the electronic instrument cluster connector C279 Pin 10, Circuit 614 (GN) and ground. If the resistance is less than 10,000 ohms, repair Circuit 614 (GN). Test the system for normal operation. If the resistance is more than 10,000 ohms, check Circuit 826 (W/PK) for an open.
Worn or damaged vehicle speed sensor (VSS)	Measure the resistance between the electronic instrument cluster connector C279 Pin 15, Circuit 826 (W/PK) and the VSS connector C115 or C122 Circuit 826 (W/PK). If the resistance is more than 5 ohms, repair Circuit 826 (W/PK). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 826 (W/PK) for a short to ground. Measure the resistance between the electronic instrument cluster connector C279 Pin 15, Circuit 826 (W/PK) and ground. If the resistance is greater than 10,000 ohms, perform the "Speedometer Gauge Test". Refer to "Component Tests" in this subject. Replace as necessary. Test the system for normal operation. If the resistance is less than 10,000 ohms, repair Circuit 826 (W/PK). Test the system for normal operation.

Problem—Incorrect Fuel Gauge Indication (Non-Electronic Instrument Cluster)

Problem—Incorrect Fuel Gauge Indication (Non-Electronic Instrument Cluster)

Problem—Incorrect Fuel Gauge Indication (Non-Electronic Instrument Cluster) (See Fig. 15 and Fig. 16)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Turn the ignition switch to the "Off" position. Disconnect the fuel gauge connector. Turn the ignition switch to the "On" position. Measure the voltage between the fuel gauge connector C2059 Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the fuel gauge. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 25 (BK/O).
Circuitry open or shorted	Turn the ignition switch to the "Off" position. Disconnect the fuel gauge connector. Measure the resistance between the fuel gauge connector C287 Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the splice and the fuel gauge. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 286 (O) for an open.
Fuel level sensor arm is damaged	Disconnect the fuel gauge connector and fuel level sensor. Measure the resistance between the fuel gauge connector C2058 Circuit 286 (O) and the fuel level sensor connector C413 Circuit 286 (O). If the resistance is more than 5 ohms, repair Circuit 286 (O) between the fuel gauge and the fuel level sensor. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 286 (O) for a short to ground.
Damaged gauge	Measure the resistance between the fuel level sensor connector C413 Circuit 286 (O) and ground. If the resistance is less than 10,000 ohms, repair Circuit 286 (O) between the fuel gauge and the fuel level sensor. Test the system for normal operation. If the resistance is more than 10,000 ohms, check the ground for the fuel level sensor.
Resistor element worn or damaged	Measure the resistance between the fuel level sensor connector C413 Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the fuel level sensor and ground. Test the system for normal operation. If the resistance is less than 5 ohms, test the fuel gauge.
Leaking fuel level sensor float	Connect the fuel gauge connectors. Using the instrument gauge system tester, connect one lead of the tester to the fuel level sensor connector C413 Circuit 286 (O) and connect the other lead to ground. Turn the ignition switch to the "On" position. Set the tester to the 270-ohm scale and wait 1 minute. The fuel gauge should read E (empty). Set the tester to the 18-ohm scale and wait 1 minute. The fuel gauge should read F (full). If the fuel gauge does not perform as specified, replace the fuel gauge. Test the system for normal operation. If the fuel gauge performs as specified, Inspect the fuel tank for any signs of distortion or damage. If the fuel tank is damaged, replace the fuel tank. See **Group 47**. If the fuel tank is not damaged, replace the fuel level sensor. See **Group 47**.

Troubleshooting

Problem—Incorrect Voltage Gauge Indication (Non-Electronic Instrument Cluster)

Problem—Incorrect Voltage Gauge Indication (Non-Electronic Instrument Cluster) (See Fig. 15)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Turn the ignition switch to the "Off" position. Disconnect the voltmeter gauge connector. Turn the ignition switch to the "On" position. Measure the voltage between the voltmeter connector C284 Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the voltmeter. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 25 (BK/O).
Circuitry open or shorted	
Incorrect battery voltage	Turn the ignition switch to the "Off" position. Disconnect the voltmeter connector. Measure the resistance between the voltmeter connector C2062 Circuit 25 (BK/O) and ground. If the resistance is less than 5 ohms, replace the voltmeter. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the splice and the voltmeter. Test the system for normal operation.
Damaged gauge	

Problem—Incorrect Oil Pressure Gauge Indication (Non-Electronic Instrument Cluster)

Problem—Incorrect Oil Pressure Gauge Indication (Non-Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Plugged or kinked oil pressure line	Verify the oil pressure line is not plugged, broken or kinked. If the oil pressure line is OK, replace the oil pressure gauge. Test the system for normal operation. If the oil pressure line is not OK, replace the oil pressure line. Test the system for normal operation.
Damaged gauge	

Problem—Incorrect Coolant Temperature Gauge Indication (Non-Electronic Instrument Cluster)

Problem—Incorrect Coolant Temperature Gauge Indication (Non-Electronic Instrument Cluster) (See Fig. 15 and Fig. 17)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Turn the ignition switch to the "Off" position. Disconnect the coolant temperature gauge connector. Turn the ignition switch to the "On" position. Measure the voltage between the coolant temperature gauge connector C280 Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the coolant temperature gauge. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 25 (BK/O). Turn the ignition switch to the "Off" position. Disconnect the coolant temperature gauge connector. Measure the resistance between the coolant temperature gauge connector C2061 Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the splice and the coolant temperature gauge. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 39 (R/W) for an open.
Circuitry open or shorted	Disconnect the coolant temperature gauge connector and engine coolant temperature sensor connector. Measure the resistance between the coolant temperature gauge connector C2060 Circuit 39 (R/W) and the engine coolant temperature sensor connector C126 Circuit 39 (R/W). If the resistance is more than 5 ohms, repair Circuit 39 (R/W) between the coolant temperature gauge and the engine coolant temperature sensor. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 39 (R/W) for a short to ground.
Worn or damaged coolant temperature sensor	Measure the resistance between the engine coolant temperature sensor connector C126 Circuit 39 (R/W) and ground. If the resistance is less than 10,000 ohms, repair Circuit 39 (R/W) between the coolant temperature gauge and the engine coolant temperature sensor. Test the system for normal operation. If the resistance is more than 10,000 ohms, check the ground circuit for the engine coolant temperature sensor. Measure the resistance between the engine coolant temperature sensor connector C126 Circuit 25 (BK/O) and ground. If the resistance is more than 5 ohms, repair Circuit 25 (BK/O) between the engine coolant temperature sensor and ground. Test the system for normal operation. If the resistance is less than 5 ohms, test the coolant temperature gauge.
Damaged gauge	Connect the coolant temperature gauge connector. Using the instrument gauge system tester, connect one lead of the tester to the engine coolant temperature sensor connector C126 Circuit 39 (R/W) and connect the other lead to ground. Set the tester to the 1.35-kohm scale and wait 1 minute. Coolant temperature gauge should read C (cold). Set the tester to the 2-ohm scale and wait 1 minute. Coolant temperature gauge should read H (hot). If the coolant temperature gauge performs as specified, replace the engine coolant temperature sensor. Test the system for normal operation. If the coolant temperature gauge does not perform as specified, replace the coolant temperature gauge. Test the system for normal operation.

Troubleshooting

Problem—Incorrect Tachometer Indication (Non-Electronic Instrument Cluster)

Problem—Incorrect Tachometer Indication (Non-Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Damaged gauge	NOTE: The tachometer has a 1 to 1-1/2 second delay time in response with the engine rpm. This condition is considered normal. Perform the "Tachometer Gauge Test". Refer to "Component Tests" in this subject. If the tachometer and the tachometer sensor do not check OK, replace the tachometer or tachometer sensor. Test the system for normal operation. If the tachometer and the tachometer sensor check OK, check the tachometer calibration. See **Subject 180** for instructions.
Worn or damaged tachometer sensor	
Improperly calibrated gauge	If the tachometer is calibrated properly, check for an intermittent malfunction. Test the system for normal operation. If the tachometer is not calibrated properly, calibrate the tachometer. Test the system for normal operation.

Problem—Inaccurate Speedometer Reading (Non-Electronic Instrument Cluster)

Problem—Inaccurate Speedometer Reading (Non-Electronic Instrument Cluster)	
Possible Cause	**Remedy**
Fuse	Perform the "Speedometer Gauge Test". Refer to "Component Tests" in this subject. If the speedometer and the vehicle speed sensor (VSS) do not check OK, replace the speedometer or the VSS. Test the system for normal operation. If the speedometer and the VSS check OK, check the speedometer calibration. See **Subject 190** for instructions. If the speedometer is calibrated properly, check for an intermittent malfunction. Test the system for normal operation. If the speedometer is not calibrated properly, calibrate the speedometer. Test the system for normal operation.
Damaged gauge	
Worn or damaged vehicle speed sensor (VSS)	
Improperly calibrated gauge	

Problem—Tachometer Inoperative (Non-Electronic Instrument Cluster) (Vehicles With ECM)

Problem—Tachometer Inoperative (Non-Electronic Instrument Cluster) (Vehicles With ECM) **(See Fig. 11, Fig. 12, Fig. 13, Fig. 18, and Fig. 19)**	
Possible Cause	**Remedy**
Fuse	Check the supply voltage to the tachometer. Disconnect the tachometer connector. Turn the ignition switch to the "On" position. Measure the voltage between the tachometer connector C233 Pin 5, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the tachometer. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 713 (W) for an open. Turn the ignition switch to the "Off" position. Disconnect the ECM connector. Measure the resistance between the tachometer connector Pin 6, Circuit 713 (W) and the ECM connector Pin 17 (Caterpillar and Cummins engine) or Pin K1 (Detroit Diesel engine), Circuit 713 (W). If the resistance is more than 5 ohms, repair Circuit 713 (W). Test the system for normal operation. If the resistance is less than 5 ohms, perform the "Tachometer Gauge Test". Refer to "Component Tests" in this subject. If the tachometer checks OK, perform diagnosis and testing of the ECM. If the tachometer does not check OK, replace the tachometer. Test the system for normal operation.
Circuitry open or shorted	
Damaged gauge	
Worn or damaged tachometer sensor	

Problem—Tachometer Inoperative (Non-Electronic Instrument Cluster) (Vehicles Without ECM)

Problem—Tachometer Inoperative (Non-Electronic Instrument Cluster) (Vehicles Without ECM)

Problem—Tachometer Inoperative (Non-Electronic Instrument Cluster) (Vehicles Without ECM) (See Fig. 11, Fig. 12, Fig. 13, Fig. 18, and Fig. 19)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Disconnect the tachometer connector. Turn the ignition switch to the "On" position. Measure the voltage between the tachometer connector C233 Pin 5, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the tachometer. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 855 (P).
Circuitry open or shorted	Measure the resistance between the tachometer connector C233 Pin 4, Circuit 855 (P) and ground. If the resistance is more than 5 ohms, repair Circuit 855 (P). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 713 (W) for an open. Measure the resistance between the tachometer connector C233 Pin 6, Circuit 713 (W) and the tachometer sensor connector C172 Circuit 713 (W). If the resistance is more than 5 ohms, repair Circuit 713 (W). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 713 (W) for a short to ground.
Damaged gauge	Measure the resistance between the tachometer connector C233 Pin 6, Circuit 713 (W) and ground. If the resistance is less than 10,000 ohms, repair Circuit 713 (W). Test the system for normal operation. If the resistance is more than 10,000 ohms, check Circuit 232 (GN/Y) for an open. Measure the resistance between the tachometer connector C233 Pin 7, Circuit 232 (GN/Y) and the tachometer sensor connector C172 Circuit 232 (GN/Y). If the resistance is more than 5 ohms, repair Circuit 232 (GN/Y). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 232 (GN/Y) for a short to ground.
Worn or damaged tachometer sensor	Measure the resistance between the tachometer connector C233 Pin 7, Circuit 232 (GN/Y) and ground. If the resistance is less than 10,000 ohms, perform the "Tachometer Gauge Test". Refer to "Component Tests" in this subject. Replace as necessary. Test the system for normal operation. If the resistance is more than 10,000 ohms, repair Circuit 232 (GN/Y). Test the system for normal operation.

Troubleshooting

Problem—Speedometer Inoperative (Non-Electronic Instrument Cluster)

Problem—Speedometer/Odometer Inoperative (Non-Electronic Instrument Cluster) (See Fig. 10 and Fig. 14)	
Possible Cause	**Remedy**
Fuse	Check Circuit 976 (BK/GN). Disconnect the speedometer connector. Turn the ignition switch to the "On" position. Measure the voltage between the speedometer connector C234 Pin 9, Circuit 976 (BK/GN) and ground. If the voltage is less than 10 volts, repair Circuit 976 (BK/GN) between the splice and the speedometer. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 614 (GN) for an Open.
Circuitry open or shorted	Turn the ignition switch to the "Off" position. Disconnect the vehicle speed sensor (VSS) connector. Measure the resistance between the speedometer connector C234 Pin 10, Circuit 614 (GN) and the VSS connector C115 or C122 Circuit 614 (GN). If the resistance is more than 5 ohms, repair Circuit 614 (GN). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 614 (GN) for a short to ground.
Damaged gauge	Measure the resistance between the speedometer connector C234 Pin 10, Circuit 614 (GN) and ground. If the resistance is less than 10,000 ohms, repair Circuit 614 (GN). Test the system for normal operation. If the resistance is more than 10,000 ohms, check Circuit 826 (W/PK) for an open. Measure the resistance between the speedometer connector C234 Pin 15, Circuit 826 (W/PK) and the vehicle speed sensor (VSS) connector C115 or C122 Circuit 826 (W/PK). If the resistance is more than 5 ohms, repair Circuit 826 (W/PK). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 826 (W/PK) for a short to ground.
Worn or damaged vehicle speed sensor (VSS)	Measure the resistance between the speedometer connector C234 Pin 15, Circuit 826 (W/PK) and ground. If the resistance is greater than 10,000 ohms, perform the "Speedometer Gauge Test". Refer to "Component Tests" in this subject. Replace as necessary. Test the system for normal operation. If the resistance is less than 10,000 ohms, repair Circuit 826 (W/PK). Test the system for normal operation.

Component Tests

Speedometer and Tachometer Gauge Test

The electronic instrument cluster gauge pointers may hang up on the stop if Pin 3 is left connected to ground when the ignition switch is actuated to the "Off" position. Actuate the ignition switch to the "On" position.

The tachometer has a 1 to 1-1/2 second delay time in response with the engine rpm. This condition is considered normal.

Disconnect Pin 3, then actuate the ignition switch to "Off" or, bring the engine speed up to 1800 rpm, and bring the vehicle speed up to 50 mph (80 km/h).

Speedometer and Tachometer Gauge Test		
Setup	**Tachometer**	**Speedometer**
Electronic instrument cluster, access the instrument cluster connector C279 Pin 3, Circuit 724 (GN/W). Non-electronic instrument cluster, access tachometer connector C233 Pin 1, Circuit 724 (GN/W). Access speedometer connector C234 Pin 3, Circuit 724 (GN/W). Turn the ignition switch "On". Back probe to ground Pin 3 (electronic instrument cluster), Pin 1 (non-electronic instrument cluster, tachometer), Pin 3 (non-electronic instrument cluster, speedometer).	Pointer sweeps to 2000 rpm for 18 seconds and returns to zero.	Pointer sweeps to 60 mph (96 km/h) for 6 seconds and returns to zero. Odometer increments 1/10 mile.
Sensor resistance check.	Magnetic sensor: 100-3200 ohms Electronic sensor: 1-kohm	Magnetic sensor: 100-3200 ohms Electronic sensor: 1-kohm or greater

Table 1, Speedometer and Tachometer Gauge Test

Instrument Cluster and Panel Lighting

Inspection and Verification

1. Verify the vehicle owner's concern by duplicating the original concern.
2. Verify the components or systems related to the fuse for proper operation. If the components or systems are not operating properly, the fuse(s), fuse feed circuits or fuse load side circuit(s) may be at fault.
3. Visually inspect for the following conditions:
   - blown fuse(s)
   - faulty bulb(s)
   - loose or corroded connections
   - circuitry open or shorted
   - bad instrument cluster printed circuit (electronic cluster only)
   - damaged dome lamp and I/P dimmer switch
4. Make sure the vehicle lighting systems are functioning properly.
5. If the concern(s) remains after the inspection, determine the possible causes and proceed to the following problem charts.

Troubleshooting

Problem—Control Illumination is Inoperative

Problem—Control Illumination is Inoperative (See Fig. 20)	
Possible Cause	**Remedy**
Fuse	Check Circuit 11 (BK/Y). Turn the ignition switch to the "Off" position. Disconnect the dome lamp and I/P dimmer switch connector C272. Turn the headlamp switch to the "Park" position. Measure the voltage between the dome lamp and the I/P dimmer switch connector C272 Pin A, Circuit 11 (BK/Y) and ground. If the voltage is less than 10 volts, repair Circuit 11 (BK/Y) between the dome lamp and the I/P dimmer switch and the headlamp switch. Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 57 (BK). Measure the resistance between the dome lamp and I/P dimmer switch connector C272 Pin E, Circuit 57 (BK) and ground. If the resistance is more than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 19 (BL/R). Make sure the dome lamp and the I/P dimmer switch is in the uppermost vertical position. Connect the dome lamp and I/P dimmer switch connector C272. Measure the voltage by backprobing the dome lamp and I/P dimmer switch connector C272 Pin C, Circuit 19 (BL/R) and ground. If the voltage is greater than 10 volts, repair Circuit 19 (BL/R) between the splice and the dome lamp and I/P dimmer switch. Test the system for normal operation. If the voltage is less than 10 volts, replace the dome lamp and I/P dimmer switch. Test the system for normal operation.
Circuitry open or shorted	
Dome lamp and I/P dimmer switch	
Headlamp switch	

Problem—Instrument Cluster Illumination is Inoperative

Problem—Instrument Cluster Illumination is Inoperative (See Fig. 20, Fig. 21, and Fig. 22)	
Possible Cause	**Remedy**
Damaged circuitry	Check Circuit 19 (BL/R). NOTE: This test applies to the electronic instrument cluster only. NOTE: Make sure the dome lamp and the I/P dimmer switch is in the upmost vertical position. NOTE: The tachometer and speedometer use Circuit 855 (P) for the illumination bulb ground circuit. Therefore the tachometer and speedometer bulb may be illuminated with the rest of the instrument cluster inoperative.
I/P printed circuit (electronic cluster only)	Disconnect the electronic instrument cluster connector C232. Turn the headlamp switch to the "Park" position. Measure the voltage between the electronic instrument cluster connector C232 Pin 5, Circuit 19 (BL/R) and ground. If the voltage is less than 10 volts, repair Circuit 19 (BL/R). Test the system for normal operation. If the voltage is more than 10 volts, check Circuit 57 (BK). Measure the resistance between the electronic instrument cluster connector C230 Pin 1, Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, check the I/P printed circuit for damage. Replace as necessary. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Problem—Climate Control Illumination is Inoperative, Front

Problem—Climate Control Illumination is Inoperative, Front	
Possible Cause	**Remedy**
Bulb(s)	Check circuit 19 (BL/R). NOTE: Make sure the dome lamp and the I/P dimmer switch is in the upmost vertical position. Disconnect wiring harness connector C227 or C2068. Turn the headlamp switch to the "Park" position. Measure the voltage between connector C227 (with A/C) or connector C2068 (without A/C) circuit 19 (BL/R) and ground. If the voltage is less than 10 volts, repair circuit 19 (BL/R). Test the system for normal operation. If the voltage is more than 10 volts, check circuit 57 (BK). Turn the headlamp switch off. Measure the resistance between connector C227 (with A/C) or connector C2068 (without A/C) circuit 57 (BK) and ground. If the resistance is more than 5 ohms, repair circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check the bulb for continuity. Measure for continuity between the terminals of the bulb. If continuity exists, replace the climate control assembly. Test the system for normal operation. If continuity does not exist, replace the bulb(s). Test the system for normal operation.
Damaged circuitry	
Climate control assembly	

Problem—Audio System Illumination is Inoperative

Problem—Audio System Illumination is Inoperative (See Fig. 23)	
Possible Cause	**Remedy**
Damaged circuitry	Check Circuit 886 (BL). NOTE: Make sure the dome lamp and the I/P dimmer switch is in the upmost vertical position. Disconnect radio wiring harness connector C219. Turn the ignition switch to the "On" position. Turn the headlamp switch to the "Park" position. Measure the voltage between the radio connector C219 Pin 5, Circuit 886 (BL) and ground. If the voltage is greater than 10 volts, remove the radio chassis for repair. Test the system for normal operation. If the voltage is less than 10 volts, repair Circuit 886 (BL). If OK, replace the dome lamp and I/P dimmer switch. Test the system for normal operation.
Radio chassis	

Troubleshooting

Problem—Single Illumination Source is Inoperative

Problem—Single Illumination Source is Inoperative	
Possible Cause	**Remedy**
Bulb	Check Circuit 19 (BL/R). NOTE: Make sure the dome lamp and the I/P dimmer switch is in the upmost vertical position. Disconnect the inoperative lamp connector. Turn the headlamp switch to the "Park" position. Measure the voltage between the inoperative lamp connector Circuit 19 (BL/R) and ground. If the voltage is less than 10 volts, repair Circuit 19 (BL/R). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 57 (BK).
Damaged circuitry	NOTE: The tachometer and speedometer use Circuit 855 (P) for the illumination bulb ground circuit. Measure the resistance between the inoperative lamp connector Circuit 57 (BK) or Circuit 855 (P) and ground. If the resistance is less than 5 ohms, replace the bulb. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 57 (BK) or Circuit 855 (P). Test the system for normal operation.

Problem—Instrument Panel Illumination Does Not Dim

Problem—Instrument Panel Illumination Does Not Dim (See Fig. 20)	
Possible Cause	**Remedy**
Circuitry shorted	Check Circuit 19 (BL/R) for a short to power. Disconnect the dome lamp and I/P dimmer switch connector C272. Turn the ignition to the "On" position. Measure the voltage between the dome lamp and the I/P dimmer switch connector C272 Pin C, Circuit 19 (BL/R) and ground. If the voltage reading is 0 volts, replace the dome lamp and the I/P dimmer switch. Test the system for normal operation. If the voltage reading is not 0 volts, repair Circuit 19 (BL/R). Test the system for normal operation.
Dome lamp and I/P dimmer switch	

Gauges and Warning Devices

Inspection and Verification

1. Verify the owner's original concern by operating the system to duplicate the concern.
2. Verify that other components and systems related to the gauge or warning indicator fuse(s) operate properly. If the other components and systems are not operating properly, the fuse(s), fuse feed circuit(s) or load side circuit(s) may be at fault.
3. Visually inspect for obvious signs of mechanical and electrical damage. Refer to the following chart.

Mechanical	Electrical
Damaged gauge Damaged sensor Bent, kinked, plugged or damaged hoses	Open fuse: instrument panel fuse junction panel Fuse 11 (20 A), 21 (10 A) or 46 (20 A) Damaged circuitry Corroded connectors

Table 2, Inspection Chart

Engine Protection System

Inspection and Verification

1. Verify the vehicle owner's original concern by operating the system to duplicate the concern.

2. Inspect to determine if one of the mechanical or electrical concerns in the following chart applies.

Mechanical	Electrical
Low coolant Low oil	Open fuse: instrument panel fuse junction panel Fuse 1 (10 A) Open/shorted circuits Damaged connectors

Table 3, Inspection Chart

3. If the concern remains after the inspection, determine the possible causes and proceed to the following problem charts.

Problem—Low Oil Pressure Warning Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern

Problem—Low Oil Pressure Warning Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern (See Fig. 24)	
Possible Cause	**Remedy**
Circuitry	Check the oil pressure switch. With the ignition switch in the "Off" position, disconnect the low oil pressure switch connector. Turn the ignition switch to the "On" position. If the symptom does not continue, replace the oil pressure switch. Test the system for normal operation. If the symptom continues, check Circuit 17 (W) for a short to ground.
Low oil pressure switch	Turn the ignition switch to the "Off" position. Disconnect instrument cluster connector C232 for vehicles equipped with an electronic instrument cluster, or connector C285 for vehicles equipped with the non-electronic instrument cluster. Measure the resistance between oil pressure switch connector C168, Pin 2, Circuit 17 (W) and chassis ground. If the resistance is less than 10k ohms, repair Circuit 17 (W). Test the system for normal operation. If the resistance is more than 10k ohms, check the engine alarm/shutdown module. Reconnect instrument cluster connector C232 for vehicles equipped with an electronic instrument cluster, or connector C285 for vehicles equipped with the non-electronic instrument cluster.
Instrument cluster printed circuit	
Engine alarm/shutdown module	Disconnect the engine alarm/shutdown module connector and turn the ignition switch to the "On" position. Observe the low oil pressure warning indicator lamp. If the lamp illuminates, replace the printed circuit. Test the system for normal operation. If the lamp does not illuminate, replace the engine alarm/shutdown module. Test the system for normal operation.

Problem—High Oil Temperature Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern

Troubleshooting

Problem—High Oil Temperature Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern

Problem—High Oil Temperature Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern (See Fig. 25)	
Possible Cause	**Remedy**
Circuitry	Check the oil temperature switch. Turn the ignition switch to the "Off" position. Disconnect the engine oil temperature switch. Turn the ignition switch to the "On" position. If the symptom does not continue, replace the engine oil temperature switch. Test the system for normal operation. If the symptom continues, check Circuit 635 (GN) for a short to ground.
Engine oil temperature switch	Turn the ignition switch to the "Off" position. Disconnect instrument cluster connector C232 for vehicles equipped with an electronic instrument cluster, or connector C285 for vehicles equipped with the non-electronic instrument cluster. Measure the resistance between oil temperature switch connector C174, Pin 2, Circuit 635 (GN) and chassis ground. If the resistance is less than 10k ohms, repair Circuit 635 (GN). Test the system for normal operation. If the resistance is less than 10k ohms, check the engine alarm/shutdown module.
Instrument cluster printed circuit	Reconnect instrument cluster connector C232 for vehicles equipped with an electronic instrument cluster or connector C285 for vehicles equipped with the non-electronic instrument cluster. Disconnect the engine alarm/shutdown module connector and turn the ignition switch to the "On" position. Observe the engine oil temperature warning indicator lamp. If the lamp illuminates, replace the printed circuit. Test the system for normal operation. If the lamp does not illuminate, replace the engine alarm/shutdown module. Test the system for normal operation.
Engine alarm/shutdown module	

Problem—Coolant Temperature Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern

Problem—Coolant Temperature Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern

Problem—Coolant Temperature Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern (See Fig. 25)	
Possible Cause	**Remedy**
Circuitry	Check the coolant temperature switch. Turn the ignition switch to the "Off" position and disconnect the coolant temperature switch connector. Turn the ignition switch to the "On" position. If the symptom does not continue, replace the coolant temperature switch. Test the system for normal operation. If the symptom continues, check Circuit 45 (Y/R) for a short to ground.
Coolant temperature switch	Turn the ignition switch to the "Off" position. Disconnect instrument cluster connector C231 for vehicles equipped with an electronic instrument cluster, or connector C285 for vehicles equipped with the non-electronic instrument cluster. Measure the resistance between coolant temperature switch connector C175, Pin 2, Circuit 45 (Y/R) and chassis ground. If the resistance is less than 10k ohms, repair Circuit 45 (Y/R). Test the system for normal operation. If the resistance is more than 10k ohms, check the engine alarm/shutdown module.
Instrument cluster printed circuit	Reconnect instrument cluster connector C231 for vehicles equipped with an electronic instrument cluster, or connector C285 for vehicles equipped with the non-electronic instrument cluster. Disconnect the engine alarm/shutdown module connector. Turn the ignition switch to the "On" position. Observe the coolant temperature warning indicator lamp. If the lamp illuminates, replace the printed circuit. Test the system for normal operation. If the lamp does not illuminate, replace the engine alarm/shutdown module. Test the system for normal operation.
Engine alarm/shutdown module	

Troubleshooting

Problem—Low Coolant Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern

Problem—Low Coolant Warning Indicator Lamp Illuminates, Audible Warning Activates and the Engine Shuts Down, No Mechanical Concern (See Fig. 1, Fig. 25, and Fig. 26)	
Possible Cause	**Remedy**
Circuitry	Check the low coolant level sensor. Turn the ignition switch to the "Off" position. Disconnect the low coolant level sensor connector. Turn the ignition switch to the "On" position. Connect a jumper between the coolant level sensor connector terminals. If the symptom does not continue, replace the low coolant level sensor. Test the system for normal operation.
Low coolant level sensor	If the symptom continues, disconnect the jumper, then check the sensor ground circuit. With the key in the "Off" position, measure the resistance between low coolant level sensor connector C103, Pin 1, Circuit 57 (BK) and chassis ground. If the resistance is more than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 670 (PK) for an open.
Instrument cluster printed circuit	Disconnect instrument cluster connector C231 for vehicles equipped with an electronic instrument cluster or connector C285 for vehicles equipped with the non-electronic instrument cluster. Measure the resistance between instrument cluster connector C231, Pin 4, Circuit 670 (PK) for vehicles equipped with an electronic instrument cluster, or connector C285, Pin 11, Circuit 670 (PK) for vehicles equipped with the non-electronic instrument cluster and coolant level sensor connector C103, Pin 2, Circuit 670 (PK). If the resistance is more than 5 ohms, repair Circuit 670 (PK). Test the system for normal operation. If the resistance is less than 5 ohms, check the engine alarm/shutdown module.
Engine alarm/shutdown module	Reconnect instrument cluster connector C231 for vehicles equipped with an electronic instrument cluster, or connector C285 for vehicles equipped with the non-electronic instrument cluster. Turn the ignition switch to the "On" position. Observe the low coolant lamp. If the lamp extinguishes, replace the engine alarm/shutdown module. Test the system for normal operation. If the lamp does not extinguish, replace the printed circuit. Test the system for normal operation.

Problem—Audible Warning Activates, but the Engine Does Not Shut Down, No Mechanical Concern

Problem—Audible Warning Activates, but the Engine Does Not Shut Down, No Mechanical Concern (See Fig. 15, Fig. 27, and Fig. 28)	
Possible Cause	**Remedy**
Engine alarm/shutdown module	Replace the engine alarm/shutdown module.

Problem—Audible Warning Activates, but the Engine Does Not Shut Down, With a Mechanical Concern

Problem—Audible Warning Activates, but the Engine Does Not Shut Down, With a Mechanical Concern	
Possible Cause	**Remedy**
Circuitry	Check for power at the fuel shutoff solenoid. NOTE: Perform this test only after correcting the engine mechanical concern. Turn the ignition switch to the "Off" position. Disconnect fuel shutoff solenoid connector C173 for vehicles equipped with a Caterpillar 3306 engine, or connector C1026 for vehicles equipped with a Cummins B5.9 or C8.3 engine. Measure the voltage between fuel shutoff solenoid connector C173, Circuit 932 (BL) and chassis ground for vehicles equipped with an electronic instrument cluster, or connector C1026, Pin 1, Circuit 932 (BL), Pin 2, Circuit 669 (R/BL) and chassis ground for vehicles equipped with the non-electronic instrument cluster. If the voltage is less than 10 volts on either circuit, replace the fuel shutoff solenoid. Test the system for normal operation. If voltage was read on Circuit 669 (R/BL), check Circuit 669 (R/BL) for a short to battery. With the ignition switch in the "Off" position, disconnect Circuit 669 (R/BL) from the starter motor relay and starter motor. Turn the ignition switch to the "On" position and measure the voltage between fuel shutoff solenoid connector C1026, Pin 2, Circuit 669 (R/BL) and chassis ground. If the voltage is less than 10 volts, see **Group 15** for troubleshooting of the starter motor and starter motor relay. If the voltage is more than 10 volts, repair Circuit 669 (R/BL). Test the system for normal operation. If voltage was read on Circuit 932 (BL), check Circuit 932 (BL) for a short to battery. With the ignition switch in the "Off" position, disconnect the fuel shutoff relay connector C2044. With the ignition switch in the "On" position, measure the voltage between fuel shutoff relay connector C2044, Pin 5, Circuit 932 (BL) and chassis ground. If the voltage is greater than 10 volts, repair Circuit 932 (BL). Test the system for normal operation. If the voltage is less than 10 volts, check Circuit 720 (BL) for power. Measure the voltage between fuel shutoff relay connector C2044, Pin 2, Circuit 720 (BL) and chassis ground. If the voltage is less than 10 volts, replace the fuel shutoff relay. Test the system for normal operation. If the voltage is more than 10 volts, check the engine alarm/shutdown module. With the ignition switch in the "Off" position, disconnect the engine alarm/shutdown module connector. With the ignition switch in the "On" position, measure the voltage between fuel shutoff relay connector C2044, Pin 2, Circuit 720 (BL) and chassis ground. If the voltage is less than 10 volts, replace the engine alarm/shutdown module. Test the system for normal operation. If the voltage is more than 10 volts, check the instrument cluster printed circuit. Turn the ignition switch to the "Off" position. Disconnect instrument cluster connector C231 for vehicles equipped with an electronic instrument cluster or connector C285 for vehicles equipped with the non-electronic instrument cluster. Turn the ignition switch to the "On" position. Measure the voltage between fuel shutoff relay connector C2044, Pin 2, Circuit 720 (BL) and chassis ground. If the voltage is greater than 10 volts, repair Circuit 720 (BL). Test the system for normal operation. If the voltage is less than 10 volts, replace the instrument cluster printed circuit. Test the system for normal operation.

Torque Specifications	
Description	**lbf·in (N·cm)**
Auxiliary Finish Panel Screws	27–35 (300–400)
Warning Lamp Module Bolts	8–10 (90–110)
Auxiliary Gauge Retaining Bolts	8–10 (90–110)

Table 3, Torque Specifications

Replacement

NOTE: The horn is located in the right front core support area and can be accessed by opening the vehicle hood.

1. Open the hood.
2. Disconnect the battery ground cable(s).
3. Press the locking tabs and remove the horn electrical connector. See **Fig. 1**.

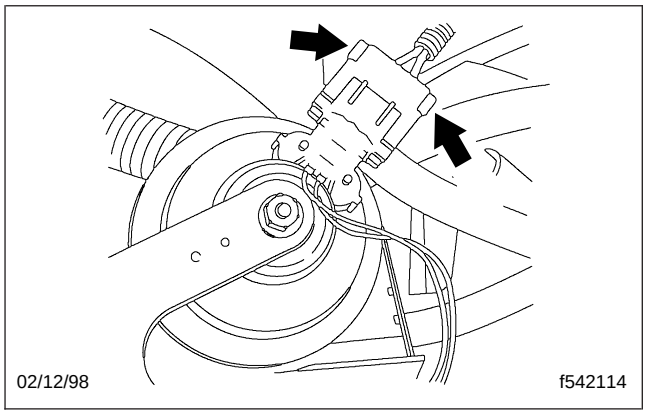

Fig. 1, Horn, Electrical Connector

4. Remove the horn retaining bolt and remove the horn(s). See **Fig. 2**.

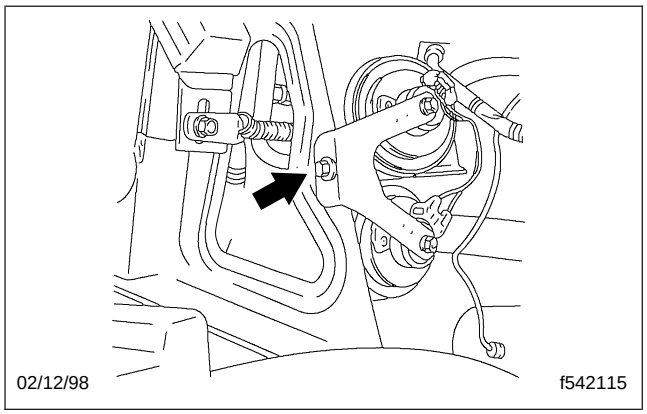

Fig. 2, Horn, Retaining Bolt

5. Position the horn and install the horn retaining bolt.
6. Connect the horn electrical connector.
7. Connect the battery ground cable(s).
8. Close the hood.

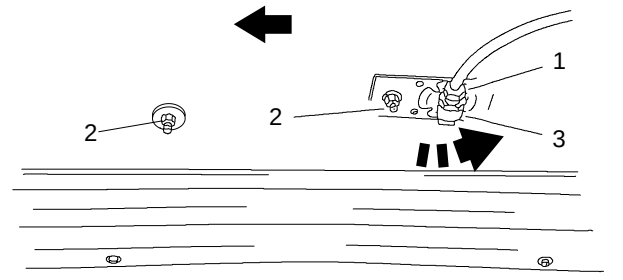
Single Base Dual Trumpet Air Horn Replacement

Replacement

WARNING

Unless the air system is bled, use care not to pull on the air horn lanyard during the removal or installation of the air horn, this could result in personal injury.

1. Remove the vehicle headliner; refer to **Group 60**.
2. Disconnect the air horn. See **Fig. 1**.



1. Air Line
2. Retaining Nuts
3. Air Line Elbow

Fig. 1, Air Horn Air Line Under Headliner

2.1 Remove the air line.

2.2 Remove the retaining nuts and washers.

2.3 Remove (unscrew) the air line elbow and washer.

3. Remove the air horn. See **Fig. 2**.

NOTE: All threaded air line connections should be sealed using Sterling Pipe Sealant with Teflon® D8AZ–19554–A or equivalent meeting Sterling specification WSK–M2G350–A2 or ESR–M18P7–A.

4. Position the air horn and install the airline washer and elbow.
5. Install the air horn retaining nuts and washers.
6. Install the air line.
7. Install the vehicle headliner; refer to **Group 60**.

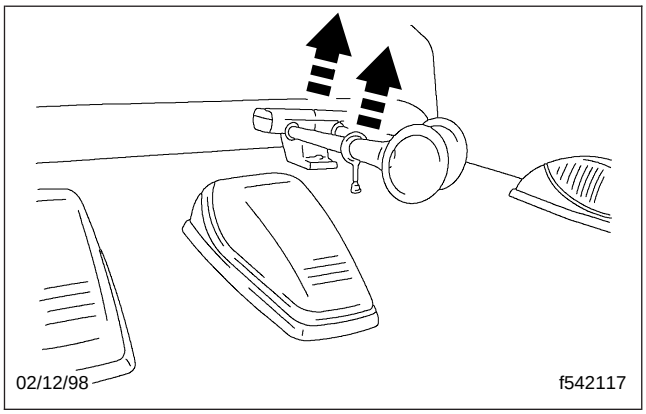


Fig. 2, Air Horn

Replacement

1. Remove one screw and four bolts from the left-hand body rocker panel, and remove the left-hand body rocker panel. See **Fig. 1**.

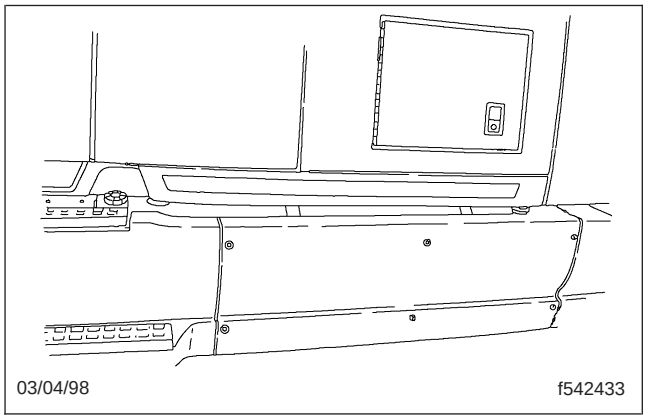

Fig. 1, Left-Hand Body Rocker Panel

2. Remove the air horn bolts. See **Fig. 2**.

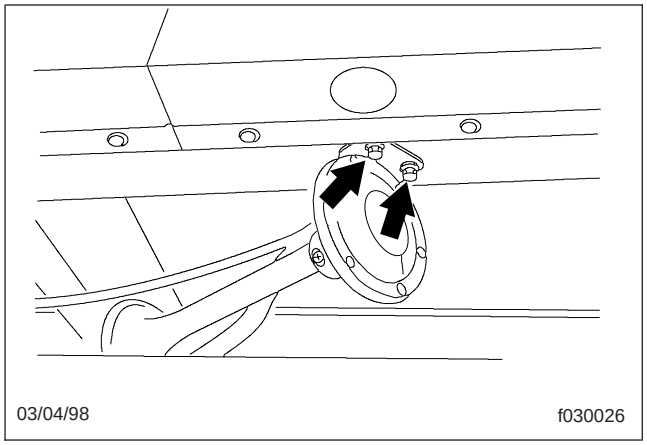

Fig. 2, Air Horn Bolts

3. Disconnect the air line, and remove the air horn. See **Fig. 3**.
4. Connect the air line and position the air horn.
5. Install the air horn bolts.
6. Install the left-hand body rocker panel.

3. Position and connect the air line.

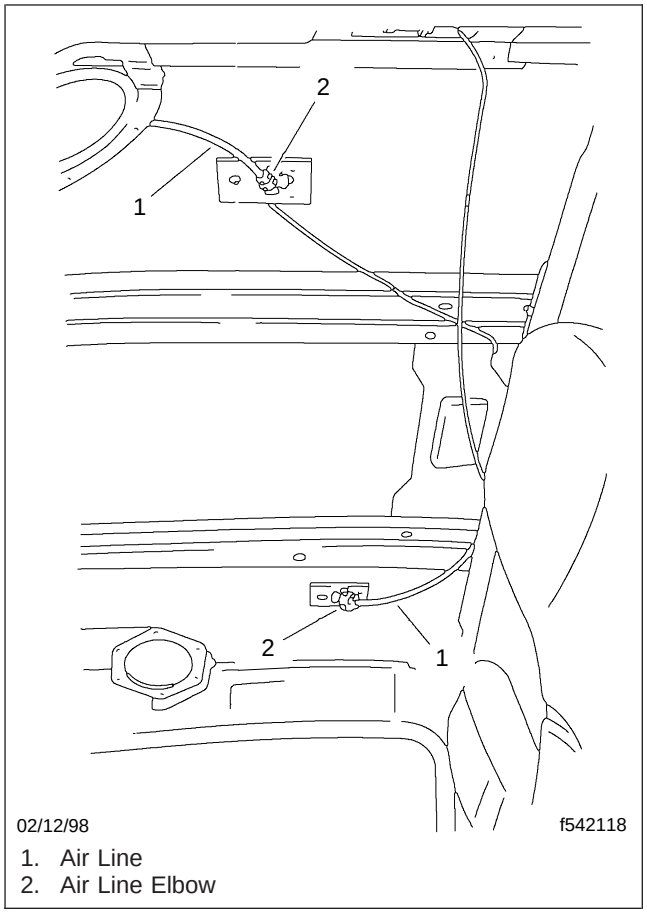
Dual Hadley Air Horn Replacement

Replacement

WARNING

Unless the air system is bled, use care not to pull on the air horn lanyard during the removal or installation of the air horn, this could result in personal injury.

1. Remove the vehicle headliner; refer to **Group 60**.
2. Disconnect the air horns. See **Fig. 1**.



1. Air Line
2. Air Line Elbow

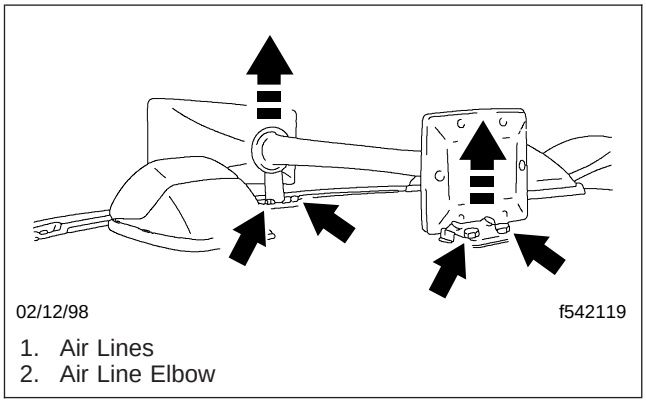
Fig. 1, Air Horn Air Lines Under Headliner

2.1 Remove the air lines.

2.2 Remove (unscrew) the air line elbows and washers.

NOTE: A backup wrench may be required on the underside of the roof to remove the air horn retaining bolts.

3. Remove the air horn retaining bolts and remove the air horn from the roof. See **Fig. 2**.



1. Air Lines
2. Air Line Elbow

Fig. 2, Air Horn Retaining Bolts

4. Repeat the previous step for the second air horn.

NOTE: All threaded air line connections should be sealed using Sterling Pipe Sealant with Teflon® D8AZ–19554–A or equivalent meeting Sterling specification WSK–M2G350–A2 or ESR–M18P7–A.

5. Position the air horn and install the bolts.
6. Install the air horn elbow and washers.
7. Install the air horn air lines.
8. Install the vehicle headliner; refer to **Group 60**.

Troubleshooting

Inspection and Verification

1. Verify customer concern by operating the horn.
2. Visually inspect for obvious signs of mechanical and electrical damage using the chart below.

Component Test

Horn Relay

Remove the horn relay and use the following procedure for testing:

1. Measure the resistance of the horn relay between Terminal 2 and all other terminals. If the resistance is 5 ohms or less between Terminal 2 and any other terminal, replace the relay. If the resistance measures greater than 5 ohms, proceed to the following step. See **Fig. 1.**

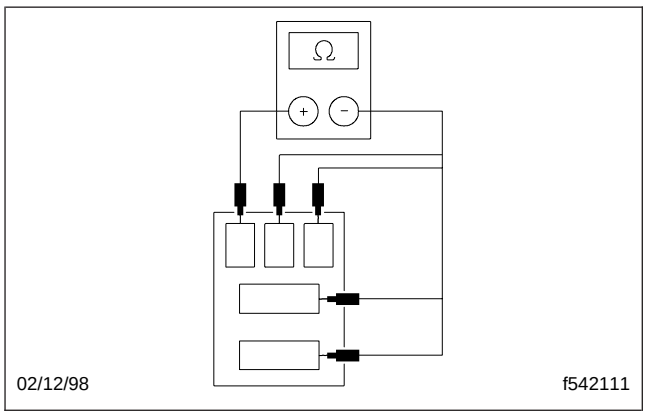


Fig. 1, Measuring Resistance

2. Connect terminals 1 and 3 directly to the positive battery terminal and measure the voltage at Terminal 4. If battery voltage is not indicated, replace the relay. If battery voltage is indicated, proceed to the following step. See **Fig. 2**.
3. Connect a third jumper wire to Terminal 2 and a known good ground, and check for voltage at Terminal 5. If battery voltage is not indicated, replace the relay. See **Fig. 3**.

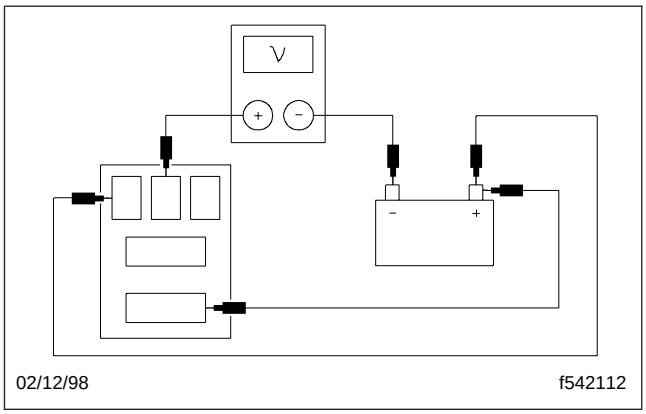

Fig. 2, Measuring Voltage

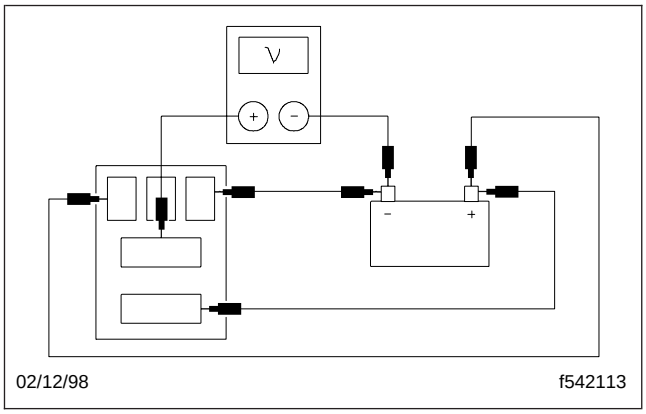

Fig. 3, Testing Ground

Visual Inspection Chart	
Mechanical	**Pneumatic**
Damaged horns	Blown fuse Damaged wiring harness Loose or corroded connections

Table 1, Visual Inspection Chart

Troubleshooting

Problem—The Horn Does Not Sound

Problem—The Horn Does Not Sound	
Possible Cause	**Remedy**
Fuse	Test the horn(s). For each horn, disconnect the horn connector harness. Connect a jumper wire from the battery positive post to the horn positive terminal. Connect a second jumper wire from the battery negative post to the horn negative terminal. If the horn(s) does not sound, replace the horn(s). Test the system for normal operation. If the horn(s) does sound, remove and test the horn relay. For instructions, see "Horn Relay" under "Component test" in this section. Replace the horn relay if it does not test OK. If the horn relay does test OK reinstall and check Circuit 33 (Y). Disconnect the instrument panel fuse junction panel fuse 32 (15 A). Disconnect the instrument panel fuse junction panel horn relay. Measure the resistance of Circuit 33 (Y) between the instrument panel fuse junction panel, fuse cavity 32 and the horn relay cavity, Pin 2. If the resistance is more than 5 ohms, repair Circuit 33 (Y). Test the system for normal operation. If the resistance is less than 5 ohms, disconnect the instrument panel fuse junction panel fuse 3 (10 A). Measure the resistance of circuit 460 (Y) between the instrument panel fuse junction panel, fuse cavity 3 and the horn relay cavity, Pin 3. If the resistance is more than 5 ohms, repair Circuit 460 (Y). Test the system for normal operation. If the resistance is less than 5 ohms, check the horn switch. Remove the horn pad switch; refer to **Group 46**. Connect an ohmmeter between the two horn switch electrical contacts. Press the horn pad switch and measure the resistance between the electrical connectors. If the resistance is more than 5 ohms, replace the horn pad switch; refer to **Group 46**. Test the system for normal operation. If the resistance is less than 5 ohms (with speed control), check the clockspring. If the resistance is less than 5 ohms (without speed control), check circuit 376. Check the clockspring. Remove the clockspring assembly; refer to **Group 46**. Measure the resistance of the clockspring between Pin 10 and Pin 5 and between Pin 4 and 6. If the resistance is more than 5 ohms, replace the clockspring assembly. Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 376 (BL/Y). Check Circuit 376 (BL/Y). Measure the resistance of Circuit 376 (BL/Y) between the horn relay cavity Pin 1 and the clockspring assembly Pin 10 (with speed control) or the horn switch (without speed control). If the resistance is more than 5 ohms repair Circuit 376 (BL/Y). Test the system for normal operation. If the resistance is less than 5 ohms check the horn switch ground. Measure the resistance of Circuit 57 (BK) between the horn switch connector and a known good ground. If the resistance is more than 5 ohms repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms check Circuit 482 (BK/Y). Disconnect the horn connector(s). Disconnect the horn relay. Measure the resistance of Circuit 482 (BK/Y) between the horn switch relay Pin 5 and the horn(s). If the resistance is less than 5 ohms repair the horn Circuit 57 (BK). Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 482 (BK/Y). Test the system for normal operation.
Circuit	
Horn Relay	
Switch	

Problem—The Horn Sounds Continuously

Problem—The Horn Sounds Continuously	
Possible Cause	**Remedy**
Circuit	Test the horn relay. Disconnect the horn relay connector harness. Test the horn relay. For instructions, see "Horn Relay" under "Component Test" in this section. If the horn(s) does not sound, replace the horn relay. Test the system for normal operation. If the horn(s) sound (with speed control), check the clockspring. If the horn(s) sound (without speed control) check the horn switch.
Horn Relay	Check the clockspring. Remove the horn pad switch; for instructions, see **Group 46**. Disconnect the clockspring connector. Measure the resistance of the clockspring between Pin 6 and Pin 10. If the resistance is less than 5 ohms, replace the clockspring; for instructions, see **Group 46**. Test the system for normal operation. If the resistance is more than 5 ohms, test the horn switch. NOTE: Do not press the switch while performing this test.
Switch	Test the horn switch. Remove the horn pad. Disconnect the horn pad switch. Measure the resistance of the horn switch. If the resistance is greater than 10,000 ohms, check the associated horn circuitry for signs of wear or exposed wiring. Repair as necessary. Test the system for normal operation. If the resistance is less than 10,000 ohms replace the horn pad. Test the system for normal operation.

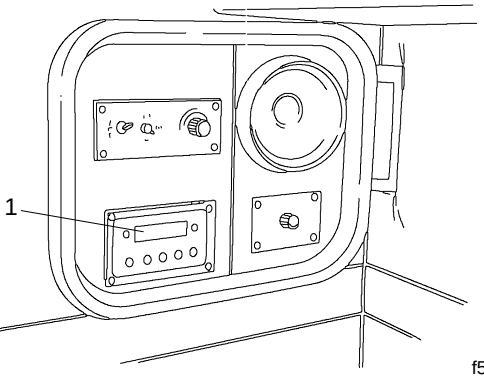
Specifications

General Specifications	
Item	**Specification**
Sterling Pipe Sealant with Teflon® D8AZ–19554–A	WSK–M2G350–A2, ESR–M18P7–A

Table 1, General Specifications

General Information

ABLE BODY CLOCK (See Fig. 1)



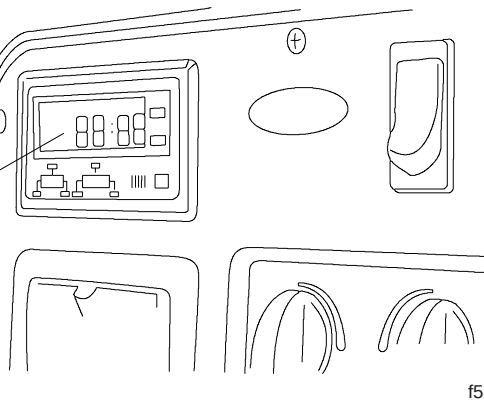
1. Electronic Clock

Fig. 1, Able Body Clock Location

The electronic clock in the Able Body sleeper is located on the left rear sleeper wall in the accessory panel.

The electronic clock control buttons are located along the bottom of the clock display. Pressing the DISPLAY ON button toggles the illumination "On" and "Off".

SILVERSTAR CLOCK (See Fig. 2)



1. Electronic Clock

Fig. 2, SilverStar Clock Location

The electronic clock in the SilverStar sleeper is located on the left sleeper wall in the accessory panel.

For information on the operation of the clock, refer to the driver's manual.

Replacement

ABLE BODY

1. Remove the Phillips screws. See **Fig. 1.**

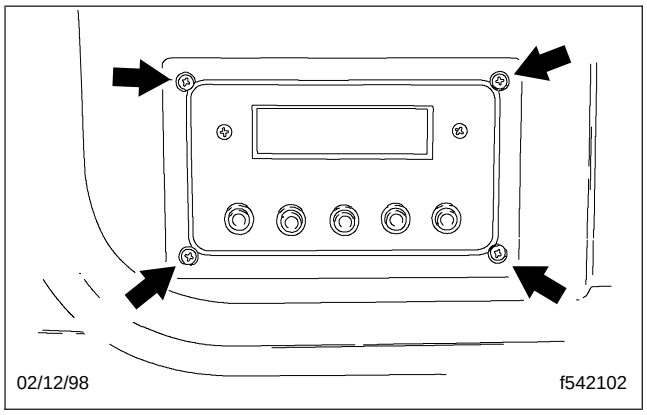


Fig. 1, Clock Screws

2. Disconnect the electrical connector and remove the clock from the accessory panel. See **Fig. 2.**

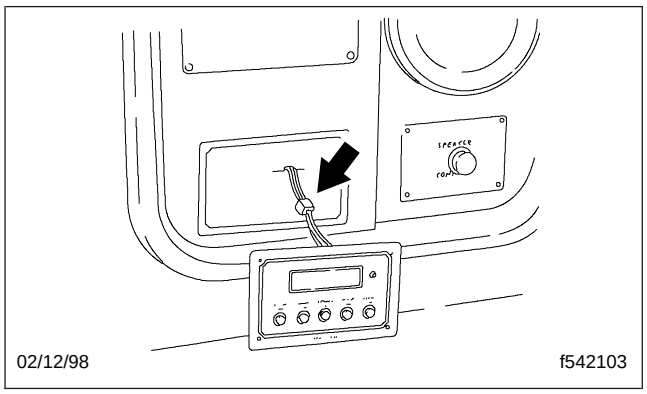

Fig. 2, Clock Electrical Connector

3. Connect the electrical connector and position the clock into the accessory panel.
4. Install the Phillips screws and tighten until firm.

SILVERSTAR

1. Pry the clock outward from the accessory panel. See **Fig. 3.**
2. Disconnect the electrical connector, then remove the clock from the accessory panel.

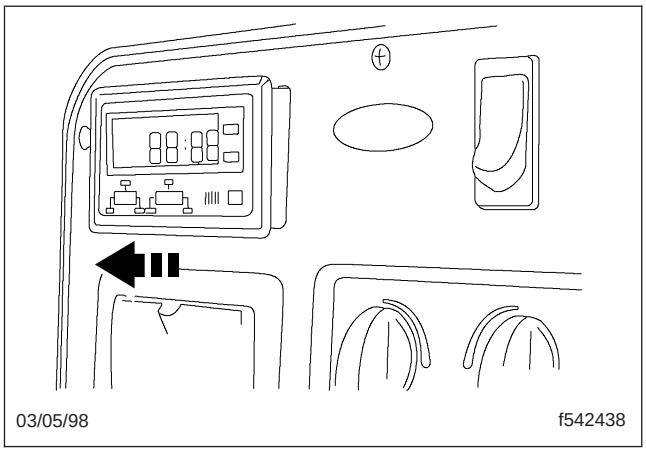

Fig. 3, Clock

3. Connect the electrical connector and install the clock into the accessory panel.

Troubleshooting

Inspection and Verification

1. Verify the vehicle owner's concern by operating the electronic clock to duplicate the original concern.
2. Verify components or systems related to the fuse for proper operation. If the components or systems are not operating properly, the fuse(s), fuse feed circuits or fuse load side circuits(s) may be at fault.
3. If the concern(s) remains after the inspection, determine the problem and proceed to the problem charts.

Problem—The Clock is Erratic or Inoperative, Able Body

Problem—The Clock is Erratic or Inoperative, Able Body (See Fig. 1 and Fig. 2)	
Possible Cause	**Remedy**
Circuitry open or shorted	Check the supply voltage to the clock. Disconnect the clock connector C717. Measure the voltage between the clock connector C717 Circuit 130 (Y) and ground. If the voltage is more than 10 volts repair Circuit 139 (Y). Test the system for normal operation. If not, check the ground circuit. Measure the resistance between the clock connector C717 Circuit 239 (BK) and ground. If the resistance is less than 5 ohms, replace the clock assembly. Test the system for normal operation. If not, repair Circuit 239 (BK). Test the system for normal operation.
Blown fuse	
Damaged electronic clock	

Problem—The Clock is Erratic or Inoperative, SilverStar

Problem—The Clock is Erratic or Inoperative, SilverStar (See Fig. 3 and Fig. 4)	
Possible Cause	**Remedy**
Circuitry open or shorted	Check the supply voltage to the clock. Disconnect the clock connector C765. Measure the voltage between the clock connector C765 Circuit 45 (Y/R) and ground. If the voltage is more than 10 volts repair Circuit 45 (Y/R). Test the system for normal operation. If not, check the ground circuit. Measure the resistance between the clock connector C765 Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the clock assembly. Test the system for normal operation. If not, repair Circuit 57 (BK). Test the system for normal operation.
Blown fuse	
Damaged electronic clock

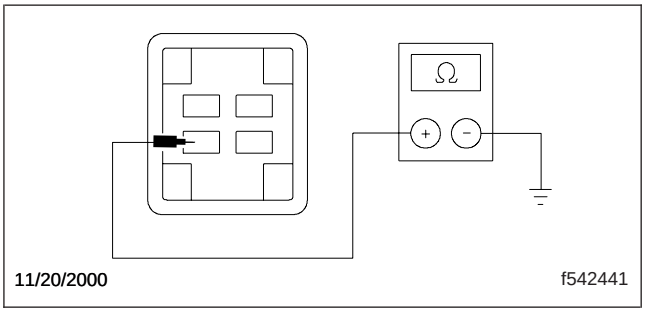

Fig. 4

General Information

MESSAGE CENTER

The message center is a microprocessor-controlled module providing service diagnostics and vehicle information to the operator with a two-line display. The message center is capable of receiving direct sensor inputs for oil temperature, transmission oil temperature, exhaust gas temperature, forward drive axle oil temperature and rear drive axle temperature. In addition, it allows the operator to view current and average fuel economy and active faults, and can alert the operator to vehicle operating conditions that are beyond normal operating range by providing an output to an audible alarm. The message center also has the capability of displaying current time and four independent odometer readings.

The message center system components are shown in **Fig. 1**.

The message center includes the following features:

- TRIP: trip odometer, trip 1, trip 2, driver 1, driver 2, display units and blank screen
- STATUS: fuel economy, engine oil temperature, transmission oil temperature, forward drive axle oil temperature, rear drive axle oil temperature, exhaust gas temperature and diagnostics
- TIME: current time, time zone, date and alarm

The features are activated by the operator via the six buttons on the face of the message center module.

MESSAGE CENTER CALIBRATION

(See Fig. 2)

The message center is calibrated for the vehicle by setting the dip switches on the back of the message center. Switch 1 must be placed in the "On" position if the vehicle is equipped with a Caterpillar engine, switch 2 must be placed in the "On" position if the vehicle is equipped with a Cummins engine, and switch 3 must be placed in the "On" position if the vehicle is equipped with a Detroit Diesel engine. If more than one of the first three switches are placed in the "On" position at the same time, a calibration error will be set. Switch 4 must be placed in the "On" position if the vehicle is equipped with a transmission oil temperature sensor and switch 5 must be placed in the "On" position if the vehicle is equipped with two drive axles. Switch 6 is not used currently and should be left in the "Off" position.

DIAGNOSTICS

The message center has the ability to display diagnostic information. This information comes from two sources and in two forms. The two sources of information are:

- Internal, directly monitored systems;
- External, data link monitored systems.

The two forms of information are:

- Warning messages, indicating the set parameters of the sensor have been exceeded;
- Diagnostic messages, indicating a failure condition in the circuit or sensor.

If a warning message or a diagnostic message occurs, it will be displayed immediately, even if the blank screen option has been selected

Both warning messages and diagnostic messages use two screens to display information being conveyed. The first depression of the STATUS button identifies the source of the message:

- ENGINE
- FAULT REPORT

The second depression of the STATUS button displays the message itself:

- ENGINE
- POWER SUPPLY LOW

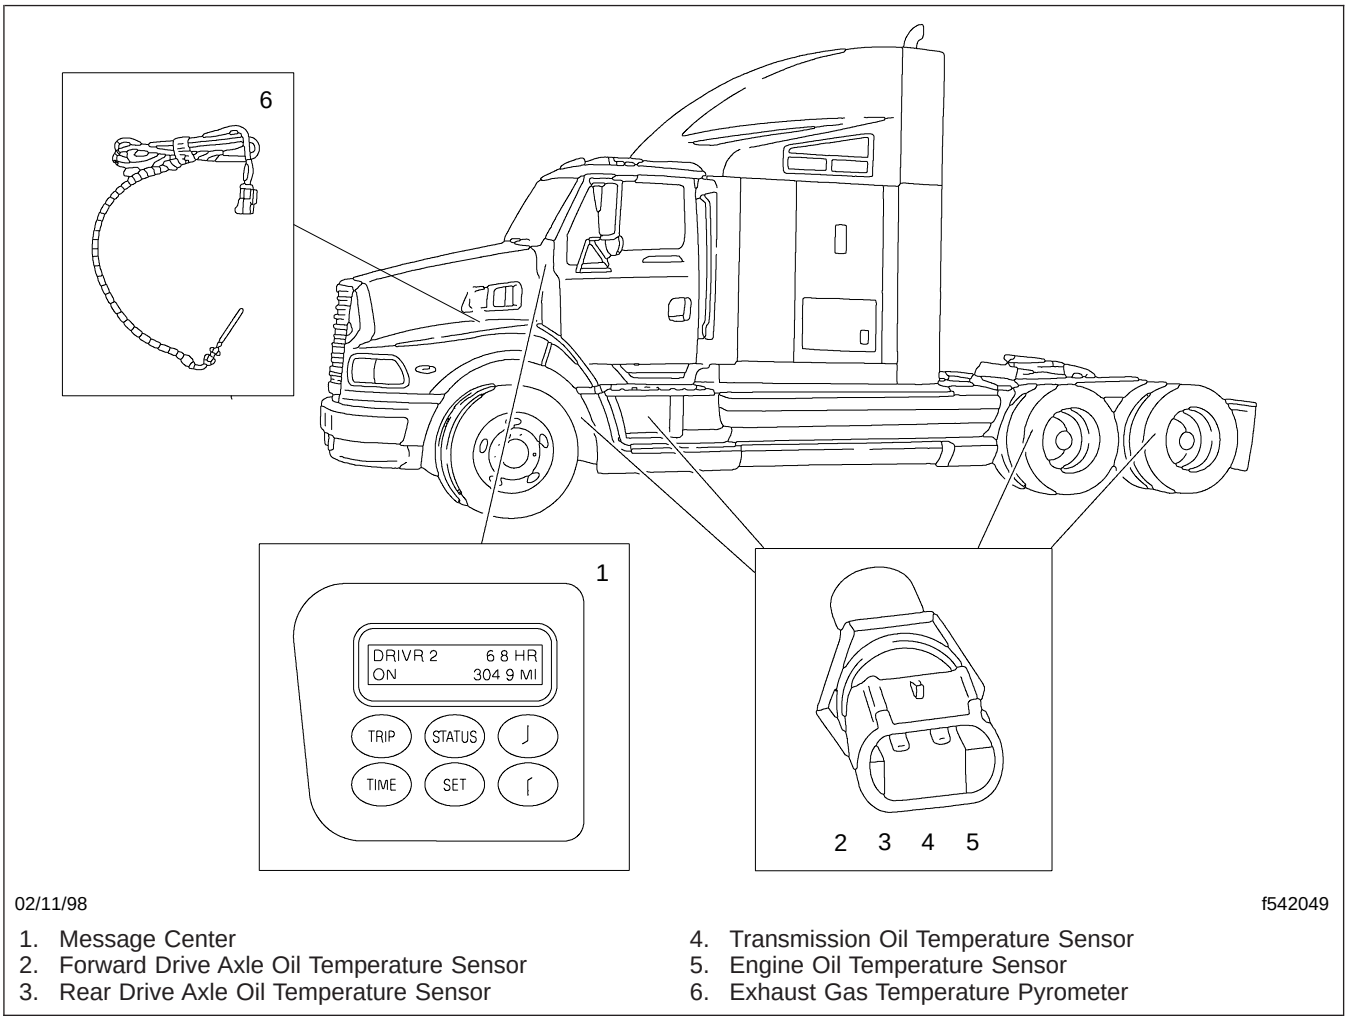
INTERNAL DIAGNOSTICS

Internal diagnostic information is used to provide the technician with information about the five systems monitored directly by the message center. This information is to be used by the technician to evaluate why the message was conveyed to the message center.

EXTERNAL DIAGNOSTICS

External diagnostic information from the data link is used to provide the technician with information about all systems connected to the data link. The message center interprets information from the major systems of the vehicle and displays results that are out of set parameters as a warning message or a diagnostic

General Information

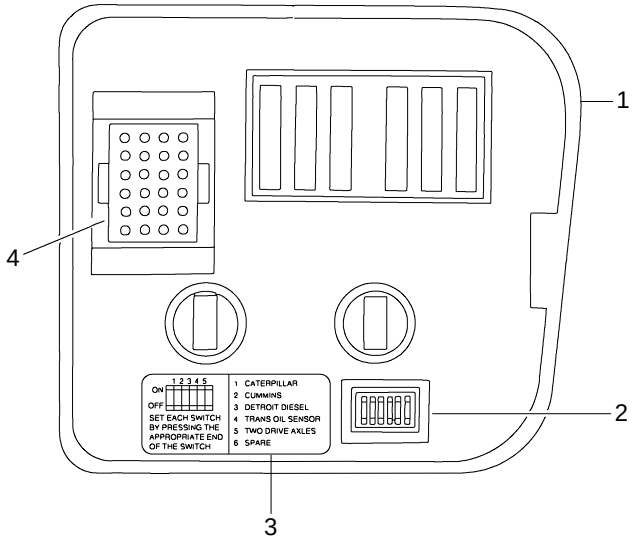


1. Message Center
2. Forward Drive Axle Oil Temperature Sensor
3. Rear Drive Axle Oil Temperature Sensor
4. Transmission Oil Temperature Sensor
5. Engine Oil Temperature Sensor
6. Exhaust Gas Temperature Pyrometer

Fig. 1, Message Center and Temperature Sensor Locations

message. Messages that cannot be interpreted directly are displayed as fault codes.

The message center can also indicate a concern with the data link itself. If information from the data link is interrupted, a message is displayed stating no data is being received.



07/09/98 f542050

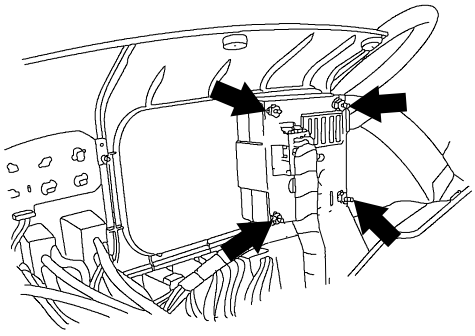
2. Retaining Nuts
3. Bracket
4. Message Center

Fig. 4, Message Center

   - 5.2 Remove the message center bracket retaining nuts.
   - 5.3 Remove the message center bracket.
   - 5.4 Remove the message center.
6. Install the message center.
   - 6.1 Connect the message center electrical connector.
   - 6.2 Install the message center bracket.
   - 6.3 Install the message center.
7. Install the message center bracket retaining nuts. See **Fig. 5**.
8. Position the right-hand instrument panel and install the screws.
9. Install the trailer brake control valve knob.

Message Center Replacement



07/18/98 f542079

A. 8 to 10 lbf·in (90 to 110 N·cm)

Fig. 5, Message Center Retaining Nuts

10. Connect the battery ground cable.

Troubleshooting

Inspection and Verification

1. Verify the vehicle owner's original concern by operating the message center to duplicate the concern. See **Fig. 1**.

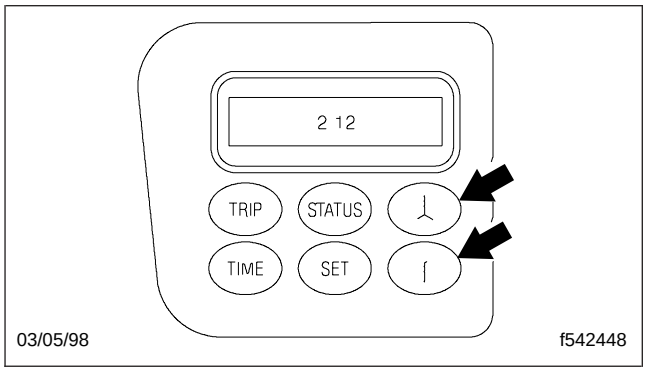


Fig. 1, Message Center

2. Simultaneously press and hold the arrow "Up" and "Down" buttons on the message center until a software revision level is displayed. If a software level of 2.12 or higher is displayed, continue with the inspection and verification. If a software revision level less than 2.12 is displayed, replace the message center.
3. Verify that other components and systems related to the message center fuses operate properly. If the other components and systems are not operating properly, a fuse, fuse feed circuit, or fuse load side circuit may be at fault.
4. Inspect to determine if one of the following mechanical or electrical concerns applies:

Visual Inspection Chart	
Mechanical	**Electrical**
Check message center for obvious damage	Open fuse: instrument panel fuse junction panel Fuse 15 (20 A) or Fuse 22 (10 A) or both
	Open/shorted circuits
	Damaged connectors

Table 1, Visual Inspection Chart

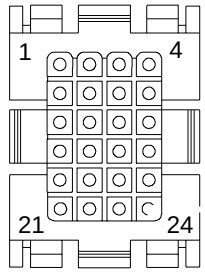
5. If the concern(s) remains after the inspection, determine the symptom(s) and proceed to the problem charts.

Troubleshooting

Problem—The Message Center is Not Operating Properly

Problem—The Message Center is Not Operating Properly (See Fig. 2)	
Possible Cause	**Remedy**
Circuitry	Check for power on Circuit 54 (GN/Y). NOTE: Make sure that the instrument cluster dimmer switch is not in full dim position. With the ignition "Off", disconnect the message center connector. Measure the voltage between the message center connector C294, Pin 24 Circuit 54 (GN/) and the chassis ground. If the voltage is not greater than 10 volts, repair Circuit 54 (GN/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check for power on Circuit 976 (BK/GN). NOTE: Make sure that the instrument cluster dimmer switch is not in full dim position.
Message center	With the ignition in the "Run" position, measure the voltage between the message center connector C294, Pin 20 Circuit 976 (BK/GN) and the chassis ground. If the voltage is not greater than 10 volts, repair Circuit 976 (BK/GN). Test the system for normal operation. If the voltage is greater than 10 volts, check for Power on Circuit 25 (BK/O). With the ignition "Off", disconnect the message center connector. Measure the resistance between the message center connector C294, Pin 5 Circuit 25 (BK/O) and the chassis ground. If the resistance is less than 5 ohms replace the message center. Test the system for normal operation. If the resistance is not less than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation.

Problem—Clock Display Malfunction



09/18/98 f542051

Fig. 2, Message Center Connector

Problem—Clock Display Malfunction (See Fig. 2)	
Possible Cause	**Remedy**
NOTE: An intermittent power condition to the message center will cause the clock to be in error, the time zone to read "PST" and the date to go back to "SUN JAN 1, 1995".	
Circuitry	Check for power on Circuit 54 (GN/Y). Disconnect the message center connector. Measure the voltage between message center connector C294, Pin 24, Circuit 54 (GN/Y) and chassis ground. If the voltage is not greater than 10 volts, repair Circuit 54 (GN/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 54 (GN/Y) for an intermittent problem.
Message center	With the voltmeter still connected, wiggle the harness between the message center and instrument panel fuse junction panel and between the instrument panel fuse junction panel and power distribution box. If the voltage fluctuates when the harness is moved repair Circuit 54 (GN/Y) or the power supply to the instrument panel fuse junction panel. Test the system for normal operation. If the voltage does not fluctuate when the harness is moved, replace the message center. Test the system for normal operation.

Troubleshooting

Problem—The Computer Fuel Economy is Incorrect

Problem— (See Fig. 2, Fig. 3, Fig. 4, Fig. 5 and Fig. 6)The Computer Fuel Economy is Incorrect	
Possible Cause	**Remedy**
Circuitry	Check for a data link diagnostic code. Turn the ignition switch to the "On" position. Press the STATUS button on the message center to bring up diagnostic mode. If the display does not read "J1708 DATA LINK BAD UPDATE RATE", refer to the engine manufacturer's service literature for diagnosis of the ECM. If the display reads "J1708 DATA LINK BAD UPDATE RATE", check the data link circuits for a short to power. Turn the ignition switch to the "Off" position. Disconnect the message center and ECM connectors. Turn the ignition switch to the "On" position and measure the voltage between message center connector C294, Pin 16, Circuit 712 (P), Pin 12, Circuit 716 (Y) and chassis ground. If the voltage is greater than 10 volts on either circuit, repair the damaged circuit. Test the system for normal operation. If the voltage is not greater than 10 volts on either circuit, check the data link circuits for a short to ground. Turn the ignition switch to the "Off" position. Measure the resistance between message center connector C294, Pin 16, Circuit 712 (P), Pin 12, Circuit 716 (Y) and chassis ground. If the resistance is less than 5 ohms for either circuit, repair the damaged circuit. Test the system for normal operation. If the resistance is not less than 5 ohms for either circuit, check the data link circuits for an open.
Engine control module	Turn the ignition switch to the "Off" position. Measure the resistance between message center connector C294, Pin 16, Circuit 712 (P) and engine control module connector; C110 Pin 1 (Caterpillar Engine), C128 Pin 8 (Cummins Engine), C135 Pin C1 (Detroit Diesel) Circuit 712 (P). Measure the resistance between message center connector C294, Pin 12, Circuit 716 (Y) and engine control module connector; C110 Pin 7 (Caterpillar Engine), C128 Pin 27 (Cummins Engine), C135 Pin C2 (Detroit Diesel) Circuit 712 (Y). If the resistance is less than 5 ohms for both circuits, refer to the engine manufacturer's service literature for diagnosis of the ECM. If the resistance is more than 5 ohms for both circuits, repair the damaged circuit. Test the system for normal operation.

Problem—The Engine Oil Temperature Warning is Inoperative/Incorrect

Problem—The Engine Oil Temperature Warning is Inoperative/Incorrect (See Fig. 2, Fig. 3 and Fig. 7)	
Possible Cause	**Remedy**
Circuitry	Check for engine oil temperature circuit diagnostic high reading. Press the STATUS button on the message center to bring up the diagnostic mode for engine oil temperature. If the message center does not read "ENG OIL TEMP SENSOR VOLTS HI", check for engine oil temperature circuit diagnostic low reading. Press the STATUS button on the message center to bring up diagnostic mode for engine oil temperature. If the message center does not read "ENG OIL TEMP SENSOR VOLTS LOW", replace the message center. Test the system for normal operation. If the message center reads, "ENG OIL TEMP SENSOR VOLTS LOW", check the engine oil temperature sensor for a short. With the engine at room temperature measure the resistance between the engine oil temperature sensor terminals. If the resistance is not 300 to 700 ohms, replace the engine oil temperature sensor. Test the system for normal operation. If the resistance is 300 to 700 ohms, check Circuit 634 (BL) for a short to ground. Measure the resistance between engine oil sensor connector C113, Pin 1, Circuit 634 (BL) and chassis ground. If the resistance is less than 5 ohms, repair Circuit 634 (BL). Test the system for normal operation. If the resistance is more than 5 ohms, replace the message center. Test the system for normal operation. If the message center reads "ENG OIL TEMP SENSOR VOLTS HI", check Circuit 634 (BL) for a short to battery. Turn the ignition switch to the "Off" position. Disconnect the engine oil temperature sensor connector and turn the ignition switch to the "On" position. Measure the voltage between engine oil temperature sensor connector C113, Pin 1, Circuit 634 (BL) and chassis ground. If the voltage is not approximately 5 volts, check Circuit 634 (BL) for an open. Turn the ignition switch to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 8, Circuit 634 (BL) and engine oil temperature sensor connector C113, Pin 1, Circuit 634 (BL). If the resistance is less than 5 ohms, replace the message center. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 634 (BL). Test the system for normal operation. If the voltage is approximately 5 volts, check Circuit 25 (BK/O) for an open. Turn the ignition switch to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 4, Circuit 25 (BK/O) and engine oil temperature sensor connector C113, Pin 2, Circuit 25 (BK/O). If the resistance is more than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check the engine oil temperature sensor for an open. With the engine at room temperature, measure the resistance between the engine oil temperature sensor terminals. If the resistance is 300 to 700 ohms, replace the message center. Test the system for normal operation. If the resistance is not 300 to 700 ohms, replace the engine oil temperature sensor. Test the system for normal operation.

Troubleshooting

Problem—The Transmission Oil Temperature Warning is Inoperative/Incorrect (See Fig. 2, Fig. 3 and Fig. 7)	
Possible Cause	**Remedy**
Circuitry	Check for transmission oil temperature circuit diagnostic high reading. Turn the ignition switch to the "On" position. Press the STATUS button on the message center to bring up the diagnostic mode for the transmission oil temperature. If the message center does not read "TRANS OIL TEMP SENSOR VOLTS HI", check for transmission oil temperature circuit diagnostic low reading. Press the STATUS button on the message center to bring up the diagnostic mode for the transmission oil temperature. If the message center does not read "TRANS OIL TEMP SENSOR VOLTS LOW", replace the message center. Test the system for normal operation. If the message center does read "TRANS OIL TEMP SENSOR VOLTS LOW", check the transmission oil temperature sensor for a short. Turn the ignition switch to the "Off" position. Disconnect the transmission oil temperature sensor connector. With the transmission at room temperature, measure the resistance between the transmission oil temperature sensor terminals. If the resistance is not 300 to 700 ohms, replace the transmission oil temperature sensor. Test the system for normal operation. If the resistance is 300 to 700 ohms, check Circuit 978 (Y) for a short to ground.
Transmission oil temperature	Disconnect the message center connector. Measure the resistance between transmission oil sensor connector C120, Pin 1, Circuit 978 (Y) and chassis ground. If the resistance is less than 5 ohms, repair Circuit 978 (Y). Test the system for normal operation. If the resistance is more than 5 ohms, replace the message center. Test the system for normal operation. If the message center reads "TRANS OIL TEMP SENSOR VOLTS HI", check Circuit 978 (Y) for a short to battery. Turn the ignition switch to the "Off" position. Disconnect the transmission oil temperature sensor. Turn the ignition switch to the "On" position. Measure the voltage between transmission oil temperature sensor connector C120, Pin 1, Circuit 978 (Y) and chassis ground. If the voltage is not approximately 5 volts, check Circuit 978 (Y) for an open. Turn the ignition switch to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 23, Circuit 978 (Y) and transmission oil temperature sensor connector C120, Pin 1, Circuit 978 (Y). If the resistance is less than 5 ohms, replace the message center. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 978 (Y). Test the system for normal operation. If the voltage is approximately 5 volts, check Circuit 25 (BK/O) for an open.
Message center	Turn the ignition switch to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 19, Circuit 25 (BK/O) and transmission oil temperature sensor connector C120, Pin 2, Circuit 25 (BK/O). If the resistance is more than 5 ohms, repair circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check the transmission oil temperature. With the transmission at room temperature, measure the resistance between the transmission oil temperature sensor terminals. If the resistance is 300 to 700 ohms, replace the message center. Test the system for normal operation. If the resistance is not 300 to 700 ohms, replace the transmission oil temperature sensor. Test the system for normal operation.

Problem—The Forward Drive Axle Oil Temperature Warning is Inoperative/Incorrect

Problem—The Forward Drive Axle Oil Temperature Warning is Inoperative/Incorrect (See Fig. 2, Fig. 3 and Fig. 7)	
Possible Cause	**Remedy**
Circuitry	Check the forward axle oil temperature circuit diagnostic high reading. Turn the ignition switch to the "On" position. Press the STATUS button on the message center to bring up the diagnostic mode for the forward drive axle oil temperature. If the message center does not read "FRONT OIL TEMP SENSOR VOLTS HI", check for forward drive axle oil temperature circuit diagnostic low reading. Press the "STATUS" button on the message center to bring up the diagnostic mode for forward drive axle oil temperature. If the message does not read "FRONT OIL TEMP SENSOR VOLTS LOW", replace the message center. Test the system for normal operation. If the message does read "FRONT OIL TEMP SENSOR VOLTS LOW", check the forward drive axle oil temperature sensor for a short. Turn the ignition switch to the "Off" position. Disconnect the front oil temperature sensor connector. With the forward drive axle at room temperature, measure the resistance between the forward drive axle oil temperature sensor terminals. If the resistance is not 300 to 700 ohms, replace the forward drive axle oil temperature sensor. Test the system for normal operation. If the resistance is 300 to 700 ohms, check Circuit 962 (R) for a short to ground.
Front drive axle oil temperature sensor	Disconnect the message center connector. Measure the resistance between forward drive axle oil sensor connector C410, Pin 1, Circuit 962 (R) and chassis ground. If the resistance is less than 5 ohms, repair Circuit 962 (R). Test the system for normal operation. If the resistance is more than 5 ohms, replace the message center. Test the system for normal operation. If the message center reads "FRONT OIL TEMP SENSOR VOLTS HI", check Circuit 962 (R) for a short to battery. Turn the ignition switch to the "Off" position. Disconnect the front oil temperature sensor. Turn the ignition switch to the "On" position. Measure the voltage between forward drive axle oil temperature sensor connector C410, Pin 1, Circuit 962 (R) and chassis ground. If the voltage is not approximately 5 volts, check Circuit 962 (R) for an open.
Message center	Turn the ignition switch to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 15, Circuit 962 (R) and forward drive axle oil temperature sensor connector C410, Pin 1, Circuit 962 (R). If the resistance is less than 5 ohms, replace the message center. Test the system for normal operation. If the resistance is more than 5 ohms, repair Circuit 962 (R). Test the system for normal operation. If the voltage is approximately 5 volts, check Circuit 25 (BK/O) for an open. Turn the ignition switch to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 11, Circuit 25 (BK/O) and forward drive axle oil temperature sensor connector C410, Pin 2, Circuit 25 (BK/O). If the resistance is more than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check the forward axle oil temperature sensor for an open. With the forward drive axle at room temperature, measure the resistance between the forward drive axle oil temperature sensor terminals. If the resistance is 300 to 700 ohms, replace the message center. Test the system for normal operation. If the resistance is not 300 to 700 ohms, replace the forward drive axle oil temperature sensor. Test the system for normal operation.

Troubleshooting

Problem—The Rear Drive Axle Oil Temperature Warning is Inoperative/Incorrect

Problem—The Rear Drive Axle Oil Temperature Warning is Inoperative/Incorrect (See Fig. 2, Fig. 3 and Fig. 7)	
Possible Cause	**Remedy**
Circuitry	Check for rear drive axle oil temperature circuit diagnostic high reading. Turn the ignition to the "Off" position. Press the STATUS button on the message center to bring up the diagnostic mode for the rear drive axle oil temperature. If the message center does not read "REAR OIL TEMP SENSOR VOLTS HI", check for rear drive axle oil temperature circuit diagnostic low reading. Press the STATUS button on the message center to bring up the diagnostic mode for the rear drive axle oil temperature. If the message center does not read "REAR OIL TEMP SENSOR VOLTS LOW", replace the message center. Test the system for normal operation. If the message center does read "REAR OIL TEMP SENSOR VOLTS LOW", check Circuit 963 (GN) for an open. Turn the ignition to the "Off" position. Disconnect the rear oil temperature sensor. With the rear drive axle at room temperature, measure the resistance between the rear drive axle oil temperature sensor terminals. If the resistance is not 300 to 700 ohms, replace the rear drive axle oil temperature sensor. Test the system for normal operation. If the resistance is 300 to 700 ohms, check Circuit 963 (GN) for a short to ground.
Rear drive axle oil temperature sensor	Measure the resistance between rear drive axle oil sensor connector C408, Pin 1, Circuit 963 (GN) and chassis ground. If the resistance is less than 5 ohms, repair Circuit 963 (GN). Test the system for normal operation. If the resistance is more than 5 ohms, replace the message center. Test the system for normal operation. If the message center reads "REAR OIL TEMP SENSOR VOLTS HI", check Circuit 963 (GN) for a short to battery. Turn the ignition to the "Off" position. Disconnect the rear oil temperature sensor connector. Turn the ignition switch to the "Run" position. Measure the voltage between rear drive axle oil temperature sensor connector C408, Pin 1, Circuit 963 (GN) and chassis ground. If the voltage is not approximately 5 volts, check Circuit 963 (GN) for an open.
Message center	Turn the ignition to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 7, Circuit 963 (GN) and rear drive axle oil temperature sensor connector C408, Pin 1, Circuit 963 (GN). If the resistance is more than 5 ohms, repair Circuit 963 (GN). Test the system for normal operation. If the resistance is less than 5 ohms, replace the message center. Test the system for normal operation. If the voltage is not approximately 5 volts, check Circuit 25 (BK/O) for an open. Turn the ignition to the "Off" position. Disconnect the message center connector. Measure the resistance between message center connector C294, Pin 3, Circuit 25 (BK/O) and rear drive axle oil temperature sensor connector C408, Pin 2, Circuit 25 (BK/O). If the resistance is more than 5 ohms, repair Circuit 25 (BK/O). Test the system for normal operation. If the resistance is less than 5 ohms, check rear drive axle oil temperature sensor for an open. With the rear drive axle at room temperature, measure the resistance between the rear drive axle oil temperature sensor terminals. If the resistance is 300 to 700 ohms, replace the message center. Test the system for normal operation. If the resistance is not 300 to 700, ohms replace the rear drive axle oil temperature sensor. Test the system for normal operation.

Problem—The Exhaust Gas Temperature Warning is Inoperative/Incorrect

Problem—The Exhaust Gas Temperature Warning is Inoperative/Incorrect (See Fig. 2, Fig. 3 and Fig. 8)	
Possible Cause	**Remedy**
Circuitry	Check the continuity of the circuits. Turn the ignition to the "Off" position. Disconnect the message center and exhaust gas pyrometer connectors. Measure the resistance between message center connector C294, Pin 2, Circuit 610 (R/Y) and exhaust gas pyrometer connector C298, Pin 2, Circuit 610 (R/Y).
Exhaust gas pyrometer	Measure the resistance between message center connector C294, Pin 6, Circuit 611 (Y) and exhaust gas pyrometer connector C298, Pin 1, Circuit 611 (Y). If the resistance is not less than 5 ohms for both circuits, repair the damaged circuit. Test the system for normal operation. If the resistance is less than 5 ohms for both circuits, check the exhaust gas pyrometer.
Message center	Temporarily install a known good exhaust gas pyrometer. Disconnect the message center and exhaust gas pyrometer connectors. Turn the ignition to the "Run" position. Press the STATUS button on the message center to bring up the exhaust gas temperature mode. If the message center functions properly, replace the exhaust gas pyrometer. Test the system for normal operation. If the message center does not function properly, replace the message center. Test system for normal operation.

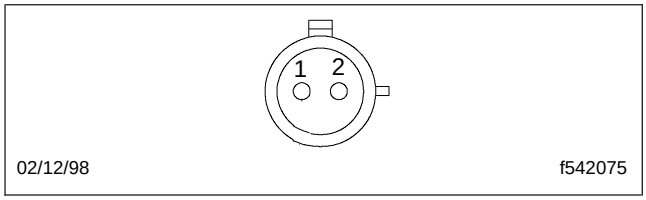

Fig. 8, Exhaust Gas Pyrometer Connector Pin Identification

See **Fig. 1** for a full view of the message center wiring.

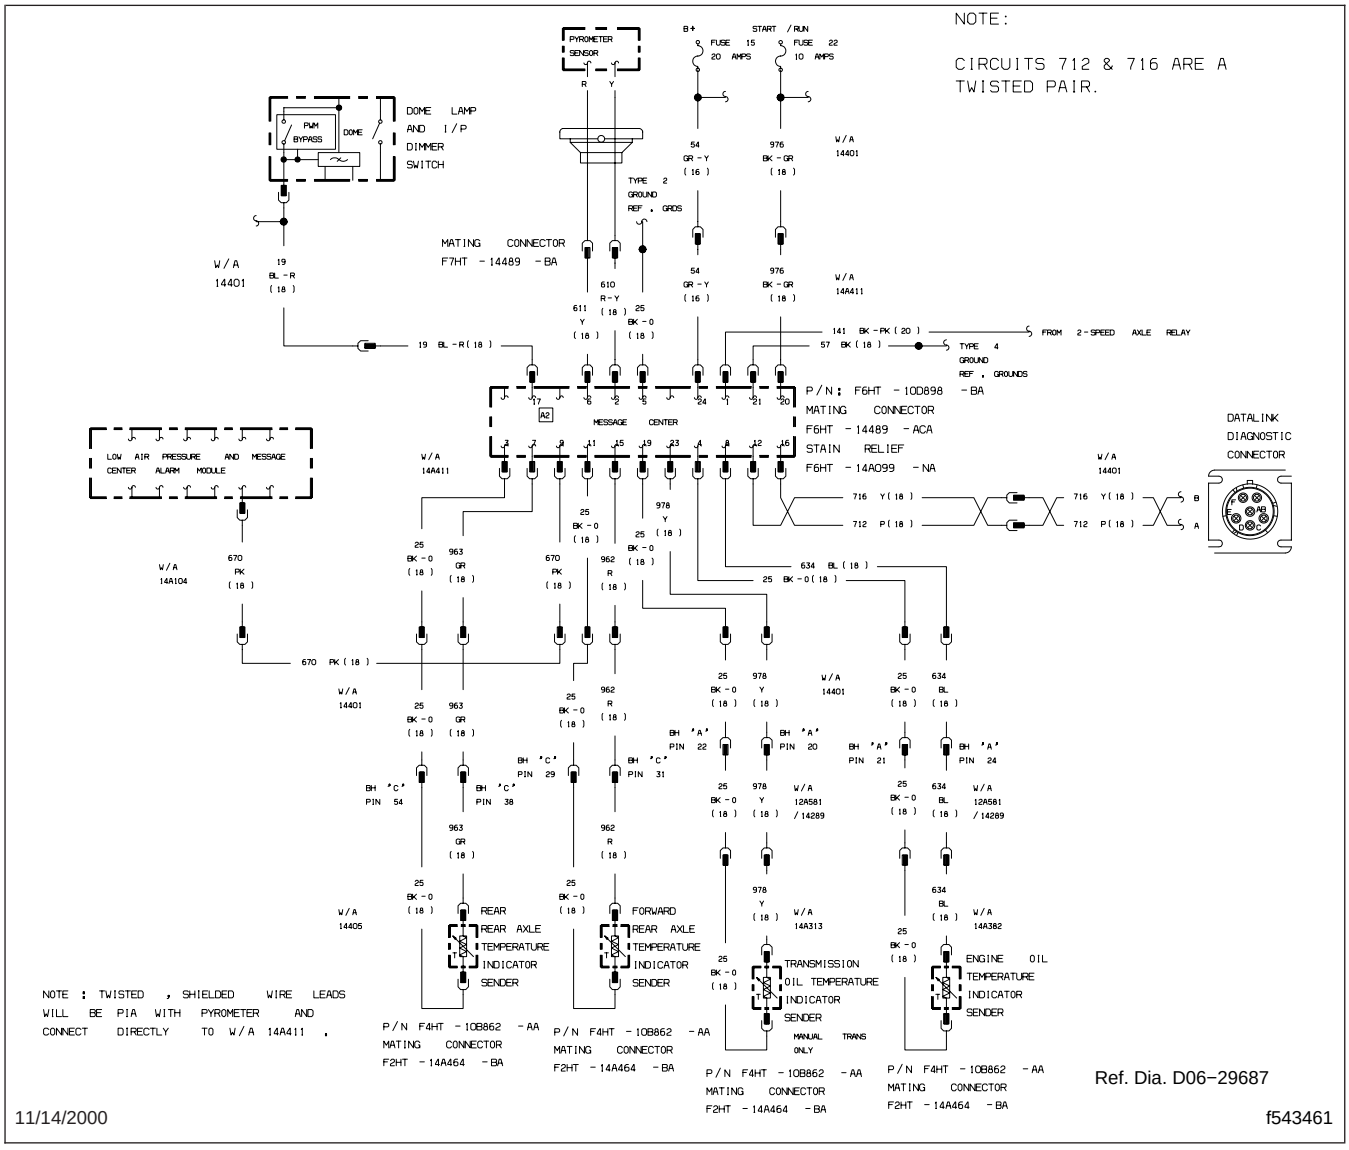

Fig. 1, Message Center Wiring

Torque Specifications	
Description	**lbf·in (N·cm)**
Message Center Retaining Nuts	8–10 (90–110)

Table 1, Torque Specifications

General Information

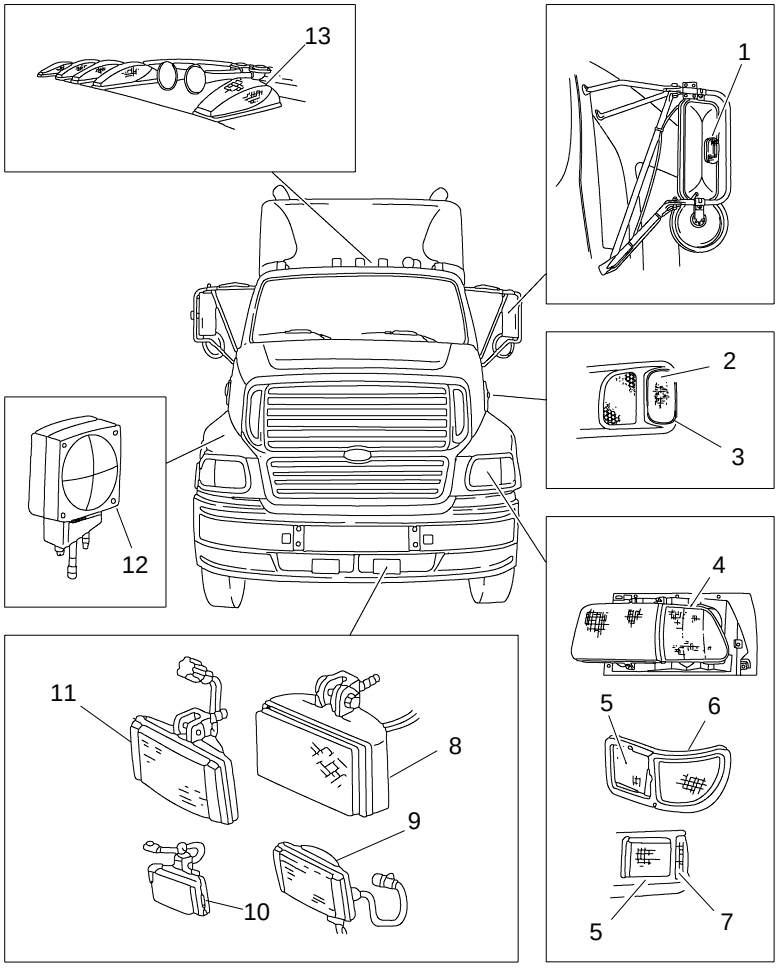
Exterior Lighting System

Fig. 1, **Fig. 2** and **Fig. 3** show exterior lighting components.

Interior Lighting System

The following components are included in the interior lighting system (see **Fig. 4**):

- vanity mirror

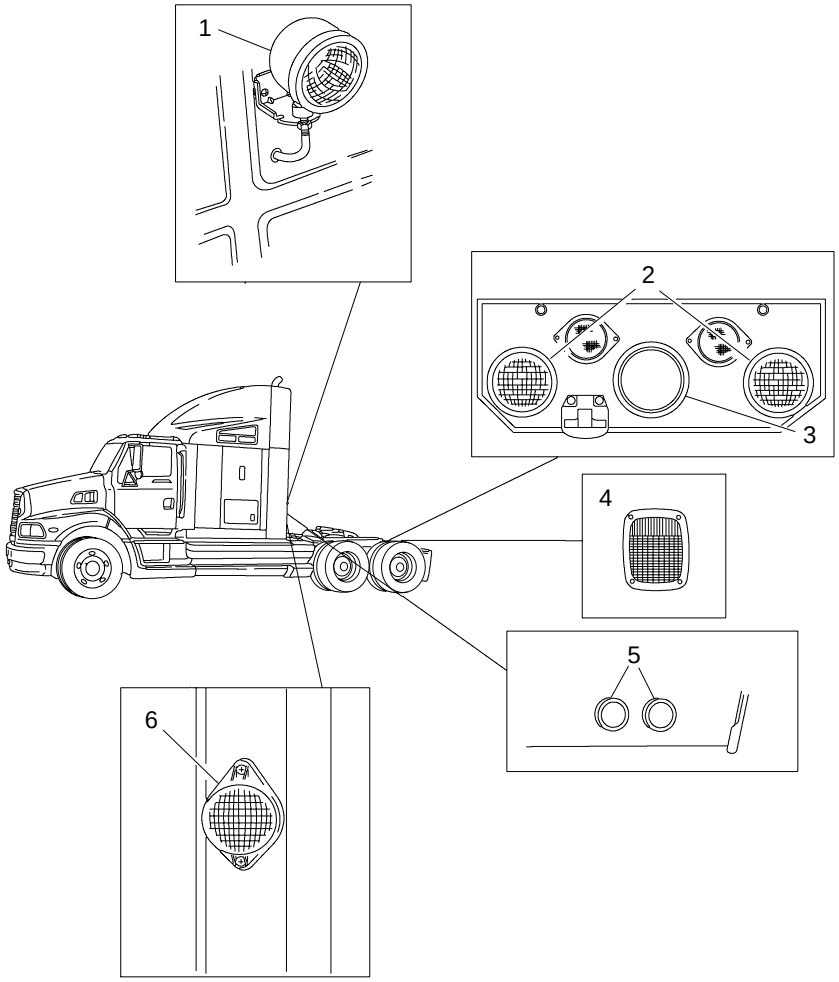


07/17/98 f542169

1. Mirror Marker Lamp
2. Hood-Mounted Turn Lamp Lens
3. Hood-Mounted Turn Lamp Housing
4. Headlamp Assembly (aerodynamic)
5. Sealed Beam Headlamp
6. Front Park/Turn Lamp and Bezel Assembly (101-inch BBC)
7. Front Park/Turn Lamp (113-inch and 122-inch BBC)
8. Fog/Road Lamp (113-inch and 122-inch BBC with steel bumper)
9. Fog/Road Lamp (101-inch BBC with full width bumper)
10. Fog/Road Lamp (113-inch and 122-inch BBC with aerodynamic bumper)
11. Fog/Road Lamp (101-inch BBC with cutoff bumper)
12. Fender-Mounted Turn Lamp
13. Roof Marker Lamp

Fig. 1, Exterior Lighting Components

General Information

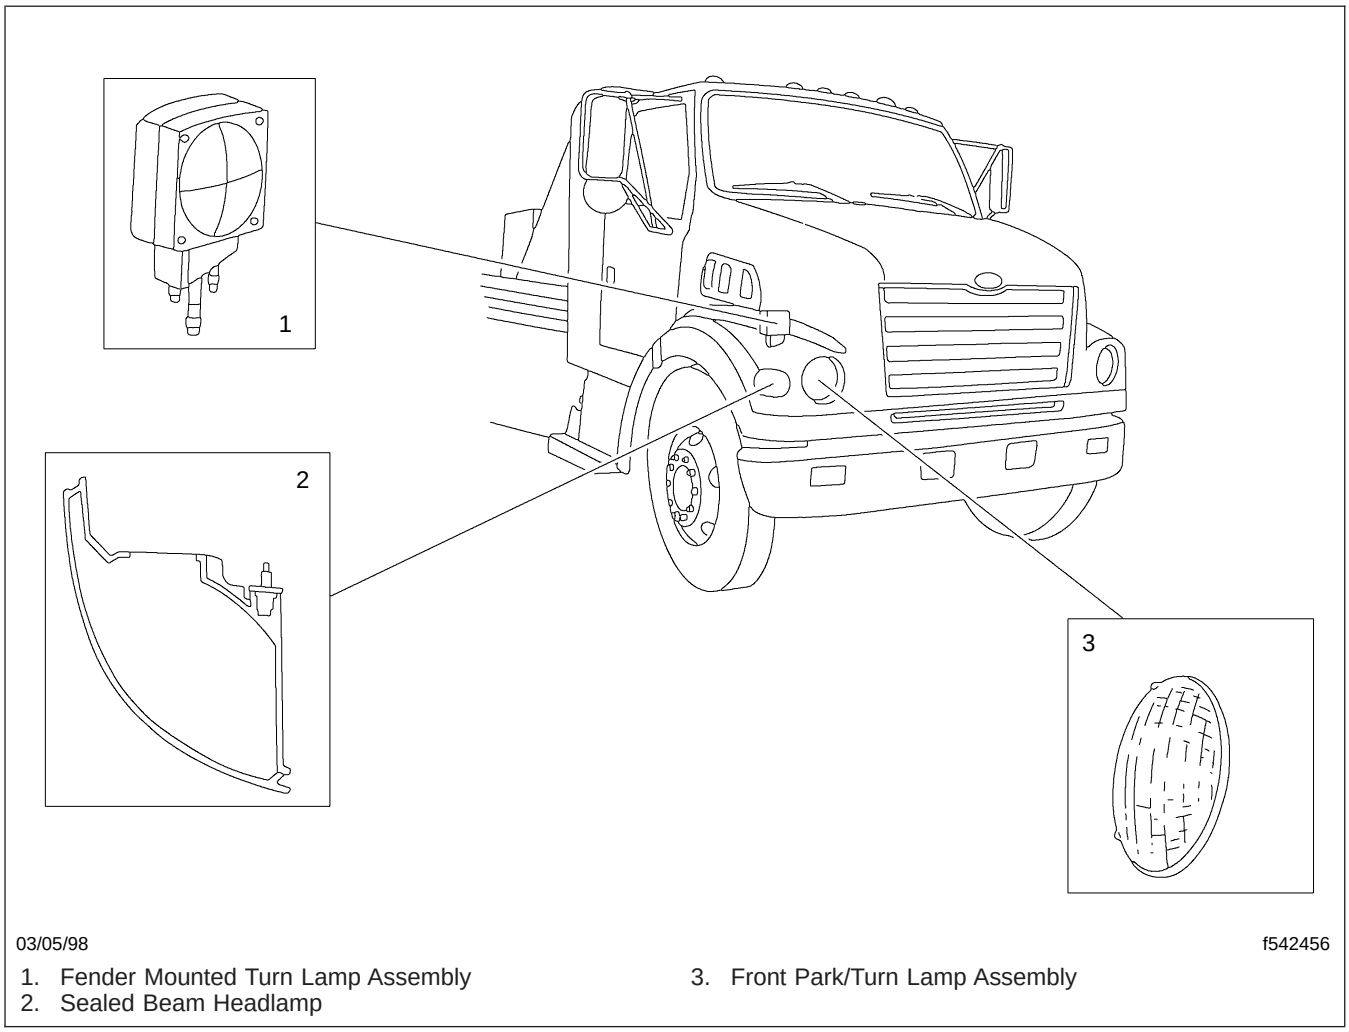


07/18/98 f542170

1. Aimable Trailer Hookup Lamp
2. Tail Lamp
3. Backup Lamp
4. Tail Lamp
5. Dual Recessed Trailer Hookup Lamps (with sleeper)
6. Fixed Trailer Hookup Lamp

Fig. 2, Exterior Lighting Components

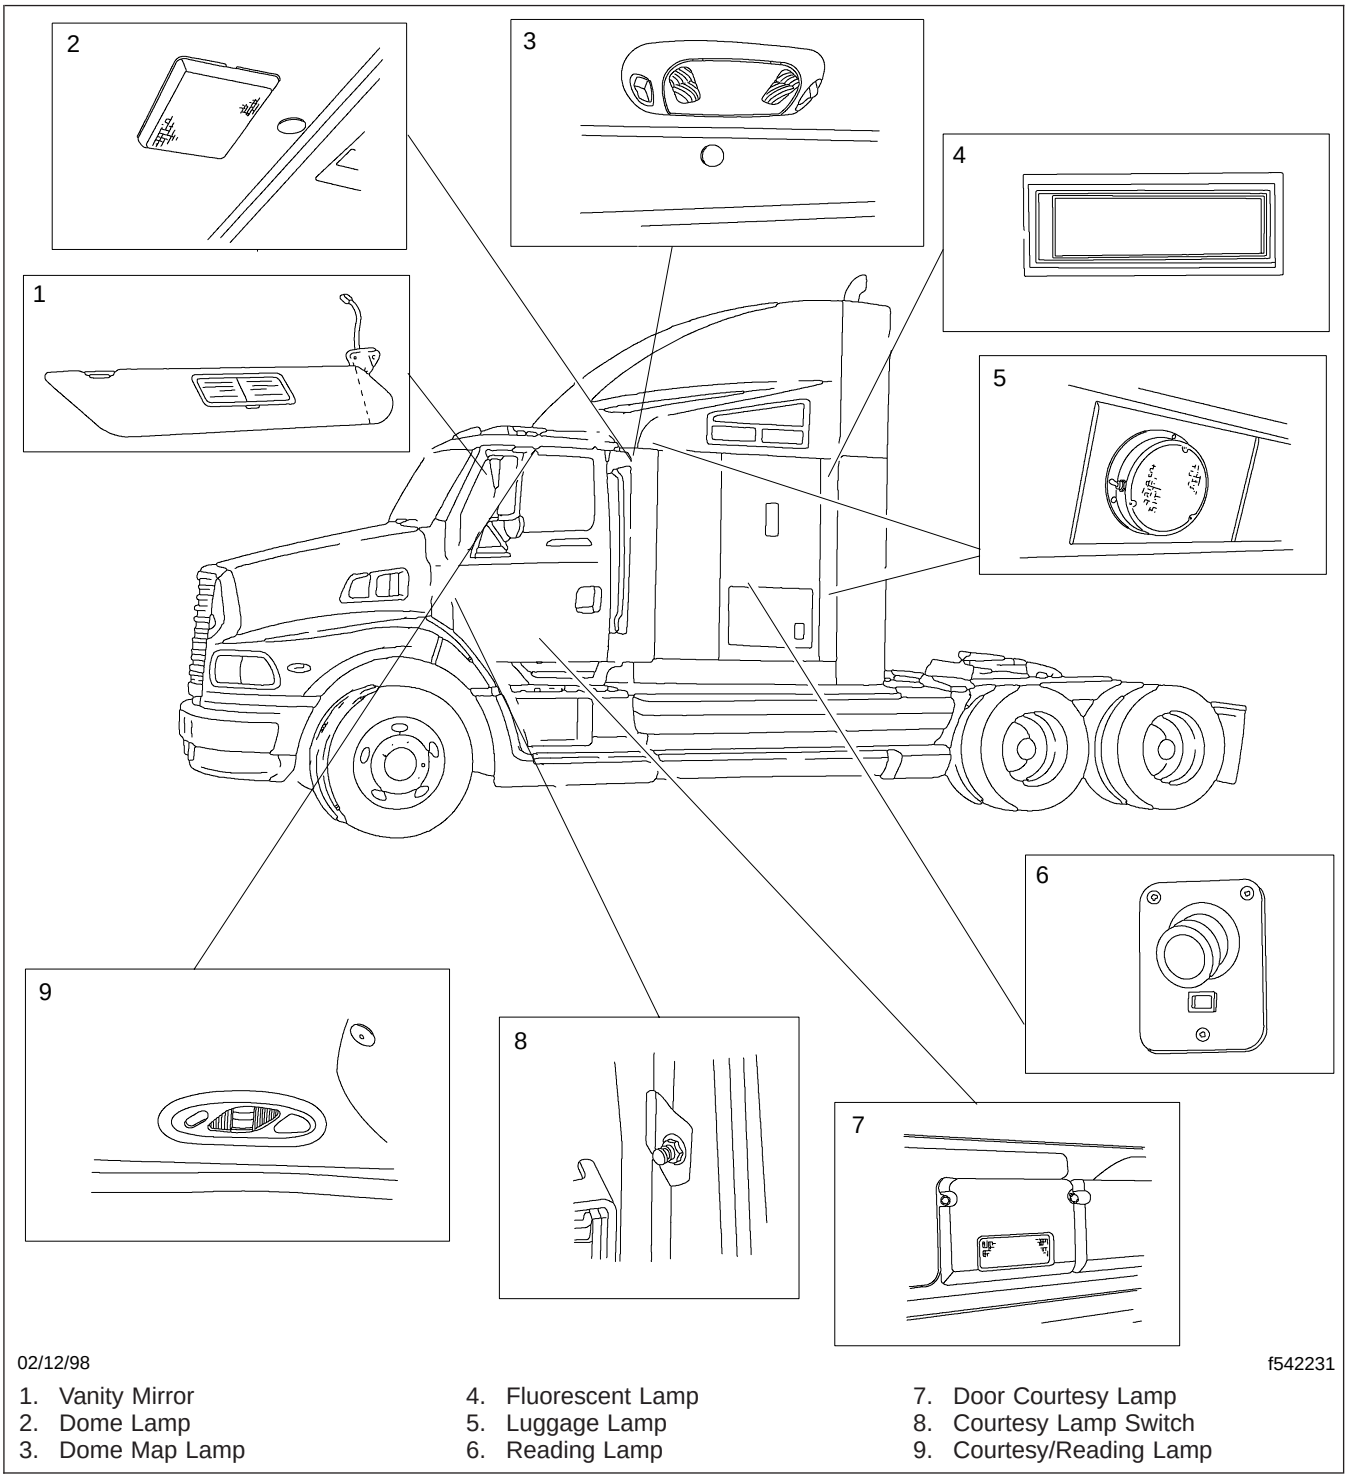
- dome lamp
- dome map lamp
- fluorescent lamp
- luggage lamp
- reading lamp
- door courtesy lamp
- courtesy lamp switch
- courtesy/reading lamp



1. Fender Mounted Turn Lamp Assembly
2. Sealed Beam Headlamp
3. Front Park/Turn Lamp Assembly

Fig. 3, Exterior Lighting Components

General Information



1. Vanity Mirror
2. Dome Lamp
3. Dome Map Lamp
4. Fluorescent Lamp
5. Luggage Lamp
6. Reading Lamp
7. Door Courtesy Lamp
8. Courtesy Lamp Switch
9. Courtesy/Reading Lamp

Fig. 4, Component Locator

Interior Light Replacement

ALL BASE-LEVEL TRIM AND L-LINE MID-LEVEL TRIM DOME LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the dome lamp lens. See **Fig. 1**.

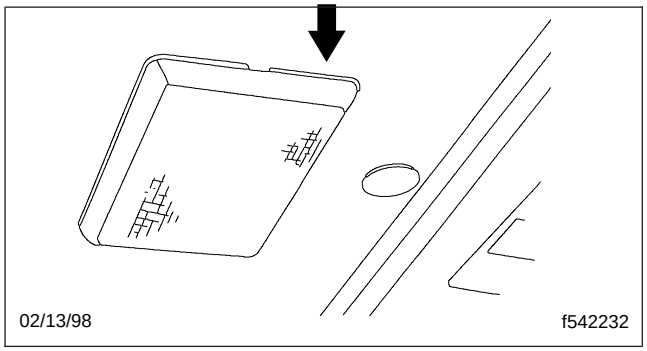


Fig. 1, Dome Lamp Lens

3. Remove the screws. See **Fig. 2**.

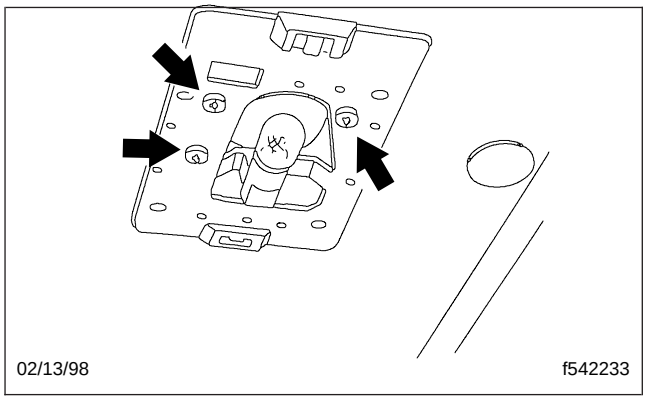

Fig. 2, Dome Lamp Screws

4. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 3**.
5. Connect the electrical connector, and install the lamp assembly.
6. Install the screws.
7. Reconnect the negative battery cable.

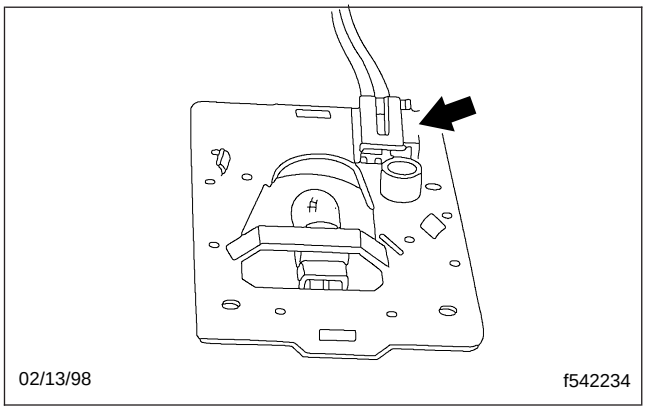

Fig. 3, Dome Lamp Electrical Connector

A-LINE HIGH-LEVEL TRIM DOME/MAP COMBINATION LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the dome lamp lens. See **Fig. 4**.

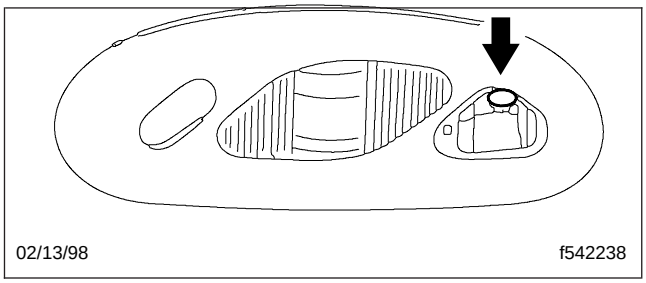

Fig. 4, Dome Lamp Lens

3. Remove the screws. See **Fig. 5**.

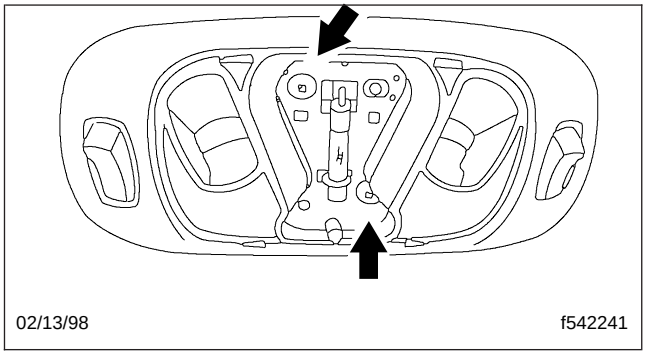

Fig. 5, Dome Lamp Screws

Interior Light Replacement

4. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 6**.

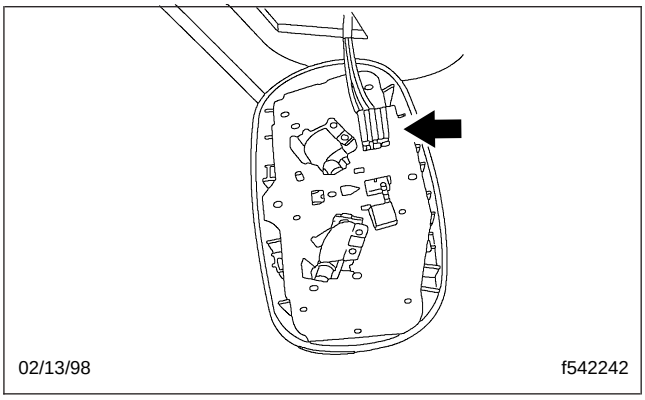

Fig. 6, Dome Lamp Electrical Connector

5. Reconnect the electrical connector and place the lamp assembly into position.
6. Install the screws.
7. Install the dome lamp lens.
8. Reconnect the negative battery cable.

COURTESY/READING LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the cover. See **Fig. 7**.

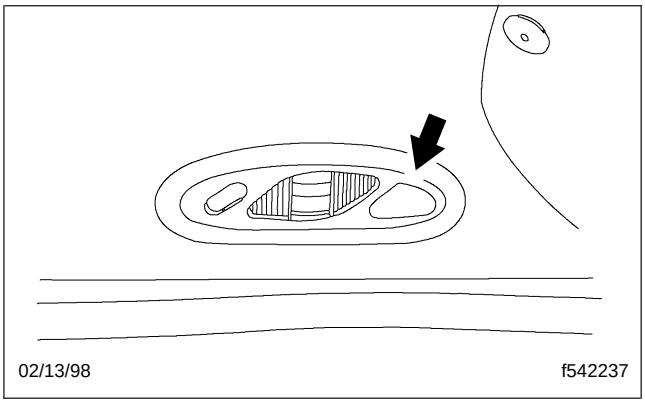

Fig. 7, Lamp Cover

3. Remove the screw. See **Fig. 8**.
4. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 9**.

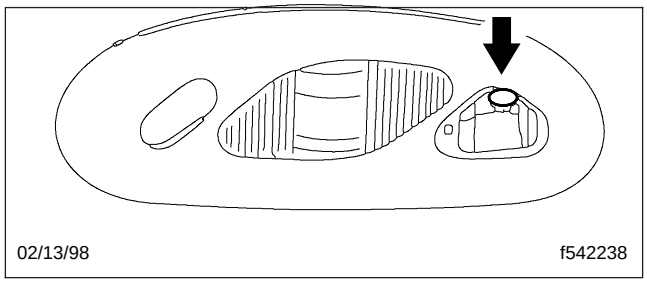

Fig. 8, Lamp Assembly Screw

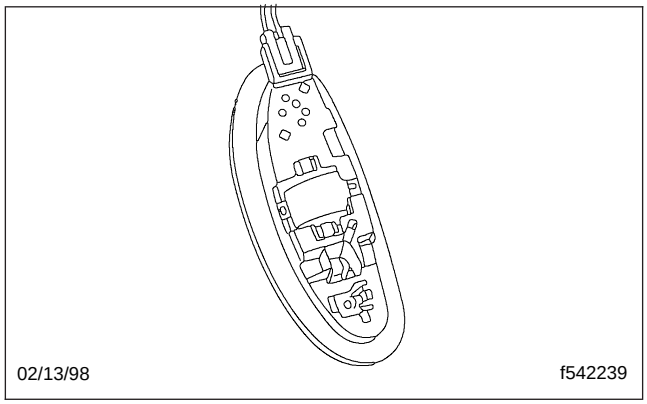

Fig. 9, Lamp Assembly

5. Reconnect the electrical connector and place the lamp assembly into position.
6. Install the screws.
7. Install the courtesy/reading lamp cover.
8. Reconnect the negative battery cable.

DOOR COURTESY LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the screws. See **Fig. 10**.
3. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 11**.
4. Reconnect the electrical connector and place the lamp assembly into position.
5. Install the screws.
6. Install the door courtesy lamp cover.
7. Reconnect the negative battery cable.

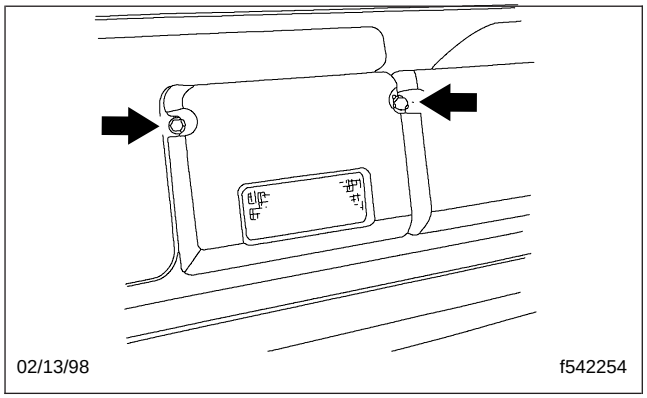

Fig. 10, Courtesy Lamp Screws

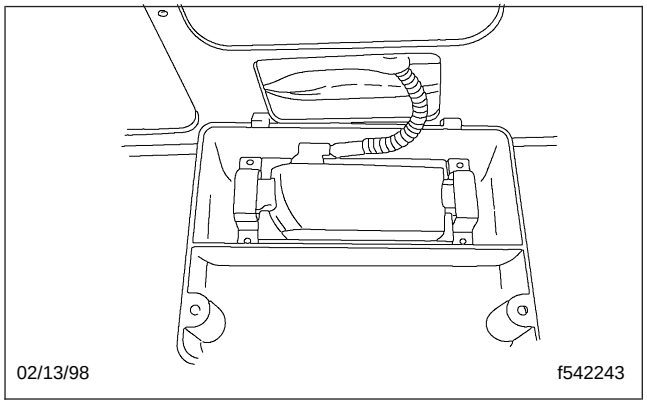

Fig. 11, Courtesy Lamp Electrical Connector

ABLE BODY FLAT TOP PLUS AND AERO BULLET PLUS READING LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the screws. See **Fig. 12**.
3. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 13**.
4. Reconnect the electrical connector and place the lamp assembly into position.
5. Install the screws.
6. Reconnect the negative battery cable.

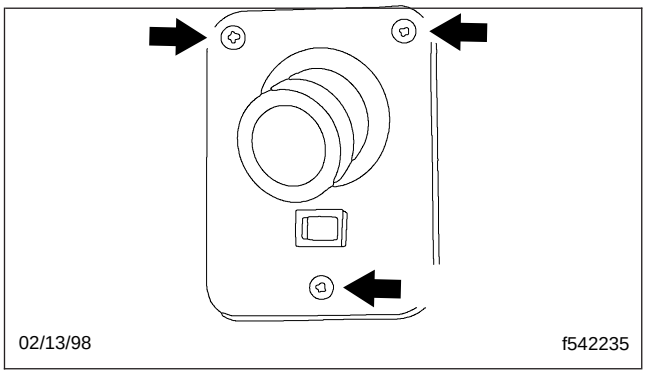

Fig. 12, Reading Lamp Screws

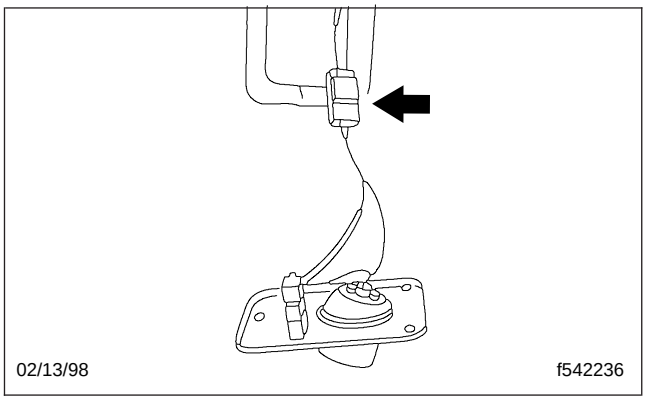

Fig. 13, Reading Lamp Electrical Connector

ABLE BODY FLAT TOP PLUS AND AERO BULLET PLUS FLUORESCENT LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the lens. See **Fig. 14**.
3. Remove the screws. See **Fig. 15**.
4. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 16**.
5. Reconnect the electrical connector and place the fluorescent lamp assembly into position.
6. Install the screws.
7. Reconnect the negative battery cable.

Interior Light Replacement

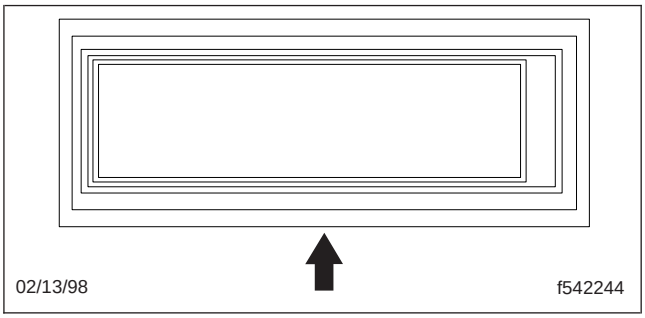

Fig. 14, Fluorescent Lamp Assembly Lens

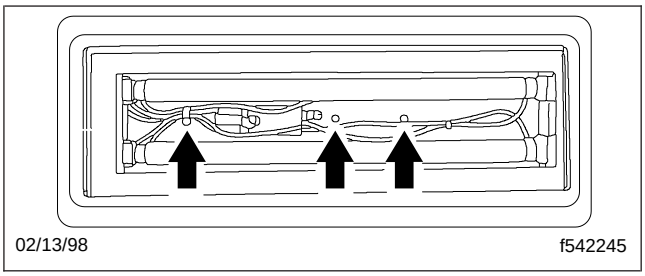

Fig. 15, Lamp Assembly Screws

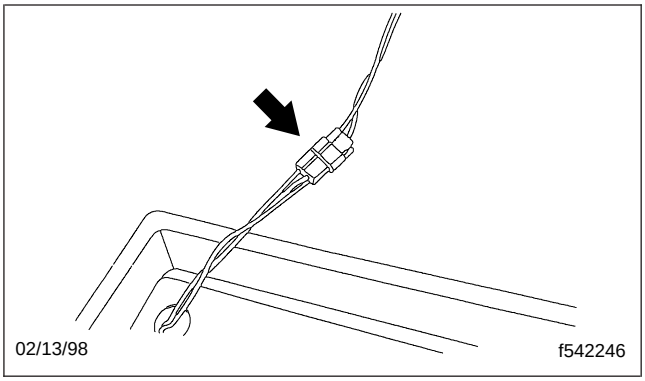

Fig. 16, Lamp Assembly Electrical Connector

ABLE BODY FLAT TOP PLUS AND AERO BULLET PLUS LUGGAGE LAMP ASSEMBLY

1. Disconnect the negative battery cable from the battery.
2. Remove the screws and the lens. See **Fig. 17**.
3. Remove the screws. See **Fig. 18**.
4. Disconnect the electrical connector, and remove the lamp assembly. See **Fig. 19**.

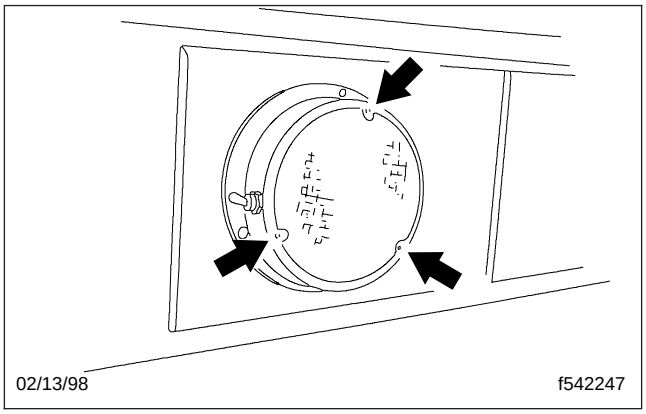

Fig. 17, Lens Screws

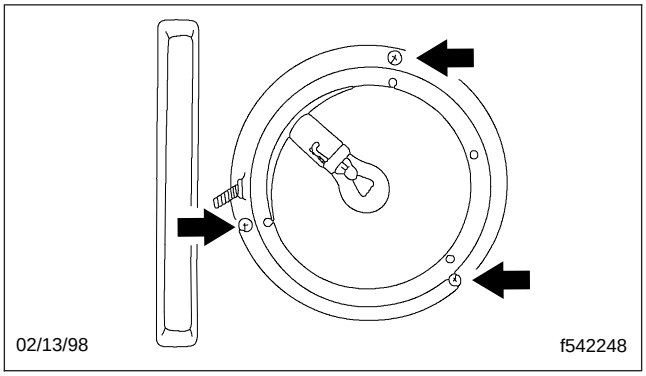

Fig. 18, Lamp Assembly Screws

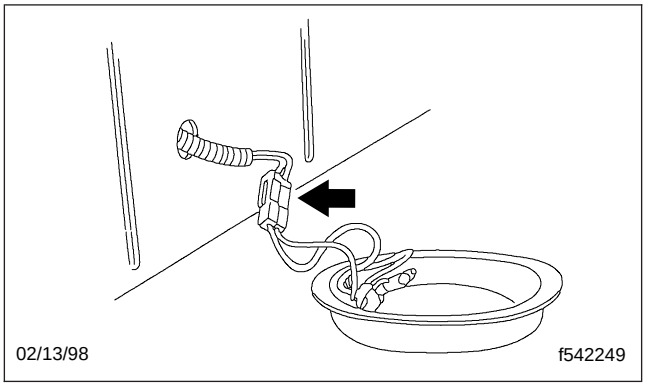

Fig. 19, Lamp Assembly Electrical Connector

5. Reconnect the electrical connector and place the lamp assembly into position.
6. Install the screws.
7. Reconnect the negative battery cable.

SILVERSTAR DOME LAMP ASSEMBLY (TYPICAL)

1. Disconnect the negative battery cable from the battery.
2. Remove the screws, and remove the lamp cover. See **Fig. 20**.

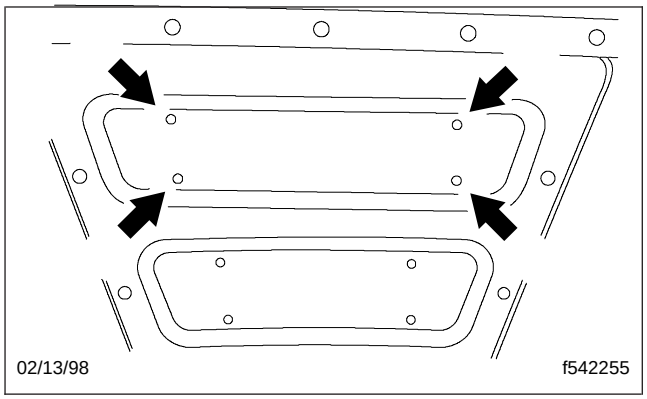

Fig. 20, Dome Lamp Screws

3. Remove the bulb. See **Fig. 21**.

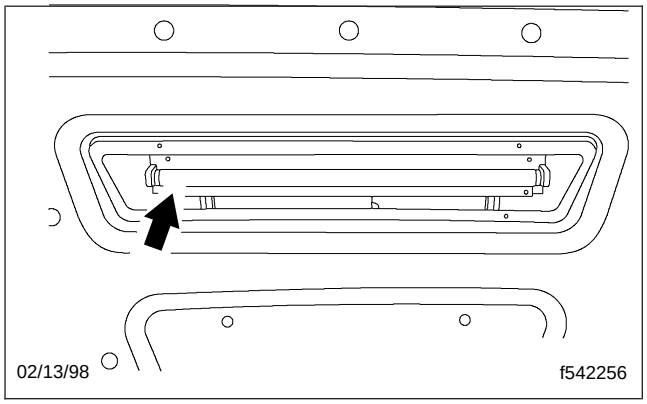

Fig. 21, Dome Lamp Bulb

4. Remove the fixture cover screws, then remove the cover. See **Fig. 22**.
5. Remove the dome lamp assembly screws. See **Fig. 23**.
6. Disconnect the electrical connector, and remove the dome lamp assembly. See **Fig. 24**.
7. Reconnect the electrical connector and place the lamp assembly into position.
8. Install the screws.

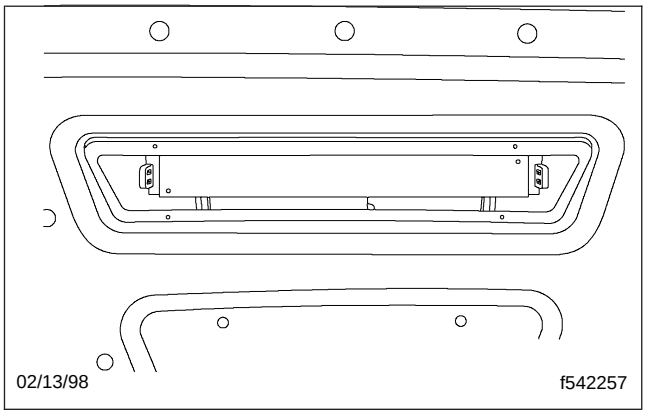

Fig. 22, Fixture Cover

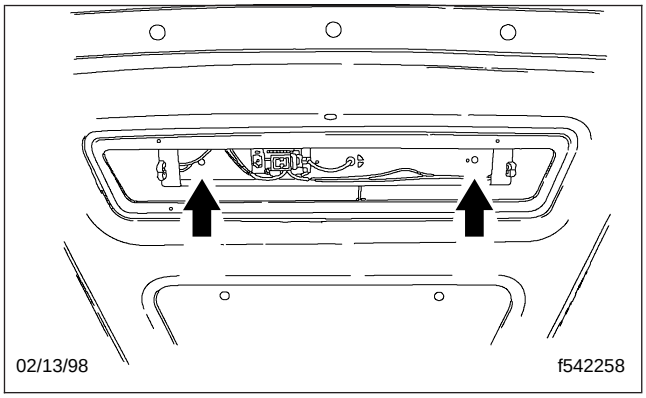

Fig. 23, Dome Lamp Assembly

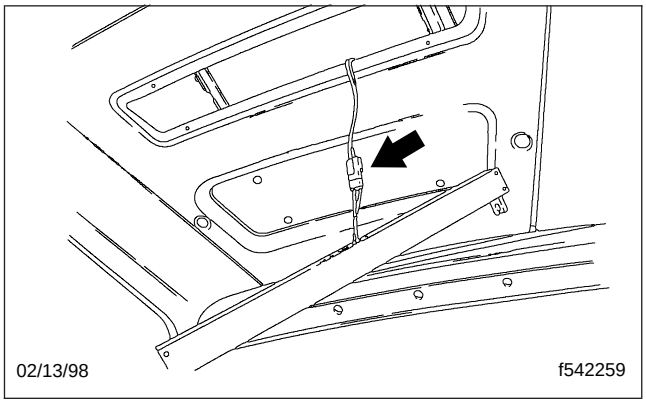

Fig. 24, Dome Lamp Assembly Electrical Connector

9. Reconnect the negative battery cable.

Interior Light Replacement

COURTESY LAMP SWITCH

1. Disconnect the negative battery cable from the battery.
2. Remove the courtesy lamp switch. See **Fig. 25**.

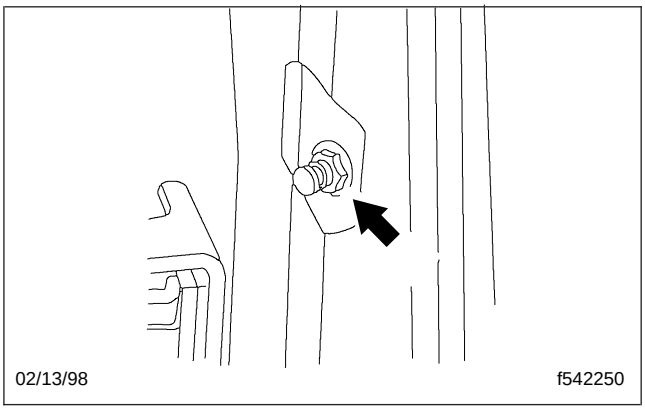

Fig. 25, Courtesy Lamp Switch

3. Disconnect the electrical connector. See **Fig. 26**.

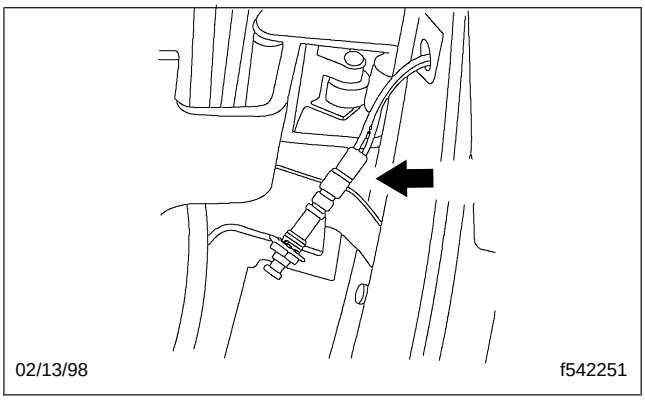

Fig. 26, Courtesy Lamp Electrical Connector

4. Reconnect the electrical connector and place the lamp assembly into position.
5. Install the screws.
6. Reconnect the negative battery cable.

ABLE BODY SLEEPER DOME LAMP SWITCH

1. Disconnect the negative battery cable from the battery.
2. Remove the screws. See **Fig. 27**.

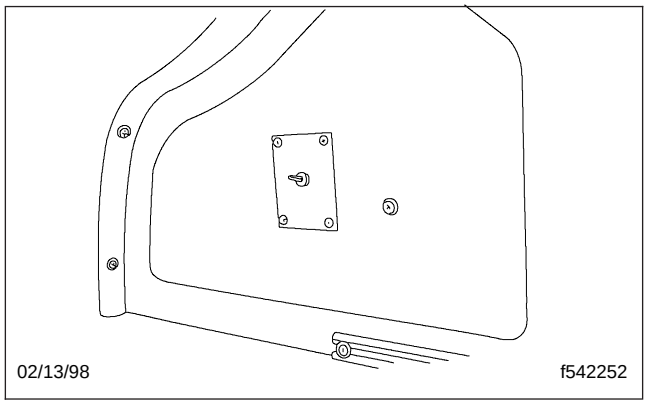

Fig. 27, Dome Light Switch Screws

3. Disconnect the electrical connections, and remove the switch. See **Fig. 28**.

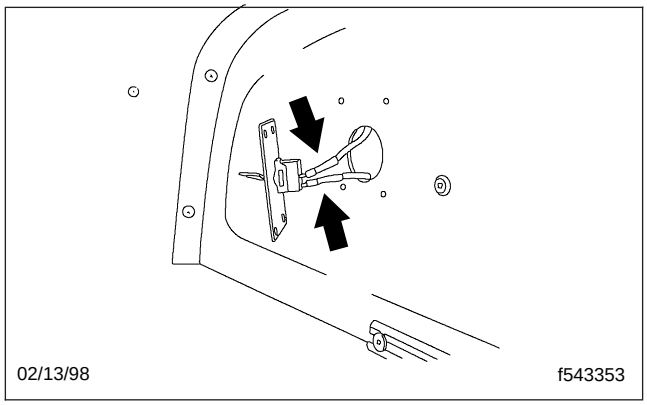

Fig. 28, Dome Lamp Electrical Connector

4. Reconnect the electrical connector and place the lamp assembly into position.
5. Install the screws.
6. Reconnect the negative battery cable.

SILVERSTAR INTERIOR LAMP SWITCH

1. Disconnect the negative battery cable from the battery.
2. Remove the cover. See **Fig. 29**.
3. Disconnect the electrical connector. See **Fig. 30**.
4. Release the locking tabs on the switch. See **Fig. 31**.
5. Remove the switch. See **Fig. 32**.

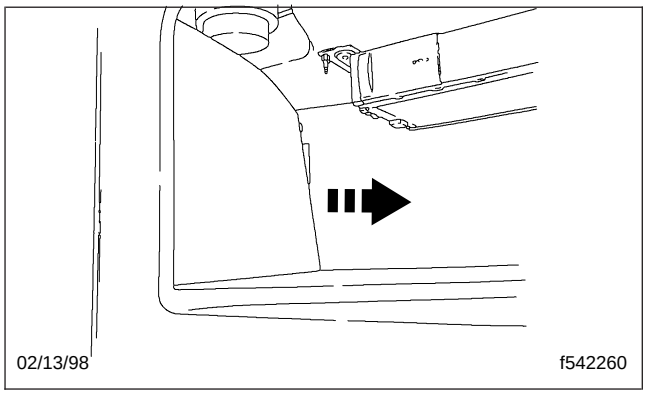

Fig. 29, Interior Lamp Switch Cover

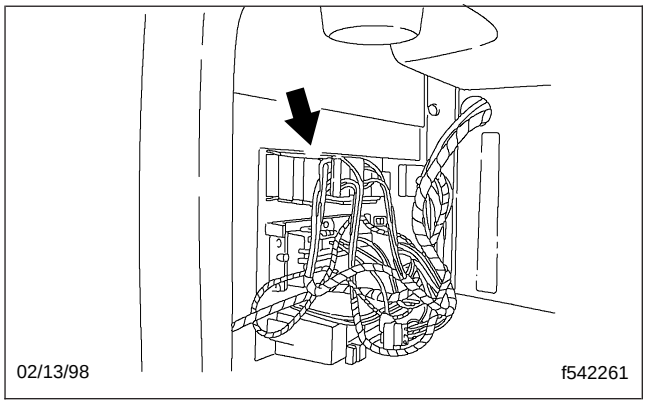

Fig. 30, Interior Lamp Switch Electrical Connector

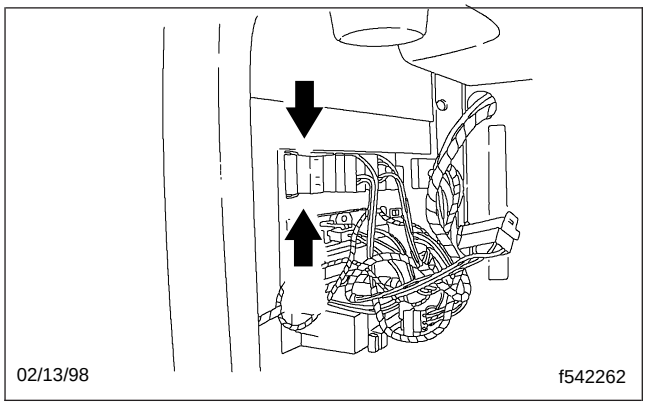

Fig. 31, Interior Lamp Switch Locking Tabs

6. Reconnect the electrical connector and place the lamp assembly into position.
7. Install the screws.
8. Reconnect the negative battery cable.

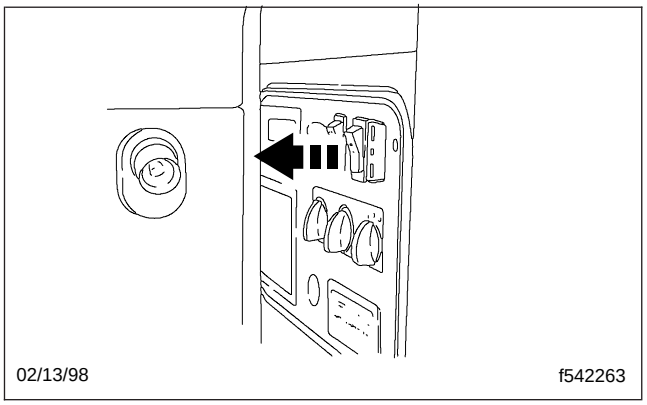

Fig. 32, Interior Lamp Switch Removal

Headlights

SINGLE AERODYNAMIC HALOGEN HEADLIGHT ASSEMBLY

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Open the hood to gain access to the headlight.
3. Disconnect the negative battery cable from the battery.
4. Remove the five rear headlight cover bolts. See **Fig. 1**.

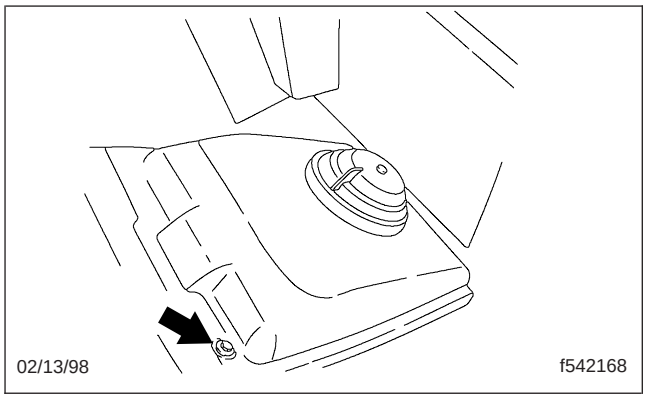

Fig. 1, Headlight Cover Panel Bolts

5. Disconnect the electrical connectors and remove the headlight assembly. See **Fig. 2**.

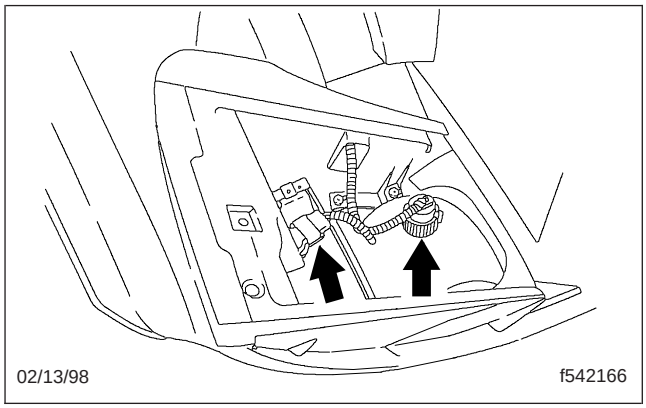

Fig. 2, Electrical Connectors

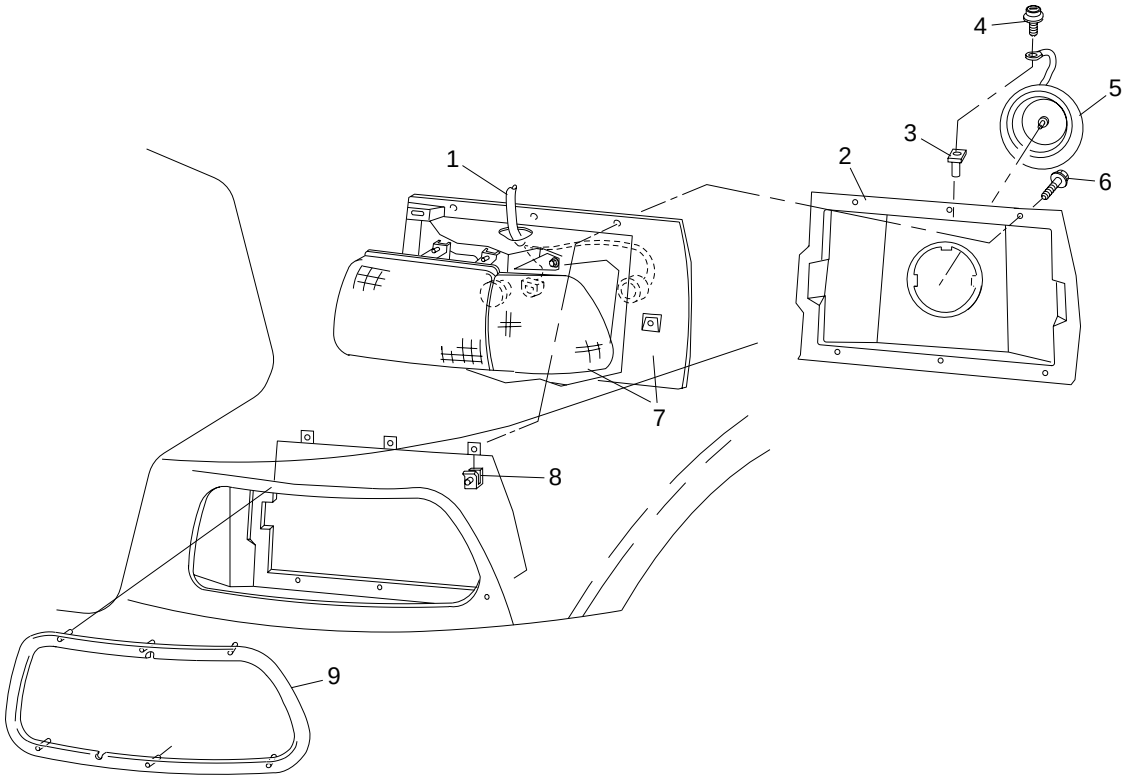
6. Remove the headlight assembly from the mounting bracket. See **Fig. 3**.
7. Install the headlight assembly on the mounting bracket.
8. Connect the electrical connectors and install the headlight assembly.
9. Install the five rear headlight cover bolts.
10. Close and latch the hood.
11. Connect the negative battery cable.
12. Remove the chocks from the rear tires.

SINGLE AERODYNAMIC HALOGEN HEADLIGHT BULB

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Open the hood to gain access to the headlight.
4. Open the headlight access cover by turning it counterclockwise. See **Fig. 4**.
5. Disconnect the electrical connector. See **Fig. 5**.
6. Remove the bulb. See **Fig. 6**.
   - 6.1 Twist the headlight bulb retaining ring counterclockwise and remove the ring.
   - 6.2 Pull the headlight bulb directly out of the headlight assembly and remove the bulb.
7. Insert the headlight bulb into the headlight assembly.
8. Twist the headlight bulb retaining ring clockwise onto the assembly.
9. Connect the electrical connector.
10. Close the headlight access cover.
11. Close and latch the hood.
12. Connect the negative battery cable.
13. Remove the chocks from the rear tires.

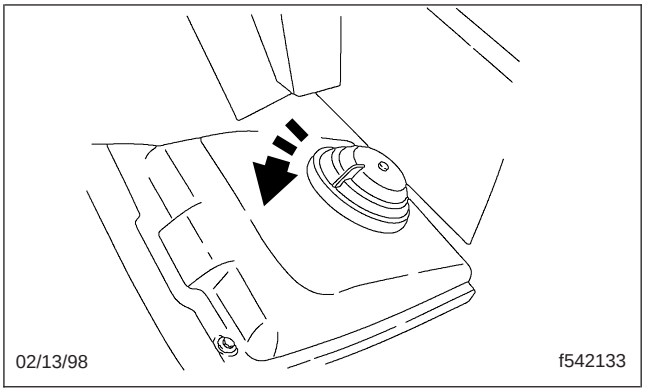
Exterior Light Replacement



11/15/1999 f542953

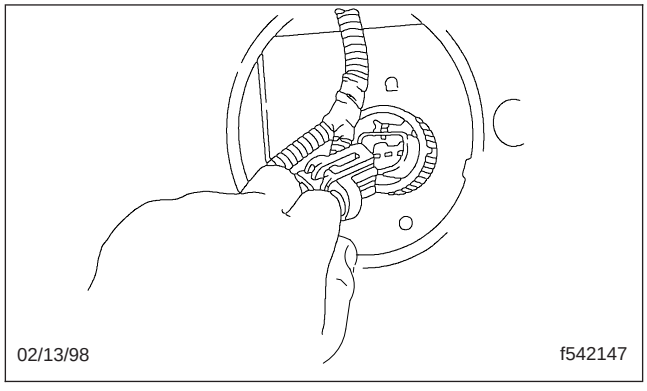
1. Headlight Wire Assembly
2. Rear Cover
3. Nut
4. Screw
5. Access Cover
6. Hexhead Screw
7. Headlight Assembly
8. Nut
9. Bezel

Fig. 3, Aerodynamic Headlight



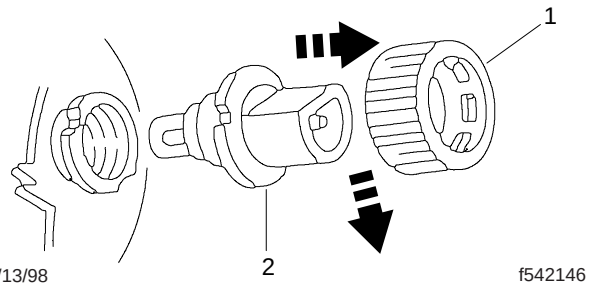
02/13/98 f542133

Fig. 4, Headlight Access Cover



02/13/98 f542147

Fig. 5, Headlight Electrical Connector



1. Retaining Ring
2. Headlight Bulb

Fig. 6, Remove the Headlight Bulb

NON-AERODYNAMIC HEADLIGHT ASSEMBLY

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Remove the retaining ring screws. See **Fig. 7**.
4. Disconnect the electrical connector and remove the headlight. See **Fig. 8**.
5. Connect the electrical connector and install the headlight.
6. Install the retaining screws.
7. Install the turnlight assembly nuts.
8. Connect the negative battery cable.
9. Remove the chocks from the rear tires.

ROUND HEADLIGHT ASSEMBLY

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Remove the retaining ring screws and the retaining ring. See **Fig. 9**.
4. Disconnect the electrical connector.
5. Remove the headlight.
6. Install the headlight.
7. Connect the electrical connector.
8. Install the retaining ring and retaining screws.
9. Connect the negative battery cable.
10. Remove the chocks from the rear tires.

VOCATIONAL HEADLIGHT ASSEMBLY

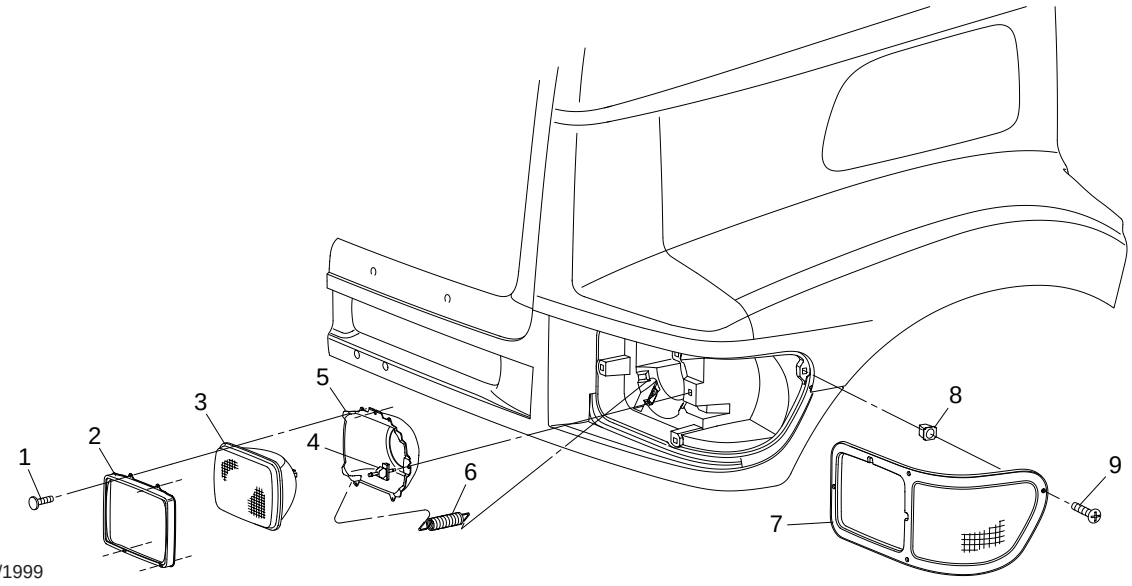
1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Open the hood.
4. From under the hood, remove the five bolts from the rear light cover and remove the cover. See **Fig. 10**.
5. Disconnect the headlight electrical connector.
6. Close the hood.
7. Remove the two retaining screws in the headlight retaining ring.
8. Remove the headlight.
9. Install the headlight.
10. Install the two retaining screws in the headlight retaining ring.
11. Open the hood.
12. Connect the headlight electrical connector.
13. Position the rear light cover and install the five bolts.
14. Close and latch the hood.
15. Connect the negative battery cable.
16. Remove the chocks from the rear tires.

Turnlights

HOOD-MOUNTED TURNLIGHT ASSEMBLY

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.

Exterior Light Replacement



1. Retaining Screw
2. Headlight Attachment Ring
3. Headlight
4. Adjustment Screw and Nut
5. Headlight Adjustment Ring
6. Spring
7. Bezel
8. Nut
9. Screw

Fig. 7, Non-Aerodynamic Headlight

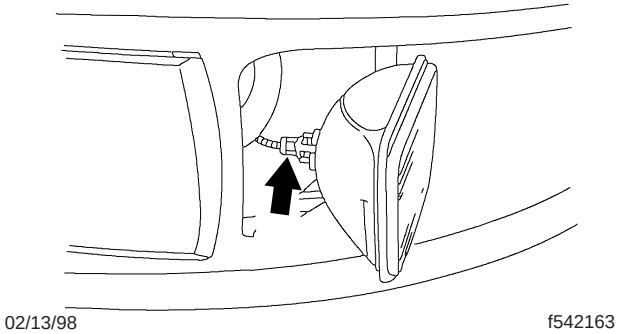


Fig. 8, Headlight Electrical Connector

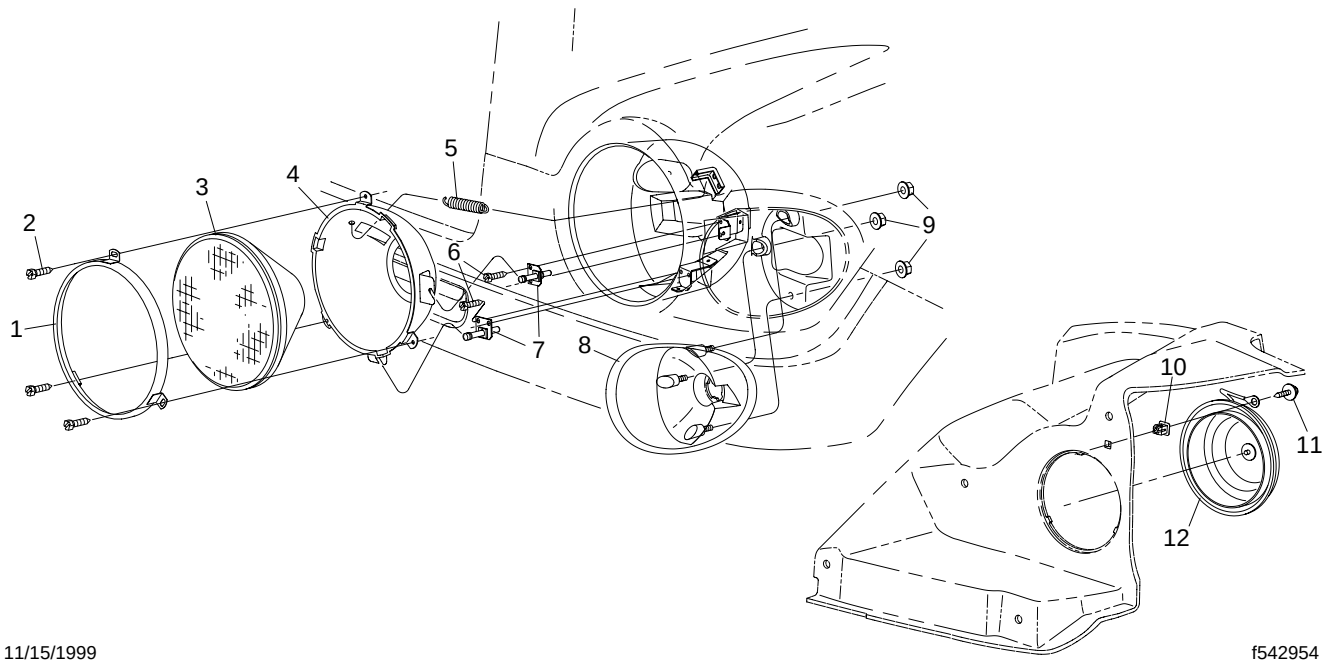
2. Disconnect the negative battery cable from the battery.
3. Open the hood.
4. Disconnect the turnlight assembly electrical connector.
5. Remove the turnlight assembly nuts. See **Fig. 11**.
6. Remove the turnlight assembly.
7. Install the turnlight assembly nuts.
8. Connect the turnlight assembly electrical connector.
9. Close and latch the hood.
10. Connect the negative battery cable.
11. Remove the chocks from the rear tires.

SIDE AIR-INTAKE-MOUNTED TURNLIGHT ASSEMBLY

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Pry the lens cover from the turnlight. See **Fig. 12**.
4. Remove the screws.
5. Disconnect the electrical connector and remove the turnlight assembly.



1. Headlight Attachment Ring
2. Retaining Screw
3. Headlight
4. Headlight Adjustment Ring
5. Spring
6. Screw
7. Adjustment Screw and Nut
8. Parking Light/Side Marker Light Assembly
9. Hexnut
10. Nut
11. Screw
12. Access Cover

Fig. 9, Round Headlight

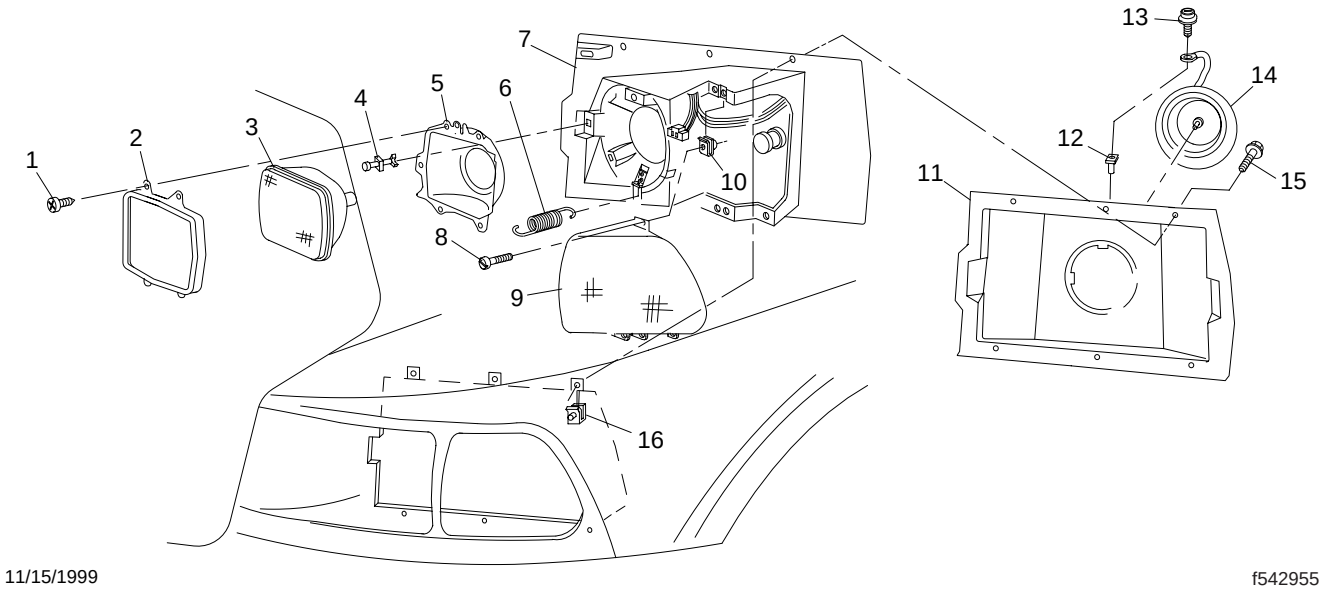
6. Connect the electrical connector and install the turnlight assembly.
7. Install the screws.
8. Install the lens cover onto the turnlight.
9. Connect the negative battery cable.
10. Remove the chocks from the rear tires.

Marker Lights

PARKING LIGHT/SIDE MARKER LIGHT ASSEMBLY

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Open the hood.
3. Disconnect the negative battery cable from the battery.
4. Rotate and remove the parking light/side marker light assembly wiring harness assembly from the housing.
5. Remove the three bolts retaining the parking light/side marker light assembly. See **Fig. 9**.
6. Remove the parking light/side marker light assembly.
7. Install the parking light/side marker light assembly.
8. Install the three bolts retaining the parking light/side marker light assembly.
9. Install the parking light/side marker light assembly wiring harness into the housing.
10. Close and latch the hood.

Exterior Light Replacement



11/15/1999 f542955

1. Retaining Screw
2. Retaining Ring
3. Headlight
4. Adjustment Screw and Nut
5. Headlight Adjustment Ring
6. Spring
7. Headlight Mounting Panel
8. Screw
9. Side Turnlight Assembly
10. Nut
11. Rear Light Cover
12. Nut
13. Screw
14. Access Cover
15. Bolt

Fig. 10, Vocational Headlight

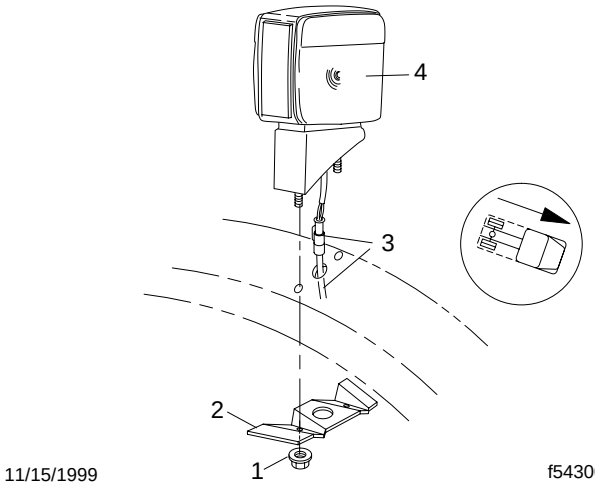
11. Connect the negative battery cable.
12. Remove the chocks from the rear tires.

ROOF-MOUNTED MARKER LIGHT ASSEMBLY (TYPICAL)

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Remove the screw and the marker light cover. See **Fig. 13**.
4. Remove the screws. See **Fig. 14**.
5. Disconnect the electrical connector and remove the marker light assembly. See **Fig. 15**.
6. Connect the electrical connector and install the marker light assembly.
7. Install the marker light assembly retaining screws. Install the marker light cover.
8. Connect the negative battery cable.
9. Remove the chocks from the rear tires.

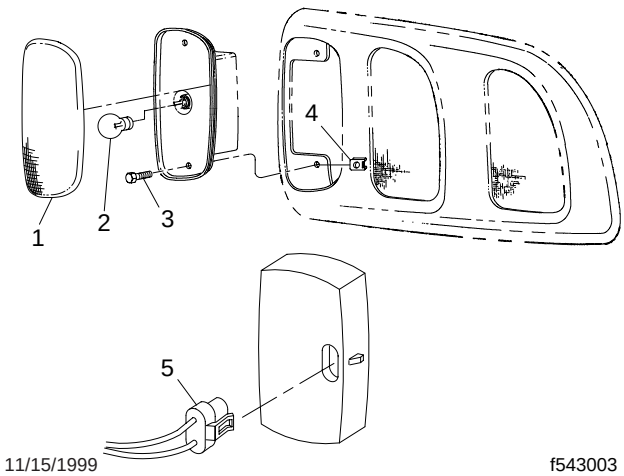
SIDE MARKER LIGHT ASSEMBLY, RIGHT-HAND-DRIVE VEHICLES

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Disconnect the side marker light electrical connector. See **Fig. 16**.
4. Remove the fasteners and remove the side marker light. See **Fig. 17**.



1. Hexnut
2. Mounting Bracket
3. Hood Wire Assembly
4. Turnlight Assembly

Fig. 11, Hood-Mounted Turnlight



1. Lens Cover
2. Bulb
3. Screw
4. Nut
5. Electrical Connector

Fig. 12, Side Air-Intake-Mounted Turnlight

5. Connect the electrical connector and install the side marker light assembly.
6. Install the side marker light assembly retaining screws.

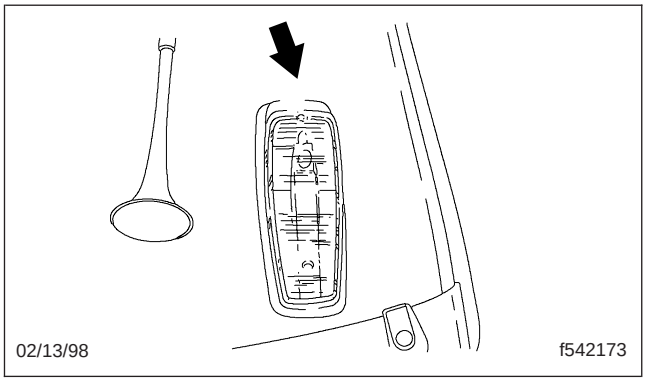


Fig. 13, Screw and Marker Light Cover

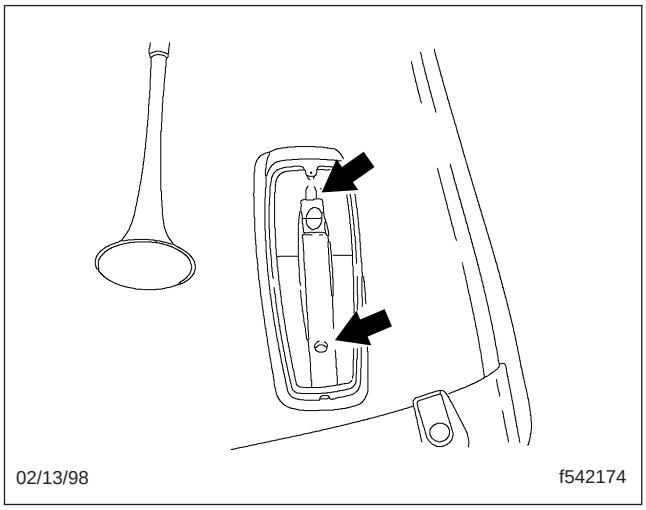

Fig. 14, Roof-Mounted Marker Light Screws

7. Connect the negative battery cable.
8. Remove the chocks from the rear tires.

Taillights

LEFT-HAND-DRIVE VEHICLES

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Disconnect the electrical connector. See **Fig. 18**.
4. Remove the fasteners and remove the taillight. See **Fig. 19**.

Exterior Light Replacement

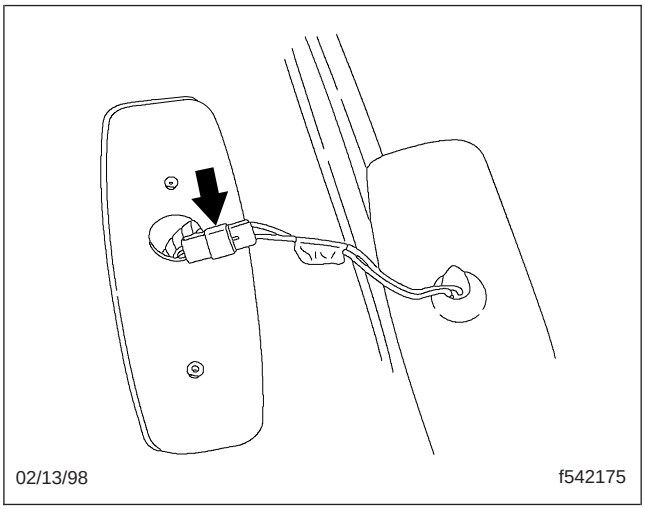

Fig. 15, Roof-Mounted Marker Light Electrical Connector

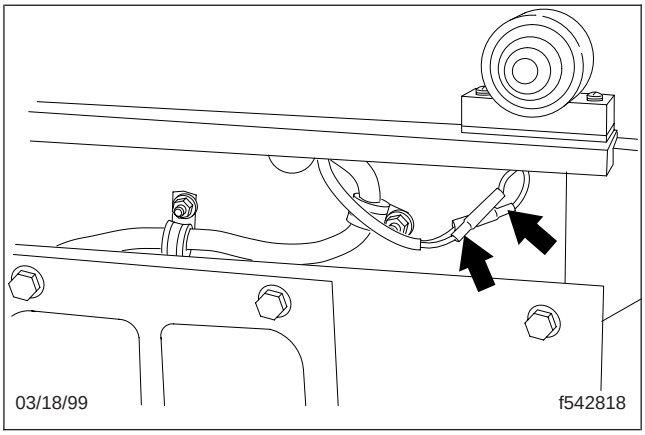

Fig. 16, Side Marker Light Connectors

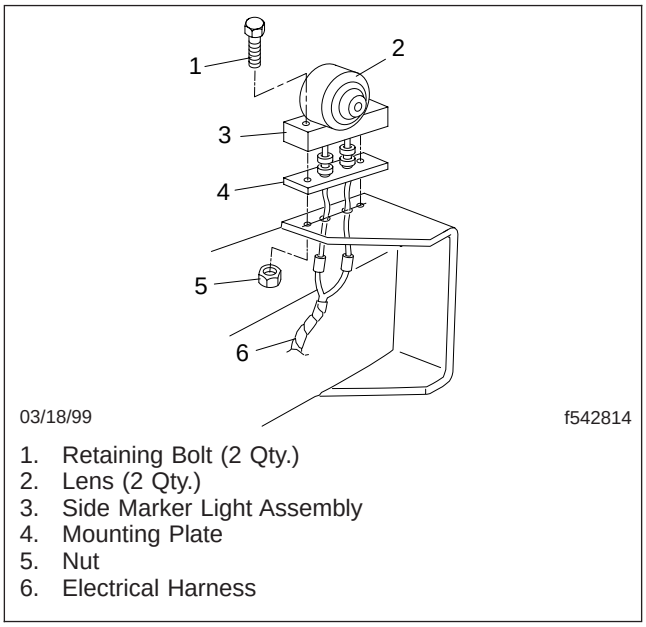
5. Connect the electrical connector and install the taillight assembly.
6. Install the taillight assembly retaining screws.
7. Connect the negative battery cable.
8. Remove the chocks from the rear tires.

RIGHT-HAND-DRIVE VEHICLES

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.



1. Retaining Bolt (2 Qty.)
2. Lens (2 Qty.)
3. Side Marker Light Assembly
4. Mounting Plate
5. Nut
6. Electrical Harness

Fig. 17, Side Marker Light and Fasteners

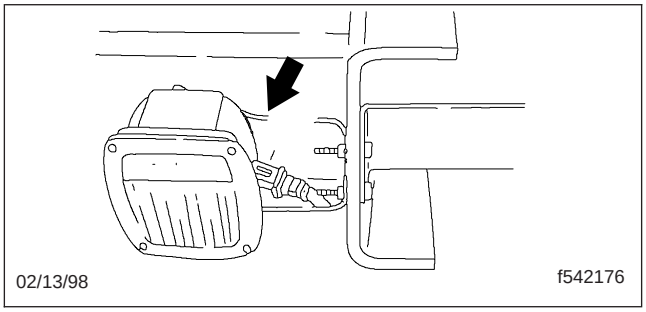


Fig. 18, Disconnect the Electrical Connector

3. Disconnect the side marker light electrical connector. See **Fig. 16**.
4. Disconnect the taillight/side marker light electrical harness connector. See **Fig. 20** and **Fig. 21**.
5. Remove the fasteners and remove the taillight assembly.
6. Connect the electrical connectors and install the taillight assembly.
7. Install the taillight assembly retaining screws.
8. Connect the negative battery cable.
9. Remove the chocks from the rear tires.

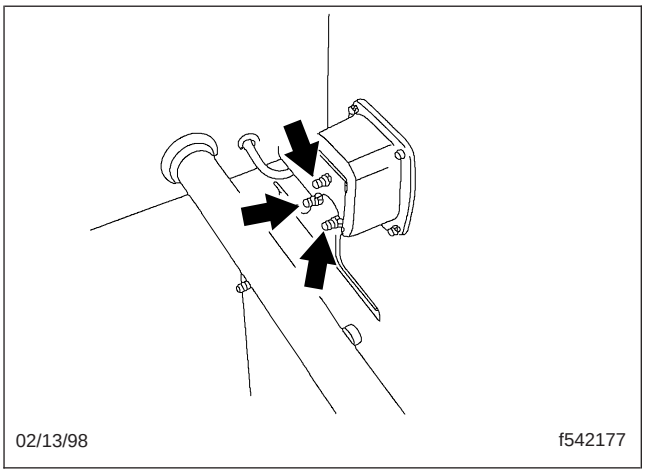

Fig. 19, Taillight Fasteners

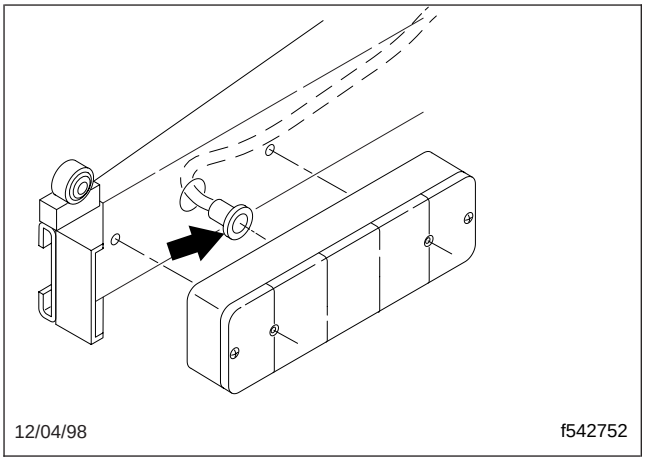

Fig. 20, Taillight/Side Marker Light Electrical Harness Connector Location

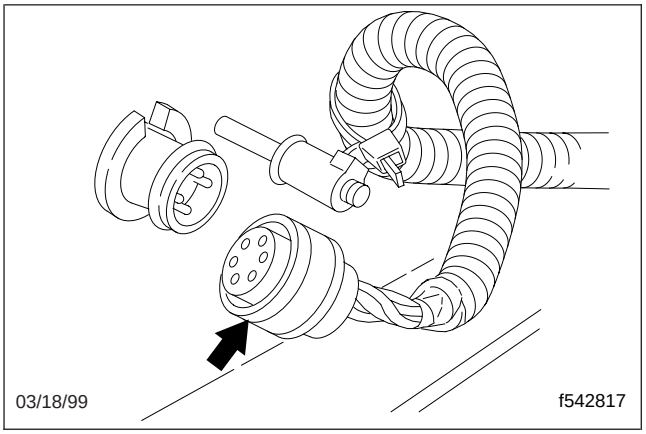

Fig. 21, Taillight/Side Marker Light Female Connector

Fog Lights

1. Park the vehicle on a level surface and apply the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the negative battery cable from the battery.
3. Disconnect the electrical connector. See **Fig. 22**.

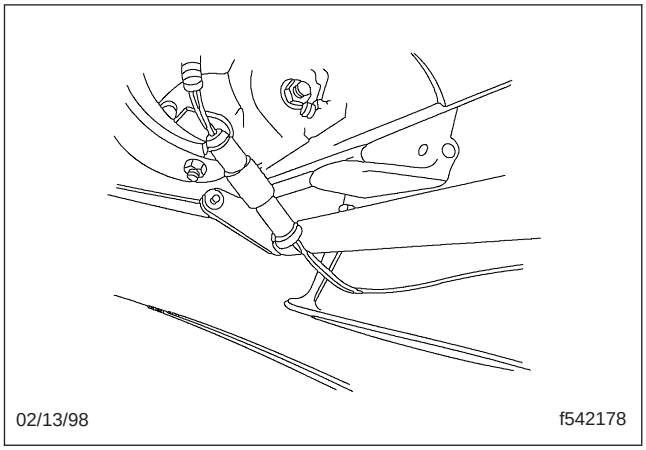

Fig. 22, Fog Light Assembly Electrical Connector

4. Remove the fastener and the fog light. See **Fig. 23**.

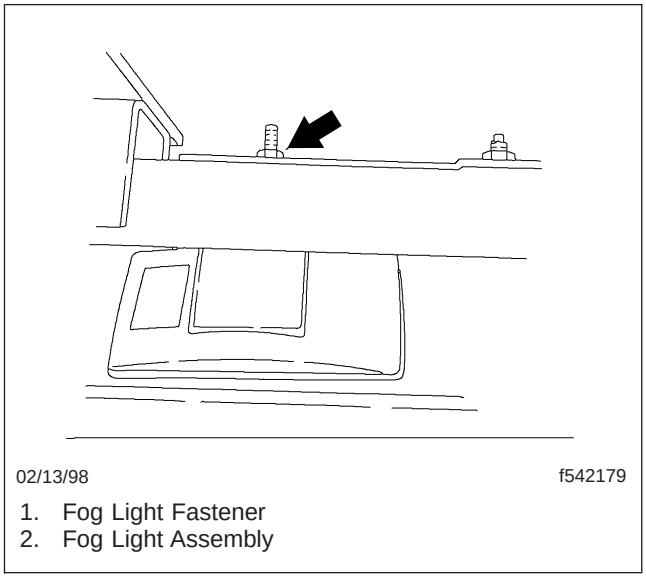

Fig. 23, Fog Light and Fastener

5. Install the fog light and fastener.

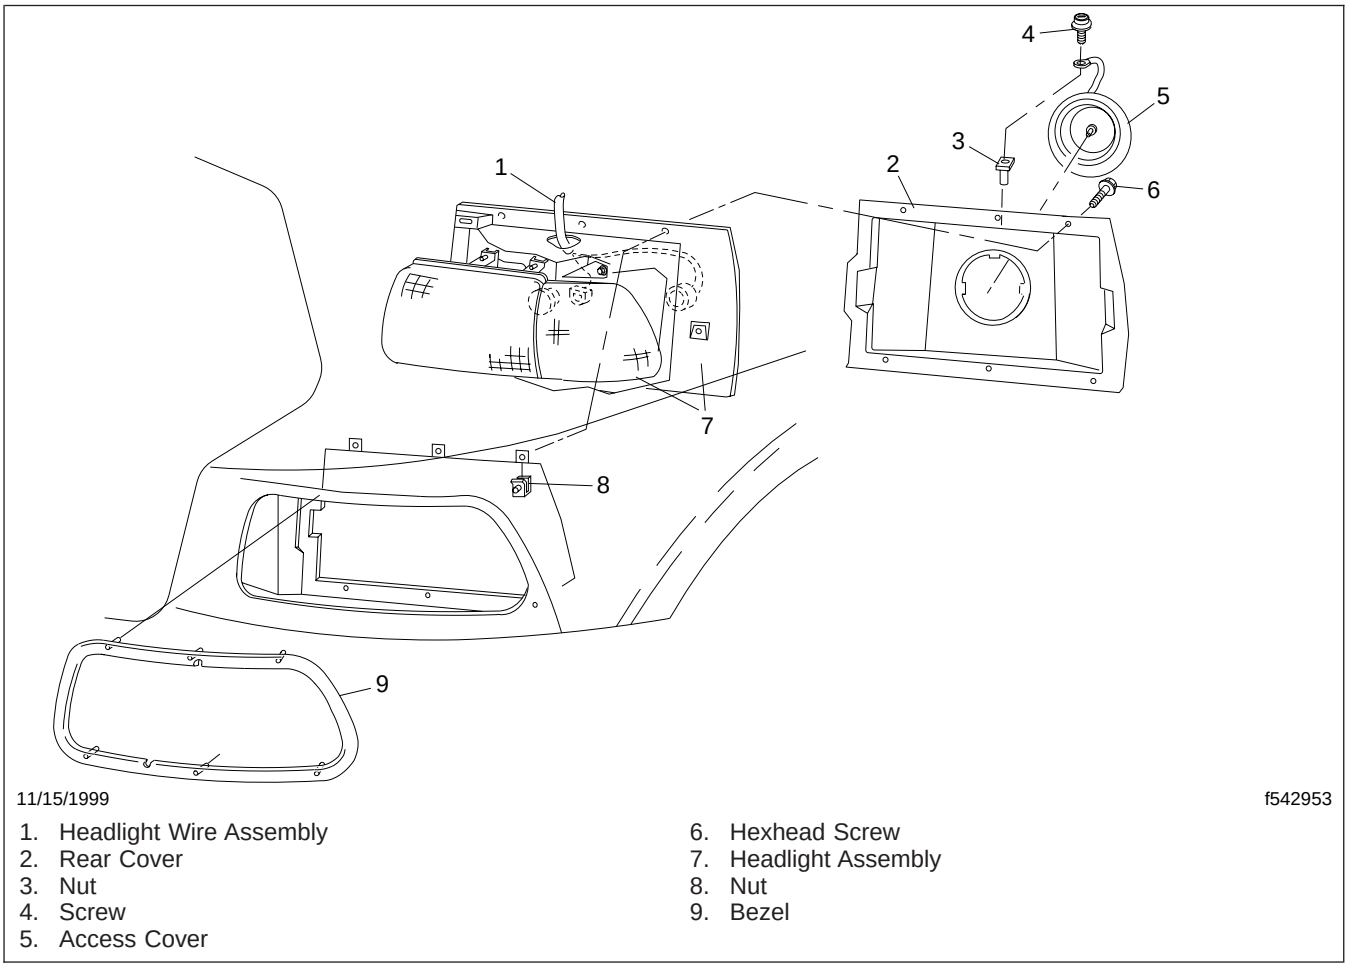
Exterior Light Replacement

6. Connect the electrical connector.
7. Connect the negative battery cable.
8. Remove the chocks from the rear tires.

Headlight Bezel Without Outside Fasteners

REMOVAL (See Fig. 1)

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the batteries.
3. Open the hood.
4. From under the hood, remove the five hexhead screws from the rear cover.
5. Remove the rear cover and set it aside.
6. Disconnect the wires to the headlights.
7. Remove the headlight assembly.
8. Remove the nuts holding the headlight bezel.
9. Remove the headlight bezel.



1. Headlight Wire Assembly
2. Rear Cover
3. Nut
4. Screw
5. Access Cover
6. Hexhead Screw
7. Headlight Assembly
8. Nut
9. Bezel

Fig. 1, Headlight Bezel Without Outside Fasteners

INSTALLATION (See Fig. 1)

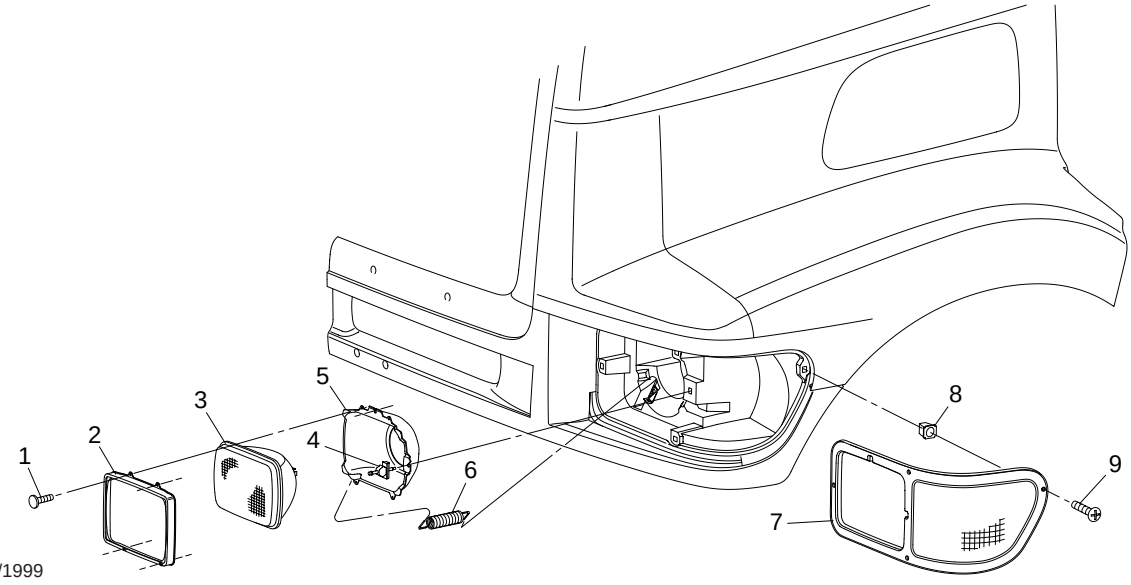
1. Position the headlight bezel and install the nuts.
2. Position the headlight assembly and connect the wires to the headlights.
3. Position the rear cover and install the five hex-head screws.
4. Close and latch the hood.
5. Connect the batteries.

Headlight Bezel Removal and Installation

6. Remove the chocks from the tires.

Headlight Bezel With Outside Fasteners

REMOVAL (See Fig. 2)



1. Retaining Screw
2. Headlight Attachment Ring
3. Headlight
4. Adjustment Screw and Nut
5. Headlight Adjustment Ring
6. Spring
7. Bezel
8. Nut
9. Screw

Fig. 2, Headlight Bezel With Outside Fasteners

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the rear tires.
2. Disconnect the batteries.
3. Remove the four screws holding the headlight bezel.
4. Disconnect the wires to the turn signal.
5. Remove the headlight bezel.

INSTALLATION (See Fig. 2)

1. Position the headlight bezel.
2. Connect the wires to the turn signal.
3. Install the four screws on the headlight bezel.
4. Connect the batteries.
5. Remove the chocks from the tires.

Headlight Aim Check and Adjustment

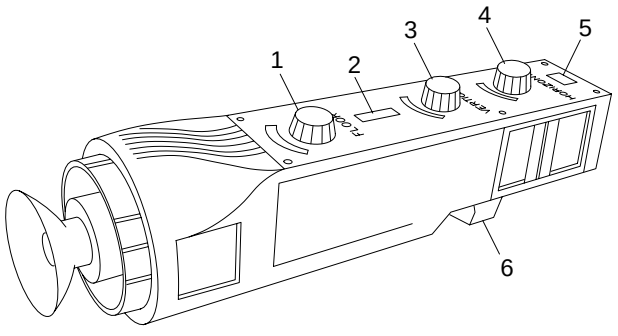
Before checking or adjusting the headlight aim, do the following:

- Remove large amounts of mud or ice from the undersides of the fenders.
- Check the springs for sagging or broken leaves. Check the suspension for proper functioning of the leveling mechanism.
- Clean the headlight lenses and aiming pads.
- Check the bulbs for burnout and broken aiming pads. Switch the beams from low to high to make sure they switch properly.
- With the vehicle unloaded, check that the tires are inflated to the recommended air pressure.

Check

For a quick check to see if the headlights need aiming, do the following procedure.

1. Move the vehicle onto a flat surface that has been calibrated for slope. Shut down the engine, set the parking brake, and chock the rear tires.
2. Attach a headlight aimer to each headlight. See **Fig. 1**.

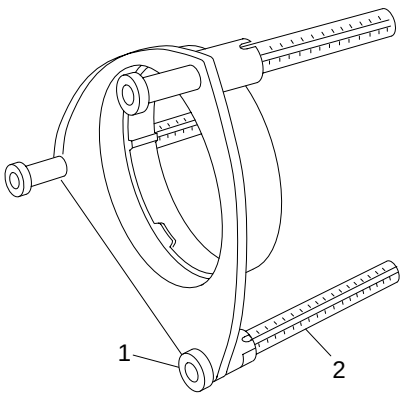


04/11/97 f580162

1. Floor Slope Dial
2. Level Vial
3. Vertical Dial
4. Horizontal Dial
5. Split Image View Port
6. Piston Handle

Fig. 1, Headlight Aimer

2.1 Attach the black universal adaptor to the aimer. Set the adjustment rods to "0" (zero). See **Fig. 2**.



04/14/97 f580165

Set the adjustment rods to "0" (zero).

1. Adaptor Foot
2. Adjustment Rod

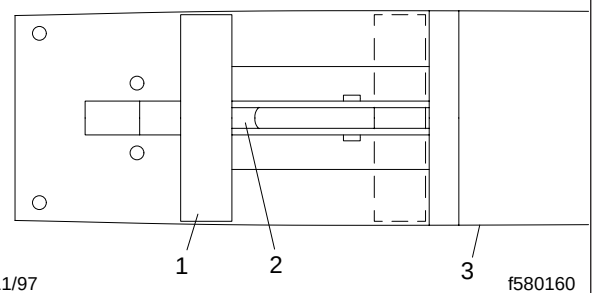
Fig. 2, Universal Adaptor

2.2 Align the adaptor with the aiming pads on the headlight lens.

2.3 Push the piston handle on the base of the aimer forward to engage the vacuum cup. Immediately pull the handle backward until it locks. See **Fig. 3**.

2.4 Do the same procedure with the other aimer.

3. Check the floor slope dial for the correct setting. See **Fig. 4**.



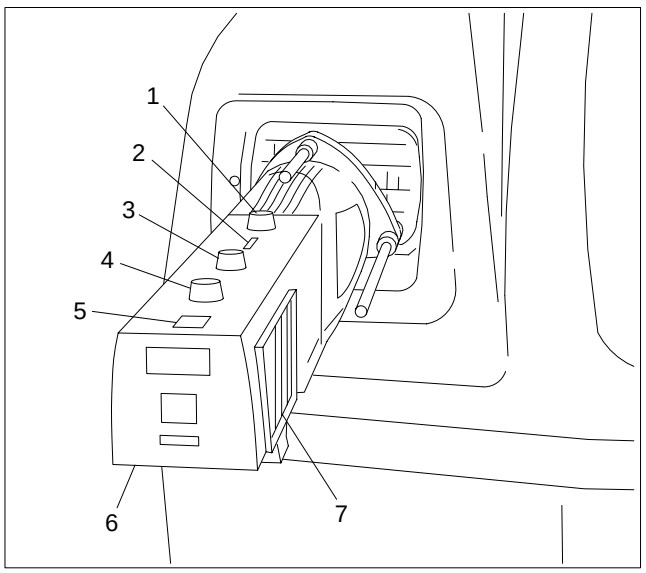
04/11/97 f580160

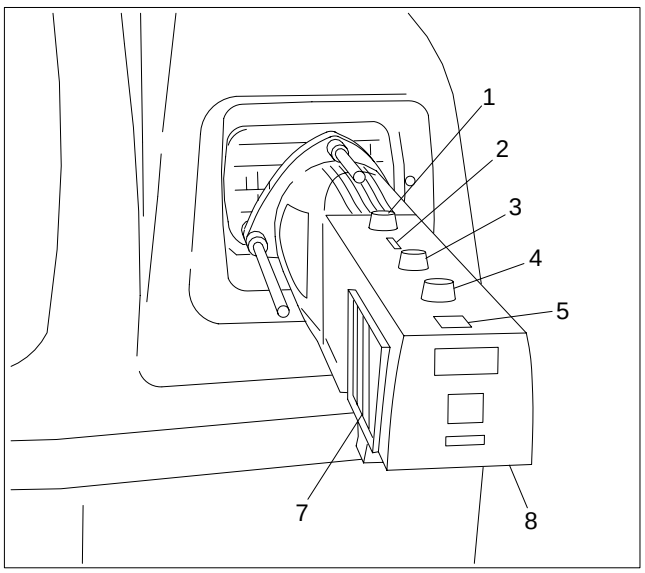
To attach, push the piston handle forward to engage the vacuum cup. Immediately pull the handle backward until it locks.
To remove, press the vacuum release button.

1. Piston Handle
2. Vacuum Release Button
3. Base of Aimer

Fig. 3, Aimer Attachment and Removal

Headlight Aim Check and Adjustment





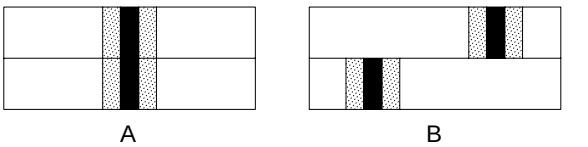
05/27/97 f580168

The sight openings must face each other.

1. Floor Slope Dial
2. Vertical Aim Level Vial
3. Vertical Dial
4. Horizontal Dial
5. Split Image View Port
6. Aimer (right-hand side)
7. Sight Opening
8. Aimer (left-hand side)

Fig. 4, Set-Up for Aiming

4. Check the horizontal aim. See **Fig. 5**.



04/11/97 f580161

View through the split image view port.

A. Split Image Aligned
B. Split Image Not Aligned

Fig. 5, Horizontal Aim Split Image

4.1 Turn the horizontal dial until the split image is in alignment.

4.2 If the horizontal dial scale on either aimer reads more than "4," re-aim the headlight.

NOTE: If adjustment is required, see the procedures under "Adjustment" below.

5. Check the vertical aim. See **Fig. 6**.

5.1 Turn the vertical dial until the level vial is centered.

5.2 If the vertical dial scale on either aimer reads more than "4," re-aim the headlight.

NOTE: If adjustment is required, see the procedures under "Adjustment" below.

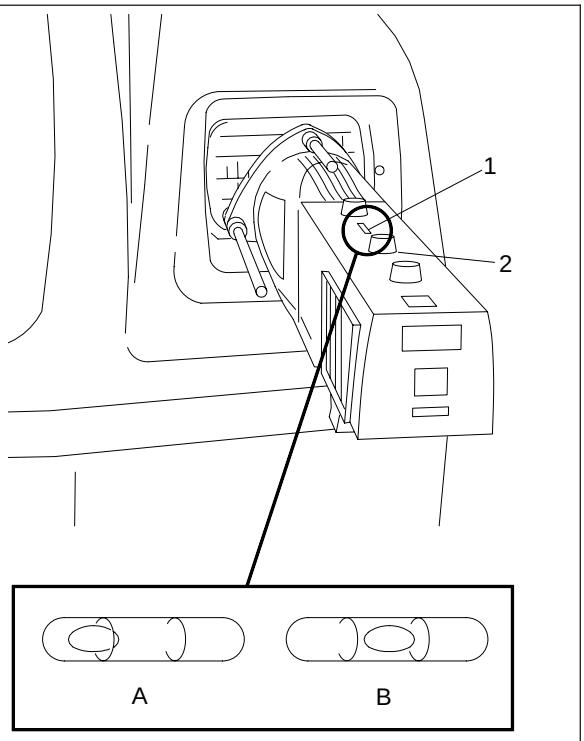
6. Remove the two headlight aimers. Hold each aimer securely, and then press the vacuum release button.

7. Remove the chocks from the rear tires.

Adjustment

If the headlights need adjusting, do this procedure.

1. If not already there, move the vehicle onto a flat surface that has been calibrated for slope. Shut down the engine, set the parking brake, and chock the rear tires.



07/28/97 f580177

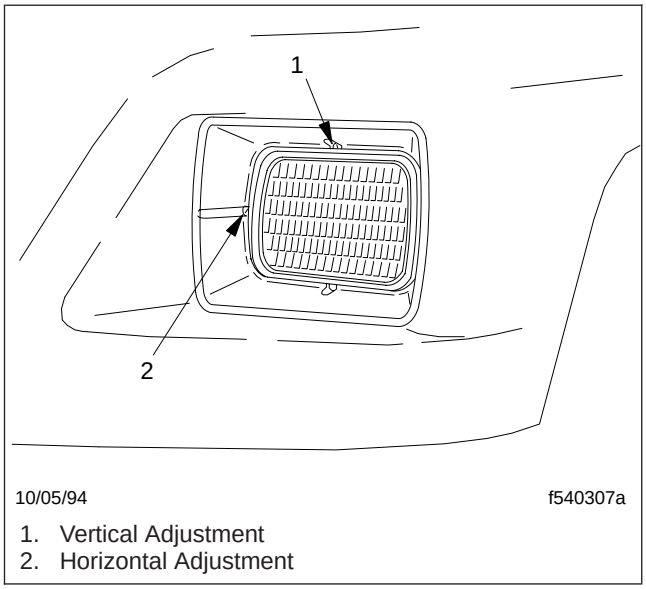
Set the vertical dial to "0" (zero).

A. Bubble Not Centered
B. Bubble Centered
1. Level Vial
2. Vertical Dial

Fig. 6, Vertical Aim Level Vial

2. Attach a headlight aimer to each headlight. See the procedures above under "Check" for detailed instructions.
3. Check the floor slope dial for the correct setting. See **Fig. 4**.
4. Adjust the horizontal aim. See **Fig. 5**.
   - 4.1 Set the horizontal dial to "0" (zero).
   - 4.2 Look in the viewing port for the split image target lines. If necessary, rotate either or both aimers until the lines are visible.
   - 4.3 Turn the horizontal adjustment screw as needed to make the split image appear as one solid line. See **Fig. 7**.

   IMPORTANT: To avoid backlash, make the final adjustment by turning the screw clockwise.



10/05/94 f540307a

1. Vertical Adjustment
2. Horizontal Adjustment

Fig. 7, Headlight Adjustment Screws

   - 4.4 Do the same procedure for the other headlight.
5. Adjust the vertical aim. See **Fig. 6**.
   - 5.1 Set the vertical dial to "0" (zero).
   - 5.2 Turn the vertical adjustment screw as needed to center the bubble in the level vial between the lines. See **Fig. 7**.

   IMPORTANT: To avoid backlash, make the final adjustment by turning the screw clockwise.

   - 5.3 Do the same procedure for the other headlight.
6. Recheck the horizontal alignment on both aimers. Readjust if necessary.
7. Remove both headlight aimers. While holding the aimer securely, press the vacuum release button. See **Fig. 3**.
8. Remove the chocks from the rear tires.

Troubleshooting

EXTERIOR AND INTERIOR LIGHTING

Problem—Both Headlamps Inoperative

Problem—Both Headlamps Inoperative	
Possible Cause	**Remedy**
Fuse	Check the supply voltage to the headlamp fuse. Measure the voltage between the power distribution box Fuse L (40 A) input terminal and ground. If the voltage is less than 10 volts, repair the fuse feed circuit. Test the system for normal operation. If the voltage is greater than 10 volts, check the headlamp switch input. Disconnect the headlamp switch connector harness connector. Measure the voltage between the headlamp switch connector C274 Pin B1, Circuit 37 (BK/Y) and ground. If the voltage is less than 10 volts, repair Circuit 37 (BK/Y). If blown, replace Fuse L (40 A). Test the system for normal operation. If the voltage is greater than 10 volts, check the headlamp switch output.
Headlamp switch	Reconnect the headlamp switch connector harness connector. Turn the headlamp switch to the full "On" position. Backprobe the switch and measure the voltage between the headlamp switch connector C274 Pin H, Circuit 15 (R/Y) and ground. If the voltage is less than 10 volts, replace the headlamp switch. Test the system for normal operation. If the voltage is greater than 10 volts, check the multi-function switch/windshield wiper control module input.
Multi-function switch	Disconnect the multi-function switch connector or the windshield wiper control module (Signal-Stat) connector harness connectors. Measure the voltage between the multi-function switch connector C252 Pin 2, Circuit 15 (R/Y) or at the windshield wiper control module (Signal-Stat) connector C244 Pin 13, Circuit 15 (R/Y) and ground. If the voltage is less than 10 volts, repair Circuit 15 (R/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check the multi-function switch/windshield wiper control module input.
Circuitry open or shorted	While actuating the multi-function switch to the high and low positions, measure the voltage between Circuit 12 (GN/BK) and Circuit 13 (R/BK) by backprobing at the multi-function switch connector C252 or the windshield wiper control module (Signal-Stat) connector C244 and ground. If the voltage is less than 10 volts, replace the multi-function switch or the windshield wiper control module (Signal-Stat). Test the system for normal operation. If the voltage is greater than 10 volts, check the headlamp feed. Reconnect the multi-function switch connector or the windshield wiper control module (Signal-Stat) connector harness connectors. Disconnect the headlamp electrical connectors.
Ground connection	While actuating the multi-function switch to the high and low positions, measure the voltage at both headlamp connectors Circuit 12 (GN/BK) and Circuit 13 (R/BK) and ground. If the voltage is is less than 10 volts, repair Circuit 12 (GN/BK) or Circuit 13 (R/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check headlamp grounds. Turn the headlamps off. Measure the resistance between the headlamp connectors Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the headlamp. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Troubleshooting

Problem—One Low Beam Headlamp is Inoperative

Problem—One Low Beam Headlamp is Inoperative	
Possible Cause	**Remedy**
Headlamp bulb	Check the supply voltage to the inoperative headlamp. Turn the headlamp switch to the full "On" position. Disconnect the inoperative headlamp harness connector. Measure the voltage between the inoperative headlamp connector Circuit 13 (R/BK) and ground. If the voltage is less than 10 volts, repair Circuit 13 (R/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check the headlamp ground. Measure the resistance between the inoperative headlamp connector Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the headlamp bulb. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.
Bad ground connection	
Circuit open	

Problem—One High Beam Headlamp is Inoperative

Problem—One High Beam Headlamp is Inoperative	
Possible Cause	**Remedy**
Headlamp bulb	Check the supply voltage to the inoperative headlamp. Turn the headlamp switch to the full "On" position. Activate the high beam headlamps to the "On" position. Disconnect the inoperative headlamp harness connector. Measure the voltage between the inoperative headlamp connector Circuit 12 (GN/BK) and ground. If the voltage is less than 10 volts, repair Circuit 12 (GN/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check the headlamp ground. Measure the resistance between the inoperative headlamp connector Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the headlamp or headlamp bulb. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.
Bad ground connection	
Circuit open	

Problem—Headlamps Stay On Continuously

Problem—Headlamps Stay On Continuously	
Possible Cause	**Remedy**
Headlamp switch	Check the headlamp switch. Turn the headlamp switch to the "Off" position. Disconnect the multi-function switch, the windshield wiper control module (Signal-Stat) harness connectors. Measure the voltage between the multi-function switch connector C252 Pin 2, Circuit 15 (R/Y) or the windshield wiper control module (Signal-Stat) connector C244 Pin 13, Circuit 15 (R/Y) and ground.
Multi-function switch	If the voltage is less than 10 volts, repair Circuit 15 (R/Y). If OK, replace the headlamp switch. Test the system for normal operation. If the voltage is greater than 10 volts, check the multi-function switch/windshield wiper control module (Signal-Stat).
Circuitry shorted	Disconnect the multi-function switch, windshield wiper control module (Signal-Stat) harness connectors. If the headlamps are off, replace the multi-function switch (Sterling) or the windshield wiper control module (Signal-Stat). Test the system for normal operation. If the headlamps are still on, check and repair any defects found in Circuit 13 (R/BK) low beams and/or Circuit 12 (GN/BK) high beams. Test the system for normal operation.

Problem—Flash-to-Pass Inoperative (Signal-Stat)

Problem—Flash-to-Pass Inoperative (Signal-Stat)	
Possible Cause	**Remedy**
Fuse 36 (I/P fuse panel)	Check Circuit 575 (R/BK) for voltage. Disconnect the windshield wiper control module C244 harness connector. Measure the voltage between the windshield wiper control module connector C244 Pin 4, Circuit 575 (R/BK) and ground. If the voltage is less than 10 volts, repair Circuit 575 (R/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check the multi-function switch.
Windshield wiper control module (Signal-Stat)	
Circuitry open	Disconnect the multi-function switch connector C247 harness connector. Measure the resistance between the multi-function switch terminals while holding the turn signal lever just before the high/low beam detent. If the resistance is greater than 5 ohms, replace the windshield wiper control module (Signal-Stat). Test the system for normal operation. If the resistance is less than 5 ohms, replace the multi-function switch (Signal-Stat). Test the system for normal operation.
Multi-function switch (Signal-Stat)	

Problem—Flash-to-Pass Inoperative

Problem—Flash-to-Pass Inoperative	
Possible Cause	**Remedy**
Multi-function switch	Verify that the headlamps are operating and the high/low beams are switching. If the headlamps operate, refer to "Headlamp Switch" in this section to verify the flash-to-pass feature. If the flash-to-pass is still inoperative, replace the multi-function switch.

Troubleshooting

Problem—Stoplamps are Inoperative

Problem—Stoplamps are Inoperative	
Possible Cause	**Remedy**
Stoplamp switch	Check supply voltage at the stoplamp switch. Measure the voltage between the stoplamp switch connector C266 or C265 Circuit 8 (O/Y) and ground. If the voltage is less than 10 volts, repair Circuit 8 (O/Y) or if blown, replace Fuse 42 (30 A). Test the system for normal operation. If the voltage is greater than 10 volts, check the stoplamp switch output. Measure the voltage by backprobing between the stoplamp switch connector Circuit 511 (GN) and ground while pressing the brake pedal. If the voltage is less than 10 volts, replace the stoplamp switch. Test the system for normal operation. If the voltage is greater than 5 volts, check the multi-function switch input.
Multi-function switch	Disconnect the multi-function switch connector harness connector. Measure the voltage between the multi-function switch connector C253 or C254 (Signal-Stat) Circuit 511 (GN) while pressing the brake pedal. If the voltage is less than 10 volts, repair Circuit 511 (GN). Test the system for normal operation. If the voltage is greater than 10 volts, check multi-function switch output.
Tail lamps	Reconnect the multi-function switch connector harness connector. Measure the voltage between the multi-function switch connector C253 or C254 (Signal-Stat) Circuits 282 (GN) right stoplamp or 283 (Y/BK) left stoplamp and ground while pressing the brake pedal. If the voltage is less than 10 volts, replace the multi-function switch. Test the system for normal operation. If the voltage is greater than 10 volts, check the stoplamp input.
Circuitry open or shorted	Disconnect the tail lamp connectors harness connector. Measure the voltage between the tail lamp connector C452 Circuit 282 (GN) right stoplamp or connector C450 Circuit 283 (Y/BK) left stoplamp while pressing the brake pedal. If the voltage is less than 10 volts, repair Circuit 282 (GN) or 283 (Y/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check the tail lamp ground. Measure the resistance between the tail lamp connectors C452 and C450 Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the bulb. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Problem—Stoplamps are On Continuously

Problem—Stoplamps are On Continuously	
Possible Cause	**Remedy**
Stoplamp switch	Check the stoplamp switch. Disconnect the stoplamp switch harness connector. If the stoplamps stay on, replace the stoplamp switch. Test the system for normal operation. If the stoplamps turn off, check Circuit 511 (GN).
Multi-function switch	Measure the voltage between the multi-function switch connector C253 or C254 (Signal-Stat) Circuit 511 (GN) and ground. If battery voltage is present, repair Circuit 511 (GN). Test the system for normal operation. If battery voltage is not present, check the multi-function switch.
Circuitry open or shorted	Disconnect the multi-function switch harness connector. If the stoplamps turn off replace the multi-function switch. Test the system for normal operation. If the stoplamps remain on, repair Circuit 282 (GN) right stoplamp or Circuit 283 (Y/BK). Test the system for normal operation.

Problem—Turn Signal Lamps are Inoperative

Problem—Turn Signal Lamps are Inoperative	
Possible Cause	**Remedy**
Multi-function switch	Check the turn signal flasher. Replace the electronic flasher. If the system operates properly with a new electronic flasher, test the system for normal operation. If the system does not operate properly, check the flasher supply voltage. Disconnect the electronic flasher connector harness connector. Measure the voltage between the electronic flasher connector C2033 Circuit 8 (O/Y) and ground. If the voltage is less than 10 volts, repair Circuit 8 (O/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 44 (BL). Disconnect the multi-function switch connector harness connector. Measure the resistance between the electronic flasher connector C2033 Circuit 44 (BL) and the multi-function switch connector C253 or C254 (Signal-Stat) Circuit 44 (BL). If the resistance is less than 5 ohms, repair Circuit 44 (BL). Test the system for normal operation. If the resistance is greater than 5 ohms, check the electronic flasher ground.
Turn signal flasher	Measure the resistance between the electronic flasher connector C2033 Circuit 57 (BK) and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check for voltage at the left-hand bulb sockets. Reconnect the multi-function switch connector and the electronic flasher connector harness connectors. Turn the ignition switch to the "On" position. Turn the multi-function switch in the left turn position. Measure the voltage between the left-hand front turn signal lamp connector C152 Circuit 3 (GN/W) and ground, and the left-hand rear turn signal connector C452 Circuit 283 (Y/BK) and ground. If the voltage does not modulate between less than 1 volt and greater than 10 volts on each circuit, repair the affected circuit(s) between the multi-function switch and the bulb socket. If OK, replace the multi-function switch. Test the system for normal operation. If the voltage modulates between less than 1 volt and greater than 10 volts on each circuit, check for voltage at the right-hand bulb sockets. Turn the multi-function switch in the right turn position.
Circuitry open or shorted	Measure the voltage between the right-hand front turn signal lamp connector C140 Circuit 2 (W/BL) and ground, and the right-hand rear turn signal lamp connector C450 Circuit 282 (GN) and ground. If the voltage does not modulate between less than 1 volt and greater than 10 volts on each circuit, repair the affected circuit(s) between the multi-function switch and the bulb socket. If OK, replace the multi-function switch. Test the system for normal operation. If the voltage modulates between less than 1 volt and greater than 10 volts on each circuit, check the ground circuit. Measure the resistance between each of the turn signal connectors Circuit 57 (BK) and ground. If the resistance is less than 5 ohms at each turn signal lamp connector, replace the bulb(s). Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Troubleshooting

Problem—Hazard Flasher Lamps are Inoperative

Problem—Hazard Flasher Lamps are Inoperative	
Possible Cause	**Remedy**
Multi-function switch	Check the turn signal operation. If the turn signals operate properly, replace the multi-function switch. Test system for normal operation. If the turn signals do not operate properly, check the turn signal flasher. Replace the electronic flasher. If the system operates properly with a new electronic flasher, test the system for normal operation. If the system does not operate properly, check the flasher supply voltage. Disconnect the electronic flasher connector harness connector. Measure the voltage between the electronic flasher connector C2033 Circuit 8 (O/Y) and ground. If the voltage is less than 10 volts, repair Circuit 8 (O/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 44 (BL).
Turn signal flasher	Disconnect the multi-function switch connector harness connector. Measure the resistance between the electronic flasher connector C2033 Circuit 44 (BL) and the multi-function switch connector C253 or C254 (Signal-Stat) Circuit 44 (BL). If the resistance is less than 5 ohms, repair Circuit 44 (BL). Test the system for normal operation. If the resistance is greater than 5 ohms, check the electronic flasher ground. Measure the resistance between the electronic flasher connector C2033 Circuit 57 (BK) and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check for voltage at the left-hand bulb sockets.
Circuitry open or shorted	Reconnect the multi-function switch connector and the electronic flasher connector harness connectors. Turn the ignition switch to the "On" position. Turn the multi-function switch in the left turn position. Measure the voltage between the left-hand front turn signal lamp connector C152 Circuit 3 (GN/W) and ground, and the left-hand rear turn signal connector C452 Circuit 283 (Y/BK) and ground. If the voltage does not modulate between less than 1 volt and greater than 10 volts on each circuit, repair the affected circuit(s) between the multi-function switch and the bulb socket. If OK, replace the multi-function switch. Test the system for normal operation. If the voltage modulates between less than 1 volt and greater than 10 volts on each circuit, check for voltage at the right-hand bulb sockets. Turn the multi-function switch in the right turn position.
Multi-function switch	Measure the voltage between the right-hand front turn signal lamp connector C140 Circuit 2 (W/BL) and ground, and the right-hand rear turn signal lamp connector C450 Circuit 282 (GN) and ground.
Turn signal flasher	If the voltage does not modulate between less than 1 volt and greater than 10 volts on each circuit, repair the affected circuit(s) between the multi-function switch and the bulb socket. If OK, replace the multi-function switch. Test the system for normal operation. If the voltage modulates between less than 1 volt and greater than 10 volts on each circuit, check the ground circuit. Measure the resistance between each of the turn signal connectors Circuit 57 (BK) and ground.
Circuitry open or shorted	If the resistance is less more than 5 ohms at each turn signal lamp connector, replace the bulb(s). Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Problem—Parking Lamps are Inoperative

Problem—Parking Lamps are Inoperative	
Possible Cause	**Remedy**
Fuse	Check the headlamp switch input. Disconnect the headlamp switch connector harness connector. Measure the voltage between the headlamp switch connector C274 Circuits 37 (BK/Y), 873 (W/BK) and ground. If the voltage is less than 10 volts, repair Circuit 37 (BK/Y) or 873 (W/BK). If OK, replace the power distribution box Fuse L (40 A) or the IP fuse junction panel Fuse 37 (15 A). Test the system for normal operation. If the voltage is greater than 10 volts, check the headlamp switch output.
Headlamp switch	Reconnect the headlamp switch connector harness connector. Turn the headlamp switch to the "Park" position. Measure the voltage between the headlamp switch connector C274 Circuit 11 (BK/Y) and ground. If the voltage is less than 10 volts, replace the headlamp switch. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 11 (BK/Y).
Circuitry open or shorted	Measure the voltage of each parking lamp connector Circuit 11 (BK/Y) and ground. If the voltage at any of the connectors is less than 10 volts, repair Circuit 11 (BK/Y). Test the system for normal operation. If the voltage at the connectors is greater than 10 volts, check the ground circuit. Measure the resistance between each parking lamp connector Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the bulb(s). Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Problem—Parking Lamps are On Continuously

Problem—Parking Lamps are On Continuously	
Possible Cause	**Remedy**
Headlamp switch	Check the headlamp switch. Disconnect the headlamp switch harness connector. If the parking lamps turn off, replace the headlamp switch. Test the system for normal operation.
Circuitry open or shorted	If the parking lamps do not turn off, repair Circuit 11 (BK/Y). Test the system for normal operation.

Troubleshooting

Problem—Fog Lamps are Inoperative

Problem—Fog Lamps are Inoperative	
Possible Cause	**Remedy**
Fuses	Check Fuse 39 supply voltage. Turn the headlamps to the full "On" position. Measure the voltage between the load side of IP Fuse 39 (10 A) and ground. If the voltage is less than 10 volts, repair Circuit 15 (R/Y). If blown, replace IP fuse panel Fuse 39 (10 A) and repair Circuit 477 (BL/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 477 (BL/BK). Disconnect the fog lamp relay harness connector. Measure the resistance between the load side of Fuse 39 (10 A) and the fog lamp relay connector C2031 Pin 30, Circuit 477 (BL/BK). If the resistance is greater than 5 ohms, repair Circuit 477 (BL/BK). Test the system for normal operation. If the resistance is less than 5 ohms, check the fog lamp relay coil feed.
Headlamp switch	Turn the headlamps to the full "On" position. Actuate the multi-function switch to the "LO Beam" position with vehicles equipped with DRL or the "HIGH beam" position with vehicles equipped without DRL. Measure the voltage between the fog lamp relay connector C2031 Pin 85, Circuit 12 (GN/BK) without DRL, Circuit 41 (BK/Y) with US DRL, or Circuit 13 (R/BK) with Canadian DRL and ground. If the voltage is less than 10 volts, repair Circuit 12 (GN/BK), 41 (BK/Y), or 13 (R/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check the fog lamp relay ground.
Fog lamp relay	Measure the resistance between the fog lamp relay connector C2031 Pin 86, Circuit 57 (BK) and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, perform the "Relay Component Test" in this section. Check the relay switch feed circuit. Measure the resistance between the fog lamp relay connector C2031 Pin 87, Circuit 477 (BL/BK) and the fog lamp switch connector C2019 Pin 2, Circuit 477 (BL/BK). If the resistance is greater than 5 ohms, repair Circuit 477 (BL/BK). Test the system for normal operation. If the resistance is less than 5 ohms, check the fog lamp switch.
Fog lamp switch	Turn the fog lamp switch to the "On" position. Measure the resistance between the fog lamp switch Terminals 2 and 3. If the resistance is greater than 5 ohms, replace the fog lamp switch. Test the system for normal operation. If the resistance is less than 5 ohms, check the fog lamp feed circuit. Measure the resistance between the fog lamp switch connector C2019 Pin 3, Circuit 478 (GY) and the fog lamp connectors C1017 and C1016 Circuit 478 (GY). If the resistance is greater than 5 ohms, repair Circuit 478 (GY). Test the system for normal operation. If the resistance is less than 5 ohms, check the fog lamp ground.
Circuitry open or shorted	Measure the resistance between the fog lamp connectors C1017 and C1016 Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the bulb(s). Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Problem—Fog Lamps are On Continuously

Problem—Fog Lamps are On Continuously	
Possible Cause	**Remedy**
Circuitry shorted	Check the fog lamp switch. Disconnect the fog lamp switch connector. If the fog lamps turn off, replace the fog lamp switch. Test the system for normal operation. If the fog lamps do not turn off, repair Circuit 57 (BK). Test the system for normal operation.
Fog lamp switch	
Fog lamp relay	

Problem—Backup Lamps are Inoperative

Problem—Backup Lamps are Inoperative	
Possible Cause	**Remedy**
Backup lamp switch	Check the fuse feed circuit. Turn the ignition switch to the "Off" position. Disconnect the IP fuse junction panel Fuse 10 (10 A) harness connector. Turn the ignition switch to the "On" position. Measure the voltage between the IP fuse junction panel Fuse 10 (10 A) fuse feed circuit and ground. If the voltage is less than 10 volts, repair fuse feed circuit. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 138 (W/P) for an open. Turn the ignition switch to the "Off" position. Reconnect the IP fuse junction panel Fuse 10 (10 A) harness connector. Disconnect the backup lamp switch connector harness connector. Turn the ignition switch to the "On" position. Measure the voltage between the backup lamp switch connector C121 (manual transmission) or connector C116 (automatic transmission), Circuit 138 (W/P) and ground. If the voltage is less than 10 volts, repair Circuit 138 (W/P). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 140 (BK/R). Turn the ignition switch to the "Off" position. Disconnect the right rear combination lamp connector or backup lamp connector. Connect a jumper wire between the backup lamp switch connector C121 (manual transmission) or connectors C116 and C114 (automatic transmission). Turn the ignition switch to the "On" position. Measure the voltage between the right rear combination lamp connector C404 or the backup lamp connector C451, Circuit 140 (BK/R) and ground. If the voltage is less than 10 volts, repair Circuit 140 (BK/R). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 57 (BK). Turn the ignition switch to the "Off" position. Measure the resistance between the right rear combination lamp connector C404 or the backup lamp connector C451, Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the backup lamp switch. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.
Circuitry open or shorted	
Backup lamp	

Troubleshooting

Problem—Backup Lamps are Inoperative (Allison Electronic Transmissions Only)

Problem—Backup Lamps are Inoperative (Allison Electronic Transmissions Only)	
Possible Cause	**Remedy**
Backup lamp switch	Check the fuse feed circuit. Turn the ignition to the "Off" position. Disconnect the IP fuse junction panel Fuse 10 (10 A) harness connector. Turn the ignition switch to the "On" position. Measure the voltage between the IP fuse junction panel Fuse 10 (10 A) fuse feed circuit and ground. If the voltage is less than 10 volts, repair the fuse feed circuit. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 138 (W/P) for an open. Turn the ignition switch to the "Off" position. Reconnect the IP fuse junction panel Fuse 10 (10 A) harness connector. Disconnect the vehicle interface module connector harness connector. Turn the ignition switch to the "On" position. Measure the voltage between the vehicle interface module connector C3006 Pin B1, Circuit 138 (W/P) and ground. If the voltage is less than 10 volts, repair Circuit 138 (W/P). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 140 (BK/R). Turn the ignition switch to the "Off" position. Disconnect the right rear combination lamp connector or backup lamp connector harness connectors. Measure the resistance between the vehicle interface module connector C3006 Pin A1, Circuit 140 (BK/R) and the right rear combination lamp connector C404 or the backup lamp connector C451 Circuit 140 (BK/R). If the resistance is greater than 5 ohms, repair Circuit 140 (BK/R). Test the system for normal operation. If the resistance is less than 5 ohms, check Circuit 57 (BK). Measure the resistance between the right rear combination lamp connector C404 or the backup lamp connector C451, Circuit 57 (BK) and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, replace the vehicle interface module. Test the system for normal operation.
Circuitry open or shorted	
Backup lamp	

Problem—Individual Backup Lamps is Inoperative

Problem—Individual Backup Lamps is Inoperative	
Possible Cause	**Remedy**
Circuitry open or shorted	Check Circuit 140 (BK/R) for an open. Turn the ignition switch to the "Off" position. Disconnect the inoperative backup lamp connector. Place the transmission selector in reverse. Turn the ignition switch to the "On" position. Measure the voltage between the inoperative backup lamp connector Circuit 140 (BK/R) and ground. If the voltage is less than 10 volts, repair Circuit 140 (BK/R). Test the system for normal operation. If the resistance is greater than 10 volts, check Circuit 57 (BK) for an open. Turn the ignition switch to the "Off" position. Measure the resistance between the inoperative backup lamp connector Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the backup lamp bulb. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.
Defective backup lamp	

Problem—Backup Lamps are On Continuously

Problem—Backup Lamps are On Continuously	
Possible Cause	**Remedy**
Circuitry shorted	Check Circuit 140 (BK/R) for a short to battery. Turn the ignition switch to the "Off" position. Make sure the gear selector is in "Park" or "Neutral". Disconnect the backup lamp switch connector, or the vehicle interface module (Allison electronic transmission) connector harness connector. Observe the backup lamps. If the backup lamps are on, repair Circuit 140 (BK/R). Test the system for normal operation. If the backup lamps do not operate, replace the backup lamp switch or if equipped with a vehicle interface module, replace the vehicle interface module. Test the system for normal operation.

Troubleshooting

Problem—Trailer Lamps are Inoperative (Stoplamps)

Problem—Trailer Lamps are Inoperative (Stoplamps)	
Possible Cause	**Remedy**
Circuitry shorted	Check Circuit 8 (O/Y). Measure the voltage between the stoplamp switch connector C265 or C266 Circuit 8 (O/Y) and ground. If the voltage is less than 10 volts, repair Circuit 8 (O/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check the stoplamp switch. Reconnect the stoplamp switch connector harness connector. Measure the voltage by backprobing between the stoplamp switch connector C265 or C266 Circuit 511 (GN) and ground while holding the brake pedal down. If the voltage is less than 10 volts, replace the stoplamp switch. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 511 (GN).
Trailer stoplamp relay	Disconnect the stoplamp low-pressure operating switch connector harness connector. Measure the voltage between the stoplamps low-pressure operating switch connector C267 Circuit 511 (GN) and ground while holding the brake pedal down. If the voltage is less than 10 volts, repair Circuit 511 (GN). Test the system for normal operation. If the voltage is greater than 10 volts, check the stoplamp low-pressure operating switch. Reconnect the stoplamp low-pressure operating switch connector harness connector. Measure the voltage by backprobing between the stoplamp low-pressure operating switch connector C267 Circuit 810 (R/BK) and ground while pressing the brake pedal down. If the voltage is less than 10 volts, replace the stoplamp low-pressure operating switch. Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 810 (R/BK).
Stoplight low-pressure operating switch	Disconnect the trailer stoplamp relay connector. Measure the voltage between the trailer stoplamp relay connector C187 Pin 85, Circuit 810 (R/BK) and ground while pressing the brake pedal down. If the voltage is less than 10 volts, repair Circuit 810 (R/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 37 (BK/Y). Measure the voltage between the trailer stoplamp relay connector C187 Pin 30, Circuit 37 (BK/Y) and ground while pressing the brake pedal down. If the voltage is less than 10 volts, repair Circuit 37 (BK/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check the relay ground. Measure the resistance between the trailer stoplamp relay connector C187 Pin 86, Circuit 57 (BK) and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, check the trailer stoplamp relay.
Stoplight switches	Measure the voltage between the trailer stoplamp relay connector C187 Pin 87, Circuit 810 (R/BK) and ground while pressing the brake pedal down. If the voltage is less than 10 volts, replace the trailer stoplamp relay. Test the system for normal operation. If the voltage is greater than 10 volts, check the trailer stoplamp feed. Measure the voltage between the trailer tow connector C193 Pin U, Circuit 810 (R/BK) and ground while pressing the brake pedal down. If the voltage is less than 10 volts, repair the trailer wiring. Test the system for normal operation. If the voltage is greater than 10 volts, repair Circuit 810 (R/BK). Test the system for normal operation.

Problem—Trailer Lamps are Inoperative (Turn Signal/Hazard/Parklamps)

Problem—Trailer Lamps are Inoperative (Turn Signal/Hazard/Parklamps)	
Possible Cause	**Remedy**
Multi-function switch Circuitry Trailer right-hand and left-hand turn keys Turn signal flasher Trailer parklamp relay Headlamp switch	Check Circuit 8 (O/Y). Disconnect the electronic flasher harness connector. Measure the voltage between the electronic flasher connector C2033 Circuit 8 (O/Y) and ground. If the voltage is less than 10 volts, repair Circuit 8 (O/Y). Test the system for normal operation. If the voltage is greater than 10 volts check the turn signal flasher. Turn the ignition switch to the "On" position. Turn the multi-function switch to the right or left position. Measure the voltage between the turn signal flasher connector C2033 Circuit 44 (BL) and ground. If the voltage is greater than 10 volts, check the flasher ground. Disconnect the turn signal flasher harness connector. Measure the resistance between the turn signal flasher connector C2033 Circuit 57 (BK) and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, replace the turn signal flasher. Test the system for normal operation. If the voltage between the flasher connector C2033 and ground is less than 10 volts, measure the voltage between the multi-function switch connector C253 Circuit 44 (BL) or C254 (Signal-Stat) Circuit 44 (BL) and ground. If the voltage is less than 10 volts, repair Circuit 44 (BL). Test the system for normal operation. If the voltage is greater than 10 volts, check the multi-function switch. Turn the multi-function switch to the left position. Measure the voltage between the multi-function switch connector C253 Circuit 3 (GN/W) or C254 (Signal-Stat) Circuit 3 (GN/W) and ground. Turn the multi-function switch to the right position. Measure the voltage between the multi-function switch connector C253 Circuit 2 (W/BL) or C254 (Signal-Stat) Circuit 2 (W/BL) and ground. If the voltage is less than 10 volts, replace the multi-function switch. Test the system for normal operation. If the voltage is greater than 10 volts, check the relay feeds. Disconnect the trailer turn lamp relays harness connector. Turn the multi-function switch to the right or left position. Measure the voltage between the right or left trailer turn lamp relay connector C183 Pin 85 or connector C184 Pin 85 and ground. If the voltage is less than 10 volts, repair Circuit 2 (W/BL) or Circuit 3 (GN/W). Test the system for normal operation. If the voltage is greater than 10 volts, check Circuit 37 (BK/Y). Measure the voltage between the trailer turn lamp relay connector C184 Pin 30 or C183 Pin 30 and ground. If the voltage is less than 10 volts, repair Circuit 37 (BK/Y). Test the system for normal operation. If the voltage is greater than 10 volts, check the relay grounds. Measure the resistance between the right or left trailer lamp relay connector C183 Pin 86 or C184 Pin 86 and ground. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation. If the resistance is less than 5 ohms, perform the "Relay Component Test" in this section. Check the trailer turn lamp feeds. Turn the multi-function switch to the right or left position. Measure the voltage between the trailer tow connector C193 Pin V and Pin Z and ground. If the voltage is greater than 10 volts, repair the trailer wiring. Test the system for normal operation. If the voltage is less than 10 volts, repair Circuit 283 (Y/BK) or Circuit 282 (GN). Test the system for normal operation.

Troubleshooting

Problem—Trailer Lamps are Continuously On (Stoplamps)

Problem—Trailer Lamps are Continuously On (Stoplamps)	
Possible Cause	**Remedy**
Circuitry	Check the relay Input. Disconnect the trailer stoplamp relay harness connector. Measure the voltage between the trailer stoplamp relay connector C187 Pin 85, Circuit 810 (R/BK) and ground. If the voltage is less than 10 volts, replace the trailer stoplamp relay. Test the system for normal operation.
Trailer stoplamp relay	If the truck is a tractor, check the stoplamp low-pressure switch. Measure the voltage between the stoplamp and the low-pressure operating switch connector C267 Circuit 810 (R/BK) and ground. If the voltage is less than 10 volts, repair Circuit 810 (R/BK). Test the system for normal operation. If the voltage is greater than 10 volts, check the brake system air pressure. If the system air pressure is within an acceptable range (90 to 120 psi [621 to 827 kPa]), replace the stoplamp low-pressure operating switch. Test the system for normal operation. If the brake system air pressure is not within an acceptable range, repair the air system problem. Test the system for normal operation. Then, retest the stoplamp low-pressure operating switch.
Stoplight low-pressure operating switch	
Stoplight switches	Check the stoplamp switches. Measure the voltage between the stoplamp switch connector C265 Circuit 511 (GN), C266 Circuit 511 (GN) and ground. If the voltage is less than 10 volts, replace the stoplamp switch. Test the system for normal operation. If the voltage is greater than 10 volts, check and repair Circuit 511 (GN) or Circuit 810 (R/BK). Test the system for normal operation.

Relay Component Test

Use the following procedure to test an ISO relay.

1. Locate and remove the ISO relay in the instrument panel fuse junction panel.
2. Using two No. 10 (or larger gauge) jumper wires, connect relay Terminals 86 and 30 directly to the positive battery terminal. See **Fig. 1**.

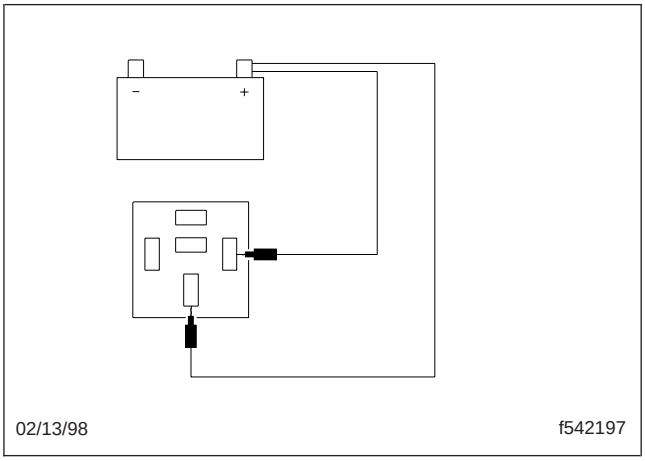


Fig. 1, Relay Terminals 86 & 30

3. Connect a volts, meter to Terminal 87a. Ten volts, or greater should be present. If 10 volts, or greater is not present, replace the relay. If 10 volts, or greater is present, continue with this test. See **Fig. 2**.

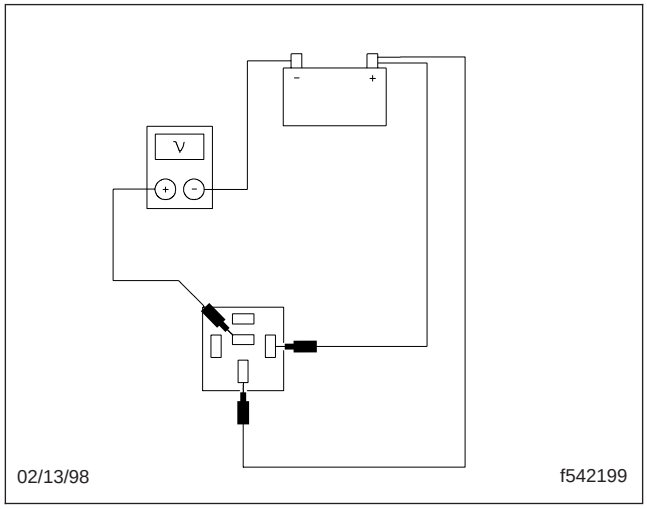

Fig. 2, Terminal 87A

4. Connect a third jumper wire to Terminal 85 and chassis ground. See **Fig. 3**.

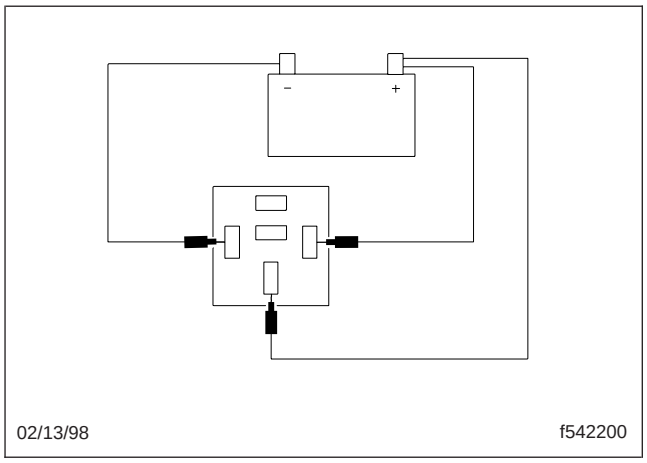

Fig. 3, Terminal 85

5. Check for voltage at Terminal 87. Ten volts, or greater should be present. If 10 volts, or greater is not present, replace the relay. See **Fig. 4**.

Interior Lighting System

1. Verify the vehicle owner's original concern by operating the courtesy lamps to duplicate the vehicle owner's concern.
2. Inspect to determine if one of the following mechanical or electrical concerns applies:

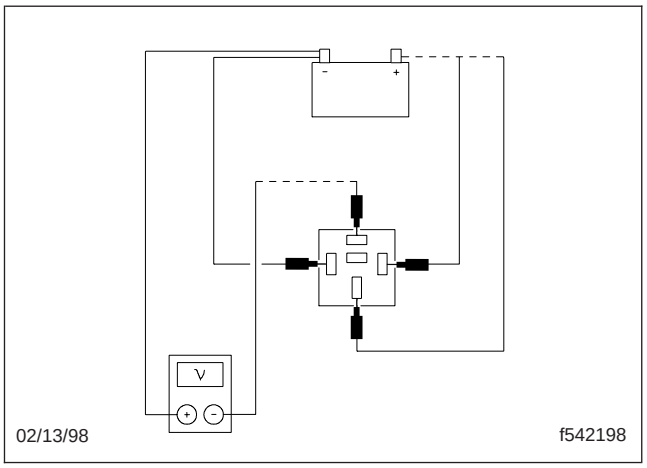

Fig. 4, Terminal 87

Visual Inspection Chart	
Mechanical	**Electrical**
Damaged lamp switch (courtesy)	IP fuse panel fuse
	Damaged bulbs
Stuck lamp switch (courtesy)	Circuitry open/shorted
	Connectors damaged/ corroded

Table 1, Visual Inspection Chart

Troubleshooting

Problem—Courtesy Lamps are Inoperative

Problem—Courtesy Lamps are Inoperative	
Possible Cause	**Remedy**
Blown fuses	Check the supply voltage at the dome lamp and IP dimmer switch. Turn the ignition to "Off" position. Measure the voltage between the dome lamp and IP dimmer switch connector Circuit 40 (BL/W) and ground. If the voltage is less than 10 volts, repair Circuit 40 (BL/W). replace the IP fuse 13 (15 A) if blown. Test the system for normal operation. If the voltage is greater than 10 volts, check the dome lamp IP dimmer switch output. Turn the dome lamps on with the dome lamp and IP dimmer switch. Measure the voltage between the dimmer witch connector Circuit 53 (BK/BL) and ground. If the voltage is less than 10 volts, replace the dome lamp and IP dimmer switch. Test the system for normal operation. If the voltage is greater than 10 volts, check the supply voltage at the courtesy lamp switches.
Open in circuitry	Disconnect the courtesy lamp switches. Measure the resistance between Circuit 54 (GN/Y) at each lamp switch and ground. If the voltage is less than 10 volts, at each lamp switch, repair circuit 54 (GN/Y) at the lamp switch. Replace the IP Fuse 31 (15 A) if blown. Test the system for normal operation. If the voltage is greater than 10 volts at each lamp switch, check the lamp switches. Measure the resistance between terminals on each lamp switch. If the resistance is less than 5 ohms, replace the lamp switch. Test the system for normal operation. If the resistance is greater than 5 ohms at any switch, check Circuit 53 (BK/BL).
Damaged courtesy lamp switches	Disconnect the dome lamp and IP dimmer switch. Measure the resistance between the dome lamp and IP dimmer switch connector Circuit 53 (BK/BL) and each courtesy lamp connector Circuit 53 (BK/BL). If the resistance is greater than 5 ohms, repair Circuit 53 (BK/BL). Test the system for normal operation. If the resistance is less than 5 ohms, check the courtesy lamp grounds. Measure the resistance between each courtesy lamp connector Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the bulb. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.

Problem—Courtesy Lamps Stay On Continuously

Problem—Courtesy Lamps Stay On Continuously	
Possible Cause	**Remedy**
Short to power	Check Circuit 53 (BK/BL) for a short. Remove the IP fuse panel Fuses 13 (15 A) and 31 (15 A). If the courtesy lamps do not turn off, repair Circuit 53 (BK/BL). Test the system for normal operation. If the lamps turn off, check the courtesy lamp switches.
Damaged courtesy lamp switches	Depress each lamp switch to the closed-door position. Measure the resistance of each lamp switch. If the resistance is greater than 10,000 ohms, replace the dome lamp and IP dimmer switch. Test the system for normal operation. If the resistance is less than 10,000 ohms, replace the courtesy lamp switch. Test the system for normal operation.

Problem—Map Illumination Lamp is Inoperative

Problem—Map Illumination Lamp is Inoperative	
Possible Cause	**Remedy**
Blown fuses	Check for power to the map lamps. Disconnect the dome/map lamp connector. Measure the voltage between the lamp connector Circuit 54 (GN/Y) and ground. If the voltage is less than 10 volts, repair Circuit 54 (GN/Y). Replace the IP fuse 31 (15 A) if blown. Test the system for normal operation. If the voltage is greater than 10 volts, turn the dome lamp and IP dimmer switch to the "On" position for dome lamp activation. Measure the voltage between the dome lamp connector Circuit 53 (BK/BL) and ground. If the voltage is less than 10 volts, repair Circuit 53 (BK/BL). Test the system for normal operation. If the voltage is greater than 10 volts, check the map lamp ground. Measure the resistance between the lamp connector Circuit 57 (BK) and ground. If the resistance is less than 5 ohms, replace the bulb. Test the system for normal operation. If the resistance is greater than 5 ohms, repair Circuit 57 (BK). Test the system for normal operation.
Open in circuitry	
Damaged courtesy lamp switches

Charging System

The alternator charging system is a negative ground system that consists of an alternator, voltage regulator, charge indicator, lead storage battery and associated wiring.

This section contains general information applicable to all charging systems and alternators. For information specific to the alternator, refer to **Group 15**.

Battery Charging

WARNING

Batteries release a gas mixture that is explosive. Don't smoke when working around batteries. Put out all flames, and remove any source of sparks or intense heat. Make sure the battery compartment has been completely vented before removing or connecting battery cables.

Battery acid is extremely harmful if splashed in the eyes or on the skin. Always wear safety goggles when working around batteries.

If excessive gassing or electrolyte spewing occurs during the charge, discontinue charging. the battery has reached serviceable charge. If the battery will not accept at least 5A after 20 minutes of charging, replace the battery.

- Before recharging a discharged battery, inspect and repair the following conditions, if they exist: loose drive belt, pinched or grounded alternator voltage regulator wiring, loose connections of the alternator voltage regulator wiring at the alternator or voltage regulator, loose or corroded connections at the battery, starter motor relay or engine, and excessive battery drain due to key off loads.
- Cold batteries will not readily accept a charge. Therefore, allow the battery to warm up to approximately 41°F (5°C) before charging. This can require 4 to 8 hours at room temperature, depending on the initial temperature and battery size.
- A battery which has been completely discharged can be slow to accept a charge initially, and in some cases will not accept a charge at the normal charger setting. When a battery is in this condition, charging can be started by the use of the dead battery switch on chargers so equipped.

1. To determine whether a battery is accepting a charge, follow the charger manufacturer's instructions for use of the dead battery switch. If the switch is the spring-loaded type, it must be held in the "On" position for up to 3 minutes.
2. After releasing the switch and with the charger still on, measure the battery voltage using Rotunda 73 Digital Multimeter. If it shows 12 volts or higher, the battery is accepting a charge and is capable of being recharged. However, it can require up to 2 hours of charging with batteries colder than 41°F (5°C) before the charge rate is high enough to show on the charger ammeter. It has been found that all non-damaged batteries can be charged by this procedure. If a battery cannot be charged by this procedure, replace it.

Regulator Output Adjustment, Delco Alternator

NOTE: After adjusting the setting, check for an improved battery condition over a service period of reasonable length. If adjusting the setting does not correct the battery condition, remove the alternator for service.

NOTE: Remember that if the battery state of charge is low, the regulator may not be limiting the voltage, and turning the adjusting screw will show no change on the voltmeter. However, turning the adjusting screw will change the voltage setting to a new value, which will be indicated by the voltmeter when the battery state of charge increases.

1. Remove the access pipe plug from the integral charging system.
2. Turn the adjusting screw one or two notches clockwise to raise the voltage setting and one or two notches counterclockwise to lower the voltage setting.
3. Replace the access pipe plug.

Troubleshooting

⚠ WARNING

Batteries release explosive gases. Do not smoke when working around batteries. Put out all flames, and remove any source of sparks or intense heat. Make sure the battery compartment has been completely vented before removing or connecting battery cables.

Battery acid is extremely harmful if splashed in the eyes or on the skin. Always wear safety goggles when working around batteries.

⚠ CAUTION

Do not attempt these tests on a lead-acid battery that has recently been recharged. Allow a reasonable amount of time to pass to allow the battery plates to cool to prevent battery damage.

NOTE: Before performing charging system tests on the vehicle, note the complaint (such as slow cranking, battery discharged or improper voltmeter reading). This information will aid in isolating the part of the system causing the symptom.

NOTE: Before any repair of the vehicle's charging system is done, perform a visual inspection. Use the following procedures for the visual inspection.

NOTE: Troubleshooting or diagnosis is required before actual service of the electrical system. Even where an obvious condition makes replacement of a component necessary, find out why the component failed.

1. Check the battery posts and battery cable terminals for clean and tight connections.
2. Remove the battery cables (if corroded), clean and install them securely.
3. Check for clean and tight wiring connections at the alternator, voltage regulator and the engine.
4. Check the drive belt tension; refer to **Group 01**.

IMPORTANT: Isolate the battery, the charging system, and the electrical circuits to correctly identify the problem area. Check the battery before performing any electrical system diagnosis. The battery must be in the proper state of charge and operation before areas of the electrical system can perform normally. Open circuits or other wiring concerns can prevent the alternator from operating normally.

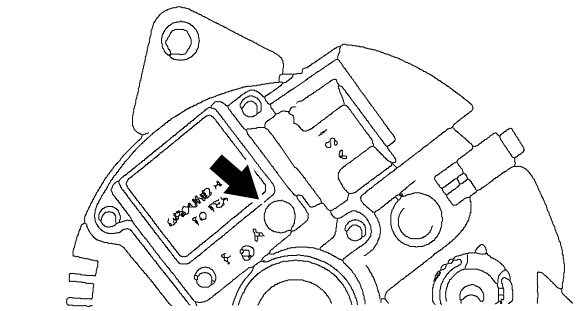
5. Check the battery state of charge. Refer to the "Component Tests" in this subject.

Troubleshooting

Problem—The System Does Not Charge

Problem—The System Does Not Charge (See Fig. 1)	
Possible Cause	**Remedy**
Battery connections	Check for an open B+ Circuit. Turn the ignition switch to the "Off" position. Measure the voltage between the B+ terminal on the alternator, Circuit 37 (BK/Y) and chassis ground. If the voltage is not equal to the battery voltage, repair Circuit 37 (BK/Y). Test the system for normal operation. If the voltage is equal to the battery voltage, check for an open ground circuit.
Battery	Measure the voltage between the B+ terminal and the ground terminal on the alternator. If the voltage is not equal to the battery voltage, repair Circuit 57 (BK). Test the system for normal operation. If the voltage is equal to the battery voltage, if the vehicle is equipped with a Delco Remy alternator, replace the alternator. If equipped with a Motorcraft alternator, check for open in Circuit A.
Drive belt	Measure the voltage between the voltage regulator test point A and chassis ground. If the voltage is not equal to the battery voltage, repair Circuit 152 (Y). Test the system for normal operation. If the voltage is equal to the battery voltage check for an open field circuit. Turn the ignition switch to the "Off" position. Measure the voltage between the voltage regulator test point F and chassis ground. If the voltage is not equal to battery voltage, check for open/shorted field. Turn the ignition switch to the "Off" position. Disconnect the primary and auxiliary or secondary battery cables. Remove the alternator and then the voltage regulator. For instructions, see **Group 15**.
Alternator/voltage regulator	Measure the resistance between the alternator slip rings. If the resistance is greater than 10 ohms or less than 1 ohm, replace the alternator. Test the system for normal operation. If the resistance is less than 10 ohms or less than 1 ohm, check for brushes less than 8 mm long or open brush leads and replace if required. If the brushes are OK, replace the voltage regulator. Test the system for normal operation.

Problem—The System Does Not Charge



10/14/98 f542086

Fig. 1, Voltage Regulator Test Point A

Problem—The System Does Not Charge (See Fig. 2 and Fig. 3)	
Possible Cause	**Remedy**
Battery connections	NOTE: The voltage regulator must be connected to the wiring harness to check for an open in the I-Circuit. If the voltage is equal to battery voltage, check for an open in Circuit I. Turn the ignition switch to the "On" position. Measure the voltage between the voltage regulator I terminal Circuit 69 (R/GN) and chassis ground. If the voltage is not 1 volt or greater, repair Circuit 69 (R/GN) or replace the voltage regulator. Test the system for normal operation. If the voltage is 1 volt or greater, check voltage drop in Circuit A.
Battery	Measure the voltage between the voltage regulator test point A and the battery positive post. If the voltage drop is not 0.25 volts or less, repair Circuit 152 (Y). Test the system for normal operation. If the voltage drop is 0.25 volts or less, check field turn-on.
Drive belt	Measure the voltage between the voltage regulator test point F and chassis ground. If the voltage is greater than 2 volts, check for open/shorted field. Turn the ignition switch to the "Off" position. Disconnect the primary and auxiliary or secondary battery cables. Remove the alternator and then the voltage regulator. For instructions see **Group 15**.
Alternator or voltage regulator	Measure the resistance between the alternator slip rings. If the resistance is greater than 10 ohms or less than 1 ohm, replace the alternator. Test the system for normal operation. If the resistance less than 10 ohms or less than 1 ohm check for brushes less than 8 mm long or open brush leads and replace if required. If the brush leads are OK, replace the voltage regulator. Test the system for normal operation. If the voltage is greater than 2 volts, check for a shorted rectifier. Turn the ignition switch to the "Off" position. Disconnect the alternator one-way connector harness connector. Measure the voltage between the alternator one-way terminal and chassis ground.

Troubleshooting

Problem—The System Does Not Charge

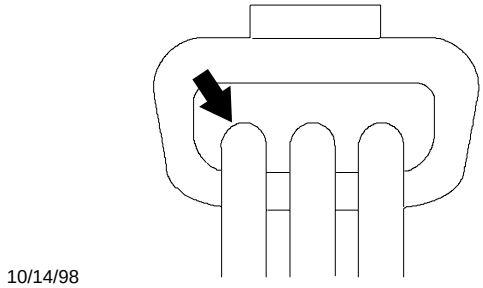


Fig. 2, Voltage Regulator I-Terminal

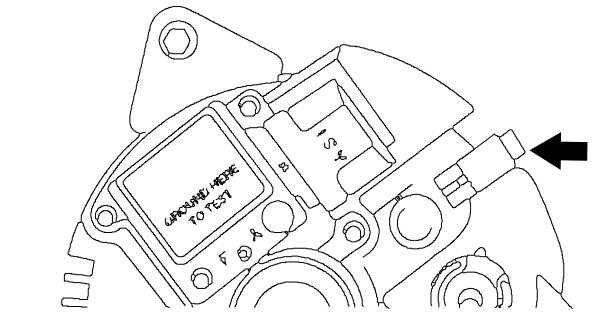

Fig. 3, Alternator One-Way Terminal

Problem—The System Does Not Charge (See Fig. 3 and Fig. 4)	
Possible Cause	**Remedy**
Battery connections	Measure the voltage between the battery positive post and the alternator one-way connector. If either voltage reading is greater than 1 volt, replace the alternator. Test the system for normal operation. If either voltage reading is less than 1 volt, check the voltage drop in the B+ Circuit.
Battery	Turn on the headlamps and the heater blower to the highest setting. Reconnect the alternator one-way connector harness connector. Turn the ignition switch to the "On" position. With the engine running at 2000 rpm, measure the voltage between the alternator B+ terminal and the battery positive post. If the voltage is greater than 0.5 volts, repair Circuit 37 (BK/Y) or Circuit 152 (Y) for high resistance. Test the system for normal operation. If the voltage is less than 0.5 volts, check for an open stator phase.
Drive belt	
Alternator/voltage regulator	Turn the ignition switch to the "Off" position. Connect a jumper wire between the voltage regulator test point F and the negative battery post. Repeat the alternator output test. If the alternator output is greater than the minimum output specified, replace the voltage regulator. Test the system for normal operation. If the alternator output less than the minimum output specified, replace the alternator. Test the system for normal operation.

Problem—The System Overcharges

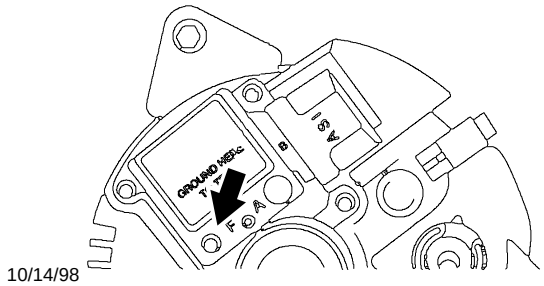

Fig. 4, Voltage Regulator Test Point F

Problem—The System Overcharges (See Fig. 2)	
Possible Cause	**Remedy**
Excessive voltage drop	Check the alternator output. Turn the ignition switch to the "Run" position. Measure the voltage between the B+ terminal on the alternator, Circuit 37 (BK/Y) and chassis ground. If the voltage is greater than 15 volts and equipped with a Delco Remy alternator, replace the alternator. Test the system for normal operation. If equipped with a Motorcraft alternator, check voltage in Circuit I. Turn the ignition switch to the "Off" position. Turn the ignition switch to the "On" position. Measure the voltage between the voltage regulator connector Pin I Circuit 69 (R/GN) and chassis ground. If the voltage is not 1 volt or greater repair high resistance or poor connection in Circuit 69. Test the system for normal operation. If the voltage is 1 volt or greater check voltage drop in Circuit A.
Poor ground	Turn the ignition switch to the "On" position. Measure the voltage between the voltage regulator test point A and the primary battery positive post. If the voltage is not 0.25 volt or less repair Circuit 37 (BK/Y) or 152 (Y). Test the system for normal operation. If the voltage is 0.25 volt or less check for poor grounds. Turn the ignition switch to the "Off" position. Check for poor ground connections between the voltage regulator and the alternator, the alternator and the engine, or the engine and the battery. If all the ground connections are not clean and tight clean and repair ground(s) as required. Test the system for normal operation. If all the ground connections are clean and tight check for field circuit drain.
Voltage regulator	Measure the voltage between the voltage regulator test point F and chassis ground. If the voltage is not equal to battery voltage replace the voltage regulator. Test the system for normal operation. If the voltage is equal to battery voltage check for grounded slip ring. Disconnect the alternator harness connector. Disconnect the voltage regulator harness connector. Remove the voltage regulator from the alternator. Refer to **Group 15**. Measure the resistance between each alternator slip ring and the alternator housing. If the resistance between any slip ring and the alternator housing is 200 ohms or less, clean the slip rings and measure the resistance of the slip rings again. If still less than 200 ohms, replace the alternator. Test the system for normal operation. If the resistance between any slip ring and the alternator housing is not 200 ohms or less, replace the voltage regulator. Test the system for normal operation.

Troubleshooting

Problem—The Voltage Gauge Reads High

Problem—The Voltage Gauge Reads High	
Possible Cause	**Remedy**
Alternator	Check the alternator. For instructions, see "Component Tests" in this section. If the alternator is OK, see "Instrument Cluster Troubleshooting" in **Section 54.04**. If the alternator is defective, repair or replace the alternator. Test the system for normal operation.
Voltage regulator	
Voltmeter	

Problem—The Voltage Gauge Reads Low

Problem—The Voltage Gauge Reads Low	
Possible Cause	**Remedy**
Alternator	Check the alternator. Perform the "Alternator On-Vehicle Tests" check. For instructions, see "Component Tests" in this section. If the alternator is OK, see "Instrument Cluster Troubleshooting" in **Section 54.04**. If the alternator is defective, repair or replace the alternator. Test the system for normal operation.
Voltage regulator	
Voltmeter	

Component Tests

BATTERY CAPACITY TESTING

NOTE: The battery must be fully charged before performing this test.

To perform this test, use a high rate discharge tester such as a Rotunda Alternator, Regulator, Battery and Starter Tester (ARBST), in conjunction with a digital multimeter.

1. Turn the high rate discharge tester off.
2. Turn the digital multimeter to the DV volt scale.
3. Connect the high rate discharge tester and the multimeter positive test leads to the positive battery post, and both negative leads to the negative battery post. The multimeter clips must contact the battery posts and not the high rate discharge tester tester clips.
4. Adjust the high rate discharge tester until the ammeter reads approximately one-half of the cold cranking amps of the battery.
5. With the ammeter reading the required load for 15 seconds, note the multimeter reading. Avoid leaving the high discharge load on the battery for periods longer than 15 seconds.
6. If the multimeter reading is 9.6 volts at 70°F (21°C) or more, the battery has a good output capacity and will readily accept a charge, if required.
7. If the voltage reading obtained during the capacity test is below 9.6 volts at 70°F (21°C), and the battery is fully charged, the battery is defective and must be replaced. If unsure about the battery's state of charge, charge the battery.
8. After the battery has been charged, repeat the capacity test. If the battery voltage is still less than 9.6 volts, replace the battery.
9. If the battery is found to be discharged only, check for a loose connection, check charging system performance, and perform a battery drain test.

BATTERY, DRAIN TESTING

⚠ WARNING

Batteries release a gas mixture that is explosive. Do not smoke when working around batteries. Put out all flames, and remove any source of sparks or intense heat. Make sure the battery compartment has been completely vented before removing or connecting battery cables.

Battery acid is extremely harmful if splashed in the eyes or on the skin. Always wear safety goggles when working around batteries.

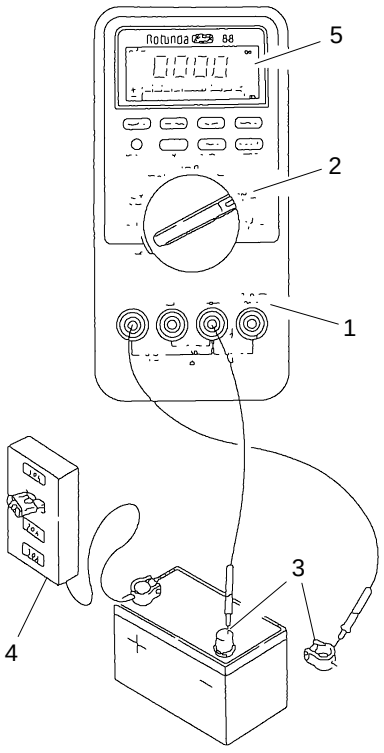
Do not attempt this test on a lead-acid battery that has recently been recharged.

⚠ CAUTION

Do not crank the engine or operate accessories that draw more than 10 amperes. Doing so can result in damage to the test equipment.

NOTE: Many on-board computers draw 10 milli-amperes or more, continuously.

Check for current drains on the battery in excess of 50 milliamperes with all the electrical accessories off and the vehicle at rest. See **Fig. 5**.



02/11/98 f542090

1. Input Terminals
2. Function Selector Set at MA/A DC
3. Negative Post and Lead
4. Fuse Panel
5. Display Window

Fig. 5, Battery Drain Test Setup

1. Insert the test leads in the input terminals.
2. Turn the switch to MA/A DC.
3. Disconnect the battery terminal and touch probes as shown.
4. Isolate the circuit causing the drain by pulling out one fuse after another while reading the display.
5. Current reading will drop when the fuse on the bad circuit is pulled. Reinstall the fuse and test the components (including connectors) of that circuit to find the defective component(s).
6. Typically, a drain of approximately 1 ampere can be attributed to an engine compartment lamp, glove compartment lamp or other courtesy lamp staying on continuously. Other components or wiring shorts can be located by selectively pulling fuses or disconnecting fuse links to pinpoint the location of the current drain. When the current drain is located, the meter reading will drop to an acceptable level. If the short is still not located after checking all fuses and fuse links, the drain may be caused by the alternator.

ALTERNATOR ON-VEHICLE TESTS

1. Connect the test block to the alternator.
2. Assemble a closed-end terminal clip with a 1/2-inch (12.7-mm) hole to the output terminal, then connect the ammeter lead clip to this terminal clip.
3. With all accessories and carbon pile turned off, increase engine speed as required to obtain maximum voltage reading.
4. If voltage exceeds 15 volts, remove the integral charging system for service.
5. If voltage does not exceed these values, proceed as follows:
   - 5.1 Make sure that accessories have not been left on for extended periods.
   - 5.2 Check the drive belt for proper tension.
   - 5.3 Inspect the wiring for wear or damage. Check all connections for tightness and cleanliness, including the cable clamps and battery posts.
6. With the engine running, connect a voltmeter from the output terminal on the integral charging system to ground. A zero reading indicates an open between the voltmeter connection and the battery.
7. If the previous steps check out, test the integral charging system as follows:

Troubleshooting

7.1 Disconnect the battery ground cable.

7.2 Connect an ammeter in the circuit at the output terminal of the integral charging system.

7.3 Reconnect the battery ground cable.

7.4 Turn on the accessories. Connect the carbon pile across the battery.

NOTE: Initial voltage buildup is by residual magnetism in the rotor. Increase the speed as required to obtain maximum current output. Operate the engine at moderate speed as required, usually 4000 alternator rpm or more, and adjust carbon pile as required to obtain maximum current output.

8. If ampere output is not within 10 amperes of the rated output as stamped on the alternator frame, remove the alternator for service. If ampere output is within 10 amperes of the rated output as stamped on the alternator frame, the integral charging system is not worn or damaged.

ALTERNATOR BENCH TEST

If system diagnosis has isolated a problem in the alternator assembly, remove it from the vehicle for bench testing and repair or replace. Refer to **Group 15** for the appropriate alternator removal or disassembly procedure. In some cases, it is possible to replace a damaged regulator or brushes without removing the alternator assembly.

NOTE: The following tests are performed with an analog (needle-type) ohmmeter. Test values shown are referenced to the Rotunda Inductive Dwell-Tach-Volts-Ohms Tester. These values may be different for other ohmmeters. If you do not have a Rotunda Inductive Dwell-Tach-Volts-Ohms Tester, use known good parts to establish reference values for your own meter. These values can be written into the spaces provided in the meter reading charts for future reference.

NOTE: The Motorcraft integral rear mount regulator, internal fan type alternator, is serviced as an assembly. If the alternator requires service, it must be replaced as an assembly.

Rectifier and Stator Grounded Tests

NOTE: This test is performed with an ohmmeter, inductive dwell-tach-volts-ohms tester. Set the multiplier setting at 1 and calibrate the ohmmeter as directed.

NOTE: Digital meters cannot be used to perform these rectifier tests.

1. Connect one ohmmeter probe to one of the alternator B+ blade terminals and the other probe to the STA blade terminal. Reverse the ohmmeter probes and repeat the test. Normally, there will be no needle movement in one direction, indicating the rectifier diodes are being checked in the reverse current direction and are not shorted. A low reading with the probes reversed indicates that the rectifier positive diodes are being checked in the forward current direction. A reading in both directions indicates a bad positive diode or shorted radio suppression capacitor. The radio suppression capacitor is built into the rectifier assembly and is not individually serviceable.
2. Perform the same test using the STA and GND (ground) terminals of the alternator. A reading (needle movement) during both tests indicates either a bad negative diode, a grounded stator winding, a grounded stator terminal, a grounded positive diode plate, or a grounded BAT terminal. Infinite readings (no needle movement) in all four probe positions in the preceding tests indicate an open STA terminal lead connection inside the alternator.

Field Open or Short Circuit Test

NOTE: This test is performed with an ohmmeter, such as the Rotunda Inductive Dwell-Tach-Volts-Ohms Tester. Set the multiplier setting at 1 and calibrate the ohmmeter as directed.

NOTE: Digital meters cannot be used to perform these rectifier tests.

NOTE: This test is performed with an ohmmeter, such as the Rotunda Inductive Dwell-Tach-Volts-Ohms Tester.

1. Connect one ohmmeter probe to one of the alternator B+ blade terminals and the other probe to

the STA blade terminal. Reverse the ohmmeter probes and repeat the test. Normally, there will be no needle movement in one direction, indicating the rectifier diodes are being checked in the reverse current direction and are not shorted. A low reading with the probes reversed indicates that the rectifier positive diodes are being checked in the forward current direction. A reading in both directions indicates a bad positive diode or shorted radio suppression capacitor. The radio suppression capacitor is built into the rectifier assembly and is not individually serviceable.

2. Perform the same test using the STA and GND (ground) terminals of the alternator. A reading (needle movement) during both tests indicates either a bad negative diode, a grounded stator winding, a grounded stator terminal, a grounded positive diode plate, or a grounded BAT terminal.
3. Infinite readings (no needle movement) in all four probe positions in the preceding tests indicate an open STA terminal lead connection inside the alternator.
4. Set the multiplier setting at 1 and calibrate the ohmmeter according the manufacturer's instructions.
5. Contact the regulator A blade terminal with one probe and the regulator F screw head with the other probe.
6. Reverse the ohmmeter probes and repeat the test. In one probe direction, the ohmmeter reading should be between 2.2 and 100 and may fluctuate while the pulley is turning. In the other probe direction, the reading should fluctuate between 2.2 and about 9 ohms.
    - An infinite reading (on meter movement) in one direction and approximately 9 ohms in the other, indicates an open brush lead, worn or stuck brushes, a damaged rotor or a loose regulator to brush holder attaching screw.
    - An ohmmeter reading less than 2.2 ohms in both directions indicates a shorted rotor or damaged regulator.
    - An ohmmeter reading significantly over 9 ohms in both directions indicates an inoperative regulator or loose F terminal screw.
7. Contact the alternator rear housing with one ohmmeter probe and touch the other probe to the regulator F terminal. Reverse the probes and repeat the test. The ohmmeter reading should be infinite in one probe direction and approximately 9 ohms in the other.
    - A reading less than infinite in both directions indicates a grounded brush lead or an inoperative regulator.
    - A reading significantly over 9 ohms in both directions indicates an inoperative regulator or a damaged A terminal connection.

FIELD COIL CHECKS, DELCO REMY ALTERNATOR

1. Disconnect the two field coil leads from the regulator.
2. Separate the drive end frame assembly from the rectifier end frame assembly. This is done by removing the shaft nut, washer, pulley, fan, slinger and through-bolts from the end drive.
3. To check for grounds, connect a test lamp, or an ohmmeter, to one field coil lead and to the end frame. If the lamp lights, or if the ohmmeter reading is low, the field coil is grounded.
4. To check for opens, connect a test lamp or an ohmmeter to the two field coil leads. If the lamp fails to light, or if the ohmmeter reading is high (infinite), the field coil is open.
5. Disconnect the two field coil leads from the regulator.

Stator and Coil Grounded Test

1. Remove the stator from the alternator and disconnect it from the rectifier assembly as outlined. Set the ohmmeter multiplier setting at 1000.
2. Connect the ohmmeter probes to one of the stator lead terminals and to the stator laminated core. Make sure that the probe makes a good electrical connection with the stator core. The meter should show an infinite reading (no needle movement).
3. If the meter does not indicate an infinite reading (needle moves), the stator winding is grounded to the core and the stator must be replaced.

Troubleshooting

Stator and Coil Open Test

1. Disconnect the stator from the rectifier assembly. Set the ohmmeter multiplier setting at 1.
2. Connect one ohmmeter probe to a stator phase lead terminal and touch the other probe to another stator lead terminal. Check the meter reading.
3. Repeat this test with the other two stator lead combinations. If no meter movement occurs (infinite resistance) on a lead paired with either of the other phase leads, that phase is open and the stator must be replaced.

Alternator Rotor Open or Short Test

1. Remove the rotor from the alternator. Set the ohmmeter multiplier setting at 1 and calibrate the meter as directed.
2. Contact each ohmmeter probe to a rotor slip ring. The resistance of the rotor should be within 2.4 to 4.9 ohms.
    - A higher reading indicates a damaged slip ring, welded connection or a broken wire.
    - A lower reading indicates a shorted wire or slip ring.
3. Replace the rotor if it is damaged and cannot be serviced.
4. Contact one ohmmeter probe to a slip ring and the other probe to the rotor shaft. The meter reading should be infinite (no needle movement).
5. A reading other than infinite indicates the rotor coil is grounded to the shaft. Replace the rotor if it is grounded and cannot be serviced.

Rectifier

NOTE: Digital meters cannot be used to perform these diode tests.

1. To test the positive diodes, contact one probe to one of the rectifier assembly B+ blade terminals and contact each of the three stator terminals with the other probe. Reverse the probes and repeat the test. All diodes should show a low reading of approximately 7 ohms in one direction and an infinite reading (no needle movement) with the probes reversed. This reading may be checked against a good rectifier if one is available.
2. Remove the rectifier assembly from the alternator. Set the ohmmeter multiplier setting at 1 and calibrate the meter as directed.
3. Perform the preceding tests for the negative diodes by contacting the rectifier assembly base plate and the three stator terminals.
4. Replace the rectifier assembly if the meter readings within an acceptable range.

DIODE TESTS, MOTORCRAFT ALTERNATOR

NOTE: Digital meters cannot be used to perform these diode tests.

1. Remove the rectifier assembly from the alternator and stator assembly (unsolder the three stator leads). Set the ohmmeter multiplier setting at 1 and calibrate the meter according to the manufacturer's instructions.
2. If a Rotunda Inductive Dwell-Tach-Volts-Ohms Tester is not available, obtain a known good replacement rectifier and check the resistance of each diode as described below. Compare results obtained from the replacement rectifier with results obtained from the original rectifier. The low resistance readings will vary with the type of ohmmeter used.
3. To test one set of diodes, contact one probe to the terminal bolt and contact each of the three stator lead terminals with the other probe. Reverse the probes and repeat the test. All diodes should show a low reading of approximately 6 ohms when tested in one direction, and an infinite reading (no needle movement) with the probes reversed.
4. Repeat the preceding tests for the other set of diodes by connecting one probe to the ground terminal.
5. Replace the rectifier assembly if the meter readings are not within an acceptable range.

General Information

Lead-Acid Batteries

Batteries are electrochemical devices that store chemical energy. When the battery is connected to an external load, such as a starter, the chemical energy is converted into electrical energy and current flows through the circuit.

The battery has three functions:

- To supply power to start the engine.
- To stabilize the voltage in the electrical system. The battery filters high voltage transients and protects electronic components in the vehicle.
- To supply power when the vehicle's electrical load requirements go beyond what the charging system can supply or when the engine is not running.

All lead-acid batteries use plates made of two unlike metals held apart by separators. One of the metals becomes the positive plate, the other the negative plate. These plates are then grouped in pairs, alternating negative and positive. The groups are connected in series, and each plate group (cell) produces about two volts. Thus, a battery with six cells is a 12-volt battery.

In conventional liquid-electrolyte batteries (wet cells), each battery contains a group of plates immersed in a solution of electrolyte (dilute sulfuric acid).

Batteries may produce hydrogen gas when being charged. The vents allow the escape of gases produced in the battery.

NOTE: Liquid-electrolyte batteries must be kept in an upright position to prevent electrolyte leakage. Tipping a wet cell beyond a 45-degree angle in any direction can allow a small amount of electrolyte to leak out the vent holes.

Proper testing will indicate the battery condition. For more information, see **Troubleshooting 300**.

Absorbed Glass Mat (AGM) Batteries

Absorbed Glass Mat (AGM) batteries are lead-acid batteries in which the electrolyte is contained in a fiberglass mat. AGM batteries are physically similar to standard batteries. Carefully check the label on every battery to be certain it is AGM, and **never install AGM batteries in the same circuit with other types of batteries.**

AGM batteries are designed for high cranking amps and repeated cycle service to accommodate many of the auxiliary loads on vehicle electrical systems. They offer good protection against damage due to vibration, and are leak- and spill-proof, even if cracked or broken. Also, they self-discharge more slowly, and generate less heat when charging or discharging.

IMPORTANT: AGM batteries may be damaged or ruined by equipment designed for other types of batteries. AGM battery chargers must be regulated to a charge voltage less than 15.4 DCV; many chargers provide excessive voltage. To get full service from AGM batteries, carefully follow the battery manufacturer's instructions regarding charging rates and procedures.

Parasitic Battery Drain

Batteries are replenished each time the vehicle is driven with normal vehicle use. In long-term parking situations, however, parasitic drains may discharge the batteries enough that the starter will not be able to crank the engine.

A parasitic drain is an electrical load that draws current from the batteries when the ignition remains off.

A typical parasitic drain falls into the 25 to 325 mA (0.025 to 0.325 amps) range. Multiply the drain (in amps) by the time (in hours) the batteries sit without being recharged. The result is the amount of ampere-hours consumed by the parasitic drain. The actual drain may be small, but over time the batteries grow steadily weaker.

At warm temperature of 77°F (25°C), using approximately 40 percent of the total available ampere-hours will bring fully charged batteries to a no-start condition. In colder temperatures, the batteries will reach a no-start condition sooner.

General Safety Precautions

⚠ WARNING

Keep sparks, flames, burning cigarettes, etc. away from batteries. Batteries generate explosive gases, which could cause a battery to explode, causing serious personal injury, including blindness.

When charging the batteries, gas forms in each cell and escapes through the vent holes. In poorly ventilated areas, the gas lingers around the battery several hours after it has been charged. The gas is explosive around sparks, flame, or other intense heat; if ignited, it could cause the battery to explode. Follow these precautions when charging the batteries.

- Wear safety glasses or a face shield when working with batteries. When many batteries are handled, wear rubber gloves and an apron to protect clothing.
- Make sure that the area is well ventilated.
- Do not install any lead-acid battery in a sealed container or enclosure. Allow hydrogen gas caused by overcharging to escape. Exploding hydrogen gas can cause blindness or other bodily injury.
- Make sure that the charger cable leads are clean and making good connections. A poor connection could cause an electrical arc which could ignite the gas mixture and explode the battery.
- Do not break live circuits at the terminals because a spark usually occurs at the point where a live circuit is broken. Use care when connecting or disconnecting booster leads or cable clamps on chargers.
- Do not smoke near batteries that are being charged or have recently been charged. Keep the batteries away from open flames or sparks.
- If the battery is frozen, let it reach room temperature and completely thaw before trying to charge it. Check for leaks and cracks before charging the battery. Replace the battery if leaks or cracks are seen.
- Take care that tools or metal objects do not fall across the battery terminals.

⚠ WARNING

Do not install any lead-acid battery in a sealed container or enclosure. Allow hydrogen gas caused by overcharging to escape. Exploding hydrogen gas can cause blindness or other bodily injury.

⚠ CAUTION

If a metal object connects an ungrounded battery terminal to a nearby metal part of the vehicle which is grounded, it could short out the batteries, causing sparks and possible property damage.

Battery Electrolyte Safety Precautions

⚠ WARNING

Protect skin and eyes from battery electrolyte (acid). Electrolyte is corrosive and could result in serious personal injury if splashed on your skin or in your eyes.

If electrolyte is splashed on your skin or in your eye, force the eye open, rinse it with cool, clean water for about five minutes and call a doctor immediately. Do not add eye drops or other medication unless advised by the doctor.

If electrolyte is swallowed, drink several large glasses of milk or water. Follow with milk of magnesia, a beaten raw egg, or vegetable oil. Call a doctor immediately.

Use extreme care to avoid spilling or splashing electrolyte. Electrolyte spilled or splashed on your body or clothing should be neutralized with baking soda or household ammonia, then rinsed with clean water.

Electrolyte can also damage painted or unpainted metal vehicle parts. If electrolyte is spilled or splashed on any metal surface, neutralize and rinse it with clean water.

To prevent possible skin burns, do not wear watches, rings, or other jewelry while performing maintenance work on the batteries.

Battery Safety Precautions

⚠ WARNING

Do not apply pressure to the end walls of a plastic-case battery. This could cause electrolyte to squirt from the vents, possibly resulting in serious injury to skin or eyes.

When handling plastic-case batteries, use a battery carrier. If one is not available, lift these batteries with your hands placed at opposite corners of the battery.

Battery Removal, Cleaning and Inspection, and Installation

⚠ WARNING

Before doing any of the following procedures, see "Battery Safety Precautions" in Subject 100. Failure to follow the safety precautions could result in personal injury.

Removal

IMPORTANT: Before working on any battery box, make sure all electrical loads (lights, ignition, accessories) are turned off.

OUTSIDE-RAIL-MOUNTED BATTERY BOX (See Fig. 1)

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the threaded fasteners that attach the side fairing, if equipped, in front of the battery box. Remove the side fairing. For instructions, see Group 31.

   If no side fairing is installed, remove the step plate, if equipped.
3. Pull on the end of each hold-down latch until the end clears the cover-mounted catch. Pivot the latches out of the way, then lift off the battery box cover.
4. For assembly reference, note the locations of the battery positive and negative terminals in relation to surrounding components. Remove the battery cables.
5. Remove the battery retainer assembly. Remove the batteries from the carrier.
6. Remove the battery box.
   - 6.1 Remove the 1/2–13 nuts, bolts and flatwashers holding the battery box to the frame rail bracket.
   - 6.2 Remove the battery box from the bracket.
7. Remove the battery box brackets from the frame rail.
   - 7.1 Remove the 5/8–11 nuts, bolts and flatwashers holding the brackets to the frame rail.
   - 7.2 Remove the brackets from the frame rail.

BETWEEN-RAIL-MOUNTED BATTERY BOX (See Fig. 2)

1. Park the vehicle on a level surface and set the parking brake. Shut down the engine. Chock the tires.
2. Remove the deck plate, if equipped. Release the handles from the tabs, unfold the handles and lift the plate.
3. Release the hold-downs and remove the battery box lid.
4. Disconnect the battery cables from the battery terminals and move the cables out of the way.
5. Remove the battery hold-down latches.
   - 5.1 Loosen the 1/2-inch nut and flatwasher holding the anchor bolt.
   - 5.2 Disconnect the anchor bolt from the box and set all hold-down hardware aside.
6. Remove the batteries from the box. For assembly reference, note the locations of the battery positive and negative terminals in relation to surrounding components.
7. Remove the battery box.
   - 7.1 From the inside of the battery box, remove the two 3/4-inch bolts and flatwashers from each side of the box.
   - 7.2 Remove the battery box from the vehicle.
8. Remove the battery box brackets from the frame rail.
   - 8.1 Remove the 15/16-inch hexhead nuts and flatwashers holding the rear bracket to the frame rail.
   - 8.2 Remove the 15/16-inch hexhead nuts and flatwashers holding the front bracket to the frame rail.
   - 8.3 Remove the brackets from the frame rail.

Cleaning and Inspection

1. Inspect all battery cables and interconnectors for wear, and replace them if necessary. Remove corrosion from cables, terminals, and battery

posts with a wire brush and a solution of baking soda and water. Rinse thoroughly with clean water, and dry.

2. Clean and tighten the battery ground cable at the weld stud on the frame rail. Inspect and ensure that the nut is self-locking and that a flat washer is used. Do not use a split-lock washer or star washer. Torque the nut 15 to 18 lbf·ft (20 to 24 N·m). Seal the area with red dielectric enamel.
3. Inspect the retainer assembly and battery box. Replace worn or damaged parts. Remove any corrosion with a wire brush and wash with a weak solution of baking soda and water. Rinse with clean water and dry. To prevent rusting, paint the retainer assembly if needed.
4. Be sure foreign objects, such as stones, bolts, and nuts, are removed from the battery box.

Installation

1. Be sure that the battery to be installed has a sufficient capacity to cover the electrical needs of the vehicle.

⚠ CAUTION

Using an undercapacity battery will result in poor performance and premature battery failure, resulting in damage or reduced life of the starter.

2. Be sure the battery is at full charge when installed. If the battery has been in storage for some time, or if the installation is being made in subfreezing temperatures, give the battery a boost-charge before installing it. For instructions, see **Subject 130**.

Battery Removal, Cleaning and Inspection, and Installation

OUTSIDE-RAIL-MOUNTED BATTERY BOX

1. Place the batteries in the carrier with the terminals in the proper position, as referenced earlier. The batteries should rest level in the carrier.
2. Install the battery retainer assembly, and tighten it until the batteries are secure. See **Fig. 1**.

CAUTION

Do not overtighten the battery retainer assembly. Overtightening could damage the batteries.

3. Connect the battery cables to the batteries.
   - 3.1 To provide corrosion protection, apply pumpable dielectric grease liberally to the terminal pads. For a list of approved suppliers, see **Specifications 400**.
   - 3.2 Install the battery cable interconnectors.
   - 3.3 Tighten the battery cables to the torque specifications listed on the battery, generally 10 to 15 lbf·ft (14 to 20 N·m). Connect the ground cable last.

CAUTION

Make sure the polarity is correct. Reversed polarity may cause serious damage to the electrical system.

   - 3.4 Check for correct polarity with respect to the vehicle.
4. Start the engine, and check the operation of the charging system. If needed, adjust or repair the charging system to obtain the correct charging output. For instructions, see the appropriate section in **Group 15**.

CAUTION

Make sure all battery posts are covered with protective caps. Failure to do so could cause the battery box cover to short across the posts.

5. Install the battery box cover. Install the threaded fasteners that attach the side fairing (if equipped). For instructions, see **Group 31**.

   If removed, install the step plate.
6. Remove the chocks from the tires.

BETWEEN-RAIL-MOUNTED BATTERY BOX

1. Install the battery box brackets on the frame rail.
2. Install the battery box.
3. Place the batteries in the battery box with the terminals in the proper position, as referenced earlier. Make sure the batteries rest level in the box.
4. Install the battery hold-down latches.

CAUTION

Do not over-tighten the battery hold-down latches. Over-tightening could damage the batteries.

5. Connect the battery cables to the batteries.
   - 5.1 To provide corrosion protection, apply pumpable dielectric grease, No. 48-02349-000, liberally to the terminal pads. For a list of approved suppliers, see **Specifications 400**.
   - 5.2 Install the battery cable interconnectors.
   - 5.3 Tighten the battery cables to the torque specifications listed on the battery, generally 10 to 15 lbf·ft (14 to 20 N·m). Connect the ground cable last.
   - 5.4 Check for correct polarity with respect to the vehicle.

CAUTION

Make sure the polarity is correct. Reversed polarity can cause serious damage to the electrical system.

6. Start the engine and check the operation of the charging system. If needed, adjust or repair the charging system to obtain the correct charging output. For instructions, see the appropriate section in **Group 15**.

CAUTION

Make sure all battery posts are covered with protective caps. Failure to do so could cause the battery box cover to short across the posts.

7. Install the battery box cover.

8. Install the deck plate, if equipped.
9. Remove the chocks from the tires.

Emergency Starting Using Booster Cables

WARNING

Before jump-starting a vehicle, read the instructions in Subject 100. Failure to follow the safety precautions could result in personal injury.

WARNING

Batteries release explosive gas. Do not smoke when working around batteries. Put out all flames and remove all sources of sparks or intense heat in the vicinity of the battery. Do not allow the vehicles to touch each other. Do not lean over the batteries when making connections, and keep all other persons away from the batteries. Failure to follow these precautions could lead to severe personal injury as a result of an explosion or acid burns.

NOTICE

Make sure both electrical systems are the same voltage. Electronic devices on both vehicles can be damaged when connected to a vehicle with a different operating voltage.

1. Apply the parking brakes and turn off all lights and other electrical devices. Ensure that the vehicles are not touching and both ignition switches are turned to the OFF position.

IMPORTANT: Do not attempt to jump start a damaged battery.

2. Remove the battery box cover. See **Fig. 1** for the standard battery compartment location.

NOTICE

Always connect the batteries and jumper cables correctly (positive-to-positive and negative-to-negative). Connecting a charging device backwards (positive-to-negative) can severely damage the vehicle electrical content and cause non-warrantable failures.

IMPORTANT: On vehicles equipped with optional jump start posts, connect to these posts instead of the battery terminals. Jump start

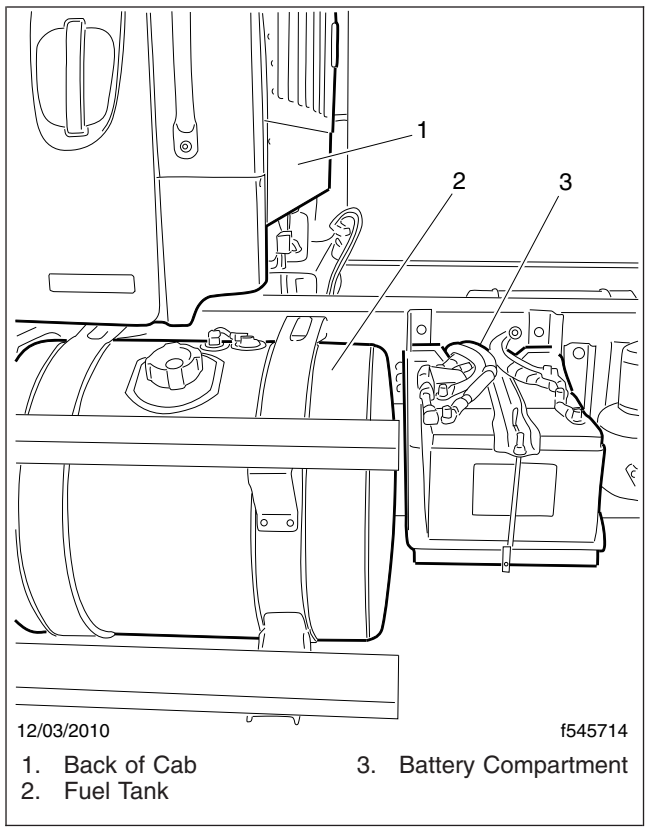

Fig. 1, Standard Battery Compartment Location

posts may be installed in various locations on the vehicle. See **Fig. 2**.

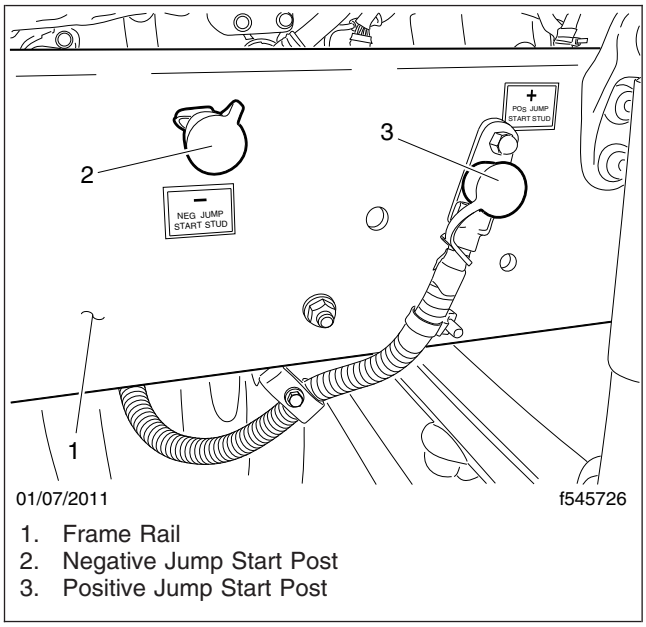
3. Connect the positive (+) jumper cable to the positive terminal or jump start post on the discharged battery. See **Fig. 3**.
4. Connect the other end of the positive jumper cable to the positive terminal or jump start post on the booster battery providing the charge.

WARNING

Do the next step exactly as instructed and do not allow the clamps of one cable to touch the clamps of the other cable. Otherwise, a spark could occur near a battery, possibly resulting in severe personal injury from explosion and acid burns.

5. Connect the negative (-) jumper cable to the negative terminal or jump start post on the booster battery.

Emergency Starting Using Booster Cables



1. Frame Rail
2. Negative Jump Start Post
3. Positive Jump Start Post

Fig. 2, Possible Jump Start Post Location (passenger-side engine compartment)

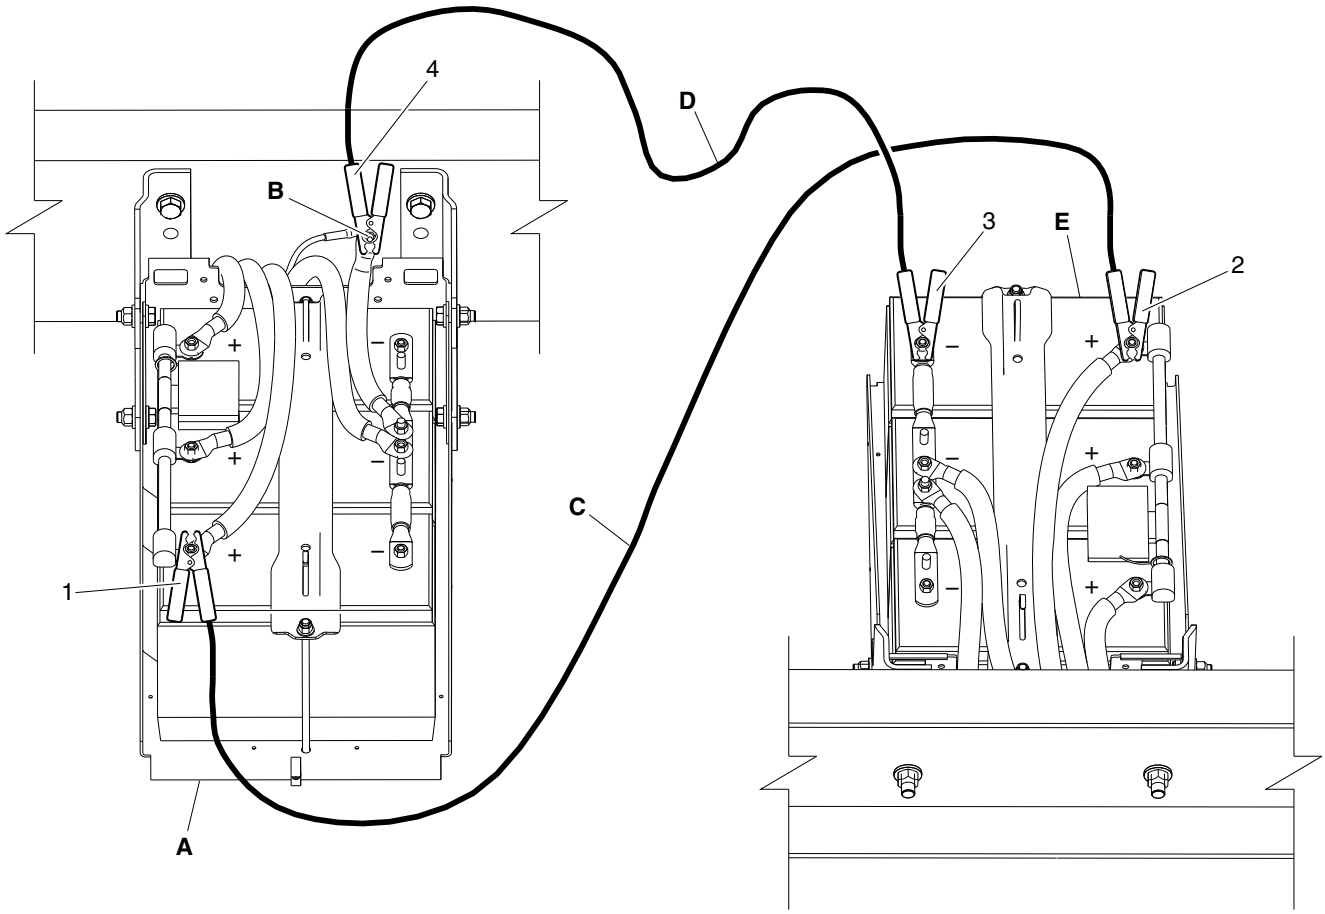
6. Connect the other end of the negative jumper cable to the negative ground stud on the vehicle requiring the jump start.
7. Start the engine of the vehicle providing the jump start and let the engine run a few minutes to charge the batteries of the other vehicle.
8. Attempt to start the engine of the vehicle receiving the jump. Do not operate the starter longer than 30 seconds, and wait at least two minutes between starting attempts to allow the starter to cool.
9. When the engine starts, let it idle a few minutes.

⚠ WARNING

Do the next step exactly as instructed and do not allow the clamps of one cable to touch the clamps of the other cable. Otherwise, a spark could occur near a battery, possibly resulting in severe personal injury from explosion and acid burns.

10. Disconnect the negative jumper cable from the negative cable stud on the jump-started vehicle.
11. Disconnect the negative jumper cable from the booster battery.
12. Disconnect the positive cable from the booster battery.
13. Disconnect the other end of the positive jumper cable from the jump-started vehicle.
14. Install the battery box cover; be sure it is positioned properly before fastening the latch.

Emergency Starting Using Booster Cables



Disconnect jumper cables in the REVERSE order that they were connected.

A. Discharged Battery
B. Negative Ground Stud
C. Positive Jumper Cable
D. Negative Jumper Cable
E. Booster Battery

1. 1st Connection: Positive Jumper Cable to Discharged Battery
2. 2nd Connection: Positive Jumper Cable to Booster Battery
3. 3rd Connection: Negative Jumper Cable to Booster Battery
4. 4th Connection: Negative Jumper Cable to Negative Ground Stud (discharged battery)

Fig. 3, Jumper Connections

⚠ WARNING

Before charging a battery, read the instructions in Subject 100. Failure to follow the safety precautions could result in personal injury.

When charging batteries, always wear eye protection. During charging, batteries give off explosive hydrogen gas. Exploding gas can cause blindness or other bodily injury.

Battery Charging

AGM batteries may be charged only with a charger that is specified for AGM batteries. Many older chargers operate at a voltage that is too high for AGM batteries and will cause permanent damage. Never combine AGM and flooded batteries together for charging or for use in a vehicle.

See **Table 1** for voltage to approximate battery state of charge for flooded batteries.

Voltage to Approximate Battery State of Charge for Flooded batteries		
Voltage		State of Charge
Flooded	AGM	
12.6	12.8	100%
12.4	12.6	75%
12.2	12.3	50%
12.0	12.0	25%
11.8	11.8	0%

Table 1, Voltage to Approximate Battery State of Charge for Flooded batteries

1. If the batteries are not installed in the vehicle, install the lead adapters on the battery positive and negative posts.
2. Connect the charger to the battery following the manufacturer's instructions. Slightly rock the charger's clamps to insure a complete connection.

IMPORTANT: If the battery feels hotter than 125°F (52°C) or if rapid gassing or spewing of electrolyte occurs, lower the charging rate or stop charging the battery and allow it to cool.

3. When finished, turn the charger off.

⚠ WARNING

Always turn the charger off before disconnecting it. Touching a charger lead when the circuit is live could create a spark and cause an explosion, resulting in personal injury.

Troubleshooting

If the batteries pass testing, check for the following causes:

1. Accessories were left on overnight.
2. A slipping alternator belt, high resistance in the wiring, or a defective alternator is causing the batteries to discharge.
3. The electrical loads are exceeding the charging system capacity.
4. Wires in the electrical system are shorted or pinched.
5. There are loose or damaged battery cable-to-terminal connections.
6. The batteries are still connected in a vehicle that has been out of service. Small current drains of accessories that are connected all the time can discharge the batteries in a few days. Batteries left in a discharged condition are subject to freezing.

Electrical Drain and Parasitic Load

Batteries are replenished each time the vehicle is driven with normal vehicle use. In long-term parking situations, however, parasitic drains may discharge the batteries enough to cause a no-start condition.

A parasitic drain is an electrical load that draws current from the batteries when the ignition remains off. Some devices, such as the electronic control unit (ECU), the bulkhead module (BHM), the chassis module (CHM), the antilock braking system (ABS), and radio memory are intended to draw a very small current continuously. These draws are measured in milliamps (mA). Current draw should be less than 325 milliamps with no circuits active and the ECU, BHM, CHM, and ABS turned off.

Problem—The Batteries Are Undercharged

Problem—The Batteries Are Undercharged	
Possible Cause	**Remedy**
The drive belt is loose.	Check the drive belt and tensioner. Refer to the drive belt subject in the appropriate engine section in **Group 01** for instructions. If necessary, tighten to the manufacturer's specifications. Start the engine and check the alternator voltage and output. Refer to the troubleshooting subject in the alternator section in **Group 15** for instructions.
The drive belt is damaged or missing.	Check the drive pulleys for locked bearings. Repair or replace any damaged components. Replace the drive belt and start the engine. Check the alternator voltage and output. Refer to the troubleshooting subject in the alternator section in **Group 15** for instructions.
The batteries are undercharged.	Perform a battery test. Charge or replace batteries as needed. If the batteries were discharged, start the engine and check the alternator voltage and output. Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.
The alternator or battery cables are undersized.	Perform a cable load drop test.
The alternator is malfunctioning.	Refer to the troubleshooting subject in the appropriate alternator section in **Group 15** for instructions.
The isolator relay is not operating correctly (optional battery isolator system only).	Refer to **Group 82, Subject 300** in this manual for instructions.

Battery Troubleshooting

1. **Check battery pack voltage to determine state of charge**.

   If equipped, set Load Disconnect Switch to "Off." With the DMM probes on the positive and negative posts of the battery pack, record the voltage. Due to differences in their design and operation, flooded cell and AGM batteries have different voltages at the same state of charge.

   Batteries should be fully charged before further testing. If batteries are not fully charged, they will draw current to recharge during testing, invalidating the troubleshooting test results. Fully charged batteries ensure reliable diagnosis.

   See **Table 1** for voltage as an approximate indicator of state of charge for AGM and flooded batteries.

   If the battery pack will not charge to 100% state of charge, there may be a shorted cell. Break the pack into individual batteries and test individually using an approved tester. Go to **Check 3, Individual Battery Testing**. After batteries have been tested individually, verify pack voltage once again.

Flooded	AGM	SoC
12.6	12.8	100%
12.4	12.6	80%
12.3	12.4	60%
12.1	12.2	40%
12	12	20%
11.8	11.8	0%

Table 1, Voltage to Approximate State of Charge (SoC)

2. **Remove surface charge: HVAC blower, lights on, 5 min.**

   Surface charge refers to a higher initial charge (volts), when discharging, in recently-charged batteries. This charge is a "shallow" charge, meaning that the charging-induced chemical reaction has mostly occurred at the surface of the lead plates, and has not equalized throughout the lead. Drawing current from the batteries before testing removes the surface charge, allowing for a better assessment of the "deep charge" state of the lead plates.

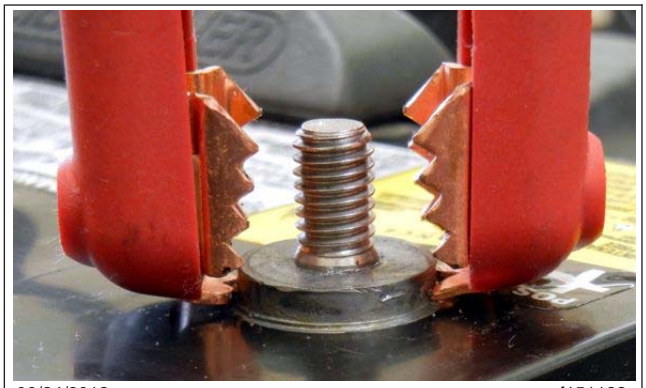
   After the surface charge is removed, the batteries need to be at least 80% SoC for further testing. See **Table 1** for voltage as an approximate indicator of state of charge.

3. **Test Individual Batteries**.

   IMPORTANT: Batteries should only be tested individually.

   3.1 Remove the negative cables of the batteries first, and secure the leads out of the way before touching the positive cables. Remove the battery cables and clean the terminal pads with a wire brush. The adapters will not make sufficient contact with dirty or corroded contact pads.

   3.2 Connect the battery tester's positive and negative clamps to the lead base terminal pads at the positive and negative studs. See **Fig. 1**.



06/24/2013 f151183

Fig. 1, Tester Clamps Attached to the Post

The threaded portion of the battery posts are *not* the right place to clip: the steel threads won't make a good connection. The base of the post, on the lead, is the best place to clip. Taking a few extra seconds to make sure the tester, DMM, and carbon pile clips are well-connected can be the difference between a useful and a useless test.

NOTE: If the lead base is too small to clamp to, only lead stud adapters should be used, never nuts. The lead stud adapters must be screwed down tight against the cleaned lead base using a

hand tool. Lead adapters are available at most tool vendors.

Refer to the battery tester instruction manual for complete testing instructions.

If the battery tester requires the CCA rating of the battery, it should be on the battery label. See **Fig. 2**.

3.3 If the battery fails, enter the battery serial number and print out the result. The sensor windows on the tester and printer must be aligned to transmit the test results to the printer.

Fig. 2, Battery Label

See **Table 1** for recharge times. Refer to the commercial batteries page at **www.dekabatteries.com** for more information.

Recharge Time Using a Typical Charger (hours)						
Open Circuit Voltage		State of Charge	Charger Maximum Rate			
Flooded	AGM		50 Amps	30 Amps	20 Amps	10 Amps
12.6V	12.8V	100%	Ready to Use			
12.4V	12.6V	75%	0.6	0.9	1.3	2.5
12.2V	12.3V	50%	1.2	1.9	2.7	5.1
12.0V	12.0V	25%	1.8	2.9	4.3	10.7
11.8V	11.8V	0%	2.5	4.0	5.7	10.7

Table 1, Recharge Time Using a Typical Charger

AM/FM Radio Antenna Replacement

Replacement

1. Loosen and remove the antenna mast from the antenna base with the proper size wrench. See **Fig. 1**.

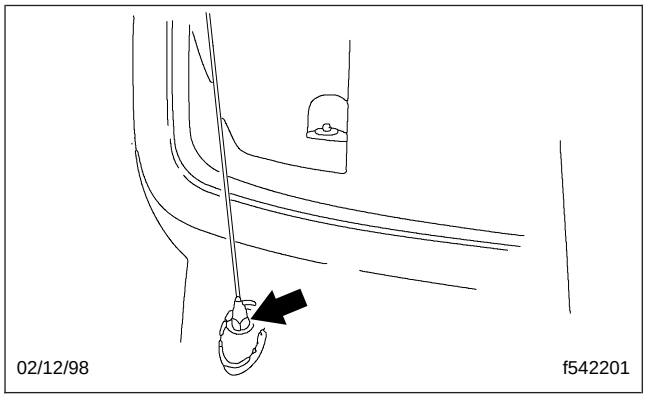


Fig. 1, Antenna Mast

2. Position the antenna mast into the antenna base and tighten with the proper wrench to specification; refer to **Specifications, 400** in this section.

AM/FM Radio Cable Replacement

Replacement

1. Remove the radio; refer to **Section 54.03** in this manual.
2. Loosen and remove the antenna mast from the antenna base with the proper size wrench. See **Fig. 1**.

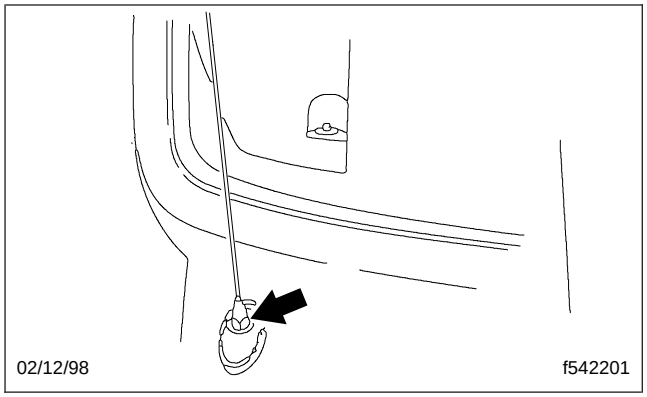

Fig. 1, Antenna Base Cap

3. Carefully pry the cap from the antenna base using both detents. See **Fig. 2**.

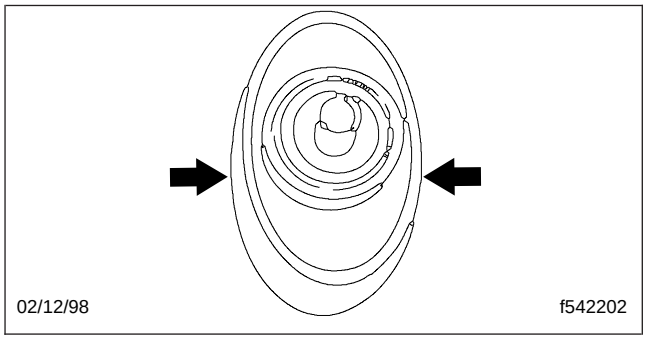

Fig. 2, Antenna Base Cap

4. Remove the antenna base retaining screws. See **Fig. 3**.
5. Raise the antenna base until the antenna lead-in cable is visible. See **Fig. 4**.
6. Pull the antenna base from the antenna lead-in cable. See **Fig. 5**.
7. Remove the screws retaining the fuse junction panel trim cover. See **Fig. 6**.
8. Disconnect the battery ground cable(s).

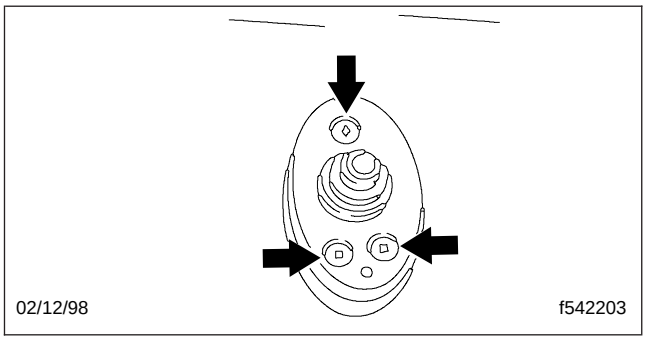

Fig. 3, Antenna Base Retaining Screws

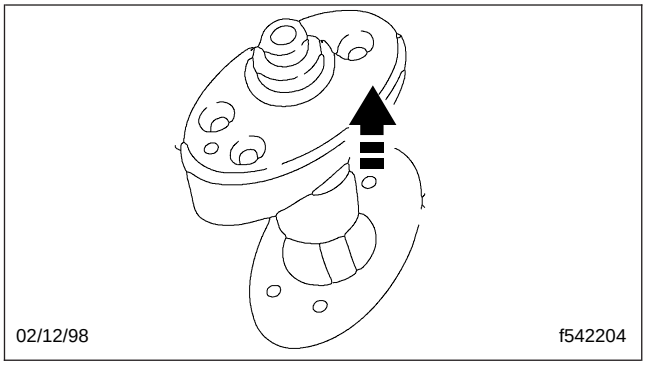

Fig. 4, Antenna Lead-In Cable

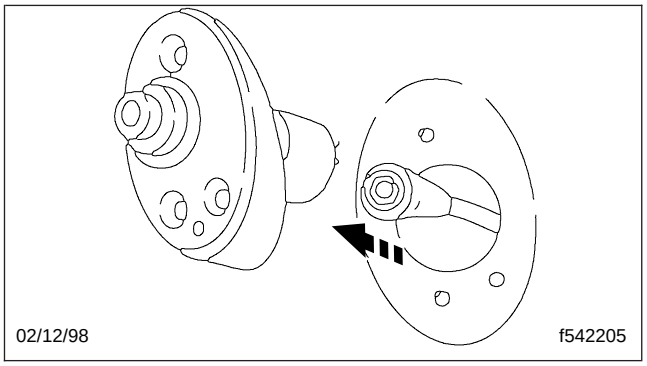

Fig. 5, Separating Antenna Base from the Antenna Lead-In Cable

9. Remove the fuse junction panel. See **Fig. 7**.
   - 9.1 Remove the fuse junction panel cover screws and remove the clear cover.
   - 9.2 Remove the fuse junction panel retaining screws.
10. Pull the fuse junction panel out of the seated position and support it. See **Fig. 8**.

AM/FM Radio Cable Replacement

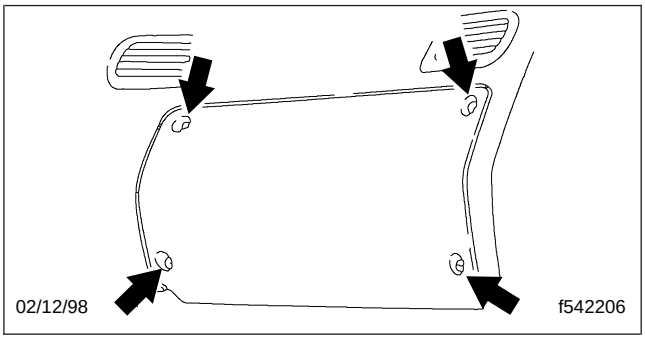

Fig. 6, Fuse Junction Panel Trim Cover Screws

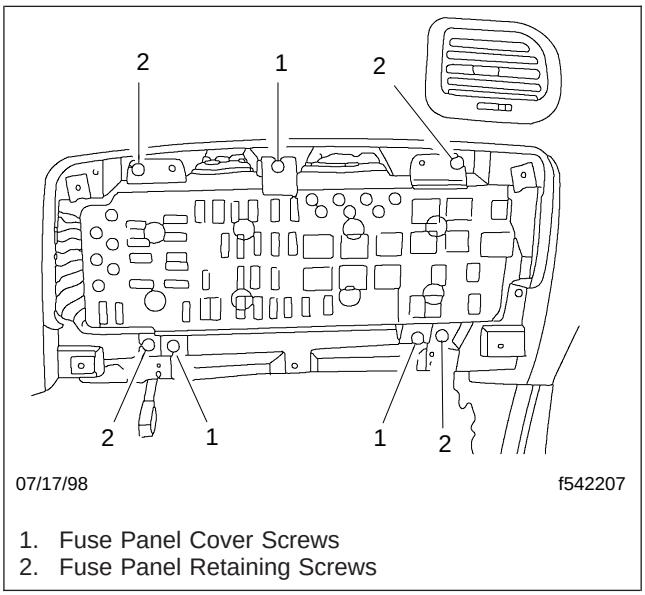

1. Fuse Panel Cover Screws
2. Fuse Panel Retaining Screws

Fig. 7, Instrument Panel Fuse Junction Panel

11. From the passenger seat, pull the antenna lead-in cable and grommet through the dash panel. See **Fig. 9**.
12. Pull the antenna lead-in cable through the back of the heater air plenum chamber, noting the current routing.
13. Route the antenna lead-in cable and grommet through the dash panel.
14. Install the fuse junction panel and retaining screws.
15. Install the fuse junction panel trim cover.
16. Connect the antenna base to the antenna lead-in cable.

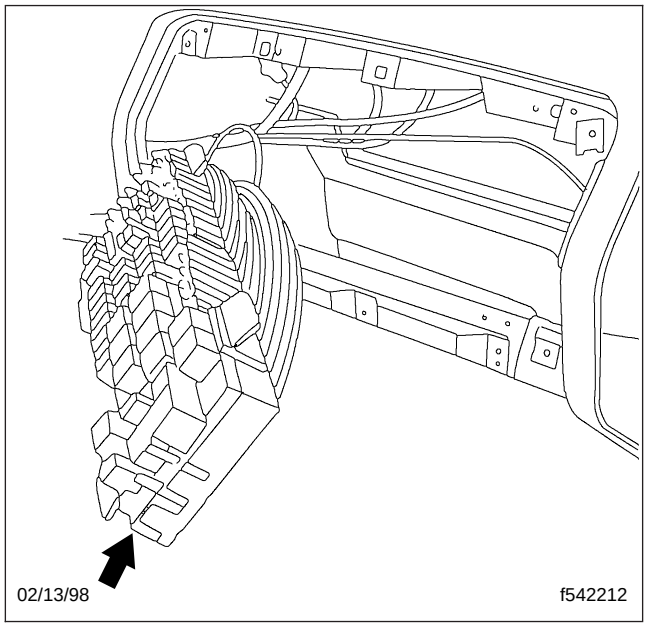

Fig. 8, Instrument Panel Fuse Junction Panel

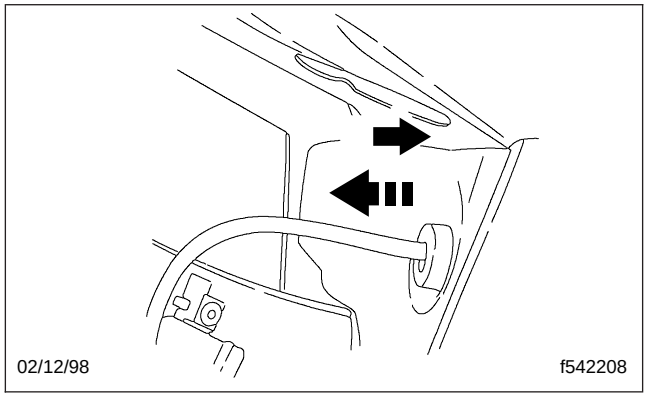

Fig. 9, Antenna Lead-In Cable and Grommet

17. Position the antenna base and install the retaining screws.
18. Install the antenna base cap.
19. Install the antenna mast.
20. Tighten the antenna mast to specification; refer to **Specifications, 400** in this section.
21. Install the radio; refer to **Section 54.03** in this manual.
22. Connect the battery ground cable(s).

CB Radio Antenna Replacement

Replacement

1. Loosen and remove the CB antenna mast from the antenna base with the proper size wrench. See **Fig. 1**.

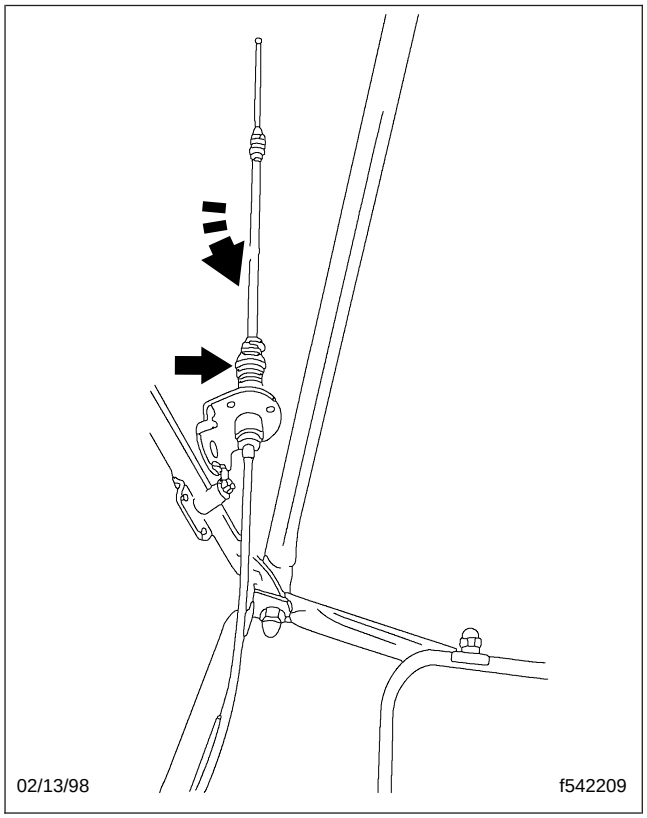

Fig. 1, CB Antenna Mast

2. Position the CB antenna mast into the CB antenna base and tighten until firm with the proper size wrench.

CB Radio Cable Removal and Installation

Removal

1. Remove the CB antenna cable from the antenna base. See **Fig. 1**.

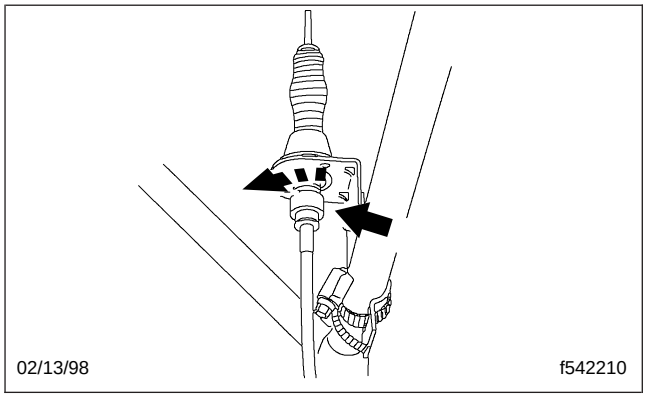

Fig. 1, CB Antenna

2. Cut the plastic ties retaining the CB antenna cable to the mirror bracket. See **Fig. 2**.
3. Remove the screws and the grab handle. See **Fig. 3**.
4. Pry the cover up from the door window handle, if so equipped. See **Fig. 4**.
5. Remove the screw and remove the door window handle, if so equipped. See **Fig. 5**.
6. Carefully pry the power mirror switch from the driver side door trim panel, if so equipped. See **Fig. 6**.
7. Press the electrical connector locking tab and separate the power mirror switch from the electrical harness, if so equipped.
8. Remove the screws and the door trim panel. See **Fig. 7**.
9. Tilt the door trim finish panel outward and disconnect the electrical connectors, if so equipped. See **Fig. 8**.
10. Remove the CB antenna cable from the plastic retainer. See **Fig. 9**.
11. Disconnect the inner door CB antenna cable connector. See **Fig. 10**.
12. Pull out the outer door grommet and remove the CB antenna cable. See **Fig. 11**.
13. Pull the door-to-A-pillar grommet from the seated position. See **Fig. 12**.

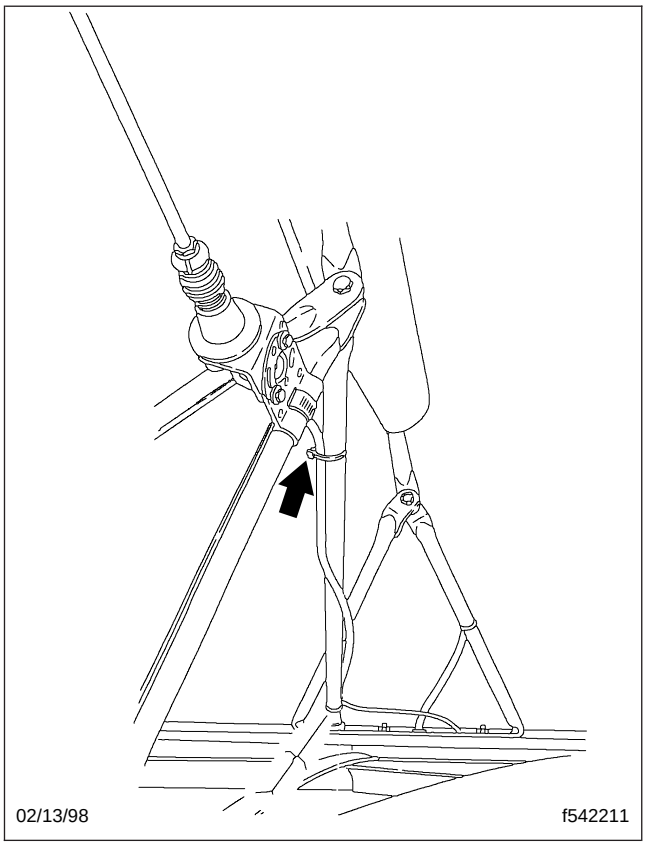

Fig. 2, Plastic Ties

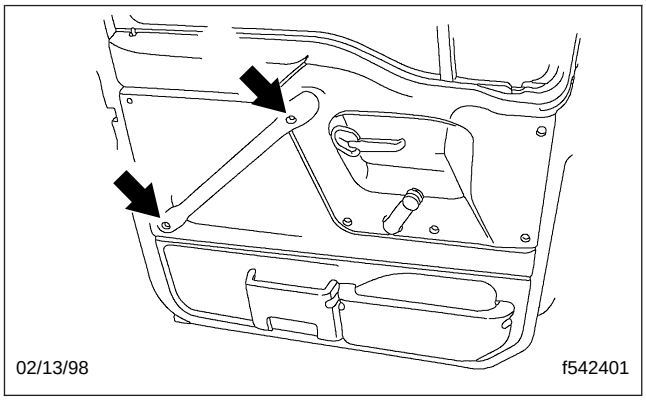

Fig. 3, Grab Handle

14. Pull the wire harness from the door until the CB antenna cable is exposed.
15. Remove the tape on the A-pillar side of the grommet and wiring. See **Fig. 13**.

CB Radio Cable Removal and Installation

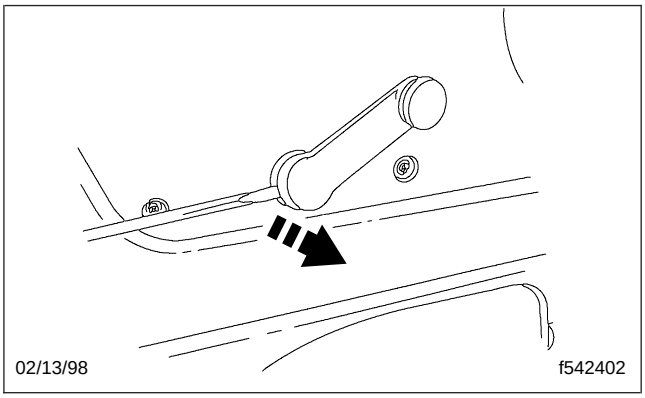

Fig. 4, Door Window Handle Cover

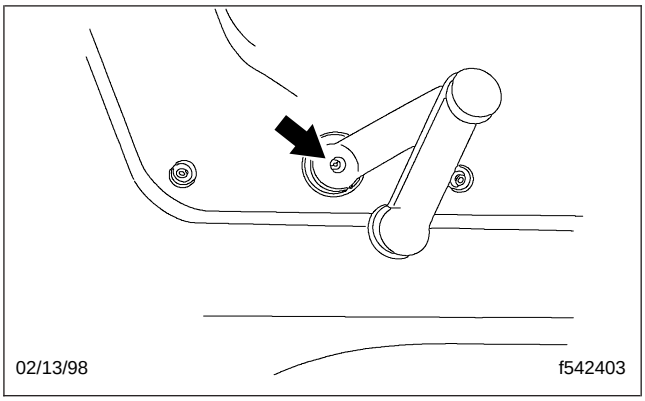

Fig. 5, Door Window Handle

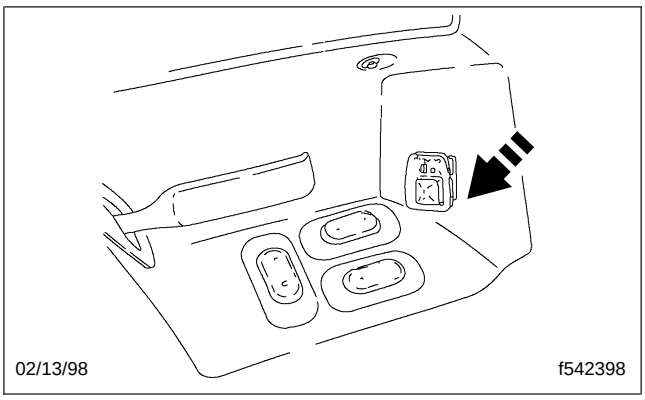

Fig. 6, Power Mirror Switch

⚠ CAUTION

Use extreme care while cutting the tape on the wire harness to prevent cutting into a wire.

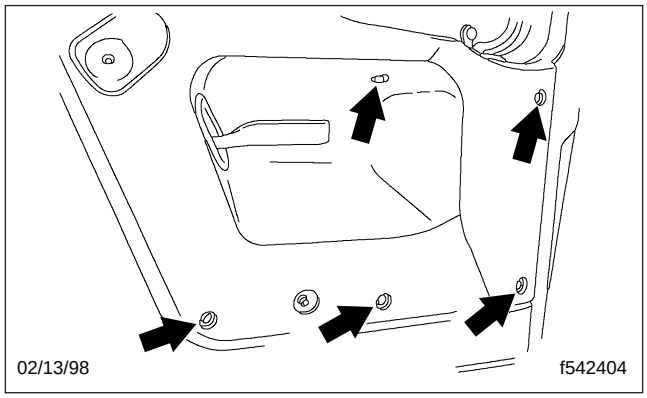

Fig. 7, Door Trim Panel

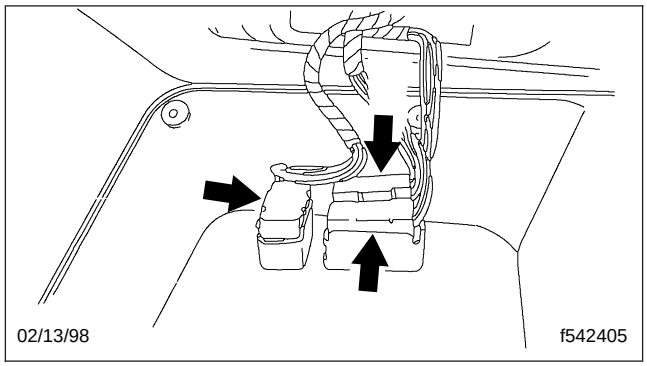

Fig. 8, Door Trim Finish Panel

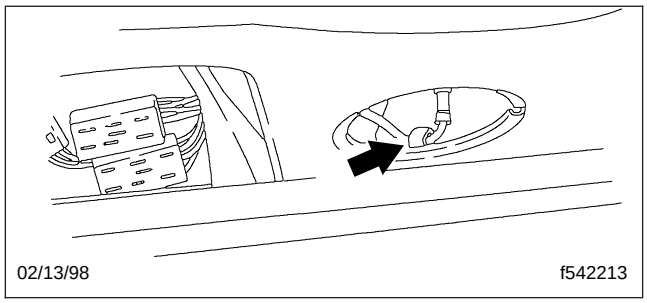

Fig. 9, CB Antenna Cable

NOTE: The door-to-A-pillar grommet must be compressed in order to cut the tape on the wire harness along the length that retains the CB antenna cable.

16. Carefully cut the tape retaining the CB antenna cable to the wire harness. See **Fig. 14**.
17. Remove the scuff panel. See **Fig. 15**.
18. Disconnect the inner cab CB antenna cable connector. See **Fig. 16**.

CB Radio Cable Removal and Installation

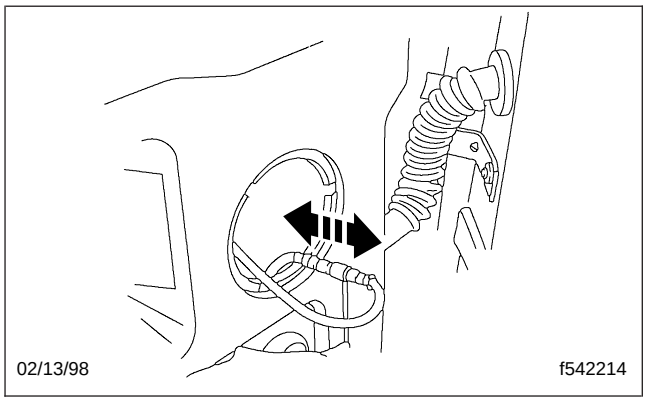

Fig. 10, CB Antenna Cable Connector

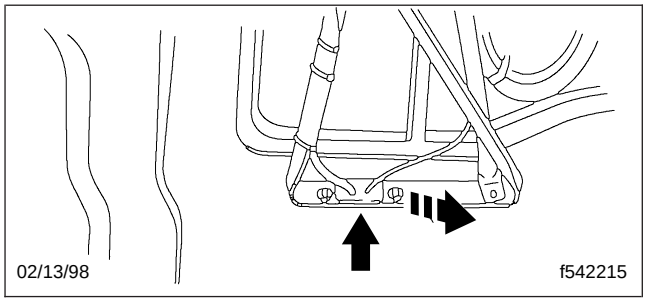

Fig. 11, Outer Door Grommet

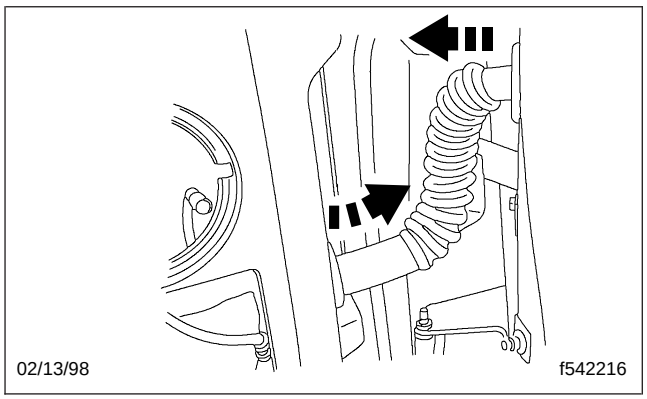

Fig. 12, Door-to-A-Pillar Grommet

19. Pull the CB antenna cable out from the inner cab.

Installation

1. Install the inner cab CB antenna cable through the cab and through the door-to-A-pillar grommet.

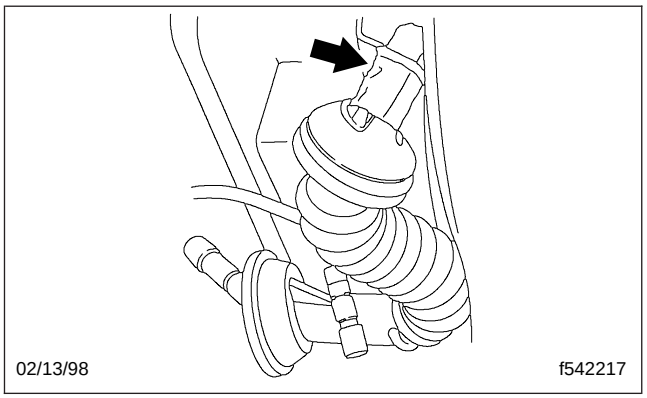

Fig. 13, Grommet and Wiring Tape

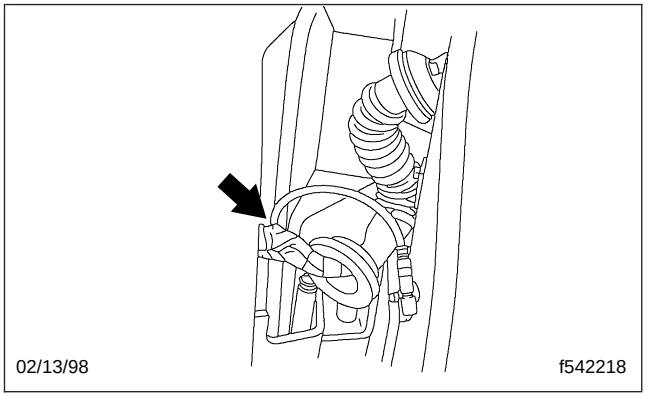

Fig. 14, Retaining Tape

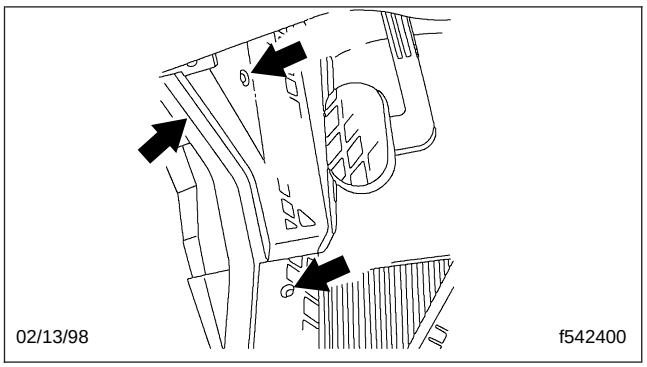

Fig. 15, Scuff Panel

2. Connect the inner cab CB antenna cable connector.
3. Install the scuff panel. See **Fig. 15**.

NOTE: The door-to-A-pillar grommet must be compressed in order to tape the CB antenna cable to the wire harness.

CB Radio Cable Removal and Installation

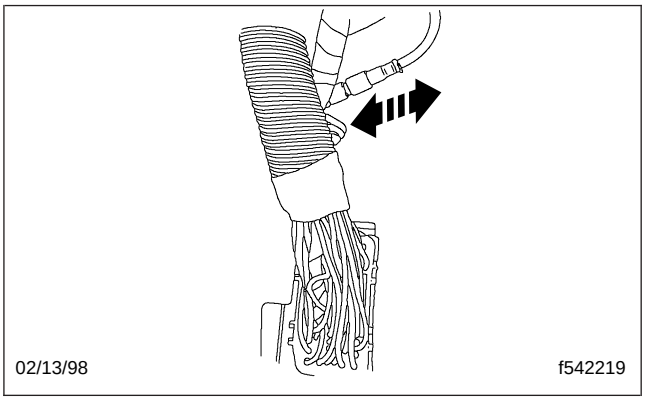

Fig. 16, Inner Cab CB Antenna Cable Connector

4. Tape the CB antenna cable to the wiring harness. See **Fig. 17**.

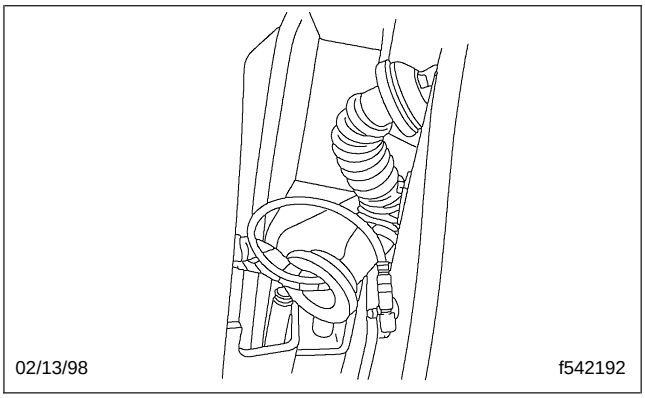

Fig. 17, Retaining Tape

5. Tape the A-pillar side of the grommet to the wiring. See **Fig. 19**.

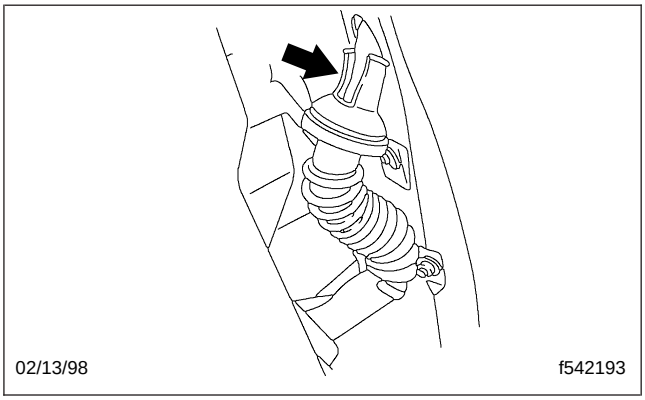

Fig. 18, A-Pillar Side Grommet

6. Install the wire harness into the door and push the door-to-A-pillar grommet into the seated position. See **Fig. 19**.

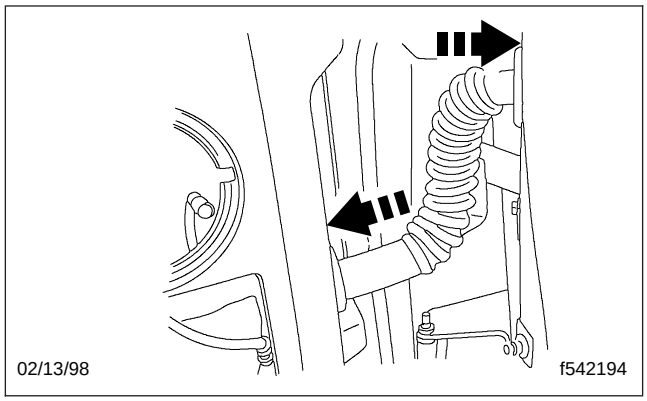

Fig. 19, Door-to-A-Pillar Grommet

7. Install the inner door CB antenna cable and install the outer door grommet. See **Fig. 20**.

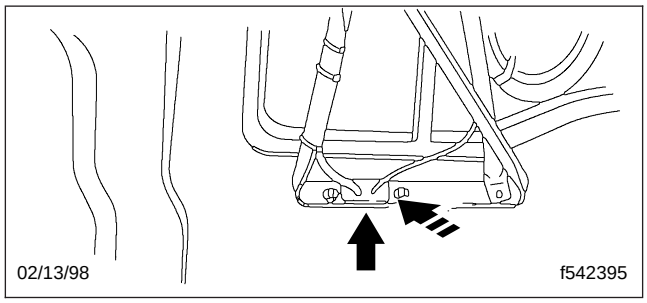

Fig. 20, Inner Door CB Antenna Cable

8. Connect the inner door CB antenna cable connector. See **Fig. 21**.

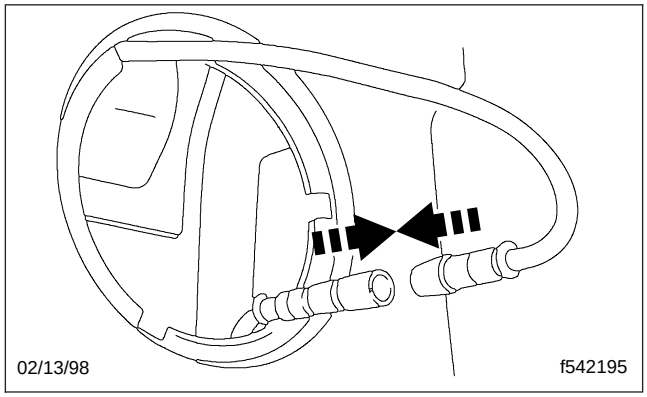

Fig. 21, Inner Door CB Antenna Cable Connector

CB Radio Cable Removal and Installation

9. Install the CB antenna cable to the plastic retainer. See **Fig. 9**.
10. Install the electrical connectors, if so equipped. See **Fig. 8**.
11. Install the door trim panel and the screws. See **Fig. 7**.
12. Install the power mirror switch to the electrical harness, if so equipped.
13. Push the power mirror switch into the driver side door trim panel, if so equipped. See **Fig. 22**.

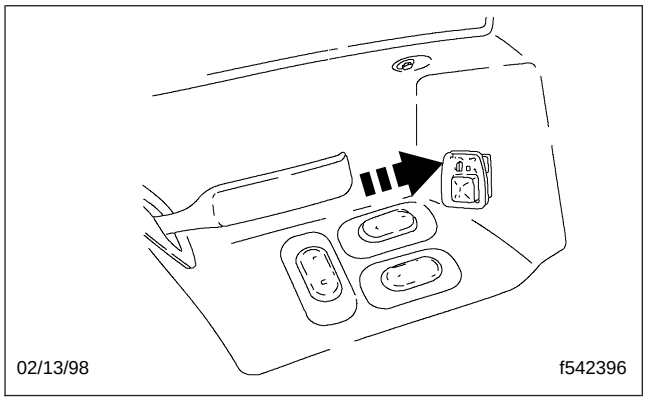

Fig. 22, Power Mirror Switch

14. Install the door window handle, screw, and door window handle cover, if so equipped. See **Fig. 5**.
15. Install the grab handle and the screws. See **Fig. 3**.
16. Install the plastic ties to the mirror bracket. See **Fig. 2**.
17. Install the CB antenna cable to the antenna base. See **Fig. 23**.

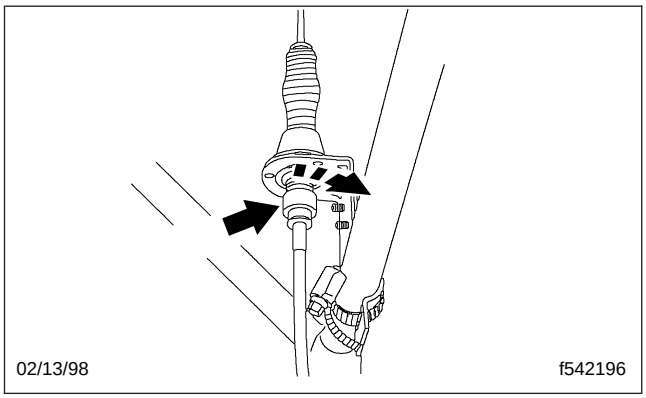

Fig. 23, CB Antenna Cable-to-Base

Specifications

Torque Specifications	
Description	**lbf·in (N·cm)**
Antenna Mast	9 (100)

Table 1, Torque Specifications

Replacement

1. Remove the radio speaker enclosure mounting screws, and remove the enclosure. See **Fig. 1**.

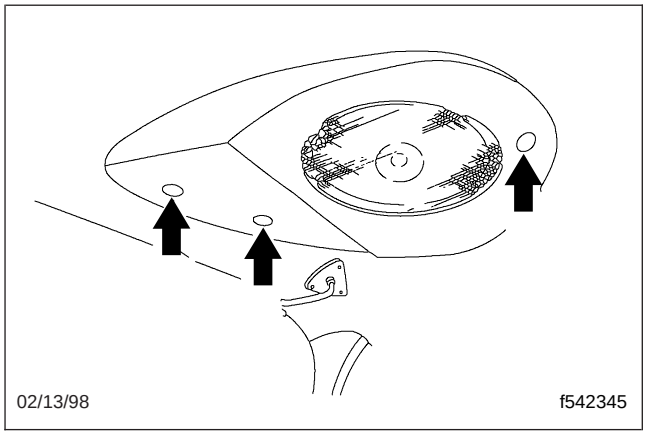

Fig. 1, Front Speaker Enclosure Mounting Screws

2. Support the speaker, and remove the retaining bolts. See **Fig. 2**.

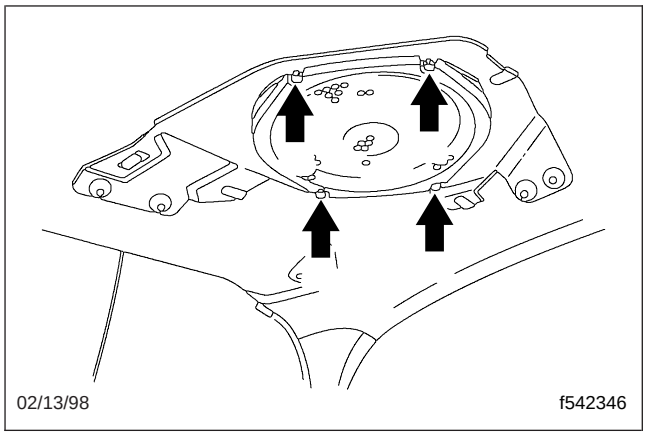

Fig. 2, Front Speaker Retaining Bolts

3. Disconnect the electrical connector, and remove the speaker from the roof. See **Fig. 3**.
4. Connect the electrical connector, and position the speaker over the bolt holes.
5. Install the speaker retaining bolts and tighten them until firm.
6. Install the front speaker enclosure and mounting screws.

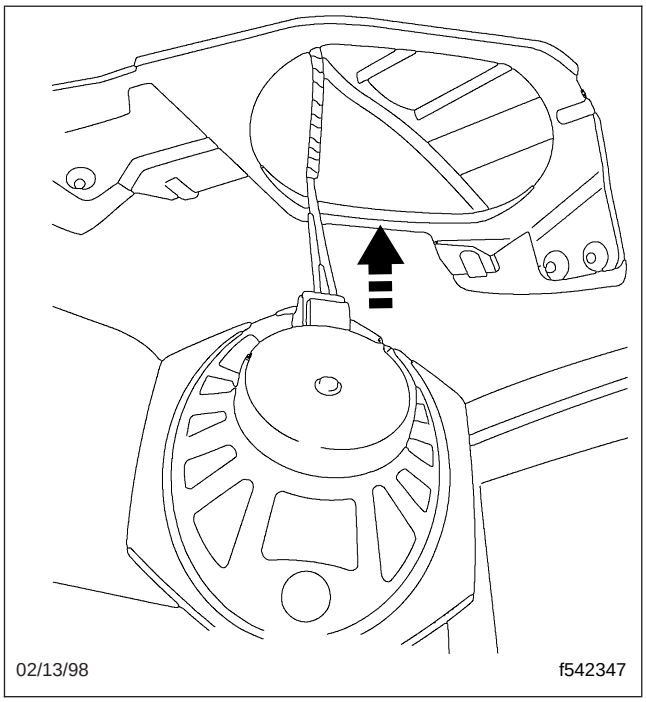

Fig. 3, Disconnecting the Front Speaker Electrical Connector

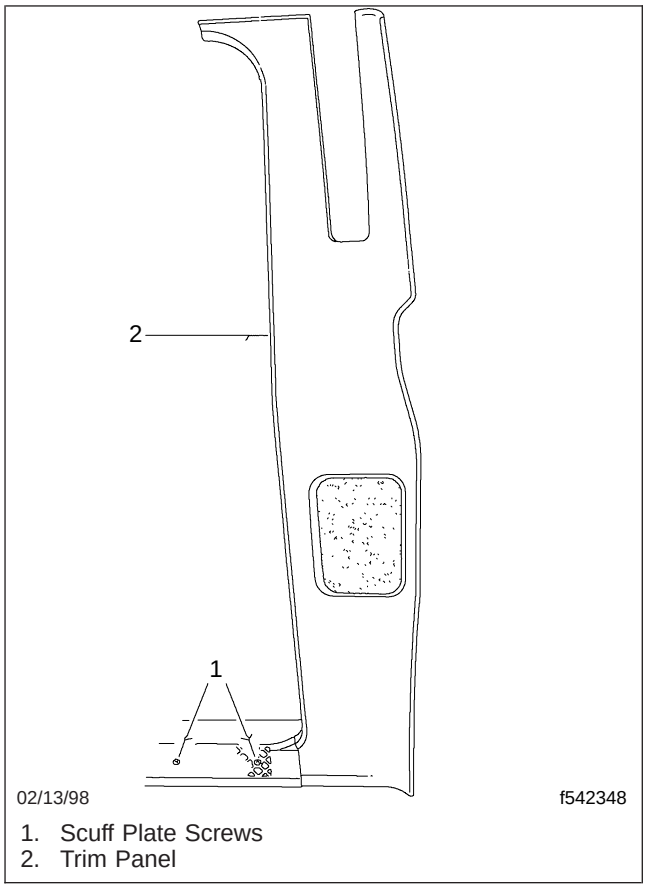
Replacement

1. Remove the B-pillar trim panel. See **Fig. 1**.



1. Scuff Plate Screws
2. Trim Panel

Fig. 1, B-Pillar Trim Panel Removal

1.1 Remove the two scuff plate screws next to the B-pillar.

1.2 Pull outward to disengage the trim panel locators, and slide the panel out through the front of the vehicle.

2. Support the speaker, and remove the retaining bolts. See **Fig. 2**.

3. Disconnect the electrical connector, and remove the speaker from the B-pillar. See **Fig. 3**.

NOTE: It may be necessary to partially remove the weatherstripping in order to install the B-pillar trim panel.

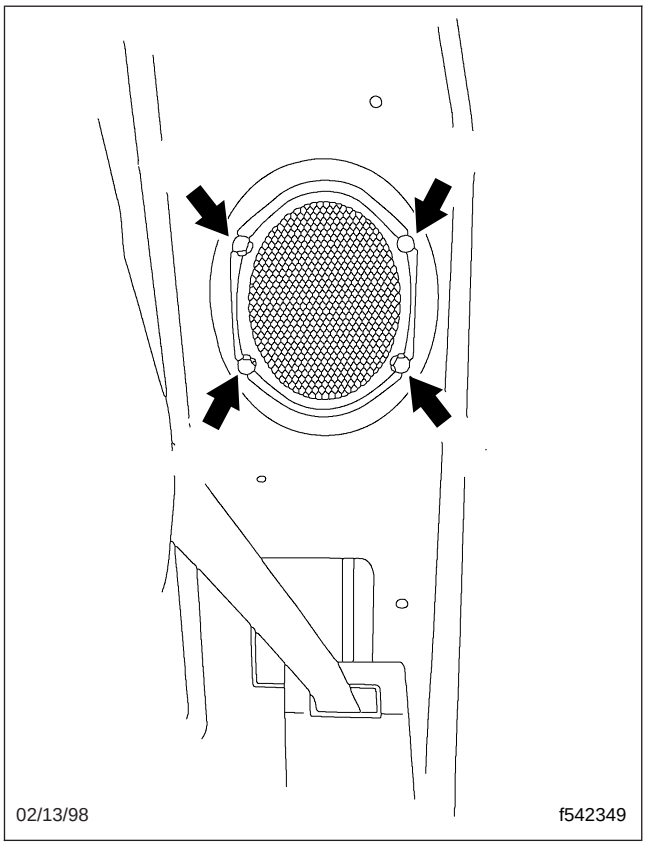


Fig. 2, Rear Speaker Retaining Bolts

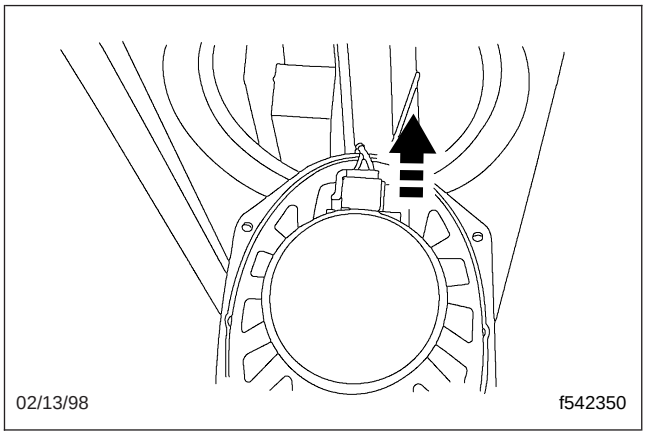

Fig. 3, Rear Speaker Electrical Connector

4. Connect the electrical connector, and position the speaker over the bolt holes.

5. Install the speaker retaining bolts and tighten them until firm.

Rear Speaker Replacement

6. Install the B-pillar trim panel.
   - 6.1 Position the B-pillar trim panel and install the trim panel locators.
   - 6.2 Install the two scuff plate screws as removed, and tighten until firm.

Roof Console Speaker Replacement

Replacement

1. Remove the roof console; for instructions, see **Group 60**.
2. Support the speaker, and remove the retaining bolts. See **Fig. 1**.

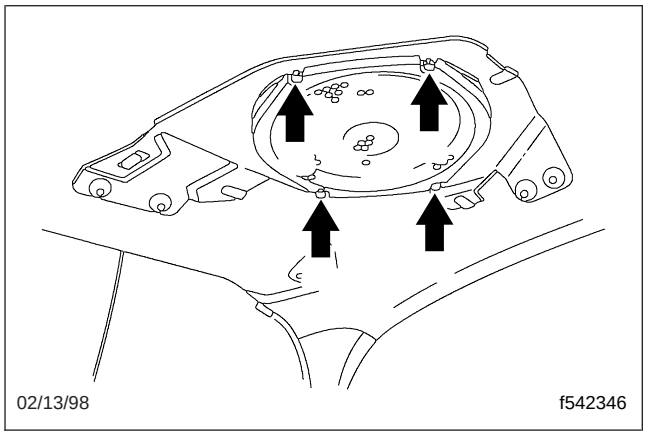

Fig. 1, Removing the Roof Console Speaker Retaining Bolts

3. Disconnect the electrical connector, and remove the speaker from the roof console. See **Fig. 2**
4. Connect the electrical connector, and position the speaker over the bolt holes.
5. Install the speaker retaining bolts, and tighten until firm.
6. Install the roof console; for instructions, see **Group 60**.

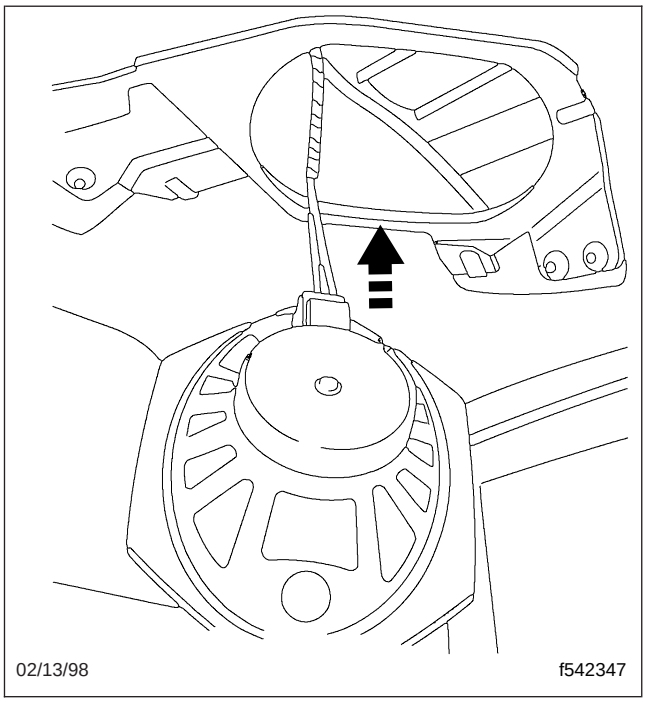

Fig. 2, Disconnecting the Roof Console Speaker Electrical Connector

Able Body Sleeper Speaker Replacement

Replacement

1. Carefully pry the speaker grille from the speaker. See **Fig. 1**.

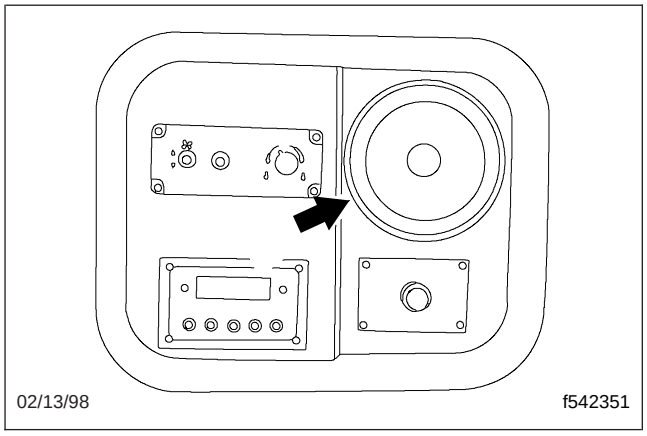

Fig. 1, Able Body Speaker Grille

2. Remove the speaker mounting screws, and support the speaker.
3. Disconnect the electrical connector, and remove the speaker from the sleeper radio control panel. See **Fig. 2**.

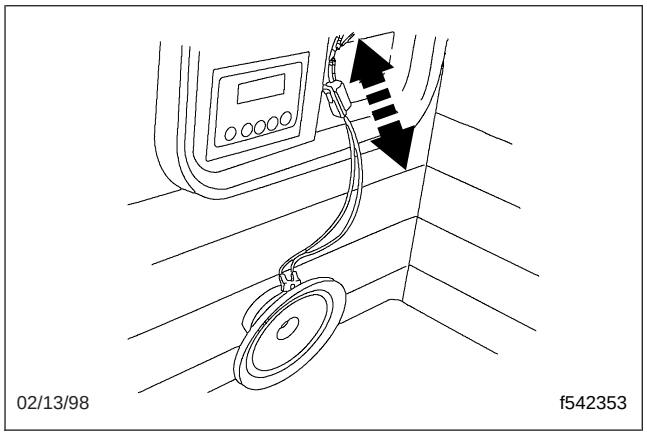

Fig. 2, Able Body Speaker Electrical Connector

4. Connect the electrical connector.
5. Install the speaker.
   - 5.1 Position the speaker over the screw holes.
   - 5.2 Install the speaker mounting screws and tighten until firm.
6. Install the speaker grille.

SilverStar Rear/Top Speaker Replacement

Replacement

NOTE: Left-hand shown, right-hand symmetrically opposite.

1. Remove the headliner. For instructions, see **Group 60**.
2. Remove the screws. See **Fig. 1.**

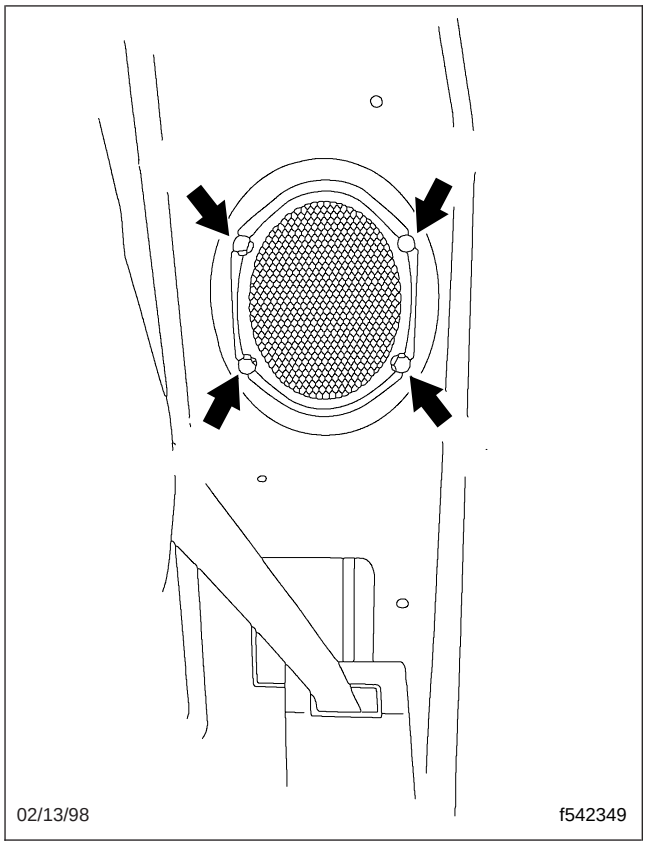

Fig. 1, SilverStar Speaker Screws

3. Disconnect the electrical connector, and remove the speaker from the roof. See **Fig. 2.**
4. Connect the electrical connector.
5. Install the speaker.
   - 5.1 Position the speaker over the screw holes.
   - 5.2 Install the speaker mounting screws and tighten until firm.
6. Install the speaker grille.

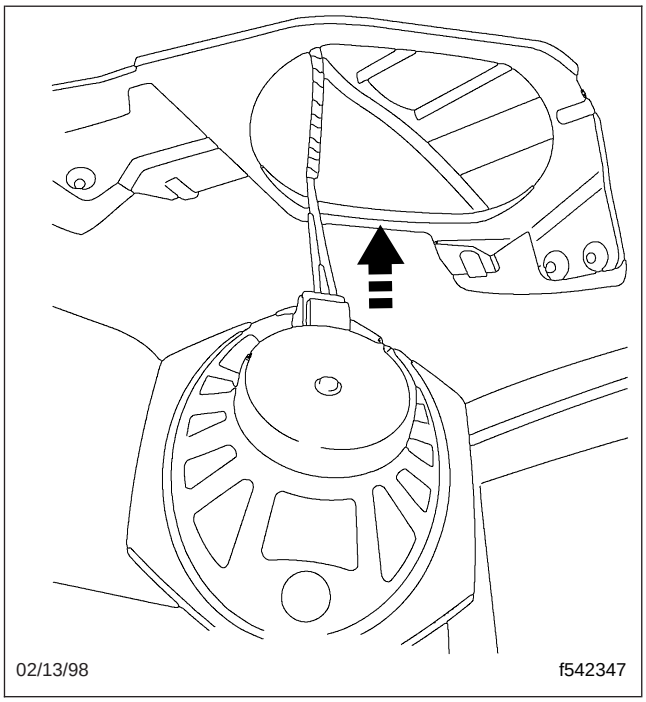

Fig. 2, SilverStar Speaker Electrical Connector

7. Install the headliner. For instructions, see **Group 60**.

SilverStar Subwoofer Speaker Replacement

Replacement

1. Raise the lower bunk assembly.
2. Remove the subwoofer assembly screws.

NOTE: Screws are on the sides of the subwoofer assembly.

3. Tilt the subwoofer assembly back, then remove the subwoofer speaker screws. See **Fig. 1**.

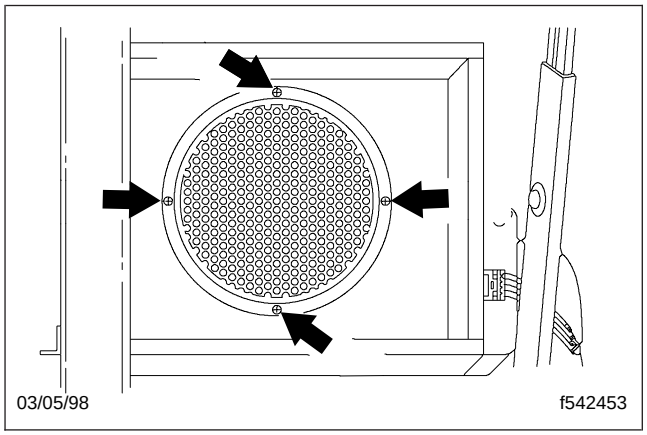

Fig. 1, SilverStar Subwoofer Speaker Screws

4. Disconnect the electrical connector, then remove the subwoofer speaker from the subwoofer assembly. See **Fig. 2**.

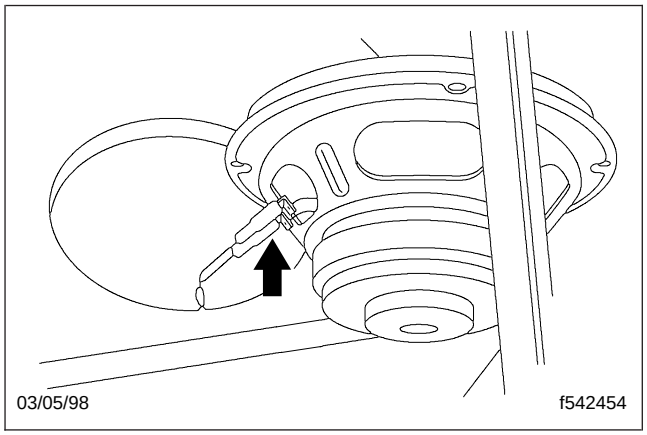

Fig. 2, Subwoofer Electrical Connector

5. Connect the subwoofer electrical connector and position the subwoofer speaker inside the subwoofer assembly.
6. Install the subwoofer speaker screws and tighten until firm.
7. Position the subwoofer assembly.
8. Install the subwoofer assembly screws and tighten until firm.
9. Lower the lower bunk assembly.

General Information

Sterling vehicles have a 12-volt, negative ground electrical system. See **Specifications 400** for a list of standard circuit numbers and circuit descriptions for vehicles built beginning February 27, 2001.

Fuses and Circuit Breakers

Sterling vehicles use blade-type fuses that have a transparent plastic housing enclosing the metal fuse element. A fuse is designed to melt the metal element at a certain amperage to protect the circuit wiring and components from damage due to an overcurrent condition. The ampere rating of a fuse can be determined by reading the number molded into the top end of the fuse or by color. See **Specifications 400** for the fuse amperage rating and color for that amperage rating.

Wire Color Code

Colored wiring aids in the diagnosis and testing of electrical systems. It allows for faster identification when testing circuits for failure. See **Specifications 400** for a list of standard wiring color-coding information for vehicles built beginning February 27, 2001.

In-Line Protection Devices

In addition to the fuses in the fuse junction panel and the power distribution module (PDM), there may be in-line fuses in the wiring harnesses. The fuses are located in the battery cable wiring assembly and provide power to the PDM fuses for the electrical, audio, and gauges in the cab. Two 10-gauge fuse links may be used on Sterling vehicles built before February 27, 2001: one is located between the starter motor battery terminal, the other is in the alternator wiring circuit protection.

Fusible Links

Fusible links are short lengths of wire that are smaller than the wires they are protecting. Fusible link wire is covered with a special, thick, non-flammable insulation. An overcurrent condition causes the insulation to blister and, if the overcurrent condition continues, the wire link will melt. To check a fusible link, look for blistered insulation. If the insulation is okay, pull lightly on the wire. If the fusible link insulation stretches, the wire has melted.

Shielded Wires

Shielding is necessary when a critical circuit is susceptible to electromagnetic interference. Shielded wire has three conducting strands. The outermost strand is grounded, which creates a ground plane around the two inner conductors. Any interference that enters the shielded cable will be conducted to ground instead of affecting the circuit's signal.

Engine, Cab, and Trailer Wiring

Sterling vehicles have two PDMs, one in the engine compartment and one in the cab. Both contain fuses, circuit breakers and relays used in the electrical system.

Engine Wiring

The engine compartment PDM has a decal identifying the location of the fuses, circuit breakers and relays on the outside of the PDM cover. See **Fig. 1** for right-hand-drive vehicles, **Fig. 2** for left-hand-drive vehicles built before February 27, 2001, or **Fig. 3** for left-hand-drive vehicles built since February 27, 2001 but prior to September 12, 2003. Depending on vehicle options, fuse/circuit breaker/relay locations may vary from those shown. For fuse/circuit breaker/relay identification information, see **Table 1** for right-hand-drive vehicles, **Table 2** for left-hand-drive vehicles built before February 27, 2001, or **Table 3** for left-hand-drive vehicles built since February 27, 2001 but prior to September 12, 2003.

Cab Wiring

The cab PDM is located on the passenger side within the instrument panel. See **Fig. 4** for right-hand-drive vehicles, **Fig. 5** for left-hand-drive vehicles built before February 27, 2001, or **Fig. 6** for left-hand-drive vehicles built since February 27, 2001 but prior to September 12, 2003. A trim panel covers the PDM and is attached to the instrument panel by quarter-turn fasteners. A decal identifying the location of the fuses, circuit breakers, and relays is attached to the back side of the trim panel. For fuse/circuit breaker/relay identification information, see **Table 4** for right-hand-drive vehicles, **Table 5** for left-hand-drive vehicles built before February 27, 2001, or **Table 6** for left-hand-drive vehicles built since February 27, 2001 but prior to September 12, 2003.

Trailer Wiring

The trailer wiring harness supplies power to the seven-pin trailer electrical supply socket located on the rear of the cab. See **Fig. 7**.

General Information

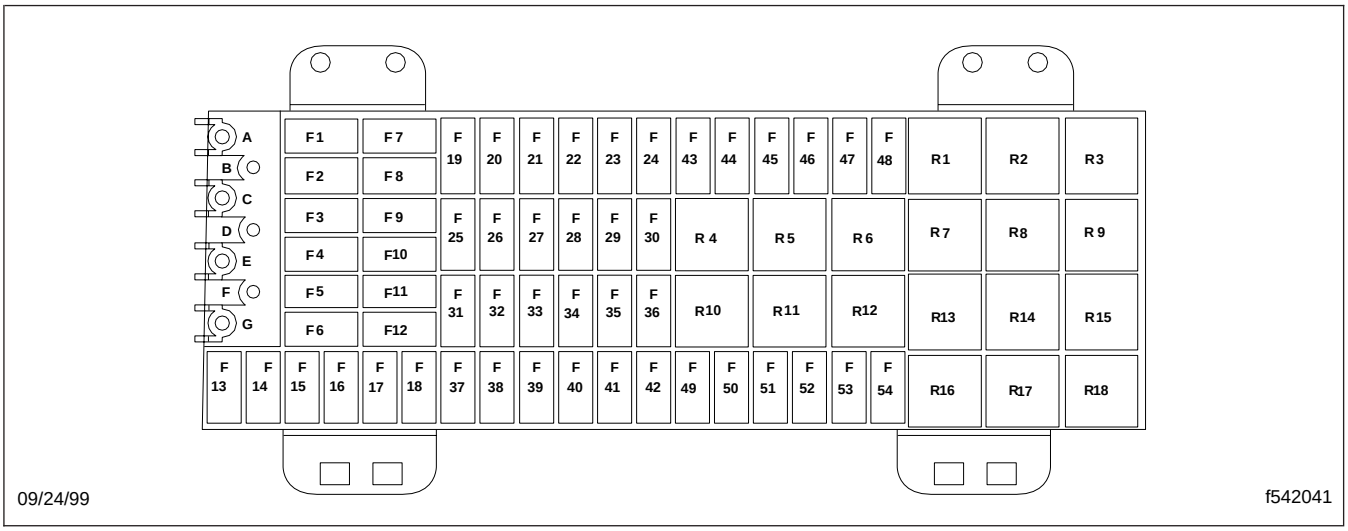

Fig. 4, Cab PDM, Right-Hand-Drive Vehicles

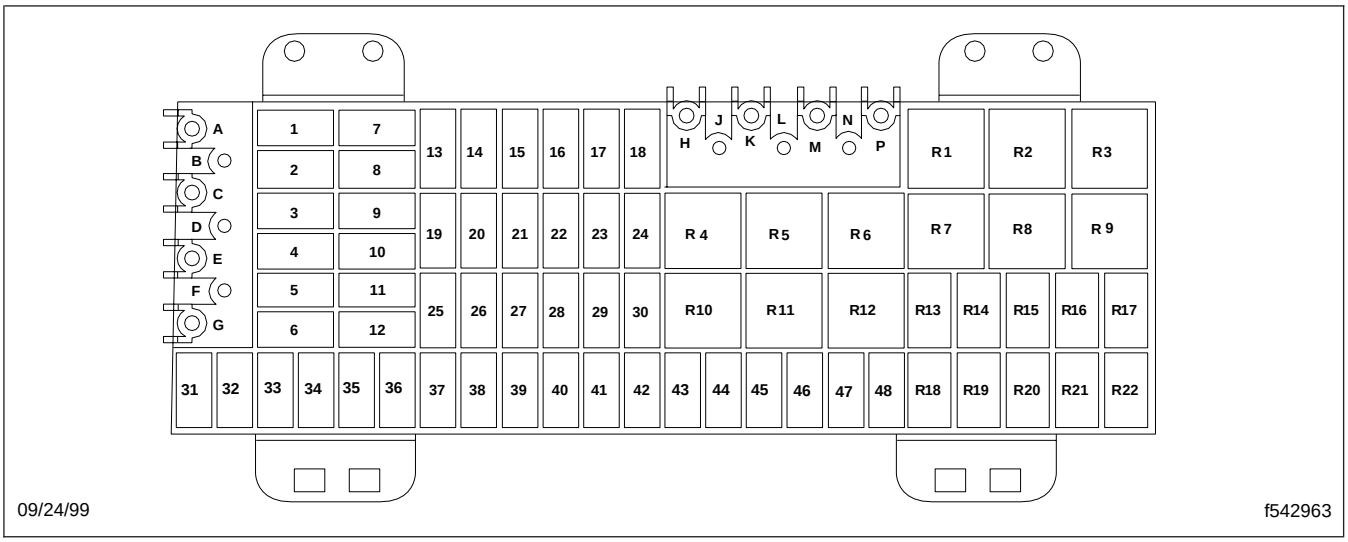

Fig. 5, Cab PDM, Left-Hand-Drive Vehicles (typical, for vehicles built before February 27, 2001)

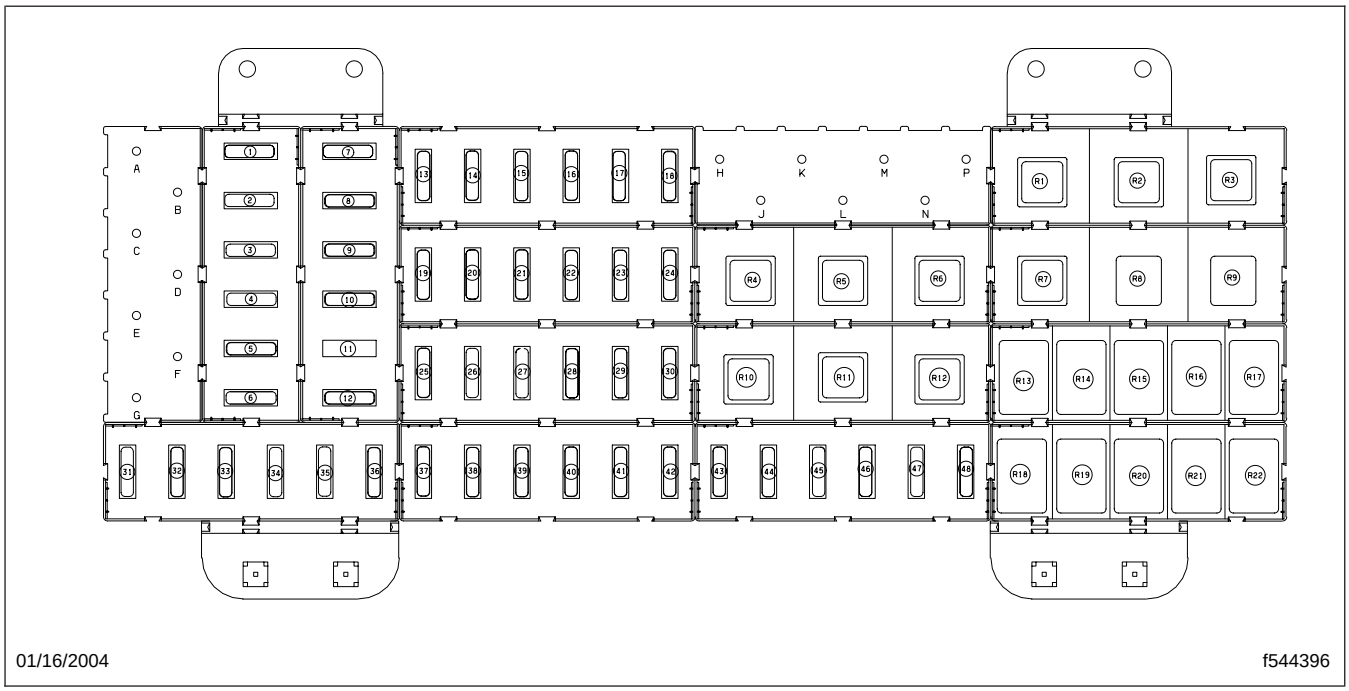

Fig. 6, Cab PDM, Left-Hand-Drive Vehicles (typical, for vehicles built since February 27, 2001 but prior to September 12, 2003)

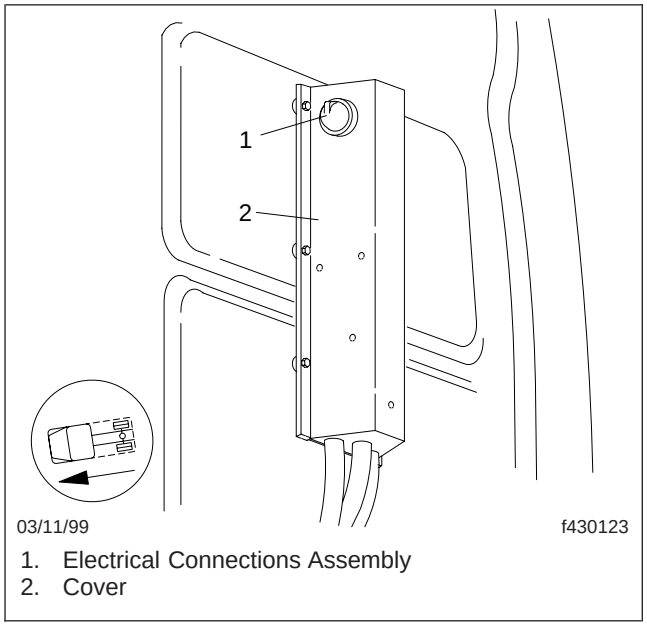


1. Electrical Connections Assembly
2. Cover

Fig. 7, Trailer Electrical Connections Socket Location

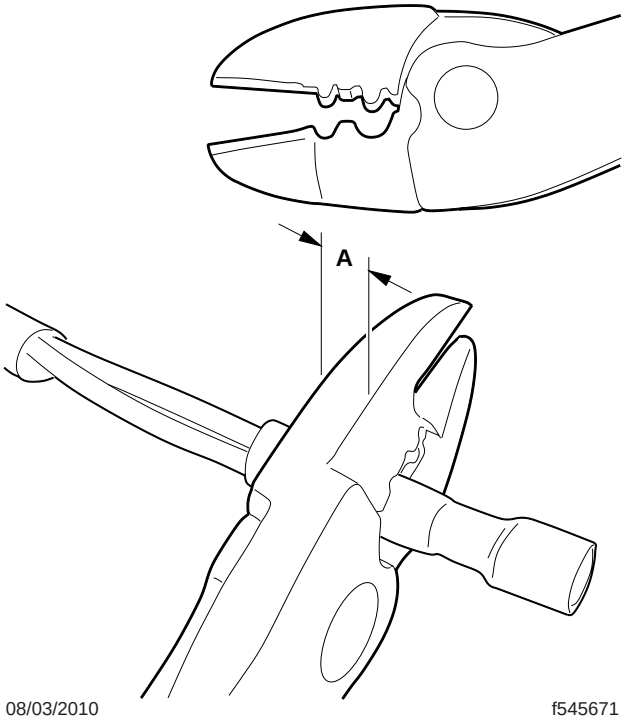
Wiring Repair Using Phillips STA-DRY® Solderless Connectors

Parts and Tools

Parts are available through the Parts Distribution Centers (PDCs) in packages of 25 connectors. Use the connectors and adhesive lined shrinkable tubing shown in **Table 1** when making a wiring splice.

Tools needed for wiring repair using solderless connectors include the following.

- A dimple-type crimp tool with a minimum 3/16-inch (7.6-cm) width. See **Fig. 1** for an example of a proper crimp tool. A typical manufacturer for this tool is Thomas & Betts.
- A heat gun rated at 1000°F (538°C).



A. Minimum 3/16-inch (7.6-cm) width.

Fig. 1, Dimple-Type Crimp Tool

Procedure

1. Dress the wires to be spliced by stripping the insulation to expose 1/4 inch (2.5 cm) of copper. Slide a 3-inch (7.6-cm) section of adhesive coated shrink tubing onto one of the wires.
2. Crimp the splice connector onto the wires. Use the type of crimp tool that makes a dimple in the connector. The dimple must be at least 3/16-inch (7.6-cm) wide or there will be too much space inside the connector and the solder will not flow into the wire. This crimp provides the mechanical retention needed. See **Fig. 2**.

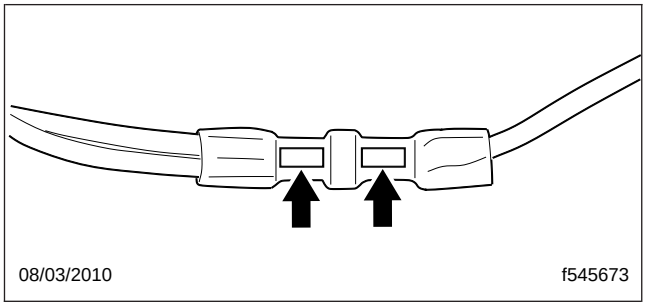


Fig. 2, Properly Crimped Splice

3. Pull test the wires by hand to ensure the crimp is mechanically solid.

IMPORTANT: A crimp tool that is too narrow will leave excessive air gaps in the crimp. The connection will not have the required amount of mechanical strength and the solder will not bond the wire to the connector. **Figure 3** shows an example of a bad crimp when the wrong tool is used.

4. Heat the properly crimped splice connector with the heat gun while slowly rotating the wire. The solder will take longer to flow than it will for the shrinkable insulation to contract. Heat until the solder band has completely melted into the connector. If the shrinkable insulation ruptures and a small amount of solder bubbles out, gently shake the splice to remove the solder. See **Fig. 4**.
5. When the connector has cooled, center the shrinkable tubing over the splice and heat the tubing until it has completely sealed the splice and a small fillet of adhesive is visible at the ends of the shrink tube. See **Fig. 4**.

6. A three-wire tap splice can be made following the same procedure. Use a connector that is large enough to fit all the strands of the wires. See **Fig. 5** for an example of the completed splice.

Solderless Connector Parts		
Wire Size: gauge (mm)	**Connector Part Number***	**Shrinkable Tubing (Daimler Part Number)**
20 to 18 (0.5 to 0.8)	PHM 1 1863	1/4 inch (2.5 cm) with internal adhesive coating (48-02461-025)
16 10 14 (1 to 2)	PHM 1 1862	1/4 inch (2.5 cm) with internal adhesive coating (48-02461-025)
12 to 10 (3 to 5)	PHM 1 1861	3/8 inch (7.6 cm) with internal adhesive coating–4 foot length (48-02461-038)
8 or larger (5 or larger)	Replace the terminal or the entire cable	Use adhesive lined red for positive cables and black for negative cables.

* Twenty-five connectors per pack.

Table 1, Solderless Connector Parts

Wiring Repair Using Daimler Trucks North America (DTNA) Kit ESY ES66 404

Parts and Tools

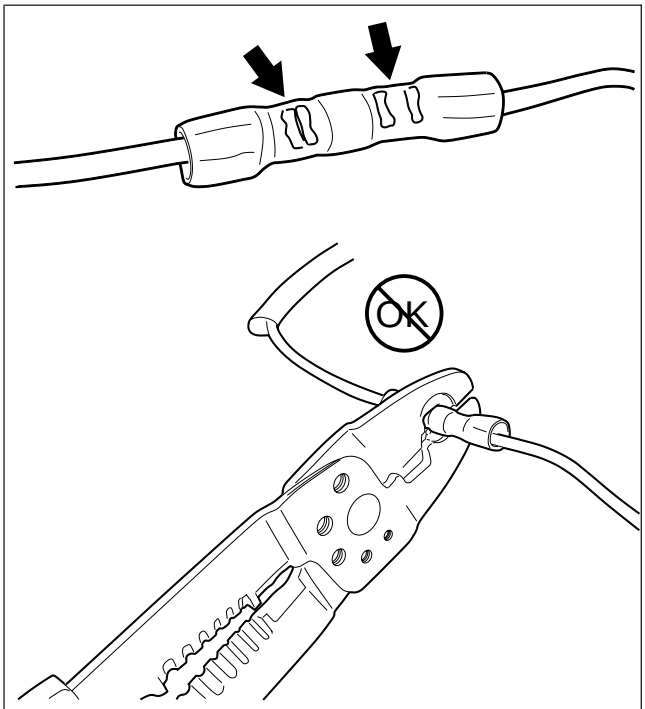
Parts are available through the Parts Distribution Centers (PDCs) in kits with material for 50 splices. This kit may be used on 16 to 14 gauge (1 to 2 mm) wire.

Tools needed for wiring repair using solderless connectors include the following.

- A dimple-type crimp tool with a minimum 3/16-inch (7.6-cm) width. See **Fig. 6** for an example of a proper crimp tool. A typical manufacturer for this tool is Thomas & Betts.
- A heat gun rated at 250°F (121°C).

Procedure

1. Dress the wires to be spliced by stripping the insulation to expose 1/4 inch (2.5 cm) of copper. Slide a piece of the shrink tubing from the kit onto one of the wires.
2. Slide a shrinkable solder sleeve from the kit onto one of the wires.
3. Place the wires that will be spliced into each end of the barrel connector. See **Fig. 7** for an example of the splice.
4. Crimp each end of the barrel using a dimple-type crimp tool to secure the wires. See **Fig. 6** for an example of a proper crimp tool.
5. Pull test the wires by hand to ensure the crimp is mechanically solid.
6. Slide the shrinkable solder sleeve onto the barrel connector so the solder band is at the center of the barrel connector.
7. Heat the splice using a heat gun rated at 250°F (121°C) until the sleeve has completely shrunk against the wire and the solder flows into the barrel connector. A small fillet of adhesive may be visible at the ends of the connector. See **Fig. 8**.
8. Slide the shrinkable tubing over the splice and apply heat with a heat gun rated at 250°F (121°C) until it has completely shrunk against the wire insulation. A small fillet of adhesive should be visible at the ends of the shrinkable tubing.



NOTE: Even with two crimps, there is too much air gap; the solder will not bond.

Fig. 3, Wrong Tool Being Used and a Crimp That Will Fail
